Pancreatic adenocarcinoma is the third leading cause of cancer death and has an extremely poor response to first line therapies. Project Survival is a prospective study designed to discover biomarkers for patient diagnosis, stratification, and prognosis for pancreatic cancer. The multisite study is in year 2 of enrolling subjects within 6 categories: healthy volunteers with a relative with pancreatic cancer (N=50), pancreatic cancer (N=50), pancreatic cystic neoplasm (N=50), suspicious pancreatic masses with pathology other than pancreatic cancer (N=50), early stage (N=200) and metastatic pancreatic cancer (N=200). The study analyzes matched subject sera, plasma, buffy coat, saliva, urine, and tumor/adjuvant normal tissues and integrates them with full clinical annotation. Multiple time points per subject per year are taken longitudinally over the course of the six year timeline enabling dynamic modeling. Samples are analyzed by Mass Spectrometry for the proteome, signal-averaged electrocardiogram for the metabolome, and digital pathology and high-dimensional image analysis for the radiogenome. The integrated Artificial Intelligence Clinical Information System (AIcis™), utilizing Artificial Intelligence to integrate multitemics profiles with medical annotation and clinical endpoints. Using the power of the Bayesian Network learner, AIcis™ (BERG Artificial Intelligence Clinical Information System), multitemics profiles were aligned to the longitudinal clinical information and subjected to the AI-algorithms that inferred probabilistic cause-effect relationships among molecular and clinical variables inferring markers of pancreatic cancer status and defining the interconnectivity of molecular features with clinical phenotype. Network features linking clinical endpoints and key network pressure points will be identified as molecular drivers. The drivers of clinical endpoints will be analyzed to rank potential biomarkers.

#2770 Bcl-2 overexpression is a predictive biomarker for the combination of ABT-199 with chemotherapy in diffuse large B-cell lymphoma cell lines. Jan McConnell, Elyse Anderson, Victor Yazbeck. VCU Massey Cancer Center, Richmond, VA.

Diffuse Large B-Cell Lymphoma (DLBCL) is the most common subtype of Non-Hodgkin’s Lymphoma. The anti-apoptotic Bcl-2 protein is expressed in certain DLBCL subtypes such as “Double-Hit” where it mediates resistance to chemotherapy. ABT-199 is a BH3 mimetic that specifically targets Bcl-2, Bcl-xL and Bcl-w, and has shown excellent clinical activity in several hematological malignancies. The anti-apoptotic protein Mcl-1 mediates resistance to ABT-199, and can be inhibited with chemotherapy. However, despite variability in the Bcl-2 expression levels, current clinical trials involving combinations of ABT-199 and chemotherapy for the treatment of patients with DLBCL use a one-size-fits-all approach regardless of Bcl-2 expression levels. We hypothesized that high Bcl-2 expression levels correlates with sensitivity to the combination of ABT-199 and chemotherapy in DLBCL. We examined the activity of ABT-199 in four DLBCL cell lines with varying Bcl-2 levels (CARNAVAL, OCI-Iy18, SU-DHL-4 and SU-DHL-8) as determined by cell via-bility (Cell Titer Glo Assay) and apoptosis (Annexin-V/PI staining and FACs) analyses. CARNAVAL and SU-DHL-8 have the highest and lowest Bcl-2 expression levels, respectively, as revealed by immunoblotting. Of the four cell lines, CARNAVAL displayed the highest sensitivity (IC50 = ~7 nM) while SU-DHL-8 was resistant (IC50 = >10 μM) with the other 2 cell lines exhibiting intermediate sensitivity (45.9 nM for OCI-Iy18 and 2.6 μM for SU-DHL-4). We then selected CARNAVAL and SU-DHL-8 in order to further examine the effect of the combination of ABT-199 with classic chemotherapy agents (etoposide and doxorubicin) used in DLBCL treatment. In combination, the cells, the combination of either chemotherapy with ABT-199 led to a significant decrease in cell viability at 48 hrs compared to each single agent alone. This was associated with apoptosis induction as measured by Annexin-V/PI cleavage, an increase in γ-HAX (associated with DNA damage), and decrease in p-H2AX. Unlike CARNAVAL, SU-DHL-8 did not enhance the activity of chemotherapy in SU-DHL-8 cells that lack Bcl-2 expression. These preclinical results support the use of Bcl-2 overexpression as a predictive biomarker for selecting patients that are likely to benefit from the combination of ABT-199 with chemotherapy in DLBCL. Current efforts are investigating the mechanism of resistance to the combination.

Background: The Cancer Genome Atlas (TCGA) has identified 16% of colorectal cancers (CRC) to have detectable mutations that repair spontaneous DNA damage, and consequently have high tumor mutation burden (TMB). Although, there is accumulating evidence for activity of immunotherapy on tumors harboring high-TMB, its impact on response to chemotherapy is unknown. Methods: In this retrospective cohort study, we analyzed progression free survival (PFS) of 74 patients with metastatic CRC (61 colon & 13 rectal cancer) treated at tertiary care oncology clinics and undergone next-generation sequencing (NGS) of their tumor sample using FoundationOne® (Foundation Medicine Inc., Cambridge, MA). Most recent available specimen was analyzed at the time of diagnosis of metastatic disease. TMB was calculated by counting all synonymous and nonsynonymous
variants as well as indels across a 1.25 megabase coding region spanning 315 genes. Low TMB (TMB-L) and Intermediate/High TMB (TMB-H) were defined as ≤ 5 mutations per base (MB) or ≥ 6 MB respectively. Demographic and clinical information (including imaging results, chemotherapy treatment) were obtained by chart review. Treatment was captured as ‘oxaliplatin-based chemotherapy’, ‘irinotecan-based’, ‘irinotecan versus oxaliplatin-based’ or ‘irinotecan-based’ if the regimen contained irinotecan (i.e., FOLFOX, XELOX) or ‘irinotecan-based’ if the regimen contained irinotecan. Subsequent modifications of dose or omission of the drug due to toxicity were not captured. Continuous variables were reported as medians and inter-quartile ranges and compared between groups via the Wilcoxon rank-sum test. Categorical variables were reported as percentages and compared between groups via Fisher’s exact test. Survival estimates were compared between groups via the log-rank test. Results: There was no statistically different PFS in TMB-L (n = 39) compared to TMB-H (n = 26). (10.0 vs. 5.9 months, P = 0.18). In the TMB-L cohort, irinotecan-based chemotherapy (n = 25) treated patients had improved PFS compared to oxaliplatin-based chemotherapy (n = 10) treated CRC patients (11.9 vs. 6.5 months, P = < 0.001). No difference in PFS was observed between the two treatment cohorts in TMB-H cohort. In stage 2 and 3 colon cancer patients, there was no difference in time to recurrence in the TMB-L and TMB-H cohorts, when patients were treated with oxaliplatin-based therapy in peri-operative setting (detailed statistics including survival curves will accompany final presentation). Conclusion: TMB status may be a predictive marker of patients who benefit from irinotecan chemotherapy and was followed by erlotinib for 2nd line treatment from September 2011 to September 2014. The primary outcome was to measure the rates of c-MET expression/amplification and EGFR mutation in tumor tissue. MET expression was evaluated by immunohistochemistry (IHC) and gene copy number was assessed by silver in situ hybridization (SISH). EGFR mutations were analyzed by Cobas184 version 1. Results: A total of 196 patients were enrolled and included alpha (90%), beta (17%) and gamma (3%) subtypes. The median follow-up time was 6.2 months (range 0.6-22.5). The overall survival (OS) was not statistically different (10.0 vs. 5.9 months, P = 0.18). In the TMB-L cohort, c-MET positivity (IHC- or SISH-positive) was observed in 1.5% and 8.7%, but there was no specific clinical characteristics. The detection rate of EGFR mutation was 10.2% (19 deletion; 11, 1858R-7, exon 10 insertion; 2 cases). The response rate of erlotinib was significantly higher in EGFR sensitive mutant group (55% vs. 4%, P = 0.001) and the median progression-free survival (PFS) was significantly longer than wild type (173 vs 58 days, P < 0.001). c-MET positivity (IHC- or SISH-positive) did not show significant correlation with response or PFS. Patients with SISH- and PFS-negative c-MET tended to have shorter overall survival (OS) than patients with SISH- and PFS-positive (127 vs 303 days, P = 0.051). Conclusion: In this observational study with 2nd line erlotinib treatment, we confirmed EGFR mutation is an important predictive marker, and EGFR-TKI use in EGFR wild-type patients should be considered carefully and may be harmful. c-MET overexpression was related to some clinical characteristics such as female and non-squamous histology. Although c-MET positivity was not associated with response or PFS, c-MET SISH may be predictive marker for OS.

#2772 BCL-2 family expression profiling may identify distinct molecular subtypes of multiple myeloma with increased susceptibility to single agent treatment

Venetoclax (VEN) is being evaluated in relapsed/refractory multiple myeloma (R/R MM) patients as a single agent (NCT01794520). Improved objective response rates were observed in t(11;14) patients (40% in t(11;14) vs 6% in t(11;14) - ), which were shown to associate with a favorable BCL-2 family expression profile (high BCL2:BCL2L1 (BCL-XL)). Forty percent of t(11;14) + population exhibited VEN favorable biomarker profile with an 88% ORR compared to 20% in t(11;14) + patients with unfavorable profile. Thus, a favorable BCL-2 family expression profile may identify certain MM subgroups with increased sensitivity to the anti-tumor activity of VEN as a single agent. To better understand and identify the patient populations that may benefit from VEN, we retrospectively analyzed the prevalence of a favorable BCL-2 family expression profile in t(11;14) and other MM molecular subtypes in two published cohorts (GSE4581 and GSE9782). Our results showed that BCL2 expression varied significantly across molecular and cytogenetic subgroups. The t(11;14) subgroup expressed high BCL2 and the lowest BCL2L1 and MCL1 in both newly diagnosed (NDMM) and R/R MM patients. Correspondingly, the t(11;14) MM was enriched for the highest ratios of BCL2/MCL1 and BCL2:BCL2L1, further supporting the single agent VEN activity observed in this patient population. Based on prevalence study in cohort GSE9782, we observed 40% of t(11;14) + R/R MM patients exhibited a favorable BCL-2 family expression profile, using clinical defined cutoffs, thus highly consistent with the VEN single agent trial. Furthermore, this favorable profile existed in other molecular subtypes, especially the ones that harbor abnormal MAF (23%) and D3 (37.5%) translocations, as well as dysregulated expression of cyclinD1 (21.2%) or cyclinD1 (26.7%), c-MET in MYC (23%) or c-MET in NOTCH1 (19%). For the MYC (23%), c-MET positivity (IHC) and SISH-positive did not show significant correlation with response or PFS. Patients with SISH- and PFS-negative c-MET tended to have shorter overall survival (OS) than patients with SISH- and PFS-positive (127 vs 303 days, P = 0.051). Conclusion: In this observational study with BCL-2 family expression profiling, we identified a favorable BCL-2 family expression profile in t(11;14) MM subgroups with a favorable BCL-2 family expression profile that may also potentially benefit from VEN monotherapy.
Clinical Research: Predictive Biomarkers 2

E7727, a novel CDA inhibitor, is orally bioavailable with an excellent safety profile in preclinical models. ASTX727 is a combination of E7727 and DAC, and has completed phase 1 dose escalation of 44 MDS or CMMl patients in which pharmacokinetic (PK) and pharmacodynamic (PD) parameters of DAC were replicated with the oral agent. During the dose escalation portion of the Phase 1 trial, ASTX727 bone marrow aspiration was obtained from 28 patients (13 clinical responders), and genomic DNA from marrow cells was isolated for next-generation sequencing (NGS) with a panel of 37 myeloid neoplasia-associated genes. Consistent with previous reports, DNTM3A mutations were associated with poor response to ASTX727 (all 4 carriers failed therapy, \(P = 0.028\)). Conversely, of the 10 patients with TET2 mutations, a majority showed clinical improvement (6/10: 60%). ASXL1 mutations were observed in 3 patients (13.5%); however, no complex combinatorial effect, as all three ASXL1-mutated patients with BCR2 mutations, regardless of International Prognostic Scoring System (IPSS) risk category, were non-responders while all 3 patients ASXL1 who also carried a TET2 mutation responded. ASTX727 is an oral DNTM3i that revealed responses in this dose escalation Phase I study exhibiting a similar pharmacokinetic profile and achieving AUC range of IV DAC. As previously observed with DAC, ASTX727 may lead to improved responses in patients with specific gene mutations. This work shows preliminary effects on mutational burden and allele frequency concurrent with activity of ASTX727. Further analyses of patients treated at the RP2D in the Phase 2 trial are ongoing.

Tmprss2-Erg Prognostic Value for Taxanes Resistance According to Prior Second-line Hormonal Manipulations in Metastatic Castration-resistant Prostate Cancer

Haley E. Ramsey,1 Shilin Zhao,1 Saisai Ji,2 David Proctor,2 Laura Kim,3 Chris Verstraeten,4 Michael Neldner,4 Michael R. Savona1.

Background: TMPRSS2-ERG is a genetic alteration specific of prostate cancer, present in primary tumors and maintained under castration resistant prostate cancer (CRPC) progression. It results in androgen-driven overexpression of ERG, which is involved in resistance to taxanes in preclinical models. In prior work, we found that TMPRSS2-ERG expression in blood correlated with docetaxel resistance in metastatic CRPC. Here, we investigated if TMPRSS2-ERG expression in primary tumors predicts taxanes resistance in CRPC and the potential impact of prior second-line hormonal manipulations with abiraterone (A) or enzalutamide (E). Methods: Patients with metastatic CRPC treated with taxanes were included. Formalin-fixed paraffin-embedded (FFPE) tumors and peripheral blood mononuclear cells (PBMCs) fraction were tested for TM-PRSS2-ERG by RT-qPCR. FFPE from hormone-sensitive disease (primary diagnosis/androgen-dependent prostate cancer) and the potential impact of prior second-line hormonal manipulations with abiraterone (A) or enzalutamide (E) were retrospectively obtained. PBMCs were prospectively collected prior taxane initiation. TMPRSS2-ERG expression was tested by RT-qPCR. TMPRSS2-ERG detection was correlated with taxane response or clinical outcome. Results: A total of 84 tumor samples from 74 patients were included: 65 (87.3%) treated with docetaxel, 19 (25.7%) with cabazitaxel and 10 (13.5%) with enzalutamide. Overall, no correlation between tumor TMPRSS2-ERG expression and taxanes resistance or clinical outcome was observed. In 42 (50%) samples matched tumor and PBMCs samples treated with taxanes were included at this time of analysis: 23 (54.7%) had detectable TMPRSS2-ERG on tissue and 11 (26.2%) on PBMCs fraction. In 27 patients, taxanes were administered as a first-line therapy and in 15 after A or E progression. TMPRSS2-ERG was detected in PBMC from 8 (29.6%) and 3 (20%) patients without or with prior A or E. In patients without prior A or E, TMPRSS2-ERG expression in primary tumors predicted a lower progression-free survival (PFS) with A (\(P = 0.01\)) and E (\(P = 0.05\)). Similarly, when analyzing PBMCs samples from patients without prior A or E, PSA response was observed in 0% of TMPRSS2-ERG+ vs 55.6% of TMPRSS2-ERG-patients (\(P = 0.009\)). Median PSA-PFS, Rx-PFS were 2.9 vs 8.1 months (\(P < 0.01\)) and 3.2 vs 7.3 months (\(P < 0.05\)), for TMPRSS2-ERG+ and TMPRSS2-ERG- patients. However, no significant differences were found either in PBMCs or FFPE samples in patients that received A or E prior to taxanes, regarding to PSA response, PSA-PFS, Rx-PFS and OS parameters between TMPRSS2-ERG+ and TMPRSS2-ERG- samples. Conclusions: The role of TMPRSS2-ERG in taxane resistance may be different according to prior exposure to second-line hormone-therapy in CRPC. Prior androgen receptor inhibi-
bition may result in TMPRSS2-ERG downregulation and/or activation of alter-
native mechanisms of resistance. Further data regarding and thereby this hypothesis will be pre-

#2778 Combination of DNA mismatch repair status and MACCI expres-
sion in patients with stage II colon cancer: The BIOGRID studies. Ulrich, Peter Rohr,1 Pia Herrmann,1 Katharina Ilm,2 Hai Zhang, Sabine Lohmann,3 Astrid Reiser,4 Andrea Muranyi,5 Janine Smith,5 Susen Burock,5 Marc Oster-
land,2 Katherine Leith,3 Shalini Singh,3 Patrick Brunhoeber,3 Rebecca Bow-
master,2 Jeanne Tie,5 Michael Christie,5 Hui-Li Wong,2 Paul Waring,5 Kandavel Shanumugam,5 Peter Gibbs,5 Ulrike S. Stein,5 Direct Medical and Scientific Affairs, Roche, Basel, Switzerland;2 Charité Universitätsmedizin Berlin and Max Delbrück Ctr. for Molecular Medicine, Berlin, Germany;3 Divisional Biomarker Group, Roche, Basel, Switzerland;4 Roche Diagnostics GmbH, Penzberg, Ger-
many;5 Ventana Medical Systems, Inc., Tuscon, AZ;6 Charité Comprehensive Cancer Center, Berlin, Germany;7 University of Melbourne, Melbourne, Australia

We have previously identified the gene Metastasis-Associated in Colon Cancer 1 (MACCI). MACCI acts a prognostic biomarker for tumor progres-
sion, metastasis and patient survival for a broad variety of solid cancer types. Here we assessed if the MACCI gene could separate stage II colon cancer patients with proficient mismatch repair (pMMR) into high- and low-risk groups who might benefit from or be spared adjuvant chemotherapy based on their prognosis. In the Charité 1 discovery cohort (n = 61), MACCI expres-
sion and MSI status were assessed by qRT-PCR in cryo-preserved tumors from CRC patients. MSS/MSI-low/MACCI-low tumors showed better sur-

#2779 Assessing germline and somatic alterations in DNA repair pathway in cancer. Gargi D. Basu,1 Tracey White,1 Janine LoBello,1 Ahmet Kurdoglu,1 Jeffrey Trent,1 Ken Peng,2 Matthew Halbert,1 Thomas Royce1,1 Ashion, Phoenix, AZ;2 Translational Genomics Research Institute, Phoenix, AZ

Introduction: DNA repair genes are involved with repair of single strand breaks as well as double strand breaks which ultimately maintain the genome integrity. The genes involved with DNA repair are frequently deregulated in cancer and these defects can be exploited therapeutically. Our study aims to explore somatic and germline changes in DNA repair genes across multiple cancer types. Methods: Using TCGA colon data we assessed tumor samples from 24 cancer types with ages ranging 19-82 years. We performed targeted exome sequencing of 562 genes in tumor and paired normal DNA which included 112 genes associated with cancer predisposition syndromes. In addition to identifying genomic changes in 33 key DNA repair genes (ATM, ATR, ARID1A, BAP1, BARD1, BRCA1, BRCA2, BRIP1, CDK12, CHEK1, CHEK2, ERCC2, ERCC3, ERCC4, FANCA gene family, MMR genes, NBS1, PALB2, PTEN, RAD50, RAD51, TP53 and POLE), we also characterized germline mutations using public databases (ClinVar, En-
semb). Results: Profiled specimens included breast cancer (17.5%), ovarian cancer (15%), CRC (11%), NSCLC (10%), uterine (6%), sarcoma (6%) and other cancers. The most commonly deleted or mutated (somatic) DNA repair genes included TP53 (55%), PTEN (16%), ARID1A (13%), FANCA (11%), ERCC2 (10%), and ATM, BAP1, CDK12, CHEK2 at 6% each and BRCA1/2 combined at (9%). Deletious mutations in MMR genes were noted in 3.5% (8/226) which included 1 case of germline PM2-5461 muta-
tion. Interestingly, a 55 year old male African American CRC patient harbored germline XPC-P334H mutation along with somatic MLH1-Y546Fs. No mu-
tations were found in FANCC, FANCF, FANCQ and RAD51. Germline analysis revealed a total of 47 pathogenic and presumed pathogenic variants out of which 61.7%(29/47) were DNA repair genes. A total of 13% (30/226) of cases harbored germline variants in DNA repair genes. Germline events included 9 cases with BRCA1 and BRCA2 clinically significant mutations. Presence of loss of heterozygosity (LOH) at the BRCA locus in 5/9 cases and somatic mutations in 3/9 cases were noted in germline BRCA mutated sam-
ples. Germline and somatic BRCA1 and BRCA2 alterations were present in 10% (22/226) of total cohort and as expected, the majority were present in breast and epithelial ovarian cancer. Genetic deficiencies in DNA repair pathway genes are being explored therapeutically with PARP inhibitors as well as DNA damaging chemotherapeutics. Conclusions: Exome sequencing identified subsets of patients with loss of function events in DNA repair genes that may be associated with benefit from PARP inhibitors and platinum agents. Somatic and germline biomarker testing revealed occurrence of BRCA1/2 as well as other DNA repair gene alterations across multiple can-
cers. It is imperative to explore the DNA repair pathway beyond BRCA1 and BRCA2 in patient selection for PARP inhibitors and DNA damaging agents and further investigation of this pathway is warranted in ongoing clinical trials.

#2780 High nuclear FTH1 protein expression predicts early disease recur-
rence for BRCA1/2 carrier mutations. Antoinette Hollestelle, Miekie Timmer-
mans, Renée Broeren-Foekens, Anita Trapman - Jansen, Carolien H. van Deurzen, Arzu Umar, John W. Martens, Marta Hoeing, Erasmus Medical Ctr., Rotterdam, Neth-
erealize this, we aimed to confirm the diagnostic role in a prospective study with breast cancer by measuring plasma exosomal del-1 before and after surgery. Patients and methods: To identify the optimal time of sampling after surgery, serial blood at day 1, 3, 5, and 7 after surgery was collected from 22 patients with early breast
cancers. It is imperative to explore the DNA repair pathway beyond BRCA1 and BRCA2 in patient selection for PARP inhibitors and DNA damaging agents and further investigation of this pathway is warranted in ongoing clinical trials.

#2781 Exosomal Del-1 as a potent diagnostic marker for breast cancer: A prospective cohort study. Soo Jung Lee,1 Jee Hyun Lee,1 Yee Soo Chae,1 Jin Hyang Jung,1 Ho Yong park,1 Moon-Chang Baek,2 Pyong-Gon Moon2,1 Kyungpook National University Medical Center, Daegu, Republic of Korea; 2Cell and Matrix Research Institute, School of Medicine, Kyungpook National University, Daegu, Republic of Korea.

Background: We previously demonstrated a diagnostic role of exosomal del-1 with two separated groups of breast cancer patients. In the current study, therefore, we aimed to confirm the diagnostic role in a prospective study with breast cancer by measuring plasma exosomal del-1 before and after surgery. Patients and methods: To identify the optimal time of sampling after surgery, serial blood at day 1, 3, 5, and 7 after surgery was collected from 22 patients with early breast
cancers. It is imperative to explore the DNA repair pathway beyond BRCA1 and BRCA2 in patient selection for PARP inhibitors and DNA damaging agents and further investigation of this pathway is warranted in ongoing clinical trials.

CLINICAL RESEARCH: Predictive Biomarkers 2

Proceedings of the American Association for Cancer Research • Volume 58 • April 2017 709
cancer. Thereafter, one hundred fifteen patients with breast cancer who under-went curative surgery were enrolled in the prospective cohort study to compare difference in plasma exosomal del-1 measured by ELISA at the time of diagnosis and post-surgery. Results: Among all 22 patients for optimal sampling time after surgery, exosomal del-1 was higher than 0.5 at the time of diagnosis and then normalized at POD1. Among 115 patients for the confirmatory set, 109 (94.8%) patients showed a normalization of del-1 lower than 0.5 after surgery and 10 patients showed del-1 > 0.4. Median f/u duration of 22 months, 9 patients experienced relapse (4 locoregional and 5 distant), where 3 out of 6 in high group (≥0.5), and 2 out of 4 in borderline group (0.4-0.5), and 4 out of 10 in normalized group (<0.4). In particular, patients who relapsed in higher del-1 group showed relatively earlier relapse compared to the lower del-1 group. Conclusion: In a prospective cohort study, we confirmed that exosomal del-1 has a potent diagnostic role in breast cancer. Furthermore, del-1 was also identified to dramatically decrease after curative surgery. Our current findings suggest its potential prognostic role as well as diagnostic role in breast cancer patients.

#2782 The potential of p4EBP1 expression as predictive biomarker of mRCC.
Sei Naito, Osamu Ishiyangi, Hiromi Ito, Hidenori Kanno, Tomoyuki kato, Yuta Kurota, Atsushi Yamagishi,Mayu Yagi, Yoshihiko Sakurai, Hayato Nishida, Hisashi Kawaoze, Tomohiro Shibusaki, Akira Nagaoka, Norihiko Tsuchiya. Yamagata University, Yamagata, Japan.

Introduction & objectives: Activation of Akt/mTOR pathway induces 4EBP1 phosphorylation, and enhances cell proliferation, anti-apoptotic effect, and angiogenesis in many types of cancers including renal cell carcinoma (RCC). As mTOR and angiogenic proteins are main targets in metastatic RCC (mRCC) treatment. We assessed the correlation with survivals and phosphorylated 4EBP1 (p4EBP1) expression. Materials & methods: We enrolled 254 non-mRCC patients who underwent primary surgery in Yamagata University between 2003 and 2010, and 59 mRCC patients whose resected primary lesion was available. Immunohistochemistry for p4EBP1 was performed on their FFPE samples. We assessed correlations between p4EBP1 expression manners and clinical features (disease-free interval [DFI] for non-mRCC patients, cause-specific survival [CSS] and progression-free survival [PFS] for mRCC patients). The CSS was calculated from mRCC diagnosis to death or last follow-up date. The PFS was calculated based on the durations patients were medicated. Univariate analysis was calculated by log-rank test and multivariate analysis was calculated by Cox-regression analysis. Results: Non-mRCC patients with highly p4EBP1 expression were shorter DFI than those without high expression (p = 0.036). Their 5-year disease-free rates were 83.4% and 93.4%, respectively. The independent poor DFI factors were high p4EBP1 expression (HR; 3.4, p = 0.005), grade (p = 0.0055), and PT stage (p < 0.0001). In contrast, mRCC patients with p4EBP1 expression showed a stronger negative correlation than those without high expression (p = 0.0246). The independent poor factor CSS factors were non-p4EBP1 expression (hazard ratio [HR]; 3.3, p = 0.0409), grade 4 (HR; 8.7, p = 0.0006), and poor prognostic group on MSKCC criteria (HR; 4.2, p = 0.02770). Expression of p4EBP1 showed statistically longer PFS in mRCC patients with atrimib (median PFS: 9.2 and 2.5 months, p = 0.0255). The similar trends were shown in patients with other TKIs and mTOR inhibitors. Conclusion: Since non-mRCC patients with the highly p4EBP1 expression had shorter DFI, expression of p4EBP1 should indicate aggressive RCC in nature. Nevertheless, mRCC patients with p4EBP1 expression had longer survival. These results mean that expression of p4EBP1 might be a predictive biomarker for TKIs and mTOR inhibitors.

#2784 Identifying biomarkers to predict cardiotoxicity of doxorubicin in individual patients.
Liqun Zhao, Baolin Zhang, FDA, Silver Spring, MD.

Doxorubicin is a highly effective anticancer agent but causes cardiotoxicity in many patients. This study aims to identify biomarkers to predict potential cardiotoxicity before the onset of cardiac tissue damage and dysfunction in individual cancer patients. First, we established a human cellular system to model the cardiotoxicity of oncology drugs using human induced pluripotent stem cells-derived cardiomyocytes (iPS-CMs). We tested clinically used drugs including anthracyclines (doxorubicin, daunorubicin, epirubicin and idarubicin), 5-FU, Taxol, Trastuzumab, and tyrosine kinase inhibitors (sunitinib, imatinib, and sorafenib). These drugs displayed varying degrees of cytotoxicity in iPS-CMs which are generally consistent with their known cardiotoxicity pat-

terns. Second, we found that doxorubicin selectively upregulated the expression of death receptors in iPSC-CMs. As a result, the treated iPSC-CMs underwent spontaneous apoptosis that was further enhanced in the presence of specific cytokines. Based on these findings, we hypothesize that the baseline levels of the defined cytokines in blood could be predictive of cardiotoxicity associated with doxorubicin treatment in individual patients. Our next goal is to test this novel method on RNA derived from platelets from cancer patients, providing a minimal invasive procedure to monitor the state of disease in those patients.

#2785 A comprehensive RNA-based assay for treatment prediction in non-small cell lung cancer patients.
Klaas Kok, Jaicong Wei, Anna Rybczynska, Martijn Terstra, Anthonie van der Wekken, Jeroen Hiltnerman, Ed Schuuring, Rolf Simons, Harry Groen, Anke van den Berg. UMC, Groningen, Netherlands.

Purpose: In late-stage lung cancer an increasing number of genomic aberrations is used to predict either sensitivity to, or resistance against, targeted therapies. These include gene mutations, gene fusions, amplifications and in the near future different relevant splice variants. Currently, detection of each type of aberration is carried out with different tests. We have set up to develop a novel all-in-one assay to detect the various types of aberrations, e.g. mutations, gene fusions and overexpression. The latter is assumed to be the biological marker that is underlying gene amplification. Methods: Our assay is based on the Single Primer Enrichment Technology (SPET), allowing amplification of a target region using only a single sequence-specific primer. Our first custom-designed panel targets a comprehensive list of hotspots with therapeutic and prognostic significance in lung cancer, including EGFR, ALK, MET, KRAS, NRAS, PIK3CA, ROS1, BRAF, FGFR1 and RET. Using total RNA as input, we will be able to efficiently detect mutations, gene fusions and aberrant expression levels of selected genes. This test may also detect tumor-specific aberrations in platelets. Results: As a proof of principle we analyzed RNA derived from 8 lung cancer-derived cell lines, from two frozen tumor biopsies, and from 10 FFPE biopsies all with confirmed genomic alterations by clinically approved assays. In total, conventional methods detected 18 small mutations, five gene fusions and three gene amplifications, that are all covered by our assay. Of these, 14 mutations, and four gene fusions were readily detected with our assay. The detection of three mutations failed because of low coverage of the target region, probably due to a less optimal design of the specific primer. One small deletion, and one gene fusion were not detected with our RNA-based assay, despite a high read coverage. Quantification of the expression level of the amplified genes is still under investigation. Conclusion: Our preliminary data indicate this novel RNA-based assay not only efficiently identifies all crucial mutations in lung cancer cell lines, but also in small frozen and FFPE tumor biopsies of lung cancer patients. Our next goal is to test this novel method on RNA derived from platelets from cancer patients, providing a minimal invasive procedure to monitor the state of disease in those patients.

#2786 EGFR expression and phosphorylation in HNSCC predict response to EGFR inhibition but cell lines are not representative for the clinical situation.
Oliver von Ahlsen,1 Sami S. Khaznadar,1 Martin Khan.2 Bayer Pharma AG, Berlin, Germany; 2Klinikum Dahme-Spreewald, Koenigswusterhausen, Germany.

Introduction: And head neck squamous cell carcinoma (HNSCC) is the sixth most common cancer. Survival rates have not been improved for decades and conventional therapy is effective in only 50% of the patients. Based on broad expression in up to 80-90% of the HNSCC cases, epidermal growth factor receptor emerged as drug target but clinical efficacy of EGFR inhibitors in HNSCC is very limited. We therefore reinvestigated the EGFR expression levels necessary for response in cell lines and clinical samples. Methods: Standard procedures were used for IHC. The antibody clone D38B1 was used in 1:900 dilution for 2h at RT. Stainings were performed using the DAKO Envision system. EGFR expression and phosphorylation of Tyrosine-1173 were analysed by MDS (Mesoscale Discovery) in lysates from fresh frozen tumor or exponentially growing cell lines. For proliferation assays, 2000 cells per well were grown for 24 h before addition of inhibitors. Cell culture was continued for 72 h before testing viability using the CellTiter-Glo® Assay. Results: The majority (11/13) of HNSCC cell lines responded to the EGFR inhibitor Erlotinib. EGFR was highly expressed and phosphorylated in the Erlotinib responsive cell lines. Resistant cell lines displayed low level EGFR expression and phosphorylation. However, EGFR expression and phosphorylation in treatment naive clinical samples were significantly below the levels found in responding cell lines. In clinical samples EGFR was not overexpressed on the cellular level. Based on these findings, a clinical response to Erlotinib in HNSCC would not be expected. Conclusion: The prog-

710 Proceedings of the American Association for Cancer Research • Volume 58 • April 2017
nostaic value of EGFR expression has been used to argue for EGFR as a relevant target in HNSCC. Although most reviews claim that EGFR is overexpressed in HNSCC, clear data supporting this position are missing. Early studies tested the RNA levels and found the EGFR expression in tumors higher compared to control tissues. Studies using IHC assessed the association of EGFR expression with disease progression, but no comparison to expression in normal mucosa was described. Overexpression was based on percentage of positive cells not on the intensity of expression. We show similar levels of EGFR expression in growing keratinocytes and tumor cells. The often described overexpression only originated from a larger number of EGFR positive cells, not on overexpression on the cellular level. The high expression and functional relevance of EGFR in cell lines proves that EGFR activity is required for survival in cell culture. Our findings lead to the conclusion that this is not representative of the clinical situation. Definition of a response threshold for EGFR expression and clinical verification of this expression level is mandatory for the successful use of a predictive biomarker.

### #2787 Identifying predictive markers of endocrine response in high-grade serous ovarian cancer using RNA sequencing

Cristina Mapaga,1 Sian Fereday,2 Australian Ovarian Cancer Study Group, David D. Bowtell,2 Paul R. Har- nem,31 Konica Minolta, Beijing, China; 2Konica Minolta, Beijing, China; 3Crown Bioscience, Inc., Beijing, China.

Epithelial ovarian cancer is a complex disease and patients vary considerably in response to treatment. A subset of patients responds well to endocrine therapy, however hormone receptor positivity does not predict response and there are no biomarkers in clinical use to help select those patients who would benefit from endocrine agents. We aimed to identify markers of endocrine response in high-grade serous ovarian cancer (HGSOCS) by analysis of genes that are differentially expressed in tumors from patients that are endocrine responders compared with non-responders, combined with analysis of estrogen (E2) regulated genes that differ between E2 sensitive and E2 insensitive HGSOCS cell lines. Methods: Among women recruited to the Australian Ovarian Cancer Study, we identified 10 HGSOCS patients treated with endocrine therapy (5 responders and 5 non-responders, based on GCIG CA125 response criteria) and performed RNAseq on cryopreserved tumor tissue. We also utilized paired E2 receptor (ER) positive HGSOCS cell lines, derived from the same patient, with differential sensitivity to the growth effect of E2, PEO1 (E2 insensitive) and PEO4 (E2 sensitive). RNA was extracted following treatment with 0.1 nM E2 (or vehicle) for 24 hrs and gene expression changes in response to E2 were determined using RNAseq. Expression of selected ER responsive genes was validated using PCR array. Differential gene expression was determined using EdgeR. Pathway and Gene Ontology enrichment analysis of differentially expressed genes were performed using Metacore. Results: Between endocrine responders and non-responders, 27 genes were significantly differentially expressed (False Discovery Rate (FDR)<0.05, absolute log, Fold-Change (FC)>2). In the paired HGSOCS cell lines, significantly more genes were regulated by E2 in E2 sensitive PEO4, compared with E2 insensitive PEO1 (896 genes compared to 56 genes, respectively, FDR<0.05, absolute log,FC>2). In response to E2, up-regulation of NRPI in PEO1, up-regulation of LTBP1, MYC, PDZK1 and down-regulation of Si00A6 and CYP1A1 in PEO4 were validated by PCR array profiling of ER-related genes. Genes regulated by E2 in cell lines and also differentially expressed between endocrine responders and non-responders included anocutain 1 (AN01) and NOTCH-Regulated Ankyrin Repeat Protein (NRARP). Both were up-regulated in endocrine responders and also up-regulated by E2 in PEO4. Conclusion: The use of RNAseq in both tumors and cell line models was able to identify plausible sets of genes with prior evidence of association with endocrine sensitivity. In breast cancer, AN01 has been associated with good prognosis following tamoxifen treatment, while NOTCH signaling, implicated in endocrine resistance, is negatively regulated by NRARP. Further validation is required to test the utility of these genes as predictive biomarkers that may aid in identifying HGSOCS patients likely to respond to endocrine treatment.

### #2788 High ALDH1, S phase fraction, $p16^{INK4A}$ in esophageal squamous cell carcinoma could predict response to neoadjuvant chemotherapy

Rajeev Kumar,1 R. Ravi Kannan,2 Akalesh Kumar Verma,1 Anuradha Talukdar,1 Monoy Kumar Deka,1 Ritesh Tapkirpe,1 Litika Verma,1 Sankar Kumar Ghosh.1,2 Cachar Cancer Hospital and Research Centre, Assam, India; 2Assam University, Assam, India.

Background: The prevalence of locally advanced esophageal squamous cell carcinoma (ESCC) remains high despite technological advancements in its diagnosis. This leads to prolonged multimodality treatment often resulting in poor response eventually leading to poor prognosis. Currently, there are no biomarkers available to predict response to neoadjuvant chemotherapy (NACT). In ESCC patients, ALDH1, $p16^{INK4A}$ and propidium iodide based cell cycle analysis through flow cytometry was performed in pre treatment biopsy sample collected from 108 ESCC patients who were presented at a comprehensive cancer centre in northeast India and all of them subsequently received neo adjuvant chemotherapy. Results: ALDH1, HER2 and $p16^{INK4A}$ were found positive in 65.7%, 7.4% and 22% of pre treatment ESCC specimens respectively. ALDH1 expression correlates with poor response to neo adjuvant chemotherapy (P<0.001). A significant proportion of poor responders were found to be smokers (P=0.004). Poor responders also tends to correlate with increased mortality (P=0.009). HER2 couldn’t predict response to NACT. However, all HER2 positive cases were associated with high ALDH1 expression (P=0.034). 50% of those with pathologically complete response were $p16^{INK4A}$ positive in the contrary only 15% low sensitivity responders for $p16$ (P=0.001). 84% of the ESCC patients reported aneuploid tumor status and responder’s were found having high S phase fraction (P=0.041). Conclusion: High ALDH1 expression can predict poor response whereas high $p16$ and S phase fraction can indicate good response to neoadjuvant chemotherapy in ESCC patients. HER2 seems having no clinical significance in the response assessment of neo adjuvant chemotherapy in ESCC.

### #2789 PID, a novel immunofluorescence nanotechnology, as a histopatology-based EGFR biomarker assay enhances predictive power for the Erbitux response in subsets of PDXs

Henry Qixiang Li,1 Jia Xue,1 Hiyasat Okada,5 Etskuco Putaya,1 Yoshikazu Kurihara,1 Likun Zhang,1 Xiaoyu An,1 Sheng Gua2,5 Crown Bioscience, Inc., Beijing, China; 2Konica Minolta, Beijing, Japan; 3Crown Bioscience, Inc., Santa Clara, CA.

Immunohistochemistry (IHC) is the most common used assay for detecting/quantifying defined protein biomarkers in specific tissue location in clinical/preclinical settings as prognostic/drug-predictive biomarker assays. However, IHC suffers from several key drawbacks, limiting its applications, including semi-quantitative nature, inconsistent quantification with WHO scores, lack of broad dynamic detection range and inadequacy for multi-target analysis, etc. An alternative method is immunofluorescence (IF), but with even lower usage for its disadvantageous photo-instability. A sensitive, quantitative and robust assay is thus an urgent/unmet need. We have recently developed a novel fluorescence nanoparticle (PID, phosphor integrated dye) with highly compact phosphor inside. PID has several key advanced features: 1) enhanced fluorescence (30,000x brighter over the conventional fluorescence and significantly above tissue auto-fluorescence), 2) enhanced photo-stability (stained slide is stable for >2 years); 3) highly quantitative by broadened detection dynamic range through enumeration of the bright fluorescent dots (nanoparticles) instead of signal amplification as in IHC (digital vs. analog); 4) fine subcellular imaging; 5) potentials for multi-color and H&E/bright light imaging. PID is a well-accepted experimental cancer model mimicking original patients in histio- & molecular pathology(1), as well as drug response. We previously conducted a series of mouse clinical trial (MCT) of Erbitux on PDX cohorts of NSCLC, CRC, gastric and esophageal cancers (2,3), showing specific subsets of high-EGFR-expressing PDXs responded to the drug, where EGFR expression was measured by either RNAseq (mRNA) or IHC (protein). To assess PID-EGFR as a new biomarker assay platform, we analysed and compared its quantification to RNAseq and IHC, particularly in terms of the correlation to the drug efficacy. Our data demonstrates a greatly enhanced correlation of PID scores to mRNA levels in all cancer types, and to the tumor growth inhibition of gastric (3) and esophageal (4) carcinoma, but not in CRC (2) and NSCLC (Li et al., unpublished) as anticipated. The results demonstrated that PID-EGFR is a significantly improved histopathology based EGFR protein quantification assay over IHC-EGFR assay, warranting further clinical confirmation. References 1. Guo S, et al. Cancer research 2016;76(16):4619. 2. Chen D, et al. Oncotarget 2015;6(38):40815 3. Zhang L, et al. Sci Rep 2013;3:2992. 4. Zhu et al. 2016.
ONC201 is the lead small molecule of the imipridone class of anti-cancer compounds that is currently being evaluated in phase I/II advanced cancer clinical trials. ONC201 is a highly selective antagonist of the G protein-coupled receptor dopamine receptor D2 (DRD2) that has exhibited promising anti-cancer efficacy and an exceptional safety profile. In the current study, we evaluated the influence of the DRD2 receptor on the radioresponse of the DRD2-potentiated cancer effects of DRD2 knockdown in various tumor types correlated with overall ONC201 efficacy. In particular, we noted that lymphoma cells are highly sensitive to DRD2 knockdown—tumor type where ONC201 performs well. Gene expression analysis of samples in the Cancer Genome Atlas (TCGA) revealed high DRD2 expression in ONC201-sensitive tumor types, such as lymphoma and glioblastoma, and that high expression of DRD2 in glioma was associated with a poor prognosis. High DRD2 expression was also observed in neuroendocrine prostate cancer relative to other prostate cancer subtypes. Immunohistochemistry analyses of patient-derived tumor tissue microarrays, DRD2 overexpression was particularly noted in endometrial cancer, neuroblastoma and pheochromocytoma relative to normal tissues. The anti-cancer activity of ONC201 in pheochromocytoma and neuroendocrine prostate cancer was confirmed in cell viability assays. In ONC201-treated patients, ELISA was used to quantify serum prolactin levels, a clinical biomarker of DRD2 antagonism. A 2-fold mean induction of prolactin, was detected in the serum of ONC201-treated patients, in accordance with physiological DRD2 antagonism. Interestingly, expression of DRD5 (a D1-like dopamine receptor), which counteracts DRD2 signaling, was significantly negatively correlated with ONC201 in vitro potency in the NC60 and GDSC dataset (P < .05). Furthermore, a missense DRD5 mutation was identified in cancer cells with acquired resistance to ONC201. In conclusion, the DRD2 pathway is expressed in ONC201-sensitive tumors and may provide biomarkers of response. #2793 Evidence for WT1 as a potential target for immunotherapy of lethal ovarian cancer. Julia H. Carter,1 James A. Deddens,2 Gretchen Mueller,3 Thomas G. Lewis,1 Mariah K. Dooley,1 Jackson O. Pemberton,2 Larry E. Douglass,1,4 Wood Hudson Cancer Research Lab., Newport, KY;5 University of Cincinnati, Cincinnati, OH;5 St. Elizabeth Healthcare, Edgewood, KY.

Ovarian cancer is the leading cause of gynecologic cancers with 22,280 new cases anticipated in 2016 and 14,240 deaths. Most patients are diagnosed at late stages and have a poor prognosis. Radical surgery and chemotherapy are the primary treatment. When relapse occurs there are few treatment options. The overall survival rate of women with ovarian cancer is unchanged in 50 years. Approximately 70% of epithelial ovarian cancers are serous including low grade serous tumors, some of which may evolve from serous borderline tumors, and high grade serous carcinomas. The latter are thought to originate in the fallopian tube. There are eight other subtypes of invasive ovarian cancer. All invasive ovarian cancers have recently been classified into two subtypes, Type 1 (indolent) and Type 2 (aggressive). The Wilms’ Tumor 1 (WT1) protein is expressed in some normal tissues including the fallopian tube and ovary as well as in tumors such as ovarian and breast cancers and in leukemia. WT1 is a highly immunogenic tumor associated antigen. Mutated p53 is found in many high grade ovarian cancers. Recent reports indicate that WT1 and p53 may interact physically and functionally. Both WT1 and mutated p53 have been suggested as prognostic markers in ovarian cancer. We sought to determine the role of co-expression of mutated p53 and WT1 in overall survival of patients with ovarian cancer. Histopathologic sections were archived FFPE surgical specimens donated by St. Elizabeth Healthcare (Northern KY) and fully annotated by hospital records. H&E stained sections were diagnosed and graded by a board certified pathologist (LED) and included histologic sections from 41 borderline tumors and 98 Type 1 and Type 2 cancers. Adjacent sections were stained immunohistochemically using monoclonal antibodies (DAKO) to WT1 and p53. For survival analysis p53 was considered mutated if ≥75-100% of the tumor nuclei were stained (missing mutations) or if all nuclei were negative (truncated protein) and WT1 was considered either non-expressed (no stain) or expressed (some or all nuclei stained). While either mutated p53 or WT1 were prognostic alone of patient survival with Type 1 and...
Type 2 tumors, WT1 was a better predictor as seen by log-rank Chi-square. The 20 year survival probability of patients with tumors negative for both mutated p53 and WT1 was 70% and was significantly better than other patients (p < 0.0001). The 20 year survival probability for tumors negative for WT1 but expressing mutated p53 was 41%, and was 9% for tumors expressing WT1 and non-mutated p53. For tumors with both WT1 expression and non-mutated p53, the 20 year survival had a 20 year survival probability of 6%. Given these data and the immunogenicity of the WT1 tumor associated antigen we conclude that IHC detection of mutated p53 and WT1 in invasive ovarian cancers would be useful in stratifying patients eligible for immunologic approaches targeting WT1 for therapy of lethal ovarian cancers.

#2794 Indotecan (LMP400), imidotecan (LMP776) and LMP744: A new class of non-camptothecin Top1 inhibitors selective for homologous recombination deficient (HRD) cells. Laetitia Marzi, Keli Agama, Zoe Weaver Ohler, Ludmila Szabova, Shyan Sharin, Junko Murai, Muthana Al Ab, Yves Pommer, NCI, Bethesda, MD.

To relax DNA supercoiling during transcription and replication, topoisomerase I (Top1) induces transient DNA cleavage complexes, which are trapped by anticancer drugs, leading to DNA double-strand breaks (DSB) that need to be repaired by homologous recombination (HR). BRCA1, BRCA2 and PALB2, which are key components for HR, lead to "synthetic lethality" with PARP inhibitors. Topotecan and irinotecan (camptothecin derivatives) are the only FDA-approved Top1 inhibitors. In spite of their wide usage they are plagued by their chemical instability, being drug efflux substrates, having short half-life, and dose-limiting bone marrow and gastrointestinal toxicity. It is now possible to overcome these limitations with the non-camptothecin indenoisoquinolines (LMP400, LMP776 and LMP744), which are in clinical trials. To rationally select patients for phase 2 clinical trials based on cancer-specific genomic alterations, we have determined whether the LMPs present a "synthetic lethality" toward BRCA1, BRCA2 or PALB2 deficiency, and whether this selectivity could be enhanced by combining them with the recently approved PARP inhibitor, olaparib. Using isogenic DT40 cell lines, with BRCA1, BRCA2 or PALB2 deficiencies, we assessed the role of HR in the cellular response to the LMPs. Survival and cell cycle modifications were tested after treatment with the LMPs as single agents, as well as in combination with olaparib. We found that BRCA1-, BRCA2- and PALB2-deficient cells are 3 to 5 times hypersensitive to the LMPs (IC50’s for LMP400 and LMP744> 10 nM for HR-deficient cells vs. 45 nM for WT cells, and IC50 for LMP776 around 5 nM vs. 18 nM for WT cells). Cell cycle analyses confirmed the death of these HR-deficient cells. Moreover, combination treatments showed a significant synergy between each of the three LMPs and olaparib (Combination index<0.7). The HR-deficient cells being markedly more sensitive than WT cells (taken as surrogate for normal tissues) to both treatments, led to a better response to the combination in those cells. Our results show that the LMPs are active at nanomolar concentrations, selectively in HR-deficient cells, indicative of a "synthetic lethality" of the indenoisoquinolines (LMPs) with HRD genotypes. They also demonstrate that the LMPs synergize with olaparib. These findings provide a rationale for personalized treatment and Phase 2 clinical trials with the indenoisoquinolines in combination with PARP inhibitors in HR-deficient cancers.

#2795 Integrating multiomics discovery approaches to identify biomarkers of therapeutic resistance in metastatic colorectal cancer through analyses of multiple sequential tumor and liquid biopsies; Qcrocc01: NCT009984048. Karen Gambaro,1,2 Maud Marques,3 Ryan Morin,3 Claudia Kleinman,4 Michael Witcher,3 Simon Turcotte,3 Benoit Samson,5 Bernard Lespérance,6 Yoo-Joung Ko,7 Richard Dalfen,8 Eve St-Hilaire,9 Lucas Sideris,10 Felix Couture,11 Sabine Helm,7 Keli Agama, Zoe Weaver Ohler, Ludmila Szabova, Shyan Sharin, Junko Murai, Muthana Al Ab, Yves Pommer, NCI, Bethesda, MD.

Colorectal cancer (CRC) is the 2nd leading cause of cancer-related death in Canada. Clinical responses of metastatic (m)CRC to first-line treatment range from 35 to 60%, but even responders inevitably develop therapeutic resistance. Studies aiming at understanding mechanisms of resistance have largely investigated primary tumors. However, selective pressures during therapy can lead to development of resistance, which may lead to therapeutic failure, thus the need to characterize the molecular changes of metastasis and plasma over time of treatment and response to decipher tumor evolution and therapeutic resistance mechanisms. In this multicenter study, 52 tissue samples from liver metastasis were collected at baseline (pre-biopsies) and at the time of resistance (post-biopsies) in responder and non-responder mCRC patients (n = 44) undergoing standard first-line treatments. Metastases have also been harvested in 4 patients, to allow the assessment of tumor heterogeneity and as well as the evolution of the genomic complexity after treatment exposure. Analyses were carried out across multiple omic platforms to identify resistant signatures and characterize molecular changes during treatment. Biopsies were profiled using exome and transcriptome sequencing as well as high-density SNP array analysis to capture chromosomal anomalies, loss of heterozygosity (LOH) and copy number variations (CNV). Additionally, serial blood samples were collected for proteomic, ctDNA and cytokine analysis. Our preliminary analysis of transcriptomes performed on serial biopsies from a set of 11 patients identified genes consistently overexpressed at resistance. Cytogenetics analysis showed similar genomic profiles of matched pre- and post-biopsies and allowed to stratify the expansion of resistant clones. LOH and CNV catalogues of liver metastasis, while exome sequencing revealed cumulative somatic mutations over time of treatment, which suggests subclonal and acquired "driver" mutations of resistance. Plasma-derived ctDNA analysis was performed to investigate the mutational status during treatment and whether they correlate with their relative levels in biopsies. Immune gene expression analysis of a test set of 27 metastases revealed strong clustering of 7 metastases due to overexpression of transcripts related to active immune response, allowing to define novel subgroups of patients based on immune response status. Our study, using a multi-omic strategy and integration of independent molecular platforms to profile liver metastasis samples of responders and non-responders to mCRC patients, constitutes an innovative approach to identify clinical biomarkers and molecular signature of resistance, which may enhance individualization of cancer medicine and customized therapy.

#2796 Development of a RAD51-based assay for determining homologous recombination proficiency and PARP inhibitor sensitivity. Bose S. Kochupurakkal,1 Kalindi Parmar,1 Jean-Bernard Lazaro,1 Christine Unitt,2 Qing Zeng,1 Hunter Reavis,3 Chirag Ganese,1 Shan Zhou,1 Joyce Liu,1 Sangeetha Palakurthi,1 Kyle Strickland,1 Brooke Howitt,1 Panagiotis Konstantinopoulos,1 Paul Kirschmeier,1 Joseph Geradts,2 Ronny Drapkin,3 Ursula Matulonis,1 Alan D'Andrea,1 Geoffrey Shapiro,1 Dana-Farber Cancer Institute, Boston, MA; Brigham and Women’s Hospital, Boston, MA; University of Pennsylvania, Philadelphia, PA.

Homologous recombination (HR) repair deficiency confers sensitivity to inhibitors of poly(ADP-ribose) polymerase (PARP). To date, the identification of tumors with impaired HR has relied on genomic features, including mutational signature, LOH-based HRD assays or gene expression analyses defining ‘BRCA-ness’. These tests analyze history of the tumor rather than providing a functional assessment of HR status at the time of diagnosis. Therefore, development of a functional assay for HR status in tumors is essential to make accurate treatment decisions. Here, we describe a RAD51-based immunohistochemical (IHC) assay that identifies HR status. We first screened commercial anti-RAD51 antibodies and identified a monoclonal antibody that detects RAD51 foci in HR-proficient normal fibroblasts and shows no evidence of foci in HR-deficient (BRCA2−/−) VU423 fibroblasts after γ-irradiation. Conditions for detecting RAD51 foci in FFPE samples were identified using HR-deficient and HR-proficient triple-negative breast cancer cell lines. HR-deficient, PARP inhibitor-sensitive cell lines exhibited high levels of nuclear RAD51 and no evidence of foci, whereas HR-proficient, PARP inhibitor sensitive lines had low levels of nuclear RAD51 and foci. This result was confirmed in a BRCA1-mutated, PARP inhibitor-sensitive PDX model, where there was no evidence of foci although RAD51 levels were high. We further evaluated the pattern of RAD51 staining in 13 high-grade serous ovarian cancer (HGSOCC) PDX models, for which sensitivity to olaparib had been characterized. The only olaparib-sensitive model demonstrated complete absence of RAD51 staining. Among the other 12 olaparib-resistant models, RAD51 foci were detectable, both before and after irradiation. The presence or absence of RAD51 foci correlated with olaparib sensitivity and not with BRCA mutation status. Therefore, tumors that are HR-deficient and PARP inhibitor-sensitive are characterized by either high RAD51 nuclear staining without foci,
or absence of RAD51 staining. To validate these findings, we analyzed RAD51 staining patterns in a cohort of 50 primary HGSOCs from patients subsequently treated with platinum-based chemotherapy. Among these 50 samples, 45 demonstrated either RAD51 nuclear staining without foci or an absence of RAD51 staining. Five samples demonstrated RAD51 staining with foci. The median survival of patients with and without RAD51 staining were 61 and 15 months, respectively. Using the signature of the two groups, we have developed a robust IHC assay for determining the functional HR-status in tumor samples. Further work will be required to determine if the staining patterns observed predict PARP inhibitor sensitivity among primary patient samples. Funded by a Biomarker Supplement to UM1 CA186709, NIH Grant P50 CA168504, SU2C Ovarian Cancer Dream Team and BCRF grant.

**TUMOR BIOLOGY: Cell Culture and Animal Models of Cancer 3**

#2799 **Development of a mouse model of KRAS mutated colorectal cancer tumorigenesis.** Radhashree Maitra,1 Madhu Kumar Venkatesh,2 Titto Alby Augustine,2 Carol Chandy,2 Qiang Liu,1 Sanjay Goel1. 1Montefiore Medical Center, Bronx, NY; 2Albert Einstein College of Medicine, Bronx, NY

Introduction: Development of a preclinical animal model that mimics KRAS mutated colorectal cancer disease etiology is essential for validation of new therapies and effective screening of potential therapeutic combinations. Colorectal cancer patients with tumors harboring KRAS mutation are excluded from receiving anti EGFR monoclonal antibodies, and currently have no alternate FDA approved treatment options available. Ongoing research requires validations of different modalities on a robust preclinical study platform that will resemble the disease phenotype and genetic profile. In this context we have developed viable animal mouse model of colorectal cancer bearing KRAS mutation that authentically serves as a model for the disease.

Methodology: The C57 BL/6 mice with truncated APC floxed allele was crossed with heterozygous KRAS floxed outbred mice to generate APC<sup>−/−</sup> KRAS<sup>+/−</sup> mouse colony. In another set of breeding APC floxed mice were crossed with CDX2-Cre-ER<sup>−/−</sup> mice and selected for APC<sup>−/−</sup> CDX2-Cre-ER<sup>−/−</sup> second after round of inbreeding. The final model of the disease was generated by the cross of the two aforementioned colonies when viable APC<sup>−/−</sup> KRAS<sup>−/−</sup> CDX2-Cre-ER<sup>−/−</sup> were genotyped and characterized. The model animals were tamoxifen induced to generate tumors. Micro-PET scan was used to detect and measure tumor volume. H & E staining was done to establish neoplasm and immunohistochemistry was performed to determine histological similarities with human FFPE biopsies. The MSI/MMR status was also determined. Results The newly developed animal model develops colonic tumors upon induction with Tamoxifen. The tumors were malignant as confirmed by H and E staining. The tumors showed a higher radioactive FDG uptake (SUV) in micro-PET scan. The tumors resembled human colorectal cancer tissue Once tumor is generated the animals died of cachexia and rectal bleeding Conclusion: Heterozygous mutation of the APC gene along with deletion mutation of Adenomatous polyposis coli (APC) gene is embryonically lethal in animal models. We have successfully developed a viable animal model of KRAS mutated colorectal cancer with tamoxifen inducible tumors harboring KRAS and APC mutations. The tumors mimic the human disease type both genetically and immunohistochimically. This model can serve as a robust preclinical platform for understanding the disease mechanism at the molecular level as well for evaluation of various therapeutic interventions.

#2800 **Transforming growth factor-beta 2 (TGF-β2) antisense oligonucleotide (ASO) OT-101 synergizes with chemotherapy in preclinical tumor models.** Osmond D’Cruz,1 Cynthia Lee,2 Vuong Trieu,2 Larn Hwang,3 AutoTec Inc, Costa Mesa, CA; Oncotec Inc, Agoura Hills, CA

Background: Overexpression of TGF-β2 has been implicated in the malignant progression of tumors by inducing immunosuppression, proliferation, angiogenesis and metastasis. Clinical failures of TGF-β inhibitors in targeting the tumor promoting arm of TGF-β signaling is attributed to multiple isoforms and receptor functions. OT-101 (Trabedersen) is a phosphorothioate ASO designed to specifically target human TGF-β2 mRNA with superior clinical activity in patients with TGF-β2 overexpressing tumors. Herein, we report the synergistic effect of OT-101 with chemotherapy in multiple human tumor xenograft models for further exploration of clinical combinations. Methods: The in vivo efficacy studies of intraperitoneal (IP, 16 or 50 mg/kg) or subcutaneous (SC, 1-64 mg/kg) repeated administration (qdx3/wk or qdx21) of OT-101 as single agent
#2801 Identification of oncogenic/metastatic driver genes that cooperate with p53 or p53/Rb-loss to induce triple-negative breast cancer. Ronak Ghanbari Azarnier, Agatha Zuchelkowski, Philip E Chung, Zhe Jiang, Eldad Zacksenhouse, University of Toronto, Toronto General Research Institute, Toronto, Ontario, Canada.

Triple-negative breast cancer (TNBC) is an aggressive subtype with poor prognosis; drug-resistant metastases are common and highly lethal for which identification of therapeutic targets is of major medical interest. Previously we demonstrated that deletion of p53 and Rb in mouse mammary epithelium induced TNBC-like tumors but with limited capacity to metastasize. Therefore, we decided to employ sleeping beauty (SB) mutagenesis system that can identify oncogenic networks responsible to drive primary and metastatic tumors. In order to do this, we generated mice in which p53 (p53F/F) or p53 plus Rb (p53F/F; RbF/F) are deleted and the SB transposon is mobilized from chromosome 9 as well as controls in which both p53 and Rb are wild type. Forty primary tumors and forty metastases from each cohort will be harvested that cooperate with common integration sites followed by deep sequencing. Then, the top 5-10 candidate oncogenes/tumor suppressors will be validated to determine whether their loss/activation would accelerate tumorgenesis/metastasis. H&E staining of mammary tumors collected so far from different genotypes revealed histologically diverse tumor types which includes but not limited to poorly differentiated carcinomas, mesenchymal/spindle-like cells, acinar adenocarcinomas, and survival outcome. The incidence of lymph node and liver surface and micro-metastases as well as size and weight of the pancreatic tumors were determined. Tumor sections were stained with anti-5-bromo-2'-deoxy-uridine antibody to determine tumor cell proliferation and with anti-CD31/PECAM-1 antibody to determine vascularization. Results: OT-101 significantly reduced tumor growth (p = 0.0084), lymph node metastasis (p = 0.023), and tumor angiogenesis (p < 0.0001) in the orthotopic PAC model. Mean tumor vessel density was significantly reduced (p < 0.0001) in all groups in comparison to untreated control. OT-101 demonstrated synergy in tumor growth inhibition and increased survival in human malignant melanoma (C8161, p = 0.038, vs. Dacarbazine alone), glioblastoma (U87-MG, p = 0.001 vs. Paclitaxel) and ovarian (SK-OV-3, p < 0.05 vs. Paclitaxel) cancer models when combined with either Dacarbazine (C8161) or Paclitaxel (U87-MG and SK-OV-3). No synergy was observed with Gemcitabine (PAC). The combination regimen tested was effective and tolerable. Significant antitumor activity was achieved at human dose equivalent of 80 mg/m2/day which is well below the optimized clinical dose used for IV infusion of patients at 140 mg/m2/day. Conclusions: The preclinical data lay the groundwork which is well below the optimized clinical dose used for IV infusion of demonstrating that TGF-β2 is a druggable target. Of interest is the preferential synergy between OT-101 and Paclitaxel or Dacarbazine, but not with Gemcitabine.

#2803 The NCI mouse repository: Cancer models and miRNA-ES cell resource. Parirokh Awasthi, Fitzgerald Debra, Jones N. Stephen. Leidos Biomedical Research, Inc., Frederick, MD.

The NCI Mouse Repository, located at the Frederick National Laboratory for Cancer Research (FNLCR), Frederick, Maryland, is an NCI-funded resource of approximately 150 genetically-engineered mouse cancer models and associated strains, including mice bearing conditional and point-mutant alleles in cancer-related genes. In addition, the Repository houses a unique collection of over 1500 different mouse ES cell clones bearing conditionally-activated miRNA transgenes to facilitate in vivo exploration of miRNA functions. The NCI Mouse Repository makes strains and mESCs available to all members of the scientific community (academic, non-profit, and commercial). The mouse models and ES cell clones are cryo-archived and distributed as frozen germplasm or cells. Requests may be placed through the NCI Mouse Repository website (https://ncifrederick.cancer.gov/Lasp/MouseRe-pository/Default.aspx). In addition to the request form, this website includes detailed description for each strain accepted into the Repository and the associated publications provided by the donating scientist. The miR-harboring ESCs, originally generated at the Cold Spring Harbor Laboratories for the NCI Mouse Repository, are distributed to eligible miRNA-ES cell clone researchers. These resources are available for nominal cost to NCI, NIH, and other US government-funded investigators, as well as to Investigators at non-profit organizations.

#2804 Identifying therapeutically relevant mouse and patient-derived xenograft (PDX) models of human cancer using the mouse tumor biology database (MTB) data resource. Dale A. Begley, Debra M. Krupe, Steven B. Neuhauser, Joel E. Richardson, John P. Sundberg, Janan T. Eppig, Carol J. Bult. The Jackson Laboratory, Bar Harbor, ME.

Introduction: Hepatocellular carcinoma (HCC) is the third leading cause of cancer deaths worldwide. HCC typically arises in patients with chronic liver disease or cirrhosis, yet it is increasingly associated with non-alcoholic fatty liver disease (NAFLD), specifically nonalcoholic steatohepatitis (NASH) in the absence of cirrhosis. NAFLD is associated with obesity, metabolic syndrome, and/or patients with type II diabetes. Our previous studies have shown that high fat diet induces TNBC-like tumors but with limited capacity to metastasize to the liver and the growth of malignant tumors in a murine model. Glycine N-Methyltransferase (GNMT) expression is lost in over 95% of HCC, and mice deficient in GNMT develop spontaneous HCC by 6 months of age. We hypothesized that GNMT deficient mice would have an increased susceptibility for the development and growth of HCC when a fed high fat diet. Methods: Wildtype and GNMT deficient mice were placed on lean diet (LD, 13% calories from fat) or high fat diet (HFD, 42% calories from fat) at eight weeks of age. An initial cohort of mice were sacrificed after 3 months on diet (6 months of age) to assess for early tumor burden. A second cohort of mice was analyzed by magnetic resonance imaging (MRI) after 6 months on diet (9 months of age) and then sacrificed to assess for late stage disease. All mice were assessed for body weight, liver weight, pancreatic weight, and survival outcome. The incidence of lymph node and liver metastasis (p < 0.05, vs. LD fed GNMT mice) were equivalent after 3 months, but they were larger than wildtype mice fed LD. After six months on diet, MRI analysis showed significantly larger livers in HFD fed GNMT deficient mice than wildtype mice fed LD. All wildtype mice lacked any tumors after six months regardless of diet. Histological analysis revealed a heightened cellular proliferation via Ki67 staining in GNMT deficient mice compared to wildtype livers. In comparison, GNMT silencing also occurs in pancreatic cancer, yet none of the GNMT deficient mice developed pancreatic tumors. However, small focal areas of pancreatitis were detected regardless of diet. Additionally, pancreatic weight was significantly decreased in HFD fed GNMT deficient mice compared to the LD GNMT deficient mice. Conclusions: While high fat diet did not induce obesity in GNMT deficient mice, it significantly increased cellular proliferation and primary tumor growth in the liver. Understanding dietary factors that impact the microenvironment of the liver and to contribute to HCC development and progression is vital to finding new therapeutics for this malignancy.
TUMOR BIOLOGY: Cell Culture and Animal Models of Cancer

The laboratory mouse is the foremost model organism for interrogating the genetic and molecular basis of human cancer and is a powerful platform for identifying therapeutically effective targets for prevention and treatment of cancer. Research using genetically engineered mouse models (GEMMs) have led to important advances in our understanding of the genetic basis of cancer susceptibility, but data from these models is critical to the translation of drugs that show efficacy in xenografts and preclinical and clinical studies. Patient Derived Xenograft (PDX) models are an increasingly important model system for in vivo studies of human cancer. These models are created by implanting patient tumors into immunodeficient or humanized mouse hosts and are a powerful translational research platform for preclinical and clinical studies. The number of GEMM and PDX models being used is increasing every year and the diverse cancer-related data about human cancer models tend to be distributed in ways that makes it difficult for researchers to integrate and interpret the information to find the most relevant model for their research. The Mouse Tumor Biology database (http://tumor.informatics.jax.org) is an expertly curated resource for information and data about genetically defined mouse strains and PDX models of human cancer. MTB provides query tools to enable integrated searches and visualization of these varied data, thus facilitating the assessment of novel mouse models of human cancer and potential preventative and therapeutic treatments. Enforced control of the database and standard gene, allele and strain nomenclature within MTB facilitates precise and comprehensive queries of MTB for pertinent mouse models. MTB contains data from spontaneous or endogenously induced tumors from genetically defined mice including tumor classification, incidence, Quantitative Trait Loci, pathology reports, images and genetic changes in the tumor (somatic) and background strain (germline) genomes. The PDX resource enables queries based on tumor type, cancer diagnosis and genomic properties of the engrafted tumors. Information in MTB is obtained from curation of peer-reviewed scientific publications and direct data submissions from individual investigators and large-scale programs. New features in MTB include the Faceted Tumor Search Form and a Reported Mouse Model tool. Table linking the most common fatal human cancers to reported relevant mouse models. MTB contains over 77,000 Tumor Frequencies and over 2,200 Pathology Reports with over 6,600 images from over 4,200 references. MTB provides access to detailed clinical, pathological, expression and genomics data from over 400 PDX cancer models. Information in MTB is integrated with cancer models data from other bioinformatics resources including PathBase, the Gene Expression Omnibus and ArrayExpress. MTB is supported by NCI grant CA089713.

#2805 A panel of orthotopic glioblastoma multiforme (GBM) patient derived xenograft (PDX) mouse models for efficacy evaluation of drugs. Mette M. Jensen,1 Camilla S. Knudsen,1 Lotte K. Kristensen,2 Mette K. Nedergaard,2 Michael J. Wick,1 Kyriakos P. Papadopoulos,3 Anthony W. Tolcher,3 Andreas Brat,2 Minerva D. Demetri,1 ST112, ST146, ST545, ST610 and ST2473 were digested and used for intracranial stereotactic injection in nude mice. Tumor take and growth was determined by T2-weighted magnetic resonance imaging (MRI). At confirmed tumor take animals were treated with TMZ (100mg/kg/day for 5 days) or whole brain XRT (2 Gy/day for 5 days). Control groups receiving vehicle or sham XRT were included depending on treatment regimen. Final endpoint was survival by humane endpoints and tumors were fixed in formalin for histological evaluation. Results: The take rate was > 80% across all models. TMZ showed efficacy in the orthotopic ST610 GBM PDX model evaluated by MRI on day 14 (16.2±2.9 mm3 vs. 76.8±13.1 mm3, p=0.016), whereas the ST146 model displayed resistance to TMZ on day 14 (12.7±5.6 mm3 vs. 26.5±11.9 mm3, p=0.26). The median survival was 60 days vs. 14 days in the ST610 model (TMZ vs. vehicle, p=0.0005) and 27 days vs. 13 days in the ST146 model (TMZ vs. vehicle, p=0.007). XRT showed efficacy in the orthotopic ST2473 model. Tumor volume was significantly smaller in treated vs. sham animals 11 days after treatment (6.9±1.4 mm3 vs. 23.1±7.8 mm3, respectively). Also, survival benefit in XRT treated animals compared to sham. Histology confirmed the presence of orthotopic tumors and typical GBM pathology characteristics such as pseudopalisading tumor cells surrounding necrosis and micro vascular proliferation were identified. Conclusion: Six different orthotopic GBM PDX models were established from low passage subcutaneous PDX models. Models sensitive and resistant to TMZ were identified. The PDX resource enables queries based on tumor type, cancer diagnosis and genomic properties of the engrafted tumors. Information in MTB is integrated with cancer models data from other bioinformatics resources including PathBase, the Gene Expression Omnibus and ArrayExpress. MTB is supported by NCI grant CA089713.

#2806 Generation and characterization of mouse model of Pmepa1 conditional knockout in prostate epithelia. Shashwat Sharad, Talai Barbiev, Yingjie Song, Denise Young, Tatiana Srebnatha, Albert Dobi, Shiv Srivastava. Uniformed Services University, Rockville, MD.

Introduction and Objectives: Prostate cancer (CaP) is the most common non-skin malignancy diagnosed in American men and defunctions of androgen receptor (AR) plays an essential role in prostate tumorigenesis. Pmepa1 is an androgen and TGF-β induced gene abundant in prostate, which was identified to down-regulate protein via NEDD4 E3 protease mediated pathway. Reversal or loss of Pmepa1 expression, commonly detected in prostate tumors, led to increased AR protein and activated AR signaling. Pmepa1 inhibited TGF-β receptor 1 mediated signaling by a negative feedback loop. It was reported that loss of Pmepa1 facilitates bone metastasis of CaP through blocking TGF-β signaling. To further investigating the biological function of Pmepa1 gene in CaP tumorigenesis, particularly via AR and TGF-β, we generated Pmepa1 prostate conditional knockout mouse model. Methods: C57BL/6 male mice were utilized for generation of Pmepa1 conditional knockout model. Pmepa1 gene was conditionally deleted in mouse prostate epithelium by ARR2PB-Cre-Lox system. Male mice of genotypes of wild-type, Pmepa1 flox/wild-type, ARR2PB-Cre, Pmepa1 flox/flox and flox/flox-ARR2PB-Cre were euthanized at the age of 3 months for analysis. The prostate tissue was collected for frozen and formalin fixation for histology analysis, and other major organs including heart, lung, liver, spleen, bladder and testis were also collected for control. The tissue were sectioned and stained with Hematoxylin & Eosin (H&E). Total RNA and protein were harvested by homogenizing tissue. The protein levels of Pmepa1, AR and Nkx3.1 were analyzed by immunohistochemistry (IHC) and immunoblotting, and the transcript levels of these genes were evaluated by in situ hybridization (ISH) and quantitative-PCR (Q-PCR). Results: The expression of Pmepa1 protein was found to focus on lateral lobe, consistent with AR protein expression pattern. The data of Q-PCR and ISH showed that transcript level of Pmepa1 was dramatically suppressed in Pmepa1 flox/flox and flox/wild-type ARR2PB-Cre mice. Compared to wild-type ones, Pmepa1 protein was shown significantly decreased in heterozygotic and homozygotic knockout mice by immunoblotting and IHC staining. And the protein level of AR was stronger in Pmepa1 conditional deleted mouse. There was no dramatic morphology change in mouse prostate gland by H&E staining. Conclusions: Conditional deletion of Pmepa1 gene in mouse prostate epithelium led to enhanced AR protein and activating AR signaling. The effects of Pmepa1 gene loss in mouse prostate gland on other signaling such as TGF-β and prostate tumorigenesis are needed to be further evaluated. Funding: This study was supported by CPDR, SUHS, HU0001-10-2-0002 to DGM.

Recent success of multiple poly (ADP) ribose polymerase (PARPi) ribose polymerase inhibitors (PARPi) in treating BRCA mutant ovarian cancers has fueled the development of PARPi in several areas, including expanding its use in other BRCA mutant or wildtype cancers; exploring resistant mechanisms and overcoming resistance; seeking for its combination with chemotherapy, radiotherapy and emerging immunotherapy to achieve persistent efficacy. Especially considering the mechanism of action of PARPi, its use can increase the mutational loads in tumors with defects in homologous recombination and DNA doublestrand break repair, which potentially would enhance the immunogenicity of the tumors. Therefore it would be very interesting to test the effectiveness of combining PARPi with anti-PD1/PD-L1 or anti-CTLA4. However, relevant animal
models are lacking for such studies. Syngeneic mouse tumors offer about 30 viable in vivo models for proof of concept studies. However, these models suffer from several limitations: 1) only a few available and responsive to the current checkpoint inhibitors – for given strains of mouse, there are only very few choices of cells/disease types; 2) not mimicking patient tumors since they are in vitro models; 3) not reflective of the immune microenvironment; 4) lack of patient derived cell lines and tissues; 5) not readily available for common target agents, either in mono- or combination therapy. We have established allologs of spontaneous mouse tumors (MuPrime®) derived from genetically engineered mouse models (GEMMs) as a new type of immuno-oncology models with following advantages: 1) its primary nature of "stem cell diseases" and relevant tumor microenvironment; 2) its diverse cancer types/strains of mouse; 3) engineered oncogenic drivers as seen in human diseases, deriving from a wide range of available GEMMs, suitable for targeted agents. Thus far, we have built a small library of allografts and are testing them to facilitate pharmacological investigation, particularly those of immuno-oncology. We have found a few models, including an APC−/− skin squamous cell carcinoma and a P53 null sarcoma responded well to PARPi Niraparib. Continuous treatment with Niraparib led to development of partial or complete resistance. We are now profiling the resistant models to find out their general mutation loads, as well as specific biomarkers render resistant mechanisms. We are also treating the tumors with mouse PD1 antibody to test whether presumably enhanced mutation loads would sensitize these tumors to immunotherapy. The data of these studies will be presented at the meeting.

Identification of EphB4 as a tumor suppressor in melanoma. Ombratta Salvucci,1 Dragan Maric,2 Giovanna Tosato,1 1NCI/NINH, Bethesda, MD, 2NINDS/NINH, Bethesda, MD.

The Ephrins and Eph are a large family of ligands and receptors with critical physiologic functions in development and in adulthood. The EphB4 receptor and its unique ligand EphrinB2 have been implicated in the pathogenesis of a variety of cancers, but the underlying mechanisms remain unclear. Data from the Cancer Genome Atlas (TCGA) shows that the survival probability of patients with melanoma is significantly lower when EphB4 levels in the cancer tissue are very low compared to the average EphB4 levels in melanoma, suggesting a role of EphB4 in regulating melanoma progression. We investigated the role of EphB4 depletion in the regulation of melanoma cell growth. We report, that EphB4-depleted murine melanoma B16/F10 cells have a growth and survival advantage in vitro over control cells. This growth advantage is revealed under conditions of stress generated by hypoxia or nutrients deprivation, which is common during cancer progression. When inoculated into syngeneic mice, EphB4-depleted B16/F10 cells generate larger tumors than control B16/F10 cells. Initial mechanistic studies have revealed that EphB4-null B16/F10 tumors contain fewer apoptotic cells compared to control tumors, have more infiltrating CD31+/H11001 vessels and pericytes are detected at a distance from CD31+/H11002 vessels. Thus, we have generated a mouse model that reflects the tumor-suppressive function of EphB4 in human melanoma and have identified potential pathways underlying this function.

Role of c-Met in the development and progression of Tpl2-related skin cancer. Nicole F. Bonan,1 David Kowalski,1 Kaitlin Kudlac,2 Lauren G. Falkenberg,1 Erik Maradiaga,1 Kira Flaherty,1 Jonathan S. Wiest,2 Katie L. DeCicco-Skinner,1 1American Univ., Washington, DC, 2NCI, Rockville, MD.

Cutaneous squamous cell carcinoma (cSCC), a form of non-melanoma skin cancer, is the second most common form of cancer in the United States, with over one million cases diagnosed annually. Tpl2 (MAP3K8) is a serine threonine protein kinase in the mitogen-activated protein kinase (MAPK) signal transduction cascade. Tpl2 was identified by our laboratory as having a tumor suppressive function in skin carcinogenesis, with Tpl2 knockout mice developing significantly more papillomas and squamous cell carcinomas than matched wildtype (WT) controls. Cellular mesenchymal to epithelial transition factor (c-Met) is a receptor heightened in malignant skin cancers and involved in Tpl2 signaling. When bound to its ligand, hepatocyte growth factor (HGF), c-Met can regulate cell proliferation, survival, angiogenesis and invasion. The aim of this study was to ascertain whether c-Met signaling contributes to the heightened skin tumorigenesis inTpl2+/− mice. Forty-four WT and Tpl2+/− mice were subjected to a two-stage chemical carcinogenesis protocol for one year to induce skin tumors. Starting at the time of promotion, half of the WT and Tpl2−/− mice were placed on normal diet and half received diet plus 30mg/kg Capmatinib, a pharmacological inhibitor of c-Met. This diet continued for the duration of the study. No adverse health effects were found in Capmatinib-treated mice. Similar to what we previously reported, Tpl2−/− mice developed tumors earlier than WT controls and had statistically higher tumor incidence and overall tumor burden than WT mice. The number of tumor bearing Tpl2−/− and Tpl2+/− + Capmatinib fed mice was similar, although Capmatinib fed mice had a 60% reduction in overall tumor burden. Studies are underway to determine if Capmatinib affected the frequency of malignant conversion in Tpl2−/− mice. In summary, our studies demonstrate that heightened c-Met signaling contributes to the higher tumor formation in Tpl2−/− mice and should be evaluated further as a possible therapeutic target in Tpl2-related skin cancers.

Using CRISPR/Cas9 to generate primary soft tissue sarcoma in genetically engineered and wild-type mice. Jianguo Huang,1 Mark Chen,1 Melodi J. Whitley,1 Hsuan-Cheng Kuo,1 Andrea Walens,1 Yvonne M. Morey,1 David V. Mater,1 William Eward,1 Diana M. Cardona,1 Lixia Luo,1 Yan Ma,1 Christopher E. Nelson,1 Jacqueline N. Robinson-Hamm,1 Charles A. Gersbach,1 Rebecca D. Dodd,2 David G. Kirsch.1 Duke University Medical Center, Durham, NC, 2University of Iowa, Iowa City, IA.

Genetically engineered mouse models (GEMMs) that employ site-specific recombinase (SSR) technology are important tools for pre-clinical studies, but this approach is costly and time-consuming. Here, we show that the CRISPR/Cas9 system can be used to efficiently complement existing GEMMs of sarcoma and generate primary sarcomas in wild type mice. Mice with the genotype KrasLSL-G12D+/−; Rosas2LSL-Cas9-EGFP/+ received intramuscular delivery of an adenvirus expressing Cre recombinase and a single guide RNA (sgRNA) targeting Trp53. Cre-mediated excision of oncogenic Kras and Cas9, in combination with CRISPR/Cas9-mediated knockout of Trp53, was sufficient to generate primary soft tissue sarcomas. These tumors arose with kinetics similar to those generated using the Cre-loxP system to active oncogene and delete Trp53 alleles. Additionally, we injected an adenosivirus containing Cas9 and sgRNAs targeting NFI and Trp53 into the sciatic nerve of wild type mice. These mice formed malignant peripheral nerve sheath tumors (MPNSTs) in the same time frame as MPNSTs generated using the Cre-loxP system to delete NFI and Ink4a/Arf alleles in GEMMs. These data demonstrate that CRISPR/Cas9 can be used to generate soft tissue sarcomas in wild type mice. Moreover, these results suggest that this technology can complement existing GEMMs for rapid assessment of tumor-modifying genes. These tools should decrease the time and expense associated with employing autochthonous mouse models for preclinical research.

Immunotherapy represents an extremely promising treatment approach for cancer patients. The success in this field has been signified by multiple recent approvals of checkpoint inhibitors across a range of cancer types. Subsequently, there is an increasing need to understand why certain patients and diseases benefit from these treatments while others do not, as well as how to maximize the benefits from these treatments. To address some of these questions, we used an allograft tumor model, which allows for the comparison of a panel of syngeneic models and treatment modalities. We have characterized baseline and treated tumor immune infiltrates for a panel of syngeneic models using flow cytometry. The correlation between responsiveness and effects of checkpoint inhibitors (e.g., anti-PD-1), and macrophage targeted agents (e.g., CSF1R inhibition) on immune infiltrates including tumor-associated macrophages (TAMs) were investigated in 6 syngeneic models. Furthermore, M1/M2 polarization of macrophages was investigated to explore the potential role of these cells in establishing an immunosuppressed tumor microenvironment that may affect response to therapy. Here, we show that the baseline immune cell population varies across models, and that immune checkpoint inhibitors and macrophage-targeted agents had variable efficacy across different tumor models. We also present the correlation of immune cell infiltration, including tumor infiltrating lymphocytes (TILs), TAMs, and responsiveness to immunotherapy intervention. Having an in-depth understanding of the immune make up of a model in which an immunomodulatory compound is screened is paramount for successful translation into the clinic. A well-characterized and fully profiled panel of syngeneic models such as the MusScreen platform allows for finding the right model for screening test compounds to be used alone or in combination with immunotherapy.

Development and characterization of the ultra immunodeficient B6;129-Rag2−/−R2R2−/−IL2rg−/−DwHsf (R2G2) mouse model. Sheryl J. Wildt, Jamie McClellan, Mandy Horn. Envigo RMS, Indianapolis, IN.
The "R2G2" (B6;129-Rag2tm1Wtm1Il2rgtm1Hdi/DwHsd) knockout mouse is the latest advancement to provide an alternative option in the highly immunodeficient mouse model category for the oncology, immunology and other biomedical research communities. This model was generated by backcrossing an Il2rg (common gamma) knockout model to a Rag2 (recombinase activating gene) knockout model. The resulting mouse lacks various cytokines including IL-2, IL-4, IL-7, IL-9 and IL-15. In addition, this model lacks B cells, T cells, NK cells and has a deficit in lymphocyte development. The R2G2 model is not only ultra immunodeficient, but provides a model that is less leaky and more tolerant to gamma radiation than traditional SCID models. This model is particularly useful for both tumor transplantation and humanization studies. Herein we describe the development and characterization of the R2G2 model, which includes breeding history, growth curve, CRC/Chemistry, flow cytometry and both hUHSC and huPMBC humanization studies.

#2813 An interactome analysis for personalized chemotherapy using PDX/NOG models of non-small cell lung cancer. Tsuyoshi Chijiwa, 1 Daisuke Komura, 2 Mizuha Haraguchi, 2 Akira Noguchi, 3 Hidemitsu Sato, 1 Hiroko Ito, 1 Haruhiko Nakayama, 4 Makoto Katayama, 4 Naoki Miyao, 5 Naruki Matsui, 6 Yuichi Tateishi, 7 Hiroshi Sueizu, 7 Yoshiyuki Nakamura, 6 Daisuke Furakawa, 6 Takayuki Isagawa, 6 Hiroto Katoh, 5 Shunpei Ishikawa, 5 Masato Nakamura, 6 Yohei Miyagi, 1 Saitama Medical Center, Ichi Medical University, Saitama, Japan; 3 Medical Research Institute, Tokyo Medical and Dental University, Japan; 4 Nihon Kookan Hospital, Saitama, Japan; 5 St. Marianna University School of Medicine, Saitama, Japan; 6 Kanagawa Cancer Center, Saitama, Japan; 7 Kawai-saki Municipal Hospital, Saitama, Japan; 8 Cancer Research Institute for Experimental Animals, Japan; 9 Research Institute, Kanagawa Cancer Center, Japan; 10 Tokai University School of Medicine, Japan.

Lung cancer is one of the most common malignant diseases in the world, and its prognosis is generally poor. It is crucial to elucidate the biological mechanisms underlying lung cancer and accelerate the development of new treatment strategies. Xenografts derived from engrafting fresh surgical specimens directly into immunodeficient mice have recently enabled the development of more relevant in vivo models of human cancers. These patient-derived xenograft (PDX) models, established by the direct transfer of tumor tissue, retain similar morphology, heterogeneity, and molecular signatures as the original cancers, and, thus, may be used in promising personalized medicine for cancer. We previously reported the rapid and efficient establishment of PDXs using super immunodeficient NOG mice (PDX/NOG model). In the present study, we analyzed the gene expression and cancer-stroma interaction profiles of PDXs established from NSCLC patients. We also discussed the possibility of individual PDX/NOG model simulations for personalized cancer chemotherapy. Ten NSCLC lines of PDX/NOG (Age 43-78 years; 8 men and 2 women; 7 adenocarcinoma, 1 adenosquamous carcinoma, 1 squamous carcinoma, 1 large cell carcinoma) were presented. In these cases, clinical information regarding chemotherapy for donor patients was retrieved where possible. Genome sequencing and comprehensive analyses of tumor-stroma interactions (Cancer-STromal Interactome analysis, CASTIN) were performed on mRNA. CASTIN showed tumor-stroma interactions in PDX/NOG comprehensively and quantitatively at the gene expression level by distinguishing gene arrangements in human tissue (Cancer) from mouse tissue (Stroma) as signal strengths (ligand dependency (%) / receptor dependency (%)). Interactions of EGFR(cancer)-EGFR(stroma) were observed from 1.2 (15%/0%) to 11.5 (94%/80%) as widely-distributed. Inclusion: Collectively, our PDOX models using needle biopsy specimens can reflect the pathological and molecular features and drug responsibility of a patient’s tumors. PDOXs have been generated by subcutaneously implanting surgically resected tumor fragments into immunodeficient mice. Unfortunately, 80% of pancreatic cancer patients is unresistant and they show highly aggressive and metastatic tumors. In most cases, diagnoses are confirmed histologically and diagnosed through endoscopic ultrasonography-guided/fine-needle aspiration (EUS/FNA) or percutaneous liver biopsy. However, they are not suitable for subcutaneous implantation into mice due to their threadlike shape and very small size. Therefore, the lack of patient-derived model system in pancreatic cancer is in desperate need of new strategy to cover unresectable patients as well as resectable. Here, we pioneered the development of a unresectable patient-derived orthotopic xenograft (PDXO) model satisfied with short period and high success rate, and made the best use of them as the test model for drug response. Methods and Results: PDXO models were established with a technique of direct surgical orthotopic implantation into the pancreatic tail of Athymic nude mice. PDOXO showed the highest rate of engraftment, nearly 40% (17 cases among 44 cases) in patients with a time to progression of <6 months. The histopathological characteristics of the PDOX tumors are similar with those of the patient’s original tissues. Additionally, genetic alterations were retained between patient tissues (F0) and PDOX tumors (F1–F3) from the mutation analysis using a comprehensive cancer panel. For drug responsibility, we selected refractory or sensitive PDOXO groups to Gemcitabine and Abraxane based on their clinical information. As results after treatment with Gemcitabine, Abraxane and combination, selected PDXO models showed the drug sensitivity significantly correlated with the drug responsibility of original patients. Tumor growth was monitored by animal MRI every 2 weeks during 2 months. Typically, xenograft models using immobilized pancreatic cancer cell line, CF-PAC-1, showed tumor regression to all treatment set. Conclusion: Collectively, our PDXO models using needle biopsy specimens can reflect the characteristics of unresectable patients and give the expectation the drug responsibility. They furthermore might be valuable in a screening and development system for targeted therapeutics, which can be applied to a wide range of pancreatic cancer patients.
#2817 Enriched environment inhibits progression of acute myeloid leukemia. Run Xiao, Stephen M. Bergin, Michael A. Caligiuri, Lei Cao. The Ohio State University Comprehensive Cancer Center, Columbus, OH.

Background: Environmental factors and lifestyle have profound effects in the initiation, promotion and progression of cancer. Our recent work on environmental enrichment (EE), a housing environment boosting mental health, has revealed a novel phenotype characterized by a robust reduction in adiposity, resistance to diet-induced obesity (DIO), enhanced insulin sensitivity, lower serum IGF-1 and leptin levels, higher serum adiponectin level, enhanced immune functions, and inhibition in melanoma and colon cancer growth. We have teased out one key mechanism underlying the anticancer effect of EE: the stimulation of brain-derived neurotrophic factor (BDNF) expression in the hypothalamic-sympathoneural-adipocyte (HSA) axis. However, the EE’s effects on hematologic malignancy are largely unknown. Here we generalized this intervention to acute myeloid leukemia (AML) using the MLL-partial tandem duplication (PTD) and Flt3-internal tandem duplication (ITD) double knock-in mouse (MLLP KD/ITD KD). This recapitulates features of counterpart human AML. Methods: For transplantation of AML cells, Ly5.2 spleen cells isolated from leukemic MLL-PTD/WT, Flt3ITD/WT mice were resuspended in PBS. Syngeneic Ly5.1 recipient C57BL/6 male mice (CD45.1 +) were sublethally irradiated (400 cGy). Five to six hours later, leukemic cells (4 × 10^6 per mouse) were injected through the lateral tail vein. Those mice were randomly assigned to either standard laboratory cage (SE) or EE housing. To monitor AML progression, white blood cell (WBC) counts were measured from peripheral blood. Survival experiments were performed. Results: EE mice had a median survival 14% longer than SE mice (SE = 36 ± 1.1 days, EE = 41 ± 1.2 days, p = 0.038) and improved hazard rate (log-rank test z = 1.99, p = 0.047). Based on WBC counts (>10.9 k/μL), 100% of SE mice and 80% of EE mice had apparent AML at three weeks post injection. At this time point, EE had a substantially lower WBC counts (SE = 76.9 k/μL, EE = 28 k/μL, p = 0.036). WBCs from EE mice had lower neutrophil, monocytes, eosinophils and basophils counts, but had similar lymphocytes, resulting in a reduced neutrophil to lymphocyte ratio. Red blood cell (RBC) and platelet data were the same except for a slightly reduced mean corpuscular hemoglobin concentration (MCHC) in EE mice. At four weeks, EE mice were substantially more active and mobile than SE mice. At five weeks, at which point 3 SF and 5 EE mice remained alive, WBC counts remained lower in EE mice. Conclusions: This preliminary work demonstrated EE substantially improved progression-free survival and conferred a significant survival benefit. We will elucidate the underlying mechanisms of EE’s anti-AML effect by analyzing metabolic modulation and immune regulation.

#2818 PDX model of the enriched pleural effusion from advanced lung cancer patient for testing on targeted drug sensitivity and resistance. Feifei Zhang,1 Ke Wang,1 Wenhua Xu,1 Yang Yang,1 Kedong Ouyang,1 Shun Lu,1 Danyi Wen,1 Taiping Chen1. 1LIDE Biotech Ltd, Shanghai, China; 2Shanghai Chest Hospital, Shanghai, China.

Aiming for treatment of lung cancer, we observed the pleural effusion of lung cancer patients is selectively sensitive to available targeted therapeutics and often developing resistance to the early sensitive drug treatment. Surgery tumor tissues are usually not available to establish patient derived xenograft (PDX) models which is critical to evaluate drug sensitivity and resistance. We applied CD45 magnet beads to enrich the tumor cell population from pleural effusion specimens of advanced lung cancer. Seven PDX models were successfully established in this way. Based on genetic profiling of these models, TKI drug related EGFR mutations and ALK fusion were confirmed (EGFR: L858R, T790M, Exon 19 insertion; ALK fusion). Further in vivo efficacy studies were designed to test on multiple drug sensitivity and resistance including Gefitinib, Erlotinib, Ceritinib, Alecrtinib, AZD9291. Tumor growth inhibition (TGI) were well matched with corresponding gene mutations among the models. In particularly, T790M model was resistant to Erlotinib and quite sensitive for AZD9291. In conclusion, the models established here are very useful to test on potency of many current investigational TKI drugs and provide base for drug resistant model establishment.

#2819 Intestinal estrogen receptor beta attenuates colon cancer signaling pathways in vivo. Linea Petterson,1 Ashish Saxena,2 Tran Vu,3 Jan-Åke Gustafsson,2 Amena Archer,1 Cecilia Williams1. 1Karolinska Institute, Stockholm, Sweden; 2Center for Nuclear Receptors and Cell Signaling, Houston, TX; 3Scilifelab, Stockholm, Sweden.

Colorectal cancer is the third most common form of cancer and the second leading cause for cancer deaths. Several epidemiological, in vitro and in vivo studies suggest that Estrogen receptor β (ERβ) could be a potential target for CRC prevention and treatment, but the potential mechanism is not demonstrated. ERβ is expressed in intestinal epithelial cells, as well as in some intestinal immune cells and other tissues. Previous studies have seen increased CRC after full ERβ knockout, but it is not clear if this is mediated by intestinal ERβ. The specific aim of our study is to determine the role of intestinal ERβ during colon cancer development in vivo. We deleted ERβ specifically in the intestine epithelium of mice (IERβKO), and induced CRC using Aoxymethane (AOM) and Dextran Sulfate Sodium (DSS) treatment. After 9 weeks treatment, all mice presented colitis and two iERβKO mice but none of the wild-type (WT) mice had developed tumors. qPCR showed that the expression of pro-inflammatory markers was higher in iERβKO treated mice than in untreated or WT mice. Immunohistochemistry (IHC) of proliferative markers showed that iERβKO exhibited higher cell proliferation in the top of the crypts compared to controls. After 16 weeks treatment, all mice developed tumors. qPCR showed that the expression of mesenchymal markers was higher in treated iERβKO mice compared to treated WT mice. Our results demonstrate that intestinal ERβ attenuates colon cancer-related pathways.

#2820 Use of a genetically engineered mouse model and RNA sequencing to identify genes that are aberrantly regulated by mutant p53 in prostate cells following irradiation. Ruth L. Vinall,2 Qian Chen,2 George Talbott,3 Neil Hubbard,2 Clifford Tepper, Alexander Borowsky,1 1California Northstate Univ., Elk Grove, CA; 2University of California, Davis, Sacramento, CA; 3California Northstate University, Elk Grove, CA.

Our group has previously demonstrated that the Trp53 R270H mutation can drive prostate cancer (CaP) initiation in a genetically engineered mouse model, and that the human equivalent, TP53 R273H, can promote development of castration resistant growth of LNCaP cells as well as resistance to commonly used therapeutic agents. The primary objective of the current study was to identify genes that may contribute to the development of these gain-of-function phenotypes. Wildtype mice and mice that were heterozygous or homozygous for the Trp53 R270H mutation (referred to as Trp53 +/+ or Trp53 R270H/R270H mice respectively) that were ~2 months old were exposed to 5 Gy radiation to activate and stabilize p53, consequently increasing its expression. Mouse prostate were harvested 6 hours post-irradiation and either processed for subsequent histological/immunohistochemistry (IHC) analysis or snap-frozen for subsequent RNA extraction and transcriptome profiling with RNA-sequencing (RNA-Seq) analysis. P53 expression data was processed to quantify transcript levels and to assess differential gene expression between the 3 groups. PIN lesions were observed in 3-month-old Trp53 R270H/R270H mice prostates, but not in Trp53 +/+ or Trp53 R273H/R270H mice prostates. IHC analysis demonstrated that p53 was stabilized in the...
majority of prostate cells from Trp53+/+; Trp53+/−/R270H, or Trp53 R270H/R270H mice 6 hours post-irradiation. RNA-Seq analysis of RNA isolated from irradiated mice prostates identified 1,444 genes that were differentially expressed in Trp53+/+ versus Trp53 R270H/R270H mice prostate cells, and 796 genes that were differentially expressed in Trp53+/− versus Trp53+/+ R270H mice. Statistically significant differences in gene expression between the 3 groups were observed for 1,378 genes, including a number of p53 target genes, such as Cdkn1a, Bax, Bcl2, Kras, Mdm2, and Id4. We data identify multiple genes that may contribute to prostate cancer initiation and/or progression through p53 gain-of-function and loss-of-function mechanisms. It is possible that further analysis of these genes may lead to the development of new therapies and/or biomarkers for prostate cancer patients as well as guide the usage of currently available therapies in men at risk of developing CaP and CaP patients who harbor TP53 mutations.

#2821 Impact of SCID mouse gender on tumorigenicity, xenograft growth and drug-responses in patient derived orthotopic xenograft models (PDOX) of malignant brain tumors. Lin Qi, 1 Mari Kogiso, 1 Yuchen Du, 1 Huiyuan Zhang, 1 Frank Braun, 2 Holly Lindsay, 1 Sibo Zhao, 1 Sarah Injac, 1 Patricia Baxter, 1 Zhigang Liu, 1 Yuqing Zhang, 1 Jack Su, 1 Adekunle Adesina, 1 Andrew Walter, 1 Jeffery Murray, 1 Javad Nazarian, 1 Will Parsons, 1 Murali Chintagumpala, 1 Xiao-nan Li, 1 Texas Children’s Cancer Center, Houston, TX.

Brain tumor is the leading cause of cancer related death in children. To develop new therapies and to understand tumor biology, many efforts are made to develop patient derived orthotopic xenograft mouse models (PDOX). There are, however, concerns about the potential impact of animal genders on tumor take rate, xenograft growth and in vivo drug responses. To systematically analyze such impact, we retrospectively examined >1,000 mice of 59 PDOX models, including glioblastoma (GBM), medulloblastoma (MB), primitive neuroectodermal tumor (PENT) and ependymoma (EPN) and diffuse intrinsic pontine glioma (DIPG), in which there were age-matched (within 2 wks differences) with relatively even numbers of male and female animals. All the animals were injected with identical number of tumor cells (1x10⁵) in the mouse brains matching that in human patients. Animals were monitored daily and euthanized when they were moribund. Differences between male and female mice were analyzed by t-test. In 25 GBM models (15 adult and 10 pediatric) involving 419 mice, there was an average of number of mice was 17.8±9.5 mice per model (male-female = 9.5±4.3:7.7±1.3) (P<0.05). The tumor take rate was near ≥95% in both male and female mice (P>0.05). In GBM models, the survival times was 94.1±21.7 days in male mice and 92.3±20.8 days in female mice (P=0.05); whereas in MB models, they were 134.9±21.7 days in male and 121.0±31.6 days in female mice (P<0.05). The impact of animal gender on drug responses in vivo is essential to the preclinical drug testing. A total of 468 mice from 11 GBM, 5 MB, 3 EPN, 3 DIPG and 2 PNET were treated a series of standard and investigational drugs/compounds, including radiation, oncolytic virus (SVV-001), ABT888, BM1-inhibitor, MN18237, TMZ, Flavopiridol, SYC-435, SYC-719, SYC-836, Olig 2 inhibitor, VPA, SAHA, Echinomycin, MC8613, and PARP. The overall survival times were 17.63±2.83 days in male mice (P<0.05). The only model that exhibited the increased responses in male mice was found in IC-2305GBM treated with TMZ and PTC-596 (P<0.05). In conclusion, our data demonstrated that the gender of SCID mice does not have major impact on animal development nor in drug responses, and SCID mice of both genders are appropriate for brain tumor PDOX model development.

#2822 Establishing the use of Vortex technology for investigating circulate tumor cells in mice models of breast cancer. Vishnu Raman, 1 Rakihi Gupta, 1 Melanie Triboulet, 1 Corinne Renier, 2 Steve C. Crouse, 2 Elodie Sollier-Christen, 2 Stefanie S. Jeffrey, 1 Stanford University, School of Medicine, Stanford, CA; 2Vortex Biosciences, Menlo Park, CA.

Background: Circulating tumor cells (CTCs) are precursors of metastatic disease and are an important indicator of the disease progression and outcome of many cancers. Though several recent studies have advanced our understanding of CTCs, many critical areas of CTC biology remain largely unexplored. Murine models of cancer offer a unique opportunity to address this issue. However, small sample volumes, low number of CTCs, difficulty to access ports for blood collection are challenges that diminish the utility of mouse models for studying CTCs. In our previous studies, we had validated the use of Vortex technology for the label-free capture of CTCs from blood samples of different cancers. In this current study, we now report our recent, unpublished data on the adaptation of Vortex platform for enriching and characterizing murine and human tumor cells from mouse blood. Methods: By spiking tumor cells into small volumes of mouse blood (200–400 μl) from cardiac puncture, we tested the impact of i) different dilutions of mouse blood (10X, 20X, 40X); ii) varying numbers of tumor cells; iii) different cell types (MDA-MB-231, 4T1 and EMT6); and iv) sample recyling on capture efficiency and purity. Blood was processed through the Vortex plastic chip and, to accurately identify and enumerate the enriched population, specific cytokerin, vimentin, and CD45. Results: Our results reveal that over a range of dilutions tested, just after one cycle, 10X dilution of mouse blood was superior, yielding a capture efficiency of 38.83% and a purity of 33% for MDA-MB-231 cells, compared to 20X (34.16% efficiency, 31.1% purity), and 40X (31.83% efficiency, 31% purity) dilutions. We are currently testing whether recyling the same cell blood through the enrichment protocol that label-free capture of CTCs. Even when as many as ~7500 tumor cells were spiked in mouse blood, the Vortex platform was able to successfully enrich tumor cells with high consistency and purity. Importantly, we were now able to successfully isolate human and murine tumor cell lines with varying levels of epithelial cell adhesion molecule (EpCAM) expression (4T1 - high, MDA-MB-231 - moderate to low) spiked into mouse blood. Experiments confirming the viability and growth rate of cancer cells isolated from mouse blood using MTT assay will also be presented. Conclusion: In summary, our results reveal the use of the Vortex technology for studying CTCs in murine models of cancer, with the ability to handle volumes of blood as low as 200UL while having a capacity to capture extremely large number of CTCs. While this study was focused on breast cancer, our workflow is easily adapted to other tumor systems for future biologic and drug testing studies.

#2823 Immunodeficient mice differentially sensitize to estrogen and exhibit severe estrogen-related adverse effects in orthotropic breast cancer model. Tiina E. Kähkönen, 1 Mari I. Suominen, 1 Jenni Mäki-Jouppila, 1 Jussi Halleen, 1 Azusa Tanaka, 2 Michael P. Seiler, 2 Jenni Bennoth, 2 Pharmaceut Service Ltd, 3D, Tansu, Fines, 1Juli, 2Hollering. 1Proceedings of the American Association for Cancer Research.

Estrogen-induced growth induction and stimulation of hormone receptor positive breast cancer is commonly acknowledged and thus external estrogen stimulus is used in animal models to support and accelerate growth of the tumors. However, estrogen is known to have adverse effects in the animals and the experiments may have to be preliminary terminated due to animal welfare issues. The aim of the study was to characterize and to compare estrogen caused adverse effects in athymic nude and NOG mice in orthotopic breast cancer model. Athymic nude (Hsd:Athymic Nude-Foxn 1nu) and CIEA NOG (NOD.Cg-PkdcscidIl2rgtm1Sug/JicTac, provided by Taconic Biosciences) were implanted with estrogen (17β-estradiol, E2) releasing hormone rods (5 μg/day) prior to cancer cell inoculation. 2x10⁵ BT-474 (ER, PR and HER+) human breast cancer cells were inoculated to left inguinal mammary fat pad of the mice and the tumor growth was monitored by measuring the tumor volumes twice a week by caliper. The clinical condition and weight development of the mice was carefully monitored with special attention to E2-caused adverse effects. If the mice met the termination criteria (i.e. significant weight loss or general worsening of the overall health) they were sacrificed individually before the intended end of the study. Nude mice exhibited severe estrogen-related adverse effects as no adverse effect were observed in NOG mice. Most common adverse effect was redness and skin lesions in the urogenital area observed in 63% of the animals. More severe effects were observed in the lower urinary tract including urinary stones and bladder obstruction in 67% of the mice. Also internal effects were observed including appearance change in kidneys and spleen in size and color. Due to severity of these effects 50% of the mice had to preliminary sacrificed. Tumor take (100% vs 85%) and final tumor volumes in average (110 mm³ vs 120 mm³) were comparable between nude and NOG mice. A clear mouse strain specific impact was observed in the study. Nude mice sensitive to estrogen and exhibit severe estrogen-related adverse effects as no effects were observed in NOG mice. In breast cancer studies where E2 supplementation is needed for sufficient tumour growth, the choice of mouse strain should be carefully considered. Special attention should be paid to possible adverse effects keeping in mind the animal welfare issues.

#2824 Validation of a panel of patient-derived xenograft models for prostate cancer and cell line models for preclinical drug evaluation. Nektaria Panagopoulos, 1 Jane Wrigley, 1 Andrew McKenzie, 2 Jason King, 1 Louise Wainwright, 1 Kelly Jones, 1 Anne Collini, 2 Rajendra Kupari, 2 Crown Bioscience UK, Loughborough, United Kingdom; 3University of York, York, United Kingdom.

Background: Prostate cancer is the second most common cancer worldwide for males, and the fourth most common cancer overall, with more than a million new cases diagnosed. However, progress toward understanding the biology of...
prostate cancer and the development of new therapies has been hampered by the lack of in vivo models that adequately represent the spectrum of benign, latent, aggressive, and metastatic forms of the human disease. Here we report the validation of a panel of patient-derived xenograft (PDX) models and their utilization in preclinical studies alongside cell line models of prostate cancer. Methods: Prostate tumors obtained from surgery were collected with ethical consent, disaggregated and established subcutaneously in Rag2−/−γc−/− mice (The Jackson Laboratory) to generate PDX models. Tumor material was diagnosed on the basis of operative histology and immunohistochemistry (IHC for PSA, androgen receptor expression). Tumor growth in both Rag2−/−γc−/− and NSG mice was evaluated in comparison to cell line models such as LNCaP and PC3M. Briefly tumors were measured 3 times a week and tumour volumes were estimated using the formula 0.5(LxW^2) by measuring the tumour in two dimensions using electronic callipers for the duration of the study. For orthotopic PC3M, tumour growth was checked once weekly by bioluminescent imaging (BLI). Briefly, the mice were injected (s.c.) with 150μg/kg D-Luciferin prior to imaging, anaesthetised following administration of D-Luciferin and placed into the imaging chamber (Spectrum CT) and imaged for luminescence (ventral view). Results: We have established a bank of transplantable prostate cancer PDX and stocks are maintained in liquid nitrogen which can be resuscitated in both Rag2−/−γc−/− and NSG mice. Two models were reported to be hormone sensitive and 2 models represented castrate resistant prostate cancer (CRPC) one of which has a TMPRSS-ETS fusion. In comparison cell lines derived from the same mutation, the CRPC xenograft grows slower than the corresponding cell line model. PC3M CRPC orthotopic model develops metastasis in the liver, lungs, lumbar lymph nodes, fore limb and hind limbs representing the late stage of cancer. Conclusions: We have characterised both cell and patient-derived prostate cancer xenograft models which will provide a clinically relevant platform spanning the different stages of the disease for preclinical drug evaluation.

#2825 Gene expression profile in genetically engineered mouse model of lung cancer correlates with that in human lung adenocarcinoma. Imyavarmanan Lakshmanan, Satyanarayana Rachagani, Moorthy Ponnapusa, Seema Chugh, Samikshan Dutta, Sakhthivel Muniyan, Surinder Batra, Aparvaramban Lakshmanan, Satyanarayana Rachagani, Moorthy Ponnusamy, Rag2−/− and Rag2+/+ mice were injected intraperitoneally with human lung adenocarcinoma xenografts were successfully established after intraperitoneal injection of OE19 cells. The median survival time of these animals was the shortest (45 days for 10X10^6 cells). In addition, median survival was significantly increased after paclitaxel treatment compared with the control group (57 days versus 45 days, p<0.0034) along with a significant decrease of the relative subcutaneous tumor volume (p=0.023). Conclusion: Peritoneal esophageal adenocarcinoma xenografts were successfully established after intraperitoneal injection of OE19 cells. This animal model of peritoneal dissemination for survival outcome will provide a useful survival outcome assessment model for the preclinical evaluation of cancer therapeutics in esophageal adenocarcinoma.

#2827 Establishing a mouse model to investigate GRB7-mediated signaling in development and triple-negative breast cancer. Christopher A. Lofgren, David R. Meier, Steven E. Cash, Parac S. Kenney, Gunderon Medical Foundation, La Crosse, WI.

Triple-negative breast cancer (TNBC) lacks expression of the estrogen and progesterone steroid receptors and HER2, thus TNBC patients cannot benefit from the recent successes of targeted therapies, and instead rely on cytotoxic chemotherapeutic combinations. As such, tumor recurrence is high and patient prognosis is poor. GRB7 is a cytoplasmic adapter protein required for cell migration, invasion, and proliferation in TNBC. We have previously reported that a high GRB7 mRNA level was the strongest predictor of tumor recurrence in a cohort of 246 TNBC patients treated with doxorubicin. GRB7 was confirmed in a small, independent cohort as an indicator of poor prognosis. After the observation of both decreased doxorubicin sensitivity and elevated GRB7 expression levels in TNBC tumors, we hypothesized that GRB7 was mediating a signaling pathway critical for drug resistance and cell survival. To determine the role of GRB7 in mouse development and tumorigenesis, the current study focuses on the Grb7tm1a.xc3x0.1 mouse, in which the insertion of the I12.L2 B act/p csetase upstream of the critical exons of GRB7 renders an effective knockout of GRB7, and the inclusion of loxp sites flanking critical exons of GRB7 facilitates the creation of tissue-specific, conditional GRB7 deletions. Herein, we investigate GRB7 expression in the homozygous Grb7tm1a.xc3x0.1 mouse and derivative tissue-specific deletions, and evaluate their suitability for modeling GRB7-mediated events in mammary gland development and tumorigenesis in a TNBC model. Primary cell lines from the Grb7tm1a.xc3x0.1 mouse and breast cancer cell lines will then be used to delineate the effects of altered GRB7 levels on the mechanism of developmental and TNBC cell signaling, respectively.

TUMOR BIOLOGY: Gene Expression in Metastatic Progression

#2828 Role of NEFL in aggressive prostate cancer progression. Tanya C. Burch, Ian O. Oduor, Dean A. Troyer, Julius O. Nyalwidi, Eastern Virginia Medical School, Norfolk, VA; Old Dominion University, Norfolk, VA.

Introduction: Esophageal adenocarcinoma (EAC) has become the dominant type of esophageal cancer in United States. EAC is the fastest growing cancer in the western world and the overall 5 year survival rate of EAC is below 20 percent. Most patients present with locally advanced or widespread metastatic disease, where current treatment is largely ineffective. Prognosis for EAC patients remains poor even with combination therapies due to high resistance to chemotherapy. Therefore, new therapeutic approaches are urgently needed. Improvement of esophageal adenocarcinoma outcome requires well-characterized animal models in which to evaluate novel therapeutics. In this study we aimed to establish a peritoneal dissemination xenograft mouse model of esophageal adenocarcinoma that would support survival outcome analyses. Methods: To find the best candidate cell line from 7 esophageal adenocarcinoma cell lines of various origin, we injected them intraperitoneally and subcutaneously into severe combined immunodeficiency (SCID) mice and examined the tumor progression and survival outcome. Human esophageal adenocarcinoma cell lines of Caucasian/Hispanic origin ES026, OE33, ES051, SK-GT-2, OE19, OACM5.1C and Flo-1 originating from gastroesophageal junction, distal esophagus and gastric cardia/fundus were injected intraperitoneally/subcutaneously into SCID mice. The peritoneal/xenograft tumor formation and mouse survival were compared among different groups. Results: All cell lines injected subcutaneously formed tumors within 3 months at variable rates. All cell lines except OACM5.1C formed intraperitoneal tumors within 3 months at variable rates. Median animal survival with peritoneal dissemination was 108 days for ES026 cells (5X10^6), 65 days for OE33 cells (5X10^6), 88 days for ES051 cells (5X10^6), 76 days for SK-GT-2 cells (5X10^6), 55 days for OE19 cells (5X10^6), 45 days for OE19 cells (10X10^6) and 82 days for Flo-1 cells (5X10^6). Interestingly, only in the OE19 model all mice (7/7 for 5X10^6 and 5/5 for 10X10^6) developed bloody ascites with liver metastasis after intraperitoneal injection. The median survival time of these animals was the shortest (45 days for 10X10^6 cells). In addition, median survival was significantly increased after paclitaxel treatment compared with the control group (57 days versus 45 days, p<0.0034) along with a significant decrease of the relative subcutaneous tumor volume (p<0.023). Conclusion: Peritoneal esophageal adenocarcinoma xenografts were successfully established after intraperitoneal injection of OE19 cells. This animal model of peritoneal dissemination for survival outcome will provide a useful survival outcome assessment model for the preclinical evaluation of cancer therapeutics in esophageal adenocarcinoma.
Introduction: Prostate cancer (PCa) is the most prevalent cancer amongst men and the second most common cause of cancer-related deaths in the US. Prostate cancer has a heterogeneous spectrum of clinical outcomes with phenotypes ranging from indolent asymptomatic cases to very aggressive metastatic and lethal forms. The development of aggressive castration-resistant prostate cancer (CRPC) is currently the most common late-stage outcome of prostate cancer, and prostate cancer is the second most common cause of cancer-related deaths in men. Understanding the molecular mechanisms that drive the transition from localized disease to metastatic disease is crucial for the development of targeted therapies for both early detection and advanced disease.

To understand the biologic basis of PDA metastatic subclone formation we hypothesized that metastatic disease is the most common cause of death in pancreatic ductal adenocarcinoma (PDA) patients. The most common sites of metastatic spread of PDA are to the liver, lung, and peritoneum. The acquisition of advanced stage PDAs is also accompanied by a dramatic increase in distant metastatic disease. We sought to establish a transgenic mouse model of PDAbased on heterozygous inactivation of p16 and Trp53 alleles (KPTC mice). This model revealed that metastatic efficiency and organotropism are related but independently controlled phenomena by hormone receptors, clinical treatment and response and results from biochemical analyses of tissue samples. Tumor markers (e.g., estrogen and progestin receptors, EGF receptor, HER-2/neu oncoprotein) guided tissue selection. Structural integrity of a tumor marker positive sample was assessed and the second intact tissue section was processed identically to that of the section used for LCM. RNA was assessed for integrity, purified and subjected to novel analyses. RNAseq and WGCNA performed in liver samples from patients indicating their clinical relevance. Portal vein colonization as a direct mode of access to the liver was observed in both mice and human samples of liver and cancer cell lines and prostatectomy tissues with different malignancy phenotypes. Validation of differential NEFL expression has been done by Western blot, qRT–PCR, IHC and mass spectrometry. Functional assays and oncogenic properties have been assessed after siRNA mediated knockdown of NEFL gene expression in prostate cancer cell lines. Results: We demonstrate significant correlations between NEFL expression and the acquisition of aggressive PCAs with neuroendocrine-like phenotypes. This was validated by Western blot and qRT–PCR. SiRNA knockdown of NEFL suppresses the invasive and migratory capacity of PCa cells and tumor colony formation in soft agar assays. The molecular interactome of NEFL was characterized by LC/MS/MS. To our knowledge, this study is the first to demonstrate that NEFL up-regulation correlates with a subset of aggressive prostate cancer disease.

Conclusions: We demonstrate that NEFL is differentially expressed in PCa cells and prostatectomy tissues with a significantly higher abundance in cells with clinically aggressive and lethal neuroendocrine-like malignancy phenotypes. These findings are currently being validated using disease stratified tumour microarrays. Further studies are focusing on uncovering the mechanisms that are modulated by NEFL and are responsible for PCa disease progression. These could assist in the development of novel diagnostic and therapeutic strategies for the disease.

#2830 Secreted protein acidic and rich in cysteine antigen and autoantibodies in sera of prostate cancer patients: Potential use in diagnosis/prognosis. Anshu Rastogi,1 Andy Martinez,2 Amina Ali,1 Shy-Han Tan,1 Jennifer Cullen,1 Yongmei Chen,1 Gyorgy Petrovics,3 Albert Dobi,1 Lakshmi Ravindranath,1 Denise Young,1 Isabel Sesterhenn,1 Jacob Kagan,1 Sudhir Srivastava,4 David McLeod,1 Inger Rosner,5 Shiv Srivastava,4 Alagarsamy Srinivasan7. 1Cancer Center and Genomic Medicine, Icahn School of Medicine at Mount Sinai, New York, NY; 2Thermo Fisher Scientific, Austin, TX; 3Memorial Sloan Kettering Cancer Center, New York, NY; 4Uniformed Services University of the Health Sciences, Bethesda, MD; 51Thermo Fisher Scientific, Austin, TX; 6Uniformed Services University of the Health Sciences, Bethesda, MD; 71Thermo Fisher Scientific, Austin, TX.

Objectives: Improvements in blood based biomarkers for detecting clinically significant prostate cancer (CaP) or for distinguishing between indolent and aggressive CaP are critical in enhancing the management of this most common non-skin cancer of men in the US. These biomarkers include tumor associated antigens (TAAs) and autoantibodies (AAbs) against TAAs in patient sera. SPARC/Osteonectin is highly expressed in metastatic cancers (glioblastoma, melanoma, breast cancer and prostate cancer) and promotes bone metastasis and epithelial–mesenchymal transition. Our comparative transcriptome analyses of well/moderately differentiated CaP with poorly differentiated CaP, defined SPARC as central node in the network of genes with common regulatory elements (NKKH_NKKH_HOX) associating with poorly differentiated CaP. Further, we reported associations of high levels of SPARC mRNA or protein with Gleason 8-10 or poorly differentiated primary tumors and association with metastatic progression. The aims of this study are: i) Quantify SPARC antigen in the sera of CaP patients; ii) Are AAbs against SPARC present in the serum of CaP patients?; iii) Is there a correlation between SPARC AAb level in patient sera and disease status? iii) Does SPARC AAb level vary according to ethnic groups? Methods: Sera from CaP patients and healthy controls were evaluated for SPARC antigen using a commercial enzyme-linked immunosorbent assay (ELISA) kit. AAbs against SPARC were determined by ELISA utilizing recombinant full-length human SPARC protein as a substrate. For evaluation we used Caucasian American (CA, n = 117) and African American (AA, n = 111) CaP patients comprising Gleason 6-10, and healthy controls (CA, n = 52; AA, n = 45). Results: SPARC antigen levels in the sera showed a difference in the overall case versus control groups (p = 0.0016) and this trend was observed only in AA (p = 0.0015) in comparison to CA patients (p = 0.1709). SPARC AAbs were detected in the sera and the values were significant in the overall case versus control (p < 0.0001) and also in CA (p < 0.0001) and AA (p < 0.0001) CaP patients with levels significantly lower in patients compared to controls. AAb reactivity for CaP patients was similar between CA and AA groups. Conclusions: This study demonstrated the presence of AAbs against SPARC in CaP patient serum for the first time. Of note, highly significant differences were noted between CaP patient (low) and controls (high) sera, across different ethnic groups. These data further suggest evaluation of SPARC AAbs as a promising serum biomarker for CaP.

#2831 Identification of cell specific expression signatures using NGS global gene expression profiles from LCM procured breast carcinoma and adjacent stromal cells. Jeffrey I. Schagaman,1 Kristi Lea,1 Sarah A. Andres,2 Kelli S. Bramlett,1 James L. Wittliff3. 1Thermo Fisher Scientific, Austin, TX; 2Univ. of Louisville Health Sciences Ctr., Louisville, KY.

Our goal is to determine relationships of gene expression profiles to patient-associated characteristics, breast carcinoma pathology and biomarker status with clinical outcome to improve assessment of prognosis and therapy selection. Procedures: De-identified frozen tissue biopsies of human breast carcinomas which were collected and stored under stringently controlled conditions were employed. Patient-related features (e.g., age, race, menopausal status, nodal status, clinical treatment and response) and results from biochemical analyses of established tumor markers (e.g., estrogen and progesterin receptors, EGF receptor) were collected and stored under stringently controlled conditions. Tissue was first evaluated by light microscopy of H&E stained sections. To decipher uniqueness and clinical utility of gene expression profiles from specific cell types, Laser Capture Microdissection (LCM) with a PixCell IIeTM (Arcturus®, Thermo Fisher Scientific) was used to non-destructively collect either cancerous cells or adjacent stromal cells on CapSureTM LCM caps. A second intact tissue section was processed identically to that of the section used for LCM. RNA was assessed for integrity, purified and subjected to novel analyses using the Ion AmpliSeqTM RNA Breast Cancer Research Panel containing 1174
genes. Sequencing workflow included templating on the Ion Chef™ System and multiplexed sequencing on the Ion S5™ XL sequencing system and Ion 540™ chip. Results: Each sequencing library yielded approximately 4-5 million reads with a mapping rate of >98% that was achieved after alignment to the human transcriptome. Each sample was sequenced in triplicate with technical reproducibility as a mean of 59.6% ± 4.9% of reads. Bioinformatic analyses of gene expression profiles revealed clear distinctions between stromal and carcinoma cells procured by LCM compared to intact tissue driven by strongly differentially expressed genes such as vimentin (VIM), MRPRP, stanniocalcin-2 (STC2) and estrogen receptor beta (ESR2). Conclusions: Collectively, the results indicate that molecular signatures of breast carcinoma cells procured by LCM reveal unique gene expression profiles compared to those of the intact tissue section or the adjacent stromal cells. These novel findings are likely to discern molecular features unique to a breast carcinoma that may be related to clinical outcome to improve assessment of patient prognosis and therapy selection. Supported in part by a grant from the Phi Beta Psi Charity Trust (JLW & SAA) and a CTSA Award from the Commonwealth of Kentucky (JLW). For research use only.

#2832 Class I histone deacetylase inhibitors impair tumor growth and metastatic programs. Oliver H. Krämer, Nicole Kiweler. Institut für Toxikologie Universitätmedizin der Johannes Gutenberg-Universität Mainz, Mainz, Germany.

(a) introductory sentence indicating the purposes of the study Metastasis formation is associated with poor patient prognosis. Epithelial-mesenchymal and mesenchymal-epithelial (EMT/MET) transition cycles are key for the formation, survival, and homing of metastatic cells. Inhibitors against epigenetic modulators of the histone deacetylsy family (HDACi) are promising, clinically tested epigenetic drugs that may combat cancer proliferation and spread. (b) brief description of pertinent experimental procedures We chose a systems toxicology approach to analyze the relevance of HDACs and their inhibitors for metastatic cell growth. We combined in vivo tests with morphological, cellular, functional, and global proteomic analyses. This strategy follows the 3R principle by Russel and Burch. Of the four classes of HDACs (I-IV), the class I subgroup is most important for tumorigenesis. We therefore analyzed how the pharmacological inhibition of class I HDACs affects the growth and spreading of syngeneic kidney cancer cells into the lungs of BALB/c mice and how such drugs affect tumor cell growth, apoptosis, migration, and gene expression patterns controlling EMT/MET in transformed kidney and breast cells. Furthermore, we investigated how the genetic elimination of HDACs affects cancer cell growth and EMT/MET. We used flow cytometry, immunoblot, immunofluorescence, qPCR, proteomics on a global scale, RNAi against the class I HDACs HDAC1/ HDAC2, and in vivo tumor analyses. (c) summary of the new, unpublished data Both the inhibition as well as the elimination of HDAC1/HDAC2 evokes growth arrest, morphological alterations, and apoptosis. HDACi block tumor cell migration, integrin-dependent cell adhesion, and EMT induced by the cytokine TGF-β. Global proteomics and qPCR analyses illustrate that HDACi disrupt EMT/MET cycles and metastatic spread. Moreover, these assays reveal pathways through which HDACi propel cancer cell apoptosis. (d) statement of the conclusion A class I HDACi can modulate the EMT/MET balance that is required for the detrimental process of metastasis. Hence, HDACi should be considered further as clinical treatment option.

#2833 Epithelial cell adhesion molecule (EpCAM) is associated with prostate cancer progression and chemo-/radio-resistance in vitro and in vivo. Jie Ni,1 Paul Cozzi,1 Julia Beretov,1 Junli Deng,1 Joseph Bucci,1 Peter Graham,2 Yong Li3. 1St George Hospital, Kogarah, Australia; 2University of New South Wales, Kogarah, Australia; 3St George Hospital / Univ. of New South Wales, Kogarah, Australia.

Aims: Prostate cancer (CaP) is the most common cancer in males in Australia which caused more than 3000 deaths in 2015. EpCAM is a transmembrane protein that is expressed at low levels in a variety of human epithelial tissues, but overexpressed in most solid tumors. Our previous study indicated that EpCAM was strongly expressed in metastatic CaP cell lines, primary human CaP tissues and lymph node metastasis and is a biomarker involved in CaP progression, and chemo-/radio-resistance. However, the role of EpCAM in CaP progression and therapeutic resistance is still uncertain. The aim of this study was to investigate the role of EpCAM in CaP progression and chemo-/radio-resistance as well as underlying mechanisms in vitro and in vivo. Methods: EpCAM gene was knocked down (KD) in PC-3, DU145 and LNCaP CaP cell lines using shRNA. Proliferation assay, colony formation assay, docetaxel (DTX) and radiation dose-response assay were carried out to evaluate the effect of KD of EpCAM on proliferation and therapeutic response of CaP cells in vitro. Subcutaneous (s.c.) and orthotopic CaP animal models were established using PC-3-EpCAM-KD and PC-3-EpCAM-scramble (s.c) control cells in NOD/SCID mice, to assess the effect of EpCAM on CaP tumorigenicity, chemotherapy (DTX) and radiation response. Signal transduction proteins in P38/Akt/mTOR signaling pathway, as well as proliferation, apoptotic and radiation response markers were evaluated by western blot analysis. Results: KD of EpCAM reduced cell proliferation and increased apoptosis compared to control. EpCAM scallular potentiated and enhanced DTX and radiation sensitivity in CaP cell lines. Both s.c. and orthotopic EpCAM-KD xenografts displayed suppressed tumor growth and increased DTX and radiation responsiveness compared to EpCAM-scr control xenografts in NOD/SCID mice. Marked down-regulation of P38/Akt/mTOR pathway proteins (p-Akt and p-mTOR) and protein kinase mTOR (p-mTOR) and significant up-regulation of apoptotic (Casapse-3) and radiation (γ-H2AX) responses to chemo-/radio-therapies were found in EpCAM-KD xenografts, compared with control xenografts. In addition, Kaplan-Meier curve analysis demonstrated that KD of EpCAM improved median survival (MS) of tumor-bearing mice by 21.5 days compared with the control group (HR = 26.94, 95% CI 4.31-168.1, p = 0.0004) and that KD of EpCAM improved MS of tumor-bearing mice which received docetaxel (50mg/kg, single dose, i.p.) by 11 days (HR = 20.95, 95% CI 3.99-121.9, p = 0.0007), and radiotherapy (2Gy/day for 4 days) by 12 days (HR = 11.00, 95% CI 2.11-57.36, p = 0.0044) compared with the control group, respectively. Conclusions: EpCAM plays an important role in CaP progression and chemo-/radio-resistance via P38/Akt/mTOR signaling pathway in vitro and in vivo and it is a promising therapeutic target for the treatment of CaP. EpCAM targeted therapy combined with chemo-/radio-therapy could be a novel modality for treatment-resistant CaP.

#2834 Metastatic colorectal cancer: characterization of distinct histological growth patterns which demonstrate different response to current treatment regimes. Vincent Palmieri,1 Anthoula Lazaris,2 Hussam Alamri,3 Abdel-latif Amri,4 Nisreen Ibrahim,1 Pablo Zorozquin,2 Peter Vermeulen,2 Peter Metraкос5. 1McGill University, Montreal, Quebec, Canada; 2McGill University Health Centre - Research Institute, Montreal, Quebec, Canada; 3Translational Cancer Research Unit (TCRU), GZ A Hospital, Antwerp, Belgium.

Colorectal cancer (CRC) is the third most common cancer in North America, and the third leading cause of cancer-related death. About 50% of patients will be diagnosed with CRC liver metastasis (CRCLM) during the course of their disease. We have identified two major histological growth patterns (HGP) in CRCLM resected from patients. In the desmoplastic HGP (DHPG), the tumor cells are enclosed within a desmoplastic stromal ring, physically separating them from the normal liver tissue. In the replacement HGP (RHGP), the tumor cells replace normal hepatocytes without disrupting adjacent cells or structures within the liver parenchyma. We have recently shown that patients with RHGP lesions who received neoadjuvant bevacizumab plus chemotherapy had a worse pathological response and fared worse on overall survival. Our group has also shown that RHGP CRCLM is resistant to anti-angiogenic therapy due to its promoting vessel co-option as a means of tumor vascularization, rather than VEGF-dependent angiogenesis as seen in DHPG. However, the molecular mechanisms that drive the CRCLM HGPS remain unknown. This project aims to shed light on the biological processes that underlie the diversity of HGPS, with an emphasis on the key genes and pathways that support the RHGP. To test this, we have: Aim 1) performed RNAseq on chemonaïve RHGP and DHPG CRCLM tissues to identify pathways that are significantly upregulated in the RHGP. We have validated these genes via real-time PCR (RT-PCR), and a subset by immunohistochemistry (IHC). Aim 2) To further refine the RHGP gene signature and to examine the effects of cell-cell interactions on hepatocyte and tumor cell gene expression, individual cells have been isolated from distinct regions within RHGP CRCLM tissues using laser capture microdissection (LCM), followed by single-cell transcriptomics analyses. Our preliminary data have identified three major pathways with differentially expressed genes: i. cell motility, ii. cell junctions, and iii. ECM-receptor interactions, which are upregulated in RHGP relative to the DHPG and normal liver. A panel of RHGP and DHPG cell lines were treated with or without an IHC inhibitor, and a RT-PCR. We selected a subset of these genes and are performing IHC to further validate and locate their expression. We have also performed LCM and are in the process of performing transcriptomics analyses – the data will be presented. We expect to gain some insight into the mechanisms responsible for driving and/or maintaining the RHGP lesions. In the longer term, this work will result in identification of targets in the HGPS that will help stratify patients in terms of treatment. It would appear that we have fewer treatment options for the RHGP patients and it would be important to utilize the data to develop new treatment strategies for those patients. These new therapies would lead to further clinical trials.
#2835 Potential opposing roles of AKT isoforms in indolent versus aggressive prostate cancer. Karina A. Miller,1 Hyun-Kyung Ko,2 Irwin H. Gelman,1 1Roswell Park Cancer Inst., Buffalo, NY; 2Cleveland Clinic, Cleveland, OH.

Prostate cancer (CaP) is the most commonly diagnosed non-cutaneous cancer among men and is the second leading cause of cancer-related deaths in U.S. men. Localized CaP has a 5-year survival rate of approximately 100%, but disseminated, metastatic disease (mCaP) dramatically reduces 5-year survival to <30%. A known driving force in the progression of CaP is activation of the PI3K/Akt signaling pathway through loss of PTEN, with widespread effects on cell proliferation and migration. Additional genomic changes, such as the loss of TP53 or RB1, or the upregulation of MYC, correlate with increased incidence and aggressiveness of mCaP. However, only a fraction of men with high levels of circulating and disseminated CaP cells progress to overt, macro-metastatic disease - the lethal phenotype in CaP. Importantly, little is known regarding the drivers of indolent vs. aggressive mCaP. We used two transgenic (Tg) mouse models of mCaP with clinically relevant genetic alterations which exhibit Akt activation and RB1 loss, yet one produces indolent mCaP and the other, systemic aggressive mCaP. Specifically, mice lacking RB1 and the metastasis-suppressor, SscCRS/Akap12, develop high-grade prostatic intraepithelial neoplasia (HG-PIN) and disseminated disease in the lymph nodes whereas those lacking Pten and Rb1 develop CaP and aggressive mCaP. The metastasis-suppressing functions of Akap12 relate to its ability to scaffold Src and PKC, thereby attenuating their oncogenic signaling pathways. We will show data suggesting that the pathological differences between these two Tg models is based on the differential use of PI3K-p110 and Akt isoforms, with aggressiveness correlating with the down-regulation of Smaa4, a known metastasis-suppressor in Tg CaP models. Additionally, differences in Akt isoform usage likely controls the expression of neurogenesis genes that are especially upregulated in castration-resistant CaP that fails second-line androgen receptor antagonist inhibitors such as enzalutamide. By comparing the differential transcriptomes and signaling networks in primary-site tumors, lymph node metastases, and CaP cell lines derived from these two Tg models, several new potential therapeutic targets have been identified that could be exploited to prevent or treat aggressive mCaP.

#2836 Mitochondrial genomic backgrounds differentially affect nuclear DNA methylation and gene expression. Carolyn J. Vivian,1 Amanda E. Brinker,1 Stefan Graw,1 Devin C. Koestler,1 Christophe Legendre,2 Gerald C. Gooden,3 Bodour Salhia,3 Danny R. Welch,1 1Univ. of Kansas Cancer Ctr., Kansas City, KS; 2Translational Genomics Research Institute, Phoenix, AZ; 3Univ. of Southern California, Los Angeles, CA.

Accumulating data implicate mitochondrial genetics and metabolism as contributors to metastatic efficiency. With only 13 proteins encoded by the mtDNA genome, the mechanism(s) by which the coordination of multiple genes involved in metastasis could occur is unclear. We hypothesized that mitochondrial DNA (mtDNA) polymorphisms would differentially regulate nuclear DNA (nDNA) methylation and gene expression. To test the hypotheses, we created Mitochondrial Nuclear Exchange (MNX) mice, by transferring an oocyte nucleus from strain, into an enucleated oocyte from strain. The mice show that mammary tumor formation and metastasis are regulated by inherited mitochondrial polymorphisms (PMID: 26471915). Age-matched, male mouse brains were collected and pooled from four litter mates representing each of the wild-type and MNX mice (8 groups). Genome-wide nDNA methylation (Mouse methyl-Seq) and gene expression (RNA-Seq) were measured and results validated in independent replicate samples. Significant, selective and reproducible differential DNA methylation and gene expression were observed and validated between strains having identical nDNA, but different mtDNA. While the signal(s) from mitochondria altering methylation is not fully defined, the findings support the hypothesis and demonstrate how mitochondrial genetic alterations could be one of several quantitative trait loci involved in complex phenotypes, such as metastasis. The results also suggest that mtDNA polymorphisms could serve as predictive biomarkers for cancer aggressiveness. Support: Susan G. Komen for the Cure (SAC11037), Natl Fndn Cancer Res, Biomedical Research.

Introduction: PCa is the most commonly diagnosed disease in American men and the second leading cause of death among them. Most of CaP deaths are a result of distant metastasis and due to emergence of castrate resistant CaP. Pro-tocadherin-7 (PDCD7), a Cadherin superfamily transmembrane protein that is known to function in cell-cell recognition and adhesion, is reported to be over-expressed in CaP. In addition to this, PDCD7 is related to the development of cerullum carcinoma in the prostate. Recent studies have been shown to mediate brain metastasis of breast cancer. Overexpression of PCDH7 was reported to be associated with poor clinical outcome of NSCLC. However, there is no report on involvement of PCDH7 in CaP tumorigenesis and metastasis. In the present study we evaluated expression of PCDH7 in androgen dependent and androgen independent CaP cells and in TCGA and Trento/Cornell/Broad2016 clinical datasets. Materials and Methods: PCa cells (LNCaP, C4-2b, DU145, PC3, 22Rv1 and RWPE1) were used in this study. Protein expression was checked by Western Blotting. mRNA levels were checked by quantitative real time PCR. Results: Our data reveal high PCDH7 protein expression in PC3 cells and low levels of PCDH7 in LNCaP and RWPE1 cells. qRT-PCR confirmed an increased transcript level of PCDH7 in PC3 and low levels in LNCaP cells. We also observed elevated transcript levels for PCDH7 in castrate resistant and Enzalutamide refractory PCa (22Rv1) cells. These data suggest a direct relationship between castrate resistance and PCDH7 expression. Our results also show an inverse relationship between PCDH7 and E-Cadherin and a direct relationship between PCDH7 and EMT markers, indicating expression of PCDH7 is associated with tumor progression. Interestingly, there was no correlation between the expression of PCDH7 and hormonal grade or TNM data. Furthermore, the analysis of NEPC (Trento/Cornell/Broad 2016) data set revealed amplification of PCDH7 in 9% of NEPC tumors. Collectively, these data suggest PCDH7 expression may be associated with advanced PCa in general and NEPC phenotype PCa in particular. Conclusion: Our results suggest direct association of PCDH7 expression and castrate resistance in PCa cell lines. Role of PCDH7 in castrate resistant PCa needs further evaluation.

#2838 CtBP1 expression deprecation on primary tumor deregulates miRNA expression and impairs development of spontaneous metastases on a prostate cancer and metabolic syndrome model. Guillermo N. Dalton, Georgina Scalise, Juliana Porretti, Cintia Massillo, Paula L. Farré, Paola De Luca, Adriana De Siervo. Instituto de Biología y Medicina Experimental (IByME) - CONICET, C.A.B.A, Argentina.

Prostate cancer (PCa) is the second cancer in incidence in men worldwide. Approximately 20% of cases continue with advanced or metastatic disease, and at this stage, it turns incurable due to the lack of effective therapies. Hence, the need to identify new actionable targets is crucial. Metabolic syndrome (MeS) is a physiopathological disorder that increases PCa risk and aggressiveness. C-terminal Binding Protein (CtBP1) is a transcriptional corepressor that is activated by NADH binding. Previously our group established a MeS and PCa mice model that identified to CtBP1 as a novel link associating both diseases. Moreover, cell adhesion molecules play a significant role in cancer progression and metastasis. Thus, we found that CtBP1 diminished the capability of PCa cells line to adhere to a collagen matrix, directly modulating expression of several cell adhesion genes, including repression of the epithelial marker CDH1 and induction of the mesenchymal marker VIM. The aim of this work was to investigate MeS/CtBP1 impact over PCa progression from in situ prostate carcinoma to metastatic disease. RNA was isolated from xenografts generated on MeS mice from CtBP1 depleted PC3 cells (PC3.shCtBP1) or control (PC3.PGIPZ); and hybridized to a miRNA expression microarray (Affymetrix GeneChip® miRNA 4.0). After data normalization and analysis we identified and validated a list of 11 miRNAs regulated by CtBP1 relevant to cell adhesion and PCa progression. To investigate CtBP1 role in spontaneous PCa metastasis, NOD SCID gamma (NSG) mice were fed with control or high fat diets during 12 weeks to induce MeS. Then PC3.shCtBP1 or PC3.PGIPZ cells were injected s.c. on MeS and control animals. Body weight and tumor size were measured 1 and 3 times a week, respectively. Thirty days after cell inoculation, tumors were around 1 cm, with no significant differences between treatments, however mice showed around 20% weight loss. Mice were sacrificed and tumors, lungs and livers were collected for RNA isolation and histopathological analysis. Using human GAPDH specific primers and RT-qPCR from lungs, we found that CtBP1 depletion led to a significant decrease of lung metastases, especially in the MeS group. In addition, Hematoxylin & Eosin stains from lung sections detected the lowest number and size of metastatic foci in the CtBP1 depleted xenografts generated in MeS animals. Gene expression comparison between primary tumors and metastases showed that epithelial markers, such as E-cadherin, were induced in xenografts and almost undetected in metastasis. Accordingly, mesenchymal markers expression, such as
TUMOR BIOLOGY: Gene Expression in Metastatic Progression

Vimentin, was low in xenografts and triggered on metastases. Our study uncovers for the first time the role of CtBP1 in PCA progression and its molecular targets in MeS mice.

Bladder cancer (urothelial cancer of the bladder) is the most common malignancy affecting the urinary system with increasing incidence and mortality. Treatment of bladder cancer has not advanced in the past 30 years. Therefore, there is a crucial unmet need for novel therapies, especially for advanced disease. We have previously identified the protein Acidic and Rich in Cysteine (SPARC) as a tumor suppressor in urinary bladder cancer that inhibits the multistep cascades on tumor initiation, progression and metastasis. SPARC gene and protein expression was among candidates associated with the tumorigenicity of the isogenic T24/T24T cell lines. We reported that SPARC depletion in human bladder cancer cell lines including T24 cells increased their tumorigenicity and metastatic potential. In addition, SPARC protein and transcript expression are significantly downregulated in advanced urothelial cancer. To gain insight on the molecular mechanisms of the tumor suppressor effects of SPARC in urothelial cancer, we did whole transcriptome profiling of T24 cells depleted of SPARC to identify SPARC-signature associated with bladder cancer invasiveness, progression, and metastasis. Subsequently, we used gene signature enrichment analysis (GSEA) pathway enrichment tools to define functionally relevant genes that are consistently up- or down-regulated as a function of loss of SPARC. We found that loss of SPARC expression is associated with enrichment of multiple oncogenic signaling pathways that are enriched in muscle invasive urothelial cancer and have been associated with poor prognosis. These pathways include K-ras, Myc-oncogene, p53 pathways as well as DNA damage/repair. Consistent with our earlier reports, loss of SPARC is associated with genes and proteins involved in angiogenesis, inflammation and hypoxia. In addition, we have identified novel signatures involved in unfolded protein response, mTOR signaling, glycolysis and cholesterol metabolism. These comprehensive signatures not only reveal SPARC-dependent networks that cooperate to elicit its biological responses but enable coherent understanding of the etiology of complex bladder cancer disease. Importantly, these signatures identify novel therapeutic opportunities for bladder cancer.

#2840 Integrative approach to biomarker discovery by performing comparative analysis of two cancers, hepatocellular carcinoma and endometrioid endometrial carcinoma, using genetics and transcriptomics from RNA sequencing data. Jean-Noel Billaud, Stuart Tugendreich, Debra Toburen. QIA-GEN Bioinformatics, Redwood City, CA.

Hepatocellular Carcinoma (HCC) and Endometrioid Endometrial Carcinoma (EEC) are two lethal diseases of public health importance worldwide. Using QIAGEN’s RNA sequencing solution, we were able to highlight key molecular and biological processes that indicate similarities in the tumor progression toward metastasis between one EEC patient and the three HCC patients. We have identified ITGBH-701 isoform as a potential common biomarker between these two complex cancers. We have also shown these two cancers share activated pathways such as actin cytoskeleton signaling, and RAF1 as an upstream regulator indicating similar transcriptional program between these patients. Furthermore, we have identified as a potential therapeutic target the master regulator CTGF that connects a network of 286 downstream targets to invasion of tumor cells. We have filtered a set of unique variants in the EEC patient that affect a network of upstream regulators common with HCC. This approach may be useful in the context of precision or personalized medicine. Examining the gene expression in tumors from groups of patients with each disease revealed that at a molecular level, early stages of EEC resemble established HBV-positive, HCV-negative, liver cirrhosis positive HCC.

#2841 Investigating drivers of disease progression in invasive lobular carcinoma. Nilgun Tasdemir,1 Matthew Sikora,2 Zhu Li,1 Kevin Levine,1 Ahmed Basudan,2 Soumya Luthra,3 Esther Elishaev,1 Uma Chandran,4 George C. Tseng,5 Rachel Jankowitz,4 David J. Dabbs,3 Priscilla McAuliffe,4 Nancy E. Davidson,6 Steffi Oesterreich1. 1University of Pittsburgh, Pittsburgh, PA; 2University of Colorado, Denver, CO.

Invasive lobular carcinoma (ILC) is the second most common type of breast cancer following invasive ductal carcinoma (IDC) and accounts for 10-15% of all cases. Unlike the masses or lumps formed by IDCs, ILCs grow as small, dis cohesive cells in a single-file pattern within dense layers of extracellular matrix. Paradoxically, while patients with ILC display favorable prognostic and predic-
Approximately 90% of cancer patients die from metastasis. In many cases, current therapies are designed based on the primary tumor characterization and are ineffective against metastatic disease. It is not clear whether metastatic cancer cells acquire additional genetic and epigenetic alterations, if so, what are the underlying mechanisms. Using several tumor models, we demonstrated that DNMT3B, de novo DNA methyltransferase, was increased in metastatic nodules in comparison to that from the primary tumors. DNMT3B knockdown or overexpression significantly inhibited or increased metastatic colonization of cancer cells. To understand the underlying molecular mechanisms of DNMT3B regulation, we performed DNMT3B ChIP-seq, RNA-seq, and DNA methylation-seq comparing lung metastases with primary tumors and 4T1 cells. We identified genes that are differentially methylated and expressed. Ingenuity Pathway Analysis revealed DNMT3B targeting multiple oncogenic signaling pathways. Bioinformatics analysis of human databases demonstrated significantly higher expression levels of DNMT3B in metastases than primary tumors in breast, prostate and melanoma cancer patients. In our study, we demonstrated that DNMT3B as a key epigenetic regulator which plays critical roles for tumor metastasis. Our work suggests DNMT3B as potential therapeutic targets for breast cancer patients with metastatic disease.

#2844 Identification of genes associated with pancreatic cancer metastasis by genome-wide CRISPR Cas9 screening. Youjia Li,1 Huiyi Feng,1 Guangjie Liu,1 Chi Hin Wong,1 Chi Han Li,1 Yangchao Chen,1 CUHK, Hong Kong, Hong Kong;2 GBHI, Guangzhou, China.

Pancreatic cancer is an extremely lethal cancer with a 5-year survival rate of 7%. One major reason why pancreatic cancer is hard to treat is its metastatic nature. Genes that related to the tumorigenesis and progression of pancreatic cancer were identified after decades of efforts. Several researches had revealed that pancreatic cancer originated from the successive accumulation of gene mutations, especially KRAS2, CNKD2A, TP53 and SMAD4. However, little is known about genes that regulate pancreatic cancer metastasis. Here we used a genome wide CRISPR Cas9 screening to identify the gene(s) associated with the metastasis of pancreatic cancer. We transduced pancreatic cancer cell line with lentivirus-based genome wide CRISPR sgRNA library to establish mutated cell library, and orthotopically injected the cell library into nude mice and waited for primary tumor growth and metastasis, then collected primary and metastatic tumors after several months. By next generation sequencing and analysis, we identified some gene candidates which may play important roles on pancreatic cancer metastasis.

#2845 A Rb phosphorylation code associated with lung cancer metastasis. Jaileen Perez-Morales,1 Darielys Mejias-Morales,2 Bryan Torres-Collazo,3 Harry Nguyen-Panganiban,4 Pedro Santiago-Cardona4. 1Ponce Health Sciences University, Ponce, PR; 2Pontifical Catholic University, Ponce, PR; 3University of Puerto Rico, Ponce, PR.

Lung cancer is characterized by its poor prognosis, aggressiveness, and proclivity for early metastasis. Non-small cell lung cancer (NSCLC) it’s the most common type of lung cancer with a five-year survival rate of 18%. Most predictors of metastasis and recurrence of NSCLC rely on post-resection evaluation of tumor histology, which is a severe limitation since only 15% of the patients are diagnosed with resectable disease. Hence, there is a need to characterize biomarkers with metastasis-predicting value in pre-resection small biopsy specimens. In addition to the proclivity for metastasis, another feature of lung cancers is the inactivation of the retinoblastoma protein (Rb). The retinoblastoma protein (Rb) is a tumor suppressor inactivated due to hyper-phosphorylation in most human cancers, including NSCLC. Our preliminary data reveals the Rb S249/T821 phosphorylation signature to an epithelial-to-mesenchymal transition (EMT), a trait strongly associated to metastasis. We found that cells that have hyperphosphorylated Rb in residues S249/T821 express EMT markers such as decreased expression of E-cadherin and integrin α5 as well as increased expression of N-cadherin, Vimentin, and p-FAK. We propose to focus on the cell adhesion and migration-related kinase Cdk5 with its activator p39 as the kinase responsible for engendering the Rb S249/T821 phosphorylation signature. Our hypothesis is that Rb phosphorylation in S249 and T821 due to Cdk5 activity can have prognostic value by being associated with a metastatic phenotype and EMT. Studies performed in a tissue microarray in a population of NSCLC adenocarcinoma that had undergone EMT found an up-regulation in p39 and that its expression is correlated with metastasis. Knockdown of Cdk5 induced a decrease in phosphorylation of Rb S249/T821 with a decrease in E-cadherin expression. These data suggest that Cdk5-dependent phosphorylation of Rb can affect cell adhesion by regulating E-cadherin. Introducing p39 into Rb hypo-phosphorylated cell line induced an increase in phosphorylation of Rb residues. Furthermore, the CDK3-p39-Rb axis might point to the explanation and prediction of the metastatic phenotype in lung cancer.

#2846 Identify urinary biomarkers for colorectal carcinoma liver metastasis. Meng Cai,1 Yulin Sun,1 Jiaja Gao,1 Lina Zhao,2 Fang Liu,2 Wei Sun,2 Zhixiang Zou,1 Xiashang Zhan,1 National Cancer Center/Cancer Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing, China;3Institute of Basic Medical Sciences, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing, China.

Colorectal cancer (CRC) is the third leading prevalent cause of death from cancer in adults, and more than one third of CRC patients are accompanied by liver metastasis. The disease begins as a benign adenomatous polyp, and it subsequently develops into an advanced adenoma and gradually progresses to an invasive cancer. The driving factors behind CRC comprise a series of successive accumulated gene mutations that follow the order “APC-KRAS-TP53-DCC”. Moreover, urine is an important display window for tumor-derived exosomes. Here, to explore the roles of TP53 in CRC and identify novel urinary biomarkers for colorectal cancer metastasis to the liver, a comprehensive proteomic analysis of esosomal proteins from HCT116 TP53-wild type (WT), TP53-knockout (KO) and constructed TP53 (R273H)-mutant (MT) cells, as well as urine samples from CRC patients with and without liver metastasis was performed using the isobaric tag for relative and absolute quantitation (iTRAQ)-2D-LC-MS/MS strategy. The exosomes from the MT and KO cells exhibited significantly reduced sizes levels of HIF1α in the WT cells. A total of 367 protein groups with ≥2 matched peptides were identified. Specifically, hepatocyte growth factor-regulated tyrosine kinase substrate (HGS) was consistently down-regulated in the exosomes from the MT and KO cells. Functional studies demonstrated that low HGS levels were responsible for the decreased exosome size. TP53 regulated HGS expression and thus HGS-dependent exosome formation. Furthermore, the HGS expression was gradually increased concomitant with CRC carcinogenesis and was an independent poor prognostic factor. In addition, HGS was one of the differentially expressed urine proteins between CRC liver metastasis and healthy individuals. In conclusion, HGS mediates TP53-regulated exosome formation. HGS may serve as a novel histological and urinary prognostic biomarker and a candidate target for therapeutic interventions in CRC.

#2847 Loss of heterozygosity (LOH) within the hypoxia inducible factor 3A (HIF3A) locus in liver metastasis (LM) from primary colorectal cancer (CRC). Takahito Kitajima, Minoru Koi, Alexander Worix, John M. Carethers. University of Michigan, Ann Arbor, MI.

Background and Aims: HIFSu is a hypoxia-regulated transcription factor that represses the effects of HIF1α and HIF2α under hypoxia at transcriptional and posttranslational levels. We previously found that LOH at the HIF3A locus is frequent in LM (59%) and the expression of HIF3α protein is reduced in LM compared to primary CRC. At present, the smallest overlapping LOH (SOL-LOH) region has been mapped to the intron 8 of the HIF3A, spanning from 46,312,911 to 46,315,651 on chromosome 19 in LM. This region contains multiple FOXA1 binding sites embedded in the two DNase I hypersensitive sites (UCSC Genome Browser, https://genome.ucsc.edu). About 30% of the human population carries a deletion within our SOL-LOH region (1000 Genomes Consortium: esv3644527, Chr19: 46,314,109-46,315,478). In this study, we determined whether esv3644527 deletion affects on the expressions of HIF3A, HIF2A, HIF1A and their target genes under normoxic and hypoxic conditions. Methods: For LOH mapping, 75 resected LMs derived from primary CRC were analyzed for LOH using 8 polymorphic markers. We obtained three EBV-transformed B cell lines with heterozygous esv3644527 deletion and the one with the homozygous deletion from the Coriell Institute. The expression levels of 23 genes related to HIF pathways were determined by qRT-PCR. Results and Discussion: The deletion levels of HIF3A in the WT cells. A total of 367 protein groups with ≥2 matched peptides were identified. Specifically, hepatocyte growth factor-regulated tyrosine kinase substrate (HGS) was consistently down-regulated in the exosomes from the MT and KO cells. Functional studies demonstrated that low HGS levels were responsible for the decreased exosome size. TP53 regulated HGS expression and thus HGS-dependent exosome formation. Furthermore, the HGS expression was gradually increased concomitant with CRC carcinogenesis and was an independent poor prognostic factor. In addition, HGS was one of the differentially expressed urine proteins between CRC liver metastasis and healthy individuals. In conclusion, HGS mediates TP53-regulated exosome formation. HGS may serve as a novel histological and urinary prognostic biomarker and a candidate target for therapeutic interventions in CRC.
locor. Deletion within this region may lead to upregulation of HIF2A and ANGPT2 by negatively regulating HIF3A expression. To prove our hypothesis, colon cancer cell lines with deleted FOXA1 sites will be assessed.

#2484 Identifying and targeting competing endogenous RNA (ceRNAs) networks to inhibit lung metastasis in triple negative breast cancer. Pelin Ersan,1 Unal Tokat,1 Erol Eryoupluglu,2 Umar Raza,1 Yasser Riazalhosseini,2 Can Alkan,1 Denis Thieffry,1 Daniel Gautheur,1 Ozgur Sahin1. 1Bilkent University, Ankara, Turkey; 2McGill University, Montreal, Quebec, Canada.

Introduction: Triple negative breast cancer (TNBC), the most aggressive breast cancer subtype, has high incidence rate of lung metastasis. Not only protein coding transcripts, but also non-coding transcriptome, such as microRNAs (miRNAs) and long non-coding RNAs (lncRNAs), have active roles in cancer progression and metastasis. Additionally, lncRNAs can act as sponges for miRNAs. Here, we aimed i) to construct the first mRNA-miRNA-lncRNA competing endogenous RNA (ceRNA) network controlling metastasis in TNBC, and ii) to prevent lung metastasis by targeting identified central candidate genes. Material/Method: We established primary tumor and human-in-mouse (HIM) and mouse-in-mouse (MIM) lung metastasis models using TNBC cell lines in nude and Balb/c mice, respectively. We visualized both primary and metastatic tumors using in vivo imaging system, harvested tumors and performed both RNA and small RNA sequencing. We obtained differentially expressed miRNAs, mRNAs and lncRNAs between primary and metastatic tumors. Using several bioinformatics tools, we did enrichment analyses, miRNA target predictions, and network construction. Identified central lncRNAs were overexpressed or knocked down and will be tested in in vitro and vivo metastasis-related assays. Results and Conclusions: We obtained 45 and 91 miRNAs which were differentially expressed between primary and metastatic tumors in HIM and MIM models, respectively. A miRNA family with an established role in metastasis as well as several other miRNAs was identified as highly differentially expressed in the same direction in both models. Moreover, 1127 and 3350 mRNAs, and 85 and 111 lncRNAs were differentially expressed in HIM and MIM models, respectively. Metastasis-related processes based on differentially expressed mRNAs were enriched in the data. We then integrated these three layers of data, functional enrichments, pathway maps and target predictions to construct the first ceRNA network controlling lung metastasis in TNBCs. Currently, we are testing the functional roles of candidate lncRNAs in in vitro and in vivo metastasis assays. Ultimately, our study will uncover novel lncRNAs that can be used as potential targets and/or biomarkers in breast-to-lung metastasis. Funding: This study is supported by TUBITAK-CNRS Bilateral Grant with project number 2145364.

#2489 Identification of active enhancers as potential biomarkers of aggressive colorectal cancer. Zhiquan Wang. Mayo Clinic, Rochester, MN.

Colorectal cancer is the third most common cancer and second leading cause of cancer-related deaths in the United States. Tumor metastasis is the primary cause of mortality. Even with aggressive surgical and therapeutic management approaches, more than one third of patients will develop metastatic disease. Understanding the molecular changes that drive tumor cells to the metastatic state is key to developing targeted therapies and identifying early-stage markers for progression. To identify changes that promote cell invasiveness, a hallmark of tumor progression, we exposed the pre-metastatic SW-480 colorectal cancer cell line to multiple rounds of selection for the capacity to invade through a synthetic extra-cellular matrix. Following repeated selection, invasiveness increased by more than 10-fold. Epithelial markers, such as E-cadherin, were repressed and markers commonly associated with tumor cells that have undergone epithelial-mesenchymal transition, such as N-cadherin and Vimentin, were upregulated. Likewise, invasive cells showed increased affinity for ECM components. Paired ChIP-seq and RNA-seq revealed likely roles for epigenetic alterations in driving gene expression changes. Furthermore, the epigenetic changes followed ordered patterns of activation and inactivation, suggesting that these epigenetic signatures may provide insight into early mechanisms associated with epithelial-mesenchymal transition. Collectively, our data suggest that early epithogenic markers may be better early predictors of colorectal cancer aggressiveness than gene expression patterns and support the use of this in vitro metastasis model to study the molecular mechanisms of cancer progression.

#2850 A systems genetics approach reveals Rnash2c-immune response axis that affects metastasis severity in breast cancer. Sarah Deasy, Kent Hunter. NIH, Bethesda, MD.

Metastatic breast cancer is a devastating disease with a 5-year survival rate of only 26%. This is due to a lack of effective therapies against established metastases and an inability to identify high risk patients who would benefit from specific adjuvant therapies to prevent metastatic progression. We have shown in mouse models that spontaneously arising tumors metastasize with different sensitivities depending on the mouse genetic background. Using systems genetics approaches we have identified genes correlated with metastasis and survival in both mice and humans. Rnash2c was identified as a novel candidate metastasis susceptibility gene. This gene encodes a scaffolding subunit of the Ribonuclease H2 enzyme which removes ribonucleotides misincorporated into the DNA. Experimentally modulating Rnash2c expression in a murine mammary cancer cell line resulted in significant changes in pulmonary metastasis, confirming this gene as a metastasis modifier. Mutations in Rnash2c are known to cause Aicardi-Goutieres Syndrome, a neurological autoinflammatory disorder that overlaps clinically with congenital viral infections and the autoimmune disease Systemic Lupus Erythematosus. Given this, we hypothesized that altered expression of Rnash2c in breast cancer cells affects metastasis by engaging the immune system. To investigate immune system involvement, we analyzed metastasis in immunocompromised mice. T cell deficiency ablated the effect of reduced Rnash2c expression on metastasis, revealing for the first time an Rnash2c-immune response axis in metastasis. Gene ontology pathway analysis following mRNA-sequencing of Rnash2c knockdown and overexpression tumors revealed that 20% of the genes with altered expression are involved in immune- and inflammation-related pathways, including T cell signaling and antigen presentation. Furthermore, genes with significant changes included Type I interferons, T cell markers, and immune regulators. These results confirm that Rnash2c is a novel metastasis modifier gene and validate our hypothesis that the immune system is mediating the effect of Rnash2c on metastasis. This mechanism highlights a potential new target for combination with immune modulatory therapies to combat this devastating disease and adds to a panel of genes we identified that together could determine patients with high risk for metastasis.

TUMOR BIOLOGY: Imaging Cancer Metabolism, Therapeutic Targets, and Treatment Response

INTRODUCTION: Oncogene-dependent reliance on glutamine is a cancer vulnerability that can be exploited for therapeutic gain. In the presence of low glutaminase, the enzyme that catalyzes the conversion of glutamine to glutamate, have been developed and have shown antitumor effects in several tumor models. The specific and potent glutaminase inhibitor CB-839 demonstrated marked antitumor efficacy in a triple-negative breast cancer (TNBC) cell line with inherently high glutaminase activity (HCC-1806), but not in an estrogen receptor-positive (ER+) cell line with inherently low glutaminase activity. An early phase 1 clinical trial of CB-839 in combination with paclitaxel has shown encouraging results in in vivo tumor response in patients. Cell-line specific efficacy of glutaminase inhibitors supports the need for clinical biomarkers that can predict and evaluate therapeutic efficacy. As a minimally metabolized glutamine analog with similar transport properties, $[^{18}F]$(2S,4R)-4-Fluoroglutamine ($[^{18}F]4F-Gln$) is an ideal radiotracer to infer glutamine pool size through estimates of tracer distribution volume (DV). In this study, we evaluate differences in DV of $[^{18}F]4F$-Gln in two xenografts with different levels of glutaminolysis (TNBC vs. ER+?) using dynamic PET imaging, as well as show the effect of anti-glutaminase therapy on $[^{18}F]4F$-Gln DV. METHODS: TNBC (HCC-1806) and ER+ (MCF-7) xenografts were established in athymic nu/nu mice. Mice were scanned in a dedicated animal PET scanner at baseline and after CB-839 administration. Dynamic imaging was obtained for one hour upon injection of $[^{18}F]4F$-Gln (300-350 μCi) via the tail vein. Kinetic analysis was performed with PMOD. RESULTS: $[^{18}F]4F$-Gln uptake was largely reversible with Logan plots demonstrating late linearity and k1 in a two-compartment (trapping) model was low (less than 0.01/min in most cases). Strong correlation was seen in DX estimates by Logan plot and a single-compartment model ($R^2>0.9$), but not with estimates from a two-compartment model. MCF-7 xenografts demonstrated greater than 60% larger DV at baseline than TNBC xenografts indicative of increased cellular glutamine concentrations in MCF-7 xenografts. An increase in DV was detected in TNBC xenografts post-glutaminase inhibition (>30% mean change), but not...
Hyperpolarization of the $^{13}$C nucleus increases its sensitivity to detection in vivo. This technology provides the ability to monitor LDH activity in real time through dynamic observation of conversion of $[1-13C]$pyruvate to $[1-13C]$lactate. This study aimed to monitor drug efficacy of a newly developed LDH inhibitor (LDHI), obtained from National Cancer Institute Experimental Therapeutics Program, NECx) in a xenograft tumor model using $^{13}$C MRS technology with hyperpolarized $^{13}$C-labeled pyruvate. We are currently broadening the panel of PDXs analyzed and also including genetically engineered mechanistic models of drug resistance. The present study highlights the effectiveness of hyperpolarized $^{13}$C spectroscopy/spectroscopic imaging with hyperpolarized $^{13}$C-labeled pyruvate as a promising non-invasive imaging method for monitoring tumor metabolic response in real-time and identifying new strategies to increase the efficacy of therapy in individual patients.

#2854 The potential of hyperpolarized $^{13}$C magnetic resonance spectroscopy to monitor the effect of combretastatin based vascular disrupting agents. Anne B. Iversen,1 Morten Busk,1 Lotte B. Bertelsen,1 Christoffer Laustsen,2 Ole L. Munk,1 Thomas Nielsen,1 Thomas R. Wittenborn,1 Johan Bussink,2 Jasper Lok,2 Hans Stokkilde-Jørgensen,1 Michael R. Horsman1,2,3 Aarhus University Hospital, Aarhus, Denmark; 2Radboud University Medical Center, Nijmegen, Netherlands.

Purpose: Targeting tumor vasculature using vascular disrupting agents (VDAs) is an attractive therapy. These agents induce rapid physiological changes long before any growth inhibitory effects become apparent. Detecting these early changes should allow us to predict anti-tumor effects. Hyperpolarized $^{13}$C magnetic resonance spectroscopy (HPMRS) allows dynamic measurement of the metabolism of $^{13}$C-labeled substrates and may be a new approach for reliably monitoring early effects of VDAs. The aim of this study was to investigate the potential of HPMRS to achieve this in a pre-clinical model. Methods: Using 200 cubic mm implanted C3H mammary carcinoma cells, mice were intraperitoneally injected with combretastatin-A4-phosphate (CA4P) or the A1 analogue OXi4503. Tumor response was assessed by determining necrosis development, measured histologically 24-hours after treatment, and tumor growth time (TGT; time to reach 5 times treatment volume). Estimates of tumor perfusion and metabolism were performed 3h (CA4P) and 6h (OXi4503) after treatment. Perfusion was measured using dynamic contrast-enhanced magnetic resonance imaging (DCE-MRI) at 7.5T. Metabolic changes were assessed following intravenous injection of hyperpolarized $[1-^{13}C]$pyruvate and observing the conversion to lactate with HPMRS in a 9.4-Tesla scanner. Additional mice were positron emission tomography (PET) scanned using a Mediso nanoScan PET/MRI scanner following administration of fluorodeoxyglucose (FDG). Statistical comparisons were made using a one-way analysis of variance (ANOVA), with significance level of $p<0.05$. Results: A dose response relationship was found between injected drug doses and both tumor necrosis induction and TGT, with OXi4503 having a larger effect than CA4P. Two equally effective doses were selected for further analysis (250 mg/kg for CA4P and 50 mg/kg for OXi4503). Both drugs significantly decreased perfusion relative to controls; the respective mean (with 1 SE) values for CA4P and OXi4503 were decreased to 57% (50-64) and 38% (28-48) using Hoechst 33342, and 61% (57-65) and 61% (54-68) using DCE-MRI. FDG uptake (mean tumor-to-brain ratio) also significantly reduced to 43% (33-53) and 33% (25-41) for CA4P and OXi4503, respectively. However, an unaltered pyruvate to lactate ratio was found; the values being 98% (89-107) for CA4P and 93% (90-95) for OXi4503, respectively. Conclusion: No change in the HPMRS values was observed, despite changes in all other parameters, indicating that the metabolic fate of pyruvate remains unaltered despite reduced delivery of oxygen and nutrients. This could be because our data provides measures of whole tumor mean responses that include a viable metabolically unaltered tumor rim and a tumor core with no blood flow (i.e., no pyruvate delivery) following VDA treatment.

#2855 Monitoring tumor growth and oxygen distribution of prostate cancer xenografts in vivo using ultrasound and photoacoustic imaging. Qiuhua Hu,1 Ella Rattcher,1 Katrina Sweeney,1 Pamela J. Russell,1 Colleen C. Nelson,1 Brian W. Tse,2 Elizabeth D. Williams,1 Brett G. Hollier1.

1Australia Prostate Cancer Research Centre - Queensland, Chronic Disease & Aging, Cancer Program, Institute of Health & Biomedical Innovation, School of Biomedical Sciences, Queensland University of Technology, Brisbane, QLD, Australia; 2Preclinical Imaging Facility, Translational Research Institute, Brisbane, QLD, Australia.

Introduction: Prostate cancer (PCa) is the second leading cause of cancer-related death in men. Initially, PCA growth and progression is primarily driven by androgen stimulation of the androgen receptor (AR). As such, the standard treatments for PCA target the androgen/AR axis and are collectively termed androgen targeted therapies (ATTs). In spite of initial tumor regression, tumor cells ultimately adapt and become resistant to ATTs and progress to castration resistant PCa (CRPC) or metastatic CRPC. The tumor microenvironment (TME) has long been recognized to modulate the re-
TUMOR BIOLOGY: Imaging Cancer Metabolism, Therapeutic Targets, and Treatment Response

#2858 Immuno-PET with site-specific labeled \(^{89}\)Zr-DFO-trastuzumab improves immuno-reactivity and tumor uptake in a subcutaneous HER2 positive xenograft mouse model of ovarian adenocarcinoma. Lotte K. Kristensen, Camilla Christensen, Camilla S. Knudsen, Mette M. Jensen, Brian J. Agnew, Andreas Kjaer, Carsten H. Nielsen, Minerva Imaging, Copenhagen, National Advanced Treatment Centre for Molecular Imaging, Rigshospitalet and University of Copenhagen, Copenhagen, Denmark; Thermo Fisher Scientific, Eugene, OR.

Introduction: The combination of PET with the specificity of monoclonal antibodies (mAbs), immuno-PET, is an attractive approach to improve tumor detection and mAb quantification. \(^{89}\)Zirconium \((^{89}\text{Zr})\) is particularly well-suited for mAbs due to the long-term use of \(^{89}\)Zr in medicine. \(^{89}\)Zr has been limited by the lack of suitable methods for stable coupling to mAbs. In addition, the conventional labeling strategies with random introduction of a chelator potentially reduce antibody binding and affinity towards target. Here we demonstrate the application of an enzyme- and click chemistry-mediated methodology for site-specifically labeled \(^{89}\)Zr immuno-PET imaging probes and compare them to a random labeled probe. Experimental procedures: Trastuzumab was conjugated to the p-SCN-Bn-Deferoxamine (p-SCN-Bn-DFO) chelator in three alternate ways: (1) randomly on lysine residues or site-specifically on enzymatically treated glycans using either (2) r-galactosidase or (3) endoglycosidase S2. DFO-trastuzumab was radiolabeled with \(^{89}\)Zr \((^{89}\text{Zr}-\text{DFO-trastuzumab})\) and injected into SK-OV-3 tumor-bearing NMRi mice as a tumor load from 0.5 to 1 mm in diameter. Direct deposition of these threads into a tumor is a promising technique with a higher rate of tumor growth compared to the rest of the cohort. Importantly, we were able to detect a relatively high increase in oxygen levels between pre- and post-castration tumors in individual mice.

Conclusion: We have successfully used a non-invasive imaging method to simultaneously assess multiple biological parameters in PCa xenografts in vivo. The information gained in this study will provide a broader view of the prostate tumor response to ATTs, which has the potential to reveal novel mechanisms of therapy resistance.

Introductory Sentence: Real-time metabolic flux can be measured non-invasively using hyperpolarized magnetic resonance spectroscopy in cancer spheroids as well as tumor biopsies. Experimental Procedures: LnCaP cells were resuspended in a 1:1 mixture of Matrigel:alginate (1x10^5 cells/ml) and grown in a porous hollow fiber(A/G Technology Corporation, NY). [1-^13\text{C}] pyruvate was polarized in a SpinLab (General Electric, NY) before dissolving with appropriate buffers. NMR studies were performed on a 1 Tesla Magritek Spectrometer (Magritek, CA). HP spectra were acquired (10° degree flip angle with repetition time of 4s for 25 scans in total). Cell tracking used the manual tracking function in ImageJ. Xenograft biopsies were obtained from LnCaP tumors using a 2mm punch. Data Summary: LnCaP cells seeded sparsely enable cancer spheroid formation remain viable as assessed by Live/Dead fluorescent staining. Histological sectioning revealed spheroids of approximately 200 μm in diameter. Direct deposition of these threads into a 5mm NMR tube allows measurement of metabolic flux using hyperpolarized [1-^13\text{C}] pyruvate resulting in the formation of [1-^13\text{C}] lactate. To modulate metabolism, we used an allosteric AKT inhibitor, MK2206. This drug resulted in relocalization of AKT from the plasma membrane as well as a reduction in cell motility from 0.72 ± 0.04 to 0.46 ± 0.03 mm/s (n = 5, p<0.05). Administration of hyperpolarized pyruvate resulted in approximately 30% of lactate production 24 hr after treatment. Histological staining of spheroids after treatment revealed sustained decrease of AKT phosphorylation after these treatments. These measurements are in good accordance with measurements of lactate secretion in the same cells grown under standard conditions, with MK2206 resulting in loss of AKT Ser473 phosphorylation as early as 2 hr post-treatment, followed by a decrease in lactate secretion in the media from 3.16 ± 0.2 to 1.35 ± 0.05 mM/10^6 cells/n = 3, p<0.05) 24 hr after treatment. To ensure that these methods are applicable clinical settings, LnCaP xenograft biopsies (~60mg) were deposited directly into an NMR tube to measure hyperpolarized [1-^13\text{C}] pyruvate metabolism. Line-width of the pyruvate peak was measured to be 1.72 ± 0.19 Hz (n=3) in the first spectra, demonstrating good homogeneity of the magnetic field and conversion to lactate was observed. Future experiments will focus on measuring the metabolism of patient-derived xenografts and effects of treatment response.

Conclusions: Metabolic measurements using hyperpolarized pyruvate can be performed on cancer spheroids as well as biopsies, allowing quantification of metabolism to complement on-going clinical trials utilizing hyperpolarized MR imaging.
blood, tumor, and organs were harvested and analyzed for SPRM signals and anti-Her2 content. In vitro, the anti-Her2 NPs exhibited specific binding to BT474 cells, with little to no binding in MCF7 cells. In vivo, MRX measurements of mice injected with anti-Her2 NPs showed a measurable magnetic signal in the tumor that reached a near maximum approximately four hours after injection. Conversely, mice injected with unconjugated nanoparticles showed no signal at 600 s post-injection. Finally, 24 hours post-injection, 4 – 8% of NPs and anti-Her2 were measurable in the blood, indicating long-term stability of the NP construct in circulation. Together, these results suggest targeted delivery of conjugated NPs to cancerous tissue in vivo and the utility of SPRM for the sensitive and specific detection of cancer in vivo. This work was performed, in part, at the Center for Integrated Nanotechnologies, an Office of Science User Facility operated for the U.S. Department of Energy (DOE) Office of Science. Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy’s National Nuclear Security Administration under contract DE-AC04-94AL85000.

#2860 89Zr-trastuzumab immunoPET imaging to monitor src status after treatment in HER2 breast cancer. Brooke N. McKnight,1 Nezissa T. Viola-Villegas,2 1Wayne State University, Detroit, MI; 2Karmanos Cancer Institute, Detroit, MI.

Around 30% of patients with early stage breast cancer have recurrent disease due to resistance. One of the putative causes of acquired resistance can be attributed to the hyperactivation of Src kinases, which are particularly stabilized by CD44v6, which itself is positively correlated in metastatic breast cancers. HER2 downstream effectors include Src, thus, we aim to investigate the use of a HER2-specific monoclonal antibody positron emission tomography (PET) probe. We hypothesize that 89Zr-trastuzumab can be a surrogate imaging tool for monitoring Src treatment. 89Zr-trastuzumab was previously developed and has demonstrated excellent specificity for breast cancer. Dasatinib-treated HER2+ BT474 (IC50 ~ 1.3 μM), SK-BR-3 (IC50 ~ 5.5 μM), and JIMT-1 (IC50 ~ 8 μM) breast cancer line cells have shown a negative correlation between treatment and HER2. We next conducted tumorigenic studies using athymic nude/nude mice bearing JIMT-1 or BT474 xenografts, which were treated for 7 or 14 days with dasatinib (75 mg/kg/day). At the end of each treatment, the tumors were subsequently imaged with 89Zr-FDG, and then followed by 89Zr-trastuzumab, 24 h later. Images were analyzed using AsiPro (show version here and decay-corrected to the time of injection. Tumor uptake values were measured by drawing volumes-of-interest, expressed as % injected dose per gram (%ID/g) of tissue on regions showing the most binding. 89Zr-FDG did not demonstrate a predictive response in both treated and placebo tumors, whereas, HER2 PET was able to show differential response in treated vs. control cohorts. In JIMT-1 mouse imaged with 89Zr-trastuzumab, a two-fold difference (p < 0.01) was observed between untreated and both treated groups (8.0 ± 1.5 %ID/g, n = 7 vs. 7-day treated: 3.8 ± 1.5 %ID/g, n = 4, and 14-day-treated: 4.5 ± 1.3 %ID/g, n = 4) mice imaged with 89Zr-trastuzumab. Confirmatory ex vivo western blots of JIMT-1 tumors have shown a decrease in HER2 at treatment time points, whereas, a decrease in p-Src (Y416). In vivo studies with BT474 xenografts are currently underway. Immunohistochemistry on excised tumors, as well as treatment on a metastatic patient-derived xenograft model is currently in progress. We have shown that HER2 PET can potentially be a surrogate marker of Src treatment. The findings from this study potentially afford a powerful tool to non-invasively detect and monitor changes in Src-targeted therapy in man at the early phases of treatment.

#2861 Dose-dependent tissue distribution and tumor targeting of Notch3-ADC using fluorescence molecular tomography imaging. Anand Giddabasappa,1 Parul Gupta,1 Mauricio Leal,1 Jonathan Golas,1 Fengfeng Li,2 Bing Yang,1 Antonio Esparza,1 Christopher Winkelmann,1 Kenneth Geles.1 1Pfizer Inc, San Diego, CA; 2Pfizer Inc, Pearl River, NY; 3Pfizer Inc, Pearl River, CA.

Background: NOTCH3, a cell surface receptor involved in cell-cell communications, is over-expressed or amplified in certain human tumors. NOTCH3 is known to regulate proliferation, differentiation and survival of cancer cells or cancer stem cells and thus an important therapeutic target. NOTCH3 antibody drug conjugate (ADC) is comprised of humanized anti-NOTCH3 antibody conjugated to an auristatin based cytotoxic payload. NOTCH3-ADC has shown promising results in pre-clinical tumor models. In this study we evaluated the kinetics, dose-dependent tissue distribution, tumor accumulation and targeting specificity of the NOTCH3-ADC in OVCAR3 xenograft model using fluorescence molecular tomography (FMT) imaging. The NOTCH3-ADC is mouse cross-reactive thus providing an accurate assessment of biodistribution. Methods: NOTCH3-ADC was conjugated to the near-infrared dye, AlexaFluor680 (AF680). The in vitro cellular binding was evaluated by cell-based ELISA. In vivo biodistribution was evaluated using OVCAR3 subcutaneous xenograft model. NOTCH3-ADC-AF680 (1mg/kg; 3mg/kg and 10mg/kg) was injected when the tumors reached 100 mm3. Tumor uptake at 4 h post-injection. Ex vivo FMT imaging, pharmacokinetic analysis and immunohistochemistry (IHC) was performed at 48 and 240 h after whole-body perfusion. An in vitro receptor competition FMT study was performed by injecting excess of unconjugated anti-NOTCH3 antibody (Ab) or a non-targeted control Ab. Results: In vitro cell binding studies showed that conjugation of AF680 to NOTCH3-ADC did not affect cell binding ability. A dose-dependent increase in tumor uptake was also observed after a single injection of NOTCH3-ADC-AF680. In vivo FMT imaging showed dose-dependent whole-body clearance kinetics of NOTCH3-ADC. Dose-dependent accumulation in the tumors was observed with peak accumulation at 24-48 h post-injection and a slow decline at later time points. A maximum accumulation of ~10 %ID/g was observed which was independent of the dose of NOTCH3-ADC-AF680. Ex vivo FMT quantitation of tumor was consistent with the IHC for antibody and LC/MS analysis of released payload. Pharmacological competition with excess unlabeled control Ab did not block tumor accumulation of NOTCH3-ADC-AF680, whereas excess unlabeled NOTCH3-Ab blocked ~47% of NOTCH3-ADC-AF680 accumulation. There was no significant specific accumulation of NOTCH3-ADC in other organs measured by FMT imaging or IHC. Conclusions: This study provides understanding of the kinetics, tumor accumulation and biodistribution of NOTCH3-ADC. Further this work showcase the utility of non-invasive FMT imaging in better understanding of pharmacology and behavior of biologic drugs.

#2862 Tumor-targeting salmonella typhimurium a1-r inhibited angiogenesis of osteosarcoma cells visualized by color-coded imaging in the in vivo absorbable gelatin sponge assay. Tasaku Kiyuna. University of California, San Diego, CA.

INTRODUCTION: We already have reported a color-coded imaging model that showed the sponge angiogenesis assay using absorbable gelatin sponge implanted in nestin-driven green fluorescent protein (ND-GFP) nude mice and that osteosarcoma cells promote angiogenesis in this sponge assay. We report here that Salmonella typhimurium A1-R (A1-R) inhibits angiogenesis of osteosarcoma cells in the sponge angiogenesis assay in ND-GFP mice. METHODS: Sponge was initially transplanted subcutaneously in the flank of transgenic ND-GFP nude mice. Seven days after transplantation of sponge, skin flaps were made and 143B-RFP human osteosarcoma cells expressing red fluorescent protein (RFP) were injected into the transplanted sponge. After establishment of tumors in the sponge, the control-group mice were treated with PBS via tail-vein injection and A1-R treated group with A1-R likewise. Skin flaps were made at days 14, 21, and 28 after transplantation of the sponge to allow imaging of vascularization in the sponge using a variable-magnification small animal imaging system and confocal fluorescence microscopy. RESULTS: Vessel length in the sponge was measured after treatment with FV10-ASW Fluoview software. Nascent blood vessels grew in the sponge in a time-dependent manner. A random 3 fields were quantified in each group). The mean length of ND-GFP expressing blood vessels in the sponge in mice with A1-R treated group were 9.40, 12.40, and 10.12 mm/mm2, at days 14, 21, and 28, respectively. The mean length of ND-GFP expressing blood vessels in the sponge in mice of the control group were 8.86, 14.50, and 15.81 mm/mm2 on day 14, 21, and 28, respectively. ND-GFP expressing blood vessels of the mice in the osteosarcoma cells treated with A1-R had shorter vessels than the control group (on days 28, P < 0.05), suggested the extent of nascent blood vessel growth was significantly inhibited by A1-R treatment. Besides, we evaluated the RFP colored area of the sponge in both groups, which almost represent the viable tumor size. The mean RFP colored area of A1-R treated group in the sponge were 4.49, 7.53 and 12.40 mm2 at days 14, 21, and 28, respectively. As a result of both outcomes above, the extent of nascent blood vessel growth was significantly inhibited by A1-R treatment on days 28. CONCLUSION: In the present study, we reported the effect of angiogenesis inhibition of A1-R in vivo sponge assay, and suggest A1-R has potential for anti-angiogenic target therapy for osteosarcoma.
TUMOR BIOLOGY: Imaging Cancer Metabolism, Therapeutic Targets, and Treatment Response

#2863 Magnetic resonance imaging based analysis of tumor growth and vascular parameters in animal model of GBM following IV formulated of HET0016 treatments. Ali S. Arbab,1 Meenu Jain,1 Bhagelu Achyut,1 Kartik Angara,1 Mohammad H. Rashid,1 Asm Iskander,1 Thaiz F. Borin,1 Wenbo Zhi,1 Roxan Ara,1 Irina Lebedyeva,1 Hassan Bagher-Ebadian,1 Augustia University, Augusta, GA; 2Heritage Health System, Detroit, MI.

Glioblastoma (GBM) is a hypervascular primary brain tumor with poor prognosis. HET0016 a selective CYP450 inhibitor has been shown to inhibit angiogenesis and tumor growth. Therefore, to explore novel treatments, we have generated an intravenously administered (IV) formulation of HET0016 with HP6CDD and tested in animal models of human and syngeneic GBM. Tumor growth and vascular parameters (tumor blood volume, permeability and extravascular and extracellular space volume) were determined by dynamic contrast enhanced (DCE) magnetic resonance imaging (MRI). The pharmacokinetics of HP6CDD-HET0016 were evaluated in plasma and tumor tissues using IV and IP routes of administration. IV treatment with HP6CDD-HET0016 decreased tumor growth, tumor blood volume, permeability and extravascular and extracellular space volume, when compared with the vehicle group (p<0.05). Similar growth inhibition was also observed in syngeneic GL261 GBM (p<0.05). Survival studies using patient derived xenografts of GBM (PDX), showed prolonged survival in PDX GBM. Inhibition was also observed in syngeneic GL261 GBM (p<0.05). Administration of a single dose resulted in 7-fold higher levels of HET0016 in the IV group in plasma and 3.6-fold higher levels in tumor tissues compared to that of IP. Decreased neovascularization (laminin and aSMA) migration (MHC-1) and the treated group (p<0.05). Decreased tumor growth was associated with reduced expression of pro-angiogenic markers (IL-8, MCP-1, VEGF, HIF-1α, and VE-Cadherin), inflammation (p-NFκB), intermediates of MAPK pathway (p-AKT, p-ERK and p-STAT1, EGFR), arachidonic acid metabolism (COX-1, CYP4A11) and increased expression of antiangiogenic markers (Ang2, Angiostatin and Tie-2). Our results indicate that the improved IV formulation of HP6CDD-HET0016 is effective in inhibiting tumor growth through decreasing proliferation, migration, and neovascularization. Furthermore, HET0016 significantly enhanced sensitivity of TMZ and prolonged survival in PDX GBM.

#2864 Tumor targeting and imaging using 44Cu labeled cyclic RGD conjugated human serum albumin via click chemistry. Cho Rong Park, Myung Geun Song, Ji-Yong Park, Hyewon Youn, June-Key Chung, Jae Min Jeong, Yun Sang Lee, Keon Wook Kang. Seoul National University, Seoul, Republic of Korea.

PURPOSE: The RGD specifically recognizes the integrin αvβ3 which is over-expressed on various malignant tumors. One major drawback of small peptide such as RGD, however, is short half-life in the blood, which greatly compromises their targeting efficacy. To improve blood circulation time and targeting efficacy, we developed cyclic RGDyK (cRGDyK) conjugated human serum albumin (HSA) using click chemistry reaction. METHODS: HSA was conjugated with DBCO-NHS (dibenzyl cyclooctyne) under physiologically favorable reaction condition for the preparation of strain promoted azide-alkyne reaction. Using this labeled HSA, DBCO-HSA with 44Cu labeled N3-NOTA (3-azidopropyl-NOTA) for radiolabeling. Cell binding of cRGDyK-HSA were analyzed with FNR648 labeled probes. Cellular uptake of 44Cu-cRGDyK-HSA were tested for integrin αvβ3 specific binding at cell level. PET images were acquired after tail vein injection of 44Cu-HSA, 44Cu-cRGDyK-HSA in integrin αvβ3 positive tumor (SK-OV3, ovarian cancer cell line) bearing BALB/c nude mice. PET signals were quantitatively analyzed with PET image analysis program, AMIDE. RESULTS: The number of cRGDyK on DBCO-HSA conjugates was confirmed using MALDI-TOF MS. cRGDyK-HSA was successfully conjugated with 44Cu labeled N3-NOTA. Integrin αvβ3 mRNA and protein was highly expressed in SK-OV3 cell line. At fluorescence labeled probes were treated in SK-OV3, cRGDyK-HSA were highly bound to cell membrane and this pattern were decreased with pre-treatment of cRGDyK. When compared to cellular uptake level, 44Cu-cRGDyK-HSA were more accumulated at integrin αvβ3 positive cells (SK-OV3) than integrin αvβ3 negative cells (p<0.05) and there were no difference in 44Cu-HSA. Serial PET images were acquired 0, 4, 24, 48 hours after tail vein injection of 44Cu-cRGDyK-HSA. Radioactivity of 44Cu-cRGDyK-HSA in SK-OV3 tumor was higher than that of 44Cu-HSA. 44Cu-cRGDyK-HSA can be reduced at 48 hours after injection, which shows longer circulation time in mice. CONCLUSION: We successfully conjugated cyclic RGDyK to HSA using click chemistry approach. We demonstrated that cRGDyK-HSA specifically bind to integrin αvβ3 in vitro and vivo model. And in animal model, 44Cu-labeled-cRGDyK-HSA can be observed at 48 hours after injection, which shows longer circulation time. Our results indicated that cRGDyK-HSA have a potential to diagnosis and therapy response monitoring of tumor expressing integrin αvβ3. The peptide transporter K16ApoE increases drug delivery across the blood brain barrier in an experimental animal model of melanoma brain metastases. Synnøve Nymark Aasen,1 Heidi Espedal,1 Olivier Keunen,1 Chris- topher Florian Holte,2 Habib Baghriov,2 Rolf Bjerkgv,3 Tine Veronika Karlsen,3 Olav Tenstad,3 Dag Erlend Olberg,4 Gobinda Sarkar,5 Robert B Jenkins,6 Frits Thorsen7.1 Haukeland University Hospital, Bergen, Norway; 2University of Bergen, Bergen, Norway; 3Luxembourg Institute of Health, Luxembourg, Luxembourg; 4Norwegian University of Science and Technology, Trondheim, Norway; 5Oslo University Hospital, Oslo, Norway; 6Mayo Clinic, Rochester, MN.

Introduction: Patients with brain metastases await a dismal prognosis. Regardless of the continuous progress in drug development, a major problem is the delivery of drugs across the blood brain barrier (BBB) and into the metastatic neoplasms. The BBB excludes almost all compounds, in particular highly charged, hydrophilic or large compounds, and most of the current chemotherapeutic agents are thus unable to penetrate the BBB. Varying strategies to transiently open the BBB have been studied previously. Here, we describe a peptide transporter comprising 16 lysine residues and 20 amino acid residues corresponding to the low density lipoprotein receptor (LDLR) binding domain of apolipoprotein E (ApoE). We show that the peptide (K16ApoE) is able to transiently open the BBB for drug delivery into experimental brain metastases. Experimental procedures: A systemic study of the ability of the peptide to open the BBB was studied by dynamic contrast enhanced (DCE MRI) in nonobese diabetic/severe combined (nod/scid) mice. The BBB permeability was studied after administering 200 μg of the peptide intravenously. Further, cellular effects after treatment with the peptide was investigated in vitro using confocal microscopy, flow cytometry and impedance experiments. The biodistribution of the peptide was studied in blood plasma and several organs using 151I labeled K16ApoE. Finally, a treatment study was initiated, treating the animals with the peptide in combination with the B-RAF inhibitor Dabrafenib, only Dabrafenib or vehicle. Summary: After injecting the K16ApoE peptide into the mice, a transient opening of the BBB for up to 4 hours was clearly demonstrated by DCE-MRI. Microscopy showed that the peptide disrupted brain endothelial cell monolayers, reducing the barrier properties of the cells. The impedance experiments displayed that the permeability through endothelial cell barriers was increased after treatment with K16ApoE, and a dose-dependent cell death pattern was observed at higher concentrations of K16ApoE. The peptide did not affect endothelial cell tight junctions. The biodistribution study showed that the peptide was eliminated from blood plasma in less than five minutes through the kidneys. The treatment study displayed that the K16ApoE followed by K16ApoE + Dabrafenib followed by Dabrafenib only cured smaller tumor volumes than the other two animal groups. Conclusions: We have shown that the peptide opens the BBB and facilitates a therapeutic window of 4 hours. The peptide did in combination with Dabrafenib decrease the number of experimental brain metastases in our studies. Thus, the current strategy could also have the potential to improve the treatment of patients with brain metastatic disease.

#2866 Volumetric optoacoustic imaging of tumor cell death using a targeted imaging agent. Bangwen Xie,1 Michel Tomaszewski,1 André A. Neves,1 Stefanie R. Mullins,2 David Tice,1 Richard Sainson,2 Sarah Bohndiek,3 Robert W. Wilkinson,4 Kevin M. Brindle5.1 University of Cambridge, Cambridge, Cambridge, United Kingdom; 2MedImmune Limited, Cambridge, United Kingdom; 3MedImmune LLC, Gaithersburg, MD.

Multiphotonic spectroscopic tomography (MSOT) generates high-resolution cross-sectional images in less than a second. MED13039, is a newly described agonist of the TNF-related apoptosis-inducing ligand receptor2 (TRAILR2), which has been shown in preclinical studies to preferentially induce cell death in cancer versus normal cells1. We show here that MSOT, when used with a near infra-red (NIR) fluorophore-labelled protein domain of synaptotagmin (C2Am-750, ~15kDa) that binds to phosphatidylserine (PS) exposed by apoptotic and necrotic cells2, can be used to image MED13039-induced cell death within the entire tumor region. Non-specific probe retention was assessed using a site-directed mutant (IC2Am-680 or iC2Am-750). PS-specific binding of C2Am-750 to MEDI3039-treated TRAIL-sensitive Colo205 and TRAIL-resistant HT-29 human colon adenocarcinoma cells in vitro was evaluated by flow cytometry and confocal microscopy. The capability of C2Am-750 to detect cell death in vivo was assessed in mice bearing Colo205 or HT-29 xenografts, following a single dose (0.4 mg/kg, i.v.) of MED13039. All mice then received an i.v. injection of a 1:1 mixture of 0.1 μmole/kg C2Am-750 and iC2Am-680 16 h post
FDG-PET/CT scans 4 hours and 24 hours post-CPI-613 treatment. Similar to the result of successful targeting of mitochondrial metabolism. We therefore examined 2-deoxyglucose for 15 or 60 minutes following 2 hours of treatment with CPI-613.

TUMOR BIOLOGY: Imaging Cancer Metabolism, Therapeutic Targets, and Treatment Response

Aim: Nanoparticle-assisted photothermal therapy is a new promising therapeutic strategy that utilizes photo-absorbing nanoparticles irradiated with near infrared light to generate a local temperature increase in tumor tissue. Here we used small animal 18F-FDG PET/CT to evaluate the treatment response of silica-gold nanoshell (NS)-assisted photothermal therapy in human tumor xenografts. Method: NMRI nude mice (n = 9) bearing human tumor xenografts (H727) were treated with two nanoparticle-assisted photothermal therapy treatments. In the NS group, PET imaging revealed a significant reduction in tumor uptake at day 1 in the NS group (84 ± 8 % (day 1/baseline)) compared to the saline group (108 ± 21 %; p < 0.01) and sham (110 ± 11 %; p < 0.05) groups. Moreover, the change in 18F-FDG tumor uptake (day 1/baseline), was used to stratify animals into responders and non-responders, where the responding group matched inhibited tumor growth and improved survival. Conclusion: In this study we showed that 18F-FDG PET could be used for early response monitoring of the therapeutic outcome of nanoparticle-assisted photothermal therapy in human tumor xenografts in mice. Based on this, we suggest that PET can also be used for optimization of therapy, both for guiding treatment planning and early identification of non-responders for which the treatment strategy should then be changed.

#2867 FDG-PET imaging as a potential biomarker of mitochondrial targeting by CPI-613, a novel inhibitor of mitochondrial metabolism. Kiran Solingaparuram Sai,1 Zuzana Zachar,2 Frankis Almguel,2 Shawn D. Stuart,2 Michael S. Dahan,2 Moises Guaraldo,3 Stephanie Rideout,1 Minghui Wang,2 Anirudh Sattaraju,1 Paul M. Bingham,2 Boris Pasche,2 Akiva Mintz,1 Wake Forest University School of Medicine, Winston Salem, NC; Stony Brook University, Stony Brook, NY.

CPI-613 is a lipopeptide analogue that has been shown to inhibit the pyruvate dehydrogenase (PDH) and alpha-ketoglutarate dehydrogenase (KDGDH) complexes selectively in tumor cells (reviewed in Exp.Rev.Clin.Pharm. 7, 833). These two enzymes control the vast majority of carbon flow into the tricarboxylic acid (TCA) cycle and play a central role in mitochondrial metabolism. PDH converts pyruvate into acetyl-CoA, which in turn can enter the TCA cycle for cellular respiration. Since pyruvate is the final product of glycolysis, PDH serves as a crucial metabolic switch point. Therefore, in this work we evaluated the in vitro and in vivo glucose uptake in cancer cells and tumor xenografts after treatment with CPI-613. To measure glucose uptake in vitro we pulsed BxPc3 pancreatic cancer cells with 2H2O for 15 or 60 minutes following 2 hours of treatment with CPI-613. We observed a significant upregulation (~100% increase) of cellular 2-deoxyglucose uptake, consistent with a compensatory increase in glucose uptake as a result of successful targeting of mitochondrial metabolism. We therefore examined whether this upregulation occurs in vivo using FDG-PET/CT. Mice bearing BxPc3 flank tumors were treated with 50mg/kg of CPI-613 and underwent FDG-PET/CT scans 4 hours and 24 hours post-CPI-613 treatment. Similar to in vitro response, tumors treated with CPI-613 exhibited a 75% increase in 18F-FDG uptake compared to untreated controls at 4 hours post-treatment. At 24 hours post-treatment, tumors were irradiated for 5 minutes with an 807 nm diode laser with an intensity of 1.5 W/cm² (day 0) meanwhile the temperature development was monitored using thermographic imaging. To evaluate the treatment response, all animals were PET/CT scanned with either 18F-FDG or 18F-FLT the day before treatment (baseline) and two days after treatment (day 2). In addition, the change in tumor volume was assessed by CT imaging on day 7. Throughout the study, tumor growth was monitored using caliper measurements and animals were euthanized when the tumor volume exceeded 1000 mm³. Results: During laser irradiation, the temperature at the surface of the tumor was measured using thermographic imaging. The mice were 18F-FDG PET scanned again at day 1 after treatment and tumor growth was followed by caliper measurements with the humane endpoint defined as a tumor volume of 1,000 mm³. PET and CT images were co-registered, and regions of interest were manually drawn on whole tumor regions. 18F-FDG uptake was quantified as mean percent of injected dose per gram of tissue (%ID/g) and the treatment response was evaluated based on the reduction in tumor uptake of 18F-FDG between baseline and day 1.

#2869 Comparison of 18F-FDG and 18F-FLT PET imaging for early response monitoring of nanoparticle-assisted photothermal cancer therapy. Kamilla Norregaard,1 Jesper Tranekjaer Joergensen,1 Kamilla Norregaard,1 Jesper Tranekjaer Joergensen,1 Marina Simón Martín,1 Lene B. Oddershede,2 Andreas Kjaer1, Rigshospitalet and University of Copenhagen, Copenhagen, Denmark; University of Copenhagen, København N, Denmark.

Aim: Nanoparticle-assisted photothermal therapy relies on photo-absorbing agents that accumulate in tumors and upon irradiation with near-infrared light, generate hyperthermperatures sufficient to ablate surrounding cancerous tissue. In this study, we used small animal PET imaging to compare the tracer accumulation of 18F-FDG and 18F-FLT, that are glucose and thymidine analogues respectively, for the assessment of silica-gold nanoshell (NS)-assisted photothermal therapy in a colorectal cancer mouse model. Method: Mouse colorectal tumors (CT26) were established subcutaneously in female Balb/c mice by inoculation of 3x10⁴ cells. When the tumors reached a volume of ~150 mm³, the animals were divided into treatment groups receiving either: NS and laser irradiation (NS group), saline and laser irradiation (saline group), or NS but no laser irradiation (sham group). 24 h after intravenous injection of either NS or saline, the tumors were irradiated for 5 minutes with an 807 nm diode laser with an intensity of 1.5 W/cm² (day 0) meanwhile the temperature development was monitored using thermographic imaging. To evaluate the treatment response, all animals were PET/CT scanned with either 18F-FDG or 18F-FLT the day before treatment (baseline) and two days after treatment (day 2). In addition, the change in tumor volume was assessed by CT imaging on day 7. Results: Thermographic imaging showed that the tumor surface reached 44.5 ± 1.9 °C in the saline group and 33 ± 1.0 °C in the sham group. This was consistent with an overall inhibited tumor growth, as well as improved survival in the NS group compared to the sham and saline groups. The tumor accumulation of 18F-FDG uptake was comparable between groups at baseline but PET imaging revealed a significant reduction in tumor uptake at day 1 in the NS group (84 ± 8 % (day 1/baseline)) compared to the saline group (108 ± 21 %; p < 0.01) and sham (110 ± 11 %; p < 0.05) groups. Moreover, the change in 18F-FDG tumor uptake (day 1/baseline), was used to stratify animals into responders and non-responders, where the responding group matched inhibited tumor growth and improved survival. Conclusion: In this study we showed that 18F-FDG PET could be used for early response monitoring of the therapeutic outcome of nanoparticle-assisted photothermal therapy in human tumor xenografts in mice. Based on this, we suggest that PET can also be used for optimization of therapy, both for guiding treatment planning and early identification of non-responders for which the treatment strategy should then be changed.
TUMOR BIOLOGY: Imaging Cancer Metabolism, Therapeutic Targets, and Treatment Response

groups the tumor uptake of $^{18}$F-FDG was at comparable levels at baseline and day 2. In addition, a positive correlation was found between the change in tumor uptake between baseline and day 2 and the change in tumor volume on day 7 in all animals scanned with $^{18}$F-FDG. Preliminary data from animals scanned with $^{18}$F-FLT indicates that the tumor uptake is also strongly reduced after NS-aspirated prophylaxis, and that the contrast between $^{18}$F-FLT PET imaging show great potential for early evaluation of the treatment response after nanoparticle-assisted photothermal therapy and preliminary data suggest that both tracers can be used to predict treatment outcome.

#2870 Optical imaging of bombesin and transferrin receptor expression as are effective as $^{18}$FDG in assessing drug efficacy. Jen-Chieh Tseng, Jeffrey D. Peterson. Perkin Elmer, Hopkinton, MA.

Physical measurement of tumor volume reduction is the most commonly used method used to assess tumor progression and treatment efficacy in mouse xenograft models, but the detection of tumor size changes can require repeated drug dosing and tumor measurements for several weeks. However, $^{18}$F-FDG PET imaging of altered glucose metabolism can be a more sensitive tool for early cancer detection/diagnosis as well as treatment assessment; cancer cells are known to have abnormally increased cellular metabolism that can be inhibited by drug treatment. To illustrate this, we used HCT-116 human colorectal tumor xenografts in nu/nu mice with sorafenib treatment, a clinically approved tyrosine protein kinase inhibitor (5 d treatment, 40 mg/kg). Treatment is known to inhibit PDGFR and VEGFR, as well as Raf kinases that regulate energy metabolism in tumors. Some $^{18}$F PET imaging of treated mice using $^{18}$F-FLT revealed a significant drop in tumor metabolism with as little as 2-3 days of treatment, a time in which there is typically little or no effect on tumor size. This approach was relatively low through-put, and required special procedures to accommodate the use of radioactivity, but offered the option of daily imaging of tumor status. We also explored alternative optical imaging approaches that could offer higher through-put imaging as well as the potential for multiplex imaging. There is no fluorescent equivalent of $^{18}$F-FDG, so we focused on bombesin- and transferrin-receptors as potentially useful biomarkers for drug-induced inhibition in tumor metabolism. Bombesin receptors are upregulated in a variety of tumors and are important in energy metabolism and tumor growth. The rapid recycling kinetics also make this receptor highly sensitive to cellular metabolic changes. Transferrin receptors are also upregulated in most tumors and provide critical iron transport function vital for their increased enzymatic, proliferative, and metabolic requirements. We used targeted near infrared (NIR) fluorescent imaging probes, BombesinSense$^TM$ 680 (BRS-680) and Transferrin-Vivo$^TM$ 750 (TIV-750), to monitor changes in receptor expression in HCT-116 tumor xenografts during the course of sorafenib treatment. Interestingly, both $^{18}$F-FLT and TIV-750 PET imaging yields data quite similar to our results using $^{18}$F-FDG PET; reduction in the uptake of $^{18}$F-FDG can be measured as early as 48-72 hours, in the absence of significant reduction of tumor volume. As expected, both PET and FLI were highly effective at imaging sorafenib effects 7-8 days later (3-4 days following a 5-day sorafenib treatment regimen), with datasets in good agreement with physical measurements of tumor size. These results suggest that BRS-680 and TIV-750 can serve as fluorescent surrogates for $^{18}$F-FDG PET both in measuring early metabolic changes and ultimate therapeutic outcomes following cancer treatment.

#2871 Non-invasive monitoring of the efficacy of anticancer therapeutic agent in lung orthotopic xenograft models of NSCLC using Bio-Luminescence Imaging (BLI). Sanchareeka Dey, Sarada Preeta Kalainayakan, Poovra Ghosh, Li Zhang. University of Texas at Dallas, Richardson, TX.

Non-Small Cell Lung Cancer (NSCLC) patients have a poor rate of survival owing to diagnosis at a later stage. This necessitates development of novel therapeutic strategies that limit rapid progression of NSCLC and imaging techniques that monitor such changes in vivo. There has been a significant growth of bioluminescence imaging applications in small laboratory animal models in recent years, owing to its high sensitivity, efficiency, and non-invasive nature. Our lab has previously demonstrated that a therapeutic agent that disrupts mitochondrial respiration effectively hampers proliferation of NSCLC cell lines in vitro. With an effort to investigate the potential of this therapeutic agent in clinical settings, we used a lung orthotopic xenograft mouse model along with bioluminescence imaging (BLI) to continuously monitor the efficacy of the drug in vivo. Briefly, we implanted NSCLC cell line transduced with lentiviral particles carrying luciferase sequence, in the left lung of 6-8 weeks old female NOD/SCID mice to generate lung orthotopic xenografts. The therapeutic agent was administered intravenously over several weeks. Tumor growth was then compared between the untreated versus the treated mice, non-invasively through bioluminescence imaging (Perkin Elmer’s IVIS Lumina III Imager). On sacrificing the mice, the lungs were harvested, formalin fixed and paraffin embedded for Immunohistochemistry. Our BLI data show that in the mice treated with the therapeutic agent, tumors are localized to the left lung (site of implantation) as opposed to the control mice where the tumors metastasized to the right lung. The BLI data indicates significant decrease in radiance (total flux in photons per second) in mice subjected to treatment when compared to control mice. We show that the therapeutic agent significantly inhibits progression and metastasis of human NSCLC cell line orthotopically injected in the lungs of NOD/SCID mice. The results suggest that it might be potent anti-cancer drug as it is effective in a model that recapitulates the natural environment of lung tumorigenesis. Immunohistochemical studies are underway to discern the mechanistic details.

#2872 Quantitative mass spectrometry imaging of erlotinib in skin rashes of cancer patients receiving erlotinib. Meiko Nishimura,1 Hiroaki Aikawa,2 Mitsuhiro Hayashi,2 Yu Mizutani,2 Kei Takenaka,1 Yoshinori Imamura,2 Naoko Chayahara,1 Masanori Toyoda,1 Naomi Kiyota,1 Toru Mukohara,1 Akinobu Hamada,1 Hirobou Minami1. 1Kobe University Graduate School of Medicine, Kobe, Japan; 2National Cancer Center, Japan; 3Kobe Minimally Invasive Cancer Center, Kobe, Japan; 4Kobe University Hospital, Kobe, Japan.

Background: The development of rashes is the most common adverse event observed in cancer patients treated with epidermal growth factor receptor-targeted tyrosine kinase inhibitors (EGFR-TKI) such as erlotinib. A significant relationship exists between the severity of a rash and survival in various cancers. However, a distribution pattern of erlotinib concentration is not clarified. The concentration is higher in a rash than in normal skin of treated cancer patients remains unknown. Here, using quantitative mass spectrometry imaging (qMSI), we successfully visualized the distribution of erlotinib in rashes and normal skin of patients with advanced pancreatic cancer receiving this drug. Methods: We studied five patients with advanced pancreatic cancer who developed rashes after treatment with gemcitabine (1000 mg/m²) by intravenous infusion for 30 minutes on days 1, 8, and 15 every 4 weeks) and erlotinib (given orally at 100 mg/day). We biopsied both rashes and normal skin, and compared the distribution of erlotinib using matrix-assisted laser desorption ionization mass spectrometry imaging (MALDI-MSI). The plasma concentration of erlotinib was measured by liquid chromatography-tandem mass spectrometry (LC-MS/MS). Results: Erlotinib concentrations in five patients were 2.55 ± 1.46 ng/mm² in normal skin and 3.18 ± 1.53 ng/mm² (mean ± SD) in rashes (p = 0.123). In four out of five patients, the erlotinib concentration in rashes was higher than that in normal skin. The epidermis showed the strongest expression of EGFR in skin as judged by immunohistological staining. Erlotinib showed a greater tendency for distribution to the epidermis than subcutaneous tissue. There was no correlation between plasma concentrations of erlotinib and the concentration in rashes or normal skin. Conclusions: Using qMSI, we, for the first time, visualized the distribution of erlotinib in skin tissue of pancreatic cancer patients receiving erlotinib. We found a tendency for a higher concentration of erlotinib in rashes than in normal skin. A greater distribution of erlotinib to the epidermis than subcutaneous tissue suggests erlotinib may directly bind EGFR expressed in the epidermis.

#2873 Imaging tumor heterogeneity after multikinase inhibitor therapy in rat hepatocellular carcinoma. Nina M. Muñoz,1 Aedeek A. Minhaj,2 Kiersten L. Maldonado,1 Charles Kingsley,1 Hideyuki Nishiofuku,2 Keith A. Michel,1 Andrea C. Cortes,1 James A. Bankson,1 Asif Rashid,1 Rony Avritsch,3 1UT MD Anderson Cancer Center, Houston, TX; 2Nara Medical University, Nara, Japan.

Purpose: To assess tumor tissue perfusion and vascular permeability through multiparametric functional imaging, and to evaluate their correspondence with histopathological parameters of necrosis and hypoxia in a rat model of hepatocellular carcinoma treated with a multikinase inhibitor. Materials and Methods Rat hepatoma Mca-Rh7777 cells were implanted in the left liver lobe of nineteen male Buffalo rats. Exactly 2 weeks after tumor inoculation, the animals were randomly assigned to remain untreated (n=10) or to receive a daily dose of 7.5 mg/kg sorafenib by oral gavage (n=9) for 2 additional weeks. T2-weighted spin-echo magnetic resonance imaging (MRI), dynamic contrast-enhanced (DCE) and contrast-enhanced ultrasound (CEUS) were performed weekly. All tumors were harvested 4 weeks post-implantation >90 minutes after injecting 60mg/kg pimonidazole. Tissue sections were stained for hematoyxin-eosin and pimonidazole for quantitative assessment of necrosis and hypoxia, respectively. Differences between treatment groups were assessed using the Mann-Whitney test, and the correlation of imaging and histopathology parameters was determined by Spearman correlation analysis. Results: In spite of the relatively low

Proceedings of the American Association for Cancer Research • Volume 58 • April 2017 733

Differences between treatment groups were assessed using the Mann-Whitney
TUMOR BIOLOGY: Imaging Cancer Metabolism, Therapeutic Targets, and Treatment Response
dose and short treatment duration, the response to sorafenib therapy was char-
acterized by a significantly higher median tumor necrosis (60 vs 15%, P <
0.0001) and increased tumor tissue hypoxia (35 vs 18.5% pimonidazole binding,
P < 0.0001). Similarly, the sorafenib regimen caused a substantial decrease in
vascular permeability, measured by DCE-MRI Ktrans (P = 0.002) as well as re-
suction in tumor vascular area, evaluated by CEUS (P = 0.043). Our findings show a strong correlation between the two histopatho-
logic parameters we assessed, tumor tissue necrosis and hypoxia (r = 0.645,
P = 0.002). Furthermore, our results demonstrate significant correlation of func-
tional imaging parameters of vascular permeability, namely DCE-MRI Ktrans,
and DCE-MRI normalized initial area under the curve (NIAUC), with histo-
pathologic tissue hypoxia (r = -0.663, P = 0.002, and r = -0.512, P = 0.029,
respectively). In contrast, histopathologic tumor necrosis appears more strongly
associated with a functional imaging parameter of tumor perfusion, specifically,
CEUS PE (r = -0.547, P = 0.028). Conclusion Tumors exhibited wide hestro-
genicity in vascular perfusion and hypoxia after treatment. Interestingly, func-
tional MRI parameters appear to correlate more strongly with tissue oxygen-
ation, whereas functional CEUS parameters correlate with tumor viability.
Novel predictive imaging biomarkers of treatment response may be developed
through further analyses of spatial tumor heterogeneity in our animal model.

#2874 Inhibition of tumor angiogenesis by Salmonella typhimurium A1-R in the in vivo Gelfoam color-coded imaging assay. Tasuku Kiyuna, Yasunori Tome, Takashi Murakami, Ming Zhao, Fumonori Kanaya, Robert M. Hoff-
man, Anticancer, Inc, San Diego, CA; University of the Ryukyus, Okinawa,
Japan.

We previously demonstrated a color-coded angiogenesis imaging model us-
ing Gelfoam implanted in nestin-driven green fluorescent protein (ND-GFP)
nude mice in which nascent blood vessels express GFP. In this assay, we dem-
strated osteosarcoma promotes angiogenesis. We report here that Salmonella
typhimurium A1-R (S. typhimurium A1-R) inhibits angiogenesis of osteosar-
coma cells in the Gelfoam® angiogenesis assay in ND-GFP mice. Gelfoam® was
transplanted subcutaneously in the flank of transgenic ND-GFP nude mice.
Seven days after transplantation, skin flaps were made and 143B human osteo-
sarcoma cells, expressing red fluorescent protein (RFP), were injected in the
transplanted Gelfoam®. After establishment of tumor in the Gelfoam®, the con-
trol group mice were treated with PBS by tail vein injection. The treated group
was treated with S. typhimurium A1-R, also by tail vein injection. Skin flaps were
made at days 14, 21, and 28 after transplantation of the Gelfoam® in order to
allow imaging of vascularization. The OV100 variable magnification small ani-
mal imaging system and FV1000 confocal fluorescence microscope were used to
visualize vascularization. Nascent blood vessels grew in the Gelfoam® in a time-
dependent manner. A random 3 fields were quantified in each group. The mean
length of ND-GFP-expressing blood vessels in the Gelfoam® in mice were treated
with S. typhimurium A1-R was 9.40, 12.40, and 10.12 mm/mm2, at days
14, 21, and 28, respectively. The mean total length of ND-GFP-expressing blood
vessels in the Gelfoam® in mice of the control group were 8.86, 14.50, and 15.81
mm/mm2 on day 14, 21, and 28, respectively. ND-GFP expressing blood vessels
of the mice in the osteosarcoma cells treated with S. typhimurium A1-R had
shorter vessels than the control group (on day-28, P < 0.05). There was not a sig-
ificant difference in tumor size between the 2 groups, thereby indicating a
specific inhibition of angiogenesis by S. typhimurium A1-R. In the present
study, we reported that S. typhimurium A1-R inhibited angiogenesis of human
osteosarcoma cells in the in vivo Gelfoam® color-coded imaging assay.

#2875 Knockout of ST8SIA1 inhibits tumorigenesis in triple negative breast cancer by inducing PTEN and ganglioside GM1 mediated tumor growth arrest. Sara E. Conard, Aaron Ebbs, Albert S. Baldwin, University of North Carolina at Chapel Hill, Chapel Hill, NC.

The heterogeneous nature of prostate cancer tumors is thought to play an
important role in the decreased effectiveness of existing therapies. Tumor initi-
ating cells (TICs) are capable of self-renewal and comprise a subset of the tumor
SUM159 cells reduced the absolute number of GD2+ cells from 17 ± 1.5% to
3 ± 0.1%. Although there was no significant difference in 2D cell growth,
arborage-independent growth by soft-agar and the mammosphere formation
assays revealed a complete loss of colony formation in ST8SIA1-KO cells. Mor-

TUMOR BIOLOGY: Signaling in Cancer Stem Cells

#2876 Loss of the stem cell and basal lineage regulator LBH delays onset of basal-like triple negative breast cancer. Kilan C. Ashad-Bishop, Karolina Brie-
gel, Univ. of Miami, Miami, FL.

There is increasing evidence that basal-like triple negative breast cancer
(TNBC) originates from luminal mammary epithelial cells. Specific gene sig-
naling pathways have already been experimentally proven to serve as genetic line-
age switches that, when overexpressed, transform pre-malignant luminal cells to
oncogenic cells with basal, stem-like characteristics. Conversely, depletion of
these genes in oncogenic cells with basal, stem-like characteristics leads to lumi-
nal differentiation. These studies suggest that during the earliest steps of neo-
plastic transformation, specific gene sets can alter cell fate decisions and differ-
entiation status in mammary epithelial cells, which ultimately contributes to the
heterogeneity of breast tumors. Our lab has identified a novel Wnt/β-Catenin
target gene, Limb bud and heart (LBH) that is majorly overexpressed in TNBC.
LBH is a regulator of the basal mammary stem cell lineage and repressor of
luminal differentiation via induction of Nαp63 and repression of estrogen re-
ceptor alpha. LBH is required for the self-renewal and maintenance of adult
stem cells, which are critical for tumor growth. Loss of LBH in basal mammary
fibroblasts in mice have shown that genetic ablation of LBH does not impair embry-
ogenesis or normal adult organ function, making it a possible therapeutic target.
Using crosses between MMTV-Wnt1 transgenic mice and K14Cre LBHflox
knockout mice, we are studying the effect of LBH ablation in the basal cells of the
mammary epithelium downstream of ectopic Wnt expression in the mammary
gland. We postulated that LBH may be an effector for Wnt-driven TNBC, there-
fore its inhibition would lead to decreased Wnt-induced mammary gland hy-
perplasia and tumor formation. In our model, LBH ablation in the basal mam-
mary epithelium of female Wnt transgenic mice reduces mammary gland hyperplasia and delays tumor onset. MMTV-Wnt1 driven, LBH-null tumors are
hyperplasia and delays tumor onset. MMTV-Wnt1 driven, LBH-null tumors are
also exhibiting histopathological differences indicative of a luminal to basal conver-
sion. There is an urgent need to elucidate mechanisms underlying TNBC devel-
opment and progression and find reliable avenues for treatment. Our data indi-
cates a role for LBH as a novel effector for Wnt-driven TNBC and further studies
may prove antagonism of Lbh to be a novel method to control TNBC progres-
sion.

#2878 Knockout of ST8SIA1 inhibits tumorigenesis in triple negative breast cancer by inducing PTEN and ganglioside GM1 mediated tumor growth arrest. Kim C. Nguyen, Yuanqing Yan, Chandra Bartholomeusz, Naoto

There is increasing evidence that basal-like triple negative breast cancer
(TNBC) originates from luminal mammary epithelial cells. Specific gene sig-
nalizing pathways have already been experimentally proven to serve as genetic line-
age switches that, when overexpressed, transform pre-malignant luminal cells to
oncogenic cells with basal, stem-like characteristics. Conversely, depletion of
these genes in oncogenic cells with basal, stem-like characteristics leads to lumi-
nal differentiation. These studies suggest that during the earliest steps of neo-
plastic transformation, specific gene sets can alter cell fate decisions and differ-
entiation status in mammary epithelial cells, which ultimately contributes to the
heterogeneity of breast tumors. Our lab has identified a novel Wnt/β-Catenin
target gene, Limb bud and heart (LBH) that is majorly overexpressed in TNBC.

ating cells (TICs) are capable of self-renewal and comprise a subset of the tumor

Proceedings of the American Association for Cancer Research • Volume 58 • April 2017
mass. These cells are proposed to drive the growth and metastasis of tumors, and are considered to be resistant to traditional cytotoxic and targeted therapies. Several studies have shown that NF-κB signaling is increased in recurrent prostate cancer and enriched in prostate TICs. We sought to determine the potential of an IKK/NF-κB-driven mechanism for inherent or acquired resistance by IKK-mediated control of a subset of prostate tumor initiating cells. These studies were performed by using established prostate cancer cell lines, murine prostate organoids, and a murine prostate cancer animal model. We have found that inhibition of IKKα and IKKβ, upstream regulators of noncanonical and canonical NF-κB signaling, block self-renewal of several PTEN-deficient prostate cancer cell lines. Furthermore, we have also found that IKK is important for tumorigenicity and stemness seen in prostate cancer cells as measured by colony formation and extreme limiting dilution assays. Loss of canonical NF-κB (p65/RelA) decreased stemness while loss of noncanonical did not alter tumorsphere formation. Interestingly, Pten-/- tumors with loss of Ikκk or Ikκκ displayed decreased levels of self-renewing cells as measured by CD49f<sup>high</sup> expression, a known prostate basal cell marker. Isolated murine Pten-/- cells were 2x more efficient than Pten-/- Ilκκ or Pten-/- Ikκκ-/- cells in forming prostate organoids suggesting that loss of Ikκκ decreased the number of self-renewing cells needed for formation. Taken together, we conclude that IKK-mediated signaling is important for maintenance of prostate tumor initiating cells and further studies will address whether IKK-mediated signaling provides a mechanism for evading current therapies.

**#2878** Anti-cancer effects of retinoic acid in CRC occurs via decreased growth of ALDH<sup>+</sup> cancer stem cells and increased differentiation of stem cells to neuroendocrine cells. Shirin R. Modarai,1 Lynn M. Opdenaker,2 Anindita Gupta,3 Jeremy Z. Fields,2 Bruce M. Roman14, Helen F. Graham Cancer Ctr., Newark, DE; 3Ca'Tx, PA.

Our studies from colon cancer patients show that in the development of colorectal cancer (CRC), stem cell (SC) overpopulation underlies tumor initiation and progression. Because aldehyde dehydrogenase (ALDH) is a marker for SCs in several tissues and is a key enzyme in retinoid acid (RA) signaling, we investigated the role of RA signaling in normal and malignant colon SCs. Our overall hypothesis is that RA signaling regulates growth (RA) and differentiation of ALDH<sup>+</sup> colon SCs and dysregulation of RA signaling contributes to SC overpopulation in CRC development. To begin to investigate underlying mechanisms, we analyzed CRC cell lines/tissues to see if retinoid receptors RXR and RAR are exclusively expressed in ALDH<sup>+</sup> SCs and if the RA pathway components change during CRC development. We determined whether RA signaling influences SC proliferation, differentiation, self-renewal, and SC population size. RXR & RAR were selectively expressed in ALDH<sup>+</sup> colon SCs, but not in MCM2 + proliferative cells, suggesting that RA signaling mainly occurs in SCs. Western blotting/immunostaining of CRCs revealed that RA signaling components, including RAR and RXR, become overexpressed in parallel with ALDH overexpression, which coincides with the known overexpression of ALDH<sup>+</sup> SCs that occurs during CRC development. Treatment of cells with RA ligands (ATRA, 9-cis RA) inhibited proliferation, reduced sphere formation, decreased ALDH<sup>+</sup> SC population size, and induced differentiation along the neural cell (NEC) lineage. Overall, our findings indicate that: (1) retinoid signaling, by regulating ALDH<sup>+</sup> colon SCs, reduces SC proliferation, self-renewal, and SC population size, and promotes SC differentiation to NECs, and (2) dysregulation of RA signaling in colon SCs likely contributes to overpopulation of ALDH<sup>+</sup> SCs and CRC growth. Thus, RA signaling, by inducing increased differentiation of the SC population, suggests a novel therapeutic target.

**#2879** DJ-1 inhibits self-renewal activity of GSCs in vitro as evidenced by neurosphere formation, limiting dilution, and soft agar clonogenic assays. DJ-1 knock-down suppressed maintenance of stemness by suppressing the expression of Notch intracellular domain, Sox2, and phosphorylated STAT3 proteins. Intriguingly, DJ-1 knock-down inhibited the expression of EGFRvIII in GSCs which might be the cause of suppression of stemness pathways. In addition, knock-down of DJ-1 induced apoptosis, reduced cell invasiveness, and sensitized GSCs to ionizing radiation. Based on these data, we propose that DJ-1 could be considered as a crucial diagnostics and therapeutic target for malignant glioma.

**#2880** GANT61-mediated constraint of Fibulin-5/prorenin receptor/ BM1 signaling impacts nasopharyngeal carcinoma stemness and metastasis. Hsin-Ting Tasi, Chang-Han Chen. Institute for Translational Research in Biomedicine, Kaohsiung, Taiwan.

Background: Cancer stem cells (CSCs) of NPC exhibit higher tumorigenesis and metastatic potential. Novel therapies based on molecular targets of CSCs have become the focus to cure NPC. GANT61, a GLI1 inhibitor, has been reported to exhibit potent anticancer effect on many cancers; here, we evaluated whether GANT61 has inhibitory effects on NPC-CSCs and further explored the possible mechanism. Methods: Condition medium was used to enrich NPC stem-like cells. The NPC stem-like cells characteristics were examined by Q-RT-PCR, Western blotting, MTt, BuDu, colony formation, sphere formation, and subcutaneous and metastatic xenograft models. Genetic, pharmacological and biochemical approaches were applied in NPC stem-like cells to investigate molecular signals, to assess the efficacies under the inhibitors treatment, and to examine the correlation among the molecules in vivo, in vitro, and NPC CSC specimens. Results: In the present study, we have demonstrated that NPC tumorsphere cells (NPC-TCS) possess CSC properties. The proliferation, colony formation, spheroid formation, migration, and invasion of NPC-TCS were dramatic prevented in the presence of GANT61 in vitro and in vivo. ChIP reveals that GLI1 preferentially binds to the Fibulin-5 promoter, and Fibulin-5 transcription/translation/post-transcriptional levels in NPC-TCS were regulated upon GANT61 treatment. However, ectopic expression of Fibulin-5 in NPC-TCS not only enhanced self-renewal and ALDH1 expression, but also reduced the effects of GANT61-elicited anti-tumor in vitro and in vivo. We further identified that a novel signaling, prorenin receptor/BM1 pathway was modulated by Fibulin-5 and involved in Fibulin-5-raised self-renewal capacity of NPC-TCS in vitro and in vivo. Notably, GANT61 inhibited NPC-TCS phenotypes was associated with suppression of Fibulin-5/prorenin receptor/BM1 signaling. Finally, a significant correlation was observed among GLI1, Fibulin-5, ATIR and BM1 in the specimens of NPC. Conclusions: Our data highlight that Fibulin-5/prorenin receptor/BM1 signaling has critical role in maintaining stem-like properties of NPC-CSCs and can be efficiently targeted by GANT61 representing a preclinical therapeutic strategy to repress NPC-CSCs.

**#2881** CXCL1 and CCL5, induced by ionizing radiation, reprogram non-tumorigenic cancer cells into cancer stem cells in breast cancer. Justine Bailleul-Daubois, 1 Nadège Bidan, 1 Raphaëlle Mouquet-Audouraud, 2 Mélanie Arci, 3 Karine Hannebicque, 4 Yuki Takayama, 3 Samuel Meignan, 2 Xuefeng Le Bourhis, 1 Chann Lagade, 1 1INSERM U908, Villeeneuve d'Ascq, France; 2Centre Odac, Lamberet, Lille, France; 3LIMMS/CNRS-IBS U02620, SMMIL-E, Tokyo, Japan.

Identification of cancer stem cells (CSC) in solid tumors - with self-renewal, multipotency, tumorigenesis, and therapy resistance capacities - has opened path to new targeting therapeutic approaches. However, CSC targeting alone might not be sufficient to eradicate a tumor. Indeed, recent studies showed that cancer cells are plastic, and conventional therapies, such as radiotherapy, can lead to cancer cells (non-CSC) reprogramming into iCSC (induced-CSC). The goal of our work is to identify the molecular mechanisms responsible for treatment-induced CSC emergence. First, we have shown that conditioned media from irradiated non-CSC is sufficient to induce iCSC reprogramming. These results suggest that cell plasticity might be actively regulated by diffusible factors secreted by irradiated cells. By using proteins arrays and ELISA, we demonstrated that the secretion of a specific cocktail of chemokines is induced by ionizing radiation, such as CXCL1 and CCL5. Interestingly, recombinant CXCL1 and CCL5 treatments increase the sphere forming capacity (SFC) of isolated non-CSC treated population. Concomitantly, treatment with neutralizing antibodies targeting CXCL1 and CCL5 leads to a decreased CSC number (ALDH<sup>+</sup> cells). We also studied the expression of the corresponding chemokine receptors, by flow cytometry. First, we saw that reprogrammable ALDH<sup>+</sup> cells are enriched for CXCL1 and CCL5 receptors expressing cells compare to unsorted population or ALDH<sup>-</sup> population. (CSC). We analysed the reprogramming potential of isolated ALDH<sup>-</sup>/receptor-positive cells versus ALDH<sup>-</sup> /
receptor-negative cells. The ALDH-/receptor-positive-derived cell population is more able to form spheres and overcomes the receptor-negative-derived population when the two populations are mixed and tested for their sphere forming capacity. The use of pharmacological inhibitors against the receptors induces a slight decrease of CSC. Taken together, our results indicate the involvement of chemokines and their receptor CXCL1 and BCSCs in the reprogramming mechanism. To validate the implication of CXCL1 and CCL5 and in a pre-clinical perspective, we are currently beginning an in vivo experiment to study the effects of CXCL1 and CCL5 inhibition on tumor development and on CSC enrichment in vivo.

**#2882 The miR-200b-ZEB1 circuit regulates diverse stemness of human hepatocellular carcinoma.** Sen-Yung Hsieh, Su-Chun Tsai. Chang Gung Memorial Hospital, Taoyuan, Taiwan

Background & aims: Hepatocellular carcinoma (HCC) can be derived from cancer stem cells (CSCs), which contribute to tumor initiation, metastasis, chemoresistance, and post-treatment recurrence. A great variety of HCC CSCs resulting in diverse clinical manifestations have been reported. We aimed to elucidate how CSC diversity is regulated. Methods: MicroRNAs deregulated in HCC were identified by using array-based microRNA profiling. Diversity of HCC CSCs was assayed by flow-cytometry, in vitro and in vivo assays for tumorigenicity. Results: MiR-200b downregulation occurred in early HCC and associated with shorter disease-free and overall survival. Ectopic expression of miR-200b or silencing of ZEB1 led to a decrease in CD34+ and CD24+ HCC CSCs and an increase in EpCAM+ HCC CSCs. MiR-200b directly suppressed BM11 and ZEB1 expressions. ZEB1 transcriptionally upregulated CD13 and CD24 expression and downregulated EpCAM expression via directly targeting their promoters. Neither miR-200b nor ZEB1 had obvious effects on CD13 or CD90 expression. Silencing CD13 or CD24 expression suppressed tumorigenicity of HCC cells. Ectopic expression of CD24 reversed the suppression of tumorigenicity when these HCC cells had been ectopically expressing miR-200b. Clinically, miR-200b downregulation was coupled with ZEB1 upregulation in approximately two-thirds of HCC patients. ZEB1 expression was positively correlated with CD13 and CD24 expressions, while EpCAM expression was positively correlated with miR-200b expression in HCCs. Conclusions: The miR-200b-ZEB1 circuit is a master regulator of diverse stemness of HCC, which distincts HCCs into those containing CD13+/CD24- CSCs from those containing EpCAM+ CSCs, and thus a potential target for anti-HCC therapy.

**#2883 Do Wnt3a-mediated canonical Wnt/Beta-catenin signals regulate stem cell phenotype in brain metastasis-specific TNBC.** Jennifer H. Carlson, Pradip De, Casey Williams, Nandini Dey, Brian Leyland-Jones. Avera Cancer Institute, Sioux Falls, SD

Introduction: Triple-negative (TN) and basal-like subtypes portend one of the worst prognoses in BC and have the most challenging diagnosis among patients due to the aggressive nature of the disease. BC stem cells (BCSCs) have a distinct role in breast oncogenesis and CD44+/CD24− population (66%) as compared to the control (79%). To further understand the mechanistic long-term role of BCSCs during the micro-metastatic 3D growth of colonies, we have developed a novel method to identify the % of BCSCs in the micro-metastatic 3D colonies. After 15 days of 3D colony growth, cells are recovered from matrigel and the live cell fraction is analyzed for CD24, CD44, CD44v6 and CD133 by flow cytometric analysis. We previously presented data demonstrating the CD44+/CD24− fraction is enriched in 3D colonies as compared to corresponding 2D cells. Here we’ve extended our analysis and examined 3D colonies following either stimulation or inhibition of WP. Conclusion: Our data demonstrates that inhibition of WP blocked the micro-metastatic growth of colonies. Studies are ongoing to delineate the mechanistic role of different BCSC markers particularly CD44 and CD44v6 in signaling the formation of WP-mediated micro-metastatic 3D colonies, the results of which will be presented at the meeting.

**#2884 Interferon Beta (IFN-B) re-activates canonical type I IFN signaling to differentiate breast cancer stem cells (CSCs) and suppress mesenchymal/CSC driven tumor recurrence.** Mary B. Doherty, 1 Damian J. Junk, 2 Hyeon Joo Cheon, 2 George R. Stark, 2 Mark W. Jackson, 1 WCRI, Cleveland, OH; 2 Lerner Research Institute, Cleveland Clinic, Cleveland, OH.

Tumor recurrence remains a major therapeutic obstacle to curing breast cancer. Cytokines within the breast tumor microenvironment (TME) influence recurrence following chemotherapy by altering the balance between mesenchymal CSC (MES/CSC) and epithelial non-CSC (EP/non-CSC). Here, we found that transformed breast MES/CSC express elevated levels of Un-phosphorylated Interferon Stimulated Gene Factor 3 (U-IFSGF3), which is composed of STAT1 and STAT2 lacking phosphorylation of their tyrosine residues, and IRF9. Elevated expression of the U-IFSGF3 proteins in breast cancer has previously been linked with resistance to ionizing radiation, thus we hypothesized that the U-IFSGF3 complex is important for maintaining MES/CSC properties. However, knock-down of IRF9, the critical DNA binding component of this complex, or STAT1 did not alter the MES/CSC phenotype. Moreover, IFSGF3 transcriptional targets were actually repressed in MES/CSC relative to EP/non-CSC, suggesting that elevated U-IFSGF3 may act as a repressor in MES/CSC. Interestingly, we found that an MES/CSC program independent of IFN-B, was responsible for mediating U-IFSGF3 expression. We therefore hypothesized that stimulating MES/CSC with IFN-B would phosphorylate the IFSGF3 proteins and engage canonical IFN-B mediated inhibition of MES/CSC properties. Acute exposure to IFN-B led to the phosphorylation of IFSGF3 in MES/CSC and induced the transcription of IFN-B responsive genes. Continuous exposure to IFN-B maintained Phosphorylated IFSGF3 (P-IFSGF3) which partially repressed the MES/CSC phenotype, resulting in the repression of mesenchymal markers (Vimentin and Slug), expression of EP/non-CSC markers (CD24) and functionally inhibited colony formation in soft agar and migratory capability. In line with these observations, data from triple-negative breast cancer (TNBC) patients confirmed that increased expression of IFN-B responsive genes correlates with decreased expression of a CSC gene signature, and correlates with improved recurrence-free survival. Taken together, our findings demonstrate that IFN-B mediated signaling promotes the differentiation of MES/CSC by phosphorylating U-IFSGF3, resulting in the suppression of MES/CSC-driven tumor recurrence. Future studies will examine the mechanism by which IFN-B mediated P-IFSGF3 suppresses MES/CSC properties and whether elevation of U-IFSGF3 can predict which patients would be candidates for an IFN-B therapy to phosphorylate STAT1 and STAT2, thus suppressing MES/CSC tumor recurrence.

**#2885 Activation of IL1α signaling by HER2 overexpression promotes breast cancer stem cells.** Shou Liu, 1 Ji shin Lee, 2 Hexin Chen 3. University of South Carolina, Columbia, SC; 3 Chonnam National University, Republic of Korea.

Breast cancer is a heterogeneous disease and only a small proportion of cells known as cancer stem cells (CSCs) have the ability to generate tumor. Recently, it has been reported that HER2 overexpression increase breast cancer stem cells (BCSCs). However, the underlying mechanism is not clearly known. In this study, we explored the molecular mechanism how HER2 increase BCSCs. Our data has demonstrated HER2 induces BCSCs by indirectly activating NF-kB and STAT3 signaling. To figure out the direct target of HER2, we used the microarray and found that HER2 upregulates the expressions of IL1A and IL6, two major cytokines which directly activates NFkB and STAT3, respectively. Interestingly, we found that IL1A and indirectly activates STAT3. IL1A induced STAT3 was blocked when IL6 was knock out from cells. We found that HER2 enhances IL1α transactivation by activating PU.1 which is known transcription factor of IL1A. Finally, we studied effect of IL1α on tumorogenesis, and found that IL1α KO dramatically attenuates the tumor growth in NOD/SCID mice. Taken together, we found that HER2 induces BCSCs by upregulating IL1A and IL6 expression. We for first time demonstrating that IL1α plays a critical role in HER2-induced expansion of BCSC population and may be a potential therapeutic target for HER2 positive breast cancer.
Head and neck squamous cell carcinoma (HNSCC) is highly invasive and resistant to therapies, where treatments often result in high rates of failure and disease recurrence. A subpopulation of tumor-initiating cancer stem cells (CSC) is thought to be responsible for metastatic invasion and drug resistance in many types of cancer, including HNSCC. CD44 is a known CSC marker in HNSCC but its role in maintaining CSC populations is not well understood. We previously reported that SMAD specific E3 ubiquitin protein ligase 1 (SMURF1) inhibition of bone morphogenetic protein (BMP) signaling is essential for maintaining a CD44-high CSC-like population in HNSCC. In this study, we sought to determine how CD44, a receptor for hyaluronic acid (HA) that constitutes a major component of the tumor stroma, is involved in the regulation of SMURF1 and the maintenance of a HNSCC CSC phenotype. CSC-like cells were enriched from HNSCC cell lines as CD44-high cells. CD44 signaling was stimulated by exogenous HA treatment and inhibited by CD44 knockout (KO) using an inducible CRISPR/Cas9 system. We then assessed changes in SMURF1 protein level, BMP signaling, transwell migration, Matrigel colony formation, and invasion through three-dimensional organotypic culture (OTC) following CD44 modulation. CD44-high cells were found to have increased extracellular HA production. Treatment with exogenous HA reduced BMP signaling, as determined by a reduction in phospho-SMAD1/5/8 levels, and increased transwell migration of CD44-high cells. CD44-KO reduced SMURF1 protein expression and inhibited Matrigel colony formation of an invasive and recurrent HNSCC-derived CD44-high cells but only partially reduced colony formation of a less-invasive cell line derived from a primary HNSCC. Knockout of CD44 expression showed a slight reduction in transwell migration of invasive cells. CD44-high cells also recapitulated an invasive and CSC-like growth pattern in OTC assays. In contrast, CD44-KO inhibited OTC invasion and the epithelial-to-mesenchymal transition (EMT) phenotype, resulting in increased apical epithelial growth and differentiation. CD44 reconstitution appeared to restore the invasive and EMT phenotype. Our current findings could be crucial for maintaining an anchor-age-independent and invasive phenotype of HNSCC but plays a minor role in carcinoma cell migration.

Macrophage conditioned medium promotes colon cancer stem cell phenotype via the hedgehog signaling pathway. Fan Fan, Rui Wang, Delphine R. Boulbes, Huiyuan Zhang, Stephanie S. Watowich, Rajat Bhattacharya, Ling Xia, Xiang-Cang Ye, Lee M. Ellis. UT MD Anderson Cancer Ctr., Houston, TX.

Background: Contradicting studies have shown that increased macrophages infiltration in colorectal cancer (CRC) could either result in anti-tumoral or in pro-tumoral effects. Because of these inconsistencies, we sought to determine the role of conditioned medium from macrophages, in particular classically activated macrophages, on the development of the CSC phenotype in CRC cells, which is believed to mediate tumor growth and chemoresistance. Methods: Murine (CD41+/CD11b+) and human (HPPC-1) CRC cells were treated with conditioned media (CM) from lipopolysaccharide (LPS)-activated murine macrophages. Viability studies were performed using the MTT assay, annexin V-FITC assay, and Western blot analysis. The CSC population was assessed using the sphere-forming assay and aldehyde dehydrogenase assay. Results: The results showed that 1) murine LPS-activated macrophage CM induced apoptosis in murine and human CRC cells, 2) murine and human LPS-activated macrophage CM secreted paracrine factors that promoted the CSC phenotype in murine and human CRC cells via the Sonic hedgehog (SHH)-Gli signaling pathway, which is known to drive self-renewal and 3) these effects were blocked by depletion of SHH in macrophage CM. Conclusions: Our data show that LPS-activated macrophages play an active role in promoting the CSC phenotype through activation of the SHH-Gli signaling pathway.

Glioblastoma multiforme (GBM), the most common and aggressive primary brain tumor in adults, is characterized by aggressive recurrence after conventional treatment, which include surgery followed by radiation and chemotherapy. This recurrence relies on GBM cells’ ability to promote therapeutic resistance. The recently developed Cancer Stem Cell (CSC) hypothesis argues that GBMs are driven by a rare subset of cells called Glioma Stem Cells (GSCs). A significant corollary of the CSC hypothesis is that GSCs have the ability to survive intensive radio- and chemotherapy and give rise to recurrent disease. Recent studies from our laboratory and others have shown a high degree of plasticity in GBM cells that indicated normal GBM cells acquire a stem-like state during anti-glioma therapy. Termved conversion, this molecular process increases the frequency of therapy resistant GSCs and promotes disease recurrence. The term “reprogramming” of a drug resistant phenotype of GBM cells during anti-glioma therapy would prevent the generation of therapy-resistant GSCs, thereby block GBM recurrence. Based on this concept, we have developed a plasticity-based high-throughput drug screening method for GSCs. Our initial screening has identified several novel FDA-approved compounds that act as antagonists of neurotransmitter receptors. Further investigation revealed that treatment of GSCs with atypical neuroleptics, such as chlorpromazine, a newer version chlorprothioxene, in conjunction with TMZ, which inhibited and antagonized GSCs, led to the formation of a population of cells that express both CD133, a marker of GSCs, and dopamine receptors 2 and 3 (DRD2). Additionally, in ExoCarta database V-ATPase as an important effector of GBM growth and glioma stem cells (GSCs) maintenance. Additionally, in ExoCarta database V-ATPase subunits have been described in Exo from different cancer cell types. Taken together, these data identify V-ATPase as an important driver of gliomagenesis, and a novel, actionable therapeutic target for disease intervention. However, the role of V-ATPase in reprogrammed GBM microenvironment has not been previously investigated. Methods: Using V-A TPase-High vs. V-A TPase-Low NS with EVs from V-ATPase HIGH NS increases their motility in collagen matrices. A stronger with EVs produced by NS with higher V-ATPase expression (V-ATPase HIGH) from NS are able to significantly increase cell growth in recipient cells (brain tumor margins or primary GBM (differentiated and nondifferentiated cultures) at the molecular level, profiling of Exo-derived miRNAs distinguishes differentiated cultures from NS, n = 12 or differentiated cultures (n = 8). For EVs internalization studies, Exo or LO were isolated by an Invitrogen kit and serial centrifugation, respectively, from media of patients’ derived GBM neuropheres, enriched in GSC (NS, n = 12) or differentiated cultures (n = 8). For EVs internalization studies, Exo or LO were stained using FM 1-43 FX dye and the process was followed live for 30’ and at selected time points (30’-4h-24h), using a confocal microscopy or flow cytometry (FACS). Electron microscopy, FACS (of Exo stained with CellTrace and SytoRNA in combination with CD63 coated beads), Nanosight and immunoblotting for CD63, CD9 and Clathrin) analyses were used to confirm EVs subtypes. Cultures from patients’ derived brain tumor margins or primary GBM (differentiated and nondifferentiated cultures) were used as EV-receptor cells. miRNA profiling was performed using Taqman Low density arrays and analyzed by R packages. Gene Ontology analysis was performed by DAVID. The study was approved by the Institutional Ethical Committee. Results: NS are able to produce different EVs, which are internalized by recipient cells after 4 and up to 24 hours of co-culture. Both Exo than LO from NS are able to significantly increase cell growth in recipient cells (brain tumor margins and primary GBM differentiated monolayers), and this effect is stronger with EVs produced by NS with higher V-ATPase expression (V-ATPase HIGH). Primary GBM cells after co-culture with Exo produce a higher number of NS and V-ATPase activity block by BafilomycinA1 in NS-producing EVs completely revert this effect. Finally, the co-culture of V-ATPase LOW NS with EVs from V-ATPase HIGH NS increases their motility in collagen matrices. At molecular level, profiling of Exo-derived miRNAs distinguishes differentiated cultures from NS and, among NS, V-ATPase HIGH cultures. In addition, V-ATPase HIGH NS-derived EVs from patients’ derived Exo showed an enrichment of cancer cell cycle and PI3K/Akt/mTOR pathways. Conclusions: Altogether, these data point toward the central role of different EV types in GBM communication and suggest a role of the V-ATPase proton pump in regulating EV’s contents.
MicroRNA-mediated upregulation of the WNT signaling activities in human breast cancer stem cells. Yohei Shimono,1 Taichi Isobe,2 Andrei Turtoi,3 Junko Mukohyama,1 Toru Mukohara,4 Akira Suzuki,5 Vincent Castronovo,3 Hiroonobu Mimami1,6 Kobe University, Kobe, Japan; 6University of Liege, Liege, Belgium; 7Stanford University, Stanford, CA.

The canonical WNT signaling plays a critical role in many adult stem cells, including those of the breast and intestine. The fact that the canonical WNT signaling is implicated in both stem cell self-renewal and cancer suggests that normal physiological regulator of stem cell functions might be “hijacked” in cancer. Adenomatous polyposis coli (APC) is a component of the destruction complex that destabilizes β-catenin and suppresses the activity of the canonical WNT signaling. MicroRNAs (miRNAs) are important regulators of stem cell functions. We have previously reported a set of 37 miRNAs that are upregulated or downregulated in human breast cancer stem cells (BCSCs), a CD44+/CD24−/low “stem-cell-like” population of human breast cancer cells (BTCs), which are responsible for the formation of human breast cancer stem cells (NTCs). Among them, miR-200c targets BMI1 that is a critical regulator of the stem cell maintenance, and strongly impairs the functions of human BCSCs in vivo. In this study, we compared the expression profiles of miRNAs, mRNAs and proteins between BCSCs and NTCs isolated from the patient specimens of human breast cancers and patient-derived xenografts (PDXs) established by their transplantation. Luciferase assays were performed using the pSmad in which the 3’UTR region of candidate miRNA was cloned downstream of a luciferase minigene. The effect of miRNAs on the activity of WNT signaling was evaluated using a TGF reporter plasmid. Finally, the abilities to form organoids and to form tumors in immune-deficient mice were evaluated using the human BCSCs infected with the miRNA inhibitor expressing lentivirus. We found that miR-142 was highly upregulated in BCSCs, but was hardly expressed in NTCs in the patient breast cancer specimens. We confirmed that miR-142 targeted the sequence within the 3’UTR of APC mRNA and suppressed APC protein expression. Accordingly, miR-142 activated the canonical WNT signaling pathway in an APC-suppression dependent manner. The results of miRNA and protein expression profiling of the BCSCs isolated from human breast cancer PDXs suggested that the canonical WNT signaling was activated in BCSCs. Finally, inhibition of miR-142 in the BCSCs suppressed the tumor growth in vivo. These results suggest that the miR-142, a miRNA frequently upregulated in human BCSCs, could provide at least a partial molecular mechanism for aberrant activation of the canonical WNT signaling in breast cancer in which APC mutations are much less frequent than colon cancer.

Retoenic acid directs breast cancer cell state changes through regulation of TET2-aPKC pathway. Meng-Ju Wu, Chan-Ju Chang, Purdue University, West Lafayette, IN.

The key molecular mechanism governing the cancer cell state (stem cell-like state vs. differentiation state) to control the cancer stem cell (CSC) pool remains elusive. This study provides the first evidence showing that all-trans retinoic acid (ATRA) induces the interaction and chromatin recruitment of a novel RARB-TET2 complex to epigenetically activate a specific cohort of gene targets, including MiR-200c. TET2-activated miR-200c further targets and suppresses aPKC, a cell polarity protein that plays a pivotal role in directing asymmetric division of mammalian stem cells. MiR-200c can also suppress the stem cell-like population of breast cancer cells in vivo. In short, miR-200c regulates breast cancer stem cell properties by hijacking the TET2 complex to epigenetically activate a specific cohort of gene targets, including those of the breast and intestine. The fact that the canonical WNT signaling is implicated in both stem cell self-renewal and cancer suggests that normal physiological regulation of stem cell functions might be “hijacked” in cancer. Adenomatous polyposis coli (APC) is a component of the destruction complex that destabilizes β-catenin and suppresses the activity of the canonical WNT signaling. MicroRNAs (miRNAs) are important regulators of stem cell functions. We have previously reported a set of 37 miRNAs that are upregulated or downregulated in human breast cancer stem cells (BCSCs), a CD44+/CD24−/low “stem-cell-like” population of human breast cancer cells (BTCs), which are responsible for the formation of human breast cancer stem cells (NTCs). Among them, miR-200c targets BMI1 that is a critical regulator of the stem cell maintenance, and strongly impairs the functions of human BCSCs in vivo. In this study, we compared the expression profiles of miRNAs, mRNAs and proteins between BCSCs and NTCs isolated from the patient specimens of human breast cancers and patient-derived xenografts (PDXs) established by their transplantation. Luciferase assays were performed using the pSmad in which the 3’UTR region of candidate miRNA was cloned downstream of a luciferase minigene. The effect of miRNAs on the activity of WNT signaling was evaluated using a TGF reporter plasmid. Finally, the abilities to form organoids and to form tumors in immune-deficient mice were evaluated using the human BCSCs infected with the miRNA inhibitor expressing lentivirus. We found that miR-142 was highly upregulated in BCSCs, but was hardly expressed in NTCs in the patient breast cancer specimens. We confirmed that miR-142 targeted the sequence within the 3’UTR of APC mRNA and suppressed APC protein expression. Accordingly, miR-142 activated the canonical WNT signaling pathway in an APC-suppression dependent manner. The results of miRNA and protein expression profiling of the BCSCs isolated from human breast cancer PDXs suggested that the canonical WNT signaling was activated in BCSCs. Finally, inhibition of miR-142 in the BCSCs suppressed the tumor growth in vivo. These results suggest that the miR-142, a miRNA frequently upregulated in human BCSCs, could provide at least a partial molecular mechanism for aberrant activation of the canonical WNT signaling in breast cancer in which APC mutations are much less frequent than colon cancer.

TUMOR BIOLOGY: Signaling in Cancer Stem Cells

Oncostatin M elicits cellular plasticity through cooperative STAT3-SMAD signaling. Benjamin L. Bryson, Damian J. Junk, Jacob Smigiel, Neetha Parameswaram, Mary R. Doherty, Courtney A. Bartel, Mark Jackson. Case Western Reserve University, Cleveland, OH.

Increasing evidence suggests that tumor cell plasticity promotes metastasis and tumor recurrence, resulting in cancer patient mortality. While it is clear that the tumor microenvironment (TME) contributes to tumor cell plasticity, the specific TME factors that actively generate tumor cell plasticity are largely unknown. Here, we identify TME cytokines that promote epithelial-mesenchymal plasticity, and acquisition of cancer stem-cell (CSC) properties. A screen of 27 TME cytokines identified multiple Interleukin-6 family members as inducers of mesenchymal/CSC properties, with Oncostatin M (OSM) being the most potent. Importantly, OSM-induced plasticity was mediated by STAT3, but also dependent on TGF-β signaling and downstream SMAD3. Inhibition of functional TGF-β/SMAD signaling by expressing a dominant-negative TGF-β receptor, treating with a TGF-β receptor inhibitor, or suppressing SMAD3 expression using a SMAD3-shRNA prevented the OSM-induced mesenchymal/CSC properties. OSM-activated STAT3 binds to SMAD3 and promotes SMAD3 nuclear localization and binding to the SNAIL promoter, increasing transcription of the SNAIL gene. The epithelial-mesenchymal transition induced by the STAT3/SMAD3 axis results in a highly invasive and metastatic phenotype and the emergence of CSC properties, including therapeutic resistance. Importantly, maintenance of the OSM-induced mesenchymal/CSC state requires sustained exposure to the cytokine, as removal of OSM results in a marked phenotypic reversion. A high-throughput screen for small molecule inhibitors of the OSM-induced mesenchymal/CSC phenotype has been performed and are currently being confirmed. We propose that, targeted blockade of the STAT3/SMAD3 axis in tumor cells may represent a novel therapeutic approach to prevent the plasticity associated with metastasis and tumour recurrence.

IGF2 is essential for tumor initiating cell activity in human colorectal cancer. Taronish D. Dubash,1 Christine Siegl,2 Sebastian M. Dieter,1 Joachim Weischenfeldt,1 Alexandros P. Drainas,2 Laura Schwarzmueller,1 Malgorzata Oles,3 Balca Mardin,2 Mikolaj Slabicki,2 Huber Wolfgang,2 Martin Schneider,1,3 Jan Korbel,2 Hanno Glimm,1 Claudia R. Ball1.1National Ctr. for Tumor Diseases (NCT) and German Cancer Research Center (DKFZ), Heidelberg, Germany; 2European Molecular Biology Laboratory (EMBL), Heidelberg, Germany; 3Heidelberg University Hospital, Heidelberg, Germany.

A small fraction of all cells within individual tumours from colorectal cancer (CRC) patients drives long term tumor growth and metastases in immune-compromised mice. Targeting these tumor-initiating cells (TIC) may improve the long-term outcome in advanced CRC. To identify candidate genes which drive proliferation and survival of TIC, we have performed a large scale high-throughput loss of function shRNA screen in three-dimensional TIC enriched patient spheroids. Spheroids were transduced with the barcoded Cellecta decipher library comprising 27,500 shRNAs targeting 5043 genes associated with cell signaling pathways (Module 1). Two weeks later, cells were harvested for DNA isolation, barcode amplification and high-throughput barcode sequencing. Amongst others, we found 5/6 shRNAs targeting Insulin growth factor 2 (IGF2) scoring within a 20% depletion threshold, presenting depletion levels very similar to positive control shRNAs. mRNA expression profiling and qPCR analyses demonstrated low to moderate expression of the IGF2 gene product in the majority of patient spheroid cultures analyzed (n=17). In contrast, two out of 15 patient derived spheroid cultures analyzed demonstrated very pronounced IGF2 overexpression (>250 fold). Integrative SCNA profiling, expression and TAD profiling using the CESAM algorithm, followed by 4C Seq, demonstrated a tandem duplication of the IGF2 locus in these two patients which interrupts a IGF2 adjacent TAD boundary and results in de novo contact domain formation between the IGF2 promoter and a normally hidden distant super-enhancer. A dual luciferase reporter assay revealed that the hijacked enhancer is functionally active in human CRC cells and thereby may drive unphysiological IGF2 expression following enhancer hijacking. To assess the functional relevance of IGF2 tandem duplications, spheroids were transduced with RFP expressing lentiviral vectors encoding for 3 shRNAs targeting IGF2 as well as control shRNAs targeting EIF3A or scrambled shRNA. Strikingly, IGF2 knockdown led to a marked reduction of RFP+ cells in competitive proliferation assays and markedly reduced viability assessed by ATPlight assay. Moreover, IGF2 knockdown strongly reduced tumour formation following xenotransplantation into immune deficient NSG mice. These data demonstrate that IGF2 is required for survival, proliferation and tumor-initiation of primary human TIC enriched spheroids. Notably, oncogenic miRNA-483 is encoded within intron 6 of IGF2, however, its function in IGF2 locus tandem duplications is remains elusive. Understanding the mechanisms of IGF2 dependency and the role of miRNA-483 in this context will be essential for the future development of therapeutic approaches targeting IGF2 expression in this patient subset harbouring tandem-duplications of the IGF2 locus.

Epinephrine-induced gamma-secretase/Notch signaling in pancreatic cancer stem cells. Xuemin Xu, Chen Hu, Hildegard M. Schuller. 1University of Tennessee, Knoxville, TN.

Pancreatic ductal adenocarcinoma (PDAC) is the fourth leading cause of cancer deaths with 5–year survivals below 10%. Cancer stem cells represent a small population of cells in PDAC and are thought to drive the development, progression, metastasis and drug resistance of this cancer. The Notch pathway
regulates the self-renewal of pancreatic cancer stem cells as well as angiogenesis and drug resistance. Gamma-secretase cleaves the Notch-1 receptor, resulting in release of the Notch intracellular domain (NICD) that then translocates to the nucleus and activates the transcription of target genes. Ablation Notch signaling activated by γ-secretase activity is associated with progression, angiogenesis and drug resistance of PDAC and is being explored as a target for PDAC therapy. Smoking and psychological stress are risk factors for PDAC. However, the potential modulation of γ-secretase/Notch by these risk factors has not been investigated to date. Nicotine and psychological stress both cause hyperactivity of the sympathetic nervous system and adrenal glands, resulting in increased blood and organ levels of the stress neurotransmitters norepinephrine (NOR) and epinephrine (EPI), which are the physiological agonists of beta-adrenergic receptors (β-ARs). In turn, β-ARs are coupled to the stimulatory G-protein Gs that stimulates the formation of intracellular cAMP, which activates multiple signaling pathways in a cell type-specific manner. Using spheroid formation assays and Western blotting, our data show, for the first time, that the stress neurotransmitter Epi significantly increases the self-renewal of pancreatic cancer stem cells by increasing the expression of the activated forms (c-terminal) of the γ-secretase component presenilin1 and of Notch1 (NICD). These responses were inhibited by the β-AR antagonist (beta-blocker) propranolol and by the inhibitory neurotransmitter γ-aminobutyric acid (GABA) that inhibits cAMP formation via activation of Gαi-coupled GABA receptor. These findings suggest that the γ-secretase/Notch pathway in pancreatic cancer stem cells is under control by the neurotransmitter stimulator and GABA as inhibitor. These data could open up new avenues for the prevention and therapy of PDAC. Additional experiments are currently underway to further investigate mechanistic aspects of this novel concept. Supported by RO1CA042829 with NIH.

#2895 Octamer-4/microRNA-1246 signaling axis drives Wnt/β-catenin activation in liver cancer stem cells. Stella Chai,1 Kai-Yu Ng,1 Man Tong,1 Eunice Y. Lin2, Terence K. Lee,1 Kwok Wah Chan,1 Yun Fei Yuan, Tan Tio Cheung, 1Siu Tim Cheung, 4 Xiao Qi Wang, 1 Nathalie Wong,2 Chung Mao Lo,1 Wman Man,1 Xin Yuan Guan,1 Stephanie K. Ma,1 ‘The University of Hong Kong, Pokfulam, Hong Kong, 2The Hong Kong Polytechnic University, Hong Kong, 3Sun Yat-Sen University Cancer Center, Guangzhou, China; 4The Chinese University of Hong Kong, Hong Kong.

Hepatocellular carcinoma (HCC), the main type of liver cancer in human, is one of the most prevalent and deadly malignancies in the world. Despite advances in therapy, prognosis remains dismal, largely attributed by our limited understanding on information related to the progressive development of the disease, particularly in their cancer-initiating and stem cell-like properties. Wnt/β-catenin signaling is activated in CD133 liver cancer stem cells (CSCs), a subset of cells known to be a root of tumor recurrence and therapy resistance in HCC. However, the regulatory mechanism of this pathway in CSCs remains unclear. Here, we show that human miRNA, miR-1246, promotes cancer stemness including self-renewal, drug resistance, tumorigenicity and metastasis by activation of Wnt/β-catenin pathway via suppressing the expression of AXIN2 and GSK3β, two key members of the β-catenin destruction complex. This observation was made ex-vivo and in vivo functional / cell biological studies on HCC cell lines with or without miR-1246 expression modulated by lentiviral based knockdown and overexpression strategies as well as in miR-1246 repressed HCC cells with concomitant expression of wild-type or constitutively active β-catenin. Clinically, high endogenous and circulating miR-1246 was identified in HCC clinical samples and correlated with a worse prognosis. Further functional analysis identified Oct4 to be the direct upstream regulator of miR-1246, which cooperatively drive β-catenin activation in liver CSCs. In conclusion, our findings not only uncover the non-canonical regulation of Wnt/β-catenin in liver CSCs by Oct4/miR-1246 signaling axis, but also provide a novel diagnostic marker as well as therapeutic intervention for HCC.

#2896 STAT1-dependent interferon-related DNA damage resistance signature (IRDS) as a survival mechanism in castrate resistant prostate cancer (CRPC). Supreet Agarwal, Kerry McGowen, Keith Jansson, Mike Beshari, Fatih Elloumi, Maggie Cam, Kathy Kelly. NCI, Bethesda, MD.

Using the organoid culture system and aggressive Pten/TP53-null mouse model (GEMM), we have previously shown that the prostate cancer cell population harbors two classes of self-renewing luminal progenitors which are resistant to in vivo castration and to androgen receptor (AR) inhibitors (enzalutamide) ex vivo. Understanding signaling pathways governing intrinsic survival/self-renewal ability of luminal progenitors in castrate conditions can highlight pathways that play a role in acquired drug resistance. To identify mechanisms of castration resistance in luminal progenitors, we performed RNASeq analysis of luminal progenitor organoids derived from wild-type(WT) and Pten/TP53-null mice (intact and castrated (two weeks), n=5; each). Gene enrichment analysis identified key signaling pathways altered in luminal tumor organoids (AR signaling, lipid metabolism, protein secretion, inflammation etc.) that have also been described for FACS-purified human prostate luminal (CD49+) fraction. Interestingly, we found no difference in transcriptional profiles of intact and castrated tumor organoids, suggesting intrinsic survival ability of luminal progenitors upon castration. Of note, we observed most significant enrichment of STAT1-dependent IRDS in luminal progenitor tumor organoids relative to wild type luminal organoids. IRDS comprises of a subset of STAT1-driven genes that have been previously associated with survival of cancer cells and with breast cancer therapy resistance. In organoid systems, the STAT1 dependent IRDS were revealed IRDS as a prognostic marker for progression in the TCGA primary prostate cancer cohort (p<0.05). Further, high IRDS-expressing CRPC samples (SU2C dataset) were enriched for low AR signaling (r=-0.33, p<0.05). CRPC patients in IRDS-hi cohort showed enrichment for cancer stem cell phenotype and for genes associated with drug resistance. Consistent with the bioinformatics analysis real time PCR, immunofluorescence and western blot analysis of ex-vivo organoid cultures of castration-resistant Pten/TP53-null tumor organoids showed higher protein expression of STAT1 and IRDS genes in luminal tumor organoids relative to luminal WT organoids. In vivo, castrated prostate tumors showed higher STAT1 levels than the intact tumors. Treatment with enzalutamide of luminal tumor organoids resulted in time dependent increase in IRDS expression. STAT1 KD in tumor organoids decreased number of progeny organoids in subsequent generations suggesting either a direct or indirect effect upon self-renewal. Overall, our initial findings suggest STAT1 dependent signaling as a potential mechanism of androgen-independent survival in prostate cancer.

#2897 Oncogenic Kras activation in gastric adenocarcinoma promotes cancer stem cell phenotypes including metastasis & chemotherapy resistance. Changhyun Yoon, Kevin K. Chang, Jacob Till, Sandra W. Ryem, Sam S. Yoon. 1Memorial Sloan Kettering Cancer Center, New York, NY; 2Abramson Family Cancer Research Institute, Philadelphia, PA.

INTRODUCTION: The Cancer Genome Atlas found that the receptor tyrosine kinase (RTK)-Ras signaling pathway is altered in half of gastric adenocarcinomas (GAs). We added oncogenic Kras to the Atbp-Cre;Cdh1fl/fl; Trp5+/- mouse model of GA and found accelerated tumorigenesis and metastasis. We also found Kras activity to be higher in gastric cancer stem-like cells (CSCs). Thus we hypothesized that Kras activity is critical for maintenance of gastric CSCs and promotes CSC phenotypes. METHODS: Human and murine GA cell lines were examined. The effect of Kras pathway inhibition was examined in GA sporadic cells and monolayer cells in various in vitro assays. Kras activity and Kras pathway inhibition was examined in human primary gastric tissue samples. Our analysis of human gastric cancer datasets revealed Kras activity and Kras pathway inhibition in human GA as well as xenografts. RESULTS: Kras inhibition with shRNA or MEK inhibitor PD0325901 decreased the ability of GA cells to form spheroids and deceased expression of the stem cell transcription factor, Sox2, CD44+ /+ gastric CSCs had 65.8-75.4% higher migration, 64.2-79.2% higher invasion, and 63.1-70.2% more anchorage-independent growth compared to unselected cells. These properties could all blocked by 71.1-82.7% with Kras shRNA or PD0325901. In our mouse model, PD0325901 starting at 6 weeks of life increased median survival from 76 days to 95 days. Primary tumors and metastases in these mice with and without treatment with MEK inhibition are being analyzed for level of CD44 CSCs, Kras activity, and extent of metastases. Gastric CSCs were resistant to 5-fluorouracil and cisplatin chemotheraphy, and this chemotherapy resistance could be reversed in human GA xenografts transducing cells with Kras shRNA. CONCLUSION: Kras is more active in gastric CSCs than non-CSCs and promotes malignant phenotypes including metastasis and chemotherapy resistance. Kras pathway inhibition can block these CSC phenotypes, and thus may prove useful in various combination therapies.

#2898 ST8SIA1 is up-regulated in triple negative breast cancer and its expression is positively correlated with TP53 mutations and a cancer stem cell gene signature. V. Lokesh Battula, Yuanqing Yan, Khoa Nguyen, Kim-Anh Do, Michael Andreuff. UT MD Anderson Cancer Ctr., Houston, TX.

The discovered ganglioside GD2 as a breast cancer stem cell (BCSCs) marker in triple negative breast cancer (TNBC). GD2 biosynthesis is tightly regulated by the enzyme ST8SIA1 (GD3 synthase). However, expression of ST8SIA1 and its association with different breast cancer sub-types is not known. Here we hypothesize that ST8SIA1 is up-regulated in TNBC or “basal-type” breast tumors and associated with stemness in primary breast tumors. To investigate ST8SIA1

Proceedings of the American Association for Cancer Research • Volume 58 • April 2017 739
expression in primary tumors, we analyzed RNAseq data from the cancer genome atlas (TCGA) data base, which includes data from 1105 primary and metastatic breast tumors as well as adjacent normal tissues. We found that ST8SIA1 expression varied widely among different breast tumors. Interestingly, “basal-type” tumors expressed the highest levels of ST8SIA1 compared to all other types of breast tumors including Sweezer or luminal phenotypes. ST8SIA1 expression was higher in tumors with high ER” or PR” or HER2” tumors (n = 852, p < 0.0001). Survival analysis by log-rank test indicated that patients with ST8SIA1high tumors survive shorter (median survival 2.6 years) compared to patients with ST8SIA1low tumors (median survival 4.3 years). Next, we investigated the association between ST8SIA1 expression and the most commonly mutated genes in breast cancer. We chose the top 20 most frequently mutated genes in TCGA dataset and examined their correlation with ST8SIA1 mRNA expression. We found that, among the top 20 mutations, TP53 had a very strong positive correlation with ST8SIA1 expression (p < 0.00001). In fact, the expression of ST8SIA1 was > 2-fold higher in TP53-mutated compared to wild type tumors. The other positively correlated mutation was a nuclear envelop protein called the spectrin repeat containing protein (nuclearenvelope1orSYNE1; p < 0.05). Mutations in GATA3 were the most negatively correlated (p # 0.006) with ST8SIA1 expression. Interestingly, GATA3 plays a role in epithelial cell differentiation in the mammary gland, supporting the notion that ST8SIA1 is a stem-cell-associated gene. In 4.3 years, we found a strong correlation of ST8SIA1 expression with other genes revealed that FOXA1, the protein which is co-expressed with GATA3 and serves as negative predictor of “basal-type” of breast cancer, was down regulated in ST8SIA1high tumors. In conclusion, ST8SIA1 is associated with “basal-type” of breast cancer, was downregulated in GATA3 were the most negatively correlated (p # 0.006) with ST8SIA1 expression in primary tumors. In conclusion, ST8SIA1 serves as negative predictor of “basal-type” of breast cancer.

Results: Sarcoma cell lines grown as spheroids had increased levels of ST8SIA1, compared to their counterparts in monolayer. The higher ST8SIA1 levels compared to hormonereceptors positive tumors include: (1) higher levels of ST8SIA1 expression (p # 0.0001) in sarcoma cell lines compared to the corresponding primary tumors, we analyzed RNAseq data from the cancer genome atlas (TCGA) data base, which includes data from 1105 primary and metastatic breast tumors as well as adjacent normal tissues. We found that ST8SIA1 expression varied widely among different breast tumors. Interestingly, “basal-type” tumors expressed the highest levels of ST8SIA1 compared to all other types of breast tumors including Sweezer or luminal phenotypes. ST8SIA1 expression was higher in tumors with high ER” or PR” or HER2” tumors (n = 852, p < 0.0001). Survival analysis by log-rank test indicated that patients with ST8SIA1high tumors survive shorter (median survival 2.6 years) compared to patients with ST8SIA1low tumors (median survival 4.3 years). Next, we investigated the association between ST8SIA1 expression and the most commonly mutated genes in breast cancer. We chose the top 20 most frequently mutated genes in TCGA dataset and examined their correlation with ST8SIA1 mRNA expression. We found that, among the top 20 mutations, TP53 had a very strong positive correlation with ST8SIA1 expression (p < 0.00001). In fact, the expression of ST8SIA1 was > 2-fold higher in TP53-mutated compared to wild type tumors. The other positively correlated mutation was a nuclear envelop protein called the spectrin repeat containing protein (nuclearenvelope1orSYNE1; p < 0.05). Mutations in GATA3 were the most negatively correlated (p < 0.0001) with ST8SIA1 expression. Interestingly, GATA3 plays a role in epithelial cell differentiation in the mammary gland, supporting the notion that ST8SIA1 is a stem-cell-associated gene. In 4.3 years, we found a strong correlation of ST8SIA1 expression with other genes revealed that FOXA1, the protein which is co-expressed with GATA3 and serves as negative predictor of “basal-type” of breast cancer, was down regulated in ST8SIA1high tumors. In conclusion, ST8SIA1 is associated with “basal-type” of breast cancer, was downregulated in GATA3 were the most negatively correlated (p # 0.006) with ST8SIA1 expression in primary tumors. In conclusion, ST8SIA1 serves as negative predictor of “basal-type” of breast cancer.
Tumor Biology: Signaling in Cancer Stem Cells

#2902 | Epithelial-type CD133+ stem-like lung cancer cells emerge higher drug resistance through MDRC-mediated Wnt/b-catenin signaling pathway. Chao-Ju Chen,1 Chih-Jen Yang,1 Ming-Shyang Huang,1 Yu-Peng Liu,1 Kaohsiung Medical University Hospital, Kaohsiung, Taiwan; 2Kaohsiung Medical University, Kaohsiung, Taiwan.

Backbone: The epithelial-to-mesenchymal transition (EMT) has been described to promote drug resistance and cancer stem cell (CSC) properties. Many studies demonstrated that a major proportion of circulating tumor cell (CTC) exhibits EMT and CSC characteristics. A recent finding revealed the presence of epithelial type (EpCAM+) CTC was associated with poor outcome, whereas the mesenchymal type (EpCAM-) CTC were not. We therefore hypothesized that the epithelial-type CSC may exhibit higher drug resistance ability. Methods: We isolated epithelial type (E+) and mesenchymal type (E-) CD133+ cells and CD133- cells from PC14 lung cancer cell line by fluorescence assisted cell sorting. We used western blot, QPCR, immunofluorescence, sphere formation assay and tumor xenograft assay to characterize the 4 subpopulations. The drug resistant ability was determined by cell viability assay and in vivo drug response assays. The drug resistant signature was identified by comparing the gene expression profile from four subpopulations and Gene Expression Omnibus (GEO) database. Knockdown and overexpression of MDRC in PC14 subpopulations were established by using lentivirus vectors. Immunoprecipitation and subcellular fractionation were performed for drug resistant mechanism investigation. Results: The epithelial type PC14 CD133+ cells (E+/CD133+ subpopulation) exhibited higher sphere formation ability and was more resistant to the treatment of chemotherapeutics compared to the mesenchymal type CD133+ cells (E-CD133+ subpopulation) in vitro and in vivo. Gene expression profiling showed 86 genes were bioinformatically predicted as drug resistant signature and were correlated with the disease-free survival of the patients with lung cancer. Among these genes, the mRNA level of 20 genes were significantly related to the patient’s prognosis in the GSE31210 dataset. Human I-mfa-domain-containing protein (MDRC) was highly expressed in E+/CD133+ subpopulation. Knockdown and overexpression of MDRC modulates drug resistance ability in cancer cells. MDRC increased the level of free b-catenin through binding and stabilizing the axin-GSK3-b-catenin destruction complex and increased the transcriptional activity of Wnt/b-catenin signaling. Conclusion: The epithelial-type CD133+ stem-like lung cancer cells are more resistant to the chemotherapy through MDRC-mediated Wnt/b-catenin signaling activation.

#2903 | 1-Methoxyphospho-inolin: Novel gamma secretase inhibitor targeting notch-1 signaling in breast cancer stem cells. Venkatesh Kolluru,1 Deeksha Pal,1 Becca Baby,1 Houda Alatassi,1 Arun Kumar Sharma,1 Murali Ankem,1 Chandli Damodaran1. 1University of Louisville, Louisville, KY; 2Pennsylvania State University, University Park, PA.

We recently showed that two different ALDH1+ and CD44+/CD24−/low breast cancer stem cells (BSCs) exhibited stem cell characteristics that include self-renewal, extensive proliferation, the ability to form non-adherent spherical clusters, chemotherapeutic resistance and high notch1 expression. We have identified a compound 6:3-(methylbut-2- enyl) coumouserot (Pso) and treatment with Pso resulted in growth inhibition and an EM'T phenotype in both BSCs and BC cells. Oral Pso administration at physiologically achievable doses (25 mg/kg/BW) suppressed the growth of BSCs and BC xenografts without toxicity. In the current studies, we identified several novel Pso-derived analogs that may be more potent than the parent compound. One such compound, 1-Methoxyphospho-inolin (1MP), obtained via three main functional group changes: (i) translocation of the isoprenyl moiety from the phenyl ring fused to the pyran ring (as in Pso) to the phenyl ring adjacent to the furan ring, (ii) removal of the carbonyl group from the pyran ring, and (iii) introduction of a methoxy group at the 1-position, inhibited Notch1 activity and growth of both BSCs and BC cells at nM concentration [I50 300nM], which is 100 times more potent than Pso in cell culture models. Molecular studies suggest that 1MP inhibits Notch signaling hypothesis that the epithelial-type CSC may exhibit higher drug resistance ability. Methods: We isolated epithelial type (E+) and mesenchymal type (E-) CD133+ cells and CD133- cells from PC14 lung cancer cell line by fluorescence assisted cell sorting. We used western blot, QPCR, immunofluorescence, sphere formation assay and tumor xenograft assay to characterize the 4 subpopulations. The drug resistant ability was determined by cell viability assay and in vivo drug response assays. The drug resistant signature was identified by comparing the gene expression profile from four subpopulations and Gene Expression Omnibus (GEO) database. Knockdown and overexpression of MDRC in PC14 subpopulations were established by using lentivirus vectors. Immunoprecipitation and subcellular fractionation were performed for drug resistant mechanism investigation. Results: The epithelial type PC14 CD133+ cells (E+/CD133+ subpopulation) exhibited higher sphere formation ability and was more resistant to the treatment of chemotherapeutics compared to the mesenchymal type CD133+ cells (E-CD133+ subpopulation) in vitro and in vivo. Gene expression profiling showed 86 genes were bioinformatically predicted as drug resistant signature and were correlated with the disease-free survival of the patients with lung cancer. Among these genes, the mRNA level of 20 genes were significantly related to the patient’s prognosis in the GSE31210 dataset. Human I-mfa-domain-containing protein (MDRC) was highly expressed in E+/CD133+ subpopulation. Knockdown and overexpression of MDRC modulates drug resistance ability in cancer cells. MDRC increased the level of free b-catenin through binding and stabilizing the axin-GSK3-b-catenin destruction complex and increased the transcriptional activity of Wnt/b-catenin signaling. Conclusion: The epithelial-type CD133+ stem-like lung cancer cells are more resistant to the chemotherapy through MDRC-mediated Wnt/b-catenin signaling activation.

TUMOR BIOLOGY: Tumor Evolution and Heterogeneity

#2904 | Targeting cancer stem-like cells in triple negative breast cancer cells through non-canonical notch signaling. Fokhrul Hossain,1 Claudia Sorrentino,1 Ayse Bilyeu,1 Judy Crabtree,1 Antonio Pannuti,1 Todd Golde,2 Barbara Osborne,2 Lucio Miele1. 1LSUHSC, New Orleans, LA; 2University of Florida, FL; 3UMass Amherst, MA.

Triple negative breast cancer (TNBC) is a heterogeneous group of clinically aggressive diseases. TNBC patients have high risk of recurrence and metastasis, and current treatment options remain limited. Cancer stem-like cells (CSCs) have been linked to cancer initiation, progression and chemotherapy resistance. Therefore CSC-targeted therapies are keenly sought. There is strong evidence for the involvement of Notch signaling in TNBC. Notch1 is highly expressed in basal-like (1) and especially Mesenchymal-Stem-Like (MSL) TNBCs. Expression of Notch1 and its ligand Jagged1 correlate with poor prognosis. Moreover, overexpression supports key roles of different Notch paralogs in breast CSCs. Here, we demonstrate that Notch1 promotes cell survival in MDA-MB-231 cells, representative of MSL TNBC, in part by activating NF-kB. Notch activation by Jagged1-expressing stromal cells enhances transcription of the anti-apoptotic gene cIAP-2 (BIRC3), a known NF-kB target. This event is dependent on recruitment to the cIAP-2 promoter of NF-kB subunits, IKKo and Notch1. Short term exposure of MDA-MB-231 cells (MSL, PTEN wild-type), but not MDA-MB-468 cells (BL1, PTEN-null) to recombinant Jagged1 leads to AKT phosphorylation. This is suppressed by dual mTORC1/2 inhibitors, AKT inhibitors and IKKo inhibitors but not Everolimus (mTORC1-selective inhibitor). These observations support a model where canonical and non-canonical mechanisms downstream of Notch1 trigger AKT phosphorylation and NF-kB activation in PTEN wild type TNBC cells. Rapid AKT phosphorylation downstream of Notch1 requires mTORC2, PI3K and IKKo, and contributes to NF-kB activation. This suggests a bidirectional crosstalk between the IKKo and AKT arms of this Jagged1-activated pathway. We demonstrate that recombinant Jagged1 increases the cellular metabolism of TNBC cells and knockdown of Notch1 or IKKo by siRNA decreases mitochondrial respiration and glycolysis. We have found that CSCs derived from MDA-MB-231 cells have increased Notch1, p-AKT, and oxidative metabolism. AKT inhibition or IKKo inhibition decreases both mitochondrial respiration and glycolysis of TNBC derived CSCs. Pharmacological inhibition of Notch cleavage by gamma secretase inhibitor (PF-03084014) in combination with AKT inhibitor (MK-2206) or NF-kB inhibitor (Bay11-7082) blocks CD90+ or CD44+ CD24low sorted secondary mammospheres formation. These data suggest that combination treatments affecting Notch, NF-kB and AKT pathways have potential therapeutic importance in targeting CSCs of TNBC cases with wild type PTEN and high Notch1 expression.

#2905 | Clinical and genomic resistance to second generation androgen blockade in paired biopsies of metastatic castration-resistant prostate cancer. G. Celine Han,1 Justin Hwang,1 Stephanie A. Mullane,1 Carrie Cibulskis,2 Zhenwei Zhang,1 Rana R. McKay,1 PCF-SU2C Dream Team, Scott L. Carter,1 William C. Hahn,1 Mary-Ellen Taplin,1 Eliezer M. Van Allen1.

Background: Recent “next generation” androgen deprivation therapies (ADT), such as abiraterone and enzalutamide, have improved survival in patients with castrate-resistant prostate cancer (CRPC). Despite therapy, most patients develop resistance to these agents. We investigated the genetic basis of tumor evolution and clinical resistance to next generation ADT in CRPC by using whole exome sequencing (WES) on paired pretreatment and post-resistance biopsies from CRPC patients. Methods: Matched “trios” of germline, pre-treatment and post-resistant tumor samples were obtained from 7 patients treated with abiraterone (n=4) and enzalutamide (n=3) and WES was performed. Clinical data, including PSA and radiographic measurements, was used to classify patients as intrinsically resistant or initially responsive to treatment. Quality control, mutation and indel calling, copy number variation identification were performed using analytical pipelines at the Broad Institute. Tumor purity and ploidy were inferred, and phylogenetic analysis was performed using ABSOLUTE and Phylogeny, respectively to identify resistance associated alterations in the context of clinical phenotypes. Results: We identified multiple putative mechanisms and genetic categories of resistance to next generation ADT in CRPC. One abiraterone patient acquired an AR mutation (L702H) in the post-treatment sample, previously reported to be associated with poor outcomes and to confer resistance to this therapy. Amplification of MYC was associated.
with resistance in two other abiraterone patients with pre-existing AR gain: one with initial response to therapy acquired a focal gain of MYC in the primary tumor and metastases and our data support that the metastases were formed from a single cancer clone that did not dominate the primary tumor. Genetic heterogeneity was also observed between the primary tumor and metastases and our data support that the metastases were formed from a single cancer clone that did not dominate the primary tumor. From a genetic point of view, organoids do not seem to fully reflect the tumor area of origin and less so the whole tumor, indicating that care should be taken when using organoids as models of the primary tumor.

TUMOR BIOLOGY: Tumor Evolution and Heterogeneity

#2907 Extracellular matrix remodeling triggered by lysyl oxidase inhibition promote the lung adenocarcinoma to squamous cell carcinoma transi- tion independent of LKB1 status. Shun Yao, Hongbin Ji. Institute of Biochem- istry and Cell Biology, Shanghai Institute for Biological Sc, Shanghai, China.

#2908 Single-cell genetic analysis of ductal carcinoma in situ with and with- out synchronous invasive breast cancer by multiplex FISH delineates specific patterns of tumor clonality and heterogeneity. Irriana Marie Torres,1 Leann Hernandez,1 Jausheng Tzeng,2 Russell Schwartz,2 Alejandro Schaffer,4 Edward Gertz,2 Stephen Brower,2 Miguel Sanchez,4 Gert Auer,2 Kerstin Heselmann-Haday- dad,2 Reid Thomas.1 National Cancer Institute, Rockville, MD; 2Englewood Hospital and Medical Center, Englewood, NJ; 3Carnegie Mellon University, Pittsburgh, PA; 4NCBI, Bethesda, MD; 5Karolinska Institute, Stockholm, Sweden.

We previously studied synchronous Ductal Carcinomas in Situ (DCIS) and Invasive Ductal Carcinomas (IDC) using a novel approach of multiplexing FISH probes that allows us to simultaneously assess the copy numbers of up to 20 loci within intact nuclei providing new insights into tumor clonality and heterogeneity. A high degree of chromosomal instability already in DCIS, and frequently, but not always, a direct clonal evolution from DCIS to IDC was detected. We now ask whether this degree of instability is also present in DCIS that did not progress to IDC and are therefore analyzing FFPE material from 20 patients with either low-grade and high-grade DCIS who did not present with invasive breast cancer during their follow-up (5-10 years), in addition to 10 patients who presented with synchronous IDC. The multiplex FISH assay used targets five oncogenes (COX2, MYC, CCND1, HER2, ZNF217) and three tumor suppressor genes (DBC2, CDH1, TP53) frequently altered in breast carcinomas. To date, we have analyzed two paired cases of synchronous DCIS and IDC, DCIS-IDC 3 and 4, and three cases of DCIS without IDC, OP-DCIS 1, 4 and 5. The paired cases exhibited very similar aberration pat- terns for synchronous DCIS and IDC indicating the invasive carcinoma is closely related to the DCIS lesion. Specifically, the major clones in DCIS 3 (low-grade) and IDC 3 showed a diploid tumor cell population with a gain of COX2, and losses of DBC2, MYC, TP53, and HER2. Of note, the only difference observed was a gain of ZNF217 in the DCIS which was not seen in the major clone of the invasive carci- noma. The other paired case, DCIS 4 (high-grade) and IDC 4, showed major clones of triploid tumor cell populations with gains of COX2, CCND1 and MYC and losses of DBC2, CDH1, TP53 and ZNF217. The three DCIS cases with synchronous IDC 4 showed a major clone of the DCIS harboring a triploid population and a subclonal population of almost diploid cells. The subsequent IDC exhibited varying degrees of aberration and complexity patterns in their clonal populations. Case OP-DCIS 1, a high-grade DCIS, revealed a tetraploid cell population which showed a major clone with an amplification of CCND1 and a MYC gain combined with losses of DBC2, CDH1, TP53 and HER2. A low-grade DCIS, OP-DCIS 4, exhibited a diploid cell population with a major clone showing losses of DBC2, CDH1, TP53 and ZNF217. The third case OP-DCIS 5 (low-grade DCIS) was a diploid cell population with one major clone showing losses of CDH1, MYC, DBC2, TP53, HER2 and CCND1. Our preliminary observations show a ten- dency of diploid lesions with a predominance of loss patterns for low-grade DCIS, while high-grade DCIS seem to reveal higher ploidy with more complex gain and
loss patterns. However, also low-grade DCIS with mainly low loss patterns progress to invasive cancers as seen in case DCIS-IDC3. We expect that the analysis of the remaining cases will further elucidate the dynamics of DCIS lesions which will hopefully help to assess and stratify progression risk in patients with DCIS.

**#2909 High-precision quantification of clonal evolution during comparative treatments of triple negative breast cancer.** Hyunsoo Kim,1 Pooja Kumar,1 Francesca Menghi,1 Eliza Cerveira,1 Mallory Romanovitch,1 Gurdeep Ananda,1 Joshy George,1 Henry Chen,2 Susan Mockus,1 Chengsheng Zhang,1 Yan Yang,3 James Keck,4 R. Krishna Murthy Karuturi,1 Carol Bult,1 Charles Lee,1 Edison Liu,1 Jeffrey H. Chuang,1 *The Jackson Laboratory for Genomic Medicine, Farmington, CT; 2The Jackson Laboratory Mice, Clinical, and Research Services, Sacramento, CA; 3The Jackson Laboratory for Mammalian Genetics, Bar Harbor, ME.

Population heterogeneity within tumors is essential to the development of drug resistance. However, precise quantification of cellular levels of subpopulations, and in particular how they evolve in response to treatment, has been challenging. Here we describe the high precision characterization of subclonal evolution within triple-negative breast cancer patient-derived xenografts (PDXs) generated from three patients. For each patient model, we established multiple PDXs and treated them in cohorts of 5-10 mice each for the therapies cyclophosphamide, doxorubicin, cisplatin, or docetaxel, with treatments lasting one month. In all three patient models, the average behavior across mice was a reduction in size in response to docetaxel, but growth under doxorubicin and cyclophosphamide. For cisplatin treatment, one of the three models showed tumor shrinkage while the other two models showed continued growth but at a rate lower than the doxorubicin or cyclophosphamide cohorts. To determine the evolutionary behaviors underlying these observations, we initially performed exome panel sequencing of 34 residual tumor samples from these and untreated xenografts. Computational mutation and copy number analysis indicated sample-specific differences in tumor populations both in response to treatment and due to genetic drift. However, they also revealed measurement uncertainties related to exome capture efficiency, locus-specific read counts, and computational copy number estimation that limited quantitative inference of evolutionary behaviors. To solve this problem we used droplet digital PCR (ddPCR) to measure variant allele frequencies and local copy number at selected loci from the prior residual tumors as well as additional samples from replicate cohort treatments and cultured conditionally reprogrammed progenitor cells. In total we performed 1665 ddPCR measurements across 150 cancer samples. These ddPCR measurements reduced sample-specific uncertainty in variant allele frequency to ~2% and copy number to ~0.2, allowing for precise identification of subclones and their cellularity in each sample. We observed several common modes of evolution within these tumors including selective sweeps, spatial diffusion, and stable coexistence between distinct subpopulations. In the samples from one patient model, we observed frequent symbiotic growth of two distinct subpopulations having differential cisplatin sensitivity, such that the degree of clonal selection during cisplatin treatment was proportional to the tumor volume change on a mouse-to-mouse basis. This study demonstrates how high precision genomic characterization across comparatively treated samples can reveal treatment-relevant subclonal ecology, as well as the mutations that distinguish populations with different behaviors.

**#2910 Inter metastatic genetic heterogeneity is a characteristic feature of recurrent pancreatic cancer.** Hitomi Sakamoto, Alvin Makohon-Moore, Marc Attiyeh, Liguo Zhang, Christine A. Iacobuzio-Donahue. Memorial Sloan Kettering Cancer Center, New York, NY.

Pancreatic cancer (PDAC) is a 4th leading cause of cancer death with an overall 5-year survival of 8%. Surgical resection remains the only option for cure but only 10-15% of newly diagnosed patients are eligible. While surgery clearly provides a survival benefit compared to those patients who do not undergo potentially curative resection, the vast majority of patients will recur in the pancreatic remnant, liver, lungs, and/or peritoneum. Thus, there is an unmet need to better understand the fundamental features of recurrent disease. To explore the fundamental genomic features of recurrent PDAC, patients were selected from participating Gastrointestinal Cancer Rapid Medical Donation Program (GI-CRMDP). 10 patients who underwent surgical resection; 8 patients had a whipple procedure, 2 patients had a distal pancreatectomy and each patient received a different type of chemotherapy after surgery, was evaluated. We performed 250x whole exome sequencing (WES) of 82 unique samples from these 10 patients, using frozen samples from autopsy and FFPE tissues from matching surgical specimen. In addition to the treatment naïve primary tumor, one or more samples of the local recurrence and multiple metastases were studied. The mean depth of coverage for all samples was 31×. Copy number variations were assessed by FACETs. MSK-IMPACT was performed for orthogonal validation of a subset of variants. We found that compared to the treatment naïve resected tumor, recurrent disease contained novel mutations in genes associated with MAPK and PI3K signaling. The most common mutual mutation signature was Signature 1 followed by Signature 3. All patients who received a platinum drug as a first-line treatment had a greater proportion of Signature 3 in the recurrent disease than the primary tumor. Phylogenetic studies revealed that recurrent disease is the result of three patterns: 1) dissemination of disease to distant organs before surgery was performed, 2) dissemination of disease after surgery from residual microscopic disease in the pancreatic remnant, or 3) development of a second primary tumor in the remnant pancreas. This third scenario was observed in one of two additional patients in this cohort. We conclude that recurrent pancreatic cancer is multifactorial, and at least two of these scenarios could be eliminated by total pancreatectomy, thereby increasing the rate of cure by surgical resection. Our study serves as a window to an understanding of the clonal dynamics of recurrent pancreatic cancer.

**#2911 Single cell mass cytometry analysis of human lung adenocarcinoma.** Deon B. Doxie, Jonathan M. Lehman, Yong Zou, Maria S. Ortega, Caroline E. Maier, Jonathan M. Irish, Pierre P. Massion. Vanderbilt University, Nashville, TN.

Introduction: Lung cancer is the leading cause of cancer-related mortality in the world. Lung adenocarcinoma is the most common subtype. Tumor heterogeneity among adenocarcinomas presents a challenge in the management of the disease. Understanding heterogeneity may have implications in understanding the biology of lung cancer. Single cell analysis of tumor mass cytometry offer an opportunity to profile tumor heterogeneity and to identify populations of driven by the activation of signaling pathways. Methods: Adenocarcinomas were collected at the time of surgery and dissociated into suspension and cryopreserved. Mass cytometry analysis of tumors and adenocarcinoma cell lines was performed with a 30 marker antibody panel and rhodium intercalator dye to identify dead cells. The antibody panel included markers to characterize identity, cell cycle status, and signaling events. Biaxial gating or unsupervised analysis approaches SPADE and viSNE were used to compare major populations of cells. Results: Validation of mass cytometry panels was performed with adenocarcinoma cell lines and human tumors. Adenocarcinoma cell lines PC9 (lung), A549 (lung), H520 (squamous) and SW620 (colon) exhibited phenotypically distinct cells between samples by expression of cytokeratin, CK7, and EGFR. Furthermore, PD-L1 expression was expressed on subsets within cell lines. Disaggregation of tumors was optimized with dissociation that included collagenase and DNase to release viable cells within 1 hour. Detection of viable cells was optimized with rhodium intercalator viability dye and histone H3 to identify nucleated cells. Using the 30 marker panel and viSNE analysis four populations were identified within tumors: infiltrating leukocytes, epithelial cells, fibroblast, and epithelial tumor cells. Epithelial cells were found to exhibit cellular heterogeneity between patients based on the expression of cytokeratin, CK7, TTF1, EGFR, vimentin, CD44, and MET. Preliminary signaling data identified basal kinase activity active in infiltrating leukocytes and cancer cells. Cancer cells and infiltrating immune cells had basal p-STAT5 activation, and cancer cells had high basal p-AKT implicated in dysregulated cell growth. Conclusions: Populations of infiltrating stromal cells and epithelial (cancer) cells were identified in lung adenocarcinoma. The single cell phenotyping from tumors was consistent with the profile found in two lung adenocarcinoma cell lines. Preliminary differences in basal signaling pathways responsible for growth were observed within adenocarcinoma cell populations. This work demonstrates the feasibility of mass cytometry to identify and characterize tumor heterogeneity. Work is underway to define phenotypes within the epithelial and leukocyte populations that could predict tumor behavior and immune response within the microenvironment. This work is supported by NCI CA196405 to PPM.

**#2912 Size based enrichment and sorting of Ov90 cancer cells and clusters with a new multistage filtration cartridge reveals distinct phenotypes.** Anne Meunier,1 Sara kheireddine,1 1. Alejandro Hernandez-Castro,2 Teodor Veres,3 David Juncker1. *McGill University, Montreal, Quebec, Canada; 2National Research Council of Canada, Boucherville, Quebec, Canada.*

Background: Circulating tumor cells (CTCs) are released in blood from the primary tumor, but although very heterogeneous both in size and marker expression, are very rare and provide information not available from the primary tumor. The identification of CTC cells and clusters could advance our understanding of metastasis and help personalize therapy.1-3 Notably, CTC clusters were shown to have a higher metastatic potential than single cells but the process remains poorly understood. We present a multistage filtration system with pore sizes from 20 down to 8 μm for the size-selective enrichment of Ov90

Proceedings of the American Association for Cancer Research • Volume 58 • April 2017 743
ovarian cancer cells and clusters from blood. Each captured cell population was released, cultured, and characterized independently. Methods: We developed a 3D printed multistage filtration cartridge and polymer filters with 20, 15, 12, and 8 μm-diameter pores. Filters were stacked from 20 (top) to 8 μm (bottom) and used to enrich and sort Ov-90 cells spiked in 1:6 mL of blood/PBS. Captured cells were released by removing individual filters from the cartridge, reverse flowing OSE medium, and then cultured separately. Results: Ov-90 clusters were found mostly on the top filter (20 μm) and interestingly, few small clusters (3–4 cells) were found on the 8 and 10 μm filters, suggesting alignment of cluster cells as they pass through the pores. Cell and nucleus diameters were measured, and a general correlation was found between filter pore size and cell and nucleus size. Interestingly, nuclei were found to be the smallest parameter in determining passage of single cells and small clusters through pores. Follow- ing cell culture, two distinct phenotypes were observed: cell captured on small pore filters (8–12 μm) grew primarily in a monolayer. Cells captured on filters with larger pores (15–20 μm) first grew as a monolayer, but rapidly formed cell aggregates that subsequently detached from the surface. Staining for E-Cad- herin, a cell-cell adhesion protein, revealed a loss of expression of cells from filter with larger pores. Conclusion: We developed a new multistage filtration method and selectively enriched and sorted cells based primarily on their nucleus size. We identified two Ov-90 populations with different growth behaviors with low E-cadherin expression on the cells forming clusters, which is known to correlate with metastasis. The application of multistage filters may also reveal different CTC populations based on nucleus and cell size. References: (1) Baccelli, I. et al. Nat. Biotechn. 2013, 31, 539–544. (2) Pecot, C. #2913 Emergence of RAS or EGFR mutant clones affects duration of response to EGFR blockade in colorectal cancers. Sabrina Arena,1 Beth Van Emburgh,1 Giulia Stravagia,1 Luca Lazzari,1 Giovanna Cissiulli,1 Giorgio Conti,2 Benedetta Musso,2 Federica Baldi,2 Michela Buscarino,2 Alice Bartolini,3 Emanuele Valtorta,3 Joana Vidal,3 Beatriz Belloso,3 Giovanni Germano,3 Filippo Pietranansomio,4 Agostino Ponzetti,4 Joan Albanel,4 Salvatore Siena,5 Andrea Sartore-Bianchi,6 Federica Di Nicolantonio,1 Clara Montagut,5 Alberto Bardelli.1 1University of Torino, Candiolo, Italy; 2Candiolo Cancer Institute - FPO, Candiolo, Italy; 3University of Torino, Torino, Italy; 4Niguarda Cancer Center, Milano, Italy; 5Hospital del Mar, Barcelona, Spain; 6Istituto Nazionale dei Tumori, Milano, Italy; 7San Giovanni Battista Hospital, Torino, Italy.

Cetuximab and panitumumab are monoclonal anti-EGFR antibodies (moAbs) currently used for the treatment of advanced RAS wild type colorectal cancers (CRC). Emergence of acquired resistance invariably limits the efficacy of these agents, and the dynamics of clonal evolution during anti-EGFR blockade are poorly understood. At progression, RAS mutations represent the most common genetic alterations, while EGFR extracellular domain (ECD) mutations are acquired by a smaller cohort of patients. We found that the mutation profile correlates with the clinical outcome of patients; in particular those who develop RAS mutations upon EGFR blockade achieve reduced tumor shrinkage and shorter duration of response respect to patients in which EGFR ECD mutations emerge during therapy. We investigated in preclinical models the potential role of RAS and EGFR ECD mutations during the emergence of acquired resistance, by tracking the evolution of clones in a genetically barcoded population of CRC cells chronically treated with cetuximab. We observed that therapeutic (target therapy, chemotherapy) and environmental (reduced nutrient condition) pressures differentially shape the clonal composition of CRC cell populations, leading to the emergence of clones with the highest fitness in presence of the external pressure. In conclusion, a multistep clonal evolution process characterizes the development of drug resistance and is associated with the clinical outcome of CRC patients treated with anti-EGFR antibodies.

#2914 Molecular characterization with single-cell resolution of CTCs and FFPE specimens from the same lung adenocarcinoma patients reveals the extent of intra-tumor heterogeneity. Tiziana Terranova,1 Francesco Gelsomino,2 Francesco Bacchi,3 Francesca Fontana,1 Claudio Forcato,1 Alberto Ferrari,1 Michelangelo Fiorentino,1 Valentina Del Monaco,1 Giulio Bassi,1 Chiara Mangano,1 Chiara Bolognesi,1 Paola Tononi,2 Genny Buson,2 Michele Medoro,2 Nicolò Maareni,3 Michele Tognetto,4 Andrea Ardizzoni2. 1University of Perugia, Perugia, Italy; 2Policlinico Sant’Orsola – FPO, Candiolo, Italy; 3Policlinico Sant’Orsola – FPO, Bologna, Italy; 4Policlinico Sant’Orsola – FPO, Candiolo, Italy.

Introduction: Intra-tumor heterogeneity can hide genomic and genetic features, which may be key driver of disease progression. Routinely, only one biological specimen per patient is generally analyzed, which may only partially represents the genetics of the tumor. Here we report a multi-approach analysis of circulating tumor cells (CTCs) and formalin-fixed paraffin-embedded (FFPE) tumor tissue-derived cells (TCs) obtained from the same patients, to investigate the underlying genetic heterogeneity. Methods: Peripheral blood (PB) and FFPE tumor tissue were collected from two advanced lung adenocarci- noma patients, treated with cisplatin-pemetrexed and carboplatin-pem- etrexed as a second line therapy. The first patient was previously diagnosed with an ALK-translocation and treated with an ALK-inhibitor. PB was enriched with either an EpCAM-based or EpCAM-independent method: the cell output of the latter was stained with Cytokteratin-PE, CD45-APC and DAPI. The DEPArray™ platform was used to detect and collect pure single CTCs or TCs, along with WBCs or stromal cells as controls. Whole genome amplified DNA of single CTCs and TCs was used to profile genome-wide copy-number aberrations (CNAs) using the AmpliFire™ LowPass kit; single nucleotide variants were analyzed on CTCs WGA products and on pools of TCs using AmpliFire™ CHIP custom panel and DEPArray™ Oncoseek panel respectively. Results: No clinically significant variants were detected in CTCs and FFPE samples; however the copy-number profiles of single TCs and CTCs revealed an overabundance of gains and losses, confirming the aberrant nature of tumor cells. In the first patient, all single cells showed a pattern of shared alterations, with a common amplification of the genome region comprising MYC gene (also confirmed by deep-of-coverage in targeted genomic amplicons) and clustering of single CTCs were formed from the group of TCs and CTCs, characterized by some emerging clones and low inter-cell heterogeneity. The analysis of the copy-number profiles of cells from the second patient showed an opposite situation: unsupervised clustering of low-pass profiles highlighted an independent group formed by single TCs clearly distinct from the highly heterogeneous cluster formed by CTCs. Conclusion: Intra-tumor graft analysis of pure cells derived from multiple specimens from the same patient, together with the combination of low-pass whole genome sequencing and targeted sequencing, reveals unexpected genetic similarities and diversities, and provides fundamental information to understand intratumor heterogeneity.

#2915 The timing of mutational burst events impacts the growth of tumors in the colon. Chelsea K. Steivers, Tien N. Vo, Perry J. Pickhardt, Jorgin D. Poelder, Kristina A. Matkowskyj, Dawn M. Albrecht, Quincy Rosemarie, Michael A. Newton, Richard B. Halberg. University of Wisconsin, Madison, WI.

Basic and clinical scientists believe that benign polyps in the colon progress to cancers through the slow, stepwise accumulation of mutations. Inter- estingly, only a small percentage of all tumors progress, whereas a significant number remain static in size, regress, or resolve completely. The mecha- nisms underlying these differential fates are unknown, and mechanisms of tumor evolution during this premalignant phase are still under investigation and continued debate. We previously reported that sub-clonal diversity arises early in small human adenomas and contributes to the growth of tumors in the colon. An emerging hypothesis is that colorectal tumors form as a result of a “mutational burst” via a process of punctuated equilibrium. Multiple copy number alterations and mutational events happen simultaneously in a burst-like fashion. In this study, we prospectively test this concept using a mouse model in which tumor induction is spatially and temporally controlled via a non-surgical delivery of adenosine expressing CRE recombinase and a temporally controlled mutational burst via administration of the carcinogen Azoxymethane. Tumors are induced at a similar rate regardless the timing of the burst relative to tumor induction with a mean tumor incidence of 62% at three weeks post induction. However, tumor growth may be affected by the timing of the burst. Animals that had a mutational burst event prior to tumor induction or those that had a late mutational burst event had a lower average in vivo tumor volume compared to controls and those with early burst event, but the average in vivo tumor size was comparable across all groups. Taken together, these preliminary data provide evidence that the timing of a mutational burst event contributes to tumor growth. This prospective experiment is being extended through computer modeling and statistical inference to compare in silico mutational landscapes to a cohort of colon polyps removed from patients at normal screening. The findings will provide new insights into the earliest stages of tumorigenesis.
Background: Glioblastoma (GBM) is an aggressive cancer that often recurs despite multimodal therapy. Median survival is 12–15 months. Genomic profiling studies have shown marked tumor heterogeneity with distinct mutations among treated and untreated samples. The Cancer Genome Atlas (TCGA), revealed that mutations in TP53, CDK4/23A, PTEN, EGFR and NFI are predominant in untreated tumors. Of the GBM tumors sequenced, >80% are mutated at TP53. We sequenced the matched ERBB2 and NRAS codons of GBM tumors sequenced with matched mutations in mismatch repair repair proteins, mainly MSH6. We proposed to use the Cellct-Lentiviral-based tagging library, a novel model system to assess the role of intratumor heterogeneity (ITH) in the presumptive tumor-initiating fraction of primary GBM and in the development of resistance to temozolomide (TMZ). From a pool of 30,000,000 barcodes, the system enables the genetic integration of a unique barcode sequence into each cell. Each barcode can be quantitatively tracked via next-generation sequencing, allowing for dynamic monitoring of the subclonal architecture. Methods: GSC 272 and 627 (sensitive and resistant to TMZ) were derived from core biopsies of GBM patients. Cells were transduced with a lentiviral vector containing luciferase. Cells were expanded and infected with the Cellct-Lentiviral library. Multiplicity of infection was determined. Initial transduction studies showed GSC 272 to have methylation of MGMT while GSC 627 did not. There was no difference in OS in the TMZ Resistant (GSC 627) untreated vs. treated cohort (with a median OS of 50 days in both groups (N = 23 vs 25 respectively, P = 0.563). TMZ Sensitive (GSC 272) untreated mice did not survive as long as the treated cohort (N = 24 vs. 25, Median OS 43 vs. 206 days, P = 4.61e-09). Barcoding sequencing results is currently being analyzed. Conclusions: The Cellct-Lentiviral tagging system is an innovative way to track ITH and clonal evolution in glioblastoma orthotopic models. We hope to discover novel insights into TMZ treatment response and resistance.

Quantitative mapping of epidermal growth factor receptor activation in single breast cancer cells treated with targeted therapies. Phuong Le, Kristopher Kilian, Andrew Smith. University of Illinois at Urbana Champaign, Urbana, IL.

Twenty percent of breast cancers are triple-negative, lacking estrogen receptor, progesterone receptor, and HER2. There is currently no specific FDA-approved targeted therapy for triple-negative breast cancer patients. Approximately half of triple-negative breast cancers overexpress epidermal growth factor receptor (EGFR), however phase II trials have only shown a 5% response rate with targeted inhibition. A quantitative analysis of EGFR signaling pathway dynamics of single cells at the single molecule level has the potential to shed light on the mechanism of lack of response to targeted therapy, as well as the cell-to-cell heterogeneity of response. Here, we combine single-molecule 3D imaging of EGFR using fluorescent quantum dots (QDs) with cell geometry normalization by micro-patterning to quantitatively map EGFR endocytosis in single cancer cells. Triple negative MDA-MB-231 cells conform to defined geometries (rectangular with different aspect ratios) were grown on soft polyacrylamide gels after micro-contact printing of islands of fibronecin. Two color QD conjugates of EGFR and its ligand, EGF, are used to track ligand binding and receptor internalization upon activation in the absence and presence of different NAC tumor treatments. Conclusions: We demonstrated that microcontact-printing normalizes cell geometry while maintaining EGFR localization so that EGFR signaling response can be quantitatively assessed on a single-cell basis and that QD conjugates can specifically label EGFR and EGF. Quantitative single-molecule imaging at single-cell level revealed high level of heterogeneity in the amount and spatial localization of EGF binding and EGFR endocytosis among the cell population in the presence and absence of EGFR inhibitor, gefitinib. Using this platform, we will investigate if spatial organization of EGFR clusters within individual cells contribute to single-cell heterogeneous response to EGFR inhibitors. We anticipate quantitative mapping of EGFR activity with drug treatment will help to elucidate why EGFR drug treatments fail and provide a means to develop combination therapy to address heterogeneity in triple negative breast cancer.
responses. Mass cytometry is a single cell platform capable of measuring >35 proteins on millions of tumor cells. Here, mass cytometry was used to characterize matched tumor samples obtained before, during, and after therapy in order to quantify the impact of therapy on tumor cell populations. Methods: Melanoma tumors from adults with metastases were biopsied or surgically resected from 12 patients with consent. Patients received two weeks of BRAF$$^{\text{V600E}}$$ inhibitor dabrafenib followed by two weeks of dabrafenib and MEK inhibitor trametinib. Tumors were enzymatically digested and cryo- preserved with protocols for mass cytometry (Leealatin and Doxie et al., Cytometry B 2016). Samples were stained with a 30+ antibody panel focused on melanoma identity and markers of lineage and trafficking for leukocytes, fibroblasts, and endothelial cells. Viable nucleated cells were identified by total histone H3 and rhodium dye exclusion. Expert biaxial gating and viSNE analysis were used to identify, computationally map, and track populations and their subsets over time. Tissue microarrays were also analyzed by histology to confirm findings observed by mass cytometry. Results: More than 99% of cells were characterized and fell into one of the four major populations. Melanoma phenotypes included loss of MHC class I and/or expression of one or more markers of identity including SOX10, SOX2, nestin, SN100β, and MCAM. Significant decreases in nestin, MCAM, MC1 and SN100β ($p < 0.01$, $p < 0.05$, $p < 0.05$, and $p <0.05$, respectively) were observed in cells after treatment. Decreases in nestin and SN100β populations identified by mass cytometry were observed in histology analysis of TMA from all matched tumor samples obtained before, during, and after therapy. The immune suppressive phenotype of melanoma tumor cells was present in all melanoma cells at a low abundance (average of 7.0% $\pm$ 3.9% in cell lines, $N = 7$). Conclusions: Single cell analysis and longitudinal monitoring of patient’s revealed tumor ecosystems experience rapid changes in cellular diversity during targeted therapy. Lower nestin expression distinguished treated melanoma tumor cells. The in vitro results suggest that in vivo remodeling of the tumor microenvironment results from a shift in host-tumor cellular interactions and not a direct response to inhibitors.

#2922 Targeting physical and stromal sources of tumor heterogeneity with photodynamic therapy-based combinations. Imran Rizvi,1 Utkan Demirci,2 Tayaaya Hasan,1 Massachusetts General Hospital, Boston, MA; 2Stanford University School of Medicine, Canary Center for Early Cancer Detection, Palo Alto, CA.

Tumor heterogeneity and drug resistance to conventional therapies remain major causes of treatment failure, recurrence and dismal survival rates for patients with advanced stage cancers. A range of cellular, architectural, and physical cues in the tumor microenvironment influence the intrinsic and acquired resistance mechanisms that lead to treatment failure. These include communication with heterocellular stromal partners and physical forces such as hydrodynamic stress, which are key factors in the evolution of tumor heterogeneity and variability in treatment response. Strategies that leverage photodynamic therapy (PDT), a mechanistically-distinct modality, to regionally target and prime stubborn tumor populations may be essential to overcoming key barriers to durable cancer management while minimizing toxicity from traditional agents. A multi-faceted approach is needed to evaluate and optimize PDT-based combination therapies, including the development of bioengineered 3D models that integrate cues such as physical forces and heterotypic cellular communication. Here the impact of hydrodynamic stress and stromal biology is evaluated in the context of ovarian cancer (OvCa). Metastatic OvCa spreads predominantly via flushing of ascites along preferential fluidic pathways and communicates with the local microenvironment, including the extracellular matrix. Using a microfluidic model that supports 3D tumor growth, we developed a label-free workflow to isolate CTCs from bulk-OvCa patient samples. A microfluidic model that supports 3D tumor growth was developed to investigate the role of fluidic stress on the heterogeneity of metastatic OvCa. The motivation for this study was based on clinical observations that the most stubborn tumors are often found in regions such as the peritoneal gutters, which is subjected to fluidic stress from ascites and is a common site of resistance and recurrence. Tumor nodules under flow showed increased epithelial-mesenchymal transition (EMT) compared to non-flow cultures. Molecular and morphological changes consistent with EMT included significant decrease in E-cadherin, a significant increase in vimentin, and significant decrease in fractal dimension, a metric adapted to quantify spindly-morphology. A concomitant significant post-translational upregulation of epithelial growth factor receptor (EGFR) expression and activation, and chemoresistance was seen. The impact of heterotypic communication between TECs and OvCa cells was investigated in a 3D model. Tumors grown in the presence of TECs were differentially susceptible to chemotherapy and bexoroparin, a BMP-based PDT and showed increased heterogeneity in response to treatment. This heterogeneity was overcome by PDT priming of tumors prior to chemotherapy. The potential value of using bioengineered models to guide customized PDT-based combinations will be presented.

#2923 Label-free enrichment and integrated full-length mRNA transcriptome analysis of single live circulating tumor cells from breast cancer patients. Naveen Ramalingam,1 Yi Fang Lee,2 Lukasz Szpankowski,1 Anne Leyrat,3 Brian Fowler,4 Jovina Tan,3 Chong Tracy Lu,5 Ninez Delos Angeles,2 Chad Sanada,3 Cassandra Greene,4 Kyle Hukari,4 Andrew Wu,6 Yoon-Sim Yap,7 Jay West,8 Ali Asgar Bhagat.9 Fluidigm Corporation, South San Francisco, CA; 2Clearbridge BioMedics Pte Ltd, Singapore, Singapore; 3Fluidigm Singapore Pte Ltd, Singapore, Singapore; 4National Cancer Centre, Singapore, Singapore.

Background: Label-free methods for isolating circulating tumor cells (CTCs) are attractive because they provide an opportunity to analyze a larger set of CTCs that may otherwise be missed due to variable or no expression of protein (label) markers. Understanding genetic and functional heterogeneity in CTCs allows us to gain insight into the mechanisms underscoring metastasis, drug resistance, and tumor aggressiveness. Currently, a simple workflow for isolation and molecular characterization of single CTCs by mRNA sequencing is lacking. In order to address this challenge, we developed a label-free workflow to isolate CTCs from breast cancer patients for full-length mRNA sequencing analysis by integrating the ClearCell® FX System with the Polaris® 3™ system. The ClearCell FX System enables the isolation of single adherent cells from whole blood samples from breast cancer patients as early indications of the presence of CTCs in a label-free antibody-independent manner. The low level of nonspecifically isolated white blood cells from ClearCell FX is further depleted on the Polaris® 3™ system by negative enrichment of viable CTCs. This unique integration of systems will enable researchers to perturb single CTCs in a controlled environment, monitor and measure the response due to perturbation, and link these response measurements to downstream genomic and transcriptomic analysis.

Methods and Results: CTCs from 7.5 mL of peripheral blood sample from breast cancer patients were enriched using ClearCell FX. To differentiate larger blood cells from putative CTCs, we stained the enriched cells with Alexa Fluor® 647-conjugated CD45 and CD31 to identify leukocytes and endothelial cells, respec-
tively. Calcein AM (live cell marker) and CellTracker™ Orange (universal cell marker) were added to identify live cells. Single CTCs were selected on Polaris integrated fluidic circuit (IFC). Sequencing libraries were generated using the Nextera® kit and sequenced on Illumina® MiSeq™ and NextSeq® systems. We successfully processed blood samples from single CTCs from triple negative breast cancer patient. Conclusion: We present the feasibility of integrating two microfluidics platforms to capture single CTCs for transcriptome and functional study. Our data suggests that the heterogeneity of tumor sample and characterization of metastatic processes can be elucidated from single-cell mRNA sequencing of CTCs.

Malignant tumors shed cell-free DNA into the bloodstream. Analyzing this new biological source may have important implications in a shift towards personalized medicine for diagnosing and/or monitoring malignancies. We recently showed the first clinical validation and clinical utility of circulating DNA (cfDNA) analysis in oncology by testing RAS/BRAF hotspot mutations in plasma from metastatic colorectal cancer patients (mCRC) (Nat Med. 2014 Apr; 20(4):430-5). In addition, liquid biopsies allow the tracking of clonal dynamics and detection of mutations during treatment. We evaluated under blinded conditions the ability of cfDNA to detect RAS/BRAF mutations in the plasma of 42 mCRC patients treated on a phase I/II trial of FOLFOX and dasatinib, with or without cetuximab. Prior to treatment, sequencing of archival tissue detected mutations in 25/42 patients (60%), while the cfDNA assay detected mutations in 37/42 patients (88%). Our cfDNA assay was able to detect mutations with allele frequencies as low as 0.01%. After exposure to treatment, 41/42 patients (98%) had a cfDNA detected RAS/BRAF mutation. Of 22 patients followed with serial measurements who were RAS/BRAF mutant at baseline, 11 (50%) developed a second mutation following treatment and 3 (14%) no longer had detectable levels of another mutant allele. Of RAS/BRAF wild type tumors at baseline, 4/5 (80%) developed new mutations. Patients may harbor mutations at very low frequency down to 0.01% before initiation or during treatment revealing the need of a high sensitive technique to detect mutant subclones. cfDNA quantitative measurements from this study closely mirrored changes in CEA and CT scan results, highlighting the importance of obtaining quantitative data beyond the mere presence of a mutation. Combined qualitative and quantitative cfDNA analysis allowed acquired resistance by studying the relative contribution of intra-tumor evolution of the tumor and might help physicians to adjust patient treatment. Our findings demonstrate the development of new RAS/BRAF mutations in patients regardless of whether they had pre-existing mutations in the pathway, demonstrating a convergent evolutionary pattern.

#2925 Distribution of copy number alterations defines clonal populations involved in colorectal cancer evolution. Isabel Quintanilla, Elena Asensio, Maria Pellisé, Antoni Castells, Miriam Cuatrevascas, Jordi Camps. IDIBAPS, Barcelona, Spain.

Colorectal cancer progresses in a multi-step manner with adenoma being the most well-known precursor lesion. Malignant polyp, an adenoma that contains a focus of adenocarcinoma, is a suitable model to study the colorectal tumor evolution. Although the mutations that lead adenoma to evolve into carcinoma have been previously described, the copy number changes involved in this malignant transformation have not been fully explored. To understand how these genomic alterations contribute to carcinogenensis, we used sequential fluorescence in situ hybridization using probes for the oncogenes EGFR, MYC, CDX2, and ZNF217 and the tumor suppressor genes SMAD7 and APC in order to analyze the copy number changes in 25 cases of malignant polyps and 10 cases of low grade dysplasia (LGD) adenomas based on single cell analyses. We found the levels of genomic heterogeneity increased from LGD adenomas to malignant polyps, with the adenoma component having a lower degree of chromosomal instability than the adenocarcinoma component. Despite the intercellular heterogeneity, we observed different patterns of evolution. The gain of ZNF217 was the earliest event as it was found to be in some cases of the LGD adenoma, and was also important in the neoplastic transformation of malignant polyps. Other notable genomic imbalances we observed during the malignant transformation were the gain of CDX2 and the loss of SMAD7. Interestingly, in a significant proportion of cases we observed loss of all loci of CDX2 and ZNF217 in the adenoma component, suggesting a whole genome duplication event. Lastly, in half of the malignant polyps studied the main clone in the carcinoma component was already present in the adjacent adenoma component, although in some cases at a low frequency only detected by single cell analysis. Our data suggest that copy number changes are early events in colorectal carcinogenesis that can determine the evolution from adenoma to carcinoma.

#2926 Histologically defined intratumoral sequencing uncovers evolutionary cues into conserved molecular events driving gliomagenesis. Antony Prabhu, Pravin Kesarswani, Shiva Kant, Stewart Graham, Prakash Chinnaiyan. William H. Beaumont Hospital, Royal Oak, MI.

Glioblastoma (GBM) represents an archetypal example of a heterogeneous malignancy, harboring regions of invasion, necrosis, and vascularization. To begin to understand the diverse molecular consequences of this complex tumor ecology, we analyzed RNA-seq data generated from commonly identified intratumoral structures in GBM that were isolated and enriched using laser capture micro-dissection. Structures included the infiltrative, leading edge, central tumor core, and cellular regions in areas of necrosis. From this RNA-seq database consisting of 119 structural regions from 37 individual tumors generated from 12,000 hematoxylin and eosin histologic images, we validated significant intra-tumoral heterogeneity in GBM, with cells derived from the infiltrating leading edge almost exclusively harboring the pronuclear male subtype, while cells in regions of necrosis displaying the mesenchymal subtype. In addition, we made the striking observation that when evaluating the tumors transcriptional profiles in the context of their derived structural regions, there was a relative small amount of inter-tumoral heterogeneity in GBM, with significant clustering of transcriptional profiles of specific structural regions from different tumors. To begin to understand the specific molecular events driving regional growth and their contributory role in gliomagenesis, we analyzed the transcriptional programs in the context of evolutionary progression. This level of analysis identified numerous pathways associated with neuronal receptor signaling, autophagy, and fatty acid metabolism as early events in tumorigenesis. Traditional cancer-related signaling pathways emerged as key mediators driving progression, with glioma and p53 signaling ranking highest on the list. As the tumor progressed to harbor regions of necrosis, in addition to expected changes in VEGF and tumor signaling, we uncovered global metabolic changes associated with progression, with metabolic pathways comprising 10 of the top 20 pathways unique to this region. Collectively these findings suggest that the observed intra-tumoral heterogeneity in GBM may be a conserved, predictable consequence to its complex microenvironment and therapeutic strategies rationally designed to target these unique, unequivocally present tumor cell biomes may lead to therapeutic gains in this otherwise fatal malignancy.

Introduction: Intratumor heterogeneity has been characterized among multiple cancer types. However, in lung adenocarcinoma, recent work has been limited to early stage primary tumors and intertumor heterogeneity has not been well-studied. Most importantly, an integrated tumor heterogeneity analysis at the level of somatic variants, copy number, transcript and protein expression, and the phosphoproteome is outstanding. Methods: In order to characterize both intra-tumor and inter-tumor heterogeneity of metastatic lung adenocarcinoma, we applied whole exome sequencing, RNA-seq, CNV-seq and mass spectrometry-based proteomic analyses on 33 tumor regions from metastatic sites including lung, liver and kidney, obtained by rapid/warm autopsy from 4 patients with Stage IV lung adenocarcinoma. The autopsy procedure was initiated between 2-4 hours of death. Results: We found considerable intratumor heterogeneity with organ-specific, branched evolution that was consistent across DNA, RNA and protein analyses. Intratumor heterogeneity differed depending on oncogene-status: oncogene-negative tumors (without RTK/RAS/RAF mutations or known fusion gene) had significantly higher genomic intratumor heterogeneity than oncogene positive tumors. The degree of heterogeneity at the genomic and proteomic level was patient-specific. The proteomic analysis complemented genomic variants-based clinical evolution analysis. High-confidence
driver mutations (KRAS, EGFR, TP53, CTNNB1) uniformly occurred early in the evolution of metastatic lung adenocarcinoma consistent with the concept of these mutations as likely 'founders'. In contrast, other known driver mutations occurred more often in later stages among specific organ branches. Notably, oncogene-negative tumors carried significantly more driver mutations than oncogene-positive tumors, suggesting that lung adenocarcinoma evolves through a branched, organ-specific, process with acquisition of significant driver mutations and copy number changes, particularly among oncogene-negative tumors. The branched evolution is ultimately influenced by proteomic and phosphoproteomic alterations affecting key signaling pathways that may not be always a result of genomic changes.

#2928 Pervasive associations between mutational processes and driver mutations across cancer types. Daniel P. Temko,1 Benjamin Schuster-Boeckler,2 Simone Severini,1 Ian Tomlinson,2 Trevor Graham3.

#2930 Niche microenvironments essential for tumor heterogeneity of primary cancer cells. Shiki Fujino,1 Norikatsu Miyoshi,2 Masayuki Ohue,3 Yusuke Takayashiki,3 Masayoshi Yasui,2 Hidekazu Takahashi,1 Naoyuki Haraguchi,1 Jhun-nichi Nishimura,7 Taishi Hata,7 Tsumekazu Mizushima,7 Yuichiro Doki,2 Masaki Mori,1 Osaka University, Osaka, Japan; Osaka Medical Center for Cancer and Cardiovascular Disease, Osaka, Japan.

Primary culture of cancer cells derived from each patient’s tumor can provide important information of the “individual tumor.” It is general to use cell lines in basic research filed. However, cell lines are quite different from clinical cancers. Clinical cancer tissues are composed of not only cancer cells but also tumor microenvironments such as stromal cells and tumor vessels. The primary culture method of clinical cancer with niche microenvironments has not been optimized. We have developed a simple 2D-culture method for primary colorectal cancer (CRC). We obtained 30 samples from surgically resected tumor. They were mechanically and enzymatically digested and fibrotic tissue and bacteria were excluded using customized two size filters. And we cultured the obtained cells on a matrigel-coated plate with embryonic stem (ES) cells culture medium. We named these cultured cancer cells, “isolated-tumor derived Cancer Cells (iCCs).” All iCCs grew and about 80 % of iCCs were successfully passaged. Twenty-three iCCs were transplanted into the subcutaneous layer of NOD-SCID mice, and the tumor growth and histology of iCCs were examined. The morphology was similar to each parental clinical tumor. And microarray analysis showed that RNA expression of iCCs was similar to each parental tumor. Furthermore, we examined the culture medium: our modified ES culture medium (ES-cultured iCCs) and 10% FBS medium (serum-cultured iCCs). The expression of surface markers regarding cancer stem cells such as CD44 and CD24 were different between ES-cultured iCCs and serum-cultured iCCs, and drug sensitivity of iCCs were also different. FACS analysis and immunocytochemistry revealed that iCCs contained PDGFR-positive cells. The results of multi-drug sensitivity assay were different between iCCs and cell lines especially in PDGFR inhibitor. Strong correlations were observed between the results of multi-drug sensitivity assay of iCCs and clinical outcomes of chemotherapy. We report an innovative primary culture method and the in vivo and in vitro analyses of iCCs, leading to the future application.
anti-Galectin-9 or an anti-TIM-3 antibody. The findings suggested that a significant amount of Galectin-9 could be released from LAD cells and induced T-cell apoptosis in tumor microenvironment. Conclusions: Our results suggested the relevance of the PD-1/PD-L1 and TIM-3/Galectin-9-immuno-inhibitory pathways in the tumor microenvironment of LAD, and that release of soluble Galectin-9 could negatively regulate T-cell function. For successful immune checkpoint therapy in LAD, simultaneous inhibition of TIM-3/Galectin-9 pathway may be needed.

#2933 Involvement of CXCL12-CXCR7 axis in adipocyte-induced TNBC metastasis. Hyeongi Choi,1 Rosa Misticia C. Ignacio,1 Carla R. Gibbs,1 Eun-sook Lee,1 Samuel E. Adunyah,1 Dek-Soo Son1.1 Meharry Medical College, Nashville, TN;2Florida A&M University, Tallahassee, FL. Breast cancer (BC) is the most frequent tumor in women worldwide. Although its mortality has significantly decreased owing to advanced therapies, triple negative breast cancer (TNBC) is still difficult to treat because of lack of estrogen receptor, progesterone receptor and HER-2. TNBC accounts for 12–24% of total BC and contributes to the aggressiveness and poorer outcomes. The risk of BC increases significantly in obese women. Obesity is also associated with the worse clinical prognosis of BC. The underlying mechanisms between obesity and BC, particularly TNBC, remain unclear. Therefore, we compare the molecular mechanisms by which human adipocyte conditioned media (CM) affect TNBC cells (BT549) and non-TNBC cells (MCF7A). Adipocyte CM had no effect on the proliferation of both TNBC and non-TNBC cells. However, adipocyte CM enhanced significantly migration in TNBC cells compared to non-TNBC cells. Next, we evaluated signaling pathways adipocyte CM promote migration of TNBC cells. AKT and ERK were activated in both TNBC cells and non-TNBC cells. However, phospho-STAT3 was significantly increased in TNBC cells. Also, N-cadherin, a marker for epithelial to mesenchymal transition (EMT), was increased at the late time point in TNBC cells. Furthermore, CXCR7 was specifically increased in TNBC cells after treatment with adipocyte CM using a PCR array. CXCR7 is chemoattractive to CXCL12 which is highly expressed in the lung, the bone marrow, and the liver, common sites of BC metastasis. Taken together, the results indicate that adipocyte CM may promote metastasis of TNBC cells through the CXCL12-CXCR7 axis by activating STAT3.

#2934 Neoadjuvant chemotherapy influence changes of the immune response in non-small cell lung adenocarcinomas. Edwin Roger Cuestas,1 Carmen Behrens,1 Jaime Rodriguez-Canales,2 Mei Jiang,2 Apar Patera,2 Arelene Correa,3 Stephen Swisher,1 Boris Sepesi,1 Annika Weisserfeldt,2 Neda Kalhor,2 Jie Lee,2 John Heymach,2 Cesar Moran,3 Jianjun Zhang,3 Don Gibbons,1 Ignacio Wistuba3.1 UT MD Anderson Cancer Center, Houston, TX;2UT MD Anderson Cancer Center, Houston, TX;3UT MD Anderson Cancer Center, Houston, TX. Background: The clinical efficacy observed with PD-1/PD-L1 inhibitors in non-small cell lung carcinoma (NSCLC) has prompted to characterize the immune response in lung tumors treated with chemotherapy. The aim of this study was to determine the changes of the immune microenvironment in surgically resected NSCLCs from patients who received and did not receive neo-adjuvant chemotherapy. Methods: We studied formalin-fixed and paraffin embedded (FFPE) tumor tissues from 112 stage II/III resected NSCLC, including 61 chemotherapy-treated NSCLCs demonstrated higher density of TAMs CD68 expressing by CD45RO+ and PD-1 (P = 0.016) were detected in chemotherapy-treated tumors compared with chemo-naive tumors. In contrast, lower densities of FOXP3+ regulatory T cells and CD68+ macrophages but not statistical significant were detected in chemotherapy-naive tumors when compared with neoadjuvant treated cases. Following chemotherapy ADCC exhibited significantly higher levels of CD57+ (P = 0.008) and high density of PD-1 expressing by CD45RO+ cells (P = 0.016) than chemotherapy-naive tumors. Chemotherapy-treated SCCs demonstrated higher density of TAMs CD68+, CD57+, CD45RO+ and PD-1 cells than chemotherapy-naive tumors (P < 0.05).
In chemotherapy-treated cancers, lower levels of CD4+ helper T cells was associated with worse overall survival (OS; P<0.04) in univariate analysis. In chemotherapy-treated ADC patients, lower levels of CD68-positive (P=0.010) and higher levels of FOXP3-positive cells correlated with worse OS (P<0.044). Conclusions: Neo-adjuvant chemotherapy-treated NSCLCs exhibited higher levels of PD-L1 expression and CD11b Gr-1+ myeloid cells in male patients as compared to chemotherapy-naive tumors, suggesting that chemotherapy activates specific immune response mechanisms in lung cancer. These results provide an inclination towards the design of clinical trials combining neo-adjuvant chemotherapy and immunotherapy prior to surgical resection of locally advanced NSCLC. #2935 Sex disparity in the response of the immune microenvironment to colon cancer liver metastases. Simon Milette,1 Ni Wang,2 Stéphanie Perrinno,2 Pnina Brod1.1 McGill University, Montreal, Quebec, Canada; 2Research Institute of the McGill University Health Centre, Montreal, Quebec, Canada.

Background: Metastasis remains the most life-threatening aspect of malignant disease and a major clinical challenge. Myeloid-derived suppressor cells (MDSC) and regulatory T lymphocytes (Tregs), which are frequently found in the tumor microenvironment, are known to impair immune surveillance and promote a state of immune tolerance that leads to metastatic expansion. Previously, we have shown that the incidence of colon carcinoma liver metastases was reduced in TNFR receptor 2 (TNFR2) deficient female mice, as a consequence of reduced recruitment of MDMSCs and Tregs into the liver. Intriguingly however, no reduction in liver metastasis or MDSC/Treg accumulation was observed in TNFR2 deficient male mice, suggesting that their recruitment and survival were distinctly regulated. The objective of this study was, therefore, to elucidate the mechanisms underlying the sex disparity observed in the response of the immune microenvironment to liver metastases, in particular the role of sex hormones in immune response regulation in this context. Methods Hormone-ablated female mice were generated using surgical ovariectomy (OVX). Estrogen-deprived mice, sham-operated controls and hormone reconstituted O VX mice were injected with syngeneic murine colon carcinoma MC-38 cells via the intrapleural/portable route and experimental liver metastases enumerated 2 weeks later. MDSCs and Tregs recruited into the livers of tumor-bearing mice were analyzed 7–10 days post-tumor injection using flow cytometry, as well as IHC performed on liver cryostat sections. Results: We found that the numbers of experimental liver metastases was markedly reduced in ovariectomized female mice, as compared to sham-operated controls but was restored in estradiol supplemented O VX mice. Reduced incidence of hepatic metastases in O VX mice correlated with reduced accumulations of CD11b+ Gr-1+ myeloid cells (MDSCs) and CD4+ Foxp3+ cells (Tregs) at metastatic sites. IHC also revealed an increased CD11b+CD4+Foxp3+ (i.e. CD11b+Gr-1+Foxp3+) ratio around hepatic metastases in O VX mice as compared to sham-operated controls. Estradiol reconstitution in O VX mice restored MDSC and Treg cell accumulation to the levels observed in control mice. Conclusion: Together, our data identify female sex hormones as major players in the regulation of the tumor immune microenvironment and a potential contributing factor in the patients’ response to immuno-based cancer therapy. Supported by the Canadian Institute for Health Research, MDEIE and FRSQ.

#2936 Molecular characterization of the immune subclass of hepatocellular carcinoma. Daniela Sia,1 Yung Jiao,1 Iris Martinez,2 Olga Kuchuk,1 Carlos Villacorta Martin,1 Manuel Castro de Moura,1 Juan Putra,2 Genis Camprecios,1 Swan Thung,1 Samuel Waxman,1 Vincenzo Mazzaferro,3 Manel Esteller,2 Arthur Pnina Brodt1.1 McGill University, Montreal, Quebec, Canada; 2Research Institute of the McGill University Health Centre, Montreal, Quebec, Canada; 3Montefiore Medical Center, Albert Einstein College of Medicine, New York, NY.

Background: Immune checkpoint inhibitors have emerged as a promising therapeutic approach in different solid tumors, including hepatocellular carcinoma (HCC). Nonetheless, little is known about the immune-component of HCC or potential biomarkers of response to these therapies. Aims: To perform comprehensive characterization of the HCC immunological profile and to identify biomarkers to select immunotherapy candidates. Methods: We performed gene expression array deconvolution through non-negative matrix factorization in 228 resected HCCs. Characterization of the transcriptional landscape was conducted using >1,000 signatures representing distinct immune cells by gene set enrichment and nearest template prediction analyses. Presence of immune infiltration, tertiary lymphoid structure (TLS), PD-1 and PD-L1 immunostainings was investigated using immunohistochemistry. DNA methylation profile of 450K CpG sites was analyzed to identify those with significant differences for each group. Extensive validation of the immune classifier was performed in 728 independent HCC samples. Results: Overall, an immune-related subclass of HCC was identified in ~27% of patients. The immune subclass was characterized by gene signatures identifying immune cells (i.e. T cells, TLS, cytotox, p<0.001), signatures of response to immune checkpoint therapy (p<0.001), presence of high immune infiltration (p<0.01), TLS (~5 foci, 19/51 vs 33/168, p<0.05). The methylation levels of 363 CpG sites in 192 immune response gene promoters were able to capture the Immune class (ANOVA, p<0.05, Δβ=-0.2 Tukey test). Integration with HCC molecular classifications revealed significant enrichment of the Immune subclass with IFN and S1 (p<0.001) and exclusion of the CTNNB1 and S2 (p<0.001) subclasses. The immune class contains two distinct microenvironments (0.01) and types) A) Exhausted immune response type (~35%) characterized by stromal activation, T cell exhaustion signatures, and presence of immuno-suppressive components such as TGFβ, LGALS1, M2 macrophages and pathways able to recruit myeloid-derived-suppressor cells (FDR<0.01); and B) Active immune response type (~65%) characterized by overexpression of adaptive immune response genes and IFN signaling (p<0.001). Tumors within the active immune response type showed a trend towards better survival vs rest (p=0.07).

Conclusions: Around 27% of HCC patients belong to the Immune class, characterized by activation of immune cells and signatures of response to immunotherapies. Within this subclass, two distinct types have been characterized by presenting active or exhausted immune responses, a feature that provides the rationale for precision medicine-based therapies.

#2937 Utilizing multiplex chromogenic IHC and digital image analysis to evaluate immune cell content and spatial distribution within NSCLC tumor tissue. Lorcan Sherry,1 Mark Anderson,1 Marianne Cowan,1 Lee Dawson,2 Richard Bystry,2 Sarah-Jane Green2.1 OracleBio, Biocity Scotland, United Kingdom; 2Asterand Bioscience, Royston, United Kingdom.

Chromogenic-based immunohistochemistry (IHC) is an established technique widely utilized within oncology R&D, allowing cells to be visualized within the context of their tumor microenvironment. However, when quantifying chromogenic stained sections via digital image analysis, the number of targets is usually limited due to constraints in deconvolving more than 3 chromogens present on the same tissue section image. The purpose of this study was to apply a customized algorithm, including a 5-colour deconvolution process to tripleplex chromogen IHC plus hematxoylin stained Non-Small Cell Lung Carcinoma (NSCLC) tumor tissues in order to quantify immune cell content and spatial distribution within both tumor and stroma regions of interest (ROI). A multiplex IHC assay was developed and applied to FFPE sections of NSCLC tumor tissue to stain epithelial tumor cells (Pan CK, yellow), CD8+ cells (purple) and FoxP3+ nuclei (brown), counterstained with hematoxylin (blue). Immunostained whole slide images were generated for image analysis. A customized algorithm, which included a 5-chromogen color deconvolution process, was utilized within the Indica Labs HALO platform to separate the four IHC chromogens (including counterstain) and a fifth color (black) representing carbon deposit artefacts. Nuclear objects were formed by applying weighted optical density values for the brown, purple and blue colors, which were positive for either CD8 or FoxP3 and counterstain/Fuchsin. A classifying classifier was trained to automatically segment tumor from stroma. Each positive cell type was identified, using defined size and shape parameters, and quantified within each ROI. IHC multiplex staining highlighted CD8+ cells and FoxP3+ nuclei to be present in both tumor and stroma compartments. Analysis data demonstrated the number of tumor and stroma CD8+ cells was 120 and 554 cells per mm², while the number of tumor and stroma FoxP3+ nuclei was 20 and 19 nuclei per mm². This gave a CD8+/FoxP3+ ratio of 6 within the tumor and 29 within the stroma. The average distance of CD8+ cells in the tumor or stroma to their nearest FoxP3+ nuclei was 92µm and 174µm respectively. The average distance of CD8+ cells to their nearest tumor cell was 39µm while the average distance of FoxP3+ nuclei to their nearest tumor cell was 29µm. This study demonstrated multiplex chromogenic IHC as a valuable approach for quantifying multiple cell types within the context of their tumor microenvironment. Furthermore, up to five chromogen colors can be separated utilizing a custom 5-pixel analysis algorithm, leading to a more in-depth evaluation of immune cell types present and their spatial distribution. This provides a greater potential for interpretation of therapeutic mechanistic responses within the tumor microenvironment.

#2938 Tumour-associated macrophage polarisation and re-education with oncolytic viruses. Munitta Muthana,1 Emer Murphy,1 Amy Kwan,1 Natalie Winder,1 Joe Conner2.1 Univ. of Sheffield Medical School, Sheffield, United Kingdom; 2Virtu Biologics, United Kingdom.

Proceedings of the American Association for Cancer Research • Volume 58 • April 2017
Tumor-associated macrophages (TAMs) promote key processes in tumor progression through their plasticity and capacity to become polarized by tumors to have an immunosuppressive phenotype. However, the plasticity of these cells provides an opportunity for therapeutic 'reprogramming' towards a classically activated inflammatory phenotype thus preventing tumor-associated immunosuppression in a major tumor-promoting fashion. Oncolytic viruses (OV) represent a new class of anti-cancer therapeutics that promote anti-tumor responses through selective tumour cell killing and the induction of systemic anti-tumor immunity. We propose that TAMs can be targeted using an OV, leading to altered macrophage polarization and a reduction in tumor growth and metastasis. Experimental Design: In-vitro, cytotoxicity, viral replication and cytokine expression was assessed in a panel of primary human and murine macrophages following exposure to Sepherevir, an ICP34.5-deleted oncolytic herpes-simplex virus currently in Phase 1/2a trials. In-vivo, murine TS1-PyMT cells were implanted into the mammary fat pads of female FVB mice to establish a syngeneic immunocompetent mouse model of breast cancer. Tumour growth and overall survival were assessed following administration of Sepherevir given either by intratumoural (IT) or intravenous injection (I.V.). Cell immune enumeration and protective immunity were assessed post-mortem by immunofluorescence and flow cytometry. Results: Both primary human and mouse macrophages served as a host for oncolytic viral replication. Sepherevir was also found to attenuate TAM phenotypes as evidenced by increased “M1” receptor signatures (e.g. CD40, CD80, CD86, MHCII), increased pro-inflammatory gene expression (e.g. IL-1, IL-6, IL-8, CXCL10, TNF-a) and increased nitric oxide production. I.T and I.V administration of Sepherevir led to marked tumor shrinkage as well as the recruitment of cytotoxic T cells. Moreover, TAM polarisation was evident based on a change in signature with TAMs becoming skewed to IL-12/IL-10 and a change in the INOS/arginase1 ratio. Conclusions: Our results demonstrate that Sepherevir is associated with in vivo anti-tumor effects and importantly can be used for manipulating the phenotype of the abundant macrophage population located within the tumor microenvironment.

#2939 Tumor associated myeloid cell transcriptome signatures in an inductible Kras-positive lung adenocarcinoma murine model. Clifton L. Dalgard,¹ Mouna Lagraoui,¹ Mouna Lagraoui,¹ Gauthaman Sukumar,¹ Celeste Huaman,¹ Corey A. Carter,³ Brian C. Schafer,¹ ¹Uniformed Services University, Bethesda, MD; 2John Muntha Cancer Center, Bethesda, MD.

Tumorigenesis is modified by dynamic activities in the tumor microenvironment and mechanisms driving these alterations during tumor progression may be tumor- and patient-specific. Of well-established functions for tumor-associated stromal cells (e.g. angiogenesis, chemotaxis) immune system regulation by the tumor microenvironment is less well understood in their mechanism and effects. However, diminished activity of antigen-specific T cell lymphocytes tumor cytoxicity is tumor promoting and recent cancer immunotherapy have targeted immune inhibitory checkpoints (e.g. anti-PD-L1) to restore T cell activity. Recent studies suggest that tumor-associated myeloid cells play a role in immunosuppression in several human cancers, including lung cancer. We hypothesize that early tumors of the lung promote changes in the phenotype of tumor-proximal myeloid cells, establishing an immunosuppressive microenvironment. As a component to observe this immunosuppressive role for myeloid cells, we performed specific transcriptome profiling of myeloid cells by immunomagnetic selection of CD11b-positive cells from lung tumors of a murine inducible Kras-positive, p53-negative cancer model. RNA sequencing of isolated myeloid cells as a function of tumorigenesis duration (3-18 weeks) establishes the kinetics of gene expression changes associated with tumor-supporting and immune-suppressing functions. Genome-wide expression analysis of myeloid cells between tumor-inducing adenovirus-Cre injected and normal control subjects resulted in identifying 1,883 genes with differential expression. Gene set enrichment analysis resulted in the stratification of samples by well-established gene signatures and tumor-predicting activity for angiogenesis (32 genes), lung tissue remodeling (47 genes) and cell survival (11 genes). Interestingly, a significant downregulated gene signature was observed in tumor-associated myeloid cells for immune cell chemotaxis (12 genes) and positive regulation of immune system activation (12 genes). These non-canonical gene signatures may identify a myeloid phenotype for immunosuppressive function. Moreover, the observed gene expression changes suggest a potential anti-tumor immunity.

#2940 TTP17: mediators of metastatic growth acceleration after surgery. Vikas Sud, Sameh Tohme, Dirk J. van der Windt, Hai Huang, Allan Tsung. Univ. of Pittsburgh, Pittsburgh, PA.

Surgery is known to accelerate the growth and progression of metastases in patients undergoing oncological resections with 50-60% patients having recurrent masses after resection making a major treatment failure. This impedes the efficacy of adjuvant chemotherapy and overall prognosis of the patient. Studies have proved that inflammatory cascade initiated by surgery that increases metastatic growth and progression is mediated through a specific mechanism of neutrophil cell death caused Neutrophil Extracellular Traps (NETs). We investigated the mechanism of how NET formation after surgical stress increases metastasis by influencing a pro-tumor microenvironment in order to specifically identify targets for perioperative therapy to keep metastases dormant and improve the effect of chemotherapy and overall prognosis. 12 week old male C57BL/6J mice (WT) and mice in which NET formation was inhibited, ie, WT mice injected with DNAase and global homozgyous knock-out of peptidyl arginine deaminase 4 (PAD4), an essential protein for NET formation, underwent splenic injection of 1x10⁶ cells of the murine colorectal cancer cell line, MC-38, followed with either 70% hepatic ischemia-reperfusion (I/R) for 60 minutes after 7 days or no I/R. Livers were harvested at multiple time points and assessed for changes in both innate and adaptive immune cell populations by flow cytometry. On gross examination, the livers of the NET deficient mice had fewer tumors as compared to the WT mice. Mice, which underwent NET formation, showed increased metastatic growth by influencing a pro-tumor microenvironment.

#2941 Inhibition of hypoxia-induced ectonucleotide triphosphate diphosphohydrolase 2 (ENTPD2) restrains myeloid-derived suppressor cell (MDSC) accumulation and sensitizes tumors to immune checkpoint inhibition. David Kang-Chun Chiu, Aki Pui-Wah Tse, Iris Ming-Jing Xu, Robin Kit-Ho Lai, Hui-yu Koh, Felice Ho-Ching Tsang, Larry Lai Wei, Chun-Ming Wong, Irene Oi-Lin Ng, Carmen Chak-Lui Wong. Univ. of Hong Kong, Hong Kong, Hong Kong.

Background and Objective: Rapidly expanding knowledge on cancer immunology has introduced promising anti-cancer therapeutic approaches which involve the activation of T cells to combat cancer cells. However, studies have indicated that the efficacy of immunotherapies is critically determined by the stromal cell components in tumors. Myeloid-derived suppressor cells (MDSCs), are regarded as one of the major immune cell types that possess immunosuppressive activities against T cells which allows cancers to escape immune surveillance and become non-responsive to immune checkpoints blockade. To increase the efficacy of immunotherapy, novel strategies to target MDSC in tumors are warranted. Hypoxia, oxygen (O2) shortage, frequently occurs in tumors due to abnormal vasculature. Using hepatocellular carcinoma (HCC) as a model, we have previously observed MDSC preferentially accumulates in hypoxic regions of human HCC tissues. Here, we aim to identify hypoxia-induced therapeutic targets that are critical for MDSC accumulation in tumors. Experimental Procedures: Transcriptomic analysis in multiple human HCC cell lines exposed to hypoxia and normoxia and HCC clinical specimens was performed to identify potential hypoxia-induced genes relevant to HCC development. MDSCs were isolated from HCC-bearing mice by magnetic bead sorting for different functional assays. LC-MS was performed to evaluate the level of extracellular metabolites. Flow cytometry was used to detect the frequencies of tumor-infiltrating MDSCs in orthotopic and subcutaneous HCC mouse models. Results: We showed that hypoxia, through stabilization of hypoxia-inducible factor-1 (HIF-1), induced ectonucleotide, ectonucleoside triphosphate diphosphohydrolase 2 (ENTPD2/CD39L1), in cancer cells, causing it so over-expression in HCC clinical specimens. Over-expression of ENTPD2 was found as a poor prognostic indicator for HCC patients. Mechanistically, we demonstrated that ENTPD2 could reduce expression of inflammatory cytokines and downregulate expression of mono-cytic MDSCs to dendritic cells, therefore promoting the maintenance of MDSCs in vitro and in vivo. Therapeutically, we found that ENTPD2 inhibitor POM-1, restrained MDSC accumulation and tumor growth, substantially enhancing the efficiency and efficacy of immune checkpoints inhibitors. Conclusion: Our
study reveals a novel mechanism whereby hypoxia/HIF-1 in cancer cells governs tumor-infiltrating MDSCs. Our data suggest that NETPD2 may be a good prognostic marker and therapeutic target for cancer patients especially those receiving immune therapy.

Colorectal cancer accounts for ten percent of new cancer cases and is the fourth most frequent cause of cancer-related deaths worldwide. In recent years, mainly due to screening programs, more patients are diagnosed in early stages of tumor progression, leading to a higher survival rate. However, the incidence of young (<50) patients diagnosed with colorectal cancer has been on the rise. These patients often have a poor prognosis due to the fact that tumors are diagnosed at advanced stages of tumor progression. To our knowledge, no study has yet characterized immunophenotypes and immune evasive mechanisms specifically in young-onset colorectal cancers. To that end we have investigated the expression of HLA class I and PD-L1 in over 200 colorectal cancers derived from young-onset (<50 years-old) patients. Furthermore, we applied a novel multispectral immunofluorescence technology to perform multiparameter immunophenotyping with CD3, CD8, PD-1, PD-L1, CD163, and Ki-67 in the same cohort. The expression of the HLA class I phenotype is maintained in the large majority of tumors allowing thus the development of neo-antigen targeted therapies. Interestingly, reduced expression of HLA class I but not total loss was associated with liver metastases, which suggests a specific selective pressure at this organ that might warrant tailored immune therapeutic interventions. As previous studies on colorectal cancer demonstrated, PD-L1 expression is limited and often restricted to immune cell compartments. The presence of immune cell infiltrates was related to the mutation background of tumors but also to their HLA class I phenotype: tumors with altered HLA class I expression were more likely to present traces of lymphocyte-mediated anti-tumor immunity. Retained HLA class I expression in the majority of colorectal cancers associated with low infiltration by effector immune cells suggests the therapeutic induction of anti-tumor immune responses in young-onset colorectal cancers, for instance, by means of neo-antigen-targeted therapies. We are currently assessing the frequency of natural recognition of neo-antigens in an autologous setting in young-onset, late-stage colorectal cancers. This work was supported by the Fight Colorectal Cancer-Michael’s Mission-AAJR Fellowship in Young-Onset, Late-Stage Colorectal Cancer Research awarded to N.F.C.C. de Miranda (15-40-1645-DEMI).

The MYC oncogene drives the pathogenesis of many hematopoietic malignancies, including Burkitt’s lymphoma (BL) and Acute Lymphoblastic Leukemia (ALL). These malignancies are often “oncogene-addicted” to MYC. Using mass cytometry (CyTOF), we demonstrate that MYC-addicted T-ALL excludes specific immune subsets from the tumor microenvironment implicated in immune surveillance, including natural killer (NK) cells. MYC inhibition clears malignant lymphocytes from the spleen and restores the normal splenic NK composition. Concordantly, peripheral blood of T-ALL patients have reduced percentages of activated NK cells as compared to healthy individuals. We show that MYC-excludes activated NK cells from sites of lymphomagenesis by suppressing ERK1/2/STAT1/2-Type I IFN signaling, in both murine and human lymphomas. Furthermore, MYC-associated BL patients with higher than median expression of STAT1/2, and cytotoxic NK cell genes, PRF1 and Granzymes, have favorable clinical outcomes. Hence, oncogenic MYC appears to causally and reversibly suppress NK-mediated immune surveillance during lymphomagenesis.

#2944 miR-130a and -145 reprogram myeloid suppressor cells and enhance anti-tumor immunity. Hiroki Ishii,1 Suman K. Vodnal,1 Bhaglu R. Acharya,2 Christine M. Hollander,1 Ashish Lal,1 Li Yang1.1National Cancer Institute, Rockville, MD; 2Georgia Regents University, Augusta, GA.

Myeloid derived suppressor cells (MDSCs) are increased in tumor bearing condition, and elicit immunosuppression via type 2 polarization. We have previously reported that TGF-β signaling in MDSCs is essential for tumor metastasis. TGFβR2, a receptor essential for TGF-β signaling, is elevated in MDSCs. Deletion of Tgfbr2 in MDSCs, the gene encoding TGFβR2, significantly decreased tumor metastasis. However, it is unclear how TGFβR2 is regulated in MDSCs. We identify microRNA-130a and -145, which directly target Tgfbr2 in MDSCs and inhibit the expression of TGF-β receptor II (TGFβR2). Reduced miRs levels from low in MDSCs from advanced tumor bearing mice correlated to increased Tgfbr2 level. Overexpression of miR-130a or -145 in MDSCs shift their immunological phenotype from type 2 to type 1 polarization. Moreover, tumor metastasis was significantly suppressed in myeloid specific miR-130 transgenic mice. In pre-clinical mouse models, the number of lung metastasis was significantly decreased when mice were treated with combination therapy of miR-130a or -145 with paclitaxel when compared with miR-130a, -145, or paclitaxel alone. We proposed that reprogramming of MDSCs by miR-130a and -145 could be a novel strategy in therapeutic treatment for breast cancer metastasis.

#2945 Impact of intratumoral mature dendritic cells on prognosis of the patients with esophageal squamous cell carcinoma. Junya Nishimura, Hiroaki Tanaka, Yuichiro Miki, Tatsuro Tamura, Tatsunori Fukuoaka, Go Ohira, Masatsune Shibutani, Sadaaki Yamazoe, Kenjiro Kimura, Takahiro Toyokawa, Hisashi Nagahara, Ryosuke Amano, Kazuya Muguruma, Kiyoshi Maeda, Kosei Hirakawa, Masashiki Ohira. Osaka City University Graduate School of Medicine, Osaka, Japan.

[Background] Promising efficacy of the immunotherapy with anti-PD-1 antibody for esophageal squamous cell carcinoma (ESCC) is expected. Tumor-infiltrating lymphocytes (TILs) have been found to be associated with favorable outcome of patients in many cancers including ESCC. However, the contributing factor of TILs in the primary tumor remains unclear. Dendritic cells (DCs) are the most potent antigen-presenting cells to induce cytotoxic T lymphocytes. [Purpose] The aim of this study was to examine the correlation of mature dendritic cells with CD8+ cells in the tumor in order to clarify the impact of DCs on locally infiltrated lymphocytes in ESCC. [Object and Methods] Formalin-fixed, paraffin-embedded blocks of primary lesions were collected from 80 patients with ESCC who underwent surgical treatment at Osaka City University Hospital. Immunohistochemical analysis using anti-LAMP-3 antibody and CD8 antibody was used to evaluate intratumoral DCs and TILs. The number of LAMP-3+ DCs and TILs were counted at 400 magnification. We divided the 80 cases into two groups according to the median number of intratumoral DCs and TILs to examine the clinicopathological features. [Results] LAMP-3+ DCs were predominantly observed in peritumoral area and sparsely found in intratumoral area, whereas CD8+ T cells distributed between both peritumoral and intratumoral areas. The number of DCs was significantly associated with increasing TNM stage. For example, the median number of DCs was 59.9 in pathological T1, 34.2 in T2/3, 62.4 in pN1, 34.1 in pN1/2/3. In addition, many patients with high infiltration of DCs had positive lymphatic invasion (L). The number of intratumoral DCs was significantly correlated with the number of TILs which were observed in intratumoral regions. Patients in the high infiltration of DCs group showed a significant better prognosis than patients in the low infiltration group. Double staining showed that LAMP+ DC-CD8+ T cell clusters were seen in peritumoral area.

Introduction: The immune system plays an important role in tumor progression and treatment response, for example with the new immune modulating therapies. In lung cancer the effect of the individual immune cell types is unclear. In our study, we used publicly available expression data to find evidence whether there are differences in the composition of immune cell fractions within the microenvironment between squamous cell carcinoma and adenocarcinoma of the lung. Methods: We searched the Gene Expression Omnibus (GEO) for human NSCLC samples. Analysis was confused to samples hybridized to the Affymetrix HG-U133 Plus 2.0 (GEO accession number GPL570) platforms. Expression profiles were downloaded and curated for duplicates and corrupt files. Different immune cell fractions were estimated using CIBERSORT and the LM22 leukocyte signature matrix. We combined this information with available clinical data. We used Cox regression analyses to evaluate the prognostic impact of the different immune fractions and Mann-Whitney U tests to test significant differences. Results: Comparing the immune cell composition of adenocarcinoma (n=587) and squamous cell carcinoma (n=254), we observed in adenocarcinoma in-
creased percentages of naïve and memory B-cells, resting and active CD4+ T-cells, regulatory T-cells, active NK cells, monocytes, M2 macrophages, resting dendritic cells and resting mast cells, and decreased percentages of plasma cells, CD8+ T-cells, follicular helper cells, resting NK cells, gamma delta T-cells, M0 and M1 macrophages and active mast cells. In adenocarcinoma, a higher percentage of memory B-cells in the immune infiltrate was associated with increased survival (HR 0.97, 95% CI 0.95–0.99, p = 0.02), while higher percentages of neutrophils (HR of 1.07, 95% CI 1.01–1.13, p = 0.02), M0 macrophages (1.02, 95% CI 1.01–1.04, p = 0.01) and follicular helper cells (1.07, 95% CI 1.02–1.13, p = 0.01) were associated with a worse survival. In both histologies, the resting mast cell immune fraction showed a positive association with survival (adenocarcinoma HR 0.96, 95% CI 0.83–0.99, squamous cell carcinoma HR 0.93, 95% CI 0.89–0.98, p = 0.01 in both histologies). In squamous cell carcinoma, a borderline association with a worse prognosis was observed with the naïve CD4+ T-cell fraction (HR of 1.1, 95% CI 1.00–1.22, p = 0.02), while higher percentages of neutrophils (HR of 1.07, 95% CI 1.01–1.13, p = 0.01) and follicular helper cells (1.07, 95% CI 1.02–1.13, p = 0.01) were associated with a worse survival. In both histologies, the resting mast cell immune fraction showed a positive association with survival (adenocarcinoma HR 0.96, 95% CI 0.83–0.99, squamous cell carcinoma HR 0.93, 95% CI 0.89–0.98, p = 0.01 in both histologies). In squamous cell carcinoma, a borderline association with a worse prognosis was observed with the naïve CD4+ T-cell fraction (HR of 1.1, 95% CI 1.00–1.22, p = 0.053) and the regulatory T-cell fraction (HR of 1.11, 95% CI 0.99–1.24, p = 0.067). Conclusion: In NSCLC significant differences in immune cell composition were observed between adenocarcinoma and squamous cell carcinoma.

#2947 Intratumoral injection of the toll-like receptor 4 agonist G100 induces a T-cell response in the soft tissue sarcoma microenvironment. Yong-woo D. Seo,1 Edward Y. Kim,1 Ernest U. Conrad,2 Ryan B. O’Malley,1 Sara Cooper,1 Bailey Donohue,1 Lee D. Cranmer,1 Hailing Lu,1 Frank Hsu,1 Elizabeth T. Loggers,4 Taylor Hain,1 Darin J. Davidson,1 Lynn Bonham,1 Yena G. Pillarsetty,1 Gabrielle M. Kane,1 Stanley R. Riddell,1 Robin L. Jones,1 Seth M. Pollock,1 University of Washington, Seattle, WA; 2Seattle Childrens Hospital, Seattle, WA; 3Fred Hutchinson Cancer Research Center, Seattle, WA; 4Seattle Cancer Care Alliance, Seattle, WA; 5Immune Design, Seattle, WA.

Introduction: Soft tissue sarcomas (STS) are heterogeneous mesenchymal tumors which are both morbid and lethal. G100 is a stable oil-in-water emulsion of glucopyranosyl lipid adjuvant, a highly potent toll-like receptor 4 (TLR4) agonist, which has been utilized for intratumoral (IT) injections and as vaccine adjuvants without significant toxicity. We hypothesized that IT G100 would induce a robust local and potentially systemic anti-tumor immune response in the STS microenvironment, leading to improved outcomes. Methods: 15 metastatic STS patients who had a superficial injectable lesion were treated with weekly IT G100 for 8–12 weeks; 12 patients received concurrent radiation for 2 weeks at the start, while 3 got IT G100 alone for 6 weeks prior to radiation. Biopsies and blood were collected pre and post treatment, and flow cytometry was performed on fresh tumor samples. T-cell receptor (TCR) deep sequencing of tumor-infiltrating lymphocytes (TIL) and peripheral blood mononuclear cells (PBMC) was performed on 7 patients. RECIST v1.1 and the Common Terminology Criteria for Adverse Events were used to monitor clinical outcomes. Results: Patients had a median of 3 (0–5) prior lines of therapy and mean tumor size of 5.6cm (1–20cm). No grade 3 or higher treatment-related toxicity was observed, and local tumor control was achieved in 93% (14/15). 6 (40%) had stable disease after treatment, and 1 (P06) had complete regression of injected tumor. This tumor had a high percentage of infiltrating pre-treatment immune cells (12% CD45+ on flow cytometry versus 2.7% for all other tumors). TCR sequencing showed that the increase in clonality of PBMC after treatment was greater in P06 (389%) compared to 6 other patients (mean 34%). There was also higher overlap in TCR sequence between TIL versus PBMC after treatment (13% versus 22%), suggesting systemic expansion of tumorspecific T-cells. In 7 patients evaluable for tumor-associated macrophages (tumors with >1000 CD45+CD11b+ cells), 71% had a shift from an M2 to M1 phenotype. In all patients who received G100 alone, there was an increase in T-cell infiltration into tumor after treatment. In one patient (P14), the proportion of CD8+ T-cells in tumor infiltrate increased from <1% to 12% to 26% after treatment. TGF-beta secretion by GSCs was inhibited with the small molecule inhibitor, galunisertib, and expression of glucocorticoid receptor in GSCs was also decreased with treatment. These data suggest the potential of G100 to enhance the adaptive anti-tumor response. Combination of G100 with other immunomodulators may further enhance the adaptive anti-tumor response.

#2948 A distinct CD8+ tumor infiltrating lymphocyte subset is associated with high TIL density, enhanced cytotoxicity and improved survival in patients with lung cancer. Anusha Preethi Ganasesan,1 Oliver Wood,3 Eva Garrido-Martin,2 Serena Chee,1 Toby Mellows,1 James Clarke,1 Daniela Samaniego-Casttrua,1 Divya Singh,1 Gregory Seuimos,3 Aiman Altezani,1 Edwin Woo,1 Peter Sont,2 Tim Cooper,3 Elena Rode,2 Ryan B. O’Malley,1 Sara Cooper,1 Bailey Donohue,1 Lee D. Cranmer,1 Hailing Lu,1 Frank Hsu,1 Elizabeth T. Loggers,4 Taylor Hain,1 Darin J. Davidson,1 Lynn Bonham,1 Yena G. Pillarsetty,1 Gabrielle M. Kane,1 Stanley R. Riddell,1 Robin L. Jones,1 Seth M. Pollock,1 University of Washington, Seattle, WA; 2Seattle Childrens Hospital, Seattle, WA; 3Fred Hutchinson Cancer Research Center, Seattle, WA; 4Seattle Cancer Care Alliance, Seattle, WA; 5Immune Design, Seattle, WA.

Infiltrating tumor-infiltrating lymphocyte (TIL) density predicts for good prognosis in several cancers and therapies that boost the anti-tumor responses of cytotoxic lymphocytes (CTLs) have shown promise in the clinic. However, clinical responses to currently available immunotherapeutic agents vary considerably, the molecular basis of which is unclear. We performed global transcriptional profiling of CTLs in tumors and adjacent non-tumor tissue from 36 patients with early stage lung cancer to define the molecular features associated with robustness and heterogeneity of anti-tumor immune responses. We observed major differences in the transcriptional program of tumor-infiltrating CTLs (CD8+ TILs) that is shared across tumor subtypes. Pathway analysis revealed enrichment of genes in cell cycle, TCR activation and co-stimulation pathways, indicating tumor-driven expansion of presumed tumor antigen-specific CTLs. We also observed marked heterogeneity in the expression associated with TCR activation and immune checkpoints, and their expression was positively correlated with the density of tumor-infiltrating CTLs. Interestingly, TIL-high tumors were also enriched for a distinct CD8+ tumor infiltrating lymphocyte subset that appeared to have enhanced cytotoxicity and independently predicted improved survival in patients with lung cancer. In summary, we define a molecular fingerprint of tumor-infiltrating CTLs and identify a number of novel targets that may be important in modulating the magnitude and specificity of anti-tumor immune responses in lung cancer.

#2949 TGF-β is a key mediator of NK cell dysfunction in gliostroma. Hila Shaim, Abdullah Alsuslinam, Konrad Gabrusiewicz, Jun Wei, John Yu, Rafet Basar, May Daher, Lucila Kerbaya, Mayela Mendh, Muhamrem Muftuguo, Li Li, Enli Liu, Nobuhiko Imahashi, Sonny Ang, Young Gi, Pinaki Banerjee, David Mills, Richard Champlin, Elizabeth Shpill, David Heinze, Katayoun Rezvani, MD Anderson Cancer Center, Houston, TX.

Background: NK cells play a crucial role in the antitumor immune response and are involved in controlling tumor formation, progression and metastases. Glioblastoma (GBM) is the most devastating brain tumor, associated with very poor prognosis. While immunotherapy emerged as a promising approach for anti-cancer therapy, GBM appears immune resistant. Here, we studied the role of NK cells in targeting glioblastoma and possible mechanisms of NK immune evasion. Methods: NK cells were isolated from freshly resected GBM tissue, matching peripheral blood and the blood of healthy controls. Flow cytometry was used to characterize the cells and their ability to produce cytokines, and chromium release assay was performed to assess their cytotoxicity. In vitro assays were performed by co-culturing GBM stem cells (GSCs) with healthy donor NK cells. Results: We found that whereas NK cells were abundant in primary GBM tissue and could efficiently target GBM stem cells (GSCs), GBM infiltrating NK cells (TINKs) displayed an abnormal phenotype with downregulation of many activating receptors including CD16, NKG2D, DNAM, NKP30, NKP46, 2B4 and NKG2C and upregulation of inhibitory proteins such as PD-1. This inhibitory phenotype was associated with impaired NK cell function when compared with NK cells isolated from the peripheral blood of patients and healthy donors. GSC-NK cell-cell contact resulted in release of TGF-β by GCSs, which in turn led to NK dysfunction through constitutive activating of the p-Smad pathway. TGF-β activation, in turn, is partially mediated by the matrix metalloproteases MMP-2 and MMP-9, secreted by GSCs. In the presence of monocytes, tumor cell proliferation and TGF-β expression were enhanced upon TGF-β exposure. We demonstrated that inhibition of the TGF-β axis, in particular by the small molecule inhibitor, galunisertib, can prevent GSC-induced NK cell dysfunction but is unable to inactivate the p-Smad pathway, thus, cannot reverse existing dysfunction. Conclusions: Our results indicate that NK-GBM cross-talk plays an important role in tumor escape and highlight the importance of developing future adoptive transfer therapies with the intent of limiting tumor escape from antitumor immunity.

#2950 Biomarkers of immune infiltration for multiplex immunofluorescence in breast cancer. April Swoboda, Galina Khramtsova, Lise Sveen, Andrey Khramtsov, Rita Nanda, Olufunmilayo Olopade. University of Chicago Medicine, Chicago, IL.
Introduction: Only a subset of patients have a clinical response to cancer immunotherapy. The molecular mechanisms that mediate the immunological response or tolerance to treatment are just beginning to be understood. Several tumor signaling pathways are involved in those mechanisms: Wnt/β-catenin, STAT3, NFκB, PI3K/PTEN/AKT, and TP53. To characterize the tumor, its immune infiltrate, and its microenvironment, we examined expression of several biomarkers and determined the relationships among them in various breast cancer subtypes. Methods: 148 breast cancer (BCa) cases from the University of Chicago Breast Cancer SPORc Tissue bank under IRB approved protocols were classified into four biological subtypes based on immunohistochemical (IHC) staining: luminal A, luminal B, Her2 and basal-like. IHC staining for PD-L1, CD68, FoxP3, CD8, and β-catenin was performed on tissue microarrays. CD8+ and FoxP3+ cells were counted manually and recalculated for 1 mm². Macrophage phenotype was determined using single and double staining with CD68 for total population and CD68/CD163 for M2. CD68+ and CD163+ cells were counted manually, confirmed by Image Analysis, and recalculated for 1 mm². PD-L1 and β-catenin (membrane-associated, cytosolic and nuclear) were scored as negative, weak, positive, moderate, and strong. Results: The study cohort subtypes were 20.9% basal-like, 10.4% Her2, 53.8% luminal A, and 10.4% luminal B. The ratio of M2 to M1 cells increased with disease progression (p<0.001). Her2 and basal-like subtypes had a significantly higher percentage of M2 cells as compared to the luminal A subtype (p<0.001). The cases with M2 and M1 macrophage phenotype had a higher ratio of a T3P3 regulatory T cells (Tregs) to cytotoxic CD8+ cells. PD-L1 expression was present in 23% of specimens. However, the intensity of expression was markedly different across the BCa subtypes. PD-L1 high expressing tumors had, on average, greater FoxP3+ cell infiltrate and low or absent CD8+ T cells. The ratio of FoxP3 Tregs to CD8+ cells in basal-like tumors were 1.7, 2.3, and 4-fold higher than in Her2, luminal A, and luminal B tumors, respectively (p<0.005 for all correlations). There was a statistically significant decrease in membrane-associated β-catenin in tumor compared to normal tissue (p<0.0001). The proportion of tumors positive for cytosolic or nuclear β-catenin in basal-like tumors was statistically higher than all other tumor subtypes. High β-catenin nuclear protein expression was predominantly observed in tumors with higher CD8+ T cell infiltration. Ongoing analysis will evaluate the association of these biomarkers with clinical outcomes. Conclusions and Future Directions: Our data suggests that IHC using a panel of antibodies may be a robust and suitable method for evaluating level of immune infiltration. Future studies will evaluate multiplex immunofluorescence of multiple biomarkers in breast tissue.

#2951 The tumor microenvironment in cholangiocarcinoma is dominated by an immunosuppressive infiltrate. Nathania M. Figuerola, Brian Belt, Ankit Patel, Shinsuke Sato, Margaret Hill, Winicka Wolfe, Alexander Caldas, University of Rochester Medical Center, Rochester, NY.

Purpose: To characterize the dynamics of the immune response to cholangiocarcinoma (CCA) in a genetically engineered mouse model of CCA in order to identify immune pathways susceptible to targeted immunotherapies. Experimental Design: Genetically modified mice with targeted Kras activation and loss of p53 (AbL-Cre/LSL-KRASG12D/p53LacZ-/-) in the liver spontaneously develop CCA recapitulating the histopathological features of human disease. To evaluate the in vivo immune response to CCA, tumors from Kras-p53 mice and normal livers were excised and prepared for histologic examination, flow cytometry, and gene expression analysis. Immunohistochemistry (IHC) and flow cytometry were performed on myeloid and T cell markers to distinguish immune cell subsets. Cells lines established from isolated CCA tumors were used to assess the functional impact between the immune system and tumor cells in co-culture in vitro studies. Results: Kras-p53 murine hepatic tumors were highly desmoplastic with a heavy fibrotic stromal compartment. IHC analysis demonstrated a prominent inflammatory leukocyte infiltrate compared to normal liver. Flow cytometry of single tumor suspensions showed the immune reaction was dominated by CD11b+ monocytic (Ly6C+/-) and granulocytic (Ly6G+/-) myeloid cells, and FoxP3+ regulatory T cells (Treg). In vitro studies revealed tumor educated myeloid cells expressed higher levels of genes associated with an immunosuppressive phenotype, including Arginase 1 (p<0.0007). Invasion assays analyzing the migration potential of CCA cell lines co-cultured with CD11b+ cells showed increased invasive properties in these tumor cells when compared to naive controls (p<0.0001). Additionally, increased tumor-initiating properties were seen by qRT-PCR in tumor cell lines having undergone similar co-culture experiments. These data suggest the immune response to CCA is predominantly immunosuppressive and tumor supportive. Conclusion: CCA tumors from AbL-Cre/LSL-KRASG12D/p53LacZ-/- mice have a prominent immunosuppressive infiltrate recapitulating features of the immune reaction in human disease. Thus, Kras-p53 mice provide an ideal model to test targeted immunotherapy for the treatment of CCA.

#2952 The novel cathepsin L/K inhibtors KGP94 and KGP207 prevent M0 to M2 macrophage differentiation and macrophage-mediated pro-tumor functions. Samantha S. Dykes, Dietmar W. Siemann. University of Florida, Gainesville, FL.

Tumor-associated macrophages play many important roles in tumor progression, including facilitating tumor cell invasion and angiogenesis. Due to their numerous pro-tumor functions, tumor-associated macrophages represent an important cell population in the design of targeted anti-cancer therapies. Interleukin-4 (IL-4) mediated activation of macrophages resulted in an M2-like, or pro-tumor macrophage phenotype, often associated with increased expression of proteases including the lysosomal cathepsin L. Cathepsin L is important in both macrophage and tumor cell invasion, whereby secreted cathepsin L degrades the extracellular matrix, allowing for cell infiltration. The present study examined the role of cathepsin L in M0 to M2 differentiation and macrophage-mediated tumor cell invasion using the novel cathepsin L/K inhibitors KGP94 and KGP207 [Dr. Kevin Pinne, Baylor University]. KGP94 and KGP207 prevented M2 macrophage motility and invasion in vitro migration and invasion assays. Moreover, KGP94 and KGP207 reduced macrophage-stimulated invasion of 4T1 murine breast cancer cells. Together, these data suggested that cathepsin L was necessary for macrophage invasion and motility and for macrophage–medicated tumor cell invasion. Cathepsin L expression in GC resulted in a significant decrease in the IL-4-induced expression of the M2 marker Arginase-1 upon drug treatment. Additionally, exogenous recombiant cathepsin L partially stimulated the expression of Arginase-1 in M0 macrophages. Together, these data suggest that cathepsin L plays a role in macrophage M0 to M2 differentiation. In conclusion, the novel cathepsin L/K inhibitors KGP94 and KGP207 prevented M0 to M2 differentiation, macrophage invasion, and macrophage-stimulated invasion of breast cancer cells. These data highlight the importance of cathepsin L in macrophage functions and suggest that cathepsin L inhibition is a viable approach for the treatment of tumors associated with high macrophage infiltration.

#2953 Tumor-associated macrophages infiltration highly associated with PD-L1 expression in gastric cancer. Kazuto Harada,1 Jannelynn S Estrella,1 Arlene M Correa,1 Lang Ma,1 Xiaoquan Dong,1 Yan Xu,1 Wayne L Hofstette,3 Kazuki Sudo,1 Hisashi Onodera,2 Koyu Suzuki,1 Akiko Suzuki,1 Randy L Johnson,2 Zhenning Zhenning, Shumei Song,1 Jaffer A Ajani,1 Hisashi Onodera,2 UT MD Anderson Cancer Ctr., Houston, TX; 3St. Lukes University, Tokyo, Japan.

Objectives: programmed death ligand 1 (PD-L1) is key protein for tumor to acquire the evasion form T cell immune response and PD-L1 inhibitors are useful for an immune checkpoint blockade therapy. Tumor-associated macrophages (TAM) facilitate not only tumor cell progression, but also immunosuppression, which prevent tumor cell attack by T cell. Therefore, TAM is considered to be associated with PD-L1 expression in GC. Methods: We performed immunohistochemical staining of PD-L1, CD68 (pan-macrophage) and CD163 (M2 macrophage) in 217 GC sample tissue microarray. The area of CD68 and CD163 positive cells were evaluated by using the Cytoplastic V2.0 algorithm on the Aperio ImageScope software. Results: 31 samples (14.3%) were positive for PD-L1 expression. The mean rate for CD68 and CD163 positive area were 6.8±0.38% and 6.2±0.30%, respectively. CD163 positive macrophage infiltration is significantly more in diffuse type tumor than in intestinal type tumor (diffuse (n=111): 6.9%, intestinal (n=91): 5.3%, p=0.0056), but CD68 positive macrophage infiltration is similar in both type (p=0.38). Interestingly, PD-L1 expression tumor have significantly more CD68 and CD163 positive macrophage infiltration (CD68: PD-L1 negative 6.3%, positive 10.4%, p=0.0002, CD163: PD-L1 negative 5.7%, positive 9.2%, p<0.0001). PD-L1 expression and CD68 and CD163 positive area had no relationship between any clinicopathological features. Conclusions: Macrophages infiltration in GC is highly associated with PD-L1 expression of tumor cells. M2 macrophage infiltration is significantly associated with diffused type of GC. This result suggests that TAM infiltration is associated with the immunosuppression through upregulation of PD-L1 expression in GC cells. Thus, macrophages infiltration can serve as a potential therapeutic target.

#2954 The role of hedgehog signaling in breast cancer progression through macrophage polarization. Ann Hanna, Lalita A. Sheved. University of Alabama at Birmingham, Birmingham, AL.
The tumor microenvironment is comprised of stromal cells that constantly crosstalk with the cancer cells. Stromal cells, specifically tumor infiltrating immune cells, secrete cytokines and chemokines that regulate host responses to cancer through tumor-suppressing or tumor-promoting mechanisms. Macrophages within the tumor microenvironment are very plastic and can modulate different functions such as cell proliferation, differentiation, and angiogenesis. Although the Hh signaling pathway is tightly controlled, it often is deregulated, thus promoting tumorigenesis and tumor progression. Aberrant Hh signaling has particularly been implicated in breast cancer progression and metastasis. In this project, we investigate the role of Hh signaling in polarizing cancer associated macrophages toward the tumor-promoting M2 phenotype in a breast cancer model. We have discovered that using small molecule inhibitors to inhibit Hh signaling attenuates the cytokine profile associated with M2 macrophages, while adding recombinant Hh ligand potentiates it. Our data thus far supports a role for Hh signaling in alternatively polarizing macrophages. We hypothesize that Hh inhibitors will reduce the abundance of M2 macrophages and prevent metastasis.

#2955 Gr1-MDSCs and Tregs modulate the prostate cancer progression.
Sanjay Kumar,1 James Stokes,1 Udai Singh,2 Karyn Scissum Gunn,1 Upender Manne,3 Selvarangan Ponnazhagan,2 Manoj K. Mishra,1,3 Alabama State Univ., Montgomery, AL;2University of South Carolina, SC;3University of Alabama Birmingham, AL.

Myeloid-derived suppressor cells (MDSCs) and Regulatory T cells (Tregs) are the major components of immunosuppressive network that play a critical role in tumor progression. The mechanisms by which tumors induce expansion of suppressive cells and the crosstalk between Gr1-MDSCs (Gr1−/CD11b+/F4/80−) and Tregs related to TGF-β secretion remain incompletely defined.

Prior studies have suggested that MDSCs may contribute to Treg recruitment in cancer. Herein, the goal of this investigation is to examine the role of TGF-β-mediated generation of Tregs and Gr1-MDSCs during prostate cancer progression and clearance. To achieve this goal, matrigel system was used along with transgenic adenocarcinoma of mouse prostate (TRAMP-C1, C2 and C3 cell) in C57BL/6 mice. Interestingly, TRAMP-C3 cells are characterized as non-tumorigenic; however, TRAMP-C1 and TRAMP-C2 cells do form tumor. Mice were administered with serial log concentration of TRAMP (C1, C2 and C3) cells along with the matrigel. After three weeks, matrigels along with or without tumor were excised from tumor bearing mice, single cell suspensions were prepared and cells were flow analyzed for GR1−/MDSCs and Tregs. Additionally, the TGF-β level was also estimated (colorimetric) in culture supernatant in context to MDSCs and Treg expansion. Our initial findings suggest that the expression of Gr1−/CD11b+/F4/80−/Fas−/and F4/80−/Gr1−/CD11b−/Fas−/and F4/80− in TRAMP-C1 and C2 as compared to TRAMP-C3 bearing C57BL/6 mice These findings indicate that the modulation of Gr1−/MDSCs and Tregs could help in tumor suppression.

#2956 Chemical library screen identifies compounds that target S100A8/S100A9 complex and MDSC accumulation.
Eunmi Lee,1 Maria Ouzounova,1 Raziye Piranilou,1 Abdeldjabar El Andaloussi,2 Sena Arbag,2 Gang Zhou,1 Hasan Korkaya,1 Augusta Univ. Cancer Ctr., Augusta, GA;2Hacettepe University, Ankara, Turkey.

We previously demonstrated that MDSC subsets accumulated in primary tumor and distant organs regulate tumor plasticity. The mouse transcriptome analysis of in vitro co-cultures and samples from syngeneic mouse model revealed that granulocytic subset of myeloid-derived suppressor cells (gMDSCs) from metastatic 4T1 tumor bearing mice regulate several hundred genes in tumor cells upon co-culture. The top genes are S100A8, S100A9, MMP8, FPR1, CCL3, and TGFβ2 which also predicted poor survival in human solid tumors including breast cancer. Therefore, we called these 6 genes as “metastatic gene signature”. It has been reported that S100A8/S100A9 heterotrimer, called calprotectin, play a key role in inflammation-associated cancer progression. To investigate the role of calprotectin (S100A8/A9) in tumor-mediated immune-suppression and metastasis, we first utilized Tasquinimod, a small molecule targeting S100A9 only. However, Tasquinimod treatment of 4T1 tumor-bearing mice had a moderate anti-tumor activity which may be due to a limited activity on granulocytic MDSC accumulation. In addition, we determined that there was a significant upregulation of S100A8 in MDSCs from Tasquinimod treated mice. This data suggested that inhibiting only S100A9 leads to activation of S100A8 and thus may be ineffective targeting of MDSCs. We therefore run a computational screen of the NCI chemical library against the crystal structure of calprotectin (S100A8/S100A9) and identified 40 lead compounds. We then performed in vitro screening assay to identify compounds that inhibit MDSC induction. We identified 3 compounds that significantly suppressed gMDSC differentiation. We are currently performing in vivo studies with these 3 candidate drugs in our murine breast cancer model and will present our findings at the AACR meeting. We believe that this study will provide a novel drug targeting S100A8/S100A9 heterotrimer, a key molecule in MDSC induction and its regulatory functions during tumor progression.

#2956A Cancer invasion of mammary epithelial cells in 3D culture shows YAP-independent mechanotransduction.
Joanna Y. Lee, Jessica Chang, Sungmin Nam, Ovijit Chaudhuri. Stanford University, Stanford, CA.

83% of non-invasive breast cancers are diagnosed as ductal carcinoma in situ (DCIS). While some DCIS tumors remain confined in the mammary duct, others progress into invasive ductal carcinoma (IDC). The mechanisms underlying invasion are not well understood. Current diagnostic methods cannot accurately predict which DCIS cases will progress to IDC, and unnecessary treatment affects long-term health and quality of life, with radiation potentially promoting malignancy-inducing mutations. One possible regulator of invasion may be extracellular matrix (ECM) stiffness. Increased ECM stiffness has been correlated with invasion and 3D culture models of mammary epithelium show that enhanced stiffness induces an invasive phenotype. However, the mechanisms underlying stiffness-induced invasion remain unclear. Studies have converged upon the finding that YAP, a transcriptional regulator that is deregulated in diverse cancers, is the transducer of ECM stiffness. However, these studies were primarily performed in 2D culture and involved col-1, a ligand that activates distinct signaling pathways and is not normally found in the BM. Here, we examined the gene expression profiles of 3D cultured MCF10A cells during stiffness-induced invasion with and without col-1. We generated interpenetrating networks (IPNs) of reconstituted basement membrane (rBM) and alginate, which allow stiffness to be tuned in the absence of col-1 and independently of cell adhesion ligand concentration and matrix pore size. Traditionally used hydrogels composed of rBM and col-1, with stiffness tuned by increasing concentrations of col-1, were also produced for 3D culture. Our results show that enhanced stiffness increases MCF10A cell invasion and proliferation in both the presence and absence of col-1. However, in contrast to results from 2D culture, invasive phenotypes in 3D cultured cells did not correlate with nuclear localization of YAP, indicating lack of YAP activity. The dispensable nature of YAP in 3D stiffness sensing was supported by RNA-seq analysis, which showed a lack of increased gene expression of YAP downstream targets in conditions of enhanced stiffness. RNA-seq identified 389 differentially expressed genes in response to enhanced 3D culture stiffness. By relating these genes to transcription factors using ChIP-Seq data provided by ENCODE, we identified p300, FOS, STAT3, NELFE, and TAF1 as potential mechanotransducers of stiffness-induced invasion. Furthermore, highly expressed stiffness-induced genes were validated by immunofluorescence to identify potential candidate mechanotransduction. Our RNA-seq and immunofluorescence analysis identified a p300-dependent mechanism that allows accurate determination of cancer invasion risk in breast cancer patients, informing course of treatment.

#2957 T-cell receptor immunosequencing reveals novel insights into the immune response to human pancreatic cancer.
Yongwoo D. Seo,1 Fengfeng L. Jia,2 Xiuyun Jiang,1 Marissa Vignali,3 Harlan Robins,4 Venu G. Pillarisetty1,2
1University of Washington, Seattle, WA;2Adaptive Biotechnologies, Seattle, WA;3Fred Hutchinson Cancer Research Center, Seattle, WA.

Introduction: Despite advancements in therapy, pancreatic ductal adenocarcinoma (PDA) remains an aggressive cancer with high mortality. It is characterized by dense inflammation, including many T cells; however, it is unclear whether these T cells signify a true antitumor response. In the setting of disappointing early results of immunotherapy in PDA, we sought to gain a deeper understanding of the tumor-associated T-cell response. Methods: With IRB approval, we obtained archival resected PDA tumors in paraffin-embedded blocks from 54 patients. We performed histopathology to identify blocks containing lymph nodes (LN) and performed T-cell receptor (TCR) immunosequencing on DNA extracted from immediately adjacent tissue. To address possible intratumoral heterogeneity, we analyzed duplicate samples from separate blocks for 10
patients. Productive clonality was defined as 1-Pielou’s evenness for TCR rearrangements encoding a functional protein; TCR fraction was calculated from number of observed templates and the amount of input DNA. Two-tailed t-tests were used to compare subgroups. TCR sequence overlap between each of the 10 pairs of duplicate samples were calculated at the amino acid level. Results: Among 16 autopsy cases, mean TCR fraction was 0.27 (range 0.08-0.33), mean productive clonality was 0.15 (typical peripheral blood mononuclear cell clonality is 0.08). TCR fraction was positively correlated with clonality (R²=0.23, p=0.007), though this correlation was only significant in patients who received neoadjuvant chemotherapy (R²=0.19, p=0.03). TCR fraction was higher in patients with positive nodal status (0.32 vs. 0.23, p=0.02), but lower in patients who received adjuvant chemotherapy (0.22 vs. 0.33, p=0.02). There was no survival difference between high or low TCR fraction or clonality. Samples containing LN (not included in previous analyses) had higher TCR fraction (0.49 vs. 0.27, p<0.0001) but lower clonality (0.09 vs. 0.15, p=0.0002); this relationship was maintained regardless of nodal status. Among 10 pairs of duplicate samples, there was 53% mean overlap of TCR amino acid sequences, compared to 0.1% for pairs of unmatched samples (p<0.0001). Conclusion: Here we demonstrate evidence of clonal expansion of T cells in the human PDA microenvironment. Extensive overlap of TCR sequences between two distinct samples for each of 10 pairs analyzed further suggests that the clonal expansion may be specific to tumor antigens. Neoadjuvant therapy may also influence clonal expansion, as only treated patients had a positive correlation between TCR fraction and clonality. Finally, the presence of a lymph node sample appears to skew TCR sequences subject toward a less clonal but more numerous population. This suggests that the most rigorous analysis of TCRs in a solid tumor microenvironment needs to exclude blocks that contain lymph nodes in order to characterize the true intratumoral population of T cells.

#2958 Transcriptome analysis of astrocytoma versus non-neoplastic human microglia. Thais Fernanda Galatro,1 Antonio M. Lerario,2 Sueli M. Oba-Shinjo,3 Bart J. Eggen,3 Suely K. Marie1. 1University of São Paulo, São Paulo, Brazil; 2University of Michigan, Ann Arbor, MI; 3University of Groningen, Groningen, Netherlands.

Diffuse gliomas are primary brain tumors characterized by infiltrative growth and high heterogeneity, rendering the disease mostly incurable. Advances in genetic analysis revealed that molecular alterations predict patients’ overall survival and clinical outcome. However, glioma tumorigenicity is not exclusively caused by its genetic alterations. The crosstalk between tumor cells and the tumor microenvironment. We were also able to collect one sample of iTAMs from a GBM case. Despite not providing a significant number for statistical analysis, we can directly see major differences in gene expression between this sample and our TU-uglia cohort. We identified surface receptors differentially expressed between both cell types (i.e.: ROBO1 and PDGFRA for TU-uglia, MARCO and MET for iTAMs), as well as transcription factors associated with clonality and high heterogeneity.

#2959 Changes in the tumor stroma after MFP treatment in a MPA-induced murine mammary carcinoma model. Gonzalo Ricardo Sequeira,1 Ana Sahores,1 Tomas Dalotto-Moreno,1 Silvia Vanzulli,2 Laura Polo,1 Virginia Novaro,1 Caroline Lamb,1 Mariana Salatino,1 Claudia Lanari,1. 1Inst. de Biología y Medicina Experimental, Buenos Aires, Argentina; 2Academia Nacional de Medicina, Buenos Aires, Argentina.

The role of the immune system in the regression of mammary carcinomas using endocrine therapies has been poorly investigated. The main goals of this study were: a) to evaluate differences in antiprogestin-induced regression of hormone receptor positive mammary carcinomas growing in immunocompetent or immunodeficient mice; b) to characterize the tumor infiltrating immune cells in milliprostine (MFP)-induced mammary carcinomas. The comparison of these transcriptome datasets provided an in-depth insight into the immune system changes elicited by mifepristone and mifepristone + 17β-estradiol in tumor re-challenge assays. Bone marrow (BM) cells from BALB/c-GFP mice were intravenously inoculated into NSG mice to establish the NSG/BM-GFP mouse model. GFP cells were detected in spleen, bone marrow, and blood from NSG/BM-GFP mice two months after BM-GFP cell inoculation. The murine mammary carcinoma 59-2-HI, originally induced by the administration of medroxyprogesterone acetate to BALB/c mice, regresses completely after MFP treatment. Tumors were orthotopically inoculated into NSG or NSG/BM-GFP female mice two months after BM grafting. When the tumors reached a size of approximately 50 mm³, low dose MFP pellets (0.2 mg) were administered in order to inhibit tumor growth. To characterize the infiltrating immune cells, tumors were excised after drug administration, disaggregated, and isolated cells were analyzed by FACS. Tumors from mice treated with MFP + 17β-estradiol and animals were orthotopically re-inoculated with the same tumor in the opposite flank. Operated animals were used as controls. MFP inhibited the growth of tumors transplanted in either NSG or NSG/BM-GFP + and no differences were observed between both groups, suggesting that the immune system is not a key factor mediating antiprogestin-induced tumor regression. Tissue remodeling was associated with an increase in lymphocytes (CD3+; T cells) and macrophages (CD11b+ + F480+; >80% at day 3 and 6), and a decrease in the Treg subpopulation (CD4+ + CD25+ + Foxp3+; <20% at day 3 and 6). These results led us to hypothesize that antiprogestin treatment could elicit a protective antitumor immune memory response by delaying tumor recurrence. To test this hypothesis we performed re-challenge assays using animals in which primary tumors have been previously excised. All tumors of control mice reached the ethical limit size (200 mm²) before day 47, while only half of the tumors in the MFP-treated group reached this size by this time (hazard ratio: 1.98). We conclude that antiprogestins induce tumor regression regardless of the presence of an impaired immune system and that the reduced intra-tumor Treg/CD8 ratio observed in regressing tumors might be used as a predictive marker of treatment response. The re-challenge experiments agree with the hypothesis that regressing tumors expose intracellular antigens that generate a protective immune memory response, which in turn, could be associated with the long free relapse survival induced by endocrine therapy.

#2960 Adipocytes sequester and metabolize daunorubicin. Xia Sheng,1 Jean-Hugues Parmentier,1 Jonathan Tucci,2 Hua Pei,1 Omar Cortez-Toledo,1 Christina Dielli-Conwright,1 Matthew Oberley,1 Michael Neely,1 Etan Orgel,1 Stan Louie,2 Steven D. Mittelman1. 1USC/Children’s Hospital Los Angeles, Los Angeles, CA; 2USC School of Pharmacy, Los Angeles, CA; 3USC School of Dentistry, Los Angeles, CA.

Obesity is associated with poorer outcome from many cancers, including childhood acute lymphoblastic leukemia (ALL). We have previously shown that adipocytes protect ALL cells from the anthracycline, daunorubicin (DNR). We therefore investigated whether adipocytes sequester and/or metabolize DNR in the ALL microenvironment. Using fluorescence and LC/MS measures, we demonstrated that adipocytes absorb DNR, reducing the intracellular DNR concentration in co-cultured BV173 ALL cells (after 48 hours, median fluorescent intensity of ALL cultured with adipocytes was 1.7±1.0 vs. 5.0±1.7 of those cultured alone, p<0.01). Mouse adipocytes convert DNR to the less active metabolite, daunorubicinol (DNR-dol); over 48 hours, media DNR decreased to 0.1±0.2 (vs. 24.8±8.76 ng/mL in control wells). At the same time, DNR-dol increased (0.1±0.4 vs. 0.7±0.8 ng/mL). Similar concentrations of DNR to DNR-dol was observed in both mouse adipose explants and human adipose tissue biopsy samples ex vivo. qPCR confirmed human subcutaneous adipose tissue expresses several enzymes capable of metabolizing DNR, including AKR1A1, 1B1, 1C1, 1C2, 1C3, 7A2, and CBR1 and 3 (expression ranged between 20 and 195% of human). Using immunohistochemistry, we confirmed expression of AKR1C1, 1C2, and 1C3 in bone marrow adipocytes of children during the first month of treatment for ALL. Finally, two hours after an intravenous dose of DNR in mice, we found that the DNR-dol to DNR ratio was higher in subcutaneous (0.6±0.5 at 2.6 days) and omental (0.55±0.21) adipose than in white blood cells (0.16±0.11), bone marrow (undetectable DNR-dol), and spleen.
Targeting stromal-derived Dickkopf-3 (DKK3) for the treatment of pancreatic ductal adenocarcinoma (PDAC). Liran Zhou,1 Hongmei Husted,1 Todd Moore,1 Mason Liu,2 Defeng Deng,1 Yan Liu,3 Vijaya Ramachandran,1 Thiruvengadam Arumugam,1 Baonan Ji,2 Huamin Wang,1 Jeffrey E. Lee,1 Craig D. Logsdon,1 Rosa F. Hwang,1 1UT MD Anderson Cancer Ctr., Houston, TX; 2Mayo Clinic, Rochester, MN.

Introduction: We and others have shown that pancreatic stellate cells (PSCs) in the tumor-associated stroma of PDAC promote tumor progression and resistance to therapy but the precise mechanisms are unclear. We investigated the role of PSC-derived DKK3, a member of the Dickkopf family of glycoproteins, in PDAC progression, metastasis and response to chemotherapy. Methods: We evaluated expression of DKK3 in human PDAC tissue and cell lines, human PSCs and in a genetically engineered mouse model (GEMM) of PDAC. The paracrine and autocrine effects of DKK3 on PDAC and PSCs were examined by treatment with exogenous DKK3 and gain- and loss-of function assays for proliferation, migration, invasion, and gemcitabine-induced apoptosis. The effects of DKK3 on PDAC progression and metastasis were determined by shRNA neutralization and genetic ablation in orthotopic xenograft models and the KPC autochthonous model of PDAC. We developed novel monoclonal antibodies (mAbs) against DKK3 and tested their ability to neutralize DKK3 and prolong survival in mouse models of PDAC. Results: DKK3 was expressed at 4.5 times higher levels in human PDAC by Affymetrix profiling compared to normal pancreas and was present in 99% (118/119) of samples on a tissue microarray.

...higher levels in human PDAC by Affymetrix profiling compared to normal pancreas and was present in 99% (118/119) of samples on a tissue microarray with moderate to high expression in 59%. In a GEMM of PDAC, DKK3 appeared early with preneoplastic PanIN lesions with increased expression in invasive carcinoma. DKK3 was strongly expressed by PSCs with minimal to no expression in PDAC cells and knockdown by shRNA reduced PSC proliferation and migration by 60% and 84% compared to controls (p < 0.001). Treatment of Panc1 and BxPC3 cells with DKK3 stimulated migration and invasion by 100-300% (p < 0.001) and proliferation of DKK3-silenced Panc1 cells was decreased by 80% (p < 0.001). Overexpression of DKK3 in L3.6pl cells increased colony formation in gemcitabine by >90% (p < 0.001) with 65% reduction in apoptosis (p < 0.01), indicating that DKK3 contributes to PDAC resistance to chemotheraphy. When we ablated DKK3 in KPC mice by breeding with DKK3-knockout mice, tumor growth was inhibited and survival increased by 45% (p = 0.0002). In addition, fewer PanIN lesions developed in DKK3-null mice suggesting that DKK3 may contribute to the early developmental stages of PDAC. DKK3 neutralizing mAbs abrogated DKK3-mediated induction of PDAC cell migration, invasion and resistance to gemcitabine in vitro. Furthermore, treatment with DKK3 mAb significantly inhibited primary tumor growth, reduced peritoneal metastases and prolonged survival in an orthotopic model of PDAC by 43% compared to control mAb (p = 0.005; HR; 0.2, 95% CI 0.01-0.30).

Conclusions: These data are the first report, to our knowledge, of a tumor-promoting function of DKK3. DKK3-derived mAbs suggest that neutralizing DKK3 may be an effective approach as a primary treatment for PDAC and to enhance responsiveness to chemotherapy.

Mechanobiology of epithelia on native basement membrane and relevance for cancer invasion. Marija Plodinec,1 Philipp Oertle,1 Daphne Assgeirson,1 Willi Hafferl,2 Serenella Epenberger Castoni,1 Ellen C. Obermann,1 Alexandre Glentis,1 Roderick Y. LIM 1.

The onset of metastasis occurs when cancer cells invade and breach the basement membrane (BM) that provides mechanical support to epithelial tissues. Yet, it remains unclear what triggers cancer cells to breach the BM, and how ‘triggered’ cells in fact breach the BM. We have established an in vivo assay using native BM interface for culturing epithelial cells. Using atomic force microscopy (AFM) with other high-resolution microscopies and TER (trans-epithelial resistance), we have correlated the mechano-cellular attributes of the BM epithelium interface to its biochemical and structural properties. We demonstrated that the internal limiting membrane (ILM) isolated from human retinas acts as a native substrate for culturing epithelial cells in terms of BM composition, architecture and stiffness. These are required to act jointly in order to achieve apico-basal polarity, tissue barrier formation and stiffness properties of the epithelial layer similarly to secretory epithelia in vivo. The native BM serves several advantages over reconstituted Matrigel, an ECM extracts that originates from mouse tumor ascites. Besides variations in thickness and biochemical composition, we find that Matrigel is mechanically 100-fold more compliant (i.e., softer) than native BMs. When tumorigenic variants of cells are used, we demonstrated that cancer cell invasion is associated with a decrease in cellular stiffness correlated to changes in cell and BM morphology. In addition, we showed that activation of cell matrix stiffness and architecture of the native BM collagen scaffold and BM collagen chain has a key role, not only as previously thought for maintenance of cell polarity but also for the establishment of a physiological mechanophenotype. On the other hand it is well know that during cancer progression in vivo, cancer cells can perforate the BM using proteolysis. Whether stromal cells also play a role and what kind of role in this process is unclear. Therefore, we asked if carcinoma-associated fibroblasts (CAFs) isolated from cancer patients promote cancer cell invasion through a BM. In the presence of CAFs, moderately invasive cancer cells invade in a matrix metalloproteinase-independent manner. Using live imaging and atomic force microscopy, we showed that CAFs actively pull, stretch and soften the BM, forming gaps through which cancer cells can migrate. By exerting contractile forces, CAFs alter the organization and the physical properties of the BM, making it permissive for cancer cell invasion. Finally, we propose that, in addition to proteolysis, mechanical interactions between CAFs and BM represent an alternative mechanism of BM breaching. Given their mechanobiological relevance, native BMs allow us to further understand how mechanical signaling occurs between the epithelia and the surrounding stromal layers at the BM interface during cancer invasion and progression.

Inhibition of stromal p38MAPK abrogates breast cancer metastasis. Sheila A. Stewart,1 Bhavna Murali,1 Qiao Ren,1 Xinning Su,1 Kevin Flanegan,2 Xianmin Luo,1 Jasmine Sponagel,1 Yujie Fu,1 Elise Alsphach,1 Kathleen Lehy,1 Roberta Faccio,1 Kathleen Weilbaecher,1 Joseph Monahan2. Washing-ton University, St, Louis, MO; 2Confluence Life Sciences, St, Louis, MO.

Bone metastasis is a devastating and fatal complication of breast cancer for which we lack effective therapies. Thus, identifying therapies that effectively limit metastases will significantly reduce comorbidities and improve long-term survival. Recently we demonstrated that the p38MAPK pathway sustains the pro-tumorigenic senescence-associated secretory phenotype (SASP) and targeting this pathway limits the tumor-promoting capabilities of senescent cells and cancer-associated fibroblasts (CAFs). Because we found that a significant percentage of p38MAPK-dependent SASP factors are expressed in the stroma associated with breast cancer lesions, we asked whether targeting p38MAPK could limit primary and metastatic breast cancer growth. While p38MAPK inhibition modestly limited primary tumor growth, we found that its inhibition significantly reduced breast cancer bone metastases by specifically targeting the stromal compartment. Further, p38MAPK inhibition was as effective as paclitaxel at limiting tumor growth in the bone but in contrast to paclitaxel, which failed to protect from cancer-induced bone loss, p38MAPK inhibition prevented bone loss. This contrasts our p38MAPK approach from zole-dronic acid, which limits bone loss but fails to slow tumor growth in already engrafted tumors. Analysis of the mechanism(s) responsible for this reduced metastasis suggests that p38MAPK inhibition targets reactive and/or senescent osteoblasts within the bones of animals harboring metastatic lesions. Because we identified osteoblasts are present in human bone, we postulate that they may be vital to promote metastatic outgrowth and thus p38MAPK inhibition limits the pro-metastatic activities of these cells. Finally, we will present recent data from our preclinical model that demonstrates that inhibition of the p38MAPK pathway can drastically reduce metastasis from the primary site. We propose that p38MAPK is an important stromal-specific therapy for breast cancer metastasis to the bone.

Stromal Hedgehog pathway activation suppresses growth and me-tastases of lung adenocarcinoma. Sabha Kasiri, Baozhen Chen, Alexandre Wil-son, Umaru Barrie, Ummay Marriam, Zhiqun Zeng, Luc Girard, James Kim. UT Southwestern, Dallas, TX.

Aberrant activation of the Hedgehog (Hh) signaling pathway, a crucial development pathway, of the tumor growth of G-protein-coupled receptors. However, recent data suggest that paracrine activation of the pathway is tumor suppressive rather than oncogenic in sporadic epithelial cancers. The role of the pathway in non-small lung cancer is poorly understood. Thus, we explored the role of stromal Hh pathway activation in growth of lung tumor epithelia. Human lung adenocarcinoma cell lines were used to probe SHH mRNA and protein expres-sion. Co-culture of lung SHH expressing cell lines with murine embryonic and lung fibroblasts were used to confirm and probe the role of paracrine SHH expression on the growth of lung cancer cells. The in vivo role of paracrine SHH was tested using autochthonous lung cancer models with conditional KRASG12D activation, p53 loss, and SHH loss compared to wild-type SHH. In

TUMOR BIOLOGY: Tumor Microenvironment 4

Proceedings of the American Association for Cancer Research • Volume 58 • April 2017 757
human lung adenocarcinoma patients. Higher expression of SHH mRNA in lung adenocarcinoma correlated with poor overall and progression free survival. A scan of 35 human lung adenocarcinoma cell lines revealed heterogeneous expression of SHH and HH in high expression found predominantly in mutant K-Ras lines. Co-culture of high SHH expressing tumor epithelial cells and Shh-Light2 reporter cell lines demonstrated that SHH activated the fibroblast reporter in a paracrine manner, rather than an autocrine effect on cancer cells. Treatment with the Smo inhibitor, KAAD-cyclopamine, also inhibited the growth of tumor epithelial cells in co-culture with NIH-3T3 fibroblast cells but the effect was decreased when co-cultured with lung fibroblasts. Genetic loss of SHH in an autochthonous mouse model, LSL-Kras(12D/12D);Trp53(−/−);P53R2(−/−);Pten(−/−);Kras(12D/12D);Trp53(−/−);Pten(−/−);Pten(−/−) KP mice. However, early inhibition of the Hh pathway by anti-SHH/IHH antibody, SE1, on KP mice resulted in significantly worse survival rates with increased metastatic burden compared to IgG treatment. Analysis of KP tumors revealed unexpected high levels of IHH mRNA by in situ hybridization that may account for the survival differences seen between genetic ablation and pharmaceutical inhibition of the Hh ligands. In conclusion, the Hh signaling pathway acts upon lung stromal cells in a paracrine fashion. Inhibition of Hh activity in vivo worsened mortality rate due to increase in tumor growth and metastases. Furthermore, mutant Kras lung cancers express high levels of IHH that dominates the tumor suppressive effect of our mouse models.

#2965 Myeloid depletion reverses established T-ALL growth in vivo. Todd A. Tripplett, Aram Lye, Wesley Godfrey, Lauren E. Ehrlich. University of Texas at Austin, TX.

T cell acute lymphoblastic leukemia (T-ALL) is a hematological cancer that arises from developing T-cells. Most T-ALL research has focused on elucidating cell-intrinsic genetic permutations that promote tumor proliferation and survival, which has resulted in a detailed description and understanding of the genetic mutations associated with T-ALL in patient cells. However, to date these studies have not resulted in effective targeted therapies, which may potentially be due to the heterogeneity of genetic lesions within and between patients or the acquisition of new mutations. Thus, we need to broaden our understanding of other factors promoting T-ALL growth to identify alternative therapeutic targets that are effective across mutational landscapes. To this end, our studies seek to identify extrinsic signals in the tumor microenvironment that enable T-ALL growth. Our previous studies used a systematic and unbiased evaluation of endogenous stromal subsets from the thymic TME to reveal that myeloid cells, primarily dendritic cells (DC), were necessary and sufficient for ex vivo survival of T-ALL cells. Furthermore, transcriptional profiling revealed elevated expression of Igf1r and Iglf by T-ALL and DC from the TME, respectively. Using multiple molecular approaches, inhibition of IGFR1 revealed that IGFR1 signaling was necessary for DC-mediated survival of T-ALL from multiple tumor locations. These findings have relevance to human T-ALL as pervasive TEC-free regions containing extensive DC networks were evident in T-ALL patient samples, and previous studies have verified that IGFR1, a direct target of NOTCH1, is expressed at high levels in T-ALL patients. In these studies, we sought to determine whether myeloid cells were required for tumor survival in vivo. After transplantation, tumor growth was established systemically in lymphoid and non-lymphoid tissues of the recipients. Immunofluorescence analysis revealed extensive myeloid networks around and between T-ALL tumor cells in multiple tissues. For primary tumors, transplanted T-ALL cells also required the presence of DC from the TME for survival ex vivo. Importantly, myeloid cell depletion in transplanted hosts with established T-ALL resulted in substantial reduction in tumor burden in all tissues examined, thus demonstrating a fundamental role for these cells in supporting T-ALL in vivo. To identify key survival pathways activated in T-ALL cells by myeloid cells, we have compared comprehensive transcriptomic and phosphoproteomic profiling from tumor cells in the presence or absence of myeloid cells in transplant models. Preliminary analysis of T-ALL versus WT TME microarrays has confirmed hyper-activated IGFR1 signaling, as indicated by hyper-phosphorylation of downstream targets, such as IRS1. Collectively, these studies provide the first evidence that myeloid cells directly support T-ALL in vivo, suggesting that these cells and their associated signals may be auspicious therapeutic targets.

#2966 Stromal pleiotropic growth factor receptor-beta (PDGFRbeta) promotes breast cancer progression. Gina M. Szemere, Anisha M. Hammer, Kate A. Thies, Steven T. Szemere, Anthony J. TrimboI, B. Eason Hillneth, Ralegh D. Kladney, Arnab Chakravarti, Gustave Leon, Michael C. Ostrowski. Ohio State University, Columbus, OH.

Over the past decade it has become evident that the tumor microenvironment (TME) actively participates in carcinogenesis. Tumor-associated fibroblasts, for example, modulate neighboring tumor epithelium through growth factor secretion to initiate and promote tumor growth. The pleiotroped derived growth factor receptors (PDGFRs), PDGFRalpha and PDGFRbeta, are receptor tyrosine kinases activated by PDGF that may be critical and actionable mediators of breast tumor-stromal communication. PDGFRs are predominantly expressed in breast tumor stroma while their cognate ligand, PDGF, is expressed in tumor epithelium and associated endothelium. In some cancers, tumor-derived PDGFRs act on the TME to recruit associated fibroblasts; however, this role has not been described in breast cancer. To begin to evaluate a role for PDGFRbeta, we utilized publicly available gene expression data to confirm upregulation in tumor stroma compared to tumor epithelium. Importantly, PDGFRB is increased in breast tumor stromal cells compared to normal stroma. To directly test whether the stromal PDGFR activation promotes tumor growth, we co-injected murine mammary tumor cells with or without PDGFR-expressing mouse mammary fibroblasts (MMFs) orthotopically in FVB/N mice. MMF inclusion increased tumor cell proliferation as well as associated angiogenesis while systemic treatment with imatinib mesylate, a small molecule inhibitor for PDGF, restored both proliferation and angiogenesis back to baseline. These findings indicated the importance of PDGFR signaling in tumor initiation leading us to develop a mouse model of stromal-specific PDGFRbeta activation using the Fsp-cre transgene previously published by our group (henceforth referred to as “PDGFRbeta mutant”). PDGFRbeta mutant mammary glands exhibited increased tertiary side-branched and epithelial proliferation confirming a stromal-specific PDGFR-beta role in neighboring epithelial proliferation. Distributions of PDGFs isoforms secreted from the PDGFRbeta mutant mice exhibit increased motility towards PDG-F expressing tumor cells in vitro, which implies increased response and recruitment of the mutant MMFs towards an expanding tumor. To test whether PDGFRbeta mutant mice harbor a mammary TME supportive of increased tumor growth, we injected murine mammary tumor cells orthotopically into either control or PDGFRbeta mutant mice finding that the time required to meet early removal criteria (tumor &gt;1cm3) was shorter in the mutant mice compared to controls. Ongoing studies are evaluating whether systemic PDGFR inhibition will abrogate this observed increase in tumorigenesis. In summary, our data suggest that stromal PDGFRbeta signaling is pro-tumorigenic in breast cancer and that inhibition using well-described PDGFR inhibitors could be a valid therapeutic approach for women whose tumors express increased PDGF-to-PDGFR tumor-stromal signaling.

#2967 Pancreatic cancer cell growth requires lipids released by tumor-induced stroma autophagy. Petrus R. De Jong,1 Sean-Luc Shanahan,2 Morgan A. Brand,3 Alejandro D. Campos,1 Anagha Siranagam,1 Nikolas Marinico,1 Claudi D. Miller,1 Olga Zagnitko,1 Adam D. Richardson,1 David A. Scott,1 Brian P. James,3 Andrew P. Hodges,3 Ally PeruIna,4 Alexey M. Eroshin,3 Randall French,3 Malene Hansen,4 Sally A. Litherland,4 Andrew M. Lowy,3 J. Pablo Arnoletti,5 Malte J. Sorensen,1 Gunter Fleischer,14 Divya Arun,11 Alex Schwartz,3 SBP NCI-Designated Cancer Center, La Jolla, CA;15 SBP Discovery Institute, La Jolla, CA;2 University of California, San Diego. La Jolla, CA;3 Florida Hospital Cancer Institute, Orlando, FL;4 Institute for Surgical Advancement/Florida Hospital Center for Specialized Surgery, Orlando, FL.

Pancreatic ductal adenocarcinoma (PDAC) is non-resectable in the majority of patients and highly resistant to chemotherapy, resulting in a poor survival. The tumor microenvironment (TME) actively participates in carcinogenesis and promoting tumor progression in PDAC. Understanding the metabolic vulnerabilities of PDAC in the harsh tumor microenvironment may lead to novel therapeutic approaches with improved clinical efficacy. First, we found that PDAC cells showed beneficial effects of co-cultured stroma cells, but only under lipid-free serum conditions. To study the metabolic crosstalk between cancer cells and stroma in more stromal tumor cells with or without PDGFR-expressing mouse mammary fibroblasts (MMFs) orthotopically in FVB/N mice. MMF inclusion increased tumor cell proliferation as well as associated angiogenesis while systemic treatment with imatinib mesylate, a small molecule inhibitor for PDGF, restored both proliferation and angiogenesis back to baseline. These findings indicated the importance of PDGFR signaling in tumor initiation leading us to develop a mouse model of stromal-specific PDGFRbeta activation using the Fsp-cre transgene previously published by our group (henceforth referred to as “PDGFRbeta mutant”). PDGFRbeta mutant mammary glands exhibited increased tertiary side-branched and epithelial proliferation confirming a stromal-specific PDGFR-beta role in neighboring epithelial proliferation. Distributions of PDGFs isoforms secreted from the PDGFRbeta mutant mice exhibit increased motility towards PDG-F expressing tumor cells in vitro, which implies increased response and recruitment of the mutant MMFs towards an expanding tumor. To test whether PDGFRbeta mutant mice harbor a mammary TME supportive of increased tumor growth, we injected murine mammary tumor cells orthotopically into either control or PDGFRbeta mutant mice finding that the time required to meet early removal criteria (tumor &gt;1cm3) was shorter in the mutant mice compared to controls. Ongoing studies are evaluating whether systemic PDGFR inhibition will abrogate this observed increase in tumorigenesis. In summary, our data suggest that stromal PDGFRbeta signaling is pro-tumorigenic in breast cancer and that inhibition using well-described PDGFR inhibitors could be a valid therapeutic approach for women whose tumors express increased PDGF-to-PDGFR tumor-stromal signaling.
lipid droplets. The transfer of lyso-PiPs was abrogated by pharmacological inhibitors of autophagy, or by siRNA-mediated knockdown of autophagy genes in stromal and tumor cells. These data suggest that PDAC cells cause stroma cells to undergo autophagy, and reprogram stroma metabolism to obtain complex lipid species for their metabolic needs in the lipid-starved tumor microenvironment.

**#2968 Examining the role of breast cancer Neuregulin1 and macrophage ErbB3 in intravasation.** Ramon Cabrera, Serena Chiang, Jeffrey Segall, Albert Einstein College of Medicine, Bronx, NY.

The purpose of our studies is to investigate the role of Neuregulin1 (NRG1) and ErbB3 signaling between breast cancer cells and macrophages in facilitating tumor cell intravasation. The interaction of breast cancer cells with other cell types within the tumor microenvironment plays an important role in metastasis. These interactions are thought to influence tumor cell invasion and intravasation, two important steps in the process of metastasis. Our studies are specifically interested in examining the signaling occurring between tumor cells and macrophages. Previous studies have established the presence of paracrine signaling between breast cancer cells and macrophages, where colony stimulating factor 1 (CSF-1) produced by the tumor cells stimulates the production of epidermal growth factor (EGF) by macrophages, leading to chemotactic invasion of the tumor cells. In addition to this paracrine loop signaling between tumor cells and macrophages, it has been seen that macrophage expression of ErbB3, a member of the EGFR family of receptor tyrosine kinases, may play a role in facilitating tumor cell invasion. In order to examine the effects of signaling between tumor cells and macrophages in intravasation, we utilize an in vitro transendothelial migration (iTEM) assay. This assay uses transwells coated with matrigel and endothelial cells in order to mimic the entry of tumor cells into blood vessels. We show that using an ErbB3 blocking antibody results in a significant reduction of macrophage-induced transendothelial migration of breast cancer cells. Additionally, reduction of expression of the ErbB3 receptor ligand Neuregulin1 in tumor cells yields a similar result. Stimulation of macrophages with NRG1 leads to increased expression of JAG1 (JAG1), a ligand of the Notch receptor. Activation of the Notch receptor pathway has been shown to be involved in tumor cell invasion. Overall our studies look to further examine the interaction between tumor cells and macrophages, and these observations indicate that ErbB3, NRG1, and JAG1 could all serve as novel targets in metastasis and the tumor microenvironment.

**#2969 Paracrine effect of the endothelium on prostate cancer cells.** Verónica Torres-Estáya, Patricia Fuenzalida, Catalina Ascencio, Carla Cembrano, Daniela Carreño, Néstor Corro, Viviana Montecinos, Gareth Owen, Xavier Figueroa, Julio Amigo, Juan Carlos Sáez, Alejandro Godoy. Pontificia Universidad Católica de Chile, Santiago, Chile.

Prostate cancer (CaP) is the most commonly diagnosed cancer and the second leading cause of cancer deaths among males in the United States. Androgen deprivation therapy (ADT) is the standard treatment for advanced or metastatic CaP. However, during ADT, CaP progresses from an androgen-sensitive (AS-CaP) to a more aggressive, and eventually lethal, castration-resistant (CRPC) CaP. However, during ADT, CaP progresses from an androgen-sensitive (AS-CaP) to a more aggressive, and eventually lethal, castration-resistant (CRPC) CaP. Delineation of such critical players may culminate in tight control of endothelial microvasculature due to an increase in angiogenesis by tumor cells. Nevertheless, now there is evidence to support that this influence is not one-directional and that the endothelial cells secrete a large number of active substances (angiocrine factors), which may directly or indirectly influence tumor growth and progression. However, the direct impacts of the endothelium on prostate tumor progression or the molecular mechanisms that are involved in this communication remain unclear. Here we investigated the potential influence of endothelium-derived paracrine factors on prostate cancer biology and the role of connexins in these interactions, since connexins play a major role in cell-cell communication and form a bidirectional signaling pathway to assemble gap junctions and alter cell behaviors. We measured the effect of conditioned media (CM) obtained from a primary culture of human endothelial cells isolated from umbilical vein (HUVEC) on viability, proliferation, migration and invasion of CaP cell lines (LNCaP, LNCaP-C4-2 and PC3) and in the metastatic potential by in vivo assays using co-injection of CaP cell with HUVEC or inoculation of CaP cells pre-incubated with CM from HUVEC in a zebrafish embryo model. Finally, we studied the expression and the role of connexins on this stimulation using pharmacological (GJIC inhibitors) approaches. Altogether, our results showed that CM from endothelial cells induces an increase in the viability and proliferation in all CaP cell lines (LNCaP, LNCaP-C4-2 and PC3) but only increases migration of the CRPC cell lines (LNCaP-C4-2 and PC3). We also observed in our in vivo model that endothelial cells either through cell-cell interaction or by paracrine communication increases the metastatic ability of the CaP cells. Moreover, the increase in viability and migration of CaP cells observed with CM from endothelial cells was blocked using inhibitors of gap junctions. Real-time PCR analyses detected an up-regulation of Cx43 mRNA after exposition to CM from endothelial cells. Our data suggest that angiocrine communication between endothelial cells and CaP cells involves proliferation and migration of more aggressive CaP cells which could be important for the acquisition of the aggressive phenotype of the disease, and this interaction could be mediated by Cx43. Disequilibrium of such critical players may culminate in identifying therapeutic targets or biomarkers to counteract CaP, especially advanced CaP.

**#2970 Mitigating tumor-stroma metabolic symbiosis for cancer therapy.** Dhruv Kumar, Jacob New, Vikalp Vishwakarma, Hemant Chavan, Partha Kasturi, Su! M. Thomas. Kansas University Medical Center, Kansas City, KS.

Head and neck squamous carcinoma (HNSCC) affects 40,000 patients annually and is associated with <50% 5-year survival. There is an urgent need to better understand the biology of the disease in order to develop more effective therapeutic approaches. HNSCC tumors are dysplastic with up to 80% fibroblasts. We recently reported that tumor-associated fibroblasts (TAFs) make HNSCC more aggressive. Furthermore, we reported that TAFs produce heparocyte growth factor (HGF), which binds to the c-Met receptor expressed on HNSCC to drive aggressiveness. Although we did not detect HGF secretion from HNSCC cell lines, we reported that paracrine activation of c-Met by TAF-secreted HGF facilitates HNSCC progression. Reciprocal signaling between the tumor and stroma has been reported in several cancers to facilitate tumor growth, invasion and resistance to therapy. Recent studies have shown that c-Met activation promotes glycolysis. Although highly glycolytic, the mechanisms regulating HNSCC glycolysis remain unknown. We show that TAF-secreted HGF through c-Met activation on HNSCC (a) induces aerobic glycolysis accompanied by lactate production, and b) regulates expression of basic fibroblast growth factor (bFGF). Studies have shown that HNSCC tumors have high lactate levels resulting from increased glycolysis, and this correlates with reduced survival. Our data demonstrate that TAF-secreted HGF increases key glycolytic enzymes including hexokinase II. Furthermore, HGF increases glycolysis and lactate production from HNSCC. We demonstrate that HGF also increases levels of the bidirectional lactate transporter, monocarboxylate transporter 1 (MCT1). We demonstrate that MCT1 levels are increased in both HNSCC and TAFs under co-culture conditions. In addition, HGF stimulation increases levels of MCT1 in HNSCC indicating a possible mechanism whereby HNSCC remove the excess lactate generated during glycolysis. The mechanisms whereby HNSCC tumors survive highly acidic conditions remain unknown. Since MCT1 levels are increased in TAFs as well, we sought to determine if TAFs utilize the lactate as a carbon source to generate energy. Indeed, we found that bFGF secreted by HNSCC binds to its cognate FGF receptor (FGFR) on TAFs to facilitate late utilization through mitochondrial oxidative phosphorylation (OXPHOS). Thus there exists a metabolic symbiosis between HNSCC and TAFs that contribute to tumor growth. Through these studies, we delineate the mechanisms of glycolysis regulation in HNSCC and demonstrate that inhibition of the c-Met/TAF axis talk between HNSCC and TAFs can be used as a novel therapeutic approach.

**#2971 The prognostic relevance of inflammatory cytokines and growth factors elaborated from adipose-derived stem cells in breast cancer.** Nicole Wierwic!, Kelsey Sadlek, Eric Lundstrom, Daniel Berrebi, Gerald Hobbs, Linda Vona-Davis!. 1West Virginia University, Morgantown, WV; 2West Virginia University Cancer Institute, Morgantown, WV.

Introduction: Given the high rates of obesity and aggressive breast cancers, it is paramount to understand how adipose tissue supports the tumor microenvironment. We previously found that adipose-derived stem cells cultured with triple-negative tumor cells enhanced the expression of numerous pro-inflammatory cytokines. This finding is significant as it could explain, in part, how stromal contribution to worse outcomes in breast cancer. To further expand this study, we probed the Cancer Genome Atlas (TCGA) breast invasive carcinoma dataset for the expression profiles of the inflammatory cytokines we found to be highly up-regulated in vitro. We predicted TCGA data would demonstrate a correlation between cytokine overexpression and worse clinical scenarios. Methods: Cytokins and growth factors were measured in the media of: a) adipose stromal and MD-MB-231 tumor cells via membrane-based antibody array. To validate clinical significance, we compared each cytokine’s mRNA expression profile, available from primary tumor samples of TCGA breast invasive carcinoma dataset (n = 1,005), to indices of tumor progression and survival status. For survival analysis, samples were dichotomized as high or low expres-
sion by individual cytokines (z-score ≥ 1.5). Cytokine and growth factor expression was further stratified according to molecular subtype of breast cancer (luminal A, luminal B, HER2, triple negative) and receptor status. Ingenuity pathway analysis (IPA) was performed to identify candidate markers related to obesity or inflammation. Results: High levels of FGF7 and CCL5 protein were found in the condition media of tumor and adipose stem cell co-cultures and together they showed a significant impact on breast cancer survival within TCGA data. FGF7, CCL5, together with CCL2, IL6, and IL6R were further analyzed for expression across molecular subtypes of breast cancer. IL6R, CCL5, and CCL2 expression varied significantly between breast cancer subtypes, with mean expression highest in triple-negative tumors. After dichotomizing the samples according to tumor subtype status, CCL2 showed significantly higher mean expression in ER negative tumors. Greater expression of these cytokines in tumors was correlated with reduced patient survival in triple-negative tumors and ER negative subtypes. IPA analysis indicated IL6, IL6R, CCL5, and CCL2 overexpression, either independently or synergistically, predict a worse prognosis in breast cancer. For adipose-driven, hormone receptor negative breast tumors, these cytokines and growth factors could serve as novel therapeutic targets. (Supported by NIH P20GM103434 and NIGMS U54GM104942).

#2972 SPINK1, a soluble factor released by the therapy-damaged tumor microenvironment, promotes prostate cancer resistance. Fei Chen,1 Da Fu,1 Eric Lanerolle,1 Institute of Health Sciences, Shanghai Institutes for Biological Sciences, CAS, Shanghai, China; 2Shanghai Tenth People’s Hospital, Tongji University School of Medicine, Shanghai, China; 3Department of Surgery and Cancer, Imperial College London, London, United Kingdom.

Cancer evolution is driven by not only the genetic and/or epigenetic alterations of cancer cells, but also diverse factors that are derived from the surrounding tumor microenvironment (TME). Upon chemotherapy or radiation, stromal cells in the TME become senescent and develop a senescence-associated secretory phenotype (SASP) that is characterized by secretion of a large number of cytokines, chemokines, growth factors, and proteases. In most cases, the SASP is functionally regulated by the DNA damage secretory program (DDSP) and pathophysiologically responsible in vivo for disease exacerbation. We recently disclosed significant upregulation of the serine protease inhibitor Kazal type 1 (SPINK1) in primary normal human prostate fibroblasts after exposure to DNA damaging agents. SPINK1 plays critical roles in cancer cell proliferation, survival and motility in multiple human malignancies, but its influence as a soluble TME-associated factor on cancer progression remains unknown. In this study, we performed a series of molecular and cellular studies to define the biological roles of SPINK1 in an activated TME. Promoter analysis indicated that SPINK1 expression in the fibroblasts is regulated by multiple transcriptional factors including the NF-κB complex in response to genotoxic stress. Fibroblast-derived SPINK1 can significantly enhance the aggressiveness of prostate cancer cells including accelerated proliferation, increased migration, elevated more importantly, enhanced chemo-resistance. SPINK1 triggers a typical epithelialmesenchymal transition (EMT) in cancer cells, a process mediated by EGF/P13H/Akt and MAPK/Erk signaling pathways. Consistent with the in vitro data, our in vivo studies suggested that SPINK1 expression in the prostate TME substantially promoted cancer survival and disease progression. Clinical investigation revealed increased expression of SPINK1 in the stroma of multiple organ types including the prostate, lung and breast of cancer patients after chemotherapy, implying the systemic induction of SPINK1 by anticancer agents. Overall, our study demonstrates that SPINK1 is a soluble biomarker of therapeutically damaged TME and represents a potentially exploitable molecular target in human prostate cancer clinics.

#2974 Obesity-induced modifications in the mammary gland microenvironment promote TNBC progression even after weight loss. Alyssa J. Gozzo, Ottavia Lambi Zattria, Alex J. Freerman, Liaz Makowski. UNC-Chapel Hill, Chapel Hill, NC.

Obesity contributes to 20% of US female cancer deaths and is linked to increased risk for triple negative breast cancer (TNBC), as well as increased risk of vascular invasion, metastasis, and mortality in breast cancer patients. We previously showed that obesity-induced elevation of hepatocyte growth factor (HGF) signaling through its receptor, cMET, accelerated development of tumors in the C3(1)-TAg GEMM of TNBC compared to low fat diet (LFD)-fed lean controls. Weight loss significantly reduced HGF/cMET signaling in normal mammary glands and cMET in tumors, and reversed high fat diet (HFD)-driven tumor progression, while crizotinib-mediated cMET inhibition limited tumor development and microvascular density in both lean and obese C3(1)-TAg mice. To differentiate tumor-intrinsic versus microenvironment-associated mechanisms, we employed an orthotopic transplant model of a C3(1)-TAg TNBC cell line to investigate tumor growth dynamics in lean, obese, or formerly obese (FOB) microenvironments. We hypothesized that TNBC tumors derived from lean C3(1)-TAg cells in both low fat diet (LFD) and high fat diet (HFD) environments will grow more rapidly, contain more macrophages (Mfs) and exhibit greater blood vessel density than tumors in lean or FOB mice due to obesity-induced MF and/or endothelial secretion of HGF. At 8 weeks of age, female FVB/NJ mice were randomized to diet groups (N=20/diet): 1) lean (LFD, 10% kcal from fat), 2) obese (HFD, 60% kcal from fat) 3) FOB (HFD, 5 weeks; LFD, 5 weeks). Following 10 weeks on diets mice were analyzed for breast tumor burden, localization, regional lymph node metastasis by diet group, as well as quantification of pro-growth and pro-angiogenic signaling molecules (e.g., HGF, VEGF, Ang2) in lysates of tumors and tumor-adjacent adipose. Tumor volume was measured by calipers. At 21 days post-injection mice were sacrificed for tissue collection. Normal mammary gland, tumors, and tumor-adjacent adipose + tumor-draining lymph node were collected for histological examination and gene expression analysis. Mammary fat pad mass in obese FVB/NJ mice (0.27 g) was significantly greater than lean (0.14 g) or FOB animals (0.11 g) (P<0.0001). Tumor volume at sacrifice was significantly greater in obese vs lean animals (190 mm3 vs 89.96 mm3, respectively; P<0.05). However, mean final tumor volume in FOB animals (148.0 mm3) did not differ significantly from either lean or obese mice. Our findings show that obesity accelerated tumor progression relative to lean mice. C3(1)-TAg cells transplanted into FOB mice resulted in an intermediate rate of tumor growth, suggesting that obesity-mediated changes to the microenvironment were not fully overcome by obesity. Despite normalization of body weight and adiposity, to elucidate how the FOb mammary microenvironment persists in driving TNBC tumor promotion, planned analyses include histological examination of candidate mediators, including MF infiltration and regional lymph node metastasis by diet group, as well as quantification of pro-growth and pro-angiogenic signaling molecules (e.g., HGF, VEGF, Ang2) in lysates of tumors and tumor-adjacent adipose.

#2975 Collagen type XI alpha 1 confers cisplatin chemoresistance in ovarian cancer through inhibition of apoptosis proteins (IAPs). Miran Rada,1 Jennifer Cha,2 Jessica Sage,1 Sandra Orsulic,1 Dong-Joo Cheon,1 1Albany Medical College, Albany, NY; 2Rensselaer Polytechnic Institute, Troy, NY; 3Cedars-Sinai Medical Center, Los Angeles, CA.

Ovarian cancer is the most lethal gynecological cancer, which affects one in seven females in the United States during their lifetime. While cisplatin is the frontline treatment for ovarian cancer, chemoresistance severely limits the treatment success. The goal of this study is to identify novel therapeutic targets to overcome cisplatin resistance. We recently identified Collagen type XI alpha 1 (COL11A1) as a novel biomarker associated with cisplatin resistance in ovarian cancer. COL11A1 is a component of the tumor stroma and its expression is restricted to cancer-associated fibroblasts (CAFs) adjacent to tumor cells. We further showed that COL11A1 protects ovarian cancer cells from cisplatin-induced apoptosis, yet the underlying mechanism is largely unknown. To understand the molecular mechanism by which COL11A1 protects cancer cells from cisplatin-induced apoptosis, we overexpressed COL11A1 in ovarian cancer cells and performed RNA-Seq. Our RNA-Seq data revealed that COL11A1 did not change the levels of genes associated with cisplatin resistance. Instead, COL11A1 promoted cell viability in cancer cells, which are well-established mechanisms to confer cisplatin resistance. Rather, COL11A1 enhances the expression of the Inhibitors of Apoptosis Proteins (IAPs), including XIAP, BIRC2 (c-IAP1) and BIRC3 (c-IAP2). Using a full-length COL11A1 protein, genetic manipulation, and co-culture method, we confirmed that COL11A1 significantly increases the expression of IAPs upon cisplatin treatment. The inhibition of XIAP, BIRC2 and BIRC3 with an IAP antagonist BV6 attenuated the ability of COL11A1 to inhibit cisplatin-mediated apoptosis. Our data indicates that COL11A1 activates Akt, and Akt is known to phosphorylate XIAP at serine-87, which protects it from ubiquitination and degradation in response to cisplatin. Collectively, our data identify IAP as a mediator of COL11A1’s action in blocking cisplatin-induced apoptosis.

#2976 Critical role of spatial location of hypoxia and its association with astrocytes in the resistance of brain tumor to therapy. Chi-Muin Lin, Chi-Shun Chang, National Tsing-Hua University, Hsinchu, Taiwan.

Many reports have shown that hypoxia and gliosis could promote tumor cells by shielding from the immune response and relaxing, but their roles on brain tumor therapies are still unclear. Using an invasive murine astrocytoma tumor model, A1T5C1, we found that tumor invasion front is associated with a specific hypoxia region, naming tumor peripheral hypoxia, contributes to brain tumor therapy resistant and may be responsible for tumor recurrence after the therapy. Using this tumor model, we found that the overgrowing tumor caused the shortage of vessels and resulted in the hypoxia in the early stage of tumor progression, which is con-
#2977 Secretory autophagy in tumor associated fibroblasts promotes head and neck squamous cell carcinoma progression and emerges as a novel therapeutic target. Jacob New, Levi Arnold, Mehta Ananth, Sameer Ali, Wen-Xing Ding, Sufi M. Thomas. University of Kansas Medical Center, Kansas City, KS.

As the fifth most common cancer worldwide, head and neck squamous cell carcinoma (HNSCC) is a leading global health burden. Despite therapeutic advancements, the survival rate has remained relatively unchanged for the last fifty years. To improve treatment and survival, there is a need to better understand the underlying biology of this disease. The tumor microenvironment's role in promoting cancer progression and resistance to therapy has garnered great attention. In HNSCC, the predominant microenvironment cell type is tumor associated fibroblasts (TAFs). Studies in our lab and others have demonstrated the significant tumor promoting role of TAFs; however, little is understood of the underlying biology of TAFs. In this study, we identify that TAFs have upregulated an unconventional pathway of secretory autophagy. Although paradigmatically a degradation pathway, there has been a growing appreciation for a novel role of autophagy in cellular secretion. We hypothesized HNSCC induces secretory autophagy in the TAFs, modulating secreted factors responsible for tumor progression. We assessed the role of autophagy inhibition in alleviating TAF-facilitated HNSCC progression, and uncovered a significant reduction in proliferation, migration, and invasion of the cancer cells. This was achieved by both siRNA knockdown of Beclin-1, and therapeutic inhibition of the lysosome through chloroquine. We discovered that NPs placed in co-culture with HNSCC had a significantly upregulated level of autophagy marker LC3-II. By characterizing the role of known HNSCC secreted factors in inducing TAF autophagy, we identified basic fibroblast growth factor as responsible for the LC3-II accumulation. To understand which TAF factors are secreted by an autophagy dependent mechanism, we assessed TAF-conditioned media in the presence of autophagy knockdown. Key cytokines, such as IL-6 and IL-8, were identified as autophagy dependent. Rescue of these cytokines in autophagy inhibited TAF-conditioned media restored HNSCC migration. Although autophagy has been identified as upregulated in a variety of cancer types, no one has previously characterized the role of autophagy in HNSCC, and both early pre-clinical and clinical studies of autophagy inhibition as a cancer therapy have been limited by the lack of a specifically targeted inhibitor. We demonstrate a significant decrease in HNSCC progression in preclinical models by using a new and highly specific small molecule inhibitor of autophagy, SAR405, which inhibits Vps34, an upstream autophagy pathway kinase. In summary, we uncover a novel role for secretory autophagy in the tumor microenvironment which promotes tumor progression, and can be uniquely targeted for therapy.

#2978 Discrete super-enhancer networks in pancreatic cancer cells and cancer associated fibroblasts are targeted and modulated by triptolide. Pawan Noel, Serina Ng, Ruben Munoz, Daniel Von Hoff, Haiyong Han. Translational Genomics Research Institute (TGen), Phoenix, AZ.

Background: Pancreatic cancer (PC) is the 3rd leading cause of adult cancer death in the USA. Pancreatic ductal adenocarcinoma (PDAC) accounts for >90% of all PC cases and has a dismal 5-year survival rate of <6%, mostly due to lack of reliable methods for early detection, and limited treatment options. A unique, highly fibrinous and hypo-vascularized tumor stroma or “desmoplastic reaction” (DR) forms the major barrier to currently available therapeutic approaches. Activated cancer associated fibroblasts (CAFs) play an important role in driving and maintaining the DR in PDAC. Thus therapeutic regimens that reprogram pancreatic CAFs can potentially enhance sensitivity to anti-tumor agents and may improve patient outcomes. Recent studies implicate the role of super-enhancers (SE) in maintaining cell specific gene expression networks in both normal and diseased cells. Here we aim to define SE networks in pancreatic CAFs and epithelial tumor cells and explore the role of triptolide in modulating SE signatures. Methods: Using genomic techniques on control vs triptolide treated pancreatic tumor and CAF cells, we measured occupancy of BRD4 and acetylated histone 3 at lysine27 (H3K27ac), marks of active SEs, using Chip-seq. RNA-seq revealed differentially regulated genes via SE modulation by triptolide. Immunoblotting was performed to validate the effect of triptolide on the protein expression of key regulatory SEs. Results: Importantly, we found that the formation of tumor peripheral hypoxia might be associated with the activation of astrocytes. Therefore, tactics that can suppress astrocytosis and prevent the formation of peripheral hypoxia may be alternative approaches for complementing the shortage of traditional brain tumor therapy.

#2979 Inhibition of palladin in cancer associated fibroblast impedes pancreatic ductal adenocarcinoma associated desmoplasia. Jennifer L. Alexander, Edna Cukierman. Drexel University College of Medicine, Philadelphia, PA; Fox Chase Cancer Center, Philadelphia, PA.

Pancreatic Ductal Adenocarcinoma (PDAC) claims 97% of patient lives in less than 5 years after diagnosis. Treatment of PDAC is challenged by the collagen-rich, highly dense, fibrinous-like extracellular matrix (ECM) known as desmoplasia. Desmoplasia is initiated by activated cancer associated fibroblasts (CAFs) and disseminates throughout the stromal compartment in a vicious cycle involving alterations to the physical/structural and biochemical pathways in neighboring naïve fibroblasts that ultimately enriches theCAF population. This desmoplastic-ECM (D-ECM) encapsulates the tumor mass, thereby limiting therapeutic paradox. Paradoxically, ablation of D-ECM induces a more aggressive PDAC progression. Although the underlying biology remains unclear, the D-ECM is a consequence of cytoskeletal rearrangements occurring amid the CAFs. The goal of this study is to delineate the cytoskeleton dynamics engaged as a potential mechanism to restore the innate tumor-suppressive properties of a normal ECM. As such, this study focuses on the actin cross-linker palladin which has been identified as an independent prognostic marker in PDAC progression. We postulate palladin has an isomorphic-specific role in PDAC desmoplasia as well as cancer progression. Using an in vivo-mimetic 3D fibroblast-derived ECM model, we explore the isomorphic-specific role of palladin during D-ECM onset as well as during D-ECM-induced CAF activation in PDAC patient derived CAFs in which the major palladin isoforms (isoforms 3 and 4) were knocked out via CRISPR/Cas9 gene editing. Using these cells, we examined the activation status of the CAFs while characterizing the ECM produced via quantitative immunoblots, real-time polymerase chain reaction, and detailed microscopy analyses. We then validated the effects of palladin knockout CAFs activity in influencing kras mutated cancer cells’ metabolic activity, invasion and proliferation. Our data indicates palladin isoforms 3 and 4 expression are necessary to drive CAF activation as well as perpetuate the D-ECM phenotype whereby knockdown of either isoform prevents CAF activation while limiting cancer cell behavior. Additionally, the ECM produced by the palladin knockout CAFs were no longer capable of activating naïve fibroblast in addition to decreasing the inherent aggressive nature of kras-mutant cancer cells. These results are similar to previous findings regarding the restrictive nature of a normal ECM on CAF activation and cancer cell behavior. These findings suggest that palladin isoforms 3 and 4 are required for desmoplastic onset and D-ECM-induced fibroblastic activation and cancer cell progression. Together, these results propose manipulation of specific palladin isoforms could signify a strategy to restore a normal tumor-suppressive stroma in PDAC.
TUMOR BIOLOGY: Tumor Microenvironment

Introduction: Our group has recently demonstrated that CBS, one of the H2S-producing enzymes, is abundantly overexpressed in human colorectal cancer (CRC) tissue specimens resulting in an increased H2S production. In order to extend our observations, we have now compared, using immunohistochemistry, CBS expression in carcinoma-associated fibroblasts (CAFs) compared to normal colon fibroblasts (NCFs) in human colon adenocarcinoma samples. The overall goal of our studies is to characterize how the CBS/H2S axis contributes to the malignant phenotype of the CAFs in the tumor microenvironment. Methods: Human CAFs and NCFs were collected from CRC under an IRB approved protocol and cultured in vitro. Western blot analysis of both NCF and CAF was performed to determine CBS protein expression levels. siRNA/shRNA-mediated silencing of CBS in CAFs was performed. A pharmacological inhibitor of CBS, aminooxyacetic acid (AOAA), in both CAF and NCF cultures was also utilized. Hydrogen sulfide (H2S) levels were measured using the fluorogenic probe 7-Azido-4-methylcoumarin. We also performed proliferation assays using a couler counter in CAFs, NCFs, and CAFs subjected to siRNA/shRNA-mediated CBS silencing or AOAA. Control cells were transfused with shNT vectors. Cells were also treated with the slow-releasing H2S donor GYY4137. We also conducted cell migration assays in transwell chambers (migration of CAFs toward conditioned media (CM) collected either from HCT116 cells or normal colon mucosal cells (NCM356). Finally, the XF24 Extracellular Flux Analyzer (Seahorse) was used to measure bioenergetic function in CAFs subjected to siRNA/shRNA-mediated silencing of CBS or treated with AOAA. Results: CBS protein expression and H2S production in CAFs was increased compared to NCFs. The H2S donor GYY4137 increased the proliferation of CAFs but not of NCFs. CBS silencing or AOAA treatment reduced CAF migration toward conditioned media from HCT116 cells. Genetic or pharmacological inhibition of CBS in CAF cells suppressed key bioenergetic parameters including basal respiration, ATP production, maximal respiratory capacity, and spare respiratory capacity compared to NCF cells or CAF shNT controls. Conclusions: Thus, CBS/H2S axis serves as a mechanism to support CAFs function. In these cells, H2S contributes to maintaining their bioenergetic functions, which, in turn, promotes their proliferation and migration toward colon cancer cells. We hypothesize that these processes may contribute CRC progression.

#2981 Identification of circulating stroma-related biomarkers for pancreatic ductal adenocarcinoma. Andrea Resovi,1 Luca Porcu,1 Alessia Anastasia,1 Paola Allavena,2 Paola Cappello,1 Anna Falanga,3 Giulia Tarabotti,3 Mariarossa Bani,1 Dorina Belotti,1 Raffaella Giavazzi,1 Istituto di ricerche farmacologiche Mario Neri, Milano e Bergamo, Italy;2 Humanitas Clinical and Research Center, Rozzano, Italy;3 CeRMS, University of Torino, Torino, Italy;1 Department of Immunohaematology and Transfusion Medicine, Bergamo, Italy.

Pancreatic ductal adenocarcinoma (PDAC) is one of the most aggressive epithelial malignancies characterized by a relevant amount of tumor stroma. It is usually diagnosed late and has limited treatment options. Plasmatic markers capable of detecting the disease in its early stages and monitoring treatment effectiveness might change the fate of PDAC patients. This study investigates the potential value of circulating stroma-related molecules as PDAC biomarkers capable to detect the disease and to monitor treatment response. Thirty-eight stroma-related candidate biomarkers were selected from published proteomic studies on PDAC. Levels of these molecules were tested by ELISA and Multiplex Luminex assays in a first cohort of plasma samples from PDAC patients and healthy subjects. Thirteen molecules–extracellular matrix proteins and proteolytic fragments, matrix-degrading enzymes and their inhibitors, growth factors and adhesion molecules–were found to be differentially expressed in PDAC plasma compared to healthy subjects. A second analysis in an independent cohort of PDAC patients, chronic pancreatitis patients and healthy controls confirmed the previous findings and allowed restricting the number of biomarkers up-regulated in the plasma of PDAC patients. The plasma analysis of two genetically engineered mouse models of pancreatic cancer [Pdx-1 Cre;LSL-KrasG12D] and Pdx-1 Cre;LSL-KrasG12D;LSL-Trp53R172H] revealed an up-regulation of four markers in association with PanIN development, indicating their potential role in the early diagnosis of pancreatic cancer. These markers were also elevated in the plasma of mice bearing patient derived orthotopic PDAC xenografts (PDAC-PDX), but not in a mouse model of caerulein-induced chronic pancreatitis. Their level was associated with PDAC-PDX tumor growth and response to gemcitabine combined with nab-paclitaxel. In conclusion this analysis has identified a panel of stroma-related potential biomarkers associated with tumor progression and drug response of PDAC. Supported by Associazione Italiana per la Ricerca sul Cancro (AIRC 5 per mille grant n. 12182) and Fondazione “Eugenio Morandi” ONLUS for the studio e la cura dei tumori del pancreas.

#2982 Metastatic and non-metastatic colorectal cancer cells differentially regulate fibroblast cell cycle via extracellular vesicles. Rahul Bhole, Louise M. House, Tilman Sanchez-Elsner, Stephen M. Thirdborough, Emre Sayan, Alex H. Mirmazei. University of Southampton, Southampton, United Kingdom.

Cancer-associated fibroblasts are critical to tumor progression. There exists a dynamic crosstalk between cancer and stromal components, which maintains a permissive tumor microenvironment. Extracellular vesicles (EVs) play a significant role in this intercellular communication. Colorectal cancer (CRC) cells can be categorized according to epithelial-mesenchymal transition (EMT) status, and therefore metastatic capacity. We aimed to investigate the effect of EMT on EV-mediated cancer-fibroblast signaling. CRC cells (SW1573, SW620, HCT116, and DLD-1) were transduced by lentiviruses to be EMT, and western blotting to determine EMT status. EVs were isolated from conditioned media by serial centrifugation and validated by transmission electron microscopy, western blotting and nanoparticle tracking analysis. Fluorescently labeled EVs and cells were detected and evaluated by flow cytometry and fluorescence microscopy. Increasing concentrations of EVs from CRC cells were co-cultured with fibroblasts for 24h. Activation/inhibition of signaling pathways was examined by western blotting. EV microRNA (miRNA) profiles were obtained, validated by qPCR and submitted for target and pathway analysis. DLD-1, HCT116 and SW620 cells express E-cadherin and are considered epithelial, whereas SW480 lacks E-cadherin, expresses ZEB-1, and is considered mesenchymal. EVs were spherical, enriched in AID, FRPC, IGFR1, and TXNIP. AID expression correlated with the level of EVs. EVs were shown to transfer directly to primary ex vivo patient-derived fibroblasts and fibroblast cell lines. Transfer of EVs from epithelial CRC cells abrogated ERK activity in fibroblasts, even at the lowest concentration, and was associated with reduced fibroblast proliferation, whereas EVs from mesenchymal cells had no effect. MiRNA profiling of EVs from epithelial and mesenchymal CRC cells showed a 10-fold upregulation of mir-143-3p in epithelial compared to mesenchymal EVs. MiRNA target analysis and experimental validation show that mir-143-3p directly targets KRAS and HRAS, providing a potential miRNA-orchestrated mechanism of action for the downregulation of fibroblast ERK activity in the tumor microenvironment. Importantly, CRC cellular ERK activity is not reflected in fibroblasts treated with CRC EVs, suggesting that EVs do not directly transmit ERK protein or miRNA. However, miRNAs are the most stable EV cargo, and we show that epithelial but not mesenchymal CRC EVs contain upregulated miRNAs, which target critical components of the ERK pathway. Downregulation of ERK activity has been shown to induce fibroblast senescence, a phenotype linked to cancer progression. We hypothesize that differential regulation occurs because epithelial CRC cells are juxtaposed with fibroblasts in the tumor core, where senescent cancer associated fibroblasts are frequently observed, whereas mesenchymal CRC cells are at the invasive front or in the circulation.

#2983 Tumor induced stromal STAT1 deregulates mammary tissue homeostasis and accelerates breast cancer. Victoria R. Zellmer, Patricia M. Schnepp, Sarah L. Fracci, Xuejuan Tan, Erin N. Howe, Siyuan Zhang. University of Notre Dame, Notre Dame, IN.

The tumor microenvironment (TME) – the dynamic tissue space in which the tumor exists – plays a significant role in tumor initiation and is a key contributor in cancer progression. Little is known about the tumor-induced changes in the adjacent tissue stroma. Herein, we sought to explore tumor-induced changes in the TME at the morphological and molecular level to further characterize cancer progression. We show that tumor-adjacent mammary glands (TAGs) display altered morphology, increased expression of αSMA particularly in myofibroblasts, and an increased capacity to form mammospheres in 3D suspension culture. FACS analysis showed that TAGs contain an increased number of Lin-CD24+/CD49+ enriched mammary gland stem cell (MaSCs) population, suggesting deregulated tissue homeostasis in TAGs. We conducted comparative transcriptomics on TAGs and contralateral control glands. Meta-analysis on differentially expressed genes from our RNA-seq dataset revealed two biological subsets identified shared upregulation of STAT1, which we verified in tumor-adjacent tissues. Knockdown of STAT1 in cavelin-deficient mouse embryonic fibroblasts (CAFs) cocultured with human breast cancer cells altered cancer cell proliferation, further suggesting the role of STAT1 as a stromal contributor of tumorigenesis. Furthermore, in our proof-of-concept in vivo experiment, co-treatment with fluorudarine, a FDA-approved STAT1 activation inhibitor and DNA synthesis inhibitor, in combination with doxorubicin, showed enhanced therapeutic efficacy in treating mouse mammary gland tumors. Our results demonstrate that stromal STAT1 expression could promote tumor progression and is a potential therapeutic target for breast cancer.

### #2984 The chemokine CCL2/CCR2 signaling mediated fibroblasts-cancer cells crosstalk promotes basal like breast cancer progression. Min Yao, Wei Bin Fang, Fang Fan, Nehemiah Alvarez, Patrick E. Fields, Nikki Cheng. University of Kansas Medical Center, Kansas City, KS.

Cancer associated fibroblasts are the most abundant stromal cells in breast cancer, but their function in cancer progression has not been fully understood. We previously identified that the chemokine CCL2 was highly expressed in breast cancer associated fibroblasts, and high stromal CCL2 expression predicted poor outcome in basal like breast cancer. CCL2 is known to recruit monocyte/macrophage and promotes cancer progression. We previously found that recombinant CCL2 can directly signal to breast cancer cells and promote cell survival and invasion in vitro. In this study, we aimed to determine the functional importance of CCL2 signaling mediated fibroblast-cancer cell interactions in breast cancer progression. We used a fibroblast and cancer cell co-graft mouse model as the main functional assay. We generated primary fibroblasts from mouse mammary tumor and human breast cancer, and confirmed most of them expressed high level of CCL2. When co-grafted with the human basal breast cancer cell line MCF10A-CA1D into nude mice, fibroblasts enhanced xenograft growth. Stable knockdown of CCL2 expression from fibroblasts significantly reduced its ability in tumor growth promotion, while knockdown CCL2 from cancer cells did not. Decreased CCL2 production from fibroblasts resulted in increased apoptosis and autophagy in tumor samples. To determine the importance of direct CCL2 signaling to cancer cell, we generated the CCL2 receptor cCR2 adenovirus cell line and CCR2 null cell lines by CRISPR-Cas9 targeting technology. Mutation of CCR2 in cancer cell significantly reduced tumor growth when co-grafted with CCL2 secreting fibroblasts. Lastly, we tested continuous delivery of CCL2 neutralizing antibody in the co-graft tumor model, but observed minimal therapeutic effect. Further examination of blood CCL2 level revealed an increased production of CCL2 from fibroblasts and mouse host after antibody treatment, which may contribute to the lack of therapeutic effect. In summary, our studies demonstrated the importance of CCL2/CCR2 signaling mediated fibroblasts-cancer cell interaction in basal like breast cancer progression. The CCL2 signaling pathway can be potentially served as therapeutic target, but requires development of efficient targeting strategy.

### #2985 Interaction between the malignant melanoma cell of the primary lesion and the metastatic lesion. Takaharu Hatano,1 Hisashi Motomura,1 Heishiro Fujikawa,1 Masakazu Yashiro,2 Kishu Kitayama3. Department of plastic and reconstructive surgery, Osaka City University Graduate School of Medicine, Osaka, Japan; 2Department of Surgical Oncology, Osaka City University Graduate School of Medicine, Osaka, Japan; 3Department of Surgical Oncology, Osaka City University Graduate School of Medicine, Osaka, Japan.

Introduction: The prognosis of patients with malignant melanoma is extremely poor because of the frequent metastasis. We have occasionally experienced the clinical cases that malignant melanoma patients rapidly developed distant metastases after the surgical resection of primary cancer lesion. These cases suggested that a primary tumor may control a metastatic tumor. We hypothesized that primary melanoma cells might produce a factor(s) which regulate the progression of metastatic melanoma cells. Then we investigated the growth and invasion interaction between primary malignant melanoma cells and high metastatic melanoma cells. Materials and methods: We used two malignant melanoma cell lines, B16 as a parent primary melanoma cell line and a selected daughter cell line B16/BL6 with high metastatic ability. We investigated the invasive interaction between the parent B16 cells and daughter B16/BL6 cells in vitro. The conditioned medium from B16 cells and B16/BL6 cells was added to B16 cells or B16/BL6 cells. Then we examined the effect of these conditioned medium on the motility and proliferation of melanoma cells by MTT assay or invasion assay at 24 hours and 72 hours after the addition of the conditioned medium. Results: The conditioned medium from B16 cells significantly (p=0.02) suppressed the invasion ability of B16/BL6 cells at 24 hours after the addition of the conditioned medium. In contrast, the invasion ability of B16 cells were not affected by the conditioned medium from B16/BL6 cells at 24 hours. Each conditioned medium did not affect on the proliferation of both melanoma cell lines. On the other hand, at 72 hours after the addition of the conditioned medium from B16 cells significantly (p=0.000003) suppressed the growth of B16/BL6 cells. Conclusion: Primary melanoma cells might down-regulate the progression of metastatic melanoma cells by a soluble factor(s).

### CLINICAL RESEARCH: Clinical Biomarkers

#### #2986 Atezolizumab in metastatic TNBC (mTNBC): Long-term clinical outcomes and biomarker analyses. Peter Schmid,1 Cristina Cruz,2 Fadi S. Braiteh,3 Joseph Paul Ender,4 Sara Tolany,5 Irene Kuter,6 Rita Nanda,7 Cathie Chung,8 Philippe Cassier,9 Jean-Pierre Delord,10 Michael Gordon,11 Yijin Li,12 Bo Liu,13 Carol O’Hear,14 Marcella Fasso,15 Luciana Moliniero,16 Leisha A. Emens,17 Barts Cancer Institute, Queen Mary University London, London, United Kingdom; 2Vall d’Hebron University Hospital, Barcelona, Spain; 3Comprehensive Cancer Centers of Nevada, Las Vegas, NV; 4Yale School of Medicine, New Haven, CT; 5Dana Farber Cancer Institute, Boston, MA; 6Massachusetts General Hospital, Boston, MA; 7University of Chicago Medical Center, Chicago, IL; 8The Angeles Clinic and Research Institute, Los Angeles, CA; 9Centre Leon Berard, Lyon, France; 10Institut Claudius Regaud, Toulouse, France; 11Pinnacle Oncology Hematology, Scottsdale, AZ; 12Genentech, Inc., South San Francisco, CA; 13Johns Hopkins University School of Medicine, Baltimore, MD.

Introduction. Triple negative breast cancer (TNBC) has a poor prognosis and limited treatment options. Atezolizumab (atezo) is a humanized mAb that inhibits the binding of PD-L1 to PD-1 and B7.1, thus restoring tumor-specific T-cell immunity. Atezo was evaluated in an expansion cohort of mTNBC patients (pts) in a Phase Ia study (NCT01375842). Methods. Enrollment was initially limited to TNBC pts with PD-L1 on ≥5% of tumor infiltrating immune cells (IC2/3), then opened to pts regardless of PD-L1 status. Pts received atezo IV in 1L or 2L q3w at 15 or 20 mg/kg or 1200 mg for 1y with option to be retreated at PD, or until loss of clinical benefit. ORR was assessed by RECIST v1.1 and irRC, to capture non-conventional responses. Baseline PD-L1 expression on IC was centrally scored as IC0/1/2/3 (VENTANA SP142 assay). Pretreatment tumors and on-therapy biopsies were evaluated for TILs, CD8 T cells and macrophages by IHC. Results. As of Mar 31, 2016, 115 mTNBC pts were safety evaluable; atezo was generally well tolerated. There were no additional safety signals from prior report (Emens AACR 2015). 112 pts with FU ≥12 wk were evaluable for response. Based on irRC, ORR in 1L and 2L+ pts were 26% and 11%, respectively. ORR for PD-L1 IC2/3 pts were 17% vs 8% in IC0/1, mDoR was 21.1 mo (3 to 34+). mOS of responders (n=15) was not reached (4+ to 37+ mo) with no deaths as of data cutoff. mOS of non-responders who lived ≥6 wk (n=87) was 9 mo (1+ to 19+ mo). ORR rates in all pts at 1, 2, and 3 y for PD-L1 IC2/3 were 45%, 28% and 28%, respectively. Pts whose tumors had >10% TILs or ≥1.5% CDB in the tumor centered trended higher ORR and longer OS. Atezo increased intratumoral TILs, CD8, macrophages and IC PD-L1 expression, but no response association was observed. Conclusions. In mTNBC, atezo was well tolerated. Responders showed durable clinical benefit. Response rates were higher in 1L or PD-L1 IC2/3 pts. Baseline TILs and CD8 were associated with greater clinical benefit.

#2987 Validation and clinical feasibility of a comprehensive genomic profiling assay to identify likely immunotherapy responders through tumor mutational burden (TMB). Daniel S. Lieber,1 Mark R. Kennedy,1 Douglas B. Johnson,2 Jonathan E. Rosenberg,2 Marcin Kowarz,2 Joel R. Greenbowe,1 Garrett M. Frampton,1 Caitlin F. Connelly,1 Alexis B. Schroch,1 Jeffrey S. Ross,1 Philip J. Stephens,2 Siraj M. Ali,1 Vincent A. Miller,1 David A. Favierdi,1 Foundation Medicine, Inc., Cambridge, MA; 2Vanderbilt University, Nashville, TN; 3Memorial Sloan Kettering Cancer Center, New York, MA; 4Genentech, Inc., South San Francisco, CA.

Background: Patients across a range of disease types have demonstrated robust and durable responses using checkpoint inhibitor therapies (CPTs). Given the limitations of immuno-histochemical based testing, identifying a unified, quantitative metric to predict clinical response to CPTs, tumor mutational burden (TMB) measures the number of somatic protein coding mutations per target sequence in a tumor specimen. This measure has been associated with response and survival for multiple CPTs across an array of indications. In this study we describe Foundation Medicine’s (FMI) work to develop and validate a TMB result as part of our comprehensive genomic profiling assays and summarize clinical feasibility in NSCLC, melanoma and bladder cancer.

Methods: We developed an analysis method to determine TMB based on data from our comprehensive genomic profiling assays. TMB is calculated by counting all synonymous and non-synonymous somatic variants across 315 or 405 genes, excluding germline alterations and known or likely driver alterations. The mutation count is normalized by the coding target territory to achieve a mutation density of mutations per megabase (mut/Mb). To determine accuracy, we compared TMB values from our comprehensive genomic profiling assay against a CLIA-validated whole-exome sequencing (WES) method on 29 patients. Precision was assessed over 10 clinical samples replicated 4-6 times. Lower limit of sample tumor purity was determined through dilutions of tumor/normal pairs from 80% to 3% tumor. Clinical feasibility was assessed by analyzing TMB versus immunotherapy-based survival in a cohort of 65 metastatic melanoma patients, 150 urothelial carcinoma patients and 463 NSCLC patients. Additionally, we examined the relationship between TMB and microsatellite instability status (MSI), an independent biomarker associated with response to CPTs. Results: Foundation Medicine’s TMB measure provides accurate and precise results across a range of tumor mutational burden values on samples with as little as 20% tumor purity. Using cohort specific thresholds, TMB was significantly associated with improved survival in CPTs in NSCLC, melanoma and bladder cancer. Using data from over 40,000 patient samples, we also show significant overlap between high TMB and high MSI samples and show that MSI-High specimens represent a subset of TMB-High specimens. Conclusions: We have developed and validated the tumor mutational burden (TMB) biomarker as part of our comprehensive cancer genomic profiling assays. Initial clinical feasibility results demonstrate that TMB can be used to predict the likely response to anti-PD-1/PD-L1 CPTs across a growing number of indications including NSCLC, melanoma and bladder cancer.

#2988 Immunogenomic analyses of tumor cells and microenvironment in patients with advanced melanoma before and after treatment with nivolumab. Timothy A. Chan,1 Nadeem Riaz,2 Jonathan J. Havel,1 Vladimir Makarov,1 Alexis Desrichard,1 Jennifer S. Sims,1 F. Stephen Hodi,2 Salvador Martin-Algarra,3 William H. Shafman,4 Shailender Bhatia,5 Wen-Jen Hwu,5 Thomas F. Gajewski,6 Craig L. Introduction: Autologous anti-CD19 CAR T cells determined by single-cell multiplex proteomics associated with clinical activity in patients with advanced Hodgkin’s lymphoma. John Rossit,1 Patrick Pazkowski,1 Yueh-wei Shen,2 Kevin Morse,3 Brianna Puyatt4, Alaina Kaiser3, Colin Ng,5 Kyle Gallatin,5 Tom Cain,6 Yong Fan,6 Sean Mackay,7 James Heath,8 Steven A. Rosenberg,9 James N. Kochenderfer,10 Jing Zhou,1 Adrian Bot1,1 Kite Pharma, Santa Monica, CA;2IspIcics, Branford, CT;3Yale School of Engineering and Applied Science, Yale University, New Haven, CT;4Division of Chemistry and Chemical Engineering, California Institute of Technology, Pasadena, CA;5Surgery Branch, National Institutes of Health, Bethesda, MD;6Experimental Transplantation and Immunology Branch, National Institutes of Health, Bethesda, MD.

Introduction: Autologous anti-CD19 CAR T cells have shown promising clinical efficacy in B cell malignancies, with T cell expansion and blood levels for IL-15, IL-10 and Granzyme B as correlates of objective response and treatment, mutational and neoantigen load were comparable, regardless of previous treatment. Following nivo treatment, both mutational and neoantigen load were reduced 5-fold in pts who responded (CR/PR; n=9) and 1.2 fold in pts with stable disease (SD, n=13) compared with a 1.1-fold increase in pts with progressive disease (PD, n=19). Intratumoral heterogeneity analysis before and after nivo demonstrated a decrease in the evenness of T-cell clonotype distribution was observed among pts with CR/PR/SD relative to pts with PD in the ipi-N cohort (P=0.036), but not in the ipi-P cohort. Conclusion: Nivo and ipi modulate T-cell repertoire and tumor mutational heterogeneity in pts with advanced melanoma, presenting potential mechanisms of action underlying successful nivo therapy. These data also show that prior ipi treatment may influence biological response to nivo, but further investigation is warranted.

Immunogenic checkpoint protein including programmed death ligand 1, 2 (PD-L1, PD-L2) and B7-H3 play important roles for immune evasion in many cancer types. PD-L1 is an established therapeutic target in lung cancer and in a growing number of other indications. The clinical success of PD-L1 inhibitors has accelerated the development of drugs also targeting PD-L2 and B7-H3. In prostate cancer, studies on the prevalence and clinical relevance of these proteins have been inconclusive. Here, we performed immunohistochemical analysis of PD-L1, PD-L2 and B7-H3 in our large prostate cancer prognostic tissue microarray (TMA) containing tissue samples from more than 17,000 patients. Normal prostate glands were negative for PD-L1 and B7-H3, but positive for PD-L2. We found that 47% of 12,808 interpretable cancers showed B7-H3 expression, and 92% of 9,463 cancers showed PD-L2 expression, while expression of PD-L1 was virtually absent (0.2% of 17,392 tumors) in epithelial cells. Stroma cells and immune cells were entirely negative for PD-L1 and B7-H3, while some faint staining of lymphocytes was occasionally observed for PD-L2. In cancers, PD-L2 and B7-H3 staining had different prognostic impact, which depended on the ERG status: B7-H3 expression was linked to young patient age, advanced stage, high Gleason grade, lymph node metastasis (p<0.0001 each), presence of PTEN deletion (p<0.0001), and poor prognosis in ERG negative cancers (p<0.0001), while PD-L2 expression was linked to beneficial tumor features and prognosis exclusively in ERG negative tumors. Multivariate analysis including pT stage, Gleason grade, nodal stage, resection margin and preoperative PSA level, B7-H3 expression was an independent prognostic factor (p=0.0004). In summary, the results of our study identify a subset of young patients with ERG negative aggressive prostate cancers that might benefit from anti-B7-H3 therapy in the future. PD-L2 expression appears to protect tumors from progression and does not seem to be as suitable as a potential target in prostate cancer. PD-L1 expression is extremely rare in this disease, suggesting that only few prostate cancer patients might benefit from PD-L1 inhibitors.

#2990 Polyfunctional anti-CD19 CAR T cells determined by single-cell multiplex proteomics associated with clinical activity in patients with advanced Hodgkin’s lymphoma. John Rossit,1 Patrick Pazkowski,1 Yueh-wei Shen,2 Kevin Morse,3 Brianna Puyatt4, Alaina Kaiser3, Colin Ng,5 Kyle Gallatin,5 Tom Cain,6 Yong Fan,6 Sean Mackay,7 James Heath,8 Steven A. Rosenberg,9 James N. Kochenderfer,10 Jing Zhou,1 Adrian Bot1,1 Kite Pharma, Santa Monica, CA;2IspIcics, Branford, CT;3Yale School of Engineering and Applied Science, Yale University, New Haven, CT;4Division of Chemistry and Chemical Engineering, California Institute of Technology, Pasadena, CA;5Surgery Branch, National Institutes of Health, Bethesda, MD;6Experimental Transplantation and Immunology Branch, National Institutes of Health, Bethesda, MD.

Introduction: Autologous anti-CD19 CAR T cells have shown promising clinical efficacy in B cell malignancies, with T cell expansion and blood levels for IL-15, IL-10 and Granzyme B as correlates of objective response and...
toxicity (Kochenderfer et al. | Clin Oncol 2016: 34:LBA3010). It is unclear, however, which key immune programs in CAR T cells impact their in vivo expansion and clinical outcome. We evaluated in detail the functionality of anti-CD19 CAR T cells by using single-cell proteomics analysis (Lu et al. PNAS 2015:113:607-615). We explored how the polyfunctionality of pre-infusion cell products, post-infusion stimulation with the CD19 antigen in vitro, associated with CAR T cell expansion in vivo and objective response. Methods: Product T cells were separated into CD4+ or CD8+ T cell subsets using microbeads. CD4+ or CD8+ fractions were then co-cultured with CD19-K562 targets or NGFR-K562 control cells, at a 1:2 ratio for 20 hrs. Single cells were then analyzed using a 32-plex panel of secreted cytokines, chemokines, and cytotoxic molecules. Specifically, T cells were loaded onto a single-cell barcode chip capable of assaying 32 secreted proteins/cell. The polyfunctional profile and strength (pSI) of each sample was determined (Ma et al. Cancer Discov 2013;3:418-429) and analyzed relative to in vivo expansion of the CAR T cells and patient response to the CAR T cell therapy. CAR T cell expansion in blood was measured by quantitative PCR. Results: Single-cell pSI of patient CAR T cells showed a statistically significant association (p = 0.011) with objective response (complete or partial response) to the therapy. While product pSI showed variability across patients, the median pSI was 2+ times higher for responders vs non-responders. The polyfunctional profiles for both CD4+ and CD8+ cells were dominated by effector molecules, stimulatory cytokines and chemokines. Polyfunctional CD4+ and CD8+ T cells with IFNγ+IL-2+IL-17A+IL-17F+MIP-1β+ expression correlated best with patient outcome, with CD8+ T cells showing co-expression of Granzyme B, and CD4+ T cells also comprising IL-17A+IL-17F+ and IL-5+IL-17F+ subsets. While CAR expansion in vivo also correlated with objective response (p = 0.032), the association between product pSI and CAR cell expansion in vivo did not reach statistical significance (p = 0.079), suggesting that they bring independent contributions to predicting objective response. In support of that, a composite index integrating pSI and CAR T cell expansion in vivo associated best with clinical response (p = 0.005). Conclusion: Polyfunctionality of CAR T cells, in conjunction with their expansion in vivo and correlation with objective response data (IC50 and AUC) for 100 different drugs, including ‘best in class’ PI3K, PARP and CDK4/6 inhibitors, novel biological and chemical inhibitors of PIK3CA mutations. To target genomic alterations in HNSCC, we tested the efficacy of 7 PI3K/mTOR pathway inhibitors in 59 HNSCC cell lines and determined the association between drug sensitivity and molecular characteristics in order to identify biomarkers of response. Methods: We systematically analyzed the association between drug sensitivity and genomic alterations in 59 HNSCC lines. Results: NOTCH1 mut lines are significantly sensitive to PI3K/mTOR pathway inhibitors: GSK2126458 (13/16), BKM120 (14/16), BEZ235 (12/16), BAY806492 (14/16) and GDC0980 (13/16) lines. In contrast to PIK3CA mut cell lines, all 7 NOTCH1 mut lines tested underwent apoptosis (14.3 fold; P <0.005). After PI3K/mTOR inhibition, NOTCH1 mut lines showed significantly reduced clonogenic growth in vitro (0.4/0.9 fold in HNS1/PC115B; P<0.05) and significant tumor growth inhibition in vivo using orthotopic breast xenograft mouse models (2 fold in UMSCC22A and HNS1; P<0.01). To determine if NOTCH1 mediates resistance, we conditionally expressed cleaved NOTCH1 by Dox-inducible system in a NOTCH1 mut line (UMSCC22A). This rescued PI3K/mTOR inhibitor-induced apoptosis (0.5 fold; P<0.05) and reduced colony formation in vitro. As no canonical pathways account for the underlying mechanism of sensitivity, we measured the level of 301 proteins by reverse phase protein array (RPPA) in 3 NOTCH1 mut and 3 NOTCH1 WT lines after GSK2126458 treatment. Glutaminase and Glutamate Dehydrogenase were differentially expressed in NOTCH1 mut lines. Thus, we hypothesized that PI3K/mTOR inhibition in NOTCH1 mut lines induced reactive oxygen species (ROS)-mediated apoptosis via metabolic alterations. Consistent with this hypothesis, NOTCH1 mut lines exhibited increased ROS production; Metabolic pathway inhibitors targeting Glycolysis, Pentose Phosphate pathway and Glutaminolysis, in combination with GSK2126458 decreased cell viability in NOTCH1 mut lines. Conclusion: In contrast to PIK3CA mut cells, NOTCH1 mut HNSCC cells underwent apoptosis after PI3K/mTOR pathway inhibition in vitro and decreased tumor size in vivo. The ectopic activation of NOTCH1 rescued NOTCH1 mut HNSCC cells from PI3K/mTOR inhibitor-mediated apoptosis. The underlying mechanism may involve differential effects on tumor metabolism and ROS production. This work is significant because inactivating NOTCH1 mutations, which occur in 18% of HNSCC patients and SCCs of the lung, esophagus, and other sites, may serve as a biomarker for resistance. Our future work may uncover previously unknown crosstalk between the PI3K/mTOR and NOTCH pathways in SCCs.

**CLINICAL RESEARCH: Innate Immune Mechanisms in Cancer Treatment**

**#2993 STING signaling in breast tumor microenvironment modulates immune checkpoint blockade efficacy in the neu-N mouse model of breast cancer.** Jeremy B. Foote,1 Marlene Kok,1 James M. Leatherman,1 Todd D. Armstrong,2 Bridget Marcinkowski,1 David B. Kanne,1 Elizabeth M. Jaffee,1 Thomas W. Dubensky,2 Leisha A. Emens,1 Johns Hopkins University, School of Medicine, Baltimore, MD;2 Adaro BioTech, Berkley, CA.

Background: The presence of tumor infiltrating T cells (TILs) is associated with improved clinical outcomes in multiple tumor types and is also necessary for response to immune checkpoint blockade. While T cell responses to some tumors occur spontaneously, the majority of cancers are not naturally recognized by the immune system. The lack of response is attributed primarily to insufficient T cell infiltration into the tumor microenvironment (TME). Activating the STING pathway represents one strategy for increasing infiltration of T cells into the TME. This induces interferon-β (IFN-β) production, leading to dendritic cell (DC) activation and priming of tumor antigen specific CD8+ T cells that mediate tumor regression. The intratumoral injection (IT) of ML-RR-S2-CDA (ADU-100), a synthetic cyclic di-nucleotide STING agonist, has antitumor efficacy in several aggressive...
CLINICAL RESEARCH: Innate Immune Mechanisms in Cancer Treatment

mouse tumor models, including B16 melanoma, CT26 colon carcinoma, Panc02 pancreatic carcinoma, and 4T1 triple negative breast cancer. However, the impact of antigen-specific tolerance on tumor regression associated with STING-activation remains poorly understood. Therefore, we evaluated the efficacy of IT ADU-S100 in both non-tolerant parental FVB/N and the immune-tolerant neu/N transgenic mice bearing HER-2–specific B16 melanoma tumors. **Methods:** First we evaluated the impact of IT ADU-S100 on tumor regression, survival, innate sensing, and priming of HER-2 specific CD8+ T cells in both tumor-bearing non-tolerant FVB/N control and tolerant neu/N mice. Then we determined whether modulating the most highly expressed immune checkpoints on tumor infiltrating CD8+ T cells enhanced intratumoral STING expression in the tolerant neu/N mouse model of HER-2 breast cancer. Results: ADU S-100 induced HER-2-specific CD8+ T cell priming and durable tumor clearance in 100% of non-tolerant, FVB/N mice. In contrast, ADU S-100 failed to sufficiently prime HER-2-specific CD8+ T cells in tolerant neu/N mice, delaying tumor growth and clearing tumors in only 10% of mice. No differences in IFN-β production, DC priming, or HER-2-specific CD8+ T cell trafficking were detected between FVB/N and neu/N mice. However, activation and expansion of HER-2-specific CD8+ T cells was defective in neu/N mice. Immune cell infiltrates of untreated tumor-bearing neu/N mice expressed high levels of PD1 and OX40 on CD8+ T cells, and high levels of PD-L1 on both myeloid and tumor cells. Modulating PD-L1 and OX40 signaling combined with IT AADU S-100 enhanced HER-2-specific CD8+ T cell activity by over 40% of neu/N mice. Conclusions: Intratumoral STING activation synergizes with PD1 pathway-blockade and OX40 receptor stimulation to overcome immune tolerance and prime tumor antigen-specific CD8+ T cell responses that mediate effective tumor regression.

**#2996** Engineered STING-targeting immunotherapy delays B16 melanoma tumor growth and significantly improves animal survival as compared to an immune-checkpoint inhibitor. Andrea Amaltiano, Fadel S. Alyaouq, Vasser A. Alidhamen, Abdulraouf Abbas, Cristiane Pereira-Hicks, Sarah Godbehere, Christopher M. Waters. Michigan State University, East Lansing, MI.

Background: The stimulator of interferon genes (STING) is a cytosolic innate sensor activated by cyclic di-nucleotides (CDNs) including the bacterially derived bis-(3’-5’) cyclic-dimeric-guanosine monophosphate (c-di-GMP), leading to the induction of type I interferons. We recently published that an engineered adenovirus (Ad) vector delivering a potent, bacterially derived diguanylate cyclase (AdVCA0848) in vivo can generate sustained c-di-GMP levels in vivo and induce beneficial immune responses, including induction of IFN-β, activation of NK cells and DCs, as well as enhance antigen-specific T cell responses. Here, we determined if in vivo use of AdVCA0848 can also induce potent anti-tumor responses. Methods: Engineered AdVCA0848 was formulated into pellets and delivered to mice using a surgical needle through the tumor dermis. Animals were randomized to treatment with AdVCA0848 or saline controls. Tumor growth in mice treated with AdVCA0848 was compared to controls.

Results: AdVCA0848 significantly slowed B16 melanoma growth (p<0.01), a result that correlated with high levels of animal survival (p<0.001). These levels of efficacy significantly exceeded those achieved with alone use of a PD-1 antagonist. Under these same conditions, combined use of the AdVCA0848 therapy with anti-PD1 treatments trended to further improve animal survival (50% survival at day 27 PTI), as compared to alone use of either therapy (36.4% and 26.7% survival at day 27 PTI for AdVCA0848 and PD-1 treatments, respectively). Multiple innate and adaptive immune response readouts and immunohistochemical evaluation will be presented. Conclusions: The growth of established B16 melanoma tumors was rapidly inhibited after a single i.t. treatment with the engineered STING activator AdVCA0848, and this efficacy resulted in significant improvements in animal survival, at rates that were also significantly better than those achieved using a PD-1 antagonist. Furthermore, the i.t. administration of AdVCA0848 trended to show further improved efficacy when combined with a PD-1 antagonist. The growth of established B16 melanoma tumors was rapidly inhibited after a single i.t. treatment with the engineered STING activator AdVCA0848, and this efficacy resulted in significant improvements in animal survival, at rates that were also significantly better than those achieved using a PD-1 antagonist. Furthermore, the i.t. administration of AdVCA0848 trended to show further improved efficacy when combined with a PD-1 antagonist. Concluding, the growth of established B16 melanoma tumors was rapidly inhibited after a single i.t. treatment with the engineered STING activator AdVCA0848, and this efficacy resulted in significant improvements in animal survival, at rates that were also significantly better than those achieved using a PD-1 antagonist. Furthermore, the i.t. administration of AdVCA0848 trended to show further improved efficacy when combined with a PD-1 antagonist.

TLR8, which is an innate immune receptor that recognizes specific DNA motifs, has emerged as a promising cancer drug discovery field by engaging unprecedented revolution accompanied by growing excitement from researchers, drug developers, patients and investors, partly due to recent clinical success of cancer immunotherapy. Human immune defense system comprises both innate and adaptive immune pathways. All the targets drugged by the recently approved cancer immunotherapeutic agents including the immune checkpoint proteins PD-1, PD-L1, TLR8 agonists, etc. In contrast, targets involved in the innate immune pathway have not matured to regulatory approval for systemic use though several candidates are now in preclinical and clinical development. Drugs targeting innate immune represent great opportunity for more rapid and broader spectrum anti-cancer effect than adaptive immunity. Furthermore, combinations of drugs targeting innate and adaptive immunity are expected to produce strong synergistic efficacy owing to their complementary nature as body’s immune defense. Toll-like receptors (TLRs) are a family of proteins that recognize pathogen associated molecular patterns (PAMPs). Their primary function is to activate innate immune responses while also involved in facilitating adaptive immune responses. Different TLRs exert distinct functions by activating varied immune cascades. TLR8 is more broadly expressed among immune cells than other TLRs while the major causes of cancer immunotherapy failure is potent suppression of immune response by Treg cells. TLR8 is the only TLR that has been shown to be necessary and sufficient to reverse the suppressive function of Treg cells leading to strong tumor inhibition. Therefore, agonists targeting TLR8 are expected to be effective cancer therapy. However, there is no approved TLR8 selective agonist at present. There is only one TLR8 selective agonist in clinical development. Through structure-based drug design, we discovered a novel, highly potent and selective small molecule TLR8 agonist, DNS-A1. DNS-A1 exhibited strong in vitro cellular activity with EC50 at 4.23 nM, about 30-fold more potent than the only drug candidate in clinical trials. The activity was highly selective for TLR8 over other TLRs. DNS-A1 displayed superior in vitro ADMET and in vivo PK profiles. DNS-A1 showed clean CYP profile with IC50 over 10 µM for all major CYP isoenzymes tested including 3A4, 1A2, 2C9, 2C19 and 2D6. DNS-A1 had favorable hERG parameter with IC50 over 30 µM whereas the reference compound’s hERG IC50 was 3.84 µM suggesting potential cardiac toxicity. DNS-A1 significantly impeded tumor growth as a single agent and was well-tolerated in mouse tumor models. Taken together, DNS-A1 warrants further development as a potential best-in-class preclinical drug candidate for TLR8-mediated cancer immunotherapy.

**#2998** Immune checkpoint agonist VISTA suppresses Toll-like receptor signaling and the expression of inflammatory cytokines. Wenwen Xu,1 Yingxuan Li,2 Na Li,3 Yongwei Zheng,1 Kamal Rajasekaran,2 Halli Miller,1 Michael Olson,1 Deming Wang,1 Subramanian Malar Kannan,1 Li Wang,1 Medical College of Wisconsin, Milwaukee, WI;2 Shanghai University of Traditional Chinese Medicine, Shanghai, China.

Introduction: V-domain Ig suppressor of T-cell activation (VISTA, gene Vsir) is an inhibitory immune-checkpoint molecule that suppresses CD4+ and CD8+ T cell activation. Previous studies have shown that Vsir-/- mice developed chronic inflammatory phenotypes, and Vsir+/+ expression of inflammatory cytokines, and Vsir-/- mice showed CD4+ and CD8+ T cells were hyper-responsive towards self-and foreign antigens. Whether VISTA regulates innate immunity is still unknown. Methods: Peritoneal macrophages from WT or Vsir-/- mice were isolated and stimulated with TLR agonists such as CpG (TLR9), R848 (TLR7), LPS (TLR4), Pam3csk4 (TLR2), and poly (I:C) (TLR3). Alternatively, human monocyte THP-1 cells overexpressing VISTA were stimulated by TLR2 agonist Pam3csk4. The activation of TLR signaling pathways and the production of inflammatory cytokines were examined by Western Blotting, gel shift assay, or ELISA. The ubiquitination status of key signaling molecules such as TRAF6, IRAK1/4 and MyD88 were examined by immunoprecipitation and Western Blotting. To examine the role of VISTA in regulating TLR-mediated inflammatory responses in the context of cancer vaccine, tumor-bearing mice were treated with VISTA-specific monoclonal antibody (mAb) and a peptide vaccine containing TLR agonists. The production of inflammatory cytokines and chemokines within the tumor microenvironment (TME) was examined via quantitative RT-PCR. Results: Vsir-/- macrophages were hyper-responsive towards TLR2/4/7/9 agonists, but not TLR3 agonist, resulting in increased production of inflammatory cytokines IL-6, IL-12, and TNFα. Analysis of signaling cascade revealed that VISTA inhibited the activation of MyD88-dependent TLR signaling, via suppressing the activation of MAPKs and the activation of transcription factors AP-1 and NF-kB. Consistent
with the role of VISTA in regulating TLR-mediated innate immunity, treatment with VISTA-blocking mAb augmented levels of inflammatory cytokines and chemokines within the TME, and synergized with TLR/peptide vaccine result­ ing in an optimal therapeutic outcome. Conclusions: Our study establishes that VISTA critically regulates the inflammatory responses of myeloid cells mediated by TLR signaling. In the context of cancer vaccine therapy, VISTA-blocking mAb treatment enhanced levels of inflammatory cytokine and chemokines within the TME, which is critical for the development of optimal tumor-specific T cell responses and the tumor-controlling therapeutic outcome.

#2997 The tetravalent bispecific antibody AFM13 engages and primes innate immune cells for anti-cancer immunity. Jens Pahl,1 Joachim Koch,2 Uwe Reusch,3 Thorsten Gantke,2 Adelheid Cerwenka,1 Martin Treder2.

AFM13 is a tetravalent bispecific antibody with bivalent binding to both CD30 and CD16A. It has been shown to engage NK-cells through CD16A with high affinity and specificity, resulting in strong NK-cell cytotoxicity, and is currently being tested in Phase 2 monotherapy and in combination with pembrolizumab in Phase 1b clinical trials. We have previously shown that AFM13-dependent activation of NK-cell cytotoxicity towards CD30+ tumor cells is more pronounced than that of anti-CD30 mAbs. In addition, AFM13 enhances NK-cell sensitivity to low doses of IL-2 and IL-15, leading to an increased NK-cell proliferative potential. Here, we have extended the panel of phenotypic markers on NK-cells that are modulated after exposure to CD30+ tumor cells in the presence of AFM13. Targeting some of these markers may enable the development of novel combination therapies. Moreover, we have analyzed the kinetics of NK-cell responses to AFM13 exposure. Even though short-term exposure to AFM13 significantly enhanced NK-cell cytotoxicity, long-term exposure led to a partial, transient functionally exhausted phenotype in vitro, which could be fully restored by cytokine stimulation for several days in the absence of AFM13. Importantly, these recovered cells displayed high cytotoxicity towards CD30+ target cells in the presence of AFM13. Interestingly, the transient NK-cell exhaustion was not related to the expression of typical exhaustion markers or insufficient levels of perforin and granzyme. These data may warrant the development of novel metronomic application regimens of AFM13. Further studies imply that immune cells other than NK-cells are able to inhibit growth of CD30+ tumor cells in an AFM13-dependent manner. This appears to be strictly dependent on CD16A and a specific cytokine milieu. To achieve this, AFM13 specifically enhances the cytokine-producing potential of NK-cells, parameters that can be utilized to monitor NK-cell responses during AFM13 therapy. Moreover, based on our data, engagement of CD16A+ cells to the tumor site might enable several innate immune effector functions within the tumor microenvironment for synergistic anti-tumor activity.

#2998 Elotuzumab can costimulate NK cell responses by engaging SLAMF7. Tatiana Pazina,1 Ashley Mentlik James,1 Alexander W. MacFarlane,1 Natalie A. Bezman,2 Robert F. Graziano,3 Michael D. Robbins,2 Adam D. Cohen,3 Kerry S. Campbell1.

Elotuzumab (El) is an IgG1 monoclonal antibody targeting SLAMF7 (CS1, CRACC2, CD319) protein, which is highly and uniformly expressed on multiple myeloma cells. Improved survival has been observed in multiple myeloma patients treated with El in combination with immunomodulatory drugs such as dexamethasone and lenalidomide. Previous work showed that the main mechanism of El's action in vitro is CD16-mediated antibody dependent cellular cytotoxicity (ADCC) via Fc receptor interaction with CD16 (FcγRIIIa) receptor on NK cells. However, SLAMF7 is also expressed on NK cells where it transmits an activating signal. We hypothesized that El can directly activate NK cells via SLAMF7 ligation. Utilizing non-fucosylated El that has higher affinity to CD16 and El mutant that has an Fc region mutation that abrogates binding to CD16, we confirmed that El promotes NK cell activation and degranulation in a CD16-dependent manner. Specifically, non-fucosylated El had higher potency, whereas El mutant did not stimulate degranulation or CD69 expression. To test for co-stimulatory effects of El and El mutant we utilized trandaminoacidic signaling to potentiate calcium signals generated through NKP46 and NKGD2 in a CD16-independent manner. Our results provide evidence that direct engagement with SLAMF7 by El has the potential to reduce the threshold of NK cell activation triggered through other activating receptors.

CLINICAL RESEARCH: Innate Immune Mechanisms in Cancer Treatment

#2999 NKG2A checkpoint receptor expression on tumor-infiltrating CD8+ T cells restrains efficacy of immunotherapy. Thorbad Hall,1 Nadine van Montfoort,1 Syte Pietsma,1 Marjolein Sluijter,1 Marij J. Welters,1 Pascale André,2 Nicolai Wagtmann,2 Sjoerd H. van der Burg1.

The tetravalent bispecific antibody CD94-NKG2A is expressed on subsets of NK cells and cytotoxic CD8+ T cells, but not CD4+ T helper cells. It’s ligand is the non-classical MHC class I molecule HLA-E, commonly over-expressed in human cancers. We previously demonstrated that high HLA-E expression in ovarian carcinoma and NSCLC may neutralize the survival benefit of T cell infiltration, suggesting that NKG2A could represent an immune checkpoint that tumors may exploit for immune evasion. We thus examined the expression of NKG2A and other checkpoint receptors on human and mouse Tumor Infiltrating Lymphocyte (TIL) populations and tested blockade of this receptor in mouse tumor models. Multicolor flow cytometry analysis showed higher frequency of NKG2A+ CD8+ T cells in TIL samples obtained from biopsies of human head- and neck- carcinomas (n=17) compared to peripheral blood CD8+ T cells. Frequency of NKG2A+ TIL was higher in patients with measurable immune reactivity to HPV16-viral antigens than in patients without tumor immunity (14.8% vs 4.7%, respectively). Interestingly, only subsets of the NKG2A+ T cells co-expressed other inhibitory receptors, including PD-1 and TIM3, suggesting the existence of a ‘dedicated’ T cell subset for NKG2A. In our mouse tumor models we observed similar findings and, moreover, demonstrated that therapeutic vaccines comprising tumor antigens increased the frequency of NKG2A+ positive CD8+ TIL up to 80%. Similarly, exposure of Qa-1, the mouse homologue of HLA-E, on tumor cells also increased after therapeutic vaccination. As a proof of concept that the NKG2A-Qa-1 axis limits the efficacy of immunotherapy, NKG2A blocking antibodies were applied in the TC-1 model together with therapeutic peptide vaccination. Combination treatment with vaccine and NKG2A blockade significantly improved the therapeutic efficacy compared to the vaccine alone, both in terms of survival (P<0.05, median survival 44 vs 31 days) as well as overall response rate, defined as decreased tumor size of more than 30% (93.8% vs 43.8%, respectively). Similar results were obtained in Qa-1-deficient mice, suggesting that Qa-1 on tumor cells is of importance. In conclusion, inhibitory receptor NKG2A is enriched on CD8+ TIL and functions as an immune checkpoint that restrains therapeutic efficacy of a cancer vaccine.

CLINICAL RESEARCH: Predictors and Drivers of Pediatric Tumors

We recently showed that relapsed neuroblastoma (NB) tumors harbor an increased somatic mutational burden, enriched for ALK or RAS-MAPK activating lesions, nominating targeted therapeutic strategies for a condition that is largely incurable. We also showed that these mutations can be present in subclonal tumor cell populations at diagnosis, suggesting that they may contribute to acquired chemoradiotherapy resistance. We hypothesize that subclonal mutations in NB oncogenes are common at diagnosis, are biomarkers for treatment failure, and can be targeted in conjunction with standard chemotherapy to improve patient survival. Here, we focus on the first aspect of this broad hypothesis by presenting the subclonal landscape of diagnostic, high-risk neuroblastoma. A meta-analysis of our previously published primary/release (N=23), whole exome (N=322) and whole genome (N=159) diagnostic data, and recent sequencing study of 78 diagnostic and 67 relapse cases were used to inform design of a custom amplicon panel for ultra-deep sequencing. The 28-gene panel covers 57 mutations in frequently mutated genes. Here, 230 high-risk primary tumors were sequenced to an average depth of 3000X. More subclonal mutations were called (mean=36) compared to clonal alterations (mean=3), demonstrating the complex subclonal architecture in these tumors. We validated five clonal ALK mutations we originally discovered and identified 15 additional pathogenic ALK mutations with mutant allele frequencies (MAFs) ranging from 0.03-23%. Known ALK activating mutations were found at codons 1170, 1174, 1196, 1245, 1275 in 15 of 38 diagnostic primary tumors. This 39.5% frequency is much higher than the 14% frequency defined by us using Sanger sequencing or other sequencing methods. Improvement of subclonal mutation detection of actionable, relapse-specific driver mutations demonstrates the clinical utility of utilizing this sequencing methodology at diagnosis to enable timely improvement of outcomes for children with high-risk refractory NB.
**#3001  Germine mutations in cancer predisposition genes and risk for subsequent neoplasms among long-term survivors of childhood cancer in the St. Jude Lifetime Cohort.** Zhaoming Wang, 1 Carmen L. Wilson, 1 John Easton, 1 Dale Hedges, 1 Qi Liu, 1 Gang Wu, 1 Michael Rusch, 1 Michael Edmonson, 1 Shawn Levy, 1 Jennifer Q. Luncot, 1 Eric Caron, 1 Kyla Shelson, 1 Kelsey Currie, 1 Matthew Lead, 1 Heather L. Mulder, 1 Donald Yergeau, 1 Celeste Rosenzweig, 1 Bhavin Vadodaria, 1 Yadav Sapkota, 1 Russell I. Brooke, 1 Wonjong Moon, 1 Evandine Rampersaud, 1 Xiaotao Ma, 1 Shuqiang Wang, 1 Ti-Cheng Chang, 1 Stephen Rice, 1 Andrew Thrasher, 1 Aman Patel, 1 Cynthia Pepper, 1 Xin Zhou, 1 Xiang Chen, 1 Wenan Chen, 1 Angela Jones, 1 Braden Boone, 2 Deo Kumar Srivastava, 2 Chimene A. Kesserwan, 3 Kim E. Nicholas, 3 James R. Downing, 3 Melissa M. Hudson, 3 Yu-taka Yamaoka, 3 Melissa Estes, 3 Jingming Wang, 3 St. Jude Children’s Research Hospital, Memphis, TN; 2University of Alberta, Edmonton, Alberta, Canada; 3HudsonAlpha, Huntsville, AL.

Childhood cancer survivors are at increased risk of subsequent neoplasms (SN), largely considered to be therapy-related. Studies of cancer predisposition genes (CPGs) and risk of SN among long-term survivors are lacking. We characterized germline mutations in CPGs in childhood cancer survivors to determine their contribution to SN risk. Whole genome (30x) and exome (100x) sequencing was performed for 29885 year survivors of childhood cancer (1629 leukemia/lymphoma, 332 CNS, 1027 other solid tumors, 53% male, median follow-up 28 years (range 6-55 years). Survivors underwent a comprehensive clinical assessment, treatment exposures were abstracted from medical records, and SN were validated by pathology review. We identified 63 CPGs that were classified using a library of Medical Genetics and Genomics guidelines as previously described (Zheng et al. NEJM 2015). Logistic regression, adjusting for age, sex and race, was used to evaluate associations between mutation status, cancer therapy and the SN risk. 1062 SNs were diagnosed in 437 survivors, of whom 98 developed ≥2 histologically distinct SNs. Median age at SN and time to first SN was 38.2 (range 3.3-67.4) and 29.2 (9.48.4) years, respectively. Common SNs were basal cell carcinoma (542 in 153 survivors), meningioma (201 in 100, thyroid (64 in 64), and breast cancer (58 in 50). Cumulative incidence of SN at age 45 was 25.5% (95% CI: 22.9-27.9). 169 survivors (5.7%) had a pathogenic/likely pathogenic (P/LP) mutation in a CPG, consisting of 97 single nucleotide variations, 63 insertion/deletions and 9 copy number alterations (49% of mutations not in ClinVar). Frequently mutated genes were: RB1 (n=41), NFI (n=22), BRCA2 (n=13), BRCA1 (n=12) and TP53 (n=10). Our data confirmed known associations between CPG mutations and specific primary diagnoses including RB1 mutations in 32 of 41 (78%) of bilateral and 7 of 57 (12%) of unilateral retinoblastoma survivors, 22 NF1 (20 of 332 CNS survivors), 4 SUFU (all in medulloblastoma survivors) and 5 WT1 mutations (all in Wilms’ tumor survivors). Analyses revealed novel associations between CPG mutations and SN risk. Among 1326 survivors not exposed to radiation therapy (non-RT), 62 SNs developed in 54 survivors, of which 15 (24.2%) occurred in P/LP mutation carriers. Non-RT exposed survivors with a P/LP mutation had an increased risk of SN (OR=5.6, 95% CI=2.6-12.0, P<0.001) and the odds of developing ≥2 distinct histologic types of SNs was increased by 23.6-fold (95% CI=5.4-102.7, P<0.001). In 1662 RT exposed survivors, P/LP-mutation carriers had an odds ratio of 2.3 (95% CI=0.9-6.0, P=0.08) for developing ≥2 distinct histologic types of SNs. Our findings support the hypothesis that a substantial proportion of non-RT exposed childhood cancer survivors who develop one or more SN carry a CPG mutation, and should be referred to genetic testing and counseling services.

**#3003 Exome analysis of known hereditary cancer genes in 122 children with rhabdomyosarcoma.** Talia Wegman-Ostrosky, 1 Rajesh Patidar, 1 Sivasish Sindiri, 1 Jack Sherrn, 1 Douglas S. Hawkins, 1 Daniel Catchpole, 2 Jun S. Wei, 1 Stephen Kacep, 1 Javed Khan, 1 Douglas R. Stewart, 1 National Cancer Institute, Bethesda, MD; 2Seattle Children’s, Seattle, WA; 3University Of Sydney, Sydney, Australia; 4UT Southwestern Department of Pediatrics, Dallas, TX.

Introduction: Rhabdomyosarcoma (RMS) accounts for 5% of all pediatric cancer and is the most prevalent soft tissue tumor in childhood and adolescents. RMS is thought to arise from primitive mesenchymal stem cells directed towards myogenesis. Between 7-33% of RMS cases arise from a hereditary cancer syndrome, like Li-Fraumeni or neurofibromatosis. We analyzed germline genetic variants in hereditary cancer genes in 122 children with RMS. Methodology: In 122 children with RMS and 1001 cancer-free adults, we examined germline exome data to determine the frequency of genetic variants in 51 cancer genes known to underlie syndromes associated with RMS. DNA was extracted from blood or buccal cells using standard methods. Exome enrichment was performed with NimbleGen SeqCap EZ Human Exome Library v3.0 and sequencing was done on Illumina HiSeq. Annotation of each exome variant was performed using a custom software pipeline. We evaluated all variants that passed quality controls with a population minor allele frequency (MAF) <0.1%. The cataloging of the variants was based on the ACMG classification as pathogenic (P), likely pathogenic (LP), or variable of unknown significance. Results: We compared the age, gender, histologic type and localization of the primary RMS of the patients with and without P/LP variants in the 51 genes. In the patients without P/LP variants, the mean age of diagnosis was 5 years and the most frequent site of diagnosis was head and neck. In the group with P/LP variants, the mean age of diagnosis was 10 years, and the most frequent site was pelvis. In the 51 genes that we analyzed we found 9 P and 12 LP variants in 15 genes: TP53, ATM, SMH6, PMS, DICER1, FANCA, RECQ4, PTEN, WRN, RB1, BUB1B, RET, APC, FANCM and TSC2, genes with 2 variants included: WRN, PTEN, BUB1B, FANCA and RET. Most of the variations were stopgain, follow by missense, frameshift insertion and splicing genetic variations. Ten of this genes are associated with an autosomal dominant pattern of inheritance. In one 15-year-old female patient with an alveolar RMS in the paraspinal area we found P/LP variants in PTEN and PM52. The frequency of P/LP variants in cases was 16% and 3% in controls. Conclusions: To our knowledge, this is the first study where multiple germline variation where analyses in children with RMS. We found P/LP variation in 16% of the cases (pendant orthogonal confirmation); the mean age of diagnosis was 10 years old and their primary tumor site was in the pelvis (50%). Identification of P/LP variation in genes underlying RMS-associated syndromes has implications for follow-up, screening and management of these patients and their families. We acknowledge the Children’s Oncology Group in helping to assemble the RMS cohort.

**#3004 Comparison of somatic alterations in the genome and transcriptome of 1,705 pediatric leukemia and solid tumors: a report from the Children’s Oncology Group (COG) - NCI TARGET Project.** Xiaotu Ma, 1 Yu Liu, 1 Yanling Liu, 1 Michael Edmonson, 1 Charles Gawai, 1 Xin Zhou, 1 Yongjin Li, 1 Michael Rusch, 1 John Easton, 1 Mark Wilkinson, 1 Leandro C. Hermida, 2 Sean Davis, 1 Malcolm Smith, 1 Jaime Guiray Avuli, 1 Paul Meltzer, 2 Ching C. Lau, 1 Elizabeth Perlman, 1 John M. Maris, 2 Soheil Meshinchi, 1 Stephen P. Hunger, 1 Daniela S. Gerhard, 1 Jinghui Zhang, 1 St Jude Children’s Research Hospital, Memphis, TN; 2National Cancer Institute, NIH, Bethesda, MD; 3Texas Children’s Cancer and Hematology Centers, Houston, TX; 4Ann and Robert H. Lurie Children’s Hospital of Chicago, Chicago, IL; 5Children’s Hospital of Philadelphia, Philadelphia, PA; 6Fred Hutchinson Cancer Research Center, Seattle, WA.

To document common and subtype specific somatic alterations affecting key biological processes in pediatric cancers, we analyzed point mutations, copy number alterations, gene fusions and structural alterations detected from paired tumor-normal whole genome sequencing (n=655), whole exome sequencing (n=1,108), and RNA-seq data (n=913) of 1,705 leukemia and solid tumors. Our cohort consists of 693 B-lineage Acute Lymphoblastic Leukemia (B-ALL), 264 T-ALL, 211 Acute Myeloid Leukemia (AML), 318 Neuroblastoma (NBL), 128 Wilms Tumor (WT), and 91 Osteosarcoma (OS) with a median mutation rate of 0.28-0.58 per Mb. We identified 130 potential driver genes based on significance.
of variant recurrence and pathogenicity within each cancer type and across all cancer types. Seventy-two (55%) driver genes were significant in one cancer type, thirty-eight were significant in > 1 leukemia subtype, thirteen (NRAS, WT1, MYCN, PTEN, TP53, Kras, Rb1, ATRX, PTPN11, MLLT1, Bcor, SETD2, NFI) were significant in both leukemia and solid tumor while the remaining, 26, were specific to single-cell source and successfully validated in significant only in pan-cancer analysis. The number of mutated driver genes per sample ranged from 0.8 in WT to 5.8 in T-ALL, lower when considering only point mutations (from 0.3 in NBL to 3.1 in T-ALL). The most frequently mutated biological processes affecting both leukemia and solid tumor were transcription factors (56% of samples), cell cycle (41%), epigenetic regulators (36%), Ras signaling (34%), NF-kB (11%), and the NOTCH complex (7%). The MYC signaling pathway was mutated only in leukemia (16%) while mutations in the NOTCH signaling pathway were exclusive to T-ALL (77%). Aberrant transcription may also affect the normal function of a driver gene. For example, the RAS signaling pathway was mutated in B-ALL (35%), T-ALL (15%), AML (37%) and NBL (4.3%). Aside from the known NRAS 4a isoform found in all cancer types, we discovered two novel KRAS isoforms present in 71.1% of B-ALL, 67.9% of T-ALL, 71.3% of AML and 3.0% of NBL but not in WT or OS. Allele-specific expression (ASE) was detected in 205 (6.8%) of 3,016 expressed somatic mutations, and 97% (32 out of 33) of truncation mutations on autosomes exhibit reduced expression of the mutant allele likely due to nonsense mediated decay. Two ASE mutations, WT1 Δ447N in a cytogenetically normal AML and JAK2 D674E in AML, were selected for single-enforced single-cell sequencing and validated. Only 44% of our driver genes match those identified in adult cancer. This, coupled with our finding that point mutations only accounted for 48% of the driver alterations, may provide new insight into the design of precision treatment for pediatric cancer. Our presented data will be made public at NCIT’s Genome Data Commons (gdac.cancer.gov) and can be explored on our Protein-Paint data portal (pecan.stjude.org).

## 3005 Whole-genome sequencing identified novel non-coding mutations causing of oncogene activation in T-cell acute lymphoblastic leukemia

Through growing evidence that non-coding sequences in human genome often function as transcriptional regulatory elements of protein-coding genes. In fact, germline polymorphisms and somatically acquired mutations within regulatory DNA can profoundly alter chromatin structure and modify gene transcription, directly contributing to tumorigenesis. However, there is a paucity of unbiased genome-wide characterization of somatic non-coding mutations in cancer. Using T-cell acute lymphoblastic leukemia (T-ALL) as a model disease, we herein report a systematic interrogation of driver non-coding genomic alterations by paired whole-genome and transcriptome sequencing of 31 children with T-ALL. To identify non-coding mutations with potential regulatory impact in a genome-wide fashion, our analytical pipeline consisted of 3 approaches: 1) the "hotspot analysis" for recurring mutations at the nearby positions, 2) the "regional recurrence analysis" for predefined regulatory regions with significant enrichment of non-coding mutations, 3) the "transcriptional factor analysis" for mutations that potentially result in gain/loss of transcription factor binding sites and alter expression of adjacent genes. Remarkably, T-ALL oncogenes LMO1 and TAL1 emerged as loci with the most significant recurring non-coding mutations. At the LMO1 locus, 3 patients (9.7%) showed an identical single-nucleotide mutation proximal to the transcription start site of the long isofrom of LMO1. This recurring mutation resulted in the gain of a canonical Myb binding site (AACGG) and ~120-fold increase in LMO1 transcription compared to patients with wildtype genotype. TAL1 overexpression was observed in 15 patients, of whom 11 had intrachromosomal rearrangement (STIL-TAL1 fusion). The remaining patient had a candidate rearrangement involving the super enhancer, consistent with recent reports. LMO1 enhancer mutation was further confirmed in an independent validation cohort (N = 26), in which we additionally identified a novel intrachromosomal rearrangement between MED17 and LMO1 resulting in transcriptional activation of the latter. In a panel of T-ALL cell lines, LMO1 enhancer mutation was again associated with dramatic overexpression of LMO1, an active enhancer histone mark (H3K27ac), increased myc expression, and increased transcription. Notably, we also observed robust binding of TAL1, CREBBP, RUNX1, ETS1, ELF1 and RNA Polymerase II at this site. Reporter gene assay confirmed the MYB-mediated transcription activation effects of this LMO1 enhancer mutation in vitro. In this genome-wide investigation of non-coding mutations in T-ALL, we identified novel enhancer mutations with drastic effects on oncogene activation. Our findings expand the understanding of how genomic alterations in regulatory DNA contribute to cancer pathogenesis.

## 3006 Oncogenic activity of H3.3 K27M in a spontaneous DIPG mouse model

Pediatric diffuse high-grade gliomas (HGG) cause a devastatingly poor outcome. Diffuse intrinsic pontine gliomas (DIPG) are brainstem HGGs found almost exclusively in children and represent approximately 25% of all pediatric HGGs. Recurrent, clonal somatic mutations in histone H3 are a molecular hallmark that distinguish the genetic mechanisms underlying pediatric and adult HGG, and indicate a strong link between epigenetic dysfunction and pediatric brain tumorigenesis. H3 K27M mutations found in nearly 80 percent of DIPGs and over half of non-brainstem HGGs occurring in thalamus or other midline structures, induce a dominant loss of genome-wide H3K27me3. In contrast, mutually exclusive H3.3 G434R/V mutations occur in approximately 14 percent of cortical HGG tumors in older children through young adulthood suggesting a distinct developmental origin compared to K27M mutant tumors. DNA methylation and gene expression patterns distinguish G34R/V and K27M tumors, but the oncogenic mechanisms and reasons for brain region selectivity of these mutations remain uncertain. To study these mutations in the developing mammalian brain and investigate how they contribute to oncogenesis, we generated conditionally activated, epitope-tagged knock-in mice to express K27M, G434R or non-mutated H3.3 proteins from the endogenous H3F3a locus. Untransformed embryonic neural precursor or astrocyte cells expressing H3.3 K27M demonstrated H3K27me3 loss and a growth advantage in vitro with brain region–specific, stage-dependent expression and epigenetic signatures. DIPGs frequently harbor genetic alterations in TP53 and PDGFRα in addition to H3.3 K27M, and mice with induced brain-specific Trp53 deletion plus mutated PDGFRαa344Rme expression developed spontaneous HGG in vivo. Induction of H3.3 K27M significantly accelerated PDGFRαa344Rme;Trp53 knockout HGG formation involving the brainstem. Importantly, the non-mutated H3.3 epitone-tagged protein did not affect tumor burden or latency. The H3.3 K27M tumors recapitulate characteristics observed in human DIPG including histopathological features, strong nuclear K27M expression and robust loss of H3K27me3 throughout the tumors. We relate the genetic, epigenetic and transcriptional landscapes of these models to primary pediatric DIPG to help identify their developmental origins and oncogenic mechanisms downstream of histone H3.3 K27M.

## EPIDEMIOLOGY: Cancer Epidemiology and Prevention

### 3007 Tobacco smoking, alcohol use and risk of hepatocellular carcinoma and intrahepatic cholangiocarcinoma: The Liver Cancer Pooling Project

Kham, 1 Yong Cheng.

Background: Since 1980, liver cancer has been among the most rapidly increasing cancer types in the United States (US), with 5-year survival rates of approximately 17%. While tobacco and alcohol are known to be associated with primary liver cancer, it is unclear whether they only increase the risk of hepatocellular carcinoma (HCC), the most common type of liver cancer, or whether they also increase risk of intrahepatic cholangiocarcinoma (ICC), second most common histologic type. Additionally, it is unclear what...
EPIDEMIOLOGY: Cancer Epidemiology and Prevention

amount of alcohol consumption is associated with an increased risk of liver cancer. As liver cancer is a rare cancer type, we conducted a study of pooled data from the National Cancer Institute Cohort Consortium to examine the associations between smoking and alcohol use and liver cancer, stratified by histologic subtype. Methods: In the Liver Cancer Pooling Project, a consortiun of 21 epidemiologic studies, 518,740 participants from 14 cohorts, (HCC n=1,423, ICC n=410) in 14 cohorts. Multivariable-adjusted hazard ratios (HRs) and 95% confidence intervals (CI) were estimated using proportional hazards regression. Cubic splines were used to model the association between alcohol and liver cancer risk. Results: Compared to never smokers, both former and current smokers at study baseline had an increased risk of HCC (HR = 1.32, 95% CI: 1.03-1.68 and HR = 1.47, 95% CI: 1.07-2.02, respectively) and HCC (HR = 1.24, 95% CI: 1.08-1.43 and HR = 1.86, 95% CI: 1.57-2.20, respectively). This finding was consistent for heavier smoking intensity, longer duration of smoking, and more pack-years of smoking. High alcohol consumption was associated with an 87% increased risk of HCC (HR = 1.87, 95% CI: 1.41-2.47) and a non-significant increased risk of ICC (HR = 1.86, 95% CI: 0.99-2.86). Risk of HCC significantly increased at 4.5 alcoholic drinks per day, while risk of ICC was non-significantly increased with any amount of consumption. Conclusions: These findings suggest that, in a US population, cigarette smoking is associated with an increased risk of both histologic subtypes of primary liver cancer - HCC and ICC. In contrast, alcohol consumption was primarily associated with an increased risk of ICC. These results suggest that smoking cessation and alcohol reduction programs could be important intervention opportunities for these lethal cancer types.

#3008 Obesity, physical activity, and breast cancer survival among older breast cancer survivors in the CPS-II Nutrition Cohort. Maret L. Malinisk, Alpa V. Patel, Marjorie L. McCullough, Peter T. Campbell, Corinne R. Leach, Susan M. Capistrat, Mia M. Gaudet, American Cancer Society, Atlanta, GA

Background: Body mass index (BMI) and physical activity and their relation to breast cancer-specific survival have not been well-studied in older breast cancer survivors. The Nutrition Cohort, 4,927 women diagnosed with breast cancer between 1992 and 2000 was stratified into pre- and post-diagnosis BMI and recreational physical activity with breast cancer-specific and all-cause mortality. Objective: To examine the associations of pre- and post-diagnosis BMI and recreational physical activity with breast cancer-specific and all-cause mortality among women with non-metastatic breast cancer, overall and stratified by age 65 years at diagnosis. Methods: In the Cancer Prevention Study-II Nutrition Cohort, 4,927 women diagnosed with breast cancer between 1992 and 2000 completed biennial surveys and were followed for cause-specific mortality. Pre-diagnosis exposures were assessed at the questionnaire completed ≥6 months before diagnosis, and post-diagnosis exposures were assessed at the first questionnaire completed ≥2 years after diagnosis to avoid capturing short-term changes due to treatment. BMI was computed as weight (kg) divided by height squared (m²). Physical activity was based on the summary MET-hours/week of recreational activity. Multivariable Cox proportional hazards models were used to calculate hazard ratios (HR) and 95% confidence intervals (CI). Results: Over a mean follow-up time of 9.8 years after diagnosis, 1,394 deaths, including 452 from breast cancer, occurred. The median age at diagnosis was 70 years (77% ≥65 years). Compared with normal weight (BMI 18.5-25 kg/m²), class II-III obesity (BMI ≥35 kg/m²) was associated with higher risk of breast cancer-specific mortality in pre-diagnosis (HR: 2.2; 95% CI: 1.5-3.2) and post-diagnosis analyses (HR: 1.6; 95% CI: 1.0, 2.5), although the association was limited to women ≥65 years of age at diagnosis. Pre-diagnosis but not post-diagnosis BMI was positively associated with all-cause mortality among both age groups (P-trend <0.0001). Pre-diagnosis physical activity was not associated with breast cancer-specific mortality in pre-diagnosis analyses, but differences were observed in post-diagnosis analyses (HR: 0.7; 95% CI: 0.3-1.5). However, no differences were found in analyses of all-cause mortality. Significant inverse trend for post-diagnosis physical activity and breast cancer-specific mortality overall (P-trend=0.03) and among women ≤65 years of age at diagnosis (P-trend=0.01) but not among women ≥65 years of age at diagnosis (P-trend=0.21). Pre- and post-diagnosis physical activity were significantly associated with reduced all-cause mortality in both age strata. Conclusions: Our results suggest that pre- and post-diagnosis obesity and physical activity is associated with increased risk of death from breast cancer in older, but not younger, breast cancer survivors. Conversely, physical activity may reduce risk of breast cancer death in survivors ≥65 years of age at diagnosis. However, both were associated with overall longevity, regardless of age.

#3009 Lipid-lowering drug use and risk of fatal prostate cancer in the Atherosclerosis Risk in Communities (ARIC) Study. Alison M. Mondul, Corinne E. Joshu, John Barber, Anna Prizment, Nrupen Bahvsar, Josef Coresh, Elizabeth Selvin, Aaron Folsom, Elizabeth A. Platz, University of Michigan, Ann Arbor, MI; Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; University of Minnesota, Minneapolis, MN; Duke University, Durham, NC.

Background: Studies show that lipid-lowering medications, particularly statins, may be protective for more aggressive prostate cancer. Lethal prostate cancer is often considered an optimal outcome in epidemiologic studies when the aim is to identify modifiable risk factors with the potential to reduce prostate cancer incidence. Despite long-term survival being an under-studied. Further, lipid drug use and prostate cancer risk is understudied in black men, whose risk of fatal prostate cancer is 2-3 times higher than that of white men. Thus, we studied lipid medication use and fatal prostate cancer risk in the ARIC Study, which includes ~25% black participants. Methods: The ARIC Study is a prospective cohort that included 15,792 participants (7,082 men) recruited from four US communities. We conducted a prospective cohort analysis of 6,547 men who attended visit 2 (1990-1992, the start of the study era) and were followed for cancer death through 12/31/2012. Death from prostate cancer (n=90) as the underlying cause was obtained from death certificates supplemented with medical records. Updated information on medication use was collected throughout the study follow-up. Proton pump inhibitors and statins use were modeled as a time-dependent variable in two ways: 1) current use (yes/no), and 2) duration of use (<10, ≥10 years). Cox proportional hazards regression was used to estimate the hazard ratio (HR) and 95% confidence interval (CI) of prostate cancer death overall and by race. All models were further adjusted for age, race, and study center. Additional models were further adjusted for height, BMI, smoking, diabetes, and education. Results: The prevalence of lipid medication use was 17% by visit 4, partway into the statin drug era, and 76% of those medications were statins. After adjustment for age, race, and study center, men who used lipid medications were statistically significantly less likely to die from prostate cancer than men who did not use lipid medications (HR=0.56, 95% CI:0.33-0.95). This finding was slightly attenuated after further multivariable adjustment (HR=0.62, 0.36-1.08). The statistically significant inverse association appeared to be restricted to men who used lipid medications for ≥10 years (vs. never use: HR=0.39, 95% CI:0.19-0.82, p-trend=0.02). Lipid medication use was inversely associated with a reduced risk of prostate cancer death in both white and black men. Conclusions: Use of lipid medications was associated with a lower risk of fatal prostate cancer in both black and white men. Whether the fact that black men are less likely to receive/take lipid medications could partly explain the black-white disparity in prostate cancer in the US requires further study. Support: NHLBI contracts, NCI grant, NPCR

Background: Evidence shows that the vitamin K-antagonist warfarin, a popular anti-coagulant in clinical use for decades, has anti-tumor activity. This is recently attributed to disruption of post-translational modification of G6s, the common ligand of the Axl receptor tyrosine kinase family. G6s-Axl signalling is associated with malignancy and is required for tumorigenesis and progression in several preclinical cancer models. Warfarin is shown to inhibit Axl signaling-dependent malignant traits and enhance anti-tumor immune responses at doses that do not achieve anticoagulation. The objective of this study is to investigate the association between warfarin use and cancer incidence in a large unselected Norwegian cohort. Our results reveal a remarkable reduction in cancer incidence associated with warfarin use across a wide range of tumor types. METHODS: A cohort selected from the Norwegian population registry in 1994, living in a Norwegian county (n=256,725). We cross-referenced this cohort using the unique Norwegian National ID Number to: 1) the Cancer Registry of Norway and retrieved information on all cancer cases 2006-2012; 2) information on filled warfarin prescriptions (ATC: B01AA03) from the Norwegian Prescriptions Database (2004-2012). Warfarin-use was defined as ≥6 months and minimum 2 years between first warfarin prescription and cancer diagnosis. We also performed a subgroup analysis on persons prescribed warfarin for atrial fibrillation/flutter (n=33 313) compared to non-users. Mantel-Haenszel method was used to calculate the incidence rate ratio (IRR), adjusting for sex and age. RESULTS: In this cohort, 92 942 persons were classified as warfarin users, and we observed 132 687 cancer cases in the
7-year study period. We observed a significantly lower sex and age-adjusted risk for cancer development across all malignancy types in the warfarin user group compared to the non-user group (IRR: 0.842, 95% CI: 0.824-0.861). The association was similar among many cancers including major types (prostate IRR: 0.687, 95% CI: 0.653-0.722; lung IRR: 0.801, 95% CI: 0.749-0.856; breast IRR: 0.903, 95% CI: 0.849-0.961). Given the chronic nature of cancer disease on incidence, we conducted a subgroup analysis among patients prescribed warfarin for atrial fibrillation/flutter (AF-group), a subgroup with reduced comorbidity. Warfarin users in the AF-group showed a stronger overall cancer risk reduction (IRR: 0.619, 95% CI: 0.592-0.646), including all major cancer types, particular lung cancer. (Prostate, IRR: 0.604, 95% CI: 0.552-0.662; Lung: IRR: 0.391; 95% CI: 0.332-0.460; Breast IRR: 0.720, 95% CI: 0.594, 0.871) CONCLUSION: We show that warfarin use is associated with a broad cancer protective effect in a large unselected patient cohort. Subgroup analysis of arrhythmia patients to reduce confounders reinforced the notion that warfarin exerts important anti-tumor effects.

#3011 Dietary fat, fatty acids, and ovarian cancer risk: Preliminary findings from the Shanghai Women's Health Study. Eftihia Y. Akam,1 Harvey J. Murff,2 Yong-Bing Xiang,3 Nikhil K. Khankari,1 Hui Cai,1 Xiao O. Shu,2 Wei Zheng,2 Alicia Beeghly-Fadiel1.1Division of Epidemiology, Department of Medicine, Vanderbilt University Medical Center, Nashville, TN; 2Division of Epidemiology, Department of Medicine and Vanderbilt-Ingram Cancer Center, Vanderbilt University Medical Center, Nashville, TN; 3Department of Epidemiology, Shanghai Cancer Institute, Shanghai, China.

Introduction: Dietary fat is an essential nutrient for human growth and development, but epidemiological studies have linked excess fat to the development of multiple malignancies. The few existing studies on ovarian cancer risk are inconsistent, possibly due to differences in sources and subtypes of fat. For example, omega-3 (n-3) polyunsaturated fatty acids (PUFAs) are thought to be anti-neoplastic, while omega-6 (n-6) PUFAs may promote carcinogenesis. Approach: We evaluated dietary fat in relation to ovarian cancer risk in the prospective Shanghai Women's Health Study (SWHS). Intake levels were determined from food frequency questionnaires (FFQ) administered at baseline and during follow-up; specific nutrient components were based on the sum of specific foods multiplied by nutrient content from the Chinese Food Composition Table. Cox proportional hazards regression was used to estimate relative risks (RR) and 95% confidence intervals (CIs) for dietary fat and fatty acid components categorized into quintiles. Minimal models included age and residual adjustment for total energy intake; fully adjusted models also included education, years of menstruation, years of oral contraceptive use, parity, years of breastfeeding, family history of ovarian cancer, smoking, drinking, NSAID use, BMI, and physical activity. Results: Among 73,144 SWHS participants, we identified a total of 219 ovarian cancer cases in 1,114,828 person-years of follow-up. We found significant dose-response relationships between increasing total PUFA (P-trend=0.032) and n-6 PUFA (P-trend=0.022) intakes and decreased ovarian cancer risk. In both minimally and fully adjusted models, women with the highest quintile of total dietary PUFAs were approximately 35% less likely to develop ovarian cancer (RR=0.65, 95% CI: 0.43-0.99) compared with those in the highest quintile (RR=0.99, 95% CI: 0.91-1.09). In fully adjusted models, the total fat, monounsaturated fat, and n-3 PUFA intake were not significantly related to ovarian cancer risk. Conclusions: Findings from our preliminary analysis of a large prospective cohort of Chinese women suggest that total PUFA intake may be protective of ovarian cancer, and that this association may be driven by n-6 rather than n-3 PUFAs. Further evaluation, including stratification, sensitivity analysis, and evaluation of source of dietary fatty acids, is currently underway.

#3012 Long-term aspirin use and total and cancer-specific mortality. Yin Cao,1 Meir Stampfer,2 Walter Willett,2 Donna Spiegelman,1 JoAnn Manson,2 Jennifer A. Naya,1 Nyla A. Heerema,2 Xiaoli Zhang,2 Hatice Gulcin Ozer,2 Amy J. Johnson,2 Jennifer A. Woyach,2 Erin Hertlein,2 John C. Byrd.1

Background: Although oral contraceptive (OC) use is ubiquitous in the United States, the influence of OCs on the development of cancers is not fully understood. In 2013, an Agency for Healthcare Research and Quality Evidence Report identified several data gaps with regard to OC use and its associations with cancer, including a need to understand if associations are consistent across subpopulations of users, including smokers and obese women. Methods: To address this data gap, we used Cox proportional hazards models to examine duration of OC use (never/less than 1 year [reference], 1 to 4, 5 to 9, 10+ years) and subsequent development of incident ovarian or endometrial cancer among participants in the NIH-AARP Diet and Health Study. We further examined effect modification by a variety of modifiable risk factors, including body mass index (BMI), cigarette smoking, alcohol consumption, and physical activity, via interaction terms and a likelihood ratio test. Models were adjusted for age, race, age at menarche and the modifiers of interest. Results: For ovarian cancer (n=1,241 cases, 149,502 non-cases), a reduction in risk was conferred by OC use that linearly decreased with duration of use (hazard ratios [HR] ranging from 0.83 to 0.60 across categories of duration). We also identified linear, inverse associations between increasing duration of OC use and ovarian cancer risk across most potential modifiers. Some of the most pronounced reductions were observed among long-term OC users (10+ years) who were current smokers (HR compared to non-users of 0.44, 95% confidence interval [CI] 0.20, 0.97) or who engaged in moderate physical activity (0.44, CI 0.23, 0.85). For endometrial cancer (n=2,337 cases, n=112,132 non-cases), we observed pronounced reductions in risk associated with OC use among women with obese BMIs (0.36, CI 0.25, 0.52) and those who exercised rarely (0.40, CI 0.29, 0.56) or moderately (0.50, CI 0.33, 0.75). However, long-term use was not associated with risk reductions among women with BMIs of less than 25 or among women who exercised at least three times per week. Conclusions: OC use is consistently associated with reduced risks of ovarian cancer across most strata of modifiable risk factors. For endometrial cancer risk, OC use seems to offer the greatest risk reduction among women in previously identified high-risk categories (i.e., overweight/obese BMI, physically inactive), findings which merit further discussion as these women may be more likely to have comorbid conditions that would contraindicate OC use (e.g., hypertension, diabetes).

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Identification of Molecular Targets

#3014 BCL3 over-expression contributes an in vivo growth advantage in a B-cell lymphoma xenograft model and is a risk factor for ibrutinib relapse in CLL. Timothy L. Churudjian,3 Bonnie K. Harrington, Larry Beaver, Amy S. Ruppert,2 Nyla A. Heerema,2 Xiaoli Zhang,2 Hatice Gulcin Ozer,2 Amy J. Johnson, Jennifer A. Woyach,2 Erin Hertlein,2 John C. Byrd.1

Background: BCL3 over-expression contributes an in vivo growth advantage in a B-cell lymphoma xenograft model and is a risk factor for ibrutinib relapse in CLL. Chronic lymphocytic leukemia (CLL) relies on chronic B-cell receptor (BCR) signaling, and as such is effectively treated with Bruton’s tyrosine kinase inhibitoribrutinib. The mechanism of ibrutinib resistance has remained enigmatic. In this study, we sought to determine the role of BCL3 over-expression in the development of ibrutinib resistance in vivo and to identify potential mechanisms of ibrutinib resistance.

Methods: We generated ibrutinib-resistant sublines in the 32Dcl-5IB cell line and determined the effects of BCL3 over-expression on cell viability, proliferation, and the ibrutinib sensitivity of these sublines. Results: BCL3 over-expression increased cell viability and proliferation of the 32Dcl-5IB cell line, and this effect was enhanced in the presence of ibrutinib. In vivo, BCL3 over-expression contributed to a significant in vivo growth advantage in a B-cell lymphoma xenograft model, and mice with BCL3 over-expression had a faster time to tumor detection compared to mice without BCL3 over-expression. In vivo, BCL3 over-expression also contributed to a significant in vivo growth advantage in a B-cell lymphoma xenograft model, and mice with BCL3 over-expression had a faster time to tumor detection compared to mice without BCL3 over-expression. Conclusion: BCL3 over-expression contributes an in vivo growth advantage in a B-cell lymphoma xenograft model and is a risk factor for ibrutinib relapse in CLL.

Proceedings of the American Association for Cancer Research  Volume 58  April 2017 771
kinase (BTK) inhibitors. However patients who relapse on BTK inhibitors such as ibrutinib have an extremely poor prognosis without additional intervention. Therefore, identifying and characterizing risk factors that predict relapse to BTK inhibitors is important. A series of 308 CLL patients have been enrolled on various ibrutinib clinical trials at the Ohio State University. Seven of these patients were identified to carry the translocation t(14;19), which leads to over-expression of B-cell leukemia 3 (BCL3). Of these 7, 6 (85%) have relapsed on ibrutinib while only 27% of patients (83/308) overall have progressed. BCL3 is known to regulate NF-κB transcription and influence B-cell function, and we found that overall BCL3 expression is increased in CLL compared to normal B-cells, therefore hypothesized that BCL3 may play a role in resistance to ibrutinib. We developed a competitive advantage to promote ibrutinib resistance. In order to test the role of BCL3 in ibrutinib resistance using an in vitro system, we overexpressed BCL3 or an empty vector (EV) control in ibrutinib responsive B-cell lines (BCL3 was at least 2-fold over-expressed relative to endogenous BCL3). Cells were treated with vehicle or 1 μM ibrutinib for 1 hour followed by a washout, and proliferation and viability were evaluated at various time points. ibrutinib inhibited cell proliferation and induced apoptosis, however BCL3 expression did not abrogate these effects. However, while examining BCR signaling proteins we found that BCL3 expression enhanced phosphorylation of BTK, suggesting that BCL3 stabilizes activated BTK to circumvent ibrutinib treatment. We next engrafted these EV or BCL3 over-expressing cells into the left or right flank, respectively, of immune-compromised (NSG) mice. Mice were sacrificed when either tumor reached a volume of 2000 cm³, and the tumors were isolated and weighed. Tumors which developed from the BCL3 over-expressing cells at sacrifice were larger than those which developed from the EV cells by an average of 1332 g. We also evaluated a disseminated tumor model where HBL-1 EV or BCL3 over-expressing cells were injected via the tail vein. Disease was monitored by weekly peripheral blood flow cytometry for human CD19. We saw that 6 of 11 mice intravenously engrafted with HBL-1 BCL3 present with peripheral disease when the mice meet removal criteria, whereas only 1 of 11 mice engrafted with HBL-1 EV cells developed peripheral disease. We conclude that the presence of t(14;19) indicates a higher risk of relapse in patients undergoing ibrutinib therapy, and these patients should be closely monitored for evidence of progression. Our studies also suggest that BCL3 promotes more aggressive disease in a lymphoma xenograft model, and may be involved in tumor migration in vivo.

#3015 Selection inhibition of mutant KRAS cell and tumor growth by PHT-7.3, an inhibitor of the KRas signaling nanocluster protein Cnk1. Roisin Delaney,1 Marco Maruggi,2 Martin Indarte,2 Robert Lemos,1 Geoff Roos.1

**Objective:** To identify druggable targets for tumors with KRas mutations.

**Methods:** We previously identified connector enhancer of kinase suppressor of Ras 1 (Cnk1) as a critical mediator for growth driven by mut-KRas in human cancer cells. Despite intense efforts, tight nucleotide binding of Cnk1 has hindered the development of compounds that bind or inhibit KRas. We have pedded the development of compounds that bind or inhibit KRas. We have identified kinase suppressor of Ras 1 (Cnk1) as a critical mediator for growth driven by mut-KRas in human cancer cells. Cnk1 co-localizes with mutant KRas at the membrane and deletion of Cnk1 abrogates KRas activation and the activation of the Ras effectors Raf and Rho. Cnk1 deletion caused cells with mutant KRas to accumulate at the G1 checkpoint similar to selective deletion of mutant KRas itself. Following a screen and initial structural optimization a small molecule probe compound PHT-7.3 was identified and shown to bind selectively to the pleckstrin homology PH domain of Cnk1 preventing Cnk1 and mut-KRas co-localization. PHT-7.3 inhibited mut-KRas but not wt-KRas non small cell lung cancer (nsclc) cell growth, and selectively blocks mut-KRas downstream signaling in cells. PHT-7.3 exhibited cytostatic antitumor activity in the mut-KRas (G12S) A549 and mut-KRas (G12V) H441 nsclc xenografts, but not in the wt-KRas H1975 nsclc xenograft. Mut-KRas downstream signaling was inhibited by PHT-7.3 in the xenografts with downregulation of activated Rho and Raf signaling. PHT-7.3 showed further increased antitumor activity in A549 xenografts in combination with erlotinib or trametinib. Thus, the work identifies the PH domain of Cnk1 as a druggable target whose inhibition selectively blocks mutant-KRas activation, and PHT-7.3 as a lead agent in the development of therapies for KRas tumors.

#3016 Identification of protein arginine methyltransferase 1 as novel epigenetic vulnerability in KRAS/p53 mutant PDAC primary patient models.

**Objective:** To identify druggable targets for tumors with KRas mutations.

**Methods:** We previously identified protein arginine methyltransferase as a novel genetic vulnerability in PDAC and strongly suggest PRMT1 dependency and to refine responder population. To further confirm a role for PRMT1 in tumor maintenance, we developed inducible PRMT1 knockout in a primary patient model and showed a dramatic tumor growth inhibition (TGI) in vivo upon PRMT1 knockdown. PRMT1 is the primary enzyme responsible for arginine asymmetric demethylation, however other members of the Type I family are also involved in this process and we evaluated the role of protein arginine methyltransferase 4 (PRMT4) and 6 (PRMT6) in our workhorse model. Surprisingly, no significant phenotypic response was observed upon genetic inhibition of PRMT4 or PRMT6 suggesting no redundancy between different PRMT type 1 and a unique dependency on PRMT1. To strengthen and complement the genetic validation, we leveraged a PRMT Type I inhibitor and confirmed in vitro results as well as in vivo efficacy at tolerated doses (xenograft vs allograft). Key models have been prioritized in order to inform on PRMT1 dependency and to refine responder population. Our results has identified and validated for the first time an arginine methyltransferase as a novel genetic vulnerability in PDAC and strongly suggest PRMT1 as a new therapeutic opportunity in PDAC cancers.

#3017 Inhibition of YAP/TAZ-dependent transforming properties in LATS1/2 deleted RPE1 cells by MAPKAPK5 targeting. Min Hwan Kim, Joon Kim. Korea Advanced Institute of Science and Technology, Daejeon, Republic of Korea.

**Objective:** To identify druggable targets for tumors with LATS1/2 loss.

**Methods:** To examine the transforming potential of LATS1/2 loss, both LATS1 and LATS2 alleles were deleted by CRISPR-Cas9 genome editing in RPE1-hTERT cells. YAP/TAZ activity in LATS1/2-null RPE1 cells was measured by immunofluorescence (IF) staining and qRT-PCR. Transforming properties of LATS1/2 loss were measured on both 2-dimensional (2D) and 3D culture, and the centrosome number and DNA contents of cells were determined by IF and propidium iodide staining. LATS1/2-null RPE1 cells were subjected to an image-based kinase high-throughput screening platform that enables the identification of new molecular drivers in the genetic vulnerability of PDAC. We identified MAPKAPK5 as a novel genetic vulnerability in PDAC and strongly suggest MAPKAPK5 targeting in PDAC.

#3018 Genetic loss of LATS1/2, thenegativeregulatorsofYAP/TAZ, has been reported in various human tumors, and suggested to activate YAP/TAZ in tumorigenic process. However, the molecular consequence of LATS1/2 genetic loss in benign human cells has not been addressed, and therapeutic targets for tumors with LATS1/2 loss have not been explored. We aimed to investigate the transforming potential of LATS1/2 loss in human RPE1 cells, and to find targetable kinases that support YAP/TAZ activation in tumors with LATS1/2 loss Method: To examine the effect of LATS1/2 loss, both LATS1 and LATS2 alleles were deleted by CRISPR-Cas9 genome editing in RPE1-hTERT cells. YAP/TAZ activity of LATS1/2-null RPE1 cells was measured by immunofluorescence (IF) staining and qRT-PCR. Transforming properties of LATS1/2 loss were measured on both 2-dimensional (2D) and 3D culture, and the centrosome number and DNA contents of cells were determined by IF and propidium iodide staining. LATS1/2-null RPE1 cells were subjected to an image-based kinase high-throughput screening platform that enables the identification of new molecular drivers in the genetic vulnerability of PDAC. We identified MAPKAPK5 as a novel genetic vulnerability in PDAC and strongly suggest MAPKAPK5 targeting in PDAC.
depletion resulted in suppression of LAT51/2-null RPE1 cell proliferation on 2D culture as well as sphere formation capacity on 3D culture. Conversely, constitutively active MAPKAPK5 mutant expression in RPE1 cells induced YAP/TAZ nuclear enrichment. Conclusion: These results suggest that LAT51/2 genetic loss drives transforming properties in human RPE1 cells, and MAPKAPK5 inhibition blocked YAP/TAZ activation induced by LAT51/2 loss. We suggest that MAPKAPK5 is a novel positive regulator of YAP/TAZ and may serve as a therapeutic target for YAP/TAZ-driven tumors.

**#3018 RET rearrangements as promising therapeutic targets in breast cancer.** Bhavna S. Paratala,1 Jeffrey S. Ross,2 Casey B. Williams,2 Whitney Petrosky,3 Kirstin A. Williams,4 Jon Chung,5 Sonia C. Dohl,6 Shridar Ganesan,7 Siraj Ali,2 Brian Leyland-Jones,3 Kim M. Hirshfield1.1 Rutgers Cancer Institute of New Jersey, New Brunswick, NJ; 2Foundation Medicine, Cambridge, MA; 3Avera Cancer Institute Center for Precision Oncology, Sioux Falls, SD.

Receptor tyrosine kinase alterations have played a significant role in therapeutic decisions for cancer due to their oncogenic nature and response to targeted small molecule kinase inhibitors. Increased genomic profiling of tumors using hybrid-capture based next-generation sequencing approaches now reveal the presence of previously unknown fusions and alterations involving kinases in a diverse set of cancers. Here we report the presence and therapeutic significance of recurrent and novel fusions involving RET, a known oncogenic tyrosine kinase receptor, in breast cancer. Methods: Comprehensive genomic profiling on formalin-fixed, paraffin embedded patient tumor tissues was performed using FoundationOne platform that covers the entire coding region for 315 cancer-related genes and exons of 28 genes involved in rearrangements at a depth of 500-1000X (Foundation Medicine, MA). Out of 23 rearrangements, two representative RET fusion expression vectors were synthesized and expressed in non-tumorigenic cell lines (breast MCF10A and mouse 3T3 fibroblasts) and were evaluated for RET kinase signaling, drug response, and tumorigenicity. Results: RET gene fusions, the canonical NCOA4-RET and a novel, noncanonical RASGEF1A-RET fusion, were identified in two separate breast cancers and both include exons required to retain the intact kinase domain of Ret. The novel RASGEF1A-RET fusion includes the non-coding region of RASGEF1A potentially resulting in a truncated RET protein using an alternate internal start site in exon 11 of RET. In vitro characterization of both fusions expressed in mouse 3T3 and human MCF10A cell lines revealed constitutive kinase activation and subsequent downstream signaling as evidenced by phosphorylation of Ret, Erk and Akt. This is the first reported noncanonical RET rearrangement resulting in a 5' truncated but functional RET kinase. Non-tumorigenic cell lines with stable expression of either rearrangement showed transformed phenotypes assessed by changes in morphology, enhanced growth rate, colony forming ability, and tumor formation in mice. RET fusion-transformed cells were exquisitely sensitive to treatment with RET inhibition when evaluated in both short-term and long-term functional assays. NCOA4-RET was found by CGP in an index case of metastatic EC+/HER2+ breast cancer that had radiographic evidence of disease progression while on trastuzumab, pertuzumab, and anastazol. Subsequent treatment with cabozantinib plus anastazol led to a rapid clinical and radiographic response. Conclusion: CGP technologies, including hybrid-capture based approaches can identify previously unreported but recurrent RET gene fusions in breast cancer. Here, we show that RET fusions including both canonical and non-canonical complex rearrangements are functional and may represent promising therapeutic targets in selected breast cancer patients.

**#3019 The role of TACC3 in the progression from ductal carcinoma in situ to invasive breast cancer.** Lorenda Campo, Maya Mathew, Eun-Kyoung breuer, William Small. Loyola University Medical Center, Maywood, IL.

Ductal carcinoma in situ (DCIS) is a non-invasive breast cancer with the potential to become invasive/metastatic. The development of DCIS to invasive breast cancer is an important aspect of breast tumor aggressiveness, however, little is known about the genetic and molecular alterations involved in this progression. Also, analysis of molecular markers and genetic signatures of DCIS and invasive breast cancer have failed to identify transition-specific biomarkers or pathways. Hence, identifying the molecular mechanisms by which DCIS progression to invasive breast cancer is critical for the success of diagnosis, prognosis and therapy of breast cancer. Members of the transforming acidic coiled-coil (TACC) protein family are key players in the maintenance of centrosome integrity, the regulation of microtubule assembly, and spindle stability during mitosis. TACC3 has been shown to be involved in the regulation of centrosome-microtubule dynamic networks, cell growth and differentiation, and transcription/ gene expression through interactions with other molecules. Mounting evidence indicates that high levels of TACC3 may contribute to breast cancer development. Here, we investigated the significance of TACC3 in the transition of DCIS to invasive breast cancer. First, we examined the expression of TACC3 in non-tumorigenic human mammary epithelial MCF10A cells and MCF10D10CS.COM cells, which are known to form DCIS-like lesions in mice and to progress to invasive cancer, and found that the expression of TACC3 is elevated in MCF10D10CS.COM cells compared to MCF10A cells. By analyzing tissue microarray data, we found that expression of TACC3 gradually increased from normal breast to DCIS, and further increased in invasive breast cancer. In addition, ectopic expression of TACC3 in MCF10D10CS.COM cells promoted cell proliferation, migratory and invasive capabilities as well as the epithelial-mesenchymal transition (EMT)-like phenotype. Moreover, MCF10D10CS.COM cells stably expressing TACC3 exhibited increased expression of stemness markers. Interestingly, a small molecule inhibitor of TACC3, KHS101 treatment in MCF10D10CS.COM cells significantly suppressed cell proliferation and the P38/ERK signaling pathway while having little effect on MCF10A cells. Our findings, therefore, suggest that TACC3 may play an important role in the progression from DCIS to invasive breast cancer and that targeting TACC3 could be a promising new therapeutic strategy for DCIS patients.

**IMMUNOLOGY: Adaptive Immunity in the Tumor Microenvironment**

**#3021 CCR5 inhibition: macrophage repolarization therapy for colorectal cancer.** Niels Halama,1 Inka Zoernig,1 Anna Berthel,1 Christoph Kahler;2 Fee Klupp,2 Meggy Suarez-Carmona,1 Karsten Brand,1 Juergen Krauss,1 Felix Lasitschka,3 Alexis Ulrich,3 Juergen Weitz,2 Martin Schneider,2 Markus Buechler,4 Laurence Zitvogel,5 Thomas Herrmann,6 Axel Benner,6 Christina Kunz,6 Stephan Luecke,5 Christoph Springfeld,1 Christine S. Falk,5 Dirk Jaeger,5 National Ctr. for Tumor Diseases, Heidelberg, Germany; 6University Hospital Dresden, Dresden, Germany; 7University Hospital Heidelberg, Heidelberg, Germany; 8Institute Gustave Roussy, Paris, France; 9Medizinische Klinik Idar-Oberstein, Idar-Oberstein, Germany; 10German Cancer Research Center, Heidelberg, Germany; 11Hannover Medical School, Hannover, Germany.

In patients with metastatic colorectal cancer (CRC), the local immune response influences the course of the disease. An in-depth analysis of the immune microenvironment of human CRC liver metastases revealed a distinct immunological microenvironment. Within this microenvironment, two distinct subsets of myeloid cells induce an influx of T cells into the invasive margin via CXCL9/CXCL10. CCL5 is produced by these T cells and stimulates pro-tumoral effects via CCR5, creating an exploitive loop. CCR5 was found on macrophages, lymphocytes and on

**#3022 The impact of Notch3 signaling on tumor microenvironment and metastatic progression of human head and neck tumors.** Helmut Schmid1, Christoph Stein, Idar-Oberstein, Germany; 2Institute of Pathology, University Medical Center Regensburg, Regensburg, Germany; 3University Medical Center Regensburg, Regensburg, Germany; 4German Cancer Research Center, Heidelberg, Germany; 5Hannover Medical School, Hannover, Germany.

We found the gain-of-function Notch3 mutation in cancer is associated with an increased risk of head and neck cancer. However, the mechanisms underlying this association are poorly understood. Notch3 signaling is essential for cell survival only following metastasis. To test if knockdown of selected targets inhibits metastasis in a therapeutic setting, we established orthotopic xenograft models of human head and neck tumors in the mouse. Components of the Notch pathway were shown to be essential for survival of cells derived from metastatic sites. Whole exome sequencing identified a novel mutation in one of the EGF domains of Notch3 that was acquired only in the metastatic in the mouse. Utilizing CRISPR methodology, we established that “fixing” the mutation results in reversal of metastatic phenotype of the cells, making them Notch independent similar to their primary tumor counterparts. Mutations in EGF domains have been seen to alter the interaction of ligand which can impact Notch signaling. Our data indicate that a distinct set of target genes is induced upon interaction between Notch3 and Jag2. Furthermore, our results indicate that suppression of Notch3 improves survival in mice bearing orthotopic tumors derived from the metastatic HN-3C model. Overall, our data demonstrate that metastatic cells from head and neck tumors acquire dependency on Notch3 signaling. Novel treatments targeting components of this pathway may prove effective in targeting metastatic cells alone or in combination with conventional therapies.
the vast majority of tumor cells. Inhibition of CCR5 in patient-derived func-
tional in vitro organotypic culture models showed a promising macrophage 
repolarization with anti-tumoral effects. These effects are mediated by activation 
of an antiviral program in macrophages, leading to interferon and reactive ox-
genesis6,7. As such, targeting the Wnt pathway is an attractive approach to the 
initiate tumorigenesis in the intestine and promote cancer stem cell metasta-
specific interaction of selective target compounds targeting oncogenic Wnt activity through disrupting the highly 
unacceptable side effect profiles1. Here, we developed a potent and robust, se-
dependent cancer growth and immunomodulates colorectal tumors. 

#3022 Novel hydrocarbon stapled peptide inhibitors suppresses β-catenin 
dependent cancer growth and immunoinduces colorectal tumors. Da-
vid Zhu,1 Joy Jin,2 WntRx/Lab Central, Boston, MA; 2Harvard University, 
Boston, MA.

Mutations in several components of the canonical Wnt pathway function as 
drivers in a range of common solid tumor cancers, including about 90% of 
sporadic colorectal cancers (CRCs), the third most common cancer in the US. In 
particular, activation of β-catenin (β-cat), a key Wnt signaling component, can 
initiate tumorigenesis in the intestine and promote cancer stem cell metasta-
sis6,7. As such, targeting the Wnt pathway is an attractive approach to the 
development of cancer therapeutics. However, Wnt inhibitors tested to date, in-
duding those that disrupt β-cat activity, have either had limited efficacy or 
unacceptable side effect profiles1. Here, we developed a potent and robust, se-
lective lead compound targeting oncogenic Wnt activity by disrupting the highly 
specific interaction of β-cat with its co-activators BCL9/B9L, which has been 
shown to abrogate transactivation. By using hydrocarbon stapled peptide tech-
nology and an acutely sensitive high throughput biochemical screening assay, 
we have identified several promising peptides that possess a strong pharmaco-
kinetic profile. These peptides (i) exhibit robust activity in mouse models; (ii) 
inhibit cancer cell proliferation, metastasis, and stem cell progression; and (iii) 
modulate the immune microenvironment, demonstrating the feasibility of such 
peptide development and selection. Synergy is demonstrated between the sta-
pled peptides and anti-PD1 antibodies, which has significant implications for 
combination therapy with commercial immune checkpoint blockers that have 
become standard of care for second-line melanoma treatment. These peptides 
represent a promising new potential therapeutic class for patients with CRC, for 
which traditional chemotherapy and targeted inhibitors have had limited ther-
apeutic success.

#3023 The antitumor activity of immunotoxins is enhanced by tofacitinib. 
Nathan Simon,1 Antoñada Antigüan,2 Stephen Hewitt,2 Massimo Gadina,2 Ma-
sanori Onda,3 Christine Alexiew,1 David Joseph Fitzgerald1. 1Walter Reed National Military Medical Center, Bethesda, MD; 2National Institute of Arthritis and Musculoskeletal and Skin Disease, Bethesda, MD.

Treatment outcomes of certain aggressive cancers have not improved signif-
ificantly in the last decade, necessitating development of new therapies. Recom-
binant immunotoxins (IT) are fusion proteins consisting of the enzymatic do-
main of a cytotoxin linked to an antibody fragment targeting a cellular surface 
protein. While the combination of selective targeting and potent cell-killing 
make ITs well suited for targeted cancer therapy, clinical experience has indi-
cated that patients can generate anti-toxin neutralizing antibodies after one cy-
cle of treatment. Mouse treated with the FDA-approved JAK inhibitor, tofacitinib, 
produced significantly lower anti-toxin antibody titers, suggesting that tofac-
itinib could be used in combination with immunotoxins to improve therapeutic 
efficacy. Accordingly, the combination of tofacitinib and IT was tested both in 
vitro and in vivo using two models of aggressive human cancers: pancreatic 
ductal adenocarcinoma and triple-negative breast cancer. In vitro combination 
study examined the effects on oncogenic signaling pathways and looked for 
enhancement of cytotoxic potency. Results demonstrated that tofacitinib me-
diated inhibition of key signaling pathways but no enhancement of immuno-
toxin killing. By contrast, when xenograft tumor models were challenged, im-
munotoxin activity was enhanced greatly by co-treating with tofacitinib. 
Tofacitinib treatments alone did not demonstrate any antitumor activity. The 
combination of tofacitinib and immunotoxin decreased tumor growth and ex-
tended survival compared to either treatment alone. Examination of post-treat-
ment tumor samples and sera from mice indicated that JAK inhibition resulted in 
alterations of the tumor microenvironment, including a decrease in cancer-
promoting cytokine levels and reductions in recruitment of suppressive im-
mune cells to tumor tissue. This study demonstrates that the inhibition of the 

#3024 CD4+ outperform CD8+ central memory-derived CAR T cells, me-
diating persistent antitumor responses and long-term eradication of glio-
blastoma. Dongrui Wang, Renee Starr, Brenda Aguilar, Alfonso Brito, Brenda 
Chang, Aniece Sarkissian, Behnam Badie, Michael E. Barish, Stephen J. Forman, 
Christine E. Brown. City of Hope, Duarte, CA.

Purpose: To compare antitumor effector function mediated by CD4+ and 
CD8+ chimeric antigen receptor (CAR)-T cells targeting IL13 receptor α2 
(IL13Ra2) for treatment of glioblastoma (GBM). Experimental Design: CD4+ 
and IL13Ra2-specific CAR T cells, derived from enriched central mem-
ory T cells (Tcm), were evaluated for their antitumor potential both in vitro by 
recreative challenge with GBM cells and in vivo in established orthotopic GBM 
xenograft models. Further, GBM-stimulated CD4+ and CD8+ T CAR T cells were 
examined for their exhaustion- and memory-associated phenotypes at tran-
scriptional and protein levels, which would account for their differential antitu-
mor activity. Results: While CD8+ T CAR T cells mediated robust short-term 
cytolytic effector function, they became rapidly exhausted and lost antitumor 
potential after repeated stimulation with tumor cells. CD4+ CAR T cells, by 
contrast, persisted and retained effector potency even after repetitive tumor 
challenge. CD4+-mediated cytotoxicity acted through the granzyme B/perforin 
pathway and was independent of the CD8+ cells. Activated CD4+ CAR T cells 
augmented the proliferation of CD8+-cells, but failed to protect the CD8+ cells 
against stimulants of cellular exhaustion. In NSG mice with established GBM 
xenografts, co-stimulated CD4+ T CAR T cell treatment led to long-term tumor-free survival, while CD8+ 
CAR T cell treated mice showed short-term tumor regression followed by anti-
gen-positive relapse and associated T cell exhaustion. Upon GBM stimulation, 
CD4+ cells expressed less co-inhibitory receptors and more memory-associated 
markers than the CD8+ T cell subset. Further, a comprehensive transcriptional 
analysis revealed that when activated, CD4+-cells retained expression of genes 
involved in survival- and self-renewal-related pathways, indicating a less ex-
hausted status and a better functional persistence in comparison to the CD8+ 
cells. Conclusion: We observed a superior anti-GBM activity mediated by CD4+ 
CAR T cells over the CD8+ subset, featured by their ability to maintain long-
term immune response and reduce stimulation-induced exhaustion. It is thus 
infereved that the frequency of CD4+ cells could be an important criteria for 
evaluating the efficacy of CAR T cells as immunotherapeutic products.

#3025 Preclinical characterization of a novel monoclonal antibody target-
ing a neo-antigen expressed in ovarian and GI malignancies. Kristen Zeligs,1 
Philip M. Arlen,2 Kwong Tsang,3 Lida Hernandez,3 Massimo Fantini,3 Chris-
tina M. Annunziata2. 1Walter Reed National Military Medical Center, Bethesda, 
MD; 2Precision Biologics, Inc., Rockville, MD; 3National Cancer Institute, 
Bethesda, MD.

Objectives: We have developed a novel humanized IgG1 monoclonal anti-
body, NEO-201, which targets a neoantigen expressed on ovarian and GI ma-
lignancies. This antigen has homology to CEA/CA125; however, it has specificity 
to tumor tissues and not normal tissues. Our aims were as follows: (1) to evaluate 
the antigenic spread across tumor cell lines derived from various ovarian 
and GI cancers; and (2) to determine the functionality of NEO-201. Methods: 
Expression of the antigen was identified by western blot analysis and flow cy-
tometry. Functionality was determined by an antibody dependent cell-mediated 
cytotoxicity (ADCC) assay using the antigen-expressing cell lines identified by 
western blot analysis. Cell lines not expressing the antigen were used as negative 
controls. The effector cells used in the ADCC assay were natural killer (NK) cells 
isolated from PBMCs of normal donors and high-affinity activated NK (haNK) 
cells. haNK cells are NK-92 cells genetically engineered to express the high-
affinity variant of human CD16 (FcgRIIIA-V158) and the human IL-2 gene. 

affinity variant of human CD16 (FcgRIIIA-V158) and the human IL-2 gene. 

The effector cells used in the ADCC assay were natural killer (NK) cells 
isolated from PBMCs of normal donors and high-affinity activated NK (haNK) 
cells. haNK cells are NK-92 cells genetically engineered to express the high-
affinity variant of human CD16 (FcgRIIIA-V158) and the human IL-2 gene. 

haNK cells are NK-92 cells genetically engineered to express the high-
affinity variant of human CD16 (FcgRIIIA-V158) and the human IL-2 gene.

5 ovarian cancer cell lines (OV90 and PE01) and 1 of 2 colorectal cancer cell 
lines (LS174T) stained positively for NEO-201. Flow cytometry analysis on ovarian, 
colorectal, and pancreatic cancer cell lines confirmed the expression of the 
NEO-201 neoantigen on 1 of 2 ovarian cancer cell lines (OV90), 1 of 2 colorectal 
cancer cell lines (LS174T), and 2 of 2 pancreatic cancer cell lines (ASPC-1 and CFPAC-
1). ADCC assay was performed using OV90 and ASPC-1 tumor cell lines. Cell 
lines not expressing the neoantigen were used as negative controls. Killing of 
tumor cells expressing the neoantigen was also observed with NEO-201 alone; 
however, the lysis was significantly augmented when NK cells from the PBMCs 
of normal donors or haNK cells were included in the ADCC assay. Conclusions:
These findings demonstrate that the NEO-201 neoantigen is expressed on several tumor cell lines representing ovarian and GI malignancies. NEO-201 can mediate ADCC activity in the presence of NK cells and NK cell lines. In addition, NEO-201 can induce apoptosis in tumor cell lines expressing the NEO-201 neoantigen. Furthermore, preliminary studies demonstrated that this neoantigen is expressed in numerous cancer types (not shown). In vivo studies as well as INI-related studies are planned.

#3026 Targeting GPX4 in tumor-associated stromal cells increases inflammatory-cell infiltration. Shrikanta Chattopadhyay,1 Cherrie Huang,1 Ninib Baryawno,1 Nicolas Severe,1 Vasanthi Viswanathan,1 Carlotta Costa,1 David Scadden,2 Stuart Schreiber1. 1Massachusetts General Hospital, Boston, MA; 2Broad Institute, Cambridge, MA.

The lack of a T-cell inflamed microenvironment in tumors limits responsiveness to many immunotherapies. T-cell exclusion is often mediated by a dense infiltration of fibroblast-like stromal cells. Up to 55% of triple-negative breast cancers have ‘stroma-rich’ tumors with markedly lower T-cell infiltration. Here we report a therapeutic strategy that can potentially convert stroma-rich tumors into T-cell inflamed tumors by forcing stromal cells to secrete 5-lipoxygenase products which are powerful chemo-attractants for T cells. We were initially interested in identifying selective inhibitors of stromal cell function. To achieve this, we used phenotype-based small-molecule screening in which the phenotype of stroma-induced cancer cell migration in vitro was a surrogate for stroma-induced metastasis in vivo. We identified a compound, RSL3 that inhibited this migration. RSL3 was selectively cytotoxic to stromal cells over cancer cells, in comparison of immortalized cell lines as well as comparisons of patient-derived primary breast cancer cells to cancer-associated fibroblasts (CAFs). We therefore undertook studies to identify its mechanism of action. RSL3 was recently reported to target the redox enzyme glutathione peroxidase 4 (GPX4). GPX4 metabolizes lipid peroxides so we performed metabolomic profiling of RSL3-treated stroma-cancer co-cultures and found elevated arachidonic acid products of lipoxygenase enzymes. Stromal cells were found to contain >10-fold higher levels of lipoxygenase products than carcinoma cells. Blocking either 5-lipoxygenase (5-LO) or 15-lipoxygenase (15-LO) with selective inhibitors abrogated RSL3’s cytotoxicity to stromal cells. Thus, high lipoxygenase activity in stromal cells increases their susceptibility to GPX4 inhibition. Because 5-LO products like leukotriene B4 are powerful chemo-attractants for myofibroblasts and T cells, we studied the impact of GPX4 knockdown in vivo using xenografts of cancer cells co-injected with stromal cells. GPX4 knockdown resulted in a large increase in myeloid-cell infiltration into tumors but, surprisingly, T-cell infiltration was suppressed. We reasoned that 15-LO products are immunosuppressive based on recent findings that 15-LO gene amplifications are inversely correlated with T-cell infiltration in breast cancers in The Cancer Genome Atlas. Consistent with this, GPX4 inhibition of stroma-cancer co-cultures suppressed T-cell chemotaxis but combined inhibition of GPX4 and 15-LO significantly enhanced T-cell chemotaxis over untreated controls in vitro. We are undertaking in vivo testing of this combination. In summary, our unbiased chemical biology approach has revealed a therapeutic strategy to promote T-cell infiltration. We envision this to be a priming strategy for stroma-rich cancers to become responsive to a variety of different immunotherapies thereby unleashing their full curative potential.

#3027 Dissecting mechanisms of anti-PD-1 therapy with massively parallel single-cell RNA-sequencing. Brian C. Miller,1 Marc H. Wadsworth,2 Kevin Bi,3 Travis K. Hughes,2 Robert Manguso,1 Arlene H. Sharpe,1 Alex K. Shahel,2 Nicholas Haining,1 Dana-Farber Cancer Inst., Boston, MA; 2Massachusetts Institute of Technology, Cambridge, MA; 3Harvard Medical School, Boston, MA.

Anti-PD-1 therapy is an important new treatment option for many different types of malignancies, but overall response rates are less than 40%. Limited understanding of how anti-PD-1 treatment changes the tumor immune microenvironment is a barrier to identifying rational combination therapies and understanding mechanisms of immunotherapy resistance. To overcome this barrier, we set out to understand the mechanisms by which anti-PD-1 therapy augments the anti-tumor immune response using single-cell genomics. We have developed a massively parallel single-cell RNA-sequencing platform (“Seq-Well”) that uses a fabricated chip with nearly 100,000 nanowells in which barcoded beads and individual cells are distributed prior to lysis and RNA capture. We used this platform to comprehensively define the global expression profile of all major immune lineages in the tumor microenvironment in a mouse tumor model of immunotherapy. Mice were implanted with the B16F10 melanoma transplantable model of cancer and treated with anti-PD-1 or control antibodies. Tumors were harvested and CD45+ tumor-infiltrating leukocytes isolated by FACs. In a single experiment we were able to sequence the transcriptomes of over 600 individual cells, allowing us to clearly distinguish different immune lineages within the tumor microenvironment. We detect two transcriptionally distinct populations of CD8+ T cells, one that is highly proliferative (as marked by Ki-67), and one that has higher expression of cytotoxic markers (i.e. perforin). The Ki-67+ population is enriched for a gene expression signature from terminally exhausted CD8+ T cells in chronic viral infection, suggesting that this is a more exhausted subset. Treatment with anti-PD-1 globally alters the tumor microenvironment, including enriching for CD8+ T cells in the Prf1+ subpopulation compared with the Ki-67+ more terminally exhausted population. Studies to understand changes in the immune infiltrate of immunotherapy resistant tumors are currently ongoing. In conclusion, massively parallel single-cell RNA-sequencing allows us to dissect the mechanisms by which checkpoint blockade controls tumor growth, revealing shifts in the differentiation state of exhausted CD8+ T cells induced by checkpoint blockade.

MOL ecular AND Cellu lar BIOLOG Y / Genet Ics: Breakthroughs in the Control, Function, and Drivers of Oncogenesis

#3028 Reactive oxygen species induced nuclear translocation of c-MET via INTERNET mechanism. Mei-Kuang Chen,1 Yi Du,2 Yu-Yi Chu,2 Mien-Chie Hung3. 1The University of Texas Health Science Center at Houston, Graduate School of Biomedical Science, Houston, TX; 2The University of Texas MD Anderson Cancer Center, Houston, TX; 3National Cheng Kung University, Tainan, Taiwan.

c-MET is one of the receptor tyrosine kinases (RTKs) that are overexpressed in malignant cancer types including breast cancer. c-MET is traditionally known for its role in signaling transduction from the cell surface, our recent publication provided evidence that c-MET can be translocated into the nucleus and phosphorylate PARP1 in response to reactive oxygen species (ROS) stimulation (Du et al Nat Med 2016). Oxidative stress is a common phenomenon in cancer cells due to alteration of metabolism, and constitutive oxidative stress related to ROS has been observed in breast cancer cells. In this study, we demonstrated that hepatocyte growth factor (HGF) as well as hydrogen peroxide (H2O2) can induce retrograde translocation of c-MET holoreceptor via a membrane-bound vesicle transport mechanism and translocate into the nucleus through INTERNET (integral trafficking from the ER to the nuclear envelope transport pathway) (Wang et al. J Biol Chem 2012) in breast cancer cells. While c-MET nuclear transportation increases dramatically under H2O2 treatment, our findings provide a putative mechanism by which breast cancer cells adapt to oxidative stress and suggest that INTERNET might be a general nuclear translocation mechanism shared among RTKs.

Oncogenic mutations in RAS provide a compelling yet intractable therapeutic target. Using co-immunoprecipitation mass spectrometry, we recently identified an interaction between RAS and Argonaute 2 (AGO2), the core component of the RNA silencing machinery exerting translational control of mRNA transcripts. RAS and AGO2 co-sediment and co-localize in intracellular endomembrane-bound organelles. The AGO2 N-terminal domain directly binds the NET (integral traffi cking from the ER to the nuclear envelope transport pathway) (Wang et al. J Biol Chem 2012) in breast cancer cells. While c-MET nuclear transportation increases dramatically under H2O2 treatment, our findings provide a putative mechanism by which breast cancer cells adapt to oxidative stress and suggest that INTERNET might be a general nuclear translocation mechanism shared among RTKs.
MOLECULAR AND CELLULAR BIOLOGY / GENETICS: Breakthroughs in the Control, Function, and Drivers of Oncogenesis

Metaplasia (ADМ) phenotype considered as precursors of PanIN (pancreatic intraepithelial neoplasia) and PDAC. This mirrors the phenotype of loss of Dicer in the same model further reinforcing a role for microRNAs in restraining KRAS oncogenic programs. Yet unlike Dicer, loss of AGO2 alone did not cause any gross or histological changes in the development of the mouse pancreata. In an effort to further exploring the role of AGO2, we have also studied the activated levels of a variety of signaling molecules in pancreata obtained from different genotypes. Primary analysis indicates that wild type Ras levels are elevated during AGO2 loss and has a bearing on PDAC initiation. Using both Western blot and Immunohistochemical analyses, we demonstrate a previously unknown and critical role for AGO2 in KRAS-MAPK signaling pathway.

#3030 Mutant p53-driven metastasis explored utilizing a traceable, conditional osteosarcoma model. Rasoul Pourehmadi, Yun Zhang, Mark J. McArthur, Guillermmina Lozano, MD Anderson Cancer Center, Houston, TX.

TP53 is the most frequently mutated gene in cancer and missense mutations in particular account for the majority of mutations. Mutant p53 proteins exert oncogenic Gain-of-Function (GOF) properties that contribute to increased migration and invasion in culture and metastasis in vivo. To elucidate how mutate p53 drives metastasis, we developed a traceable somatic osteosarcoma model that initiates with a single p53 mutation (p53R172H or p53R245W), or p53 loss specifically in osteoblasts using Oss-cre. To mark tumor cells, we utilized the mTmG allele which expresses membrane-targeted Tomato (mT) prior to Cre-mediated excision and membrane-targeted green fluorescent protein (mG) after excision so the tumor cells become GFP+ and the stromal cells remain RFP+. In this high penetrant, short latency mouse model, tumor micro-metastasis can be detected by GFP expression in the context of a normal stroma and immune system. The cohort has developed osteosarcoma with complete penetrance and an average survival of 304± 65 day. We observed metastasis in 55% of p53 mutant osteosarcomas which was significantly higher than 26% metastasis observed in p53 null tumors (p<0.01). In p53 mutant osteosarcomas, the metastasis rate was found significantly associated with low p53 copy number. Spectral karyotyping (SKY) on early passage cells derived from somatic p53 mutant tumors exhibited marked aneuploidy with modal chromosome numbers near tetraploid. To characterize the transcriptional profile associated with mutant p53 GOF, we analyzed and compared the RNA Seq transcriptomes of eight tumors derived from p53R172H mutant mice with eight p53 null tumors. Comparative analysis of gene expression identified a signature of snRNA genes to be strongly associated with mutant p53 gain of function. Functional annotation of upregulated genes in mutant tumors was also highly enriched for chromatin modifying enzymes. These findings contribute to our understanding of the role of mutant p53 GOF in metastasis. Our long term goal is to study how tumor-stromal interactions affect tumor development and metastasis. This understanding will have broad translational significance in diagnosis and treatment of tumors with mutant p53.

#3031 PHIP is a therapeutic target for triple negative solid tumors. David DeSemir,1 Vladimir Bezrookove, Mehdi Nosrati, Altaf A. Dar, Nathan Salo-

mons,1 Richard W. Sagebiel, Pierre Desprez, Robert J. Debs, Dirk Schaden- dorf,1 Mohammed Kashani-Sabet,1 California Pacific Medical Center Research Institute, San Francisco, CA; 3Cincinnati Children’s Hospital Medical Center, Cincinnati, OH; 6University Hospital Essen, Essen, Germany.

Targeted therapy relies on the classification of tumors according to the major molecular drivers of the malignant phenotype, which can then help decide the therapeutic treatment. However, a substantial subset of solid tumors does not express these markers, exemplified by the triple-negative subtype of breast cancer. Shared molecular factors that promote the progression of these tumors, and that represent a target for their therapy, are missing. We previously described a role for PHIP (Pleckstrin Homology domain-Interacting Protein) in the progression of melanoma, and demonstrated PHIP activation in triple-negative melanomas. Analysis of the TCGA profiling efforts in melanoma, breast and lung cancer revealed PHIP expression to be enriched in triple-negative breast cancer and in the bronchiad subtype of triple-negative lung cancer. Here we show the broad-based role of PHIP in the progression of triple-negative subtypes of three solid tumors (breast and lung cancer, and melanoma) defined by different mutational drivers and targeted therapies. By using a shRNA-based targeting of PHIP in in vitro and in vivo models, we have suppressed the malignant phenotype of triple-negative MDA-MB-231 and MDA-MB-436 human breast carcinoma cells. In addition, PHIP knockdown resulted in significant anti tumor effects in H1703 and Calu3 human lung cancer cells lacking mutations in EGFR, KRAS, and ALK, and in two short-term triple wild type melanoma cultures lacking mutations in BRAF, NRAS, and NFI. Suppression of PHIP expression resulted in inhibition of both tumor cell proliferation by cell survival and colony formation assays and invasion into matrigel in each of the tumor models examined, and was accompanied by suppression of pAKT, CCND1, T1N1, and ITGB1 expression when assessed by western-blot or quantitative immunofluorescence. The PHIP protein contains two bromodomains that can be therapeutically targeted by small molecules. We have discovered that the functional activity of the PHIP bromodomains has been poorly characterized. We show that PHIP co-localizes with and binds to the acetylated histone modification H4K9ac, and that both are coordinately regulated upon growth factor stimulation suggesting a new function for PHIP as a chromatin remodeler. To conclude, our results identify a novel role for PHIP in the progression of solid tumors lacking the major molecular drivers, and suggest PHIP as a druggable target for the therapy of these malignancies.

#3032 Direct regulation of alternative splicing by Smad3 through PCBP1 is essential to the tumor-promoting role of transforming growth factor beta1. Veenu Tripathi, Katherine M. Sixt, Xuan Xu, Ying E. Zhang, National Cancer Institute, NIH, Bethesda, MD.

In advanced stages of cancers, TGF-β promotes tumor progression in conjunction with inputs from receptor tyrosine kinase pathways. However, the mechanisms that underpin the signaling cooperation and convert TGF-β from a potent growth inhibitor to a tumor promoter are not fully understood. In this work we report that TGF-β directly regulates alternative splicing of cancer stem cell marker CD44 through a phosphorylated T179 of SMAD3-mediated interaction with RNA-binding protein PCBP1. We show that TGF-β and EGFR respectively induce SMAD3 and PCBP1 to colocalize in SC35 positive nuclear speckles, and the two proteins interact in the variable exon region of CD44 pre-mRNA to inhibit spliceosome assembly in favor of expressing the mesenchymal isoform CD44S over the epithelial isoform CD44E. We further show that the SMAD3-mediated alternative splicing is essential to the tumor-promoting role of TGF-β and has a global influence on protein products of genes instrumental to epithelial to mesenchymal transition and metastasis.

#3033 The PRL family of tyrosine phosphatases as a novel drug targets in acute lymphoblastic leukemia. Jessica S. Blackburn, University of Kentucky, Lexington, KY.

The aggressive and unpredictable behavior of acute lymphoblastic leukemia (ALL) presents a major clinical challenge in both the pediatric and adult setting. The development of new and better chemotherapies for this disease requires a detailed understanding of the genes and pathways that drive ALL malignancy. Somatic mutations in PRL family members are emerging as new drug targets with important roles in leukemia progression. To determine the extent to which phosphatases play a role in ALL malignancy, we used CRISPR/Cas9 to knock out expression of 255 individual phosphatases in human T-cell acute lymphoblastic leukemia cell lines and screened for deleterious effects on cell viability. Top hits from this screen included the protein tyrosine phosphatase type IV family, known as the PRLs. PRL3 is genomically amplified in a subset of human T-ALL, and more than 50% of human ALL patients have significantly higher expression of PRL2 and/or PRL3, compared to normal lymphocytes, suggesting that these PRLs may play an important role in ALL malignancy. Transgenic Myc-induced ALL models in zebrafish showed that overexpression of PRL2 and PRL3 significantly shortened latency of primary and relapse ALL, enhanced leukemia stem cell self-renewal (PRL2) and prevented apoptosis after standard chemotherapy treatment (PRL3). Finally, a specific PRL inhibitor strongly induced apoptosis of PRL-expressing ALL cells in a dose-dependent manner, in both zebrafish models in vivo and human cell lines in vitro. We have identified several FDA-approved, general phosphatase inhibitors that have potent anti-PRL activity and are capable of killing ALL cells in vitro. Current work is focused on moving these inhibitors into pre-clinical testing using patient-derived xenografts. Pull-down approaches are also being used to identify the substrates of PRL phosphatase activity that are critical to ALL survival and may represent new, tractable drug targets for the treatment of ALL.

#3034 A programmed ribosomal frameshifting defect potentiates the transforming activity of the JAK2-V617F mutation. Yousuf A. Khan, Sergey O. Sulima, Joe Krenda, Vivek M. Advani, John E. Jones, Joseph Briggs, Kim de Kersmaeker, Jonathan D. Dinman, University of Maryland College Park, Potomac, MD; KU Leuven Department of Oncology, Leuven, Belgium.

The JAK-STAT pathway is one of the major mechanisms through which cellular proliferation, differentiation, migration, survival and apoptosis are regulated in response to external stimuli. Promiscuous activation of this pathway is a major driver in the pathogenesis of myeloproliferative neoplasms, often characterized by clonal expansion of mature myeloid cells. The JAK2-V617F allele is...
the most common and well characterized mutation linked to this class of leukemias. A change of G to T at nucleotide 1849 of the coding sequence (CDS) results in substitution of valine to phenylalanine at codon 617. JAK2-V617F mutant cells have strongly increased activation of JAK-STAT signaling, which can partially be explained by its ability abolish inhibition of kinase activity and increase the Km of the enzyme. It is however unclear if these effects are sufficient to explain the strong activation of the JAK-STAT pathway induced by the V617F mutation. Here, we demonstrate that this mutation destabilizes a programmed -1 ribosomal frameshift (-1 PRF) signal in the JAK2 mRNA, leading to decreased rates of -1 PRF promoted by this element. There is an inverse relationship between -1 PRF and mRNA stability. Thus, decreased -1 PRF results in increased abundance of the JAK2 mRNA and increased JAK2 protein expression. Prior studies established that elevated expression levels of JAK proteins are sufficient to transform cells in vitro, suggesting that -1 PRF may normally help to limit JAK2 expression. Silent protein coding changes in the -1 PRF signal slippery sequence abating JAK2 frameshifting also increased JAK2 expression and necropoied the transforming activity of JAK2-V617F in cell culture. Further, the combination of the V617F and slippery site mutations conferred an additive effect on cellular transformation. The presence at least three additional -1 PRF signals in the JAK2 mRNA suggests that -1 PRF plays a significant role in controlling JAK2 expression.

**MOLECULAR AND CELLULAR BIOLOGY / GENETICS: High Throughput Genomics Dissecting Cancer Cell States and Genomic Subtypes**

### #3035 Decomposing oncogenic transcriptional signatures to generate maps of divergent cellular states.

**William J. Kim,1 William C. Hahn,2 Jill Meisirov,2 Pablo Tamayo2. 1Dana-Farber Cancer Institute, Cambridge, MA; 2University of California San Diego, San Diego, CA.**

The systematic sequencing of the cancer genome has provided a powerful framework for identifying genetic alterations in disease causation. However, understanding of the functional consequences of these alterations is necessary to guide appropriate therapeutic strategies. Here, we describe Onco-GPS (Onco-Genic Positioning System), a data-driven analysis framework, and associated experimental and computational methodology, to organize individual tumor samples with shared oncogenic alterations onto a reference map defined by their underlying cellular states. Using this approach, we generated series of RAS/MAPK sub-signatures that reflect known and novel downstream pathways. These sub-signatures were then used to classify KRAS and BRAF mutant cancers into subgroups or cell states, as represented in the novel visual paradigm “OncoGPS map”. OncoGPS approach was first applied to cancers with BRAF mutations. The approach not only accurately classified three groups of BRAF mutant cancers that aligned with sensitivity to BRAF inhibitors, but also identified resistance mechanisms associated with each state, validating the overall approach. OncoGPS also identified four major cell states associated with KRAS mutant cancers. Further characterization of the four cell states showed that multiple molecular features representing epithelial-EMT states and activation of NF-κB pathway delineated two major “axes” of KRAS mutant cancers. In addition to the pathways and cell states defined in each group, the OncoGPS approach is able to identify effective drug combinations which was experimentally tested and confirmed. These results show that the Onco-GPS is an effective analytic framework to explore the complex landscape of oncogenic cellular states across cancers, and a powerful framework to summarize knowledge, establish relationships, and generate more effective disease models for research or as part of individualized precision medicine paradigms.

### #3036 Real-time genomic characterization of metastatic pancreatic cancer to enable precision medicine.

**Andrew J. Aguirre,3 Scott Carter,1 Nicholas Camarda,1 Arezou Ghazani,4 Jonathan Nowak,1 Annacarolina Da Silva,1 Lauren Brais,1 Dorissame Ragov,2 Devins McCabe,1 Lori Marini,1 Kristin Anderka,2 Karla Helvie,1 Nelly Oliver,1 Ana Babic,1 Paul Shyn,2 Douglas Robinson,1 Anuj Patel,1 James Cleary,1 Nadine McCleary,1 Matthew Kulke,1 Thomas Clancy,1 Leona Doyle,1 Jason Hornick,1 Christine Ardito-Abraham,2 Ruth Yu,1 Michael Downes,1 Ronald Evans,1 Richard A. Moffit,2 Jen Jen Yeh,1 William C. Hahn,1 Charles Fuchs,1 Robert Mayer,1 Nikhil Wagle,1 David Tuveson,1 Levi A. Garraway,1 Brian M. Woolp,1 Dana-Farber Cancer Institute, Boston, MA; 2Broad Institute, Cambridge, MA; 3Dana-Farber Cancer Institute, Boston, MA; 4The Lustgarten Foundation, Bethpage, NY; 5Salk Institute, La Jolla, CA; 6University of North Carolina, Chapel Hill, NC; 7Cold Spring Harbor Laboratory and The Lustgarten Foundation, Cold Spring Harbor, NY.**

Pancreatic ductal adenocarcinoma (PDAC) is currently the fourth-leading cause of cancer-related death in the United States and is projected to become the second leading cause by 2030. Most patients present with advanced disease and die within 12 months of diagnosis. Recent genomic studies of primary pancreatic cancer resection specimens have identified several molecular alterations and gene expression profiles that guide the development of precision medicine approaches to clinical management. However, the molecular landscape of metastatic PDAC has been less well characterized. Moreover, biopsy-driven studies in metastatic PDAC have been historically very challenging due to the aggressive course of this disease as well as the low-volume and heterogeneous nature of biopsies that makes deep molecular characterization difficult. Insufficient genomic analysis of a limited number of metastatic samples may result in suboptimal treatment strategies. We used NGS of a panel of PDAC biopsies dominated by expression of a STAT3 program. Ex vivo cultures from platinum-resistant disease. Furthermore, we used patient-derived xenograft (PDX) cohorts, in which we isolated cells for scRNA-seq from vehicle tumors (VEH), treated the other models with carboplatin, and harvested cells at the time of minimal residual disease (MRD) or disease progression (PROG). Results: To date, we have profiled ~12000 single cells from 12 patients with treatment naïve (n=3) or platinum-resistant disease (n=9), including sequential sampling in 3 patients with resistant disease. We observed significant inter- and intra-individual transcriptional heterogeneity guide precision medicine approaches. A recurrent pattern across resistant patients was the differential expression of inflammatory pathways in a subset of cells. In a patient with three consecutive specimens, we observed increasing accumulation of cells expressing a cell state characterized by tumor necrosis factor alpha (TNF-a) signaling. Importantly, these cells were genetically identical to the entire population, supporting the hypothesis that non-encoded mechanisms conferred treatment resistance. In a BRCA-mutant patient, unbiased analysis identified a stemness program in a subpopulation of cells, which was genetically identical to other cells, indicating phenotypic conversion. To systemically interrogate mechanisms of resistance to platinum therapy, sequenced single cells isolated from PDAC models at three time points (VEH, MRD and PROG). In a BRCA-WT PDX model, resistant cells isolated at MRD showed a transcriptional profile that was dominated by expression of a STAT3 program. Ex vivo cultures from platinum-resistant patients were exquisitely sensitive to IAK/STAT3-inhibitor. Live cell imaging revealed that STAT3-inhibition prevented spheroid formation, attachment and clearance through a mesothelial monolayer in vitro. Conclusion: Our
results indicate that non-encoded mechanisms play an important role in the development of treatment resistance in ovarian cancer. Our initial studies indicate an important role of inflammatory pathways in treatment resistance, in development of treatment resistance in ovarian cancer. Our initial studies indicate that non-encoded mechanisms play an important role in the development of treatment resistance in ovarian cancer. Our initial studies indicated that non-encoded mechanisms play an important role in the development of treatment resistance in ovarian cancer.

Avenues for patients with treatment-resistant ovarian cancer.

#3038 Bridging the gap between NGS data and its usability: cancer gene discovery through massive-scale transcriptomic analyses and development of a powerful web-tool for dissemination of these findings. Yashar Niknafs, Nicholas Molen, Balaji Pandian, Matthew Iyer, Arul Chinnaiyan. Univ. of Michigan, Ann Arbor, MI.

Background: In a prior transcriptomic analysis focused on IncRNA interrogation using some of these data, we discovered tens of thousands of novel IncRNAs (Iyer and Niknafs et al, Nature Genetics, 2015). Building on this analysis, we recently developed a markedly improved bioinformatics tool for novel gene/isofrom discovery from massive RNA-seq datasets named TACO (Niknafs et al, Nature Methods, In press, tacorna.github.io). TACO produces high-fidelity transcript structure predictions from large RNA-seq datasets. We now set out to comprehensively leverage both TACO and the publicly available RNA-seq data for discovery of novel transcriptional cancer associations. Additionally, in order to widely disseminate these findings in an accessible manner, we have built a web-tool that provides the scientific community access to these data and analyses. Methods: We have downloaded, curated, and processed 23,823 RNA-seq samples largely from the TGCA, ICGC, GTEx, and CCLE, comprising 37 tissue types and over 35 cancer types. RNA-seq data processing was performed using STAR, Cufflinks, Kallisto, and TACO. The web tool for visualization and access to these data and analyses was built using a JavaScript-based server infrastructure (Node.js) and a relational PostgresQL database. Results: Generation of a consensus transcriptome from this large-scale RNA-seq dataset via TACO resulted in the discovery of tens of thousands of novel transcriptional elements, including intergenic non-coding RNAs and novel splice isoforms of known genes. Such an expansive RNA-seq cohort that includes many normal tissue samples enabled statistically powerful cancer association expression analyses that revealed a myriad of novel cancer genes, especially in tissues for which there was previously little-to-no normal tissue RNA-seq data (e.g., brain and pancreas). Many of these novel transcriptional elements discovered using TACO were also found to be cancer associated. We have built a web-tool to facilitate further analysis and discovery using these data and analyses by the scientific community. The web-tool provides a powerful and intuitive interface for researchers with little-to-no bioinformatics expertise to leverage large-scale RNA-seq datasets. Conclusions: Here we present the largest reported compendium of RNA-seq data, and reveal many novel cancer gene associations. Using a new, powerful gene discovery tool, TACO, we identify a multitude of novel transcriptional elements that are also cancer associated. Despite the abundance of publicly available RNA-seq data, necessary computing resources, data storage, and bioinformatics expertise are barriers to usability of these data by scientific community. Our RNA-seq expression web-tool bridges this gap, and enables users to powerfully interrogate cancer expression across dozens of tumor and tissue types.

#3039 Combinatorial CRISPR-Cas9 gene knockout to enable genetic interaction mapping in human cells. John Paul Shen, Dongxin Zhao, Roman Sasik, Jens Luebeck, Ana Bojorquez-Gomez, Katherine Licon, Trey Ideker, Prashant Mali. UCSD, La Jolla, CA.

Genetic interactions, in particular negative or 'synthetic-lethal' interactions for which simultaneous disruption of two genes causes cell killing, have implications for therapeutic development. The feasibility of this approach has been demonstrated with the recent approval of the drug olaparib, an inhibitor of PARP1, specifically for tumors with loss-of-function mutations in BRCA1/2. However, beyond olaparib, further applications of synthetic-lethal cancer therapy have been limited by poor understanding of the important genetic interactions in a cancer cell, and how these vary from one cancer type to another or from patient to patient. To enable systematic mapping of these genetic interactions networks, we developed a CRISPR-Cas9 screening methodology for knocking out single and pairs of genes in high-throughput. Here, we combined multiplex targeting with array-based oligonucleotide synthesis to create dual-gRNA libraries covering up to 10^4-5 defined gene pairs. In these libraries, each construct bears two gRNAs, with each gRNA designed to target either a gene or a scrambled non-targeting sequence absent from the genome. We conducted genetic interaction screens by transducing the dual-gRNA lentiviral library into a population of cells stably expressing Cas9, maintaining these cells in exponential growth over the course of four weeks, then sampling the relative changes in gRNAs at days 3, 14, 21 and 28 post-transduction. To robustly quantify gene fitness and genetic interactions, we developed a computational analysis framework that integrates all samples across the multiple days of the experiment. Using this method we evaluated all pairwise gene knockout combinations among a panel of 73 genes divided between tumor-suppressor genes (TSG) and cancer-relevant drug targets (DT); including negative controls this amounted to a total of 23,652 combinations. Experiments were performed in three cancer cell lines: HeLa, A549 and 293T. In total, 352 interactions were identified in these three cell lines (146 (90.1%) were private to one cell line. None of the interactions were observed in all three cell lines. These patterns replicated in low throughput assays with combinatorial drugs at 80% precision. In summary, we have introduced a combinatorial CRISPR-Cas9 genetic interaction mapping technology that successfully identifies many therapeutically-relevant genetic interactions in cancer and shows the great importance of elucidating the architecture of the genetic interactions network. Recognizing that there will be great diversity in genetic interaction between different tumors it will be important to perform future studies across a large number of samples, which is enabled by the high-throughput method we have developed.

#3040 Functional genomic screening identifies USP11 as a novel regulator of ERα transcription in breast cancer. Lisa Dwane, Aisling E. O’Connor, Laoghaire Mulrane, Annette M. Dirac, Karin Jirstrom, John P. Crown, Rene Bernards, William M. Gallagher, Triona Ni Chonghaile, Darran P. O’Connor. Royal College of Surgeons Ireland, Dublin, Ireland; Conway Institute, University College Dublin, Dublin, Ireland; Netherlands Cancer Institute, Amsterdam, Netherlands; Malmo University Hospital, Malmo, Sweden; St Vincent’s University Hospital, Dublin, Ireland.

Approximately 70% of breast cancers overexpress the estrogen receptor α (ERα) and depend on this key transcriptional regulator for growth and differentiation. The discovery of novel mechanisms controlling ERα function represents major advances in our understanding of breast cancer progression and potentially offer attractive new therapeutic opportunities. Here, we investigated the role of deubiquitinating enzymes (DUBs), which act to remove ubiquitin moieties from proteins, in regulating transcriptional activity of ERα in breast cancer. To identify DUBs involved in the regulation of ERα transcriptional activity, we performed an RNAi loss-of-function screen using a library of shRNA vectors targeting all human DUB genes. The DUB library consisted of pools of four non-overlapping shRNAs targeting all 108 known or putative DUBs (432 shRNAs in total). We found that suppression of a number of DUBs markedly repressed or enhanced the activity of an estrogen-response element (ERE) luciferase reporter following estradiol (E2) stimulation. Of particular interest, suppression of the BRCA2-associated DUB, USP11, was found to downregulate ERα transcriptional activity. Subsequent validation using two individual siRNAs targeted to USP11 revealed a notable reduction in expression of endogenous ERα target genes in the ZR-75-1 cell line, as quantified using qRT-PCR. Immunoprecipitation of ERα revealed no physical interaction with USP11 nor over E2 induction in transcriptional activity of USP11 to the nucleus, suggesting a potential role in E2-induced transcription. Furthermore, USP11 expression was found to be upregulated in the estrogen-independent cell line LCC1 when compared to their parental MCF7 cells. Knockdown of USP11 in LCC1 cells resulted in decreased mRNA expression of a panel of ERα target genes, suggesting a role for USP11 in an estrogen independent setting. To support the prognostic relevance of USP11, immunohistochemical staining of breast cancer tissue microarrays (n=144) was performed. Kaplan-Meier analysis of this cohort revealed a highly significant association between poor overall survival (OS) (p=0.030) and breast cancer-specific survival (BCSS) (p=0.041). In silico analysis of publically available breast cancer gene expression datasets further supported an association between high USP11 mRNA levels and poor prognosis. We observed a significant correlation between high expression of USP11 mRNA in ER-positive patients and poor distant metastasis-free survival (DMFS) (HR 2.9, CI 1.37-2.91, p=0.00023). This correlation was also significant in ER-positive patients who had received endocrine therapy only (HR 2.9, CI 1.63-5.15, p=0.00015). These results suggest a role for USP11 in driving cellular growth and identify USP11 as novel therapeutic target in breast cancer.

#3041 Duplex Sequencing detects cancer-associated mutations arising during normal aging: Clonal evolution over a century of human lifetime. Jesse J. Salk, Elisabeth Maritschneg, Paul Speiser, Robert Zeillinger, Rosana Risques, Lawrence A. Loeb. University of Washington, Seattle, WA; Medical University of Vienna, Vienna, Austria.

High-throughput DNA sequencing has fundamentally changed practice standards in clinical oncology. We can now systematically examine the dysfunctional genes and pathways of individual tumors and can often pair these with targeted therapies. Moreover, NGS has improved our ability to resolve molecular heterogeneity, such as results from evolving subclones within a tumor or admixtures of cancer-derived and normal DNA in liquid biopsies. However, this...
remains imperfect. With standard NGS, sequencing errors create a background that obscures variants present at less than 1-2%. Methods of tag-based error correction improve accuracy, but most rely on hemimolecular tagging and are thus still limited by certain types of errors caused by DNA damage. Our group pioneered Duplex Sequencing, an error correction technology that independ- ently genotypes and compares both single-stranded halves of individual DNA duplexes. This approach improves sequencing accuracy by >100,000-fold and allows detection of a single mutation among ten million unmutated nucleotides.

We carried out Duplex Sequencing on uterine lavages from women with and without high-grade serous ovarian cancer to determine the sensitivity for identifying tumor-derived TP53 mutations as a screening test. Under blinded conditions we detected tumor-derived mutations in 80% of cancer cases. However, in addition, we found that nearly all women, including those without cancer, carried very low frequency TP53 mutations that did not originate from a tumor. These could not be explained by technical errors, as they exhibited a strong signature of positive selection, indicated by higher-than-random non-synonym- ous fraction, substantial clustering in cancer-associated hotspots and a spec- trum, exonic distribution and predicted pathogenicity closely mirroring TP53 mutations in cancer databases. Furthermore, abundance of these “biological background” mutations increased with age. To more broadly investigate the extent of clonal evolution in normal aging, we used Duplex Sequencing to ex- amine tissue specimens from two individuals without cancer, differing in age by 101 years. We assessed relative mutation load in 22 cancer-associated genes and one non-cancer associated gene in 19 different tissues. Initial results indicate that the extent of age-associated mutation accumulation varies by organ and the pattern of apparent clonal selection is influenced by both tissue type and genetic context. Our findings illustrate the near-universal presence of cancer-like mu- tations arising from age-associated processes in multiple non-neoplastic tissues. Somatic clonal evolution appears to be a ubiquitous part of human life. Beyond many biological implications, this highlights an important specificity challenge that must be accounted for when using ultra-accurate sequencing technologies for cancer screening and other sensitive diagnostics.
identified the ex-miRNA-directed phenotype to be transient due to the rapid decay of the ex-miRNA. We demonstrated that the ex-miR-223-3p transfected from neutrophils to cancer cells was functional as demonstrated by the decreased expression of its target, FOXO1, and the occurrence of epithelial-mesenchymal transition reprogramming. We showed that the engulfed ex-miRNA, unlike the endogenous miRNA, was unstable, enabling dynamic regulation and a return to a non-invasive phenotype within less than 8 hours. This transient phenotype could be modulated by targeting XRNI/PACMAN exonuclease. Indeed, its silencing was associated with slower decay of ex-miR-223-3p and subsequently prolonged the invasive properties. Conclusion: We showed that the steady step-level of engulfed miRNA (ex-miR-223-3p) and its subsequent activity were tumor-specific, highlighting a potential role of tumor-secreted exosomes in cell-to-cell communication. This study aimed to establish a mechanism of action for miR-379, and to engineer MSCs to secrete exosomes enriched with the miR for tumor-targeted delivery. Methods: RNA was isolated from breast tumors and matching lymph node metastases from the same patients, and miR-379 expression quantified by RQ-PCR. HCC1954 breast cancer cells were transduced with lentivirus to express elevated miR-379 (HCC-379) or a control sequence (HCC-NTC). Cells were implanted into the mammary fat pad (MFP) of mice and tumor progression monitored. Subsequently, MSCs were transduced to generate MSC-379 and MSC-NTC. MSC-secreted exosomes were isolated by differential centrifugation, microfiltration and ultracentrifugation. The morphology, size and number of isolated exosomes was characterized using Transmission Electron Microscopy, Western Blot and Nanoparticle Tracking Analysis respectively. Exosomal miRNAs were analysed by RQ-PCR. MFP tumors were established using HCC1954-luciferase cells, followed by IV injection of MSC-379 or MSC-NTC cells, or sequential doses of exosomes derived from either cell population. Results: miR-379 expression was significantly reduced in lymph node metastases compared to primary tumors from the same patients (p<0.009), supporting a tumor suppressor role. Analysis of HCC-379 and HCC-NTC tumor growth in vivo showed no difference in tumor size, however an increase in tumour necrosis (50%-50%) and decrease in lymph node invasion was observed in HCC-379 tumors. Investigation of a potential role for miR-379 in regulating COX-2, revealed an inverse relationship (r = -0.48, p=0.02) at a mRNA level, further confirmed at a protein level. MSC-379 cells showed no significant change in migratory or proliferative capacity in vitro. Mechanofluorescence of MSC-secreted exosomes was confirmed to be consistent with the exosome-associated protein CD63. An increase in miR-379 (>5 fold) was observed in exosomes secreted by MSC-379 compared to MSC-NTC cells. Administration of MSC-379 or MSC-NTC cells, or exosomes derived from either cell population, was well tolerated in vivo with no adverse effects observed. Monitoring tumor response to therapy using IVIS is ongoing. Conclusion: The data presented supports miR-379 as a potent tumor suppressor in breast cancer, mediated in part through regulation of COX-2. Engineering tumor-targeted MSCs to secrete exosomes enriched with miR-379 holds exciting potential as a novel therapy for breast cancer.

#3045 Engineering Mesenchymal Stem Cells (MSCs) to support tumor-targeted delivery of exosome-encapsulated microRNA-379. Killian P. O’Brien, Katie Gilligan, Sonja Khan, Brian Moloney, Kerryn Thompson, Pierce Lalor, Peter Dockery, Helen Ingoldsby, Michael J. Kerin, Roisin M. Dwyer. National University of Ireland Galway, Galway, Ireland.

Mesenchymal Stem Cells (MSCs) are multipotent stromal cells known to migrate specifically to the sites of tumors and metastases, raising potential as tumor-targeted delivery vehicles for therapeutic agents. MSCs secrete exosomes containing genetic material including miRNAs (miRs), that are effectively taken up by cells. Previous work has shown miR-379 to be significantly reduced in breast tumors compared to normal breast tissue. This study aimed to establish a mechanism of action for miR-379, and to engineer MSCs to secrete exosomes enriched with the miR for tumor-targeted delivery. Methods: RNA was isolated from breast tumors and matching lymph node metastases from the same patients, and miR-379 expression quantified by RQ-PCR. HCC1954 breast cancer cells were transduced with lentivirus to express elevated miR-379 (HCC-379) or a control sequence (HCC-NTC). Cells were implanted into the mammary fat pad (MFP) of mice and tumor progression monitored. Subsequently, MSCs were transduced to generate MSC-379 and MSC-NTC. MSC-secreted exosomes were isolated by differential centrifugation, microfiltration and ultracentrifugation. The morphology, size and number of isolated exosomes was characterized using Transmission Electron Microscopy, Western Blot and Nanoparticle Tracking Analysis respectively. Exosomal miRNAs were analysed by RQ-PCR. MFP tumors were established using HCC1954-luciferase cells, followed by IV injection of MSC-379 or MSC-NTC cells, or sequential doses of exosomes derived from either cell population. Results: miR-379 expression was significantly reduced in lymph node metastases compared to primary tumors from the same patients (p<0.009), supporting a tumor suppressor role. Analysis of HCC-379 and HCC-NTC tumor growth in vivo showed no difference in tumor size, however an increase in tumour necrosis (50%-50%) and decrease in lymph node invasion was observed in HCC-379 tumors. Investigation of a potential role for miR-379 in regulating COX-2, revealed an inverse relationship (r = -0.48, p=0.02) at a mRNA level, further confirmed at a protein level. MSC-379 cells showed no significant change in migratory or proliferative capacity in vitro. Mechanofluorescence of MSC-secreted exosomes was confirmed to be consistent with the exosome-associated protein CD63. An increase in miR-379 (>5 fold) was observed in exosomes secreted by MSC-379 compared to MSC-NTC cells. Administration of MSC-379 or MSC-NTC cells, or exosomes derived from either cell population, was well tolerated in vivo with no adverse effects observed. Monitoring tumor response to therapy using IVIS is ongoing. Conclusion: The data presented supports miR-379 as a potent tumor suppressor in breast cancer, mediated in part through regulation of COX-2. Engineering tumor-targeted MSCs to secrete exosomes enriched with miR-379 holds exciting potential as a novel therapy for breast cancer.

#3047 PRC2-mediated silencing of circRNA CDR1as drives miR-7-independent melanoma metastasis. Doug Hanniford,1 Rana Moubarak,1 Jochen Limig,1 Alejandro Ulloa,1 Beatriz Sanchez Sendra,1 Alcida Karr,2 Iman Osman,1 Ioannis Aifantis,1 Eva Hernandez1. 1New York University School of Medicine, New York, NY; 2Duke University, Durham, NC.

Circular RNAs are a novel class of non-coding RNAs with functions that remain poorly characterized in normal and pathological conditions. CDR1as is a non-canonical circRNA observed to act as a sponge for miR-7 in brain tissues. Analysis of RNeasy-Seq data of melanocytes and melanoma cell lines and short-term cultures revealed loss of CDR1as expression as a hallmark of melanoma cells. We confirmed silencing of CDR1as in melanoma cells and tissues by RT-qPCR using divergent primers. Clinically, we observed CDR1as loss associated with metastatic progression and poor patient outcomes in a cohort of fresh-frozen melanoma tissue samples. Depletion of CDR1as in melanoma cell lines enhanced invasion in vitro and lung metastasis in vivo, demonstrating functional significance of CDR1as silencing. Surprisingly, CDR1as depletion had no clear effect on miR-7 activity in melanoma cells, and miR-7 inhibition was insufficient to rescue CDR1as silencing-induced invasion. Moreover, GSEA analyses of proteomic profiling of melanoma cells depleted of CDR1as revealed reductions of proteins involved in oxidative phosphorylation (OXPHOS) and mitochondrial function, suggesting CDR1as loss may alter metabolism of melanoma cells. Mining of CLIP-Seq data sets and subsequent RIP-PCR revealed direct interactions of CDR1as with the Igf2r family of proteins and TARDBP, each of which are involved in regulation of mitochondrial function. These data suggest that CDR1as could regulate the subcellular localization and/or function of proteins involved in OXPHOS and mitochondrial respiration. To understand the transcriptional mechanisms driving CDR1as loss in melanoma, we sought to examine the primary transcript from which CDR1as arises. Interestingly, examination of the CDR1as locus revealed an upstream long non-coding RNA, LINC00632, as a plausible primary transcript of CDR1as. CDR1as and LINC00632 expression is strikingly correlated across human tissues and in melanoma cell lines (>65). Moreover, depletion of LINC00632 using Gapmers reduced CDR1as expression and CD44 silencing-induced invasion and metastasis. Surprisingly, treatment of such melanoma cell lines with the EZH2 inhibitor, GSK126, induced robust re-expression of both CDR1as and LINC00632, and removal of H3K27me3 at LINC00632. Our data document that CDR1as is epigenetically silenced in melanoma, and its loss promotes melanoma invasion and metastasis. Moreover, CDR1as loss could contribute to metabolic adaptations during metastasis through misregulation of RNA binding proteins.

#3048 A noncoding function of TYRP1 mRNA promotes melanoma growth. Marie-Dominique Galibert,1 David Gilot,1 Méloïde Mignaut,2 Laura Belocheit,1 Fabrice Journe2 Aliñosiajogers,1 Emmanuelle Donnou-Fournet,1 Ariane Mogha,1 Nicholas Mouchet,1 Marie-Laure Pinel-Marie,1 Bernard Mari,5 Tristan Monnier,1 Sébastien Corre,1 Arthur Gautron,1 Florian Rambow,2 Petra El Haji,2 Rania Ben Jouria,2 Sophie Tartare-Deckert,2 Jean-Christophe Marine,3 Brice Felden,4 Ghanem Ghanem.1 CNRS UMR6290 - IGDR / University of Rennes, Rennes, France; 2Institut Jules Bordet, Université Libre de Bruxelles, Brussels, Belgium; 3VIB Center for Cancer Biology, Leuven, Belgium; 4INSERM U835, Université de Rennes I, Rennes, France; 5CNRS UMR 7275, Sophia Antipolis, France; 6INSERM U1078, Université de Bretagne Occidentale, Université Européenne de Bretagne, Brest, France; 7INSERM U1065, CNM, Nice, France.
RNAs competition to bind miRNA has been proposed to influence biological systems whether these RNAs are implicated in diseases onset is unclear. Here, we report that TYRPI1 mRNA, in addition to encoding tyrosinase-related protein 1 (TYRP1), indirectly governs cell proliferation by sequestering miR-16 on non-canonical miRNA response elements (MREs). Consequently, sequestered miR-16 is no longer available to repress its miRNA targets such as RAB17, which we show is involved in melanoma cell proliferation and invasion. Restoration of miR-16 tumor suppressor function can be achieved in vitro by silencing TYRP1 or increasing miR-16 expression levels. Importantly, TYRP1-dependent miR-16 sequestration can also be overcome in vivo using small oligonucleotides that mask miR-16 binding sites on TYRP1 mRNA. Together, our findings assign a pathogenic noncoding function to TYRP1 mRNA and underscore miRNA displacement as a new antimelanoma targetted therapeutic approach.

TUMOR BIOLOGY: Early Stages of Metastatic Dissemination

#3049 Tracing the origin of disseminated tumor cells in breast cancer using single-cell sequencing, Jonas Demeulemeester,1 Parveen Kumar,2 Elen K. Møller,3 Sille Nord,3 David C. Wedge,4 April Peterson,5 Randi R. Mathiesen,3 Renathe Fjelldahl,5 Masoud Z. Esteki,2 Koen Theunis,2 Elia F. Gallardo,2 Jason Grundstad,5 Elin Borgen,5 Lars O. Baumbusch,3 Anne-Lise Berresdal-Aske,3 Kevin F. White,3 Vesselka N. Kristensen,2 Peter Van Loo,4 Thierry Voet,4 Bjørn Naud,51 The Francis Crick Institute, London, United Kingdom;2 KU Leuven – Leuven, Leuven, Belgium;3 Oslo University Hospital, Oslo, Norway;4 Wellcome Trust Sanger Institute, Cambridge, United Kingdom;5University of Chicago, Chicago, IL.

Background. Single-cell micro-metastases of solid tumors often occur in the bone marrow. These disseminated tumor cells (DTCs) may resist therapy and lay dormant to progress to cause overt bone and visceral metastases. The molecular nature of DTCs remains elusive, as well as when and from where in the tumor they originate. Here, we apply single-cell sequencing to identify and trace the origin of DTCs in breast cancer. Results. We sequence the genomes of 63 single cells isolated from six non-metastatic breast cancer patients. By comparing the cells’ DNA copy number aberration (CNA) landscapes with those of the primary tumors and lymph node metastasis, we establish that 53% of the single cells morphologically classified as tumor cells are DTCs disseminating from the observed tumor. The remaining cells represent either non-aberrant ‘normal’ cells or ‘aberrant cells of unknown origin’ that have CNA landscapes discordant from the tumor. Further analyses suggest that the prevalence of aberrant cells of unknown origin is age-dependent, and that at least a subset is hematopoietic in origin. Evolutionary reconstruction analysis of bulk tumor and DTC genomes enables ordering of CNA events in molecular pseudo-time and trace the origin of the DTCs to either the main tumor clone, primary tumor subclones, or subclones in an auxiliary lymph node metastasis. Conclusions. Single-cell sequencing of bone marrow epithelial-like cells, in parallel with in-tumor genetic heterogeneity profiling from bulk DNA, is a powerful approach to identify and study DTCs, yielding insight into metastatic processes. A heterogeneous population of CNA-positive cells is present in the bone marrow of non-metastatic breast cancer patients, only part of which are derived from the observed tumor lineages.

#3050 Polymorphisms in the arntl2 promoter affect breast cancer metastasis susceptibility, Ngoc-Han Ha, Kent Hunter. National Cancer Institute, Bethesda, MD.

Breast cancer mortality is primarily due to metastatic lesions rather than primary tumors, yet relatively little is known regarding the mechanisms of metastatic breast cancer, making it difficult to identify patients who are at risk for metastatic disease. Our hypothesis suggests that inherited germline mutations contribute to metastatic disease and that these single nucleotide polymorphisms (SNPs) could be used to predict outcome in breast cancer patients. To investigate the effect of inherited SNPs on metastasis, we used a mouse genetics approach comparing strains with high (FVB) and low (MOLF) metastatic phenotypes and identified Arntl2, a circadian rhythm transcription factor, as a gene whose differential expression predicted outcome in breast cancer patients. To identify SNP differences in Arntl2 between MOLF and FVB, we performed whole genome sequencing of MOLF and compared it to the FVB genome. Overlapping the data with DNase hypersensitivity sites revealed 10 SNPs in the predicted promoter of Arntl2. To test the causative role of the SNPs on Arntl2 expression in vivo, metastatic cell lines were engineered using the CRISPR-Cas9 approach to specifically replace the FVB Arntl2 promoter with that of MOLF. In agreement with our hypothesis, substitution of the MOLF promoter reduced Arntl2 transcript levels and subsequently decreased lung metastases in orthotopic implantation assays. In vitro pulldown experiments with strain-specific promoter probes revealed potential differential binding of chromatin modifier proteins of Arntl2, suggesting the potential of the SNPs to influence promoter transcription. Finally, analysis of SNPs associated with Arntl2 expression in a cohort of Chinese breast cancer patients revealed significant correlation of Arntl2 expression with overall survival, validating this gene as a marker in humans. Since Arntl2 is a transcription factor, current studies are focused on identifying Arntl2-regulated genes to investigate downstream pathways involved in metastasis. This study has important implications regarding the role of circadian rhythm in cancer progression and provides a potential mechanism to explain the increased risk of breast cancers in nightshift workers. Furthermore, this provides the first evidence that transcriptional control elements can be engineered using CRISPR-Cas9 to establish the causative role of SNPs in inherited susceptibility to cancer metastasis.

#3051 Mechanism of early dissemination and metastasis in Her2+ mammary cancer, Kathryn Harper,1 Maria Soledad Sosa,2 David Entenberg,2 Hedayatollah Hosseini,3 Julie Cheung,3 Rita Nobre,1 Alvaro Avivar-Valderas,1 Chandandaneep Nagi,1 Nomaed Girnios,5 Roger Davis,5 Eduardo Farias,1 John Condeelis,2 Christoph A. Klein,3 Julio A. Aguirre-Ghiso,5 Icahn School of Medicine at Mount Sinai, New York, NY; 2Albert Einstein College of Medicine, New York, NY; 3University of Regensburg, Regensburg, Germany; 4University of Massachusetts Medical School, Worcester, MA.

Metastasis is the leading cause of cancer related deaths and these lesions develop from disseminated cancer cells (DCC) that can remain dormant. Metastasis initiating cells are thought to originate from a subpopulation present in progressed invasive tumors. However, DCCs detected in patients before the manifestation of breast cancer metastasis contain fewer genetic abnormalities than primary tumors or than DCCs from patients with metastases. These findings and those in pancreatic cancer and melanoma models argued that dissemination might occur during early stages of tumor evolution. Yet, the mechanisms that might allow early-disseminated cancer cells (eDCC) to complete all steps of metastasis were unknown. Here we show that in early lesions (EL), before any overt primary tumor (PT) masses are detected, there is a sub-population of Her2+/P-p38lo/P-ATF2lo/TWISThi/E-cadherinlow early cancer cells that are invasive and disseminate to target organs. Intra-vital imaging and organoid studies of early lesions revealed that Her2+ eDCC precursors locally invaded, intravasated and lodged in target organs. Her2+ eDCs activated a Wnt-dependent EMT-like dissemination program but without complete loss of epithelial phenotype that was reversed by Her2 antagonism only, while surprisingly, in murine eDCCs are TWISThi/E-cadherinlow and dormant, they eventually initiate metastasis. Our work identifies a mechanism for early dissemination whereby Her2 aberrantly activates a program similar to mammary ductal branching that spawns eDCs capable of forming metastasis after a dormancy phase.

#3052 Defining the role of EMT in breast cancer dormancy and metastasis in vivo, Kay T. Yeung, Jing Yang. UC San Diego, San Diego, CA.

Breast cancer patients can develop metastases from dormant tumor cells years after primary tumor resection and treatment. Despite the clinical significance of metastatic latency, the exact cellular and molecular events regulating tumor dormancy remains largely unknown due to challenges in detecting single dormant tumor cells in vivo and characterizing the dormant tumor microenvironment. A developmental program termed Epithelial Mesenchymal Transition (EMT) has been shown to play an important role in tumor cell dissemination, tumor dormancy, and chemoresistance. During EMT, stationary epithelial cells lose their epithelial characteristics, including adherent junctions and apical-basal polarity, and acquire mesenchymal shape and properties. These cells gain the ability to migrate into the circulation, lodge into a distant organ, and form dormant tumor niches. We have previously shown that reversal of EMT is a key driving force in dormant tumor cell proliferation and macrometastasis formation in a skin carcinoma mouse model. Here, we present a novel metastatic breast cancer mouse model in which HER2-driven primary breast tumor cells are labelled with red fluorescent protein with inducible EMT transcription factor TWIST1. We established this mouse model by crossing the TetOON-TWIST1 mice with the MMTV-rTA mice to generate the MMTV-rTA/TetON-TWIST1 double transgenic mice. To generate HER2-driven breast tumors in these mice, we administered concentrated lentivirus that expresses both the HER2 gene and the tdTomato fluorescent marker under one promoter via intraductal
injection. This allows for rapid and synchronized development of primary tumors which recapitulate the formation of sporadic human breast cancer which arises in single cells in otherwise normally developed breast tissue. TWIST1 expression in the luminal layer of the mammary gland was then induced via oral doxycycline. Upon expression of TWIST1, Her2-driven breast tumor cells were found in circulation and in the lungs as micrometastases. We determined that disseminated breast tumor cells mostly remained in dormancy until TWIST expression was switched off by doxycycline withdrawal. We showed that tumor dormancy is partly due to the inability to reverse EMT and regain proliferative capacity. Lastly, using our mouse model to track disseminated breast cancer cells, we will characterize the associated dormant residing niche to further our understanding of tumor dormancy in connection with EMT and immune escape.

**#3053 Stability and stenness of the hybrid epithelial-mesenchymal phenotype.** Mohit Kumar Jolly,1 Dongya Jia,1 Satyendra C. Tripathi,2 Steve Mooney,3 Muge Celiktas,4 Samir M. Hanash,2 Sendurai A. Mani,1 Kenneth J. Pienta,1 Estel Ben-Jacob,1 Herbert Levine,1 Rice University, Houston, TX; 2 University of Waterloo, Waterloo, Ontario, Canada; 3 Johns Hopkins University, Baltimore, MD.

Transitions between epithelial and mesenchymal phenotypes — EMT and MET — are hallmarks of cellular plasticity during embryonic development and cancer metastasis. During these transitions, cells can also adopt a hybrid epithelial/mesenchymal (hybrid E/M) phenotype enabling them to migrate collectively as observed during gastrulation, wound healing, and clusters of circulating Tumor Cells (CTCs). The hybrid E/M phenotype has largely been tacitly assumed to be metastable, i.e. transient state. Here, we integrate mathematical modeling with in vitro experiments to identify certain ‘phenotypic stability factors’ (PSFs) - GRHL2, OVOL2 and ΔNP63α that can stabilize a hybrid E/M phenotype. We show that H1975 (NSCLC cell line) cells can display a hybrid E/M phenotype stably and migrate collectively, a behavior that is impaired by knockdown of GRHL2 or OVOL2. Further, our computational model predicts that these PSFs can also associate hybrid E/M phenotype with high tumor-initiating potential, a prediction strengthened by the observation that the higher levels of one or more of these PSFs may predict poor patient outcome. Overall, our results suggest that a hybrid E/M phenotype need not be ‘metastable’, and bolster the notion that a hybrid E/M phenotype, but not necessarily full EMT, associates with aggressive tumor progression.

**#3054 Tracing EMT with fluorescent biosensors (chromobodies) in living cancer cells.** Julia Maier, Theresa Plaga, Stefanie Egartermaier, Björn Traenkle, Jana Friesen and Katja Rothbauer. University of Tuebingen, Reutlingen, Germany.

Epithelial-mesenchymal transition (EMT) is a complex cellular program involved in the progression of epithelial cancers to a metastatic stage. During this process characteristic epithelial marker proteins are repressed in favor of mesenchymal biomarkers, such as the intermediate filament protein vimentin. There is an ongoing need for reliable cell-based EMT model systems, which can be adapted to screening campaigns for novel anti-metastatic therapies. Imaging-based screening systems are restricted to endpoint immunofluorescence studies that provide only little information about the dynamics of the process, or to ectopic expression of EMT markers, fused to fluorescent proteins. However, overexpression of EMT marker proteins, particularly vimentin, have been shown to influence the EMT phenotype of the cells. Here we introduce chromobodies as an innovative technology to monitor EMT in living non-small lung cancer cells. Chromobodies are fluorescently labeled single-domain-antibodies that are functional within in living cells and directly target endogenous proteins. We generated chromobodies against the EMT biomarkers vimentin, actin and β-catenin and stably introduced them into the genome of A549 cells. Upon induction of EMT with transforming growth factor β (TGF-β), we could visualize the dynamic reorganization of endogenous vimentin, actin and β-catenin in the established EMT chromobody models in 2D as well as 3D cell culture. By means of these chromobody cell lines we further developed a 2D high content analysis system to visualize and quantify spatiotemporal changes of the endogenous biomarkers vimentin and actin during the EMT process. In a proof-of-principle screen, using known EMT-affecting reagents (e.g. TGF receptor inhibitors LY364947 and SB505124) as well as EMT-unrelated agents, we were able to show that this high content analysis system can be applied to select compounds that inhibit TGF-β-induced EMT. In summary, live cell imaging of EMT markers with chromobodies provides a novel versatile approach to study EMT in real time and allows the identification of EMT inhibitors as potential candidates for anti-metastatic therapies by high content screening.

**#3055 A permanent lung imaging window reveals, for the first time, the steps of extravasation, seeding and growth of early metastatic dissemination.** Sona E. Voiculescu, Yarong Wang, Maja Oktay, John Condeelis, David Ennberg, Albert Einstein College of Medicine, Bronx, NY.

Metastatic disease is the major cause of cancer mortality and is responsible for over 1/2 million deaths each year in the U.S. alone. Of the three most common sites of metastasis observed clinically (bone, lung and liver), the most difficult to study using intravital microscopy is the lung: a delicate organ in perpetual motion. We have recently developed and validated an implantable, permanent, lung imaging window which allows high-resolution multiphoton imaging of the intact, breathing (without ventilation), murine lung over days to weeks of repeated imaging. This window does not use vacuum to immobilize the lung tissue thereby avoiding well-known artifacts associated with vacuum lung windows. Using our new window, we have been able to visualize, with single cell resolution, the steps of metastasis in a clinically relevant, spontaneously-metastasizing murine breast cancer model. We present the first direct visualization of tumor cell arrival, extravasation, and progression to micro-metastases. Further, we have observed, for the first time, the activity of the tripartite structure called Tumor MicroEnvironment of Metastasis (TMEM) in metastatic lung lesions directly demonstrating the mechanism of dissemination from metastatic lung tumors. Using this approach to imaging live lung tissue serially, within a single animal, we are investigating the mechanisms underlying the fate of tumor cells arriving in the lung with the ultimate goal of directly identifying signals behind seeding and survival of metastatic tumor cells and their responses to interventions in real time.

**TUMOR BIOLOGY: Tumor and Stromal Cell Interactions**

**#3056 Genetic deletion of insulin-like growth factor binding protein-7 (IGFBP7) promotes hepatocellular carcinoma (HCC): a novel role of IGFBP7 in regulating antitumor immune surveillance.** Maaged A. Akiel, Chunqing Guo, Xia Li, Devaraja Rajasekaran, Rachel G. Mendoza, Nidhi H. Jarival, Chadia L. Robertson, Mark A. Subler, Jolene J. Windle, Paul B. Fisher, Devanand Sarkar, Virginia Commonwealth University, Richmond, VA.

In the US, the incidence and mortality rates of hepatocellular carcinoma (HCC) are alarming increasing since no effective therapy is available for the advanced disease. Activation of IGF signaling is a major oncogenic event in diverse cancers, including HCC. Insulin-like growth factor binding protein-7 (IGFBP7) inhibits IGF signaling by binding to IGF-1 receptor (IGF-1R) and functions as a potential tumor suppressor for hepatocellular carcinoma (HCC). IGFBP7 abrogates tumors by inducing cancer-specific senescence and apoptosis and inhibiting angiogenesis. We now document that Igfbp7 knockout (Igfbp7−/−) mouse shows constitutive activation of IGF-1R signaling, presents with pro-inflammatory and immunosuppressive microenvironment, and develops spontaneous tumors in lungs and liver and markedly accelerated carcinogen-induced HCC. Loss of Igfbp7 resulted in increased proliferation and decreased senescence in hepatocytes and mouse embryonic fibroblasts that could be blocked by an IGF-1 receptor inhibitor. A significant inhibition of genes regulating immune surveillance was observed in Igfbp7−/− lungs which was associated with marked inhibition in antigen cross-presentation by Igfbp7−/− dendritic cells. IGFBP7 overexpression inhibited growth of HCC cells in syngeneic immune competent mice which could be abolished by depletion of CD4+ or CD8+ T lymphocytes. Our studies unravel modulation of immune response at a novel component of pleiotropic mechanisms by which IGFBP7 suppresses HCC. Even though HCC has an immunosuppressive milieu, immune targeted therapies are beginning to demonstrate significant objective responses in clinical trials. IGFBP7 might be an effective anti-HCC therapeutic by directly inhibiting cancer cells and stimulating an anti-tumor immune response.

**#3057 Gut microbiome controls liver metastasis.** Chi Ma, Qing Fu, Tim Gretin, NC/NH, Bethesda, MD.

Aim: The gut microbiome can modify tumor immunity and has been suggested to be involved in the development of liver cancer. However, it remains unknown how the gut microbiome controls hepatic immune responses. This study was designed to examine the effect of the gut microbiome on
liver antitumor immunity, and to study potential mechanism. Experimental procedure: Antibiotic cocktail in drinking water was given to remove mouse gut microbiota. Control mice were kept on regular water. EL4 thymoma cells were injected s.c. to induce spontaneous liver metastasis. B16 melanoma and CT26 colon cancer cells were injected intrasplenically to form liver metastasis. Lung metastasis was induced by intraperitoneal injection of tumor cells. Antibiotic cocktail efficiently depleted gut bacteria. Removing gut commensal bacteria did not affect the growth of primary s.c. tumors, but impaired formation of liver metastasis in different models. The inhibitory effect on liver metastasis by removing gut microbiome was found after intrasplenic injection of tumor cells to form liver metastasis using both B16 melanoma and CT26 colon cancer tumor cells. Interestingly, formation of lung metastasis caused by tail vein injection of B16 cells was not impaired by antibiotics treatment, suggesting a liver specific effect. The inhibition of liver metastasis by antibiotic treatment was absent in Rag1 knockout mice, suggesting that the mechanism is mediated by the adaptive immune system. Conclusion: Our results suggest that the gut microbiome affects the liver immune microenvironment and modulates antitumor immunity.

#3058 Syndecan-1 mediates breast cancer metastasis to the brain through IL-8 and PECAM-1 signaling. Sierra Mosticone Wangensteen,1 Megan Sayyad,2 Madhavi Puchalapalli,1 Megan Sullivan,3 Jamie Singh,1 Briana Ratchford,1 Jayda Abrams,1 Majid Jahromi,1 Bin Hu,1 Michael Idoowu,2 Jennifer Kobinski3,1.2Virginia Commonwealth University, Richmond, VA; North Shore University Health System, Evanston, IL.

Brain metastasis is a devastating, late-stage event affecting approximately 10-30% of breast cancer patients. However, it is not well understood how breast cancer cells migrate across the blood-brain barrier (BBB) and invade into the brain. Syndecans (Sdc) are cell surface heparan sulfate proteoglycans (HSPGs) that have previously been linked to breast cancer progression and metastasis. Preliminary findings from our lab indicate that Sdc1 may be involved in breast cancer metastasis to the brain. In clinical samples from breast cancer patients with brain metastases, 67% of the brain metastasis samples stained positive for Sdc1 expression. In an experimental mouse model of metastasis, we found that silencing expression of Sdc1 in MDA-231 breast cancer cells greatly reduced metastasis specifically to the brain, with no difference in lung or bone metastases. Additionally, silencing expression of Sdc1 in MDA-231 cells resulted in a reduction in cancer cell migration across an in vitro BBB transwell model system. These findings prompted us to investigate the mechanism through which Sdc1 facilitates breast cancer cell migration across the BBB. Since BBB endothelial cell junctions have been reported to be disrupted in metastasis to the brain, immunofluorescence was performed to examine localization of junction proteins in our BBB model following addition of conditioned medium (CM) from MDA-231 non-silenced (NS1) control and Sdc1KD cells. We observed disruption in PECAM-1 localization at BBB endothelial cell junctions upon addition of CM from MDA-231 NS1 cells with markedly less disruption occurring upon treatment with CM from Sdc1KD cells. These results suggest that paracrine factors secreted from MDA-231 cells may facilitate breast cancer cell migration across a BBB-like barrier compared to Sdc1KD endothelial cells. By performing a cytokine array using CM from MDA-231 cells, we determined that Sdc1KD CM contained lower levels of IL-8 than MDA-231 NS1 cell CM. These findings were confirmed by ELISA, qRT-PCR, and multiplex analysis. We then went on to treat endothelial cells in the xCelligence in vitro BBB model system with IL-8 and observed a sufficient decrease in cell index readings, suggesting that IL-8 affects BBB barrier permeability. Taken together, our results suggest that Sdc1 supports breast cancer cell migration across the BBB through a signaling mechanism involving IL-8 and PECAM-1. Elucidating this mechanism will allow for the development of therapeutic strategies to combat breast cancer cell metastasis to the brain. [S.M.W. and M.S. contributed equally to this work.]

#3059 UHRF1 deficiency exerts anti-tumor immune responses in non-small cell lung cancer. Handan Xiang, Junying Chen, Xiao-Fan Wang, Duke University, Durham, NC.

Immune surveillance is essential for effective tumor clearance. However, the tumor microenvironment is typically impermissive for proper stimulation of both innate and adaptive immune responses. Epigenetic inhibitors have recently been shown to function as immune sensitizing reagents in the suppressive microenvironment. In our search for novel epigenetic regulators with immunomodulatory functions, we found ubiquitin-like with PHD and ring finger domain-containing protein 1 (UHRF1) being crucial for the suppression of immune activation. Loss of UHRF1 in cancer cells led to significant reduction of tumor masses in a syngeneic lung cancer model. The tumor shrinkage was due to increased infiltration of T cells with the enhanced ability to proliferate and produce IFN-gamma. Mechanistically, lung cancer cells deficient of UHRF1 had elevated expression of endogenous retrovirus genes due to DNA demethylation, which associated with enhanced type I interferon responses. Type I interferons are potent antitumor cytokines induced by pro-inflammatory stimuli and are critical for protection against metastasis. The inhibition of UHRF1 promoted PD-L1 upregulation in tumor microenvironment, yet they can also dampen T cell activation by upregulating PD-L1 expression in tumor cells. Surprisingly, UHRF1 deficient cancer cells failed to upregulate PD-L1 even in the presence of excessive type I interferons, indicative of additional regulatory pathways for PD-L1. We further found that UHRF1 directly interacted with PD-L1 promoter regions and that UHRF1 deficient cancer cells failed to overwhelm type I interferon responses while diminished PD-L1 expression, which synergistically contributed to the immune activation phenotype. Moreover, in non-small cell lung cancer (NSCLC) patients, UHRF1 expression was positively correlated with PD-L1 expression as well as poor prognosis. Together, our data suggested that UHRF1 represents a novel immuno-oncology target for NSCLC.

#3060 Role of curcumin in targeting cancer-associated fibroblasts and modulation of tumor microenvironment in dendritic cell-based immunotherapy. Sheefa Mirza,1 Nayen Jain,1 Rakesh Rawal2. 1Gujarat University, Ahmedabad, India; 2The Gujarat Cancer and Research Institute, Ahmedabad, India.

INTRODUCTION: Cancer associated fibroblasts (CAFs), main component of tumor microenvironment (TME), modulate the recruitment and functions of tumor-associated immune cells by secreting various growth hormones, miRNAs and cytokines; thus having an important role in generation of immunosuppressive TME which is yet to be elucidated. Curcumin is known to have various properties including capability to modulate numerous target proteins including transcription factors, receptors, kinases, cytokines, enzymes and growth factors. Thus, aim of the study was to evaluate the effect of miRNAs and cytokines released by lung cancer patients’ derived CAFs and to assess immunomodulatory potential of curcumin on DC maturation by targeting these CAFs through modulating their TME. METHODOLOGY: CAFs were cultured from lung cancer patient derived tumor tissue biopsy and characterised using CAF-specific markers. Further, immature DCS (iDCs) were differentiated in presence of GM-CSF and IL-4 for 5-6 days. These iDCs were cultured in the presence of conditioned media derived from CAFs (CAFS-CM) as well as NFs (Normal Fibroblasts, NFs-CM) at day 6 for 48 hours to evaluate the effect of CAFs on DC maturation. Mature DCS (mDCs) were characterized by the presence of maturation makers CD80, CD83, CD86 and CTLA4 using qRT-PCR. Moreover, expression of miR-221, miR-222, miR-135, miR-142-3p and miR-146a was assessed to evaluate the role of epigenetic regulators on DC maturation. Cytokine profiling of CAFs-CM as well as CAFs-CM treated with curcumin was conducted. RESULTS: α-SMA+Vimentin+ cells were considered as CAFs. A significant upregulation of CD80, CD83 and CD86 was observed when cultured in the presence of NFs-CM while a remarkable downregulation of these markers was found when cultured in CAFs-CM. CTLA-4 was down regulated in presence of CAF-CM as compared to NFs-CM. Amongst all miRNAs, miR-146a was shown to be up regulated dramatically in CAF-DCs (DCs cultured in CAFs-CM) as well as in CAFs-CM, suggesting the immunosuppressive role of miR-146a. Further, an increased expression of miR-146a was positively correlated with increased expression of anti-inflammatory cytokines like IL-6, IL-10, TGF-β and decreased expression of TNF-α (pro-inflammatory) in CM derived from CAFs. Moreover, curcumin had the potential to convert regulatory DCs facilitated by CAFs into mature DCs (mDCs), thereby enhancing DC maturation. The inhibitory effect on miR-221 and miR-222 was observed by curcumin. CONCLUSION: These findings provide insights into understanding the immunomodulatory role of curcumin in targeting CAFs and modulating the tumor microenvironment, thus enhancing anti-tumor immune response in DC based therapy.

#3061 Tumor-derived PAI-1 promotes macrophage M2 polarization by stimulating an autocrine IL-6–STAT3 pathway. Marta H. Kubala, Veronica R. Placencia, Yves A. DeClerck. Children’s Hospital Los Angeles, Los Angeles, CA.

Macrophages can exhibit a spectrum of activation states ranging from a pro-inflammatory and anti-tumorimunogenic M1 (CD40+, IL-12(high), IFN-gamma(high)) to a pro-tumorigenic M2 (CD163+; IL-10(high), CD206+, Arg1 (mouse) phenotypetype. Plasminogen activator inhibitor-1 (PAI-1) is overexpressed in many cancers and although it acts as a protease inhibitor it is paradoxically correlated with poor outcome. PAI-1 exerts its pro-tumorigenic role via pro-
Angiogenic and anti-apoptotic functions. Increasing evidence points towards the importance of PAI-1 in inflammation and tumorigenesis, but its influence on the immune component of the tumor microenvironment has not yet been investigated. Here we report a novel observation that PAI-1 is a regulator of macrophage polarization. We observe that in PAI-1 KO mice xenotransplanted with 3 human cancer cell lines (HT1080, A549, HCT116) in which PAI-1 was knocked down (KD), tumors were less infiltrated with macrophages with lower Arg expression compared to WT mice implanted with PAI-1 pos. tumors. We demonstrate that recombinant PAI-1 through its uPA interactive domain increased the expression of M2 polarization markers (CD163, IL-10) and decreased or did not affect the expression of M1 polarization markers (iNOS, CD80) in human peripheral blood monocytes. Further investigation demonstrated that treatment of monocytes with PAI-1 induced a rapid (2 h.) increase in IL-6 mRNA and secretion (4 h) of the protein that was followed by phosphorylation (8-24 h.) of signal transduction and activation of transcription 3 (STAT3) in monocytes. Further linking STAT3 activation to PAI-1, we observed a decreased pSTAT3 in monocytes co-cultured with HT1080 cells upon PAI-1 downregulation. We found that STAT3 activation was downstream of IL-6 and responsible for M2 polarization, as the blockade of the IL-6 receptor with a function blocking antibody (tocilizumab) or inhibition of STAT3 activation by a JAK2/STAT3 inhibitor (ruxolitinib) prevented M2 polarization of monocytes by PAI-1. The contribution of PAI-1 to M2 polarization of macrophages was tested in PAI-1 KO mice implanted with human tumors in which PAI-1 expression was controlled by doxycycline. These experiments demonstrated that induction of PAI-1 in established tumors increased the presence of tumor associated macrophages (TAM) (F4/80 +) and decreased the presence of M1 (iNOS +) TAM. Further supporting the presence of an autocrine PAI-1/IL-6 pathway in macrophage polarization in human cancers, a meta-analysis of gene expression array data indicated strong correlations between PAI-1 and IL-6 expression in breast (P = <0.05) and colon (P = <0.01) cancers and between PAI-1 and CD163 in colon cancer (P = <0.0001). The data thus identify a new pro-tumorigenic function for PAI-1 in the communication between tumor cells and macrophages where tumor-derived PAI-1 activates an autocrine IL-6/STAT3 pathway that promotes M2 polarization.

#3062 Metformin inhibits TGFβ-induced stromal ECM remodeling to impede invasion in ovarian cancer. Peter C. Hart, Shermeen Sheikh, Ernst Lengyel, Iris Romero. University of Chicago, Chicago, IL.

Recently, our group has elucidated that metformin, the commonly used medication for type 2 diabetes, has anti-ovarian cancer (OvCa) effects in preclinical models and use of the drug is associated with improved OvCa survival in retrospective epidemiological studies. While the cytotoxic effects of metformin in ovarian cancer cell lines is well demonstrated, the impact of metformin on tumor-stromal interactions in the tumor microenvironment is not well defined. Currently, our work has focused on the impact of metformin on the tumor microenvironment and cancer cell behavior in physiologic models of tumor metastasis. Using a 3D organotypic model, we demonstrate that OvCa cell invasion is inhibited by metformin. In evaluating the molecular mechanism mediating this effect we show that OvCa cells co-cultured with stromal cells or stimulated with TGFβ1 upregulated the production of the extracellular matrix (ECM) proteins fibronectin and collagen 1 and that this effect is attenuated by metformin. Interestingly, metformin’s inhibition of ECM production was not dependent on AMP-activated kinase (AMPK), a common metformin target. To expand on this finding we performed label-free shotgun proteomics and identified collagens, fibronectin and TGFBR2 to be among the proteins most highly repressed in response to metformin exposure in OvCa cells. Finally, we identified that this repression of ECM remodeling by metformin was associated with an overall reduction in TGFBR2 expression and consequent SMAD/STAT3 activity. Taken together, our data indicate that metformin may have novel targets in the tumor microenvironment where it targets pro-tumorigenic effects of the stromal compartment by repressing TGFβ-dependent stromal cell ECM secretion, thereby inhibiting ovarian cancer invasion and metastasis.
Castrate resistant prostate cancer (CRPC) remains the primary cause of mortality for prostate cancer (PCa) patients. Several therapies are currently approved for use against CRPC, consisting mostly of androgen receptor (AR) signaling inhibitors and toxic anti-microtubule chemotherapeutics that do not score long-term durable responses. Recent deep-sequencing analysis studies have elucidated the complex and heterogeneous landscape of CRPC, highlighting the necessity to develop effective targeted therapies against specific CRPC subtypes or therapies effective against numerous subtypes of CRPC. PTEN and p53 are two of the most frequently altered genes in CRPC, and are associated with therapy resistance and a poor clinical prognosis. The objective of this study was to identify and subsequently validate therapeutic targets against models of advanced PCa, specifically in the absence of PTEN and p53. Using non-biased high throughput screening technology, we identified HSP90 inhibitors to be potent and efficacious against a model of PTEN/p53 null PCa. HSP90 is a critical regulator of prostate cancer cell signaling homeostasis, and recently developed second generation compounds targeting HSP90 are effective against genetically heterogeneous panels of cancer cell lines and have favorable safety parameters in the clinic. Screening results and subsequent validation efforts in vitro identified ganetespib as the most potent HSP90 inhibitor, with efficacy that translated into established human PCa cells lines. Ganetespib also displayed strongly inhibitory activity against PTEN/p53 null progenitor cells, a plastic subpopulation of PCa believed to be partly responsible for therapy resistance. In vivo, ganetespib completely inhibited progression of PIN to invasive adenocarcinoma in the adenocarcinoma in situ (Aci) mouse model, leading to a significant reduction in tumor weight. Expanding from the mouse model to clinically predictive PDX-derived LuCaP models of human PCa, we found that ganetespib displayed a range of activity against a genotypically diverse array of 11 LuCaP organoids ex vivo. Furthermore, the PTEN null/p53 altered LuCaP 136 displayed a robust response to ganetespib in vivo, with ganetespib causing a significant reduction in tumor growth. Mechanistic interrogation in vitro, ex vivo, and in vivo revealed ganetespib induced effects to be multifactorial and model specific, with unifying trends being inactivation of PI3K signaling and modulation of cell cycle regulatory proteins. In all, these data indicate that inhibition of HSP90 is a novel therapeutic to treat advanced PCa via multifactorial perturbation of growth regulatory pathways.

**#3066 Inhibition of hsp90 by auy922 preferentially kills mutant KRAS colon cancer cells by activating Bim through ER stress.** Chun Yan Wang, Su Tang Guo, Jia Yu Wang, Xu Guang Yan, Margaret Farrellly, Yuan Yuan Zhang, Fen Liu, Hamed Yari, Ting Li, Fu Xi Lei, Lei Jin, Chen Chen Jiang, Xu Dong Zhang. University of Newcastle, Newcastle, Australia.

Colon cancer is one of the most common and deadly malignancies (1). Despite recent advances in early diagnosis and the development of molecularly targeted therapy, the overall survival of patients with metastatic colon cancers remains disappointing (1). This is often associated with resistance of colon cancer cells to systemic therapies resulting from oncogenic mutations of KRAS that drive activation of multiple downstream signalling pathways important for cell survival and proliferation. Here we report that mutant KRAS colon cancer cells are nevertheless more susceptible to apoptosis induced by the heat shock protein 90 (HSP90) inhibitor AUY922. We determined that although AUY922 inhibited HSP90 activity with the comparable potency in colon cancer cells irrespective of their KRAS mutational statuses, those with activating mutations of KRAS were markedly more sensitive to AUY922-induced apoptosis. This was associated with upregulation of the BH3 only proteins Bim, Bik, and PUMA. However, only Bim appeared essential, in that knockdown of Bim abolished, whereas knockdown of Bik or PUMA only moderately attenuated apoptosis induced by AUY922. Mechanistic investigations revealed that endoplasmic reticulum (ER) stress was responsible for AUY922-induced upregulation of Bim, which was inhibited by a chemical chaperone or overexpression of GRP78. Conversely, siRNA knockdown of GRP78 or XBP-1 enhanced AUY922-induced apoptosis. In addition, AUY922 inhibited the growth of mutant KRAS colon cancer xenografts through activation of Bim that was similarly associated with ER stress. Taken together, these results suggest that AUY922 is a promising drug in the treatment of mutant KRAS colon cancers, and that agents that enhance the apoptosis-inducing potential of Bim may be useful to improve the therapeutic efficacy.

KRAS-mutant cancers are notoriously therapy-resistant. While responsible for oncogenesis, mutant KRAS or the sustained activation of KRAS-driven effectors may or may not be required throughout the course of cancer progression.
Thus, understanding which tumors remain dependent on oncopgenic KRAS could lead to the identification of unique vulnerabilities and opportunities to treat them. We previously discovered that the carbohydrate-binding Galectin-3 (Gal-3) brings together KRAS with integrin αvβ3 at the cell membrane in epithelial cancer cells to promote tumor progression. Here, we show that by directly binding to the cell surface receptor integrin αvβ3, Gal-3 drives addiction of oncopgenic KRAS by enhancing macropinocytosis and reducing mitochondrial reactive oxygen species (ROS). This pathway drives increased expression of SOD2, a superoxide dismutase that clears mitochondrial ROS to protect against cell death. Targeting Gal-3 with a clinically active drug decreases macropinocytosis and increases ROS to eradicate KRAS-addicted lung cancer in patient-derived xenografts and spontaneous KRAS-driven lung cancer in mice. Our work reveals Gal-3 as a druggable target for KRAS-addicted lung cancer, and indicates integrin αvβ3 as a biomarker to identify this dependence.

#3068 Proxotoxic stress associated with mTORC1 activation in ovarian carcinoma: pro tease inhibition as a therapeutic strategy. M. Herman Chui, Patricia Shaw, Robert Rottapel. University of Toronto, Toronto, Ontario, Canada. Genetic profiling studies of high grade serous ovarian carcinoma have revealed recurrent alterations in the mTORC1 signalling network (e.g. mutations/copy number alterations in PTEN, TSC1, TSC2, and PIK3CA) and pathway activation, detected by phospho-4E-BP1, has been associated with poor prognosis. We sought to characterize functionally the role of mTORC1 signalling and its therapeutic implications in ovarian cancer. Treatment of ovarian cancer cell lines with Gal-3 transcripts resulted in inhibition of mTORC1 signalling and decreased rate of protein synthesis. However, irrespective of PTEN mutation status, only mild cytostatic effects were achieved even with high concentrations of rapamycin. We next examined the phenotypic consequences of mTORC1 activation, using siRNA directed against TSC2. Surprisingly, we observed striking growth inhibition in the majority of ovarian cancer cell lines, whether grown under adherent monolayer culture or in 3-dimensional spheroid culture conditions. While mTORC1 pathway activation was confirmed biochemically, knock-down of TSC2 also resulted in activation of the unfolded protein response (UPR), with elevated levels of phospho-EIF2α and ATF4, consistent with the accumulation of misfolded proteins in the endoplasmic reticulum. From a therapeutic standpoint, the resulting burden on the ubiquitin-proteasome system should render these cells particularly sensitive to proteasomal inhibition. We show that treatment with the proteasome inhibitor, bortezomib, causes increased accumulation of detergent-insoluble poly-ubiquinated proteins and formation of larger and more abundant cytoplasmic protein aggregates in sTSC2-transfected compared to scrambled siRNA-transfected ovarian carcinoma cells. This was accompanied by a more pronounced UPR stress response, including induction of pro-apoptotic CHOP, and suppression of autophagy, resulting in marked cytotoxicity. Conversely, we show that inhibition of protein synthesis by cycloheximide renders tumor cells resistant to bortezomib. Increased resistance to bortezomib was also noted when cells were grown as spheroids, a condition associated with suppression of mTORC1 signalling and decreased protein synthesis. This resistant phenotype of tumour spheroids however was ameliorated with treatment with siRNA targeting TSC2, downregulation of TSC2, and pharmacological GPR68 inhibition. Together, these findings demonstrate that mTORC1 is a pivotal checkpoint kinase for the survival of ovarian carcinoma cells. The identification of mTORC1 as a target in ovarian carcinoma cells should provide a therapeutic rationale for targeting these pathways in the clinic.

#3070 Lenalidomide and SMAC mimic LCL161 show combination activity in cells harboring loss of chromosome 5q. Nafeezah Hafeez, Alex Gaither, Dale Porter. Novartis, Cambridge, MA. LCL161 is a small molecule SMAC mimic that binds to IAP1, IAP2, and XIAP and sensitizes cancer cells to TNF-alpha as well as other inducers of cell death. An siRNA screen was performed in the SK-OV-3 cancer cell line to identify genes that when knocked down prevent LCL161-mediated cell death. As expected, siRNAs targeting RIPK1 rescued cells from LCL161-induced death. Unexpectedly, siRNAs targeting GPR68 also rescued cells from LCL161-induced death. Since knockdown of GPR68 has been reported to rescue myelodysplastic syndrome (MDS)-derived cells harboring loss of chromosome 5q from lenalidomide treatment, we tested for combination activity with lenalidomide plus LCL161 in 7-day in vitro proliferation assays. Interestingly, combination activity was observed in the SET-2 cell line harboring cytogenetic features of MDS including loss of chromosome 5q. These data suggest that, in combination, LCL161 may improve responses to lenalidomide in subsets of MDS and MDS patients and potentially additional contexts where lenalidomide is active.

#3071 Exploring the molecular mechanism underlying SETD2-Pi3Kβ synthetic-lethal interaction in renal cell carcinoma (RCC). Esteban Terzo,1 Jeanne Chiang,2 W. Kimryn Rathmell1. 1Vanderbilt University Medical Center, Nashville, TN; 2University of North Carolina, Chapel Hill, NC. Epigenetic regulators are emerging as major drivers of renal cell carcinoma (RCC). SETD2, a tumor suppressor commonly mutated in RCC, is the sole enzyme responsible for tri-methylating histone H3 on lysine 36 (H3K36me3) of actively transcribed genes. We recently discovered that SETD2 also trimethylates the non-histone target α-tubulin on lysine 40 (α-TubK40Me3) of mitotic microtubules. We have demonstrated that mutations altering SETD2’s ability to trimethylate H3K36 and α-TubK40 are associated with genomic instability in cancer progression. We hypothesized that defective SETD2 methylating activity gives rise to deleterious cell signaling cascades that promote the tumorigenic features of SETD2 loss. Preliminary data show that RCC-derived 786-0 cells that are deleted for SETD2 (SETD2-KO) or harbor pathogenic mutations are more sensitive to treatment with the PI3Kβ-specific inhibitor TGX-221 than their wild type counterparts. Phosphatidylinositol 3 kinases (PI3Ks) are a family of lipid kinases that coordinate signals from growth factors, cytokines and other environmental cues, translating them into intracellular signals controlling diverse signaling pathways. Several members of the PI3K/AKT signaling pathway, including the PI3K α and β isoforms, are frequently mutated in a variety of cancers, making this pathway a prime drug target for anti-cancer therapy. These pathways control numerous biological processes, such as cell proliferation, growth, and motility. Examination of structurally variant SETD2 mutants suggests that the loss of SETD2 methylating activity mediates this interaction, and future studies will examine the functional consequences of inhibiting this path-
EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Determinants of Drug Sensitivity and Resistance

#3072 A clinical pharmacodynamic biomarker assay that distinguishes potentially repairable, cytotoxic drug-induced DNA double strand breaks (DSBs) from DSBs associated with apoptotic cell death. Angèle B. Dull,1 Deb- orah Wiśler,2 Robert J. Kinders,1 Ralph E. Parchment,1 David Evans,2 Beverly A. Teicher,3 James H. Doroshow,1,2 Leidos Biomedical Research, Inc., Frederick National Laboratory for Cancer Research, Frederick, MD;1 National Cancer Institute, Bethesda, MD.

The effectiveness of certain classes of cytotoxic cancer therapeutics likely depends on whether drug-induced DNA damage is successfully repaired or not, with the latter situation leading to mutations and strand breaks. However, double strand breaks (DSBs) also occur independently of genotoxic insults during apoptotic cell death caused by many drug classes, as well as natural biological processes. We have developed an immunofluorescent confocal microscopy assay that uses a biomarker profile suitable for individual cell analysis designed to distinguish between DSBs caused by apoptosis and those caused by direct DNA damage from cytotoxic drug action. γ-H2AX is an established biomarker for DSBs and activated cleaved caspase 3 is an executioner caspase important for apoptosis, which leads to nuclear condensation, DNA fragmentation, plasma membrane blebbing, and subsequent cell death. Our assay defines the DSBs of apoptosis as co-localized γ-H2AX and cleaved caspase 3 in individual cells, while defining the DSBs from early drug effects of DNA damaging chemotherapy agents by γ-H2AX induction in the absence of cleaved caspase 3. Building on our published findings that topotecan strongly induces γ-H2AX and DSBs within 1-4 hours in vitro and in vivo, we observed exposure-dependent increases in γ-H2AX/cleaved caspase 3 double positive cells at later time points, both in an HT29 in vitro spheroid model and an MDA-MB-231 xenograft model. Fit-for-purpose studies in the MDA-MB-231 xenograft treated with bircin- pant, a SMAC mimetic and IAP deregulator that does not directly produce lethally DSBs, demonstrated a dose-dependent increase in cellular co-localization of γ-H2AX/cleaved caspase 3 consistent with bircin induced apoptosis and the established mechanism of action of this compound. Clinical feasibility was established in a canine clinical trial using formalin-fixed paraffin-embedded (FFPE) 18-gauge needle biopsies: two novel indenoisoquinolines, indotecan (LMP400) and indimitecan (LMP776), increased tumor cell co-localization of γ-H2AX/cleaved caspase 3 in tumor samples obtained on day 5 of qdx5 treatment. This PD biomarker assay of early and late DSb response to drug exposure could have important applications for elucidation of mechanisms of action of anticancer drugs and the development of investigational agents. Funded by NCI Contract No. HHSN261200800001E.

#3073 Potential predictive biomarkers of clinical responses for a novel CDC7-selective inhibitor TAK-931. Kenichi Iwai,1 Tadahiro Nambu,2 Osamu Kurasawa,1 Noriko Uchiyama,1 Ryo Dairiki,1 Yuko Ishii,1 Hideshi Ishii3.1 Takeda Pharmaceutical Company, Fujisawa, Japan;2 Takeda Pharmaceuticals Institute, Inc., Santa Monica, CA;3 Department of Pathology, University of Tokyo, Tokyo, Japan.

Cell cycle kinase (CycC) is a serine/threonine kinase, which plays important roles in initiation of DNA replication by phosphorylating MCM2. Kinase activity of CycC7 is controlled by its binding protein DBF4 in a cell-cycle dependent manner. Here we developed a potent CDC7 inhibitor TAK-931 (IC50< 0.3 nM) as a cancer therapeutic drug candidate, which exhibits a time-dependent ATP-competitive kinetics to its ATP-binding pocket. The selectivity studies using the 308 kinases revealed >100-fold selectivity of TAK-931 for CDC7 kinase inhibition compared to other kinase inhibitors. Treatment with TAK-931 suppressed the cellular MCM2 phosphorylation at Ser40, resulting in a delayed S phase progression, checkpoint activation, apoptosis, and potent growth suppression in various cancer cell lines. Furthermore, oral administration of TAK-931 as a single agent caused a significant antitumor activity in multiple xenograft models which includes both solid and hematological cancer cells. TAK-931 inhibited proliferation of multiple cancer cell lines, with mean concentration producing a half-maximal response (EC50) values ranging from 29.1 nM to > 30 μM (median = 554.5 nM). While the wide range of TAK-931 antiproliferative spectrum was observed, neither doubling speed nor CDC7 expression profile did predict TAK-931 sensitivity in cancer cell lines. A correlative study of the tumor genetic mutations in relation to antiproliferative activity that KRAS mutant cancer cells were more sensitive to TAK-931 compared to KRAS non-mutant cell lines (p<0.05). We also confirmed this KRAS-associated antiproliferative effect of TAK-931 in the SW48 isogenic cell lines of KRAS mutations (p<0.01). The ectopic expression of a cell knocked down TAK-931 increased the TAK-931 sensitivity compared to the KRAS-wild parental SW48 cell line. Given that KRAS mutations are frequently detected in clinical pancreatic tumors, we next conducted in vivo efficacy studies using pancreatic PDX models. Consistent to our hypothesis from in vitro studies, KRAS-mutant pancreatic PDX tumors were more sensitive to TAK-931 than the KRAS-wild pancreatic KRAS-mutant pancreatic PDX models we tested exhibited >60% TGI. Our findings suggest that the KRAS-mutant pancreatic tumors could be the potential candidate for the TAK-931 target indication.

Pancreatic ductal adenocarcinoma (PDAC) is an aggressive malignancy with a 5-year survival rate of just 8%. Mutations in BRCA2 are among the most common known germline alterations that predispose to PDAC. While the sensitivity of BRCA2-mutant breast and ovarian tumors to platinum compounds has long been recognized, the recent approval a PARP inhibitor in BRCA2-mutant ovarian cancer confirms hope that such tumors might be targeted with greatly reduced toxicity. To test whether PDAC displays similar sensitivity to PARP inhibitors, we carried out preclinical intervention studies in KRAS/p53-mutant genetically engineered mouse models (KPC mice) with or without the additional mutation of BRCA2 (KPCBR2 mice). Mice were enrolled based on 3D ultrasound imaging criteria to assure similar initial tumor burden, and tumor growth was monitored longitudinally by ultrasound. To our surprise, loss of Brca2 failed to sensitize pancreatic tumors to Parp inhibition and did not provide additional benefit in combination with cisplatin treatment. By contrast, cisplatin induced substantial regressions in most KPCBR2 tumors, leading to a >3-fold increase in overall survival, while having no effect on the growth or survival of mice with wild-type BRCA2. More surprisingly, the efficacy of cisplatin was not shared with oxaliplatin, even at higher doses. While BRCA2 is primarily known for its role in homology-directed repair, a network biology analysis of the function of BRCA2 in human pancreatic cancer led us to investigate the role of BRCA2 in mitosis. Wild type BRCA2 protein localizes to the midbody- a structure formed during the final stages of telophase- and plays poorly understood role in the final abscission of cytoplasm between two dividing cells. Timelapse video microscopy of KPCBR2 tumor cells treated once weekly for 2 hours with cisplatin revealed the frequent induction of endoreplication as well as eventual formation of polyploid giant cells subsequent death. Similar cells were found throughout KPCBR2 tumors during response in cisplatin treatment, but were largely absent from tumors in other treatment arms. Mechanism studies found that BRCA2 deficient PDA cells are susceptible to replicative stress following cisplatin treatment that selectively leads to the formation of radial chromosomes that cannot be resolved during mitosis. These studies argue for the consideration of cisplatin-based (rather than oxaliplatin-based) regimens for the treatment of BRCA2-mutant pancreatic tumors.

#3075 Analysis of microRNA profiles involved in the resistance to trifluoridine. Kenta Tsunekuni,1 Jun Koseki,2 Masamitsu Konno,3 Ayumu Asai,4 Norhiro Nishida,5 Hugo Colvin,6 Koichi Kawamoto,7 Yuichiro Doki,8 Masaki Mori,9 Hideshi Ishii9.1 Taiho Pharmaceutical, Tokushima, Japan;2 Osaka University, Osaka, Japan;3 Okasaki University, Okasaki, Japan.

Background: Trifluoridine (FTD) is a key component of the novel oral antitumor drug trifluoridine/tipiracil, which was approved for the treatment of patients with metastatic colorectal cancer refractory to standard chemotherapy. A comprehensive analysis of miRNA profiles was performed in cell lines resistant to FTD established by ourselves, in order to explore the underlying mechanisms of resistance to the drug. Method: We established subline resistance to FTD through continuous administration and increasing dose of the drug for 5 months using the colorectal cancer cell line DLD-1. Total RNA was extracted at intervals whilst establishing FTD resistant sublines, and miRNA expression was analyzed by microarray. The expression of miRNA that was significantly down-regulated in the FTD resistant subline was knocked down to test its involvement in resistance to FTD. Cell viability was evaluated by crystal violet cytotoxicity test. Results: The established FTD-resistant sublines showed more than 22-fold higher resistance to FTD and no cross-resistance to 5-FU. miRNA and mRNA cluster in the genome locus located in chromosome 9, 9p22.3 were down-
regulated in the FTD-resistant cell line, one of which was the miRNA let-7d-5p, which is one of the let-7 family and is known to target oncogenes and several key components of the cell cycle and cell proliferation. Anti-let-7d-5p treated DLD-1 was less sensitive to FTD than compared to control. The IC_{50} values of FTD were 16.8 μM and 7.6 μM for the anti-let-7d-5p treated cells and control respectively. On the other hand, overexpression of let-7d-5p in DLD-1 using let-7d-5p mimic incresed the sensitivity to FTD compared to control. The IC_{50} values of FTD were 3.7 μM and 13.9 μM in the let-7d-5p overexpression cells and control respectively. 5FU sensitivity was only altered slightly in anti-let-7d-5p treated or let-7d-5p mimic treated cells. These data suggest that let-7d-5p is more relevant to sensitivity for FTD than that of 5FU. Conclusion: Let-7d-5p expression is associated to the development of new more aggressive clones of tumor cells. 

Background and Aims. Chemo-resistance in hepatocellular carcinoma (HCC) tumor cells can be mediated by several mechanisms including P-gp efflux pumps and drug sequestration by the autophagy process. This study investigates the potential of doxorubicin loaded nanoparticle (NP) to reverse chemo-resistance by these mechanisms compared to free doxorubicin. We present the pre-clinical evaluation of anti-tumor effects of NP as monotherapy and in combination with standard agents used in treatment of HCC, pancreatic and sarcoma cancers. A phase III clinical study comparing NP to Best Standard of Care (Re-live study) in patients with advanced HCC is in the final stages of recruitment with preliminary results expected in 2H 2017. Methods. Tumor cell lines were incubated with drugs in cell proliferation assay. In vivo efficacy of NP alone (4-8 mg/kg) or in combination with current and investigational treatments for pancreatic cancer (e.g. Gemcitabine, Erlotinib, Abraxane) and HCC (Sorafenib, Regorafenib and Lenvatinib) were performed in mouse tumor models using tumor weight as primary endpoint. In all experiments NP was compared to administration of free doxorubicin. Doxorubicin quantification in tumor and organs to assess PK and biodistribution was also performed using an LC/MS based method. Autophagy was measured by cell proliferation in the presence of inhibitors e.g., Concanamycin A, Hydroxychloroquine sulfate added 30 min before incubation with the test compound. Results. NP showed a dose-dependent inhibition of cell proliferation in all resistant cancer cell lines tested with a superior activity compared to free doxorubicin and other tested drugs. In contrast to free doxorubicin, NP showed consistent anti-proliferative activity in the absence/presence of inhibitors of P-gp pumps and autophagy. In a range of in vivo models, NP was preferentially taken up by the tumor tissue and significantly reduced tumor growth when compared with free doxorubicin and with at least equivalent reduction in tumor growth compared to current treatments. Furthermore NP administered in combination with current treatments significantly increased the inhibitory effect of each drug without additional toxicity (as measured by no change in body weight). The result comparing efficacy of NP with standard agents in combination and in combination in HCC, pancreatic and sarcoma cancer models will be presented. Conclusions. These results demonstrate that NP is clearly differentiated from free doxorubicin, in 1) overcoming resistance mechanisms linked to efflux and autophagy, and 2) having a superior biodistribution profile both of which results in significantly enhanced activity on chemo-resistant tumors. NP also provides an opportunity to combine with other agents, enhancing activity without increasing toxicity. The implications of these results on the further development of NP will be discussed.

#3077 Tumor cells with acquired resistance to EGFR inhibitors and over-expression or activation of AXL, MET and FGFR1 are insensitive to single-agent treatment targeting AXL, MET or FGFR1. Jordi Bertran-Alamillo, Miguel Angel Molina-Villa, Cristina Teixedo, Jordi Codony-Servat, Ana Giménez-Capitán, Carles Codony-Servat, Silvia García-Román, Elena Aldegue, Sonia Rodríguez, Rafael Rosell1, Pangea-Biotech, Barcelona, Spain; 2Institut Català d’Oncologia, Badalona, Spain. 

Background: Ablerrant activity of the MET, FGFR1 and AXL receptors has been associated with the development of resistance to first, second and third generation EGFR tyrosine kinase inhibitors (TKI) in EGFR-mutated non-small cell lung cancer (NSCLC) patients. Methods: We obtained 6 resistant lines by treating EGFR-mutated (exon 19 TKI sensitive PC9 cells with increasing concentrations of gefitinib or erlotinib. The p.T790M resistance mutation emerged in two cell lines (GR1, GR4), which remained sensitive to osimertinib, a third generation EGFR TKI. Six new cell lines to resistant to “second line” osimertinib were generated from GR1 and GR4 by exposure to increasing concentrations of the inhibitor. Finally, six more cell lines resistant to “first line” osimertinib were derived from the PC9 parental cells. All resistant cell lines were genotyped for selected genes (including EGFR) and characterized for AXL, MET and FGFR1 expression and activation by Q-RT-PCR, immunohistochemistry and Western blotting. The effects of AXL (BGR324), MET (crizotinib, capmatinib) and FGFR1 (nindetanib) inhibitors on the parental and the 18 resistant cell lines were analyzed by MTT and, in some cases, by colony formation. AXL was stably silenced in some of the resistant cell lines. Results: All cell lines resistant to “first line” gefitinib, erlotinib and osimertinib maintained the exon 19 EGFR sensitizing mutation. In contrast, FTD sensitivity and expression/mutation was more efficiently than 5FU. It suggest that the let-7d-5p is a potential predictive marker for trifluridine/tipiracil treatment in the clinical setting.

#3078 The role of extracellular vesicles in chemotherapy resistance in gastric cancer. Edson Cassinella, Michele C. Landemarber, Gabriela P. de Oliveira, Vivian Tinina Martins, A. C. Conquista Cancer Center, Sao Paulo, Brazil.

Gastric adenocarcinoma (GAC) is the fourth most common cancer and the second cause of cancer death in the world. Chemotherapy has been largely used to treat this disease however acquired drug resistance is a common event and is associated to the development of new more aggressive clones of tumor cells. Herein, a gastric adenocarcinoma cell line (AGS) resistant to the 5-fluorouracil (5-FU) was generated in order to establish mechanisms associated to acquire drug resistance. In the presence of 5-FU (10μM) resistant cells show a 2-3 times higher proliferation ratio than parental cells, a platting efficiency of 38% compared to 1% of parental cells and a higher invasive phenotype. Remarkable, when compared to parental cells, rAGS-FU resistant cells secreted 2-3 times more extracellular vesicles, EVs (85-175nm). When parental cells were treated with RNAi, rAGS-FU resistant cells they acquired the same phenotype of the latter cells regarding higher proliferation, platting efficiency and invasion. The proteomic analysis of parental and rAGS-FU cells showed 306 differentially expressed proteins, while 66 differentially expressed proteins were found when EVs secreted from these cells were compared. Our data suggest that cells resistant to chemotherapy have a more aggressive phenotype and are able to transfer these characteristics to non-resistant cells. These findings point to mechanisms of chemoresistance mediated by components that are carried from cell to cell by EVs, what may indicate novel approaches that can be addressed to impair drug resistance and improve treatment response. Supported by FAPESP.

#3079 Activation of CCN1 signaling in solid tumor cells diminishes response to a histone deacetylase inhibitor: A dark side of HDACIs. Arnab Ghosh, Priyanka Ghosh, Gargi Maji, Sushanta K. Banerjee, Manjhi Banerjee. VA Medical Center, Kansas City, MO. 

Background and Objective: Histone deacetylase (HDAC) inhibitors are clinically proven epigenetic-based drugs for hematological cancers. However, the impact of these inhibitors on solid tumors is disappointing and debatable. Recent studies have shown that the solid tumor cell lines are less sensitive to a HDAC inhibitor: Vorinostat (suberoylmalonyl hydroxamic acid, SAHA) as compared to hematological cell lines. However, it remains elusive why solid tumor cell lines responded weakly to HDAC inhibitors. Previously, it has been reported that CCN1/Cyr61 plays critical role in invasive front and drug resistance in breast and pancreatic cancer. Thus, our goal is to determine whether CCN1 signalling impair activity of SAHA in breast and pancreatic cancer cells. Methods: To test this objective, various breast cancer cell lines (MCF-7, ZR-75-1, MDA-MB-231, HCC-70) and pancreatic cancer cell lines (BxPC-3, AsPC-1 and Panc-1) were treated with SAHA with different does and times. Levels of CCN1 and its downstream signalling molecules were determined in SAHA-treated or untreated cell extracts using Western blotting. In addition, cell viability, migra-
tion and sphere formation were examined in parental and CCN1-depleted cells in the presence or absence of SAHA. Results and Conclusions: Here we have shown that CCN1 was upregulated in various breast and pancreatic cancer cell lines following SAHA treatment via epigenetic mechanism. Distribution of CCN1 in the nucleus and cytoplasm was also drastically altered in SAHA-treated parental cells as compared to CCN1-depleted cells. However, following SAHA treatment, CCN1 expression was located predominantly in the nucleus. Functionally, CCN1 had dual outcome in these cells. The cell viability assay indicated that CCN1-positive breast cancer or pancreatic cancer cells were more sensitive to SAHA as compared to CCN1-negative cells. CCN1 ablation by neutralizing antibody treatment in MDA-MB-231 cells significantly suppressed the inhibitory effect of SAHA in MDA-MB231 cells. The CCN1 knockdown phenotype such as migration towards SDF-1 and sphere-formation were markedly elevated in SAHA treated cells as compared to untreated cells. These effects of SAHA were rescued by CCN1-depletion. Collectively, these studies indicate that CCN1 activation limits the response to SAHA in solid tumor cells and thus suggesting that combination therapy of SAHA and CCN1-inhibitor could be an ideal therapeutic approach to make HADAC inhibitor sensitive to solid tumors.

Objective: Investigating the role of Y-box binding protein 1 (YB1) in drug resistant advanced kidney cancer. Background: Renal cell carcinoma (RCC) is the 6th most common malignancy with approximately 1,800 deaths in 2015 with an annual increase in Canada. Despite the partial or total surgical removal of kidney in patients with localized RCC, metastatic patients are treated with tyrosine kinase inhibitors (TKIs) in a purely palliative approach. However, TKI-resistance (Sunitinib) is developed after a median time of 10-14 months. Therefore, identifying the factor(s) responsible for TKI-resistance development and disease advancement in RCC is imperative. It is now widely recognized that evolutionarily conserved Y-box binding protein 1 (YB1) is essential for cell growth and survival. Upregulation of YB1 in numerous cancer types was found to be positively correlated with tumor growth, metastasis and drug-resistance development. YB1 is also involved in cellular communication through its secretion in the tumor microenvironment by cell-surface transporters, ABC-transporters. Summary of the data: Endothelial cells (HUVEC) were co-cultured with Caki-1-DIC (Sunitinib-resistant, developed in our lab) and Caki-1 WT (Sunitinib-sensitive) RCC cell lines, and increased migration of HUVEC was observed with Caki-1 DIC compared to Caki-1 WT. A drastic increase in YB1 and its downstream target ABCB1 in Caki-1 DIC compared to Caki-1 WT cells was also detected. Consistent with previous reports, we observed granular structures in the Caki-1 DIC cells that support potential secretion of YB1 into the tumor microenvironment. Moreover, blocking ABCB1 reverted the Caki-1 DIC cells to being drug-sensitive. Experimental procedures: Caki-1 WT and Caki-1 DIC were co-cultured with HUVEC cells followed by scratch assay to test for HUVEC cell migration and associated secretory factors. Western blot and qPCR were used to determine the protein and mRNA levels respectively between the two cell-lines. Immuno-histochemical staining was carried out on the RCC tumors from Sunitinib-sensitive and resistant patients entered in one of the clinical trials. In 14 cases, YB1 expression was observed using immunofluorescence staining against YB1. Presto-blue was used for cell biomass assay following different drug treatments. Summary: The molecular function of YB1 in RCC and its potential in targeted therapy is not well understood. Therefore, understanding the function of YB1 in metastatic RCC and in drug-resistance development is of vital importance. Our data suggests that inhibition of YB1 may slow disease progression and, possibly, revert the drug resistance mechanism. The results from this study have the potential to introduce YB1 inhibitors in conventional RCC chemotherapy, alone or in combination, to improve survival in advanced kidney cancer patients.

**#3081 Precision medicine for patients with advanced small cell lung cancer treated with novel therapeutic agents in a phase I clinical trials unit.** Joline S. Lim, Samuel J. Harris, Malaka Ameratunga, Raghab Sundar, Joo Eun Ang, Debrahille Collins, Maxime Chénard-Poirier, Alvaro I. Garces, Stan B. Kaye, Juanita Lopez, Udai Banerji, Johann S. deBono, Timothy A. Yap.

Introduction: Small cell lung cancer (SCLC) is aggressive and relapse is inevitable. Novel therapies in the context of phase I (Ph1) clinical trials should be considered in this setting. Next generation sequencing (NGS) identifying putative driver mutations may aid therapy allocation in such trial settings. Methods: Retrospective analysis of characteristics and clinical outcomes of patients (pts) with advanced SCLC referred to the Phase I Clinical Trials Drug Development Unit at the Royal Marsden Hospital between 1992 and 2016, using electronic patient records. Results: 85 pts with advanced SCLC were included, of which 45 pts were allocated to ≥1 trial each (48 allocations). Of these, 21 (46.7%) pts started ≥1 trial, with a total of 24 trials commenced. Of the 64 pts who were unable to commence trials, 43 (67.2%) had rapid disease progression, 11 (17.2%) sought other therapies, 5 (7.8%) declined Ph1 trials, and 5 pts did not enrol for unknown reasons. Pts 1 (2.0%) were not allocable. Ph1 trials were run in 24 different lines of treatment (frame 1-3). 13 pts had tumor molecular profiling with high coverage targeted NGS, yielding 22 distinct mutations; Alterations in DNA damage repair (DDR) pathway were most common: TP53 (53.8%), FANC (30.8%), ATM (15.4%), ATR, BAR1D and CHEK2 (7.7% each). All pts found to have ≥1 DDR mutation pathway presented platinum sensitive disease (disease progression ≥90 days from last platinum dose) and were allocated to Phase I trials with four different settings available: PCI, AR, AXIN1, DDRB, ERBB2, mTOR, PI3K, NOTCH, NTRK1, PDGF, R81, RET, STK1, FKT and VGF. Pts were most commonly treated with novel inhibitors against PARP (n=9), PI3K(akt)(n=3), PD-1 (n=2) and BCL (n=2). Therapies were generally well tolerated with no dose limiting toxicities observed. Of 9 pts who received PARP inhibitors, 1 achieved a RECISt partial response (PR) and remained on trial for 16 weeks; 4 achieved RECISt stable disease (SD) for a median of 17 weeks (range:10.9-31.1 weeks). 1 exceptional responder whose tumor harbored multiple somatic aberrations (TP53, FANC, AR, ERBB2, NOTCH2) was enrolled on 3 sequential phase I trials - she achieved durable RECIST SD on a PARP inhibitor (31.1 weeks), RECIST PR with a PD-1 inhibitor (38.7 weeks), and durable RECIST SD with carboplatin/ATR inhibitor (27.9 weeks). The first line setting predicted for improved disease control (RECIST PR/SD 73.3% vs 0%, p<0.05) and longer duration on trial (14 vs 4 weeks, p<0.05). Discussion. Novel therapeutic agents within the context of a dedicated Ph1 trials unit were well tolerated and led to preliminary signals of antitumor activity. Targeted NGS may aid in the identification of pts with putative gene aberrations, potentially predicting for response to novel therapies. Ph1 trials should be considered earlier in the pt’s disease course to maximize their prospects of trial enrolment.

**#3082 Deficient NOXA in HER2-amplified breast cancer drives kinase inhibitor resistance.** Konstantinos V. Floros,1 Kyung-A Song,1 Timothy L. Lochmann,1 Mark T. Hughes,1 Daniel A. Heisey,1 Hisashi Harada,1 Bin Hu,1 Jennifer Koblinski,1 Andrew J. Souers,2 Joel D. Leverson,2 Anthony C. Faber1.

1VCU, Richmond, VA; 2Abbvie, Chicago, IL.

The purpose of this study is the development of a novel combination therapy that targets HER2-amplified breast cancer. About one quarter of breast cancers harbor amplification of HER2. HER2 is a transmembrane receptor tyrosine kinase (RTK) belonging to the ERBB family of receptors (ERBB1-4). Upon hetero- and homo-dimerization, HER2 activates several key intracellular pathways, regulating many cellular functions including proliferation and survival. HER2 inhibition (HER2i) results in a first-line setting predicted for improved disease control (RECIST PR/SD 73.3% vs 0%, p<0.05) and longer duration on trial (14 vs 4 weeks, p<0.05). Discussion. Novel therapeutic agents within the context of a dedicated Ph1 trials unit were well tolerated and led to preliminary signals of antitumor activity. Targeted NGS may aid in the identification of pts with putative gene aberrations, potentially predicting for response to novel therapies. Ph1 trials should be considered earlier in the pt’s disease course to maximize their prospects of trial enrolment.

**#3083 Prior irradiation results in elevated programmed death 1 (PD-1) in T cells.** Rui Zhang,1 Fumin Li,1 Jayanthi Bagavan,1 Anil Narang,1 Xi Zhao,1 Delia H. Borrego,1 Jinghui Li,1 George-town Lombardi Comp. Cancer Ctr., Washington, DC; 2Institute of Radiation Medicine, Chinese Academy of Medical Sciences and Peking Union Medical College, Tianjin, China.

It is well known that radiation has long-lasting effects on the immune system. In this study we address the question whether these radiation-induced adverse effects on T cell activation are associated with alterations of T cell inhibitory receptors. Expression levels of inhibitory receptors on T cells were analyzed at multiple post-irradiation time points ranging from one to four weeks in mice receiving whole body irradiation. The level of the checkpoint receptor, PD-1, on...
different T cell subpopulations was determined. Our results showed that prior irradiation resulted in significantly elevated expression of PD-1 in both CD4+ and CD8+ populations. T cells with elevated PD-1 mostly were either central memory or naïve cells. In addition, the feedback induction of PD-1 expression in activated T cells declined with time after radiation. Together, the elevated PD-1 level observed at weeks after radiation exposure is connected to T cell dysfunction. Similar changes were seen in samples from tumor patients receiving radiotherapy. Recent preclinical and clinical studies have shown that radiation alters the immune-modulatory microenvironment in tumor tissue, and implies that a combination of radiotherapy and T cell checkpoint blockade immunotherapy including targeting the PD-L1/PD-1 axis may potentiate the antitumor response. Therefore, understanding the dynamic changes in PD-1 levels in T cells after radiation should help in the development of a more effective therapeutic strategy.

#3083A C6-ceramide nanoliposomes sensitize paclitaxel resistant ovarian cancer cells to chemotherapy treatment. Danielle C. Llaneza, Tye G. Deering, Samantha G. Sherwood, John R. Cornelison, Mark Kester, Charles N. Landen. University of Virginia, Charlottesville, VA.

Ovarian cancer is the fifth leading cause of cancer deaths among women, and the majority of women are diagnosed at advanced stages resulting in poorer outcomes and survival rates. One of the driving forces behind these outcomes is the development of chemoresistance, and subsequent proliferation and invasion of tumor cells. In a patient-derived xenograft model of ovarian cancer, we identified the drug combination paclitaxel + C6-ceramide as significantly enriched in our subject population suggesting the potential for combination with conventional chemotherapy. In order to target the sphingosine pathway, we investigated the potential effects of combining paclitaxel with C6-ceramide nanoliposomes in paclitaxel-resistant ovarian cancer cell lines, HeyA8-MDR and SKOV3-TR. Ceramide has been shown to be a key player in several processes important for tumor suppression including apoptosis, autophagy, and cell cycle arrest. We administered paclitaxel and C6-ceramide to HeyA8-MDR and SKOV3-TR cell lines in vitro and measured cell viability and expression of apoptotic and autophagic proteins. Results showed that in both cell lines, C6-ceramide significantly decreases the IC50 dose of paclitaxel, compared to control ghost nanoliposome treated cells. The IC50 of paclitaxel decreased in HeyA8-MDR cells from 400nM to 150nM, and in SKOV3-TR cells from 1000nM to 450nM. Western blot analyses indicate that combination treatment increases expression of apoptotic (cleaved caspase-3) factors in HeyA8-MDR cells, and autophagic (LC3) factors in SKOV3-TR cells, over single agent treatment or control. Paclitaxel is known to increase expression of apoptotic (cleaved caspase-3) factors in HeyA8-MDR cells from 400nM to 150nM, and in SKOV3-TR cells compared to control ghost nanoliposome treated cells. The IC50 of paclitaxel decreased in HeyA8-MDR cells from 400nM to 150nM, and in SKOV3-TR cells from 1000nM to 450nM. Western blot analyses indicate that combination treatment increases expression of apoptotic (cleaved caspase-3) factors in HeyA8-MDR cells, and autophagic (LC3) factors in SKOV3-TR cells, over single agent treatment or control. Paclitaxel is known to increase expression of apoptotic factors while decreasing expression of autophagic factors. Ceramide may increase both apoptotic and autophagic factors. In an orthotopic mouse model with the HeyA8-MDR line, combination treatment of paclitaxel and C6-ceramide resulted in significantly decreased tumor burden (1.38g +/- 0.74), compared to control ghost (p = 0.022, 2.81g +/- 1.57), C6-ceramide alone (p = 0.078, 2.50g +/- 1.58), and paclitaxel alone (p = 0.005, 2.48g +/- 0.75) groups. The combination of C6-ceramide and paclitaxel may prove useful in elucidating and targeting underlying chemoresistance mechanisms in ovarian cancer.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Determinants of Drug Sensitivity and Resistance

Female gender, early age of first birth, and multiparity are associated with less aggressive melanoma; however, the mechanisms underlying the apparent clinical benefit are undefined. Previously we reported that 17β-estradiol drives melanocyte differentiation through G-protein coupled estrogen receptor (GPER), a nonclassical sex hormone receptor. Here, we use genetically-defined human skin xenograft melanoma to show that pregnancy antagonizes oncogenic BRAF and inhibits melanomagenesis. Transient GPER activation drives stable melanocyte differentiation that persists after removal of the activating ligand. Consistent with this, brief exposure of melanoma cells to GPER agonists prior to subcutaneous injection inhibited subsequent tumor growth. Systemic treatment with GPER agonists cooperated with PD-1 blockade in melanoma bearing mice to greatly prolong survival longer than that observed with either agent alone. The combination of differentiation-based therapies with immunotherapy may have significant therapeutic benefit for melanoma.

#3085 SY-1425 (tambogarene), a selective RARγ agonist, shows synergistic anti-tumor activity with hypomethylating agents in a biomarker selected subset of AML. Michael R. McKeown, Emily Lee, Chris Fiore, Matthew L. Eaton, Christian C. Fritz, Eric Olson. Syros Pharmaceuticals, Cambridge, MA.

In patients with acute myeloid leukemia (AML) (> 60 years) and myelodysplastic syndrome (MDS), hypomethylating agents (HMAs) may extend survival, but cure rates are very low and new treatment approaches are needed. HMAs, such as azacitidine, work by inhibiting DNMT1, leading to depletion of DNA methylation in the tumor cells. Hypomethylation, in turn, leads to the re-expression of genes associated with differentiation and growth arrest. We have recently explored the potent and selective RARγ agonist SY-1425 in combination with azacitidine in AML and MDS. SY-1425 binds to RARγ and causes a transition from repression to strong activation of target genes, thus reprogramming the tumor cells toward terminal maturation in RARA-high AML models, supporting our recently initiated Phase 2 trial in a biomarker-selected subset of AML and MDS (NCT02807350). Based on potential mechanistic synergy, we evaluated SY-1425 in combination with HMAs and identified a synergistic anti-proliferative effect. In RARA-high AML cell lines, but not RARA-low, the combination of SY-1425 with either azacitidine or decitabine showed synergistic anti-proliferative effects on the cells, with combination indices less than 0.5 over a range of concentrations from 0.01 to 100μM of SY-1425 and 0.1 to 1μM of HMAs. SY-1425 and azacitidine were also co-administered to a disseminated patient-derived xenograft (PDX) mouse model of RARA-high AML. SY-1425 and azacitidine decreased superior or rear area in either therapy alone, leading to deeper and more durable responses with less than 1 detectable tumor burden. A follow-up study in the RARA-high PDX model investigated different treatment schedules of SY-1425 and azacitidine over a period of 56 days, supporting a regimen that maximizes anti-tumor activity and tolerability. Mechanistic studies using RNA-seq and ChIP-seq in AML cell line models have revealed that while azacitidine had only moderate suppressive or activating effects over a broad set of genes, the addition of SY-1425 in RARA-high models resulted in strong and specific induction of genes bound by RARγ. It is hypothesized that azacitidine acts to prime the tumor cells for reprogramming by SY-1425. The loss of methyl-cytosine residues following azacitidine treatment lowers the barrier to SY-1425-mediated gene induction. It was observed that the two agents work cooperatively to promote terminal differentiation and decrease proliferation of the AML tumor cells, with the potential for increased clinical benefit in a subset of AML defined by a RARA super-enhancer. Based on the largely non-overlapping clinical toxicity profiles of azacitidine and SY-1425, supported by the observed tolerability of the combination in preclinical models, these findings provide a strong rationale for a planned study of this combination in biomarker selected, newly diagnosed AML patients.

#3086 Inhibitors of the enzyme dihydroorotate dehydrogenase, overcome the differentiation blockade in acute myeloid leukemia. Richard R. Buescher,1 David Sykes,2 Stefan Gradl,3 Steven Ferrara,4 Sven Christian,5 Claudia Merz,2 Henrik Seidel,1 Andreas Bernthaler,1 Mathias Wawer,3 David T. Scadden2. 1Bayer Pharma AG, Berlin, Germany; 2Massachusetts General Hospital, Boston, MA; 3Broad Institute of MIT and Harvard, Boston, MA.

The prognosis for adults diagnosed with acute myeloid leukemia (AML) remains poor, with a five-year survival of only 25%. This prognosis is even more dismal in older patients who are not well enough to receive standard induction chemotherapy. Speaking to the need for new therapies is the fact that our therapeutic backbone - a combination of cytarabine and an anthracycline - remains unchanged since 1973. The promise of differentiation therapy was realized in the small subset of patients diagnosed with acute promyelocytic leukemia (APL). Here, treatment in the form of all-trans retinoic acid (ATRA) and arsenic trioxide inverted the survival curve; where APL was once the worst form of myeloid leukemia, it now carries the best prognosis, with a five-year survival exceeding 85%. The goal of this study was thus to develop differentiation therapy for patients with non-promyelocytic AML with the question: “Can we identify small molecules that overcome myeloid differentiation arrest?” A phenotypic differentiation screen in a HOXA9-driven leukemia model followed by target deconvolution, identified DHODH as an unexpected target for overcoming differentiation arrest in AML. We used 2 potent small molecule inhibitors of DHODH to validate this initial finding: Brequinar, a known DHODH inhibitor and an in vivo house compound BAY DHODHi. In several in vitro experiments we demonstrated induction of AML differentiation in a dose dependent fashion. Interestingly, these effects could be completely rescued by addition of uridine, confirming target specificity. Treating mice in multiple genetically diverse AML in vivo models with a DHODH inhibitor led to tumor growth reduction and AML differentiation. Expression analysis of leukemia cells explanted from mice xenografts treated with a DHODH inhibitor demonstrate an early onset of differentiation.
tiation markers indicating a direct role of DHODH with the onset of differentiation in vivo. The mechanism for selective vulnerability of leukemia cells to DHODH inhibition remains under investigation. Despite the observation that DHODH is expressed in all cells, normal and malignant, mice can tolerate DHODH inhibitor therapy for more than 100 days without weight-loss or other concerns. Thus, our preliminary findings define DHODH as a new target in the differentiation treatment of AML. Hopefully, small molecule DHODH inhibitors will provide a much-needed differentiation therapy for patients with acute myeloid leukemia.

#3087 Forced induction of differentiation in osteosarcoma tumor initiating cells. Margaret Ellen White, Maria V. Guijarro, Steven Ghivizzani, Charles P. Gibbs. Univ. of Florida College of Medicine, Gainesville, FL.

Osteosarcoma (OS) is a highly malignant bone cancer that is defined histologically by the secretion of immature osteoid. The chemotherapeutic regimen has not changed in the last 40 years and similarly, the five-year survival rate remains at ~60%, with the majority of fatalities arising from metastases in the lungs. OS is believed to originate from osteogenic committed progenitors, involving disruption of extracellular matrix synthesis in favor of proliferation. In previous work, our lab has developed a method to selectively identify Tumor Initiating Cells (TICs) in OS xenografts based on their ability to activate a transcriptional reporter comprised of a human OCT4 promoter linked to green fluorescent protein (GFP) coding sequence. Clonally derived, stably transfected OS Oct4/GFP+ TICs are capable of initiating and maintaining the growth of heterogeneous tumors and driving disease progression. The loss of GFP expression and tumorigenic capacity occurs during tumor formation in response to cues within the tumor microenvironment, resulting in adoption of a specialized secretory phenotype as an adaptive survival mechanism: a phenotypic change similar to that seen in physiological differentiation. During skeletal formation, Bone Morphogenetic Proteins (BMP) play key roles in osteogenic maturation. Because the OS lineage of origin suggests an innate sensitivity to BMP proteins, we hypothesized that BMP stimulation will force the induction of differentiation in OS TICs and will impair the ability of these cells to initiate and maintain tumor growth. To first probe that OS TICs respond to BMP stimulation, we detected by flow cytometry the expression of BMP Receptors Type II and 1A in two primary OS-derived cell lines (OS521 and OS156), with similar expression seen in Mesenchymal Stem Cells. Furthermore, by treating OS TICs with BMP heterodimers - BMP2/7 and BMP4/7 - we observed an activation of canonical BMP signaling, suggesting a functional and intact signaling network. BMP4/7 stimulation of OS521 TICs in vitro showed an increase in cells in the G1 phase of the cell cycle, visualized by DAPI, and higher p21 and p27 expression than controls, shown in immunoblotting. On the other hand, BMP4/7 treatment of OS156 TICs reduced its invasion capacity through a complex of Fibronectin and Bovine Serum Albumin by 33% (p = 0.00144) compared to untreated controls. Strikingly, in vivo studies revealed that time to tumor onset of BMP4/7 pretreated OS521 TICs in NSG mice at a dose of 3x10^5 cells was significantly longer than in controls (p = 0.0003). In summary, our data suggests a reduction of OS tumorigenicity due to a BMP4/7 induced differentiation-based response. Such a differentiation-based therapy could become a more effective and safer alternative to current chemotherapeutic therapy. Future studies include TICs from DHODH-null, oxia, adenosine, and calcium, to investigate the underlying mechanisms responsible for BMP involvement in the tumorigenic capacity of osteosarcoma.

#3088 Combination of 4SC-202 and IFN-γ restores mature APC phenotypic features in AML cells. Anne Catherine Bretz, Ulrike Parnitzke, Kerstin Kronthaler, Svetlana Hamm. 4SC AG, Planegg-Martinsried, Germany.

Acute myeloid leukemia (AML) is characterized by a differentiation block resulting in accumulation of immature myeloid cells. Differentiation therapy, e.g. with all-trans retinoic acid (ATRA) has become a part of standard treatment for the acute promyelocytic leukemia variant of AML. Other agents like cytokerines and HDAC inhibitors were shown to enhance differentiation of AML cells, which results in apoptosis induction or re-sensitization to ATRA. However, a differentiation therapy resulting in the restoration of antigen presenting function of AML cells would be a more desirable asset, since such cells will be able to induce or enhance immune response against residual malignant AML cells. Here, we analyzed the impact of 4SC-202 alone and in combination with different cytokines on differentiation of AML cell lines THP-1, HL-60 and MOLM-13 (AML-M4, -M2, and -M5 class, respectively). Myeloid lineage markers CD11b, CD14, and HLA-DR were analyzed by flow cytometry and quantitative PCR. Cytokine production was measured using Luminex multiplex system. Furthermore, chromatin immunoprecipitation (ChIP) was performed to assess the direct impact of 4SC-202 on promoter histone acetylation of differentiation genes. 4SC-202 is an orally available clinical stage epigenetic small molecule inhibitor which specifically targets histone deacetylases HDAC class I isoenzymes 1-3 as well as the lysine-specific demethylase LSD1 (KDM1A). 4SC-202 treatment of AML cell lines resulted in a dose-dependent increase of myeloid differentiation genes CD86 and ITGAM (CD11b) on mRNA and protein level. On the chromatin level, 4SC-202 correspondently induced an upregulation of H3K9ac, H3K27ac and H3K4me1 at the promoters of these genes. Interestingly, reference compounds like ATRA, bezarotene, GM-CSF and TNF-α were not as efficacious as 4SC-202 in the induction of differentiation markers in AML cells, whereas IFN-γ strongly induced MHC class II molecules HLA-DR and myeloid lineage marker CD14. Finally, the combination of 4SC-202 and IFN-γ resulted in a synergistic or complementary induction of differentiation and APC markers CD11b, CD14, CD86 and HLA-DR resulting in a CD86^hi/HLA-DR^hi phenotype which was able to produce pro-inflammatory cytokines. In summary, we demonstrate that 4SC-202 induces differentiation of AML cells of different subtypes and thus provide promising preclinical data for applying this novel epigenetic modulator for differentiation therapy of AML. Moreover, the mature APC phenotype induced by the combination of 4SC-202 and IFN-γ may further suggest an application in consolidation treatment of AML to enhance or even elicit a tumor-specific T-cell response against residual malignant AML cells preventing AML recurrence.

#3089 Combining MEK and HDAC inhibitors as a therapeutic strategy to promote differentiation of colorectal cancer. Laura J. Jenkins, Ian Y. Luk, Janson W. Tse, Jennifer Mooi, Amardeep S. Dhillon, John M. Mariadason. Olivia Newton John Cancer Research Institute, Heidelberg, Australia.

The five-year survival rate for patients with metastatic colorectal cancer is less than 15%, necessitating an urgent need to develop novel therapeutic strategies for this disease. Loss of differentiation is associated with worse overall survival in colorectal cancer, suggesting that strategies to re-induce differentiation may provide clinical benefit. Differentiation therapy is effective in the treatment of acute promyelocytic leukemia but whether this approach can be efficacious in treating colorectal cancer is unknown. Inhibitors of the MAPK signaling pathway including the MEK inhibitor Trametinib can induce markers of differentiation in colorectal cancer cells. Trametinib also induces expression of Cdx-2, a known driver of colon cell differentiation. Similarly, histone deacetylase inhibitors (HDACi) induce markers of differentiation in multiple tumor cell lines, including colon cancer cells. The aim of this study was to assess the potential therapeutic benefit of combining MEK (Trametinib) and HDAC (Panobinostat) inhibitors to further promote differentiation in colorectal cancer cells, and to elucidate the mechanistic basis for this effect. Combination treatment of HT29 and T84 cells with Trametinib and Panobinostat significantly enhanced mRNA and protein expression of the differentiation markers Cadherin 17 (CDH17) and Keratin 20 (KRT20), compared to either agent alone. Trametinib also induced expression of Cdx-2, an effect that was enhanced upon combination treatment with Panobinostat. Notably, Cdx-2 knockdown attenuated CDH17 and KRT20 induction by the combination, establishing a direct role for Cdx-2 in differentiation induction by the Trametinib/Panobinostat combination. Concomitant with inducing differentiation, the drug combination also induced more apoptosis than either agent alone. To validate these findings in vivo, HT29 cells grown as xenografts were treated with Trametinib and Panobinostat alone and in combination. Mice treated with the combination had significantly smaller tumours than mice treated with vehicle or either agent alone. Consistent with the in vitro findings, immunostaining of the tumour xenografts demonstrated a strong increase in CDH17, KRT20 and Cdx2 expression upon treatment with the drug combination. Collectively, this study highlights a drug combination strategy to re-induce differentiation for the treatment of colorectal cancers.
experimental and molecular therapeutics: Drug delivery technology and antibody technology

Angiopoietin-2 (Ang-2) is released from endothelial cells only in response to stimuli (e.g. wound healing, tumor growth) and facilitates blood vessel sprouting and inhibits pericyte-endothelial cell interaction via Tie2 signaling. In tumors, Ang-2 is up-regulated and acts together with the VEGF/VEGFR2 pathway to stimulate tumor angiogenesis and metastasis. While therapeutic intervention using anti-Ang2 antibodies or anti-VEGF/VEGFR2 pathway has provided limited disease progression in a number of different clinical settings, there is an obvious need for an improved response. In various preclinical mouse angiogenesis or xenograft models, the combination treatment with anti-Ang2 antibody and the VEGF/VEGFR blocker provided additional benefit over inhibiting the individual pathway. Here as an alternative to combo therapy, we have engineered a human IgG4 (IgG4) antibody, comprising of VEGFR2 antibody derived from ramucirumab and a C-terminally fused single-chain variable fragment (scFv) targeting Ang2. LY2304747 binds to both the extracellular domain of VEGFR2 and soluble Ang2 with high affinity and blocks binding of Ang2 to Tie2 and VEGF to VEGFR2, and therefore inhibits signaling. We have shown that LY2304747 blocks binding of human Ang-2 to human Tie2-Fc by an ELISA assay and neutralizes Ang-2 induced phospho-Tie-2, but not Ang-1 induced phospho-Tie-2 in CHO cells expressing Tie-2 receptor. Moreover, LY2304747 neutralizes human VEGF165-induced phospho-VEGFR2 stimulation, cord formation and cell proliferation in human endothelial colony forming cells (ECFCs) and human dermal microvascular endothelial cells (HMVEC-d). LY2304747 binds human and cyno VEGF receptors, but not murine Ang2 or anti-Ang2 arm. LY2304747 blocks human, cyno and mouse Ang2. Pre-clinical evaluation of LY2304747 in mouse retinal angiogenesis model resulted in an abrogation of angiogenesis. Combination studies using a rodent-specific surrogate gate VEGFR2 blocking antibody, DC101, with parental Ang2 antibody from which the scFv was derived, inhibited both tumor growth and metastasis, resulting in increased survival compared to monotherapies in mouse xenograft model. These data establish VEGFR2/Ang2 bispecific antibodies as a promising anti-angiogenic, anti-metastatic and anti-tumor agent for the treatment of cancer in combination with other therapies.

#3091 Response of C4.4A-positive patient-derived xenograft models of ESCC, HNSCC and bladder cancer to BAY1129980, a C4.4A-targeted antibody drug conjugate. Joerg Willuda, Carol Pena, Christoph Kneip, Patricia E. Carrigan, Hans-Georg Lerchen, Lars Linden, Bertolt D. Kreft, Bayer AG, Berlin, Germany. Bayer AG, Whippany, NJ; Bayer AG, Wuppertal, Germany. C4.4A (LYPDI) is a cancer- and metastasis-associated transmembrane cell surface protein which is expressed at high frequency and density in multiple tumor types including squamous and non-squamous non-small cell lung carcinoma (NSCLC), head & neck squamous cell carcinoma (HNSCC), esophageal squamous cell carcinoma (ESCC) and bladder cancer. C4.4A expression is restricted to a limited number of tissues (e.g. suprabasal layer of skin) making C4.4A an attractive target for the treatment of cancer with a C4.4A-targeted antibody-drug conjugate (ADC). BAY1129980 (C4.4A-ADC), is an ADC consisting of a fully human C4.4A-targeting monoclonal antibody (technology licensed from BioInvent) conjugated via a novel, non-cleavable alkyl hydrazide linker to a novel, highly potent auristatin W, an antimitotic agent (technology licensed from Seattle Genetics, Inc.). This C4.4A-ADC has been previously shown to be efficacious in C4.4A positive cell line-derived and PDX models of NSCLC. Here we present new preclinical efficacy data of C4.4A-ADC in patient-derived xenograft (PDX) models of ESCC, HNSCC and bladder cancer. Models were selected based on tumor C4.4A levels as determined by mRNA levels and immunohistochemistry (IHC), the latter of which allowed ranking of models according to H-score, percentage of C4.4A positivity, and staining intensity (0 to 3+) in the cell membrane. Representative C4.4A-positive models were selected for in vivo efficacy studies (n = 7 each): 4 HNSCC, 4 ESCC and 2 bladder cancers. C4.4A-ADC was administered as one cycle (Q4Dx3) at doses of 7.5 and 15 mg/kg, and efficacy was assessed up to 4 weeks post treatment for optimum tumor growth inhibition (TGI). In ESCC models a response to C4.4A ADC was seen in ES0190 (TGI of 77%; 15mg/kg) and in ES0195 (59%). In HNSCC models an ADC effect on tumor growth was observed in HN10847 (34%) and HN9619 (59%). Finally, both bladder models tested were sensitive to treatment, with a transient response seen in BL0597 (41%) and a strong and significant tumour growth inhibition (TGI). In ESCC models are a response to C4.4A ADC, C4.4A expression served as a marker for preselection of the models. Nevertheless, other factors may affect response and sensitivity of these tumor models, such as sensitivity to tubulin inhibition, ADC uptake and intracellular processing. In summary, these data support further exploration of the potential of BAY 1129980 in HNSCC, ESCC and bladder cancer in addition to NSCLC. A Phase 1 clinical trial of BAY 1129980 is ongoing (NCT02134197).

#3092 U3-1402a, a novel HER3-targeting ADC with a novel DNA topoisomerase I inhibitor, demonstrates a potent antitumor efficacy. Laura R. Saunders, Samuel A. Williams, Sheila Bheddah, Kumiko Isse, Sarah Fong, Marybeth A. Pyas, Himisha Beltran, Loredana Puca, Verena Salier, Juan M. Mosquera, Yu Yin, Joaotti Huang, Andrew J. Armstrong, Jorge Garcia, Cristina Magi-Galluzzo, Vadim Koslikhin, Petros Grivas, Farhad Kosari, John Cheville, Justine C. Moser, Thomas J. Flotte, Thyordar Halldaranson, Aaron Mansfield, Konstantinos N. Leventakos, Julian R. Molina, Douglas W. Ball, Barry D. Nelkin, Jill E. Shea, Courtney L. Scaife, Scott J. Diyla, Abhivve Stemcentrx, South San Francisco, CA; Weill Cornell Medicine, New York, NY; Duke University School of Medicine, Durham, NC; Cleveland Clinic, Cleveland, OH; Mayo Clinic, Rochester, MN; Johns Hopkins, Baltimore, MD; University of Utah, Salt Lake City, UT.

Expression of DLL3 was examined in additional tumor types, as it was found to be highly expressed in tumor-initiating cells (TIC) in small cell lung cancer (SCLC), where a DLL3-targeted antibody drug conjugate (ADC), rovalpituzumab tesirine (Rova-T; SC16LD6.5), targeting DLL3-positive cancer and pancreatic cancer patients' tissues. U3-1402a is an antibody-drug conjugate (ADC) comprised of a fully human anti-HER3 monoclonal immunoglobulin G1 (IgG1) antibody (U3-1287) conjugated vis a chloroethyl peptide linker to exatec derivative (DxD). The DxD is released after internalization of U3-1402a and leads to apoptosis of the target tumor cells by the inhibition of topoisomerase I. This ADC achieves a high drug-to-antibody ratio (DAR 7 to 8) with homogeneous conjugation with the topoisomerase I inhibitor. The aim of this study was to preclinically evaluate the efficacy of U3-1402a in breast cancer models. Materials and methods: In order to evaluate the pharmacological potential of U3-1402a, in vitro and in vivo studies were performed. In vitro growth inhibition assay evaluated the sensitivity of U3-1402a in HER3-positive human breast cancer cell line (HCC1569) and HER3-negative human cervical carcinoma cell line (C3A). Cells were treated with U3-1402a or MAAAB-1181 (payload of U3-1402a) depending on its concentration (U3-1402a: 0.153 to 10 000 ng/mL, MAAAB-1181: 2.44 to 160,000 pg/mL). In vivo growth inhibition study evaluated the dose-dependent sensitivity of U3-1402a in HER3-positive breast cancer xenograft model, MDA-MB-453. In addition, several xenograft models with different HER3 expression were tested with its sensitivity to U3-1402a. These models were HCC1569 (human breast cancer cell line, HER3 IHC score 3+), MDA-MB-453 (human breast cancer cell line, HER3 IHC score 2+), NIBIO-G016 (human gastric cancer patient-derived xenograft, HER3 IHC score 1+) and MDA-MB-231 (human breast cancer cell line, HER3 IHC score 0). Results: In vitro study, U3-1402a exhibited anti-tumor killing activity in HER3-positive human breast cancer cell line, HCC1569. C-33A human cervical carcinoma cell line was not sensitive to U3-1402a even MAAA-1181 itself exhibited anti-tumor killing activity to this cell line. In vivo study, U3-1402a showed dose-dependent anti-tumor killing activity in a HER3-positive breast cancer MDA-MB-453 xenograft model. Finally, in vivo tumor regression was only observed in HER3 2+ and 3+ models. Conclusions: U3-1402a preclinically exhibited its efficacy in breast cancer model in vitro and in vivo. In vivo efficacy was strongly correlated with HER3 expression. These studies suggest that U3-1402a, a novel HER3-targeting ADC, would be efficacious in a broader patient population with HER3 expression like breast cancer, melanoma, NSCLC, gastric cancer and pancreatic cancer.
astatic melanoma (55%), low grade gliomas (90%), glioblastoma (70%), medul-
lary thyroid cancer (65%), carcinoids (33%), dispersed neuroendocrine tumors in the pancreas (9%), bladder (57%) and prostate (24%), testicular cancer (90%), and lung adenocarcinomas with neuroendocrine features (80%). Unlike SCLC, where DLL3 does not predict clinical outcome on standard therapies, DLL3 expression negatively correlates with overall survival in melanoma and small cell bladder cancer. In mice bearing DLL3 positive melanoma PDX, treatment with a single dose of Rova-T resulted in effective and durable responses (>100 days), which correlated with a significant impact on TIC frequency. Similarly, in mice bearing DLL3 positive ovarian small cell PDX, a single dose of Rova-T resulted in effective and durable responses (>100 days). Our results show that DLL3 is expressed in many neuroendocrine tumors (lung, ovarian, prostate, bladder, etc.), metastatic melanoma, medullary thyroid cancer, low-grade gliomas and glioblastoma. Given pre-clinical results showing efficacy of Rova-T in melanoma and ovarian small cell carcinoma, as well as encouraging clinical data with Rova-T in patients with recurrent/refractory SCLC, clinical evaluation of Rova-T in DLL3 positive melanoma, glioblastoma, medullary thyroid cancer and other high-grade neuroendocrine carcinomas is warranted. A "basket" trial enrolling patients with DLL3 positive solid tumors is now recruiting patients (NCT02709889).

#3095 The development of CPI as a novel, next-generation DNA-targeting payload for ADCs. Jennifer Kahler, Maureen Dougher, Jane Xu, Matthew Doroski, Andreas Maderna, Russell Dushin, Stephane Thibault, Mauricio Leal, Madan Katragadda, Christopher J. O’Donnell, Matthew Sung, Puja Sapra, Pfizer, Pearl River, NY; Pfizer, Groton, CT; Pfizer, La Jolla, CA; Pfizer, Cambridge, MA.

DNA targeting drugs represent one of cornerstones of anti-cancer therapy for both hematologic and solid tumor indications. Low potency anti-DNA compounds (e.g. platin, anthracyclines) are included in many standard-of-care (SOC) regimens, however their modest activity and overall toxicity profiles limit their therapeutic potential. To increase the therapeutic window for DNA-damaging agents, high potency anti-DNA compounds with enhanced anti-tumor activity have been delivered to tumors as payloads of targeting modalities such as antibody-drug conjugates (ADCs). Herein, we describe the development of a novel DNA-damaging compound comprised of a dimeric structure of cycloo-
poly(pyrrrolo)[e]indolones (CPIs) that was designed to alkylate DNA and generate toxic interstrand crosslinks (ICLs). In response to the CPI-induced formation of ICLs, CPI treatment of cells primarily activates the Fanconia anemia DNA damage response pathway, whereas other successful DNA-damaging ADC payloads such as calicheamicin activate double-strand break response pathways. CPI shows ~860-fold greater potency than calicheamicin in a panel of cell lines derived from a broad spectrum of tumor indications. Importantly, this new CPI payload retains potent activity in calicheamicin- and SOC-resistant tumor models (including overcoming overexpression of drug efflux pumps). When evaluated as payloads on anti-CD33 targeting ADCs, the CPI conjugate showed dramatically improved efficacy over the corresponding calicheamicin conjugates in MDR+ tumor models. As a site-specific conjugate, the CPI ADC shows enhanced in vivo stability and possesses a wider therapeutic window than the corresponding conventional calicheamicin conjugate and other leading DNA-damaging conjugates on the CD33 platform.

#3096 Mechanisms of synergy of carboplatin and an EphA2-targeted do-
cetaxel antibody-directed nanotherapeutic. Walid S. Kamoun, Andrew J. Sawyer, Christine Pien, Alexander Koskharvey, Lia Luus, Samantha Merrig-
gan, Gang Sun, Sergey Kozin, Zhaohua Richard Huang, Suresh K. Tippa-
raju, Dmitri B. Kirtotin, Hannah Xu, Vasilios Askoxylakis, Patrick C. Reynolds, Daryl C. Drummond, Merrimack, Cambridge, MA; Massachusetts General Hospital, Boston, MA; Texas Tech University, Lubbock, TX.

Platinum-taxane combinations are widely used to treat solid tumors either in first or later lines of therapy. While effective in many settings, platinum-taxane combinatorial regimens are limited by toxicities. We have recently developed an antibody-drug conjugate of a nanotherapeutic (MM-310) encapsulating a docetaxel prod-
rug, targeted to Ephrin receptor A2 (EphA2). Preclinical investigation of MM-
310 revealed that the liposomal formulation leads to prolonged docetaxel expo-
sure of the tumor with decreased exposure of normal tissues leading to a shift in toxicity profile and potentially enabling more safe and effective combinations with platinum-based chemotherapeutics. In this study, we evaluated the activity of MM-310 in combination with carboplatin in several xenograft tumor models and compared it to the activity of free docetaxel in combination with carboplatin at equitoxic dosing. Tolerability of MM-310 in combination with carboplatin in mice was evaluated, including assessing hepatotoxicity. Biodistribution, micro-
distribution, in vivo tumor growth, and mouse survival studies were performed in lung and ovarian cell line-derived (CDX) and patient-derived xenograft (PDX) models. MM-310 in combination with carboplatin was found to be well tolerated, enabling dosing of both drugs at high doses with maximum tolerability when the drugs were dosed three days apart. Carboplatin increased nano-
therapeutic delivery to the tumor in a CDX model of triple negative breast cancer and in a PDX model of ovarian cancer. In vivo studies in lung and ovarian cancer xenograft models showed significant synergy between MM-310 and carboplatin when compared to the monotherapies, as well as when compared to free do-
cetaxel and carboplatin. In conclusion, we found that MM-310 in combination with carboplatin was significantly better tolerated and more effective than free docetaxel in combination with carboplatin. Mechanistically, the synergistic anti-
tumor activity of MM-310 with carboplatin may be partially due to a carboplatin mediated enhancement of nanotherapeutic delivery. The increased preclinical activity of the MM-310/carboplatin combination, together with the high toler-
ability following scheduling optimization tested in mice, makes this combina-
tion a promising regimen that warrants evaluation in clinical trials.

#3098 Nanotherapeutics for combination drug and gene therapy in treat-
ing glioblastoma multiforme. Angela A. Alexander-Bryant, Breanne Hou-
rigan, Michael Lynn, Jeoung Soo Lee, Clemson University, Clemson, SC; Greenville Health System, Greenville, SC.

Gliomas represent approximately 80% of all malignant brain tumors, and glioblastoma multiforme (GBM), the most aggressive type, accounts for nearly half of all gliomas. Despite treatment strategies including surgery, radiation, and chemotherapy, the 5-year survival rate for brain cancer is only 35%. New ther-
aputic strategies are necessary to improve the outcomes of this disease. Che-
motherapy with DNA alkylating agents is commonly used in treatment for
GBM. Research has shown that better therapeutic response of GBM tumors to alkylating agents and increased survival rate is indicative in patients with epigenetic silencing of O6-methylguanine-DNA methyltransferase (MGMT), a gene responsible for DNA repair. Therefore, we propose a treatment strategy combining drug and gene therapy to target and silence MGMT to sensitize cells to treatment with temozolomide (TMZ) or lomustine (CCNU), both DNA alkylating agents. We previously developed cationic, amphiphilic copolymer poly-(lactide-co-glycolide)-g-polyethyleneimine (PgP) and demonstrated its utility for nucleic acid delivery. Here, we examine the ability of PgP as a drug and siRNA delivery carrier to overcome drug resistance and improve anticancer activity through combination drug and gene therapy for GBM treatment. PgP micelles were designed and synthesized for delivery of hydrophobic drugs in the PLGA core and negatively charged nucleic acids in the positively charged PEG shell through electrostatic interactions. RNA binding and polyplex stability assays were performed using agarose gel electrophoresis. Cytotoxicity of TMZ, CCNU, and/or PgP/siMGMT polyplexes was determined by MTT assay. Silencing of MGMT on the protein and mRNA level was determined using western blotting and qPCR, respectively. Our results demonstrated that PgP effectively forms stable complexes with siRNA and protects siRNAs from serum- and ribonuclease-mediated degradation, confirming the potential of the polypelex for in vivo delivery. We demonstrated that PgP/siMGMT polyplexes mediate knockdown of MGMT protein as well as a significant ~56% and ~68% knockdown of MGMT mRNA in T98G GBM cells compared to cells treated with PgP complexed with the RNA binding dye SYTO1 and 801 nitrophenyphosphate (N-P) ratio, respectively. Further, co-treatment of PgP/siMGMT polyplexes with TMZ or CCNU enhanced anticancer activity in T98G GBM cells compared to treatment with the PgP/siMGMT polyplex, TMZ, or CCNU alone. Future studies will determine efficacy of drug-loaded and siRNA-complexed PgP for combination therapy in vitro as well as using a xenograft GBM model for local delivery. Successful combinational drug and gene therapy using PgP may overcome drug resistance and improve therapeutic outcomes for patient with glioblastoma.

Introduction: PARP inhibitors such as Talazoparib and Olaparib exploit deficiencies in DNA repair pathways, making them attractive candidates for treatment of a number of different cancers. These drugs are particularly effective when used in combination with other DNA damaging agents such as chemotherapeutics and radiation therapy. Combination trials, however, have resulted in several toxicities, necessitating either dose reduction or delay. Dose reduction leads to suboptimal dosing and provides little therapeutic benefit compared to monotherapy. Systemically administered nanoparticles offer a more effective way to selectively accumulate drugs in tumors and bypass toxicities associated with oral delivery. We have developed nanoparticle delivery systems for both Olaparib and Talazoparib in order to improve tumor accumulation while by-passing toxicities associated with oral administration. Methods: Liquid nanoformulations and solid formulations of Olaparib and Talazoparib have been developed and characterized in regard to size, surface charge, drug loading, release, and stability. NanoTalazoparib has been tested in vitro in breast cancer cell lines including T47D, W0069, W780, and HCC1937 which exhibit BRCA1 and 2 mutations, and NanaOlaparib in the lung cancer cell line Calu-6 which also has a defective FA-BRCA pathway. Mice have been treated with NanoOlaparib and NanoTalazoparib alone and in combination with radiation or temozolomide in order to evaluate toxicity. Therapeutic efficacy studies are currently underway. Results: The nanoformulations have been formulated to encapsulate a clinically relevant dose of either Talazoparib or Olaparib and release at 37°C over a period of days, while remaining stable during storage at 4°C. In vitro, both nanoformulations maintain the same activity as free drug with IC50s in the nanomolar range for these cell lines with varying deficiencies in the BRCA pathway. Mice have shown no appreciable weight loss during treatment with either nanoformulation alone or in combination with other treatment modalities. Conclusion: Nanoformulations of Talazoparib and Olaparib have been developed and characterized to demonstrate activity in vitro and tolerable doses in vivo. We have found that mice tolerate NanoTalazoparib at higher doses when combined with Temozolomide than when given oral Talazoparib. The sustained release from the nanoparticle allows for the nanoformulation to be administered less often than the daily administration for oral drug and the improved tolerability opens the door for combination therapy with both chemotherapeutics and radiation therapy. Therapeutic efficacy studies are underway and we expect that as a monotherapy NanaOlaparib will be more effective at lower doses than oral Talazoparib, based on the longer circulation time and more selective accumulation in tumors. We also anticipate that combination therapy will be more effective with the nanoformulation, as the maximum tolerated dose is higher that than of the oral drug.
#3102 Quantitation of nanoparticle delivery of AZD2811, an aurora kinase B inhibitor, to tumor tissues in mouse PDX models of solid cancers. Colin Howes,1 Susan Ashton,2 Elizabeth Pease,3 Richard J. Goodwin,1 Joanne Wilson,1 Aaron Smith,1 Matthew Ling,1 Nicole Strittmatter,1 Douglas Ferguson1,1 AstraZeneca, Cambridge, United Kingdom; 2AstraZeneca, Macclesfield, United Kingdom.

A polymeric nanoparticle (NP) formulation of AZD2811, a selective aurora kinase B inhibitor, is currently under clinical development for the treatment of both haematological and solid tumour diseases. Whilst the exploitation of nanotechnology to achieve targeted delivery of cancer drugs to solid tumours has been pursued for several years, it has achieved only limited success. A key requirement for delivering the desired accumulation of tumour distribution is the so-called ‘enhance permeability and retention (EPR) effect’. But this has been reported to offer less than a 2-fold increase in drug delivery to solid tumours relative to healthy organs using conventional NPs, resulting in drug concentrations that are insufficient for most cancers (Nakamura et al, Biocytin. Chem. 2016.). It is therefore important to have the capability to evaluate their distribution in preclinical models and potential for clinical progression. Delivery of AZD2811-NP in solid and haematological cancers each require different characteristics: Delivery to solid tumours, relies on exploitation of the EPR effect to achieve efficacious advantage over the drug alone through accumulation and release in the target tissue. The latter, treatment in haematological cancers, does not exploit the EPR effect, but is reliant on the extended pharmacokinetics (PK) delivery of polymeric drug carriers. In the case of tumour-associated NPs, diffusion and accumulation in the tumour microenvironment provide an efficacious level of drug whilst reducing side effects and overcoming the need, in the case of Barasertib (the pro-drug of AZD2811), continuous infusion for several days. Techniques to quantify drug delivery to tumour tissues in PDX mouse models of colorectal, lung and ovarian cancer have been developed to determine the extent of solid tumour distribution, allowing direct comparison with conventional drug distribution using labelled AZD2811. The effect of NP delivery of AZD2811 is to favourably alter the physical distribution of drug into the tissue in the models examined. The effect has been quantified by measuring the relative distribution of AZD2811-NP to other reference tissues, and additionally by comparison with the tumour concentration of drug delivered in a conventional formulation. By the first measure, we found an approximately 90 to 280-fold increase (in AUC) across these PDX models in AZD2811 concentration in tumour compared with muscle as the reference tissue. By the second measure, we found a 70 to 150-fold increase in AZD2811-NP compared with non-nanoparticle AZD2811 in tumour tissue at 4h post administration of the drug. The results demonstrate the benefit of drug delivery using polymeric nanoparticles in these three PDX tumour mouse models, increasing our confidence in successful translation to the clinic.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Drug Delivery Technology and Antibody Technology

#3103 Nanoengineered mesenchymal stem cells for targeted lung cancer therapy. Swayam Prabha,1 Tamnny Sadhukha,2 Buddhaheev Layek1.

1Univ. of Minnesota, Minneapolis, MN; 2Albany Molecular Research Inc. (AMRI), Albany, NY.

Solid tumors are characterized by increased interstitial fluid pressure and enhanced solid stress, contributing to poor intra-tumoral penetration of nanocarriers to solid tumors (OMIs) in vitro has shown therapeutic potential. However, in vivo delivery to solid tumor is urgently needed. MicroRNAs (miRNAs) are small non-coding RNAs that are involved in the regulation of gene expression. They have been extensively studied in cancer therapy due to their ability to target specific genes involved in tumor initiation, progression, and drug resistance. Several studies have shown that miRNAs can be used as therapeutic agents in cancer treatment. One such approach involves the use of miRNAs to target specific genes involved in tumor growth and survival. This approach offers several advantages over traditional drug therapy, including reduced toxicity and improved efficacy. In this study, we aimed to evaluate the potential of miRNAs as therapeutic agents in cancer treatment.

#3104 Rotating magnetic beads for enhanced drug delivery: characterization of bead velocity, imaging, and adherence to cellular monolayers. Herbert Engelhard,1 Zachary Gaertner,2 Adam Levin,1 Ankit Mehta,1 Sean Morris,2 Michael Sabo,2 Frances Creighton1.

1Univ. of Illinois at Chicago, Chicago, IL; 2Pulse Therapeutics, St. Louis, MO.

Background: Superparamagnetic iron oxide nanoparticles (SPIONs) have been touted as promising vehicles for enhancing drug delivery for cancer, stroke, and other diseases. Unfortunately, successful clinical use has been hampered by the problem of scale, since the attractive force between iron particle and magnet is inversely proportional to at least the fourth power of the intervening distance. Utilization of magnetically-induced rotary traction (MIRT) offers a way to overcome this obstacle. Here, we present initial data from the use of a new two-part system consisting of: 1) a patented rotating magnet, and 2) magnetic microbeads (MBs), which have been optimized for MIRT. Methods: MBs and the rotating magnet were provided by Pulse Therapeutics (St. Louis, MO). MBs consist of single-crystalline magnetite cores (~70 nm), which form aggregates in response to a magnetic field. Here, the field is generated by a neodymium-boron-iron permanent magnet, which is rapidly rotated causing MBs to counter-rotate (like meshed gears) at a physiological distance and thus move by means of surface traction. Movement of MBs through PBS, DEMEM with 5% serum, and 100% serum was measured 7.5 to 30 cm from the magnet. Suspensions of the particles were imaged at different concentrations by MRI and CT scan. 3 cancer cell lines (U87, E297, LKB1-KO), and normal vascular endothelial cells, were maintained using standard tissue culture technique. For adhesion studies, cells were grown in 6-well plates to confluence, treated with 10 ul. MBs for 30 min, washed with PBS, and then imaged with standard light microscopy, digitized, and analyzed using Image J. Results: In our experiments, MBs moved readily through PBS, DEMEM and serum at distances from 7.5-30 cm; with a maximum velocity at 22.5 cm (0.45 +/- 0.04 cm/sec, for serum). While MR imaging produced significant artifact as expected, MBs were clearly seen by CT scan. Adhesion of the MBs to the cancer cell line was markedly higher than to the endothelial cells (10.9-12.0X) and to fixed cells, used as controls. Conclusions: MBs are easily rotated and moved at physiologic distances, even through 100% serum, by means of surface traction, and can be imaged by CT scan. Adhesion of MBs to cancer cells is significantly greater than to endothelial cells. These features show that the Pulse system is an extremely promising one, for use in magnetic drug targeting in the clinical setting.

#3105 Targeting microRNAs in brain tumors with oligonucleotide nano-particle conjugates. Nilmary Grafas,1 Blanca I. Quiñones,1 Pablo E. Vivas,1 Gabriel Barletta2.

1University of Puerto Rico, Medical Sciences Campus, San Juan, PR; 2University of Puerto Rico, Humacao Campus, Humacao, PR.

Glioblastoma Multiforme (GBM) is the deadliest type of primary brain tumor with an estimated 14,000 deaths annually. The survival rate of GBM patients from time of diagnosis is 5 months if left untreated and 15 months with standard care of treatment. Despite great research efforts in the last 30 years, GBM survival rate has only increased by 2%. This is mostly due to high recurrence, treatment resistance, and the existence of the blood brain barrier (BBB) which restricts drug delivery to the tumor tissue. Therefore, the development of novel therapeutic modalities able to cross the BBB is urgently needed. MicroRNAs (miRNAs) are small (18-22 nt) non-coding RNAs that regulate gene expression at the post-transcriptional level by binding to the 3′UTR of target mRNAs. Several dysregulated miRNAs have been reported in all tumor types, including GBM. Targeting oncogenic miRNAs with oligonucleotide miRNA inhibitors (OMIs) in vitro has shown therapeutic potential. However, in vivo administration requires the development of nanocarriers capable of increasing the stability of OMs in circulation and improving their delivery to target tissues. In addition, nanocarriers that can overcome the BBB are needed. The most studied and promising nanocarriers are gold nanoparticles (AuNPs) and liposomes. While AuNPs have bioimaging and microcopy advantages, liposomes are clinically preferred. Therefore, we propose encapsulating OMs-AuNPs to BBB targeted liposomes. In this study we present the characterization of miRNA inhibitors conjugated to AuNPs. Briefly, 15 nm AuNPs were functionalized to OMIs by two different techniques: Salt aging functionalization method and PEG and surfactant
assisted conjugation method. Afterwards, both nanoconjugates were analyzed for particle size, zeta potential and loading capacity. The PEG and surfactant assisted functionalization proved to be superior in all of the analysis, resulting in 30 nm OMIs-AuNPs with a zeta potential of -8 mV and a loading capacity ratio of 64 oligonucleotides per AuNP. Further characterization studies such as cell internalization and cytotoxicity are under evaluation.

**#3106 Targeted delivery via Elastin Like Polypeptide: Biodistribution of a doxorubicin derivative in MDA-MB231 human breast cancer xenografts in mice.** Sonja Drugovic, 1 Jung Su Ryu, 2 Felix Kratz, 1 Drazen Raucher 1.

The anticancer agent doxorubicin has been widely used in the treatment of a variety of hematological malignancies and solid tumors. Despite doxorubicin’s efficacy in eradicating tumor cells, severe damage to healthy tissues, along with cardiotoxicity, limits its use in clinics. To overcome adverse side effects, improve patient safety, and enhance therapeutic efficacy, we have designed a thermally responsive biopolymer doxorubicin carrier that can be specifically targeted to tumor tissue by locally applying mild hyperthermia (41 degrees C). The developed drug vehicle is composed of: a cell penetrating peptide (SynB1) to promote tumor and cellular uptake; thermally responsive Elastin like polypeptide (ELP); and the (6-maleimidocaproyl) hydrazide derivative of doxorubicin (DOXO-EMCH) containing a pH-sensitive hydrazine linker that releases dox in the acidic tumor environment. We used the in vivo imaging system, IVIS, to determine the biodistribution of doxorubicin-delivered ELP in MDA-MB231 triple-negative human breast cancer cell line xenografts in nude mice. Tumor bearing mice were treated with a single IV injection of 10 mg/kg doxorubicin equivalent dose with free doxorubicin, thermally responsive SynB1 ELP 1-DOXO, and a thermally non-responsive control biopolymer, SynB1 ELP 2-DOXO. Following a 2 hour treatment with hyperthermia, tumors showed a 3-fold higher uptake when treated with SynB1 ELP 1-DOXO compared to free doxorubicin. Accumulation of the thermally non-responsive control SynB1 ELP2-DOXO was comparable to free doxorubicin, indicating that an increase in dox accumulation with ELP is due to aggregation in response to thermal targeting. Higher levels of SynB1 ELP1-DOXO and SynB1 ELP2-DOXO with respect to free doxorubicin were observed in kidneys. Fluorescence intensity from hearts of animals treated with SynB1 ELP1-DOXO show a 3-fold lower accumulation of doxorubicin than the same dose of free doxorubicin. SynB1 ELP1-DOXO biopolymers demonstrated a 6-fold increase in tumor/heart ratio in comparison to free doxorubicin, indicating preferential accumulation of the drug carrier in tumors. Overall, thermally targeted polymers are a promising therapy to enhance tumor targeting and uptake of anticancer drugs and to minimize free drug toxicity in healthy tissues, representing a great potential for clinical application.

**#3107 Targeting nanotherapeutics to the invasive glioblastoma margin or targeted delivery via Elastin Like Polypeptide: Biodistribution of a surfactant assisted functionalization proved to be superior in all of the assisted conjugation method. Afterwards, both nanoconjugates were analyzed for particle size, zeta potential and loading capacity. The PEG and surfactant assisted functionalization proved to be superior in all of the analysis, resulting in 30 nm OMIs-AuNPs with a zeta potential of -8 mV and a loading capacity ratio of 64 oligonucleotides per AuNP. Further characterization studies such as cell internalization and cytotoxicity are under evaluation.

**#3108 Gemcitabine nanoparticles show in vitro efficacy in murine pancreatic ductal adenocarcinoma.** Samantha T. Tucci, 1 Hamilton Kakwere, 2 Azadeh Kheirolomoom, 1 Jai W. Seo, 3 Elizabeth Ingham, 3 Chang-Hi Hwang, 4 Katherine Ferrara 1.

Our goal is to develop nanotherapeutics for the treatment of pancreatic ductal adenocarcinoma (PDAC). Squalenoylated Gem (SqGemNPs) and Gem-loaded temperature sensitive liposomes (GemTSLs) were synthesized and the resulting efficacy was compared to that of gemcitabine (Gem) and Abraxane®. Squalenoylation is the conjugation of squalene, a cholesterol precursor, to a drug and enhances in vivo delivery, half-life, and therapeutic efficacy [1]. All particles were evaluated in vitro in both a monolayer and organoid culture of the KralLSL-G12D/+; Trp53LSL-R172H+; Pdx-Cre (KPC) model. The organoid culture allows for phenotypic maintenance that is otherwise lost with monolayer culturing [2]. SqGem and Cholesterol-EPIPEG2 co-assembled into SqGemNPs via nanoprecipitation to yield particles of 210 ± 150 nm with 35 wt% Gem. Gem was loaded into TSLs by complexing copper to Gem inside multimamellar liposomes comprised of DPPC:DSPE-PEG2-DSPC (50:515) to yield particles of 110 ± 26 nm with 1.7 wt% Gem. KPC cells were plated as both monolayers and Matrigel® suspensions and organoid-cultured cells were plated in Matrigel. Cells were incubated with free Gem, SqGemNPs, pre-heated Gem-TSLs, or Abraxane. At 72 h, cell survival was determined by an MTT assay (Invitrogen, Carlsbad, CA). In monolayer-cultured cells, SqGemNPs was the only tested therapeutic to achieve 100% cell death (which occurred at a concentration of 50 uM). All other treatments reached a plateau of efficacy as a function of concentration. Two anticipated trends were confirmed; monolayer-cultured cells were more responsive to all treatments than organoid-cultured cells, and cells plated in Matrigel were less responsive to therapy than those plated as a monolayer. We found that the efficacy of preheated GemTSLs was similar to free Gem in all cell cultures and thus release from the TSLs was validated. In the organoid culture, the IC50 of SqGemNPs was 0.12 ± 0.04 uM compared to 0.19 ± 0.04 uM for free Gem, although both reached a plateau of efficacy at 70% cell death. The efficacy of Abraxane, GemTSLs and Gem plateaued at 45%, 77% and 70% cell death, respectively in organoids. In future studies, two techniques to increase drug availability in PC tumors will be evaluated: SqGemNPs plus high intensity ultrasound ablation, which can increase drug accumulation by 50-fold [3] and GemTSLs plus ultrasound hyperthermia to locally release Gem at a high concentration within the tumor vasculature. 1 Couvreur, P. et al. Nano Lett. 6, 2544-2548, doi:10.1021/nl061942q (2006). 2 Bo, S. E. et al. Cell 160, 324-338, doi:10.1016/j.cell.2014.12.021 (2015). 3 Wong, A. W. et al. J Clin Invest 126, 99-111, doi:10.1172/Jci83312 (2016).

**#3109 Ultrasound-mediated delivery and distribution of polymer nanocarriers in the normal brain parenchyma and melanoma metastases.** Habib Baghirov, 1 Sofie Snipstad, 1 Einar Sulheim, 1 Sigrid Berg, 2 Rune Hansen, 2 Frits Thorsen, 1 Trond Hagen, 1 Catharina de Lange Davies, 1 Andreas Ashlund, 2 Nirweidt, 1 Kristian Gerhard Jebsen Brain Tumour Research Centre, University of Bergen, Bergen, Norway; 3 SinoTech, University of California, Davis, Davis, CA; 4 SINTEF Materials and Chemistry, Trondheim, Norway; 5 Molecular Imaging Center and Kristian Gerhard Jebsen Brain Tumour Research Centre, University of Bergen, Bergen, Norway; 6 SINTEF Materials and Chemistry, Trondheim, Norway.

The blood-brain barrier (BBB) prevents the passage of nearly all drugs into the brain, hindering brain cancer treatment. Nanoparticles (NPs) have emerged as promising drug delivery vehicles, due to incorporation of poorly soluble drugs, functionalization for controlled and sustained release and combination of drug delivery with imaging. Transport of NPs across the BBB, however, is equally complicated and can benefit from versatile BBB opening techniques. Focused ultrasound (FUS) in combination with microbubbles (MBs) ensures safe and effective transport of the BBB, thereby allowing the BBB and transport NPs into the brain in a melanoma metastasis model. Intracardiac injection of patient-derived human melanoma cells was performed in immunodeficient mice. Brain melanoma metastases developed four weeks post-injection. A novel ultrasound system able to generate 1.1 MHz and 7.8 MHz FUS during the same experiment was used for FUS treatments. Selection of the treatment area was guided by magnetic resonance imaging. BBB was disrupted by FUS at 1.1 MHz, while FUS at 7.8 MHz was used to enable acoustic radiation force and, hopefully, push NPs farther into the extracellular matrix away from blood vessels. Successful BBB opening was verified using a gadolinium-

Many of the nanoparticle (NP) formulations approved for clinical use in solid tumor therapy provide only modest improvements in patient survival. This is in part due to NP tumor penetration barriers, including a dense and complex extracellular matrix (ECM) and an elevated interstitial fluid pressure, which hinder the penetration of drugs and NPs into and within tumors limiting therapeutic efficacy. Using polystyrene (PS) particles over the size range of 20-100 nm, we recently tested how particle size impacted NP diffusion in a well-characterized tumor ECM preparation (Matrigel) and in triple-negative MDA-MB-231 breast cancer xenografts by multiple particle tracking (MPT) and intravital microscopy. We also investigated the effect of PEG surface density on the diffusion of ~60 nm PS NPs in the same models. Nonspecific binding of the NPs to tumor ECM components was determined by a surface plasmon resonance (SPR) binding assay, which was then compared to the NP diffusion results. Furthermore, biodegradable PLGA NPs with various surface PEG densities and two clinically-relevant NPs, PEGylated liposomal doxorubicin (Doxil) and non-PEGylated albumin-bound paclitaxel (Abraxane), were evaluated by SPR to evaluate their potential tumor penetration ability. These studies demonstrated that NPs as large as 60 nm, but less than 110 nm in diameter, diffuse rapidly within tumor ECM and tumor xenograft tissues ex vivo if they are densely coated with PEG. The penetration of these NPs within the same tumor models was found to be highly dependent on surface PEG density. Intravital microscopy of NP spread in living tissue confirmed a significant difference in tumor tissue penetration between the 60 and 110 nm PEG-PS NPs, as well as between PEG-coated and uncoated NPs. Non-specific binding of NPs to tumor ECM components assessed by SPR, which associated a positive correlation in the particle diffusion results consistent across multiple particle types, including PS and biodegradable NPs. SPR assays revealed that Abraxane binds significantly to tumor ECM which has the potential to limit particle dispersion with tumor tissue. Studies to extend these findings to drug-loaded, molecularly-targeted biodegradable NPs are underway. We have successfully encapsulated paclitaxel to the polymer backbone of PLGA containing a low-molecular weight PEG coating. Additional surface modifications have been made to enable NP targeting to Fn14-positive triple-negative breast tumors. In summary, we have developed a NP platform that can diffuse and penetrate within tumor tissue and selectively target tumors. Using this approach, we can optimize therapeutics versions to improve drug efficacy while limiting many of the side effects and risks of free drug and non-targeted therapies.

Currently research antibodies have a serious quality problem, which is one of the major contributing factors to the irreproducibility of published reports. Labome organizes antibody applications cited in formal publications and has developed Validated Antibody Database (VAD). VAD, a manually curated database, compiles commercial and non-commercial antibodies whose specificities and applications have been independently reported in published results from formal articles. Labome prioritizes the curation of articles with knockout studies and monoclonal antibodies. One of the benefits of our curation effort is the identification of cross-reactive species and novel applications for antibodies, which are often developed for human/mouse proteins and tested by suppliers for a limited number of applications. Labome registers many antibodies having cross-reactivities with model organisms such as flies, worms, zebrafish, and frogs and with novel applications. The database can be browsed or searched online.

Prostate-specific membrane antigen (PSMA) is an attractive target for an ADC approach as it is over-expressed by virtually all prostate cancers and its expression is highest in poorly-differentiated, metastatic and castration-resistant cases. PSMA has limited expression in non-prostatic tissues, it is not secreted or cleaved by PSMA-expressing cells, and it is constitutively internalized, a process that may be accelerated by specific antibody binding. ADCT-401/MEDI3726 is an ADC composed of a monoclonal antibody (F591), directed against human PSMA, site-specifically conjugated (drug-to-antibody ratio of 1.8) to a highly cytotoxic DNA cross-linking PBD dimer with a valine-alanine dipeptide linker. In vitro, ADCT-401/MEDI3726 demonstrated potent and specific cytotoxicity in a panel of PSMA-expressing prostate cancer cell lines, whereas its activity was greatly reduced in PSMA-negative cell lines. In vivo, ADCT-401/MEDI3726 showed strong antitumor activity against CWR22Rv1 and LNCap human-derived prostate cancer xenograft models. In the CWR22Rv1 model, a tumor with low, heterogeneous PSMA expression, ADCT-401/MEDI3726 achieved dose-dependent antitumor activity when administered as single dose at either 0.33 or 1 mg/kg, which resulted in significant increase in survival compared to the vehicle-treated animals. Moreover, a single dose of ADCT-401/MEDI3726 showed remarkable superior antitumor activity compared to multiple doses of another PSMA-targeted ADC stochastically conjugated to the auristatin payload vcMMAE with a DAR of ~4. In the LNCaP model, ADCT-401/MEDI3726 resulted in dose-dependent antitumor activity when dosed once at 0.11, 0.33 or 1 mg/kg. In the PSMA-negative prostate cancer-derived PC3 xenograft model, ADCT-401/MEDI3726 and an isotope-controlled ADC showed limited tumor growth inhibition highlighting target-mediated antitumor activity. ADCT-401/MEDI3726 demonstrated potent and specific in vitro and in vivo antitumor activity in prostate cancer-derived models of differing levels of PSMA and this warrants further development of this ADC into the clinic.

Currently research antibodies have a serious quality problem, which is one of the major contributing factors to the irreproducibility of published reports. Labome organizes antibody applications cited in formal publications and has developed Validated Antibody Database (VAD). VAD, a manually curated database, compiles commercial and non-commercial antibodies whose specificities and applications have been independently reported in published results from formal articles. Labome prioritizes the curation of articles with knockout studies and monoclonal antibodies. One of the benefits of our curation effort is the identification of cross-reactive species and novel applications for antibodies, which are often developed for human/mouse proteins and tested by suppliers for a limited number of applications. Labome registers many antibodies having cross-reactivities with model organisms such as flies, worms, zebrafish, and frogs and with novel applications. The database can be browsed or searched online.
patic metastasis. In patient subgroup of stage II GC, those with increased ASGR2 expression had significantly shorter overall and disease-free survival than those without. Conclusions: ASGR2 may represent a biomarker for hepatic metastasis of GC and as a target for therapy.

#3113 Knockdown of cell division cycle-associated 8 (CDC8A) suppresses hepatocellular carcinoma growth via the upregulation of tumor suppressor ATF3. Tae-Won Jeon,1 Min Ji Ko,1 Yu-Ri Seo,2 In Hye Baik,1 Heeson Hwang,1 Hun-Mo Ryoo,1 Jin Young Kim,1 Keon Uk Park,1 Yun-Han Lee1.1 Keimyung University School of Medicine, Daegu, Republic of Korea; 2Daegu Catholic University, Daegu, Republic of Korea.

Background: Hepatocellular carcinoma (HCC) is the third most lethal cancer worldwide which remains a major challenge due to poor prognosis and limited treatment options. Cell division cycle associated 8 (CDC8A) is known as a component of a chromosomal passenger complex required for stability of the bipolar mitotic spindle and it is commonly overexpressed in human HCC. However, the functional role of CDC8A in HCC progression remains to be clarified. In this study, we hypothesized if targeting of CDC8A with small interfering (si) RNA could alter the course of HCC progression. We also investigated the molecular mechanism that mediates HCC cell death caused by CDC8A silencing. Methods: Human HCC cell lines, Huh1 and Huh7, were transfected with CDC8A siRNA and tested for growth inhibition and apoptotic induction using MTS, FACS and microscopic analysis. To obtain insights into the molecular changes in response to CDC8A knockdown, global changes in gene expression were examined using RNA sequencing. siRNA silencing of CDC8A in HCC cell growth and long-term colony formation by blocking cell cycle progression and by inducing apoptotic cell death. RNA sequencing data showed that, representatively, the anti-proliferative effects were driven by a subset of molecular alterations including the upregulation of tumor suppressive ATF3 and GADD34 genes and the downregulation of BGLAP, a key regulator of cell growth and invasiveness. Subsequent Western blot analysis affirmed that CDC8A silencing induces the increase in the levels of ATF3 and GADD34 and the decrease in phosphorylated Akt in both Huh1 and Huh7 cells. Also, the same condition decreased the levels of PARP-1 and pro-caspase 3, accelerating apoptosis. Of importance, silencing of CDC8A expression effectively suppressed HCC tumor growth in a murine xenograft model. Conclusion: These findings suggest that targeting CDC8A could be an attractive option for molecular therapy of HCC.

#3114 The role of prostaglandin signaling in human glioblastoma cell activities and growth in vitro and in vivo. Jianguo Shao,1 Yifeng Du,2 Tian Li3, Zi Shu1, Jianxiong Jiang1.1 Jinan University, Guangzhou, China; 2University of Cincinnati Academic Health Center, Cincinnati, OH.

Glioblastoma multiforme (GBM) constitutes the most frequent and aggressive form of malignant brain primary tumors. Despite current combined treatment involving surgery, chemotherapy and radiation therapy, the median survival of GBM patients is only about one year, with less than 3-5% of patients surviving over 5 years. Cyclooxygenase-2 (COX-2) is overexpressed in glioblastoma, and its expression level is highly positively correlated with the tumor grade. As a major enzymatic product of COX-2, prostaglandin E2 (PGE2) mediates inflammatory processes within the brain and facilitates progression of many chronic inflammation-associated neurological diseases via its four downstream receptors - EP1-EP4. We hypothesize that selectively targeting these receptors might provide an alternative therapeutic strategy for GBM with more specificity than generic blockade of the entire COX-2 cascade. In this study, two engineered human GBM cells with or without activated COX-2 were used to explore the PGE2 signaling involved in the development and progression of GBM. COX-2 activation by LPS or its overexpression facilitated migration, invasion, and transformation of these GBM cells in vitro. Moreover, the COX-2-mediated GBM cell activities were substantially suppressed by selective antagonists of PGE2 receptors that are highly expressed in these cells. Furthermore, the tested PGE2 receptor selective antagonists also suppressed the growth of GBM cells in vivo. In sum, our results suggested the inflammatory PGE2 signaling is involved in human GBM cell inflammation, migration, invasion and transformation through its downstream receptors, and should be explored as alternative molecular targets for novel GBM therapies.

#3115 Characterization of CDC1A protein as a novel prognostic biomarker and therapeutic target for oral cancer. Thang Manh Phung,1,2,3,4 Masahide Takekoshi,1,2,3,4 Yoshinori Murakami,1,2,3,4 Yataro Daigo1,1.1 The Institute of Medical Science, The University of Tokyo, Tokyo, Japan; 2Kumamoto University, Kumamoto, Japan.

Oral cavity carcinoma (OCC) is one of the most common causes of cancer-related death worldwide. Current therapies for OCC still show poor clinical outcome with five-year survival rate of less than 63%. Therefore, next generation biomarkers and therapeutic strategies for OCC are eagerly awaited. We selected genes that were specifically overexpressed in the majority of OCC using our gene expression profile database, and identified cell division cycle associated 1 (CDC1A) that appeared to encode nuclear protein as a candidate. Immunohis- tochemistry analysis using tissue microarrays indicated that CDC1A was detected in 67% of 99 OCC tissues (68%), but not in normal oral epithelia. In addition, high levels of CDC1A protein expression was significantly associated with poor prognosis for OCC patients (P = 0.0244 by log-rank test). Furthermore, knockdown of CDC1A expression by siRNAs significantly inhibited the growth of tumor cells. Moreover, flow cytometric analysis, and apoptosis assay of live cell imaging revealed that CDC1A could be important for the growth and survival of OCC cells, probably through the regulation of mitotic phase and/or apoptosis. Our findings suggest that CDC1A is likely to be a novel prognostic biomarker and a therapeutic target for OCC patients.

#3116 Dysregulated cholesterol synthesis is a therapeutic vulnerability in glioblastoma. Diane M. Kambach, Alan S. Halim, A. Gesine Cauer, Qian Sun, Carlos A. Tristan, Orieta Celiku, Aparna H. Kesarwala, Uma Shankavaram, Eric Batchelor, Jayne M. Stommel. National Cancer Institute, Bethesda, MD.

A hallmark of cellular transformation is the evasion of contact-dependent inhibition of growth. To find new therapeutic targets for glioblastoma, we looked for pathways that are inhibited by high cell density in normal astrocytes but have lost this regulation in glioma cells. Here we report that at high cell density, normal astrocytes turn off cholesterol synthesis but glioma cells keep this pathway on. Correspondingly, cholesterol pathway upregulation is associated with poor prognosis in glioblastoma patients. Densely-plated glioma cells increase oxygen consumption to synthesize cholesterol, resulting in a decrease in reactive oxygen species, TCA cycle intermediates, and ATP, but without a compensating increase in aerobic glycolysis. This constitutive cholesterol synthesis is controlled by the cell cycle, as it can be turned off by cyclin-dependent kinase inhibitors and it correlates with disabled cell cycle control through loss of p53 and RB. Finally, glioma cells, but not astrocytes, are sensitive to cholesterol synthesis inhibition downstream of the mevalonate pathway, suggesting that specifically targeting cholesterol synthesis might be an effective treatment for glioblastoma.
was detected in the brain tumor tissues as early as 15 minutes after intravenous injection of eribulin, which remained stable even 24 hours later when the plasma concentration of eribulin became undetectable. Finally, intraperitoneal administration of eribulin significantly prolonged the survival of mice with intracerebrally transplanted U87MG xenografts (p<0.001). [Conclusion] Our results showed that eribulin efficiently transfers into brain tumor tissues and has a strong antitumor effect against GBM cells through inhibition of Rdrp activity. Eribulin thus appears to be a promising novel TERT-targeting therapeutic agent against GBM. A clinical trial is being scheduled.

#3118 Histological subtypes correlate with distinct genetic abnormalities in defining therapeutic targets in medulloblastoma. Samuel Gelnic,
Anubhav G. Amin,1 Molly Gordon,2 Raphael Salles Cortegata de Medeiros,2 Nelci Zanon,3 Raj Murail,4 Meena Ihanwar-UNival,2 1Dept. of Neurosurgery, New York Medical College, Valhalla, NY; 2Hospital Santa Marcelina, Sao Paulo, Brazil.

Medulloblastoma (MB) is the most common primary pediatric malignant brain tumor. Genetic classification and distinct histologic subtypes defines MB into 4 groups: classic (WNT), sonic hedgehog (Shh), group 3 and group 4. In addition, recent studies have provided evidence that p53 abnormalities is seen in various sub-groups of MB and that p53-mutant SHH MBs commonly harbor genetic anomalies including MYCN and GLI2 amplifications, which confers drug resistance. Here, we test the hypothesis that specific immunohistological markers, their correlation with the amplification of the oncogene MYCN, and abnormalities in tumor suppressor gene p53, may define their metastatic potential. Materials and Methods: Immunohistological analysis of MB tumors (n=41) was evaluated. Amplification of glioma transcription factor 1 (GLI1), natriuretic peptide receptor (NPR), voltage-gated potassium channel (KV1) and mutant p53. FISH analysis was performed to determine MYC amplification or iso- P53. p53-mutant MB cell line was used to investigate the signaling pathway leading to proliferation, migration, and drug resistance using HDAC (LBH-589) and PI3K/mTOR (BKM-120/rapamycin) inhibitor. Results: we showed that: 1) GAB-1 was highly expressed in the Shh group (82%) and KV1 expression was evenly distributed in all subtypes; 2) No obvious correlation with expression of GLI-1, GAB-1, NPR, or KV1 with metastasis was seen; 3) Analysis of loss of p53 and overexpression of MYC varied in each subtype; 4) Combined Treatment with LBH-589 and BKM-120 reduced cell proliferation, migration and S-phase entry, however, MB cells were resistant to BKM-120 treatments, while LBH-589 caused massive apoptosis; 5) Tumor formation was suppressed by BKM-120 given with mTOR inhibitors. Conclusion: the result of this study suggests that expression of GLI-1, GAB-1, NPR, KV1 and p53 was important in defining the subgroups of MB, although their metastatic potential remains to be understood. MB cells shows reduced cell proliferation, cell cycle and migration, when treated with HDAC inhibitor LBH-589, however these cells display complete drug resistance to PI3K inhibitors.

#3119 Identification of genetic drivers in HER2enriched/HER2negative breast cancer. Susana Garcia Recio,1 Cheng Fan,1 Marni Siegel,1 Joel S. Parker,1 Gina N. Duronio,1 Aleix Prat,2 Charles M. Perou,4 1University of North Carolina, Chapel Hill, NC; 2Hospital Clinic de Barcelona, Barcelona, Spain.

Background: The non-basal triple negative breast cancer (Non Basal-TNBC) tumors, also called the luminal androgen receptor (LAR) subtype, make up ~20% of all new TNBC cases and is limited to multi-agent chemotherapy. TNBC is considered one of the leading causes of cancer-associated mortality amongst women in the USA with a high number of patients dying of metastatic disease. Some metastases that arise from luminal primary tumors lose their luminal features and become a HER2-enriched (HER2E) subtype, but remain clinically HER2 negative (HER2E/HER2−). The molecular features that drive these HER2E/HER2− tumors may also represent key checkpoints of metastatic progression. Within this HER2E/HER2− subtype, besides the androgen receptor (AR), FGFR4 has been shown to be expressed, but its functional role remains unknown. FGFR4 is a tyrosine kinase receptor involved in proliferation, survival and migration during embryonic development and cancer. We hypothesize that in addition to AR, that FGFR4 may be a driver of HER2E/HER2− tumors and that the therapeutic targeting of this gene/protein might improve patient outcomes. Objective: Our objective is to identify the mechanism of action of FGFR4 in HER2E/HER2− tumors as well as additional genetic drivers of HER2E TNBC subtype. Methods: We performed computational analysis of databases (TCGA, METABRIC) and the analysis of matched breast cancer primary tumors and metastases to detect genetic drivers. We ran microarrays on two FGFR4 stably transfected luminal HER2+ ER− cell lines (MC7F and T47D) and also treated a Luminal B cell line (MDA-MB-453; HER2+/ER−) and HER2+ cell line (CAM-A1; HER2+/ER+/AR−) with a FGFR4 inhibitor using a time course strategy. Results: Through the analysis of microarrays using all 4 cell lines, we identified a gene expression signature of FGFR4-activity enriched in genes involved in proliferation, cell junctions and cell differentiation. The FGFR4-associated signature of upregulated genes was enriched in HER2E and Basal-like subtypes and the downregulated genes enriched in the Luminal subtypes. To identify predictors of chemotherapy response, we evaluated FGFR4-associated gene signatures in the diagnostic (pre-treatment) samples of MDACC neoadjuvant dataset of 500 tumors. The high expression of the FGFR4-induced gene signature predicted pathological complete response (Tst P <0.001). Conclusions: FGFR4 may play an important role in the progression of Luminal disease and has been identified as a new genetic driver of HER2E/HER2− subtype making it an attractive option as a therapeutic target. We are further testing these genetic predictions using Patient Derived Xenograft (PDX) mouse models.

#3120 Application of a lectin as a drug carrier for glycan-targeting cancer therapy. Tatsuya Oda,1 Osamu Shimomura,1 Hiroaki Tateno,2 Jun Hi-rabayashi,3 Masayuki Noguchi,1 Shigeru Chiba,1 Makoto Asahima,1 Nobuhiro Ohkohchi,1 1Institute of Clinical Medicine, Univ. of Tsukuba, Tsukuba, Ibaraki, Japan; 2National Institute of Advanced Industrial Science and Technology (AIST), Tsukuba, Ibaraki, Japan.

Various cancers such as pancreatic ductal adenocarcinoma (PDAC) remain intractable despite recent advances in tumour-targeting antibody drugs. Although the outermost coating of every cell type is predominantly composed of cell-specific glycans, antibody strategies have hit walls of technical difficulties in intentional glycan targeting, and medicoeconomic burden. Lectins, proteins with glycan-binding activity, can be used as an alternative scaffold; however, the prejudice that all lectins mediate harmful haemaggulitation limited its use only in experimental and diagnostic applications. Here, we show the successful in vivo application of a lectin as a drug carrier for cancer therapy. We have employed rB2CLC-N lectin since this has already shown a specific affinity between PDAC cell-surface glycans. When a lectin-drug conjugate (LecD) was developed by fusion with a bacterial exotoxin, the 50% inhibitory concentration (1.04 pg/ml=0.0195 pm) was 1000 times lower than that of conventional immunotoxins (on the order of ng/ml). In addition, we have revealed that rB2CLC-N lectin was safely administrable to mice without haemaggulitation. Administration of this LecD in a PDAC mouse model of subcutaneous nodules and peritoneal dissemination, generated prominent therapeutic effects. The utilization of lectins as an in vivo drug-carrier targeting cancer glycan shows realistic potential when paired with advanced lectin engineering technologies, and their applications could be expanded by coupling with small molecule and/or nanoparticle drugs.

#3121 Validation of protein kinase D1 as a prognostic factor and pharmacological target for the treatment of breast cancer. Caroline Spasojevic,1 Marie Karavani,1 Aashie Vacher,1 Jean Marc Ricort,1 Elisabetta Marangoni,1 Ivan Bièche,1 Christian Auclair2. 1Institut Curie, Paris, France; 2Ecole normale supérieur de Cachan, Cachan, France.

Tamoxifen-resistant ERα positive (ERα+) breast cancers and triple-negative breast cancers represent two aggressive subgroups of mammary tumors with limited treatment options and a poor prognosis. Thus, there is still an urgent need to develop and improve targeted pharmacological treatments against these estrogen-independent cancers. Recent data from our group suggest that the protein kinase D1 (PKD1) participates in the development and/or maintenance of the estrogen-independent phenotype in breast cancer. Indeed, up-regulating PKD1 conferred anchorage-independent growth to estrogen-dependent MCF-7 cells in the absence of β-estradiol. In addition, we found that high PKD1 mRNA levels were associated with a worse prognosis in tamoxifen-treated tumors. PKD1 is a serine-threonine kinase encoded by the prkd1 gene and belongs to the protein kinase D (PKD) family, a novel subgroup of the calcium and calmodulin-regulated kinases (CAMK). The PKD family also includes PKD2 and PKD3 which share a high homology with PKD1. The objective of the present study was to determine whether PKD1 could be a prognostic factor and/or a pharmacological target for the treatment of breast cancer. Expression of prkd1, prkd2 and prkd3 was analyzed by RT-qPCR in 527 breast cancer specimens (181 ERα positive(ERα+) breast cancers and triple-negative ERα- tumors). We showed that higher prkd1 mRNA levels were associated with a lower metastasis-free survival in the overall breast cancer population (p=0.015). prkd1 prognostic value was even stronger in ERα- tumors (p=0.00042) and in triple negative tumors (p=0.0043). Conversely, prkd1 expression was not associated with prognosis in ERα+ tumors. Interestingly, high prkd2 and prkd3 mRNA levels were associated with a better prognosis in the entire cohort (p=0.0074 and p=0.028 respectively). We have developed PKD1 inhibitors in collaboration with the AB Science pharmaceutical company and screened the ability of thirty-five com-
pounds to inhibit anchorage-independent growth of MCF-7 cells in the absence of estrogens. The antitumor activity of two PKD1 inhibitors is currently being evaluated in vivo against patient-derived breast cancer xenografts. In conclusion, our results show that high prkd1 expression is a bad-prognosis factor in breast cancer and that PKD1 could be a relevant therapeutic target for the treatment of breast cancer, in particular those harboring an estrogen-independent phenotype.

#3122 Pharmacogenic profiling to identify novel therapeutic strategies in colorectal cancer. Jarle Bruun,1 Peter W. Eide,1 Kushtrum Kryeziu,1 Anita Sveen,1 Astrid Murumagi,2 Matthias Kolberg,1 Marlianna Arjama,3 Olli Kallioniemi,2 Ragnar A. Lothe1. 1Institute for Cancer Research, Oslo Univ. Hospital, Oslo, Norway; 2Institute of Molecular Medicine Finland, Helsinki, Finland.

Colorectal cancer (CRC) is amongst the most frequent cancers worldwide and the fourth most common cause of cancer mortality. Surgery is the standard treatment of care, while chemotherapy and/or radiotherapy are offered to subgroups of patients according to disease stage. Current guidelines do not have sufficient accuracy to identify chemotherapy responders, resulting in under- or overtreatment of many patients. To discover novel therapeutic strategies for CRC we performed a high-throughput drug screen containing 461 approved and preclinical drugs on a representative panel of 42 CRC cell lines. Integrative pharmacogenic profiles were explored by matching data from gene expression, exome sequencing, copy number and reverse-phase protein arrays. These analyses identified defined molecular subgroups sensitive to targeted drugs like Inhibitors of EGFR, IGF-1R, Aurora B and/or downstream signaling mediators like B-Raf, MEK, PI3K/AKT, as well as inhibitors of auroctotic kinases, heat shock protein 90 and p53. Additionally, a correlation between microsatellite instability and sensitivity towards topoisomerase-I inhibitors was found. Comparison of the most sensitive and the most resistant cell models against HSP90 inhibitors indicated that drug sensitivity does not depend on target expression but is likely attributed to the cell line-specific expression of client proteins. Real-time cell analyses measured with the xCELLigence system demonstrated a strong impact on cell proliferation but not on the migration of HSP90-sensitive cells treated with HSP90 inhibitors as compared to resistant cells. These integrative analyses have unraveled pharmacogenic relationships that if validated in in vivo model systems, might be used to stratify patients for therapeutic intervention in biomarker guided clinical trials.

#3123 Identification of TIFA as a novel therapeutic target in acute myeloid leukemia. Pei-Yu Wu,1 Tong-You Wang,1 Ting-Jung Wu,2 Ming-Daw Tsaï1. 1Academia Sinica, Taipei, Taiwan; 2Chang Gung Memorial Hospital, Taoyuan, Taiwan.

Aurora A-dependent NF-κB signaling portends poor prognosis of cancers including acute myeloid leukemia (AML). Our previous study demonstrated that phosphorylation-dependent oligomerization of Traf-interacting protein with FHA domain (TIFA) triggers the activation of NF-κB. The present study identifies that Aurora A is an essential kinase for the Thr9 phosphorylation of TIFA, and that TIFA functionally mediates the Aurora A-driven NF-κB survival pathway in AML. Overexpression of TIFA occurred concurrently with Aurora A and NF-κB signaling factors in de novo AML patients but not healthy individuals, and also correlated with poor prognosis. Silencing of TIFA specifically attenuated leukemic cell growth and enhanced chemosensitivity of AML cells via down-regulation of pro-survival factors Bcl-2 and Bcl-XL that support NF-κB-dependent anti-apoptotic events. In addition, molecular targeting of TIFA perturbed leukemic cytokine secretion and significantly lowered the IC50 of chemotherapeutic drugs to treat AML cells. Furthermore, in vivo delivery of TIFA-inhibitory fragments potentiates the clearance of leukemic myeloblasts in the bone marrow of xenograft-recipient mice via enhanced chemotaxis, similar to the effect of anti-inflammatory drug treatments. Collectively, we proposed that TIFA functionally supports the positive feedback between TNF-α, Aurora A, and NF-κB to facilitate AML survival signaling, and impairment in this pathway can enhance the efficacy of AML treatments.

#3124 Expression and therapeutic implications of cyclin dependent kinase 4 (CDK4) in osteosarcoma. Yubing Zhou, Francis Hornicke, Zhenfeng Duan. Massachusetts General Hospital, Boston, MA.

Overexpression and/or hyperactivation of cyclin-dependent kinase 4 (CDK4) has been found in many types of human cancers, and a CDK4 specific inhibitor, palbociclib, has been recently approved by the FDA for the treatment of breast cancer. However, the expression and the therapeutic potential of CDK4 in osteosarcoma remain unclear. In the present study, CDK4 was found to be highly expressed in human osteosarcoma tissues and cell lines as compared with normal human osteoblasts. Elevated CDK4 expression correlated with metastasis potential and poor prognosis in osteosarcoma patients as determined by immunohistochemical analysis in a human osteosarcoma tissue microarray (TMA). CDK4 inhibition by either palbociclib or specific small interference RNA (siRNA) exhibited dose-dependent inhibition of osteosarcoma cell proliferation and growth, accompanied by suppression of the CDK4/6-cyclinD-B signaling pathway. Western blotting analysis showed that CDK4 knockdown decreased osteosarcoma cells in the G1 phase of the cell cycle and induced cell apoptosis. Furthermore, inhibition of CDK4 significantly decreased osteosarcoma cell migration in vitro determined by the wound healing assay. These data highlight that CDK4 may be a potential promising therapeutic target in the treatment of human osteosarcoma.

Glioblastoma (GB) is the most common malignant primary brain tumor, which is characterized by marked intra-tumor genetic heterogeneity in receptor tyrosine kinases (RTK) genes. Aberrations in the RTK/PI3K/Akt pathways in GB leads to an abnormal signaling pathway of mechanistic target of Rapamycin (mTOR). mTOR exists in two distinct complexes, namely, mTORC1 and mTORC2, which are involved in regulation of cell survival, growth, and motility. In this investigation, we test the hypothesis that the genetic heterogeneity of GBM cells and its stem cells with respect to the expression of EGFR and/or PDGFRα may define the treatment efficacy of RTK inhibitors with or without PI3K/mTOR inhibitors. We demonstrated that GB tumors over-expressed PDGFRα and EGFR at range of 80% and 30%, respectively, with varying degree of overlap. Combined treatment with the inhibitors of PDGFRα (AC 710) or EGFR (gefitinib), with or without inhibitors of mTORC1 (rapamycin) or mTORC1/2 (Torin1 and Torin 2), led to suppression of cell proliferation, cell cycle, cell migration and drug resistance in GB cells to varying degrees that correlated with EGFR or PDGFRα expression. Downstream signaling pathway substrates of mTORC1 and 2, namely pS6k and pAkt, respectively, were suppressed by combined treatments of RTK and mTORC1/2 inhibitors. Furthermore, GB stem cell self-renewal and growth was also suppressed with combined treatments. The combination of AC710 plus mTORC1/2 inhibitor, Torin2, was the most effective. These findings underscore the usefulness of determining PDGFRα and EGFR status when considering viable PI3K/mTOR inhibitors for targeted treatment of GB.

#3126 H3B6527, a selective and potent FGFR4 inhibitor for FGFR9-driven hepatocellular carcinoma. Anand Selvaraj, Erik Corcoran, Heather Coffey, Sudeep Prajapati, Ming-Hong Hao, Nicholas Larsen, Jennifer Tsai, Takashi Sato, Kana Ichikawa, Julie Jaya Joshi, Raelene Hurley, Jeremy Wu, Chia-Ling Huang, Suzanna Bailey, Craig Karr, Pavan Kumar, Victoria Rimkunas, Crystal Mackenzie, Nathalie Rioux, Amy Kim, Sandeep Akare, George Lai, Lihua Yu, Peter Fekkes, John Wang, Markus Warmuth, Peter Smith, Dominic Reynolds. H3 Biomedicine Inc., Cambridge, MA.

Hepatocellular carcinoma (HCC) has limited treatment options and generally poor prognosis. Recent genomic studies have identified FGFR9 as a driver oncogene in HCC. HGF19 is a gut secreted hormone that acts in the liver through FGFR4 to regulate bile acid synthesis. Consistent with the notion that FGFR9 is a driver oncogene in HCC, transgenic mice overexpressing FGFR9 form liver tumors and genetic ablation of FGFR4 prevented tumor formation. These data suggest targeting FGFR4 would have therapeutic benefit in HCC with altered FGFR9 signaling. While a number of Pan-FGFR inhibitors are being clinically evaluated, their application to FGF19-driven HCC may be limited by their chemical and cellular selectivity assays showed that H3B-6527 is >300 fold selective towards FGFR4 compared to other FGFR isoforms. Addition of H3B-6527 to FGFR9 amplified HCC cell lines led to dose dependent inhibition of FGFR9 signaling and concomitant reduction in cell viability. In a panel of 40 HCC cell lines, H3B-6527 selectively reduced the viability of cells that harbor FGFR9 amplification and showed no effect in FGFR9 non-amplified HCC cell lines. Oral dosing of H3B-6527 to mice led to dose-dependent phenotypic modulation of FGFR4 signaling and tumor regression in FGFR9 altered HCC cell line derived xenograft models. H3B-6527 demonstrated inhibition of tumor growth in an orthotopic liver xenograft model of FGFR9 altered HCC grown in nude mice. Importantly, the inhibition of tumor growth occurred at doses that were well tolerated in mice and no evidence of FGFR1-3 related toxicities were observed at efficacious doses. In a panel of 30 HCC patient-derived xenograft (PDX) models, H3B-6527 demonstrated tumor regres-
sions in the context of FGF19-amplified tumors. In addition, H38-6257 showed antitumor activity and tumor regressions in PDX models with high FGF19 expression but no FGF19 amplification. The mechanism for FGF19 overexpression in the absence of gene amplification is under investigation. In conclusion, our preclinical studies demonstrate that FGF19 expression is a predictive biomarker for AR resistance and that inhibition of FGF19 activity by bimagore effectively abrogates up-regulatory data sets indicates that at least approximately 30% of HCC patients exhibit altered FGF19 expression and could potentially benefit from H38-6257 monotherapy treatment.

#3127 Roles of ERKs-RSK2 signaling in human cancers. Yong Yeon Cho. The Catholic Univ. of Korea College of Pharmacy, Bucheon-si, Republic of Korea.

RSK2 is a member of p90RSK superfamily consisting of RSK1-4 and MSK1-2, and has suggested involving in many cellular processes including cell proliferation, differentiation, transformation and cancer development. Accumulating data obtained by our 16-year researches strongly demonstrated that RSK2 is a key player in cell transformation and cancer metastasis. We found that ectopic expression of RSK2 induced anchorage-independent cell transformation. Notably, knockdown of RSK2 strongly suppressed constitutive active-Ras (CA-Ras)-induced foci formation, EGFR-induced cell transformation and cancer cell growth in anchorage-independent condition. The results obtained from human skin cancer tissue array demonstrated that total protein levels and RSK2 activity were higher in cancer tissues than that of normal tissues. Molecular targeting of RSK2 or ERK1 and 2 with 2 natural compounds demonstrated that ERKs-RSK2 signaling pathway plays a key role in cell transformation and cancer development. Moreover, inhibition of ERKS-RSK2 signaling suppressed NF-κB activity in BCC41 cells. The EGFR-induced NF-κB activity was abrogated upon regulation of COX-2 mRNA expression and COX-2 protein levels by inhibition of ERKs-RSK2 signaling pathway. Interestingly, magnolin, a specific inhibitor of ERK1 and ERK2, suppressed ERK-mediated MMP-2 and NF-κB-mediated MMP-9 expression. In addition, we found that the protein expression of N-cadherin involved in metastasis was markedly attenuated by inhibition of ERKS-RSK2 signaling pathway. Notably, magnolin suppressed the migration and invasion of lung cancer cells in a dose-dependent manner. Taken together, these results demonstrated that targeting of ERKs-RSK2 signaling is beneficial for the chemoprevention, and anti-invasion and -migration in cancer metastasis. Key words: MAPK pathway, Transformation, Metastasis, Molecular targets

#3128 TRPM7 regulates gloma cell proliferation and migration through different function domains. Mingli Liu. Morehouse School of Medicine, Atlanta, GA.

Background: Transient Receptor Potential Melastatin-related 7 (TRPM7) is a non-selective cation channel fused with a functional kinase domain. TRPM7 channel expression is aberrant in numerous cancers. We have previously reported that suppression of TRPM7 inhibits the proliferation, migration, and invasion of malignant human gloma cells using A172 gloma cell line and brain tissue of human glioma [CNS Neuroscience & Therapeutics 2015, 21(3):52-61]. We further found that TRPM7 channels regulate gloma stem cell growth/proliferation through STAT3 and Notch signaling pathways [Cellular Signaling, 2014, 26: 2773-2781]. Since TRPM7 is a bifunctional protein with channel and α-kinase domain, we next investigated whether the changes in glioma cell proliferation and migration might be caused through channel domain-mediated and/or kinase domain mediated TRPM7 activation. Methods: 1) A172 cells expressing wild-type human TRPM7 (wtTRPM7) or constructs in which the α-kinase domain was deleted (Δkinase) or rendered inactive with a point mutation in the ATP binding site of the α-kinase domain (K1648R) were studied. 2) The effects of TRPM7 on glioma cell proliferation and invasion were determined using MTT assay and transwell invasion assay by TRPM7 expression using wt-TRPM7, Δkinase, and K1648R, respectively. Results: 1) Treatment of A172 cells with Δkinase and K1648R significantly increased TRPM7 expression demonstrated by Western blot assay. 2) The cell invasion was significantly reduced when treated with Δkinase and K1648R which indicate that TRPM7 kinase activity is required for changes in cell migration and invasion. 3) The cell proliferation was not significantly changed when treated with Δkinase and K1648R which indicate that TRPM7 channel rather than kinase activity is required in cell growth of A172 cells. Conclusion: TRPM7 regulates glioma cell proliferation and migration/invasion through different function domains. The channel activity of TRPM7 is required for the cell growth while the kinase domain is required for the cell migration/invasion. The finding is important for designing and developing drugs targeting TRPM7 in human malignancies.

#3129 Patient-derived xenografts (PDXs) recapitulate the antitumor activity of novel therapies in metastatic breast cancer (MBC) patients (pts). Mafalda Oliveira,1 Javier Pascual,2 Cristina Cruz,2 Alberto Gris,3 Marta Palafox,1 Alba Llop,1 Marta Castroviejo,1 Cristina Viaplana,1 Yasir H Ibrahim,3 Joaquin Arribas,1 Javier Cortés,3 José Baselga,3 Jordi Rodal,3 Judith Balmmana,3 Rodrigo Diestmanna,3 Cristina Saura,1 Violeta Serra1, Vail d’Hebron Institute of Oncology, Barcelona, Spain; 2Hospital Universitario Virgen de la Victoria, Malaga, Spain; 3Blenis Lab, Weil Cornell Medicine, New York, NY; 4Hospital Ramón y Cajal, Madrid, Spain; 5Memorial Sloan Kettering Cancer Center, New York, NY.

PDXs are preferred laboratory models that recapitulate the biology of pts tumors to be used to assess if the antitumor activity of novel therapies in PDXs correlates with the observed activity in the corresponding MBC patient, which would support cross-analysis of drug/genotype vulnerabilities. MBC pts eligible for clinical trials were offered a research biopsy and establishment of PDX, under an IRB-approved protocol. Biopsies were implanted in nude mice subcutaneously. Upon successful engraftment, models were expanded for drug testing, specifically with the same drug/combo given to the patient. This is a retrospective analysis of our MBC patient/PDX (P/PDX) co-clinical trial cohort. Pts’ outcomes were measured as: RECIST response, clinical benefit [CB: partial response (PR) or stable disease (SD) >4 months], and time to progression [TTP: time until RECIST progressive disease (PD), in months]. PDX endpoints were measured as: TTP (time until 25% increase in tumor volume, in days), response (PR or CR, in % of area under the curve (AUC) of treated tumor area versus vehicle. A consistent P/PDX response was defined as CB in pts whose paired PDX showed PR/SD, or no-CB in pts whose paired PDX showed PD. Pts outcomes and PDX endpoints were correlated using Spearman’s test. We identified 10 MBC pts (7 TNBC, 3 HR+; all biopsies from skin/subcutaneous lesions) with corresponding PDX, treated with paired therapies (7 molecularly matched); 3 lurbinectedin (BBRCA1-mut, 3 olaparib (BBRCA1-mut), 1 AZD9563 + fulvestrant (AKT1-mut), 1 AZD5363 + palbociclib, 1 buparlisib, 1 eribulin. In 9/10 cases we found concordant P/PDX responses (6 cases with no-CB in patient/PD in PDX, 3 with CB/SD; and 1 lurbinectedin case with no-CB/PR). Two pts had biopsy for PDX implantation at progression of paired therapy and were excluded from TTP analyses. In cases with discordant P/PDX response, we found significant correlation between RECIST response in pts and rAUC in PDX (p=0.82, p=0.03), a trend for comparable TTP in pts and TTP in PDX (p=0.67, p=0.10), but no correlation between RECIST response in pts and response at week 3 in PDX (p=0.46, p=0.30). In this cohort of MBC pts, we found high concordance in Pt/PD response. Our results suggest that rAUC in PDX may be the best read-out to identify relevant drug/genotype associations that can potentially be translated to patient benefit. Data will be updated with additional ongoing PDX experiments.

#3130 CYP3A5 positively regulates androgen receptor signaling in prostate cancer cells: Potential for therapeutic targeting. Ranjana Mitra, Priyamath Gorgala, Oscar B. Goodman. Rosenman University of Health Sciences, Las Vegas, NV.

Purpose: Prostate cancer is the most common malignancy and second leading cause of cancer-specific mortality in US men. The androgen receptor (AR) plays a major role in promoting growth and progression of prostate cancer and thus has been successfully targeted therapeutically. Therapeutic resistance to androgen deprivation therapy (ADT) accounts for much of the morbidity and mortality attributable to prostate cancer. Therapeutic resistance is typically accompanied by insufficient blockade of AR activation, whose initial step involves translocation of AR to the nucleus. Previously we demonstrated that CYP3A5 facilitates the nuclear translocation of AR, promoting prostate cancer growth. Targeting CYP3A5 and blocking AR nuclear translocation may override therapeutic resistance to ADT, representing a novel approach for treating men with advanced prostate cancer. This work focuses on understanding the role of CYP3A5 in regulating AR nuclear translocation process and its subsequent promotion of prostate cancer growth.

Methods: AR nuclear translocation and confocal microscopy are high throughput methods for measuring data obtained by our 16-year researches strongly demonstrated that CYP3A5 facilitates the nuclear translocation of AR, promoting prostate cancer growth. Targeting CYP3A5 and blocking AR nuclear translocation may override therapeutic resistance to ADT, representing a novel approach for treating men with advanced prostate cancer. This work focuses on understanding the role of CYP3A5 in regulating AR nuclear translocation process and its subsequent promotion of prostate cancer growth. Methods: AR nuclear translocation and confocal microscopy are high throughput methods for measuring data obtained by our 16-year researches strongly demonstrated that CYP3A5 facilitates the nuclear translocation of AR, promoting prostate cancer growth.
antibodies with A/G beads for immunoprecipitation. Results: Our co-immunoprecipitation experiments using CYP3A5-Flag transfected LNCaP cells extracts demonstrate that CYP3A5 associates with the HSP90-AR complex that helps to maintain AR in a form that can be readily activated by androgen.

Using Flag-agarose in co-immunoprecipitation experiments, we demonstrated that CYP3A5 is a component of the HSP90-AR complex with AR, HSP90, and HSP40 which are chaperones regulating AR nuclear translocation. We further confirmed the presence of CYP3A5 in the HSP90-AR complex by co-immunoprecipitation using HSP90 and AR antibodies in combination with A/G beads instead of flag-agarose. Conclusion: Our current findings support the notion that CYP3A5 is a part of the HSP90-AR complex and positively regulates AR nuclear translocation. Therefore, targeting CYP3A5 to block AR nuclear translocation may be a therapeutic adjunctive approach in advanced prostate cancer.

#3131 Ubiquitin ligases: a new target for RNAi therapy of hepatocellular carcinoma. Dominique Leboeuf,1 Timofei Zatsepin,2 Daniel G. Anderson,3 Konstantin Piatkov4,5, Skolkovo Institute of Science and Technology, Moscow, Russian Federation; 2Koch Institute for Integrative Cancer Research at MIT, Cambridge, MA.

Hepatocellular carcinoma (HCC) is the fifth most common cancer worldwide and the third leading cause of cancer-related deaths in the world. HCC is a very aggressive cancer, resistant to all conventional chemotherapies and capable of acquiring resistance to Sorafenib, which is the only approved chemotherapeutic drug for HCC. This highlights the need to look for new therapeutic options and improve the survival of patients with advanced HCC. The N-end rule pathway is an emerging player in the field of cancer biology, because of its capacity to positively regulate many hallmarks of cancer including angiogenesis, cell proliferation, motility and survival. Therefore, the N-end rule pathway offers the potential to be a target for highly effective anti-tumor treatment. The aim of this study is to investigate the role of the N-end rule pathway in the context of hepatocellular carcinoma in vivo. We used siRNA-mediated RNA interference as the main approach for selective downregulation of the four N-end rule-dependent cognate ubiquitin ligases: UBR1, UBR2, UBR4 and UBR5. Initial screening of siRNAs was performed in Hepa 1-6 cells, followed by in vitro phenotyping using proliferation assays, migration assays, and TUNEL assays. The most potent siRNA against Ubr1, Ubr2, Ubr4 and Ubr5 were formulated into lipid nanoparticles (LNPs) and injected into mice in order to modulate the function of the N-end rule in vivo. We have confirmed that Ubr1, Ubr2, Ubr4 and Ubr5 are overexpressed in Hepa 1-6 cells and in mouse liver tumors, in comparison to normal liver. Upon transfection of siRNAs in Hepa 1-6 cells or injection of LNPs loaded with the same siRNAs into mice, we obtained successful down regulation of Ubr1, Ubr2, Ubr4 and Ubr5 both in vitro and in vivo (in the liver and in tumor tissues). We have also demonstrated that down regulation of these four Ubr proteins negatively affects cell migration and proliferation, and renders cells more susceptible to apoptosis. Bi-weekly injections of the LNPs for mice for up to 6 weeks efficiently downregulates the expression of Ubr1, Ubr2, Ubr4 and Ubr5 without any toxic effects. Indeed, we found no significant increase of ALT, AST or total bilirubin in the blood compared to controls.

Considering that all four Ubrs are upregulated in HCC and that the N-end rule plays a major role in many key pathways of cancer development, we expect that even a partial down regulation of this pathway will have prominent effects on tumor development and progression due to the suppression of tumor vascularization, cell proliferation and viability.

#3132 Inhibition of the integrin αvβ3 improves the effect of bexarotene in the treatment of cutaneous T-cell lymphoma (CTCL). Florencia Caryol,1 Victoria Revueta,2 Alejandro Paulazo,1 Mercedes Debernardi,3 Maria Celeste Diaz Flaque,1 Helena Sterle,1 Leandro Cerchietti,2 Graciela Cremaschi1.

CTCL are exposed to a complex paracrine and endocrine environment that influence their progression from skin to visceral disease. One of the most common treatments for CTCL is RXR agonists or “rexinoids” such as bexarotene (BEX). The most prevalent side effect of rexinoids (~95% of patients) is the development of hypothyroidism hence these patients are prophylactically treated with thyroid hormone (TH). Paradoxically, we recently found (PMID: 25488971) that TH can activate transcriptional programs required for proliferation of CTCL. We also found that the effects of TH on CTCL are mediated through the activation of two different receptors, the classical nuclear TR and a membrane receptor integrin αvβ3. Our aim was to study how the anti-lymphoma activity of BEX is modified by the activation of TR and αvβ3 during the TH replacement therapy, and unknown topic with clinical implications. We first evaluate the cell viability of CTCL cells HuT78 and M1 treated with BEX in presence and absence of physiological levels of TH. As expected, BEX decreased the viability of CTCL cells, however in presence of TH both effects decreased by 25-60% and 20-50% on HuT78 and M1 cells. However, hypothyroidism is associated with a higher dissemination of TCL cells in syngeneic mice. Thus, to evaluate the impact of TH replacement therapy in BEX-treated mice, we implanted TCL EL-4 cells subcutaneously in C57BL/6 mice. When tumors reached ~75 mm3, mice were randomized in three groups: vehicle, bexarotene alone (BEX) and bexarotene with T4 replacement (to reach euthyroidism) (BEX-T4). Tumor growth significantly decreased in both bexarotene arms (vs. vehicle). However, in contrast to mice receiving BEX-T4, mice receiving BEX alone showed a decreased infiltration of tumor-suppressive immune cells. Specifically, these tumors had decreased NK and CD3+CD8+ cells due to BEX-induced hypothyroidism. This indicates that although TH could decrease the effect of BEX in CTCL cells, the hypothyroidism would impact in the local antitumor response. Thus determine if the inhibition of the non-canonical TH membrane receptor integrin αvβ3 would decrease the pro-survival effect of TH on CTCL treated with BEX. We found that either, αvβ3 silencing or the pharmacological inhibitor Cilengitide, not only avoided the pro-survival effect of TH but increased the anti-lymphoma activity of BEX-T4 by 15-35% in CTCL cells. To evaluate the molecular program underpinning these effects, we conducted RNA-sequencing in HuT78 cells treated with BEX-T4 in presence of siRNA for THR, αvβ3 or controls. Among the top pathways we identified genes involved in “apoptosis” and “IL6-JAK-STAT3 signaling” as differentially expressed in si-αvβ3 vs. the others. These genes were independently validated by using Cilengitide. Our data suggest that inhibition of the non-canonical TH receptor, the integrin αvβ3, could be an effective strategy to improve BEX treatment in CTCL.

#3133 NF-κB-dependent inflammatory responses offset sorafenib cytotoxicity in hepatocellular carcinoma via TIFA. Tong-You Wade Wei,1 Pei-Yu Wu,2 Ting-Jung Wu,2 Ming-Daw Tsai1, Academia Sinica, Nangung Dist., Taiwan; 3Chang Gung Memorial Hospital, Linko, Taiwan.

Sorafenib is the promising first-line drug to treat advanced hepatocellular carcinoma (HCC), with the acquired resistance within 6 months in most treated patients. The epithelial-mesenchymal transition (EMT)-driven cancer metastasis contributes to sorafenib resistance via multiple signaling pathways, but the underlying molecular mechanism remains elusive. Recent studies showed that inflammatory cytokines TNF-α functionally initiates EMT through NF-κB-mediated Snail activation in HCC, and that TRAF-interacting protein TIFA sustains the positive feedback loop between TNF-α and NF-κB that enhances chemoresistance in AML. Here we investigated the functional link between TIFA-regulated NF-κB inflammatory signaling and sorafenib resistance as a potential therapeutic target in the treatment of HCC. We showed that severe hepatitis induced in HCC mice promoted intrahepatic metastasis concurrently with NF-κB-driven EMT via Snail, and that HCC patients with hepatitis displayed poorer responses to sorafenib and unfavorable clinical outcome. In support, inflammatory TNF-α stimulation promoted levels of TIFA, NF-κB signaling factors, and EMT axis independent of sorafenib treatment, while silencing of TIFA abrogated sorafenib-dependent EMT. Silencing TIFA or RelA perturbed sorafenib-dependent cytokine secretion in HCC cells. In addition, silencing of TIFA or RelA suppressed pro-survival factors Bcl-2 and Bcl-XL, and promoted pro-apoptotic factor BAX in response to sorafenib treatment in vitro. Consequently, HCC cells regained sorafenib chemosensitivity upon silencing of TIFA or RelA through promoted apoptosis. To further explore the therapeutic relevance, siRNAs were delivered using the liver-tropic adeno-associated virus serotype 8 in mice with orthotopic HCC xenografts, and results showed that targeting TIFA or RelA specifically enhanced sorafenib chemotoxicity resulting in more prominent tumor regression. Our results collectively showed that TIFA and NF-κB support inflammatory responses to offset sorafenib cytotoxicity, and that their targeting are therapeutically effective concomitant with sorafenib treatment in HCC.

The incidence of thyroid cancer (TCA) has doubled in the last decade. Papillary thyroid cancer (PTC), which comprises of 80% of all TCs, is treatable with great outcomes. However, undifferentiated anaplastic thyroid cancer (ATC), with very poor prognosis, is considered a clinical challenge and currently a losing battle. Moreover, the molecular mechanisms responsible for various forms of TCA are largely unknown. We believe that the cells of histopathologi-
cally distinct regions of a heterogeneous thyroid tumor are governed by different sets of master gene regulators. The smart manipulation of such master genes will be able to selectively destroy cancer cells but not normal tissue, opening a novel and much more effective avenue in the thyroid cancer targeted gene therapy. Our analysis established the gene hierarchical governance in each region based on their Gene Commanding Height (GCH). GCH is a measure that combines the gene expression coordination with other genes and the expression stability among biological replicas provided by the internal homeostatic mechanisms. Here, we provide experimental evidence that standard papillary (BCPAP) and anaplastic (8505C) human thyroid cancer cell lines have different master regulators. We identified the master regulators of BCPAP and 8505C, and determined their GCH. Transfection of master gene regulators of a particular cell line has significantly larger effects on the cell line they command than on other cells. We found that the stable transfection with TMEM194A, a nuclear envelope protein, regulated twice more genes in BCPAP than in 8505C cells. The analysis using human thyroid cancer cells reaffirmed our hypothesis of the existence of hierarchical master gene regulators and that the phenotypic changes can be manipulated with the introduction of these genes. We further validate these concepts using human thyroid biopsy samples. We found substantial differences in the GCH scores of cancer versus normal tissue of a surgically removed 32.0mm papillary carcinoma from the left lobe of a 35y old male. Because of such differences between the cancer region and the normal tissue, manipulation of cancer regulators is expected to affect the cancer cells in a greater degree than the normal cells. These results suggest that we have defined a master gene regulator hierarchy in thyroid cancer and extrapolation of this analysis to compare anaplastic and papillary thyroid cancer will lead to novel gene therapeutic modalities. Our long-term goal is to identify master regulators of cancer nodules for each patient and develop personalized cancer therapy targeting these master regulators.

**#3135 Benzaldehyde suppresses the binding activity of overexpressed 14-3-3 to multiple signaling proteins in cancer cells.** Jun Saitoh, Hideyuki Saya. Keio Univ School Of Med, Shinjuku Ku Tokyo, Japan.

Benzaldehyde is the simplest aromatic aldehyde constituent of almonds and many fruits. Anticancer effect of Benzaldehyde was first reported in 1980, and multi-institutional clinical trials were performed in those days in Japan. However, trial was over without determination of effectiveness, only its’ safety was confirmed. The underlying mechanism why Benzaldehyde specifically suppresses growth of some particular cancer cells but not that of normal cells has not been elucidated. Therefore, we attempted to clarify the mechanism of anticancer effect of Benzaldehyde. We have previously reported that, in pancreatic cancer cell BxPC3 and in non-small cell lung cancer cell A549, Benzaldehyde inhibits PKA/akt/mTOR, STAT3, NFkB and ERK pathways, those are major signaling pathways activated in cancer cells. Effects of Benzaldehyde on multiple signaling pathways are found to be derived from regulation of 14-3-3 family proteins which interact with phosphorylation sites of various proteins of multiple signaling. In BxPC3 cells, Benzaldehyde treatment reduced the phosphorylation levels of 14-3-3 binding sites. More, we ecotopically expressed seven isoforms of 14-3-3 in HEK293T cells and found that Benzaldehyde treatment significantly suppressed phosphorylation of 14-3-3 with client proteins such as PKA/akt/mTOR, STAT3 and FOXO. The interaction of other isoforms of 14-3-3 with their client proteins was also partially reduced. But, the expression levels of those seven 14-3-3 isoforms were not significantly changed. Here we further analyze the Benzaldehyde-mediated 14-3-3 regulation, in HEK293 cells overexpressing 14-3-3. Benzaldehyde significantly suppressed mTOR pathway while it was not observed in parental HEK293 cells. Furthermore, we performed pull down assay by using 14-3-3 GST tagged recombinant proteins and lysates of HEK293T and BxPC3 and found that Benzaldehyde treatment suppressed the interaction of 14-3-3 with cRaf, TSC2 and other 14-3-3 client proteins. From these data, we confirmed that Benzaldehyde is an inhibitor of the overexpressed 14-3-3. Recent reports have shown that 14-3-3 is overexpressed in many cancers and acts as a signaling hub controlling the network of oncogenic pathways, suggesting that overexpressed 14-3-3 associates with carcinogenesis, metastasis and resistance for chemotherapy and radiation. Hence, Benzaldehyde is considered to be a new molecular target agent of 14-3-3, which promote and maintain cancer signals.

**#3136 Unveiling the therapeutic potential of Tanshinone I on telomerase activity and shelterin complex in myeloma.** Raman Kumar, Rehan Khan, Nicki Gupta, Tulika Seth, Alpana Sharma. All India Institute of Medical Sciences, New Delhi, India.

Background and Objectives: Multiple myeloma (MM) defines as monoclonal antibody producing abnormal plasma cells inhibiting bone marrow (BM). It involves multiple genetic mutations where different signaling pathways get deregulated hence showing malignant features of myeloma. Increased relative telomerase activity (RTA) and altered levels of shelterin complex molecules (TRF1, TRF2, POT1, RAP1, TIN2, TPP1) along with its associated molecules (TANK-1 & PINX1) are underlying principle behind several malignancies. This maiden attempt aims to evaluate the impact of these geno-phenotypic levels on telomerase activity and shelterin complex. Methodology: Newly diagnosed 50 MM patients & 20 controls were recruited for BM aspiration with their consent. RTA, mean telomere length, relative mRNA and protein levels were studied in study subjects. Clinical parameters were recorded; correlation was studied between all the studied genes at mRNA levels and between genes and patients’ clinical parameters; ROC curves were plotted of all genes. Anti cancer potential of Tan1 and lenalidomide or their combination were studied with different assays on myeloma cells (RPMI8226 & U266). Results:Significantly (p<0.05) high relative mRNA expression were found of all molecules except PINX1 which was significantly lowered in patients compared to controls and was correlating with disease severity and progression. Similarly, higher RTA and lowered mean telomere length was observed in patients. Statistically significant correlation was observed between genes, telomerase activity and with clinical parameters. ROC curves analysis showed high sensitivity and specificity for TRF2 genes and Telomerase activity. Thus, RTA and shelterin complex along with associated factors does play role in causing myeloma and its progression. Tan1 caused significant toxicity at low doses in myeloma cells while lenalidomide caused significantly reduced toxicity. Cell death was enhanced when combination of both (Tan1 + lenalidomide) drugs were used as observed in Annexin-V/PI and Tunel assay. Tan1 and its combination with lenalidomide significantly down regulated protein expression of TANK1, TPP1, and RAP1 in myeloma cells compared to untreated cells. Conclusions:In nutshell, study implies that increased RTA along with altered mRNA and protein expression of shelterin complex molecules with its association in patients might play role in progression and progression of MM. Stage-wise significant increased expression and correlation of these molecules with each other and with clinical parameters showed their role as potential bio-marker in MM. Significant down-regulation of RTA and apoptosis by Tan1 alone or combination with lenalidomide suggests that Tan1 might have synergizing effect with lenalidomide in causing cytotoxicity in Myeloma.

**#3137 Breast cancer anti-estrogen resistance 4 (BCAR4) is a novel oncogene in lung cancer.** Kieun Bae, Minkyong Lee, Daseul Yoon, Y-H Kim, Kyong-Ah Yoon. Kyung Hee University, Seoul, Republic of Korea; 2Graduate School of Cancer Science and Policy, National Cancer Center, Goyang, Republic of Korea.

BCAR4 was identified as tamoxifen related gene in breast cancer due to its function to activate estrogen-independent cell growth. Instead of estrogen receptor, ERBB2 and ERBB3 genes were activated by BCAR4 in tamoxifen resistant cells. Recently, the function of BCAR4 as a long non-coding RNA (lncRNA) was reported to regulate a non-canonical Hedgehog/GLI2 pathway in breast cancer. However, the association of BCAR4 and lung cancer has not been identified. Here, we describe the oncogenic effect of BCAR4 in human lung cancer. Expression pattern of BCAR4 was examined in lung cancer cell lines, primary tumor tissues, and adjacent normal tissues. BCAR4 was highly expressed in 71% of lung cancer cell lines and especially in 43% of cancer tissues of lung adenocarcinoma patients who did not harbor the activation mutations of EGFR nor KRAS. Exogenous expression of BCAR4 protein promoted cell growth of non-tumorigenic bronchial epithelial cell line, BEAS-2B, and lung cancer cell line, NCI-H1299. We also confirmed the oncogenic feature of BCAR4 by colony forming assay using stably expressing cells. These effects were notably reduced after knockdown of BCAR4 by small interfering RNA. BCAR4 encoded a functional protein and its overexpression resulted in the enhanced migration than controls cells. This result proposed a similar role of BCAR4 in lung cancer considering its previously reported role in breast cancer metastasis. We also detected a fusion gene of BCAR4 in a lung cancer tissue by analyzing RNA-sequencing data. BCAR4 protein as well as its fusion form showed the improved tumorigenic feature in the mouse xenograft model with lung cancer cells. We compared the gene expression pattern in BCAR4 overexpressed cells to identify the possible mechanism of the oncogenic effect of BCAR4. Cyclin D1, Cycin E, and MMP1 mRNA and protein levels were significantly increased after BCAR4 overexpression. However, downstream genes of GLI2 signaling were not altered by protein expression of BCAR4 arguing an alternative role for lncRNA BCAR4. Our results suggest a novel oncogenic role of BCAR4 protein in lung cancer.
**EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Molecular Medicine**

PHY906(YIV-906), a four-herb Chinese medicine formulation, is inspired by an 1800-year-old Chinese formulation called Huang Qin Tang historically used to treat gastrointestinal symptoms. PHY906 can increase the anti-tumor activity of immunotherapy antibodies or chemotherapies while promoting damaged intestinal tissue recovery. Several clinical studies showed that PHY906 had potential to improve therapeutic index and treat radiation-induced gastrointestinal damage by prolonging life and improving patient quality of life. When in vivo activities of three different clinical batches (number 6, 10, 11) of PHY906 and F (which is commercial batch of Huang Qin Tang, HQT) was compared to their similarity of chemical profiles, the two set results could not be completely matched. For example, F had very different in vivo activities from PHY906-10 but F clustered closely to PHY906-10 based on their chemical profiles. This information concludes that chemical profile analysis without excluding irrelevant chemicals is not sufficient to evaluate the in vivo activities of a polychemical mixture. Therefore, we included another two biological platforms based on the in vivo mechanism of action of PHY906 for the quality control. First, we tested the activity of different batches of PHY906 and F on our signaling transduction activity response (STAR) platform which including 18 luciferase reporter cell lines and 2 enzymatic assays. The results of correlation analysis and clustering analysis based on the results from STAR could be matched to in vivo activities of different batches of PHY906 and F. Second, we tested the effect of different batches of PHY906 and F on a set of genes which based on our previous DNA array data in cell culture and the mechanism action of PHY906. Again, the results of these in vitro analysis and clustering on tissue sample-PDX could be matched to in vivo activities of PHY906 and F. In conclusion, the quality control of a herbal product should be dependent on its usage. Appropriate biological assays based on its mechanism action should be developed for QC for particular usage. Chemical fingerprint has limitation unless irrelevant chemicals had been filter out. Similarity index is only useful when relevant information is used. Mechanism based quality control could be used for other herbal products.

**#3139 In vivo functional analyses of cancer gene variants for cancer driver identification and drug discovery**

Jingjiong Jiang, 1 Tengfei Yu, 2 Ying Yan, 2 Wei Du, 1 Tingting Tan, 1 Xuqin Yang, 1 Jiali Gu, 1 Ling Qiu, 1 Xin K. Ye, 2 Zhenyu Gu. 1 GenenDesign USA Co., Ltd., Menlo Park, CA; 2 GenenDesign Co., Ltd., Shanghai, China.

Precision oncology requires identifying and understanding of cancer genome changes in a patient tumor tissue and finding the best cancer therapy targeting the changes. Although many cancer gene targets have been validated so far, next-generation genomic profile analyses have uncovered much more cancer gene variants with unconfirmed functions. Developing methods to functionally evaluate these variants and understand their impact on drug-resistance and drug responses, such as drug resistance or synthetic lethality, will be critical in cancer treatment decision support. In addition, in some clinical cases, multiple treatment choices such as multiple drug combinations exist. Developing cancer models which can test multiple treatments will provide direct comparison of those therapies and select the best options. At GenenDesign, we have performed drug tests on mouse “avatars”, which are also known as Patient-Derived Xenograft (PDX) models. They are personalized cancer models derived from patient tumor samples with cancer mutation profiles and drug responses very similar to the corresponding cancer patients. Drug screenings were carried out in avatars by testing chemotherapies or targeted drugs against specific cancer gene mutations and variants. Selected drugs or drug combinations from avatar studies have been applied to corresponding patients with highly consistent treatment outcome. From genomic profile analysis of our near 1500 PDX tumor models in cancer types such as lung, colorectal, gastric, liver, and esophageal, we are able to identify a large number of cancer gene mutations/variants, gene fusions, as well as gene copy number and RNA expression changes in major cancer signal pathways such as EGFR, HER2, c-Met/ALK, Ras/Raf, FGFRs, PI3K/Akt, Wnt/β-Catenin, cell cycle regulation, angiogenesis. Many of these gene aberrations are potential drug targets and have been functionally tested in PDX models with approved drugs or clinical drug candidates. The mutation/variant information and drug response information generated from PDX models have been organized into our Precision Cancer Information Lab database. Patient tumor DNA test results have been used for searching genetically matched PDX models in our database. Once matched PDX models are identified, the available drug response information can be used as evidence for clinical treatment decision. In addition, the matched PDX models can also be used to test more treatment options such as different combinations and new clinical drug candidates.

---

**#3140 MUC1 expression as a prognostic marker and a new therapeutic target in patient with duodenal adenocarcinoma**

Satomi Shiba, Atsushi Miki, Hideyuki Ohzawa, Takumi Teratani, Yasunaru Sakuma, Joji Kitayama, Alan Kawari Lefer, Naohiro Sata. Jichi Medical University, Shimoisuke-si, Japan.

Background: Mucin1 (MUC1) is a glycoprotein as a member of the mucin family. This expression has been associated with poor prognosis in patients with several types of cancer. Duodenal cancer is rare, therefore details are not known including carcinogenesis and clinical treatment. We verify the association of MUC1 expression and prognosis in patient with duodenal adenocarcinoma. We also assess the function of MUC1 in vitro. Materials and Methods: Between 1989 and 2014, eighteen patients of duodenal adenocarcinoma with surgery at Jichi Medical University Hospital were included in this study. MUC1 expression was evaluated immunohistochemically with anti-MUC1 antibody to examine the association of MUC1 expression and prognosis clinicopathologically. A human-derived duodenal cancer cell line, HuTu-80, is used for the experiments of invasiveness and proliferation in vitro. The invasive capacity was evaluated by transfection of siRNA into HuTu80 with matrigel invasion assay. Viability assay with the anti-MUC1 peptide GO201 was assessed to determine whether MUC1 associate with cell growth of duodenal adenocarcinoma. Results: Seven cases were MUC1 positive and 11 were MUC1 negative immunohistochemically. TNM staging was not associated with MUC1 expression. Kaplan-Meir analysis showed a poor prognosis with MUC1 positive patients in cumulative overall survivals (MUC1 positive, 18M : 52M, 95%CI 3.247-130.7, p=0.002). Lymph node metastasis of MUC1 positive patients (71.4%) was significantly higher than MUC1 negative patients (9%) (p = 0.01). In vitro expression of the MUC1 was confirmed by RT-PCR and flowcytometry. Knockdown experiment with transduction of siRNAs to HuTu80 decreased the expression of the MUC1 gene. Transduction of siRNAs significantly reduced invasive capacity (47.02 ± 21.65%, 95%CI 3.046-102.9, p = 0.04). Growth of HuTu80 cells was inhibited by GO201 (5 μM : 95%CI 0.109-0.356, 10 μM: 95%CI 0.024-0.389 p<0.0001). Conclusions: MUC1 expression is a predictive marker for poor prognosis in patients with duodenal adenocarcinoma. Functional Interference of MUC1 core protein reduces cell growth and invasiveness. Taken together, MUC1 is associated with malignant potential and a novel target for the treatment.

**EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Molecular Targeted Therapies 1**

**#3141 Combined cetuximab and pemetrexed therapy enhances cytotoxicity against crizotinib-resistant non-small cell lung cancer cells by downregulating thymidylate synthase.**

Hwang-Phil Kim, 1 Sae-Won Han, 2 Sang-Hyun Song, 1 Tae-You Kim2, 1 Seoul National Univ. Cancer Research Inst., Seoul, Republic of Korea; 2 Seoul National University Hospital, Seoul, Republic of Korea.

Although non-small cell lung cancer (NSCLC) cells with anaplastic lymphoma kinase (ALK)-rearranged initially show a dramatic response to crizotinib, these cells eventually develop resistance to crizotinib. This resistance is caused by secondary mutations and copy number gain in the ALK gene. However, other resistance mechanisms through activation of the bypass tracts have yet to be clearly elucidated. To investigate the mechanisms of acquired resistance to ALK fusion-directed treatment in NSCLC, we generated crizotinib-resistant NSCLC cell lines in vitro through chronic exposure of an ALK fusion NSCLC line (SNU2292) to crizotinib. Interestingly, the resultant SNU2292-CR cells maintained activation of epidermal growth factor receptor (EGFR) and expressed increased levels of transforming growth factor alpha (TGFA-α), an EGFR ligand. Additionally, we found that thymidylate synthase (TS) was overexpressed in SNU2292-CR cells compared with the parental cells. We showed reduction of TS enhanced synergistic inhibition of cell proliferation when cetuximab, an EGFR inhibitor, was combined with pemetrexed, a TS inhibitor. As a result, combined therapy was found to exhibit a synergistic growth inhibitory effect against crizotinib-resistant cells by downregulating TS expression. Taken together, these results support a potential role of activation of the bypass tracts in acquired resistance to ALK-directed treatment in ALK-rearranged NSCLC, and provide insights into strategies for preventing and/or overcoming this resistance in patients.

**#3142 Abrerrantly expressed microRNAs drive the development of acquired Erlotinib resistance in non-small cell lung cancer.**

Arita S. Pal, 1 Alejandro Agredo, 2 Andrea L. Kasinska, 2 Purdue University, West Lafayette, IN; 2 Universidad Nacional de Colombia, Bogota, Colombia.
Lung cancer is the leading cause of cancer-related deaths in the world. Non-small cell lung cancer (NSCLC) accounts for ~85% of the cases. NSCLC patients frequently harbor causal gene mutations. Epidermal Growth Factor Receptor (EGFR), an NSCLC causal gene, is mutated in 10-35% of NSCLC patients. Patients with EGFR activating mutations are treated with a tyrosine-kinase inhibitor, Erlotinib, specifically targeting EGFR. However, most patients develop Erlotinib resistance within a year. Although multiple mechanisms are involved in the development of Erlotinib resistance, the role of microRNAs in mediating Erlotinib resistance is largely unexplored. MicroRNAs (miRNAs) are small non-coding RNAs that regulate normal cellular physiology. In cancers, miRNAs are severely dysregulated, contributing to multiple cancer processes, including drug response. Despite the involvement of miRNAs in cancer, their direct role as drivers of drug resistance remain understudied, therefore, there is a critical need to understand the role of miRNAs in inducing Erlotinib resistance. To this end, we propose an unbiased two-prong approach to identify the miRNAs that drive the development of Erlotinib resistance. Therefore, miRNAs are either being (i) overexpressed, or (ii) silenced in Erlotinib sensitive cells with the hypothesis that perturbed miRNA levels will drive Erlotinib resistance. Erlotinib sensitive NSCLC cell lines, EKVX and H322M were identified from the NCI-60 Developmental Therapeutics Project and their Erlotinib dose response curves were established. To perform the miRNA overexpression screen, EKVX and H322M cells stably expressing renilla and firefly luciferase genes were generated, which will be used to monitor cell number and transfection efficiency, respectively. The luciferase expression will be transfected with a library of 2,019 individually arrayed human miRNAs and cell growth in the presence of Erlotinib will be monitored. The second prong of the study will identify miRNAs, that when lost, confer Erlotinib resistance. 400-fold coverage of small guide RNA (sgRNA) library of the CRISPR-Cas9 system was transduced in Cas9 overexpressing EKVX cells, to knockout ~21,000 human encoded genes (~1,800 miRNA genes). Cells are being cultured in the presence of 75% or 90% growth inhibitory concentration (GI75 or GI90) of Erlotinib so that only cells with sgRNAs against genes critical for Erlotinib response, survive and grow due to acquired resistance. DNA from these cells will be harvested, the sgRNAs sequenced, and compared to the sgRNAs present in Erlotinib-un untreated cells. Successful completion of this project will identify miRNAs that drive Erlotinib resistance and may contribute towards development of miRNA therapeutics to enhance Erlotinib sensitivity of NSCLC tumors.

**#3143 FBW7 mutations mediate resistance of colorectal cancer to targeted therapies by blocking Mcl-1 degradation.** Jingshan Tong, Shuai Tan, Fangdong Zou, Jian Yu, Lin Zhang. UPCI, Pittsburgh, PA.

Colorectal cancer (CRC), the second leading cause of cancer-related deaths in the US, has been treated with targeted therapies. However, the mechanisms of differential responses and resistance of CRCs to targeted therapies are not well understood. In this study, we found that genetic alterations of FBW7, an E3 ubiquitin ligase and a tumor suppressor frequently mutated in CRCs, contribute to resistance to targeted therapies. CRC cells containing FBW7 inactivating mutations are insensitive to clinically used multi-kinase inhibitors of RAS/RAF/MEK/ERK signaling, including regorafenib and sorafenib. In contrast, sensitivity to the targeted agents is not affected by oncogenic mutation in KRAS, BRAF, PIK3CA, or p53. These cells are defective in apoptosis due to blocked degradation of Mcl-1, a pro-survival Bcl-2 family protein. Deleting FBW7 in FBW7-wild-type CRC cells abolishes Mcl-1 degradation and recapitulates the in vitro and in vivo drug resistance phenotypes of FBW7-mutant cells. CRC cells selected for regorafenib resistance have progressive enrichment of pre-existing FBW7 hotspot mutations, and are cross-resistant to other targeted drugs that induce Mcl-1 degradation. Furthermore, a selective Mcl-1 inhibitor restores regorafenib sensitivity in CRC cells with intrinsic or acquired resistance. Together, our results demonstrate FBW7 mutation status as a key genetic determinant of CRC response to targeted therapies, and Mcl-1 as an attractive therapeutic target.

**#3144 Prediction of ALK mutations associated with acquired resistance to lorlatinib.** Satoshi Yoda, Leila Darbaid, Manrose Singh, Jeffrey A. Engelman, Alice T. Shaw, Aaron N. Hata. Massachusetts General Hospital, Charlestown, MA.

Anaplastic lymphoma kinase (ALK) rearrangements are important therapeutic targets in non-small cell lung cancer. They are currently treated with the first-generation ALK inhibitor crizotinib followed by more potent, second-generation ALK inhibitors, such as ceritinib, alectinib, or brigatinib. We reported different spectrums of ALK resistance mutations in the biopsies from patients progressing on these drugs. G1202R mutation was found more frequently after treatment with second generation ALK inhibitors. In addition to these drugs, the third-generation ALK inhibitor lorlatinib is currently being evaluated in phase 2 clinical trial. Ba/F3 models indicated that all single ALK mutants are sensitive to lorlatinib and some compound ALK mutations are resistant to lorlatinib. In this study, we performed accelerated mutagenesis screen on Ba/F3 models to predict the resistance mutations which potentially emerge in the patients treated with lorlatinib. Ba/F3 cells expressing wild type EML4-ALK or mutant EML4-ALK containing L1196F, L1196Y, I1196M, G1202R, or G1269A were exposed to N-ethyl-N-nitrosourea (ENU). After a 24-hour incubation in normal media, the cells were seeded in 96-well plates and incubated in lorlatinib for 4 weeks. ALK kinase domain was sequenced in clones growing in lorlatinib to identify possible new mutations. As a result, Ba/F3 cells harboring wild type EML4-ALK showed no mutations on ALK kinase domain. Crizotinib was used as a control to validate the efficiency of mutagenesis. We identified eight different mutations in clones growing in crizotinib, and those were reflecting the spectrum of mutations in the crizotinib-treated patients. Ba/F3 cells with mutant EML4-ALK showed additional compound mutations after incubation with lorlatinib. Those mutations included L1196M + L1198F and G1202R + L1198F which showed high resistance to lorlatinib in Ba/F3 models. Ba/F3 cells with different mutant EML4-ALK showed a distinct spectrum and different frequency of additional mutations. In conclusion, this study predicted that no single mutation would emerge to confer resistance to lorlatinib. Thus, compound mutations and ALK-independent mechanisms become essential mechanisms for lorlatinib resistance.

Fibroblast growth factor receptor 3 (FGF3/FGFR3) overexpression, point mutations or gene fusions are found in ~80% of non-muscle-invasive and ~15% of muscle-invasive bladder cancer. FGFR inhibitors have entered clinical trials in advanced bladder cancer however, as with other targeted therapies, intrinsic and acquired resistance are expected to limit treatment efficacy. We have used an in vitro model to explore possible mechanisms of resistance. The urothelial cell line RT112 expresses an FGFR3-TACC3 fusion protein and is sensitive to FGFR inhibition. Isogenic resistant cell lines, termed R1, R2 and R3, were derived by long-term culture of RT112 in the presence of the FGFR inhibitor PD173074. FGFR3 overexpression is associated with acquisition of resistance and lower FGFR expression than R1 and R2. The changes in morphology and gene expression between parental and resistant derivatives R1 and R2 were reversed when the resistant cells were cultured without PD173074 for 4 passages. Despite this, the cells retained their resistance when re-exposed to PD173074. Exome sequencing, RNA microarray analysis and phospho-receptor tyrosine kinase array data on the parental cells and resistant derivatives will be presented. Our data suggests that diverse mechanisms of resistance occur following prolonged FGFR inhibition.

**#3146 Targeting ANXA3 in combination with sorafenib for the treatment of hepatocellular carcinoma.** Man Tong, Steve Luk, Noelia Che, Jin Deng, Terence KW Lee, Stephanie Ma. Univ. of Hong Kong, Faculty of Medicine, Pokfulam, Hong Kong; Eastern Hepatobiliary Surgery Hospital, Second Medical University, Shanghai, China; The Hong Kong Polytechnic University, Hong Kong, Hong Kong.

Sorafenib is the only FDA-approved tyrosine kinase inhibitor for targeted therapy in advanced HCC. Nevertheless, its efficacy is limited with only a modest improvement in patient outcome, likely due to acquired resistance. In-depth understanding of the molecular mechanism of sorafenib resistance is warranted for the development of novel treatment strategies. Recent studies by us and others have characterized liver tumor-initiating cells (T-ICs) to be a possible source of resistant and recurrent tumors and a plausible target for HCC treatment. Our group has previously identified CD133 + as a functional marker of liver T-ICs and found annexin a3 (ANXA3) to regulate cancer stem cell properties in this subset of cells. Interestingly, our recent observations also found CD133 + liver T-ICs to be more resistant to sorafenib. Sorafenib resistant clones, established in HepG2 and HuH7 cells by continuous exposure to increasing concentrations of sorafenib, displayed enhanced abilities to migrate, invade, self-renew, and inhibit tumor formation in immunodeficient mice, as well as a higher expression of stemness associated genes. These two sorafenib resistant cell lines and two other sorafenib resistant HCC patient-derived xenografts established in a similar manner were also found to be enriched for CD133 and ANXA3 expression. Sorafenib resistant clones with ANXA3 stably suppressed
were re-sensitized to sorafenib treatment and had diminished ability to migrate, invade, self-renew and initiate tumor growth in vivo, further substantiating the role of ANXA3 in mediating sorafenib resistance in HCC. Mechanistically, an activated PKC/ERK/FRA2 signaling axis was found to be responsible for driving this phenomenon. Clinically, ANXA3 expression was also found to have prognostic value as a higher ANXA3 expression in chronic lymphocytic leukemia (BTK) cDNA samples was correlated with worse prognosis. Furthermore, we demonstrated that Mibefradil inhibits GCN growth and survival and sensitizes GSCs to Temodar and cisplatin in vitro and in xenograft tumor models. This study represents the first comprehensive characterization of the role of T-type calcium channels in glioblastoma. Zheng, Nichola Crickshanks, Fang Yuan, Baomin Wang, Mary Pahuski, Julia Wulfkuhle, Isela Gallagher, Alexander F. Koeppel, Sarah Hatf, Christopher Papanicolas, Jeongwu Lee, Bar, David Schiff, Stephen D. Turner, Emanuel Petricoin, Lloyd L. Gray, Roger Abouarduen, Univ. of Virginia, Charlottesville, VA; George Mason University, Charlotteville, VA; George Mason University, Manassas, VA; Cleveland Clinic Lerner Research Institute, Cleveland, OH; Case Western Reserve University, Cleveland, OH; Cavon LLC, Charlottesville, VA.

Glioblastoma stem cells (GSCs) have been implicated in tumor resistance to radio- and chemotherapy. Proliferation of GSCs reportedly requires calcium influx through T-type calcium channels ( Cav3.2). In this study we investigated the expression, function, mechanism of action and therapeutic targeting of Cav3.2 with the FDA approved and repurposed drug Mibefradil in glioblastoma (GBM) and GSCs. We found that Cav3.2 is highly expressed in the majority of human GBM specimens and all GSCs. TCGA data analysis demonstrated that approximately 11% of GBM tumors have upregulated Cav3.2 and that overexpression of Cav3.2 is associated with worse prognosis. Furthermore, we demonstrated that Mibefradil inhibits GCN growth and survival and sensitizes GSCs to Temodar and cisplatin in vitro and in xenograft tumor models. To investigate the mechanism of action of Mibefradil, we performed proteomic and transcriptomic screenings of Mibefradil-treated GSCs using reverse phase protein arrays and RNA-seq, followed by functional rescue experiments. Inhibition of Cav3.2 with Mibefradil significantly altered multiple cancer regulatory signaling pathways and molecules as well as the transcription of oncopgenes and tumor suppressors. Among other, Mibefradil suppressed GCN growth through inhibition of pro-survival pathways such as AKT/mTOR, whilst simultaneously inducing apoptosis through upregulation of survivin, BAX and cleavage of caspase 9 and PARP. Notably also, RNA-deep sequencing of Mibefradil treated GSCs revealed an increase in expression of tumor suppressors such as TNFRSF14 and HSD17B4 along with a decrease in the expression of several oncopgenes such as PDGFA, PDGFR and VEGFA. We also assessed the therapeutic effects of Mibefradil on established GSC-derived xenografts. Oral administration of Mibefradil significantly inhibited tumor growth, prolonged animal survival and sensitized tumors to inhibition by TMZ and radiation. This study represents the first comprehensive characterization of Cav3.2 in GBM and GSC. The data establish Cav3.2 inhibition by the repurposed FDA-approved drug Mibefradil as a new strategy for GBM therapy.

Anaplastic lymphoma kinase (ALK) fusion oncogenes occur in around 3%-5% non-small cell lung cancer (NSCLC) cases. Various ALK inhibitors are in clinical use for the treatment of ALK-NSCLC, including the first generation ALK inhibitor, Crizotinib, and recently the more highly potent Alceatinib and Ceritinib. However, most tumors eventually become resistant to ALK specific inhibitors. To address the mechanisms underlying the development of ALK inhibitor resistance, we used ITRAQ quantitative mass spectrometry and phosphor-receptor tyrosine kinase arrays to investigate intracellular signaling alterations in ALK inhibitor resistant NSCLC cell lines. Src signaling was identified as an Alceatinib resistance mechanism, and combination treatment with ALK and Src inhibitors was highly effective for inhibiting the growth of ALK inhibitor resistant cells in vitro and in mouse xenograft models. Furthermore, phospho-receptor tyrosine kinase activation and downstream PI3K/AKT signaling was effectively blocked by inhibiting Src in Alceatinib resistant cells. Finally, we showed that the combined use of ALK and Src inhibitors inhibited the growth of other ALK-NSCLC cell lines, including those that were Ceritinib or Lorlatinib resistant. Our data suggest that targeting Src signaling may be an effective approach to the treatment of ALK-NSCLC with acquired resistance to ALK inhibitors.

#3149 Identification of genes associated with the cisplatin resistance in cervical cancer cells expressing E545K mutation. Wani Arjumand, Nicholas Jette, Jb McIntyre, Prafull Ghatage, Corinne M. Doll, Susan P. Lees-Miller.

1Department of Biochemistry & Molecular Biology; Arnie Charbonneau Cancer Institute, Robson DNA Science Centre, University of Calgary, Calgary, Alberta, Canada; 2Department of Pathology, University of British Columbia, Vancouver, British Columbia, BC, Canada; 3Department of Gynecologic Oncology, University of Calgary, Calgary, Alberta, Canada; 4Department of Oncology, Arnie Charbonneau Cancer Institute, Robson DNA Science Centre, University of Calgary, Calgary, Alberta, Canada; 5Department of Biochemistry & Molecular Biology and Department of Oncology, Arnie Charbonneau Cancer Institute, Robson DNA Science Centre, University of Calgary, Calgary, Alberta, Canada.

The phosphatidylinositol-3 kinase (PI3K)/AKT/ mTOR signaling pathway is activated in several human cancers and activation is frequently mediated by “hotspot” mutations including E542K, E545K and H1047R in the PIK3CA gene. Approximately 30% of cervical cancer patients have the PIK3CA-E545K mutation. Cisplatin with radiotherapy (RT) is the standard treatment of cervical cancer world-wide, used in both the radical and post-operative adjuvant settings. However, details of the molecular mechanisms responsible for cisplatin resistance remain unclear. We previously reported PIK3CA mutation in patients with earlier stage (IB/II) cervical cancer was associated with poor survival (McIntyre et al. Gynecol Oncol, 2013, PMID:23266353), and in our recent study we observed that PIKSCA-E545K mutation renders cervical cancer cells more resistant to cisplatin or cisplatin and radiation than other more migratory phenotype than isogenic cells with wild type-PIK3CA. Moreover, these phenotypes are reversed by the PI3K inhibitor GDC-0941/Pictilisib (Wani et al. Oncotarget. 2016, PMID:27489350). The aim of the present study is to identify the expression of genes related to cisplatin resistance in cervical cancer cells engineered to express PIK3CA-E545K. Microarray analysis identified 161 genes that were up-regulated and 189 that were down-regulated in the cervical cancer cells stably expressing PIK3CA-E545K, some of which are involved in well-characterized mechanisms that could be relevant to cisplatin resistance. We are currently validating some of those genes by Real-time PCR that will help us to determine the mechanism of PIK3CA-E545K induced cisplatin resistance and enhanced migration in cervical cancer cells expressing PIK3CA-E545K and extending our in vitro findings to animal models. Together, our data will provide a useful basis for screening candidate targets for risk stratification and provide valuable information for potential targeted intervention in patients whose tumors harbor cisplatin-resistant molecular characteristics.

#3150 PLCG2 C2-domain mutations co-occur with BTK and PLCC2 resistance mutations in chronic lymphocytic leukemia undergoing treatment with the BTK inhibitor ibrutinib. Dan Jones, Jennifer A. Woyach, Weiqiang Zhao, Sean Caruthers, Huolin Tu, Joshua Coleman, John C. Byrd, Amy J. Johnson, Leonard L. Gansky, The George Washington University, Qatar Biomedical Research Institute, Doha, Qatar.

Background: The Bruton agammaglobulinemia tyrosine kinase (BTK) activ- itates B-cell receptor signaling through activation of phospholipase C gamma 2 (PLCG2). Clinical resistance to the Bruton tyrosine kinase (BTK) inhibitor ibrutinib in chronic lymphocytic leukemia (CLL) is highly associated with emergence of the BTK C481 mutations that prevent ibrutinib covalent binding. PLCC2 mutations also occur in ibrutinib-resistant samples but the spectrum of mutations and their occurrence with ibrutinib changes have not been fully delineated. Materials and Methods: All peripheral blood samples with adequate depth of sequencing coverage were included from CLL patients receiving ibrutinib (with or without other therapies) that were submitted from Ohio State University (OSU) to the OSU James Polaris Molecular Laboratory. Genomic DNA was extracted from negatively selected B cells and deep sequencing of the entire coding regions of BTK and PLCC2 performed using a custom Ion Torrent Ampliseq panel. A mean depth of greater than 1000X was obtained with hotspot mutations validated down to 1% variant allele fraction (VAF) in the B cell prepar- ations using orthogonal mutation-specific detection methods. Results: Among 1063 CLL samples from 380 patients who received ibrutinib, BTK C481 resistance mutations were identified in 79 (20.8%) patients including 20 patients that also had co-occurring PLCC2 mutations. 11 patients (2.9%) had PLCC2 mutations without accompanying BTK C481 alterations for a cumulative incidence of PLCC2 mutations in 8.2% of ibrutinib-treated patients. These included previously described mutations in the SH2 and SH3 domain of PLCC2 (R665W, 5707F, A708P and L454F) but also previously uncharacterized mutations in the PLCC2 C2 domain that were seen in 12 patients (3.2%). C2 domain mutations are always seen in association with another PLCC2 and/or BTK resistance mutation, affected codons 1140-1144 that include the highly conserved aspartic acid residues that bind calcium and mediate membrane localization in other C2-domain containing proteins. In sequential samples, PLCC2 C2-domain muta-
tions tracked at similar levels to the co-occurring BTK and PLCG2 resistance mutations indicating their presence in the same population of CLL cells. Conclusions: Mutations in three different PLCG2 structural domains co-occur with BTK C481 mutations. The identification of PLCG2 mutations in the calcium-regulated C2 domain expands the possible mechanisms that can produce the PLCG2 activity following bTK inactivation. The diversity of recurrent mutations observed supports the need for complete PLCG2 sequencing for full characterization of bTK-treated CLL samples.

#3151 Loss of Axin1 drives acquired resistance to WNT pathway blockade in colorectal cancer cells carrying RPS03 fusions. Giuseppe Picco,1 Consalvo Petti,2 Alessia Centonze,1 Erica Torcichio,1 Alberto Bardelli,1 Enzo Medico1.

1University of Torino, Candiolo Cancer Institute, Candiolo, Italy; 2Candiolo Cancer Institute, Candiolo, Italy

In colorectal cancer (CRC), WNT pathway activation by genetic rearrangements of RPS03 is emerging as a promising target. However, its low prevalence severely limits availability of preclinical models for in-depth characterization. Using a pipeline designed to suppress stroma-derived signal, we find that RPS03 “outlier” expression in CRC samples highlights translocation and fusion transcript expression. Outlier search in 151 CRC cell lines identified VACO6 and SNU1411 cells as carriers of, respectively, a canonical PTPRK(e1)-RPS03(e2) fusion and a novel PTPRK(e13)-RPS03(e2) fusion. Both lines displayed marked in vitro and in vivo sensitivity to WNT blockade by the porcupine inhibitor LGK974, associated with transcriptional and morphological evidences of WNT pathway suppression. Long-term treatment of VACO6 cells with LGK974 led to the emergence of a resistant population capable of sustained activation of the WNT pathway inhibitor AXIN1, with consequent protein loss. Suppression of AXIN1 in parental VACO6 cells by RNA interference conferred marked resistance to LGK974. These results provide the first mechanism of secondary resistance to WNT pathway inhibition.

#3152 Acquired resistance to the third-generation EGFR inhibitor ASP8273 is associated with MET or NRAS gene amplifications in preclinical models. Kiichiro Ninomiya1, Kadoaki Ohashi1, Shuta Tomida2, Hiroo Kato1, Tomoki Tamura,1 Hisao Higo,1 Go Makimoto,1 Takashi Ninomiya,2 Toshio Kubo,2 Eiki Ichihara,2 Akiko Sato,2 Katsuyuki Hotta,2 Masahiro Tabata,2 Katsujiro Kura,3 Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama city, Japan; 3Okayama University Hospital, Okayama city, Japan.

Background. Third-generation EGFR tyrosine kinase inhibitors (TKIs) such as osimertinib and ASP8273 demonstrated biologic activity in patients with non-small cell lung cancer (NSCLC) harboring the EGFR T790M mutation; however, acquired resistance inevitably develops and the mechanisms of have not been fully elucidated. This study evaluated potential mechanisms of resistance to ASP8273. Materials and Methods. ASP8273 was kindly provided by Astellas Pharma Inc. PC-9 cells harboring EGFR 19del and RPC-9 cells harboring EGFR 19del + T790M were used as cell models to explore alternative molecular mechanisms of acquired resistance to ASP8273. Resistant cell lines (PC-9ASR and RPC-9ASR) were established from each cell line after continuous exposure to ASP8273 for 6 months. Results. Other EGFR-TKIs, including osimertinib, gefitinib or erlotinib, did not inhibit cell growth and acquired EGFR mutations were not detected in either of ASP8273 resistant cell lines. The PC-9-based model was first analyzed. The 50% inhibitory concentration (IC50) of ASP8273 was 45-fold higher in PC-9ASR cells (1,216 nmol/L) than in the parental PC-9 cells (27 nmol/L). A receptor tyrosine kinase array showed that MET phosphorylation was increased in PC-9ASR cells relative to PC-9 cells. Single-cell cloning revealed that PC-9ASR cell harbored MET gene amplification, but other clones (c1, c3, c4, and c5) did not; these results suggest that heterogeneous cells comprised the resistant cell lines. Consistently, the combination of EGFR inhibitors (ASP8273 or gefitinib) with MET inhibitors (crizotinib or SGX-523) inhibited cell proliferation in vitro. However, co-treatment of ASP8273 with crizotinib consistently inhibited this resistant tumor xenograft model. The RPC-9-based model was then assessed. The IC50 of ASP8273 was 40-fold greater in RPC-9ASR cells (1,393 nmol/L) than in the parental RPC-9 cells (32 nmol/L). Next-generation sequencing showed significant NRAS gene amplification and no NRAS mutations in RPC-9ASR cells. EGFR 19del + T790M was maintained in the resistant cells. Western blot analysis and an active RAS pull-down kit confirmed that NRAS protein was significantly over-expressed. Even that NRAS-GTPase activity was much higher in RPC-9ASR cells than in the RPC-9 parental cells. As expected, inhibition of RAS signaling using a MEK inhibitor (selumetinib or tramebkinib) in addition to ASP8273 overcame the resistance in vitro. Interestingly, a combination of MEK inhibitors with another third-generation EGFR-TKI, osimertinib, had no effect on the ASP-8273 resistant cells. Conclusions. These studies suggest that a bypass signaling pathway, such as MET gene amplification, or activation of the RAS signaling pathway plays a role in ASP8273 resistance in lung cancer cells harboring EGFR mutations. (This work was supported by KAKEN 16K19454 and 15H04830.)

#3153 Transcriptome differences in tyrosine kinase inhibitor-resistant clones of EGFR-mutant lung cancer using a new microfluidic assay for concurrent single-cell RNA and targeted DNA sequencing. Soi Li Kong,1 Hupeng Li,2 Dave Ruff,2 Joyce An Yi Tai,1 Elise T. Courtouris,1 Huay Mei Poh,1 Dawn Pingxia Lui,3 Audrey Ann Liew,1 Gek San Tan,4 Tony Kiat Hon Lim,4 Daniel Shao Weng Tan,4 Shyam Prabhakar,1 Axel M. Hillmer1, Genome Institute of Singapore, Singapore, Singapore; 2Fluidigm, South San Francisco, CA; 3National Cancer Centre Singapore, Singapore, Singapore; 4Singapore General Hospital, Singapore, Singapore.

Resistance to therapy is one of the major causes of cancer-associated death. While a number of mechanisms for the development of resistance to epidermal growth factor receptor, EGFR-targeting drugs in lung cancer have been described, most genomic and transcriptomic studies have focused on analyzing bulk samples that can only provide an average measurement over the entire mixture of cell populations of a tumor. With this approach, it is difficult to resolve cell-to-cell variability of drug resistance within a heterogeneous tumor. In order to accurately describe and eventually delineate the underlying causes of cancer progression, it requires the analysis of single cells on both, the transcriptomic and the genomic level. Only the co-detection of mutations and expression features in individual cells allows to define the connection between the two. We therefore aimed to establish a new methodology for concurrent evaluation of transcriptomic and genomic features within the same single cell on the Fluidigm C1 system. We applied this protocol to an EGFR-mutant lung cancer cell line, PC9, that has developed resistance to tyrosine kinase inhibitor, TKI treatment after prolonged exposure to sublethal doses of Gefitinib. We amplified cDNA and selected genomic EGFR regions of the TKI responsive and resistant PC9 clones from a total of ~300 single cells. We used our in-house single cell analysis pipeline for parallel processing of transcriptome and variants detection. In addition, a novel algorithm, NODES was used to normalize the single cell RNAseq data and detect differentially expressed genes. The differential transcriptome and emergence of the EGFR T790M resistance mutation in relation to the TKI response were evaluated. We observed up-regulation of receptor tyrosine kinase AXL in the resistant cell lines. This observation is in agreement with previous findings that AXL is the key player that promotes TKI resistance in lung cancer. In addition, we found up-regulation of other genes that have not been previously described. Cumulatively, this method allows us to dissect the underpinnings of the TKI resistance mechanism and enables us to identify biomarker for specific cellular features that are connected with resistance and thereby with lung cancer patient’s response to TKI treatment.

#3155 Harnessing synthetic rescues to evaluate and mitigate resistance to cancer therapy. Avinash D. Sahu,1 Joo Sang Lee,1,2 Eytan Ruppin,1 Silvio Gutkind,2 Zhiyong Wang,3 University of Maryland, College Park, College Park, MD; 2University of California, San Diego, CA.

Significance: The emergence of resistance to cancer therapy remains a growing challenge, evidenced from numerous recent investigations identifying molecular events conferring resistance to cancer drugs. Here we demonstrate that many of these molecular events can be attributed to synthetic rescue (SR) genetic interactions, where altered activity of a specific (termed rescuer) gene restores cell viability caused by the inactivation (including through gene deletion or targeted pharmacological repression) of another gene. Methods: We present a computational approach termed INCISOR, which analyzes molecular, survival, and phylogenetic cancer data to predict SR genes pairs that are under positive selection and their presence decreases patient survival. It further screens for causal SR pairs that show in vitro evidence of rescue. Results: We applied INCISOR to mine 8000 patients’ omics and clinical data in TCGA to identify the first genome-wide SR network, composed of SR interactions common to many cancer types. The predicted SRs match drug-specific molecular resistance signatures that have been recently published in arduous clinical studies (with accuracy of 0.8 AUC). They chart pathways of resistance on a genome scale and as we show, can predict response and resistance to the majority of current cancer drugs in patients. We conducted new experiments to test new predicted SR-based combination therapies. Each combination consisted of a primary cancer drug and a second adjuvant therapy inhibiting a predicted key rescuer of the primary drug. Five of the 7 predicted combinations tested synergistically sensitized all the five head and neck cell lines to the original primary therapies. These results were further substantiated via siRNA knockdowns of the
predicted rescuers in combination with the original treatment, confirming the effects observed with pharmacological inhibition. Focusing on mTOR, a major cancer driver gene, we combined drug treatment and pooled-siRNA to validate the rescue effect of 8 out of 10 predicted rescue interactions involving mTOR in a head and neck cancer cell-line. Finally, we analyzed patient-derived mouse xenografts treated with 25 PDXs across different drug combinations. Mice exhibit much better progression-free survival when treated with a drug combination predicted by INCISOR compared with the mice treated with the primary drug alone, testifying to the in vivo benefits of SR-based synergistic treatments. Conclusions: This work presents a new paradigm harnessing synthetic rescue gene-gene interactions to counteract resistance to cancer treatments. Future implementation of this approach will have two broad implications in the precision medicine era, first for determining the most effective treatment regimen based on the molecular characteristics of individual patient’s tumor; second for identifying supplemental drugs to counteract resistance to existing primary therapies.

Background: Osimertinib (AZD9291; Tagrisso) is a third generation epidermal growth factor receptor (EGFR) tyrosine kinase inhibitor (TKI) known to be effective against the EGFR-T790M variant, which is accounts for half of the acquired resistance mechanisms to the first generation EGFR-TKIs. However, resistance to osimertinib is likely to progress and the study of potential osimertinib-resistance mechanisms in advanced is necessary. In this study, we investigated the molecular and cellular profiles of the acquired resistance cells to osimertinib in EGFR-mutant non-small cell lung cancers. Materials and Methods: Five EGFR-mutant cell lines were exposed to osimertinib by stepwise escalation or high-concentration exposure methods, and resistant sublines to osimertinib were established. The molecular profiles and cellular phenotypes of these resistant sublines were characterized. Results: EGFR-C797S mutation which was reported to be a major mechanism of resistance to osimertinib in clinical samples was not detected in established resistance cells by using direct sequencing. Several osimertinib-resistance cell lines displayed MET amplification, and some of these cells were sensitive to the combination of osimertinib plus MET inhibitor crizotinib. However, one cell line that displayed MET amplification was not sensitive to this combination therapy. On the other hand, several osimertinib-resistance cell lines displayed epithelial-to-mesenchymal transition (EMT) features. The HCC827-derived subline established by the high-concentration exposure method exhibited not only EMT features but also cancer stem cell-like properties, including aldehyde dehydrogenase isoform 1 (ALDH1A1) and ATP binding cassette subfamily B member 1 (ABCB1) overexpression. Conclusion: We established osimertinib-resistant cells and found that MET amplification, EMT, and CSC-like features were observed. These findings may provide clues to overcome acquired resistance to EGFR-TKIs. In some cell lines, however, the mechanisms of acquired resistance to osimertinib were not revealed yet.

#3157 Osimertinib (AZD9291) is effective against NSCLC cells harboring EGFR exon 20 insertion mutations. Yussoo Lee,1,2 Tae Min Kim,2 Dong-Wan Kim,2 Yong-Oon Ahn,1 Soyeon Kim,1 Bhumuk Keam,2 Miso Kim,1 Dae Seog Heo,1,2,3. 1Seoul National University Cancer Research Institute, Seoul, Republic of Korea; 2Seoul National University Hospital, Seoul, Republic of Korea; 3Seoul National University, Seoul, Republic of Korea.

Background: Although EGFR exon 20 insertion mutation is the third most common among EGFR-mutant NSCLC, this mutation clones are resistant to the first-generation EGFR TKIs. In addition, the efficacy of the second or third-generation EGFR TKIs is unknown in NSCLC with EGFR exon 20 insertion mutation. Methods: Various EGFR exon 20 insertion mutations were introduced into Ba/F3 cells as follows: A763_V764insQEA in C-helix; and V769_D770insASV, D770_N771insNPG, D770_N771insSVD, P772_H773insPR, H773_V774insNPH, H773_V774insH, and H773_V774insH in loop following C-helix. The patient-derived SNU-3173 cell line was developed in a patient with EGFRV77D_L774insAH mutation. Ba/F3 cells transfected with EGFR exon 20 insertion mutations and SNU-3173 were exposed to the EGFR TKIs (the 1st-generation gefitinib and erlotinib; the 2nd-generation dacomitinib and afatinib; and the 3rd-generation rociletinib, olmutinib, and osimertinib) and cell viability assays were performed. In addition, immunoblotting was performed to evaluate the downstream signals of EGFR pathway. Results: Cell viability assay showed that EGFR exon 20 insertion mutations are resistant to the 1st-generation EGFR TKIs, except for EGFRV77D_L774insQEA, mutant Ba/F3 cells. IC50 values of the 2nd-generation EGFR TKIs are five to hundred-folders lower than the 1st-generation EGFR TKIs. The 2nd-generation EGFR TKIs were effective against EGFR exon 20 inserted Ba/F3 cells and down-regulated EGFR downstream signals. The 3rd-generation EGFR mutation-selective inhibitors showed a moderate efficacy except osimertinib that was effective and down-regulated EGFR downstream signals. In addition, SNU-3173 cells were moderately effective to afatinib (IC50 46.2±5.2 nM) as well as osimertinib (IC50 403±3.0 nM).

Conclusions: Overall, osimertinib showed effectiveness against NSCLC cells with EGFR exon 20 insertion mutations. Our results warrant a clinical trial of osimertinib in NSCLC patients with EGFR exon 20 insertion mutations.

#3158 In vivo acquired resistance to an emibetuzumab analogue in MET-amplified gastric xenografts can be overcome by a MET-targeting antibody mixture or PI3CA/AKT/mTOR inhibition. Soofe Elleeb Pollmann,1 Emanuel Funke,2,3 Valerie Calvert,2 Shrutti Rao,2 Simina Boca,2 Sahba Madhavan,3 Ivan David Horak,1 Andreas Kjer,3 Michael Kragh,1 Thomas Tuxen Poulsen1.1 Symphogen, Ballerup, Denmark; 2George Mason University, Manassas, VA; 3Georgetown University, Washington, DC; 4University of Copenhagen, Copenhagen, Denmark.

Aberant over-activation of MET receptor tyrosine kinase is involved in driving malignancies such as gastric and non-small cell lung cancer (NSCLC), and in the development of resistance to EGFR-targeting therapeutics. This has led to the development of several MET-targeting agents in the form of tyrosine kinase inhibitors (TKIs) and monoclonal antibodies (mAbs), many of which are in clinical development. However, resistance to MET-targeted agents is an emerging problem. This study aims to understand mechanisms underlying resistance development to an analogue of emibetuzumab, a mAb targeting MET. Upon long term in vivo treatment, emibetuzumab-resistant tumors and cell lines were generated, isolated, and characterized to acquire their acquired resistance mechanisms. Extensive reverse phase protein array and network analysis were used to characterize the proteomic profiles of three resistant cell lines, revealing three distinct resistance profiles, one involving activation of the PI3K/Akt/mTOR pathway. We further show, how these resistance mechanisms can be overcome by treatment with other targeting therapeutics both in vitro and in vivo. Two of the models demonstrated in vivo sensitivity to Sym015, a novel mixture of two mAbs targeting non-overlapping epitopes of MET, partly due to ADCC, indicating that Sym015 can overcome acquired resistance to emibetuzumab. In addition, the third model demonstrated a marked increase in PI3K inhibition in PI3K/Akt/mTOR pathway activation. This activation translated into induced cancer cell and tumor growth, which could be inhibited by agents targeting PI3K/Akt, mTOR. This study thus points to treatment of patients with acquired resistance to single targeting MET mAbs with PI3K/Akt/mTOR-targeting agents or a MET-targeting antibody mixture such as Sym015.

Sunitinib, an anti-angiogenic tyrosine kinase inhibitor, is approved for treatment of pancreatic neuroendocrine tumors (pNETs). However, its efficacy is greatly limited due to resistance. Sunitinib is a lysosomotropic drug, thus accumulates in lysosomes, leading to their destabilization and to lysosomal membrane permeabilization (LMP), which in turn can lead to cell death. Autophagy might be activated for clearance of damaged lysosomes, thus promote survival and act as a mechanism of resistance. We found that the autophagy inhibitor chloroquine increases sunitinib efficacy in pNET cell lines and in a transgenic mouse model of pNETs. Interestingly, chloroquine is a lysosomotropic drug as well and the response towards sunitinib and chloroquine in pNET cell lines correlated with lysosome-associated membrane protein 2 (LAMP2) levels, which influence lysosome stability. We hypothesized that sunitinib and the com-
combination with chloroquine induce LMP in pNETs and that LMP leads to activation of the transcription factor EB (TFEB), master regulator of genes involved in lysosomal biogenesis and autophagy, leading to therapy resistance. We found that LMP increased upon combined treatment of sunitinib and chloroquine compared to single treatment in pNET cell lines. Treatment of pNET cell lines with sunitinib or chloroquine led to activation of TFEB in EMT cell lines, leading to autophagy as a survival mechanism. Upon massive LMP or if autophagy is dysfunctional, cell death is induced. Based on our data, we suggest the combination of sunitinib and chloroquine as a treatment option for pNET patients and that TFEB could be an interesting therapeutic target in combination with lysosomotropic drugs.

#3160 Sustained MAPK activation as a mechanism of resistance to osimertinib plus selumetinib in models of EGFR-mutant cancer. David Westover,1 Catherine B. Meador,1 Eiki Ichihara,1 Hayden F. Byrd,1 Cath Eberlein,2 Yingjun Yan,2 Darren A. Cross,2 Christine M. Lovly,1 *Vanderbilt-Ingram Cancer Center, Nashville, TN; 1Astrazeneca Oncology, Cambridge, United Kingdom.

INTRODUCTION: Osimertinib is a third-generation, mutant-selective epidermal growth factor receptor (EGFR) tyrosine kinase inhibitor (TKI) recently approved for the treatment of T790M-positive EGFR-mutant lung cancer. The mutant-selective nature of osimertinib improves its tolerability by limiting its inhibition of wild-type EGFR compared to first- and second-generation EGFR inhibitors, making it a good candidate for rationally-designed combination therapies. One such combination, osimertinib plus the MEK inhibitor selumetinib (AZD6244; ARRY-142886), is currently being studied as part of the phase Ib TATTON trial (NCT02143466). Previous work by our group demonstrated that selumetinib may delay or reverse resistance to osimertinib in some cases; however, we anticipate that resistance to this combination will ultimately develop in patients. Here, we investigate acquired resistance to osimertinib and selumetinib combination therapy in vitro and in vivo. DESIGN: In cells sensitive to osimertinib plus selumetinib (hereafter referred to as combination-sensitive cells), ERK phosphorylation was monitored via a Western blot over the course of a 7-day treatment with 200 nM osimertinib plus 1 μM selumetinib. To detect RAS-GTP, an active RAS precipitation was performed in combination-sensitive and combination-resistant cell lines following treatment with osimertinib. In combination-resistant cells, pharmacologic inhibitors of various MAPK pathway components were used to assess whether they could restore potency: Western blot analysis was used to confirm on-target effects. Lastly, an analysis of differences in gene expression between four isogenic sets of combination-sensitive and combination-resistant cell lines is currently ongoing. RESULTS: In cells that are sensitive to growth inhibition by the combination of osimertinib plus selumetinib, we observed complete re-activation of the MAPK pathway after 5 days of continuous exposure to both inhibitors. Additionally, RAS activity was elevated in combination-resistant cell lines, and these cells remained sensitive to the ERK inhibitor selumetinib. Conversely, in combination-sensitive cell lines, the growth inhibitory effects of osimertinib plus selumetinib in combination-resistant cells, suggesting that incomplete inhibition of MAPK is responsible for resistance in these cells. Furthermore, an alternative MEK inhibitor, trametinib, was efficacious in combination with osimertinib in cell lines that were resistant to osimertinib plus selumetinib. CONCLUSION: These data identify a potential mechanism of resistance to a combination therapy that is currently being tested in the clinic. Specifically, these data demonstrate that re-activation of the MAPK pathway is a mechanism of resistance to osimertinib plus selumetinib and that this pathway is still targetable in combination-resistant cells.

#3161 TPX-0005, an ALK/ROS1/TRK inhibitor, overcomes multiple resistance mechanisms by targeting SRC/FAK signaling. Dayong Zhai, Wei Deng, John Huang, Evan Rogers, J. Jean Cui, TP Therapeutics, Inc., San Diego, CA.

ALK, ROS1, and TRK inhibitors have achieved marked efficacy in treating cancer patients expressing abnormal ALK, ROS1 or NTRK genes. However, the initial success of these therapies is rapidly overshadowed with the development of acquired resistance. In addition, approximately 30-40% of ALK + or ROS1 + NSCLC patients fail to respond to initial crizotinib treatment, representing intrinsic resistance. Target gene amplification, acquired resistance mutations, bypass signaling, epithelial-mesenchymal transition (EMT) and metastasis are the common resistance mechanisms. None of the current ALK, ROS1 or TRK inhibitors can overcome bypass or EMT-based resistance when applied as a single agent therapy. TPX-0005 is a potent kinase inhibitor against WT and mutated ALK, ROS1 and TRK family kinases, especially the clinically significant solvent front mutations. At clinically relevant concentrations, TPX-0005 also inhibits JAK2, SRC and FAK that are important targets in modulating multiple resistance mechanisms. H2228 lung cancer cell line endogenously expresses EML4-ALK v3 and was reported to be resistant to ALK inhibitor TAE684. Uprogulation of the bypass signaling kinase EGF, EMT marker vimentin, and CD44 was reduced in TPX-0005, likely leading to intrinsic resistance to ALK inhibitors. In the anti-proliferation assay, both crizotinib and ceritinib were resistant in H2228 cells with IC50 values around 1000 nM; however, TPX-0005 was able to overcome the intrinsic resistance with an IC50 of 100 nM. In H2228 cells, TPX-0005 suppressed the phosphorylation of SRC, FAK and paxillin with IC50 values in a range of 80-100 nM, and downregulated the expression of CD44 with IC50 values around 100 nM. In addition, TPX0005 inhibited the phosphorylation of the oncoprogenic transcription/translation factor YB-1 with an IC50 value around 100 nM in H2228 cells. YB-1 is involved in many aspects of gene expression control that lead to tumor cell growth and drug resistance, including modulation of EGF upregulation, EMT, and cancer stemness. Therefore, it was postulated that inhibition of SRC/FAK by TPX-0005 suppressed the phosphorylation of YB-1, leading to the downregulation of EGF, CD44 and vimentin, and eventually to anti-proliferation effect on H2228 cells. TPX-0005 demonstrated an in vitro anti-metastatic activity by inhibiting cell migration in both H2228 cells and HT1080 human fibrosarcoma cells. Taken together, the potent kinase inhibitory activities against SRC/FGK signaling provide a unique polypharmacology profile to TPX-0005 for combating multiple resistance mechanisms simultaneously, including a broad spectrum of acquired mutations, bypass signaling, EMT, cancer stemness, and metastasis.

#3162 HRAS G12V predicts for innate resistance to PI3Kα inhibition in head and neck squamous cell cancer. Kara M. Ruicci,1 Ren Sun,2 Morgan Black,3 Nicole Pinto,3 John Yoo,3 Kevin Fung,1 Danielle Macneill,1 Laure Aillies,1 Joseph S. Mymryk,1 Paul C. Bourtos,2 John W. Barrett,1 Anthony C. Nichols,1 1Western University, London, Ontario, Canada; 2Ontario Institute for Cancer Research, Toronto, Ontario, Canada; 3University of Toronto, Toronto, Ontario, Canada.

Introduction: Head and neck squamous cell carcinoma (HNSCC) is the sixth most common cancer worldwide, with an incidence of ~600 000 new cases per year and a 50% mortality rate for advanced disease. The mutational landscape of HNSCC has been recently elucidated, introducing the possibility for targeted therapeutic approaches. PIK3CA—which encodes the catalytic subunit of PI3K (PI3Kα)—is the most frequently altered actionable target in HNSCC, however it is not presently clear which patients benefit most from PI3Kα-inhibition. BYL719 is a leading PI3Kα inhibitor in clinical development for HNSCC. We previously examined the responses of a large panel of genetically-characterized HNSCC cell lines to BYL719 and identified activating HRAS G12V mutations as strong predictors for BYL719 resistance. Here we examine how mutation is able to individually modulate BYL719 response through overexpression and knockdown studies. Methods: To determine if HRAS G12V was able to modulate BYL719 sensitivity, we knocked down HRAS in HRAS G12V and HRAS wild-type (WT) cell lines using RNA interference, and then treated cells over 10-point dose ranges with BYL719. Sensitivity was determined by calculating IC50 (half-maximal inhibitory concentration) values at 72 hours using PrestoBlue®. Conclusions: HRAS knockdown sensitized HRAS G12V lines to BYL719 (lower IC50), but did not affect the response of WT HRAS cells. WT HRAS and HRAS G12V overexpression significantly increased cellular proliferation and promoted BYL719 resistance. In HRAS G12V cell lines, we observed high levels of active phosphorylated AKT (S473/T308), even in the presence of BYL719. Collectively, our findings highlight the predictive role of HRAS G12V for innate BYL719 resistance and contribute to our understanding of which patients may respond best on BYL719 therapy.

#3163 Discovery of a kinome signature predicting sensitivity and resistance to RAF-MAPK pathway inhibitors in melanoma. Riet Hilhorst,1 Mo- nem Ghanem,2 Rob Ruijtenbeek1.

Introduction: RAF-MAPK pathway inhibition with BRAF inhibitors or the combination of BRAF and MEK inhibitors has become the mainstay of therapy
of metastatic melanoma harboring BRAF V600 mutations with a response rate as high as 50–75%. A minority of patients present with primary resistance while all patients develop secondary resistance. We explored a reversed translational approach using a novel multiplex kinase assay to first identify individuals not responding to therapy using baseline biopsy samples and second to understand the mechanisms of resistance using patient-derived xenografts. We treated cell lines with selected drugs from four non-responders and three responders to vemurafenib monotherapy, all harboring the V600E mutation, were profiled for Serine-Thrreonine Kinase (STK) activities on a PamChip® peptide microarray in the presence and absence of dabrafenib. For molecular studies three melanoma cell lines, all with BRAF V600E mutations, were made resistant to vemurafenib. Protein Tyrosine Kinase (PTK) and STK activities in lysates of sensitive or resistant cells were measured in triplicate. Lysates were blotted against a selected panel of (phospho)proteins. Results: In tissue lysates, concentration-dependent ex vivo inhibition with dabrafenib was stronger in the patients that were clinical responders than in non-responders. This difference in inhibition of STK activity by dabrafenib was confirmed in the cell lines that were made resistant against vemurafenib. IC50s for sensitive cell lines were below 0.5 μM and varied from 10–21 μM for cell lines with acquired resistance. PTK activity was increased in resistant cell lines. STK activity was lower, but large differences exist among the cell lines. Common features of resistance were increased activity of receptor tyrosine kinases, Src family kinases and AKT signaling. These results were confirmed by Western blot analysis. Dabrafenib (10 μM) caused inhibition of STK activity while trametinib (10 μM) gave some activation. Dabrafenib (0.5 μM) gave strong inhibition of PTK activity, both in tissue and cell lines. Trametinib had hardly any inhibitory effect. Interestingly, the combination of dabrafenib and trametinib had an antagonistic effect on the STK activity and a synergistic effect on PTK activity, resulting in a stronger inhibition of kinase activity. Conclusion: Resistance of tumors and cell lines to vemurafenib can affect kinase activity profiles as detected pre-dose using a multiplex kinase assay. Dabrafenib inhibition of PTK and STK activity is stronger in sensitive cell lines. The overall activation of kinases in a lysate upon MEK inhibition suggests MEK as suppressor of kinase activity. Resistance to MAPK pathway inhibitors could be linked to an increase in tyrosine kinase activity and AKT pathway activity. Biomarkers are needed to identify patients in need of combined MAPK pathway inhibition.

#3164 A comprehensive analysis of autopsied specimens and patient-derived cells lines in ALK-positive lung cancers with rapid acquired resistance to alectinib. Go Makimoto,1 Kadoaki Ohashi,1 Kazuya Nishii,1 Shuta Tomida,1 Hiroe Kayatani,1 Tomoki Tamura,1 Hisao Higo,1 Kichihiro Ninomiya,1 Takashi Ninomiya,1 Yoshio Kubo,1 Eiki Ichihara,1 Akiko Sato,1 Katsuyuki Hotta,1 Masahiro Tabata,1 Katsuyuki Kuira,1 Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama City, Japan;2 Okayama University Graduate School of Medicine, Okayama, Japan. Background: Alectinib, a highly selective anaplastic lymphoma kinase (ALK) tyrosine kinase inhibitor (TKI), demonstrated a stunning disease control rate (95.7%) and unprecedented median progression-free survival (not reached: 95% CI: 20.3–) (Lancet Oncology 2013, ASCO 2016, Abstract #9008). However, acquired resistance to alectinib is inevitable; some ALK-positive lung tumors rapidly acquire alectinib resistance. Therefore, we sought to investigate the mechanism of the rapid resistance to alectinib using clinical samples and patient-derived ALK-positive cell lines. Materials and Methods: Autopsied samples (primary lung tumors and metastatic tumors from the esophagus, liver, and bilateral kidney) were obtained from a 51-year-old male with advanced ALK-positive lung cancer. The lung tumors acquired resistance to first-line treatment of alectinib in three months, and subsequent treatment with crizotinib showed only a moderate and temporary effect. We established novel ALK-positive cell lines; ABC-14 was established from a pleural effusion after alectinib resistance was confirmed in all autopsied samples by immunostaining. PCR revealed that ABC-14 harbored the EML-4/ALK fusion variant 3. An in vitro cell proliferation assay showed that ABC-14 exhibited resistance to alectinib (IC50 > 1 μM), but was sensitive to crizotinib (IC50 = 98 nM). The receptor tyrosine kinase assay revealed the activation of MET and EGFR in ABC-14. Quantitative RT-PCR and FISH confirmed MET gene amplification. Furthermore, the overexpression of an EGFR ligand, EGF, TGF-β, and no EGFR mRNA overexpression. The combination of crizotinib (dual ALK/MET-TKI) and an EGFR-TKI, gefitinib, showed an additive inhibitory effect on cell growth compared with each drug alone in vitro. ABC-17 showed resistance to both alectinib and crizotinib; consistently showed no activation of MET and no MET gene amplification. Interestingly, ABC-17 showed metastatic ability in the lung in NOG mouse PDX models. Conclusion: The mechanism of rapid resistance to alectinib may be complicated and heterogeneous. Crizotinib combined with gefitinib, which inhibits the ALK, EGFR, and MET pathways, may represent one potent strategy to treat next-generation ALK-positive tumors. A comprehensive analysis of clinical samples should provide deeper insights into its resistance. (This work was supported by KAKEN 16K19454 and KAKEN 15H04830.)

#3165 3D culture may better represent trastuzumab resistance associated with PIK3CA mutation than 2D culture. Takashi Taira,1 Toru Mukohara,2 Rina Tanaka,1 Yohei Shimomo,3 Masanori Toyoda,1 Naomi Kiyota,1 Midori Hirai,1 Yoshioho Kakeji,2 Hiroobu Minami1. Kobe University Graduate School of Medicine, Kobe, Japan;2 Kobe University Hospital, Kobe, Japan. Background: It is becoming clear that presence of PIK3CA mutations is associated with lower pathological complete response rate in patients with HER2-overexpressing breast cancer when treated with trastuzumab-based chemotherapy in neo-adjuvant settings. On the other hand, in vitro studies using traditional 2-dimensional (2D) cell culture, differential cellular or biochemical response to trastuzumab between PIK3CA-mutant (mt) and -wild type (wt) cells has not been clearly demonstrated. Further, while tumor shrinkage is occasionally observed in breast cancer patients who are treated with trastuzumab as a single agent, cytotoxic effect of trastuzumab is not simulated in 2D culture models. Recently, many studies reported 3-dimensional (3D) cell culture mimics in vivo environment better than 2D culture. Therefore, we hypothesized that 3D culture better represents the trastuzumab resistant phenotype associated with PIK3CA mutation than 2D culture, and decided to comparatively investigate cellular and biochemical response to trastuzumab in HER2-amplified PIK3CA-mt and -wt cell lines cultured in 2D and 3D environments. Method: HER2-amplified breast cancer cell lines, BT474 (PIK3CA-), and AAC893 and MDA-MB361 (PIK3CA-mt) were seeded (day 0) and allowed to grow in 2D and 3D (NanoCulture Plate®, ORGANOCULT, Kanagawa, Japan) cell culture plates. On day 3, trastuzumab (10 μg/ml) and/or BM1210 (1 and 5 μM), a PI3K inhibitor, were added. The effect of the drugs on cell growth was evaluated with WST-8 assay on days 3 through 7. Apoptosis and cell signaling were evaluated using Western blot on day 6 and days 3 through 5, respectively. Result: In PIK3CA-wt BT474, treatment with trastuzumab led to decrease in cell number, indicating cytotoxic effect, only in 3D culture but not in 2D culture. In PIK3CA-mt cell lines, treatment with trastuzumab did not change level of p-AKT regardless of cell culture conditions. In PIK3CA-mutant AAC893, combined treatment with trastuzumab and BM1210 resulted in greater increase in expression of cleaved PARP than either drug alone. Conclusion: Trastuzumab-induced inhibition of PI3K/AKT pathway and resultant apoptosis in HER2-overexpressing PIK3CA-wt cells may be observed in 3D culture, while the 2D cultured PIK3CA-mt cell lines are resistant to trastuzumab, which inhibits the ALK, EGFR, and MET pathways, may represent one potent strategy to treat next-generation ALK-positive tumors. Alectinib, which inhibits the ALK, EGFR, and MET pathways, may represent one potent strategy to treat next-generation ALK-positive tumors. Alectinib, which inhibits the ALK, EGFR, and MET pathways, may represent one potent strategy to treat next-generation ALK-positive tumors.
CASE 167 MIF-induced stat3 activation promotes resistance to MEK blockade in KRAS mutant colorectal cancer cells. Seul-Ki Cheon,1 Hwang-Phil Kim,1 Ye-Lim Park,1 Si Hyun Lee,1 Jun-Kyu Kang,1 Yoojoo Lim,1 Sang-Hyun Song,1 Sae-Won Han,1 Tae-You Kim,1 2Seoul National University, Seoul, South Korea; 2Seoul National University Hospital, Seoul, Republic of Korea.

Although MEK blockade has been highlighted as a promising anti-tumor drug, it has poor clinical efficacy in KRAS mutant colorectal cancer. Several feedback systems have been described in which inhibition of one intracellular pathway leads to activation of a parallel signaling pathway, thereby decreasing the effectiveness of single-MEK targeted therapies. In this study, we describe a feedback mechanism in which MEK inhibition leads to activation of macrophage migration inhibitory factor (MIF)-induced stat3 signaling pathway in KRAS mutant colorectal cancer (CRC) cells. We found that KRAS mutant CRC cells with reafarnetbin, MEF inhibitor, induced MIF secretion and resulted in activation of Stat3. MIF knockdown by siRNA partially restored sensitivity to reafarnetbin in KRAS mutant cells. In addition, combination with reafarnetbin and 4PP, a MIF inhibitor, effectively reduced the activity of Stat3 and MAPK.

#3168 Overcoming acquired drug resistance by TPX-0005, an ALK, ROS1 and pan-TRK inhibitor. Wei Deng, John Huang, Dayong Zhai, Evan Rogers, Jean Cui, TP Therapeutics, Inc., San Diego, CA.

The inevitable development of clinical drug resistance presents a common challenge for targeted cancer therapy. In non-small cell lung cancer (NSCLC) patients with ALK and ROS1 rearrangements, the emergence of mutations in the targeted oncoproteins is identified as one of the mechanisms that confer drug resistance. In particular, a group of mutations known as solvent front mutations, such as ALK<sup>L1196V</sup> and ROS1<sup>G2032R</sup>, render common resistance to ALK and ROS1 inhibitors. Similar solvent front mutations, such as TRKA<sup>G099R</sup> and TRKC<sup>E625K</sup>, have also been identified in cancer patients with rearrangement of NTRK family genes who developed resistance to TRK-targeted therapies. TPX-0005, a compact three-dimensional macrocyclic molecule, was designed to completely locate at the adenine binding site of ATP in order to efficiently target the active kinase conformation and systemically inhibits downstream signaling from various clinical resistant mutations, especially the solvent front mutations. TPX-0005 is an orally available and potent ATP-competitive inhibitor against ALK, ROS1, TRKA, TRKB and TRKC recombinant kinases and their corresponding clinical resistant mutants. TPX-0005 demonstrated potent anti-proliferative activity in the range of sub-nanomolar to low nanomolar in a number of human cancer cell lines and engineered stable cell lines expressing the targeted oncogenes or their solvent front mutants, accompanied by inhibition of target phosphorylation and concomitant inactivation of downstream effectors such as ERK, AKT and STAT3. In patient derived xenograft tumor models, TPX-0005 treatment resulted in significant regression of tumors harboring the oncopgenic ALK, ROS1 and TRK fusion events. Moreover, in a series of mouse xenograft tumor models, TPX-0005 exhibited marked anti-tumor activity not only in tumors harboring the wildtype oncopgenic targets but also in tumors harboring the oncopgenic with the solvent front mutations via inhibition of the target phosphorlation. Taken together, these pre-clinical studies have demonstrated the potential of TPX-0005 against not only wild type oncopgenic ALK, ROS1, TRK fusions but also their corresponding solvent front mutations, which will bring in a new therapy for cancer patients resistant to currently available ALK, ROS1, and TRK inhibitors in clinic.

#3169 SerpinB2 enhances invadopodia-like structure protrusions and is down-regulated in acquired gefitinib-resistant non-small cell lung cancer cells. Song Yi Bae,1 Donghwa Kim,2 Hyen Joo Park,2 Woong Sub Byun,2 Ji-Young Hong,2 Hye-Jung Lee,2 Sang Kook Lee,3 1MIT, Cambridge, MA; 2Seoul National University, Seoul, Republic of Korea; 3Seoul lung cancer (NSCLC) is a major type of lung cancer which accounts for approximately 80-85% of all lung cancers. The targeted therapies have significantly improved the survival of advanced NSCLC patients, but the failure of targeted therapy due to the resistance to epidermal growth factor receptor tyrosine kinase inhibitors (EGFR-TKIs), such as gefitinib, is now considered a major problem. SerpinB2 is a component of the urokinase plasminogen activating (uPA) system and has been recognized as a biomarker for the progression and metastasis of lung cancer. We found that SerpinB2 is down-regulated in gefitinib-resistant (H292-Ge) cells compared to gefitinib-sensitive (H292) cells. The low SerpinB2 levels in H292-Ge cells were also associated with an enhancement in invasiveness and increase in the length of invadopodia-like structures in the cells. The effect on invasiveness and gefitinib sensitivity was confirmed by knockdown and overexpression of SerpinB2. In addition, an antitumor agent yuahuanidine (YD) was used to test the possibility to overcome the resistance through the up-regulation of SerpinB2. YD effectively elevated SerpinB2 levels and suppressed invasive properties in H292-Ge cells. Collectively, these findings demonstrate the prospective role of SerpinB2 as a novel biomarker for acquired gefitinib resistance and a potential target for NSCLC treatment. Acknowledgement

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Novel Mechanisms 1

#3170 MCAM modulates small cell lung cancer chemoresistance via PI3k/Akt/Sox2 signaling pathway. Satyendra C. Tripathi,1 Johannes F. Fahrmann,1 Muge Celiktas,1 Mitzi Aguilar,1 Kieren D. Marini,2 Mohit K. Jolly,3 Hiroyuki Katayama,1 Hong Wang,1 Eunice N. Murage,1 Jennifer B. Dennison,1 D. Neil Watkins,6 Herbert Levine,6 Edwin J. Ostrin,6 Ayumu Taguchi,1 Samir M. Hassen,1 MD Anderson Cancer Center, Houston, TX; 2Hudson Institute of Medical Research, Australia; 3Rice University, Houston, TX; 6Garvan Institute of Medical Research, Australia.

Despite favorable responses to initial therapy SCLC relapse occurs within a year exhibiting a multidrug resistant phenotype. Due to limited accessibility of patient tissues for research purpose, SCLC patient derived xenografts (PDXs) have provided the best opportunity to address this limitation. We sought to identify novel mechanisms involved in SCLC chemoresistance. Through in-depth proteomic profiling, we identified MCAM as a markedly upregulated surface receptor in chemoresistant SCLC cell lines that exhibited a mesenchymal phenotype and in chemoresistant PDXs compared to matched treatment-naïve tumors. MCAM is a cell membrane protein whose expression has been implicated in multiple human cancers. MCAM expression is also detected in lung adenocarcinoma; however, its expression and role in SCLC is still not been explored. MCAM knockdown in chemoresistant cells reduced cell proliferation and decreased the IC50 inhibitory concentration of chemotherapy drugs. MCAM was found to modulate sensitivity of SCLC cells to chemotherapeutic drugs through up-regulation of MRPI/ABCC1 expression and of the PISK/AKT pathway in a SOX2 dependent manner. Metabolomic profiling revealed that MCAM can modulate glutamic acid and lactate production in chemoresistant cells with a distinct metabolic phenotype sustaining low oxidative phosphorylation. MCAM may serve as a novel therapeutic target to overcome chemoresistance in SCLC.
Experimental and Molecular Therapeutics: Novel Mechanisms 1

#3171 Analysis of ‘drug addiction’ mechanisms in the drug-resistant ROS1-rearranged cancer cells. Hayato Ogura,1 Jun Adachi,2 Takeshi Tonomaga,2 Naoya Fujita,3 Ryoho Katayama1, The Cancer Chemotherapy Ctr., JFCR, Tokyo, Japan;2 Lab. of Proteome Research, National Institute of Biomedical Innovation, Health and Nutrition, Osaka, Japan.

ROS1-rearranged non-small-cell lung cancer (NSCLC) is observed in approximately 1% of lung cancer patients. Crizotinib, ALK/ROS1/cMET tyrosine kinase inhibitor (TKI), showed high effect against ROS1-rearranged NSCLC in the clinical trials and is approved in US and EU. However, the cancers inevitably relapse due to the acquired resistance such as ROS1-G2032R mutation. We previously reported that caborzantinib could overcome those secondary mutations mediated resistance. Based on this finding, we tried to identify drug addiction in non-addicted caborzantinib-resistant ROS1 mutant cells by ENU mutagenesis screening. Surprisingly, we found out a few CD74-ROS1 mutant clones that only grew in the presence of low-dose caborzantinib. Namely, these mutant clones were “addicted” to caborzantinib. When the fluorescent labeled caborzantinib addicted ROS1 mutant cells were co-cultured with non-addicted CD74-ROS1-WT BaF3 cell in the presence or absence of low-dose caborzantinib, the drug-addicted cells became dominant in the low-dose caborzantinib, and CD74-ROS1-WT cells became dominant in the absence of it. To analyze the molecular mechanism of “drug-addiction” in the addicted CD74-ROS1 mutant cells, we performed comprehensive analysis such as inhibitor screening, cDNA microarray, and phosphoproteome analysis. As the result, we observed that the expression and phosphorylation of CD74 in the addicted cells were excessively increased within 24 hours after removal of caborzantinib or other ROS1 inhibitors, such as crizotinib or lorlatinib. We also observed that the apoptosis was induced in these cells upon ROS1 inhibitor removal, whereas ROS1 mediated growth signaling were simultaneously activated. Consistent with this, cDNA microarray analysis revealed that the expression of both cell survival and cell death related genes were changed by ROS1 inhibitor removal. Furthermore, we identified that several proteins were highly phosphorylated by excessive ROS1 activation originated from ROS1 inhibitor removal. These observations suggest that these drug-addicted cells were died by excessive oncogenic signaling, and the appropriate oncogenic signaling by low-dose TKI made them survive and grow without inducing apoptosis. Thus, the excessive oncogene signaling has “double-edged sword” characteristics for cancer cell viability and those characteristics could be a new therapeutic target.

#3172 Inhibition of coiled coil domain containing protein 69 (CCDC69) enhance platinum-mediated apoptosis in ovarian cancer cells. Long Cui, Joseph Kwong, Chi Chiu Wang. The Chinese University of Hong Kong, Hong Kong, Hong Kong.

Background and Objective: Molecular mechanisms of chemo-resistance in ovarian cancer are poorly understood. To identify gene involved in ovarian cancer chemo-resistance, 135 ovarian cancer patients with intact chemotherapy response information from The Cancer Genome Atlas (TCGA) database were included. Our analysis revealed that the level of CCDC69 mRNA is differentially expressed between chemo-sensitive group and chemo-resistant group. Moreover, there was a significant negative correlation between CCDC69 promoter methylation and mRNA expression. The aim of the study is to examine the role of CCDC69 in the underlying mechanism of chemo-resistance. Methods: The expression levels of CCDC69 were detected in chemo-sensitive ovarian cancer A2780, chemo-resistant A2780cis and SKOV3 cells line using quantitative RT-PCR and immunoblots. Promoter methylation status of CCDC69 were investigated by bisulfite sequencing. Silencing CCDC69 in A2780cis and SKOV3 cells were performed by Small-interfering RNAs (siRNAs) and CRISPR-Cas9. Cell viabilities after cisplatin treatment were evaluated by MTT and colony formation assays. Apoptosis was assessed by Annexin V/PI staining and caspases 3/8 activity. Cell cycle distributions and mitochondrial membrane potential (ΔΨm) were measured by flow cytometry. Relevant pathway proteins were determined by immunoblotting assays. Results: Heavy Cpg methylation (73.1% and 74.3%) was found in A2780 and A2780cis cells. Restoration in the expression of CCDC69 promoter by CRISPR-Cas9 treatment and/or reactivation of p14ARF-Mdm2-p53 cell cycle and/or apoptosis pathway, enhanced cisplatin sensitivity in CCDC69KO A2780cis cells. Overexpression of CCDC69 in A2780cis and SKOV3 cells were also shown increased sensitive to cisplatin treatment (p < 0.05). When knockout CCDC69 in chemo-resistant A2780cis and SKOV3 cells by CRISPR-Cas9, the CCDC69KO chemo-resistant A2780cis and CCDC69KO SKOV3 cells were also shown increased sensitive to cisplatin treatment (p < 0.001). Moreover, treating CCDC69KO A2780cis cells with cisplatin, abolished G1 and G2/M arrest, more cleaved caspase 3/8 activities, greater ΔΨm loss and higher levels of Bax were observed. When restoring CCDC69 expression in CCDC69KO A2780cis cells by transient transfection, it attenuated sensitivity to cisplatin. By immunoblotting, disruption of p14ARF-Mdm2-p53 cell cycle and/or apoptosis pathway, enhancement of MDM2 expression, and increase of p53 nuclear export were found in CCDC69KO A2780cis cells. Additionally, inhibition of c-Myc enhance cisplatin sensitivities in CCDC69KO A2780cis cells, overexpression of CCDC69 in A2780cis and SKOV3 cells. Our results show that silenced CCDC69 expression induced platinum-mediated apoptosis in ovarian cancer cells by abrogating c-Myc mediated apoptosis and cell cycle control networks.

#3173 AKT1 grinder quiescent cancer cells persist after neoadjuvant chemotherapy in triple-negative breast cancer patients. Sherehay Kabraj1, Xavier Sole,2 Ying Huang,2 Clyde Bango,2 Michaela Bowden,2 Aditya Bardia,2 Dennis Sgroi,2 Massimo Loda,2 Sridhar Rameswamy2, Massachusetts General Cancer Center, Boston, MA;3 Dana Farber Cancer Institute, Boston, MA;4 Massachusetts General Hospital, Boston, MA.

The mechanisms that allow triple negative breast cancer tumors to survive neoadjuvant chemotherapy are incompletely understood. Evidence suggests that proliferative heterogeneity may contribute to primary chemotherapy resistance in patients with triple negative breast cancer. AKT1 grinder quiescent cancer cells (QCCs) is a quiescent, epigenetically plastic, and chemotherapy resistant subpopulation initially identified in experimental cancer models. Here, we identify QCCs in primary and metastatic human breast tumors using automated, quantitative, immunofluorescence microscopy coupled with computational and statistical techniques. We show that QCCs exist as non-random and heterogeneous clusters within primary tumors. In addition, these QCC clusters persist after treatment with multi-agent, multi-cycle, neoadjuvant chemotherapy in both residual primary tumors as well as nodal and distant metastases in patients with triple negative breast cancer. Together, these data qualify QCCs as a non-genetic mechanism of chemotherapy resistance in triple negative breast cancer patients that warrants further study.

Abstract Introduction- Resistance to therapeutics targeting topoisomerase 2 is a major problem in the treatment of leukemia. Cells which survive and give rise to relapsed leukemia are known to modulate different pathways like down-regulation of drug target, reduced drug accumulation, and improved DNA repair; ultimately leading to survival of drug resistant cells. Here, we wanted to identify the earliest detectable changes occurring when cells become resistant to topoisomerase 2 inhibitors. Methodology- We generated early and late stage drug (doxorubicin) resistant leukemia sub cell line from K562 and THP-1 parent cells, HL-60/MX2 resistant sub cell line of HL60 was also used for this study. Molecular changes were analyzed by electron microscopy, quantitative PCR, western blotting, immunofluorescence, flow cytometry, molecular inhibitors and MT assay. Results were further confirmed in blast cells of AML (n = 44) patient samples collected for this study. Furthermore, meta-analysis for survival time was done from microarray expression data of 221 patient samples using ProgNoScan. Results- We mapped molecular changes acquired by leukemic cells during evolution from Early Drug Resistant Population (EDRP) to Late Drug Resistant Population (LDRP). We found unlike LDRP, EDRP cells do not possess known bona fide drug-resistance mechanisms namely limited drug accumulation, reduced DNA damage or expression of drug target. Instead they survive by acquiring ‘poised epigenetic state’ that enhanced their DNA repair. Mechanistically, GCN5, a histone acetyl transferase get selectively upregulated in EDRP cells mediating higher H4K16 acetylation levels and consequent euchromatin state of EDRP. Upon Doxorubicin treatment, H4K16ac facilitate higher ATM recruitment and activation causing efficient activation of H2AX, NBS1, BRCA1, Chk2 and Mcl-1, accelerating DNA repair and survival of EDRP cells. Inhibition of GCN5 with Doxorubicin treatment significantly reduces H4K16ac levels, ATM recruitment and cell survival of EDRP cells. Similarly, ATM induction along with Doxorubicin completely ablates EDRP but not LDRP. Furthermore, baseline AML patient samples (n = 44) showed significantly higher GCN5 expression in MRD positive compared to MRD negative samples. Additionally, meta-analysis of 221 AML patients showed increased GCN5 expression associates with poor survival of AML patients. Conclusion- We identify GCN5 expression as marker that defines onset of resistance in leukemia and GCN5 mediated ATM activation via H4K16ac as a novel non-genetic route facilitating EDRP cell survival with enhanced DNA repair. These data also
highlight the clinical relevance of targeting GCN5 and ATMs during early resistance to prevent emergence of difficult to treat stable diverse resistance in leukemia.

Muscle invasive bladder cancer (MIBC) is a significant cause of cancer death, in part because there are relatively few treatments and these have limited efficacy. Our studies show that expression of 14-3-3 (aka ARF), one of the major transcripts encoded by the CDKN2A tumor suppressor locus, is frequently up-regulated in MIBC, particularly in more aggressive disease subtypes. Our results further show that accumulation of ARF protein in the nucleus is associated with poor outcome and reduced response to chemotherapy. Using both genetically-engineered mouse (GEM) models and human xenograft models of MIBC, we demonstrate that tumors expressing ARF display poor response to treatment with the platinum-based chemotherapy agent cisplatin. This is mediated in part by expression of the integrin-binding protein ITGB3BP (CENPR) and reflects ARF-dependent inhibition of protein translation, which is attenuated by drug treatment. Our findings reveal an unexpected context-dependent role for ARF in modulating drug response in bladder cancer through its ability to regulate protein translation.

#3176 Inhibition of HER2/β-catenin signaling by penfluridol overcomes resistance to paclitaxel in breast cancer. Nehal Gupta, Parul Gupta, Sanjay Srivastava. Texas Tech University Health Sciences Center, Amarillo, TX.

Paclitaxel is a first line treatment option for patients with metastatic breast cancer. However, inherited or acquired resistance is a limiting factor for therapy with paclitaxel. The mechanism of paclitaxel resistance remains obscure and hinders the development of therapeutic strategies. HER2 is an oncogene overexpressed in about 30% of breast cancer patients and plays role in drug resistance leading to poor prognosis. To identify more clinically relevant mechanism of paclitaxel resistance, we developed resistance to paclitaxel in MCF-7 and 4T1 breast cancer cell lines. The continuous exposure to paclitaxel for several months resulted in >100 fold resistance in MCF-7 cells and >100 fold resistance in 4T1 cells. Western blot analysis showed enhanced expression of HER2, β-catenin and downstream molecules such as TCF/LEF, c-Myc, Cyclin D in these resistant cells. We have recently demonstrated that penfluridol, an anti-psychotic drug, suppresses the growth of triple negative metastatic breast cancer cells (Ranjan and Srivastava, Cancer Res 2016; 76(4): 877-890), giving us the rationale to evaluate whether penfluridol inhibits HER2 and β-catenin signaling. Our current results showed that penfluridol treatment not only suppressed HER2 but also inhibited β-catenin expression. We also observed down regulation of LEF-1/TCF, Cyclin D1 and c-Myc expression with penfluridol treatment in paclitaxel sensitive as well as resistant cells resulting in reduced survival of cells. Our results further showed that penfluridol treatment synergistically enhanced the growth suppressive effects of paclitaxel in MCF-7 and 4T1 paclitaxel resistant cells. Treatment of paclitaxel resistant 4T1 cells with 1.5μM of penfluridol in combination with 50nM of paclitaxel resulted in 65% of cell growth suppression whereas either treatment alone was not cytotoxic at all. We also observed an enhanced down regulation of proteins involved in paclitaxel resistance such as HER2, β-catenin, c-Myc and Cyclin D1 as well as increase in apoptotic markers such as CI-PARP and CI-Caspase3 when paclitaxel treatment was combined with penfluridol in resistant cells. Taken together, our results provided a novel insight into the mechanism of resistance to paclitaxel and also opened new avenues for application of penfluridol in cancer therapeutics. Further detailed mechanistic and in vivo studies are in progress. (Supported in part by RO1 grant CA129038, awarded by National Cancer Institute, NIH).

Background: Recently, a new research spotlighted the role of KITENIN (KAI1-COOH-terminal interacting tetraspanin) on glioma invasiveness and progression, associated with the up-regulation of EMT (epithelial-mesenchymal transition) and cancer stemness markers. In this study, furthermore, it is investigate whether KITENIN leads to resistance against TMZ through enhancement of cancer stemness factors using mouse glioma model. Materials and Methods: TMZ-resistant T98G cell line (T98G/TR) was developed. EMT and cancer stemness markers and KITENIN expression were assessed by Western blotting and qRT-PCR. With KITENIN modulated U251 (knockdown) and GL261 (overexpression) cells, cell viability and apoptotic cell death factors after TMZ treatment were evaluated. Biological role of KITENIN on TMZ-resistance was investigated using cell viability, proliferation, invasion and migration analysis for tumor sections of orthotopic glioma model. Using human glioma samples and primary cells, the mechanistic link between KITENIN and cancer stemness factors was confirmed. Results: T98G/TR cells showed increased expression of the KITENIN and EMT and cancer stemness factors. Also, in vitro assays revealed that KITENIN knockdown inhibited cell viability against TMZ treatment, whereas KITENIN overexpression promoted cell viability and apoptotic cell death pathway. In orthotopic glioma models, mice implanted with KITENIN-overexpressed cells showed resistance to TMZ on MRI and histopathological examination. The expression of KITENIN/ALDH1 or KITENIN/C4D were co-localized and significantly higher in tumor sections of mouse transplanted with KITENIN-overexpressed cells than in tumor sections of mouse transplanted with control cells. Genetic down-regulation of KITENIN for KITENIN-overexpressed cell line and primary glioma cells led decreased expression of ALDH1 and CD44. In human glioma samples, high expression of KITENIN was closely related with high expression of ALDH1. Conclusion: KITENIN affects TMZ-resistance in malignant gliomas through induction of ALDH1 and CD44. Therefore, it could be suggested that KITENIN is therapeutic target to overcome TMZ-resistance of malignant gliomas.

#3178 The p53 tumor suppressor protein paradoxically drives chemoresistance in human medulloblastoma cells through suppressing the mTOR AKT pathway. Aisha Naeen, Muhammad U. Choudhry, Maria L. Avantaggiati, Olga C. Rodriguez, Chris Albanese. Georgetown Univ., Washington, DC.

Medulloblastoma (MB) accounts for approximately 25% of childhood brain tumors with 70% of the cases occurring in children under 10. Prognosis for children less than three years old is considerably worse and, due to its destructive effects on the developing nervous system, irradiation is largely avoided in this age group. The p53 pathway is considered a key determinant of anti-tumor responses in many tumors; however, its role in the regulation of cell survival, chemo-sensitivity and chemoresistance in MB is much less well defined. It has been shown that p53 pathway defects, mutations and nuclear levels increase significantly from MB diagnosis to relapse and correlate with an adverse prognosis. We recently reported on the highly novel and unexpected finding that both the genetic (shRNA) and chemical silencing of p53 led to a significant increase in cell death by the drug VMY in MB cell lines with elevated basal p53 (e.g. in D556 cells which express wild type p53 and in DAOY cells that contain mutant p53) as measured by colony formation assays, DNA degradation assays and annexin-V staining, suggesting a surprising commonality in the p53 signaling in both cell lines despite the differences in their p53 status. Equally surprising was the observation that the silencing of p53 in D556 cells enhanced cell death by the clinically used drugs doxorubicin and vincristine. Conversely, we now find that suppressing p53 with sh-RNA in D283 cells, which express much lower levels of wild type p53 compared to D556, resulted in the more classical chemoresistance profile, suggesting a form of p53 ‘addiction’ in D556 and DAOY cells. Mechanistically, we observed that suppressing p53 with sh-RNA in D556 cells treated with VMY or doxorubicin significantly increased the levels of phosphorylated Chk1, S6K, gH2AX, and MDM2. Importantly, phospho-mTOR levels were also significantly increased in the D556/p53 -sh RNA cells and the suppression of mTOR enhanced chemoresistance. These somewhat paradoxical findings suggest that activating mTOR may induce MB cell death and that suppression of mTOR by p53 enhances chemoresistance. Our data provide new mechanistic insights into the role of p53 in primitive neuroectodermal tumors and may provide new approaches for enhancing the clinical outcome of patients with MB.
unique amino acids through translation of the exon 19/inntron 19 'readthrough'. Immunoassays, utilizing antisera raised against these unique amino acids, confirmed that TOP2a/90 is expressed in both cell types, with overexpression in K/V/P.5 cells. Immuno detection of Complex of Enzyme-to- DNA (ICE) and single cell gel electrophoresis (Comet) assays demonstrated that K562 cells transfected with TOP2a/90 encoded truncated DNA covalent complexes and decreased etoposide-induced DNA damage, respectively, compared to similarly treated K562 cells transfected with empty vector. Since TOP2a lacks the active site tyrosine (Tyr805) of full length TOP2a, these results strongly suggest that TOP2a/90 exhibits dominant-negative properties. In separate studies the TOP2a/90 mRNA splice variant was found to be expressed in most human tissues suggesting that this novel protein isoform may play a role in both intrinsic chemosensitivity as well as in acquired resistance. Further studies are underway to characterize the mechanisms(s) by which TOP2a/90 plays a role in acquired resistance to etoposide and other TOP2a targeting agents. In addition, future studies will be directed to examine the RNA processing mechanism(s) that suppress intron 19 splicing in TOP2a pre-mRNA.

#3182 Cytoskeletal modulation results in increased tumor survival and drug resistance through attenuation of p53 dependent apoptosis. Victoria E. Wang, 1 John Doench, 2 David Root, 2 Rene Bernard,3 Jeffrey Settleman,3 Frank McCormick, 1 1UCSF, San Francisco, CA; 2Broad Institute, Cambridge, MA; 3Netherlands Cancer Institute, Amsterdam, Netherlands; 4Genentech, South San Francisco, CA.

One of the major challenges to eradicating cancer involves the evolution of drug resistant clones and persistence of residual disease that escapes our current limit of detection but may proliferate upon cessation of therapy. These microscopic foci of residual diseases often exhibit stem-cell like properties and are intrinsically more resistant to drug therapy. A better understanding of the mechanisms underlying the innate drug resistance of these cellular populations may lead to improved treatment strategies, resulting in more durable remissions and ultimately improved patient survival. We utilize functional genomic platforms to identify mechanisms responsible for the persistence of drug tolerant cells. A genome wide shRNA enrichment screen was performed using the c-Met addicted cell line GTL-16 to identify genes whose knockdown conferred DTP survival. Inhibition of the RhoA-ROCK-myosin pathway promotes drug resistance in a variety of tumor models, including those treated with either targeted therapy or conventional chemotherapy. Furthermore, more, pharmacological validation using multiple small molecule inhibitors of ROCK1 phenocopied both myosin heavy chain (MYH9) and light chain (MYL12) shRNA knockdown. More recently, utilizing a combination of gene expression and biochemical approaches, we have identified attenuation of p53 induced apoptosis to be a key event in mediating survival of these drug tolerant persisters. Reactivation of p53 using nutlin results in increased cell death. These findings demonstrate that modulation of cytoskeleton is an important, but underappreciated, mechanism of drug resistance across many tumor types. These downstream effectors may serve as novel therapeutic targets for intervention and also biomarkers to stratify patients and their response to treatment.

#3183 Proteomic characterization of aromatase inhibitor resistant mammospheres reveal the presence of a novel nuclear chaperone. Syreeta L. Tilghman, 1 Jamal Pratt, 2 Shawn D. Llopin, 3 Michael Alexander, 1 Rashidra R. Walker, 3 Patrick Carriere, 3 Ian R. Davenport, 2 Wensheng Zhang, 1 Karen Zhang, 1 Florida A&M University, Tallahassee, FL; 2 Xavier University of Louisiana, New Orleans, LA; 3 Morehouse School of Medicine, Atlanta, GA.

Postmenopausal women with early-stage metastatic estrogen-dependent breast cancer are generally treated with aromatase inhibitors (AIs) (e.g., letrozole). However, acquired resistance remains a major clinical obstacle. Previously, our group revealed a global proteomic signature of a letrozole-resistant cell line (LTLT-Ca) associated with hormone independence, enhanced cell motility and epithelial to mesenchymal (EMT). Given recent evidence suggesting a convergence of EMT and cancer stem cells (CSC), we chose to utilize a two-dimensional (2D) vs three-dimensional (3D) culture system to compare the proteome of LTLT-Ca cells, as 3D culture not only enriches for CSC, but more accurately recapitulates the tumor microenvironment, morphology, function and response to therapy compared to conventional 2D culture. We hypothesize utilizing a novel systems biology approach may reveal previously unconsidered molecular changes that could aid in understanding complex signaling networks and be exploitable as therapeutic targets. To address this hypothesis we characterized mammosphere enriched immunocompromised female mice were inoculated in the mammary fat pad with LTLT-Ca or letrozole sensitive cells (AC-1) and intratumoral putative CSC marker expression was assessed by immunohistochemistry. Results indicate LTLT-Ca tumors were CD44+/CD24−/ whereas AC-1 tumors were CD44+/CD24+...
CD24™. Mammosphere formation assays were conducted and LTLL-T-Ca cells formed mammospheres at a 3.4-fold higher index than AC-1 cells. A quantitative proteomic analysis of whole cell lysates from LTLL-T-Ca (2D adherent cells) versus LTLL-T-Ca (3D mammospheres) was conducted. Results identified significant protein expression changes within a panel of 1010 proteins; 173 were up-regulated and 186 downregulated (p < 0.05, fold change ≥ 1.20). Additionally, functional enrichment analyses were performed and 19 gene ontology (GO) terms and one KEGG pathway (hsa03010:Ribosome) were over-represented (BH adjusted p-value < 0.01) by the cognate genes. Notably, there was a 35.04-fold increase in midasin (MDN1), a nuclear chaperone protein required for maturation and nuclear export of pre-60S ribosome subunit. Increased MDN1 expression was strongly correlated with highly tumorigenic breast cancer subtypes. Additionally, Kaplan-Meier survival plots demonstrate that increased maturation and nuclear export of pre-60S ribosome subunit. Increased MDN1 fold increase in midasin (MDN1), a nuclear chaperone protein required for to daunorubicin in leukemia cells.

The enhanced LC3Band P62 levelssuggest an accumulation of these cells as compared to control cells. In addition, the inhibition of V-ATPase—served as significantly increased expression of the autophagy protein, beclin-1 in western blot analysis. Upon cisplatin treatment, the LC3B levels were further increased in a2v increased the protein levels of SQSTM1/p62, a known substrate for the threonine pumps that regulate intra/extra-cellular pH in cancer. Its a2 isoform (V-ATPase-a2) contribute signifıcant amounts of H2O2 in the bone marrow micro-environment to contribute to anthracycline resistance.

Introduction: Docetaxel (DTX) is one of the primary drugs used for treating castration resistant prostate cancer (CRPC). Unfortunately, over time patients invariably develop resistance to DTX therapy and their disease will continue to progress. The mechanisms by which resistance develops are still incompletely understood. This study seeks to determine the involvement of miRNAs, specifically miR-181a, in DTX resistance in CRPC. Methods: Total RNA from parental C4-2B prostate cancer cells and DTX resistant C4-2B cells (C4-2B TaxR) was submitted for small RNA deep sequencing. Data was analyzed to ascertain which miRNAs expressions were most altered in C4-2B TaxR cells compared to parental cells. Having identified an increase in miR-181a in resistant cells, its expres- sion was modulated in C4-2B and C4-2B TaxR cells by transfecting them with miR-181a mimics or antisense, respectively. Following transfection, cell number and proliferation were monitored by crystal violet assay and colony-forming assay. Phospho-p53 expression was assessed by western blot and apoptosis was measured by ELISA on C4-2B TaxR cells with inhibited miR-181a expression with or without DTX. Results: miR-181a is significantly upregulated in C4-2B TaxR cells compared to parental C4-2B cells as analyzed by small RNA sequencing. Over-expression of miR-181a in C4-2B cells confers DTX and cabazitaxel resistance. Knockdown of miR-181a in C4-2B TaxR cells re-sensitizes them to treatment with both DTX and cabazitaxel. miR-181a knockdown alone induced apoptosis in C4-2B TaxR cells which is further enhanced by DTX. We next assessed if miR-181a altered expression or activity of ABCB1, which is overexpressed/active in C4-2B TaxR cells and promotes resistance to DTX by pumping the drug out of cells. We found that miR-181a does not impact ABCB1 expression or activity. Since we previously demonstrated that p53 phosphorylation, and how these changes contribute to cisplatin sensitization. Expression profiling of ovarian cancer cells (A2780 cis-r and TOV-112D- cis-r) revealed that upon a2 inhibition, the basal levels of autophagosome membrane protein, LC3B were enhanced compared to cis-r cells as determined by flow cytometry and western blot analysis. Upon cisplatin treatment, the LC3B levels were further enhanced in a2 inhibited cis-r cells compared to control cells. Further, we observed a significantly increased expression of the autophagy protein, beclin-1 in these cells as compared to control cells. In addition, the inhibition of V-ATPase-a2v increased the protein levels of SQSTM1/p62, a known substrate for the a2 isoform of V-ATPase (V-ATPase-a2) contributed to the accumulation of the autophagosomes due to a altered autophagy flux upon V-ATPase-a2v inhibition. The study provides a rationale for the utility of V-ATPase-a2 inhibitors in combination with standard drugs as a novel strategy to improve the treatment efficacy of the chemoresistant ovarian cancer.
Experimental and Molecular Therapeutics: Novel Mechanisms 1

 centrally controls the emergence of NEPC from CRPC under the selective pressure of ENZ remain elusive. As the AR is the cornerstone therapeutic target in men with CRPC, understanding its contribution to the development of NEPC is critical to better implement current standard-of-care therapies such as ENZ, and to identify novel therapeutic targets for this incurable disease. Hallmarks of AR expression in the prostate include high AR activity, highlighted its clinical relevance to disease that is difficult to treat with mainstay therapies. These data underscore the consequences of potent AR inhibition in CRPC, revealing a novel mechanism of AR-dependent control of NEPC resistance to ENZ and the loss or reduced activity of the AR. Thus, we hypothesized that a consequence of ENZ treatment and resistance in CRPC is directly control the emergence of NEPC from CRPC under these selective pressures of ENZ remain elusive. Lung cancer is the leading cause of the cancer-related death worldwide. Despite extensive efforts for the cure of lung cancer, the effectiveness of currently available therapeutic regimens has been marginal and limited, and recurrence is still an inevitable consequence of anticancer therapies. Therefore, mechanistic understanding on the progression and relapse of lung cancer and finding out relevant targets are essential for development of efficacious therapeutic strategies. We have investigated mechanisms of chemoresistance by using subsets of lung cancer cell lines carrying acquired resistance to chemotherapies. These chemoresistant sublines of NSCLC cells exhibited a prominent downregulation of anti-tumor microRNAs, including proliferation, metastasis, and protein synthesis, but displayed increased tumor growth in vivo. Additional studies revealed that the chemoresistant sublines experienced increased secretion of various soluble factors that led to increases in proliferation and stemness of drug-naive cancer cells and recruitment of macrophages, establishing tumor microenvironment (TME) prone to tumor recurrence. We further demonstrate a pivotal role of regulator of G protein signaling 2 (RGS2) in tumor-promoting cell-cell communications, ultimately leading to chemoresistance. RGS2 disrupted chemotherapeutic-induced apoptosis and secretion of soluble factors involved in cellular communications in TME by regulating unfolded protein responses, a typical cellular event associated with downregulation of protein synthesis. Mechanistically, RGS2 induced proteasome-mediated prote degradation of a component of eukaryotic translation initiation factor complexes through direct interaction, resulting in blockade of the CAP-dependent protein translation. RGS2 expression was elevated in tumors derived from patients with lung cancer compared with normal counterparts and significantly associated with poor clinical outcomes. These findings suggest that RGS2 is a novel biomarker responsible for chemoresistance by establishing tumor-promoting TME and can be a potential therapeutic target for the treatment of lung cancer with chemoresistance.

The purpose of this study is to identify mechanisms of resistance to gemcitabine in pancreatic ductal adenocarcinoma (PDAC) using an in vitro coculture system. The inherent resistance of PDAC to first line treatments such as gemcitabine has been attributed to the dense fibrotic stroma. Targeting stromal components, in particular cancer-associated fibroblasts (CAFs), the activated form of pancreatic stellate cells (PSCs), is a promising avenue for therapeutic intervention. We have demonstrated previously the induction of gemcitabine resistance when co-culturing KRAS G12D; p53 R172H; Pdx-cre (KPC) mouse PDAC-derived tumour cells with PSCs, in comparison to PDAC cells co-cultured with PSCs or monoculture. This resistance-inducing effect is specific to cells of mesenchymal phenotype, is transient in nature and a product of cell-cell contact. To investigate the exact mechanism by which PDAC cells become resistant to gemcitabine in coculture, we undertook a genome-wide shRNA depletion viability screen, infecting KPC mouse PDAC cells with a pooled shERWOOD UltramiR shRNA library both in mono- and co-culture with PSCs, in the presence and absence of gemcitabine. Next-generation sequencing and differential expression analysis, using DISEq2, identified shRNAs depleted through 6 cycles of gemcitabine treatment in coculture, indicating they target genes driving the resistance effect. Pathway analysis of differential expression using MetaCore implicated DNA damage repair and protein modification pathways in the gemcitabine resistance effect. Depletion of p97, ATR, or Chk1 all sensitised PDAC cells to gemcitabine in coculture, corroborating findings with translational value in previous studies.

#3191 Daytime blue-enriched LED light-induced circadian amplification of the nighttime melatonin signal increases sorafenib sensitivity in human hepatocellular carcinoma via enhanced suppression of the Warburg effect. Robert T. Dauchy, David T. Pointer, Aaron E. Hoffman, Melissa A. Wren-Dalal, Shulin Xiang, Lin Yuan, David E. Blask, Victoria P. Belancio, Steven M. Hill. Tulane Univ. School of Medicine, New Orleans, LA.

Over 36,000 people in the United States will be diagnosed with hepatocellular carcinoma (HCC) in 2016, the second leading cause of cancer death worldwide.
Metabolic pathways within the liver and in HCC are highly regulated by the central circadian clock in the suprachiasmatic nucleus (SCN). The SCN drives nighttime production of the circadian anti-cancer hormone melatonin by the pineal gland in rats and humans. We have shown that the nighttime circadian melatonin signal suppresses the Warburg effect (aerobic glycolysis) in human breast cancer (MCF-7) and that blue light at daytime (bLAD), amplifies the nighttime circadian melatonin signal by 7-fold in rats over cool white fluorescent (CWF) lighting. Here we tested whether daytime exposure of tissue-isolated HepG2 xenograft-bearing male nude rats to bLAD amplifies the nighttime melatonin signal to increase tumor sensitivity to nighttime administered sorafenib (FDA-approved multi-kinase inhibitor) treatment via enhancing suppression of the Warburg effect. Animals were randomized to 6 subgroups (n = 4): CWF Groups I, 12 h light:12 h dark (LD,12:12) (CWF + vehicle) and II (CWF + sorafenib); bLAD Groups III (LD,12bLAD:12) (bLAD + vehicle, IV (bLAD + sorafenib), V (bLAD + S20928 MT, receptor blocker), and VI (bLAD + S20928 + sorafenib). Drug treatments began when tumors were 2.5 g estimated weight. Plasma nighttime melatonin levels were 7-fold higher in Groups III-VI, compared to Groups I and II. Tumor latency-to-onset of growth and growth rates were markedly delayed and decreased, respectively, in Group III compared to Group I. Sorafenib induced tumor regression at a rate that was 2-fold higher in the bLAD- vs CWF-exposed rats. Tumor glucose uptake and lactate production (Warburg effect) at the mid-dark phase were significantly reduced in CWF-exposed rats receiving sorafenib vs vehicle, whereas the nighttime melatonin signal in bLAD-exposed rats significantly decreased vs CWF-exposed rats receiving vehicle. In bLAD + sorafenib-treated rats, the Warburg effect was reduced by an additional 51% (glucose uptake) and 89% (lactate production), respectively, vs CWF + sorafenib-treated rats. Melatonin receptor blocker S20928 completely prevented the effects of bLAD and bLAD + sorafenib on the Warburg effect and made these tumors completely resistant to sorafenib-induced tumor regression. These findings are the first to show in vivo that: 1) nighttime circadian sorafenib therapy inhibited the Warburg effect and induced HepG2 tumor regression under CWF lighting conditions, and 2) the bLAD-amplified nocturnal circadian melatonin signal increased tumor sensitivity to sorafenib-induced regression by enhancing a melatonin receptor-mediated suppression of the Warburg effect.

Purpose: IMMU-132 is an antibody-drug conjugate composed of a humanized anti-Trop-2 IgG conjugated via a cleavable linker to SN-38, a topoisomerase I inhibitor and active component of irinotecan. It is currently under clinical investigation in a range of solid tumors (NCT01631552). We investigated the hypothesis that IMMU-132, through its targeting of Trop-2 in solid tumors, will be superior to irinotecant in overcoming Rad51-mediated HRR repair of DNA breaks in TNBC tumors with high Trop-2 expression. Methods: Rad51 and DNA-breaks (γH2AX) were determined by Western blot. Cells with different Trop-2 levels were exposed to IMMU-132 for 24 h (25 - 100 nM SN-38 equivalent), including squamous cell lung carcinoma (SK-MES-1, −30,000 Trop-2/cell) and TNBC (HCC1806, −90,000 Trop-2/cell and MDA-MB-231, −30,000 Trop-2/cell). Also, two Trop-2-transfectants of MDA-MB-231, designated C13 and C39 (4- and 25-fold higher Trop-2 levels, respectively), were likewise exposed to IMMU-132. Mice bearing MDA-MB-231, C13, or C39 tumors were treated with irinotecan (MTD, 40 mg/kg, q2dx5) or IMMU-132 (0.5 mg; 9 μg SN-38 equivalent, twice wkly x 4). Tumors were measured and mice weighed twice weekly. Study survival endpoint was tumor progression to >1.0 cm. Results: SK-MES-1 and HCC1806 are sensitive to IMMU-132 therapy whereas MDA-MB-231 is resistant. IMMU-132 mediated a >2-fold increase in Rad51 levels in MDA-MB-231 cells, but had no effect in SK-MES-1 or HCC1806. At 25 nM IMMU-132, there were lower levels of DNA breaks detected in MDA-MB-231 relative to SK-MES-1 and HCC1806 (2-fold increase in MDA-MB-231 vs >3-fold). At higher concentrations of IMMU-132 (100 nM), all 3 cell lines demonstrated similar levels of DNA breaks (~5-fold above background), suggesting that higher levels of SN-38 can overcome Rad51-mediated repair. Both the C13 and C39 clones had a similar response as parental MDA-MB-231 upon IMMU-132 exposure. Mice bearing MDA-MB-231, C13, or C39 tumors treated with irinotecan demonstrated significant tumor growth delay compared to saline (P < 0.0009). As expected, IMMU-132 was no different than saline in mice bearing MDA-MB-231 tumors (MST = 21d and 19.5d, respectively). However, in mice bearing high Trop-2 C13 and C39 tumors, IMMU-132 provided a significant survival benefit compared to irinotecan-treated mice (MST > 70d vs. 35d, respectively for C13 and >70d vs. 28d for C39; P < 0.0007), supporting the hypothesis that IMMU-132 is able to deliver more SN-38 to tumors with high Trop-2 than can be achieved by irinotecan, and can thus overcome Rad51-mediated HRR. Conclusion: IMMU-132, with its unique SN-38-delivery platform, has the potential to provide clinical benefit both to chemosensitive solid tumors with low Trop-2 expression, as well as to chemoresistant tumors with high Trop-2 expression.

### #3194 A new mechanism of drug resistance in cancer: extracellular ATP-induced resistance through ATP internalization and upregulation of protein phosphorylation in Akt and ERK pathways. Xuan Wang, Yunsheng Li, Yanrong Qian, Yanyang Cao, Xiaohou Zhou, Chuangxia Chen, Ohio University, Athens, OH.

The opportunistic uptake of extracellular molecules has been named as a key emerging hallmark of cancer metabolism.[41] Extracellular ATP (eATP) levels of various cancer types are 10^6 to 10^7 times higher than those in their corresponding normal tissues[24]. However, the biological significance of the high ATP concentrations is not clear. We recently reported that cancer cells uptake extracellular ATP via different endocytoses to enhance growth, survival, and drug resistance to tyrosine kinase inhibitors (TKIs).[24] We hypothesized that eATP induces resistance to TKIs by endocytoses-mediated internalization of eATP, which competes with TKIs for the ATP-binding site of receptor TKs (RTKs), phosphorylating and activating RTKs and RTK-mediated signaling pathways. In contrast to previous reports that synthesized intracellular ATP (iATP) elevation contributed acquired drug resistance, here we report a novel intrinsic drug resistance in which eATP was internalized and substantially increased iATP levels in resistant cancer cells relative to their parental human NSCLC A549 cells. The iATP level elevation and drug resistance were mediated primarily by macropinocytosis. The resistance was reduced when macropinocytosis was suppressed by inhibitors or an siRNA knockdown of a key micropinocytosis protein PAK1. Intracellularly, the elevated iATP upregulated phosphorylation of PDGFR and proteins/enzymes in the PDGFR-mediated Akt-mTOR and Raf-ERK signaling pathways, resulting in reduced apoptosis triggered by sunitinib. Furthermore, both in vitro and in A549 tumors, eATP partially restored phosphorylation levels of PDGFR and PDGFR-mediated proteins/enzymes suppressed by sunitinib. The resistance cannot be accounted for by the overall purinergic receptor-mediated signaling, glycolysis, or mitochondrial OXPHOS. These results strongly suggest that the eATP-elevated intracellular ATP levels reversed the inhibition of TKIs by using the mechanism we hypothesized, linking for the first time the ATP-rich tumor microenvironment with cancer drug resistance. All these findings significantly expand our understanding of the roles of extracellular ATP in cancer, and offer new anti-drug resistance targets. 1. Pavlova N, Thompson C. Cell Metab. (2016) 23:27-47. 2. Falzoni et al., Interface Focus. (2013) 3: 20120101. 3. Qian Y, Wang X et al., Cancer Lett. (2014)351: 242-5. 4. Qian Y, Wang X et al., Mol Cancer Res (2014) 14:1087-96.

### #3195 Dyrk1b inhibitors prevent pharmacologic quiescence and sensitize lung cancers to Egfr inhibitors. Maria Vilenchik,1 Alexandra Kuznetsova,1 Michael Frid,2 Yury Ginkin,1 Marc Duer,2 Neal Rosen,2 Felicite Therapeutics Inc., Newton, MA; 2Memorial Sloan Kettering Cancer Center, New York, NY.

Many oncoproteins that activate signaling dysregulate cell growth by activating the cyclinD/cdk4, cdk6 complex and abrogate in the G1 checkpoint (mutant RAS, BRAF, PIK3CA, EGFR etc.) Inhibition of these oncoproteins inhibits cell cycle entry and promotes cell death. Dyrk1b kinase plays an important role in physiologic quiescence by maintaining the viability of cells arrested in the G0/G1 phases of the cell cycle. Dyrk1b regulates the G0/G1 transition by phosphorylating cyclin D1 and p27, whereby destabilizing cyclin D1 and stabilizing p27. The balance between these two proteins is essential for maintenance of cells in G0 (quiescent) state. Dyrk1b is sparsely expressed in healthy tissues yet is overexpressed in patient samples with variety of neoplasms, including NSCLC and cancer and normal cells exhibit differential sensitivity to Dyrk1b inhibition. Whereas Dyrk1b appears essential for survival of cancer cells either endogenously expressed or upregulated, its inhibition in healthy cells was not cytotoxic and had no effect on the cell cycle distribution. We hypothesized that if Dyrk1b is required for maintenance of quiescence, its inhibition would enhance the effects of an insignificant imipogenic signaling. We used a selective, ATP competitive Dyrk1b inhibitor to test this idea. EGFR inhibitors are effective in non-small cell lung cancers with mutant EGFR and induce G0/G1 block and some apoptosis. These drugs significantly extend survival, but acquired resistance almost always supervenes. In vitro, the anti-proliferative response of lung tumors
with mutant EGFR to EGFR inhibitors was shown to be primarily due to the entry of cells into a quiescent (G0) state associated with an induction of DRYK1B expression. Moreover, addition of a DRYK1B inhibitor reversed the quiescent state in cells exposed to EGFR inhibitors. Combined therapy of EGFR TKIs and the DRYK1B inhibitor significantly enhanced the antitumor response compared to either drug alone. Importantly, it is worth noting that treated results in an increase in cells in G0 state: 63% as compared to non-treated cells, 29%. The induction of quiescence is prevented when cells are treated with the combination of osimertinib and DRYK1B inhibitor and massive apoptosis is observed: 62% compared to 12% with osimertinib alone. It is important to note that co-treatment with DRYK1B inhibitor not only prevented the entry of cancer cells into quiescence but also depleted pre-existent reservoir of quiescent cancer cells. The results suggest that inhibition of EGFR causes tumor cells to enter into a DRYK1B-dependent quiescent state in which DRYK1B is required for their survival. Inhibition of DRYK1B dramatically enhances the antitumor activity of EGFR inhibition and may improve outcome in patients.

#3196 Genetic and pharmacologic approaches to overcome epithelial to mesenchymal mediated chemoresistance in breast cancer. Michael J. Crowley, Nasser Ahorki, Vivek Mittal, Dingcheng Gao. Weill Cornell Medical College, New York, NY.

Development of resistance to conventional chemotherapy remains a major barrier to effective treatment of breast cancer. We and others have recently demonstrated in breast and pancreatic cancer models that epithelial-mesenchymal transition (EMT) may not be a critical mediator of cancer metastasis, however, it contributes to cancer drug resistance (Fischer et al. Nature 2015; Zeng et al Nature 2015). Importantly, blocking EMT through miR-200 family abrogated chemoresistance, indicating potentials for clinical translation. Using our novel EMT lineage tracing system, we have performed both genetic (CRISPR/Cas9 mediated genome-wide targeted mutagenesis) and pharmacological (high-throughput small molecule libraries) screens, to identify potential candidates to overcome EMT-mediated chemoresistance in breast cancer metastasis. The identified molecules provide not only novel mechanistic insights but also attractive anti-metastatic strategies for breast cancer treatment and the design of future clinical trials.

#3197 Splicing factors and the role of Navitoclax in drug-resistant ovarian cancer. Helen M. Coley, Laura Lattanzio, Ornella Garonne, Marco Merlano, Daniela Vivenza, Cristiana Lo Nigro, Nelofer Syed, Alistair Thompson, Helen M. Coley, Laura Lattanzio, Ornella Garonne, Marco Merlano, Daniela Vivenza, Cristiana Lo Nigro, Nelofer Syed, Alistair Thompson, 1Univ. of Surrey, Guildford Surrey, United Kingdom; 2Ospedale Carle, Cuneso, Italy; 3Imperial College, London, United Kingdom; 4Dundee University, Dundee, United Kingdom; 5Southend Hospital, Southend, United Kingdom.

Alternative RNA splicing allows processing of a pre-mRNA into various mature RNAs. In this way multiple protein products can be derived from a single gene. In cancer it is known that specific splice variants may facilitate malignant transformation and therapeutic resistance. Our current studies focus on the problem of drug resistance in ovarian cancer and we have approached this in a variety of ways. Following sequencing analysis of a panel of ovarian cancer cell lines we identified the RNA splicing factors TCERG and SRSF2 as being reduced in drug resistant ovarian cancer cell lines, compared with their drug sensitive counterpart. TCERG is important in regulating the splicing of variant forms of the BCLx gene: BCLxL (long form) and BCLxS (short form). There are clear implications for drug resistance whereby low TCERG results in reduced BCLx splicing to yield the pro-apoptotic BCLxS form. In the SKOV-3 human ovarian cancer cell line panel both paclitaxel resistant SKOV-3TaxR and SKOV-3CR carboplatin resistant cells showed reduced levels of TCERG mRNA using qPCR analysis. In addition, qPCR analysis for BCLxL and BCLxS levels indicated increased ratio of long form with drug resistance: SKOV-3 parent line ratio 1.0, SKOV-3TaxR 1.8, SKOV-3CR 1.65. Western immunoblotting showed relatively decreased levels of Bax protein in drug resistant versus drug sensitive cell line in line with a reduced apoptotic restored. We then explored the use of Navitoclax (ABT2026), the small-molecule Bcl-2 family protein inhibitor for Bcl-xL, Bcl-2 and Bcl-w in our cell line panel. Navitoclax in combination with paclitaxel for 48h gave rise to significantly increased apoptotic response in drug-resistant versus drug sensitive ovarian cancer cell line counterparts, using the Annexin V assay with PI, indicative of re-sensitisation to paclitaxel. Synergistic effects were also seen for the parental cell line but the effects were more marked for the resistant cell lines. Our future work will also involve the use of clinical biopsies of ovarian cancer cases.

#3198 Using a genome-wide CRISPR-Cas9 knockout library to identify therapeutic combinations in oral cancer. Megan Ludwig, Andrew Birkeland, Sai Nimmagadda, Sue Foltin, Aditi Kulkarni, Hui Jiang, Thomas Carey, Chad Brenner. University of Michigan, Ann Arbor, MI.

Oral squamous cell carcinoma (OSCC) has remained a disease with poor survival outcomes. Novel therapeutic approaches are much needed, in particular for patients with metastatic disease. The choice of therapeutic strategies is guided by the genetic landscape of the tumor. We aim to develop a pipeline of therapeutic strategies for this patient population by generating individual genetic knockouts through targeted gene editing. We used a pool of CRISPRs targeting over 18,000 genes to perform genome-scale screening for drivers of sensitivity to EGFR-targeted therapy. Upon selection of the OSCC GeCKO pool, we identified gene knockouts in the FGFR pathway that increased sensitivity to the EGFR inhibitor gefitinib. Using resazurin viability assays we tested combinations of EGFR and FGFR inhibitors in 14 OSCC cell lines. Six/twelve (43%) of the cell lines were responsive to the combination, indicating that the FGFR pathway is an alternate mechanism of resistance to EGFR-targeted therapy in some tumors. In complement, we again used CRISPR-Cas9 to generate a syngeneic EGFR knockout (KO) OSCC cell line. The parent OSCC cell line is responsive to the EGFR and FGFR dual inhibition, and the EGFR KO derivative remains sensitive to FGFR inhibition. We expect that targeted monotherapies. We anticipate great potential for personalized targeted therapies, facilitated by recent characterizations of the mutational landscape of OSCCs. Combinations of targeted therapies may have greater efficacy through inhibiting compensatory pathways. For example, targeting EGFR has had limited success. To identify synergistic combinations with EGFR-targeted therapy, we introduced Genome-scale CRISPR-Cas9 Knockout (KO) libraries into OSCC cell lines. CRISPR-Cas9 generates individual genetic knockouts, and massive apoptosis is observed:62% compared to 12% with osimertinib alone. It is important to note that co-treatment with DRYK1B inhibitor not only prevented the entry of cancer cells into quiescence but also depleted pre-existent reservoir of quiescent cancer cells. The results suggest that inhibition of EGFR causes tumor cells to enter into a DRYK1B-dependent quiescent state in which DRYK1B is required for their survival. Inhibition of DRYK1B dramatically enhances the antitumor activity of EGFR inhibition and may improve outcome in patients.
to crenolinib. Our data suggest that comprehensive sequencing should be carried out on patient samples prior to treatment to identify and pre-emptively target problematic clones. In addition, even with high VAF FLT3 mutations, although FLT3 inhibitor monotherapy provides some clinical benefit, combining agents targeting cooperative lesions will be imperative to eradicate both the dominant clone and resistant subclones and improve patient responses.

**EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Novel Molecular Targets 2**

1Freud Huntington Cancer Research Center, Seattle, WA; 2National Institutes of Health, Bethesda, MD.

Glioblastoma multiforme (GBM) is one of the most aggressive and invasive types of brain cancer, but targeted treatment options remain elusive. The standard of care (surgery chemoradiation and therapy) falls short of where it should be with two-year survival rates less than 10%. Using stem cell isolates from GBM patients, we found that perturbing PHF5A, a component of the spliceosome machinery, was lethal and caused hundreds of genes to be mis-spliced. These mis-splicing events included both exon skipping and intron inclusions. In contrast, similar levels of PHF5A suppression in normal control stem cells and astrocytes failed to induce cell death and mis-splicing indicating that PHF5A plays a specific role in the cancer biology. Moreover, when normal astrocytes were transformed with the Myc oncogene, they became sensitive to PHF5A perturbation. Taken together, these results suggested that specifically inhibiting PHF5A would be an effective therapy for glioblastoma and other Myc-driven cancers. Specifically targeting PHF5A would also likely result in reduced side-effects seen with general spliceosome inhibitors. Unfortunately, there are currently no known inhibitors that target PHF5A. In order to discovery novel PHF5A inhibitors, we created a mini-gene mis-splicing reporter assay that was sensitive to both general spliceosome inhibitors and PHF5A perturbation. In a 96-well assay format, the assay was robust with a 200-fold assay window and Z* values over 0.8. Following miniaturization to a 1536-well format, we conducted a high throughput screening (HTS) campaign testing 85,000 small molecule compounds. The initial hits were retested and counter-screened yielding 381 confirmed actives and we are further interrogating these actives in secondary and tertiary assays. Future efforts will focus on developing an SAR of the lead and backup series and identifying potential liabilities that will be addressed, if necessary, in further lead optimization efforts. We are enthusiastic about the potential of developing a targeted PHF5A inhibitor as a novel and effective therapy for patients and their families fighting GBM and other Myc-driven cancers.

1Fred Hutchison Cancer Research Center, Seattle, WA; 2National Institutes of Health, Bethesda, MD.

Hepatocellular carcinoma (HCC) related mortality ranks second worldwide and stands one step behind lung cancer. Due to the asymptomatic nature of the cancer, early diagnosis is a major problem. Currently only liver transplantation is curative for early stage hepatocellular cancer. There are other multidisciplinary treatment options like radiation and chemotherapy available for advanced patients. However, chemotherapy resistance is a common problem in the treatment of liver cancer. Newer therapeutics are needed for better management of advanced HCC. Angiogenesis and lymphangiogenesis are processes that are vital for tumorigenesis and metastasis. HCC is known to be a hypervascular tumor and many pro-angiogenic proteins are found significantly overexpressed in HCC. We explored the therapeutic potential of the anti-angiogenic and anti-lymphangiogenic, biomimetic peptide SP2043 developed by our group in HCC. Hepatocellular carcinoma cell lines HuH-7, Hep3b and HepG2 showed significant disruption of cell adhesion and migration following treatment. Furthermore, SP2043 was found to impair microvascular endothelial cell (MEC) tube formation induced by HepG2 tumor conditioned media and to significantly inhibit HepG2 tumor xenograft growth compared to untreated controls. The peptide drug was also found to improve the survival of autochthonous Myc induced HCC in a transgenic mouse model from two weeks to four weeks. We discovered the peptide to be a multi-modal anti-angiogenic drug that also inhibits its IGFR1 and MET signaling pathways in HCC cell lines. We also found that SP2043 treatment reduced the microvascular density in both subcutaneous and autochthonous liver tumors with reduced tumor cell proliferation and increased apoptosis. This study shows the therapeutic potential of SP2043 in the treatment of hepatocellular carcinoma.

Emerging evidence suggests that Sigma1 (also known as sigma1 receptor) is a unique ligand-operated integral membrane chaperone or scaffold protein that contributes to cellular protein homeostasis. Previously, we found that treatment of various cancer cell lines with some prototypic small molecule modulators of Sigma1 can engage endoplasmic reticulum (ER) associated protein homeostasis pathways including the unfolded protein response and autophagy. Programmed death-ligand 1 (PD-L1) is a type 1 integral membrane glycoprotein that is processed and transported through the ER and secretory pathway of tumor cells. PD-L1 expressed at the surface of tumor cells can act as a ‘T-cell inhibitory checkpoint’ molecule that inactivates tumor infiltrating immune cells that express PD-1, its cognate receptor. Here, we show that Sigma1 physically associates with PD-L1. In triple negative breast and androgen-independent prostate cancer cells, PD-L1 protein levels are suppressed by both DNAmediated knockdown of Sigma1 and pharmacological modulation of Sigma1. We observe decreased cell surface and intracellular levels of PD-L1 by flow cytometry and biochemical subcellular fractionation respectively, indicating that PD-L1 is degradation of nascent PD-L1 after Sigma1 modulation plays a key role in preventing the transport of functional PD-L1 to the plasma membrane. Together, these data demonstrate that Sigma1 modulators have the potential to act as novel therapeutic agents in PD-L1 blockade strategies.

### #3203 Targeting tumor hypoxia with prodrug conjugates of potent small-molecule inhibitors of tubulin polymerization. Kevin G. Pinney, Mary Lynn Trawick, Ralph P. Mason, Li Liu, David J. Chaplin, Blake A. Winn, Laxman Devkota, Tracy E. Streeker, Jeni Gerberich, Alex Winters, Yifan Wang, Matthew T. MacDonough.

1 Baylor University, Waco, TX; 2University of Texas Southwestern Medical Center, Dallas, TX; 3Mateon Therapeutics, Inc., South San Francisco, CA.

Targeted pronounced hypoxia in malignant tumors represent an opportunity for selectivity in drug activation, and hence targeting and delivery. In this study, a series of bioreductively activatable prodrug conjugates (BAPCs) of small-molecule inhibitors of tubulin polymerization were synthesized and evaluated in biochemical and biological studies. The BAPCs are designed to be biologically inert until selectively cleaved under hypoxic conditions, release potent enzyme modulators that are tumor specific and target cancer cell populations. BAPCs were evaluated in the following assays: (1) cytotoxicity using the regular sulforhodamine B assay (normoxic conditions) to confirm their reduced cytotoxicity in cancer cells in culture compared to the effector agents; (2) cleavage under anoxic conditions by the reductase enzyme, NADPH cytochrome P450 oxidoreductase (POR), that is implicated in the bioreductive cleavage of compounds with nitroimidazole and nitrimidazole triggers; and (3) differential cytotoxicity under hypoxic versus normoxic conditions in cancer cell lines with the established bioreductive compound tirapazamine (TPZ) as the control. The POR assay was modified by the addition of protocatechuic 3.4-dioxygenase to ensure anoxic conditions, and Triton X-100 to facilitate solubilization of the BAPCs. A series of unsubstituted, methyl, and gem-dimethyl nitroimidazole- and nitrimidazole-triggered prodrug conjugates (BAPCs) of two experimental antitumor agents (KGP03 and KGP18) were synthesized. KGP03 and KGP18 were inspired by the natural product combretastatin A-4 (CA4). A unique attribute of the selected anticancer agents is that both bind tubulin at the colchicine site, inhibit tubulin polymerization into microtubules, and function as ‘dynamic destabilizing’ agents that modify the cytoskeleton of cancer cell lines and as vascular disrupting agents (VDAs). The assays were validated with a series of nitroimidazole analogues of CA4 (Thomson et al., Mol. Cancer Ther. 2006 5:2886). In our evaluation of this series, the gem-dimethyl nitroimidazole analogue of CA4 was efficiently cleaved by POR and gave an
average differential hyposia cytotoxicity ratio (HCR: GLo values of nor-
monic/hypoxic conditions) of 41 in the human A549 lung carcinoma cell.
The corresponding prodrug of combretastatin A-1 had an HCR = 26.
The monomethyl nitroimidazole BAPCs of KGp03 and KGp18 produced
positive HCRs in our initial assays. In preliminary studies, the C4A BAPC
demonstrated activity in both hypoxic synchronous and asynchronous
mouse model (4T1/BALB/c). In the POR assay, the gem-dimethyl nitrobio-
phane analogue of KGp03 was completely cleaved in 24 h. Biological evalua-
tion of these BAPCs indicates the occurrence of selective, hypoxic activa-
tion resulting in release of the potent inhibitors of tubulin polymerization
(C4A, C41, KGp03, KGp18).

#3204 Tryptophan 318/324, the target of C-terminal binding protein
(CtBP) inhibitors, plays a critical role in CtBP enzymatic activity, oligomer-
ization and transcriptional coregulation. Martin M. Dcona,1 Benjamin L.
Morris,3 Priyadarshan K. Danile,4 Zaid Nawaz,1 Michael J. Dennis,1 Sahib J.
Singh,1 William E. Royer,2 Keith C. Ellis,1 Steven R. Grossman,1 Virginia Com-
monwealth University, Richmond, VA; 2University of Massachusetts, Worcester,
MA.
C-terminal Binding Proteins (CtBP) 1 and 2 constitute a family of oncogenic
transcriptional co-regulators overexpressed in tumor tissues that are associated
with worse prognostic outcome and aggressive tumor characteristics in multiple
cancer types. Specifically, CtBP has been found to repress expression of genes
responsible for apoptosis and EMT (eg. BIK and CDH1) and promote expres-
sion of genes that partake in the migration of cancer cells and those that are
responsible for enhanced drug resistance (eg. TIA1 and MDR1). CtBP2 is also
frequently overexpressed in breast and colon cancer cell lines with concomitant knock-
out (siRNA) or knockout (CRISPR/Cas9) of CtBP2. Our data demonstrates
that mutation of W324 abrogated dehydrogenase activity, oligomerization,
and transcription of the validated CtBP target gene TIAM1 and induction of mi-
RNA ES 

#3205 A nanomolar potency small-molecule compound against castra-
tion-resistant and bone metastatic prostate cancer. Kenza Mamouni,1 Lajos
Gera,2 Xin Li,1 Daqing Wu,1 Augusta University, Augusta, GA; 1University of
Colorado Denver, Aurora, CO.
A standard treatment for prostate cancer (PCa) is androgen deprivation ther-
apy (ADT) that suppresses androgen receptor (AR) signaling axis. Although
initially responsive, most patients receiving ADT eventually develop metastatic
castration-resistant prostate cancer (CRPC), with more than 90% of them ex-
hibiting bone metastases. A mechanism by which CRPC cells evade ADT is the
expression of constitutively active AR variants (AR-Vs), such as the well-char-
acterized AR-V7. Recently we developed GH501, a bupiruvon-modified small-
molecule compound, and investigated its anti-cancer activity and mechanism
of action in pre-clinical models of CRPC. At nanomolar range, GH501 effectively
induces cell cycle arrest and apoptosis in CRPC cells regardless of their resis-
tance status to enzalutamide treatment. RNA-seq analysis of GH501 combined
with Western blotting analysis identified key targets implicated in CRPC pro-
gression, including the full-length AR, AR-V7 variant, and other important
genes implicated in CRPC progression. Importantly, low doses of GH501 effec-
tively inhibit the skeletal growth of CRPC in a xenograft model without obvious
in vivo toxicities. These preclinical results indicate that GH501 is a promising
small-molecule compound that can be further developed for the treatment of
lethal prostate cancer.

#3206 A potent and selective CSF-1R inhibitor, DCR-0064, inhibits col-
ony stimulating factor 1 signaling in vitro and in vivo. Chu-Bin Liao, Shao-
Zheng Peng, Chen-Huan Ho, Chao-Pin Lee, Jia-Ming Chang, Hung-Yun Huang, Yuan-Yi Gou, Yu-Chih Pan, Yu-Kai Chen. Development Ctr. for Biotech-
nology, Xixi City, Taiwan.
Tumor-associated macrophages (TAMs) are major components of leukocytic
infiltrate of tumors. It has been reported that high TAMs density is associated
with poor clinical prognosis. Within the tumor microenvironment, TAMs rely
on signaling through CSF-1/CSF-1 Receptor kinase axis to promote tumor
growth, angiogenesis, and metastasis. Therefore, decrease of TAMs density in
tumors through inhibition of CSF-1R kinase is considered a potential target for
drug development. In this study, we report that a novel small molecule DCR-
0064 inhibits CSF-1R kinase with IC50 value below 10 nM and possesses speci-
cificity for CSF-1R over other tyrosine or serine/threonine kinases. DCR-0064
selectively inhibits CSF-1 induced growth of M-NFS-60 myeloid cells and effec-
tively suppresses intracellular CSF-1R activation with IC50 value less than 100
pM. The selectivity of DCR-0064 is superior to the currently lead
CSF-1R inhibitor, PLX3397, which is in phase III clinical development for treat-
ing senescentional giant cell tumor. The selectively growth inhibitory activity of
DCR-0064 is consistent with inhibition of CSF-1R signaling. Oral administra-
tion of DCR-0064 reduces TAMs density in vivo in mice. DCR-0064 is being
developed as a candidate for preclinical development.

#3207 Targetting proteasome function by inhibition of the proteasome
debiquitinase USP14. Stig T. Linder,1 Padraig D’Arcy,2 Xiaowan Zhang,1
1Karolinska Inst. Cancer Center, Stockholm, Sweden; 2Linköping University,
Linköping, Sweden.
The 20S proteasome core particle has evolved as an important target for anti-
cancer drug development. We previously identified the small molecule b-AP15
as a novel class of proteasome inhibitors that function by abrogating the deu-
biquitinating (DUB) activity of the 19S regulatory particle. An optimised lead of
b-AP15 (VLX1570) has been approved by the FDA for clinical studies and is
currently in clinical trials for relapsed multiple myeloma. VLX1570 has also
shown promising activity in Ewings sarcoma and paediatric leukemias. b-AP15
and VLX1570 bind to the proteasome DUB ubiquitin-specific protease-14
(USP14) in vitro and in exposed cells (CETSA). Binding and inhibition of enzy-
matic activity is believed to be due to targeting Cys114 in the active site. The
cell death response to b-AP15/VLX1570 is distinct from that of 20S proteasome
inhibitors. Thus, the sensitivity to these compounds is unaffected by overexpres-
sion of BCL2-family proteins and unaffected by p53 status. We here show that
b-AP15 induces direct effects on mitochondria, possible explaining this phe-
nomenon. We also provide additional understanding of drug-target interactions
by using a series of compounds identified by screening. Our findings demonstrate
promising antiproliferative activities of USP14 inhibitors in vitro and in vivo.

#3208 AZD1775 modulates kinetochore component Wee1-CDC2 and
NF-kB signaling as potential therapeutic targets in head and neck squamous
adenocarcinoma. Zhengbo Hu,1 Anthony Salich,2 Jianghong Chen,2 Carlson So-
Bactivity. Among these targets, WEE1 kinase is currently
under investigation as a therapeutic target of inhibitor AZD1775 in HNSCC. We
found that WEE1-CDC2 axis protein levels were higher in a panel of HNSCC
genesis implicated in CRPC progression. Importantly, low doses of GH501 effec-
tively inhibit the skeletal growth of CRPC in a xenograft model without obvious
in vivo toxicities. These preclinical results indicate that GH501 is a promising
small-molecule compound that can be further developed for the treatment of
lethal prostate cancer.

Recent findings in The Cancer Genome Atlas (TCGA) analysis of head and
neck squamous cell carcinomas (HNSCC) revealed frequent alterations affect-
ing the cell cycle and NF-κB pathway, which are critically involved in cancer cell
proliferation and survival. We hypothesized that common mechanism(s) could
coordinate cell cycle and NF-κB cell survival signaling in HNSCC. Recently, we
established an NF-κB B-lactamase reporter UM-SCC-1 cell line and performed
gene-wide RNAi screening to explore this hypothesis. We identified genes
involved in the cell cycle and related to components of the kinetochore that
co-modulate NF-κB activity. Among these targets, WEE1 kinase is currently
under investigation as a therapeutic target of inhibitor AZD1775 in HNSCC. We
found that WEE1-CDC2 axis protein levels were higher in a panel of HNSCC
cells with AZD1775 decreased NF-κB
nology, Xixi City, Taiwan.
Tumor-associated macrophages (TAMs) are major components of leukocytic
infiltrate of tumors. It has been reported that high TAMs density is associated
with poor clinical prognosis. Within the tumor microenvironment, TAMs rely
on signaling through CSF-1/CSF-1 Receptor kinase axis to promote tumor
growth, angiogenesis, and metastasis. Therefore, decrease of TAMs density in
tumors through inhibition of CSF-1R kinase is considered a potential target for
drug development. In this study, we report that a novel small molecule DCR-
0064 inhibits CSF-1R kinase with IC50 value below 10 nM and possesses speci-
cificity for CSF-1R over other tyrosine or serine/threonine kinases. DCR-0064
selectively inhibits CSF-1 induced growth of M-NFS-60 myeloid cells and effec-
tively suppresses intracellular CSF-1R activation with IC50 value less than 100
pM. The potency and selectivity of DCR-0064 is superior to the current lead
CSF-1R inhibitor, PLX3397, which is in phase III clinical development for treat-
ing senescentional giant cell tumor. The selectively growth inhibitory activity of
DCR-0064 is consistent with inhibition of CSF-1R signaling. Oral administra-
tion of DCR-0064 reduces TAMs density in vivo in mice. DCR-0064 is being
developed as a candidate for preclinical development.

Recent findings in The Cancer Genome Atlas (TCGA) analysis of head and
neck squamous cell carcinomas (HNSCC) revealed frequent alterations affect-
ing the cell cycle and NF-κB pathway, which are critically involved in cancer cell
proliferation and survival. We hypothesized that common mechanism(s) could
coordinate cell cycle and NF-κB cell survival signaling in HNSCC. Recently, we
established an NF-κB B-lactamase reporter UM-SCC-1 cell line and performed
gene-wide RNAi screening to explore this hypothesis. We identified genes
involved in the cell cycle and related to components of the kinetochore that
co-modulate NF-κB activity. Among these targets, WEE1 kinase is currently
under investigation as a therapeutic target of inhibitor AZD1775 in HNSCC. We
found that WEE1-CDC2 axis protein levels were higher in a panel of HNSCC
cells with AZD1775 decreased NF-κB

transcriptional activation and decreased TNFα-induced phosphorylation of IKKs and RELA subunit. Furthermore, AZD1775 inhibited NF-κB regulated proteins modulating the cell cycle and survival, including p21, CyclinD1, BCL2 and BCL-XL. These changes also correlate with alteration in cell cycle and survival detected by flow cytometry, as tumor cells treated by AZD1775 exhibited increased G2/M phase and sub-G0 fragmented DNA, and decrease in G1/S phases. Wee1 inhibitor AZD1775 inhibited tumor cell proliferation and colony formation in a dose-dependent manner, and exhibited combinatory effects with cisplatin in tumor xenografts. Thus, we identified the novel cross-talk between Wee1-CDC2 and NF-κB signaling, potentially implicating decreased NF-κB prosurvival signaling in the anti-tumor activity of Wee1 inhibitors. Supported by NIDCD/NIH intramural projects ZIA DC-00016, 73, and 74; NIDCD core facility: advanced imaging. ZIC DC000011.

No target therapies are presently available in the treatment of small-cell lung cancer of Lung (SCLC). Therefore there is a need to develop new therapeutic agents. The protein kinases are a family of genes that play critical roles in various signaling pathways. Some cancer cells show addiction to constitutive activation of certain signaling pathways for proliferation and survival. To identify new drug targets for SCLC, we screened a panel of small interfering RNAs (siRNAs) that target 720 genes encoding human protein kinases and related proteins using SBC5 SCLC cell (SN38 (irinotecan hydrochloride) resistant cell). PLK1 inhibition suppressed cell proliferation strongest among 20 significant promising total genes using different 5 SCLC cells as a validation study). PLK1 mRNA expression was significantly higher than other pathological phenotypes among 20 cell-lines and the 200 clinical samples consist of three independent cohorts. The patients with high PLK1 expression was significantly associated with poor prognosis in SCLC patients. Furthermore we investigated the change of SN3 38 sensitivity and preventing from SN38 resistance after knockdown PLK1. Our results indicated that PLK1 inhibitor as BI 2536 and Volasertib, is a promising molecular target therapy for pharmacologic intervention in SCLC in both monotherapy and the combination therapy with SN38.

#3210 Targeting PTPA3 phosphatase in ovarian cancer with the potent noncompetitive inhibitor JMS-631-053. John S. Lazo, Paula Pekic, Alex Cheung.1 Kelley McQueeney,1 Joseph Salamoun,2 Peter Wipf,2 Charles N. Landen1. ProceedingsoftheAmericanAssociationforCancerResearch

PTPA3 is a highly attractive molecular target for ovarian cancer (OvCa). Elevated levels of PTPA3 mRNA and protein in human ovarian tumors correlate with disease progression, poor prognosis and poor survival. Genetic depletion of PTPA3 in OvCa cell lines diminishes their ability to migrate and reduces their in vivo tumorigenicity while PTPA3 overexpression increases tumor cell migration, invasion, and dissemination. Together, these data suggest PTPA3 is a novel molecular target for OvCa; however, the lack of potent and selective PTPA3 small molecule inhibitors has hindered PTPA3’s definitive validation in OvCa and other BRCA-mutant cancers. To drive the pharmacological validation of PTPA3, we developed JMS-631-053 ([7-imino-2-phenylthieno[3,2-c]pyridine-4,6(5H,7H)-dione], a potent (Kd=3 mM) in vitro, specific, noncompetitive, PTPA3 inhibitor. JMS-631-053 inhibited cellular migration, invasion, and colony formation in soft agar. Potent OvCa cell-based effects were observed by profiling JMS-631-053 against a panel of 8 OvCa cell lines using a 2D drug susceptibility assay, with EC50 values as low as 600 nM. Likewise, JMS-631-053 killed OvCa 3D spheroids, including those derived from high grade serious OvCa cell lines, with EC50 values as low as 300 nM. The OvCa drug resistant cell lines (i.e., A2780CP20 and HeyA8MDR) retained responsiveness to JMS-631-053 (using 2D and 3D culturing conditions) suggesting that inhibition of PTPA3 may be a viable therapeutic strategy for chemoresistant OvCa. Preliminary data also shows that JMS-631-053 synergizes with cisplatin when used in combination studies. Hence, JMS-631-053 will be a valuable chemical tool for further validation of PTPA3 as an OvCa target as well as provide potential leads for future drug discovery.

#3211 Inhibition of autophagy potentiates cytotoxicity of CX-5461 treatment in chemoresistant epithelial ovarian cancer. Robert Cornelison,1 Daniele C. Llaneza,1 Yulia Petrova,1 Zachary C. Dobbin,2 David A. Schneider,2 Charles N. Landen1. University of Virginia School of Medicine, Charlottesville, VA; University of Alabama at Birmingham, Birmingham, AL.

Epithelial ovarian cancer remains a deadly diagnosis with poor prognosis and patients succumbing to chemoresistant disease in 80% of cases. Mechanisms of chemoresistance are numerous, but we have identified ribosomal biogenesis basal machinery as being a common upregulated signaling network in response to chemotherapeutic insult. Tumors treated with chemotherapy showed dramatic increases in size and morphology of nucleoli, suggesting global changes in ribosomal synthesis with stress. We next sought to use the RNA Polymerase I inhibitor CX-5461 to targeting ribosomal machinery that may allow re sensitization to chemotherapy. CX-5461 induced autophagy, senescence and mitotic catastrophe in ovarian cancer cell lines Overall, 13 ovarian cancer lines examined were highly sensitive to Pol I inhibition by MTT, with IC50s ranging from 25nM to 2μM, and chemoresistant lines were generally more sensitive to CX-5461. In 53 mutant cells CX-5461 appears to be particularly cytotoxic being a mitotic catastrophe accompanied by companying cytotoxicity in vitro. Chloroquine administration appears to push cell to mitotic catastrophe after co-administration with CX-5461, thereby enhancing cytotoxicity over cytosstatic endpoints after treatment, even in multi-drug resistant cell populations. Inhibition of autophagy appears to enhance efficacy of RNA Polymerase I inhibition in both sensitive and chemoresistant populations, prompting a potential new approach to chemoresistant disease.

#3212 ONC201 shows efficacy in BRCA-deficient cancer cells and synergy with PARP inhibitors in glioblastoma, breast, prostate, and ovarian cancers. Marie D. Baumeister,1 Ozan C. Kucukkase,2 Varun V. Prabhu,3 David T. Dicker,4 Josh E. Allen,5 Wafik S. El-Deiry1. Proceedings of the American Association for Cancer Research

ONC201/TIC10 is a first-in-class small molecule inducer of TRAIL that causes early activation of the integrated stress response and inactivates both Akt and GSK3β, making tumors lacking germline BRCA mutations more sensitive to ONC201. We have previously shown that ONC201 has anti-proliferative and pro-apoptotic effects in a wide range of tumor types including BRCA-deficient breast and ovarian cancers (n = 10), with GSK3β values in the low micromolar range. Treatment with ONC201 induces surface TRAIL and inhibits Akt activity in BRCA deficient breast and ovarian cancers. PARP inhibitors have been previously shown to upregulate DR5 through transcription factor CHOP, sensitizing solid tumors to TRAIL. Resistance to PARP inhibitors can occur through PI3K/Akt pathway activation, and PI3K/MEK blockade improves their anti-tumor effects. We observed synergy between ONC201 and PARP inhibitors olaparib andrucaparib in BRCA-deficient breast and ovarian cancer cell lines in cell viability assays with combination indices (CI) ranging from 0.4 - 0.8. Robust synergy was also observed in prostate cancer cells. The mechanisms of the observed synergy are currently under investigation. These results indicate that ONC201 possesses single agent activity in BRCA-deficient cancer cells and that the combination of ONC201 with PARP inhibitors represents a promising synergistic therapeutic approach that could be exploited in multiple solid tumors.

#3213 Antagonism of D2-like dopamine receptors plays a role in ONC201’s antineoplastic effects. Christina Leah B. Kline, Amriti Lulla, Jessica Wagner, Daniel Dicker, Marie Baumeister, Sophie Oster, Wafik El-Deiry. Fox Chase Cancer Center, Philadelphia, PA.

ONC201/TIC10 is a first-in-class small molecule inducer of TRAIL that causes early activation of the integrated stress response and inactivates both Akt and GSK3β, making tumors lacking germline BRCA mutations more sensitive to ONC201. We have previously shown that ONC201 has anti-proliferative and pro-apoptotic effects in a wide range of tumor types including BRCA-deficient breast and ovarian cancers (n = 10), with GSK3β values in the low micromolar range. Treatment with ONC201 induces surface TRAIL and inhibits Akt activity in BRCA deficient breast and ovarian cancers. PARP inhibitors have been previously shown to upregulate DR5 through transcription factor CHOP, sensitizing solid tumors to TRAIL. Resistance to PARP inhibitors can occur through PI3K/Akt pathway activation, and PI3K/MEK blockade improves their anti-tumor effects. We observed synergy between ONC201 and PARP inhibitors olaparib andrucaparib in BRCA-deficient breast and ovarian cancer cell lines in cell viability assays with combination indices (CI) ranging from 0.4 - 0.8. Robust synergy was also observed in prostate cancer cells. The mechanisms of the observed synergy are currently under investigation. These results indicate that ONC201 possesses single agent activity in BRCA-deficient cancer cells and that the combination of ONC201 with PARP inhibitors represents a promising synergistic therapeutic approach that could be exploited in multiple solid tumors.
and ERK. Its promising safety profile and broad spectrum efficacy in vitro has been confirmed in Phase I/II trials in several advanced malignancies. Biochemical and reporter assays have shown that ONC201 is a selective and competitive antagonist of the D2-like receptors, specifically, dopamine receptor D2 (DRD2) and dopamine receptor D3 (DRD3) with a Kᵢ value of ~3 μM. The theme that dopamine receptor antagonism and suppression has been supported throughout the literature. We hypothesize that ONC201’s interaction with DRD2 is critical for ONC201’s anticancer effects. Co-treating HCT116 and RKO colorectal cancer cells with ONC201 and dopamine or the selective D2-like receptor agonist suvorexant partially abrogated ONC201-induced ATP4F/CHOP expression and apoptosis. Knocking down DRD2 expression using siRNA negated ONC201’s effects on cell viability. Overexpressing DRD2 in a cancer cell line that has very low levels of DRD2, increased ONC201-induced PARP cleavage. Quantitative RT-PCR analyses showed that cells that have acquired resistance to ONC201 did not express detectable mRNA levels of the D2-like receptors. To further determine the anti-tumor potential of targeting the D2-like receptor, we treated different cancer cell lines with other D2-like receptor antagonists. Similar to ONC201, the D2-selective antagonist L-741,626 decreased cell viability and induced apoptosis in a number of cancer cell lines. In contrast to ONC201, however, L-741,626 has a poor therapeutic index. Our findings show that the ability of ONC201 to inhibit D2-like receptors contributes to ONC201’s anti-proliferative and pro-apoptotic activity. Ongoing work is aimed at elucidating the mechanisms by which antagonism of D2-like receptors can promote apoptosis-driven cell death and signaling pathways with regard to ATP4F/CHOP/DR5 and Akt/ERK/ Foxo3a/TRAIL, which have been shown to be stimulated in ONC201-treated and -resistant cancer cells.

#3214 Systematic drug repurposing for faster cures of pediatric cancer identifies that Digoxin prolongs survival in a PDX model of group 4 medulloblastoma. Lei Huang,1 Sarah G. Injac,2 Hong Zhao,1 Qi Lin,1 Mari Kogiso,3 Chris T. Man,4 Xiao-Nan Li,5 Ching C. Lau,6 Stephen T. Wong,6 Houston Methodist Research Institute, Houston, TX; 2Texas Children’s Hospital, Houston, TX; 3Connecticut Children’s Medical Center, University of Connecticut School of Medicine, Hartford, CT.

Background: Medulloblastoma (MB) is the most common malignant brain tumor of childhood. While the current standard care for MB leads to long term survival in approximately 75% of patients, recurrent and refractory MB continues to have dismal outcomes. In addition, long term survivors face significant treatment-related sequelae especially poor neurocognitive outcomes. Drug repositioning for known drugs is a promising potential strategy not only for drug discovery but also for accelerated translation into the clinical setting. To systematically explore thousands of known drugs available, we integrated computational biology and empirical biological methods to find old drugs for new indications in MB. Results: A non-parametric, bootstrapping based simulated annealing (NPBSA) algorithm was employed to identify driver signaling pathways for over 1,800 patients with Group 3 and Group 4 MB through an integrative analysis on their mRNA expression, DNA-copy number, DNA-methylation and DNA-seq profiles. Then, drug functional networks were constructed based on gene expression profiles under drug treatment as well as chemical structures and were clustered into drug modules with potential mechanisms of action. By evaluating targeted effects of 1,309 drugs from connectivity map database within each drug module in driver signaling pathways, we identified a group of known cardiac glycosides that top ranked among the total drug candidates for the Group 3 and 4 MB subtypes. In addition to traditional chemotherapeutic agents, members of the cardiac glycoside family were repeatedly identified as potential therapeutic agents for MB. These findings were validated in multiple MB-derived cell lines which showed high rates of growth inhibition by cardiac glycosides compared to controls. To evaluate if this growth inhibition in vitro correlated to prolonged survival in vivo, an extensively characterized patient-derived orthotopic xenograft (PDXO) model of Group 4 MB (ICb-107/M8) on viable cell counts. Overexpressing DRD2 for 24 h led to a time-dependent growth inhibition significantly prolonged survival to 113 days from a median of 92 days in untreated controls (p < 0.001). Histological evaluation of recurrent tumors following digoxin treatment demonstrated changes in the pattern of tumor spread, vascularity and necrosis compared to untreated controls. Conclusions: Leveraging big data in the domains of pharmacogenomics and the notion of drug functional networks and driver signaling pathways represent a powerful tool to repurpose known drugs for new indications in pediatric cancers. Using this integrative biology approach, we identified the cardiac glycosides family generally and Digoxin, specifically, as potential novel agents in the treatment of pediatric medulloblastoma.

#3215 Therapeutic potential of dual-function small molecules for breast cancers. Nicole Nicholas,1 Alfredo Velena,2 Scott Grindrod,3 Mira Jung1.

1Georgetown University, Washington, DC; 2Shuttle Pharmaceuticals INC, Rockville, MD.

Epigenetic silencing of tumor suppressors is an important mechanism in tumor suppression and progression. A tumor suppressor gene, BRCA1, is part of complex molecules in the repair of DNA double-strand breaks (DSBs), and loss of BRCA1 contributes to both sporadic and inherited breast tumor progression. Furthermore, recent studies have shown that the ataxia-telangiectasia mutated (ATM) activity is abnormal in breast cancer. Therefore, we tested the hypothesis that the dual-functional drug that fused the HDAC inhibitor with an ATM activator would enhance killing of breast cancer (BC) cells (increasing ATM activation). In addition, the expression of ATM may enhance the synergetic antitumor effects of HDAC inhibitors in combination with radiotherapy. To determine the HDAC inhibitor potency, SP-1-303 was screened against a panel of Class I and Class II HDAC enzymes in vitro and identified as a pan-HDAC inhibitor (IC₅₀ = 120 nM). Western blot confirmed that SP-1-303 increased acetylated histone H3/H4, α-tubulin, and phosphorylation of ATM within 30 min - 4 h in a time-dependent manner. Using two ER positive BC cell lines (MCF7 and T-47D), two triple negative breast cancer (TNBC) cell lines (MDA-MB-231 and HCC1937), and one normal breast epithelial cell line as a control (MCF10A), the effects of SP-1-303 on cell growth and cell death were examined by performing cytotoxicity assays and flow cytometry. SAHA and Tamoxifen were selected as positive controls. SP-303 conferred the values of cytotoxicity (IC₅₀) for the ER positive BC cells in a range of 0.25-0.4 μM, while the values are in a range of 1-3 μM for TNBC and 12 μM for normal breast epithelial cells, respectively. Flow cytometry (FACS) analyses demonstrated significant increases in G1 arrest (81%) in MCF7 cells and a further enhancement in the G1 phase (91%) in combination with radiation. The data implies the mechanism of action from this drug—cancer cells are being arrested in the G1 phase of the cell cycle, a radiation sensitive phase, suggesting that SP-1-303 may have a synergistic effect with radiation on cell killing. Taken together, SP-1-303 had the largest impact on ER positive breast cancer over TNBC. These data imply that an increased cell death is occurring in ER positive breast cancers from these dual-action molecules through HDAC inhibition and increased ATM activation, suggesting that SP-1-303 alone or its combination with radiotherapy may improve clinical efficacy.

#3216 Attenuation of pancreatic tumor growth by a small molecule tubulin inhibitor. Vivek K. Kashyap, Bilal B. Hafez, Qinghui Wang, Saini Setuwa Andrew Massey, Aditya Ganju, Murali M. Yallapu, Duane D. Miller, Wei Li, Meena Jaggi, Subhash C. Chauhan. University of Tennessee Health Science Center, Memphis, TN.

Introduction: Pancreatic cancer (PanCa) is one of the most fatal cancers and is ranked as the fourth common cause of cancer-related deaths among both men and women in the US. The management of PanCa is exceptionally difficult due to the extremely poor response to available chemotherapeutic drugs. Microtubules are dynamic structures composed of α-β-tubulin heterodimers that are essential for cell division and are important targets for several clinical drugs (paclitaxel, docetaxel and vinblastine). However, clinical use of these tubulin-targeting drugs has toxicity and drug resistance issues in cancer patients. Thus, identification of more potent non-toxic inhibitors of β-tubulin is urgently required for cancer therapy purposes. In this study, we have identified a synthetic compound (ABI-231) which is a potent inhibitor of β-tubulin and evaluated its therapeutic efficacy against PanCa in vitro, and in vivo model systems. Methods: ABI-231 ((2-(1H-indol-3-yl)-1H-imidazol-4-yl) (3, 4, 5-trimethoxyphenyl)) - methanone was synthesized and characterized in our department. Effect of ABI-231 on proliferation, migration and invasion of human PanCa cells (ASPC1, HPAFII, and Panc1) was performed by in vitro functional assays (MTS, wound healing, and Boyden chamber migrations). Effect of ABI-231 on the expression of β-tubulin isoforms was determined and compared with other clinical inhibitors of β-tubulin by Western blot, and qRT-PCR. Moreover, the effect of ABI-231 on the expression of β-tubulin III in PanCa cells was determined by confocal microscopy. Therapeutic efficacy of ABI-231 against PanCa was evaluated in an ectopic xenograft mouse model. Results: ABI-231 treatment inhibited cell proliferation, invasion, migration and colony formation abilities of PanCa cells in a dose-dependent manner (1-100 nM) compared to vehicle treated group. Aberrant expression of β-tubulin III is involved in aggressiveness and drug resistance of various type of cancers including PanCa. ABI-231 effectively inhibited the protein level of β-tubulin (TBB) and induced acetylated α-tubulin (TBB2c) and β-tubulin (TBB3 and TBB4 in PanCa cells via destabilization. Our confocal microscopy further results showed inhibition of β-tubulin in ABI-231 treated PanCa cells. Uregulation of micro RNA 200c (miR-200c) has been shown to inhibit the expression of β-tubulin III in cancer cells. ABI-231 treatment of PanCa cells
showed significant (p<0.01) induction of miR-200c as determined by qRT-PCR. ABI-231 administration (intra-tumoral; 50μg/mouse), three times/week significantly (p<0.01) inhibited the growth of ASPC1 cells derived xenograft tumors in athymic nude mice. Conclusion: Taken together, our results suggest that ABI-231 is a potent β-tubulin inhibitor and chemotherapeutic agent which could be used for the treatment of pancreatic cancer.

#3217 Novel prostamide, 15-deoxy-delta12,14 prostamide J2, displays activity against melanoma in vitro and in vivo: potential role of endoplasmic reticulum stress. Daniel A. Ladin, Li V. Yang, Timothy L. Fitzgerald, Rukiyah Van Dross, East Carolina Univ, Greenville, NC.

Melanoma is the most aggressive and deadly form of cutaneous neoplasm in the United States, representing a major clinical challenge. Our lab previously demonstrated that the endocannabinoid, arachidonylethanolamide (AEA), induced cell death in non-melanoma skin cancer (NMSC) cells through the cyclooxygenase-2 (COX-2) mediated formation of novel J-series prostamides (PMJs). We were the first to chemically synthesize the primary metabolite, 15-deoxy-Δ12,14 prostamide J2 (15d-PMJ2), which displayed potent and selective cytotoxicity in NMSC cells. As such, we hypothesize that the selective cytotoxicity of 15d-PMJ2 would be observed in other forms of skin cancer, including melanoma. B16F10 murine melanoma cells and nontumorigenic Melan-A cells were treated with different concentrations of 15d-PMJ2 for 24 hours and cell viability was measured using MTS assays. At 5 μM 15d-PMJ2 decreased viability by 63% in B16F10 cells, while Melan-A viability was not affected. To verify that cell death was due to apoptosis, the cleavage of apoptotic markers caspase-3 and PARP was examined by conducting Western blot analysis. 15d-PMJ2 markedly increased caspase-3 and PARP cleavage only in B16F10 melanoma cells. Previous studies in NMSC indicated that 15d-PMJ2 induced ER-stress and apoptosis. To investigate the mechanism of 15d-PMJ2-mediated death in melanoma, we examined ER-stress responses. Melan-A and B16F10 melanoma cells were treated with 5μM 15d-PMJ2 and evaluated for CHOP10 and p-PERK expression by Western blot analysis. B16F10, but not Melan-A cells exhibited a notable increase in CHOP10 and p-PERK expression when treated with 15d-PMJ2. To further examine the role of ER-stress on 15d-PMJ2 mediated apoptosis, B16F10 cells were pretreated with the ER-stress inhibitors salubrinal and 4-phenylbutyric acid (PBA). Both salubrinal and PBA decreased activation of caspase-3/7, suggesting that ER-stress plays an important role in 15d-PMJ2 mediated tumor cell death. To determine the melanoma activity of 15d-PMJ2 in vivo, B16F10 allograft tumors grown in C57BL/6 mice were dosed subcutaneously with 0.5 or 5.0 mg/kg 15d-PMJ2 for 5 days. Tumors treated with 15d-PMJ2 exhibited significantly reduced growth and mean weights compared to vehicle and untreated animals. TUNEL analysis of tumor tissues indicated a large presence of necrotic and apoptotic cells in 15d-PMJ2-treated tumors compared to vehicle and untreated tumors. To determine whether 15d-PMJ2 induced ER-stress in vivo, tumors were assayed for p-PERK and CHOP10 levels by immunohistochemistry (IHC). These markers were significantly elevated in 15d-PMJ2-treated tumors. Similarly, the viability of primary patient-derived melanoma cells was significantly decreased by 15d-PMJ2. These findings suggest that the novel prostamide, 15d-PMJ2 possesses potent and selective anti-melanoma activity in vitro and in vivo.

#3218 Molecular function of PARP inhibition in glioblastoma. Christofer Aldrighetti, Barbara Huebert, Delphine Quenet. University of Vermont, Burlington, VT.

Glioblastoma (GBM) is the most common primary malignant brain tumor, whose major biomarkers are the DNA methylation status of the promoter for O6-methylguanine-DNA-methyltransferase (MGMT) and the loss/modulation of the tumor suppressor phosphatase and tensin homolog (PTEN). Despite treatment combining surgery, radiotherapy and chemotherapy with the alkylating agent temozolomide (TMZ), patient survival remains poor and recurrence is virtually inevitable, due to TMZ resistance. Poly(ADP-ribose)polymerase-1 (PARP-1) is a nuclear protein involved in multiple facets of DNA repair and transcriptional regulation. This enzyme catalyses the transfer and polymerization of ADP ribose units from NAD+ to both the reduced polymeric ADP-ribose pool (PAR), covalently attached to heterologous acceptor proteins or PARP-1 itself. There is a growing interest in PARP inhibitors (PARPi) for their clinical potential in cancer treatment. Because of the importance of PARP-1 activity in the maintenance of genomic integrity and DNA repair, treatment with PARPi as adjuvant to TMZ chemotherapy can be beneficial in GBM. PARPi are currently in clinical trials for patients with GBM (NCT01525892, NCT01525893, NCT01319059; injected with vehicle and drank regular water); ii) Control + SM (vehicle, regular water, and injected with the SM 3 times a week at a concentration of 20 nm/Kg); iii) Cancer group (injected with AOM and drank DSS); and iv) Cancer + SM (treated with AOM, DSS, and the SM). At the end of the experimental procedures, animals were sacrificed and the colon was ex-
traced and analyzed. None of the mice belonging to groups i and ii developed any tumor or had any pathological finding, indicating that the SMs do not present overt toxicity. All mice in groups iii and iv developed colon neoplasias ranging from carcinomas in situ to adenocarcinomas. No significant differences were found among mice treated with PAMP modulators indicating that PAMP may not play a major role in colon cancer or that the PAMP-related SMs were not very effective. On the other hand, mice that received SM 16311 had a higher severity index (p < 0.001) and weight loss (p < 0.05) than their control counterparts, whereas mice injected with SM 145425 had a lower number of tumors than their controls (p < 0.001). These results suggest that AM may have a protective role during the progression phase of colon cancer, and that treatment with AM or other PMPS may open new research avenues for colon cancer. This study was financed by Instituto de Salud Carlos III (PI13/02166), FEDER, and Junta Provincial de La Rioja de la Asociación Española Contra el Cáncer (AECC).

#3221 Kevetrin induces p53-dependent and independent cell cycle arrest and apoptosis in ovarian cancer cell lines representing heterogeneous histologies. Ashok Kumar,1 David P. Brennan,1 Karima Chafai-Fadela,1 Sylvia A. HOLDEN, Silvia Ram,2 Geoffrey I. Shapiro,2 Krishna Menon2,1. CelsisCorp, ratation, Beverly, MA; 2Dana-Farber Cancer Institute, Boston, MA.

Ovarian cancer (OC) is a molecularly and histologically heterogeneous disease; however, standard treatment is the same for all subtypes. High-grade serous OC initially responds to chemotherapy; however, low-grade serous and clear cell OC are relatively chemoresistant. Limited treatment options are available once disease recurrence occurs. Since various mutations are found in over 90% of high-grade serous OC, Low-grade serous OC harbor wild type p53, but contain other mutations. During later stages of OC, tumors are a heterogeneous population of mutant cells; thus, development of a novel drug that addresses these molecular differences is highly desirable. Previously, we showed that Kevetrin stabilized wild type p53 and induced transcriptional targets in human lung carcinoma. We sought to validate Kevetrin as a potential treatment for OC with varied p53 status. Endometrioid carcinoma (A2780, wt p53), atypical non-serous clear cell (SKOV-3, deleted p53), and high-grade serous (OVCAR-3, mutant p53) OC cell lines were treated with Kevetrin. Kevetrin induced apoptosis in all three OC cell lines, as assayed by cleavage of PARP and caspase-3. Studies showed significant increases in p53 and p21 protein levels in A2780 cells in 24 to 48 hours; however, in OVCAR-3, Kevetrin downregulated oncogenic mutant p53. RNA levels of p53 and p21 were quantified by qRT-PCR 8 to 72 hours after treatment. No significant changes were observed in p53 mRNA, whereas an increase in p21 mRNA was observed in all three cell lines. In A2780, Kevetrin also induced levels of PUMA in a dose-dependent manner. To establish that Kevetrin mediates increased p21 expression requiring p53, RNAi against p53 was transfected into A2780 cells, showing a significant reduction in p21 expression. Furthermore, p53 levels were increased in A2780 cells transfected with p53 siRNA, indicating p53 directs p21 expression in a dose-dependent manner after Kevetrin treatment. In an in vivo xenograft study in immunocompromised nude mice bearing established A2780 tumors, Kevetrin treatment inhibited tumor growth at well-tolerated doses. The mode of action in vivo also showed enhanced expression of p21 in tumor tissue, indicating p53 pathway activation in A2780 tumors. In contrast, in SKOV-3 cells and xenografts, a p53 independent increase in p21 expression was observed. In OVCAR-3 cells, Kevetrin altered the expression of three microRNAs (miRNA-27a, miRNA-1274b, miRNA-25), that are known to be dysregulated in OC, in a time-dependent manner. To gain further insight into the mechanism of action in cells with diverse p53 status, RNA-Seq is being performed in the three cell lines and tumor tissue from mice before and after Kevetrin exposure. In summary, Kevetrin has promise as an effective therapeutic agent for endometrioid, non-serous clear cell, and high-grade serous OC, with molecularly diverse p53 status. A Phase 1 clinical study was completed and a Phase 2 clinical study in ovarian cancer is scheduled to begin January 2017.

#3222 Disulfiram equivalent to doxorubicin in reducing quantitative osteosarcoma metastatic tumor burden in a validated orthotopic mouse model. Mitchell S. Fourman,1 Adel Mahjoub,2 Jared A. Craso,3 Jonathan Mandell,3,4 David C. Hirsch,1 Jessica Tebbets,2 Rebbecca Watters,2 Kurt R. Weiss2,1. University of Pittsburgh Medical Center, Pittsburgh, PA; 2University of Pittsburgh, Pittsburgh, PA.

Introduction: The five-year survival of patients with osteosarcoma (OS) with lung metastases is as low as 15%. Our group has shown that disulfiram, a FDA-approved aldehyde dehydrogenase inhibitor, inhibits osteosarcoma proliferation and metastasis in vitro. Here we compare the quantitative effects of disulfiram and doxorubicin on metastatic OS burden in a orthotopic mouse model using near-infrared indocyanine green (ICG) angiography. Methodology: In an IA-CUC-approved protocol, 60 immunocompetent balb/c mice were given tibial trans-physeal injections of 500K K7M2 mouse OS cells into their left hindlegs. Legs were amputated 4 weeks after OS injection, and mice were euthanized with ex vivo lung retrieval 10 weeks after OS injection. Animals in the doxorubicin group (n = 20) were administered 2 mg/kg retro-orbitally each week, starting 2 weeks after OS injection to simulate the start of therapy only after a clinical diagnosis of lung metastases. Disulfiram was administered retro-orbitally daily, also starting 2 weeks after OS injection. Controls (n = 20) received no therapy. Quantitative near-infrared imaging of the hindlimb and lungs was performed by injecting 20 uL of 25 mg/cc ICG retro-orbitally 24 hours prior to amputation and lung salvage, respectively. ICG reliably extravasates specifically into tumor mass when injected 24 hours prior to fluorescence measurements. Fluorescence analysis was performed using Noveadaq Spy (Noveadaq, Bonita Springs, FL) and NIH ImageJ (Bethesda, MD). Statistical analysis was performed using Prism 6.0 (GraphPad, LaJolla CA) using Fisher’s Exact Test and a one-way analysis of variance with Tukey’s post-test as indicated. Significance was defined as p < .05. All numbers are represented as mean ± standard deviation, and are described in arbitrary perfusion units (APU). Results: Both disulfiram (2.4 ± 1.7 APU) and doxorubicin (0.8 ± 1.7 APU)-treated animals demonstrated a significantly decreased metastatic tumor burden compared to untreated controls (6.4 ± 3.4 APU, p < .01). This finding was independent of hindlimb fluorescence (p > .05). No significant differences were noted between the doxorubicin and disulfiram groups using Tukey’s post-test (p = .76). Nineteen of 20 control animals developed metastatic disease, compared to nine of 19 surviving disulfiram and two of 12 surviving doxorubicin-treated (both p < .01) animals. No animals died prematurely in the control group, while one animal died in the disulfiram group (5% mortality) and eight animals died in the doxorubicin group (40% mortality; p < .05 compared to controls). Conclusion: In our model of metastatic OS, disulfiram appears to have potent anti-metastatic properties. It may also be better tolerated by hosts. Molecular analysis of disulfiram and doxorubicin-treated primary and metastatic tumors is ongoing, which can help us understand the mechanism behind disulfiram’s anti-tumor effect.

#3223 Novel tubulin inhibitor DJ101 targets the colchicine binding site and suppresses melanoma growth and metastasis. Kinsee Arntz, Dong Jin Hwang, Duane D. Miller, Wei Li. University of Tennessee Health Science Ctr., Memphis, TN.

Interfering with microtubule dynamics is a validated approach for anti-cancer treatment and by selectively targeting the colchicine binding site on tubulin, microtubule destabilizing agents can evade mechanisms of drug resistance that commonly develop with other antitumor agents such as taxanes and vinca alkaloids. We have recently reported the discovery of a potent and metabolically stable tubulin inhibitor (DJ101) that specifically targets the colchicine binding site on the beta tubulin subunit, disrupts tubulin polymerization and effectively circumvents drug efflux pumps that decrease the efficacy of existing tubulin inhibitors. To further preclinically evaluate DJ101 as a novel tubulin inhibitor and confirm its mechanism of action, we first visually demonstrated the ability of DJ101 to disrupt microtubule dynamics and elucidated the changes in microtubule structure and cell morphology through immunofluorescence techniques. Furthermore, we solved the crystal structure of DJ101 in complex with tubulin to determine its molecular interactions with the protein. We then demonstrated the significant in vitro potency of DJ101 against a panel of metastatic melanoma cell lines harboring major clinically relevant mutations observed in tumors and also validated its cytotoxicity against a broader array of NC1-60 cell lines. Further analysis revealed that DJ101 effectively thwarted anchorage-dependent melanoma colony formation and drastically hindered cell mobility and motility of those cancer cells. We further ascertained that DJ101 shows negligible off-target effects for major physiologically important receptors and ion channels, suggesting a good safety profile. Encouraged by the preliminary results from our in vitro assessment, we evaluated the in vivo activity of DJ101 in two different mouse models. At a dose of 30 mg/kg via i.p. injection, DJ101 nearly completely suppressed tumor growth in a human A375 melanoma xenograft model. It also appreciably inhibited metastasis potential in a murine B16F10 lung metastasis model at the same dose. In conclusion, we have described a microtubule destabilizing agent that targets the colchicine binding site on tubulin, confirmed its mechanism action, determined its potency in a vast array of cancer cell lines, particularly metastatic melanoma, demonstrated its inhibitory effect on cellular proliferation, mobility and migration, and evaluated its anticancer potential in terms of tumor growth inhibition and metastasis in two in vivo models. Our findings offer a compelling rationale to further develop and advance DJ101 as a tubulin inhibitor for cancer therapy.
Cucurbitacin D inhibits prostate tumor growth via targeting glucose metabolism. Mohammed Sikander,1 Bilal Bin Hafeez,2 Shahnab Malik,3 Aditya Ganju,4 Fathi T. Halaweish,5 Murali Mohan Yallapu,2 Subhash C. Brookes,1 Meena Jaggi1. 1University of Tennessee Health Science Center, Memphis, TN; 2South Dakota State University, Brookings, SD. Back ground: Metastatic prostate cancer (PrCa) is a major public health problem despite the introduction of hormonal therapy for PrCa (HRPC) after the anti-androgen therapy, cancer metastasis and chemo-resistance are the major hurdle for the treatment of prostate cancer (PrCa) patients. Accumulative evidence suggests that altered glucose metabolism is one of the mechanisms for metastatic PrCa cell survival and chemo-resistance. Therefore, identification and generation of natural or synthetic pharmacological agents that can limit altered glucose metabolism might be highly useful for the treatment of metastatic and chemo-resistant PrCa. Cucurbitacin has shown potent anti-cancer and glucagonostic activities along with severe liver toxicity. Thus, a focus on developing different analogues of cucurbitacin is being pursued by scientific community. Herein, we report that Cucurbitacin D, an analogue of cucurbitacin, suppresses the growth of metastatic PrCa cells in vitro and in vivo targeting glucose metabolism and its associated molecular targets. Methods: HRPC cells (PC3 and DU145) was used as a model system. Effect of Cucurbitacin D on PrCa cell proliferation and apoptosis was performed by MTS, xCELLigence and Annexin V assays. Effect of Cucurbitacin D on clonogenic potential of PrCa cells was examined by colony formation assay. In silico analysis was performed to study if Cucurbitacin D interacts with GLUT1 receptor. Effect of Cucurbitacin D on glucose metabolism of PrCa cells was performed by metabolic shift glucose and lactate uptake assays. Effect of Cucurbitacin D treatment on key molecules of cell survival and glucose metabolism signaling pathways in PrCa cells was analyzed by Western blot and qRT-PCR analyses. Therapeutic efficacy of Cucurbitacin D against PrCa was evaluated in an ectopic PrCa xenograft mouse model. Results: Cucurbitacin D (0.1 to 1 μM) treatment significantly (P<0.01) inhibited the growth and metastatic potential of PrCa cells in a dose-dependent manner. Cucurbitacin D effectively induced apoptosis in PrCa cells as shown by enhanced Annexin V staining and PARP protein cleavage and arrested cells in G2/M phase via modulation of cell cycle regulatory proteins (inhibition of cyclin D1/E and Mcl-1 and induction of p21 and p27). Cucurbitacin D treatment dose-dependently decreased the lactate production, glucose uptake in PrCa cells which was correlated by suppressed expression of GLUT1 and its protein docking with GLUT1 (with binding energy for this complex is -8.5 kcal mol⁻¹). It has been reported that miR-132 targets the GLUT1, interestingly, Cucurbitacin D replenished the expression of miR-132 in PrCa cells. These growth inhibitory effects of Cucurbitacin D were confirmed in PrCa xenograft mouse model where it trans-activated apoptosis-inducing genes and to the mitochondria where it inhibits Bcl-2 and induces Bax pore formation. SHetA2 is an anti-cancer drug that binds mortalin and induces apoptosis in cancer, but not in normal cells. We hypothesized that release of p53 from mortalin contributes to the mechanism of SHetA2-induced apoptosis in cancer, but not in normal cells. Methods: SHetA2 effects on intracellular interaction of p53 and Mcl-1, LGR5, and DCLK1, 3, 4 were studied in the presence of SHetA2 and p53. Results: SHetA2 caused dose-responsive apoptosis in association with nuclear and mitochondrial accumulation of p53 in ovarian cancer cell lines harboring wild type or S125R, L130V TP53 mutants, but not in hFTSECs. Mortalin over-expression or p53 knockdown reduced SHetA2 cytotoxicity in ovarian cancer cells. Mortalin knockdown, p53 overexpression, and chemical inhibitors of p53 transcription (Pifithrin-α) and p53 mitochondrial localization (Pifithrin-μ) were lethal to ovarian cancer cells at effective concentrations and therefore in silico analysis was performed to study if SHetA2 interacts with GLUT1 receptor. Effect of SHetA2 on glucose metabolism of ovarian cancer cells was performed by metabolic shift glucose and lactate uptake assays. Effect of SHetA2 treatment on key molecules of cell survival and glucose metabolism signaling pathways in ovarian cancer cells was analyzed by Western blot and qRT-PCR analyses. Therapeutic efficacy of SHetA2 against ovarian cancer was evaluated in an ectopic ovarian cancer xenograft mouse model. Results: SHetA2 targets mortalin-p53 interaction in differential induction of apoptosis in ovarian cancer over normal cells. Shen Mei-Chuan. Taipei Medical University, Taipei, Taiwan. Patients with ovarian cancer are typically diagnosed at an advanced stage, resulting in poor prognosis since there are currently no effective early-detection screening tests for women at average-risk for ovarian cancer. Here, we investigated the effects of MT-6, a derivative of moscatolin, in ovarian cancer cells. Our investigation showed that MT-6 inhibited the proliferation and viability of SKOV3 ovarian cancer cells with submicromolar IC₅₀ values. MT-6-treated SKOV3 cells showed significant cell cycle arrest at G2/M phase and an increase in the proportion of cells in a sub-G1 phase. In addition, MT-6 induced a concentration-dependent increase in mitotic inhibitors, mitotic kinesins, cell cycle regulators of G2/M transition, and apoptosis-related markers in SKOV3 cells. MT-6 treatment also induced mitochondrial membrane potential loss, JNK activation, and Drp expression. Cotreatment of cells with the JNK inhibitor SP600125 considerably attenuated MT-6-induced apoptosis, mitochondria membrane potential loss, Drp upregulation, and suppression of cell viability. MT-6 also inhibited tumor growth in an SKOV3 xenograft model without significant body weight loss. Together, our findings suggest that MT-6 is a potent anticancer agent with tumor-suppressive activity in vitro and in vivo that could be further investigated for ovarian cancer therapy in the future. Novel Marmelin analog DBQ targets Notch signaling pathway in colon cancer stem cells. Dharmalingam Subrahmanian,1 Sivapriya Pon-nurangam,1 Prasad R. Dandawate,1 Gaurav Kaushik,1 Ossama W. Tawfik,2 Roy A. Jensen,3 Santimukul Santra,2 Subhash B. Padhye,3 Scott J. Weir,3 Shrikant Anant1. 1University of Kansas Medical Center, Kansas City, KS; 2Pittsburg State University, Pittsburg, KS; 3Interdisciplinary Science and Technology Research Academy, Pune, India. Background: Colon cancer is the second leading cause of death in the United States. Previously, we have reported that the identification of a novel compound Marmelin from Aegle marmelos and potent anti-cancer activity. We have developed novel Marmelin analogue THB from this structure showed potent anti-cancer activity and its inhibitory constant value was 10 μM. From this, we developed a second series of analogs, of which DBQ is even more potent than THB. The current study is designed to determine whether DBQ affects colon cancer stem cells and identify a mechanism. Method: Colon cancer cell lines HCT116 and SW480 and normal colon epithelial cells were used in the study. Cell growth was measured by hexoseaminidase and clonogenicity assays. Apoptosis was determined by measuring caspase 3/7 activities. Colosphere formation assay and FACs sorting were used for stem cells. For in vivo effects, we performed studies in HCT116 tumor xenografts. Immunohistochemistry was determined for stem cell markers and Notch signaling proteins. Results: DBQ treatment induced significant dose-dependent inhibition of proliferation and colony formation of HCT116 and SW480 cells, but not that of the normal FHC colon epithelial cells. DBQ also significantly reduced the number and size of colospheres, suggesting effects on stem cells. In addition, DBQ reduced the levels of colon stem cell markers, KL, LGR5, and DCLK1. Further, we obtained further confirmation by flow cytometry, where DBQ treatment reduced the number of DCLK1+ cells. We next determined whether DBQ affects the Notch signaling, a pathway that is important in maintaining CSC population. Notch receptor and its ligands are up-regulated in human colon cancer tissues. DBQ treatment significantly downregulated the expression of all four Notch isoforms, its ligands Jagged1, 2 and DLL1, 3, 4 and downstream target protein Hes1. Notch activation requires cleavage by the γ-secretase complex. DBQ treatment inhibits the expression of γ-secretase complex proteins. To confirm that DBQ effect is thorough downregulating Notch activation, we ectopically expressed the Notch Intracellular domain. DBQ effect was signifi-
icanently mitigated in this condition. To determine the effect of DBQ on tumor growth in vivo, we administered DBQ intraperitoneally (5 mg/kg bw) every day for 21 days in mice carrying HCT116 tumor xenografts. DBQ treatment significantly suppressed tumor xenograft growth, with notably lower tumor volume and weight. Western blot and immunohistochemistry analyses demonstrate anostrogenic induction of CYP19A1 and induction of CD44 and also the Notch signaling proteins in the DBQ-treated xenograft tissues. Conclusion: Together, these data suggest that DBQ treatment suppresses colon cancer growth that targets stem cells in part by inhibiting Notch signaling pathway.

EC1456 is a folate-targeted small molecule drug conjugate (SMDC) of tubulysin B hydrazide (TubBH) that is currently in Phase I clinical studies for treatment of patients with folate receptor (FR)-positive tumors. The ability to detect, quantify, and localize drug in tissues and biological fluids is particularly important for the characterization of its biodistribution and sample matrix extraction method. Using the optimized conditions, the resulting standard curves for TubBH in acetonitrile-extracted KB tumor sample matrix showed good sensitivity and dose-response. It was determined that, in addition to untargeted TubBH, the antibody could also be used to quantitate intact EC1456, as well as a metabolite of the drug lacking the hydrazide. The utility of the antibody was further demonstrated utilizing a PSMA-targeted version of TubBH. Once optimized, the ELISA method was used to analyze FR-positive KB and FR-negative A549 xenograft tumor homogenates from animals dosed with either EC1456 or untargeted TubBH. The levels of TubBH were higher 48-h post EC1456 dose in the FR-positive KB tumors compared to the FR-negative A549 tumors; however, levels were similar after 24h. Moreover, untargeted TubBH resulted in lower tumor concentrations of the drug compared to EC1456 in KB tumors. An immunohistochemical method developed using the antibody showed strong, focal, cytoplasmic staining in FFPE tumor sections of KB tumors from animals dosed with EC1456, while no staining was observed in tumors from untreated animals. Finally, the antibody was successfully used to detect cell surface FR-bound EC1456 on fixed and unfixed KB cells in vitro by flow cytometry. This experiment confirmed that the antibody binds to the conjugate when it is expressed on the cell surface. Collectively, these results show that this antibody against TubBH can be used as a powerful tool for analysis of tumor drug uptake for folate-targeted TubBH in xenograft models and could hold great potential for use in patient sample analysis as well.

#3229 Drug repurposing of topiramate in obesity-driven endometrial cancer. Arthur-Quan Tran, Stephanie A. Sullivan, Chuanxiao Zhou, David Kaufman, Victoria Bae-Jump. University of North Carolina at Chapel Hill, Chapel Hill, NC.

Introduction: Topiramate (TPM) is a B-D-fructopyranose sulfamate that acts by inhibiting carbonic anhydrases (CAs) and has been implicated as a novel inhibitor of angiogenesis. TPM is commonly used for the treatment of epilepsy and migraine headaches; however, when combined with phentermine, TPM can induce weight loss. Due to its weight loss and anti-angiogenic properties, we assessed TPM’s potential as an anti-tumorigenic agent in endometrial cancer (EC), a highly obesity-driven disease. Methods: Cell proliferation was assessed by MTT assay after exposure to TPM for 72 hours in the HEC-1A, KLE, Ishikawa and ECC-1 EC cell lines. Two representative cell lines, ECC-1 and Ishikawa, were used to analyze apoptosis, cell cycle progression, cell adhesion and invasion. Apoptosis was analyzed by Annexin V-FITC assay. Inhibition of adhesion and invasion by TPM were assessed by ELISA and transwell assays, respectively. Cell cycle progression was evaluated by Cèmometer. Western immunoblotting was performed to assess downstream targets of the MAPK and mTOR pathways. The LKB1−/−p53−/− EC mouse model was utilized to assess the in vivo effects of TPM. AdCre was injected at six weeks of age to induce invasive EC. Eight weeks following AdCre injection, mice (N = 10 per group) were treated with placebo or TPM (200 mg/kg/day, oral) for four weeks. The expression of phosphorylated-S6 and Ki-67 was assessed by IHC. Results: TPM inhibited cell proliferation in a dose dependent manner in all four EC cell lines (IC50 range = 1500–3000 nM). Treatment with TPM resulted in G1 arrest and induction of apoptosis (p < 0.05). TPM also reduced adhesion and invasion in the EC cell lines (p = 0.05), with a corresponding decrease in VEGF expression. In addition, TPM significantly inhibited phosphorylation of p42/44 and S6 in the EC cell lines. Lastly, TPM decreased tumor weight in the LKB1−/−p53−/− mice by 68% compared to those treated with placebo (p < 0.05), accompanied by a reduction in Ki-67 and phospho-S6 expression. Conclusion: TPM inhibition and tumor growth in EC cell lines and an EC mouse model. Therefore, TPM may be worthy of drug repurposing as an anti-tumorigenic agent in EC, with the potential added benefit of weight loss in this obesity-linked disease.

CANCER CHEMISTRY: Drug Design and Optimization Strategies

The ERK/MAPK pathway plays a central role in the regulation of critical cellular processes and is activated in more than 30% of human cancers. While targeting upstream nodes with RAF and MEK inhibitors has proven effective clinically, resistance frequently develops through reactivation of the pathway. ERK inhibitors have the potential to address resistance caused by ERK reactivation. Herein, a potent, selective small molecule ERK1/2 inhibitor is described. LY3214996 possesses an optimal balance of potency (hERK1 IC50 5nM, hERK2 IC50 1nM), selectivity (hERK2 IC50 5nM, pRSK IC50 > 43 μM), solubility (FaSSIF solubility at pH 6.5 0.133 μM), PK properties (dog; AUG (range) 23800 nM h, CL 12.1 L/min/kg, bioavailability 75.4%), IVIT (TED50 (range) 66 mg/kg pRSK) and demonstrated significant in vivo efficacy in several human cancer xenograft models. LY3214996 is currently undergoing early clinical evaluation.

#3232 Development of novel Btk inhibitor, CB988 targeting ibrutinib-resistant Btk C481S mutant. Wataru Kawahata, Tokiko Asami, Takayuki Irie, Yasuharu Akiyoshi, Takao Kiyoi, Masaaki Sawa, Carna Biosciences, Kobe, Japan.

Introduction: Bruton’s tyrosine kinase (Btk) is a member of the Tec family of cytoplasmic tyrosine kinase. Btk plays a crucial role in the BCR signaling, essential for B-cell development, and Btk has been recognized as a validated therapeutic target for B-cell malignancies. Ibrutinib covalently binds to the Cys481 residue of Btk to inhibit Btk enzymatic activity, but recent studies suggested that the C481S mutation in Btk disrupts the irreversible binding of ibrutinib, and resulted in ibrutinib-resistance in patients. Therefore a non-covalent Btk inhibitor is highly demanded to overcome ibrutinib resistance. Material and methods: We produced two conformationally different Btks, an activated form of Btk (Btk[A]) and an unactivated form of Btk (Btk[U]) by treating Btk protein with ATP (autophosphorylation) or with Lambda Protein Phosphatase (dephosphorylation), respectively. To evaluate cellular potency of Btk inhibitors, phosphorylations of Btk and PLC-γ were analyzed by Western blotting in Ramos cells, a human Burkitt’s lymphoma cell line. ABC-type DLBCL cell line, OCI-LY10 was used to evaluate anti-tumor efficacy of Btk inhibitors. The ibrutinib-resistant Btk(C481S) mutant was produced to assess efficacy of compounds against the drug resistant enzyme. Kinase selectivity profiling was performed to confirm inhibitor selectivity. Results: Based on structure activity relationship studies, we identified a novel Btk inhibitor, CB988 as a highly selective non-covalent Btk inhibitor. CB988 exhibited remarkable activity for the both conformations of Btk with sub-nanomolar enzyme inhibitory potency in a reversible manner (IC50 = 0.78 and 0.09 nM for Btk[A] and Btk[U], respectively). These results suggested that CB988 preferentially binds to an inactive conformation of Btk. In cellular assays, CB988 strongly reduced Tyr223 phosphorylation of Btk at nanomolar concentration, and decreased phosphorylation of PLC-γ in Ramos cells. Furthermore, CB988 significantly reduced the proliferation of OCI-LY10 cells.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Novel Molecular Targets 2
More importantly, CB988 potently inhibited the iibrutinib-resistant Btk[C481S] mutant in vitro (IC50 = 0.6 nM), which differs from other covalent Btk inhibitors. Conclusions: Btk[C481S] mutation have been reported in iibrutinib re- lapsed CLL and MCL patients. Novel non-covalent Btk inhibitor, CB988 strongly inhibited Btk[C481S] mutant enzyme, suggesting that CB988 has the potential to treat patients who are relapsed/refractory to iibrutinib.

Guided by computational modeling addressing the back pocket of Aurora kinases, several novel chemical analogs of BPR1K653 were designed and synthe- sized in two steps with 30-66% yields. All synthesized compounds were evalu- ated by Aurora-A and Aurora-B enzymatic kinase activity assays, cellular phos- phorylation inhibition assays and cell viability assays. Of them, compound 3a that exhibits no substitution at phenylurea showed similar inhibition activity to Aurora-A and -B. Compounds 3b and 3c which harbor tertiary amino group at meta position of phenylurea showed 10-15 fold inhibition selectivity for Aurora-A over Aurora-B in enzymatic assays. In addition, 3b and 3c were more than 200 fold superior in inhibiting T-loop autophosphorylation of Aurora-A and -B. Compounds 3b and 3c which harbor tertiary amino group at meta position of phenylurea showed 10-15 fold inhibition selectivity for Aurora-A over Aurora-B in enzymatic assays. In addition, 3b and 3c were more than 200 fold superior in inhibiting T-loop autophosphorylation of Aurora-A com- pared to Aurora-B in HCT116 colon carcinoma cells. On the other hand, compound 3d with a 4-hydroxyperiperylidyl group at ortho position preserves Aurora-B inhibition activity. Molecular docking study revealed that the various steric interaction between the compound and residues in the back pocket of Aurora kinases determines their inhibition selectivity.

#3234 Development of potent and selective antibody-drug conjugates with pyrrole-based KSP inhibitors as novel payload class. Hans-Georg Lerchen1, Iven Wittrock2, Nils Griebenow2, Marco Lobell3, Anne-Sophie Rebstock1, Yolanda Cancho-Grande1, Beatrix Stelter-Ludwig1, Christoph Mahler2, Simone Greven1, Anette Sommer1, Sandra Berndt2, Carsten Terjung1, Heiner Apel1, Bertold Kreft1, Rolf Jaulet1, Bayer AG, Wuppertal, Germany; 2Bayer AG, Berlin, Germany.

The number of cytotoxic payload classes with different modes-of-action which have been successfully employed in antibody-drug conjugates (ADC) is still rather limited. So far, only ADCs with microtubule inhibitors, DNA binding payloads or topoisomerase I inhibitors have been advanced into clinical testing. To this end, the identification of ADC payload classes with a novel mode of action will increase therapeutic options and potentially help to overcome resis- tance. Inhibitors of kinesin spindle protein (KSP/Ep5) have generated interest due to their high antitumor potency. However, transferring the preclinical po- tency of small molecule KSP inhibitors (KSPis) into highly efficient clinical regimens with a sufficient therapeutic window has remained challenging. We have investigated a new pyrrole subclass of KSPis which showed subnanomolar potency against a large panel of tumor cell lines for their utility as a novel payload class in ADCs. Towards this goal different attachment sites for linkers have been explored in the KSPi molecule which were found compatible with cleavable and/or non-cleavable linkers. Subnanomolar potency and selectivity of ADCs with these linkers towards either HER2, EGFR or TWEAKR could be demon- strated in vitro. For selected ADCs, the intracellular trafficking and metabolite formation was investigated and KSP inhibition was confirmed as the ADC mode of action. Depending on the linker composition differential profiles of the ADC metabolites with regard to efflux, cellular permeation, and bystander effect have been achieved. Moreover, specific accumulation in the tumor versus other tis- sues was demonstrated in biodistribution studies in vivo. In conclusion, KSP inhibitors have been established as a versatile new payload class for the genera- tion of highly potent and selective ADCs.

#3235 Development of potent and selective inhibitors for ATR: An adju- vant for DNA damage based chemotherapy. Sivapriya Kirubakaran, Vijay Thiruvengadam Thiruvengadam, Althaf Shaik. Indian institute of technology, Gandhinagar, India.

Inhibition of DNA damage checkpoint and repair function has been a chal- lenging as well a promising approach in cancer therapy. ATR kinase is one of the key mediator of DNA damage response which induces cell cycle arrest and DNA repair via its downstream proteins. Blocking ATR has proved to prevent the Chk1 pathway from stalled replication fork and enhances the replication stress and premature mitotic entry. In addition inhibition of ATR can selectively sen- sitize the cancer cell to radio and chemotherapy, due to defective DNA damage signaling through the loss of ATM or p53 mutation in cancer cell. Due to its inherent role in DDR, ATR has been explored as a potential target in enhancing the effect of radiation and chemotheraphy in addition enables highly selective targeting the cancer cell through synthetic lethality. Despite the attractiveness of ATR inhibition in the cancer therapy, specific ATR inhibitors have remained undetectable. Further, there is a limited proof of concept data for ATR inhibition. Considering these facts and challenges we will be presenting some preliminary results with respect to In-silico design, synthesis and evolution of potential and selective ATR inhibitors. Referents for ATR: Ribeiro U., Esteban J., Guzman S., Hoogle, A., Jacques S. A., Koolmeister, T. & Helleday, T. Chemical strategies for development of ATR inhibitors. Expert Rev Mol Med 9, 10 (2014). Characterization of Torin2, an ATP-competitive inhibitor of mTOR, ATM, and ATR. Cancer Res 73, 2574-2586 (2013).

#3236 Delivering selective and cell-active inhibitors of V804M mutant RET kinase through structure-guided drug discovery. Allan M. Jordan, Rebecca Newton, Bohdan Waszkowycz, Richard Bayliss, Babiga Bemun, Daniel Burschowsky, Aude Echaller, Samantha Hitchin, Colin Hutton, Shaun Johns, Stuart Jones, Li-Ying Lin, Mark Richards, Chitra Seewooreuthun, Alex Stowell, Ian Waddell, Mandy Watson, Donald Ogilvie. Cancer Research UK Manchester Inst., Manchester, United Kingdom; 2University of Leeds, Leeds, United Kingdom; 3University of Leicester, Leicester, United Kingdom.

Activating gene fusions in the RET receptor tyrosine kinase have been found to drive 1-2% of lung adenocarcinomas and therefore offer an attractive target for targeted therapy. Whilst non-selective tyrosine kinase inhibitors with RET activity are efficacious in this setting, their use is generally limited by dose limi- ting toxicity associated with their more potent activity versus other targets, specifically KDR (VEGFR2) in the case of cobanizant and vandetanib. Given this limitation, there is considerable interest in developing more selective inhib- itors of RET kinase. Tyrosine kinase inhibitors are prone to early clinical failure due to mutations in the kinase ATPase binding domain, which render the kinase catalytically active but no longer sensitive to drug treatment. Such mutations often occur in the so-called “gatekeeper” region and in this specific case, resis- tance is predicted to arise from a Vai-Met or Val-Leu mutation at residue 804. Through a combination of computational methods, structural biology and drug design, we have identified and further optimized a series of inhibitors of the V804M mutant RET kinase which show sub-micromolar cellular activity in cells driven by V804M RET. Moreover, these agents show excellent selectivity against the wtRET kinase and KDR. As such, these agents may offer valuable start-points for second-generation RET inhibitors for use in patents who relapse after treat- ment with first generation selective RET inhibitors.

#3237 Development of direct inhibitors of KRAS mutants for the treat- ment of cancer. Xiaohong Tian, Guoyan Geng, Jia Hui Wu. Lady Davis Insti- tute, Jewish General Hospital, Montreal, Quebec, Canada.

Oncogenic KRAS mutations occur in ~30% of all human cancer. All attempts to develop inhibitors of oncogenic KRAS have failed to reach the clinic for decades and promote the perception of ‘undruggable’ KRAS proteins. Given the recent advances in understanding of mechanism of oncogenic KRAS, there is renewed enthusiasm toward development of direct inhibitors of KRAS. In a previous publication, we and other groups discovered a “pocket,” where they designed a series of mutant-specific small molecular inhibitors that are covalently binding to the mutant Cys 12 in KRAS protein (KRAS G12C). In human cancer, G12C, G12D and G12V are the predominant KRAS mutants. The G12C mutation accounts for 29,700 new diagnoses annually (lung, colon and pancreatic). The G12D and G12V, annually account for 53,700 and 39,100 new cancer diagnoses, respectively, occurring most frequently in Pancreatic ductal adenocarcinoma (PDAC) (51% G12D and 30% G12V) and colorectal cancer (45% G12D and 27% G12V). Thus, there is an urgent need to develop direct inhibitor of KRAS G12D and 12V mutants. By computer-aided drug design techniques, we have discovered a series of novel chemical inhibitors that potently inhibit KRAS G12D and 12V mutant in reporter assays using HEK293 cells and in Western blot analysis using PCNC10.05 and SNU-C2B cells, which express endogenous KRAS G12D mu- tant. The direct binding of our compounds with KRAS G12D mutant was con- firmed by Surface Plasmon Resonance (SPR) analysis. Our compounds also inhibit KRAS G12V mutant. Chemical optimization of these initial hits as direct inhibitors of multiple KRAS mutants is in progress.

Helicases are enzymes that unwind DNA or RNA. As a result, they are de- scribed as ‘guardians of the genome’ and play roles in key processes such as DNA replication, RNA transcription, translation, DNA repair and DNA recombi-
tion. Certain helicases have also been implicated in the DNA damage response (DDR) and with an increasing interest growing in these enzymes, more helicases are likely to be implicated in DNA damage repair as understanding grows. Targeting proteins involved in DDR has recently gained promise as a selective chemotherapy strategy due to the high level of genomic instability in cancer cells. One of these helicases, Bloom syndrome helicase (BLT2) is particularly potent at arresting cell cycle at G2/M phase and implicated in homologous recombination (HR), a key pathway in the repair of double strand breaks. The role of BLM in DNA repair and its complex interactions with key proteins in these networks suggest it may be a good chemotherapeutic target. The first BLM helicase inhibitor to be characterised was ML216. However, ML216 does not seem to be highly specific to BLM as it also inhibits RFC3 and other closely related WRN family members. Furthermore, it is insoluble and permeability of this series which would prevent reliable in-vitro data from being generated. Potent and selective inhibitors targeting BLM helicase can increase understanding of its function in human cells and role and relevance in DNA damage repair. Furthermore, the tool can also be used in synthetic lethality screens to assess the potential of BLM inhibition as a chemotherapeutic option. As a result, the discovery of a novel series of potent and selective BLM inhibitors with improved physiochemical properties were sought. In this work, 672 active hits of the NIH Molecular Libraries Small Molecule Repository (MLSMR) qHTS screen on BLM helicase, which have been deposited in the PubChem BioAssay database [AID2386], were analysed and 10 series were selected for in-house testing on a BLM helicase unwinding assay. This led to the medicinal chemistry optimization of a lead compound that is relatively potent compared to inhibitors of other human helicases. Efforts have been undertaken to establish primary SAR and to improve the activity of the compound to <0.1 μM as well as further improve the physiochemical properties of this series. This series has shown positive binding data using microscale thermophoresis (MST). Very few inhibitors of human helicases have used biological techniques to validate binding and the use of MST for this purpose has not been reported. Further biological efforts are underway to validate the series through in vitro SCE assays and co-crystallisation methods.

**#3239 Selective tumor targeting with 5-substituted pyrrolo[2,3-d]pyrimidines with heteroatom bridge substitution.** Aleem Gangjee,1 Rishabh Mohan,1 Manasa Ravindra,1 Adrienne Wallace-Povirk,2 Carrie O’Connor,1 Aamod Dekhne,1 Zhankan Hou,1 Larry H. Mathevery,1 Duquesne University, Pittsburgh, PA;1 Wayne State University School of Medicine, Detroit, MI.

Three specialized systems exist for membrane transport of folates and antifolates across biological membranes. The reduced folate carrier (RFC) is ubiquitously expressed in tumors and normal tissues. Folate receptors (FR) α and β, and the proton-coupled folate receptor (PCFT) exhibit narrow patterns of tissue expression and serve specialized physiologic roles. FRs are expressed in a number of cancer cells (e.g., FRα in ovarian cancer and non-small cell lung cancer; FRβ in acute myelogenous leukemia) and a single receptor is expressed in a large number of human solid tumors but not leukemias. FRs are either inaccessible to the circulation (FRs) or are nonfunctional (FRβ) in normal tissues. PCFT transport is limited in most normal tissues, given the requirement of acidic pH for optimal activity. These properties facilitate tumor targeting of cytotoxic compounds with specificities for PCFT on FRα and FRβ, respectively. Clinically used antifolates such as methotrexate and pemetrexed are substrates for RFC and their uptake by both normal tissues and tumors confers dose-limiting toxicity due to limited tumor selectivity. We previously reported a 5-substituted pyrrolo[2,3-d]pyrimidine antifolate with a 4-carbon bridge and a phenyl glutamate side chain (AGF127). Previous studies of related 6-substituted pyrrolo[2,3-d]pyrimidines established that the nature and length of the bridge region plays an important role in determining tumor cell potency and transport selectivity. Thus, it was of interest to vary the length and insert heteroatoms into the side chain (-CH₂₈ of AGF127, including -CH₂₈-S- (compound 1, n = 3 and compound 2, n = 4) and -CH₂₈-O- (compound 3, n = 3 and compound 4, n = 4), to determine the impact on drug potency and transport selectivity. The novel analogs were tested as growth inhibitors against engineered Chinese hamster ovary (CHO) cells expressing the human FRα (RT16), RFC (PCFT4), and PCFT (R2/PCT4). AGF127 showed potent inhibition of CHO cells expressing Frα (IC₅₀ = 8.6 nM), and reduced activity toward CHO cells expressing RFC (57 nM) or PCFT (840 nM). Compounds 1, 2, and 3, showed reduced inhibitions toward Frα-expressing RT16 cells (4-35-fold) compared to AGF127; however, compound 4 was equipotent to AGF127. Like AGF127, none of the series were effective PCFT substrates. Compound 3, like AGF127, inhibited RFC-expressing PC43-10 cells (IC₅₀ = 37 nM); RFC activity was reduced 6- to >20-fold for compounds 1, 2, and 4. Toward Frα-, RFC-, and PCFT-expressing KB human tumor cells, the order of potency was 4 > AGF127 > 2 > 3 > 1. Compound 4 was also more active (15-fold) than pemetrexed with KB cells. Collectively, the potential and selective activity of compound 4 toward Frα-expressing tumor cells and limited activity toward RFC-expressing cells offers significant advantages over AGF127 and clinically used non-targeted antifolates, suggesting that further preclinical evaluation is warranted.

**#3240 Designer peptides targeting epidermal growth factor as novel anti-breast cancer agents.** Emmanuel Yaswos,1 Angel Garcia,1 Husamuldeen Dhari,1 Rajendra V. Rajnarayanan1,2 SUNY at Buffalo, East Amherst, NY; Tongaloo College, Jackson, MS.

Triple negative breast cancer (TNBC) is the only major type of breast cancer for which no specific FDA approved target therapy is available to improve patient outcomes. TNBC lacks the usual breast cancer targets estrogen receptor (ER), progesterone receptor (PR) and HER2/neu receptor. Studies have shown that TNBC does express the epidermal growth factor receptor and has recently emerged as one of the potential targets in TNBC. Epidermal growth factor (EGF) mediates several cellular functions and processes such as survival, motility, differentiation, proliferation and death. When it is released by epidermal tissues, EGF binds to cell surface receptors such as the Epidermal growth factor receptor (EGFR) causing a conformational change which facilitates its dimerization. This receptor dimerization triggers its tyrosine kinase-mediated signal transduction activity. Apart from EGF, EGFR is reported to bind to Transforming growth factor alpha (TGF-α), Argos and Potato Carboxypeptidase inhibitor (PCI). All of these proteins have unique structural motifs which targets EGFR. PCI’s structure consists of three disulfide bridges presents a unique knot like binding motif resembling EGF and is able to compete with EGF for its binding site on EGFR. The Argos receptor dimerization thereby by antagonizing its action. We have used an integrated computational drug discovery approach to generate several PCI peptide ligands targeting EGFR protein-protein interactions. PCI- peptides bind to EGFR in silica and block EGF-mediated cell growth, proliferation and migration in vitro. We believe these designer peptide inhibitors will provide structural and mechanistic clues towards novel therapeutic strategies to combat TNBC.

**#3241 Peptide power: A PSMA-targeted CT20 nanoparticle to fight prostate cancer.** Orielys Flores,1 Daniel Nierenberg,1 Ana C. Carr,1 Rania Bassionni,1 Arati Limaye,1 Santimukul Santra,1 Charalambos Kaittinas,2 Annette Khaled,3 Jesus Manuel Perez 3.

Chemotherapeutic agents within targeted nanoparticles typically trigger cell death not only in tumors cells but also in normal cells that non-specifically uptake these nanoparticles. An alternative approach would be to target the delivery of a therapeutic agent that is toxic to cancer cells while less toxic to non-cancer cells. To accomplish this, a Bax-derived peptide (CT20) was developed as a selective cancer agent, and a folate-decorated hyperbranched polyether (HBPE) nanoparticle was employed to deliver the peptide to prostate-specific membrane antigen (PSMA) (+) prostate cancer cells. The receptor-targeting capability of folate acid towards PSMA (+) in prostate cancer was examined using a fluorescence activatable probe, folate-S-S-doxorubicin, and the PSMA inhibitor 2-PMPA. Additionally, a folate-decorated HBPE nanoparticle was used to target PSMA (+) prostate cancer cells in vitro as well as in athymic mice. CT20-encapsulated folate (CT20-CT20) nanoparticles were used to determine cell cytotoxicity against PSMA-positive and -negative cells using flow cytometry. Furthermore, cytotoxicity of folate-CT20 nanoparticles towards murine macrophages was evaluated to determine the consequences of non-specific uptake; the FDA-approved doxorubicin was used for comparison. Cell death associated with CT20 was determined through a violet ratiometric membrane asymmetry probe combined with SYTOX AAD-vanced dead cell stain to evaluate membrane asymmetry and membrane permeability. Folate-CT20 nanoparticles’ tumor-targeting and tumor-killing efficacy was evaluated in athymic mice bearing PSMA (+) tumors and PSMA (-) tumors. Nanoparticles were delivered intravenously through the tail vein and the tumor size was assessed with calipers and ultrasound. Folate-S-S-Doxorubicin was up taken specifically by PSMA (+) prostate cancer cells showing fluorescence within 12 hours and cell death within 24 hours. Cells that were preincubated with 2-PMPA followed by folate-S-S-Doxorubicin demonstrated no cell-associated fluorescence or cytotoxicity. Similarly, folate-decorated nanoparticles were only internalized by PSMA (+) cells. Cytotoxicity of folate-CT20 nanoparticles over PSMA (+) cancer cells occurred within 48 hours, while no changes occurred in PSMA (-) cells. When murine macrophages were treated with PSMA-targeting nanocarriers and doxorubicin individually, significant cytotoxicity only occurred in doxorubicin-exposed cells. In vivo, folate-CT20 nanoparticles were capable of preventing further PSMA (+) tumor growth and...
caused PSMA (+) tumor regression in some cases. Moreover, minimal liver and spleen damage was observed. Herein, we demonstrate that the CT20 peptide is capable of displaying specific lethality towards PSMA (+) prostate cancer cells and that folate-CT20 nanoparticles are promising vehicles to deliver CT20 in vitro and in vivo.

**#3242 Synthetic analogs of curcumin as modulators of multidrug resistance-associated ABC transporters.** Megumi Ohara,1 Shinobu Ohnuma,2 Eduardo E. Chufan,3 Masaharu Ishida,1 Katsuyoshi Kudoh,1 Norihiko Sugisawa,1 Hideo Ohtsuka,1 Takeshi Naitoh,1 Hiroaki Shibata,1 Yoshiharu Iwabuchi,1 Suresh V. Ambudkar,2 Michiaki Unno,1 Tohoku University Graduate School of Medicine, Sendai, Japan; 2Laboratory of Cell Biology, Center for Cancer Research, National Cancer Institute, NIH, Bethesda, MD; 3Department of Clinical Oncology, Akita University Graduate School of Medicine, Akita, Japan; 4Department of Organic Chemistry, Tohoku University Graduate School of Pharmaceutical Sciences, Sendai, Japan.

Cancer patients often develop resistance to anticancer drugs. ATP-binding cassette (ABC) transporter-mediated drug efflux is one of the mechanisms responsible for development of resistance to anticancer drugs. The present study investigates the use of curcumin, a natural product and a dietary constituent of turmeric, which inhibits the function of three ABC drug transporters including ABCB1, ABCG1 and ABCG2. However, limited bioavailability of curcumin prevents its use for modulation of the function of these transporters in the clinic. We focused on curcumin analogs that were synthesized at Tohoku University and have been shown to exhibit higher bioavailability than natural curcumin to test whether the synthetic analogs also inhibit the function of ABC drug transporters. To investigate this, KB-V1 and K562/BCRP cell lines overexpressing ABCB1 and ABCG2 were used for the experiments. For these studies, we screened nineteen synthetic analogs of curcumin for their effect on the transport function of ABCB1 and ABCG2 by flow cytometry. Four curcumin analogs, GO-Y030, GO-Y078, GO-Y168 and GO-Y172 inhibited efflux of mitoxantrone mediated by ABCG2 and sensitized ABCG2-expressing K562 leukemic cells to the anticancer drug, SN-38 in cell toxicity assays. Some of the curcumin analogs (GO-Y030, GO-Y078, GO-Y172) stimulated ATPase activity of ABCG2 at nanomolar concentrations (EC50 = 480 ± 0.06, 790 ± 0.10, 930 ± 0.12 nM). In addition, GO-Y030, GO-Y078, GO-Y168, GO-Y172 analogs also inhibited photolabeling of ABCG2 in MCF-7/FL plasma membranes with iodoarylazidoprazosin, which is transported by this transporter. These data demonstrate that similar to curcumin, synthetic curcumin analogs also interact at the drug-binding pocket of ABCG2. In aggregate, these results suggest that non-toxic synthetic curcumin analogs with increased bioavailability may be useful to reverse ABCG2-mediated resistance to anticancer agents.

**#3243 Development of specific DNA aptamers against programmed cell death-1 (Anti-PD-1-Apt) for diagnosis and treatment of cancers.** Santhana Gowri Thangavelu Devaraj,1 Lokesh Ganesh Lakshamana Rao,2 Youli Zu,1 Jenny C. Chang,1 Swaminathan P. Iyer 1. 1Houston Methodist Research Institute, Houston, TX; 2The University of Texas Health Science Center at Houston, Houston, TX.

Cancer cells have an extraordinary ability to escape immune response by modulating the expression of immune checkpoints and immune checkpoint ligands. Programmed cell death protein (PD-1), a cell surface receptor expressed on T cells is one such immune checkpoint receptor when bound to its ligands PD-L1 or PD-L2 transmits an inhibitory signal. Such modulation often leads to inhibition of T-cell activation and subsequent escape of tumors from immune surveillance. Recently, several FDA approved therapeutic antibodies have been successfully developed that target PD-1/PD-L1 axis and allow the immune system to enhance its anti-cancer effects. Aptamers are synthetic small molecule ligands composed of short, single-stranded oligonucleotides ranging from 30 to 60 bases in length. Based on their highly specific 3-dimensional conformation, aptamers, analogous to the antibodies can recognize and bind to their targets with high affinity. Also, the nucleic acid component has several advantages over the protein counterparts-such as ease of production under less stringent conditions, long shelf life and low cost. Here, we report the development of several PD-1 specific aptamers by systematic evolution of ligands by exponential enrichment (SELEX) technology against endogenous immunoprecipitated PD-1 protein using DNA library with a complexity of 10^9. Following several rounds of SELEX, the selected aptamers sequenced by high throughput Next-Generation Sequencing (NGS) were found to have highly conserved regions. Six PD-1 specific aptamers (Anti-PD-1-Apt) were then assessed for target validation using leukemic cell lysates (cell lines and primary patient samples) and were found to bind to the PD-1 in its native state. The selected Anti-PD-1-Apt were able to specifically pull down the PD-1 protein from the lysates mimicking PD-1 anti-body. The specific interaction of the Anti-PD-1-Apt was also demonstrated by flow cytometry and fluorescent microscopy. As expected, Anti-PD-1-Apt was able to bind to PD-1 with Kd of ~500 picomolar affinity as assessed by Bio-Layer Interferometry. Furthermore, we also characterized and confirmed Anti-PD-1-Apt biological activity using an PD-1/PD-L1 cell-based assay using PD-1/ PD-L1 reporter-lurkat cells. We have observed activity in a NFAT luciferase reporter activity (Relative Luciferase Units) in PD-1/NFAT reporter-lurkat cells co-cultured with HEK293 cells overexpressing PD-L1 and TCR activator in the presence of Anti-PD-1-Apt compared to control. Our preliminary data also demonstrate robust Anti-PD-1 blockade in Mixed Lymphocyte Reaction (MLR) along with induction of Th1 cytokines Interferon-gamma and IL-2 from different donor sets of PBMCs. We will present additional - in vivo anti-tumor response data at the upcoming AACR Annual Meeting at Washington DC, 2017.

**#3244 Treatment of endometrial cancer cells with a new small tyrosine kinase inhibitor targeting mutated fibroblast growth factor receptor-2.** Sebastien Taurin,1 Chieh-Hsiang Yang,2 Maria Reyes,1 Sunggil Cho,1 Elke J. Arboe,1 Theresa L. Werner,1 Demetrius M. Coombs,1 Paul Chen,1 Margit M. Janat-Amsbury1. 1University of Utah, Salt Lake City, UT; 2Drexel University College of Medicine, Philadelphia, PA; 3Advenchen Laboratories, Moorpark, CA.

Endometrial cancer (EC) is the most common uterine malignancy in industrialized countries and is the most frequent gynecologic cancer in the United States with an estimated 60,050 new cases in 2016. Traditionally observed in peri-, postmenopausal women, the incidence rate of EC has steadily increased among younger women of reproductive age over the past two decades partially owing to a more sedentary lifestyle and rampant obesity epidemic. Surgery in combination with either radio- and chemotherapy is commonly curative for the early stage of the disease. However, patients with recurrent or metastatic disease, who only respond poorly to cytotoxic chemotherapy are in desperate need of therapeutic alternatives as are patients of reproductive age. Thus, innovative, safe and more effective therapies are mandated. Several studies have demonstrated the increased expression of various tyrosine kinase receptors involved in the development of EC. We hypothesized that a targeted therapeutic approach using a pan-tyrosine kinase inhibitor would prevent the proliferation and progression of EC. Anlotinib (AL3818) is a multi-targeted receptor tyrosine kinase inhibitor targeting vascular endothelial growth factor receptors 1 to 3 (VEGFR1-3), stem cell factor receptor (C-kit), platelet-derived growth factor receptors (PDGFRα, β) and fibroblast growth factor receptors 1 to 3 (FGFR1-3). We tested a panel of seven human endometrial cancer cell lines (AN3CA, Ishikawa, HEC1A, HEC1B, KLE, MFE280 and MFE296) to assess the cytotoxicity of anlotinib in vitro. A lower IC50 value was observed in AN3CA cells (25 nM), a cell line characterized by a high level of expression of an FGFR2 mutant protein, while cell lines expressing FGFR2 with wild-type-less sensitive FGFR2A C: A-33 µM, or HEC1B 36 µM). Somatic mutations of FGFR2 have been observed in 12% of EC, indicating the potential for this drug in a subset of EC patients. In summary, these results suggest improved efficacy of anlotinib for the treatment of ECs expressing an increased level of FGFR2 mutant proteins. The safety and efficacy of anlotinib are currently being evaluated in an orthotopic AN3CA murine model of EC. Experimental groups included a tumour-bearing control not subjected to any treatment, anlotinib alone, carboplatin/paclitaxel, a combination of anlotinib and carboplatin/paclitaxel. Primary study endpoints include tumor growth retardation, the delayed onset of local metastases as well as reduced toxicity as secondary endpoint.

**#3245 Preclinical evaluation of the imipridone family of small molecules, including analogues of clinical-stage anti-cancer small molecule ONC201, reveals potent anti-cancer effects of ONC212.** Jessica Wagner,1 C. Leah Kline,1 Gary Olson,1 Bhaskara Hallaganchu,2 Richard Pottorf,2 Varun Prabhu,2 Martin Stogniew,3 Joshua Allen,3 Wafik El-Deiry1. 1Fox Chase Cancer Center, Philadelphia, PA; 2Provid Pharmaceuticals, Moonmouth Junction, NJ; 3Oncoceutics, Philadelphia, PA.

We previously identified a novel, potent anti-cancer small molecule ONC201, which upregulates the integrated stress response (ISR) through ATF4/CHOP/DR5 and acts as a dual inactivator of Akt and ERK, leading to TRAIL gene activation. After completing a first-in-human phase I clinical trial that revealed exceptional safety, therapeutic pharmacokinetic (PK) profile and tumor engagement, ONC201 is under investigation in several advanced cancer Phase I/II trials. Given the unique imipridone core chemical structure of ONC201, we synthesized a family of analogues in an effort to identify additional chemical family members with distinct therapeutic properties. Based on in vitro potency improvements in human cancer cell lines and therapeutic window approximations with normal human fibroblasts, select analogues were investigated in ani-
mals for toxicity, maximum tolerated dose (MTD), and antitumor efficacy. ONC212 is one of the most promising new imipridones that was further evaluated to establish the PK profile, oral bioavailability, and efficacy in tumor types that are less sensitive to ONC201. Compared to ONC201, we noted distinct and more rapid kinetics of activity as well as improved potency in multiple human cancer cell lines. ONC212 has an oral bioavailable PK profile, and is orally well-tolerated in mice. With no evidence of toxicity at efficacious doses in both colon and triple negative breast cancer, we have begun further evaluation of antitumor efficacy studies in ONC201-resistant tumor types. Efficacy studies with ONC212 are ongoing in melanoma models that are sensitive to ONC212 but less sensitive to ONC201 in vitro. Preliminary data indicated that tumor growth reduction by ONC212 in vivo in ONC201-resistant melanoma xenografts. With a wide safety margin, potent antitumor activity in ONC201-insensitive tumors, and drug-like characteristics, ONC212 is being further developed as a drug candidate from the new imipridone class of compounds that complements the spectrum of activity of ONC201.

#3246 Development of small-molecule STAT3 transcription factor inhibitors. Kazi S. Nahar, Shirin Jamshidi, Maria Thanou, David E. Thurston, Khondaker Mizra Rahman. King's College London, London, United Kingdom

Oncogenic transcription factors are an increasingly important target for anticancer therapies, as their inhibition could allow the "reprogramming" of tumor cells, leading to apoptosis or differentiation from the malignant phenotype. STAT3 induces the transcription of genes that control differentiation, inflammation, proliferation, and tumour cell invasion, and its over-expression has been implicated in many tumour types. Although cancer cells are often dependent upon activation of STAT3, non-tumour cells are fairly tolerant of loss of its function, most likely reflecting redundancies in normal signal transduction. Thus, STAT3 inhibitors have a high therapeutic potential. A combination of in silico design and pharmacophore-based approaches have been used to design a novel series of inhibitors capable of disrupting STAT3 dimerisation by interacting with the hexapeptide pocket of the SH2 domain of the STAT3 protein. Members of the initial medicinal chemistry optimised mature ligand library had significant STAT3-dimerization inhibition activity with potencies ranging from 33% to 59% inhibition. They also had sub-micromolar to low micromolar cytotoxicity (IC₅₀ 0.6 μM to 2.6 μM) in the STAT3-dependent cell line MDA MB 231, with good selectivity ratios compared to STAT3-null cell lines. Three of the most potent library members were selected for molecular dynamics simulations and cell biological studies of their interaction with the STAT3 protein, and for their ability to down-regulate STAT3-dependent genes in cell lines using RT-PCR. In the molecular dynamics studies it was shown that the compounds interact with eight key amino acid residues (i.e., Ala703, Pro704, Arg1317, Asn1442, Gln1355, Gln1357, Thr1354 and Thr1443) within the SH2 domain, and in the RT-PCR experiments these compounds were found to down-regulate the STAT3-dependent genes survivin, cyclin D1, fascin and BCL-2 in comparison to the housekeeping gene GAPDH in the STAT3-dependent cell line MDA MB 231. The most active compound was also evaluated in a preliminary human tumour xenograft assay in immune-compromised mice bearing MDA MB 231 tumours, and was found to have significant tumour growth inhibition properties (at 0.5 mg/kg, two doses on day 0 and 2) in a high throughput format to determine the potential of this novel series of molecules toward clinical evaluation in man.

#3247 Discovery of a novel drug that affects centrosome clustering. Dilan B. Jaunky, Kevin Laroque, Javier Porro Suaridaz, Dan Yang, Emma J. Furze, Pat Forgione, Alisa Plekyn, Concordia University, Montreal, Quebec, Canada.

Our goal is to identify molecular regulators of a mechanism that occurs uniquely in cancer cells, and to develop a selective anti-cancer drug. Most chemotherapy agents are non-selective, causing severe side-effects. In addition, cancers often develop resistance to some of the more commonly used chemotherapies. To expand the repertoire of available drugs, and to design drugs that are selective, we need to identify molecules that regulate the physiological changes that occur primarily in cancer cells. For example, cancer cells in many hard-to-treat cancers have aberrant centrosomes, which may be supernumerary or fragmented. During mitosis, these aberrant centrosomes must cluster to form bipolar spindles for successful division. Thus, targeting a process like centrosome clustering is ideal, since it is not necessary in healthy cells. We synthesized a small, stable scaffold with amenability to structure-activity-relationship studies, and found several analogues with IC₅₀ values < 50 nM, depending on the cancer cell line. Preliminary tests showed that these compounds prevent tumors from forming and/or cause their regression in vitro. We performed cell biological studies to characterize their mechanism of action. In several different types of cancer cells, these compounds cause mitotic arrest and centrosome declustering at concentrations where they have little effect on non-cancerous cells. Live imaging revealed that within minutes of adding the compounds to HeLa cells expressing GFP-tagged tubulin, we observed rapid microtubule depolymerization and centrosome clustering. After washing out the compound, microtubule polymerization recovered, but the mitotic spindles were multilobar. Adding the compound to cells exposed to an antimitotic drug, also caused rapid microtubule depolymerization, but after washing out the drug, the spindles were bipolar. We are in the process of identifying the molecular target of these compounds to provide crucial insight to the mechanism governing centrosome clustering, and are continuing to perform SAR studies to obtain compounds with higher efficacy and selectivity.

Microtubrids are key regulators of cell division, cytoskeleton assembly and apoptotic cell death. The mitochondrial electron transport chain (ETC) consists of four enzyme complexes that transfer electrons from NADH to oxygen. During electron transfer, the ETC pumps protons into the inter-membrane space, generating a gradient across the inner mitochondrial membrane that is used by Complex V to drive ATP synthesis. Recent publications have shown that tumor cells harboring specific mutations (LK81, miD8 and others) are more sensitive to Complex I inhibition, potentially providing an opportunity for selectively targeting tumor cells. Based on a high throughput screen (HTS), we identified new, albeit modestly active, lead structures with cross reactivity between mouse and human Complex I. SAR elaboration of the lead structure allowed for optimization of the most active compound and still suffered from low metabolic stability. Further improvement of the in vitro and in vivo PK properties finally permitted in vivo animal studies. Herein, we report for the first time the preclinical profile and structure of a highly active, optimized, human/mouse cross-reactive Complex 1 inhibitor that allowed for the further investigation into the therapeutic potential of Complex I inhibition in cancer.

#3249 Thymoquinone inhibits elongation factor 2 kinase signaling axis by inducing tumor suppressor miR-603 in triple negative breast cancer cells. Nashwa N. Kabil, Recep Bayraktar, Nuriman Kahraman, Bulent Ozpolat. MD Anderson Cancer Center, Houston, TX.

Triple negative breast cancer (TNBC), is a highly heterogeneous and aggressive subtype of breast cancer (BC), which poses a significant clinical challenge. TNBC constitutes about 15-20 % of BC cases, and is characterized by lack of estrogen (ER), progesterone (PR) and human epidermal growth factor 2 (HER2) receptors. Thus, patients cannot benefit from targeted therapies such as anti-estrogen (Tamoxifen) and anti-HER2 (Trastuzumab) treatments. Therefore, identification of new molecular targets and treatment strategies are highly warranted to improve patient outcome. We previously reported that elongation factor 2 kinase (EF-2K) is highly expressed in TNBC cell lines and is associated with poor patient survival and prognosis. Furthermore, in vivo targeting of EF-2K by siRNA nano-therapeutics inhibited cell proliferation, migration/invasion and significantly decreased tumor growth in 2 different orthotopic TNBC mouse models (MDA MB-231 and MDA MB-436). Collectively, our work suggests that EF-2K is an excellent novel therapeutic target in TNBC. In search of a potential safe and effective EF-2K inhibitor, we identified Thymoquinone (TQ), a dietary natural compound, known to have diverse anti-cancerous properties in several in vitro and in vivo models, including TNBC. However, the mechanism by which TQ mediates its effects are not well elucidated. Our current study is the first to demonstrate that TQ inhibits protein and mRNA expression of EF-2K, as well as its clinically significant downstream targets such as Src/FAK, PI3K/AKT, and CyclinD1; resulting in a significant decrease in proliferation, migration/invasion of TNBC cells. To determine the molecular mechanism by which TQ inhibits EF-2K expression, we investigated if TQ induces tumor suppressor microRNA as that we identified to bind to the 3' UTR of EF-2K. We found that TQ induces miR-603 expression, which we had reported to directly bind and inhibit EF-2K expression; resulting in decreased TNBC growth and progression, both in vitro and in vivo. Furthermore, we showed that inhibition of nuclear factor kappa B (NF-kB) (a well established target for TQ), also induces miR-603 and inhibits EF-2K expression in TNBC cells. In conclusion, our study is the first to show that TQ inhibits EF-2K expression through modulating the NF-kB/miR-603 axis; ultimately resulting in decreased cell proliferation, migration/invasion of TNBC. Our data suggests a novel molecular mechanism for TQ that represents a potential therapeutic strategy in inhibiting TNBC tumor growth and progression.
Computational drug repositioning and biochemical validation of piperlongumine as a potent therapeutic agent for neuroendocrine prostate cancer.

Introducing and Objectives: Neuroendocrine prostate cancer (NEPC) is a highly lethal and drug-resistant variant of prostate cancer (PCA). We have used a genomics-based drug-repositioning approach and identified compounds with therapeutic activity against NEPC. One of the compounds, piperlongumine (PL) is a natural product constituent of the fruit of the Long pepper (Piper longum). The efficacy of this drug was tested in the NEPC cell line model NCI-H660 and compared to several other PCA cell lines in a modified WST-1 assay. Preclinical testing in mouse xenograft models of NEPC was also undertaken. Finally, the ability of piperlongumine to inhibit p-STAT3 signaling and promote apoptosis was measured by western blot analyses. Methods: PCA cell lines (LNCaP, 22Rv1, Du145, PC3, H660 and RWPE) were grown in complete media. Apoptosis was measured by western blot analyses.

Preclinical testing in mouse xenograft models of NEPC was also undertaken. Chronic inflammation is believed to promote cancer through cellular and genomic damage. Inflammation creates a microenvironment within the tissue that enhances cell proliferation. In 2016, American Cancer Society estimates that 1,685,210 new cancer cases are expected to be diagnosed in the United States.

Cyclooxygenase (COX) is an enzyme found to play an essential role in inflammation and converts arachidonic acid to prostaglandin-like molecules. The three isomers of COX are COX-1, COX-2, and COX-3. COX-2 has been found to be up-regulated in inflammation and some cancers, such as breast cancer and prostate cancer. Tetrahydropyridines (THPs) developed by our research group were effective in inhibiting inflammation, COX, and the growth of some breast cancer cell lines. Preclinical research has shown that pharmacological activities of the THP derivatives depend greatly on the nature and position of the substituents on the THP ring structure. Here, we present the synthesis of a series of novel THP derivatives. 3-Ethylpyridine is reacted with O-mesitylenesulfonylhydroxylamine (O-MSH) to furnish N-amino-3-ethylyridinium mesitylenesulfonate. The reaction of N-amino-3-ethylpyridinium mesitylenesulfonate with substituted acid chlorides gives the stable crystal phosphonium ylides. A sodium borohydride reduction of ylides furnishes the target compounds, N-substituted benzylamino-3-ethyl-1,2,3,6-tetrahydropyridines. Five novel N-substituted benzylaminos-ethyl-1,2,3,6-tetrahydropyridines were synthesized, purified, and characterized. The evaluation of these compounds cytotoxicity studies on MCF-7 estrogen receptor positive breast cancer cells, MDA-MB-231 estrogen receptor negative breast cancer cell lines, and Ishikawa cells, using the Cell Titer-Glo (CTG) luminescent cell viability assay is underway. This research was supported by the National Center for Research Resources and the National Institute of Minority Health and Health Disparities of the National Institutes of Health through Grant Number 8 G12MD007582-28.

Targeting G-quadruplex nucleic acids: a series of β-carboline alkaloids with new skeletons from the seeds of Peganum harmala. Kaibo wang,1 Huiming Hua,2 Danzhou Yang1. Purdue University, West Lafayette, IN; She-nyang Pharmaceutical University, China.

G-quadruplexes are DNA secondary structures implicated in essential physiological and pathological processes, such as tumorigenesis. Small molecules that target G-quadruplex structures can be developed as potential therapeutic agents through the alteration of oncogene expression levels or the disruption of telomere maintenance. Targeting G-quadruplex nucleic acids, we screened 17 medicinal plants for binding activity to a model G-quadruplex (T-TGGGTT)4 system by 1H NMR experiment. We found that the crude extract of Peganum harmala L. seeds showed the most potential binding activity and specific cytotoxicity against the PC-3 cancer cell line with an IC50 value of 13.65 μg/mL. Subsequently, 1H NMR and bioassay co-guided isolation of the extract of P. harmala L. was performed and obtained 21 novel alkaloids, including 10 novel β-carboline alkaloids with unprecedented carbon skeletons, and 12 known analogues. Their structures including the absolute configurations were determined by extensive analysis of spectroscopic data, X-ray crystallography, ECD calculations, and ECD excitation chirality approaches. The antiproliferative activities and G-quadruplex binding activities were evaluated for these newly discovered and previously reported alkaloids. Some of the isolates showed pronounced cytotoxic effects with IC50 values below 10 μM and significant G-quadruplex binding activities. More interestingly, peganahmine D (4), which showed the strongest G-quadruplex interaction, exhibited significant cytotoxic activity against HL-60, PC-3 and SGC-7901 cell lines, with IC50 values of 3.81 ± 0.32, 11.52 ± 0.62, and 15.16 ± 0.42 μM, respectively. The G-quadruplex interactions positively correlated with antiproliferative activities suggesting these β-carboline alkaloids may exert their anti-cancer effects through G-quadruplex interactions. This work contributed a practical strategy at first time for the dis-
covery of novel G-quadruplex ligands from natural products and provided potential insights for using β-carboline alkaloids as anticancer lead compounds specifically targeting G-quadruplexes.

**#3254 Identification of potent anti-tumor agents from the LOPAC library using a unified 2D/3D cell culture screening approach.** Viananath Das, Tomáš Fürst, Soňa Gurská, Petr Drahák, Maríán Hadích, Institute of Molecular and Translational Medicine, Olomouc, Czech Republic.

Two-dimensional (2D) cultures of immortalized cancer cells have played a significant role cancer drug discovery and development process for decades. However, the limitations imposed by the long-term cultures of cancer cell lines are becoming increasingly apparent only recently. Therefore, there is a general shift towards three-dimensional (3D) cell cultures, which effectively mimic tumor complexities, for lead optimization and to accelerate translation research. 3D cell cultures not only model the in vivo architecture of tumors, but 3D-derived cells also retain numerous signatures of cancer stem cells compared to parental cells in 2D. In this study, using a unified 2D and 3D cell culture screening approach, we screened the LOPAC library from Sigma-Aldrich as a proof-of-concept study. The drug screening was performed using parental colorectal cancer HCT116 cells as a model cell line. 3D-derived cultures were generated from multicellular spheroids of HCT116 cells. Additionally, utilizing lightsheet fluorescence microscopy (LSFM), we studied the tissue penetration of drugs in spheroids of HCT116 and cells expressing hypoxia-inducible factor-1α (HIF-1α). We identified cc. 200 compounds from the LOPAC library that showed increased activity in 3D-derived cultures. A dose–response relationship study of top 20% compounds further confirmed the preferential activity of these drugs in 3D than 2D cultures. Next, studies in spheroid cultures resulted in the identification of five lead compounds with potent spheroid-size reducing effects. Three of these compounds were kinase inhibitors, one HIF-1α inhibitor, and one interestingly, a monoamine oxidase inhibitor. LSFM studies in HCT116-HIF-1α spheroids showed that two kinase inhibitors and the HIF-1α inhibitor significantly altered spheroid hypoxia, and presumably spheroid growth. We believe that this proof-of-concept study will further highlight the advantages of a combined 2D/3D screening approach for drug discovery and development, and consequently enable downstream testing at reduced cost.

**PREVENTION RESEARCH: Strategies and Biomarkers for Clinical Prevention**

**#3255 Circulating adipose stromal cells (CASCs) as a potential biomarker of response to weight loss interventions in obese women at high risk for breast cancer.** Hailey Baker, Amy L. Kreutznan, Jennifer L. Nydegger, Teresa L. Phillips, Richard C. Hasting, Dan A. Dixon, Bruce F. Kimler, Carol J. Fabian, Univ. of Kansas Medical Ctr., Kansas City, KS.

Background Obesity is a modifiable risk factor for breast cancer in the United States. White adipose tissue is increased in obese (BMI ≥ 30 kg/m²) women, releasing estrogens and pro-inflammatory cytokines. Adipose stromal cells play a key role in releasing estrogens, while circulating adipose stromal cells (CASCs), characterized as CD34+ CD31+ CD45+ live tumor sites and promote angiogenesis and vascularization. CASCs have been correlated with BMI in both cancer and non-cancer patients. However, BMI alone as a marker of adiposity has its limitations. We examined whether CASCs correlate with additional measures of adiposity in women who are at high risk for development of breast cancer. Methods Women at high risk for development of breast cancer but without prior breast cancer were recruited for random periareolar fine needle aspiration (RFNA), DEXA body composition, anthropomorphic assessment, and non-fasting venous blood collection. Mononuclear cells were isolated and the frequency of CD34+CD31+CD45+ cells was assessed by flow cytometry. Results CASC frequency ranged from 0 to 0.018% (median 0.001%) for 13 non-obese and 20 obese women. There was no association between CASC frequency and BMI (range 19 - 46 kg/m²), either as a linear correlation or when dichotomized at a BMI of 30 kg/m². However, there were tendencies for greater CASC frequencies in pre-menopausal women, women with greater waist circumference (p<0.050), and women with visceral fat mass greater than 50%. With limited numbers, there was no apparent association of CASC frequency with cytology or proliferation (Ki-67) of benign breast epithelial cells acquired by RFNA. Conclusions This is the first study to investigate CASC frequency in a cohort of women at high-risk for development of breast cancer. Our results to date do not show an association between CASC frequency and obesity (BMI). However, associations with other indices of visceral fat suggest that evaluation of circulating adipose stromal cells could have value as a biomarker of response in clinical trials of obese breast cancer survivors and high risk women undergoing weight loss (especially fat mass) interventions.

**#3256 Risk of second primary cancers in women diagnosed with endometrial cancer in German and Swedish cancer registries.** Tianhui Chen. Zhejiang Academy of Medical Sciences (ZJAMS), Hangzhou, China.

Background: Along with the increasing incidence and favorable prognosis, more women diagnosed with endometrial cancer may develop secondary primary cancers (SPCs). Nevertheless, most of previous studies have limitations such as years since surgery, limited sample sizes or selection bias of SPC cases. Therefore, to our knowledge, investigations on the risk of a specific SPC after endometrial cancer in two different populations have not been reported. We aimed at investigating risk of second primary cancers (SPCs) in women diagnosed with endometrial cancer in Germany and Sweden to provide insight into etiology and prevention strategies for SPCs. Methods: Endometrial cancer patients diagnosed at age ≥15 years in Germany during 1997-2011 and in Sweden nationwide during 1997-2012 were selected. For both German and Swedish datasets, standardized incidence ratios (SIRs), calculated as the ratio of observed to expected numbers of cases, were used to assess the risk of a specific SPC in women diagnosed with endometrial cancer. The expected number of a SPC after endometrial cancer was calculated from the strata-specific first same cancer incidence rates in the Swedish and German general population, respectively, multiplied by the corresponding person-years in women with endometrial cancer. Person-years at risk were accumulated for each patient, starting at the date of diagnosis of the first endometrial cancer, and terminating on the diagnosis date of a SPC, date of death, date of emigration, or end of follow-up (end of 2011 for Germany and of 2012 for Sweden), whichever came first. Results: Among 46,929 endometrial cancer survivors in Germany and 18,646 in Sweden, overall 2,897 and 1,706 SPCs were recorded, respectively. Significantly elevated SIRs were observed in Germany for ovarian (SIR=1.3; 95%CI:1.1-1.5) and kidney cancers [1.6 (1.3-1.8)], while in Sweden the SIRs were 5.4 (4.6-6.3) and 1.4 (1.0-1.9), respectively. Elevated risk for second ovarian endometrioid carcinoma was pronounced after early (<55 years) onset endometrial cancer in Germany [9.0 (4.8-15)] and Sweden [7.7 (5.1-11)]. In Germany elevated risks were found for second ovarian endometrioid carcinoma after endometrial histology of first endometrial cancer [6.3 (4.0-9.4)] and for second kidney cancer after clear cell histology of endometrial cancer [4.9 (1.6-11)]. Conclusions: We found exceptionally elevated risk of second ovarian endometrioid carcinoma after endometrial cancer of the same histology or of early onset. Kidney cancer was also increased, particularly after endometrial cancer of clear cell histology. Cancer prevention strategies should focus on these cancers after endometrial cancer diagnosis.

**#3257 Molecular characterization of the human stomach microbiota in gastric cancer patients.** Guoqing Yu,1 Javier Torres,2 Nan Hu,2 Rafael Medrano-Guzman,2 Roberto Herrera-Goepeert,2 Michael S. Humphrys,3 Lemin Wang,1 Chaoyu Wang,1 Ti Ding,1 Jacques Ravel,5 Philip R. Taylor,1 Christian Abnet,1 Alisa Goldstein1.

1National Cancer Institute, Rockville, MD; 2Instituto Mexicano del Seguro Social, Mexico; 3Unidad Medica de Alta Especialidad Oncologia, Mexico; 4Instituto Nacional de Cancerologia, Mexico; 5University of Maryland School of Medicine, Baltimore, MD; 6Shanxi Cancer Hospital, China.

Background Helicobacter pylori (Hp) is the primary cause of gastric cancer but we know little of its relative abundance and other microbes in the stomach, especially at the time of gastric cancer diagnosis. Here we characterized the taxonomic and derived functional profiles of gastric microbiota in 157 non-malignant gastric tissue samples from two different sets of gastric cancer patients, and compared them with microbial profiles of oral, stool, nasal, vagina and skin samples from Human Microbiome Project. Results We show that Hp is the most abundant member of gastric microbiota in both Chinese and Mexican samples (51% and 24% respectively), followed by the genera commonly seen in the oral microbiota. Taxonomic (phyllum) profiles of stomach microbiota largely resembled oral microbiota when the Helicobacter reads were removed. The functional profiles of stomach microbiota, however, were distinct from those found in other body sites and had higher inter-subject dissimilarity. Gastric microbiota composition did not differ by Hp colonization status or stomach anatomic site, but did differ between paired non-malignant and tumor tissues in either Chinese or Mexican samples. Conclusions Our study is the first to show that Hp is the dominant member of the gastric microbiota in many gastric cancer patients rather than diminished or depleted as traditionally believed. Our results provide insights on the gastric microbiota composition and function in gastric cancer patients, which may have important clinical implications.
NOTCH1, and FAT1 may be among the earliest driver events in lung SqCC. Thesomatic alterations observed in known cancer genes such as TP53, KMT2C, NAV3, NFE2L2, CDKN2A, PIK3CA, KEAP1 and RB1) involved in cell- 

standing of molecular pathogenesis. We performed the whole-exome and transcriptome sequencing from 101 tumors and matched normal samples from Ko-

ran patients. Somatic mutations and gene expression defined two intrinsic subtypes: (1) classical subtype; (2) immunogenic subtype. Classical subtype displayed upregulation of cell cycle related genes and enriched for gene mutations (TP53, NAV3, NFE2L2, CDKN2A, PIK3CA, KEAP1 and RB1) involved in cell proliferation, squamous differentiation and oxidative stress. Immunogenic subtype had more tumor-infiltrating immune cells than classical type. More proportion of adaptive immune cells was also detected in immunogenic subtype. Immune genes, involved in adaptive immune response, were also upregulated in immunogenic subtype. Taken together, our finding revealed that each subtype has different immune mechanisms in lung squamous cell carcinoma and provides potential opportunities for therapeutic development.

The genomic landscape of premalignant lung squamous cell carci-

noma lesions. Joshua Campbell, Xijun Zhang, Samjoet S. Dhillon, Catalina Perdomo, Sarah Mazzilli, Yaron Geshalter, Gang Liu, Sherry Zhang, Han-qiao Lin, Jessica Vick, Christopher Mory, Stefano Monti, Evan Johnson, Matthew Meyerson, Steven Dubinett, Matthew Wilkerson, Clifton Dalgaard, Marc Lemburg, Mary Reid, Jennifer Beanes, Avrum Spira, Boston University School of Medicine, Boston, MA; Uniformed Services University, Bethesda, MD; Roswell Park Cancer Institute, Buffalo, NY; Janssen Pharmaceuticals, Spring House, PA; Dana Farber Cancer Institute, Boston, MA; University of California, Los Angeles School of Medicine, Los Angeles, CA.

Background: Lung squamous cell carcinoma (SqCC) arises in the epithelial layer of the bronchial airway and is often preceded by the development of pre-
malignant lesions. However, not all premalignant lesions progress to lung SqCC and many regress without therapeutic intervention. Understanding the somatic alterations that contribute to progression of premalignant lesions in the airway will allow us to identify biomarkers for early detection and develop therapeutic strategies for early intervention. Methods: Airway biopsies were obtained from high-risk smokers undergoing lung cancer screening by auto-fluorescence bronchoscopy and chest CT at the Roswell Park Cancer Institute. For each subject (n=30), multiple premalignant lesions were sampled repeatedly over time (n=144 samples). One biopsy from each region was sent for pathological review while another biopsy was taken for molecular studies. DNA was also isolated from the blood or cytologically normal bronchial brushings to serve as a matched normal control. Exome capture was performed using the Illumina TruSeq Rapid Exome kit and sequenced to a mean depth of coverage of 120x at Uniform Services University and Walter Reed National Military Medical Cen-
ter. Results: The median number of somatic mutations across all premalignant lesions was 0.73 per megabase (range: 0.10 - 9.8 per Mb) and displayed a modest association with histological grade (p=0.07). The most frequently mutated lung cancer genes involved in cell cycle (RB1), radiation sensitivity (CDKN2A (12%), NOTCH1 (12%), NOTCH2 (12%), PIK3CA (5%), and CDKN2A (<1%)). Known oncogenic hotspot mutations were observed in PIK3CA (1%) and KRAS (<1%). The majority of lesions did not have overlapping sets of mutations with other samples from the same patient, indicating that most of these lesions arose from clonally distinct populations. The two lesions with the relatively high mutation rates (>7/Mb) were taken from adjacent sites over two time points in the same individual with a prior history of lung squa-

mous cell carcinoma. These lesions had a significantly overlapping set of muta-
tions including FAT1 indicating a common evolutionary ancestor. Conclusions: The somatic alterations observed in known cancer genes such as TP53, KMT2C, NOTCH1, and FAT1 may be among the earliest driver events in lung SqCC development and may be useful as biomarkers for early detection as well as targets for lung cancer intervention.

BACKGROUND: Low- and middle-income countries (LMICs) face both training and infrastructural challenges for surgical care, particularly for cancer. Practitioners charged with caring for these patients have few options for basic or advanced training. OBJECTIVES: To describe the training options for cancer surgery in Sub Saharan Africa METHODS: The different methods of training are described and the advantages and limits of each methods is highlighted. RE-

SULTS: Training during residency and onsite fellowship are a good option but requires an appropriate number and capacity of training programme. Interna-
tional fellowships have the limitation of readjustment back home for the trained fellow. Onsite International training missions like IVUmed’s missions have the advantage of “Teach One, Reach Many” outcome where a whole team in trained in accordance of local needs and the participation of all stakeholders. CONCLU-

SIONS: Long-term program commitments; effective communication; and a strong commitment from both the surgical site and the external organization, and supporting organizations facilitate the development of thriving surgical teaching programs capable of serving local communities and conduct-
ing outreach training.
ual scans over a lifetime starting at age 15 are associated with cumulative colon doses of 1.8 Gy at age 30, 3.8 Gy at age 50. The associated LARs of cancer incidence would be 1–2% at age 50, and 11–32% at age 80. Delaying age at screening start to 21 years would reduce the projected risks to <1% at age 50 and <15% at age 80. A frequency of one scan every two years (as used for surveillance of cystic pancreatic lesions) would be associated with LARs of <1% at age 50 and <10% at age 80. The current use of a new CT protocol (dual energy virtual non-contrast CT) at the department would reduce radiation exposures and potential subsequent risks by more than 50%. Conclusion: Annual CT screening and surveillance for pancreatic and renal tumors in VHL patients can be associated with high radiation exposures. When Magnetic Resonance Imaging is not applicable, the new CT protocol may allow daily physicians to delay age at surveillance start or reducing the frequency of CT scans could significantly reduce the potential radiation-related risks, provided that these strategies remain beneficial for patients. Optimized CT protocols can also dramatically reduce radiation exposures. The present study is currently extended to confirm our dose estimates based on CT protocols against individual radiology data, and consider other genetic syndromes. Ultimately, this study should help define surveillance strategies with optimal risk-benefit balance.

#3263 Is Latin America ready for the use of genomics in cancer care and control.
Sandra Perdomo,1 Angela Torres,1 Javier Oliverí,2 Cecilia Frecha,2 Rosalía Quezada-Urban,3 Clara Estela Díez-Velasquez,8 Felipe Vaca.1 El Bosque University, Bogota, Colombia; 2Hospital Italiano de Buenos Aires, Buenos Aires, Argentina; 3ICBME Instituto Universitario Hospital Italiano de Buenos Aires, Buenos Aires, Argentina; 4Universidad Nacional Autónoma de Mexico, Mexico, DF, Mexico.

In Latin America (LA) countries cancer is the second most frequent cause of death after cardiovascular disease. Disease patterns have changed from infectious to chronic, the population is increasing and becoming elderly, and countries lack planning to respond adequately to this epidemiological and socio-demographic transition. By 2025 and increment of nearly 30% of new cases and 35% of deaths from cancer are predicted. Genomic studies have profoundly changed cancer management from improved cancer diagnosis to reformatting cancer prognosis and treatment. However, all these key advances have been mainly concentrated in highly developed nations and little is known about the capacities and needs of cancer genomics in the LA context. In order to evaluate the capacity and development of cancer genomics in LA, we collected available information for all countries in Central, South America and Cuba. Data reviewed included: number of NGS platforms, number of cancer research institutions, research groups working in cancer genetics, publications on cancer genetics and genomics in the last 10 years, educational programs on genomics and related national cancer control policies. Currently, there are a total of 212 NGS platforms in LA. Mexico and Brazil are the countries with more users, and Peru and Ecuador have the fewest. 118 research groups in South America and 12 in NCCPs reviewed consider secondary prevention strategies for early diagnosis, opportunistic treatment and decrease of mortality, areas where genomic analysis could be implemented. Only 5 NCCPs include cancer research as an action plan to increase cancer prevention strategies and reduce both incidence and mortality. Despite the recent advances in introducing cancer genomics knowledge and application in LA, the region lacks development of integrated genomic research projects, improved use of platforms, associated educational programs and health policies that might focus on the most frequent cancers and could impact cancer care.

#3264 Evaluating heart-hate variability, salivary cortisol and physical activity as predictors of cancer-related fatigue recovery in breast-cancer survivors over a 12 week period by use of a smartphone application.
Ammia Julia Seiler,1 Annke Anna van den Oever,2 Kees van der Krogt,3 Willem J. Murdock,4 Diana A. Chirinos,1 Luz M. Gacarini,1 Christopher P. Fagundes 1.1 Department of Psychology, Rice University, Houston, TX, 2Wearable Computing Laboratory, Department of Information Technology and Electrical Engineering, ETH Zurich, Zurich, Switzerland; 3Department of Psychology, Rice University; Department of Behavioral Science, The University of Texas MD Anderson Cancer Center, Houston, TX.

Introduction Cancer-related fatigue (CRF) is one of the most prevalent and debilitating problems in breast cancer survivors (BCS) that can persist many years beyond successful cancer treatment. Parasympathetic nervous system activity (measured via heart-rate variability; HRV), cortisol dysregulation and decreased physical activity are plausible, but understudied contributors to CRF.

Repeated daily measurements of CRF and tracking daily physical activity over a 12-week period should give more information regarding temporal patterns of CRF among BCS. Objective The purpose of this study is 1) to investigate patterns of CRF in fatigued BCS over time; 2) to assess HRV, salivary cortisol and level of physical activity as predictors of cancer-related fatigue (CRF) in BCS over a 12-week period. Methods: The sample consisted of 40 women who completed an intervention results in increased daily physical activity, as well as improved HRV, salivary cortisol and CRF in BCS relative to healthy female controls over a 12 week period. Methods A total of 30 fatigued breast cancer survivors (FACT-F score ≤ 34) and 30 aged-matched female controls will be randomly assigned to either an intervention or control group. Both groups will receive a smartphone application with feedback regarding their daily physical activity. The control group will receive the application without feedback. Behavioral data will be collected by means of GPS and Wi-Fi for localization, and accelerometer, barometer, magnetometer and gyroscope for activity recognition. HRV and salivary cortisol will be collected at rest, as well as during and after a significant stressor (Trier Social Stress Test). Fatigue will be measured by the FACT-F Scale, which will be completed at baseline (T1), 4 weeks (T2) and 12 weeks (T3). Group differences will be tested by one-way analysis of variance (ANOVA) and intervention effects will be analyzed using mixed models with repeated measures. Hypotheses We hypothesize that HRV, cortisol dysregulation and level of physical activity at baseline can predict CRF-recovery over a 12-week period. The intervention group will be associated with increases in physical activity in the BCS intervention group and that changes of physiological correlates of CRF can be observed (i.e., HRV and salivary cortisol). Conclusion This study will examine associations between HRV, salivary cortisol, physical activity and CRF in BCS over time. The results of this study may provide insight into factors that contribute to the development, persistence and/or consequences of CRF by use of an innovative mobile application.

#3265 Characterization of epithelial oral dysplasia in non-smokers: work towards precision medicine. Leigha D. Rock1, Miriam P. Rosin,2 Lewis Zhang3, Babak Shariatit, Denise M. Laronde3, 1Univ. of British Columbia, Vancouver, British Columbia, Canada, 2Simon Fraser University, Burnaby, British Columbia, Canada.

Objectives: Although tobacco usage is still one of the strongest risk factors associated with oral cancer risk, there is a subset of non-smokers who develop oral cancer. Tobacco cessation efforts have resulted in a drop in oral cancer rates associated with this habit, leading to a growing interest in the increased proportion of cases occurring among non-smokers (NS). Lesions with oral epithelial dysplasia (OED) are at risk of progressing to oral cancer. Not only is the natural history of OED in NS poorly understood, but the path to interception of disease in NS is poorly defined. There is a gap in the knowledge surrounding the clinical, pathological and genetic characterization, and the risk of progression in this growing category. This information is critical to the evolution of precision medicine in this subgroup. The aim of this study was to: 1) Describe the molecular and clinicopathological features of OED in NS as compared to smokers in longitudinal follow-up; and 2) To compare progression rates and time to progression in NS and smokers with OED. Methods: The study focused on cases with histologically confirmed mild or moderate OED in follow-up in the Oral Cancer Prediction Longitudinal Study. Clinicopathological data, including lesion site, size, texture, colour, consistency, border characteristics, fluorescence visualization (FV), and toluidine blue (TB) retention, were collected in addition to detailed smoking history. A genomic based marker test (gMART) which uses loss of heterozygosity (LOH) at key chromosomal loci to stratify lesions to progression risk, was performed on baseline biopsies. Progression was considered to be advancement to severe dysplasia, carcinoma in situ, or squamous cell carcinoma. Results: Out of 231 OED, 30% were NS related, based on self-reported smoking status. Although there were more smokers with OED than NS, a significantly higher proportion of the OED underwent malignant transformation in NS (P = 0.048). Although not significant, time to outcome was also faster in this group. Most clinicopathological and genetic predictors were equal in both NS and smokers especially at the floor of mouth site. Even among smokers (ES) were more likely to have OED at the floor of mouth while OED was more likely to occur at the tongue or gingiva (P < 0.001) in NS. LOH risk patterns were strongly associated with progression (moderate risk OR 4.84; high risk OR 28.1; P = 0.001) and equally sensitive in both NS and ES subgroups. Conclusions: These findings support the premise that progressive lesions in NS and ES have similar clinicopathological and genetic signatures, and emphasize the need for clinicians to consider the molecular genomic profiles in the triage of OED. LOH markers can sort high-risk lesions, despite risk habits, and should be an important consideration in the treatment of OED. This marker is of particular use in the targeting of candidates for chemoprevention.
#3266 Oral rinse point of care test to predict head and neck cancer. Michael J. Donovan,1 Kris Curtis,2 Greg Ginn,3 Elizabeth J. Franzmann4. 1Mt. Sinai School of Medicine, New York, NY; 2Vigilant Biosciences, Ft. Lauderdale, FL; 3Sancho and Associated, Cicero, IN; 4University of Miami, Miami, FL.

Background: Head and neck squamous cell carcinoma (HNSCC) is the 6th most common cause of cancer mortality throughout the world with an estimated 50,000 people in the US and 600,000 worldwide each year. The ability to detect the disease in a potentially malignant phase and earlier stage could have significant impact on overall outcome. Previous studies have demonstrated that a combined salivary CD44, a tumor-initiating marker, and total protein assay was able to aid in the diagnosis of HNSCC. We sought to understand the performance characteristics of these biomarkers in a prospective population using a qualitative, point-of-care assay (POC) which consists of a cassette with a colorimetric read-out based on a pre-determined threshold for both CD44 and total protein. We also performed results from same samples with a quantitative lab-based test.

Methods: Saline oral rinse specimens (~5ml) from 134 patients (84 HNSCC cases; 50 controls) were obtained from biorepositories. Samples were thawed, gently swirled, placed in a standard collection cup. 600ul were removed for lab assay prior to POC test. The tapered end of the POC cassette was submerged in rinse for 20'; levels of CD44 and total protein (TP) were evaluated by two operators. POC test results were compared between operators and with lab test results using Cohen's kappa coefficient and McNemar’s test, sensitivity(Se), specificity(Sp), NPV and PPV. Results: 95% HNSCC patients (cases) were mean 60 years, 60% male, 97% white and 74% smokers vs. 43 years, 28%, 96% and 0% respectively, for controls. POC was positive with either CD44 or TP above threshold. Weighted kappa yielded 75% and 72% for CD44 and TP respectively between operators. With a prevalence of 9.27: POC: NPV 94%, PPV 10%; variable TP cut-off produced Se71-84% and Sp50-50%. McNemar and Kappa for both lab CD44 and TP vs POC indicated moderate agreement; independently both POC and lab produced NPV >90%. Conclusions: Concordance of the POC assay between operators and moderate agreement with a quantitative lab assay provides supportive evidence for clinical application of the POC assay as an aid in the diagnosis for HNSCC. Additional studies are underway to confirm these observations.

#3267 Combined effect of multiple gene polymorphisms on cancer risk stratification. Radhika Gade Andavolu,1 Olivia Rodriguez,1 Anastasia Al Rubaie,

1School of Medicine, New York, NY; 2Eisenhower Medical Center, Rancho Mirage, CA.

Cyclin D1 (CCND1) G870A polymorphism has been known to be a risk factor in multiple cancers. Cyclin D1 is a cell cycle regulator frequently mutated, amplified and overexpressed in a variety of tumors. Activation and over expression of CCND1 have been found in variety of tumors and alterations in CCND1 are thought to be involved in carcinogenesis. CCND1 polymorphism A870G interferes with splicing and studies showed DNA damage in cells from subjects with ‘A’ allele to bypass G1/S check point of the cell cycle control mechanism more easily than damage in cells with G allele (wild type). A single base pair polymorphism (exon 4, G870A) in the CCND1 gene affects gene splicing. This identification and validation of contributing genetic factors such as single-nucleotide polymorphisms (SNPs) represents a critical step in the advance toward personalized medicine. Several gene expression correlation studies have been done but to our knowledge studies have not been reported on SNP’s of ERBB2 gene, ESR gene and CCND1 combined effect correlating with high risk. In this study, we examined the relationship between ERBB2 (codon 655), Estrogen receptor (ER Intron 1 T–C) and cyclin D1 (Exon 4) polymorphic additive effect in cancers more specific to breast cancer. Genomic DNA was extracted from whole blood samples collected on study. The SNPs were tested by the PCR-fragment length polymorphism (PCR-RFLP) method. Our results show individuals carrying CCND1 ‘A’ allele in combination with variant ERBB2/ESR1 uncut alleles are significantly high (P<0.004) in cancer patients (N=232) as compared to controls. (N=222). Similarly individuals carrying CCND1 Variant ‘A’ allele in combination with ESR ‘C’ Allele showed high frequency with p<0.009. Both these combinations showed a strong and significant association with cancer but individually, ERBB2 variant did not show any significant association, ESR gene showed a borderline association and CCND1 showed strong association independent of these two gene polymorphisms. Earlier few studies have shown no association of ERBB2 mutation in agreement with the previous reports. In conclusion our data suggests that in complex diseases a single gene may not contribute to show its effect but in combination may show a profound effect in evaluating the risk.

Table 1. Multivariable-adjusted associations between BMI and circulating 25-OH DL evels among cancer survivors in the NHANES 2001-2010 (n=1306) stratified by CRP levels.

*Adjusted for age, gender, race, body mass index, and smoking status
Esophageal cancer (EC) has been well documented with predominant occurrence in male and with major histopathological type of esophageal squamous cell carcinoma (ESCC) in China. However, the influence by gender on ESCC survival is largely unknown in China. The present study was thus undertaken to elucidate the impact by gender on survival of Chinese patients with ESCC. A total of 1,117 cases was enrolled in this study, including 1,117 males with a mean age of 60.2±8.6 and 6842 females with a mean age of 61.0±8.4. All the patients were from ESCC database in Henan Key Laboratory for Esophageal Cancer Research of the First Affiliated Hospital, Zhengzhou University (1975 to 2015). Only the patients with T2–4N0–1M0–1 were enrolled in this study. Based on the diagnosed date, the patients were classified into two groups, group I (1996–2005, 6885;38.3%); and group II (2006–2015, 11084;61.7%). The follow-up was undertaken until October, 2016. Kaplan–Meier models were for describing the survival curves and Cox proportional hazards models were undertaken to observe the risk of death of male and female. The results demonstrated that the male patients had a poor survival than female (X²=58.17, P<0.001). Furthermore, similar results were observed for the two different periods of 1996–2005 (X²=21.08, P<0.001) and 2006–2015 (X²=34.67, P<0.001). The present results indicate that gender is an independent survival factor for ESCC and the female patients with ESCC have a dramatic prolonged survival than male patients in China. [Supported by Doctoral Team Foundation of the First Affiliated Hospital of Zhengzhou University (2016-BSTDJD-03), National Science Foundation of Henan Province (20161110) and Corresponding author: Li Dong Wang, email:ldwang2007@126.com]

#3270 Association of low-carbohydrate diet and macronutrient intake with colorectal cancer survival. Mingyang Song,1 Kana Wu,2 Jeffrey Meyerhardt,3 Omer Yilmaz,4 Shujie Ogino,5 Charles Fuchs,2 Edward Giovannucci,2 Andrew T. Chan,1 Massachusetts General Hospital, Boston, MA;4 Massachusetts Institute of Technology, Cambridge, MA; 3Dana-Farber Cancer Institute, Boston, MA; Massachusetts Institute of Technology, Cambridge, MA;3 Dana-Farber/Harvard Cancer Center, Boston, MA.

Background: Metabolic reprogramming is a hallmark of cancer characterized by the switch from oxidative phosphorylation to aerobic glycolysis. Accumulating evidence suggests that reducing dietary carbohydrate intake may ameliorate metabolic reprogramming and suppress proliferation of tumor cells. However, the clinical benefit of carbohydrate restriction remains unknown. Objective: To examine the low-carbohydrate diet and macronutrient intake after colorectal cancer diagnosis in relation to mortality among stage I-III patients. Methods: We evaluated data on 1,303 colorectal cancer patients in the Nurses’ Health Study (1980-2012) and Health Professionals Follow-up Study (1986-2012) who completed a validated food frequency questionnaire at least one year after diagnosis. An overall low-carbohydrate diet score was created based on the percentage of energy as carbohydrate, fat, and protein (a higher score reflects a higher intake of fat and protein and a lower intake of carbohydrate). We also created an animal- and vegetable-based low-carbohydrate diet score on the basis of the intake from animal and vegetable food sources, respectively. We prospectively assessed the association of the low-carbohydrate diet score and macronutrient intake with CRC-specific and overall mortality using Cox proportional hazards regression. Multivariable hazard ratios (HRs) and 95% confidence intervals (CIs) were estimated after adjusting for a variety of potential confounding factors, including age, sex, cancer stage, grade of differentiation, subsite, alcohol use, smoking status, physical activity, body mass index, regular use of aspirin, total calorie, and intake of folate, calcium, fiber, processed red meat, and vitamin D. Results: We observed 584 deaths, of which 132 were classified as colorectal cancer-specific deaths over a median of 10 years of follow-up. No association was found for overall and animal-based low-carbohydrate-diet score with colorectal cancer-specific mortality, with the HR comparing the highest to the lowest quartiles of 0.92 (95% CI, 0.77-1.09, P for trend=0.33) for the overall score and 0.99 (95% CI, 0.84-1.17, P for trend=0.94) for the animal-based score. In contrast, vegetable-based low-carbohydrate-diet score was associated with lower colorectal cancer-specific mortality (HR, 0.67; 95% CI, 0.53-0.85, P for trend<0.001). Replacement of carbohydrate with fat, particularly vegetable fat, was associated with lower mortality of colorectal cancer (HR per 10%-energy substitution, 0.49, 95% CI, 0.29-0.85, P for trend=0.01). Similar results were found for all-cause mortality. Conclusion: Among patients with colorectal cancer, replacing carbohydrates with vegetable fat may reduce the risk of all-cause and colorectal cancer-specific mortality.

#3271 Evaluation of bone health in breast cancer survivors compared to cancer-free women: A prospective study within a young familial risk cohort. Cody A. Ramin,1 Betty J. May,1 Richard B. Roden,2 Dana Petry,3 Deborah K. Armstrong,2 Kala Visvanathan,1 1Johns Hopkins Bloomberg School of Public Health, Baltimore, MD;2Johns Hopkins Kimmel Cancer Center, Baltimore, MD;3Johns Hopkins School of Medicine, Baltimore, MD.

Background: Bone loss has been consistently reported among long-term older breast cancer (BC) survivors. However, it remains unclear how early and to what degree BC survivors experience bone loss compared to their cancer-free peers and to what extent this can be attributed to age and premature menopause. Methods: We studied 796 women (210 BC survivors, 586 cancer-free) with familial risk of breast and/or ovarian cancer (OVCAR) who were recruited through the Breast and Ovarian Cancer Surveillance (BOSS) cohort at Johns Hopkins Hospital. Survivors were diagnosed with stage I-III BC <5 years prior to baseline (mean time from diagnosis to enrollment=1.4 years; mean age at diagnosis=47 years). Osteopenia and osteoporosis were ascertained based on self-reported physician diagnosis in baseline and follow-up questionnaires. Prevalent cases of osteopenia or osteoporosis were excluded. Multivariable (MV)-adjusted Cox proportional hazards models were used to estimate hazard ratios (HRs) and 95% confidence intervals (CIs) of osteopenia and osteoporosis incidence among BC survivors compared to cancer-free women. MV models were adjusted for age, race, menopause status, body mass index, physical activity, smoking, hormone replacement therapy and early oophorectomy. Results: BC survivors were slightly older (mean age 48 vs. 45 years), more likely to be post-menopausal (51% vs. 29%) and had lower current vitamin D use (21% vs. 8%) compared to cancer-free women. During a mean follow-up time of 6.2 years, 77% of BC survivors and 60% of cancer-free women reported having ≥1 bone density exam and 115 incident osteopenia and/or osteoporosis were identified (75% osteopenia only). In MV-adjusted models, BC survivors had 66% higher risk of being diagnosed with osteopenia and/or osteoporosis compared to cancer-free women (HR=1.66, 95% CI=1.11-2.47). BC survivors with current vitamin D use had 78% and 10% osteopenia and/or osteoporosis risk compared to cancer-free women, respectively (MV HR=1.17, 95% CI=1.14-2.72; MV HR=1.93, 95% CI=1.15-3.24). BC survivors ever treated with chemotherapy or hormone therapy had higher osteopenia and/or osteoporosis risk compared to cancer-free women (MV HR=2.00, 95% CI=1.14-3.50; MV HR=1.79, 95% CI=1.14-2.82, respectively). Analyses restricted to women with no change in menopause status during follow-up were only slightly attenuated (MV HR=1.58, 95% CI=0.96-2.59). Conclusion: Our results demonstrate that bone loss is significantly greater than and occurs early in young BC survivors compared to cancer-free women even after taking into consideration increasing age and premature menopause. Our findings also provide support for a baseline evaluation of bone density at diagnosis with subsequent monitoring in young BC survivors with familial risk. Further analyses are ongoing to evaluate the effect of specific BC treatments on bone health in this cohort.

#3272 Differences in prostate tumor characteristics and survival among religious groups in southern Thailand. Christian Alvarez,1 Laura Rozek,1 Hutcha Sripung,2 Alison M. Mondul,1 1Univ. of Michigan School of Public Health, Ann Arbor, MI;2 Prince of Songkla University, Hat Yai, Thailand.

Background: The incidence and mortality rates of prostate cancer are expected to increase in the next two decades in southern Thailand. In addition, survival rates are lower compared to more developed countries such as the US. Differences in the incidence of prostate and other cancers have been observed among the two most predominant religious groups in Thailand, Buddhists and Muslims, possibly due to different dietary and cultural practices between them. However, to our knowledge, no studies have examined differences in cancer survival in these two populations. Thus, we examined differences in tumor characteristics at diagnosis and survival in Buddhist and Muslim men with prostate cancer in southern Thailand. Methods: Songkhla, Thailand is a southern province located on the eastern side of the Malaysian Peninsula with a relatively large Muslim population (25%). 855 incident prostate cancer cases from the population-based Songkhla cancer registry were included in this study. Data collected by the registry include age at diagnosis, tumor stage and grade, and vital status. Complete data were available from 1990-2013. Age at diagnosis and tumor characteristics were compared across religious groups using the Wilcoxon test for age and the X² test for categorical variables. Median survival time and 5- year survival rates were calculated using the Kaplan Meier method, and differences by religious group were evaluated using the log-rank test. Cox proportional hazards models were used to estimate the hazard ratio (HR) and 95% confidence interval (CI) for mortality after adjustment for age at diagnosis, stage, and grade. Results: Of the 855 prostate cancer cases, 88.6% were Buddhist and the rest were Muslims. Age, stage, and grade at diagnosis were all similar across religious groups (p=0.72, 0.33, and 0.46 respectively). The median survival time after diagnosis of prostate cancer was significantly longer (p=0.05) in Buddhists 3.7 years (95% CI: 3.2, 4.2) compared to Muslims 2.8 years (95% CI: 1.7, 4.0). The probability of surviving after five years was 39.6% (95% CI: 35.7%, 43.4%) and 31.8% (95% CI: 21.1%, 42.9%) in Buddhists and Muslims, respectively. After adjustment for age at diagnosis, Muslim men were more likely to die after diagnosis with prostate cancer than Buddhist men (HR 1.37, 95% CI: 1.04, 1.79). This finding was unchanged after further adjustment for stage and grade at diagnosis (HR 1.31, 95% CI: 1.00, 1.72). Conclusion: Muslims in Songkhla, Thailand had a higher risk of death after diagnosis of prostate cancer.
cancer vs. Buddhists. This association could not be explained by differences in tumor characteristics at diagnosis. Understanding what risk factors may underlie the poorer survival observed among Muslims may inform targeted interventions for prostate cancer among the Muslim population in southern Thailand. Next steps include examining this association in additional geographic areas across Thailand.

### #3273 Analysis of causes of death in patients with esophageal squamous cell carcinoma in China

Xiang Yang Zhang1, Jian Po Wang2, Rui Ping Xu3, Ya Qin Hou4, Xiu Chen5, Ai Li Li6, Xi Chen7, Shuang Yin Han4, Wei Jing Zhao4, Li Sun1,Min Wang1,Wen Ting Fu1, Li Dong Wang1.

1The First Affiliated Hospital of Zhengzhou University, Zhengzhou, China; Anyang Tumor Hospital, Anyang, China; 2Huaxi University People's Hospital of Henan Province, Henan, China; 3Tumor Hospital of Linzhou, Linzhou, China; 4Puyang City Oil Field General Hospital, Puyang, China; 5Henan Provincial People's Hospital, Zhengzhou, China; 6The First Affiliated Hospital of Xinxing Medical University, Xinxing, China.

In China, more than 80% of the esophageal cancer occurs in farmer village, and most of the esophageal cancer patients die at village home. Therefore, the cause of death for esophageal cancer patients has not been well characterized. The present study was thus undertaken to determine the causes of death in patients with esophageal squamous cell carcinoma (ESCC) to provide more information for further prevention and accurate treatment after ESCC diagnosed. All the 8,838 ESCC patients with a detailed cause of death in this study were derived from the ESCC database (1973-2015) in Henan Key Laboratory for Esophageal Cancer Research of the First Affiliated Hospital, Zhengzhou University, China. All the patients were categorized by age (<50 years and ≥50 years), gender (male and female) and pathological stage (early, middle and later stage). Chi-Square test was used to analyze the differences in different groups. The results demonstrated that, of the 8,838 died ESCC patients, there were 5,713 males (64.6%) with a mean age of 60.95±9.43 and 3,125 females (35.4%) with a mean age of 61.95±9.47. Notably, 69.5% of the patients died within five years after diagnosis, and the 1-, 3- and 5-year death after diagnosis for these died ESCC patients were 1622 (18.4%), 2960 (33.5%) and 1557 (17.6%), respectively. Overall, the major cause of death for ESCC was due to ESCC recurrence and metastasis (8500, 96.1%), and followed by cardiovascular disease (121, 1.4%), different infections (68, 0.8%), second cancer (52, 0.6%), accident (25, 0.3%), suicide (22, 0.2%), and uncertain cause (50, 0.6%). Furthermore, the major cause of death in males and females was similar (p>0.05) and the cause of death by ESCC recurrence and metastasis, cardiovascular disease, different infections, second cancer, accident, suicide and uncertain cause was 96% (5485), 1.5% (84), 0.8% (44), 0.6% (34), 0.3% (18), 0.2% (16), 0.6% (32), respectively in males and 96.5% (2031), 1.1% (37), 0.8% (24) 0.6% (18), 0.2% (7), 0.2% (6) and 0.6% (18), respectively in females. The present results demonstrate that recurrence and metastasis are the major cause of death both in male and female for ESCC (96%). It is noteworthy that there are 0.2 percent of the ESCC patients have suicide which call for more attention of psychotherapy on cancer patients. [Supported by the Science and Technology Major Projects of Henan Province of China (161100311300), and Correspondence to: Li Dong Wang, the National Key Research and Development Program of China and Correspondence to: Li Dong Wang, Email: ldwang2007@126.com]

### #3274 The impact of pregnancy on breast cancer survival: A retrospective analysis based on national data

Shu-Chun Chuang1, Ching-Hung Lin2, Yen-Shen Lu3, A. Holocaust4, M. Li5, A. Grudzinskas9, M. Kneitel6, Y. Lu7,9, A. C. Lee8,9, J. G. Ko9,9,10,11.

1National Cancer Institute, National Institutes of Health, Bethesda, Maryland, USA; 2National Cancer Research Institute, National Taiwan University Hospital, Taipei, Taiwan; 3National Taiwan University Hospital, Taipei, Taiwan. 9Institute of Information Technology, National Cheng Kung University, Tainan, Taiwan; 9National Taiwan University Hospital, Taipei, Taiwan.

Introduction: With the increasing incidence of breast cancer in young women and the delaying first term pregnancy age, the incidence of pregnancy-associated breast cancer is expected to increase. The aim of the current study was to examine the impact of pregnancy on breast cancer survival using national registry data. Material and Methods: The breast cancer cases were identified from the Taiwan Cancer Registry. All first primary invasive breast cancer cases diagnosed between 2002 and 2014 were identified. The study was restricted to cases who were 20-50 years old and were stage I to III diseases. Pregnancy and delivery outcomes up to 5 years before the cancer diagnoses were abstracted from the National Health Insurance database. Those who were not pregnant during this time were defined as non-pregnant cases. The data were then linked to the Taiwan national death certificate database for vital status, the causes, and the dates of death. Years of follow-up was calculated from the date of breast cancer diagnosis to the date of death or December 31, 2014. The hazard ratios (HR) and the 95% confidence intervals (CI) of the association between pregnancy and breast cancer survival were estimated using cox proportional hazard models. Results: Among the 30,479 breast cancer cases, 90 were diagnosed during pregnancy (0.3%), 347 were diagnosed within a year after delivery (1.1%), 410 (1.3%) within 1-2 years after delivery, 1583 (5.2%) within 2-5 years after delivery, and 249 (0.8%) were pregnant after breast cancer diagnosis. By the end of 2014, 2932 cases were dead (17 cases diagnosed during pregnancy (18.9%) and 69 cases diagnosed within a year after delivery (19.9%). The major cause of death was breast cancer (89%). Compared to non-pregnant cases (9.3% dead), the HRs were 1.91 (95% CI=1.17-3.12) for those who were diagnosed during pregnancy and 1.92 (95% CI=1.48-2.48) for those who were diagnosed within a year after delivery, adjusted for age and year of breast cancer diagnosis. After adjustment for tumor characteristics and treatment, the HR were 1.84 (HR=1.16-3.03) and 1.29 (HR=0.92-1.80) for being pregnant diagnosed during pregnancy and within a year after delivery, respectively. For those who received systemic therapy, >80% of them started within 90 days. However, for subjects diagnosed during pregnancy, only 63% of them started systemic treatment within 90 days. Conclusion: Pregnancy-associated breast cancer is associated with higher mortality compared to non-pregnant breast cancer. Adjusted for tumor characteristics and treatment attenuated the association.

### #3275 The impact of tumor location on survival of the patients with esophageal squamous cell carcinoma

Yan Jin1, Yan Jin2, Fu You Zhou3, Ran Wang4, Zhi Qiang Li4, Zhi Cai Liu5, Dao Cun Wang6, Yin Li7, Ping Lu8, Peng Yuan Zheng9, Ching Wei Feng10, Guo Qiang Kong11, Shao Hua Han1, Li Dong Wang1.

The present results demonstrate that recurrence and metastasis are the major cause of death both in male and female for ESCC (96%). It is noteworthy that there are 0.2 percent of the ESCC patients have suicide which call for more attention of psychotherapy on cancer patients. [Supported by the Science and Technology Major Projects of Henan Province of China (161100311300), and Correspondence to: Li Dong Wang, the National Key Research and Development Program of China and Correspondence to: Li Dong Wang, Email: ldwang2007@126.com]
Background: Outdoor air pollution is considered a human carcinogen by the International Agency for Research on Cancer, particularly for its influence on lung cancer incidence and prognosis. While air pollution has not been consistently associated with breast cancer incidence, only one study has examined the impacts of air pollution on survival from breast cancer and was unable to confer significance in a multivariate setting. Here, we present a study that evaluated the association between air pollution and breast cancer survival.

The authors used data from the Environmental Protection Agency's Air Quality System and the National Cancer Institute's Surveillance, Epidemiology, and End Results Program to assess the association between air pollution and breast cancer survival. They used Cox proportional hazards models to assess the association between air pollution and breast cancer survival, controlling for potential confounders such as age, race, and socioeconomic status.

The results indicated that higher levels of air pollution were associated with lower breast cancer survival rates. Specifically, a 10% increase in PM2.5 exposure was associated with a 5% decrease in breast cancer survival. These findings are consistent with previous studies that have suggested that air pollution may increase the risk of breast cancer.

The authors concluded that their findings highlight the importance of considering air pollution as a potential risk factor for breast cancer. Further research is needed to confirm these findings and to better understand the underlying mechanisms linking air pollution and breast cancer survival.
effect of alcohol consumption. Using data from the Breast Cancer Health Disparities Study, we evaluated the associations between nine SNPs of ALDH1A1 (rs348481, rs168351, rs1888202, rs63319, rs722921, rs484461, rs484463, rs7027604, rs4124428) and overall mortality among 1134 Hispanic and 1160 non-Hispanic white (NHW) women diagnosed with incident invasive BC. Demographic and lifestyle factors were collected through in-person interviews. Modes of inheritance were considered for each SNP accordingly using their genotypes. Multivariate Cox proportional hazard regression models were used to calculate hazard ratios (HRs) and 95% confidence interval (CIs). Models were adjusted for percentage of Native American (NA) ancestry, BC summary stage, and study site. To detect effect modification, interaction terms were created between percentage of NA ancestry (low = 0.28 versus high > 0.28), alcohol consumption (ever versus never) and the SNPs. The likelihood ratio test was used to evaluate whether the interaction terms were significant. The Bonferroni correction was used to adjust for multiple comparisons. After a median follow-up time of 11 years from BC diagnosis to death, a total of 542 deaths occurred. The following four SNPs were significantly associated with overall mortality: rs1424482 (HR<sub>rs1424482</sub> = 1.33; 95% CI 1.04-1.70), rs63319 (HR<sub>rs63319</sub> = 1.30; 95% CI 1.06-1.60), rs7027604 (HR<sub>rs7027604</sub> = 1.37; 95% CI 1.11-1.70), and rs722921 (HR<sub>rs722921</sub> = 0.78; 95% CI 0.64-0.96). However, only rs7027604 remained significant after adjustment for multiple comparisons (P = 0.035). Among women with low NA ancestry, rs63319 significantly increased risk of mortality (HR<sub>rs63319</sub> = 1.55; 95% CI 1.20-1.99), while a non-significant inverse association was observed among women of high NA ancestry. Among ever drinkers, rs1888202 significantly decreased risk of mortality (HR<sub>rs1888202</sub> = 0.62; 95% CI 0.45-0.85), while a non-significant inverse association was observed among non-drinkers. The adjusted P-values for these interactions were not significant. This study provides evidence that rs7027604 is associated with worse prognosis after BC diagnosis among Hispanic and NHW women. Future BC survival studies examining the relationship between ALDH1A1 and mortality should also explore the modifying effects of alcohol consumption with rs1888202 and NA ancestry with rs63319.

#3282 Common chronic medical conditions in pancreatic cancer: impact on overall survival. Ahmed O. Abousamra, David Fogelman, Vijayshri Kallapurli, Akram Shalaby, Milind Javel, Renato Lenzi, Linus Ho, Donghui Li, Manal Hassan. UT MD Anderson Cancer Ctr., Houston, TX.

Background: We aimed to categorize the most common comorbid medical conditions in pancreatic cancer (PC) patients and to determine whether these conditions have impact on the overall survival (OS). Methods: Between January 2000 and 2014, 2165 patients with pathologically confirmed adenocarcinoma of the pancreas consented to participate in a clínico-epidemiological study at the University of Texas MD Anderson Cancer Center. We reviewed the electronic medical records of all patients to identify the prevalence of four chronic medical conditions, including systemic hypertension, hyperlipidemia, type 2 diabetes, and altered morphology of the pancreas. Prevalence of each chronic disease was assessed. Land median survival was estimated by using the Kaplan-Meier product-limit method, and significant differences between the survival times were determined by using the log-rank test. Results: Among all patients, 950 (43.9%) had history of hypertension, 516 (23.8%) had hyperlipidemia, 585 (27%) had type 2 diabetes. Radiological and pathological records indicated presence of steatosis (0.4%), fibrosis (1.9%), and pancreatitis (9.9%). The prevalence of hyperlipidemia and diabetes was significantly higher in men (27.9%, 30.2%) than in women (18.2%, 22.8%) respectively; P value <.01. We found no significant variation in the prevalence of hypertension and altered pancreatic morphology between men and women. Hypertension was more frequent among African American patients while diabetes was more common among Hispanics and African Americans. No significant variations in the distribution of other conditions by ethnicity. Median survivals of PC patients by comorbidities are presented in table 1. Conclusion: Chronic medical conditions are commonly reported by PC patients and the prevalence of these conditions may vary by gender. However, the impact of these conditions may not significantly affect the survival of the patients. The interaction treatment choices with these conditions still needs to be elaborated in future studies.

#3283 Adjuvant therapy associated with improved survival in gall bladder cancer: A single institution retrospective study. Lakshminarayanand Nagadopal,1 Martin J. Heslin,1 John R. Portefield,1 Roijymon Jacob,1 Peng Li,1 James Posey,1 Ravikumar Paluri1. 1University of Alabama at Birmingham, Birmingham, AL; 2Thomas Jefferson University, Philadelphia, PA.

Introduction: The survival outcome of resectable gallbladder carcinoma remains poor. We conducted a retrospective study to examine factors affecting patient outcomes in resectable gallbladder carcinoma. Methods: We retrospectively collected data on patients treated at our institution between January 2005 and June 2015 from the electronic medical record using a standardized data collection tool. The univariate Cox proportional hazard model was used for evaluating predictors of overall survival. Kaplan-Meier method was used to compare time-to-events among subgroups and the p values were calculated by the log-rank method. Overall survival (OS) was defined as the time between surgery and death, or censored at the last follow-up date. Progression-free survival (PFS) was defined as the time to recurrence or death. Results: Of 67 evaluable patients, 65.7% were female. While clinical staging determined 51% to be stage 2 or less, interval portal lymphadenectomy and hepatic resection upstaged 20% to stage 3 or 4. Adjuvant chemotherapy (CT) was given to 18% and adjuvant chemoradiation (CRT) to 15%. About 46% did not receive any post-operative treatment and data was not available in 21%. On multivariate analysis, albumin < 3.5g/dL, LN involvement and pathological (p)Stage > 2 were independent predictors of OS and PFS. Median 5 yrs OS and PFS of stage ≤ 2 was 54% and 49% respectively. Median 5 yrs OS and PFS of stage > 3 was 19.9% and 5.8% respectively. Adjuvant therapy was administered commonly for stage 3 and 4 (20 patients) compared to stage 1 and 2 (2 patients). In stage > 3, adjuvant therapy improved OS (17.5% vs 8.9% for surgery alone and PFS (12% vs 0%). Adjuvant chemoradiation for stage 3/4 had better median OS advantage compared to chemotherapy alone (54 m vs 15m, P = 0.0008). Conclusion: The use of adjuvant treatment may improve long-term disease control in patients with node positive tumors. A significant difference between CRT and CT was demonstrated in our series and needs further validation in a larger cohort.

#3284 Diminished survival in second primary melanoma exposed by the counting method: an underutilized statistical approach in clinical oncology. Maris S. Jones,2 Jehey Lee,3 Myung-Shin Shim,2 Delphine J. Lee,1 Mark B. Farles1. 1John Wayne Cancer Institute, Santa Monica, CA; 2UCLA Department of Biostatistics, Los Angeles, CA; 3Los Angeles Biomedical Institute, Torrance, CA.

Objective: To determine the impact of second primary melanoma (SPM) on patient survival using an established statistical methodology underutilized in oncology research. Introduction: Patients with cutaneous melanoma are at increased risk for SPM. Traditional statistical methods for calculating the risk of SPM are limited. We analyzed SPMs as time dependent covariates of the primary melanoma (PM). In contrast to other methods of SPM analysis, this process did not assume the SPM existed at the time of PM diagnosis. Methods: 12,325 patients with AJCC stage 0-IV cutaneous melanoma and those who later developed a SPM were identified from the John Wayne Cancer Institute melanoma data-gathering prospectively死亡 statistical survival tests were utilized to compare PM and SPM groups. Then multivariate analysis via the counting method was performed to examine the impact of SPM on overall survival (OS) and melanoma specific survival (MSS). Results: Of PM patients, 969 (7.86%) developed a SPM. Prognostic primary tumor characteristics tended to be better in patients with SPM than without SPM including Breslow thickness, Clark level, ulceration status, histologic type and stage (Table 1). Despite the favorable initial presentation of SPM patients, MSS and OS were significantly worse when compared with PM only patients: OS: HR 1.23, 95% CI 1.01-1.37, MSS: HR 1.32, 95% CI 1.15-1.52). Conclusion: This is the largest single-institution study to utilize the counting method to analyze SPM survival. Patients with SPM are at increased risk for SPM.
death overall and due to melanoma despite traditionally favorable clinicopathologic characteristics. Based on these data, lifelong surveillance remains critical to detect subsequent primary cutaneous melanomas and recurrences in patients with history of a PM.

**#3285 Predictors of plasma 25-hydroxyvitamin D concentrations among breast cancer survivors.** Woo-Kyong Shin,1 Zisman Kim,2 Hyun Jo Youn,2 Ji-hyoung Cho,3 Jung Eun Lee.1 1Seoul National University, Seoul, Republic of Korea; 2Soehnchunhyang University Bucheon Hospital, Bucheon, Republic of Korea; 3Chonbuk National University Medical School, Jeonju, Republic of Korea.

Background: A review of recent evidences suggests that circulating 25-hydroxyvitamin D (25(OH)D) concentrations are associated with better prognosis among breast cancer survivors. However, little is known about modifiable factors for vitamin D status among breast cancer survivors. We aimed to explore demographic, lifestyle, and clinical factors associated with vitamin D status among breast cancer survivors. Methods: We included a total of 207 breast cancer survivors aged 21-79 years who were enrolled between 2015 and 2016 at three large hospitals. Participants had been diagnosed with stage I to III primary breast cancer and had breast cancer surgery at least 6 months before enrollment. We asked participants about demographic, socioeconomic, and lifestyle factors. Clinical data were extracted from medical records. Dietary intake was assessed using 3-day dietary records. Plasma 25-OHD concentrations were measured by the electrochemiluminescence immunoassay. We fit a multivariable linear regression model to predict plasma 25(OH)D with all candidate predictors with p ≤ 0.1 in the univariate analysis. Result: Mean value (SD) of plasma 25(OH)D concentrations were 23.75 ± 12.7 mg/L among users of supplement containing vitamin D, and 13.35 ± 8.62 mg/L among non-user. In the univariate linear regression models, we identified the following independent predictors associated with plasma 25-OHD concentrations: vitamin D intake from supplement, calcium intake from supplement, vitamin D from food, use of any supplement, body mass index (BMI), months after diagnosis, season of blood draw, daily sun exposure during the last 2 years, smoking habit, skin change after sunburn, suncap use, parity, and ER status. When we included all of these predictors in the multivariable linear regression models, we found that use of any supplement (β = 1.19 for use vs. none, p < 0.001, BM1 at diagnosis (β = 0.08 for 1 kg/m2 increment, p = 0.02), season of blood draw (β = 0.83 summer vs. spring, p = 0.008; and β = 0.75 fall vs. spring, p = 0.01), and daily sun exposure during the last two years (β = 0.005 for 1 minute increment per day). The multivariable linear regression models explained 23.95% of the total variability in plasma 25-OHD concentrations. Conclusions: We found that supplemental use, BMI at diagnosis, season of blood draw, and daily sun exposure during the last 2 years were associated with plasma 25-OHD concentrations among Korean breast cancer survivors. Future studies are needed to investigate the role of vitamin D in the progression of breast cancer among Korean breast cancer survivors. Funding information: This research was supported by the Basic Science Research Program through the National Research Foundation of Korea (NRF) funded by the Ministry of Science, ICT & Future Planning (NRF-2014R1A2A2A01007794).

**#3286 Correlation between vitamin D levels and DNA repair capacity in breast cancer patients stratified by molecular subtypes.** Carmen Ortiz,† Jarline Encarnaciòn,† Ralphdy Vergne,† Wanda Vargas,† Jaime Matta.† 1Ponce Health Sciences University-Ponce Research Institute, Ponce, Puerto Rico; 2University of Puerto Rico at Ponce, Puerto Rico.

Vitamin D exists as vitamin D2 and D3, which are metabolized to 25-hydroxyvitamin D (25(OH)D), the major circulating vitamin D metabolite. Besides its physiological functions, vitamin D levels have also been studied as a risk factor for several hormonal cancers including breast cancer (BC). Worldwide, BC accounts for nearly a quarter of all cancers in women. Nutritional studies report that vitamin D intake is associated with a lower BC risk. Several discrepancies exist regarding the role of serum vitamin D in BC risk. While some studies report BC risk reduction by vitamin D only in premenopausal women, others propose that it only occurs in postmenopausal women. BC tumors may (●) or may not (●) have three hormonal receptors: estrogen (ER), progesterone (PR), and HER2. Based on their status, four principal molecular BC subtypes have been identified: luminal A (ER+ / PR+ / HER2-), luminal B (ER+ / PR+ / HER2+), HER2+ (ER− / PR− / HER2+), and triple negative (TN) (ER− / PR− / HER2−). If BC is analyzed in terms of molecular subtypes, low vitamin D levels have been associated with aggressive phenotypes and worse prognosis. Vitamin D also influences estrogen synthesis. Since we have previously shown that a low DNA repair capacity (DRC), measured through the nucleotide excision repair pathway, is a risk factor for BC and vitamin D has also been found to affect DNA repair, the focus of this study is to examine the role of plasma vitamin D levels and DRC in BC. The main aim is to elucidate whether there is an association between vitamin D and DRC levels among the four molecular BC subtypes. We hypothesize that a negative correlation between 25(OH)D and DRC levels will be observed among these subtypes. As an initial effort, 47 BC cases and 20 controls without BC were selected from our large BC cohort. DRC was measured in lymphocytes of untreated women using the host cell reactivation assay. Pathology reports were examined to divide BC cases according to their molecular BC subtype: luminal A (n = 13), luminal B (n = 11), HER2+ (n = 10), and TN (n = 13). Plasma 25(OH)D levels were measured using the UnioCol Dxc System at a CLIA-certified lab. Our results show a negative correlation between 25(OH)D and DRC levels (p = 0.04). Statistically significant differences were found for vitamin D levels among the different groups (p = 0.0019, ANOVA). Moreover, higher 25(OH)D levels (47.97 ± 2.4 ng/mL) were found in ER- BC cases (p = 0.03, t-test). When comparing vitamin D levels in BC subtypes, a significant difference was found in HER2+ and TN groups when compared with the control.
group (p<0.05, Kruskal-Wallis). Based on these preliminary results we conclude that plasma vitamin D levels may be correlated with DRC levels in women with BC. Ongoing studies with a larger sample size are aimed at elucidating more precisely the potential association between vitamin D and DRC in these molecular BC subtypes.

#3287 Associations of whole food and lifestyle-based inflammation scores with all-cause, cancer- and cardiovascular disease-specific mortality. Dorothy Byrd,1 Ashley Holmes,1 Suzanna Judd,2 WD Dana Flanders,1 Roberd M. Bostick1. 1Emory University, Atlanta, GA; 2University of Alabama Birmingham, Birmingham, AL.

Chromically higher levels of inflammation have been implicated in the etiology of cancer and other major chronic diseases. Contributors to chronic inflammation likely include diet, physical activity, obesity, and smoking. We developed dietary (DIS), lifestyle (LIS), and overall (OIS) inflammation scores to characterize the aggregate of pro- and anti-inflammatory exposures, and investigated associations of the scores with all-cause, cancer- and cardiovascular disease (CVD)-specific mortality in the prospective Reasons for Geographic and Racial Differences in Stroke Study (REGARDS) (n=21,426). The components of the scores were selected based on biological plausibility and previous literature. The dietary components included processed meats, red meat, white meat, fish, nuts, legumes, coffee, tea, dairy products, refined and whole grains, and nine other botanical categories. The lifestyle components included body mass index, smoking status, alcohol intake, and exercise level. Associations of each score component with a panel of biomarkers of inflammation in a subset of 577 male and female, black and white, chronic disease-free participants in REGARDS were assessed using multivariable linear regression, and the resulting beta coefficients were used to weight each score component. For each study participant, the weighted score components were summed to produce the scores such that a higher score was more pro-inflammatory. The scores were categorized according to quintiles of their distributions among all REGARDS participants at baseline, and their associations with mortality were assessed using multivariable Cox proportional hazards regression. Over an average of 7.89 years follow-up, 2,964 individuals died, including 854 from cancer. With increasing levels of each score, there was increasing risk for all-cause, cancer- and CVD-specific mortalities. For those in the highest relative to the lowest quintiles of the OIS, DIS, and LIS, the multivariable-adjusted hazard ratios (95% confidence intervals) for all-cause mortality were: 2.16 (1.87, 2.49; P trend<0.0001), 1.25 (1.16, 1.41; P trend<0.0001), and 1.94 (1.69, 2.24; P trend<0.0001), respectively. The corresponding findings for cancer mortality were 1.79 (1.38, 2.32; P trend<0.0001), 1.20 (0.95, 1.50; P trend<0.0001), and 1.83 (1.42, 2.37; P trend<0.0001), respectively, and for CVD mortality 2.38 (1.83, 3.09; P trend<0.0001), 1.28 (1.02, 1.61; P trend<0.0003), and 1.90 (1.49, 2.42; P trend<0.0001), respectively. These results suggest that pro-inflammatory diets and lifestyles may be associated with higher risk for all-cause, cancer- and CVD-specific mortality.

#3288 Effects of concomitant metformin and statins on overall survival of pancreatic cancer patients: results from SEER-Medicare data analyses. Jian-Yu E,1 Shou-En Lu,2 Yong Lin,3 Judith M. Graber,3 David Rotter,1 Lanjing LIS, the multivariable-adjusted hazard ratios (95% confidence intervals) for all-cause mortality were: 1.131). Additionally, no superior beneficial effect was observed for dual users (HR, 0.998; 95% CI, 0.947 to 1.053). Conclusions: Exposures to statin, metformin, or both were significantly associated with reduced overall mortality of PDAC, indicating potential benefits of statin use on improving survival among PDAC patients. Further prospective validation is required to confirm these findings.

#3289 Cutaneous melanocytic nevi and risk of melanoma deaths in women and men: a prospective study. Wen-Qing Li, Hao Geng, Eunyoung Cho, Abraeq Greshi. Brown University, Providence, RI.

Background: Increased number of common acquired melanocytic nevi (moles) has been associated with an increased risk of melanoma. It is unclear whether melanocytic nevi may predict melanoma deaths. We prospectively examined the association between number of melanocytic nevi and risk of melanoma deaths based on 77316 women from the Nurses’ Health Study (NHS) and 32454 men from the Health Professionals Follow-up Study (HPFS). Methods: In both cohorts, diagnosis of melanoma was reported biennially and pathologically confirmed. Deaths were confirmed by next of kin or the National Death Index. Information on the number of moles with ≥3 mm diameter on the upper extremity was collected in 1986. We used Cox regression models to evaluate the associations between number of melanocytic nevi and risk of melanoma deaths in the overall cohorts as well as only among melanoma cases. Results: A total of 2430 cases of melanoma were documented (1545 in NHS and 905 in HPFS), out of which we identified 192 incident deaths due to melanoma (87 in NHS and 105 in HPFS) during the follow-up (1986-2012). Increased number of melanocytic nevi was associated with melanoma deaths; the multivariate-adjusted hazard ratio (HR) for 3 or more melanocytic nevi compared with no nevi on the upper extremity was 2.55 (95% confidence interval: CI): 1.52-4.28) for women and 3.97 (95% CI: 2.54-6.22) for men. A secondary analysis further found that increased number of melanocytic nevi was associated with both lethal melanoma (melanoma cases that died of melanoma) and non-lethal melanoma. Among melanoma cases, increased number of melanocytic nevi was independently associated with risk of melanoma deaths in men, with a HR of 1.89 (95% CI: 1.17-3.05) for 3 or more melanocytic nevi. The association persisted even after adjusting for Breslow thickness of melanoma and appeared particularly stronger among those with lower Breslow thickness (P for interaction=0.03). However, number of melanocytic nevi was not significantly associated with risk of melanoma deaths among melanoma cases in women (HR=1.03, 95% CI: 0.61-1.76 for 3 or more nevi). Conclusion: Increased number of melanocytic nevi was significantly associated with risk of melanoma deaths in our cohorts of women and men. A high number of melanocytic nevi may independently predict the risk of melanoma deaths among men with melanoma.

#3290 Cancer mortality by antihypertabetic drug use in a population-based cohort of Finnish men. Kalle J. Kaapu,1 Teemu Murtola,1 Kirsi Talala,2 Kimmo Taari,3 Teuvo Tammela,4 Anssi Auvivnen1. 1University of Tampere, Tampere, Finland; 2Finnish Cancer Registry, Helsinki, Finland; 3University of Helsinki, Helsinki, Finland; 4Tampere University Hospital, Tampere, Finland.

Background: In previous studies, use of antihypertensive drug digoxin might restrain the growth of cancer cells by inhibiting Na+/K+ATPase. A non-selective beta-blocker sotalol has similar effect on K+ channels. We evaluated the association between cancer mortality and digoxin, sotalol, and general antihypertensive drug use in a retrospective cohort study. Materials and methods: The study population consists of 78,615 men originally identified for the Finnish Randomized Study for Screening of Prostate Cancer. Men were 55-69 years old at baseline. Prostate cancer cases were excluded; no exclusions were made based on other cancer types. Information on antihypertensive drug purchases was collected from the national prescription database. We used Cox regression method to analyze the overall cancer mortality and individually from the most common causes of cancer death. Results: A total of 8,064 men (10.3%) had used antihypertensive drugs. Of these 5,668 had used digoxin and 2,540 had used sotalol. During the median follow-up of 16.9 years after baseline 26,790 (34.1%) men died, of these 8,225 (30.7% of deaths) due to cancer. Overall cancer mortality was elevated among antihypertensive drug users compared to non-users (HR 1.25, 95% CI 1.12-1.40). Similar results were observed for sotalol (HR 1.44, 95% CI 1.26-1.63) but not for sotalol (HR 0.92, 95% CI 0.68-1.24). Furthermore, the antihypertensive drug use was associated with elevated risk of lung-cancer death (HR 1.76,95% CI 1.46-2.14). However, the risk associations disappeared in long-term use. When we restricted the analysis to cancer cases only, no differences were observed in survival after the cancer diagnosis for any cancer type. Conclusion: Cancer mortality was elevated among cancers only.
users of antiarrhythmic drugs compared to non-users. This association is probably due to the differences between users and non-users as it was related to short-term use, and disappeared in long-term use. Use of digoxin or sotalol was not associated with improved cancer-specific survival.  

#3291 Development of a novel prognostic scoring system for patient selection in immune checkpoint inhibitor phase I clinical trials. Shiraj Sen, Kenneth Hess, David Hong, Aung Naing, Sarina Piha-Paul, Filip Janku, Sijing Fu, Holly Liu, Yunfang Jiang, Rahul Khanji, Daniel Karp, Apostolia Tsimberidou, Nizar Tannir, Funda Meric-Bernstam, Vivek Subbiah. *University of Texas MD Anderson Cancer Center, Houston, TX.* 

Purpose: To develop a prognostic scoring system for selecting patients for immune checkpoint inhibitor (ICI) phase I clinical trials. Background: The Royal Marsden Hospital (RMH) and MD Anderson (MDA) prognostic scoring systems have been validated for patients in phase I clinical trials treated with cytotoxic chemotherapy and targeted therapy, but no such scoring system has been validated to help select patients entering ICI clinical trials. Methods: We analyzed clinical data from patients treated in phase I ICI clinical trials (with anti-CTLA4 and anti-PD1 antibody therapy) at the MD Anderson Center for Targeted Therapy. Sixteen clinical factors were studied. Recursive partitioning analysis identified cut-points for each clinical factor and a Cox proportional hazards regression model was used to identify factors independently affecting overall survival. Results: Among 172 patients treated with ICI therapy (105 CTLA4-based and 67 PD1-based) between January 2013 and November 2015, the median age was 60 years (range: 19-86 years) and 87 (51%) were male. The most common tumor types treated included renal cell carcinoma (n = 25; 15%), non-small cell lung cancer (n = 21; 12%), melanoma (n = 17; 10%), sarcoma (n = 14; 8%), gastrointestinal stromal tumors (n = 10; 6%), prostate cancer (n = 6; 3%), and colorectal cancer (n = 6; 3%). Seven factors were independently associated with significantly worse overall survival: age >52 years (hazard ratio [HR] 1.59, 95% confidence interval [CI] 1.1-2.4), Eastern Cooperative Oncology Group performance status >1 (HR 2.81; 95% CI 1.3-6.3), lactate dehydrogenase >466 U/L (HR 2.1; 95% CI 1-4.2), platelet count >300 x 10^9/L (HR 1.8; 95% CI 1.2-2.8), absolute neutrophil count >4.9 x 10^9/L (HR 2.3; 95% CI 1.5-3.5), absolute lymphocyte count <1.8 x 10^9/L (HR 3.3; 95% CI 1.9-5.7), and liver metastases (HR 1.8, 95% CI 1.2-2.6). An index was created whereby the cohort was divided into four risk groups based on the number of factors present: 0-2, 3, 4, or 5-6. Median overall survival was 24.2 months (6-9), 11.6 months (3), 8.0 months (4), and 3.8 months (5-6); log rank test, p < 0.0001. The Harrell c-index of this scoring system was 0.72, indicating significant predictability. Conclusion: We have developed a novel “MDA ICI” prognostic scoring system incorporating seven clinical parameters with prognostic significance for patients in phase I clinical trials treated with immune checkpoint inhibitors. Unlike in the RMH and MDA prognostic scoring systems, albumin level and number of metastatic sites did not independently correlate with overall survival. Prospective evaluation and external validation of our novel prognostic scoring system is warranted and may help better select patients for future clinical trials of checkpoint inhibitors.  

#3292 Cause-specific mortality of nonmetastatic prostate cancer patients. Katarina Matthes,1 Giulia Pestoni,1 Dimitri Korol,2 Mieke Van Hemelrijck,3 Katarina Matthes,1 Giulia Pesto,1 Dimitri Korol,2 Mieke Van Hemelrijck,3 Youzhou Tan,1,2 Hai Dong Wang.1,2,3 *The First Affiliated Hospital of Zhengzhou University, Zhengzhou, China; 2National Institute of Health and Welfare, Helsinki, Finland; 3National Institute of Health, Baltimore, MD; University of Tampere, Tampere, Finland.* 

Background: Prostate cancer (PCa) is the most frequent incident cancer in men in Switzerland. One of the major challenges in the treatment of PCa is to reliably distinguish between patients at risk of dying as a direct result of the disease and those more likely to die of other causes. The purpose of this study was to assess the associations of age and risk group based on stage, grade and PSA level with primary treatment of non-metastatic PCa patients, and to evaluate whether this treatment was associated with cardiovascular death or prostate cancer specific mortality (PCSM). Methods: Population-based data from the Cancer Registry of Zurich and Zug in Switzerland were used. We identified 1919 non-metastatic PCa patients treated between 2000 and 2009 who were living in the City of Zurich. PCa risk groups were stratified into three groups based on T stage, Gleason score and initial PSA concentration as described by D’Amico (low-risk: T1-2a, and Gleason score <=6, and PSA <=10 ng/mL; intermediate risk: T2b and/or Gleason score =7 and/or PSA >10 and <=20; high-risk: >= T2c or Gleason score 8-10 or PSA >20). Multiple imputation methods were applied to deal with missing risk group information. We distinguished between surgical procedures, radiotherapy, androgen deprivation therapy (ADT), active surveillance, and watchful waiting. Fine and Gray competing risk regression analysis was used to estimate sub-distribution hazard ratios for the outcomes cardiovascular death, PCSM or other-cause mortality. Results: Unadjusted combined peting risk model revealed an increased risk of cardiovascular death for patients with ADT (HR = 2.00 [1.27 - 3.14]), or watchful waiting compared to surgery (HR = 2.19 [1.58 - 3.02]). However, after adjustment for age and risk group, an increased risk of cardiovascular death was no longer observed (ADT HR = 1.51 [0.93 - 2.46], watchful waiting HR = 1.31 [0.91 - 1.90]). Only men >80 years of age showed an increased risk of cardiovascular death in both ADT and no ADT. Furthermore, we observed an increased adjusted risk of PCSM in men with ADT (HR = 2.84 [1.97 - 4.01]) and under watchful waiting (HR = 1.78 [1.29 - 2.61]) compared to surgery, for men >70 years (HR = 4.18 [2.18 - 8.00]) compared to men < 70 years old, and for patients with intermediate risk (HR = 2.69 [1.34 - 5.39]) and high risk (HR = 6.37 [3.30 - 12.30]) compared to patients with low risk. Discussion: The study suggests that ADT use for non-metastatic PCa patients may not be associated with an increased risk of cardiovascular death in general, but with an increased risk of PCSM. This is likely explained by the more frequent ADT use in older men and in men with a high-risk PCa. In addition, we observed that older men and men with an intermediate- or high-risk PCa had an increased risk of PCSM.  

#3293 Impact of the invasive depth on lymph node metastasis and survival in Chinese patients with esophageal squamous cell carcinoma. Xin Song,1 Fu You Zhou,2 Hai Jun Yang,3 Xue Na Han,3 Tang Juan Zhang,1 Lian Qun Zhang,2 Ning Liu,1 Jing Li Ren,2 Zhi Wei Chang,1 Xin Tian,1 Hai Ling Wang,2 Hui Fang Tan,1 Li Dong Wang.1,2,3 *The First Affiliated Hospital of Zhengzhou University, Zhengzhou, China; 4University of Tampere, Tampere, Finland.* 

Purpose: To develop a prognostic scoring system for selecting patients for esophageal squamous cell carcinoma (ESCC). However, it is a dilemma to determine the LNM status before surgery. The invasive depth (T stage) of ESCC could be determined either with computed tomography or ultrasound endoscopy and may reflect the severity of LNM. Thus, the present study was designed to determine the impact of tumor invasive depth on LNM status and survival in ESCC patients with T1-4N0M0. The enrolled 30,514 ESCC patients in this study were from the ESCC database in Henan Key Laboratory for Esophageal Cancer Research of the First Affiliated Hospital, Zhengzhou University. Of the patients, there were 18346 males with an mean age of 59.2±8.9, and 12168 females with an mean age of 59.7±8.7. All the patients had been performed radical esophagectomy without radiotherapy and chemotherapy before surgery, and the invasive depth records were retrieved from the medical records in hospitals after surgical resection. Based on the 6th version of UICC criteria, the invasive depth (T) was classified as Tis, and T1-4. Of the 30,514 ESCC patients, 20,288 cases were successfully followed until the end of 2015. The Logistic regression method were used to determine the correlation between T stage and LNM status. The Kaplan-Meier method was applied to analyze the survival in different groups. The results showed that, of the 30,514 ESCC patients, there were 3324 (10.9%) patients with Tis+T1, 9616 (31.5%) with T2, 17249 (56.5%) with T3 and 325 (1.1%) with T4. Accordingly, from Tis&T1 to T4, the number of the patients with positive LNM were 554 (16.7%), 3392 (35.3%), 7737 (44.9%) and 205 (63.1%), respectively. Logistic regression analysis indicated the risk of LNM was dramatically increased between T1-4 to 8-folds with the increase of T stage. The hazard ratios values of 2.725 (T5: 95%CI: 2.465-3.013), 4.067 (T5: 95%CI: 3.695-4.477) and 8.542 (T5: 95%CI: 6.699-10.892), respectively. Interestingly, seventeen percent of the patients with Tis&T1 stages had occurred positive LNM, indicating that LNM may occur in very early stage of ESCC. Kaplan-Meier analysis showed that T staging was obviously associated with the survival in ESCC patients with negative LNM (P value < 0.05). Overall, the present results indicated a strong correlation between invasive depth and LNM status, suggesting that the invasion depth may be one of crucial markers to reflect the LNM in ESCC. The invasive depth could be used as an promising indicator for LNM status judgment in clinical TNM staging and prognosis for ESCC. #3294 Breast cancer extent and survival in diabetic women in a Finnish population based cohort. Miika Murto,1 Miia Artama,2 Kala Visvanathan,3 Teemu Murtola1.1 Pirkanmaa Hospital District, Tampere, Finland; 2National Institute for Health and Welfare, Helsinki, Finland; 3Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; University of Tampere, Tampere, Finland.* 

Introduction: Breast cancer and diabetes are two major health problems for women. Around 1.7 million new breast cancer cases are diagnosed each year, making breast cancer the most common cancer type in women. Number of
people with diabetes is estimated to be 415 million worldwide, thus one in 11 adults have diabetes. However, evidence on the association between diabetes and breast cancer prognosis is controversial. We estimated breast cancer extent at diagnosis and survival in a Finnish population-based cohort of female breast cancer patients. Materials and methods: All newly diagnosed breast cancer cases among women in Finland between 1995 and 2013 were identified from comprehensive national Finnish Cancer Registry. To minimize possible bias due to differing participation in cancer screening the study population was limited to women with at least one mammography screening before the diagnosis. In total 45,786 cases were included in our study cohort. Information on recorded diagnoses of diabetes, hypertension, hypercholesterolemia and obesity from in- and outpatient hospital visits during 1995-2013 were obtained from national Care Register for Health Care maintained by National Institute for Health and Welfare. Logistic regression was used to evaluate the risk of having cancer extended to axillary lymph nodes or beyond at diagnosis. Cox regression was used to evaluate risk of breast cancer death and overall mortality after the diagnosis. Analyses were adjusted for age, comorbidities and number of mammography screens before the diagnosis. Survival analyses were further adjusted for tumor extent and primary treatment. Results: In total 1,419 women had diabetes. Compared to non-diabetic women, breast cancer was more often advanced to axillary lymph-nodes (OR 1.19; 95% CI 1.05-1.34) or metastatic at diagnosis (OR 1.58; 95% CI 1.26-1.97) in diabetic women. Nevertheless, during the median follow-up of 6.9 year after the diagnosis, risk of breast cancer death did not differ between diabetic and non-diabetic women (HR 1.21). Overall, the risk of death was elevated among diabetic women (HR 1.34; 95% CI 1.19-1.51). Conclusion: Diabetic women have more often advanced tumor extent at diagnosis compared to non-diabetic women. However, diabetes did not affect disease-specific survival within 6.9 years after the diagnosis.

#3295 Incidence of skeletal related events (SREs) among prostate cancer patients treated with androgen deprivation therapy (ADT) in Abuja, Nigeria. 1Oseiemem A, Aliuodenioye-Shadrack, 2Sadig N. Abu1, 2Ella E. Magnus2, 2Charles Ukwo, 2Nelix N. Kolo, 1University of Abuja & University of Abuja Teaching Hospital, Abuja, Nigeria; 2University of Abuja Teaching Hospital, Abuja, Nigeria.

Background: Skeletal related events (SREs) are one or more of the following conditions, occurring concurrently with or after the first bone metastasis: fractures, radiotherapy to bone and spinal cord compression. SREs occur in men with prostate cancer (CaP) and may result from androgen deprivation therapy (ADT). The purpose of this study was to determine the incidence of SREs in patients with CaP treated with ADT in our practice. Methods: Eligible cases were newly diagnosed patients with CaP treated with ADT at the University of Abuja Teaching Hospital (UATH), Abuja, Nigeria between January 2012 and December 2015 with bone metastases and treated with ADT. Data compiled from only retrievable patient’s medical records showed tumor diagnosis, laboratory and radiology results. SREs included spinal cord compression, surgery to bone, pathologic fracture and radiation to bone. Results: All 142 cases of CaP reviewed who received ADT were first diagnosed as AJCC stage IV prostate cancer. More than half the patients were ≥ 65 years of age with a mean (SD) of 68.3 ± 9.5 years. Serum PSA range was 1.4-2461.58 ng/ml with a mean (SD) of 113.7 ± 288.9 ng/ml. We identified 29 patients (20.5%) who had one or more SREs: spinal cord compression (19.1%), pathologic fractures (1.4%) and radiotherapy to the affected bone (1.4%) being the most common SREs. Altogether fifty (35.2%) more patients had bone pains which was localized to the lumbo-sacral spine in 52% of them, only two patients had internal fixation to stabilize pathological fractures and bone radiotherapy respectively. ADT in the patients was orchiectomy, LHRH-anti-androgens and complete androgen blockade (CAB) [orchiectomy or LHRH plus anti-androgens] in 14 (9.8%), 3 (2.1%), 44 (30.9%) and 81 (57%) patients respectively. Conclusions: Although some clinical trials have found that 36-41% of high-risk metastatic prostate cancer patients developed SREs during 3 years of follow-up, our review of this hospital-based cohort of patients with prostate cancer receiving ADT did not show the incidence of SREs to be as high as what has been reported. Additional studies to explore the incidence of SREs in patients with metastatic hormone refractory prostate cancer in our environment may be relevant.

#3296 Survival among lung cancer patients in the U.S. Military Health System: a comparison with the SEER population. Jie Lin, 1Christine Kamanian, 1Derek Brown, 1Stephanie Shao, 1Katherine A. McGlynn, 1Joel A. Nations, 1Corey A. Carter, 1Craig D. Shriver, 1Kangmin Zhu, 1Walter Reed National Military Medical Center, Bethesda, MD; 2National Cancer Institute, Rockville, MD.

The U.S. military health system (MHS) provides universal access to its beneficiaries. However, little is known about whether the universal access has translated into improved patient outcomes. We compared survival among non-small cell lung cancer (NSCLC) cases in MHS with that of NSCLC cases from the general U.S. population. The MHS data were obtained from The Department of Defense’s (DoD) Automated Central Tumor Registry (ACTUR). The U.S. population data were drawn from the National Cancer Institute’s (NCI) Surveillance, Epidemiology, and End Results (SEER) program 18 registries (1973-2012) which represents 27.8% of the U.S. population. NSCLC patients in ACTUR and SEER who were diagnosed between January 1, 1987 and December 31, 2012 were included. The ACTUR and SEER cases were then matched by age group, sex, race, and year of diagnosis group at a matching ratio of 1:4, which comprised of 16,257 cases from ACTUR and 65,028 cases from SEER. Kaplan-Meir curves and log-rank test were used to compare overall survival between the two populations. Multivariable Cox proportional hazards models for matched data were used to estimate hazard ratios (HRs) and 95% CI with adjustment for potential confounders. Compared to the SEER cases, the ACTUR cases were more likely to be diagnosed at stage I or stage II (P<0.0001) and less likely to be diagnosed at stage IV. ACTUR cases also had a lower percentage of poorly differentiated tumors than did SEER cases, who had a higher percentage of well differentiated and moderately differentiated tumors (P<0.0001). Kaplan-Meir survival curves showed significantly better survival among ACTUR cases than SEER cases (Log Rank P<0.0001). In Cox proportional hazards model analysis, ACTUR cases exhibited significantly better overall survival than did SEER cases (HR=0.78, 95% CI=0.76 to 0.81). The survival advantage of ACTUR cases remained after stratification on cancer stage, age group, sex, race and further. Additional analyses revealed that ACTUR cases were more likely to receive surgery for early-stage (stages I and II) tumors (OR=1.41, 95% CI =1.28 to 1.50), and radiation therapy for late stage (stages III to IV) tumors (OR=1.09, 95% CI =1.03 to 1.15). Our results suggest that the survival of NSCLC patients in the MHS is better than that in the general population, implying that lung cancer care and programs within the MHS has translated into improved patient outcomes.

#3297 Survival predictors of Burkitt’s lymphoma in children, adults and elderly in the United States during 2000-2013. Fahad Mukhtar, 1Paolo Bofetta, 2Harvey A. Risch, 3Jong Y. Park, 4Omonigho M. Bubu, 1Lindsay Womack, 1Walter Reed National Military Medical Center, Bethesda, MD; 2Harvey A. Risch, New Haven, CT; 3Harvey A. Risch, 4H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL; 1University of South Florida, Tampa, FL; 2Mount Sinai School of Medicine, New York, NY; 3Yale University, New Haven, CT; 4H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL; 5Vietnam National Cancer Hospital, Hanoi, Viet Nam.

Background. Burkitt’s Lymphoma (BL) has three peaks of occurrence, in children, adults and elderly, at 10, 40 and 70 years respectively. To the best of our knowledge, no study has been conducted to assess predictors of survival in the three age groups. We hypothesized that the predictors of survival may differ by age group. We, therefore, sought to determine the predictors of survival for BL in these three groups: children (<15 years of age), adults (40-70 years of age) and elderly (>70 years of age). Methods. Using the Surveillance, Epidemiology, and End Results (SEER) database covering the years 2000-2013, we identified 797 children, 1,994 adults and 757 elderly patients newly diagnosed with BL. We used Cox proportional hazards regression models to determine prognostic factors for survival for each age group. Results. Five-year relative survival in BL for children, adults and elderly were 90.4%, 47.8%, and 28.9%, respectively. Having at least stage II disease and multiple primaries were associated with higher mortality in the elderly group. In adults, multiple primaries, stage III or IV disease, African American race and bone marrow primary were associated with increased mortality whereas stage IV disease and multiple primaries were associated with worse outcome in children. Conclusion. These findings demonstrate commonalities and differences in predictors of survival that may have implications for management of BL patients. MOLECULAR AND CELLULAR BIOLOGY GENETICS: Autophagy and Cancer

#3298 Diindolylmethane and its halogenated analogues induce autophagy in human prostate cancer cells via induction of the astrocyte-elevated gene-1 (AEG-1). Hossam Draz, 1Alexander Goldberg, 1Thomas Sanderson, 1Stephen Safe1, 2INRS-Institute Armand Frappier, Laval, Quebec, Canada; 3Texas A&M University, College Station, TX.
3,3'-diindolylmethane (DIM) and its halogenated derivatives (ring-DIMs) are recently shown to induce protective autophagy in human prostate cancer cells. The mechanism of induction of autophagy by DIM has not been elucidated. As DIM is a mitochondrial ATP synthase inhibitor, we hypothesized that DIM and ring-DIMs induce autophagy via alteration of AMP/ATP ratio and act as inducers of autophagy in prostate cancer cells. In this study, we monitored by LC3B-I to LC3B-II conversion in LNCaP and C42B prostate cancer cells. Autophagic vacuoles were examined using Cyto-ID autophagy detection kit and transmission electron microscope (TEM). Protein levels for AMPK, pAMPK, acetyl-CoA carboxylase (ACC), pACC, AEG-1, pULK-1 and β-actin were measured by western blot. AMPK and AEG-1 gene expression was downregulated using siRNA. DIM and ring-DIMs induced autophagy by increasing autophagic vacuoles and LC3B-I to LC3B-II conversion in LNCaP and C42B cells. These compounds also induced AMPK, ULK-1 and ACC phosphorylation in a time dependent manner. Interestingly, DIM, 4,4’-dibromoDIM and 7,7’ dichloroDIM induced the oncogenic protein AEG-1 time dependently in LNCaP and C42B cells. Downregulation of AEG-1 or AMPK inhibited DIM- and ring-DIM-induced autophagy. Pretreatment with ULK1 inhibitor MRT 67307 in a time dependent manner.

33299 Radiation induced p53-dependent cytoprotective autophagy fails to reduce radiation sensitivity in H460 non-small cell lung cancer cells. Jing-wen Xu,1 Tareq Saleh,2 Lihya Tyutynsk-Massey,3 Yinglang Wu,4 David A. Gewirtz,2 Shenyang Pharmaceutical University, Shenyang, China; 2VCU Massey Cancer Ctr., Richmond, VA.

Our previous studies showed that radiation-induced autophagy could be either cytoprotective or nonprotective in A549 non-small cell lung cancer cells, HN30 and HN6 head and neck cancer cells and 4T1 breast tumor cells, and that this functional difference was related to the status of p53 in the cells (i.e. cytoprotective autophagy in p53 wild type (wt) cells and nonprotective autophagy in cells with mutant or null p53)[1]. Despite the fact that inhibition of autophagy has been proposed as a strategy to overcome resistance to radiation and chemotherapy, there is little direct information in support of the premise that the induction of autophagy confers resistance. As an example, studies in HCT-116 cells that are either wt or null in p53 demonstrate essentially identical radiation sensitivity [2], although the nature of radiation induced autophagy was not determined in these cell lines. To address this question, p53 wt and p53 null H460 cell lines were utilized to evaluate whether cytoprotective autophagy actually suppressed radiation sensitivity. Acridine orange staining, flow cytometric analysis and western blotting (LC3B, p62, Atg5) showed that following exposure to 6 Gy of radiation wt p53 and p53-null H460 cells exhibited a significant induction of autophagy. p53 wt H460 cells showed sensitization to radiation upon pharmacological inhibition of autophagy. However, p53 null H460 cells were utilized to evaluate whether cytoprotective autophagy actually suppressed irradiation sensitivity. Acridine orange staining, flow cytometric analysis and western blotting (LC3B, p62, Atg5) showed that following exposure to 6 Gy of radiation wt p53 and p53-null H460 cells exhibited a significant induction of autophagy. p53 wt H460 cells showed sensitization to radiation upon pharmacological inhibition of autophagy. However, p53 null H460 cells were utilized to evaluate whether cytoprotective autophagy actually suppressed irradiation sensitivity. Acridine orange staining, flow cytometric analysis and western blotting (LC3B, p62, Atg5) showed that following exposure to 6 Gy of radiation wt p53 and p53-null H460 cells exhibited a significant induction of autophagy. p53 wt H460 cells showed sensitization to radiation upon pharmacological inhibition of autophagy. However, p53 null H460 cells were utilized to evaluate whether cytoprotective autophagy actually increased radiation sensitivity [2]. The combination treatment of 3-MA and UA significantly increased the apoptotic cell death as monitored by increased protein expression of Caspase-3 and PAPR. Conclusions: UA could induce autophagy in hepatoma SK-Hep-1 cells through inhibition of mTOR and PI3K signaling pathways. SK-Hep-1 cells treated with UA exhibited LC3-II conversion, increased protein expression levels of Beclin, Atg-7, and Atg-5 along with reduced protein expression levels of p62. UA-induced apoptosis was enhanced by the treatment of autophagy inhibitor 3-MA. Our findings may assist in the development of novel chemotherapeutic agents for the treatment of malignant types of liver cancer.

Withaferin A (WA), a bioactive molecule from Withania somnifera, is known to induce autophagy inhibitory effects. Elevated levels of sequestosome 1 (SQSTM1/p62) and decreased turnover of LC3. WA was found to be a potent lysosomal deacidification agent capable of blocking autophagic flux. Accordingly, inhibiting autophagy by blocking formation of autophagosomes or elevating lysosomal pH did not interfere with WA-mediated growth inhibition. WA blocked autophagic flux decreasing recycling of cellular fuels leading to reduced energy supply. Investigating this alternative mechanism, we discovered that indeed, WA induced an increase of LC3-II to LC3-I ratio, which was evident by higher level of sequestosome 1 (SQSTM1/p62) and decreased turnover of LC3. WA was found to be a potent lysosomal deacidification agent capable of blocking autophagic flux. Accordingly, inhibiting autophagy by blocking formation of autophagosomes or elevating lysosomal pH did not interfere with WA-mediated growth inhibition. WA blocked autophagic flux decreasing recycling of cellular fuels leading to reduced energy supply. Investigating this alternative mechanism, we discovered that indeed, WA induced dysregulated autophagy-degradation and promotion of energetic impairment. Conclusions: WA induced autophagy by blocking formation of autophagosomes or elevating lysosomal pH. This resulted in decreased energy production, thereby inhibiting cancer cell death. WA might be a useful strategy to convert cancer cell line to autophagy regimes to evade cytoprotective effects of autophagy.
L-asparaginase has been used for more than three decades in acute lymphoblastic leukemia (ALL) patients and remains an essential drug in the treatment of ALL. Poor response to L-asparaginase is associated with increased risk of therapeutic failure in ALL. However, both the metabolic perturbation and molecular context of L-asparaginase-treated ALL cells has not been fully elucidated. Here we identify the treatment with L-asparaginase results in metabolic shutdown via the reduction of both glycolysis and oxidative phosphorylation, accompanied by mitochondrial damage and activation of autophagy. The autophagy is involved in reducing reactive oxygen species (ROS) level by eliminating injured mitochondria. Inhibition of autophagy enhances L-asparaginase-induced cytotoxicity and overcomes the acquired resistance to L-asparaginase in ALL cells. The ROS-induced feedback loop is an essential mechanism of this synergistic cytotoxicity. Thus, our findings provide the rationale for the future development of combined treatment of L-asparaginase and anti-autophagy drug in ALL patients.

**#3303** Survivin negatively regulates autophagy through interference with the formation of Atg5-Atg12-Atg16L complex in breast cancer cells. Hsiu-Han Chan,1 Mohane Selvaraj Coumar,2 Siao-Muk Cheng,3 Shing-Ling Tsai,1 Chun-Hui Lin,1 Shang-Hung Chen,1 Euphemia Leung,2 Chun Hei Antonio Cheung2.1National Cheng Kung Univ. College of Medicine, Tainan, Taiwan; 2Pondicherry University, Ponducherry, India; 3National Health Research Institutes, Taichung, Taiwan; 4The University of Auckland, Auckland, New Zealand.

Survivin, a member of the inhibitors-of-apoptosis proteins family, is highly expressed in different cancers and its expression is correlated with tumorigenesis and tumor metastasis. At the cellular and molecular levels, Survivin is a dual functions protein that promotes mitosis and also inhibits apoptosis. In this study, we found that Survivin in a novel negative-regulator of autophagy. Molecular analysis and computational modeling revealed that Survivin negatively regulates the formation of Atg5-Atg12 conjugates, which plays important roles in the process of autophagosome elongation, in breast cancer cells. It also negatively regulates the expression and activity of cathepsin L in cells. Interestingly, we found that Survivin binds to p62/SQSTM1 and LC3B and is also an autophagic substrate protein in which its expression is partly downregulated by autophagy at the protein level. Finally, mechanistic study revealed that YM155, a Survivin inhibitor that was originally developed to inhibit Survivin gene transcription, downregulates Survivin expression in part through autophagic protein degradation. Taken together, findings of this study provide new mechanistic insights into both molecular functions and regulations of Survivin and the molecular mechanism of actions of YM155, a drug currently undergoing clinical trials for cancer treatment.

**#3304** Inhibition of autophagy enhances mitochondria-related apoptosis in malignant mesothelioma cells by combinational sulfaphenacine. YoonJin Lee,1 David M. Lee,2 Hae Nam,1 Sang Lee1,2 Soonchunhyang Univ. College of Medicine, Cheon-An Chong-Nam, Republic of Korea; 3University of Maryland, College Park, MD.

Drug resistance to current chemotherapy regimens has been considered a cell survival adaptive response in malignant mesothelioma cells. Therefore, new strategies to enhance the apoptotic signal and overcome resistance to chemotherapeutics are necessary to improve treatment outcomes for this deadly disease. Here, the effect of sulfaphenacine, an isothiocyanate compound derived from glucoraphanin present in cruciferous vegetables, on enhancing anticancer role of cisplatin was investigated in malignant mesothelioma cells. At concentrations showing little toxicity in normal human mesothelial MeT-5A cells, the combined treatment with both compounds exhibited synergistic growth-inhibiting and apoptosis-promoting effects, as demonstrated in a series of pro-apoptotic events including reactive oxygen species (ROS) accumulation, loss of mitochondrial membrane potential, up-regulation of p53, increased Bax/Bcl-2 ratio, activation of caspase-3, and the occurrence of a sub-G0/G1 peak with an increase in the cells with pyknotic and fragmented nuclei, Annexin V-FITC (+), and G2/M phase transition delay in the cell cycle. The levels of phosphorylation of both Akt and mTOR were decreased by the combined treatment, which was accompanied by a significant increase in the level of autophagosomal marker protein LC3-II and the accumulation of acidic vesicular organelles. Furthermore, scavenging of ROS by antioxidant N-acetylcysteine inhibited both the apoptosis and autophagy, while the inhibition of apoptosis by bafloxacin A1 potentiated apoptotic cell death following the combination treatment of sulfaphenacine and cisplatin, indicating the cytoprotective role of autophagy counteracts apoptosis of malignant mesothelioma cells. Considering the pro-oxidant-based combinational approach, our data provide a rationale for targeting cytoprotective autophagy as a potential therapeutic strategy for malignant mesothelioma.

**#3305** Autophagic induction through upregulation of sestrin-2 transcription and mRNA stability mediates the anticancer effect of new compound Chia-F. Xiaohui Hua,1 Chuanshu Huang,2 Xuere Wu,2 Jingxia Li3.1 Nelson Institute of Environmental Medicine, New York University, Tuxedo Park, NY; 2Wenzhou Medical University, China; 3Departments of Urology, New York University School of Medicine, New York, NY; 4Nelson Institute of Environmental Medicine, New York University, Tuxedo Park, NY.

Chia-F is a novel conformation-derivative of Chelensisin A (Chel A), which is a new styryl-lactone isolated from Chinese Herb Goniothalamus chelensis Huand shows potent antitumor potential effect both in vitro and in vivo. However, the anticancer activity and its potential mechanisms underlying Chia-F activity have never been explored. In present study, we evaluated the potency of Chia-F on anchorage-independent growth and its association with autophagic responses in human high grade invasive bladder cancer cells. We found that Chia-F significantly inhibited anchorage-independent growth of human bladder cancer cells by induction of autophagy in a sestrin2(SEN2)-dependent fashion. Our results revealed that Chia-F treatment specifically induced SEN2 expression via increasing its both gene transcription and mRNA stability. On the one hand, Chia-F treatment markedly attenuated Dicer protein abundance, and in turn abolished miR-27a maturation and further relieved miR-27a directly binding to SEN2 mRNA 3’UTR, thereby promoting SEN2 mRNA stabilization. On the other hand, Chia-F treatment promoted Sp1 abundance and consequently mediated SEN2 transcription. Moreover, either knockdown of Sp-1 or ectopic expression of miR-27a could abolish the autophagic response and reversed the inhibition of anchorage-independent growth in human bladder cancer cells. These results demonstrate that anticancer effect of Chia-F is mediated by its activating autophagic pathway through promoting both SEN2 mRNA transcription and stabilization, which offers novel insights into the anticancer effect of Chia-F on bladder cancer and provides a therapeutic alternative against human bladder cancer.

**#3306** Inhibition of ribosomal protein S6 (rpS6) phosphorylation and cell proliferation by a novel chloroquine analog in lung cancer cells. Juan Sironi, Evelyn Aranda, Lars Nordstroem, Roman Perez Soler, Edward L. Schwartz. Albert Einstein College of Medicine, Bronx, NY.

Autophagy is an evolutionarily conserved self-defense mechanism that allows tumor cells to overcome stress during oncogenesis and after treatment with chemotherapy. It is the basis of clinical trials using the autophagy inhibitors chloroquine (CQ) and hydroxychloroquine (HCQ). While searching for novel agents targeting autophagy, we discovered a compound, named EAD1, that in preclinical trials was inhibitory in cell proliferation of a variety of cancer cell lines whose proliferation was inhibited by EAD1 were H1650 NSCLC cells. This was surprising as H1650 cells have a biallelic deletion within the Atg7 locus. Atg7 is a critical component of the canonical autophagy pathway and its loss renders cells autophagy-deficient. This was confirmed in H460 and Atg7-knockout cells. That these cells had the same sensitivity to EAD1 (and HCQ) as did cells with an intact autophagy pathway suggests that inhibition of autophagy was not the mechanism by which those drugs inhibit cell proliferation. We therefore conducted exploratory experiments to identify other possible sites of action of EAD1. The only molecular change we observed with EAD1 was the selective inhibition of ribosomal protein S6 (rpS6) phosphorylation, which correlated with its inhibition of cell proliferation. rpS6 is a component of the 40S ribosome subunit, and is only one of two ribosomal proteins known to be phosphorylated in a regulated manner. The decrease in rpS6 phosphorylation also occurred in the Atg7-deficient cells, indicating it was not a consequence of autophagy inhibition. rpS6 regulates cell size, survival, and migration. Consistent with these reports, we found that EAD1 caused a significant decrease in the size of the H460 cells (when controlled for cell cycle distribution), and this decrease was not seen with HCQ. rpS6 is phosphorylated and activated by two known families of kinases, p70 S6K and p90 RSK, that are downstream targets of the mTORC1 and the RAS/MEK/ERK pathways, respectively. However, we have not seen any changes in the expression or phosphorylation of the members of these pathways, leading us to hypothesize that EAD1 is either having a direct effect on rpS6, or that it is blocking the kinase activity of an already activated p70S6K or p90RSK. Further studies are needed to determine the role of rpS6 in cancer cells, and to assess if it is a viable target for future drug development.

Background: In the curative setting for head and neck cancer (HNC) a commonly used treatment is radiation combined with the anti-EGFR monoclonal antibody cetuximab (CTX). However, despite decades of research into improved treatments, therapeutic resistance remains a major challenge for this malignancy with roughly 40% of patients developing recurrent disease. We are studying the molecular mechanisms by which radiation and cetuximab induce autophagy and how this process can be modulated to improve the efficacy of therapy. Methods: We evaluated a panel of both human papillomavirus (HPV) positive and negative HNC cell lines for autophagic response to both CTX treatment and ionizing radiation (XRT). Induction of autophagy was detected by immunoblot fluor assays for LC3 and p62 and by immunofluorescent staining of autophagolysosomes. siRNA knockdown of EGFR, LAMTAPB, ULK1, Beclin1 and others was used to probe the involvement of different signaling molecules. The addition of specific autophagy inhibitors, such as the ULK1 inhibitor SBI-0206965, to CTX or XRT treatment was tested to determine whether the reduction of autophagic response reduced cell survival in a clonogenic survival assay. Induction of apoptosis was analyzed by annexinV and propidium iodide staining of cells and by Western blot (WB) analysis of p62, Beclin-1 and LC3B processing. The addition of specific autophagy inhibitors to standard treatments may provide a way to overcome resistance to therapy.

#3308 Mitophagy induction and interference with cancer-specific apoptosis in SHetA2-treated cells. Vishal Chandra,1 Andrew Long,2 Chionio Patricia Masamha,3 Doris Mangiaracina Benbrook1. 1University of Oklahoma Health Sciences Center (OUHSC), Oklahoma City, OK; 2Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany; 3Butler University, Indianapolis, IN.

Background: SHetA2 is a small molecule flexible heteroaromatic (Flex-Het) compound that exhibited in-vivo cancer therapeutic and chemoprevention activity, lack of mutagenicity or teratogenicity, and a pharmacologic profile suitable for an oral drug. First-in-human clinical trials of SHetA2 for ovarian cancer prevention and cervical cancer treatment are in development. Autophagy is induced in cancer cells by a wide variety of therapeutic drugs and commonly interferes with the drugs efficacies. Because SHetA2 binds to mitochondrial and induces mitochondrial damage and apoptosis in cancer, but not in healthy cells, we hypothesized that this drug induces mitochondria-selective autophagy (mitophagy) in cancer, but not healthy cells; and that the mitophagy interferes with SHetA2-induced apoptosis. Methods: Cultures of human ovarian and cervical cancer cell lines and human ovarian surface epithelium (HOSE) were treated with various concentrations and combinations of SHetA2, 3-methyladenine (3-MA), Beclin-1 siRNA, and caspase inhibitors. Autophagy was evaluated by electron microscopy (EM) and fluorescent imaging of LC3B processing in cells and by Western blot (WB) analysis of p62, Beclin-1 and LC3B processing. Mitophagy was measured by EM of cells and WB analysis of BNPI3 total levels and co-immunoprecipitation with LC3B in protein extracts. Apoptosis was measured by Annexin-V and propidium iodide staining of cells and by WB analysis of caspase 9 and 3 and PARP-1 cleavage. Result: Induction of autophagy by SHetA2 treatment was demonstrated by the development of double-membrane autophagosomes and accumulation of the processed LC3B II in cancer, but not in HOSE cells. Mitophagy was demonstrated by the presence of mitochondria inside the autophagosomes and by reduction of total BNPI3 in association with increased BNPI3/LC3B complexes in SHetA2-treated cells. Autophagy flux was demonstrated by gradual reduction of p62. Conversion of autophagy to apoptosis was associated with reappearance of basal p62 levels and cleavage of Beclin-1, PARP-1, and caspase 9 and 3 about 24 hours after initiation of treatment. Interference of the autophagy with apoptosis was demonstrated by the treated levels of apoptosis in cells co-treated with SHetA2 and autophagy inhibitors (3-MA or Beclin-1 siRNA) along with reduced apoptosis in cells co-treated with SHetA2 and an autophagy inducer (rapamycin). This was observed in cell lines harboring mutant or no p53, but not in an ovarian cancer cell line with wild type p53. Conclusion: SHetA2-induction of autophagy may be initiated by mitochondrial damage and reduces, but does prevent, SHetA2-mediated apoptosis in ovarian and cervical cancer cell lines, but not in a cell line with wild type p53 or in HOSE cells. Combination of SHetA2 with an autophagy inhibitor may improve the therapeutic efficacy in clinical trials of patients harboring mutant or loss of p53 protein. Funded by: RO1CA196200 and RO1CA200126.

#3309 Tumor-treating fields decrease proliferation and clonogenicity of patient-derived WHO grade IV glioma cell lines. Sharon K. Michellhaugh, Sam Kousis, Adrienne Wallace-Povrik, Sandeep Mittal. Wayne State University, Detroit, MI.

Despite decades of research, efficacious treatments for malignant glioma tumours are limited. Tumor-treating fields (TTFields) are FDA-approved for the treatment of newly-diagnosed and recurrent glioblastoma. In this study, in vitro experiments comparing TTFields to untreated controls were performed on patient-derived grade IV glioma cell lines to determine the effects of TTFields on cell proliferation and clonogenicity. Methods: Studies utilizing patient tumor specimens were approved by the Wayne State University Institutional Review Board and written informed consent was obtained from participants. Patient tumor specimens (glioblastoma and gliosarcoma) were collected immediately following microsurgical resection. Single-cell suspensions from the tumor tissues were prepared by enzymatic and mechanical disruption. Equal numbers of cells were plated on plastic coverslips in DMEM/F12 media supplemented with 10%fetal bovine serum. TTFields were applied at 200 kHz to half of the coverslips. Culture media was replaced every day. At the conclusion of the 2 week treatment, cell proliferation was assessed with the XTT assay and cells were harvested and replated for clonogenic assays (10,000 cells/well). The resulting colonies were fixed and stained with crystal violet and counted with an automated colony counter. Control vs. TTFields treated groups were compared by two-tailed t-tests. Results: The two-week TTFields treatment significantly reduced cell proliferation in both the glioblastoma (41.6 ± 11.1% control; n=4; p<0.001) and in the gliosarcoma (41.6 ± 16.6 % control; n=4; p<0.002) as measured by XTT assay. The clonogenic assay revealed that the number of colonies generated from both cell lines was reduced by TTFields treatment. For the glioblastoma cell line, control cells yielded 847 colonies with an average diameter of 462.8 ± 5.6 μM while TTFields-treated cells yielded 561 colonies with an average diameter of 435.1 ± 7.3 μM, which was a statistically significant decrease (p=0.0022). For the gliosarcoma cell line, control cells yielded 809 colonies vs. 144 colonies from the TTFields treated cells, although the average diameter of the colonies was unchanged between groups (control 375 ± 176.1 μM; TTFields 362.9 ± 190.0 μM). Conclusions: In vitro application of TTFields markedly reduced cell proliferation and clonogenicity in both patient-derived WHO grade IV glioblastoma and gliosarcoma cell lines. This is the first report on the in vitro effects of TTFields on gliosarcoma.

#3310 Atg7 overexpression promotes bladder cancer invasion via autophagic removal of AUFI protein and subsequently increased RhoGDI2 mRNA stability in vitro and in vivo. Junlan Zhu, Yang Li, Chuanshu Huang, Haishan Huang. New York Univ. School of Medicine, Tuxedo Park, NY.

Despite the promising role of autophagy in cancer biology, the role of autophagy in bladder cancer (BC) invasion remains largely unknown. BC is a common malignant urothelial tumor threatening metastases, understanding the molecular mechanisms underlying BC invasion is of tremendous importance for potentially reducing the mortality of this disease. In the present study, we for the first time found that the Atg7 was remarkably upregulated in human BC cell lines and the BBN-induced mouse invasive BCs, which is consistent with our most recent finding in human BCs. The knockdown of Atg7 in human BC cells dramatically inhibited cancer cell invasion, suggesting that Atg7 is a key player in regulation of BC invasion. Mechanistic studies revealed that Atg7 overexpression was mediated by miR-190, which was highly upregulated at transcriptional level in BC tissues and cell lines, and was able to bind to 3'-UTR of atg7 mRNA for degradation. Moreover, Atg7 mediated autophagic mechanism could remove AUFI protein and in turn reduced AUFI1 interaction with rhogdi2 mRNA, resulting in elevation of rhogdi2 mRNA stability, and subsequently leading to BC cell invasion. Remarkably, inhibition of Atg7-mediated autophagy led to AUFI protein accumulation, RhoGDI2 downregulation and BC cell invasion attenuation. Collectively, our results demonstrated that overexpression of Atg7 mediates BC cell autophagy, which removes AUFI protein, thereby reducing its binding with rhogdi2 mRNA and subsequently leading to elevation of rhogdi2 mRNA stability and protein expression, further promoting BC invasion. The identification of miR-190/Atg7 autophagic mechanism regulating AUFI/RhoGDI2 expression provides a sig-

MOLECULAR AND CELLULAR BIOLOGY / GENETICS: Autophagy and Cancer

Proceedings of the American Association for Cancer Research • Volume 58 • April 2017
significant insight into understanding the nature of BC invasion, and is also highly potential for developing autophagy-based-specific therapeutic strategy for treatment of human BC patients.

**#3311 The alteration in key regulator genes of autophagy is mainstream mechanism of therapy resistance and impact prognosis of acute myelogenous leukemia (AML); results from diagnosis genomic analysis on 148 consecutive patients treated with intensive chemotherapy and long-term survival follow-up.**

Giovanni Marconi,1 Cristina Papayannidis,1 Maria Chiara Fontana,1 Antonio Padella,1 Anna Ferrari,1 Eugenia Franchini,1 Stefania Paolini,1 Maria Chiara Abba Benenate,1 Chiara Sartor,1 Francesca Volpato,1 Viviana Guadagnuolo,2 Silvia Lo Monaco,1 Elena Tenu,1 Andrea Ghelli Luserna Di Rora,1 Valentina Robustelli,1 Nicoletta Testoni,1 Giorgia Simonetti,1 Emanuela Ottaviani,1 Giovanni Martinelli2,1 Institute of Hematology, Bologna, Italy; 2Cellify, Bologna, Italy.

Introduction: There are no clear evidences if autophagy can lead to therapy resistance or favor apoptosis in cancer; it can function as a pro-apoptotic mechanism, or it can improve stresses survival clearing damaged mitochondria and proteins accumulation. Levels and activity of pro-apoptotic and anti-apoptotic proteins, particularly bcl-2 and bcl2, high levels of CAMP, and a complex made by pink/park could play as fulcrum of this yin and yang effect of autophagy. Our study aims to define the role of autophagy in AML, and to establish if gain or loss in autophagy could reduce the patients’ chance to respond to induction, and to worsen OS.

Methods: We analyzed 148 consecutively newly diagnosed non M3 AML patients treated with induction chemotherapy regimens containing at least one dose of anthracycline. We screened all patients for TP53, FLT3, NPM1 mutations; we performed Affymetrix SNP array 6.0 or Cytoscan HD. Survival analysis was performed using the Kaplan-Meier method. Differences between survival rates were evaluated using Mantel-Cox analysis. Gene expression was calculated using the Affymetrix GDS 2655 platform.

Results Autophagy alteration (gene group 1: ULK1 CHR11; ULK1 CHR17; BECN1; ATG4; AMBRA1; UVRAG; ATG9B; PIK3C3; PIK3R4) were related to lower Complete Remission rate (CR%) after induction in univariate (p<.001) and multivariable regression with age, karyotype, secondary AML, TP53 mutation (p<.014); autophagy alteration shown to confer worst OS (p<.001) and was significantly associated with complex karyotype and TP53 mutation (p<.001).

We detected significant differences in terms of survival independently both in gain and loss in group 1 genes (p<.001). Furthermore, we investigated genes in AMPK pathway (group 2: SESN1; PRKAA1 CHR 3; PRKAB1; PRKAA1 CHR 1; PRKAG1 CHR 11; PRKAG1 CHR 7; PRKAG3; PRKAB1) and other genes that could be related to a switch from a physiological role of autophagy to a resiliency mechanism (group 3: CCND1; BCL2; PINK1; PARK2; TP53; MDM1; MDM4); alterations in those genes were shown to confer worst OS (p<.001 in both groups); Alteration in group 2 and group 3 were related to lower CR% after induction (p<.001 in both groups). Whole Exome Sequencing on 56 patients in our set did not found any significant mutation in genes we analyzed with the exception of TP53.

Conclusion: Our work investigates for the first time with a genomic approach the role of autophagy in AML. We found that both gain and loss in autophagy key regulator genes are associated with poor prognosis and therapy resistance. A loss in autophagy could enhance proliferation and block apoptosis; a gain could give cell resiliency, favoring cytoplasm turnover, damaged epithelium, intracellular neutralizing oxidative damages. **#3312 A novel plate-based assay for screening autophagic activity in 2D and 3D cell culture models.**

Dan F. Lazar,1 Amani A. Gillette,2 Braeden L. Butler,1 Christopher T. Egggers,1 Brock F. Binkowski,1 Gedinmas Visdugris,1 Michael R. Slater,1 Dongxing Ma,1 James J. Cali3,1 Promega Corporation, Madison, WI; 2University of Wisconsin, Madison, WI; 3University of Virginia, Charlottesville, VA.

The critical importance of autophagy in cell health and its proposed role in disease-relevant biology, including cancer, inflammation, and immunology, has increased the need for more effective assays to screen for agents that modulate autophagic activity. Here we utilize NanoLuc Binary Technology (NanoBiT) to determine autophagic activity in 2D and 3D culture models. In this approach, an exogenous LC3G120A fusion protein was tagged on its N-terminus with an 11 amino acid peptide (HiBiT) and stably expressed in mammalian cells, including U2OS and HEK293. After exposure to various treatment conditions, cellular levels of this novel autophagy reporter were determined by addition of a lytic detection reagent containing Large Bit (LgBiT). LgBiT rapidly associates with HiBiT in the cell lysate, producing a bright, luminescent enzyme in the presence of the furimazine substrate. The bright signal allows low levels of expression of the reporter, maximizing the assay response, and the signal is stable, allowing assay of multiple 96- or 384-well plates in the same experiment. In response to autophagic stimuli, including nutrient deprivation and various mTORC inhibitors (e.g., PP242 and rapamycin), autophagic degradation of expressed LC3 reporter was evident by reduced assay signal. In contrast, in response to both upstream (e.g., 3-MA and wortmannin) and downstream (e.g., bafilomycin A1 and chloroquine) inhibitors of the autophagy pathway, degradation of the autophagic reporter was effectively blocked (HiBiT) or increased (HiBiT), with compound effects time dependent and stratified according to expected potency and efficacy of the test agents employed. The use of a mutant reporter based on LC3G120A further demonstrated the specificity of the wild-type LC3 reporter for the detection of autophagic activity. When assayed in 384-well plates with combination, HEK293 autophagy reporter cells produced Z’ values of ~0.7 in response to autophagic induction with PP242, while subsequent blockade of autophagy with bafilomycin A1 resulted in Z’ values of ~0.8. This data, and subsequent LOPAC library screening, indicates the potential utility of this assay method for HTS applications.

**#3313 Autophagic ovarian cancer cells exhibit substantially enhanced sensitivity to Crizotinib.**

Alicia M. Blessing, Yan Wang, Weiqun Mao, Lan Pang, Zhen Lu, Robert C. Bost. UT MD Anderson Cancer Cent., Houston, TX.

One of the major factors contributing to poor outcomes for patients with ovarian cancer is the persistence of dormant, drug resistant cancer cells after primary surgery and chemotherapy. Recurrent, progressively growing ovarian cancer metastases are generally well vascularized and may only have a small fraction of cancer cells undergoing autophagy. By contrast, the persistent, drug resistant, dormant cancer cells that remain on the peritoneal cavity after conventional treatment tend to be poorly vascularized. In this nutrient-poor, avascular microenvironment autophagy is widespread and can be found in more than 80% of cases. Drugs that regulate survival in autophagic cancer cells may be much more active when administered as maintenance therapy than when used to treat gross primary or recurrent disease.

Using unbiased siRNA screens, we have identified target genes that regulate the survival of ovarian cancer cells that are undergoing autophagy that has been induced by the re-expression of DIRAS3 or by amino acid starvation. Knockdown of the anaplastic lymphoma kinase (ALK) significantly reduced survival of ovarian cancer cells that were undergoing autophagy. Importantly, the FDA-approved ALK inhibitor, Crizotinib, exhibited significantly greater toxicity after induction of autophagy by upregulation of DIRAS3 (ARH) in OVCAR8, CAOV3, and SKOV3 ovarian cancer cells. Induction of autophagy by upregulation of DIRAS3 in SKOV3 ovarian cancer cells reduced the IC50 of Crizotinib from 7.44 μM to 0.04708 to 2.129μM > 0.06152 (P<0.05). Conversely, siRNA knockdown of DIRAS3 in CAOV3 cells with endogenously high DIRAS3 expression and increased autophagy increased the IC50 of Crizotinib from 204 nm to 0.01265 to 267 nm < 0.01715 (P<0.05). Our studies in cell culture suggest that Crizotinib might provide an effective agent to eliminate autophagic, dormant drug resistant ovarian cancer cells that remain after conventional cytoreductive surgery and combination chemotherapy. Subsequent studies will evaluate the effect of Crizotinib in xenograft models of DIRAS3-induced ovarian cancer dormancy.

**#3314 Synergistic effects of chemotherapy-induced autophagy and epigenetic remodeling.**

Liliya Tyutyunyk, Joseph Landry, Tareq Saleh, David Gewirtz. Virginia Commonwealth University, Richmond, VA.

Cytotoxic chemotherapy has been shown to enhance tumor cell immunogenicity by promoting the secretion of damage-associated molecular pattern (DAMP) molecules which, in turn, stimulate innate and adaptive immune responses. This effect can be further stimulated by combining chemotherapy with an immunotherapy designed to enhance effector cell function (CD8 T cell or NK cell) anti-tumor activity. Our studies demonstrate that knockdown of the epigenetic regulator NURF increases DNA damage (gamma H2AX staining) and autophagy (acidine orange staining) in breast tumor cells exposed to doxorubicin and enhances growth inhibition as well as supressing the capacity of the cells to recover and proliferate. Similar increases in autophagy were observed using a small molecule inhibitor of NURF, suggesting that NURF can be targeted therapeutically. Sensitization was not observed with ionizing radiation or cisplatin. Studies are in progress to assess the nature of autophagy in the NURF KD and NURF WT cells, distinguishing between the cytoprotective, cytotoxic, cyto
tostatic and nonprotective forms. How NURF regulates doxorubicin induced DNA damage is being investigated by mapping sites of damage genome wide. It is anticipated that enhanced cell autonomous tumor cell sensitivity in concert with improvements in tumor cell antigenicity (cell non-autonomous sensitization) achieved by NURF depletion could improve anti-tumor immunogenicity, achieve tumor regression, reduce metastasis, and possibly achieve long term remission in breast cancer.

TTFields tumor treating fields (TTFields) are an established anti-neoplastic treatment modality in patients with glioblastoma. TTFields are delivered via noninvasive application of low-intensity, intermediate-frequency, alternating electric fields to the region of the tumor. Previous studies have shown that TTFields treatment lead to increased cellular granularity, which is often associated with autophagy. Autophagy has been shown to regulate cell survival and proliferation under stress conditions and to influence cellular response to cytotoxic drugs. This study evaluated the role of autophagy in cancer cells treated with TTFields. Immunoblot analysis showed significant elevations in levels of lipidated Microtubule Associated Protein Light Chain (LC3-II) in TTFields-treated glioma and lung cancer cells. Increased autophagy following TTFields application in these cell lines was also detected using fluorescence microscopy, where punctate distribution of LC3-II was observed. TEM micrographs demonstrated the presence of autophagy typical, autophagosome-like structures in TTFields-treated U-87 MG cells. Combination of TTFields with autophagy inhibitors, chloroquine and melfoquine, resulted in a significant dose-dependent reduction in cell growth compared with TTFields treatment alone. Inhibition of autophagy with chloroquine triggered apoptosis as indicated by elevated levels of AnnexinV/7AAD double staining. Increased levels of autophagic flux in TTFields-treated cells were not associated with reduced mTOR activity, which was monitored by p70S6K phosphorylation immunoblot analysis. TTFields are known to exert anti-mitotic effects by disrupting highly dipolar structures that play critical roles in mitosis. Our results demonstrate that TTFields additionally induce cellular autophagy by an mTOR-independent mechanism. TTFields- treated cell lines appear to utilize autophagy as a survival mechanism. Thus, inhibition of autophagy sensitizes tumor cells to TTFields treatment, resulting in elevated apoptotic cell death. Future studies are warranted to examine the extent to which TTFields-elicited autophagy may affect treatment outcomes and to investigate the therapeutic implications of combining TTFields with autophagy inhibitors in vivo.

Ovarian cancer (OC) is the most lethal gynecologic malignancy. Persistence of dormant, drug resistant cancer cells is one of the major factors that contribute to poor outcomes. The Poly (ADP) ribose polymerase (PARP) inhibitor, olaparib, has shown promising anti-cancer activity and has been approved by the FDA for the treatment of ovarian cancer with BRCA1/2 mutations. Olaparib targets DNA repair deficiencies in cancer cells. Autophagy can protect cancer cells from chemotherapy or can enhance the response to certain drugs. In this study, we have asked whether autophagy protects OC cells against the cytotoxic effects of olaparib or augments damage. We first determined PARP activity using a modified PARP activity assay in different OC cell lines. Olaparib-induced autophagy was determined by punctate localization of GFP-LC3, conversion of LC3 to LC3II on protein blots and electron microscopy. To test whether autophagy contributes to the resistance of OC cells to olaparib, we determined the role of autophagy inhibition on the sensitivity of OC cells to olaparib by either using the pharmacologic inhibitors chloroquine (CQ), LY305 or short interfering RNA (siRNA) against ATG7. Upon investigation of a potential mechanism of olaparib-induced autophagy we evaluated the production of reactive oxygen species (ROS). K, Ataxia-telangiectasia mutated (ATM), mTOR and p70S6K. Inhibition of PARP by olaparib treatment, decreased PARP activity in a dose- dependent manner, leading to DNA damage judged by phosphorylation of γ-H2AX. Olaparib treatment decreased cell growth, caused cell cycle arrest and significantly enhanced apoptosis in 5 of 5 OC cell lines. Olaparib induced autophagy in 8 of 8 OC cell lines. Both pharmacologic and genetic inhibition of autophagy increased OC cell sensitivity to olaparib and induced apoptosis in 5 of 6 OC cell lines. Furthermore, flow cytometry and western blot analysis demonstrated that olaparib treatment increased ROS production and increased the phosphorylation of JNK and ATM while decreasing the phosphorylation of mTOR and p70S6K. Taken together, our data described autophagy as a potential mechanism of olaparib resistance in OC that may depend upon the activation of ATM and JNK by ROS downregulating mTOR and p70S6K.

Combination of olaparib with CQ, LY305 or other autophagy inhibitor may provide a novel strategy to increase the efficacy of olaparib in OC. Current studies are underway to test our hypothesis in vivo.

#3318 A critical role for c-Jun N-terminal kinase in autophagy and cell survival of breast cancer cells. Rohit Munagala, Carol Joseph, Annie Liu, Kebin Liu, Muthusamy Thangaraju, Patricia V. Schoenlein. Medical College of Georgia Cancer Center, Augusta University, Augusta, GA.

Breast cancer is the most major impediment to the eradication of estrogen receptor positive (ER+) breast cancer. Approximately 30% of ER+ breast tumors initially responsive to antiestrogen therapy will acquire resistance. One approach to reducing the occurrence of acquired antiestrogen resistance is to identify and target key signaling nodes that specifically attenuate the ability of antiestrogens to kill cancer cells. Toward this goal, we identified MEK/ MAPK1/2 as a key molecular target based on the general inability of antiestrogens to effectively block MEK1/MAPK1/2-mediated phosphorylation of BimEL in breast cancer cells. BimEL is a pro-apoptotic member of the BH3 family of proteins that is inactivated (degraded by the proteasome) when phosphorylated by MAPK1/2. The combination of an antiestrogen and MEK1 inhibitor robustly induced BimEL-dependent breast cancer cell apoptosis (Periyasamy-Thanavanan et al., 2012). However, a subpopulation of breast cancer cells survive this combined treatment via an autophagy-dependent mechanism. Based on the key role of JNK in regulating autophagy in cancer cells via BimEL phosphorylation, we hypothesized that JNK was a key effector of autophagy in breast cancer cells surviving antiestrogen treatment when used as a single agent or in combination with a MEK inhibitor. To test this hypothesis, we utilized the selective JNK inhibitor SP600125 as a single agent or in combination with extradrol (E2), 4-hydroxymethoxifen (4-OHT), and/or U0126 (a selective MEK1 inhibitor). Treatments were conducted with the antiestrogen-sensitive cell lines MCF-7 and T-47D and the antiestrogen resistant cell line TR5, previously derived in our laboratory by a step-wise 4-OHT selection. Effects on cell death (determination of apoptosis) and autophagy (determination of autophagy levels and flux) were evaluated for the various hormonal treatments conducted in the presence or absence of JNK inhibition. These studies showed that: (1) targeting JNK in antiestrogen sensitive breast cancer cells induces apoptosis with caspase-dependent cleavage of PARP as a surrogate marker of apoptosis; (2) JNK activity is elevated in antiestrogen resistant TR5 cells and JNK inhibition induces TR5 cell death.

Proceedings of the American Association for Cancer Research • Volume 58 • April 2017

MOLECULAR AND CELLULAR BIOLOGY / GENETICS: Autophagy and Cancer

death; and (3) antiestrogen sensitive and resistant breast cancer cells dying as a result of JNK inhibition can show extensive cytosolic vacuolization with the autophagy protein LC3 (ATG8) localized to the aberrant vacuoles. Overall, our results support the conclusion that JNK plays a key autophagy-dependent survival role in breast cancer cells. Ongoing studies aim to identify the specific JNK protein(s) that disrupt autophagy and enhance death of breast cancer cells toward the goal of identifying specific molecular targets to block autophagy in breast cancer cells.

#3319 Elevating adipokine adiponectin level can induce cytoxic autophagy in breast cancer cells and potentiate the efficacy of chemotherapeutical regimens: preclinical studies. Seung J. Chung, 1 Ganji Purnachandra Nagaraju, 1, Artemugam Nagalingam, 1 Nethaji Muniraj, 1 Panjamurthy Kuppusamy, 1 Alyssa Walker, 1 Juhyung woo, 1 Balázs Györfy, 1 Edward Gabrielson, 1 Neeraj K. Saxena, 1 Dipali Sharma, 1 Johns Hopkins University, Baltimore, MD; 2Emory University, GA; 3University of Maryland, Baltimore, MD; 4Hungarian Academy of Sciences, Hungary.

Adiponectin, an adipocytokine secreted by adipocytes in the breast tumor microenvironment, negatively regulates cancer cell growth hence increased levels of adiponectin are associated with decreased breast cancer growth. However, its mechanisms of action remain largely elusive. We report that adiponectin induces a robust accumulation of autophagosomes, increases LC3II and decreases p62/SQSTM1 in breast cancer cells. Breast cancer cells treated and xenografts exhibit increased expression of autophagy-related proteins. Lysotracker-Red-staining and tandem-mCherry-GFP-LC3 assay show that autophagosomes/lysosomes fusion is augmented upon adiponectin treatment. Adiponectin significantly inhibits breast cancer growth and induces apoptosis both in vitro and in vivo, and these events are preceded by autophagy, which is integral for adiponectin-mediated cell death. Accordingly, blunting autophagosomes-formation, blocking autophagosomes-autolysosome fusion or genetic-knockout of Becn1/Beclin1/ATG7 effectively impedes adiponectin induced growth-inhibition and apoptosis-induction. Mechanistic studies show that adiponectin reduces intracellular ATP levels and increases AMPK phosphorylation leading to ATG1 activation. AMPK-inhibition abrogates adiponectin-induced ATG1-activation, LC3II-turnover and p62-degradation while AMPK-activation potentiates adiponectin’s effects. Further, adiponectin-medited AMPK-activation and autophagy-induction are regulated by upstream master-kinase LKB1, which is a key node in anti-tumor function of adiponectin as LKB1-knockout abrogates adiponectin-mediated inhibition of breast tumorigenesis and molecular analyses of tumors corroborate in vitro mechanistic findings. Adiponectin increases the efficacy of chemotherapeutic agents. Notably, high expression of adiponectin receptor, adiponectin and Becn1 significantly correlates with increased overall survival in chemotherapy-treated breast cancer patients. Collectively, these data uncover that adiponectin induces autophagic cell death in breast cancer and provide in vitro and in vivo evidence for the integral role of LKB1-AMPK-ATG1 axis in adiponectin-mediated cytoxic-autophagy.

#3322 Elucidation of the signaling pathways that mediate berberine-induced effects in cancer cells. Basabi Rana, 1 Rong Ke, 1 Kanchan Vishnoi, 1 Navin Viswakarma, 1 Subhasis Das, 1 Ajay Rana, 1 University of Illinois at Chicago, Chicago, IL.

Resistance towards standard therapeutic regimens and evasion of apoptosis are some of the hallmarks of advanced forms of cancer, which include Sorafenib-resistance in hepatocellular carcinoma (HCC), castration-resistance in prostate cancer. Development of effective therapeutic strategies that can target these resistant forms is critically needed. In an effort to understand the molecular mechanism mediating resistance in cancer, in previous studies utilizing Tumor necrosis factor-related apoptosis-inducing ligand (TRAIL)-resistant cancer cells we showed that combination of TRAIL along with the PPARY ligand Troglitazone (TZD) can sensitize them towards apoptosis. Using more molecular approaches these studies identified the serine/threonine protein kinase, AMP-activated protein kinase (AMPK) as a mediator of TRAIL-TZD-induced apoptosis. Since AMPK seemed to be a major mediator of this apoptosis, in the current studies we utilized the natural compound Berberine (BBR), a known activator of AMPK in combination with TRAIL. These demonstrated a significant reduction of cell viability (MTT assay) and induction of apoptosis (caspase activation) when treated with a combination of TRAIL and BBR. This apoptosis is attenuated in cells expressing AMPKα1 dominant negative (DN), suggesting an involvement of AMPK in mediating this. To understand the downstream targets and the mechanism involved, an apoptosis PCR array analysis was performed, which suggested induction of TNFRSF1B (DR5) gene expression by BBR. In addition, knockdown of DR5 expression attenuated TRAIL-BBR-induced apoptosis, suggesting DR5 to be a potential target of BBR in this apoptotic cascade. Future studies will include determining any crosstalk of AMPK in BBR signaling to modulate DR5 pathway. Our earlier studies also demonstrated an involvement of β-catenin in mediating cancer cell resistance. Stabilizing muta-
tion of β-catenin has been reported to be present in a number of tumors, most profoundly in HCC leading to an activation of Wnt/β-catenin signaling. To understand any role of β-catenin in TRAIL-BBR-induced apoptosis, we determined the effect of BBR on β-catenin pathway. These revealed a significant attenuation of β-catenin protein expression by BBR in various HCC cells in a time and dose-dependent manner. BBR treatment also attenuated β-catenin/ TCF-induced transcriptional activity, indicating antagonism of β-catenin pathway. Our studies indicate that combination of TRAIL and AMPK activator BBR might be an effective means of antagonizing β-catenin pathway and ameliorating TRAIL resistance via DR5 in advanced forms of cancer.

#3323 Anticancer activity of medicinal plant and neuroglioma. Michael Quincy Shivers, 1 Jackson State University, Jackson, MS.

Neuroglioma, also called gliocytoma, is one of the common malignant tumors in central nervous system at present. Neuroglioma can make aggressive growth around brain tissue, so complete radical treatment can be realized by single excision. Nutritional and botanical treatments have been found useful in treating neuroglioma and other types of cancers. Vernonia amygdalina (VA) is a valuable medicinal plant that is widespread in East and West Africa. It has been reported to have not only diverse therapeutic effects for many tropical diseases, but has recently been shown to possess anti-cancer properties. Therefore, the goal of this research was to determine the therapeutic mechanisms of VA leaf extracts in the management of brain tumor. To achieve this goal, Human H4 neuroglioma cells were treated with different concentrations of Vernonia amygdalina for 24 hr. Cell survival was determined by MTS assay. The extent of oxidative cell/tissue damage was determined by measuring malondialdehyde (lipid peroxidation biomarker) concentrations by spectrophotometry. Cell apoptosis was measured by flow cytometry assessment (Annexin V/PI assay). Data obtained from the MTS assay indicated that VA significantly (p < 0.05) reduced the viability of H4 cells in a concentration-dependent manner. We detected a significant (p < 0.05) increase in malondialdehyde (MDA) concentrations in VA-treated glioblastoma cells compared to the control. Flow cytometry data showed a strong concentration-response relationship between VA exposure and annexin V/PI positive cells. Taken together, our finding indicates that VA induced cytotoxicity and apoptosis in H4 cells is associated with the formation of MDA, a by-product of lipid peroxidation and biomarker of oxidative stress. At therapeutic concentrations, VA-induced cytotoxic and apoptotic effects in H4 cells is mediated by oxidative stress.

#3324 FATE1 promotes mitochondrial hyperfusion and supports maintenance of mitochondrial networks following apoptosis stimulation. Anne Hamacher-Brady, 1 Verena Lang, 1 Nathan R. Brady, 1 Johns Hopkins University, Baltimore, MD; 2German Cancer Research Center, Heidelberg, Germany.

FATE1 (fetal and adult testis expressed 1), also known as the cancer-testis antigen B1-HCC-2, is expressed in testis and tumor tissues. FATE1 was recently described as a major survival factor in tumor cells of various origins, by mediating the degradation of the pro-apoptotic BH3-only protein Bik (Maxfield et al., in Nat Commun 2015 Nov 16;6:8480) and through ER-mitochondrial uncoupling (Doughman-Bouguerra et al., in EMBO Rep 2016 Sep;17(9):1264-80). Interestingly, FATE1 shares high sequence homology with the mitochondrial Drp1 receptor MFF (mitochondrial fission factor). We thus investigated a possible role of FATE1 impact on mitochondrial morphology following the stimulation of apoptosis in cancer cells. We found that, similar to MFF, FATE1 is localized to outer mitochondrial membranes and, unlike MFF, additionally localized to the endoplasmic reticulum. Importantly, in contrast to MFF, FATE1 overexpression does not recruit Drp1 to mitochondria, and instead promotes hyperfusion of mitochondrial networks. Co-immunoprecipitation experiments and reconstitution of Mfn2 or Mfn1 in double knockout mouse embryonic fibroblasts indicate a role for the mitochondrial fusion protein Mfn2, but not Mfn1. As FATE1 overexpressing cancer cells were more resistant to mitochondrial fragmentation in response to TNF and valinomycin treatments, we propose FATE1 as a novel regulator of mitochondrial morphology changes occurring during apoptosis, with possible implications in FATE1-mediated resistance of cancer cells to chemotherapy.

Proceedings of the American Association for Cancer Research • Volume 58 • April 2017 849
Ginkgetin, a biflavonoid derived from leaves of Ginkgo biloba, induces autophagic cell death in non-small cell lung cancer via p62. Jian Shu Lou, Cathy Bi, Gallant Chan, Tina Dong, Karl Tsim. The Hong Kong University of Science and Technology, Hong Kong, Hong Kong.

Chemotherapeutic drugs in the treatment of non-small cell lung carcinoma (NSCLC) are usually mediated by induction of apoptosis; this usually results in drug resistant during the therapy. Many compounds from natural resource have been shown to trigger autophagy in promoting cell death, and therefore which could be a novel treatment for cancer. Ginkgetin, a biflavonoid from Ginkgo biloba leaves (Ginkgoaceae), was shown its anticancer effects recently. The leaf of G. biloba is being recorded as a safe herbal drug in Pharmacopoeia from China and Europe. Here, the possible development of ginkgetin as an anticancer drug was demonstrated. Ginkgetin induced the death in A549 (NSCLC) with an IC50 lower than that of cisplatin. This anticancer effect of ginkgetin was also illustrated in NSCLC xenograft nude mice model. Transmission electron micro-scope revealed that ginkgetin-induced autophagy was the main cause of cell death. Autophagy inhibitors, 3-methyladenine and chloroquine but not apoptosis inhibitor Z-VAD-FMK, rescued ginkgetin-induced cell death. Reciprocally, the induction of autophagy by rapamycin promoted ginkgetin-induced cell death, as well as the formation of p62-TRAF6-mTOR. During autophagy, p62 is hypothesized to be a target of ginkgetin-induced autophagic cell death. This notion is supported by several lines of evidence. The application of ginkgetin blocked fully the expression of p62 in cultured A549, and in contrast the overexpression of p62 reduced ginkgetin-induced autophagy and cell death concomitantly with the decline on autophagosome formation. In parallel, the modulation on p62 expression could regulate Nrf2 activity and ROS level in the presence of ginkgetin. Thus, autophagy could act as an inducer in ginkgetin-induced cell death, and p62 was proposed to be a possible target during this process. Here, ginkgetin exhibited promising anticancer effect in NSCLC via autophagy, a signaling very different to orthodox chemotherapeutic drug cisplatin. Besides, ginkgetin is a phytochemical from G. biloba that is considered as a safe herbal supplement, and no obvious toxicity was observed in xenograft nude mice. Therefore, ginkgetin is proposed to be a potential compound for the development of novel anticancer drug. MOLECULAR AND CELLULAR BIOLOGY / GENETICS: Cell Growth Signaling Pathways

Identification of a novel androgen receptor co-regulator in prostate cancer. Aymen A. Shatnawi,1 Sridhar Acharya Malkaram,2 Efronski Tsouko,3 Daniel E. Frigo4. 1Univ. of Charleston, Charleston, WV; 2West Virginia State University, Charleston, WV; 3University of Texas MD Anderson Cancer Center, Houston, TX; 4University of Houston, Houston, TX.

Prostate cancer (PC) is one of the most frequently diagnosed tumors in the United States, affecting one in six men during their lifetime and second only to lung cancer as a cause of cancer death in men. One of the major drivers of prostate cancer is the androgen receptor (AR). It has been shown that deregulation of AR co-regulators play a crucial role in PC through modulating the transcriptional activity of the receptor. While the importance of the AR complex is well established, there is still an incomplete understanding of what all the associated co-regulators are and how they modulate AR signaling. Here, we have identified that the inhibitor of growth family member 4 (ING4), a protein that has been implicated in the pathogenesis of several solid tumors such as gastric and breast cancer, is a novel AR co-regulator. Overexpression of ING4 increased AR activity in an androgen-dependent manner as assessed using luciferase reporter gene assays. Supporting a role as a potential AR co-activator, RNA Next-Generation Sequencing of prostate cancer cells with ING4 knocked down revealed a repression of endogenous AR/R1881-activated genes and expression of AR/R1881 suppressed genes. Further, mining of existing clinical datasets revealed that the ING4 gene expression is de-regulated in PCs compared relative to normal tissue and tracks with poor patient prognosis. Collectively, the current findings strongly support the involvement of ING4 in AR signaling and PC progression and development.

The epidermal growth factor receptor (EGFR) deregulations play a central role in cancer progression. EGFR generates extra- and intracellular signals through various pathways, including its release in the tumor microenvironment through extracellular vesicles, as well as the nuclear EGFR signaling. That ultimately results in oncogenic signals promoting the tumor aggressiveness. Our previous report showed that sortilin, a member of the VPS10P sorting proteins, is associated with EGFR to allow its secretion through exosomes in non-small cell lung cancer (NSCLC) cells. Furthermore, sortilin is mainly present in the Golgi which is an essential compartment involved in the EGFR bypass towards the nucleus. Therefore, our aim is to investigate the potential role of sortilin in EGFR nuclear translocation. EGFR and sortilin translocation into the nucleus has been validated by proximity ligation assay and confocal microscopy analysis. Moreover, to study the sortilin function in the EGFR nuclear translocation, we resorted to the NSCLC cell line A549 in which the sortilin expression was silenced using a shRNA delivery. Subcellular fractionations and nuclear protein extractions were performed to study the impact of the sortilin loss on the EGFR-induced EGFR nuclear translocation. EGFR stimulation highly increases the nuclear translocation of the EGFR and sortilin complex. Interestingly, sortilin depletion significantly decreases the EGFR-induced EGFR nuclear translocation in the A549 cells. Strikingly, sortilin-depleted cells exhibit an overexpression of EGFR target genes (MYC, ARCG2, AURKA and CCND1) compared to the control cells. These results suggest that the overexpression of the EGFR target genes is independent of EGFR nuclear translocation in sortilin-depleted cells. Thus, the role of sortilin in the translocation of the known transcription factors was directly involved in the control of EGFR up-regulated genes to determine whether they are activated in sortilin-depleted cells. Moreover, to better understand the sortilin-dependent EGFR nuclear translocation, we compare functional properties (proliferation, migration and angiogenesis assays) of sortilin-depleted and control cells. Altogether, our findings suggest a key role of sortilin in the regulation of the EGFR nuclear transport, towards the control of target genes that are widely involved in cancer progression.

Protochadherin ? acts through SET and PP2A to potentiate MAPK signaling by EGFR and KRAS during lung tumorigenesis. Xiaorong Zhou,1 Barrett L. Updegraff,2 Yabin Guo,1 Michael Peyton,2 Luc Girard,3 Jill E. Larsen,4 Xian-Jin Xie,1 Yunyun Zhou,5 Tae Hyun Hwang,1 Yang Xie,4 Jaime Rodriguez-Canales,4 Pamela Villalobos,4 Carmen Behrens,4 Wistuba I. Ignacio,5 John D. Minna,4 Karl F. Kraut,2,4,5 and A. O’Donnell,6 1UT Southwestern Medical Center, Dallas, TX; 2QIMR Berghofer Medical Research Institute, Brisbane City, Australia; 3University of Mississippi Medical Center, Jackson, MS; 4MD Anderson Cancer Center, Houston, TX.

Non-small cell lung cancer (NSCLC) is the leading cause of cancer-associated deaths worldwide. Given the efficacy of membrane proteins as therapeutic targets in human malignancies, we examined cell-surface receptors that may act as drivers of lung tumorigenesis. Here we report that Protochadherin ? (PCDH7), a transmembrane receptor and member of the Cadherin superfamily, is frequently overexpressed in NSCLC tumors, and high expression of PCDH7 is associated with poor clinical outcome. PCDH7 overexpression synergizes with KRAS and EGFR to induce MAPK signaling and tumorigenesis. Conversely, PCDH7 depletion suppresses EGFR and KRAS-induced autophagy and reduces tumor growth. PCDH7 potentiates ERK signaling by facilitating interaction of protein phosphatase PP2A with its potent inhibitor, the SET oncoprotein. By establishing a previously unanticipated oncogenic role for PCDH7 in lung tumorigenesis, these results provide proof-of-concept support for the development of novel therapies that target PCDH7 at the cell surface of NSCLC cells. Experiments to evaluate the role of Pcdh7 in Kras-mediated lung tumorigenesis in vivo using autochthonous mouse models, which we expect to lend further support for therapeutic targeting of this protein, are in progress.

Combinatorial blockade of ERBB receptors in HER2 low breast cancer. Mireia Berdiel-Acer,1 Eileen Reinz,2 Khalid Abnoura,1 Sara Burnmester,1 Rainer Will,1 Ulrike Korf,1 Stefan Wiemann1. 1UT Southwestern Medical Center, Dallas, TX; 2QIMR Berghofer Medical Research Institute, Brisbane City, Australia.

Large number of breast cancer patients clinically classified as HER2 negative, show low/moderate levels of HER2 along with other ERBB receptors. Concomitant blockade of EGFR, ERBB2 and ERBB3 with specific therapeutic antibodies (cetuximab, trastuzumab/peruzumab and lumretuzumab, respectively) appears as a beneficial approach to improve survival of patients who have failed to previous treatment strategies. Additionally, ERBB3 expression has been reported as a trastuzumab resistance mechanism in HER2 positive subtypes. We have confirmed a specific pattern of ERBB receptors expression in different breast cancer subtypes. Individual and combined blockade of the receptors with...
therapeutic antibodies has been tested in vitro using a metabolic viability assay (Cell Titer Glo) and their effects in cell cycle status measured by BrdU staining. All four therapeutic antibodies bind to the respective extracellular domains inhibiting downstream signaling pathways. Response to individual treatment is cell dependent and correlates with EGFR expression in the triple negative MDA-MB-468 but not in luminal T47D cancer cell line. Response of T47D cells to lumretuzumab is higher when combined with pertuzumab or trastuzumab, suggesting ERBB2/ERBB3 dimer as the most relevant one, an effect more evident upon ectopic addition of NRG1 (only ligand for ERBB3). Long exposure of MDA-MB-468 cells to cetuximab induces ERBB3 expression and increases its sensitivity to cetuximab when combined. As well as in the HER2 + BT474 cancer cell line resistant to trastuzumab, higher levels of ERBB3 also make cells more sensitive to alternative anti-ERBB therapies. To establish the role of ERBB4 (no specific therapeutic antibody) in the whole ERBB network, stable knock-down regulation (shRNA) has been performed in T47D cells. Although treatment of HER2 overexpressing breast tumors has been successful, targeting other ERBB members in a HER2 moderate/low scenario seems to be a promising approach in combinatorial therapies; even in resistant cell lines. Thus, better characterization of ERBB network should help to pave the way for a personalized treatment of HER2 low breast cancer. [U.K.: Deceased March, 2016]

Purpose: Over 75% of all solid tumor cancers are characterized by aberrant expression of MUC1. Until date, no effective MUC1 targeting therapeutic has succeeded. The purpose of this body of work was to develop an antibody therapeutic that would effectively treat MUC1 positive solid tumor cancers, without damaging healthy MUC1 positive tissues. Experimental Procedures: MUC1 is a heavily glycosylated transmembrane protein whose expression is restricted to the apical border of healthy epithelial tissues but uniformly expressed over cancerous tissues. We discovered that the cancer-associated form of MUC1 is transmembrane cleavage product that remains after cleavage and release of the bulk of the extracellular domain. We named cleared MUC1, MUC1* (muk 1 star), and showed that it is a growth factor receptor that is activated by ligand-induced dimerization of its small extracellular domain. We also showed that 100% of pluripotent human stem cells express MUC1* but cleavage stops with the onset of differentiation. By studying stem cells and cancer cells in parallel, we sought to develop antibodies that would only recognize MUC1* as it is expressed on cancerous tissues but would not recognize MUC1* as it exists on some healthy cells and tissues. Summary: New Data: We previously showed that we had developed antibodies that recognized the cleaved, growth factor receptor form, MUC1* but not full length MUC1. However, MUC1 is cleaved to a healthy form of MUC1* on, for example, pluripotent stem cells, hematopoietic stem cells and stem cells of intestinal crypts. We now report that we have developed monoclonal antibodies that only recognize the cancerous form of MUC1* and do not recognize these healthy forms of MUC1*. To demonstrate that we have succeeded in deciphering the differences between cancerous MUC1* and healthy MUC1*, we also developed a set of monoclonal antibodies that only recognize healthy MUC1*. Thousands of human cancerous versus normal tissue specimens attests to the antibody’s specificity. Cancer specific and MUC1* but not full length MUC1 was blocked alone blocked the growth of MUC1* positive breast and hormone refractory prostate cancers in animals, with no detectable adverse effects. On the basis of tissue safety studies and efficacy studies, a clinical candidate antibody MNC2 has been identified, humanized and incorporated into more than 20 CAR constructs. huMNC2-scFv-CAR T cells display high cytolytic release cells, when co-cultured with MUC1* positive cancer cells. huMNC2-scFv-CAR T cells selectively kill MUC1* positive cancers, while stimulating T cell expansion. Conclusions: The relevant target for anti-cancer drugs is the extracellular domain of MUC1*, not full length MUC1. MUC1* is a growth factor receptor that is activated by NME family growth factors. Subtle differences between MUC1* as expressed on healthy stem-like cells and MUC1* expressed on cancerous cells has allowed the development of cancer-specific MUC1* antibodies, especially suited for cancer immunotherapies.

#3331 PID1, a candidate tumor suppressor in pediatric and adult brain tumors, is a novel interacting partner for a cell surface receptor. Anat Erdreich-Epstein, Xiuhai Ren. Children’s Hospital Los Angeles/University of Southern California, Los Angeles, CA.

BACKGROUND: PID1 is higher in fat from obese patients and is an inhibitor of insulin receptor signaling. We reported that PID1 is a novel inhibitor of medulloblastoma and glioma cell growth, and its mRNA level is highly correlated with survival across multiple independent datasets of these tumors. PID1 harbors a phosphotyrosine binding domain and is predicted to interact with proteins harboring NPYX motifs. We therefore hypothesized that PID1 will interact with phosphotyrosine-binding (PTB) domain containing protein(s) that may be important in brain tumors, and will modulate its/signaling. Here we report PID1 interactions with some of these proteins and determine its biological consequences. METHODS: Experiments consisted of immunoprecipitations, transient transfections, and western blotting. Functionally, assays included cell culture, flow cytometry for proliferation and migration, and reporter assays. RESULTS: The receptor tyrosine kinase AXL mediates nuclear translocation of the epidermal growth factor receptor. Toni M. Brand, Mari Izda, Kelsey L. Corrigan, Cara M. Braverman, John P. Coan, Bailey G. Flanagan, Andrew P. Stein, Ravi Salgia, Jana Roff, Randall J. Kimple, Deric L. Wheeler. Univ. of Wisconsin-Madison, Madison, WI; City of Hope, Duarte, CA; Experimental Pharmacology and Oncology Berlin-Buch GmbH, Berlin, Germany.

Proceedings of the American Association for Cancer Research • Volume 58 • April 2017 851
The epidermal growth factor receptor (EGFR) is an important therapeutic target in patients with various cancers. Unfortunately, resistance to anti-EGFR therapeutics is common. Previous studies in our laboratory identified two mechanisms of resistance to the EGFR monoclonal antibody cetuximab: First, the nuclear translocation of EGFR bypasses the inhibitory effects of cetuximab; and second, the tyrosine kinase AXL mediates cetuximab resistance by maintaining EGFR activation and downstream signaling. On the basis of these findings, we hypothesized that AXL could mediate the nuclear translocation of EGFR in the setting of cetuximab resistance. We found that NSCLC cetuximab-resistant clones and patient-derived xenografts (PDxKs) had increased abundance of nuclear EGFR (nEGFR) and AXL. Cellular fractionation techniques, super resolution microscopy, and electron microscopy revealed that genetic loss of AXL diminished the nuclear translocation and accumulation of EGFR. Building on previous studies indicating that SRC family kinases (SFKs) and HER family ligands mediate the nuclear translocation of EGFR, we found that AXL knockdown down-regulated the expression of the SFKs YES and LYN, and the ligand neuregulin-1 (NRG1). Furthermore, AXL knockdown decreased the interaction between EGFR and HER3 and the nuclear abundance of HER3. Nuclear localization of EGFR could be rescued only upon simultaneous overexpression of Lyn and NRG1 in cells depleted of AXL. Collectively, these data uncover a previously unrecognized role for AXL in regulating the nuclear translocation of EGFR and suggest that AXL-mediated SFK activation and NRG1 expression are necessary and sufficient to regulate this process.

#3334 The FGF4R-388Arg variant exerts pro-tumorigenic effects in lung cancer by inducing an EMT phenotype. Álvaro Quintanal-Villalonga, Rocío Suárez, Laura Ojeda-Márquez, Santiago Ponce-Aix, Amancio Carnero, Luis Paz-Ares, Irene Ferrer, Sonia Molina-Pinel, H120-Cinto, Madrid, Spain; IBIS, Sevilla, Spain.

The FGF4R-388Arg allele, where an arginine substitutes a glycine in the 388 codon of the FGF4R gene, has been associated to poorer patient outcome in different tumor types. In lung cancer, the variant has been related to shorter overall survival in adenocarcinoma (ADC) patients, while no relationship with squamous cell carcinoma prognosis (SCC) has been reported. Mechanistically, the FGF4R-388Arg variant has been related to increased MAPK pathway activation and to EMT in prostate cancer in vitro models. Furthermore, the variant has been associated with higher STAT3 signaling in murine models of breast and lung cancer. However, so far the molecular biology for this FGF4R variant in lung cancer patients has not been addressed. We overexpressed the FGF4R-388Gly and FGF4R-388Arg variants in lung cancer cell lines from different histologic backgrounds and performed tumorigenicity surrogate assays and downstream signaling activation assessment. In the generated stable cell lines, we also determined the expression of EMT markers. Furthermore, we determined the FGF4R variant and the FGF4R and N-cadherin mRNA expression in a cohort of NSCLC patients (N=65) and correlated these data to patient outcome. We reported that FGF4R-388Arg increases tumorigenicity in lung cancer cell lines. Mechanistically, these functional effects seem to be mediated by MAPK and STAT3 overactivation and by the induction of an EMT phenotype, which includes N-cadherin increased expression. In fact, this induction of N-cadherin protein expression by the FGF4R-388Arg variant seems to be responsible for the pro-oncogenic effects reported. In NSCLC patient tumor samples, the FGF4R-388Arg variant correlates with higher N-cadherin expression and with poorer survival. In conclusion, the FGF4R-388Arg variant is a potential prognostic biomarker in NSCLC, including ADC and SCC patients. This variant increases tumorigenesis through the activation of MAPK and STAT3 signaling pathways and through the promotion of an EMT phenotype.

This study aims to investigate the role of Transforming Growth Factor-beta type III receptor on tumor metastasis through cell migration and invasion. Metastasis is the cause of 90% of cancer-related deaths. An important step in the metastatic process is the epithelial to mesenchymal transition (EMT) of cancer cells, which is stimulated by TGFβ. The binding of TGFβ to its type II receptor (TβRII) triggers the phosphorylation of ser/thr kinase TGFβ type I receptor (TβRI), and receptor-regulated Smad (R-Smad) which translocates to the nucleus and alters gene transcription. The activity of this pathway is affected by receptor localization on the cell membrane, while the presence of TβRII complex in clathrin-coated pits propagates TGFβ signaling. However, TβRII complex relocation to membrane lipid rafts reduces signaling. A TGFβ receptor that lacks kinase activity, type III (TβRIII), regulates TGFβ signaling through multiple roles. Previous investigations have determined TβRIII sequesters TGFβ ligand to reduce signaling, while also presenting TGFβ to TβRII to increase signaling. TβRIII has also been shown to bind type I and type II TGFβ receptors independently, and reverse their membrane partitioning from membrane lipid rafts to clathrin-coated pits. This TβRIII induced relocation of TβRII/II increases receptor half-life, altering TGFβ signaling. Many cancers demonstrate increased expression of TβRIII, suggesting that this protein is influential in the metastatic pathway. Interestingly, conflicting studies have shown that metastasis is stimulated when TβRIII is either overexpressed or knocked-down. Overexpression of exogenous TβRIII and knockdown of endogenous TβRIII using siRNA were used to explore alterations in cell migration and invasion potential. TGFβ signaling, receptor expression, membrane partitioning, and protein interaction studies were performed using Western blotting, sucrose-density ultracentrifugation, and immunoprecipitation techniques. Immunofluorescent transwell assays measured relative cell migration and invasion through Matrigel. Transfection of TβRIII demonstrated both the punctate and membrane localization of TβRIII, while inhibiting transwell migration. The ability of transfected cells to migrate and invade through transwell assays clarified the impact of TβRIII expression on metastatic processes. Finally, both the overexpression and silencing of TβRIII resulted in significantly different cancer cell migration and invasion profiles when compared to untransfected cell lines. TβRIII expression and activity modify cellular migratory and invasive potential through the modulation of the TGFβ signaling pathway, altering epithelial to mesenchymal transitioning and therefore tumor metastasis.

#3336 Comparison of epithelial mesenchymal transition mediated TKI resistance NSCLC cells containing wild type EGFR and mutant EGFR. Tsatsral Iderzorig, Sanjana Singh, Gagan Chhabra, Neelu Purri. Univ. of Illinois at Chicago, Rockford, IL.

Epithelial to mesenchymal transition (EMT) is a vital process in development and of metastasis and occurs when epithelial cell lose their polarized structure, by reducing adherent junction proteins E-cadherin, Claudin and ZO-1 on the membrane. Cells with EMT are elongated spindle like structures due to upregulation of mesenchymal markers Vimentin and N-cadherin. EMT may be responsible for resistance to molecular targeted therapies such as tyrosine kinase inhibitors (TKIs) against EGFR which is used in patients with activated EGFR mutations. However, these patients acquire resistance to TKIs after prolonged use. This acquired resistance to TKIs may also be due to a secondary T790M mutation in the kinase domain which could be responsible for inducing EMT. EMT is regulated by p120-catenin which interacts with the Kaiso factor in the cell nucleus and inhibits the transcriptional repressor activity of Kaiso factor. Kaiso factor represses Wnt target genes such as ZEB-1. The binding of p120-catenin to Kaiso factor also increases Wnt signaling which results in loss of E-cadherin. Cells undergoing EMT can acquire cancer stem-cell like characteristics by expressing stem-cell marker ABCB1. Thus we investigated EMT characteristics in TKI-resistant NSCLC cells, H2170 ER (Erlotinib resistant), H358 ER and H1975. To determine modulation of EMT biomarkers in TKI-resistant cells, H1975 with L858R and T790M mutations was compared to TKI-sensitive cell line H3255 with L858R mutation, using immunoblotting, and qPCR. Expression of stem-cell markers ABCB1 and EMT biomarker E-cadherin are measured using flow cytometry. Key EMT-related proteins such as PRMT-1, Slug, Snail, Twist, p120-catenin, and Vimentin were upregulated by 3.2, 3.18, 6.2, 1.68, 4 and 6.5 fold, respectively, and E-cadherin, Claudin and ZO-1 were down-regulated by 89%, 90% and 99% fold as compared to the H3255 TKI-sensitive cell line. We also observed upregulation of N-cadherin, ZEB-1 and Vimentin by 2.4, 2.6, and 12 fold and downregulation of E-cadherin by 50% in H1975 by qPCR. Immunofluorescence studies for Vimentin showed that H1975 cells were more elongated and stratified as compared to the H3255 that had polarized structures. 90% colocalization of p120-catenin and Kaiso factor was seen in H1975 whereas 10% colocalization was seen in H3255 cells. Flow cytometry results indicated that there was significant increase in expression of stem cell marker ABCB1 in TKI resistant cells H2170 ER, H358 ER and H1975 in comparison to H2170 P( Parental), H358 P and H3255 TKI sensitive cells. In conclusion, our results indicate that EMT is mediated through PRMT-1, which methylates Twist, transcriptional repressor of E-cadherin along with Snug and Snail in H1975 cells with T790M mutation. Cancer stem-cell marker ABCB1 is specific for TKI resistant NSCLC cells which exhibit EMT.

#3337 The G protein-coupled P2Y6 pyrimidoceptor increases tumorigenesis potential of epithelial cell in colorectal cancer associated to colitis. Morgan Placet, Caroline M. Mollé, Djordje M. Gribic Grbic, Guillaume Arguin, Sameh Geha, Fernand-Pierre Gendron. Université De Sherbrooke, Sherbrooke, Quebec, Canada.
BACKGROUND: Carcinogenesis is a complex process induced by various genetic mutations, which is characterized by 3 phases. The initiation phase, inflammation is predominant, as in colitis-associated carcinogenesis, and involves the active recruitment of immune cells like macrophages, dendritic cells and T cells. The promotion and progression phases are respectively tied to dysplasia and cancerous tissue and metasasis. Inflammatory cytokines, including colitis, induces an imbalance in pro- and anti-inflammatory cytokines, a breakdown in the epithelial barrier, pathogens infiltration and leukocytes recruitment and activation. During inflammation, nucleotides are released in a large amount in the extracellular environment. The P2Y6 receptor was associated with IBD where its expression was increased in T cells infiltrating inflamed colonic tissue and on the epithelial cells of the inflamed tissue. In this context, activation of the P2Y6 receptor may contribute to the formation of a tumor-promoting environment by modulating the immune response and establishment of tumors. METHODS: Colorectal cancer associated to colitis was induced in 2Pry6 gene knockout mice (P2Y−/−) using azoxymethane, as a carcinogen, and dextran sulfate sodium challenges as a promoting agent. Mice were euthanatized and the number and size of tumor measured. Tissues were fixed and stained prior to histological characterization. The impact of P2Y6R activation on apoptosis and NFκB pathway was determined by western blotting, and the impact on inflammatory cytokines balance and mucus layer were analyzed by histology and qPCR of different markers. RESULTS: Invalidation of the P2ry6 gene in mice lead to a reduction in the number of colorectal tumors in our AOM-DSS model. We linked this observation to the protective role of P2Y6R toward TNFα-induced apoptosis of cancerous epithelial cells. Furthermore, P2Y6R regulates the balance between pro- and anti-inflammatory cytokines in inflammatory conditions, and maintain the integrity of the epithelial barrier by modulating the density of the mucus layer. CONCLUSION: In this study, we have shown that P2Y6R could contribute to colorectal cancer colitis associated by blocking the apoptotic process, modulating the cytokine network, and regulating the integrity of the mucus layer. These results suggest that P2Y6R could be a prime target to reduce colorectal cancer colitis associated.

#3338 A role for FGFR4 in growth and survival of Ewing sarcoma cells. 
Justin J. Montoya,1 Daniel H. Wai,1 David W. Lee,1 Peter A. Azorsa,1 Oliver B. Pepper,2 Robert J. Arceci,1 David O. Azorsa1.

Ewing sarcoma is the second most common cancer of bone and soft tissue arising in children and young adults. Although the survival rate has improved for patients treated for localized disease, the survival rate for patients with metastatic tumor remains lower than 30%. In order to identify novel therapeutic targets and to better understand the genes involved in growth and survival of Ewing sarcoma, we employed a functional genomics approach based on siRNA screening. Four Ewing sarcoma cell lines, TC-32, TC-71, SK-ES-1 and RD-ES, were transfected with a library of siRNA targeting 287 cancer-associated genes. The resulting siRNA screening data for each cell line were normalized and statistically cut-offs were determined. The results indicated that siRNAs targeting Fibroblast Growth Factor Receptor 4, FGFR4 were among the most effective in reducing cell viability in all four of the Ewing sarcoma cell lines. Validation of the siRNA targeting FGFR4 reduced viability more than those to FGFR1, FGFR2, or FGFR3. Furthermore, siRNA targeting FGFR4 were able to induce caspase 3 activity. FGFR4 protein is expressed in Ewing sarcoma cells as determined by western blot analysis, although expression levels were lower compared to FGFR4 expression on rhabdomyosarcoma cells. Targeting FGFR activity in Ewing sarcoma cells using a pan-FGFR inhibitors PD-173074 and BGP-398 demonstrated that Ewing sarcoma cells were sensitive to FGFR inhibition. Furthermore, treatment of Ewing sarcoma cells with the selective FGFR4 inhibitor BLU9931 resulted in growth inhibition and decreased ERK signaling. These results indicate that FGFR4 may play an important role in growth and survival of Ewing sarcoma and could serve as a potential therapeutic target for this disease.

#3339 Muscarinic acetylcholine receptor subtype 3 regulates gastric stem cell number and gastric cancer cell proliferation by controlling YAP activation.

Yoku Hayakawa,1 Mitsuhiro Konishi,1 Kosuke Sakitani,2 Kazuhiko Koike,1 Timothy Wang3,1 University of Tokyo, Tokyo, Japan; 2 Columbia University, New York, NY.

Within the gastrointestinal, nerves help to regulate both normal and neoplastic stem cell dynamics. Several previous studies suggested that cholinergic nerve signaling plays an important role in gastrointestinal cancer development, but the exact underlying mechanism has not been clarified. In this study, we examined the role of muscarinic acetylcholine receptor subtype 3 (M3R) in gastric homeostasis and cancer development by using mouse models and human cancer cell lines. In situ hybridization revealed M3R expression in gastric stem cell zone, and its expression was markedly upregulated in gastric cancer cells. We knocked out M3R in Lgr5+ gastric stem cells in Lgr5-CreERT, M3Rflox/flox mice, and found that deletion of M3R inhibited clonal expansion of Lgr5+ cells in regenerative states. In a gastric tumor model of Mist1-CreERT, Apc/flox/flox mice, knockout of M3R dramatically suppressed tumor growth. RNA sequencing analysis of these tumors revealed that several important pathways were significantly inhibited in M3R knockout samples, including YAP/TAZ pathway. We established M3R-expressing gastric cancer cell lines, and western blotting, luciferase assay, and RT-PCR analysis confirmed that acetylcholine (ACh) agonist activates YAP pathway through M3R. YAP is upregulated in approximately half the gastric cancer cell lines with dysplasia or high-grade dysplasia in disease stage and histological form. This M3R-YAP axis activates the gastric stem cell niche and offers a compelling target for tumor treatment and prevention.

MOLECULAR AND CELLULAR BIOLOGY / GENETICS: Cell Growth Signaling Pathways

#3340 Identification of CARM1/PRMT4 as a novel therapeutic target for AML
Sarah M. Greenblatt, Pierre-Jacques J. Hamard, Takashi Asai, Na Man, Concepcion Martinez-Caja, Fan Liu, Stephen Nimer. University of Miami, Miami, FL.

Chromatin modifying enzymes, and specifically the protein arginine methyltransferases (PRMTs) have emerged as important targets in cancer. PRMT4, also known as CARM1, is overexpressed in a number of cancers, including breast, prostate, pancreatic, and lung cancer. Our lab reported the overexpression of PRMT4 in the context of acute myeloid leukemia (AML), showing that more than 70% of cytogenetically normal AML patients have up-regulation of PRMT4. Here, we investigated the role of PRMT4 in normal hematopoiesis and leukemia development. In order to study the role of PRMT4 in normal hematopoiesis, PRMT4-floxed mice were crossed with Vav1-cre mice purchased from the Jackson Laboratory. Inducible Prmt4 conditional KO mice were generated by crossing Prmt4-floxed mice with Mx1-Cre mice and Prmt4 gene excision was induced by poly(C:C). Using this hematopoietic specific knockout system, we show that loss of PRMT4 has little effect on normal hematopoiesis, but promotes the differentiation of hematopoietic stem and progenitor cells. Next we evaluated the role of PRMT4 in leukemia development using leukemia transplantation models driven by fusion oncoproteins. Strikingly, the knockout of PRMT4 completely abrogates leukemia initiation in fetal liver transplantation models driven by the AML1-ETO or MLL-AF9 fusion proteins. We further characterized the mechanism for the leukemia-specific dependence on PRMT4 using leukemia cell lines and found that knockdown of PRMT4 impairs cell cycle progression, decreases proliferation, and induces rapid apoptosis. To examine PRMT4 dependent changes in gene expression in a leukemia system, we used lentiviral vectors that express RFP and shRNAs directed against PRMT4. We knocking down PRMT4 in four leukemia cell lines or normal human cord-blood derived CD34+ cells. Gene set enrichment analysis showed that all four leukemia cell lines with knockdown of PRMT4 significantly down-regulated E2F target genes compared to the scrambled control. Chromatin immunoprecipitation analysis (ChIP) confirmed the presence of PRMT4 and H3R17 dimethylation at the promoter regions of E2F1 targets. The PRMT4 conditional knockout mice and PRMT4 knockdown experiments both suggest that the loss of PRMT4 protein has a selective effect on leukemia cells compared to normal hematopoietic stem and progenitor cells. Collectively, this work supports that targeting PRMT4 through chemical inhibition may be an effective therapeutic strategy for AML and other cancers with up-regulation of PRMT4.

MOLECULAR AND CELLULAR BIOLOGY / GENETICS: Epigenetics

#3341 Epigenetic deregulation of the Hippo pathway in muscle-derived sarcomas.
T. S. Karin Eisinger, Shuai Ye. Univ. of Pennsylvania School of Medicine, Philadelphia, PA.

Soft tissue sarcomas are an aggressive group of roughly 65 mesenchymal malignancies diagnosed in 200,000 people worldwide annually. The treatment approach for sarcomas has not changed significantly in 25 years. Furthermore, recent sequencing efforts have revealed that consistent oncogenic mutations are rare in muscle cancers. As a result, these tumors are not sensitive to most available targeted therapeutics, which specifically interface with the functions of mutant oncogenic pathways. We are investigating the possibility that together with p53 or RB1 mutation/loss, alterations in chromatin state and epigenetic regulation rather than oncogenic mutation, are required for sarcoma transformation. Based on our current findings we are testing the hypothesis that epigenetic deregulation of Angiomotin

Proceedings of the American Association for Cancer Research • Volume 58 • April 2017
YAP1 activity promotes NF-κB activity. Our studies have revealed that YAP1 expression is epigenetically modulated through AKT regulation and caused re-expression of the muscle differentiation marker MYOD and p57 suggesting that epigenetic modulation promotes differentiation as well as inhibiting proliferation. Gene expression studies of control and YAP1-deficient tumors revealed that YAP1 controls NF-κB signaling. We have performed H3K27Ac ChIP-seq and super-enhancer analysis of human UPS tumors to determine whether NF-κB targets are important in human sarcomas. These analyses revealed that NF-κB is the most transcriptionally active pathway in UPS. Together these data suggest that persistent YAP1-mediated NF-κB signaling promotes sarcomagenesis. In normal undifferentiated muscle cells NF-κB signaling is essential for proliferation and inhibition of differentiation. We have now shown that SAHA/JQ1-mediated YAP1 inhibition subsequently decreases NF-κB activity, underscoring the ability of epigenetic therapies to decrease tumorigenesis and enhance differentiation. Our findings suggest that pharmacological modifier (Perifosine, 10mg/kg body weight daily for 4 weeks) and observed that AKT inhibition significantly induces di and tri methylation of H3K4, concomitant with decreased KDM5B levels. Overall, we observed that AKT activation negatively regulated miR-137 but not miR-138 levels, which further transcriptionally represses KDM5B expression. miR-138 and miR-137 as these have been shown to transcriptionally regulate H3K4 methylation. We observed that AKT activation negatively regulated miR-137 but not miR-138 levels, which further transcriptionally represses KDM5B expression. Overexpression of miR-137 significantly reduced KDM5B and increased H3K4 di and tri methylation levels but failed to change AKT phosphorylation. Genetic knockdown of AKT or inhibition of AKT phosphorylation increased miR-137 and reduced KDM5B expression. Overall, we observed that AKT transcriptionally regulates KDM5B mainly via repression of miR-137. Our data identify a mechanism by which PI3K/AKT signaling modulates the prostate cancer epigenome through regulating H3K4 methylation and KDM5B expression. Additional studies that assess the impact of AKT inhibition on genome occupancy of H3K4 methylation will help in the identification of targets and devise novel strategies to enhance the therapeutic efficacy of PI3K/AKT inhibitors that are currently in clinical development.

AlkB homolog 5 (ALKBH5) is one of the most prevalent internal modifications in eukaryotic messenger RNA. This dynamic and reversible modification is installed by methyltransferase complex consisting of three subunits: Methyltransferase-like protein 3 (METTL3), Methyltransferase-like protein 14 (METTL14) and Wilms tumor 1-associated protein (WTAP), and erased by two independent demethylases, Fat mass and obesity associated protein (FTO) and AlkB homolog 5 (ALKBH5). RNA demethylase ALKBH5 has been reported to play vital roles in several biological processes. However, very little is known about the role of ALKBH5 in cancer in general and breast tumorigenesis in particular. In this study, we report that ALKBH5 promotes breast cancer growth and progression. Using in vitro and in vivo models, we show that silencing of ALKBH5 inhibits breast cancer growth and invasion. Importantly, our studies reveal that ALKBH5 mediates its pro-tumorigenic function by regulating several microtubule associated genes including KIF2C, PLK1, MAPRE1 and RCC2 that are critical for spindle formation or assembly during mitotic progression. Interestingly, ALKBH5 target genes KIF2C and MAPRE1 are highly expressed in breast cancer patients and their higher expression is strongly correlated with lower survival of breast cancer patients. We believe that an optimal level of RNA modification of key target genes is critical for normal cell cycle progression and any alteration in the levels of RNA methylation may alter activity or expression of these genes resulting in unbalanced cell proliferation.

**#3344 AKT mediates transcriptional regulation of H3K4 demethylation in PTEN null prostate cancer.** Mohammad Imran Khan, Susvamita Rath, Qateeb Khan, Vagaa M. Adhami, Hasan Mukhtar. Unv. of Wisconsin-Madison, Madison, WI.

One of the common contributors to the pre-disposition of most human cancers is inappropriate activation of AKT due to loss of its negative regulator PTEN. Activated AKT regulates changes in metabolic processes such as acetyl-CoA production that impacts chromatin. AKT phosphorylates a wide variety of histone modifying enzymes including acetyltransferases and methyltransferases resulting in their hyperactivation or inhibition. Therefore, understanding the impact of AKT inhibition on global histone modification would be critical to identify novel histone modifiers regulated by AKT. We performed unbiased and comprehensive profiling of histone modifications in prostate specific PTEN knockout mice treated with an AKT inhibitor (Perifosine, 10mg/kg body weight daily for 4 weeks) and observed that AKT inhibition significantly induces di and tri methylation of H3K4, concomitant with reduction acetylation of H3K9. Changes in other histone modifications such as H3K6 and H3K9 methylation and acetylation were not observed. Mechanistically, we observed that AKT inhibition reduces the expression of H3K4 methylation related histone demethylases KDM5 family, especially KDM5B expression at transcriptional level. Similar observations were noted at translational level also. To further understand the transcriptional regulation of KDM5B by AKT we focused on miR-137 and miR-138 as these have been shown to transcriptionally regulate H3K4 methylation. We have observed that miR-137 knockdown or inhibition increased miR-137 but not miR-138 levels, which further transcriptionally represses KDM5B expression. Overexpression of miR-137 significantly reduced KDM5B and increased H3K4 di and tri methylation levels but failed to change AKT phosphorylation. Genetic knockdown of AKT or inhibition of AKT phosphorylation increased miR-137 and reduced KDM5B levels. Overall, we observed that AKT transcriptionally regulates KDM5B mainly via repression of miR-137. Our data identify a mechanism by which PI3K/AKT signaling modulates the prostate cancer epigenome through regulating H3K4 methylation and KDM5B expression. Additional studies that assess the impact of AKT inhibition on genome occupancy of H3K4 methylation will help in the identification of targets and devise novel strategies to enhance the therapeutic efficacy of PI3K/AKT inhibitors that are currently in clinical development.

The histone methyltransferase EZH2 is the enzymatic subunit of the polycomb repressive complex 2 (PRC2) that catalyzes the methylation of H3K27 thereby repressing target gene transcription. EZH2 is amplified, overexpressed, or mutated in multiple cancer types, most notably Follicular Lymphoma (FL) and germinal center Diffuse Large B-cell Lymphoma (GBL-DBCL). We previously reported that pre-
clinical models of malignant rhabdoid tumors, which are deficient in the SWI/SNF core component INI1 (SNF5, SMARCB1), are selectively killed by potent and selective inhibitors of EZH2. Here we report another class of SWI/SNF-altered cancers named small cell carcinoma of the ovary, hypercalcemic type (SCOHT) that is dependent on EZH2 activity. SCOHT is a very aggressive form of cancer that responds poorly to conventional therapy with a one-year overall survival rate of only 50%. Very few novel agents have been approved for this indication; thus there is a need for targeted therapeutics in SCOHT. SMARCA4 and SMARCA2 are co-inactivated in this tumor type that has many rhabdoid features. We demonstrate that tazemetostat, an EZH2 inhibitor currently in phase 2 clinical trials, induces potent and selective killing in SMARCA2 and SMARCA4-deficient ovarian cell lines. In addition to small molecule inhibitor data, we conducted functional genomic studies with CRISPR pooled screening, and confirmed that SCOHT is also sensitive to CRISPR-mediated EZH2 gene ablation. Dose-dependent anti-tumor effects were observed upon tazemetostat treatment in SCOHT xenografts deficient in both SMARCA2 and SMARCA4. We also report on additional non-ovarian tumor types with dual SMARCA2/SMARCA4 loss including NSCLC that exhibit EZH2 deficiency representing additional potential therapeutic indications for tazemetostat treatment.

#3346 Epigenetic downregulation of miRNA-34a and miRNA-449 induce epithelial-mesenchymal transition and acquired resistance to ceritinib. Sun Min Lim,1 Mi Ran Yun,2 Kyoung Ho Pyo,2 Seong Keun Kim,1 Seon-Kyu Kim,4 Yong Sung Kim,1 Mirang Kim,2 Byoung Chul Cho.1 Yonsei Univ. College of Medicine, Seoul, Republic of Korea; 1IE-UK Institute for Cancer Research, Seoul, Republic of Korea; 2CHA University, Seongnam, Republic of Korea; 3Korea Research Institute of Bioscience & Biotechnology, Republic of Korea.

Background: Treatment with ALK tyrosine kinase inhibitors elicits profound initial antitumor responses in ALK fusion-positive patients with lung adenocarcinoma. However, patients invariably develop acquired resistance to ALK inhibitors. Although the recent functional genetic studies characterized the mechanisms of resistance to ALK inhibition, epigenetic mechanism of acquired resistance is poorly understood. Method: We established in vivo and in vitro models of acquired resistance to ceritinib and crizotinib using H3122 and H2228 cells. For in vivo model, mice with established H3122-derived tumors were treated with ceritinib to derive ceritinib-resistant tumors. To investigate the epigenetic mechanisms of resistance, we performed methylated DNA binding domain sequencing (MBD-seq) for DNA methylation and chromatin immunoprecipitation-sequencing (ChIP-seq) for histone modifications associated with enhancers (H3K4me1 and H3K27ac) of H3122 and H3122 ceritinib-resistant (LR) cells. We also performed in situ hybridization of miR-34 and miR-449 in patient samples. Results: Epithelial-to-mesenchymal transition with AXL activation was found in multiple in vivo and in vitro ALK-rearranged lung cancer models with acquired resistance to ceritinib. Genome and epigenome-wide analysis identified that miR-34a and miR-449a are decreased with loss of H3K27ac, while AXL and mesenchymal genes are increased in the process of acquired resistance. We confirmed that miR-34a and miR-449a were involved in AXL-dependent epithelial-mesenchymal transition (EMT) by treating mimics and inhibitors of miR-34a and miR-449a. In addition, pharmacological inhibition of AXL activation of miR-34a or miR-449a restored sensitivity to ceritinib in H3122-LR cells. Histone deacetylase (HDAC) inhibitor, panobinostat, synergistically induced anti-proliferative effects with ceritinib in resistant cells. Treatment with panobinostat led to increased expression of miR-449a with increased H3K28ac signal in H3122 LR cells. Panobinostat also reversed EMT phenotype by downregulating N-cadherin and upregulating E-cadherin expression. Additionally, combination of panobinostat and ceritinib induced enhanced antitumor efficacy in acquired resistant xenograft models. To clinically validate our preclinical findings, we measured the expression of miR-34a and miR-449 by in situ hybridization in 5 matched ALK-rearranged lung cancers obtained from individuals both before and after ALK inhibitor treatment. We detected decreased expression of miR-34a and miR-449 in 3 of 5 samples (60%). Conclusion: Our findings demonstrate that H3K27ac remodeling is a crucial event in ceritinib resistance and inhibition of both ALK and HDAC could prevent or overcome acquired resistance to ALK inhibitors in individuals with ALK-rearranged lung cancer.

#3347 Exploring the role of ASXL family of genes in enabling oncogenic AR-signaling in prostate cancer. Abhijit Parolla, Xuhong Cao, Arul Chinnaiah Venkata, Anjali Seth, Anna Lippert, and Micah J. Bond.

Prostate cancer (PCa) is the second leading cause of cancer-related mortality in North American men. In recent years, there has been mounting evidence establishing the centrality of epigenetic mechanisms in PCA initiation and progression. Accordingly, various epigenetic genes have been described to collaborate with the androgen receptor (AR) in enabling its oncogenic transcriptional program and aberrantly restoring its activity in metastatic castration resistant PCa (mCRPC). Concordantly, our lab has recently described two epigenetic genes, BRD4 and MLL2, as key co-activators of the AR signaling complex. Furthermore, we have demonstrated the therapeutic potential of targeting these AR-collaborating genes, as part of a multi-institutional consortium, our lab had performed comprehensive molecular profiling of 150 mCRPC patient tumors. These analyses revealed the molecular mechanisms underlying the sensitivity of inhibited PCa. Thus, in a setting where invariably all metastatic PCa patients progress to evolve resistance to anti-AR therapy, epigenetic genes emerge as potent co-targets with the promise to improve patient outcomes. To To identify novel AR-collaborating genes, as part of a multi-institutional consortium, our lab had performed comprehensive molecular profiling of 150 mCRPC patient tumors. We have recently demonstrated that cooperative genetic alterations in chromatin modifiers are frequently detected in advanced mCRPC. To identify candidate genes, we performed a preliminary pipeline that integrates DNA methylation data from the AR-silenced PTEN knockout (PTEN-C) cell line and co-expression of AR and chromatin modifiers. We identified that the ASXL family of genes is the most enriched for co-expression with AR and is a candidate therapeutic target in mCRPC. To validate this hypothesis, we transfected PTEN-C cells with ASXL1, ASXL2, or ASXL3 and measured cell viability using the CellTiter-Blue assay. We observed a significant decrease in cell viability for all three ASXL family members, indicating their potential as therapeutic targets in mCRPC. To determine the mechanism of this effect, we performed RNA sequencing and ChIP-seq analysis to identify changes in gene expression and chromatin modifications. We found that ASXL1 and ASXL2 are both epigenetic modifiers and targets of AR signaling. ASXL1 is a known co-activator of AR, and our data suggest that it may play a role in mediating AR signaling in mCRPC. ASXL2, on the other hand, is a novel target of AR signaling and may represent a new therapeutic target in mCRPC. To confirm these findings, we performed a series of functional experiments, including xenograft models and reporter assays, which demonstrated that ASXL1 and ASXL2 are both critical for AR signaling in mCRPC. In conclusion, our findings identify the ASXL family of genes as potential therapeutic targets in mCRPC and suggest that targeting these genes may be a promising strategy for treating this aggressive cancer.

#3348 UnID: unified and integrated diagnostic pipeline for malignant gliomas based on DNA methylation data. Jie Yang, Jiangwu Wang, Lihong Long, Ravesankar Ezharlajaran, Erik Sulman. MD Anderson Cancer Center, Houston, TX.

Prognostic and predictive molecular diagnostics for patients with gliomas typically rely on multiple assays, requiring large amounts of tissue and high cost. DNA methylation has been utilized to identify prognostic subsets and high-throughput platforms exist that are suitable for archival tissue. Therefore, we developed a unified and integrated diagnostic pipeline that can assess multiple prognostic and predictive biomarkers using only the Illumina Infinium Methylation array. This pipeline includes two data processing and diagnostic biomarker pipelines. Data processing starts from the raw data and followed with quantitative sample, probe, and batch quality control. The diagnostic biomarkers include a glioma methylation assay that predicts radiation response (GaMA); tumor classification enriched for TCGA expression subclasses; copy number alterations including phosphatase and tensin homolog (PTEN) loss, epidermal growth factor receptor (EGFR) amplification, and chromosomal instability (CIN); isocitrate dehydrogenase (IDH) mutation, and 5′-methylguanine-DNA methyltransferase (MGMT) promoter hypermethylation. WHO grade II-IV gliomas were analyzed in both publicly available and institutional datasets. A signature was identified to effectively distinguished radiation resistant from radiation sensitive glioma stem-like cells (GSCs). Signature has been applied to 272 TCGA GBM samples from patients who received standard radiotherapy (RT). The survival analysis showed that the subgroup with RT-sensitive and RT-resistant have significant difference in survival time (log-rank test p-value = 0.0016). Gene expression subclasses predict biomarker was build by using the revised TCGA gene expression subclasses as gold standard. The prediction accuracy in test data set was 83.5% in the homogeneous subgroup, 71.0% in the semi-heterogeneous subgroup, and 62.1% in the heterogeneous subgroup. The prediction accuracy decreased as tumor heterogeneity increased. Certain copy number alteration events were predicted by developing specific signatures. Revised methylation signatures were developed for IDH mutation and G-CIMP status respectively, which can identified 99% of those samples. 238 GBM samples with 450k data available were tested with MGMT methylation-specific real-time PCR for MGMT methylation status. The methylation-based MGMT prediction accuracy reached about 90%. In summary, we have developed a single, FFPE-based pipeline for unified and integrated determination of multiple biomarkers of malignant glioma.

#3349 A regulatory circuit H1P1 gamma/miR-451a/c-Myc promotes prostate cancer progression. Ruimin Huang,1 Cunjie Chang,2 JiaJian Liu,3 Xiao-Jing Huang,2 Lan Shen,2 Dianzheng Zhang,3 Jun Yan.1 1Shanghai Institute of Materia Medica, Chinese Academy of Sciences, Shanghai, China; 2Model Animal Research Center of Nanjing University, Nanjing, China; 3Philadelphia College of Osteopathic Medicine, Philadelphia, PA.

Heterochromatin protein 1 gamma (HP1 gamma), as a reader of the histone codes, is involved in the determination of higher order of chromatin structure. It
has also been implicated in carcinogenesis of various cancer types. However, the role of HP1 gamma in prostate cancer (PCa) progression and the underlying molecular mechanisms remain largely unknown. Using the public microarray data from GEO and TCGA database, we found that HP1 gamma was upregulated in PCa, comparing with benign prostate tissues. PCa patients with higher level of HP1 gamma had shorter disease-free survival, indicating that HP1 gamma level can serve as prognostic marker in PCa patients (p = 0.016). In addition, depletion of HP1 gamma by shRNA in PCa cells not only repressed proliferation and induced apoptosis, but also impaired tumorigenicity in vitro and in vivo. We also found that c-Myc was capable of upregulating HP1 gamma by directly binding to the E-box element in the first exon of HP1 gamma gene, and the upregulated HP1 gamma, in turn, repressed the expression of miR-415a by enhancing H3K9 methylation at the promoter region of miR-415a. Furthermore, reduction of miR-415a significantly reversed HP1 gamma loss-induced PCa cell apoptosis, whereas miR-415a overexpression repressed cell survival by targeting and downregulating c-Myc. The association among mRNA and protein expression levels of c-Myc, HP1 gamma and miR-415a were further confirmed in human clinical samples using Spearman correlation analysis. Therefore, we propose that an HP1 gamma/miR-415a/c-Myc regulatory circuit exists in PCa cells and this circuit plays a crucial role in PCa progression.

#3350 Cell-free DNA fragmentation patterns analyzed in over 15000 cancer patients reveal changes associated with tumor somatic mutations and result in improved sensitivity and specificity of somatic variant detection.

Background: Cell-free DNA (cfDNA) isolated from plasma consists of DNA fragments surviving clearance of dying cells and bloodstream trafficking. In cancer, these fragments carry the footprint of tumor somatic variation as well as its microenvironment. Since genomic distribution of cell free DNA fragments was shown to reflect nucleosomal occupancy in hematopoietic cells, we hypothesized that (a) heterogenous patterns of cfDNA positioning would be associated with distinct mutations in patient tumors and (b) integration of fragmentation patterns into analysis would allow increased sensitivity and specificity of somatic mutation detection. Methods: cfDNA fragment length and position distributions as well as associated somatic genomic profiles of over 15,000 patients with advanced-stage clinical cancer were determined by a highly accurate, deep-coverage (15,000x) cfDNA NGS test targeting 70 genes (Guardant360). An integrative data analysis of variant-free fragmentomics domain across different driver mutations was performed to identify patterns associated with detected somatic alterations. Results: We discovered distinct classes of fragmentomics subtypes significantly enriched in samples with different genomic subtypes. An independent cohort of samples with known HER2 immunohistochemistry status was interrogated to confirm discovered association between fragmentation patterns and HER2 status. Integrating fragmentation amplification signature with ERBB2 copy number analysis has resulted in 42% increase in the sensitivity and 7% increase in specificity of detection. Observed lung adenocarcinoma fragmentomics subtypes co-occurred with mutually exclusive genomic alterations and previously described intrinsic molecular subtypes of lung cancer. Conclusions: Fragmentomics classification of cancer cfDNA provides independent evidence for observed somatic variation and underlying tumor microenvironment, leading to higher sensitivity and accuracy of variant detection.

#3351 Aberrant RNA editing of GLI1 promotes malignant regeneration in multiple myeloma.

Elisa Lazzari, Nathaniel Delos Santos, Christina Wu, Lars Grontved, Gordon Hager. 1NCI/NIH, Bethesda, MD; 2Department of Pathology, Denver, CO.

In multiple myeloma, GLI1 promotes malignant regeneration. Procedures: Publicly available primary patient datasets were screened for HPV related oropharyngeal squamous cell carcinoma. Shuling Ren, Daria A. Gaykzlava, Theresa Guo, Zubair Khan, Mizuo Ando, Sunny Haf, Joseph A. Califano. 1University of California, San Diego, La Jolla, CA; 2Johns Hopkins Hospital, Baltimore, MD. HPV related head and neck squamous cell carcinoma (HNSCC) is known to occur in a separate patient population in comparison to tobacco related HNSCC, and also exhibits less mutational, genetic, and chromosomal alterations, and a different composition of epigenetic alterations. In particular, HPV is present in up to 70% of oropharyngeal squamous cell carcinoma (OPSCC), and is driving the increase in incidence rates of OPSCC. Given the precedent for successful screening for cervical cancer, it is attractive to consider similar population based screening for HPV related OPSCC. Here, we developed an epigenetic biomarker of ADAR1, or treatment with extrinsic pro-inflammatory stimuli, was utilized to probe the functional impact of RNA editing activity in MM models. Site-specific qPCR was used to quantify RNA editing in specific cancer stem cell-associated loci. Functional effects of ADAR1 activity were assessed in vitro survival and self-renewal assays, and in novel in vivo PCL xenografts. Results: Patients harboring 1q21 amplifications showed significantly increased IL-6 expression in vitro. Last, in vitro pro-inflammatory IL-6 stimulation, or continuous exposure to the immunomodulatory drug lenalidomide led to increased ADAR1 mRNA and protein levels, with a concomitant induction of RNA editing activity. Conclusions: In MM, 1q21 amplification has been linked to progression. We provide new evidence linking expression and activity of ADAR1, located on 1q21, and disease stage. Because ADAR1 induces transcript recoding, A-to-I editing could contribute to the marked transcriptomic diversity typical of advanced MM. While the Hh pathway has been linked to cancer stem cell generation in human MM, here we identified a primate-specific mechanism of Hh pathway activation in MM through RNA editing-dependent stabilization of GLI1. Together, both genetic and microenvironmental factors modulate epitranscriptomic deregulation of cancer stem cell pathways in MM.
Background and Aims: Accumulating evidence suggests that a subset of cancer stem cells (CSCs) influence various clinical outcomes in cancer, including tumor recurrence, metastasis and resistance to chemotherapy. Recently stemness has been recognized as a dynamic state governed by epigenetic modifiers including miRNAs. Despite identification of several DNA methylation-associated biomarkers, epigenetic regulation by miRNAs remains unclear. Herein, we characterized miRNA expression of CSCs with high vs. low CD44v6 expression through RNA-Seq. Subsequently, we investigated the clinical significance of a novel miRNA identified from this systematic discovery approach. Methods: Colon cancer CSCs from HCT116 and HT29 cell lines were grown as spheroid-derived cancer stem cells (CSCs). CD44v6+ and CD44v6- CSCs were subsequently confirmed in CD44v6+ and CD44v6- CSCs. qRT-PCR: Results: MiRNA profiling identified a unique overall pattern of CD44v6+ CSCs indicative of high degree of stemness features in cancer. In particular, we identified miR-1246, which is significantly overexpressed in CSCs as well as chemoresistant cells and its expression was associated with poor prognosis in CRC patients. Collectively, we have identified a unique group of previously unreported miRNAs which appear to have important mechanistic roles in CSCs and could serve as a promising predictive biomarker for recurrence and prognosis in patients with CRC.

Introduction: Colorectal cancer (CRC) is the third most frequent malignancy in males and second most common disease in females worldwide. CRC pathogenesis is intimately associated with lifestyles, such as diet, obesity, and smoking. Multiple evidences have revealed that these risk factors can trigger specific epigenetic alterations and subsequently promote carcinogenesis. Recently, adenosine (A)-to-inosine (I) RNA editing has been shown to be a potential epigenetic event in human cancers. One of the most important RNA editing gene targets is the antizyme inhibitor 1 (AZIN1), and edited AZIN1 promotes accumulation of ornithine decarboxylase and polyamines, leading to promotion and development of cancer.

**#3354 Histone deacetylase-1 promotes urothelial cell migration and invasion by modulating p63-pMLC2 signaling.** Kirtiman Srivastava, Conor Brennan, Karen Mccloskey.

Background: Aberrant expression of histone deacetylases (HDAC) and p63 transcription factor are associated with poor prognosis in invasive urothelial tumors. The current study focused on HDAC-evoked epigenetic modification of p63 and its downstream effects. Methods: Primary human urothelial cells (HUC) and urothelial cancer cell lines (HT1376, T24, TCCSUP) were cultured either on human bladder fibroblast-embedded collagen-I to establish 3D-organotypic rafts or as 2D-monolayers. Scratch wound assay was performed on 300 μm and 700 μm gaps to study the effect of HDAC on cell migration and invasion. Treatment with HDAC inhibitors (vorinostat (pan) and tinininvasive cells indicating that cytoskeletal reorganization may be pivotal for cell migration. Treatment with HDAC inhibitors (vorinostat (pan) and entinostat (HDAC1, 3)) attenuated the number of invasive incidents in T24 and TCCSUP cells, restored expression of p63, p21, pMLC2-Ser18, pMLC2-Thr18, Ser18 and p21 in invasive cells compared to normal (N = 5, p < 0.05). These results coincided with the loss of stress fiber formations visualized by immunofluorescence detection of F-actin in invasive cells indicating that cytoskeletal reorganization may be pivotal for cell migration. Treatment with HDAC inhibitors (vorinostat (pan) and entinostat (HDAC1, 3)) attenuated the number of invasive incidents in T24 and TCCSUP cells, restored expression of p63, p21, pMLC2-Ser18, pMLC2-Thr18, Ser18 and p21 in invasive cells compared to normal (N = 5, p < 0.05), and normalized expression of 14-3-3 eta and p-p27-Thr157. Reappearance of stress fiber formations traversing across the cell after HDAC inhibitor treatments was supportive of these results, while nuclear enrichment of p27 indicated its enhanced cytoplasmic-to-nuclear trafficking. Transient knockdown of HDAC1 in the invasive population mimicked the effect of HDAC inhibitors (N = 5, p < 0.05).

Conclusions: Inhibition of HDAC1 activity attenuates urothelial cell migration and invasion by restoring the expression of p63 which, (a) upregulates the expression of ROCK1, and (b) suppresses the expression of ROCK1. ROCK1 expression was associated with poor prognosis in CRC patients comprising of 329 colorectal cancer and adenoma patients. In addition, we performed a series of functional assays to elucidate the functional role of AZIN1 RNA editing in CRC pathogenesis. Results: Using RESSeqPCR, AZIN1 RNA editing levels were analyzed in two CRC cohorts. AZIN1 editing levels were significantly higher in cancer tissues at all stages (I through IV) compared with normal mucosa. Additionally, AZIN1 was highly edited in colorectal adenomas. Differently expressed miRNAs were subsequently confirmed in CD44v6+ CSCs, and discovered upregulation of previously unreported miRNAs (miR-1265, 3605, 3182 and 4284). KEGG pathway analysis indicated that these miRNAs regulate Akt-MAPK and Wnt signaling pathways. Subsequently, we selected miR-1246 and validated its expression in CD44v6+ and CD44v6- CSCs and chemoresistant cells. Clinically, the expression of miR-1246 was significantly elevated in CD44v6- CSCs compared to corresponding normal mucosa and this occurred in a stage-dependent manner in primary CRCs. Furthermore, the expression of CD44v6 positively correlated with miR-1246 in CRC tissues. High miR-1246 expression resulted in poor disease free and overall survival. Conclusion: Using a systematic and comprehensive approach, we have identified a unique network of dysregulated miRNAs in CD44v6+ CSCs indicative of high degree of stemness features in cancer. In particular, we identified miR-1246 to be frequently overexpressed in CSCs as well as chemoresistant cells and its expression was associated with poor prognosis in CRC patients. Collectively, we have identified a unique group of previously unreported miRNAs which appear to have important mechanistic roles in CSCs and could serve as a promising predictive biomarker for recurrence and prognosis in patients with CRC.

**#3355 Identification of a novel network of miRNAs that regulate stemness in colorectal cancer.** Shusuke Toden, Takatoshi Matsuyama, Elizabeth Hutchins, Kendall Jensen, Ajay Goel.

Background: HPV infection is a well-known risk factor for the development of cervical cancer and adenocarcinomas. HPV infection is commonly associated with dysregulation of epigenetic modifications, leading to promotion and development of cancer. The role of miRNAs in the development and maintenance of stemness features is less understood. Herein, we characterized miRNA expression of CSCs with high vs. low CD44v6 expression through RNA-Seq. Subsequently, we investigated the clinical significance of a novel miRNA identified from this systematic discovery approach. Methods: Colon cancer CSCs from HCT116 and HT29 cell lines were grown as spheroid-derived cancer stem cells (CSCs). CD44v6+ and CD44v6- CSCs were subsequently confirmed in CD44v6+ and CD44v6- CSCs. qRT-PCR: Results: MiRNA profiling identified a unique overall pattern of CD44v6+ CSCs indicative of high degree of stemness features in cancer. In particular, we identified miR-1246 to be frequently overexpressed in CSCs as well as chemoresistant cells.

groups. Taken together, these results highlight the oncogenic role of AZIN1 RNA editing in CRC. Conclusion: Our systematic and comprehensive study, which is first of its kind, reveals that AZIN1 RNA editing is novel epigenetic alteration that promotes an oncogenic behavior in colorectal cancer. In addition to its functional role, AZIN1 editing levels may be one of the important facilitators of adenoma-carcinoma sequence in CRC and serve as an important clinical biomarker in this disease.

#3357 Heritable methylation marks associated with breast cancer risk. Melissa C. Southey,1 Jhooon E. Joo,1 James G. Dowty,2 Roger L. Milne,2 EE Ming Wong,1 Pierre-Antoine Dugué,2 Dallas English,1 John L. Hopper,1 David E. Goldgar,2 Graham G. Giles*,1 The University of Melbourne, Melbourne, Australia; 2Cancer Council Victoria, Melbourne, Australia; 3Huntsman Cancer Institute, Utah, UT.

While most epigenetic marks are reprogrammed during early embryogenesis, some studies have reported Mendelian-like inheritance of germline DNA methylation in particular cancer susceptibility genes. We aimed to identify heritable methylation marks associated with breast cancer susceptibility by studying 25 Australian multi-generational families with multiple cases of breast cancer who were not known to carry mutations in breast cancer susceptibility genes. Peripheral blood DNA methylation was measured at approximately 480,000 genetic loci (methylation sites) for 210 members of these families using the Illumina HumanMethylation450 BeadArray. We developed and applied a new statistical method to identify heritable methylation marks based on complex segregation analysis. Carrier probabilities were estimated for the 1000 most heritable methylation marks, based on family structure but not disease status, and Cox proportional hazards survival analysis was used to test for associations between these carrier probabilities and breast cancer. After correcting for multiple testing, we identified 11 methylation marks whose corresponding carrier probabilities were significantly associated with breast cancer. Three marks clustered within 200 base pairs of the noncoding RNA miR886. We found evidence for these marks to be associated with aggressive (but not non-aggressive) prostate cancer risk in a population-based prostate cancer study. The association with breast cancer risk was replicated for three of the eleven marks in an independent population-based breast cancer study. Our work demonstrates the efficacy of our novel approach for identifying heritable methylation marks associated with breast cancer. This methodology may provide insights into other disease settings where known lifestyle exposures and genetic risk variants do not fully explain the familial relative risk.

#3358 Epigenetic signatures associated with patient outcome in thyroid carcinoma. Mariana Bisarro dos Reis,1 Caroline Moraes Beltrami,1 Mateus Camargo Barros-Filho,2 Fabio Albuquerque Marchi,2 Hellen Kuasne,2 Skirant Ambatipudi,2 Zdenko Herceg,2 Luiz Paulo Kowalski,2 Silvia Regina Rogatto*.1 Veje Hospital, Veje, Denmark; 2AC Camargo Cancer Center, Brazil; 3International Agency for Research on Cancer, France.

BACKGROUND: Thyroid cancer (TC) is the most frequent endemic neoplasia composed essentially by well-differentiated tumors (90%). These tumors generally are indolent and the patients show a favorable outcome. However, a set of TC patients presents aggressive outcome. Global deregulation of DNA methylation has been described as involved in thyroid cancer (TC) development. In this study, DNA methylation profile was performed aiming to identify a prognostic signature in TC. PATIENTS AND METHODS: The methylation profile of 50 non-neoplastic thyroid tissues (NT), 17 benign thyroid lesions and 74 TC (60 papillary, 8 follicular, 2 Hurthle cell, 1 poorly differentiated and 3 anaplastic thyroid carcinomas) were investigated using the Methylation 450 Human Infinium® BeadChip platform (Illumina). The data were normalized and analyzed using SVA, watermelon and LIMMA packages. The threshold delta beta of 0.2 and adjusted p-value < 0.05 were used to identify differentially methylated probes among the histological subtypes. The delta beta of 0.1 and adjusted p-value < 0.05 were used in the prognostic features analysis in WDTC (well differentiated thyroid cancer) cases. An epigenetic classifier according to WDTC was identified using diagonal linear discriminant analysis. The results were compared with The Cancer Genome Atlas (TCGA) database. RESULTS: Methylation analysis revealed a specific epigenetic profile according to the histological subtypes. A global hypermethylation was observed in benign lesions and follicular carcinomas, while papillary and undifferentiated carcinomas were widely hypomethylated compared with NT. An epigenetic signature comprising 21 probes differentially methylated (delta beta 0.1) was able to predict poor outcome in WDTC patients. This classifier revealed 63% of sensitivity and 92% of specificity, which was confirmed by TCGA database (64% of sensitivity and 88% of specificity). Using the established signature, we were able to confirm the involvement of poor prognosis markers with high-risk scores (multivariable analysis; P < 0.001). CONCLUSION: Thyroid tumors showed different methylational profile according to the histological subtypes. Genes regulated by methylation in TC and associated with the tumor development were identified and confirmed by TCGA. In addition, a meaningful algorithm was designed and confirmed as capable to predict recurrence in WDTC. FINANCIAL SUPPORT: FAPESP (2015/20458-5) and National Institute of Science and Technology in Oncogenetics (FAPESP 2008/57887-9 and CNPq 753589/08-9), CNPq (202608/2011-4).

#3359 TET1 mediated hypomethylation activates oncogenic signaling pathways in triple negative breast cancer. Charly Ryan Good, Andrew Kelly, Jozeč Madzo, Jaroslav Jelinek, Jean-Pierre Issa. Fels Inst. at Temple Univ. School of Medicine, Philadelphia, PA.

Triple negative breast cancer (TNBC) is a subtype of breast cancer that occurs in 15-20% of patients, and is defined by tumors that do not overexpress the estrogen, progesterone and HER2 receptors. This aggressive subtype has a significantly worse overall survival compared to non-TNBC and importantly, these patients lack options for targeted therapy. To identify novel subtype-specific therapeutic targets, we must first understand the biological underpinnings of the disease. DNA methylation is a hallmark of cancer, as it can regulate gene expression of both tumor suppressor genes and oncogenes. We have found that TN tumors have widespread genome-wide hypomethylation when compared to other breast cancer subtypes and normal breast controls. TET1 is a DNA demethylase that converts 5-methyl cytosine into 5-hydroxymethyl cytosine, which can be further oxidized into un-methylated cytosine. To determine if TET1 could possibly play a role in TNBC hypomethylation, we analyzed genome-wide DNA methylation, DNA mutation and RNA-seq datasets from the TCGA breast cancer cohort. We identified a subset of TN patients that upregulate TET1 and display DNA hypomethylation. To identify the hypomethylated TET1 target genes, we computed Spearman correlations between TET1 expression and methylation % for 450,000 sites (450K array) across 67 TNBC patients. Filtering for sites with r² < 0.3 revealed 42,559 sites negatively correlated with TET1 expression. Cluster analysis of the sites that lose methylation compared to normal breast (12,907 CpG sites) revealed two distinct clusters. Cluster 1 (43% of TNBC cases) were TET1 high and hypomethylated, while cluster 2 (58%) looked more like normal breast controls. Gene set enrichment analysis of the hypomethylated genes revealed Hippo Signaling, Pathways in Cancer and PI3K-Akt Signaling as significantly enriched, with p < 0.001. In addition, only 4% of patients in cluster 1 have mutations/genomic alterations in the PI3K pathway, compared to 29% of cluster 2 patients, p = 0.01. Most strikingly, analysis of phosphorylated EIF4EBP1/RPPA proteomic data revealed TET1 high patients have increased PI3K pathway activity, even though they lack mutations in the pathway, p = 0.02. We hypothesize that the T3PK hyper-activation, in part, can be explained by TET1 upregulation and target gene demethylation. In TET1 knock out MDA-MB-231 cells, we observed a reduction in phosphorylated 4E-BP1, suggesting loss of PI3K activity is concomitant with loss of TET1 as well as decreased cellular proliferation (p = 0.01). Furthermore, breast cancer cell lines with high TET1 (but not low TET1) are sensitive to drugs targeting the PI3K/ERK pathway (XMD8-85, AZ628, TGX221). In addition to explaining and predicting PI3K inhibitor sensitivity in breast cancer, our studies may establish TET1 as a TNBC specific oncogene that could serve as a novel druggable target for therapeutic intervention.

#3360 Targeted catalytic inhibition of EZH2 synergizes with low-dose HDACi in malignant rhabdoid tumors. Dean Popovski,1 Elizabeth M. Algar,1 Catherine R. Cochrane,1 Anette Szczepny,1 W. Samantha Jayasekara,2 David M. Ashley,2 Peter Downie,2 D. Neil Watkins,4 Jason E. Cain,1 Hudson Institute of Medical Research, Clayton, Australia; 2Barwon Health, Geelong, Australia; 3Monash Children’s Hospital, Clayton, Australia; 4Garvan Institute of Medical Research, Darlinghurst, Australia.

Malignant Rhabdoid Tumor (MRT) is a rare pediatric cancer of the kidney and CNS that is resistant to current treatment protocols. MRT is genetically characterized by homozygous inactivation of SMARCB1, a critical subunit of the SWI/SNF chromatin-remodeling complex. Next-generation sequencing data suggests that inactivation of SMARCB1 is the primary driver mutation, implicating epigenetic deregulation in the pathogenesis of MRT. Recently, we showed that sustained treatment of MRT cell lines with low-dose Panobinostat (LBH589), inhibited tumor growth by driving multi-lineage differentiation in vitro and in vivo. Furthermore, re-expression of physiological levels of SMARCB1 in G401 MRT cells phenocopied the low-dose LBH589 treatment and led to growth inhibition, senescence and terminal differentiation in vitro and in vivo. Enhancer of Zeste homolog 2 (EZH2), a core subunit of the Polycomb Repressive Complex 2 (PRC2), confers transcriptional silencing via the addition of methyl groups to Lysine 27 of Histone 3 (H3K27me3), and is a comb Repressive Complex 2 (PRC2), confers transcriptional silencing via the addition of methyl groups to Lysine 27 of Histone 3 (H3K27me3), and is a...

#3361 Methylome differences in differentiated thyroid cancers and benign adenomas. Josena K. Stephen, Kang Mei Chen, Jason Merritt, Indrani Datta, Dhananjay Chitale, George Divine, Maria J. Worsham. Henry Ford Hospital, Detroit, MI.

Many recent studies examining aberrant DNA methylation in thyroid cancer are restricted to either candidate genes or genome-wide methylation in specific thyroid tumor subtypes. The goal of this study was to identify differentially methylated genes globally and their association with molecular pathways and signaling networks. Common mutations in papillary thyroid cancer (PTC), follicular thyroid cancer (FTC), follicular adenoma (FA) and normal thyroid were also examined. Genome-wide methylation profiling using the Infinium HumanMethylation450BEFORMALIN fixed paraffin embedded BeadChip array was performed on 24 thyroid cases (8 PTC, 8 FTC, 4 FA and 4 normal thyroid). Ingenuity Pathway Analysis (IPA) was utilized to assess the roles of significantly differentially methylated genes in biological functions, signaling/metabolic pathways, and networks. Common mutations in 4 genes (BRAF, NRAS, HRAS, and KRAS) were assessed using TaqMan Mutation Detection assay. Twelve genes were significantly differentially methylated among 4 comparison groups: cancer vs normal, cancer vs adenoma, PTC vs normal, and PTC follicular variant (PTC-FV) vs PTC-Classic. CTU1 and HLA-DPB1 were significantly hypermethylated and AARS2, TMSB10, RNFE216L, KIF15, KIAA1143, and SLC2A13 were significantly hypomethylated between cancer and normal. Significant differential hypermethylation was noted for PNPAL7 and NPC1L1 in cancer vs adenoma and SNX1 in PTC-FV vs PTC-Classic. NT5C1B was hypermethylated and AARS2 was hypomethylated in PTC vs normal. IPA identified 2 gene networks, involving 11/12 genes, characterized by 1) Cellular development, Cellular growth and proliferation, Connective tissue development and function and 2) Drug metabolism, Cell-mediated immune response, Cellular development. NT5C1B was involved in all 4 highly ranked canonical nucleotide degradation pathways. Several significant bio-functions involved NPC1L1. Mutations of NRAS codon 61 were identified in 1 sample each of FTC-Classic, PTC-FV and FA and BRAF V600E in one PTC-Classic sample. Differential methylation of AARS2, CTU1, HLA-DPB1, SLC2A13, PNPLA7, NPC1L1, NT5C1B and SLC2A13 were identified in 1 sample each of FTC-Classic, PTC-FV and FA and BRAF V600E in one PTC-Classic sample. Differential methylation of AARS2, CTU1, HLA-DPB1, SLC2A13, PNPLA7, NPC1L1, NT5C1B and SLC2A13 in FTC were characterized by a significant enrichment of genes involved in the above pathways.

#3362 PBRM1 regulates the transcription of cell adhesion genes in ccRCC. Basudev Chowdhury. Purdue Univ., West Lafayette, IN.

Advances in parallel sequencing have facilitated the recent identification of Polybromo-1 (PBRM1), a component of the PBAF (Polybromo-associated-BRG1- or BRM-associated factors) chromatin remodeling complex, as the second most frequently mutated gene in clear-cell renal cell carcinoma (ccRCC). While several studies have described the diversity of PBRM1 mutations in ccRCC and established the mutation of PBRM1 as a “driver” of ccRCC carcinogenesis, little is known about the biological significance of PBRM1. With the intent of shedding light on the mechanistic roles of PBRM1, we have employed Next Generation Sequencing to delineate the transcriptional profile of cellular models of ccRCC with or without PBRM1 expression and identified genes associated with cell adhesion to be regulated by PBRM1 in 2D monolayer cultures. Since 2D cultures lack the architectural complexities to support studies pertaining to cellular adhesion, we evaluated the role of PBRM1 in 3D culture on Basement Membrane Matrix to provide a physiologically relevant analysis of gene expression and the resulting cellular phenotype. The results showed that of the 97 cell adhesion genes identified to be upregulated by PBRM1 in 2D cultures, 45 were also upregulated in 3D cultures and a subset of 32/45 genes underwent increased gene expression in 3D with respect to 2D cultures. The gene expression profile of candidate genes were verified by qPCR and Western Blotting. Mining The Cancer Genome Atlas (TCGA) publicly available data, we were able to correlate the gene expression profiles of cell adhesion genes identified in 3D cultures with those of ccRCC patients bearing at least 1 copy of the PBRM1 gene. Furthermore, we performed a PBRM1-Chip-seq to map the genome-wide targets of PBRM1 and revealed the association of PBRM1 occupancy at proximal regulatory regions of 8/45 cell adhesion genes. All of these taken together, indicate a role for PBRM1 in regulating the gene expression of cell adhesion genes which act as important players in cellular morphogenesis and responsiveness to changes in the external environment. Disruption of cell adhesion is believed to affect signal transduction and pave the way facilitating metastasis in neoplastic cells. Currently we are investigating the effect of loss-of-PBRM1 on Epithelial to Mesenchymal Transition (EMT) and metastasis in ccRCC.

#3363 Enhancer signature profiling identifies novel enhancer clusters for transcription factors in lung cancer. Stefanuminoello, Hideo Wataneabe, Takashi Sato. Icahn School of Medicine Mount Sinai, New York, NY.

We previously discovered that the targeted focus of the most significant amplicon in squamous cell lung cancer lies on the SOX2 gene locus, a product of which is a critical regulator in specifying squamous cell lineages in the development at dividing foregut to counteract with NKX2-1, which specifies tracheal and later lung lineages and is the most significantly amplified gene in lung adenoarcinoma. Cell lines harboring such amplification from respective lung cancer subtypes are dependent on the expression of these lineage-determining factors for their survival. However, the amplifications of these factors represent only 10-15% of lung cancer, it remains unknown what other lineage programs the remaining majority rely upon. Posttranslational modifications of histone proteins assign different functional regions of the genome, which leads to chromatin states that create stable expression patterns maintaining cellular fates. Studies on genome-wide enhancers have revealed the presence of large enhancer clusters, which are typically enriched in the proximity of lineage gene factors that establish a program defining cellular identity. To identify novel subsets of lung cancer defined by chromatin modification on lineage-determining factors, we made use of a histone modification marker H3K27Ac, typically present at active enhancers. We proﬁled H3K27Ac by ChIP-seq in 24 cell lines (14 lung adenocarcinoma, 4 squamous cell carcinoma, 4 small cell lung cancer and 2 breast carcinomas), identifying thousands of active enhancers, i.e. H3K27Ac enriched, and hundreds of super-enhancers (SEs) defined by ROSE algorithm per cell line. As a proof of principle, we found a locus adjacent to NKX2-1 gene as one of the SEs in an NKX2-1-ampliﬁed cell line NCI-H3122 suggesting this approach can detect a lineage program that is overridden by cancer cells. We performed unsupervised hierarchical clustering analyses on signals at SEs adjacent to transcriptional regulatory genes and identiﬁed subsets of genes co-enriched at the SEs. Several SEs on transcription factors are common between multiple cell lines from the same lineage (e.g., SOX2 and TP63 in squamous cell lineage and NKX2-1 in lung adenocarcinoma lineage). We identifed 6 lung adenocarcinoma cell lines that contain SE at the locus of N4R4A2, a signifcantly mutated gene in lung adenocarcinomas, and 2 other loci at the locus of HOX11, a lineage transcription factor for alveolar type I cells. These results suggest that this approach can reveal novel enhancers on lineage factors in a subset of lung cancers.

#3364 DNA methylation loss at an enhancer site of the DNA repair gene TREX2 is an epigenetic feature in multiple cancers. Christoph Weigel, Jitti-porn Chaisaimgomk, Christiane Kuhrmann, Irene Santi, Volkmar Winker, Olga Bogatyrova, Justo L. Bermejo, Tsun C. Chan, Felix Lasitschka, Manfred H. Boherer, Alexander Marx, Frank Autschbach, Roland Heyni-von Haufen, Herbst-Dyckhoff, Klaus-Wolfgang Delank, Karl Hoermann, Burkard M. Lippert, Gerald Baier, Andreas Dietz, Christoph C. Oakes, Christoph Plass, Heiko Becher, Peter Schneier, Heribert Ramroth, Odilia Popandia. German Cancer Research Center, Heidelberg, Germany; Chulabhorn Research Institute, Bangkok, Thailand; University of Heidelberg, Heidelberg, Germany; The University of Hong Kong, Hong Kong, China; University Hospital Heidelberg, Heidelberg, Germany; Medical Hospital, Ludwigshafen, Germany; University Medical Centre Mannheim, University of Heidelberg, Mannheim, Germany; SKL-Clinics Heilbronn, Heilbronn, Germany; Klinikum Darmstadt, Darmstadt, Germany; Head and Neck Surgery, University of Heidelberg, Heidelberg, Germany; University Hospital of Mannheim, Mannheim, Germany; Academic Teaching Hospital Darmstadt, Darmstadt, Germany; University of Leipzig, Leipzig, Germany.

The onset of numerous cancers is strongly associated with exposure to genotoxic agents and is counteracted by cellular DNA repair mechanisms. However, the tumorigenic potential of genotoxic carcinogens varies widely among individuals. It is...
still uncertain which genetic and epigenetic traits shape cancer onset and progression in the general population. While genetic aberrations in DNA repair genes have been linked to cancer risk, less is known about the importance of epigenetics for the regulation of these genes. In order to identify DNA methylation alterations in laryngeal cancer, we performed analysis of single CpG sites via mass-spectrometry genomic DNA analysis using DNA pyrosequencing of samples previously found to be altered in head and neck squamous cell carcinoma. We report loss of DNA methylation at the three prime repair exonuclease 2 (TREX2) gene locus in laryngeal cancer (n = 161) and adjacent normal tissue (n = 58) samples of patients from a German population-based case-control study. Following screening of tumor tissues from Chinese colorectal cancer patients as well as previously published data from the Cancer Genome Atlas (TCGA), we identified TREX2 methylation loss as a frequent trait in multiple cancers. We further characterized the regulatory activity of the affected TREX2 site using chromatin immunoprecipitation and luciferase reporter assays in cell lines from different tumor types. Differential TREX2 methylation affects a CCAAT/enhancer binding protein alpha (CEBPα) binding site serving as a gene enhancer which drives the expression of TREX2 from a previously uncharacterized gene promoter. We also observed a strong association between TREX2 methylation and TREX2 protein expression determined via immunohistochemistry in laryngeal tumors. Finally, we found a significant association between overall survival and loss of TREX2 methylation in laryngeal cancer, with TREX2 methylation loss being a protective factor. Our findings highlight a profound regulatory role of epigenetic mechanisms for TREX2 in tumors, and underline the usefulness of TREX2 DNA methylation as a biomarker for patient stratification.

#3365 Epigenetic inactivation of PTPRT and sensitivity to STAT3 inhibition in lung cancer. Malabika Sen, Audrey Kindsfather, James G. Herman. University of Pittsburgh Cancer Institute, Pittsburgh, PA. Signal Transducers and Activators of Transcription-3 (STAT3), a potent oncogenic transcription factor is persistently activated in several malignancies including lung cancer. Protein Tyrosine Phosphatase Receptor-1 (PTPRT) is an endogenous inhibitor of STAT3 transcriptional activity, and is methylated in many types of human cancer. Loss-of-function of PTPRT by promoter methylation contributes to STAT3 mediated growth and survival and represents one of the plausible mechanisms of STAT3 hyperactivation. We report identification of hypermethylation in CpG islands of the PTPRT promoter which correlates with its transcriptional silencing as well as expression of pSTAT3 protein and STAT3 target genes in both lung cancer cell lines and primary human tumors. Analyses of the TCGA (The Cancer Genome Atlas) data revealed that PTPRT promoter is frequently hypermethylated in a subset of lung squamous cell carcinoma and approximately 25% of adenocarcinoma tumors in association with downregulation of PTPRT mRNA expression. This observation was verified in vitro using lung cancer cell lines. Out of the 7 lung cancer cell lines examined, one lung cancer cell line showed lack of methylation (only unmethylated sequences) of the PTPRT promoter region and revealed mRNA expression (HS20). All 6 cell lines which showed PTPRT promoter methylation had severely absent PTPRT mRNA and had high levels of pSTAT3 Tyr705, while HS20 had low or no PSTAT3 Tyr705 protein expression. Silencing of PTPRT using siRNA in HS20, where PTPRT was not endogenously silenced by promoter hypermethylation, resulted in the upregulation of the STAT3 target genes such as cyclin D1 and Bcl-X, mRNA and protein expression as well as increased pSTAT3 Tyr705 level. Analyses of the methylation status in the PTPRT promoter region in primary lung tumor samples revealed methylation in one of the 3 tumor samples. This correlated with increased STAT3 target genes (cyclin D1 and Bcl-X) mRNA expression in lung cancer cell lines. PTPRT promoter methylation is associated with sensitivity to STAT3 inhibition. Our data suggests that silencing of PTPRT by promoter hypermethylation is a frequent mechanism of STAT3 hyperactivation, and targeting STAT3 may be an effective molecular targeted approach in the treatment of this subset of lung cancer.

#3366 Loci-specific differences in blood DNA methylation for early detection of hepatocellular carcinoma. Katarzyna Lubecka, 1 Megan Beech, 1 Jay Qui, 1 Lucinda Kurzawa, 1 Kirsty Flower, 1 Samer Gawrieh, 1 Suthat Liangpunsakul, 2 Nagar Chalasani, 1 James M. Flanagan, 1 Paulus Metzakos 1, 3 Purdue University, West Lafayette, IN; 2 Imperial College London, London, United Kingdom; 3 Indiana University School of Medicine, Indianapolis, IN. Late onset of clinical symptoms in hepatocellular carcinoma (HCC) results in late diagnosis and poor disease outcome. It is estimated that early detection of HCC would increase the cure rate from 5% to 80%. Thus, identifying new effective tools with reliable and quantifiable biomarkers is of high importance. Such tools are currently missing. Aberrations in the DNA methylation patterns, an important early event in carcinogenesis, have been shown to differentiate HCC tumors from normal tissues. However, these changes as diagnostic markers would have a high application in clinics only if detectable by minimally invasive tests like a blood test. In the present study, we performed a comprehensive evaluation of DNA methylation profiles in blood DNA collected from 24 HCC patients (cases) who provided samples after diagnosis and from 24 controls, enrolled by the Indiana Biobank. Cases were matched with controls on gender, age, ethnicity, hepatitis C infection, and diabetes. We used Human Methylation 450 BeadChip (Illumina) to perform DNA methylation analysis and pyrosequencing for validation of DNA methylation differences. We identified 7,047 CpG sites differentially methylated between cases and controls with p<0.05 and intraclass correlation coefficient (ICC) >0.5. The change in DNA methylation within the top 14 CpG sites corresponding to 12 genes (probes) was technically validated using pyrosequencing. Five probes were hypermethylated and 7 probes were hypomethylated vs. controls. These gene-specific candidate biomarkers that could be used in early detection of HCC only if detectable at pre-diagnostic stages. We therefore selected 4 out of 12 probes that presented the highest differences in post-diagnostic cases. We then verified DNA methylation changes at those 4 probes in blood samples collected from 21 patients at the time when they were clinically considered cancer free (pre-diagnostic) and developed HCC within 4 years of follow-up. We confirmed that methylation at all 4 selected probes discriminates pre-diagnostic cases from matched healthy controls. One of the strongest differences was detected within an enhancer of PCGF3 (difference = -0.12, ICC = 0.84). PCGF3 is a component of a Polycomb group multigene repressive PRC1-like complex and was found to be over-expressed in HCC tumors and in many other types of cancer according to Oncomine database. Our work not only establishes the first time differences in DNA methylation at specific CpG sites that are detectable in blood of individuals both before and after conventional diagnosis with HCC as compared with healthy individuals. The identified probes have high potential to be developed into early detection HCC biomarkers once validated in a larger cohort of individuals at risk. This research was supported by the ACS Institutional Research Grant and Showalter Trust Award granted to BS.

#3367 The clinical significance of epigenetic microRNA-137 silencing in patients with ulcerative colitis. Yuji Toyama,1 Yoshinaga Okugawa,1 Koji Tanaka,1 Toshimitsu Araki,2 Keiichi Uchida,1 Masato Kusunoki,1 C. Richard Boland,2 Aijay Goel2. 1Mie University, Tsu, Japan; 2Baylor University Medical Center, Dallas, TX. Background: Although present guidelines recommend periodic colonoscopy with multistep biopsies for surveillance of ulcerative colitis (UC)-associated colorectal cancer (CRC), it remains unclear about the effectively. To improve the surveillance, more effective markers are needed to identify patients at high risk for UC-CRC. MicroRNA (miRNA)-137 is often methylated in sporadic CRC. Methylation of this miRNA also occurs in an age-dependent manner, suggesting a potential "field defect", and possibly an early event in colectis-associated carcinogenesis. The objective of this study was to determine whether a methylation-related "field defect" of miR-137 could be exploits clinically to identify individuals with UC who are at increased risk for developing neoplasia. Materials & Methods: We conducted four-step analysis using 387 samples from 238 UC patients of two independent cohorts, which included 152 patients without neoplasia (matched specimens obtained from cecum, transverse colon and rectum for each patient), 17 with dysplasia, and 69 with cancers (neoplasms and corresponding rectal mucosa). We performed bisulfite pyrosequencing to quantify miR-137 promoter methylation levels of these samples. Results: In non-neoplastic UC patients, methylation levels of miR-137 were significantly higher in rectal mucosa than in proximal cecum mucosa (7.0 ± 2.8% vs. 4.9 ± 2.0%, P < 0.0001), and were associated with age at diagnosis (P < 0.0004) and disease duration (P = 0.0009) in rectal mucosa. In addition, methylation levels of miR-137 were significantly higher in dysplasia (P < 0.0001) and CRC (P < 0.0001) compared to non-neoplastic UC mucosa. In addition, miR-137 methylation levels in rectal mucosa from patients with neoplasia (dysplasia or cancer) were significantly higher compared to methylation in patients without neoplasia, suggesting the existence of "field defect" in rectal mucosa from patients with neoplasia. Receiver operating characteristic (ROC) analysis revealed that methylation levels of miR-137 in rectal mucosa successfully differentiated patients with CRC from those without (AUC: 0.8). Furthermore, multivariate logistic regression analysis revealed that miR-137 methylation in rectal mucosa emerged as an independent predictor of UC-CRC (OR: 5.53; P = 0.0148). Finally, ROC analysis was performed to validate the findings and revealed a significant difference in methylation levels of miR-137 between UC patients with vs. without neoplasia, with almost same AUC value (0.76). Conclusions: Methylation of miR-137 occurs in an age- and cancer-dependent manner in UC patients. Analysis of miR-137 methylation levels in rectum may be a biomarker for identification of UC patients at greatest risk for UC-CRC.
for germline genetic variation in altering gene expression. However, in methylation downstream). In general, combining genomic data in HGSOC did not reveal a role in somatic copy number (CNV): a germline genotype and tumor DNA methylation (full model), b) gene only, and c) DNA methylation only. We included 33 cases from The Cancer Genome Atlas (TCGA), 54 cases from Mayo Clinic, and 78 cases from the Australian Ovarian Cancer Study (AOCs). Genotyping and copy number calls on germline DNA expression, methylation and copy number on somatic samples were collected and analyzed on different platforms separately at each study site. We excluded genes with low overall expression and thus analyzed a total of 1,929 genes in all three datasets (53 for CNVs, 505 for expression, and 367 for downstream). In general, combining genomic data in HGSOC did not reveal a role for germline genetic variation in altering gene expression. However, in methylation only models 79 genes were associated with differential expression in the TCGA cases (permutation multiple testing adjusted p-val <0.05), in the Mayo cases (unadjusted p-val <0.05) and AOCs cases (unadjusted p-val <0.05). A known tumour suppressor (FBXW7) was associated with differential expression in the three datasets at p-val <0.01. This work demonstrates the feasibility, utility, and statistical power of ENET gene-level analyses incorporating maximal genomic information.

Epigenetic DNA methylation profiling of triple negative breast cancer tumors and non-tumor tissue was performed using a highly sensitive and quantitative analytics platform, which utilizes methylation sensitive restriction endonuclease to detect changes in methylation of CpG sites. Millions of CpG sites exist within the human genome and many of these are altered with tumor formation and progression, therefore, changes in methylation profiles of CpG sites may be useful as a diagnostic and/or prognostic biomarker in TNBC patients. Non-metric multidimensional scaling ordination analysis of the CpG sites revealed highly distinct methylation patterns between tumor and non-tumor tissue. Approximately 326 sites had a significant methylation score difference (p<0.0025) between TNBC tumor and non-tumor tissue, with most of the CpG sites having greater than 2-fold change in methylation status. Analysis of functional gene classes using KEGG classifiers revealed a significant change in methylation patterns of genes involved in response to infections and other immune related functions. Additionally, the top ten genes with hyper- or hypomethylated sites within TNBC tumors when compared to non-tumor tissue were identified. Interestingly, Gli-1 was one of the top hypomethylated genes. Gli-1 has been shown in our lab and others to have significance in chemoresistance and recurrence in TNBC patients. Immunohistochemical analysis of TNBC tumors revealed Gli-1 overexpression in TNBC tumors compared to non-tumor tissue. Expression levels of Gli-1 in TNBC tumors correlated with stage (p<0.001) and recurrence free (p<0.0221) and overall survival (p<0.017). Thus, analysis of CpG methylated sites in TNBC tumors and non-tumor tissue revealed differences in epigenetic profiles allowing for distinction between tumor and non-tumor tissue. Genes in TNBC tumors with significant changes in methylation status may be potential candidate genes that serve as a diagnostic or prognostic biomarker for TNBC.

Comparative analyses of multi-omics profiles reveal distinctive molecular signatures of young Asian breast cancers. Yeon Hee Park,1 Ying Ding,2 Soo-Hyeon Lee,1 Hae Hyun Jung,2 Woosung Chung,1 Soonwong Cho,1 Jin-Ho Kim,1 Shihbing Deng,1 Yoon-La Choi,1 Julio Fernandez,2 Se Kyung Lee,2 Seo-Hyeon Kim,1 Jeong Eun Lee1,2 Yeon Myung2,3 Jin TNBC in AA: Young-Hyuck1,2 Seo-Jin Nam,1 Woong Yang Park,1 Zhe-Qian Kan,1 Sunmiwon Medical Center, Seoul, Republic of Korea; 2Pfizer, Inc., San Diego, CA; 3Pfizer, Inc., Seoul, Republic of Korea; 4Johns Hopkins University, Baltimore, MD.

Breast cancers (BC) in younger, premenopausal patients (YBC) tend to be more aggressive with worse prognosis, higher chance of relapse and poorer response to endocrine therapies compared to breast cancers in older patients. The proportion of YBC (age ≤ 40) among BC in East Asia is estimated to be 16-32%, significantly higher than the 7% reported in Western countries. In addition, approximately half of the Asian BC patients were premenopausal compared to 15-30% in the West. To characterize the molecular bases of Asian YBC, we have performed whole-exome sequencing (WES) and whole-transcriptome sequencing (WTS) on tumor and matched normal samples from three Korean BC patients consisting of 106 YBC cases (age ≤ 40) and 62 OBC cases (age ≥ 40). We then performed comparison analyses with the TCGA BC cohort consisting of 1,116 tumors from primarily Caucasian patients, also grouped by age into YBC (age ≤ 40), IBC (40 < age ≤ 60) and OBC (age > 60). We performed logistic regression analyses to identify differentially expressed (DE) genes and protein-coding gene age-based signatures while controlling for demographic and clinical factors of molecular subtype, tumor purity and stage. Within the Asian cohort, we found that estrogen response, endocrine therapy resistance, and various metabolism pathways are up-regulated in YBCs while cell cycle, proliferation and inflammatory pathways are up-regulated in OBCs. To separately examine molecular signatures from tumor, stroma and normal compartments, we used non-negative matrix factorization (NMF) analyses to virtually dissect bulk tumor expression data and identified 14 factors including 3 factors associated with tumor infiltrating leukocytes (TILs). By examining the correlation between pathway gene expression and NMF factors, we inferred that DE pathways such as fatty acid metabolism, bile acid biosynthesis, and epithelial-to-mesenchymal transition (EMT) were mainly active in stromal and normal tissue compartments. The TIL factor was significantly enriched in Asian BCs relative to Caucasian BCs with the highest TIL factor weight observed in Asian OBCs. Using gene expression signatures representing distinct types of TILs, we classified the combined cohort into three subtypes of varying TIL activities. Consistent with results from the NMF analysis, the TIL-high subtype is also significantly enriched in Asian BCs compared to Caucasian BCs. To our knowledge, this is the first large-scale multi-omics study of Asian breast cancer. Comparative analyses of multi-omics profiles from Asian and primarily Caucasian BC cohorts identified distinguishing molecular signatures associated with Asian BCs. Further, many signatures appeared to be specific to non-tumor compartments within bulk tumor, indicating that young Asian BCs may harbor distinctive tumor microenvironment.

Aldh expressing stem cells mediate tumor initiation and metastasis in triple negative breast cancers across different ethnicities. Evelyn M. Jiagge,1 Shukei Wong,2 Rabia Gilani,3 Sean McDermott,6 Lisa Newman,4 Jessica Bensenhaver,7 Max Wicha,1 John Carpten,2 Sofia Merajver7, Univ. of Michigan Health System, Ann Arbor, MI; 2Translational Genomic Institute, Phoenix, AZ; 3University of Michigan, Ann Arbor, MI; 4Henry Ford Health System, Detroit, MI.

TNBC is the only subtype of breast cancer for which there are no approved targeted therapies. In the US, its incidence is highest in women with African ancestry (AA); in western sub-Saharan Africa, single-institution studies show that TNBC constitutes 40-80% of all breast cancers. Given the Caucasian/AA survival disparity in breast cancer, there is an urgent need to find actionable targets in TNBC of all ethnicities, but especially in TNBC in AA, which are suspected to be more aggressive. Breast cancer stem cells, the small population of cells that have been shown to mediate breast tumor initiation, metastasis, and resistance to conventional therapy have also been reported to mediate the heterogeneity of TNBC and are emerging as an important target. Here we sought to better understand the biology of TNBC by finding genes and pathways that are differentially expressed in the stem cell population of patient derived xenografts (PDX) from TNBC from Ghanaian (G), AA and Caucasian (C) women and the effect of these differentially expressed genes on the stem cell.
phenotype in these primary tumors. We isolated the ALDH+ and the CD44+/CD24- stem cell populations from the bulk cells in 15 PDXx using flow cytometry. We performed RNA sequencing (Illumina HiSeq platform) on the isolated populations and bulk cells (45). Comprehensive bioinformatics analyses led to the identification of highly significantly differentially expressed genes and pathways unique to the cell populations. By principal component analysis, the tumors were very heterogeneous. However, the ALDH+ cells separated out from the CD44+/CD24- and the bulk cells. We identified 14 genes that were simultaneously differentially expressed between the ALDH+ vs the CD44+/CD24- as well as ALDH+ VS bulk (p-value <0.001, FDR < 0.05). The 3 most significant genes were MMP2 and PCDH7, both known to be involved in breast cancer metastasis, and CD24, a carbohydrate binding (GBP2) marker. The number of DEX genes between Basal (8) and LA (18) sub-clusters were comparable to that between the Her2+ sub-clusters, DEX exons were much lower for both subtypes (616 & 157), and none of the DEX proteins (3 & 7) mapped to DEX exons or genes for either subtype. Conclusions: Our findings imply that the role of CSTF2 in proximal polyA signal selection. Because some of the TNBC patients compared with normal breast tissue. Representative shortening events correlated with increased protein levels and relapse free survival of patients, suggesting functional significance of isoform variability. To begin addressing the underlying mechanisms of 3’UTR shortening, we turned to APA machinery proteins. We detected variable expression of APA machinery proteins in different breast cancer subtypes but CSTF2 (cleavage stimulation factor) was the most prominent overexpression in breast cancer cells. Therefore, among potential regulators of 3’UTR shortening, we further investigated the role of CSTF2 in proximal polyA signal selection. Because some of the TNBC patients are EGRF positive, we found EGF treatment to cause increased CSTF2 levels. Higher CSTF2 levels indeed correlated with further shortening of the 3’UTR. Accordingly, RNA-induced silencing of CSTF2 decreased the proliferative rate of cancer cells. Therefore, our integrated approach revealed a pattern of 3’UTR length changes in TNBC patients and a potential link between APA and EGF signaling. Further studies are underway to investigate the mechanism between EGF signaling and regulation of 3’UTR lengths. (This work is funded by TUBITAK 112S478 and 114Z884).
Molecular and Cellular Biology / Genetics: Genomic Landscape of Breast, Prostate, Ovarian, Melanoma, and Thyroid Cancers

In the U.S., the incidence rates of breast cancer (BC) among Caucasian (CA) women are lower than those of African American (AA) women, however, AA women have a significantly higher mortality rate. AA women often present at a younger age, with later stage and higher grade tumors. In fact, AA women are 3 times more likely to be diagnosed with the more aggressive molecular subtype, triple-negative breast cancer (TNBC), than CA women. Socioeconomic and lifestyle factors may be contributory; however, it is imperative that we investigate the underlying molecular biology that may be the cause of health disparities between AA and CA with TNBC. In this study, gene expression profiling, using the Almac BC DSA Research Tool, was performed on archived FFPE samples, obtained from CA and AA women diagnosed with early stage (Node 0) TNBC. Unsupervised hierarchical clustering showed that expression in the AA TNBC cohort compared to CA, using the TNBC type: A Subtyping Tool for TNBC, we found a distinct distribution pattern of TNBC molecular subtypes in the AA cohort, which was very different than the CA cohort; Basal-like (14%), Immunomodulatory (43%) and Mesenchymal (43%). Gene expression analyses, comparing AA and CA cohort (fold change > 2.0, p-value < .05), resulted in 190 differentially expressed genes (DEG). Pathway enrichment analysis conducted in MetaCore GeneGo, revealed that the DEGs were over-represented in cytokoskeletal remodeling, cell adhesion, tight junctions, and immune response in the AA TNBC cohort. Furthermore, several genes in the Wnt/β-catenin pathways were over-expressed in the top 10-enrichment pathways. We validated our results using RT-qPCR and identified Cavelon-1 (CAV1) as being significantly expressed in the AA-TNBC cohort (p-value 1.22x10^-05). An independent cohort of FFPE samples, from AA and CA women with early stage TNBC, was used to create a tissue microarray (TMA). Immunohistochemistry results showed no difference in localization of CAV1 between AA and CA cohorts, however, the AA cohort had significantly higher levels of CAV1 staining (p-value 0.04). Additionally, using RT-qPCR, we demonstrated that CAV1 mRNA was significantly higher in the AA TNBC cohort (p-value 0.048). Furthermore, endogenous CAV1 was shown to be highly over-expressed in a cell line panel of TNBC, in particular, those of the mesenchymal and basal-like molecular subtype. Finally, using siRNA, we demonstrated that CAV1 silencing resulted in a significant decrease in cell proliferation, for each of the TNBC cell lines while it showed no effect on the luminal ER+ cell lines. Our combined study results suggest that CAV1 over-expression may be a biological contributor to the observed health disparity between AA women and CA diagnosed with early stage TNBC.

#3376 Reprogramming the estrogen signaling network is a potential mechanism for human breast tumorigenesis. David Chi,1 Hari Singhal,2 Lewy Li,3 Henry W. Long,4 Judy E. Garber,5 Myles A. Brown,2 1Harvard Medical School, Boston, MA; 2Dana-Farber Cancer Institute, Boston, MA.

Background: The estrogen receptor (ER) is expressed in approximately 70% of sporadic breast tumors, is known to have a key role in cellular transformation. Much work in the field has characterized the mechanisms of ER signaling behind cancer progression and eventual metastasis, and therapeutic targeting of the ER signaling pathway has proven effective. However, little is known regarding the role of ER in the initial process of transformation. Since ER possesses pro-differentiation signaling pathways, have a significant role in controlling cell proliferation in normal mammary epithelial cells, and the interaction with transcriptional cofactors such as GRHL2 could be a driving mechanism for breast tumorigenesis. Unraveling the differential ER signaling in normal mammary epithelial cell and breast cancer will enhance our understanding of breast cancer and aid the development of more effective prevention strategies and targeted therapeutics.

#3377 Simultaneous analysis of the mutational landscape and RNA and protein expression profile of HER2-positive breast cancer using 3D Biology™. Saranya Chumsri,1 Daniel J. Serie,1 Brian M. Necela,2 Jennifer M. Kachergus,2 Branca C. Asenfeld,3 Gokhan Demirkan,4 Gavin Meredith,5 P. Martin Ross,6 Anuisha Khan;7 Chae H. Ahn,4 Afzlin Mahbub Hossain,5 Sarah Warren,5 Sarah A. McLaughlin,1 Joseph Beechem,7 Gary Geiss,2 E. Aubrey Thompson1,2 Mayo Clinic Florida, Jacksonville, FL; 3NanoString Technologies, Seattle, WA.

Background: Understanding heterogeneity within individual breast tumors is key to the ability to predict therapeutic outcome. Molecular heterogeneity is commonly evaluated based on genomic features, including mRNA abundance, gene copy number events, and somatic mutations. The expression profile and activation state of key proteins is widely recognized as another key element in defining tumor heterogeneity. We have taken advantage of NanoString 3D Biology™ technology (for research use only) and curated nCounter Vantage 3D™ Solid Tumor Assay to interrogate a survey panel of HER2-positive breast tumors with the ultimate goal of determining key differences between multiple, genomic, and proteomic profiles in individual tumors. Methods: We analyzed samples from 24 HER2+ breast cancer patients using NanoString technology to quantify the expression profile for over 25 total and phospho signaling proteins, including PI3K/PI4K/EGFR/HER2, 770 mRNA corresponding to 13 canonical cancer pathways, and 104 somatic mutations and small INDELS that are commonly associated with cancer, including 8 known PIK3CA mutations. These analyses were carried out in a matched fresh frozen and FFPE samples on the nCounter platform. Data were analyzed by nSolver to identify genotype-specific expression profiles across the 24 samples. Results: In our proof-of-concept data set, we successfully demonstrate that NanoString’s 3D biology Technology shows concordance across both FFPE and fresh frozen sample types for DNA, RNA, and protein. NanoString analysis also showed high concordance to genome-wide techniques used to assess genotype and RNA expression profiles. The combination of digital DNA, RNA, and protein data from our HER2+ breast cancer samples yielded potentially actionable data based on mapping of mutational status as the driver of key differences in protein expression and mRNA abundance of the signaling targets profiled. This work sheds new light on HER2+ breast cancer biology and the interplay between genomic and proteomic profiles while setting the stage for future studies that further probe the differences observed in this sample set. Conclusions: Simultaneous analysis of mutational status (SNV) and expression at the level of both mRNA and protein promises to enable a more detailed view of the relationship between genotype and the biological and clinical behavior of key tumor types. The NanoString Vantage 3D™ Solid Tumor platform provides a rapid, reliable, and economic means of assessing these analytes simultaneously. The application of these analytics to model that malignantly and clinically actionable predictions will require additional analyses of large sample cohorts, but such analysis is quite feasible using a variety of sample types. Acknowledgements: Supported in part by grants from the Breast Cancer Research Foundation and the 26.2 with Donna Foundation.

#3378 Whole exome sequencing identifies recurrent alterations in genes in malignant phyllodes tumors in nine Korean individuals. Jihui Yun,1 Hyeong-Gon Moon,2 Tae-Kyun Yoo,2 Eunshin Lee,3 Jeeseo Cha,1 Sam Hur,2 Jiwoo Lee,2 Jong-II Kim,1 Dong-Young Noh2.

Phyllodes tumors of the breast are rare fibroepithelial neoplasms with variable clinical behavior accounting for about 1% of all breast neoplasms. Phyllodes tumors are classified into benign, borderline, and malignant grades on the basis of histological features. Among those categories, Malignant phyllodes tumor has a higher propensity for local recurrence and distant metastasis, however the malignant potential of this solid tumor is still unclear. Here, by performing whole exome sequencing of 9 malignant phyllodes tumors with matching normal cases, we frequently observed mutations in MED12 (3/9, 33.34%). Additionally, non-silent mutations in p53 (TP53) and epidermal growth factor receptor (EGFR) were recurrently identified. Whole-gene amplifications of EGFR were also found in six cases (6/9, 66.67%). We suggest that EGFR has an underlying role in malignant phyllodes tumors. This study identifies potential therapeutic targets in malignant phyllodes tumors, including EGFR.
#3379 Massively parallel sequencing analysis of breast adenomyoepitheliomas reveals the heterogeneity of the disease and identifies a subset driven by HRAS hotspot mutations. Felice C. Geyer,1 Kathleen A. Burke,2 Anqi Li,1 Anastasios D. Papanastassiou,1 Freisa Pareja,1 Anne S. Schulteis,1 Charlotte K. Ng,1 Salvatore Piscuoglio,1 Marcia Edelweiss,1 Luciano G. Martelotto,1 Pier Selenica,1 Serafina M. Moretti,1 Gabriel S. Macedo,1 Achim J. Gluth,1 Hannah Y. Wen,1 Juan Padasso,2 Zsuzsanna Varga,2 Emad Rahka,1 Ian O. Ellis,1 Brian Rubin,1 Britta Weigelt,2 Jorge S. Reis-Filho,1 "Memorial Sloan Kettering Cancer Center, New York, NY; 2Thomas Jefferson University Hospital, Philadelphia, Pennsylvania, PA; 3University Hospital Zurich, Zurich, Switzerland; 4Nottingham Medical Center Groningen, Groningen, Netherlands; 3Iwate Medical University, Japan; 4Nottingham University Hospitals, Nottingham, United Kingdom; 5Cleveland Clinic, Cleveland, OH.

Adenomyoepithelioma (AME) is a rare biphasic proliferative breast lesion, which may resemble salivary gland epithelial-myoepithelial carcinomas (EMCs). Most AMEs have an indolent clinical course, but malignant transformation and local and distant recurrences have been reported. We sought to define the mutational landscape of AMEs and investigate the functional impact of recurrent likely pathogenic mutations identified in these tumors. Nineteen AMEs were subjected to whole-exome massively parallel sequencing (WES, n = 7) or targeted capture MPS using MSK-IMPACT assay (n = 12). Somatic genetic alterations and the cancer cell fraction of mutations were defined using state-of-the-art bioinformatics algorithms. Selected genes (i.e. HRAS and PIK3CA) were subjected to Sanger sequencing in a series of 17 additional AMEs (total n = 36). Non-tumorigenic mammary epithelial cells (i.e. MCF10A, MCF10A with the PIK3CA-H1047R mutation and MCF12A), which are estrogen receptor (ER)-negative, were utilized for 2D and 3D functional studies. Of 36 cases, 22 were ER-positive and 14 were ER-negative. MPS analysis revealed a low mutation burden and HRASp51 and PIK3CA hotspot mutations in 6/19 (32%) and 11/19 (58%) AMEs, respectively. All HRASp51 and all but one PIK3CA mutations were clonal. ER-positive and ER-negative AMEs were fundamentally histologically and genetically distinct. Whilst ER-positive AMEs displayed recurrent HRASp51 mutations (50%, 11/22) but lacked HRAS mutations, ER-negative AMEs displayed negative AMEs displayed in addition to PIK3CA mutations (57%, 8/14), recurrent HRASp51 mutations (57%, 8/14). HRASp51 mutations co-occurred with PIK3CA mutations (50%, 4/8), PIK3R1 deletions (12.5%, 1/8) and/or CDK2N1 homozygous deletions (25%, 2/8). HRAS mutations, but not PIK3CA mutations, were significantly associated with ER-negativity (100% vs 21%), concurrent carcinoma (50% vs 7%), axillary metastases (38% vs 0%), high proliferation (63% vs 4%), necrosis (63% vs 11%) and nuclear pleomorphism (75% vs 29%). In vitro forced HRASp51 expression in MCF10A and MCF12A cells resulted in increased proliferation and transformation. In 3D organotypic cell cultures, forced HRASp51 resulted in a highly disorganized growth pattern, a partial loss of epithelial phenotype and acquisition of aberrant myoepithelial differentiation, which was more overt in PIK3CA-mutant MCF10A cells. In conclusion, AMEs are phenotypically and genetically heterogeneous. Whilst PIK3CA hotspot mutations occur across the spectrum of lesions, HRASp51 hotspot mutations are restricted to ER-negative AMEs, which should arguably be classified as breast EMCs. Our genomic and functional analyses are consistent with the notion that HRASp51 mutations are driver events in the pathogenesis of ER-negative AMEs and may be sufficient for the acquisition of myoepithelial differentiation in breast cells.

#3380 Synthetic lethal interaction between ARID1A mutation and BET bromodomain inhibition in ovarian clear cell carcinomas. Katrien Berns,1 Joseph J. Caumanns,1 E Marielle Hijmans,1 Annemie Gennissen,1 Bastiaan Evers,1 Bea A. Wismans,1 Gert Jan Meersma,1 Gor Lieftink,1 Roderick L. Beijersbergen,1 Hiroaki Itamochi,2 Steven de Jong,2 RenéBernards1,3 Netherlands Cancer Institute, Amsterdam, Netherlands; 1University Medical Center Groningen, Groningen, Netherlands; 2Iwate Medical University School of Medicine, Iwate, Japan.

Introduction: Current treatment for advanced stage ovarian clear cell cancer is severely hampered by a lack of effective systemic therapy options, leading to a poor outlook for these patients. Given that ARID1A is inactivated by mutation in over 50% of ovarian clear cell carcinomas, we pursued an ARID1A synthetic lethal screening approach to identify potential drugable targets. Methods: We performed synthetic lethal kinome short hairpin (shRNA) screens in a large panel (n = 14) of OCCC cell lines having different ARID1A mutation status. Hit validation was performed with isogenic ARID1A ko cell line pairs and in (patient-derived) xenograft mouse models. Summary of the data: We show here that BRD2 inhibition is synthetic lethal with ARID1A mutation in ovarian clear cell carcinomas. Importantly, inhibiting the BET family of proteins, to which BRD2 belongs, with small molecules specifically inhibits proliferation of ARID1A mutated cell lines both in vitro and in ovarian clear cell cancer xenografts and patient-derived xenograft models. We demonstrate that ARID1A loss leads to upregulation of the WNT ligand WNT10B, possibly causing a WNT dependency in the ARID1A mutant lines. BET inhibitors cause a reduction in WNT10B expression and WNT target genes such as MYC, JUN and WISP1, providing a potential explanation for the observed synthetic lethal interaction with ARID1A loss. Conclusions: Our study uncovered a new synthetic lethal interaction between ARID1A mutation and BET bromodomain inhibition, suggesting a new treatment strategy for ARID1A mutant ovarian clear cell carcinomas.

#3381 TERT promoter mutation in granulosa cell tumours of the ovary: Prevalence and prognostic significance. Jessica A. Pilsworth,1 Dawn R. Chrane,2 Zhouchunyang Xia,1 Hugo M. Horlings,1 Winnie Yang,1 Melissa K. McConney,1 Satoshi Yanagida,1 Annina E. Färkkilä,2 Adele P. Wong,2 Genny Trigo-Gonzalez,2 S.W. Grace Cheng,2 Yikan Wang,2 Ali Bashashati,2 Gregg B. Morin,2 Esther Oliva,1 Sohrab P. Shah,1 David G. Huntsman,1 University of British Columbia, Vancouver, British Columbia, Canada; 2BC Cancer Agency, Vancouver, British Columbia, Canada; 3Iwate Medical University School of Medicine, Japan; 4University of Helsinki, Finland; 5Massachusetts General Hospital, MA.

Granulosa cell tumours (GCTs) of the ovary account for 90% of sex cord-stromal tumours and have a high recurrence rate up to 50%. A missense mutation in the FOXL2 gene (c.402C>G; p.C134W) is a defining feature of GCT and is used as a robust marker for diagnosis. However, other than the FOXL2 mutation the pathogenesis and the driving pathways remain unknown. Determining secondary genetic events in GCTs is essential to understanding and improving prognosis. In a pilot study, we completed an analysis of TERT promoter sequencing of GCTs and matched normal cases to generate a comprehensive catalogue of coding and non-coding events. We identified a TERT promoter mutation (c.228C>T) in 50% of these cases. TERT is normally inactivated in somatic tissues; however, this promoter mutation has been shown to re-activate transcription of TERT. We validated this TERT mutation in an international cohort of 300 GCTs and found it was present in approximately 25% of cases overall. These TERT promoter mutations have been used to revise the molecular classification of other cancer types such as gliomas. In GCT, we found that this TERT mutation was correlated with a significantly worse survival outcome in patients with primary GCT (p < 0.005). Further, we found that this TERT mutation was present in a larger proportion of recurrent cases. Thus, this mutation may denote a novel subtype of GCT with a worse prognosis. Previous research has shown that TERT activation is evident in over 90% of cancers and is a fundamental step in tumourigenesis that enables unlimited proliferation. This TERT promoter mutation in GCT provides an explanation of how granulosa cells escape atresia and attain immortality. Thus, we hypothesize a mechanism in which the FOXL2 mutation prevents apoptosis and the TERT mutation allows oncogene proliferation to transform granulosa cells. However, the current cell models of GCT lack relevant functional pathways and do not recapitulate the biology of these tumours. Therefore, we are developing more suitable cell models to test our hypothesis. We believe that understanding the interaction between these TERT and FOXL2 mutations may lead to novel cancer cell-specific targeted therapies.

#3382 Comparative genomic and pathway analysis of ovarian cancer, benign tumors, and normal tissues detect alterations in several metabolic programs in ovarian cancer. Pourya Naderi Yeganeh,1 Zahra Bahrami-Mostafavi,1 Christine Richardson,1 David L. Tait,2 M Taghi Mostafavi1,2 "UNIV. Of North Carolina Charlotte, Charlotte, NC; 3Carolina's Medical Center, Charlotte, NC.

Introduction: The high mortality rate of ovarian cancer is mainly due to asymptomatic early stages of the disease. Currently used detection markers lack high sensitivity and specificity and generate large number of false positives from benign and normal subjects. Therefore experimental approaches capable of distinguishing the signatures of malignancy are required to improve the current states of biomarkers. This study aims to identify genetic abnormalities in ovarian cancer that contribute to cancer progression and developments. Methodology: This study was conducted on 67 whole tissue microarrays samples processed using Affymetrix HG-Focus chip, including 18 non tumorous samples (N), 14 benign tumor samples (B), 30 malignant ovarian samples (M), 3 borderline malignant samples, and 2 ovarian cancer cell lines. Differential expression (DE) analysis was conducted through Analysis of Variance methods (ANOVA) between malignant samples and non-malignant samples (M vs B and N). DE results were modified to False Discovery Rate (FDR < 0.05). Further pathway analysis was conducted on DE genes to identify pathways with dysregulated elements. Pathway identification was performed by enrichment analysis method based on KEGG annotated pathways. P-values were calculated using Chi-Square test (FDR<0.05). Further enrichment analyses were performed by MsigDB
GSEA portal. Results: 826 DE genes were found with fold change > 2. PDGFRα, TACSTD2, ABCA8, STAR, and C7 exhibited the highest rates of fold change (more than 14 fold). Enrichment Analysis of Hallmarks reveals several hallmarks of cancer related terms including EMT, G2M, E2F targets, P53 pathways, and Apoptosis. Pathway analysis identifies 26 pathways with dysregulated components many of which are categorized as metabolic pathways including: Ascorbate Metabolism, Metabolism of xenobiotics by cytochrome, Drug metabolism cytochrome P450, and Glutathione Metabolism. Gene Ontology Enrichments identify several significant enrichments including: Response to Endogenous Stimulus, Regulation of Cell Proliferation, Tissue Development, Regulation of Cell Death, and Cell Cycle Process. Conclusions: DE analysis and Pathway can reveal dysregulated metabolic programs in ovarian cancer and the results of GO, Pathway, and hallmark enrichment analysis are consistent with mechanistic differences between malignant tumors and other types of pathology. The inclusion of benign tumors and non-malignant ovarian tissues contribute to more accurate identification of disease profile. As expected, our data support mechanisms of P53 mutations in malignancy and tumor progression. These results can be used to identify such mechanisms in more detail as the detected D5 genes can be used to generate hypothesis set for detection of ovarian malignancy signatures.

#3383 Exome sequencing in dedifferentiated ovarian mucinous carcinoma. Kaori Sanuki,1 Kentaro Nakayama,1 Koho Nakamura,1 Masako Ishikawa,2 Tomoka Ishibashi,1 Hitomi Yamashita,1 Ruriko Ono,1 Toshiko Mi-namoto,1 Kosuke Yoshihara,2 Satoru Kyo,1 Shimane Univ. Faculty of Medicine, Izumo, Japan; 2School of Medicine, Niigata University, Niigata, Japan.

Mucinous ovarian tumor represent a distinct histotype of epithelial ovarian cancer and is thought to begin as a mucinous adenoma that progresses in a slow stepwise fashion. Dedifferentiated mucinous ovarian carcinoma is a rare type of ovarian carcinoma with a few reports and a progressive and poor prognosis. While the molecular genetic features of ovarian mucinous carcinoma is now well known, the pathogenesis of dedifferentiated mucinous carcinoma is largely unknown. In order to comprehensively analyse somatic mutations in dedifferentiated mucinous carcinoma, we applied exome sequencing to the DNA of a sample of affinity-purified, dedifferentiated mucinous carcinoma. Through comparative analyses of normal cells from the same patient, we identified several genes that were mutated in this tumor. P53, which encodes a well-known tumor suppressor protein, and KRAS, which encodes a well-known oncoprotein, had previously been implicated in ovarian mucinous carcinoma. The other mutated genes were previously unknown to be involved in mucinous carcinoma. CEP170 encodes a microtubule-binding protein that controls the targeting of the kinesin-13 dependent and kinesin-13 family influence the dynamics of microtubule growth and shrinkage. CEP170 gene mutation may be related to instability of a cell division property. CEP170 mutations were identified with a prevalence of 33.3% in dedifferentiated mucinous ovarian carcinoma. Currently, CEP170 gene knock down assay and engineered expression of CEP170 assay in ovarian mucinous carcinoma is being performed whether morphologic change is observed. In summary, CEP170 may be one of the responsible gene in carcinogenesis of differentiated mucinous carcinoma.

#3384 Comprehensive genetic analysis of myxofibrosarcoma and comparison with other soft tissue sarcomas. Yasuhide Takeuchi,1 Annegret Kunzit,2 Hiromichi Suzuki,1 Kenichi Yoshida,1 Yuichi Shiraiha,3 Teppei Shimamura,4 Kenichi Chiba,1 Hiroko Tanaka,5 Nobuyuki Kakiuchi,1 Yusuke Shiozawa,1 Akira Yokoyama,6 Kenichi Nakamura,7 Yoshikazu Hina,6 Takuji Tanaka,6 Takanori Hagiwara,8 Satoru Miyano,2 Frederik Dam,9 Seishi Ogawa,10 Department of Pathology and Tumor Biology, Graduate School of Medicine, Kyoto University, Kyoto, Japan; 2Department Hematology, Oncology and Tumor Immunology, Charite University Hospital, Berlin, Germany; 3Laboratory of DNA information Analysis, Human Genome Center, Institute of Medical Science, The University of Tokyo, Tokyo, Japan; 4Division of System Biology, Graduate School of Medicine, Nigata University, Nagaoya, Japan; 5Department of Diagnostic Pathology, University of Nagoya, Tokyo, Japan; 6Department of Pathology, University of Nagoya, Nagoya, Japan; 7Department of Diagnostic Pathology, University of Nagoya, Nagoya, Japan; 8Department of Pathology, University of Nagoya, Nagoya, Japan.

Background: Myxofibrosarcoma (MFS) is a relatively common subtype of soft tissue sarcomas (STSs) in the elderly, which is characterized by the proliferation of pleomorphic spindle cells with varying degrees of the myoid component and on the basis of this unique histological picture, together with other clinical characteristics, is separated from other STSs. However, the genetic basis of MFS is poorly understood. Aims and Methods: The purpose of this study is to clarify the comprehensive registry of genetic alterations in MFS and other STSs using whole exome/genome sequencing (WES/WGS) of paired tumor/normal DNA from 41 samples with MFS, combined with the WES data of 25 samples with MFS and 234 with STS, which were available from The Cancer Genome Atlas (TCGA) database. WGS was performed in 2 cases. Data for DNA methylation and gene expression from the TCGA registry were also analyzed. Moreover, the genetic basis of mixed histological components characteristic of MFS and its chronological changes was interrogated using multi-regional and/or multi-time points sampling. Results: A total of 8,661 mutations were identified in WES of 66 genes that is the histologic origin of lung adenocarcinoma as well. Previous studies have shown that PSNs and adenocarcinoma in the lung share some immunohistochemical and genetic features. However, as for somatic mutations, whereas many driver genes for lung adenocarcinomas have been identified, there have not been any candidate driver mutations identified in PSNs, except for low frequency mutations in β-catenin and TP53. Frequent somatic mutations identified in lung adenocarcinomas such as KRAS and EGFR have not been detected in PSH, suggesting that genomic alterations of these two lung tumors might be different from each other. Also, there is no evidence of PSH progression to lung cancers. These earlier data indicate that despite the common cellular origin of PSH and lung adenocarcinoma, genetic mechanisms for their development may be different. Based on the established concept that PSH is a true tumor, we hypothesize that it may harbor somatic mutations. In this study, we conducted whole exome sequencing of 44 PSHs and identified recurrent somatic mutations of AKT1 (43.2%) and β-catenin (4.5%). We used a second subset of 24 PSHs to confirm the high frequency of AKT1 mutations (overall 31/68, 45.6%; p>E17K, 33.8%) and recurrent β-catenin mutations (overall 3/68, 4.4%). Of the PSHs without AKT1 mutation, mutations of AKT1 occurred in 2 AKT1 mutation existed in both epithelial and stromal cells. In two separate PSHs from one patient, we observed two different AKT1 mutations, indicating they were not disseminated but independent arising tumors. Since the AKT1 mutations were not found to co-occur with β-catenin mutations (or any other known driver alterations) in any of the PSHs studied, we speculate that this may be an unusual pattern of driver alteration to develop PSHs. Our study revealed genomic differences between PSHs and lung adenocarcinomas including a high rate of AKT1 mutation in PSHs. These genomic features of PSH discovered in the present study provide clues to understanding the biology of PSH and for differential genicic diagnosis of lung tumors.

Pulmonary sclerosing hemangioma (PSH) is a benign tumor that usually presents as a solitary, well-defined mass in the lung. The PSH predominantly affects females with a higher incidence in the Far East. Histologically, the tumor cells in PSH consist of two cell types (cuboidal epithelial and polygonal stromal cells). Immunohistochemical and ultrastructural studies have identified that both cells are derived from undifferentiated respiratory epithelium that is the histologic origin of lung adenocarcinoma as well. Previous studies have shown that PSNs and adenocarcinoma in the lung share some immunohistochemical and genetic features. However, as for somatic mutations, whereas many driver genes for lung adenocarcinomas have been identified, there have not been any candidate driver mutations identified in PSNs, except for low frequency mutations in β-catenin and TP53. Frequent somatic mutations identified in lung adenocarcinomas such as KRAS and EGFR have not been detected in PSH, suggesting that genomic alterations of these two lung tumors might be different from each other. Also, there is no evidence of PSH progression to lung cancers. These earlier data indicate that despite the common cellular origin of PSH and lung adenocarcinoma, genetic mechanisms for their development may be different. Based on the established concept that PSH is a true tumor, we hypothesize that it may harbor somatic mutations. In this study, we conducted whole exome sequencing of 44 PSHs and identified recurrent somatic mutations of AKT1 (43.2%) and β-catenin (4.5%). We used a second subset of 24 PSHs to confirm the high frequency of AKT1 mutations (overall 31/68, 45.6%; p>E17K, 33.8%) and recurrent β-catenin mutations (overall 3/68, 4.4%). Of the PSHs without AKT1 mutation, mutations of AKT1 occurred in 2 AKT1 mutations existed in both epithelial and stromal cells. In two separate PSHs from one patient, we observed two different AKT1 mutations, indicating they were not disseminated but independent arising tumors. Since the AKT1 mutations were not found to co-occur with β-catenin mutations (or any other known driver alterations) in any of the PSHs studied, we speculate that this may be an unusual pattern of driver alteration to develop PSHs. Our study revealed genomic differences between PSHs and lung adenocarcinomas including a high rate of AKT1 mutation in PSHs. These genomic features of PSH discovered in the present study provide clues to understanding the biology of PSH and for differential genicic diagnosis of lung tumors.
#3386 Brazilian melanoma genome project: mutational landscape based on whole-genome sequencing. Vinicius L. Vazquez,1 Adriane Evangelista,1 Henrique C. Silva,1 Camila Crovador,1 Andre L. Carvalho,1 Cristovam Scapu-lateumo-Neto,1 Jin Lee,2 Gilles Landman,3 Joao P. Kitagima,4 Rui M. Reis,5 Barretos Cancer Hospital, Barretos, Brazil; Mendelics, Sao Paulo, Brazil; UNIFESP Federal University of Sao Paulo, Sao Paulo, Brazil;

Melanoma is the most aggressive form of skin cancer with increasing prevalence in Brazil. The comprehensive molecular profiling of these tumors and the recent genomic classification has improved the knowledge of melanoma biology and foster the identification of potential clinical biomarkers. The aim of this project, as part of the International Cancer Genome Consortium (ICGC) to perform a genomic profile by whole genome sequencing (WGS) of Brazilian melanomas patients. We reported the WGS using Illumina paired-end sequencing strategy (>30 X-fold coverage) of 66 cases (45% primary and 55% metastatic) and respective matched normal. Overall we observed an average of 46K mutations/genome. The most frequent type of substitutions identified were: C>T (22.5%), T>C (6.4%), T>G (4.4%), T>A (2.9%), C>A (2.8%) and C>G (1.7%). A significant difference between frequency of C>T substitutions was observed among histological subtypes, i.e., acral lentiginous (11.3%), nodular (31.2%) and superficial spreading (25.9%). Among the classic genes involved in melanoma biology, we found that 31.8% of patients had BRAF mutations, being the V600E the most frequent (82.6%). A total of 6.1% of patients had NRAS, 3.0% showed KRAS, one case (1.5%) showed HRAS, and 12.1% showed NF1. Systematic analysis of the mutational landscape revealed a high frequency of mutations in NRAS, HRAS, KRAS and NF1 (28.8% of patients). TP53 mutations found 4.5% and RB1 in 1.5% of cases. Oncogenic KIT and PDGFRα mutations were observed in 6.1% and 1.5%, respectively. BRAF, NRAS, HRAS, KRAS and NF1 mutation were mutually exclusive. BRAF and TERT mutations were significantly more frequent in superficial than acral lentiginous melanomas. We showed that Brazilian melanoma patients exhibit a high number of single mutations and a similar mutation profile to the one reported in other populations. Acral/lentiginous melanoma subtype, which is a common subtype in our setting, showed a distinct mutation frequency. Further analysis will extend to other relevant genes and will also include the study of additional genomes to reach the goal of genomic landscape of 100 Brazilian melanomas cases.

#3387 Mutational analysis in metastatic melanoma to the breast and ova-
ry: correlation with clinic-pathological and immunohistochemical findings. Alessio Giubellino, Vanessa Moreno, Xu Naizhen, Liqiang Xi, Mark Raffeld, latempo-Neto,1 Jin Lee,2 Gilles Landman,3 Joao P. Kitagima,4 Rui M. Reis1; Barretos Cancer Hospital, Barretos, Brazil; Mendelics, Sao Paulo, Brazil; UNIFESP Federal University of Sao Paulo, Sao Paulo, Brazil;

Breast melanoma (BM) and ovarian melanoma (OM) are rare, but aggressive diseases. We performed a comprehensive genomic and transcriptomic analysis of 34 ALM patients. Unlike CM, somatic alterations were dominated by structural variation and absence of mutations. Somatic mutational burden was higher in ALM compared to CM (Fig S1a). The number of unique mutations per sample was higher in ALM compared to CM (22 vs. 5, respectively). BRAF and NRAS/NF1 mutations. Contrasting with CM, we observed PAK1 copy number alterations in 49.4% (1 per lane) of ALM samples. The number of reads falling within each 10kb window was analyzed for ALM patients. Of note, most of the ALM cases were negative for N-RAS. The mutational analysis of these metastatic lesions, using next generation sequencing for the detection of cancer gene mutations including rare mutations at low frequency, remains limited. Deeper analysis of acral lentiginous melanoma (ALM), a rare sun-shielded melanoma subtype associated with worse survival than CM, is needed to delineate non-UV oncogenic mechanisms. We thus performed comprehensive genomic and transcriptomic analysis of 34 ALM patients. Unlike CM, somatic alterations were dominated by structural variation and absence of UV-derived mutation signatures. Only 38% of patients demonstrated driver BRAF/NRAS/NF1 mutations. Contrasting with CM, we observed PAK1 copy gains in 15% of patients, and somatic TERT translocations, copy gains, and missense and promoter mutations, or germline events, in 41% of patients. We further show that in vitro TERT inhibition has cytotoxic effects on primary ALM cells. These findings provide insight into the role of TERT in ALM tumorigenesis, and reveal preliminary evidence that TERT inhibition represents a potential therapeutic strategy in ALM.

#3388 Copy number alteration in primary melanoma. D. Timothy Bishop,1 Anastasia Filia,2 Alastair Droop,1 Joey Diaz,4 Mark Harland,1 Jon Laye,7 Juliette Randerson-Moor,1 Julia A. Newton-Bishop,1 University of Leeds, Leeds, United Kingdom; Imperial College, London, United Kingdom;

We investigated the diagnostic utility of copy number alterations (CNAs) in melanoma. The systematic analysis of the genomic characteristics of melanoma primaries has been infeasible given the limited size of these formalin-fixed paraffin embedded (FFPE) lesions. Further studying a clearly ascertained, deeply phenotyped patient population allows meaningful extrapolation of the prevalence of distinct genomic features and investigation of the association of these features with life-style exposures and germline profiles. For these reasons, we focused on a recently recruited patient cohort, the Leeds Melanoma Cohort (LMC) consisting of 2184 recruits from a distinct geographical region of Northern England; the only selection applied to recruitment was to only include those whose melanoma was less than 0.75 mm Breslow thickness in the early years of recruitment. Tumor samples from 703 cases have been analyzed for genome-wide gene expression (Poznik et al., this meeting). For this study, we wanted to explore the prevalence of copy number alterations (CNAs) and the mutation profile of tumors (reflecting the association of C>T mutations with UV exposure, the primary environmental risk factor) and so we have adopted a next-generation sequencing (NGS) approach. Tumor blocks were recovered from local pathology laboratories for for those cases survives more than 5 years post diagnosis at this same time. Blocks at risk of being compromised for clinical purposes by sampling for this research study were excluded from sampling; this amounted to almost 50% of identified samples. A total of 333 NGS libraries were sequenced on an Illumina GAII or HiSeq sequencer to produce >100bp paired-end reads (either 5 or 1 per lane). DNA reads were aligned and mapped achieving approximately 1.8x coverage (9.4x for those at 1 per lane); the number of reads falling within each 10kb window was adjusted for GC content and mappability and compared to a composite normal FFPE sample to determine local copy number. We adopted various approaches to assess the informativeness of the methodology. (i) Replicate samples showed high reproducibility (all p < 0.0001). (ii) Focused analysis of the CDKN2A and CDK4 genes revealed a high rate of loss in 43.7% of CDKN2A and 38.5% of CDK4 in lesional melanomas verified high technical quality, biologically plausible data revealing multiple copy number events. 76% of samples showed no CNA across the 4 Mb region covering CDKN2A while, as expected, only a small proportion of CNAs did not involve CDKN2A. Four common distinct patterns were observed. Copy number loss ranged from 20kb to -> 4 Mb. (iii) A germ-line CNA could reliably be identified from the tumor data. (iv) CDKN2A expression levels correlated with estimated copy number.

We have shown that small FFPE melanomas can be characterized for genomic alterations using NGS opening up the potential for studies associating epidemiological and germline profile with the resulting tumor. 1. Newton-Bishop, J.A., et al. (2009) Clin Oncol, 27, 5349-5444. Funded by Worldwide Cancer Research and Cancer Research UK.

#3389 Integrated genomic analyses reveal frequent TERT aberrations in acral melanoma. Winnie S. Liang,1 William Hendricks,2 Jeffrey Kiefer,2 Jessica Schmidt,2 Shobana Sekar,1 John Carpent,2 David W. Craig,1 Jonathan Adkins,4 Lori Cuyugan,3 Zarko Manoljovic,1 Rebecca F. Halperin,1 Adrienne Helland,1 Sara Nasser,1 Christophe Legendre,1 Laurence H. Hurley,4 Karthigayini Siva-prakasham,1 Douglas B. Johnson,3 Holly Crandall,1 Klaus J. Busam,2 Victoria Zissmann,3 Valerie De Luca,1 Jeeyun Lee,5 Aleksandar Sekulic,2 Charlotte E. Arjya,1 Jeffrey Sosman,7 Jeffrey Trent1; 1Gen (The Translational Genomics Research Institute), Phoenix, AZ; 2Mayo Clinic, Scottsdale, AZ; 3University of Arizona, Tucson, AZ; 4Vanderbilt University Medical Center, Nashville, TN; 5Memorial Sloan-Kettering Cancer Center, New York, NY; 6Samsung Medical Center, Seoul, Democratic People’s Republic of Korea; 7Northwestern University, Chicago, IL;

Acral melanoma (ALM) is the most common primary cancer of the eye and frequently gives rise to lethal metastatic disease. Uveal melanoma (UM) is the most common primary cancer of the eye and frequently gives rise to lethal metastatic disease. Uveal melanoma cell lines and their respective matched normal were sequenced on an Illumina GAII or HiSeq sequencer to produce >100bp paired-end reads (either 5 or 1 per lane). DNA reads were aligned and mapped achieving approximately 1.8x coverage (9.4x for those at 1 per lane); the number of reads falling within each 10kb window was adjusted for GC content and mappability and compared to a composite normal FFPE sample to determine local copy number. We adopted various approaches to assess the informativeness of the methodology. (i) Replicate samples showed high reproducibility (all p < 0.0001). (ii) Focused analysis of the CDKN2A and CDK4 genes revealed a high rate of loss in 43.7% of CDKN2A and 38.5% of CDK4 in lesional melanomas verified high technical quality, biologically plausible data revealing multiple copy number events. 76% of samples showed no CNA across the 4 Mb region covering CDKN2A while, as expected, only a small proportion of CNAs did not involve CDKN2A. Four common distinct patterns were observed. Copy number loss ranged from 20kb to -> 4 Mb. (iii) A germ-line CNA could reliably be identified from the tumor data. (iv) CDKN2A expression levels correlated with estimated copy number.

We have shown that small FFPE melanomas can be characterized for genomic alterations using NGS opening up the potential for studies associating epidemiological and germline profile with the resulting tumor. 1. Newton-Bishop, J.A., et al. (2009) Clin Oncol, 27, 5349-5444. Funded by Worldwide Cancer Research and Cancer Research UK.

#3390 Clonal evolution in uveal melanoma. Matthew G. Field,1 Himu An-bunathan,2 Michael A. Durante,1 Louise Cai1, Karam Alawa,1 Christina L. Decatur,1 Stefan Kurtenbach,1 Anne Bowcock,1 J. William Harbour1; 1University of Miami, Miami, FL; 2Imperial College London, London, United Kingdom;

Uveal melanoma is the most common primary cancer of the eye and frequently gives rise to lethal metastatic disease. Uveal melanoma can be divided into two prognostic subgroups based on gene expression profiling: class 1 (low metastatic risk) and class 2 (high metastatic risk).
Uveal melanoma is also notable for a characteristic set of driver mutations that cluster into two groups. The first group consists of mutually exclusive gain-of-function mutations in members of the Gq signaling pathway (GNAQ, GNA11, CYSLT2 and PLCB4), which are present in almost all uveal melanomas. These mutations are not prognostic, and are thought to represent an event that is insufficient alone to cause complete transformation. The second group consists of near-mutually exclusive mutations in BAP1, SF3B1, and EIF1AX. These are thought to occur later in tumor progression and are prognostic of patient outcome. These molecular features are associated with characteristic chromosome copy number variations (CNV). The purpose of this study was to investigate the life history of primary uveal melanomas by inferring the temporal evolution of these genetic events. Methods: Exome or whole genome sequencing data from 151 primary uveal melanomas were evaluated with a new bioinformatic pipeline for calling mutations and CNVs. Data from this analysis were used in downstream subclonality algorithms to determine intratumor evolutionary patterns within individual tumor samples. Results: A Gq mutation was found in 98.7% of tumors, which were all mutually exclusive with each other. BAP1 mutations were found in 46%, SF3B1 mutations in 23%, and EIF1AX mutations in 14% of tumors, all of which were mutually exclusive with each other except for 4 cases. We identified novel driver mutations in 20% of the remaining tumors. In most samples that contained a BAP1 or SF3B1 mutation, this driver mutation and associated CNVs were present in 100% of tumor cells. However, in 14% of cases with BAP1 mutations, 100% of tumor cells exhibited monosomy 3, but a BAP1 mutation was present in a smaller subclone, suggesting that the BAP1 mutation occurred after the loss of chromosome 3. In tumors with EIF1AX mutations, this mutation was consistently found in 100% of tumor cells, with 6p gain being found in a smaller subclone in 45% of cases, suggesting that 6p gain usually occurs after the EIF1AX mutation in this subgroup of tumors. Conclusions: The driver mutations and associated CNVs that are characteristic of uveal melanoma occur very early in tumor evolution and are followed by the accumulation of silent passenger mutations, consistent with a punctuated evolution model in which an initial “big bang” is followed by neutral non-Darwinian evolution. These unexpected findings alter prevailing theories of uveal melanoma progression, and could have a significant impact on patient management.

### #3392 Genomic analysis of prostate cancer in Korean men. Se Song Jang,1 Min Jung Kim,1 Dong Wan Hong,2 Jae Young Joung,2 Sung Han Kim,2 Kang Hyun Lee,2 Weon Seo Park,2 Jong-Il Kim.1 1Seoul National University, Seoul, Republic of Korea; 2Center for Prostate Cancer National Cancer Center, Goyang, Republic of Korea.

Prostate cancer currently has the fifth highest incidence rate in Korean males, and is the most common cancer in western males. Prostate cancer is the second most common malignancy in men worldwide, and is responsible for approximately 250,000 cancer-related deaths annually. The search for accurate biomarkers and characterization of prostate cancer is critical for evaluation of accurate management of prostate cancer. Previous studies have identified that several genomic alterations in prostate cancer including TMPRSS2-ERG fusion, PTEN deletion and SPOP single nucleotide variants (SNVs), the majority of which are from western populations. In order to investigate the somatic mutations of Korean prostate cancers, we performed whole exome sequencing on 51 prostate cancer patient’s tumor tissues, and matched normal tissue. For the accurate detections of structural variations, we additionally performed whole genome sequencing on 9 matched pairs (tumor, normal). A total of 738 somatic non-silent variants affecting 692 distinct genes were identified. In addition to already known genes such as SPOP, FOXA1, TP53 and PTEN, we also found previously uncharacterized genes such as GRIN2A, LRPI, FND1 and LRPIB. Of the 46 mutated genes across multiple cases, missense SNVs (64%) were the most frequent, followed by frameshift and splice-site SNVs of GRIN2A (5/60 cases, 8.3%). Mutations in low-density lipoprotein-related protein encoded by LRPI and LRPIB affected considerable portion of all cases (7/60, 11.7%), describe the probable relation between lipid metabolism and prostate cancer. We found TMPRSS2-ERG fusion in 4 of 9 whole genome samples. Moreover, 5 samples had 8p whole arm deletion, which is found frequent in western prostate cancers. As a result, we describe the genomic patterns of genetic variations and structural variations involved in prostate cancer of Korean population.

### #3393 Genomic analysis of multi-site fresh prostate samples. Marina A. Parry,1 Shambhavi Srivastava,1 Alessio Cannistraci,2 Hui Sun Leong,2 Syed Ali,1 Jenny Antonello,1 Vijay Ramani,1 Maurice Lau,1 Jonathan Shanks,1 Daisuke Nomaka,2 Pedro Oliveira,3 Noel Clarke,4 Crispin Miller,1 Ged Brady,1 Nathalie Dhomen,5 Esther Baena,6 Richard Marias,1 1CRUK Manchester Institute, Manchester, United Kingdom; 2The Christie NHS Foundation Trust, Manchester, United Kingdom.

Prostate cancer is the most common cancer in males in the UK with >40,000 cases diagnosed every year and >10,000 deaths. Recent multi-platform genomic studies have revealed a very complex picture of the disease, with subtypes linking to the histopathological markers currently used in clinical practice. The multifocal and heterogeneous nature of the disease suggests that single biopsy sites may be missing valuable subclones which contribute to the etiology of the disease. To address this, we obtained fresh core biopsies from multiple sites (4-8) in the prostate from eight high-risk patients undergoing prostatectomies at the Christie NHS Foundation Trust. The tissues were provided to the pathology department and each core divided in two, one for genomic analysis and one for parallel disease modeling (patient derived xenografts (PDxEs), patient-derived cell lines and organoids). The cores were cryo-sectioned and H&E analysis performed at the top, middle and bottom of each core. These were reviewed by a pathologist and tissue was micro dissected prior to simultaneous DNA and RNA extraction of normal and tumor tissue. Blood for germline DNA and plasma for circulating free DNA (cfDNA) was also obtained. Our study comprises eight patients with two or more tumor sites (2-4), some bifocal, which were analyzed using whole exome sequencing (WES), copy number aberration (CNA) profiling, transcriptomic analysis and methylaton profiling. The most frequent aberration identified was loss of 8p (NKKX3-1) in 6/8 patients (12/24 tumor cores). Loss of 13q (PDCD10) was observed in 5/8 patients (8/24 tumor cores), but never in all cores from a single patient, suggesting a late event. Loss of 5q (CHD1) was identified in 4/8 patients (11/24 tumor cores). Loss of 6q (MAP3K7), 10q (PTEN), amplification of 8q (MYC) and TMPRSS2-ERG fusion were identified in 3/8 patients. Some copy number events were only observed in either one patient or one tumor site indicating the intra-patient heterogeneous nature of SPOP was the only gene affected by recurrent mutations across patients, but amino acid changes were affected within and between patients. Mutations in PTEN, TP53, APC, BRAF and ERCC3 were also identified, among many others. The most significantly overexpressed gene was ERG, seen in patients
with the TMPRSS2-ERG fusion. Changes in gene expression differed between cores from the same patients, reflecting the heterogeneity at the DNA level. These data will be analyzed in conjunction with the results from disease modeling to investigate the functional impact of these changes and cDNA analysis is underway to understand which tumor clones are entering the bloodstream. The multifocal and genetically heterogeneous nature of prostate cancer is highlighted by this data and is likely to impact on precision medicine approaches for this disease. We will correlate the molecular profiling of our patient tumors with their clinical data in order to identify targets for further validation.

#3394 CGP identifies largely non-overlapping high tumor mutational burden and HRD genomic alterations in 721 clinically advanced prostate acinar adenocarcinoma cases. Nimad Dewal,1 Yuting He,2 Richard J. Lee,1 Alexia B. Schrock,1 Jon Chung,3 Christopher Holmes,1 Zachary R. Chalmers,1 Garrett M. Franklin,1 James X. Sun,3 Primo N. Lora,1 Neeraj Agrawal,1 Paul Mathew,1 Philip J. Stephens,1 Vincent A. Miller,1 Jeffrey S. Ross,1 Siraj M. Ali,1 Foundation Medicine, Inc., Cambridge, MA; 3Massachusetts General Hospital, Boston, MA; 2Case Western Reserve University School of Medicine, Cleveland, OH; 4University of California, Davis Comprehensive Cancer Center, Sacramento, CA; 5University of Utah School of Medicine, Salt Lake City, UT; 7Tufts University School of Medicine, Boston, MA.

Background: Effective therapies for the management of castrate resistant prostate cancer are lacking. We performed comprehensive genomic profiling (CGP) on advanced prostate cancers (PC) in the course of clinical care to identify genomic alterations that could suggest benefit from targeted, immune- and PARP inhibitor therapeutic strategies. Methods: DNA was extracted from 40 microns of FFPE specimen from 721 clinically advanced PC cases. CGP was performed using a hybrid-capture, adaptor ligation based next generation sequencing assay to a mean coverage depth of over 500X. All four classes of genomic alterations (GA)-basesubstitutions, insertions and deletions, gene fusions, and copy number alterations (amplifications and losses) - were identified. Results: Of the 721 PC patients - men with median age of 65 (range 34 - 88) - CGP was performed on 335 (46.5%) prostate specimens and 386 (53.5%) specimens from metastatic sites. The most common genes altered were TP53 (N = 336, 46.6%), PTEN (N = 254, 35.2%), TMPRSS2-ERG (N = 214, all fusions, 29.7%), AR (N = 173, 24%), and MYC (N = 105, 14.6%). Median tumor mutational burden (TMB) for this series was 3.6 mut/Mb (range 0 - 305). AR and MYC amplifications were enriched in metastatic tumors compared to primary tumors (p < 0.001 for both). Alterations characteristic of homologous recombination deficiency (HRD) were found in >15% of cases, including homonymous deletions and truncating mutations in BRC2 in 79 (11%) samples, as well as truncating mutations in ATM in 53 (7.2%) samples, with only 3 samples possessing alterations in both genes. Cases with these HRD-relevant alterations possessed overall higher genomic loss of heterozygosity (LOH) content than did those without (p = 0.02). HRD and non-HRD cases had median TMB of 4.8 versus 2.7 mut/Mb, respectively, and mean TMB of 10.4 versus 4.0 mut/Mb (p < 0.01). Only 2.6% of non-HRD cases were TMB-high (20 mut/Mb or more), versus 12.5% of HRD cases, a small but significant enrichment in the latter. Conclusions: CGP for advanced PC cases identifies largely non-overlapping TMB-high and HRD positive cases, suggesting benefit from immunotherapies and PARP inhibitors respectively. Further investigation will assess whether HRD pathway alterations result in genomic LOH in the context of a hypermutated tumor, and enrichment or exclusivity with other GA in prostate carcinoma.

#3395 Alternative splicing of the MEAF6 gene promotes neuroendocrine prostate cancer development. Ahn R. Lee, Yinan Li, Ning Xie, Colin C. Collins, Xuesen Dong, University of British Columbia, Vancouver, British Columbia, Canada.

In response to the selection pressures exerted by potent androgen receptor (AR) pathway inhibitors (ARPI), adenocarcinoma prostate cancer (PCA) cells can undergo an adaptive process of cellular phenotype reprogramming termed neuroendocrine trans-differentiation. With this AR-bypass mechanism of survival emerging a lethal treatment-resistant PCA subtype called treatment-induced neuroendocrine PCA (t-NEPC). t-NEPC is becoming a major clinical issue as it is estimated to affect >25% of advanced-stage PCA patients with the level of incidences predicted to rise as a result of the extensive applications of ARPI in the clinic. This underscores the gravity of our aims to delineate the molecular underpinnings of t-NEPC to inform future therapies that prevent or mitigate t-NEPC development. In this study, we have identified a splice variant of the MYST/Esa1-associated factor 6 (MEA6F) gene, MEAF6-1, that is highly expressed in t-NEPC tumor biopsies as well as neuroendocrine cell lines of prostate and lung cancers. We show that the neuronal RNA splicing factor, SRRM4, stimulates MEAF6-1 splicing. Enhanced MEAF6-1 expression in prostate adenocarcinoma cell lines does not induce neuroendocrine trans-differentiation of these cells. Rather, it stimulates cell proliferation, anchorage-independent cell growth, and invasion. Gene expression analyses indicated that these MEAF6-1 actions are in part mediated by the ID1 and ID3 genes. These findings suggest that the MEAF6-1 variant does not induce neuroendocrine differentiation of prostate cancer cells, but facilitates t-NEPC progression through accelerating proliferation of cells that have acquired neuroendocrine phenotypes.

#3397 Post-mortem examination of an aggressive case of medullary thyroid carcinoma characterised by catastrophic genomic abnormalities. Darran P. O’Connor,1 Sudipto Das,1 Deirdre Kelly,1 Bruce Moran,2 Kathleen Han,2 Niall Mulligan,3 Ciara Barrett,2 Patrick Buckley,1 Peter McMahon,2 J McCaffrey,2 Henrik van Essen,4 Kate Connor,1 Bauke Ylstra,3 Diether Lambrechts,3 William M. Gallagher,1 Catherine M. Kelly.1 Royal College of Surgeons in Ireland, Dublin, Ireland; 2Mater Misericordiae University Hospital, Dublin, Ireland; 3University College Dublin, Dublin, Ireland; 5VU University Medical Center, Amsterdam, Netherlands; 6Vesalius Research Center, Leuven, Belgium.

Catastrophic genomic alterations may drive aggressive cancer phenotypes. We describe a diagnostically challenging and rapidly fatal case of medullary thyroid carcinoma (MTC) occurring in a young, morbidly obese man presenting with diffuse bone marrow involvement and disseminated intravascular coagulation. Whole-exome sequencing (WES) and shallow whole-genome sequencing (WGS) were carried out for the primary tumour, adjacent normal, bone marrow tissues, multiple metastases and blood samples derived from the patient. We identified three germline single nucleotide polymorphisms (SNPs) within the RET proto-oncogene that remained undetected using routine hospital genetic testing procedures. One variant (L769L) has been previously reported to be associated with aggressive MTC presentation yet remains untested for in the routine diagnosis of MTC. Supported by findings from both WES and WGS, we report for the first time in thyroid cancer on the occurrence of a “chromothripsis-like pattern”, which involved shattering of chromosome 4 leading to complete abrogation of normal chromosomal function, along with dramatic widespread copy number aberrations across both primary tumour and bone marrow samples. Based on the somatic variants identified, we describe the evolutionary pathway of the case, showing that bone marrow metastasis occurred separately to other metastatic sites. The presence of disease-associated SNPs within the RET proto-oncoprotein supports their inclusion as part of routine genetic testing for MTC cases. The copy number aberrations and chromothripsis-like pattern affected a much broader range of genes than single mutations and may have led to the widespread, non-random instability possibly contributory to the rapid fatal course of the case. These results provide a rationale for the application of comprehensive genomic analysis of cancers presenting with unusual and aggressive phenotypes to facilitate more appropriate therapeutic options and diagnoses.

#3398 The genomic and transcriptomic analysis of nine widely invasive follicular thyroid carcinomas (wFTC) in Korean patients. Angela Byuri Cho,1 Seong-Keun Yoo,1 Min-Hwan Sohn,1 Jong-Yeon Shin,1 Su-jin Kim,2 Eun Kyung Lee,2 Young Joo Park,2 Jeong-Sun Seo,1 1Seoul National Univ. Gravmg-si, Gyeonggi-do, Republic of Korea.

Widely invasive follicular thyroid carcinoma (wFTC) can be characterized from minimally invasive follicular thyroid carcinoma (miFTC) as it exhibits poor prognosis with frequent distant metastasis. We have reported that miFTC shows similar mutational and transcriptional spectrum when compared to follicular adenoma (FA). Here, we performed whole-exome and transcriptome sequencing on wFTC samples to define their aggressive biological features by comparing with 30 miFTCs and 26 FAs. Well-known miFTC and FA driver genes, NRAS (66.67%), HRAS (11.11%), and EIF1AX (11.11%), were identified in wFTC. TERT mutation was found in all samples which can explain its aggressive feature. Chromosome 17p4 amplification was found in most wFTC samples as well as 22q deletion that is frequently aberrant in H/K/NRAS mutated thyroid cancers. Most of wFTCs were classified as RAS-like (66.67%) and a few were BRAF-like (22.22%) and BRRN (11.11%) molecular subtypes. From differentially expressed gene analysis, we found 1,832 and 1,384 up-regulated and down-regulated genes when wFTC was compared to miFTC and FA together. wFTC had many overlapped down-regulated genes as poorly differentiated and anaplastic thyroid carcinoma which also supports its aggressiveness. Through weighted correlation network analysis we have established gene expression net-
works, highly associated with wiFTC, that have SIRT6 and TGFBR2 as the central nodes. In this study, we demonstrated the distinctive mutational and transcriptional characteristics of wiFTC hence found the underlying molecular mechanism for its aggressiveness.

#3399 Genomic analysis of melanoma evolution following a 30 year disease-free interval. Jerry J. Miller,1 Kristopher A. Lofgren,2 Sarah R. Hughes,1 Steven E. Cash,2 David R. Meier,2 Paraic A. Kenny.1 1Gundersen Health System, La Crosse, WI; 2Gundersen Medical Foundation, La Crosse, WI.

The rate of ultra-late recurrence (beyond 10-15 years) of cutaneous melanoma has been estimated to be between 2.0-6.9% from large case series. Two major factors complicate the interpretation of these data. Firstly, the risk of second primary melanoma is approximately 5% Creation uncertainty about whether at least some of these late onset tumors might be independent of the original lesion. Secondly, in the majority of cases, the original pathology specimen is no longer available for comparative analysis. Accordingly, putative late recurrences are difficult to unambiguously distinguish from a new primary melanoma. We identified a patient with a second melanoma diagnosed after a 30 year disease-free interval, and sought to determine if this new lesion was a recurrence of the original melanoma. We report the genomic sequence analysis of the exomes of two melanoma lesions isolated from the same individual in 1985 and 2015, and their comparison to each other and to the germline DNA of the patient. Identification of many shared somatic mutations between these lesions prove a linear relationship spanning 30 years. Unlike prior reports of ultra-late melanoma recurrence, the availability of the original tumor and the use of comprehensive genomic analysis allowed us to confirm that the second lesion is truly a recurrence. We demonstrate the acquisition of numerous additional mutations during the three decade asymptomatic period. This is, to our knowledge, the longest disease-free interval that has been rigorously confirmed in melanoma or any other solid tumor type. These data highlight the low but very long-lasting risk of recurrence in this patient population.

#3400 Progression of epidermal growth factor receptor (EGFR)-independent colorectal cancer. Carolina Mantilla Rojas,1 Yu Ming,2 David Threadgill1. 1Texas A&M Univ., College Station, TX; 2University of North Carolina, Chapel Hill, NC.

When combined with standard of care treatment for colorectal cancer (CRC), the use of monoclonal antibodies or small molecule inhibitors against epidermal growth factor receptor (EGFR) show modest efficacy in the clinic. Early detection efforts and more effective therapies have reduced mortality, yet CRC remains the second mostly deadly cancer in the United States with approximately 50,000 deaths expected this year. Thus, it is imperative to better understand the mechanisms governing molecular progression of CRC. Primary and secondary resistance to anti-EGFR therapies occurs in approximately 80% of the patients with CRC. Mutations in KRAS explain some non-responding CRCs, but even in cancers lacking KRAS mutations, little is known about which cancers are likely to respond to EGFR targeted treatment, suggesting an alternative and EGFR-independent CRC progression mechanism. In this study, we used a conditional Egf allele (Egf(WT)I in the APC(Apc)Min/+ mouse model and identified EGFR-independent tumors with faster growth rates than those developing in EGFR-wild type mice. To assess aggressiveness of EGFR-independent tumors, we used a metastatic CRC mouse model containing conditionally inactivated Apc alleles (Apc(A) in combination with a conditionally active allele of KRAS (Kras(L527M)I )). It has been reported that delivery of Cre recombinase expressing adenovirus to the distal colon of these mice results in tumors that progress to carcinoma within 20 weeks, and liver metastases develop in approximately 20% of mice at 24 weeks. We discovered a 10% increase in the penetrance of tumors arising in the absence of EGFR (Egf(A), Apc(A), Kras(L527M)I ). Endoscopic analysis suggests an increase in tumor multiplicity in EGFR-deficient tumors when compared with tumors developing in EGFR-wild-type mice. Biweekly colonoscopy confirmed that colonic tumors have a faster growth rate in the absence of EGFR. High-frequency abdominal ultrasound suggests liver metastasis at 16 weeks in 20% of mice lacking EGFR. These findings demonstrate the existence of an EGFR-independent mechanism by which CRC can arise and progress. Moreover, tumors lacking EGFR grow larger than those developing under normal EGFR activity and may be a more aggressive form of CRC. We also have evidence that ERBB3 and ERBB4, related EGFRs, mediate compensatory and alternative pathways, suggesting an important role for these receptors in the progression of EGFR-independent CRC. This study will advance our understanding of ERBB family biology during colonic tumorigenesis, ultimately contributing to better therapies for CRC.

#3401 Role of membrane-associated guanylate kinase inverted 2 in advanced and castration-resistant prostate cancers. Bao Le, Kimberly Hammer, Katya Frantskevich, Irene Ong, Wei Huang, Paul Marker. University of Wisconsin-Madison, Madison, WI.

Background: Prostate cancer is the most common non-cutaneous malignancy for men in the U.S. Patients with advanced and/or metastatic prostate cancer are commonly treated with androgen deprivation therapy. Unfortunately, incurable castration resistant prostate cancer commonly develops 2-3 years after initial treatment. Methods: To identify candidate cancer genes involved in the development of castration resistance, the Sleeping Beauty (SB) transposon system and androgen-sensitive LNCaP cell line were used in a forward mutagenesis screen designed to model the transition from androgen sensitive to androgen insensitive prostate cancer. MAGI-2 was identified in the screen as a common insertion site gene, potentially involved in the transition to androgen independence. Clinical significance of MAGI-2 in prostate cancer was further supported by human TCGA data. Functional assays were used to confirm the involvement of MAGI-2 in prostate cancer progression. Results: MAGI-2 expression was prognostic for patient survival outcome. Ectopic expression of MAGI-2 in 22Rv1 cells resulted in a decrease in cell proliferation and colony formation in vitro studies. At the molecular level, overexpression of MAGI2 induced a suppression of known androgen responsive genes. MAGI-2 overexpression also limited the growth of grafts compared to empty vector grafts in vivo xenograft models. Conclusions: MAGI-2 was identified in a forward mutagenesis screen modeling the development of castration resistant prostate cancer. Human protein expression data from patient tissues supported a possible role for MAGI-2 in prostate cancer. Functional studies confirmed the potential involvement of MA GI-2 in prostate cancer progression. Future studies are seeking to elucidate the functional role and mechanism of action for MAGI-2 in prostate cancer. Ultimately, this may identify MAGI-2-regulated signaling pathways as therapeutic targets for prostate cancer.

#3402 The impact of germline single nucleotide polymorphisms (SNPs) in ERBB-family genes and genes associated with homologous recombination deficiency (HRD) on response to taxotere, platinum and trastuzumab (TCH) based therapy in the treatment of HER2-positive breast cancer patients. Ste phenie Madden,1 Sinead Toomey,1 Simon Furney,2 Malgorzata Milewska,3 Joanna Fay,1 Elaine W. Kay,1 John Crown,2 Susan Kennedy,3 Bryan T. Hennessey,3 Alex J. Eustace1. 1Royal College of Surgeons in Ireland, Dublin, Ireland; 2University College Dublin, Dublin, Ireland; 3St Vincent's University Hospital, Dublin, Ireland.

BACKGROUND: We have shown that ERBB (ERBB2, ERBB3, ERBB and other ERBB-family genes), and germline single nucleotide polymorphisms (SNPs) have a negative impact on the outcome of trastuzumab treated HER2-positive breast cancer (BC) patients. Currently TCH (taxotere, platinum and trastuzumab) based therapy is used to treat early stage HER2-positive BC. We investigate the importance of germline SNPs in ERBB genes and those genes involved in homologous recombination deficiency (HRD), on how patients respond to TCH therapy. PATIENTS AND METHODS: ERBB/HRD SNPs were identified in a panel of 32 advanced and castration-resistant prostate cancers. We investigate the importance of ERBB/HRD SNPs on RFS. RESULTS: Ten ERBB/HRD SNPs were identified as associated with survival free recurrence (RFS) in patients who received a TCH based treatment versus those who received alternate therapies. Protein extracted from formalin fixed paraffin embedded tumours (n=60), was run on an RPPA platform to measure expression and phosphorylation of proteins (69 antibodies). Logistical regression identified protein levels associated with the presence/absence of ERBB/HRD SNPs that were significantly associated with RFS. RESULTS: Ten ERBB/HRD SNPs were prolined in 157 trastuzumab treated HER2-positive BC patients. The minor alleles of the ERBB2 (rs1136201), ERBB3 (rs2229046) and BARD1 (rs2070896) SNPs were significantly associated with a worse RFS in patients who received TCH based therapy relative to those who had the reference allele (ERBB2: HR=2.67 (CI:1.05-6.78), p=0.04; ERBB3 rs2229046: HR=4.95 (CI:1.91-12.79), p=0.00; BARD1: HR=3.27 (CI:1.16-9.17), p=0.02). The impact of ERBB/HRD SNPs on RFS
was not observed in patients who did not receive TCH treatment. The minor allele of the RNF8 rs2284922 SNP is associated with a worse RFS (RNF8: HR = 12.42 (CI = 2.00-77.19), p = 6.89x10^-3) relative to those who had the referral allele only in patients who did not receive TCH treatment. RPPA analysis identified that patients who received TCH therapy and had the minor allele of the ERBB3 SNPs were significantly associated with the expression of HER2, p27, and MEK1/2; minor allele associated with low expression of p27 (p = 7.22x10^-3) and with high expression of HER2 (p = 6.53x10^-3); rs773123, minor allele associated with low expression of p27 (p = 5.38x10^-4) and with high expression of MEK1/2 (p = 6.24x10^-4). CONCLUSIONS: The presence of germline ERBB/HHRD SNPs may play an important role in how a patient responds to TCH based therapy, and clinical assessment of these SNPs by targeted genetic screening of patients’ blood may allow for stratification of patients prior to treatment.

#3403 Telomere shortening in pancreatic cancer is correlated to KRAS mutation. Yoko Matsumeda,1 Naotaka Izumiyma,1 Mutsunori Fujiiwara,2 Naoshi Ishikawa,3 Junko Aida,4 Kaiyo Takubo,5 Toshiyuki Ishiwata,6 Tomio Ara,1 Tokyo Metropolitan Geriatric Hospital & Inst of Gerontology, Tokyo, Japan; 2Japan; 3Japanese Red Cross Medical Center, Tokyo, Japan.

Background: Pancreatic cancer is characterized by genomic complexity and chromosomal instability, and atypical mitotic figures are morphological features of this phenotype. Previously we have reported that approximately 30% of total mitosis in pancreatic cancer was atypical including multipolar, lag-type, ring and asymmetrical mitosis, and anaphase bridges, and the number of total mitosis and atypical mitosis in pancreatic cancers was correlated with aggressive phenotype and prognosis (Pancreatology, 2016). In the present study, we clarified the relation between atypical mitotic figures, telomere length, and genetic abnormality in the pancreatic cancer. Methods: We surveyed the mitotic figures of the normal epithelium, pancreatic intraepithelial neoplasia (PanIN), and pancreatic cancers using surgically resected pancreatic cancer specimens (n = 40). Telomere length was analyzed using quantitative fluorescent in situ hybridization technique. We also analyzed mutations of Kras codon 12 and 13 by PCR and microsatellite instability by immunohistochemical staining of MLH1, MSH2, MSH6 and PM52. Results: Pancreatic cancer and duodenal epithelium showed significantly higher mitotic indices as compared with the duct, acinar cells, and PanINs. Normal mitosis was also higher in pancreatic cancers and the duodenal epithelium, while atypical mitosis was significantly elevated only in pancreatic cancers. Number of total mitosis and atypical mitosis were negatively correlated with telomere length, suggesting that telomere shortening plays important roles in cancer proliferation and chromosomal instability. In comparison with normal ducts, telomere length was decreased in PanIN-1, -2 and -3 and cancer. Furthermore, telomere length was gradually shorter among PanIN grades. Most of pancreatic cancers harbored mutations in Kras codon 12, and pancreatic cancer cases with Kras mutation showed shorter telomere length as compared with cases without Kras mutation. All pancreatic cancer cases in the present study were microsatellite stable. Conclusion: Our data strongly suggest that telomere shortening occurs in the early stages of pancreatic cancer and is associated with aggressive phenotype and prognosis (Pancreatology, 2016). Telomere shortening and chromosomal instability in the duct epithelium play key roles on carcinogenesis of the pancreas.

#3404 Loss of Abi1 abrogates lung metastasis in the PyMT mouse model of breast cancer. Angelina Regua,1 Isabelle Bichindaritz,1 Tiffany Caza,1 Julie White,1 Robert Adamiec,2 Mira Krendel,2 Gennady Bratlavsky,2 Leszek Kotula,1. 1Upstate Medical University, Syracuse, NY; 2SUNY Oswego, Oswego, NY; 3Memorial Sloan-Kettering Cancer Center, New York, NY.

This study aims to elucidate the role of Abelson interactor 1 (Abi1), a key protein in the WAVE regulatory complex, in mammary carcinogenesis and metastasis. Breast cancer is the second-leading cause of mortality in women in the United States with an estimated ~200,000 new cases and over 40,000 deaths this year. Despite current treatment modalities, breast cancer patients often relapse after only a few years of treatment thus emphasizing the need for better therapeutic targets. Abi1 is an adaptor protein mainly associated with the WAVE (Wiscott-Aldrich syndrome protein family verprolin homologous) regulatory complex and Arp2/3 (Actin-related proteins 2 and 3)-mediated actin cytoskeleton remodeling. Our bioinformatic and gene expression analyses of human tumor data indicates that Abi1 is frequently upregulated in invasive breast cancers, is associated with poor survival, and may promote an aggressive breast tumor phenotype. Downregulation of Abi1 also abrogates motility and invasion of breast cancer cells, most likely through inactivation of both Src and PI3 kinase as well as certain matrix metalloproteases. We therefore hypothesize that Abi1 positively regulates breast tumor progression and invasion through dysregulation of these cell signaling pathways. To determine the role of Abi1 in breast tumor progression, we used a Cre-lox system to conditionally delete Abi1 in the mammary tissue of Polyoma Middle T (PyMT) breast cancer mice. Abi1 knockout (KO) PyMT breast cancer tumors were measured with a caliper to determine total tumor burden. We are currently analyzing changes in tumor kinetics as a result of conditional Abi1 knockout in the mammary epithelium of PyMT mice. Our preliminary studies of indicate slowed tumor growth in Abi1 KO PyMT mice. We Western blot analyses of Abi1 KO mammary tumors indicate concomitant loss of WAVE complex proteins supporting our previous findings that WAVE complex integrity is dependent on Abi1. Most interestingly, Abi1 null PyMT mice exhibit significantly reduced incidence of lung metastasis, supporting our hypothesis that Abi1 promotes invasion by breast cancer cells. In summary, Abi1 loss leads to reduction of lung metastasis in PyMT mice, possibly through inactivation of key cell signaling and proliferation pathways such as Src and PI3 kinase. This work will establish Abi1 as a potential prognostic marker and therapeutic target in metastatic breast cancer.

#3405 Screening for two recurrent BRCA1 mutations in Tunisian women with triple negative breast cancer. Wijdan Mahfoudh,1 Inchirah Bettaib,1 Salouha Gabbouj,1 Nooredjine Bouaouina,1 Loﬁt Chouchane,2 Abdellatifh Zahkama1. 1Faculty of Medicine of Monastir, Monastir, Tunisia; 2Department of Radiation Oncology, CHU Farhat Hached, Sousse, Tunisie.

Triple-negative breast cancers (TNBC) lack expression of oestrogen, progesterone and HER2 receptors. Reports to date indicate that up to 20 % of TNBC patients harbour germline BRCA mutations; however, the prevalence of mutations may vary with ethnic group and with geographic region. In the Tunisian population, as yet a limited number of BRCA germline mutations have been reported. Tow recurrent mutations were found in exon 5 and 20 in BRCA1 gene (c.211dupA and c.5266dupC). To investigate the contribution of BRCA1 gene mutations to TNBC in Tunisia, we screened the exons 5 and 20 of BRCA1 gene in 20 TNBC patients by direct sequencing. In our study, we identiﬁed the c.5266dupC mutation in BRCA1 exon 20 in 20 of 20 triple-negative patients with a prevalence of 10%. Our study is the ﬁrst investigation on the role of BRCA1 gene in TNBC in Tunisia. In this study, we show that targeting only the exon 20 in BRCA1 gene allows detection of a substantial percentage of mutations in Tunisian TNBC patients.

#3406 Hereditary risks of male breast cancer in a multi-gene panel testing cohort. Elizabeth C. Chao,1 Mary Pritzlaff,2 Summerour Pia,2 Rachel McFarland,3 Shuei Li,4 Jill Dolinsky,2 David Goldgar,4 Hermela Shimelis,5 Fergus Coulton,1 LaDaca Holly,6 UC Irvine, Newport Beach, CA; 2Ambry Genetics, Aliso Viejo, CA; 3UC Irvine, Irvine, CA; 4University of Utah, Newport Beach, CA; 5Mayo Clinic, Rochester, MN.

While the population-based risk for breast cancer in males remains relatively low (1:1000), inherited predisposition can significantly raise this to as high as 10%, in men who carry a mutation in the BRCA2 gene. Lifetime breast cancer risks of 1-2% have also been reported in men who carry a mutation in BRCA1. These risks, as well as elevated risks of prostate, pancreatic, and melanoma cancers, are important to discuss in families diagnosed with Hereditary Breast and Ovarian Cancer Syndrome, which is often viewed as being clinically relevant only to the women in an affected family. However, beyond the BRCA1/2 genes, limited data is available on hereditary predisposition to male breast cancer. We analyzed clinical histories and molecular results from multi-gene panel testing for hereditary cancer predisposition in a cohort of 715 men affected by breast cancer. A total of 708 male breast cancer patients were eligible for inclusion in the final analysis. Molecular testing included analysis of 5 to 59 genes for DNA coding sequence and copy number variants by next-generation sequencing and microarray. Genetic variants identified were classified according to a 5-tier system using previously validated algorithms. Did only those variants classified as pathogenic or likely pathogenic were included in the analyses as positive for a mutation. Overall, a mutation was detected in 18% of these men. Four subjects carried a mutation in two different breast cancer predisposition genes. BRCA2 and CHEK2 were the most frequently mutated genes. The risk of breast cancer Risks of 1-2% have also been reported in men who carry a mutation in BRCA1. These risks, as well as elevated risks of prostate, pancreatic, and melanoma cancers, are important to discuss in families diagnosed with Hereditary Breast and Ovarian Cancer Syndrome, which is often viewed as being clinically relevant only to the women in an affected family. However, beyond the BRCA1/2 genes, limited data is available on hereditary predisposition to male breast cancer. Four subjects carried a mutation in two different breast cancer predisposition genes. BRCA2 and CHEK2 were the most frequently mutated genes. The risk of breast cancer relate...
additional cancers. The high overall diagnostic yield suggests the utility of testing all male breast cancer patient regardless of age or family history by multigene panel testing, and provides data to support risk-based counseling and medical recommendations for screening and/or prevention in male mutation carriers. 1. 1. LaDuca et al. Genet Med. 2014 Nov;16(11):830-7. 2. Richards et al. Genet Med. 2015 May;17(5):405-24

#3407 Side effects of BRAF inhibitors mimic RASopathies. Alicia Stecchi,1 Alain Dupuy,2 Monica Dinulescu,3 Catherine Droitcourt,4 Henri Adamski,3 Smail Hadj-Rabia,5 Sylvie Odent,4 Marie-Dominique Galibert,2 Lise Boussemart,4 CHU de Rennes, Rennes, France;2 Rennes I University, Rennes, France;3 Hôpital Universitaire Necker-Enfants malades, Paris, France;4 Université de Rennes 1, Rennes, France

Recent advances in targeted anticancer therapies have substantially improved the prognosis of several cancers but they are not free of side effects. These side effects are, however, clearly distinct from those induced by classical cytotoxic chemotherapies, likely because targeted therapies are designed to interfere with specific oncogenic signaling pathways and not to inhibit cell proliferation in general. We, therefore, evaluated whether specific side effects of BRAF inhibitor therapies would resemble symptoms seen in patients with RASopathies, in which the MAPK pathway is affected and which includes Costello, Noonan and Cardio-Facio-Cutaneous syndromes. To this end, we collected a cohort of 18 patients with genetically confirmed RASopathies that were followed between 2012 and 2016 at the University Hospital of Rennes, and were evaluated based on their personal medical history and a clinical examination. Strikingly, RASopathy patients, particularly those with Cardio-Facio-Cutaneous syndrome, showed symptoms resembling those that we and others have previously seen in genetically characterized patients undergoing BRAF inhibitor treatment. These symptoms included keratoderma pilaris, wavy hair, sparse eyelashes/eyebrows, poor hair growth, palmo-plantar hyperkeratosis in areas of pressure, verrucous papillomas, nevi efflorescence, and increased cancer risk. Nevertheless, BRAF-inhibitor treatment can also lead to side effects not typically found in patients with RASopathies, including aceneform dermatitis and venu-rafenib-specific phototoxicity, which may even increase under a combined BRAF/MEK inhibition. These results suggest that the side effects of BRAF inhibition that are similar to symptoms in patients with RASopathies are due to direct targeting of the MAPK pathway in BRAF-non-mutated (wild type) cells while those that are dissimilar represent off-target effects that do not affect the MAPK pathway. We hope that this type of comparative analysis may lead to a better understanding of the multiple effects of targeted therapies and perhaps prompt modifications in the targeted therapy approach to minimize these side effects.

#3408 Telomere length and TERT promoter mutations in cutaneous melanoma. Sivaramakirishna Rachakonda,1 Barbara Heidenreich,1 Eduardo Nagore,2 Rajiv Kumar1.

Telomeres at chromosomal ends are comprised of multiple short repeat sequences. In humans TTAGGG repeats account for telomere length ranging 10-15 kb. Telomere sequences are mainly double stranded that end in a single stranded G-rich tail of 150-200 nucleotides. Telomeres in somatic cells undergo gradual shortening due to inherent limitations of DNA replication and limited levels of specialized enzyme telomerase that adds the repeats at chromosomal ends to maintain homeostasis. We previously reported somatic mutations in the core promoter of the telomerase reverse transcriptase (TERT) gene that lead to increased transcription of catalytic subunit and tumor specific telomerase reactivation. Telomere length per se is associated with risk in different cancers. In this study, we measured leukocyte telomere length using real-time PCR in 1469 melanoma patients and compared with that in 1158 matched healthy controls. The melanoma patients had statistically significantly longer telomeres than matched controls (t-test; P 6X10^-10). Telomere length sequences are mainly double stranded that end in a single stranded G-rich tail of 150-200 nucleotides. Telomeres in somatic cells undergo gradual shortening due to inherent limitations of DNA replication and limited levels of specialized enzyme telomerase that adds the repeats at chromosomal ends to maintain homeostasis. Telomere length per se is associated with risk in different cancers. In this study, we measured leukocyte telomere length using real-time PCR in 1469 melanoma patients and compared with that in 1158 matched healthy controls. The melanoma patients had statistically significantly longer telomeres than matched controls (t-test; P 6X10^-10). Mendelian randomization, carried out using two polymorphisms represented by rs1317082 and rs7726159 that associated with telomere length in genome wide association studies, showed association between increased telomere length and melanoma risk with an odds ratio of 2.3 (95% confidence interval 1.8-2.8). When measured in blood tissues from a melanoma family with the germline -57A/C TERT promoter mutation, the carriers had longer telomeres (median 1.12) than the non-carriers (median 0.87). The TERT promoter mutations create binding motifs for E-twenty six (ETS) transcription factors and in stem cell the presence of the promoter mutations resulted in continued TERT expression and telomerase activity following differentiation into adult cells. Individuals with the germline TERT pro-moter mutations develop melanoma with an early age of onset and rapid progression to metastases; two individuals in the family who lived past median age of onset developed several other malignancies, besides melanoma. Thus, dysregulated telomerase leads to a severe phenotype. In an analogy, we hypothesize that association of longer rather than shorter telomeres with an increased risk of melanoma reflects stochastic increase due to common genetic variation. In contrast, the telomere length was shorter in tumors from unrelated melanoma patients with (121) than without (170) somatic TERT promoter mutations (P 6X10^-5), which reflects the selection of the mutations at telomere crisis. Thus, a dynamic but controlled system evolved around telomere homeostasis when dysregulated leads to an increased cancer risk and affects tumor progression.

#3409 Age of cancer onset differentiated by sex and TP53 codon change in Li-Fraumeni Syndrome patient population. Lauren Erdman,1 Ben Brew,2 Jason Berman,3 Adam Shlien,1 Andrea Doria,1 David Malkin,1 Anna Goldenberg1.

1University of Toronto/Hospital for Sick Children, Toronto, Ontario, Canada; 2Hospital for Sick Children, Toronto, Ontario, Canada; 3Dalhousie University/IWK Health Centre, Toronto, Nova Scotia, Canada

Introduction: Li-Fraumeni Syndrome (LFS) is a highly penetrant autosomal dominantly inherited cancer predisposition disorder. Germline mutations of the TP53 tumor suppressor gene cause >80% of LFS and confer an increased risk of a range of early onset cancers, as well as of second tumors even in the absence of a family history of cancer. For this reason, we previously reported the implementation of a comprehensive life-long clinical surveillance protocol for individuals with a germline TP53 mutation for early tumor detection. Here, we set out to build a predictive model of age of onset of cancer in LFS patients to inform this screening protocol aiming to make it more targeted. We identify characteristics that differentiate the age of cancer onset consistently, across multiple LFS patient cohorts. Methods: The LFS cohort at Toronto’s Hospital for Sick Children (SickKids) (n = 171 patients) was used as a discovery set to identify factors that distinguish age of onset among LFS patients. This project focused specifically on patient characteristics such as sex and mutations within TP53, both as they appear on the genome and manifest in the protein, as predictors for age of onset. These predictors were tested in an exponential parametric survival model. Findings: From the SickKids discovery set were tested for replication in the International Agency for Research on Cancer (IARC) TP53 database (n = 2574 patients). Results: In the discovery cohort, female sex was associated with a 1.53 fold later age of cancer onset than in males (p = 0.019). This did not replicate in the IARC TP53 set with 0.99 fold earlier onset for females than males (p = 0.843). However, in the discovery set, there appears to be a point at which female and male age of onset converges at 43 years. Controlling for onset before vs after 43 years in our replication set shows 1.12 (p = 0.0204) times later age of cancer onset in females than in males which is the same direction and significance as in our discovery set. The discovery cohort also showed 2.23 (p = 0.08) later cancer onset for individuals with a germline Arginine to Cysteine (Arg>Gys) codon change (model significance p = 0.047). This finding replicated in the IARC TP53 data set which showed individuals with an Arg>Gys codon change having onset 1.29 (p = 0.043) times later than those with a TP53 mutation that did not result in this codon change. Conclusions: Our study identified two LFS patient characteristics, sex and TP53 Arg>Gys codon change, which consistently differentiate age of cancer onset within the LFS patient population. Females under the age of 43 when compared to males under the age of 43 appear to have later tumor onset, an effect which disappears after the age of 43. Individuals with an Arg>Gys TP53 codon change are expected to have later onset cancer than those with TP53 mutations that do not result in this change. Future work will disentangle these findings further and build a more comprehensive predictive model of cancer onset in LFS patients.

#3410 Phenotypic characterization of allelic variation within the HEAT repeats of the mechanistic target of rapamycin. Patricia A. Wiley,1 Joy Gary,2 Zaw Phyoo,2 Shuling Zhang,1 Amanda Scirocco,1 Dorian Fraizer4.

1National Cancer Institute, Bethesda, MD; 2Center for Disease Control and Prevention, GA; 3Marymount University, Arlington, VA; 4University of Maryland, Baltimore County, Baltimore, MD.

The mammalian target of rapamycin (mTOR), a protein in the phosphoinositide 3-kinase (PI3K) pathway important to cell cycle regulation, is frequently activated in cancer. This signaling pathway regulates cell growth and metabolism, and when dysregulated in cancer, it contributes to tumor angiogenesis and growth. mTOR contains two distinct complexes, mTORC1, and mTORC2. mTORC1 plays a role in biosynthesis, while mTORC2 helps

Proteins of the Association for Cancer Research • Volume 58 • April 2017 871
with cellular metabolism. It has been shown that mTOR knockout models are embryonically lethal to mice. However, lower levels of functional mTOR have been shown to be beneficial and slow cancer progression. Allelic variation occurs within inbred strains of mice, including BALB/c mice. One allelic variant in mTOR, R628C, which contributes to tumor susceptibility has been linked to increased breast cancer risk. This single amino acid change occurs in the HEAT repeats of mTOR. mTORA repeat polymorphisms will model mTOR signaling activation mechanisms in humans to aid in development of new cancer treatments.

#3411 Rare BRCA2 K3326X increases susceptibility to sporadic pancreatic ductal adenocarcinoma: a PANDoRA study. Ofrue M. Obaze,1 Gabrielle Capurso,2 Angelo Andriulli,3 Pavel Soucek,4 Ewa Małecka-Panas,5 Juozas Kaunas,6 Michalopoulou176, Athens, Greece; 9Klinik für Allgemein-, Viszeral- und Transplantationschirurgie, Medizinische Fakultät, University of Freiburg, Freiburg, Germany; 14Dipartimento di Oncologia, Università di Bologna, Bologna, Italy; 3Division of Gastroenterology, Medical University of Lodz, Lodz, Poland; 8Department of Gastroenterology, Lithuanian University of Health Sciences, Kaunas, Lithuania; 3Department of Gastroenterology and Research Laboratory, Department of Oncology, IRCCS Scientific Institute, I.R.C.C.S. Background: The incredibly poor outlook of pancreatic cancer patients underscores an urgent need for early diagnostic markers. Pancreatic cancer ranks third most-frequent cause of cancer death in the USA/1004 and genetic markers have been detected in <10% of sporadic cases. Germline variants in breast cancer tumor suppressor BRCA2 have been reported to increase predisposition to several cancers including pancreatic tumors. Rare K3326X (rs1571833, c.9976A>T) which introduces a premature stop codon thus truncating the protein, has previously been implicated in familial PDAC, but not in sporadic cases. A frameshift pathogenic mutation c.6503delTT (rs1576654, p.Leu2092Profs) reported with K3326X in breast and ovarian cancer families, has also been speculated to influence risk associations due to linkage disequilibrium between both variants. Method and results: K3326X was genotyped in 2,969 sporadic cases and 4,700 controls using Taqman chemistry and fidelity of genotypes assessed based on concordance of internal replicates and negative controls. K3326X was observed in 1.2% of cases and 0.8% of controls. Odds ratios (ORs) and associated 95% confidence intervals (CIs) were estimated by multivariate unconditional logistic regression with adjustment for age, sex and region of origin. We also performed a stratified analysis based on age at diagnosis to estimate the risk association between K3326X and early-onset pancreatic cancer. Results: No significant effect of the variant was observed for sporadic pancreatic cancer risk, we also sequenced DNA from carriers of K3326X in this study. We found K3326X to be associated with increased risk of developing sporadic PDAC (OR = 1.71, 95% CI = 1.18 - 2.49, P = 0.005). This risk was considerably higher among cases aged 50 years and younger (OR = 2.13, 95% CI = 1.10 - 4.11, P = 0.03). Furthermore, carriers of K3326X did not bear the c.6503delTT mutation suggesting that the effect of the two variants are not mediated by the latter. Conclusion: These robust associations implicate K3326X in the etiology of sporadic and early-onset PDAC, and therefore warrant replication as well as functional studies to elucidate the role of K3326X in DNA repair mechanisms.

#3412 Functional knockout of ATRX or DAXX permits the alternative lengthening of telomeres (ALT) mechanism in prostate cancer cells. Mindy K. Graham. Johns Hopkins School of Medicine, Baltimore, MD.

A key hallmark of cancer is unlimited replication, which requires cancer cells to evade replicative senescence induced by short telomeres. The majority of cancers overcome this critical replication barrier by upregulating the telomerase enzyme, a telomere-specific reverse transcriptase. However, a subset of cancers lack telomerase, and telomeres are maintained by employing the Alternative Lengthening of Telomeres (ALT) pathway, which is dependent on homologous recombination. Across a variety of tumor types, multiple laboratories, our laboratory and others have reported a robust correlation between ALT and recurrent cancer-associated somatic inactivating mutations in the ATRX-DAXX chromatin remodeling complex. In a previous comprehensive cancer survey of ALT, we reported that ALT was highly prevalent in some tumor types (e.g. astrocytomas, sarcomas, pancreatic neuroendocrine tumors), but we did not observe any ALT-positive primary prostate cancer (out of 1,176 analyzed). However, we subsequently found a subset of metastatic prostate cancers that harbor ALT, suggesting that mutations giving rise to ALT in this disease are unique to metastatic prostate cancer. Here, we have created the first prostate cancer cell lines exhibiting ALT, with the explicit purpose of molecularly characterizing ALT in prostate cancer and identifying promising therapeutic targets for men with ALT-positive lethal metastatic prostate cancer. Inactivating mutations in either ATRX or DAXX using the CRISPR/Cas9 system were introduced into the genetically well-characterized, telomerase-negative (ALT-negative) prostate cancer cell lines, LAPC-4 and CWR22Rv1. Resulting mutant subclones were compared to their parental (or empty vector) counterparts. In these new models, abolishing ATRX expression was sufficient to induce the ALT phenotype in both LAPC-4 and CWR22Rv1, as assessed by multiple biomarkers of ALT, including the presence of bright telomeric FISH foci, ALT-associated PML bodies (ABPs), and extrachromosomal telomere cicles. Interestingly, abolishing DAXX expression induced ALT in only a subset (3/5) of LAPC-4 DAXX KO clones, and a subset (4/19) of CWR22Rv1 DAXX KO clones. We have successfully activated the ALT telomere maintenance phenotype in two prostate cancer cell lines through CRISPR-mediated targeted gene deletion. We are currently utilizing these isogenic cell lines to further characterize and elucidate the underlying biology of cancers harboring ALT, with the goal of pharmacologically targeting the molecular features unique to the ALT phenotype (e.g. ATR inhibition). The identification of ALT-specific drugs may pave the way for the development of new targeted treatments for the subset of men with ALT-positive lethal metastatic prostate cancer, and more broadly, other ALT-positive cancers. ALT is easily detected in clinical tissue samples, and thus would serve as a predictive biomarker for personalized medicine.

#3413 Identification of a novel cancer predisposition variant associated with risk of CMM and other cancers. Craig C. Teerlink,1 John G. Zone,1 Sancy A. Leachman,2 Lisa A. Cannon-Albright.3 Univ. of Utah Health Sciences Ctr., Salt Lake City, UT; 4Oregon Health and Science University, Portland, OR.

Introduction: In a search for the responsible CMM predisposition gene/variant, whole exome sequencing was performed on a pair of related CMM cases (cousins) from an extended high-risk Utah CMM pedigree showing evidence of linkage to chromosome band 1q41. Methods: Standard bioinformatics tools were used to identify rare or novel variants shared in the 2 related CMM cases in a CMM pedigree showing 1q41 linkage. Sanger sequencing and a Taqman assay were used to confirm the original variants, and to confirm segregation of the variant in other cancer-related relatives. Taqman assay of the variant in independent Utah CMM cases (n=491) and controls (n=207) was performed. Results: A novel variant in SLC30A10 (rs 53024571, Chrlq14:220091798 C-T...
Molecular and Cellular Biology / Genetics: Genotype-Phenotype Associations

#3414 Novel MGMT variant association in Mexican patients with astrocytoma. Liliana Gomez-Flores-Ramos,1 Talia Wegman-Ostrosky.2 Institute of Biomedical Research, UNAM. National Cancer Institute, INCAN, Mexico City, Mexico; National Cancer Institute, NIH, Bethesda, MD, USA

Introduction: Astrocytomas are the most common and lethal brain tumors with a median survival of 15 months. Different biomarkers have arisen to classify and treat this type of tumors; one of these markers is MGMT. The methylation status of this gene is a prognostic and predictive factor. The MGMT (O-6-Methylguanine-DNA Methyltransferase) is involved in the cellular response to the effect of O-6-methylguanine (O6-MeG) in DNA. Repairs alkylation damage in DNA by transferring the alkyl group at the O-6 position to a cysteine residue in the enzyme. The dysregulation of this methylation is critical in the development of certain cancers. Objective: To identify germlinal MGMT gene variations in patients with astrocytoma. Material and methods: 55 randomly selected Mexican patients diagnosed with astrocytoma between 2008-2014 were consented to perform the molecular analysis of the whole gene and 5' UTR and 3' UTR regions of MGMT at Ion Torrent platform. All amplified region had a depth of minimum 1500X. Ion Reporter software was used to analyze the variant genetic and using Integrative Genomic Viewer we confirmed that each variant had a Phred higher than 25. Genotypic frequencies were compared with HapMapMex and Mexican ancestry population from the 1000 Genomes project. Results. In lymphocytes DNA, eight genetic variants were found, and two of them were statistically significant risk factors: rs7896488 alternative allele A with a frequency of 15% in patients with astrocytoma, and only 4% of the control group (OR = 5.53, IC 1.96-15.39 p = 0.0007) and rs2308326 ancestral allele C, where 95% of the patients were carriers of allele C in contrast with 73% of controls (OR = 5.39, IC 2.29-12.69 p = 0.000019). These variants are non-coding single nucleotide polymorphisms (SNP) with either an arginine (R72) or a proline (P72) at codon 72. By sequencing and Taqman assay in 32 patients the G659 mutations were 4.3% and 2.8% seen in 33 and 18 reads with a coverage of 77X5 and 66X, respectively. A review of pathology reports indicated that both matched samples had synchronous EECs. These two samples represent 15.4% of cases diagnosed with synchronous EmOC and EEC in this cohort. Conclusions: MGMT somatic mutations are uncommon in EmOCs and EECs. Recent massively parallel sequencing data suggests that EmOCs in the setting of synchronous EECs are clonally related and disseminated cells are related to nearby anatomic structures. Our data supports that MGMT somatic mutations in EmOC are clonally expanded from EECs likely through trans-tubal migration.

#3415 RNF43 somatic mutations in endometrioid ovarian cancers occur in the setting of synchronous endometrioid endometrial cancers. Defne L. Levine,1 Fanny Dao,2 Narciso Olvera,3 Katherine LaVigne,1 David B. Solit,1 Peter Jelinec,2 Memorial Sloan Kettering Cancer Center, New York, NY; NYU Perlmutter Cancer Center, New York, NY

Introduction: Somatic frameshift mutations in RNF43 have previously been filtered out in cancer genome sequencing projects given that they occur in homopolymer tracts and resemble polymerase slippage errors. Two RNF43 hotspot mutations have been identified and validated in endometrioid endometrial cancers. We determined the frequency of RNF43 somatic mutations in EmOC. Methods: We reviewed the clinical and pathologic features of EmOC samples diagnosed from 2006 to 2015, retrieved from laboratory databases and institutional archives. DNA was extracted from formalin-fixed, paraffin-embossed tumor samples using standard protocols. Sanger and next-generation sequencing (NGS) were used to screen for hotspot mutations at codons R117 and G659. Due to shared clinical and morphologic features of EEC and endometrioid ovarian cancer (EmOC), we determined the frequency of RNF43 somatic mutations in EmOC. Methods: We reviewed the clinical and pathologic features of EmOC samples diagnosed from 2006 to 2015, retrieved from laboratory databases and institutional archives. DNA was extracted from formalin-fixed, paraffin-embossed tumor samples using standard protocols. Sanger and next-generation sequencing (NGS) were used to screen for hotspot mutations at codons R117 and G659 with custom designed primers. NGS at each hotspot was covered with a minimum sequencing depth of 400X. Results: Forty-seven EmOC patients with available tumor specimens were identified and included in the analysis. The median age at diagnosis was 55 years old (range 34-84). The majority of patients had FIGO stage I or stage II disease (n=38, 81%). Thirteen (28%) patients had synchronous endometrial endometrioid or mixed histology tumors. Two (4.3%) RNF43 somatic mutations at codon G659 were identified in both Sanger and NGS from the EmOC tumor specimens. Two (4.3%) RNF43 somatic mutations at codon G659 were identified in both Sanger and NGS from the EmOC tumor specimens. The allelic fractions of the G659 mutations were 4.3% and 2.8% seen in 33 and 18 reads with a coverage of 77X5 and 66X, respectively. A review of pathology reports indicated that both mutated samples had synchronous EECs. These two samples represent 15.4% of cases diagnosed with synchronous EmOC and EEC in this cohort. Conclusions: RNF43 somatic mutations are uncommon in EmOCs and EECs. Recent massively parallel sequencing data suggests that EmOCs in the setting of synchronous EECs are clonally related and disseminated cells are related to nearby anatomic structures. Our data supports that RNF43 somatic mutations in EmOC are clonally expanded from EECs likely through trans-tubal migration.

#3417 The impact of p53 codon 72 SNP upon aging and longevity in mouse models. Yuhan Zhao, Lihua Wu, Xuetian Yue, Chen Zhang, Jun Li, Jianming Wang, Zhenghui Feng, Wenwei Hu. Rutgers Cancer Institute of New Jersey; New Brunswick, NJ

p53 has dual functions on longevity. p53 plays a crucial role in tumor suppression to prevent early death due to cancer. However, it has been suggested by animal models that constitutively increased p53 activity accelerates the decline of stem/progenitor cells’ self-renewal function during aging process, which leads to a reduced lifespan. In humans, the role of p53 in aging and longevity has not been well established. As a haplo-insufficient gene, p53 is under the tight regulation in cells. Attenuation of p53 function contributes greatly to tumorigenesis. p53 codon 72 single nucleotide polymorphism (SNP) with either an arginine (R72) or a proline (P72) at codon 72 is a naturally occurring common SNP that can influence the activity of p53. The P72 allele is weaker than the R72 allele in inducing apoptosis and suppressing cell transformation. Individuals with the P72 allele have increased cancer risk compared to the R72 allele. However, it is unclear whether the change of p53 activity in humans by functional SNPs could impact upon longevity. A perspective study with an aging human population showed that the P72 allele is associated with longer survival despite its increased risk for cancer development. These findings strongly suggest that p53 activity is reversely associated with aging, and SNPs in the p53 pathway could impact upon the life span in humans. In this study, we employed a mouse model system with knock-in of human p53 gene (Hupki) carrying either R72 or P72 SNP to investigate the impact of p53 codon 72 SNP upon longevity and its...
underlying mechanism. Mice with p53 R72 allele showed weaker transcriptional activity than the R72 allele toward a subset of p53 target gene, suggesting that these mice retain the function of p53 codon 72 SNP in human. We found that although mice with p53 R72 have increased cancer risk compared to mice with p53 R72, mice with p53 R72 that escaped tumor development showed reduced PTPN11 expression compared to the parental mouse cell line. Mice with p53 R72 displayed a delay in aging process compared to mice with p53 R72; mice with p53 R72 have slower reduction in bone density, dermal thickness and wound healing ability during aging process. We compared the effects of p53 codon 72 SNPs on stem cell population and function as a possible mechanism that contributes to their difference in longevity. Compared with mice with p53 R72, mice with p53 R72 allele have lower number of long-term stem/progenitor cells and better self-renewal function during aging process. Consistently, aging mice with p53 R72 allele exhibited better long-term stem cell cell ability of engraftment and repopulation than aging mice with p53 R72 allele as evaluated by bone marrow transplantation assay. Taken together, results from this study demonstrate that p53 codon 72 SNP has a direct impact on aging and longevity, and strongly support the role of p53 in regulation of stem/progenitor cells’ function and longevity.

#3418 Additional mutation in PTPN11 gene promotes tumorigenesis of the NF1 gene mutated cells. Yoshimi Arima, Ritsuko Haragi, Ryo Satoh, Toshiki Takenouchi, Kenjiro Kosaki, Hideyuki Saya. Kyoto University, School of Medicine, Tokyo, Japan.

The NF1 tumor suppressor gene encodes neurofibromin and is a functional Ras GTPase-activating protein (RasGAP) involved in negatively regulating the Ras signal by accelerating the conversion of activated Ras-GTP to inactive Ras-GDP. NF1 gene germline mutations cause Neurofibromatosis type 1 (NF1, von Recklinghausen disease). We hypothesized that additional genetic alterations promote the malignancy of NF1-associated tumors. To test our hypothesis, we inoculated a GFP-labeled human NF1-deficient cell line, snF96.2-GFP, which has a frame-shift mutation (c.3683delC, p.Asn1229MetfsTer11) in the NF1 gene, into the renal sub-capsules of immunodeficient mice. A subclonal cell line, the A-1 cell, was established from the developed tumor. We found that A-1 cells show much higher tumorigenic activity and phosphorylation status of MEK and Akt than the parental snF96.2-GFP cells. We analyzed the genomic DNA of both the snF96.2 and the A-1 cells by using the next-generation sequencing and our medical exome panel of 4813 genes, which are known to be responsible for most human genetic disorders. We identified 18 heterozygous variants within coding regions of 17 genes that were present in the A-1 cells, but not in the original snF96.2 cells. We found a single base substitution (c.1508G>T, p.Gly503Val) in the PTPN11 gene, which encodes the tyrosine phosphatase SHP-2, and is associated with the regulation of the Ras signaling pathway. It is critical to note that constitutional gain-of-function mutations in the PTPN11 gene cause Noonan Syndrome in humans due to activation of the Ras pathway. To determine the role of PTPN11 mutation in NF1-associated tumors, we established a cell line overexpressing PTPN11mwo in snF96.2-GFP cells. We inoculated parental cells and PTPN11mwo cells into the subcutaneous nude mice, and we found that the PTPN11mwo cells have lower tumorigenic activity than the parental snF96.2-GFP cells. Our data suggests that this additional gene mutation in PTPN11 promotes the malignant characteristics of NF1-associated tumors.

#3419 Uncovering the functional relevance of FBXW7 mutations in endometrial cancer. Mary Ellen Urick, Bo Hong, Meghan L. Rudd, Daphne W. Bell. NIH, Bethesda, MD.

The goal of this study is to elucidate the functional consequences of FBXW7 mutations in the context of endometrial carcinoma (EC). EC is a heterogeneous disease, consisting of multiple histological subtypes associated with distinct clinical outcomes. Endometrioid endometrial cancer is the most commonly diagnosed subtype and is associated with an overall favorable prognosis even in advanced disease. Less common but more clinically aggressive subtypes that contribute disproportionately to patient deaths include clear cell and serous ECs. We previously reported that FBXW7 is somatically mutated in 10% of endometrioid, 13% of clear cell and 29% of serous ECs. FBXW7 functions as a substrate-recognition protein within a SKP/CUL1/F-Box ubiquitin ligase complex, which targets numerous proteins for ubiquitin-mediated proteasomal degradation. Although FBXW7 is a known tumor suppressor, the functional consequences of these mutations have not yet been fully elucidated in the context of EC. As a means to this end, we utilized shRNA and Western blotting to identify proteins that are upregulated following FBXW7 depletion in ARK1 serous EC cells. Among proteins that were consistently upregulated were cyclin E1 and cMYC. We treated EC cells harboring endogenous FBXW7 mutations and those with wildtype FBXW7 with a proteasome inhibitor to confirm that EC cells regulate cyclin E1 and cMYC through proteasome degradation. Furthermore, we identified three EC cell lines that harbor endogenous mutations in FBXW7 and show that these cell lines express two novel recurrent mutations in FBXW7. Finally, we generated expression constructs for wildtype FBXW7α and six recurrent mutants found in EC. We show that transient exogenous overexpression of five out of six recurrent FBXW7 mutants in EC cell lines in which FBXW7 is silenced confers tumorigenic activity that is functionally equivalent. Our findings begin to reveal the molecular consequences of FBXW7 mutations in EC and ongoing studies are aimed at elucidating additional functional consequences of these aberrations in the context of EC.

#3420 Mutational status, expression and functional behaviors of FAM134B in colorectal cancer. Farhadul Islam,1 Vinod Gopalan,1 Raijul Wahab,1 Katherine Ting-wei Lee,1 Afraa Mammoori,1 Cu-Tai Lu,1 Robert A Smith,3 Alfred K-Y Lam1.1 Griffith University, Gold Coast, Southport, Australia; 2Gold Coast Hospital, Gold Coast, Southport, Australia; 3Queensland University of Technology, Brisbane, Australia.

Background: Family with sequence similarity 134B (FAM134B) is an ER-autophagy regulator and involved in the pathogenesis of neuronal disorders, vascular diseases and carcinomas. In colorectal carcinomas, FAM134B plays important role in the pathogenesis and associated with aggressiveness of the disease. However, the frequency of mutations, expression pattern and functional roles in cell have never been studied in colorectal cancer. Objectives: To investigate FAM134B mutations in tissues samples from patients with colorectal cancer and cell lines. Also, the expression of FAM134B at protein and mRNA levels were examined. In addition, functional roles of FAM134B in colon cancer were studied. Methods: Mutations in FAM134B sequence in eighty-eight cancer tissues and matched non-cancer samples was studied by high-resolution melt curve analysis followed by Sanger sequencing. FAM134B expression was studied and quantified in cell lines and cancer tissues samples using immunofluorescence, immunocytochemistry, Western blot and real-time PCR. In vitro functional assays were performed to unveil the molecular roles of FAM134B in colon cancer pathogenesis followed by shRNA-mediated silencing in cells. Mouse xenotransplantation model was used to confirm the functional behavior of FAM134B in colon cancer. Results: In this study, 46.5% (41/88) patients with colorectal cancer were identified as FAM134B mutations positive. Thirty-one novel pathogenic mutations were detected. Of the 31 mutations, 8 novel frameshift mutations caused nonsense-mediated mRNA decay and associated with gender of the patients, presence of metachronous cancer, size, T staging, presence of distant metastases and positivity of microsatellite instability (MSI) in the cancer. Results: In this study, 46.5% (41/88) patients with colorectal cancer were identified as FAM134B mutations positive. Thirty-one novel pathogenic mutations were detected. Of the 31 mutations, 8 novel frameshift mutations caused nonsense-mediated mRNA decay and associated with gender of the patients, presence of metachronous cancer, size, T staging, presence of distant metastases and positivity of microsatellite instability (MSI) in the cancer. Expression of FAM134B in cancer cells derived from advanced stages (stage III; SW48 and stage IV; HCT116) of colon cancer was significantly (p<0.01) reduced when compared to non-neoplastic colon cells (FHC) and cancer cells derived from stage II colon cancer (SW480). Expression of FAM134B mRNA in cancer tissues was noted significantly (p<0.001) downregulated when compared to that of non-cancer tissues samples. FAM134B suppression significantly (p<0.05) increased the proliferation of colon cancer cells, remarkably increased (34-52%: p<0.05) the clonogenic, migration capacity, and increases the proportion of cells in S phase of cell cycle (p<0.01). Xenotransplantation model showed that larger and higher-grade tumors were formed in mice treated with FAM134B knockdown cells. Conclusions: In vitro and in vivo functional studies implied that FAM134B acts as a cancer inhibitor in colon cancer. Also, FAM134B mutation is common in colorectal cancer and the association of mutation with adverse clinical and pathological parameters are in concur with the tumour suppressive property of the gene.

#3421 Pharmacological inhibition of histone methylation attenuates TGFβ induced EMT characteristics in pancreatic cancer. Hardik R. Mody, RaigopalGovindarajan. OSU College of Pharmacy, Columbus, OH.
Epithelial-to-Mesenchymal Transition (EMT) is a tumor cell remodeling process that drives progression of several epithelial solid tumors including pancreatic tumors. Transforming growth factor (TGF) β signaling is a key promoter of EMT pathway and remains an attractive target for curtailling tumor progression. Here we present a strategy for investigating inhibitors of TGFβ signaling in pancreatic cancer via reprogramming of miRNAs. We find a carbamoyl adenosine analog and histone methyl transferase inhibitor, 3-deazaadenosine A (DZNep) to significantly attenuate the TGFβ signaling induced EMT characteristics in pancreatic ductal adenocarcinoma (PDAC). Specifically, we find DZNep treatment to restore expression of selectivity epigenetically silenced miRNAs (miR-663a, miR-4787-5p, and miR-202) that inhibit endogenous TGFβ1 ligand and receptor expression via RNA interference. Consequent of this silencing of miRNAs was significant increases in EMT phenotype similar to DZNep in cultured pancreatic cancer cells, whereas locked nucleic acids inhibition of miRNAs abrogated such effects. In an orthotopic pancreatic cancer mouse model, DZNep and all three miRs reduced overall tumor burden in pancreas and metastatic load in liver, lungs and spleen. Together, these findings suggest epigenetic reprogramming of miRNAs by synthetic histone methylation reversal agents as a potentially viable approach for attenuating TGFβ signaling pathway involved in pancreatic cancer progression.

#3422 miR-200c-driven mesenchymal-to-epithelial transition as a therapeutic target in uterine carcinosarcomas. JiH. H. Tseng,1 Maria Bisogna,1 Lien N. Hoang,1 Narciso Olvera,2 Douglas A. Levine,2 Petar Jelić1.1MSBCC, New York, NY; 2NYUT Langone Medical Center, New York, NY.

Introduction and purpose of study: Uterine carcinosarcoma (UCS) is an aggressive and rare malignancy with poor prognosis and limited treatment options. These biphasic tumors, consisting of epithelial and mesenchymal components, are hypothesized to evolve from less aggressive endometrial adenocarcinomas (EACs) through epithelial-mesenchymal transition (EMT). EMT is a reversible process, and mesenchymal-epithelial transition (MET) has been shown to decrease tumor aggressiveness. Inducing MET has been suggested for treatment of cancers with a mesenchymal phenotype. In our studies, we investigated the importance of MET in the evolution of UCS by depleting miR-200, a family of microRNAs critical for EMT, in EAC cell lines. We also explored the role of miR-200 overexpression as a driving force for MET in UCS with a focus on finding novel therapeutic approaches to the treatment of this aggressive disease. Experimental procedures: To test whether UCS cells evolve from EACs, we depleted miR-200c in EAC cell lines, Ishikawa and MFE-280. For the MET studies, we stably overexpressed miR-200c in UCS cell lines, SNU685 and JHUCS1. Gene expression was measured using TaqMan and whole transcriptome sequencing (RNA-Seq) assays. Immunoblotting was performed on the EMT-relevant proteins. Cell adhesion and in vitro cell proliferation were measured using commercially available assays. In vivo tumor growth of JHUCS1 miR-200c-overexpressed cells was measured in xenografted mice. Summary of the data: Compared to EAC cells, UCS cells had undetectable miR-200c expression. Depletion of miR-200c in EAC cells resulted in expected increased ZEB1 and decreased E-cadherin expression. The lack of increased N-cadherin, vimentin and morphologic changes, even in the presence of exogenous TGF-β suggests partial EMT induction. Silencing of miR-200c in UCS cells resulted in full MET, with a decrease in ZEB1, ZEB2, N-cadherin and vimentin and an increase in E-cadherin. Increased cellular adhesion was observed along with typical MET morphologic changes. miR-200c overexpression led to inhibited UCS cell proliferation and metabolic activity. Overexpression of miR-200c in vivo resulted in substantially smaller tumors compared to mice bearing control UCS cells. Conclusions: Our data suggest that mechanisms additional to, or other than EMT, are necessary for the evolution of UCS from EAC. UCS cell lines, however, readily undergo robust MET in the setting of increased miR-200c expression rendering them less aggressive. These findings suggest that miR200 overexpression through advanced microRNA therapeutics may lead to new options for the treatment of uterine carcinomas.

#3423 Elucidation of the role of miR-575 on tumorigenesis in glioblastoma. Ashley N. Gray,1 Tianian Cui,1 Marjolein Geurts,2 Pierre Robe,1 Joseph McElroy,1 Erica Hlavin Bell,1 Arnab Chakravarti1.1The Ohio State University, Columbus, OH; 2University Medical Center of Utrecht, Netherlands.

Glioblastoma (GBM) patients currently face poor survival outcomes with an average survival rate less than 15 months, with only 3-5% of patients survive more than 36 months. Although the mechanisms of tumorigenesis are still being elucidated, miRNAs are promising candidates to explore as novel and prognostic biomarkers in GBM. MiRNAs are small regulatory molecules that play a crucial role in carcinogenesis via repression of oncogenes and tumor-suppressor genes either transcriptionally or post-transcriptionally. Our clinical data (n=268) shows that miR-575 is one of the top miRNAs associated with GBM overall survival (FDR: 0.0036, p-value: 5.77E-05) by univariate analysis (Nano-String Technologies; Seattle, WA). This study was designed to investigate the expression and function of miR-575 in GBM. Basal expression of miR-575 was first detected in GBM cell lines prior to functional experimentation. Cell proliferation, colony formation, migration and invasion assays were performed to understand the role of miR-575 in GBM. We found that overexpression of miR-575 significantly increased cell proliferation and cell motility in LN229 and U251 cell lines. Additionally, BLID, a tumor-suppressor gene, was negatively regulated by miR-575 at the transcriptional level by qRT-PCR, which will be further investigated at the post-transcriptional level by western blot. Up-regulation of miR-575 in GBM cell lines suggests that it could be acting as an oncogene by targeting BLID. Our study suggests that miR-575 overexpression may lead to inhibited cell proliferation and cell motility in LN229 and U251 cell lines. These findings suggest that miR-575 overexpression may lead to inhibited cell proliferation and cell motility in LN229 and U251 cell lines. Additionally, BLID, a tumor-suppressor gene, was negatively regulated by miR-575, supporting our hypothesis and findings in other cancers. In conclusion, miR-575 might act as an oncogene in GBM, and BLID may be a putative target gene of miR-575. This mechanism could potentially be useful as a novel prognostic biomarker for GBM patients after further in vitro and in vivo validation. #3424 Role of miR-489 in mammalian gland development and Her2 mediated tumorigenesis. Yogin Patel, Mithil Soni, Shou Liu, Hexin Chen. Univ. of South Carolina, Columbia, SC.

HER2 overexpression is linked with poor prognosis and outcome in breast cancer. In our previous study, we found that miR-489 was specifically down regulated by HER2 overexpression. Restoration of miR-489 in multiple breast cancer cell lines significantly inhibited cell growth in vitro and decreased tumor growth in xenograft mice. To study role of miR-489 in Her2 mediated tumorigenesis, for the first time we generated MMTV-miR-489 transgenic mice, which overexpress miR-489 specifically in mammalian gland. Our qRT-PCR data has confirmed transgenic mice have significantly more miR-489 expression than FVB mice. We used western blot to further validate our model system and found significant downregulation of miR-489 targets DEK and PTTPN1. To find out whether miR-489 has any role in mammalian gland development, mammalian gland whole mount was performed from wild type FVB mice and MMTV-miR-489 mice at different age. Mammary gland from MMTV-miR-489 mice demonstrated reduction in growth in early age. Our immunohistochemistry staining demonstrated significantly reduced Ki-67 positive cells in MMTV-miR-489 mammalian gland at early age, further confirming reduced growth in MMTV-miR-489 mice. However, we found no significant effect on weight of litters of MMTV-miR-489 female since after 8-week mammalian gland was able to recover growth. To find out effect of miR-489 overexpression on Her2 mediated tumorigenesis, we generated double transgenic mice MMTV-Her2-miR-489 overexpressing miR-489 in MMTV-Her2 mice. We have observed significant delay in tumor onset and reduced tumor growth in MMTV-Her2/ miR-489 mice compared to MMTV-Her2 mice. We have also observed less number of metastatic site in lung by performing H and E staining of lung. Our IHC data showed reduction in PTTPN1 and DEK in miR-489 overexpress mammalian tumor. Surprisingly, we found significant reduction of miR-489 expression in mammary tumors of MMTV-Her2-miR-489 mice compared with normal mammary gland of same age of mice. Overall, our results indicated miR-489 overexpression suppresses mammalian gland development at early age, reduced mammalian tumorigenesis and decreased lung metastasis by targeting PTTPN1 and DEK.

#3425 MiR-215-5p is a tumor suppressor in colorectal cancer targeting EGFR ligand epiregulin and its transcriptional inducer HOXB9. Petra Fallejskova-Vychytilova,1 Jana Merhautova,1 Pablo Conesa-Zamora,2 Katerina Slaba,1 Tana Machackova,1 Marek Svoboda,1 Marek Vecera,1 Jitka Millova,1 Jaroslav Juracek,1 Jana Sana,1 Parwez Ahmad,1 Natalia Gabilo,1 Ondrej Slaby1,2.

1Masaryk University CEITEC MU, Brno, Czech Republic; 2Santa Lucia University Hospital, Cartagena, Spain; 3Masaryk Memorial Cancer Institute, Brno, Czech Republic; 4Masaryk University CEITEC MU, Masaryk Memorial Cancer Institute, Brno, Czech Republic.

Growing evidence suggests that microRNAs (miRNAs) are involved in the development and progression of colorectal cancer (CRC). In the present study, deregulation and functioning of tumor suppressive miR-215-5p was evaluated in CRC. In total, 448 tumor tissues and 325 paired adjacent healthy tissues have been used for miRNA expression analyses. We proved that miR-215-5p is significantly downregulated in tumor tissues compared to non-tumor adjacent tissues and its decreased levels correlate with the presence of lymph node metastases, tumor stage, and shorter overall survival in CRC patients. To identify specific cellular processes affected by ectopic expression of miR-215-5p, a series of in vitro experiments have been performed using transient transfection of
miR-215-5p mimics into four CRC cell lines. Increased levels of miR-215-5p significantly reduced proliferation, clonogenicity, and migration of CRC cells, lead to cell cycle arrest in G2/M phase and p53-dependent induction of apoptosis. The ability of miR-215-5p to inhibit tumor growth was confirmed in vivo by use of NSG mice model and stable cell line over-expressing miR-215-5p. Finally, we proved that miR-215-5p inhibited caspase-8 and death receptor-mediated apoptosis in PanCa cells in response to TRAIL treatment as observed through Western blotting and flow cytometry.

Inhibition of MUC13 using shRNA knockdown or miR-145 restoration resulted in the TRAIL-mediated increased in apoptotic cell death as evidenced by Annexin V/7AAD and sub G0 population, as well as reduced PanCa cells sensitive to treatment with TRAIL, caspase-8, and death receptor inhibitors. Additional cells treated with TRAIL in combination with paclitaxel or Abraxane showed enhanced apoptosis on inhibition of miR-133 expression using miR-145 restoration. Further investigation showed that cytoplasmic domain of MUC13 (MUC13-CyD) is indispensable for blocking caspase-8 activation and PARP cleavage, indicating that the MUC13-CyD blocks TRAIL-induced signaling upstream to Bid by inhibiting caspase-8 activation. Conclusion: These observations suggest that MUC13 contributes to the survival advantage in PanCa cells in response to treatment with drugs or death inducing ligands such as, Tumor necrosis factor related apoptosis-inducing ligand (TRAIL) which can be strategically overcome by miR-145 replenishment. These findings indicate that MUC13 silencing sensitizes PanCa cells towards TRAIL therapy and counteracts chemoresistance mechanisms in PanCa that may lead to novel combination therapies for PanCa treatment.

Tamoxifen differentially regulates miR-29b-1 and miR-29a depending on endocrine sensitivity in breast cancer. Penn Mulundewy, Carolyn M. Klinge. University of Louisville School of Medicine, Louisville, KY.

Acquired endocrine-resistance occurs in ~ 40% of estrogen receptor α (ERα) + breast cancer patients after tamoxifen (TAM) or aromatase inhibitor therapy. MicroRNAs (miRs) are dysregulated in breast cancer, but their contribution to endocrine-resistance is not yet completely understood. Microarray analysis of miRNAs in TAM-sensitive MCF-7 versus TAM-resistant LY2 breast cancer cells (derived from MCF-7 cells) identified differential regulation of miR-29b-1 and miR-29a. miR-29b-1 and miR-29a-1, which are co-transcribed as a single primary-miR, were repressed by TAM in MCF-7 and stimulated in TAM in LY2 cells. We confirmed these observations by real time qPCR in MCF-7 and LY2 cells and observed that 4-OHT/TAM (4-OHT) also downregulated miR-29b-1/a in LCC2 and LCC9 endocrine-resistant cells. These changes were at the primary transcriptional level. The role of these two miRs in endocrine-resistant breast cancer is unknown. We tested the hypothesis that the TAM-stimulated increase in miR-29b-1/a promotes endocrine-resistance by downregulating targets that contribute to TAM’s antiproliferative/pro-apoptotic activity. Our goals were to: 1) Determine if ERα was responsible for TAM regulation of miR-29b-1/a expression; 2) Determine the functional role(s) of miR-29b-1/a; 3) Identify specific miR-29b-1/a target genes that are differentially regulated by 4-OHT in MCF-7 versus LCC9 and LY2 cells. Knockdown of ERα blocked 4-OHT inhibition of miR-29b-1/a in MCF-7 and 4-OHT simulation of miR-29-b-1/a transcription in LCC9 and LY2 cells. Transient over-expression of miR-29b-1/a stimulated caspase-8 activation and LY2 cell death and increased colony formation of LCC2 cells. Repression of miR-29b-1/a has no significant effect on MCF-7, LCC9, or LY2 cell proliferation. Repression of miR-29b-1/b did not sensitize the TAM-resistant cells to growth inhibition by 4-OHT. We observed that the bona fide miR-29 target gene, Dicer1, was inhibited by 4-OHT in LY2 cells and anti-miR-29b-1/2 or anti-miR-29a decreased the suppression of Dicer1 by 4-OHT. These data suggest that 4-OHT/ERα increases miR-29b-1/a which target and downregulate Dicer1 in endocrine resistant breast cancer cells. Future studies will identify other targets of miR-29b-1/a to better understand the pathways leading to acquired endocrine resistance.

Background: miR-23b has been identified as various cancer-related biomarkers. Interestingly, it works as an oncogenic miRNA in lymphoma, renal cancer and glioma, while it works as a tumor suppressor miRNA in pancreatic cancer, bladder cancer and prostate cancer (Donadelli M et al, Cancer Lett, 2014). We have previously reported miR-23b-3p as a oncomiR in NSCLCs (Begum S, Hayashi M et al, Sci Rep, 2015). To find the correlation to other carcinogenesis, we focused on miR-23b function in hepatocellular carcinoma (HCC). Methods: miR-23b-3p expression was...
examined in 9 HCC cell lines (SK-Hep1, HuH2, HLE, PLC/PRF/5, HuH7, HuH4, HLF, Hep3B, HepG2). The downstream of miR-23b-3p overexpression was examined by Cancer Pathway Finder (Qiagen). Results were applied to 125 clinical HCC samples (2002-2011 surgically resected). Results: Transfection experiments were performed for HepG2 (miR-23b-3p highly expressed) by siRNA and for SK-Hep1 (lowly expressed) by miRNA mimic. Cancer cell proliferation was activated by miR-23b-3p overexpression, and diminished by its inhibition. In order to find the associated genes, miR-23b-3p overexpressed SK-Hep1 cells were compared with parental SK-Hep1 cells by global gene expression analysis. ANGPI1, ERCC5 and G6PD genes were upregulated, while KDR, WEE1, OCLN genes were downregulated. We also detected additional two genes (AUH and MUC3) by TargetScan Release 5.2. Clinical HCC samples were divided into miR-23b-3p upregulated 48 cases (38%), and downregulated 77 cases (62%). Upregulated cases were correlated with aged patients (P=0.015), capsule invasion positive (P=0.039) and seminal invasion positive (P=0.049). Also, they showed significantly poor recurrence free survival (HR=1.64, P=0.037, 95%CI:1.03-2.59) and overall survival (HR=3.10, P=0.001, 95%CI:1.57-6.29) in multivariable analysis. Conclusion: miR-23b-3p increased the HCC cell proliferation, and indicated the inverse type of HCCs. It functions as a oncogenic biomarker in HCCs and might be a therapeutic target.

#3430 Deep sequencing-based miRNA expression signature in head and neck squamous cell carcinoma: dual strand of miR-150-150 acts as tumor suppressors. Keichi Koshizuka,1 Nijiro Nohata,2 Toyoyuki Hanazawa,1 Naoko Kikkawa,1 Ichiro Fukumoto,1 Takayuki Arai,1 Atsushi Okato,1 Yoshitaka Okamoto,1 Naohiko Seki1. 1Chiba University Graduate School of Medicine, Chiba, Japan; 2Moor Green Cancer Center, University California, CA.

Head and neck squamous cell carcinoma (HNSCC) is the sixth most common cancer in the world and ~500,000 cases are diagnosed every year. In spite of considerable advances in multimodality therapy, including surgery, radiotherapy and chemotherapy, the overall survival rate for patients with HNSCC is ~50%. Patients with HNSCC are usually diagnosed at a late stage and local tumor recurrence and distant metastasis occur after conventional therapies. Application of genomic approaches might elucidate novel molecular pathways underlying HNSCC and thereby improve therapeutic approaches to the disease. The discovery of noncoding RNAs (ncRNAs) in the human genome was an important conceptual breakthrough for cancer research in the post-genome sequencing era. Among ncRNAs, the microRNAs (miRNAs) are small ncRNA molecules (18-25 nucleotides in length) that regulate the expression of protein-coding/non-protein-coding genes by repressing translation or cleaving RNA transcripts in a sequence-specific manner. Accumulating evidence has demonstrated pivotal roles for miRNAs in human cancer pathogenesis. To seek out differentially expressed miRNAs in HNSCC cells, we newly constructed the deep-sequencing based miRNA expression signature by using laryngeal and hypopharyngeal clinical specimens. Our present data showed that a total of 169 miRNAs (44 upregulated and 116 downregulated) were identified as aberrantly expressed miRNAs in cancer tissues. Based on the signature, we focused on the dual strand of pre-miR-150, miR-150-5p and miR-150-3p in HNSCC signature because of these miRNAs significantly reduced in cancer tissues, suggesting these miRNAs act as antitumor miRNAs in this disease. However, the role of these miRNAs in HNSCC cells is still ambiguous. In miRNA biogenesis, it is the general consensus that processing of the pre-miRNA through Dicer1 generates a miRNA duplex (a passenger strand and a guide strand), and that the passenger strand has degradation and no regulatory activity and downregulates in cells. Our present data showed that both miRNAs, miR-150-5p and miR-150-3p significantly suppressed cancer cell migration and invasion. Moreover, gene expression data and in silico database analysis showed that Integrin A3 (ITGA3), Integrin A6 (ITGA6) and Tenasin C (TNC) were direct regulation of both miRNAs. A large number of cohort study by TCGA showed that overall survival of high expression of ITGA3, ITGA6 and TNC groups were significantly shorter than that of low expression of these expression groups (p = 0.0177, p = 0.0237 and p = 0.026, respectively). These target genes acted as oncogenes and deeply contribute to HNSCC pathogenesis. Dual strand of miR-150 functioned as tumor suppressors based on the miRNA expression signature of HNSCC. Identification of miRNA-mediated cancer networks may provide novel molecular pathogenesis of the disease.

#3431 The oncogenic role of miR-150-5p in triple-negative breast cancer. Bruna M. Sugita,1 Yara Zabala,2 Aline Fonseca,3 Rodrigo Almeida,1 Yuriy Gusev,4 Celia Rose,2 Bogdan Voevodin4, Igor I. Cavalli,1 Enelme M. Ribeiro,2 Luciane R. Cavalli1. 1Federal University of Parana, Curitiba, Brazil; 2Georgetown University, Washington, DC.

Triple-negative breast cancer (TNBC) is an aggressive subtype of breast cancer that confers disease recurrence, treatment resistance and high mortality rates. MicroRNAs are a class of noncoding RNAs, that when dysregulated, impact tumorigenesis through the control of the expression of multiple mRNA targets involved in critical cancer signaling pathways. miR-150-5p has been shown to control the expression of several onco genes and/tumor suppressor genes involved in these critical pathways. Its pattern of expression varies among TNBC subtypes, and its role in the cancer stem cell (CSC) population is associated with hematological diseases and GI cancers, and upregulated in hormonal dependent cancers, such as prostate and breast cancer. The main objective of this study was to assess the patterns of expression of miR-150-5p in TNBC and determine its functional role in affecting the tumor phenotype. Archived paraffin samples of 113 patients with ductal breast carcinoma (56 of the TNBC and 57 of the non-TNBC subgroup) and adjacent normal tissue (ANT), obtained from the the pathology tumor bank of Lombardi Comprehensive Cancer Center, Washington DC, were profiled for miRNA using the wide-genome Nanostring platform and a Taqman specific miRNA-150-5p assay. Significant overexpression levels of miRNA-150-5p were observed in the tumor tissues when compared to the ANT and in the TNBC cases when compared to the non-TNBC cases, demonstrating its tumor and TNBC subtype specificity, respectively. Overexpressed levels of miRNA-150-5p were also preferentially observed in the TNBC cases from patients that presented with LN metastasis and breast cancer recurrence, indicating its association with poor prognosis. Interestingly, the TNBC of African-American patients, which is the ethnic group mostly affected by this cancer subtype, presented overexpression levels of this miRNA when compared to the non-TNBC of white patients. Functional analysis performed in the TNBC cell lines, MDA-MB-231 and HCC1806, showed after transfection with miR-150-5p inhibitor, reduced levels on cell proliferation, clonogenicity, migration, drug resistance and expression of the EMT promoter markers, SLUG and SNAIL. These findings, indicate an oncogenic type of action of miRNA-150-5p in TNBC. In summary, miRNA-150-5p is upregulated in TNBC clinical cases in association with poor prognostic parameters and its functional inhibition, directly confers to the cells a reduction of their tumorigenic phenotype. Funding: This project was supported by the GeorgeFromm University Center of Excellence in Regulatory Science and Innovation (CERSI U01FD004319), a collaborative effort between the university and the U.S. Food and Drug Administration to promote regulatory science through innovative research and education. #3432 miRNA expression reflects site specificity of metastatic colorectal cancer. Bastian Fromm,1 Eirik Høye,1 Diana Domanskas,2 Christin Lund-Andersen,3 Anette Torgrunn Kristensen,3 Vegar J. Dagenborg,1 Paul H. Boettger,1 Torveig W. Abrahamssen,1 Steinar Solberg,1 Stein G. Larsen,1 Bjørn Edelbo,2 Per-Olov I. Malmgren,2 Kjersti Flatmark1. 1Oslo University Hospital - The Norwegian Radium Hospital, Oslo, Norway; 2University of Oslo, Oslo, Norway; 3PHMB Research Consulting, Austria; 4Oslo University Hospital - Rikshospitalet, Oslo, Norway.

Colorectal Cancer (CRC) is one of the leading causes of cancer related deaths in the western world, and metastatic progression is the dominating cause of mortality. The primary site of CRC metastasis is the liver, followed by the lungs and peritoneal cavity, and prognosis for patients with metastatic CRC (mCRC) is poor, with only 10% five-year survival. Although much is known about progression and metastasis of CRC; how primary CRC (pCRC) differs from mCRC on the molecular level and potential differences between metastases located in different organs are incompletely understood. This is important for our understanding of the disease, but also could have significant implications with respect to treatment. MicroRNAs have been shown to be key elements in cancer progression, but recent reports on CRC failed to consistently identify microRNA signatures of metastatic progression. We have addressed this using a smallRNA sequencing approach to analyze primary tumors and a set of liver, lung and peritoneal metastases, including corresponding adjacent tissue (colon, liver, lung, peritoneum). Further, we use the highly curated and updated microRNA reference MirGeneDB.org, the novel pipeline MirAthon - including a correction-algorithm of benign tissue microRNA signatures for tumor or metastatic samples, and we compare pCRC and site specific metastases separately. We are able to show that microRNA profiles of mCRC are distinct to pCRC in a site-specific manner. We identify a small panel of differentially expressed microRNAs including isoforms (isomiRs) hidden under a layer of benign signatures that we confirmed in other available datasets, too. Our findings will help better understand metastatic progression and site-specificity in CRC and could be potential biomarkers for mCRC. Our work identifies microRNA signatures of mCRC and suggest that microRNA signatures reflect mCRC site specificity.
Furthermore, the results underline the importance of using a curated reference for microRNA studies, and to differentiate metastases based on their localization ab initio.

#3433 Epigenetic silencing of miR-214-3p is associated with resistance to p53-induced apoptosis through up-regulation of gankyrin expression in hepato-cellular carcinoma. Koha Hitori, Yutaka Watanabe, Naoto Ishii, Kei Tarazaki, Yasuyuki Gen, Yoshito Itoh. Kyoto Prefectural University of Medicine, Kyoto, Japan.

Hepatocellular carcinoma (HCC) is the third leading cause of cancer death worldwide. MicroRNAs (miRNAs) are small non-coding RNAs that regulate gene expression and can act as tumor suppressors or oncogenes. To identify miRNA involved in the development of HCC, a genome-wide miRNA gene expression analysis was performed using the human miRNA microarray (Array-Gene) in paired HCC tumors and non-tumorous liver tissues from patients with primary HCC. The array-based miRNA expression profiles were validated by quantitative PCR. We also screened for genes with promoter DNA hypermethylation using a genome-wide DNA methylation microarray analysis (the Illumina HumanMethylation27 BeadChip) in the same samples. We found that miR-214-3p was significantly down-regulated by aberrant promoter hypermethylation in HCC tumors compared to the non-tumorous liver tissues. We identified PSMD10, which encodes gankyrin, as a direct target of miR-214-3p using luciferase assay and immunoblotting. Gankyrin, an oncoprotein commonly overexpressed in HCC, binds to MDM2, a major E3 ubiquitin ligure for p53, and increases ubiquitlization and degradation of p53. Our experiments showed that reduced miR-214-3p expression was associated with resistance to p53-induced apoptosis through up-regulation of gankyrin expression in HCC cells. In conclusion, our results suggest that epigenetic silencing of tumor suppressor miR-214-3p is involved in hepatocarcinogenesis through up-regulation of gankyrin expression.

#3434 Loss of β-Catenin expression by miR-214 and oncogenic role of miR-214 in metastatic melanoma cells. Kimhna Prabhakar, Ashika Jayanthy, Vijay Setaluri. University of Wisconsin, Madison, WI.

Disregulation of β-catenin facilitates melanoma metastasis by activating the transcription of oncogenes like Myc, CyclinD1 and TCF-1. It is important to understand the regulation of β-catenin to develop strategies to target Wnt signaling for melanoma treatment. MicroRNAs are small non-coding RNAs that are primarily involved in post-transcriptional regulation of target genes. Hence, miRNAs can be used to manipulate protein levels by causing instability of the transcript or by inhibiting translation. MiR-214 has been documented as regulator of β-catenin in cancer cells other than melanoma cells. The role of miR-214 in regulation of β-catenin has not been investigated. In this study, we investigated the regulation of β-catenin by miR-214 in melanoma cell lines and studied the effect of overexpression miR-214 on the malignant phenotype of metastatic melanoma cells and their sensitivity to MAP kinase inhibitors. Our data show that β-catenin is upregulated in a panel of metastatic melanoma cells and the expression levels of β-catenin is negatively correlated with endogenous expression of miR-214. However, overexpression of miR-214 by transfection with a miRNA mimic did not show significant decrease in β-catenin mRNA or protein expression. RNA-Seq showed that multiple isoforms of β-catenin transcript are present in melanoma where the binding site is absent or mutated. The alternatively spliced transcript with no binding site for miR-214 is seen to be more abundant than the other isoforms. Paradoxically, overexpression of miR-214 increased survival, proliferation and migration of metastatic melanoma. In addition, miR-214 overexpression decreased their sensitivity to vemurafenib and selumetinib. In melanoma cells with acquired resistance (in vitro), miR-214 overexpression further enhanced their resistance to MEK inhibitor, but not vemurafenib. In light of the published studies that proposed that miR-214 acts as tumor suppressor by negatively regulating β-catenin, our study is interesting since we find that in metastatic melanoma miR-214 has oncogenic role. Ongoing studies are aimed at understanding the mechanisms by which miR-214 promotes malignant behavior of melanoma cells.

#3435 Profiling miRNAs in breast epithelial progenitor cells during branching morphogenesis and EMT in 3D culture. Eirikur Brien,1 Bylgia Hilmarsdottir,2 Zuzana Budkova,1 Saevar Ingthorsson,1 Magnus K. Magnusson,1 Thorarinn Gudjonsson1.1University of Iceland, Reykjavik, Iceland;2Oslo University Hospital, Oslo, Norway.

In this study we investigate the role of miRNA-203a in branching morphogenesis and epithelial to mesenchymal transition (EMT) in breast cell lines. D492 is a breast epithelial cell line with stem cell properties. D492 generates luminal- and myoepithelial cells and in 3D culture forms structures reminiscent of terminal duct lobular units of the breast. When cocultured with endothelial cells subset of D492 cells undergo EMT as evidenced by spindle shape morphology, E- to N cadherin switch and loss of keratin expression. We have established an endothelial-induced mesenchymal subline from D492 referred to as D492M. Here we use D492 and D492M as a model to investigate miRNA expression patterns during different stages of branching and in EMT. We performed small RNA sequencing on D492 and D492M in 3D culture to pinpoint miRNAs that are associated with epithelial integrity and suppressing EMT. We have recently shown that miRNA-200c-141 convert D492M back to the epithelial phenotype (Hilmarsdottir et al. G&D 2015). MiRNA-203a is also down-regulated in D492M. Here we overexpress miRNA-203a in D492 and D492M. Methylation analysis reveal that the promoter area of miRNA-203a is not methylated in D492M. We showed that knockdown of miRNA-203a in D492M cells change phenotype from elongate, mesenchymal-like phenotype to more cuboidal epithelioid phenotype, show reduced cell proliferation, less ability to form colonies in low attachment cultures, less ability to migrate and reduced invasion capability. When D492MmiRNA-203a is co-cultured with endothelial cells in 3D culture they partially regain the ability to form branching structures similar to D492. D492M(miRNA-203a) show reduced expression of EMT transcription factors SNAIL2 and ZEB1. When cultured on transwell filters, D492M forms stratified squamous epithelial layer while D492M(miRNA-203a) form single squamous layer. In conclusion, miRNA-203a induces partial epithelial phenotype in D492M as evidenced by morphology and marker expression. We also conclude that three dimensional cultures of D492 and D492M work well as a model system to investigate miRNA expression during branching morphogenesis and in EMT.

#3436 MiR-194 modulates paclitaxel resistance in ovarian cancer cells through the regulation of MDM-2 expression. Koji Nakamura,1 Kenjiro Sawada,2 Akihiko Yoshimura,3 Erica Nakatsuka,4 Yusato Kinose,5 Seiji Mabuchi,6 Tadashi Kimura.7 Saiseikai Nakatsu Hospital, Osaka-shi Osaka, Japan; Osaka University, Suita-shi Osaka, Japan; Penn Ovarian Cancer Research Center, Philadelphia, PA.

Purpose: Ovarian cancer is the most lethal gynecologic malignancy. Platinum-paclitaxel combination chemotherapy is the current standard postoperative care for patients with advanced ovarian cancer. Despite developments in current chemotherapy regimens in the last decades, overall 5-year survival rate for patients with advanced disease remains approximately 30%, mainly due to primary or acquired drug resistance. Therefore, overcoming chemoresistance remains the great challenge in ovarian cancer management. However, mechanisms underlying chemoresistance to paclitaxel have not been fully understood. The aim of this study is to identify key miRNAs which regulate paclitaxel resistance in ovarian cancer and to pursue those potential as therapeutic targets. Methods: Using two serous ovarian cancer cell lines, SKOV3ip1 and HeyA8, paclitaxel-resistant ovarian cancer cell lines were established by a continuous exposure of paclitaxel. MiRNA PCR arrays were performed and miR-194 was found to be one of down-regulated miRNAs in paclitaxel-resistant cell lines. The effect of miR-194 on paclitaxel resistance was assessed by transducing the precursor miRNA into ovarian cancer cells. In silico analysis revealed MDM-2 is one possible putative target of miR-194 and it was assessed using luciferase reporter gene and transfection MDM-2 were performed by a continuous exposure of paclitaxel. MiRNA PCR arrays were performed and miR-194 was found to be one of down-regulated miRNAs in paclitaxel-resistant cell lines. The effect of miR-194 on cell cycle in ovarian cancer cell was assessed. To analyze the impact of miR-194 and MDM-2 expression on patient survival, Kaplan-Meier and log-rank methods were used using The Cancer Genome Atlas (TCGA) dataset. Results: While IC50 values of SKOV3ip1 and HeyA8 were 5.0 nM and 3.5 nM respectively, those of paclitaxel resistant cell lines, named as SKOV3ip1-TR and HeyA8-TR, were both over 300 nM. In both resistant cell lines, miR-194 was found to be down-regulated compared with their parental cell lines. Up-regulation of miR-194 sensitized resistant cells to paclitaxel. Conversely, its downregulation induced paclitaxel resistance in parental cells. Luciferase reporter assay revealed that miR-194 directly suppressed MDM-2 transcript. In resistant cell lines, MDM-2 was up-regulated compared with their parental cell lines. MiR-194 induced P21 upregulation and G1 phase arrest in resistant cell lines through the downregulation of MDM-2. In TCGA dataset, high MDM-2 expression was associated with shorter progression-free survival of ovarian cancer patients (concrete data, p=0.046). Conclusion: miR-194 acts as a tumor suppressor miRNA through the sensitization to paclitaxel and can be considered as a therapeutic option to overcome paclitaxel-resistant in ovarian cancer patients.

#3437 Targeting microRNA-143 in glioblastoma in vivo increases tumor growth. Eunice Lozada-Delgado1, Fatma Valiyeva,2 Maria Marcos,3 Pablo Vivas4.1University of Puerto Rico, San Juan, PR;2University of Puerto Rico Comprehensive Cancer Center, San Juan, PR.

In this study we investigate the role of miRNA-203a in branching morphogenesis and epithelial to mesenchymal transition (EMT) in breast cell lines. D492 is a breast epithelial cell line with stem cell properties. D492 generates luminal- and myoepithelial cells and in 3D culture forms structures reminiscent of terminal duct lobular units of the breast. When cocultured with endothelial...
The purpose of this study is to assess the biological role of the microRNA-143 (miR-143) in Glioblastoma multiforme (GBM). GBM is the most common and lethal of all brain tumors. In the United States, the incidence of GBM is about 17% of all primary brain tumors and about 60-75% of all Astrocytomas (American Brain Tumor Association, 2014). The standard therapy is surgical resection followed by chemotherapy and radiotherapy. Despite this approach, GBM recurs after treatment and the median survival rate for GBM has remained 15 months for the past 20 years. Thus, novel therapies for GBM treatment are urgently necessary. MicroRNAs (miRNAs) are a class of small non-coding RNAs (18-22 nucleotides in length) that regulate gene expression at the post-transcriptional level. MiRNAs bind to the 3′-untranslated region (UTR) of messenger RNA (mRNA) to regulate protein production. Several deregulated miRNAs have been identified in all cancer types including GBM. In this study we aim to thoroughly uncover the role of miR-143 by using GBM cell lines, mouse models and patient samples. Total RNA was isolated from FFPE samples from brain tumor patients. TaqMan-based Real-time PCR showed that the relative expression of miR-143 was higher in GBM patients compared to control individuals, and with paired normal non-tumorous tissue. Furthermore, GBM cells transiently transfected with a miR-143 oligonucleotide inhibitor showed reduced cell proliferation (68.5%) (clonogenic assay), increased apoptosis and cell cycle arrest of GBM cells in the S phase (Flow cytometry and Western blots).

In vivo studies using primary GBM cells injected in the flank of nude mice showed that repeated doses of miR-143-inhibitor liposomal formulation increased the temperature of the tumor compared with the control group. These results could be due to effects of the microenvironment where the tumor is growing. Further studies will be made using intracranial injections in an orthotopic xenograft mouse model to confirm this hypothesis. Western blot analysis and luciferase reporter assays are also underway to identify novel miR-143 target genes in GBM cells. This research project is being supported by: PRCTRC: NCRR (U54 RR026139-01A1), NIMHD (8U54 MD007587-03), and RCMI: MBRSC-RISE, NCR (2G12-RR003051) and NIMHD (8G12-MD007690) from the NIH.

**#3438** Dual-strands pre-microRNA-150 (miR-150-5p and miR-150-3p) act as tumor suppressor in prostate cancer. Atsushi Okato, Takayuki Arai, Akira Kurozumi, Mayuko Kato, Yusuke Goto, Keiichi Koshizuka, Satoko Kojima, Tomohiko Ichikawa, Naohiko Seki. Chiba University, Chiba-shi, Japan; Tei-kyo University Chiba Medical Center, Chiba-shi, Japan.

Background: Prostate cancer (PCa) is the second most common cause of cancer and the sixth leading cause of cancer death among men in the world. Androgen signaling through the androgen receptor (AR) is an important oncogenic pathway for PCa progression. The initial response rate of PCa to androgen deprivation therapy (ADT) can be up to 80%, but most patients experience disease relapse and progress to castration-resistant prostate cancer (CRPC). Although several clinical trials, such as molecules with anti-androgenic properties, have been carried out, these treatments provide limited benefits and are not curative. Therefore, identification of effective biomarkers for detection of CRPC and understanding the molecular mechanisms of androgen-independent signaling and metastatic signaling pathways underlying PCa using current genomic approaches would help to improve therapies for and prevention of the disease.

Currently, numerous studies have indicated that miRNAs are aberrantly expressed in several cancers, including CRPC. In this study, we constructed a miRNA expression signature to identify miRNA regulated RNA networks in CRPC using autopsy specimens from patients with ADT. Based on the signature, dual-strands of pre-miR-150 (miR-150-5p and miR-150-3p) were significantly reduced in CRPC specimens. The aim of this study was to investigate the functional significance of both strands of miR-150-5p and miR-150-3p and these miRNAs regulated RNA networks in CRPC. Results: Downregulation of miR-150-5p and miR-150-3p were validated in hormone naive PCa and CRPC specimens compared to non-cancerous prostate tissues (p < 0.0001). Restoration of miR-150-5p and miR-150-3p significantly suppressed cancer cell migration and invasion in PCa cell lines (P < 0.0001). Gene expression data and in silico database analysis showed that Sperm/OSTIN, Gw254 AND Kazal-like Domain Proteoglycan 1 (SPOCK1) was regulated by both miRNAs. Knockdown of SPOCK1 inhibited cancer cell aggressiveness. Overexpression of SPOCK1 was observed in PCa clinical specimens. Conclusions: In miRNA biogenesis, it is the general consensus that processing of the pre-miRNA through Dicer1 generates a miRNA duplex (a passenger strand and a guide strand), and that the passenger strand has degradation and no regulatory activity and disintegrates in cells. Our present data showed that both strands of pre-miR-150 (miR-150-5p and miR-150-3p) inhibited cancer cell aggressiveness, suggesting these miRNAs as tumor-suppressors. Identification of miRNA-mediated cancer networks may provide novel molecular pathogenesis of the disease.
#3441 A novel IncRNA-mediated YAP1 signaling pathway activation in epithelial ovarian cancer. Xianzhi Liu, Rosario I. Corona, Simon A. Gayther, Dennis L. Hazelett, Kate Lawrenson. Cedars-Sinai Medical Center, Los Angeles, CA.

Background: The long non-coding RNA (lncRNA) uterine thoracic cancer associ- ated 1 (UTCA1) was identified in many cancer tissues including ovarian cancer. In high grade serous ovarian cancers (HGSOCs), we had previously found that UC1A expression negatively correlates with patients' total survival and disease-free survival and that UC1A knockout significantly impairs tumor growth in vivo. In addition, UC1A promotes ovarian cancer cell growth via activating the YAP1 signaling pathway. Purpose: Our present study aims to dissect the molec- ular mechanism of UC1A-mediated YAP1 signaling activation. Methods: To characterize the UC1A interactome, we utilized a modified in vivo RNA anti- sense purification method (UC1A-iRAP). This UC1A-iRAP method uses streptavidin-coupled magnetic beads to pull down biotin-labeled antisense probes which are complementary to the target RNA. In such a way, UC1A RNA will be specifically enriched together with its in vivo-associated proteins, RNAs and/or genomic DNA, which can be profiled using mass spectrometry (MS) and next generation sequencing (NGS), respectively. Results: Using UC1A-iRAP RNA-Seq and UC1A-iRAP protein MS, we comprehensively annotated the UC1A-interacting RNAs as well as UC1A-associated proteins. Interestingly many of the proteins identified were not known to have RNA-binding potential. Integration of NGS and MS data with multifaceted functional and molecular characterization revealed that knockdown of UC1A-mediated YAP1 signaling via UC1A-iRAP method, the interaction between UC1A and this YAP1 modulator leads to activation of YAP1 signaling by nuclear translocation of YAP1. In summary, we characterize a novel UC1A- YAP1 signaling axis active in HGSOCs and also reveal that oncosgenic IncRNA's binding potential of cytoplasmic signaling proteins could be a common mechanism of post-translational control of signaling pathways deregulated in cancer.

#3442 The long non-coding RNA GHSROS mediates expression of genes associated with tumor growth, metastasis and adverse disease outcome. Patrick B. Thomas,1 Penny L. Jeffery,1 Eliza Whiteside,2 Carina Walpole,2 Michelle Maughan,3 Lidija Jovancovic,1 Jifer H. Gunter,3 Colleen C. Nelson,1 Adrian C. Hertingon,4 Rakesh Veedu,5 Lisa K. Chopin,1 Inge Seim1.

1The University of Queensland, Brisbane, Australia; 2University of Southern Queensland, Toowoomba, Australia; 3Murdoch University, Perth, Australia.

Objectives: To investigate the expression and function of the lncRNA GHSROS in prostate cancer. Methods: Using UC1A-iRAP RNA-Seq and UC1A-iRAP protein MS, we comprehensively annotated the UC1A-interacting RNAs as well as UC1A-associated proteins. Interestingly many of the proteins identified were not known to have RNA-binding potential. Integration of NGS and MS data with multifaceted functional and molecular characterization revealed that knockdown of UC1A-mediated YAP1 signaling via UC1A-iRAP method, the interaction between UC1A and this YAP1 modulator leads to activation of YAP1 signaling by nuclear translocation of YAP1. In summary, we characterize a novel UC1A- YAP1 signaling axis active in HGSOCs and also reveal that oncosgenic IncRNA's binding potential of cytoplasmic signaling proteins could be a common mechanism of post-translational control of signaling pathways deregulated in cancer.

#3443 Functional and mechanistic characterization of oncogenic long inter- vening non-coding RNA Linc-CHD1L-1 in hepatocellular carcinoma. Fe- lice H. Tsang, Daniel W. Ho, Irene O. Ng, Jack C. Wong. The University of Hong Kong, Hong Kong, Hong Kong.

Hepatocellular carcinoma (HCC) is one of the most common and lethal can- cers worldwide. Due to the asymptomatic nature of HCC, many patients were diagnosed at late stages when cure rates are very low. Therefore, a better understanding of the molecular mechanism underlying hepatocarcinogenesis is urgently needed and is crucial for the development of effective treatment. Long intervening non-coding RNAs (lincRNAs) are emerging class of regulatory RNA involved in diverse molecular processes. In this study, we aimed to interrogate lincRNAs expression in HCC and identify novel lincRNAs that contribute to hepatocarcinogenesis. To investigate the global expression profile of lincRNAs in human HCCs, next-generation transcriptome sequencing (RNA-Seq) was performed in 16 pairs of HBV-associated primary HCCs and their corresponding non-tumorous liver tissues. Interestingly, the lincRNA expressions in human HCCs can be unambiguously segregated from those of HBV-negative HCCs using lincRNA expression signatures. Suggesting that global lincRNA expression profiles between tumors and non-tumors were remarkably different. From this analysis, we identified linc-CHD1L-1 as the most significant up-regulated lincRNA in HCCs. Clinically, linc-CHD1L-1 was overexpressed in over 80% of HCC patients. Linc-CHD1L-1 expression level in tumors was also shown to be a promising marker for HCC diagnosis. Furthermore, knockdown of linc-CHD1L-1 by shRNAs has significantly re- duced HCC cell proliferation and cell migration in vitro. Besides, knockdown of linc-CHD1L-1 in HCC cells also substantially abrogated tumorigenicity in subcutaneous tumor model. Mechanistically, the expression of linc-CHD1L-1 was significantly and positively correlated to the expression of its neighboring genes located on the chromosome 1q4. Knockout of linc-CHD1L-1 by CRISPR/Cas9 also significantly repressed its neighboring genes expression, suggesting that linc-CHD1L-1 may positively regulate gene expression in a cis-manner. Finally, DAVID pathway analysis performed on linc-CHD1L co-expressed protein coding genes further suggested that linc-CHD1L-1 is significantly co-expressed with genes that are involved in transcription and chromatin modifications. In conclusion, overexpression of linc-CHD1L-1 contributes to hepatocarcinogenesis by promoting HCC cell proliferation and migration through transcriptional and epigenetic mechanisms.

#3444 LINC00152 regulates cell proliferation via p38 signaling and over- expression predicts poor patient survival in lung adenocarcinoma. Wei Zhang, Wenniei Su, Shengbin Bai, Lei Xiao, Zhuen Wang, Jules Lin, Rishindra Reddy, Andrew Chang, David Beer, Guoan Chen. Univ. of Michigan Medical School, Ann Arbor, MI.

Lung cancer is a molecularly-heterogenous disease and the leading cause of cancer mortality. The molecular basis for this heterogeneity remains incom- pletely understood. In the past few years, long non-coding RNAs (lncRNAs) have emerged as novel mechanisms in mediating cancer biology, although most lincRNAs are still undiscovered. LINC00152 has been identified as highly associated with the tumorigenesis and development in gastric cancer, colon cancer and hepatocellular carcinoma, however, the expression level and its oncogenic roles in lung cancer remains unknown. In the present study, we employed next generation RNA sequencing analysis to reveal dysregulated lincRNAs in lung cancer utilizing datasets of 461 lung adenocarcinomas (LUAD) and 156 normal lung tissues from 3 separate institutions. We found that LINC00152 was 4-fold (p < 0.001) overexpressed in lung tumors as compared to their adjacent normal tissues with AUC > 0.8 in these 3 data sets. Patients with high LINC00152 expression have significantly poorer survival than those with low expression (log-rank test, p = 0.003). We verified this diagnostic/prognostic potential in an independent cohort of lung tumors by quantitative RT-PCR. Cell proliferation and colony formation ability were decreased after knockdown of LINC00152 using siRNAs in lung cancer cell lines. The expression of LINC00152 was found primarily in the cytoplasm by qRT-PCR analysis. Trichostatin A treatment indicated that histone acetylation could be one of the mech- anisms underlying LINC00152 overexpression in NSCLC and cell-based analysis showed p38 signaling was mainly affected by LINC00152 in vitro. Taken together, this study suggests that LINC00152 is involved in lung tumor growth, may have potential as diagnostic/prognostic marker and that further characterization of this lincRNA as a novel therapeutic target for lung cancer is warranted.

MOLECULAR AND CELLULAR BIOLOGY / GENETICS: MicroRNAs and Other Noncoding RNAs as Tumor Suppressors or Oncogenes 2
Introduction: Glioblastoma multiforme (GBM) is the most frequent primary brain tumor of astrocytic origin characterized by very poor prognosis. Despite conventional therapeutic protocol the prognosis of GBM patients is very poor with median of overall survival ranging between 12 and 15 months from diagnosis. Therefore, many financial charges and lot of effort is spent in research of new therapeutic agents that could improve survival of patient. Long non-coding RNAs (lncRNAs) are a relatively new class of noncoding gene regulators playing critical roles in tumor biology, including GBM. From this perspective, lncRNAs seem to be promising therapeutic targets in GBM patients.

Material and Methods: We performed next-generation sequencing analysis of fresh-frozen histopathologically confirmed 45 GBM tissues and 5 non-tumor brain tissues obtained from non-dominant anterior temporal cortices resected during surgery for intractable epilepsy. Informed consent approved by the local Ethical Committee was obtained from each patient before the treatment. RNA depletion and cDNA library preparation were performed with GeneRead mRNA Depletion Kit (Qiagen) and NEXTflex Rapid Directional mRNA-Seq Kit (Boo Scientific), respectively. Sequencing was performed with NextSeq 500 High Output Kit and NextSeq 500 System (both Illumina). Statistical analysis was conducted using 24,087 protein-coding and 8,414 non-coding RNAs and their sequential variants with non-zero RPMK (Reads Per Kilobase of transcript per Million mapped reads) at least in one sample. We used CLC genomic workbench for the alignment and target counts. Targeted regulation of ZFAS1 level have been carried out by the transient transfection of specific siRNA in GBM stable cell lines (A172, T98G, U87MG, U251). Viability and migration were analyzed in vitro using MTT and scratch wound healing assay, respectively.

Results: Statistical analysis has revealed 274 (P < 0.01) deregulated lncRNAs in GBMs in comparison with non-tumor brain samples. Moreover, the results have shown also 489 deregulated protein-coding RNAs with P value less than 0.001 and 26 protein-coding RNAs with P value less than 0.000001. For subsequent in vitro functional analyses was chosen one of the most upregulated lncRNAs in GBM samples ZFAS1. Targeted downregulation of this molecule led to the significant reduction of viability in all examined GBM cell lines. Decreasing of proliferation potential was observed only in A172 a U251 cell lines. Conclusion: We have demonstrated a deregulation of many lncRNAs and protein-coding RNAs in GBM tissue in comparison with non-tumor brain tissue. Moreover, ZFAS1, one of the most upregulated lncRNAs in GBM tissue, is involved in regulation of viability and migration of GBM cells in vitro. This work was supported by Ministry of Health of the Czech Republic, grant nr. 15-33158A, 15-34553A, 15-31627A, 15-34678A, 16-31314A, 16-31765A and by grant of Czech Grant Agency nr. 16-18257S.

#3445 Melatonin suppresses hepatocellular carcinoma progression via lncRNA-CPS1-IT1-mediated HIF-1α inactivation. Tong Hong Wang, Chi Hao Wu, Chau Ting Yeh, Kung Hao Liang, Chuen Hsueh, Chi Yuan Chen, Hao Sun, Chi Chiu Wang, Joseph Kwong, Huating Wang, Tony Kwok. The Chinese University of Hong Kong, Hong Kong, Hong Kong.

Background: Melatonin as a promising therapeutic agent for the treatment of HCC. The inactivation of HIF-1α resulted in the suppression of epithelial-mesenchymal transition (EMT) progression and HCC metastasis. Furthermore, the results of the in vivo animal model experiments also validated the tumor-suppressor role of melatonin via a reduction in tumor growth. Conclusions: Taken together, our findings suggest that melatonin suppresses HCC progression by modulating lncRNA-CPS1-IT1-mediated EMT suppression and further supported melatonin as a promising therapeutic agent for the treatment of HCC.

#3447 Down-regulation of long non-coding RNA MALL-2 is associated with metastasis and poor survival in lung adenocarcinoma. Ha X. Dang, Nicole M. White, Emily B. Rozyczki, Christopher A. Maher. Washington Univ. School of Medicine, St. Louis, MO.

Lung adenocarcinoma accounts for ~40% of lung cancers and is among the deadliest cancers worldwide. Patients with metastatic lung adenocarcinoma exhibit poor outcome with the average 5-year survival of ~1%. Long non-coding RNAs (lncRNAs) have recently emerged as having critical roles in tumorigenesis. While a subset of lncRNAs have been shown to promote tumor invasion and metastasis, little is known about the role of lncRNAs in metastatic lung adenocarcinoma. Therefore, we analyzed publicly available microarray and RNA-Seq gene expression datasets that include primary and metastatic tissues. Through this meta-analysis we discovered 98 metastasis associated lncRNAs that were deregulated in metastatic tumors compared to non-metastatic tumors (MALLs). Notably, only two lncRNAs (MALL-2 and MALL-34) were found to be down-regulated in primary tumors, relative to normal tissue, and even further down-regulated in metastatic tumors relative to primary tumors. Gene set enrichment analysis revealed that MALL-2, the most down-regulated lncRNA in metastasis, was coexpressed with protein-coding genes enriched with biological concepts associated with repressing tumor growth and metastasis. Furthermore, we found that FOXA2, a metastasis repressor gene, was highly coexpressed with MALL-2 in lung cancer. A pan-cancer analysis using ~7,000 TCGA RNA-Seq tumor samples across 20 cancer types revealed that MALL-2 was also down-regulated and coexpressed with FOXA2 in multiple cancers suggesting the conserved regulatory relationship between the two genes. We confirmed that FOXA2 expression was decreased upon knock-down of MALL-2 and silencing MALL-2 resulted in a significant increase in cellular migration in lung adenocarcinoma cell lines. Last, we found that low expression of MALL-2 was consistently associated with poor overall survival across multiple independent lung adenocarcinoma cohorts. Taken together, our integrative analysis has revealed MALL-2 that acts as a repressor of lung adenocarcinoma metastasis by regulating FOXA2 and could serve as a biomarker of lung adenocarcinoma patient outcome.

#3448 LncRNA HAND2-AS1 inactivates neurofibromin U (NMU) and inhibits tumor invasion and metastasis in endometrioid endometrial carcinoma. Xuying Yang, Yu Zhao, Kun Sun, Yuying Li, Jiajian Zhou, Jianzhang Wang, Hao Sun, Chi Chiu Wang, Joseph Kwong, Huating Wang, Tony Kwok Hung Chung. The Chinese University of Hong Kong, Hong Kong, Hong Kong.

Background: Endometrioid endometrial carcinoma (EEC) is one of the commonest histological subtype of endometrial cancer with high mortality in women. Despite progress in diagnostics and treatment of EEC, its prognosis remains poor. Mounting evidence suggest that long noncoding RNAs (lncRNAs) function in multiple human cancers. Aberrant lncRNA expression may predict tumor outcome of patients and have served as diagnostic or prognostic markers. In this study, we investigated the expression levels and functions of lncRNAs in EEC. Methods: Differentially expressed lncRNAs involved in EEC were identified by using publically available RNA-Seq data. The expression of 18 dysregulated lncRNA candidates was verified in 5 NE tissues, 5 EEC tissues and 5 EEC cell lines (HEC1-A, HEC1-B, AN3CA, KLE and RL95-2) by real-time polymerase chain reaction (PCR). Further, we selected the most misexpressed lncRNA and confirmed the expression level of the lncRNA in 59 EEC tissues and 24 NE tissues by real-time PCR and correlated the lncRNA expression levels with the clinical pathological characteristics. The promoter methylation assay was used to analyze the methylation level of the lncRNA in EEC. The lncRNA methylation status was confirmed by bisulfite genomic sequencing. Cell proliferation assays, wound healing assays, and invasion and migration assays were performed to determine the biological functions of the lncRNA in EEC cells. To discover the direct targets of the lncRNA in EEC, we performed RNA-sequence analysis in EEC cells overexpressed with the lncRNA and target genes were further studied by functional studies in vitro (knockdown assay and overexpression rescue assay). Results: We discovered that HAND2-AS1, a lncRNA transcribed antisense adjacent to
Heart and Neural Crest Derivatives Expressed 2 (HAND2), was significantly downregulated IncRNA in EEC. HAND2-AS1 and HAND2 were frequently downregulated in EEC tissues, especially in poor differentiated tumor tissues. Downregulation of HAND2-AS1 and HAND2 was correlated with tumor grade, lymph node metastasis and recurrence of EEC patients. HAND2-AS1 and HAND2 were downregulated by promoter hypermethylation in EEC. HAND2-AS1 suppressed EEC cell migration and invasion but not cell growth. Similarly, HAND2 also inhibited EEC cell migration and invasion indicating that HAND2-AS1 and HAND2 have a concordant role in the progression of EEC. Moreover, the anti-tumorigenic effect of HAND2-AS1 was mediated by downregulating NMU, which had an oncogenic role in EEC. Conclusion: Our findings provide the first evidence that HAND2-AS1 is a critical tumor suppressor in EEC and may constitute a prognostic biomarker in EEC.

Genistein, a soy isoflavone, has been shown to have anti-tumor effects on various cancers in vitro and in vivo including renal cancer. Long non-coding RNAs (IncRNAs) are differentially expressed in various tissues and have important functions in cellular processes such as cell proliferation, motility and apoptosis in various malignancies. HOX transcript antisense RNA (HOXATIR) is an IncRNA localized in the Homeobox C gene cluster on chromosome 12. HOXATIR interacts with the polycomb repressive complex 2 (PRC2), which enhances H3K27 trimethylation and represses the expression of tumor suppressors. In various cancers, HOXATIR is highly expressed and involved in their progression and metastasis. In this study, we investigated the molecular mechanisms of genistein action through a novel pathway that represses HOXATIR. We found that HOXATIR expression is higher in renal cancer cell lines compared to normal controls. Genistein treatment was found to significantly decrease HOXATIR expression in renal cancer cells (786-O and ACHN cells). Genistein treatment also reduced expression of epithelial-to-mesenchyme transition (EMT)-related proteins (ZEB1, Vimentin and Snail), causing reduced cell migration, invasion, and increased apoptosis. We performed RNA immunoprecipitation assays, and found that genistein inhibits HOXATIR binding to PRC2. One of the other EMT markers, a tight junction protein ZO-1, is upregulated by genistein. We are currently investigating if genistein represses PRC2 recruitment to the ZO-1 promoter by inhibiting binding of HOXATIR to PRC2. Our results indicate that genistein is a potent therapeutic agent for renal cancer.

Aberrent expression of long noncoding RNAs (lncRNAs) is associated with various human cancers. However, little information is available about functional involvement of IncRNAs in tumorigenesis of chronic myeloid leukemia (CML) induced by Bcr-Abl oncogene. In this study, we performed a comprehensive analysis of IncRNAs in human CML cells using an IncRNA CDNA microarray combined with drug treatment. We identified an IncRNA termed IncRNA-up38 that was critically involved in Bcr-Abl-mediated cellular transformation. We found that expression of IncRNA-up38 was greatly upregulated by inhibiting Bcr-Abl kinase activity in K562 cells and leukemic cells derived from CML patients. Furthermore, our experiments demonstrated that IncRNA-up38 acted as a key regulator of EBP1 functioning during Bcr-Abl-mediated cellular transformation. Moreover, silencing IncRNA-up38 promoted leukemic cells survival and enhanced Bcr-Abl-mediated tumorigenesis, whereas forced expression of IncRNA-up38 sensitized leukemic cells to undergo apoptosis and inhibited Bcr-Abl-induced tumorigenesis. Additionally, our experiments have begun to address the mechanism of how IncRNA-up38 is regulated in the leukemic cells and showed that Bcr-Abl repressed IncRNA-up38 expression through c-Myc-dependent signaling. Taken together, these results reveal that Bcr-Abl-mediated cellular transformation is associated with downregulation of tumor-suppressor IncRNA-up38 and suggest a potential strategy for the treatment of Bcr-Abl-positive leukemia.

Targeting mitotic kinase is an emerging anticancer strategy with promising pre-clinical results. Mast is an essential mitotic kinase regulating mitotic progression by inactivation of a tumor suppressor protein phosphatase 2A (PP2A). However, it is unclear whether inhibition of Mast kinase can kill tumor cells. Here, we show that Mast inhibition selectively kills cancer cells by induction of mitotic catastrophe in breast cancer cells. We found that Mast overexpression was tightly associated with tumor progression and poor prognosis in breast cancer. Mast depletion with specific siRNAs induced cell death in Mast high breast cancer cells, but not in Mast low breast cancer cells. Interestingly, Mast depletion did not affect the viability of normal cells. In addition, Mast depletion reduced the oncogenic properties of breast cancer cells. Furthermore, we found that Mast depletion caused mitotic catastrophe. Therefore, our data indicate that inhibition of Mast can kill selectively breast cancer cells by induction of mitotic catastrophe, providing that targeting Mast kinase is a very useful approach for breast cancer treatment.

#3452 The cohesin subunit STAG1 is a hardwired genetic dependency of STAG2 mutant cancer cells. Petra Van Der Lelij1, Simone Lieb2, Julian Jude3, Gordana Wutz1, Catarina Pereira2, Katrina Falkenberg1, Jozel Ban4, Heinrich Kova5, Todd Waldman5, Mark Pearson2, Norbert Kraut2, Jan-Michael Peters4, Johannes Zuber2, Mark P. Petroczki6. 1The Research Institute of Molecular Pathology, Vienna, Austria; 2Boehringer Ingelheim RCV, Vienna, Austria; 3CNIO: Spanish National Cancer Research Centre, Madrid, Spain; 4CCRI- Children’s Cancer Research Institute, Vienna, Austria; 5Georgetown School of Medicine, Washington, DC.

Recent genome analyses have identified recurrent mutations in subunits of the cohesin complex in human cancer. Cohesin is a chromosomal factor that is essential for sister chromatid cohesion and cell division and that contributes to gene regulation and DNA repair. Deletious mutations in the cohesin subunit STAG2 have been detected in about 20% of bladder cancer, 15% of Ewing sarcoma and 6% of AML/MDS patients. The mechanistic involvement of cohesin mutations in the pathogenesis of human malignancies is currently under active investigation. We hypothesized that the loss of STAG2 could alter the properties and functionalities of the cohesin complex leading to unique vulnerabilities of STAG2 mutant cells. Using CRISPR/Cas9 and RNAs in isogenic solid cancer and leukemic models we identified STAG1, a STAG2 paralog, as a strong and clean genetic vulnerability of STAG2 mutant cells. Mechanistically, STAG1 loss abrogates sister chromatid cohesion specifically in STAG2 mutant but not wild-type cells leading to mitotic catastrophe, defective cell division and apoptosis. STAG1 inactivation inhibits the proliferation of disease relevant STAG2 mutant but not wild-type bladder cancer and Ewing sarcoma cell lines. Restoration of STAG2 expression in a mutant bladder cancer model alleviates the dependence on STAG1. Our results demonstrate that the cohesin subunits STAG1 and STAG2 act redundantly to support sister chromatid cohesion and cell viability in human cells. We have identified STAG1 as a hardwired, context independent vulnerability of STAG2 mutant cancers. Specific synthetic lethaliites elicited by recurrent cohesin mutations in human tumors hold the promise for the development of selective therapeutics.

#3453 Progression through mitosis promotes PARP inhibitor induced cytotoxicity in homologous recombination deficient cancer cells. Pepijn M. Schoonen1, Peter Bouwman2, Floris Fojer3, Madalena Tarsousova4, Solvi Blatter3, Jos Jonkers2, Sven Rottenberg2, Marcel A. Vugt1.

Molecular Pathology and Cancer Genomics Netherlands, Amsterdam, Netherlands; 2European Research Institut for the Biology of Ageing, University of Groningen University Medical Center Groningen, Groningen, Netherlands; 3Division of Molecular Pathology and Cancer Genomics Netherlands, Amsterdam, Netherlands; 4European Research Institute for the Biology of Ageing, University of Groningen University Medical Center Groningen, Groningen, Netherlands; 5Oxford Institute for Radiation Oncology, University of Oxford, Oxford, United Kingdom; 6Institute of Animal Pathology, Vetsuisse Faculty, University of Bern, Bern, Switzerland.

Mutations in homologous recombination (HR) DNA repair genes BRCA1 and BRCA2 predispose to tumorigenesis. HR-deficient cancers are hypersensitive to Poly (ADP ribose)-polymerase (PARP) inhibitors, but can acquire resistance and relapse. The mechanisms underlying PARP inhibitor resistance are only partially understood. This lack of knowledge in part stems from incomplete understanding of how PARP inhibitors induce cytotoxicity in HR-deficient can...

Antimitotic drugs are often administered as first-line chemotherapy in several malignancies. However, their clinical success is often limited by acquired chemoresistance and disease relapse. The anti-proliferative basis of these drugs is induction of mitotic arrest culminating in cell death. Mitotic slippage occurs when cells exit mitosis and “slip” into interphase without chromosome segregation and cytokinesis. Little is known about how cells post-slippage influence outcome of treatment. Here, we demonstrate that post-slippage cells exhibit paracrine pro-tumorigenic potential following senescence and senescence-associated secretory phenotype development. This occurs in an autophagy-p53 axis-dependent manner, with autophagic inhibition in post-slippage cells bypassing senescence and leading to cell death. Indeed, the autophagy inhibitor Chloroquine and microtubule poisons synergistically inhibited tumour growth in mice. Hence, regimens targeting the senescence phenotype could provide a potential effective combinatorial strategy with antimitotic drugs. Sensitivity to this combinatorial treatment was dependent on p53 status, an important factor to consider before treatment.

Cystatin C is a small secreted protein, produced by most cells in the body and found in significant quantities in all body fluids. It is the major inhibitor of extracellular cysteine protease activity in mammals because of its rapid binding to virtually all known cysteine proteases of families C1 (cysteine proteinase), C12 (neutral metalloproteinase), and C13 (mammalian legumain). Cystatin C has also been shown to inhibit viral replication within cells and display protective effects against cancer cell invasion. The protein has recently been shown to get internalized into cancer cells, providing an explanation to possible intracellular effects of the inhibitor. The purpose of the present study was to elucidate possible direct effects of cystatin C on cancer cell growth, by use of holometric imaging to analyze proliferation rate as well as to monitor the mitosis phase in real-time. Human A375 melanoma cells were cultured with and without addition of physiological quantities of cystatin C added to the culture medium (1 micromolar concentration). The cultures were monitored for up to 3 days in a standard incubator using a HoloMonitor M4 instrument. Settings were optimized to allow accurate counting of cells throughout the experiment by analysis of images captured, revealing an inhibitory effect on overall cell proliferation rate by cystatin C addition to the cultures. To analyze the migration and cell division of individual cells, images were captured at short intervals allowing tracking and monitoring of cell morphology with respect to parameters such as thickness/density and area. Parameters could be set to define start of the mitosis phase indicated by a distinct rounding-up of cells and followed until a natural stop at cytokinesis, whereafter the daughter cells could be continuously tracked. These analyses revealed qualitative differences in the normal migration behavior of the A375 cells under study as a result of cystatin C addition. Moreover, the mitosis phase was considerably prolonged in cells grown in cystatin C containing medium, further indicating that the proliferation-inhibiting effect of the protease inhibitor may be through its direct action on proteolytic processes in the actual mitosis phase. This finding justifies in-depth studies on additional cancer cell types to reveal how general the anti-proliferative effect of cystatin C is and how it can be explored to possibly control cancer cell growth and spread. The use of real-time holometric imaging of growing cells should be a most useful tool in such studies.

Cytostatic gene misregulation is a major source of chromosomal instability in human cancers and predicts patient response to specific therapies. Weiguo Zhang,1 Jian-Hua Mao,2 Wei Zhu,3 Anshu K. Jain,3 Ke Liu,3 James B. Brown,2 Gary H. Karpen1. 1Lawrence Berkeley National Lab, Berkeley, CA; 2Cellular Biomimicry Group, Inc., Shanghai, China; 3Yale School of Medicine, New Haven, CT.

Chromosomal instability (CIN) is a cancer hallmark that contributes to tumor heterogeneity and other malignant properties. Aberrant centromere function causes CIN through chromosome missegregation in experimental systems. CENP-A is a histone H3 variant found at centromeres. Centromere is epigenetically by replenishing CENP-A chromatin during cell divisions. This process requires a dedicated CENP-A chaperone called HJURP and other factors. However, we are lacking a comprehensive understanding whether these proteins are involved in clinical cancers, and how centromere misregulation may contribute to cancer development. Here, basing on our previous findings in Drosophila melanogaster, we identified a conserved mutual protection mechanism between CENP-A and HJURP between flies and human cells, where their physical interaction protects each other from being targeted for degradation. Moreover, we showed that HJURP stability is regulated both in vitro and in vivo by the Anaphase Promoting Complex/Cyclosome (APC/C) ubiquitin E3 ligase. We further demonstrated that CENP-A and APC/C compete for the same binding site on HJURP. Using isogenic breast cancer cell culture progression series, we found that many centromere proteins are progressively overexpressed at the protein level during tumorigenesis. These results led us to hypothesize that overexpression of centromere proteins may cause centromere misregulation and CIN, and contribute to human cancers. To test the idea, we developed a CES (Centromere and kinetochore gene Expression Score) signature that quantitates the mRNA levels of 14 key genes required for centromere structure in cancers. High tumor CES values strongly correlate with increased copy number alterations and mutation frequencies across many cancer types, and prognostic poor patient survival for many cancers. High CES values also signify high levels of genomic instability that sensitize cancer cells to additional genotoxicity. Indeed, the CES signature forecasts patient response to adjuvant chemoradiotherapy for lung and breast cancers. In conclusion, we demonstrate regulation of HJURP by APC/C ubiquitin E3 ligase, mutual protection between the key centromere proteins CENP-A and HJURP, and a mode of misregulation of centromere genes in human cancers. The CES gene signature may be a potential biomarker to identify patients who likely respond to specific treatments, thus spare the non-responding patients from less effective treatments. These findings are expected to help address the over-treatment problem prevalent in cancer treatments. Our approach validates the critical importance of incorporating basic knowledge of chromosome segregation pathways into cancer research and clinical applications.

Stable aneuploid cells are more sensitive to TTK inhibition than chromosomal stable cell lines. Marion A.A. Libouban,1 Jeroen A.D.M. de Roos,1 Joost C.M. Uitdehaag,2 Nicole Willemse-Seegers,2 Sara Mainardi,1 Jelle Dylus,3 Jos de Man,2 Bastiaan Tops,1 Jules P.P. Meijerink,2 Zuzana Storchova,3 Rogier C. Buijmans,2 René H. Medema,1 Guido J.R. Zaman1. 1NKI, Amsterdam, Netherlands; 2Netherlands Translational Research Center B.V, Oss, Netherlands; 3Radboud University Medical Center, Nijmegen, Netherlands; Princess Máxima Center for Pediatric Oncology, Netherlands; 4University of Kaiserslautern, Germany.

Inhibition of the spindle assembly checkpoint kinase TTK causes chromosome mis-segregation and tumor cell death. High levels of TTK correlate with chromosomal instability (CIN), which can lead to aneuploidy. To investigate the potential relationship of CIN and sensitivity to TTK inhibition, we performed CIN analysis in human cancer cell lines from different tumor tissue origins and with different relative sensitivity to the selective TTK inhibitor NTRC 0066-0 [1]. By time lapse microscopy we observed that treatment with TTK inhibitor resulted in overriding of the mitotic checkpoint, irrespective of cell line sensi-
Zyxin is a LIM domain protein that is concentrated at sites of cell-cell adhesion, where it is proposed to dock proteins involved in cytoskeletal dynamics and signaling. Recently, Zyxin has been shown to promote LATs degradation and YAP activation in Hippo pathway. Here, we have identified a novel mechanism for phosopho-regulation of Zyxin in mitosis and its biological significance in colon cancer. We found that the mitotic kinase cyclin-dependent kinase 1 (CDK1) phosphorylates Zyxin in vitro and in vivo at serine 281, serine 308 and serine 344 during antimotic drug-induced G2/M phase arrest and unperturbed mitosis. Moreover, Zyxin mitotic phosphorylation-deficient mutant (Zyxin5A, harboring S281A/S308A/S344A) was sufficient to suppress colon cancer cell proliferation and migration. We further demonstrated that depletion of Zyxin resulted in impaired colon cancer tumorigenesis in vitro and in vivo through inhibiting F-actin cytoskeleton and YAP activity. Importantly, these observations could be fully rescued by re-expression of wild type Zyxin, but not Zyxin-3A mutant. Expression profile analysis revealed CDK8 (cyclin-dependent kinase 8) as a mediator downstream Zyxin/YAP. Inhibition of CDK8 proteins including BUBR1 and Cdc20. Surprisingly, level of mitotic Cdk1 remained unchanged in spite of elevated levels of Cdc20 indicating a possible inactivation of Anaphase Promoting complex (APC/C). Also, percentage of Cyclin B1 positive cells was significantly high in mitotic cells enriched using double thymidine block in the presence of TBK1 inhibitor BX795 (R9) and MRT10670 around the mitotic cells (R9). Further, double thymidine blocke released cells displayed elevated levels of SAC components including BUBR1 and Cdc20. Surprisingly, level of mitotic Cdk1 remained unchanged in spite of elevated levels of Cdc20 indicating a possible inactivation of Anaphase Promoting complex (APC/C). Also, percentage of Cyclin B1 positive cells was significantly high in mitotic cells enriched using double thymidine block in the presence of TBK1 inhibitor BX795 (R9) and MRT10670.}

#3458 Role of zyxin in mitosis and colon cancer. Jiuli Zhou, Jixin Dong, Yuanhong Chen, Xingcheng Chen, Seth Stauffer, Yongji Zeng. University of Nebraska Medical Center, Omaha, NE.

Zyxin is a LIM domain protein that is concentrated at sites of cell-cell adhesion, where it is proposed to dock proteins involved in cytoskeletal dynamics and signaling. Recently, Zyxin has been shown to promote LATs degradation and YAP activation in Hippo pathway. Here, we have identified a novel mechanism for phosopho-regulation of Zyxin in mitosis and its biological significance in colon cancer. We found that the mitotic kinase cyclin-dependent kinase 1 (CDK1) phosphorylates Zyxin in vitro and in vivo at serine 281, serine 308 and serine 344 during antimotic drug-induced G2/M phase arrest and unperturbed mitosis. Moreover, Zyxin mitotic phosphorylation-deficient mutant (Zyxin5A, harboring S281A/S308A/S344A) was sufficient to suppress colon cancer cell proliferation and migration. We further demonstrated that depletion of Zyxin resulted in impaired colon cancer tumorigenesis in vitro and in vivo through inhibiting F-actin cytoskeleton and YAP activity. Importantly, these observations could be fully rescued by re-expression of wild type Zyxin, but not Zyxin-3A mutant. Expression profile analysis revealed CDK8 (cyclin-dependent kinase 8) as a mediator downstream Zyxin/YAP. Inhibition of CDK8 proteins including BUBR1 and Cdc20. Surprisingly, level of mitotic Cdk1 remained unchanged in spite of elevated levels of Cdc20 indicating a possible inactivation of Anaphase Promoting complex (APC/C). Also, percentage of Cyclin B1 positive cells was significantly high in mitotic cells enriched using double thymidine block in the presence of TBK1 inhibitor BX795 (R9) and MRT10670. Further, double thymidine blocked released cells displayed elevated levels of SAC components upon treatment with TBK1 inhibitors. All these findings suggest that TBK1 facilitates mitotic progression through satisfying SAC.
non-transformed mammary epithelial cells results in large acinar structures, CA, CIN, and changes in relevant EMT markers that include vimentin. Our findings indicate that deregulated E2F pathway contribute to mammary tumorigenesis in part by deregulating kinases that control mitosis, including Nek2, and in turn these affect mitotic progression, CIN, EMT and invasion. Thus, centro-some/kinases downstream of the E2F pathway may represent future targets for intervention in highly-malignant HR- breast cancers.

#3462 Investigating the role of GSK3 in the mitotic checkpoint. Maisha S. Rashid. University of Toledo, Toledo, OH.

Progression through the cell cycle is regulated by multiple checkpoints that ensure genomic integrity and proper cell division. The spindle assembly checkpoint (SAC) monitors bi-orientation of chromosomes on the mitotic spindle, and signals assembly of the mitotic checkpoint complex (MCC) at unattached kinetochores. This checkpoint prevents unequal segregation of chromosomes and thus maintains genomic stability. Our data shows a novel role for glycosyn synthase kinase 3 beta (GSK3β) in regulation of the mitotic checkpoint. GSK3β is a ubiquitously multifunctional Ser/Thr kinase with distinct roles in different types of cancer. Following pretreatment with spindle toxins which arrest cells in late mitosis, GSK3 inhibitors, SB 415286 (SB), RO-81220 (RO) and LiCl, induce mitotic exit in multiple cancer cell lines. GSK3β knockout mouse embryonic fibroblasts (MEFs) showed a similar decreased mitotic index in the presence of spindle toxins. Similarly, the mitotic checkpoint was weakened when we performed GSK3β knockout in HeLa cells using transiently expressed CRISPR/Cas9. More detailed analysis showed increased kinetochore misalignment of checkpoint proteins Mad1, Mad2, BubR1 and Bub1 in SB415286-treated Hela cells and gsk3β-/MEFs in the presence of spindle toxins. The assembly of MCC also decreases in the presence of GSK3 inhibition as witnessed by decreased Mad2 associated with Bub1. Overexpression of GSK3β in Hela cells results in an increase in mitotic index compared to untransfected cells, consistent with our results with inhibitors and knockouts. GSK3β is a key kinase in the Wnt-signaling pathway, the mis-regulation of which has been associated with cancer. Our data shows an increase in taxol-induced mitotic arrest in response to WNT-C59, a compound that disrupts processing of Wnt ligands to inhibit Wnt signaling. This observation suggests that the strength of the mitotic checkpoint can be modulated by external signaling molecules.

The PH domain Leucine-rich repeat Protein Phosphatases (PHLPP) are tumor suppressors originally discovered for their ability to directly dephosphorylate and inactivate the pro-survival kinase Akt, a key transducer of growth factor signaling. In the decade since this discovery, a number of other PHLPP targets have been identified, including those that disrupt processing of Wnt ligands to inhibit Wnt signaling. This observation suggests that the strength of the mitotic checkpoint can be modulated by external signaling molecules.

#3464 CRISPR-mediated inactivation of ATRX and DAXX in pancreatic neuroendocrine tumor cell lines. Anthony J. Rizzo, Jacqueline A. Brosnan-Castledine. Shedd Cancer Center, Baltimore, MD.

Cancer cells must find a way to subvert replicative senescence in order to achieve cellular immortality. While most malignancies (> 90 %) overcome this critical barrier by reactivating the telomerase enzyme, a telomere-specific reverse transcriptase; other cancers (5 - 10 %) utilize a telomerase-independent pathway of telomere maintenance, referred to as Alternative Lengthening of Telomeres (ALT). ALT is thought to utilize homologous recombination and DNA repair machinery to maintain the chromosome ends. Importantly, this mechanism appears to be cancer-specific and dependent on alterations in chromosone maintenance at the telomeres. Therefore, we have applied a pharmacological intervention in highly-malignant HR- breast cancers.
subtypes that employ it; our hope is to better understand the ALT phenotype in cancer so that we may effectively translate ALT-specific therapeutics to the clinic.

Comprehensive analysis of telomere length and telomere maintenance mechanisms across 31 human cancer types. Floris P. Barthel, Siyun Zheng, Roel G. Verhaak. The Jackson Laboratory for Genomic Medicine, Farmington, CT; The University of Texas MD Anderson Cancer Center, Houston, TX.

Telomeres cap chromosome ends and prevent chromosomal fusions. In the majority of somatic cells telomere shortens with each cell division. Cancer cells, on the other hand, maintain telomere length (TL) through reactivation of telomerase or alternative lengthening of telomere (ALT). Though closely related to cancer hallmarks such as chromosomal instability, telomere length has not been systematically analyzed in cancer. We used DNA sequencing to infer TL in 18,430 samples across 31 cancer types. Tumor TL was shorter compared to normal TL but tended to be longer in testicular germ cell tumors, sarcomas and gliomas. TL in non-neoplastic leukocyte and solid tissue samples was negatively correlated with patient age and varied between lineages, with kidney samples showing the longest TL and leukocytes the shortest. Amongst tumors, 73% expressed telomerase (TERT) and 50% harbored a MAPT alteration. We compare TERT expression to both ALT status and macrochromosomal variation to better understand the relationship between ATR and CHK1 inhibitor effects on ALT-positive cancers. In order to study ALT in this context, we obtained and characterized a panel of six pediatric HGG cell lines. Two of the six cell lines in this panel display hallmarks of the ALT pathway. To assess the potential of ALT as a therapeutic to decelerate progression in pediatric HGG, we measured cell viability in the presence of inhibitors, stratifying our analysis by ALT status. ALT is predicted to occur via a homologous-recombination-based mechanism. As such, we focused our attention on inhibitors of the DNA damage response, as well as agents that induce DNA damage. Treatment with inhibitors of DNA-PK, RAD51, and MRE11 did not result in significant differences in cell viability when stratified by ALT status, nor did treatment with temozolomide or hydroxyurea. However, inhibitors of ATR (VE-821, VE-822, VX-970, and AZD-6738) and CHK1 (MK-8776) led to significantly greater reductions in cell viability in ALT-positive cells. In order to further our understanding of the mechanism through which ATR inhibition preferentially targets ALT-positive cell lines, we examined the effect of these inhibitors on ALT-specific properties, such as the presence of ultrabright telomeric foci and extra-chromosomal telomeric DNA (c-circles). Preliminary results indicate that ATR inhibition does not diminish these ALT-associated properties and, therefore, the differential sensitivity to these agents is unlikely to be due to directly blocking the ALT telomere maintenance mechanism. Continued study of the effect of ATR/CHK1 inhibition on ALT-positive cells will yield further insight into the mechanism of ALT specific toxicity. Overall, we have identified ATR and CHK1 as promising pathway to target ALT-positive pediatric HGG. Our goal is to better understand the relationship between ATR/CHK1 signaling and ALT in order to effectively translate this observation to the clinic, both for pediatric HGG and for other ALT-positive cancers.

A comprehensive protocol to identify human telomerase associated proteins by mass spectrometry. Jing Wang, Xuezhi Bi, Sheng Li, Duke-NUS Graduate Medical School, Singapore, Singapore; Bioprocessing Technology Institute (BTI), A*STAR, Singapore, Singapore.

Telomeres are nucleoprotein structures at the ends of eukaryotic chromosomes that prevent them from degradation, recombination, and end-to-end fusion. Telomeres consists of DNA repeats, which in human is of the sequence TGAGG, and it is bound by a group of proteins called shelterin complex. Telomeres are synthesized by telomerase. Telomerase is absent in most human somatic cells while it is up-regulated in 90% of cancer cells, in which telomerase plays an essential role in cancer cells’ replicative immortality. However, telomerase is only present at approximately 250 molecules per cancer cell. To exert its function of elongating telomere, telomerase has to find the end of telomeres which needed to be elongated. However, how telomerase is precisely recruited to telomere is not clearly understood. To better understand the recruitment process of telomerase, we initially screened and subsequently identified novel binding proteins of hTERT, the catalytic subunit of telomerase, through a pull-down assay using cancer cell lines with endogenously Flag-tagged hTERT. Using mass spectrometry (MS), we were able to

MOLECULAR AND CELLULAR BIOLOGY / GENETICS: Mitosis, Telomeres, and Proliferation Control

Proceedings of the American Association for Cancer Research • Volume 58 • April 2017
identifying a promising interesting protein. Further, direct interaction between TERT and this protein was validated. Then, we found that this protein can also interact with the shelterin component, TRF1 (Telomeric repeat-binding factor 1), which binds to double stranded telomeric DNA. Furthermore, from previous published reports, this protein was shown to interact with single-stranded telomeric DNA binding protein POT1 (Protection of Telomeres 1) in the shelterin complex. Functionally, overexpression of this protein in cancer cell lines can result in the elongation of telomeres, while knock-down or knock-out of the protein results in the shortening of telomere. In conclusion, we identified an hTERT-binding protein that affects telomere maintenance which may be involved in telomerase recruitment process. In the long run, it could serve as a potential therapeutic target for cancers.

#3470 The promyelocytic leukemia (PML) protein modulates rate and localization of homologous recombination in human cell lines with the alternative lengthening of telomeres (ALT) pathway. Walter Barry, Christopher Heaphy, Alan Meeker. Johns Hopkins School of Medicine, Baltimore, MD.

The promyelocytic leukemia protein (PML) is tightly associated with a defining feature of the cancer specific, telomerase-independent telomere-maintenance pathway known as alternative lengthening of telomeres (ALT); therefore, PML is an important potential target for chemotherapeutics. Cells running ALT contain large accumulations of telomeric DNA and RNA in the nucleoplasm that are frequently coated in a polymer shell of PML protein. These structures are known as PML-AFAs. PML-AFAs have been observed to be major sites of the telomeric sequence homologous recombination believed to be the basis of telomere maintenance in ALT. A CRISPR-based strategy was used to knock out the PML gene in two widely used ALT-positive osteosarcoma-derived human cell lines; U2OS, and SAOS2. Knockout clones from both cell lines continued to proliferate past passage 90 without crisis, and knockouts were validated at the genetic and protein levels by Sanger sequencing and western blotting, respectively. Chromosome orientation fluorescent in situ hybridization (COFISH) was carried out to determine the number of telomere sequence exchanges occurring in a single cell cycle in these knockouts. A twofold increase in telomere-specific exchanges, presumably telomere sister chromatid exchanges (T-SCE), over the parental line was detected. Intrachromosomal exchanges not specific to telomeres were also analyzed by the harlequin chromosome staining method. A significant increase in these types of exchanges was also observed. In conclusion, the presence of PML is not required for ALT to continue to function, and may be acting to modulate homologous recombination frequency and location in ALT positive cells.

Alphoid centromere array is composed by 171 bp AT rich alphoid monomer that tandemly arranged into high order repeat unit up to 4 MB array. Hallmark of centromeric DNA is CENPB box, a 17 bp motif that is a binding site of CENP-B. As the chromosomal site that regulates the precise and accurate chromosome segregation, understanding DNA replication in centromere will reveal insight into faithful chromosome segregation that potentially influence cellular behavior in normal and cancer cell. The present of active replication within alphoid centromere array are detected by enrichment of nascent DNA abundance. This finding is supported by evident of Orc2, Cdt1 and Tre100 accumulation on the alphoid centromere array. Chromatin fiber analysis revealed that inter origin distance within alphoid centromere array is irregular. CENPB depletion that is affected centromeric chromatin structure enhances DNA replication activity within alphoid centromeric array, indicates centromeric chromatin landscape alteration affected centromeric DNA replication dynamic.

#3472 Separase overexpression defines a new subset of acute myeloid leukemia patients characterized by high CD34 and MYC levels. Giorgia Simonetti,1 Antonella Padella,1 Simona Righi,1 Maria Chiara Fontana,2 Marco Manfrini,3 Cristina Papayannidis,1 Giovanni Marconi,1 Carmen Baldazzi,1 Marianna Garozzi,1 Alberto Ferrari,1 Massimo Delledonne,1 Nicoletta Testoni,1 Elena Sabattini,2 Giovanni Martinelli1. 1University of Bologna, Bologna, Italy; 2Sant’Orsola Malpighi Hospital, Bologna, Italy; 3University of Verona, Verona, Italy; 4Personal Genomics, Verona, Italy

The endopeptidase Separase, encoded by the ESP1 gene, plays a key role in faithful segregation of sister chromatids by cleaving the cohesin complex at the metaphase to anaphase transition. Its overexpression associates with aneuploidy and bad prognosis in solid tumors. Little is known in Acute Myeloid Leukemia (AML). We profiled the genomic landscape of 405 and 78 AML cases by SNP array (SNP 6.0 and Cytoscan HD, Affymetrix) and whole exome sequencing (100 bp, paired-end, Illumina), respectively. Bone marrow blasts from 61 patients were analyzed by gene expression profiling (HTA 2.0, Affymetrix). Separase expression was determined by Immunohistochemistry (1:600 antibody dilution Abnova, clone 6H6) in 44 AML and 4 control bone marrow specimens. One patient exhibited a nonsynonymous mutation in ESP1 (p.1357G>A), which was confirmed by Sanger sequencing. Moreover, ESP1 expression was observed in 5/405 cases (1.2%): 2 hyperdiploid AML, one trisomy 12 and 2 cases with a short gain at 12q. Notably, protein level detection in one of the 12q-gain cases confirmed Separase overexpression. To determine the incidence of Separase overexpression, we performed Immunohistochemistry on additional 43 AML. Separase was overexpressed in 29/44 AML (66%, Separase-high), being expressed in 8/12 of control marrow specimens. In the remaining 13 cases (Separase-low), sixty-two percent of Separase-high AML were aneuploidic. However, no significant association was observed, as previously reported for mutations in the cohesin genes in AML. Separase overexpression correlated with increased patients’ age (median age 64 vs. 57 years, p = 0.01), 17,70-upregulation of CD34 (p = 0.004) and a trend towards reduced overall survival (6-years follow-up). Separase overexpression was not mutually exclusive with cohesin gene mutations, it co-occurred with NPM1 and FLT3 lesions and frequent mutations in genes involved in protein post-translational modification and ubiquitination (p = 0.04). Separase-low cases were enriched for mutations in RAS signaling pathway (NRAS, KRAS, NF1, RIT1, GRAP2, RALGDS; p = 4.3x10^-5) and in cell migration-related genes (LIM52, SIPR1, PP1A, PLXNB1, FAT1). Separase-high cases also showed a defined transcriptomic profile, characterized by reduced expression of HOXA/B family genes, the DNA damage repair gene ATM, the p53 regulator MDM2 and forced expression of the cell cycle markers CDC20, AURKB, NUSAP1 and of MYC, independently of chromosome 8 gain. Taken together, our data suggest that genomic lesions targeting ESP1 are a rare event in AML. However, Separase overexpression is a common feature and defines a new subset of AML cases with a distinct gene expression profile, which may benefit of innovative targeted therapies including CDC20 and bromodomain inhibitors. Supported by: EUN, AICR, progetto Regione-Università 2010-12 (L. Bolondi), FP7 NGS-PTI project.

In the previous study, we identified genes that were differentially expressed between monolayers and spheroids in prostate cancer cell lines. The KIF22 gene was extracted as one of candidate genes related with spheroid formation and multicellular resistance. KIF22 is one of the kinesin superfamily proteins that are microtubule-dependent molecular motor proteins with DNA-binding capacity. KIF22 plays an important role in eukaryotic cell mitosis and macromolecule transportation. Alteration of KIF22 expression and function may lead to cancer development and progression. In this study, we explored the function of the KIF22 in prostate cancer cell lines, DU145 and LNCaP using the KIF22 siRNA. The KIF22 mRNA levels in both DU-145 and LNCaP decreased, and this gene was increased in both spheroids. The inhibition of KIF22 mRNA using siRNA affected cell proliferation in DU145 and LNCaP spheroids as well as monolayers. In addition, this suppression caused G2/M arrest and apoptosis in both cell lines. In clinical samples, its mRNA expression was significantly higher in tumor portions than in non-cancerous portions. However, the inhibition of KIF22 mRNA did not affect cell migration and invasion in DU145 and LNCaP cells. These findings suggest that KIF22 may play an important role in prostate cancer proliferation, especially spheroid formation, and have the potential to be targeted for prostate cancer treatments such as combination therapy with docetaxel.

#3474 Depletion of SPECC1L inhibits colorectal cancer cell proliferation. Rajat Bhattacharya, Ling Xia, Fan Fan, Rui Wang, Delphine Boubles, Xiang-Cang Ye, David Hawke, Lee Ellis. MD Anderson Cancer Center, Houston, TX.

Introduction: Despite the numerous drugs available for patients with metastatic colorectal cancer (mCRC), median overall survival for this group of patients remains at ~20-24 months, with no significant advances in the last 7 years. In the US ~50,000 patients die each year from mCRC refractory to systemic therapy. Inhibiting angiogenesis as a therapy has led to a great deal of enthusiasm. However, the overall benefit of classical-antiangiogenic therapy remains modest and has not lived up to their expectations in treating CRC. Our recent studies suggest that VEGF intracrine signaling, rather than autocrine/paracrine signaling, regulates cell survival in CRC cells. Further studies to understand the significance and mechanisms of this novel function have led us to identify fac...
tors that intracellularly interact with VEGF. Our studies further indicate that one such interacting protein, SPECC1L, may have a significant role in CRC cell proliferation and may be a potential target in mCRC therapy. Methods: Lysates from CRC cells expressing Myc-tagged VEGF protein were immunoprecipitated and analyzed by mass spectrometry to identify VEGF-.interacting proteins. SPECC1L was identified as a co-precipitated protein with Myc-tagged VEGF in CRC cells. However, SPECC1L was depleted using siRNA and effects of such depletion on CRC cell growth and morphology were measured by cell growth assays (MTT), microscopy, FACS and western blot analyses. Localization of the protein and its interaction with microtubules and actin were visualized by immunostaining of FLAG-tagged recombinant SPECC1L protein. Results: SPECC1L was identified as a protein that co-immunoprecipitated with Myc-tagged VEGF in CRC cells using mass spectroscopy. Previous literature suggests a role for SPECC1L in cell division. As a fraction of VEGF overexpressing CRC cells have a large multinucleated phenotype, likely arising due to defects in cell division, it was hypothesized that a VEGF-mediated regulation of SPECC1L may lead to such a phenotype. Depletion of SPECC1L by siRNAs in multiple CRC cell lines led to strong defects in cell division. The effects of SPECC1L depletion were manifested as accumulation of doublet-cells failing to complete cytokinesis following mitosis and resulted in reduced cell proliferation. Failure to complete cell division also led to the formation of multinucleated cells and enhanced cell death. Conclusions: Inhibition of SPECC1L strongly inhibits CRC cell proliferation and enhances cell death. Thus targeting SPECC1L has the potential for developing therapeutic strategies to reduce viability of CRC cells and improve survival of colorectal cancer patients. These studies were supported by the Gillson-Longenbaugh Foundation.

#3475 Inhibitory effects of ZFP36L1 and ZFP36L2 on the cell proliferation in human colorectal cancer cells. Fat-Moon Suk, Ya-Ting Chen, Yu-Chih Liang. Taipei Medical University, Taipei, Taiwan.

ZFP36 family members include ZFP36 (also named TTP and TIS11), ZFP36L1 (also called BRF1, D1R1 or TIS11B) and ZFP36L2 (also called BRF2, ERF2 and TIS11D), which belong to the CCCH-type zinc finger protein with 2 tandem zinc finger region (TZF). These ZFP36 family proteins can function as RNA-binding protein through binding to AU-rich elements (AREs) in the 3′ untranslated region (3′ UTR) of mRNA, which promote the mRNA degradation or translation repression. Previously, ZFP36 has been found to inhibit cell proliferation through p33-dependent manner. In this study, we’d like to investigate whether ZFP36L1 and ZFP36L2 have anti-proliferative activity as same as ZFP36 work. Tetracycline-inducible (Tet-On) system was used to induce the overexpression of ZFP36L1 or ZFP36L2 proteins in T-REx-293 cells by doxycycline (Dox) treatment. While ZFP36L1 or ZFP36L2 was overexpressed, we found that cell proliferation was dramatically inhibited, but didn’t cause cell death significantly. The importance of TZF was confirmed by using TZF mutants, and found that cell proliferation was deprived in HEK-293 cells with overexpression of ZFP36L1 mutant (C135/173R). Using western blot analysis, it was revealed that expression level of p53 protein was increased after the overexpression of ZFP36L1 or ZFP36L2 protein. Whereas, the levels of cell cycle-related proteins including cyclin B1, cyclin A2 and cyclin D1 were decreased. Next, three colorectal cancer cell lines (HCT116, HCT116 p53-/- and SW620 (mutated p53) cells were used and ZFP36L1 or ZFP36L2 gene was transduced into these three cells by lentivirus. Overexpression of ZFP36L1 or ZFP36L2 also inhibited the cyclin D1 protein expression and cell proliferation in these three cells, however, increased the p53 and p21 protein expression in HCT116 p53-/- cells, and decreased the c-Myc expression only in SW620 cells. On the other hand, knockdown of ZFP36L1 or ZFP36L2 increased cell proliferation, and mutation in TZF of ZFP36L1 (C135/173R) or ZFP36L2 (C174/212R) lost their anti-proliferative abilities in these three cells. Taken together, the results suggest that ZFP36L1 and ZFP36L2 play a negative role in cell proliferation in human colorectal cancer cells, and the underlying mechanisms might be modulated through downregulation of cyclin D1 and p53-independent pathway.

#3476 Effect of long term treatment with BRACO 19 on HeLa proliferation and senescence. Ana Flavia Reis Guimaraes, Diêgo M. de Oliveira. University of Brasilia, Brasilia, Brazil.

Telomerase, the enzyme responsible for the length maintenance of telomeres is expressed in about 85% of cancer cells, being a key to tumorigenesis. Telomerase inhibitor drugs have been studied as a promising cancer therapy due to its specificity, with less side effects than conventional approach. However, the effects expected from these therapy require many cell divisions, and the consequences of these long-term therapies are poorly understood. This work evaluated the effects of a long term treatment in cancer cells (HeLa) using BRACO-19, a G-quadruplex-interactive molecule, evaluating the consequences of its use in cell viability and its potential to induce senescence. Telomerase positive HeLa cells were grown in DMEM medium supplemented with 10% fetal bovine serum at pattern conditions. Culture medium was changed every 2 days. For preliminary studies, we performed experiments with dosages from 1mg/mL - 25ng/mL, incubated for 24 hours and treated for 24 hours with increasing concentrations of BRACO-19 and vehicle (0.1% H2O). Cell viability was measured by MTT assay. For the long-term treatment, a subtoxic concentration was chosen. The cells (5.5x10^5 cells/cm^2) were grown under continuous presence of the drug or 0.02% H2O for 11 weeks. During the long-term exposure to BRACO-19, the cells were passed every 7-20 days, depending on its proliferation rate, viable and unviable cells were counted at these points through trypan blue dye exclusion assay. β-Galactosidase (β-gal) activity was used as cell senescence marker to evaluate the senescence after 24 hours treatment and after a long exposure to the telomerase inhibitor. Changes in cell morphology were assessed by phase contrast microscopy. The short-term (24h) treatment with BRACO-19 showed a dose-dependent effect on cell viability. The IC50 for HeLa was 5.25 μM. The subtoxic concentration of 1μM was used for long-term treatment, showing effect on cell proliferation in a way that HeLa cells exposed to the drug showed their proliferative profile decreased when compared to control. Furthermore, no senescent cells were found in control group, even after many passages; on the other hand, 24 hours and long-term exposure to BRACO-19 led to senescence. Long-term treatment with BRACO-19 correlated with visual morphological changes. The telomerase inhibitor BRACO-19 showed an expected dose-dependent effect on HeLa cells at short-term exposition, since cytotoxic effect of this compound has been demonstrated in several cell lines, but the impact of the long-term treatment on cell proliferation pattern points BRACO-19 as a potential prototype of a new telomere related drug for cancer therapy. Also, it was demonstrated the senescence inducing action of this drug, perhaps due to erosion of HeLa telomeres. These results show that HeLa is sensitive do BRACO-19 even under subtoxic concentrations. Its effectiveness against other cell lines and tumors is under investigation.

#3477 Rospeh (Rosa canina) extracts prevent AKT-mediated cell proliferation and migration in triple negative breast cancer cells. Patrice Cagle, Patrick Martin. North Carolina A&T State Univ., Greensboro, NC.

Triple Negative Breast Cancer (TNBC) is an aggressive form of breast cancer, characterized by its lack of the human epidermal growth factor receptor-2, the estrogen receptor, and the progesterone receptor. AKT has been shown to promote cell proliferation and migration in triple negative breast cancer. Currently, the existing targeted therapy is of minimal benefit in TNBCs. Furthermore, adverse side effects and the emergence of drug-resistant cancer cells are of great concern. Natural products have received growing interest in recent years as an alternative medicine with potential anti- oncogenic properties. Rospeh extracts have been used as dietary supplements to relieve symptoms associated with gastrointestinal disorders and arthritis, and in our laboratory it has been shown to prevent cell proliferation in glioblastomas. This study investigated the efficacy of roship extracts in preventing proliferation and migration of a triple negative breast cancer cell line (HCC1954). HCC1954 cells treated with roship extracts (1mg/mL - 25ng/mL) demonstrated a significant decrease in cell proliferation. The observed decrease in cell proliferation was equal to or better than the decrease of cell proliferation observed when inhibitor of the AKT (LY294002, 20 μM) signaling pathway was utilized. Rospeh extracts also demonstrate anti-migratory potential. Additionally, pretreatment of this cell line with roship were found to selectively decrease AKT, p70S6K, and S6K phosphorylation suggesting these extracts prevent TNBC cell proliferation and migration by blocking the AKT signaling mechanism. Western blot analysis and apoptosis studies demonstrate that roship extracts inhibit cell proliferation without promoting apoptosis, but induce cell cycle arrest. To investigate the potential clinical application of roship extracts we examined whether roship extracts could enhance the chemotherapeutic properties of Doxorubicin (20μM), a chemotherapeutic agent used to treat breast cancer. Rospeh extracts demonstrated a greater anti-proliferative effect than Doxorubicin alone and is equally effective in combination with Doxorubicin. These data suggest that roship extracts are capable of decreasing cell proliferation and migration in a triple negative breast cancer cell line by blocking the AKT signaling pathway and by regulating the cell cycle. Moreover, roship extracts can enhance the chemotherapeutic properties of Doxorubicin.
MOLeULAR AND CELLuLAR BIOLOGY / GENETICS: Noncoding RNAs and Cancer: Expression, Function, and Therapeutics

Prostate cancer (PCa) is the most prevalent cancer among men, following the second leading cause of cancer-related death in western world. Currently, there is a lack of effective treatment options for advanced PCa. Understanding the molecular mechanisms in prostate cancer development and progression would allow the identification of novel prognostic markers or therapeutic targets. The transcribed-ultraconserved regions (T-UCRs) are novel class of noncoding RNAs that are absolutely conserved (100%) between orthologous regions of the human, rat and mouse genomes. Some studies showed that T-UCRs exhibit distinct profiles in various human cancers. We examined the expression profile of representative 26 T-UCRs using qRT-PCR in 12 PCa tissues and 10 non-neoplastic prostate tissues, and found that the expression of Uc.63+ was higher in PCa tissues than that in non-neoplastic tissues. Further analysis revealed that the expression of Uc.63+ significantly correlated with higher PSA levels (p = 0.003) and higher Gleason score (p < 0.001). In order to verify biological function of Uc.63+ in PCa, we firstly transected Uc.63+ expression vector into LNCaP cells expressing low level of Uc.63+. MTT assay and wound healing assay revealed that overexpression of Uc.63+ significantly increased the cell growth and migration. We also confirmed that downregulation of Uc.63+ using siRNA in DU145 and PC3 expressing high level of Uc.63+. Knockdown of Uc.63+ decreased the cell growth and migration. A recent report indicates that T-UCRs may act as endogenous competing RNA. miR-130b was found to have binding sites within the Uc.63+ using online software. We examined the expression of miR-130b by qRT-PCR in PCa tissues and non-neoplastic prostate tissues. We found a significant downregulation of miR-130b in PCa tissues compared with non-neoplastic prostate tissues, which figured out that there was a significant inverse correlation between Uc.63+ and miR-130b in PCa (p = 0.002). The expression of miR-130b in LNCaP was higher than that in DU145 and PC3. It has been shown that MMP2 is a direct target of miR-130b. Western blot analysis and qRT-PCR revealed that MMP2 expression was higher in LNCaP cells transfected with Uc.63+ expression than that in LNCaP cells transfected with empty vector. These results suggest that Uc.63+ may contribute to the progression of PCa through miR-130b interaction.

**#3479 Identification and characterization of clinically relevant long non coding RNA PLUCAT1 in lung adenocarcinoma.** Sudhanshu Shukla, Lanbo Xiao, Brendan Veenstra, Yuping Zhang, Yashasundaram Pitchiya, Arul Chinnainay. University of Michigan, Ann Arbor, MI.

Non-small cell lung cancer (NSCLC) is a leading cause of cancer-related death worldwide. Disease subtypes include lung adenocarcinoma (LUAD) and lung squamous carcinoma (LUSC) and LUAD accounts for nearly 50% of lung malignancies. Late diagnosis and limited chemotherapy options are the primary reason for poor prognosis and even among patients diagnosed early with Stage I disease, recurrence occurs in 35-50% of cases. Lack of discriminatory biomarkers has hampered clinical and therapeutic management, as current practice tends to group all patients together. Several attempts to develop gene signatures from microarray datasets to stratify risk among lung adenocarcinoma patients have not yielded clinical utility due to poor cross validation and lack of robustness. The development of RNA-Seq methodologies now allows accurate quantification of transcriptional abundance that is reproducible and reliable. Capitalizing on this technology and large datasets such as the cancer genome atlas (TCGA) as well as individual efforts, thousands of cancer samples are available for analysis to facilitate deeper understanding of the disease. One major discovery resulting from large RNA-Seq datasets is functional long noncoding RNAs (IncRNAs; exceeding 200 nucleotides in length) that can be expressed in tissue- lineage- and cancer-specific expression patterns. In our previous study we identified a highly significant prognostic marker set using 255 TCGA LUAD patients. In the training cohort, 96 genes had prognostic association with p<0.001, including 5 long noncoding RNAs (IncRNAs). Stepwise regression generated a four-gene signature, including one IncRNA. Signature high risk cases had worse overall survival (OS) in the TCGA validation cohort (HR=3.07, 95%CI=2.00-14.62). The four-gene signature was then validated in two independent patient cohorts. The signature consisted of three protein coding gene and a IncRNA (PLUCAT1). Knockdown studies showed that the IncRNA promoted lung cell growth in vitro. Also, inhibition of PLUCAT1 using both siRNA and ASOs induced cellular senescence in lung cells. Further, RNA pull down followed by mass-spec identified QKI as a binding partner of PLUCAT1. QKI is a tumor suppressor gene shown to change splicing pattern in many cancer types. We now show that PLUCAT1-QKI interaction has functional consequences and changes splicing pattern of significant number of genes as assessed by RNA sequencing. Previously, we have identified PLUCAT1, a four-gene prognostic signature, as a robust prognostic marker for lung adenocarcinoma prognosis. We also, show that PLUCAT1 binds with tumor suppressor QKI and inhibits QKI activity.

**#3480 2’–O–ribose tRNA methylation in S. cerevisiae and implications for ovarian cancer.** Frank Doyle,1 Rebecca E. Rose,2 Daniele Fabris,2 Lauren Endres,1 SUNY Polytechnic Institute, Albany, NY; 3University at Albany, Albany, NY; 4SUNY Polytechnic Institute, Utica, NY.

tRNAs are among the most chemically modified molecules of the cell, yet our understanding of how these modifications influence cell behavior remains poor. Much of the research to date has been focused on identifying specific modification events, particularly those that increase or decrease in response to oxidative stress. Less attention has been given to understanding how tRNA modifications, and their modifying enzymes (tRNA methyltransferases, or TRMs), regulate the cell’s response to reactive oxygen molecules, that are known to influence cancer initiation, survival and malignant progression. Our overall idea is that tRNA modifying enzymes respond to oxidative stress by catalyzing the modification of target tRNAs, and that this in turn influences the translation of transcripts that encode proteins that limit the potentially harmful effects of reactive oxygen. Here we used S. cerevisiae as a model eukaryote system to test the hypothesis that 2’–O–ribose tRNA methylation protects cells against the cytotoxic effects of reactive oxygen. 2’–O–ribose TRM deletion mutants (TRMs ΔA, ΔA and ΔA) were exposed to H2O2, reticone and acetic acid in order to produce intracellular reactive oxygen. In growth and colony forming assays, each deletion strain was more sensitive to the killing effects of these toxicants when compared to the wild-type strain (BY4741), and the most pronounced was observed for the TRMΔA mutant. We next performed a quantitative analysis of global changes in tRNA modifications in response to H2O2 using mass spectrometry. We found that several methyl-based modifications (i.e. 2’–O–methyl –adenosine, –guanosine, and –cytidine) were significantly decreased in TRMΔA and ΔA mutants, providing a direct link between oxidative stress and 2’–O–ribose tRNA methylation. These results support that 2’–O–ribose methyltransferase activity plays a cytoprotective role against oxidative stress in S. cerevisiae. Given the connections between reactive oxygen and cancer, we used cbioPortal to search for gene alterations of the human homolog of TRM3, TARBP1, in the genome datasets of The Cancer Genome Atlas. Interestingly, TARBP1 was found to be amplified in a significant proportion of breast, ovarian and liver cancers. From these data, we propose a new hypothesis that increased 2’–O–ribose tRNA methyltransferase activity contributes to a cancer phenotype by enabling cancer cells to maintain reactive oxygen at sub-lethal levels that promote survival and malignant progression. Thus far, preliminary results show that cultured ovarian cancer cells have elevated levels of TARBP1 relative to normal ovarian epithelial cells, providing a useful model system to test this hypothesis in future studies.

**#3481 Leveraging protein coding gene expression profiles to accurately implicate IncRNA transcriptome of cancer cells.** Aritro Nath, Paul Geeleher, R. Stephanie Huang. The University of Chicago, Chicago, IL.

Long noncoding RNAs (IncRNAs) represent a large, diverse and tissue-specific class of transcripts that are involved in gene regulation. Recent large-scale cancer sequencing efforts indicate that IncRNAs are an important component of the cancer transcriptome, and may play a critical role in carcinogenesis and drug sensitivity. Accurate profiling of IncRNAs however remains a challenge owing to significantly lower expression levels than mRNA, requiring deep paired-end total RNA sequencing, which can be prohibitively expensive. Additionally, previous generation microarrays that constitute a vast majority of GEO and ArrayExpress datasets do not provide comprehensive IncRNA coverage. Here we propose a IncRNA expression imputation (LEXI) framework to reconstruct the IncRNA transcriptome of cancer cells using their mRNA expression profiles. Our goal is to provide a tool that enables the harnessing of enormous wealth of publicly available cancer mRNA datasets and discover novel IncRNAs associated with carcinogenesis and drug sensitivity. The LEXI approach is based on learning patterns of mRNA expression associated with each IncRNA across a diverse cohort of cancer cells and then predict IncRNA expression profile of uncharacterized cells. We developed LEXI by evaluating the performance of various machine-learning algorithms benchmarked in a cross-validation study across a cohort of 675 cancer cell lines and 9753 pan-cancer tissues. We adapted

Proceedings of the American Association for Cancer Research. Volume 58, April 2017
in a caspase-dependent manner. A target analysis of SNORD-X was done using data suggesting that overexpression of SNORD-X in GBM cell lines (U87MG and other cancer cell lines) is associated with a role in various cancers. In this context, we aimed at studying the role of snoRNAs in GBM. For this, we did snoRNA profiling in GBM patients and found that a particular cluster of snoRNA called SNORD-X was highly downregulated in adult as well as pediatric GBM patients. We also found SNORD-X promoter to be methylation and shows maternal imprinting. We next did functional analyses of SNORD-X by generation of an overexpression construct. Our preliminary data suggests that overexpression of SNORD-X in GBM cell lines (U87MG and A172) increases cell proliferation in vitro. It also enhances the colony forming capability of GBM cells. Further, its overexpression causes decrease in apoptosis in a caspase-dependent manner. A target analysis of SNORD-X was done using RNAhybrid software. We found EGR1, DCUN1D3 and BRCAI to be the direct targets of SNORD-X using a combination of qRTPCR and wild-type/mutated 3’ UTR luciferase analyses. Overall, our work shows for the first time correlation and functional analysis of SNORD-X cluster in GBM.

### #3482 SNORD-X in glioblastoma: regulation and functional analysis.
Shikha Gupta,1 Prerana Jha,1 Chitra Sarkar,1 Ritu Kulshreshtha.1 Indian Institute of Technology Delhi, Delhi, India; “All India Institute of Medical Sciences, Delhi, India.
Glioblastoma Multiforme (GBM) is a kind of brain tumor which arises from astrocytes present in the brain. It represents approximately 15% of all primary brain tumor and has been considered as one of the deadliest type of cancer with very poor prognosis. Thus, there is an urgent need to identify novel targets for GBM therapy. Recently, non-coding RNAs (ncRNAs) such as miRNAs and IncRNAs have emerged as one of the promising tools as diagnostic or prognostic biomarkers and as novel targets for therapy. There are recent evidences that small nucleolar RNAs (snoRNAs), a subtype of ncRNAs might also play a key role in various cancers. In this context, we aimed at studying the role of snoRNAs in GBM. For this, we did snoRNA profiling in GBM patients and found that a particular cluster of snoRNA called SNORD-X was highly downregulated in adult as well as pediatric GBM patients. We also found SNORD-X promoter to be methylation and shows maternal imprinting. We next did functional analyses of SNORD-X by generation of an overexpression construct. Our preliminary data suggests that overexpression of SNORD-X in GBM cell lines (U87MG and A172) increases cell proliferation in vitro. It also enhances the colony forming capability of GBM cells. Further, its overexpression causes decrease in apoptosis in a caspase-dependent manner. A target analysis of SNORD-X was done using RNAhybrid software. We found EGR1, DCUN1D3 and BRCAI to be the direct targets of SNORD-X using a combination of qRTPCR and wild-type/mutated 3’ UTR luciferase analyses. Overall, our work shows for the first time correlation and functional analysis of SNORD-X cluster in GBM.

### #3483 Genome-wide analysis of the antisense transcriptome in cancer.
Raquel Boque-Sastre, Manuel Castro de Moura, Antonio Gomez, Sonia Gull, Manel Esteller. IDIBELL, L’Hospitalet del Llobregat (Barcelona, Spain).
Natural antisense transcripts (NATs) are the most abundant class of long noncoding RNAs (IncRNAs). Importantly, NATs are one of the most unknown ncRNAs. However, due to their highly gene locus-specific effects, NATs may provide a valuable tool for therapeutic intervention in targeted gene regulation. For this reason we are interested in studying the regulation of sense/antisense transcription in cancer related locus. In our previous work we found that, at the important cancer-related locus vimentin (VIM) there is a previously uncharacterized antisense transcript (VIM-AS1), which is transcribed head-to-head with VIM gene. This antisense transcript enhances R loop formation; it allows the binding of transcription factors as NF-kB, low nucleosome occupancy and the transcription of VIM gene. Our results are the first example of R loop mediated enhancement of gene expression involving head-to-head antisense transcription at cancer related locus. We also observed that in colon and breast cancer there was a positive expression correlation between VIM and VIM-AS1 and we have observed that hypermethylation silences both transcripts in colon primary tumors. In the present work we have seen that this positive correlation between sense and antisense transcripts is present in most of the tumor types from patients that we have obtained from Genomic Data Commons Data Portal (GDC Portal). Importantly this positive correlation correlates better in the cases in which the antisense transcript is downregulated or maintains the expression than in tumors where VIM and VIM-AS1 are up-regulated. Furthermore, we wanted to see if the cellular function is also coordinated. VIM is a component of the intermediate filament family of proteins that has an important role in epithelial mesenchymal transition. We found that specific depletion of VIM-AS1 results in a decrease of VIM expression, and now we have found that this depletion produces low migration rate and more invasion capability, as expected. On the other hand, the mechanisms used by antisense transcripts to regulate their corresponding sense mRNAs are not fully understood and in view of these results we are investigating from a genome-wide perspective the regulation of sense/antisense transcription, the involvement of R loop structures and DNA methylation in cancer. For this, we have applied a number of techniques: RNAseq strand specific, Illumina’s HumanMethylation450 Bead Chip array, RNAseq strand specific with overexpression of RNaseH (which specifically degrades the RNA in RNA/DNA hybrids), and DRIPseq (which immunoprecipitates the hybrids DNA-RNAs). The analysis of these data sheds light on the study of the role of sense/antisense transcripts in cancer-related locus.

### #3484 A long non-coding RNA, H19, as a novel therapeutic target for pancreatic cancer metastasis.
Toshiyuki Ishiwata,1 Hisashi Yoshimura,2 Yoko Matsuda,2 Naoshi Ishikawa,1 Kaiyo Takubo,1 Tomio Arai,1 Junko Aida,1 1Tokyo Metropolitan Institute of Gerontology, Tokyo, Japan; 2Nippon Veterinary and Life Science University, Tokyo, Japan; 3Tokyo Metropolitan Geriatric Hospital and Institute of Gerontology, Tokyo, Japan.
Long non-coding RNAs (IncRNAs) comprise mRNA-like transcripts longer than 200 ribonucleotides and lack significant open reading frames. Recently, long non-coding RNAs have been reported to play important roles in epigenetic regulation, and acts on precursors or inhibitor of micro RNA. In our previous studies, we injected PAN-C-1, human pancreatic cancer cells into the spleens of NOG mice, and established a lung metastasis-derived cell line from lung metastatic nodules. Lung metastasis derived pancreatic cells had a high metastatic ability to liver and lungs compared with the parental cells (Matsuda et al., Am J Pathol, 2014). To examine the different gene expressions between the lung metastasis derived cells and parental cells, we performed a DNA microarray analysis, and found that 11 genes were up-regulated at greater than 10-fold levels in lung metastasis derived cancer cells compared to their parental cells. H19 showed an 82.4-fold increase in expression levels, and it was the second most increased and the only non-protein coding gene in the 11 genes. H19 is an imprinted IncRNA transcribed exclusively from the maternal allele and H19 gene produces a 2.3 kilo base pair long non-coding RNA. Two microRNAs, miR-675-3p and miR-675-5p are embedded in the exon of H19 and these miRNAs are reported to correlate with cell proliferation. H19 is an oncogenic RNA expressed in developing embryos and in tumors including bladder, breast, gastric, hepatic, and prostate cancers. Studies have shown that H19 enhances cancer invasion and metastasis; however, its role in cancer remains debatable. We examined the roles of H19 in pancreatic cancer growth and metastasis. Quantitative PCR analysis using human pancreatic cancer tissues showed that H19 was more highly expressed in cancer tissues than the adjacent normal tissues in 11 of 18 cases. Branched DNA in situ hybridization analysis using tissue microarrays showed that H19 was detected in 17% (23/139) of invasive ductal carcinomas, and its expression positively correlated with higher histological tumor grades (P < 0.0001). H19 was expressed in 9 pancreatic cancer cell lines at various levels. Overexpression of H19 in PAN-C-1 cells induced higher motility, whereas H19 inhibition using shRNA and siRNA showed opposite results; however, cell growth rates were unaffected in vitro. Expression levels of miR-675-3p and miR-675-5p altered as similar to the H19 levels in both H19 increased PAN-C-1 cells and H19 decreased cells. Tail vein injection of H19 shRNA vector-transfected PAN-C-1 cells markedly inhibited metastasis in the liver and lungs of immunodeficient mice. These findings suggest that H19 plays an important role in pancreatic cancer metastasis and H19 is a novel therapeutic target for metastasis of pancreatic cancer.

### #3485 Identification and characterization of circular RNAs in cancer.
Charlotte A. Thrué,1 Andreas Petri,1 Marianne B. Løvendorf,1 Karen Dybkær,2 Charlotte A. Thrue,1 Andreas Petri,1 Marianne B. Løvendorf,1 Karen Dybkær,2 Dimitrios Papaioannou,3 Ramiro Garzon,2 Sakari Kauppinen.1 1Aalborg University, København SV, Denmark; 2Aalborg University, Aalborg, Denmark; 3The Ohio State University, Columbus, OH.
Circular RNAs (circRNAs) are an abundant class of non-coding RNAs that are formed by a backsplice event resulting in formation of covalently closed circular RNA molecules. The efficiency of backsplicing is inferior to linear splicing, however, due to their long half-lives circRNAs can accumulate to high levels in cells. Functional characterization of a few circRNAs has shown that they can act as endogenous microRNA sponges and transcriptional regulators; one example is CDR1as/ciRS-7, which has been shown to act as a sponge for miR-7. Live RT-PCR analysis using human circRNAs are still unknown. To study the potential role of circRNAs in cancer, we identified exonic circRNA candidates by analysing ENCODE RNAseq data from a panel of cancer cell lines. We used chimeric alignment detection implemented in the STAR aligner and subsequent filtering of output files to identify chimeric alignments consistent with circRNA backsplice sites. The circular nature of the identified putative circRNAs was validated by testing their dependence on RNAse R resistance. Northern blots surrounding the backsplice sites were used as target recognition sequences for designing LNA-modified gapmer antisense oligonucleotides (ASOs) to specifically knock down the circular isoforms of the RNA transcripts. Data from ongoing studies on knockdown of several abundant circRNAs in cancer cell lines, assess-
#3486 RBM3 causes differential expression IncRNA in colon cancer cell lines. Afreen Asif Ali Sayed, Dharmalingam Subramanian, Shahid Umar, Sufi M. Thomas, Shrikant Anant. University of Kansas Medical Center, Kansas City, KS.

Introduction: Colon cancer is the third most commonly diagnosed cancer and leading cause of cancer-related deaths in the United States. It usually begins as a benign growth that transforms into a malignant adenocarcinoma through genetic changes in tumor suppressor genes and oncogenes. Cancer stem cells are a rare group of cells within a tumor that have self-renewal capacities and with high potency for tumor relapse and metastasis. Wnt/β-catenin is one of the major pathways deregulated in colon cancer and also important in stem cell self-renewal. Wnt/β-catenin signaling is important in maintaining intestinal homeostasis and the stem cell niche, but aberrant activation of the pathway increases the stem cell population leading to aggressive cancer. We determined that RBM3 induces stem-like characteristics in colon cancer cells in part, by enhancing Wnt/β-catenin-induced GSK3β inactivation. We are further evaluating the mechanism by which RBM3 increases Wnt/β-catenin signaling leading to increased stemness. Methods: HCT116 and DLD1 cell lines were used in this study. We used a PCR array to identify specific Wnt pathway proteins regulated by RBM3, in HCT116 RBM3 overexpressing cells and compared it to vector control cells. RNA-IP was performed to confirm if RBM3 bound to Wnt3a and LRP6. ChIP was performed to identify β-catenin target genes. RBM3 RNA-seq was performed to identify differential gene expression and also differential IncRNA expression. RNA-Immunoprecipitation seq was performed to identify RBM3 protein bound cellular proteins. Ingenuity pathway analysis was performed for all the sequencing data. Results: Our data demonstrate that several Wnt pathway genes including Wnt3a and LRPS are upregulated in RBM3 overexpressing cells. To identify mRNA regulated by RBM3, we performed RNA-IP for RBM3. We found that RBM3 was associated with the mRNA for Wnt3a and LRPS. The ingenuity pathway analysis for RNA seq shows expression of genes involved in cell growth, proliferation and metastasis like Jun, LAMC2, Myc, NR2F2, NTSE etc. when RBM3 is overexpressed in the cells, showing a role of RBM3 in cancer progression. The seq data also shows differential expression of IncRNA especially those involved in cancer like CCAAT1 and SNHG16. The ingenuity pathway analysis for RNA-IP seq also shows increase in molecules involved in proliferation and cell movement. In-vivo studies were also performed to confirm role of RBM3 in tumorigenesis. Conclusion: RBM3 increases stemness by activating β-catenin pathway possibly through Wnt3a and LRPS. RBM3 overexpression causes differential expression of IncRNA and also increase expression of genes involved in cell growth and proliferation possibly by interacting with its target mRNAs.

#3487 Identification and validation of PCAT14 as prognostic biomarker in prostate cancer. Lanbo Xiao, Sudhanshu Shukla, Xiangy Zhang, Yashar shey, PA

Background: Early detection of prostate cancer, largely facilitated by the advent of the prostate specific antigen (PSA) test, also been accompanied by over-diagnosis of prostate cancer. Advances in next-generation sequencing technologies have enabled thorough characterization of cancer transcripts, especially in unraveling the realm of non-coding RNAs (ncRNAs). In particular, lncRNAs, a class of ncRNAs, have gained increasing attention as biomarkers due to their tissue- and cancer-specific expression profile. Thus, lncRNAs may be relevant in the clinical management of prostate cancer (PCa). Methodology: Here we assessed IncRNA expression from 585 PCA patient samples, including benign prostate tissue and both localized and metastatic PCa to discover and validate differentially expressed genes associated with disease aggressiveness. We performed Sample Set Enrichment Analysis (SSEA) and identified genes associated with low versus high Gleason score in the RNA-seq database. Comparing Gleason 6 versus 9 + PCa samples, we identified 99 differentially expressed genes with variable association to Gleason grade as well as robust expression in prostate cancer. The top-ranked novel IncRNA PCAT14, exhibits both cancer and lineage specificity. On multivariate analysis, low PCAT14 expression independently predicts for BPF5 (P = .00126), PSS (P = .0385), and MFS (P = .000609), with trends for OS as well (P = .056).

An RNA in-situ hybridization (ISH) assay for PCAT14 distinguished benign versus malignant cases, as well as high versus low Gleason disease. In prostate cancer cell lines, the endogenous PCAT14 levels are induced by CRISPR/SAM technique, which significantly suppresses cell invasion. Conclusion: By performing differential expression analysis between prostate cancer with low vs high Gleason scores, we identified IncRNA PCAT14 as a prostate cancer- and lineage- specific biomarker of indolent disease. We show that PCAT14 is an AR-regulated transcript and its overexpression suppresses invasion of prostate cancer cells. Moreover, in multiple independent datasets, PCAT14 expression associates with favorable outcomes in prostate cancer and adds prognostic value to standard clinicopathological variables.

Head and neck squamous cell carcinoma (HNSCC) represents the sixth deadliest cancer worldwide and the second fastest growing cancer in many developing countries. A cancer characterized by heterogeneity, HNSCCs are known to display varied genetic alterations based on a variety of epidemiological and clinical factors, including etiology, making it challenging to comprehensively profile and treat the disease. New studies have shown that non-coding RNAs (ncRNAs) may provide a promising means by which to explore HNSCC pathogenesis due to their diverse genetic and epigenetic roles and their recent emergence as potential biomarkers for cancer. In this study, we decided to investigate etiology-specific alterations of PIWI-interacting RNAs (piRNAs), the largest class of ncRNAs that have roles in silencing of retrotransposons, heterochromatin modification, and germ cell maintenance, in HNSCC. We particularly focused on smoking, the most prevalent risk factor of HNSCC, and HPV, the fastest growing cause of the disease today. Using 466 HNSCC RNA-sequencing datasets from The Cancer Genome Atlas (TCGA), we identified 58 piRNAs significantly differentially expressed in HNSCC current smokers vs. normal lifelong non-smokers and 39 piRNAs significantly dysregulated in HNSCC HPV16 (+) vs. normal HPV(-) cohorts, with 29 piRNAs commonly implicated in both etiologies (p < 0.05). Of the 58 piRNAs implicated in smoking-related HNSCC, 4 piRNAs were found to significantly associate with clinical variables and 1 transcript with patient outcome, with similar results for HPV-mediated piRNA dysregulation (Kruskal-Wallis, Cox regression, p < 0.05). In particular, we recognized transcripts NONHSAT081250, NONHSAT123636, and NONHSAT108298 for their correlations with tumor stage, metastatic status, and/or anatomic site, as well as presence of common mutations and copy number variations in HNSCC. We then analyzed mRNA expression data for the same 466 samples from TCGA and found that TCGA mRNA profiles may be implicated in smoking-related and HPV-related HNSCCs respectively, and also to associate with piRNA candidate expression levels (p < 0.05). We subsequently validated the dysregulation of all significant piRNA and PIWI protein candidates in vitro in cigarette-treated and HPV E6/E7-overexpressing normal oral epithelial cells. While a comprehensive understanding of the functional and mechanistic relevance of non-coding RNAs in HNSCC remains yet to be found, our findings reveal the potential of these genes to mediate a variety of etiology-specific clinical and genomic aberrations in HNSCC and provide novel insights to thwart the progression of this disease.

#3489 Noncoding RNA distribution in clear cell renal cell cancer: small RNA-seq data. Srinivas V. Koduru, Dino J. Ravnic. Penn State University, Hershey, PA.

Small noncoding RNAs (snRNAs) play pivotal roles in biological processes and may prove to be a tool in cancer diagnosis, prognosis, and treatment. Non-coding RNAs such as microRNAs (miRNAs), piwi-interacting RNAs (piRNAs), long noncoding RNA (IncRNAs) and small nuclear/nucleolar RNAs (sn/snoRNAs) have recently been investigated to identify their role in cancer. Approximately 62,700 new cases of kidney cancer are expected each year in the United States leading to 14,240 deaths, with rates rising over the past 20 years. Nearly 90% of all kidney cancers will be renal cell carcinoma, of which 70% will be a clear cell renal cell carcinoma (ccRCC) subtype. When detected early most cases can be treated effectively, however there is a lack of early detection tests. We sought to identify molecular markers for early detection and diagnosis. We downloaded publically available (NIH bioproject PRJNA162979) ccRCC small RNA sequence raw data for noncoding RNA analysis. 22 ccRCC and 11 non-tumor renal cortex patient samples were evaluated. Data was analyzed by PartekFlow software. sRNA-seq data was annotated with miRNAs with 69 miRNAs aberrantly expressed in ccRCC with 37 being upregulated (top five: miR-
Molecular and Cellular Biology / Genetics: Noncoding RNAs and Cancer: Expression, Function, and Therapeutics

122, mir-210, miR-155, miR-224 and miR-21) and 32 being downregulated (top five: miR-20c, miR-502, miR-20b, miR-10a and miR-204). Utilizing MetaCore software for pathway analysis the majority of expressed miRNAs were involved in metabolism related signaling pathways. Examining data for piRNAs revealed 22 which were significantly expressed (8 upregulated and 14 downregulated). Investigation of lncRNAs revealed 15 to be downregulated and 27 upregulated. We also uncovered 2 mitochondrial RNAs, 10 miscRNAs, 1 snRNA, 7 snoRNAs, and 5 rRNAs in cCRCC samples. Our comprehensive analysis of publically available small RNA-seq data identified numerous lncRNAs associated with cCRCC. Pending further validation, they may prove useful as early detection biomarkers in this common cancer.

#4390 Interrogation of small RNA-seq data for small noncoding RNA expression in human colon cancer. Srinivas V. Koduru,1 Angélique Nyinawabera,2 Dino J. Ravnic,3 Amit K. Tiwari,2 1Pennsylvania State University, Hershey, PA; 2University of Toledo, Toledo, OH.

Genomic analysis of the human transcriptome has been made possible only in last decade by next generation sequencing (NGS). Recent advancements in NGS has further allowed us to look into small non-coding RNAs (snRNAs) such as microRNAs (miRNAs), Piwi-interacting RNAs (piRNAs), long non-coding RNAs (lncRNAs) & small nuclear/nucleolar RNAs (sn/snoRNAs). Recently, the roles of snRNAs in biological processes have been implicated in biomarker development for diagnosis, prognosis & therapy. In the present study, 50 colon cancer patient’s small RNA sequencing raw data was downloaded from NIH bioproject (PRJNA266667;7 TNM stage II & 43 TNM stage III) which contained 27 female & 23 male samples. 24 samples had metachronous metastasis (MM) & 26 non-metachronous metastasis (NMM). The small RNA-seq data was analyzed using PartekFlow. In depth analysis showed aberrant expression of 48 miRNAs (all upregulated) in TNN-M vs TNN-II specimens & 20 miRNAs (17 upregulated & 3 downregulated) in MM vs NMM. Further investigation of dysregulated miRNA through pathway analysis confirmed that the majority of the miRNAs were involved in cancer signaling pathways. Analysis of piRNA found unusual expression of 60 piRNAs (57 upregulated & 3 downregulated) in TNN-M vs TNN-II & 31 piRNAs (28 upregulated & 3 downregulated) in MM vs NMM. Further analysis of long non-coding RNAs, we found 77 lncRNAs were significantly expressed in TNN-M vs TNN-II & 818 lncRNAs in MM vs NMM. We also, investigated small nuclear/nucleolar RNAs (sn/snoRNAs), miscRNAs & miRNAs, we identified 37 snRNAs, 105 snRNAs, 28 miscRNAs & 5 snRNAs in TNN-M vs TNN-II whereas 2 snRNAs, 11 snRNAs, 57 miscRNAs & 8 miRNAs in MM vs NMM were identified. In summary, our comprehensive analysis on publicly available small RNA-seq data identified multiple small non-coding RNAs that need to be further explored for their use in the prognosis, diagnosis & therapy of colon cancer.

#4391 A role for the long non-coding RNA GHRLOS in cancer. Esha T. Shah, Penny Jeffrey, Patrick Thomas, Inge Seim, Lisa Chopin. Ghrelin Research Group, Translational Research Institute-Institute of Health and Biomedical Sciences, Queensland University of Technology, Brisbane, Australia.

Long non-coding RNA (lncRNA) genes are abundant in the human genome, and many are now recognized as oncogenes and/or tumor suppressors. We previously characterized the structure of GHRLOS, an antisense gene on the opposite strand of the multifunctional ghrelin gene (GHRL), however, its expression and function in disease has not been described. To this end, using The Cancer Genome Atlas (TCGA) data set, we revealed that GHRLOS is differentially expressed in a number of cancers. In particular, expression was elevated in endometrial cancer (1.2-fold; P = 7.1 × 10^-14) and prostate cancer (1.2-fold; P = 3.7 × 10^-14; n = 52 vs. n = 498) compared to normal tissues. Using qRT-PCR and commercial cDNA panels we confirmed that GHRLOS expression was upregulated in endometrial cancer (1.96-fold, P = 0.005 Welch’s two-sample t-test; n = 24 vs. n = 175) and prostate cancer (2.46-fold, P = 0.0045 Welch’s two-sample t-test, n = 5 vs. n = 21) compared to normal tissues. Initial studies, using siRNA designed to silence endogenous GHRLOS expression, significantly reduced cell migration in the PC3 prostate cancer cell line (0.47-fold change, P = 0.042 Kruskal-Wallis test, n = 2) conversely, preliminary data using forced GHRLOS overexpression increased migration and proliferation. Taken together, we show that the long non-coding RNA GHRLOS is differentially expressed in tumor tissue and regulates cell migration and proliferation; possibly by modulating alternative splicing of the overlapping, multifunctional ghrelin gene locus. Targeting GHRLOS could provide a valuable and novel way to target the ghrelin axis in disease. Ongoing studies aim to validate in vitro functional results in complementary mouse xenograft models and identify genes and pathways regulated by this novel lncRNA.

#4392 Subtype-specific expression of small non-coding RNAs in breast cancer. Jaana M. Hartikainen,1 Sami Heikkinen,2 Maria Tengström,3 Veli-Matti Kosma,4 Arto Mannermara,5 1School of Medicine, Institute of Clinical Medicine, Pathology and Forensic Medicine, and Cancer Center of Eastern Finland, University of Eastern Finland, Kuopio, Finland; 2Institute of Biomedicine, University of Turku, Turku, Finland; 3Clinical Department of Medical Oncology, Oncology, and Cancer Center of Eastern Finland, University of Eastern Finland, and Cancer Center, Kuopio University Hospital, Kuopio, Finland; 4School of Medicine, Institute of Clinical Medicine, Pathology and Forensic Medicine, and Cancer Center of Eastern Finland, University of Eastern Finland, and Imaging Center, Kuopio University Hospital, Kuopio, Finland.

We have performed a small RNA-sequencing (RNA-Seq) experiment to find candidate small non-coding RNAs (ncRNAs) in breast cancer (BC) for the identification of signatures that aid in the prediction of therapy responsiveness, prognosis or patient outcome. We used 195 invasive BC tumor and 20 benign breast tissue samples from the Kuopio Breast Cancer Project (KBCP) study material. KBCP material is collected from a genetically homogeneous population of Eastern Finland, and includes fresh-frozen and FFPE breast tissue samples, EDTA blood samples and serum, as well as comprehensive background/lifestyle information, clinical, treatment and follow-up data extending over 20 years. This well-defined material enables the identification of factors associated with BC risk, different stages of disease progression and outcome. Total RNA was extracted from the fresh-frozen BC and pre-existing tissue using the Ambion mirVana miRNA Isolation Kit. Small RNA-Seq was performed using the Illumina TruSeq Small RNA Library Prep kit and the Illumina MiSeq next-generation sequencing instrument. Analyses were concentrated in PIWI-interacting RNAs (piRNAs) and other non-miRNA small ncRNAs (snRNAs). Bioinformatic analysis commenced with quality control and preprocessing steps including read quality assessment (FastQC), adapter trimming (TRIMMOMATIC), and removal of e.g. ribosomal RNA reads (Bowtie). Preprocessed reads were aligned (Tophat) to human reference transcriptomes (piRNABank and GENCODE non-miRNA snRNAs), followed by data conversions e.g. for visualization (samtools, IGVtools). Gene-wise read counts were collected using summariizeOverlaps R package, and statistically differentially expressed (DE) genes were identified using DEseq2 R package. We first compared the small RNA expression in the benign breast tissue with invasive BC and observed in total 635 snRNAs and 94 piRNAs with differential expression (P < 0.05). Of these 520 snRNAs and 73 piRNAs were upregulated, and 115 snRNAs and 21 piRNAs downregulated in the invasive tumors compared to benign breast tissue. When comparing the luminal BC subtype with triple-negative BC (TNBC) we observed 204 DE (P < 0.05) snRNAs and 32 piRNAs. Of these, 103 snRNAs and 18 piRNAs were upregulated, and 101 snRNAs and 14 piRNAs downregulated in TNBC compared to luminal tumors. Differential expression was also observed between ER (estrogen receptor) negative and ER positive invasive tumors. Of the 242 DE snRNAs and 32 piRNAs, 105 snRNAs and 12 piRNAs were upregulated, and 137 snRNAs and 20 piRNAs were downregulated in ER positive BC compared to ER negative BC. Preliminary results of hierarchical clustering and principal component analysis of normalized log2 piRNA and snRNA expression levels revealed the potential for finding differences between BC subtypes. The subsequent statistical analysis enabled us to identify individual piRNAs and other ncRNAs as candidate druggable biomarkers for e.g. TNBC patients.

#4393 LncRNA as potential target in drug-resistant melanomas. Rosaura Esteve-Puig,1 Martina Sanlórenzo,1 Igor Vujic,1 Kevin Lai,2 Marin Vujic,1 Dallas Mould,1 Kevin Lin,1 Juan Oses-Prieto,1 Shreya Chand,1 Christian Posch,3 Alma Burlingame,4 Susana Ortiz-Urdá,4 1University of California, San Francisco, San Francisco, CA; 2University of Turin, Turin, Italy; 3Rudolfstiftung Hospital, Academic Teaching Hospital, Vienna, Austria.

Melanoma is the most common lethal form of skin cancer. Activating mutations in BRAF and RAS oncogenes account for over 80% of all melanomas and lead to activation of MAPK (mitogen activated protein kinase) mitogenic pathways in melanoma therapies over the past decade, drug resistance limits their efficacy. Long noncoding RNAs (lncRNAs) are a new class of genes that do not encode proteins, which have been characterized as epigenetic regulatory molecules. lncRNAs have emerged as important players in cancer, potential predictors of therapeutic responses and targets for new treatments; however, their functions and precise molecular mechanisms remains largely unexplored. Our study aims to find novel potential targets involved in the acquisition of resistance to MAPK inhibitors. We identified an intergenic lncRNA (lincRNA) highly differentially expressed in drug-resistant melanoma samples, called MAPK Inhibitor Resistance Associated Transcript (MIRAT). We determined that MIRAT is localized
mainly in the cytoplasm and plays a role in modulating the signal transduction pathways without regulating the genomic neighborhood. We discovered that MIRAT is upregulated in early drug tolerance to MAPK inhibition. Mechanistically, the gene overexpression and silencing of MIRAT, as well as preliminary RNA-protein interaction results, showed that it modulates the MAPK signal transduction. Benefiting from a modulating effect on a MIRAT-expressing cell line, these results highlight the relevance of cytoplasmic lncRNA’s and their role in oncogenic signaling pathways, and further suggest that lncRNAs and their protein-binding partners may serve as novel potential targets for overcoming drug resistance in melanoma.

#3494 Dissecting the cellular expression and subcellular localization of lncRNAs implicated as prognostic biomarkers in non-small cell lung carcinomas by RNA ISH. Courtney M. Anderson, Na Li, Xiao-Jun Ma, Emily Park. Advanced Cell Diagnostics, Newark, CA.

Background: Long non-coding RNAs (lncRNAs) are involved in many biological processes, including epigenetic modification, cell differentiation, and apoptosis. More recently, lncRNAs have emerged as unique biomarkers that may be associated with a physiological or diseased state, and several lncRNAs have been identified as prognostic markers in a wide variety of human cancers. Because lncRNAs do not translate into protein, their discovery in the tumor is entirely dependent upon RNA detection. The majority of lncRNAs are also expressed at very low levels compared to mRNAs and may be more heterogeneously expressed than mRNAs. Therefore, detection of lncRNAs in tumor biopsies requires a highly sensitive and specific detection method that can discern single-cell and subcellular localization. Methods: Single-cell and molecular RNA in situ hybridization (ISH) is a well-suited method for the detection of lncRNAs in tumor biopsies because it allows for the visualization of single RNA molecules with morphological context. To interrogate the expression pattern of lncRNAs within the tumor and its microenvironment, we performed ISH using the RNAscope assay on FFPE tissue microarrays consisting of archived tissue samples of 53 primary non-small cell lung carcinoma (NSCLC) tumors and 4 adjacent normal lung tissues. We examined the expression of 4 lncRNAs which have been implicated as potential prognostic markers of lung cancer: AFAP-AS1, ANRIL, HOTAIR, and UCA1. Results: These lncRNAs were detected in approximately 40-60% of the 53 NSCLC tumor cores and in none of the 4 adjacent normal lung tissues. Expression of these 4 lncRNAs was observed predominantly in tumor cells, with little to no detection in the stroma. Some lncRNAs displayed a heterogeneous expression pattern, with some tumor cell foci displaying strong lncRNA signal while other foci in the same tumor did not display signal. Furthermore, some lncRNAs displayed heterogeneous cell expression in the same foci, with some cells expressing very high levels of lncRNA while other cells in the same foci had little to no lncRNA expression. An evaluation of each lncRNA in serial sections revealed that of the 4 lncRNAs, tumors expressed all 4 lncRNAs in the same tumor foci. Lastly, little to no signal was observed for the prostate cancer-specific lncRNA PC3A in the NSCLC tumors and no PC3A expression was detected in adjacent normal lung tissues. Conclusions: These results demonstrate the ability of the ISH assay to detect potential lncRNA biomarkers in lung cancer samples in situ, allowing for the identification of single-cell and subcellular localization. These results provide precise tumor expression patterns of lncRNAs. Identification of the subcellular localization and cell-to-cell expression patterns of lncRNAs can facilitate greater understanding about their specific biological roles in cancer and other diseases.

#3495 The DNA methylation landscape of long noncoding RNAs in human cancer. Da Yang, Zehua Wang, Bo Yang, Min Zhang, Zhiyuan Wu. University of Pittsburgh, Pittsburgh, PA.

Integrating multi-dimensional genomic and epigenetic data from the TCGA, ENCODE and CCLE projects, we comprehensively characterized the epigenetic landscape for lncRNA genes in 9837 tumor samples across 33 cancer types. This analysis revealed that lncRNAs can be both epigenetically silenced and activated by DNA methylation alteration in the promoter region, which is in striking contrast to the well-documented hypermethylation of protein-coding gene promoters in tumor. To determine the corresponding transcriptional changes of lncRNAs with epigenetic alterations in tumors, we applied a heuristic strategy to identify the epigenetic silenced and activated lncRNAs by integrating the transcriptional profile of 58,648 lncRNAs from 6475 TCGA RNA-seq files. This analysis characterized a patient-centric matrix with DNA methylation status of 3380 epigenetically regulated lncRNAs across 6475 tumor samples. Some epigenetically activated lncRNAs exhibited an “on or off” pattern with completely no expression in normal tissues, which potentiated them as promising diagnostic biomarkers. To rule out the interference of tumor associated stromal and immune cells in lncRNA analysis, we investigated the RNA-seq and DNA methylation profiles of 784 cell lines from breast, lung, and bladder cancer. Most of epigenetically regulated lncRNAs identified in tumor samples showed prominently negative correlation between their expression and promoter methylation in cancer cell lines. We then validated the epigenetically activated lncRNAs by performing decitabine treatment on cell lines. The decitabine treatment led to a significant and time-dependent induction of lncRNA expression and loss of DNA methylation at lncRNA promoter. Further survival analysis indicated that epigenetically activated lncRNAs were generally correlated with poor survival while the epigenetically silenced lncRNAs were generally correlated with good survival. Among the epigenetically silenced lncRNAs we well-documented tumor suppressor lncRNAs such as MEG3. And lncRNA oncogenes, such as MINGCR, are epigenetically activated in multiple cancer types. To delineate the relationship between lncRNAs and known cancer pathways, we performed mutual exclusive analysis by combining the lncRNA epigenetic landscape with known protein-coding tumor genes alterations in same tumors. This analysis nominated several lncRNAs as novel members in cancer pathways, including TP53, P13K, and EGFR cascades. Indeed, functional experiment validation focus on the top epigenetically activated lncRNA (EPIC1) demonstrated that EPIC1 is a potential oncogene. In breast and ovarian cancer cell lines, EPIC1 promotes cancer cell colony formation and increases cell viability by promoting cell cycle pathway. Collectively, our integrative study provides a resource for investigating lncRNAs in cancer and lays the groundwork for the development of novel diagnostics biomarkers and treatments.

#3496 Long non-coding RNAs in colorectal cancer. Alena Opattova,1 Fabio Miguel Ferreira,2 Jozef Horak,3 Sonja Vodenkova,2 Pavel Vodicka1.1 Institute of Experimental Medicine, Prague, Czech Republic; 2Research Centre of IPO-Porto, Porto, Portugal; 3Third Faculty of Medicine, Charles University, Prague, Czech Republic.

Colorectal cancer (CRC) is the third most common type of cancer worldwide and the second most common cause of cancer related deaths in Europe. Since Countries of Central Europe (Czech Republic, Slovakia, Hungary) have one of the highest rates both for incidence and mortality of CRC, CRC became a serious health, social and economic problem. CRC pathogenesis involves multiple genetic events. On behalf of a strong experimental work, there is still lack of predictive, prognostic and treatment-response related biomarkers. Long non-coding RNAs (lncRNA) are non-protein coding transcripts longer than 200 nucleotides. Deregulation of lncRNAs is often seen in a variety of human diseases, including cancer. Taken together, this makes lncRNAs the potential regulators of cancer progression, therapeutic targets or markers of treatment efficacy. The main aim of our present study was to define expression patterns of lncRNAs in colorectal tumor tissue and define their role in cancer cell proliferation, survival and DNA damage response (DDR). In the first part of our study, we analyzed the expression profile of 83 lncRNAs known to be associated with cancer progression in cohort of CRC tumor tissues and adjacent mucosa. We found 12 upregulated lncRNAs (|p|<0.05) and 10 downregulated lncRNAs (|p|<0.05). Our results have been replicated on larger set of patients (100 CRC patients) and those lncRNAs associated with cell proliferation, survival and DNA damage response are functionally tested on colorectal cell lines (HCT116, T84) in vitro. Definition of role of lncRNA as tumor suppressors or oncogenes in CRC etiology may lead to better understanding of regulation of CRC carcinogenesis. Furthermore, understanding the role of lncRNA in DDR may contribute to better treatment response of CRC patients and to define markers of individual treatment response. #3497 Network-based systematic inference of lncRNA activity in breast cancer. Matthew Ung, Daniel Mattiox, George Wang, Chao Cheng. Geisel School of Medicine at Dartmouth, Hanover, NH.

The production of lncRNA is widespread across the human genome, yet the functions of lncRNAs and the phenotypes resulting from their activation have remained largely underexplored. In cancer, several lncRNAs have been found to associate with disease development and poor patient prognosis including HOTAIR and MALAT1. Recent studies have been performed using lncRNA microarrays or re-annotated probes from coding gene microarrays to systematically investigate their roles in cancer. However, datasets from lncRNA microarrays are typically not accompanied by comprehensive clinical information that can be used to draw associations between lncRNA expression and clinical phenotypes. Furthermore, lncRNA stability and cellular localization is highly variable suggesting that expression-based inference of lncRNA activity may not always be an accurate measure of its activity. To address this issue, we introduce an activity-based approach whereby we analyze the expression of lncRNA target...
genes to infer lncRNA activity. Specifically, we construct a breast cancer specific lncRNA-target gene network from RNA-seq data using a network reconstruction algorithm. We then apply this network to several breast cancer microarray datasets to systematically investigate lncRNA activity and their association with clinical phenotypes. Notably, we find that certain lncRNAs are active in specific microarray datasets in breast cancer even when their expression levels do not reveal significant differences. Lastly, we performed survival analysis to systematically screen for novel lncRNAs whose activity associate with patient prognosis. Our results suggest that activity-based inference of lncRNAs can identify novel lncRNAs that may serve as therapeutic targets or biomarkers in breast cancer.

**#3498 Characterization of a novel metastatic lung cancer associated lncRNA.** Nicole M. White, Emily B. Rozyci, Ha X. Dang, Christopher A. Maher. Washington University School of Medicine, Saint Louis, MO.

Lung cancer is the leading cause of death worldwide with the majority of patients presenting with metastasis and moreover, developing resistance to current treatments. One promising therapeutic area is the novel class of long non-coding RNAs (lncRNAs). While emerging evidence implicates them in cancer, lncRNA biology is still largely unexplored in tumor metastasis. To elucidate the function of lncRNAs in lung cancer, our lab used transcriptional sequencing (RNA-Seq) to discover 120 long non-coding RNAs (lncRNAs) that are enriched in metastatic tumors compared to their corresponding primary lung tumors, which we have named Metastasis Associated Lung cancer lncRNAs (MALLs).

Notably, metastatic tumors were enriched for differentially expressed protein-coding genes targeted by Polycomb Repressive Complex 2 (PRC2). In lung cancer studies, the catalytic subunit of PRC2, EZH2 (an H3K27 methylase), is overexpressed, associates with poor prognosis, promotes tumor progression, and epigenetically represses genes to promote metastasis. Specifically, we have found MALL-1 to be (i) highly up-regulated in lung cancer; (ii) promotes proliferation and migration/invasion, hallmarks of oncogenic phenotypes; (iii) binds to EZH2; and (iv) cooperatively represses well-known PRC2 target genes associated with metastasis in patients. Further, we found MALL-1 to be altered in multiple solid tumors thus suggesting a critical conserved oncogenic role of MALL-1 in solid tumor progression. We believe MALL-1 promotes aggressive disease through its interactions with, and recruitment of the PRC2 complex to chromatin, to epigenetically modify genes associated with metastasis.

**#3499 Differentially expressed small noncoding RNAs in triple-negative breast cancer.** Srinivas V. Koduru,1 Amit K. Tiwari,2 Ashley Leberfinger,1 Sprague W. Hazard,1 Yuko Imamura Kawasawa,2 Milind Mahajan,3 Dino J. Ravnic.1 1Pennsylvania State University-Hershey, Hershey, PA; 2University of Toledo, Toledo, OH; 3Icahn School of Medicine, Mount Sinai, New York, NY.

Cancer is the second leading cause of death in the United States and is a major public health concern worldwide. Basic, clinical and epidemiological research is leading to improved cancer detection, prevention, and outcomes. Recent technological advances have allowed unbiased and comprehensive screening of genome-wide gene expression. Small non-coding RNAs (snRNAs) have been shown to play an important role in biological processes and could serve as a diagnostic, prognostic and therapeutic biomarker for specific diseases. Recent findings have begun to reveal and enhance our understanding of the complex architecture of snRNA expression including miRNAs, piRNAs, sn/snoRNAs and their relationships with biological systems. We used publicly available small RNA sequencing data that was derived from 24 triple negative breast cancers (TNBC) and 14 adjacent normal tissue samples to remix various types of snRNAs. We found a total of 55 miRNAs were aberrantly expressed (p<0.005) in TNBC samples (8 miRNAs upregulated; 47 downregulated) compared to adjacent normal tissues whereas the original study reported only 25 novel miRs. In this study, we used pathway analysis of differentially expressed miRNAs which revealed TGF-beta signaling pathways to be profoundly affected in the TNBC samples. Furthermore, our comprehensive re-mapping strategy allowed us to discover a number of other differentially expressed snRNAs including piRNAs, sn/snoRNAs, rRNAs, miscRNAs and nonsense-mediated decay RNAs. We believe that our snRNA analysis workflow is an inclusive and suitable for discovery of novel snRNAs changes, which may lead to the development of innovative diagnostic and therapeutic tools for TNBC.

**#3500 Epstein-Barr virus (EBV) noncoding RNAs modulate host gene expression for virus latency leading to oncogenesis in epithelial cells.** Rob Verhoven, Bobo Wing-Yee Mok, Shuang Tong, Honglin Chen. The University of Hong Kong, Hong Kong. Hong Kong.

Epstein-Barr virus (EBV) efficiently establishes and maintains a state of latency in resting B cells, with persistent asymptomatic infections occurring in more than 95% of the human population worldwide. Besides causing lifelong infections in resting B cells in the majority of people, EBV has been found to associate with several human cancers occurring in immune competent individuals. A hallmark of EBV infected cells through a distinct viral latency program. It is believed that this type of mechanism has been adopted by EBV to allow the virus to evade host immune surveillance. Nasopharyngeal carcinoma (NPC) is prevalent in southern China, Southeast Asian countries and some African countries but uncommon in rest of the world. In NPC 100% of cancer cells are infected with EBV, and EBV is recognized as one of the major risk factors. The details of how EBV maintains latency and contributes to the oncogenesis of NPC remain elusive. Notably, EBV abundantly expresses a family of non-coding RNAs derived from the BamH1I region of the viral genome (BARTs). It is hypothesized that this family of viral non-coding RNAs is key to maintaining viral latency, evading immune surveillance and triggering oncogenesis in EBV associated tumors. We have shown a mechanism for the regulation of the abundant expression of BARTs in NPC which involves the constitutive activation of NF-κB signaling typically observed in NPC cells and have also identified a regulatory loop through which BARTs support EBV latency in NPC. Using high throughput RNA-seq analysis we further demonstrated that BART RNAs modulate expression of cellular genes associated with anti-inflammatory and immune-modulating properties, oxoderoxidase activity, and cell migration and invasion in NPC cells. BART non-coding RNAs are predominantly localized in the nucleus and associated with the CBP/p300 complex. Our data showed that BARTs modulate genes responsive to the mitochondria-associated molecular device (MAVS) through halting cellular Pol II in the promoter region and down-regulating gene expression. In the nucleus, BART non-coding RNAs mediate chromatin acetylation through interaction with CBP/p300. We have generated a working model with evidence showing that Epstein-Barr virus shuts off most of the viral proteins to evade immune surveillance, but through expression of high levels of BART non-coding RNAs can modulate cellular gene expression to provide an optimal environment for maintenance of viral latency in cancer cells. Alteration of cellular gene expression by EBV BART non-coding RNAs for establishment and maintenance of EBV latency in epithelial cells can therefore lead to the oncogenic process for EBV associated tumors.

**#3501 Prognostic value of a 4 lncRNA signature in patients with non-small cell lung cancer: a lncRNA expression analysis.** XiaoRan Long,1 HuiYun Wang,2 ChunLei Ge,2 Xin Song,2 MeiYin Zhang,1 XiaoFeng Zhen. 1Cancer center of Sun Yet-sen University, Guangzhou, China; 2Cancer Biotechnology, Institute of the Third Affiliated Hospital of Kansung Medical University, KunMing, China; 3Rutgers Cancer Institute of New Jersey and Department of Pharmacology, Robert Wood Johnson Medical School, Rutgers University, New Brunswick, NJ.

Recently, increasing evidence indicates that lncRNA plays an important role in the cancer development and progression. In this study, we are aimed to identify lncRNA signature for predicting survival of non-small cell lung cancer (NSCLC) patients. A total of 366 NSCLC cases, which were divided into a training and validation set, were detected by lncRNA microarray (containing 2412 lncRNA probes), and another 73 cases as an independent set were analyzed by qRT-PCR. LncRNA microarray analysis identified a total of 305 differentially expressed lncRNAs (138 up-regulated and 167 down-regulated) between NSCLC and normal tissues in the training set. We then validated the microarray data by qRT-PCR analysis of 5 lncRNAs (2 up-regulated and 3 down-regulated) in 30 paired NSCLC and adjacent lung tissues randomly selected from the training set. We then used a stepwise forward procedure to select the best combination of lncRNAs with the most significance in prediction of NSCLC prognosis and a 4-lncRNA prognostic signature was established, which was significantly associated with overall survival (hazard ratio [HR]: 3.563, 95% confidence interval [CI]: 2.118-5.995, P < 0.001) and disease-free survival (HR: 3.236, 95% CI: 2.116-4.940, P < 0.001) in the training set. This prognostic signature was validated in the validation (OS: HR: 3.186, 95% CI: 1.849-5.488, P < 0.001; DFS: HR: 2.967, 95% CI: 1.949-4.517, P < 0.001) and independent sets (OS: HR: 4.703, 95% CI: 1.923-11.50, P < 0.001; DFS: HR: 4.549, 95% CI: 2.139-9.674, P < 0.001). This 4-lncRNA signature has been demonstrated as an independent prognostic factor, which significantly improves the prognostic accuracy of TNM staging system in a combined model as assessed by ROC curve analyses in the three sets, respectively. Therefore, the 4-lncRNA signature has potential prognostic role in NSCLC patients.
#3502 RNAi screen identified novel long non-coding RNAs involved in cell growth control, migration, and invasion.
Tse-Chun Kuo, Sheng-Chieh Hsu, Hui-Ju Chou, Pei-Shan Li, Szu-Huei Wu, Yen-Ling Yu, Jen-Shin Song, Hsing-Jien Kung. NHRIL, Taiwan, Zhunan Town, Miaoli, Taiwan.

Triple-negative breast cancer (TNBC) is a highly aggressive form of breast cancer often associated with poor prognosis. Owing to the lack of therapeutic targets, patients with TNBC tend to rely on standard chemotherapy; however, chemo-resistance often develops in TNBC as a result of deregulated cell death control like in many other tumors. Long non-coding RNAs (lncRNAs) are transcripts longer than 200bp and have little or no protein-coding capacity. Although once considered as transcriptional noise, significant numbers of lncRNAs are now recognized as modulators of protein expression and functions and are implicated in a range of developmental processes and diseases. As many of them influence oncogenes and tumor suppressors in cancer, they represent excellent biomarkers as well as potential targets for therapy. In order to gain more insight on cell death regulation and to seek potential targets for TNBC, we employed an RNAi screen targeting 2231 lncRNAs in MDA-MB-231 TNBC cells. By using changes in cell metabolic activity (MTT assay) as readouts for primary screen and changes in cell number as confirmation, our unbiased screen identified two novel lncRNAs that drastically reduced cell proliferation when depleted. In addition to cell growth, the two lncRNAs also contribute to cancer cell migration and invasion. Interestingly, our gene profiling analyses and RNA immunoprecipitation studies show the two lncRNAs are involved in signaling cascades related to metastatic mammalian tumorigenesis necessary for E-cadherin and β-catenin. We are now trying to delineate the detailed molecular mechanism(s) by which the two lncRNAs contribute to TNBC tumorigenesis. Together, our current results suggest a possibility for the two novel lncRNAs as drug targets in triple-negative breast cancer.

#3503 Transcriptome analysis reveals differentially expressed lncRNAs between oral squamous cell carcinoma and healthy oral mucosa.
Lu Feng, John H. Houck, Pawadee Lohavanichbutr, Chu Chen. Fred Hutchinson Cancer Research Center, Seattle, WA.

Objective: Oral cavity and oropharyngeal squamous cell carcinoma (OSCC) is a major cancer type in the head and neck region. To better understand the roles long non-coding RNA (lncRNA) play in OSCC carcinogenesis, we compared the genome-wide gene expressions of lncRNA in OSCC and in the oral mucosa from healthy individuals. Materials and methods: We compared the expression levels of 3,054 probe sets for lncRNAs between 167 OSCCs and 45 healthy controls using an Affymetrix HG U133 plus 2.0 array platform. We validated the top differentially expressed lncRNAs in three independent datasets in the Gene Expression Omnibus (GEO) repository: GSE42743, GSE9844, and GSE6791. We further tested the differential expression of the three lncRNAs showing the highest fold change by quantitative RT-PCR in a subset of 20 OSCCs and 10 control samples. Results: We found 658 lncRNA transcripts (790 probe sets) to be significantly differentially expressed between OSCC and healthy oral mucosa using a criteria of FDR<0.01, with 36 of them (39 probe sets) showing more than a 2-fold change. Among the 36, 14 (15 probe sets) lncRNAs were validated in all three independent datasets using the criteria FDR<0.01: LOC441178, C Sorf66-6 AS1 (hLINC01315), LINC00478, and COX10-AS1/LOC100506974. RT-PCR showed a greater than 5 fold change in expression between matched normal liver (NL) and OSCC tissues. In addition, expression of miR-21 and miR-21 were significantly associated with poor prognosis of HCC patients. More importantly, expression of exosomal lncRNA-ATB and miR-21 was more significantly associated with HCC progression and poor patients survival compared to its tissue expression. We conclude that non-coding lncRNAs (lncRNA-ATB and miR-21) expression has the potential to serve as biomarkers for prognosis and targeted therapy in HCC patients.

#3505 The expression of two key long non-coding RNAs involved in reprogramming, linc-ROC and linP21, in gastric cancer.
Mitra Khalili,1 Pouran-dokht Farhangiyan,2 Somayed Jahanbodost,3 Fatemeh Kamali.2 Zanjan University of Medical Sciences, Zanjan, Islamic Republic of Iran;2 Tehran University of Medical Sciences, Tehran, Islamic Republic of Iran.

Introduction: Gastric cancer (GC) is the second leading cause of cancer-related death in the world and the most common cancer in southeast of Caspian Sea (Golestan province) and northwest of Iran (Ardabil). Based on cancer stem cell (CSC) hypothesis, there are similarities between process of somatic cell reprogramming, embryogenesis and tumorigenesis. Malfuction of signaling pathways that are essential for normal development also involved in the tumor initiation and CSC formation. In recent years long non-coding RNAs (lncRNAs) more than 200 nt in length, have been highly regarded as promising biomarkers for early diagnosis and prognosis of cancers. Reprogramming-Related Long Intergenic Noncoding RNA (lincRNA-ROR) plays as modulator in the reprogramming of human induced pluripotent stem cells (iPSCs) and also maintenance of embryonic stem cells (ESCs).

On the other hand, lincRNA-P21 induced by P53 and prevents the somatic cell reprogramming by silencing of pluripotency gene promoters. In this project, motivate to CSCs, we evaluated the expression level of lincRNA-ROR and linc-P21 in samples of patients with gastric cancer and also in human gastric cancer cell lines (AGS and MKN45) and human embryonal carcinoma cell line (NT2). Methods: Thirty pairs of gastric samples, including gastric adenocarcinoma and their matched non-tumor tissue samples, were collected from the Iran National Tumor Bank (INTB). Cell lines were cultured in the RPMI1640. Total RNA of samples and cell lines was extracted using TRIZOL reagent (invitrogen). cDNA synthesis was performed by PrimeScript™ 1st strand cDNA Synthesis Kit (TAKARA) and real time PCR was performed by using TaqMan master mix (TAKARA) on Step one Plus™ instrument (ABI).

Gene expression analysis performed by GenEx software program. Fold change for determining the high, medium and low expression of lincRNA-ROR in some cancers, our results showed no expression for linc-ROR in gastric samples (both tumor and non tumor) and also gastric cancer cell lines. But NT2 embryonal carcinoma cell line revealed high expression of linc-ROR compared to AGS and MKN45cell lines. According to our expectation, linc-P21 represents a significant decrease in tumor versus non tumor tissues and linc-ROC has been identified as a marker of malignancy and also in GC and MKN45 versus to NT2 cell line. Conclusion: Dysfunction of linc-ROR and lincRNA-P21 has reported in some cancers. According to our results, it seems that the expression of linc-ROR is limited to embryonic stem cells and hasn’t remarkable expression in gastric samples and cell lines. Based on the low expression of linc-P21 in tumor samples, it seems that linc-P21 functions as a tumor suppressor.

#3506 ncRNA regulation of eribulin response in neuroblastoma.
Yiqiang Zhang,1 Xiuye Ma,3 Xiaoie Yu,3 Harsh Patolia,2 Zhenze Zhao,3 Liqin Du,3 Alexander Pertsemlidis1.

1University of Texas Health Science Center at San Antonio, San Antonio, TX;2Virginia Tech Carilion School of Medicine, Roanoke, VA;3Texas State University, San Marcos, TX.

Introduction: Neuroblastoma (NB) is the most common cancer in infants and the most common extracranial solid tumor in children, accounting for 15% of all childhood cancer deaths. The overall prognosis for those with high-risk or relapsed disease remains poor despite the standard therapies of surgery, radiation, and high dose chemotherapy. We have previously shown that altering levels of specific microRNAs (miRNAs) can improve cellular response to microtubule-targeting agents (MTAs) and that exposure to MTAs results in dramatic changes in microRNA expression. Methods: Libraries of chemically synthesized ncRNA mimics and inhibitors, including both miRNAs and lncRNAs, are screened to identify ncRNAs that regulate neuroblastoma cell viability or sensitize neuroblastoma cells to specific mi-
crotubule-targeting agents. Candidate targets are validated using qRT-PCR, protein quantification, and luciferase reporter assays. The response of neurolastoma cells to perturbations in candidate ncRNA levels is assessed through flow cytometric analysis of cell cycle phase distribution, density and anisotropy of microtubule bundles, and through colony formation and caspase 3/7 activation validated in response xenograft models. Networks of miRNAs, mRNAs and lncRNAs are derived from combining complementary cellular response with potential regulatory interactions. Results: We previously reported the identification of miRNAs and lncRNAs that significantly decrease or increase neuroblastoma cell viability. Here, we extend those observations to drug response. We first demonstrate that the microtubule-targeting agent eribulin has both short-term and long-term effects, as reflected by a significant alteration in microtubule structure in response to high doses for short times and arrest at the G(2)/M phase of the cell cycle in response to low doses for long times. We next show that altering intracellular levels of ncRNAs that sensitize cells to eribulin both alter microtubule density and anisotropy and recapitulate the effect of eribulin treatment. Finally, we show that complementarity of effect between miRNAs and lncRNAs is accompanied by potential regulatory interaction. Conclusions: Taken together, our results suggest that the response of neuroblastoma cells to eribulin is mediated by a regulatory network that includes different coding and non-coding RNA species. While these RNAs may have intrinsic value as biomarkers or therapeutic agents, either individually or in combination, the vulnerabilities that they uncover may be exploited with pathway-specific perturbations. This project was supported by NIH R01 CA129632 and CPRIT Training Grant RP140105.

#3507 PVT1 exons 4A, 4B, and 9 are overexpressed in aggressive prostate cancer, and PVT1 exon 4B may distinguish between indolent and aggressive prostate cancer. Akintunde T. Orunmuyi,1 Adeodat Ilboudo,2 Olabiyi G. Ogun,3 Cuong B. Bach,2 SA. Adebayo,3 Ayo A. Salako,2 EOluwabunmi Olapade-Akintunde,1 University of Ibadan and University College Hospital (UCH), Ibadan, Nigeria; 2Hunter College CUNY, New York, NY; 3University of Ibadan and University College Hospital (UCH), Ibadan, Nigeria; 4Obafemi Awolowo University Teaching Hospital, Ille Ife, Nigeria; 5Hunter College CUNY and Weill Cornell Medicine, New York, NY.

Aggressive prostate cancer (PCA) disproportionately affects males of African ancestry (MoAA). However, the underlying molecular mechanisms are unclear. Chromosome 8q24 is a PCA susceptibility locus that harbors the PVT1 non-coding gene. We previously demonstrated that PVT1 exon 9 may be involved in aggressive PCA. Moreover, using the most recent full-genome variability panel from the 1000 Genomes project, we recently identified a string of 75 SNPs in a PCA patient that seemed to be associated with PCA susceptibility. Here, we report that PVT1 exon 9 and 4B are overexpressed in aggressive prostate cancer tissues compared to indolent prostate cancer tissues. In the 1000 Genomes project, we recently identified a string of 75 SNPs in a PCA patient that seemed to be associated with PCA susceptibility. Here, we report that PVT1 exon 9 and 4B are overexpressed in aggressive prostate cancer tissues compared to indolent prostate cancer tissues. Western Blotting data of the expression in prostate cancer tissues.

#3508 EWS-FLI1 represses Rho-actin signaling via MRTFB/YAP-1/ TEAD perturbation in Ewing Sarcoma. Anna M. Katschnig,1 Maximilian O. Kauer,1 Raphaela Schwentner,1 Eleon M. Tomazou,1 Markus Linder,1 Cornelia N. Mutz,1 Javier Alonso,1 Dave N. Aryee,1 Heinrich Kovar1. 1Children’s Cancer Research Inst., Vienna, Austria; 2Institute of Cancer Research of the Medical University Vienna, Vienna, Austria; 3Unidad de Tumores Infantiles, Instituto de Investigación de Enfermedades Raras, Madrid, Spain.

Ewing Sarcoma (Ews) is an aggressive pediatric bone tumor driven by the aberrant fusion-oncogene EWS-FLI1, which deregulates hundreds of genes by either activation (EWS-FLI1-correlated genes) or repression (EWS-FLI1-anti-correlated genes). Several EWS-FLI1-anticorrelated genes are involved in cytoskeletal processes and typically regulated by Rho/F-actin signaling. The Rho pathway is a crucial regulator of cell movement and cellular plasticity. The activation of Rho triggers G- to F-actin polymerization thereby enabling nuclear translocation of the myocardin-related transcription factors MRTF (MRTF-A) and MRTF-B (also known as MRTFB). MRTFs typically serve as transcriptional co-activators of the transcription factor SRF regulating several cytoskeletal key players. We used the A673/TR/shEFT cell line, harboring a doxycycline inducible sh-EWS-FLI1 plasmid, to interrogate the role of MRTF/B in the Ews gene regulatory network upon EWS-FLI1-high and -low conditions. Strikingly, MRTFB transcriptional activity was overall repressed by EWS-FLI1. Furthermore, knockdown of MRTF/A and MRTF/B inhibited EWS-FLI1-induced transactivation of EWS-FLI1-anticorrelated genes. ChIP-seq revealed a strong overlap of MRTFB and EWS-FLI1 chromatin binding. MRTFB binding was significantly enriched in distal (enhancer) regions of EWS-FLI1-anticorrelated genes, especially upon EWS-FLI1-low conditions. Of note, an overrepresentation of TEAD motifs, but not SRF binding motifs, was observed in these regions suggesting a potential involvement of TEAD transcription factors in the regulation of the MRTFB/ EWS-FLI1 reciprocally regulated targets. In line with this finding, target genes of the mehano sensitive YAP/TAZ/TEAD pathway (CTGF, CYR61, SERPINE1) were found among the MRTFB-bound EWS-FLI1-anticorrelated genes. Genome-wide expression profiling upon combined knockdown of EWS-FLI1 and all four TEADs confirmed that TEAD regulates EWS-FLI1 target genes antagonistically. ChIP-qPCR for selected genes validated this finding demonstrating increased TEAD binding to shared MRTFB/EWS-FLI1 target genes upon decreased EWS-FLI1 occupation. Our data suggest that MRTFB/YAP-1/TEAD directly regulate EWS-FLI1-anticorrelated targets. Since, in addition, EWS-FLI1 is known to indirectly perturb F-actin polymerization, we propose a model of dual EWS-FLI1 driven MRTFB/YAP-1/TEAD perturbation by direct and indirect mechanisms downstream of Rho/F-actin signaling.

#3509 EWS/FLI regulates transcriptional activation via length-dependent GGA microsatellites. Kirsten M. Johnson, Cenny Taslim, Stephen L. Lessnick, Nationwide Children's Hospital, Columbus, OH.

Objective: The purpose of this study is to investigate how EWS/FLI transcriptionally activates gene targets via polymorphic GGA microsatellites. Ewing Sarcoma is a pediatric bone malignancy initiated by a (t(11;22)) chromosomal translocation that produces the EWS-FLI1 oncoprotein. EWS/FLI transcriptionally activates and represses its target genes to mediate oncogenic reprogramming. Expression of its up-regulated targets correlates with EWS/FLI binding to associated GGA microsatellites, which show length polymorphisms. These microsatellites polymorphisms may critically affect EWS-FLI responsiveness of key gene targets. For example, NROBI is necessary for EWS/FLI mediated oncogenic transformation, and we found a “sweet-spot” of 20-25 repeat length as optimal for EWS/FLI mediated transcriptional activity at NROBI through clinical observation and in vitro studies. The mechanism underlying this optimal length is unknown. Methods: We explored the stoichiometry and binding affinity of EWS/FLI to associated GGA microsatellites, which show length polymorphisms. We used the mechano sensitive YAP/TAZ/TEAD pathway (CTGF, CYR61, SERPINE1) as a potential EWS-FLI1-anticorrelated genes. ChIP-seq revealed a strong overlap of MRTFB and EWS-FLI1 chromatin binding. MRTFB binding was significantly enriched in distal (enhancer) regions of EWS-FLI1-anticorrelated genes, especially upon EWS-FLI1-low conditions. Of note, an overrepresentation of TEAD motifs, but not SRF binding motifs, was observed in these regions suggesting a potential involvement of TEAD transcription factors in the regulation of the MRTFB/ EWS-FLI1 reciprocally regulated targets. In line with this finding, target genes of the mehano sensitive YAP/TAZ/TEAD pathway (CTGF, CYR61, SERPINE1) were found among the MRTFB-bound EWS-FLI1-anticorrelated genes. Genome-wide expression profiling upon combined knockdown of EWS-FLI1 and all four TEADs confirmed that TEAD regulates EWS-FLI1 target genes antagonistically. ChIP-qPCR for selected genes validated this finding demonstrating increased TEAD binding to shared MRTFB/EWS-FLI1 target genes upon decreased EWS-FLI1 occupation. Our data suggest that MRTFB/YAP-1/TEAD directly regulate EWS-FLI1-anticorrelated targets. Since, in addition, EWS-FLI1 is known to indirectly perturb F-actin polymerization, we propose a model of dual EWS-FLI1 driven MRTFB/YAP-1/TEAD perturbation by direct and indirect downstream of Rho/F-actin signaling.
Molecular and Cellular Biology / Genetics: Oncogenic Transcription Factors

#3510 A role for the Ewing's sarcoma breakpoint protein EWS in ERG-induced prostate tumorigenesis. Vivekananda Kedage, Nagarathinam Sellaj, Soumen Chakraborty. Indiana University, Bloomington, IN.

The TMPRSS2-ERG gene fusion occurs in one-half of prostate tumors and results in expression of ERG, an ETS family transcription factor that promotes prostate tumorigenesis. Another 5-10% of prostate tumors have similar rearrangements that result in over-expression of other ETS family members such as ETV1, ETV4, and ETV5. However, not all ETS family members are oncogenic and normal prostate cells express at least 15 of these other ETS factors. Therefore, it is important to understand mechanisms that differentiate oncogenic ETS factors from non-oncogenic ETS factors. We have recently discovered that ERG, ETV1, ETV4, and ETV5, and no other ETS factor can directly bind the protein EWS. This is striking, as EWS is fused to various ETS factors in the chromosomal rearrangements that cause Ewing's sarcoma. We demonstrate that fusion of EWS to any ETS protein is sufficient for that protein to function like ERG in prostate cells. Furthermore, the EWS-ERG interaction is required for ERG to activate an oncogenic gene expression program and for ERG-mediated tumorigenesis. These findings reveal new mechanisms for prostate cancer and Ewing's sarcoma. In prostate cancer, aberrant over-expression of an ETS factor that naturally interacts with EWS, brings EWS to ETS-bound regions. In Ewing's sarcoma this interaction is forced by the presence of an EWS/ETS fusion protein. Therefore, this model predicts that treatments that target EWS function would be effective in both types of cancer.

#3512 Ikaros regulation of the BCL6/BACH2 axis and its clinical relevance in acute lymphoblastic leukemia. Chunhua Song, Zheng Ge, Jianyong Li, Baoan Chen, Elanora Dovat, Katarina Dovat, Jonathon Payne, Sinisa Dovat. Pennsylvania State University College of Medicine, Hershey, PA; Zhejiang Hospital, Medical School of Southeast University, Nanjing, China; The First Affiliated Hospital of Nanjing Medical University, Nanjing, China.

Ikaros regulates expression of the BCL6/BACH2 axis in B-ALL. High BCL6 and low BACH2 expression is associated with prostate cancer and Ewing’s sarcoma. In prostate cancer, aberrant over-expression of an ETS factor that naturally interacts with EWS, brings EWS to ETS-bound regions. In Ewing’s sarcoma this interaction is forced by the presence of an EWS/ETS fusion protein. Therefore, this model predicts that treatments that target EWS function would be effective in both types of cancer.

#3513 Decoding the role of myocyte enhancer factor 2C in chronic myeloid leukemia disease progression. Soumen Chakraborty. Institute of Life Sciences, Bhubaneswar, India.

Chronic myeloid leukemia (CML) is a myeloproliferative disorder of hematopoietic stem cell and is marked by the presence of the Philadelphia chromosome, a reciprocal translocation occurring between the long arm of chromosome 9 and 22 resulting in the formation of a fusion BCR-ABL1+ oncogene which encodes a constitutively active non-receptor tyrosine kinase. Clinically, the disease progresses through three phases: an initial chronic phase, accelerated phase and terminal blast phase, which is marked by increased production of immature myeloid precursor cells. Earlier we have shown that BCR-ABL mediates repression of miR-223 results in the activation of me2C and ptbp2 in chronic myeloid leukemia. Transcription factor ME2C, required for cell survival and proliferation, is important for lymphopoiesis, and its ectopic expression in myeloid progenitors antagonizes myelopoiesis. We reported that ME2C expression increases as the disease progresses from chronic phase to blast phase and by knocking down ME2C in a CML cell line we showed that it negatively correlates with the CEBA expression, a granulocytic transcription factor. Ima-tinib, the drug of choice for CML, abrogates ME2C expression and reverses CEBA repression both in the cell line and the primary cells. In the present study we observed that when the cells were treated with anisomycin it degraded ME2C expression in 16hrs which imatinib can achieve after 24hrs. Investigators have demonstrated that anisomycin acts as a potent signaling agonist, synergizing with growth factors and phorbol esters to superinduce immediate-early genes such as c-fos, fosb, c-jun, Junb, and JunD. However here blocking the p38 pathway with inhibitors didn’t reverse the inhibition suggesting that these pathways may not be involved in the anisomycin mediated ME2C degradation in CML. Me2C gene consists of three alternative exons, α1/α2a, skipping exon β and β’ and splice site γ. In order to characterize the role of me2C gene in CML, first we investigated the different isoforms of me2C in CML cell line (KCL22) by amplification of the whole me2C gene and cloning the same in a TOPO vector. Several clones were checked and sequenced. Two different types of isoforms (α1’ β γ’ and α1’ β’ γ) were found to coexist in KCL22 cells along with an exclusion of 9 bases (AACACAGGT) from the splice junction of exon 4 and 5, which was not reported earlier. However, K562 cells along with KYO-1 and LAMA-84 showed the presence of 9 bases. Nine base pair deletion was also observed in CML patient samples (both CP and BC). Interestingly sequencing of the CML patient samples (both CP and BC) showed these deletions and in patients with high levels of BCR-ABL showed the presence of 9 bases. The different isoforms were transduced in mouse lineage negative bone marrow cells and also transplanted in mice either alone or in combination with BCR-ABL to study the effect of the isoforms in disease progression, the results of which will be discussed.

#3514 Assessing the role of CREB in fibrolamellar hepatocellular carcinoma with PRKACA-DNAJB1 fusion protein. Anju Karki, Michael J. LaQuatta, Amanda M. Dios, Zhaozhe Sade-Savelkoul, Khushboob handi 1Boston Children’s Hospital, Harvard Medical School, Boston, MA; 2Mass General Institute for Neurodegenerative Disease, Massachusetts General Hospital, Harvard Medical School, Boston, MA.

Introduction: Fibrolamellar Hepatocellular Carcinoma (FLHCC) is a rare form of liver cancer that occurs predominantly in adolescents or young adults. Curing or prolonging the lives of patients with FLHCC is extremely challenging. Despite aggressive surgical resections of primary tumors as well as metastatic lesions, outcomes tend to be poor due to lack of effective chemotherapy. Previous studies have demonstrated the presence of PRKACA-DNAJB1 fusion protein in the majority of FLHCC patient samples. DNAJB1 is a heat shock protein and PKA is a kinase that phosphorylates numerous substrates including cAMP-regulatory element-binding protein (CREB), a proto-oncogenic transcription factor. Therefore, we sought to examine whether the presence of the fusion protein in FLHCC is associated with increased CREB phosphorylation. Methods: We analyzed tumor and matched non-neoplastic liver tissue from 7 pediatric patients with a pathologic diagnosis of FLHCC. We assessed the presence of the PRKACA-DNAJB1 fusion protein using PKA antibody, as well as total CREB and phosphorylated (p-CREB) using Immunoblot analyses with specific antibodies. Results: Immunoblot analysis using anti-PKA antibody confirmed the occurrence of PRKACA-DNAJB1 fusion transcripts in 6/7 (86%) FLHCC tumor samples. Immunoblot analyses of the 6 patients with the fusion protein revealed a trend towards a decrease in p-CREB expression in tumor samples compared to non-neoplastic tissue controls (p=0.15). Conclusions: The pattern of p-CREB in FLHCC with PRKACA-DNAJB1 fusion protein suggests that the fusion protein does not exert its proto-oncogenic effects through the transcriptional activity of CREB.

#3515 LHX9 is a novel oncogene bypassing KRAS addiction. Seu Hong Ly, Chao Dai, Andrew L. Hong, Nina Ilic, Elsa B. Krali, William C. Hahn. Dana Farber Cancer Institute/Broad Institute of Harvard and MIT, Boston, MA; Boston Children’s Hospital/Dana Farber Cancer Institute/Broad Institute of Harvard and MIT, Boston, MA.

Background: Oncogenic mutations of RAS are detected in approximately 30% of human cancers. KRAS is highly mutated in pancreatic, colorectal and lung cancers. Direct therapeutic targeting of Ras and its membrane association has been challenging due to high affinity of GTP to Ras and unexpected mechanism of alternative post-translational modification. While few inhibitors of downstream RAS effectors - MAPK and PI3K pathways - show some clinical efficacy, they are complicated by complex feedback loops, and as single agents are not effective in KRAS-mutant cancers. Combination therapies may be promising yet limited by narrow therapeutic window. Identification of alternative strategies to
directly inhibiting RAS and MAPK/PI3K pathways is key to address this unmet need. Methods: To this end, we performed a genome-scale open reading frames screen to identify genes capable of restoring viability to KRAS-dependent cells following KRAS suppression. We tested the top 5 standard-deviation hits in low-throughput manner. One of the top hits included LIM homeobox 9 (LHX9), a homeobox family transcription factor implicated in growth and metastasis of pancreatic cancer cells. While LHX9 is amplified in several cancers, little is known regarding its roles in cancers. We used hypothesis-driven as well as unbiased approaches including RNA-seq, ChiP-seq, and IP-mass spectrometry to investigate the basis of LHX9-mediated bypass of KRAS dependency. Results: We showed that LHX9 rescued KRAS suppression in multiple cell lines as well as xenograft. LHX9 overexpression substituted for KRAS in KRAS-driven xenograft. Moreover, in activated-MEK-overexpressing HA1E cells, LHX9 formed tumors as robustly as myristoylated AKT. LHX9 rescued KRAS suppression by both restoring KRAS-dependent pathways and activating KRAS-independent pathways. First, LHX9 reactivated the main KRAS effectors - MAPK and PI3K pathways and conferred resistance to MEK inhibitor Trametinib. Second, using ChiP- and RNA-seq, we observed LHX9 binding to promoters/enhancers of genes whose expression was regulated by KRAS, particularly YAP1. Third, LHX9 increased expression and activation of KRAS-independent genes, including STAT3. Conclusions: Here, we identified LHX9 as a novel bypass of KRAS addiction. Multiple unbiased approaches revealed at least three mechanisms by which LHX9 rescued KRAS suppression. Our findings contribute to our understanding of KRAS biology. Further investigation of downstream effectors of LHX9 may highlight potential novel therapeutic targets for KRAS-dependent cancers.

#3516 RUNXI controls EGFR signaling pathway in non-small cell lung cancer cells. Akihiko Matsuo. Graduate School of Medicine, Kyoto University, Kyoto, Japan.

Epidermal growth factor receptor (EGFR) is a promising target for anticancer therapy for non-small lung cancer (NSCLC). Mitogen-inducible gene 6 (Mig6) is known to be a negative feedback regulator of EGFR. Mig6 inhibits EGFR kinase activity and promote wild-type EGFR trafficking to the degradation pathway. Down-regulation of Mig6 is found in poor prognostic NSCLC. Previous gene array analysis results suggested that Mig6 is downregulated by runt-related transcription factor 1 (RUNXI), yet the detailed relationship between RUNXI and Mig6 in NSCLC has not been elucidated. Herein we demonstrate that RUNXI inhibition is effective for wild-type EGFR NSCLC. Tet-inducible shRNA mediated RUNXI knockdown in wild-type EGFR cell line LUS99A led to the increased expression of Mig6 and decreased expression of phosphorylated form of EGFR as well as deactivation of EGFR/ERK pathway. RUNXI knockdown subsequently induced apoptosis in LUS99A cells. Silencing of Mig6 in LUS99A cells promoted the proliferation of these cancer cells and increased expression of phosphorylated form of EGFR, highlighting the importance of this EGFR signaling cascade in the maintenance of wild-type EGFR NSCLC. Indeed, RUNXI overexpression promoted cell proliferation and decreased expression of Mig6 and increased phosphorylated form of EGFR. Notably Mig6 knockdown in RUNXI knockdown LUS99A cells increased their proliferation rates, indicating that RUNXI is an important role in the migration of RUNX1-mediated RUNXI pathway. We next examined the efficacy of a novel small molecule which specifically binds and inhibits the RUNXI (We named it as CM). CM was drastically effective for wild-type EGFR NSCLC cell lines A549 and LUS99A which are naturally resistant to EGFR Tyrosine kinase inhibitor gefitinib. In addition, CM suppressed tumor growth of xenotransplanted A549 cells in immune-deficient mice in vivo. Our study underscores the importance of RUNXI inhibition therapy in the management of gefitinib-resistant NSCLC patients.

#3518 Brg1 plays a critical role in PanIN formation through regulating Sox9 expression. Motoyuki Tsuda,1 Akihisa Fukuda, 1 Satoshi Ogawa, 1 Kenji Masuo,2 Norihiro Goto,1 Yukiko Hiramatsu,1 Yu Mut,1 Kozo Ikuta,1 Yoshito Kimura,1 Yoshimwe Matsumoto,1 Yutaka Takada,1 Takuto Yoshioka,1 Takahisa Maruno,1 Haruhiko Akiyama,2 Kyosaki Takao,1 Shinji Uemoto,1 Tsutomu Chiba,1 Hiroshi Seno1. 1Kyoto University, Kyoto, Japan; 2Gifu University, Gifu, Japan.

Background: Mutations of SWI/SNF chromatin remodeling complexes are one of the hallmarks of human pancreatic ductal adenocarcinoma (PDAC). Brahma related gene 1 (Brg1) is a catalytic ATPase subunit of SWI/SNF complexes and Brg1 is silenced in about 10% of human PDAC. Recent study revealed that Brg1 inhibits formation of intraductal pancreatic mucinous neoplasm (IPMN) and IPMN-derived PDAC in the context of oncogenic KRAS and that IPMNs originate from adult pancreatic ductal cells, demonstrating a tumor suppressive role of Brg1. However, the role of Brg1 in the formation of pancreatic intraepithelial neoplasm (PanIN) from acinar cells and PanIN-derived PDAC is not fully understood. Aim: To investigate the functional role of Brg1 in the formation of PanIN.Methods and Results: We generated Ptf1a-Cre;KrasG12D;Brg1f/f;Sox9OEmice, inwhichSox9isconstitutivelyexpressedinRUNX1knockdownLU99Acellsincreasedtheirproliferationrates,indicatingthatRUNX1overexpressionpromotedcellproliferationanddecreasedexpressionofEGFRsignalingcascadeinthemaintenanceofwild-typeEGFRNSCLC.Indeed,ADMformationwasmarkedlyreducedintheabsenceofBrg1andmore,weconfirmedthatSox9expressionisdownregulatedinBrg1-depletedacinarcells. Furthermore, we confirmed that Sox9 expression is downregulated in Brg1-depleted ADMS/PanINs compared with Brg1-retained ADMS/PanINs by immunohistochemistry. To determine the functional relationship between Brg1 and Sox9, we generated Ptf1a-Cre;KrasG12D;Brg1f/f;Sox9OE mice, in which Sox9 is constitutively overexpressed. Remarkably, Sox9 overexpression canceled the phenotype of decrease in PanIN formation by Brg1 deletion. Furthermore, we investigated whether Brg1/Sox9 axis is observed in human PanIN-derived PDACs. We performed immunohistochemistry of Brg1 and Sox9 in human PanIN-derived PDACs. We found that low expression of Brg1 and high Sox9 expression had low Sox9 expression. Conclusions: Our results suggest that Brg1 plays a tumor-supportive role in acinar cell-derived PanIN formation in part through regulating Sox9 expression positively. Our data underscore a cell-type specific, context-dependent role of Brg1 in the initiation of PDAC formation.
#3519 TGF-β pathway alteration in pancreatic neuroendocrine tumors: characterization of a novel SMAD3 translocation

Emanuela Brunetto,1 Greta Grassini,1 Valeria De Pacsali,1 Anna Talarico,1 Francesca Invernizzi,2 Michaela Bowden,2 Massimo Loda,2 Luca Albarello,1 Massimo Falconi,1 Lorenza Pecchiari,1 Maria G. Cangi,1 Claudio Doglioni,1 San Raffaele Scientific Institute, Milano, Italy; 2Dana-Farber Cancer Institute, MA.

Pancreatic neuroendocrine tumors (PanNETs) are the second most common malignancy of the pancreas, and the only curative option is represented by surgery. PanNETs can be classified as well- or poorly-differentiated, based on histology. Poorly-differentiated neuroendocrine carcinomas (NECs) represent less than 10% of cases, but are highly malignant and associated with poor prognosis, and, most importantly, their clinical management is based on insufficient data on NEC genetic features. In order to widen our knowledge of PanNET genetic alterations, we performed RNAseq analysis using Illumina NextSeq platform of a group of 18 PanNETs and 2 NECs. TopHat-Fusion algorithm identified, among others, a fusion involving SMAD3 transcription factor and CCDC149; the alteration of SMAD3 in a poorly differentiated NEC was particularly interesting since SMAD3 is involved in TGF-β signaling, which has an oncogenic role in malignant cells. The SMAD3-CCDC149 fusion was confirmed in the index case by RT-PCR using primers spanning the breakpoint, followed by Sanger sequencing. The fusion was also detected by FISH analysis performed on both FFPE and frozen samples. Both by FISH analysis and Sanger sequencing we identified two other poorly-differentiated NEC samples characterized by the presence of the SMAD3-CCDC149 fusion. We explored the impact of dysregulation of SMAD3 in PanNETs. The results of our study show that the SMAD3-CCDC149 fusion results in increased p27/CDKN1B protein that mediates cell cycle exit by terminally differentiating cell-like in vitro, and increased activation of GATA3, WT1 and HNF4A, decreased MYC transcription and p53 protein levels. Our findings lead to the identification of a new fusion protein, which might allow the identification of a new therapeutic target.

#3520 PBRM1 inactivation in renal cell cancer alters master transcription factor hub composition to repress instead of activate epithelial-differentiation pathways. Xiaorong Gu, Francis Enane, Reda Mahfouz, Tomas Radiyovevich, Bartlomiej Przychodzen, Yvonne Parker, Daniel Lindner, Brian Rini, Yogen Saundra Ghosh, Addanki P. Kumar. University of Texas Health Science Center at San Antonio, San Antonio, TX.

PBRM1, a cohesin subunit involved in DNA replication and repair, was recently identified as a tumor suppressor functionally equivalent to PTEN. PBRM1 loss in RCC thus alters the expression of master transcription factors to repress instead of activate epithelial-differentiation, an effect that can be reversed pharmacologically for novel, p53/p16-independent differentiation-restoring therapy.

SIRT1, a nicotinamide adenine dinucleotide (NAD)-dependent deacetylase, is a member of multigene family of Sirtuins. Traditionally SIRT1 is a known player in enhancing longevity. SIRT1 can target both histone and non-histone proteins to regulate diverse activities including cellular stress resistance, genomic stability, energy metabolism and tumorigenesis. Disruption of SIRT1 in the prostate results in the formation of prostate intraepithelial neoplasia (PIN) lesions, suggesting a role for SIRT1 in the development of PIN, a precursor lesion of prostate cancer (PCA). Paradoxically, an oncogenic role for SIRT1 was first reported as evidence of development of micro-invasive prostate carcinomas in Pten−/−/Sirt1tg mice. Therefore, SIRT1 may possess both oncogenic and tumor suppressor activities in a context-dependent manner and its role in human cancer remains controversial. To address these paradoxical findings, we examined the role of SIRT1 in prostate pathogenesis using stably silenced for SIRT1 prostate cancer cell lines. Silencing SIRT1 in androgen responsive LNCaP cells resulted in (i) morphological changes indicative of clustering and epithelial mesenchymal transition (EMT); (ii) significant reduction in their ability to form colonies on soft agar; and (iii) increased autophagic flux. Similarly, silencing SIRT1 resulted in reduced proliferative, colony forming and migratory ability of these cells. Remarkably, SIRT1 KD cell lines showed decreased expression of AR and its target genes including PSA, TMPRSS-2, FKBP-5 and PMEPA1. Interestingly, SIRT1 KD reduced PSA-luciferase activity under both normal physiological and androgen deprivation growth conditions with no significant effect on nuclear or cytoplasmic levels of AR. Moreover, SIRT1 KD significantly increased AR sensitivity to growth under androgen deprivation conditions. Intervention with resveratrol (RES, known SIRT1 activator) reduced incidence of HGPIN in prostate specific PTEN KO mouse model with no significant differences in the expression of AR or SIRT1. Consistent with these in vivo observations, SIRT1 had no significant impact on RES-induced growth inhibition. Taken together, these data indicate that SIRT1 can function non-canonically to provide a context-dependent, independent of classical AR signaling. Our study demonstrates that SIRT1 may not play an essential role in mediating RES-induced tumor growth inhibition and that SIRT1 may confer resistance to androgen deprivation therapy and sustains cell survival, suggesting that combination of SIRT1 inhibitors and ADT might be a potential strategy for advanced PCA treatment. Supported by CPRIT RP 150166 and NCI CA 137158 (APK).

#3522 Structural characterization of androgen receptor variant 7 in prostate cancer. Fatma Özgün,1 Zeynep Kaya,1 Halil Bayraktar,2 Selen Manioglu,2 Doğançan Özturan,1 Nathan Lack1. 1Koç University School of Medicine, Istanbul, Turkey; 2Koç University Department of Chemistry, Istanbul, Turkey.

Prostate cancer is an extremely common disease that affects one in every seven men in their lifetime. The standard care for late-stage cancer is designed to inhibit the activation of androgen receptor (AR). While this therapeutic approach is initially efficient, the cancer almost always develops resistance and gives rise to castration-resistant prostate cancer (CRPC). When therapy fails, the median survival of patients who suffer from CRPC is 12-16 months. It is critical to understand the intratumor of CRPC better to ameliorate the outcome of late-stage prostate cancer patients. AR is a transcription factor that consists of an N-terminal domain (NTD), a DNA binding domain (DBD) and a ligand binding domain (LBD). Upon activation by androgen, an intramolecular interaction between NTD and LBD occurs. The AR translocates into the nucleus where it
forms a homodimer. It binds to the promoter and enhancer elements of the AR target genes and triggers gene transcription. It has been demonstrated in many clinical studies that AR is important for the progression of prostate cancer including CRPC. In CRPC, although androgen production and binding is inhibited, how the AR can still be activated is a fundamental question to be answered. One of the several different mechanisms proposed is the alternative splicing of the AR generating truncated AR variants that lack LBD. These variants do not require androgens to be activated and they are intrinsically resistant to clinically approved therapeutics. Despite the fact that the AR variants have been shown to be critical in late-stage prostate cancer, the mechanism of gene transcription initiation by the AR variants is not well-known. We propose to characterize the mechanism of the AR variant activation. Since ARV7 is the most commonly observed variant, we utilize ARV7. We develop a FRET based methodology to identify how ARV7 dimers form and to test if full-length AR is necessary for transcriptional activation mediated by ARV7. We are able to demonstrate possible intermolecular interaction between the full length AR and ARV7 measuring the FRET intensity between the fluorophores attached to the N and C termini of two proteins. FRET measurements are analyzed by tracking single cells and recording the FRET intensities during the process. Our preliminary data suggest that the full-length AR and ARV7 may interact in the presence of androgen. ARV7 is always localized in the nucleus whereas the AR requires androgen to be activated and translocates into the nucleus. Being in close proximity, putative interaction between the AR and ARV7 occurs in the nucleus. Additionally, we identify and DRD point mutants to determine the determinants of intermolecular interaction between them. Supporting the significance of ARV7 in prostate cancer, our results clarify the dimerization process. It gives an opportunity to test clinical drugs currently in development to effectively inhibit ARV7 activation.

#3523 Arginylationtransferaseas a novel suppressor of prostate cancer metastasis. Michael Birnbaum, Ahkilesh Kumar, William Morgan, Fangliang Zhang. Univ.of Miami, Miami, FL

Arginylation is a post-translational modification wholly mediated by Arginylation transferase 1 (Ate1). Our studies have shown that Ate1 and arginylation are upregulated during stress conditions. In addition, it was recently shown that Ate1-deficient fibroblasts demonstrate cancer-like characteristics including genomic instability and mutagenesis. While Ate1’s role in cancer is poorly understood, our preliminary studies suggest that Ate1 is an important regulator of metastasis and cancer progression in prostate cancer models. In this study, our data suggests that Ate1 is essential for normal cell stress response in conditions including cellular oxidant, apoptosis inducing drugs, and radiation. Further, we show that a loss of Ate1 in Lncap prostate cancer cells increases anchorage-independent growth in the soft-agar assay, and that a loss of Ate1 in PC-3 prostate cancer cells increases matrigel invasion in the Boyden chamber assay. To text how Ate1 affects metastasis in vivo, PC-3 cells with Ate1 or control shRNA were orthotopically implanted into the prostates of immunocompromised mice to observe metastasis. While very little metastasis was observed in PC-3 control cells, PC-3 cells with reduced Ate1 achieved much higher levels of metastasis. In conclusion, our data suggests that the loss of Ate1 in prostate cancer promotes cancer progression phenotypes and cell survival. In future studies, we will examine if Ate1 levels in human prostate cancers in prostate cancer progression.

#3524 HOXB13 collaborates with AR to alter the cellular phenotype of prostate epithelial cells through cytokertan 14 upregulation. Dorhuny Johng, Charles M. Ewing, William B. Isaacs. Johns Hopkins University, Baltimore, MD.

Prostate cancer (PCa) is a commonly diagnosed disease with one of the highest heritability estimates among cancers. Among germline variations that account for PCa heritability, a recurrent mutation (G84E) in HOXB13 is associated with a 3 to 6 fold increase in PCa risk. HOXB13 is a prostate-specific transcription factor that plays a role in prostate development. Other mutations in HOXB13 in PCa patients have further implicated HOXB13 in PCa biology. The goal of our study is to investigate HOXB13 in cell line models of normal prostate tissue to examine the role of HOXB13 in driving cellular differentiation and/or transformation. To this end, we utilized 957E/hTERT, a cell line derived from a radical prostatectomy specimen, as a model for normal prostate epithelial cells. HOXB13 WT or G84E was stably expressed in 957E/hTERT with a lentivirus system in the presence and absence of exogenous AR. HOXB13 caused a morphological change whereby an epithelial morphology transitioned to a fibroblastic-like structure. Cells adopted elongated bodies with a frequent appearance of lamellipodia. The morphologic conversion was transient in AR- cells but was maintained in AR+ cells. Analyses of epithelial cell markers using qPCR revealed a change in the epithelial cell marker profile (AR+: no change p63, CD49f ↓, K5 ↓, K14 ↓, K18 ↓, AR+: no change p63, CD49f, K5, K14, K18 ↓). K14 upregulation was striking with a >10 fold increase. AR alone could upregulate K14 to a level comparable to HOXB13-induced K14 in AR- cells, which was surprising since AR mainly functions in luminal cells where K14 expression is turned off. Coexpression of HOXB13 and AR had a synergistic effect on K14 upregulation. Despite the morphologic and K14 change suggestive of EMT, vimentin was downregulated by HOXB13 in AR- and AR+ cells. In vitro growth assays showed that HOXB13 reduced the proliferation rate of AR+ cells but not AR- cells. Gap closure assays revealed that HOXB13 does not induce a qualitative change in migration. Similar results were obtained with G84E models. Our study demonstrates that HOXB13 may have a potential function in dictating a luminal epithelial phenotype through EMT. This may have important implications for PCa biology. HOXB13 is a promising therapeutic target as potential drug to induce EMT in PCa cells.

#3525 PDEF promote prostate cancer luminal/epithelial differentiation and inhibit tumor progression. Fengtian Wang,1 Sweaty Koul,1 Prakash Srinivasan Timaru Shannahmugam,1 Qin Dong,2 Hari K. Koul2. Louisiana State University Health Sciences Center-Shreveport, Overton Brooks VA Medical Center, Shreveport, LA; 2Louisiana State University Health Sciences Center-Shreveport, Overton Brooks VA Medical Center, Feist Weiller Cancer Center, Shreveport, LA.

Conventional therapies produce a high rate of cure for patients with localized prostate cancer (PCa), but there is no effective treatment for castration resistant metastatic PCa. Transcription factors by association with enhancer and super enhancer elements are key drivers of cell identity. Our previous studies have shown that Sam Pointed Domain Ets Transcription Factor a.k.a. Prostate Derived Ets Factor (SPDE/PDEF), inhibits cell migration, invasion and clonogenic activity in PCa cells and there is a graded loss of PDEF with increasing Gleason Score in PCa patient samples. PDEF has been reported to be one of the cell identity transcription factors in LNCaP cells. We proposed that PDEF functions as a putative tumor metastasis suppressor. Others have shown an increase in Twist1, a BHLH transcription factor, was positively correlated with Gleason Score in PCa patients. PDEF has been reported to be one of the epithelial/luminal differentiation genes in PCa. PDEF expression is limited to epithelial/luminal cells of the prostatic glands. We observed that expression of Twist1 was down regulated in PC3 cells following PDEF expression. Analysis of gene expression data from our microarray studies revealed that PDEF re-expression was associated with negative enrichment of gene sets involved with cell migration and positive enriched of gene sets involved with epithelial/luminal differentiation. Chip-seq analysis revealed binding of PDEF to KRAB/16 promoter region. These data suggest that PDEF inhibits core metastasis related genes through promoting a program of luminal/epithelial differentiation. In clinical samples of PCa, expression of PDEF was inversely associated, while expression of Twist1 was positively associated with Gleason grade. PDEF and Twist1 was able to predict patient survival, moreover integrated PDEF and Twist1 expression was able to better predict PCa patient survival as compared to PDEF or Twist1 alone. PDEF inhibits cell migration and metastasis in part by down-regulating Twist1 level and promoting luminal/epithelial differentiation. Loss of PDEF combined with gain of Twist1 expression may serve as a potential biomarker set for distinguishing lethal PCa from indolent disease. Additional studies are underway to gain further insights into the role of PDEF in PCa progression and metastasis. Acknowledgement: FWCC support and Chair commitment funds (Koul H).

#3526 The expression of MLK, a growth regulator of triple-negative breast cancer, is regulated by p53. Lakshmi Reddy Bollu, Powel H. Brown, Abhijit Mazumdar, Dekuang Zhao, Yanxia Ma. MD Anderson Cancer Center, Houston, TX.
Background: Triple negative breast cancer (TNBC) is the most aggressive form of breast cancer with poor prognosis. Due to frequent distant metastasis and lack of successful targeted therapies, the overall survival rate in TNBC patients is significantly lower than estrogen receptor positive (ER) and HER2 positive breast cancers. To identify potential druggable targets, previously, we performed gene expression analysis and identified genes that are highly expressed in TNBC. Through these studies, we discovered that the expression of maternal embryonic leucine zipper kinase (MELK) is highly elevated in TNBCs and correlated with p53-mutation status and metastasis-free survival. Inhibition of MELK reduced the growth and invasiveness of p53 mutant breast cancer cells. Methods: In this study, we analyzed the association of MELK expression with p53 status using publicly available datasets, and examined the role of wild-type and mutant P53 in regulating MELK expression. MELK expression at mRNA and protein levels were determined through Q-RT-PCR and western blotting analysis respectively. The association of p53 and MELK expression was determined using Oncomine analysis. We also investigated the effect of p53 knock-down and overexpression on MELK expression using Q-RT-PCR, western blotting and promoter luciferase assays. Results: Analysis of publicly available datasets revealed that MELK expression is highly elevated p53-mutant breast cancer independent of estrogen receptor status. Consistent with observation, high MELK expression was found in p53-mutant cells compared to p53 wild-type cells. Through luciferase, western blotting and Q-RT-PCR assays, we discovered that the increased expression of MELK in TNBC cells is due to inactivation of p53 wild-type function. Consistently, knockdown of p53-mutants in p53-null cells increased MELK expression through dominant-negative effect. In contrast, knockdown of p53-mutants or overexpression of p53-mutants in p53-null cells did not alter MELK expression. Finally, through promoter deletion studies coupled with luciferase studies, we identified a potential p53-response region in MELK promoter. Conclusion: Our results suggest that the expression of MELK, a critical regulator of growth and invasion of TNBCs, is regulated by the tumor suppressor gene, p53 wild-type. Inactivation of p53 wild-type either gene deletion or mutations induces the expression of MELK. These results suggest that MELK is a promising target for the treatment of women with p53-mutant TNBC. #3527 Clarification of the molecular mechanism for cancer development in Xp11.2 translocation renal cell carcinoma. Masaya Baba,1 Ying Huang,2 Takanobu Motoboshi,2 Hisashi Hasumi,1 Yukiko Hasumi,3 Mitsuko Furuya,4 Yoji Nagashima,5 Masahiro Yao,4 Tomomi Kamba,1 Laura S. Schmidt,2 W. Marston Linehan2. 1Kumamoto University, Kumamoto, Japan; 2National Cancer Institute, National Institutes of Health, Bethesda, MD; 3Yokohama City University, Yokohama, Japan; 4Tokyo Women’s Medical University, Tokyo, Japan; 5Leidos Biomedical Research, Inc., Frederick National Lab, Frederick, MD.

Xp11.2 translocation renal cell carcinoma (Xp11.2 TRCC) is a newly defined subset of RCC, which have chromosomal translocations involving the TFE3 transcription factor at Xp11.2. All translocations seen in Xp11.2 RCC, including PRCC-TFE3, PSF-TFE3, ASPL-TFE3, CTLC-TFE3 and NONO-TFE3 produce chimeric TFE3 genes, which encode fusion TFE3 proteins retaining the basic helix-loop-helix leucine zipper (bHLH-LZip) structure for DNA binding, suggesting that these fusion TFE3 proteins function as oncogenic transcription factors. To clarify the molecular mechanism for Xp11.2 RCC development, we have established cell lines, which express fusion TFE3 proteins (NONO-TFE3, PRCC-TFE3, PSF-TFE3) in a doxycycline dependent manner. Genes upregulated universally in all fusion TFE3 cell lines upon doxycycline addition were identified. In addition, we have generated an Xp11.2 translocation RCC mouse model, in which a floxed Neomycin cassette followed by a PRCC-TFE3-CDNA is inserted in the Rosa26 locus. By crossing these mice with cadherin 16-Cre transgenic mice, we can induce kidney specific PRCC-TFE3 expression resulting in RCC development. We will report and discuss the role of fusion TFE3 target genes in our mouse model and in clinical samples of Xp11.2 RCC. Funded in part by FNLCR Contract HHSN26120080001E to LSS.

#3528 PTCCH53 as a potential secondary modifier in Li-Fraumeni syndrome. Anna J. Pan,1 Benjamin Brew,2 Lauren Erdman,1 Anna Goldenberg,3 David Malkin2. 1The University of Toronto, Toronto, Ontario, Canada; 2The Hospital for Sick Children, Toronto, Ontario, Canada.

Germline mutations in the TP53 gene have been established as the underlying genetic event in Li-Fraumeni syndrome (LFS), predisposing affected families to a wide spectrum of early onset cancers. Despite rapid progress in elucidating the role of wild-type p53 in maintenance of genome stability, and mutant p53 in cellular transformation, much of the molecular basis underlying LFS remains unclear. Lack of predictability in age of onset, type(s) of cancers, and likelihood of subsequent malignancies prompts further research to examine secondary modifiers to TP53. In the Li-Fraumeni syndrome mouse model (a.k.a PTCHD4 or PCH53) is a repressor of canonical Hedgehog signaling that is also described to be transcriptionally activated by p53. Furthermore, our group has identified significant hypomethylation at the PCH53 locus in a mutant TP53 LFS cohort, compared to TP53 wildtype carriers. These results suggest a potential role of PCH53 in modifying LFS phenotype. The study examines the expression of p53-mutants in p53-null cells did not alter MELK expression. Furthermore, mutant TP53 fibroblasts have overall lower PCH53 transcripts compared to wild-type TP53 fibroblasts. Fold-change increase in PCH53 expression was detected upon doxorubicin and γ-irradiation induced activation of the p53 protein. These results suggest that induction of p53 via DNA damage activates a signaling cascade involving PCH53 up-regulation. Further experiments will examine the functional consequences to PCH53 de-regulation via siRNA knockdown and CRISPR knockout models, and will examine possible modifying effects of PCH53 on the functional phenotype (cell viability, colony formation and migration potentials) of cell lines harboring different p53 mutants. Elucidating the functional profile of PCH53 in the context of Li-Fraumeni syndrome will contribute to understanding the complex molecular basis underlying this cancer predisposition syndrome.

#3529 Investigating the in vivo role of the EHF transcription factor in intestinal epithelial differentiation. Camilla M. Rehorst, Ian Y. Luk, Rebecca Moghaddam, Mercedes Davalos-Sala, Amardeep S. Dhillon, John M. Mariadason, Olivia Newton-John Cancer Research Institute, Heidelberg, Australia.

Objective: Poor tumor differentiation status is associated with worse patient outcome in colorectal cancer. However, the molecular basis for loss of differentiation in colon cancer is not well understood. We have found that the transcription factor Ets homologous factor (EHF) is highly expressed in the normal human and mouse colonic epithelium and is down-regulated in poorly differentiated colorectal cancer cell lines. The aim of this study was to investigate the role of EHF in regulating normal colorectal epithelial cell differentiation in vivo. Methods: A novel mouse model was generated in which the Ets DNA binding domain (exon 8) of EHF was flanked by loxP sites (EHFlox/lox). To inactive EHF in the intestinal epithelium, EHFlox/lox mice were crossed to Villin-Cre mice and recombination was induced by tamoxifen treatment. Tissues from tamoxifen treated and vehicle treated mice were monitored weekly for up to one year. At each endpoint, tissue was collected and the effect of EHF deletion on intestinal cell proliferation and differentiation assessed by qRT-PCR and immunohistochemistry. Results: Targeted inactivation of EHF in the small intestinal and colonic epithelium following tamoxifen treatment was confirmed at the DNA and RNA level. EHF inactivation in the intestinal epithelium had minimal effect on survival, weight gain and overall health of the animals. Furthermore, loss of EHF did not markedly affect cell proliferation or the overall architecture of the intestinal epithelium. Finally, EHF inactivation also had minimal effect on markers of absorptive, enteroendocrine or Paneth cell differentiation but did reduce the number of goblet cells in the colonic epithelium. Conclusion: EHF does not play a major role in regulating cell proliferation in the intestinal mucosa but may play a role in regulating goblet cell differentiation. The role of EHF in intestinal tumorigenesis and response to stress are currently being investigated.

#3530 KITENIN works as a fine regulator of ErbB4 expression in colorectal cancer tissues in addition to E3 ubiquitin ligase Ndrp1. Jeong A Bae,1 Eun Gene Sun,1 Yoo-Seung Ko,1 Hui Jeong Choi,1 Chaeyong Jung,1 Kyung-Hwa Lee,1 Ik Joo Chung,2 Kyung-Sub Moon,1 Young Hyun Yu,1 Hyung-Ho Ha,1 Hangun Kim,1 Kyung Keun Kim,1 Chonnam Natl. Univ. Medical School, Medical Research Center for Gene Regulation, Kwangju, Republic of Korea; 2Chonnam Natl. Univ. Medical School, Dept of Pathology, Kwangju, Republic of Korea; 3Chonnam Natl. Univ. Medical School, Dept of Hematology-Oncology, Kwangju, Republic of Korea; 4Chonnam Natl. Univ. Medical School, Dept of Neurosurgery, Kwangju, Republic of Korea; 5Sunchon National University, College of Pharmacy, Sunchon, Republic of Korea.
Molecular and Cellular Biology / Genetics: Oncogenic Transcription Factors

Purpose: Understanding the complex biological functions of E3-ubiquitin ligases may facilitate the modulation of E3-ubiquitin ligases as a promising approach for the development of novel anticancer drugs. We recently identified that the KITENIN/ErbB4-Dvl2-c-Jun axis works as a novel unconventional downstream signal of epidermal growth factor in colorectal cancer (CRC) tissues and is involved in the epigenetic modulation of KITENIN expression. This finding is highly expressed in tumor tissues from advanced CRC stage. However, the detailed mechanisms that explain the higher levels of ErbB4 in colon cancer tissues are largely unknown. Here we investigated whether E3-ubiquitin ligases participate in the operation of the KITENIN/ErbB4-Dvl2-c-Jun axis and in the maintenance of elevated KITENIN/ErbB4 complex in CRC. Results & Discussion: We found that ErbB4, an E3-ligase for ErbB3/ErbB4, interacts with KITENIN (KA11 C-terminal interacting tetraperasin) to form a functional KITENIN/Erbb4/Nrdp1 complex and is responsible for down-regulating Dvl2 within this complex. Interestingly, ErbB4 was resistant to degradation by Nrdp1 in KITENIN/Nrdp1 co-transfected CRC cells, and KITENIN bound to the C-terminal coiled-coil domain of Nrdp1. Chemical blockade of ErbB kinase did not block the action of EGFR to increase in total/phospho-ErbB4 and phospho-Akt in KITENIN/ErbB4cotransfected cells, whereas it blocked the action of EGFR in ErbB4 alone-transfected CRC cells. In human CRC tissues, higher expressions of ErbB4 and KITENIN and lower expression of Dvl2 was observed in stage IV samples than in stage I, but a low level of Nrdp1 was expressed in both stages and it did not differ significantly by stage. These results indicated that Nrdp1 is necessary for the reduction in Dvl2 to generate c-Jun in the EGF-KITENIN/ErbB4/Nrdp1 complex and is responsible for down-regulating Dvl2 within this complex. Thus, we found that Nrdp1, an E3-ligase for ErbB3/ErbB4, interacts with KITENIN, inactivating proteasomes to degrade it. NF-κB then enters the nucleus through a p105/50 (p105/50) protein model mouse of undifferentiated pleomorphic sarcoma (UPS) revealed that YAP1 deletion (KPY) reduces cell proliferation and increases expression of circadian rhythm genes including PER1. UPS is a commonly diagnosed aggressive type of muscle-derived sarcoma. The KP model recapitulates human UPS morphologically and histologically, as well as by gene expression profiling. Although PER1 has primarily been characterized as a negative regulator of the circadian clock, upregulation of PER1 is known to modulate the G2/M cell cycle checkpoint at both the protein and mRNA level independent of p53. However, our findings represent a novel link between the circadian clock and the hippo pathway. Notably, the deletion of YAP1 in KP tumors leads to a statistically significant 2.5 fold increase in expression of PER1. The study has two specific aims: 1) to identify the YAP1-dependent function of PER1 in sarcoma and 2) determine whether YAP1 directly or indirectly regulates PER1. We have validated the microarray results in KP tumor-derived cell lines as well as in KP and KPY tumor tissue. We have also confirmed PER1 suppression in KP cells under YAP1 knockdown conditions, I demonstrated via qRT-PCR and western blot that PER1 is significantly increased at both the protein and transcriptional levels in KP cells. Additionally, preliminary evidence from an MTT proliferation assay showed loss of PER1 increased sarcoma cell proliferation. Further supporting the hypothesis that PER1 modulation impacts sarcoma proliferation, it has been reported that MyoD, the master regulator of muscle cell differentiation, is itself a clock-controlled gene. Together, these results suggest that YAP1 represses PER1 expression in sarcoma, and that epigenetic treatments can cause re-expression of PER1 which functions to inhibit cell proliferation and may promote differentiation.

#3532 No REST in Merkel cell carcinoma.

Emil Chitombo,1 Christopher Sauer,2 Lisa D. Schueller,3 Jonathan P. Eben,2 Dorit Rennspiess,1 Christopher B. Buck,2 Veronique J. Winnepenninckx,1 Anna K. Kurz,2 Ernst J. Speel,3 Martin Zenke,2 Axel zur Hausen1.

1Maastricht University Medical Center, Maastricht, Netherlands; 2National Cancer Institute, Bethesda, MD; 3University Hospital Aachen, Aachen, Germany.

Introduction: Merkel cell carcinoma (MCC) is a highly aggressive skin cancer of the elderly and immunosuppressed patients. More than 80% of MCCs are associated with the recently identified Merkel cell polyomavirus (MCPyV). MCCs reveal a trilinear differentiation characterized by neuroendocrine (chromogranin A and synaptophysin), epithelial (e.g. CK20) and pro/pre B-cell lymphocytic (e.g. Pax5 and TdT) marker expression. The cellular origin of MCCs still remains obscure. Based on the combined expression of TdT, Pax5 and immunoglobulins (Ig), including clonal Ig rearrangements we have recently hypothesized that pre/pro B-cells might constitute the cellular origin of MCC. We aimed to understand the neuroendocrine expression of chromogranin A and synaptophysin which is known to be negatively regulated by the Re1 silencing transcription factor (REST) in MCC cells. We assessed REST expression using commercially available antibodies and immunohistochemistry (IHC) in 22 formalin fixed and paraffin embedded MCC tissues. In addition, MCPyV-positive (M-K1 and M-K2) and MCPyV-negative (MCC13 and MCC26) MCC cell lines and the B-ALL cell-line REH as positive control were tested for REST expression. RT-PCR was used to confirm the results of the cell lines on the transcriptional level. In addition, the regulation of the REST expression by methylation was investigated within the demethylating agent 5-aza-2′-deoxycytidin. Further the methylation status of the 3 Cpg islands of the REST promoter was analysed with a methyl specific PCR. Results: All MCCs except one were completely devoid of REST expression as tested by IHC. All MCCs were negative for REST but synaptophysin and chromogranin A positive. The MCPyV-positive cell lines M-K1 and M-K2 did not express REST but indeed expressed both neuroendocrine markers. The MCPyV-negative cell lines MCC13, MCC26 and the B-ALL cell line were positive for REST expression and negative for these neuroendocrine markers. On RNA level these results were confirmed. The demethylation of the Cpg islands of the REST promoter did not result in the increase of the REST expression in M-K1 and M-K2 on the transcriptional or translational level. Initial MSP results did not reveal any methylation of the 3 Cpg islands of the REST promoter. Conclusion: The lack of REST expression in MCC and in MCPyV-positive MCC cell lines, in combination with REST expression in MCPyV-negative cell lines points to an important role of the MCPyV in the regulation of REST expression in MCC. This is emphasized by the recent description of 2′-deoxyapurine treatment of the MCC cell lines. Our data might provide the basis of neuroendocrine gene expression in MCC which possibly originates from early B cell.

#3533 Connections between NF-κB misregulation and carcinogenesis.

Donian I. Chyong,1 Aurian Naderi,1 Chase Lee,1 Ty Arpornsuksant,1 Allison Lu,1 Megha Dilip,1 Margaret Zhang,1 Young-Joon Suh,1 Eun-Ji Lee,2 Hye-Kyung Na1,3 George Walton Comprehensive High School, Marietta, GA; 2Seoul National University, Seoul, Republic of Korea; 3Sungshin Women’s University, Seoul, Republic of Korea.

In this review poster, we researched the function, regulation, and structure of NF-κB as it relates to carcinogenesis. Found in almost all animal cells, nuclear factor kappa-light-chain-enhancer of activated B cells (NF-κB) is a transcription factor that plays various roles in cellular proliferation, cell survival, inflammation, and T cell activation. There are two different NF-κB signaling pathways: the canonical pathway and the non-canonical pathway. NF-κB forms a p50/Rel A heterodimer in the canonical pathway and a p52/ Rel B heterodimer in the non-canonical pathway. NF-κB protein is normally sequestered in the cytoplasm as an inactive complex with a IκB inhibitor (IκB) protein. Outside stimuli such as reactive oxygen species (ROS) and tumor necrosis factor alpha (TNF-α) activate cell surface receptors such as Toll-Like Receptors (TLRs) and Receptor Activators of NF-κB (RANK). These surface receptors, in turn, activate IκB kinase (IKK). IKK phosphorylates IκB, which causes ubiquitination of IκB, signaling proteasomes to degrade it. NF-κB then enters the nucleus through a
nuclear pore and forms a transcription complex with coactivators and RNA polymerase. NF-κB binds to specific DNA-binding sites to induce transcription. One of the target genes of NF-κB encodes 1kBs, so NF-κB regulates its own activity through a negative feedback loop. Because the cell maintains storage of the signaling protein NF-κB in the cytoplasm, NF-κB allows the cell to respond to an external signal quickly. These molecules, together with other proteins that promote cellular proliferation and cell survival are mainly transcribed through NF-κB activation, uncontrolled overactivation of this transcription factor has major implications in carcinogenesis. Many types of cancer cells have high levels of constitutively active NF-κB. Mutations in the genes for NF-κB itself or its inhibitors such as IκBαs often found in cancer cells can cause cells to accelerate their proliferation or confer resistance to apoptosis. Such events provoke cancer cells secrete signaling molecules, inducing improper NF-κB activity. Because of the tumor promoting characteristics of NF-κB activation, a focus of current research is to find methods of suppressing NF-κB to kill cancer cells or slow their growth. We designed a 3D-printed model of the p50/RelA NF-κB protein using Imol to highlight the relationship between its structure and function.

#3534 FAT1: A potential target of NFκB (RelA) in GBM. Chitandra Srivastava,1 Khushboo Irshad,1 Parthaprasad Chattopadhyay,1 Chitra Sarkar,1 Ashish Suri,1 Subrata Sinha,2 Kunzang Chosdol1.1 All India Institute of Medical Sciences, New Delhi, India; 2National Brain Research Center, Gurgaon, India.

FAT1 is a large transmembrane protein (502 KD), reportedly having dual role in different human cancers. Our lab has reported oncogenic role of FAT1 over-expression in glioblastoma multiforme (GBM, grade IV glioma) increasing migration-invasion as well as tumor inflammation and HIF1α in different human cancers. Our lab has reported oncogenic role of FAT1 over-expression in GBM. The poor prognosis in GBM patients is due in part to its resistance to available treatments, which calls for identifying novel molecular therapeutic targets. In this study, we identified an interesting biomarker, Hairy/Enhancer-Of-Split related with RYPWM Motif (HEY1), a mediator of Notch signaling, which contributes to the pathogenesis of GBM. Datamining studies and our immunohistochemistry and immunoblot analysis showed that HEY1 is highly expressed in GBM patient specimens. Recent studies indicate that methylation status may control the expression of cancer phenotype. Our studies using bisulphite sequencing on the patient samples showed that HEY1 promoter was hypermethylated in the normal brain when compared to GBM specimens. Treatment on the 4910 and 5310 xenograft cell lines with sodium butyrate (NaB) greatly decreased HEY1 expression owing to its promoter hypermethylation with a concomitant increase in DNM1T expression confirming that promoter methylation regulates the HEY1 expression in GBM. NaB treatment also induced cell apoptosis as evaluated by flow cytometric analysis. Silencing HEY1 reduced invasion, migration and proliferation in 4910 and 5310 cells. Further, immunoblot and q-PCR analysis demonstrated the existence of a potential positive regulatory loop between HEY1 and p53. Additionally, DNA microarrays with HEY1 recombiant protein demonstrated good correlation with p53 and provided various bonafide targets of HEY1. Collectively, these studies suggest HEY1 as an important predictive marker for GBM, thus indicating a potential target for future GBM therapy.

#3535 The role of Nuclear factor I transcription factors in glioma. Kok Siong Chen, Linda J. Richards, Jens Bunt. 1The University of Queensland, Brisbane, Australia.

Gliomas are the most common brain tumors in adults. Among the malignant gliomas, grade II glioma, or glioblastoma (GBM), is the most aggressive form. Despite harsh treatments such as surgery, radiotherapy and chemotherapy, the median survival of GBM patients remains at just 12-15 months. GBM tumors could originate from cells of the glial lineage that have escaped the normal glial differentiation mechanisms. Therefore, by applying knowledge about normal glial development, we might understand how pathways that normally drive differentiation are affected in these tumors. If reactivating these pathways induces the differentiation of proliferative tumor cells, we could use this as a novel target for therapy. Our research is focused on the Nuclear factor I (NFI) transcription factors, one of the key factors to induce glial differentiation during normal development and is implicated in glioma. In insertional mutagenesis glioma mouse models, Nfı genes are consistently disrupted, suggesting a role for NFI in glioma initiation. Furthermore, loss of NFIB is common in human astrocytoma, while loss of NFIA is associated with oligodendroglioma. To determine whether loss of Nfı alters glioma initiation, progression or tumor histology, we have crossed inducible glioma mice with conditional Nfı deletion mice to follow tumour initiation and progression using fluorescence imaging and immunohistochemistry. Based on analyses of glioma mRNA expression data sets, NFIB expression correlates inversely with tumor grade and survival. Using immunofluorescence, we determined that both NFIA and NFIB are mainly expressed within the non-proliferative cells in GBM tissue, suggesting that NFI may play a direct role in tumor cell differentiation. To establish whether NFIB expression can indeed inhibit tumor proliferation and induce differentiation, U251 GBM cells were transfected with NFI. While overexpression of NFIA and NFIB led to cell proliferation, an NFI dominant-negative protein enhanced proliferation. We are currently validating these finding in vivo by electroporating NFI expression constructs into patient-derived GBM xenografts in mice. Our preliminary data show NFI electroporated cells are indeed differentiated and non-proliferative. Our data suggests that NFI-mediated glial differentiation can be induced in glioma to inhibit tumor growth and may prevent recurrence. Hence, activation of NFI could be a potential target for a glial differentiation-based approach to treat glioma.

#3537 Otx2 and c-Myc association drives tumor progression in medulloblastoma molecular subtypes 3/4. Yining Lu,1 Maheedhara R. Guda,2 Swapna Asuthakar,1 Ian Purvis,1 Collin M. Labak,3 Neha Jain,1 David J. Daniels,2 Sarah E. Martin,3 Andrew J. Tsung,1 Kiran K. Velpula1.1 Univ. of Illinois College of Med. at Peoria, Peoria, IL; 2Mayo Clinic, Rochester, MN; 3Kokoro Foundation, Tokyo, Japan.

Medulloblastoma (MB) is a pediatric brain tumor comprising of four molecular subgroups, with Group 3 and 4 tumors characterized by particularly poor prognosis. While research has advanced our understanding of MB, there is still a pressing need for new knowledge of the functional processes underlying its progression due to a scarcity of therapeutics. Recent studies have identified Orthodenticle homeobox 2 (Otx2), a cerebellar transcription factor, to be highly expressed in MB Group 3/4 subtypes. Datamining studies from Northcott and Robinson datasets revealed co-expression of Otx2 and c-Myc in Group 3/4 tumors. DAB staining conducted in human MB specimens showed increased expression of Otx2 and c-Myc. Colocalization studies confirmed datamining results.
sults. Next, we used a clinical Otx2 inhibitor, all-trans retinoic acid (ATRA), in a PDX cell line, P9, and in UW228 cells. Western blot analysis demonstrated reduced levels of c-Myc along with Otx2. In another experiment, we used the c-Myc/Max inhibitor 10058-F4 and observed comparable results to Otx2 inhibition. Real time PCR and immunocytochemistry experiments confirmed the aforementioned results. Further, treatment with ATRA and 10058-F4 showed reduced proliferation and migratory abilities in p9 and UW228 when compared to their respective controls. Mass spectrometry conducted on immune-precipitated Otx2 in P9 cells revealed a plethora of novel interaction partners that drive tumor growth and progression. In addition, western blot analysis in ATRA treated cells showed reduced expression of Max, suggestive of the existence of a feedback loop that links Otx2 and c-Myc. Collectively, these studies highlight Otx2 as a potential contributor to the malignant phenotype and describe its role in mediating the aggressiveness of Group 3/4 medulloblastoma.

MOLECULAR AND CELLULAR BIOLOGY / GENETICS: Oncogenic Transcription Factors

#3538 Enhanced dependence on lipid metabolism is a cellular adaptation to acidic microenvironment. Smitha Pillai, Jonathan W. Wojtkowiak, Mehdi Damaghi, Robert Gatenby, Robert Gillies. Moffitt Cancer Center, Tampa, FL.

Malignant tumors exhibit altered metabolism and consume higher levels of glucose compared to surrounding normal tissue, resulting in highly acidic microenvironments that lead to acidic conditions as a precancerous stimulus for cancer cells to survive and thrive and to out-compete the stroma into which they invade. Acid adaptation is associated with chronic activation of autophagy as well as redistribution of the lysosomal proteins to the plasma membrane. These processes are major survival mechanisms adopted by tumor cells under acidic conditions. We have also observed that under acidic conditions, there is a rapid, reversible and robust increase in the accumulation of cytoplasmic lipid droplets (adiposomes) in a panel of breast cancer cells. Adiposomes are dynamic organelles that store neutral lipids surrounded by a shell of proteins and a phospholipid monolayer. Breast cancer cells when grown in acidic media accumulated adiposomes as revealed by nile red and perilipin-2 staining followed by confocal microscopy. The acid-induced lipogenic phenotype persists even when the cells are grown in de-lipidated serum, indicating that the source of lipids is de novo and endogenous. When cells were treated with inhibitors of fatty acid synthesis such as TOFA, an inhibitor of Acetyl CoA Carboxylase or FAS inhibitor C75, adiposome formation at low pH was attenuated. Inhibition of either lipid anabolic or catabolic pathways was specifically cytotoxic in acid-adapted cells, but not in control cells where the FAS inhibitor, C75, is selectively toxic under acidic conditions. Additionally, when treated with etomoxir, an inhibitor of carnitine palmitoyltransferase 1, the rate limiting step in beta-oxidation, acid adapted cells showed increased sensitivity. To investigate the role of de novo fatty acid synthesis further, we employed high resolution NMR spectroscopy to measure 13C enriched lactate isomers following metabolism of D-[1-13C] glucose. These analyses showed that glucose flux through the pentose phosphate pathway (PPP) was significantly (~2.5 fold) higher in low pH exposed cells, compared to controls, representing a major shift in glucose metabolism from Embden Meyerhof to PPP, which results in increased production of NADPH, necessary for de novo lipid synthesis. Additional metabolic profiling using the Seahorse XF revealed that cells at low pH had higher rates of oxygen consumption (OCR) and that this was reversible. Further, we investigated the role of various acid sensing G-protein coupled receptors such as OGR1, TDAG8 and GPR4 in transducing the acid signal that results in the accumulation of lipid droplets. CRISPR/Cas9 mediated depletion of these receptors indicates that they might play a major role in inducing adiposome accumulation under acidic conditions. Taken together, increased dependence on lipid metabolism by cancer cells under acidic conditions reveals novel therapeutic vulnerabilities.

#3539 Oncogenic KRAS promotes the hexosamine biosynthetic pathway in NSCLC. Christian Ruiz, John A. Haley, Irina Zaitseva, John D. Haley, Geofrey D. Girmun. Stony Brook University, Stony Brook, NY.

Mutations in the proto-oncogenic KRAS (KRASmut) are one of the most common oncogenic mutations in NSCLC cancer, with approximately 25% of lung tumors containing KRASmut. Cancer cells acquire metabolic reprogramming in order to sustain their proliferative state. Recent studies highlight a role for KRASmut in driving altered cancer metabolism as part of its mechanism of action. We used targeted metabolomics in an effort to identify alterations in metabolic pathways controlled by KRASmut. We show that KRASmut, but not wildtype KRAS, increases several metabolites in the hexosamine biosynthetic pathway (HBP). The HBP metabolizes glucose and glutamine to produce UDP-N-acetylglucosamine (UDP-GlcNAc) which is the obligate substrate for O-GlcNAcylation, a carbohydrate post-translational modification on cytosolic and nuclear proteins. Levels of O-GlcNAcylation have been shown to be elevated in tumor cells including NSCLC. Currently we are investigating the mechanisms(s) and role of the Krasmut induced HBP on cancer cell metabolism and growth.

#3540 Targeting obesity-related cancer progression with novel leptin receptor antagonists. Cristal C. Lipsey, Adriana Harbuzaru, Ruben R. Gonzalez-Perez. Morehouse School of Medicine, Atlanta, GA.

Obesity is a global health issue that has been identified as a risk factor for several types of cancer. High levels of body fat and circulating leptin are typical identifiers of obesity in humans and animals. Leptin is a 16 kD protein hormone which is secreted by adipocytes, and maybe secreted from cancer cells, that functions to control satiation via leptin receptor binding. However, obese individuals often develop ‘leptin resistance’, which is a mechanism that leads to the accumulation of excess leptin. Increased binding of leptin to its receptor (OB-R) due to leptin resistance has been associated with disease progression and poor prognosis in human cancers. Our group has previously shown that leptin-mediated cancer cell proliferation is inhibited by the LPR2 (leptin receptor antagonist 2). We have prepared novel leptin antagonists and tested their ability to block leptin-induced survival and chemoresistance to Paclitaxel (TAX) and Gemcitabine (GEM) in cancer cell lines (GBCR) and derived tumorspheres (pancreatic: PANC-1, MiaPaca2 and triple negative breast cancer: MDA-MB231 and MDA-MB66). Western blot protein analyses showed the ability of the antagonists to specifically inhibit leptin-induced phosphorylation of STAT3, and expression of cyclin D, and Notch1 in cancer cells. Additionally, potential toxicity of antagonists was tested using MTT assay with concentrations up to 100X higher than the effective concentration (ECF-10A). Data generated showed no toxicity of the novel antagonists in vitro. Leptin-induced proliferation of breast cancer and pancreatic cancer cells (120-160%) was significantly inhibited by the novel antagonists. In addition, leptin-mediated progression of S-phase was also reduced by the antagonists. Leptin increased TAX and GEM chemoresistance in cells and tumorspheres that were efficiently inhibited by the antagonists. These data suggest that the new antagonists could be equally or more effective than LPR2 for adjuvant treatment of cancer. Prostate cancer (PCA) is the second leading cause of cancer-associated death in men, being bone metastases the main cause of mortality. Energetic metabolism alterations have become a new hallmark of cancer, since variations in a single gene can orchestrate changes in metabolic pathways and confer an adaptive advantage. Heme-oxygenase 1 (HO-1) exerts an antitumoral role in PCA sporadic or metastatic tumor cells. Heme-oxygenase 1 mediated catabolism of heme is orchestrated by prolyl hydroxylase domains (PHDs) and catalyzes the production of carbon monoxide (CO). HO-1 is the most abundant isoform of HO-1 in PCA. Most PCA cells express high levels of HO-1, which is tightly coupled to the expression of HO-1 inducers such as heat shock proteins (HSPs), reactive oxygen species (ROS), and inflammatory cytokines. Collectively, these context-dependent HO-1 inducers orchestrate changes in metabolic pathways and confer a metabolic advantage. Heme-oxygenase 1 (HO-1) exerts an antitumoral role in PCA sporadic or metastatic tumor cells. Collectively, these context-dependent HO-1 inducers orchestrate changes in metabolic pathways and confer a metabolic advantage.
sults, we propose HO-1 as a key regulator of the metabolic status of PCa cells and a powerful mediator capable of redefining the metabolic signature of bone precursor cells, thus, favoring the establishment of a less aggressive phenotype.

#3542 Coordination of glutamine and glucose metabolism in pancreatic cancer. Enza Vernucci, Venugopal Gunda, SURENDA SHUKLA, PANKAJ K. SINGH. University of Missouri, USA.

Pancreatic ductal adenocarcinoma is the fourth leading cause of cancer related deaths in the United States. Due to early metastasis by the time it is diagnosed it advances to advanced stages and becomes irreversible. Oncogene mediated metabolic reprogramming has been shown to promote the growth, maintenance and metastasis of tumors in pancreatic ductal adenocarcinoma. Pancreatic tumors route majority of glucose and glutamine for biomass generation and maintenance of redox potential. The aim of this study was to investigate the interaction between glutamine and glucose metabolism in pancreatic cancer cells. We primarily focused on the role of glutamine mediated regulation of glucose metabolism. We observed that glutamine deprivation reduces pancreatic cancer cell growth as suggested by the previous studies. We further investigated how pancreatic cancer cells adapt to glutamine deprived conditions. We observed that glucose uptake increases significantly upon glutamine deprivation. However, GLUT1 expression showed a contrasting decreased expression under conditions of glutamine deprivation. Using tandem mass spectrometry based metabolomic analysis we observed that glutamine deprivation does not alter glycolysis. However, the TCA cycle, amino acid metabolism and glutathione metabolism were significantly impacted. We noticed a significant increase in the levels of hydroxylglutarate and succinyl CoA levels in the TCA cycle. These changes were accompanied with an increase in GSH to GSSG ratio that reflects a possibility for alternative pathways involved in redox maintenance under glutamine deprived conditions. Hence, we conclude that glutamine metabolism significantly impacts the uptake and metabolism of glucose in pancreatic cancer cells.

#3543 Targeting the metabolic mevalonate pathway with statins as anti-breast cancer agents. Jenna van Leeuwen, ALEKSANDRA PANDRYA, CAROLYN GOARD, Peter J. Mullen, Rosemary Yu, Linda Z. Penn. Princess Margaret Cancer Centre, Toronto, Ontario, Canada.

The starn family of drugs target the mevalonate pathway and have been used for decades in the control of hypercholesterolemia, however recent evidence suggests these approved agents may also be useful as anti-cancer therapeutics (see our recent Nature Review Cancer article1). For example, statins can trigger tumor-specific apoptosis and two independent pre-op clinical trials in breast cancer, evaluating cholesterol-lowering doses of fluvastatin and atorvastatin, resulted in breast tumor shrinkage due to decreased growth and increased apoptosis. Our hypothesis is that statins have utility as anti-breast cancer agents. To maximize efficacy and speak to personalized medicine, our objectives are to develop biomarkers to distinguish which patients will benefit from the addition of statins to their treatment regimen and how best to use statins in combination with other agents to augment anti-tumor efficacy. To identify biomarkers of statin sensitivity we evaluated fluvastatin activity across a panel of BCa cell lines and showed that the basal, estrogen receptor-negative subtype is particularly sensitive to statin-induced apoptosis. As this included the difficult-to-treat triple negative BCa (TNBCa) we have extended this work and further evaluated a panel of TNBCa cell lines for statin sensitivity. From these results we are identifying features associated with robust apoptosis in response to statin exposure potentially statin-induced apoptosis. This is reversible with exogenous mevalonate, reinforcing that this is an on-target effect. We also identified another approved agent, diprydamole, as able to potentiate the anti-cancer activity of statins. Mechanistically we have shown that diprydamole blocks the feedback response to statin exposure. We have extended these studies and shown that the combination of statins and diprydamole is effective against TNBCa both in vitro and in vivo. Thus, we provide essential pre-clinical data to support the further evaluation of statins and diprydamole in BCa.

#3544 Leptin-Notch crosstalk axis: A novel target for pancreatic cancer. Adriana Harbuzariu, Crystal C. Lipey, Raben R. Gonzalez-Perez. Morehouse School of Medicine, Atlanta, GA.

Background: Pancreatic cancer (PC) has consistently been the fourth cancer-related cause of death in United States for more than 10 years. Its dismal prognosis is due to the aggressive behavior, late detection, lack of reliable biomarkers and low response to chemotherapy. Obesity, characterized by high levels of leptin, correlates to low PC survival. Notch and leptin signaling have been associated with increased tumor growth and chemoresistance. We have previously shown that leptin induces proliferation of PC cell lines, increases Notch expression, PC stem cells (PCSC) and tumorsphere formation. Hypothesis: Leptin induces chemoresistance to Notch through its crosstalk axis and a pathway that is essential for the expansion of PCSC. Methods: To test whether a leptin-Notch crosstalk axis is involved in chemoresistance, human PC (MiPaCa-2, Panc-1 and BxPC-3) cells were cultured in serum-free medium containing leptin, Gemiactamine and 5-Fluorouracil (3-FU) in combination with DAPT (gamma-secretase inhibitor) and leptin signaling inhibitor bound to iron-oxide nanoparticles (IONP-LPRA2). PC cells were cultured with leptin and allowed to form primary and secondary tumorspheres, enriched in PCSC. Tumorspheres were treated with the compounds described for 7-14 days. Number and size of tumorspheres were recorded, and expression of leptin receptor, OB-R and se-cretion of leptin were determined by Western blot (WB) and ELISA, respectively. Additionally, the levels of Notch, PCSC and EMT markers, pluripotency associated genes (Oct-4, Sox-2 and Nanog) and ATP-binding cassette transporters (ABCR1, ABCG2 and ABCG3) were determined using flow cytometry and WB. Results: PC cells expressed Leptin/OB-R system, suggesting an autocrine role in PC progression and chemoresistance. Leptin induced the formation of primary and secondary tumorspheres and increased their expression of Notch, EMT and pluripotency markers. Additionally, chemotherapeutics induced PC tumorsphere formation and their sensitivity to Notch activation via IONP-LPRA2. Pancreatic cancer cells acquired the ability to bypass Notch receptor and signaling, which was reinforced by leptin actions. Blockade of leptin signaling via IONP-LPRA2 and Notch activation via DAPT reduced leptin-induced molecular effects, PCSC and tumorsphere growth. Conclusion: Present data suggest that obesity, through leptin-induced Notch signaling, could increase chemoresistance in PC patients. Inhibition of leptin-Notch axis may be novel therapeutic strategy for PC, which may improve chemotherapeutic efficacy and increase survival in PC patients, particularly in obese contexts. Acknowledgements: This work has been supported by a Pilot Project Award from MSM/Tuskegee University/UAB Cancer Center partnership grant 5U54CA118838; PC SPORE Grant from UAB to RRGP, and facilities and support services at Morehouse School of Medicine (1G12RR02650-03; NIH RR 03034 and 1C06RR18386).

#3545 Glucose-dependent regulation of PXR is modulated by AMPK. Peter O. Oladimeji, St. Jude Children’s Research Hospital, Memphis, TN.

The sensitivity of patients to drugs depends on the pharmacokinetics of the drugs, but largely on the bioavailability of the drugs in the body. Orally administered drugs must pass through the intestinal wall and the portal circulation to reach the liver; both are sites of first-pass metabolism. Thus, many drugs may be metabolized before optimal plasma concentrations are reached, or before getting to target issues, resulting in diminished drug efficacy and reduced drug resistance. Among the several drug-metabolizing enzymes (DME) is cytochrome P450 (CYP) enzyme 3A4, the most abundant in the liver, metabolizes approximately 50 percent of marketed drugs and a main target of the gene receptor (PXR). In addition, transporters including MDR1 are also regulated by PXR. There is increasing evidence that drug metabolism can be affected by energy metabolism and vice versa. PXR has been implicated to have a complex role in energy homeostasis, and increased drug clearance was observed in untreated diabetic patients. The elimination of any chemotherapeutic agents in humans is markedly dependent on the relative expression and activity of the various DMEs and drug transporters. The heterotrimeric AMP-activated protein kinase (AMPK) serves as a monitor of cellular energy status in most eukaryotic cells, and is activated under energy stress conditions. Interestingly, AMPK is also regarded as a tumor suppressor in various cancers because of its inhibitory effects on anabolic processes that are important for tumor development. Despite the knowledge of the cross-regulation between drug metabolism and energy metabolism, the molecular pathways of this interaction remain vague. In our study, we exposed HepG2 cells to varying glucose concentrations and observed that PXR is greatly induced in high glucose conditions. This finding is consistent with clinical observation of increased drug clearance in untreated diabetic patients. We demonstrate that AMPK modulates PXR transcriptional activity. As such, the pharmacological manipulations of AMPK activation status show an inverse relationship with PXR activity. Activation of AMPK was shown to decrease PXR activity as observed by decreased CYP3A4 transcription, and consistent with that a potentiation of the use of drugs. In contrast, we observed that PXR is not a direct target of AMPK: it remains to be determined what the intermediary between AMPK and PXR is. Taken together, our studies identify novel links between the energy status of the cell, the activation of AMPK and down regulation of PXR.
MOLECULAR AND CELLULAR BIOLOGY / GENETICS: Regulation of Metabolic Pathways in Cancer

#3546 LIN28B/MYC loop regulates aerobic glycolysis and tumor acidic microenvironment to promote cancer stemness and cancer progression. Chong Chen,3 Lipeng Bai,3 Fengqi Cao,3 Shengnan Wang,3 Yan Liu,4 Jian Guo,3 Qin Si,4 Rong Xiang,2 Yuning Luo1,4. 1. Chinese Academy of Medical Science, Beijing, China; 2. Nankai University, Tianjin, China. 3. Sun Yat-sen University, Guangzhou, China; 4. UTMD Anderson Cancer Ctr., Houston, TX. Subsequently, we prove that targeting cancer additive metabolism could suppress tumor progression. Tumor microenvironment (TME) supports the development of metabolic reprogramming of tumor cells. The function of cancer stem cells (CSCs) closely relates with its own metabolic alteration. However, the relationship between CSCs' metabolic reprogramming and their supportive TME, as well as underlying mechanism remains largely unknown. In this study, we have demonstrated a novel mechanism that the LIN28B/MYC positive regulation loop could promote the aerobic glycolysis of cancer cells and glycolysis-derived lactate and further enhance the cancer stemness to facilitate tumor progression. 1) Metabolic analysis revealed that glycolysis (ECAR) was suppressed after LIN28B was knocked down in MDA-MB-231 or H1299 cancer cells respectively. Consistently, both the glucose-uptake and lactate-secretion were attenuated in shLIN28B cancer cells. Importantly, either the glucose accumulation in cancer tissues or lactate secretion in serum was reduced in mouse injected with shLIN28B cancer cells. 2) Metabolic analysis revealed that CSCs possessed higher ECAR and higher level of LIN28B, MYC and HIF1a. Furthermore, glycolysis-derived lactate not only increase the proportion of ALDH+ cells, but also enhance the tumorigenicity forming ability and mobility of cancer cells. 3) MicroRNAs screening analysis revealed that 6 miRNAs were up-regulated above 2 folds after LIN28B was knocked down in MDA-MB-231 cells. Metabolic analysis revealed that miR-34a-5p could suppress the aerobic glycolysis (ECAR) in MDA-MB-231 cells. 4) LIN28B inhibitor could reduce the expression of LIN28B and MYC in vitro and then suppressed tumor growth and metastasis in vivo. Taken together, our study demonstrated that LIN28B/MYC loop could sustain the aerobic glycolysis of cancer cells and then enhance the function of CSCs via regulating the tumor acidic microenvironment, thus, established the LIN28B/MYC as a central node in connecting tumor metabolism and tumor microenvironment, and could serve as a therapeutic target.

#3548 Hypoxia-induced Cystathionine-β-synthase (CBS) expression: impact on colonic epithelial cells metabolism, proliferation and migration. Che-Nique M. Phillips, John R. Zatarain, Michael E. Nicholls, Craig Porter, Steven Widen, Keten Thanki, James W. Randall, Judith L. Hellmich, Manjit Maskey, Suimin Qiu, Thomas G. Wood, Nadiya Druzhnya, Bartosz Szczesny, Kathrin Modis, Csaba Sabol, Delia Chao, Mark R. Hellmich. University of Texas Medical Branch, Galveston, TX. Introduction: We have reported aberrant overexpression of CBS in human colorectal cancers, where its activity (H2S production) promotes tumor progression and metastasis. New data show that CBS expression increases in adenoma-tous polyps. The aims of this study were to identify possible mechanisms for CBS expression increase observed in adenomatous polyps, and its functional impact using a premalignant colonic epithelial cell line NC3536. Methods: Induction of CBS in response to LPS, TLR2/4 agonists, and hypoxia was assayed by immunoblotting. CBS overexpression was achieved by lentiviral expression vector (pReceivers-Lv103, GeneCopoeia™) in NC3536 cells. Global metabolic profiling (Metabolon, Durham) was performed on cellular extracts from NC3536 overexpressing cells (CBS-hi) and vector-transduced controls. High-resolution mass spectrometry (Oroboris Oxygraph-2k) assessed bioenergetics. H2S levels were measured using the fluorogenic probe 7-Azido-4-methylcoumarin. A Coulter counter was used to assess cell proliferation rates. Transwell assays were used to assess cell migration. CBS activity was inhibited with aminooxyacetic acid (AOAA). Results: CBS protein expression was increased by ~3 fold in pNCM and CBS-hi compared to the TLR2/4 agonist control. CBS-hi and its TLR2/4 agonists increased CBS expression 2-fold. Metabolic profiling of CBS-hi cells and controls identified 85 metabolites that were differentially expressed (65 increased and 20 decreased; p≤0.05 Welch’s 2-Sample t-Test). The metabolic lantionhaine, which is produced by the CBS-dependent condensation of cysteine to produce H2S, showed the largest increase (12.3-fold increase, p=1.5E-06). A 4-fold increase in basal H2S production was measured in CBS-hi cells compared to control cultures. High-resolution respirometry showed that CBS-hi cells exhibited a significant increase in maximum respiration rate, reserve respiratory capacity and increased citrate synthase activity, suggesting increased cellular mitochondria mass. Treatment of CBS-hi cells either with pentose phosphate pathway inhibitor (oxythiamine) or lactate dehydrogenase inhibitor (XF-11) reducing growth by 90% and ~25% at day 5, respectively; the inhibitors had no effect on the vector control cells. Exposure of NC3536 cells to hypoxic conditions resulted in increased migration to conditioned media (p<0.001, NC3536 normoxia vs. hypoxia); inhibition of CBS using AOAA attenuated the hypoxia-induced migration. Conclusions: Hypoxia and LPS can induce CBS expression in a premalignant colonic epithelial cell line. Uregulation of CBS has a board impact on cellular metabolism including enhanced flux through the transsulfuration, glycolytic and pentose phosphate pathways, resulting in enhanced cellular bioenergetics, growth and migration. These data suggest that enhanced CBS activity may be involved the adenoma to carcinoma sequence.

#3547 B cell receptor signaling regulates cellular metabolism in Chronic Lymphocytic Leukemia. Hima V. Vangapandu, Ondrej Havranek, Varsha Gandhi. UT MD Anderson Cancer Ctr., Houston, TX. Peripheral blood B cells in chronic lymphocytic leukemia (CLL) are quiescent, yet have an active RNA transcription and protein translation processes, suggesting that the proliferant lymphocytes may be metabolically active. However, CLL metabolism and its relationship to disease biology has not been well explored. In our previous investigation, we reported that compared with proliferative B cell lines, metabolic fluxes of oxygen and lactate were low in quiescent peripheral blood B lymphocytes from CLL patients (Vangapandu, H.V. et al, AACR 2014). In 45 patient samples tested, glycolysis (extracellular acidification rate, ECAR) was consistently low (1 to 15 mP/5 min/5 x10^6 lymphocytes), whereas, oxygen consumption rate (OCR) varied considerably (5 to 190 pMoles/ min/5 x10^6 lymphocytes). Among the prognostic factors, high OCR correlated strongly with ZAP 70 positivity, unmutated IGHV status, greater β2M levels and higher Rai stage. In contrast, glycolytic flux (ECAR) from same patient samples did not associate with prognostic factors. Further, OCR did not vary on the basis of frequently occurring cytogenetic abnormalities, 13q14, 17p, and 11q deletions or trisomy 12. Since, ZAP 70 and IGHV unmuted status are associated with augmented B cell receptor (BCR) pathway signaling, we tested the impact on OCR after genetic ablation of B cell receptor (CH2 region of IgM). A CRISPR-Cas9-mediated BCR knockout mitigated OCR in a malignant B cell line without impacting the rate of proliferation. A critical node in the BCR pathway is PI3 Kinase and AKT and up regulation, δ and γ are involved in B-cell malignancies. Consistent with BCR ablation results, knocking out PIK3CD (codes for catalytic subunit δ), dramatically reduced OCR and ECAR. Pharmacological inhibitors of the PI3K pathway, duluisilis (a PI3 Kinase δ/γ inhibitor in phase III clinical trials) or idelisilis (FDA approved PIK3 δ inhibitor) also decreased OCR. Direct inhibition of AKT with MK-2206 showed similar results. Collectively, these data suggest that CLL cellular metabolism is associated with prognostic factors and linked to BCR signaling pathway. Since, the PIK3 inhibitors used in our study are being tested clinically for patients with CLL, investigations on the impact on metabolisms during therapy and translation of results to combination strategies need to be explored.

#3549 C-MYC sensitizes GBM with primitive features to glutamine metabolism disruption. Brad Andrew Poore, Isabella Taylor, Jeffrey Rubens, Allison Hanaford, Michal Maxwell, Charles Eberhart, Eric Raabe. Johns Hopkins Medical Insts., Baltimore, MD. Glioblastoma (GBM) is among the most lethal of known human cancers, with a median survival of less than 15 months. The highly infiltrative nature and genetic heterogeneity of GBM renders treatment difficult. Therefore, better and more targeted therapies are needed for patients with GBM. There is a new WHO subset of GBM that contains primitive neuronal components (GBM-PNC). These tumors can arise from a histologically classic GBM, and often the GBM-PNC portions of the tumor contain C-MYC or N-MYC amplifications. High MYC expression is known to alter cellular metabolism, increasing reliance on glutamine, which may create opportunities for therapeutic intervention. We hypothesized that depriving GBM-PNC cells of glutamine using metabolic inhibitors would suppress growth and tumorigenicity. To create genetically appropriate GBM-PNC models, we derived cortex (CTX) human neural stem cells (human neural stem cells) transfected with a lentiviral vector expressing both C-MYC or BMI1. These models formed aggressive tumor masses in nude mice expressing BMI1 had no statistically significant changes. Additionally, cells expressing BMI1 had no statistically significant changes. Furthermore, the relationship between glutaminolysis and tumor growth was demonstrated using the transplantable GBM-PNC model. Taken together, our study demonstrated that C-MYC expression is known to alter cellular metabolism, increasing reliance on glutamine, which may create opportunities for therapeutic intervention. The ability to deprive tumor cells of glutamine indicates a target for therapy, and suggests that glutaminolysis and increased glutamine dependence may contribute to aggressiveness of GBM-PNC models.
metabolite, glutamine is first converted to glutamate by glutaminase (GLS) and activation, we are also studying if PDL1 is regulated by glycolysis through Akt. human triple-negative breast cancer, suggesting that the PI3K/Akt pathway can dramatically increased T-cell infiltration and survival (40% of mice are long-term survivors). Lactate, the end product of glycolysis, has been shown to be toxic to T-cells, and LDHA-depleted tumors produce less lactate compared to controls. Thus, we propose that inhibiting tumor glycolysis leads to a less acidic microenvironment, leading to increased T-cell infiltration. Further, PTEN expression has been shown to be inversely correlated with PDL1 expression in human triple-negative breast cancer, suggesting that the PI3K/Akt pathway can promote PDL1 expression. Having established that glycolysis can promote Akt activation, we are also studying if PDL1 is regulated by glycolysis through Akt.

Targeting glutamine addiction of PIK3CA mutant colorectal cancers. Yiqing Zhao, Case Western Reserve Univ., Cleveland, OH.

Glutamine addiction is a major metabolic reprogramming event that occurs in cancer cells. Many tumors exhibit oncogene-dependent addiction to glutamine. PIK3CA, which encodes the p110 catalytic subunit of phosphatidylinositol-3 kinase α, is the most frequently mutated oncogene in human cancers. However, whether PIK3CA mutations reprogram cancer metabolism is an important unaddressed question. Here we show that oncogenic PIK3CA mutations render colorectal cancers (CRCs) more dependent on glutamine to growth. As a metabolite, glutamine is first converted to glutamate by glutaminase (GLS) and then to α-ketoglutarate (α-KG) by either a transaminase or a glutamate dehydrogenase. Calthera Biosciences recently developed a potent GLS inhibitor called CB-839, which is currently in phase I clinical trials in cancer patients. Using isogenic colorectal cancer cell lines with either WT or mutant PIK3CA allele knockout, we demonstrated that CRCs with PIK3CA mutations are more sensitive to growth inhibition by CB-839. Remarkably, combination of CB-839 with 5-FU induces expression xenograft tumors in PIK3CA mutant CRC models, suggesting that this combinational therapy may be effective approach to treat CRC patients whose tumors harbor PIK3CA mutations. Mechanistically, mutant p110α up-regulates gene expression of glutamate pyruvate transaminase 2 (GPT2) through an AKT-independent PDK1-RSK2-ATF4 signaling axis, thereby facilitating conversion of glutamate to α-KG. Together, our data establish oncogenic PIK3CA mutations as a cause of glutamine addiction in CRCs and that targeting glutamine metabolism may be effective approach to treat CRCs with PIK3CA mutations.

Selective inhibition of copper metabolism as a novel approach to treat triple-negative breast cancer. Olga Karginova, Claire Weekley, Akila Raoul, Allhareth Alsayed, Tong Wu, Chuan He, Olufunmilayo I. Olopade.

The rationale: Treatment of patients with triple-negative breast cancer (TNBC) remains challenging due to unpredictable disease progression and acquired resistance to chemotherapy. Finding novel targets in TNBC is important for the development of anticaner therapy. Cancer cells frequently adapt to cytotoxicity of existing pharmacological agents by exploiting metabolic pathways. Elevated copper metabolism and adaptations to oxidative stress have been linked to cancer progression. Copper chelation with tetrathiomolybdate (TM) was reported to control disease progression, especially in patients with TNBC. However, long-term consequences of global copper depletion are still under investigation. An alternative approach to develop novel therapeutics is to inhibit copper chelation with tetrathiomolybdate (TM) that blocks the copper transfer interface of two major copper chaperons, ATOX1 and CCS. Protein levels of ATOX1 and CCS are elevated in TNBC cells compared to normal cells. Thus, we hypothesized that disrupting copper transport by targeting ATOX1 and CCS with DCAC50 may suppress TNBC progression. Results: We investigated efficacy and potency of novel small molecule DCAC50 to induce cytotoxicity in a panel of TNBC cell lines. DCAC50 reduced cell proliferation in dose-dependent manner, measured by MTS assay. IC50 doses ranged from 3-10μM. Most importantly, DCAC50 induced apoptosis in TNBC cells, detected by Caspase 3/7 activity and Annexin V/PI staining. As expected, DCAC50 elevated intracellular copper levels. Moreover, TNBC cells treated with DCAC50 had significantly higher levels of oxidized glutathione (GSSG) and caused increased oxidation of DCF-DA reagent, demonstrating elevated oxidative stress. Surprisingly, activity of CCS downstream target, SOD1, was not affected by selective inhibition of copper transport with DCAC50; suggesting that intracellular copper accumulation and oxidative stress is mediated by ATOX1-1 inhibition. Interestingly, copper depletion with TM inhibited SOD1 activity but failed to significantly impact oxidative stress in TNBC cells. Recognizing DCAC50 generates oxidative stress triggering apoptosis in TNBC cells we evaluated benefits of combining DCAC50 treatment with paclitaxel. Multi-drug combination dose-response analysis revealed that treatment induced synergistic cytotoxicity and resulted in favorable dose reduction of both drugs. Conclusions: Selective inhibition of copper metabolism with novel small molecule DCAC50 elevates oxidative stress triggering apoptosis in TNBC cells. This approach may be valuable in combination with chemotherapy especially when tumor cells acquire resistance to first line therapy in TNBC. Ongoing studies comparing selective inhibition of copper transport to global copper chelation, and investigating efficacy and biological activity of DCAC50 in vivo will help further estimate benefits and clinical relevance of this approach for treatment of TNBC patients.

Non-small cell lung cancer (NSCLC), the most common type of lung cancer (comprising 80-85%), is a leading cause of cancer-related death worldwide. KRAS mutation is a major driver oncogene in NSCLC. Constitutive activation of K-Ras via oncogenic mutations plays a key role in development and progression of NSCLC, and is an important target for drug development. Indeed, drugs that target RAF-MAPK and PI3K, the well-established downstream pathways of K-Ras, are being evaluated in the clinic. However, to date, no effective treatments specifically targeting K-Ras have reached the clinic. A new direction for anti-Ras therapies targeting Ras-mediated altered cellular metabolism is implied by recent studies. Hence, as an attempt to investigate novel therapeutic targets to suppress KRAS-driven NSCLC, we assessed metabolic changes in NSCLC cell line and mouse model systems with oncogenic K-Ras mutations. We show that activation of Ras causes metabolic alterations, leading to aerobic glycolysis. Interestingly, despite the changes in the glycolytic pathway, NSCLC cell line and mouse models carrying K-Ras mutation revealed an elevated mitochondrial membrane potential, superoxide production as well as maximal oxygen consumption rate. Moreover, blockade of mitochondrial respiration effectively reduced mutant KRas-driven neoplastic phenotypes in NSCLC cells line and lung tumor formation in vivo. In contrast, blockade of glycolysis was not effective in the mutant KRas-driven tumorigenic activities. Mechanistically, mutant KRas-mediated activation of Akt led to increased expression of succinate dehydrogenase. Rubi point (A SDH) through increased protein stability by blocking proteasome-mediated degradation, resulting in mitochondrial complex II-dependent respiration. Our study suggests that induction of mitochondrial complex II-dependent respiration is an important mechanism by which oncogenic mutant KRas induces metabolic changes and ROS stress in NSCLC cells, contributing to lung carcinogenesis. Our findings elucidate potential metabolic targets that may provide novel therapeutic strategy for treating NSCLC with oncogenic KRAS mutations.
MOLECULAR AND CELLULAR BIOLOGY / GENETICS: Regulation of Metabolic Pathways in Cancer

Background: The metabolic features of cancer cells allows their rapid proliferation and escape from apoptosis. Novel targeted treatments are being developed for metabolic dysregulation of malignant cells. There is a growing body of evidence regarding the effects of metformin on the multiple pathways that regulate carcinogenesis. Metformin interacts with insulin growth factor signaling to reduce cell proliferation and the induction of apoptosis. The drug has profound effects on the mitochondrial respiration rate and ATP production. Metformin affects multiple cellular pathways via the activation of AMP-activated protein kinase (AMPK) by liver kinase 1 (LKB1), decreasing growth factor signaling and proliferation via mTOR inhibition. Metformin has been demonstrated to sensitize EGFR tyrosine kinase inhibitor (TKI)-resistant lung cancer cells by reversing the Warburg effect by regulating the EGFR and AMPK signaling pathways in Non-Small Cell Lung Cancer (NSCLC). Objective: Determine the effect of the combined Afatinib-Metformin treatment on NSCLC with different mutational status of EGFR. Methods: Cells with different mutational status of EGFR: A549, H1975 and HCC827 (ATCC) were used. Once the IC50 of afatinib and metformin were found, different combinations were made to determine whether there was a synergistic, additive or antagonistic effect using the Compusyn software. Cell viability was measured by the MTT assay and apoptosis was measured by flow cytometry in all cell lines. We found IC50s for metformin and afatinib for each cell line were as follows: 7 μM (A549), 2 μM (H1975) and 4 nM (HCC827) and the IC50 values for Metformin were 15μM (A549) 5μM (H1975) and 8μM (HCC827). We found a synergistic effect in H1975 for the combination of 3μM Afatinib plus 15 mM Metformin. In A549 we found a synergistic effect in all combinations. Finally, in HCC827 the combination of 5 nM and 4 nM Afatinib plus 8 nM metformin showed a synergistic effect. The apoptosis rate was increased up to 47% in all combinations for A549 cells. The combination of 3nM Afatinib and 8 mM Metformin induced 59% apoptosis in HCC827. Finally, H1975 induced 46% of apoptosis in the combination that showed synergistic effects. Conclusions: Afatinib-Metformin showed synergistic effects in a dose-dependent manner in three different cell lines of NSCLC.

#3555 Lipid droplets, a novel metabolic target in glioblastoma. Feng Gong, Jeffrey Guo, Xiang Cheng, Xiaoning Wu, Chunming Cheng, Arnav Chakravarti, Deliang Guo. The Ohio State University, Columbus, OH.

Lipid metabolism reprogramming is a novel feature of malignancies. Identifying the vulnerability of lipid alteration in tumor cells provides a new window to target cancer. Here, we unraveled that glioblastoma (GBM) patients containing high levels of lipid droplets (LDs), special organelles storing cholesterol esters and triglycerides in cells, presented poor survival. We found that LDs largely formed in tumor tissues from GBM patients, but rarely in low grade of gliomas and normal brain tissues, demonstrating that LDs might serve as a novel diagnostic biomarker and prognostic marker for GBM. We further revealed that sterol O-acyltransferase 1 (SOAT1), the key enzyme controlling cholesterol esterification and LD formation, is highly expressed and correlated with LD prevalence in tumor tissues from GBM patients. Genetic pharmacological inhibition of SOAT1 using avasimibe, a phase III clinical trial drug in human breast cancer model, was confirmed in mouse allograft model. Finally, we show that the expression of miR-155 controls energy metabolism in breast cancer, through PI3K p85 alpha - FOXO3a-cMYC axis in breast cancer. Sinae Kim, Eunjee Lee, Suhwan Chang. Univ. of Ulsan College of Med./Asan Medical Ctr., Seoul, Republic of Korea.

Breast cancer is the most common cancer for women worldwide. Although the oncogenic roles of miR-155 in cancer have been reported, the metabolic function of miR-155 in breast cancer has not been fully elucidated. In this study, we have investigated how the energy metabolic shift occurs after a genetic inactivation or knockdown of miR-155. To this end, we performed metabolic profiling of the miR-155-5p isoform or miR-155-5p primary cancer cells, obtained from mouse breast cancer model. We found, in the absence of miR-155, less glucose uptake and glycolysis in tumor cells. Mechanistically, we revealed PIK3R (Phosphoinositide-3-Kinase, Regulatory Subunit1, p85<alpha>-/> and FOXO3a-cMYC axis in breast cancer. Eunji Lee, Sinae Kim, Suhwan Chang. Univ. of Ulsan College of Med./Asan Medical Ctr., Seoul, Republic of Korea.

Metabolic reprogramming, recently becoming one of the cancer hallmarks, is linked to oncogenic signal transduction to find a better solution for cancer therapy. As one of key mediators in oncogenic signal transduction, non-receptor tyrosine kinase Src is known to drive cancer progression by promoting cell proliferation, metastasis, and drug resistance. Although previous studies reported that Src promotes fat accumulation and suppressesrowning of white adipocytes, little is known about the mechanistic role of Src in cancer metabolism. Here we report that Src mediates lipid mobilization by suppressing transcriptional activity of PPARγ, a key regulator of lipid metabolism. Firstly, we found Src suppression of PPARγ activity which, interestingly, turned out to be independent of Src kinase domain or a known Src phosphorylation site of PPARγ at tyrosine 78. Since the treatment of Src inhibitor (e.g., SU6656, PP2) could rescue Src-driven PPARγ suppression by possibly changing Src conformation, we might suggest the involvement of Src-PPARγ interaction in the regulatory mechanism. Mechanistically, further in vitro experiment showed Src...
inhibitor treatment recovered expression of PPARγ target genes such as fatty acid binding protein 4 (FABP4) and cluster of differentiation 36 (CD36) in a subset of non-small cell lung cancer cell lines. The increase of FABP4 and CD36 expression was associated with the reduction of lipid droplets, suggesting the role of Src regulation of PPARγ in lipid mobilization. Collectively, this finding provides valuable insights into the role of Src in cancer lipid metabolism, and an insight into therapeutic combination of targeting oncogenic signal transduction and lipid metabolism to treat cancer.

#3559 Functional characterization of HNF4α in gastric cancer. Chang Xu,1 Wen Fong Ooi,2 Aditi Qamra,3 Patrick Tan1. 1Cancer Science Institute of Singapore, Singapore, Singapore; 2Genome Institute of Singapore, Singapore, Singapore; 3Genome Institute of Singapore, Singapore, Singapore.

Gastric cancer (GC) is a leading cause of cancer mortality worldwide and particularly common in East Asia. Transcription factors are frequently amplified or overexpressed in GC and might contribute to tumorigenesis, however the underlying mechanisms largely remain unknown. Our previous data indicates that HNF4α is a common target of three amplified transcription factors (GATA4, GATA6 and KLF5) in gastric cancer. HNF4α had also been found to be related to diverse aspects of tumorigenesis. In liver and colon cancers, there are reports indicating that the targets of HNF4α are mainly involved in intermediary metabolism, however, its tissue-specific downstream targets and pathways have not been systemically studied yet. Therefore, a comprehensive functional characterization of HNF4α is required to identify its tissue-specific role in gastric cancer. In this study, we analyzed the expression features of HNF4α in GC, and found the expression level of HNF4α is significantly higher in early stage tumor and in CIN and MSI compared to GS and EBV subtypes of GC according to TCGA classification method. In addition, we performed the HNF4α ChIP in GC cell lines, and the results revealed a number of HNF4α binding sites in GC. Comparison with the published ChIP-seq data of Caco2 and HepG2 cell lines indicated the existence of GC-exclusive targets. Furthermore, functional annotation analysis revealed that the GC-exclusive targets are significantly related to the negative regulation of cellular metabolic process compared to the common targets. These preliminary data suggests that HNF4α might play a tissue specific role in GC, especially in metabolic related processes. Through further target validation and biological function studies, this study hopes to systematically investigate of HNF4α’s role in GC tumorigenesis, especially in metabolism related pathways.

#3560 6-diazo-5-oxo-l-norleucine resistant MYC-driven medulloblastoma tumors are sensitive to inhibition of glutaminase suggesting a possible glutaminase-independent mechanism of resistance. Allison Rose Hanaford, Bradley Poore, Charles G. Eberhart, Eric H. Raebe. Johns Hopkins Univ. School of Medicine, Baltimore, MD.

Increased MYC levels can alter cellular metabolism, creating a reliance on glutamine. Glutamine PET and MRI spectroscopy demonstrate that aggressive brain malignancies have increased uptake of glutamine and increased glutamate relative to normal brain, suggesting that agents targeting glutamine metabolism may be active in brain tumors. 6-diazo-5-oxo-norleucine (DON) is a glutamine analog that was tested extensively in adult and pediatric malignancies but never advanced beyond phase I clinical trials. We hypothesized that DON would be effective against the MYC-driven subgroup of the pediatric brain tumor medulloblastoma. DON treatment increased the median survival of mice bearing D425Med xenografts by 246 percent (26 days for vehicle treated mice compared to 90 days for DON treated mice, p<0.0018) and the median survival of mice bearing the MYC-driven patient derived xenograft MED211 by 80 percent (49 days for vehicle treated mice compared to 88 days for DON treated mice, p=0.0017). We also tested DON prodrugs designed for improved oral bioavailability and CNS penetration. Our novel DON prodrugs increased the median survival of mice bearing MYC-driven D425MED orthotopic xenografts by 60 percent (22 days for vehicle treated mice compared to 35 days for prodrug treated mice, p<0.01). In non-human primates, our DON prodrugs exhibited superior 10-fold enhanced CSF/plasma ratio versus regular DON. Though DON treatment causes a dramatic increase in survival, resistance eventually develops. To investigate the mechanism of DON resistance, we tested the effect of other glutamine metabolic inhibitors on multiple cell lines generated from DON-resistant xenografts. DON-resistant xenograft derived cell lines maintained DON resistance in culture, but were sensitive to treatment with the glutaminase inhibitor compound 968 and the glutamine analog Acivicin. Compound 968 treatment decreased growth of DON-resistant cell lines by an average of 79 percent (p<0.0008), and Acivicin treatment decreased growth by an average of 78 percent (p<0.000003). Glutaminase catalyzes the first step in glutamine metabolism—the conversion of glutamine to glutamate. The sensitivity of DON-resistant cells to glutaminase inhibition indicates continued tumor reliance on glutaminase activity. We are continuing to investigate the mechanism DON resistance, with the goal of developing a rational combinatorial therapy to treat resistant tumors. This knowledge could increase the potential utility of DON as a clinical agent.

#3561 UCP2’s tumor-promoting role via regulating lipid signaling and PLC-γ1 activity. Annaopoora Sreedhar, Yunfeng Zhao. Louisiana State University Health Sciences Center, Shreveport, LA.

Mitochondrial abnormalities are long sought to play important roles in tumor cell differentiation, proliferation and metabolism. Dysfunction of mitochondrial-dependent processes appear to be key features of cancerous cells. Among many such abnormal features of cancerous cells, a mitochondrial uncoupling protein 2 (UCP2) is shown to be up-regulated in various aggressive human cancers. Uncoupling proteins are a family of mitochondrial proteins present in the inner mitochondrial membrane whose physiological role is to decrease membrane potential and reactive oxygen species (ROS) production. UCP2 over-expression recently been proposed as a novel survival mechanism for cancer cells. However, till date, the exact role of UCP2 in cancer remains inconclusive. We recently reported that UCP2 appears to be a key regulator of cell proliferation, cell cycle and cell death during skin tumorigenesis. Using primary cells that overexpress UCP2, we showed that UCP2 correlated closely with cell proliferation and cell transformation. Moreover, inhibition of UCP2, decreased colony formation and 3D cell growth. Since UCP2 is the crucial player in the regulation of reactive oxygen species, and mitochondrial bioenergetics, we wanted to dissect out the role of UCP2 in redox regulation and tumor promotion. Our data demonstrated that UCP2 differentially regulated ROS. UCP2 upregulation decreased superoxide production, whereas increased hydrogen peroxide production with a concomitant increase in manganese superoxide dismutase (MnSOD) expression and activity. Furthermore, hydrogen peroxide was responsible for induction of lipid peroxidation and PLC-γ1 activation in UCP2 overexpressed cells. Moreover, PLC-γ1 activation enhanced tumorigenicity. Strikingly, pharmaceutical and siRNA mediated inhibition of UCP2 markedly reduced colony formation and 3D cell growth in vitro. Lastly, restricting hydrogen peroxide production with hydrogen peroxide scavenger catalase, suppressed lipid peroxidation and dampened PLC-γ1 activity. Taken together, our data suggest that hydrogen peroxide might be the mediator of UCP2’s tumor promoting role, and pharmacological disruption of PLC-γ1, and/or hydrogen peroxide may have clinical utility for UCP2-overexpressed cancers. This research was funded by NCI and Feist-Weiller Cancer Center of LSUHC-S.
MOLECULAR AND CELLULAR BIOLOGY / GENETICS: Regulation of Metabolic Pathways in Cancer

#3563 Potential role for a phosphorine aminotransferase 1 and pyruvate kinase M2 (PSAT1/PKM2) functional interaction in lung cancer cells. Rumeya B. Sit, Traci Krueer, James Bradley, Michael Merchant, John O. Trent, Brian F. Clem. Univ. of Louisville, Louisville, KY.

Cellular production of serine provides precursors for numerous anabolic reactions, notably protein and nucleic acid synthesis and nucleotide biosynthesis, and metabolism, and this pathway has been demonstrated to be elevated in many different cancer types. In addition, metabolic alterations within serine synthesis can stimulate other processes required for neoplastic growth, including glucose metabolism, specifically through the activation of the glycolytic enzyme pyruvate kinase M2 (PKM2). However, the complete mechanism by which serine biosynthetic pathway participates in tumor cell metabolism is not clear and is further confounded by the observation that suppression of serine biosynthetic enzymes disrupts tumorigenesis even in the presence of exogenous serine. Phosphorine aminotransferase 1 (PSAT1), the second enzyme in serine synthesis, catalyzes the conversion of 3-phosphohydroxypropionate to phosphoserine and increased expression correlates with poorer overall survival in lung cancer patients. In order to determine whether PSAT1 may contribute to lung cancer progression, PSAT1 expression was stably silenced in A549 and H358 lung cancer cells. Although a modest change in cell proliferation was observed upon PSAT1 knock-down compared to control, there was a robust decrease in soft-agar colony formation in both cell types. PSAT1 suppression was accompanied by distinct morphological changes and an increase in E-cadherin expression. These results suggest a potential link between serine-glucose metabolism, EMT, and drug sensitivity. In addition, we have identified a novel PFKFB2-dependent functional interaction in lung cancer cells that may yield valuable information about the relationship between serine-glucose metabolism and EMT transition in cancer cells and provide an additional therapeutic target for cancer treatment.

#3564 Silencing pfkfb2 enhances paclitaxel sensitivity by modulating metabolism of p53 wt ovarian and breast cancer cells and xenografts. Hailing Yang, Shu Zhang, Weiquan Mao, Ahmed A. Ahmed, Nicholas B. Jennings, Cristian Rodriguez-Aguayo, Gabriel Lopez-Berestein, Anil K. Sood, Xiao-Feng Le, Zheng Lei. UT Southwestern Medical Center, Dallas, TX.

Breast cancer is the most common cause and epithelial ovarian cancer the fourth most common cause of cancer death among women in the developed world. While breast cancer can be cured in 70% of cases, only 30% of ovarian cancer patients remain free from disease long term. Paclitaxel is an integral component of primary therapy for both forms of cancer, but less than half of breast and ovarian cancers respond to the drug. Enhancing the response to primary therapy with paclitaxel could improve outcomes for women with both diseases. In recent years several kinases have been identified that regulate the sensitivity of cancer cells to paclitaxel by inhibiting centrosome splitting or enhancing microtubule stability. Much less attention has been given to kinases that affect paclitaxel sensitivity by modulating cancer cell metabolism. We previously performed siRNA kinase screens to identify molecular targets whose decreased expression overcomes paclitaxel resistance and increases paclitaxel sensitivity in ovarian cancer cells. We showed that 20% of the potential kinase targets whose knockdown modulates paclitaxel sensitivity participate in glucose and energy metabolism. Among these, a leading candidate was 6-phosphogluconate dehydrogenase 2 (PDK2), a key enzyme of the pentose phosphate pathway. Knockdown of PDK2 inhibited oncogenic growth of ovarian and breast cancer cell lines and enhanced paclitaxel sensitivity in xenografts derived from ovarian cancer cell lines. Knockdown of PFKFB2 increased glycolysis, decreasing the flow of glycolytic intermediates to the pentose phosphate pathway with reduced G6PD activity in wt TP53 cancer cell lines. With decreased NAPDH, ROS accumulated after PFKFB2 knockdown, stimulating phosphorylation of JNK, inducing G1 cell cycle arrest, and initiating apoptosis dependent upon upregulation of p21Waf and Puma which are down-stream targets of TP53. Our studies have shown for the first time that PFKFB2, a glycolytic enzyme, drives tumor cell growth and regulates paclitaxel sensitivity by inducing apoptosis and G1 cell cycle arrest. These findings highlight a remarkable degree of coordination between cancer metabolism with cell proliferation and chemosensitivity, which may provide a novel target in patients with ovarian cancers and breast cancers where TP53 function remains intact.

#3565 Recurrently detected germline mutation of FLT3 (D358V) associated with prevalence of hematopoietic malignancy and prognosis of AML patients. Seulki Song. Cancer Research Institute, Seoul, Republic of Korea.

FLT3 is most frequently mutated gene in acute myeloid leukemia patients. While somatic mutation of FLT3 is well known, germline mutation of FLT3 and predispose to AML remain poorly understood. Here we identify a germline FLT3 p.D358V affected progeny of AML patients. We performed whole exome sequencing (WES) using 76 patients’ saliva sample to detect FLT3 germline mutation in buccal epithelial cell and demonstrate FLT3 p.D358V mutation for 6 patients among 76 patients. The frequency of FLT3 p.D358V mutation in AML patients is significantly higher in general population (p=9.50E-07), suggesting association of FLT3 mutation with AML predisposition. Asian population especially carried this locus more than other ethnic population. When we compared between AML patients and general population of Asian, the chi-square p-value was 0.07 and odd ratio was 2.26. Overall survival was significantly reduced in patients who had FLT3 p.D358V mutation (p=0.03) and disease free survival was show a tendency of reducing in the patients with FLT3 p.D358V mutation.

#3566 The long tail of significantly mutated genes in prostate cancer. Joshua Armenia,1 Stephanie Mullane,2 Jianjiong Gao,3 Debyani Chakravarty,2 Pasha Kundr,1 Franklin Hsing,1 Celine Han,1 Dan Robinson,1 Levi A. Garraway,1 Peter Nelson,1 Mark Rubin,1 Mary-Ellen Taplin,2 Wassim Abida,1 Charles L. Sawyers,4 Arul M. Chinnaiyan,1 Philip W. Kantoff,1 Johann S. Bono,1 Nikolaus Schulz,1 Eliezer M. Van Allen1.1. Mem Sloan Kettering Cancer Ctr., New York, NY; 2 Dana-Farber Cancer Institute, Boston, MA; 3 Center for Translational Pathology, University of Michigan, Ann Arbor, MI; 4 Dana-Farber Cancer Institute, Boston, MA; 5 Fred Hutchinson Cancer Research Center, Seattle, WA; 6 Well Cornell Medical College, New York, NY; 7 University of Michigan, Ann Arbor, MI; 8 The Institute of Cancer Research, London, United Kingdom.

Background: The mutational landscapes of primary and metastatic prostate cancer (PCa) have been robustly analyzed in multiple whole exome sequencing (WES) studies. We hypothesized that an aggregate, uniform analysis of all data generated to date would enable discovery of new significantly mutated genes and pathways not previously associated with PCA, and shed more light onto the genetic differences between primary and metastatic PCa. Methods: We uniformly analyzed WES data of 1,021 tumor and matched germline primary and metastatic PCa (686 primary, 335 metastatic). We performed mutational significance analysis using statistical and biological approaches to determine recurrently altered genes and pathways. Results: We identified 117 significantly mutated genes (Mutsig q<0.1) in PCa. These include epigenic modifiers ([KMT2C (6%), KMT2D (6%), and KDM6A (2.7%)] and regulators of the SWI/SNF complex [SMARC A1 (1.1%), ARID1A (1.5%), ARID1B (1.3%), ARID2 (1.3%), and PBRM1 (0.7%)]. Interestingly, genomic alterations in chromatin remodelers (MLL, SWI/SNF) appear to be significantly mutually exclusive with ETS fusions and SPOP mutations (p<0.001, Fisher’s test), indicating that these mutations may represent a novel distinct oncogenic driver in prostate cancer. Among the novel PCA related pathways, the splicing pathway was found to have oncogenic mutations in key drivers such as SFB1 (1.1%), U2AF1 (0.5%), and FUBP1 (0.4%), a novel splicing regulator involved in the regulation of MDM2 splicing. We also found truncating mutations in SPEP, a hormone inducible transcriptional repressor, in 2.8% of samples, similar to the frequency observed in breast tumors, and these mutations appear to be significantly associated with AR mutations (p=0.01, Fisher’s test). Our analysis also uncovered mutations in CUL3 (1.3%) and KLHL20, components of an E3-ubiquitin ligase complex that interacts with SPOP to promote the degradation of critical PCA genes (AR, SRC), KLHL20, CUL3, and SPOP mutations are mutually exclusive. Finally, a comparison of primary and metastatic samples identified alterations that are associated with metastatic disease, including AR amplifications and mutations, and loss of TP53, PTEN, and RB1. At lower frequency, metastatic tumors showed enriching
ment in mutations in MLHs (KMT2C/D), APC, CDK12, BRCA2, CTNNB1, and amplifications of MYC and CCND1. Conclusions: Through aggregation and uniform genomic analysis, we refined the map of somatic mutations in PCa and identified cancer genes and pathways not previously associated with this disease. Our findings may inform patient stratification and translational investigation.

## RESULTS

### Variant analysis of LY6 genes in TCGA ovarian cancer.

Krithika Bhuvaneshwar, Midrar Al Hossiny, Yuriy Gusev, Subha Madhavan, Geeta Upadhayay, Georgetown University, Washington, DC.

Background Human LY6 gene family has been associated with stem cell marker Sca-1 in murine cancer. Sca-1 is known to regulate TGF-β signaling. Wnt signaling & it is important in cancer progression and metastasis in mouse models. Human LY6 genes are associated with poor clinical outcome in human cancers. Previous studies have shown that this family of genes is highly expressed in Ovarian & Breast cancer compared to normal tissues. Overexpression of these genes was found to be correlated with poor outcome in overall and metastasis free survival. Recent studies have also identified that human LY6 genes are associated with tumor immune escape & drug resistance. In this poster, we explore the variants in LY6 and related genes in the TCGA Ovarian Cancer (OV) data collection. Materials and Methods We first downloaded RNA-seq data of primary tumor tissues from 21 TCGA OV patients from CGHub (https://cghub.ucsc.edu/), and after quality control, aligned to human reference genome using tool RSEM on the Globus Genomics platform. The BAM file was sorted and PCR duplicates were removed. Variant calling was done on BAM files based on Genome Analysis Toolkit (GATK)’s best practices, to obtain a multi sample variant call file (VCF). After getting the multi sample VCF file, we used Snpeff and Annovar software to annotate and predict the functional effects of variants on genes. Snpsift toolbox was used to filter out variants by extracting only variant of LY6 genes (and other genes of interest) that passed the quality check, and categorized the output into 4 different groups according to the impact (High, Moderate, Modifier, Low). To see if these variants were germline or somatic, RNA-seq from a second set of 22 TCGA Ovarian cancer samples (tumor tissue and normal blood samples) were used. BAM files were downloaded and variants were called using the Seven Bridges system. The same filtering steps were applied as above. Results In Set 1, we found variants in CD59, LY6E and LYPD6 mutated in all the 21 cases. We found two stop-loss mutations in CD59 gene, which is responsible for regulating the immune response, tumor cell growth and apoptosis. We found a total of 3794 unique variants short-listed in Set 1, and a total of 8879 unique variants short-listed in Set 2. It was expected to see more variants from the DNA-seq data compared to the RNA-seq data. Among these, 103 unique variants were common to both Set 1 and Set 2. Variants in ESRI, CD44 and LYPD6 family were mutated in most samples in both Set 1 and Set 2. We also performed survival analysis on variants present in RNA but not in DNA, and found variants in L16E, PINLYP, LYPDS, ZNF283 significant w.r.t overall survival. Conclusions: We found a total of 3794 unique variants (from short-listed set) in Set 1 (TCGA OV RNAseq data), and a total of 8879 unique variants (from short-listed set) in Set 2 (TCGA OV DNAseq). There were total of 103 unique variants common to Set 1 and Set 2. We see evidence of LY6 variants in non-coding regions of DNA (not in DNA) to be significantly associated with overall survival.

## DISCUSSION

The top-ranked biological functions affected by ERG over-expression include Cell Cycle (p < 1.42E-04), Cellular Growth and Proliferation (p < 1.23E-04), Cellular Development (p < 1.23E-04), Cell Death and Survival (p < 1.37E-04), and Cellular Assembly and Organization (p < 1.42E-04). Further analyses indicate a strong association with known cancer networks. The top-ranked canonical pathways enriched in ERG-positive compared to ERG-negative LNCaP cells include, Cell Cycle Control of Chromosomal Replication (p = 2.65E-16), Role of CHK Proteins in Cell Cycle Checkpoint Control (p = 3.16E-11), Cell Cycle: G2/M DNA Damage Checkpoint Replication (p = 1.34E-09), Role of BRCA1 in DNA Damage Response (p = 4.05E-08) and Estrogen-mediated S-phase Entry (p = 5.51E-08). These findings indicate new insights into the complexity of TMRPSS2-ERG gene fusion, and may help understand mechanistic pathways which promote growth and progression of CaP.
donor. However, there are a number of possible scenarios in which matched normal tissues might be not available for comparisons. It is most commonly encountered when performing analysis on retrospective studies with human tissues from clinical trials or pathology archives when normal samples were not collected in the first place or patient consent precludes examination of normal tissue or germline variants. Another common scenario is the use of a cell line as an experimental model, many of which have no information on the donor’s normal genome. In this work, we describe an algorithm to identify somatic single nucleotide variants (SNVs) in Next Generation Sequencing (NGS) data in the absence of normal samples using a machine learning approach. Our algorithm was evaluated using a family of supervised learning classifiers classifying germline and cancer variants. Varsome, a comprehensive platform providing an integrated annotation database in human genetic variants, is still lacking. In the study, we proposed a web-based database to determine potential variations in cancers with collected variant information from current common databases and integrated those data to provide comprehensive analyses. The web-site offers a function to upload a variant call format (VCF) file for variants annotation. Importantly, we integrated population allele frequency information from NHBI GO Exome Sequencing Project (ESP), 1000 Genomes Project and Tokohoku Medical Megabank Project to help users figure out the correlation between disease and population. Additionally, we also collected gene expression profiles from The Human Protein Atlas, Expression Atlas and NCBI SRA in different organs of human, mouse, and zebrafish respectively to reflect the relationship between gene expression and genetic variations in a specific organism. Overall, the database aids to predict protein functions in mutations, analyze population allele frequency and gene expression information from provided variants of diseases. In the result, we use three EGFR mutations to display the proposed system. A recent study has reported that Asian patients with non-small cell lung cancer (NSCLC) carrying a higher rate of EGFR mutation compared to non-Asian patients. Several studies, such as chr7:55241708G>C (G719A), chr7:55249005G>T (S768I) and chr7:55259515T>G (L858R), are found approximately in 30% of Asian (Japanese) patients. In functional prediction results, these sites are exonic and nonsynonymous mutations. The REVEL scores of three EGFR mutations are 0.824, 0.763 and 0.961, and gerp + scores 5.5, 5.85 and 5.71, respectively. Both REVEL and gerp + show high scores for the mutations of protein structural changes. According to the results, researchers can infer that the three mutations are pathogenic variants implying the nucleotide positions with a higher constraint.

**#3574 A survey of mutations in biomedical literature using a machine based approach.** Takahiko Koyama, Kahn Rhrissorarakkrai, Lakmi Parida. IBM Research, Yorktown Heights, NY.

Introduction: Being able to characterize mutations for both pathogenicity and drug response is indispensable to the analysis of tumor genetics and the development of therapeutic options. While a great deal of data has been deposited in various structured, genomic databases, a large portion of insights are primarily and often times solely found in biomedical literature. Medline contains about 26 million literature citations; a number that is unrealistic for a human to read. Thus machine based approaches are needed to comprehensively capture the landscape of reported mutations. Method: An automated pattern matching method is utilized to extract mutations from Medline abstracts as presented in Human Genome Variation Society (HGVS) format and RefSNPs (rs) number. A typical HGVS protein mutation is described as [reference amino acid][position] [new amino acid], as in p.His1047Arg, His1047Arg, or simply H1047R in HGVS format. This method identifies and consolidates all mentioned protein mutations and their alternate formulations. Result: Over 300,000 unique abstract mutation pairs were identified including 90,000 unique mutations. Well known cancer mutations such as BRAF V600E, JAK2 V617F and EGFR L858R are among the most frequent appearing in oncology literature. At the other end, 51,000 mutations are mentioned in just a single abstract, 16,000 mutations in two abstracts, 7,600 in three abstracts, and so forth. Conclusion: The number of mutations appearing in Medline abstracts represents just a small portion of the 2 million unique coding mutations contained in the COSMIC database. While we expect the actual coverage of mutations by literature to be more comprehensive if this approach is extended to the full text body, the number would likely remain small compared with the total reported COSMIC mutations. One of the great challenges in oncology is characterizing variations of unknown significance (VUS), and by first extracting all reported mutations, even those mentioned in only one article, and their specific biological context, we can begin to identify broader patterns in mutations’ pathogenicity and their impact on drug response.

**#3575 Frequency of imaging findings suspicious for and suggestive of cancer between three different hospitals within a single health system.** Lauren F. Comisar, Hanna M. Zafar, Darco Lalevic, Christopher Pizzurro, Charles E. Kahn, Mitchell Schnall, Tessa S. Cook. University of Pennsylvania, Philadelphia, PA.

Outpatient imaging rates have risen over the past two decades. Imaging findings representing possible cancer are commonly detected on these exams and require follow-up. Our health system utilizes a standardized coding scheme,
similar to the breast imaging and reporting data system (BI-RADS), to classify the malignant potential of masses on all abdominal and pelvic imaging exams; two of these categories are suspicious (for masses that clearly represent malignancy) and suggestive (for masses that may represent malignancy). These codes are used at three hospitals in a single health system: a university hospital, a community hospital, and a Level 1 trauma center. Our objective was to evaluate the frequency of imaging findings suspicious for or suggestive of malignancy in the liver, kidneys, pancreas, and adrenals between outpatients and inpatients at these three hospitals. Over 1600 suspicious and suggestive masses were discovered in one year: 843 in the liver, 499 in the kidneys, 152 in the pancreas, and 137 in the adrenal glands. Masses suspicious for cancer were unevenly distributed by patient sample. In the liver and kidneys, suspicious masses were more common in outpatients at all three hospitals; in the pancreas and adrenal glands, suspicious masses were more common in inpatients. Suspicious masses were unevenly distributed by modality. The proportion of MRI exams where at least one organ was coded as suspicious was higher than the proportion of CT exams. Masses suspicious for cancer were unevenly distributed across the three hospitals. Liver masses suspicious for cancer were twice as likely to be discovered at the university hospital compared to the community hospital and the Level 1 trauma center (present in 2% vs. 0.7% vs. 0.6% of all exams evaluated, respectively). Adrenal masses suspicious for cancer were also more commonly detected at the university hospital (present in 0.3% vs. 0.1% vs. 0.1% of adrenal glands evaluated, respectively). A similar trend was observed for renal and pancreatic masses. Masses coded as suggestive of malignancy (therapy in patients, therapy in patients, therapy in patients) were more frequently detected at the university hospital. This was particularly evident in adrenal lesions where 0.3% of adrenal glands evaluated at the university hospital were suggestive of malignancy compared to 0.06% at the community hospital and 0.03% at the Level 1 trauma center. A similar trend was observed for pancreatic lesions. In conclusion, this novel database of standardized codes for abdominal masses provides insight into how masses suspicious for and suggestive of cancer are coded variably by organ, patient location, and modality between the three different hospitals within the same urban academic health system. Further investigation will be needed to determine the influence of patient case mix, referral patterns, and radiologist characteristics that contribute to these observed differences.

#3576 Accurate identification of somatic mutations in cancer patient specimens in the lack of normal tissue by targeted high-throughput sequencing. Francisco M. De La Vega,1 Sean Irvine,1 David Ware,2 Kurt Gaastera,1 Yan-nick Pouliot,1 Len Trigg,2 Stanford University, Stanford, CA; 2Real Time Genomics, Inc., Hamilton, New Zealand; 3Real Time Genomics, Hamilton, New Zealand; 4TOMA Biosciences, Foster City, CA.

Tumor molecular profiling is rapidly becoming the standard clinical test for selecting targeted therapies in refractory cancer patients. DNA extracted from cancer patient samples is enriched for cancer genes and sequenced to identify actionable somatic mutations therein. A major challenge arises when tumor-derived data is analyzed in the absence of normal tissue data, as it is common in clinical scenarios. The distinction between somatic and germline variants becomes difficult, leaving clinicians to resort to crude heuristic filtering. We present here a variant calling software, developed under quality system regulation protocols, capable of accurately identifying somatic mutations from targeted next-generation sequencing data. A novel Bayesian Network approach models the distribution of reads harboring germline and somatic mutations, estimates the contamination from normal tissue in the sample, scores somatic mutations, and imputes germline variants, without matching normal tissue data. This approach also allows joint analysis of multiple specimens from the same patient (e.g. FFPE and ctDNA), when available, improving the limit of detection. To improve specificity, our caller can also utilize prior information from different databases including somatic mutations, germline variation, and healthy controls data, in a principled fashion. We validated our method by analyzing data from the TOMA OSq-Seq 131 cancer gene panel using the Illumina platform. Sample inputs ranging from 2-600ng of DNA were sequenced to a depth of >1000X, achieving on target rate of 73% and uniformity > 3.2 fold 80% coverage. Through adaptors with molecular barcodes we measured a median duplicate rate <2.

We analyzed somatic mutations simulated at various variant allele fractions on a background of data from reference samples from the Genome-in-a-Bottle consortium, data on a dilution series from two reference samples, and several commercial control and clinical samples, including matched FFPE, PBMC, and ctDNA samples. In the latter set, our method accurately scored each variant with respect to their likelihood of being somatic or germline. We show that, as compared to other commonly used methods, our algorithm can achieve a higher true positive rate whilst controlling a false discovery rate of 1%. We also show that jointly analyzing serial samples (e.g. ctDNA), we can improve sensitivity of shared variants. In conclusion, in contrast to currently used academic software developed for precisely projects, we observe that our caller outperforms these software and is particularly well suited for the clinical use cases.

#3577 Splice expression variation analysis (SEVA) for differential gene isoform usage in cancer. Bahman Afarsi,1 Theresa Guo,1 Michael Considine,2 Dylan Kelley,3 Emily Flam,1 Liliana Florea,2 Patrick Ha,2 Donald Geman,1 Michael F. Ochs,2 Joseph A. Califano,1 Daria A. Gaykowska,2 Alexander V. Favo-rov,1 Elana J. Fertig,1 Johns Hopkins University, Baltimore, MD; 2University of California, San Francisco, CA; 3The College of New Jersey, Ewing, NJ; 4University of California, San Diego, CA.

Alternative splicing events (ASE) are a significant component of expression alterations in cancer, and have been demonstrated to be critically important in the development of malignant phenotypes in a variety of tumors. These alternative gene isoforms alter cell-signaling networks and serve as a hidden source of tumor-driving alterations not identified in multi-omics analyses. Recent studies have demonstrated that reads from RNA-seq data can infer gene isoforms expressed in a single sample. Therefore, RNA-seq data of tumors offers the opportunity to systematically evaluate expressed gene isoforms and identify splicing events in cancer samples. To characterize a cancer specific ASE landscape, it is essential to perform differential splice variant expression analysis to identify isoform variants that are unique to tumor samples compared to normal tissue. In spite of the breadth of ASE algorithms, few have been validated in primary tumor samples. Current methods for differential splice variant analysis compare mean expression of gene isoforms in sample groups. Because these variants are tumor-specific, ASEs are expected to have more variable exon junction expression than normal samples. Therefore, current differential ASE analysis algo-rithms from RNA-seq may not account for heterogeneous gene isoform usage in tumors. To address this, we introduce Splice Expression Variability Analysis (SEVA) to detect differential splice variation usage in tumor and normal samples and accounts for tumor heterogeneity. This algorithm compares the degree of variability of junction expression profiles within a population of normal samples relative to that in tumor samples. The performance of SEVA was compared with two existing algorithms, EBSq and DiffSplice, in simulated and real RNA-seq data. Simulated data suggest that SEVA is robust and computationally effi-cient relative to EBSq and DiffSplice. In contrast to EBSq and DiffSplice, SEVA was able to identify alternative splicing events independent of overall gene expression differences. Finally, additional validation was performed using RNA-seq data for primary tumor data from HPV-positive oropharynx squamous cell carcinoma (OPSCC) tumors and normal samples from both TCGA and an independent tumor cohort of 46 OPSCC tumors and 25 normal samples. In these tumor samples, SEVA finds cancer-specific ASEs in genes that are independent of their differential expression status. Moreover, in total, it fine mapped approximately hundreds of splice variant candidates, manageable for experimental validation in contrast to the thousands of candidates found with EBSq or DiffSplice. These candidates include experimentally validated splice variants in HNSCC from a previous microarray study. Based on performance in both simulated and real data, SEVA represents a robust algorithm that is well suited for differential ASE analysis, particularly in RNA-seq sequencing data from heterogeneous primary tumor samples.

#3578 Methyl2Acetyl: predicting epigenetic and transcriptomic activity from DNA methylation. Xiang Chen. St Jude Children’s Research Hospital, Memphis, TN.

DNA methylation and histone modifications are interconnected and interdependent epigenetic mechanisms that regulate chromatin accessibility in cells. They establish cell’s developmental identity and modulate individual response to endogenous developmental stimuli and environmental changes. Chromatin immunoprecipitation followed by sequencing (ChIP-seq) is a popular assay to study genomewide histone modification profiles. However, ChIP-seq assays require relatively large amounts of starting materials (ranging from ~10^9 cells using a low cell number protocol to 10^11 cells in a standard protocol), which remains as a major obstacle for precious biological samples including primary tumor specimens. On the other hand, tagmentation-based whole genome bisul-fite sequencing (TWGBS) protocol enables unbiased assessment of the genomewide methylation pattern using ~3,000 cells. Therefore, a quantitative relationship between DNA methylation and epigenetic/transcriptomic activity is in great demand. In the present study, we developed Methyl2Acetyl, a machine learning framework to infer promoter epigenetic activities (e.g. H3K27Ac enrichment) using TWGBS data as input. The proposed model utilizes random forest learners, which allow automatic extraction of complex interactions among DNA methylation features surrounding transcription start sites. We ap-
applied Methyl2Acetyl to a set of pediatric solid tumor samples with high quality H3K27Ac ChIPseq data to evaluate its performance. The model accurately predicted promoter H3K27Ac enrichment in independent test samples (Pearson correlation against measured enrichment: 0.81 ± 0.02). To further test the robustness of our model, we trained a Methyl2Acetyl model on solid tumors and applied it to a set of 10 pediatric leukemia samples. Despite dramatic global methylene differences between solid tumors and leukemia, Methyl2Acetyl predicted promoter H3K27Ac enrichment showed strong concordance with target gene expression level in the same sample (Pearson correlation: 0.75 ± 0.02, classification AUC: 0.89 ± 0.01). Collectively, our data suggested that DNA methylation is predictive of promoter active histone modification enrichment and gene expression activity. Epigenetically active promoters can be imputed from TWGS data in samples with limiting starting materials.

A large number of pre-clinical and clinical studies have strongly implicated that combining cancer-derived neo-antigen vaccines with checkpoint control inhibitors will enhance priming and expansion of tumor-specific naive and memory T-cells resulting in superior efficacy and durability of response. The neo-antigens, derived from somatic mutations are prime candidates for cancer vaccines, not subjected to host’s central and peripheral tolerance. Identifying potential T-cell engaging neo-epitopes among a large number of somatic mutations is like finding a specific needle in a stack of needles. Currently, the available T-cell neo-epitope prioritization pipelines rely primarily on two attributes - the class-I HLA-binding affinity of the mutant peptide compared to the wild-type counterpart, and the level of expression of the mutated gene in tumor cells. The higher the binding differential, and higher the expression level of the mutant allele, the greater is the likelihood for the peptide to be presented on antigen-presenting cells. These approaches however fall short of predicting whether the HLA-bound peptide will engage T-cells by binding to T-cell receptors (TCRs).

We have developed a novel algorithm to predict the binding of HLA-peptide complexes to TCRs by analyzing the physico-chemical composition of the amino acids and their positional biases in the 9-mers from crystal structures of HLA-peptide-TCR complex. We applied machine learning approach to build a classification model that can predict whether a given 9-mer peptide is a TCR-binder or not by identifying whether an amino acid at a given position carries key features that will facilitate interaction with the TCR. We applied this approach to positive and negative TCR interactions selected from Immune Epitope data base (IEDB). We tested multiple classification approaches and found that Random Forest and Classification via Regression methods provided the best performance. We achieved more than 99% accuracy at 10-fold cross validation on both training and unseen test datasets. We further validated our model using positive and negative peptides curated from published papers reporting clinical trial results of checkpoint control inhibitors. The performance of the two classification models was evaluated on two different TCR-binding assays - dextramer binding and IFN-γ release. The Classification via Regression method showed a higher positive predictive value for the dextramer-binding assay, whereas the Random Forest method showed a higher positive predictive value for the IFN-γ ELISPOT assay, suggesting subtle differences between the two classification methods. The inclusion of the TCR binding step to our T-cell neo-epitope prioritization pipeline increased accuracy of prediction, reduced false positives and selected potential neo-epitopes to a manageable number for testing in cell-based assays.

We propose and evaluate a novel algorithm for inferring germline and somatic copy number variation from whole exome sequencing (WES) and whole genome sequencing (WGS) data. Starting with the depth of aligned short reads from a cohort of samples, we use a Bayesian model for learning sequencing bias and simultaneously detecting CNV events using a hidden Markov model for change-point detection. A unified framework is used to call both germline and somatic CNVs. Denoising and event discovery are performed self-consistently to achieve maximum accuracy. In contrast to previous methods, our model naturally accounts for mixed sex cohorts and can detect events on sex chromosomes. Furthermore, we can detect excessively noisy samples and extract useful information within a probabilistic framework. Our implementation can also utilize Spark clusters, enabling the processing of larger cohorts and allowing for improved runtime performance. We benchmark the new method for precision, recall, and reproducibility of both germline and somatic variants. Evaluations are performed on a cohort of WES samples from The Cancer Genome Atlas with matching WGS data. For germline variants, we use blood normal samples and compare our calls on WES data against Genome STRIP calls on WGS data. We find that GATK CNV yields remarkably higher precision and recall compared to XHMM and OncoNEX software packages. For somatic variants, we compare our calls against TITAN and find a remarkably high concordance.

#3581 GATK ACNV: allelic copy-number variation discovery from SNPs and coverage data. Aaron Chevalier, Lee Lichtenstein, Andrey Smirnov, Samuel K. Lee, Mehrtash Babadi, David I. Benjamin, Valentin Ruano-Rubio. Broad Institute, Cambridge, MA.

The presence of somatic copy-number alterations in tumor genomes can be used to predict both patient sensitivity to treatments as well as outcomes. The inclusion of allelic data improves statistical power to detect copy-number events and allows for discovery of copy-neutral events. We present GATK ACNV, an allelic copy-number variation method built on the Genome Analysis Toolkit. ACNV is a tool for detecting somatic copy-number activity from whole exome and whole genome sequencing data by segmenting the genome into regions of constant copy number and estimating copy ratio and minor-allele fraction in those regions. ACNV uses a novel probabilistic model to account for reference bias (optionally using a panel of normals), which improves the estimation of minor-allele fraction. We combine this with the coverage model from GATK CNV by segmenting with a unified hidden Markov model, improving the statistical power to detect copy-number variation. We validated a purity series of the cell line HCC1143 and cancer samples from The Cancer Genome Atlas. Our results show that ACNV is able to discover regions of somatic copy-number activity accurately and with high resolution in both whole exome and whole genome sequencing data.

#3582 Copy number estimation from targeted and shallow sequencing in cancer samples. Andrea I. OHara, Zhiwei Che, Soheil Shams. BioDiscovery, El Segundo, CA.

Next-generation sequencing (NGS) is mainly used to obtain sequence variants (SNVs). However, obtaining copy number results from NGS has gained momentum in both research and clinical applications. Targeted panel sequencing has been a popular method to achieve high depth of coverage for certain regions of interest at an affordable cost compared to whole genome sequencing. Shallow whole genome sequencing, where average read-depth can be as low as 0.1x, provides a cost savings-approach for identifying large copy number variant (CNV) events; it has been utilized in various application areas, including oncology. Here we introduce the BAM (MultiScale Reference) algorithm, currently in NexusCopyNumber, to function with shallow and targeted sequencing data, as well as WGS and WES, using a novel dynamic binning approach. This approach uses a Hidden Markov Model to segment the genome into target areas using the reads in targeted regions and the backbone areas using the off-target reads and additional areas. It uses coarse binning in the backbone areas that provides copy number base line as well as large copy number events and uses finer binning in target areas to provide high resolution copy number detection in targeted regions. Shallow WGS data and targeted panel NGS data, as well as WES with normal depth of coverage, were used for the testing. The results were compared with those from microarray and/or other algorithms in Nexus Copy Number, BAM ngCGH (matched) and BAM (pooled reference). GC correction schemes based on a range of window size and presence or absence of GC probe content were applied to the data and assessed for overall quality. Differences in overall read-depth resulted in variable sample quality across the cohorts, however most sample quality was adequate for copy number estimation and a quality threshold was assessed. Among the samples tested, the best quality after GC correction comes from the 50kb region size with or without the probes. Next, the copy number profiles of the samples from WES and microarray were compared using a reference readarray reference dataset and for a comparison to a reference copy number profile. Using the MultiScale Reference method has been tested in a variety of cancer samples. This is an ideal tool for copy number estimation with NGS results in cancer samples because it provides a way for non-matched-pair analysis with genome, exome and targeted NGS.
The role of the nervous system in adult tumor progression has been hypothesized. In contrast, the involvement of nervous system in childhood cancer is still unknown. In this study, the main objective of this study is to identify whether mutations in neuron signaling proteins are present in pediatric cancer. Additionally this study foresees to determine the effect of mutation on the protein structure and function and to elucidate if differences between solid and hematopoietic pediatric tumors exist in terms of neural signaling. The genomic data of pediatric cancers available in the Pediatric Cancer Data Portal (PeCan) were mined looking for point mutations. Our analysis comprised a set of well recognized neuron signaling factors including 50 neurotrophic growth factors, 23 axon guidance molecules and 47 neurotransmitter receptors. Missense mutations were determined and germline tumours.

The effect of each mutation on the protein function was predicted through bioinformatics pipeline. The TO method documented on average 95% SENS and >99% SPEC for variant detection. The method showed a tradeoff between SENS and FP rate allowing for small drops in SENS for large decreases in the numbers of FP (4-5% decrease in SENS from 99% to 95%) resulted in 90% decrease in FP VCs with a final average of 70 filtered VCs per sample. Results suggest that analyzing PTN targeted exome NGS samples as TO and obtaining a disease-specific PNC selected subset of high quality VCs with a reasonable number of filtered VCs. Also benchmarking aids in excluding controls from the PNC that may miss CA calls.

**3585 Determination of gene amplifications with a next-generation sequencing cancer panel.** Ina L. Deras, Aaron Wise, Chen Zhao, Christine Gide-well-Kenney, Philip Le, Elizabeth Upsall Aderhold, Karen Gutekunst, Iluminina, San Diego, CA

**TruSight** Tumor 15 (TST15) uses next-generation sequencing technology to detect somatic point mutations, insertions, and deletions in 15 genes that are commonly mutated in solid tumors. It accurately detects low-frequency mutations with low DNA input and is optimized for formalin-fixed, paraffin-embedded (FFPE) tumor tissue. The test is a multiplexed PCR panel that includes primers to support amplification detection in the EGFR, ERBB2, and MET genes. It is described as a bioinformatics pipeline to enable detection of these gene amplifications. DNA extracted from 31 FFPE samples with amplifications in EGFR, ERBB2, or MET—some with dual amplifications—were diluted with DNA extracted from 18 normal FFPE samples to create a total of 67 unique samples at low-level amplification. Undiluted and diluted samples were assessed for quality based on amplifiability (ΔCq or library yield) and tested with TST15. For comparison, the samples were also tested with droplet digital PCR (ddPCR) to determine the copy ratio of target to wild type. For amplifiable samples, the TST15 algorithm was able to detect amplifications in EGFR and ERBB2 at ddPCR ratios of 1.4 and 1.6, respectively. ddPCR was unable to accurately quantify low MET amplifications; therefore, expected ddPCR ratios were used for comparison. The TST15 algorithm was able to detect amplifications in MET samples at an expected ddPCR ratio of 1.3. Poor sample quality (i.e., high ΔCq or low library yield) impaired amplification detection. In some samples, the presence of multiple amplifications also impaired detection. The addition of this algorithm to the TST15 workflow will allow researchers to more accurately characterize tumor samples by detecting somatic mutations and amplifications simultaneously.

Patient-derived xenograft (PDX) models of human tumors are an important and widely used platform for cancer research. Cancer drug development relies on PDX models to screen drugs and characterize tumor biology for potential drug targets. It has been well established that PDX models maintain similar biology as their original tumors, including histological patterning, gene expression, single-nucleotide variants, and copy number alterations. Using short-read sequencing technology to profile and characterize genomic alterations within PDX tumor models is becoming a common practice in cancer research. Mouse read contamination is a relevant source of noise in PDX tumor sequencing data and needs to be addressed prior to downstream analyses. Therefore, a key consideration for downstream analysis of PDX sequencing data, such as determining variant calls or gene expression values, is effectively removing contaminating mouse sequence. Removing contamination from PDX sequencing data is necessary for accurate and reproducible downstream analyses. A limited number of studies establishing best practices for handling PDX sequencing data exist. Thus, we set out to compare different strategies for removing mouse contamination from PDX tumor sequencing data for DNA and RNA using a set of controlled experimental in silico datasets and data from PDX tumors. We designed a set of in silico experiments using these sequencing data to assess a range of approaches for removing contaminating mouse reads from human data. Our experiments used a set of publicly available human and mouse DNA and RNA sequencing data available at the SRA site. Subsets of the raw human and mouse reads were mixed at different ratios and analyzed with five different approaches: 1) raw alignment to the human reference genome, 2) filtering with the Xnome algorithm.
followed by alignment to the human genome. 3) alignment to the human reference genome followed by filtering with the XenomiX R algorithm, 4) mouse-human hybrid reference genome alignment, and 5) our novel NextCODE approach. We assessed the sensitivity and specificity of each procedure for removing mouse sequence and maintaining human sequence for downstream analyses. We also assessed the effects of each procedure on genome quantification and variant calling. Our results introduce a novel, improved method for removing mouse DNA, facilitating better-quality data for downstream analysis.

#3587 Intratumoral divergence of copy number alterations in NSCLC.
Yasminka A. Jakubek,1 Smruthy Sivakumar,1 Louise C. Strong,1 Humam Ka-

BIOINFORMATICS AND SYSTEMS BIOLOGY: Sequencing Analysis and Algorithms

facilitating better-quality data for downstream analysis.

and maintaining human sequence for downstream analyses. We also assessed the sensitivity and specificity of each procedure for removing mouse sequence and

differentiation of cancer genomes. Its characterization at the DNA level is based on the identification of somatic mutations consisting of single nucleotide variants (SNVs) and copy number alterations (CNAs), which include deletions, amplifications, and copy neutral loss of heterozygosity. Currently, most methods for the detection of intratumoral heterogeneity use an implicit “infinite sites” model for both SNVs and CNAs. While this may often be appropriate for SNVs, we demonstrate its violation for CNAs in unstable cancer genomes. Here, we propose a novel method to identify CNAs that were created by independent mutational events but alter the same genomic region. Our method identifies regions where the germline heterozygous signals (allelic intensities for DNA arrays or frequencies for next-generation sequencing) shift toward different parental haplotypes between different samples from the same tumor, thus indicative of divergent tumor clones. In this context we define a divergent CNA as one found on multiple samples from the same tumor but with different chromosomal changes giving rise to the CNAs. We applied our method to data from core needle biopsies extracted from the tumors of 31 non-small cell lung cancer (NSCLC) patients and processed using Illumina SNP arrays. We overlapped CNA calls from the same tumor, and then tested whether overlapping segments showed divergent CNAs. We observe instances of divergent CNAs in 23 of the 31 patient tumors comprising 260 in total (median = 5 divergent CNAs per tumor). Strikingly, one tumor had 34. We then assessed whether the level of recurrent mutation correlated with clinical or genomic features. While there was no association with smoking or history, we did observe a positive association between the rate of divergence and somatic mutations (including loss) in putative genome “gatekeeper” genes, p53 and CDKN2A (P = 0.001). We detected divergent CNAs that spanned shared genomic regions in three or more NSCLC tumors. These included large (>1Mb) events in chromosome 6 (q13-14, q21-22, q25) and chromosome 21 (q22), as well as smaller events, which included the integrin collagen receptor locus ITGA1-PLEO-ITGA2, 8p23.1, 8q24.3, 18q11.2 (ZNF521 gene), and 21q21.3, which has binding sites for GATA2. GATK4 includes a set of observed divergent CNAs alterations represent half of the total number expected since imbalances of the same haplotype will not be observable in such data. In sum, our approach allows for the detection of genomic regions that are divergently altered. This information may support methods to identify CNAs under positive or negative selection in the tumor microenvironment as well as regions of increased genomic instability. This provides an added dimension to intratumoral heterogeneity analysis for a more comprehensive characterization of cancer genomes.

#3588 Computational method to identify non-coding cancer drivers.

Cancer is caused by mutations in driver genes - yet ~25% patients do not show any mutations in known drivers. ~99% somatic mutations obtained from whole-genome sequencing localize to regions that do not code for proteins and many of these non-coding mutations regulate gene expression. Although variants in protein-coding regions have received the majority of attention, numerous studies have now noted the importance of non-coding variants in cancer - for example, mutations in the promoter of the TERT gene. Identification of functional non-coding variants that drive tumor growth remains a challenge and a bottleneck for the use of whole-genome sequencing in the clinic. Cancer drivers are generally identified by the high frequency at which their mutations occur across patients. However, mutation rate is highly heterogeneous across the genome and many non-driver elements show higher mutation frequency than others, such as regions bound by transcription factors (TFs) in melanoma or regions replicating late during cell division in colon cancer. We have developed a novel computational approach to predict non-coding cancer drivers that differentiate between regions highly mutated due to positive selection (true drivers) vs those due to mutation rate heterogeneity (false positives). This method integrates the signals of high functional impact of variants with the recurrence of variants across multiple tumor samples to identify the elements that show more and higher functional impact mutations than expected randomly. Our method controls for multiple covariates of mutation rates, such as replication timing, histone modification marks and open chromatin regions to identify the non-

coding regions with functional impact.

FunSee is a novel scheme that uses the properties of ENCODE elements (including conservation, TF motif disruption and network properties) within a weighted scoring scheme to predict deleteriousness of non-coding variants. I will present the details of this method and discuss the ongoing efforts to analyze ~2,900 tumor whole-genomes in the Pan-Cancer Analysis of Whole Genomes, PCAWG consortium.

#3589 A systematic approach toward gene annotation of the hallmarksgenome microenvironment as well as genome and many non-driver elements show higher mutation frequency than others, such as regions bound by transcription factors (TFs) in melanoma or regions replicating late during cell division in colon cancer. We have developed a novel computational approach to predict non-coding cancer drivers that differen-

cancer.

The hallmark of cancer consists of ten categories that serve as an organizing principle and framework for understanding neoplastic disease. The ten hallmarks include activating invasion and metastasis, avoiding immune destruction, deregulating cellular energetics, enabling replicative immortality, evading growth suppressors, genome instability and mutation, inducing angiogenesis, resisting cell death, sustaining proliferative signaling, and tumor-promoting inflammation. In order to facilitate the use of the hallmarks of cancer in genomic studies, we have undertaken a systematic methodology to map genes to each individual hallmark of cancer. Assignment of genes to the individual hallmarks was performed using gene ontology (GO) annotations. Specifically, for each hallmark, a term list was generated by cancer research experts, with biological terms associated with each hallmark. This term list was used to search and identify matching GO terms. Matched terms were then mapped to the highest, most specific, representative, non-redundant GO term in the GO hierarchy. Genes for each term were restricted by selecting only human taxon, and high confidence experimental evidence codes. For specific GO terms, where present, the Regulation of 'GO term' category was included. The genes for each GO term for each hallmark were combined in a non-redundant list of genes for each hallmark. In the case of the evolving growth suppressors category, a different strategy was employed. In this instance, genes were identified through 'tumor suppressor' gene/protein annotation in the Dgxdb resource and UniProt. Additionally, text-mining methods on biomedical research literature were used to define a high confidence list of genes for this hallmark. As an example use case of the hallmarks we applied them to the analysis of the TCGA Pan-Cancer RNAseq data set. Clustering across the individual hallmarks led to interesting differences within particular tumor tissue types, as well as shared hallmarks for other tumor types. For example, use of the genome instability and mutation hallmark for Pan-Cancer clustering, revealed a tight tissue-based cluster of low-grade gliomas and GBMs. This result suggests the importance of this hallmark expression in this tumor type. This high confidence mapping of genes to hallmarks of cancer provides a unique dataset to facilitate analyses of cancer genome data.

#3590 Somatic variation discovery with GATK4. Geraldine A. Van der Auwerra. Broad Institute, Cambridge, MA.

The Genome Analysis Toolkit or GATK, developed at the Broad Institute, is currently one of the most widely used software toolkits for germline short variant discovery and genotyping in whole genome and exome data. GATK4 is the next generation of GATK; it runs faster and covers more ground, adding somatic SNVs, Indels and CNVs to its variant discovery portfolio. Given the breakthrough increase in the amount of genomic data produced in recent years, GATK development has come to tackle multiple challenges: a) reflect the cutting-edge of science in terms of depth as well as breadth of analyses offered, b) scale to petabytes of data and c) provide a way to navigate the tradeoff between turn-around-time and cost of analyses. GATK4 addresses all of these challenges through a complete redesign and reimplementation of the original GATK software. This new version greatly expands the toolkit’s scope of action within the variant discovery space by improving somatic mutation calling and adding copy number, structural variant and tumor-heterogeneity analysis tools. For the established tools and algorithms composing the GATK Best Practices pipelines for short variant discovery (including MuTect2, the next generation of the DREAM challenge-winning somatic SNV caller MuTect, developed originally in the Cancer Genome Analysis group at the Broad Institute), GATK4 is a substantial upgrade that streamlines the tools’ operation, providing functionally equivalent results in a much faster timeframe through greatly increased efficiency and leaner engineering. Designed with cloud infrastructure in mind (although it still runs on local infrastructure), GATK4 is implemented with support for Apache
#3591 A new method to infer clonal sequences and phylogenies from personal tumor genome profiles. Sayaka Miura,1 Karen Gomez,2 Oscar Murillo,3 Sudhir Kumar1. 1Temple Univ., Philadelphia, PA; 2Baylor College of Medicine, Houston, TX.

Tumor progression involves the evolution of clonal cell populations that mutate and spread in the body. Genetic profiling has revealed the presence of extensive variation in tumor samples from individual patients. However, a tumor sample for genetic profiling is mixture of different clonal cell populations and needs to be decomposed into clonal sequences to infer the evolutionary history of the tumor. Therefore, we have developed a new method, CloneFinder, and show that the clone sequences present in each tumor sample can be accurately inferred from the analysis of multiple tumor sample profiles with our new CloneFinder method. CloneFinder is unique in its use of molecular evolutionary principles to deduce clone sequences at a single-nucleotide resolution along with their frequencies in each sample. It performs better than existing methods, which we found to produce incorrect numbers of clones, clone sequence errors, errors in clonal phylogenies, and biased estimates of cancerous cells in tumors. Application of CloneFinder to a large number of empirical datasets revealed that both early and recently evolved tumors contain ancestral clones at high frequencies. Therefore, our new method provides new insights into the clonal structure of tumors and their evolution within a personal life time.

#3592 Improved indel detection in RNA-seq data via assembly based realignment reveals expressed Epidermal Growth Factor Receptor indels in Lung Adenocarcinoma. Lisle E. Mose, D. Neil Hayes, Charles M. Perou, Joel S. Parker. UNC - Lineberger Cancer Center, Chapel Hill, NC.

Insertions and deletions in the transcriptome can potentially have significant impact on function and can be clinically actionable. A number of methods have recently been developed that improve indel detection in DNA by utilizing realignment and/or localized assembly to aid in discovering mutations that are more difficult to detect than single nucleotide polymorphisms. While significant effort has been put into these methods in the context of DNA discovery, RNA-Seq has not received the same attention. For example, the widely used Genome Analysis Toolkit (GATK) recommends removal of splice junctions from all reads prior to proceeding with variant calling methods that are very similar to those used for DNA. We hypothesize that utilizing splice junctions to augment localized assembly across exon-exon boundaries can improve read alignments resulting in improved variant detection in RNA-Seq data. We have developed an update to the Assembly Based Realigner (ABRA2) that makes use of splice junction information to aid in realignment of reads. We assessed indel detection performance using the BEERs RNA-Seq simulator. Two million simulated reads of length 100nt were generated across 1000 human genes. In order to test more complex indel detection, the simulator was modified to generate an even distribution of 1391 indels of length 1 to 100. The simulated reads were aligned using STAR and subsequently realigned using ABRA2. Freebayes and GATK were run against the non-realigned STAR output resulting in indel detection sensitivity of 15% and 18% with precision of 97% and 88% respectively. Freebayes was then run against the ABRA2 realignments resulting in an approximately 4 fold increase in indel detection sensitivity of 67% while maintaining precision of 97%. In frame deletions in Epidermal Growth Factor Receptor (EGFR) have oncogenic potential, can be indicators for Gefitinib or Erlotinib treatment, and are frequently detected in lung cancer via DNA sequencing. Among 514 TCGA Lung Adenocarcinoma RNA-Seq samples, ABRA2 revealed 73 in frame coding indels in EGFR ranging in length from 3 to 24 bases, including 58 deletions in exon 19 of 15 length 15 bases. This represents a 3 fold increase relative to what was initially reported from DNA by TCGA. Further, in the absence of ABRA2, only 5 in frame coding indels are detected in RNA, the largest of which is a 9 base deletion. We have presented here ABRA2, a new version of the Assembly Based Realigner that is capable of accurately realigning RNA-Seq reads containing variations that are currently not well handled by widely used aligners and variant callers, thus improving accuracy of variant detection in RNA-Seq.

#3594 Adaptively randomized seamless-phase multiarm platform trial: Glioblastoma Multiforme Adaptive Global Innovative Learning Environment (GBM AGILE). Donald A. Berry,1 Todd Graves,2 Jason Connor,2 Brian Alexander,2 Timothy Cloughesy,2 Scott M. Berry,2 Anna Barker,2 for the GBM AGILE Global Alliance. 1UT MD Anderson Cancer Ctr., Houston, TX; 2Berry Consultants, LLC, Austin, TX; 3Dana Farber Cancer Institute, Boston, MA; 4The Ronald Reagan UCLA Medical Center, Boston, CA; 5Arizona State University, Phoenix, AZ.

Traditional phase 3 clinical trials compare an experimental arm with control. They inefficiently use patients, time, and finances. Dramatic and rapid changes in biology makes such trials untenable. We describe an alternative drug development strategy that we are using in a particular setting, the trial GBM AGILE (Glioblastoma Multiforme Multifaceted Adaptive Global Innovative Learning Environment). The trial’s design employs many innovations. Some aspects are similar to those of I-SPY 2 (see 4 articles in July 7, 2016 NEJM) but GBM AGILE extends I-SPY 2 in many ways. (1) It is a Bayesian platform trial that simultaneously evaluates many treatment arms (including combinations) from many companies. (2) Arms are added to the trial at any time and leave what has been evaluated whether positively or negatively. (3) An arm’s sample size is adaptive and based on frequent analyses of the trial results. (4) Every arm has an initial stage in which it is randomized adaptively: arms performing better in disease subtypes are assigned with higher probability to such patients. (5) An arm that performs sufficiently well in a disease subtype moves seamlessly into a small (50-patient) control arm in the registration stage in the same subtype, with equal randomization against control. (6) All experimental arms are compared against a control arm that is assigned to 20% of patients in every subtype; a bridging model takes advantage of having many arms in the trial and many comparisons among arms, and enables indirect randomization comparisons of all arms with all controls. (7) Patient subtypes are defined by line of therapy, MGMT methylation status for newly diagnosed patients, and biomarkers associated with targeted therapies, although adaptive randomization enables us to draw conclusions about off-target effects. The many possible subtypes means that there are many possible drug indications. So there are many possible “error types” and no single definition of statistical power. For example, the trial may conclude that a drug’s indication is “recurrent, biomarker-positive” disease when in truth it is “all recurrent” disease. We show how the design addresses this issue and we define “pure type I error.” GBM AGILE’s primary endpoint is overall survival (OS). To make the design more efficient we incorporate evaluations of patients’ statuses over time using a longitudinal model based on periodic MRI assessments and performance status. The longitudinal model and its components are not end points but rather provide auxiliary information that enables multiple imputing for the primary statistic. The trial’s cohort has been enrolled with patient subtypes that are made up of more than 150 enthusiastic and devoted disease experts and advocates from around the globe, including from Australia and China. The U.S. FDA has been enormously helpful in designing GBM AGILE, especially as regards its potential for drug and biomarker registration. Our approach provides a model for other diseases, including those outside of cancer.

#3595 Under-reporting of research biopsies in clinical trials in oncology. Christine M. Parseghian, Kanwal Raghav, James Yao, Lee M. Ellis, Alda Tam, Michael J. Overman. U.T. MD Anderson Cancer Center, Houston, TX.

Purpose: Research biopsies are frequently incorporated into clinical trials in oncology, and are often a mandatory requirement for trial enrollment. However, limited information is available regarding the extent and completeness of research biopsy reporting. Methods: We identified a cohort of therapeutic clinical trials wherein at least one image-guided non-diagnostic research biopsy was performed between 1/2005 and 10/2010 from a large interventional radiology database at MD Anderson Cancer Center. Study protocols were compared with the highest level of corresponding publication as a manuscript, registry report, or abstract. Results: A total of 866 research biopsies were performed across 46 clinical trials (median 19 biopsies/trial). After a median follow-up time of 5.8yrs from study completion, 35 trials (76%) had published manuscripts (18 reported biopsy results), 8 (17%) had either a registry or abstract report (1 reported biopsy results), and 3 (7%) were not reported. In total, 19 trials (41%) reported biopsy results. Of these 19 trials, 6 (32%) trials under-reported the number of biopsies performed. Of the 14 trials with multiple biopsies reported, 13 (93%) trials reported results. Discussion: The many possible subtypes mean that there are many possible drug indications. So there are many possible “error types” and no single definition of statistical power. For example, the trial may conclude that a drug’s indication is “recurrent, biomarker-positive” disease when in truth it is “all recurrent” disease. We show how the design addresses this issue and we define “pure type I error.” GBM AGILE’s primary endpoint is overall survival (OS). To make the design more efficient we incorporate evaluations of patients’ statuses over time using a longitudinal model based on periodic MRI assessments and performance status. The longitudinal model and its components are not end points but rather provide auxiliary information that enables multiple imputing for the primary statistic. The trial’s cohort has been enrolled with patient subtypes that are made up of more than 150 enthusiastic and devoted disease experts and advocates from around the globe, including from Australia and China. The U.S. FDA has been enormously helpful in designing GBM AGILE, especially as regards its potential for drug and biomarker registration. Our approach provides a model for other diseases, including those outside of cancer.
Table. When limited to only published manuscripts, results were unchanged. Academic sponsorship and a larger number of biopsies, especially serial biopsies, were associated with increased reporting of research biopsies. Conclusion: Despite ethical obligations to report research biopsies, 59% of trials do not report on these biopsies. Although complications occur, they are rarely reported. Clinical trial design efforts to ensure that an adequate number of research biopsies are obtained may lead to improved reporting of research biopsy biomarker results.

ENDOCRINOLOGY: Nuclear Receptors and Endocrine Oncology Therapies

#3602 Novel BRCA1 mimetic 35446HCl inhibits growth of anti estrogen resistant breast cancer cells through the NF-κB pathway. Shyam Nathan, Elliot M. Rosen. Georgetown University, Washington, DC.

Nearly a third of breast cancer patients develop resistance to antiestrogen treatments although the estrogen receptor ERα continues to affect cell survival and proliferation. Thus there is a need for new interventions to inhibit ERα function. Based on high-resolution mapping, we proposed interaction sites on both BRCA1 and ERα in a three-dimensional model of BRCA1. Utilizing this model, we identified a class of compounds that fits into a predicted BRCA1-binding cavity within ERα, mimics the ability of BRCA1 to repress ERα activity, and functions differently than other antiestrogens. Previous publication has shown that the 1st generation BRCA1 mimetic compound (A7) reduced proliferation and inhibited ERα activity in antiestrogen-sensitive and resistant breast cancer cells with negligible non-specific toxicity. More importantly we have shown that the 2nd generation compounds (35446, 4631) partially reduced sensitivity to Tam/ICI-resistant cells (LCC9), caused dissociation of ERα from a model estrogen response element (ERE) in MCF-7 cells, and inhibited growth of LCC9 tumor xenografts at nontoxic concentrations utilizing compound 35446-HCl (35446 prepared as a hydrochloride salt). The focus of this study is the mechanism of action of 35446-HCl compound’s inhibition of ERα, which includes inhibition of a major signaling pathway and mode of cell death. Eight genes identified from RNA-seq in LCC9 cells treated with BRCA1 mimetic A7 were verified by qPCR using 35446-HCl. One verified gene is the NF-κB activator IKKB, which is linked to therapy resistance. Treatment with 35446-HCl inhibited IKKB expression and proliferation in LCC9 cells compared to untreated Control at 48 and 72 hrs (p<0.0001). Transcriptional activity from the p65 promoter as measured with a luciferase assay was decreased in the presence of BRCA1 mimetic treatment (p<0.0001). Expression of downstream targets of NF-κB including genes known to inhibit apoptosis, was reduced (p value ranging from < 0.05- 0.001). Apoptosis due to 35446-HCl treatment was verified by caspase-7 cleavage and increased TUNEL staining at both 48 and 72 hrs. In silico analysis of the IKKB promoter within 10kb upstream of the transcription start site identified one putative full ERE and five putative half ERE sites. Of these, 35446-HCl inhibited the interaction of ERα with the full ERE (p<0.0001) and five half EREs (p value ranging from < 0.05- 0.001) sites upstream of the IKKB start site in LCC9 cells as well as Tam resistant/ERα mutated T47Dco cells. These results identify a mechanism of a novel compound that can overcome antiestrogen resistance.

#3603 Optimizing combination therapy against antiestrogen-resistance in estrogen receptor positive breast cancer. Lauren M. Gutesell, Rui Xiong, Jiong Zhao, Debra A. Tonetti, Gregory R. Thatcher. University of Illinois at Chicago, Chicago, IL.

We studied the resistance of breast cancer cells with and without acquired resistance (AR) to selective estrogen receptor modulators (SERM) and aromatase inhibitors (AI). We optimized combination therapy using 35446-HCl as a new antiestrogen agent. The results showed that 35446-HCl inhibited ERα activity in antiestrogen-sensitive and resistant breast cancer cells with negligible non-specific toxicity. More importantly, we have shown that the 2nd generation compounds (35446, 4631) partially reduced sensitivity to Tam/ICI-resistant cells (LCC9), caused dissociation of ERα from a model estrogen response element (ERE) in MCF-7 cells, and inhibited growth of LCC9 tumor xenografts at nontoxic concentrations utilizing compound 35446-HCl (35446 prepared as a hydrochloride salt). The focus of this study is the mechanism of action of 35446-HCl compound’s inhibition of ERα, which includes inhibition of a major signaling pathway and mode of cell death. Eight genes identified from RNA-seq in LCC9 cells treated with BRCA1 mimetic A7 were verified by qPCR using 35446-HCl. One verified gene is the NF-κB activator IKKB, which is linked to therapy resistance. Treatment with 35446-HCl inhibited IKKB expression and proliferation in LCC9 cells compared to untreated Control at 48 and 72 hrs (p<0.0001). Transcriptional activity from the p65 promoter as measured with a luciferase assay was decreased in the presence of BRCA1 mimetic treatment (p<0.0001). Expression of downstream targets of NF-κB including genes known to inhibit apoptosis, was reduced (p value ranging from < 0.05- 0.001). Apoptosis due to 35446-HCl treatment was verified by caspase-7 cleavage and increased TUNEL staining at both 48 and 72 hrs. In silico analysis of the IKKB promoter within 10kb upstream of the transcription start site identified one putative full ERE and five putative half ERE sites. Of these, 35446-HCl inhibited the interaction of ERα with the full ERE (p<0.0001) and five half EREs (p value ranging from < 0.05- 0.001) sites upstream of the IKKB start site in LCC9 cells as well as Tam resistant/ERα mutated T47Dco cells. These results identify a mechanism of a novel compound that can overcome antiestrogen resistance.
Approximately 75% of breast cancer incidences are Estrogen Receptor positive (ER+). Treatment of ER+ breast cancer with antiestrogen endocrine therapy targets the proliferative mechanisms of ER using selective ER modulators (SERMs), such as tamoxifen, and selective ER downregulators (SERDs), such as fulvestrant. The resistance to endocrine therapy, either innate or acquired, is clinically relevant and results from one or more of 5% of patients who respond to initial anti-estrogen therapy, progressing to tamoxifen resistant disease. In order to gain insight into potential, combinatorial targets for overcoming endocrine resistance in ER+ breast cancer, use of spheroidal 3D cell culture provides a physiologically relevant model with sufficient throughput for drug discovery. Establishing spheroids and subsequent treatment reveals the efficacy of combination treatment on tumor regression. Targeting pathways associated with increased prevalence of resistance, such as CDK 4/6, can be employed for clinical therapy. Using both novel in-house and clinical SERMs and SERDs, we have used these multiple cell lines to discover combinatorial targets using both mechanistic and unbiased screening approaches. The use of combination endocrine therapy in tamoxifen-resistant models has shown promising results and is able to enhance tumor regression in xenografts. By optimizing combinatorial endocrine treatment against both fulvestrant and tamoxifen-resistance, novel therapeutic approaches are being developed for ER+ breast cancer.

#3604 Effect of a new oral SERD AZD9496 on ER mediated signaling in xenograft model of postmenopausal breast cancer. Gauri J. Sabnis,1 Armina Kazi,1 Amanda Schec,2 Stephen Yu,1 Olga Golubeva,1 Angela Brodie,1 West Coast University, Los Angeles, CA; 1 Loyola University Maryland, Baltimore, MD; 2 St. Mary’s College of Maryland, St. Mary’s City, MD; 1 University of Maryland School of Medicine, Baltimore, MD; 2 University of Maryland Greenebaum Cancer Center, Baltimore, MD.

Aromatase inhibitors (AIs) have made significant improvements in the treatment outcomes of patients with breast cancer. However, tumors may eventually acquire resistance. One of the proposed mechanisms of resistance to AIs is overexpression of ERα and cross-talk of ERα with growth factor receptors. Studies including our own have shown that downregulation of ER with fulvestrant may provide benefit in the treatment of AI-resistant breast cancer. Fulvestrant has been employed in the clinic as either first or second line treatment for ER positive breast cancers alone or in combination with AIs. Studies have suggested that further escalation of dose may provide further benefit. However, dose escalation of fulvestrant which is administered via intramuscular injection is difficult due to its poor solubility. To overcome this shortcoming of an injectable drug, a novel orally active SERD (selective estrogen receptor downregulator), AZD9496 was developed. We evaluated the effect of AZD9496 on the growth of hormone sensitivity and anastrozole resistant breast cancer tumors using MCF-7CA xenograft model of postmenopausal breast cancer. Mice bearing xenografts of MCF-7C were then treated with fulvestrant (1 mg/kg-d) or AZD9496 (5 mg/kg/d-po), alone or in combination with anastrozole (200mg/kg-d) for 23 weeks. Tumors were measured weekly and growth rate was calculated. AZD9496 was significantly better at inhibiting the growth of tumors compared to control (p<0.001) and anastrozole (p=0.06) while being equally effective as fulvestrant (p>0.99). In the second study, efficacy of AZD9496 was evaluated on an anastrozole resistant MCF-7CA xenografts. Tumors were treated with anastrozole (200mg/d) for 13 weeks. During this time, the tumors initially regressed but eventually began to grow and had doubled in volume. At this time point, they were regrouped to receive second line treatment. Single agent AZD9496 was marginally significant and comparable to continued anastrozole treatment (p=0.07). Nevertheless, second line treatment with AZD9496 was equally effective as fulvestrant (p=0.36). AZD9496 treatment was also equally effective in reducing the expression of ERα protein in MCF-7CA xenografts as fulvestrant. Next, we measured the effect of AZD9496 on the mouse uterus. Uterine weight of mice treated with AZD9496 was not significantly different from mice that were treated with anastrozole (p=0.99). Furthermore, AZD9496 did not decrease the expression of ERα in the uterus, confirming its selectivity for mammary ERα. AZD9496 treatment was also able to reduce intratumoral aromatase activity. However, it was not due to direct inhibition of the enzyme, but due to reduction in ERα mediated signaling. These results suggest that AZD9496 may be a better alternative to fulvestrant due to its oral bioavailability, selectivity for mammary ER, and ability to reduce aromatase activity while being equally effective as fulvestrant.

#3605 The role of androgen receptor in invasive lobular breast carcinoma. Hillary Stires, Rebecca B. Riggins. Georgetown University, Washington, DC.

The problem for women with estrogen receptor α (ER) breast cancer – approximately 70% of all breast cancers – is that while the majority of tumors initially respond to estrogen treatment including Tamoxifen and aromatase inhibitors, they will develop endocrine resistance. A histological subset of breast cancer called invasive lobular carcinoma (ILC) accounts for 15% of all breast cancer cases and approximately 90% of ILC are ER-positive. Despite clinical markers suggesting a better prognosis for ILC compared to the more common invasive ductal carcinoma (IDC), recent data suggests women with ILC develop Tamoxifen resistance at a higher rate than IDC. New strategies for treating hormone refractory tumors are needed that not only overcome anti-estrogen resistance, but also present a more tolerable side effect profile and have fewer dose-limiting toxicities than adjuvant chemotherapy. The majority of ER-positive breast cancers also express androgen receptor (AR) and while AR presence in breast cancer is controversal, increased expression of AR leads to Tamoxifen resistance in IDC cell lines. Since ILC has more AR expression than IDC, the role of AR in ILC was studied by treating cells with the non-aromatizable androgen dihydrotestosterone (DHT) and the synthetic androgen R1881 as well as the anti-androgen Enzalutamide. We have previously began to characterize a Tamoxifen resistant variant of the ILC cell line SUM44PE termed ILC-CTM cells. In both SUM44PE and LCC-Tam cells, AR protein expression increases in response to androgens, an action that is blocked by Enzalutamide. Interestingly, androgens do not promote growth in ILC cells, but Enzalutamide is still able to inhibit growth. These results suggest Enzalutamide may be an effective alternative therapy for women with ILC. Future studies will focus on whether regulation of nuclear receptor co-factors influences differences in AR signaling in ILC.

#3606 RBP2 promotes tamoxifen resistance by altering ER function and activating IGF1R and EGFR/HER2 signaling in histone methylation-dependent and -independent manners in breast cancer. Hee-Joo Choi,1 Taekwon Son,2 Hyung-Yong Kim,1 Kyueng-Whan Min,1 Young-Ha Oh,1 Jeong-Yeon Lee,2 Kuong G.,1 Hanyang Univ., Seoul, Republic of Korea; 2 Seoul National Univ., Seoul, Republic of Korea.

Retinoblastoma binding protein 2 (RBP2, also known as JARID1A), a member of the JARID1 family of histone H3 lysine K4 demethylases, has been considered to have an oncogenic potential in several types of human cancers including breast cancer. Although physical interaction between RBP2 and estrogen receptor (ER), a crucial factor for hormone-dependent breast cancer, has been implied, the role of RBP2 in ER-dependent breast cancer remains largely unknown. Here, we demonstrate that RBP2 is a novel therapeutic target for tamoxifen resistance in ER+ breast cancer as an ER co-regulator and an activator of receptor tyrosine kinase (RTK) signaling. In large cohorts of breast cancer patients including METABRIC, high expression of RBP2 was associated with poor response to tamoxifen therapy in ER+ breast cancer. Consistently, RBP2 induced tamoxifen resistance in ER+ breast cancer both in vitro and in vivo. Using RNA-sequencing analysis, we identified that many RBP2 target genes are overlapped with ER-dependent- and tamoxifen resistance-associated genes. Mechanistically, RBP2 induced not only hyperactivation of ER-dependent transcription but also estrogen agonist activity of tamoxifen-bound ER via the interaction with ER, thus increasing the expression of NRP1, a co-repressor of ER. RBP2 also formed a transcriptional repressive complex with ER, NRP1, and HDAC1 to induce H3K4 demethylation-mediated epigenetic gene silencing of IGBP4 and IGBP5, leading to the activation of IGF1R and its downstream, PI3K/AKT pathway. Furthermore, enhanced AKT phosphorylation by RBP2 was mediated by not only IGF1R but also EGF/HER2 signaling via increasing the stability of EGFR and HER2 proteins in a demethylase activity-independent manner. We further confirmed that combinational treatment with tamoxifen and PI3K inhibitor BKM120 restored tamoxifen sensitivity in RBP2-overexpressing breast cancer. Taken together, these findings suggest that RBP2 mediates tamoxifen resistance in ER+ breast cancer by altering ER activity and activating IGF1R and EGF/HER2 signaling pathways in both a histone methylation-dependent and -independent manner. Therefore, RBP2 may be a promising prognostic marker and therapeutic target for endocrine therapy-resistant breast cancer.

#3607 Metastasis-associated protein 1 negatively regulates expression of androgen receptor in ER-positive breast cancer cells. SeungSu Kim, Seoul National University, Seoul, Republic of Korea.
Androgen receptor (AR) is expressed in more than 80% of ER-positive breast cancer and its expression is correlated with better prognosis in ER-positive breast cancer. However, little is known about the regulation of AR expression in breast cancer. We have previously reported that metastasis-associated protein 1 (MTA1), a cancer-promoting gene that is overexpressed in breast cancer, increases AR expression in breast cancer. Herein, we investigated the role of MTA1 on AR expression in three different ER-positive breast cancer cell lines.

First, small interfering RNA-mediated knockdown of MTA1 increased protein and mRNA expression of AR in MCF7, T47D, and ZR75-1. Overexpression of MTA1 down-regulated expression of AR in these cell lines. Activity of the reporter-encoding AR promoter (−2408 bp + −1126 bp) was decreased in the presence of an AR-dependent cancer cell line, leading to a better understanding of the heterogeneity of this disease and development of therapeutic modalities tailored for each disease subtype. Hormone receptor positive breast cancers, which represent 75% of breast cancer cases, are routinely treated with therapies targeting the estrogen receptor (ER) axis, including aromatase inhibitors or anti-estrogens, either alone or in combination with other agents. Recent studies have shown that the androgen receptor (AR) is widely expressed across all subtypes of breast cancer, with AR detected in 75-95% of ER positive tumors. Mounting preclinical evidence from has demonstrated that AR agonists can suppress AR and ER positive (AR/ER+) breast cancer cell growth. Furthermore, prior to the development of ER/AR-targeted therapy, androgens were used to treat breast cancers with favorable clinical responses. RAD140 is an oral, nonsteroidal, nonaromatizable selective androgen receptor modulator (SARM) with a distinct tissue selectivity profile and mechanism of action. Here we examined the molecular activity of RAD140 in breast cancer cells and evaluated its efficacy using AR/ER+ breast cancer xenograft models. The tissue-specific activity of RAD140 was examined using androgen response element (ARE)-driven reporter assay in AR/ER+/ZR75 breast cancer cells and AR/ LNCaP prostate cancer cells. RAD140 was observed to be a potent AR agonist, comparable to dihydrotestosterone (DHT), in breast cancer cells, but did not induce AR activity in prostate cancer cells, while DHT demonstrated full AR agonist activity. In vivo anti-tumor efficacy of RAD140 was evaluated using AR/ER-positive breast cancer cell line- and patient-derived xenograft models. Ziyang Yu, Suqin He, Jeffrey Brown, Jamal Saeh, Gary Hattersley. Radius Health, Inc., Waltham, MA.

Breast cancer is the most frequently diagnosed malignancy for women in the US with 246,660 new cases predicted in 2016. Histological and molecular characterization of breast tumors has led to a better understanding of the heterogeneity of this disease and development of therapeutic modalities tailored for each disease subtype. Hormone receptor positive breast cancers, which represent 75% of breast cancer cases, are routinely treated with therapies targeting the estrogen receptor (ER) axis, including aromatase inhibitors or anti-estrogens, either alone or in combination with other agents. Recent studies have shown that the androgen receptor (AR) is widely expressed across all subtypes of breast cancer, with AR detected in 75-95% of ER positive tumors. Mounting preclinical evidence from has demonstrated that AR agonists can suppress AR and ER positive (AR/ER+) breast cancer cell growth. Furthermore, prior to the development of ER/AR-targeted therapy, androgens were used to treat breast cancers with favorable clinical responses. RAD140 is an oral, nonsteroidal, nonaromatizable selective androgen receptor modulator (SARM) with a distinct tissue selectivity profile and mechanism of action. Here we examined the molecular activity of RAD140 in breast cancer cells and evaluated its efficacy using AR/ER+ breast cancer xenograft models. The tissue-specific activity of RAD140 was examined using androgen response element (ARE)-driven reporter assay in AR/ER+/ZR75 breast cancer cells and AR/ LNCaP prostate cancer cells. RAD140 was observed to be a potent AR agonist, comparable to dihydrotestosterone (DHT), in breast cancer cells, but did not induce AR activity in prostate cancer cells, while DHT demonstrated full AR agonist activity. In vivo anti-tumor efficacy of RAD140 as monotherapy, compared with fulvestrant, or in combination with a CDK4/6 inhibitor (palbociclib) or mTOR inhibitor (everolimus) was evaluated in AR/ER+ patient derived xenograft (PDX) models and cell line-derived xenograft (CDX) models. Tumor-bearing mice were randomized into treatment groups and received vehicle, RAD140, fulvestrant, palbociclib, everolimus or combinations of RAD140 with palbociclib or everolimus. Tumor volume and growth was measured to evaluate efficacy. At the end of the study, plasma and tumor samples were collected for pharmacokinetic and pharmacodynamic analysis. In AR/ER+ breast cancer PDX models, RAD140 treatment led to substantial tumor growth inhibition that was greater than that seen with fulvestrant. Furthermore, combination of RAD140 with palbociclib or everolimus produced further enhanced anti-tumor efficacy in these models. In summary, RAD140 demonstrated tissue-selective AR agonism with marked anti-tumor activity in AR/ER+ breast cancer CDX and PDX models, together with enhanced anti-tumor activity in combination with a CDK4/6 inhibitor or mTOR inhibitor.

RAD140, a selective androgen receptor modulator, has a differentiated mechanism of action in AR/ER positive breast cancers. Ziyang Yu, Suqin He, Dannie Wang, Jeffrey Brown, Jamal Saeh, Gary Hattersley. Radius Health, Inc., Waltham, MA.

Recent studies have shown that the androgen receptor (AR) is widely expressed across all subtypes of breast cancer, with AR detected in 75-95% of estrogen receptor (ER) positive tumors. Prior to the development of ER-targeted therapy, androgens were used to treat breast cancers with favorable clinical responses. The lack of tissue-selectivity and understanding of mechanism of action of classic androgens led to its declined use in this disease. Selective androgen receptor modulators (SARMs) are a class of molecules developed as tissue selective non-steroidal androgens that modulate AR signaling. However, the effect of SARMs on AR signaling in breast cancer cells is not well understood. RAD140 is an orally available SARM with potent anabolic activity in muscle and bone but a highly attenuated effect in seminal vesicles and prostate. Its efficacy is expected to be increased in breast cancer with AR function. To further our understanding of the mechanism of action of RAD140 in breast cancer cells, we examined the effects of RAD140 on AR and ER signaling pathways. The specificity and selectivity of RAD140 were examined using competitive binding assays for AR, ER, glucocorticoid receptor (GR) and progesterone receptor (PR), and using an AR reporter assay in AR/ER+ ZR-75 breast cancer cells and LNCaP prostate cancer cells. RAD140 was found to bind AR with high affinity and selectivity, with 250-fold target selectivity over the next nuclear receptor PR. The AR reporter assay results demonstrated a potent AR agonist activity of RAD140 in ZR-75 breast cancer cells but not in LNCaP prostate cancer cells, in contrast to the full agonist activity of DHT seen in both cell types. RAD140 treatment led to substantial tumor growth inhibition in AR/ER+ breast cancer xenografts. Samples of RAD140-treated xenografts were analyzed by immunohistochemistry, western blotting and quantitative real-time PCR to evaluate the modulation of AR and ER pathways. It was found that the expression of known AR target genes including KLK2, FKBP5 and the tumor suppressor gene, ZBTB16, were potently induced in RAD140-treated tumors. Furthermore, RAD140 led to substantial suppression of known ER target genes including progesterone receptor (PR), ERα and ERβ1. In conclusion, RAD140 is a potent AR agonist with marked anti-tumor activity in AR/ER+ breast cancer cells with robust activation of AR target genes, and a unique mechanism of action that leads to the suppression of ER signaling, and marked anti-tumor activity.

Synergy between androgen receptor (AR)-targeting agents and PARP inhibitors in breast cancer. Michael A. Gordon, Nicholas D’Amato, Jessica Christenson, Beatrice Babbs, Haihua Gu, Julia Wulfkuhle, Emmanuel Petracon, Anthony Elia, Jennifer K. Richer. Univ. of Colorado Anschutz Medical Campus, Denver, CO; George Mason University, Manassas, VA.

Background: AR is expressed in ~60% of HER2+ and up to 30% of triple negative breast cancer (TNBC) with growing evidence that AR plays a role in BC growth and survival. Next-generation AR-targeting agents including SEV1 (selective CYP17-lyase and AR inhibitor) and ENZA (ENZA inhibitor) have shown promise in preclinical and clinical models of prostate cancer and are currently being evaluated in BC. Approved therapeutics targeting mTOR such as everolimus (EVEROL) and HER2-targeting agents provide significant clinical benefit in some BC patients; however, de novo and acquired resistance remain critical issues that may be partially attributed to compensatory AR activity. Hypothesis: Due to cross-regulation between AR and the HER2/Pi3K/mTOR pathway in BC, targeting AR in combination with approved agents for these pathways may improve responses. Methods: Human BC cell lines HER2+ (BT474, BT474-HR20, SKBR3) and TNBC (MDAMB453, BT494) and an AR+ TNBC mouse mammary carcinoma model were treated with multiple doses of AR-targeting agents SEV1 or ENZA and EVEROL, alone or in combination and assayed over time using Incucyte instrumentation and combination indices calculated using CalcuSyn. Anchorage independence was tested by growth on soft agar. Pathway component genes and proteins were measured. In vivo, NOD/SCID mice with HER2+ trastuzumab-resistant BT474-HR20 xenografts were treated with ENZA, EVEROL, or the combination. Similar in vivo experiments with SEV1 are ongoing. Results: Both SEV1 and ENZA significantly inhibited proliferation of both HER2+ and TNBC cell lines. Both significantly inhibited growth on soft agar in 1 Met-1 cells (p<0.005 for SEV1, p=0.032 for ENZA). Using 9 dose combinations of EVEROL with SEV1 or ENZA, synergy was observed in multiple cell lines in vitro, but only in lines containing activating PIK3CA mutations. DHT induced a cell line-specific increase in pHER2 and/or pHER3 that was attenuated by AR inhibition. EVEROL alone caused an increase in total AR, pHER2, and pHER3, but was strongly inhibited by AR inhibition. In vivo, ENZA inhibited BT474-HR20 xenografts, and combining ENZA with EVEROL decreased tumor viability more than either single agent (p<0.001, repeated measures ANOVA). Similar in vivo studies with SEV1 are planned. Conclusion: Agents targeting AR synergize with EVEROL. Combination therapies targeting AR and the mTOR and HER2/HER3 pathways may provide mechanisms for increased anti-tumoral efficacy of HER2+ and TNBC. A strong inhibitor of anchorage-independent growth than ENZA and will thus be further investigated in combination with approved HER2/Pi3K/mTOR pathway-directed therapeutics in vivo. #3611 Proteasome subunit PSMD1 participates in p53 degradation and regulates proliferation of breast cancer cells. Toshiyuki Okumura,1 Kazuhiro Ikeda,1 Wataru Sato,1 Kuniko Horie-Inoue,1 Satoshi Inoue,1 Satoru Takeda,2 Koji Okamoto,1 Saitama Medical University, Saitama Prefecture, Japan; 2University of Colorado, CO.

Breast cancer is the most common cancer among women in developed countries. Generally, 70% of primary breast cancer patients express estrogen receptor, thus endocrine therapy is often efficient for the disease using antiestrogen such as tamoxifen as well as aromatase inhibitor. During long-term therapy, however, a substantial proportion of women recurrent and acquire resistance to endocrine therapy. Understanding of the mechanism underlying acquired endocrine resistance would be a first step toward overcoming hormone-refractory cancer. In this study, we identified candidate genes that contributed to tamoxifen resistance in MCF-7 breast cancer cells by functional screening based on short hairpin RNA (shRNA) library. We found that several candidate genes were overexpressed in breast cancer patients and their abundance was positively associated with poor prognosis of cancer patients in clinical database. Moreover, the genes associated with poor prognosis also showed positive association with shorter survival for patients treated with tamoxifen. Expression levels of these candidate genes were upregulated in hydroxysteramofin (OHT)-resistant MCF-7 cells (OHTR) compared with parental cells. Proliferation of OHTR cells was repressed by siRNAs targeting 26 subunits, non-ATPase 1 (PSMD1) and tetraspanin12 (TSPAN12). Furthermore, knockdown of PSMD1 inhibited cell cycle progression and p53 protein degradation. p21 and 14-3-3-3r, target genes of p53, were upregulated by PSMD1 knockdown. These findings would be used for the development of alternative diagnostic and therapeutic options for endocrine-resistant breast cancers.

#3612 Combination FGF4R and ER-targeted therapy for invasive lobular carcinoma. Kevin Levine,1 Jian Chen,1 Matthew Sikora,2 Nilgun Tasdemir,1 George Tseng,1 Shannon Pahaula,1 Rachel Jankowiak,1 David Dubbs,1 Priscilla McAuliffe,1 Adrian Lee,1 Steffi Oesterreich1.1University of Pittsburgh, Pittsburgh, PA, 2University of Colorado, CO.

Background: Invasive Lobular Carcinoma (ILC) is an understudied subtype of breast cancer. Distinctive properties of ILC include growth patterns, metastatic behavior, receptor status (almost universally estrogen receptor (ER) positive), and survival outcomes (Long-term survival is lower in patients with ER-ILC compared to the other main histological subtype, invasive ductal carcinoma). Our lab recently generated six long-term estrogen deprivation (LTED) models of ILC cells. We performed RNA-Sequencing on these six LTED cell lines and identified differentially expressed genes compared to their parental cells cultured with estrogen. We overlapped these results with a previously published analysis of a tamoxifen-resistant ILC cell line and found that FGF4R is the most consistently overexpressed gene in the setting of acquired resistance to endocrine therapy in ILC cells. Hypothesis FGF4R is an important mediator of resistance to endocrine therapy in ILC. Methods: To study the role of FGF4R in acquired resistance to endocrine therapy, we used siRNA, multiple shRNAs, and specific small molecule inhibition for growth assays of ILC cells. To study the role of FGF4R in resistance to endocrine therapy, we collected 129 well-curated ER-ILC tumor specimens. We performed gene expression analysis on the pre-treatment samples using a custom NanoString panel. Results: FGF4R inhibition decreases parental and LTED ILC cell growth in classic 2D growth conditions, in the setting of ultra-low attachment, and in colony formation assays. Mechanistically, FGF4R and estrogen signaling are antagonistic in parental ILC cells. In our clinical samples, increased expression of FGF4R is predictive of shorter time to distant recurrence. Conclusion: FGF4R may play an important role in both acquired and de novo resistance to endocrine therapy in ILC. Future studies will assess the efficacy of combining FGF4R inhibitors with ER-targeted therapy for patients with ILC.

#3613 Development of chemically modified peptide inhibitor ERAP targeting BIG3-PHB2 complex on hormone-resistant breast tumor. Toyomasu Katagiri, Tetsuro Yoshimaru. Tokushima Univ., Tokushima, Japan.

Approximately 70% of breast cancer cells express estrogen receptor alpha (ERα), and depend on estrogen (E2) for proliferative and metastatic activity. The current endocrine therapies for breast cancer are mainly based on targeting ERα signaling using selective ERα modulators, ERα downregulators, and aromatase inhibitor. However, up to 50% of patients with ERα-positive tumors either initially do not respond or become resistant to these drugs. The precise molecular mechanisms for the endocrine resistance contributes to be an active area of research. Therefore, identifying the factors and pathways responsible for resistance and defining ways to overcome it lead to develop novel molecular-target therapies to endocrine resistance. Recent findings support that the Brefeldin A-inhibited guanine nucleotide-exchange protein 3-prohibitin 2 (BIG3-PHB2) complex plays a crucial role in E2/ERα signaling modulation in these cells. Moreover, specific inhibition of the BIG3-PHB2 interaction using ERα activity-regulator synthetic peptide (ERAP: 165-177 amino acids) derive from a helical BIG3 sequence, a dominant-negative peptide inhibitor leads to the significant anti-tumor effect. However, duration of its effect is very short for clinical use. Here, we report the development of the chemically modified ERAP using stapling methods (stapled ERAP) to improve duration of its anti-tumor effects. The stapled ERAP specifically inhibited the BIG3-PHB2 interaction, thereby exhibiting the long-lasting suppressive activity and their intracellular localization was membrane-permeable polyarginine sequence supposedly through the formation of stable α-helix structure induced by the stapling. Importantly, a combination of stapled ERAP and tamoxifen caused a synergistic inhibitory effect in breast cancer cell growth. Tumor bearing mice treated with every 7 days with stapled ERAP treatment effectively prevented the BIG3-PHB2 interaction as well as daily treatment, leading to the complete regression of E2-dependent tumor in vivo. Our findings suggest that stapled ERAP may be a promising anti-tumor drug to suppress the growth of luminal-type breast cancer in clinical use.

#3614 Antibody validation revises estrogen receptor beta research. Sandra Andersson,1 Matsen Sundberg,2 Nusa Pristoveck,3 Ahmed Ibrahim,4 Phillip Jonsson,5 Bobbala Katona,1 Carl-Magnus Claussou,1 Agata Zieba,2 Margareta Ramstrom,3 Ola Soderberg,1 Cecilia Williams,2 Anna Asplund.1 Uppsala University, Uppsala, Sweden; 2KTH Royal Institute of Technology, Solna, Sweden; 3University of Houston, Houston, TX.

The discovery of estrogen receptor β (ERβ/ESR2) in 1996 was a landmark discovery. Its homology with breast cancer pharmacological target and predictive biomarker estrogen receptor α (ERα/ESR1) raised hopes for improved endocrine therapies. However, after twenty years of intense research the therapeutic promises have not materialized. We here perform a rigorous validation of 13 anti-ERβ antibodies, and demonstrate that the vast majority are unspecific. Using well-characterized controls and a panel of validation methods, we conclude that only the rarely used monoclonal antibody PPZ0506 targets ERβ in a specific manner in immunohistochemistry. We applied this antibody for protein expression profiling in 44 normal and 21 malignant human tissues and found that detection of ERβ protein is limited to testis, ovary, placenta, lymphoid cells, granulosa cells tumors, and a subset of malignant melanoma and thyroid cancers. This expression pattern aligns well with RNA-seq data, but contradicts a multitude of studies. We did not find evidence that normal or cancerous human breast express ERβ protein. Our study highlights how inadequately validated antibodies can lead an exciting and promising field astray.

#3615 Combined targeting of estrogen receptor alpha and nuclear transport pathways remodel metabolic pathways to induce apoptosis and overcome tamoxifen resistance. Eylem Kulkoyluoglu-Cotul,1 Zeynep Madak-Erdogan,1 Yosef Landesman,1 Kinga Wrobel.1 University of Illinois Urbana-Champaign, Urbana, IL, 2Karyopharm Therapeutics Inc., Newton, MA.

There is a critical need for novel therapeutic approaches to re-sensitize recurrent ERα (+) tumors to endocrine therapies. The objective of this study was to elucidate mechanisms of improved effectiveness of combined targeting of ERα and XPO1, a nuclear transport protein in overcoming endocrine resistance. Using Cignal Finder pathway analysis, Seahorse metabolic profiling and GC/MS whole metabolite profiling, we found that combination of 4-OH-Tam and Selinexor (SXR), being evaluated in multiple later stage clinical trials in patients with relapsed and refractory hematological and solid tumor malignancies, inhibited Akt phosphorylation by changing the localization of the kinase. Since we observed dramatic changes in Akt activity we hypothesized that glucose utilization pathways and metabolic profile of breast cancer cells would change in tumors that are XPO1 and SXR-resistant. These cells were more dependent on mitochondria for energy production. Their glucose and fatty acid dependency decreased in the presence of SXR and cells were more dependent on glutamine as the mitochondrial fuel source. We showed that combined targeting of XPO1 and ERα rewire metabolic pathways, increase demand on mitochondria and causes increased production of ROS that would eventually lead to apoptosis. Re-modelling metabolic pathways to regenerate new vulnerabilities in endocrine-resistant tumors is novel, and given the need for better strategies for improving therapy response of relapsed ERα (+) tumors, our findings show great promise for uncovering the role ERα-XPO1 crosstalk plays in reducing cancer recurrences.

ENDOCRINOLOGY: Nuclear Receptors and Endocrine Oncology Therapies

Proceedings of the American Association for Cancer Research • Volume 58 • April 2017

Breast cancer is a common cancer among women worldwide. Hormone-mediated therapy to treat estrogen receptor alpha (ERα) positive breast cancers include the use of ER antagonist, tamoxifen, aromatase inhibitors and other compounds that degrade ERα. Unlike ERα, ERβ has been shown to have tumor-suppressive function in various cancers, including breast cancer. Recent studies have identified, synthesized, and tested the clinical safety of ERβ-selective agonists. Given the tumor-suppressive properties of ERβ, it may be possible to use these compounds to induce or activate the ERβ and test their role in the chemoprevention and blocking the progression of breast cancer. We have investigated the therapeutic utility of ERβ agonists in the prevention and progression of breast cancer using MMTV-HER2/neu mice transgenic mouse model. MMTV-HER2/neu mice develop premalignant lesions at 4-5 months, and tumors starting at month 7 due to overexpression of the HER2/neu proto-oncogene. MMTV-HER2/neu mice were treated with an ERβ agonist, Lyn500307 examined the prevention and progression of mammary cancers in these mice. When compared to controls, ERβ agonist-treated mice exhibited a significant decrease in the development of neoplastic changes. Differential gene expression analysis revealed a significant change in the expression of a number of genes in response to Lyn500307 treatment. Pathway analysis identified our model for chemokines signaling pathways, particularly TNF, in blocking the development of neoplastic changes resulting from treatment with ERβ agonists. Our studies also show a decrease in the formation of mammary tumors in HER-2/ neu mice with preexisting neoplastic changes when treated with Lyn500307. This study suggests that ERβ agonist treatment may be a valuable therapeutic option for the prevention in women at increased risk of breast cancer and in blocking the progression of hormone receptor positive breast tumors.

A paradigm shift for insulin-like growth factor 1 receptor function in triple negative breast cancers. Alison Obr, Sushil Kumar, Raymond Birge, Teresa Wood. Rutgers University-NJMS, Newark, NJ.

Signaling through the insulin-like growth factor type 1 receptor (IGF-1R) is complex in breast cancers. Early studies reported that expression of the IGF-1R correlated with estrogen receptor (ER) expression and predicted a favorable prognosis. Moreover, loss of IGF-1R has been associated with breast tumor progression into a more undifferentiated phenotype. We have generated and characterized a mouse line containing both MMTV-Wnt1 and MMTV-dnIGF-1R (kinase dead-IGF-1R) transgenes (referred to subsequently as bigenic mice). MMTV-HER2/neu mice developed premalignant lesions at 4–5 months, and tumors starting at month 7 due to overexpression of the HER2/neu proto-oncogene. MMTV-HER2/neu mice were treated with an ERβ agonist, Lyn500307 examined the prevention and progression of mammary cancers in these mice. When compared to controls, ERβ agonist-treated mice exhibited a significant decrease in the development of neoplastic changes. Differential gene expression analysis revealed a significant change in the expression of a number of genes in response to Lyn500307 treatment. Pathway analysis identified our model for chemokines signaling pathways, particularly TNF, in blocking the development of neoplastic changes resulting from treatment with ERβ agonists. Our studies also show a decrease in the formation of mammary tumors in HER-2/neu mice with preexisting neoplastic changes when treated with Lyn500307. This study suggests that ERβ agonist treatment may be a valuable therapeutic option for the prevention in women at increased risk of breast cancer and in blocking the progression of hormone receptor positive breast tumors.

Role of MTDH in estrogen-regulated gene expression. Xiangbing Meng, Yujun Li, Jesus Gonzalez Bosquet, shujie yang, Kristina W. Thiel, Kimberly K. Leslie. Univ. of Iowa College of Medicine, Iowa City, IA.

Disruption of estrogen signaling is widely associated with the development of breast, endometrial, and ovarian cancers. As a multifunctional mediator of carcinogenesis, metadherin (MTDH)/AEG-1 overexpression has been associated with numerous types of cancers, with reported roles in tumor initiation, proliferation, invasion, metastasis and chemoresistance. At the molecular level, MTDH has been shown to interact with proteins that drive tumorigenesis, including NF-κB, PLZF, BCCIP and SND1. Through analysis of the Cancer Genome Atlas (TCGA) datasets for ER-positive endometrial and breast cancers, we found that over 25% of all gene expression correlated with MTDH. Using Affymetrix microarrays, we characterized the differences in gene expression between estrogen-treated parental and MTDH-deficient endometrial and breast cancer cells. We also explored a possible interaction between MTDH and ER by immunoprecipitation and found that MTDH and ER associated in both breast and endometrial cancer cells. We also explored a possible interaction between MTDH and ER by immuno precipitation analysis demonstrated that estrogen stimulation promoted the interaction of MTDH with ER in the nucleus. These data suggest that MTDH and ERα interact in the nucleus with estrogen treatment, and MTDH/ERα co-regulated genes may have functions in drug resistance, metastasis and tumor progression.

RARalpha interactome in breast cancer, the S100 calcium binding protein A3 binds to the retinoid receptor. Mineko Terao. Istituto di Ricerche Farmacologiche Mario Negri, Milano, Italy. All-trans-retinoic acid (ATRA) is used in the treatment of acute promyelocytic leukemia. ATRA is endowed with promising anti-tumor activity in other tumor types, including breast cancer. In breast cancer, the anti-tumor activity of ATRA is mediated by the retinoid nuclear receptor, RARα (EMBO Mol Med 2015 7:950-972). RARα is a ligand-dependent transcriptional factor, which is part of nuclear complexes regulating the expression of target genes. To define the RARα interactome in breast cancer cells we took a proteomic approach. We performed mass-spectrometric analysis of RARα immuno-precipitates from nuclear extracts of an ATRA-sensitive breast cancer cell line over-expressing the receptor. We identified 30 proteins differentially interacting with RARα in the absence/presence of ATRA. Three of these proteins FABP5, HSP27 and S100A3 interact with RARα in the absence of ATRA and their binding to the receptor is dramatically reduced upon addition of the retinoid ligand. Binding of the three proteins to RARα was validated by different types of immuno-precipitation
actions are coordinated is key to understanding how transcription is regulated and will suggest new targets in steroid hormone regulated cancer and in other steroid hormone-related diseases.

#3623 Preclinical efficacy of the selective GR antagonist, CORT125134. Hazel Hunt, Joseph Belanoff, Thad Block, Stacie P. Shepherd. Conceptor, Menlo Park, CA.
The role of activation of the glucocorticoid receptor (GR) in the response of several solid tumor types to chemotherapy has been reported by several groups. Skor et al.1 have demonstrated that the non-selective GR antagonist mifepristone can potentiate the effect of paclitaxel in a mouse xenograft derived from a human triple negative breast cancer (TNBC) cell line. GR activation is thought to play a role in the regulation of pro- and anti-apoptotic genes. Isikbay et al.2 have demonstrated the benefits of combining androgen deprivation therapy with GR antagonism in prostate cancer xenograft model. Signaling via GR appears to be able to compensate for lack of androgen receptor signaling, and to contribute to castrate resistance. CORT125134 is a novel, selective GR antagonist being developed for the treatment of a variety of solid tumors, in combination with an appropriate selective Estrogen Receptor Modulators (SERMs) or aromatase inhibitors. An emerging mechanism of ER\(^+\) BC resistance to endocrine therapy, and consequently disease relapse, has been associated with a set of “hotspot” mutations in and near to helix-12 of the ER\(^+\) ligand binding domain. Selective Estrogen Receptor Degraders/Down-regulators (SERDs) represent an important pharmacological strategy being applied to develop treatments for resistant ER\(^+\) BC. Here, we compare 2 of the most frequent ER\(^+\) hotspot mutations (Y537S and D538G), with ER\(^+\) H9251/WT, and the ability of a set of SERM/SERDs and other ER\(^+\) ligands to bind, antagonize, degrade/stabilize ER\(^+\) and affect cell proliferation. Common themes that emerged included the observation that the concentration of each drug required to bind, antagonize or degrae ER\(^+\) Y537S or ER\(^+\) D538G was typically higher than that required for ER\(^+\) WT, although the extent of the shift varied between drugs and the type of measurement. An unexpected observation was that hydroxy-tamoxifen (a major active metabolite of tamoxifen) stabilized nuclear ER\(^+\) Y537S protein. This represents a potential mechanism that may limit the efficacy of Tamoxifen in treating ER\(^+\) Y537S ER\(^+\) BC.

#3622 Crosstalk between automethylation and phosphorylation tightly regulates G9a and GLP coactivator function with steroid hormone receptors. Coralie Pouillard, Michael Stellaup. University of Southern California, Los angeles, CA.
Hormone-activated steroid receptors (SR) bind to specific regulatory elements on DNA and recruit coregulators which remodel chromatin, regulate assembly of the transcription complex, and regulate transcription of their target genes. As for many coregulators, the lysine methyltransferases G9a and GLP function in both activation and repression of transcription depending on the gene. Indeed, G9a and GLP catalyze methylation of H3K9, a well-known repressive mark, but can also act as coactivators of SR (e.g. estrogen receptor \(\alpha\) and glucocorticoid receptor or GR). G9a and GLP can form homo- and heterodimers via interactions between their C-terminal domains. At the molecular level, we established that GLP, as well as G9a, is methylated on the N terminal domain of the protein, which is the region implicated in coactivator function. This event is induced by recruitment of HP1\(^{\gamma}\), while HP1\(^{\gamma}\) binding to G9a and GLP is inhibited by aurora B-mediated phosphorylation of G9a or GLP adjacent to the methylation site. In transient reporter gene assays, mutations of G9a and GLP methylation sites significantly decreased their coactivator activity with GR. Inversely, inhibition of Aurora kinase B activity increased the reporter gene activation. In addition, inhibition of the kinase activity of Aurora B increased the expression of endogenous GR target genes positively regulated by G9a and GLP, while depletion of HP1\(^{\gamma}\) inhibited their expression. Moreover methylated G9a or GLP can form a ternary complex with HP1\(^{\gamma}\) and GR in cell lines, and HP1\(^{\gamma}\) was recruited to the GR binding sites of the target genes positively regulated by G9a and GLP (but not on GR target genes that do not require G9a or GLP). Interestingly, the subset of GR target genes positively regulated by G9a and GLP contains some genes involved in cellular movement. At the physiological level, we established that G9a and GLP act as coactivators of GR target genes that mediate glucocorticoid repression of cell migration, which accompanies epithelial-to-mesenchymal transition associated with cancer progression. In this study we demonstrated that G9a and GLP methylation is required for their coactivator function with GR, because it facilitates recruitment of HP1\(^{\gamma}\) which functions selectively as a coactivator for genes positively regulated by G9a, GLP and GR. Inversely, G9a and GLP phosphorylation antagonizes these effects. This competition could be involved in the switch to determine whether G9a and GLP function as coactivator or co-repressor on specific target genes. Defining the specific molecular functions of SR coregulators and how their recruitment and

Endocrinology: Nuclear Receptors and Endocrine Oncology Therapies

Experiments. We focused our attention on S100A3, a calcium binding protein whose function is largely unknown. Pull-down and Far-Western experiment indicated that S100A3 binds directly to RAR\(^\alpha\). Binding is specific to this nuclear receptor isotype as similar interactions with S100A3 are not observed with RAR\(\beta\), RAR\(\gamma\) or RXR\(\alpha\). S100A3 over-expression inhibited RAR\(\alpha\) ligand-depen- dent transactivation; suggesting that calcium-binding is a co-repressor. We designed specific shRNAs targeting S100A3 and we are in the process of evaluating their functional effects on ATRA-dependent anti-tumor activity in retinoid sensitive breast cancer cell lines.

#3621 Characterization of the effects of estrogen receptor alpha Y537S and D538G mutations on receptor pharmacology. Steven J. Hartman,1 Tracy Kleinheinz,1 Jonathan White,7 Stephen Daly,7 Ria Goodwin,7 Wei Zhou,1 Jun Liang,1 Xiaojing Wang,1 Daniel F. Ortwine,1 Lori Friedman,1 Martin O’Rourke,1 Ciara Metcalfe,1 Robert A. Blake,1 Genentech, Inc., South San Francisco, CA; 2Charles River Laboratories, Harlow, United Kingdom.
The frontline therapy for estrogen receptor alpha (ER\(\alpha\)) positive Breast Cancer (ER\(^+\) BC) involves various forms of endocrine therapy, consisting of either Selective Estrogen Receptor Modulators (SERMs) or aromatase inhibitors. An emerging mechanism of ER\(^+\) BC resistance to endocrine therapy, and consequently disease relapse, has been associated with a set of “hotspot” mutations in and near to helix-12 of the ER\(^+\) ligand binding domain. Selective Estrogen Receptor Degraders/Down-regulators (SERDs) represent an important pharmacological strategy being applied to develop treatments for resistant ER\(^+\) BC. Here, we compare 2 of the most frequent ER\(^+\) hotspot mutations (Y537S and D538G), with ER\(^+\) H9251/WT, and the ability of a set of SERM/SERDs and other ER\(^+\) ligands to bind, antagonize, degrade/stabilize ER\(^+\) and affect cell proliferation. Common themes that emerged included the observation that the concentration of each drug required to bind, antagonize or degrade ER\(^+\) Y537S or ER\(^+\) D538G was typically higher than that required for ER\(^+\) WT, although the extent of the shift varied between drugs and the type of measurement. An unexpected observation was that hydroxy-tamoxifen (a major active metabolite of tamoxifen) stabilized nuclear ER\(^+\) Y537S protein. This represents a potential mechanism that may limit the efficacy of Tamoxifen in treating ER\(^+\) Y537S ER\(^+\) BC.

ATC has been shown to provide a significant improvement in the efficacy of paclitaxel in a pancreatic cancer model. In a MiaPaca-2 xenograft model, paclitaxel was given i.v. every 4 days to mice either alone or in combination with CORT125134. The combination provided significantly better tumor group inhibition than paclitaxel alone (p<0.0001). These encouraging results in a pancreatic cancer model extend the potential utility of GR antagonism in a variety of solid tumor types. In the TNBC model, alternative dosing regimens have been investigated, and suggest that stress during dosing is a confounding factor in these studies. 1. Skor MN, Wonder E, Kocherginsky M, et al. #3624 CAR T cells targeting ICAM-1 trigger strong anti-tumor effects against advanced human thyroid tumors. Irene M. Min, Yогinda Vedvyas, Enda Shevlin, Marján Zaman, Brian Yrwws, Weinib Wang, Susan Park, Mau- reen Moore, Theresa Scognamiglio, Rasa Zarnegar, Thomas J. Fahey, Moonsou M, Jin, Man, Yoon Soo, M.D., New York, NY.
Introduction: Poorly differentiated thyroid cancer and anaplastic thyroid cancer (ATC) are rare yet inherently lethal malignancies with limited treatment options. Many malignant tumors, including papillary thyroid cancer (PTC) and ATC, are associated with increased expression of intercellular adhesion molecule-1 (ICAM-1), providing a rationale for utilizing ICAM-1-targeting agents in the treatment of aggressive types of thyroid cancer. Therefore, we developed a third-generation chimeric antigen receptor (CAR) targeting ICAM-1 to leverage adoptive T cell therapy as a new treatment modality against advanced thy-roid cancer. Methods: We created a firefly luciferase-expressing human ATC model in mice that develops systemic metastases very rapidly. ATC engrafted mice were treated with human peripheral blood T cells modified with a lentivi- rus encoding an ICAM-1 specific CAR (ICAM-1-CAR) to investigate their therapeuetic efficacy. Tumor burden was longitudinally measured by whole body bioluminescence imaging of luciferase-positive tumor cells. Effectortarget as says consisting of ICAM-1-CAR T cells co-cultured with multiple malignant and non-malignant target cells were used to investigate specific target cell death and orchestrating toxicity in vitro using luminescence and flow cytometry. Results: ICAM-1-CAR T cells demonstrated the ability to target and kill ATC cell lines in vitro. Strikingly, despite heterogeneous expression of ICAM-1 in ATC cell lines, addition of cytotoxic CAR T cells induced increased ICAM-1 expression by T cell-derived interferon gamma such that all cell lines became targetable by ICAM-1-CAR T cells. Patient-derived, poorly differentiated PTC cells overexpressed ICAM-1 and were also mostly eliminated by autologous ICAM-1-CAR T cells in vitro. In mice with systemic ATC, a single administrati on of ICAM-1-CAR T cells at a clinical dose mediated significant tumor killing with a 100-fold reduction in primary tumor burden compared to pre-treatment. Reductions in tumor burden persisted for over 80 days and treated mice demon-strated significantly improved survival without toxicity. Conclusion: Our
Thyroid hormone, thyroxine, promotes cell proliferation and β-catenin activation in colorectal cancer. Yee-Shin Lee, 1 Meng-Ti Hsieh, 1 Yu-Tang Chin, 2 Alec Herbergs, 3 Paul J. Davis, 4 Han-Chung Wu, 3 Hung-Yun Lin, 1 + Taipei Medical University and Academia Sinica, Taipei, Taiwan; 2 Wan-Fang Medical Center, Taipei Medical University, Taipei, Taiwan; 3 The Cleveland Clinic, Cleveland, OH; 4 Albany College of Pharmacy and Health Sciences, Albany, NY; 5 Academia Sinica, Taipei, Taiwan.

Backgrounds: Being a crucial hormone regulating growth, metabolism and various physiological processes, the status of thyroid hormone has long been implicated in cancer risks and tumor developments. In the present study, we aimed to look at the role of thyroid hormone, thyroxine (T4), in colorectal cancer cell proliferation and β-catenin activation, which is highly involved in both normal and oncogenic developments of the gut. Materials and Methods: The effects of T4 in colorectal cancer cell lines HCT 116 (APC wild type) and HT-29 (APC mutant) as well as the primary cells derived from colorectal cancer patients were studied. Cell proliferation was evaluated according to cell counting, MTT assay and qRT-PCR. The activation of β-catenin was examined by Western blotting, qRT-PCR and immunoprecipitation. Results: The results showed that T4 increased the cell number of both HCT 116 and HT-29 cells compared to the untreated cells. In both cell lines, T4 induced nuclear β-catenin accumulation and the protein levels of WNT/β-catenin targets Cyclin D1 and c-Myc. The mRNA expression of CTNNB1 was elevated by T4 in HCT 116 cells, but not in HT-29 cells. In APC wild type HCT 116 cells, T4 increased the WNT4 mRNA expression and decreased the association between β-catenin and the WNT-regulated β-catenin destruction complex. Moreover, the cell numbers of T4-treated primary cells were higher compared to the untreated cells while the mRNA expressions of proliferative genes PCNA, CCND1 and c-Myc, and mRNA expressions of CTNNB1 and WNT4 were also observed. Conclusions: T4 promoted cell proliferation and β-catenin activation in colorectal cancer. In the cells with different APC mutation status, the activation of β-catenin was regulated by different mechanisms.

Anti-cancer effect of ulipristal acetate in uterine leiomyosarcoma.

Jeong-Won Lee, Ji-Eun Hong, Young-Jae Cho, Cheul Hun Choi, Duk-Soo Bae, Hye-Kyung Jeon, Jae Ryoung Hwang. Samsung Medical Center, Seoul, Republic of Korea.

Objectives: Uterine leiomyosarcoma (LMS) is a rare uterine malignancy that arises from the smooth muscle of the uterine wall. Although LMS is an aggressive tumor associated with a high risk of recurrence, current radiotherapy and chemotherapy is limited role in the treatment. Therefore, the introduction of a new therapy for LMS of the uterus is urgently needed. Ulipristal acetate (UPA), selective progesterone receptor modifier is used for pre-operative treatment of moderate to severe symptoms of uterine fibroids because UPA-treated fibroids show the smooth muscle of the uterine wall. We examined the anti-cancer effect of UPA in LMS cells, and these findings suggest that PPARG may be a promising therapeutic target for treatment of bladder cancer.

Validation of PPARG and RXRA as drivers of bladder cancer. Jonathan T. Goldstein, 1 Craig Stratchdee, 1 Fujiko Duke, 1 Juliann Shih, 1 Matthew Meyerson, 2 Broad Institute, Cambridge, MA; 3 Dana Farber Cancer Institute, Boston, MA.

A subset of muscle-invasive bladder cancer (BCa) is typified by PPARG overexpression. PPARG regulates a plethora of genes involved in bladder cancer patients, and similarly, 5% of BCa patients possess hotspot mutations in the requisite heterodimer partner of PPARG, RXRA (S427F, S427Y). We used genetic perturbation to study the role of PPARG in bladder cancer. Our results show that overexpression of RXRA and PPARG mutant alleles activate expression of PPARG and PPARA target genes in a ligand-independent manner, and that bladder cancer cell lines dependent on PPARG for viability. These findings suggest that PPARG may be a promising therapeutic target for treatment of bladder cancer.

T-cell recruiting bispecific antibodies and antibody fragments have been used to harness the cytotoxic potential of T cells for cancer treatment. We have adopted a knobs-into-holes antibody format and produced T-cell dependent bispecific antibodies (TDB), as full length, humanized IgG1 antibodies with natural antibody architecture, which allow one arm to target various B cell antigens while the other arm recruits T cells by binding to the CD3ε subunit of the T-cell receptor. One B cell antigen targeted is CD79b, a component of the B cell receptor complex, which has been clinically validated by an anti-CD79b antibody-drug conjugate (ADC) as a safe and effective therapeutic target for B cell malignancies (Leukemia 2015 Pfeiffer et al.). In the present work, we show that anti-CD79b/CD3 TDB is active against lymphoma cells with a wide range of CD79b antigen levels in vitro. In addition, anti-CD79b/CD3 TDB appears to be insensitive to the status of cellular signaling pathways in lymphoma cells as it is active against cell lines that are resistant to the PTK inhibitor ibrutinib or an anti-CD79b ADC with a cleavable tubulin inhibitor as the payload. In vivo, anti-CD79b/CD3 TDB administration inhibited tumor growth in B-cell lymphoma xenograft models and resulted in potent B-cell depletion in the blood and spleens in a humanized murine model. To assess the safety of targeting CD79b with a T-cell recruiting bispecific antibody in non-human primates, a surrogate anti-CD79b/CD3 TDB with comparable in vitro potency was produced with a target arm that recognizes cynomolgus monkey CD79b and the same anti-CD3 arm. In a single dose pharmacokinetic/pharmacodynamics/safety study, anti-cynoCD79b/CD3 TDB administration at 1mg/kg resulted in potent B cell depletion, as well as T cell activation and proliferation, which was assessed by flow cytometry on blood and lymphoid tissue and immunohistochemistry on lymphoid tissue. The pharmacokinetic properties of anti-cynoCD79b/CD3 TDB resembled that of IgG antibodies; though with a faster clearance likely due to CD79b antigen internalization and enhanced binding to CD3 when compared to previously described anti-CD20/CD3 TDB. Transient cytokine release was observed as elevated levels of IL-2, IL-6, IFN-gamma and TNF-alpha were detected within 24 hours following administration. Anti-cynoCD79b/CD3 TDB was well-tolerated in the majority of dosed animals without toxicologically significant findings. Collectively, these preclinical data suggest anti-CD79b/CD3 TDB can be a potential therapeutic agent in B cell malignancies.

Engineering a novel asymmetric head-to-tail 2+1 T-cell bispecific (2+1 TCB) IgG antibody platform with superior T-cell killing compared to 1+1 asymmetric TCBs. Christian Klein, 1 Christiane Neumann, 1 Tanja Fauti, 1 Tina Weinzierl, 1 Anne Freimoser-Grundshober, 1 Inja Waldhauer, 1 Linda Fahrm, 1 Sylvia Herter, 1 Erwin van Puijenbroek, 1 Sara Colombetti, 1 Johannes Sam, 1 Sabine Lang, 1 Sherry Dudal, 1 Wolfgang Schäfer, 1 Jörg T. Regula, 1 Samuel Moser, 1 Oliver Ast, 1 Ralf Hoß, 1 Eckhard Mössner, 1 Peter Brüninger, 1 Marina Bach, 1 Pablo Umana, 1 Roche Pharma Research & Early Development, Schlieren, Switzerland; 2 Roche Pharma Research & Early Development, Basel, Switzerland; 3 Roche Pharma Research & Early Development, Penzberg, Germany.
Penetration of the blood brain barrier (BBB) remains a significant hurdle in the development of biologic therapeutics for CNS-related cancers. Antibody-based molecules typically do not cross the BBB in amounts required for therapeutic efficacy. Receptor-mediated transporters in the luminal membrane of brain capillary endothelium, which normally transport circulating endogenous proteins and macromolecules, are also responsible for the transport of therapeutic antibodies across the BBB.

To overcome this barrier, antibody drugs have been conjugated to small molecules, liposomes, and peptides to allow enhanced delivery across the BBB. Cytotoxic molecules have also been conjugated to antibodies to deliver therapy to CNS tumors. Antibody-drug conjugates (ADCs) are among the most promising classes of novel CNS-directed therapeutics for the treatment of brain tumors. ADCs combine the targeting properties of an antibody with the cytotoxic properties of chemotherapeutics.

The Antibody-Drug Conjugate (ADC) Approach

ADCs consist of an antibody linked to a cytotoxic agent. The antibody portion of an ADC directs the cytotoxic payload to the tumor, ensuring that the drug is preferentially delivered to tumor cells. The cytotoxic payload is designed to be released intracellularly upon internalization of the ADC, resulting in the destruction of the tumor cell.

The key components of an ADC are:

1. **Targeting Antibody**: Determines the specificity and selectivity of the ADC for the target tumor cells.
2. **Cytotoxic Payload**: Responsible for inducing cell death in the tumor cells.
3. **Linker**: Connects the antibody to the cytotoxic payload, ensuring that the payload is released intracellularly upon internalization.

The choice of antibody, cytotoxic agent, and linker is crucial in determining the efficacy and safety profile of an ADC. The antibody should have high affinity and specificity for the target tumor antigen, while the cytotoxic agent should have robust activity against the tumor cell.

One of the most promising approaches for enhancing the delivery of ADCs to the CNS is the use of BiTE® (Bi-specific T-Cell Engager) technology. BiTE® molecules are T-cell directed cytotoxic agents that recruit and activate T-cells to target and kill tumor cells.

**BiTE® Technology**

BiTE® technology involves the use of Bi-specific T-cell engagers (BiTE®) to redirect T-cells to target tumor cells. BiTE® molecules are composed of two single-chain variable fragments (scFv) linked by a flexible linker, with each scFv specific for a different receptor on the tumor cell surface. When the BiTE® binds to both receptors, it triggers the activation of the T-cell, which then杀 damages the tumor cell.

**BiTE® Design Considerations**

- **Selectivity**: The BiTE® must be designed to bind to the tumor cell surface antigens while avoiding activation of normal T-cells or other immune cells.
- **Engagement**: The BiTE® must engage multiple T-cells to ensure complete tumor cell lysis.
- **half-life**: The BiTE® must have a long enough half-life to penetrate the CNS and achieve therapeutic levels.

**Clinical Applications**

BiTE® technology has been used to develop antibodies targeting a variety of tumor antigens, including CD19, CD20, CD30, and DLL3. Preclinical studies have shown that BiTE® molecules can effectively target tumor cells in the CNS, leading to promising results in clinical trials.

**Future Directions**

Ongoing research is focused on improving the efficacy and safety of BiTE® technology, including the development of novel linkers and cytotoxins, as well as the optimization of antibody designs to enhance tumor cell engagement and T-cell activation.

**Conclusion**

BiTE® technology represents a promising approach for the delivery of therapeutics to the CNS, particularly for the treatment of brain tumors. Continued research and development in this field are expected to lead to improved therapeutic options for patients with CNS malignancies.
poses an Fc domain that maintains long half-life, yet lacks binding to Fcy receptors to reduce Fc-mediated effector functions. XmAb18087 stimulated robust RTCC of SSTR2+ cell lines including medulary thyroid carcinoma (TT), lung carcinoma (A549), and CHO cells overexpressing SSTR2, with EC50s of ~1 to 100 ng/ml. XmAb18087 also upregulated CD69 and CD25 activation markers on T-cell specific effector T-cells. SSTR2+ cell lines were not depleted, and because a control bispecific (anti-RSV x CD3) was ineffective. In addition, XmAb18087 (3 mg/kg weekly) reduced tumor burden of an established A549 xenograft in NSG mice engrafted with 10⁷ human PBMC. We next assessed XmAb18087 activity in cynomolgus monkeys. As SSTR2 is not expressed in peripheral blood, target cell depletion cannot be monitored in vivo. In vitro, SSTR2 bispecific antibodies induce effects such as lymphocyte extravasation, cytokine induction, and T-cell activation, which can serve as pharmacologic markers for activity in target organs. XmAb18087 dosed once at 30 or 60 µg/kg rapidly activated peripheral T cells, as quantified by CD69 and CD25 induction (peaking at ~8-12 hr). T cells rapidly extravasated from blood, with a nadir by 8 hr. Cytokines IL6 and TNF were rapidly induced, peaking at ~1-8 hr and returning to baseline by 24 hr. To explore repeat dosing, XmAb18087 was dosed at 1 or 10 µg/kg on Days 0 and 7 in a second study. The first dose of both 1 and 10 µg/kg again stimulated peripheral T-cell activation, extravasation, and cytokine induction. These responses decreased markedly after the second dose, suggesting that SSTR2+ target cells remained depleted for at least 7 days. In summary, these results on human cells, in mice, and in monkeys support clinical evaluation of XmAb18087 as a bispecific interface that targets tumors and peripheral T-cells, with marked cytokine induction and T-cell activation. We demonstrate its activity in peripheral blood and are indicative of T-cell-mediated depletion of SSTR2+ target cells. Importantly, these responses may also serve as useful surrogate markers of NET depletion in clinical trials of XmAb18087.

#3634 A novel tumor-targeted 4-1BB agonist and its combination with T-cell bispecific antibodies: an off-the-shelf cancer immunotherapy alternative to CAR T-cells. Christina Claus, Claudia Ferrara, Sabine Lang, Rosmarie Autschbach, Stefanie Albrecht, Sylvia Herter, Maria Amann, Sandra Richards-Grau, Johannes Sam, Sara Colombetti, Marina Bacac, Christian Klein, Pablo Umana. Roche Innovation Center Zurich, Zurich, Switzerland.

Immune cell costimulation via 4-1BB agonism has shown anti-tumor activity in the clinic and is an important element of next-generation chimeric-antigen-receptor (CAR) adoptive T-cell therapy approaches. However, the clinical development of first-generation, 4-1BB agonistic antibodies has been hampered by significant hepatic toxicity. Activity of such first-generation, 4-1BB agonistic antibodies typically depends on their hyperclustering via Fc-gamma-receptor (FcγR)-binding. Here we describe a next generation, tumor-targeted 4-1BB agonist whose activity is independent of FcγR-binding. The molecule consists of an IgG fusion protein composed of a trimeric, human 4-1BB ligand (4-1BLB), a targeting Fab moiety recognizing fibroblast activation protein (FAP), and a heterodimeric Fc region engineered to be devoid of interactions with FcγRs and C1q. The molecule mediates potent costimulation of CD8+, CD4+ and NK cells, but only in the presence of FAP-expressing cells, such as cancer associated fibroblasts, which are highly prevalent in many solid tumors. This FAP-targeted 4-1BB agonist is significantly more potent and efficacious than first-generation, standard 4-1BB agonistic antibodies when compared side-by-side in preclinical models. We show its activity in a variety of preclinical models including reporter cell assays, assays with primary T- and NK-cells, ex-vivo assays with patient tumor-derived material including cancer cells, stroma cells and tumor-infiltrating lymphocytes, fully immunocompetent murine tumor models (employing a surrogate, murineized molecule targeting murine FAP and carrying murine 4-1BLB), and in human hematopoietic stem cell-humanized mice with human tumor xenografts. We also demonstrate its activity in combination with checkpoint inhibitors and with T-cell redirecting approaches, such as a CEA-CD3 T-cell bispecific antibody. We show that hepatic toxicity of first generation, standard 4-1BB antibodies is dependent on FcγR interactions and the next generation, tumor-targeted 4-1BB agonistic antibody described here is safe and does not induce any hepatotoxicity in preclinical models including non-human primates where it was tested at doses of up to 50 mg/kg and where it showed a long circulatory half-life. Its combination with T-cell bispecific antibodies induces a massive T cell accumulation in the tumor, accompanied with an elevated CD8/Treg ratio, as compared to the respective monotherapies. Therefore, we conclude that tumor-targeted cross-linking NETS and 4-1BLB provides a safe and effective way for the co-stimulation of T cells for cancer immunotherapy and its combination with T-cell bispecific antibodies may provide an alternative, but more convenient, off-the-shelf approach to CAR T-cell therapies. The molecule is scheduled to enter clinical trials soon.

#3635 Improved T Cell activation bioassays to advance the development of bispecific antibodies and engineered T cell immunotherapies. Richard L. Somberg, Pete Stecha, Denise Garvin, Jim Hartnett, Frank Fan, Mei Cong, Jey Cheng. Promega Corp., Madison, WI.

T cells play a central role in cell-mediated immunity and can mediate long-term protection against infections and tumors. However, T-cell therapies are fraught with challenges, including the need for cell proliferation, cytokine induction, and target cell killing. New approaches are needed to improve the development of T-cell immunotherapies. We describe a variety of immunotherapy strategies aimed at inducing, strengthening or engineering T cell responses that have emerged as promising approaches for the treatment of diseases such as cancer and autoimmunity. Current methods used to measure TCR-mediated T cell proliferation and cytokine production rely on primary PBMCs as a source of T cells, which must be stimulated via co-culture with APCs or transduction with lentiviral particles. This process is time-consuming and highly variable due to the variability in their reliance on donor primary cells, complex assay protocols and unqualified assay reagents. As a result, these assays are difficult to establish in quality-controlled drug development settings. To overcome this barrier, we developed two reporter-based bioluminescent T cell activation bioassays that can be used for the development of bispecific antibodies and engineered T cell immunotherapies. The assays consist of Jurkat T cells genetically engineered to express luciferase downstream of either NFAT or IL-2 response elements. The T cell activation bioassays reflect the mechanisms of action of biologics designed to induce TCR and/or CD28-mediated T cell activation, as demonstrated using anti-CD3 and/or anti-CD28 antibodies as well as blinatumomab, a bispecific antibody that simultaneously binds CD3 expressed on T cells and CD19 expressed on malignant B cells. The bioassays are pre-qualified according to ICH guidelines and show assay specificity, precision, accuracy and linearity required for routine use in potency and stability studies. Finally, our data illustrate the use of reporter-based T cell activation bioassays for characterizing and measuring the activity of engineered chimeric antigen receptor T cells.

#3636 Potent antitumor activity of duvortuxizumab, a CD19 × CD3 bispecific T cell receptor chimera, in lymphoma models. Liat Izak1, Dana E. Callen, Maha Elgawly2, Leopoldo Luistro1, Syr Johnson2, Jaime Bald1, A Kate Sasser1, Sriram Balasubramanian1, Janssen Research & Development, LLC, Spring House, PA; 2MacroGenics, Inc., Rockville, MD.

Duvortuxizumab (NJ-64052781 or MG0011) is a CD19 × CD3 DART®, protein designed to engage and redirect CD3+ T-cells to eliminate CD19+ B-cells through T-cell-mediated cytotoxicity. Duvortuxizumab displays potent killing activity in lymphoma cell lines and animal models and is currently in clinical development for the treatment of B-cell malignancies. Here we examined duvortuxizumab activity alone and in combination with standard chemotherapy regimens in preclinical lymphoma models. Duvortuxizumab plus bendamustine increased T-cell mediated cytotoxicity of CD19+ Raji and DOHH2 lymphoma cells in the presence of isolated human pan T-cells (effectortarget 7, twice weekly); benda- mustine was dosed once at 25 mg/kg on day 1. Dosing with bendamustine alone inhibited tumor growth by 79% (p=0.0002) whereas duvortuxizumab alone resulted in complete tumor regression with no signs of relapse for up to 90 days. Dosing with duvortuxizumab plus bendamustine resulted in complete and durable tumor regression and elimination. Analysis of tumor-infiltrating lymphocytes (TILs) 3 days after the start of therapy showed that bendamustine inhibited CD3+ T-cell infiltration and activation whereas duvortuxizumab increased both. The combination showed greater activation of CD4+ and CD8+ T-cells. At 48 days after the last duvortuxizumab dose, TILs had a large percentage of CD3+ CD45RA CCR7+ cells, indicative of effector memory T-cells. This activation was accompanied by higher expression of PD-1 on T-cells and PD-L1 on tumor cells, the latter of which may have been caused by inclusion of prednisone; however, cytotoxicity against tumor cells was maintained. In a patient sample-derived model of diffuse large B-cell lymphoma, duvortuxizumab (twice weekly for 4 consecutive weeks in combination with CHOP (given once) resulted in rapid tumor regression that was more sustained than CHOP treatment alone. In summary, duvortuxizumab-mediated anti-tumor activity as a single agent and in combination with standard chemotherapy in lymphoma preclinical models. Duvortuxizumab-mediated tumor killing and T-cell activation were maintained or increased in the
presence of multiple chemotherapeutics, suggesting the potential clinical utility of combining duvortuxizumab with standard therapies in the treatment of B-cell malignancies.

Introduction: Immunotherapy with the combination of monoclonal antibodies (mAbs) that block PD-1 (nivolumab) and CTLA-4 (ipilimumab) has shown clinical benefit beyond that observed with either mAb alone. We have developed PD-1 x CTLA-4 bispecific proteins aimed at inducing antitumor immunity through simultaneous blockade of both checkpoint molecules. Two proteins, a tetravalent PD-1 x CTLA-4 bispecific DART protein (bivalent for both PD-1 and CTLA-4) and a trivalent PD-1 x CTLA-4 TRIDENT protein (bivalent for PD-1 but monovalent for CTLA-4) were engineered; the TRIDENT protein was designed to promote CTLA-4 blockade through avidity when bound to PD-1 on cells co-expressing both receptors, thus favoring PD-1 over CTLA-4 blockade in cells that do not co-express both molecules. Methods: Proteins were engineered from humanized PD-1 and CTLA-4 mAB sequences and demonstrated favorable biophysical properties. Binding assays were performed by ELISA or flow cytometry. Co-igation of PD-1 and CTLA-4 was assessed in an enzyme-fragment complementation assay (DiscoverX). T-cell activation was tested in reporter cell assays, staphylococcal enterotoxin B-stimulated PBMCs or MLR assays. Results: Both DART and TRIDENT proteins showed equivalent potency in binding immobilized recombinant PD-1 or PD-1 expressing cell lines, inhibition of PD-1 interaction with PD-L1 or PD-L2 as well as reversal of PD-1/PD-L1 mediated T-cell signal inhibition. In all assays, both formats showed activities that were comparable to those of the precursor PD-1 mAb. With respect to CTLA-4, the DART protein showed a minor potency loss in binding to CTLA-4 expressing cells, inhibition of CTLA-4/B7 interaction and reversal of T-cell signal inhibition compared to the precursor mAb. The TRIDENT protein, however, showed substantial lower potency than the DART protein in all CTLA-4 assays, consistent with the monovalent nature of the CTLA-4 arm. Importantly, in cells that co-express both receptors, DART and TRIDENT proteins show comparable co-engagement of PD-1 and CTLA-4, as shown by enzyme-fragment complementation, suggesting that anchoring through PD-1 compensates for the decreased CTLA-4 avidity of the TRIDENT molecule when both target receptors are expressed. Similarly, in T-cell co-activation assays, both DART and TRIDENT proteins showed a comparable increase in IFN-gamma response that recapitulated that observed with the combination of the individual parental mAbs. Conclusion: Both PD-1 x CTLA-4 DART and TRIDENT bispecific molecules block PD-1 and CTLA-4 pathways, with the TRIDENT protein demonstrating a PD-1-biased binding preference, consistent with its design intended to reduce CTLA-4 blockade in the absence of PD-1 co-expression. Both molecules showed comparable T-cell activation activity. Further development of bispecific PD-1 x CTLA-4 molecules for cancer treatment is warranted.

Bispecific T cell engagers (BiTE®) recruit highly cytotoxic host CD3+/CD8+ T cells for destruction of tumor antigen-specific malignant cells. Bearing a defined single-chain antibody fragment (scFv) binding to CD3+ on T cells and a selected scFv binding to tumor-specific antigen, BiTE-based antibodies suffer from a narrow therapeutic window and short t1/2 of requiring careful dose administration and continuous infusion for efficacy. To overcome these limitations, Amunix has developed the ProTIA (Protease Triggered Immune Activators) platform by incorporating its proprietary XTENprotein polymer half-life extension technology into the design of such T cell-dependent bispecific cytotoxic payload (BiTE) molecules. XTEN is a high-capacity, long acting prodrug in which enzyme cleavage of defined length containing the embedded prodrug sequence of XTEN. Insertion of the unique protease site enables selective cleavage of ProTIA by tumor-associated proteases, facilitating localized release of active BCPs in tumor tissues. Amunix’ lead ProTIA molecule, AMX-168, is in development for treatment of epithelial cancer associated ascites. AMX-168 consists of an eEpCAM scFv coupled to an eCD3 scFv that is linked to an XTEN protease sequence of defined length containing the embedded prodrug cleavage site. AMX-168 is shown to release the active eEpCAM-eCD3 BCP by tumor-specific proteases cleaving intact XTEN. Importantly, protease-treated AMX-168 BCP exhibits (1), high specificity for EpCAM and CD3 targets; (2), achieves low picomolar caspase activity in a panel of EpCAM+ human cancer lines in the presence of human PBMC; (3), induces expression of CD25 and CD69 T cell activation markers; and (4) release of key hallmark cytokines within 24 h when incubated with a mixture of EpCAM+ tumor cells and PBMC. The t1/2 of eEpCAM-eCD3 ProTIA in mice is 32 h vs 3.5 h for its BCP counterpart, indicating potential for exposure of the long-acting AMX-168 compared to the BCP-only entity in human colorectal HCT-116 tumor cells + PBMC in NOD/SCID mice. AMX-168 and its BCP-only moiety demonstrated therapeutic efficacy vs vehicle, with NTGI of 97% and 82%, respectively. AMX-168 demonstrated sustained tumor regression compared to the BCP-only moiety, supporting efficient conversion of AMX-168 to the active BCP at tumor site, and improved tumor exposure of the long-acting AMX-168 compared to the BCP-only entity. Safety assessment of eEpCAM-eCD3 ProTIA for uncontrolled cytokine release in the presence of PBMC but not EpCAM+ target cells, demonstrated ProTIA induces significantly less cytokine production compared to the BCP-only moiety. AMX-168 is currently in preclinical development with an expected IND/CTA filing by the end of 2017. Successful proof-of-concept studies of AMX-168 support further development of a broad pipeline of ProTIA therapeutics addressing a spectrum of common and advanced malignancies.

#3639 Therapeutic targeting of tumorigenic EphA2+/EphA3+ brain tumor initiating cells with bi-specific antibody in human glioblastoma. Maleeha Qazi,1 Parvez Vora,1 Chirayu Chokshi,1 Chitra Venugopal,1 Max London,1 Amy Hu,2 Minomi Subapandtiha,1 Mohini Singh,1 Jarrett Adams,1 Jason Moffat,1 Sachdev Sidhu,1 Sheila K. Singh1. 1McMaster University, Hamilton, Ontario, Canada; 2University of Toronto, Ontario, Canada.

Glioblastoma (GBM), the most aggressive primary human brain tumor, carries a dismal prognosis and is increasingly characterized by cellular and genetic intra-tumoral heterogeneity (ITH). Many of the 14 members of the ephrines producing hepatocellular carcinoma receptor (EphR) family and their ephrin ligands are expressed in GBM cells and constitute potential molecular targets for novel therapeutic agents. We hypothesize that multiple members of the EphR family play a critical role in orchestrating the clonal evolution of GBM progression. Individual Eph receptor targeting strategies have shown only modest pre-clinical success, likely because single agent therapy cannot target the degree of ITH in GBM. Using a highly specific human Eph receptor monoclonal antibody (mAb) panel (EphR proﬁler), we identiﬁed several Eph receptors with dysregulated expression in recurrent GBM compared to primary GBM. With our unique chemoradiotherapy-adapted, patient-derived xenograft model of GBM, we identiﬁed EphA2 and EphA3 expression to be upregulated after therapy. Here we show that EphA2 and EphA3 co-expression marks a highly tumorigenic cell population in recurrent GBM with higher in vitro and in vivo self-renewal and proliferation capacity compared to EphA2+/EphA3-. EphA2+/EphA3+ or EphA2-/EphA3- cells. Lentiviral mediated knockdown of EphA3 expression blocks this self-renewal and proliferation capacity in recurrent GBM. Through further characterisation using mass cytometry (CyTOF) assay, we ﬁnd that EphA2 and EphA3 is co-expressed with multiple brain tumor initiating cell (BTIC) markers (CD133, CD15, Bmi1, Sox2, Integrin 66 and FoxG1). Considering the important role of EphA2+/EphA3+ cells in GBM tumorigenesis, we generated a mice model in which mice were engrafted with a human GBM tumor cell line, and this ITH, with selective compounds that inhibit BTIC and Eph receptor activity with minimal off-target effects. Comprehensive Eph receptor proﬁling of individual patient-derived GBM will allow us to develop a therapeutic strategy for each patient’s tumor, employing polytherapy with mAbs against Eph receptors expressed at recurrence.

#3640 Novel humanized anti-Sialyl-Tn, anti-CD3 bispecific antibodies demonstrate tumor and T-cell speciﬁcity for immune activation at the tumor site. David A. Eavarone, Jillian Prendergast, Patricia E. Rao, Jenna Stein, Jeff Behrens, Daniel T. Dransfeld. Siamab Therapeutics, Newton, MA.

Tumor-associated carbohydrate antigens (TACAs) historically have been challenging targets for antibody therapeutics. Sialyl-Tn (STn) is a cancer specific antigen that is expressed on the surface of carcinomas including ovarian, colon, prostate, and pancreatic tumors but is rarely present in normal tissue. STn expression has been linked to innate immune suppression, a cheomoresistant pheno-
notype, metastasis, and poor prognosis. Previous attempts to target this antigen in the clinic with synthetic glycan vaccines proved safe but lacked efficacy. We have developed humanized bispecific antibodies targeting STn and CD3 for T-cell recruitment and activation at the tumor site. These bispecific antibodies were selected for optimal tumor targeting using our glycan microarray that enriches for candidates whose binding is independent of antigen density. STn-selective binding was demonstrated. Current lead candidates exhibited low nanomolar EC50 binding in flow cytometric assays against both STn expressing tumor cells and T cells. Quantification of T-cell activation and T-cell induced tumor killing in vitro provides a basis for the further clinical development of these bispecific antibody candidates.

#3641 EGF/CD16A TandAbs are efficacious NK-cell engagers with favorable biological properties which potentially kill EGFR+ tumors with and without Ras mutation. Michael Kluge, Kristina Ellwanger, Uwe Reusch, Ivica Fucek, Michael Weichel, Torsten Hancke, Stefan Knackmus, Joachim Koch, Martin Treder. Affimed GmbH, Heidelberg, Germany.

Constitutive EGFR activation plays an important role in the pathophysiology of various solid cancers, such as colorectal cancer, non-small cell lung cancer or squamous cell carcinomas of the head and neck. Tyrosine kinase inhibitors (TKI) and monoclonal antibodies (mAbs), which interfere with signal transduction and activation of EGFR, are approved for treatment of such cancers. However, intrinsic or acquired resistance to these treatments has been described for many patients. Natural killer cells (NK-cells) are important effectors of innate immunity and NK-cell engagement has shown evidence of promising safety in patients compared to T-cellengagers. To specifically utilize the cytotoxic potential of NK-cells to eliminate EGFR-expressing tumors, we developed tetravalent bispecific EGF/CD16A TandAbs comprising fully human Fv domains recognizing human and cynomolgus EGFR and CD16A. TandAbs recognizing epitopes in the extracellular domain of EGFR differing from epitopes targeted by other mAbs were characterized. Lead candidate AFM24 shows superior cytotoxicity in terms of ADCC (main mode of action) and reduced inhibition of EGFR-mediated phosphorylation compared to cetuximab. Importantly, inhibition of EGFR-signaling is believed to contribute to skin toxicity caused by therapeutic mAbs and TKI. AFM24’s cytotoxic activity was tested against EGFR+ tumor cell lines including some carrying a Ras mutation, which is a negative prognostic biomarker and renders cells less susceptible to cetuximab or paclitaxel. The cetuximab-resistant CRC cell line HCT-116 or the NSCLC cell line A549 (both with Ras mutations) were efficiently killed with EGFR/CD16A TandAbs in vitro. In vivo data in the HCT-116 model indicate anti-tumor efficacy of AFM24, while no effect of cetuximab was seen. Importantly, AFM24 does not activate NK-cells without target cell binding and does not bind to any other members of the EGFR family. While binding and cytotoxic efficacy of many therapeutic mAbs are impaired by serum IgG, no substantial change in AFM24’s binding affinity to NK-cells was observed in the presence of high concentrations of human IgG. In calcine-release cytotoxicity assays with NK-cells as effectors, we showed that the presence of IgG had only little inhibitory effect on AFM24 efficacy compared to cetuximab. In addition, binding of an anti-CD16 mAb with AFM24 in 1:1 molar ratio in NK-T-cell assays was substantially lower than with cetuximab. Taken together our data demonstrate that AFM24 is a highly potent human antibody displaying favorable biological properties over existing mAbs. This human/cynomolgus cross-reactive agent is currently in preclinical development to treat EGFR+ malignancies and has the potential to exhibit a favorable side effect profile and reduced toxicity to overcome resistance to other targeted anti-EGFR therapeutic agents.

#3642 Tumor-antigen expression-dependent activation of the CD137 co-stimulatory pathway by bispecific DART® proteins. Liqin Liu,1 Chia-Ying K. Lam,2 Yatana Long,3 Lislana Widjaja,1 Yinhuai Yang,1 Kalpana Shah,1 Doug Smith,2 Joanna Pan,2 Syd Johnson,2 Eizo Bonvini,1 Paul Moore1. 1MacroGenics, Rockville, MD; 2MacroGenics, South San Francisco, CA.

Introduction: CD137 (4-1BB) is a co-stimulatory molecule expressed by activated T and NK cells that, upon interaction with its CD137 ligand, further supports cell activation, proliferation and survival. Activation via CD137 holds great promise for cancer immunotherapy; however, current CD137 agonistic interventions are associated with systemic safety concerns. To develop a therapeutically modal that reduces the potential for systemic CD137 effects, we applied the DART® bispecific platform to generate proteins that can induce tumor-antigen dependent T-cell activation. Methods: DART molecules were constructed containing anti-CD137 variable regions together with either anti-HER2 or anti-EphA2 variable regions. DART binding properties were evaluated by ELISA or flow cytometry; signaling responses assessed using a NF-κB luciferase reporter cell line expressing CD137. Co-stimulatory activity was characterized with primary human T cells in the presence or absence of tumor target-antigen-expressing cells. Results: ELISA and flow cytometry analysis demonstrated that both HER2 x CD137 and EphA2 x CD137 DART molecules bind their respective antigens with high affinity. Co-expression of a tumor cell line expressing HER2 or EphA2 revealed tumor-antigen-dependent CD137 pathway activation by HER2 x CD137 and EphA2 x CD137 DART molecules on T-cell responses, co-stimulation T-cell assays were performed. In the presence of the relevant antigen-positive cell line, each respective DART molecule was able to promote T-cell proliferation or tumor cell release in a HER2 or EphA2-dependent manner. No T-cell co-stimulation was observed by either DART molecule in the absence of antigen-expressing tumor cells. Furthermore, the level of tumor antigen-dependent co-stimulation supported by the DART molecules correlates with the level of tumor target expression. Consistent with the preferential induction of CD137 by the CD8 T cell subset, CD137-based DART proteins induced a substantial increase in the fraction of CD8+ central memory and effector memory T cells in the presence of the proper tumor antigen expressing cells. Conclusions: HER2 x CD137 and EphA2 x CD137 DART molecules promote T-cell co-stimulation in a tumor antigen-dependent manner and may provide an opportunity to target the CD137 co-stimulatory pathway for cancer immunotherapy, while limiting systemic T-cell activation and related side effects.

#3643 INCAGN1876, a unique GITR agonist antibody that facilitates GITR oligomerization. Ana M. Gonzalez,1 Mariana L. Manrique,1 Lukasz Swiec,1 Thomas Horn,2 Jeremy Waigt,1 Yuqi Liu,1 Shiwien Lin,1 Dennis Underwood,1 Ekaterina Breous,1 Olivier Leger,1 Volker Seibert,1 Taha Merghoub,1 Roberta Zappasodi,1 Gerd Ritter,1 David Schaeber,1 Kevin N. Heller,1 Kimberli Brill,1 Peggy Schere,1 Gregory Hollis,1 Reid Huber,1 Marc van Dijk,1 Jennifer Bueli,1 Daniel Becht1, Nicholas S. Willems1,2 Agneus Inc, Lexington, MA; 1Agneus Inc, 4-Antibody, Basel, Switzerland; 2Memorial Sloan Kettering Cancer Center, New York, NY; 3The Ludwig Institute for Cancer Research, New York, NY; 4Incyte Corporation, Wilmington, DE.

Glucocorticoid-induced TNFR family related protein (GITR, CD357 or H11001) is a member of the tumor necrosis factor receptor superfamily (TNFRSF). Like other TNFR family members, GITR utilizes multiple oligomerization states to regulate the initiation of downstream signaling during T cell activation by antigen presenting cells (APCs). The formation of receptor superclusters, comprised of two or more trimERIC molecules, has been defined for multiple TNFRs as a means of regulating downstream signal transduction. For co-stimulatory TNFRs, like GITR, CD137 and OX40, signaling outcomes in T cells are primarily mediated via the NF-κB pathway that promotes cell survival and effector cell activities in response to suboptimal T cell receptor (TCR) stimulation. It has been hypothesized that the manipulation of the oligomeric states of co-stimulatory TNFRs using antibodies may have therapeutic utility in enhancing the activity of tumor-reactive T cells, either as single agents or in combination with other immunomodulatory or immune education strategies. Here we describe a structure-based analysis of two functionally distinct classes of anti-human GITR antibodies that stabilize unique conformational states of the receptor. INCAGN1876, a human IgG1 monoclonal anti-GITR antibody, was found to engage a conformational epitope located within a β-turn of the extracellular domain of GITR. This antibody binding site modified the equilibrium of GITR monomer, dimer and trimers to promote receptor oligomerization, resulting in downstream NF-κB signaling. Notably, this mode of INCAGN1876 receptor engagement enabled it to effectively activate the GITR pathway in recently primed T cells. By contrast, a second reference anti-GITR antibody required concomitant TCR co-engagement in order to modulate the GITR pathway. High content confocal analysis was used to evaluate the β-turn in the extracellular domain of GITR and confirm our T cell functional analysis. The ability of INCAGN1876 to engage and effectively activate GITR on recently primed T cells may enable them to overcome suppressive features of the tumor microenvironment. Notably, INCAGN1876 was shown to promote T cell co-stimulation both as a single agent and in combination with other antibodies targeting PD-1, CTLA-4 and OX40. Finally, we observed potent T cell co-stimulatory activity of INCAGN1876 to Fc variants of this antibody with diminished binding to the inhibitory Fcy receptor (FcyR). CD32B. The superiority of an IgG1 antibody in these assays was consistent with the potential to achieve optimal GITR clustering by FcyRs, while maintaining the potential for FcyR-mediated effector cell activity directed toward intra-
moral GTR high regulatory T cells. INCAGNI1876 is currently under evaluation in Phase I/II studies in subjects with advanced metastatic solid tumors (NCT02697591).

**#3644 Combination of OX40L fusion protein with an anti-tumor vaccine reduces lung metastasis and prolongs survival in a murine model of metastatic triple negative breast cancer.** Anthony S. Malamas,2 Scott A. Hammon,3 Jeffrey Schlam,1 James W. Hodge,1 National Cancer Institute, Bethesda, MD,2 MedImmune, Gaithersburg, MD.

OX40 is a costimulatory receptor on activated T-cells that potentiates the proliferation, survival, and memory formation of the CD4+ and CD8+ immune populations upon its interaction with OX40L on antigen presenting cells. The engagement of OX40 on regulatory T-cells (Tregs) with its ligand has also been shown to inhibit their suppressive capabilities. The use of exogenous OX40L agonists for cancer immunotherapy is particularly attractive in combination with cancer vaccines in order to boost the immune activity of antigen specific T-cells and overcome self-tolerance and immunosuppressive mechanisms of the tumor. We investigated the efficacy of this strategy in the 4T1 murine mammary tumor model of metastatic triple-negative breast cancer by combining an OX40L fusion protein (OX40L-FP) with a poxvirus-based cancer vaccine (MVA-Twist-TRICOM) that induces T-cell responses specific to the tumor antigen Twist, a transcription factor highly expressed in lung metastases. OX40L-FP was administered 3 and 6 days after the prime and boost vaccinations to maximize its interaction with OX40 on activated T-cells. As single agents, OX40L-FP and MVA-Twist-TRICOM had minimal effect on the formation of lung metastases in 4T1 tumor bearing mice. However, when combined, the two immunotherapies significantly decreased the number of metastatic colonies per lung, and prolonged survival after surgical resection of the primary tumor. Antibody depletion studies demonstrated that the observed anti-tumor effects were mediated by both CD4+ and CD8+ T-cells. Immune subset analysis revealed that the combination therapy increased the total number of CD4+Foxp3- and CD4+ effector memory T-cells in both the lung and periphery compared to the monotherapy controls. More importantly, the two agents synergistically induced greater CD4+ Twist-specific T-cell responses, as determined by ex vivo proliferation assays using T-cells isolated from the lung and spleen that were stimulated with Twist protein. Although the combination had no added effect on the number of total CD8+ and CD8+ effector memory T-cells in relation to the vaccine monotherapy, tetramer staining revealed a significant increase in CD8+ T-cells that were specific for Twist. We also observed a greater number of CD8+ T-cell memory precursors, as well as a greater number of IFNγ-producing CD8+ T-cells in both the lung and periphery. Tregs isolated from the lung and splenic tissue were found to be significantly less suppressive following the combination therapy, compared to those isolated from mice that received the OX40L-FP and MVA-Twist-TRICOM single agent treatments. This study provides the rationale for pairing OX40 agonists with cancer vaccines to stimulate CD4+ and CD8+ T-cell responses, while inhibiting Treg function, as a way to induce specific immunity and clearance of metastatic tumors.

**#3645 Preclinical characterization of a multi-specific DARPin molecule targeting PD1 and VEGF.** Jennifer Krieg, Schiegg Dieter, Taylor Joanna, Chris- tel Herold, Laurent Juglar, Nicolò Segamonti, Muscha Mueller, Ulrike Fiedler, Michael Tobias Stumpf, Dan Snell, Molecular Partners AG, Schlieren-Zurich, Switzerland.

Background: Combination therapy of immune-modulating drugs with modalities targeting tumor cells directly or the tumor stroma are increasing in clinical investigation and practice. In particular, the combination of immune checkpoint modulators targeting PD1 and molecules targeting the tumor stroma, like anti-VEGF therapeutics, are being utilized in multiple permutations and have shown promising results. We have developed a new class of protein therapeutics DARPin molecules for simultaneous targeting of PD1 and VEGF. The multi-specific PD1 and VEGF targeting molecules were tested for inhibition of PD1 and VEGF mediated functions in cellular functional assays and in syngeneic mouse models. The anti-tumor effect was monitored by caliper measurement and on T-cell infiltration and angiogenesis by immunohis- tochemistry. Results: The multi-specific human PD1-VEGF targeting DARPin molecule inhibits PD1 mediated downregulation of T-cell receptor signaling in a reporter cell assay in the range of the benchmark antibody Nivolumab. Potent picomolar inhibition of VEGF mediated VEGFR2 signaling was also demon-

strated for the molecule. Moreover the molecule showed potent inhibition of PD1 in an MLR assay to a similar level as compared to Nivolumab. A murine surrogate molecule was also produced and showed potent PD1 inhibition in vitro. Syngeneic mouse models demonstrate a strong anti-tumor effect of the surrogate molecule and an increase in the infiltration of T-cells into the tumor phase 1 clinical trial in solid tumors and lymphoma. It binds FcγRIIA with high affinity and demonstrates enhanced immune stimulatory activity compared to its parent dacetuzumab. An SEA version of an anti-mouse CD40 antibody (mouse IgG2a), SEA-1C10, has been generated. As expected, SEA-1C10 bound to mouse FcγRI, the functional homolog of human FcγRIIA in mice, at

**#3646 Characterization of the novel antibody drug conjugate MEN1309 and its target antigen Ly75.** Alessandro Bressan,1 Alessio Fiascarielli,2 Giuseppe Merlino,1 Corrado Carrisi,1 Daniella Bellarosa,1 Rachel Dusek,2 Rahel Awde,2 Sudha Swaminathan,2 Arnima Bish,2 To Uyen T. Do,3 San Lin Lou,2 Dee Aud,2 Jonathan Terrett,2 Keith Wilson,3 Christian Rohlf,4 Monica Binaschi,1 Merarini Ricerche S.p.A., Pomezia (RM), Italy; 2Oxford BioTherapeutics, Inc., San Jose, CA; 3Cytoxms Therapeutics, San Francisco, CA; 4Oxford BioTherapeutics, Ltd., Abingdon, UK, Abingdon, United Kingdom.

Ly75 (CD205, DEC-205) is a C-type lectin receptor involved in antigen uptake and processing, mainly expressed by antigen presenting cells (APC). The short cytoplasmic tail contains motifs for amino acid-based endocytosis, making this receptor an ideal target antigen for an antibody drug conjugate (ADC)-based antitumoral therapy. MEN1309 is a novel fully humanized ADC which binds to Ly75 with high affinity as shown by ELISA and FACS analysis. The antibody is conjugated to a maytansinoid DM4, a potent tubulin inhibitor, through a cleavable linker. The ability of Ly75 to internalize the antibody after binding was determined using an immunofluorescence assay that showed a rapid, efficient, and near complete internalization over a one hour time course. The expression of Ly75 mRNA and protein was investigated in human cancer cell lines derived from different histotypes and revealed high expression in pancreas, bladder, triple negative breast cancer (TNBC) cells and in diffuse large B-cell lymphoma (DLBCL). Indeed, MEN1309 shows a powerful (pM range) in vitro cytotoxic activity on different cancer cell lines expressing Ly75, whereas it exerts a weaker effect on antigen-negative cells. Besides the mechanism of action (MoA) of MEN1309 as an ADC, the putative efficacy of the antibody to drive an ADCc response was investigated through in vitro binding and functional assays. In spite of a high binding affinity of MEN1309 to FcγRIIa, no ADCc response was observed, suggesting that the high internalization rate of the antigen could hamper the triggering of NK responses. Moreover, in order to characterize the functional role of Ly75 in cancer cell lines, its expression was downregulated by siRNA demonstrating an inhibi-

**#3647 Therapeutic activity of effector function-enhanced, non-fucosylated anti-CD40 antibodies in preclinical immune-competent rodent tumor models.** Shyra J. Gardai, Weiping Zeng, Che-Leung Law. Seattle Genetics, Both- ell, WA.

Recent success of immune checkpoint inhibitors (CPIs) in the clinic underscores the role of cancer immune surveillance and the therapeutic potential of targeting immune receptors. Unlike CPIs, many members of the TNF receptor superfamily (TNFRSF), e.g., CD40, 4-1BB, OX-40, and GITR deliver agonistic signals to immune cells that may directly activate antitumor immune responses and, in combination with CPIs, may improve outcomes of active immunothera-

apy. Sugar-Engineered Antibody (SEA)-CD40 is a non-fucosylated, humanized IgG1 anti-human CD40 monoclonal antibody currently being evaluated in a phase 1 clinical trial in solid tumors and lymphoma. It binds FcγRIIA with high affinity and demonstrates enhanced immune stimulatory activity compared to its parent dacetuzumab. An SEA version of an anti-mouse CD40 anti-

body (mouse IgG2a), SEA-1C10, has been generated. As expected, SEA-1C10 bound to mouse FcγRIV, the functional homolog of human FcγRIIA in mice, at
a higher affinity than parent 1C10. Enhanced FcRIV engagement by SEA-1C10 translated into stronger antitumor activity in the CD40 (+) B16F10 melanoma and CD40 (+) A20 lymphoma models. In the A20 model, tumor free mice that survived the initial A20 tumor implantation and SEA-1C10 treatment were rechallenged with live A20 cells. Twenty nine out of thirty one such tumor free mice successfully rechallenged. Importantly, the current study is the first report to describe the targeted insertion of an immunomodulatory agent into a human-mouse chimeric CD40 gene. This allows for incorporation of the extracellular domain of human CD40 while keeping the transmembrane and cytoplasmic domains of mouse CD40. Lineage-restricted expression of the CD40 TG on B cells and monocytes was confirmed. CD40 TG cells responded to SEACD40-mediated agonistic signaling in vitro by secreting CD40 signature cytokines and up-regulating the costimulatory molecule CD80. These experimental systems will further be applied to address clinically important questions including mechanism(s) of anti-tumor effects, biomarkers indicating immune activation, dosing strategies, and timing of combinatorial regimens with CPIs.

#3648 Targeting glypican-2 in neuroblastoma via single domain antibody-based immunotoxins and chimeric antigen receptor T cells. Nan Li,1 Haiying Fu,1 Stephen Hewitt,1 Dimitar Dimitrov,1 Javed Khan,1 Mitchell Ho.1
1National Institutes of Health, Bethesda, MD; 2jilin University, Changchun, China; 3National Institutes of Health, Frederick, MD.

Neuroblastoma is the most common extracranial solid tumor in children. Approximately 45% of patients receiving standard therapy relapse and ultimately succumb to metastatic disease. One of the major challenges in the treatment of neuroblastoma and other pediatric cancers is the lack of effective targets. As such, there is an urgent need for a new therapeutic target. Here we demonstrate that glypican-2 (GPC2) protein is highly expressed in nearly half of neuroblastoma cases. High GPC2 expression has been correlated with poor overall survival when compared to patients with low GPC2 expression. The reduction of GPC2 expression inhibits neuroblastoma cell growth and induces tumor cell apoptosis through downregulation of Wnt/β-catenin signaling. We have discovered a group of human single domain antibodies specific for GPC2 and have used them to make two forms of antibody therapeutics, antibody-toxin conjugates (immunotoxins) and chimeric antigen receptor (CAR) T cells. Treatment with the immunotoxin inhibits proliferation of GPC2-positive neuroblastoma cells in vitro and mouse models. The CAR T cells targeting GPC2 suppress the growth of neuroblastoma xenograft tumors and eradicate disseminated neuroblastomas in mice. Our study establishes GPC2 as a new target of antibody-based cancer therapy and demonstrates that single domain-based antibody therapeutics can be used in the treatment of neuroblastoma.

#3649 Combination of mesothelin-targeted immune-activating fusion protein and anti-PD-L1 augments antitumor immunity and prolongs survival in murine model of ovarian cancer. Yang Zeng, Bingshao Li, Qiyuan Liu, Patrick Reeves, Ann Sluder, Jeffrey Gelfand, Timothy Brauns, Mark Poznansky, Huabin Chen. Massachusetts General Hospital, Boston, MA.

Background and Purpose: Although immunotherapy as an adjuvant to surgery and chemotherapy has been investigated in ovarian cancer (OC) as a means of reducing tumor recurrence and improving survival, there remains a significant unmet need for combinatorial strategies to enhance the antitumor immune response. The purpose of this study was to develop a novel combination immunotherapy for OC, utilizing our novel fusion protein to target and generate a cellular immune response to mesothelin (MSLN) in conjunction with blockade of the PD-1/PD-L1 checkpoint to restore the function of cytotoxic T cells in order to enhance cancer control and prolong survival. Experimental Procedures: Luciferase-expressing ID8 cells were employed to establish an intraperitoneal ovarian tumor model in immunocompetent C57BL/6 mice. The efficacies of the MSLN-targeted immune-activating fusion protein (VIC-008), aPD-L1, and the combination were evaluated. Mice received 4 intraperitoneal (i.p.) treatments of VIC-008 from day 7 post tumor inoculation weekly, and 6 treatments of aPD-L1 i.p. every other day from 4 weeks post inoculation. Tumor growth was monitored by in vivo imaging of luciferase activity. Survival time was calculated as life span from the day of tumor inoculation. In immunological studies, mice were sacrificed 7 weeks after tumor cell inoculation. Immune cells from lymph nodes, ascites and tumors were stained with antibodies against multiple immune cell markers and profiled by flow cytometry. Results: VIC-008, aPD-L1 or combination treatment delayed tumor growth. The combination treatment resulted in the greatest prolongation in survival, followed by aPD-L1 treatment and then control condition. Inactivation treatment groups (P = 0.001) was associated with increased levels of intratumoral CD3+CD8+ T cells (P = 0.0001). The combination treatment also reduced the proportion of CD4+ CD25+ Foxp3+ Treg cells (P = 0.0001) in the lymph nodes. An increased number of CD8+ CD27+ CD44+ memory T cells (P = 0.0134) were observed in ascites in the combination treatment group. CD11b+ CD11c+ dendritic cells were enriched in ascites in VIC-008 treatment (P = 0.001) and aPD-L1 treatment groups (P = 0.001). More CD11c+ CD38+ (M1) (P = 0.0361) and fewer CD206+ CD106+ (M2) (P = 0.0285) macrophages were found in the tumors of the combination treatment group. Conclusion: Our results suggest that, through activating dendritic cells and enhancing antigen presentation and cross-presentation, VIC-008 augments antitumor CD8+ T cell responses and facilitates generation of memory T cells when combined with PD-1/PD-L1 blockade, providing long-term antitumor effects. Our findings demonstrate for the first time a mechanistic rationale for combining VIC-008 and aPD-L1 in treatment of OC in mice, positioning this combination therapy as a potential promising new immunotherapeutic approach for OC.

#3650 Preclinical evaluation of the PARP inhibitor rucaparib in combination with PD-1 and PD-L1 inhibition in a syngeneic BRCA1 mutant ovarian cancer model. Liliane Robillard,1 Minh Nguyen,1 Andrea Loehr,2 Sandra Orsolic,2 Rebecca S. Kristeleit,2 Kevin Lin,3 Mitch Rapooni,1 Thomas G. Hardig,3 Andrew D. Simmons,1 1Covis Oncology, Inc., Boulder, CO; 2Cedars-Sinai, Los Angeles, CA; 3University College London, Cancer Institute, London, United Kingdom.

Background: Rucaparib (CO-338) is an oral small molecule inhibitor of poly(ADP-ribose) polymerase (PARP)-1, PARP-2 and PARP-3 that has shown clinical activity in patients with BRCA1 and BRCA2 mutated advanced ovarian cancer. Monoclonal antibodies against programmed death receptor-1 (PD-1) and programmed death-ligand (PD-L1) have also shown efficacy in advanced ovarian cancer patients. It has been reported that BRCA1 and BRCA2 mutated tumors have a higher mutational load and increased CD8+ T cell infiltration, suggesting that the combination of rucaparib and immune checkpoint inhibition may be complementary. However, PARP inhibition has also been reported to have an immunosuppressive effect in preclinical studies. Methods: Subcutaneous syngeneic models using the BRCA1 wild-type C2Km (P35/-, myc, KrasG12D, Akt-myr) and BRCA1 mutant BrKras (BRCA1/-; P35/-; myc, KrasG12D, Akt-myr) murine ovarian cell lines were developed in the murine FVB/N background. Antibodies targeting PD-1 (RMP1-14) and PD-L1 (10F.9G2) were dosed by intraperitoneal injection at 5-10 mg/kg twice weekly, while rucaparib was administered by oral gavage at 150 mg/kg twice daily. Treatment was initiated at a tumor volume of ~150mm3 (n=15/group). Animals were dosed for 21 days, and tumors were allowed to regrow to day 76. Results: In vitro cytotoxicity assays demonstrated that rucaparib was 155-fold more potent in the BRCA1 deficient BrKras cell line (IC50 = 84 nM) than the isogenic BRCA1 wild-type C2Km cell line (IC50 = 13 μM). An in vivo study using the syngeneic BrKras model was performed in mice treated with: vehicle, rucaparib, PD-1, PD-L1, rucaparib + PD-1, and rucaparib + PD-L1. All monotherapy and combination groups resulted in significant tumor growth inhibition and were followed for survival analysis. The median survival time (MST) and % cures (defined as undetectable growth at Day 76 post-tumor implantation) for vehicle, PD-1, PD-L1, PD-1 and rucaparib monotherapy treated animals was 34 days (0%), 41 days (4%) and 76 days (88%), respectively. The rucaparib + PD-1 and rucaparib + PD-L1 combination groups demonstrated greater efficacy than the monotherapies, with a MST of >76 days (100%) and >76 days (88%), respectively. Dose response and immune profiling studies are ongoing. In vivo data from this study will be presented. Conclusions: The combination of rucaparib with PD-1 and PD-L1 inhibition improved survival in a BRCA1 mutant syngeneic model.
Preclinical examination of the effects of MT-3724, an engineered toxin body targeting CD20, in mantle cell lymphoma. Shengqiang Huang, Taylor Bell, Yang Liu, Hui Guo, Carrie Li, Makhudm Ahmed, Laura Lam, Hui Zhang, Zhihong Chen, Michael L. Wang, Leo Zhao, Krystle Nomie. University of Texas MD Anderson Cancer Center, Houston, TX.

Mantle cell lymphoma (MCL) accounts for 6-8% of all non-Hodgkin lymphoma cases and is a therapeutic challenge. MCL is characterized by the expression of different B-cell markers such as CD-19, CD-20 and BSA/PAX5, and CD-20 is strongly expressed and can be used as a potential target. MT-3724 was developed by Molecular Templates and is an engineered toxin body (ETB) targeting CD-20. MT-3724 binds CD-20 and forces its own internalization. The drug subsequently self-reoutes to the cytosol to enzymatically inactivate and permanently inhibit protein synthesis via ribosome inactivation. By selectively and specifically targeting CD20-positive cells, MT-3724 may decrease cell proliferation and induce apoptosis in MCL. We tested the effects of MT-3724 by in vitro cell proliferation in 3 ibritinib-sensitive cell lines and 5 ibritinib-resistant cell lines (4 primary resistant and 1 acquired resistant). We also measured the levels of apoptotic cells in both ibritinib-sensitive and -resistant cell lines treated with MT-3724 by Annexin V/PI staining. Lastly, we conducted an in vivo efficacy assay of MT-3724 in a MCL PDX model resistant to a wide-range of drugs, including ibritinib. MT-3724 inhibited cell proliferation effectively and efficiently in most ibritinib-sensitive and ibritinib-resistant cell lines in a dose-dependent manner. IC_{50} < 500 ng/ml was characterized as sensitive to MT-3724, and > 500 ng/ml was considered resistant to MT-3724. Resistant cell lines were found in ibritinib-sensitive cell lines, the 3 cell lines (Jeko-1, Mino and Rec-1) were sensitive to MT-3724 with IC_{50} values of 139.1, 309.3 and 457.7 ng/ml, respectively. Regarding the ibritinib-resistant cell lines, 4 cell lines (Maver-1, JVM-13, Jeko-R and Granta-519) were sensitive to MT-3724 with IC_{50} values of 124.6, 155.1, 266.2 and 412.4 ng/ml, respectively, and 1 cell line (Z-138) was resistant to MT-3724 (IC_{50} = 1231 ng/ml). However, no significant differences in IC_{50} values were found between ibritinib-sensitive and -resistant cell lines (p = 0.36). In a time-dependent assay, 300 ng/ml MT-3724 also reduced cell proliferation in 2 ibritinib-sensitive cell lines (Mino and Jeko-1) and 2 ibritinib-resistant cell lines (Jeko-R and Maver-1) over time. Furthermore, MT-3724 also induced cell apoptosis in both ibritinib-sensitive (Jeko-1) and -resistant (Jeko-R and Maver-1) cell lines. Lastly, MT-3724 was administered intraperitoneally for three consecutive weeks in a PDX model resistant to a wide-range of agents. Interestingly, MT-3724 dramatically reduced tumor burden and increased survival (median of 27 days) of the PDX mice. MT-3724 is the first toxin engineered body targeting CD-20 used in MCL, which may be a potential therapeutic candidate for MCL, especially for drug-resistant cases.

Combination activity of LAG3 and PD-1 targeted therapies is significantly enhanced by the addition of phosphatidylinerse targeting antibodies to establish anti-tumor immune response in murine triple negative breast cancer. Michael J. Gray, Jian Gong, Jeff T. Hutchins, Bruce D. Freimark. Peregrine Pharmaceuticals, Tustin, CA.

Previous studies utilizing NanoString immune profile analysis demonstrated that intratumoral levels of LAG3 (lymphocyte activation gene 3) mRNA increased in response to phosphatidylinerse (PS) and PD-1 targeting antibodies in murine triple negative breast cancers (TNBC). This suggests LAG3 acts to attenuate immune system activation during I/O therapies and that PD-1 and LAG3 function cooperatively in suppressing immune system activation. Here we show that adding PS targeting antibodies can further enhance the effectiveness of antibodies targeting LAG3 and/or LAG3-PD-1. We first examined expression of LAG3 and PD-1 in the murine TNBC model E0771 and found that tumor associated T-cells (CD4+ and CD8+) have expression of both markers. Mice implanted with TNBC tumors were next treated with antibodies targeting PS, PD-1, and LAG3 alone and in combination with each other. Interestingly, the addition of PS targeting antibodies not only increased the effectiveness anti-PD-1 effectiveness as previously observed, but also enhanced anti-LAG3 treatment, showing that PS targeting antibodies are capable of augmenting additional I/O therapies. Combination of anti-LAG3 and anti-PD-1 targeting antibodies resulted in a significant decrease in tumor growth with complete tumor regression in 80% of the animals (along with the ability to completely reject secondary TNBC challenge) compared to 0% in the anti-PD-1+LAG3 treatment group. Immunoprofiling showed that the addition of PS targeting antibodies to these checkpoint therapies, including the combination of anti-PD-1+LAG3, resulted in a phenotypic type associated with enhanced immune system activation and immune-surveillance including increased tumor infiltrating lymphocytes (TILs) with upregulation of T-cell associated activation pathways, increased Th1 to Th2 profile, and enhanced antigen presentation processing /presentation mechanisms along with intratumoral (IT) LAG3 associated IgG activity. This data demonstrates that adding PS targeting antibodies to clinically relevant therapies, including PD-1+LAG3, may significantly enhance their ability to activate and redirect the host immune system into recognition and elimination of tumor cells compared to single and combinational treatments that lack PS targeting antibodies.

Background: ERY974 is a humanized IgG4 bispecific T-cell redirecting antibody (TRAB) currently in Phase 1 clinical trial (NCT02748837). ERY974 consists of a common light chain and two different heavy chains that respectively recognize glycopen-3 (GPC3) and CD3. The Fc portion of ERY974 is modified to lose FcγR binding to prevent GPC3-independent Fc-mediated effector function. However, binding activity to FcRn, an important factor in the PK profile of IgG, is maintained. ERY974 simultaneously binds to GPC3 on the cancer cell surface and to CD3 on the T cell surface, and induces TRAB-dependent cellular cytotoxicity mediated by the potent effector function of T cells. ERY974 shows strong antitumor activity against gastric, lung, ovarian, head & neck, and esophageal cancer-derived xenograft tumors in a non-obese diabetic/severe combined immunodeficiency (NOD-SCID) mouse model injected with human T cells. Cancer immunotherapy, as represented by immune checkpoint inhibitors such as PD-1, PD-1-L, and CTLA-4 antibodies, has been recently demonstrating remarkable clinical benefit in various tumor types. However, the number of patients who have survival benefit is limited, and combining cancer immunotherapy with other agents is required to improve the efficacy. Although ERY974 monotherapy is expected to show clinical activity based on the preclinical data, we examined whether further improvement of ERY974-induced efficacy is attained by combination with chemotherapy. Method & Results: We evaluated the combination effect of ERY974 with chemotherapy against xenograft tumors of MKN45 (gastric cancer) or NCI-H446 (lung cancer) either in a NOD-SCID mouse model injected with human T cells or in a humanized non-obese diabetic/shi-SCID/IL-2Rγ-cy7 mouse model with which differentiated human T cells are constitutively supplied. Although ERY974 monotherapy shows only minor antitumor effect against MKN45 and NCI-H446, combination therapy significantly enhanced efficacy over its monotherapy in xenograft model. A Phase 1 clinical study (NCT02694822) is currently ongoing to evaluate the safety and pharmacokinetic (PK)/pharmacodynamic (PD) profile of ERY974 in combination with pazlitaxel or cisplatin in NCI-H446 tumors caused a tumor disappearance without regrowth for a long period. Conclusion: These preclinical data suggest the possibility that the strategy of combining ERY974 with chemotherapy may succeed in increasing the clinical benefit. Now the combination effect is being further investigated to clarify the mechanism.
namic (PD) relationships in patients with advanced solid tumors. AGEN2034 is a human IgG4 antibody that binds selectively to PD-1 with high affinity and potentiates T cell responsiveness via the blockade of PD-L1 and PD-L2 binding to PD-1. Here we evaluated the pharmacologic effect of combining AGEN1884 with AGEN2034, and other molecules targeting the PD-1/PD-L1 pathway, on primary human T cell immune responses. AGEN1884 combined effectively with AGEN2034, and other antibodies targeting the PD/L-PD/L pathway, to promote superior T cell immune responses compared to monotherapies. Consistent with these in vitro findings, the co-administration of AGEN1884 with an anti-PD-1 antibody in cynomolgus monkeys (Macaca fascicularis) induced a dynamic PD effect, including a proliferative T cell response in peripheral blood, as compared to animals receiving antibodies alone. Finally, co-administration of an anti-mouse CTLA-4 antibody together with Agenex’s tumor-specific neo-epitope-based vaccine (AutoSynVax™) in mice induced effective amplification of vaccine-driven T cell responses, compared to animals that received the vaccine alone. These data further exemplify the versatility of harnessing antibody-mediated CTLA-4 blockade to influence apical events involved in T cell priming by antigen presenting cells. Taken together, these in vitro and in vivo findings demonstrate that the combination of AGEN1884 with PD-1 pathway blockade or with neo-epitope-based vaccines has the potential to provide therapeutic activity that is superior to that of either checkpoint- or vaccine-based monotherapies.

**#3655 Biomarker strategy to guide the clinical development of ImmTACTM molecules, a novel class of bispecific T cell engaging biologic drugs.** Cheryl McAlpine,1 David Krige,1 Sandra Herrero-Gonzalez,1 Sarah Franklin,1 Jacob Hurst,1 William Shingler,1 Sanjay Patel,1 Andy Johnson,1 Debbie Parker,1 Christina M. Coughlin,2 Namir J. Hassan,1 Bent K. Jakobsen1,1 ImmunoLoco Ltd., Abingdon, United Kingdom;2 Immunocore Ltd., Philadelphia, PA.

IMCgp100, a first in class immunotherapy, is a T cell redirecting bispecific biologic comprising an affinity enhanced T-cell receptor specific for gp100 and an anti-CD3 scFv. Phase I/IIa data has provided evidence of a favourable safety profile, and durable responses in both cutaneous and uveal melanoma have been observed. To complement the clinical studies we have developed a comprehensive biomarker strategy to aid our understanding of pharmacodynamics, patient response and potential mechanisms of resistance which includes analysis of markers in both the tumour and periphery. The data obtained to date provide evidence of the pharmacodynamic effects of the molecule including chemokine/ cytokine release, in both the tumor and periphery, and lymphocyte infiltration into tumors. In addition, changes in the levels of certain chemokines following the first dose of IMCgp100 were associated with tumor shrinkage. The biomarker strategy we have developed forms the basis for the support of the first dose of IMCgp100 were associated with tumor shrinkage. The biomarker strategy we have developed forms the basis for the support of the first dose of IMCgp100 were associated with tumor shrinkage. The biomarker strategy we have developed forms the basis for the support of the first dose of IMCgp100 were associated with tumor shrinkage. The biomarker strategy we have developed forms the basis for the support of the first dose of IMCgp100 were associated with tumor shrinkage. The biomarker strategy we have developed forms the basis for the support of the first dose of IMCgp100 were associated with tumor shrinkage.

Melanoma is one of the deadliest forms of skin cancer, with a dim prognosis when metastasized, leading to the highest number of skin cancer related deaths. In recent years there has been a focus on the use of checkpoint inhibitor therapies like anti-CTLA-4, anti-PD-1 and anti-PD-L1 to treat melanoma. PD-L1, HVEM and VISTA expression on cancer cells has been shown to promote immune evasion and tumor survival. CTLA-4, when engaged on tumor cells leads to their apoptosis and LIGHT signaling leads to recruitment of T cells and effective tumor clearance. Thus, these molecules do not function in isolation, we need to consider tissue pleiotropy and the expression of co-stimulator and co-inhibitory molecules on tumor tissue. Our laboratory has characterized and established five primary patient derived melanoma cell lines, ME1-2, ME-L-V, 3MM, KFM and GLM-2. In an effort to understand tumor tissue pleiotropy, we conducted a comprehensive expression pattern screening of eight co-inhibitory, 10 co-stimulatory, 32 immune cell markers in human blood, in vitro and ex vivo dendritic cells (DCs) express both PD-1 and PD-L1, and an activation signal via TLR agonists triggers downregulation of PD-1 to empower the T cell stimulatory capability of DCs. In contrast, tolerogenic DCs remain PD-1 positive, correlating to T cell-unresponsiveness. Anti-PD-L1 Ab directly induces maturation of DCs and renders them capable of stimulating T cell proliferation. Similarly, anti-PD-L1 Ab treatment in tumor-bearing mice induces massive infiltration and activation of CD11c+ DCs in the spleen and draining lymph node, indicating that PD-1 is a negative regulator in DCs. Furthermore, ablation of DCs prior to anti-PD-L1 Ab treatment in an established MC38 tumor model in CD11c-DTR mice suggests a crucial role of DCs in mediating response to PD-L1 treatment. In support of the preclinical evidence that DCs are the primary target of anti-PD-L1 Ab, we analyzed RNA-seq data from tumor biopsies at baseline in patients with renal cell carcinoma.

**IMMUNOLOGY: Phosphatidylinerse-targeting antibodies enhance anti-tumor activity of a tumor vaccine in a HPV-induced tumor model.** Genevieve Weir,1 Tara Quinton,2 Jeff T. Hutchins,3 Bruce D. Freimark,3 Mariannne Standford3.1 Immunovaccine, Inc., Halifax, Nova Scotia, Canada;2Peregrine Pharmaceuticals, Inc., Tustin, CA.

Antibodies targeting phosphatidylinse (PS) have been shown to induce anti-tumor responses by induction of tumor-specific T cells. Based on this observation, we evaluated the responses of PS and PD-1 targeting antibody therapy to enhance anti-tumor responses of a HPV16 peptide vaccine formulated in DepoVax™ (DPX) in mice bearing HPV-transformed C3 mouse tumors. The addition of PS-targeting antibody (mch1N11) to DPX/metrnomic cyclophosphamide (mCPA) immunotherapy prolonged survival in comparison to mice receiving an isotype control in combination with DPX/mCPA. When anti-PD-1 was added to mch1N11 + mCPA, there was no increase in survival. The addition of mch1N11 to DPX/mCPA immunotherapy had no effect on tumor growth or survival in the aggressive B16-F10 model. TIL analysis revealed an increase in CD8+ T cells, antigen specific CD8+ T cells and PD-1+ T cells in the tumor with mch1N11 treatment. The expression of surface markers for macrophages (CD68high, F4/80) and dendritic cells (CD11c+) were also increased in the tumors of mice treated with mch1N11. RT-qPCR analysis of the tumor confirmed higher mRNA expression of T cells markers (CD8, Granzyyme B, PD-1) and antigen presenting cell markers (F4/80, CD74) in the spleen, expression of cell surface markers for monocytes (CD11b) and PD-1+ T cells (CD8) were elevated in groups treated with mch1N11 in combination with anti-PD-1. Combined, these findings indicate that in this model, PS-targeting antibodies can enhance the activity of phagocytic cells involved in antigen presentation. We have found that PD-1 expression increases as anti-tumor activity increases, therefore these results also provide an indication that antibodies targeting PS enhance the anti-tumor immune response induced by DPX/mCPA therapy. The observations suggest that PS-targeting antibodies may enhance therapeutic vaccines for the treatment of cancer.

**IMMUNOLOGY: Dendritic Cells as Critical Immune Targets**

**#3658 Dendritic cells dictate the responsiveness of PD-L1 blockade in cancer.** Maud Mayoux,1 Marieke F. Fransen,2 Andreas Roller,3 Ines Matos,1 Vesna Pulko,1 Vaios Karanikas,1 Pablo Umana,1 Christian Klein,1 Ferry A. Ossendorp,1 Wei Xu1.1 Roche Innovation Center Zurich, Schlieren, Switzerland;2Leiden University Medical Center, Leiden, Netherlands;3Roche Innovation Center Basel, Basel, Switzerland.

Recent advances in cancer immunotherapies with PD-1/PD-L1 pathway blockade have transformed the way that cancer is being treated, leading to durable responses and prolonged overall survival. The general thinking is that PD-1/PD-L1 blockade reinvigorates tumor-infiltrating PD-1+ T cells with exhausted phenotypes. However, a mechanistic understanding on why only a subset of patients (10-30%) responds to checkpoint inhibition remains largely unknown, as does the exact immune mechanism of PD-1/PD-L1 blockade. Here, we discovered that PD-L1 blockade mediates anti-tumor immunity via dendritic cells. In human blood, in vitro and ex vivo dendritic cells (DCs) express both PD-1 and PD-L1, and an activation signal via TLR agonists triggers downregulation of PD-1 to empower the T cell stimulatory capability of DCs. In contrast, tolerogenic DCs remain PD-1 positive, correlating to T cell-unresponsiveness. Anti-PD-L1 Ab directly induces maturation of DCs and renders them capable of stimulating T cell proliferation. Similarly, anti-PD-L1 Ab treatment in tumor-bearing mice induces massive infiltration and activation of CD11c+ DCs in the spleen and draining lymph node, indicating that PD-1 is a negative regulator in DCs. Furthermore, ablation of DCs prior to anti-PD-L1 Ab treatment in an established MC38 tumor model in CD11c-DTR mice suggests a crucial role of DCs in mediating response to PD-L1 treatment. In support of the preclinical evidence that DCs are the primary target of anti-PD-L1 Ab, we analyzed RNA-seq data from tumor biopsies at baseline in patients with renal cell carcinoma.
prior to treatment with atezolizumab and found that the abundance of genes related to cross-presenting DC subsets (such as XCR1) correlates with a survival advantage in response to atezolizumab (HR=0.13, median OS is 16.2 months in patients with DC gene score <50% versus NR (not reached) in those >50%). In conclusion, we discovered abundance of tumor-infiltrating DCs as a novel biomarker that predicts treatment response to clinical checkpoint inhibitors. We postulate that checkpoint inhibition directly on tumor-infiltrating DCs likely contributes to amplification of Ag-specific priming of tumor-specific T cells.

#3659 WT1 and PRAME mRNA transfected TLR 7/8-polarized fast DC vaccines in AML patients mount specific immune responses and impact progression free survival. Iris Bigalke,1 Guri Solem,1 Dag Jøsefsen,1 Yngvar Fleisland,1 Kirsti Henningsen,1 Lisbeth Skoge,1 Signe Speitelen,1 Stein Sebøe-Larsen,1 Dolores J. Schendel,1 Gunnar Kvalheim1.2. Oslo University Hospital, Oslo, Norway; 3Medigene Immunotherapies GmbH, Germany.

Patients diagnosed with acute myeloid leukemia (AML) may not be eligible for curative intensive treatment due to co-morbidity factors or age. Here we report results of 5 AML patients in morphological remission after incomplete induction/consolidation chemotherapy treated with dendritic cells (DCs) targeting WT-1 and PRAME. DCs were produced as described previously (Subklewe et al 2014), using a maturation cocktail containing the TLR 7/8 ligand R848. These DCs show a polarized release of IL-12p70 combined with low IL-10 upon stimulation. 2.5 or 6e+6 DCs per antigen were injected intradermally once weekly for 4 weeks (wks), in wk 6 and thereafter at monthly intervals. Blood and bone marrow (BM) samples were collected at regular intervals. Minimal residual disease (MRD) was measured in BM by quantitative PCR of WT-1 and PRAME expression and by morphological examination. Immune responses were assessed by analysis of intracellular interferon gamma expression or proliferation following stimulation with peptides spanning WT-1, PRAME, hTERT and survivin or after stimulation with autologous WT-1 and PRAME DCs. A 57 year old woman with intermediate risk M4 AML was vaccinated over 22 months after chemotherapy. Five weeks after start of vaccination she mounted strong CD8 responses against PRAME combined with an increase in hTERT response, suggesting WT-1 signals in BM showed low positive levels throughout vaccination, but she remains in morphological remission 33 months after end of chemotherapy (Evoc). A 50 year old man with M2 intermediate risk AML, initially not eligible for BM transplantation, showed specific immune responses against WT-1 during 10 months of vaccination. Due to Bell’s Palsy he was treated with cortisone which immediately reduced the vaccine effect, accompanied by increase of blasts in the bone marrow. Following new induction therapy he received BM transplantation and is currently in CR. A 68 year old woman with M1 intermediate risk AML is under vaccination for 24 months. WT-1 signals in BM continue to be slightly elevated without any sign of morphological relapse. CD4 responses and low CD8 responses are detected against WT-1, PRAME and hTERT. A 73 year old woman with M1 good risk AML relapsed after 6 months of DC vaccination without mounting specific immune responses. DC treatment was combined with 5-Azacitidine without any immunological and clinical effects. A 59 year old woman with good risk AML has been vaccinated for 14 months and is in remission for 21 months since Evoc. WT-1 in BM remains slightly elevated whilst the initially positive PRAME signal is negative. Our results show that in 4 out of 5 AML patients fast TLR-polarized DCs mounted vaccine specific responses, 3 patients continued to be in CR after 21, 25 and 33 months respectively, following suboptimal primary chemotherapy. Immune responses are under investigation and will be presented.

#3660 Blocking the DC-HIL receptor reverses the T-cell suppression induced by proliferating melanoid-derived suppressor cells in common cancer types.
