Myeloid-derived suppressor cells (MDSC) are the most potent suppressors of T-cell function, and their exponential proliferation in cancer states counteracts the benefits of immunotherapy given to these patients. Having discovered the T-cell-inhibitory DC-HIL receptor, we showed that DC-HIL is responsible for MDSC’s T-cell suppressive function. We found that melanoma patients (but not healthy controls) harbor in the blood an expanded population of DC-HIL+ MDSC, whose suppressor effects in vitro can be blocked by our 3D4 anti-DC-HIL mAb. To determine whether similar outcomes apply to non-melanoma cancers, we recruited patients with metastases from bladder (BL, n=44), kidney (KI, n=44), melanoma (MEL, n=20), pancreatic (PA, n=17), and prostate (PR, n=9) cancer. FACs analysis of blood samples showed all cancer types (except LU) were associated with elevated blood HLA-DRlowCD14+ MDSC vs. age-matched controls (n=21, median of 0.5%). % DC-HIL+ MDSC in PBMC was also significantly high in all cancer types; median of 2.5% for BL; 1.7% for BR; 3.5% for CO; 3.6% for KI; 0.3% for LU; 1.8% for PA; and 4.8% for PR, vs. 0.04% for healthy controls. MDSC in all cancer types showed high DC-HIL+positivity (20-90% vs. 8% for controls). We assayed T-cell functions and cytokine production in vitro by co-culturing them at varying cell ratios, with co-stimulators. Activity was determined by % suppression in IFN-γ secretion, which was correlated with % DC-HIL+positivity of MDSC. MDSC from KI (n=3) were more suppressive than those from CO and PA, with suppressor activity correlating with DC-HIL-positivity; Pearson’s r for 0.5 for CO (n=13) and 0.73 for PA (n=8). We evaluated the effects of 3D4 anti-DC-HIL mAb on MDSCs of melanoma patients following new induction therapy (EoC). A 50 year old man with M2 intermediate risk AML, initially not eligible for BM transplantation, received BM, which immediately reduced the vaccine effect, accompanied by increase of blasts in the bone marrow. Following new induction therapy he received BM transplantation and is currently in CR. A 59 year old woman with M1 intermediate risk AML is under vaccination for 24 months. WT-1 signals in BM continue to be slightly elevated without any sign of morphological relapse. CD4 responses and low CD8 responses are detected against WT-1, PRAME and hTERT. A 73 year old woman with M1 good risk AML relapsed after 6 months of DC vaccination without mounting specific immune responses. DC treatment was combined with 5-Azacitidine without any immunological and clinical effects. A 59 year old woman with good risk AML has been vaccinated for 14 months and is in remission for 21 months since Evoc. WT-1 in BM remains slightly elevated whilst the initially positive PRAME signal is negative. Our results show that in 4 out of 5 AML patients fast TLR-polarized DCs mounted vaccine specific responses, 3 patients continued to be in CR after 21, 25 and 33 months respectively, following suboptimal primary chemotherapy. Immune responses are under investigation and will be presented.

#3661 Breaking down the barrier restricting infiltration and differentiation of APC in the tumor microenvironment with a first-in-class antibody targeting Semaphorin4D, and rational combination therapies. Elizabeth E. Evans,1 Holm Bussler,1 Crystal Malloy,1 Christine Keily,1 Sebodl Torno,1 Maria Scribner,1 Cathie Foster,1 Alan Howell,1 Stephen R. Comey,1 Leslie Baich,1 Alyssa Knapp,1 John E. Leonard,1 Terrence L. Fisher,1 Siwen Hu-Lieskov,2 Antoni Ribas,3 Ernest S. Smith,1 Maurice Zauner,11. Vaccinex, Rochester, NY; 2UCLA, Los Angeles, CA.

Purpose: We expand mechanistic findings in preclinical studies to demonstrate that antibody blockade of Semaphorin 4D (SEMA4D, CD100) reduces expansion of MDSC and shifts the balance of myeloid cells within the TME to facilitate tumor rejection. Efficacy is further enhanced when combined with various immunotherapies. Design of Phase 1b/2 combination trials of VX15/2503 was completed, and several 1b/2 combination immunotherapy trials are planned. Results: SEMA4D restricts migration of monocytes and promotes expansion of suppressive myeloid cells in vitro. Strong expression of SEMA4D at the invasive margins of actively growing tumors in vivo restricts the infiltration and modulates polarization of leukocytes in the TME. Antibody blockade of SEMA4D facilitates recruitment of activated DCs and T lymphocytes in preclinical models. M-MDSCs were significantly reduced in tumor and blood following treatment. A significant shift towards increased TH1 cytokines (IFNγ, TNFα) and CTL activity was observed in tumor significantly inhibited tumor growth by 50-70%, reduced blood levels of MDSC, and enhanced cytotoxic T lymphocyte response. Our findings support DC-HIL blockade as a potential treatment for metastatic cancers, with high blood levels of DC-HIL+ MDSC as a prognostic marker for the best responders.

IMMUNOLOGY: Dendritic Cells as Critical Immune Targets
IMMUNOLOGY: Dendritic Cells as Critical Immune Targets
1b/2 trials of combination therapy with avelumab in NSCLC patients who
are immunotherapy naïve, and combinations with anti- anti-PD-1 and/or
anti-CTLA-4 in melanoma and HNSCC patients who are refractory to PD1
inhibitors are planned in 2017.

Activation of CD40 while inhibiting IL6/STAT3 using oncolytic
viruses induces mature DCs with high cytokine production but blocks PDL1
expression. Emma Eriksson,1 Ioanna Milenova,1 Jessica Wenthe,1 Anna Dimberg,1 Rafael Moreno,2 Gustav Ullenhag,1 Ramon Alemany,2 Angelica Loskog1.
1
Uppsala University, Uppsala, Sweden; 2IDIBELL, Barcelona, Spain.
The tumor microenvironment (TME) consists of tumor cells and stroma,
including fıbroblasts, blood vessels, immune cells and extracellular matrix. The
TME supports tumor progression, metastasis as well as resistance to cancer
therapeutics. In pancreatic cancer, the TME is dense due to overproduction of
collagen and the tumor is infıltrated with suppressive myeloid cells such as M2
macrophages and myeloid suppressor cells. One key regulator of myeloid cells is
CD40, a receptor expressed on a variety of cell types. CD40/CD40L signaling
results in production of cytokines and chemokines by myeloid cells but also
endothelial and epithelial cells to alert the immune system of immediate danger.
4-1BB is expressed by lymphocytes and dendritic cells (DCs). Stimulation via
4-1BBL drives lymphocyte expansion and regulates memory formation. IL6 signaling leads to STAT3 phosphorylation in myeloid cells and tumor cells leading
to suppressive phenotypes, tumor proliferation, and angiogenesis. Further,
STAT3 signaling enhances production of TGFb, which in turn leads to overexpression of collagen. We have constructed a family of oncolytic adenoviruses
(LOAd) activating the CD40, 4-1BB and/or inhibiting IL6 signaling. The LOAd
viruses (-, 700, 703, 713) were investigated for their capacity to activate human
monocyte-derived DCs as well as their effect on pancreatic tumor cells and
stroma (fıbroblastic stellate cells, endothelial cells) using flow cytometry, MTS
assay and ProSeek Proteomics. The LOAd viruses expressing a trimerized
CD40L, 4-1BBL and/or a scFv IL6R showed effıcient oncolysis of tumor cells but
primary stellate cells were unaffected. However, stellate cells reduced tumorpromoting factors such as FGF5, PlGF, amphiregulin, Gal3, TGFb and collagen
type I. Dendritic cells increased costimulators, cytokines as well as chemokines
but PDL1 was not expressed when IL6/STAT3 was blocked. Infected endothelial
cells upregulated receptors important for lymphocyte transmigration (ICAM,
VCAM and E-Selectin). Taken together, our data demonstrates that it is possible
to utilize oncolytic adenoviruses to spark immune activation at the same time
changing biological processes via STAT3 blockade and/or CD40/4-1BB pathway
activation to reduce factors that promotes tumor progression.

#3663 An anti-CD4 depleting antibody reverses regulatory T-cell-induced

suppression of dendritic cells while preventing nonspecifıc CD4ⴙ T cell responses in tumor-bearing mice. Satoshi Ueha,1 Haru Ogiwara,1 Shoji Yokochi,2 Yoshiro Ishiwata,2 Francis Shand,1 Shohei Hori,3 Kazuhiro Kakimi,4 Satoru Ito,2 Kouji Matsushima1. 1The University of Tokyo, Tokyo, Japan; 2IDAC
Theranostics, Inc, Tokyo, Japan; 3RIKEN, Yokohama, Japan; 4The University of
Tokyo Hospital, Tokyo, Japan.
Administration
of an anti-CD4 depleting antibody induces tumor-specifıc
⫹
CD8 T cell responses in tumor-bearing mice, although the mechanisms underlying this phenomenon remain unclear. CD4⫹ Foxp3⫹ regulatory T cells (Treg)
impair antigen presentation by DCs through CTLA4-mediated down-regulation of CD80/CD86. In the present study, we investigated the effects of an antiCD4 depleting monoclonal antibody (mAb) on DC responses in the B16F10 and
LLC subcutaneous tumor models, and compared these effects with those of Treg
targeting therapy. Administration of anti-CD4 mAb up-regulated CD80/CD86
in tumor-infıltrating DCs, and in migrating-type but not resident-type DC subsets in the tumor-draining lymph node. The upregulation of CD80/CD86 on
these DC populations was correlated with increased proliferation of tumorspecifıc CD8⫹ T cells in the tumor-draining lymph node. Anti-CD4 mAb-induced CD80/CD86 up-regulation and tumor-specifıc CD8⫹ T cell responses
were remarkably higher than that induced by an anti-CD25 depleting mAb or an
anti-CTLA4 blocking mAb, and were equivalent to that induced by diphtheriatoxin-induced selective depletion of Tregs in Foxp3-DTR mice. Importantly, the
activation of CD4⫹ conventional T cells and B cells in the peripheral lymph
nodes that was observed following Treg depletion was not observed following
anti-CD4 mAb administration. In conclusion, anti-CD4 depleting antibody
therapy is an effective way to evoke anti-tumor CD8⫹ T cell responses by reversing regulatory T cell-induced suppression of dendritic cells, and to reduce the
risk of severe autoimmunity in cancer patients.

#3664 CDX-1402, a dendritic cell targeted fusion protein designed to elicit
immunity to mesothelin and HER2 expressing tumors. Li-Zhen He,1 Jenifer
Widger,1 James Testa,1 Laura Mills-Chen,1 Biwei Zhao,1 Jeff Weidlick,1 Crystal
Sisson,1 Anna Wasiuk,1 Laura Vitale,1 Joel Goldstein,1 Henry Marsh,2 Tibor
Keler,1 Venky Ramakrishna1. 1Celldex Therapeutics, Inc., Hampton, NJ; 2Celldex
Therapeutics, Inc., Needham, MA.
The use of mAbs to target antigens to the endocytic receptor Dec205 on
dendritic cells (DC) is an effective means to elicit helper and cytolytic T cell
responses in the presence of appropriate adjuvants to activate DC. We have
translated this concept to clinical studies using a fully human Dec205-specifıc
mAb genetically altered to include the entire NY-ESO-1 cancer antigen (CDX1401), which when combined with TLR agonists results in effective stimulation
of both cellular and humoral NY-ESO-1-specifıc responses in cancer patients
concept, we developed a new fusion protein in which the Dec205 mAb is engineered to carry two tumor-related antigens in tandem [ECDs of mesothelin
(MSLN) and HER2]. HER2 and MSLN are broadly expressed in selected tumor
types and provide an expanded opportunity for this immunotherapy approach.
We previously generated an anti-mouse DC-targeted HER2 vaccine (␣Dec205HER2) and a MSLN vaccine (␣Dec205-MSLN) and demonstrated in mouse
studies that they were potent in eliciting strong and broad CD4 T cell immunity,
cross priming of CD8 T cells and humoral responses specifıc for HER2 or MSLN
antigens, respectively. In this work we tested the impact of expressing two tumor
antigens in the same construct on the immune responses to each antigen. Mice
of various genetic backgrounds were immunized with equimolar amount of
␣Dec205-HER2 (6.8 ␮g), ␣Dec205-MSLN (5 ␮g) or ␣Dec205-MSLN-HER2
(8.3 ␮g) in combination with poly IC-LC plus anti-CD40 or anti-CD27 as adjuvant. Similar levels of CD4 and CD8 T cell responses upon single or dual antigen
vaccination were observed in the assessment of intracellular cytokines and
IFN␥-ELISPOT after ex vivo stimulation with peptide pools derived from either
HER2 or MSLN. High titers of anti-HER2 and anti-MSLN IgG, including IgG1
and IgG2a, were elicited upon ␣Dec205-MSLN-HER2 vaccination. Both humoral and cellular responses were boosted by multiple dosing of the vaccine.
Based on these data we developed CDX-1402 using our anti-human Dec205
mAb genetically fused to MSLN and HER2. CDX-1402 was shown to effectively
deliver these antigens to human DC in vitro for activation of antigen-specifıc T
cells. In vitro stimulation of healthy volunteer circulating T cells with autologous
DC treated with CDX-1402 plus TLR agonist resulted in T cell cultures that
produced IFN␥ only when presented with CDX-1402-treated DCs or DC loaded
with a select panel of HLA-I/II synthetic peptides derived from either MSLN or
HER2 but not with control peptides. We also observed that T cells sensitized to
CDX-1402 recognize cancer cell lines that express the vaccine antigen and HLA.
Altogether, the data lend support for the use of CDX-1402 as a novel immunotherapeutic for treatment of multiple cancer types expressing MSLN and/or
HER2.
#3665

Tumor Treating Fields (TTFields) plus anti-PD-1 therapy induce
immunogenic cell death resulting in enhanced antitumor effıcacy. Tali Voloshin, Orna Tal-Yitzhaki, Noa Kaynan, Moshe Giladi, Anna Shteingauz, Mijal
Munster, Roni Blat, Yaara Porat, Rosa S. Schneiderman, Shay Cahal, Aviran
Itzhaki, Eilon D. Kirson, Uri Weinberg, Yoram Palti. Novocure, Haifa, Israel.
Tumor Treating Fields (TTFields) are an effective anti-neoplastic treatment
modality delivered via noninvasive application of low intensity, intermediate
frequency, alternating electric fıelds. TTFields is approved for the treatment of
both newly diagnosed and recurrent glioblastoma. TTFields interrupt cancer
cell mitosis by disrupting microtubules and septin fılaments, which play key
roles in mitosis. The mitotic effects of TTFields include abnormal chromosome
segregation and ER stress, which trigger different forms of cell death. We evaluated the in vitro and in vivo effects of TTFields combined with an immune
checkpoint inhibitor (anti-PD1) on immunogenic cell death. Murine Lewis lung
carcinoma (LLC) and ovarian surface epithelial (MOSE) cells were treated with
TTFields using the inovitroTM system. Levels of calreticulin (CRT) on the surface of treated cells and intracellular ATP levels were evaluated using flow cytometry. High mobility group box 1 (HMGB1) secretion was measured using an
ELISA assay. Mice were implanted with LLC cells were treated with TTFields,
anti-PD-1, or a combination of the two modalities. Tumor volume was monitored; flow cytometry analysis was performed for phenotypic characterization of
infıltrating immune cells. TTFields induced elevated cell surface expression of
CRT, decreased intracellular ATP levels, and promoted HMGB1 secretion. In
vivo, the combined treatment of lung tumor-bearing mice with TTFields plus
anti-PD-1 led to a signifıcant decrease in tumor volume compared to anti-PD-1
alone or to the control group. Signifıcant increases in CD45⫹ tumor infıltrating
cells were observed in the TTFields plus anti-PD-1 group. Infıltrating cells dem-

Proceedings of the American Association for Cancer Research Y Volume 58 Y April 2017


onstrated a significant upregulation of surface PD-L1 expression. Both F4/80+CD11b+ cells and CS11c+ cells exhibited higher tumor infiltration and elevated PD-L1 expression as compared to infiltrating immune cell in the control group. Our results demonstrate that TTFIELDS treatment potentiates immunogenic cell death in cancer cells. Combining TTFIELDS with specific immune therapies such as anti-PD-1 may enhance antitumor immunity and result in increased tumor control.

Diverse chemotherapeutic agents, including Docetaxel, have been reported by us and others to specifically target myeloid-derived suppressor cells (MDSCs) which mediate tumor-associated immune repression. However, the mechanism is unknown. To find a less toxic anticancer drug, we focused on Curcumin which exhibits natural anti-oxidant and antitumor activities with low toxicity to normal cells. Here, we demonstrate that curcumin, like Docetaxel, promotes cytotoxic function against tumors and depletes MDSC populations in vivo and in vitro. In 4T1 mammary tumor-bearing BALB/c mice treated with curcumin, we observed dose-dependent tumor reductions in mice treated with curcumin compared to DMSO controls, indicating that curcumin can be an effective antitumor agent. To elucidate the mechanism, we embarked on examining different populations of myeloid-derived suppressor cells (MDSCs). Flow cytometric analysis of splenic cells from tumor bearers indicated that the antitumor effect by curcumin is due to depletion of immunosuppressive Ly6G−granulocytic (G)-MDSC lineage with selective promotion of Ly6C+ monocytic (M)-MDSC towards the CCR7+ F4/80+ M1 subset. Furthermore, the increase in M1 MDSCs correlated with greater T-cell adaptive immune response and cytotoxicity against 4T1 tumor cells. Since clearance of G-MDSCs was mediated by apoptosis as evidenced by our Annexin V staining, we hypothesized that clustin (sCLU), a potent anti-apoptotic protein, unrelated to the Bcl-2 family, may be the under-lying mechanism by which M-MDSCs and M1 cells are selected out following treatment of curcumin. Western blot analysis revealed that sCLU was indeed, differentially expressed in M1-MDSCs but not in G-MDSCs. Antisense-CLU transfection into M-MDSCs reduced chemoresistance not only to curcumin but also to Docetaxel, confirming the critical involvement of CLU in selective survival of M-MDSCs. Using both curcumin and Docetaxel we confirmed that sCLU works by binding Bax, preventing its translation to the mitochondria to initiate apoptosis. For clinical relevance, we examined human breast cancer samples and noted that the tumor microenvironment is replete with immature CD33+ MDSCs which lack sCLU expression, unlike infiltrating mature CD68+ macrophages which possess high sCLU expression. Our results taken together indicate that selective survival of M-MDSCs under chemotherapy dictates their survival advantage, allowing for maturation into M1 cells and promotion of adaptive T cell immunity against cancer.

#3667 Promotion of immunogenicity using epigenetic modulation and immune checkpoint inhibition in mouse models of breast cancer. Evanthia T. Rousos Torres, Hayley Ma, Brian Christmas, Todd Armstrong, Elizabeth M. Jaffe, François Fauteux. National Research Council of Canada, Ottawa, ON.

Checkpoint inhibition is a very successful treatment strategy in cancers that are naturally immunogenic by attracting T cells into the tumor microenvironment (TME) and promoting cytotoxic signaling pathways. While this strategy has shown some efficacy in metastatic breast cancer, most breast cancers are not highly immunogenic likely due to an immunosuppressive microenvironment and a lack of a tumor antigen expression and recognition. One strategy to transform the breast TME into one that is immune responsive, is to use epigenetic modulation to expose tumor antigens, promote cytokine production, thus, attracting inflammatory cells into the tumor. Epigenetic modulation also has the potential to affect activation and trafficking of myeloid derived suppressor cells (MDSCs), known to alter the immunogenicity of the TME and thus, sensitizing tumors to checkpoint modulation. We hypothesize that combinatorial therapy primes the TME by increasing immunogenicity via alteration of T cells and MDSCs. We also hypothesize that combination therapy will significantly affect immune modulatory pathways. Alterations in these could serve as a functional read out of combinatorial therapy. We are using a Her-2/neu (neu-N) mouse model which through the use of various syngeneic cell lines has the capability to inform the response of Her2 and triple negative subtypes of breast cancer to immunotherapy. This model enables us to study the efficacy of different combinations of an epigenetic agent, the histone deacetylase inhibitor entinostat, and checkpoint inhibitors anti-CD28 programmed cell death protein (PD1) and anti-cytotoxic T-lymphocyte-associated protein 4 (CTLA4) antibodies, on tumor growth and metastatic progression, and to help identify co-stimulatory and inhibitory factors regulating T cell and MDSC responses. Characterization of tumor infiltrating lymphocytes and their functional capabilities are being investigated in primary tumors and metastases using fluorescence-activated cell sorting and immunohistochemistry. Thus far, there is a significant improvement in survival and delay in development of lung metastasis as well as with anti-PD1 in combination with Entinostat. Preliminary results also suggest that epigenetic modulation with entinostat in combination with checkpoint inhibition improves the immune response within these tumors as evidenced by increased CD8+/T- regulatory cell infiltration, and increased mono-cytic MDSCs within the TME. We are ongoing survival studies evaluating this combination therapy in mice inoculated with triple negative breast tumor cells. Future studies will further delineate the mechanisms by which epigenetic therapy alters the function of the inflammatory response to immunotherapy.

#3668 Oncolytic adenoviruses expressing OX40L or GITR1 immune modulators show antitumor effect on immune-competent mouse breast cancer models. Francisco W. Puerta Martinez, Yisel A. Rivera, Teresa Nguyen, Xuejun Fan, Jared M. Henderson, Shifat Rehnuma, Mohammad B. Hossain, Hong Jiang, Juan Fuego, Candelaria Gomez Manzano. MD Anderson Cancer Center, Houston, TX.

Metastasis of advanced stage cancers remains as the main cause of morbidity and mortality in oncologic patients. Metastatic cancers, especially those that metastasize to the brain, are generally resistant to conventional therapies. Thus, more innovative and efficacious therapies are urgently needed. Therapeutic goals are the specific targeting of malignant cells, shrinkage of stabilized tumors, prevention and/or eradication of metastases and, ultimately, induction of a specific anti-tumor immune response. In this study we tested the efficiency of a treatment regimen consisting of oncolytic adenoviruses combined with specific immune regulators to prevent tumor progression and metastasis. In order to do so, mouse metastatic breast cancer cells 4T1 or 66c14, were orthotopically implanted in female BALB/c mice. The resulting primary tumors were treated with multiple doses of third generation adenoviruses targeting different immune checkpoints, such as, OX40/OX40L and GITR/GITR1 pathways in the immune synapse. The treatment with these adenoviral constructs resulted in T cells activation and reduction of the metastases in 50% of the mice. In addition, the size and number of the metastases detected in lungs were significantly lower comparing with those observed in the control groups. Survival rates were also significantly different (P < 0.046) when compared to controls. FACS analysis of isolated tumor-infiltrating lymphocytes, as well as, splenocytes showed that OX40/OX40L or GITR/GITR1 immune therapies were able to activate and increase the number of cytotoxic T cells and suppress tumor anergy. In summary, we demonstrated for the first time that Delta-24-RGDox and Delta-24-GREAT, expressing OX40L and GITR1, respectively, display antitumor effect on immune competent models of metastatic breast cancer.

#3669 Screening platform for development of antibody-drug conjugates against novel targets at the National Research Council of Canada. Maria Luz Jaramillo,1 Luc Meury,1 Patrice Bouchard,1 Allan Matte,1 Anne Marcil,1 Mauro Acchione,1 Jennifer Hill,2 Francois Fauteux.1 National Research Council, Montréal, Quebec, Canada; 2National Research Council, Ottawa, Ontario, Canada.

One of the most promising of the next generation of biologic-based cancer therapeutics builds on the molecular targeting abilities of antibodies by combining them with drugs to generate highly specific antibody-drug conjugates (ADCs). However, the development of ADCs requires time-consuming selection of the antibody for every target and cancer type. High-throughput screening technologies based on the use of conjugated secondary antibodies provide a fast and efficient surrogate assay from which to identify which antibodies are best internalized and suitable for immunono conjugate development into ADCs. As part of its integrated antibody development initiative, NRC has isolated and characterized anti- mouse Fc and anti-human Fc monoclonal antibodies to serve as very selective detective reagents for various IgG isotypes. We have shown that these secondary antibodies are species specific, selective and of high affinity. When conjugated to pH sensitive fluorophores, we have used them to specifically identify internalizing antibodies against tumor targets, which were later validated as ADCs. Furthermore, these secondary conjugates exhibit high specific potency and low background toxicity once conjugated to linker drugs. This approach allow us to optimize the selection of an antibody for a particular target, tumor type, linker and drug for ADC development. NRC will present results of a screen of 285 mouse antibodies against 20 different targets in 7 different cancer cell lines, using either MCC-DM1 or vc-MMAE-conjugated secondary antibodies. The NRC ADC discovery platform is combining this...
methodology with our proprietary mRNA and DNA expression database for the selection of appropriate ADC targets. NRC Biologics and Biomanufacturing program is in the process of screening thousands of NRC antibodies generated against a variety of cancer-associated cell surface targets to deliver a steady pipeline of ADCs as part of its drug discovery efforts. This functional screening platform further promotes the integration and advancement of NRC’s capabilities and strengths in the area of biologic-based therapeutics lead candidate selection, including quality attributes and characterization and biomanufacturing. The combined expertise in cell biology, high throughput screening, antibody generation and selection, bioinformatics and expression analysis forms the foundation by which NRC can establish strategic collaborations with other Canadian or international partners to develop antibodies into novel ADC biologics.

#3670 Treatment of epithelial ovarian cancer with folate receptor (α/β) targeted chemotherapy is enhanced by CTLA-4 blockade: Learning from animal models. Yingjuan Lu, Theresa P. Johnson, Leroy W. Wheeler, Alex M. Lloyd, Vicky A. Cross, Elaine M. Westrick, Nikki L. Parker, Christopher P. Leamon. Endocytosis, West Lafayette, IN.

Epithelial ovarian cancer (EOC) remains to be the most lethal form of gynecologic malignancies despite aggressive cytoreductive surgery (i.e. debulking) followed by standard chemotherapy. The alpha folate receptor (FRα) has long been recognized as a tumor target for EOC due to its frequently intense overexpression (>80%) in the most common serous histotype. Recently, the beta folate receptor (FRβ) has been discovered on tumor-associated macrophages (TAMs) which are present at various densities in solid tumors but are also found abundant in malignant ascites of EOC patients. The ascites TAMs are strongly immunosuppressive, and high TAM frequency is correlated with poor patient prognosis and treatment resistance. Respectively, tumor- and TAM-associated FRα and FRβ are both functionally active which allows for folate-targeted delivery of small-molecule drug payloads via receptor-mediated endocytosis. Using flow cytometry, we characterized total ascites cells harvested from human IGROV1 xenograft (hFRα) and murine ID8-CL15 syngeneic (mFRα) models at the time of euthanasia. Approximately 70% of IGROV1 and 25% of ID8-CL15 ascites TAMs (F4/80+/CD11b+) were found to express a functional mFRβ. While ascites fluids from both models caused a dramatic reduction of FRα functionality on tumor cells in vivo and ex vivo, FRβ expression and functionality on ascites TAMs were largely unaffected. Interestingly, in the ID8-CL15 model, the ratio of ascites CD8+ T cells to CD4+ T cells decreased as total FR functionality on TAMs increased. Two small-molecule folate-drug conjugates with different mechanisms of action showed activity in extending the survival of mice surviving in the IR+anti-PD-1 group (p = 0.657). Conclusions: Anti-PD-1 mAbs potentiates the radiation-induced pneumonitis, likely mediated by increased CD8+ cytotoxic T lymphocytes. Anti-PD-1 mAbs may increase the radiation-related mortality although it was not statistically significant at the day 120 following IR. Care should be taken for excessive lung toxicities during the clinical trials of combination of anti-PD-1 with radiotherapy. We will collaborate with NRG to further investigate clinical lung toxicities from combining thoracic radiotherapy with Nivo in the ongoing RTOG 3505 though analyzing the collected biospecimens.

#3672 Semaphorin 4D in human head & neck cancer: A promising predictive biomarker for the peri-tumoral stromal phenotype. Rania H. Younis,1 Roshanak Derakhshandeh,2 Ahmed Sultan,1 Haiyan Chen,1 Kyu Lee Han,1 Tonya J. Webb.1 1Univ. of Maryland School of Dentistry, Baltimore, MD; 2Univ. of Maryland School of Medicine, Baltimore, MD.

Semaphorin 4D in human head and neck cancer: A promising predictive biomarker for the peri-tumoral stromal phenotype The search for biomarkers that can predict the tumor stromal phenotype in cancer patients is a challenge in the field. Semaphorin 4D (Sema4D), known for its various effects in the nervous, vascular and immune system, plays an important role in regulating pro- and anti-inflammatory responses. It is over-expressed in Head and Neck cancer (HNC) as well as in other epithelial malignancies. We have recently described that HNC-associated Sema4D modulates the inflammatory profile to an immune-suppressive phenotype by inducing the expansion of myeloid derived suppressor cells. The purpose of this study was to determine the prognostic value of Sema4D as a biomarker for immune suppression in human HNC tissue and sera. Immunohistochemistry showed Sema4D+ve high expression in patients with Stage III/IV disease (p = 0.014), and nodal metastasis (p = 0.117). Sema4D+ve high tumors correlated directly with dense fibrotic peri-tumoral stroma (p = 0.0001) and inversely with tumor-associated inflammatory cells (TAs) (p = 0.0006). Knockdown of Sema4D in HNC cell lines resulted in significant reduction of TGF-β1 production (p = 0.001) and Sema4D+ve high tumor cells inversely correlated with the programmed death ligand 1 (PD-L1) positive tumors. Finally, Sema4D was detected in sera of HNC patients at higher levels compared to healthy donors (p < 0.0001). In conclusion, we present a novel Sema4D+ve high HNC tumor phenotype; with dense fibrotic peri-tumoral stroma. We also present Sema4D as a diagnostic biomarker in sera of HNC patients that can also be a promising predictor of the tumor stromal phenotype. This is of clinical interest as a predictive biomarker and a promising target for co-inhibition to sensitize patients for standard immunotherapy. [1-4] References: 1. Younis RH, Han KL and Webb TJ. #3671 Anti-PD-1 treatment may potentiate the radiation-induced lung injury. Jianxin Xue, Shisuo Du,1 You Lu,1 Adam Dicker,1 Bo Lu,1 Thomas Jefferson Hospital, Philadelphia, PA; 2West China Hospital, Sichuan University, Chengdu, China.

Purpose: Combination of radiation therapy and anti-PD1 immunotherapy has been investigated both in the lab and in the clinic. Pneumonitis is a rare but potentially fatal toxicity of anti-programmed death-1 (PD-1) monoclonal antibodies (mAbs). The purpose of our study is to address whether anti-PD-1 mAbs will potentiate radiation-induced lung toxicity and mortality in a murine model using Small Animal Radiation Research Platform (SARRP) for lung-targeting irradiation (IR). Methods: Both lungs of male C57bl/6 mice were targeted for 20 Gy using the SARRP. Mice were strated into 4 treatment groups receiving IgG, anti-PD1, IR + IgG, or IR + anti-PD1. IgG or anti-PD-1 mAbs administered via i.p. injection, with a dosage of 10mg/kg, twice per week for five doses. Acute lung injury was assessed by H&E staining and flow cytometry to measure CD4+ or CD8+ positive T lymphocytes. A duplicate study (n=10) was performed to determine long-term survival following lung irradiation. Results: 30 days following lung irradiation, lung tissues exhibited abnormal alveoli, with exudates and inflammatory cells in the alveolar septa (H&E staining). The extent of these changes was more prominent in IR + anti-PD-1 group. Moreover, there were significantly (2.1 fold increase; p < 0.05) more CD8+ cytotoxic T lymphocytes, rather than CD4+ cells lymphocytes, in the irradiated lung tissues in the group of IR + anti-PD1 compared to that of IR + IgG. Up to 120 days post IR, 90% mice survived in the group of IR + IgG while 70% mice survived in the IR +anti-PD-1 group (p = 0.657). Conclusions: Anti-PD-1 mAbs potentiates the radiation-induced pneumonitis, likely mediated by increased CD8+ cytotoxic T lymphocytes. Anti-PD-1 mAbs may increase the radiation-related mortality although it was not statistically significant at the day 120 following IR. Care should be taken for excessive lung toxicities during the clinical trials of combination of anti-PD-1 with radiotherapy. We will collaborate with NRG to further investigate clinical lung toxicities from combining thoracic radiotherapy with Nivo in the ongoing RTOG 3505 though analyzing the collected biospecimens.

Background. - 4-1BB (CD137) is a key costimulatory immunoreceptor and a highly promising therapeutic target in cancer. To overcome toxicity and efficacy limitations of current 4-1BB targeting antibodies, we have developed PRS-343, a 4-1BB/HER2 bispecific based on Anticalin™ technology. We have previously reported on the generation and characterization of PRS-343 with regard to preclinical proof-of-concept and basic drug-like properties. Here, we describe the preclinical dataset supporting initiation of a first-in-patient trial. Methods and Results. The pharmacology of PRS-343 was investigated by ex vivo assays based on mixed culture of human PBMC and tumor cell lines. We find that 4-1BB costimulated T cells prominently increase production of IL-2, GM-CSF, TNF-α and IFN-γ. Using a set of immortal cancer cell lines spanning a range of HER2 surface copy numbers, we identified a copy number threshold above which PRS-343 reliably elicited T cell costimulation with a high potency and an EC50 in the subnanomolar range. PRS-343 was well tolerated in a repeat-dose study in cynomolgus monkeys, with no overt toxicity and no significant drug-related toxicity observed.
toxicological findings. Pharmacokinetic assessment confirmed dose-proportional exposure of the animals during the course of the study. In a mouse model of human PBMC-induced xenograft vs-host disease (xGvHD), PRS-343 did not show an acceleration of xGvHD development, in contrast to a 4-1BB targeting benchmark. Again utilizing ex vivo assays, we found no PRS-343 induced T cell costimulation. This result was not unexpected as the primary HER2 gene alteration targeted by HER2 is insufficient for activation. In a cytokine release assay, proinflammatory cytokine induction by PRS-343 in the absence of a primary TCR stimulation was negligible. Conclusion. The ex vivo experiments described indicate that HER2 expression level is expected to be a reliable marker for patient stratification for PRS-343. The toxicology assessment of PRS-343 indicates that the bioactivity and safety profile of the compound is suitable for clinical development. HER2 positive tumors. This is in agreement with in vivo mouse model data showing that PRS-343 leads to tumor-localized CD8+ T cell expansion, and supports the potential of PRS-343 as a efficacious yet well tolerable 4-1BB costimulating agent in the treatment of cancer. Antitumor effects on local and distant metastatic tumors generated by an anti-HER2 antibody were observed in a higher ratio of effector-to-suppressor cells in the tumor microenvironment. Furthermore, local irradiation, although inducing Treg cells, can eventually increase the expression of HMGB-1 in apoptotic tumor cells and stimulate DC maturation. Therefore, in an attempt to understand these first steps of immune reaction, leukocyte migration, cytokines synthesis and monocyte phagocytosis promoted by the vaccine components were studied in vitro. Methods: Cell migration of healthy donors’ leukocytes or mononuclear cells (MN) towards vaccine components were studied in vitro. Results: Tumor-bearing mice treated with local RT (6Gy twice per week) and the CTGF/E7 DNA vaccine exhibited a dramatic increase in the number of E7-specific CD8+ cytotoxic T cell precursors and anti-E7 Abs from Tumor-bearing mice treated with local RT (6Gy twice per week) and the CTGF/E7 DNA vaccine were evaluated. Abscopal effects were also monitored. HMGB-1 and DC maturation from local irradiation were analyzed by flow cytometry. The ratio of effector-to-suppressor cells in the tumor microenvironment was also investigated. Results: Tumor-bearing mice treated with local RT (6Gy twice per week) and the CTGF/E7 DNA vaccine exhibited a dramatic increase in the number of E7-specific CD8+ cytotoxic T cell precursors, higher titers of anti-E7 Abs, a significant reduction of tumor size, and longer survival. The combination of local RT and the CTGF/E7 vaccine also elicited abscopal effects on non-irradiated local subcutaneous and distant pulmonary metastatic tumors. Local irradiation can induce the expression of HMGB-1 in apoptotic tumor cells and stimulate DC maturation, which results in inducing antigen-specific immune responses. In addition, local irradiation, although inducing Treg cells, can eventually increase a higher ratio of effector-to-suppressor cells in the tumor microenvironment. Conclusions: Local irradiation can enhance the antigen-specific immunity and antitumor effects on local and distant metastatic tumors generated by an antigen-specific DNA vaccine. Irradiation combined with antigen-specific immunotherapy is a potential new strategy for cancer therapy.

#3674 Local irradiation promotes antitumor immunity and abscopal effect of antigen-specific immunotherapy by enhancing dendritic cell maturation. Ming-Cheng Chang, Jason Chia-Hsien Cheng, Ying-Cheng Chiang. National Taiwan Univ. Hospital, Taipei, Taiwan.

Background: Ionizing radiation therapy (RT) is a well-established method to eradicate locally advanced tumors. Whether or not local RT can enhance the potency of an antigen-specific DNA vaccine and the possible underlying mechanism were evaluated. Materials and Methods: The number of E7-specific CD8+ cytotoxic T cell precursors and anti-E7 Abs from Tumor-bearing mice treated with local RT (6Gy twice per week) and the CTGF/E7 DNA vaccine were evaluated. Abscopal effects were also monitored. HMGB-1 and DC maturation from local irradiation were analyzed by flow cytometry. The ratio of effector-to-suppressor cells in the tumor microenvironment was also investigated. Results: Tumor-bearing mice treated with local RT (6Gy twice per week) and the CTGF/E7 DNA vaccine exhibited a dramatic increase in the number of E7-specific CD8+ cytotoxic T cell precursors, higher titers of anti-E7 Abs, a significant reduction of tumor size, and longer survival. The combination of local RT and the CTGF/E7 vaccine also elicited abscopal effects on non-irradiated local subcutaneous and distant pulmonary metastatic tumors. Local irradiation can induce the expression of HMGB-1 in apoptotic tumor cells and stimulate DC maturation, which results in inducing antigen-specific immune responses. In addition, local irradiation, although inducing Treg cells, can eventually increase a higher ratio of effector-to-suppressor cells in the tumor microenvironment. Conclusions: Local irradiation can enhance the antigen-specific immunity and antitumor effects on local and distant metastatic tumors generated by an antigen-specific DNA vaccine. Irradiation combined with antigen-specific immunotherapy is a potential new strategy for cancer therapy.

#3675 Novel immune oncology strategy for targeted cytotoxic lymphocyte activation. Eric Lazier,1 Sarah Hein,2 John Westwick,2 Dan Watkins,2 Alexander J. Mulrain,2 Ming-Cheng Chang, Jason Chia-Hsien Cheng, Ying-Cheng Chiang. National Taiwan Univ. Hospital, Taipei, Taiwan.

In clinical trials (CASVAC-0401, NCT01729663), cutaneous melanoma (CM) patients (pts) stages II/III were randomized to receive CSF-470 vaccine or IFN-α (21). Vaccine-CSF-470 is composed of four locally-irradiated allelic CM E7 mRNA + BCG (bacille Calmette-Guérin) and rhGM-CSF were used as adjuvants. At the end of the Phase II part of the study (30 pts), a higher distant-metastases-free-survival was observed in vaccinated pts. All vaccinated pts developed inflammation at the vaccination site. Therefore, in an attempt to understand these first steps of immune reaction, leukocyte migration, cytokines synthesis and monocyte phagocytosis promoted by the vaccine components were studied in vitro. Methods: Cell migration of healthy donors’ leukocytes or mononuclear cells (MN) towards vaccine components were assayed in 0.5 μm transwells. Cytokines were measured by ELISA in supernatants of CSF-470 vaccine and MN (1:1, 0.5×10^6 each) cultures. For phagocytosis assays, CM cell lines were labeled with PKH67 lipophilic dye, irradiated, and cocultured with purified monocytes. After 24 hs, cultures were stained with CD14 and double staining (CD14+ PKH67) was analyzed by flow cytometry. Results: In migration assays, CSF-470 vaccine induced higher attraction of leukocytes as compared to culture medium (p=0.003, unpaired-T-test). GM-CSF exerted little attraction, although combined with BCG it increased the migration triggered by CSF-470 (vaccine vs vaccine plus adjuvants, p=0.034, unpaired-T-test). When using MN, CSF-470 alone or plus adjuvants, highly attracted monocytes, which represented 10%-65% of the migrating CD45+ population (before migration 6-15%) (p<0.0001, paired-T-test). In the lymphocyte population, natural killer cells were mainly attracted towards the vaccine either with or without adjuvants, representing 12%-33% of total migrated lymphocyte population (before migration 4-25%) (p<0.002, paired-T-test). Regarding cytokine production, 6 hs cocultures of CSF-470 vaccine plus adjuvants MN, promoted CM E7 mRNA (385±217 pg/ml), IFNα release was detected in CSF-470-MN cocultures after 48 hs (109.2 pg/ml). BCG appears to be the most important adjuvant for production of these proinflammatory cytokines. IL-10, but not IL-12p70, was also detected. Interestingly, approximately 60% of monocytes phagocytosed CSF-470 cells after 24 hs of coculture, either in the presence or absence of adjuvants. Conclusions: Our in vitro results suggest that recruitment of leukocytes, mostly from the innate immune system, is an early event after CSF-470 vaccine + BCG + GM-CSF interaction with immune cells. Also, early release of TNFα and IFNγ proinflammatory cytokines and efficient vaccine phagocytosis by monocytes would favor subsequent antigen processing and presentation. Further experiments will be performed to address the initial steps triggered after CSF-470 vaccination.
#3670 Cancer-killing viruses combined with tumor-targeting immune checkpoint modulation elicits an in situ vaccination effect and expansion of tumor-specific T cells responsible for efficacious systemic anti-cancer activity. Hong Jiang, Andrew Dong, Yisel Rivera-Molina, Karen Clise-Dwyer, Xuexun Fan, Francisco W. Martinez, Teresa Nguyen, Verlene Henry, Caroline Carillo, Candelaria Gomez-Manzano, Juan Fuego. UT MD Anderson Cancer Ctr., Houston, TX.

Oncolytic viruses are cancer-selective and disrupt immunosuppression within the tumor, but they show suboptimal efficacy in patients. Immune checkpoint modulation is efficacious in a variety of cancers but is associated with nonspecific T-cell activation and a limited effect in tumors with a nonimmunogenic microenvironment. We hypothesized that combining these two strategies likely resulted in both efficacious and specific cancer therapy. Therefore, we constructed oncolytic adenovirus Delta-24-RGDox expressing the immune co-stimulator OX40L and tested its activity in orthotopic GL261-C57BL/6 glioma and B16-C57BL/6 melanoma mouse models. Compared to its predecessor Del-ta-24-RGD, Delta-24-RGDox was more effective to induce inflammatory activation within the tumors, enhanced the capability of the tumor cells to directly activate cancer-specific T cells and the proliferation of the cell population through OX40L expression on the cell surface, resulting in specific anti-tumor immunity. To track the expansion and migration of tumor-specific T cells during treatment, we first injected OVA-specific, CD8+ T cells into TLL/Lu transgenic mice in the first tumor derived from B16-OVA cells, followed by Delta-24-RGDox injection in the same tumor. Monitoring the T cells with bioluminescent imaging revealed that the viral injection greatly augmented the T cell population than the PBS treatment within the tumor, and promoted the T cell migration to distant B16-OVA tumor but not to B16 tumor, suggesting local viral treatment enhanced the expansion of tumor-specific T cells and the migration of these cells to a distant tumor with the same tumor antigen. Consistently, flow cytometry analysis with OVA-tetramer staining showed that virus treatment greatly increased the frequency of OVA-specific CD8+ T cells in the local and distant tumors, peripheral blood and spleen (from high to low frequency). 70-80% cells of this cell population were CD44+ and CD62L+ that are markers for central memory T cells. Hence, this new virus was efficacious to inhibit the virus-infected tumor and distant tumor, prolong the survival of the treated mice and induce immune memory specific to the virus-infected tumor type. Importantly, intratumoral injection of Delta-24-RGDox and an anti-PD-L1 antibody synergized to reject gliomas and significantly increased survival in mice. Our data demonstrate that combining an oncolytic virus with tumor-targeting immune checkpoint modulation elicits potent in situ cancer vaccination and skews the injected tumor microenvironment from tumorigenic to immunogenic, resulting in a local expansion of the tumor-specific T cells. Moreover, this local effect is capable to extend to distant tumors, achieving specific and long-lasting therapeutic efficacy.

#3680 Patients derived ex vivo platform CANScript™ predicts distinct therapeutic outcomes to multiple PD-1 checkpoint inhibitors in single tumor biopsies. Padhma Radhakrishnan,1 Vasanthagam Sekar,2 Nilesh Brijwani,2 Priyanka Chevour,2 Babu Balakrishnan,2 Dency D Pinto,3 Mathusamy Oliyarasi,2 Debapriya G. Mehrotra,2 Manjusha Biswas,2 Sabitha K S,4 Kovanavan Thiyagarajan,2 Biswanath Majumder,2 Aaron Goldman1.

Background: Emerging clinical evidence using immunotherapy in recent years has demonstrated its power to suppress tumor growth by releasing the brakes on the immune system. For example, blockade of immune checkpoints, such as PD-1, has revolutionized treatment options for patients with aggressive cancers such as head and neck squamous cell carcinoma (HNSCC). However, clinical responses to PD-1 inhibition vary widely among patients while majority of them do not show any anti-tumor response. Multiple FDA-approved drugs against the same immune checkpoints have resulted in globally distinct outcomes in the clinic. There is a huge unmet need to understand these disparities at the individual patient level and to maximize the clinical benefits of these agents. Methods: Here, we employed a patient-derived ex vivo model, CANScript™ (Majumdar B et al. Nat Immun Cancer 2015 Feb 27:6:6169 and Goldman A et al. Nature Commun

Vascular Endothelial Growth Factor (VEGF) is a key factor for tumor progression through induction of angiogenesis and other actions including immune alteration. Myeloid-derived suppressor cells (MDSC) are a major type of immune-suppressing cell that appear in cancer or inflammation and that have been reported to express the VEGF receptor and be activated by VEGF. To study the clinical importance of VEGF and MDSC for cancer, peripheral blood was collected from patients with gastrointestinal, ovarian, breast, thyroid and pulmonary cancers. Peripheral blood mononuclear cells (PBMC) were separated using a Ficoll-density gradient and were used for the detection of MDSC (CD11b+CD14-CD33+) using flow cytometry and for cytokine-production assays. For these assays, PBMC were stimulated with PHA and the production of cytokines including IL-12 (Th1 inducer), IL-10, (anti-inflammatory cytokine) and IL-17, (pro-inflammatory cytokine), were measured over 24 h using ELISAs. Serum concentrations of IL-10 and VEGF were also measured using ELISAs. The serum levels of both VEGF and MDSC were significantly increased in almost all types of cancer tested and significantly correlated with each other. Their levels also significantly correlated with neutrophil/lymphocyte ratios (NLR) (inflammation marker) and CRP levels, and were inversely correlated with the PHA-stimulation index (SI) (cell mediated immune response marker) and serum concentrations of rapid-turnover protein (RTP) (nutrition marker). VEGF levels also correlated with serum concentrations of IL-10 and VEGF, and production of IL-17, and inversely correlated with production of IL-12. The prognosis of stage IV colorectal cancer with high VEGF was significantly worse than that with low VEGF. In thyroid cancer, the number of MDSC was significantly higher, NLR and CRP levels were higher, and RTP levels were lower in patients with undifferentiated carcinoma than in those with differentiated carcinoma including papillary and follicular carcinomas. Thus VEGF was increased in cancer and correlated with immune suppression driven by MDSC, inflammation and malnutrition. Although cancer immunotherapy is currently in use for a number of cancers, MDSC have been reported to be a major inhibitor of cancer immunotherapy even in cases in which an immune checkpoint inhibitor was used. An anti-VEGF treatment strategy has now been established in combination with chemotherapy for many types of cancer. Among various types of anti-MDSC trials, anti-VEGF treatment seems to be an effective adjuvant therapy of cancer immunotherapy.
2015 Feb 11;61(139), which recreates the native 3D tumor microenvironment, autocrine-paracrine dynamic and response to therapy by incorporating fresh tumor tissue and autologous immune cells with immunotherapy agents. Utilizing late stage HNSCC (N=50) we interrogated phenotypic response to two FDA-approved PD-1 inhibitors, Pembrolizumab (KEYTRUDA) and Nivolumab (OPDIVO). The tumor microenvironment (TME) is complex and characterized by dynamic cellular interactions and cytokine signaling that can influence immune responses. The analysis was extended to include IHC for arginase (Arg, a marker of functional immunosuppression activity), Subpopulations of cells identified included CD163+, CD163+/H11001, CD163+/H11545, CD163+/H11290, CD163+/H11538, CD163+/H11215, and Arg+/H11001. t-test one-sided. *p < 0.05, **p < 0.01, ***p < 0.001. N = 6 mice per group.

#3684 Inhibition of STAT3 by antisense oligonucleotide treatment decreases the immune suppressive tumor microenvironment in syngeneic and GEM tumor models.

Rich Woessner,1 Vasu Sah,1 Patricia McCoon,1 Shaun Grosskurth,1 Nanhua Deng,1 Rachel DuPont,2 Deborah Lawson,1 Lourdes Pablo,1 Corinne Reimer,1 Marco A. De Velasco,1 Hirotsugu Uemura,1 Juliana Candido,1 Paul Lyne,1 AstraZeneca Pharmaceuticals LP, Waltham, MA;2 Kindai University Faculty of Medicine, Osaka, Japan;3 Barts Cancer Institute, Queen Mary University, London, MA.

AZD9150, a gen2.5 antisense oligonucleotide (ASO) targeting human STAT3, has improved drug-like properties compared to previous generation ASO therapeutics, including increased stability and resistance to nucleases, reduced proinflammatory effects, and enhanced potency. We have previously reported that in tumors, STAT3 ASOs are taken up preferentially in stromal and immune cells within the tumor microenvironment (TME). Since AZD9150 is selective for human STAT3, we used a surrogate ASO (muSTAT3 ASO) to explore the pharmacodynamics of ASO-mediated STAT3 inhibition in syngeneic and genetically engineered mouse (GEM) tumor models, focusing on effects in the TME. In mice bearing subcutaneous CT-26 tumors, treatment with muSTAT3 ASO at 50 mg/kg, i.c., on a qx5/5 wk schedule decreased STAT3 levels in immune cells in the tumor and in circulating leukocytes by 40 - 60%, similar to the decrease in STAT3 ASO achievable in circulating leukocytes in human patients after AZD9150 treatment. In a Nanostring analysis (nCounter mouse immunology panel) of CT-26 tumors from muSTAT3 ASO treated mice, CD163+ (M2 macrophage/microglia marker) was the gene most consistently and significantly downregulated, by an average of 84% in three independent experiments, and was confirmed by immunohistochemistry (IHC). Flow cytometry analysis of myeloid subpopulations - tumor associated macrophages (F4/80+ TAMs), monocyte myeloid derived suppressor cells, and granulocytic cells - showed a decrease in TAMs averaging 69% across three independent experiments. The analysis was extended to include IFNγ for arginase (Arg, a marker of functional immunosuppression activity). Subpopulations of cells identified included CD163+, CD163+/H11001, and Arg+ cells. These cells decreased these populations by 79%, 88% and 97% respectively, compared to control treatment. These populations were also analyzed in two GEM tumor models - the KPC pancreatic cancer model, and a PTEN -/- prostate cancer model - which have a TME more representative of that found in tumors in the clinic. While the specific changes varied across the models, likely reflecting differences in the TME immunology, in general, the observation that STAT3 ASO decreased these populations by 79%, 88% and 97% respectively, compared to control treatment. These populations were also analyzed in two GEM tumor models - the KPC pancreatic cancer model, and a PTEN -/- prostate cancer model - which have a TME more representative of that found in tumors in the clinic. Overall, these results suggest that selective STAT3 inhibition can reduce immune suppressive cell populations in the TME, and suggest that STAT3 inhibition has the potential to enhance the antitumor activity of other tumor antigens released during radiotherapy and improve the presentation of antigens to professional antigen presenting cells (APCs). Methods: We developed several types of antigen-capturing nanoparticles (AC-NPs) using poly (lactic-co-glycolic acid) (PLGA), a biocompatible and biodegradable polymer. The surfaces of nanoparticles were

#3683 Melphalan stimulates dendritic cell and CD8+ T cell expansion by inducing immunogenic cell death in melanoma cells.

Jungo Johansson, Roberta Kiffin, Per Lindnér, Peter Naredi, Roger Olfosson Bagge, Anna Martner.

University of Gothenburg, Gothenburg, Sweden.

Background: Regional hyperthermic perfusion with the alkylating agent melphalan is a treatment option for patients with metastatic melanoma confined to the limbs or the liver. Following a single perfusion, tumors often decrease gradually in size during several months, suggesting an immune-mediated mechanism of action, in addition to the direct cytotoxic effects of melphalan. This study was designed to characterize the immunogenic effects of melphalan. Materials and methods: We have established an in vitro model of regional hyperthermic perfusion where human melanoma cell lines are exposed to melphalan at 40°C for 1 h, thus mimicking the currently employed clinical protocol. The melanoma-exposed melanoma cells were analyzed for markers of immunogenic cell death and were co-cultured with peripheral blood mononuclear cells (PBMCs) in the presence or absence of IL-2. The number and activation status of various immune populations were analyzed by flow cytometry. Results: Melphalan exposure triggered the expression of several immune-related markers on melanoma cells, including calreticulin, MHC class I, Hsp70 and PD-L1. Melphalan-treated, but not untreated melanoma cells, triggered an increase in dendritic cell (DC) numbers along with a dramatic expansion of CD8+ T cells in co-cultured PBMCs. The expanded CD8+ T cells showed an activated phenotype with the majority of cells belonging to the effector memory subtype. Conclusions: The tumor cells induced immunogenic cell death and trigger DC expansion with subsequent expansion and activation of CD8+ T cells. We propose that these events may contribute to the antitumor efficacy of regional hyperthermic perfusion with melphalan in metastatic melanoma.

#3682 Synergistic immunostimulatory effects and therapeutic benefit of combined histone deacetylase and bromodomain inhibition in non-small cell lung cancer.

Dennis O. Adeegbe,1 Yan Liu,1 Patrick Lizotte,2 Yusuke Kaminaka,1 Matthew Wander3, David Barbier,1 Jerome Ritz,1 Simon Jones,1 Steven Quayle,5 Peter Hammerman,1 Kwok-Kin Wong1.

1 Dana Farber Cancer Institute, Boston, MA; 2 Belfer Institute for Applied Cancer Science, Boston, MA; 3 Brigham and Women’s Hospital, Boston, MA; 4 Acetylon Pharmaceuticals, Inc, Boston, MA; 5 Acetylon Pharmaceuticals Inc, Boston, MA.

Effective therapies for non-small cell lung cancer (NSCLC) remain challenging despite an increasingly comprehensive understanding of somatically altered oncogenic pathways. It is now clear that effective agents with potential to impact the tumor immune microenvironment potentiate immune-orchestrated therapeutic benefit. This study evaluated the immunoregulatory properties of two classes of drugs that modulate the epigenome, histone deacetylase (HDAC) and bromodomain inhibitors with a focus on key cell subsets that are engaged in an immune response. By evaluating human peripheral blood and NSCLC tumors, we show that the selective HDAC6 inhibitor ricolinostat promotes phenotypic changes associated with enhanced T-cell priming and function of antigen presenting cells. The bromodomain inhibitor IQ1 attenuated CD4+ Tfh3+ T regulatory cell suppressive function and synergized with ricolinostat to facilitate immune-mediated tumor growth arrest, leading to prolonged survival of mice with lung adenocarcinomas. Collectively, our findings highlight immunomodulatory effects of two epigenetic modifiers that together promote T-cell-mediated anti-tumor immunity and demonstrate their therapeutic potential for NSCLC treatment.

#3685 Antigen-capturing nanoparticles improve the abscopal effect and cancer immunotherapy.

Yuanzeng Min. USC Chapel Hill, Chapel Hill, NC.

Introduction: Cancer immunotherapy, the utilization of patients’ own immune system to treat cancer, has emerged as a powerful new strategy in cancer treatment. The main limitation of this strategy is the low long-term durable response rate. Therefore, there has been high interest in developing strategies to further improve cancer immunotherapy. We hypothesized that antigen-capturing nanoparticles (AC-NPs) could improve immune responses to checkpoint inhibitors. The NPs can induce the abscopal effect by capturing tumor antigens further improving cancer immunotherapy. We hypothesized that antigen-capturing nanoparticles improve the abscopal effect and cancer immunotherapy. We hypothesized that antigen-capturing nanoparticles improve the abscopal effect and cancer immunotherapy.
modified to enable capturing tumor antigens released after radiotherapy. Unmodified PLGA NPs absorb antigens via hydrophobic-hydrophobic interactions. AC-NPs with positive charged bind antigens through ionic interactions. AC-NPs having maleimide group on the surface (Mal AC-NP) bind to antigens by reaction to thiols groups of antigens. The B16-F10 tumor, a syngeneic mouse melanoma model on C57BL/6 mice was employed to evaluate the efficacy of AC-NPs to improve immune responses of checkpoint inhibitor combining radiotherapy. Results: The in vivo efficacy study showed that AC-NPs can significantly improve the efficacy of oPD-1 treatment in the B10F10 melanoma model, which generates up to 20% cure rate as compared to 0% without AC-NP. Mechanistic studies demonstrated that the AC-NPs can drain to lymph node model, which generates up to 20% cure rate as compared to 0% without AC-NP. In the meantime, it was found that there are significant increases in CD4\(^+\) and CD8\(^+\) T cell to T, B, N ratios, which indicate an expansion of the T-helper cells and cytotoxic T cells. We also found that AC-NPs can induce increased level of antitumor cytokine interferon-\(\gamma\) (IFN-\(\gamma\)) following stimulation ex vivo, which implied that AC-NPs were able to elicit systemic T cell activation. Therefore, a novel strategy for improving cancer immunotherapy with nanotechnology was presented by our work. Acknowledgements: The authors would also like to thank our funding sources. \#3686 Generation of an off-the-shelf cell-based platform (PDC-vac) for active antitumor immunotherapy, Joel Plumas,1 Kevin Lenogue,1 Alexandre Walencik,2 Jean-Paul Molens,3 Laurence Chaperot,3 Martin Pule4.

Inflammation in the Tumor Microenvironment

\#3687 Bexarotene activates type 1 antigen presenting cells, increases tumor infiltrating CD8 T-cells, and augments the anti-tumor activity of chemotherapy in breast cancer. Sasha Elizabeth Stanton, Ekram Gad, Lauren R. Corulli-Rastetter, Mary L. Disis. Univ. of Washington, Seattle, WA.

Bexarotene is an oral retinoic receptor (RXR) agonist that has anti-proliferative activity in breast cancer. RXRs are nuclear receptors that heterodimerize, including with the retinoic acid receptor (RAR), to activate transcription for processes including cellular differentiation, embryonic development, proliferation, and metabolism. We have demonstrated that bexarotene can enhance cancer vaccine efficacy by synergizing with a multi-antigen vaccine to prevent breast cancer in the TgMMTV-neu model. Bexarotene as a single agent increased CD8 T-cell tumor infiltration. We therefore questioned the mechanism by which bexarotene acts as an immunomodulatory drug. Evaluating XR expression in human peripheral blood monocytes (PBMC) (n=10), we found that XR is not expressed in NK T-cells or B-cells and in only a minority of CD4\(^+\) (5.1 \pm 4\%) and CD8\(^+\) T-cells (3.6 \pm 3\%). XR, however, is expressed in 24.9 \pm 13\% of monocytes (5.6 \pm 16\% of monocyctic dendritic cells (mDC), PMBC treated with increasing doses of bexarotene for 48 hours had increased co-stimulatory CD40 expression on mDC (p = 0.0011 between 0 and 20 um bexarotene) and increased type 1 cytokine release including IL-1\(\beta\) (p = 0.03 between 0 and 20 um bexarotene) and TNF\(\alpha\) (p = 0.02 between 0 and 20 um bexarotene) but not type 2 cytokine release of IL-10 (p = 0.21 and IL-4 (p = 0.5)). These data demonstrate that bexarotene can activate type 1 dendritic cells since activated type 1 dendritic cells are effective at presenting tumor antigens from dying tumor cells, we wanted to determine if bexarotene could increase type 1 immunity in the tumor and thereby enhance the efficacy of paclitaxel chemotheraphy. In TgMMTV-neu mice with 100 mm\(^3\) established spontaneous tumors (n=5), 50 mg/kg bexarotene inhibited tumor growth by 49\% and increased the influx of intratumoral CD8\(^+\) T-cells by 61\% as compared to PBS treated mice (p=0.01). 10 mg/kg paclitaxel inhibited tumor growth by 57\% and increased intratumoral CD8\(^+\) T-cells by 45\% as compared to PBS treated mice (p=0.003). Paclitaxel and bexarotene together inhibited tumor growth by 83\% (p=0.02 compared to bexarotene or paclitaxel alone) and increased intratumeral CD8\(^+\) T-cell infiltrate by 58\% as compared to PBS treated mice (p=0.01). These data demonstrate that bexarotene can activate type 1 dendritic cells and enhance the efficacy of paclitaxel. These data suggest concurrent administration of immunomodulatory bexarotene with paclitaxel may result in augmentation of the anti-tumor activity of chemotherapy in breast cancer.
TNF-α, functional mediators produced by these monocyte populations. Together, these data show that Imprive drives the concerted activation of multiple innate immune subtypes and promotes the appearance of unique monocyte populations that may be critical for an Imprive-induced anti-cancer immune response.

#3689 Jak3 mutations in colorectal neoplasia - Preliminary data on a not so silent minority. Martin Tob, Xiaping Zhao, Durshana Jhala, Rebecca Rodriguez, Fadi Antaki, Levi Edv, Paula Sochacki, John Lieb, MaryAnn Rambus, Tapan Ganguly, Martin Bluth, Michael J. Lawson, Saginaw VA Medical Ctr and Medical Disciplines, Central Michigan University College of Medicine, Saginaw, MI; Detroit VAMC Re-D, Central Michigan University College of Medicine, Detroit, MI; Philadelphia VAMC and the University of Pennsylvania School of Medicine, Philadelphia, PA; Philadelphia VAMC, Philadelphia, PA; Detroit VA Medical Ctr and Wayne State University School of Medicine, Detroit, MI; Detroit VA Medical Ctr, Detroit, MI; University of Pennsylvania School of Medicine, Philadelphia, PA; Wayne State University School of Medicine, Detroit, MI; Kaiser Permanente Medical Center, Sacramento, CA.

As a tumorigenesis model, colorectal cancer is associated with multiple gene mutations accumulating progressively but also has mutations that alter disease course and provide a therapeutic target. Good examples of this are EGFR and VEGF. In melanoma, PD-1 interactions involving the immunobiome are therapeutically important. We conducted a study to detect potential mutations that might enhance therapy in colorectal cancer guided by expression of p87, a product of innate immune system Paneth cells. Methods: Adnab-9 immunohistochemistry or ELISA was used to define significant p87. Adenoma-associated antigen field effects (EF) in 10 patients with >1cm large high grade dysplastic adenomas (LHiGDA) and 3 with smaller high grade dysplastic adenomas (SHiGDA). We postulated that SHiGDA are not immunologically recognized by host defenses leading to negative outcomes. We used Ion Torrent sequencing (ITS) to find mutations in DNA (QiaAmp kit) extracted from 4 normal-appearing colonic segments taken from 1 patient in each group. Novel mutations found on ITS would then be sought using PCR with appropriate primers and subsequent sequencing of the PCR product circulating DNA extracted from available serum samples. These samples were taken from the Large- and SHiGDA groups described above and from 17 patients undergoing colonscopy for diverse indications. Results: p87 FE were found in 40% of 10 LHiGDA and 0% of 3 SHiGDA patients. The ITS in the 2 representative patients showed unique mutational fields in: KRAS, APC, p53 in the LHiGDA and Jak3, PIK3Ca, p53, APC in the SHiGDA patient, both of whom lacked p87 FE. PCR using the Jak3 primers used in the ITS and subsequent sequencing revealed the same non-synonymous mutation in the serum of a FAP patient after colonic resection and an additional colonic segment of the selected ShiGDA patient but not in his serum. Other Jak3 mutations were found in 1 of 8 LHiGDA, 1 (the selected patient) of 3 SHiGDA, 1 of 7 patients with FAP and 1 of 10 colonoscopy patients with a family history of colorectal cancer with a FE and an untoward outcome. The selected SHiGDA patient subsequently contracted and died of NSCLC adenocarcinoma. The positive LHiGDA and FAP patients had a severely dysplastic anal condyloma and severe pancreatitis, respectively. Overall, the non-synonymous mutation occurring in FAP and SHiGDA patient occurred in the absence of p87 FE. Conclusions: In this pilot study we demonstrate the presence of Jak3 mutations likely associated with the lack of p87 expression in patients with high grade dysplastic adenomas and 1 FAP patient. Most of these patients had a clinical course which may have differed from their group members suggesting an altered immune system milieu. If confirmed in SHiGDA and FAP, Jak 3 mutations, associated with the SCID and late onset combined immunodeficiency, may allow for intervention with currently available medications to potentially avert a deleterious clinical outcome.

#3690 The leukocyte chemotactic chemerin modulates PTEN via CMKLRI in human tumors. Keith R. Rennier, Ping Wang, Robert Crowder, Russell K. Pachynski. Washington University School of Medicine in St. Louis, St. Louis, MO.

Background: Recent data in preclinical models has shown that phosphatase and tensin homolog (PTEN) loss correlated with decreased tumor immune cell infiltration as well as decreased response to T cell-based immunotherapy. Chemerin (RARRES2) is a recently identified endogenous leukocyte chemotactic trant into recruit innate immune cells through its G-protein coupled receptor CMKLRI. Chemerin/RARRES2 is commonly downregulated in prostate and other cancers (e.g. sarcoma) compared to their normal tissue counterpart parts. Myelohsme-wide studies in multiple tumor types have identified RARRES2 as being one of the most hypermethylated genes, potentially leading to decreased chemerin expression. Our previous preclinical studies showed that forced overexpression of chemerin in tumors was capable of recruiting immune effector cells, including T cells, into the tumor microenvironment and suppressing tumor growth. Methods: In order to study the effects of chemerin overexpression on tumor cell intrinsic processes we exposed prostate and sarcoma tumor lines to exogenous recombinant chemerin in vitro. Evaluation of PTEN was performed for both the 1920 and 1920neotg at protein level using RT PCR and Western blotting, in comparison with normal prostate epithelia RWPE-1 as well as PTEN-null PC3 cells as controls. In vitro invasion assays were performed to investigate the functional impact of chemerin exposure on tumor intrinsic activity. Knockdown of CMKLRI using siRNA was performed to determine its role in tumor response. Results: Using both prostate and sarcoma tumor cell lines, we found exogenous chemerin was able to upregulate PTEN expression at both the mRNA and protein levels in a dose-response manner. Exposure to chemerin did not result in increased apoptosis or altered in vitro proliferation. Importantly, chemerin treatment significantly decreased in vitro tumor invasion. Knockdown studies showed CMKLRI abortion resulted in restored tumor migration, suggesting a link between this GPCR and PTEN expression and activity. Conclusions: For the first time, to our knowledge, we have shown a link between chemerin and PTEN expression and activity in both prostate and sarcoma tumor lines. Our collective study shows chemerin’s ability to upregulate PTEN activity and to mitigate tumor cell migration via CMKLRI. This work has functional implications on both tumor cell intrinsic and extrinsic responses to chemerin-based immunotherapeutic strategies. Further studies are needed to investigate the interaction between chemerin and PTEN signaling, and its connection to oncogenic signaling pathways manipulated in malignant tumors. Additionally, future in vivo studies using these tumor lines will help further elucidate the chemerin-PTEN axis and its role in tumor immunosurveillance. We hypothesize that increased chemerin-driven PTEN activity may help facilitate an improved immunotherapeutic response and functional ability to attack cancer cells.

BRCA1 and BRCA2 are essential homologous recombination (HR) repair proteins; germline mutations confer elevated risk for breast and ovarian cancer. Defects in BRCA can lead to immune-related effects including depletion of peripheral T-cell pools and increased somatic mutational burden. We investigated the immunophenotypic properties of breast and ovarian cancers associated with germline BRCA1/2 mutations. We determined neoantigen load in 16 breast and 26 ovarian tumors with germline BRCA1/2 mutations and 30 non-BRCA1/2 tumors for each disease using whole exome sequencing data from the TCGA. Although neoantigen load (IC50 < 500 nm) was variable across tumors, it did not differ between BRCA1/2 mutant and non-BRCA tumors. Leveraging RNAseq data from the TCGA, we investigated immune-related transcriptomic features within each disease. Cytolytic index, a measure of PRF1 and GZMA expression, was higher in non-BRCA1/2 tumors than BRCA1/2 mutant for breast (p < 0.01) tumors and correlated more closely with neoantigen load than in non-BRCA1/2 tumors. HRD score exhibited evidence of a more inflamed phenotype than BRCA1/2 breast tumors or non-BRCA1/2 tumors. HLA expression was significantly lower (p < 0.01) among BRCA mutant breast tumors, indicating immune escape by HLA down-regulation. We classified non-BRCA breast tumors by their level of HR deficiency (HRD score), as HRD by both BRCA and non-BRCA mediated mechanisms can lead to increased somatic mutational burden. Non-BRCA breast tumors irrespective of HRD score exhibited evidence of a more inflamed phenotype than BRCA1/2 mutant tumors, indicated by higher inferred immune cell infiltration, immune checkpoint expression, and neoantigen load. In contrast, ovarian non-BRCA1/2 tumors did not differ from non-BRCA1/2 tumors. HLA expression also correlated with cytolytic index (p < 0.05) in non-BRCA1/2 tumors but not BRCA1/2 mutation associated tumors for both breast and ovarian cancers, suggesting more robust antigen-driven adaptive immunity in non-BRCA tumors. HLA expression was significantly lower (p < 0.01) among BRCA mutant breast tumors, indicating immune escape by HLA down-regulation. We classified non-BRCA breast tumors by their level of HR deficiency (HRD score), as HRD by both BRCA and non-BRCA mediated mechanisms can lead to increased somatic mutational burden. Non-BRCA breast tumors irrespective of HRD score exhibited evidence of a more inflamed phenotype than BRCA1/2 mutant tumors, indicated by higher inferred immune cell infiltration, immune checkpoint expression, and neoantigen load. In contrast, ovarian non-BRCA1/2 tumors did not differ from non-BRCA1/2 tumors. HLA expression also correlated with cytolytic index (p < 0.05) in non-BRCA1/2 tumors but not BRCA1/2 mutation associated tumors for both breast and ovarian cancers, suggesting more robust antigen-driven adaptive immunity in non-BRCA tumors. HLA expression was significantly lower (p < 0.01) among BRCA mutant breast tumors, indicating immune escape by HLA down-regulation. We classified non-BRCA breast tumors by their level of HR deficiency (HRD score), as HRD by both BRCA and non-BRCA mediated mechanisms can lead to increased somatic mutational burden. Non-BRCA breast tumors irrespective of HRD score exhibited evidence of a more inflamed phenotype than BRCA1/2 mutant tumors, indicated by higher inferred immune cell infiltration, immune checkpoint expression, and neoantigen load. In contrast, ovarian non-BRCA1/2 tumors did not differ from non-BRCA1/2 tumors. HLA expression also correlated with cytolytic index (p < 0.05) in non-BRCA1/2 tumors but not BRCA1/2 mutation associated tumors for both breast and ovarian cancers, suggesting more robust antigen-driven adaptive immunity in non-BRCA tumors. HLA expression was significantly lower (p < 0.01) among BRCA mutant breast tumors, indicating immune escape by HLA down-regulation. We classified non-BRCA breast tumors by their level of HR deficiency (HRD score), as HRD by both BRCA and non-BRCA mediated mechanisms can lead to increased somatic mutational burden. Non-BRCA breast tumors irrespective of HRD score exhibited evidence of a more inflamed phenotype than BRCA1/2 mutant tumors, indicated by higher inferred immune cell infiltration, immune checkpoint expression, and neoantigen load. In contrast, ovarian non-BRCA1/2 tumors did not differ from non-BRCA1/2 tumors. HLA expression also correlated with cytolytic index (p < 0.05) in non-BRCA1/2 tumors but not BRCA1/2 mutation associated tumors for both breast and ovarian cancers, suggesting more robust antigen-driven adaptive immunity in non-BRCA tumors. HLA expression was significantly lower (p < 0.01) among BRCA mutant breast tumors, indicating immune escape by HLA down-regulation. We classified non-BRCA breast tumors by their level of HR deficiency (HRD score), as HRD by both BRCA and non-BRCA mediated mechanisms can lead to increased somatic mutational burden. Non-BRCA breast tumors irrespective
remodeling in breast and ovarian cancer. Our work provides early evidence that BRCA1/2 breast and ovarian tumors initiate intratumoral adaptive immunity by T-cell exclusion, so that despite higher mutational burden, they may not respond to checkpoint blockade.

#3692 Long-lived pancreatic ductal adenocarcinoma slice cultures enable precise study of the immune microenvironment. Xiaoyun Jiang, David Hao, Jae Chang, Edam Nighe, Zheng Pan, Florencia Jalkis, Venu Pillarsetty. University of Washington, Seattle, WA.

Introduction: Pancreatic ductal adenocarcinoma (PDAC) remains a deadly disease that is rarely cured. Given the recent successes with immunotherapy for other malignancies and the fact that PDA is heavily infiltrated by effector T cells, we postulate that accurate modeling of the PDA immune microenvironment would allow us to unveil mechanisms of immunosuppression that could be overcome for therapeutic benefit. Methods: PDA tumors were collected from the operating room and transported to cold media to the laboratory, where 250µm slices were cut using a vibratome and placed on 0.4µm pore size membrane inserts pre-coated with collagen gel and culture. Proliferation was measured using MTT assay and weight-adjusted optical density. Slices were fixed in 4% PFA for imaging after live immunofluorescence (IF) staining or for subsequent immunohistochemistry (IHC) prior to imaging. For proteomic analysis, slices were digested with trypsin and analyzed by mass spectrometry. To assess for immune cell migration into the tumor slices, isolated autologous splenocytes were stained with CFSE and added to the slice culture and imaged using IF after 6 days.

Results: Using light microscopy, we confirmed that cultured slices maintained their baseline morphology, architecture and surface area over 9 days in culture. The MTT assay showed stable growth over the same period; IHC for Ki-67 and cleaved Caspase-3 corroborated a similar pattern of proliferation and apoptosis after 6 days culture when compared to day 1. T cells (CD3, CD8 and FOXP3), macrophages (CD68, CD163, and HLA-DR), and stromal myofibroblasts (αSMAct) were confirmed to be present through day 6 using IHC. Quantitative proteomic analysis of over 3000 proteins showed that only 2-3% of proteins showed significant changes of abundance greater than 2 fold after 6 days in culture. However, when slice were challenged with cytotoxic drugs (stauroporine and cyclohexamide), there was a time- and dose-dependent response in proliferation and apoptosis compared with controls. The demonstration of the live and dynamic microenvironment was performed first via live multicolor IF including PDA cells (EpCAM), fibroblasts (fibronectin) and immune cells (both CD11b and CD16 cells) within the microenvironment. Furthermore, co-culture of CFSE-labeled splenocytes on top of slices for 6 days. Z-stacked live confocal imaging confirmed their migration from the surface into the slice microenvironment.

Conclusion: Our study demonstrates that the PDA slice culture maintains original tumor microenvironment, and overall proteomic production and dynamic function response in vivo. PDAC slice culture model is now available to examine both pharmaceutical and cell-based immunotherapies for mechanisms of action and potential synergies, effects on specific cell types of the microenvironment, and tumor-specific immunogenic potential.

#3693 Single cell RNA-Seq of primary lymphomas reveals the diverse transcriptional states of the cancer immunologic milieu. Noemi Andor1, Erin Simonds2, Jiamin Chen1, Christina Wood1, Susan Grimes3, Debra Czerwinski1 and tumor-specific immunogenic potential. Tumor B cells consistently demonstrated downregulation of β-2-microglobulin and for those cases that harbored a founder CREBBP mutation, a downregulation of MHC II, that would cause an alteration in antigen presentation and evasion of the T cell immune system. Moreover, we characterized the transcriptional profiles of the infiltrating T-cell populations within each tumor, providing a fresh perspective of immunologic cellular interactions. Overall, we identified the diverse transcriptional states at single cell resolution among different tumors and discovered specific genes that were aberrantly expressed compared to normal B cells within the same microenvironment. Our findings provide a unprecedented resolution of distinct immune lineages as seen by transcriptionally characterized cell diversity. Studies using single cell genomics may have implications for considering immunotherapeutic efficacy.

#3694 FOXP1 suppresses immune cell migration in breast tumors. Pushpamali De Silva1, Soizic Garaud1, Roland de Wind1, Gert Van den Eynden2, Anais Boisson1, Cinzia Solinas1, Edoardo Migliori1, Hugues Duvillier1, Denis Larsimont1, Martine Piccart-Gebhart1, Karen Willard-Gallo2. 1Institut Jules Bordet, ULB, Brussels, Belgium; 2GZA Hospital Sint-Augustinus, Antwerp, Belgium.

Tumor infiltrating lymphocytes (TIL) play an essential role in mediating response to chemotherapy and improving clinical outcomes in breast cancer (BC). Extensive TIL infiltration is characterized by their organized into tertiary lymphoid structures (TLS). TIL infiltration and TLS formation may be regulated, in part, by transcription factors (TF) controlling cytokine/chemokine production within the tumor microenvironment. The forkhead box protein 1 (FOXP1) is a TF shown to be aberrantly expressed in a variety of human tumors and play an important role in T cell cytokine production. Therefore we aimed to study FOXP1-mediated regulation of TIL in BC. Investigation of FOXP1 expression in public microarray data from untreated BC patients, BC cell lines [Luminal A (MCF7), HER2+ (BT474) and triple negative (TN; MDA-MB-231)] and prospectively collected formalin-fixed paraffin-embedded (FFPE) primary breast tissues showed that FOXP1 is repressed at transcript and protein level in HER2+ or TN breast tumors compared to estrogen receptor positive tumors (Luminal A and B). Moreover HER2+ and TN subtypes, which showed decreased FOXP1 levels, are 2 well known highly infiltrated BC. Based on our hypothesis that FOXP1 could play a role on immune cell infiltration in breast tumors, data analysis of the prospective BC cohort showed that high FOXP1 (FOXP1hi) expression is significantly associated with a lower percentage of TIL and number of TLS compared to FOXP1low (FOXP1lo) tumors. To investigate the impact on specific cytokines/chemokines involved in TIL recruitment and/or TLS formation, FOXP1 was silenced in MCF7 (FOXP1hi tumor cell line) or upregulated in MDA-MB-231 (FOXP1lo tumor cell line) followed by gene expression analysis using a RT-qPCR based human cytokine/chemokine array. FOXP1 repression upregulated major T and B cell chemoattractant chemokines and overexpression repressed most of these molecules in the cell line experiments. Next we analyzed major chemoattractant molecule expression in FOXP1hi and FOXP1lo prospective breast tumors and found that FOXP1hi tumors having a significant decrease in CXCL9, CXCL10, CXCL11, CXCL13, CX3CL1, CCL20, IL2, and FOXP1 repressed tumor conditioned media (TCM) of MCF7 compared to the TCM of control or medium alone. Finally analysis of lymphocyte migration to FOXP1hi and FOXP1lo tumor supernatants (SN) from primary tumors that we consistently prepare without enzymatic digestion, showed that there was a significant decrease in number of lymphocytes migrated towards FOXP1hi tumor SN including the migration rates of individual T and B lymphocyte populations compared to FOXP1lo tumor SN. These data suggest that FOXP1 could play a critical role in establishing effective anti-tumor immune responses by negative regulation of TIL via suppression of cytokine/chemokine expression in breast tumors.

#3695 The interplay between neutrophils & It CD8+ T cells.Proceedings of the American Association for Cancer Research • Volume 58 • April 2017
cluding >650 evaluable CRC samples. Phenotypic profiles of tissue infiltrating and peripheral blood CD66b+ cells were evaluated by flow cytometry. CD66b+/CD8+ cells crosstalk was investigated by in vitro experiments. Results: CD66b+ cell infiltration in CRC is significantly associated with increased survival. Interestingly, neutrophils frequently co-localize with CD8+ T cells in CRC. Functional studies indicate that although neutrophils and T cells are independently associated with antitumour potential, co-culture with peripheral blood or tumor associated neutrophils (TANs) enhances CD8+ T cell activation, proliferation and cytokine release induced by suboptimal concentrations of anti-CD3 monoclonal antibody (mAb). Moreover, under optimal activation conditions, CD8+ cells initially stimulated in the presence of CD66b+ cells show decreased expression of PD-L1 ‘exhaustion’ marker and are significantly less susceptible to apoptosis. Their associations with the relationships between HER3 signal and PD-L1 expression by using three basal-like breast cancer cell line; MDA-MB-231, HCC70, and MDA-MB-468. MDA-MB-231 is HER3-negative, and HCC70 and MDA-MB-468 are HER3-positive cell lines. We added neurelin 1 (NRG1; HER3 ligand) to those three cell lines and analyzed PD-L1 expression of protein by flow cytometry and mRNA by qRT-PCR. Both factors and mRNA levels of PD-L1 on HCC70 and MDA-MB-468 treated with NRG1 are increased as compared with those without NRG1 while there was no change of PD-L1 expression of MDA-MB-231 either with or without NRG1. In order to confirm the significance of potential treatment target of HER3, we evaluated HER3 expression in biopsy samples by immunohistochemistry before neoadjuvant chemotherapy (NAC) including all phenotypes. Thirteen pathological complete response (pCR) cases after NAC and non pCR cases were included. We scored the HER3 stability from 0 to 3 and found that non pCR cases showed significantly higher HER3 score than pCR cases (84.6% and 33% respectively, p=0.0149). Although further study is needed, these results suggest that HER3 signal possibly regulates PD-L1 expression in HER3-positive basal-like breast cancer and treatment with anti-HER3 targeting therapy combination with an immune checkpoint inhibition therapy for HER3 positive NAC resistant patients might be warranted.

#3696 Tumor-intrinsic PD-L1 alters tumor chemokines, NK cell trafficking and function, and renders distant PD-L1 null tumors responsive to αPD-L1. Curtis A. Clark, 1 Harshita B. Gupta, 1 Alvaro Padron, 1 Deyi Zhang, 1 Vincent Hurez, 1 Mary Jo Turk, 2 Rong Li, 1 Tyler Curiel 1.

Programmed death ligand (PD-L1) is expressed on many tumors and inhibits anti-tumor T cells through programmed death (PD)-1. PD-L1 tumor predictors αPD-L1 treatment effects, but mechanism(s) for PD-L1 tumor response to αPD-L1 are unclear. Our studies suggest tumor-intrinsic PD-L1 signals and spatially varied PD-L1 expression may contribute to response deviation. We used PD-L1−/− B16 melanoma (ctrl) and made PD-L1−/− by CRISPR. αPD-L1 slowed ctrl but not PD-L1−/− B16 growth in mice as expected, but PD-L1−/− also responded to αPD-L1 if ctrl B16 was on the trans flank. αPD-L1 elicited similar CD3+ T cell infiltration into ctrl vs. PD-L1−/− tumors, but without detectable B16-specific T cell increase. CD11b+ cell infiltration was similar in ctrl and PD-L1−/−. Strikingly, NKp46+ and NK1.1+ natural killer (NK) cells infiltrated PD-L1−/− > ctrl. NK cells increased significantly (∼2-fold) after αPD-L1 in PD-L1−/− vs. ctrl, along with NK effector functions (e.g., IFN-γ). Tumor PD-L1−/− altered tumor chemokines (e.g., CXCL12, CCL2) that could explain trafficking. CD4+ and CD8+ T cells chemotaxed to PD-L1−/− slightly > ctrl (with slightly > PD-L1−/−) in transwells, but NK cells migrated ∼2-fold more to PD-L1−/− vs. ctrl (with increased activation (e.g., PD-L1, CD69), also seen in vivo). We observed that tumor B2 microglobulin (B2M) expression was suppressed by αPD-L1 directly altered tumor cell chemokine production in vitro, suggesting additional, novel αPD-L1 treatment mechanisms requiring more study. Our models are useful to understand αPD-L1 (and likely αPD-1) responses based on tumor PD-L1 expression and will help define strategies to improve responses in PD-L1−/− tumors, and possibly poorly responsive PD-L1+ tumors.

#3697 The impact of HER3 signaling mediated PD-L1 regulation in triple negative breast cancer. Ayane Yamaguchi, 1 Eiji Suzuki, 1 Kousuke Kawaguchi, 2 Mariko Nishie, 1 Moe Tsuda, 1 Takeshi Kotake, 1 Masakazu Toi, 1 Kyoto Univ. Hospital, Kyoto, Japan; 2Massachusetts General Hospital, Harvard Medical School, Massachusetts, MA.

Triple negative breast cancer (TNBC) is still difficult to treat partly because of lacking specific target. Although 50-70% of TNBC expresses EGFR, it is less sensitive to the treatment of EGFR inhibition for TNBC as compared to the efficacy of HER2 inhibition for HER2-positive breast cancer. Several phase II study on EGFR blockade treatment has been reported, however it was not applied in a clinical setting yet. It was reported that residual tumors after treatment with EGFR-targeted antibodies showed increased HER3 abundance leading to EGFR/HER3 receptor dimerization. The signals of HER3/EGFR dimerization to PI3K/AKT/mTOR pathways are thought to be involved in cancer survival, proliferation and also up-regulation of PD-L1 expression. Thus, we hypothesized that up-regulation of HER3 signal caused by anti-cancer treatment might induce increased PD-L1 expression which is a potential target for the tested inhibitors. To confirm the relationship between HER3 signal and PD-L1 expression by using three basal-like breast cancer cell line; MDA-MB-231, HCC70, and MDA-MB-468. MDA-MB-231 is HER3-negative, and HCC70 and MDA-MB-468 are HER3-positive cell lines. We added neurelin 1 (NRG1; HER3 ligand) to those three cell lines and analyzed PD-L1 expression of protein by flow cytometry and mRNA by qRT-PCR. Both factors and mRNA levels of PD-L1 on HCC70 and MDA-MB-468 treated with NRG1 are increased as compared with those without NRG1 while there was no change of PD-L1 expression of MDA-MB-231 either with or without NRG1. In order to confirm the significance of potential treatment target of HER3, we evaluated HER3 expression in biopsy samples by immunohistochemistry before neoadjuvant chemotherapy (NAC) including all phenotypes. Thirteen pathological complete response (pCR) cases after NAC and non pCR cases were included. We scored the HER3 stability from 0 to 3 and found that non pCR cases showed significantly higher HER3 score than pCR cases (84.6% and 33% respectively, p=0.0149). Although further study is needed, these results suggest that HER3 signal possibly regulates PD-L1 expression in HER3-positive basal-like breast cancer and treatment with anti-HER3 targeting therapy combination with an immune checkpoint inhibition therapy for HER3 positive NAC resistant patients might be warranted.

#3698 Associations of the immune microenvironment with PD-L1 copy number alterations and PD-L1 expression in resected non-small cell lung cancer. Katsuhiko Yoshimura, 1 Yusuke Inoue, 1 Tomoaki Kihyo, 1 Akizaka Kawa, 1 Masayuki Tanahashi, 2 Hiroshi Ogawa, 1 Naoki Inui, 1 Kazuhiito Funai, 1 Kazuya Shimura, 1 Hiroshi Niwa, 1 Takafumi Suda, 1 Haruhiko Sugimura, 1 Hanamatsu University School of Medicine, Hanamatsu, Japan; 2Seirei Mikashima General Hospital, Hamamatsu, Japan.

Background: The relationships between tumor PD-L1 expression and the tumor immune microenvironment (TIM) have gained attention in a variety of cancers including non-small cell lung cancer (NSCLC). However, the relevance of TIM according to the tumor PD-L1 copy number alterations (CNAs) whose significance have been shown in several malignancies remains to be uncovered. Methods: We evaluated PD-L1+, CD8+, and Foxp3+ lymphocytes in tumor nest and surrounding stroma separately using microarrayed 636 resected NSCLC. Their associations with PD-L1 CNAs and PD-L1 expression were analyzed. Tumor-infiltrating lymphocytes (TILs) were counted under high-power fields (×200), PD-L1 CNAs were assessed with fluorescent in situ hybridization, and were classified into three categories by the inferior category (non-amplification, polymy, and dysmy). PD-L1 expression was evaluated using immunohistochemistry (clone E1L3N), and positivity of ≥5% was used as the cut-off. Results: In the entire cohort, the median age was 68 years (23-88 years). The cohort comprised 444 (68.0%) men and 197 (30.2%) never-smokers. The median follow-up duration was 3.6 years. The numbers of TILs in stroma were much greater than those in tumor nest. Smoking history and squamous histology were significantly associated with increased PD-L1 expression in both stroma and tumor nest, except for CD8+ TILs in stroma. There were 20 tumors with PD-L1 amplification (1.7%) and 84 tumors with polyomy (13.2%). PD-L1 expression was positive in 201 tumors (30.8%). In tumor nest, the numbers of individual TILs significantly increased according to the increase of PD-L1 copy number (Kruskal-Wallis, p<0.001 for PD-1+, p<0.001 for CD8+ and p=0.0087 for Foxp3+). In stroma, only PD1+ TILs were significantly associated with PD-L1 CNAs (p=0.0032), and CD8+ TILs tended to correlate with PD-L1 CNAs (p=0.079). The numbers of CD8+, PD-1+, and FOXP3+ TILs were significantly greater in PD-L1-positive tumors than in PD-L1-negative tumors, in both tumor nest and stroma (p<0.001). Neither kind of TIL, PD-L1 expression, nor PD-L1 CNAs alone was independently predictive factor for overall survival in a multivariate analysis with Cox hazard models. However, when the PD-L1 copy numbers were combined with Foxp3+ TILs, cases with tumor high PD-L1 copy numbers (≥5 copies per nucleus) and high Foxp3+ TILs had independently worse prognoses in both tumor nest and stroma inshow and stroma infiltration (hazard ratio (HR), 4.38; 95% confidence interval, 2.26-8.49, for tumor nest model; HR, 1.96; 95% CI, 1.04-3.68, for stroma model). Conclusion: CD8+ TILs and Foxp3+ TILs in tumor nest were significantly associated with PD-L1 CNAs and PD-L1 expression. Cases with both increased PD-L1 copy numbers and Foxp3+ TILs have independently worse survival outcomes. Additional data of other TIL subgroups related to PD-L1 CNAs and expression will be discussed.
**IMMUNOLOGY: Inflammation in the Tumor Microenvironment**

#3699 Activation of NK cells cytotoxicity mediated by alveolar macrophages in the lung against murine melanoma metastases by combined aerosol immunotherapy. Michele Sommariva,1 Valentino Le Noci,1 Elda Tagliabue,2 Andrea Balsari,1 Lucia Sfondrini,2 University of Milan, Milan, Italy; 2Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy.

INTRODUCTION: Taking advantage of aerosol for repeated local applications in the lung, we previously demonstrated that combination of Poly(LC)/ CpG-ODN, TLR3 and 9 ligands capable to activate innate effectors, induced a significant antitumor effect against B16 melanoma lung metastases, which correlated with a strong activation of NK cells. We investigated the sequence of events that lead to NK cells activation by aerosolized TLR agonists in the lung. Although NK cells express certain TLRs, controversy exists regarding their direct responsiveness or dependence on macrophages. Alveolar macrophages have several unique features both promoting host defense mechanisms against invading microorganisms, but also establishing an immunosuppressive microenvironment to avoid inflammatory responses to inhaled particles. Our findings, establishing the sequence of events of lung immune cells activation, might represent the basis for the development of combined aerosol therapies that favor NK cell triggering. EXPERIMENTAL PROCEDURE: Alveolar macrophages and NK cells were recovered by bronchoalveolar lavage and spleen of C57BL/6 mice, respectively. Mice i.v. injected with 5x10⁵ B16 cells were treated starting 7 days later every three days with aerosolized Poly(LC)/CpG-ODN alone or combined to nebulized myeloid derived suppressive cells (MDSC)-depleting RB6-8C5 antibody. Immune cell populations and expression of M1/M2 markers were analyzed by FACS and RT-PCR respectively, in tumors and spleens. Cytotoxic activity of NK cells was assessed by ⁵¹Cr release assay. RESULTS: In vitro TLR3/TLR9 stimulation induced IFN-γ secretion by naïve NK cells, but an increase in their cytotoxicity was detected only when NK cells were cocultured with alveolar macrophages pretreated with the two agonists. Alveolar macrophages from melanoma lung metastases-bearing mice treated with aerosolized TLR agonists also promoted NK cell cytotoxicity ex vivo. Moreover, naïve alveolar macrophages incubated with activated NK cells from lungs of melanoma metastases-bearing mice aerosolized with TLR9/TLR3 agonists, up-regulated M1- and downregulated M2-related genes, suggesting a bidirectional crosstalk between NK cells and macrophage. Thus, TLR agonists-activated lung macrophages promote NK cell cytotoxicity and, reciprocally, NK cells have the potential to shape the macrophage programmed to M1-like phenotype. Our results also indicate that the positive interplay can be further improved by the depletion of myeloid derived suppressive cells that exert a negative effect on macrophage activation. CONCLUSION: This study points to the promises of combinations of immunotherapeutic agents delivered locally by inhalation to promote macrophages-NK cell activation in the lung as a novel strategy to treat lung cancer patients.

#3700 Prognostic value of the expression of NKG2D and CD96 in early stage non-small cell lung cancer (NSCLC). Marcin Skrzypski,1 Michal Marczyk,1 Anna Lechowicz,1 Anna Trojani,1 Ryszard Pawlowicz,1 Wojciech Bienrat,1 Joanna Połanowska,2 Jacek Jaszem1.

Background: Immune checkpoint inhibitors showed impressive activity in advanced NSCLC and are expected to be effective in postoperative treatment of early disease. New therapies aimed at T and NK cell activation are in development to expand treatments options. It is conceivable that markers of ‘inflamed,’ ‘immune system ignorant’ and ‘immune system excluding’ tumor phenotypes may be predictive for specific immune-targeting therapies. Aim: We assessed prognostic value of expression of CD8(+) T and NK cell markers: CD96 and NKG2D in early stage NSCLC. In addition, we analyzed expression of 11 transcripts of APOBEC genes with hypothesis that APOBEC induced mutation burden may affect tumor immunogenicity or host adaptive immune responsiveness. Methods: mRNA levels were measured by RT-PCR in frozen tumor tissue from 65 NSCLC stage I-IIIA patients who underwent pulmonary resection (75% lung adenocarcinoma, 33% never-smokers, 44% with subsequent dissemination), and in 11 NSCLC cell lines. The relative gene expression (vs. 5 normal immortalized TLBs, used as a comparator) was measured in cells that did and did not disseminate and in relation to clinico-pathological features. Results: After Bonferroni correction for multiple testing, NKG2D and CD96 mRNA expression was significantly lower in tumors with subsequent dissemination (p.adj.=0.045). Out of 11 APOBEC genes, expression of AICDA, APOBEC3A and APOBEC3G was lower in tumors with subsequent dissemination (p.unadj.=0.025). The NSCLC lines did not express NKG2D, CD96, AICDA or APOBEC3A. The Spearman correlation coefficient between the expression of NKG2D, CD96 and APOBEC3G was r=0.8. AICDA expression was correlated with CD96, NKG2D and APOBEC3G with Spearman correlation coefficient in the range of 0.5-0.62. Expression of CD96 and NKG2D was significantly lower in tumors with vs. without subsequent brain metastasis (p.unadj.=0.048). The negative prognostic impact of low NKG2D and CD96 expression was independent from patient smoking status (FC <1, irrespective of smoking status). In the subset of never-smokers, the fold difference of NKG2D expression between tumors with vs. without subsequent dissemination was particularly pronounced (HR=0.37, p.unadj.=0.023). In multivariate Cox analysis low NKG2D and NKG2D expression in early stage NSCLC may be predictive for high propensity to dissemination, including metastasis to the brain. The expression of APOBEC transcripts does not seem to correlate with metastatic potential.

#3701 Mutant p53 cancers reprogram tumor-associated macrophages via exosomal miR-1246. Tomer Cohen,1 Ioannis S. Pateras,1 Keval Jassim1.

INTRODUCTION: Mutantp53proteinsgainoncogenicfunctionsofGOF distinct from the tumor suppressor activity of the wild-type protein. Tumor-associated-macrophages, a hallmark of solid tumors, are typically correlated with poor prognoses due to a non-cell-autonomous mechanism whereby mutp53 cancer cells reprogram TAM to a tumor supportive and anti-inflammatory state. The colon cancer cells harboring GOF mutp53 selectively shed miR-1246-enriched exosomes. Uptake of these exosomes by neighboring macrophages triggers their miR-1246 dependent reprogramming into a cancer-promoting state. Mutp53-reprogrammed TAM favor anti-inflammatory immunosuppression with increased activity of TGF-β. These findings, observed also in colon cancer patients, strongly support a microenvironmental GOF role for mutp53 in actively engaging the immune system to promote cancer progression and metastasis.

#3702 Quantitative imaging of metabolic changes in macrophage subsets. Tiffany M. Heaster,1 David L. Elion,2 Rebecca S. Cook,3 Melissa C. Skala,1 University of Wisconsin-Madison, Madison, WI; 2Vanderbilt University, Nashville, TN; 3Morgridge Institute for Research, Madison, WI.

Macrophages play an important role in tumor therapeutic response. However, current methods cannot image heterogeneities in macrophage activity on a single-cell level over time within intact, living samples. Macrophage metabolism is closely linked to macrophage function, as M1-like macrophages rely on aerobic glycolysis and M2-like macrophages rely on fatty acid oxidation and oxidation-dependent phosphorylation. Thus, we propose to develop optical metabolic imaging (OMI) using two-photon microscopy to monitor cell-level changes in macrophage polarization and functional activity. OMI exploits the auto-fluorescence intensities and lifetimes of the metabolic co-enzymes NAD(P)H and FAD, and has been previously used to dynamically image in vivo tumors with cell-level resolution. The optical redox ratio (fluorescence intensity of NAD(P)H divided by FAD) provides a global measure of redox balance within individual cells. The fluorescence lifetimes of NAD(P)H and FAD provide information in protein-binding activities in metabolic reactions. OMI was used to monitor metabolic changes in macrophages on a single-cell level during polarization and after metabolic perturbations. RAW 264.7 macrophages were stimulated towards an M1- or M2-like phenotype, and imaged with OMI at 24, 48, and 72 hours post-polarization. M1- and M2-like macrophages exhibited significant differences (p<0.05) in redox ratio and FAD fluorescence lifetime values at 48 and 72 hours post-polarization. The M1-like and M2-like character of the macrophages were validated with quantitative polymerase chain reaction (qPCR) analysis. Population density modeling of single-cell metabolism established differences in intracellular heterogeneity across subsets over time. M1- and M2-like macrophages were further characterized between groups that did and did not disseminate and in relation to clinico-pathological features. Results: After Bonferroni correction for multiple testing, NKG2D and CD96 mRNA expression was significantly lower in tumors with subsequent dissemination (p.adj.=0.045). Out of 11 APOBEC genes, expression of AICDA, APOBEC3A and APOBEC3G was lower in tumors with subsequent dissemination (p.unadj.=0.025). The NSCLC lines did not express NKG2D, CD96, AICDA or APOBEC3A. The Spearman correlation coefficient between the expression of NKG2D, CD96 and APOBEC3G was r=0.8. AICDA expression was correlated with CD96, NKG2D and APOBEC3G with Spearman correlation coefficient in the range of 0.5-0.62. Expression of CD96 and NKG2D was significantly lower in tumors with vs. without subsequent brain metastasis (p.unadj.=0.048). The negative prognostic impact of low NKG2D and CD96 expression was independent from patient smoking status (FC <1, irrespective of smoking status). In the subset of never-smokers, the fold difference of NKG2D expression between tumors with vs. without subsequent dissemination was particularly pronounced (HR=0.37, p.unadj.=0.023). In multivariate Cox analysis low NKG2D and NKG2D expression in early stage NSCLC may be predictive for high propensity to dissemination, including metastasis to the brain. The expression of APOBEC transcripts does not seem to correlate with metastatic potential.
IMMUNOLOGY: Inflammation in the Tumor Microenvironment

Testicular germ cell tumors (TGCT) are a histologically diverse set of tumors that are the most common cancer type in young men. As part of the TCGA effort, we analyzed tumors from 133 patients including 4 patients with asynchronous double primary TGCTs (137 primary tumors) by histopathologic, genomic, epigenomic, transcriptomic, and proteomic methods. We noted molecular signatures of various immune cells were greater in seminomas than other histologies. Specifically, we find seminomas show elevation of expression signatures for B-Cells, Cytotoxic T Cells, and T-regulatory cells. This increase in immune cells were accompanied by high expression of specific cytokines and key immune checkpoint molecules such as CTLA4, LG3, and PD-L1. Strong positive correlations were identified between immune cell signatures and increases in T-Cell and B-Cell receptor diversity measures. Interestingly, increases in receptor diversity also showed strong positive associations to gene expression scores of anti-tumor immune responses. This indicates that anti-tumor immune responses in seminomas may be polyclonal. We found no evidence for relationships between immune cells and mutation load, neoantigen load, or detected viruses. We do observe that seminomas have significantly high expression of the testis specific antigens, yet the contribution of these antigens to the immune response did not show strong or uniform statistical indications. Instead, the strongest association between expanded immune cells populations in seminomas were the presence of activating mutations in KIT accompanied by elevation of gene expression of signatures associated with KIT and expression of MHC class I and II genes. Together, these data describe the immune microenvironment of seminomas and suggest alterations and events in the kit pathway as being critical to the nature of the immune microenvironment in seminomas.

Targeting M2-Tumor associated macrophages (M2-TAMs) using enriched glycoproteins in lethal prostate cancer. Jelani C. Zarif, James R. Henandez, Weiming Yang, Hui Zhang, Kenneth J. Pienta. Johns Hopkins University School of Medicine, Baltimore, MD.

Prostate cancer is a leading cause of cancer-related deaths of men in the U.S., and in the past year, over 30,000 men died from this disease. While localized prostate cancer is highly treatable by surgical resection and radiation, cancer that has metastasized remains incurable. Alternatively activated macrophages, also known as M2-macrophages, primarily scavenge debris and in the process, promote angiogenesis and wound repair. M2-macrophages are phenotypically similar to M2 tumor-associated macrophages (M2-TAMs) have been reported to associate with solid tumors such as prostate cancer to facilitate epithelial to mesenchymal transition (EMT), tumor invasiveness, metastasis, and resistance to therapy. As an invasive species within the tumor microenvironment, this makes M2-TAMs an ideal therapeutic target in prostate cancer. The purpose of this project is to develop novel therapeutics that will directly target M2-TAMs for destruction and subsequently attenuate prostate tumor growth, progression, and metastasis. Our hypothesis is to determine if targeting of M2-TAMs by using enriched surface antigens that are targeted by antibody-drug-conjugates (ADCs), be an effective therapy for lethal prostate cancer while simultaneously eliciting an immune response. To identify novel surface antigens expressed on M2-macrophages, we developed a novel method of creating homogenous populations of human macrophages from CD14+ monocytes in vitro. Our homogenous M1 macrophages secrete pro-inflammatory cytokines and our M2 macrophages secrete anti-inflammatory cytokines as well as VEGF. We then performed solid-phase extraction of N-linked glycopeptides (SPEG) followed by liquid chromatography-tandem Mass Spectrometry (LC-MS/MS) on our homogenous macrophage populations. We discovered five novel peptides that are enriched exclusively on M2-macrophages relative to M1 macrophages and CD14+ monocytes. Lastly, we determined if these surface antibodies, found enriched on M2 macrophages, were also expressed in human metastatic castrate-resistant prostate cancer (mCRPC). Using mCRPC tissues from rapid autopsies supplied by the Departments of Urology and Surgical Pathology, we were able to determine M2-macrophage infiltration by using immunohistochemistry and flow cytometry. The studies described here outline a method of altering the tumor immune microenvironment. To target M2 macrophages, we used small peptides as well as antibody drug conjugates (ADCs) that targeted the enriched surface glycoproteins expressed on M2-macrophage. We then tested their efficacy in vitro and in a syngeneic prostate tumor mouse model to assess tumor shrinkage and effector and cytotoxic T Cell infiltration. By identifying specific markers on M2-TAMs, we predict that this method of targeting will provide a better prognosis for patients who have been diagnosed with lethal prostate cancer.

Targeting interleukin-1 to increase cetuximab efficacy in head and neck cancer. Madelyn Espinosa-Cotton, Ayana J. McLaren, Adam T. Koch, Andread L. Simons. The University of Iowa, Iowa City, IA; Lincoln University, Lincoln University, PA; Loma Linda University School of Medicine, Loma Linda, CA.

Treatment for head and neck squamous cell carcinoma (HNSCC) patients includes the epidermal growth factor receptor (EGFR) monoclonal antibody cetuximab. However, response to cetuximab is low and resistance remains a critical issue. Therefore, it is imperative to develop strategies to enhance tumor response to this drug. Inflammation plays an important role in tumor progression by increasing the release of cytokines that promote tumor cell survival. Our prior work has shown that a variety of pro-inflammatory cytokines involved in tumor survival are upregulated upon treatment with EGFR inhibitors in HNSCC cells, suggesting that poor tumor response to EGFR inhibitors may be due to increased tumor-associated inflammation. Our lab has shown that the increased proinflammatory tumor response due to EGFR inhibition may be activated by interleukin-1 (IL-1) signaling, suggesting that the IL-1 pathway may be an important target to enhance the efficacy of anti-EGFR therapy. Here we investigated the effect of IL-1 blockade on HNSCC tumor response to cetuximab treatment. We found that cetuximab induced IL-6 secretion from SQ20B HN SCC cells and knockdown of the adapter protein MyD88, which is essential for IL-1-induced IL-6 secretion, reduced cetuximab-induced IL-6 secretion. This increase in immune cells were accompanied by elevation of gene expression of signatures associated with KIT and expression of MHC class I and II genes. Together, these data describe the immune microenvironment of seminomas and suggest alterations and events in the kit pathway as being critical to the nature of the immune microenvironment in seminomas.

Validation of human and mouse myeloid panels on the NanoString nCounter® Platform. Sushil Kumar, Sarah Warren, Tiziana Cotechini, Terry Medler, Christina Bailey, Joseph M. Beechem, Joseph M. Beechem, Lisa M. Coussens. Oregon Health and Science University, Portland, OR; NanoString Technologies, Seattle, WA; Oregon Health and Science University, Seattle, WA.

Introduction: The innate immune system profoundly influences cancer development as well as its response to various therapeutic approaches. Multiple myeloid cell lineages are central to the innate immune response during cancer and have been found to regulate diverse cellular processes encompassing immunosuppression, angiogenesis, invasion, metastasis, and drug resistance. NanoString has collaborated with the laboratory of Prof. Lisa M. Coussens to develop research gene panels for quantitative and qualitative analysis of various myeloid subsets by evaluating relative enrichment of genes that mark recruitment and presence of select myeloid subtypes (e.g., granulocytes, dendritic cells, monocytes, macrophages, mast cells), their cell function, activation and effector status. Methods: Gene content for human and murine versions of the myeloid panels were developed from an in-house high content proteomic screen of macrophage activation (unpublished), genomic analysis of human tumor associated macrophages (unpublished), and data mining from publically available datasets featuring myeloid transcriptomes. In total, 692 genes were included in the human panel and 675 genes in the murine panel. The panels were optimized to simultaneously analyze 18 samples in a single run. The murine panel was comprised of five cell types: macrophages, neutrophils, dendritic cells, mast cells, and granulocytes. Results: To validate the panel content, we are profiling myeloid infiltrates in syngeneic murine models of mesothelioma and mammary tumorigenesis by flow cytometric analysis and the nCounter myeloid panels. Since the quality of the myeloid tumor response can skew toward adaptive immune activating (Th1) or suppressive (Th2) phenotypes, we will profile the same tumors with the NanoString PanCancer Immune Profiling panel to evaluate T cell activation status by gene expression and flow cytometry as well as global immune response. Finally, myeloid complexity and T cell activation status in both primary tumor and lung metastases will be evaluated by NanoString to
assess regulation of adaptive immune responses by the innate compartment in distinct tumor microenvironments. Conclusions: Upon validation with these assays, the myeloid gene panels may provide insight into how the innate immune system regulates cancer development and response to therapeutic pressure. Improved characterization of the myeloid compartment may lead to greater insight into the fundamental biology of tumor-immune interactions, novel therapeutic strategies, and other applications.

To date there has been an increasing focus on the interactions between inflammatory myeloid cells and T cells in the tumor microenvironment because cytotoxic anti-tumoral T cells represent the chief effector mechanism of anti-tumoral immunity. Tumor-associated neutrophils (TANs) represent a significant portion of inflammatory cells in lung tumors; however, whether specialized neutrophil subpopulations capable of regulating T cell responses exist in human cancers is unknown. Our goal was to identify subsets of TANs and determine their specific roles in the regulation of T cell responses in patients at early stage lung cancer. An extensive phenotypic analysis of 55 early-stage human lung tumors revealed that TANs, defined as CD11b+ Arg1+ MPO+ CD66b+ CD15+ cells, contained two major sub-populations. One subset of "canonical" TANs expressed classic neutrophil markers. A second subset of TANs displayed a combination of neutrophil and myeloid markers (CD14+ HLA- DR+ CCR7+ CD68+ ) normally expressed on antigen-presenting cells (APC). We termed this unique neutrophil population "APC-like hybrid TANs". The frequency of these hybrid TANs varied widely within lung cancers and ranged from 0.5-25% of all TANs. Interestingly, the frequency of this hybrid population declined as tumors enlarged, and they were almost completely absent in tumors greater than 5 cm in diameter. Mechanistically, we determined that low doses of IFN-γ and GM-CSF in the tumors were required for the development of APC-like hybrid neutrophils. The high proportion of hybrid TANs (>10% of all TANs) directly correlated with the presence of IFN-γ and GM-CSF in the autologous tumor tissue. Using bone marrow-derived immature granulocytes, which were found to have prolonged survival in vitro, we discovered that these APC-like hybrid neutrophils originate from CD11b+ CD15+ CD10+ CD16- immune neutrophil progenitors in the presence of IFN-γ and GM-CSF or in tumor-conditioned media. Functionally, the APC-like hybrid neutrophils are superior to canonical neutrophils in their ability to: 1) stimulate antigen non-specific autologous T cell responses 2) directly stimulate antigen-specific autologous T cell responses by providing a co-stimulatory signal through the OX40L, 4-1BB, CD86, CD84, molecules, and 5) cross present tumor-associated antigen as IgG immune complex. In summary, we provide the first evidence of two subsets of TANs in lung cancer. All TANs had an activated phenotype and could support (rather than inhibit) T cell functions to some degree. However, we identified a subset of TAN in early-stage lung tumors that can undergo a unique differentiation and gene expression pattern. In particular, the combination of certain myeloid lineage cells, myeloid dendritic cells, neutrophils, fibroblasts and endothelial cells in tumor tissues. Immune cell compositions were correlated with mutational load, the activity of 27 mutational signatures (MutSig) and PD-L1 mRNA expression. Correlation strength was assessed using Spearman’s rank statistics. Multiple testing was addressed using the Benjamini-Hochberg method and FDR control at 5%. MutSig 1 (clock-like, age-related) showed significant positive correlations with immune cell infiltrations in low-grade gliomas, negative correlations in breast cancer, melanoma, stomach cancer, lung and prostate adenocarcinoma, but no significant correlations in the remaining 15 cancer types. Of the two APOBEC-related signatures, MutSig 2 showed positive significant correlations with immune cell infiltrates in cervical cancer, bladder cancer; lung adenocarcinoma, head and neck cancer and thyroid cancer, MutSig 13 in breast and cervical cancer. In particular, correlation of MutSig 2 with cytotoxic lymphocytes was significant in cervical cancer, bladder cancer and lung adenocarcinoma (R = 0.29, R = 0.17 and R = 0.17), the corresponding correlation of MutSig 13 in breast cancer (R = 0.17). MutSig 4 (tobacco smoke-related) showed a significant correlation with CD8+ T cells and NK cells in lung adenocarcinoma (R = 0.15 and R = 0.14). In contrast, correlation of MutSig 4 with immune cell infiltrates was non-significant or negative in head and neck cancer. In colorectal cancer, MutSig 6 (defective mismatch repair) showed significant positive correlations with NK cells, cytotoxic lymphocytes, mononuclear lineage cells and neutrophils infiltration (R = 0.45, R = 0.37, R = 0.23 and R = 0.19). PD-L1 mRNA expression and immune cell infiltrates correlated positively in almost 75% of the analyzed types of cancer and showed a positive correlation between PD-L1 expression and different immune cell infiltrates in 12 cancer types. Correlation with CD8+ T cells was positive and significant in 18 cancer types and strong in 10 cancer types. In summary, pan-cancer analysis of DNA and RNAseq data showed that specific mutational signatures contribute to cancer cell immune immunogenicity, while the ubiquitous clock-like mutational process did not positively correlate with immune cell infiltrates in 20 of 21 cancer types. Moreover, PD-L1 mRNA expression strongly correlated with infiltrates of immune cells in the majority of cancer types.

#3708 RAS-MAPK signal is required for enhanced PD-L1 expression in human lung cancers. Hidetoshi Sumimoto, Atsushi Takano, Koji Teramoto, Shiga University of Medical Science, Otsu, Japan.

Ectopic programmed cell death ligand 1 (PD-L1) expression in non-small cell lung cancers (NSCLCs) is related to immune evasion by cancer, and it is a molecular target of immune checkpoint therapies. Since the precise mechanisms responsible for ectopic PD-L1 expression remains obscure, we analyzed the molecular mechanisms of ectopic PD-L1 expression in human lung cancers, focusing on the MAPK signal. Because we found a higher frequency of EGFR/ KRAS mutations in NSCLC cell lines with high PD-L1 expression (p < 0.001), we evaluated the relationships between downstream signals and PD-L1 expression, particularly in three KRAS-mutant adenocarcinoma cell lines. The MEK inhibitor U0126 (20 μM) significantly decreased the surface PD-L1 levels by 30-60% compared with dimethyl sulfoxide (p < 0.0001). Phorbol 12-myristate 13-acetate stimulation (100 nM, 15 min) increased (p < 0.05) and two ERK2 siRNAs as well as KRAS siRNAs decreased (p < 0.05) PD-L1 expression. Post-transcriptional mechanism by miR-200s appears not to be in general under the downstream of MAPK in the PD-L1 expression. The transcriptional activity of the potential AP-1 site (+4785 to +5056 from the transcription start site) in the PD-L1 gene was demonstrated by luciferase assays, which was inhibited by U0126. The chromatin immunoprecipitation assay demonstrated the binding of cJUN to the AP-1 site. Two STAT3 siRNAs decreased PD-L1 expression by 10-32% in two of the three KRAS-mutant lung adenocarcinoma cell lines (p < 0.05), while the PI3K inhibitor LY294002 (40 μM) did not change the expression level. Supervised cluster analysis and gene set enrichment analysis between the high- and low- PD-L1 NSCLCs revealed a correlation between PD-L1 expression and genes/pathways related to cell motility/adhesion. These results indicate that MAPK signaling is the dominant downstream signal responsible for ectopic PD-L1 expression at a transcriptional level, in which STAT3 is also involved to some extent. Furthermore, MAPK signaling may control the expression of PD-L1 and several genes related to enhanced cell motility. Our findings suggest that MAPK is important for determining PD-L1 expression, which could be useful for targeted therapies against lung cancers.

#3709 Deciphering the impact of tumor genetics on immune cell infiltration in major solid cancer types. Jan Budcza,1 Michael Bockmayer,2 Frederick Klausch,3 Abrecht Stenzinger,2 Carsten Denkert,1 Charité - Universitätsmedizin Berlin, Berlin, Germany; 2Heidelberg University Hospital, Heidelberg, Germany.

With the advent of immune therapies including inhibition of the PD-1/PD-L1 axis there is an urgent need to identify cancer patients that benefit from these therapies and to overcome mechanisms of resistance. Here, we analyzed the impact of tumor genetics on the composition of tumor microenvironment across 21 solid cancer types from the TCGA project. Using specific mRNA markers of 16 cell populations (MCPCounter), we estimated the content of T cells, CD8+ T cells, CD4+ T cells, B lineage cells, NK cells, mononuclear lineage cells, myeloid dendritic cells, neutrophils, fibroblasts and endothelial cells in tumor tissues. Immune cell compositions were correlated with mutational load, the activity of 27 mutational signatures (MutSig) and PD-L1 mRNA expression. Correlation strength was assessed using Spearman’s rank statistics. Multiple testing was addressed using the Benjamini-Hochberg method and FDR control at 5%. MutSig 1 (clock-like, age-related) showed significant positive correlations with immune cell infiltrations in low-grade gliomas, negative correlations in breast cancer, melanoma, stomach cancer, lung and prostate adenocarcinoma, but no significant correlations in the remaining 15 cancer types. Of the two APOBEC-related signatures, MutSig 2 showed positive significant correlations with immune cell infiltrates in cervical cancer, bladder cancer, lung adenocarcinoma, head and neck cancer and thyroid cancer, MutSig 13 in breast and cervical cancer. In particular, correlation of MutSig 2 with cytotoxic lymphocytes was significant in cervical cancer, bladder cancer and lung adenocarcinoma (R = 0.29, R = 0.17 and R = 0.17), the corresponding correlation of MutSig 13 in breast cancer (R = 0.17). MutSig 4 (tobacco smoke-related) showed a significant correlation with CD8+ T cells and NK cells in lung adenocarcinoma (R = 0.15 and R = 0.14). In contrast, correlation of MutSig 4 with immune cell infiltrates was non-significant or negative in head and neck cancer. In colorectal cancer, MutSig 6 (defective mismatch repair) showed significant positive correlations with NK cells, cytotoxic lymphocytes, mononuclear lineage cells and neutrophils infiltration (R = 0.45, R = 0.37, R = 0.23 and R = 0.19). PD-L1 mRNA expression and immune cell infiltrates correlated positively in almost 75% of the analyzed types of cancer and showed a positive correlation between PD-L1 expression and different immune cell infiltrates in 12 cancer types. Correlation with CD8+ T cells was positive and significant in 18 cancer types and strong in 10 cancer types. In summary, pan-cancer analysis of DNA and RNAseq data showed that specific mutational signatures contribute to cancer cell immune immunogenicity, while the ubiquitous clock-like mutational process did not positively correlate with immune cell infiltrates in 20 of 21 cancer types. Moreover, PD-L1 mRNA expression strongly correlated with infiltrates of immune cells in the majority of cancer types.
such as pancreatic cancer, has not been elucidated. Our recent results show that human pancreatic cancer cell lines have high total and cell-surface expression of β₂m, HLA-A, and HLA-B, with the exception of one pancreatic cancer cell line that we found exhibits low expression of HLA-B. Furthermore, differential gene expression analysis performed on laser capture-microdissected human pancreatic cancer patient samples revealed that the HLA-B gene is reduced in pancreatic ductal adenocarcinoma cells, compared to precursor (PanIN) epithelial or stromal cells. Together, our results indicate that pancreatic cancer cells have not selectively down regulated HLA class I molecule expression. This observation suggests that HLA class I molecules might provide some benefit to pancreatic cancer cells that counterbalances any risk of immune attack caused by HLA class I molecules. To examine whether the components of the HLA class I molecule actually confer potential advantages to pancreatic cancer cells, we transfected siRNA specific for β₂m, HLA-A heavy chain, or HLA-B heavy chain into several pancreatic cancer cell lines and evaluated the effects on their proliferation and migration. Down-regulation of either β₂m or HLA-B expression slowed the proliferation of one pancreatic cancer cell line, whereas down-regulation of HLA-A expression had the inverse effect on the same cell line. Two other pancreatic cancer cell lines had an opposite phenotype: proliferating more slowly when HLA-A expression was reduced, but more rapidly when HLA-B expression was decreased. Our investigation of the impact of down regulating HLA class I molecule components on the migration of pancreatic cancer cells showed the same trends with each cell line as we had observed in our proliferation analyses. In conclusion, we found that pancreatic cancer cells express substantial levels of HLA class I components, and their components influence the proliferation and migration of pancreatic cancer cell lines in a manner that varies for HLA-A versus HLA-B, and that also varies in pattern among the types of pancreatic cancer cell lines.

#3711 R-Ras is required for T cell trafficking in high endothelial venues and implicated in anti-tumor immunity. Andrew M. Chan,¹ Xiaocai Yan,¹ Wai Nam Liu,² Mingjie Yan.¹ ¹Chinese University of Hong Kong, Hong Kong, Hong Kong; ²The Medical College of Wisconsin, Milwaukee, WI.

R-Ras belongs the RAS superfamily of small GTP-binding proteins implicated in cell adhesion signaling. Unlike classical Ras proteins, R-Ras is not activated by growth factor receptors. Rather, its GTPase activity is modulated by molecules implicated in cell-cell adhesion including semaphorins and notch. Using an R-Ras knockout mouse strain, we have previously reported that R-Ras is required for murine dendritic cell functions. Further characterization of this mouse strain revealed reduced cellularity of peripheral lymph nodes (PLNs) by 40% with T cell regions in the paracortex in which high endothelial venues (HEV) resided were less prominent when compared with wild-type (WT) mice. Consistently, immunohistological analysis for MECA-79, a marker of mature HEV, showed a 3-to 4-fold decrease in staining intensity. This is correlated with a 30-40% reduction in the number of CD62L⁺ CD4 and CD8 T cells in PLNs. Furthermore, R-Ras null T cells had reduced proliferative and homing capacity when compared with WT. More importantly, we demonstrated for the first time that the chemokine CCL21 was able to stimulate the GTP-loading of R-Ras within 15 seconds of addition. Indeed, R-Ras null T-cells displayed reduced binding to soluble ICAM-1 as well as to 2H11 endothelial cells. To explore the role of R-Ras in anti-tumor immunity, B16/F10 melanoma cells were injected subcutaneously to WT and R-Ras null mice. In addition, a mouse breast tumor model was generated in neither WT or R-Ras-null genetic background. Tumor development and the number of infiltrating immune cells were analyzed to examine if R-Ras was involved in either anti- or pro-tumor immune responses. This work was supported by NIH CA78509 (AMC), MS9771 (AMC). AMC was supported by Hong Kong PhD Fellowship Scheme (PF12-13584) and AMC was supported by the Lo Kwee- Seong Seed Fund, and a General Research Fund Grant, 14120915, from Hong Kong University Grants Committee.

#3712 Mechanistic link between phosphatidylinositol-4,5-bisphosphate 3-kinase catalytic subunit alpha (PIK3CA) activity and PD1L1 expression in head and neck squamous cell carcinoma (HNSCC). Rebecca C. Hoesli, Nicole L. Schumacherzien, Vivek Nair, Chloe M. Novotina, Elizabeth Leonard, Matthew E. Spector, Carol R. Bradford, Mark E. Prince, Andrew C. Birkeland, J Chad Brenner. University of Michigan, Ann Arbor, MI.

Introduction: HNSCC is an immunosuppressive disease, with multiple functional and quantitative defects contributing to immune evasion and tumor escape. One of the identified areas for therapy development is the Programmed Death-1 (PD-1) Programmed Death Ligand 1 (PD-1L) pathway, as this pathway has been hypothesized to allow cancer cells to evade the immune system by promoting T cell anergy and apoptosis. Pembrolizumab, a PD-L1 inhibitor, has recently been approved for the treatment of recurrent/metastatic HNSCC. As regulation of PD-1L1 expression could play an important role in the effectiveness of therapy, we further explored the regulation of PD-L1 expression in HNSCC cells. Specifically, we targeted our investigation by evaluating the effects on expression of one of the most frequently mutated genes in HNSCC, PIK3CA. We evaluated this with and without interferon-γ, which has previously been shown to affect PD-L1 expression, possibly through activation of the STAT1 pathway. While HPV+ HNSCC cell lines were grown in cell culture and treated with selective and non-selective PI3K inhibitors, in combination with interferon-γ. After 72 hours, cells were harvested and flow cytometry was used to measure the expression of PD-L1. Protein expression of various pathway intermediaries was evaluated via western blot to better delineate the mechanism of PD-L1 upregulation. Results: Treatment with selective PI3K inhibitors in combination with interferon-γ in several cell lines significantly increased expression of PD-L1, beyond the increase noted after treatment with interferon-γ alone. Maintenance of STAT1 phosphorylation correlated with upregulation of PD-L1 expression, while total STAT1 expression remained stable. The majority of the cell lines maintaining STAT1 phosphorylation were HPV+, but a few HPV- cell lines also maintained this phosphorylation with a correlating upregulation in PD-L1 expression. Additionally, mutation in PIK3CA despite HPV-status was noted to maintain phosphorylation of STAT1 with upregulation of PD-L1 expression. Conclusions: Treatment with PI3K inhibitors in combination with interferon-γ significantly upregulated PD-L1 expression in several cell lines, suggesting a possible synergistic effect. Since PD-L1 expression correlated with maintenance of phosphorylation of STAT1, these results suggest a pivotal link between PIK3CA signaling, STAT1 activity and PD-L1 expression in PIK3CA aberrant HNSCC.

#3713 Higher numbers of cancer stem cells in the peripheral blood of children with B-ALL upon conventional chemotherapy. Mohamed L. Salem. Tanta University, Tanta, Egypt.

Background: Acute lymphocytic leukemia (ALL) is biologically and clinically considered as a heterogeneous neoplasm of lymphoid progenitor cells in the bone marrow (BM). 15-20% of children with ALL who achieve an initial remission, will show relapse. One potential mechanism behind this relapse could be the emergence of cancer stem cells (CSCs) which are considered the driving force of tumourigenesis due to their ability of self-renewal as well as the emergence of immune regulatory cells including myeloid-derived suppressor cells (MDSCs) and regulatory T cells (Treg). Aim: the main aim of this study was to analyze the numbers of CSCs and correlate these numbers with the numbers of blast cells, MDSCs and Treg cells in children with B-ALL before and after induction of chemotherapy. Materials and Methods: CSCs were defined as CD45⁺CD19⁻CD10⁻CD34⁺CD38⁺, MDSCs were defined as Lin HLA-DR⁻CD33⁺CD11b⁻and Treg cells were defined as CD4⁺CD25⁺CD127⁻. The frequencies of these cells were analyzed in the peripheral blood of 15 ALL patients before and after (n = 10) and after (n = 10) induction of chemotherapy using flow cytometry. Results: Significant increases in the numbers of CSCs were shown in B-ALL patients after induction of chemotherapy as compared to newly diagnosed patients (7.6 ± 8.3 vs. 2.7 ± 2.4, P<0.05). The numbers of CSCs in ALL patients before and after induction of chemotherapy inversely correlated with the numbers of the blast cells. Additionally, the frequency of the MDSCs and Treg cells were higher and lower, respectively, in patients after induction of chemotherapy as compared to before chemotherapy. Conclusion: Our results indicate that chemotherapy of B-ALL patients results in emergence of high numbers of CSCs and MDSCs which might be contributing, respectively, to tumor relapse and creation of systemic immune suppression. This pilot study opens a new avenue to investigate the mechanism mediating the emergence of these cells on larger population of B-ALL patients at different treatment stages.

#3714 Muc5ac plays an essential role in promotion of k-ras mutant lung cancer. Misha Umer,¹ Amber M. Cumpian,² Nasim Khosravi,² Zouliik Azegzagh,¹ Maede Mohebsab,¹ Mauricio S. Caetano,¹ Edwin J. Ostrin,¹ Ignacio I. Wistuba,¹ Burton Dickey,¹ Humam Kadara,² Christopher M. Evans,³ Seyed J. Moghaddam,¹ UT MD Anderson Cancer Center, Houston, TX;²University of Pittsburgh School of Medicine, Pittsburgh, PA;³University of Medicine and Dentistry of New Jersey, New Jersey, NJ and University of California, San Francisco, CA. ¹University of Michigan, Ann Arbor, MI. ²University of Pittsburgh School of Medicine, Pittsburgh, PA. ³University of Virginia, Charlottesville, VA. 4University of California, San Francisco, CA.

Worldwide, lung cancer is the leading cause of cancer mortality, and cigarette smoking (CS) is its principal cause. However, several studies have found that smokers with chronic obstructive pulmonary disease (COPD), an inflammatory disease of the lung, have an increased risk of lung cancer (3 to 10-fold) compared to smokers with comparable cigarette exposure but without COPD. Importantly, among smokers with COPD, even following withdrawal of cigarette smoke, inflammation persists and lung function continues to deteriorate as does the increased risk of lung cancer. These facts suggest a strong link between COPD-related lung inflammation and lung cancer, however, the precise mech-
anesthetic link is not known. Mucociliary dysfunction and mucin hyperproduction are important features of COPD with inflammation being the major trigger. Interestingly, lung cancer with mucin overexpression has higher malignancy potential and poor prognosis, which around 76% having mutations in K-ras oncogene, the most frequent oncogenic mutation in lung adenocarcinoma. Taken together, mucociliat dysfunction and K-ras mutant lung cancer by inflammation. Here we first investigated whether Muc5ac, predominant airway mucin that plays a primary role in inflammatory lung diseases, is predictive of clinical outcome in KRAS-mutant human lung adenocarcinomas. We determined Muc5ac mRNA expression by array analysis of 150 lung adenocarcinomas from patients that did not received neoadjuvant therapy. Muc5ac mRNA expression was predictive of poor disease-free survival in KRAS-mutant lung adenocarcinomas. We have further found increased mucin and high expression of Muc5ac in lung tumor tissues of the mice with airway specific expression of a mutant form of K-ras (CC-LR mice). Then, we crossed previously developed Muc5ac knockout (KO) mice to CC-LR mice in order to develop a K-ras mutant lung cancer mouse model with lack of Muc5ac (CC-LR/Muc5ac KO mice). This resulted in a significant tumor reduction by ~54% (2.2-fold) in lung of CC-LR/Muc5ac KO mice compared to age and sex matched control CC-LR mice. Lung inflammation was evaluated by analysis of bronchoalveolar lavage fluid and revealed a significant reduction (3-fold) in number of macrophages, and levels of IL-6 and IL-17 in CC-LR/Muc5ac KO mice compared to CC-LR control mice. Immunohisto-pathological analysis of lung sections confirmed lower inflammation, decreased tumor number and size, less adenomatous lesions, and reduced tumor cell proliferation and angiogenesis in CC-LR mice with lack of Muc5ac compared to control CC-LR mice. Our experimental results suggest that Muc5ac has an essential role in promotion of K-ras mutant lung cancer through autocrine cell intrinsic and paracrine immune cell mediated mechanisms.

**#3715A Effusions of mesothelioma patients: What’s in it for immunotherapy.** Elly Marcq,1 Jorrit De Waele, 1 Jonas van Audenaerde, 1 Eva Lion,2 Eva Santermans,3 Niel Hens,3 Patrick Pauwels,4 Jan P. van Meerbeeck,5 Roger A. Greenberg,6 Anthony S. Lopes,7 Fiona Simpkins,8 Robert Doot, Sharon Lee,9 and Santermans1.

1Center for Oncological Research, University of Antwerp, Antwerp, Belgium; 2Interuniversity Institute for Biostatistics and Statistical Bioinformatics, Hasselt University, Diepenbeek, Belgium; 3Department of Pathology, Antwerp University Hospital, Antwerp, Belgium; 4Thoracic Oncology-MOCA, Antwerp University Hospital, Antwerp, Belgium.

Malignant pleural mesothelioma (MPM) is an aggressive cancer with a poor prognosis for which new therapeutic strategies are available. Data derived from a large cohort of mesothelioma patients suggest that blocking immune checkpoints could offer new treatment opportunities. Gaining more insight in the immunological aspect of the tumor microenvironment (TME) in MPM is essential to develop an effective immunotherapy. In this context, we investigated expression of the immune checkpoint molecules TIM-3, LAG-3, PD-1 and its ligand PD-L1 on cells in human pleural (collected via thoracocentesis, n=6) and ascites (collected via paracentesis, n=5) MPM fluids and identified different subsets of immune cells in the TME using multicolor flow cytometry. Different types of immune cells in the fluids could be detected, with predominant occurrence of CD3+/CD4+ T cells, CD64+ macrophages and CD11c+/CD303+ dendritic cells (DCs). CD3+/CD8+ T cells, CD3+CD56+ natural killer (NK) cells and CD19+ B cells were also present to a lesser extent. While CD4+ and CD8+ T cells and CD64+ macrophages were expressed in all samples in the case of the other cell types. Ascites fluids contained more podoplanin+ (PDPN) tumor cells compared to pleural fluids (average 3.0% vs 0.3%). PD-1+ T cells and NK cells could be detected in all pleural and 80% of the ascites samples. 64% of all samples contained LAG-3-expressing cells, most frequently in pleural fluids. In all samples CD4+ and NK cells showed TIM-3 expression and in 82% of the samples TIM-3 was also expressed on CD8+ T-cells. In all ascites samples PD-L1 was expressed on DCs, B cells, macrophages and PDPN+ MPM tumor cells. PD-L1 was also expressed on DCs in all pleural samples while in 67%, 83% and 83% of those samples CD19+, CD64+ and PDPN+ cells were PD-L1+, respectively. Based on the mean fluorescence intensity PDPN+ tumor cells showed the highest PD-L1 expression in both fluids. In conclusion, we provide a detailed analysis of a diversity of immune cells present in MPM fluid samples. We are the first to demonstrate TIM-3 and LAG-3 expression in mesothelioma effusions. Statistical analysis is ongoing to investigate whether there are differences between both fluid types and whether there are associations between the cellular composition of the fluids and survival of the patients. The finding of expression of PD-1, PD-L1, TIM-3 and LAG-3 on immune cells in MPM fluids warrants further investigation of the effect of immune checkpoint blockade in MPM, with TIM-3 and LAG-3 as interesting new targets.

**IMMUNOLOGY: Inflammation in the Tumor Microenvironment**

**#3715 Analysis of tumor infiltrating lymphocytes and in vitro exhausted tumor-derived T-cells to identify unique Immuno-Oncology targets.** Joanne Berry,1 Yaoyao Fu,2 Joanne Goodchild,1 Haining Huang,2 Livija Deban,1 Robert Boyd1. 1Oxford BioTherapeutics Ltd, Abingdon, United Kingdom; 2Oxford BioTherapeutics Inc, San Jose, CA.

In cancer, T cells are exposed to persistent antigen stimulation and/or inflammatory signals. Such prolonged stimulation is often associated with deterioration of T cell effector functions resulting in a functional state termed ‘exhaustion’. Exhausted T cells are characterized by expression of multiple inhibitory receptors, loss of cytolytic function and decline in cytokine production capability. T cell exhaustion is likely associated with inefficient control of tumor progression. Identification of cell surface proteins involved in induction and maintenance of the exhausted state could inform novel immunomodulatory cancer therapies. To comprehensively investigate cell surface signature of the exhausted state and identify potential immunoncology (I-O) targets, we conducted in-depth expression profiling of membrane proteins from intact tumors (Colonorectal, Pancreatic, Lung, Breast and Prostate cancer), different in vitro models of T cell exhaustion and primary tumor-derived lymphocytes (Colonorectal, Breast and Lung cancer) by targeted proteomics for known cell type and activation markers. Using proteomic expression analysis and statistical clustering analysis methods, novel I-O targets were identified in both the in vitro models of T cell exhaustion and primary tumor-derived lymphocytes (TILs). The cancer specify of novel I-O targets was then interrogated using the expression profiling of cell membrane proteins from intact tumors. Using this approach we identified most known T cell inhibitory receptors (PD-1, CTLA-4, BTLA, TIM-3, KIRs, LAG-3 and TIMG72) and their described ligands (B7-H1 to B7-H7). To generate more precise expression data to validate I-O targets emerging from the above discovery approaches and their role as interacting partners we analyzed single tumors using an integrated evaluation methodology. Tumors were subject to multiple parallel analysis steps: (i) proteomic analysis of the tumor and TILs; (ii) TILs were subject to flow cytometry analysis for specific proteins; (iii) tumor tissue sections were subject to immuno-histochemical analysis for specific proteins. The multiple analysis platforms were integrated by key cell type and functional markers allowing the different types of information provided by each technique to be placed in an overall 3-D tumor context. We present one example of a potential I-O target identified using our integrated proteomic discovery approach which is further validated at the expression level using multiple whole tumor and TIL analyses.
expression were evaluated. In parallel clinical PET/CT imaging of PARP-1 was performed in epithelial ovarian cancer patients with correlative tissue histology. Results: Our studies indicate there is a spectrum of PARP-1 expression in epithelial ovarian cancer and in vitro BRCA1 mutants show higher PARP-1 expression compared to non-BRCA mutants. In addition, PARP-1 expression is required for PARP inhibitor efficacy in vitro and is either more significant or equal to BRCA1 mutational status. Also, high PARP-1 expression corresponded with platinum sensitivity in vitro. Furthermore, we observed PARP-1 expression increased in response to genotoxic insult relative to DNA damage measured by gH2AX. Lastly, our observations have been further supplemented by clinical \[\text{[18F]}\text{FTT}\] PET/CT images in ovarian cancer patients, which showed a spectrum of PARP-1 expression. DNA damage measured by gH2AX and DNA repair deficiencies and to provide a biomarker for assessing response to PARP-1 expression that corresponded with DNA damage measured by gH2AX. Conclusion: PARP-1 expression has the potential to identify functional DNA repair deficiencies and to provide a biomarker for assessing response to DNA damaging therapies. In complement, clinical PET imaging with \[\text{[18F]}\text{FTT}\] offers a novel technology to determine PARP-1 expression in ovarian cancer patients and warrants further study.

#3719 Bicyclic peptides for PET imaging of MT1-MMP expressing tumors. Daniel Teufel,1 Helen Harrison,2 Spencer Campbell,1 Catherine Stace,3 Edward Walker,1 Robert J. Lutz,1 Peter Park,1 Matthias Eder,2 Ulrike Bauder-Wüst,2 Ursula Schierbaum,1 Karin Leotta,2 Klaus Kopka,1 Uwe Haberkorn1.

1Bicycle Therapeutics Limited, Cambridge, United Kingdom; 2German Cancer Research Center (DKFZ), Heidelberg, Germany.

The Bicycle\textsuperscript{TM} technology is based on repertoires of short peptides displayed on the surface of bacteriophages which can be modified with homo-trifunctional organochemical scaffolds, thus creating large diverse libraries of constrained, bicyclic peptides. These large combinatorial libraries have been extensively used for iterative selections to identify high affinity binding peptides to a wide array of targets, including receptors, interleukins and proteases. Bicyclic peptides are chemically synthesized macrocyclic entities with drug-like properties that exhibit sub-nanomolar affinities and exquisite selectivity towards targets. Unlike biologics, their synthetic nature allows facile modulation of metabolic and pharmacokinetic properties, as well as site-specific conjugation to effector molecules such as fluorophores, radionuclides, and cytotoxic drugs. In the present work, novel phage display-derived bicyclic peptides were identified targeting the matrix metalloproteinase 14 (also known as MT1-MMP), a tumor associated surface protein overexpressed in a variety of cancers (i.e. lung, breast). A prototype bicyclic peptide with high affinity to MT1-MMP (Kd at ~1 nM) was identified, and confocal microscopy using fluoresceinated bicyclic peptide derivatives shows target-dependent internalisation in MT1-MMP\textsuperscript{TM} cells. In the in vivo setting, a tumor binding contrast agent, \[\text{[18F]}\text{FTT}\] labeled with a DOTA conjugate loaded with Ga-68 or Lu-177. Upon proteolytic optimization of the prototype bicycle peptide, a striking enhancement in tumor signal is observed in biodistribution studies. Compared to radiolabeled antibodies directed against the same target, the lead compound showed fast background clearance (< 1 %ID/g for all organs apart from kidneys) resulting in high imaging contrast in \(\mu\)PET studies as early as 30 minutes post injection. Importantly, most of the non-tumor associated bicyclic peptide rapidly clears into the bladder. Together, tumor targeting bicyclic peptides can, through their small size and high selectivity, facilitate efficient penetration and visualization of tumors in vivo, demonstrating their potential as diagnostic imaging agents in profiling and therapeutic management of patients.
for the better outcome for CTL mediated immunotherapy for cancer. Somdutta Roy, Kevin Martínez, Archana Dilip, Holger Karinskyy, Scott Dylla, Abbvie STemCenters, South San Francisco, CA.

Small cell lung cancer (SCLC) is an aggressive neuroendocrine tumor with early dissemination and poor prognosis that accounts for 15-20% of all lung cancer cases worldwide. Most cases are inoperable and biopsies to investigate SCLC biology are rarely obtainable. Circulating tumor cells (CTCs), which are prevalent in SCLC, present a readily accessible liquid biopsy. Here we present CTC data from aggressive, late stage SCLC patients who were enrolled on a Phase 1 trial studying Rova-T (anti-DLL3 antibody drug conjugate). CTCs were captured using a microfluidic platform (IsoFlux) that uses flow control and immunomagnetic capturing of epithelial cell surface marker (EpCAM)-positive cells. CTCs were isolated before dosing (baseline) of Rova-T and at successive time points post treatment. CTCs from each time point were distinguished and enumerated using DAPI, EpCAM and the cytoplasmic marker (pan-Ck), in addition to the absence of CD45. Enriched CTCs were also collected for RT-PCR for expression analysis of genes confirmed to be absent in blood. The number of CTCs varied among the 58 baseline samples collected, ranging from 5-1000 CTCs per 7.5 ml of blood. When the CTCs were assessed for DLL3 target expression, 37/58 baseline samples expressed DLL3 by RT-PCR. Interestingly, the expression of DLL3 on the baseline CTCs correlated with treatment outcome. When additional time points after treatment were enumerated for CTCs, patients who responded to Rova-T had DLL3+ CTCs at baseline. Patients with DLL3+ CTCs at baseline showed a significant decrease in DLL3 after treatment. This suggests that Rova-T might kill DLL3-expressing CTCs. These data support continued investigation of DLL3 expression on CTC in SCLC patients with the goal of facilitating a liquid biopsy able to assess DLL3 status as a prospective companion diagnostic for Rova-T.

#3722 In vitro induced regulatory T cells for the understanding of the nature of peripherally induced regulatory cells in relation to cell mediated immunotherapy for cancer. Upendra P. Hegde, Nitya G. Chakraborty, Univ. of Connecticut Health Ctr., Farmington, CT.

Background: pTregs are appearing to be one of the major obstacles of cellular immunotherapy of cancer. Tumor specific in vivo induced Cytotoxic T lymphocytes (CTL) are rapidly eliminated with concomitant expansion of pTreg cells. In human melanoma in ex vivo condition, tumor antigen specific CTL generated with CD8+ cells persisted for months while ex vivo induced CTL with whole PBL stimulated with Mart-1, A2 (tumor antigen) pulsed autologous DC, died within three weeks. Whereas Influenza (Flu 36-45) antigen specific CTL continued to expand and remained functional beyond four weeks. Method: Peripheral blood and tumors were obtained from patients diagnosed with metastatic melanoma after informed consent. Blood derived dendritic cells, PBL, CD8+ and CD4+ cells were isolated for in vitro co-cultures with Mart-1 or Flu peptide pulsed autologous DC or autologous tumor cells. CD8+ CTL response and CD4+ positive Treg responses were measured. Freshly obtained tumor tissue derived lymphocytes (TIL) were also used for the study. Results: Our results show that CTL response against Flu survived longer in culture with total PBL than CTL response against Mart-1 in identical culture conditions. CTL response using autologous tumor cells with PBL in culture lasted for a shorter duration but growth of Treg cells were observed. Cytokine analysis with expanding Treg cells showed secretion of IL-10 upon re-stimulation with autologous DC or anti-CD3 ab. Similarly, CD4+ cells isolated from freshly obtained tumor tissue (TIL, representing in vivo condition), suppressed T cell activation and secreted high amount of IL-10 upon re-stimulation. Conclusion: These findings suggested that in vitro induced iTreg from cultures or pTreg from TILs (in vivo), work identical way, to negatively regulate effector immune response by secreting IL-10. Further analysis with iTregs for their use of metabolic pathways would be important to identify the specific signaling molecules used by autologous (person specific) pTregs, as target molecules, to block the expansion of such pTregs for the better outcome for CTL mediated immunotherapy for cancer.

#3723 Assessing the reproducibility of computer-aided nodule assessment and risk yield (CANARY) method to characterize lung adenocarcinomas. Erica C. Nakajima,1 Michael P. Frankland,2 Tucker Johnson,3 Sanja L. Antic,1 Ronald A. Karwoski,2 Bennett Landman,3 Heidi Chen,1 Ronald C. Walker,1 Brian J. Bartholmai,1 Tobias Peikert,1 Srinivasa Rajagopalan,1 Pierre P. Massion1, Fabien Maldonado1,1 Vanderbilt University Medical Center, Nashville, TN;2Vanderbilt University, Nashville, TN;3Mayo Clinic, Rochester, MN.

This study assessed the inter-user reproducibility of Computer-Aided Nodule Assessment and Risk Yield (CANARY), a novel analytical tool that risk stratifies lung adenocarcinomas (ADCs) according to defined computed tomography (CT) structural characteristics. CANARY detects nine distinct voxel signatures in ADCs based on standard CT imaging, thereby defining nodule characteristics correlating with patient outcomes, and corresponding to invasion or lepidic growth histologically. A software user segments the borders of each ADC prior to voxel analysis, introducing potential variability into the assessment. While CANARY is a promising tool, it requires validation of analytical variability between users and prediction of accuracy in an independent cohort. To evaluate the reproducibility of CANARY analysis, three independent users who are not part of the CANARY development team segmented and analyzed 50 biopsy-confirmed primary lung ADCs from Vanderbilt University Medical Center. The CT scans of ADCs were selected retrospectively based on the following criteria: ADC histology proven on biopsy, diagnosed between 2009-2015, less than 3cm in greatest diameter, and stages IA-IV. Users followed a standard operating procedure established at the Mayo Clinic, and were blinded to clinical characteristics and patient outcomes. Results: To measure inter-user variability of ADC voxel composition, the intraclass correlation coefficient (ICC) was calculated based upon the percentage of each voxel subtype within the whole ADC. An ICC of 1 reflects high reproducibility between users. Among all 50 ADCs, the average ICC for all nine voxel types was 0.828 (95% CI 0.76, 0.895). The ICC of the four voxel types associated with invasive features on CT was 0.865 (95% CI 0.805, 0.924). ICCs were also calculated using a logarithmic transformation for data normalization, generating an ICC of 0.745 (95% CI 0.663, 0.826) for all nine voxel types, and an ICC of 0.995 (95% CI 0.993, 0.997) for four voxel types associated with invasion. Conclusions: (1) CANARY analysis of lung ADC voxel signatures appears to be reproducible amongst users, making it a reliable tool for the evaluation of ADC voxel density. (2) Correlation of invasive signatures associated with more aggressive ADCs was nearly perfect amongst users. Additional validation metrics for CANARY with larger datasets are being evaluated, including the accuracy of tumor prognostic predictions between users and analysis of ADC datasets from other institutions.

#3724 PD-L1 protein expression and tumor mutation burden in hematologic malignancies: correlation with Hodgkin and high grade lymphoma. Lina Abdul Karim,1 Peng Wang,2 Jose de Guzman,1 Brandi Higgins,3 Jeffery Chahine,1 Christine Sheehan,2 Bhaskar Kallakury,1 Jeffrey S. Ross2. 1Medstar Georgetown University Hospital, Washington, DC; 2Albany Medical College, Albany, NY.

Background: The success of anti PD-1 therapy in Hodgkin lymphoma has led to clinical trials in other types of lymphomas. However, there is limited data on PD-L1 expression in acute leukemias. In this study, we analyzed PD-L1 protein expression and tumor mutational burden in various hematologic malignancies including leukemias, lymphomas and myelomas. Methods: In the IHC cohort, formalin fixed paraffin embedded sections from 92 hematologic malignancies including acute myeloid and lymphoblastic leukemia (AML, ALL), Hodgkin lymphoma (HL), diffuse large B-cell lymphoma (DLBCL), low-grade non-Hodgkin lymphoma (LGNL) and myeloma were immunostained using the PD-L1 approved PD-L1 IHC 22C3 pharmDx and mouse anti-PD-L1 antibody (DAKO clone 22C3). Any perceptible partial or complete membrane staining in all viable tumor cells was scored as follows: <1%-negative, 1-49%-low level and >50%-high level PD-L1 expression. In the second cohort of 2064 cases, comprehensive genomic profiling (CGP) was performed using a hybrid–capture, adaptor ligation assay to a mean depth of >672X. Tumor mutation burden (TMB) was calculated from a minimum of 1.11MB of sequenced DNA as previously described and reported as mutations/Mb. High PD-L1 expression was noted in 100% of HL, DLBCL showed significantly higher PD-L1 positivity compared to LGNHL (p=0.01). No correlation for PD-L1 expression was noted between AML and ALL (p = 0.2). On CGP analysis of the second cohort, TMB was significantly higher in DLBCL as compared to LGNHL (p<0.0001). Conclusion: The high PD-L1 expression in both HL and DLBCL and high TMB in DLBCL may be linked to enhanced responsiveness to checkpoint inhibitor therapy in these cancers. PD-L1 expression and TMB are relatively infrequent and at low levels in acute leukemias. Additionally, novel anti PD-1/PD-L1 therapeutic strategies are worthy of consideration for both advanced stage refractory/relapsed acute myeloid and lymphoblastic leukemias.
Introduction: Everolimus is an oral mTOR inhibitor. It is used for its antitumor effect in breast cancer. This study summarizes the clinical outcomes and noted adverse events from sequencing-derived combination treatments that include everolimus in the neoadjuvant setting. Material and Methods: To date, 57 breast cancer patients have been enrolled to clinical trial NCT02470715 and treated in the neoadjuvant setting. The data presented here focus specifically on 17 patients that have long enough follow up and that have been treated with everolimus-based combinations. FoundationOne© test and Theralink© assay was used for genomic profiling and proteomic analysis respectively. Clinical outcomes were assessed at the time of surgery. A pathological complete response was defined as the absence of residual disease. Results: Everolimus was prescribed for the patients in this study based on the findings from their genomic or proteomic testing, targeting PI3K/AKT/mTOR pathway. The evidence for using everolimus in ER+ patients (n=13) includes alterations in PIK3CA (n=9), PTEN (n=7), 5FGS (n=2), and phospho-S6 ribosomal protein (Ser235/236)/4E-BP1 (phospho-S65) which was targeted in the Her2+ (n=1) patient. PIK3CA (n=2) and PIK3CB (n=1) presented in the 3 triple negative (TN) patients. Everolimus and paclitaxel was used in all patients as the backbone combination while trastuzumab was added for Her2+ patients and hormonal therapy was added for ER+ patients. Aromatase inhibitors were used in most of the cases as hormonal therapy in ER+ patients while goserelin was used in 3 cases for premenopausal patients. Pazopanib and temsirolimus were added to two of the TN patients and palbociclib was added for one ER+ /Her2- patient targeting other alterations. From the 17 patients (clinical stage I to III) treated with everolimus in the neoadjuvant setting, pathological complete response was achieved in 4 (23%) patients (2 ER+, 1 Her2+ and 1 TN). 65% (n=11) patients had partial response (10 ER+, 1 TN). Only one TN patient did not respond to the neoadjuvant treatment. Over half of the patients (59%) tolerated the treatment well while 6 patients (35%) developed adverse events which resulted in a change of regimen. Grade 3 and above adverse events including mucositis, cough and fever were observed in ER+/Her2- patients who were treated with everolimus + paclitaxel + hormonal therapy. The symptoms were managed by a dose reduction or a period of treatment hold. When one of the patient treated with everolimus + paclitaxel + anastrozole + trastuzumab developed a UTI, diarrhea, mucositis and edema after 7 weeks of treatment. Treatment was stopped in this case. Conclusion: Based upon our findings, everolimus is an effective drug in the neoadjuvant treatment of early stage breast cancer. Even though the numbers are small, our outcomes show significant promise. Adverse events related to the treatment were manageable and did not negatively impact our ability to give the treatment in most cases.

**#3725 Neooadjuvant everolimus as a targeted therapy for early stage breast cancer.** Bing Xu, Casey Williams, Brian Leyland-Jones. Avera Cancer Institute, Sioux Falls, SD.

**#3726 INCISB2793 JAK1 inhibitor synergizes with ATRA to inhibit expansion of AML.** Haley E. Ramsey,1 P. Brent Ferrell,1 Melissa A. Fischer,1 Agnieszka E. Gorska,1 Caroline Maier,2 Jeremy Norris,2 Melissa Farrow,2 Danielle SiouxFalls,SD.1

**#3727 Plasma inhibitory activity (PIA) is a possible pharmacodynamic marker for clinical development of a next generation pan-TRK inhibitor, ONO-3590556.** Ryohye Kozaki, Ryu Fujikawa, Hikaru Kato, Natsuka Goto, Toshio Yoshizawa. Ono Pharmaceutical, Osaka, Japan.

Background: Colorectal cancer and Mammary analogues secretory carcinoma harboring Neurotrophic tyrosine receptor kinase (NTRK/TRK) gene rearrangements developed resistance to Entrectinib, ALK/ROS/TRK inhibitor. We previously demonstrated that the next generation pan-TRK inhibitor, ONO-3590556 may potentially overcome Entrectinib-resistance mutations. Furthermore, inhibition of Trk phosphorylation in tumors has excellent correlation with the in vivo anti-tumor effect by ONO-3590556 (AACR2016, Kozaki et al). Purpose: Accurate measurement of target inhibition in a phase 1 clinical trial is critical to informing selection of appropriate doses for ONO-3590556 in more advanced clinical trials. Plasma inhibitory activity (PIA) assay has recently been performed as a surrogate assay in clinical trials of FLT3, MET and ALK kinase inhibitors. The assay employs the incubation of Tyrosine Kinase expressing cell lines in aliquots of plasma collected at various time points from patients treated with TKI. Herein, we report the preclinical evaluation of PIA assay in accordance with an inhibition of TRK phosphorylation in tumors. Methods: KM12 cells, human colorectal cancer cell lines expressing TPM3-TRKA, were implaned subcutaneously into nude mice. Mice were randomized when the mean tumor volume was 150-600 mm3. Tumors and blood were collected from mice, 2, 4, 7 and 24 hours after the single treatment of ONO-3590556 with the doses of 0.06 and 0.6 mg/kg. The collected tumors were disrupted and phosphorylated Trk phosphorylation in tumors was measured. Results: Pilot M1 assay, KM12 was incubated in plasma from the collected blood for 4 hours and phosphorylated TrkA in the cells was detected by ECL. Results: Treatment with ONO-3590556 at doses of 0.06, 0.6 mg/kg resulted in a significant inhibition of Trk phosphorylation in tumors up to 24 hours. Compared to inhibition of P-TRK in tumors, the inhibition of P-TRK in PIA sustained until 7 hours but rapidly decreased at 24 hours after administration. The levels of both tumors and PIA showed in a dose-dependent inhibition and an excellent correlation until 7 hours. Conclusion: Plasma inhibitory activity (PIA) assay correlates with inhibition of P-TRK in tumors. Our results demonstrated that the potential utility of PIA as a PD marker may contribute to determining the effective dose of ONO-3590556 in the clinical development.

**#3728 Imaging biomarkers of aromatase-inhibitor induced joint pain.** Brian A. Goldstein, Miha Tanajonvic, Pavani Chalasani, C. Kent Kwoh, Amanda Hadden, Russell Witte, Jessica Martinez. University of Arizona, Tucson, AZ.

Aromatase inhibitor positive (ER+) breast cancer patients undergoing treatment with aromatase inhibitors (AI) tend to discontinue the supplement when to painful side effects appear. It is believed that women with AI-induced musculoskeletal syndrome (AIMSS) have specific physiological conditions that differentiate them from women with normal aging-related in.
flamatory processes (e.g., rheumatoid arthritis or RA). Ultrasound shear wave elastography (USWE) provides a real-time, quantitative assessment of the elastic modulus of soft tissue, which is a potential biomarker that is altered in women with AIMSS. Because USWE is a completely noninvasive technique available on state-of-the-art clinical ultrasound scanners, it can be repeatedly used in calculating the shear modulus of patients whose elastographic images change due to the presence of adverse effects during therapy. A Siemens s3000 clinical scanner and 9 MHz linear probe were used for USWE of the hands and wrists in postmenopausal women on AI, postmenopausal women with RA and healthy postmenopausal women. The scans included an evaluation of major wrist tendons, nerves, and joints with shear wave velocities ranging from 0.5 to 15 m/s, which are directly related to the local shear modulus – an absolute measure of tissue stiffness. The ultrasound images and raw shear wave data were then analyzed in MATLAB™ using a custom graphical user interface (GUI) to calculate the distribution of velocities (or shear moduli) in a user-defined region of interest (ROI). The results were exported to a spreadsheet in Excel for further analysis and comparison among the different groups. Initial results suggest the shear wave velocity and estimated Young’s modulus (A) were significantly higher in AI patients (14.6 ± 0.2 m/s, λ=642 ± 17 kPa) compared to RA (6.84 ± 1.1 m/s, λ=143 ± 43 kPa) and healthy (7.58 ± 0.9 m/s, λ=174 ± 42 kPa) patients. These values suggest that the mechanical properties of tendons in the wrist may change during treatment with AI and contribute to joint pain in these subjects. It is critical that ER+ patients on AI can be monitored for signs of joint pain, and if found, to monitor for a biopsy as a possible source of pain. Patients on AI + USWE may help predict which patients are most susceptible to these side effects, promote early intervention to reduce or eliminate symptoms, and help increase adherence to AI therapy.

Tumor-specific antibody labeling of pancreatic cancer in a patient-derived orthotopic xenograft (PDOX) mouse model using a fluorescent humanized anti-CEA antibody. Thinzar Lwin, Takashi Murakami, Robert M. Hoffman, Paul J. Yazaki, Michael Bouvet 
University of California, San Diego, La Jolla, CA; City of Hope Medical Center, Duarte, CA.

Introduction: Delineation of tumor margins is critical in oncologic surgery, particularly in resection of pancreatic cancer. Surgeons are limited in visualization with bright light surgery. Fluorescence guided surgery (FGS) can help surgeons better visualize all potential cancer cells during the operation. In the present study, we used the fluorescent dye Anti-CEA-800 conjugated to an 800 nm NIR fluorescent dye can selectively label pancreatic cancer in both pancreatic cancer cell lines and patient derived xenograft mouse models (PDOX). Materials/Methods: BxPC3-GFP cells or pancreatic cancer tissue specimens were grouped into flanks of nude mice. Both types of tumors were allowed to grow until 1 cm. Each tumor was then treated with a single injection of anti-CEA-800 dye at the tail base (LI-COR 800 CW IRDye®, Lincoln, NE). Mice were imaged via the Maestro CRI imaging system. Result: Images obtained after injection of Anti-CEA-800 dye were injected into the tail-base (LI-COR 800 CW IRDye®, Lincoln, NE). Mice were imaged via the Maestro CRI imaging system. Perkin Elmer, Waltham, MA) 24 hours after injection. Results: Images obtained after injection of Anti-CEA-800 dye were injected into the tail-base (LI-COR 800 CW IRDye®, Lincoln, NE). Mice were imaged via the Maestro CRI imaging system. Perkin Elmer, Waltham, MA) 24 hours after injection. Images obtained after fluorescence antibody injection showed that anti-CEA-800 specifically labeled both the cell-line-derived tumors and patient-derived tumors with an adequate tumor to background contrast at 24 hours. The dye co-localized with GFP in both the cell-line-derived tumors and patient-derived tumors with an adequate tumor to background contrast at 24 hours. The dye co-localized with GFP in both the cell-line-derived tumors and patient-derived tumors. Conclusion: Anti-CEA-800 conjugated with the IR-800 dye is a promising agent for future clinical FGS applications.

Early metabolic response to tumor-treating fields in patients with recurrent glioblastoma. Sandeep Mittal, Geoffrey R. Barger, Edit Bosnyák, Varun B. Shah, Csaba Juhász. Wayne State University, Detroit, MI.

PURPOSE: Tumor-Treating Fields (TTFields) is an FDA-approved treatment approach for patients with newly-diagnosed and recurrent glioblastoma. The main purpose of the present study was to explore if amino acid position expression tomography (PET) is able to detect an early, objective metabolic tumor response during the first months of TTFields therapy. METHODS: Patients with MRI signs of recurrent glioblastoma eligible for TTFields along with maintenance temozolomide were recruited for PET scanning with alpha-[C-11]-methyl-L-tryptophan (AMT) at baseline (before start of TTFields application) and up to 3 months later. Serial MRIs were also performed in 1-2 months intervals. MRI accumulation in the MRI-detected tumor mass was measured by standardized uptake values (SUVRs), and PET-based tumor volume was calculated from the PET scans. Further, MRI and PET data were compared to changes in areas of MRI enhancement. RESULTS: Out of 7 recruited patients, 5 showed appropriate compliance (>75%) with the device and underwent follow-up PET. Four of the 5 patients showed a clear metabolic response during TT treatment on PET imaging. Two patients, who received TTFields treatment only (in addition to maintenance temozolomide), showed 25% and 100% decrease of PET-based tumor volumes, respectively. MRI was stable (patient #1) or showed increasing contrast enhancement (#2) during the same period. In this latter patient, TTFields was continued with bevacizumab treatment, leading to decreased contrast enhancement and further decrease of AMT uptake on a second follow-up PET. In two patients (#3 and #4), TTFields were combined with bevacizumab rescue treatment. Patient #3 showed a markedly decreased tumor AMT uptake and metabolic volume along with stable MRI enhancement. Patient #4 showed interval decrease of tryptophan PET uptake 2 months after initiation of TTFields therapy. Finally, patient #5 showed an interval expansion of the PET-based tumor volume along with MRI progression during a 2-month follow-up despite TTFields combined with bevacizumab and carboplatin. CONCLUSIONS: This is the first study to demonstrate an objective metabolic response of recurrent glioblastoma within 1.5-3 months after initiation of TTFields. The data suggest that amino acid PET can identify early responders to TTFields therapy.
#3734 Pharmacokinetics of sacituzumab govitecan (IMMU-132), an anti-body-drug conjugate (ADC) targeting Trop-2, in patients with diverse advanced solid tumors. Robert M. Sharkey, 1 Allyson J. Ocean, 2 Alexander N. Starobud, 3 Aditya Bardia, 4 Michael Guarino, 5 Wells A. Messersmith, 6 Jordan D. Berlin, 7 Vincent J. Picozzi, 8 Rebecca Moroose, 9 William A. Wegener, 1 Pius Ma- li, 10 Volker Endris, 11 Martina Kirchner, 12 Matthias Kloor, 13 Anna-Lena Volkmar, 14 Magnus von Knebel Doeberitz, 15 Roland Penzel, 16 Peter Schirmacher, 17 Albrecht Stenzinger. 18 Univ. of Heidelberg, Heidelberg, Germany.

#3735 Detection of microsatellite instable colorectal cancers from routine NGS panel sequencing data. Volker Endris, Martina Kirchner, Matthias Kloor, Anna-Lena Volkmar, Magnus von Knebel Doeberitz, Roland Penzel, Peter Schirmacher, Albrecht Stenzinger. Un. of Heidelberg, Heidelberg, Germany.

Introduction: In about 15% of all colorectal cancers, microsatellite instability (MSI) caused by defects in the DNA mismatch repair machinery can be detected. MSI driven tumors have a better prognosis compared to microsatellite stable (MSS) tumors and show good response to drugs targeting the PD-1-PD-L1 axis. Current molecular diagnostic procedures for colorectal cancer are primarily focused on the detection of oncoclonic mutations in RAS family genes by either classical PCR, next generation sequencing (NGS) or panel testing. The MSI status for therapeutic purposes is still rare and usually carried out by a different array of methods including PCR and immunohistochemistry. Experimental procedures: In our routine diagnostic CRC screening, we sequenced more than 600 colorectal tumors with an entity specific customized 180 ampli- con NGS panel encompassing HotSpot regions of 31 genes. This panel includes several homopolymeric regions of genes that are known to be affected by MSI. We retrospectively analysed this data set for MSI signatures, including deletion/insertion mutations in 20 different homopolymeric regions (>7) and mutations/deletions of MLH1, MSH3, MSH6 and TGBFR2. Cases with a MSI signa- ture detected by panel sequencing were reevaluated by PCR-based screening.
#3736 Characterization of tumor cells and assessment of PD-L1 expression in pleural effusions of metastatic non-small cell lung cancer patients. Jeffrey C. Thompson, 1 Samantha L. Savitch, 2 Ryan Fan, 2 Stephanie S. Yee, 2 Christian A. Powers, 2 Gordon Yu, 3 Lauren Gebrian, 1 Chandra Rao, 1 Steve Gross, 1 Michael Feldman, 2 Anil Vachani, 1 Erica L. Carpenter, 1 1Division of Pulmonary, Allergy, and Critical Care Medicine, Thoracic Oncology Group, Department of Medicine, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA; 2Division of Hematology-Oncology, Department of Medicine, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA; 3Department of Pathology and Laboratory Medicine, Hospital of the University of Pennsylvania, Philadelphia, PA; 4Janssen Pharmaceutical, Johnson & Johnson, Pennsylvania, PA.

Introduction: Malignant pleural effusions (MPE) occur as a frequent complication of advanced non-small cell lung cancer (NSCLC), and denote a poor prognosis. Cytological evaluation of MPEs has a sensitivity of only 40-60%. The CellSearch technology (Janssen Diagnostics, LLC) is an FDA approved method of detecting rare circulating tumor cells (CTCs) in blood. Assessment of pleural fluid samples using CellSearch provides an approach to enrich often undetectable CTCs and phenotype these cells for markers of interest. PD-L1 staining of tumor tissue is essential for determining patient candidacy for checkpoint inhibitor therapy, however, tissue can often be difficult to obtain. Here, we demonstrate the feasibility of applying the CellSearch CTC enrichment platform to measure PD-L1 expression and enumerate tumor cells in MPE of NSCLC patients. Methods: This was a single center, prospective observational study of NSCLC patients with a pleural effusion. The anti-human CD45 (PD-L1) antibody (Biologend) was used as a marker with the CellSearch CXC CTC kit and was detected in the open 4th channel of the CellTracks Analyzer. Determination of CTC PD-L1 expression was validated through peripheral blood spiking experiments. 7.5ml of pleural fluid was collected from NSCLC patients, preserved in CellSave tubes and processed within 72 hours. Identification and enumeration of CTCs was performed using the CellTracks Analyzer. The CellSearch results to conventional cytological analysis. Results: Pleural effusion samples from 66 patients between the ages of 43 and 80 (median =69) were obtained following thoracentesis. The majority of patients were former (40; 60.6%) or never (21; 31.8%) smokers. At the time of effusion, 23 (34.8%) patients were found to have a MPE (median 1798, range: 7 to 114,920) compared to patients with a benign effusion (median 8, range: 0 to 953; p=0.005). In the MPE group, 18 (45.0%) samples demonstrated >10% PD-L1 positivity with 9 (22.5%) samples showing >50% PD-L1 positivity. Conclusion: The CellSearch CTC enumeration and characterization platform can be successfully adapted for detection of CTCs in MPE of NSCLC patients. Our preliminary results suggest this approach may be a useful, non-invasive diagnostic adjunct for the determination of a MPE and assessment of PD-L1 expression in NSCLC patients. In this study, we warranted to determine what role this test could play in assessing patients for checkpoint inhibitor therapy and its relationship with tissue based tests.

#3738 Use of tumor mRNA expression for patient selection in a phase I study of the pan-fibroblast growth factor receptor inhibitor BAY 1163877. Peter Ellinghaus, 1 Matthias Ocker, 1 Sebastian Bender, 1 Christoph Naegele, 1 Stuart Ince, 1 Markus Joerges, 1 Martin Schuler, 1 Bayer AG, Wuppertal, Germany; 2Bayer AG, Berlin, Germany; 3Bayer HealthCare Pharmaceuticals Inc, Whippany, NJ; 4Kantonsspital St. Gallen, Zürich, Switzerland; 5West German Cancer Center, University Hospital Essen, Essen, Germany.

BAY 1163877 is a potent and selective, oral, small molecule pan-FGFR inhibitor with anti-tumor activity in a wide range of cancer types. In vivo profiling in xenograft models identified tumor FGFR mRNA levels as a predictor of drug efficacy. Anti-tumor efficacy was largely independent of the tumor type surveyed or the FGFR isoform being overexpressed. Preclinical models included a patient-derived squamous head and neck cancer (HNSCC) xenograft (PDx) model overexpressing FGFR3 mRNA, a bladder cancer PDx model overexpressing FGFR2 mRNA, and a squamous NSCLC xenograft (PDx) model overexpressing FGFR1 mRNA. Against this background, clinical proof-of-concept was assessed by enrolling patients into the stratified expansion cohort of a Phase 1 study of BAY 1163877 (NCT01976741) based on tumor FGFR1-3 mRNA levels. FGFR1-3 mRNA was quantified in archival or newly obtained FFPE tumor biopsies by RNA in situ hybridization (RNAscope, ACD) and digital transcript counting (NanoString). In total, biopsies from >500 patients were studied for FGFR1-3 mRNA expression. An initial xenograft experiments showing that low to moderate FGFR1-3 mRNA overexpression was not sufficient for a robust drug response, only patients with an RNAscope score of 3 or 4 (range 0-4) or a normalized Nanorstring signal of 800 counts were eligible for enrollment. By applying these stringent criteria, FGFR1-3 mRNA positivity was on average observed with a 2-3 fold higher prevalence than published data for genetic aberrations of FGFRs in the respective tumor types (including amplifications, translocations, mutations). We further identified FGFR mRNA (+) tumor types in which genetic FGFR aberrations have not been previously reported. FGFR1-3 mRNA positivity ranged from 10% in lung adenocarcinoma to 45% in squamous non-small cell lung cancer (sqNSCLC) and 54% in HNSCC. As of August 2016, 57 FGFR mRNA (+) patients were enrolled and treated with BAY 1163877. Six patients were enrolled in a partial cohort (PD) by RULE 500, including an FGFR3 mRNA (+) HNSCC patient without FGFR3 amplification or translocation, an FGFR1 mRNA (+) adenoid cystic carcinoma patient, and an FGFR1 mRNA (+) sqNSCLC patient (both without FGFR1 gene amplification), as well as an FGFR3 mRNA (+) bladder cancer patient without FGFR3 amplification, mutation or translocation. These results suggest that high FGFR1-3 mRNA expression identifies patients sensitive to FGFR inhibition. This population includes patients and without known genetic aberrations of FGFR1-3 encoding genes. In summary, an mRNA expression-based selection approach may identify a broader patient population with potential benefit from BAY 1163877, including tumor types not previously associated with altered FGFR signaling.

#3739 Comparison of technologies for EGFR analysis within a subset of a randomized clinical trial. Mirko Marabese, 1 Massimo Broganni, 1 Martin Reijns, 1 Cedric Gouedard, 1 Geert Maertens, 1 Erwin Sablon, 1 Monica Ganzellini, 1 Marina G. Garassino, 1 Samuel Murray, 1 Mario Negri Inst. for Pharmacol. Research, Milan, Italy; 2Biocartis, Mechelen, Belgium; 3BioPath Innovations SA, Athens, Greece; 4Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy; 5Biomarker Solutions Ltd, London, United Kingdom.

Background: EGFR mutation analysis is laborious often requiring >5 working days and multiple slices of formalin-fixed paraffin-embedded (FFPE) tissue. Idylla™ is a fully integrated, automated molecular diagnostics platform combining speed, ease of use, high sensitivity, multiplexing capabilities, offering sensitive detection of 52 mutations including insertions and deletions in exons 18-21. Methods: We assessed 149 cases from the phase III TAILOR study (Garassino et al, Lancet Oncology 2013;14:981-8), where EGFR was centrally assessed. Relatative concordance between study entry classification to TAILOR (Sanger sequencing, Idylla™ and next generation sequencing (NGS) for EGFR were investigated. Single unprocessed sections were used per Idylla™ and NGS following pathological review. NGS was performed using the Ampliseq™ Colon and Lung Cancer Panel v2 on an Ion Torrent PGM™ (Thermo Fisher) in a reference laboratory; Idylla™ (Biocartis NV) was performed at Biocartis1. Samples and study genotypes were blinded to NGS and Idylla™. Results: There were 132 eligible calls to compare NGS vs Idylla™ (14 fails NGS, 1 Idylla™, 2 both); 108 to compare Sanger vs Idylla™ (38 fails Sanger, 2 Idylla™, 1 both); 101 to compare Sanger vs NGS (31 fails Sanger, 7 NGS, 9 both). For NGS, a minimum coverage of 500 reads was set at a clinically relevant LOD of 5% mutant allelic frequency for calls. Comparison NGS vs Idylla™: 46 EGFR (34.8%) mutation positive by Idylla™ vs 43 (32.6%) by NGS; Sensitivity 93.48%; Specificity 100.00 %. Comparison Sanger vs Idylla™: 41 EGFR (38.0%) mutation positive by Idylla™ vs 38 (35.2%) by Sanger; Sensitivity 85.37%; Specificity 95.52 %. Sanger v NGS: 39 EGFR (38.6%) mutation positive by NGS, 39 (38.6%) by Sanger; Sensitivity 87.18%; Specificity 91.94 %. Of 16 NGS failures 14 were reportable by Idylla™. Conclusions: Idylla™ proved to be a reliable platform for rapid EGFR mutational status evaluation after NGS failure. Compared to NGS, Idylla™ has several advantages: its ease of use, hands on time <5 mins, all-inclusive lyophilized cartridge requiring only one section of 5µm FFPE, restricted secondary manipulation errors in a busy workflow. Positive and Negative predictive values for both Idylla™ and NGS were excellent. Although NGS offers significant additional
clinical data availability through multiplexing, the number of samples classified as inadequate for NGS (14/16 giving result with Idylla”) indicates a likely requirement of more sample robust platforms in diagnostic workflows.

#3740 The pursuit of genetic mechanisms underlying supreme response to pazopanib treatment. Emmanuel Salouistros,1 Helen Latsoudis,2 Despoina Vassou,2 Irene Stratidaki,2 Niki-Antonia Gouvalaki,1 Vasiliki Fadoulouglo,2 Ioannis Drositis,1 Emmanouil Koundopidis,1 Kitty Pavlaki,2 Dimitrios Mavroudis,2 Nikolaos Androulakis,1 Dimitrios Katseopoulos2. General Hospital of Heraklion ‘Venezilo’, Heraklion, Greece; Institute of Molecular Biology and Biotechnology, FORTH, Heraklion, Greece; National and Kapodistrian University of Athens, Athens, Greece; University General Hospital of Heraklion, Heraklion, Greece.

Aim: Studying exceptional responders to standard treatments may provide broader insights into the genetic mechanisms underlying such responses and suggest therapeutic options that weren’t previously apparent. In this study we unravelled the genetic signature of undifferentiated sarcomas in order to disclose the molecular mechanisms that may underlie the patient’s exquisite sensitivity to Pazopanib. Methods: A female patient with massive undifferentiated gynaecological sarcoma experienced a dramatic response to Pazopanib that made debulking surgery possible. We performed whole exome sequencing on DNA isolated from both blood and formalin fixed paraffin-embedded (FFPE) tumour employing Ion Torrent technology. Variant annotation was performed using the Ion ReporterTM v5.0 (MA, USA) tool after application of specific filters. Subsequent curation of annotated data was completed using a combined semi-automated data analyses workflow developed by Minotech Genomics Facility with the implementation of two in house-developed lists regarding 24 pazopanib-related genes, and 96 angiogenesis-associated genes. We also performed targeted sequencing of Ion Ampliseq Comprehensive Cancer panel (CCP) that is strategically designed to interrogate coding DNA sequences and splice variants across 409 tumour suppressor genes and oncogenes. Results: Whole exome sequencing was conducted at 20x coverage for 91.9% and 60.5% of > 10,000 genes for germline and FFPE DNA samples, respectively. Targeted sequencing was conducted at 20x for > 97% of 409 genes of the comprehensive cancer panel. Comparative analyses revealed two variants common in germline and FFPE samples, localized in LTK(p.Val541Ile) and FGFR4 (p.Gly388Arg). Interestingly, examination of the annotated data for biologically plausible mechanisms revealed 2 yet uncharacterized heterozygous variants in two other members of the FGFR family, FGFR2 (c.2183A>G, p.Asn728Ser) and FGFR3 (c.2050G>A, p.Val684Ile) that were present only in the FFPE samples. Even though both variants reside within the catalytic tyrosine kinase domains, they are predicted to exert tolerable effects on the encoded FGFR2 and FGFR3 proteins. Since, Asn728Ser is highly conserved among different kinases of the FGFR family we chose this variant to predict a possible effect on Pazopanib binding. Specifically, protein structure simulation of FGFR2 revealed that asparagine residue at position 728 is located in the external side of the drug binding cavity and is thus predicted to not affect Pazopanib binding. Conclusion: We pursue the possible genetic or somatic modifiers underlying the excessive response to Pazopanib. The detection of two, yet uncharacterised, variants in known Pazopanib targets highlights the potential of next generation sequencing in disclosing the genetic signature of undifferentiated sarcomas in relation to the activity and effectiveness of certain therapeutic agents.

We have recently shown that quantification of Gleason 4 patterns (Q-Gleason) provides strong prognostic information beyond traditional Gleason grade groups (3+3, 3+4, 4+3, 8, 10-10) in prostate cancer, and that the prognostic power of this approach can be further integrated to build the Integrative Quantitative Gleason (IQ-Gleason) score, a continuous value ranging from 0 – 117.5. The current study was undertaken, to determine whether (and how) factoring in molecular markers could further improve the predictive power. We selected deletions of PTEN and 6q (by FISH analysis) as well as DNA ploidy information obtained by flow cytometry as examples for established molecular prognostic markers that provided strong and independent prognostic information in our study cohort of more than 17,000 prostate cancers. A “molecular score” was established for these markers including “penalty” points for presence of deletions/aneuploidy and “bonus” points for lack of deletions/diploid DNA status. Penalty and bonus points were separately determined for each parameter based on differences in the recurrence rate between cancers with and without deletions or aneuploidy. The “penalty” points were then added to the IQ-Gleason score points while the “bonus” points were subtracted from the IQ-Gleason in order to obtain the MIQ-Gleason score. The MIQ-Gleason provided strong prognostic information in univariate analyses when including 3, 5, and 9p in molecular data and including clinical stage, status of the resection margin and status of the resection margin. Comparison of Receiver Operator characteristics (ROS) between the MIQ-Gleason and the quantitative Gleason or classical Gleason revealed only a slight increase of the prognostic power for the MIQ-Gleason (AUC=0.781) as compared to the IQ-Gleason (AUC=0.771), while a massive difference was found as compared to the classical Gleason grade groups (AUC=0.719). In summary, our data demonstrate the power of quantitative Gleason scoring strategies as compared to classical Gleason grade groups. That adding selected molecular features improved predictive power only slightly demonstrates how difficult it is for molecular markers to compete with optimized morphological grading systems. However, the use of more and better molecular testing may provide further improvement beyond quantitative Gleason scoring.

#3742 Exposure burden for patients during an experimental study using a dual-energy contrast-enhanced spectral mammography. Kamila Rawojc,1 Ka-mil Kisielewicz,2 Anna Dziechciowicz,3 Monika Tomaszuk,2 Anna Cegi,2 Jankowska Anna,2 Cieśa Izabela,2 Najberg Dominika,2 Luczynska Elzieta,2 Bartosz Kietycha,3 The University Hospital, Krakow, Poland; Maria Sklodowska – Curie Memorial Cancer Center and Institute of Oncology, Krakow, Poland; M. Smoluchowska Institute of Physics, Jagiellonian University, Krakow, Poland.

Mammography provides early micro-calciﬁcation recognition, that is important for further breast cancer (BC) diagnosis. Imaging choice for BC detection is X-ray mammography (MG) with the use of high-resolution digital modality combined with iodinated contrast agents. However, a conventional MG has some sensitivity limitations, especially in patients with densely treated breasts. Moreover, MG contributes radiation risk for BC that is correlated with an exposure to ionizing radiation. Patients, for whom MG study does not give a clear interpretation are often further diagnosed by contrast-enhanced breast MRI, the most sensitive BC detection technique. Alternatively, it is limited by higher costs, lower availability and increased false positives. Dual-energy contrast-enhanced spectral mammography (CESM) is a new method applied in BC that enables accurate detection of malignant breast lesions similar to breast MRI. The aim of this study was to compare the usefulness of CESM versus MG in BC detection. Additionally, doses given to the BC patients during imaging were compared. In this study, 250 consecutive women (144 MG vs. 105 CESM), that were screened mammography between 2011 and 2014 were retrospectively enrolled in the study. The comparison of entrance surface air kerma and mean glandular dose values for both options were recorded, respectively and analyzed using different statistical and retrospective approach. Results of presented study showed that CESM might be a new diagnostic tool allowing an accurate detection of BC lesions, giving results similar to those received from magnetic resonance imaging. A good agreement found between sensitivity of the method and tumour diameters measurements based on CESM, supports this method as a useful tool as a potential replacement for breast MRI in the preoperative evaluation of BC patients. However, a radiation burden for patients might be signiﬁcantly higher than that for a standard full-ﬁeld digital mammography procedure. In summary, each method has its own benefits with respect to specific applications that are further discussed in the study.

Background: Neoadjuvant chemotherapy (NAC) is widely performed for patients with locally advanced breast carcinomas. It is important to obtain precise information using imaging modalities about the distribution of residual carcinomas after NAC to predict the success of breast conserving surgery. However, the relationship between magnetic resonance imaging (MRI) shrinkage patterns and molecular subtypes of breast carcinomas has not yet been investigated. Methods: We analyzed the MRI shrinkage and pathological patterns of residual carcinomas after NAC in 54 consecutive breast carcinomas. The shrinkage patterns were classified into five categories: Type I and II (concentric shrinkage with or without any surrounding
lesion), type II (shrinkage with residual multinodular lesions), type IV (diffuse contrast enhancement in the entire quadrant), and non-visualization. Results: The most common MRI shrinkage pattern was type I (39%) followed by non-visualization (28%). The most common pathological shrinkage pattern was type III (33%), followed by type II (28%) and non-visualization (22%). The concordance rates of the MRI patterns of non-visualization and type I were significantly lower than those of the MRI patterns of type II, III, and IV (p = 0.018). Moreover, in the luminal subtypes, the concordance rates of the MRI patterns of non-visualization and type I were significantly lower than those of the MRI patterns of type II, III, and IV (p = 0.026); however, in the non-luminal subtypes, this correlation was not significant. Conclusions: The results of the present study suggest that the cases with MRI shrinkage patterns of non-visualization and type I require caution regarding the surgical margins compared with the other types, especially the luminal subtypes.

Introduction: Since the association between certain oncogenic (high-risk) strains of HPV and cervical cancer is well established. Searching for HPV became a basic step in all screening programs. Laboratory HPV testing is costly and unavailable in developing countries. Objective: To compare the diagnostic indices of office cervicoscopy against cytology and punch biopsy for detection of underlying HPV lesions in women with suspicious cervix. Design: An analytic cross-sectional research design Setting: Early cervical cancer Detection Unit of the Women’s Health University Hospital, Assiut, Egypt. Patients and methods: A total of 274 non-pregnant women with clinical diagnosis of suspicious cervix were included in this study. After cervical smearing with Ayre’s spatula, they were subjected to cervicoscopy utilizing 2.6 mm telescope and a 3.2 mm outer sheath office hysteroscope. Evaluation of the vulva, vagina, ectocervix, endocervical canal and the endometrial cavity were done. The cervix was then painted with saline, acetic acid and Schiller’s iodine stains successively as used during colposcopic examination. Abnormal lesions were biopsied using punch biopsy forceps. Cytologic evaluation relied on both classic and non-classic (secondary) criteria for the diagnosis of HPV including ‘mild koilocytosis,’ ‘mild dyskeratosis,’ ‘hyperchromatic nuclei,’ bi- and multinucleation, and cleared cytoplasm. Punch biopsies were taken from every case based on cervicoscopic localization after staining. Results: The main complaint was abnormal vaginal discharge in 197 cases (71.4%). Pap smear sampling was negative for HPV in 188 cases (68.6%) and positive in 86 cases (31.4%). Cervicoscopic findings suggestive of HPV infection were positive in 77 cases (28.1%) and negative in 197 cases (71.9%). Gold stand histopathology diagnosed HPV in 53 cases only (19.3%). All diagnostic indices of cervicoscopy significantly improved after combination with cytology positive results except false positive results. Conclusions: Cervicoscopy as a simple, cheap and office procedure can be used as a quick screening tool of HPV infection in women with suspicious cervix. It has the advantage of screening of the rest of the genital tract. In the absence of laboratory HPV testing, cervicoscopy in conjunction with cytology screening of high-risk cases should be encouraged.

#3746 Plasma membrane spanning and linker-domains from tumor necrosis factor superfamily (TNFRSF) proteins provide novel functionality to chimeric antigen receptors (CARs) expressed in human T cells. Dina Schneider, Ying Xiong, Darong Wu, BoroDropulic, Rimas Orentas. Lentin Technology Inc., a Millen biotech Company, Gaithersburg, MD.

Chimeric antigen receptor T cells redirected to the B cell antigen CD19 (CAR19) have shown efficacy in the treatment of B-lineage acute lymphoblastic leukemia, and are being evaluated in other hematologic malignancies as well. The prevalent configuration of CAR19 for clinical application is comprised of the extracellular single chain targeting domain (scFv) derived from the FMC63 antibody, a CD8 linker and transmembrane domain, a CD137 signaling domain, and a CD3-zeta signaling domain. Transmembrane domains from other immunologically-active proteins, including CD3, CD28, or CD4, and spacer domains from IgG have been employed as structural components of CARs as well. The relationship between the composition of the CAR linker and transmembrane domain and CAR T function is, however, poorly understood. We hypothesized that CAR transmembrane and linker domains derived from proteins of the tumor necrosis factor receptor superfamily (TNFRSF), whose expression is associated with normal T cell functions, may optimize the anti-tumor activity of CAR19. Therefore, primary human T cells were transduced with lentiviral expression vectors (LV) expressing new combinations of linker and transmembrane sequences encoded by various TNFRSF members. As one of the CAR transmembrane domains, CD19 was chosen, and the CAR T function was examined by engaging Raji cells (a Burkitt’s lymphoma line) in an NSG leukemia mouse model. On the other hand, the transmembrane domain derived from TNFRSF16/LANGFR, a low affinity neurotrophin receptor, created a CAR19 construct that had no functional activity either in vitro or in vivo, despite high levels of surface CAR expression in human T cells. In conclusion, the magnitude of CAR T response can be enhanced by the use of novel linker and transmembrane domains derived from TNFRSF proteins, such as TNFRSF16. Thus, the transmembrane domain can play a determining role in CAR T function beyond a direct topographical connection between the extracellular and the intracellular domains of the chimeric protein. Studies are underway to elucidate the mechanistic role of TNFRSF-derived linker and transmembrane domains in CAR T function.
#3747 msa2 biotin-binding CAR combined with biotynilated tumor-specifie antibodies or DNA aptamers for universal cancer immunotherapy. 

Jason L. Lohmueller,1 James D. Ham,2 Olivia J. Finn,3 University of Pittsburgh School of Medicine, Pittsburgh, PA; 2Carnegie Mellon University, Pittsburgh, PA.

Chimeric antigen receptor T cells (CAR-Ts) are highly promising as cancer therapeutics, but the creation of CARs for new antigens remains a laborious process. As an alternative strategy researchers are designing universal “tag-CARs” that instead of directly recognizing tumor antigens, recognize tags on tumor-specific antibodies bound to tumor cells, thereby activating T cell effector functions. Here we report the creation of a novel tag-CAR that uses the high-affinity monomeric streptavidin 2 (msa2) biotin binding domain to target cancer cells labeled with biotynilated tumor-specific antibodies or DNA aptamers. We constructed lentiviral vectors encoding msa2 CARs with three different signaling architectures - CD28-zeta, CD28-OX40-zeta, and 4-1BB-zeta. After confirming that each msa2 CAR was efficiently expressed on the surface of Jurkat and primary human T cells, we found that plate-immobilized biotin was capable of specifically inducing T cell activation markers and cytokine production. We then stained a variety of cancer cell lines with various tumor-specific biotynilated antibodies or DNA aptamers targeting tumor antigens such as MUC1, CD19, CD20, and EGFR and found that the stained cells specifically activated the msa2-CAR cells and led to cytokine production. We are currently investigating the ability of msa2-CAR cells to lyse antibody and aptamer-bound cancer cells and will be assessing their ability to shrink tumors in a human tumor xenograft mouse model.

#3748 Development of anti-human mesothelin chimeric antigen receptor (CAR) messenger RNA (mRNA) transfected peripheral blood mononuclear cells (CARMA) for the treatment of mesothelin-expressing cancers. 

Chien-Fu Hung,1 Xuequn Xu,1 Linhong Li,2 Ying Ma,1 Qiu Jin,1 Angelia Viley,2 Cornell Allen,2 Pachai Natarajan,2 Madhusudan V. Peshwa,2 Leisha E. Enzens,2 Johns Hopkins University, Baltimore, MD; 2MaxCyte, Inc., Gaithersburg, MD; 3Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins University, Baltimore, MD.

CD19-targeted chimeric antigen receptor (CAR)-engineered T/NK-cell therapies can result in durable clinical responses in B-cell malignancies. However, CAR-based immunotherapies have been less successful in solid cancers. This is partly due to specificity for shared tumor antigens also present on normal host tissues that leads to ‘on-target/off-tumor’ toxicity. We therefore developed a non-viral approach using repeated infusions of mesothelin-specific messenger RNA (mRNA) CAR-transfected T cells to permit prospective control of ‘on-target/off-tumor’ toxicity. Early trials provided preliminary evidence of the safety and anti-tumor activity of this strategy, but the ex vivo selection, activation and expansion of lymphocytes is laborious and expensive. We therefore explored the feasibility of using a rapid, automated, closed system for GMP-compliant mRNA CAR transfection into freshly isolated peripheral blood mononuclear cells for clinical scale manufacture (CARMA). The resulting cryopreserved cellular product expressed CAR in >95% of cells, and recognized and lysed tumor cells in an antigen-specific manner. Expression of CAR was detectable for 5-7 days in vitro, with a progressive decline of CAR expression related to in vivo antigen content in murine ovarian cancer model, wherein high affinity monomeric streptavidin (IP) injection of CARMA resulted in the dose-dependent inhibition of tumor growth and prolonged the overall survival (OS) of mice. Multiple weekly IP injections of the optimal CARMA dose enhanced disease control and further prolonged OS, both of which improved with an increasing number of injections. No significant off-tumor toxicities were observed. These data support further investigation of a serial IP CARMA administration as a potential treatment for ovarian cancer and other mesothelin-expressing tumors involving the peritoneum, and provide preclinical proof of principle of CARMA for solid tumors.

#3749 Genetic blockade of the protein tyrosine phosphatase SHP1 augments CAR T cell activity against PDL1 expressing solid tumors. 

Edmund Moon, Soyeon Kim, Naomi Saint Jean, Shaun O’Brien, Steven Macekyo, Jing Sun, Karl June, Steven Albeda. Univ. of Pennsylvania, Philadelphia, PA.

Background: Immunotherapy using chimeric antigen receptor (CAR) T cells has demonstrated profound, durable success in hematologic malignancies. Solid tumors present hurdles to the successful application of CAR T cells. One is the upregulation of inhibitory receptors (IRs), like PD1 and CTLA4, many of which rely on shared signaling molecules to shut off T cell activation. One such molecule is SHP1 (Src homology region 2 domain-containing phosphatase-1) which dephosphorylates key components of T cell receptor (TCR) signaling. We have engineered a unique dominant-negative SHP1 (dnSHP1) that is able to augment CAR T cell control of PDL1 positive solid tumors. Materials and Methods: The human mesothelioma cell line, EMP, was transduced to express high levels of mesothelin and PDL1 (EMMESO-PDL1). Activated human T cells from healthy donors were lentivirally transduced to express a mesothelin-directed CAR (mesoCAR) with and without a dnSHP1. MesoCAR and mesoCAR/dnSHP1 T cells were cocultured with tumor cells x 18hrs and specific lysis was measured. These T cells were also restimulated with plate-bound anti-CD3 overnight and were subjected to intracellular flow cytometry staining (ICS) of cytokines. NSG mice were injected subcutaneously in the flanks with 5x10^6 EMMESO-PDL1 tumor cells. After tumors established and grew to ~150mm^3, mice were randomly assigned to one of the following treatments: 1) non-transduced (NDT) T cells, 2) mesoCAR T cells, 3) mesoCAR T cells + sodium stibogluconate (SSG; a chemical inhibitor of SHP1), 4) mesoCAR/dnSHP1 T cells. T cells were injected IV once at a dose of 10x10^7 T cells/mouse. SSG was administered IM at 20mg/kg every 2 days throughout tumor growth. At the end of the study, mice were sacrificed, tumors were harvested, digested, processed into single cell suspension, and subjected to flow cytometry analysis. The tumor infiltrating lymphocytes (TILs) were also isolated and tested for function ex-vivo. Results/Conclusion: In vitro, mesoCAR T cells demonstrated suppressed lysis of EMMESO-PDL1 tumor cells compared to EMMESO cells. MesoCAR/dnSHP1 T cells were able to lyse EMMESO-PDL1 and EMMESO tumor cells with similar efficiency. Anti-CD3 restimulation of T cells revealed enhanced secretion of TNF-alpha and IL2 by mesoCAR/dnSHP1 vs. mesoCAR T cells as measured by ICS. In vivo, SSG injections had minimal impact on mesoCAR T cell control of tumors, whereas mesoCAR/dnSHP1 T cells demonstrated significantly enhanced control of EMMESO-PDL1 tumor growth compared to mesoCAR T cells (60% greater decrease in tumor volume compared to mesoCAR T cells). Tumor regression was attributed to dnSHP1 TILs that were isolated and subjected to flow cytometry analysis. The tumor infiltrating lymphocytes (TILs) were a powerful and novel way of blocking the suppression of CAR T cells by PD1 and other similar IRs.

#3750 Micromolar affinity CAR T cells to ICAM-1 achieves rapid tumor elimination while avoiding systemic toxicity. 

Enda Shevlin, Spencer Park, Yo-gindra Vedvyas, Marjan Zaman, Susan Park, Irene M. Min, Moonsoo M. Jin. Weill Cornell Medicine, New York, NY.

Introduction: Adoptive immune therapy has achieved great success in eradicating blood-borne cancers, prominently, the CD19 CAR T cells in B cell leukemia and lymphomas. However, CAR T cell therapy in solid tumors has been limited due to the scarcity of tumor antigens that are deemed safe for targeting. One strategy to overcome scarcity of tumor antigen is by tuning the affinity of CAR to limit T cell reaction with cells overexpressing target antigen while sparing cells with basal level expression. To rigorously test the idea of “affinity tuning”, we built variants of CARs possessing one million-fold difference in affinity spanning low nanomolar to high micromolar affinity to a target antigen, and examined the influence of CAR affinity on the rate of tumor killing and systemic toxicity. Methods: Antigen-binding domain of CAR was built from the inserted or 1 domain belonging to integrin LFA-1. Affinity of CAR expressed in T cells was confirmed by ICAM-1 binding by flow cytometry. For in vivo study, mice with systemic growth of ICAM-1 positive thyroïd tumor were used, where tumors grew in lungs, liver, and bones. Tumor growth and killing were monitored by whole body luminescence imaging. Sera were collected for cytokine analysis. Body weight, cytokine profile, and overall behavior were used to assess the severity of systemic toxicity. Results: CAR T cells with a step-wise, one million-fold variation in affinity to ICAM-1 resulted in a rate of target killing in proportion to the increase in affinity and in ICAM-1 density. Owing to cross-reaction of human LFA-1 with murine ICAM-1, the influence of CAR affinity on efficacy and on-target, off-tumor toxicity was tested in mice bearing ICAM-1 positive human tumors. In vivo tumor elimination by CAR T cells was in contrast to in vitro affinity-dependent rate of target killing, demonstrating that micromolar affinity CAR T cells was superior to nanomolar affinity T cells in both tumor killing and safety aspects. Highest affinity CAR T cells led to uniform death of the host, caused by on-target, off-tumor toxicity, and high level cytokine release. Conclusion: Our study is the first comprehensive report examining the effect of CAR affinity on the rate of tumor killing, efficacy, and toxicity. In contrast to in vitro tumor killing effect, the increase in affinity of CAR beyond certain threshold was deleterious to T cell persistence and associated with more frequent tumor relapse. Our study highlights that CAR T cells expressing natural T cell receptor affinity is more efficacious in eliminating tumors with overexpressed antigens, and is safer by avoiding potential reaction with normal cells with basal expression of the same antigen.

#3751 Allogeneic EGRFvIII chimeric antigen receptor T cells for treatment of glioblastoma.

CLINICAL RESEARCH: Innate Effectors in Immunity to Cancer

Proceedings of the American Association for Cancer Research. ● Volume 58 ● April 2017 957
Glioblastoma multiforme (GBM) is a highly aggressive form of brain tumors with a 5-year survival rate of less than 10%. Standard-of-care combining radiation therapy with temozolomide only yields a median survival of 14.6 months and more effective therapeutic options to extend patient lives are urgently needed. EGFR variant III (EGFRvIII) is a tumor specific mutant of EGFR found in 25-30% of GBM but not in normal tissue. The structure of EGFRvIII has been shown to drive the growth and survival of glioblastoma cells and be a potential target for therapies. However, clinical trials using anti-EGFRvIII antibodies have yielded disappointing results. Our group has identified a tumor-associated MMP1-derived peptide in an HLA-A*02 context by exploiting the knowledge of tumor and healthy tissue immunopeptidomes. By this approach, MMP1-003, an HLA-A*02/MMP1-003 complex was identified as a promising therapeutic target presented by several tumor types, including colorectal and lung cancer, but absent on normal tissues. These findings are underlined by RNAseq analysis of the source antigen which also points to MMP1 being a highly attractive tumor-associated target. Consequently, a fully human antibody phage display library was screened to identify highly specific candidate monoclonal antibodies. The lead TandAb showed excellent target specificity across a wide range of peptide-pulsed and endogenously expressing cell lines as well as potent cytotoxicity with picomolar EC50. In summary, we have developed a combinatorial tumor recognition system, diminshed-off-tumor cytotoxicity, and multifaceted effector function make natural killer (NK) cells a prime candidate for a universal approach to cancer immunotherapy. In addition, NK cells are the principal mediator of antibody-directed cellular cytotoxicity (ADCC). However, NK cell function is often impaired in the setting of cancer, reducing the effectiveness of the endogenous immune system and the therapeutic efficacy of monoclonal antibodies. To address the need for advanced combinatorial cancer therapies, we developed a unique and effective strategy to create a renewable source of engineered “off-the-shelf” NK cells with augmented function, including enhanced ADC and persistence. Key challenges associated with genetic editing, limited expansion, persistence and variability of peripheral blood (PB)-derived NK cells were overcome by utilizing our induced pluripotent stem cell (iPSC) technology as the unlimited starting material for the reproducible and consistent derivation of engineered NK cells. Through targeted transgene integration, we produced a clonal iPSC master cell line to continuously produce NK cells engineered to uniformly express a high affinity, non-cleavable version of CD16 (hCD16-NK). In directed differentiation, the hCD16-NK cells displayed homogeneous expression of CD16.
type CD8+ T cells. Patient #2 received up to 8.2x10^6/kg HLA-A*02:01 donor derived and patient #3 up to 6x10^6/kg autologous allorestricted TCR transgenic CD8+ T cells. All patients were treated with the same TCR complementary determining region 3 allorecognition sequence for CHM1. Results: HLA-A*02:01/CHM1 specific allorestricted CD8+ T cells showed specific in vitro lysis of ES cells. Therapy was well tolerated and did not cause graft versus host disease (GVHD). Patients #1 and #3 showed slow progression, whereas patient #2, while having BM involvement, showed partial metastatic regression associated with T cell homing to involved lesions. CHM1/TCR transgenic T cells could be tracked in his BM for weeks. Conclusions: CHM1/TCR transgenic T cells home to affected BM and may cause partial disease regression. HLA-A*02:01/CHM1specific allorestricted T cells proliferate in vivo without causing GVHD.

#3758 The efficacy of CD133 BiTEs and CAR-T cells in preclinical model of glioblastoma. #3759 PiggyBac-manufactured anti-BCMA Centyrin-based CAR-T therapeutic exhibits improved potency and durability. David Hermanson,1 Bur-}

cal data presented herein highlight the therapeutic value of hCD16-iNK cells as an ideal ADCCC-mediated “off-the-shelf” NK cell-based immunotherapeutic product with augmented persistence, anti-tumor capacity, manufacturing reliability and preclinical efficacy.

#3756 Efficient generation of CAR T cells by site-specific gene addition into the TRAC locus. Baekseung Lee,1 Wai-Hang Leung,1 Mark Gordon,1 Jordan Jarjour,1 Alexander Astrakhan,1 bluebird bio, Seattle, WA.

Genetically engineered T cells represent a promising new approach to the treatment of cancer. Positive results in recent clinical trials exploiting T cells engineered to express chimeric antigen receptors (CARs) have highlighted the potential for these cells to be translated into therapies in patients with B cell malignancies. To extend these successes to a broader range of tumor types may require additional CAR T cell engineering beyond simple CAR addition, such as gene knockout and/or coupling deletion of a target gene with site-specific addition of a CAR transgene. To this end, we have developed a genome editing strategy for the simultaneous elimination of an endogenous target gene with site-specific addition of a CAR via homology-directed repair (HDR). To demonstrate the utility of this approach, we used a previously characterized megaTAL (an engineered nuclease created by the fusion of an engineered meganuclease and a transcription activator like (TAL) -DNA binding domain) specific for the T cell receptor alpha constant region gene (TRAC). Delivery of this megaTAL to primary human T cells via mRNA electroporation results in efficient and specific disruption of the TRAC locus (Boiselle et al, 2013). To achieve simultaneous target gene disruption with site-specific CAR transgene insertion, we designed an adeno-associated virus (AAV) vector for DNA template delivery encoding the CAR and flanked by regions of DNA homologous to the genome immediately surrounding the megaTAL cleavage site. Co-delivery of the megaTAL and AAV encoding a CD19-CAR with TRAC homology arms resulted in >50% CAR + TRAC- cells. In vitro assays of cytotoxicity and cytokine responses against CD19+ Nalm-6 cells confirmed that TRAC-targeted CAR-T cells were comparable to CD19-CAR-T cells generated by lentiviral transduction. Interestingly, a similar level of CAR expression was observed even though CAR-T cells expressed lower amounts of the CAR, as determined by flow cytometry. Similar CAR integration efficiency and functional efficacy was observed using a TRAC-targeting AAV vector containing a distinct B cell maturation antigen (BCMA)-specific CAR. These findings demonstrate megaTAL-mediated targeted gene addition as a feasible, efficient, and potentially safer approach for generation of gene-edited CAR T cell product. Moreover, the ability to combine the disruption of a target gene with the site-specific integration of the CAR eliminates the need for randomly integrating viral vectors while satisfying the potential need for more complex genome-edited T cell products.

#3757 Ewing Sarcoma regression by Allo-MHC/Chm1 specific T cells without GVHD. Uwe Thiel,1 Sebastian Schober,1 ingo Einspieler,1 Andreas Marquardt,1 Uwe Thiel,1 Alexander Astrakhan,1 bluebird bio, Seattle, WA.

Globoloblastoma (GBM) is a uniformly fatal primary brain tumor, characterized by a diverse cellular phenotype and genetic heterogeneity. Despite the use of multi-modal treatment including surgical resection, radiotherapy and chemotherapy, the outcome of patients with GBM remains poor. Numerous studies have implicated CD133 as a marker for the tumor initiating population in GBM. However, therapeutic strategies that specifically target CD133 have not yet been developed for recurrent GBM. Using a novel methodologic that combines use of phase-displayed synthetic antibody libraries and DNA sequencing, we developed the CD133-specific monoclonal antibody ‘RW03’. We constructed CD133-specific BiTEs that consist of two arms; one arm recognizes the tumor antigen (CD133) while the second is specific to CD3 antigen. The dual binding specificity was confirmed using flow cytometry. Using CD133high and CD133low primary GBM lines, we validated the binding of BiTEs to CD133+ cells. Further analysis showed binding of BiTEs to human T cells known to express CD3 within a population of healthy donor peripheral blood mononuclear cells. We observed BiTEs redirecting T cells to kill GBMs, with greater efficiency observed in CD133high GBMs, validating BiTe target specificity. Incubating T-cells with BiTEs and the CD133high GBMs resulted in increased expression of T cell activation markers. In parallel, we derived the single chain variable fragment (scFv) from previously generated RW03 and generated a second-generation CAR. Anti-CD133 scFv with a myc tag was cloned in frame with a human CD8 leader sequence, CD8a transmembrane domain, CD28, and hCD3 γ signaling tail in the lentiviral construct pCCL-ΔNGFR. Following lentiviral packaging, the T cells isolated from PBMCs were transduced with all patatred or unique CAR constructs. Using mice expressing a humanized BM microenvironment, we observed extended survival in mice and significant reductions in brain tumor burden. The results of this study will establish a translational research program that will form the basis of early phase clinical trials of a promising CD133-based therapeutic strategy for patients with GBM.
BCMA-specific Centryrin rather than a single chain variable fragment (scFv) for antigen detection and is engineered using piggyBac (PB). Centryrins are fully human and have similar binding affinities but are smaller, more thermostable and predicted to be less immunogenic than a scFv. Furthermore, PB modification of human T cells requires only in vitro transcribed mRNA and plasmid DNA, eliminating the need for lentiviral packaging and resulting in the increased cargo capacity of PB permits the incorporation of a safety switch and a selectable gene into the product. The former is incorporated for optional depletion of the increased cargo capacity of PB permits the incorporation of a safety switch and a selectable gene into the product. The former is incorporated for optional depletion

The latter allows enrichment of CARTyrin + cells using the non-genotoxic drug methotrexate (MTX), leading to greater consistency in patient product material. Characterization of P-BCMA-101 revealed >70% of cells possessed memory phenotype (CD45RA- CD95+) and >95% of the cells were CARTyrin +. In addition, no tonic signaling or T cell exhaustion was observed, highlighted by low levels of PD-1, Lag3, and Tim-3. Cells exhibit specific and robust in vitro target-cell killing, cytokine production, and proliferation in response to BCMA + tumor cells. In vivo anti-tumor efficacy of P-BCMA-101 has been evaluated in NSG mice bearing luciferase + MM-1S cells, an aggressive human MM-derived cell line, monitoring tumor growth by bioluminescence imaging (BLI). Following tumor implantation, animals received a single IV administration of either 4 x 10 6 or 12 x 10 6 P-BCMA-101 cells. All untreated control animals succumbed to disease within four weeks of the treatment date. Conversely, tumor burden was reduced to the limit of detection by BLI within 7 days of P-BCMA-101 treatment. As opposed to lentivirus-based products in the same animal model, PB modification of human T cells is non-toxic, but leaves endogenous and exogenous antigens from the CAR transduction and ongoing immune responses. Finally, the effectiveness of the safety switch has been demonstrated both in vitro and in vivo. P-BCMA-101 is the first-in-class of Centryrin-based CAR therapeutics modified using PB and is predicted to have improved potency and durability given the phenotype and non-immunogenic properties of Centryrins. We plan to initiate a phase I clinical trial of P-BCMA-101 for the treatment of patients with relapsed and/or refractory MM.

#3760 Preclinical optimization of a low cost PiggyBac transposase (PB) generated CD19-specific chimeric antigen receptor T cell (CART19) product for a first in man trial using local hospital cell manufacture. David Bishop,1 Ning Xu,2 Sylvie Shen,2 Tracey O’Brien,2 David Gottlieb,1 Alla Dolnikov,2 Ken- neth Micklethwaite1. 1Westmead Institute for Medical Research, Sydney, Australia; 2Children’s Cancer Institute, Sydney, Australia.

BACKGROUND: CAR T cells show remarkable efficacy against relapsed/refractory B cell malignancies. PiggyBac offers a less complex and more cost effective means for generating CAR T cells compared to viral vectors typically used, so we aimed to use PiggyBac to generate a product suitable for translation to the clinic. METHODS: CAR T cells utilizing the CAR1928z construct have been found to perform well in vivo in preclinical models; however, these tumors often relapse and prolong survival, with most animals surviving 100 days post-tumor implant. Finally, the effectiveness of the safety switch has been demonstrated both in vitro and in vivo. P-BCMA-101 is the first-in-class of Centryrin-based CAR therapeutics modified using PB and is predicted to have improved potency and durability given the phenotype and non-immunogenic properties of Centryrins. We plan to initiate a phase I clinical trial of P-BCMA-101 for the treatment of patients with relapsed and/or refractory MM.

#3761 Specific and dynamic tumor antigen-specific immune responses were elicited in patients with hepatocellular carcinoma after cell-based immunotherapy. Yanyan Han,1 Ye Wu,2 Chou Yang3, Jing Huang,1 Yabin Guo,1 Li Liu,1 Ping Chen,1 Dongyun Wu,4 Junyun Liu,1 Jin Li,1 Xiangjun Zhou,1 Jinlin Hou2. 1HRYZ Biotech Co., Shenzhen, China; 2State Key Laboratory of Organ Failure Research, Guangdong Provincial Key Laboratory of Viral Hepatitis Research, Department of Infectious Diseases, Nanfang Hospital, Southern Medical University, Guangzhou, China.

Hepatocellular carcinoma (HCC) is one of the most common cancers in China and frequently occurs with chronic hepatitis B virus (HBV) infection. To investigate whether cell-based cancer immunotherapy induces tumor specific immune responses in patients with HCC and provides clinical benefits, as well as to elucidate the most immunogenic tumor associated antigens (TAAs), multiple antigen stimulating cellular therapy (MACST) was applied in addition to standard of care. Mature dendritic cells (DCs) and activated T cells prepared for MACST were generated from autologous peripheral blood mononuclear cells (PBMCs). DCs were loaded with a peptide pool of multiple HCC-related tumor antigens, and T cells were stimulated by these DCs. Thirteen patients with HCC received repeated MACST after tumor resection during which their immune responses were examined. After three courses of MACST, the frequency of regulatory T cells in the patients’ PBMCs significantly decreased (p < 0.001), while the antigen peptide pool-triggered T cell proliferation (p < 0.001) and IFNγ production (p = 0.001) were significantly enhanced. The specific T cell responses against each antigen in the pool were detected in five patients. Ane sex-specific and pattern recognition. The most immunogenic TAA for HCC are survivin, CCND1, and RGS5. Moreover, the antigen-specific immune responses observed in tumor-free patients’ PBMCs were significantly stronger than that in the patients with recurrence (p = 0.037). Conclusion: Our study demonstrates that MACST is well-tolerated by patients with HCC and elicits strong and dynamic immune responses specifically against multiple tumor associated antigens, which may correlate with clinical outcomes.

#3762 Superior T cell activity of a membrane-proximal binding antibody when targeting Glypican-3 with an antibody-coupled T cell receptor (ACTR) armed T cell. Greg Motz,1 John Shin,1 Kathleen Whiteman,1 Birgit Schultes,1 Tapasya Pai,1 Lori Westendorf,2 Seth Ettenberg,1 Travis Biechele,1 Diego Sussman,1 Heather Huett1. 1Unum Therapeutics, Cambridge, MA; 2Seattle Genetics, Bothell, WA.

Glypican-3 (GPC3) is a GPI-anchored member of the heparan sulfate proteoglycan family. GPC3 is an oncofetal antigen expressed transiently during fetal development with re-expression during malignant transformation. GPC3 is an ideal tumor target as expression has been found in numerous epithelial malignancies, with high-expression in hepatocellular carcinoma (HCC) and non-small cell lung carci- noma (NSCLC), and normal tissue expression is highly restricted (Baumhoer D, Am J Clin Pathol, 2008.). Adoptive T cell therapy with single-chain variable fragment (scFv)-derived chimeric antigen receptors (CARs) has transformed cancer therapy, but the broad applicability of this approach has been limited in part by safety concerns due to the constitutive expression of a biologically active targeting receptor. The Antibody-Coupled T cell Receptor (ACTR) platform is a universal, engineered T cell therapy designed to engage the Fc domain of therapeutic antibodies specific to tumor cells to provide T cell-selective tumor killing. The ACTR is therefore both regulatable and flexible, providing enhanced therapeutic control and improved safety of the T cell therapy. Using both HCC and NSCLC tumor cell lines, we tested a panel of wild-type and fucosylated antibodies with similar binding affinities that bound to regions spanning the GPC3 protein across unique epitopes. We found that for GPC3 targeting antibodies, the greatest activity in a Jurkat-NFAT reporter assay was observed for the fucosylated antibody that bound GPC3 most proximal to the membrane. Further, the antibody that bound membrane proximal also had the most potent activity in primary ACTR T cell cytotoxicity and cytokine release assays. The physical distance between T cells and tumor targets has been previously determined to impact T cell activation for both peptide-MHC and CAR-T interaction. Similarly, our results demonstrate a potential relationship between spatial distance of tumor targets and T cells in determining the activity ACTR transduced T cells when targeting GPC3. Our data demonstrate that ACTR T cell activity is antibody-specific and dose-irratable, highlighting both efficacy and improved safety of the ACTR T cell platform when targeting GPC3+ solid tumor malignancies.

#3763 UCART22: autologous adoptive immunotherapy of leukemia by targeting CD22 with CAR T-cells. Agnès Gouble,1 Cécile Schiffer-Mannioui,1 Severine Thomas,1 Anne-Sophie Gautron,1 Laurent Poirot,2 Julianne Smith2. 1Institut Curie, Paris, France; 2Collectis, Paris, France; 3Collectis, New York, NY.

Adoptive immunotherapy using autologous T-cells endowed with chimeric an- tigen receptors (CARs) has given rise to long-term durable remissions and remark- able objective response rates in patients with refractory leukemia, raising hopes that

CLINICAL RESEARCH: Innate Effectors in Immunity to Cancer

Proceedings of the American Association for Cancer Research • Volume 58 • April 2017

960
a wider application of CAR technology may lead to a new paradigm in cancer treatment. However, a limitation of the current autologous approach is that CAR T-cells must be manufactured on a ‘per patient basis’. To overcome this limitation, we have developed a standardized platform for manufacturing T-cells from third-party healthy donors to generate allogeneic ‘off-the-shelf’ engineered CAR T-cell-based products. Our allogeneic platform utilizes the Transcription Activator-Like Effector Nuclease (TALEN) gene editing technology to inactivate the TCRα constant (TRAC) gene, significantly reducing the potential for T-cells bearing allogeneic TCRs to mediate Graft-versus-Host Disease (GvHD). We have previously demonstrated the precise and efficient disruption of the TRAC gene by gene editing, yielding up to 85% of TCRαβ-negative cells. This allows the production of TCRαβ-deficient T-cells that no longer mediate allograft activity in a xenogeneic mouse model. In the clinic, the proof of concept of the applicability of our allogeneic platform was achieved with early compassionate use for patients treated with UCART19, an allogeneic engineered CAR T-cell product directed against CD19. UCART19 clinical trials are currently ongoing. Here, we have developed T-cells targeting CD22 which is expressed on tumor cells from the majority of patients with B-cells leukemia. In a first step, we have screened multiple antigen recognition domains in the context of different CAR architectures to identify effective CAR candidates displaying activity against cells expressing variable levels of the CD22 antigen. As a safety feature, T-cells are engineered to co-express a depletion gene, rendering them sensitive to the monoclonal antibody rituximab. Several constructs of depletion genes have been evaluated in the context of the CD22 CAR. In addition, experiments in an orthotopic ALL mouse model using UCART22 cells demonstrated important anti-tumor activity in vivo. The ability to carry out large scale manufacturing of allogeneic, non-alloreactive CD22 specific T-cells from a single healthy donor can offer the possibility of an off-the-shelf treatment that would be immediately available for administration to a large number of leukemic patients. UCART22 could also offer an alternative to patients who may relapse with CD19-negative tumors after CD19 CAR T-cell treatment.

**#3764** Targeting GPR64 in pediatric sarcomas with CAR transgenic T cells, David Schürmer,1 Isabel Storz,2 Karin Wisskirchen,2 Regina Feederle,3 Oxana Schmidt,1 Hinrich Abken,4 Crystall Mackall,5 Ulrike Prozet,6 Stefan Burdach,6 Günther H. Richter1.1 Technical University Munich, Munich, Germany;2 Technical University Munich, Helmholtz Zentrum Munich, Munich, Germany;3 Helmholtz Zentrum Munich, Munich, Germany;4 University Hospital Cologne, Cologne, Germany;5 Stanford University, Stanford, CA.

Introduction: Ewing Sarcoma (ES) is the second most common bone malignancy in children and young adolescents with a high potential of dissemination into lung and bone. Patients with disseminated disease into the bone have an approximate long-term survival rate of only 10%, compelling the search for new therapeutic treatment modalities like engineered T cell therapy. Here the therapeutic potential of chimeric antigen receptor (CAR) transgenic T cells directed against Ewing Sarcoma protein receptor 64 (GPR64) was examined. Experimental procedure: Two different monoclonal antibodies (mAbs) directed against the extracellular region of GPR64 were generated and characterized. Subsequently, retroviral constructs containing second generation CARs together with the scFv fragments of the respective mAbs were designed. Constructs consisting of different spacers and co-stimulatory elements were compared (dIgG1-CD28-CD3z vs. CD3z-4-1BB-CD3z). Primary lymphocytes were transduced and tested in vitro by flow cytometry, ELISpot and xCelligence assay as well as in immunodeficient xenograft mice. Results: Antibodies specifically stained ES cells as determined by flow cytometry and immune histology. The signal intensity was reduced after RNAi mediated down-regulation of GPR64 in ES cell lines confirming specificity of the isolated mAbs. Following sequence determination of those mAbs two different CAR constructs were designed. Retroviruses containing such CARs transduced primary lymphocytes with high efficiency. The CAR transgenic T cells were enriched for CD8+ CAR+ cells via microbead isolation and demonstrated strong proliferative capacities in vitro. Furthermore, target structures were specifically recognized as determined by ELISpot and xCelligence assay. Co-transduction with CD28 and CD137 resulted in one hybridoma, revealed hints of early exhaustion via auto-activation. Conclusion: CAR transgenic T cells targeting GPR64 show a promising approach to transfer the success of CARs in hematological malignancies to solid tumors. The cells generated in this study show strong specificity towards GPR64 and are able to control tumor cell growth. Since GPR64 expression is not restricted to ES but also up-regulated in a number of carcinomas derived from prostate, kidney or lung, GPR64-specific CARs may also be a future treatment option for other tumor entities.

---

T cell receptor (TCR) engineered adoptive T cell transfer (ACT) has shown remarkable antitumor efficacy in several clinical trials. However, low persistence of modified cells limits long-term clinical responses. To overcome this hurdle, we propose a clinical trial co-administering genetically modified T cells and stem cells. Prior clinical work has shown the potential to engineer a source for constant renewal of modified T cells. Here we report a preclinical IND-enabling study performed at UCLA under Good Laboratory Practice (GLP) compliance to assess whether co-administration impacts (I) safety; (II) engraftment and cell lineage differentiation of gene modified stem cells; and (III) persistence of adoptively transferred T cells and stem cell-derived progeny. We performed 12 optimization studies to define the optimal conditions for TCR gene modified ACT and TCR gene modified hematopoietic stem cell (HSC) bone marrow transplantation (BMT). Sixty-four HLA-A2/kb transgenic mice were myelodepleted and received syngeneic BMT with Lineage depleted bone marrow (Lin-) cells transduced with the LV-NY-ESO-1 TRC/s39TR and ACT with T cells transduced with the RV-NY-ESO-1 TCR. Control groups were as follows: NOD-SCID mice receiving transduced Lin- cells and mock transduced T cells, mice receiving mock transduced Lin- cells and transduced T cells (n = 16 per group).

Overall survival at 3 months was 87.5%; no significant differences in survival were observed among cohorts. After BMT we observed a decrease in body weight, elevation in kidney and transaminasins, and gonadal germ cell ablation in all cohorts. Three months after BMT, all blood cell lineages were reconstituted in surviving mice. Using digital droplet PCR and flow cytometry, we confirmed that transduced stem cells engrafted and their progeny persisted long term. In the bone marrow, NY-ESO-1 TCR was expressed intracellularly among progenitor cells (Lin-, LSK and HSC) as well as all hematopoietic cell lineages within the spleen (CD8+ T cells, CD4+ T cells, NK cells, B cells and granulocytes). Co-administration with genetically modified stem cells did not affect engraftment, cell lineage differentiation or persistence of the gene modified stem cells. Moreover, co-administration with stem cells did not affect persistence of adoptively transferred T cells. These data demonstrate that 1) NY-ESO-1 TCR genetically modified stem cells engraft and differentiate into all hematopoietic cell lineage progeny, which persists at 3 months; 2) adoptively transferred NY-ESO-1 TCR T cells persist at 3 months; 3) co-administration of stem cells and T cells genetically modified to express an NY-ESO-1 TCR is safe and does not negatively impact stem cell engraftment, lineage differentiation and progeny persistence or T cell persistence.

---

**#3766** MG7-car, a first-in-class T-cell therapy for gastric cancer, Jijun Yuan, Shanghai Genechem Co., Ltd., Shanghai, China.

Gastric Cancer, with increasing incidence and mortality, has become a major public health problem in China. According to the most recent study in China, Gastric Cancer is the second most common cancer with an incidence of 680,000 cases and mortality of close to 500,000 cases. Therefore, it is important to find an effective way to target the gastric cancer. MG7 antigen is a highly specific gastric cancer antigen identified by immunohistochemistry in late 80’s, unfortunately most work since then has been focused on MG7 antigen as a diagnosis marker without any treatment approach. Chimeric Antigen Receptor (CAR) T cell therapy is a newly developed technique, the called adoptive cell transfer. T cells from the patient are able to recognize and kill the tumor cell by grafting a tumor specific antigen binding single chain variable fragment (scfv) onto the T cell. In the past couple of years, CART therapy has demonstrated tremendous success in eradicating hematological malignancies, but no big improvement has been achieved in solid tumors. In this study, we converted an MG7 antibody into a scfv and co-engrafted the scfv as an ACT cell as an MTRA for the treatment of gastric cancer. To our knowledge, this is the first CART therapy being studied on gastric cancer. First to investigate the Gastric Cancer specificity of MG7 antigen, we did immunohistochemistry study on 485 samples (including 325 gastric cancer samples). It showed that MG7 antigen can’t be detected in normal gastric samples (0/50) and only 8% in chronic atrophic gastritis samples (4/50), but the positive rate increased to 58% and 70% in gastric dysplasia tissues (35/60) and gastric cancer tissues samples (227/325). At the same time, we compared MG7 antigen with other cancer biomarkers in gastric cancer tissues. Within 50 cancer samples, MG7 antigen has positive rate of 73%, much higher than the other markers, including CA199 (53%), CEA (51%), CA72-4 (31%) and CA125 (14%). For
CLINICAL RESEARCH: Innate Effectors in Immunity to Cancer

MG7-CAR, we converted the MG7 antibody to a scfv without losing any antigen binding affinity and “scfV-CD41BB-CD3ε” structure was used for the MG7-CAR. The study showed that the MG7-CAR can be well expressed with transduction rate close to 40%. The in vitro data showed that MG7-CART can efficiently kill gastric cancer cell line KATO3, but not colorectal cancer cell line SW620. In both gastric cancer antigen CEA overexpressed. The cytotoxicity assay also showed that IFN-gamma releasing result is highly correlated to the cell killing result. In order to further estimate the efficacy of the MG7-CAR, we set up a patient derived xenograft (PDX) model with gastric samples highly expressing both CEA and MG7 antigen. With one time intratumor injection of 1.5 million CART cells, both MG7 CART and CEA CART regressed the PDX models, while the MG7 CART had higher efficacy of tumor regression than CEA CART and showed in vivo antitumor activity of the PDX models. Our work demonstrated that MG7 antigen is very specific for gastric cancer and can be a novel treatment target by applying CAR T cell therapy.

#3767 Identification of a novel and a shared H3.3K27M mutation derived neoantigen epitope and H3.3K27M specific TCR engineered T cell therapy for glioma. Zinal Chheda,1 Gary Kohanbash,1 John Sidney,1 Kaori Okada,1 Naznin Jahan,1 Diego Carrera,1 Payal Watchmaker,1 Kira Downey,1 Shuming Liu,1 Shrutti Shrivastav,1 Sabine Mueller,1 Ian F. Pollack,1 Angel M. Carcaboso,1 Alessandro Sette,1 Yafei Hou,1 Hideho Okada1. UCSF, San Francisco, CA; 2La Jolla Institute for Allergy and Immunology, La Jolla, CA; 3University of Pittsburgh School of Medicine, Pittsburgh, PA; 4Hospital Sant Joan de Deu Barcelona, Spain.

Brain cancers are the leading cause of cancer related mortality in children and young adults with median overall survival of 9-12 months and hencerepresents a significant unmet medical need. Genome-wide sequencing efforts of pediatric gliomas have identified a recurrent and shared missense mutation in the gene encoding the replication-independent variant of histone 3, H3.3. Approximately 70% of diffuse intrinsic pontine gliomas (DIPG) and 50% of thalamic and other midline gliomas harbor the amino acid substitution from lysine (K) to methio- nine (M) at the position 27 of H3.3 gene. Tumor specific missense mutations are not subjected to self-tolerance and can be suitable targets (neoantigens) for cancer immunotherapy. Herein, we evaluated whether the H3.3K27M mutation can induce specific cytotoxic T lymphocyte (CTL) response in HLA-A2+ T cells. In vitro stimulation of HLA-A2+ donor derived CD8+ T cells with a synthetic peptide encompassing the H3.3K27M mutation (H3.3K27M epitope) induced CTL lines which recognized not only T2 cells loaded with the synthetic H3.3K27M epitope peptide but also lysed the HLA-A2+ DIPG cells which endogenously harbor the H3.3K27M mutation. On the other hand, the CTL lines did not react to either HLA-A2+ but H3.3K27M- negative DIPG cell lines or HLA-A2+ but H3.3K27M negative DIPG cells. The H3.3K27M epitope peptide but not the non-mutant counterpart indicated an excellent binding affi- nity (Kai=5.104 M) to HLA-A2 based on competitive binding assays. From CTL clones with high and specific affinities to HLA-A2-H3.3K27M-te- tramer, cDNAs for T cell receptor (TCR) alpha and beta chains were cloned into a retroviral vector. Human HLA-A+2 T cells transduced with the TCR demonstrated antigen specific reactivity as well as anti-glioma responses in vitro. Peps- tide titration assays suggested that the H3.3K27M specific TCR had the half-maximal reactivity for peptide recognition of around 100 nM. Furthermore, it is critically important for safety of clinical application, alanine scanning demon- strated that the key amino acid sequence motif in the epitope of the TCR reac- tivity is not shared by any known human protein. Finally, intravenously adminis- tration of T cells transduced with H3.3K27M specific TCR significantly inhibited the growth of intracranial HLA-A2+ H3.3K27M positive glioma xenografts in immune deficient NSG mice. These data provide us with a strong basis for developing peptide based vaccines as well as adoptive transfer therapy using autologous T cells transduced with the H3.3K27M specific TCR. Acknowledge- ments: This study is supported by the NIH/NINDS (1RO1NS096954), V Foundation and Parker Institution for Cancer Immunotherapy.

#3768 CAR T cells specific for CD19 can be redirected to kill CD19 negative tumors. Christine Ambrose, Lihe Su, Lan Wu, Roy L. Cobb, Paul D. Rennert. Aleta Biotherapeutics, Natick, MA.

Introduction. Remarkable progress has been made in the treatment of re- lapsed/refractory Acute Lymphocytic Leukemia and Non-Hodgkin Lymphoma with CAR-CD19 T cells. In contrast, progress against CD19-negative hematological cancers and solid tumors has been limited. Intensive efforts to optimize cellular therapies for better efficacy include provision of cytokine support and countering immunosuppression. However, lack of sufficient antigen is a significant additional hurdle that CAR-T therapeutics for solid tumors must overcome. We present a novel strategy to utilize CD19 for sustained antigen presentation in order to promote cellular therapy expansion, efficacy and persistence. The strategy, called IMPACT (Integrated Modules ofTimmize Adoptive Cell Therapy), employs a methodology that is modular in design and can be applied to diverse antigens and tumor types, yet retains the well-establish- ed advantages of CAR T cells directed to CD19. Experimental Procedures. A 3rd generation CAR-T was constructed in a lentiviral vector using the FMC63 domain of VEGFR2 and the FMC63 domain of CD28, with the FMC63 domain of CD137 downstream of the CAR-T cassette, was constructed using a secretion signal sequence and exons 1 - 4 of the human CD19 protein linked in frame to a trastuzumab-derived VH/VL sequence. This integrated-gene module thus encodes a fusion protein (FP): CD19-anti-HER2-scFv. Results. ELISA and flow cytometry analyses were used to demonstrate bridging between HER2+ and CD19- targets by the FP. ELISA analyses further demonstrated wild type binding of the 2 FP domains (i.e. CD19/FMC63 and the scFv/HER2). In vitro cytotoxicity studies showed robust redirected killing of HER2+ (CD19+ tumor) cells by CAR19 T cells that is mediated by the secreted FP. The efficiency of cytotoxicity was enhanced by the presence of CD19+ B cells. A tumor xenograft model was used to demonstrate effective killing in vivo when HER2+ BT474 cells were injected in one flank and CD19+ RAMOS cells were injected in the opposite flank, but not when HER2+ cell were injected alone. Thus, in vivo, redirected killing required CD19+ cells for expansion and persistence sufficient to promote anti-HER2 cytotoxicity. Conclusions. A CD19-anti-HER2-scFv FP was able to redirect the cytotoxicity of CAR19 T cells in order to kill HER2+ tumor cells. In vivo modeling demonstrated that CAR-T cell expansion and anti-HER2 cytotoxicity was limited by the antibody (scFv/HER2) used for cytotoxicity. The IMPACT technology is modular, allowing for FPs having diverse protein domains paired with diverse, distinct scFvs to allow CAR T cells to CD19 or other targets to be used to kill any tumor. We have further developed the technology to address antigens of utility for hematopoietic and solid tumors, including BCMA, ROR1, and PD-L1. The technology is broadly applicable and syner- gistic with existing cellular therapies.

#3769 Stem cell-engineered invariant natural killer T cells for cancer ther- apy. Lili Yang, Drake Smith, Siyuan Liu, Sunjong Ji, Bo Liu. Univ. of California, Los Angeles, Los Angeles, CA.

Invariant natural killer T (iNKT) cells comprise a small population of ββ T lymphocytes. They bridge the innate and adaptive immune systems and mediate strong and rapid responses to many diseases, including cancer, infections, aller- gies and autoimmunity. However, the study of iNKT cell biology and the ther- apeutic applications of these cells are greatly limited by their small numbers in vivo (~0.01-1% in mouse and human blood). Here, we report a new method to generate large numbers of iNKT cells in mice through T cell receptor (TCR) gene engineering of hematopoietic stem cells (HSCs). We showed that iNKT TCR-engineered HSCs could generate a clonal population of iNKT cells. These HSC- engineered iNKT cells displayed the typical iNKT cell phenotype and function- ality. They followed a two-stage developmental path, first in thymus and then in the periphery, resembling that of endogenous iNKT cells. When tested in a mouse melanoma lung metastasis model, the HSC-engineered iNKT cells effec- tively protected mice from tumor metastasis. This method provides a powerful and high-throughput tool to investigate the in vivo development and function- ality of clonal iNKT cells. More importantly, this method takes advantag- e of the self-renewal and longevity of HSCs to generate a long-term supply of engineered iNKT cells, thus opening up a new avenue for iNKT cell-based immu- notherapy.

#3770 CAR-T cell harboring a camelid single domain antibody as a target- ing agent to kill tumors expressing VEGFR2. Heman Chao, Baomin Tian, Marni Uger, Wai Wong. Heils BioPharma Corp., Toronto, Ontario, Canada.

Modulation of the immune system is showing tremendous promise in the treatment of malignancies. In addition to checkpoint inhibitors that re-activate T cells present in the tumor microenvironment, exogenously transduced chimeric antigen receptor (CAR) T cells are providing excellent responses in clinical trials for the treatment of leukemias. In this study, we describe CAR-T cells that target VEGFR2 expressing tumors. Camelid antibodies are small (14 kD) sin- gle chain antibodies. To generate a camelid antibody targeting the extracellular domain of VEGFR2, a llama was immunized with recombinant VEGFR2/Fc. A phage display library was generated and screened to identify an antibody with high binding affinity to VEGFR2. The selected antibody was expressed in the E.
Complementary.

the seefforts are underway in the clinic. In contrast to immune checkpoint block-
target VEGFR2-expressing tumors provides hope that camelid single domain
antisense-VEGFR2 CAR-T may be useful in directly targeting VEGFR2-expressing
tumors. We previously showed the utility of camelid antibodies in CAR T-con-
structs as anti-CEACAM6 CAR-T cells show both in vitro and in vitro efficacy
against the pancreatic tumor Bx-PC3. The use of the camelid V21 antibody to
target VEGFR2-expressing tumors provides hope that camelid single domain
antibodies can be developed for CAR-T therapies.

#3771 Concurrent GVAX and anti-OX40 therapy in murine intracranial
glioma model. Nusrat Jahan, Hammad Talat, William T. Curry, Department of
Neurosurgery, Massachusetts General Hospital, Harvard Medical School, Boston,
MA.

Introduction: Malignant glioma is the most aggressive brain tumor with a
median survival time of less than 1.5 years post diagnosis despite standard treat-
ments. However, recent advancements in immunotherapy hold significant
promise. Irradiated whole tumor cell vaccination stimulates antitumor immu-

ities and oncophenotypes are not known. Methods: To investigate how inflam-
correlations and risks attributed to inflammatory diseases of the abdominal cavi-
and mouse models. We applied an integrative informatics approach with exper-
mental validation to understand the associations between inflammatory dis-

coli. BL21 (DE3) pG7 system. The purified antibody was characterized by SEC,
LC-MS peptide mapping and ELISA. CAR-T cells were engineered to express
the camelid anti-VEGFR2 antibody in combination with the CD28 and 4-1BB
co-stimulatory molecules and the CD3 zeta chain. Tumor cells were screened for
expression of VEGFR2, and the HL-60 acute promyelocytic leukemia, ZR-75-30
breast ductal carcinoma and NCI-H460 non-small cell lung adenocarcinoma
cells were identified. Co-incubation of anti-VEGFR2 CAR-T cells with the VEGFR-
2-expressing cell lines resulted in dose-dependent target cell toxicity as mea-
sured by LDH release. In addition, T cell activity was confirmed, as high levels of
IL-2 and IFN-γ were detected in the cell culture media. These results suggest that
anti-VEGFR2 CAR-T may be useful in directly targeting VEGFR2-expressing
tumors. We previously showed the utility of camelid antibodies in CAR T-con-
structs as anti-CEACAM6 CAR-T cells show both in vitro and in vitro efficacy
against the pancreatic tumor Bx-PC3. The use of the camelid V21 antibody to
target VEGFR2-expressing tumors provides hope that camelid single domain
antibodies can be developed for CAR-T therapies.

#3772 A multi-scale survey to assess the impact of inflammatory diseases
of the abdominal cavity and prostate cancer severity. Khusher Shams, Kam-
lesh Kumar Yadav, Li Li, Shalini S. Yadav, Benjamin Glicksberg, Irtaza Khan,
Kipp W. Johnson, Marcus A. Badgley, Cordelia Eliaho, Ben Readhead, Brian A.

Introduction and Objectives: Prostate cancer (PCa) is the most common can-
dered in men (181,000 annual cases), and nearly 26,000 American men die
each year due to PCa and related complications. Reports have shown that PCa
is more aggressive when its comorbid with inflammatory diseases. However, the
correlations and risks attributed to inflammatory diseases of the abdominal cav-
y and oncophenotypes are not known. Methods: To investigate how inflam-
matory pathways and PCa genes induce aggressive oncophenotypes in the set-
ing of PCa, we have compiled a multiscale survey that includes data from
surgical observations, inflammatory phenotypes, clinical registries, biomarkers
and mouse models. We applied an integrative informatics approach with exper-
imental validation to understand the associations between inflammatory dis-
es (e.g., Crohn’s disease, ulcerative colitis, collagenous colitis, indeterminate
coli, ischemic colitis, diverticulitis, hernia, etc.) and PCa. Results: We found distinct patterns of shared molecular features—gene sets, pathways, and net-
works—and comorbidities across inflammatory disease and PCa. For example,
we found that diverticulitis tend to increase inflammation in the abdominal cavity and could potentially lead to aggressive prostate oncophenotypes. To test
these findings, we observed that several inflammatory disease and pros-
tate cancer genes share genetic modules. Conclusion: Collectively, our findings
provide the first set of computational, experimental and clinical evidence to
recommend clinicians to evaluate the impact of inflammatory disease induced
oncophenotypes in patients with PCa. Given that 1.3 million patients undergo
prostate-specific antigen (PSA)-triggered invasive trans-rectal biopsy, the pres-
ent findings in combination with PSA could facilitate the identification patient
subset with aggressive cancer. Stratifying patients at risk for prostate cancer who
are undergoing surgical interventions of abdominal cavity for inflammation
diseases could also evaluate other non-surgical or therapeutic strategies. Fund-
ing acknowledgements: AKT is supported by grants from Prostate Cancer Found-
ation and Deane Prostate Health. JT is supported by grants from National Cancer Institute (NCI-U54-CA182012-02, National Center for Advancing

#3773 Tapping CD4 T cells for cancer immunotherapy, Sébastien Walchi,
Marit R. Myhre, Nadia Mensali, Anne Fane, Kari Liserud, Gunnar Kvalheim,
Gustav Gaudernack, Else M. Inderberg, Oslo University Hospital-The Norwegian
Radium Hospital, Oslo, Norway.

T-cell based immunotherapy represents an attractive strategy for the treat-
mant of cancer. Whereas cellular anti-tumor immune responses have
typically been attributed to CD8 T cells, CD4 T cells play a critical role in
tumor elimination and the priming and maintenance of CD8 T-cell re-
sponses. Recent findings have highlighted new opportunities for CD4 T cells
in cancer immunotherapy. We have isolated CD4+ T cells reactive against
tumor antigens from patients who experienced clinical benefit from treat-
ment with cancer vaccines targeting antigens such as HTERT, survivin and
frequent neoantigens such as frameshift mutated TGFβRII. Strong T-cell re-
ponses against the vaccine or unrelated cancer antigens suggesting
epitope spreading correlated with enhanced survival and tumor regression
in late stage cancer patients. These HLA class II restricted T-cell clones
recognised target cells loaded with long peptides or protein and for some
CD4+ T cell clones we could also show direct tumor recognition. TCRs were
expressed in expanded third-party T cells by mRNA electroporation or ret-
roviral transduction and tested for functionality. Both CD8+ and CD4+ T cells
expressing the TCRs produced TNF-α, IFN-γ and redirected T cells had
the capacity to kill following co-incubation with their targets. Selecting
higher fun inflation. TCRs correlation and redirecting T cells treated on the
basis of finding a unique set of CD4+ T cells raised against tumor antigenic
specific antigens from patients with clinical responses after treatment with
immunotherapy is a successful method for identifying highly functional
HLA class II restricted TCRs for adoptive immunotherapy. These HLA class
II restricted TCRs may be of therapeutic value both in haematopoietic ma-
lignancies and in melanoma where tumor cells frequently express HLA class
II. Furthermore, combining HLA class I- and class II-restricted TCRs for
T-cell redirection may provide a more potent therapeutic effect in adoptive T

#3774 A high-throughput process for the development and characteriza-
tion of chimeric antigen receptors (CARs). Sabarinath Venkylal Radhakrish-
nan, Adam Miles, Djordje Atanackovic, Tim Luetkens, Adam Martin,1
Huntsman Cancer Institute, University of Utah, Salt Lake City, UT; 2Wasatch Microfluidics, Salt
Lake City, UT.

INTRODUCTION: Chimeric antigen receptors (CARs) expressed by T cells
bind to surface antigens via a single-chain variable fragment (scFv) and are able
to elicit potent anti-tumor efficacy. To our knowledge no rapid CAR develop-
ment platforms exist to facilitate the high-throughput generation and character-
ization of novel CARs to allow head-to-head comparisons and to determine the
influence of scFv properties on CAR T cell activation, phenotype, and persis-
tence. EXPERIMENTAL PROCEDURES: We have established a rapid process
for the development of functional novel CARs using fully human antibody
phage display, vector systems for bacterial and mammalian expression, as well as

Proceedings of the American Association for Cancer Research • Volume 58 • April 2017
963
high-throughput functional and biochemical characterization assays. We validated individual parts of the workflow using different tumor antigens and completed the entire workflow for one model antigen expressed on the surface of multiple melanoma cells. An initial population of scFvs against the model antigen was selected from a large naïve fully-human antibody phage display library by performing a single user of vimentin for cancer diagnosis is limited. This comprehensive study including immuno-markers screening and their applicability test with clinical samples demonstrates the clinical utility of the present device and hydrogel-assisted cell block for CTC isolation and cancer studies.

#3776 Examination of ERCC1 status in circulating tumor cells as a prog-

nostic tool for patients with nasopharyngeal carcinoma. Edwin P. Hui,1

Brigitte By Ma,1 KC Allen Chan,1 Charles ML Chan,1 SC Cesar Wong,2 Ka Fai

To,1 Herbert HP Loong,1 Frankie KF Mo,3 Roger KC Ngan,1 Anthony TC

Chan.1, 1Chinese Univ. of Hong Kong, Shatin, NT, Hong Kong; 2Hong Kong Poly-

technic University, Hong Kong, Hong Kong; 3Queen Elizabeth Hospital, Hong

Kong, Hong Kong.

Investigation of the expression pattern of DNA-repair protein excision repair cross-complementation group I (ERCC1) has been reported to allow selection of patients with non-small cell lung cancer who are likely to benefit from cisplatin-based therapy. Recent evidence suggests that ERCC1 expression may also find prognostic use in patients with nasopharyngeal carcinoma (NPC). We evaluated ERCC1 expression and genotype from NPC tissues and peripheral blood mononuclear cells of patients with NPC. ERCC1 expression was detected in 61/77 cases (79.2%) with varying intensities, where high ERCC1 expression was significantly associated with favorable RFS and overall survival (OS) in a subgroup of patients with undetectable post-treatment plasma EBV DNA. These findings support a prognostic role for ERCC1 examination in NPC. However, the invasive nature of obtaining biopsy samples or tumor marker studies may be a hindrance of this approach. To facilitate the investigation of ERCC1 expression in a noninvasive manner, we have developed a negative selection immunomagnetic method for isolating circulating tumor cells from patient blood. Cell line spike-in experiments reveal a mean recovery rate of 66% for NPC cells with greater than 99% removal of non-targeted blood cells. Specificity of CTC identification was confirmed by detection of the expression of the Epstein-Barr virus encoded small RNA (EBER) in the CTCs. This method also allowed the simultaneous analysis of the expression of multiple protein markers including CD45, cytokeratin and ERCC1. It is expected that the development of noninvasive methodologies for tumor marker studies will facilitate their clinical application for improved patient care and monitoring in the future.

**#3777 DNA profiles of circulating tumor cells and extracellular vesicles for therapy stratification of metastatic breast cancer patients. Corinna Keup,1

tial of Essen, Essen, Germany; 2QIAGEN GmbH, Hilden, Germany; 3Depart-

ment of Internal Medicine (Cancer Research), University Hospital of Essen, Essen, Germany; 4Clinic for Gynecology and Obstetrics, Marienhospital Bottrop gGmbH, Bottrop, Germany.

Background: Blood analytes, as liquid biopsies, are discussed to be surrogate markers for therapy stratification of metastatic breast cancer (MBC) patients. Repeated analysis is enabled by the minimal invasive nature of blood draw. Analysis of RNA enclosed in circulating tumor cells (CTCs) or extracellular vesicles (EVs) may be sensitive enough to detect disease progression earlier than contemporary visual staging methods. A prediction of the ideal therapy strategy via characterization of CTCs or EVs would be even more beneficial. Here we compare RNA profiles of CTCs and EVs in MBC patients to get insight into their feasibility for therapy stratification. Patients and methods: Blood was collected from 10 MBC patients at the time of disease progression (T0) and at two consecutive clinical staging time points (T1 and T2) during therapy. Two cohorts were separated according to RECIST criteria a) Overall Responder showed response at T1 and T2 and b) Late Non-Responder displayed stable disease or partial remission at T1, but showed progressive disease at T2. CTCs were isolated from 5 ml blood by positive immunomagnetic selection targeting EpCAM, EGFR and HER2 (AdnaTest EMT2/STEMCell Select TM, QIAGEN, Germany). EVs were isolated from 4 ml pre-filtered plasma by affinity-based binding to a spin column (exoRNeasy, QIAGEN, Germany). mRNA bound to Oligo-dT beads was purified and reverse transcribed (AdnaTest EMT2/STEMCell Detect TM, QIAGEN, Germany). Pre-amplified cDNA was analysed by a multimeric

Introduction: Circulating tumor cells (CTCs), defined as tumor cells de-
tached from the primary tumor site and circulating in the peripheral blood, are a potential myeloma to observe specific killing of tumor cells and no overt toxicities.

CONCLUSION: We show that our process allows the generation, screening, as well as functional and biochemical characterization of novel CARs to toxicities. CONCLUSION: We show that our process allows the generation, screening, as well as functional and biochemical characterization of novel CARS within 2 months. Our approach enables researchers to easily carry out head-to-head comparisons allowing comprehensive lead identification and the determination of binding domain properties which may shape CAR T cell function and phenotype.

qPCR (AdnaPanel TNBC, QIAGEN, Germany). RNA profiles of 18 genes (including AKT2, ALK, AR, AURKA, BRCA1, cKIT, cMET, EGFR, ERCC1, HER2, HER3, KRT15, NOTCH1, PARP1, P63, SRC1, GAPDH) were normalized by data of healthy donors (n = 20) and CD45 served as leukocyte control in the CTC preparation. Results: In general, data analysis showed great differences in RNA profiles of EVs and CTCs. However, in similar signal courses for P3K and cMET were found in all time points, revealing P63 as potential positive response marker and cMET as potential negative response marker in both blood analytes. Conclusions: Expression profiling in CTCs as well as in EVs is enabled by the described workflows. Preliminary data indicated great differences in RNA profiles of EVs and CTCs. The amount of included patients is continuously increased to validate the preliminary results obtained until now.

#3777 PD-L1 expression on circulating tumor cells and its comparison with tumor tissues in Japanese lung cancer patients. Hiroaki Akamatsu,1 Yasuhiro Koh,1 Satomi Yagi,1 Satoshi Kambayashi,1 Ayaka Tanaka,1 Kuninobu Kanai,1 Atsushi Hayata,1 Nahomi Tokudome,1 Keiichiro Akamatsu,1 Masayuki Higuchi,2 Hisashige Kanbara,1 Masanori Nakashima,1 Hiroki Ueda,2 Nobuyuki Yamamoto.1

Background: Blockade of programmed death receptor-1 (PD-1) pathway is effective against solid tumors including lung cancer. Although PD-ligand 1 (PD-L1) expression on tumor tissue is expected as a potent predictive biomarker, its detection remains challenging due to its dynamic and unstable status. Circulating tumor cells (CTCs) have potential as an alternative material for non-invasive and real-time diagnosis. Here, we evaluated the PD-L1 expression on CTCs in patients with lung cancer and investigated the agreement between tumor tissues and CTCs. Material and methods: CTCs were captured and immunestained using microcavity array system. CTCs were defined as those positive for DAPI and cytokeratin (CK) and negative for CD45. PD-L1 expression on CTCs was evaluated by addition of the process of PD-L1 immunocytochemistry. For CTCs detection, 3 ml of peripheral whole blood was collected from the patients who consented in written form and PD-L1 immunohistochemistry was performed using corresponding tumor tissues. Results: Sixty-seven lung cancer patients were enrolled in the study between July 2015 and April 2016 at Wakayama Medical University. Patient characteristics were as follows: median age 71 (range, 39 to 86); male 72%; stage II-III/IV, 15/85%; non-small cell lung cancer (NSCLC)/small cell lung cancer (SCLC)/Other, 73/21/6%. CTCs were detected in 66 out of 67 patients (median 19; range, 0 to 115) and more than 5 CTCs were detected in 78% of patients. PD-L1-expressing CTCs were detected in 73% of patients and the proportion score (PS) of PD-L1-expressing CTCs ranged from 3% to 100%, suggesting intra-patient heterogeneity of PD-L1 expression on CTCs. Significantly more PD-L1-expressing CTCs were detected in patients with EGFR mutations than those without (P = 0.0433). Tumor tissues were available from 28 patients and were immune-stained for PD-L1. Seventeen showed the PS of PD-L1-expressing tumor cells < 1%, 11 showed 1-49%, and 10 showed ≥ 50%. No positive correlation was observed on PD-L1 expression between tumor tissues and CTCs based on PS (R² = 0.0034). Three adenocarcinoma cases with PD-L1-positive tumor tissue did not harbor any PD-L1-expressing CTCs and conversely, three adenocarcinoma cases with PD-L1-negative tumor tissue harbored PD-L1-expressing CTCs, showing the discrepancy between tumor tissues and CTCs. It is also noteworthy that SCLC patients had perfect agreement on PD-L1 expression between tumor tissues and CTCs. Conclusions: PD-L1 expression was detectable on CTCs in lung cancer patients. Intra-patient heterogeneity of its expression was observed. There was no agreement between tumor tissues and CTCs on PD-1 expression. Further investigation is warranted to better understand the clinical significance of PD-L1-expressing CTCs.

#3778 Incorporating in-line sample pre-enrichment with FACS and single cell mRNA-seq to facilitate isolation and characterization of prostate cancer circulating tumor cells. Liping Yu, Silin Sa, Michael Tycon, Xiaoyang Alice Wang, Yun Wang, Zhaohua Zhang, Jie-Fu Chen, Sarah Hoffe, William J. Higuchi,2 Hisashige Kanbara,2 Masanori Nakanishi,1 Hiroki Ueda,1 Nobuyuki Yamamoto.1

For decades, circulating tumor cells (CTCs) have been used as biomarkers to indicate disease progression and survival in patients with metastatic tumors. Detection of CTCs is an attractive, non-invasive blood test for early diagnosis of many types of cancer. However, CTCs are present at extremely low frequency in blood, and it is challenging to recover them in typical multi-step sample processing workflows. EpCAM, the widely accepted marker for CTC, has been found being down regulated in protein expression and RNA expression analysis in many cases thus EpCAM-dependent CTC detection might not be sensitive enough. We have developed a new sample preparation workflow to miniaturize, enrich and activate CTCs (cell sorting (BD FACs) platform) to demonstrate a one-step sample processing workflow to minimize cell loss and maximize CTC recovery. The pre-enrichment technology combines magnetic depletion of white blood cells and acoustic removal of lysed red blood cells, sending enriched tumor cells directly to a cell sorter for single CTC isolation. The in-line enrichment and sorting technology has shown 90% removal of CD45+ cells and over 90% recovery of target cells going through the system. Furthermore, we have incorporated molecular indexing technology for next generation sequencing (NGS) into the single CTC isolation to streamline gene expression analysis. We conducted a pilot study in which prostate cancer cell lines PC3, DU145, and LNCaP were spiked in healthy donors’ peripheral blood, quantitatively recovered, and individually sorted in 96-well 8D® Precise barcoded plates using a BD Influx™ sorter equipped with the in-line pre-enrichment module. The sorted cells were then sequenced for a prostate cancer targeted gene panel with approximate 100 genes including EpCam. Single cell sorting and sequencing were also performed on cell line cells directly and confirmed the workflow did not affect the gene expression. In LNCaP and PC3 cells, PD-L1 was not the high confidence CTC marker in both workflow and its protein expression was also heterogeneous. The highly expressed genes discovered by single cell mRNA sequencing such as GSTP1 and CA9 were investigated to provide additional cell surface markers for more sensitive CTC detection. Finally, CTCs from blood samples collected from prostate cancer patients were isolated based on marker panels beyond EpCam and characterized at the single cell level. The differences between gene expression profiles of patient sample CTCs and cancer cell line cells were revealed.

#3779 Bio-competition-based smart NanoVelcro Chip for isolation and gene expression analysis of circulating tumor cells from prostate cancer patients, Jie-Fu Chen,1 Mo-Yuan Shen,1 Chun-Hao Luo,1 Shirley Cheng,1 Sangjun Lee,1 Shuang Hou,1 Edwin M. Posadas,1 Hsiao-Hua Yu1,2

1 Cedars-Sinai Medical Ctr., Los Angeles, CA; 2 Academia Sinica, Taipei, Taiwan; 3 University of California, Los Angeles, Los Angeles, CA.

Introduction and Objective: Circulating tumor cells (CTCs) are being used in efforts to identify important transcriptomic features such as androgen receptor (AR) splicing variants in prostate cancer (PCa) and other malignancies. The low abundance of CTCs and the fragility of the genetic materials create a need for efficient and high-quality sample handling with high yields (greater than 90%) and their protein expression was also heterogeneous. The highly expressed genes discovered by single cell mRNA sequencing such as GSTP1 and CA9 were investigated to provide additional cell surface markers for more sensitive CTC detection. Finally, CTCs from blood samples collected from prostate cancer patients were isolated based on marker panels beyond EpCam and characterized at the single cell level. The differences between gene expression profiles of patient sample CTCs and cancer cell line cells were revealed.

Proceedings of the American Association for Cancer Research, Volume 58, April 2017
This in turn allows for detection of disease-relevant RNA signals. Further this new tool is being moved into clinical studies that will validate its performance in CTC purification and subsequent RNA detection.

**#3781 Expression of neuroendocrine markers in circulating tumor cells from patients with prostate cancer visceral metastases.** Jamie M. Spenger, Anupama Singh, David Niles, Charlotte N. Stahlfeld, David J. Beebe, Joshua M. Lang. University of Wisconsin, Madison, WI.

Purpose: Therapeutic resistance to Androgen Receptor (AR) targeted therapies in patients with Castration Resistant Prostate Cancer (CRPC) is complex and originates from a wide range of molecular alterations including AR point mutations, gene rearrangements and splice variant expression. An aggressive subtype of CRPC involves neuroendocrine de-differentiation that is often found in patients with visceral metastases. To evaluate neuroendocrine signatures in patients progressing on AR targeted therapies, we measured gene expression in circulating tumor cells (CTCs) as a minimally-invasive approach to examine putative resistance mechanisms to AR targeted therapies. Methods: We utilized the VERSA platform, an integrated CTC capture and analysis technology, to capture CTCs using antibodies for EpCAM or TROP2 in parallel. mRNA was extracted on chip from live cells for comparison of gene expression profiles for markers of neuroendocrine de-differentiation (SYT, CHGA, GHGB, MYCN, NCAM). Myeloid capture pathway fixed PMBC were stained and imaged with EpCAM or TROP2 captured, intact nuclei, negative for CD45/CD11b/CD14/CD34 and cytookeratin positive. Synaptophysin or Chromogranin A protein expression was quantified in individual CTCs and compared to tumor biopsy results where available. Results: Expression of the Synaptophysin (SYT) gene was found in 39% of the patients in our initial 18 patient cohort. These patients could be split into two groups. Group 1 patients had low AR expression with minimal detection of AR target genes. Of these four patients, three had visceral metastases. Group 2 patients had high levels of AR expression including expression of the splice variants ARV7 and ARV9, and robust expression of KLK3 (PSA) and PSM. From these three patients, two had visceral metastases. Subsets of the patients in both groups also exhibited expression of genes identified in neuroendocrine prostate cancer including Chromogranin B, MYCN, and NCAM. A subset of the patients tested for gene expression are being screened for CTC detection of protein markers of neuroendocrine phenotypes including Chromogranin A and Synaptophysin. Conclusions: We report the first identification of neuroendocrine gene expression signatures in CTCs from patients with CRPC experiencing disease progression on advanced AR targeted therapies. These signatures may serve as predictive biomarkers of resistance to AR targeted therapies. Future studies will evaluate these signatures in prospective clinical trials.

**#3782 Genetic analysis using a novel high-purity enrichment system for circulating tumor cells independent of epithelial cell antigen.** Hidenori Takagi,1 Masahiro Kozuka,1 Hiroshi Ito,1 Soo Hyeon Kim,2 Mitsuharu Hirai,1 Teruo Fujii3. 1ARKRAY, Inc., Kyoto, Japan; 2Institute of Industrial Science, The University of Tokyo, Tokyo, Japan.

Background: Genetic analysis of circulating tumor cells (CTCs) is useful as a liquid biopsy. However, there are 3 challenging issues in processing of CTC samples for clinical use of the analysis: [1] numerous residual blood cells in processed samples, [2] loss of CTCs that do not express epithelial markers, and [3] very laborious process. Here, we developed a novel system capable of overcoming all of these problems. Methods Our CTC analysis system is composed of 3 steps: [1] filtering of whole blood followed by immunostaining and magnetic labeling of cell population on the filter, [2] depletion of white blood cells (WBCs) in the cells recovered from the filter by magnetic separation, and [3] trapping the resultant cells at an observation chamber in a microfluidic enrichment device using dielectrophoresis, followed by recoverying them as a concentrated sample after fluorescence microscope observation. SNV and CNV analysis was conducted using the collected concentrated sample, and the system performance was substantiated. Genetic mutations of the cells in the collected sample were detected by the Quenching Probe method. On the other hand for CNV analysis, cells in the collected concentrated sample were immobilized on slide glass and analysis of gene amplification conducted by FISH. Results With SNV analysis, our system successfully detected EGFR, KRAS or PIK3CA mutations of cancer cell lines spiked in 8 mL of whole blood (Table). The detection sensitivity of our method was 1 cell/mL, and both the cancer cells and their genetic mutations were detected within 9 hours of starting the processing of whole blood. Additionally, with CNV analysis, HER2 gene amplification was confirmed with cell lines spiked in 8 mL of blood. This detection result was obtained within 48 hours. Conclusion Our system would be useful for the analysis of gene mutations in a wide range of CTC types independent of certain epithelial antigens, such as CK and EpCAM, and can be used for various genetic analyses.

**#3783 Circulating tumor cells measured in the pulmonary vein and the radial artery during surgery of non-small cell lung cancer.** Menno Tamminga,1 Sanne de Wit,2 Joost F. Swennenhuiz,2 Caroline van de Wauwer,3 Theo J. Klinkenberg,1 T. Jeroen Hiltermann,1 Harry J. Groen,1 Leon W. M. Terstappen2. 1University Medical Centre Groningen, Netherlands; 2University of Twente, Enschede, Netherlands.

Background: The number of circulating tumor cells (CTC) detected by the Cell-Search system is low or absent in 7.5 mL of venous peripheral blood of metastatic and non-metastatic non-small cell lung cancer (NSCLC) patients. Our hypothesis is that CTC can be detected in the pulmonary vein draining the lobe containing the primary tumor before its removal and would be influenced by manipulation of the lobe during surgery. Methods: Patients with early stage NSCLC undergoing open lobectomy were included. During surgery, blood was drawn centrally (pulmonary vein draining the lobe containing the tumor) and peripherally (radial artery) at two time points: directly after thoracotomy and identification of the draining pulmonary vein (T1) and just before closure of the draining pulmonary vein after manipulation, dissection and closure of the pulmonary artery (T2). EpCAM+ and CTC were detected by CellSearch. The EpCAM+ CTC depleted sample was subsequently filtered through 5 μm microsieves and fluorescently labeled for identification of EpCAM+. Results: So far, three patients have been included. Remarkably, cell clumps were detected among EpCAM+ CTC at T1 in the pulmonary vein in all patients, and as well at T2 in patient #3. CTC in the pulmonary vein at T1 was morphologically different than those detected at T2 and in the arteries. Experiments to confirm malignancy of both subtypes of CTC are pending, using chromosome aneuploidy status and copy number variation analysis to compare them with the resected tumor. Conclusion: In early stage NSCLC high amounts single and clumps of CTC are observed in the draining pulmonary vein during surgery. The amount measured in the radial artery is lower, indicating loss of CTCs in the circulatory system before peripheral measurement. If the cells found really are CTC that are shed from the primary tumor during surgery, it will have clinical consequences for the surgery techniques used.

**#3784 Expression of estrogen receptor specific signaling transcriptome in epithelial cell adhesion molecule (EpCAM) capturing circulating tumor cells from patients with breast cancer.** Ashok Singh, Jamie M. Sperger, Jennifer Schehr, Tessa Witkowski, Beth A. Weaver, Mark E. Burkard, Joshua M. Lang. Univ. of Wisconsin-Madison, Madison, WI.

Background: Breast cancer (BC) is the second leading cause of cancer related death in American women. There is a critical need for new biomarkers to evaluate treatment response and emerging mechanisms of resistance. The identification and characterization of new biomarkers such as Circulating Tumor Cells (CTCs) may be helpful tools for these purposes as well as understanding the biology of metastatic BC. Methods: Blood samples were processed with a Ficollic gradient to isolate nucleated cells. CTCs were isolated from these samples using an exclusion-based sample
preparation technology known as the VERSA (Versatile Exclusion-based Rare Sample Analysis) platform. EpCAM positive CTCs were captured in the VERSA followed by RNA extraction for gene expression profiling for the estrogen receptor (ER) and other breast cancer relevant targets. CTCs were defined as Hoechst positive, CD45/CD11b/CD14 negative, and cytokeratin positive. Captured CTCs were evaluated for ER protein staining intensity and localization. Results: The VERSA platform was validated to capture and enumerate CTCs from patients with breast cancer using EpCAM capture and immunofluorescent staining for intact nucleus, ER, and cytokeratin while negative for multiple immune markers (CD45, CD11b, CD14). The VERSA can capture cells with >90% capture efficiency with EpCAM antibody in MCF7 and T47D cell lines. ER specific transcriptome analysis in BC patient CTCs and cell lines was performed. We evaluated the performance of ROSCEXP signaling pathway, prognostic, metastatic/EMT- stemness; epithelial markers with concordant expression of RPLP0 and HPRT1. We identified expression of ER in 6 out of 7 BC samples. Expression of PR and HER2 in a subset of samples confirms capture of breast cancer cells for further molecular interrogation. Conclusion: In conclusion, we report the expression profiles of ER signaling genes in EpCAM captured CTCs from BC patients. These tools will be used to compare subpopulations of CTCs from patients with BC as predictive and pharmacodynamic biomarkers of response to targeted therapies or chemotherapies.

#3785 Self-sorting microwells to isolate and expand single circulating tumor cells. Joost F. Svennenhuis, 1 Kiki C. Andree, 1 Frikki Abali, 1 Michiel Steens, 1 Joska Broekmaat, 2 Fiona F. Passanha, 1 Cees J. van Rijn, 3 Leon W. Terstappen, 1. Twente University, Enschede, Netherlands; 2Vycap bv, Deventer, Netherlands; 3Wageningen University, Wageningen, Netherlands.

Introduction: Circulating tumor cells (CTC) can be isolated from blood and serve as a source of tumor material. Expansion of CTCs may permit functional treatment-efficacy tests in combination with genetics, epigenetics and proteomics screening. We present a fast workflow to isolate, capture, grow and image cells inside a self-sorting microwell chip using the VyCAP single cell isolation platform. After seeding single cells in a microwell chip, they grow inside the chip or can be transferred to a tissue culture plate for clonal expansion or downstream analysis.

Materials and methods: The Rosette-Sep™ Human CD45 depletion cocktail (Stem Cell Technologies) was used to enrich spiked cells from 1 ml of fresh EDTA blood. Cells were stained with CellTrace™ violet for tracking spiked cells, calcein for live cells, ethidium bromide for dead cells, α-CD45-PERCP as negative marker and α-EpCAM-AF647 as positive marker. After density gradient separation using Ficoll-Paque™, the cell suspension was measured and quantified using flow cytometry for Rosette-Sep™ efficiency. Cell suspensions were seeded in the self-sorting microwell chips using a negative pressure of 40-70 mbar using the VyCAP filtration system. After seeding single cells in the microwells, the chips were imaged with the VyCAP Puncher system and either placed immediately into culture medium for cell expansion or selected cells were transferred into a 96 well tissue culture plate. Cell expansion in microwell chips and plates was followed up to 14 days. Results: Cultured MDA-MB-231 and MCF-7 cells were single-cell-trapped in the microwells with an efficiency of 82% ± 9% and 74% ± 15% respectively, after direct filtration without enrichment. Immediately after capturing in microwells 93% of the MCF7 cells were viable. Rosette-Sep™ enriched MDA-MB-231 and MCF-7 cells with an efficiency of 81% ± 10% and 74% ± 7% respectively, when measured with flow cytometry. The Rosette-Sep™ procedure followed by capture of the MDA-MB-231 and MCF-7 cells in the microwells resulted in an efficiency of 50% ± 11% and 52% ± 11% respectively. 92% of the cells were found back in a culture plate after punching of single cells from the chip, and of these cells, 80% were alive 4 hours after punching. 82% of these cells were alive and still growing after 14 days. In total 53% of cells spiked in blood, could be found back in the cups of which after punching into individual wells, 77% were alive and growing. Conclusion: We present a single cell capture and isolation method for clonal expansion of viable tumor cells. The VyCAP single cell isolation platform used for these experiments provides an easy separation of the single cells from a CTC enriched cell suspension and allows on-chip expansion as well as immediate separation of the CTCs into culture plates. About 50% of spiked cells could be retrieved inside the microwell chip and of these 77% were alive after punching into individual wells of a culture plate.

#3786 Multicenter evaluation of technology platforms for the enumeration of circulating tumor cells. Sebastian Bender, 1 Merlin V. Lütke-Eversloh, 2 Rui P. Neves, 3 N Nikolas H. Stoecklein, 1 Leon W. Terstappen, 2 Barbara Bagiani, 1 Martin H. Neumann, 1 Thomas Krahn, 1 Klaus Pantel, 1 Thomas Schlange, 1 Eppendorf, Hamburg, Germany; 2Vycap bv, Deventer, Netherlands; 3Twente University, Enschede, Netherlands; 4University of Padova, Padova, Italy; 5IOV-IRCCS, Padova, Italy; 6Heinrich-Maximillians-University, Munich, Germany; 7Gustave Roussy, Villejuif, France; 8Institute of Cancer Research, Sutton, United Kingdom.

Introduction: The presence of circulating tumor cells (CTC) enumerated by the CellSearch system in blood of patients with cancers of epithelial origin is strongly associated with a poor prognosis of these patients. CTCs are enriched by targeting the EpCAM antigen, raising the question which the EpCAM subtypes are present as well in patients. In the EU-FP7 CTCTrap program, we investigated the presence of EpCAM- CTC in blood samples after depletion of EpCAM+ CTC by CellSearch. Studies were performed and validated at the participating laboratories by distribution and analysis of blood samples spiked with cancer cells and by testing blood from 73 metastatic prostate and 22 metastatic breast cancer patients. Methods: Blood samples were processed according to the standard operating procedures and tools developed in the program (https://www.ut-wente.nl/tum/mcbp/protocolsandtools/). First, CellSearch was performed for EpCAM+ CTC, followed by filtration and fluorescent labeling of the blood discarded by CellSearch for EpCAM- CTC. To validate the procedures across the 6 participating clinical sites, 3x3 tubes with aliquots of healthy donor blood, spiked with either PC3, MDA-MB-231 or no cells, were prepared at one site and shipped to all other sites for simultaneous processing. Metastatic prostate and breast cancer patients were processed with the same procedures. Results: 27% of PC3 cells were recovered by CellSearch and 21% by filtration, leaving 52% unaccounted for. CellSearch and filtration were performed by 6 different laboratories, leaving 56% accounted for. Differences in recovery between sites were not significant. In patients both EpCAM+ and EpCAM- CTC were detected (see table). Conclusion: In a multicenter study EpCAM+ and EpCAM- CTC were present in blood of metastatic prostate and breast cancer patients. Spiking ex-
CLINICAL RESEARCH: Liquid Biopsies 3: Circulating Tumor Cells, Extracellular Vesicles, and Exosomes

Experiments showed that the developed methods can be further improved to increase the CTC yield. Molecular characterization of the CTC subtypes and relation with clinical outcome is ongoing.

#3788 Monitoring of multimodality immune checkpoint inhibitor treatment efficacy in metastatic melanoma patients through molecular analysis of circulating tumor cells. Selena Lin,1 Stella Lam,1 Siuichu Ohe,1 Kevin Tran,1 Irene Ramos,1 Ali Asgar Bhagat,2 Chwee Teck Lim,3 Steven J. O'Day,1 Leland Foshag,1 Dave Ramirez,1 Tomohisa Okuno, Kishu Kitayama, Tatsuro Tamura, Takahiro Toyokawa, Hiroyuki Yamada,1 Arturo B. Ramirez,1 Sarah B. Crist,2 Tyler Yeats,2 Jeffrey L. Werbin,1 Jackie L. Stillwell,1 Eric P. Kaldjian1,1 RareCyte, Inc., Seattle, WA; 2University of Washington, Seattle, WA.

Background: Circulating tumor cell (CTC) monitoring in patients with metastatic melanoma has become an important tool for the evaluation of therapeutic efficacy and patient outcome. RNA-based detection methods have been developed to facilitate effective monitoring of CTCs, especially in patients who are unresponsive to treatment. In this study, we aimed to evaluate the utility of RNA-based detection of CTCs in metastatic melanoma patients undergoing immune checkpoint inhibitor therapy.

Methods: To establish RNA detection in model CTCs (mCTCs), we used SKBr3 cells with BRAF V600E mutation. RNA was extracted from RNA-locked samples and used to develop a process to simultaneously stain for Her2, UBC (positive control) and dapB (negative control) expression in mCTCs. A process to simultaneously stain for RNA and protein was then developed to allow identification of mCTCs by positive control (negative control) expression in mCTCs. A process to simultaneously stain for Her2, UBC (positive control) and dapB (negative control) expression in mCTCs. A process to simultaneously stain for Her2, UBC (positive control) and dapB (negative control) expression in mCTCs.

#3790 Circulating tumor cells at disease recurrence in patients with head and neck cancer after curative therapy. Jason Chia-Hsun Hsieh,7 Ting-Hsuan Yeh,1 Hung-Ming Wang,1 Yung-Chang Lin,1 Nina Ming-Jung Lin,2 Siou-Ru Ye,3 Jane Ying-Chieh Lee,4 Min-Hsien Wu.5 Chang Gung Memorial Hospital at Linkou, Taoyuan, Taiwan; 2Chang Gung University, Taoyuan, Taiwan.

Background: Circulating tumor cell (CTC) monitoring has been prognostic and predictive in numerous types of cancer; however, its role in early diagnosis of relapse remains unclear. Methods: Eighty-six patients were prospectively enrolled between March 2015 and June 2016. Among these patients, 51 head and neck squamous cell carcinoma (HNSCC) patients had suspicious recurrent lesion(s), while 35 HNSCC patients were newly diagnosed. CTC test was performed by negative selection strategy and CD45-negative and EpCAM-positive cells were identified as CTCs. Biopsy on suspicious lesion(s) and CTC analysis were performed simultaneously. We analyzed the differences of CTC numbers among HNSCC patients with true recurrence, biopsy-negative and newly-diagnosed. Results: Mean ± standard deviation (SD) of CTC numbers in baseline at diagnosis (n = 35), true recurrence (n = 40) and biopsy-negative (n = 11) groups were 41.98 ± 32.02, 81.75 ± 64.91 and 16.55 ± 6.82 cells/mL, respectively. The difference of CTC numbers among three groups was significant (P = 0.001). CTCs (mean ± SD) among different failure types were 110.89 ± 84.69, 105.67 ± 50.77, 73.31 ± 37.82 and 59.12 ± 54.09 in lung metastasis, second primary tumor, extrapulmonary metastasis and locoregional recurrence respectively and significantly different (P = 0.049). Also, CTC numbers between first cancer (baseline at diagnosis) and second primary tumor were different (P = 0.004). Conclusion: CTC numbers are significantly higher in true recurrence than the biopsy-negative group when a patient had a lesion suspected to be a recurrence. CTC test may be useful to help distinguish true recurrence in HNSCC patients after curative therapy.

Background: It has been reported that the examination of circulating tumor cells (CTCs) is beneficial for predicting tumor stage or treatment response. The epithelial cell adhesion molecule (EpCAM) and cytokeratin has been used as epithelial markers for the identification of CTCs. Since the epithelial-mesenchymal transition is one of malignant phenotype of cancer cells, it is necessary to investigate other markers which might detect mesenchymal CTCs. Aim: This study aims to clarify the clinical significance of EpCAM negative and CEA positive CTCs in patients with gastric carcinoma. Forty patients who underwent surgery for gastric cancer were enrolled in this study. A total of 10ml peripheral blood samples were obtained pre-operatively. Informed consent to participate in this study was obtained from all of the patients before their surgery. This study was approved by the Human Ethics Review Committee of our University. After collection of mononuclear cell fraction, these cells were stained by FAP1, anti-CLD45, anti-EpCAM, anti-cytokeratin, and anti-CEA (CD66c) antibody. We enumerated the number of cells which showed EpCAM, cytokeratin, and CEA positive expression among CD45 negative cells. ROC analyses were performed for investigating predictive value of these cell counts for distant metastasis. We examined association between these cell counts and clinicopathological features. Results: ROC analyses revealed that the AUC for predicting
distant metastasis using EpCAM, Cytokeratin, and CEA positive cell counts were 0.583, 0.638, and 0.769, respectively. The median number of EpCAM negative and CEA positive cells was 231 (range: 0-61897). The cell counts of EpCAM negative and CEA positive cells were significantly associated with Tumor depth (p = 0.0084), lymph node metastasis (p = 0.0107), and tumor size (p = 0.023). Conclusions: CEA might be useful marker for detecting high risk of recurrence in patients with gastric cancer.

#3792 Improved isolation and detection of circulating tumor cells of pancreatic cancer patients with characterization by mutational analysis. Oliver von Ahsen, Nora Brychta, Thomas Krahn. Bayer Pharma AG, Berlin, Germany.

Introduction: Isolation of circulating tumor cells based on cell surface markers is often hindered by epithelial to mesenchymal transition with loss of epithelial antigens. Low numbers of CTCs and fewer cases of CTC positive pancreatic cancer compared to other cancers (e.g. breast cancer) lead to the assumption that pancreatic tumors do not release CTCs as frequently or that the pancreatic CTCs lack EpCAM expression. Isolation of CTCs based on their size is independent of EMT-like phenotypical changes. We therefore compared a filtration-based isolation method with an EpCAM-based isolation method. We optimized CTC detection by using a highly sensitive anti-cytokeratin antibody panel for the detection of cancer cells with moderate cytokeratin expression. In order to use isolated CTCs as liquid biopsy for tumor characterization and treatment selection, downstream analysis is necessary.

We here show the feasibility of mutational analysis of isolated CTCs by castPCR. Methods: EpCAM high, medium and low cells were enriched and isolated by an EpCAM-based immunomagnetic procedure (Isoflux) and a filtration device (Sie- mens) to determine recovery rates of both methods. Isolated cells were detected by an improved immunofluorescent staining with an anti-Cytokeratins, anti-EpCAM and anti-PMBC panel and characterized by competitive allele-specific TagMan PCR (castPCR) for KRAS mutations. Results: Cytokeratin expression is crucial for detection of CTCs in a high background of blood cells. Improvement of the staining protocol helps to increase the sensitivity of detection. The filtration based approach is superior to the surface antigen-based isolation. With the size-dependent method we obtained a recovery rate of 52 % even for EpCAM-low cells compared to only 1 % based on the immune-affinity purification. Cells isolated by filtration can be characterized for expression of therapeutic targets by immunostaining. The utility of the size dependent platform for subsequent functional characterization of the CTCs was also demonstrated by detection of k-ras mutations in single isolated CTCs by castPCR.

Conclusion: For CTCs undergoing EMT, filtration yields higher recovery compared to the standard surface antigen (EpCAM)-based methods. Isolation by filtration also allows for mutational analysis which can be used to confirm the identity of the isolated cell as CTC. In addition, mutational analysis of CTCs can be used to guide the treatment of patients. Use of liquid biopsies for treatment selection will facilitate truly personalized medicine.

#3793 Discovery and isolation of enormous number of circulating tumor cells in breast cancer patient’s blood based upon cell attachment property. Yeon-a Choi, Hyun Ju Han, Ae-Ran Choi, Jeong Dong Lee, Gun Min Kim, Hyung Seok Park, Seho Park, Seung Il Kim, Joonhyuk Sohn. Yonsei Univ Medical Center, Seoul, Republic of Korea.

Circulating tumor cells (CTCs) are detached from primary tumors into the bloodstream. It is known that CTCs can be a biomarker for early detection of breast cancer patients and for drug resistance. CTCs can be differentiated by cell attachment property. In order to isolate CTCs, we developed a new method to collect CTCs from breast cancer patient, and handled as described above. Our method showed higher detection sensitivity for 6 breast cancer cell lines. We confirmed that breast cancer cell lines were collected more than 80% of spiked cell number in 2 hours. This technique is applied to isolation of CTCs in actual breast cancer patients, and unexpectedly considerable numbers of CTCs were observed. We found in a range of CTCs from 0.5 × 10⁶ to 1 × 10⁷ per ml of blood.

These numbers are in striking contrast to previous studies. CTCs were observed in 61 of 114 samples (53.51%) from metastatic breast cancer patients and 15 of 48 samples (31.25%) from early breast cancer patients. We also discovered that there are various sized CTCs, and categorized these CTCs according to their diameter; small (<5 μM), medium (5-10 μM), and large (>10 μM) CTCs. All the thirty CTCs appeared in large numbers. HER2 and EpCAM expression of CTC vary by patients and didn’t always coincide with expression in primary tumor. In summary, we have developed a promising strategy for CTC isolation by using the preference of cancer cells to adhere to cell culture plates. We have demonstrated that this is a simple yet very efficient approach to isolate CTCs and broadly applicable to capturing heterogeneous CTCs populations independently of their marker expression and size. Our study discovered that enormous amount of CTCs are existing in the blood of breast cancer patient in a variety of sizes.

#3794 Selective isolation of epithelial to mesenchymal transitioned circulating tumor cells in NSCLC using novel magnetic nanocubes. Dhanjay Suresh, Shreya Ghoshdastidar, Soumavo Mukherjee, Abilash Gangula, Anandhi Upendra, Raghuraman Kannan. University of Missouri, Columbia, MO.

The 5-year survival rate for early to advanced NSCLC patients is 10-5%. Once the tumor metastasizes, the survival rate often drops below 1%. One of the major challenges is to select the patient for appropriate therapy, and the selection process involves invasive biopsy that is difficult to recurrently perform during treatment. Recent studies have shown that liquid biopsy is an attractive alternative. Liquid biopsy involves analysis of either CTCs or ctDNA to understand the tumor therapy. Isolating entire tumor cells provides an opportunity to perform whole genome sequencing for in depth understanding of the tumor. However, frequent changes in cancer signaling and acquired mutations during treatment lead to drug resistance that cannot be diagnosed using current CTC techniques. These oncogenic biochemical modifications that are often associated with metastasis involve upregulation of epithelial to mesenchymal transition (EMT) pathway that change the elasticity of tumor cells for easy shedding into the blood stream. Consequently, EMT transition leads to depletion in epithelial markers such as EpCAM and cytokeratin that are to be targeted. This effect largely limits the use of present technologies utilizing EpCAM as a marker to isolate the CTCs. We hypothesized that these cells can be captured by targeting surface markers that are overexpressed in EMT transitioned CTCs. For example, markers such as EGFR and HER2 have been shown to be overexpressed pre and post EMT tumors and therefore can present as a new strategy for non-invasive diagnosis before and during treatment. In this study we have shown that EGFR and HER2 receptors are overexpressed in EGF and KRAS mutated NSCLC cells. We artificially activated EMT in NSCLC cells and compared their face biomarker concentrations. Furthermore, we used microfluidic analyzer data using western blotting to identify our targets after EMT. Based on the biomarker concentrations, we designed and developed magnetic nanocubes (MNC) surface attached with antibodies to target the selected biomarkers to capture EMT CTCs. The capture efficiency of these magnetic nanocubes was compared in multiple cell lines (HCC427 and A549). Overall we could capture CTC as low as 0.01% of the spiked cells. We used the MNCs to capture cancer markers such as EGFR and HER-2 that are highly expressed in tumors, once shed as CTCs can be targeted for diagnosis. Therefore, we have developed a novel method to capture EMT CTCs with high selectivity and this method presents a minimally-invasive method for real-time monitoring of patients during drug treatment.

#3795 Dynamic acquisition of HER2 expression on circulating tumor cells in gastric cancer patients correlates to developing therapeutic resistance. Yi Lin,1 Xiaotian Zhang,1 Dan Liu,1 Jifang Gong,1 Daisy Dandan Wang,2 Peter Lin Peng,2 Lin Shen1. 1Peking University Hospital University & Institute, Beijing, China; 2Cyteligen, San Diego, CA.

Introduction: It has been hypothesized that molecular characters of circulating tumor cells (CTCs) is dynamically evolved during cancer development. However, how the evolutive CTC subtypes support tumor progression and drug resistance remains unclear. In this study, converted phenotypic HER2 expression and karyotypic chromosome 8 ploidy of CTCs in gastric cancer patients who developed therapeutic resistance were systematically investigated. Methods: Ninety-eight prospectively enrolled patients with diagnosis of advanced gastric cancer (AGC) were histologically classified into 2 cohorts of HER2+ (hHER2+, 53 patients, subjected to the combined chemo- and anti-HER2 targeted therapy), and hHER2- (42 patients, subjected to chemotherapy alone). Integrated EpCAM-independent subtraction enrichment and immunostaining-fluorescence in situ hy-
bridization (SE-iFISH) was applied to monitor and characterize HER2 expression and chromosome 8 ploidy of CTCs in patients following multiple courses of therapy until disease progression. Results: HER2 expression on CTCs was heterogeneous and interconverted compared to its relatively stable status on primary tumor. Among those prior-to-therapy patients, HER2+ CTCs were detected in 33.3% (9/27) of total, and HER2- CTCs were detected in 66.7% (18/27) of total, limiting their clinical utility. There were two CTCs in a hHER2+ patient identified in 29.5% (13/44) of hHER2+ cohort. Whereas can also be detected in 19 out of 21, 90.5% and 6 of hHER2+ cohorts (6 out of 8, 75%), respectively. Further karyotyping of CTCs in those patients developing therapeutic resistance indicated that most of the CTCs with acquired HER2 expression had multiploid (6x) chromosome 8, implying that aneuploid chromosome 8 in acquired HER2+ CTCs were likely related to development of therapeutic resistance, both chemotherapy alone and the combined chemo- and targeted therapy. Genomic profiling of the single CTC subtype by FISH upon phenotypic HER2 expression and karyotypic chromosome 8 ploidy is currently under investigation. Conclusion: Dynamic profiling gene signature and molecular characterization of CTCs might be significant in terms of predicting therapeutic resistance, and further help select an alternative effective intervention to overcome the acquired therapeutic resistance.

#3796 An intravascular magnetic wire for high-throughput in vivo enrichment of rare circulating cancer biomarkers. Ophir Vermesh, Amin Asloun, Tianjia J. Ge, Yamil Saenz, Yue Guo, Seung-min Park, Yoshiaki Mitsutake, Michael Bachmann, Chin Chun Ooi, Kerstin Mueller, Hamed Arami, Alfredo Green, Shan X. Wang, Sanjiv S. Gambhir. Stanford University, Stanford, CA.

Background: Liquid biopsies have long promised to enable earlier cancer diagnosis and tailored therapy. However, circulating tumor cells (CTCs) are extremely rare (1–10 CTCs per mL) and limiting their clinical utility. There are few CTCs in a patient’s peripheral blood, whereas can also be detected in 29.5% (13/44) of hHER2+ cohort. whereas can also be detected in 19 out of 21, 90.5% and 6 of hHER2+ cohorts (6 out of 8, 75%), respectively. Further karyotyping of CTCs in those patients developing therapeutic resistance indicated that most of the CTCs with acquired HER2 expression had multiploid (6x) chromosome 8, implying that aneuploid chromosome 8 in acquired HER2+ CTCs were likely related to development of therapeutic resistance, both chemotherapy alone and the combined chemo- and targeted therapy. Genomic profiling of the single CTC subtype by FISH upon phenotypic HER2 expression and karyotypic chromosome 8 ploidy is currently under investigation. Conclusion: Dynamic profiling gene signature and molecular characterization of CTCs might be significant in terms of predicting therapeutic resistance, and further help select an alternative effective intervention to overcome the acquired therapeutic resistance.

BACKGROUND: Circulating tumor cells (CTCs) are expected to be utilized for decision-making in precision cancer medicine and further elucidation of cancer biology. However, it remains challenging to detect and isolate CTCs without any damages, that is critically important to analyze the molecular and biological properties of CTCs. Near infrared (NIR) imaging is one of the emerging technologies in the field of molecular imaging, which can detect and visualize tumor cells, nerves, and muscles under the skin or mucosa. Here we attempted to apply the NIR imaging technologies to distinguishing tumor cells from normal blood cells. METHODS: To obtain NIR images, real-time composition imaging system Compvision® (Sumitomo Electric Industries, Ltd.) was used. This system is equipped with an NIR spectroscopic camera and this camera processes hyperspectral data, in which each pixel has information of the wavelength band of 1,000–2,350 nm. The X-axis and Y-axis of the sensor chip correspond to the spatial direction and wavelength. Thus, hyperspectral data stores both image and spectral information. For this feasibility study, lung cancer cell lines with varying EpCam expression levels such as A549, PC-9, PC-14, H23 were used. Lymphocytes and red blood cells were obtained from the peripheral blood of healthy volunteers. Phosphate-buffered saline (PBS) was used as a negative control. After we obtained NIR hyperspectral data, multivariate analysis such as principal component analysis (PCA) was performed for precise analysis. RESULTS: We were able to obtain the hyperspectral data from all the lung cancer cell lines, lymphocytes, red blood cells and PBS alone and the spatially averaged spectrum was extracted from each data. Then the spectra were converted to absorption spectra and analyzed by PCA using the Unscrambler®. Two principal components were selected from results to separate data. Two-dimensional PCA score plot showed the clear separation between tumor cells and normal blood cells such as lymphocytes and red blood cells, indicating the potential of non-invasive detection of tumor cells. In addition, obtained spectra from both EpCam-expressing and EpCam-non-expressing tumor cells were successfully segregated from those from normal blood cells. According to these results, it is suggested that segregating cells based on the difference in cytoskeletal components between epithelial cells and blood cells is feasible using the NIR imaging technology. CONCLUSIONS: Using the NIR composition imaging technology, we were able to obtain different spectral characteristics between tumor cells and normal blood cells, suggesting that this technology holds the potential to detect and isolate CTCs without any invasive labeling. This should be further explored for its application to the identification of CTCs.

#3798 Multiplex phenotyping of circulating cancer associated macrophe- like cells in patients with solid tumors. Daniel L. Adams, Katherine Alpaugh, Thai H. Ho, Steven H. Lin, Jeffrey R. Marks, Raymond Bergan, Stuart S. Martin, Saranya Chunsmir, Cha-Mei Tang, Massimo Cristofanilli. 1Cromart MicroTech, Inc., Monmouth Junction, MD; 2Fox Chase Cancer Center, Philadelphia, PA; 3Mayo Clinic Cancer Center, Phoenix, AZ; 4MD Anderson Cancer Center, Houston, TX; 5Duke University, Durham, NC; 6Oregon Health and Science University, Portland, OR; 7University of Maryland, Baltimore, MD; 8Mayo Clinic Cancer Center, Jacksonville, FL; 9Cromart MicroTech, Inc., Potomac, MD; 10Northwestern University, Chicago, IL.

Background: Circulating cancer associated macrophage-like cells (CAMLs) are cancer specific giant cells circulating in the blood of patients with solid tumors. Since their discovery, few studies have been done to elucidate their lineage or phenotypic identity. The difficulty in classifying CAMLs is exemplified by their expression of multiple heterogeneous markers that defy conventional identification. Recently, we described a restaining method (QUAS-R) to screen individual cells using an array of up to 15 biomarkers. We used this method to screen CAMLs isolated from 152 cancer patient samples in 4 types of solid tumors to classify CAMLs by phenotypic immunostaining. These data suggest that CAMLs are a morphologically diverse and phenotypically heterogeneous population of cancer specific giant cells with overlapping myeloid, ep- thelial, and endothelial phenotypes. Methods: This multi-institutional study used peripheral blood samples from 152 cancer patients (stage I-IV) from breast (n = 42), lung (n = 39), renal cell carcinoma (36) and prostate (n = 35). Blood was processed using the CellSieve™ microfılter technique at 8 institutions and stained for vimentin/CD146/CD144, CD11b/CD68/CD41, CD11c/CD68/TIE2, or CD34/ CD41/CD61. After staining, QUAS-R was again used to remove the fluorescence and samples restained with a third panel. Each patient sample was stained quenched and restained with the above mentioned panels. Results: In agreement with a number of studies, CAMLs were found in 86% of cancer patients (n = 131/ 152), with increased detection from stage 1 (71%), followed by stage 2 (94%), stage 3 (88%) to stage 4 (88%). Breast cancer had the most CAMLs per sample
Clinical Research: Liquid Biopsies 3: Circulating Tumor Cells, Extracellular Vesicles, and Exosomes

Clinical research: Liquid Biopsies 3: Circulating Tumor Cells, Extracellular Vesicles, and Exosomes

Analysis of circulating tumor exosomes: their ability to serve as a biomarker for recurrence in lung cancer. Nicholas Serrano, John Blue, Asim Alam, Christopher S. Rabender, Elisabeth Weiss, Mitchell S. Anscher, Rose B. Mikkelsen, Vasily A. Yakovlev. VCU Massey Cancer Ctr., Richmond, VA.

Objectives: Exosomes (Exos) are 30-150 nm wide nanovesicles originating from the endosomal network and are found in most body fluids. Production of Exos increases in cancer, making Exos potential biomarkers. Exos are a fundamental driver of intercellular communication by transferring proteins, lipids and mRNA. Analysis of Exos and their interaction with the microenvironment may uncover cellular pathways involved with disease progression. We hypothesized that Exos may serve as a liquid biopsy for tumor recurrence. Materials and Methods: Six lung cancer patients (LCPs) were prospectively enrolled on an IRB approved study. Exos were precipitated and purified with a Norgen kit from 0.7 ml of blood samples collected prior to, during and 6 months after radiation therapy (RT). Exos numbers were quantified by ExoCet Exosome Quantitation Kit (System Biosciences). Total exosomal RNA was isolated by the Norgen RNA/DNA/Protein Purification kit. For the miRNAs expression profiling we used the miRCURY LNA® Universal RT microRNA PCR assay (Exiqon) and Exiqon’s LNA probe sets for 40 different miRNAs (let-7a-5p, miR-20a-5p, miR-21-5p, miR-30b-5p, miR-106a-5p, miR-146a-5p, miR-155-5p, miR-200b-5p, miR-203a, miR-208a) for all samples were determined. Human lung fibroblasts (MRC-5s) in serum-free medium for 24 hrs were treated with Exos, TGF-β (positive control) or PBS (negative control) to determine their relative effects on MRC-5 proliferation. Results: Of the 6 LCPs, 4 showed a 2-5-fold increase both on small and large scale. Three patients were diagnosed with recurrence at the time of their post-RT blood draw. Six miRNAs demonstrated significantly different expressions between recurrent and non-recurrent groups of LCPs: let-7a-5p, miR-20a-5p, miR-21-5p, miR-106a-5p, miR-146a-5p, and miR-203a. MRC-5 proliferation increases 2-fold when treated with Exos from blood collected prior to RT compared to PBS (p < 0.01). There is <2-fold increase compared to TGF-β (p = 0.03). Plasma Exos levels decrease during RT as do their relative effects on MRC-5 proliferation when compared at equivalent numbers. Exos collected at 6 months from patients with recurrent significantly stimulated MRC-5 proliferation (p = 0.03), whereas Exos from patients without recurrence do not. Western blot analyses of MCR-5 cells stimulated with Exos revealed increased PTEN but enhanced CD44, CD9, and increased AKT and SMAD phosphorylation, regardless of when the Exos were collected. Conclusions: Recurrent and non-recurrent groups of LCPs demonstrated significant differences in exosomal miR profile before and after RT. Exos from untreated LCPs, and recurrent LCPs after RT, stimulate MCR-5 proliferation and possible conversion to CAFs. Our results suggest that Exos could serve as a ‘liquid biopsy’ to assess the potential for recurrence when imaging modalities are equivocal.

A novel sensitive flow-cytometry based platform for isolation and molecular characterization of circulating tumor single cells and clusters. Neha Bhagwat,1 Charles H. Pletcher,2 Ling Wang,3 William DeMuth, Keely Dulmage,4 David Ball,5 Stephanie S. Yee,6 Liping Yu,7 Jonni S. Moore,7 Ben Z. Stanger,8 Eric P. Dixon,9 Erica L. Carpenter,7 1Division of Gastroenterology, Department of Medicine, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA; 2Department of Pathology and Laboratory Medicine, Perelman School of Medicine, Philadelphia, PA; 3BD Technologies, Research Triangle Park, NC; 4Division of Hematology and Oncology, Department of Medicine, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA; 5BD Biosciences, San Jose, CA.

Circulating tumor cells (CTCs) are shed from solid tumors and found at extremely low frequencies in the blood of patients in most cancers. A subset of these cells (CTC+) give rise to distant metastases and which is the primary cause of cancer-related mortality. Isolation and characterization of these cells from blood as a ‘liquid biopsy’ can be a sensitive, non-invasive method for early detection, disease monitoring and therapy selection. CTCs can be found even at early disease stages in preclinical models and patients. There is increasing evidence that clusters of CTCs in blood are associated with higher metastatic potential; however, efficient isolation and interrogation of these rare clusters is challenging. In this study, we utilize an in-line rare cell enrichment platform developed by Becton Dickinson (BD), coupled with the BD FACSTM Influx cell sorter to rapidly isolate both single cells and clusters from blood. This platform utilizes magnetic particle-based depletion of unwanted leukocytes and combines acoustic focusing to remove red blood cells and debris while enriching for rare cells of interest. We achieved 30-fold enrichment of tumor cells spiked into blood along with >6-fold improvement in sort efficiency with the enrichment process as compared to without. Importantly, the large 200μm nozzle and low sheath pressure (3.5 psi) on the Influx minimizes shear forces and maintains cell viability and integrity of clusters during sorting, thereby enabling discrimination of single cells and clusters based on side scatter. Using this strategy, we could sort enriched populations of viable cell clusters (range 2-10 cells). Finally, this workflow can be integrated with single cell sequencing (sc-RNAseq) on cells isolated with this streamlined platform where pooled cells and bulk RNA were used as comparisons. As proof of principle, we used this optimized workflow to isolate and characterize CTCs from a pancreatic cancer mouse model (KPCy) in which all tumor cells are labeled with Yellow Fluorescent Protein (YFP). We sorted YFP+ CTCs and CD45+ white blood cells (WBCs) from the blood of 7 KPCy mice along with YFP+ cells from the matched tumor. We recovered an average of 88 CTCs/ml of blood (range 5-258). RNA sequencing was completed on pooled and single cells from all samples. Epithelial genes including Krt18 and Krt19 as well as lineage specific genes such as Sox9 were significantly
CLINICAL RESEARCH: Liquid Biopsies 3: Circulating Tumor Cells, Extracellular Vesicles, and Exosomes

overexpressed in CTCs and tumors compared to WBCs, suggesting the utility of this approach. This integrated CTC workflow provides a sensitive approach to identify pancreatic cancer-specific markers, which will be evaluated for their ability to improve sensitivity of positive-selection of CTCs in patient blood and for development of a clinically relevant diagnostic assay.

#3802 A novel uracil-DNA glycosylase, UdgX, as a new biochemical tool to directly detect uracils in DNA, Jessica Stewart,1 Shiangao Wei,2 Madhurima Datta,2 Umesh Varshney,2 Ashok Bhagwat1,1 Wayne State University, Detroit, MI;2Indian Institute of Science, Bangalore, India

The enzyme activation-induced deaminase (AID) is essential to the B lymphocyte development and antibody maturation. It converts cytosines in DNA to uracil. The unregulated expression of AID in many B cells is correlated with an increased load of mutations. AID also promotes DNA strand breaks and is required for chromosomal translocations such as IgH/Myc in these tumors. We have previously showed that B cell cancer cell lines and patient tumors which express AID at high levels also have high levels of uracil in their genomic DNA. We accomplished this by excising the uracils using a uracil-DNA glycosylase (Ung) and labeling the resulting in an abasic site with an aldehyde reactive chemical (ARP). ARP contains a biotin tag and was detected using a fluorescently labeled streptavidin. The results from this assay showed B cell tumors have as much as 100-fold higher levels of genomic uracils. Further development of this assay has allowed the detection of uracils in the blood plasma and buffy coat of B cell cancer patients. This “liquid biopsy” assay technique has the potential to work as a simple surveillance tool for B cell cancer patients who are in remission. In addition, we are exploring the possibility of a direct detection of uracil in DNA, which would provide greater sensitivity to this assay and simplify it. A unique uracil-DNA glycosylase was recently isolated from M. smegmatis, UdgX that binds covalently to uracils in DNA. We are developing multiple ways to detect uracil-DNA-UdgX complexes and amplifying the resulting signal. We expect that this will allow us to directly visualize uracils in B-NHL tumors and detect uracils in circulating B-NHL tumor DNA from a drop of patient plasma.

#3803 Characterization of fluid biopsy using the HD-SCA platform to re-stratify intermediate-risk organ-confined prostate cancer patients, Paymaneh D. Malihi,1 Kenneth Pienta,2 James Hicks,1 Michael Gorin,2 Carmen Ruiz Velasco,1 Anders Carlsson,1 Anand Kolatkar,1 Mariam Rodriguez Lee,1 Michael Morikado,1 Peter Kuhn1.1 Wayne State University, Detroit, MI;2Johns Hopkins Hospital, Baltimore, MD.

Recent studies have demonstrated that even with current risk stratification of intermediate-risk organ-confined prostate cancer patients, 30-50% of patients are incorrectly categorized and overtreated. As the second leading cause of cancer in men, 90% of prostate cancer patients are diagnosed at organ-confined stages, where radical prostatectomy (RP) is the “golden standard” of treatment. However, deferring intervention is becoming a more popular option for low-risk patients, with a 15-year progression-free survival of 95%. High-risk patients greatly benefit from RP, but have a 5-year progression-free survival of 85%, while the decision to proceed with RP is not so candid for intermediate-risk patients. Using the high-definition single cell assay (HD-SCA) platform, circulating tumor cells (CTCs) from peripheral blood (PB) and disseminating tumor cells (DTCs) from bone marrow aspirate (BMA) will be analyzed for morphological, genomic, and proteomic profiling. We hypothesize that by using morpho-proteo-genomic parameters we may develop predictive markers for a more accurate stratification of intermediate-risk patients, offering a more personalized treatment for each individual. Preliminary data shows 86% (n=43) of PB samples and 5% (n=40) of BMA are positive for Cytokeratin (CK) expressing rare circulating cells, as defined by ≥5 cells/mL. The incidence of CK+ cells in PB did not correlate with PSA, Gleason score, or clinical parameters. However, incidence of CK+ cells in PB was higher in high-risk group, though not statistically significant (p=0.784) when compared to intermediate-risk groups. Additionally, higher levels of CK expression (p=0.0001), as measured by relative intensity of fluorescent staining, were detected in cells detected in PB of high-risk patients relative to intermediate- and low-risk groups as measured by an analysis of variance (ANOVA) statistical model. Low levels of genomic aberrations are observed in CTCs from circulating cells (0.18), which may point to the fact that these patients are in early stages of their disease. The use of the HD-SCA platform to characterize the fluid biopsy may result in the identification of predictive markers of treatment response for intermediate-risk patients, resulting in reduction of overtreatment.

CLINICAL RESEARCH: Predictive Biomarkers 3

#3804 Comprehensive comparison of bisulfite conversion kits: A guide for optimal sensitivity and specificity of circulating cell-free DNA methylation-based biomarkers, Sarah Ø. Jensen, Mai-Britt W. Ørntoft, Jesper B. Bramsen, Torben F. Ørntoft, Claus L. Andersen. Aarhus University Hospital, Aarhus, Denmark.

Analysis of circulating cell-free DNA (cfDNA) is a promising approach for non-invasive detection of human cancers. The approach has wide-spread applications including early detection of disease in asymptomatic individuals, residual disease detection and disease monitoring. A challenge for the clinical utilization of cfDNA is the small fragment size of cfDNA and the limited amount of cfDNA present in blood. For detection of circulating tumor DNA (ctDNA) highly sensitive methods for cfDNA detection e.g. targeted sequencing and digital droplet PCR (ddPCR) target tumor specific mutations or DNA methylation alterations. Detection of methylation-based biomarkers requires that cfDNA is bisulfite converted prior to biomarker detection, which is known to be associated with some loss of cfDNA. Yet, surprisingly few efforts have focused on ensuring high cfDNA bisulfite conversion (BSC) efficiency and -recovery, and few commercial kits are especially designed for this purpose. In this study we aimed to find a BSC method suited for ctDNA methylation biomarker research, with high BS conversion efficiency and minimum loss of cfDNA, in order to increase the amount of cfDNA template available for downstream analysis.

We studied 13 different methods for BSC and examined both the recovery and the BSC efficiency using quantitative real-time PCR (qPCR), polyacrylamide gel electrophoresis (PAGE) and ddPCR. A significant variation in DNA recovery was observed between the 13 methods tested using both high and low molecular weight DNA templates. Especially five kits performed consistently well on all DNA templates tested, as evaluated by qPCR and PAGE. As the lengths of cfDNA is 146-167 base pairs, only methods that are able to recover fragments of this length is suitable for cfDNA pipelines. Results showed that few methods enabled recovery of DNA fragments ≤ 150 base pairs. However, three kits showed a higher amount of 150 base pair fragments compared to the other methods tested. In a clinical setting it is expected that the target cfDNA compose only a minor fraction of the total cfDNA in plasma. Thus, the five best performing kits were tested using ddPCR on serial dilutions of leucocyte DNA fragmented to ~ 150bp to mimic cfDNA. The best performing kit had a recovery of 69% of the initial input compared to only 13% for the poorest performing kit. Collectively, our comprehensive comparison hereby guide which BS conversion methods are suited for cfDNA methylation-based biomarker pipelines.

#3805 Pre-diagnostic statin use among breast cancer patients - the relation to HMG-CoA reductase expression and disease-free survival, Helga Tryggvadottir, Emma Gustbée, Andrea Markkula, Maria Simonsson, Björn Nordin, Karin Jirström, Carsten Rose, Christian Ingvar, Signe Borgquist, Helena Jernström. Lund University, Lund, Sweden.

Background: The purpose of this study was to investigate whether pre-diagnostic statin use was associated with tumor expression of HMG-CoA reductase (HMGCR) and disease-free survival (DFS) in breast cancer. Previous studies have shown anti-carcinogenic properties of statins and a significantly longer survival among breast cancer patients using statins. We recently showed, that the target of statins, HMGCR, was up-regulated in breast cancer among patients preoperatively treated with statins in a window-of-opportunity trial. Methods: A population-based cohort of primary breast cancer patients in Lund, Sweden was assembled between October 2002 and June 2012. Patients completed a questionnaire including information on medication use. Statin use in relation to DFS was analyzed in 985 patients. Tumor tissue microarrays were constructed and stained with a polyclonal HMGCR antibody to assess HMGCR expression (n=848). Results: Patients were followed for up to 11 years (median follow-up time 5.0 years). In the present study, pre-diagnostic statin use was neither associated with HMGCR expression (P=0.53) nor with DFS (P=0.92), overall or separately in any of the HMGCR expression groups (negative, weak, moderate/strong). Moreover, statin use was not associated with clinical tumor characteristics (tumor size, axillary lymph node involvement, histological grade, hormone receptor status or HER-2 amplification). Conclusion: In contrast to previous studies, the present study did not show any significant association between pre-diagnostic statin use and DFS. It is possible that patients who already used statins have developed tumors that are less dependent on cholesterol metabolism and consequently less influenced by statin treatment. The timing of statin use in relation to breast cancer diagnosis and prognosis should be evaluated in another cohort with preferably longer follow-up time.

972 Proceedings of the American Association for Cancer Research • Volume 58 • April 2017
expression was detected among 5% of this cohort of advanced solid cancers, primarily in breast and gastrointestinal tumors. Sensitivity to platinum therapy is significantly higher in ATM loss colorectal cancer. Further prospective studies with larger cohorts are required to validate these findings.

#3808 TM4SF1 regulates cell cycle and ROS status in bladder cancer cells by targeting FOXO3a via PPARγ-SIRT1 negative feedback loop.

While gemcitabine has been the mainstay therapy for advanced pancreatic cancer, newer combination regimens (e.g. FOLFIRINOX) have extended patient survival, though carry greater toxicity. Biomarkers are needed to better stratify patients for appropriate therapy. Previously, we reported that one-third of pancreatic cancers harbor deletions or deleterious mutations in key subunits of the SW itch/Sucrose NonFermentable (SWI/SNF) chromatin remodeling complex. The SWI/SNF complex mobilizes nucleosomes on DNA, and plays a key role in regulating DNA transcription and repair. Thus, we hypothesized that pancreatic cancers with SWI/SNF aberrations might exhibit compromised DNA repair, and show increased sensitivity to DNA damaging agents. Here, we studied pancreatic cancer cell lines with deficient (or else exogenously reconstituted) SWI/SNF subunits, as well as normal pancreatic epithelial cells (HPDE) following SWI/SNF subunit knockdown. Cells were challenged with DNA damaging agents, including those used in current combination regimens, and then cell viability assayed. We found that pancreatic cells with SWI/SNF dysfunction showed markedly increased sensitivity to DNA damaging agents, in particular DNA crosslinking agents (cisplatin and oxaliplatin). Assaying clearance of γH2AX foci confirmed that SWI/SNF dysfunction impaired DNA damage re-

Proceedings of the American Association for Cancer Research, Volume 58, April 2017

973
sponse/repair. Finally, by analyzing pancreatic cancer patient data (TCGA), we found that pancreatic cancers with SWI/SNF deficiency (subunit mutation and/or decreased expression) showed a strong trend towards extended survival with platinum containing chemo regimens. Thus, SWI/SNF dysfunction sensitizes pancreatic cancer cells to DNA crosslinking agents, and SWI/SNF mutation status may provide a useful biomarker to predict which patients may benefit from platinum-containing chemotherapy regimens.

#3810 Validation of novel high-plex protein spatial profiling quantitation based on NanoString’s Digital Spatial Profiling (DSP) technology with quantitative fluorescence (QIF). Maria I. Toki, 1Chris Merritt, 1Giang Ong, 1Joseph M. Beechem, 2Daniel E. Carvalaj-Hausdorf, 1Yalai Bai, 1David Rimm, 1Yale University School of Medicine, New Haven, CT; 2NanoString Technologies, Seattle, WA.

Background: Protein expression in formalin-fixed, paraffin-embedded (FFPE) tissue is routinely measured by Immunohistochemistry (IHC) on only one protein, or with quantitative fluorescence (QIF) on a handful of proteins on a single section. NanoString’s Digital Spatial Profiling (DSP) technology can detect and quantify proteins at significantly higher multiplex (currently 30plex, potential for up to 800plex) with spatial resolution using molecular digital color-coded “barcodes”, within specific regions of interest on FFPE tissue. Here, we compare Nanostring DSP technology to automated QIF (AQUA), for accurate and reproducible measurement of protein expression on a continuous scale. Additionally, using the multiplexing potential of Nanostring technology, we did a pilot study to assess cold ischemic time as a variable to monitor tissue quality by assessing protein degradation and quantification in FFPE tissue (NSCLC).

Methods: The DSP technology uses a cocktail of primary antibodies conjugated to indexing DNA oligos with a UV Photocleavable linker that can be counted on the nCounter platform. Regions of interest (ROI) on the tissue are selected with fluorescently labeled antibodies, and oligos from that region are released via UV mediated linker cleavage. Free oligos are captured via microcapillary fluidics into a microtiter plate and then quantitated on the nCounter. The comparator for this technology was the AQUA method of QIF. We examined a breast cancer tissue microarray with a range of HER2 expression, and a NSCLC time to fixation standardization array with timepoints from 20 min to 48 hrs. Results: Multiple markers were assessed and a high correlation was found between Nanosting DSP counts and QIF scores (R²>0.7), when the measurements were performed in the same region of interest (defined by cytokeratin expression). The dynamic range of DSP exceeded the quantification range of QIF (nearly 4 logs vs about 2 logs). When the 28 protein markers’ expression was compared at different fixation timepoints, most were found to be stable over different cold ischemic timepoints. Two markers, including phospho-ERK (Extracellular Signal-Regulated Kinases) and phospho-GSK (Glycogen Synthase Kinase) showed epitope loss as a function of delay to fixation (R²=0.0064 and R²=0.05 respectively). Conclusion: The Nanostring DSP is a reproducible method with the capability of highly multiplexed measurements of protein expression on a field of view averaged basis. It shows high concordance with the AQUA method of QIF, an extensively validated technique for protein quantification. For the first time, the high-plex capacity of DSP allows inclusion of markers that are sensitive to time to fixation as an intrinsic control for tissue quality. *FOR RESEARCH USE ONLY. Not for use in diagnostic procedures.

Decades of cancer research including comprehensive molecular profiling combined with the development of a broad array of targeted therapies have created the opportunity to transform cancer care by implementing precision oncology based approaches. An important element of this system is the widespread availability of robust and cost-effective multi-variant profiling methods to characterize relevant cancer associated molecular alterations in the future. Current commercially available multi-variant profiling methods vary dramatically with regard to the number of cancer genes that are interrogated. Given that many large scale and detailed molecular profiling studies have been completed, the landscape of somatic alterations in solid tumors is reasonably well-known. Furthermore, the specific gene variants that are relevant to application of targeted therapies are also a matter of record. Therefore, we set out to define the number of relevant cancer genes for precision oncology research based on the currently available empirical evidence. To define recurrent somatic alterations in solid tumors, we created a compendium of variant calls from >15,000 exomes, defined focal amplifications and deletions from >30,000 arrays, and defined recurrent fusions from several thousand RNAseq profiles. Statistical approaches were implemented to define genes containing recurrent missense mutations (i.e., hotspots), enriched in truncating mutations or subject to recurrent copy number gain/loss or translocation. This gene set was then used to comprehensively search approved cancer drug targets and clinical practice guidelines to identify genes containing published evidence that specific recurrent somatic gene variants were used as part of the indication statement of an approved targeted therapy, were recommended for testing as part of clinical practice for therapeutic decisions, or were used as enrollment criteria in clinical trials. The relevant cancer genome thus defined consists of <100 genes. These results suggest that targeted multi-variant profiling approaches may be sufficient to support precision oncology goals in the future.

#3812 JAK2 and PTPN11 mutations as potential biomarkers for BCL-xL inhibition as monotherapy and in combination therapy for acute myeloid leukemia. Richard J. Bellin, Valerie Hilgenberg, Rejla Popovic, Tamar Uziel, Lloyd T. Lam. Abbvie, North Chicago, IL.

Acute Myeloid Leukemia (AML) is a heterogeneous disease where major distinct functional mutations have been identified. While mutations in FLT3, NRAS, NPM1, and IDH genes have been well characterized in de novo AML, a subset of AML associated with leukemia transformation of chronic myeloproliferative neoplasms (MPNs) are enriched in mutated JAK2 and PTPN11. MPNs are a set of disorders characterized by the chronic and abnormal overproduction of blood cells which can ultimately progress to AML. Targeted therapy against mutated JAK2 and PTPN11 with small molecule inhibitors against the JAK-STAT and RAS-ERK pathways, respectively, are being actively investigated in AML. However, acquired resistance and non-durable responses are already being demonstrated in monotherapy treatment. Thus, AML that has arisen from leukemic transformation of MPNs remains an area of unmet medical need. This need is underscored by the fact that these patients suffer from poor outcomes and low response rates to standard chemotherapy. Together, these results indicate the need for rational combinations in this population. In this study, we sought to better define the dependencies of AML cells on BCL-2 family members by screening AML cell lines with selective small molecule inhibitors to the BCL-2 family members. The screen revealed that the majority of AML cell lines depend on BCL-2, or BCL-2 together with MCL1 for survival. Intriguingly, a subset of AML cell lines is exquisitely sensitive to BCL-xL inhibition. Treating these cell lines with BCL-xL-selective inhibitor or with navitoclax, a dual BCL2/BCL-xL inhibitor induces apoptosis. These BCL-xL inhibitor-sensitive cell lines express high levels of BCL-xL, but not BCL-2 and MCL1. Genomic analysis of BCL-xL inhibitor-sensitive AML cell lines revealed that this subset is also enriched in JAK2V16F and PTPN11 mutations. We further demonstrate positive combination effect between BCL-xL inhibitor or navitoclax with JAK inhibitor (ruxolitinib) and two MEK inhibitors (trametinib and AZD6244) in cell lines with JAK2V16F and PTPN11 mutations, respectively. Together, these results demonstrate the potential utility of a BCL-xL inhibition as a combination partner in JAK2 and PTPN11 mutated cancers. Importantly, JAK2 and PTPN11 mutations in addition to expression of BCL-xL, BCL-2, and MCL1 could also be further tested as potential biomarkers for the utility of BCL-xL inhibition based treatments for patients with these mutations.

#3813 MPF as a monitoring biomarker for a mesothelin-targeted therapy against malignant mesothelioma and other cancer. Yunkai Yu, Raffit Hassan, Jingli Zhang, Masanori Onda, Ira Pastan, Liang Cao. National Cancer Institute, Bethesda, MD.

Introduction: Tumor antigen mesothelin had been shown to be elevated in mesothelioma, ovarian, pancreatic, and lung cancer. The mesothelin gene encodes a precursor protein of 69 kDa, which is cleaved into a 31 kDa soluble megakaryocyte potential factor (MPF), and a cell membrane-bound 40 kDa mesothelin. There is a high degree of interest in targeting mesothelin for mesothelioma and other cancers with various antibody-based agents, and some successes in early stage clinical trials with some of the agents. For the development of these targeted therapeutics, specific biomarkers would be needed for monitoring treatment responses, and detecting and evaluating tumor progression. The current test that detects mesothelin is not suitable due to the antigen-binding from the therapeutic antibodies. There is an urgent need to develop and validate an alternative test to support these clinical trials and for disease management.

Methods: Using ECLIA technology and proprietary antibody reagents, we developed a new test for the cleaved MPF polypeptide. We further conducted comprehensive analytical and clinical validation of the test according to the guidelines for tumor antigen tests. Using samples from a retrospective clinical trial with an anti-mesothelin immunotoxin and the standard 1st line chemo-
therapeutic agents for newly diagnosed malignant mesothelioma patients, we examined the effectiveness of the test for treatment monitoring of the investigational therapy. Results: Our data gives a strong validation for the analytical and clinical performances of MPF test. While no other current test has been proven to be able to monitor response of mesothelioma to systemic therapies, our data provides the proof of MPF test’s feasibility. Conclusion: Our study demonstrates that MPF test in the elevated tumor antigen, there is a specific and highly significant reduction of MPF at the end of each treatment cycle for a total of 6 cycles in the patients with objective response. Later, about half of these patients with objective response and MPF reduction regained the levels of MPF at the time of disease progression. Conclusion: The study indicates that MPF test is effective in monitoring the treatment response to systemic therapies for mesothelioma patients with elevated MPF. It may also provide pivotal information on the expression of target mesothelin protein when tumors progress.

Introduction The Tumor Inflammation Signature (TIS) is an 18 gene signature in development for the detection of adaptive immune response within tumors by measuring expression of genes associated with cytotoxic cells, antigen presentation, and IFNγ activity. The TIS has been previously shown to enrich for a population of patients who respond to the anti-PD1 therapy pembrolizumab. We characterized the behavior of the TIS across a range of tumor gene expression data downloaded from the TCGA in order to understand the distribution of TIS within and between tumor types, with special emphasis on those tumors for which anti-PD1 therapy is approved for use. Methods: The TIS was trained to predict response to pembrolizumab using gene expression profiles from 289 biopsies from 11 different tumor types. Its association with clinical response was retrospectively assessed in an independent set of 200 samples from 14 additional tumor types. We calculated TIS scores in over 9000 samples from 31 TCGA RNASeq datasets. We contrasted TIS with mutational load, with overall survival, and with other gene expression signatures. Results: While TIS scores are higher in classically immunogenic tumor types, they display a significant amount of intersample variability within most tumor types, and a subset of patients can be identified that possess elevated TIS scores consistent with responsiveness to pembrolizumab. TIS genes have highly conserved co-expression patterns across tumor types, consistent with a model in which the genes measure immune-intrinsic transcriptomic activity with minimal contribution of tumor-intrinsic gene expression. Notably, ranking tumors by median TIS score is superior to mutational load ranking at predicting clinical response to anti-PD1. TIS was minimally correlated with mutational load in most tumor types, except in tumor types known for hypermutation-driven by mismatch repair deficiency. TIS and mutation burden had their greatest variability in melanoma; in most other tumors, TIS retains more variability than mutation burden, possibly reflecting patients with anti-tumor immune responses driven by one or a few mutation-derived neoantigens. Average mutation burden and average TIS are positively correlated within most tumor types. Notable exceptions to this trend include two tumors for which anti-PD1 is currently approved. Bladder urothelial carcinoma has the highest average TIS over mutation burden would predict and kidney renal clear cell carcinoma has much higher average TIS than its mutation burden would predict. Conclusion: The TIS has the potential to enrich for anti-PD1 responders independent of tumor type. It may identify rare potential responders in tumors with low average response rates. These results support further research into the efficacy of anti-PD1 in patients with high TIS scores, regardless of tumor type.

#3815 The clinical impact of c-MET over-expression in advanced biliary tract cancers. Mi Hwa Heo, Seung Tae Kim, Young Suk Park, Joon Oh Park, Hansang Lee. Samsung Medical Center, Seoul, Republic of Korea.

Background: c-MET is a proto-oncogene that encodes the tyrosine kinase receptor for hepatocyte growth factor (HGF). Activation of HGF-c-MET signaling involves cell invasiveness and evokes metastasis through direct involvement of tumor angiogenesis. However, the value of c-MET overexpression is still unknown in metastatic BTC. Methods: We analyzed the incidence and clinicopathologic characteristics of c-MET overexpression in advanced BTC. Moreover, we investigated the value of c-MET overexpression in predicting response to gemcitabine plus cisplatin (GC), a first line standard regimen, and as a prognostic marker in metastatic BTC. Results: The BTC subtype distribution (N=44) was as follows: intrahepatic cholangiocarcinoma (IHCC, n=7), extrahepatic cholangiocarcinoma (EHCC, n=25) and gallbladder cancer (GBC, n=12). Liver (52.3%) was the predominant metastatic site, followed by lymph nodes (36.4%) and bone (15.9%). Among the 44 patients analyzed for c-MET expression, 15 (34.1%) exhibited c-MET overexpression in tumor tissues. There was no significant difference in the prevalence of c-MET overexpression among primary sites in EHCC (7/25, 28%), IHCC (3/7, 42.9%), and GBC (5/12, 41.7%). There was also no significant correlation between specific clinicopathological variables and c-MET expression. Conclusion: The c-MET expression according to c-MET overexpression (overexpression vs. non-overexpression), there was no significant difference in either RR or DCR (p = 0.394 and 1.000, respectively). PFS for all 44 patients was 9.00 months (95% CI, 7.47-10.53 months) and there was no significant difference for PFS between patients with c-MET overexpression and those without (p = 0.917). The median OS was 14.00 months (95% CI, 10.21-17.79). There was a significant difference in OS between patients with c-MET overexpression compared to those without (13.7 vs. 14.4 months, respectively, p = 0.708). Conclusions: c-MET overexpression was detected in 34.1% of advanced BTC patients irrespective of tumor location. c-MET overexpression did not predict response to GC or survival. Further studies are needed to fully elucidate the value of c-MET overexpression as a novel biomarker in these patients.

#3816 Mutations of the lim protein ajuha mediate sensitivity of head and neck squamous cell carcinoma to treatment with cell cycle inhibitors. Ming Zhang, 1 Singh Ratnakar, 2 Shaohua Peng, 2 Mazumdar Tuhina, 2 Shen Li, 2 Pan Tong, 2 Curtis Pickering, 3 Jeffrey N. Myers, 2 Jing Wang, 2 Faye M. Johnson. 4

1Fudan Univ., Shanghai, China; 2MD Anderson Cancer Center, Houston, TX.

The genomic alterations identified in head and neck squamous cell carcinoma (HNSCC) tumors have not resulted in any changes in clinical care, making the development of biomarker-driven targeted therapy for HNSCC a major translational gap in knowledge. To fill this gap, we used 59 molecularly characterized HNSCC cell lines and found that mutations of AJUBA,SMAD4 and RAS predicted sensitivity and resistance to treatment with inhibitors of polo-like kinase 1 (PLK1), checkpoint kinases 1 and 2, and WEE1. Inhibition or knockdown of PLK1 led to cell-cycle arrest at the G2/M transition and apoptosis in sensitive cell lines and decreased tumor growth in an orthotopic AJUBA-mutant HNSCC mouse model. AJUBA protein expression was undetectable in most AJUBA-mutant HNSCC cell lines, and total PLK1 protein expression was increased in cell lines wild-type for AJUBA. Exogenous expression of wild-type AJUBA in an AJUBA-mutant cell line partially rescued the phenotype of PLK1 inhibitor-induced apoptosis and decreased PLK1 substrate inhibition, suggesting a threshold effect in which higher drug doses are required to affect PLK1 substrate inhibition. PLK1 inhibition was an effective therapy for HNSCC in vitro and in vivo. However, biomarkers to guide such therapy are lacking. We identified AJUBA, SMAD4 and RAS mutations as potential candidate biomarkers of response of HNSCC to treatment with these mitotic inhibitors.

Introduction Inflammatory bowel disease (IBD) can affect the lower part of the small intestine (ileum) and the colon. It can, however, occur in any part of the large intestine, small intestine, or stomach. Recent evidence suggests that several factors may tip the balance between homeostasis and intestinal inflammation, presenting future challenges for the development of new therapies for IBD. In this study, we use normal small intestine as a model to identify multiple immune targets using mouse and rabbit monoclonal antibodies. Peyer Patches are lymphoid tissues in the wall of the small intestine that are involved in the development of immunity to antigens presented in that milieu. Small intestine and cases of IBD were evaluated as a potential model using immunohistochemistry (IHC) to identify categories of immune cells including cytotoxic T-cells, costimulatory cells (agonists), T-regulatory cells (TREGS), T-cell effector cells (regulators) and checkpoint inhibitors. cases of IBD were also examined for the utilization of single and double/triple stains. Design Formalin-fixed paraffin-embedded cases of small intestine and IBD were cut to 4 micron thickness and stained with H&E, Mouse and rabbit monoclonal antibodies including CD3 (natural killer cells), CD163 (macrophages), CD8 and CD4 (cytotoxic T-cells and helper T-cells), CD103, OX40 and CD137 (costimulatory), FOXP3 and LAG3 (TREGS), T-bet and RORγT (T-cell effectors), and PD-1 and PD-L1 (immune checkpoints) were tittered for optimization and evaluated for IHC. Several IHC multiplex stains (double and triple stains) were also developed and compared with the relevant single stains. Results Single, double and triple stains utilizing CD66 (natural killer cells), CD163, CD4, CD8, CD103, OX40, CD137, FOXP3, LAG3, T-Bet, RORγT, PD-1 and PD-L1 antibodies were successfully established using small intestine as staining model for IBD cases. All single stains versus double and triple stains gave equivalent results. Double stains and/or co-expression of CD8 + CD103, CD8 +
PD-1, and triple stain CD8 + PD-1 + FOXP3 were easily visualized by blue, brown, red or black chromogen staining. Conclusion Small intestine is a good model to develop single or multiplex stains for a host of immune cell targets. Enhanced visualization of these targets is possible with the use of double and triple stains; thus, this technique may help facilitate acquisition of important prognostic information and help support new strategies for inflammatory bowel disease in targeted therapeutic treatment.

#3818 Identification of a FGFR3-TACC3 fusion in esophageal cancer. Takuro Mizukami,1 Kazuko Sakai,2 Saeko Naruki,1 Tomoko Taniyama,1 Yo-shiki Horie,1 Naoki Izawa,1 Takashi Tsuda,1 Takashi Fujino,1 Narikazu Boku,1 Hiroshi Yasuda,1 Tetsu Fukunaga,1 Takako Eguchi Nakajima,1 Kazuto Nishio.1

1St. Marianna University School of Medicine, Kanagawa, Japan; 2Kinki University Faculty of Medicine, Osaka, Japan; 3Juntendo University School of Medicine, Tokyo, Japan.

Ablerrant activation of fibroblast growth factor (FGF) signaling has been found to contribute to carcinogenesis. Recently, activating FGFR fusions are detected in several malignancies. However, limited information is available regarding the existence of FGFR fusions in esophageal squamous cell cancer (ESCC) and gastric cancer (GC). In this report, we explored major FGFR1, FGFR2, and FGFR3 fusion transcripts in ESCC and GC specimens (n = 74 and 114, respectively) using a most comprehensive next-generation sequencing panel. We detected a targetable fusion between exon 18 of FGFR3 and exon 11 of TACC3 at a frequency of 1.4% (1/74) in ESCC, whereas other FGFR fusions were not detected in the GC specimens. Furthermore, split FGFR3 signals were apparent in this specimen by fluorescence in situ hybridization (FISH) with break-apart probes. The patient, a 64-year-old man with unresectable T4bN3M1 poorly differentiated ESCC of stage IV, was treated with palliative chemoradiotherapy followed by taxane chemotherapy. The patient died of cancer progression, with his overall survival time having been 9.5 months. Our results provide sequence information that should prove useful for development of simple and cost-effective diagnostic assays as an alternative to FISH for patients with ESCC harboring the FGFR3-TACC3 fusion.

#3819 Identification and quantification of isoforms of eukaryotic initiation factor 4E as biomarker in Mkn inhibitor-treated mouse model by capillary-based immunoassay platform. Zhiyuan Ke,1 Sifang Wang,1 Vithya Mano-haran,1 Susmitha Vuddagiri,1 Esther Ong,1 Sharon Lim,2 Sin Tong Ong,2 Kanda Sangthongpitag,1 Nacro Kassoum,1 Jeffrey Hill,1 May Ann Lee.1

1Experimental Therapeutics Centre, Agency for Science, Technology and Research, Singapore, Singapore; 2Duke-NUS Medical School, Singapore, Singapore.

Elevated levels of the phosphorylated mG cap binding protein, eukaryotic initiation factor 4E (eIF4E) are associated with neoplasia. An observed oncogene signaling effect upon activation of Erk1/2 or p38 MAPKs in cells is the eIF4E-overexpressing K562 cells. siRNA knockdown of eIF4E expression resulted in growth arrest and apoptosis in eIF4E-overexpressing K562 cells. siRNA knockdown of eIF4E expression reduced both isoforms, while treatment with Mnk inhibitor only reduced phosphorylated eIF4E level. The measurement and quantification of the relative changes of phosphorylated eIF4E by this method can potentially be used in monitoring the efficacy of Mnk inhibitors in xenograft and future clinical trials.

#3820 Hepatitis B virus gene pre-S2 mutant as a high risk serum marker for hepatoma recurrence after a hepatic resection. Wen-Ya Huang. Cheng Kung University Hospital, Tainan, Taiwan.

Background: Chronic hepatitis B virus (HBV) infection is the major cause of hepatocellular carcinoma (HCC). The pre-S2 mutant large HBV surface antigen (LHBs) is highly associated with HCC. This study aimed to evaluate the serum pre-S2 mutant LHBs as a high-risk recurrence marker in HCC patients after a hepatic resection. Methods: The pre-S gene chip was used to analyze 175 patients with HBV-related HCC who underwent a hepatic resection between 2008 and 2012. Thirty independent pre-S clones in every patient were analyzed for a semi-quantitative detection. Results: Multivariate regression analysis showed that the serum pre-S2 mutant level (> 5%) and the American Joint Committee on Cancer (AJCC) tumor stage were two independent high-risk factors for HCC recurrence. A Cox proportional hazards analysis also showed that the combined evaluations of the AJCC stage and serum pre-S2 mutant level provided a more effective predictive marker for HCC recurrence after hepatectomy. We developed a Cox prediction model, which indicated the recurrence-free survival rates along with the time after surgery. This model was validated in an independent HCC cohort. Receiver operating characteristic curve analysis revealed that the model showed close sensitivities in the main and validation cohorts (AUC values: 0.741 and 0.704, respectively). Conclusions: The relation of serum pre-S2 mutant level, independent of the AJCC stage, is an important predictive high-risk marker for HCC recurrence after a primary hepatectomy. The combined evaluations of the AJCC tumor stage and serum pre-S2 mutant level potentially serve as a convenient high-risk predictive marker for HCC prognosis.

#3822 Expression of androgen receptor and CD24 correlates with improved 5-year survival in Pakistani patients with invasive breast cancer. Nazia Riaz,1 Romana Idrees,2 Sadia Habib,3 Azhar Hussain,3 El-Nasir Lalani.1

1Centre of Regenerative Medicine and Department of Surgery, Aga Khan University, Karachi, Pakistan; 2Department of Pathology and Laboratory Medicine, Aga Khan University, Karachi, Pakistan; 3Centre of Regenerative Medicine, Aga Khan University, Karachi, Pakistan.

Introduction: Androgen receptor (AR) expression has been shown to correlate with improved survival in luminal A, B and triple negative (TN) breast cancer (BCa). Cancer stem cells (CSC) with CD44+/CD24- and ALDH1+ phenotype is associated with pro-invasive gene signature in BCa. Aim of our study was to evaluate prognostic significance of AR expression in relation to CD44-, CD24- and ALDH1+ BCa. Methodology: Immunohistochemical expression of AR, CD44, CD24 and ALDH1 was evaluated in 180 FFPE blocks of BCa cases from one institution. Clinico-pathological details and follow-up data were collected from medical charts. Data was analyzed on SPSS 19. Five-year survival was estimated by Kaplan Meier. Results: Median age of patients was 55 years (range: 28-87). Fifteen percent of patients were diagnosed with stage I, 52.2% with stage II, 25% with stage III and 7.8% with stage IV disease. Mean duration of follow-up was 4.5 years (SD = 2.7) and 29% mortalities were attributed to BCa. AR was expressed in 63.9%, ER in 61%, PR in 51% & HER-2/neu in 30% of tumors. CD44, CD24 and ALDH1 were expressed in 60%, 43.3% & 28.3% of tumors respectively. AR expression was associated (p-value < 0.001) with stage II tumors expressing ER, PR and CD24 but lacking ALDH1. Multivariable analysis confirmed AR (adjusted HR 0.43, 95% CI 0.19-0.95) and PR (adjusted HR: 0.20, 95% CI 0.07-0.60) to be independently associated with better outcome. Five year survival of patients with AR+ versus AR- expressing tumors, showed that patients with AR+ tumors had significantly better outcome (p-value = 0.03) with survival advantage of 39.6 months. Survival advantage decreased by 9.6 months in tumors expressing CD44+/CD24-AR- (p-value = 0.01) phenotype and by 12 months in patients whose tumors were phenotypically ALDH1+/AR- (p-value = 0.12). We stratified TN tumors into three risk groups: AR-, TN/CD24+/CD44+/ALDH1+; AR+; TN/CD24-/CD44+/ALDH1-. We found that group A tumors had a trend towards better survival (p-value = 0.09). Conclusions: Three individual markers (CD44, CD24, AR) may afford prognostic information. Combinations of CD44, CD24 and AR permitted patient stratification into 3 risk categories: poor risk CD24-/AR-; intermediate risk CD44+/CD24-/AR-; and good risk CD24+/AR+. Stratification of TN group showed that loss of AR and CD24 was associated with poorest outcome. These results underscore the relevance and importance of AR and CD24 as prognostic markers in invasive BCa.

Introduction: Fluoropyrimidines (FP) are of major use in treating cancer. Dihydropyrimidine dehydrogenase (DPD) is the main enzyme responsible for FP catabolism. Low DPD activity screening has proven its predictive clinical value in identifying patients at risk for toxicity. However, high DPD activity may translate to decreased FP activation and efficacy. Patients and methods: One hundred and forty-three patients (monocentric retrospective study) underwent a pretreatment assessment of DPD activity in lymphocytes between 01/01/2004 and 20/04/2016. Included patients were male or female, >18 years, FP-treatment-based. Cut-off for DPD activity was assessed using smoothing spline curves. Results: Median patient follow-up was 30 months [C95%: 27.3-36.2],

Proceedings of the American Association for Cancer Research • Volume 58 • April 2017
mean age 63 +/- 3 years, females accounted for 53%, 90% of patients had a good performance status (0 or 1). Fifty-eight percent of FP indications (65% 5-FU and 35% capecitabine) were adenocarcin or neoadjuvant and 42% were prescribed for local or metastatic recurrences. Tolerance was poor for 43% of patients and 49% needed dose reduction. Objective response (complete and partial) was observed in 50% of patients, stable disease in 38% and progression in 12%. No significant correlation was observed between DPD activity and response to treatment.

Conclusions: DPD activity screening could lead to a two-pronged approach: FP dose reduction in the event of low DPD and dose increase for high DPD. Such a strategy needs to be prospectively validated under personalized DPD-based treatment.

#3824 Analysis of TOPO II and p53 by immunohistochemistry and qPCR in sarcoma patients with ChemFx assay to determine sensitivity against Adriamycin and Etoposide. Max Henry Jacobson,1 Lijun Ni,2 Sandy Althouse,3 Nagendra Prasad,1 George Sandusky,1 Daniel Rushing1. 1Indiana Univ. School of Medicine, Indianapolis, IN; 2Stanford University, Stanford, CA

Sarcomas are a heterogeneous group of tumors that account for about 200,000 cancers diagnosed each year and represent 15% of all pediatric malignant tumors. They comprise over fifty subtypes that include bone and soft tissue sarcomas. Bone sarcomas represent about 20% of all sarcomas. It is estimated that over 50% of human sarcomas have a TP53 mutation. Topoisomerase II (TOPO II) is the target for doxorubicin which is the most effective chemotherapeutic agent, although it is sometimes replaced with etoposide to decrease risk of cardiac toxicity. In this study, 83 clinical sarcomas were evaluated from the IU Medical Center. Of these 83 clinical cases, 34 were primary tumors, 46 were metastatic tumors. Subtypes included in this study are: Liposarcoma, Leiomyosarcoma, Fibrosarcoma, Malignant Fibrous Histiosarcoma (MFH), Synovial Sarcoma, Osteosarcoma, and Ewings. Paraffin-embedded tissue blocks were obtained from the Indiana University Heath Pathology Laboratory under IRB approved protocols. Immunostainings with TOPOII and P53 antibodies (DAKO) were performed using the DAKO platform with LSAB2 system at the IU Health Pathology Laboratory. The stained tissues were scanned using Aperio Imaging System and analyzed using the positive-pixel algorithm. In addition, qPCR (TagMan assays) was performed using the RNA isolated from the same tissues to analyze TOPO II by a second technique. Live tissue testing was also employed using ChemFX assay performed on fresh specimens to determine Adriamycin and Etoposide (VP-16) sensitivity and/or resistance. Response to Adriamycin and Etoposide were combined to form a composite precision value and then compared with Clinical Response. This showed a 100% positive predictive value and 90% negative predictive value. We combined the two together to create an overall “Combined Response” Variable. This variable was compared to Immunohistochemistry for both TOPO II and P53, and the expression levels of TOPOII RNA. The results showed that the lung metastases expressed a higher level of TOPO II and P53 then did the primary tumors. qPCR and Immunohistochemistry data did not correlate with each other. The positive pixel data in the primary tumors were 5.238% for TOPO II and 2.4818% for P53, compared to the metastatic lung lesions with 9.64% for TOPO II and 4.5692% for P53. The combined response versus the categorized TOPO II IHC (into categories of increasing intensity, 1,2,3) had a Chi-squared p-value of 0.656. The combined response versus the categorized P53 IHC (<5% and >5%) had a Fisher-Exact test p-value of 0.082. There were approximately 40 resistant and 16 sensitive combined responses available for comparison. We conclude that P53 is a negative predictor for clinical response, with 12 of 40 resistance cases stained positive for P53, whereas 15 of the 16 sensitive cases were negative for P53.

#3825 Digital PCR-characterized, highly multiplexed, oncology RNA fusion reference materials: Performance on multiple NGS platforms. Catherine Huang, Yves Konigshofer, Lequan Nguyen, Rajeswari Venula, Praveena Kamineni, Deepika Philkana, Ekta Jaiswal, Bhalwar Anekella. Seracare Life Sciences, Gaithersburg, MD.

Introduction: Genomic structural alterations are increasingly actionable for targeted therapeutics and personalized medicine. Molecular diagnostics are rapidly being introduced for detection of fusion RNAs by highly multiplexed next-generation sequencing assays. However, reference materials to aid in the development, optimization and validation of these assays are lacking. We developed Seraseq FFPE Fusion RNA Reference Material to fill this unmet need and show that this material is compatible across a wide range of NGS assay platforms. Methods: Biosyntheses were used for transcription of clinically actionable RNA fusion RNAs using the primers in a plasmid vector containing a T7 promoter. The RNA fusion RNAs were introduced into GM24385 reference cell line (The 1000 Genomes Project, Coriell). The cells were collected, fixed in formalin, and total RNA was isolated. Digital PCR with TagMan® chemistry was used to determine the target Fusion RNA copies per microliter. Use of fusion-specific digital PCR provides an orthogonal method of verifying transcript levels and serves as the “ground truth” for the abundance of each RNA. NGS testing of the purified RNA used the ArcherDx FusionPlex™ CTI Panel, QIAGEN QIAsert Targeted RNAscan Panel, and the Thermo Fisher Oncomine Focus Assay. Results: All sixteen (16) fusions present in the prototype were detected as expected on each NGS platform. Results among the three different NGS platforms were generally concordant, although the reads across the fusion junctions did vary slightly among NGS assays and with digital PCR results. However, all methods indicated that the reference material gave low positive results, similar to a patient sample, and that the single reference material could serve as a positive control for detection of sixteen different fusions, which represent a variety of different solid tumor types. Conclusions: Seraseq FFPE RNA Fusion Reference Material allows simultaneous evaluation of detection for sixteen fusions observed in a variety of solid tumors, both common and rare. It provides a consistent, unlimited supply of QC materials particularly valuable for difficult to find rare fusions. The reference material generates low positive results on three leading assays, and this is important to truly challenge the assay system. This material is handled identically to a patient sample from extraction through analysis, and verifies performance at levels expected for patient samples.
#3827 NCI 8628 - A randomized phase II study of Ziv-ailfercept (Z) and high dose Interleukin-2 (IL-2) or IL-2 alone for inoperable stage III or IV melanoma. Ahmad A. Tarhini,1 Paul H. Frankel,2 Christopher Ruell,2 Marc S. Ernstoff,2 Timothy M. Kuzel,3 Theodore F. Logan,4 Nikihi I. Khushalani,5 Hussein A. Awadhi,6 Kim A. Margolin,7 Sanjay Avashtii,8 David F. McDermott,9 Ailne Chen,9 Primo N. Lara,10,11 John M. Kirkwood.12 1Univ. of Pittsburgh Cancer Inst. Pittsburgh, PA; 2City of Hope, Duarte, CA; 3Roswell Park Cancer Institute, Buffalo, NY; 4Northwestern Memorial Hospital, Chicago, IL; 5Indiana University, Indianapolis, IN; 6Moffitt Cancer Center, Tampa, FL; 7MD Anderson, Houston, TX; 8Beth Israel Deaconess Medical Center, Boston, MA; 9NHN/NCI, Rockville, MD, 10University of California Davis, Sacramento, CA.

Background: [IL-2], a centrally regulated antitumor immune modifier, has been proposed as a potential treatment for inoperable stage III or IV melanoma. Efficacy of IL-2 in comparison to placebo and other active regimens was reported in several phase III trials, randomized 2:1. Eligible patients (pts): Stage III inoperable or Stage IV melanoma. Up to two prior regimens for metastatic melanoma and stable treated brain metastases were allowed. The primary endpoint was progression-free survival (PFS). Results: A total of 89 pts were enrolled, but 5 who never started study treatment were excluded. Six pts (4 in A and 2 in B) were treated but withdrew early without a response assessment were considered non-responders in this analysis. Pt and disease characteristics are summarized in Table 1. Median number of IL-2 cycles was 3 (A) and 2 (B) and of Z cycles in A was 3 (1 - 3). Median follow up for all alive patients was 19 months. Among 84 treated pts (55 in A and 29 in B), there was significant improvement in PFS in favor of A: median and 95% CI of 6.9 (4.2 - 8.8) months vs 2.1 (1.7 - 4.1), logrank p < 0.001. No significant difference in OS: median and 95% CI of 23.1 (14.4 - 35.0) months vs 22.3 (12.6 - NA). Response rate (RECIST) was 22% in A (5CR, 7PR) and 17% in B (5PR). Stable disease or PR or CR was seen in 69% in A and 48% in B. Adverse events were consistent with the AE profile of monotherapy with IL2 and Z. Grade 4 events in A included decreased lymphocytes (41 pts) and platelets (6), renal (1), hypophosphatemia (4), hypertension (2) and thromboembolism (1).

Conclusions: The combination of Z and IL2 significantly improved PFS over IL2 alone, meeting the study's primary endpoint. The regimen was relatively safe and manageable. Correlative and mechanistic studies are ongoing.

#3829 TCIRG1, T-cell immune regulator 1, functions as a metastatic enhancing gene in liver tumorigenesis. Hee Dooy Yang, Jung Woo Eun, Yingyu Shen, Hyung Seok Kim, Sang Yeon Kim, Suk Woo Nam. Lab of Coding & Non-coding Genomics, Department of Pathology, College of Medicine, The Catholic University of Korea, Seoul, Republic of Korea.

Recurrence and metastasis are major challenges in the management of hepato-cellular carcinoma (HCC) patients after HCC resection. In order to identify metastatic molecular signature, we performed comparative gene expression profiling analysis with resected HCC tissues from HCC patients who underwent partial or total hepatectomy and non-metastatic primary HCC. From this, we were able to recapitulate molecular signatures associated with HCC recurrence, and found that TCIRG1 (T-Cell Immune Regulator 1) was one of the aberrantly overexpressed gene elements in recurrent HCC patients with total hepatectomy. We then observed that TCIRG1 is significantly overexpressed in TCGA-LIHC (Liver Hepatocellular Carcinoma Dataset of The Cancer Genome Atlas), and high expression of TCIRG1 was significantly associated with poor prognosis of HCC patients in 5-year disease-free. TCIRG1 knockdown suppressed tumor cell growth and proliferation in Huh7 and SNU475, liver cancer lines. In addition, sustained expression of TCIRG1 in liver cancer cell line reduced tumor growth rate in mouse xenograft model. Moreover, targeted-disruption of TCIRG1 significantly attenuated the metastatic potential of ras-transformed NIH-3T3 cells in vitro and in vivo. In conclusion, our findings suggest that TCIRG1 functions as metastatic enhancing gene by modulating cellular growth, death, and EMT in liver cancer cells providing TCIRG1 as a therapeutic target for the treatment of liver malignancy and metastasis.

#3830 Plucked anagen scalp hair: A reproducible surrogate tissue to monitor drug induced transcriptional changes and provide pharmacodynamic biomarker and target engagement information from cancer patients. Benjamín J. Reed, Timothy Mefo, Elliott Harrison, Ross Haggart, Emma Grimes, Alan Murdoch, Gino Miele. Epistem Ltd., Manchester, United Kingdom.

Monitoring target engagement is crucial to inform on early drug development decisions, and development of a peripheral tissue-based gene expression signature for the indication of pathway inhibition could facilitate the clinical development of compounds. Plucked anagen scalp hair is an ideal source of epithelial tissue to monitor drug induced transcriptional changes. High vascularisation of the hair follicle, frequent epithelial origin of tumors, ease of sampling and high degree of congruence of expression in hair of pathways dysregulated in cancers, make the cellular bulb of plucked human scalp hair an excellent surrogate tissue for the non-invasive monitoring of pharmacodynamic (PD) and mechanism of action (MOA) effects in clinical trials. Using our ex vivo plucked hair culture platform, hair bulbs from several healthy donors were exposed to BEZ235, a dual pan-class PI3K and mTOR inhibitor at different concentrations and durations. Total RNA was isolated from the cellular bulb of individual anagen hair post-culture and used for microarray analysis to assess global transcriptional alterations and develop a gene expression signature indicative of BEZ235 exposure. The results of the ex vivo plucked assessment generated a dose dependent appreciable and biologically relevant transcriptional signature following exposure to BEZ235. Transcriptional readouts from patients also revealed strong correlations (0.97-0.99) in the genes expressed in anagen scalp hair between donors and across samples taken from the same donor. In addition, global gene expression data indicated that assessing three plucked scalp hairs or less at each collection point was sufficient to detect significant differential expression (p<0.05 & 1.5 fold change) underpinning the low variance in the majority of target genes in plucked hair as a biomarker platform. Gene signatures for compounds targeting the PI3K/mTOR pathway that were established using the ex vivo plucked scalp hair platform were used to support clinical trials and scalp hair taken from patients receiving treatment showed an excellent post-exposure target signature modulation. In summary, our results substantiate that plucked anagen scalp hair is an ideal non-invasive surrogate tissue to obtain drug-induced pharmacodynamic biomarker and target engagement information from oncology patients.
The development of an immunohistochemical digoxigenin-labeled mouse on mouse single and double stain methodology. Joseph Vargas, David Tacha, Sara Figueroa. Biocare Medical, Concord, CA.

Introduction When a mouse or monoclonal antibody is desired for immunohistochemical detection on mouse tissues, the anti-mouse secondary antibody will also bind to endogenous mouse IgG in the tissue and may produce an unwanted background staining. In the past, mouse-on-mouse (MM) detection utilized a biotinylated primary antibody or biotinylated kit. Tissues rich in endogenous biotin such as kidney or liver made it difficult to use, as streptavidin-horseradish peroxidase is required for detection. Attempts to completely negate endogenous biotin are ineffective as avidin-biotin blocking steps are unlikely to work accurately in problematic tissues. Therefore, the design of a digoxigenin-labeled detection system is advantageous for MM detection as it would eliminate these issues. This technology has broad application as it allows the use of a variety of monoclonal antibodies reactive on mouse tissues. Materials and Methods 

Mice tissues were formalin-fixed for 24 hours and embedded in paraffin (FFPE). Sections were cut and dried on slides before deparaffinizing and peroxidase blocking in the usual manner. Slides were then HER in a citrate-based buffer prior to application of antibody. Mouse antibody concentrations were selected and mixed with a Digoxigenin Anti-Mouse Linker and incubated at room temperature (RT) for 1 hour. An Absorption Reagent is then added to the mixture, and further incubated for 30 minutes. The mixture is then diluted in antibody-diluent to the desired concentration and applied to the mouse tissue for 60 minutes at RT. Following a rabbit-anti-digoxigenin antibody for 15 minutes. Detection of anti-digoxigenin is performed with an incubation in either a goat anti-rabbit HRP or AP polymer for 30 minutes. Visualization is accomplished by using a DAB or Fast Red chromogen. For double stains, a sequential DS method using two monoclonal antibodies was employed using a heating step in retrieval solution after the first chromogenic reaction followed by a second monoclonal antibody and detection with either a rabbit-AP or HRP polymer. Visualization of the second antibody target is accomplished by using Fast Red or a blue chromogen. Slides were coveredslipped with a permanent mounting medium and evaluated using brightfield microscopy. Results MM single stains with a variety of antibodies were easily achieved with specific, clean and biotin-staining-free staining. Sequential DS techniques using monoclonal antibodies were also achieved and visualized with DAB, Fast Red or blue chromogens. Both manual and automated procedures were used. Conclusion The replacement of biotin-labeled MM technology with a digoxigenin MM technology is a superior method that not only eliminates endogenous biotin, but allows utilization of HRP and AP polymers for double stain technology.

Optimization strategy for fluorescent multiplex immunohistochemistry tissue staining. Yi zheng, Carla Coltharp, Ryan Dilworth, Linying Liu, Danielle Unricht, Cliff Hoyt, Milind Rajopadhye, Peter Miller. PerkinElmer, Hopkington, MA.

Introduction: Recent insights into the tumor microenvironment have fueled the need for additional information beyond the one or two phenotypes provided by traditional immunohistochemistry (IHC). As a response, manual and automated fluorescent multiplex immunohistochemistry (IHC) techniques have been recently developed and accepted by the immuno-oncology space. Fluorescent multiplex immunohistochemistry (IHC) assays are designed to simultaneously measure multiple biomarkers in tissue sections with visual context that is lost in other methods, such as flow cytometry. Here we describe a novel optimization strategy to achieve quantitative, robust, and specific multiplex IHC staining results with both manual and automated multiple-color Opal procedures. Methods: Formalin-fixed paraffin-embedded samples of primary tumors were immunostained using Opal™ reagents both manually and on a fully automated Leica BOND RX® stainer. The impact of different reagent concentrations and quantities were analyzed in respect to signal specificity and robustness, stripping efficiency, signal co-localization, signal to noise, and color separation. Images were acquired on a Vectra 3.0 automated imaging system, and analyzed with inForm™ software. Results: The goals of this study were two-fold: to understand the impact of Opal reagent concentrations/quantities on fluorescent signal intensities acquired from cells within the context of tissue. -to develop an Opal reagent optimization method that yields more consistent, quantitative results from separated and co-localized fluorescent signals. We’ve applied this novel fIHC experimental approach and optimization strategy to Opal monoplex and multiplex assays and explored staining robustness, contextual specificity, staining order independence, and co-localized signal separation. Using the novel optimization strategy, we have achieved optimal staining patterns with improved confidence in the quantitative characteristics of the assay. Tissue sections stained after optimization have exhibited staining order independence and closely align with traditional IHC patterns. Conclusion: This novel optimization strategy, developed for Opal fIHC assays, is more quantitative, improves staining results, and minimizes interference between co-localized biomarkers.

Systematic evaluation of transcriptome sequencing shows comparable profiles for an exome-capture method for formalin-fixed, paraffin-embedded (FFPE) breast cancer tissues and the standard poly-A method for matched fresh frozen (FF) tissues. Xi Zhao, Marianna Zavodovskaya, Luting Zhuo, Kevin Kwei, Xin Guo, Zhaohui Jiang, Scott D. Patterson, Carrie B. Brachmann. Gilead, Foster City, CA.

Background: Tissue samples are routinely preserved as FFPE blocks. This abundant sample reservoir holds promises in clinical omics for disease diagnosis and precision cancer medicine. However, due to extensive cross-linking, nucleic acids are not efficiently extracted from FFPE samples and are heavily degraded, posing challenges for molecular assays including next generation sequencing. Our study aims to identify the RNA sequencing (RNA-seq) library prep method for FFPE samples that provides comparable data to the established poly-A enrichment method for FF tissue. Methods: RNA-seq data were collected on matched FF and FFPE samples from triple negative breast cancer (TNBC; n=7) and normal breast tissues (n=2). Tissues were sourced from a commercial vendor. Three library preparation protocols from Illumina were tested: poly(A) enrichment protocol (Poly-A: FF only), ribosomal RNA depletion protocol (Ribo-Zero Gold), and exome-capture based protocol (RNA-Access). Data were compared on absolute and differential gene expression, as well as molecular subtyping for breast cancer (PAM50; Parker 2009). Results: Both absolute expression and log fold change between mRNA expression in FF and FFPE tissues correlate strongly across different tissue preservation and library preparation methods. Among tested methods, RNA-Access had the highest yield of mappable reads on coding region and provided uniform transcript coverage with less rRNA contamination. Regardless of the protocol, all TNBC samples were classified as PAM50 basal-like subtype. As expected, FF, with either Ribo-Zero or RNA-Access had the strongest correlation with FF Polya for. Hh the subset of the poly(A) staining results. Data were compared on absolute and differential gene expression, as well as molecular subtyping for breast cancer (PAM50; Parker 2009). Principal component analysis showed that samples were primarily segregated by technical differences (library preparation or tissue preservation method) rather than biological differences (tumor/normal status or patient identification), suggesting a strong technical bias in the data. Gene families and biological processes underlying the differentially expressed genes due to technical variations included ribosomal, histone and metabolic pathways proteins. The aforementioned technical bias may be largely eliminated by a batch effect adjustment method (COMBAT; Johnson 2007). Conclusion: As expected, RNA-seq data is primarily impacted by technical differences. RNA-Access based transcriptome sequencing on breast FFPE samples generated highly concordant gene expression profiles when compared to data derived from FF samples. Our study supports the use of RNA-Access based transcriptome sequencing on FFPE samples when FF samples are not available.

Tracking CAD-ALK gene translocation in urine and plasma of a colorectal cancer patient treated with ALK blockade. Giulia Siravegna,1 Andrea Chillemi,1 Jacopo Palleschi,1 Berenice M. Tosi,2 Andrea Cassignella,2 Luca Novara,2 Michela Buscarino,2 Giorgio Corti,3 Giovanni Crisafulli,1 Alice Bartolini,1 Mark Erlander,2 Federica Di Nicolantonio,1 Salvatore Siena,1 Alberto Bardelli,1 IRCC, Candidio, Italy; “Niguarda Cancer Center, Milano, Italy; 3Trovagene Inc, San Diego, CA.

A metastatic colorectal cancer (mCRC) patient carrying CAD-ALK translocation achieved partial response to an experimental ALK inhibitor and then progressed after 5 months. We studied whether urine cell-free, trans-renal DNA (tr-DNA) could be used to monitor tumor burden and patient’s response. A NGS panel was developed to interrogate 52 common cancer gene rearrangements and 14 frequently mutated genes in cancer patients. A TP53 p.R248W mutation and the CAD-ALK genomic breakpoint (rarrangement) were identified in the tumor tissue and matched plasma circulating DNA (cDNA) DNA. cDNA samples were longitudinally obtained from the patient during ALK inhibitor treatment in parallel with blood. To detect the CAD-ALK translocation in urine tr-DNA we designed ultra-short (51 bp amplicon) primer pairs spanning the genomic breakpoint as a unique tumor marker. This approach allowed the non-invasive monitoring of the gene fusion in urine with amounts paralleling tumor burden. Of note, CAD-ALK gene fusion was apparent in urine tr-DNA before radiological confirmation of disease progression. The same strategy was applied to plasma cDNA and the results were compared. To detect point mutations in urine tr-DNA, we explored a peptide nucleic acids (PNA)-CLAMP PCR coupled with droplet digital PCR (ddPCR) analysis to specifically suppress amplification of wild-type DNA fragments. Custom PNA
probes were designed for TP53 codon 248, and a ddPCR assay was optimized to detect the TP53 p.R248W mutation, which was then identified in all urine tr-DNA samples, with absolute copies correlating with tumor burden throughout ALK inhibitor treatment. In conclusion, we find that urine tr-DNA can be exploited to non-invasively monitor tumor burden by detecting tumor-specific gene fusions as well as point mutations.

TUMOR BIOLOGY: Cell Culture and Animal Models of Cancer 4

#3835 High-purity patient-derived cells: An advanced cell culture model for precision cancer medicine. Seok-Young Kim,1 Hwan Kim,2 Sung-Moo Kim,1 Hye Ryun Kim,1 Mi Ran Kim,1 Ji Min Lee,1 Hun G Choi, Byung Cheol Cho2.1 Yonsei Cancer Research Institute, IE-UK Laboratory of Molecular Cancer Therapeutics, Seoul, Republic of Korea; 2Division of Medical Oncology, Department of Internal Medicine, Yonsei University College of Medicine, Seoul, Republic of Korea.

Purpose: Patient-derived cells (PDCs) established from malignant effusions can represent an excellent tool for the study of non-small cell lung cancer (NSCLC) with oncogenic driver mutations. However, because of cellular paucity and low tumor purity, PDCs have a limited utility for in-depth molecular analysis. In this study, we developed a high-purity patient-derived cell (HP-PDC) method for primary culture of malignant effusions. Experimental design: HP-PDCs were established by a multistep tumor cell isolation protocol as follows. 1) Initial cultures of malignant effusions were observed under a light microscope to identify spherical-forming cells. 2) Tumor purity of PDCs was analyzed by Immunofluorescence (IF) and flow cytometry. 3) Mutation status of EGFR or ALK in PDCs was screened by direct or PCR-based sequencing and RT-PCR and then was compared with driver mutations detected in matching patient tumor samples. 4) HP-PDCs were tested for drug efficacies by a cell viability assay, a colony-forming assay, and western blot. 5) HP-PDCs were screened with a panel of 84 kinase inhibitors to identify effective drugs. Results: A consecutive series of 45 malignant effusion samples was collected from 36 patients with advanced NSCLC. Spherical-forming cells were detected in 19 samples (42.2%) which were cultured in AR5 media to establish PDCs. IF analysis revealed that TFF-1 was upregulated in 9 PDCs. These 9 PDCs with high TFF-1 expression also showed EPCAM-positive cell population in flow cytometry with high purity of over 70%. Using Sanger sequencing, EGFR exon 19 deletion was detected 3 cases. TERT T970M with L858R in 2 cases, and ALK rearrangements in 4 cases. Two of PDCs established from patients, who carried EGFR mutations and progressed on gefitinib, showed resistance to gefitinib in vitro. One of gefitinib-resistant PDCs was sensitive to AZD9291 with IC50 value of 47 nM. Three of PDCs established from patients, who carried ALK fusion genes and progressed on ALK inhibitors (crizotinib, alectinib, and ceritinib respectively), also recapitated patient’s response to the ALK inhibitors. In an alectinib-resistant PDC, crizotinib and ceritinib exhibited potency with IC50 values of 321 nM and 215 nM respectively. Colony-forming assay and western blot results were correlated with the cell viability assay data. Time spent for establishment of HP-PDCs ranged from 26 days to 132 days. Conclusions: Nine HP-PDCs established by multistep tumor cell isolation protocol had high tumor purity, and recapitated patient’s genomic profile and drug responses. HP-PDC is a powerful preclinical model which predicts responses to targeted drugs in a short period of time and may provide an excellent platform for personalized therapies in patients with advanced NSCLC.

#3836 New type of drug resistant isogenic cancer cell model created by CRISPR genome editing. Lydia Anne Volpe,1 Meteoro Selaanum,2 Luping Chen,1 Michael Jackson,1 Catherine Nguyenngo,1 John Foulke,1 Fang Tian1.1 ATCC, Manassas, VA; 2 ATCC, Gaithersburg, MD.

Mutant BRF1 gene can lead to uncontrolled cell growth through overactivation of Ras-Raf-MAPK signaling pathway. BRF600E mutation occurs in approximately 40% to 50% of melanomas. Although BRF1 inhibitors have been used to successfully treat melanomas containing the BRF600E mutation, patients often become resistant to BRF1 inhibitors within a few months. A number of studies have indicated that secondary mutations such as NRAS or NFI are significantly associated with BRF1 resistance by sequencing patient samples. However, due to the genetic heterogeneity commonly observed in tumors, it is unclear if those secondary mutations already existed within low percentage subclones or if they were acquired through drug treatment. It’s yet to be determined whether such mutations are only associated with resistance, or they actually cause the resistance. In this study, we used genome editing CRISPR technology to generate a drug resistant mutation NRAS Q61K within A375 melanoma cell line which naturally contains BRAFV600E. When compared to the parental line, this isogenic cell line demonstrated that genetically modified NRAS gene at the endogenous level directly leads to a significant resistance to BRAF inhibitors. Method and results: Single guide RNAs (sgRNAs) were designed and built to guide Cas9 to bind and cut desired regions in the NRAS gene target. Melanoma cell line A375 was co-transfected with the single guide and CRISPR all-in-one plasmid alongside donor plasmid. Transfected cells were sorted into single cells and expanded for subsequent screening of desired gene mutation events. The introduction of NRAS Q61K mutation in the cells was then confirmed via Sanger sequencing and NGS at the genetic level and transcriptional level. Drug responses to BRAF specific inhibitors and non-specific chemotherapy drugs were compared between A375 NRAS Q61K isogenic cell line and parental cell line in 2D and 3D culture environment. Testing results demonstrated that the isogenic cell line created by CRISPR showed significant resistance to BRAF inhibitor in comparison to the parental control in both 2D and 3D culture environment. In summary, we utilized the CRISPR/Cas9 genome editing platform to target endogenous loci in human cells and create the intended genetic mutation event. This new approach provides direct bio-functional evidence of acquiring a drug resistant gene drives tumor cells survival under targeted therapeutic treatment. Furthermore, unlike conventional drug resistant cell models that have been developed through drug selection, the A375 NRAS Q61K isogenic cell line represents a new type of drug resistant model that contains a defined genetic resistance mechanism. It reserves the permanent and genetically stable resistance characteristics without being maintained in drug selection culture environment. Therefore, it provides a valuable tool for developing next generation therapeutics that can overcome BRAF drug resistance in melanoma.

#3837 Primary tumor cell lines derived from gastric PDX tumors displays differences in chemosensitivity. Xiaomei Ge,1 Fulin Qiang,2 Yixin Zhang,2 Jibing Liu,2 Lei Yang,2 Yingying Qu,2 Fubo Xie,2 Xueting Li,2 Ying Gu,2 He Zhou1.1 Shanghai ChemPartner Co., Ltd., Shanghai, China; 2Nantong Cancer Hospital, Nantong, China.

Gastric cancer is a multifactorial and fatal disease with limited effective therapeutic options. Its overall mortality ranked third among cancer-related deaths worldwide. Patient-derived-xenograft (PDX) models have been widely used in the biomedical research. They recapitulate the genomic diversity/heterogeneity of patient tumors, maintain a lot of the characteristics of the original tumors and showed much better correlation with clinical outcome comparing to traditional cell line derived xenograft models. However, the relatively low throughput and time-consuming nature of PDX studies prevent them from being used in large scale screening or mechanistic studies. To facilitate drug development in gastric cancer, different cancer cell lines have been developed in our laboratory from gastric PDX tumors. We performed STR analyses to validate their identity and RNAseq data also showed high similarities to their parental PDX tumors. These primary gastric tumor cell lines displayed differences from each other in their chemo-sensitivities in vitro and in vivo. They also differ in their protein expression such as the HER-2 expression level. Pharmacology studies using different compounds showed similar drug responses of these cell lines in tissue culture, xenografts using these cell lines and the original PDX models. Our data demonstrated the high fidelity of these cell lines to their parental PDX tumors and serve as a bridge between the high-throughput drug screening and highly clinical relevant PDX models and will greatly facilitate the drug development in gastric cancer.

#3838 Drug sensitivity profile of 5TGM1 murine multiple myeloma cell lines emphasizes the translational potential of the syngeneic in vivo model. Jenni Mäki-Jouppila,1 Jenni Bemoulli,1 Mari I. Suominen,1 Tiina Kähkönen,1 Jenni M. Halleen,1 Sanna Timonen,2 Elina Huovari,1 Katja Suomi,2 Swapnil Potdar,2 Maria Nurmia,1 Päivi Oslting,1 Janni Saarela,2 Katja M. Fagerlund1.1 Institute for Molecular Medicine Finland FIMM, Helsinki, Finland; 2Institute of Molecular Medicine Finland, Helsinki, Finland.

Multiple myeloma (MM) is the second most common hematologic malignancy that originates from B-cells (plasma cells) and causes 2% of cancer-related deaths. Symptoms of MM include bone pain caused by multiple osteolytic lesions, pathologic fractures, and hypercalcemia. Typically, MM has a low growth fraction and it is highly dependent on the microenvironment. These properties have made it hard to target by conventional chemotherapy, but could now be exploited by novel stroma-targeting drugs and immunotherapy. These new approaches underline the need for well characterized models with functional immune system and appropriate tumor microenvironment. To gain additional information supporting the use of the syngenic 5TGM1 murine multiple myeloma model in drug development, we tested drug sensitivity of 5TGM1 cells by screening an extensive panel of drugs. The compound library consisting of 460 compounds included conventional chemotherapy, kinase inhibitors, metabolic modifiers, rapalogs, differentiating/epigenetic modifiers, kinesin inhibitors, apoptosis modulators, NAIADs, hormone therapy, immunomodulators and HSP.

CLINICAL RESEARCH: Predictive Biomarkers 3
inhibitors. The compounds were tested in five concentrations covering a 10,000-fold drug-relevant concentration range in 384-well format. Cells were seeded to plates with a compound library, followed by cell viability measurements (Cell-Titer-Glo) after 72 hours. Maximal and minimal responses to drugs were analyzed, and the EC50 values were calculated. Drug Sensitivity Score (DSS) was calculated using a measure of relative sensitivity of a test tumor cell line to a reference cell line to determine changes in drug sensitivity. DSS analysis, STGM1 cells showed sensitivity to conventional chemotherapies, such as antimitic drugs, and kinase inhibitors, such as MEK1/2 inhibitors. In addition, the cells showed particular sensitivity to several HSP90 inhibitors currently in phase I/II clinical development for MM. Lenalidomide and pomalidomide, efficient in treating multiple myeloma in humans, both gave low DSS value indicating that STGM1 cells are not sensitive to these drugs, which is expected because they do not bind to murine form of the target cereblon. In contrast, STGM1 cells were highly sensitive to the proteasome inhibitor bortezomib (DSS 32.2), which is currently in clinical use. In conclusion, the murine STGM1 cells show sensitivity to various MM drugs used in the clinic and under development. Evaluating the effects of the microenvironment on the growth and drug sensitivity of STGM1 cells in vitro and in vivo will be essential. Furthermore, the cell-based compound screening combined with DSS analysis provides a possibility to profile cellular responses to an extensive collection of anti-cancer compounds enabling identification of vulnerabilities in cancer cells and functional investigation of cellular pathways behind drug sensitivity or resistance.

#3839 MLN8237 treatment in an orthoxenograft rodent model for malignant peripheral nerve sheath tumors. Oliver Mrowczynski, Penn State Hershey, PA

Malignant peripheral nerve sheath tumors (MPNSTs) are soft tissue sarcomas that arise from peripheral nerves and often occur in the extremities. MPNSTs arise sporadically or in the neurofibromatosis type one (NF1). NF1 is a autosomal-dominant disorder characterized by neurofibromas, cutaneous hyperpigmentation, and intellectual deficits affecting 1 in 3000 births. The lifetime risk of a person with NF1 developing a MPNST ranges between 8-13%. MPNSTs have increased expression of the oncogene Aurora kinase A. This leads to enhanced cell proliferation, making MPNSTs extremely aggressive, with high potential for metastasis, and devastating prognosis, with five year survival estimates ranging from a dismal 15-60%. MPNSTs are currently treated with surgical resection, sometimes requiring limb amputation, as well as chemotherapy, all of which demonstrate limited effectiveness, and highlight the necessity for novel therapies. To evaluate the effectiveness of new treatments, a translationally accurate, robust, and cost-effective model is crucial. A major goal of this study was to produce an orthotopic xenograft murine MPNST model for evaluation of novel therapies, which we created by intra-neural injection of luciferase transfected MPNST cells into the mice sciatic nerve. Our model circumvents drawbacks of previous in vivo models by producing a robust tumor in the physiologically relevant microenvironment of the nerve that allows for accurate tumor burden quantification through luciferin fluorescence. Another goal of this study was to demonstrate the effectiveness of MLN8237 for MPNST treatment. MLN8237 is an aurora kinase A inhibitor that we demonstrate to decrease MPNST burden and increase survival significantly. This study provides a robust and reproducible model, allowing for the advancement of MPNST therapy. This study also demonstrates the effectiveness of MLN8237 for MPNST treatment. Together, our data has major implications on the future of MPNST research by providing a robust murine model as well providing evidence that MLN8237 is an effective treatment for MPNSTs.

#3840 The National Cancer Institute’s patient-derived models repository (PDMR). Yvonne A. Evrard, 1 Michelle Aalil-Gotholin, 2 Sergio Akcose, 2 Carrie Bonomi, 1 Suzanne Borgel, 1 John Carter, 1 Biswajit Das, 1 Vivekananda Datta, 1 Cheryl Davis, 1 Kelly Dougherty, 1 Michelle Eugeni, 2 Marion Gibson, 2 Catherine Karangwa, 1 Jason Lih, 1 Dianne Newton, 1 Han Si, 1 Shivaani Kummar, 3 Larry Rubinstein, 1 Alice Chen, 1 P. Mickey Williams, 2 Melinda G. Hollingshead, 3 James H. Doroshow, 1 Frederick National Laboratory for Cancer Research, Frederick, MD; 2 National Cancer Institute, Frederick, MD; 3 Stanford School of Medicine, Stanford, CA; 4 National Cancer Institute, Bethesda, MD.

The National Cancer Institute (NCI) is developing a Patient-Derived Models Repository (PDMR) comprised of quality-controlled early-stage clinically-annotated patient-derived xenografts (PDXs) and in vitro patient-derived cell cultures (PDCs), including tumor cell and cancer-associated fibroblast cell cultures, to serve as a resource for public-private partnerships and for academic drug discovery efforts. These PDMRs will be clinically-annotated with molecular information (whole exome sequence, RNAseq) available in a publicly accessible database and will be available to the extramural community for research use. The PDMR was established by NCI at the Frederick National Laboratory for Cancer Research (FNLCR) in direct response to discussions with academia and industry: the oncology community’s highest priority need is better preclinical models that more faithfully reflect the patient’s tumor and are associated with the patient’s treatment history. NCI has focused on collecting specimens from patients with cancer that are under-represented in many other PDX collections such as PDAC, medulloblastoma, mesenchymal cancers, melanomas and sarcomas. In addition, NCI is increasing its focus on creating PDXs from minority/underserved populations and will soon be expanding to include pediatric cancers. The PDMR generates the majority of its PDXs by subcutaneous implantation; however certain histologies have better take-rates in either orthotopic or alternate implant sites. All SOPs and quality-control standards developed under the PDMR as well as those shared by collaborators will be posted to the public web site that houses the PDMR database. The overall goal of NCI is to create a long-term home for at least 1000 models such that sufficient biological and clinical diversity is represented to allow researchers to ask questions such as: what is the impact of tumor heterogeneity on target qualification or clinical response; do PDXs more faithfully represent the human tumor for pharmacodynamic assay and predictor marker development; or can an adequately powered preclinical PDX clinical trial lead to better evaluation of therapies for future clinical use? Grant Support: This project has been funded in part with federal funds from the National Cancer Institute, National Institutes of Health, under Contract No. HHSN261200800001E. The content of this publication does not necessarily reflect the views or policies of the Department of Health and Human Services, nor does mention of trade names, commercial products, or organizations imply endorsement by the U.S. Government.

#3841 A hybrid mapping approach improves genomic and transcriptional analysis of patient derived orthotopic xenograft (PDXO) models of pediatric CNS tumors. Oliver A. Hampton, 1 Michael C. Gundry, 1 Mari Kogiso, 1 Lin Qi, 1 Yuchi Du, 2 Yulan Huang, 1 Frank K. Braun, 1 Huiyuan Zhang, 1 Sibo Zhang, 2 Holly Lindsay, 2 Sarah J. J. D. 2 David A. Wheeler, 1 Xiao-Nan Li, 2 D. William Parsons, 1 Baylor College of Medicine, Houston, TX; 2 Texas Children’s Hospital Cancer Center, Houston, TX.

Background. Patient derived orthotopic xenograft (PDXO) models are an important tool for cancer research, including personalized preclinical testing of targeted therapies. PDXO models of CNS tumors faithfully replicate the invasive nature of pediatric tumors, resulting in variable contamination of the harvested xenograft tissues by mouse brain cells. This presents technical challenges to genomic and transcriptomic analyses, including correct alignment of sequencing reads to human or mouse genomes, and can result in identification of false positive tumor mutations. Improved bioinformatic methods for systematic correction of such errors are needed. Methods. Whole exome sequencing (WES) was performed on 32 diverse childhood CNS tumors (mean of 109 M reads/sample) and matching PDXO models (mean of 62 M reads/sample), including atypical teratoid rhabdoid tumor (ATRT), glioblastoma (GBM), and medulloblastoma (MBM). Patient-matched blood DNA was also subjected to WES. Whole transcriptome sequencing (WTS) was performed on a subset of tumors and PDXO models (mean of 94 M reads/sample). Integrated WES and WTS analysis pipelines were constructed to unequivocally identify each sequencing read’s species-of-origin prior to genomic and transcriptomic variant calling, expression profiling, and fusion gene analysis. Xenograft NGS reads were competitively mapped to a hybrid reference created by merging the human (hg19) and mouse (mm10) genomes, with reads segregating to their respective genomes based on mapping score. Reads that mapped exclusively to the human reference were selected for analysis. Results. Mouse DNA contamination varied widely between PDXO tumors (1% to 94%; mean 40%). Hybrid mapping resulted in 2.4-fold higher combined sensitivity and specificity for identification of somatic variants as compared to direct human reference mapping followed by mouse polymorphism subtraction. WES analysis confirmed the maintenance of somatic driver mutations in PDXO models, including SMARCB1 in ATRT, TP53 and NF1 in GBM, and IDH1 in MBM. In contrast, in PDXO models with non-somatic mutations, exhibited significant allele fraction changes between the primary tumor and PDXO model. WTS analysis based on hybrid mapping resulted in an increase in positive predicted value (PPV) for correlation of FPKM values between tumor and PDXO model, with greater PPV in cases with high levels of mouse contamination, albeit with lower sensitivity due to decreasing coverage. Hybrid mapping based WES and WTS analysis identifies fewer false positives than direct bigWig mapping and represents a more streamlined process of species-of-origin sequencing read classification and filtering at the alignment stage. This method has the potential to improve molecular characterization of PDXO models and inform the design of rational preclinical studies.
Without confounding genetic responses, enogenous leukocytic infiltration into the tumor has been shown. STAT3 signaling in the tumor compartment in these autologously reconstituted human tumor xenografts (PDX) cancer models from patient tumors in the immunocompromised NOD.Cg-Prkdcscid IL2rgtm1Wjl/SzJ (aka, NSG™) mouse strain, spanning more than 30 tumor types. At low passages, these engineered models are known to retain similar molecular characteristics and heterogeneity to the original patient tumors. As such, PDX models offer an excellent preclinical platform to test drug responses of novel cancer therapeutics and a powerful resource for conducting preclinical cancer pharmacogenomic studies. To aid the selection of suitable PDX models for preclinical studies and for the research purpose to understand tumor biology and response or resistance to a given treatment, we have characterized the PDX models for their transcriptional, mutational and copy number profiles using sequencing and array approaches. We have established a compendium of PDX-tailored computational pipelines as the analysis of genomic data from PDX models could be challenging due to a) the contamination of PDX sample with mouse stroma, which complicates downstream bioinformatics analyses as mouse genome is almost 90% homologous to the human genome, and b) the lack of matched normal material to call somatic events. Our pipelines incorporate various filters to identify tumor specific single-nucleotide variants, indels, copy number changes and expression profiles in the PDX model. For the purpose of validating the accuracy of our analysis pipelines and demonstrating that the JAX PDX models are indeed representative of patient tumors, we compared JAX’s PDX cohort with patient cohorts in TGCA for mutations, copy number aberrations and RNA expression concordance. Using gene sets representative of each tumor type, we found that the overall genomic profile of each PDX tumor type is more correlated to the same tumor type in TGCA than other tumor types. In addition, an integrative analysis across all data types reveals that there are more common affected pathways between the same tumor type in PDX and TGCA. This comprehensive analysis revealed that the PDX and patient cohorts exhibit similar molecular characteristics, hence establishing the suitability of JAX PDX models as in vivo models to study fundamental tumor biology as well as to carry out preclinical studies of cancer drugs, including identification of biomarkers of response or resistance.

Autologous reconstitution of human cancer and immune system in vivo. Juan Fu,1 Rupashree Sen,1 David L. Masica,1 Rachel Karchin,1 Drew Pardoll,1 Young Kim2. 1Johns Hopkins University, Baltimore, MD; 2Vanderbilt School of Medicine, Nashville, TN.

Correlative studies from checkpoint inhibitor trials have indicated that better understanding of human leukocytic trafficking into the human tumor microenvironment can expedite the translation of future immune-oncologic agents. In order to directly characterize signaling pathways that can regulate human leukocytic trafficking into the tumor, we have developed a completely autologous xenotransplantation method to reconstitute the human tumor immune microenvironment. When we analyzed the human head and neck squamous cell carcinoma (HNSCC), we found that STAT3 signaling was associated with worse prognostic mesenchymal subtype. We silenced STAT3 signaling in the tumor compartment in these autologously reconstituted humanized mice, and we noted increased tumor infiltrating lymphocytes and slower tumor growth rate. We also used this novel agent that can alter endogenous leukocytic infiltration into the tumor, taken together, we present a valuable method to study individualized human tumor microenvironments in vivo without confound allogeneic responses.

Identification and validation of novel therapeutic targets driving clonal heterogeneity in treatment-refractory GBM. Chirayu Chokshi, Nick Yelle, Parvez Vora, Chitra Venugopal, Malehaa Qazi, Mohini Singh, Minomi Shigapuniga, Anurita Dive, Sarah Hart, Nick D. Singh, McMaster Stem Cell & Cancer Research Institute, Hamilton, Ontario, Canada.

Glioblastoma (GBM) is the most common primary adult brain tumor, characterized by extensive cellular and genetic heterogeneity. Even with surgery, standard chemotherapy with temozolomide (TMZ), and radiation, tumor re-growth (or recurrence) and patient relapse are inevitable. Patients face a median survival of <15 months, with uniformly fatal outcomes upon disease progression post-treatment. Recent profiling of GBM-initiating genes has shown that evolution of cancer-driving clones or cell populations within a solid tumor may progress through (and possibly be driven by) cancer treatment, such that GBM recurrence may no longer resemble the genetic landscape of the original primary tumor. Understanding and mapping clonal evolution of the primary GBM through therapy and at recurrence will allow for the discovery of targets specific to treatment-refractory GBM. Here, we have developed early passage patient-derived brain tumor initiating cell (BTIC) lines that have been annotated by genomic deep-sequencing technologies to systematically characterize and describe the extent of intratumoral heterogeneity. Tagged and fluorescent protein, these BTIC lines were engineered in immunocompromised NOD SCID mice. Following half-maximal tumor engraftment, tumor bearing mice underwent a clinically relevant chemoradiotherapy regimen, with 2 Gy gamma-irradiation on the first day and 66 mg/kg temozolomide for five consecutive days. Following therapy, mice were kept alive until tumor recurrence. Engrafted BTICs were harvested at initial tumor formation, minimal residual disease after chemoradiotherapy, and tumor recurrence. Samples were analyzed by RNA and genomic deep-sequencing technologies to map cancer progression and identify novel therapeutic targets in treatment-refractory GBM. Potential therapeutic targets were validated by their effect on self-renewal and proliferation of patient-derived BTIC lines of human GBM in vitro and in vivo. Using CISPR Cas9, potential targets were knocked out in patient-derived BTIC lines of human GBM in order to characterize the effect on sphere formation and proliferation in vitro, and tumor formation in vivo. Following validation of new therapeutic targets of treatment-refractor GBM, we aim to build novel biotherapeutics against highly validated cell surface targets, and establish preclinical testing protocols using our novel patient-derived and therapy-adapted xenograft model of treatment-resistant GBM.

Establishment and characterization of patient-derived xenografts of clear cell carcinoma of the ovary. Hidemichi Watari,1 Daïsuke Endo,2 Koutaro Konishi,3 Hiroki Hara,2 Mihoko Kuragaki2. 1Hokkaido University, Sapporo, Japan; 2Takeda Pharmaceutical Co. Ltd., Fujisawa, Japan.

Background: The patient-derived xenograft (PDX) model is likely to reflect original human cancer biology compared to cultured cell lines, since tumor tissues are directly implanted into animals. PDX models of ovarian cancer have been developed, but were not fully characterized at the molecular level, especially for clear cell carcinoma (CCC), which is more prevalent in Japan than western countries, exhibits chemoresistant phenotype and poor survival. The development of new treatment strategies and the better understanding of biology of CCC both depend on clinically relevant animal models. In particular, molecular annotated PDX models are useful for the preclinical investigation of anticancer drugs and individualized anticancer therapy. Methods: We transplanted 19 parent (primary or metastatic) tumors directly into NOG mice. The histologic characteristics were compared between parental tumors and PDX ones. Among CCC pairs, gene expression analysis, gene mutation analysis were conducted on parental tumors and corresponding PDX tumors. Response to chemotherapeutic agents was analyzed using PDX tumors of CCC, and correlated with clinical outcome. Results: Six of nineteen (31.6%) transplanted tumors could be passaged. Gene expression profiles revealed that engrafted tumors expressed more proliferation-related genes than those of non-engrafted ones. Among 6 PDX models established, two were found to be CCC. Two PDX tumors of CCC maintained the histologic characteristics of parental CCC tumors. Gene expression profile revealed similar results between primary CCC and PDX tumors of CCC, except that PDXs lost expression of immune-related genes. Gene mutation analysis showed similar pattern between primary CCC and PDX of CCC. Drug-sensitivity test showed resistance to carboplatin in two PDX tumors of CCC, which is consistent with their clinical outcomes. Conclusions. PDXs of CCC were established and found to retain histologic and clinical features of original tumors, and can be utilized to screen new target drugs for platinum-resistant CCC.

Imodi initiative: A novel holistic and integrative approach with patient-derived tumor models against pancreatic cancer. Juan Iovanna,1 Nelson Dussetti,2 Florence Meyer-Josic,2 Frédérique Le Vaconn,3 Loreday Calvet,4 Norico Fariz,4 Kevin Dhondt,5 Mariana Kuras,5 Christophe Lautrette,5 Sérénée Tabone-Eglinger,5 Philippe Vaglio,10 Olivier Duchamp5,11 INSEER, Marseille, France; 12IFEN Innovation, Les Ulis, France; 13BioForts-Merieux NutriSciences, Saint-Herblain, France; 14Sanofi, Limoges, France; 15Centre Léon Bérard, Lyon, France; 16Modul-Bio, Marseille, France; 17OncoDesign S.A., Dijon, France.

Patient-derived xenografts (PDX) are appearing as a prime approach for preclinical studies despite being insufficiently characterized as a model of the human disease and its diversity. Many reports support that xenografts from PDX in mice recapitulate well the molecular diversity, cellular heterogeneity, and histology seen in patient tumors. However, several lacks such as the limited clinical diversity of the PDXs, the absence of human drug metabolism and the reduced immune system are limiting the predictive values of these PDX models. To
set-up a holistic integration of these criticisms, we have associated efforts from public hospitals, academic groups, biotech and private pharmaceutical companies with the financial support of the French Ministry of Industry. First, to improve the clinical diversity of the PDX collections, surgical specimens or biopsies from patients with 9 different types of cancers (pancreas, lung, breast, ovary, liver, prostate, AML, myeloma, lymphoma) are collected since 2013 to establish large collections of PDXs in mice. In addition, primary cultures of cells from these samples are established leading to a collection of cell lines from the stroma and the tumoral compartment. Pancreatic PDX from primary tumors and its metastasis were obtained from either surgery or by endoscopic ultrasound-guided fine needle aspirate and therefore representing a bio-banking with a unique diversity. The established pancreatic models are being evaluated for histological, extensive molecular characteristics and in vitro and in vivo sensitivities to relevant anticancer drugs. We found i/ a variable sensitivity on PDX-derived cells when treated in vitro with increasing concentrations of clinically relevant drugs; ii/ that sensitivity to one drug does not predict the sensitivity to the another one; and iii/ sensitivity to drugs in vivo reproduce, but not systematically, the results in vitro. To be noted, no correlation between sensitivity and genetic characteristics (mutations or CNV) or histological proprieties was found. All model characteristics are being compiled in a web-based database for efficient features search and interconnection. Second, we are generating mice with humanized liver showing human drug pharmacokinetic and metabolism profiles We will present the first pancreatic cancer models characterized and will discuss their usefulness and chance to bring benefit to patients via this holistic strategy developed within IMODI initiative.

#3847 Oral cavity squamous cell carcinoma xenografts display conservation of primary tumor genomic heterogeneity. Katie M. Campbell,1 Tianxiang Lin,2 Ashley E. Winkler,3 Paul Zolkind,4 Zachary L. Skidmore,5 Erica K. Barnett,5 Ian Hagemann,6 Elaine R. Mardis,7 Malachi Griffith,8 Rebecca D. Cherboni,9 Ossama Tawfik,10 Joan Lewis-Wambi1.

Purpose: Patient derived xenograft (PDX) models represent a platform for defining therapeutic opportunities based on their ability to maintain the genomic and molecular features of their respective tumors. We used a comprehensive genomics approach to analyze PDXs for oral squamous cell carcinoma (OSCC), which had not been previously described. This involved confirming that the PDXs conserve the heterogeneous somatic landscape of the primary tumors from which they were derived. Methods: We established a large panel of OSCC PDX models by engrafting fresh, primary tumor samples into NOD scid gamma (NSG) mice. We performed whole genome sequencing (WGS; n = 10), whole exome sequencing (WES; n = 15), and transcriptome sequencing (RNAseq; n = 15) on matched primary and first passage xenografts. Somatic events, including mutations, copy number alterations (CNAs), loss-of-heterozygosity (LOH) regions, and structural variation (SV), were detected independently in tumors and PDXs. Conservation was defined by the correlation of variant allele frequency (VAF) distributions and gene expression patterns, presence of larger somatic events, and predictions made about the subclonal architecture of the xenograft. Resulta: PDXs were established with an overall success rate of 47% (56/118). The somatic landscape of primary tumors was representative of the published genomic data on OSCC, including amplifications of CCND1 and EGFR family members, inactivating mutations and loss of TP53 and CDKN2A, and chromosome 3q amplification. These somatic events were also strongly conserved in matched xenograft samples. Mutations that were detected in either the xenograft or primary tumor, but not its matched sample, consisted primarily of low-frequency mutations. The predicted clonal architecture, however, revealed correlated subclonal heterogeneity between matched xenograft and primary tumor. This includes maintenance of founding clone mutations and consistent VAF distributions, indicating that a heterogeneous tumor population engrafted. Conclusions: This comprehensive analysis establishes early-passage PDXs as high fidelity models for OSCC. Their ability to maintain the genomic heterogeneity detected in primary OSCC tumors presents a clinically relevant platform for understanding tumor biology and identifying novel therapeutic strategies.

#3848 The clinical relevance of targeting IFITM1 in three distinct subtypes of aggressive breast cancer. Asona Iliu,1 Joshua Ogony,1 Jordan Marques,1 Eric Grandi,1 William Jowett,2 Ihaba El Ayash,3 Gustav Miranda-Carboni,2 Ossama Tawk,2 Joan Lewis-Wambi1. 1Univ. of Kansas Medical Ctr., Kansas City, KS; 2University of Tennessee Health Science Center, Memphis, TN.

Breast cancer can be separated into estrogen receptor/ progesterone receptor positive (ER+/PR+), Her2/2neu positive (HER2+), and triple negative (ER-/PR-/HER2-) subtypes. Additionally, breast cancer may manifest clinically as either non-inflammatory or inflammatory disease. Inflammatory breast cancer is a highly lethal subtype of breast carcinoma that may express any of the three aforementioned receptors. Our laboratory has found that a novel marker, interferon-induced transmembrane protein 1 (IFITM1), is overexpressed in multiple subtypes of breast cancer and is predictive of poor prognosis and resistance to endocrine therapy, chemotherapy, and radiation. IFITM1 is a type I interferon (IFN) stimulated gene that is not expressed in normal breast tissue, and is only induced upon IFN exposure. In this study, we conducted immunohistochemical staining for IFITM1 in 94 ER+ human breast tumor samples and discovered that high IFITM1 expression was associated with increased clinical stage and resistance to endocrine therapy. We therefore explored the expression of IFITM1 in human triple negative breast cancer (TNBC) samples as compared to normal breast tissue. Notably, this overexpression was most pronounced in TNBC tumors from African American (AA) patients. We screened a panel of nine cell lines that represent all major subtypes of breast cancer and found IFITM1 overexpression in ER+ aromatase inhibitor-resistant MCF-7/5C, AA-derived triple negative MDA-MB-468 and MDA-MB-157, and triple negative inflammatory SUM149 cells. We used inducible shRNA and CRSPR/Cas9 respectively, to investigate the effect of IFITM1 knockdown on MCF-7/5C and SUM149 xenograft tumors using two in vivo breast cancer models. The orthotopic (mammary fat pad) model evaluated tumor proliferation, and the mammary intraductal (MIN) model assessed tumor cell invasion out of the milk duct. We found that loss of IFITM1 in MCF-7/5C and SUM149 cells significantly reduced tumor growth and invasion in vivo, blocked xenograft tumors from outgrowing, and reduced their ability to invade out of the milk duct. Additional studies indicated that hyper-activated JAK/STAT signaling was responsible for driving IFITM1 expression in MCF-7/5C, MDA-MB-468, and SUM149 cells. Furthermore, we demonstrated that JAK/STAT activation can be targeted in vivo with the FDA approved JAK inhibitor ruxolitinib (Jakafi®). Oral treatment of mice with 50µg/g bodyweight ruxolitinib reduced IFITM1 expression and inhibited the growth of both MCF-7/5C and MDA-MB-468 tumors by loss of STAT1/2 phosphorylation. The overexpression of IFITM1 in three distinct breast cancer subtypes indicates that IFITM1 may be a targetable marker of aggressive disease in general and may open the door for novel therapies of treatment-refractory breast cancer.

#3849 HuPBL humanized models as a tool to evaluate the efficacy and immune regulation of immune checkpoint inhibitors. Xu zun Tang, Xianzhi Zhai, Hui Qi, Qin Hong, Qiyou Zhang, Lei Jin, Shaoyen Yuan, Zhuozhi Wang, Yong Sheng, Qingyang Gu, Norman Zhang, Jing Li, Qunsheng Li. WuXi AppTec (Shanghai) Co., Ltd., Shanghai, China.

After the success of PD-1, PD-L1 and CTLA-4 antibodies, a number of immune-checkpoint inhibitors are already in advanced stages. Meanwhile, tumor infiltrating lymphocytes (TIL) are well recognized as features of tumor progression and loss of effectiveness of cancer immunotherapy. Therefore, there is a need to establish an effective pre-clinical platform for the evaluation of therapeutic outcomes in the human immune system and the understanding of TILs. Either traditional syngeneic models or human target knockin models have their drawbacks: syngeneic models disable the development of antibodies that do not recognize mouse receptors; neither of them can achieve a good clinical response. HuPBL humanized models can provide a solution to these issues. In this study, in vitro characterization and functional analysis of human TILs from TILs subsets and related immune-checkpoint expression. These models can
be used for the purpose of pre-clinical immune-checkpoint inhibitor and bi- specific antibody screening under human background, as well as for further investigations regarding distinct functions of TILs subsets and target expression.

### #3850 Establishment of patient derived model of high-risk endometrial cancer for pre-clinical combined carboplatin and decitabine therapy, Weimei Peng, Mei Yang, Zhen Liu, Ya Yu, Wei Jiang. Obstetric and Gynecology Hospital of Fudan University, Shanghai, China.

Objective: The high risk endometrial cancers (EC), including high grade EC, serous carcinoma (SC), clear cell carcinoma (CC) and carcinosarcoma, account for 50% of death. Therapies for them are limited and patient derived tumor xenograft (PDX) model become useful tools to predict response to treatment. Here we compared the two methods of establishment of PDX models and evaluated the efficacy of carboplatin and decitabine in two high grade EC PDX models. Methods: Fresh tumor tissues collected from 11 primary high risk EC patients (6 high grade ECs, 4 SCs, 1 CC and 1 carcinosarcoma) were engrafted subcutaneously and in subrenal capsule in SCID mice. For those subcutaneous models, tumors were then orthotopic transplanted into uterine cavity. Histology, vimentin, cytokeratin, ER, PR, PS3 expression were evaluated, together with mutation profiles by next generation sequencing for 500 cancer-panel genes. The efficacy of carboplatin and decitabine were evaluated in two high grade EC models. Results: The total tumor take rate was 81.8% (9/11), without regard to engraft models. The tumor take rate was higher in subrenal capsule models than subcutaneous models (70% vs 54.5%, respectively). The time for tumor formation (from transplantation to 1 cm in diameter) varies greatly from 4 weeks to 5 months. We observed good similarity between primary tumors and corresponding different passage of xenografts. One high grade EC model was sensitive to carboplatin and decitabine treatment whereas another was drug resistant. Two models harbor different genetic mutation profiles. Conclusion: The high tumor take rate ensures the establishment of the high risk EC biobank which provides a powerful resource for pre-clinical drug-sensitive tests as well as identification of biomarkers of response or resistance.

### #3851 Targeting HER2 in gastric cancer: Hints from a gastric PDX platform. Simona Corso,1 Cristina Migliore,1 Maria Apicella,1 Silvia Menegon,2 Eirini Pectasides,2 Tania Capeola,2 Stefania Durando,2 Marilisa Cargarutti,2 Paola Cassoni,1 Anna Sapino,1 Maurizio de Giuli,1 Adam Bass,2 Silvia Giordano1,7, Universita’ di Torino, Italy; 2Candiolo Cancer Institute-FPO, IRCCS, Italy; 3Beth Israel Deaconess Medical Center, boston, MA; 4Candiolo Cancer Institute-FPO, IRCCS, Candiolo, Italy; 5Dana Farber cancer Institute, MA.

Introduction: Gastric cancer is the 3rd leading cause of cancer mortality worldwide. Surgery is the only curative treatment strategy and conventional chemotherapy has shown limited efficacy. Trastuzumab (a HER2 mAb), is the only therapy targeting molecular alterations approved so far in gastric cancer, for HER2+ patients with advanced disease. However only a fraction (<20%) of HER2 amplified patients benefits from treatment. Methods: We have recently generated a molecularly annotated colony of gastro-esophageal PDXs (at the moment, > 70 PDXs). The platform also comprises primary cell lines and 3D- cultured organoids derived from gastric cancer PDXs. Results and Discussion: At present, we have identified several HER2+ PDXs and generated the corresp- onding in vitro derivatives. Four HER2+ PDXs, showing 3+ HercepTest score and HER2 amplification > 8 copies (thus theoretically sensitive to Trastuzumab), were selected to undergo ‘xenotrials’ with the following anti-HER2 drugs/combos: Trastuzumab (T); Pertuzumab (P, anti-HER2 mAb); Lapatinib (L, a dual HER2-EGFR tyrosine kinase inhibitor). According to RECIST-like criteria, T induced tumor regression in only 1 out of 4 HER2+ PDXs. Interest- ingly, in all the tumors but one the combos T+P and T+L, were able to bypass resistance to T monotherapy and to induce tumor regression. One tumor was resistant to all the tested therapeutic approaches. Conclusion: We identified PDXs displaying HER2 gene amplification. Only a minor fraction of them ben- efited from the anti-HER2 mono-therapy, despite the presence of a strong HER2 gene amplification, while the association of two HER2 inhibiting drugs resulted in intense and prolonged response. This suggests that monotherapy with T might not be the most effective therapeutic approach in gastric cancer patients. We are currently investigating the cause of resistance to anti-HER2 drugs to identify mutations/CNV in tumors showing resistance to Trastuzumab.

### #3852 Validation of synthetic lethality of PARP and NAMPT dual inhibi- tion in a small cell lung cancer PDX model. Zhixiang Zhang, Dongfang Li, Chen Chen, Bo Zhang, Xuzhen Tang, Hao Ye, Qingyang Gu, Qunsheng Ji. West China Hospital of Sichuan University, Chengdu, China.

Small cell lung cancer (SCLC) is a highly malignant cancer type with a 5-year survival rate of less than 10%. Different from non-small cell lung cancer (NSCLC), no effective target therapies have been approved to treat SCLC. Poly (ADP) ribose polymerase (PARP) overexpression in SCLC has prompted great efforts to evaluate the role of PARP inhibitors in clinic. To maximize their therapeutic value it is urgent in need to explore the best combination strategies between PARP inhibitors and other pathway modulators. In this study we identified a SCLC patient-derived xenograft (PDX) model with high PARP level and low nicotinamide phosphoribosyl- trasferase (NAMPT) level. Furthermore, synergistic effect of PARP and NAMPT dual inhibition was demonstrated, supporting translational research of PARP inhibi- tors and NAMPT inhibitors in this model. The mRNA expression of PARP as well as its 30 most-studied synthetic lethality genes was compared between SCLC and NSCLC in both PDXs and cancer cell lines. We found that NAMPT levels decreased most significantly in SCLC compared with NSCLC across the 30 synthetic lethality genes of PARP. As NAMPT is the rate-limiting enzyme for the synthesis of the PARP substrate β-NAD+, we hypothesized that low β-NAD+ level due to low NAMPT level might render SCLC sensitive to PARP inhibition. LU-01-0547, a SCLC PDX model with high PARP and low NAMPT expression, was identified here. To test our hypothesis, we investigated the preclinical efficacy of ABT888, a PARP inhibitor, with or without FK866, a NAMPT inhibitor, in this subcutaneous xenograft model. The single-agent efficacy of ABT888 was demonstrated (TGI=96%±100 mg/kg, BID), at a sub-optimal dose (50 mg/kg, BID), treatment of ABT888 alone produced little activity in the same model, while its combination with a NAMPT inhibitor, FK866, significantly boosted the antitumor response indicating the synergistic effect (TGI=117%, ORR=6/6, CR=4/6). When nicotinamide (NA) was supplied to promote β-NAD+ biosynthesis in other way other than the NAMPT-mediated transformation, the PARP inhibitor’s effectiveness was greatly antagonized (TGI=70% vs. 13%), suggesting β-NAD+ level might correlate with PARP inhibitor sensitivity. In conclusion, this study identified a SCLC PDX model with high PARP and low NAMPT expression. Synergistic inhibition of PARP and NAMPT in this model was demonstrated superior to either treatment alone in efficacy, which warranted its future application in drug discovery. To our knowl- edge, this was the first in vivo evidence of synthetic lethality in SCLC PDX, support- ing future clinical test of combination of PARP and NAMPT inhibitors in SCLC patients.

### #3853 Patient-derived xenograft models from peritonal metastasis of colorectal carcinoma as novel platform for biomarker analysis and drug test- ing. Wolfgang Walther,1 Eva Pachmayr,1 Bernadette Brzeziczka,2 Britt Bütt- ner,2 Beate Rau,1 Ulrike S. Stein,1 Charité Universitätsmedizin Berlin and Max Delbruck Ctr. for Molecular Medicine, Berlin, Germany; 2epp GmbH, Berlin, Ger- many; 1Charité Universitätsmedizin Berlin, Berlin, Germany.

Colorectal carcinoma (CRC) is associated with high incidence and mortality rate, particularly if metastasized to distant sites, such as the peritoneum. At time of first diagnosis 4 to 7 percent of the patients suffer from peritonal metastasis (PM) of CRC. The PM is associated with poor prognosis and limited therapeutic options. Therefore, availability of adequate in vivo models for PM will promote the search for novel prognostic or even predictive biomarkers as well as the evaluation of chemothera- peutic combinations targeted towards standard, targeted and novel drugs. In this regard such models could be employed for more individualized concepts to improve the therapeu- tic outcome of PM patients. During the last decade patient-derived xenograft (PDX) mouse models have gained importance, since they closely resemble the mo- lecular and biological features of the original primary tumors. However, until now no PM PDX models have been established from CRC. We therefore focused on the establishment and characterization of a novel CRC PM panel of PDX as useful platform for preclinal studies. For the PDX establishment colorectal surgical spec- imens were subcutaneously (s.c.) transplanted onto immunocompromized NOD scid gamma (NSG) mice. The successfully engrafted tumors were transferred to NMRI nu/nu mice for further passaging. Engrafted tumors were characterized by histopathology, immunohistochemistry and gene expression analyses using real- time RT-PCR. Chemosensitivity of PDX models was evaluated in vivo by applica- tion of a panel of conventional chemotherapeutic and of targeted drugs. For PDX establishment 68 CRC surgical specimens were transplanted onto NSG mice. From those, currently 22 PDX have engrafted and are stably growing on NMRI nu/nu mice. From those, 13 models of 10 patients have been analyzed. Their tumor dou- bling times ranged between 4 to 28 days. The histopathological evaluation revealed maintenance of the original CRC histology in the PDX. The chemosensitivity testing of conventional and of targeted drugs in the 13 PM PDX models revealed the indi- vidual, diverging response of the PDX, such as for 5-FU, irinotecan, oxaplatin, cetuximab and erlotinib. For selected PDX, orthotopic tumor transplantation into the peritoneum revealed their potential to form disseminated tumors in kidney, ovaries and abdominal diaphragm. Our results demonstrate, that this novel panel of PDX maintains the morphology of the patient tumor in early passages, reflect heterogene- neous response rates, and can be used as preclinical in vivo platform for translational
identification of circulating tumour cells in breast cancer patient-derived xenograft models. Chiara Agnoletto,1 Linda Minotti,2 Marco Galasso,3 Fabio Corrà,1 Federica Baldassari,1 Stefano Cairo,3 Jean-Gabriel Judde,4 Aurelie Sauvage,4 Olivier Deas,2 Lorenzo Pasquali,1 Stefano Vollinia,1 University of Ferrara, Ferrara, Italy; XenTech, Evry, France; Karolinska University Hospital, Stockholm, Sweden.

Metastases from primary tumours accounts for the great majority of cancer-related deaths. This process is thought to involve a series of sequential steps, with the release of circulating tumour cells (CTCs) into the bloodstream. CTCs have been detected in the peripheral blood of patients with advanced cancers of different origin and in some localized cancers. Recently, liquid biopsy focusing on the analysis of CTCs has received enormous attention because of its obvious clinical implications for personalized medicine. Clinical applications of CTCs detection include early detection of cancer, prediction of the risk for metastatic relapse or progression, monitoring the effects of systemic therapies, and stratification of patients based on the detection of therapeutic targets on resistance mechanisms. To date, only few data are available about the numbers of these cells, their molecular and biological heterogeneity, and their significance. CTCs comprise a minute fraction of mononucleated cells in the circulation, posing a serious challenge for any analytical system. Multiple technologies have been developed for CTC capture, but there is still a critical need for increased sensitivity in rare tumour cell isolation within blood samples. Most of the current CTC detection techniques rely on immunobased capture of cells, and epithelial markers have been frequently used to distinguish cancer cells from normal blood cells. However, the phenotypic changes that occur in CTCs, due predominantly to the epithelial-mesenchymal transition process, could be responsible for the failure to detect them in blood samples. We describe a novel approach for the identification of molecular markers to detect CTCs in peripheral blood of patient-derived xenograft (PDX) models. We analyzed the transcriptome in more than 10,000 samples of primary and metastatic tumours deposited in public databases, and identified a small set of cancerspecific genes coding for membrane protein. Putative markers were assayed by reverse transcription PCR with species-specific primers in blood samples from breast cancer PDXs, testing their ability to detect human CTCs. Thus, we identified human membrane proteins, which can be used for CTC monitoring in peripheral blood. The use of multiple targets for CTC capture and identification increases the sensitivity of CTC detection, allowing the isolation of all heterogeneous CTCs subpopulations.

Identification of circulating tumour cells in breast cancer patient-derived xenograft models. Chiara Agnoletto,1 Linda Minotti,2 Marco Galasso,3 Fabio Corrà,1 Federica Baldassari,1 Stefano Cairo,3 Jean-Gabriel Judde,4 Aurelie Sauvage,4 Olivier Deas,2 Lorenzo Pasquali,1 Stefano Vollinia,1 University of Ferrara, Ferrara, Italy; XenTech, Evry, France; Karolinska University Hospital, Stockholm, Sweden.

Metastases from primary tumours accounts for the great majority of cancer-related deaths. This process is thought to involve a series of sequential steps, with the release of circulating tumour cells (CTCs) into the bloodstream. CTCs have been detected in the peripheral blood of patients with advanced cancers of different origin and in some localized cancers. Recently, liquid biopsy focusing on the analysis of CTCs has received enormous attention because of its obvious clinical implications for personalized medicine. Clinical applications of CTCs detection include early detection of cancer, prediction of the risk for metastatic relapse or progression, monitoring the effects of systemic therapies, and stratification of patients based on the detection of therapeutic targets on resistance mechanisms. To date, only few data are available about the numbers of these cells, their molecular and biological heterogeneity, and their significance. CTCs comprise a minute fraction of mononucleated cells in the circulation, posing a serious challenge for any analytical system. Multiple technologies have been developed for CTC capture, but there is still a critical need for increased sensitivity in rare tumour cell isolation within blood samples. Most of the current CTC detection techniques rely on immunobased capture of cells, and epithelial markers have been frequently used to distinguish cancer cells from normal blood cells. However, the phenotypic changes that occur in CTCs, due predominantly to the epithelial-mesenchymal transition process, could be responsible for the failure to detect them in blood samples. We describe a novel approach for the identification of molecular markers to detect CTCs in peripheral blood of patient-derived xenograft (PDX) models. We analyzed the transcriptome in more than 10,000 samples of primary and metastatic tumours deposited in public databases, and identified a small set of cancerspecific genes coding for membrane protein. Putative markers were assayed by reverse transcription PCR with species-specific primers in blood samples from breast cancer PDXs, testing their ability to detect human CTCs. Thus, we identified human membrane proteins, which can be used for CTC monitoring in peripheral blood. The use of multiple targets for CTC capture and identification increases the sensitivity of CTC detection, allowing the isolation of all heterogeneous CTCs subpopulations.

Identification of circulating tumour cells in breast cancer patient-derived xenograft models. The use of multiple targets for CTC capture and identification increases the sensitivity of CTC detection, allowing the isolation of all heterogeneous CTCs subpopulations.
were treated with different chemotherapies used in early stages and metastatic settings: anthracyclines combined to cyclophosphamide (AC), taxanes, platins, cephalosporins, and gemcitabine. Drug responses in PDX were compared to responses in patients who recurred after surgery and were treated in the metastatic setting. Results: overall tumor take of residual tumors was 40% and 75% for TNBC, with 15/20 PDX established, more than twice the tumor take of treatment naive TNBC (34%). Median latency time, defined as time from implantation till first tumour growth, was only 60 days and was further reduced to 3-4 weeks during successive tumor passages. On the 8 TNBC PDX evaluated for chemosensitivity, 7 exhibited a multidrug-resistance phenotype with resistance or limited response to AC, taxanes and platins. Capecitabine, a chemotherapy given in the advanced stage as second or third line, was efficient in 5 out of 8 PDX tested with 3 models showing stable disease and 2 models durable tumor regressions. Interestingly, capecitabine efficacy was decreased when xenografts were pre-treated with a first line containing platins, suggesting that in some tumors capecitabine might have superior activity when given in the adjuvant setting or as a first line. In one third of TNBC patients, time to recurrence, comprised between 7 and 12 months after surgery, was compatible with xenograft establishment and drug testing. Conclusions and perspectives: we established a unique panel of PDX models from patients with residual disease after neoadjuvant chemotherapy. These aggressive PDX recapitulate the resistance phenotype of patients’ tumors to treatments given in neo- and metastatic settings. We identified capecitabine as efficient first line chemotherapy for residual chemoresistant PDX. In 30% of cases, PDX models could have been used to evaluate chemotherapy responses in tumor recurrence occur in patients. In order to identify predictive biomarkers of capecitabine response, additional experiments are ongoing in 25 supplementary TNBC PDX, established from treatment-naive patients.
Development of testicular cancer patient derived xenograft models to test combination therapies targeting PI3K/Akt and MDM2. Gerda de Vries,1 Ximena Rosas-Plaza,1 Marcel A. van Vught,1 Albert J.H. Swurmeijer,2 Jorik A. Gietema,1 Steven de Jong1,1 Department of Medical Oncology, Cancer Research Centre Groningen, University Medical Centre Groningen, Groningen, Netherlands; 2Department of Pathology, University Medical Centre Groningen, Groningen, Netherlands.

Metastatic testicular cancer (TC) is highly sensitive to cisplatin-based chemotherapy. However, patients with advanced disease in the poor prognosis group only have a 50% 5-year survival resulting from chemoresistance. Previous data showed that both the PI3K/Akt pathway and the MDM2/p53 axis are involved in cisplatin resistance of TC cells. In this study, we sought to establish and characterize TC patient-derived xenografts (PDX) in order to investigate PI3K/Akt and/or MDM2 inhibition as possible treatment options for TC. Excised and minced (8mm3) primary TC tissue was implanted subcutaneously into male NSG mice to obtain a first generation PDX model (F1). Animals were sacrificed when tumor volume exceeded 1500mm3. The tumor was harvested and minced. Small pieces (8mm3) were implanted in a second generation (F2), as well as in FCS-5% DMSO to establish a biobank. In a panel of TC cell lines, combination treatment of Akt inhibition with or without cisplatin or Nutlin-3a was performed. Cleaved caspase-3 staining was assessed to measure apoptosis, and western blot was used to determine the effect of different treatments on subcellular localization and phosphorylation status of MDM2. We have established 3 TC PDX models. In silico analysis of the primary tumors included subtypes: mixed germ cell tumors with embryonal- and yolk sac carcinoma and teratoma components. Engraftment efficacy was 100% and tumor growth initiated within 4-5 weeks after implantation. Interestingly, we successfully implanted a biopsy taken from a metastatic lesion of a patient presenting with progressive refractory disease after receiving standard chemotherapy. Histology of the different PDX generations was comparable to the patient material, although a loss of the teratoma component was observed. In our cell line panel, Akt inhibition using MK2206 sensitized the acquired cisplatin resistant cell line TeraCP towards cisplatin treatment, whereas an additive effect was observed in other cell lines. Combination of Akt and MDM2 inhibition was highly synergistic in apoptosis induction in all cell lines. No relation was observed between the synergistic effect of Akt combined with MDM2 inhibition and sub-cellular localization or phosphorylation levels of MDM2. Taken together, we have successfully established 3 TC PDX models, including a chemo-resistant model. The biobank is currently being expanded. Combined Akt and MDM2 inhibition resulted in sigmoidic induction of apoptosis, and these combinations or other novel therapies will be tested in established TC PDX models. Supported by Dutch Cancer Society grant RUG 2014-6901 and CONACyT grant 381543.

In vivo chemopreventive of pseudosemiglabrin via inhibition of tumor angiogenesis and manipulation of hormones in estrogen-responsive breast cancer. Loey E. Ahmed Hassan. Faculty of Science and Technology, Omdurman, Sudan.

Breast cancer is the most frequently diagnosed form of malignancy and the second leading cause of death in Western women. Mortality and most of the complications associated with breast cancer are due to metastasis developing in regional lymph nodes and in distant organs, including bone, lung, liver and brain. Chemopreventive is administration of chemical agents to prevent the initiation and promotional events associated with carcinogenesis. Some chemopreventive agents can prevent reaction or attacking molecules by different ways, these agents can suppress growth factors or signaling pathway. On this study we examined (-)-Pseudosemiglabrin (SSG) a natural compound extracted from Tephrosia apollinea on breast cancer cells and tumor vascularization in vitro and in vivo. Hormone sensitive breast cancer cell MCF-7 was found subtile susceptible to SSG, it showed profound anti-tumorgenesis via inhibiting breast cancer cell migration, invasion and colony formation in vitro settings. In silico investigation of potential PARP inhibitor, SSG showed high binding affinity comparable to Rucaparib (standard PARP inhibitor). The natural compound significantly inhibited the sprouting of new blood vessels in ex vivo rat aorta ring assay. Antiangiogenic efficacy is perturbed by targeting VEGF expression and VEGFR phosphorylation. SSG completely inhibited the onset of breast cancer in animals pretreated with the compound. Molecular docking study showed that SSG binds to active site of Aromataze (the enzyme responsible for a key step in the biosynthesis of estrogens) with binding affinity better than standard aromatase inhibitor (Arimidex), moreover the compound has inhibitory activity against estrogen receptor in the breast cancer cells comparable to Tamoxifen. Our findings reveal that (-)-Pseudosemiglabrin can potentially be beneficial in preventing breast cancer in high-risk women or it can be adjuvant therapy with standard chemotherapy or even can be used for the treatment of women who have been diagnosed with breast cancer.

A subset of poorly prognostic pediatric posterior fossa ependymomas exhibit lowered H3K27me3 and DNA hypomethylation and show epigenetic similarities with H3K27M mutant diffuse intrinsic pontine gliomas. Sriman Venkett,1 Jill Bayliss,2 Piai Mukhuerjee,2 Chao Lu,2 Siddhant Jain,1 Chan Chung,1 Daniel Martinez,2 Benjamin Saburi,2 Ashley Margin,2 Pooja Panwalkar,3 Abhijit Parolaio,2 Melike Pekmezci,1 Richard Mc Eachin,1 Marcin Cieslik,2 Benita Tamraz,2 Benjamina Garcia,2 Gaspare La Rocca,3 Mariarita Santi,2 Peter Lewis,1 Cynthia Hawkins,1 Ari Melnick,2 C David Allis,4 Craig B. Thompson,5 Arul Chinnaiyan,1 Alexander R. Tudkins,6 University of Michigan Medical School, Ann Arbor, MI;5 Epigenomics Core Facility, Weill Medical College of Cornell University, New York, NY;7 The Rockefeller University, New York, NY;8 University of Wisconsin, Madison, WI;2 Children’s Hospital of Philadelphia, University of Pennsylvania, Philadelphia, PA;4 Children’s Hospital Los Angeles, Keck School of Medicine University of Southern California, Los Angeles, CA;6 University of California, San Francisco, San Francisco, CA;9 Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA;6 Memorial Sloan Kettering Cancer Center, New York, NY;2 Department of Laboratory Medicine and Pathobiology, Faculty of Medicine, University of Toronto, Toronto, Ontario, Canada.

Pediatric posterior fossa ependymomas are poorly understood. Childhood brain tumors and have no effective treatments. The biology of these tumors is obscure as recent sequencing efforts suggest that they lack recurrent genetic alterations. A subset of these tumors termed PF-A ependymomas exhibits CpG island hypermethylation implicating epigenetic alterations in their pathogenesis. Through comprehensive analyses of histone modification, we discovered global H3K27me3 reduction in a subset of these tumors. Tumors with lowered H3K27me3 showed many clinical and biologic similarities with PFA-ependymomas. Global reduction in H3K27me3 is likewise observed in pediatric gliomas that bear histone H3K27M mutations termed diffuse intrinsic pontine gliomas (DIPG) that also arise in the posterior fossa of young children. Analyses of ependymomas with reduced H3K27me3 and H3K27M mutant DIPGs showed many similarities in DNA methylation and enrichment of H3K27me3 in many genomic loci important for neuronal specification. Combined integrative analysis of both tumor types uncovered common epigenetic deregulation of select factors that control radial glial biology and radial glia in the developing posterior fossa showed lowered H3K27me3. Finally, PF ependymomas with lowered H3K27me3 were more invasive radiologically and exhibited poor prognosis in three independent cohorts (P<0.001 in all three cohorts, collective n>300). These data have clinical implications for biomarker development and to inform epigenetic approaches to treat PF ependymomas.

Combined targeting of the EWS/ETS transcriptional program by blocking epigenetic readers and transcription initiation in Ewing sarcoma. Ziaurrahman Chowdhury,1 Rockford Owoibi,1 Federica Crippa,2 Brian Seftor,1 Malak Shehadeh,1 Geoffrey Field,1 Becker-Dettli Fox,3 Frauke Neff,2 Oxana Schmidt,2 Shudong Wang,2 Beat W. Schafer,2 Stefan Burdach,1 Gunther HS Richter1,1 Laboratory for Functional Genomics and Transplantation Biology, Children’s Cancer Research Centre and Department of Pediatrics, Munich, Germany;2 Department of Oncology and Children’s Research Center, University Children’s Hospital, Zurich, Switzerland;3 Helmholz Zentrum München, - German Research Centre for Environmental Health (GmbH), Neuherberg, Germany;9 School of Pharmacy and Medical Sciences, University of South Australia, Adelaide, Australia.

Introduction: Previously, we reported blocking of BET bromodomain binding proteins (BRDs) by use of an inhibitor (JQ1) and the associated strong down-regulation of the predominant EWS-ETS protein EWS-FLI1 in Ewing sarcoma (ES). Here we analyzed in depth the mechanistic effects of this treatment by EWS-FLI1 interaction studies and the evaluation of possible combined targeting. Experimental procedures: Function of BRDs was analysed by application of specific inhibitors (JQ1, I-BET151), RNA interference (RNAi) with the generation of stable and inducible knockdowns or knockouts by the generation of BRD4 CRISPR/Cas9 cell lines. To analyse the resulting changes Co-IP, ChIP-qPCR, RT-PCR, western blotting, cycle analysis, proliferation and invasion assays, whole transcriptome analysis via microarrays as well as xenograft mouse models were utilized. Results: By use of JQ1 or I-BET we strikingly observed a strong down-regulation of the predominant EWS-ETS protein EWS-FLI1 and subsequent microarray analysis revealed JQ1 treatment to block the typical ES associated expression program. The effect on this expression program was paricularly striking for JQ1 but not I-BET. In addition we knocked out studies of BRD4 by CRISPR/Cas9 as well as knockdowns of individual BRD2, 3 or 4 did not recapitulate JQ1-mediated proliferation restrictions and blockade and tumor development in xenograft mice as observed for JQ1. However, co-immunoprecipitation experiments revealed an DNA independent in-
teration of BRD4 with EWS/FLI1 and further interaction with CDK9. Treatment of ES cells with a specific CDK9 inhibitor demonstrated a rapid downregulation of EWS-FLI1 expression and block of contact dependent growth. Furthermore, CDK9 inhibition induced apoptosis in ES as depicted by downregulation of XIAP and CFLAR and consequently cleavage of Caspase 8, PARP and increased CASP3 activity, similar to JQ1. Combined treatment of BRD4 and CDK9 inhibitors was more effective than individual drug application. Conclusion: Translocation driven tumors such as ES are very susceptible to combined treatment with epigenetic inhibitors. Here we demonstrate that treatment with inhibitors targeting the p-TFEB complex could interrupt communication between EWS-FLI1, BRD4 and CDK9 further impeding EWS-ETS transcriptional activity and its associated pathognomonic expression program.

#3865 Targeting the epigenetic modifier HMGA2 in lethal adult and pediatric gliomas inhibits invasion, growth and tumorigenicity. Harpreet Kaur,1 Sabeen Z. Ali,2 Huizi Guo,2 Sepehr Akhtarkhavari,2 Fausto Rodriguez,2 Charles G. Eberhart,3 Eric H. Raabe3. 1Department of Oncology, Johns Hopkins Univ. School of Medicine, Baltimore, MD; 2Department of Pathology, Johns Hopkins Univ. School of Medicine, Baltimore, MD.

Glioblastoma (GBM) and diffuse intrinsic pontine glioma (DIPG) are highly infiltrative, incurable adult and pediatric brain tumors characterized by the presence of tumor stem-like cells. Although GBM and DIPG have different epigenetic drivers, we found increased expression of an epigenetic modifier and stem cell factor HMGA2 in both tumors by immunohistochemistry and western blotting. HMGA2 is a DNA-binding protein that regulates transcription during normal embryogenesis and in cancer stem cells. We hypothesized that HMGA2 contributes to high grade glioma tumorigenicity through its ability to alter the transcription of many genes. Lentiviral short hairpin RNA (shRNA)-mediated reduction of HMGA2 in multiple patient-derived GBM cell lines significantly reduced invasion in transwell assay (shHMGA2 vs. shControl, P<0.01). Similarly, shRNA mediated suppression of HMGA2 in DIPG cell lines reduced proliferation (BrDU incorporation), reduced invasion (transwell assay), inhibited clonogenicity (soft agar assay) and increased apoptosis of DIPG neurospheres (P<0.03). Treatment of shHMGA2 vs. shControl P<0.01). Microarray analysis revealed that treatment with shHMGA2 resulted in downregulated transcription of many genes involved in tumor stemness. Furthermore, CDK9 inhibition induced apoptosis in ES as depicted by downregulated XIAP and CFLAR and cleavage of Caspases 8, 9, PARP and increased cleaved caspase 3 (CASP3) activity, similar to JQ1. Combined treatment of ES with BRD and CDK9 inhibitors was more effective than individual drug application. Conclusion: Translocation driven tumors such as ES are very susceptible to combined treatment with epigenetic inhibitors. Here we demonstrate that treatment with inhibitors targeting the p-TFEB complex could interrupt communication between EWS-FLI1, BRD4 and CDK9 further impeding EWS-ETS transcriptional activity and its associated pathognomonic expression program.

#3867 Epigenetic siRNA and chemical screens identify SETD8 inhibition as a therapeutic strategy to reactivate p53 in high-risk neuroblastoma. Veronica Veschi,4 Zhiihue Liu,4 Ty C. Voss,4 Laurent Ozben,4 Berkley Gryder,4 Chunhua Yan,4 Ying Hu,4 Anqi Ma,5 Jian Jin,5 Sharyl J. Mazur,5 Norris Lam,5 Barbara K. Souza,5 Giuseppe Giannini,5 Gordon L. Hager,5 Cheryl H. Arrowmith,6 Javed Khan,2 Ettore Appella1, Carol Thiele1. 1National Institutes of Health, Bethesda, MD; 2Icahn School of Medicine at Mount Sinai, New York, NY; 3University la Sapienza, Rome, Italy; 4University of Toronto, Toronto, Ontario, Canada.

Neuroblastoma (NB) is considered a failure of sympathoadrenal differentiation. High-risk neuroblastoma (HR-NB) is an aggressive pediatric tumor accounting for 15% of all pediatric oncology deaths. Less than 50% of HR-NB patients have long-term survival, despite intense multimodality treatment. Given the paucity of drugable mutations and findings that epigenetic drivers contribute to NB tumorigenesis, we undertook a chromatin-focused siRNA screen to uncover epigenetic regulators critical for survival of high-risk NBs. Of the 400 genes analyzed, high-content Opera imaging identified 53 genes whose loss of expression led to significant decreases in NB cell number with 16 also inducing differentiation. A screen with 21 epigenetic compounds in 8 NB cell lines and 2 non-transformed cell lines prioritized those siRNA hits with active tool compounds in the drug development pipeline. This revealed UNC0379 (targets SETD8) inhibited NB cell growth and identified SETD8 as an important and drugable NB target. SETD8 is the H4K20me1 methyltransferase which regulates DNA replication, chromsome condensation and gene expression. Analysis of primary NB revealed that high expression of SETD8 is associated with poor prognosis in NB (R2 platform ex. Kocak: p = 1.4e-07). Levels of SETD8 were not significantly different between Stage 4 MYCN-amp compared to MYCN-WT tumors but high SETD8 levels were only associated with poor prognosis in the Stage 4 MYCN-WT (p=0.03). To understand SETD8-mechanism of action, we performed RNA-seq transcriptome analyses after genetic or pharmacological inhibition of SETD8. Ingenuity Pathway Analysis revealed that SETD8 ablation rescued p53 pro-apoptotic and cell-cycle arrest functions by activating the canonical p53 pathway. Functional studies showed SETD8 methylates p53 (K382) leading to its inactivation. Levels of p53K382m1 are higher in MYCN-WT NB cell lines compared to those with MYCN-amp. Less than 2% of NB samples have p53 mutations but multiple mechanisms have been identified in MYCN-amp NB that functionally inactivate p53. This study identified that SETD8 inactivates p53 in NB and may be an important mechanism to inactivate p53 in MYCN-WT HR-NB. This subgroup represents 60-70% of HR-NB tumors. SETD8 inhibition led to increases in caspase-dependent cell death only in p53-WT but not -mutant or -null NB cells. Gene expression experiments confirmed that SETD8-induced cell death is p53 dependent and p53K382 is important for this activity. Our in vivo xenograft NB models, showed that genetic or pharmacologic (UNC0379) inhibition of SETD8 confers a significant survival advantage. This work identifies that SETD8 is a novel therapeutic target and its inhibition may be especially relevant for the subset of high-risk NB tumors with wildtype MYCN. This is the first in vivo preclinical study showing that targeting SETD8 inhibits tumor growth.

#3868 The stem cell factor LIN28B regulates proliferation and apoptosis in diffuse intrinsic pontine glioma. Huizi Guo,1 Sepehr Akhtarkhavari,1 Charles G. Eberhart,1 Harpreet Kaur,1 Eric H. Raabe1. 1Department of Oncology, Johns Hopkins University, Baltimore, MD; 2Department of Pathology, Johns Hopkins University, Baltimore, MD.

Diffuse Intrinsic Pontine Glioma (DIPG) is an incurable, invasive and aggressive pediatric brain tumor. Identifying molecular markers that regulate tumor growth and invasion are needed for developing efficient treatment strategies. LIN28B is a stem cell factor expressed during normal fetal development and re-expressed in cancer cells. We had previously shown that LIN28A, another...
family member of LIN28 proteins, regulates invasion and tumorigenicity in adult high grade gliomas. We observed increased LIN28B expression in patient-derived DIPG neurosphere cell lines using western blotting. We hypothesized that LIN28B promotes proliferation and prevents apoptosis in DIPG. Using two different lentiviral transduced short hairpin RNAs (shRNA), we suppressed LIN28B protein levels in DIPG neuropheres, as confirmed by western blotting. DIPG neuropheres that have been treated with LIN28B shRNA showed reduced proliferation as measured by BrdU incorporation (P<0.01) and increased apoptosis as measured by cleaved caspase-3 (CC-3) expression (P<0.01). To determine the molecular mechanism of LIN28B-mediated phenotypes in DIPG, we studied the canonical downstream effector of LIN28B called HMG2A, which is a DNA-binding protein that functions as a transcriptional regulator. Using western blotting, we found decreased HMG2A protein levels in DIPG neuropheres infected with LIN28B shRNA. Taken together, our results suggest that LIN28B is important for promoting DIPG cell proliferation and preventing apoptotic cell death. Additionally, we also found that LIN28B regulates HMG2A expression in DIPG neuropheres. Future studies will focus on expanding our understanding of the molecular mechanisms of LIN28B-regulated malignancy in DIPG.

Modeling the chromatin and transcriptional landscape of MYC and MYCN driven neuroblastoma in zebrafish. Mark W. Zimmerman,1 Shuning He,2 Shizhen Zhu,3 Song Yang,4 Yi Zhou,4 Leonard I. Zon,4 A Thomas Look,5 Dana-Farber Cancer Institute, Boston, MA; 4Mayo Clinic, Rochester, MN; 7Boston Children’s Hospital, Boston, MA.

Elevated expression levels of MYC family genes are frequently observed in human cancer cells and correlate with tumor aggressiveness and poor prognosis. In neuroblastoma 40% of all cases are high-risk, of which 20% harbor amplification of the MYCN proto-oncogene. In high-risk cases lacking MYCN gene amplification, high expression levels of c-MYC (MYC) are often present and are associated with unfavorable histology and a poor survival. Unlike MYCN amplification, which is frequently observed in the presence of segmental chromosomal aberrations, MYC overexpression is not associated with genetic abnormalities or somatic mutations. In order to study this newly defined subgroup, we have created a novel transgenic zebrafish model in which overexpression of MYC alone in the peripheral sympathetic nervous system (PNS) drives early onset neuroblastoma in nearly every fish by seven weeks of age. The tumors resulting from MYC overexpression arise in the interrenal gland, which is the fish counterpart of the adrenal medulla, and are histologically identical to human neuroblastoma. We next performed the Assay for Transposase Accessible Chromatin (ATAC) sequencing and RNA-seq to identify open chromatin regions that correlate with activation of gene transcription. Lineage specific genes essential for neuronal precursor cell identity, such as PHOX2B, HAND2, and TFAP2A are highly expressed in both MYC-expressing and MYCN-amplified human neuroblastoma cell lines and are actively transcribed in zebrafish models of MYC- and MYCN driven neuroblastoma. Furthermore, these studies reveal shared and differential regulatory effects of MYC relative to MYCN activity in maintaining the malignant phenotype of neuroblastoma in vivo. Additional insight into the mechanisms of aberrant transcriptional regulation will inform the future design and use of therapeutic strategies targeting transcription in this high-risk malignancy of childhood.

Clonal evolution of medulloblastoma BTICs in response to therapy. David Bakhshiyani, Thuythanh Vijayakumar, Chitra Venugopal, Mohini Singh, Maleeha Qazi, Sujeivan Mahendran, Sujeivan Mahendran, Bravanlan Manoranjan, Nicole McFarlane, Ashley Adile, Sheila Singh. McMaster University, Hamilton, Ontario, Canada.

Medulloblastoma (MB) is the most common malignant pediatric brain tumor. Global gene expression arrays performed on human MBs have divided this tumor entity into 4 distinct molecular subgroups. Out of all the subgroups, Group 3 patients face the highest incidence of leptomeningeal spread and overall patient survival of less than 50%. Current clinical trials for recurrent MB patients based on genomic profiles of primary, treatment-naive tumours, provide limited clinical benefit since recurrent metastatic MBs are highly genetically divergent from their primary tumors. By adapting the existing COG (Children’s Oncology Group) Protocol for children with newly diagnosed high-risk MB for treatment of immuno-deficient mice intracranially engrafted with human MB brain tumor initiating cells (BTICs), we aim to identify and characterize the rare treatment-resistant refractory cell population in Group 3 MBs. MB cell populations recovered separately from brains and spines at (i) engraftment; (ii) post-radiation; (iii) post-radiation and chemotherapy; and (iv) recurrence, during the course of tumor development and therapy were comprehensively profiled for gene expression analysis, stem cell and molecular features to generate a global, comparative profile of MB cells through therapy to relapse. One of the most intriguing observations from our gene expression data was consistent over-expression of proteins belonging to inhibitor of DNA-binding/differentiation (ID) family, transcription factors with a basic helix-loop-helix motif that act as suppressors of cellular differentiation and a longevity associated protein bacterial/permeability-increasing fold-containing-family-B-member-4 (BPIFB4) in our refractory population. The persistent upregulation of genes preserving undifferentiated state and cellular longevity further strengthens the hypothesis of stem-cell like cells driving tumor relapse in MB. We then set out to determine whether genes upregulated at relapse correlated with patient outcome in our therapy-adapted patient-derived xenograft model. Interestingly, the upregulation of the top 90 genes in our relapse cohort was predictive of worse overall survival in patients with group 3 MB. In the next set of experiments, through application of cellular barcoding technology we determined how brain MB BTICs evolve in response to therapy by tracking unique vector DNA sequences integrated at a single copy level into individual cells. Our differential genomic profile of the “treatment-responsive” tumors against those that fail therapy will thus contribute to discovery of novel therapeutic approaches for the most aggressive subgroup of MB.
targets. Upregulated genes were related to biological functions like negative regulation of cell growth and transcription, nervous system development. To probe the underlying mechanism, in-silico analysis indicated RA decreased Wnt/β-catenin, eNOS and PTEN pathways while stimulating cAMP, Integrin linked kinase and G-coupled protein pathways. Evaluation of the cAMP pathway (ε-allyl 3-Br-cAMP at 0.5 μM for 24 h) on MLL-R G3 and SOCS5 mRNA expression in ALL-SIL cells showed a 2-fold increase in SOCS5 mRNA. In primary NB tumors, microarray studies indicate that low levels of CNR1 and DUSP6 are associated with poor prognosis. RA stimulates 10-fold and 2-fold increases in CNR1 and DUSP6 levels, respectively. RA treatment inhibits EZH2 binding to its target genes thereby activating pathways involved in reprogramming of HR-NBs to a more differentiated state. Studies are underway to further evaluate the molecular mechanism leading to decreased EZH2 binding upon RA treatment.

#3873 Novel non-genetic mechanisms drive rhabdomyosarcoma tumorigenesis. Justin McEvoy,1 Michael Dyer,7 Xiang Chen,6 University of Arizona, Tucson, AZ; 2St. Jude Children’s Research Hospital, Memphis, TN.

Most pediatric solid tumors originate from perturbations during development, however the mechanisms that drive these disruptions and promote tumor progression are still poorly understood. We believe that epigenetic deregulation of cancer genes and developmental pathways is a common driver in pediatric cancers, especially those with a low mutation rate. To test this novel idea, we are focusing on rhabdomyosarcoma (RMS), a developing muscle tumor with striking genetic differences between two of the major subtypes. We hypothesize that differential epigenetic deregulation of differentiation programs and cancer genes between the two RMS subtypes are essential for tumorigenesis. Indeed, our preliminary integrative analysis reveal distinct epigenetic landscapes between the two subtypes particularly at the loci of HOX cluster genes A-C, including an oncogenic HOXc long non-coding RNA (IncRNA) called HOTAIR. Knockdown of HOTAIR led to derepression of HOXD10, a candidate tumor suppressor, and a decrease in RMS proliferation, migration, and invasion. Thus, we believe HOX gene deregulation is required for tumorigenesis, and their implication in several adult cancers suggests this currently underappreciated mechanism is likely to be more broadly relevant. In addition, we identified a group of RMS specific novel IncRNAs, of which one demonstrates an essential role in cell survival. Our innovative approach to integrate epigenetic data sets from tumor subtypes with varying genetic differences shed light on the mechanisms that drive tumorigenesis, which may lead to identifying previously unknown potential therapeutic targets. Since current therapeutic options have not changed over the last twenty-five years, these data will especially provide a strong translational impact for children with RMS, whose survival outcomes are less than 20% in the case of metastatic disease.

#3874 Epigenetic deregulation of SOCS expression in T cell lineage lymphoblastic leukemia. Nitish Sharma,1 Huining Kang,2 Christian C. Nickl,7 Scott A. Ness,7 Stuart S. Winter,1 Ksenia Matlawska-Wasowska,1 University of New Mexico Health Sciences Center, Albuquerque, NM; 2University of New Mexico Comprehensive Cancer Center, Albuquerque, NM.

For children, adolescents and young adults with T-lineage acute lymphoblastic leukemia, event free survival following relapse is ~10%. A variety of hematologic malignancies activate JAK-STAT signaling through activating mutations in JAK1-3, IL7R and downregulation of negative regulators, SOCS5 belongs to the suppressor of the cytokine signaling (SOCS) family, which are known cytokine-inducible negative regulators of JAK-STAT and other signaling pathways. SOCS5 is involved in negative regulation of Th2 development. However, the roles of SOCS5 in blood cancer, in particular T-ALL have not been elucidated so far. Using Affymetrix U133 Plus 2.0 microarrays we assessed SOCS5 expression levels in a cohort of 100 T-ALL samples derived from AALL0343 COG study. SOCS5 was deregulated in T-ALL cells, and its expression was lowered in cases harboring MLL gene rearrangements (MLL-R) compared to the remaining cases (P < 0.0001). Because we did not identify any mutations in SOCS5 gene in the cohort of 100 cases, we hypothesized that SOCS5 expression is regulated by aberrant DNA methylation in T-ALL. Using methyl-specific PCR (MS-PCR) and bisulite sequencing we found that SOCS5 expression is regulated by promoter/1st exon CpG island methylation in T-ALL. cCRF-CEM and ALL-SIL cells, and selected primary T-ALL samples showed hypermethylation in promoter/1st exon region corresponding to lower levels of SOCS5 expression. In contrary, KpT1 and PF382 cells, and T-ALL samples with higher levels of SOCS5 had hypomethylated SOCS5 promoter/1st region. SOCS5 transcript and protein expression were induced by DNA demethylating agent, 5-azacitidine in ALL-SIL and cCRF-CEM cells (P < 0.0001). The increase in SOCS5 expression was correlated with its promoter demethylation as shown by MS-PCR. SOCS5 mRNA and protein levels were also increased in ALL-SIL cells transduced with DNMT1 shRNA compared to negative control (P < 0.0001) indicating that inhibition of DNA methyltransferase activity restores SOCS5 expression in T-ALL. To assess whether histone deacetylation is involved in epigenetic regulation of SOCS5 expression, we treated cCRF-CEM and ALL-SIL cells with deacetylase inhibitor Trichostatin A (TSA). Treatment with TSA restored histone marks in SOCS5 promoter and increased SOCS5 mRNA levels in TSA-sensitive ALL-SIL cells compared to TSA-resistant cCRF-CEM cells. We next examined the effects of SOCS5 on leukemogenesis by shRNA-mediated knock down of SOCS5 in KpT1 and PF382 cells. Silencing of SOCS5 increased cellular proliferation as shown by an increase in T-ALL cell number (P < 0.0001). Reduced expression of SOCS5 led to an increase in MYC, IL4, IL4Ra, IL7R expression and STAT6 activation. These results indicate that SOCS5 is epigenetically deregulated in T-ALL. Future studies are required to evaluate the tumor suppressor roles of SOCS5 in a subset of T-ALL, in particular, in MLL-R cases via the regulatory effect on cytokine and growth factor receptor signaling.

#3875 SSX drives gain-of-function BAF complex chromatin affinity and genomic targeting in synovial sarcoma. Matthew J. McBride,7 John L. Pulice,4 Robert T. Nakayama,4 Nazar Mashalilar,1 Davis R. Ingramp,5 Jack F. Shern,5 Javed Khan,7 Jason L. Hornick,7 Alexander J. Lazar,7 Cigall Kadoch1. Dana Farber Cancer Institute and Harvard Medical School, Boston, MA; 2University of Texas MD Anderson Cancer Center, Houston, TX; 3Genetics Branch, National Institutes of Health, Bethesda, MD; 4Brigham and Women’s Hospital, Boston, MA.

Synovial sarcoma (SS) is a soft-tissue malignancy driven by a recurrent chromosomal translocation (t(X;18)) that uniformly produces the SS18-SSX oncogenic fusion product. SS is an example of a subtype of the mammalian SWI/SNF (BAF) complexes, which remodel nucleosomes in an ATP-dependent manner and antagonistically oppose gene-silencing activity of polycomb complexes to maintain transcriptional control throughout development and differentiation. We previously discovered that in SS, incorporation of the oncogenic SS18-SSX fusion into BAF complexes leads to eviction of the tumor-suppressor BAF47 (1N11/SMARCBA1) subunit, and aberrant activation of polycomb target genes by displacement of H3K27me3-mediated repression. However, uncoupling the oncogenic consequences of two co-occurrent BAF complex perturbations, gain of 78- amino acids to SS18 and loss of BAF47 has remained a challenge for the field; understanding gain- versus loss-of-function properties of these molecular events is critical to the identification of effective targeted therapies for this patient population. Here we show that synovial sarcoma primary tumors and cell lines harbor a transcriptional signature markedly distinct from sarcomas such as malignant rhabdoid tumors, which are driven solely by biallelic loss of BAF47. Indeed, we show that SS18-SSX-containing BAF complexes exhibit distinct chromatin localization in that suppression of SS18-SSX results in a near complete genome-wide re-targeting of BAF complexes. We find that SS18-SSX directs BAF complexes to polycomb-repressed sites to activate embryonic development and neuronal gene pathways hallmark to SS primary tumors. Strikingly, using biochemical affinity assays, we demonstrate that the SSX 78aa tail dramatically increases the affinity of BAF complexes for chromatin as well as their genomic footprint sizes upon ChIP-seq analyses. This is in stark contrast to the demonstrated decrease in chromatin affinity and genomic occupancy resulting from loss of function of BAF47 in MRT. Moreover, using ChIP-seq analysis of BAF47/CcA9-mediated KO of BAF47 in SS cell lines, we show that the proliferative arrest of SS cell lines upon suppression of SS18-SSX is independent of the BAF47 reassembly into BAF complexes, thereby demonstrating a unique SSX-driven oncogenic mechanism distinct from BAF47 loss. Taken together, these studies uncover a novel functionality of the SSX tail that is required for SS oncogenesis, and inform the selection of appropriate targeted therapeutic agents for this gain-of-function BAF complex-driven cancer.

Background: Cellular heterogeneity within tumors is increasingly recognized as a source of therapeutic failure. However, the cis-regulatory landscapes driving transcriptional states of intra-tumor heterogeneity, drug-resistance and relapse remain elusive. Results: Here, using H3K27Ac chromatin immunoprecipitation followed by sequencing (ChIP-seq) we characterized the active super-enhancer (SE) landscape in neuroblastoma, a pediatric cancer of the sympathetic nervous system. Analysis of differentially active SEs identified cis-regulatory modules associated with distinct transcriptional states in material derived from individual patients. These transcriptional states associated with two phenotypically divergent cellular subtypes. One subtype is referred to as adrenocortical (ADN) and...
expresses classic neuroblastoma markers from the peripheral sympathetic nervous system. In contrast, the other subtype referred to as mesenchymal (MES) has similarity to neural crest cells, expresses mesenchymal genes, is motile and lacks adrenergic markers. In contrast to ADN cells, MES-type cells are resistant to a wide variety of chemotherapeutics used in clinical management of neuroblastoma. Computational reconstruction identified core transcription factor modules associated with ADN- and MES-type cells. DNA binding profiles of adrenergic TFs MAML3 and GATA3 suggest feed-forward activation of the adrenergic SE-associated TFs. Interconversion of FACS-sorted MES- and ADN-type cells is observed in vitro. Induction experiments with the mesenchymal TF PRRX1 efficiently converted ADN-type cells to an induced-MES (iMES) state. These iMES cells acquired many features of MES cells including motility, mesenchymal gene expression and -histone modifications as well as chemo-resistance. Primary neuroblastoma biopsies included a small fraction of PRRX1-positive MES-type cells, as determined by immunohistochemistry. Importantly, the proportion of both cell types appears dynamic upon therapy and in relapse development, suggesting selective pressure of treatment. Conclusions: Here we establish that intra-tumor heterogeneity in neuroblastoma follows a bi-phasic structure characterized by two different SE-associated TF programs that reflects stages of the normal developmental programs. The detailed understanding of core regulatory modules and pathways may redesign strategies for therapeutic intervention.

#3877 Relationship of DNA methylation to mutational changes and transcriptional organization in fusion-positive and fusion-negative rhabdomyosarcoma tumors. Wenye Sun,1 Bishwaresh Chatterjee,1 Jack F. Shern,2 Sivasish Sindiri,1 Yonghong Wang,1 Holly S. Stevenson,1 Daniel C. Edelman,1 Paul S. Meltzer,2 Iaved Khan,2 Frederic G. Burt,2 NCI - Laboratory of Pathology, Bethesda, MD;2 NCI - Pediatric Oncology Branch, Bethesda, MD;2 NCI - Genetics Branch, Bethesda, MD.

Rhabdomyosarcoma (RMS) is the most common soft-tissue sarcoma of childhood and comprises two major subtypes: fusion-positive (FP, most commonly PAX3-FOXO1 [P3F] or PAX7-FOXO1 [P7F] resulting from 2;13 and 1;13 chromosomal translocations) and fusion-negative (FN). Our previous study demonstrated that FP and FN RMS tumors exhibit distinct DNA methylation profiles. To further examine the significance of DNA methylation, we generated genome-wide DNA methylation profiles for a new cohort of 48 RMS tumors for which we previously assessed mutation, copy number and expression status. Investigation of the RMS subsets defined by methylation clustering revealed a significant association between methylation and P3F binding sites in the PAX3/PAX7 intron, and an association of methylation with RAS mutation status in the FN subset. Localization studies of differentially methylated probes showed these probes were not evenly distributed with respect to annotated genomic features. In particular, hypomethylated probes were enriched in FP tumors in the promoter region and in the intergenic region, whereas hypermethylated probes were enriched in these regions in FN tumors. In contrast, hypermethylated probes were enriched in FP tumors in the 3' UTR regions of genes in these regions. In our new larger cohort of cases, there was a significant difference in the distribution of P3F binding sites between genes with and without differential methylation. Integrative analysis of P3F binding sites, promoter methylation and gene expression demonstrated that genes with P3F binding sites tend to be more highly expressed in FP tumors (compared to FN tumors) than genes without P3F binding sites regardless of promoter methylation status. Though promoter hypomethylation is most highly associated with enhanced expression among genes with P3F binding sites, the group of genes with P3F binding sites and promoter hypomethylation is small in number compared to the much larger group of genes with P3F binding sites but without promoter hypomethylation. In conclusion, these results demonstrate the interaction of these epigenetic changes with mutational alterations and transcriptional organization in RMS tumors and provide a direction for future studies of these epigenetic events.

TUMOR BIOLOGY: Targeting Cancer Stem Cells

#3878 Musashi-2 (MS12) regulation of ERBB family proteins in non-small cell lung cancer (NSCLC). Alexander Kudinov,1 Alexander Deneka,1 Anna N. Nikonova,1 Emmanuelle Nicolas,1 Vladislav A. Korobeynikov,2 Ilya G. Serebriskii,1 John Karanicolas,1 Erica A. Golemis,1 Yanis Boumber1, Fox Chase Cancer Center, Philadelphia, PA;2 Columbia University, New York, NY.

The purpose of this study is to establish whether a new signaling axis we recently described can be targeted to improve patient survival in lung cancer, one of the leading causes of death worldwide, with over 1.6 million deaths annually. Non-small cell lung cancer (NSCLC) is the most common form of lung cancer. A small number of targeted therapies have been shown to be useful in advanced metastatic NSCLC, particularly those targeting the EGFR pathway, but these drugs are active in only a subset of tumors that maintain epithelial characteristics. Musashi-2 (MS12), a RNA-binding protein that regulates mRNA translation, has been linked to maintenance of a stem cell state in multiple hematologic and solid tumor malignancies. We recently established (Kudinov et al, PNAS 2016, PMID:27274057) that MS12 is elevated in a subset of NSCLC tumors upon progression and drives NSCLC invasion and metastasis. MS12 overexpression is probably driven by claudin signaling cascade that enhances epithelial-mesenchymal transition (EMT). Using reverse phase protein array (RPPA) analysis of MS12-depleted versus control KrasG12D/P53R172H murine NSCLC cell line models identified a significant 2.7-fold upregulation of HER3 upon MS12 depletion. Negative MS12-dependent regulation of ERBB3 protein expression was confirmed in multiple additional murine and human KRAS-dependent NSCLC models, based on analysis of MS12 depletion or overexpression. In contrast, MS12 positively regulated expression of the EGFR/ERBB1 protein in the same models. In detailed analysis, we have addressed the mechanism by which MS12 regulates expression of the ERBB group of receptor tyrosine kinases. In addition, these data suggested the hypothesis that MS12 expression might predict response to EGFR-targeted agents, as MS12 inhibition may be synergistic with currently approved agents for NSCLC and may be therapeutically valuable. We will present data on the activity of EGFR inhibitors in the context of depleted or elevated MS12 expression, and the effect of combining inhibition of EGFR with recently developed MS12 inhibitors. In summary, these results for the first time indicate a role of MS12 in supporting EGFR expression in NSCLC and suggest that MS12 may drive NSCLC development and progression in part via EGFR, and may modulate response to EGFR-targeted agents.

#3879 Expression of sox2 and oct4 in human oral squamous cell carcinoma and its relationship with clinical factors. Tetsuya Matsumato,1 Natsumi Takamuru,2 Go Ohe,3 Keiko Kudo,4 Takaharu Kudo,4 Akira Takahashi,5 Yoshiko Yamamura,1 Kenji Fujisawa,2 Hirokazu Nagai,2 Youji Miyamoto.1 Institute of Biomedical Sciences, Tokushima Univ Graduate School, Tokushima, Japan.

Background: A cancer stem cell (cancer initiating cell, CSC) is considered capable of self-replication, self-differentiation, drug resistance, and immune evasion. Recently, CSC has become increasingly important in the treatment of malignant tumors. Cancer stem cells express specific molecules termed CSC marker, including sex determining region Y-box2 (SOX2), and octamer-binding transcription factor 4 (Oct4), and their expression has been reported to be the potential prognostic values. However, the prognostic values of SOX2 and Oct4 expression in patients with oral cancer are less understood. [Purpose] The aims of present study were to evaluate the expression of SOX2 and Oct4 in oral squamous cell carcinoma (OSCC) and to elucidate the relationships among the CSC marker expression, clinical stages, histological differentiation, the classification of invasion mode, cerebral lymph node metastasis, distant metastasis, and disease-free survival rate. Materials and Methods: Tissue specimens were obtained from 108 patients with OSCC after surgery or biopsy. Immunohistochemistry was used to assess SOX2 and Oct4 protein using at least 10% staining-positive cells as the definition of positive staining. Results: Immunohistochemical analysis of 108 cases showed that 42 cases (39%) expressed SOX2. There was no significant association between SOX2 expression and tumor size, invasion mode or histological differentiation. However, there was significant association between SOX2 expression and distant metastasis or disease-free survival rate at stage 1 and 2 patients (73 cases). Otherwise, seventy cases (65%) cases of 108 OSCC patients expressed Oct4. There was significant association between Oct4 expression and histological differentiation. There was no significant association between Oct4 expression and tumor size, invasion mode, metastasis, or disease-free survival rate. Conclusions: These findings suggested that the expression of SOX2 may be a good marker indicating survival in patients with OSCC.

Neuroblastoma is a tumor derived from immature neureoblasts predestined to form the sympathetic nervous system. Children with aggressive neuroblastoma are at high-risk of disease relapse despite their initial response to treatment. The molecular mechanisms underlying these relapses are poorly understood, al-
TUMOR BIOLOGY: Targeting Cancer Stem Cells

though clonal expansion and de novo mutations have been suggested as potential mechanisms. An alternative hypothesis is that neuroblastoma initiating capacity and resistance to chemotherapy reside in a subpopulation of tumor initiating cells or cancer stem cells, which are not genetically different from most tumor bulk cells but through unknown mechanisms differ phenotypically and functionally. Here we examine aldehyde dehydrogenase (ALDH) expression and activity in neuroblastoma patient-derived xenograft (PDX) cells, cultured under stem cell-promoting conditions, as a potential marker for neuroblastoma stem cells. We found that neuroblastoma PDX cells in general expressed higher levels of various ALDH isoforms as compared to an aggressive classical serum-grown neuroblastoma cell line. Also, a distinct subgroup with high ALDH activity in vitro more metastatically than cells with low ALDH activity. In conclusion, our results suggest that ALDH activity is associated with an immature phenotype, which is of clinical importance since less differentiated tumors are more aggressive and associated with poor prognosis. Also, cells with high ALDH activity showed higher in vivo tumor initiating capacity. We are currently pursuing a more extensive characterization of neuroblastoma cells with high ALDH activity.

#3881 The expression of CD98hc might be a marker of radiation resistance in HNSCC. Yohse Kawasaki, Yasufumi Omori. Akita University, Akita, Japan.

Introduction: Head and Neck squamous cell carcinoma(HNSCC) represents an aggressive malignancy. Although new advanced therapeutic strategies have been applied to date, the 5-year survival rate has not been considerably improved. Generally speaking, high radio-sensitive HNSCC has good prognosis, however, there are radio-resistant HNSCC. Recently, Same et al, have reported CD98 is one of the markers of Cancer Stem Cell. Moreover, the over expression of CD98hc is high associated with different cancers including the colon cancer, renal cancer. CD98 is heterodimeric protein that comprises a heavy chain and a light chain. The CD98 heavy chain is type 2 linkage to one of 6 amino acid transporters. We hypothesize that irradiation may contribute to overexpression of CD98hc and expansion Cancer Stem Cell population in HNSCC. Methods: Cells culture: Ho-1-u-1(Mouth floor), Sa3(Gingiva), HSC2, HSC3,HSC4(tongue) were used for this experiment. These cell lines were exposed to 60 Gy (2Gy/day) to establish stable cell lines to radiation. Flow cytometry: For analysis of CD98-positive fraction, cell pellets were incubated with FITC-conjugated anti-human CD98hc mAb at the dilution of 1:11 at 4° for 15min.

Sphere formation assay: Cells were cultured in a serum-free medium. 1x10⁴ cells that irradiation may contribute to overexpression of CD98hc and expansion Cancer Stem Cell population in HNSCC. cancer stem cell-like properties and EMT in liver cells. DCLK1 appears to enhance active β-catenin levels and its cellular localization to the nucleus. Thus, the DCLK1 represents an important target for HCC therapy.

#3885 Establishment, characterization and drug response of primary and metastatic prostate organoids. Sofia Karkampouna, 1 Federico la Manna, 1 Eugenio Zoni, 1 Liikle Beimers, 2 Peter Kloen, 1 Antoine Wetterwald, 1 Iod Grojean, 1 Irena Klima, 1 Marco Giovanni Cecchini, 1 Martin Spahn, 4 George Nikolias Thalmann, 4 Marianna Kruthof-de Julio, 4 University of Bern, Bern, Switzerland; 2 Slotervaart Medical Centre, Amsterdam, Netherlands; 3 Academic Medical Centre, Amsterdam, Netherlands; 4 University of Bern, Inselspital, Bern, Switzerland.

Introduction & objectives: Prostate cancer (PCa)-associated mortality results from metastasis to bone and resistance to androgen deprivation or cytotoxic therapy. Despite early detection of primary PCa, advanced castration resistant prostate cancer (CRPC) and bone metastases (BM) are detected in 10% of patients already at the time of initial diagnosis. The majority of recurrences might be due to cancer cells with stem cell-like properties (cancer stem cell-like, CSC-like). These could be therapy-resistant in a dormant state at the primary site or have metastasize prior to diagnosis of the primary tumor. CSC-like cells are the most tumorigenic and metastatic, however, current treatments target the differentiated tumor bulk cells. Understanding the mechanisms of PCa tumor initiation and metastasis by CSC-like cells is crucial for proper prognosis of high risk patient groups. Materials & methods: To model CSC-like cells we generated organoids from patient-derived tissues (here termed as ‘canceroids’) and established patient-derived xenografts (PDXs). Canceroids were derived from bulk tumor tissues; primary PCa, bone metastasis from PCa tissue (BM-PCa), established PDX models LAPC9 and BM18 and lymph node (LN) metastasis from PCa (LAPC4) PDX models. Cytotoxic compounds and androgen inhibitors are tested on the canceroids from different BM or LN tissues using viability assays (CellTiter Glo assay) and 3D imaging by confocal and light sheet microscopy. Results: We have generated several canceroid lines from human primary PCa and from established PDX models that maintain key features of the CSC-like cells, previously characterized on the tumor itself (AR, PSA, Cytokeratins). The luminal phenotype of BM18 is evidently maintained in the BM18 canceroids, based on positive cytokeratin (CK)18 and absent CK5 expression. LAPC4 organoids contain CK5 and CK18 cells, in line with the mixed basal and luminal phenotype. Imaging of PSA and cytokeratin distribution confirms the luminal phenotype of the canceroids. BM18 and LAPC9 canceroids are maintained both in presence and absence of dihydrotestosterone indicating that androgen independent growth properties of the tumors are conserved in the canceroids. Viability assays indicate that canceroids respond to chemotherapeutics (cabacitaxel, docetaxel) and partially to androgeninhibitors, indicating that androgen-independent growth properties of the tumors are conserved in the canceroids. Viability assays indicate that canceroids respond to chemotherapeutics (cabacitaxel, docetaxel) and partially to hormone inhibitors (abiraterone, enzalutamide). Conclusions: Identification of the oncogenic properties of metastatic CSC-like (sub)populations has both prognostic and therapeutic applications. Establishment of CSC-derived organoids is the first step towards routine derivation from metastasis or primary PCa tissues as a potential platform for personalized drug compound evaluation.

#3887 GNA13 is a theranostic target that drives drug resistance and cancer stem-like phenotypes in solid tumors. Suhail Ahmed Kabeer Rasheed,1 Hui Sun Leong,2 Manikandan Lakshmanan,2 Anandikumar Raja,2 Dhivya Dadalani,1 Fui-Teen Chong,2 Ravisan K Rajarethinam,2 Thakshayeni Skanthakumar,2 Ern Yu Tan,4 Jacqueline Siok Gek Hwang,5 Kok Hing Lim,2 Daniel Shao-Weng Tan,2 Paolo Ceppi,6 Mei Wang,7 Vinay Tergaonkar,8 Patrick J. Casey,1 N. Gopalakrishna Iyer,1 Duke-NUS Medical School, Singapore, Singapore; National Cancer Centre, Singapore, Singapore; Institute of Molecular and Cell Biology, Singapore, Singapore; Tan Tock Seng Hospital, Singapore, Singapore; Singapore General Hospital, Singapore, Singapore; Friedman-Alexander-Universitats-Erlangen-Nuernberg, Germany, Germany.

Treatment failure in solid tumors occurs due to the survival of specific sub-populations of cells that possess stem cell-like (CSC) phenotypes. Studies have implicated G protein-coupled-receptors (GPCRs) in cancer progression and the acquisition of aggressive phenotypes. Many of the implicated GPCRs signal through the G12 subfamily, comprised of GNA12 and GNA13. In this study, we demonstrate that GNA13 is upregulated in many solid tumors and impacts survival and metastases in these patients. Consistent with this, we show that GNA13 expression modulates drug resistance through its effect on the CSC sub-population in a panel of patient-derived head and neck (HNSCC) and breast cancer cells. These data were validated in vivo, where GNA13 over-expression in patient-derived xenografts increased tumor initiating capacity, tumorigenicity and drug resistance, with no effect on growth or proliferation. Signaling through NFkB and MAPK pathways appear to be critical to the observed phenotype. Importantly, blockade of GNA13 expression, or select downstream pathways using small-molecule inhibitors, abrogates GNA13-induced CSCs, rendering cells vulnerable to standard-of-care cytotoxic therapy for these cancers. Taken together, these data indicate that GNA13 expression is a potential prognostic biomarker, and interfering with GNA13-induced signaling provides a novel strategy to block CSCs and drug resistance in solid tumors.

#3888 DCLK1 is part of an EMT feedback loop and promotes colorectal cancer cell invasion and drug resistance. Dongfeng Qu,1 Nathaniel Weygant,1 William L. Berry,1 Randel May,1 Parthasarathy Chandrakasan,1 James J. Tomasek,1 Sripathi M. Sureban,1 Courtney Houchen,1 Yang Ge,1 Jiannan Yao,2 Guangyu An,2 Edwin Bannerman-Menson3. 1 Univ. of Oklahoma Health Sciences Ctr., Oklahoma City, OK; 2 Beijing Chao-Yang Hospital, Beijing, China; 3 COARE Biotechnology Inc., Oklahoma City, OK.

Colorectal cancer (CRC) is the third leading cause of cancer death in the U.S., with only a 6% 5-yr survival rate for stage IV disease. Its spread and acquisition of resistance to chemotherapy, which are fueled by the epithelial–mesenchymal transition (EMT) process and supported by tumor stem cells (TSCs), are major challenges to improving patient outcomes. New therapies that target stemness and EMT are desperately needed to prevent or delay metastasis and improve patient survival. Recently doublecortin-like kinase 1 (DCLK1) has been definitively proven to mark TSCs in CRC by two independent groups. Previous studies have demonstrated that DCLK1 is a prognostic factor in CRC and that targeted downregulation or inhibition of DCLK1 results in decreased CRC proliferation, migration, invasion, and other anti-oncogenic effects. However, the effect of overexpression of DCLK1 and its kinase active mutant on CRC has not been assessed. In this study, we investigate the correlative role of EMT and DCLK1 expression in CRC progress. Human colon cancer cells (HCT116) were infected with Lentivirus containing wild type DCLK1 or mutant DCLK1R326C cDNA sequences to overexpress DCLK1. DCLK1R326C or green fluorescence protein (GFP) cDNA sequence as control. The expressing levels of DCLK1 and EMT factors were analyzed by western blotting. The proliferative and invasive potential of these cells were compared using a MTT assay for proliferation, wound healing assay for migration, and Matrigel coated transwell assay for invasion. Knockdown of either ZEB1 or DCLK1 by specific siRNA in HCT116 cells was
performed. The effects of siDCLK1 on 5-FU were performed in both HCT116 and SW480 cells using a Caspase 3/7 activity assay. Analysis of human CRC was performed using TCGA COADREAD dataset. Here we report that compared to GFP control cells, HCT116-DCLK1 and HCT116-DCLK1R326C cells exhibited a more than 20% increase in proliferation, approximately 30% increase in migration, and a 2-fold increase (p < 0.05) in invasion. DCLK1 expression level is decreased more than 30% by knocking down ZEB1 in HCT116 cells. In addition, knockdown DCLK1 increased 5-FU induced cell apoptosis more than 50% (P < 0.05). Evidence from TCGA COADREAD demonstrated that EMT predicts survival in CRC patients, and increased expression level of DCLK1 in CRC patients correlate to EMT and mesenchymal phenotype. These data suggest that DCLK1 is a part of the EMT feedback-loop and may be exploited with DCLK1-targeted therapeutics for CRC.

#3889 Novel drug candidates cepi430 and cepi507 for targeting pancreatic patient-derived xenograft cancer stem cell and circulating tumor cell models. Michael Sharma,1 Maulik Jain,1 Cristian Sharma,1 Karina Amezgua,1 Natalee Amezgua,1 Reed Hasson,1 Miriam Navel,1 Donna Stanton,1 Satya Narayan,2 Karl Kramberger,1 Rubio Punzalan,1 Jitesh Jani,1 Douglas Foster,1 Jay P. Sharma,1 Colpogen, Inc., Torrance, CA; 2RSS Medical School, Dominican, Dominica; University of Florida, Florida, FL

Pancreatic cancer is the fourth leading cause of cancer mortality in the US, despite significant improvements in diagnostic imaging and operative mortality rates. The 5-year survival rate remains less than 6% because of microscopic or gross metastatic disease at time of diagnosis. Although the treatment of pancreatic cancer remains a challenge, it is entering a new era with development of new strategies and trial designs. Because there is an increasing number of novel therapeutic agents and potential combinations available to test in patients with pancreatic cancer and in their PDX models, the identification of robust prognostic and predictive markers for Cancer Stem Cells (CSC) PDX and Circulating Tumor Cells (CTC) PDX and of new targets and relevant pathways is a top priority as well as the design of adequate trials incorporating molecular-driven hypothesis. Here, we examined the efficacy of combined treatments of CEP1430 and CEP1507 in human pancreatic patient-derived xenograft (PDX) cancer cells, and pancreatic PDX CSCs models from the same donors. CEP1430 inhibited the growth of CSCs and CEP1507 inhibited growth of CTCs, while gemcitabine suppressed the viability of non-CSCs [70%] (differentiated tumor Cells). Consistently, in vivo studies showed that CEP1507 when combined with gemcitabine could eliminate the grafting of human pancreatic cancer CTCs [85%] (n = 5, p = 0.001) and CEP1430 with gemcitabine selectively inhibited [80%] CSCs (n = 5, p = 0.001), more effectively than the individual agents. These data indicated that administration of CEP1430, which targets CSCs and CEP1507 targets CTCs, may constitute a potential therapeutic strategy for improving the efficacy of gemcitabine to eradicate advanced pancreatic cancer. This study has indicated the potential molecular targets for pancreatic targets to eradicate the tumor – and metastasis-initiating cells (CTCs) and their progenies and development of new effective combination therapies against locally advanced and metastatic pancreatic cancer. Using PDX models, we confirmed the effectiveness and selectivity of the identified treatment responses with TGI at 97% with CEP1430.

#3890 Mitochondrial MCL1 maintains triple negative breast cancer stem cells and contributes to chemotherapy resistance. Kyung-min Lee, Jennifer Giltname, Justin Balko, Luis Schwarz, Michael Sharma, Cristian Sharma, Karina Amezgua,1 Nadia Annin,1 John P. Sharma,1 Colpogen, Inc., Torrance, CA; 2Russ Medical School, Dominican, Dominica; University of Florida, Florida, FL

Cytotoxic chemotherapy is the standard of care for patients with triple negative breast cancer (TNBC). Most patients with advanced TNBC progress after chemotherapy and die from metastatic disease. MCL1 is an anti-apoptotic Bcl-2 family member known to sequester and inactivate pro-apoptotic Bcl-2 family proteins and, thus, contribute to chemotherapy resistance. We previously reported that ~45% of residual TNBCs that remain in the breast after neoadjuvant chemotherapy harbor MCL1 amplification, suggesting a causal role for MCL1 in drug resistance. A recent report (Goodwin et al. 2015) suggested that siRNA-mediated ablation of MCL1 does not induce apoptosis in low TNBC. In this case a cancer stem cell (CSC) gene expression signature. CSCs comprise a rare population of cells with tumor-initiating properties and refractoriness to chemotherapy. In this study, we showed that MCL1 expression is elevated in claudin-low TNBC SUM159PT and MDA436 CSCs as measured by ALDH1 by flow cytometry and ability to form mammospheres. RNA interference of MCL1 in SUM159PT cells reduced CSCs and attenuated tumor formation in vivo. Mitochondrial oxidative phosphorylation (mtOXPHOS) plays a crucial role in maintenance of CSCs. MCL1 has been shown to localize in the mitochondrial matrix and contribute to mitochondrial respiration. Thus, we hypothesized that MCL1 contributes to enrichment of TNBC CSCs and chemotherapy resistance via mitochondrial regulation. Stable transfection and overexpression of MCL1 in MDA468 cells increased oxygen consumption ratio, mitochondrial membrane potential, and production of reactive oxygen species (ROS), all features of activated mtOXPHOS. Conversely, RNAi-mediated ablation of MCL1 in SUM159PT and MDA436 cells repressed these markers of activated mtOXPHOS. A mutant of MCL1 lacking its mitochondrial target sequences (Mts) was unable to localize in mitochondrial matrix and disrupted the CD44hi/CD24mo fraction and mammosphere formation. We next tested U65951B, a BH3 mimetic in development at Vanderbilt that disrupts MCL1 interactions with BH3 domain-containing proteins, such as BID, BIM, NOXA and PUMA. Treatment of SUM159PT cells with U65951B increased caspase activity but did not attenuate mammosphere formation. Analysis of mRNA expression in TCGA revealed that genes induced by mtOXPHOS involved in the hypoxia pathway are significantly up-regulated in MCL1 amplified breast cancers. Finally, pharmacological inhibition of HIF-1α, a key regulator of hypoxia, with digoxin decreased CSCs and attenuated tumor formation in vivo. These data suggest that 1) MCL1 confers resistance to chemotherapy by expanding CSCs via mtOXPHOS independent of its BH3 domain-mediated, anti-apoptotic function, and 2) targeting mitochondrial respiration and the hypoxia pathway may delay or reverse chemotherapy resistance in MCL1 amplified TNBC.

#3891 Chemoresistant cancer stem cells undergo gene changes that drive tumor recurrence. Prithy C. Martins,1 Atiya Dudley,1 Melissa A. Laramore,1 Hunter L. Gazda,1 Michael P. Markey,2 Barry H. Smith,1 Lawrence S. Gazda1.

1The Rogosin Institute, Xenia, OH; 2Wright State University, Dayton, OH; 3The Rogosin Institute, New York, NY

Despite the efficacy of chemotherapy, resistant cells are thought to contribute to tumor recurrence. In vitro models of recurrence must mimic the complexity and heterogeneity of in vivo tumors and provide the longevity needed to capture tumor dormancy following chemotherapy. We have previously described a 3D in vitro model that simulates in vivo tumors containing cancer stem cell niches. Encapsulation of murine renal adenocarcinoma (RENA) cells in a double layer of agarose that form spherical macrobeads allows for the development of 3D tumor colonies comprised of tumor-initiating and tumor-amplifying cells within the inner agarose matrix. In the current study, we used the RENCA macrobead in combination with chemotherapy to evaluate genetic regulation that allows tumor dormancy and drives recurrence. RENCA macrobeads treated with docetaxel (5 μg/ml) undergo a significant loss of cell mass and a period of latency followed by tumor recurrence. RNA isolated from docetaxel-resistant cells (Wk 6 post-treatment), recurrent tumors (Wk 20 post-treatment) and paired vehicle controls were characterized using whole-transcriptome profiling (GeneChip® WT Pico Kit with Transcriptome Analysis Console, Affymetrix). At Wk 6 post-treatment, genes associated with a stem cell phenotype (Car12, Arrib1, Nos2, Alldh112) and members of the ABCG1 family associated with multidrug resistance were enriched in docetaxel-resistant cells. Genes regulating the canonical Wnt signaling pathway, specifically LRPs, family members, were significantly upregulated. Pathway analysis revealed dysregulated focal adhesion, PI3K-Akt-mTOR-signaling, including genes modulating integrin adhesion (Itgα5, Itgα7), ECM receptor interaction ( Lama5, Lamb2, Lamc1) and actin cytoskeletal remodeling (Vcl). Supporting the quiescent nature of the docetaxel-resistant population, genes implicated in DNA replication (Dbf4, Cdc6, Mcm5), transcriptional (Id1, Id2, Grh21), protein synthesis (Rpl39) and protein metabolism (Rpl7a) were significantly down regulated. At Wk 20 post-treatment, up regulation of matrix metalloproteinasises (Mmp13) and partial retention of stem cell (Nos2, Car12) and drug resistant (Abcb1) genes supports the evolution of regenerated tumors to a metastatic phenotype. Genes involved in fatty acid β-oxidation (Acds, Lipf), oxidative phosphorylation (Ndu, Nd6) and the electron transport chain (Cox2) were down regulated in concert with up regulation of Me2 suggesting reduced flux through the TCA cycle and use of aerobic glycolysis in rapidly growing cells. This study further supports the RENCA macrobead as a model system to evaluate the biology of chemotherapy-resistant cells and tumor recurrence in a 3D microenvironment. These data are in line with the notion that chemotherapy-resistant cells exhibit a period of quiescence with a stem cell-like gene profile and experience an intrinsic transformation towards an invasive phenotype that drives tumor recurrence.

#3892 Delineating the role of ZEB1 loss in the chemotherapeutic and radioresistance of glioma stem cells. Mecca Madany,1 Lincoln Edwards,2 John S. Yu,1 Cedars-Sinai, Los Angeles, CA; 2Cornell, Ithaca, NY

The most prevalent brain cancer, Glioblastoma Multiforme (GBM) has an average survival of less than 2 years. Despite advances in therapy there is still an overall poor response to treatment which has been attributed to glioma stem cells (GSCs), a subset of tumor cells that are able to self-renew, inhibit differentiation and are often chemo and radioresistant. The genetics and mechanisms underlying how glioma stem cells are able to repopulate tumors and affect patient survival desperately need...
to be defined. We are interested in delineating the role that ZEB1 (zinc finger e-box binding homebox-1) loss has on GSCs and what role this loss plays in the chemo and radioresistance of GSCs. Most insights into ZEB1 regard it as tumorigenic and an initiator of EMT (epithelial mesenchymal transition). Surprisingly, in this study, we have shown that in TCGA datasets ZEB1 deletion frequently occurs and this loss actually results in higher survival in ovarian patients that can take targeted therapeutic regimens. Immunohistochemistry on patient samples shows that ZEB1 loss occurs both at the gene and protein level. Stable ZEB1 knockdown in our patient derived glioma stem cell lines results in increased proliferation and a resistance to differentiation. Following chemotherapy as well as radiotherapy, knockdown cell lines show increased cell viability as well as higher levels of secondary neurosphere formation. Decreased apoptosis and changes in cell cycle as well as the DNA damage response pathways were also observed in the knockdown lines following chemo and radiotherapy. Overall, this data indicates that loss of ZEB1 in GSC's results in enhanced resistance to standard therapy. With these results, we have reason to believe that ZEB1 may be used as a novel therapeutic target to combat the chemo and radioresistance of glioma stem cells.

#3894 A positive feedback loop prevents differentiation of endocrine resistant luminal progenitor breast cancer cells. Brendan Fironch,1 Sara Charmaz,2 Eamon Breen, Arnold Hill, Leonie Young.1 Royal College of Surgeons in Ireland, Dublin 2, Ireland; 2Trinity College Dublin, Dublin 8, Ireland. 

Introduction: Treatment of breast cancer patients has advanced greatly with the stratification of ER+/HER2+ and triple negative cohorts. ER+/breast cancer is the most commonly diagnosed mammary malignancy and is managed with anti-hormone therapies. Therapy resistant disease emerges in approximately one in three women. Within the ER+ cohort, breast cancer remains a heterogeneous disease, particularly at the cellular level. For example; ER+/breast cancer can range from <10% to >90% ER+/cells within a tumor. This study set out to define and target differences in cellular heterogeneity between endocrine sensitive and resistant ER+/breast cancer. Methods: A flow cytometry based cell surface protein (CSP) screen (37 proteins) identified changes in cellular heterogeneity between endocrine sensitive and resistant ER+ models. FACS isolation and single cell plating characterized the self-renewal and differentiation potential of the identified sub-populations. Conditioned media experiments assayed secretory activity of the endocrine resistant phenotype. Results: The CSP screen identified FUT4+/MUC1- cells as central to the endocrine resistant phenotype. The endocrine sensitive model (MCF7) was found to contain roughly equal proportions of FUT4+/MUC1- (31.2 ± 1.6 %), FUT4-MUC1- (38.5 ± 7.1 %) and FUT4-MUC1+ (23.0 ± 6.9 %) cells. While two independent models of resistance were found to be dominated by FUT4+MUC1+ cells (LY2: 86.0 ± 5.5 %; TMR: 80.6 ± 6.5 %). Conventional theory suggests that these resistant FUT4+/MUC1- cells are the apex cancer stem cells (CSCs). To test this hypothesis, single cell clonogenicity assays were carried out on FUT4+MUC1- cells isolated from the endocrine sensitive model. It was found that these FUT4+/MUC1- cells were not apex CSCs, but rather mid-tier progenitor cells, as they could not produce all the cell types of the sensitive model. Paired conditioned media and clonogenicity studies demonstrated that the resistant secretome is sufficient to trap FUT4+MUC1- cells isolated from the sensitive model in a self-renewing, stem-like state (termed the MUC1- stem cell). Moreover, resistant cells which were removed from treatment conditions for >8 weeks maintained the resistant FUT4+MUC1- phenotype. These data indicate co-operation between cell- and treatment-driven mechanisms creating a FUT4+MUC1- resistant phenotype. Conclusions: Chronic tamoxifen therapy drives heterogeneity towards a FUT4+/MUC1- phenotype. Single cell self-renewal and differentiation studies identify this cell type as a mid-tier progenitor cell rather than an apex cancer stem cell. A positive feedback loop supplements the treatment induced change, to maintain the resistant phenotype in the absence of further tamoxifen treatment. Targeting this feedback loop or its downstream effectors may allow for re-sensitization of endocrine resistant disease.

#3895 Verrucarin J targets both cancer cells and cancer stem cells. Kelsey Carter,1 Seema Parte,2 Surinder K. Batra,3 Mariusz Z. Ratajczak,2 Sham S. Kakar.2 1University of Louisville, Louisville, KY; 2Univ. of Louisville, Louisville, KY; 3Univ. of Nebraska, Omaha, NE.

Ovarian cancer is the fifth leading cause of death among women in the United States. The American Cancer Society estimates that approximately 22,280 women in the United States will be diagnosed with ovarian cancer and approximately 14,240 women will die as a result of ovarian cancer in 2016. The most common treatment for ovarian cancer is cytoreductive surgery, followed by chemotherapy (combination of carboplatin and paclitaxel). Although this regimen is initially effective in a high percentage of cases, unfortunately, within few months of initial treatment, tumor relapse occurs because of platinum-resistance. The presence of cancer stem cells (CSCs) are the main cause of this phenomenon. CSCs are a small population (2-5%) of cells in solid cancer which are chemo-resistant, highly tumorigenic, possess a self-renewal capacity, and the capability to differentiate into multiple lineage. Therefore, there is an urgent, unmet need for a more effective therapy that targets cancer cells as well as cancer stem cells. Therefore, targeting Verrucarin J, a metabolite of the Myrothecium fungus family, has not been tested for its antitumor activity. In our experiments, we treated two cisplatin-sensitive ovarian cancer cell lines (A2780 and OVCARS) and one cisplatin-resistant cell line (A2780/CP70) with various concentrations of Verrucarin J. After treatment of cells, Verrucarin J showed: i) a highly significant inhibition of colony formation in a dose- and time-dependent manner, with an IC50 value of approximately 10 nM after 48 h of treatment for all the three cell lines, ii) a significant increase in cell apoptosis, iii) a significant increase in DNA damage and generation of reactive oxygen species (ROS) compared to vehicle treated cells, iv) a significant down regulation of expression of cancer stem cells markers, and v) a significant inhibition of Notch1, Wnt1 and Shh signaling genes in a dose-dependent manner. Notch1, Wnt1 and Shh are major regulatory pathways for self-renewal and maintenance of cancer stem cells. Additionally, our experiments revealed that Verrucarin J inhibited the tumorogenic function (spheroid formation on ultra-low attachment plates) of isolated ALDH1 positive CSCs from ovarian cancer cell line A2780. Based on our results, we conclude that Verrucarin J is a highly potent anticancer drug and targets both cancer cells and cancer stem cells. Therefore, it may serve as a potential candidate for ovarian cancer treatment and currently used chemo-therapy.

#3896 Exosomes derived from CD133+ hepatocellular carcinoma (HCC) cell promote the acquisition of stem cell-like properties of the targeted HCC cell via the Akt/GSK3β/Snail and cyclin D1 pathways. Pengyu Guo,1 Haitao Yu,2 Xiaohai Xie,1 Yi Wang,2 Gang Chen.1 The First Affiliated Hospital of Wenzhou Medical University; Wenzhou Medical University, Wenzhou, China; Wenzhou, China.

Backgrounds and Aims: Liver cancer stem cells are closely related to the recurrence and metastasis of hepatocellular carcinoma (HCC). However, the mechanism underlying the reciprocity between liver cancer stem cells and HCC cells in the tumor microenvironment remains unclear. Exosomes act as natural shuttles to deliver bioactive molecules that alter the behavior of the recipient cells, offering a new means of cell-cell communication for physiological and pathological processes in the liver. This study aimed to clarify whether the exosomes derived from the liver stem cells could facilitate the acquisition of stem cell-like properties of the adjacent HCC cells, thereby promoting the malignant process of HCC. Methods: CD133+ liver cancer stem cells were isolated from the highly invasive HCC-LM3 cells or tumor tissues of HCC patients using flow cytometry and were identified using qPCR and immunofluorescence. The exosomes from CD133+ liver cancer stem cells were identified using CD133 and other stem cell markers, and they were then used to treat HepG2 and Hep3B cells. The cell viability, invasion ability, sphere formation, and expression abilities in vitro and tumorigenesis in vivo. In additional, we found that CD133+ exosomes activated the P38/Akt/GSK3β/Snail and cyclin D1 pathway, thereby reducing the expression of E-Cadherin and promoting the epithelial-mesenchymal transition (EMT) of HCC cells. Conclusions: Our results suggest that exosomes derived from CD133+ HCC cells can change the malignant behavior and promote the acquisition of stem cell-like properties of targeted HCC cells via the Akt/GSK3β/Snail and cyclin D1 pathways.

#3897 Novel inhibitor of GBM stem cells targets unique CREB & Myc-mediated self-renewal pathways regulated by CDK5. Subhas Mukherjee, Carol Tucker-Burden, Changming Zhang, Jun Kong, Monica Chau, Renee Read, Daniel J. Brat. Emory University School of Medicine, Atlanta, GA.

Cancer stem cells exert enormous influence on neoplastic behavior, in part by governing asymmetric cell division and the balance between self-renewal and multifactorial differentiation. Growth is favored by deregulated stem cell division, which enhances the self-renewing population & diminishes the differentiation program. To uncover mechanisms relevant to deregulated cell division in human glioma stem cells, we first developed a novel adult Drosophilia brain tumor.
TUMOR BIOLOGY: Targeting Cancer Stem Cells

model, 100% enriched with tumor stem cells. Using this model, we performed a suppressor screen for kinases and found brain-specific dCDK5 partially reverses the tumor phenotype. dCDK5 and its human ortholog CDK5 (79% identity) are atypical protein kinases because they do not regulate cell cycle in normal cells, but are crucial for neurogenesis & survival of mature neurons. Interestingly, many cell survival/activation of these CDK5BPs in glioblastomas leading to uncontrolled proliferation. Our analysis of TCGA data shows that IDH wt GBM has significantly high level of CD5K compared to the IDH wt lower grade glioma. Additionally, we found a strong positive correlation between CDK5 & several stem cell markers in GBM. To date, not much is known about the role of CDK5 in glioblastoma GBM & glioma stem cell self-renewal. Using patient-derived (GBM) neurosphere cultures & in vivo xenograft tumors in mice, we further demonstrated that a novel pharmaceutical suppressor of CDK5 signaling axis can suppress self-renewal properties through a new CDK5 phosphorylation site on CREB and Myc. Together, our results show that the CDK5 signaling pathway is important for glioma stem cell survival & that suppressing CDK5 could be a novel therapeutic approach to eliminate glioma stem cells.

Emerging role of Fra-1 as a novel target for radiosensitization in HPV-associated cancers. Abhishek Tyagi,1 Shilpi Gupta,1 Prabhat Kuamr,1 Alok C. Bharti,2 Bhudev C. Das1. 1Amity University Uttar Pradesh, Noida, India; 2University of Delhi, Delhi, Delhi, India.

Background: Activator protein-1 (AP-1) plays a central role in HPV-mediated cervical and tongue cancer (subset of HNSCC). AP-1, a homo/heterodimeric protein composed of Jun and Fos family proteins, has been implicated in chemoradioresistance but the mechanism(s) remained unexplored. In the present study, AP-1 family protein Fra-1 has been shown to play a critical role in promoting radiosensitization in enriched cervical cancer stem-like cells (CaCxSLCs) and can serve as a target for drug intervention in cervical and other HPV-associated cancers. Experimental Procedure: Cervical cancer stem-like cells (CaCxSLCs) were isolated and enriched by sequential gating HPV-ve and HPV-ve human cervical cancer cell lines, SiHa, and C33a using a set of functional and phenotypic markers (ABC2, CD49f, CD71, CD133) in defined conditioned media (DCM) with intermittent culturing. CaCxSLCs were also assessed for their ciliacversus foramorphing ability, exclusion of DCV dye for generating SP cells, self-renewal ability and quiescence. Both CaCxSLCs and Non CaCxSLCs were exposed to different dose of UV irradiation and a herbal compound curcumin, a potent inhibitor of AP-1 was used to examine the role of AP-1 and its family proteins in the radiosensitization of cancer stem cells. Results: Upon UV irradiation, CaCxSLCs showed a dose-dependent higher proliferation and highly increased AP-1 activity whereas it was completely abolished in non-stem cancer cells. CaCxSLCs also showed differential overexpression of c-Fox and c-Jun at transcriptional and protein level. The loss of AP-1 activity & expression was accompanied by decrease in cell viability and proliferation in UV irradiated non-stem cancer cells. Interestingly, CaCxSLCs treated with curcumin prior to UV irradiation ablated AP-1 activity and a concomitant reduction in SP cells leading to abrogation of stage formable ability, loss of proliferative ability, induction of apoptosis and the cells were poorly tumorigenic. The c-Fox and c-Jun protein level with GL treatment had no effect on CD133+/CD44+ or CD44+/CD24+ populations in PC3 cells, which don’t express pSTAT3. Of note, both CD133+/CD44+ and CD44+/CD24+ cells responded to treatment with GL, as proliferation decreased in a dose-dependent manner. Treatment with GL significantly reduced the ability of CSCs to form colonies in a concentration-dependent manner. Conclusion: This study suggests that the role of AP-1 protein in the manifestation of radioresistance but curcumin pretreatment helps in radiosensitizing CaCxSLCs through upregulation of Fra-1 which may serve as a potential target for elimination of radioresistant cancer stem cells in HPV-associated malignancies.

Synthetic small molecule targeting CD24/CD44/ALDH1+ cell population inhibits cancer stem cell activities in breast cancer. Luxi Chen, Chao Long, Kha A. Tran, Jiyong Lee. University of Texas at Dallas, Richardson, TX.

Purpose of the study: Cancer stem cells (CSCs) have been described as the “seed of tumor”, and have been suggested as the driving force of tumor relapses. In this study we aimed to isolate small molecules via screening of the combinatorial chemical library. The isolated molecules bind CD24/CD44+/ALDH1+ breast cancer cell subpopulations with high selectivity and specificity. Experimental design and plan: Through the unbiased cell based chemical library screening, we identified compound candidates that specifically bind the stem-like cancer cell subpopulations in breast cancer cells and tissues. By performing in vitro, tissue and in vivo-based assessments on ligand-binding specificity and functional activities, we ensured that the isolated ligands target tumorigenic stem-like breast cell or tissue preferentially. Summary of discoveries and findings: The in vitro compound binding validations proved the specificity of the isolated compound candidates toward breast cancer cells and tissues displaying cancer stem cell properties. The compound-targeting cell populations display significantly-higher expressions of the well-known stem cell markers than the unbound cell populations. On the other hand, a series of biological and biochemical functional assays also confirmed the compound candidates exert tumor-suppression activities on breast cancer cell lines, such as slow down proliferation and reduce cell viability. More importantly, our study demonstrated that both isolated compounds have preferential selectivity and higher binding affinity to the TNBC cells and tissues, which have been reported for higher percentage of stem-like cancer cell population detected than in non-TNBC cells or tissues. Through mouse xenograft study followed by histological analysis, we further confirmed the binding specificity of the compound towards cell line models could be retained in vivo in mouse xenograft model. Conclusion: We demonstrated our ligand screening technique is able to identify synthetic compounds targeting cell subgroups or sub-populations of defined interest within one particular type of tumor. High specificity of the isolated molecules could be utilized to develop chemical probes for quantification of percentage of CSC in the tumor, which facilitates clinical evaluation of tumor relapse risk. The screening strategy also provides a new methodology in discovering novel drug targeting CSC subpopulations, not only in breast tumor, but also other types of human cancers. Funding: This project is supported by the Cancer Prevention and Research Institute of Texas (CPRIT) grant, award ID: RP150713.

STAT3 inhibition with Galiellalactone effectively targets the prostate cancer stem-like cell population. Giacomo Canesin,1 Anne T. Collins,2 Rebeca Hellsten,1 Norman J. Maitland,2 Anders Bjartell1. 1Lund University, Malmo, Sweden; 2University of York, York, United Kingdom.

Introduction and objectives Cancer stem-like cells (CSCs) represent a small subpopulation of largely quiescent cells that reside within tumors. Several studies have demonstrated that this small population is more resistant to current therapies and is therefore directly responsible for tumor recurrence. The transcription factor STAT3 has been recently related to the regulation of the stem cell niche in prostate cancer (PCa), and inhibition of activated STAT3 (pSTAT3) seems to be a valid strategy to selectively target PCa CSCs. We have previously shown that pSTAT3 blockade by Galiellalactone (GL) not only reduces proliferation and induces apoptosis of prostate cancer cells in vitro, but also inhibits the growth of prostate tumors and the metastatic spread to regional and distal lymph nodes in vivo. Here we performed experiments aimed at studying the effect of the inhibitor GL on PCA CSCs, in order to increase our understanding on this compound as a promising therapeutic approach for prostate cancer patients. Materials and methods The expression of stem, basal and luminal cell surface markers (CD133+/CD44+/CD24-) was analyzed by FACS on DU145 and PC3 cells treated with GL. DU145 cells were sorted based on expression of the above markers and then plated for further analysis, including expression of pSTAT3 by IHC and cell proliferation by the WST1 assay. The effect of GL on clonogenic recovery of PCa CSCs was studied by colony formation with sorted cells. Results Our results show that the CSC populations (CD133+/CD44+/CD24-) express high levels of activated pSTAT3 compared to the CD44+/CD24- cell population. Treatment with GL decreased the number of CSCs in DU145 cells after 48h, whilst the number of CD44+/CD24+ cells was less affected. Importantly, GL had no effect on CD133+/CD44- or CD44+/CD24- populations in PC3 cells, which don’t express pSTAT3. Of note, both CD133+/CD44+ and CD44+/CD24+ cells responded to treatment with GL, as proliferation decreased in a dose-dependent manner. Treatment with GL significantly reduced the ability of CSCs to form colonies in a concentration-dependent manner. Conclusion This study demonstrates that the STAT3 inhibitor Galiellalactone can specifically target the prostate cancer stem-like cell population in vitro, implying that pSTAT3 inhibition by GL could represent a valid therapeutic strategy to antagonize CSCs in human prostate cancer. Future experiments will be aimed at validating these data and relating the clonogenic inhibition to the effects of pSTAT3 blockade by GL on tumor initiation by prostate cancer stem-like cells in vivo.
oncogenic functions. The role of CtBP in APC mutant neoplasia remains obscure even though APC is responsible for degradation of both α-catenin and CtBP in suppressing colorectal tumorigenesis. Our prior work demonstrates that CtBP proteins can be effectively therapeutically targeted with substrate analogues of their intrinsic dehydrogenase domains. We now observe that pharmacologic inhibition of CtBP using either the 1st generation inhibitor 2-keto-4-methylthiobutyrate (MTOB) or the 2nd generation inhibitor hydroxymyoino-3-phenylpropanoic acid (HIPP) significantly reduces the burden of intestinal polyps in the Apcmin mouse model of the human cancer predisposition syndrome Familial Adenomatous Polyposis. The number of intestinal polyps in mice with CtBP2 inhibitors were significantly lower (21 polyps/mouse for MTOB, 15 polyps/mouse for HIPP) as compared with vehicle treated mice (45 polyps/mouse) with a P value < 0.0001. Pointing to the anti-neoplastic mechanism of MTOB and HIPP, polyps that did grow in MTOB or HIPP treated mice demonstrated robust downregulation of β catenin and Cbp2 proteins. This observation points to the role of Ctbp2 as a putative driver oncogene that can be therapeutically targeted in vivo. In addition, CtBP2 has been reported to play an important role in human colon cancer stem cells via its interaction with the transcription factor TCF4 on chromatin. We now show that inhibiting CtBP with HIPP or HIPP analogues attenuates CtBP2 protein levels in colon cancer stem cells with resultant decreased expression of CtBP transcriptional target genes, such as the motility/invasion regulator TIM1, and c-MYC, a known driver of the cancer stem cell phenotype. Moreover, colonospheres treated with CtBP inhibitor showed downregulation of the CSC markers CD133 and c-MYC, as compared with vehicle treatment. Flow cytometry analysis of intestinal epithelium from Apcmin mice treated with CtBP inhibitor vs. vehicle indicated a significant reduction in CD133+/CXCR4+ cells that are associated with a tumor initiating cell phenotype. Our data demonstrate that CtBP inhibition may reduce colon neoplasia via downregulation of c-MYC and the cancer stem cell/tumor initiating cell compartment, and that CtBP is promising and novel target for therapy in colon cancer.

**#3902 Interleukin-6 blockade, a novel cancer stem cell targeted therapy, attenuates lung cancer tissue invasion.** Hiroiuki Ogawa, Michiyo Koyanagi-Aoi, Yoshisama Maniwa, Takashi Aoi. Kobe University, Kobe City, Japan.

Background: Lung cancer stem cells are considered to be responsible for lung cancer progression and metastasis. However, little is known about how they actually promote aggressive behaviors of lung cancer. Methods: We transduced OCT3/4, SOX2, and KLFL4 (hereafter, OSK) into a KRAS-mutated (G12S) human lung adenocarcinoma cell line (A549) using retrovirus vector. Organoids were formed from the A549 and CT1 cells using a 3D semi-defined media. Organoids were treated with IL-6 blockade (200ng/ml XMD8-92) or vehicle and treated for 2 weeks. Organoid cell number was measured by ImageJ analysis. Results: IL-6 blockade inhibited the growth of OSK-A549-Colony cells. Although IL-6 blockade did not inhibit the growth of OSK-A549-Colony cells in normoxic conditions, the blockade enhanced growth of the colony in hypoxic conditions (0.2%O2). The expression of marker genes such as CD44 and CD133 were downregulated in hypoxic conditions. Conclusion: Our data suggest that IL-6 blockade may inhibit lung cancer stem cell by targeting hypoxic CSCs.

**#3903 Targeting oral cancer stem cells in the hypoxic niche by BCG infected mesenchymal stem cells.** Bidisha Pal,1 Seema Bhuyan,2 Jaishee Garghyan,1 Hong Li,1 Rashmi Bhuyan,1 Herman Yeger,1 Bukil Das1. 1The Forsyth Institute, Cambridge, MA; 2KaviKrishna Laboratory, Indian Institute of Technology (IIT), Guwahati, India; 3Hospital for Sick Children, Toronto, Ontario, Canada.

Background: Tumor hypoxia is a major contributing factor in cancer therapeutics. The microenvironment of hypoxia/oxidative stress may program cancer cells to highly tumorigenic, metastatic, angiogenic and stem cell-like state. We have characterized in vitro and in vivo models of hypoxia-induced cancer cell reprogramming to cancer stem cell (CSCs) like cells including an immunocompetent model of oral cancer. These CSCs exhibit ABCG2 cell surface marker. Numerous approaches including targeted therapy using oncolytic virus and bacteria have been attempted to target cancer cells in their hypoxic niche without major therapeutic success. Major therapeutic challenges include the inaccessibility of hypoxic niche by therapy-agents and the poor replication of viruses or bacteria intracellular to hypoxic cancer cells. Furthermore, the immune privileged niche of tumor hypoxia leads to viral/bacterial-induced immunity against the tumor. In this context, here we have tested a novel stem cell based approach to deliver BCG infected stem cells to the hypoxic core of tumors. Methods: Human SCC-25 cell line-derived xenograft in NOD/SCID mice exhibit hypoxic zones, where ABCG2+ resides (1). SCC-25 tumor-bearing mice were injected i.v with CD271+ bone marrow mesenchymal stem cells (BM-MSCs). We recently found that CD271+ BM-MSCs could be infected with M. tuberculosis. The BCG infected CD271+ BM-MSCs were injected to SCC-25 xenograft-bearing mice. The mice were sacrificed on day-20 of stem cell injection and then evaluated for the hypoxic CSCs. Next, we have developed a 4-NQO induced oral cancer cell line, which was injected orthotropically to the tongue of congenic mice. The mice developed tumors, which was treated with BCG. In these BCG-treated mice, BCG-infected murine CD271 BM-MSCs were injected i.v., and animals were monitored for four weeks for tumor growth. On day-20 of injection, mice were sacrificed, and the tumors were collected. In a control group, BCG alone was injected. Results: In both the SCC-25 and an immunocompetent mouse model, we found that BCG or CD271+ BM-MSCs injection alone did not result in marked anti-tumor activity and or elimination of ABCG2+ cells from their hypoxic niche. In contrast, the injection of BCG infected CD271+ BM-MSCs led to marked reduction of tumor growth. Importantly, we observed marked replication of BCG intracellular to CSCs. These results indicate that CD271+ BM-MSCs facilitated the transfer of BCG to cancer cells residing in the hypoxic zone. Importantly, the transfer of BCG was seen more in the immunocompetent model, suggesting potential role of immune system. Conclusions: Our findings indicate that hypoxic CSCs may be targeted by a BCG infected CD271 BM-MSCs. We propose this could be a novel therapeutic approach to target drug resistance cancer stem cells residing in the hypoxic niche of tumors.1 Bhuyan R et al, Cancer Research, 2016; Volume 76, Issue 14 Supplement, pp. 935.

**#3904 Inhibition of the ERK5 pathway as a novel approach to target human chronic myeloid leukemia stem cells.** Ignazia Tusa,1 Giulia Cheledoni,1 Na-ver Campoy,1 Paola Dello Sbarba,2 Elisabetta Rovida1. 1Universita di Firenze, Firenze, Italy; 2Dana Farber Cancer Institute, Harvard Medical School, Boston, MA; 3Hematology Unit, AOU Careggi, Firenze, Italy.

Tyrosine kinase inhibitors (TKI) targeting BCR/ABL are very effective for the treatment of Chronic Myeloid Leukaemia (CML). However, resistance mechanisms or their inefficacy on CML leukaemia stem cells (LSC) may lead to relapse. Therefore, there is urgent need to identify new molecular targets. The Extracellular signal-Regulated Kinase 5 (ERK5) is a Mitogen-Activated Protein Kinase that is maintained in severe hypoxia. In K562 and KCL22 cells and in primary cells non-selective normoxic secondary cultures (LC2), to measure LC2 repopulation as a read-out of progenitor/stem cell potential (CRA assay). Compounds: XM8-92 (ERK5 inhibitor) and BIX02189 (MEK3 inhibitor); imatinib (BCR/ ABL inhibitor, IM). We previously showed that stem cell potential of CML LSC is maintained in severe hypoxia. In K562 and KCL22 cells and in primary cells derived from 9 CML patients, the treatment in hypoxic LC1 with XM8-92 or BIX02189, but not with IM, impaired progenitor/stem cell potential. The same results were obtained by combined treatment of XM8-92 with IM. Importantly, XM8-92 did not affect progenitor/stem cell potential of CD34+ cells from healthy donors. In colony formation ability assays ERK5 inhibition decreased colony formation by human primary CML cells to a higher extent than that by normal human CD34+ hematopoetic cells. Interestingly, in hypoxia, combined treatment XM8-92/IM decreased the expression of genes relevant for stem cell maintenance such as p21, nanog and c-myc and the expression of CD26, a CML LSC marker. Moreover, combined XM8-92/IM maintained low the expression...
of p27, another gene involved in stem cell maintenance, that is increased by either drug when administered alone. This indicates that the ERK5 pathway inhibitors impaired LSC maintenance of CML cell lines and primary CML cells.

#3905 Development of anticancer aptamers targeting cancer stem cells. Yuh-Ling Chen, I-Shan Hsieh, Keng-Fu Hsu, Tse-Ming Hong. National Cheng Kung University, Tainan, Taiwan.

Background: Cancer stem cells (CSCs), also called tumor initiating cells (TIC), are a small population of cancer cells within a tumor that drive the tumor initiation, metastasis, and resistance to chemotherapeutic drugs. An effective cancer stem cell targeting strategy by oligonucleotide-based approaches such as aptamers in diagnosis and treatment are urgently needed. In this study, we aimed to develop an effective aptamer-based biomarker for CSCs in cancer detection and therapy. Material and methods: E-cad/herin-null lung cancer cells, shEcad-AS49, was confirmed with stemness properties and used as targeting cells. The isolation of DNA aptamers binding to CSCs was by using a Cell-SELEX (systematic evolution of ligands by exponential enrichment). By combining the aptamer-pull-down approach with proteomics, we identified the potential binding proteins of CSC-aptamer. Flow cytometry, gene silencing and lung cancer xenograft models were used to explore the functions of CSC-aptamer and its targeted protein in lung cancer formation. Results: The aptamer AP-9R was identified to bind lung CSCs with high affinity and specificity. AP-9R reduced lung cancer cell stemness and migration but no apparent cytotoxicity. By using proteomic approaches, the target protein of AP-9R in non-small cell lung cancer was further identified, which characterized its immunosuppressive function. For cell detection, we developed AP-9R conjugated beads and confirmed their effective captured rate of lung CSCs in vitro. Moreover, administration of AP-9R significantly reduced lung tumor growth in the xenograft model. Conclusions: Our data are moving closer to understand the significance of cancer stem cells during cancer progression and demonstrate that aptamer-based therapies will be useful as therapeutic and diagnostic agents for lung cancer.

Acute myeloid leukemia (AML) is a lethal blood cancer. Clinical evidence has highlighted the critical role for leukemic stem cells (LSCs) in the high relapse rate of AML patients. Understanding the signaling pathways critical for LSC function will facilitate the development of new therapies to target LSCs. G protein-coupled receptors (GPCRs) are the most successful drug targets with approximately 36% of currently marketed drugs targeting human GPCRs (Rask-Andersen et al., Nat Rev Drug Discov 2011). Aberrant expression of GPCRs has been observed in various cancers and the importance of GPCRs in cancer stem cells has begun to be appreciated. In this study, we tested gene expression profiling analysis identified a novel GPCR (hereafter named NG), which was suppressed in LSCs compared to normal hematopoietic stem cells. Overexpression of NG in pre-LSCs severely impaired leukemia initiation and progression in mice, whereas knockdown of NG significantly accelerated the disease onset. Our data also showed that NG overexpression substantially downregulated several well-known Wnt/β-catenin targets (e.g., Tcf7l2, c-Fos and Ccnd1). This data support a tumor suppressive role for NG in inhibiting leukemogenesis via downregulation of Wnt/β-catenin signaling. Consistent with these observations, treatment with an agonist that specifically activates the NG signaling pathway induced a marked decrease in cell viability and growth in murine LSCs and in human AML THP-1 cells, but had no effects on human AML MOLM-13 cells. This agrees with our finding that NG specifically targets the Wnt/β-catenin signaling, and the inhibitory effect of the agonist might largely depend on β-catenin expression levels in human AML cells, wherein THP-1 has been reported to express endogenous β-catenin but MOLM-13 exhibits no detectable β-catenin expression (Man CH. et al. Blood 2015). In summary, our data support a tumor suppressor role for NG in leukemogenesis and the forced expression of NG may provide a means to eradicate LSCs. Thus, restoring NG by the agonist treatment represents a promising therapeutic strategy for AML treatment of NG may provide a means to eradicate LSCs. Thus, restoring NG by the
viation of CCL2 was observed in bone marrow–derived stromal cells of FBXW7-deficient mice. 3. Administration of SK-818 blocked the enhancement of lung metastasis in FBXW7-deficient mice. 4. In human breast cancer patients, low FBXW7 mRNA expression in peripheral blood showed high concentration of CCL2 in serum & poor prognosis. Conclusions: We found that the FBXW7/ NOTCH2 pathway plays a key role in the metastasis of breast cancer cells through the formation of premetastatic niches, & that SK-818 inhibit cancer metastasis in mice. SK-818 is currently administered clinically for the treatment of patients with hepatitis B virus infection in Japan. Based on these findings, we have been conducting Phase I clinical trial to assess the safety of SK-818 for breast cancer patients.

Skeletal metastasis is the most life-threatening complication in prostate cancer. The molecular mechanisms behind the interactions between prostate cancer and the bone marrow premetastatic niche remain unknown. Understanding and preventing such interactions could lead to new promising therapeutic strategies against lethal prostate cancer. Annexin 2 receptor (ANXA2R) was originally identified as a cell surface receptor for Annexin 2 (ANXA2) that mediates the stimulatory effects of ANXA2 during osteoclastic activation and osteoblast mineralization. Moreover, ANXA2R is able to induce apoptosis independent of its ligand, partially through activating caspases using non-conventional apoptotic pathways. Osteoblasts and marrow endothelial cells express ANXA2 which functions as a regulator of hematopoietic stem cell engrafment. Previous studies demonstrated blocking ANXA2 or its receptor prevents prostate cancer cells from establishing bone metastases in mouse models. It has been recently proven that ANXA2R does not bind to ANXA2 directly but to S100A10 present in the complex annexinA2 heterotetramer (AIIt), composed of 2 ANXA2 bound to a S100A10 dimer. Higher levels of ANXA2 and S100A10 are associated with proliferating and invasive cancers and correlate with poor prognosis. However, the loss of ANXA2 expression appears to be specific for prostate cancer. Previous work on prostate cancer has focused solely on ANXA2 as a ligand. In this study, we demonstrate that S100A10 and ANXA2 are co-localized in prostate cancer, and their expression and ANXA2R levels vary with grade in primary tumors as well as within the different metastatic sites. Given prostate cancer cells as well as bone marrow stroma can simultaneously express the ligand and receptor and levels of AIIt decrease with tumor stage in the primary site, we hypothesize that prostate cancer cells require S100A10 and not only ANXA2 to spread to bone and other tissues. ANXA2R could act as a dependence receptor, mediating withdrawal-induced programed cell death in prostate cancer cells in the absence of AIIt. Furthermore, AIIt-ANXA2R interactions between prostate cancer cells and the premetastatic bone marrow niche might play an important role in the development of skeletal metastasis by inducing selective pressures on prostate cancer cells to metastasize to the bone marrow which is abundant of AIIt.

#3910 Analysis of metastatic potential by breast cancer type through a microfluidic blood-brain niche. Christopher Ryan Oliver,1 Megan Altemus,1 Brendan Leung,2 Aki Morikawa,1 Michele Dziubinski,1 Maria Castro,1 Sofai Merajver1. 1Univ. of Michigan, Ann Arbor, MI; 2Dalhousie, Halifax, Nova Scotia, Canada

Metastasis from the primary tumor site to the brain is the most lethal complication from advanced cancer. 15% of breast cancers metastasize in the brain with a median survival of 5-14 months depending on the subtype. Therefore it is critical to identify when a tumor has the clonal potential to metastasize to the brain. Current detection methods and treatment therapies have continued to improve but do not shed light on clonal metastatic potential. Models for characterizing metastatic potential of clonal populations currently used include murine in vivo and simple in vitro systems. Murine models are costly, time intensive, slow to manifest metastasis and are not easy to analyze. On the other hand, in vitro systems are faster and more cost effective but currently do not recapitulate the complexity of the “live” micro-environment. We have developed a microfluidic device that mimics the cellular and physical components of the human blood-brain niche to study the brain metastatic process. The device is composed of two chambers separate by a porous membrane. The top chamber and apical side of the membrane is seeded with human brain endothelial cells and uses flow to mimic shear stress encountered within the vasculature. Cancer cells are introduced into this chamber in which they adhere to and migrate through the endothelium into the bottom chamber. The bottom chamber contains astrocytes suspended in a collagen gel to mimic the brain stroma and provide room for invading cancer cells to colonize and grow. Barrier integrity is monitored using TEER (trans-endothelial electrical resistance), and fluctuates as the tight junctions of the endothelium are compromised by invading cancer cells. This is characterized by IF and tight junction staining. Throughout all time points, from introduction into the flow chamber, adherence to the endothelium, extravasation through the barrier, migration into the stroma, and proliferation the cancer cells can be monitored via both microscopy and TEER. We have applied this microfluidic blood-brain niche model to compare breast-seeking and -avoiding breast cancer subclones from cell lines that show different metastatic potential in the brain. Our data suggests that ANXA2R does not bind to ANXA2 directly but to S100A10 present in the complex annexinA2 heterotetramer (AIIt), composed of 2 ANXA2 bound to a S100A10 dimer. Higher levels of ANXA2 and S100A10 are associated with proliferating and invasive cancers and correlate with poor prognosis. However, the loss of ANXA2 expression appears to be specific for prostate cancer. Previous work on prostate cancer has focused solely on ANXA2 as a ligand. In this study, we demonstrate that S100A10 and ANXA2 are co-localized in prostate cancer, and their expression and ANXA2R levels vary with grade in primary tumors as well as within the different metastatic sites. Given prostate cancer cells as well as bone marrow stroma can simultaneously express the ligand and receptor and levels of AIIt decrease with tumor stage in the primary site, we hypothesize that prostate cancer cells require S100A10 and not only ANXA2 to spread to bone and other tissues. ANXA2R could act as a dependence receptor, mediating withdrawal-induced programed cell death in prostate cancer cells in the absence of AIIt. Furthermore, AIIt-ANXA2R interactions between prostate cancer cells and the premetastatic bone marrow niche might play an important role in the development of skeletal metastasis by inducing selective pressures on prostate cancer cells to metastasize to the bone marrow which is abundant of AIIt.

The platelet derived growth factor (PDGF) pathway is a prime example of tumor-stroma signaling in a number of cancer types. Others have shown that PDGF receptors are expressed in breast fibroblasts and pericytes while PDGF ligands are often expressed in breast cancer cells and tumor-associated endothelium; however, how PDGF signaling mediates breast cancer initiation, progression and metastasis remains unclear. Importantly, our evaluation of publicly available datasets revealed that PDGF expression correlates with breast cancer progression and metastasis. Given that PDGF-B preferentially activates PDGFRβ, we established an in vivo system to investigate this pathway during breast cancer progression. We utilized a mesenchymal-specific promoter to drive Cre recombinase and conditionally activate PDGFRβ by way of the endogenous Pdgfrb promoter (hereafter “PDGFRβ mutant”). A murine mammary tumor cell line which expresses high levels of PDGFB was injected either by tail vein or intracranially to evaluate metastatic seeding and distant tumor growth. Following tail vein injection of tumor cells, we observed 50% incidence of brain metastases in the PDGFRβ mutant mice while no brain lesions were seen in the controls. There was no difference in incidence of lung, liver or bone metastases (other common sites of breast cancer metastasis). Not surprisingly, larger tumors formed in the brains of PDGFRβ mutant mice when cells were injected intracranially. Brains were stained for phospho-PLCγ as a way to confirm activation of PDGFRβ. To our knowledge, this is the first example where genetic manipulation of the stroma leads to an increased incidence of breast brain metastases. Furthermore, this study highlights a role for stromal activation of PDGFRβ in the brain microenvironment and during metastatic progression. For the 20-30% of patients that develop breast cancer brain metastases, the one-year survival rate is sadly less than 20%, and how the brain microenvironment contributes to metastatic seeding and subsequent growth of tumor cells remains poorly understood. To confirm translational relevance, we analyzed a small cohort of matched primary breast tumors and brain metastases for PDGFRβ expression observing strong stromal staining in fibroblasts and pericytes and around cancer lesions in primary tumor tissues and brain metastases from 16 patients. Importantly, high PDGFRβ expression was found in the perivascular space of all associated brain metastases suggesting a functional role in the establishment or growth at this site. Combined, our findings strongly suggest that high primary tumor expression of PDGFB/PDGFRβ might define a subset of breast cancer patients predisposed to brain metastases. These patients may benefit from therapeutic targeting of PDGFR signaling as a means to thwart metastatic seeding in the brain.

#3912 Pancreatic cancer cell interaction with platelets impedes cell cycle progression and increases viability. Andrew C. Cannon, Sushil Kumar, Brad Hall, Rakesh Bhatia, Rakesh Singh, Surinder Batra. University of Nebraska Medical Center, Omaha, NE.

Background: Metastasizing cancer cells rapidly associate with platelets in circulation, but the nature and functional consequences of this interaction have yet to be fully elucidated. Here we investigated the physical interaction of platelets with pancreatic cancer (PC) cells and the contribution of platelet-derived platelet factor 4 (PF4) mediated signaling in PC cells. Methods: Immunohistochemistry (IHC) and western blot analysis were performed to characterize the expression of PF4 receptor, CXCR4, in 42 Whipple samples and 8 PC cell lines, respectively. Physical interaction of human platelets with PC cell lines and its impact on PC cell proliferation in low attachment conditions was analyzed by flow cytometry. Cell viability was assayed by MTT analysis. Immunofluorescence analysis was performed to evaluate PF4 induced autophagy. Results: IHC

TUMOR BIOLOGY: Tumor Cell Dissemination and the Premetastatic Niche
and western blot analysis in Whipple samples showed CXCR3 expression in 86 percent of the pancreatic tumors and on all the tested PC cell lines respectively. Flow cytometry demonstrated that 24 percent of Capan1 cells interacted with platelets. Interestingly, incubation of platelets with cell-cycle-synchronized Capan1 cells under low attachment conditions inhibited the proliferation of PC cells (~20%) compared with that of detached cells (~40%). This effect was abrogated in a pharmacological inhibition of CXCR3 with AMG487. Concurrently, the viability of Capan1 cells grown in low attachment conditions and treated with platelets for 72 hours was greater than that of control and AMG487 with platelets treated groups as assessed by MTT assay. Mechanistic studies suggested that recombiant PF4 augments autophagosome formation as an early event and increases the expression of p21 as a late event. Of note, both p38 and p21 expression are abrogated by concomitant incubation with PF4 and AMG487. Conclusion: Platelets appear to rapidly interact with cancer cells in suspension. Additionally, in a PF4-CXCR3 signaling dependent manner, platelets inhibit cell cycle progression and increase PC cell viability in low attachment conditions. Cumulatively, these data suggest that platelets aid in the metastatic dissemination of pancreatic cancer cells.

#3913 CXCL1 is critical for pre-metastatic niche formation and metastasis in colorectal cancer. Dingzhi Wang,1 Haiyan Sun,2 Raymond N. Dubois1. 1Medical Univ. of South Carolina, Charleston, SC; 2Arizona State University, Tempe, AZ.

Emerging evidence suggests that the primary tumor induces the formation of pre-metastatic niches in certain distant organs. However, the mechanisms underlying the contributions of the primary tumor to pre-metastatic niche formation are not fully understood. Here we demonstrate that colorectal carcinoma cells secrete VEGF-A that stimulates tumor-associated macrophages to produce CXCL1 in the primary tumor. Elevation of CXCL1 in pre-metastatic liver tissue recruits CXCR2-positive myeloid-derived suppressor cells to form a pre-metastatic niche that ultimately promotes liver metastases. Importantly, we found that pre-metastatic liver-infiltrating MDSCs induce tumor cell survival without involvement of innate or adaptive immune responses. Our work reveals a novel mechanism by which the interactions of malignant cells with their stromal counterparts in the primary tumor contribute to the formation of a pre-metastatic niche that favors tumor cell survival, but also provides a rational for development of CXCR2 antagonists to inhibit or prevent metastatic spread of disease. Overall, our study provides the first evidence we know of showing that primary malignant cell-secreted VEGF-A stimulates tumor-associated macrophages to produce CXCL1 in the primary tumor.

#3914 KLJ4-dependent perivascular plasticity enhances pre-metastatic niche formation and metastasis. Meera Murgai, Wei Ju, Matthew Eason, Jessica Kline, Rosandra N. Kaplan. National Cancer Institute, National Institutes of Health, Bethesda, MD.

Metastasis causes most cancer deaths, and new therapies that are based on a deeper understanding of this process are required to improve patient survival. Metastatic tumor cell colonization and growth is facilitated by a pre-metastatic niche microenvironment composed of hematopoietic cells, stromal cells, and extracellular matrix that support tumor survival and growth. Perivascular cells, including vascular smooth muscle cells (vSMCs) and pericytes, are a key cell population involved in new vessel formation critical to primary tumor development. Given the well-described plasticity of perivascular cells, we sought to determine whether perivascular cells regulate tumor cell survival and proliferation at metastatic sites. Using perivascular cell-specific and pericyte-specific lineage tracing models, we demonstrated that perivascular cells lose traditional vSMC/pericyte marker expression in response to tumor-secreted factors, and exhibit increased proliferation, migration and extracellular matrix (ECM) synthesis. Expression of the pluripotency gene KLJ4 is increased and is critical for this phenotypic transition to a less differentiated state characterized by increased proliferation and ECM production. Genetic inactivation of KLJ4 specifically in perivascular cells decreases pre-metastatic perivascular cell proliferation and consequently integrin-fibronectin dependent tumor metastasis. Our data reveal a previously unidentified role for perivascular cells in pre-metastatic niche formation, and suggest that modulation of stromal cell plasticity may provide a novel strategy for limiting metastasis.

#3915 Copper depletion as an approach for metastatic dissemination in Triple Negative Breast Cancer. Divya Ramchandani, Vivek Mittal, Linda Vahdat. Weill Cornell Medical College, New York, NY.

Triple-Negative Breast Cancer (TNBC) occurs in approximately 17-20% of all breast cancer patients, and has an aggressive clinical course even in patients with early-stage disease. Metastasis occurs in 35%-40% of TNBC patients relapsing within 5 years of diagnosis. Targeted therapies do not exist for TNBC. Recently, copper (Cu) has emerged as an essential factor in tumor growth and metastasis supporting the notion that Cu-depletion may serve as an attractive therapeutic strategy. Using historical controls, a promising single arm Phase II trial of Tetrathiomolybdate (TM1) in metastatic breast cancers patients, who were at a high-risk of relapse (Stage 3 and Stage 4 with no evidence of disease BC and Stage 2 if triple-negative), was conducted at Weill Cornell. At a median follow-up of 5.9 years, the progression-free survival for all patients enrolled in this study is 72% and the overall survival is 84%. Importantly, levels of circulating LOXL2 and VEGFR2+ endothelial progenitor cells were decreased with Cu-depletion (Chan et al. 2016). With the knowledge about the efficacy of TM1, it is currently unknown where the effectiveness of Cu-depletion lies, whether it acts at the pre-metastatic site, on circulating tumor cells, or at the primary tumor site. We utilized an immunodeficient in vivo breast cancer model that metastatizes to lungs (MDA231-LM2) in order to evaluate the effect of Cu-depletion in metastasis, where the animals were either TM1-treated or untreated. To identify whether LOXL2 is down-stream of TM1-Cu axis in metastasis suppression, as observed in clinical trials (Chan et al. 2016), we used “LOXL2-depletion, Cu-repletion” strategy. We also examined the global functional changes between TM-treated and untreated groups for various Cu-dependent proteins and angiogenic factors at the pre-metastatic site and primary tumors. We found that TM-treatment in the in vivo model significantly lowered disseminated tumor cell population in animals that were successfully Cu-depleted. Cu-depletion also altered pre-metastatic niche formation. We are currently exploring the effect of Cu-depletion on primary tumor and its surrounding microenvironment that might affect tumor cell shedding, leading to metastasis. In summary, this study holds essential groundwork for the identification of a strong mechanistic arm for TM therapy in the suppression of metastasis/metastatic relapse in TNBC patients. Thus, aiding in the development of additional therapeutic options, which may be particularly useful for a subset of TNBC patients impervious to Cu-depletion with single-agent therapy, or for whom Cu-depletion is insufficient to prevent metastasis, and may also be extended to other metastatic solid tumors that are responsive to Cu-depletion therapy.

#3916 Disease-specific markers can be used for the identification of disseminated tumor cells in the bone marrow of patients with prostate cancer. Emma E. van der Toom, Stephanie A. Glavaris, Michael A. Gorin, James A. Verdone, Kenneth J. Pienta, Heather J. Chalfin. The Johns Hopkins School of Medicine, Baltimore, MD.

Introduction: The detection of microscopic disseminated disease in prostate cancer has largely been attempted with the study of circulating tumor cells (CTCs). Little is known about the character and clinical significance of disseminated tumor cells (DTCs) that have reached the bone marrow (BM) niche, and prior studies has relied on epithelial markers. Yet, it is known that such markers are also expressed on normal erythroid precursor cells in the BM, thus providing an assay for prostate-specific DTC identification. Materials and Methods: BM aspirates from 18 men with localized and 2 men with metastatic prostate cancer were collected at time of RP or clinic visit respectively, and processed with the AccuCyte system (RareCyte, Inc., Seattle, WA). Slides were immunostained with DAPI (nuclear), anti-pan-lymycotin (epithelial), anti-CD45/CD66b/CD11b/CD14/CD34 (white blood cell), and the prostate-specific markers HOXB13 and NKKX3.1 (prostate). DTCs were detected using the CytewiseFisher system. DTCs were required to have positive prostate channel staining and no white blood cell signals. Results: DTCs were present in 89% (16/18) of patients at time of RP, with range 0 to 3592 cells/4mL sample (average 270, median of 39.5). Two patients with metastatic prostate cancer had 52 and 105 DTCs/4mL BM (Table 1). Notably, only 5% of all DTCs were epithelial marker positive (CK+), and only 44% (8/18) of patients had any CK+ DTCs. Conclusions: The RareCyte system is a promising selection-free system for DTCs detection that does not rely on epithelial markers. Here we report on a novel assay to distinguish DTCs from other cells in the bone marrow using the presumed prostate-specific markers HOXB13 and NKKX3.1. Furthermore, we show that the majority of prostate-specific marker positive DTCs did not express the epithelial marker CK. Analysis of the association of DTC count with clinicopathologic variables are ongoing.
#3917 GenoCTC, a liquid biopsy device using microfluidic enrichment for affinity-based isolation of circulating tumor cells. Jiyee Ryu,1 Do Hyung Kim,1 Gyeong-Mi Kim,2 Jin Soo Kim,2 Youngkee Shin,1 Jaeuk Lee,1 Hun Seok Lee.1 GenoBio. Corp, Seoul, Republic of Korea;2 Seoul National University Boramae Medical Center, Seoul, Republic of Korea;3 Research Institute of Pharmaceutical Science, Seoul National University, Seoul, Republic of Korea.

To achieve a complete remission of cancer is still challenging that most patients with solid cancer ultimately experience metastasis. Detection of circulating tumor cells (CTCs) from the peripheral blood is promising key to solve the cancer cell dissemination and make accurate diagnosis, therefore, many efforts have been made to isolate the CTCs. Here, we newly developed the liquid biopsy device, GenoCTC, with microfluidic chips isolating CTCs from the patient whole blood. To isolate CTCs, EpCAM+ CTCs in the whole blood are first bound with magnetic beads conjugated with human-EpCAM antibody, and GenoCTC and its chip can isolate the EpCAM+ CTCs through magnetic based method. With 7.5 ml whole blood from lung cancer patient, we isolated EpCAM+ CTCs, and these CTCs were validated by immunofluorescence assay using anti-EpCAM and anti-CD45. We also enumerated EpCAM+ CTCs in 17 whole blood samples from 10 lung cancer patients that various number, 2 to 114, of CTCs were found from each patient. The number of CTCs is known to have a correlation with disease progression and chemo-resistance, so the clinical meaning of this result is needed to be investigated. Furthermore, some CTCs are also found to be EpCAM independent which is regarded to have clinical utility involved in EMT. We used plastin-3 as its marker, and it was confirmed with HS 578T breast cancer cell line which shows low expression of EpCAM but high expression of plastin-3. The various molecules expressed on CTCs can be isolated and expanded reliably in 3D organoid culture from as few as 10 CTCs/mL. Separation and processing of the buoyant coat enriched for the number of viable CTCs isolated. EpCAM positive CTCs were isolated from 6/6 blood samples from patients with advanced PDAC. Updated results will be presented. Conclusions: The current size-based filtration system allows for collection of viable CTCs from human PDAC blood samples. Current work will use this system to grow, expand and characterize human PDAC CTCs in organoid culture. Genetic, transcriptional, and epigenetic characteristics will be compared with the primary tumor. CTC characteristics will be studied as biomarker of treatment response and resistance.

#3918 Identification of disseminated prostate tumor cells in bone marrow during radical prostatectomy from patients with localized prostate cancer. Stephanie A. Glavaris, Emma E. van der Toom, Michael Gorin, James Verdone, Changxue Lu, Jun Luo, Kenneth Pienta, Heather Chalmin. Johns Hopkins University, Baltimore, MD.

INTRODUCTION AND OBJECTIVES: In prostate cancer, disseminated tumor cells (DTCs) can escape the primary lesion and enter the bone marrow (BM) niche, representing an initial step towards conventionally detectable metastasis. The frequency of occurrence is elusive in clinically localized prostate cancer. We detected and characterized these cells by measuring gene expression of prostate-specific markers from BM samples collected at the time of radical prostatectomy (RP). METHODS: 5 mL of BM were harvested at RP for 36 clinically localized patients. A whole cell extract was assayed with the AdnaTest ProstateCancer-Select kit (Qiagen). Reverse transcription (SensScript RT kit, Qiagen) and real-time qPCR quantified expression of RPL13A (control, ribosomal protein), EP-CAM (epithelial), NKX3.1 and HOXB13 (prostate-specific), and AR-FLO (andro-gen receptor full length). Prostate markers known to be less sensitive or specific were also assayed in a subset of patients (TMPRSS2-ERG, AR-V7, PSA, and PSA). DTC detection was defined as prostate-specific marker expression in the BM. Quality control was performed with Sanger sequencing. The association of PSA and Gleason score (GS) with DTC detection were evaluated with the Mann-Whitney U Test and Fisher’s exact test respectively. RESULTS: DTCs were detected via NKX3.1 expression in 30/36 patients (83%). 100% of patients were EPCAM+, consistent with the known non-specific expression of EPCAM in the BM. HOXB13, AR-V7, and TMPRSS2-ERG were not detected in any specimen. PSA was also non-specifically expressed in 67% of NKX3.1+ and 83% of NKX3.1- patients. There was a pattern with DTC detection and higher PSA and GS, with 100% of NKX3.1+ patients having low-risk PSA less than 10, and only one with primary GS greater than 3 (17%, 1/6). Conversely 47% (14/30) of NKX3.1+ patients had primary GS greater than or equal to 4, and 27% (8/30) had PSA greater than 10. Yet, this was not statistically significant (GS p = 0.302, PSA p = 0.262), and DTC detection across all cases were independent. DTCs were detected based on NKX3.1 positivity in a large portion of clinically localized prostate cancer patients at all Gleason scores. Ongoing investigation with healthy patient BM will clarify whether NKX3.1 is truly prostate-specific, and if its expression associates with clinico-pathologic outcomes.

#3919 Isolation and characterization of viable pancreatic cancer circulating tumor cells using size-based filtration system. Kenneth H. Yu,1 Benjamin D. Krempel,2 Brian McCarthy,3 Memorial Sloan Kettering Cancer Center, New York, NY; 4 Charles E. Schmidt College of Medicine, Boca Raton, FL; 5 Viator CTC Solutions Inc, Lowell, MA.

Introduction: Circulating tumor cells (CTCs) are important actors in metastasis, a key feature of pancreatic ductal adenocarcinoma (PDAC). The ability to isolate, characterize and culture viable CTCs holds promise for understanding biology, treatment response, and resistance. Methods: Peripheral blood samples from healthy donors and patients with advanced PDAC were processed using an innovative size filtration system (Viator LLC, Lowell MA). Normal human blood samples were spiked with varying numbers of human PDAC organoid cells. The impact of buffy coat separation was studied. Isolated CTCs were cultured in Matrigel to generate organoids as previously described. Cells were imaged with fluorescently labeled antibody to EpCAM. Data: Using spiked normal human blood samples, viable CTCs can be isolated and expanded reliably in 3D organoid culture from as few as 10 CTCs/mL. Separation and processing of the buoyant coat enriched for the number of viable CTCs isolated. EpCAM positive CTCs were isolated from 6/6 blood samples from patients with advanced PDAC. Updated results will be presented. Conclusions: The current size-based filtration system allows for collection of viable CTCs from human PDAC blood samples. Current work will use this system to grow, expand and characterize human PDAC CTCs in organoid culture. Genetic, transcriptional, and epigenetic characteristics will be compared with the primary tumor. CTC characteristics will be studied as biomarker of treatment response and resistance.
showed that early DCCs contributed to metastasis formation together with late-disseminate and, as disseminated cancer cells (early DCCs), enter a non-proliferative condition. How early stages of tumor progression (before detection of palpable tumors), can cascade. However, new evidence shows that Neu primary tumors are known to be able to complete all steps of the metastatic cascade. How early dormant DCCs and consequently metastatic relapse. Our findings provide for the first time evidence that NR2F1 functions as a suppressor of stemness and dissemination during early stages of tumor progression. We propose that therapies that restore expression of NR2F1 might limit early dissemination and the progression of early and late-arriving DCCs toward metastatic outgrowth.

The role of pyruvate kinase M2 isoform (PKM2) in tumor progression is controversial. Previously, it was reported that PKM2 has an oncogenic function in promoting tumor growth in xenograft models; however, PKM2 was indicated non-oncogenic or even anti-oncogenic because depletion of PKM2 accelerates mammary tumor growth in the Brca1 knockout mouse model of breast cancer. Since tumors frequently harbor various abnormally activated oncogenic kinases, we hypothesized that phosphorylation of PKM2 by oncogenic kinases in tumor cells enables PKM2 to promote tumor growth, while unphosphorylated PKM2 in non-transformed cells cannot promote tumor growth. Here, we report that PKM2 proteins were largely unphosphorylated and formed tetramers in normal mammary epithelial cells (MCF10A, MCF12A). On the other hand, PKM2 proteins were phosphorylated at Y105 and formed dimers in breast cancer cells (MDA-MB-231, MDA-MB-435). Knocking down PKM2 didn’t affect normal mammary epithelial cell (MCF10A) growth but significantly decreased breast cancer cell MDA-MB-231 proliferation. In addition, introducing the PKM2 Y105D phosphomimetic mutant into MCF10A cells induced epithelial to mesenchymal transition, increased CD44+/CD24− stem-like cell population, formed slower initially, but reached a higher velocity after two or three deformations. Interestingly, PKM2 Y105D increased YAP1 protein nuclear localization in MCF10A cells, whereas inhibiting YAP1 by siRNA or a chemical inhibitor (Verteporfin) decreased PKM2 Y105D-induced cancer stem cell-like population and colony formation ability. The data indicate that YAP1 is a novel downstream target of PKM2 in promoting the stem-like property and triggering mammary tumor initiation. Next, we performed receptor tyrosine kinase array and identified several oncogenic tyrosine kinases (AXL, EPHA2, FAK, Src, Jak3 and so on) that effectively phosphorylate PKM2 at Y105. Currently, we are testing the efficacy of targeting these oncogenic tyrosine kinases in reversing the phosphorylation of PKM2 and blocking its tumor-promoting function. Together, our data indicate that oncogenic kinases-induced phospho-Y105-PKM2, but not the unphosphorylated PKM2, promotes mammary tumor initiation by increasing cancer stem cell populations.

Tumor cells derived from MMTV-Neu mouse models or human ErBb2+ primary tumors are known to be able to complete all steps of the metastatic cascade. However, new evidence shows that Neu+ early cancer cells derived from early stages of tumor progression (before detection of palpable tumors), can disseminate and, as disseminated cancer cells (early DCCs), enter a non-proliferative state for prolonged periods of time at secondary organs. We recently showed that early DCCs contributed to metastasis formation together with late-arriving DCCs (those coming from overt tumors). However, the mechanisms that would allow these early cancer cells, considered sessile and with few genetic alterations, to complete all steps of metastasis are unknown. Here we report that downregulation of the orphan nuclear receptor NR2F1 in Neu+ early cancer mammary epithelial cells (MECs) further activated a motile phenotype and this was coincident with previously described detection of circulating cancer cells (CCCs) and lung and bone marrow DCCs in MMTV-Neu mouse model. Knock down of basal NR2F1 levels in Neu+ early cancer cells induced cell motility, loss of laminin-V deposition, β-catenin delocalization from the membrane, dramatic loss of E-cadherin junctions and increased percentage of leader cells positive for CK14 and PRX1 staining. Interestingly, TWIST and PRX1 levels became upregulated upon NR2F1 depletion in 3D structures. These results suggest that NR2F1 expression maintains epithelial identity and suppresses epithelial-mesenchymal transition (EMT). Knock down of NR2F1 in Neu+ early cancer cells enhanced mammosphere formation efficiency and this was accompanied by upregulation of the pluripotency transcription factor NANOG and EMT master regulator TWIST. Interestingly, early dormant DCCs (negative for proliferation markers) showed re-expression of NR2F1 levels while micro-metastases (cycling cells) had reduced levels of NR2F1. This result suggests that downregulation of NR2F1 in early DCCs may contribute to the dormancy escape of early DCCs and consequently metastatic relapse. Our findings provide for the first time evidence that NR2F1 functions as a suppressor of stemness and proliferation and colony formation ability. The data indicate that YAP1 is a novel downstream target of PKM2 in promoting the stem-like property and triggering mammary tumor initiation. Next, we performed receptor tyrosine kinase array and identified several oncogenic tyrosine kinases (AXL, EPHA2, FAK, Src, Jak3 and so on) that effectively phosphorylate PKM2 at Y105. Currently, we are testing the efficacy of targeting these oncogenic tyrosine kinases in reversing the phosphorylation of PKM2 and blocking its tumor-promoting function. Together, our data indicate that oncogenic kinases-induced phospho-Y105-PKM2, but not the unphosphorylated PKM2, promotes mammary tumor initiation by increasing cancer stem cell populations.

#3923 Oncogenic kinase-induced PKM2 Y105 phosphorylation promotes tumorigenesis and cancer stem cell-like property. Zhuo Zhou, Lin Li, Zhang, Dihua Yu. MD Anderson, Houston, TX; Baylor College of Medicine, Houston, TX.

The role of pyruvate kinase M2 isoform (PKM2) in tumor progression is controversial. Previously, it was reported that PKM2 has an oncogenic function in promoting tumor growth in xenograft models; however, PKM2 was indicated non-oncogenic or even anti-oncogenic because depletion of PKM2 accelerates mammary tumor growth in the Brca1 knockout mouse model of breast cancer. Since tumors frequently harbor various abnormally activated oncogenic kinases, we hypothesized that phosphorylation of PKM2 by oncogenic kinases in tumor cells enables PKM2 to promote tumor growth, while unphosphorylated PKM2 in non-transformed cells cannot promote tumor growth. Here, we report that PKM2 proteins were largely unphosphorylated and formed tetramers in normal mammary epithelial cells (MCF10A, MCF12A). On the other hand, PKM2 proteins were phosphorylated at Y105 and formed dimers in breast cancer cells (MDA-MB-231, MDA-MB-435). Knocking down PKM2 didn’t affect normal mammary epithelial cell (MCF10A) growth but significantly decreased breast cancer cell MDA-MB-231 proliferation. In addition, introducing the PKM2 Y105D phosphomimetic mutant into MCF10A cells induced epithelial to mesenchymal transition, increased CD44+/CD24− stem-like cell population, formed slower initially, but reached a higher velocity after two or three deformations. Interestingly, PKM2 Y105D increased YAP1 protein nuclear localization in MCF10A cells, whereas inhibiting YAP1 by siRNA or a chemical inhibitor (Verteporfin) decreased PKM2 Y105D-induced cancer stem cell-like population and colony formation ability. The data indicate that YAP1 is a novel downstream target of PKM2 in promoting the stem-like property and triggering mammary tumor initiation. Next, we performed receptor tyrosine kinase array and identified several oncogenic tyrosine kinases (AXL, EPHA2, FAK, Src, Jak3 and so on) that effectively phosphorylate PKM2 at Y105. Currently, we are testing the efficacy of targeting these oncogenic tyrosine kinases in reversing the phosphorylation of PKM2 and blocking its tumor-promoting function. Together, our data indicate that oncogenic kinases-induced phospho-Y105-PKM2, but not the unphosphorylated PKM2, promotes mammary tumor initiation by increasing cancer stem cell populations.

#3924 Single-cell mechanical characteristics of human breast cell lines analyzed by multi-constriction microfluidic channels. Xiang Ren, Parham Ghassemi, Hesam Babahosseini, Jeannine S. Strobl, Masoud Agah. Virginia Tech, Blacksburg, VA.

Analysis of the mechanical characteristics of single cancer cells have shown that non-metastatic and metastatic cells have significant differences in stiffness. We used a microfluidic multi-constriction channel device to differentiate cancer cells and normal cells based upon differences in their mechanical properties. We fabricated the multi-constriction channels on a silicon wafer with SU-8 photolithography and polydimethylsiloxane (PDMS) soft-lithography, followed by PDMS microfluidic device formation and surface modification. The multi-constriction microfluidic channel contains five constriction channels each 50 µm in length separated by relaxation sections of 50 µm between every constriction channel. We used MDA-MB-231 as the cancer cell line and MCF-10A as the normal cell line, and utilized a smart phone to record video via a microscope. Our measurement by smart phone slow-motion video through microscope reliably collected the velocities of over 200 cells. We focused on comparing the initial velocity change due to cell deformation at the entrance of the first constriction channel and the exiting velocity at the last segment of the final constriction channel, where the cells have experienced sequential deformations. The multiple deformation paradigm tests cells’ resilience towards deformation and shape recovery. Cancer cells recovered back to a round cell shape quickly, and therefore experienced deformation at the entrance to each conformation, possibly cell migration and result in a decrease in velocity. The initial velocities of MDA-MB-231 cells were ~1.1 mm/s, and exiting velocities were ~2.2 mm/s. In contrast, normal cells deformed slower initially, but reached a higher velocity after two or three deformations, because normal cells stay in a rod-like shape without fully recovering back to an original spherical cell shape. The initial velocities of MCF-10A cells were ~0.5 mm/s, and exiting velocities were ~3.8 mm/s. When normal cells enter the fourth and fifth constriction channels, the cells’ shapes were almost fixed. The entrance time of cancer cells into the fourth and fifth channel was longer than the normal cells. After calculating the velocity increments in the fourth channel and fifth channel compared to the initial velocity, the Mafab
scatter plot of the velocity data of each MDA-MB-231 (n = 108 cells) and MCF-10A (n = 105 cells) showed clear separation of the two cell lines into distinct regions. Algorithms based upon these criteria successfully differentiated ~94.4% of the cancer cells from normal cells. Our experimental results indicated that multi-constriction microfluidic channels can be used to differentiate metastatic MDA-MB-231 and MCF-10A cells at the single cell level and may have further applications in high-throughput cell sorting and analysis. The authors would like to thank National Institute of Health (NIH) R21CA210126 for supporting this research.

#3925 Integrative platform for the reconstruction and modeling of mechanically arrested single cells in the brain vasculature under spatial constraint and shear stress. Wendy V. Alvarez Barrios,1 Huijie Lu,2 Kyle R. Cowdrick,3 Michelle Galarneau,1 Lan Jiang,2 Melinda Lake,3 Lin Yang,2 Danny Chen,3 David Hoelze,2 Zhangli Peng,2 Siyuan Zhang1,3 1University of Notre Dame, South Bend, IN; 2Ohio State University, OH.

During metastasis of breast cancer, tumor cells dissociate from the primary tumor, disseminate through the vasculature, and colonize secondary organs such as the brain, lungs, liver and bones. The mechanical arrest of circulating tumor cells (CTCs) in capillary beds is an essential step in the metastatic cascade for the successful early colonization of secondary organs. During mechanical arrest, tumor cells are subjected to extreme physical stresses such as shear stress and spatial constraint exerted by blood flow, as well as from compression by the constricting capillary on the restricted cell. These mechanical stresses may critically impact metastatic success. However, the precise physical and mechanical response of the disseminated tumor cells at the time of arrest in the vasculature to the forces of spatial constraint and shear stress remain largely unknown. Here we present an integrative platform that combines the use of a microfluidic device and computational model as a tunable system to reliably reproduce the mechanical arrest of single cells and quantitatively determine their physical response to precisely controlled mechanical forces of shear stress and spatial constraint. Using confocal microscopy and computational modeling we demonstrate that during mechanical arrest, single tumor cells undergo extreme morphological deformations. Furthermore, the cell morphology is dependent on the magnitude of shear stress applied; with magnitudes above 60Pa inducing elongation, blebbing, and rupture of the cell membrane. Our results demonstrate that our integrative platform is a viable model system for the qualitative and quantitative study of physical cell behavior precisely at the metastatic stage of mechanical arrest. Particularly, our results highlight the direct influence of physical forces on the restricted tumor cell, and suggest the importance of these external cues as dynamic determinants of cellular processes and ultimately of metastatic success. We anticipate our platform to be a starting point for future studies seeking to understand the reciprocal molecular and biophysical interplay imposed by mechanical forces at the greatly understudied stage of mechanical arrest in metastasis.

#3926 Is FGD3 a potentially prognostic marker for breast cancer. Yuliang Sun, Scooter Willis, Xiaoxian Lin, Justin Achua, Casey Williams, Brian Leyland-Jones. Avera Center for Precision Oncology, Sioux Falls, SD.

Background: Prognostic factors are capable of providing information on clinical outcomes at the time of diagnosis; they are usually indicators of growth, invasion, and metastatic potential. FGD3 (GeneID: 22852) was found to be overexpressed in breast cancer tissues (GC: 550616, p = 0.0001, 1998). Tissue marker is one of the prognostic factors; to date, only a small proportion of markers are ultimately clinically useful, including Ki-67 and HER2. While metastatic cancer is not usually a single, clear-cut disease, it is clearly a disease that has many different stages and types of progression. We also demonstrate that invasive BC cells are tolerant to supra-physiological calcium levels and that their adaptation to high calcium occurs via up-regulation of the calcium-sensing receptor (CaSR). This up-regulation might be induced by the immunosuppressive microenvironment, resulting in immune escape, and might be induced by the immune microenvironment, resulting in immune escape, and might be enhanced by the high calcium levels or risk of high calcium-driven aggressive BC outcomes. The commonly diagnosed mild increase in circulating calcium activates the calcium sensing receptor (CaSR) and has been shown to be associated with localized and more aggressive breast tumors in postmenopausal and premenopausal patients, regardless of histologic stage. Whether differences in circulating calcium and/or specific inactivating CaSR variants play any role in disparities in BC outcomes remains unclear.

DESIGN METHODS: We identified 199 BC cases and 384 age and genetic ancestry-matched controls with calcium assay and genotyping data from the Vanderbilt University DNA biorepository (BioVU) linked to de-identified electronic medical records. The linear mixed effects and codominant models were used to assess the relationship between inactivating CaSR mutations at rs1801725 (codon 986) and rs1801726 (codon 1011) and either circulating calcium levels or risk of high calcium-driven aggressive BC outcomes. RESULTS: We observed that circulating calcium levels were significantly higher in BC cases compared to control subjects (p = 0.001) and interestingly, in subjects of African ancestry compared to Caucasians (p = 0.001). The A986S mutant CaSR is common among Caucasians while the Q101E mutant receptor is common among African Americans. However, only inactivating mutations at rs1801725 locus were significantly associated with higher calcium levels (p = 0.006) and a higher (69%) risk of high calcium-driven aggressive BC outcomes compared to the wild type receptor. We also demonstrate that invasive BC cells are tolerant to sustained high calcium and that their adaptation to high calcium occurs via up-regulation of calcium-activated early response and malignancy-associated genes. CONCLUSION: These data suggest that inactivating CaSR polymorphisms at rs1801725 predispose BC patients to hypercalcemia and that high circulating calcium-driven aggressive disease outcomes occur via calcium modulated malignancy-associated genes such as MAGEC2/CT10.
Heterogeneity in circulating tumor cells in blood samples of metastasis-causing resistant prostate cancer patient: comparison of isolation technique. Gerit Theil, Christine Weiss, Kersten Fischer, Andre Schumann, Pauloa Fornara, Martin Luther Univ. of Halle-Wittenberg, Halle/Saale, Germany.

Introduction/Objectives: Metastasis-causing resistant prostate cancer (mCRPC) is a heterogenous disease. Since most prostate cancer patients have a biopsy performed only at the time of diagnosis, representative tumor tissue sample giving real time information about the disease status is generally missing. CTC enumeration is a biomarker associated with clinical outcomes in patients with mCRPC. However, capturing these rare cells from whole blood is still a major challenge because they are extremely rare. Furthermore CTCs mark a feature of epithelial-mesenchymal transition. First we assessed the method is best suited for the isolation of CTCs in mCRPC patients. Additionally was to evaluate the association between CTCs counts and ERG rearrangement in tumor samples. Materials & Methods A tumor sample from metastatic site, along with blood samples were collected from mCRPC patients. Tumor samples were characterized of ERG rearrangement by fluorescence in situ hybridization. CTCs were detected using two methods. One was SreenCells system, CTC isolation based on size exclusion. The second method was the CellCollector which CTC captured using monoclonal specific antibody to EpCAM. This system can be used for CTC isolation ex vivo and in vivo. We used it here ex vivo. Captured CTCs were identified based on histological cell architecture by immunofluorescence staining (8, 13). Both methods detected CTCs in 8 of 10 blood samples, detection rate is 80%. CTCs were in average of 22.6 CTCs (range of 0-80 CTCs). The CTC counting rate in SreenCells system and CellCollector isolation methods. Both methods detected CTCs in 8 of 10 blood samples, detection rate is 80%. SreenCells isolated in average of 22.6 CTCs (range of 0-80 CTCs). The CellCollector captured CTCs in vivo in average of 3 CTCs (range of 0-6 CTCs). In a direct comparison of the SreenCells system and CellCollector isolation methods. Both methods detected CTCs in 8 of 10 blood samples, detection rate is 80%. SreenCells isolated in average of 22.6 CTCs. The CellCollector captured CTCs in 3 CTCs. Therefore, both methods have a high positive correlation (r 0.776) and also with the ERG rearrangement (r 0.5). Our results demonstrate that CTC isolation based on the physical properties has a higher sensitivity as the CTC isolation technique based on the biological cell properties in mCRPC patients. The size exclusion technique coupled with characterization of specific staining morphologies might be used to identify a heterogeneous CTC population which is always present in advanced cancer. It should be decided in dependence of the advanced cancer stage which CTC isolation technique can be used. The cost of the material and the hours of work are equal in both systems.

ZEB1 is regulated by PKCs in breast cancer cell lines. María Candela Llorens,1 Cynthia Lopez-Haber,2 Laura Barrio-Real,2 María V. Vaglentí,1 Marcelo G. Kazanietz,2 Ana M. Cabanillas1. 1School of Chemical Science, National University of Córdoba, Córdoba, Argentina; 2University of Pennsylvania, Philadelphia, PA.

Breast cancer is the second leading cause of cancer deaths in women. Cytokine signals triggering kinase pathways play key roles in cancer progression which regulate transcription factors such as ZEB1 or Snail. Our goal is to uncover the role of PKC signaling pathway in the regulation of the biological action of ZEB1. The protein expression of ZEB1, PKC isoforms, epithelial-to-mesenchymal transition (EMT) markers were determined by Western Blotting (WB) in nine breast cancer cell lines. PKCa and ZEB1 had a significant positive correlation (p=0.05), and both proteins were highly expressed in mammary cell lines with a more aggressive phenotype (such as MDA-MB-231, BT-549 and MDA-MB-453). Interestingly, silencing PKCa using siRNA significantly reduced ZEB1 expression in MDA-MB-231, MDA-MB-453 and BT-549 cells, as determined by Western blot. Likewise, the pan-PKC inhibitor (Gö6983) and the ePKC inhibitor (Gö6976) reduced ZEB1 expression in breast cancer cells. However, the EMT markers vimentin, ZO1 and N-cadherin did not change their expression. ZEB1 mRNA levels did not change significantly in PKCa knockdown cells, suggesting that PKCa possibly regulates ZEB1 expression by affecting its protein stability. In addition, we found that the motile and invasive capacity of MDA-MB-231 cell lines was markedly affected in both PKCa and ZEB1 knockdown cells. Interestingly, depletion of PKCa from MDA-MB-231 cells markedly reduced the formation of ruffles and lamellipodia in response to serum, whereas ZEB1 depletion did not. In summary, our results revealed that PKCa regulates the expression of the EMT marker ZEB1 in basal-like breast cancer cell lines, and that in addition PKCa is important for the control of cell invasion and migration through regulation of ZEB1, thereby arguing that it could be a potential target for breast cancer metastasis. Our results also suggest that PKCa may control important phenotypic responses both through ZEB1-dependent and ZEB-independent mechanisms.

Sodium-calcium exchanger-1 regulates the epithelial phenotype and is lost in renal cancers. Sona Lakshmi Balasubramanian,1 Anikumar GOPalakrishnapillai,2 Nicholas J. Petrelli,3 Sonali P. Barwe,2 1 Nemours/A. I. duPont Hospital for Children, Wilmington, DE; 2 Christiana Care Health System, Newark, DE.

Epithelial cells that line the renal tubules possess apico-basal polarity and a defined cellular structure maintained by junctional proteins. The underlying mesenchymal cells are fibroblastic with a non-uniform cell structure and secrete extracellular matrix proteins. Mesenchymal to epithelial transition (MET) and epithelial to mesenchymal transition (EMT) are required for renal tubule formation during kidney development. Failure of renal mesenchymal cells to undergo epithelial transformation leads to the initiation of Wilms tumor, the most frequently occurring renal cancer in children. Conversely, aberrant mesenchymal transformation of tubular epithelial cells in the nephron contributes to the development of renal cell carcinoma, which constitutes 85-90% of the adult tubular malignancies. The role of calcium regulators in governing MET and MET is becoming evident. Sodium calcium exchanger 1 (NCX1), located on the basolateral surface of tubular epithelial cells, is the principal calcium regulator that mediates calcium reabsorption in these cells. NCX1 mediates the extrusion of one calcium ion and the influx of three sodium ions in one calcium exchange process. We demonstrated earlier that NCX1 regulates epithelial cell motility. However, the role of NCX1 in EMT was undetermined. We observed that knockdown of NCX1 in renal epithelial cells (MDCK) induced fibroblast morphology, and increased permeability to rhodamine indicative of leaky cell-cell junctions. Electron micrographs of these cells displayed increased inter-cellular junctional distance also suggesting that NCX1 knockdown altered junctions between adjacent cells. Cells with NCX1 knockdown showed loss of apico-basal polarity in three-dimensional cultures accompanied by expression of mesenchymal markers. Furthermore, NCX1 knockdown cells were capable of anchorage independent growth suggesting that these cells had acquired tumorigenic potential. Interestingly, we show for the first time that NCX1 mRNA and protein expression is greatly reduced in both Wilms tumor and renal cell carcinoma demonstrating a direct correlation between NCX1 expression and the epithelial phenotype. Mechanistically, we provide evidence that NCX1 interacts with and anchors E-cadherin, a classical adhesion molecule, to the cell surface independent of NCX1 ion transport activity. MDCK cells with NCX1 knockdown exhibited β-catenin nuclear localization and enhanced transcriptional activity. Taken together, knockdown of NCX1 in MDCK cells induces mesenchymal transition by destabilization of E-cadherin and induction of β-catenin transcriptional activity.

Dual role of p120ctn in cancer: epithelial vs mesenchymal. Pamali Fonseka, Suresh Mathivanan, Michael Liem, Ishara Atukorala. La Trobe University, Melbourne, Australia.

Neuroblastoma, a paediatric cancer, accounts for 15% of childhood cancer mortality. Even though the cells resist treatment is poorly understood. Here, we hypothesise that neuroblastoma cells have high expression of mesenchymal markers. Interestingly, we found that deletion of NCX1 in neuroblastoma patient tissues suggested that p120ctn is highly abundant. How, the knockdown of NCX1 in renal epithelial cells (MDCK) induced fibroblast morphology, and increased permeability to rhodamine indicative of leaky cell-cell junctions. Electron micrographs of these cells displayed increased inter-cellular junctional distance also suggesting that NCX1 knockdown altered junctions between adjacent cells. Cells with NCX1 knockdown showed loss of apico-basal polarity in three-dimensional cultures accompanied by expression of mesenchymal markers. Furthermore, NCX1 knockdown cells were capable of anchorage independent growth suggesting that these cells had acquired tumorigenic potential. Interestingly, we show for the first time that NCX1 mRNA and protein expression is greatly reduced in both Wilms tumor and renal cell carcinoma demonstrating a direct correlation between NCX1 expression and the epithelial phenotype. Mechanistically, we provide evidence that NCX1 interacts with and anchors E-cadherin, a classical adhesion molecule, to the cell surface independent of NCX1 ion transport activity. MDCK cells with NCX1 knockdown exhibited β-catenin nuclear localization and enhanced transcriptional activity. Taken together, knockdown of NCX1 in MDCK cells induces mesenchymal transition by destabilization of E-cadherin and induction of β-catenin transcriptional activity.
induced EMT, proliferation and migration. These results suggest that the role of p120ctn is cell type dependent. Overall, the findings from this study suggest that p120ctn plays a pivotal role in progression of neuroblastoma.

#3933 Characterization of oncogenic activity of interferon-induced protein with tetratricopeptide repeats 1 and 3 in human oral squamous cell carcinoma progression. Vijaya Kumar Pidugu, Ai-Hsin Yen, Ying-Chen Chen, Mei-Maan Wu, Chung-Ji Liu, Te-Chang Lee. 1Program in Molecular Medicine, Taiwan International Graduate Program, National Yang-Ming University and Institute of Biomedical sciences, Academia Sinica, Taipei, Taiwan; 2Institute of Biomedical sciences, Academia Sinica, Taipei, Taiwan; 3School of Public Health, Taipei Medical University, Taipei, Taiwan; 4Department of Oral and Maxillofacial Surgery, Mackay Memorial Hospital, Taipei, Taiwan.

Interferon-induced protein with tetratricopeptide repeats (IFITs) family has multiple tetratricopeptide repeats with helix-turn-helix structural motifs that mediate a variety of protein–protein interactions. There are four IFIT genes that have been identified namely, ISG56/IFIT1, ISG54/IFIT2, ISG60/IFIT3, and ISG58/IFIT5. IFIT proteins have been documented to involve in various cellular functions, such as cell proliferation, migration, virus-induced translation initiation, replication and double-stranded RNA signaling. Our previous study has demonstrated that IFIT2 inhibits oral squamous cell carcinoma (OSCC) metastasis. However, little is known about IFIT1 and IFIT3 in the progression of OSCC. In the present study, we are investigating the functional role of IFIT1 and IFIT3 genes in OSCC tumor progression.

Immunohistochemical analysis of 147 patients derived tumor specimens with OSCC revealed a strong correlation between IFIT1 and IFIT3 proteins (p<0.001). Clinicopathological characteristics correlation of IFIT1 and IFIT3 expression levels were positively associated with regional lymph node invasion and nerve invasion. IFIT1 was also associated with venous invasion. Ecopic expression of IFIT1 and IFIT3 proteins in Ca9-22 and SAS cells inducing PCK, EGFR, and AKT activation, resulting in OSCC cells resistance to cisplatin but highly susceptible to tyrosine kinase inhibitor gefitinib, whereas IFIT1 and IFIT3 knockdown SCC25 cells have shown opposite effect. Interestingly, IFIT1 and IFIT3 expression is associated with enhanced cell invasion activity and altered expression of epithelial-mesenchymal transition markers. These data suggested that IFIT1 and IFIT3 may serve as potential biomarkers for the OSCC treatment. The study on how IFIT1 and IFIT3 cause PCK, EGFR, and AKT activation and resistance to DNA damaging agents is ongoing. Our further investigations may explain the molecular signaling mechanism of IFIT1 and IFIT3 in OSCC tumor progression.

TUMOR BIOLOGY: Tumor Evolution and Heterogeneity 2

Survival rates for patients with muscle-invasive bladder cancer have not improved in the past 20 years, and new therapies are imperative. Intratumor heterogeneity can complicate molecular profiling attempts to optimize therapy for cancers harboring several actionable tumor subclones. To develop personalized treatment strategies, there is a need for assays to measure intratumor heterogeneity in bladder cancers. We conducted a pilot study of two muscle invasive high-grade transitional cell carcinoma cases. We used a comprehensive cancer panel (Thermo Fisher) covering >400 cancer genes to analyze distinct tumor loci and matched normal tissues. Based on the identified somatic mutations, we designed a bladder-specific panel to (1) validate our results with increased coverage, and (2) analyze liquid biopsy samples. Using the comprehensive cancer panel, we sequenced 6 tumor loci to an average sequencing depth of approximately 100x. We detected intratumor heterogeneity in both patients: By applying a combination of frequency-based (minor allele frequency >10%) and probabilistic (probability of difference between observed frequencies due to sampling) filters, we identified 44 credible somatic SNVs, including mutations that were not chemically altered by cisplatin or intercalating agents. We used these SNVs to design a custom amplicon panel covering 42 SNVs across 38 genes that is suitable for highly fragmented DNA. The custom panel was used to validate the SNVs in the same tumor regions and in liquid biopsy samples from plasma and urine (approximate coverage 6,000x). In both cases, we identified private mutations re-ported in The Cancer Genome Atlas Urothelial Bladder Carcinoma (TCGA-BLCA) data collection, reflecting tumor evolution. Liquid biopsy samples from urine revealed all trunk mutations but only 1 out of 5 private mutations. We conclude that tumor evolution can affect distinct loci within bladder tumors, which may not be fully represented in liquid biopsy samples. These results suggest a need for analyzing multiple tumor regions to identify all actionable driver mutations. In the future, we plan to apply our assay to additional loci and patients in order to identify optimal bladder tumor sampling strategies.

Introduction: Small cell lung cancer (SCLC) is a high grade neuroendocrine carcinoma of the lung responsible for up to 25% of lung cancer deaths. Treatment in SCLC has not changed significantly in the last 20 years. SCLC initially responds well to chemotherapy, but inevitably recurs. Characterization of tumor heterogeneity and changes in SCLC cell signaling and phenotypes after chemotherapy could yield new insights and therapeutic options. Mass cytometry uses metal labeled antibodies to profile expression and phosphorylation of more than 40 proteins in single cells and offers the opportunity to identify new subpopulations including potential cancer stem cell populations as well as targets for novel therapies in SCLC. Methods: Nude mice with SCLC patient derived xenografts (PDXs) were treated with one cycle of carboplatin/etoposide or saline injection. Tumors were harvested at ~2000mm3, disaggregated, and cryopreserved. PDXs were stained with a 22 marker panel and an intercalator dye to identify nucleated cells. This panel measured phospho-signaling, neuroendocrine, immune, and mesenchymal cell markers, and functional markers including ki67 and cleaved caspase 3. VSI NE analysis and biaxial gating were used to identify major subpopulations of interest. Results: PDX tumors released viable tumor and stromal cells suitable for cryopreservation and mass cytometry. ACK buffer and enzymatic dissociation yielded the best quality cells by depleting red blood cells. Mouse cells, including leukocytes, were excluded using mouse MHC1 gating and iodamer intercalator was used to identify nucleated cells. Single cell protein expression and phosphorylation was analyzed using VSI NE and yielded at least 9 distinct subpopulations based on density islands with neuroendocrine (CD56+) and non-neuroendocrine (CD56-) populations. Chemotherapeutic created cells had dramatic changes in subpopulation distribution compared to matched mock treated tumor. This included 2-3 fold expansion of SOX2+, CD117+, and pSTAT3+ populations with chemotherapy treatment. A small CD44+ tumor subpopulation identified in the chemotherapy treated cells was not present in the matched mock treated tumor suggesting a potential chemotherapeutic resistant/ stem-like subpopulation. Kinase activity showed stable p-AKT overall, but increased p-4E-BP1 in the chemotherapy treated cells. Conclusions: Mass cytometry was able to identify multiple neuroendocrine and non-neuroendocrine cell populations from SCLC PDXs and characterize their signaling. Chemotherapy treated PDX had differential subpopulation distribution with enrichment of multiple stem-like signaling factors. This work demonstrates the utility of mass cytometry and viSNE as novel techniques to identify subpopulations associated with chemoresistance for future targeting and demonstrates the feasibility of this technique for characterizing signaling heterogeneity in human SCLC tumors.

#3936 A branching evolution model at relapse characterizes multiple myeloma patients who responded to upfront combination therapy including new drugs. Carolina Terragna, Marina Martello, Barbara Santacroce, Vincenti Solini, Lucia Pantani, Elena Zamagni, Paola Tacchetti, Beatrice Zanetti, Katia Mancuso, Giulia Martocci, Nicoletta Testoni, Gaia Amel, Rosalinda Termini, Angelo Flores Dico, Enrica Borsi, Giovanni Martinelli, Michele Cavo. 1University of Bologna, Bologna, Italy; 2Fondazione Umberto Veronesi, Milano, Italy.

Intro: Multiple Myeloma (MM) is a biologically complex disease, whose genetic plasticity favors the coexistence of genetically heterogeneous subclones, selected in a Darwinian fashion throughout the disease course. Therapy might represent a major selective pressure over the different subclones, thus supporting an evolutionary model of the disease. Aim: To explore the existence of different clonal evolution patterns in MM, eventually driven by therapeutic selective pressure. P&M The study included 33 pts with symptomatic MM, up-front treated either with combination regimens including a proteasome inhibitor (28), or with cyclophosphamide. For each patient, single MM + plasma samples were collected both at diagnosis and at relapse. SNP array analyses were performed on the CD138+ enriched cell fractions. Results: Two approaches were applied: a) monitoring the variations of macro CNAs; b) focusing on changes of CNAs frequencies, as observed in 27 genes of interest. Both approaches were consistent in highlighting three major evolution patterns: in 7/33
(21%) pts, the genomic background at relapse was almost identical to that of diagnosis. In 13/33 (39%) pts, an overall increase in the frequencies of the same CNAs as observed at diagnosis was detected at relapse. Finally, in 13/33 (39%) pts, either increased or decreased frequencies of several CNAs, as well as several differences in the CNAs type’s prevalence were observed at relapse, as compared to diagnosis. Of interest, we noted overexpression of clonal CNAs mediates the remaining disease to relapse (226 vs 507, respectively) - supported by acquisition of CNAs either commonly described as secondary genomic events (i.e. del17p13, amp1q21, del1p23), or associated to the resistance to bortezomib (i.e. del8p21) - any peculiar CNAs resulted significantly prevalent in the 3 identified subgroups of pts. A high rate (92%) of achievement of VGPR or better quality of response to upfront therapy characterized the subgroup of pts. clonal CNAs in both groups of pts. At the first median of pts was only 20% and PR or SD were observed in 9 and 7 pts, respectively. Finally, the median time to first progression of this subgroup of pts was significantly shorter as compared to that of pts with branching evolution (24 vs 35 months, range 4-41 and 7-123 months, respectively, p=0.01). Conclusion: The genomic architecture of a subgroup of relapsed MM pts, up-front responsive to new drugs-based combination therapies, resulted overall different from that of diagnosis, suggesting a branching evolution of the disease, sustained by the shrinking of the most prevalent clone (therapy-sensitive), as well as by the expansion of subclones (therapy-resistant) not already evident at diagnosis. This observation raises the question whether re-treatment of relapsed pts should be appropriate in the case of branching evolution. Acknowledgements: AIRC (MC), Fondazione Berlucchi (CT), FUV (EB).

#3937 Diversity index as a novel predictor of tumor progression in breast cancer. Yul Ri Chung,1 Hyun Jeong Kim,2 Young A Kim,3 Mee Soo Chang,3 Ki-Tae Hwang,3 So Yeon Park1. 1Seoul National University College of Medicine, Seoul National University Bundang Hospital, Seongnam, Republic of Korea; 2Queen Elizabeth Hospital, Hong Kong, SAR, Hong Kong, Hong Kong; 3Seoul National University Bundang Hospital, Seongnam, Republic of Korea; 3Seoul National University Boramae Hospital, Seoul, Republic of Korea.

Intratumoral genomic heterogeneity leads to tumor progression and therapeutic resistance. However, due to the difficulty associated with its assessment, application of intratumoral genetic heterogeneity as a prognostic or predictive marker is limited. We investigated the significance of Shannon diversity index as a tool for measuring genetic heterogeneity by performing fluorescence in situ hybridization of c-Myc gene in invasive breast cancers, and correlated the Shannon diversity index for c-Myc copy number variation with clinicopathologic features of tumor including patient survival. Shannon index for c-Myc copy number variation strongly correlated with average c-Myc copy number and was significantly higher in tumors with c-Myc genetic or regional heterogeneity than in those without c-Myc amplification. High Shannon index was associated with high histologic grade, lymphovascular invasion, p53 overexpression, high Ki-67 proliferation index, hormone receptor negativity, and HER2 amplification. In survival analyses, c-Myc amplification or c-Myc copy number variation was associated with patient survival. However, a high level of Shannon index was associated with poor disease-free survival. In subgroup analyses, it was found to be an adverse prognostic factor in hormone receptor-positive group, but not in hormone receptor-negative group. In a validation set, high Shannon diversity index for c-Myc copy number variation was also found to be associated with poor survival. We further investigated the correlation with clinicopathologic features and predictive power of Shannon index using another gene, fibroblast growth factor receptor 1 (FGFR1) and observed that high Shannon index for FGFR1 gene copy number variation was an independent prognostic factor for poor clinical outcome in a whole group and in hormone receptor-positive subgroup. In conclusion, this study demonstrated that higher diversity index was associated with adverse pathologic parameters of breast cancer and poor clinical outcome suggesting that Shannon diversity index, which represents intratumoral genetic heterogeneity, can be used as a potential biomarker for tumor progression and prognosis in patients with breast cancer.

#3938 Dynamic interconversion of cancer cells: single-cell analysis of population-based equilibrium. Yuen San Chan,1 Edwin-Wai Kin Yu,2 William Weimann Wong1,2 Chi-shun Wong,1 Tsz Wai Tang,1 Tsz Kai Fong,1 Tiffany Yee,1 Chiu Xin Yip,1 Joseph Siu-Kiu Au,1 Mengsu Yang1. 1City University of Hong Kong, Hong Kong, Hong Kong; 2Queen Elizabeth Hospital, Hong Kong, SAR, Hong Kong, Hong Kong.

Background: Multiple subpopulations of cells with different phenotypes and genotypes coexist within malignant tumours. Different subpopulations seem to maintain themselves in an equilibrium position via stochastic interconversion. Such plasticity plays an important role in cancer progression, such as transition from epithelial states to mesenchymal state during metastasis, dedifferentiation of non-CSCs to CSCs and rapid transition to MDR cells during drug exposure. We attempt to explore this interconversion plasticity at both population and single cell levels to better understand the dynamics of phenotypic transition. Methods: We isolated CD90+ and CD90- cells from A549 lung adenocarcinoma cell line by flow cytometry and then characterized their phenotypic behaviors and interconversion dynamics at both population and single cells level. Single cells were cultured in 96 well plate for 13 days. Viable cells were then transferred into 6 well plate for further expansion until enough cells were collected for measurement of CD90 expression in flow cytometry. Results: A549 maintains a stable expression of CD90 (~50%) which is bimodal distributed. The sorted subpopulations eventually achieved a new equilibrium (CD90+ à 60%, CD90 - 30%) and did not converge during the bulk cell interconversion. Individual single cell clones showed large variation of CD90 expression. The distribution of CD90 expression was significantly different between CD90+ and CD90- single cell whereas the bulk populations achieved a similar average equilibrium as compared with the bulk cells. We noted two types of clones defined as transition clones and committed clones with differential interconversion capacities. The later one showed no sign of interconversion and was committed to the original CD90+/− expression level. Further experiments showed that the committed CD90+ cells were more mesenchymal with higher migration ability, while the committed CD90- cells were more epithelial and tumorigenic. Conclusions: Interconversion plasticity varied from cell to cell and the committed cells prohibited the return of sorted cell subpopulations returned back to the original equilibrium. Phenotypic studies of CD90+ and CD90- revealed that the interconversion between them was EMT related.

#3939 Evolution and drug resistance of primary and relapse tumors in diffuse large B-cell lymphoma. Rainer Lehtonen,1 Amjad Alkodsi,1 Kaiyang Zhang,2 Mikko Kivikoski,3 Emilia Kozlowska,4 Alejandro Cervera,1 Annika Pasanen,2 Harald Holte,3 Sirpa Leppa,3 Sampsan Hautaniemi,1 1University of Helsinki, Helsinki, Finland; 2University of Oslo, Norway.

Our integrated multi-omics analysis of paired primary and relapse DLBCL tumors provides comprehensive view to tumor evolution, drug resistance and disease heterogeneity. DLBCL is an aggressive systemic disease in which tumors can arise in virtually any part of the body. Activated B-cell (ABC) and germinal center B-cell (GCB)-like subtypes differ molecularly and clinically. Three-year progression-free survival (PFS) in ABC is around 40% vs over 80% in GCB. Whole genome (WGS, 7 patients), transcriptome (total RNA, 7 patients) and methylome sequencing data produced using the Illumina HiSeq platform was complemented with Illumina TruSeq amplicon sequencing covering 102,571 bp of the genome on 788 custom selected targets. Altogether 23 fresh frozen and 28 paraffin embedded tumor samples from 24 patients with an advanced disease and at least one relapse event were included in the study. To investigate the clonal hierarchy of the primary and relapsed tumors we employed dirichlet process clustering using cancer cell fraction (CCF) estimates or variant allele frequencies from somatic point mutations. Divergent evolution was prominent in the GCB subtype whereas in ABC subtype subclonal mutations are rare and only few genomic differences were detected between primary and relapse tumors (p-value=0.047, Pearson’s Chi-squared test on 7 patients with WGS data). suggesting pre-treatment drug resistance which is probably triggered by global hypo- or hypermethylation at relapse stage. In the GCB subtype primary and relapse branches have diverged much before diagnosis and subsequently developed independently. Number of emerging primary or relapse specific clonal and subclonal mutations correlate with PSF and overall survival (OS). Mutational signatures were concordant with the inferred evolutionary models in four out of five GCB cases. Contribution of the somatic hypermutation signature was higher in resistant tumors and correlated with time to progression of the disease. We identified 72 relapse tumor related genes including many known B-cell lymphoma genes such as CD79B, IGLLS, PIM1, SGK1. These were used in survival analysis in the CGCI RNA data set derived from 92 diagnostic DLBCL tumors. Patients with subclonal mutations in these genes had shorter PSF and OS (Kaplan-Meier p-values 0.0122 and 0.0071, respectively). To validate and further define our hypothesis we are simulating DLBCL evolution as a discrete time branching process model (Galton-Watson branching processes). The goal is to reconstruct phylogenetic trees from a simulated tumor and explain different types of evolutionary models inferred from the patient data. Despite of remarkable heterogeneity in DLBCL we observed two main evolutionary models which are concordant with disease subtype, patient’s survival, treatment response at diagnosis and relapse, and molecular features of a tumor.
Analysis of metabolic gene expression is compromised by tumor hétérogène-
ity. Therefore, we investigated the use of RNA expression levels from ENO1, which
encodes enolase 1, to adjust for glycolytic heterogeneity within glioblas-
tomas attributed to irregular vascularization, necrosis, surgical removal, etc.
Recently, this approach revealed relationships between carbonic anhydrases and
aromatic aminopeptidases (Beckmann et al. 2018). The use of such expression data from
frozen tissue samples to 22 glioblastomas, expression of the metabolic gene encod-
ing hypoxia inducible factor - 1A (HIF1A) and its target, vascular endothelial growth
factor A (encoded by VEGFA), were contrasted with two non-metabolic genes, i.e. those encoding platelet derived growth factor A (PDGFA) and epider-
mal growth factor (EGF) using RT-qPCR analysis. Genes of interest (GOI) were
initially normalized with delta-delta threshold methodology using housekeeping genes, ACTB and GAPDH. Then, concurrent expressions of ENO1 (ave 0.83 +/- 0.18 CI (95%), range of 0.22 - 1.97 times normal) were used to
mathematically transform expressions of GOI to multiples of ENO1 to puta-
tively correct for glycolytic variation. Expressions of PDGFA (ave 1.90 +/- 0.69
CI (95%), 0.17 - 4.01 times normal) and EGF (ave 1.25 +/- 0.57 CI (95%), 0.07 -
5.14 times normal), had correlations, r = 0.65 and 0.66, unranked (Pearson’s) and
ranked ( Spearman’s) data, respectively, among the 22 tumors. After ENO1
transformation, r = 0.68 for their unranked data & the difference in their ranges
rose to 1.31-fold. Prior to ENO1 transformation, expressions of HIF1A (ave 1.33
+/- 0.28 CI (95%), 0.25 - 2.53 times normal) and VEGFA (ave 2.89 +/- 1.36
CI (95%), 0.17 - 9.94 times normal) had negative correlations, r = -0.15 and -0.09,
unranked and ranked data, respectively. However, after transforming HIF1A
and VEGFA expressions to multiples of concurrent ENO1 expression, their
correlation became positive in both unranked and ranked data, with r = 0.30 for
the ranked (Spearman) data. The difference in the ranges of the two metabolic
genes expanded to 6.76-fold. Whereas the Wilcoxon Rank Sum of VEGFA’s
transformed values, with versus without 2.02-fold elevations of HIF1A ex-
pression, was insignificant, p = 0.704, using ENO1 transformed values indicated
a significant relationship, p = 0.042. Therefore, ENO1 transformation revealed
the anticipated relationship between HIF1A and its target, VEGFA, at the RNA
expression level that was not initially apparent in this small group of tumors.
Transformation via expression levels of ENO1 compensates for glycolytic het-
erogeneity to reveal and highlight relationships among metabolic genes when
analyzing resected tumors. Support from The Pittsburgh Foundation’s Walter L.

TUMOR BIOLOGY: Tumor Evolution and Heterogeneity 2

#3941 Assessing heterogeneity in DCE-MRI data of breast cancer patients
to predict treatment response. Anum Syed, 1 Anna G. Sorace, 1 Stephanie L. Barnes, 1
Lori Arlinghaus, 2 Xia Li, 3 Thomas E. Yankelov 1.

Introduction: We investigate the ability of multi-parametric, voxel-based
classifications of tumor heterogeneity from magnetic resonance imaging (MRI)
to predict the response of breast cancer patients to neoadjuvant therapy (NAT).
In particular, we use high-dimensional analysis of the longitudinal changes
in the vascular and cellular characteristics provided by quantitative dynamic
counter enhanced MRI (DCE-MRI) to predict response. Methods: DCE-MRI data was acquired from 34 patients with stage II/III breast cancer before
initiating NAT (t1) and after one cycle of NAT (t2). Pathological complete response (pCR) and non-pCR was defined at the time of surgery. Non-pCR
patients were further subdivided into partial response (>30% decrease in tumor
volume), progressive disease (PD, >20% increase in tumor volume), and stable
disease according to the Response Evaluation in Solid Tumors (i.e., RECIST)
criteria. For each tumor voxel, DCE-MRI data was modeled to extract the extravascular, extracellular volume fraction, \( v_e \), the plasma volume fraction, \( v_p \), and the volume transfer coefficients, \( k^\text{trans} \) and \( k^\text{app} \) which correspond to the rate of wash-in and wash-out of contrast agent, respectively. Multi-parametric voxel-

#3943 Determination of the molecular profile of Chilean patients with
sporadic colorectal cancer. Ana Maria Wielandt. Clinica Las Condes, Santiago, Chile.

Introduction: Colorectal cancer (CRC) represents a major health problem
worldwide, ranking third among the most frequent cancers and fourth in
cancer mortality. In Chile CRC is the third leading cause of cancer death. CRC is
a heterogeneous disease, and three carcinogenic pathways have been described
to determine the molecular profile: The microsatellite instability (MSI), chromo-
somal instability (CIN) and methylator phenotype (CIMP). Several studies have
 tried to propose CRC molecular subtypes based on the ways described above
since CIN, MSI and CIMP are not mutually exclusive and overlapping of the 3
ways is still unclear. The most recent subtyping of CRC was in 2015, where four
molecular subtypes consensus (CMS 1 to 4) were established according to clini-
copathological features, molecular pathways involved and mutational status of

Proceedings of the American Association for Cancer Research • Volume 58 • April 2017

1007
KRAS, BRAF and PI3KCA genes in order to encourage clinical translation. 21% of tumors failed to be categorized into these subtypes. This classification allows us to understand and determine the clinical, pathological and biological characteristics of CCR to provide customized therapies to patients. Aim: To describe the molecular profile of carcinogenic pathways in HCC, MSI CIMP in Chilean patients, covering advances in the molecular characterization, both the of 56 patients operated between 2010-2016 at Clinica Las Condes, without neo-

adjuvant treatment. DNA was extracted from normal and tumor tissue of each patient and using PCR amplification of several markers CIN, MSI and CIMP were defined. By combining the 3 variables analyzed, tumors were classified in Group-A (CIN-high), Group-B (CIN-low / CIMP-high / CIN-high), Group-C (CIN-low / CIMP-low / CIN-low), and Group-E (CIN- neg / CIMP-neg / CIN-neg). Results: In this study, tumors in Group-A (17%) are located on the right side in patients older than 60 years and early stages. Tumors Group-B / C (18,9%) occur in patients older than 60 years and BMI=25 kg / m², with wall invasion pT3-T4 and late stages. Tu-

mors of Group-D / E (54,7%) are the most frequent, located on the left side, without vascular invasion and moderately differentiated. Conclusions: This study allowed to classify Chinese patients in 3 subgroups considering the 3 main routes described for carcinogenesis development: CIN, MSI and CIMP, which are consistent with the percentages described by the global consortium. Studies that analyze MSI and CIMP or MSI and CIN have consistently shown that patients with MSI-high tumors have a better prognosis in our case (17%). De-

spite therapeutic advances based on this molecular characterization, both the of tumors and the different combinations of pathways involved have shown that the response to therapy varies depending on the individual profile of each patient, therefore in clinical practice it would be important to establish that profile for each of them. #3944 Characterization of molecular heterogeneity in hepatocellular car-

cinoma: Trunk and branch drivers. Sara Torrecilla, Daniela Sia, Andrew N. Harrington, Zhongyang Zhang, Genis Camprero, Agrin Moeni, Toffanin Sara, Isabel Fiel, Ke Hao, Monica Higueras, Lasa Caballero, Helena Cornella, Mih-

ind Mahajan, Yujin Hoshida, Augusto Villanueva, Sander Florman, Myron Schwartz, Josef Llovet. Icahn School of Medicine at Mount Sinai, New York, NY.

Introduction: Molecular heterogeneity occurs in Hepatocellular carcinoma (HCC), but its implications in clinical decision-making are unknown. The clonal evolution model explains that trunk alterations arise at early stages and are shared by all malignant cells, whereas branch alterations occur in subclonal tumor cells. We aim to characterize the genomic landscape of HCC through the identification of trunk driver alterations and the study of its distribution in intra- and inter-tumor heterogeneity. Methods: 153 HCC samples representing the multiple steps of hepatocarcinogenesis were analyzed by deep targeted-se-

genomic sequencing and promoter regions of the most frequent mutated drivers in HCC. Genes mutated in early lesions [39 dysplastic nodules and 54 early HCCs (eHCC) defined as <2cm, without satellites or vascular invasion] were classified as candidate trunk genes. Candidate trunk genes were further explored in two additional cohorts: a) intra-tumor heterogeneity cohort: 42 tumor regions of 21 tumors (>4cm: 2-3 regions/tumor); and 2) inter-tumor heterogeneity cohort: 39 tumors from 17 patients with multinodular lesions (2-3 nodules/patient). Transcriptome and copy-number variations (CNVs) were an-

alyzed using expression and SNP arrays, respectively. Results: A total of 46 mu-

tations were identified in the cohort of early lesions. Average number of muta-

tions and CNV aberrations were higher in eHCCs than in dysplastic nodules (1.1 vs 0.5, mutations/patient (p=0.03), and 8% vs 0.6% of aberrant chromosomal arms (p<0.0003), respectively). Overall, 72% (23/32) of the sequenced eHCCs presented at least 1 trunk mutation, being TERT, TP53 and CTNNB1 the most frequent (21/23, 91%). In the intra-tumor heterogeneity cohort, 81% (17/21) tumors showed at least 1 shared mutation in TERT, TP53 and/or CTNNB1 between different tumor regions (trunk drivers). In the inter-tumor heterogene-

cy cohort, the similarity of the CNV-profile of multinodular tumors was used to classify tumors as intra-heterogeneity (26% of tumors) or non-shared (74% of tumors). 6/17 (35%) of patients harbored clonal tumors according to their CNV profiles (Pearson p<0.05). Clonality classification was further confirmed by gene expression-based hierarchical clustering. 82% (9/11) of the sequenced clonal tumors shared TERT, TP53 and/or CTNNB1 as trunk alterations. In contrast, no trunk mutations were shared across non-clonal tumors. Conclu-

sions: TERT, TP53 and/or CTNNB1 are trunk drivers mutated in early HCC tu-

mors that remained as trunk aberrations across different regions of the same tumor and between primary and metastatic nodules. These mutations are early trunk drivers that can be captured with single biopsies and could represent ideal therapeutic targets in the future.
Intratumor heterogeneity impacts treatment response in rectal carcinoma. Rüdiger Meyer,1 Nicole E. McNeil,2 Darawalee Wassaga,1 Lena Anthuber,1 Noam Auslander,3 Danny Wangsa,1 Zhongqiu Zhang,1 Daniel Rosenberg,4 Eytan Ruppin,2 Jens K. Habermann,3 Thomas Ried1. National Cancer Institute/NIH, Bethesda, MD; 2University of Maryland, College Park, MD; 3Watterson Hospital/University of Connecticut School of Medicine, Waterbury, CT; 4University of Connecticut Health Center, Farmington, CT; 2University of Lübeck, Lübeck, Germany.

Individual response to radiochemotherapy (RCT) in rectal cancer patients is highly variable and the underlying mechanisms of treatment resistance of cancer cells are poorly understood. Recent studies revealed a considerable degree of genomic tumor heterogeneity. We hypothesize that this heterogeneity has a direct impact on treatment response as subpopulations of cancer cells are resistant to currently used RCT and facilitate tumor growth under treatment. To address this highly relevant clinical issue, patient-derived rectal cell lines were established. The tissue was derived from a 59-year-old male presenting with an adenocarcinoma of lower rectum (T3,N1,M0), who was treated by neoadjuvant RCT (50.4 Gy plus 5-FU) and low anterior resection. The neoadjuvant treatment induced a shrinkage of the tumor (staging of the surgical specimen: ypT3,N0), suggesting a partial response to RCT. A biopsy of the treatment naïve tumor was implanted heterotopically into an immunodeficient nude mouse. After in vivo growth, the tumor was dissociated and introduced to an in vitro culture where murine stromal cells were depleted using antibody-based columns. The cell line proved to be highly responsive by immunofluorescence for human microsatellite instability as well as genotyping using short tandem repeat profiling. The characterization of the genome by array CGH and spectral karyotyping (SKY) revealed a highly complex near-triploid karyotype with numerous chromosomal imbalances, which are specific for colorectal cancers, including gains in chromosomes 7, 13 and X. We also observed other structural abnormalities including an anisochromosome 1q. Multiplex-FISH by consecutive hybridization of probes for 15 gene loci, which are known to be relevant in colorectal cancer genesis, revealed a significant degree of clonal heterogeneity of the cell line. Single cell sorting was then performed to establish single cell derived cell lines from the genomically well characterized parental cell line. Exposure of the single cell derived cell lines to irradiation in combination with 3 μM 5-FU revealed substantial differences in treatment response. Analyses of the genome by array CGH and transcriptome by RNA-Seq of the respective single cell derived cell lines are currently underway. This will allow the comparison of the respective sensitivities to RCT to the identified aberration profiles. These data will facilitate the understanding of therapy resistance and potentially allow a reliable prediction of the patient’s response. A tailored therapy is an important step towards individualized treatment in colorectal cancer patients to avoid therapy resistance.

Comprehensive characterization of genomic and transcriptomic heterogeneity in advanced bladder cancer by multiplexed analysis. Thordis Thomsen,1 Philippe Lamy,1 Noam Auslander,2 Danny Wangsa,1 Søren Vang,1 Line Reinberg,4 Eytan Ruppin,2 Jens K. Habermann,3 Thomas Ried1. National Cancer Institute/NIH, Bethesda, MD; 2University of Maryland, College Park, MD; 3Watterson Hospital/University of Connecticut School of Medicine, Waterbury, CT; 4University of Lübeck, Lübeck, Germany.

Barrett’s esophagus (BE) is defined as metaplasia of the squamous epithelium to a specialized columnar epithelium, and is a well-known high risk factor for the development of esophageal adenocarcinoma. Challenges remain in early detection and predicting which patients may progress to dysplasia. Here we describe a method by which we compare human clinical IRB-approved BE biopies and adjacent normal squamous epithelium using tissue dissociation and deep immunophenotyping by flow cytometric collection and analysis. A cassette of canonical epithelial or tumor stem cell-associated targets (EpCAM, CD24, CD44, CD49f, Her2/neu, CD133, CD90, CD166, and CD29), immune cell markers (CD3, CD4, CD8, CD25, and CD19), as well as epithelial or tumor stem cell-associated targets (EpCAM, CD24, CD44, CD49f, Her2/neu, CD133, CD90, CD166, and CD29), immune cell markers (CD3, CD4, CD8, CD25, and CD19) as well as targets associated with myeloid derived suppressor cells (CD14, CD15, CD33, CD11b, HLA-DR, CD31, and CD86) were used to discern differences across subjects and between cellular compartments in normal and BE tissue. The Barret’s samples show a majority population with a characteristic phenotype (EpCAM+CD133lowCD49flow) when compared with normal squamous tissue samples (EpCAM-CD133-CD49frich). The samples separate into two discrete groups using hierarchical clustering based on differential surface marker expression of combined epithelial and immune cell markers, and also reveal unexpected, shared phenotypes for some normal and BE samples. Principal component analysis supports this grouping and was used to identify more compelling targets for categorization, such as CD133 and CD49f. The resulting expression and distribution of targets offer a phenotypic fingerprint characterizing both the epithelial cell and immune cell compartment. Besides providing the potential for revealing clinically relevant differences between BE and normal tissue, as well as across subjects, the discovered surface immunophenotypes can be used to target specific subpopulations from dysplastic tissue for further molecular investigation. A deeper understanding of the role of such specific subpopulations should increase the prospects for more complete understanding of BE and its progression.

A novel combination therapy targeting BCL6 and phospho-STAT3 defeats intratumor heterogeneity in a subset of non-small cell lung cancers. Dhruba Deb,1 Satwik Rajaram,2 Jill E. Larsen,3 Patrick P. Dospopy,2 Rossella Marullo,3 Longshan Li,1 Kimberley Avila,1 Leandro Cerchietti,3 John D. Minna,1 Lani F. Wu,2 Steven J. Altschuler2. 1Becton Dickinson Technologies, Research Triangle Park, NC; 2University of Pennsylvania, Philadelphia, PA; 3Becton Dickinson Life Sciences, San Jose, CA.

Bladder cancer is a highly heterogeneous disease - both clinically and at the genomic and the transcriptomic levels. Despite complete tumor resections, recurrent tumors share a high number of mutations with the initial or earlier tumors, indicating that new tumors arise from fields of transformed areas of cells in the urothelium (i.e. field disease). Furthermore, the high mutational load found in bladder cancer and the assumed high degree of heterogeneity may have large implications on therapy response. Thus, detailed knowledge on tumor heterogeneity and mutational dynamics in adjacent normal urothelial cells is needed in order to understand field disease, disease development and disease progression. To address this, we performed comprehensive genomic and transcriptomic analysis of multiple samples of tumor and normal tissue procured from four cystectomy specimens and assessed the heterogeneity. Multiple tumors, lymph node metastasis, relapse biopsies and adjacent normal tissue from four patients with muscle invasive disease were analyzed. A targeted panel (illumina TruSeq Custom Amplicon v1.5) was designed from whole exome sequencing of bulk tumor DNA and germline DNA. Targeted sequencing of DNA from small cellular regions procured by laser-microdissection from tumor biopsies and from adjacent normal tissue was used for generating a comprehensive genomic map of the bladder. Transcriptomic profiling (Fluidigm GE) was carried out using RNA from LMD procured tumor regions matching the regions used for targeted sequencing. Results: In total, whole exome sequencing was performed on DNA from 15 bulk tumors with an average coverage of 39X. We identified a total of 331, 862, 685 and 1344 mutations, respectively, in the four patients with 15-85% of the mutations being ancestral. Of all the mutations, 95, 130, 117 and 335, respectively, were estimated to have a functional impact. Targeted sequencing of 207, 595, 538 and 483 mutations in the four patients was performed on DNA from 137 small cellular regions, including DNA from 17 adjacent normal tissue regions. We observed low local heterogeneity while comparing more distant regions revealed significantly higher levels of heterogeneity. This observation was in agreement with the heterogeneity observed at the transcriptomic level, where some regions within the same bladder appeared to have basal characteristics while others appeared to have luminal characteristics. Conclusion: Large intra-patient genomic and transcriptomic heterogeneity can be observed in bladder cancer. However, even in multifocal tumors, all the regions shared a substantial number of mutations, indicating a common origin. Ongoing investigations indicate the presence of low frequency tumor associated mutations in normal appearing tissue.

Deep immunophenotyping using flow cytometry of dissociated cells from Barrett’s esophagus and matched adjacent squamous epithelium defines distinct phenotypic clusters. Friedrich G. Hahn,1 Eileen Snowden,1 Warren Porter,1 Mitchell Ferguson,1 William S. Dillmore,1 Stephanie S. Yee,2 Taylor Black,2 Maureen DeMarshall,2 Aaron Middlebrook,2 Smita Ghanekar,1 Aníl Rustgi,2 Erica L. Carpenter,2 Rainer Blaesi,3 1Becton Dickinson Technologies, Research Triangle Park, NC; 2University of Pennsylvania, Philadelphia, PA; 3Becton Dickinson Life Sciences, San Jose, CA.

Barrett’s esophagus (BE) is defined as metaplasia of the squamous epithelium to a specialized columnar epithelium, and is a well-known high risk factor for the development of esophageal adenocarcinoma. Challenges remain in early detection and predicting which patients may progress to dysplasia. Here we describe a method by which we compare human clinical IRB-approved BE biopies and adjacent normal squamous epithelium using tissue dissociation and deep immunophenotyping by flow cytometric collection and analysis. A cassette of canonical epithelial or tumor stem cell-associated targets (EpCAM, CD24, CD44, CD49f, Her2/neu, CD133, CD90, CD166, and CD29), immune cell markers (CD3, CD4, CD8, CD25, and CD19), as well as targets associated with myeloid derived suppressor cells (CD14, CD15, CD33, CD11b, HLA-DR, CD31, and CD86) were used to discern differences across subjects and between cellular compartments in normal and BE tissue. The Barret’s samples show a majority population with a characteristic phenotype (EpCAM+CD133lowCD49f) when compared with normal squamous tissue samples (EpCAM-CD133-CD49frich). The samples separate into two discrete groups using hierarchical clustering based on differential surface marker expression of combined epithelial and immune cell markers, and also reveal unexpected, shared phenotypes for some normal and BE samples. Principal component analysis supports this grouping and was used to identify more compelling targets for categorization, such as CD133 and CD49f. The resulting expression and distribution of targets offer a phenotypic fingerprint characterizing both the epithelial cell and immune cell compartment. Besides providing the potential for revealing clinically relevant differences between BE and normal tissue, as well as across subjects, the discovered surface immunophenotypes can be used to target specific subpopulations from dysplastic tissue for further molecular investigation. A deeper understanding of the role of such specific subpopulations should increase the prospects for more complete understanding of BE and its progression.
ERK/2 among a collection of Human Bronchial Epithelial Cells (HBECs) that have been oncogenically transformed with combinations of TP53, K-RAS, and MYC, commonly found alterations in non-small cell lung cancer (NSCLC). We studied ~3000 cells/signaling marker/HBEC oncogenotype variant using immunofluorescence assays and single-cell image analysis (>1M data points). For downstream analysis, we created data sets that were curated with respect to the Western blot and siRNA mediated knockdown assays. We utilized inhibitors to STAT3 and BCL6 in MTI drug sensitivity and colony formation assay in a panel of NSCLC lines. We used xenografted subcutaneous tumors for the in vivo validation of our results. Results: When all three oncogenic changes were present and the HBECs were tumorigenic, we observed STAT3 upregulation and SMAD2/3 downregulation. Interestingly, these STAT3 and SMAD2/3 signaling changes were found to be mutually exclusive in single cells within the transformed HBEC strain. We targeted the STAT3 upregulated subpopulation with the STAT3 inhibitor Stattic. But, Stattic treatment failed to eliminate the SMAD2/3 downregulated subpopulation. To target the SMAD2/3 down-regulated subpopulation, we identified BCL6, a downstream gene of SMAD2/3, as a novel target in transformed HBECs. Next, to test the generality of BCL6 as a target, we studied 5 NSCLC cell lines with various levels of BCL6 expression: H1693, H1819, H1993, HCC827 and H2009. Our data suggests that BCL6 can also be a therapeutic target in a subset of NSCLC lines. Then we tested the response of these NSCLC lines to a combination of BBI608 (potent STAT3 inhibitor) and FX1 (BCL6 inhibitor). The combination treatment eliminated more cancer cells than the single treatments alone. Finally, we confirmed the response of these NSCLC lines to a combination of BBI608 (potent STAT3 inhibitor) and FX1 (BCL6 inhibitor). The combination treatment eliminated more cancer cells than the single treatments alone.

**#3951** Colony lysate arrays for proteomic profiling of drug-persistent cancer cell subpopulations.

Colonal heterogeneity of cancer cells is one of the key properties by which to understand relapse after anticancer drug therapy. However, a very limited number of technologies are available for individually profiling these heterogeneous drug-resistant subpopulations. Therefore, the development of techniques to monitor molecular changes in the subpopulations responsible for drug-resistance, namely, colony-forming drug-tolerant persisters (DTPs), is needed in order to understand the occurrence of cancer relapse. To profile DTPs at the molecular level in relation to the colony-forming function, this study aimed to develop colony lysate array (CoLA) for the quantitative measurement of protein levels in individual colonies. To investigate multiple parameters that may affect the emergence of DTP, DTPs derived from 5 cancer cell lines grown in the presence of 6 doses of 4 different drugs were collected. A set of >2,000 colony lysates was printed onto a nitrocellulose-coated glass slide using a microarrayer, which has been used for the production of reverse-phase protein arrays (RPAs). Each resulting CoLA slide was stained with a specific antibody from the list of 44 functionally-diverse proteins. Immunostained slides were then scanned using an optical flatbed scanner for quantifying the spot intensity. To evaluate whether the CoLA system produced biologically relevant data relating to the DTPs, the epithelial/non-epithelial protein relationship between E-cadherin and vimentin was examined. With the proteomic profiling of >2,000 DTPs, E-cadherin was negatively correlated with vimentin (r = -0.74, P < 0.0001) and positively correlated with CK-8 (r = 0.86, P < 0.0001), suggesting that DTPs may flexibly transit their biological entity in response to drug administration. A set of hierarchical clustering of DTPs displays proteomic patterns in each dose, allowing the comparison of proteomic changes in a dose-response manner. For example, the “cispactin-induced cluster” demonstrated similar proteomic patterns regardless of the drug dose. In contrast to cispactin, the gefitinib-induced cluster indicated that the proteomic patterns were similar at different concentrations from 0 to 0.1 μM; however, those at 1 and 10 μM were distinct from those at lower concentrations. Individual protein analyses of the DTPs revealed that the level of STAT3 decreased while that of OCT4A increased according to the gefitinib concentrations. An RPPA-modified method, CoLA, for individual colony profiling has been successfully established. The results of validation studies suggest that CoLA can be a tool for understanding the emergence mechanism of DTPs. The molecular characteristics of DTPs may reflect the entity of cancer cell subpopulations that contribute primarily to post-chemotherapeutic cancer relapse. Further technical development will enhance understanding of the occurrence of cancer relapse.

**#3952** Rapid autopsy programs: A systematic review.

Brian Li,1 Neesha Dhanl,1 WeiYan Wu,2 Shawn Khan,2 Elysa Grose,2 Princess Margaret Cancer Centre, Toronto, Ontario, Canada; 2McMaster University, Hamilton, Ontario, Canada.

A Rapid Autopsy Program (RAP) is an advanced method of biopsy specimen procurement and processing that addresses the current limitation in the method in order to obtain substantial amounts of high-quality, fresh tissue in support of current and future research. Rapid autopsies were first introduced in the late 1980’s and are still a relatively novel approach, but growing in popularity as a viable alternative to traditional tissue sampling methods for cancer research. In oncology, primary tumour, metastatic, and normal tissue from uninvolved organs if available are sampled snap frozen or fixed in formalin for downstream proteomic and transcriptomic analysis. The aim of this review is to inform best practice for collection and use of biospecimen in oncology. Medline, Embase, Cochrane Database of Systematic Reviews, Cochrane CENTRAL, and Ovid MEDLINE will be searched with devised strategies and screened from inception until present. In addition, grey literature will be reviewed. Two independent reviewers will be responsible for study selection and data extraction. The results of the systematic review are pending.
comprising less than 5% of the total lesion - these would not be reliably detected by standard methodology, and would likely be responsible for the failure of targeted therapy. More generally, we envisage that Basescope™ technology will be a useful tool in basic research, and furthermore is readily transferrable to clinical applications.

#3954 Single-cell misregulation of NRF2 in basal-like breast cancer. Elizab- eth Pereira, Kevin Janes. University of Virginia, Charlottesville, VA

Cancer is driven by a complex and heterogeneous combination of genes and pathways, many of which are not explicitly oncogenic on their own. These so-called non-oncogenes are required for maintenance of the tumorigenic state, but they are not mutated themselves. One way to identify “non-oncogene” pathways is to evaluate how proliferating cells adjust to variable and evolving environ- ments. By examining heterogenous transcriptional states of single cells in a 3D culture model of breast epithelial organization, we uncovered NRF2 as a candidate transcription factor upstream of an important regulatory state for morphogenesis. NRF2 is a known oncogene in lung cancer, but mutations in the transcription factor are uncommon in breast cancer. To examine the functional impact of NRF2 signaling, we engineered several triple-negative breast cancer cell lines with inducible short hairpin RNA to knockdown NRF2. In claudin-low MDA-MB-231 cells, knockdown of NRF2 caused dramatic reduction in stellate invasion compared with shGFP control. In basal-like HCC-1806 cells, knockdown of NRF2 caused a reduction in “ruptured” tumorspheres, in which cells disseminate from their originating site. In a non-transformed breast epithelial cell line, overexpression of a non-degradable form of NRF2 caused greater vari- ation in the size of acini, while knockdown of NRF2 narrowed the size distribu- tion of acini. Therefore, knockdown of NRF2 substantially normalizes the size and shape of both non-transformed and cancerous 3D structures. We also ana- lyzed expression levels of the genes in the provisional NRF2-regulated cluster after NRF2 knockdown or overexpression. Upon NRF2 knockdown, the p53-regulated transcripts CDKN1A (p21) and RPS27L were strongly induced, sug- gesting that p53 may be activated after NRF2 loss. Our results suggest a func- tional importance for NRF2 in multiple breast-epithelial and TNBC contexts, and raise the possibility of interplay between NRF2 and p53. A detailed under- standing of NRF2 regulation and dynamics could enable new strategies to dis- rupt this non-oncogene addiction and re-sensitize cancer cells to their environment and to chemotherapy.

#3955 Spatially resolved, multiplexed digital characterization of protein and mRNA distribution and abundance in formalin-fixed, paraffin-embed- ded (FFPE) tissue sections based on NanoString’s Digital Spatial Profiling (DSP) technology: applications to immune-oncology (IO) and tumor hetero- geneity. Chris Merritt, Jae-Seung Jung, Chang Young Jun, Han Eun Kim, Jia-Ping. 1NanoString Technologies, Inc., Seattle, WA; 2MD Anderson Cancer Center, Houston, TX

Introduction: As intra-tumoral heterogeneity has emerged as a challenge in development of targeted cancer therapeutics, the tissue context of biomarker levels and colocalization of key immune-regulatory proteins has become an increas- ingly important aspect for understanding tumor immune responses, pa- tient classification and stratification. Historically, immunohistochemistry and in situ hybridization have been used to assess spatial heterogeneity of targets in clinical samples. These approaches, however, have limited multiplexing capacity and dynamic range. Here, we use DSP technology, a spatially resolved approach for quantifying up to 800 protein or RNA targets with over 5 logs of dynamic range in a single FFPE slide to overcome these limits. Methods: The technology uses DNA oligo tags for either protein or RNA detection. For protein detection, a cocktail of 30+ primary antibodies (Abs), each with a unique, photo cleavable oligo tag, and 1-3 fluorescently (FL) labeled Abs was applied to a slide-mounted FFPE tissue section. Regions of interest (ROI), selected based on a FL imaging scan of the entire tissue, were illuminated sequentially with focused UV light to release the oligos. Following each UV cycle, eluent was collected from the local ROI, moved to a microtiter plate, hybridized to NanoString® barcodes, and then analyzed with an nCounter® Analysis System. The resulting digital counts cor- responded to the abundance of each targeted protein in the ROI. For RNA detection, a cocktail of multiple UV- cleavable in situ hybridization probes were used in a similar manner. Results: We demonstrate multiplexed detection from discrete ROIs within a tumor and adjacent normal tissue, enabling systematic interroga- tion of a heterogeneous tumor microenvironment. In control samples, we found expected levels of protein and RNA targets. We further demonstrate that this approach enables analysis of target abundance from individually se- lected cells, both contiguous and non-contiguous with the same phenotype, and enables multiplexed detection of key IO targets. Finally, we demonstrate detec- tion of key IO RNA targets using direct hybridization of oligo-labeled probes. Conclusions: With further development, our novel DSP approach to capture the spatial context of protein and RNA levels will have many applications in bio- marker and translational research. The ability to digitally measure RNA and protein at up to 800-plex from FFPE tissues could facilitate drug mechanism-of- action and resistance studies as well as tumor microenvironment. Quantitative, high-plex data should also greatly accelerate the discovery of IO biomarkers in tumors and the development of companion diagnostics for targeted therapies.

#3956 Intra-individual genomic heterogeneity of ovarian cancer and clinical utility of ascitic cancer cells for mutation profiling. Youn Jin Choi, Min Sung Kim, Sung Hyung Lee. Catholic Univ. of Korea, Seoul, Republic of Korea

Intra-individual tumoural heterogeneity (ITH) is a hallmark of solid tumours and impedes accurate genomic diagnosis and selection of proper therapy. The purpose of this study was to identify ITH of ovarian high-grade serous carcino- mas (OSCs) and to determine the utility of ascitic cancer cells as a resource for mutation profiling in spite of ITH. We performed whole-exome sequencing, copy number profiling, and DNA methylation profiling of four OSC genomes using multiregional biopsy from 13 intra-ovarian lesions, 12 extra-ovarian tu- mour lesions (omentum/peritoneum), and ascitic cells. We observed substantial levels of heterogeneity in mutations and copy number alterations (CNAs) of the OSCs. We categorized the mutations into ‘common’, ‘shared’ and ‘private’ ac- cording to the regional distribution. Six common, 8 shared, and 24 private mu- tations were observed in known cancer-related genes. Common mutations had a higher mutant allele frequency and included TP53 mutations in all four OSCs. Region-penalized copy number and interstitial amplifications and deletions involving BRCA1, PIK3CA, and RB1 were also identified. Of note, the mutations detected in ascitic cancer cells represented 92.3-100% of overall somatic mutations in the given case. Phylogenetic analyses of ascitic genomes predicted a poly-seeding origin of somatic mutations in ascitic cells. Our results demonstrate that despite ITH, somatic mutations, CNAs, and DNA methylation in both “common” category and cancer-related genes were highly conserved in ascitic cells of OSCs, high- lighting the clinical relevance of genome analysis of ascitic cells. Ascitic tumour cells may serve as a potential resource to discover somatic mutations of primary OSC with diagnostic and therapeutic relevance.

#3957 Characterization of functional heterogeneity and in vivo dynamics of clonal cell populations derived from the triple-negative breast cancer cell line MDA-MB-468. Hendrik J. Kuiken, Sabin Dhakal, Laura M. Selsor, Jett P. Crowdis, Hyo-eun C. Bang, Frank Stegemeier, Gordon B. Mills, Joan S. Bruggl, Harvard Medical School, Boston, MA; Novartis, Cambridge, MA; MD Anderson Cancer Center, Houston, TX

Tumors evolve through progressive accumulation of (epi)genetic alterations, favoring expansion of the fittest cell populations as a result of stimuli and selec- tive pressures in the microenvironment. Intratumor heterogeneity and the in- terplay of tumor cells with the microenvironment present an order of complex- ity that can have profound effects on tumor progression and drug sensitivity. While tumor cell heterogeneity has been described at many levels, there is a poor understanding of the extent of functional heterogeneity within a single tumor, and the dynamics and spatial organization of distinct cell populations over time. The overall objective of this study is to characterize the functional heterogeneity of breast tumor cells and evaluate the dynamics of clonal populations within mixtures during tumor progression. We have generated and characterized 31 clonal cell populations (SCP) from the triple-negative breast cancer cell line MDA-MB-468. These SCPs display considerable phenotypic heterogeneity with respect to morphology, proliferation rate, survival in suspension, colony forma- tion in soft agar, and tumorigenicity. We have also performed whole-exome sequencing for 7 SCPs, and RNA-seq and RPPA analysis for all SCPs and the parental cell line. These analyses revealed SCP-unique single nucleotide vari- ants, and differential expression of numerous genes. To study the dynamics of SCP mixtures during the development of xenograft tumors, we have transduced 22 SCPs with unique DNA barcodes derived from the ClonTracer DNA barcode library. The 22 barcoded SCPs were mixed in equal proportions and subse- quently injected into the mammary fat pad of NOD/SCID mice. Tumors and lungs were collected at different time points (3 weeks, 2 months and 4 months) to determine the relative changes in clonal representation during tumor pro- gression by next generation sequencing. We identified highly reproducible patterns of clonal expansion, with SCP01 and SCP03 being temporarily enriched for in tumor samples collected 3 weeks and 2 months, respectively and SCP32 becoming progressively enriched for in tumors over time. In addition, we found recurrent enrichment for SCP01 in most lung samples. Moreover, in contrast to the tumor samples, we found a slight enrichment for SCP13, but not SCP32, during in vitro propagation of the SCP mixture. Together these results suggest
the existence of distinct competitive advantages of individual clonal populations within certain spatial and temporal windows. In addition, the discordance in SCP dynamics between the in vivo and in vitro arms suggests that enrichment for SCPS1, SCPS3 and SCPS32 is the result of stimuli or selective pressures that are specific to the tumor microenvironment. Guided by the RNA-seq and RPPA analyses, we are currently testing several hypotheses that may explain the observed enrichment patterns.

**TUMOR BIOLOGY: Tumor Microenvironment 5**

#3958 The importance of co-localized resting CD8+ T cells and proliferating tumor cells in gastric cancer. Mehmet Yigitsoy,1 Sophie Earle,2 Armin Meier,3 Nathalie Harder,4 Matthew Hale,4 Aleksandra Zuraw,4 Takaki Yoshikawa,5 Günter Schmidt,1 Ralf Huse,4 Heike I. Grabsch,4 Definium AG, Munich, Germany; 5University of Leeds, Leeds, United Kingdom; 4Kanagawa Cancer Treatment Center, Yokohama, Japan; 2Maastricht University Medical Center+ F, Maastricht, Netherlands.

Gastric cancer (GC) is the third leading cause of cancer-related death worldwide. With the advent of immunotherapies, there is a need to characterize the phenotype of tumor infiltrating immune cells and co-localized cancer cells. We have shown previously that high density of CD45RO+ T cells is related to better prognosis in Japanese GC. However, the variation of T-cell infiltration in GC is still not understood. We hypothesized that the timing of CD8+ T-cell infiltration is related to the patient’s spatial and temporal windows. The purpose is: To establish the frequency of co-occurrence of Ki67+ and CD8+ in T cells and their co-localization with tumor cells and evaluate the relationship with clinicopathological variables including survival. Patients and Methods: Immunohistochemistry for T cells (CD8), proliferation (Ki67), and epithelial cells (CK) was performed on tissue microarrays (TMA) from 213 GC from the Kanagawa Cancer Centre Hospital (Yokohama, Japan). Stained slides were scanned, quality controlled, and analyzed using Tissue Phenomics (Definium, Munich, Germany) for cell/nuclei segmentation and automatic co-registration of consecutive sections. The TMA cores were subdivided into tiles of size 64 μm2 to count co-localized positive cells. Average ratio of CD8+ cells and Ki67+ cells per tile/patient was used for statistical analyses. The relationship with pT, pN and histological tumor type was assessed using the Kruskal-Wallis test. Prognostic features were determined by univariate stratification which optimizes Kaplan-Meier p-value using 50 independent pre-validated with 3 folds and ranked by the median pre-validated p-values. P-values < 0.05 were considered significant. Results: 60887 tiles were analyzed in total. Median (range) number of tiles analyzed per patient was 291 (81-345). Median (range) CD8+/Ki67+ ratio was 0.39 (0.01-0.92). Manual inspection of selected image tiles showed that CD8+ cells are rarely Ki67-. Median (range) % of tiles/patient where CD8+ and Ki67- co-localized with Ki67+ tumor cells was 17% (0%-93%). Significant difference of ratio was observed between histological subtypes (p = 0.0096). There was no significant relationship between CD8+ and Ki67+ and pT or pN. A high CD8+/Ki67+ ratio was related to better survival (p = 0.012). Conclusion: This is the first study to suggest that the majority of CD8+ T cells in GC appear to be resting (Ki67-) T cells rejecting our hypothesis that high numbers of intratumoral T cells are due to high intratumoral T cell proliferation. The co-localization of CD8+ T cells and Ki67+ tumor cells seems to be clinically relevant and characterizes certain histological phenotypes in GC. However, the potential underlying biological mechanisms of interaction between T cells and tumor cells is currently unknown. Further studies are needed to validate our findings and characterize the interface between tumor and immune cells.

#3959 CCL18-recruited naive CD4+ T cells are converted to tumor-infiltrating regulatory T cells in breast cancer and suppress antitumor immunity. Shiceng Su, Jianyou Liao, Jiang Liu, Qiang Liu, Erwei Song. SunYat-Sen Memorial Hospital, SunYat-Sen University, Guangzhou, China.

Tumor-infiltrating regulatory T cells (Tregs) play a central role in tumor immunosuppression. However, it remains unclear whether they are directly recruited from peripheral blood or converted from infiltrating naive T cells. Here, full-length TCR α/β repertoire analysis of different T cell subsets from peripheral blood, primary tumors and draining lymph nodes in patients suggests that Tregs in human breast cancer are mainly converted from tumor-infiltrating naive CD4+ T cells. Infiltration of naive CD4+ T cells and Tregs are closely correlated, both indicating poor prognosis for breast cancer patients. Naive CD4+ T cells in the tumors are recruited by tumor-associated macrophages (TAMs) via CCL18. In addition, naive T cells and memory T cells exhibit distinct chemotactic response due to different expression of regulator of G-protein signaling 1 (RGS1). Specific silencing CCL18 receptor-PTPN3M in naive CD4+ T cells using CD4 aptamer-siRNA blocks their chemotaxis, and thus reduces infiltrating Tregs and inhibits tumor progression in humanized mice. By comparison, silencing RGS1 in memory CD8+ T cells using CD8 aptamer-siRNA blocks their recruitment to tumors and anti-tumor immune response in vivo. These findings provide mechanistic insights for Treg enrichment in breast cancer and suggest that modification of the CCL18-PTPN3M-RGS1 signaling pathway may be an attractive strategy for anticancer immunotherapy.

#3960 Tumor cell drug resistance induced by the programmed death ligand 1 (PD-L1) immune checkpoint is associated with autophagy. Loni M. Minassian, Shannyn K. MacDonald-Goodfellow, Peter Truesdell, Daniel Sanwal, Andrew W. Craig, Madhuri Koti, D Robert Siemens, Charles H. Graham. Queen’s University, Kingston, Ontario, Canada.

The interaction between the Programmed Death Ligand 1 (PD-L1) immune checkpoint on the tumor cell surface with the Programmed Death-1 (PD-1) receptor on cytotoxic T lymphocytes (CTLs) leads to CTL inactivation, thereby promoting tumor cell escape from adaptive immunity. We previously demonstrated that signaling by PD-L1/PD-1 is bidirectional and leads to activation of oncogenic pathways as well as drug resistance in tumor cells. We also have preliminary evidence that Immunity Related GTPase, an important mediator of autophagy, is up-regulated by PD-1/PD-L1 reverse signaling. Autophagy is a well-established mechanism of drug resistance in cancer cells. This led us to hypothesize that PD-1/PD-L1 signaling induces drug resistance in tumor cells by up-regulating autophagy. The MEK/ERK and the PI3K/Akt signaling pathways are known to increase and decrease autophagy, respectively. Breast cancer cells exposed to PD-1 showed a time-dependent increase in extracellular signal-regulated kinase (ERK) activation and a decrease in protein kinase B (Akt) activation. Conversion of microtubule-associated protein light chain 3 (LC3-I) to LC3-II is a requirement for autophagosome formation and is a robust marker of autophagy. Exposure of human breast cancer cells to recombinant PD-1 (PD-1) showed a time-dependent increase in LC3-II. We are currently conducting additional studies to confirm that the activation of PD-L1 signaling in tumor cells up-regulates autophagy. These results provide evidence that PD-1/PD-L1 reverse signaling activates autophagy as a potential mechanism of cancer cell chemoresistance. (Supported by a grant from the Canadian Institutes of Health Research.)

#3961 Increased CCR4-positive regulatory T cells in biopsy specimen of poor prognosis prostate cancer. Masahito Watanabe, Kent Kano, Susumu Suzuki, Hiroyuki Muramatsu, Shingo Morinaga, Keishi Kajikawa, Ikuo Kobayashi, Genny Nishikawa, Yoshiharu Kato, Kogenta Nakamura, Kazuhiro Yoshikawa, Ryozu Ueda, Makoto Sumitomo. Aichi Medical University, Nagakute, Aichi, Japan.

Introduction & Objective: Regulatory T cells (Treg) play important roles in suppression of the immune response, including anti-tumor immunity. C-C chemokine receptor 4 (CCR4) is highly expressed on effector Tregs, and the anti-CCR4 antibody is attracting attention as a novel immunotherapeutic agent for solid tumors. The purpose of this study was to evaluate the expression of CCR4-positive Tregs in biopsy specimens of men with prostate cancer with a poor prognosis and to estimate the clinical potential of CCR4-targeting therapy for prostate cancer. Material & Methods: Data for 60 men diagnosed with prostate cancer based on transrectal 12-core systemic biopsy were retrospectively analyzed. They were divided into two groups, a good prognosis group comprising men with no disease progression during the observation period and a poor prognosis group comprising men with progression to castration resistant prostate cancer. In the biopsy cores, the core with the highest tumor volume was selected for immunohistochemical evaluation. Tregs were evaluated using immunohistochemistry with double staining using anti-forkhead box protein 3 (FOXP3) antibodies and anti-CCR4 antibodies. The number of CCR4+/-FOXP3+ cells in the biopsy specimens were compared between the two groups. Furthermore, the correlation between the number of CCR4+/-FOXP3+ cells and clinical stage, PSA at diagnosis, and Gleason score were evaluated. Results: The good prognosis group included 29 men and the poor prognosis group included 31 men. Approximately 70-80% of FOXP3+ cells were positive for CCR4. There was no significant difference in the ratio of number of CCR4+/-FOXP3+ cells to the number of total FOXP3+ cells between the poor and good prognosis groups. However, the total number of FOXP3+ cells significantly increased in the poor prognosis group than in the good prognosis group (200.1 ± 174.8 vs. 38.1 ± 38.1, p < 0.01). Furthermore, the number of CCR4+/-FOXP3+ cells significantly increased in the poor prognosis group than in the good prognosis group (123.6 ± 99.1 vs. 58.88 ± 26.4, p < 0.01). The number of CCR4+/-FOXP3+ cells
**#3962 High-dimensional flow cytometric immune profiling of malignant gliomas.** Amber J. Giles,1 Caitlin M. Reid,1 Deric M. Park,2 Mario Roederer,2 Mark R. Gilbert1.1NCI-NIH, Bethesda, MD; 2NIAD-NIH, Bethesda, MD.

**INTRODUCTION:** Immune therapy is emerging as a treatment modality for patients with solid tumors including intracranial metastases. Similar immune strategies are being tested in patients with malignant gliomas; diseases with uniformly poor prognosis. Whereas, recent work has demonstrated a correlation between the immune landscape of solid tumors and response to immune therapy, the immunologic landscape of CNS tumors has not been thoroughly defined. To capture the phenotypic diversity of immune cells in CNS tumors, we developed an 18-color flow cytometry panel and applied it to mononuclear cells isolated from acutely resected brain tumor, matched patient blood, and healthy donor blood specimens. **METHODS:** Linear discrimination analysis (LDA) and T-distributed stochastic neighbor embedding (tSNE) dimensionality reduction techniques were used to analyze flow cytometry data acquired from brain tumor, patient-matched peripheral blood, and healthy donor peripheral blood specimens. **RESULTS:** LDA of 13 parameters collected by flow cytometry revealed that CD8+ tumor-infiltrating lymphocytes (TILs) differed notably from peripheral blood. Lymphocyte clusters created from TILs were easily distinguished from clusters enriched in peripheral blood. Analysis of TIL clusters identified markers consistent with activated/memory populations as well as elevated levels of CTLA-4 (TILs) and CD3 (peripheral blood) provided the greatest degree of separation. Using the tSNE algorithm to analyze the same 13 parameters on CD8 T cells, we rapidly reduced 78 potential parameter combinations by creating a clustering pattern representing lymphocytes with similar staining patterns. Lymphocyte clusters created from TILs were easily distinguished from clusters enriched in peripheral blood. Analysis of TIL clusters identified markers consistent with activated/memory populations as well as elevated levels of CTLA-4, LAG-3, and PD-1 relative to peripheral blood; due to a higher percentage of cells expressing these markers rather than increased expression on individual cells. Identifying individual specimen points as well as clusters of specimens (e.g. patients with the same tumor classification), enabled comparisons across individual patient specimens (intra-patient blood vs tumor), across tumor type or grade, and across disease state (patient vs healthy donor). **CONCLUSIONS:** Dimensionality reduction techniques provided a rapid means to identify markers that were differentially expressed in TILs relative to peripheral blood. Importantly, these analyses were unrestricted by canonical gating strategies. CD8 TILs express multiple markers of activation and maturation, suggesting reactivity to tumor antigens and potential for immune therapy. Application of these analyses to a broader patient population will reveal the immunologic landscape of primary CNS tumors and provide insight into the immunologic consequences of current therapies. Further, this may lead to identification of specific immune signatures that may predict therapeutic response to immune therapy.

**#3963 Neoadjuvant chemotherapy promotes prometastatic changes in the primary breast tumor microenvironment in mice and humans.** George S. Karagiannis,1 Jessica Pastoriza,1 Jeanine Pignatelli,1 Yarong Wang,1 Allison S. Harney,1 David Entenberg,1 Ved P. Sharma,1 Emily Xue,1 Esther Cheng,2 Timothy M. D’Alfonso,2 Joan G. Jones,3 Jesus Anampa,3 Thomas E. Rohan,4 Joseph A. Sparano,5 John S. Condieels,1 Maja H. Oktay,1 Albert Einstein College of Medicine, Bronx, NY, 2Weill Cornell Medicine, New York, NY, 3Montefiore Medical Center, Bronx, NY.

Chemotherapy induces influx of bone marrow-derived proangiogenic Tie2+ monocytes in primary tumors. Tie2+ perivascular macrophages specifically induce the prometastatic Mena isoforms in tumor cells and can assemble specialized microanatomical sites called “tumor microenvironment of metastasis” (TMEM), structures that may serve as doorways for invasation of tumor cells in mammary tumors. Both TMEM and MenaNV are required for tumor cell invasation and dissemination. Thus, we hypothesized that chemotherapy may increase the density of TMEM sites and MenaNV-expressing, invasation-competent tumor cells, resulting in increased tumor cell invasation and metastasis. We studied these potential pro-metastatic effects of chemotherapy in a neoadjuvant setting (NAC) by either administering paclitaxel or a combination of doxorubicin and cyclophosphamide in several mammary carcinoma mouse and human breast cancer models. As expected, chemotherapy delayed tumor growth, yet it significantly increased the recruitment of TMEM-forming, perivascular Tie2+Vegf+ macrophages and TMEM density. Using high-resolution multiphoton intravital imaging in live tumor-bearing mice, we observed that paclitaxel also increased the activity of TMEM sites, visualized as endothelial cell tight-junction disruption around TMEM and subsequent intravasation of the migratory cancer cell subpopulation. Indeed, paclitaxel-treated mice have higher numbers of circulating tumor cells, single cell seeding in lungs and incidence and number of micrometastatic foci, all associated with increased TMEM activity, as demonstrated by high-resolution imaging techniques. Tie2 inhibitors reversed paclitaxel-induced pro-metastatic phenotypes without affecting the assembly of TMEM, indicating that Tie2-mediated signaling is required for paclitaxel-mediated cancer cell dissemination via TMEM. Paclitaxel also caused a significant increase in the expression of MenaNV at both the gene and protein levels. Furthermore, paclitaxel treatment in Mena−/− breast tumor-bearing mice resulted in failure to assemble TMEM and to increase circulating tumor cell numbers. Despite the fact that Tie2+ macrophages are attracted to perivascular niches as a result of paclitaxel treatment. This indicated that Mena is involved in the paclitaxel-mediated increase in cancer cell dissemination but not required for Tie2+ macrophage recruitment. These pre-clinical data are further supported by findings from a cohort (N=20) of breast cancer patients, who received pre-operative paclitaxel-based chemotherapy and demonstrated significant increases in TMEM density and MenaNV expression. Together, our data provide solid evidence that NAC leads to metastasis in rodent via TMEM/ MenaNV-mediated mechanisms, and to cancer cell dissemination in certain clinical scenarios in humans.

**#3964 Reducing systemic arginine with arginase (AEB1102) therapy does not suppress the immune response induced by anti-PD-1 and anti-PD-L1, and exerts an additive anti-tumor and synergistic survival benefit.** Giulia Agello, Susan E. Alters, David G. Lowe, Scott W. Rowlinson. Aegle BioTherapeutics Inc., Austin, TX.

Tumor dependence on specific amino acids for survival and proliferation is well recognized and has been explored effectively with the use of asparaginases for the treatment of acute lymphoblastic leukemia. Sensitivity of tumors to L-Arginine (L-Arg) deprivation results from an impaired ability to make L-Arg as a result of decreased functional expression of one or more of the three enzymes of the L-Arg biosynthetic pathway: ornithine transcarbamylase (OTC), argininosuccinate synthase (ASS1) and argininosuccinate lyase (ASL). Native human arginase I is not a viable drug candidate due to low activity and low stability in serum. We have developed an alternative approach using a bioengineered human PE Gyalted arginase I (AEB1102) with enhanced pharmacological properties. We and others have successfully utilized arginase I to impart a direct tumor cell killing effect through L-Arg starvation in multiple tumor types e.g. AEB1102 single agent efficacy in melanoma, small cell lung cancer (SCLC) and sarcoma PDx models. However, the compatibility of AEB1102 with checkpoint inhibitors is unclear as arginase I has been shown to be both immune suppressive and immune neutral (PMID: 23717444), or immune promoting (PMID: 27043409). Because of these conflicting reports we decided to investigate the impact of systemic L-Arg removal on the anti-tumor efficacy of checkpoint inhibitors. Murine syngeneic models (e.g. CT26, MC38 and LLC) were dose with AEB1102 alone and in combination with anti-PD-L1 and anti-PD-1 monoclonal antibodies (mAbs). Depending on the model, in vivo treatment with AEB1102 mono-therapy resulted in tumor growth inhibition (TGI) ranging from 52% to 72% compared to the untreated control group whereas standard monotherapy using immunomodulatory mAbs that target PD-1 and PD-L1 resulted in TGI ranging from 12% to 60%. Of significance, combination therapy of AEB1102 with anti-PD-1 or anti-PD-L1 resulted in additive anti-tumor effect with TGI ranging from 60% to 86%. In the CT26 model, when AEB1102 was administered in combination with anti-PD-L1 for at least 6 weeks, a 33% frequency of complete tumor regression (non-palpable tumors) was observed, indicating that synergy occurs with combination therapy. Collectively these results demonstrate that disrupting the L-Arg physiological balance in the tumor microenvironment inhibits tumor growth and further sensitizes the tumor to immunotherapy when AEB1102 is combined with anti-PD-1 and anti-PD-L1. These data open the possibility of further improving outcomes in L-Arg dependent tumors through combination of AEB1102 with anti-PD-1 and anti-PD-L1 inhibitors.

**#3965 Epithelial membrane protein-2 is a novel regulator of immune editing in breast cancer.** Jessica Tsui, Negin Ashki, Yuling Chang, Devon Patel, Jasmine Sjarif, Madhuri Wadhera. UCLA David Geffen School of Medicine, Los Angeles, CA.

Cancer immune-editing is a process that describes the interaction between immune cells and tumor cells. This interaction can result in elimination of a developing tumor, tumor dormancy, or tumor cells that are capable of surviving in an immune–competent host. We have recently uncovered a novel mechanism of immuneediting by the tetraspan protein Epithelial membrane protein or EMP2. We propose that EMP2 serves as a bridge between innate and adaptive
immunity via tumor mediated type I interferon expression. Most tumor cells evade the immune system through suppression or ignorance. EMP2 levels promote type I interferon expression which was found to correlate with PDL1 expression in a number of cell lines. Concordantly, in vivo, in multiple breast cancer cell lines, EMP2 promoted tumor growth. In contrast, reduction in EMP2 levels correlated with a reduction in tumor growth in a corresponding syngeneic mouse model. Given that tumors with lower levels of EMP2 grow poorly, we hypothesized that targeting EMP2 may provide a therapeutic benefit. Recently, we have developed a panel of novel IgG1 monoclonal antibodies to EMP2 and tested their ability to treat both xenograft and syngeneic mouse models. Our results show that anti-EMP2 IgG1 significantly reduces tumor load in both models in part through the recruitment of M1 macrophages. To explore this observation more fully, experiments using murine syngeneic models were employed. Anti-EMP2 therapy elicits a robust ADCC response, producing an immune infiltrate rich in macrophages, NK cells, and lymphocytes. In addition, we show that CD8 cells show reduced exhaustion in the presence of anti-EMP2 antibodies. Conclusions: EMP2 is a protein upregulated in a number of cancers in women including breast, ovarian, and endometrial tumors. Our work collectively show that EMP2 is a novel immune regulator where its expression creates an immunosuppressive tumor microenvironment. We thus predict that targeting EMP2 may improve therapeutic outcomes for cancers in women.

**#3966 Targeting integrin αβ3-expressing cancer stem cells to manipulate tumor-associated macrophages.** Hiromi I. Wettersten, Toshiyuki Minami, Megan M. Kaneda, Laetitia Seguin, Judith A. Varner, Sara M. Weis, David A. Cheresh, UC-San Diego, La Jolla, CA.

Tumor associated macrophages are involved in regulation of cancer growth and aggressiveness. Whereas M1 macrophages trigger an inflammatory response and inhibit tumor growth, M2 macrophages secrete pro-tumor cytokines into the microenvironment to support tumor progression. A macrophage switch from M1 to M2 has been associated with lung cancer progression, and cancer stem cells have been implicated as a driver of this reprogramming. We recently reported that integrin αβ3 expression is induced on lung adenocarcinoma cells during drug resistance and is both necessary and sufficient to reprogram these tumors to a stem-like state. Given the role that cancer stem cells play in switching M1 to M2 macrophages, we asked whether αβ3 expression on lung adenocarcinoma cells account for this macrophage conversion. The M1/M2 macrophage ratio in αβ3-positive tumors was markedly decreased relative to tumors lacking αβ3. We next treated mice bearing αβ3-positive tumors with a monoclonal antibody (LM609) targeting this receptor to assess its ability to alter the macrophage phenotype within these tumors. LM609 was able to selectively eliminate the αβ3-positive cancer stem cells via antibody-dependent cell-mediated cytotoxicity (ADCC), and this not only increased the M1 macrophage population, but also markedly enhanced the sensitivity of these tumors to the effects of these therapies. These findings reveal that αβ3-expressing cancer stem cells favor the pro-tumor M2 macrophage phenotype. Eliminating αβ3-positive cancer stem cells via ADCC serves to both increase pro-inflammatory macrophages within the tumor microenvironment and prolong tumor sensitivity to therapy.

**#3967 High microsomal PGE synthase-1 levels associate with low CD8 T cells and poorer melanoma patient survival.** Sun-Hee Kim, Jason Rozsik, Weiyi Peng, Suhendan Ekmekcioglu, Elizabeth A. Grimm. UT MD Anderson Cancer Ctr., Houston, TX.

COX-2 and its product PGE2 are reported to enhance carcinogenesis and tumor progression and to support immunosuppression, as reported by others in melanoma and other cancers. As most COX-2 inhibitors result in cardiotoxicity, the downstream microsomal PGE2 synthase-1 (mPGES1) is now also an alternative consideration for therapeutic targeting. Our previously published results (Kim, et al., 2016) showed that mPGES1 protein increased with melanoma patient clinical stage and that its intense expression was associated with reduced patient survival. We also reported that mPGES1 inhibition attenuated cell survival and metastasis in human melanoma cells and significantly suppressed tumor growth in melanoma xenografts. This current study was designed to evaluate whether expression of mPGES1 contributes to immune evasion. Tumors in a Stage III melanoma TMA analysis demonstrated that high mPGES1 expression (intensity 3) was significantly associated with low CD8 levels (lower than median CD8 percent value) (r=-0.2722, p=0.0128). Importantly, stage III melanoma patients with this high mPGES1 and low CD8 signature had significantly increased risk of death as determined by Kaplan-Meier method and Uni- variate Cox proportional hazards regression models, and compared with patients with low mPGES1/low CD8 and low mPGES1/high CD8. Furthermore, the differential levels of several chemokines including CXCL1 and CXCL2 to regulate T cell migration were correlated the mPGES1 expression in the TCGA melanoma data set. Collectively, our study continues to resolve the potential role of mPGES1 in regulation of immune evasion and is designed as a preclinical approach to develop a rational therapeutic strategy targeting PGE2-driven inflammatory mediators as useful adjuncts for immune-based therapy.

**#3968 Canonical NFκB signaling in myeloid cells is required for the glioblastoma growth.** Bhagel R. Achuty, Jennifer Bradford, Kartik Angara, Mohammad Rashid, Meenu Jain, Thaiz Borin, ASM Iskander, Roxan Ara, Ali Arbab. Augusta University, Augusta, GA.

Glioblastoma (GBM) development and therapeutic resistance has been accompanied with the tumor-associated macrophages (TAMs) in the tumor microenvironment (TME). TAMs are heterogeneous cell populations of immune regulatory myeloid-derived suppressor cells (MDSCs) and polarization of anti-tumor macrophages (M1) into pro-tumor macrophages (M2). We investigated the role of myeloid cell NF-κB signaling in orthotopic GBM model using immune deficient and immune competent hosts. Interestingly, conditional deletion of canonical NF-κB signaling (p65) with Lysm-Cre (p65 KO) in myeloid cells, significantly inhibited syngeneic GL261 tumor growth in immune-compotent mice compared to control mice. We studied the TAMs recruitment to the tumor and their polarization under the influence of TME. p65 KO mice displayed decreasing trend of immune cell infiltration (CD45), which phenotyped as decreased F4/80+, CD68+, CD206+ (M2) and Gr1+CD11b+ (MDSCs) macrophages, compared to control mice. This was associated with the increased CD80+ (M1) macrophages, increasing trend of CD4+ and CD8+ cytotoxic T cells, and decreased CD4+ and mesenchymal cancer stem cells (CSCs) population in the TME. Cytokine array data indicated that loss of canonical NF-κB signaling within the TAMs was implicated in increased production of INFγ, IFGI, MCP1, MIP1α, and TNFα cytokines. Co-culture of T cells with p65 KO or control MDSCs identified increased proliferation of T cells with p65 KO MDSCs compared to control MDSCs. Conversely, GBM patient-derived xenografts and U251 GBM cell-line-derived tumors showed increasing trend of growth in immune-deficient mice, following the transplantation of p65 KO bone marrow (BM) compared to control BM. Pro-tumor macrophages and CSCs were increased and T cell populations were decreased in human tumors grown in immune deficient mice transplanted with p65 KO BM, compared with control BM. In addition, analysis of human data set revealed higher expression of p65 subunit of NF-κB complex in brain tumor stroma compared to the tumor cells. This study suggests that canonical NF-κB signaling in TAMs is required for the tumor-promoting macrophage polarization and GBM growth in immunocompetent host compared to immune deficient host. Therefore, targeting myeloid-specific NFκB signaling in GBM could inhibit the immune suppressive TAMs and improve the anti-tumor immunity.

**#3969 AFIq/MBL11 regulates the expression of intercellular adhesion molecule-1 in breast cancer.** Jin Park, Soojin Kim, William Tse. Univ. of Louisville, Louisville, KY.

Intercellular adhesion molecule-1 (ICAM-1) is a cell surface glycoprotein in the immunoglobulin superfamily. ICAM-1 expression is frequently observed on many cell types including endothelial cells and different cancer cell entities. ICAM-1 expression is strongly correlated with a reduction in tumor size and a correlation with metastatic capacity. The specific signaling pathways in cancer cells leading to enhanced cell motility, invasion and metastasis. In clinical investigation, however, ICAM-1 expression was negatively correlated to tumor size, lymph node metastasis, and tumor infiltration. Also, there was improved relapse-free and overall survival in patients with ICAM-1 positive tumors. Yet, the function of ICAM-1 expression during malignant progression in breast cancer patients is not understood clearly. However, ICAM-1 is still considered as a breast cancer target and biomarker may lead to the development of a new strategy and platform for breast cancer patients. We observed AFIq, a metastasis enhancer, is only expressed in metastatic cells, MDA-MB-231LN (invasive sub line from MDA-MB-231), not in the primary tumor cells. To investigate whether AFIq has a responsibility in acquisition of metastatic phenotype, we performed RNASeq and applied the Metacore network building algorithm. Intriguingly, most genes were directly linked with Intercellular Adhesion Molecule-1 (ICAM-1). Likewise, we identified that ICAM-1 expression is attenuated in MDA-MB-231LN compared to MDA-MB-231. Moreover, the expression of ICAM-1 was negatively regulated, when AFIq was overexpressed in MDA-MD-231LN. Suppressed endogenous AFIq by shRNA could effectively increase the ICAM-1 expression. Attenuation of ICAM-1 by AFIq on tumor cells would disadvantage host anti-tumor defenses by trafficking of lymphocytes, which affect tumor progression and metastasis. We observed that NF-κB activity which regulates ICAM-1 expression is attenuated in response to AFIq expression in breast cancer cells. Published reports...
shown that Wnt/β-catenin negatively regulates NF-κB activity through protein-protein interaction in colon and breast cancer cells. Previously, we reported that AF1q enhances the TCF7/LEF/β-catenin complex binding affinity as a cofactor. Structurally, AF1q has highly acidic peptide regions highly conserved between species that fulfill the criteria for an acidic blob, a typical feature for cofactors. When we performed immunoprecipitation with NF-κB antibody in MDA-MB-231LN overexpressed AF1q, we observed that β-catenin and AF1q were pulled down together. However, it is not clear yet whether AF1q promotes protein interaction between β-catenin and NF-κB. These results suggest that activated β-catenin by AF1q would achieve higher affinity to bind with NF-κB and thereby attenuate ICAM-1 expression.

#3970 Targeting the adenosine immunosuppressive pathway for cancer immunotherapy with small molecule agents. Pierre Fons,1 Michael Esquerré,2 Stéphanie Verslues,1 Giglida Mambrini,1 Michael Paillasse,1 Andy Bell,2 Adrian Schreyer,1 Richard Cox,3 Richard Bickerton,1 Jobsan Listzwan,1 Mark Whittaker,1 Françoise Bono,1 Craig Johnstone,1 Andrew Hopkins3. EVOTEC, Touhouse, France; 2 Exscientia, Exdorf, United Kingdom

Adenosine (ADO) is released by tumor cells and suppresses T cell immune response by binding to A2A and A2B receptors. The A2A receptor is predominantly expressed on regulatory T cells (Tregs). A2A receptor activation by adenosine is known to induce upregulation of cyclic GMP (cGMP) levels in Tregs. cGMP further inhibits NO production by Tregs. Thus, the adenosine-A2A receptor pathway can be a potential target for cancer immunotherapy. We previously reported that the A2A receptor antagonist CGTHW1 (CGTHW1) that is known to have anti-tumor effect is not only a potential immunomodulator but also significantly increases anti-tumor effect when combined with anti-PD-1 immunotherapy. This is most likely due to the fact that the A2A receptor is expressed on a wide range of immune cells including T cells, Tregs, dendritic cells, and macrophages. Thus, targeting A2A receptors can be used as a strategy to enhance T cell mediated antitumor immune responses. We therefore investigated the adenosine receptor binding affinity and capacity of a newly developed small molecule A2A receptor antagonist EV-163. We performed a Biacore analysis to determine the binding affinity of EV-163. A2A receptor was covalently immobilized on a sensor chip. EV-163 was serially injected to the Avant chip and the accumulation of EV-163 was measured using the response units (RU). The maximum response (MRU) and equilibrium dissociation constant (KD) were determined using a standard curve and equilibrium binding analysis respectively. EV-163 had a KD value of 440 nM, which is comparable to the KD value of CGTHW1. We further performed a competition binding assay using different concentration of EV-163 in the presence of 100 nM of A2A agonist (ectoA2A) to determine the receptor capacity of EV-163. The competition binding assay was performed with a fixed concentration of 250 nM A2A receptor and varying concentrations of EV-163. The inhibition of A2A agonist was determined by measuring RU. EV-163 was able to competitively inhibit the binding of A2A agonist with a high capacity. The IC50 of EV-163 was found to be 0.8 nM. These results indicate that EV-163 can be a potential small molecule A2A receptor antagonist for cancer immunotherapy.

#3971 MTA-mediated inhibition of human T cells: Mechanism and Ex vivo profiling of PD-1 blockade using organotypic thyroid spheroids. Carolin D. Strobl,1 Frederik Henrich,2 Katrin Singer,2 Katrin Peter,2 Marina Kreutz,2 Anita Kremmer,1 Andreas Mackensen,1 Michael Aigner3.1 University Hospital Erlangen, Erlangen, Germany; 2 University Hospital Regensburg, Regensburg, Germany

Metabolic changes of malignant cells lead to the secretion of tumor metabolites which contribute to the shaping of a favorable milieu for tumor immune escape facilitating cancer development and resistance to anti-tumor immunotherapy. Recent studies have shown that methylthioadenosine (MTA) as a tumor-specific metabolite is capable to interfere with signal transduction pathways and to induce programmed cell death. We therefore investigated the secreted cytokine/chemokine response to PD-1 blockade using organotypic thyroid spheroids (MTDS/PDTS) in a 3-dimensional microfluidic system. Spheroids derived from fresh mouse and human thyroid cancer samples through partial collagenase digestion and filtration retain autologous tumor infiltrating immune cells, including PD-1 positive CD8 T lymphocytes. Using murine syngeneic mouse cancer models with known responsiveness or resistance to PD-1 blockade, we demonstrate the ability to recapitulate tumor killing ex vivo or lack thereof. Multiplexed cytokine profiling of conditioned media in this system further enables characterization of the cytokine response to PD-1 blockade across a large panel of PDTS, and observed pronounced induction of CCL19/CXCL13, which associated with %PD-1 positive CD8 T cells. This strategy further uncovered the secreted cytokine profile of tumor-derived cytokines and cytokine responses in the combined effect of MTA and PRMT5 inhibition on T cells. Several metabolic studies focusing on glycolysis and fatty acid metabolism could confirm our findings that MTA keeps T cells in a rather inactive, naïve state. Finally, we found MTA to interfere with DC maturation and their potential to induce cytokine production by activated T cells. Our studies provide a new perspective on the crucial role of MTA in the tumor milieu for immune escape and open up new strategies for targeting immune escape in a personalized manner.
folicular and anaplastic thyroid cancer exosomes was observed, when compared to papillary thyroid cancer exosomes. We detected a down regulation of miR-138-5p, miR-146a-5p, miR-26a-5p, miR-26b-5p, miR-34a-5p and miR-31-5p in anaplastic and folicular thyroid cancer exosomes, which may play a role in promoting cancer invasion and metastasis. In comparison to papillary thyroid cancer exosomes, with surprising miR-214-3p, miR-298-5p, miR-299-3p and miR-302a-3p was ascertainment in folicular thyroid cancer exosomes. Conversely, we noted a down regulation of these miRNAs in anaplastic thyroid cancer exosomes. These distinct miRNA expressions in cancer secretome will provide new insights into the tumor development and dissemination. Our findings suggest an important crosstalk between the secretome of thyroid cancer cells and immune cells in tumor microenvironment, defining thyroid cancer phenotype. These exosomal miRNA serve as early diagnostic markers of thyroid cancer differentiation as well as targets for novel therapies specifically for anaplastic thyroid cancer.

### #3974 Gender specific function of epithelial IL-6-STAT3 pathway in K-ras mutant lung cancer. Mauricio S. Caetano,1 Hieu Van,1 Emmanuel Bugarin,1 Amber Cumpian,1 Christina L. McDowell,1 Huiyuan Zhang,1 Scott E. Evans,1 Stephanie Watowich,1 Human Kadara,2 Seyed J. Moghaddam,1 UT MD Anderson Cancer Center, Houston, TX;2 American University of Beirut, Beirut, Lebanon.

Activating mutations of K-ras are the most common oncogenic alterations found in lung cancer, and are heavily associated with tobacco exposure and poor prognosis. Using a conditional lung cancer model (CC-LR), we showed that K-ras mutant lung tumors have inflammatory characteristics with activation of NF-kB pathway, release of IL-6 and activation of its downstream target, STAT3. We further demonstrated that IL-6 blockade results in significant tumor reduction as well as decreased pSTAT3 expression, tumor cell proliferation, angiogenesis and a reduction in tumor-associated immune suppressive myeloid populations concomitant with induction of an anti-tumor phenotype. These indicate essential autocrine and paracrine roles for IL-6-STAT3 pathway in promotion of K-ras mutant lung cancer, largely via perpetuating inflammation introducing it as a vulnerability factor for this type of tumors. Here we generated a lung epithelial specific K-ras mutant/STAT3 conditional knockout mouse (LR/STAT3Δ/Δ) to further study the role of epithelial STAT3 activity in K-ras mutant lung cancer. We found that in female mice, lack of epithelial STAT3 inhibited lung cancer, and significantly decreased the lung inflammatory cell population, particularly macrophages, whereas in male mice, STAT3-deficiency surprisingly promoted lung cancer and significantly increased lung neutrophil population. To understand genome-wide mechanisms underlying this intriguing gender disparity, we performed RNA-sequencing of whole lungs from male and female LR/STAT3Δ/Δ and control CC-LR mice. Using a mixed effects model, we found 339 transcripts that were significantly modulated differently between LR/STAT3Δ/Δ and control CC-LR mice in males relative to females. Pathways and gene network analyses of the transcripts demonstrated that lungs of male LR/STAT3Δ/Δ mice exhibited markedly reduced Th1 immune T-cell signatures. We corroborated these findings and found significant phenotypic change in the lung tumor microenvironment (TME) with male mice exhibiting increased pro-tumor inflammatory markers. Markedly, we found opposing IL-6 expression patterns with LR/STAT3Δ/Δ females expressing low IL-6 while LR/STAT3Δ/Δ males expressed high levels of IL-6. We then blocked IL-6 in male LR/STAT3Δ/Δ mice, which resulted in a significantly reduced lung tumorigenesis, and reformatted lung TME towards an anti-tumor phenotype with a Th1/CD8+ T-cell signature. By contrast, estrogen receptor (ER) signaling blockade by tamoxifen in female LR/STAT3Δ/Δ mice promoted lung cancer, and reprogrammed lung TME toward a pro-tumor phenotype with an increase in Th17/Treg cell signature. Taken together, we conclude that epithelial STAT3 signaling has an important gender-specific role with autocrine and paracrine effects in K-ras induced lung tumorigenesis, which might be mediated by the interplay between ER signaling, and NF-kB mediated cytokine network.

### #3975 Ovarian cancer cells release arginase-1-containing exosomes to suppress antitumor immune response. Malgorzata Czystowska,1 Marta Szajnik,2 Kavita Ramji,1 Slawomir Gruca,1 Artur Stefanowicz,1 Jakub Golab,1 Do- minika Nowis,1 Malgorzata Czystowska,1 Marta Szajnik,2 Kavita Ramji,1 Slawomir Gruca,1 Artur Stefanowicz,1 Jakub Golab,1 Dominika Nowis,1 Medical University of Warsaw, Warsaw, Poland;2 Military Institute of Medicine, Warsaw, Poland;3 Praski Hospital, Warsaw, Poland.

Background: Depletion of essential (L-tryptophan) or semi-essential (L-arginine) amino acids has been shown to suppress antitumor immune responses. Arginase-1 (Arg-1) is a cytosolic enzyme catalyzing degradation of L-arginine to L-ornithine and urea. Several studies have shown the presence of abundant Arg-1 in either tumor cells or in tumor-infiltrating myeloid cells of neutrophilic or monocytic origin. This in turn, leads to downregulation of CD3-zeta levels in T cells and correlates with suppressed antitumor immunity and anti-tumor innate immunity. Metabolites released by tumor cells (TEX) are detected in body fluids including plasma or ascites and carry proteins that are expressed by OvCa cells. Here we report that OvCa cells release Arg-1 in TEX and investigate the influence of OvCa TEX-derived Arg-1 on the antitumor effector mechanisms of immune response. Methods: TEX were isolated by ultracentrifugation or exclusion chromatography and verified by Western blotting, NanoSight and electron microscopy. The presence of Arg-1 in TEX was determined by Western blotting and the Arg-1 activity was assessed using an enzymatic assay that measured conversion of arginine into urea. Immunohistochemical Arg-1 expression data in primary OvCa lesions were correlated to clinico-pathological characteristics. Effects of TEX Arg-1 on immune cells were analyzed by in vitro proliferation assay and flow cytometry. Results: OvCa ascites contained higher levels of exosomal Arg-1 as compared with the fluids obtained from benign ovarian cysts. Enzymatically active Arg-1 was detected in TEX derived from patients’ ascites as well as from ovarian cancer cell lines. High Arg-1 expression in correlated negatively with intratumoral T-cell infiltrates and CD3-zeta expression and was associated with shorter time to recurrence (TTTR). In vitro, OvCa-derived Arg-1-positive TEX inhibited CD8+ and CD4+ T-cell proliferation and decreased T-cell receptor expression. We also observed that co-culture of bone-marrow-derived dendritic cells (DC) with TEX isolated from OvCa cells results in the transfer of functionally active Arg-1 that inhibits DCs-primed proliferation of OVA-antigen specific OT-1 T cells. We have used TEX isolated from OvCa cells transfected with V5-tagged Arg-1 for these experiments to ensure that this is OvCa-derived, but not endogenous DC-derived arginase that suppresses T cell proliferation. All these in vitro effects were reversed by a novel Arg-1 inhibitor (OAT-1746). Conclusions: Our findings provide the first evidence for the role of Arg-1 in the formation of an immunosuppressive microenvironment in OvCa. We identify a novel mechanism of exosomal Arg-1 distribution from the tumor cells to antigen presenting cells. Inhibition of Arg-1 activity may be an attractive novel anti-cancer strategy. Funding: NCN - OPUS 6 Program 2013/11/B/ NZ6/02790, NCbir – STRATEGMED2/265503/3/NCbir/15.

### #3976 Resolving cellular complexity in renal cell carcinoma with droplet-based single cell transcriptomics. Siva Vijayakumar, Mohan Bolisetty, Santosh Sivajothi, Paul Robson. The Jackson Laboratory, Farmington, CT.

Purpose: The development, growth, invasion and metastasis of cancer is supported and sustained by crosstalk between the stromal cells, cancer cells and immune cells through autocrine and paracrine signaling, influencing many stages of cancer progression. Furthermore, understanding the identity of the tumor infiltrated immune cell populations is known to predict survival outcomes. Kidney cancer is the 12th most prevalent cancer in the world and is predicted to affect 62,700 new cases in 2016 in the United States alone (American Cancer Society). Existing studies on renal cell carcinoma utilizing bulk profiling methods have been unable to deconvolute the role of the various cell types in promoting the progression this cancer type. Method: Single cell transcriptomics of primary tumors is a powerful approach to study not only the cancer cells but also the cells of the microenvironment. We profiled the various cell types that comprise primary renal cell carcinoma using the Chromium Single Cell 3’ system (10X Genomics). Results: With this single cell approach, we have generated thousands of single cell transcriptomes leading to the identification of numerous cell types and cell states in renal cell carcinoma and matched normal kidney. The microenvironment of renal cell carcinoma tumors contains a heterogeneous mix of stromal, immune and kidney cell types. Compared with the matched normal, the tumors are heavily infiltrated with lymphocytes, mast cells and cells of the myeloid lineage. We identified pathways enriched in specific cell types that illuminate potential mechanisms underlying the cell-cell interactions between cancer cells, stromal cells, and the infiltrating immune cells thus highlighting potentially new targeting strategies for the treatment of this disease. In addition, the single cell data described here will be used to deconvolute existing and new bulk analyses of renal cell carcinoma patients and to establish targeted antibody panels for use in flow and imaging mass cytometry. We anticipate both will lead to better patient stratification to inform patient-specific treatment regimes. Conclusion: Droplet-based single cell transcriptomics can successfully identify the numerous cell types that comprise a tumor, providing a foundation of knowledge to inform biomarker selection and patient-stratification.

TUMOR BIOLOGY: Tumor Microenvironment 5
provide insight into novel treatment strategies. This approach reflects a more comprehensive view of renal tumors that is often masked by bulk profiling analyses.

#3977 Neutrophils fertilize the pre-metastatic omental niche in ovarian cancer. Wonjae LEE, Honami Naora. MD Anderson Cancer Center, Houston, TX.

More than 60% of ovarian cancer patients present with peritoneal carcinomatosis that almost always involves the omentum, a fat pad that suspends from the stomach. However, the mechanisms that promote the tropism of ovarian cancer cells for the omentum are poorly understood. Because the omentum is the major peritoneal conduit and reservoir for immune cells, we hypothesized that immune cells control the propensity of ovarian cancer cells to implant on the omentum. In this study, we evaluated changes in immune cell populations in the omentum and in other visceral fat pads in the peritoneal cavity in mouse xenograft models of ovarian cancer. Intriguingly, the proportion of neutrophils was observed to dramatically increase in the omentum prior to tumor cell implantation at this site. On the other hand, the proportion of neutrophils did not substantially increase in other visceral fat pads. Furthermore, the proportion of macrophages did not significantly increase in any of the fat tissues prior to tumor cell implantation. Collectively, these findings raise the possibility that early recruitment of neutrophils to the pre-metastatic omental niche promotes a microenvironment that is conducive to ovarian cancer cell implantation at this site.

Aberrent expression of the B7-H1/PD-L1 immunomodulatory molecule is evident in many forms of cancer. The evidence for increased protein levels of B7-H1/PD-L1 comes largely from immunohistochemistry analysis of surgical and biopsy specimens. While several studies attempt to correlate B7-H1/PD-L1 expression with poor prognosis, there are studies that conclude no correlation based on technical difficulties associated with detecting B7-H1/PD-L1 protein expression on the cell surface. We were able to quantitatively measure soluble B7-H1/PD-L1 in conditioned medium from tumor cell cultures using two new immunomassays, a Quantikine® ELISA and a Simple Plex™ Assay. We show that breast, prostate, glioma, and non-Hodgkin’s lymphoma cells express various levels of B7-H1/PD-L1 which correlate to their PTEN or proliferation status. This is in agreement with previous findings showing that increases in B7-H1/PD-L1 expression levels are frequently coincident with loss of the PTEN tumor suppressor or increased activation of the phosphoinositide 3-kinase (PI 3-K) pathway. The androgen-responsive LNCaP prostate cancer cell line does not exhibit measurable B7-H1/PD-L1 in any instance, while the androgen-independent prostate cancer cell line PC-3 expresses measurable B7-H1/PD-L1 that is further inducible with PMA treatment. In all cell lines included in our study, incubation with PMA increases the level of B7-H1/PD-L1 released into the culture media, while pretreatment with the PI 3-K inhibitor, LY294002, abrogates this increase. Importantly, the Simple Plex platform is able to quantify very low levels of B7-H1/PD-L1 that are below detection by ELISA. Our data suggest that combining the Quantikine ELISA and Simple Plex platforms is a powerful strategy for reliably and quantitatively assessing soluble B7-H1/PD-L1 levels.

#3979 Immune correlates of pathologic response in bladder cancer patients undergoing neoadjuvant chemotherapy. Philip H. Abbosh,1 David Liu, Woonyoung Choi,1 Wake S. El-Deiry,1 Jonathan E. Rosenberg,5 David McConeky,5 Elizabeth R. Plimack,1 Eliezer M. Van Allen2. Dana Farber Cancer Institute, Boston, MA; 3Center de recherche du CHU de Québec, Quebec, Canada; 4Dana Farber Cancer Institute, Boston, MA; 5Memorial Sloan Kettering Cancer Center, New York, NY.

Introduction and Objective: The immune system is increasingly recognized as both a key player in cancer and a druggable target. We hypothesized that the immune system impacts pathologic response in patients undergoing cisplatin-based neoadjuvant chemotherapy (NAC) for muscle-invasive bladder cancer though the immune system. Methods: Whole exome sequencing (WES) was performed on tumor DNA from patients in two independent cohorts who underwent cisplatin-based NAC. The Memorial Sloan Kettering/Dana Farber Cancer Institute (n=50, 25 responders) and Philadelphia cohorts (n=48; 20 responders) were treated with gemcitabine/ cisplatin or methotrexate/ vinblasia/ docorubicin/ cisplatin. Mutation analysis was performed using standard analytical pipelines. Macrohistocompatibility complex (MHC)-restricted neoantigens were identified with netMHCPan and PolySolver. High affinity neoantigens were defined to have ≤500 nM binding affinity (Kd). Pathologic response was defined as ≤ypTis cystectomy specimen. CIBERSORT was used to infer immune cell infiltrate based on DASL Illumina microarray expression profiles (n=41, 17 responders). Results: Chemoresponders had >twice as many putative neoantigens as nonresponders (471 vs 207 neoantigens respectively; p=1×10^-8, Wilcoxon). A positive relationship of >1.4-fold was noted with median survival when neoantigens were limited to $K_d$≤100 nM or ≤50 nM, and when chemoresponse was defined as ypT0-only, or ≤ypT1. ERCC2 loss-of-function mutations were 36% sensitive in identifying chemoresponders but 96% specific. Above-median neoantigen burden was 81% sensitive in identifying chemoresponders and 78% specific. CD8+ cells were enriched in responders (13.5% vs 8.4% of infiltrate; p<0.0008, t-test) as were many PD-1+ cells (15.2% vs 12.7% NK=0.05). In 27 cases where CIBERSORT data was available, the neoantigen burden was correlated to the CD8+ infiltrate value (R²=0.33, Pearson). Conclusions: Neoantigen burden and CD8+ infiltrate correlate strongly with chemoresponse. Neoantigen burden and CD8+ infiltrate are directly proportional. NAC may therefore exert known tumor cell autonomous effects and an extrinsic effect involving the immune system via neoantigens. Anti-neoantigen responses have been shown to impact immune checkpoint responses and a similar mechanism may mediate cytotoxic chemoresponses. Experimental studies are underway to directly and functionally characterize the effect of the immune system in chemoresponse.

#3980 Ly6G+ neutrophils and polymorphonuclear myeloid derived suppressor cells promote the survival of tumor cells. Sarah Herlihy, Cindy Lin, Maria Ozeriva,1 Alfred Garfall,2 Dan Vogl, Dmitry Gabrilovich,3 Yulia Nefedova1.

A heterogeneous group of immature myeloid cells which suppress the immune system are termed myeloid derived suppressor cells (MDSC). Collectively a MDSC population is comprised of monocye-like MDSC and polymorphonuclear MDSC (PMN-MDSC). MDSC are increased in the presence of a number of different tumors. We previously demonstrated that PMN-MDSC represent the majority of MDSC in tumor-bearing mice. In a mouse model of multiple myeloma (MM) depletion of myeloid cells in vivo results in increased survival. Direct co-culture of neutrophils (CD11b+ Gr1+ cells from tumor-free mice) or PMN-MDSC (CD11b+ Gr1+ cells from tumor-bearing mice) and MM cells increases the survival of the MM cells from chemotherapeutic-induced death. Cell-cell contact is not necessary for the protective effect. Neutrophil and PMN-MDSC supernatants protect MM cells from cell death, suggesting the factor protecting tumor cells is soluble. Results in the mouse were confirmed using human MM cells and replicated on breast cancer cells with neutrophils or PMN-MDSC. Several cytokines and growth factors, such as IL-6 and fibroblast growth factor, are implicated in chemoresistance. The role of these neutrophil and PMN-MDSC soluble factors and the identification of novel contributors to chemoresistance are under investigation.

#3981 The Shc1 scaffold protein simultaneously balances Stat1 and Stat3 activation in breast cancer to promote immune suppression and resistance to immunotherapy. Ryuhjin Ahn,1 Kévin Jacquet,2 Marc Fabian,3 Sidong Huang,4 Nicolas Bisson,4 Josie Ursini-Siegel1. 1Lady Davis Institute, Montreal, Quebec, Canada; 2Centre de recherche du CHU de Quebec, Quebec, Canada; 3Rosalind and Morris Goodman Cancer Research Centre, Montreal, Quebec, Canada.

Receptor and cytoplasmic tyrosine kinases are key signal integrators in poor outcome breast cancers that are central to the establishment of an immunosuppressive microenvironment. Immunotherapies represent an emerging approach within the armament of anti-cancer agents. Although the efficacy of tyrosine kinase inhibitors relies, in part, on their ability to augment adaptive immunity, the increased heterogeneity and functional redundancy of the tyrosine kinase in poor outcome breast cancers represents a significant hurdle to achieving durable responses to immunotherapies. We previously identified the Shc1 (ShcA) scaffold protein, a central regulator of tyrosine kinase signaling, as essential for promoting immune suppression. We recently showed that the ShcA pathway simultaneously activates STAT3 immunosuppressive signals and impairs STAT1-driven immune surveillance in breast cancer cells. Impaired phosphorylation of select tyrosine residues on ShcA potentially and selectively reduces STAT3 activation in breast tumors, profoundly sensitizing them to immune checkpoint inhibitors and tumor vaccines. Meanwhile, impaired phosphorylation of other select tyrosine residues on ShcA potently increased antigen presentation and sensitivity to tumor vaccines in preclinical mouse models. Based on these results, we have set out to elucidate protein interactors dependent on distinct ShcA phospho-tyrosines to regulate STAT1 and STAT3 signaling axis that aid tumor driven immune suppression. We combined affinity-purification mass spectrometry (AP/MS) and proximity-dependent biotin identification
#3982 Tumor exosomes lead to positive feedback in tumor associated macrophages leading to increased invasion and metastasis. Daniel C. Rabe, Felicia D. Rustandy, Rebecca Sturey, Marsha R. Rosner. University of Chicago, Chicago, IL.

Triple-negative breast cancer (TNBC) patients have the highest risk of recurrence and metastasis. This is in part due to the infiltration of macrophages into the tumor that promote growth, survival, invasion, and therapy resistance through secretion of growth factors and cytokines. We previously demonstrated the metastasis suppressor Raf Kinase Inhibitory Protein (RKIP) regulates the number and phenotype of tumor-associated macrophages (TAMs) by blocking CCL5. Although CCL5 protein is sufficient to recruit pro-invasive TAMs, alone it does not robustly induce expression of pro-invasive genes, nor does it lead to a pro-inflammatory macrophage phenotype. We therefore tested whether exosome crosstalk within the tumor microenvironment was responsible for transmitting a pro-inflammatory phenotype between tumor cells and TAMs. To determine the role of exosomes in macrophage phenotype, we programmed naïve mouse macrophage derived macrophages (BMDMs) with conditioned media (CM) from TNBC cells, CM depleted of exosomes, or tumor exosomes alone. Only tumor exosome treatment increased levels of pro-invasive genes MMP12, PGRN, and CCL7, while CM or CM depleted of exosomes did not. This pro-inflammatory macrophage phenotype was lost if exosomes from non-invasive (RKIP+) tumor cells were used or if tumor exosome secretion was inhibited. We determined that RKIP regulated the pro-inflammatory phenotype of macrophages in part through cytokine mRNA in exosomes. Levels of pro-inflammatory mRNAs like CCL5 were drastically lower in exosomes from RKIP+ cells compared to control. Additionally, exosomes from CCL5 over-expressing cells further increased the pro-inflammatory nature of macrophages while those from tumor cells with CCL5 knocked out using CRISPR not drive a pro-inflammatory phenotype. For in vivo validation, mice were injected with exosome-depleted tumor cells or co-injected with exosome-programmed BMDMs. These results indicate exosomes reprogram TAMs to reflect increased invasiveness of the tumor cells, leading to positive feedback onto the tumor cells to drive invasion and metastasis.

#3983 A cross comparison of technologies for the detection of immune system related gene expression signatures in clinical FFPE samples of metastatic prostate cancer patients. Kimberly Kruse,1 Fang Yin Lo,1 Ryan Fleming,1 Douglas Chung,1 Vickie Satle,1 Linden Maasell,1 Tuuli Saloranta,1 Inah Golez,1 Saman Tahir,1 Sally Dow,1 Evan Anderson,1 Spencer Chee,1 Raghave Venkatraman,1 Steve Anderson,2 Peter S. Nelson,1 Colm Morrissey,1 Anup Madan,1 Sharon Austin,1 Kellie Howard2,3, Covance, Redmond, WA, 2Covance, Durham NC,3Fred Hutchinson Cancer Research Center, Seattle, WA, 4University of Washington, Seattle, WA.

The success of immunotherapy for the treatment of metastatic cancers relies on the prediction and identification of potential neo-antigens. In recent years expression levels of these neo-antigens along with other immune system related genes have been evaluated in an effort to better understand response rates for immunotherapy in various cancers. Gene expression levels can be assessed by numerous techniques including hybridization-based or direct sequencing technologies. Two platforms-HTG Molecular and NanoString nCounter have been utilized to profile changes in gene expression and offer unique advantages for analyzing challenging specimens such as formalin-fixed paraffin embedded (FFPE) tissues. The NanoString nCounter platform utilizes hybridized fluorescent probes targeted against genes of interest for a non-amplified measurement of gene expression. Several studies have been shown that the NanoString platform has good sensitivity, specificity, and reproducibility for the assessment of gene expression levels from FFPE samples. The HTG platform is relatively new and also uses a hybridization based method to enrich genes of interest without first isolating RNA. To determine the robustness of the HTG platform, we profiled a set of 30 metastatic prostate cancer samples using the HTG Molecular EdgeSeq Immuno-Oncology Assay. In these experiments, we found that expression data obtained by using both extracted RNA and lystate from FFPE slides was highly reproducible (Spearman coefficient $> 0.85$). In addition, the expression profile of targeted genes obtained by using different slides from the same blocks was also highly correlated (Spearman coefficient $> 0.90$). Our experiments also showed a high correlation between gene expressions profiles obtained by HTG, the NanoString PanCancer Immune Profiling panel and RNA-Seq from the same set of 30 metastatic prostate cancer samples. Further analysis to evaluate and compare the sensitivity of different platforms is being performed and results of these will be presented.
NCoR2 regulates GBM progression and resistance to therapy potentially via inducing a stem-like phenotype as well as responding to the tumor-promoting mechanical cues within the GBM microenvironment.

**#3986 Regulation mechanism and clinical significance of KPNA2 promotes MDCSs infiltrating in epithelial ovarian cancer.** Shuting Huang, Min Zheng, Yuanzhong Wu. Sun Yat-Sen University Cancer Center, Guangzhou, China.

Myeloid-Derived Suppressor Cells (MDCSs) are a population of immune cells that negatively regulate immune responses, which could promote tumor invasion and metastasis. Recent research has revealed that tumor could actively reshape the immune-microenvironment for its progression. We recently demonstrated that KPNA2 is a candidate oncogene in ovarian cancer that was closely related to MDCSs density, and found there was a positive position feedback between KPNA2 expressed and MDCSs density, which might contribute to the poor prognosis of patients. Based on these results, we combined clinical sample analysis, animal model and experimental studies to do further molecular and genomic research. The conduction of this project will help explain the molecular mechanisms of how KPNA2 regulates ovarian cancer through suppressing the immune system, and provide new strategies by molecular targeted therapy combining biological therapy for ovarian cancer.

**#3987 Solid stress and elastic energy as measures of tumor mechanobiology.** Hadi Nia,1 Hao Liu,1 Giorgio Seano,1 Meenal Datta,1 Dennis Jones,1 Nuh Rahbari,1 Joao Incio,1 Vikash Chauhan,1 Keehoo Jung,1 John Martin,1 Vasileios Asksylakis,1 Tim Pader,1 Dai Fukumura,1 Yves Boucher,1 Francis Hornick,1 Alan Grodzinsky,1 James Baish,1 Lance Munn,1 Rakesh Jain,1 MGH/Harvard Medical School, Boston, MA;1 MIT, Cambridge, MA;2 Bucknell University, Lewisburg, PA.

Introduction: Increased tissue stiffness is a widely accepted and actively studied biomechanical property of desmoplastic tumors, and has been linked to several hallmarks of cancer, such as growth, invasion and metastasis. The abnormal mechanics of tumors, however, are not limited to tissue stiffening. We recently demonstrated that solid stress represents a new mechanopathology that is consistently elevated in mouse and human tumors. The solid stress, transmitted by solid elements of the extracellular matrix, is distinct from interstitial fluid pressure. Therefore, tumors are not only more rigid than many normal tissues, but cancer cells also produce and are exposed to these physical forces. Composed of a combination of tension and compression, these forces are significant in tumors, but negligible in most normal tissues. Methods and Results: We developed the experimental and mathematical frameworks to provide (i) two-dimensional spatial map of solid stress in tumors (planar cut method), (ii) sensitive estimation of solid stress in small tumors with small magnitudes of solid stress, e.g., metastatic lesions (slicing method), and (iii) in situ quantification of solid stress in tumors, which retains the effects of the normal surrounding tissues (needle biopsy method). All three methods are based on the physical concept of releasing the solid stress in a controlled way with defined geometry, and then quantifying the stress-induced deformation by high-resolution ultrasonography or optical microscopy. Given the specific topography of the stress relaxation and the geometric and material properties of the tumor, the solid stress and discharged elastic energy is estimated using mathematical modeling. Applying these novel methods to multiple mouse cancer models in primary and metastatic settings has led to the following novel findings: (i) solid stress and elastic energy may be different between primary vs. metastatic settings, as they depend on both cancer cells and their microenvironment; (ii) tumor with higher elastic energy are not necessarily stiffer, and the stiffer tumors do not necessarily have higher elastic energy; (iii) solid stress increases with tumor size; and (iv) the normal tissue surrounding a tumor significantly contributes to the intratumoral solid stress. Conclusions: We developed three distinct methods to perform in situ and sensitive measurement of solid stress and obtain 2-D spatial map of solid stress in human and mouse tumors. Application of these methods in models of primary tumors and metastasis revealed that: (i) solid stress depends on both cancer cells and their microenvironment; (ii) tumor growth with tumour size; and mechanical confinement by the surrounding tissue substantially contributes to intratumoral solid stress. Further study of the genesis and consequences of solid stress, facilitated by the engineering principles presented here, may lead to significant discoveries and new therapies.

**#3988 Antigen presentation by tumor-infiltrating B cells associates with CD4 T-cell phenotype and function in NSCLC patients.** Tullia C. Bruno. University of Pittsburgh, Pittsburgh, PA.

Despite improvements in surgical techniques and combined chemotherapies, the 5-year survival rate for all stages of non-small cell lung cancer (NSCLC) is only 18%. The focus of immunotherapy has been on subsets of CD8 and CD4 Tumor infiltrating lymphocytes (TILs); however, tumor infiltrating B cells (TIL-Bs) have been reported in tertiary lymphoid structures (TLS) with CD4 TILs, and both TIL-Bs and TLS correlate with NSCLC patient survival. While TIL-Bs have been identified in NSCLC patients, their function in the tumor microenvironment has been understudied with no focus on their role as antigen presenting cells (APCs) and their influence on CD8 and CD4 TILs. We hypothesize that TIL-Bs help generate potent, long-term immune responses against presenting tumor antigens to CD4 TILs. Using unmanipulated, primary human B cells from fresh tumor, tumor adjacent and normal (cancer-free) lung tissue, we observed that the total number of B cells at the site of the tumor versus the tumor-adjacent tissue was increased compared to other immune subsets. We generated a specific antigen presentation assay in vitro, and we observed three types of CD4 TIL responses when TIL-Bs presented autologous tumor antigens. There were activated CD4 TIL responses; CD4 TIL proliferation when combined with TIL-Bs alone, which indicates stimulation with endogenous tumor antigens. This was associated with exogenous antigen presentation by TIL-Bs that did not respond to antigen presentation by TIL-Bs alone. Within the activated and antigen-associated responders, the TIL-B phenotype associated with the CD4 TIL phenotype; if the TIL-Bs were activated (CD69+CD27+CD21+), the CD4 TILs were T helper (antigen) tumor CD4 T cells and if the TIL-Bs were exhausted (CD69-CD27-CD21-), the CD4 TILs were T regulatory cells (pro-tumor). These data suggest that TIL-Bs influence the phenotype and function of CD4 TILs in NSCLC patient tumors. In conclusion, TIL-Bs are increased in NSCLC primary tumors, they can present antigen to CD4 TILs and influence their overall phenotype. Determining if TIL-Bs are activated or exhausted in NSCLC patients will determine the extent of their anti-tumor function in the cancer. Ultimately, results from this study will help predict how to target TIL-B functions in future TIL-B-specific immunotherapies or in combination with current immunotherapies for NSCLC patients like blockade of the inhibitory receptor, PD-1.

**#3989 Different expression and prognostic effect of PD-L1/PD-1 in SCC and non-SCC of non-small cell lung cancer.** Yunpeng Liu, Shuo Wang, Xiujuan Qu, Zhi Liu, Xiaofang Che, Xu Ling, Kezuo Hou, Yibo Fan, Na Song, Ti Wen, Ce Li. The First Hospital of China Medical University, Shenyang, China.

Although checkpoint inhibition targeting PD-1/PD-L1 pathway have demonstrated similar clinical activity in treatment of NSCLC both for squamous (SCC) and non-squamous carcinoma (non-SCC) patients, the predictive role of PD-L1 expression is distinct between two histologies in clinical trials. In order to investigate the expression and prognostic roles of PD-1/PD-L1, data from TCGA and GEO database were analyzed and further validated with our original data by IHC in 133 selected NSCLC tumor tissues (49 SCC and 84 non-SCC). Through the analysis of online data, we concluded that PD-L1 expression in SCC was significantly higher than that of non-SCC. In addition, in non-SCC, PD-L1 was associated with immune response and indicated worse prognosis while no such results were observed in SCC. Further, our original data demonstrated PD-L1 expression in tumor cells(TC) and immune cells(IC) were significantly more often and more intense in SCC (P<0.001). In survival analysis, PD-L1 expression in TC and IC were associated with shorter overall survival in non-SCC (P=0.019 and 0.003, respectively). However, in SCC, PD-L1 did not demonstrate any significant effect neither in TC or IC (P=0.526 and 0.674, respectively) which consistent with online data. Contrary to PD-L1, no significant differences of PD-1 expression in tumor infiltrating lymphocytes(TILs) were showed between two histologies. PD-1 in TILs of SCC correlated with worse prognosis (P=0.025) while in non-SCC there was no correlation (P=0.986). Taken together, these findings suggest distinct regulation mechanisms and clinical significance of PD-L1/PD-1 pathway in NSCLC subgroups.

**#3990 Use of 3D tumoroid systems to define immune and cytotoxic therapeutic responses based on tumoroid and tissue slice culture molecular signatures.** Niklas K. Finngberg,1 Prashanth Gokare,2 Avital Levy,1 Alexander W. MacFarlane,1,2 Kerry S. Campbell,1,2 Karen Kaputa,1 Jeffrey Farma,1 Luigi Grasso,2 Nicholas C. Nicolaides,1 Wafik El-Deiry2,1 Fox Chase Cancer Center, Philadelphia, PA;3 Morphotek, Inc., Exton, PA.
Historically, the successful establishment of exponentially growing viable in vitro tumor cell cultures has been found to occur from a minority of tumor tissues following artificial selection of a sub-population of tumor cells. Such limitations make it difficult to model patient variability in drug responses in vitro. Moreover, the lack of stromal cells that play a critical role in tumor viabil-
ity has hindered efforts to create in vitro models including anti-tumor immunity. Although evi-
dences from preclinical and clinical settings suggest that dissemination of ma-
lignant cells is an early process, majority of disseminated cells either eliminated or remain dormant in distant organs, while very few cells eventually develop successful metastasis. Therefore, it is widely accepted that dynamic and revers-
ible tumor cell plasticity is required for metastasis, however, in vivo steps and mechanisms involved remain poorly elucidated. We provide evidence that mono-
cytic and granulocytic subsets of myeloid derived suppressor cells (m-MDS, g-MDS) infiltrated in primary 4T1 tumor and distant organs with different time kinetics regulate spatiotemporal tumor plasticity. Using co-culture experi-
ments and syngeneic mouse models of murine 4T1 (metastatic) tumor, we demonstrated that tumor infiltrated m-MDSs facilitate tumor cell dispensa-
tion from the primary site by inducing the EMT/CSC phenotype. In contrast, g-MDSs infiltrated in the lungs support metastatic growth by reverting the EMT/CSC phenotype and thus promoting tumor cell proliferation. In contrast, less invasive EMT6 tumors fail to induce efficient pulmonary infiltration of g-
MDSs and results in clearance of disseminated tumor cells in the lungs. Gene expression analyses of tumors and MDSs subsets in primary tumor site and in recurrent tumors (n=12) corroborated the cell plasticity and generation of permissive or anti-tumorigenic microenvironment in distant organs determining the fate of disseminated tumor cells.

#3991 Profiling the immune tumor microenvironment in primary and recurrent epithelial ovarian cancer. Laureen S. Ojalvo, Elizabeth D. Thompson, Tian-Li Wang, Alan K. Meeker, Je-Ming Shih, Amanda N. Fader, Ashley A. Camino-Mathews, Leisha A. Emens, Johns Hopkins Hospital, Baltimore, MD.

Clinical trials targeting the immune tumor microenvironment (TME) in epi-
theelial ovarian cancer (EOC) typically have included patients with heavily pre-
treated advanced disease and demonstrated only marginal efficacy. A better understand-
ing and harnessing of EOC TME recurrent with progression from primary to recur-
dent disease may inform future immunotherapy trials. Here, we evaluate the immune TME in primary and recurrent EOC using tissue microarrays. Our cohort included matched primary and recurrent tumors from 17 patients, and ad-
ditional non-matched primary tumors from 20 patients and recurrent tumors from 15 patients. We stained for CD8 (FOXP3 (regulatory T cells (Tregs)), CD68 (tumor associated macrophages (TAMs)), programmed cell death protein 1 (PD-1) and programmed death ligand 1 (PD-L1) by immunohistochemistry to interrogate the immune composition of the TME. Tregs increased in recurrent tumors compared to primary tumors (8.0 vs 14.2/HPF, p = 0.0210). Higher TAM density was associated with higher levels of Treg and CD8+ T cell infiltrates in recurrent tumors (p = 0.001 and p = 0.001, respectively), and with higher Treg but not CD8+ T cell infiltrates in primary tumors (p = 0.027 and p = 0.200). TAM-dense recurrent tumors had increased PD-L1 on tumor cells and immune cells, whereas TAM-dense primary tumors had increased PD-L1 only on im-
mune cells. Increased Tregs in primary tumors correlated with decreased time to first recurrence (17.0 vs 28.5 months, p = 0.022). Conversely, increased Tregs in recurrent tumors correlated with longer overall survival (OS) from recurrence (median not reached vs 26.0 months, p = 0.022). Although TAM density did not affect patient survival, analysis of matched primary and recurrent tumors revealed that patients with increased TAMs at recurrence (n = 5) had a longer median OS from recurrence than patients without increased TAMs at recurrence (n = 12). Tregs increased at recurrence in the majority of matched tumor pairs (n = 12), but there was no correlation with survival. In conclusion, the TME of EOC is im-
munologically active. TAM-dense recurrent diseases had higher CD8+ T cell and Treg infiltrates and PD-L1 expression. In this study, patients with increased cellular recruitment to the TME at recurrence had improved survival. Larger, more detailed studies characterizing the evolution of the TME with progression from primary EOC to recurrence are warranted.

Metastatic disease is the end stage of extremely inefficient processes that entail complex changes in vivo similar to those occurring in vitro during immune-based therapeutics challenging. Through recent advances in three-di-

mensional (3D) culture (“tumoroid”) methodologies some of these hurdles are be-

gun to be addressed. However, it is currently unclear to what extent such models can be engineered to retain important phenotypic properties of infiltrat-

ing immune from the tumor tissue of origin. To better understand these limitations, we have cultivated tumor slice cell culture slices from tumors derived from patients with colorectal cancer (CRC) to evaluate immune cell populations infiltrating cultured CRC tissues. Furthermore, we have developed a system whereby the patient’s immune cells are re-incorporated into tumoroid in vitro cultures to evaluate the ability of the culture to mimic an immunosuppressive tumor microenvironment (TME). Here we demonstrate the development of a propagating 3D epithelial tumoroid culture system from re-

sected CRC tissue where we assessed the response to standard FDA approved therapy within weeks of surgical resection. Interestingly, tumoroid cultures from a CRC patient were highly sensitive to the thymidylate synthase inhibitor flurouracil (adriam) but less sensitive to the combination of the nucleoside analog trifluridine and the thymidine phosphorylase inhibitor tipiracil (Lon-

sur). We have also shown that the tumoroid is sensitive to cell cycle and cell density gradient centrifugation and flow cytometry. Re-introduction of isolated immune cells derived from surrounding and infiltrating tumor tissue and CD45+ tumor infiltrating hematopoietic cells displayed prolonged (>10 days) survival in co-culture. Moreover, established tumor slice cultures contained both an outer epithelial and inner stromal cell compartment mimicking tumor structure in vivo. Collectively, these data suggest that CRC tumoroid in vitro assays can be used for the assessment of some therapeutic responses. While further work is required to optimize this system, 3D tumoroid and slice culture assays may represent a novel in vitro approach to assess therapeutic efficacy of novel therapies and evaluate mechanisms of therapy resistance in general as well as for patient-specific response.

#3993 A different spatiotemporal distribution of TIL subtypes is associ-

ated with response to neoadjuvant chemotherapy in locally advanced breast cancer patients. Lisa Koenig,1 Fabian Dominik Mairinger,2 Oliver Hoffmann,1 Anu-Kathrin Bittner,1 Kurt Werner Siegal,3 Rainer Kimmig,1 Sabine Kasimir-

Bauer,1 Agnes Bankfalvi,2 1Department for Gynecology and Obstetrics, University Hospital of Essen, Essen, Germany; 2Institute for Pathology, University Hospital of Essen, Essen, Germany.

Background: Tumor infiltrating lymphocytes (TILs) are described as an im-
portant immune modulator in the tumor microenvironment in cancer and were shown to be associated with breast cancer (BC) outcome. Besides the analysis of total TILs, the discrimination into TIL subtypes is essential as they exhibit pro-
tumor-immunogenic potential. The spatiotemporal TIL distribution at the inva-
sive front (ITF) and the tumor center (TC) might provide insights into tumor progression. Here we analyzed TIL infiltration in core biopsies of BC patients (pts) prior to neoadjuvant chemotherapy (NACT) and correlated these findings with clinical parameters and tumor cell spread. Material and Methods: Core biopsies from 87 pre-NACT BC pts were cut, deparaffinized and antigen retrieval and automated immunohistochemistry were performed using the fol-
lowing primary antibodies: CD3 (clone: SP7; 1:400, DCS Innovative Diagnostic Systems, Hamburg, Germany), CD4 (clone: IF6; 1:40, Eryzomed Systems, Berlin, Germany), CD8 (clone: C8/144B; 1:150), CD20 (clone: L26; rtu), CD68 (clone: PG-M1; 1:500, all DakoCytomation, Glostrup, Denmark). Binding of primary antibody was visualized using the OptiView DAB kit (Ventana Medical Systems, Tucson, USA). The densities of total TILs (H&E staining) and TIL subtypes were evaluated microscopically at the TC and ITF and classified into three categories: Low = 0-10%, Moderate = 11-30%, High = 31% infiltration. TIL results were correlated with clinical parameters and disseminated tumor cells (DTCs) in the bone marrow, determined by immunocytometry applying the pan cytoker-
atin antibody A45-B/B3. Results: TILs were differentially distributed at both tumor areas. The ITF was mainly infiltrated by CD3+ T- and CD20+ B cells, while low amounts of CD68+ macrophages, CD4+ and CD8+ T cell subtypes were present. Only CD3+ T cells were present in a higher level at the TC. A high positive correlation was observed between the ITF and breast tissue infiltration from poorly differentiated tumors. Pre-NACT tumors < T2 had a high CD4+ T cell infiltration at the TC, whereas in small post-NACT tumors a high infiltration of total TILs and all TIL subtypes at the ITF, except CD68+ cells, was observed. BC pts responding to NACT exhibited significantly more total TILs (p = 0.02) and

1020
Proceedings of the American Association for Cancer Research • Volume 58 • April 2017
CD3+ T cells (p = 0.02) at the TC. A high CD4+ T cell infiltration at the TC was significantly associated with the presence of DTCs post-NACT (p = 0.029). CD8+ macrophages located at TC or ITF were not related to any clinical parameter. Conclusion: The differential association of TIL subtypes with clinical parameters and NACT response underlines the necessity of detailed TIL analysis for gastric cancer patients to improve immune modulation of tumor microenvironment. In this regard, BC patients not responding to standard NACT might be identified for application of additional immunotherapy.

The tumor microenvironment (TME) is made up of stromal cells, immune cells, signaling molecules, and blood vessels surrounding the tumor cells. It has emerged as a key factor in multiple stages of cancer progression, immune-escape, and disease progression. The composition and activity of TME co-evolve with tumor cells and may likely affect how the cancer responses to immunotherapy. A clear understanding of the functional effect and evolution of the TME necessitates a comprehensive approach to identify key immune cells as well as to characterize signaling and inflammatory (immune-editing) activities at the tumor site. Here we are describing the use of a targeted NGS panel to detect aggregated gene expression and a novel AmpliSeq™ approach to profile the relative abundance of different T cell clones at the TME. Specifically, we measured the expression of 395 relevant genes that capture interferon and chemokine signaling, T and B cell activation, checkpoint pathway, tumor proliferation, and antigen presentation. By looking at the expression of markers specific to different effector cell types, this gene panel offers a high-level view of the composition of different lymphocyte infiltrates. Complementarily, the TCR sequence assay provides an estimate of T cell diversity and therefore offering a different dimension of the immune response. We studied 40 NSCLC tumor samples, of which we have matched FFPE and fresh frozen specimens. With a targeted panel, we could detect expression of transcripts present as few as 50 copies in 10 ng of total RNA as input. Across 40 NSCLC samples, we were able to measure expression of many low expressing cytokines such as IL2, IL11, IL23, IFNG and TNF. We observed strong co-expression pattern among genes involved in type II interferon signaling, indicating that they’re informative of T cell activation. More specifically, we found strong correlation between CD8 expression and other T cell co-stimulatory receptors (CD28, CD80, CD86, CD40), suggesting that expression of these genes can be reliable surrogates for the protein counterparts as markers for CD8+ T cells. TCRβ was sequenced for each of the matched fresh frozen sample in duplicates. Clonotype abundance of replicates was highly correlated with each other, indicating that the assay was reliable, and the samples were sequenced to appropriated depth. We identified 200,000 unique clones in each tumor sample; with the diversity index moderately correlated with the percentage of tumor infiltrating lymphocytes provided by pathology review. Together, these two assays provide a convenient means to characterize T cell phenotypes and activities in tumor microenvironment, offering insights into how that tumor may respond to a particular immunotherapy.

**#3995 Identification of receptor tyrosine kinases (RTKs) expression in tumor-infiltrating lymphocytes (TILs) and peripheral blood mononuclear cells (PBMC).** Dmitry Khochenkov,1 Maria Volkova,1 Ilya Tsimaflayev,2 N.N. Blokhin Russian Cancer Research Center, Moscow, Russia; Russian Federation; 2Kidney Cancer Research Bureau, Moscow, Russian Federation.

Aim of this study is to discover expression levels of RTKs (VEGFR1, VEGFR2, PDGFRα, PDGFRβ) in CD45+ population of PBMC and TILs isolated from patients with clear cell renal cell cancer (RCC). Here we present preliminary data. Species of tumors and blood were prospective collected from 9 patients with RCC after radical nephrectomy or tumor resection from July to October 2016. TILs isolation was performed under standard protocol with slight modification. Briefly, tumor was shredded with scissors on small pieces of 2-3 mm, and twice washed in RPMI 1640 media by centrifugation for 10 min at 1500 rpm. After centrifugation, pellet was diluted RPMI 1640 with enzyme mix (Collagenase and Dispase II) on Petridish and placed on shaker-thermostat and incubate After centrifugation, pellet was diluted RPMI 1640 with enzyme mix (Collagenase and Dispase II) on Petridish and placed on shaker-thermostat and incubate for 1 hour. Expression on CD45+ cell population were evaluated. Among PMBC 86.9% of cells was CD45+ and positive expressed RTKs (10%+ cells were positive for VEGFR1 and PDGFRβ, and 6%+ cells were positive for PDGFRα and PDGFRβ). TILs contained 65.3% of CD45+ positive cells and did not express RTKs on the cell surface (less than 1% of cells), but intracellular staining showed presence of RTKs: 8.2% of cells were VEGFR1 or VEGFR2 positive. 20.8% of cells were PDGFRα or PDGFRβ positive. Preliminary data demonstrate extracellular expression of RTKs on PBMC and intracellular expression of RTKs in TILs. The study will be continued.

**#3996 MDSC depletion combined with CTLA-4 blockade cause tumor regression in a syngeneic model of oral cavity cancer.** Paul Esteban Clavijo, Ellen Moore, Jianhong Chen, Ruth Davis, Carter Van Waes, Zhong Chen, Clint Allen. NIH, Bethesda, MD.

Carcinogen-associated head and neck cancers are a heterogeneous group of aggressive cancers with a high recurrence rate and poor 5-year survival. Many of these cancers are T-cell inflamed but only a subset of patients respond to checkpoint blocking immunotherapy. Local immunosuppression mediated by both the tumor cells and other infiltrating immune cells are likely a major mechanism of resistance to immunotherapy. The mouse oral cancer (MOC) model includes genetically defined cell lines derived from carcinogen-induced tumors that generate tumors with variable T-cell inflamed phenotypes when transplanted into wild-type C57BL/6 mice. Mice bearing MOC1 tumors display a T-cell inflamed phenotype but do not significantly respond to PD-L1 checkpoint inhibition alone, which models a significant subset of human cancers from the oral cavity. Conversely, MOC2 tumors are non-T-cell inflamed. Using these MOC models, we have demonstrated an inverse relationship between accumulation of granulocytic MDSCs (gMDSCs) and effector immune cells (CD8/4+ T-cells, and NK cells) in the tumor microenvironment. Functionally, these gMDSCs suppressed CD8+ T-cell proliferation, IFNy production, and antigen-specific killing. Depletion of these gMDSCs with a systemic anti-Ly6G antibody (1A8) did not change CD8/4+ T-cell or NK cell accumulation but restored tumor T-cell and NK cell activation and draining lymph node antigen-specific T-lymphocyte activation that was lost with tumor progression. Depletion of gMDSCs also significantly sensitized established MOC1 tumors to CTLA4-based checkpoint inhibition. CTLA-4 blockade alone induced tumor regression in a subset of mice and a marked delay in others. However, gMDSC depletion plus CTLA-4 blockade resulted in complete tumor rejection and development of immunologic memory in all treated mice. Peripheral gMDSCs were found to express the chemokine receptor CXCR2 but no other myeloid chemokine receptors, and expression of CXCR2 ligands CXCL1 and CXCL2 increased within the tumor microenvironment during tumor progression. Macrophage chemotaxis components CSF1R and CSF1 were not significantly expressed in these models. TCGA data analysis demonstrated an MDSC-rich gene expression profile in >60% of head and neck cancers, along with significant CTLA4, CXCR2, CXC1L1, and CXCL8 (IL-8) expression within both HPV-positive and negative head and neck cancers. Functional inhibition or elimination of MDSCs from the tumor microenvironment may significantly reverse local immunosuppression and enhance responses to checkpoint inhibition in patients with head and neck cancer.

**#3997 Interleukin-4 receptor-targeted cytotoxic T cells enhances the therapeutic efficacy of adoptive T cell therapy against melanoma.** Gowri Rangaswamy Gunasekaran, Sri Murugan Poongkavithai Vadevoo, Guruprasath Padmanaban, Lianhua Chi, Ha-Jeong Kim, Byung Heon Lee. 1Kidney Cancer Research Bureau, Moscow, Russian Federation; 2Department of Medical Cell Therapy, Kyungpook National University, Daegu, Republic of Korea.

Melanoma, the deadliest form of skin cancer, has long been a major focus of immunotherapy. Adoptive T cell therapy-based cancer immunotherapy has been used to enhance the specificity and potential of host immune system to treat melanoma. However, the infiltration and antitumor function of cytotoxic T cells (CTLs) are blocked or down-regulated by various signals derived from tumor cells and cells in tumor microenvironment. A novel approach to specify and enhance the homing ability of CTLs to tumor is of high demand. Interleukin-4 receptor (IL-4R) is over-expressed on many types of cancer cells, including melanoma, and has been widely employed for targeted drug delivery. In this work, we examined whether the tumor homing efficiency and anti-tumor therapeutic efficacy of CTLs could be heighten by labeling CTLs with IL4RPeP-1, a targeting peptide that binds to IL-4R. The labeling was empowered by conjugating IL4RPeP-1 with Dicyclophosphatidylethanolamine-biological anchor for targeting peptide that bindstoIL-4R. The labeling was empowered by conjugating IL4RPeP-1 with Dicyclophosphatidylethanolamine-biological anchor for
membrane (DOPE-BAM), an oleoyl-acid-derived membrane anchor that incorporates into lipid membrane of cells. Tumor-specific CTLs isolated from the mice immunized by irradiated B16F10 melanoma cells were highly populated with CD62+CD44+ activated T cells. After labeling with IL4RPeptide 1 via DOPE-BAM, CTLs were still functionally active, as determined by intracellular interferon gamma (IFNg) production and gamma release assay (Fig. 38). Moreover, such labeling did not affect the proliferation of T cells. Adoptive transfer of IL4RPeptide 1-labeled, IL-4R-targeted CD45.1 + CTLs into CD45.2 mice bearing B16F10 melanoma enhanced their accumulation at tumor compared to that of unlabeled T cells. Tumor homing of IL4RPeptide 1-labeled T cells was further validated by in vivo fluorescence imaging of mice bearing 4T1 tumor at mammary gland. Adoptive transfer of IL-4R-targeted CTLs induced remarkable antitumor growth activity in mice bearing B16F10 tumor compared to untreated CTLs. After the transfer, flow cytometric study of immune cells showed significant increase of CD8+ T cells and F4/80+CD86+M1-polarized macrophages with noticeable decrease in tumor-promoting immune cells, such as F4/80+CD206+M2-polarized macrophages, GR1+CD11b+ myeloid derived suppressor cells, and CD3+CD4+ T cells. The CTLs accumulated at the tumor were mostly exogenous CD45.1+ T cells. These results implicate that IL-4R-targeted CTLs, which is enabled by labeling of with IL4RPeptide 1, can be a promising strategy in the field of adoptive T cell therapy against IL-4R-overexpressing tumor.

#3998 Alerting the immune system by removing epigenetic silencing of TH1 chemokines. Heather M. Sonnemann, Amber J. Giles, Caitlin M. Reid, Marsha-Kay N. Hutchinson, Deric M. Park, Mark R. Gilbert.

BACKGROUND: Solid tumors employ multiple mechanisms to evade an immune response. However, the potential to enhance the immune response to cancer has been proven in several malignancies and is under investigation in many others, including primary CNS tumors. Brain tumors in particular lack robust T-cell infiltration. Recent studies have found that certain tumors can be induced to express T-cell attracting chemokines. CXCL9 and CXCL10, by interferon gamma (IFNg). This response is further amplified using methyltransferase inhibitors (Peng, et al. Nature 2015. Vol 527: 249-253.), resulting in increased T-cell trafficking to tumors both in vitro and in vivo. We hypothesized that T-cell trafficking to brain tumors could likewise be enhanced with DNA and histone methyltransferase inhibitors to induce CXCL9 and CXCL10 transcription. METHODS: Assays were performed on 7 human glioma brain tumor cell lines. CXCL9 and CXCL10 expression were measured by real-time PCR. Two commercially available methyltransferase inhibitors, 5-aza-dC and GSK126, were utilized to demethylate DNA and histone H3 (K9 and K27), respectively. Histone methylation status was examined using Western blot. T-cell migration was measured using transwell migration assays. RESULTS: IFNg increased CXCL9 and CXCL10 transcription in brain tumor lines. GSK126 and 5-aza-dC enhanced expression of CXCL9 and CXCL10 compared to IFNg alone. Migration assays confirmed T-cell trafficking towards chemokines produced by tumor cells in response to methyltransferase inhibitors. CONCLUSIONS: These studies demonstrate that brain tumors express T-cell attracting chemokines CXCL9 and CXCL10 in response to IFNg. Furthermore, GSK126 and the combination of GSK126 and 5-aza-dC enhanced expression of CXCL9 and CXCL10 transcription by real-time PCR and T-cell trafficking by migration assay. Together, these data provide a potential means to increase T-cell trafficking into tumors and potentially enhances the efficacy of immune therapies for brain tumors.

#3999 Cross talk between tumor cell derived HMGB1 and adaptive B cells in the tumor microenvironment of esophageal squamous cell carcinoma. Nigar Woon Kam, Xin-Yuan Guan, Dora Lai-Wan Kwong. Clinical Oncology and the Centre for Cancer Research, Hong Kong, Hong Kong.

Esophageal squamous cell carcinoma (ESCC) is the most aggressive type of cancer among gastrointestinal cancers. The lack of effective anti-tumor immunity strategy for ESCC patients imposes urgent demand for new treatment paradigm. Tumor microenvironment (TME) is characterized by diverse cell populations (tumor cells, immune cells, and stromal cells) and multiple types (cellular and inhibitory receptors) whose alternations are closely related with tumor progression. High mobility group box chromosomal protein 1 (HMGB1) has been recognized to be expressed in various tumor cells, and importantly it has also been identified as one of the key factors regulating inflammatory reactions. By comparing differentially expressed genes between ESCC tumors (T) and their corresponding non-tumorous (NT) tissues high-throughput transcriptome sequencing system (RNA-Seq, Illumina HiSeq 2500), we found that the ligands of TIM-3 (an inhibitory receptor), HMGB1 and galectin-9, but not, cell-surface phosphatidylinerine, were overexpressed in all ESCC samples when compared to their NT counterparts. We further characterized HMGB1 and galectin-9 gene expression changes in 37 matched primary ESCC T and NT control samples by qRT-PCR. We found that HMGB1-1 and galectin-9 mRNA is constitutively expressed in all samples, while ESCC T tissue significantly expressed ~2 fold higher of HMGB-1, but not galectin-9, mRNA as compared to paired NT tissue. Histopathological characterization of ESCC tissue by sequential single staining (immunohistochemistry) and phenotypic release assay (Fig. 38), demonstrated that HMGB1 was dominantly expressed by CD20+ B cells lacking of terminal differentiation into plasma cells. Additionally, CD20+ B cells infiltrates were negative for CD27 (marker for memory B cells) and IgD (marker for naive B cells). Additionally, we isolated CD20+ B cells from healthy peripheral blood mononuclear cells (PBMC), and stimulated with/without HMGB-1/IgM. Conditional medium (CM) were collected from these B cells demonstrating that B cell lines KYSE30 and KYSE180 have better capacity for proliferation when culture with activated B cells CM as compared to unstimulated B cells. Collectively, we believe that the suboptimal clinical outcomes relies on CD20+HMGB1 receptor + B cells that are exposed to high HMGB1 concentrations in the ESCC microenvironment may eventually become pro-tumor B cells subset.

#4000 Establishing the natural history of the immunosuppressive myeloid microenvironment in an inducible model of lung adenocarcinoma. Mouna Lagrouai,1 Clifton L. Dalgard,1 Gauthaman Sukumar,1 Celeste Huaman,1 Thomas Summers,1 Corey A. Carter,2 Brian C. Schaefer3.1 Uniformed Services University, Bethesda, MD; 2John Murtha Cancer Center, Bethesda, MD.

Tumorogenesis is accompanied by broad changes to the surrounding tissue microenvironment in a tumor- and patient-specific manner. Phenotype shifts in tissue-resident immune cells promote tumor progression by establishing a proliferative inflammatory environment, activating angiogenesis, stimulating tumor cell invasion and suppressing anti-tumor immunity. While the former mechanisms are well appreciated and often targeted by current cancer therapeutics, the nature of the mechanisms controlling establishment of the local immunosuppressive state that contribute to a failure of anti-tumor immunity are less clearly defined. Blockade of tumor antigen-specific T cell killing is clearly a major contributor to the failure to control tumorogenesis. However, evidence suggests that phenotypic shifts in innate immune cell populations also contribute to the failure of anti-tumor immunity. We hypothesize that the emergence of early lung adenocarcinomas is accompanied by a shift in myeloid phenotypes, rapidly establishing a microenvironment favorable to tumor growth, survival and vascularization, and hostile to cell-mediated anti-tumor immune responses. Through the utilization of a Cre-inducible mouse model of p53-null, KrasG12D+ lung adenocarcinoma, we have begun to define the natural history of the myeloid component of the tumor microenvironment, from tumor initiation to a point equivalent to human stage I adenocarcinoma. Histological, flow cytometry and real-time PCR approaches collectively demonstrate that tumor-associated myeloid phenotypes emerge at a very early stage of disease. These data are consistent with our hypothesis that the myeloid component of the tumor microenvironment plays a crucial role in establishing an immunosuppressive state during early tumorogenesis. Implications of these findings for current and emerging immunotherapies will be discussed.

#4001 Infiltration of neutrophils in the tumor is associated with poor prognosis of patients with gastric cancer. Hiroaki Tanaka, Soichiro Hira-tani, Tatsuo Tamura, Hisashi Nagahara, Kenjiro Kimura, Masatsune Shibutani, Go Ohira, Takahiro Toyokawa, Sadaaki Yamazoe, Ryosuke Amano, Kazuya Muguruma, Kiyoshi Maeda, Kosei Hirakawa, Masachi Ohira. Osaka City Univ. Grad. School of Medicine, Osaka, Japan.

Background: Recent evidence shows that neutrophils often migrate into the tumor and are associated with tumor progression. These tumor associated neutrophils (TANs) neutrophils have potential to induce angiogenesis, lymphangiogenesis and immunosuppression by inhibiting cytotoxic T lymphocytes. Immune status is one of the important prognostic factor of gastric cancer. We previously reported that lymphangiogenesis was augmented in the primary tumor of gastric cancer. Aim: The aim of this study was to investigate the correlation between CD15+ TANs and clinicopathological features of patients with gastric cancer. Materials and Methods: We investigated the association of the density of TANs in primary tumor with clinicopathological features by immunohistochemistry. We used specimens from a total of 143 primary tumor and 497 lymph nodes from 120 patients underwent gastrectomy between 2007 and 2008 in our department. We examined prognostic value of TANs identified as positive CD15 cells in both of the primary tumor and tumor draining lymph nodes. Results: The median number of TANs in primary tumor and tumor draining lymph nodes were 18.4 and 23 cells/HPF, respectively. High TANs in both of the primary tumor and lymph nodes had correlation with depth of invasion (primary tumor P<0.001, lymph nodes P=0.036) and lymph nodes
metastasis (primary tumor P<0.001, lymph nodes P=0.002). Kaplan-Meier analysis showed that patients with high TANs in both primary tumor and lymph nodes had worse prognosis than patients with a low TANs (primary tumor P=0.031, lymph nodes P=0.014). Multivariate analysis revealed that high TANs in lymph nodes were independent prognostic factors. (P=0.038) Conclusion: Our results with these patients with AKM and NALM showed that cancer tissues had poorer prognosis because of increasing lymph nodes metastasis. These findings suggested the TANs might have important role of tumor lymphangiogenesis in microenvironment of gastric carcinoma.

#4002 Neutrophil extracellular traps (NETs) in abdominal cavity have supportive roles on postoperative development of peritoneal metastasis

Rhito Kanamaru, Hidenori Tsuku, Shin Saito, Kentaro Kurasinha, Takashi Ui, Shiro Matsumoto, Hiroino Yamaguchi, Yasunari Sakuma, Hisanaga Horie, Yoshinori Hosoya, Naohiro Sato, Joji Kitayama. Jichi Medical University, Tochigi, Japan.

Background: Peritoneal lavages just after abdominal surgery contain many immune cells which consist mainly of granulocytes. Recent studies have demonstrated that neutrophil extracellular traps (NETs) play important roles not only on capture of pathogenic microbes but also on autoimmune disease, thrombus formation and tumor metastasis. Here, in this study, examined the NET forming capacity of granulocytes in postoperative peritoneal washings and assessed the possible role of the NETs on metastasis formation on peritoneum. Method: In patients who underwent laparotomy due to digestive malignancies, abdominal cavity were washed with 1000 ml of normal saline at the timing of laparotomy (Preoperative) and just before wound closure (Postoperative). Cells recovered from the peritoneal washings were centrifuged on Ficoll-Hypaque solution and cultured at 37°C in 5 percentage CO2 condition for 24 hour. Then, extracellular ds-DNA were stained with membrane impermeable dye, SYTOX. Also, the granulocytes were immunostained with mAbs against CD66b, histone, myeloperoxidase (MPO), neutrophil elastase (NE) and Matrix metalloproteinase (MMP)-9, and NETs formation was observed under fluorescence copy. In adhesion experiments, human gastric cancer cells were stained by PKH-26 and mixed with the granulocyte culture for 5 min and gently washed. Results: 1. After Ficoll separation, CD66b (+) granulocytes were contained both in polymorphonuclear PMN and mononuclear cell (PMBC) layers, which are considered to be normo-density granulocytes (NDG) and low density granulocytes (LDG), respectively. The percentage of LDG in PMBC layer was markedly elevated in postoperative as compared preoperative lavages (Pre: M=0.71%, 0.8-8.9% vs Post: M=61.3%, 3-86.7% n=39, p<0.001) The LDG in postoperative sample showed multianchored morphology. 2. The short term culture of the postoperative peritoneal LDG, but not preoperative or peripheral blood granulocytes, many SYTOX (+) fibrous structures were observed, suggesting the vigorous NETs formation. The NETs appeared several min after the incubation, peaked at 2 hour and gradually decreased thereafter. Immunostaining showed that histone and MPO were co-localized on the NETs, while NE or MMP-9 were less clear on NETs. 3. After 5 min co-incubation, human gastric cancer cell, OCUM-1 and MKN45, were selectively attached on the NETs. 4. Similar SYTOX (+) NETs-like structure were clearly detected on the surface of human omental tissue resected after abdominal surgery. Conclusion: Our preliminary results evidence NETs formation in human abdominal cavity which produce large amounts of NETs on peritoneal surface. The NETs efficiently trap the floating tumor cells, which may have positive roles on peritoneal recurrence in advanced cancer.

#4003 Acral lentiginous melanoma and infiltrating lymphocytes in a Latin American population. Carlos Castaneda,1 Carlos Torres-Cabala,2 Sandro Ojuelo,3 Miluska Castillo,1 Valeria Villegas,1 Joseyn Sanchez,2 Claudia Flores,3 Henry Gomez,2 Tatiana Vidaurre,1 Instituto Nacional de Enfermedades Neoplasicas, Lima, Peru; 2University of Texas MD Anderson Cancer Center, Houston, TX; 3Oncosalud, Lima, Peru.

Background: Acral lentiginous melanoma (ALM) is unusual in Caucasian but is the most common subtype in Hispanic populations, and has been associated to poor prognosis. Herin we compare clinicopathological features associated to ALM in a Latin-American population and prospectively evaluate its association with tumor infiltrating lymphocytes (TIL). Patients and Methods: All patients with melanoma presenting from 2005 to 2012 at Instituto Nacional de Enfermedades Neoplasicas in Lima, Peru, were retrospectively identified. Analysis of association between clinicopathological features and ALM was performed. Survival analysis compared the outcome of ALM to whole group and extremity NALM. We performed prospective evaluation of TIL following Azimi et al recently presented classification. Results: A total of 537 ALM and 287 NALM cases were identified. Older age (p=0.02), thicker Breslow (p=0.008), positive lymph node (p=0.051) and ulceration (p<0.001) were found to be more frequent in ALM. Acral had worse OS compared with both whole group (p=0.04) and extremity NALM (p<0.001). Stage I-II patients had a median OS of 5.3 (95%CI: 4.3-6.2) for ALM and 9.2 (95% CI: 5.0-7.0) for extremity NALM (p=0.016). TIL was prospectively evaluated in 490 cases, and Grade 0-1, II and III of TIL represented 44.7%, 33.6% and 27.1%, respectively. Higher TIL grade was associated to less Breslow thickness (p=0.021), less mitosis index and NALM. Higher TIL grade was also associated to better OS (p<0.001). Conclusion: ALM is highly prevalent in Latin-America and carry poor outcome. Lower TIL levels was associated to poor outcome and ALM.

#4004 Rapamycin selectively targets obesity-polarized macrophages in the prostate tumor microenvironment.

Gloria C. Galvan,1 Tommy Pham,2 Brittany Harlow,2 Christian Johnson,1 Riddhi Patodia,1 Duan Quach,1 Michael A. Liss,2 Linda A. deGraffenried1,2,1 The University of Texas at Austin, Austin, TX; 2University of Texas Health Science Center San Antonio, San Antonio, TX.

Background: Obesity is associated with prostate cancer progression and mortality. Previous studies in our laboratory suggest that obesity drives prostate cancer progression in part by increasing macrophage recruitment and by polarizing macrophages in the tumor microenvironment into a tumor promoting M2/TAM phenotype. Rapamycin, a mammalian target of rapamycin (mTOR) inhibitor, has been used for several decades in transplant patients, and in the last several years has been shown to be an effective disease suppressor in certain cancer types. Intriguingly, mTOR has been shown to be especially important for M2 polarization and mobilization. Hypothesis: Based upon published data and our preliminary studies, we hypothesize that rapamycin will selectively target obesity-polarized macrophages and will provide a survival benefit to the obese prostate cancer patient. Methods: To address this hypothesis, we used our in vitro model of obesity-induced macrophage polarization that includes two different prostate cancer cell lines, macrophages, and sera from obese and non-obese men. qPCR was used to measure expression levels of markers associated with an M2/TAM phenotype. MTT assays were conducted to measure cell viability, and flow cytometry and Western blot analyses were used to determine cell cycle status and apoptosis. Results: Obese conditions increased expression of M2/TAM markers in macrophages and rapamycin selectively decreased viability of obesity-activated M2/TAMs compared to M1 macrophages. Conclusions: Our in vitro study suggests that obesity promotes a tumor-associated phenotype in macrophages and that the mTOR pathway is involved in the survival of M2/TAM macrophages. This study offers a novel mechanistic approach to treat obese patients with prostate cancer.

#4005 HDAC inhibitors regulate M2 pro-tumor-associated macrophage function through histone acetylation.

Amber E. de Groot, Jelani C. Zard, Kenneth J. Pienta. The James Buchanan Brady Urological Institute, Johns Hopkins School of Medicine, Baltimore, MD.

Macrophage tumor infiltration in metastatic prostate cancer is a predictor of patient prognosis. Macrophages influence tumors in contrasting ways depending on their polarization: M1 macrophages have anti-tumor functions while M2 macrophages are pro-tumor. The finding of stimuli influencing macrophage differentiation and M2 polarization have been largely elucidated but the resulting downstream changes remain unknown. There are a number of epigenetic differences between M1 and M2 macrophages that act as important functional determinants. Recent work studying these epigenetic changes has implicated histone deactetylases (HDACs), as critical regulators in macrophage differentiation and in maintaining M1 or M2 function. Pan-HDAC inhibitors (HDIs) such as the clinically utilized suberanilohydroxamic acid (SAHA) target a wide range of HDACs and provide a means for manipulating macrophage histone acetylation. Though HDIs have been found to attenuate inflammatory functions in M1 macrophages, the field has yet to explore effects of histone acetylation in M2 macrophages. Using M2 macrophages derived from human CD14+ monocytes, we found that SAHA regulates M2 macrophage polarization and function through alteration of histone acetylation. Work is ongoing to test expression levels of canonical M2 markers such as the mannose receptor CD206 and scavenger receptor CD163 in M2 macrophages exposed to SAHA either during or after M2 polarization. Additionally, these results contribute to scientific knowledge of epigenetic regulation in macrophage function and elucidate strategies to decrease the pro-tumor function of tumor-infiltrating M2 macrophages. This work lays the foundation for using epigenetic regulators to modulate the tumor microenvironment and advance cancer medicine.

Introduction Immune profiling is a necessary step in understanding tumor microenvironment and predicting the response to immunotherapies. Methods We used the expression of genes exclusively expressed by immune cells in tumors, to classify 703 formalin-fixed primary melanomas from the Leeds Melanoma Cohort. Transcriptomes were generated from tumor cores using Illumina DASL HT 12.4 array. In the obtained tumor subgroups with differing immune profiles, we tested the hypothesis that β-catenin signaling controls immune suppression in primary tumors as earlier reported in vitro and murine data. Results We found and validated 6 tumor classes, which showed consistency with other published gene signatures, and predicted melanoma-specific survival (HR = 1.8, P = 0.003, adjusted for AJCC stage, site, age, sex, ulceration, mitotic rate, BRAF/NRAS mutation). Tumors of good prognosis expressed markedly a large number of markers of T cell cytotoxicity, dendritic cells, macrophages, NK CD56 dim cells and genes coding for checkpoint co-inhibitor molecules (Table 1). They also had upregulation of β-catenin suppressors and downregulated β-catenin itself (Table 1). By contrast, poor prognosis tumors (the largest group) lacked both innate and adaptive immunity, and had activation of canonical β-catenin signaling (CTNNB1, its targets and WNT receptors) and WNT-independent β-catenin signaling (Table 1). Conclusion In a large subset of this population-based cohort of primary tumors, we report evidence of immune evasion through β-catenin signaling pathway. These results obtained from archival material suggest that transcriptomic profiling is a viable alternative to flow cytometry in understanding tumor biology and in determining the effectiveness of immunotherapies.

**#4007** Differential macrophage programming is associated with the aggressiveness of gliomas. Nai-Wei Yao, Fang Liao, Chen Chang, Joanne Jeou-Yuan Chen. Academia Sinica - Inst. of Biomedical Sci., Taipei, Taiwan.

Tumor-associated macrophages (TAMs), a major component of immune cells in the tumor microenvironment, have been shown to be associated with enhanced malignancy of gliomas. The polarization of macrophages toward a pro-inflammatory phenotype M1 or an anti-inflammatory phenotype M2 governed by niche factors in the tumor microenvironment may dictate the malignant outcome of gliomas. In this study, we examined the effects of differential programming of TAMs on the development of C6 gliomas in different host microenvironment using SD and Wistar rats. Using multi-parametric MRI measurements, we show that C6 cells implanted into SD rats developed larger tumors as compared to those in Wistar rats (p = 0.0199), which was accompanied with a shorter survival of SD rats (p = 1.06 × 10^-7). The increased tumor growth in SD rats was associated with increased angiogenesis and higher levels of VEGF and VEGFR2 expression. We also observed a significantly increased ratio of M2/M1 in the tumors of SD rats while a decreased ratio of M2/M1 in those of Wistar rats, suggesting that the milieu of C6 gliomas in SD rats favors for the polarization of macrophages toward the pro-tumorigenic M2 phenotype. Most importantly, Induction of M1 polarization by IFNγ treatment greatly reduced tumor growth in SD rats associated with increased angiogenesis and higher levels of VEGF and VEGFR2 expression. We therefore sought to determine the role of conditioned medium from activated human macrophages on CRC cells. Methods: Human CRC cell lines HCP-1 and HCT116 were treated with conditioned media (CM) from Phorbol Myristate Acetate (PMA)-activated human macrophages cell lines THP-1 and U937. Viability studies were performed using the MTT assay, the invasion and migration were performed in Boyden chambers, co-cultured with a collagen matrix for the invasion assay. Results: The results showed that PMA-activated human macrophages 1) dramatically increased both migration and invasion abilities of HCP-1 and HCT116 CRC cell lines, 2) stimulated Epithelial-Mesenchymal Transition (EMT) and 3) had no effect on the response of CRC cells to chemotherapy. Our PCR results also showed that PMA-activation greatly increased the expression of growth factors and cytokines in human macrophages that could be involved in the changes described above and are currently under investigation. Conclusions: Our data show that PMA-activated human macrophages play an active role in promoting EMT of human CRC cell lines.

**#4008** Human macrophage CM promotes EMT in human colon cancer. Delphine R. Boulbes, Fan Fan, Rui Wang, Huiyuan Zhang, Stephanie S. Wotwich, Rajat Bhattacharya, Ling Xia, Xiang-Cang Ye, Lee M. Ellis. UT MD Anderson Cancer Ctr., Houston, TX.

Background: Although most studies support the observation that increased macrophage infiltration is associated with better patient prognosis and overall survival in patients with CRC (in contrast to other malignancies), others have shown that macrophages can have a pro-tumoral and pro-metastatic effect via epithelial-mesenchymal transition and the secretion of growth factors and cytokines. Therefore, we sought to determine the role of conditioned medium from activated human macrophages on CRC cells. Results: Human CRC cell lines HCP-1 and HCT116 were treated with conditioned media (CM) from Phorbol Myristate Acetate (PMA)-activated human macrophages cell lines THP-1 and U937. Viability studies were performed using the MTT assay, the invasion and migration were performed in Boyden chambers, co-cultured with a collagen matrix for the invasion assay. Results: The results showed that PMA-activated human macrophages 1) dramatically increased both migration and invasion abilities of HCP-1 and HCT116 CRC cell lines, 2) stimulated Epithelial-Mesenchymal Transition (EMT) and 3) had no effect on the response of CRC cells to chemotherapy. Our PCR results also showed that PMA-activation greatly increased the expression of growth factors and cytokines in human macrophages that could be involved in the changes described above and are currently under investigation. Conclusions: Our data show that PMA-activated human macrophages play an active role in promoting EMT of human CRC cell lines.

Tumor-associated macrophages play an important role in presenting tumor antigens to T cells and are being investigated for their role in sensitivity to immune checkpoint inhibitors such as PD-1 inhibitors. The M2 macrophage subtype, characterized by CD163 expression, is immunosuppressive and associated with poor prognosis. A multiplex CD68/CD163 immunohistochemical assay was developed to characterize the density of cells expressing each marker and determine the percentage of macrophages that are of the M2 subtype. The assay was used to analyze 22 normal tissue types and 50 tumor tissues within different conditions. The results were analyzed by image analysis and results were analyzed as percent positive and density per mm2. Cancer tissues expressed a greater percentage of CD163+ macrophages than normal tissues.

**#4010** Tonggyu-tang, a traditional Korean medicine, suppresses inflammation, potential implications in tumor microenvironment. Hyon Kim, Seong-Gyu Ko, Yong Cheol Shin, Ji Hye Kim, Hye-Sook Seo, Tai Young Kim, Se Hyang Hong, Kangwook Lee, Jin Mo Ku, Myeong-Sun Kim, Yu-Jeong Choi, Soo-yeon Kang, Chunhoo Cheon, Youme Ko, Huang Ching Wen, Yui Sasaki, Sohyeon Kang, Kyung He University, Seoul, Republic of Korea.

The critical roles of inflammation in the development of cancer have long been appreciated. A growing body of evidence supports the notion that infiltrates of inflammatory cells into tumor microenvironment influence the tumor progression by providing bioactive molecules including pro-inflammatory cytokines. Importantly, the increased number of mast cells within tumor microenvironment has been associated with a poor survival in cancer patients. More-
over, keratinocyte inflammation is known to be crucial for skin tumor development. The use of natural products to reduce inflammation in tumor microenvironment is gaining an interest, because of their reduced toxicity toward normal cells. In this study, we tested the effects of Tonggyu-tang (TGT) which is composed of 14 different herbal extracts on the activity of mast cells. We found that TGT significantly reduced the expression and production of inflammatory cytokines such as IL-4, IL-6, IL-8, and TNF-α in PMA and ionomycin-stimulated HMC-1 (human mast cell line-1). In an attempt to determine molecular mechanism underlying the inhibitory effects of TGT on cytokine expression, we revealed that TGT suppressed MAPK signaling pathway including ERK, p38, and JNK as well as NF-κB pathway, which are known to regulate inflammatory cytokine expression. Similar results were obtained from the LPS-stimulated HaCaT cells, immortalized human keratinocytes. Taken together, our results demonstrate that TGT suppresses inflammation by inhibiting the expression of pro-inflammatory cytokine in both mast cells and keratinocytes, thereby potentially leading to inhibition of tumor progression.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Assay Technology

#4011 Validation of novel continuous live-cell assays for immune cell activation and killing of blood cell cancers. Nicola Bevan,¹ Hinnah Campwala,¹ Clare Seybut,¹ Kalpana Patel,¹ Dan Appleford,² Tim Dale,² Derek Trezise.¹ ¹Essen BioScience Ltd, Welwyn Garden City, United Kingdom; ²Essen BioScience Inc, Ann Arbor, MI.

The blood cancers leukaemia, lymphoma and myeloma are expected to cause the deaths of > 55,000 people in the US in 2016. New immunological approaches afford great promise for improved therapies. Here, we describe novel high throughput live-cell image-based assays for immune cell activation and killing of target cells that are geared toward screening for new treatments for these malignancies. Myeloid and lymphoid cells (Jurkats, Raji, Ramos, WIL2-NS, THP-1, PBMCs) were plated on poly-L-ornithine (PLO) or fibronectin coated 96-well flat plates and monitored over time (h to days) using non-invasive live-cell analysis (Incucyte). The dynamics of proliferation were quantified via phase contrast image analysis (% confluency), and validated as a robust measure of cell number by correlating to direct cell counts (Sceptor, Millipore) and ATP assays (PerkinElmer). Anti-CD3/IL-2 (0.1-100/10 ng/mL) or anti-CD28 activation (1-100 ng/mL) of PBMCs evoked time-dependent proliferation (0-5d) that was sensitive to the initial cell density and concentration of stimulus. L-Kynurenine (4.69 - 300 μM), a metabolite of the amino acid L-tryptophan caused concentration and time-dependent inhibition of proliferation of PBMCs. To quantify immune-cell killing in co-cultures, WIL2-NS and Ramos B-cell myelomas were first transduced with nuclear-targeted RFP (NucLight Red) to enable direct cell counting. PBMCs, either pre-activated or activated in situ (IL-2/CD3), were then added and the time-course of killing quantified through live (RFP) and dead/apoptotic ( annexin-V) cell counting. Together, these protocol developments and validation data illustrate non-invasive continuous measurement of proliferation, activation, clustering and immune-cell killing of non-adherent tumour cells at industrial scale. Unlike flow cytometry, this approach follows the full time-course of the biology without perturbing the cells and allows cell-cell interactions to be visualised. These assays are amenable to testing new therapeutic antibodies, small molecules and genetic T-cell modulation such as CAR-T.

#4012 Visualization of EPR effect and active targeting by using microscopic mass spectrometry. Masahiro Yasaki,¹ Masaru Furuta,² Koretugu Ogata,³ Yuki Fujiwara,¹ Yoshikatsu Koga,¹ Yasuhiro Matsumura¹ ¹National Cancer Ctr. EPOC, Kashiwa, Japan; ²Shimadzu Corporation, Kyoto, Japan.

Microscopic mass spectrometry (MMS), in which a microscope is coupled with an atmospheric pressure matrix-assisted laser desorption/ionization (MALDI) and quadrupole ion trap time-of-flight (TOF) analyzer has been developed for the investigation of the distribution of various molecules including drugs. The matrix-coated drug sample is ionized and then separated on the basis of its mass-to-charge ratio (m/z). Images were acquired from imaging mass spectrometry (IMS) or tandem mass spectrometry (MS/MS) data. Recently, pharmacokinetic (PK) and pharmacodynamic (PD) studies have become important to evaluate the efficacy and toxicity of these molecules. Tissue homogenates are generally used for the quantification by high-performance liquid chromatography (HPLC) or liquid chromatography mass spectrometry (LC-MS). However, they lack the information regarding the drug distribution in a specific anatomical area. The information of the drug distribution would allow us to optimize the drug design enabling more efficient drug delivery. (1) We studied the tissue distribution of paclitaxel (PTX) and its micellar formulation (NK105) using a MMS. NK105 showed much stronger antitumor effects on a human pancreatic cancer BxPC3 xenograft than PTX. In the drug imaging, we demonstrated that NK105 delivered more PTX to the whole tumor tissue. In the mouse model, PTX caused the peripheral neurotoxicity but NK105 did not. Multiple high drug-signal areas surrounding and inside the caudal nerve were observed in the case of PTX, whereas the signals after NK105 administration were quite low. (2) The tissue distribution and controlled drug release of ADC (antibody-drug conjugate) consisting of a tissue factor specific antibody (TF) linked to the anticancer agent monomethyl auristatin E (MMAE) was evaluated in comparison with control-ADC (control antibody-MMAE conjugation). TF-ADC showed stronger antitumor effect on BxPC3 xenograft than control-ADC.

We then established the selective detection method of MMAE for distinguishing free MMAE and its conjugated form. The released MMAE signal followed the accumulation of TF-ADC was greatest 24 h after the administration, compared with the control-ADC at the same time (P < 0.01). In summary, we succeeded in visualizing (1) the EPR (Enhancement of permeability and retention) effect and (2) active targeting using MMS. The data obtained will facilitate more efficient drug development in the preclinical setting.

#4013 A novel multifunctional protein tag enables simple and sensitive bioluminescent quantification of tagged proteins. Christopher Eggers, Braeden Butler, Robin Hurst, Mary Hall, Brock Binkowski, Lance Encell, Marie Schwinn, Thomas Machleidt, Keith Wood, Frank Fan. Promega Corp., Madison, WI.

Disregulation of protein expression is a key mechanism of tumorigenesis. The most commonly used approach to monitor changes in expression is to perform SDS-PAGE, followed by immunoblotting, a labor-intensive process that requires high-quality antibodies to detect proteins at endogenous levels of expression. We have developed a novel protein tag utilizing NanoLuc Binary Technology (NanoBiT), a binary complementation system based on NanoLuc luciferase. The tag, designated High Bit (HiBiT), is only 11 amino acids in length, which minimizes potential interference with protein function. The amount of HiBiT-tagged protein is measured using a lytic detection reagent containing Large Bit (LgBiT), which binds with high affinity to HiBiT (Kd ~ 1 nM) to reconstitute a bright, luminescent enzyme. HiBiT-tagged proteins can be quantified in cell lysates over 7 orders of magnitude of linear dynamic range with a limit of detection of less than 10-19 mole (3 fg of 30 kDaprotein). The simple add-mix-read assay protocol can be completed in minutes, providing an assay that is compatible with high-throughput applications. The sensitivity of the assay allows quantification of expression at endogenous levels, and the small tag size is ideal for CRISPR-mediated genome editing. HiBiT-tagged proteins separated by SDS-PAGE can be detected on blots at picogram levels with a detection reagent containing LgBiT. By eliminating the multiple steps of blocking, binding, and washing of traditional blotting techniques, the protocol takes minutes instead of hours. Additionally, the cell surface expression, internalization, or secretion of HiBiT-tagged proteins can be measured in minutes using a non-lytic detection reagent containing the cell-impermeable LgBiT protein. HiBiT represents a next-generation protein tag that enables simple and sensitive quantification of proteins of interest in their cellular context or following SDS-PAGE.

The inability of most systemically delivered therapeutics to cross the blood-brain-barrier (BBB) is considered a major barrier to effective brain cancer treatment. In malignant glioma the tumor neoangiature is known to be leaky, however invasive cells remain protected behind an intact BBB, and continue to thrive within the brain, ultimately leading to tumor regrowth and patient death. This leaves us with an urgent unmet need for the development of next-generation therapeutics with improved brain delivery. For the first time, we describe here the utility of 3D multicellular BBB spheroids made of primary human brain endothelial cells (ECs), pericytes and astrocytes as a screening tool for brain-penetrating agents. We show that the outer surface of the spheroids, composed primarily of ECs and pericytes, form a tight barrier which is permeabilized in the presence of VEGF. The barrier is characterized by the presence of intact tight junctions and efflux-pump activity (i.e., P-glycoprotein). Furthermore, we have used this model to successfully demonstrate the transport of angiopep-2 (a well-known brain delivery vector) and its conjugates (containing cargoes of various sizes such as peptide, protein and affibody), thereby displaying the versatility of this model to screen and study a wide range of therapeutic agents. We demonstrate that this model is superior to the conventional transwell model in main-
taining essential BBB characteristics (i.e., tight/adeherens junctions and P-glyco-
protein expression) and as a drug-screening tool. We have utilized the spheroid model
to screen a panel of cell-penetrating peptides (CPPs) to identify several candidates with high brain-penetration potential. We then verified the ability of the top 4 candidate CPPs to cross the BBB in mice. This high-throughput model can lead to a refined understanding of preclinical glioma therapeutics, and improve prediction of drug penetration in a living model, paving the way for breakthrough discoveries in brain cancer.

#4015 A comparative study of PD-L1 IHC 22C3 and 28-8 FDA-approved diagnostic assays in cancer. Cary Batrenchuk,1 Maher Albitar,2 Sucha Sudarsana-
am,2 Vladislav Chizhevsky,2 Chelsea Jin,1 Virginia A. Burns1. 1Bristol-Myers Squibb, Princeton, NJ; 2NeoGenomics Laboratories, Aliso Viejo, CA.

Background: Higher levels of PD-L1 expression at the surface of tumor cells have been associated with increased response to anti-PD-1 therapies (Sanatbar-
emocin Laboratories lately supplied a subset of the samples received for PD-L1 testing with both 22C3 and 28-8 on the same biopsy specimen. This dataset presents an opportunity to explore real-world concordance testing for 22C3 and 28-8 anti-
bodies. Methods: The analysis was performed on a dataset obtained from Sym-
phony Health Solutions describing the PD-L1 biomarker test results and anno-
tations reported by NeoGenomics Laboratories between Oct 7, 2015, and Aug 31, 2016. A total of 5217 biomarker test results were available for 4528 patients affected by diverse malignancies. Concordance testing was performed on 556 unique patients that had a single 22C3/28-8 pairing collected from the same biopsy specimen. All staining was performed using the FDA-approved in vitro diagnostic assay using the 22C3 antibody or the 28-8 antibody on the Dako Link 48. Cases were reviewed and scored randomly across multiple pathologists, who received special training and certification in scoring. All statistical analyses were performed in SAS. Results: Paired biopsy specimens stained with both 22C3 and 28-8 displayed higher degrees of correlation (Spearman’s correlation co-effi-
cient = 0.97). In addition, Bland-Altman analysis revealed that the mean differ-
ence in the percentage of tumor cells positively stained for PD-L1 between the paired 22C3 and 28-8 assay findings was 0.48% (95% prediction limit (-12.41% to 13.37%)]. Across expression levels both antibodies displayed a similar prob-
ability of being interpreted as greater than one another (43 of 556 where 28-8 displayed an expression higher than 22C3 was 0.48% [95% prediction limit (-12.41% to 13.37%)].). The overall rate of agreement was between the paired 22C3 and 28-8 antibody displaying greater sensitivity. When analyzed at the ≥1%, ≥5%, ≥10%, ≥25% and ≥50% thresholds, the overall rate of agreement was between 96.8% and 98.2% and associated with a level of agreement (Cohen’s kappa) between 0.92 and 0.96. Conclusion: Both the 22C3 and 28-8 diagnostic assays show strong agreement in a single central laboratory real-world setting. These assay results, in agreement with previous publications, have shown consistency in diagnostic interpretation.

#4011 Homogeneous BTK occupancy assay for pharmacodynamic assess-

Burton’s Tyrosine Kinase (BTK) plays an important role in B cell signaling, cell proliferation and survival. Hence, it is an attractive target for therapeutic intervention in B cell malignancies and autoimmune disorders. GS-4059 (ONO-4059) is a covalent, potent and selective inhibitor of BTK in clinical development for CLL, NHL and rheumatoid arthritis. Accurate measurement of target cov-
erage in early stage clinical studies is critical to informing dose selection for GS-4059 in more advanced clinical studies. We developed a novel duplex ho-
mogeneous BTK occupancy assay to enable quantitative measurement of GS-
4059 binding to human BTK for assessing target coverage in the clinic. The assay is based on Time-Resolved Fluorescence Resonance Energy Transfer (TR-
FRET) and simultaneously measures the levels of free BTK (BTK that is not bound to GS-4059 in treated human PBMCs ex vivo or PBMCs from patients treated with GS-4059 in clinical studies) as well as the levels of total BTK protein. We took advantage of the dual wavelength emission property of Terbium (Tb) to serve as energy donor for 2 fluorescent energy acceptors with distinct excitation and emission spectra. We designed and synthesized a GS-4059 analog with bi-
oxin conjugate which showed equal potency to GS-4059, suggesting that it binds in the same BTK pocket. To detect free BTK, a Tb-bound anti-BTK antibody was used as the FRET energy donor and G2-streptavidin-bound biotinylated GS-4059 as the energy acceptor. Total BTK was detected in the same well with a second D2-bound anti-BTK antibody that binds to a different BTK epitope as a secondary detection reagent. When GS-4059 was used, this multiplexed format allows measurement of free and total BTK levels in the same well. The assay was characterized and qualified using full length purified recom-
binant human BTK protein and PBMCs derived from healthy volunteers and CLL patients. Preliminary data indicate the assay is also suitable for assessing BTK occupancy in bone marrow derived cells. Using this assay, we evaluated the BTK synthesis rate following a 1 hour high dose (5 μM) treatment of GS-4059 in BTK inhibitor resistant ABC-DLBCL and GCB-DLBCL tumor cells. While neg-
ligible new BTK synthesis was observed in BTK inhibitor sensitive DLBCL cells, the free BTK level in the inhibitor resistant tumor cells recovered rapidly post-
treatment. In summary, we have established a homogeneous TR-FRET based BTK occupancy assay that simultaneously measures free and total BTK levels in the same well, yielding quantitative BTK occupancy data to support GS-4059 clinical development.

With the development of molecularly-targeted therapeutics, it is critical to have a reliable method for predicting response to therapy of patients with target-
expressing diseases. Folate receptor (FR) is overexpressed in a number of disease states while it is low in most healthy individuals with the exception of the kidney. FR-targeted small molecule drug conjugates (SMDCs) are currently under de-
velopment and have shown promising pre-clinical and clinical results. Two premises that a patient would respond to the folate-drug conjugates are: 1) FR expression in diseased tissues is functionally competent for folate binding and 2). functional FR is accessible to intravenously-infused SMDCs. Although anti-FR antibody-based immunohistochemical (IHC) assays are being deve-

goped as companion diagnostic strategies for antibody-drug conjugate (ADC) therapies, it fails to address the functionality and accessibility of FR in an in vivo context. To circumvent these limitations, we have developed an FR-targeted, crosslinkable small molecule reporter conjugate (SMRC), FRRC, which contains three modules: 1. a high-affinity folate ligand that binds with FR on diseased cells; 2. a small hapten, FITC, which can be detected by anti-FITC antibodies; and 3. an amino acid spacer in between these two modules that can crosslink FRRC to FR in situ during formalin fixation. After intravenous (i.v.) injection, FRRC would dock to the accessible and functional receptors in vivo. By process-
ing biopsied tissues and performing anti-FITC IHC staining, we can evaluate the cellular localization and relative abundance of functional FR in heterogeneous tissues. To evaluate our design, we synthesized a compound we refer to as FRRC and examined its properties both in vitro and in vivo. By testing FRRC in cell lines, we found that it can bind to FR and is detected in formalin-fixed cells by using conventional immunohistochemistry (IHC) staining. After intravenous injection of FRRC in vivo, the tail vein into mice bearing FR-positive KB tumor xenografts and its specific accumulation and kinetics in tumor and other tissues were evaluated by per-
forming anti-FITC IHC staining on formalin-fixed paraffin embedded tissues. Our results were shown to be in agreement with previous folate-based functional FR imaging and bio-distribution studies. In contrast, EC17, which lacks the crosslinkable spacer module, showed significantly reduced binding in vitro and in vivo assays. Owing to its modular design, additional SMRCs with differ-
ent ligands and small haptenes (rhodamine, DNP) have also been designed to assess the functional binding of other receptor and membrane-expressed pro-
teins. In conclusion, our assay is an effective tool for evaluating functional and accessible receptor expression in vitro and in vivo, and has the potential to be useful in patient or disease selection for our SMDC therapeutic.

#4018 Identifying allosteric modulators of KRas using second harmonic generation. Elizabeth Donohue Vo,1 Gabriel Besserer Mercado,2 Patrick Alex-
ander,3 Ben Morer,4 Que Van,3 Andrew G. Stephen,3 Joshua Salafsky,2 Frank McCormick1. 1UCSF, San Francisco, CA; 2Biodex, Inc., South San Francisco, CA; 3Frederick National Laboratory for Cancer Research, Frederick, MD.

The Ras protein family consists of small GTPases that are critical signaling transducers regulating cellular processes including proliferation, differentia-
tion, and survival. As monomeric GTPases, Ras proteins cycle between an inac-
tive GDP-bound state and an active GTP-bound state. Oncogenic mutations in one of the Ras isoforms, H-, N-, and K-Ras, impair GTP hydrolysis, thus de-
**EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Assay Technology**

Background: Identification and characterization of novel molecular inhibitors that target key regulators of cancer stem cell (CSCs) self-renewal is promising in cancer therapeutics. MYC and p53, the two major cellular transcription factors, acts as key molecular regulators in stem cells and cancer stem cells self-renewal. While MYC enhances, p53 inhibits the self-renewal of stem cells. However, tumor cells bearing both mutations would potentially benefit from targeting MYC and p53. They are critical for self-renewal of stem cells, and therefore, targeting them might be a promising therapeutic strategy. However, the search for small molecules that could target the self-renewal aspect of these two proteins has been elusive. Previously, we demonstrated that squalene molecule squalene could enhance bone marrow hematopoietic and mesenchymal stem cells (MSCs) by modulating MYC. Importantly, we found that ursoic acid, an isoprenoid molecule, regulated the transcriptional network portrayed by MYC and p53. Hence, having these prior experiences on isoprenoids, we speculate that novel isoprenoid may exist that could modulate MYC's role in cancer self-renewal. We are especially interested in identifying novel isoprenoid molecules (metabolites of mevalonate pathway) found in medicinal plants of North East India, where KaviKrishna laboratory is located. Methods: For the study, we proposed to develop an in vitro self-renewal based assay platform (henceforth known as STEM-TECH platform) to identify novel molecules that act on self-renewal aspect of MYC and p53. In this assay, we subjected the oral cancer cell line SCC-25 to 3-D tumorogenic growth using methylcellulose based method. Using this assay, we have screened 20 herbal extracts of North East India, and selected 3 herbal extracts for further evaluation. For the in vivo study, we added these herbal extracts to drinking water of C57BL/6 mice treated with 7-NQO (an oral carcinogen) and FVB/N mice with induced thymic lymphoma. The mice were observed in 10 weeks and subjected to evaluation of tumor growth, and also evaluation of cancer stem cells using ABCG2, a cell surface marker expressed by cancer stem cells. Results: We found that herbal extracts from Tulsi and Soalu exhibited strong anti-tumor activity in the in vivo mouse models. Importantly, these extracts exhibited the ability to inhibit the self-renewal of MYC driven ABCG2+ cancer cells (1). Also, these extracts were subjected to in vitro Stem-Tech assay and we found that one herbal extract could modulate the transcriptional binding of MYC. Importantly, we found that squalene, an isoprenoid found in several herbal extracts in NE India could modulate MYC activity by an unknown mechanism. Conclusion: Our results indicate that the vast, untapped herbal plants available in India's remote North East contain valuable herbal medicinal plant having potential MYC inhibitor. 1. Das B et al. MYC through HIF-2alpha regulates the self-renewal program in cancer stem cells (under review).

**#4019** A PCR-bias free capture-based library preparation platform permitting highly accurate and sensitive CNA detection in tumor molecular profiling and liquid biopsy. Anna Vilborg,1 Yosr Bouhlal,1 Ryan Bou Khalil,1 Francisco De La Vega,1 Hanlee Jj,1 1TOMA Biosciences, Foster City, CA; 2TOMA Biosciences, Foster City, CA; 3TOMA Biosciences, Stanford University, Foster City, Palo Alto, CA; 4Stanford University, Palo Alto, CA.

Next Generation Sequencing is increasingly implemented as a diagnostic test to identify actionable mutations in cancer patient samples. However, for routine diagnostics, tumor DNA is extracted from formalin-fixed, paraffin-embedded (FFPE) samples, which yields low quantity of damaged DNA. Inability to accurately repair the ends of these DNA fragments impairs adapter ligation by standard double stranded ligation methods. The resulting low yield of adapter-ligated DNA introduces the need for whole-genome PCR amplification prior to target capture. The drawback of such PCR amplification is the introduction of PCR biases, caused reduced sensitivity in the detection of copy number alterations (CNAs), an important biomarker for targeted therapy. To address the need for a library preparation platform that performs well with low quality and quantity DNA, and without relying on massive PCR amplification, we developed an improved, in-solution, version of the OS-Seq targeted enrichment assay. OS-Seq circumvents the reliance on PCR amplification by using a single-stranded adapter ligation approach. Damaged bases induced by formalin fixation are removed by excision instead of attempting repair, and then DNA is denatured prior to adapter ligation. This method of adapter ligation result in yields of ~50% for low quality samples, eliminating the need for whole genome PCR. OS-Seq directly uses the adapter-ligated DNA in a linear targeted primer-extension, followed by low-cycle post-capture PCR expansion with Illumina bridge PCR primers prior to library sequencing. We investigated the PCR duplication rate of the OS-Seq libraries by including an 11-mer random barcode to track unique molecules. We found that most input molecules were present in the sequencing reads at only one copy. Further, we demonstrate a linear correlation between the amount of DNA input (ranging from 1 to 600 ng) and the number of unique molecules sequenced (R²=0.94). Importantly, we show that this low PCR bias allows OS-Seq to detect CNAs in Coriell and Horizon Diagnostic cell lines highly concordant to digital PCR detection (R²=0.96). Further, we present CNA calling on cell line DNA sonicated to 200 bp fragments at 10 ng DNA input, mimicking cell-free DNA. In addition to CNA detection, OS-Seq detects SNVs with a sensitivity of 92-97% and a specificity of 100% down to 5% VAF. In conclusion, the OS-Seq library preparation method relies on single stranded adapter ligation and in-solution target capture, which generates uniform coverage with minimal PCR requirement, resulting in highly sensitive CNA calling.

**#4020** Identification and characterization of Novel MYC and p53 target molecules from medicinal plants of North East India. Sora Sandhya,1 Joyeeta Talukdar,1 Bidisha Pal,2 Seema Bhuyan,2 Debabrata Baishya,2 Bikul Das2,1 KaviKrishna Laboratory, Gauhati Biotech Park, IIT, Gauhati, India; 2Forsyth Institute, Cambridge, MA; 3Gauhati University, Gauhati, India.

Dendritic cell (DC) based immunotherapy is a promising treatment alternative for various solid tumor and hematological malignancies. DCs are capable of initiating and propagating antigen-specific adaptive immune responses through their intrinsic maturation process. Identifying novel, effective adjuvant drug candidates that can stimulate DC maturation while understanding and accounting for the variability of patient-specific DC responses to the immunostimulatory adjuvants is essential for development of such immunotherapies. Reliable, high throughput assay platforms that characterize patient-specific modulatory effects during the DC maturation process in vivo and in vitro are also highly desirable. In this study, we present a high throughput in vitro primary cell assay to evaluate dose-dependent DC maturation in a panel of human leukocyte antigen (HLA) typed individual donors. CD14+ monocytes from four healthy donors were isolated from leukapheresis derived peripheral blood mononuclear cells (PBMC) and cultured for seven days with GM-CSF and IL-4 to achieve differentiation to DC. Cells were then stimulated for 24 hours with lipopolysaccharide (LPS), CpG oligonucleotides, or nine different novel toll-like receptor 4 (TLR4) ligands at three concentrations. To quantify the differentiation of monocytes into DC and subsequent maturation, flow cytometry was used to measure the expression of biomarkers, MHC-II, CD40, CD80, CD83, and CD86. Greater than 99% MHC-II expression was observed across all donors and confirmed successful differentiation to DC. The TLR4 ligands showed reduced biomarker expression, as compared to pathogenic E. coli LPS but similar to PHAD, a synthetic TLR4 agonist currently used in adjuvants. While monocytes from all donors responded to the ligands tested, the intensity of activation marker expression varied among donors with LPS/TLR4 ligand induced maturation process showing 43-91% CD40 and 27-82% CD83 expression, highlighting the necessity of multi-donor screening for drug development. In conclusion, a high through-
put in vitro primary monocyte derived DC differentiation assay has been develope-
ded and is commercially available to assist researchers in characterizing donor-specific
DC responses to immunostimulatory adjuvants.

#4022 Validation of label-free impedance analysis as a versatile tool for
cancer molecular therapeutics screening. Fabio Cerignoli, Biao Xi, Brandon
Lamarche, Yiming Acosta, Yimen Abasaei, Yiyan Abasaei. ACEABiosciences Inc., San Diego, CA.

In vitro monitoring cancer cells response to treatment often involves labori-
ous sample processing and collects single data points that are against the dy-
namic nature of cancer cells. Here we present the adaptation of an impedance-
based methodology to dynamically monitor cancer cell behavior and therapeutic
response. The technology detects cell death, proliferation or migra-
tion by measuring changes in conductance of microelectrodes embedded in 96
and 384-wells cell culture plates. It avoids sample labeling and processing and
allows continuous monitoring of cell response. Our data shows validation with
cancer cell lines and primary cells monitored for cell invasion/migration, anti-
cancer drug response and receptor signaling activation, with similar results over
end point assays. Easy experiment set up and minimal sample processing make
the technology ideal for applications in large screening campaigns, while label-
free technology allows further analysis on the same samples through orthogonal
assays.

#4023 The SABRE platform: A novel, unbiased technology for drug dis-
cover and prioritization. Shelli M. Morris,1 Andrew J. Mhyre,2 Savanna S. Carmack,2 Connor Burns,2 Marc Ferrer,2 Wenjuan Ye,2 James M. Olson,1 Rich-
ard A. Klinghoffer2.1 Fred Hutchinson Cancer Research Center, Seattle, WA; 2Presage Biosciences, Seattle, WA; NIH/NCAATS, Rockville, MD.

Targeted therapies designed to inhibit hyperactive oncogenic signaling have
demonstrated some encouraging clinical responses. However, most of these
responses are not durable as tumors “work around” pathway inhibition, often
reactivating the inhibited pathway, leading to drug resistance and disease relapse. New technologies that enable more efficient discovery and development of
“suites” of drugs that comprehensively inhibit multiple pathway nodes are
needed. The SABRE (Splice Acceptor Brilliant Reporter) platform was devel-
oped to provide an unbiased method to screen large compound libraries and
dramatically improve the speed and efficiency of which novel targeted therapeu-
tics can be identified. SABRE is built off the premise that oncogenic output is
exerted through changes in gene transcription and that such changes can be
harnessed as powerful reporters of pathway activation status. SABRE utilizes
the power of gene trap technology coupled with a drug selection process to isolate
cells that generate a robust “off to on” signal in response to target or pathway
inhibition. Via massively parallel comparative analysis, multiple traps let nature
provide the best reporter for further analysis and drug discovery. In this proof-
of-concept study, we employed the SABRE technology to identify insertion sites
that are specifically regulated by the MAPK pathway. Experiments were per-
formed using the human BRAFV600E mutant melanoma cell line A375. SABRE
lentiviral transduced A375 cells were treated with trametinib, a MEK inhibitor,
and clones were isolated that emitted a positive luciferase signal upon drug
treatment. To determine if these reporters were MAPK pathway specific, the
platform was miniaturized to a 1536 well plate equipped to screen a 6000+ com-
 pound library. Results from the screen found that 70% (2840) of the top
drug hits were known to directly modulate the MAPK pathway. Since drug
resistance is a common occurrence in melanoma, we generated a “resistant
A375 SABRE reporter line to increasing concentrations of vemurafenib
and interrogated the top drug candidates identified in the screen. As expected, the
resistant SABRE line failed to respond to BRAFV600E specific inhibitors but
continued to respond to downstream MEK inhibitors, which is helping to de-
line the mechanism of resistance. We were also interested in the screening
hits that were not previously known to influence the MAPK pathway including
baftinib and a Tie2 inhibitor. In follow-up testing, we found that these drugs
induced robust and titratable reporter signals in both the SABRE A375 vemur-
afenib sensitive and resistant lines. In addition, treatment of either baftinib or
the Tie2 inhibitor reduced ERK phosphorylation in the vemurafenib resistant
cells, suggesting that these drugs could be useful in the treatment of drug resis-
tant melanomas. Studies are currently underway to determine the in vivo effi-
cacy of these drugs in A375 SABRE reporter xenograft models.

#4024 Physiologically relevant target engagement using the cellular ther-
mal shift assay (CETSA). Jakob Karen, Catrine Sieberg, Nancy Dekki Shalaby,

Targeted therapies are dependent on adequate occupancy and target engage-
ment to reach their efficacy measure. Yet, more than half of novel candidate
drugs entering clinical trial stage fail before proof of concept is achieved. Inad-
equate target engagement is often at the root cause of these failures. Therefore,
we have developed a versatile label-free method to quantify the target engage-
ment of drugs on their native physiological relevant targets. The method is
validated in multiple sample matrices, using different technical platforms to
allow studies of target engagement from bench to bedside: in living cells and
their metabolites and mass spectrometry. CETSA(1) is a patented biophysical method
measuring the thermal stability of drug target proteins and the shift induced by their
ligands. By quantifying the melting temperature and shift induced by the ligand
we can quantify the potency of target engagement. This potency determination
allows filtering of candidate drugs by their ability to engage the target in its
physiologically relevant form, in relevant sample formats such as intact cells or
tissue. We present several applications of the method and the utility in preclin-
ical in vitro studies and translation to in vivo systems. In addition, new powerful
detection formats are being evaluated and will be presented. The utility and
value of the CETSA(1) method enabling preclinical development of novel drugs
is substantiated by the examples included here. We show the value of the method
both for compound/drug profiling, for target profiling and for unbiased drug
screening in whole proteomes in response to drug treatments. Such datasets can
be generated from in vitro systems to clinical samples and may reduce the high
attrition rate in proof of concept studies by facilitating the discovery, develop-
ment and evaluation of novel drugs.

#4025 Accelerating drug repurposing for cancer therapy using multi-
plexed viability assays. Steven M. Corsello,1 Christopher C. Mader,2 Jordan
Bryan,1 Jennifer Roth,1 David Peck,1 John Davis,1 Samantha Bender,1 Li Wang,1
Alice Prisby-laRossa,2 Joshua Bittker,1 Francesca Vanacur,2 Aarv Trisnesh,1
Todd R. Golub1.1 Dana-Farber Cancer Institute, Boston, MA; 2Broad Institute, Cambridge, MA.

New therapies are desperately needed for patients with advanced cancer, but
making safe and efficacious drugs remains expensive and time consuming.
Meanwhile, multiple non-oncology drugs have been successfully repurposed for
cancer, including thalidomide for multiple myeloma and aspirin for prevention
of colorectal cancer. While the benefits of repurposing are clear, successes to date
have been largely serendipitous. We have created two foundational tools to
identify drug repurposing opportunities at a much greater scale: a new world-
class screening library of more than 4,000 drugs/cancer cell lines and a mul-
tiplexed method to rapidly conduct cellular viability assays across hundreds of
cell lines. PRISM, a recently developed high-throughput assay, employs DNA-
barcoded cell lines to enable rapid testing of many drugs against pools of cancer
cell lines. We have tested 4,100 compounds against 578 genomically charac-
terized cancer cell lines using PRISM. Our experiment is among the largest cell line
screens ever undertaken. Global analysis has revealed multiple strong clusters of
active drugs, including vitamin D agonists, bromodomain inhibitors, and st-
atins. In addition, many novel and established drug-biomarker relationships
were identified, including alkylation agent response and low MGMT expression,
BRAF inhibitor response and BRAF mutation, and MDM2 inhibitor response
and TP53 wild-type status. Surprisingly, more than 100 non-oncology drugs
unexpectedly killed multiple cancer cell lines, making them attractive repurpos-
ing candidates. For example, the FDA-approved phosphodiesterase inhibitor
anagrelide selectively kills PDE3A-high lung cancer and melanoma cell lines.
Confirmaotary experiments are underway to validate screening results, evaluate
putative biomarkers, and test drug activity in preclinical models. Importantly,
this approach is expected to enable rapid initiation of clinical trials, dramatically
accelerating patient access to potential new therapies.

#4026 Bioluminescent metabolite assays enable easy measurement of
changes in tumor biology. Michael Valley, Mary Sobol, Donna Leippe, Jolanta
Vidugiriene. Promega Corp, Madison, WI.

Tumor cells rely on metabolic reprogramming to meet their increased de-
mands for energy and biomass. Such reprogramming is exemplified by in-
creased rates of glucose uptake, greater utilization of glycolysis, and a reliance on
glutaminolysis. Cancer cells also have a strong dependence on lipids and cho-
lesterol and thus feature enhanced rates of biosynthesis and uptake of these
molecules as well. We have developed a suite of bioluminescent assays that can
monitor metabolites in all of these important pathways. These assays share a
core technology that couples the production of NAD(P)H to the generation of light
through a variety of metabolite specific dehydrogenases. Changes in glyco-
lysis and glutaminolysis can be followed by measuring glucose, lactate, gluta-
mate, and/or glutamine through their respective dehydrogenases (and glutam-
ase). Glucose uptake is typically monitored through the accumulation and
phosphorylation of 2-deoxyglucose to produce 2-deoxyglucose-6-phosphate,
and this can be measured by employing glucose-6-phosphate dehydrogenase.
These bioluminescent assays are homogeneous and can be multiplexed with

REFERENCES

viability, cytotoxicity, and protein quantitation assays. Metabolites can be measured extracellularly (i.e. from media) or intracellularly and the assays can be performed in 96- or 384-well plates. These assays are simple and sensitive and can provide a greater understanding of how various treatments affect the metabolic state of a tumor cell.

#4027 Developing biophysical platforms to study KRAS membrane interaction in artificial membranes, Frantz L. Jean-Francois, Andrew G. Stephen.

In our studies, we leverage the techniques that we believe will allow us to better understand and tackle KRAS membrane interaction. RAS proteins are small GTPases that oscillate between an active GTP-bound and inactive GDP-bound state to function as plasma membrane localized molecular switches in growth factor regulated signaling pathways. Mutation in HRAS, KRAS and NRAS are present in nearly 30% of human tumors. In particular, KRAS is mutated in almost 90% of pancreatic adenocarcinomas. Considering the requirement of the plasma membrane for KRAS activity, we are setting up ‘screenable’ biophysical platforms to understand the importance of lipids and find small molecules that could prevent KRAS membrane association in reconstituted systems. The two main techniques that are being developed are Surface Plasmon Resonance and Confocal Imaging in model membranes. Using these two techniques, we have been able to better understand the main lipids that drive KRAS membrane association and set up platforms that can be screened by small/large molecules. Biophysical techniques are frequently used by pharmaceutical companies as primary or secondary screening platforms. Developing such platforms for KRAS membrane interaction could enable the discovery of anti-cancer tool compounds.

#4028 Analysis and recovery of functionally defined single immune cell clones through opto-electro-positioning technology, Xiaohua Wang, Yelena Vanyan, Louis Gardner, Animesh Shukla, Thomas Miller, Su Wang, Sheldon Grove, Andrew Chow, Jessica Suschak, Sarah Wheeler, Anu Mathew, Martin K. Stengelin, Jacob N. Wohlstadter.

Cancer patients mount protective innate and adaptive immune responses against tumor cells. Such responses are able to control or even eliminate tumor burden if harnessed properly. Identifying clonal adaptive immune cells targeting tumor cells with designated function is extremely valuable as these cells are able to either fight the tumor directly or provide tumor targeting immune receptors to engineer other effector cells like autologous CD8 T cells or NK cells. The process of isolating specific immune cells and their receptors, however, remains technically challenging and labor intensive. Opto-Electro-Positioning (OEP) technology employs a light actuated dielectrophoretic force to maneuver live cells in their culture environment. We have combined OEP with a nanofluidic cell culture system to produce an integrated microfluidic platform that enables multi-dimensional investigation of lymphocyte specificity and function. The system is able to 1) deterministically capture designated lymphocytes, 2) actively maintain and observe colony growth, and 3) conduct cytokine release assays, all in a single enclosed microfluidic chip. The new platform is suitable for high throughput screening to identify and harvest antigen specific and/or functionally defined T cells. We have successfully applied it to isolate primary human T cells targeting either EBV/Tetanus toxin antigens or tumor associated antigens such as MART-1 through tetramer staining or a proliferation assay. The system is also exceptionally efficient for investigating immune cells from clinical specimens typically of low cellularity. From tumor biopsies, we are able to capture tumor infiltrating T cells, stimulate proliferation, investigate their TNF-α secretion on chip, and obtain full transcriptomic analysis after export. Overall, our data suggest the OEP nano-fluidic environment provides a powerful high throughput screening tool to identify rare lymphocytes against tumor associate antigens or neo-antigens and to investigate precious clinical samples for biomarker discovery.

#4029 Robust Ras inhibition assay utilizing fully synthetic Ras-binding domain, Lyuba Khavrutskii, Sergey G. Tarasov, Colin Fields, Karen Stefanisko, Nadya Tarasova.

Intensifying efforts to develop clinically useful inhibitors of Ras proteins resulted in increasing need for quantitative, reliable and robust in vitro assays of Ras activity. The vast majority of detection methods used in the assays require fusion, chemical modification or immobilization of the protein. We have found that K-Ras modifications have significant impact on its activity and function because of the highly allosteric nature of the protein. We have attached three different fluorescent moieties to two sites distant from the active site of the protein in a site-selective manner. All six modifications resulted in significant decreases in affinity towards Ras-binding domain of one of Ras’s major effectors c-Raf as determined by Microscale Thermophoresis (MST). Fluorescent labeling of recombinant Raf1 RBD also resulted in inhibition of K-Ras binding. To produce a pair that interacted as unlabeled proteins, we have generated RBD with a single-site attached fluorescent moiety utilizing microwave-assisted high efficiency solid phase peptide synthesis. Optimization of coupling and deprotection protocols and the type of the solid support allowed conducting the synthesis of 76 residues long protein in fully-automated manner in one run. Refolding of the product yielded RBD that was indistinguishable from the recombinant one in CD spectra, melting temperature and K-Ras binding affinity as determined by isothermal calorimetry and microscale thermophoresis. K-Ras RBD produced significant changes in both thermophoretic signal and fluorescence anisotropy upon binding to K-Ras. Both MST and fluorescence polarization assays have proven sensitive, reproducible and straightforward for determination of Ras inhibition constant for Ras inhibitors identified by virtual screening and rational design. They can be easily adapted to high throughput screening formats. Developed synthetic protocols allow for straightforward generation of proteins with various natural and non-natural modifications.

Tumors are comprised of heterogeneous cells. Only a specific or rare population of tumor cells is capable of metastasizing through blood. While mapping out the genome of cancer cells, gene expression variations indicative of more aggressive cancer cells might be missed among the noise. Therefore, single cell gene expression and mutation analysis provide a more comprehensive and most precise information about the heterogeneity of cancer progression and metastasis. Although there has been a surge in technologies used for selection and analysis of single cells, single cell analysis of rare cells such as circulating tumor cells (CTCs) is fraught with technical challenges. Among many used techniques to isolate single cells, the most common cell separation method is cell sorting by flow cytometry, which requires cell labeling. The numerous steps involved in cell labeling and centrifugation result in significant cell loss and changes in gene expression. In addition, centrifugation may also cause shear-induced gene expression changes in viable cells. For other single cell analysis platforms, there is a minimum input of cells ranging from 200 - 1000 cells. Rare cells like CTCs are found in the range of 1-10 per mL of blood. Another challenge is that the input volume required for these systems is very low usually in microliters. Here, we introduce a novel microfluidic chip with 250,000 microwells which captures cells at 100% efficiency down to one cell with a dynamic range over 5 logs. The underlying principle of this technology is that the geometric pattern of the microfluidic chip captures a single cell from an initial volume of up to 1 mL of fluid due to cell settling. The unique microwell structure promotes easy fluid exchange without perturbing the cells from their captured locations, thereby eliminating cell loss during multistep downstream processing. Preliminary tests have shown that single or cluster of spiked cancer cells in blood can be immunostained, bound or fixed and can also be retrieved very efficiently from the chip using a micro capillary. The retrieved single cells can further be used for several single cell genetic analysis. We will present data describing cancer gene expression and gene mutation analysis in isolated single cells.

#4030A S-PLEX™ Troponin I assay with fg/mL sensitivity, Anahit Aghvanyan, Louis Gardner, Animesh Shukla, Thomas Miller, Su Wang, Sheldon Grove, Andrew Chow, Jessica Suschak, Sarah Wheeler, Anu Mathew, Martin K. Stengelin, Jacob N. Wohlstadter. Meso Scale Diagnostics, LLC, Rockville, MD.

Cardiovascular toxicity is a potential complication of multiple anticancer therapies. Some drugs, such as anthracyclines, have been implicated in irreversible cardiac dysfunction. Cardiac troponin is a specific and sensitive marker of myocardial injury. Serum and plasma concentrations of troponin are often below the limits of detection in apparently healthy individuals. Sensitivity of troponin assays has improved by two orders of magnitude over the last several years, but few assays can detect basal levels of serum troponin in more than 50% of apparently healthy individuals, limiting the utility of the assay for early detection of low levels of cardiac damage. S-PLEX is a novel ultrasensitive immunoassay platform based on MSD’s MULTI-ARRAY™ electrochemiluminescence technology. An S-PLEX cardiac troponin I assay was developed and analytically characterized for research use. Serum and plasma samples from 24 apparently healthy individuals, 90 individuals with cardiovascular complications, and 25 individuals receiving anthracycline chemotherapy were measured. The assay required 25 μL of sample per measurement and was run on the MESO SECTOR S 600 and MESO QuickPlex™ SQ 120 instruments. The lower limit of detection was determined to be 10 fg/mL and the limits of quantitation ranged from 31 fg/mL to 160,000 fg/mL. The assay was anchored to the NIST reference material SRM 2921. Control samples run at 3 levels (n=8 per plate, 8 plates, 2 days, 2 operators) had total CV’s of 7% to 8% (n=64). Spike recovery and dilution linearity had recoveries between 80% and 120%. Specificity of the assay was 1029

Proceedings of the American Association for Cancer Research. Volume 58 • April 2017 1029
and R132C) were analyzed by pyrosequencing. To determine the in vitro antitumor effect of GBM (IC-4687-GBM and IC-3752-GBM) were included. IDH1 mutations (R132H) xenograft (PDOX) model of recurrent AOA (IC-V0914AOA), and 2 PDOX models (BT142) of anaplastic oligoastrocytoma (AOA), and a patient-derived orthotopic xenograft mouse models. Background: Mutation in isocitrate dehydrogenase 1 (IDH1) occurs in >70% of WHO grades II and III astrocytomas and oligodendrogliomas and secondary glioblastoma (GBM). The mutant enzyme catalyzes the reduction of α-ketoglutaric acid to D-2-hydroxyglutaric acid, leading to cancer initiation. In this study, we examined the therapeutic efficacy of SYC-435 (1-hydroxypyridin-2-one), a newly developed mutant IDH1 inhibitor, both in vitro and in vivo in IDH1 mutant gliomas as compared with IDH1 wild type GBMs. Methods: An established nudeusphere line (BT142) of anaplastic oligoastrocytoma (AOA), and a patient-derived orthotopic xenograft (PDOX) model of recurrent AOA (IC-V0914AOA), and 2 PDOX models of GBM (IC-4687GBM and IC-3752GBM) were included. IDH1 mutations (R132H and R132C) were analyzed by pyrosequencing. To determine the in vitro antitumor activity of SYC-435, tumor cells were exposed to SYC-435 (0.02 to 20 μM) and examining for changes of cell proliferation every 3-4 days till day 13 by Cell Counting Kit-8 assay. For in vivo effects, orthotopic xenograft mouse models of IC-BT142AOA and IC-V0914AOA were treated with vehicle (as control), SYC-435 (i.p., 15 mg/kg/day x 28 days), temozolomide (TMZ, oral, 30 mg/kg/day x 5 days) + fractionated radiation (XRT, 2 Gy/day x 5 days) (as standard therapy), and combination of SYC-435 with standard therapy starting 2 weeks after intracranial tumor implantation. Animal survival times were analyzed by log rank analysis. Results: IDH1 R132H mutation (homozigous) was detected in BT142AOA nudeusphere line and R132C mutation (patient allele frequency 39-42%) in IC-V0914AOA xenograft cells, while the two GBM models (IC-4687GBM and IC-3752GBM) carried wild type IDH1. Suppression of cell growth was observed in time- and dose-dependent manner by SYC-435, particularly at the IDH1 mutant models. At 0.5 μM, SYC-435 inhibited cell growth by 90% in BT142 and 60% in IC-V0914AOA cells, whereas in IDH1 wild-type GBMs only by 17% in IC-4687GBM and 19% in IC-3752GBM cells at day 13, indicating the high selectivity of SYC-435 of mutant over wild type IDH1. Systematic in vivo treatment with SYC-435 alone did not alter survival times in neither IC-BT142AOA nor IC-V0914AOA models when compared with the control group. Although standard therapy significantly prolonged animal survival times in both models (P<0.0005), combining SYC-435 with standard therapies further extended the median survival times from 106 days (in the standard therapy group) to 124 days (P<0.05) in IC-V0914AOA and exhibited similar trend in IC-BT142AOA. Conclusion: SYC-435 possesses antitumor effects that are highly selective in IDH1 mutant gliomas, and generated strong synergistic activities with standard therapies in vivo. Our data support the clinical testing of SYC-435 in patients with IDH1 mutant glioma.

preliminary results indicate that the drug combination is well tolerated and is able to significantly reduce tumor growth in patient-derived xenograft models (n=4). Our studies provide significant evidence that combined inhibition of MEK and BCL-2/Xi may be an effective drug combination for treatment of HGSOC and that the pro-apoptotic protein BIM may serve as a predictive biomarker to stratify patients that can benefit from these targeted therapies.

### #4035 A novel combi-molecule engineered to target the putative synthetic lethal interactions between the epidermal growth factor receptor (EGFR) and poly(ADP-ribose)polymerase (PARP).

Zhor Senhaji Mouhri, Martin Rupp, Bertrand J. Jean-Claude. McGill University Health Centre, Montreal, Quebec, Canada.

Over the past decade, PARP inhibition has been actively pursued as a novel approach for the selective therapy of tumors with BRCA1/2 mutations. The therapeutic benefits of PARP inhibitors have now been proven in the clinic against BRCA1/2 mutant ovarian cancers. This is hitherto limited to BRCA1/2 mutations, which only accounts for 5-10% of all cancers with hereditary mutations in the homologous recombination pathway. Therefore, new strategies are not only required to enhance the potency of PARP inhibitors but also to expand their use beyond BRCA mutation. While several combination modalities have been reported for PARP inhibitors, the concept of targeted PARP inhibitor has not yet been explored. Here using our novel combi-targeting approach, we report on the design of PARP inhibitors targeted to EGFR, a tyrosine kinase receptor overexpressed in several solid tumors. Recently, reports on the relationship between EGFR, PARP and BRCA have begun to emerge, one of which described a contextual synthetic lethality between EGFR and PARP (PloS one 7.10 (2012)). Here we report on the design and synthesis of novel PARP-EGFR combi-molecule based on structural modification of olaparib as a PARP inhibitor warhead and the quinazoline moiety for targeting EGFR. The results showed that: (a) it is capable of inducing a dose-dependent inhibition of PARP in isolated enzyme assay, (b) it induced a dose-dependent inhibition of EGFR in an isolated kinase assay, (c) it showed a dose-dependent inhibition of EGFR phosphorylation and downstream signaling in whole-cell assay, (d) it was selectively potent towards BRCA2 mutant and also EGFR-overexpressing cell lines, (d) it was extremely potent with activities superior to that of olaparib or gefitinib alone and their corresponding equimolar combination in three established triple negative breast cancer cell lines, (e) subcellular distribution analysis showed that it was abundantly localized in the perinuclear region. These results in tota suggest that this new combi-molecule could be developed as a single drug modality emulating the combination of PARP and EGFR inhibitors with the added benefit of being targeted to EGFR-expressing tumor cells.

### #4036 Induction of detrimental aneuploidy in basal breast cancer cells treated by MPS1 inhibitors in combination with paclitaxel.

Basal-like breast cancer has received considerable attention in recent years, but despite all efforts, conventional chemotherapy remains the main therapeutic option in the clinic with taxane therapy, the most frequently prescribed treatment. A significant reason for the lack of effective therapeutics may be related to the high degree of heterogeneity and aneuploidy which is characteristic for basal-like breast cancer. A new approach in this field is the concept that cancer cells may be targeted by the introduction of a detrimental level of aneuploidy. Inhibition of one of the main spindle assembly checkpoint kinases, MPS1 is a rational choice to achieve this goal. We report here the identification of a synergistic effect between the novel, oral, highly potent and selective MPS1 inhibitor CCT289346 and paclitaxel. We demonstrate robust synergism in multiple basal-like breast cancer cell lines and provide mechanistic insights into how both compounds' individual properties work together to maximise mitotic defects thereby increasing aneuploidy and cell death in a single round of mitosis. Additionally, in vivo studies in basal-like breast cancer xenograft models, including patient derived xenografts and systemic metastatic models, using clinically relevant doses of paclitaxel with well-tolerated doses of CCT289346, demonstrate significant benefit of combination of the two agents in comparison to paclitaxel alone.

### #4037 High throughput kinase inhibitor screen reveals novel inhibitor combinations acting in synergy with TUB83/BIII-tubulin suppression in non-small cell lung cancer.

Wee Siang Teo, Tanya Dwarte, Tim W. Failes, Greg M. Arndt, Joshua A. McCarroll, Maria Kavallaris. Children's Cancer Institute, Randwick, NSW, Australia.

Background: Non-Small Cell Lung Cancer (NSCLC) survival rates remain dismal and this malignancy is poorly responsive to current therapy. The mechanisms contributing to this resistance phenotype and aggressive behavior of this disease are not well defined. TUB83/BIII-tubulin is aberrantly expressed in NSCLC and its expression correlates negatively with disease free survival of patients. Our group has previously shown that BIII-tubulin plays a functional role in cell cycle and therapy resistance in NSCLC via modulation of the PTEN/AKT signaling pathway. This study aimed to identify kinase inhibitors that synergize with BIII-tubulin inhibition in NSCLC using a high-throughput cell-based screen. Methods: A high-throughput cell-based screen of a kinase inhibitor library was performed against our previously described NSCLC H460 cells, expressing either BIII-tubulin shRNA or control non-targeting shRNA. The primary screen consisted of a total of 210 kinase inhibitors tested at a single, fixed concentration and cell viability determined using the Alamar blue assay. Secondary screens were performed using a five point dose response. Further validation of the kinase inhibitors was performed against two independent NSCLC, H460 and A549 expressing either BIII-tubulin shRNA or control non-targeting shRNA. Results: A number of kinase inhibitors that act on bIII-tubulin. Activity of the hits was verified to act in synergy with TUB83/BIII-tubulin knockdown to inhibit NSCLC cell growth. Interestingly, several different inhibitors which target mTOR were identified as top candidates for acting in combination with BIII-tubulin knockdown to inhibit NSCLC cell growth. Treatment of cells with clinically approved mTOR inhibitors, temsirolimus and rapamycin, resulted in a significant decrease in cell viability in the bIII-tubulin knockdown cells compared to control. Notably, mTOR acts downstream of AKT signalling and further highlights a potential connection with BIII-tubulin and the AKT signal transduction cascade. Other kinase inhibitors that act on key signaling cascades including Amuvatinib-Multi Kinase Inhibitor (Fh3, Met, Kit, c-Ret & PDGFR); Mubritinib-HER-2 inhibitor; and Neratinib HER2, EGFR, also acted in combination with BIII-tubulin knockdown to inhibit NSCLC cell growth. Our results suggest that clinically approved therapies designed to target mTOR combined with inhibition of TUB83/BIII-tubulin may offer a novel therapeutic strategy for the treatment of NSCLC patients. ### #4038 Exploring optimal targeted combination therapies with neratinib for HER2+ breast cancer.

Ming Zhao,1 Stephen Scott,2 Kurt Evans,1 Erkan Yuca,1 Rashmi Murthy, Francesca Avogadri-Connors,2 Richard Cutler,2 Al-Shaif S. Al-Sani,2 Sarina Piha-Paul,1 Funda Meric-Bernstam1.

The University of Texas MD Anderson Cancer Center, Houston, TX; 2Puma Biotechnology, Inc., CA.

Activation by amplification or overexpression of the proto-oncogene HER2 (also known as ERBB2) is associated with the development and progression of breast cancer. Neratinib is a novel, irreversible, pan-HER tyrosine kinase inhibitor which selectively inhibits EGFR, HER2 and HER4. In this preclinical study, we explored the efficacy of neratinib in combination with other clinically relevant targeted agents for optimal treatment of HER2-positive breast cancer in in vitro and in vivo models. Western blot (WB) analysis of a panel of breast cancer cell lines showed that BT-474, SKBR3, and HCC-1954 cells displayed elevated HER2 expression levels (here denoted as HER2+), while MDA-MB-361, MDA-MB-435, and CAMA-1 breast cancer cells expressed relatively lower HER2 expression levels. The results of this screen were validated in a subsequent high throughput inhibitor screen, using efficacy at low and high doses of 10 mg/kg (p<0.0001). The activity of neratinib in combination with other targeted agents was then evaluated in vitro in the HER2+ breast tumor cell lines using a Chou-Talalay method. Neratinib showed synergistic anti-proliferative activity in combination with the PI3K alpha inhibitor BLY719 in all the HER2+ cell lines tested. By contrast, synergy with mTOR inhibitors (everolimus and TAK288) and with the MEK inhibitor trametinib was only observed in BT-474 and HCC-1954 cells. HCC-1954 cells had the best response to neratinib combinations among all HER2+ cell lines tested, with combination index values <0.5. Immunoblot analysis demonstrated that neratinib treatment displayed complete inhibition of HER2 phosphorylation in these cells. Substantial inhibition of downstream signaling path-
ways following single agent neratinib treatment was evident by reduced phosphorylation levels of AKT, S6K1, S6, 4E-BP1, ERK1/2 and MEK1/2. Consistently with the cell viability data, the combination of neratinib with OTS193320 and MAPK inhibitors showed a synergy on signaling blockage in these two downstream pathways respectively. Taken together this data shows that neratinib in combination with single agent OTS193320 in HER2+ breast tumors and its anti-proliferative activity in vitro was enhanced when combined with OTS193320 and MAPK pathway inhibitors. Further studies of neratinib-based combination treatments are underway in HER2+ breast cancer xenograft and PDX models to further corroborate these findings.

#4039 Riluzole synergizes with paclitaxel to induce apoptosis and inhibit cell growth in triple negative breast cancer. Miriam A. Bukhsh,1 Cecilia L. Speyer,2 Waris S. Jafry,2 Rachel E. Sexton,2 David Thomas,1 David Goriki4. Oak-land University William Beaumont School of Medicine, Rochester, MI; 1Wayne State University School of Medicine, Detroit, MI; 4Michigan State University, Lansing, MI; 2Barbara Ann Karmanos Cancer Institute, Detroit, MI.

Introduction: Systematic treatment for triple negative breast cancer (TNBC) includes paclitaxel, which works by inhibiting the breakdown of microtubules. We previously observed that riluzole, an FDA-approved drug for treatment of amyotrophic lateral sclerosis, can inhibit TNBC proliferation, invasion, and colony formation. We now test whether riluzole can act synergistically with paclitaxel to inhibit TNBC growth and induce apoptosis in TNBC. Methods: After treatment of various TNBC cell lines with constant ratio concentrations of riluzole and paclitaxel we conducted cell proliferation transformation assays (MTT) to measure cell inhibition potential. Synergy or additivity was determined by the Chou-Talalay using Compusyn software. PARP cleavage normalized to GAPDH was also measured by Western blot to estimate apoptosis due to the riluzole-paclitaxel combination. In vivo synergy was studied using a xenograft study with MDA-MB-231, a human TNBC cell line sensitive to riluzole. Results: MTT results show that riluzole and paclitaxel work synergistically to inhibit cell proliferation in all TNBC cell lines tested, as determined by isobolegrams and CI values <1. The strongest synergistic effect was observed in the cell lines SUM159, SUM149, and SUM229, where synergism occurred at Fa values as low as 0.5 (50% inhibition of cell proliferation). Measuring PARP cleavage, we demonstrated that the riluzole-paclitaxel drug combination induces greater ap- optosis than does either drug alone. The significant impact of the drug combi- nation was best demonstrated in cell lines SUM159, SUM149 and SUM229, but was observed in all cell lines tested. In the xenograft study, the highest non-toxic dose of paclitaxel (7.2 mg/kg) combined with riluzole resulted in 8/9 tumor-free mice, with a tumor growth inhibition ratio (T/C) of 0%, where <10% is consid- ered highly therapeutic. This result was better than riluzole monotherapy (0/9 tumor-free and T/C = 78%) or paclitaxel monotherapy (4/8 tumor-free and T/C = 8%). Conclusions: Our results demonstrate that the combination of riluzole and paclitaxel results in at least additive and in many cases synergistic effects against TNBC. Our observations thus suggest that repurposing riluzole, which is an oral drug with an excellent safety profile, to add to paclitaxel to treat TNBC repre- sents a potential strategy to improve the efficacy of adjuvant and neoadjuvant treatments for TNBC and/or reduce chemotherapy doses and toxicity in patients. Our data support the need to proceed to clinical trials to test this approach in patients.

#4040 Short-term romidepsin treatment combined with clotrimazole or bifonazole leads to decreased mitochondrial hexokinase 2 and apoptosis in cancer cells. Robert W. Robey,1 Andrew J. McDonald,1 Hanna Kozlowski,1 Michael M. Gottesman,1 Susan E. Bates2. 1NCI-CCR, Bethesda, MD; 2Columbia University Medical Center, New York, NY.

In light of disappointing clinical trials in solid tumors, we have sought novel combinations to increase the efficacy of the histone deacteylase inhibitor (HDAC) romidepsin. Hexokinase 2 (HK2) expression is increased in cancer cells and is postulated to prevent Bax-mediated cytochrome C release from mitochondria. Since romidepsin treatment induces apoptosis via the mitochondrial pathway, combining romidepsin with agents that detach mitochondrial HK2 might result in synergistic apoptotic effects. HCT-116 colon carcinoma cells were treated with 25 ng/ml romidepsin alone for 6h, or with romidepsin in the presence of 25 μM clotrimazole or bifonazole, compounds known to detach mitochondrial HK2. The medium was removed and cells were treated for an additional 42 h with or without clotrimazole or bifonazole. Cells were also treated with clotrim- azole or bifonazole alone for 48 h. Apoptosis was then quantitated by annexin staining. While short-term romidepsin treatment alone induced modest annexin staining and 25 μM clotrimazole or bifonazole had little effect, the combination resulted in significant apoptosis. Similar effects were observed for A549 lung cancer cells, MDA-MB-231 breast cancer cells and 786-0 renal carcinoma cells. We also treated HCT-116 and A549 cells lacking Bax, Bax or both with the clotrimazole/romidepsin combination. Apoptosis was slightly increased in Bax−/− cells, reduced in Bax+/− cells and nearly completely abrogated in cells lacking both proteins compared to wild-type cells suggesting apoptosis occurred through the intrinsic pathway. The clotrimazole analog TRAM-34 was similarly active to clotrimazole. Protein expression was determined in cytoplasmic and mitochondrial fractions of cells treated with romidepsin, clotrimazole or both and we found a >60% decrease in mitochondrial HK2 in cells treated with the combination versus untreated cells. Our results suggest that combining ro- midepsin with a compound that leads to decreased mitochondrial hexokinase, such as clotrimazole or bifonazole, results in increased apoptosis. We postulate that the following combination death romidepsin and clotrimazole treatment re- quires an intact intrinsic apoptotic pathway and that HK2 serves an anti-apo- ptotic function at the mitochondria.

Accumulating evidence has demonstrated the biological importance of pro- tein methyltransferases in human tumorigenesis, and several small molecular inhibitors targeting these enzymes have been developed. Moreover, inhibiting pathways involved in DNA repair has been shown to enhance the cytotoxicity of DNA-damaging agents. Herein, we report the development of a potent SUV39H2 inhibitor (OTS193320) that decreases global histone H3 lysine 9 tri- methylation (H3K9me3) levels in cancer cells and attenuates cancer cell prolifer- ation, and suppresses the tumor growth in mouse xenograft models. SUV39H2 (Suppressor of variation 3-9 homolog 2), is a protein methyltrans- ferase known to methylate histone H3 at lysine 9 (H3K9), and recently reported to methylate histone H2AX at lysine 134, which enhances the accumulation of phosphorylated H2AX (γ-H2AX) and regulates the DNA repair pathway in human cancer. SUV39H2 is highly expressed in many cancer types, including lung and breast cancers, while its expression levels are restricted to testis in normal adult tissues. Exposure of OTS193320 to two triple negative breast cancer cell lines attenuated H3K9me3 levels in a dose-dependent manner and trig- ered apoptotic cell death. Combination of OTS193320 and doxorubicin (DOX) resulted in reduction of γ-H2AX levels compared to single agent DOX, as vis- ualized on western blot and immunocytochemical analysis. Furthermore, combi- nation therapy attenuated the levels of p53-binding protein 1, which is reported to co-localize with γ-H2AX foci, compared to single agent DOX. Cell viability assays demonstrated a significant growth suppressive effect when OTS193320 was combined with DOX, compared to single agent treatment of either drug, suggesting chemosensitization to DOX. Importantly, in a mouse xenograft model, SUV39H2 inhibitor OTS193320 decreased the tumor growth in xenografts by 90.8% at day 14 with 25mg/kg intravenous administration of the inhibitor, with- out significant body weight loss or toxicity. Immunohistochemical staining of tumors treated with the inhibitor demonstrated a significantly lower number of Ki-67 positive cells and attenuated distribution patterns of H3K9me3 compared to the control tumors. Collectively, our results demonstrate that SUV39H2 in- hibition may be a promising approach to develop a novel class of anti-cancer treatment.

#4042 N-121, a novel polypeptide conjugate of SN-38, demonstrated enhanced intratumoral accumulation and sustained release of free SN-38 with potent antitumor activity. Haojun Wang,1 Wei Li,2 Xiaojian Zhou,2 Liuyi Wan,1 Guanghui Wen1. 1LabWorld Bio-Medicine Technology Corp. Ltd., Beijing, China; 2Pharmeva LLC, Arlington, MA.

Introduction: SN-38 is a critical chemotherapeutic agent active against a va- riety of solid tumors including advanced colorectal cancer. Clinical use of SN-38 is hampered by its poor solubility in pharmaceutically acceptable solvents. Although irinotecan, the only approved prodrug of SN-38, is widely used, its effi- cacy is limited by low conversion to the active SN-38 as well as hematologic and gastrointestinal dose-limiting toxicities. In an attempt to improve the water solubility, antitumor activity and safety profiles of SN-38, we synthesized a water soluble polypeptide-SN-38 conjugate (N-121) and examined its antitumor ac- tivity and pharmacokinetics (PK) in mouse models. Methods: Antitumor activ- ity and PK of SN-38, administered as N-121 or irinotecan, was evaluated follow- ing tail vein injection in male nude mice with subcutaneous orthotopic xenografts of the HCT116 human colon cancer. Mice received N-121 400 mg/kg (mg/kg) (32 mg/kg of eq. SN-38) or irinotecan 80 mg/kg once a week for 2 weeks and were followed for up to 46 days. Results: N-121 drastically improved by over 1000 fold the water solubility of SN-38. At a SN-38 equivalent dose of less than half of that of irinotecan, N-121 resulted in a much longer tumor growth delay.
(36 days) than irinotecan (14 days). The more durable tumor growth inhibition with N-121 was consistent with its enhanced intratumoral accumulation: intratumoral trough levels of SN-38 were about 250-fold higher than those observed in plasma, compared with only 15-fold with irinotecan. With N-121, intratumoral levels of SN-38 remained stable over the PK observation period (48 h), contrasting to a marked decline in SN-38 levels with irinotecan; intratumoral trough levels of SN-38 from N-121 were about 50-fold higher than those achieved with irinotecan. N-121 was well tolerated with a slight weight loss of 7.2%. Conclusion: N-121, a novel water soluble polypeptide-SN-38 conjugate, exhibited enhanced and sustained intratumoral exposure of SN-38 with high antitumor activity in a mouse xenograft tumor model. These promising results warrant further evaluation of N-121.

Temozolomide (TMZ) is an oral alkylating agent commonly used as a first-line chemotherapeutic agent for the treatment of high-grade gliomas and medulloblastomas. Alkylation of the O6-position of guanine in DNA is mainly responsible for the antitumor effect of TMZ. The primary mechanism of chemoresistance to TMZ has been shown to be the overexpression of the DNA repair enzyme O6-methylguanine methyltransferase (MGMT) that specifically removes the methyl lesions from the O6-position of guanine. While O6-benzylguanine (O6-BG), a potent inhibitor of MGMT, was shown to sensitize tumor cells to TMZ in vitro and in vivo, the O6-BG-TMZ combination failed in clinical trial due to acute hematologic toxicity. To circumvent this problem, we wish to target O6-BG to the epidermal growth factor receptor (EGFR), a receptor that is not generally expressed in the hematological cells but overexpressed in many solid tumors. We have now successfully designed and synthesized one such molecule termed MR30 and showed that: 1) MR30 is capable of blocking EGFR and depleting MGMT levels in whole cells; 2) MR30 is a unique molecule capable of inducing stronger growth inhibition than the 2-drug combination involving clinical EGFR and MGMT inhibitors in a panel of melanoma, lung, prostate and ovarian cancer cell lines; 3) MR30 in vitro potentiated the effect of TMZ on MGMT positive cell lines; 4) its kinase inhibitory profiling over 25 different kinases demonstrated selectivity for EGFR, HER2 and EGFR mutant forms; 5) an in vivo model showed more than 70-fold selectivity towards EGFR expressing cells in growth inhibitory assay; 6) MR30 showed good cell penetration with distribution in the perinuclear region. The results in vitro suggest that MR30 has the potential to be developed as a tumor selective potentiator of TMZ.

#4044 LY3039579, a novel Notch inhibitor, potentiates the anti-tumour effects of sorafenib in hepatocellular carcinoma (HCC). Annemilai Tijeras-Rahalland,1 Christina Johelia,2 Elise Ayala,2 Mathieu Arnoux,3 Philippe Bonnin,3 Karim A. Benhadjil,4 Bharvin R. Patel,5 Clarisse Eveno,3 Marc Pocard,3 Sandrine Faivre,6 Eric Raymond,9 Armand de Gramont9,1, 1AFROncology, Paris, France; 2Inserm U965-Lariboisiere University Hospital, Paris, France; 3Inserm U965-Lariboisiere University Hospital, Paris, France; 4Eli Lilly Company, News #4072#4046 Targeting jak/stat adaptive mechanism with jak1 inhibitor azd4205 reduces residual disease and prolongs benefit of osimertinib. Huawei (Ray) Chen,1 Geraldine Bebernet1, Kirsten Bell,7 Erica Anderson,2 Nanhua Deng,1 Jason Kettle,2 Paul Lynre,1 Richard Woessner1. "AstraZeneca Re&D Boston, Waltham, MA; 2AstraZeneca, Merside, United Kingdom.

EGFR kinase inhibitors have provided tremendous benefit for non-small cell lung cancer (NSCLC) patients with EGFR driver mutations. However, many patients fail to respond or have responses of limited duration. Accumulating evidence suggests that the JAK1/STAT3 axis plays a role in tumor escape, and that combined inhibition of EGFR and JAK1 may drive more complete and durable responses. Here we report AZD4205, a potent ATP-competitive inhibitor that inhibits JAK1 with a Ki of 2.8 nM and exhibits excellent selectivity vs. other JAK family kinases and across the kinome. Combination of AZD4205 (dosed at 12.5, 25 or 50 mg/kg BID, PO) with Osimertinib (doses ranging from 1 to 5 mg/kg, QD, PO) led to enhanced in vivo anti-tumor activity in several NSCLC xenograft models driven by mutant EGFR: H1975 (L858R/T790M), PC-9 (del19), and HCC827 (del19). In the H1975 model, after 18 days of treatment beginning with 188mg established tumors, treatment with osimertinib at 2.5 mg/kg led to tumor growth inhibition of 92% relative to vehicle. Addition of AZD4205 at 12.5 and 50 mg/kg led to 30% and 69% tumor regression, respectively. AZD4205 dosed at 12.5 and 50 mg/kg BID resulted in pSTAT3 (Y705) knockdown of 72% and 91% at peak plasma concentration (2H) respectively, and 42% and 86% at 8H. In the PC-9 model, after 22 days of treatment beginning
The goal of this study is to identify clinically used drug candidates for repurposing to treat drug-resistant lung cancer cells. Drug repurposing is the application of clinically approved drugs, with optimized dosing regimens and known side effect profiles, to new indications. EGFR TKIs have unprecedented clinical efficacy in advanced lung cancer. However, their usefulness is limited by drug resistance of various mechanisms, the most important of which is the secondary EGFR T790M mutation. The mutation blocks the binding of EGFR TKIs to the receptor kinase domain and thereby abolishing the therapeutic efficacy. In this study, we have used our in-house developed protein-ligand docking software “idock” (http://istar.cscue.hku.idock/) to screen FDA-approved small molecule drugs against EGFR bearing the resistance-causing mutations. The computationally selected drug candidates were evaluated in vitro in non-small cell lung cancer (NSCLC) cell lines resistant to EGFR TKIs. Mechanistic studies were performed to investigate the specificity of the compounds towards inhibiting the kinase activity of the various EGFR mutants, and induction of apoptosis. Based on the simulation score, thirty-six drug candidates were chosen from the in silico screening for in vitro testing in NSCLC cell lines with wide-type EGFR, EGFR L858R (del19 activating mutation), or EGFR L858R/T790M (resistance-causing mutation). Three drugs were found to exhibit anticancer activity in the cancer cells and two of them were more potent in NSCLC harboring EGFR L858R/T790M than those with EGFR L858R. Their specificity towards inhibiting EGFR L858R/T790M were further confirmed by cell-free biochemical kinase assay and Western blot analysis in the NSCLC cell models. The positive hits were also showed to inhibit the EGFR-Pi3K-Akt signaling pathway and cause apoptosis. Interestingly, the drug candidates also gave rise to pronounced synergistic anticancer activity specifically in NSCLC cells harboring EGFR T790M when used in combination with gefitinib. The drug candidates identified may be repurposed for treating NSCLC resistant to EGFR TKIs. The same in silico screening approach may be used to hunt for other clinically used drugs for repurposing to treat cancer cells resistant to other molecular targeted agents.

#4050 Multifaceted targeting of drug-resistant EGFR+ and HER2+ breast tumors

Unmet needs in the breast cancer field include the development of effective treatments for 1) drug-resistant HER2+ breast cancers, 2) Triple-Negative (HER2-, ER-, PR-) Breast Cancers (TNBCs), and 3) Inflammatory Breast Cancers (IBCs). Treatment-refractory HER2+ tumors retain HER2 expression after acquiring drug resistance, and large fractions of TNBCs and IBCs overexpress either HER2 or EGFR. Thus, drugs that selectively kill breast tumors that over-express EGFR or HER2 could benefit patients suffering from these three classes of treatment-refractory tumors. Our team has identified a class of compounds termed Disulfide bond Disrupting Agents (DDAs) that selectively kill cancer cells that overexpress HER2 or EGFR. DDA-mediated cancer-selective cytotoxicity results from A) downregulation of the EGFR/HER2/HER3 proteins, B) inactivation of the Akt oncogene, and C) activation of the Unfolded Protein Response (UPR). Importantly DDAs only elicit these responses in cancer cells that overexpress HER2. DDA treatments exhibit significant anti-tumor effects in human HER2+ xenografts grown orthotopically in mice, with no evidence of toxicity. DDAs function through mechanisms distinct from those of HER2 specific monoclonal antibodies and tyrosine kinase inhibitors, and biochemical studies indicate that DDAs are complementary with Lapatinib with respect to blockade of HER2 driven proliferative and survival signaling. Current efforts are directed toward identifying mechanism-based drugs that synergize with DDAs to potentiate HER1-3 downregulation, Akt inhibition, and UPR, and to kill HER2+/EGFR+ patient-derived xenograft tumors that are refractory to current therapies.

#4051 Combination efficacy of HDAC inhibitor vorinostat and CDK-4/6 dual inhibitor palbociclib against therapy-resistant mantle cell lymphoma
Nagendra K. Chaturvedi, Nathan D. Hatch, Garrett L. Sutton, Matthew J. Kling, Julie M. Vose, Shantanam S. Joshi. University of Nebraska Medical Center, Omaha, NE.

Mantle cell lymphoma (MCL) is an aggressive B-cell lymphoma accounting for about 7% of all non-Hodgkin’s lymphoma. While multiple therapy regimens are available to treat MCL patients, ultimately relapse from therapy-resistant MCL, making MCL the worst prognosis of all B cell lymphomas. Emerging evidence suggest that, dysregulated histone deacetylases (HDACs) and the key molecules of cell cycle regulator cyclin-dependent kinases (CDKs) have been shown to be commonly associated with many lymphomas including MCL, and are considered as promising targets for relapsed lymphoma therapy. Several inhibitors of these target pathways/molecules are in clinical trials as monotherapies or in combination with other drugs. Therefore, in this study, we investigated the single agent and combination efficacies of the HDACs inhibitor vorinostat, and CDK-4/6 dual inhibitor palbociclib on MCL cell growth/survival and underlying molecular mechanism(s) using different MCL cell lines (Granta 519, Jeko-1 and JVM-2) including therapy-resistant MCL cell lines derived from Granta-519 (GRL, GRK and GRR). We used MTT assay to measure the survival and proliferation, agar colony formation assay to determine the effects of the drugs on the anchorage independent growth, Annexin-V analyses to examine the cells undergoing apoptosis following treatments and western blot analyses to determine the expression levels of target molecules including pRb, histone acetylation, cyclin-D1 and Bcl-2. The concentration of these inhibitors used in this study were similar to the published literature including sub-IC50 levels determined in our laboratory. Our results showed that both inhibitors as single agents or combined, significantly suppressed the cell growth, and induced apoptosis in therapy-resistant and other MCL lines in vitro. The single agent and combined anti-lymphoma efficacies of these inhibitors were further confirmed with the colony formation ability of the MCL cells grown in 0.3% agar semisolid media. In addition, combination of vorinostat and palbociclib treatment significantly inhibited the activation of phospho-c-Jun N-terminal kinase (pJNK) and phospho-p38 MAPK (p-p38), key molecules of cell cycle and increased the expression of acetylated-Histone H3 (H3-Ac) as determined by western blot analyses. Subsequently, the expression of Cyclin D1 (proliferation, MCL hallmark) and anti-apoptotic Bcl-2 proteins were also downregulated by these inhibitors. Together, our findings suggest that combination of vorinostat and palbociclib showed a significant synergistic anti-MCL activity by targeting associated pathways/molecules. This targeted approach warranted further preclinical evaluation for translation to the clinic.

#4052 Enhancing estrogen receptor beta mediated tumor suppression by lysine specific demethylase 1A inhibitor for the treatment of ovarian cancer
Gangadhara Reddy R. Sareddy,1 Jinoua Liu,2 Lauren Garcia,1 Suryavathu Vithala-nadhapalli,1 Mei Zhou,1 Takayoshi Suzuki,2 Edward Kost,1 Ratna K. Vadlamudi1. 1UT Health Science Center at San Antonio, San Antonio, TX; 2Kyoto Prefectural University of Medicine, Kyoto, Japan.

Ovarian cancer (OCa) is the deadliest of all gynecologic cancers in the United States. Although patients with OCa respond initially to standard combinations of surgical and cytotoxic therapy, nearly 90% will develop recurrence and inevitably succumb to chemotherapy-resistant disease. Estrogen mediates its effects through the estrogen receptor α (ESR1) and estrogen receptor β (ESR2). Recent studies suggest that OCa cells and OCa stem cells express ESR2, which functions as a tumor suppressor and identified synthetic compound LY503037 as a potent ESR2 specific agonist. However, ESR2 expression decreases during tumor progression and under the selection pressure of chemotherapy; this decrease occurs via epigenetic mechanisms. The lysine-specific histone demethylase 1A (KDM1A/LSD1) is overexpressed in OCa and plays a vital role in metastasis and cancer stemness. Our group recently developed a novel KDM1A-specific inhibitor (NCD-38) based on an innovative concept of direct delivery of phenylcyclopropylamine to the KDM1A active site. We reason that agents that restore the expression and function of ESR2 by increasing expression of KDM1A will provide a novel therapeutic opportunity to reactivate ESR2 for suppression of OCa. The objective of this study is to test whether KDM1A inhibitor could enhance the expression and tumor suppressive functions of ESR2 and to test the combination of KDM1A inhibitor along with ESR2 agonist using in vitro and in vivo preclinical models. Our results demonstrated that combination of ESR2 agonist and KDM1A inhibitor reduces the cell viability of OCa cells synergistically.

#4053 Disulfiram-copper combination induces cell death time- and schedule-dependently in glioblastoma (GBM) and medulloblastoma cell lines, and enhances temozolomide sensitivity of methylator+ve GBM cells in vitro and in vivo
Mostafa Gabr,1 Stephen Marcus,2 Hanumantha R. Madala,3 Kalkunte S. Srivenugopal,3 Francis Ali-Osman.1 Duke University School of Medicine, Durham, NC; 2Cantex Pharmaceuticals, Weston, FL; 3Texas Tech University Health Sciences Center, Amarillo, TX.

Background. Disulfiram (DSF), a carbamate derivative and a potent aldehyde dehydrogenate inhibitor, is used clinically to treat alcoholism. Although, relatively nontoxic, DSF exhibits significant anticancer effects, when administered with heavy metals (Cu and Zn). Because of this and the fact that DSF crosses the blood-brain barrier, DSF is being investigated as a potential agent for brain tumor therapy. In a preclinical GBM model, DSF treatment significantly reduced the in vivo tumor growth in orthotopic models. Since ESR2 agonists and KDM1A inhibitors are currently in clinical trials for other clinical indications and are well tolerated, identification of KDM1A inhibitor and ESR2 agonist combination therapy as a novel therapeutic can be readily transferred to clinical use for enhancing survival in OCa patients.

#4054 Combination Therapies and Approaches to Sensitize Cancer Cells to Drugs

Procedures of the American Association for Cancer Research • Volume 58 • April 2017 1035
lomide resistance was examined in vitro and in vivo in two methylator-ve GBM cell lines, UW18 and UW28. Results. DSF and copper, as single agents, up to 100 uM for 4-7 days, had little to no toxicity on any of the GBM cell lines. In contrast, all the cell lines were highly sensitive to DSF, when combined with copper. The efficacy of the combination was highly dependent on the time (minimum 6 hrs) and schedule (DSF prior to copper) of cellular exposure. The UW228 medulloblastoma cell line was approx. 4-fold more sensitive to DSF and to the DSF-copper combination than GBM cells. We observed a direct correlation between the levels of cellular ROS production and MAP activation, and the level of cytotoxicity of the DSF-copper combination. The temozolomide sensitivity of the cell lines was significantly enhanced by the DSF-copper combination and in vivo xenograft studies showed that treatment of two temozolomide-resistant, methylator-ve GBM cell lines was significantly inhibited and their temozolomide sensitivity enhanced by the DSF-copper combination and was associated with significant inhibition of MGMT in the tumor cells. Conclusion: The results demonstrate significant sensitivity of GBM and, for the first time, medulloblastoma, cells to DSF-copper, which is dependent on both the duration of cellular exposure to and the scheduling of DSF and copper. The DSF-copper combination increases the sensitivity of temozolomide-resistant, methylator-ve GBM cells to temozolomide. The findings support DSF-copper as a treatment strategy for GBM and medulloblastoma.

#4054 Development of dual function small molecules as therapeutic agents for cancer treatment. Scott Grindrod, Alfredo Velena, Mira Jung. Shuttle Pharmaceuticals, Rockville, MD; 2Georgetown University, Washington, DC.

Inhibitors of histone deactylases (HDACs) are emerging as potent anti-cancer agents for treatment of patients with hematopoietic and solid tumors. However, most of these compounds exhibit limitations, including off-targets and toxicity. To improve the efficacy and target specificity of drugs, we developed the compound, SP-1-161 conferring HDAC inhibition activity and ataxia-telangiectasia mutated (ATM) activation. The purpose of this study is to develop a therapy that optimizes the protective effects of ATM activation in normal tissue with the sensitizing effects of HDAC inhibition in cancerous tissue into a single molecule. The compound SP-1-161 was rationally designed by optimizing ATM activation by the cap domain of a hydroxamic acid, screened against a panel of Class I and Class II HDAC enzymes, and identified as a pan-HDAC inhibitor with nano-molar potency (IC50 = 8 nM). Western analysis confirms that SP-1-161 increases acetylated histone H3/H4 and α-tubulin and ATM activation in MCF7 cells. Phosphorylated ATM was gradually increased within 1-4 hrs in a time-dependent manner. SP-1-161 was then tested in normal breast epithelial (184A1) and breast cancer (MCF7) cell lines to determine its cytotoxicity and effect on radiation clonogenic survival in combination with graded radiation exposure. The data showed that the cytotoxicity values (IC50) were low micro-molar ranges. Furthermore, SP-1-161 protected 184A1 cells (from D0 = 1 GY to D0 = 1.4 GY) while increasing sensitivity of MCF7 cells to IR (from D0 = 1.6 GY to D0 = 1.12 GY). Together, our results demonstrate that SP-1-161 is an unprecedented radio-chemo therapeutic agent for treatment of cancers while protecting normal cells.

Histone deacetylases (HDACs), were originally described in a limited context as histone modifiers. New evidence has demonstrated that HDACs are also involved in a diverse range of cellular processes that are not restricted to the chromatin environment, such as the regulation of the cell cycle/apoptosis and, more recently, a modulator of immune response. However, much remains unknown about the mechanism of action of HDACs and their roles in the immune biology of cancer. The non-specific nature of pan-HDAC inhibitors results in a narrow therapeutic window of use, limiting the dose and duration due to toxicity. Our group has focused on one specific HDAC, HDAC6, and shown that both the genetic abrogation and pharmacological inhibition of this HDAC modulates the expression of a variety of immune-regulatory proteins in the tumor microenvironment, including PD-L1, PD-L2, MHC class I, B7-H4 and TRAIL-R1. In particular, we have previously demonstrated that both pharmacological inhibition and/or genetic abrogation of HDAC6 plays a critical role in the immune check point blockade by down-regulating the expression of PD-L1 and other check-point modulators such as PD-L2, B7-H4, etc. Moreover, we have also observed that in vivo inhibition of HDAC6 reduces tumor growth in B16 and SM1 murine melanoma models within syngeneic immunocompetent hosts. Additionally, we have found that the combination of low doses of the HDAC6i Nexurastat A and checkpoint immune blockade, including anti-PD-1 and anti-CTLA4, results in an important improvement in anti-tumor immune responses and tumor growth when compared to treatment with individual stand-alone agents. In these studies we also evidenced an increased production of IFNγ and IL-2 in the stand-alone check-point inhibitor treatments, which leads to an upregulation of PD-L1 and PD-L2. Similar levels of IFNγ and IL-2 were found in the combination groups. However, the expression level of PD-L1 and PD-L2 were comparable to the non-treated group. Taking all together, we have found that HDAC6 could be used as a potential adjuvant in ongoing therapeutic options involving immune check-point blockade.

#4056 A modulator of multidrug resistance protein 1 selectively depletes glutathione and synergizes with L-buthionine sulfoximine to sensitize MRPI-expressing cancer cells to chemotherapy. Christine C. Gana, Kimberly Hansen, Denise M. Yu, Claudia Fleming, Murray Norris, Michelle Haber, Jamie Fletcher. Children’s Cancer Institute, Sydney, Australia.

Multidrug resistance protein 1 (MRP1) is frequently overexpressed in tumors where it effluxes chemotherapeutic agents, protecting tumor cells from chemotherapy. This is clearly illustrated in the pediatric solid tumor neuroblastoma, where MRPI expression is highly prognostic of clinical outcome (1,2) and contributes to chemo-resistance in mouse models (3). MRPI also effluxes low levels of glutathione (GSH), a crucial intracellular antioxidant that avoid damage from the reactive oxygen species induced by radiotherapy and chemotherapy and an important component of both Phase II and Phase III drug metabolism. Depletion of GSH in cancer cells would be of therapeutic value, however the GSH synthesis inhibitor L-buthionine sulfoximine (BSO) has only limited selectivity for tumor over normal cells. We have identified a novel MRPI inhibitor, 7-methyl-5-phenyl-2-[(4-phenyl-1-piperazinyl)carbonyl]pyrazolo[1,5-a]pyrimidine, that blocks MRPI-mediated drug efflux while greatly enhancing MRPI-mediated GSH efflux and are investigating the utility of this dual-function inhibitor for the treatment of MRPI-overexpressing cancers. Methods: Cells expressing high levels of MRPI were treated with MRPI drug substrates in combination with MRPI inhibitors. Viability was assessed by short-term cytotoxicity or clonogenic assays and GSH levels determined by glutathione recycling assay. Results: Our MRPI modulator depleted intracellular GSH in an MRPI-dependent manner and sensitized MRPI-expressing human neuroblastoma, lung and ovarian cancer cell to chemotherapeutics. This effect was highly synergistic with BSO, both in depleting GSH (CI<0.36, p<0.05) and abolishing colony formation (CI<0.01, p<0.05). Conclusion: Our MRPI modulator blocks MRPI mediated drug efflux and is predicted to effectively deplete MRPI-mediated GSH efflux in MRPI expressing cells, potentially providing an increased therapeutic window for chemotherapeutics in MRPI-overexpressing cancers. Synergy with BSO could widen the range of drugs and cancers that this could be beneficial for. References: 1. Haber, M., et al., (2006) J.Clin Oncol 24, 1546-1553. 2. Norris, M. D., et al., (1996) New Engl J Med 334, 231-238. 3. Burkhart, C. A., et al., (2009) Cancer Res 69, 6573-6580.

#4057 Inhibition of polypoloyd and senescence induces intrinsic apoptosis in double hit or double expresser DLBCL. Shariful Islam, Wenqing Qi, Carla Morales, Laurence Cooke, Catherine M. Spier, Daruka Mahadevan. 1.Univ. of Arizona, Tucson, AZ; 2.University of Tennessee Health Science Center, Memphis, TN; 3.St. Jude Children’s Research Hospital, Memphis, TN.

Introduction: Double Hit (DH) or Double Expresser (DE) DLBCL are aggressive Non-Hodgkin’s Lymphomas (NHLs) with translocation or over-expression of MYC and BCL-2 which are incurable with current therapies. MYC is a critical driver of oncogenic phenotypes and regulates expression of numerous genes including aurora kinases (AKs), which are validated drug targets. AKs are over-expressed in DLBCL and AK inhibition in two Phase II trials of relapsed and refractory B/T+NHL resulted in 20%-30% overall response rate. Bruton’s tyrosine kinase (BTK) plays a central role in B-cell receptor (BCR) signaling and inhibitors of BTK have shown efficacy in B-NHL clinical trials. Targeting CD20 (rituximab) in DLBCL inhibits BCL-2 and induces apoptosis via caspase-3 activation. We hypothesized that DH/DE-DLBCL are amenable to a novel therapeutic strategy of AK, BTK and CD20 inhibition. Methods: Four DH/DE-DLBCL cell lines were evaluated for their viability by MTS; polypoloyd, senescence and apoptosis by flow cytometry; DNA damage by TUNEL assay. Phospho-BCL-2, -AK and -BTK analysis by western. Safety and efficacy of drug combinations in a mouse xenograft model. Analysis of patient samples and mouse tumors by IHC. Results: DH/
#4058 Preclinical and phase-2 clinical study of valproic acid administered in combination with cisplatin and cetuximab in recurrent/meta- statistical head and neck cancer. Alfredo Budillon, Andrea I. Zotti, Carlo Vita-gliano, Elena Di Gennaro, Francesco Caponigro. Instituto Nazionale Tumori, Napoli, Italy.

Recurrent metastatic (R/M) squamous cell carcinoma of the head and neck (SCCHN) is a devastating malignancy with a poor prognosis and the combination of cisplatin (CDDP) and cetuximab (CX) is one of the gold standard for treatment. However, this therapy is often associated with high toxicity and resistance, suggesting that the concomitant use of novel compounds represents a critical strategy to improve treatment results. Histone deacetylase inhibitors (HDACi) enhance the activity of several anticancer drugs including CDDP and anti-Epidermal Growth Factor Receptor (EGFR) compounds. EGFR overexpression is involved in chemotherapy resistance and recently it has been demonstrated that EGFR nuclear localization represents one of the mechanism of resistance to both CDDP and CX. Our group have demonstrated that HDACi synergize with anti-EGFR agents by modulating ErbB receptors expression including EGFR. In this study we evaluated the capability of Valproic acid (VPA), a generic low-cost anticon- vulsant drug with HDACi activity, to enhance the efficacy of CDDP-CX association in SCCHN cells with different EGFR basal expression and genetic backgrounds. We showed, by the calculation of combination indexes, an antiproiferative synergistic interaction between equipotent doses of VPA and CDDP-CX in CAL27 and FaDu SCCHN cells using either simultaneous or sequential (with delay) schedule of administration. The antiproliferative effect was not observed in immortalized human fibroblasts BJ-hTERT, sug- gesting a selective effect toward tumor cells. Next, we confirmed synergistic interaction by testing clinically achievable concentrations of VPA/ CDDP-CX combination also on CAL27 and FaDu 3D spheroid cultures, showing inhibition of first- and second-generation spheroids formation by triple combination, compared to single agent treatments. Moreover we demon- strated that VPA was able to down-regulate EGFR and to prevent EGFR nuclear translocation induced by CDDP and CDDP-CX combination, thus preventing the activation of DNA repair and survival pathways. Indeed, we showed that VPA was able to increase DNA damage and apoptosis induced by CDDP-CX combination, evaluated by gamma-H2AX foci and Annexin V-FITC assay, respectively. In vivo preclinical study is currently ongoing. All together these data represent the rationale of the ongoing V-CHANCE phase-2 clinical trial evaluating VPA/ CDDP-CX combination in R/M SCCHN patients. We are also currently investigating pharmacodynamics/predictive biomarkers of treatment efficacy/resistance on patient’s samples.

#4059 KPC34: a co-drug that combines a DNA damaging agent with a targeted therapy for the treatment of AML. Gregory L. Kucera, Peter Alexander, Kristin Pladna, Timothy S. Pardee. Wake Forest School of Medicine, Winston-Salem, NC.

AML occurs in the elderly with ~18,000 new US cases in 2014. Mortality is an estimated 10,050 US deaths in 2014. Elderly patient prognosis is a dismal 6.6%, 5 year survival rate. AML treatment involves induction chemo- therapy with Ara-C followed by consolidation therapy or stem cell transplant. The major obstacle to long-term disease-free survival is relapse after treatment due to chemoresistance. Chemoresistance occurs by several mech- anisms including reduced activation of Ara-C via down-regulated deoxycy- tosine kinase 1, increased levels of the anti-apoptotic protein Bcl-2, and increased BCR-ABL kinase (BCR-ABL1 gene product, a downstream target of the oncogenic activity of thePhiladelphia Chromosome). Our work was designed to characterize the role of the K9H3 Histone Methyltransferase A (KMT6A) in the AML pathology. KMT6A is a histone lysine methyltransferase that is upregulated in AML and promotes cell growth and chemoresistance in AML cell lines. We have previously demonstrated that KPC34 is active against AML in vivo. KPC34 is highly cytotoxic to a variety of leukemia cell lines in vitro, with IC50 of ~90% and was well tolerated. Survival analysis: 67% of mice alive at day-89 with triple therapy versus 20% with ibritunib + rituximab. Other treatments showed no survival past day-52. Conclusions: A novel triple ther- apy consisting of alisertib + ibritunib + rituximab inhibits PASCs induced by AK inhibition in DH/DE-DLBCL leading to a significant anti-prolifera- tive signal and intrinsic apoptosis. Our work provides a rationale for exploring these combinations in the clinic.

#4060 Pharmacological targeting of the Aurora A and Histone 3 lysine 9 methyltransferase pathways in pancreatic cancer induces mitotic catastro- phe. Angela Mathison,1 Ann Salmonson,1 McKenna Missfeldt,1 Thiago de As- severo Bintz,2 Tao Shi,1 Susan Lin,1 Suncao,1 Jennifer Bintz,1 Trace Christensen,1 Sarah Kossak,1 Asha Nair,1 Juan Iovanna,2 Robert Huebner,1 Gwen Lomberk,1 Mayo Clinic, Rochester, MN; 2Cancerology Research Center of Marseille (CRCRM); INSERM U1068, Marseille, France.

By regulating gene expression networks that mediate neoplastic behavior, epigenetic protein complexes are the ultimate effectors of oncogenic pathways. This hierarchical position of epigenetic pathways within the mechanisms that regulate cancer makes them ideal candidates for therapeutic targets. The current work was designed to characterize the role of the K9H3 Histone Methyltrans- ferase (HMT) pathway in mediating oncogenic signals downstream of Aurora Kinase A (Aurka), with the goal of designing efficient combinatorial therapeutics against PDAC. Alfinity protein purification, combined with mass spectrometry, demonstrates that HP1γ isolated from mitotic cells interacts with Aurka and the HMTs, G9a and GLP. We also find that this complex is critical for mitotic progression and cell proliferation. Congruently, treatment of PDAC cells with individual drugs against Aurka or HP1-HMT inhibits cell growth by inducing senescence, a cytostatic response. However, the combination of these agents has a synergistic effect of reducing cell growth in both, monolayer and spheroid cultures to result in a cytotoxic effect. Confocal and electron microscopy, along with cell cycle analysis, demonstrate that the cytotoxic effect of this combination is due to induction of mitotic catastrophe, a distinct form of cell death that occurs during mitosis. Molecularly, the combination of Aurka and HP1-HMT inhibition bypasses G2/M arrest with downregulation of the Chk1-Cdc25c path- way. In vivo treatment of PDAC orthotopic xenografts with the HP1-HMT inhibitor alone demonstrated reduced PDAC growth, and increased efficacy in PDAC growth reduction was observed in combination with the Aurka inhibitor over either individual treatment. Thus, our data demonstrate a novel Aurka- HP1-HMT mitotic pathway that holds promise for potential pharmacological targeting in combinatorial therapy for this malignancy.
EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Mechanistic Understanding of Novel Anticancer Therapies

The pharmacokinetics of antibody drug conjugate (ADC) therapeutics typically show a discrepancy between the PK of total antibody (conjugated and unconjugated antibody) and that of conjugated antibody, carrying one or more payload molecules. This discrepancy is often attributed to deconjugation (Kamath, 2014), however recent evidence suggests that the underlying mechanisms may be more complex. This work employs a computational quantitative systems pharmacology (QSP), or mechanistic PK/PD approach to understand the impact of drug antibody ratio (DAR) and the resulting changes in molecular properties on overall PK and relative payload disposition as observed in preclinical and clinical studies. Our work establishes the benefit of using computational models to design novel ADCs and to optimize the discovery and development of existing ADCs.

#4062 A computational driven protocol of metronomic oral vinorelbine in metastatic non small cell lung cancer. Diane-Charlotte Imbs,1 Raouf El Cheikh,2 Joseph Ciccolini,1 Raphaël Serre,1 Fabrice Barlesi,2 Dominique Barbou-los1. 1Aix-Marseille University, Marseille, France; 2 Assistance Publique Hôpitaux de Marseille, Marseille, France.

Over the last decade, metronomic chemotherapy (MC) has emerged as an alternative way to administrate chemotherapy. MC can be defined as regular administration of low/less-toxic doses without extended drug-free breaks. Because countless schedules are possible, testing them empirically looks like an unachievable goal. Therefore, mathematical modeling can be an effective tool to determine appropriate metronomic strategies. A phase Ia/Ib study based on a mathematical model of oral vinorelbine in metastatic NSCLC and malignant pleural mesothelioma was designed to confirm safety and consolidate the calibration of model parameters. The model was used to simulate alternative metronomic scenarios targeting higher efficacy with similar toxicity. Simulations showed that the initial proposed schedule was the most appropriate in terms of efficacy/toxicity balance. Its efficacy will be evaluated in the second part of the study. This trial can be considered as a proof-of-concept study demonstrating the feasibility to run a computational-driven protocol to ensure an optimal efficacy/toxicity balance in cancer patients.

#4063 Design and synthesis of indole derivatives as ABCG2 mediated resistance reversal agents. Chao-Yun Cai1, Hong Zhai,2 Zhi-Ning Lei,1 Bao-Li Chen,1 Zhao-Yu Du,2 Yun-Kai Zhang,1 Yi-Jun Wang,1 Bo Wang,2 Zhe-Sheng Chen1. 1St. John’s University, Queens, NY; 2 Sun Yat-Sen University, Guangzhou, China.

Multidrug resistance is a phenomenon that cancer cells become resistant to anticancer drugs. Multidrug resistance has been shown to be related with the overexpression of ATP-binding (ABC) transporters, including ABCG2. Therefore, ABCG2 as a target for new strategies against resistance reversal agents. Fumitremorgin C, with an indole group which is an important pharmacophore in many drugs, is a known ABCG2 inhibitor. Inspired by this, we synthesized two series of indole derivatives as ABCG2 mediated resistance reversal agents. With MTT assay, we found that two compounds from the two series of indole derivatives respectively exhibited good reversal activity against ABCG2. The two compounds did not significantly alter the expression of ABCG2 in ABCG2-overexpressing cell lines and they stimulated the basal ATP hydrolysis of ABCG2.

#4064 Relating tumor drug concentrations to target effect with semi-physiologic PK-PD modeling in drug development: an application using a novel dCK inhibitor. Mina Niknamj,1 Soumya Poddar,2 Edmund Capparelli,2 Thuc Le,1 Liu Wei,1 Caius Radu1. 1 University of California Los Angeles, Los Angeles, CA; 2 University of California San Diego, San Diego, CA.

Introduction: While plasma concentrations are commonly studied in preclinical and clinical studies, drug concentrations in tumors and effects on molecular targets may be more appropriate for determining drug dosing and predicting response to therapy. The current study assessed tumor and plasma drug levels of DI87, a novel deoxycytidine kinase (dCK) inhibitor, and determined the relationship to dCK activity using a PET biomarker and imaging. Methods: NSG mice with CEM tumors were treated with DI87 (25 or 50 mg/kg) by oral gavage for a single dose. Tumor and plasma concentrations were assessed over 24 hrs (50 mg/kg, dose, 5 times points, N=4 separate mice per time point). Plasma and tumor DI87 concentrations were quantified by LC-MS/MS. dCK activity was determined by PET imaging of a biomarker for dCK activity over 27 hrs ([18F]-clofarabine probe was injected 3 hrs prior to imaging) after a single dose of DI87 (50 mg/kg or 25 mg/kg, 5 time points, 4 mice per time point). Nonlinear mixed effects modeling (NONMEM v. 7.2) was used to build a semi-physiologic pharmacokinetic (PK) model to describe tumor and plasma concentrations (tumor volume fixed to observed median tumor size). The PK model was linked to an inhibitory indirect response pharmacodynamic (PD) model of dCK activity in the tumor using a pooled naive approach to describe the relationship between drug levels in the tumor and dCK inhibition. Results: Peak tumor DI87 concentrations were lower (1.15 ± 0.64 μg/mL vs. 13.5 ± 4.5 μg/mL) and occurred later (9 vs. 3 hr) than peak plasma concentrations. Despite limited tumor sampling, the semi-physiologic model described tumor concentrations well (R²=0.71). The PK model had a plasma clearance of 0.52 L/hr/kg with a half-life of 3.7 hr. DI87 exposure in the tumor (AUC) was 17% of that observed in plasma. Maximal and near complete dCK inhibition occurred at 9 hr for both the 50 mg/kg and 25 mg/kg doses with recovery of dCK activity beginning at 27 hr post-dose. The predicted tumor concentration at 12 hr of 0.36 μg/mL was sufficient to maintain maximal dCK inhibition. The initiation of recovery of dCK activity corresponded to the decline in tumor DI87 concentrations, but maintained significant inhibition at 27 hr (25% of baseline). The relationship between dCK activity and DI87 tumor concentrations was well characterized by a sigmoidal Emax PD model with a large Hill coefficient. This resulted in a dramatic increase of effect over a small range of concentrations. The EC50 was within the range of tumor concentrations observed in the study (0.21 μM/mL). Conclusions: The use of semi-physiologic PK models that include tumor drug concentrations from limited preclinical data can increase knowledge of the PK-PD for novel therapeutics. This approach enhances understanding of time-dependent effects on molecular drugs targets and can improve selection of rational clinical dosing regimens for phase 1 clinical trials.

#4065 Association study between iron and cholesterol for the treatment of drug resistant neuroblastoma. Sung Y. Lee, Becky Slagle-Webb, Cara-Lynne Schengrund, James Connor. Penn State Univ. College of Medicine, Hershey, PA.

Neuroblastoma is the most common childhood extracranial solid malignancy. Although cancer cells need more iron and lipids for their active cell metabolism, possible links between iron, mutations in genes involved in iron metabolism (e.g., HFE) and lipid metabolism have not been studied well. We determined the HFE genotype in human neuroblastoma cells as well as patients. Neuroblastoma cells and patients have C282Y HFE mutation rates (~12%) that are similar to those of the general Caucasian population. While cultured cells derived from drug resistant neuroblastomas had less cholesterol, they expressed more ferritin, and contained more iron, than cells derived from drug susceptible tumors. In drug resistant neuroblastoma CHLA-171 cells, cellular alteration of HFE expression had no effect on their iron levels but decreased their cholesterol. Results of in vitro experiments indicated that simvastatin, an inhibitor of 3-hydroxy-3-methylglutaryl coenzyme A reductase (HMCO-Ar), was cytotoxic to drug resistant cells as was the iron chelator di-2-pyridylketone-4- cyclohexyl-4-methyl-3-thiosemicarbazone (DpC). In vivo, the anti-tumor effect of simvastatin administered orally was minimal. In summary, we found i) an inverse association between ferritin and HMCO-Ar expression in neuroblastoma cells that was reflected in their iron and cholesterol levels, and ii) that the most cytotoxic cholesterol inhibitor of neuroblastoma cells was simvastatin, while the most cytotoxic iron chelation agent was DpC. Our results indicate that
it may be possible to use HFE genotype to develop a precision medicine approach to use certain iron chelators and/or cholesterol decreasing agents in the treatment of drug resistant neuroblastomas. Our results also indicate that alterations in iron and cholesterol metabolism are part of the cell’s drug resistance mechanism in neuroblastomas.

**#4066** The dihydroartemisinin oxime dimer (NSC725847) displays a selective toxicity in colon cancer cells which is potentially mediated by endoplasmic reticulum stress. Ahmed E. Elhassany, 1 Eman Soliman, 2 Paul McGuire, 1 Mahmoud ElSohly, 2 Waseem Gul, 3 Rukiyah Van Dross 4, 3 Brody School of Medicine, East Carolina University, Greenville, NC; 1 Faculty of Pharmacy, Zagazig University, Sharkia, Egypt; 2 ElSoLyh Laboratories Inc. and National Center for Natural Products Research, School of Pharmacy, The University of Mississippi, Oxford, MS; 3 ElSoLyh Laboratories Inc., Oxford, MS; 4 Brody School of Medicine and Center for Health Disparities East Carolina University, Greenville, NC.

Colorectal cancer (CRC) is the third leading cause of cancer-related deaths in the United States. Common chemotherapeutic regimens for CRC include a combination of chemotherapeutic agents to produce synergistic drug activity and reduce adverse effects. However, adverse effects due to lack of selective toxicity is still a major problem with many chemotherapeutic agents. Novel drugs that display tumor selective toxicity are desperately needed. Several studies have shown that artemisinin monomers (Clinically used anti-malarial agent) possess antineoplastic activity with minimal toxicity. Interestingly, artemisinin dimers showed more potent antineoplastic activity compared to the monomers. However, few studies have fully characterized the activity of these molecules. In this study, we tested the antitumor activity of five chemically-synthesized dihydroartemisinin (DHA) dimers using the human colon cancer cell lines, HT29 and HCT116 and the non-tumorigenic colon cell line, FHC. Compared to other tested dimers, the DHA oxime dimer, NSC735847 showed pronounced selective toxicity in HT29 and HCT116 colon cancer cells compared to the non-tumorigenic FHC cells. In addition, NSC735847 significantly increased caspase 3/7 activity in HT29 and HCT116 cells but not in FHC cells which suggests that this compound causes selective apoptosis in these colon cancer cell lines. The combination of NSC735847 and the topoisoenserase I inhibitor, irinotecan (commonly used chemotherapeutic agent for colorectal cancer) showed synergistic antitumor activity in HT29 cells. The combination of the two drugs caused a significant increase in cell death and caspase 3/7 activity which were greater than those caused by the individual drugs. Previous studies using other tumorigenic cell lines, suggested that NSC735847 induces oxidative and endoplasmic reticulum (ER) stress. To gain insight into the potential mechanisms of anti-colorectal cancer activity of NSC735847, we tested if this compound caused ER stress and/or oxidative stress in HT29 cells and whether ER stress was required for NSC735847-induced apoptotic cell death. NSC735847 increased the expression of ER stress marker C/EBP homologous protein 10 (CHOP10) in HT29 cells and the use of ER stress inhibitor, salubrinal, significantly decreased NSC735847-induced cell death and apoptosis. Additionally, NSC735847 caused oxidative stress in HT29 cells which was inhibited by pretreatment of the cells with the antioxidant, trolox. The crosstalk between oxidative stress and ER stress in NSC735847-induced apoptosis in colon cancer cells is still under investigation. Our results suggest that NSC735847 causes ER stress in HT29 cells which plays a major role in drug-induced cell death and apoptosis in these cells.

**#4067** BPM31510, a clinical stage metabolic modulator demonstrates therapeutic efficacy in an in vivo C6 rat glioma model and synergizes with temozolomide. Stephane Gesta, 1 Semma Nagpal, 2 Tulin Dadali, 1 Milton Mercant, 2 Taichang Jan, 2 Anne R. Diers, 1 Michael Kiebish, 1 Joaquin Jimenez, 3 Barbi Akl, 1 Ann Marie Stephens, 1 Berge Smedes, 1 David S. Margolis, 2 Recht 2.

BPM31510 is a parenteral nanodispersion of ubidecarenone that is in clinical testing for solid tumors, effectuates an anti-cancer effect in highly metastatic cancers by eliciting an anti-Warburg effect. Intraperitoneal (i.p.) administration of BPM31510 reverses paraglia in a rat CNS leukemia model demonstrating the bioavailability of the drug to the central nervous system. The study describes data demonstrating the therapeutic utility of BPM31510 in glioblastoma multiforme (GBM). BPM31510 decreased cell proliferation rates in patient-derived GBM cell lines compared to temozolomide (TMZ), pretreatment with BPM31510 followed by TMZ challenge was associated with significant synergy in reducing cell proliferation compared to monotherapy. In a C6 gliona allograft rat model treatment with BPM31510 alone (n=30/group) (i.p., 50mg/kg, b.i.d.) increased overall survival compared to untreated control group. BPM31510 in combination with procarbazine (oral, 60mg/kg; d 8, 21) and vin-cristine (IV, 1.4mg/kg; d 8, 29) significantly improved overall survival compared to BPM31510 alone or chemotherapy. Furthermore, long term survival was achieved in four of twenty rats with C6 gliomas receiving BPM31510 doses between 10 to 50 mg/kg/day and compared with no treatment or irradiation (P < 0.02, Fisher exact test). Interestingly, the long term survival persisted for over two months after all treatment was discontinued; MR imaging confirmed the presence of static masses in these long term survivors. Collectively, the data demonstrate that BPM31510 has a robust effect in a preclinical model of GBM. Intravenous BPM31510 is currently in Phase 1/2 clinical trial for TMZ+BEV refractory GBM patients.

**#4068** HH-002, a derivative of Homoharringtonine, show promising in diverse cancer models in preclinical characterization. Hank Rui, Bensheng Pharma Co. Ltd., Pudong, China.

Homoharringtonine (HHT) is an anti-cancer drug used to treat imatinib resistant CML, and a reversible inhibitor of translation acting upon the early steps in polypeptide chain elongation. BS-HH-002.SA is a derivative of HHT. BS-HH-002.SA was shown to decrease the phosphorylation of Janus protein tyrosine kinase 2 (JAK2) as well as downstream targets, such as signal transduc- ter activation of transcription 3 and 5 (STAT3 and STAT5), it also reduced Myeloid cell leukemia-1 (Mcl-1) protein level significantly and resulted in apoptosis. Evaluation of BS-HH-002.SA efficacy was test in HEL, an erythroleuко- mia cell line carrying a Jak2V617F mutation which is seen in 90% of patients with polycythemia vera (PCV) and half of those with essential thrombocythemia or primary myelofibrosis. HH-002.SA was showed highly potent (at low nM concentration) in HEL. Efficacy of BS-HH-002 was tested in a recombinant human erythropoietin injection (rEpo)-induced murine model of polycythe- mia Vera, Treatment with BS-HH-002.SA BID for 4 days showed a significant inhibitory effect on rEpo induced increase in reticulocytes, hematocrit and splenomegally, as well as in red blood cell, white blood cell and platelet counts. Furthermore, histology evaluations revealed that BS-HH-002.SA exerted an inhibitory effect on rEpo induced extramedullary hematopoiesis in spleen, and decreasedcellularity in bone marrow with more predominant effect on erythroid cells than on myeloid cells. Also, BS-HH-002.SA also show potent in vitro and in vivo efficacy in pancreatic cancer cell line KP-4 and non-small cell lung cancer (NSCLC) NCI-H1975, BS-HH-002.S inhibited STAT3 Tyrosine 705 phosphorylation and reduced anti-apoptotic proteins expression Mcl-1 protein levels in both two cancer cell lines.

**#4069** Trimethylation and acetylation of Histone H3K27 modulates 5-fluorouracil response by regulating DPD expression. Rentian Wu, Mayo Clinic, Rochester, MN.

The antimitabolite 5-fluorouracil (5-FU) is one of the most widely used chemotherapeutics drugs. Dihydropyrimidine dehydrogenase (DPD) initiates the catalytic degradation of 5-FU to inactive metabolites and is widely accepted as a major determinant of 5-FU response and toxicity. While genetic variants in DPD have been shown to variants may affect 5-FU metabolism, they are rare events and do not completely explain the variable variability in DPD function or the resultant differences in treatment response. Here, we report that DPD expression is epigenetically regulated by histone modification at relevant promoter and enhancer regions. Using both chemical inhibitors and genetic approaches, we show that H3K27 tri-methylation (H3K27me3) at the DPD promoter is regulated by the epigenetic modifiers Ezh2 and UTX. Promoter H3K27me3 suppresses DPD expression by inhibiting the binding of the transcription factor PU1. Binding to the promoter increases sensitivity leading to increased resistance to 5-FU. In a cohort of healthy volunteers, H3K27me3 levels were inversely correlated with an enhancer that regulates DPD expression was also identified. Modifying the H3K27 status of the DPD promoter or enhancer matures DPD gene expression. Deletions and mutations on the DPD promoter or enhancer abolish their transcription regulation function. Enrichment of H3K27me3 at the DPD promoter was negatively correlated with DPD expression and DPD enzyme activity in peripheral blood mononuclear cells specimens from healthy volunteers. Lastly, tumor expression data suggests that DPD expression by Ezh2 is a strong predictor of poor survival in 5-FU treated cancers. By using a combination of in silico prediction and in vitro reporter assays we also identified a functional enhancer region for DPD that is also likely to be clinically relevant to 5-FU treatment outcome. Collectively, the present thefindings suggest that a previously uncharacterized mechanisms regulates DPD expression and may likely contribute to tumor resistance to 5-FU.
Pancreatic cancer (PaCa) is highly refractory to treatment, with a median survival of 6 months. Currently, gemcitabine (Gem), a difluoro analog of deoxy-cytidine, is the standard care for PaCa, but it renders only a modest survival benefit. Combination therapy, integrating novel agents into standard-of-care regimens, may maximize efficacy of Gem-based therapy. Fibroblast growth factor receptor (FGFR) tyrosine kinase is a potential therapeutic target in pancreatic cancer.

FGFR1 is overexpressed in various carcinomas and is overexpressed in various cancers and therefore represents a considerable chemotherapeutic target. Inactivation of FGFR1 reduces tumor cell survival and growth and inhibits tumor cell migration and invasion.

FGFR inhibitors can impact Gem receptor (FGFR) function is aberrant in pancreatic cancer, and suppression of FGFRs inhibits pancreatic cancer growth and invasion. However, the mechanisms of FGFR action and their therapeutic utility in pancreatic cancer remain to be elucidated. Here we tested the hypothesis that FGFRs can impact Gem sensitivity of PaCa cells by employing pan-FGFR inhibitors and shRNAs against FGFRs. NVP-BG139 and AZD4547 are novel FGFR inhibitors (FGDRI and FGFR3, and are in various stages of clinical trial. The FGFRs modestly but significantly inhibited proliferation, migration, and invasion of Panc-1, MiaPaCa-2 cells in wound-healing and trans-well assays. Treatment with low-concentration Gem (7.5 nM) enhanced MiaPaCa-2 cell migration at 24 hrs, but migration was reduced subsequently, suggesting a sequence of delayed effects of Gem upon cell migration. After 72 hrs of exposure, the combination of FGFRs reduced MiaPaCa-2 cell proliferation significantly compared to controls or Gem- and FGFR1 alone. Pharmacodynamic modeling was employed to evaluate drug interaction, and the interaction coefficient Psi was estimated by simultaneous modeling of 16 different drug combinations over a period of 0-96 hrs. The analysis estimated Psi = 0.78, which indicates synergism. Compared to BG139 or Gem alone, the combination also increased the pharmacokinetics for a longer period of time. We detected a trend of increased expression of RRM1, whereas knockdown of FGFR2 and FGFR3 mediated an increase in RRM1 expression, implicating FGFR1 suppression in improving Gem sensitivity. These results suggest that inhibition of FGFR1 could potentially enhance sensitivity of PaCa to Gem therapy, and that combining FGFRs with gemcitabine is a promising treatment strategy in pancreatic cancer.
intact and permeable BTB. In conclusion, S-222611 is expected to be useful for the treatment of patients with HER2-positive breast cancers, including those with brain metastases.

**#4074 Effect of PEG chain length on antibody-drug conjugate tumor and permeability changes and effect of chemotherapy in brain adjacent with brain metastases.**

Aroz Shareef Mohammad, Chris E. Adkins, Neal Shah, Rawaa Aljammal, Jessica Griffith, Paul R. Lockman. West Virginia Univ., Morgantown, WV.

Background: Brain metastases vasculature is compromised and more permeable than that of vasculature in normal brain. Unfortunately, little is known about vascular permeability changes in brain adjacent to tumor (BAT). It is critical to understand the potential changes as chemotherapy penetration and accumulation brain tumors positively correlate with breakdown of the brain vasculature. Herein, we evaluate quantitatively measure permeability, drug accumulation and cytotoxicity in normal brain that is adjacent (<500 microns) to a tumor. Methods: The subclone population of brain seeking metastatic breast cancer cells (MDA-MB-231Br) were injected into the left ventricle of female NuNu mice. Mice were given a chemotherapeutic regimen of vinorelbine (10mg/kg), erubulin (1.5mg/kg) or docetaxel (10mg/kg). Progression occurred until neurological compromise was noted, at which time animals were injected with texas red 625 Da(TR) and texas red dextran 3kDa (TRD). Dye concentrations (measuring passive permeability changes) were determined in lesions and the BAT using quantitative fluorescent microscopy. Chemotherapeutic induced cytotoxicity was observed by staining for activated astrocytosis and DNA damage in neurons, glia and endothelium. Results: We observed permeability of TR is highly heterogeneous both within and between the tumors (normal brain Kin values and Area Under the Curve (AUC) were calculated for each cell line. Hierarchical clustering was performed to determine similar responses between cell lines. The use of targeted drug therapy is rising in the pediatric oncology field. Development of novel therapeutic agents for Down syndrome patients with AML. Apurvi R. Patel, Justin J. Montoya, Daniel H. Wai, David W. Lee, Robert J. Arceci, David O. Azorsa. Phoenix Children's Hospital, Phoenix, AZ.

Patients with Down's syndrome who develop acute myeloid leukemia (AML) are at increased risk of toxicity secondary to chemotherapy regimens. These patients are harder to treat with conventional therapies at relapse. Overall, the use of targeted drug therapy is rising in the pediatric oncology field. Development of novel therapeutic agents for Down syndrome patients with AML.

**#4075 Effect of PEG chain length on antibody-drug conjugate tumor and tissue distribution in tumor bearing xenograft mice.** Nagendra V. Chemuturi, Martha Anderson, Julia Cochran, Thomas Pires, Josh Hunter, David Meyer, Jason Neale, Alice Chin, Paul Pittman, Cindy Balasubramanian, Francisco Zapata, Jessica Simmons, Robert Lyon, Steve Alley. Seattle Genetics, Bothell, WA.

Antibody-drug conjugates (ADCs) are a promising new therapeutic modality having demonstrated clinical efficacy in the treatment of cancer. While ADCs have better exposures than their constitutive chemotypes, it is important that they maintain the favorable pharmacokinetics of their antibody backbones. Previous work incorporating PEG into the drug-linker as a sidechain helped to mask the hydrophobicity of the chemotype, resulting in improved ADC exposure in rats, compared to ADCs with non-PEGylated drug-linkers. The current studies were aimed at understanding the effect of PEG chain length on ADC efficacy, tumor and tissue distribution in tumor bearing mice. Efficacy and biodistribution of radiolabeled ADCs with 2, 4, 8, 12 and 24 PEG units in the drug-linker as a side chain were investigated in SCID mice bearing a subcutaneous xenograft of L540 cytumor cells. A non-PEGylated ADC was used as control. Antibody based radioactivity in plasma, tumor, liver, lung, kidney, spleen and brain were measured over 14 days. MMAE, the free drug released from the ADC, was measured by mass spectrometry. Reduction in tumor weight was determined as a measure of efficacy. Compartmental analysis of the plasma exposure data was conducted to understand the change in rate constants with change in PEG chain length. ADCs with side chain PEGylated drug-linkers had greater plasma and tumor exposures than the non-PEGylated control ADC. Increasing PEG chain length in the linker led to increased plasma and tumor exposures, and lower plasma clearances. Tumor distribution was binary with ADCs 2 and 4 PEG units in the linker showing similar tumor exposures while the ADCs with 8, 12 and 24 PEG units provided similar but significantly higher tumor exposures. ADCs with 8, 12 and 24 PEG units in the linker had significantly higher tumor to plasma exposure ratios than ADCs with 2 and 4 PEG units in the drug-linker. The reduction in tumor weights was also binary. ADCs with 2 and 4 PEG units provided a 35-45% decrease in tumor weights while ADCs with 8, 12 and 24 PEG units in the linker provided 75-85% reduction in tumor weights. The non-PEGylated control ADC decreased the tumor weights by 11%. In general, PEGylated ADCs increased the extent of tissue distribution, but the tissue to plasma ratios remained the same indicating that the increased tissue exposures was a function of increased plasma exposures. However, PEGylated ADC tumor exposure increased beyond that expected based solely on the increase in plasma exposure. Incorporation of PEG as a side chain into the drug-linker improved tumor accumulation of ADCs with little alteration. ADCs with 8, 12 and 24 PEG units in the drug-linker showed preferential uptake into tumor, but not the tissues as evidenced by tumor (or tissue) to plasma exposure ratios. Over all, the ADCs with 8, 12 and 24 PEG units in the linker provided the optimal combination of tumor distribution, efficacy and tissue distribution.

IDO1 catalyzes degradation of tryptophan (Trp) into kynurenines, which plays an important role in the regulation of immune responses by triggering anergy on reactive effector T cells and by modulating differentiation and activation of regulatory T cells (Treg). Indoximod has been demonstrated to relieve IDO-mediated immunosuppression in vitro and in vivo, by creation of an artificial Trp-sufficiency signal that bypasses activation of GCN2 and inhibition of mTOR in conditions of Trp deprivation. Inhibition of the IDO pathway by indoximod in combination with immune-stimulatory treatments leads to increased T cell proliferation, Treg reprogramming and antitumor effect. Indoximod has demonstrated an excellent safety profile in human clinical trials and is being dosed orally at 1200 mg bid. Increases in doses above this level do not generally result in increased plasma concentration or drug exposure due to limiting dose-dependent oral bioavailability. Animal models suggest that increased therapeutic benefit could be achieved at higher levels of exposure. For this reason, we synthesized and tested the pharmacokinetic profile of several indoximod prodrugs in mice, rat and monkeys in both liquid and capsule formulations. We selected clinical development drug candidate NLG802, which increases indoximod exposure and plasma concentration ~2-fold in rats and ~5-fold in monkeys dosed with capsules of comparable formulation to that being used in clinical trials. NLG802 is rapidly absorbed and metabolized in vivo to indoximod. NLG802 DMPK profile and GLP toxicity studies have been carried out in rats and monkeys suggesting a safe toxicological profile at predicted therapeutic doses. In a preclinical tumor model of mice bearing established B16F10 tumors, administration of NLG802 markedly enhanced the anti-tumor responses of naïve, restting peml-1 cells to vaccination with cognate hgp100 peptide plus Cpg-1826 in IFA. In this tumor model, NLG802 plus peml-1 vaccine produced significant tumor size reduction within 4 days of vaccination. Moreover, the tumor response was achieved at lower doses (equivalent to ~30% of the equivalent molar doses of indoximod). In conclusion, NLG802 is a prodrug of indoximod predicted to increase clinical drug exposure to indoximod above the current achievable levels and will soon enter Phase 1 safety testing in oncology clinical trials.

Patients with Down's syndrome who develop acute myeloid leukemia (AML) are at increased risk of toxicity secondary to chemotherapy regimens. These patients are harder to treat with conventional therapies at relapse. Overall, the use of targeted drug therapy is rising in the pediatric oncology field. **EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Mechanistic Understanding of Novel Anticancer Therapies**

Phoenix Children’s Hospital, Phoenix, AZ.

Patients with Down’s syndrome who develop acute myeloid leukemia (AML) are at increased risk of toxicity secondary to chemotherapy regimens. These patients are harder to treat with conventional therapies at relapse. Overall, the use of targeted drug therapy is rising in the pediatric oncology field. Development of novel therapeutic agents for Down syndrome patients with AML.
ing results showed improved sensitivity of the CMK and CMY cells to Navito- 
clax and 17-AAG under normoxic and hypoxic conditions. Validation of the 
screening results was done using a 10-concentration drug dose response assay. 
Future studies will explore the mechanism by which the Down’s syndrome AML 
cells have increased sensitivity to these targeted agents under both normoxic and 
and hypoxic conditions. In Down’s syndrome AML, we will investigate the effects of combina-
tions of these targeted therapies with conventional therapies. The results from 
these studies could lead to the establishment of improved therapeutic regimens 
for Down’s syndrome patients with AML.

**#4078** Tumors with class 3 BRAF mutants are sensitive to the inhibition of 
activated RAS. Zhan Yao,1 Rona Yaeger,1 Vanessa S. Rodrik-Outmezguine,1 
Anthony Tao,2 Neilawatte M. Torres,3 Matthew T. Chang,1 Matthias Drosten,1 
Huaying Zhao,1 Fabiola Cocchi,3 Todd Hembroug,4 JudithMichels,5 Hervé 
Baumert,6 Linde Miles,1 Naomi M. Campbell,1 Elisa de Stanchina,1 David B. 
Solit,5 Mariano Barbacid,2 Barry S. Taylor,7 Neal Rosen1,2, Mem. Sloan Kettering 
Cancer Ctr., New York, NY; 3New York University, New York, NY; 4Centro Na-
acional de Investigaciones Oncológicas, Madrid, Spain; 5NanOtics, LLC, Rock-
ville, MD; 6Gustave Roussy Cancer Campus, Paris, France; 7Saint Joseph Hospital, 
Paris, France.

Approximately two hundred mutant BRAF alleles have been identified in 
human tumors. Physiologic activation of RAF isoforms requires RAF-depen-
dent induction of their dimerization. Activating BRAF mutants cause ERK de-
pendent feedback inhibition of protein phosphatase 1, thereby repressing ERK 
signaling in tumors requires concurrent dysregulation of RAF activation. Thus, 
melanomas with Class 3 mutations usually harbor coexistent RAS mutation or 
NF1 mutants/deletion, whereas receptor tyrosine kinase signaling is activated in 
lung and colorectal cancers with these mutants. Our model suggests that these 
tumors will be sensitive to the inhibition of RAS activation. Currently, no direct 
inhibitors of RAS activation are available. However, in support of this idea, 
inhibitors of activated RTK signaling in carcinomas with Class 3 BRAF mutants 
and wild type RAS is sufficient to markedly inhibit ERK signaling and their 
growth in vivo murine models and in patients. We have thus defined a third 
subset of BRAF mutants, which is RAF-dependent. Tumors harboring such 
mutants are sensitive to tyrosine kinase inhibitors in tumors expressing wild 
type RAS and NF1.

**#4079** Pre-clinical toxicity and safety of SH7139: The first of a new class 
type RAS and NF1. mutants are sensitive to tyrosine kinase inhibitors in tumors expressing wild 
and advancing SH7139 into clinical trials, acute dose range find-
ing from each of the linked ligands) that inhibit a series of cellular activities 
concentrated and subsequently metabolized, releasing toxic metabolites (de-
binding to its HLA-DR target, SH7139 is carried into the cytoplasm where it is 
epitopewithintheantigen-bindingpocketofHLA-DR10. HLA-DRscontaining 
drug conjugate and a pro-drug, SH7139 targets and binds to a unique structural 
exvivo, drug screening is limited to short-term assessments due to de-differentiation. This limits their efficacy in testing slow-clearing, large-
molecule compounds such as antibody-based therapies and low-turnover drugs. 

**#4080** Cytochrome P450 enzyme activity is enhanced in hepatocytes 
grown using a perfused 3D cell culture drug screening system. James T. Shoe-
maker, Jelena Vukasinovic. Lena Biosciences, Atlanta, GA.

A critical requirement for assessing drug toxicity in vitro is cytochrome P450 (CYP) 
function that is physiologically representative. Due to low levels of CYP 
ezyme activity, cell lines such as HepG2 hepatocytes have largely been sup-
planted with primary cells derived from human donor tissue. While these cells 
retain CYP activity ex vivo, drug screening is limited to short-term assessments 
due to de-differentiation. This limits their efficacy in testing slow-clearing, large-
molecule compounds such as antibody-based therapies and low-turnover drugs. 

**#4081** Superior SN-38 pharmacodynamic and tumor-accretion profiles of 
labetuzumabgovitecan (IMMU-130) versus irinotecan in experimental hu-
man colon cancer models. Thomas M. Cardillo, Robert M. Sharkey, Serengu-
lam G. Govindan, Jennifer Donnel, Maria Zalath, David M. Goldenberg. Immu-
nomelics, Inc., Morris Plains, NJ.

BACKGROUND: IMMU-130 is an antibody-drug conjugate (ADC) under-
going clinical investigation in patients with metastatic colorectal cancer (Clini-
icalTrials.gov, NCT016053188). It is composed of a humanized anti-CEACAM5 
IgG conjugated via a cleavable linker to SN-38, a topoisomerase-I inhibitor and 
active form of irinotecan. We investigated the potential advantage of IMMU-130 
versus irinotecan for SN-38 delivery in nude mice bearing CEA-expressing hu-
man colon tumor xenografts (LS174T or GW-39). METHODS: Mice were 
infected with irinotecan (~900 μg; SN-38 equivalents = ~500 μg) or 1.0 mg of 
IMMU-130 (16 μg SN-38 equivalents). Irinotecan-treated animals were necrop-
sied 5 min, 1, 2, 6-8 h post-injection, while IMMU-130-treated animals were 
evaluated at 1, 6, 24, 48-72 h. Serum and homogenates of tumors, liver, and small 
testes were harvested, and SN-38, SN-38, SN-38g, and irinotecan concen-
trations were determined by reversed-phase HPLC. For IMMU-130-treated 
specimens, SN-38 concentrations were assessed in the extracted samples (Free 
SN-38), as well as in acid-hydrolyzed samples to determine Total SN-38 (Free + 
bound). IgG was measured by ELISA. RESULTS: Irinotecan cleared quickly from 
serum, with SN-38 averaging ~900 ng/ml to 200 ng/ml from 5 min to
EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Mechanistic Understanding of Novel Anticancer Therapies

6 h. SN-38G and SN-38 levels were similar. With IMMU-130, Free SN-38 was detected in serum over the entire monitoring period, but levels were only a small fraction of the Total SN-38 (~10%). Importantly, Free SN-38G was very low, being detected only within the first 6 h. Total SN-38 levels dropped more quickly than the IgG, confirming in vitro studies showing gradual SN-38 release from the ADC. In tumors, for irinotecan-treated animals, SN-38 peaked at 5 min, representing ~0.2% of the SN-38 equivalent given. In IMMU-130-treated animals, no Free SN-38 was detected in tumors, but levels of Total SN-38 peaked at 6 h, with ~5% of the injected SN-38 dose present at that time, and were sustained longer than SN-38 delivered by irinotecan. Area under the curve analysis found SN-38 levels were ~10- and 17-fold higher in LS174T and GW-39 tumors, respectively, from IMMU-130-dosed versus irinotecan-dosed animals. This delivery advantage is amplified >30-fold when normalized to SN-38 equivalents injected for each product, illustrating the improved bioavailability with IMMU-130-targeted SN-38. Levels of SN-38 and SN-38G were appreciably lower in the liver and small intestinal contents, which likely explains the lower incidence of severe diarrhea reported in patients given IMMU-130. CONCLUSION: IMMU-130 delivers >100-fold more SN-38 to CEA-producing tumors compared to irinotecan, while also reducing levels of potentially harmful SN-38 and SN-38G in normal tissues. These observations are consistent with preclinical data showing improved efficacy and safety.

A 1010 Brutton’s Tyrosine Kinase (BTK) plays an important role in B-cell signaling, cell proliferation and survival and is an established drug target in B-cell malignancies. GS-4059 (ONO-4059) is an irreversible, small molecule inhibitor of BTK, which is in development for hematological malignancies and rheumatoid arthritis. A Phase 1 study to evaluate the effect of oral anion transporting polypeptide (OATP) 1B1 and 1B3 inhibitors and inducers of cytochrome P450 3A (CYP3A) on GS-4059 Pharmacokinetics (PK) was performed in healthy subjects (N=15). Subjects were administered a single dose of 100 mg GS-4059 alone or in combination with a single or multiple doses of rifampin (600mg) and blood samples were collected up to 48 hours post dose to evaluate PK and Pharmacodynamic (PD) markers in peripheral blood mononuclear cells (PBMCs). PD biomarkers were exploratory endpoints and are reported here. PD was evaluated using the BTK occupancy assay and the Basophil Activation Test (BAT). A novel duplex homogeneous BTK occupancy assay was used to quantitatively measure GS-4059 binding to human BTK to assess target coverage. The assay is based on Time-Resolved Fluorescence Resonance Energy Transfer (TR-FRET) and simultaneously measures the level of free BTK as well as total BTK protein in PBMCs collected from subjects in the study. Free BTK levels in PBMCs decreased rapidly on treatment with GS-4059 with no detectable free BTK 3-24 hours post dose and no notable changes in total BTK. All subjects had free BTK levels below the limit of detection (LOD 6.8 ng/mL) 3-24 hours after dosing. Free BTK levels started to increase after 48 hours. Free BTK levels on treatment with multiple doses of rifampin plus GS-4059 followed a similar trend with no free BTK detected 3-6 hours post dose but resulted in shorter duration of inhibition and more rapid recovery of free BTK levels. GS-4059 plasma exposure (Cmax and AUC) was ~70% lower after multiple doses of rifampin, due to a drug-drug interaction. As a second PD marker, inhibition of CD63 basophil activation in the BAT was measured. In this functional assay the median inhibition of CD63 basophil activation was between 90% and 100% at the time of maximum inhibition (3 hours post dose). At the peak of inhibition 13 of the 14 subjects had inhibition of basophil activation higher than 97%. In line with the BTK occupancy data, inhibition of CD63 basophil activation was significantly lower with reduced GS-4059 plasma exposure. BTK occupancy as a direct measure of target binding and the functional assay measuring the inhibition of basophil activation showed a similar time course with maximum effects at both assays achieved at 3-6 hours post dose. These data demonstrate that a single 100 mg dose of GS-4059 results in full BTK occupancy in healthy subject PBMCs as well as functional changes measured in basophil activation as a surrogate for BTK signaling pathway inhibition.

#4083 Basic mechanisms of Vernonia amygdalina exert antitumor activities in breast cancer cells. Clement G. Yedjou, Paul B. Tchounwou. Jackson State Univ., Jackson, MS

Breast cancer continues to represent the largest cause of mortality in the world especially among women. It is estimated that cancer kills more women in the USA than any other illness and it is also the leading cause of death among all Americans. Traditional medicine represents the first-choice of healthcare treatment for at least 80% of people living in developing countries. Preliminary studies from our laboratory have shown that a novel natural product, extracts of Vernonia amygdalina (VA) leaf exerts DNA-damaging anticancer activities against breast cancer. There is a need to develop targeted approaches for the treatment of human breast cancer. Therefore, the goal of this research was to determine the therapeutic mechanisms of V. amygdalina leaf extracts as anti-cancer agent in the management of breast cancer. To achieve our goal, cell viability, live and death cells were determined by trypan blue exclusion test. The extent of oxidative cell/tissue damage was determined by measuring malondialdehyde (MDA) levels. Expression of p53 tumor suppressor gene was assessed both by immunofluorescent and western blot analyses. Cell apoptosis was measured through determination of caspase-3 activity and DNA fragmentation associated with the formation of MDA, a by-product of lipid peroxidation and biomarker of oxidative stress. This result suggests that V. amygdalina treatment may be a good anti-cancer candidate for the treatment of breast cancer. Research supported by NIH Grant No. NIMHDG12MD007581.

S-222611 is a potent and selective reversible tyrosine kinase inhibitor of epidermal growth factor receptor (EGFR), human EGFR2 (HER2), and human EGFR4 developed in Shionogi. Greater potency of anti-tumor activity than lapatinib was demonstrated in vitro and in animal models. In the intracranial implantation mouse model implanted the HER2-positive cell line (MDA-MB-361-luc-2), S-222611 showed more potent anti-tumor activity than lapatinib. On the basis of higher penetration in brain of S-222611 than lapatinib indicated by the preclinical pharmacokinetic studies, we demonstrated the application of S-222611 to brain metastases with breast cancer. In order to enhance the clinical predictability of S-222611 to the treatment of brain metastases, we have developed the experimental brain metastases models in mice of HER2-positive breast cancer (MDA-MB-361-luc-2-BR2/BR3) and T970M-EGFR expressing lung cancer (NCI-H1975-luc). After a single oral administration of S-222611 or lapatinib, the concentrations of S-222611 and lapatinib in the brain metastatic regions of these mice models were analyzed by quantitative imaging mass spectrometry (QIMS). In the breast cancer model, the concentrations of S-222611 in brain metastases quantified by IMS were comparable to those of lapatinib. In contrast, in the MDA-MB-361 breast cancer model (intraventricular injection model), the concentrations of S-222611 in brain metastases were over 10 times higher than those of lapatinib, and the tumor-to-normal brain ratio of S-222611 was significantly higher than those of lapatinib in the breast cancer mice model. In addition, the blood-tumor barrier (BTB) permeability in each brain metastatic region using these mice models was assessed simultaneously. In the lung cancer model, fluorescently labeled dextran was highly detected in the brain metastatic regions than brain parenchyma. However, in the breast cancer models, fluorescence intensities for dextran in the brain metastatic regions and brain parenchyma were comparable, indicating that the BTB was remained to be largely intact in brain metastases of the breast cancer model but disrupted in the lung cancer model. These results show that S-222611 is expected to be useful for the prevention and the prompt treatment of patients with HER2-positive breast cancer having brain metastases.
Introduction: Doxorubicin is a highly effective chemotherapeutic agent, but its use is limited due to cumulative and dose-dependent effects that can lead to irreversible heart damage. Despite efforts in understanding the mechanisms, the precise genes and pathways implicated in doxorubicin-induced cardiotoxicity still remain elusive. We hypothesized that by exploring time- and dose-depen- dent changes in expression in human FLT3-ITD cell lines in vitro, we could identify genes and signaling pathways related to doxorubicin-induced cardiotoxicity. Methods: hiPSC-CM were treated with 0, 50, 150, or 450 nM of doxorubicin for 2, 7, or 12 days then subjected to RNA sequencing for assessment of gene expression. Sequenced reads were aligned to the human reference genome (GRCh37) with STAR, and a read count matrix was generated with the R package GenomicConsensus. Global variation and differential gene expression analyses were performed using DESeq2 software (P < 0.05). For time course analysis, log2 fold-changes in gene expression for pairwise comparisons between any two time points or doses were calculated using DESeq2 and a Time x Dosage interaction model. For Ingenuity Pathway Analysis of time course genes, input genes were selected based on a cutoff > 2.0 and < 2.0 average log2 fold-change in expression. Results: Hierar- chical clustering of expression profiles of 40,861 genes produced by DESeq2 revealed 192 genes downregulated following doxorubicin exposure related to mitotic roles of polo-like kinase, cell cycle control chromosomal replication, and DNA damage checkpoint regulation pathways. This included a set of nine genes with the highest variation in expression, MCM5, PRC1, NUSAP1, CENP, CCNB1, MKL, AURKB, RAGAP1, and TROAP, with functions in microtu- bule stabilization and cell cycle regulation. Following a 2-day exposure to doxo- rubin, 242 genes, including the top nine genes, were differentially expressed between untreated and treated with enrichment in ribosomal processes, DNA repair and damage, and oxidation-reductase activity. Time course analysis re- vealed 289 genes between 0 nM and 150 nM on days 2, 7 and 12 with enrichment in fatty acid oxidation, MIF-mediated glucocorticoid regulation, and relaxin signaling pathways. Transcription regulator, SMARCA4, was identified as the only upstream regulator with elevated expression following a later recovery time (day 7 to day 12) compared to shorter or earlier time point comparisons at 150 nM dose. Conclusion: Overlapping genes and pathways identified in these analyses provide additional support for a role of reactive oxygen species and mito- chondrial dysfunction linked to DNA damage in doxorubicin-induced cardio- toxicity. This study also warrants further investigation of SMARCA4 since it is a direct regulator of genes with overlapping functions described for the top nine genes.

#4087 Development of a potent, dual pan-PIM/FLT3 inhibitor for the treatment of heme malignancies. Wojciech Czardybon,1 Renata Windak,1 An- iela Golas,1 Michal Gałówski,1 Aleksandra Sabiniarz,1 Izabela Dolata,1 Magdalena Salwinska,1 Paweł Guzik,1 Magdalena Zawadzka,1 Ewelina Gabor- iela Gołas,1 Michał Gałeżowski,1 Aleksandra Sabiniarz,1 Izabela Dolata,1 Wojciech Czardybon,1 Renata Windak,1 Anna Jabłońska,3 Maciej Szydłowski,3 Tomasz Sewastianik,3 Bartosz Puła,3 Anna Porembicka,3 Weronika Domek,3 Marta Buga,3 Monika Danieliewicz,3 Grzegorz Dubin,2 Ewa Jabłońska,1 Maciej Szydłowski,1 Tomasz Sewastianik,3 Bartosz Puła,2 Anna Szumula-Cieciewicz,3 Monika Prochoriec-Sobieszek,2 Elżbieta Mądro,2 Ewa Lech-Maranda,1 Krzysztof Warzocha,1 Jerome Tamburini,2 Przemysław Juszczyszyn,1 Krzysztof Brzózka,1 Selvita S.A., Kraków, Poland; 2University of Wroclaw, Wroclaw, Poland; 3Institut Hematologi i Transfuzjologii, Warszawa, Poland; *Inserm, France.

Despite huge effort spent on understanding the pathogenesis of acute myeloid leukemia (AML), current standards of care are still based on the same chemo- therapy agents as two decades ago - combinational treatment of cytarabine with an anthracycline. Fms-like tyrosine kinase 3 internal tandem duplication (FLT3- ITD) is one of the most common genetic lesions in AML. Although FLT3 inhibitor- s initially exhibit clinical activity, resistance to treatment inevitably occurs within months. PIM kinases are thought to be major drivers of the resistance phenotype and their inhibition in relapsed samples restores cell sensitivity to FLT3 inhibitors. Thus, simultaneous PIM and FLT3 inhibition represents a promising strategy in AML therapy. Selvita has developed a potent and selective first-in-class, dual PIM/FLT3 kinase inhibitor, the SEL24-B489 compound, and profiled its activity in vitro and in vivo AML models showing significantly broader anti-tumor activity of SEL24-B489 than selective FLT3-ITD or PIM inhibitors. We compared SEL24-B489 head-to-head with a selective PIM inhibitor (AZD1208) and a selective FLT3-ITD inhibitor (AC220) in a panel of AML cell lines with FLT3-ITD or unmutated kinase (FLT3-WT) as well as peripheral AML cells and CD34+ bone marrow blasts. SEL24-B489 exhibited a signifi- cantly broader activity, irrespective of FLT3 status, than either of the selective inhibitors. Since PIM kinases have emerged as important mediators of FLT3- inhibitor resistance, we hypothesized that the dual specificity of SEL24-B489 might overcome the phenotype of resistance. We utilized previously developed MOLM-14 cells transfused with either FLT3-WT or FLT3 alleles containing TKD point mutations to show that neither of these mutations decreased the cellular sensitivity to SEL24-B489. Higher cellular activity and biomarker re- sponse of SEL24-B489 than competitive inhibitors was shown by inhibition of specific biomarkers such as S6 and STAT5 phosphorylation at nanomolar con- centrations in both FLT3-ITD positive and FLT3-WT cell lines in vitro. We have also demonstrated SEL24-B489 superior potency of SEL24-B489 in xenograph models in vivo. Consistent with the experiments in vitro showing marked synergy between SEL24-B489 and AraC, a combination of these agents resulted in almost completely blocked tumor growth in vivo. Most importantly, SEL24- B489 has been selected as a clinical candidate and is currently in phase I clinical trials.

ALKS 4230 is an engineered fusion protein comprised of a circularly per- muted interleukin-2 (IL-2) and the IL-2 receptor (IL-2R) α chain, CD25, de- signed to selectively activate the intermediate-affinity IL2R, but not the high- affinity IL-2R. Selective activation of the intermediate-affinity IL-2R by ALKS 4230 has the potential to provide enhanced tumor killing as well as improved safety and tolerability. Various in vitro and in vivo studies were conducted to characterize the primary and secondary pharmacodynamics (PD) of ALKS 4230 as well as its pharmacokinetics (PK). The results guided the selection of the starting dose for the ALKS 4230 first-in-human (FIH) clinical study based upon the Minimal Anticipated Biological Effect Level (MABEL) approach. The PK-PD relationship for ALKS 4230 was evaluated in in vitro pharmacology studies in target cells from murine, human primary and human donors. The mean EC50 values for activation of NK cells, memory CD8 T-cells and Tmem in target cells from human donors were 0.09, 0.18 and 0.13 nM, respectively. Using the lower EC50 value of 0.09 nM (0.0031 µg/mL) as a surrogate for the MABEL, assuming IV administration to a 70 kg human with 3 L plasma volume, a dose of 0.1 µg/kg would be expected to result in an immediate post-dose concentration of 0.0031 µg/mL. The mean EC50 values for activation of NK cells, memory CD8 T cells and Tmem in target cells from human donors were 0.46, 1.1 and 0.59 nM, respectively. Using the EC50 value as surrogate for minimal effective ALKS 4230 concentration that induces activation of human IL-2R complex, the projected minimal efficacious dose (MEDI) in humans to achieve a concentration of 0.46 nM (0.016 µg/mL) to 1.1 nM (0.038 µg/mL) is 0.7-1.6 µg/kg. Based on a MABEL dose of 0.1 µg/kg and projected MEDI of 0.7-1.6 µg/kg, the proposed doses to be evaluated in the FIH Phase 1 study are 0.1, 0.3, 1, 3, 10, and 30 µg/kg. In comparison, the projected Cmax, at the proposed starting dose of 0.1 µg/kg is > 750-fold lower than the Cmax at the no-observed adverse effect level (NOAEL) in safety and toxicology studies conducted in cynomolgus monkeys. It is also about 3-fold lower than the lowest concentration of ALKS 4230 (0.01 µg/mL) tested in the cytokine release assays at which only slight elevations were observed for IL6, IL-8, and IFN-γ in a small number of whole blood samples from healthy human donors, similar to those in the low-response control across the concentration range evaluated. Therefore, 0.1 µg/kg is considered a safe starting dose for the FIH study. The PK, PD and toxicology assessments conducted to date support the FIH investigation of ALKS 4230 at the proposed starting dose of 0.1 µg/kg.

#4089 Quantitative prediction of human pharmacokinetics for duvor- tuxizumab from cynomolgus monkey data: a translational pharmacokinetic modeling approach. Xiling Jiang,1 Hui Liu,2 Jeff Nordstrom,3 Jennifer Brown,2 Liqun Liu,2 Sid Johnson,2 Ralph Alderson,2 Pamela L. Clemens,1 Jacintha Shen- don,1 Inran Khan,1 Olivia Gardner,1 Yu-Nien Sun,1 Weirong Wang3,1 Janssen Research & Development LLC, Spring House, PA; 2MacroGenics, Inc., Rockville, MD; 3Janssen Research & Development LLC, Raviraj, NJ.

Duvortuxizumab (also known as JNJ-64052781 and MGD011) is a bispecific CD19 x CD3 DART® molecule designed to simultaneously target CD19-positive cells for recognition and elimination by CD3-expressing T-lymphocytes as ef- fector cells. Duvortuxizumab is currently in clinical development for the poten- tial treatment of B-cell malignancies. Here we report the results from a transla- tional PK model that utilized duvertuxizumab pharmacokinetic (PK) data from cynomolgus monkeys to predict duvortuxizumab PK in humans. The PK of duvortuxizumab administered by intravenous infusion was evaluated in cyno- molgus monkeys in two separate studies. Study 1 evaluated intra-animal escala- lating doses from 0.5 to 100 µg/kg or repeated doses from 0.005 to 0.5 µg/kg administered over a period of up to 4 weeks. Serum concentrations of duvortuxiz- umab above the lower limit of quantification were obtained at dose levels >0.5 µg/kg. Study 2 evaluated duvortuxizumab doses of 0.2, 2, 5, or 10 µg/kg administered once weekly for 4 weeks. Dose-proportional increases in maxi-
Pharmacokinetic studies of CASC-578 were conducted in mice, rats, and onlyaslightinductionofCYP3A4wasseenat10uMdrugconcentrationin
humans and no significant differences between male and female animals were observed. PK
modeling analysis, which integrated data from both study 1 and study 2 at 0.2 to
100 μg/kg dose levels, was performed to further understand the PK behavior of
duvortuxizumab in cynomolgus monkeys. Duvortuxizumab PK was reasonably
characterized using a two-compartment PK model with linear clearance (CL) from
the central compartment. Model estimated parameters were CL = 0.797 mL/h/kg;
volume of distribution for the central compartment (V1) = 51.7 mL/kg; intercompartmental clearance (Q) = 2.29 mL/h/kg; and volume of distribution for
the peripheral compartment (V2) = 88.8 mL/kg. Assuming a body weight of
3 kg and 70 kg for a cynomolgus monkey and a human, respectively, human PK
parameters were estimated using an allometric scaling factor of 0.775 for CL and
1.0 for volume in the translational PK model. Observed duvortuxizumab PK
values obtained from an ongoing, first-in-human (FIH), phase 1 dose-escalation
trial in patients with relapsed or refractory B-cell malignancies (NCT02454270)
were used to validate the translational PK model. Comparison of the predicted
and observed duvortuxizumab PK profiles suggested that the translational PK
model using the allometric scaling method reasonably predicted duvortuxi-
zumab PK profiles in humans at multiple dose levels (15 to 100 ng/kg). In con-
clusion, the developed translational PK model successfully predicted duvortuxi-
zumab PK in humans and has been used to aid dose escalation of
duvortuxizumab in the ongoing FIH study. This work showcases the potential
of translational PK modeling in supporting the selection of a FIH dose escalation strategy utilizing preclinical PK information.

**#4090 Preclinical pharmacokinetics of CASC-578, a novel, selective, po-
tent, and orally bioavailable small molecule checkpoint kinase 1 inhibitor.**
Dina Leviten,1 Teresa Sierra,1 Ashley Dozier,2 Richard Boyce,3 Bob Boyle,3 Scott
Peterson,4 Alex C. Vo1.1 Cascadian Therapeutics, Seattle, WA; 2Sentinel Oncol-
yogy, Cambridge, United Kingdom.

Introduction: Checkpoint kinase 1 (Chk1) is a serine/threonine protein ki-
nase that regulates cell division in response to genotoxic stress by arresting cell
cycle progression in the S & G2 phases. Pharmacological inhibition of Chk1 is
proposed to selectively uncouple the completion of DNA replication from G2/M
phase transition in tumor cells that have impaired DNA damage response net-
works, resulting in mitotic catastrophe and cell death. CASC-578 is a novel small
molecule inhibitor of Chk1 that is selective, highly potent and orally bioavailable
in multiple preclinical species. Methods: The in vitro ADME properties of
CASC-578 were evaluated, including in vitro intrinsic micromolar clearance.
Caco2 permeability, plasma protein binding and stability, blood to plasma par-
titioning, cytochrome P450 inhibition and induction, and transporter inhibi-
tion. Pharmacokinetic studies of CASC-578 were conducted in mice, rats, and
cynomolgus monkeys for 5-7 days. Results: CASC-578 is highly bound in
plasma protein across all species. The apparent permeability is high in Caco2
bi-directional transport study and correlated well with a rapid absorption profile
observed in vivo. CASC-578 is not a substrate of P-glycoprotein (efflux = 1).
There was no direct or time dependent inhibition on human CYP450 enzymes
and only a slight induction of CYP3A4 was seen at 10 μM drug concentration in
a transporter cell-based induction assay. In all animal species, CASC-578 exhib-
ted species-dependent systemic clearance resulting from both phase I and phase
II metabolism, and a moderate to high volume of distribution. The elimination
kinetics appeared to be monophasic. Oral bioavailability was high in all species
studied (>50%). There was no significant difference in the pharmacokinetics
of the drug between genders. Maximal plasma concentration and total drug
exposure (AUC) appeared to be proportional from repeat dose studies. Overall,
CASC-578 has very desirable drug-like properties and ideal pharmacokinetics
for an oral once daily drug, and represents a suitable candidate for clinical de-
velopment as a novel potential therapeutic approach for the treatment of solid
and hematological malignancies.

**#4093 t-Darpp stimulates protein kinase A activity by interacting with its
RI regulatory subunit.** Dirk Theile,1 Shuhui Geng,1 Erin Denny,1 Jamil Mo-
mand,1 Susan E. Kane 1.1 City of Hope, Duarte, CA; 2California State University,
Los Angeles, Los Angeles, CA.

t-Darpp is the truncated form of the dopamine- and cAMP-regulated phosphoprotein of 32 kDa (Darp-32) and has been demonstrated to confer resis-
tance to trastuzumab, a Her2-targeted anticancer agent, via sustained signaling through the phosphatidylinositol-4,5-bisphosphate 3-kinase (PI3K)/Akt path-
way. t-Darpp over-expression results in enhanced activity of protein kinase A (PKA), but the mechanism of t-Darpp-mediated PKA activation is poorly
understood. In the PKA holoenzyme, when the catalytic subunits are bound to
regulatory subunits RI or RI, kinase activity is inhibited. We investigated PKA activity and holoenzyme composition in cell lines that express t-Darpp
(SK.686p) or a 775A phosphorylation mutant (SK.686p.T75A), as well as an

**#4091 AKT can modulate the in vitro response of HNSCC cell to irrevers-
ible EGFR inhibitors.** Renato José Silva-Oliveira,1 Matias Melendez,1 Olga
Martínez,2 Maicon Fernando Zanon,3 Luciano de Souza Viana,4 André Lopes
Carvalho,1 Rui Manuel Reis1.1 Barretos Cancer Hospital, Barretos, Brazil; 2Life
and Health Sciences Research Institute, Braga, Portugal.

Epidermal growth factor receptor (EGFR) is overexpressed in up to 90% of head
and neck squamous cell carcinoma (HNSCC) tumors. Cetuximab is the first tar-
geted (anti-EGFR) therapy approved for the treatment of patients with locally ad-
vanced HNSCC. However, its efficacy is limited due to primary and secondary re-
sistance, and there is no predict biomarkers of response. New generation of EGFR
inhibitors with pan HER targeting and irreversible action, such as afatinib and al-
latinib represents a significant therapeutic promise in HNSCC treatment. In this
study, we intend to compare the potential cytotoxicity of two irreversible anti-EGFR
inhibitors (afatinib and allatinib) with cetuximab and to identify potential predictive
biomarkers of response in a panel of HNSCC cell lines. The mutational analysis in
hotspot regions of EGFR, KRAS, NRAS, PIK3CA and PTEN in the eight HNSCC
cell lines and the PIK3CA and PTEN transcriptome profiles in the HN13 cell lines,
and KRAS mutation in the JHU-28 cell line. According to the growth inhibition score (GI), allatinib was the most cytotoxic drug, followed by afatinib and
finally cetuximab. The HN13 cell line exhibited a less responsive behavior to all
drugs assessed, and interestingly, also displayed the higher levels of AKT phosphor-
ylation. Therefore, we further performed drug combinations and found that with
anti-AKT agent (MK2206), afatinib and allatinib, but not cetuximab, sensitivity was
restored. Additionally, AKT1 gene editing in afatinib and allatinib-treated cell lines
showed that AKT1 silencing-induced cell line decreased viability and increased cy-
totoxicity through caspases 3/7/activation. Additionally, in silico analysis of TCGA
database showed that AKT1 overexpression was present in 14.7% (41/279) of HN-
SCC cases, and was associated with perinuclear invasion in advanced stage. In con-
cclusion, allatinib presented a greater IC50 cytotoxic profile when compared to
cetuximab, and the AKT pathway constitutes a predictive marker of allatinib re-
sponse. Importantly, in allatinib and afatinib-resistant cases, the pharmacological
combination with AKT inhibitors could restore response and increase treatment
success.

**#4092 Targeting compensatory mechanisms of resistance to phosphati-
dylinositol 3-kinase inhibitors in head and neck squamous cell carcinoma.**
Nicola L. Michmerhuizen, Elizabeth Leonard, Susan K. Foltin, Aditi Kulkarni,
Thomas E. Carey, Carol R. Bradford, Hui Jiang, Chad Brenner. University of
Michigan, Ann Arbor, MI.

Recent sequencing studies of head and neck squamous cell carcinomas (HN-
SCCs) have identified the phosphatidylinositol 3-kinase (PI3K) pathway as the
most frequently mutated, oncogenic pathway in this cancer type. Despite the frequency
of activating mutations or amplification in PIK3CA (the gene encoding the catalytic
subunit of PI3K), targeted inhibitors of PI3K have not shown clinical efficacy as
monotherapies. We tested a panel of more than 20 patient-derived oral cavity squa-
mos cell carcinoma (OCSCC) cell lines, which were profiled by Nimblegen V3
exome sequencing, and observed resistance to PI3K inhibitors despite PIK3CA copy
number amplification and/or mutation. Of six inhibitors tested, only alpha-isoform
selective and pan-PI3K agents were somewhat effective; these inhibitors, despite
on-target and downstream activity, did not cause an appreciable reduction in cell
viability when administered at submicromolar concentrations. We hypothesized
that other oncogenic pathways might still be functional in the presence of PI3K
inhibitors and might serve as mediators of this resistance. For example, our group
and others have evaluated co-dependence on the Ras-MEK-ERK pathway in OC-
SCC. We found that in a panel of PI3K inhibitor-resistant cell lines, treatment
with A-443638, a selective and pan-PI3K inhibitor, restored sensitivity to
afatinib. Additionally, the PI3K inhibitor vatalanib also restored sensitivity in
these cell lines. To confirm these findings and determine whether PI3K inhibitors
are good targets in PI3K-sensitive cell lines, we performed a high-throughput
screening approach that utilizes a resazurin cell viability assay. This screen
seems an unbiased means of testing ~1400 inhibitors as monotherapies and in
combination with alpha-isoform selective PI3K inhibitor HS-173 in several OC-
SCC cell lines. Further validation of "hits" from this screen, which are drugs that are
effective in combination but not

**Molecular Targeted Therapies 2**
empty vector control cell line (SK-empty). We also evaluated protein-protein interactions between t-Darp and PKA catalytic (PKAc) or regulatory subunits RI and RII in these cell lines. Whereas SKt-Darp cells had elevated PKA activity, SKt-Drap.T75A cells did not. In agreement with the effects on activity, a proximity ligation assay showed that SKt-Drap cells, but not SKt-Drap.T75A cells, had diminished interaction with PKAc. Moreover, t-Darp was seen to bind directly to RI in co-immunoprecipitation studies. Cells that express both Darp-32 and t-Darp had PKA activity levels and RI-PKAc association that were similar to control SK-empty cells. This is consistent with our published findings that Darp-32 reverses t-Darp’s effects on trastuzumab resistance and CREB DNA binding activity (downstream of PKA). Taken together, our data suggest that inhibition of this interaction is crucial for t-Darp-mediated bortezomib-induced apoptosis. This activation and this activation appears to occur through direct binding to RI and release of RI from PKAc. The t-Darp-RI interaction could be a druggable target to reduce PKA activity in drug-resistant cancer.

#4094 Accumulation of hepatoma up-regulated protein in prostate cancer cells inhibits bortezomib-induced apoptosis. Mohamed Hassan,1 Aboulouhid Elkhattouti,2 Nasir Butt,2 Ingrid Espinoza,2 Christian Gomez2.1 Tulane University, New Orleans, LA; 2Univ. of Mississippi Medical Ctr., Jackson, MS.

The increased understanding of cellular signaling pathways in the regulation of tumor progression and resistance, together with the identification of key molecular markers has allowed for considerable advances in the establishment of therapies for therapy-resistant Prostate cancer (PCa). Hepatoma Up-Regulated Protein (HURP), is overexpressed in several tumors, and has been identified as a potential chaperone protein with tumorigenic capacity. We previously reported on HURP as an essential modulator of PCa resistance to radiation therapy. Bortezomib, a proteasome inhibitor used clinically for multiple myeloma, has been shown to induce apoptosis in PCa cells. In the present study, we evaluate HURP’s role in PCa resistance pathways by analyzing its effects on bortezomib-induced apoptosis. LNCaP-Tet-On-HURP, DU145-Tet-On-HURP, and PC3-Tet-On-HURP clones were established for the expression of HURP. HURP expression was induced with doxycycline (Dox) for 48 h. Next, cells were treated with bortezomib (50 nM) for 24 h. To assess the effect of HURP on bortezomib-induced apoptosis, the cells were harvested and subjected to flow cytometry (FC) analysis using annexin V/PI staining. Apoptosis was observed in control cells (-Dox) following the treatment with bortezomib. Induction of HURP expression (+Dox), blocked bortezomib-induced apoptosis. This effect was observed only in LNCaP- and DU145-Tet-On-HURP cells with a 1.8 and 2.1 fold decrease in apoptosis, respectively; but not in PC3-Tet-On-HURP cells. In addition, we performed FC analysis of DHR123 to analyze the effects of HURP on bortezomib-induced accumulation of reactive oxygen species (ROS). HURP blocked bortezomib-induced ROS accumulation in LNCaP- and DU145-Tet-On-HURP cells with a 0.3 and 0.15 fold change, respectively. Bortezomib also induced the expression of p53 and Noxa, and enhanced the cleavage of PARP in LNCaP- and DU145-Tet-On-HURP control cells (-Dox), but not in (+Dox) PC3-Tet-On-HURP cells. Induction of HURP, however blocked effects on apoptosis effectors in LNCaP- and DU145-Tet-On-HURP. Western blot analysis also demonstrated that in HURP-expressing cells, bortezomib-inhibited the phosphorylation of AKT, JNK or PKC. Finally, t-Darp expression on the cytoplasmic localization of Noxa, a mediator of bortezomib-induced apoptotic signaling by immunocytochemistry. Noxa staining was weakly detectable or absent in HURP expressing cells, suggesting the ability of HURP overload to block bortezomib-induced Noxa expression. Overall, our results show that HURP-induced resistance of PCa cells to bortezomib is attributed to the effects of this protein on mechanisms related to a non-specific overload response leading to the activation of ubiquitin system. #4095 c-Met activation mediates resistance to polo-like kinase 1 inhibitor-induced apoptosis in non-small cell lung cancer. Ratnakar Singh, Li Shen, Pan Tong, Jing Wang, Faye M. Johnson. MD Anderson Cancer Center, Houston, TX.

Background: Inhibition of polo-like kinase 1 (PLK1) may be an effective treatment for non-small cell lung cancer (NSCLC). PLK1 inhibition may be an effective treatment for non-small cell lung cancer (NSCLC). PLK1 is a key regulator of mitosis and DNA damage checkpoints. PLK1 inhibitors are well tolerated, but only a few unselected patients with NSCLC respond to single-agent therapy. However, predictive biomarkers have not been used to select patients who are likely to experience a response to PLK1 inhibitors, and the mechanisms of resistance to PLK1 inhibitors have not been elucidated, making these unknowns a major gap in knowledge. To address this gap, we compared basal gene and protein expression in 63 NSCLC cell lines and discovered that mesenchymal NSCLC cell lines were more sensitive to PLK1 inhibitors than epithelial cell lines in vitro and in vivo. The induction of apoptosis in some NSCLC cell lines at very low drug concentra-
however, ibritinib resistance inevitably develops. Once patients relapse after ibritinib treatment, the 1-year survival rate is only 22%; therefore, there is an urgent unmet need to overcome ibritinib resistance and to study alternative treatment options. Constitutive NF-κB activation is the hallmark of MCL. Indeed, next generation sequencing analysis of 110 MCL patient samples revealed NF-κB activation was present in 80 (72.7%), including those with high mutation rates of MET (28.8%), indicating the significant contribution of NF-κB signaling to MCL malignancy. Mucoса-associated lymphoid tissue transformation protein (MALT1) plays a crucial role in NF-κB signaling. MALT1 is a unique paracaspase within the human genome, and the proteolytic activity of MALT1 has been found to be constitutively active in many MCL samples, suggesting MALT1 may be a potential target of all target drugs in this context. Moreover, a specific inhibitor of MALT1 and its efficacy and safety are currently being evaluated in a clinical trial with ABC-type diffuse large B cell lymphoma patients. Mice treated with M2-1 did not have detectable physiological, histological or biochemical signs of toxicity. However, whether MALT1 activity contributes to ibritinib resistance and whether targeting MALT1 can overcome ibritinib resistance in refractory MCL patients remain unclear. In this study, we found that both canonical and non-canonical NF-κB signaling is activated in ibritinib-resistant MCL cells, which correlates with constitutive MALT1 activity. Interestingly, we found that MALT1 is highly mutated in four clusters, including the death domain, TRAF6-binding site, Caspase-like domain, and IKKγ-binding site in MCL samples. Occurrence of L799P, K80R, E519D, L445P and N446S was also strongly correlated with resistance in resistant cell lines and disease progression, which requires more detailed investigation. Treatment with M2-1 significantly reduced cell viability in several MCL cell lines with nanomolar activity. MI-2 treatment inhibited NF-κB activation, IL-6 production and its downstream STAT3 activation. Combining MI-2 with ibritinib resulted in synergistic growth inhibition in both ibritinib-resistant MCL cell lines and primary MCL cells. These findings suggest that targeting MALT1 catalytic activity in MCL is a promising therapy to overcome ibritinib resistance in relapsed/refractory MCL patients. The effect of MI-2 in vivo PDX models is currently under investigation. This work and follow-up in vitro and in vivo studies will provide strong evidence that targeting MALT1 with MI-2 may be an effective novel therapeutic approach to overcome ibritinib resistance.

4100 Mechanisms of resistance to type I and type II MET inhibitors in non-small cell lung cancer. Magda Bahcall, Yanan Kuang, Cloud P. Pawelczk, Pasi A. Jänne. Dana Farber Cancer Institute, Boston, MA.

Background: MET targeted therapies are clinically effective in MET amplified and MET exon 14 deletion mutant non-small cell lung cancers (NSCLC). At least 8 MET tyrosine kinase inhibitors (TKIs), including both type I and II, have been developed and are under clinical evaluation. We recently described a resistance mechanism in a patient with a unique MET secondary mutation, D1228V, resistant to all type I but sensitive to type II MET TKIs (Bahcall et al. Cancer Discovery 2016). We examined whether the sensitivity and resistance of other MET secondary mutations were similarly dependent on the mode of inhibitor binding, and sought to determine the optimal sequence of MET inhibitor use, so as to achieve the longest combined latency before the emergence of resistance. Methods: TPR-MET Ba/F3 cells were mutagenized with ENU and treated with each of the type I TKIs - crizotinib, savolitinib; capmatinib, or type II TKIs - cabozantinib, glesatinib; metrestinib, until resistant clones emerged. Resistant mutations were identified by sequencing, constructed in the TPR-MET background, and expressed in Ba/F3 and NIH3T3 cells. Cross-resistance to the 6 MET TKIs was evaluated. Next, low frequency (0.1%) of mutant Ba/F3 cells was spiked into parental TPR-MET Ba/F3 cells and sequentially exposed to different MET TKIs to identify the sequence associated with the longest combined time to resistance. Clonal evolution was assessed by droplet digital PCR (ddPCR). Results: Of 300 plated wells per drug used at either 0.1μM or 0.5μM, crizotinib yielded 210 and 2 clones; savolitinib 51 and 1 clone; capmatinib 9 and 3 clones; cobozantinib 38 and 3 clones; glesatinib 300 and 300 clones; metrestinib 18 and 3 clones, respectively. Of the mutations, those at Y1230 were common to all 3 type II TKIs and the most frequently seen with savolitinib and capmatinib. D1228 was shared by savolitinib and capmatinib; V1155, the most common mutation with crizotinib, was shared with savolitinib; M1211 L emerged with capmatinib. Mutated F1200 residue was shared by and exclusive to all type II TKIs and was the single identified mutation for both glesatinib and metrestinib. Cobozatinib gave rise to a broader array of unique mutants - with F1200 mutations being the most common and shared G1163R and H1248Y with crizotinib. With D1228 and Y1230 mutations being moderately resistant to crizotinib and strongly resistant to both cobozatinib and glesatinib, while retaining sensitivity to all type II TKIs. G1163R and L1195V were slightly to moderately resistant to crizotinib, cobozatinib and glesatinib, but strongly sensitive to savolitinib and capmatinib. In
this assay, merestinib had the broadest, while crizotinib most narrow activity with EGFR inhibitors such as afatinib in vitro significantly suppressed cell viability by 85.2% and 80% in 201T and H1975 respectively, as compared to CS3M. CS3D also caused a 2-fold reduction in expression of STAT3-target genes c-Myc, Bcl-xl, and IL-6. Compared to CS3M, CS3D inhibited colony formation by 70%. Using an in vivo mouse xenograft model of 201T and H1975, CS3D caused a 96.5% reduction in tumor growth in 201T (P < 0.001) compared to CS3M, while an 81.7% inhibition was seen in H1975 (P < 0.0001). Utilizing IHC, analysis of residual tumors also illustrated that CS3D induced more caspase3 cleavage relative to CS3M. Additionally, western blot analysis showed 70% reduction in c-Myc protein level in response to CS3D. These results suggest CS3D can be effective as a single therapeutic agent. Combining CS3D with EGFR inhibitors such as afatinib in vitro significantly suppressed cell viability by 85.2% and 80% in 201T and H1975 respectively, as compared to single treatment (CS3D alone reduced cell viability by 53% and 51.5%, and afatinib alone reduced viability by 31.4% and 34.63% in 201T and H1975 respectively). The combination of CS3D and afatinib warrants further testing in vivo. These data suggest that CS3D alone or in combination with EGFR tyrosine kinase inhibitors produces anti-tumor effects in NSCLC with intrinsic and acquired resistance to EGFR TKIs. Supported by funding to the Masonic Cancer Center from the Minnesota 5th Order of Eagles.

Aberant signalling of the epidermal growth factor receptor (EGFR) plays an integral role in the tumorigenesis of many cancer types, including head and neck squamous cell carcinoma (HNSCC), making it a compelling drug target. After the initial promising results of EGFR-targeted therapies, the problem of therapeutic resistance is emerging and new treatment options are necessary. In contrast to the first generation EGFR inhibitors, afatinib is an irreplaceable ErbB family blocker that inhibits EGFR as well as HER2 and HER4. The objective of this study was to investigate whether afatinib is able to overcome intrinsic and acquired cettuximab resistance in human papillomavirus (HPV) positive and negative HNSCC cell lines under normal and reduced oxygen conditions and to identify the molecular mechanisms underlying afatinib's cytotoxic effect. Sensitivity to cettuximab treatment was investigated in a panel of HPV positive and negative HNSCC cell lines using the colorimetric sulforhodamine B (SRB) assay (168h, 0-2 μM). Cettuximab sensitive and intrinsically resistant cell lines were identified. Acquired cettuximab resistant cell lines were generated by chronically exposing initially sensitive cell lines to cettuximab. In parallel, control cell lines were established by exposing these cells to the vehicle control (PBS). Cytotoxicity of atafinib (24h, 0 - 5μM) was assessed under normoxic and hypoxic (1% O2) conditions. Cell cycle distribution and induction of apoptotic cell death were assessed flow cytometrically using the Vindelov method and Annexin V-FITC/PI assay, respectively. Data analysis was performed using WinNonlin and FlowJo software. We identified intrinsic cettuximab resistance in 5 out of 7 HNSCC cell lines (i.e. LICR-HN1, Cal-27, SQ99, 93-VU-147T and UM-SCC104) and generated acquired cettuximab resistant cell lines (i.e. SCC22B-R and SC263-R). Afatinib showed a clear concentration-dependent cytotoxic effect in both cettuximab sensitive and resistant cell lines with IC50 values ranging between 0.019 and 4.04 μM. Furthermore, afatinib maintained its cytotoxic effect under hypoxic conditions. Treatment with afatinib led to an increase in the proportion of cells in the G0/G1 phase of the cell cycle. Afatinib also induced an increase in the percentage of AAnV-/+PI- and AAnV+/+PI+ cells with a corresponding decrease of the percentage viable (AAnV-/+PI-). In conclusion, our results suggest that afatinib has the potential to overcome cettuximab resistance, as it was able to establish cytotoxicity in HPV positive and negative HNSCC cell lines that were intrinsically and acquired resistant to cettuximab. Furthermore, treatment with afatinib caused a G0/G1 cell cycle arrest and induced apoptotic cell death. These data support the hypothesis that afatinib might be a promising novel therapeutic strategy to treat HNSCC patients experiencing intrinsic or acquired cettuximab resistance.

IL-6 dynamics regulate neuroendocrine transformation in gefitinib resistant acquired resistance EGFR mutant lung cancer cells. Shang-Yin Wu,1 Hsuan-Heng Yeh,2 Chun-Hua Hung,3 Chien-Chung Lin,1 Wen-Pin Su1,2 Wu-Chou Su2. Graduate Institute of Clinical Medicine, Department of Internal Medicine, National Cheng Kung University, TAINAN, Taiwan; 3Department of Internal Medicine, National Cheng Kung University Hospital, College of Medicine, National Cheng Kung University, TAINAN, Taiwan.

Transformation to small-cell lung cancer (SCLC, one of aggressive neuroendocrine (NE) tumor) is reported when activating epidermal growth factor receptor (EGFR) mutant non-small-cell lung cancer acquired resistance to tyrosine kinase inhibitors (TKI, such as gefitinib). IL-6 activation confers to TKI resistance and associates with p53 and RB inactivation those are SCLC hallmark changes. Whether NE transformation could phenocopy in isoegenic acquired resistance cell line and the role of IL-6 in this process remain unknown. We established 827GRs (including 827GR, 827GR-M and 827GR-M6) acquired resistance to gefitinib from HCC827 cells by long term stepwise treatment with gefitinib and they still had EGF receptor exon 19 deletion without acquired T790M. 827GR was parental resistance line with unstable gefitinib resistance in drug-free medium by passage. We maintained 827GR in medium with or without 1μM gefitinib over 6 months to generate stable clones: 827GR-M and 827GR-M6. 827GRs had SCLC hallmark changes, i.e., inactivation of p53, RB and Notch by western blot and gene set enrichment analysis. Compared to HCC827, 827GRs were more sensitive to cisplatin and etoposide but not paclitaxel. IL-6 level was positive correlated with gefitinib resistance among 827GRs by cytokine array and ELISA. Interestingly, among 827GRs, 827GR-M6 harbored low IL-6 secretion had obviously NOTCH-ASCL1-DLL3 alteration, high NE marker expression and significant inter-rater agreement with selected Byers' SCLC gene signature. Compared to high IL-6 secreting clones, 827GR-M6 highly regulate NE marker expression. IL-6 genetic manipulation in HCC827 and 827GRs also demonstrated this phenomenon. Moreover, IL-6 dynamics correlate with NE expression also showed in patient derived lung cancer cell line in published microarray dataset (GSE64322). In conclusion, our work demonstrated activating EGFR mutant lung cancer acquired resistance to TKI with NE transformation could phenocopy in isoegenic cell line model and IL-6 dynamics might regulate this process.
formed retrospective genomic profiling of 25 CRC patients treated at Samsung Medical Center from 2006-2015. Patients received cetuximab containing chemo regimens with varying duration of responses, including acquired resistance cases. Our analysis identifies mutations in receptor tyrosine kinases, such as EGFR, NTRK1, and PDGFRα, as well as RAS/MAPK pathway genes that affect cancer cell survival and resistance to EGFR/ERBB2 and ERBB3/ERBB4, as potential novel mechanisms regulating sensitivity to anti-EGFR antibodies. Additional genomic analyses of acquired resistance tumors and in vitro studies of a patient-derived cell line provide added insights into clonal selection and signaling pathways that bypass the EGFR blockade. Overall, our study elucidates important new facets in the landscape of anti-EGFR resistance mechanisms.

Introduction: Glioblastoma multiforme (GBM) accounts for the most aggressive form of tumor showing poor prognosis. Prevailing treatment modality includes chemotherapy with temozolomide (TMZ) concomitant with surgical resection and/or irradiation. However, it has been observed that a number of patients are developing resistance to TMZ owing to its high dosage regimen. The aim of this study is to examine the effects of diosgenin (DSG), a natural steroidal saponin obtained from fenugreek, in combination with TMZ in human GBM cells and TMZ resistant GBM cells. Methodology: The potential of combinatorial chemotherapy for overcoming TMZ resistance was evaluated through development of TMZ resistant GBM clones. These clones were generated by treatment of GBM cells with sub-lethal dose of TMZ over several cycles. Cellular effects were studied by viability assay, flow cytometry and wound healing assay on both single and combined drug treated GBM cells and TMZ resistant cells, respectively. The morphological study and cellular uptake in combined or individual drug treated cells was assessed by microscopy and immunofluorescence staining. The time dependent effect of drugs on invasive and migratory potential of GBM cells and TMZ resistant cells was analysed through zymography for matrix metalloproteinases (MMPs) activity and western blot for apoptotic proteins, epithelial and mesenchymal (EMT) markers, MMPs and VEGF expression. Further, the drug induced apoptosis was also assessed through chromatin condensation and DNA ladderization assay. Results: Our investigation shows that co-administration of DSG and TMZ resulted in a substantial increase in GBM cell apoptosis and marked inhibition of cell growth in vitro. Anti-angiogenic and anti-invasive potential of DSG and TMZ were assessed through in vitro studies. At molecular level, DSG and TMZ synergistically lower XIAP expression and cleavage of intracellular death substrates such as PARP thereby shifting the balance from survival to apoptosis as indicated by the rise in the sub-G1 cell population. This combination also alters EMT markers, downregulates the expression of Bcl-xL, Bcl-2, Mcl1, MMPs and VEGF and induces expression of Bax, AIF, cytochrome C. Conclusion: The results suggested that DSG in combination with TMZ reduced the dose of TMZ, when administered singly, and also inhibited the migration and invasion of GBM and TMZ resistant cells. It induced apoptosis and altered the expression of EMT markers. These findings reveal a new therapeutic potential for overcoming TMZ resistance in GBM. This novel modality may be a promising tool for GBM treatment.

Background: Soft tissue sarcomas are a heterogeneous group of malignant tumors including more than 70 histological subtypes. We have recently demonstrated that dual targeting of PI3K/mTOR pathway is associated with significant anti-tumor activity in vitro and in vivo models of leiomyosarcoma (LMS), one of the most frequent sarcoma subtype. Secondary resistance limits the efficacy of all targeted therapies. We have developed and characterized resistance models to a dual PI3K/mTOR inhibitor in order to describe underlying resistance mechanisms and develop alternative strategies. Methods: To develop in vitro BEZ-235 (dual PI3K/mTOR inhibitor) resistance models, 3 LMS and 1 myofibrosarcoma cell lines were exposed to increasing doses of BEZ-235 several months. To characterize the resistance models, sensitivity to BEZ-235 was assessed by MTT assay and Annexin V-PI staining. To test in vivo the resistance models, effects of BEZ-235 treatment were observed in mice with subcutaneous cell-line derived xenograft tumors for 3 weeks. The transcriptome profile of sensitive and resistant tumors to BEZ-235 was analyzed by using RNA-seq. Results: After prolonged exposure of cell lines to BEZ-235, we obtained secondary resistant cell lines characterized by an IC50 value 5- to 21-fold higher than parental sensitive cells. Resistant cells were also significantly less sensitive to BEZ-235 induced apoptosis than parental cells. We confirmed the resistance patterns in vivo with a significantly higher anti-tumor effect of BEZ235 in sensitive cell-line derived xenograft group compared with resistant cell-line derived xenograft group. Deep transcriptome profiling indicated overexpression of stem cells related genes in resistant cells as well as re-activation of the cellular metabolism. By using 1) RNA-mediated suppression of pyruvate carboxylase (PC), a potential key player in our resistance models and 2) hallmarks of CSC like CD133 and enhanced aldehyde dehydrogenase (ALDH) activity, we confirmed that resistant tumors were characterized by a significantly higher proportion of cancer stem cells and by a metabolic shift with a strong deregulation of glucose metabolism. Conclusions: Selection of CSC subpopulation and metabolism shift play a crucial role in secondary resistance to dual PI3K/mTOR inhibition in sarcoma. Strategies assessing anti-CSC agents to suppress acquired resistance may have major implications to improve efficacy of dual PI3K/mTOR targeting in human malignancies.

#4107 Acquired resistance to EGFR-TKI in an uncommon G719S EGFR mutation. Atsushi Osogawa, Tomonori Yamada, Yahi Kihumi, Takefumi Ohara, Atsushi Osoegawa, Tatsuro Okamoto, Kenji Sugio. Oita University Faculty of Medicine, Oita, Japan.

Background: Acquired resistance (AR) to EGFR-TKI is a common event and several underlying mechanisms, including T790M, MET amplification and PTEN downregulation have been reported for the common EGFR mutations: Deletion 19 and L858R. An EGFR G719S mutation is an uncommon mutation that was reported only by a few groups to confer acquired resistance to EGFR-TKIs. In this study, we report our experience of 1 patient and experiments using transformed cultured cells. However, no established lung cancer or resistant cell lines harboring the EGFR G719X mutation have been reported in the literature. We established a lung adenocarcinoma cell line (G719S-GR) from the malignant pleural effusion of a patient whose tumor developed acquired resistance from initial treatment with gefitinib. Materials and methods: G719S-GR cells were established and maintained in RPMI1640 medium supplemented with 10% FBS and 10 μM ROCK inhibitor (Y-27632, Wako). The ROCK inhibitor was removed from the medium for the following experiments. Cell growth inhibition was examined with gefitinib and afatinib using CellTiter-Glo (Promega), and a comprehensive genomic analysis was performed using hybrid capture-based NGS (NCC oncopanel, Agilent; MiSeq, Illumina) for G719S-GR and MLPA (Salsa, MRC-holland) was used for the analysis of clinical tumor samples. Results: A cell growth inhibition test revealed EGFR-TKI resistance in G719S-GR cells with an LC50 of more than 100 μM for either gefitinib or afatinib, indicating that the G719S-GR cells are also resistant to EGFR-TKI in vitro. The NGS analysis showed that G719S-GR cells harbor EGFR mutations (G719S and E709A) as well as the amplification of EGFR, IL7R, MET, and the EGFR locus. The homozygous deletion of PTEN and the loss of PTEN and TSC1 were also detected. In order to estimate the mechanism underlying the development of EGFR-TKI resistance, copy number analyses of several tumor suppressor genes were performed by an MLPA using genomic DNA from G719S-GR and a tumor biopsy sample (obtained before gefitinib treatment). Losses of CDKN2A, PTEN and TSC1 were confirmed in G719S-GR cells. However, the GBM tumor collected before treatment with gefitinib was not investigated. Conclusions: The resistance pattern of the G719S cell line is similar to the findings that Pten and Tsc1 inactivation are the major mechanisms of resistance in GBM. The development of EGFR-TKI resistance in uncommon mutations have not been investigated. The newly established G719S-GR cell line could be a useful tool for investigating the mechanism underlying the development of AR in the G719X mutation; the loss PTEN could be such mechanism. Further experiments are warranted.

Head and neck squamous cell carcinoma (HNSCC), the sixth most common cancer worldwide, has a five-year survival rate of only 50%. The first FDA approved agent for treatment of HNSCC was cetuximab, a monoclonal antibody targeting the epidermal growth factor receptor (EGFR). Despite EGFR overexpression in up to 90% of HNSCC tumors and ample evidence supporting EGFR as a therapeutic target in HNSCC, the response rate for single-agent cetuximab is below 20%, and resistance to cetuximab-containing therapy remains a major obstacle in the effective treatment of HNSCC. Identification and targeting of mediators of cetuximab resistance is needed to improve patient outcomes. Secretion of the cytokine interleukin 6 (IL-6) has been proposed as a mechanism of resistance to cetuximab in HNSCC, and inhibition of signal transducer and activator of transcription 3 (STAT3), a downstream mediator of IL-6
signaling, has been shown to overcome cetuximab resistance in preclinical HNSCC models. Thus, we hypothesize that IL-6 signaling mediates resistance to cetuximab and that co-treatment with agents targeting the IL-6 pathway will enhance the therapeutic efficacy of cetuximab in HNSCC. We have generated cetuximab-resistant variants of the cetuximab-sensitive HNSCC cell lines Cal33 and PEA15 using adaptive stress and reverse metabolic investigations. The combination of cetuximab and lapatinib resulted in suppression of cell growth more effectively than either of the single inhibitors alone in vitro and in SCCHN PDX models. Furthermore, we have shown that targeting IL-6 using bispecific antibodies (BAs) and other strategies (eg, IL-6 receptor antagonists) reduces cell growth in cetuximab-resistant SCCHN cells.

**#4109 HER3 mediates acquired resistance to cetuximab in head and neck squamous cell carcinoma.** Yeon Ju Yang,1 Min Hee Cho,1 Yoojung Oh,1 Hyeung Kwon Byeon,2 Da Hee Kim,1 Jung Min Kim,1 Ji Hoon Kim,1 Myun Jeong Ban,1 Jae Wook Kim,1 Eun Chang Choi,1 Yoon Woo Koh,1,1 Yonsei University College of Medicine, Seoul, Republic of Korea; 2Yonsei University College of Medicine, Wonju, Republic of Korea; 3Soochunhyang University College of Medicine, Cheonan, Republic of Korea; 4Soochunhyang University College of Medicine, Seoul, Republic of Korea.

Cetuximab, an EGFR monoclonal antibody, is used to treat in head and neck squamous cell carcinoma (HNSCC). Despite the clinical efficacy of cetuximab, the majority of patients who do initially respond suffered acquire resistance to cetuximab as severe side effect. To understand mechanisms of acquired cetuximab resistance, we developed a model of acquired resitance to cetuximab by exposing head and neck cancer cell line Cal27 to increasing concentration of cetuximab and established cetuximab-resistant (Cr) clones derived from the cetuximab sensitive (Cp). Cetuximab-resistant (Cr) clones showed robustly overexpression on the HER family receptors HER3. Cr clones also expressed upregulated EGFR, HER2, and HER3 activation resulting in activation of P13K/ ATK and ERK signaling. We also showed that Cr clones exhibited increased EGR/HER3 dimerization. Treatment of cetuximab and siHER3 RNA reduced EGR activation in Cr clones and decreased robustly cell proliferation to resis- sitize cells against cetuximab. Next, we examined lapatinib, a tyrosine kinase inhibitor inhibiting HER3 on cetuximab-resistant clones. Combined treatment of Cr clones with cetuximab and lapatinib lead to potent anti-proliferative effects. Co-treatment with cetuximab and lapatinib blocked EGRF, HER2 and HER3 activities and inhibited downstream signaling pathways. Co-treatment with cetuximab and lapatinib resulted in suppression of cell growth more efficiently than each drug alone and induced apoptotic cell death through mitochondrial ROS. Furthermore, Co-treatment with cetuximab and lapatinib also lead to decreased tumor growth in HNSCC tumor xenograft mouse model. These results showed the upregulation of HER3 as one mechanism underlying resis- tance to cetuximab in HNSCC, supporting further clinical treatment strategy for tumors displaying acquired resistance to cetuximab.

Squamous cell carcinoma of the head and neck (SCCHN) cells that escape cetuximab inhibition exhibit HER2, HER3, and/or c-MET activation. Simultaneous inhibition of EGRF, HER2, HER3 and c-Met presents an attractive clinical strategy for treating SCCHN that has progresses despite EGFRTK-targeted therapy. In an effort to develop new combination drug therapy options for recurrent SCCHN, we evaluated three different c-Met inhibitors in combination with a pan-HER inhibitor (afatinib/crizotinib, afatinib/tivantinib, afatinib/cabozan- tinib) and investigated their anti-tumoral effects. SCCHN cell lines (HU202, highly expresses c-Met, and SCC1-C is cetuximab resistant) as well as patient derived xenograft (PDX) animal models from patients with recurrent SCCHN were investigated. In our cell line study, western-blot assay indicated that activi- ation of EGRF, HER2, and c-Met was blocked in all three combinations. In addition the downstream P13K/ATK and ERK signaling pathways were inhib- ited. Sulfordhamin B colorimetric assay (SBR) revealed SCC1-C cell growth was more effectively inhibited by the combinations compared to any of the single inhibitors in vitro. Furthermore, the combination was more potent in inducing apoptosis when compared to each of the single treatments. Finally in the PDX study, all treatment groups had significantly greater efficacy compared to the non-treated control group (p<0.005) and all combination treatments exhibited better efficacy in tumor growth inhibition than their respective single inhibitors (p<0.01). In conclusion, our study demonstrates that targeting EGRF, HER2, and c-Met with combination of their inhibitors is more effective than each of the single inhibitors alone both in vitro and in SCCHN PDX models. This study strongly suggests the development of this combination in patients with SCCHN who have progressed after cetuximab-based therapy. (This study is supported by NIH/NCI R21 CA182662-01A1 to NFS and ZGC).

**#4111 EGFR wild type allele amplification induces acquired resistance to mutation-specific EGFR tyrosine kinase inhibitors in non-small cell lung cancer cells.** Keigo Kobayashi,1 Shigeneri Nukaga,1 Hiroyuki Yasuda,1 Keita Masuzawa,2 Yunko Hamamoto,1 Ichiro Kawada,1 Katsuhiko Naoki,1 Sachiyu Mimaki,2 Shingo Matsumoto,3 Koichi Goto,2 Katsuya Tsuchihara,2 Tomoko Betuyaku,1 Kenzo Sejima,1,1 Keio University, Tokyo, Japan; 2Division of Translational Research, Exploratory Oncology Research and Clinical Trial Center, National Cancer Center, Tokyo, Japan.

Purpose: Third-generation EGFR-tyrosine kinase inhibitors (TKIs) are mutation-specific inhibitors that generally have minimal effects on wild type protein. The mechanisms underlying acquired resistance to third-generation EGFR-TKIs remain relatively uncharacterized. The purpose of this study is to clarify the mechanisms of acquired resistance to third-generation EGFR-TKIs in order to improve the prognosis of lung cancer patients harboring EGFR mutations. Experimental design: We established third-generation EGFR-TKIs resistant cells using a dose-escalation method. The PC9 (EGFR E746-A750del) and H1975 (EGFR L858R/T790M) human NSCLC cell lines were cultured with crizotinib (CO-1686) or osimertinib (AZD9291) for several months. Their resis- tance to a third-generation EGFR-TKIs was confirmed by the MTS cell pro- liferation assay. To clarify the heterogeneity of potential resistance mechanisms, those resistant cell lines were subcloned to isolate resistant clones. DNA isolated from the parental and resistant cell clones was then subjected to whole exome sequencing. Copy number alterations and several genetic alterations potentially relevant to EGFR-TKIs sensitivity were detected. Results: We identified Src-AKT pathway contribute to acquired resistance. In addition, we identified that EGFR wild type allele, but not mutation allele, amplification induced acquired resistance. It mirrors the decreased inhibitory pressure for wild type EGFR by mutation-specific EGFR-TKIs. Conclusion: We provide evidence of wild type allele-mediated resistance, a novel concept of acquired resistance, occurring in response to mutation-specific inhibitor therapy in cancer treatment. 1833 /2600 characters

**#4112 Overgrowth of competing resistance mechanisms, such as an ac- quired KRAS mutation, underlies a poor prognosis subtype of acquired re- sistance to osimertinib in T790M-positive NSCLC.** Geoffrey R. Oxnard,1,2 Yuqiao Hu,1 Philip Tracy,1 Nora Feeney,1 Cloud P. Paveletz,1 Kenneth S. Thress,2 Pasi A. Jänne1,3 Dana-Farber Cancer Institute, Boston, MA; 2AstraZeneca, Waltham, MA.

Introduction: Osimertinib is a third-generation EGFR tyrosine kinase inhibi- tor (TKI) which is highly active in EGFR-mutant NSCLC with resistance to prior EGFR TKI. Acquired resistance to osimertinib had been observed clinici- anally; an improved understanding of the molecular mechanism of resistance is needed. Methods/Results: We initially studied an institutional cohort of 86 pa- tients (pts) treated with osimertinib for advanced T790M-positive NSCLC. 50 pts had progressed on therapy, of whom 25 underwent a resistance biopsy and 17 had NGS results available. 6 pts maintained the T790M mutation at resistance, of whom 3 also acquired an EGRF C797S mutation. The remaining 11 pts had loss of T790M, of whom 5 had evidence of a competing resistance mechanism: 2 with histologic transformation to SCLC, one with BRAF V600E, one with an EGFR3- TACC fusion, and one with KRAS Q61K. For the final case, we confirmed the acquired KRAS Q61K on therapy using serial plasma genotyping. Time to treat- ment failure (TTF) on osimertinib was 3 months median in pts with loss of T790M and 14 months median in pts with maintained T790M. To test the hypothesis that loss of T790M is a poor prognosis subtype of resistance, we analyzed 127 pts treated for T790M-positive NSCLC on the phase I AURA trial of osimertinib. Plasma drawn after progression was submitted for genotyping using droplet digital PCR. 88 pts had a detectable EGFR driver mutation and were eligible for resistance analysis. 45 pts (51%) had detectable T790M at resistance, 17 (19%) of whom also acquired a C797S mutation; the remaining 43 pts (49%) had loss of T790M and no C797S. Median TTF on osimertinib was 6 months in pts with loss of T790M and 11 months in pts with maintained T790M; among pts with TTF <5 months, 72% had loss of T790M. To study whether baseline plasma genotyping could predict the eventual pattern of resistance on osimertinib, we studied 30 pts from the AURA trial with pretreatment plasma
#4113 Acquired resistance to cetuximab is mediated by HER3 activation in head and neck squamous cell carcinoma. 

Acquired resistance to cetuximab is a significant challenge in the treatment of head and neck squamous cell carcinoma (HNSCC). Cetuximab, an EGFR monoclonal antibody, is commonly known to be an effective treatment agent in head and neck squamous cell carcinoma (HNSCC). However, despite the clinical efficacy of cetuximab, a majority of patients with good initial response still suffer from side effects as the acquired resistance to cetuximab. To understand the mechanisms of acquired resistance to cetuximab, we developed a model by exposing a head and neck cancer cell line Ca27 to increasing concentrations of cetuximab and established cetuximab-resistant clones (CETr) derived from the cetuximab sensitive (CETp). We examined how the acquired resistance in the CETp influenced the signaling pathway compared to the CETr. We investigated the effect of lapatinib, a tyrosine kinase inhibitor inhibiting HER3, with or without cetuximab combination on CETr clones and in a xenograft mouse model. Cetuximab-resistant (CETr) clones showed robust overexpression on the HER family receptors HER3. CETr clones also expressed upregulated EGFR, HER2, and HER3 activation resulting in activation of PI3K/AKT and ERK signaling. We also showed that CETp clones exhibited increased EGFR/HER3 dimerization. Treatment of cetuximab and siHER3 RNA together reduced EGFR activation in CETp clones to re-sensitize cells against cetuximab and robustly decreased cell proliferation. Combined treatment of CETp clones with cetuximab and lapatinib led to potent anti-proliferative effects. Co-treatment with cetuximab and lapatinib blocked EGFR, HER2 and HER3 activities and inhibited downstream signaling pathways. Co-treatment resulted in suppression of cell growth more effectively than each drug alone and induced apoptotic cell death through mitochondrial ROS. Furthermore, Co-treatment with cetuximab and lapatinib also led to suppression of tumor growth in orthotopic xenograft mouse model of oral tongue cancer. Our results suggested the upregulation of HER3 as a mechanism underlying resistance to cetuximab in HNSCC, supporting further clinical treatment strategy for tumors displaying acquired resistance to cetuximab.

#4114 Polyclonal secondary FGFR2 mutations drive acquired resistance to FGFR inhibition in FGFR2 fusion-positive cholangiocarcinoma patients. 

Polyclonal secondary FGFR2 mutations drive acquired resistance to FGFR inhibition in FGFR2 fusion-positive cholangiocarcinoma patients. Lipika Goyal,1 Supriya K. Saha,2 Leah Y. Liu,1 Giulia Siravegna, Ignaty Leshchiner,1 Leanne G. Ahronian,1 Jochen K. Lennerz,1 Phuong Vu,1 Benedetta Mussolin,1 Stephanie Reyes,1 Pascal Fuel,1 A. John Iafriate,1 Gad Getz,1 Diana G. Porta,1 Ralph Tiedt,1 Alberto Bardelli,1 Dejan Juric,1 Ryan B. Corcoran,2 Nabeel Bardeesy,1 Andrew X. Zhu1,2 Massachusetts General Hospital, Boston, MA; 3Fred Hutchinson Cancer Research Center, Boston, MA; 4Candiolo Cancer Center-FPO, Italy; 5Brod Institute, Cambridge, MA; 6Novartis Institutes for Bio-Medical Research, Switzerland.

Genetic alterations in the fibroblast growth factor receptor (FGFR) pathway are promising therapeutic targets in a broad range of cancers and occur in ~20% of ICCs. As seen with other targeted therapies, however, acquired resistance has limited the efficacy of selective FGFR kinase inhibitors such as BGJ398. In a phase II trial of patients with advanced refractory cholangiocarcinoma harboring an FGFR gene alteration, BGJ398 displayed an overall response rate of 22%, but the durability of response was short in some patients. We report the molecular basis of acquired resistance in 4 patients with advanced FGFR2-fusion positive ICCs via integrative genomic characterization of cell-free circulating tumor DNA (cfDNA), the primary tumor, and metastases. Each patient enjoyed an initial response, but all subsequently progressed within 10 months. Serial analysis of cfDNA revealed multiple point mutations in the FGFR2 kinase domain at progression (Table 1). The gatekeeper mutation, p. V564F, sterically hinders drug binding and was identified in 3 of 4 patients. In patient #1, five different FGFR2 mutations were detected in the post-progression cfDNA but only one, p. K641R, was identified in the post-progression biopsy. A rapid autopsy was performed, and genomic characterization of 12 metastatic lesions revealed marked inter- and intra-lesional heterogeneity, with different FGFR2 mutations in individual resistant clones. Molecular modeling and in vitro studies indicated that each mutation lead to BGJ398 resistance that was surmountable by structurally distinct FGFR inhibitors. Thus, our report provides the first genetic evidence of clinical acquired resistance to FGFR inhibitor therapy in patients and informs future strategies for detecting mechanisms of resistance and promoting more durable remissions.

#4115 Combination of FTY720 and tamoxifen inhibits drug-resistant ovarian cancer cell proliferation. 

Kelly Marie Kreitzburg,1 Charles N. Landen,2 Tracy Gamblin,1 Rebecca Arend,1 Ronald Alvarez,3 Karina Yoon,1 Univ. of Alabama at Birmingham, Birmingham, AL; 2University of Virginia School of Medicine, Charlottesville, VA; 3Vanderbilt University Medical Center, Nashville, TN.

Despite satisfactory initial responses to frontline therapies that combine surgical debulking with platinum based chemotherapy, virtually all women with advanced ovarian cancer relapse with drug resistant disease. There is a critical need to identify alternative, effective therapies. Previously, we used patient derived xenograft (PDX) models of ovarian cancer in mice to identify the sphingosine phosphate (S1P) pathway as one of the pathways most affected by two agents frequently used to treat ovarian cancer, carboplatin and paclitaxel. The S1P pathway contributes to multiple biological processes recognized as essential for tumor development, and aberrations in sphingolipid metabolism have been directly correlated with advanced disease and with resistance to chemotherapy and radiation. Further, recent studies indicate that tamoxifen may counteract resistance mechanisms through modulation of sphingolipid metabolism, specifically through inhibition of the ceramide converting enzymes acid ceramidase and glucosylceramide synthase. Therefore, we evaluated the efficacy of modulating S1P metabolism using the sphingosine analog FTY720 and tamoxifen as an approach to inhibit the proliferation of drug-resistant ovarian tumor cells. We used alamarBlue cell proliferation assays to compare the anti-proliferative effect of FTY720 and tamoxifen with the effect of each drug as a single agent. FTY720 + tamoxifen synergistically decreased the cell viability of 3/3 ovarian cancer cell lines: estrogen receptor alpha (ERα) positive SKOV3.T3 (taxane resistant), ERα negative A280.cp20 (platinum resistant) and HeyA8.MDR (taxane-platinum resistant). The combination also increased levels of apoptosis as reflected by Annexin V staining and cleaved caspase 3 levels. Further, administration of 3mg/kg i.p. FTY720 + 20mg/kg p.o. tamoxifen daily for 21 days to PDX-bearing mice demonstrated that FTY720 + tamoxifen suppressed tumor growth by ~60% compared to vehicle controls. Notably, immunohistochemical staining of tumors harvested from treated mice showed that the combination decreased expression of the proliferation marker Ki-67 and increased expression of apoptosis indicators ceramide and cleaved caspase 3 to a greater degree than in tumors exposed to either drug alone. We conclude that FTY720 + tamoxifen merit further investigation as potentially effective agents for the treatment of drug-resistant ovarian cancer.

#4116 Acquired lapatinib resistant tumour induces EMT-phenotype in breast cancer cells via Src and RUNX3. 

So Hyun Kim,1 Ahrum Min,1 Seongyong Kim,1 Dong Hyeon Ha,1 Hyemin Jung,1 Yu Jin Kim,1 Kyung-Hun Lee,2 Tae-Yong Kim,2 Seoek-Ah Im2.

Lapatinib is an example of an agent targeting the epidermal growth factor receptor (EGFR) and the human epidermal growth factor receptor 2 (HER2). In breast cancer, acquired resistance to this and other similar agents is a significant clinical problem. We report lapatinib resistant tumour induced epithelial-to-mesenchymal transition (EMT) phenotype in breast cancer cells via Src and RUNX3. So Hyun Kim,1 Ahrum Min,1 Seongyong Kim,1 Dong Hyeon Ha,1 Hyemin Jung,1 Yu Jin Kim,1 Kyung-Hun Lee,2 Tae-Yong Kim,2 Seoek-Ah Im2. Cancer Research Institute, Seoul National University College of Medicine, Seoul, Republic of Korea; 2Seoul National University Hospital, Seoul, Republic of Korea.

Background: Lapatinib is an effective EGFR and HER2 targeting small molecular tyrosine kinase inhibitor which is widely used for HER2 positive breast cancer patients. However, patients eventually acquire resistance, limiting its long-term use. Overexpression of heregulin, a HER3 ligand, acquired stemness were mechanism that confers resistance to the anti-Her2 lapatinib. However, still, unknown of developing lapatinib resistant remain as a question to solve. Thus, we tried to find out there is a novel mechanism which related to lapatinib resistant, and any specified molecules were involved in this process. Methods: Acquired resistant SK-BR-3 cells were established by chronic exposure to lapatinib or trastuzumab. Lapatinib or trastuzumab sensitivity were confirmed by MTT assay. Western blotting was used to determine signal transduction mechanism and association of binding assay. Furthermore, gene expression were conducted for verifying invasive ability. Whole exome sequencing (WES) and siRNA knock-down system were used for further analysis. Results: Lapatinib resistant (LR) cell lines showed down-regulation of p-HER2, p-Akt, and p-Erk. The activity of Src family kinase was increased in LR cells. Vimentin, famous EMT marker, is also increased in LR cells. Migration and invasion were significantly increased in LR cells. Correlated with a missense mutation of RUNX3, which identified by WES, expression of RUNX3 was decreased in LR cells. Moreover, siRNA knock-down parental cells showed more resistance to lapatinib. Conclusion: The increase of Src activation, cell migration, and invasion was observed in LR cells. RUNX3, which identified by WES, affected to lapatinib sensitivity in SK-BR-3 cells. Therefore, RUNX3 might be a specified molecule, which partially contributes resistance to lapatinib.

#4117 Mechanisms of acquired resistance to c-Src kinase inhibitor in triple negative breast cancer. Rabia A. Gilani, Eric J. Lachacz, Sameer Phadke, Li Wei Bao, Xu Cheng, Evelyn M. Jiagge, Matthew B. Soellner, Sofia D. Merajver. Univ. of Michigan, Ann Arbor, MI.

Triple negative breast cancers (TNBCs) are especially lethal due to their high metastatic potential and propensity to recur. TNBCs comprise the only subset of breast cancer for which there are no FDA-approved targeted therapies. We have developed a mechanistically novel dual c-Src/p38 inhibitor, UM-164, that has potent in vivo anti-TNBC activity. However, single-agent targeted therapies are prone to resistance and rational drug combinations can overcome or prevent resistance. We developed TNBC cell lines that are resistant to UM-164. Significant morphology and cell signaling changes occurred in the drug-resistant cell lines. Most crucial is the observation that in drug-resistant cell lines the expression of c-Src and/or p38 does not return in the presence of UM-164, suggesting that resistance is not occurring via constitutive activation enabling mutations of c-Src and/or p38 kinases. However, compared to their drug-sensitive counterparts, the UM-164-resistant cells have significantly hyperactivated MEK1/2 and ERK1/2 signaling when treated with UM-164. Thus, we tested combinations of UM-164 + MEK1/2 inhibitors in several TNBC cell lines and patient derived xenografts. We found that trametinib (MeKi1), a FDA-approved inhibitor of MEK1/2) is synergistic (Chou-Talay CI at ED90 = 0.4. CI < 1 denotes synergy) with UM-164 to inhibit the growth of UM-164-resistant MDA-MB-231 and SUM-149 cell lines. These results support our hypothesis that activation of MEK/ERK signaling can act as an escape mechanism that leads to resistance to UM-164. Future research into rational combinations of targeted therapies delivered in data driven schedules may hold the key to improving survival in TNBC.

#4118 The EMT transcription factor TWIST1 mediates resistance to EGFR inhibitors in EGF-mutant non-small cell lung cancer. Zachary A. Yochum,1 Haiyun Wang,2 Jessica A. Cades,1 Sushel Khetarpal,1 Eric H. Huang,2 Phouc T. Tran,2 Timothy F. Burns,1 University of Pittsburgh School of Medicine, Pittsburgh, PA; Johns Hopkins University School of Medicine, Baltimore, MD.

Recent advances in the treatment of non-small cell lung cancer (NSCLC) stem from the paradigm shift of classifying patients into subtypes based upon the presence of distinct molecular drivers. Subsets of patients, such as those with EGFR mutations and ALK translocations, have dramatic responses in their tumors to tyrosine kinase inhibitors (TKIs) that specifically inhibit these oncogenic drivers. While mechanisms that lead to resistance to TKIs therapeutic resistance is inevitable. For EGFR-mutant NSCLC, there are multiple described mechanisms of resistance to EGFR TKIs, including epithelial-mesenchymal transition (EMT). Previous studies have implicated the AXL kinase and ZEB1, an EMT transcription factor (EMT-TF), in EMT-mediated EGFR TKI resistance. We have previously demonstrated that the EMT-TF, TWIST1, is required for oncogene-driven NSCLC tumorigenesis, including those tumors with EGFR mutations. In this study, we investigated the role of TWIST1 in EMT-mediated resistance to EGFR TKIs. We have demonstrated that genetic or pharmacologic inhibition of TWIST1 resulted in growth inhibition in a panel of EGF-mutant NSCLC cell lines and apoptosis in a subset of these lines. Interestingly, TWIST1 overexpression in EGFR-mutant NSCLC cell lines led to EGFR TKI resistance. Conversely, knockdown of TWIST1 in an erlotinib resistant EGFR-mutant NSCLC cell line restored erlotinib sensitivity. We found that TWIST1 mediates resistance to EGFR TKIs through suppression of apoptosis possibly through decreasing the expression of the pro-apoptotic Bcl-2 member, BCL2L11 (BIM). We observed that TWIST1 knockdown increased BIM levels, while TWIST1 overexpression inhibited the growth of BIM+ cells. Furthermore, TWIST1-mediated resistance was overcome by treatment with the BCI-2/BCL-XL inhibitor, ABT-737. Knockdown of BIM recapitulated the resistance seen following TWIST1 overexpression, suggesting that TWIST1 suppression of BIM is a mechanism through which TWIST1 leads to EGFR TKI resistance. To explore the role of TWIST1 in modulating EGFR inhibitor sensitivity in vivo, we used an inducible EGFR transgenic mouse model, CCSP-rTA/ERGFL858R(CE), which expresses ERGFL858R in the lung and a EGFR-mutant/Twist1 transgenic model, CCSP-rTA/ERGFL858R/Twist1- tetO- luc (CET), which expresses both EGFRFL858R in the lung, the CET mice had a significantly increased tumor burden, decreased apoptosis and a decreased overall survival compared to CE mice following erlotinib treatment. In summary, we found that TWIST1 overexpression leads to EGFR TKI resistance by suppressing EGFR TKI-induced apoptosis through suppressing BIM expression. Future studies aim to establish the mechanisms of TWIST1 suppression of BIM expression and determine if our TWIST1 inhibitor, harmine, is effective in overcoming EMT-mediated resistance.

#4119 The development of EGFR resistant mutation, T790M, in lung adenocarcinoma is acquired through a specific cytosine deamination mechanism. Khaled Hassan, 1 Najwa El Kadi, 1 April Davis, 2 Gregory Kalemkerian, 1 Luo Wang, 1 Hasan Korkaya 2. University of Michigan, Ann Arbor, MI; 1Georgia Cancer Center, Augusta, GA.

EGFR resistant mutation, T790M, in lung adenocarcinoma is acquired through a specific cytosine deamination mechanism. Background: Epidermal growth factor receptor (EGFR) activation mutations occur in 15% of lung adenocarcinomas. This leads to constitutive activation of EGFR, which triggers multiple downstream survival and proliferation pathways. Currently, EGFR tyrosine kinase inhibitors (TKIs) are first line therapy for stage IV non-small cell lung cancer (NSCLC) patients with EGFR mutations. Despite initial significant response to TKIs, most tumors develop resistance. The main mechanism of resistance detected in 50-60% of cases is a cytosine to thymine (C>T) single nucleotide transition mutation at position 2369. This causes a threonine to methionine amino acid change at position 790 (i.e. T790M). Our data suggests that the C>T mutation is an acquired event secondary to cytosine deamination by Activation Induced Cytosine Deamination enzyme (AICDA). Results: Single cell clones of lung adenocarcinoma cell line, PC9, were treated with EGFR TKI. At baseline, these clones have EGFR exon 19 deletion but no evidence of T790M mutation by digital droplet PCR (ddPCR). However, after treatment with a serial increasing dose of EGFR TKI, T790M mutation was detected by ddPCR. Assessing whether cytosine deamination enzymes were altered by this treatment, a significant increase in AICDA expression was seen. Furthermore, a recombinant AICDA protein could deaminate cytosine at position 2369 in vitro. In addition, using mass spectrometry and methylation specific primers, we determined that cytosine at position 2369 is in fact methylated. This further supports our hypothesis since 5-methylcytosine is deaminated into thymine directly. Since in germinal center B-lymphocytes, AICDA is activated through a non-canonical NFkB mechanism, we assessed NFkB pathway in PC9 cell line. RelB and p52 expression were significantly increased after TKI treatment. In addition direct interaction between RelB and AICDA promoter was confirmed by ChIP Assay. These findings were also seen in a mouse PC9 xenograft model. Daily oral gavage of EGFR TKI caused significant increase in the expression of RelB as well as AICDA. Adding NFkB inhibitor twice weekly inhibited the expression of RelB and AICDA. Finally, knocking down AICDA by shRNA prevented the development of T790M mutation in PC9 cell lines after TKI exposure. Conclusion: Our data suggest that the T790M mutation could be actively acquired after TKI treatment through a cytosine deamination process by AICDA. This would have significant implications for treatment with targeted therapy. In fact, Imatinib resistance in CML and GIST tumors have a similar C>T single nucleotide transition mutation.

#4120 Acquisition of chemoresistance to mTORC1 inhibition due to activation of the GSK-3 β/4E-BP1 pathway might predict poor prognosis of mRCC patients. Hiromi Ito,1 Akira Nagaoaka,1 Norihiko Tsuchiya,1 Yamagata University, Yamagata, Japan; 2Niigata graduate school of medical and dental science, Niigata, Japan.

1The acquisition of chemoresistance to mTORC1 inhibition due to activation of the GSK-3 β/4E-BP1 pathway might predict poor prognosis of mRCC patients. Purpose: PI3K-pathway activation is the second most common genetic abnormality occurring in head and neck squamous cell carcinomas (HNSCC). Mutation or amplification of PIK3CA, the gene coding for the p110alpha subunit of PI3K, occur in 34%-56% of HNSCC and there is evidence that targeting PI3Ka in these tumors can be radiosensitizing. Small molecule kinase inhibitors of PI3Kalpha are showing promising activity. However, the use of this molecule is limited by its high systemic toxicity and severe side effects. In this study we aimed to apply novel nanotechnology for targeted drug delivery via the cell adhesion molecule P-selectin, which was previously shown to be overexpressed in tumor microvasculature. Furthermore, P-selectin is up regulated following radiation therapy (RT), which could enhance drug delivery using targeted nanoparticles. Experimental design: We explored the efficacy and specificity of targeted delivery of BYL719, a potent alpha-specific PI3K inhibitor, using nanoparticles that selectively target P-selectin present in the tumor microvasculature in PIK3CA-mutated HNSCC. We compared the antitumor effects of nanoparticle delivery versus standard oral gavage with free drug in PIK3CA mutated HNSCC cell line- and patient-derived xenografts (PDxAs). In addition, we compared blood glucose and insulin levels between standard BYL719 administration and nanoparticle delivery to test different treatment modalities. Furthermore, we sought to evaluate the radiosensitizing properties of BYL719 when combined with fractionated RT of 5X4Gy. Results: P-selectin targeted delivery of 50 mg/kg/week BYL719 resulted in a significant tumor growth delay, which was comparable to the standard drug administration of 350 mg/kg/week (50 mg/kg/day). While blood glucose and insulin levels were spiking after standard oral gavage of BYL719, these parameters were virtually unchanged upon nanoparticle administration of the drug. The radiosensitizing abilities of low-dose nanoparticle-linked BYL719 were comparable to the drug concentrations used in standard daily BYL719 administration. When concomitantly with fractionated RT, both methods showed robust enhancement of radiotherapy response in all the models tested resulting in durable control of tumor growth. Conclusions: P-selectin targeted delivery of a PI3K inhibitor in in vivo models yielded enhanced radiosensitization by the inhibition of the PI3K/Akt/mTOR pathway without affecting glucose or insulin levels. The magnitude of pathway inhibition was sufficient to radiosensitize several HNSCC animal models. This novel targeting strategy could be translated to the clinic to treat patients with PIK3CA activated and radioresistant HNSCC tumors sparing most of the systemic adverse effects of PI3K inhibition.

A major focus in immuno-oncology research is finding new immuno-oncology targets, including those that alter the character and frequency of T-cell-mediated anti-tumour responses. Screens using CRISPR (Clustered Regularly Interspaced Short Palindromic Repeats)-Cas9-mediated genome editing seem well placed to identify new targets. However, although CRISPR-Cas9 gene editing works well in primary T cells using electroporation, use of a lentivirus one vector system has proved challenging in primary T cells. We have used several different approaches to identify the most useful method for transduction of primary human T cells with CRISPR components. Electroporation of sgRNAs and mRNA encoding Cas9 into proliferating T cells achieves transduction with high efficiency, but this is less effective for primary T cells. We have used CRISPR-Cas9 mediated gene editing in T cell lines to assess the gene targeting rates of around 37% for gene knockout. Thus, primary T cells are amenable to CRISPR-Cas9 gene editing, and the capacity to rapidly modify loci enables generation of primary T cell models suitable for comprehending the function of modified receptor-ligand pairs involved in an immune checkpoint response. Our pooled sgRNA-Cas9 screens in cancer cell lines have used our limited library of libraries, which include genes such as CD3. However, we have not achieved sufficient coverage to include many of the key regulators of T cell function. CRISPR-Cas9 technology might be useful for this purpose. This work marks a significant step toward understanding the full potential of CRISPR-Cas9 gene editing in primary T cells.
tion in myeloid derived suppressor cells (MDSCs). We are using an siRNA approach in these cells, which are generated by PBMC co-culture with cancer cell lines for 7 days, or by culture in the presence of recombinant GM-CSF and IL-6 for 7 days. Our initial data indicate that these MDSCs can effectively suppress autologous, as well as allogeneic, CD8 T cell proliferation mediated by anti-CD3 and anti-CD28 stimulation, suggesting that siRNA lipid delivery is effective in MDSCs. We will use our druggable genome plus arrayed siRNA library to identify targets that when knocked down inhibit the capacity of MDSCs to suppress T cell proliferation. We anticipate that these data will be useful in identifying new targets that are involved in regulating an immune response to tumour development and progression.

#4124 POPDC1 inhibits breast cancer cell migration and proliferation, and is regulated by EGFR (ErbB1) and CAMP. Johanna N. Amunjela, Steven J. Tucker. Univ. of Aberdeen, Aberdeen, United Kingdom.

Despite progress in the development of new treatments, breast cancer remains the second leading cause of global cancer morbidity and mortality (1). Identification and validation of effective therapeutic targets is thus essential for the development of better breast cancer treatments and improved prognoses. This project seeks to develop POPDC proteins as potential therapeutic targets for inhibiting breast cancer migration and proliferation. POPDC1 (also known as blood vesel epiderial substance or BVE5), is a cAMP-binding transmembrane protein encoded by the POPDC1 gene. Loss or suppression of POPDC1 has been correlated with enhanced aggressive cancer cell behaviour (2-6). Suppression of POPDC1 promotes cell migration and invasion in hepatocellular carcinoma and tumourigenesis in colorectal cancer (2,4,5,7). Furthermore, we have previously shown that loss of POPDC1 promotes cell proliferation and migration in breast cancer and glioblastoma cells (3,8). Using a cAMP-agarose pulldown assay, we confirmed that POPDC1 interact with, and is upregulated by cAMP in luminal A (MCF7) and triple-negative (MDA231) breast cancer cells. Furthermore, immunocytochemistry and Western blotting has shown that POPDC1 expression is abrogated in MCF7 and MDA231 breast cancer cells compared to normal breast cells (HMePc). To confirm that POPDC1 negatively regulates migration and proliferation in breast cancer cells, we conducted knock-in experiments where overexpression of POPDC1 significantly inhibited cell migration and proliferation in MCF7 and MDA231 cells. Interestingly, epidermal growth factor receptor (EGFR/ErbB1) signalling negatively regulates POPDC1 expression in MCF7 and MDA231 cells and reduces the capacity of POPDC1 to inhibit cell migration. Epidermal growth factor reversed POPDC1-mediated inhibition of cell migration, an effect blocked by the AG 1478 (an EGFR inhibitor), suggesting EGFR-dependent modulation of POPDC1 activity. Furthermore, we have established for the first time using human breast tissue sections that Her2- status correlates with low POPDC1 expression while Her2+ status correlates with high POPDC1 expression. This suggests further investigation between EGFR and POPDC1 and that any links between these molecules diverges at the level of the different EGFRs. Taken together, this strong dataset shows that POPDC1 plays a major role in breast cancer tumourigenesis that is at least in part, modulated by EGFR and cAMP signalling pathways. Indeed, these seem to demonstrate differential control of POPDC1 expression. This interplay and the fact that POPDC1 expression, which is associated with a downregulation of the MUC1 and CIN85 complex in breast cancer, seems to be associated with HER2 status in breast cancer. We are currently investigating the MUC1/CIN85-dependent signaling pathway with a particular focus on the ability of CIN85 to modulate MUC1 glycosylation by controlling its plasma membrane-Golgi trafficking. Ongoing experiments in an in vivo mouse model will confirm the ability of these drug compounds to decrease tumor growth and metastasis and validate CIN85/MUC1 complex as a viable therapeutic target and support development and testing of more potent antagonists.

#4125 Comparison between knockdown of Pim-1, Pim-2 and Pim-3 identifies Pim-2 as the most relevant Pim oncogene in hepatocellular carcinoma. Ulrike Weihrach, Pia Kärrz, Achim M. Aigner. Univ. of Leipzig, Leipzg, Germany.

Introduction: Pim-Kinases (Pim - proviral integration site for moloney murine leukemia virus; Pim-1, -2, -3) are a family of serine/threonine kinases with anti-proliferative (low dose, 0.05-0.3 M) effects in all three cell lines, including p53 mutant Huh-7 and p53 null Hep3B cells. The same cell lines were strongly resistant to Nutlin-3a. Gene expression analyses were conducted with cells exposed to NSC207895 to examine effects of MDM4 inhibition on p53 targets Bax, Puma, and p21. In SK-Hep1 cells, NSC207895 treatment led to 2.5-fold overexpression of Bax, 27.4-fold of Puma, and 23.1-fold of p21. Huh-7 showed 11.8-fold upregulation of Puma and 12.4-fold of p21, and Hep3B exhibited a very strong 58.4-fold increase in p21 gene expression with the same treatment. Interestingly, Hep3B showed 3.9-fold overexpression of p63 and 1.99-fold of p73 gene expression with NSC207895 exposure, suggesting novel interactions between MDM4 and p63/p73 in the absence of p53. Conclusions: Inhibition of MDM4 shows efficacy in in vitro models of HCC through upregulation of p63, p73, and p53 to activate p53 tumor suppressive signaling. Thus, targeting MDM4 may be a viable option for all HCC patients, no matter the p53 mutation status.

**#4128** Mechanism of action of G-quadruplex forming oligonucleotide homologous to the telomere overhang in melanoma. Gagan Chhabra, Luke Woodby, Anita Sanjali, Mark Fakes, Marko Ivanovic, Pooja Vinay, Zachary Schrank, Benjamin E. Ramirez, Neelu Puriri. 1Univ. of Illinois at Chicago, Rockford, IL; 2Univ. of Illinois at Chicago, Chicago, IL

T-oligo, a guanine-rich oligonucleotide (GRO) homologous to the 3’ telomeric overhang of telomeres, elicits potent DNA-damage responses (DDRs) in cancer cells. However, the detailed molecular mechanism of action of T-oligo in cancer cells is largely unknown. Recent studies suggest that GROs can form G-quadruplexes (G4) which are stabilized by the hydrogen-bonding of guanine residues. This study aims to examine the G4-forming capabilities of T-oligo in vitro and to investigate the molecular mechanism of G4 single-stranded (SS) T-oligo G4-T-oligo induced DDRs in melanoma cells (MM-AN). G4-formation by T-oligo was confirmed using the SS-T-oligo and G4-T-oligo on a polyacrylamide gel under non-denaturing conditions. NMR studies for T-oligo in KCl confirmed that T-oligo forms G4 structures. Immunofluorescence studies conducted with an anti-G-quadruplex antibody (BG4), a G4 detecting antibody, showed 88.4% co-localization of T-oligo and BG4 in the nuclei of melanoma cells confirming the ability of T-oligo to form G-quadruplexes inside melanoma cells. While G4-T-oligo was found more stable in nuclease degradation assay by DNase I, it had a decreased anti-proliferative effects compared to SS-T-oligo. However, G4-T-oligo had similar cellular uptake as SS-T-oligo. Further, two telomere complex proteins TRF2 and POT1 which are mainly found at the telomere ends were found to be upregulated (2.0 fold) by T-oligo suggesting TRF2 and POT1 mediated telomere overhang dissociation. We also found that T-oligo can co-localize with telomere binding proteins TRF2 and POT1 by 88.4±4.5% (n=12) and 84.5±8.8% (n=10) respectively. Western blot analysis results also showed upregulation of both p-JNK and total JNK by 4.0- and 2.0-fold respectively. To further confirm the involvement of p-JNK in T-oligo mediated apoptosis we used a specific JNK inhibitor SP600125. Western blot analysis showed that T-oligo mediated upregulation of p-JNK was reversed in presence of SP600125. Results from an MTT assay showed a 73.8% decrease in cell viability after T-oligo treatment alone; however, cell viability was decreased to 45.8%, and 25.3% when SP600125 was present at concentrations of 10 µM, and 12 µM respectively, in comparison to diluent. T-oligo also inhibited mRNA expression of hTERT, a catalytic subunit of telomerase by 50%. We further investigated the effect of the JNK inhibitor SP600125 on hTERT expression and found that treatment with SP600125 in presence of T-oligo partially reversed the downregulation of hTERT. We found a 16% decrease in hTERT expression in comparison to 50% reduction by T-oligo treatment alone. In conclusion, these studies demonstrate that T-oligo can form G-quadruplexes and the anti-proliferative mechanism of T-oligo may be mediated through POT1 and TRF2 as well as via JNK-activation inducing hTERT-inhibition in melanoma cells.

**#4129** Novel oncogenic BRAF fusions and impact on targeted therapies. Sonia C. Dolfı, Ann Silk, Bhavna Paratala, Whitney Petrosky, Srilatha Simhadri, Rutger Cancer Inst. of New Jersey, New Brunswick, NJ

BRAF mutations are driver events in a number of cancers including thyroid cancer and melanoma. The most common, BRAF V600E, alters normal BRAF protein activity in the mitogen-activated protein kinase (MAPK) pathway by constitutively activating BRAF and inducing proliferative signaling and tumor growth. Small molecule tyrosine kinase inhibitors targeting tumors with the V600E mutation have been evaluated in clinical trials and are now approved for melanoma. While BRAF missense mutations have been extensively characterized for oncogenic potential and actionability in genomically-guided therapy, BRAF gene fusions have been underappreciated for not only their functional role in cancer but also in differential drug response. More recently, data suggest that alternative approaches may be needed for treatment of patients with BRAF fusion-containing tumors. We have identified two novel BRAF fusions in tumors from patients with papillary thyroid cancer and melanoma. Both fusions result in an in-frame fusion of a novel gene partner at the 5’ end of the fusion, an intact BRAF reading frame at the 3’ end, and loss of the BRAF auto-inhibitory domain. We hypothesized that these novel BRAF fusions act as oncogenic drivers, and the mechanism of BRAF activation differs from that caused by V600E mutations and may be fusion partner-specific. These fusions have been engineered in the laboratory and tested for tumorigenic potential and functional activity. BRAF fusion expression in non-transformed cells induces colony formation similar to the V600E mutation indicating tumorigenic potential. These BRAF fusions also constitutively activate the MAPK pathway in the absence of stimulation as demonstrated by phosphorylated ERK and MEK proteins. Additionally, BRAF fusion-expressing cells form tumors in vivo similarly to the BRAF V600E-expressing cells. These tumors are highly proliferative as demonstrated by strong Ki67 immunohistochemical staining and display MAPK pathway activation as evidenced by phosphorylated ERK. BRAF fusion-expressing cells have differential sensitivity to MAPK pathway inhibitors compared to cells with the V600E mutation as measured by reduced MAPK signaling. Inhibition of the MAPK pathway is relevant in targeting BRAF fusion-containing cells but not always the same paradigm at point mutations. Collectively, our data suggest that BRAF fusions are functional and represent novel therapeutic targets, but may need an alternative approach as compared to tumors with BRAF missense mutations.

**#4130** Characterization of URS1 as a prognostic biomarker and therapeutic target for lung cancer. Atsushi Takano, Yohei Miyagi, Yataro Daigo. 1Institute of Medical Science, The University of Tokyo, Tokyo, Japan; 2Kanagawa Cancer Center Research Institute, Yokohama, Japan; 3Shiga University of Medical Science, Otsu, Japan

Lung cancer is the most frequent cause of cancer deaths worldwide and its overall prognosis remains poor. Therefore, next generation of biomarkers and therapeutic strategies for lung cancer are eagerly awaited. We selected genes that were overexpressed in the majority of lung cancer using our gene expression profile database. During this process, we identified URS1 (Up-regulated in lung cancer) (1). As a candidate, immunohistochemical analysis showed that URS1 expression was observed in the majority of non-small cell lung cancer (NSCLC) patients (P = 0.0013 by log rank test). Multivariate analysis revealed highest level of URS1 expression was an independent prognostic factor for NSCLC patients. Moreover, reduction of URS1 by siRNA or treatment with URS1 inhibitor significantly suppressed lung cancer cell growth probably through cell cycle arrest at G2/M. Exposure of cancer cells to URS1 inhibitor significantly suppressed These data suggest that URS1 is a possible prognostic biomarker and therapeutic target for lung cancer.

Triple negative breast cancer (TNBC) - defined as estrogen receptor- (ER), progesterone receptor-(PR), and human epidermal growth factor receptor 2-(HER2) negative - is a highly aggressive form of breast cancer prevalent in African-American (AA) women. Because ER- and HER2-targeted therapies are ineffective in TNBC, current treatment strategies rely on cytotoxic chemotherapy. There is a tremendous need for new approaches that can identify effective therapies with less toxicity for this devastating form of breast cancer. Nuclear receptors are highly druggable targets. Classical examples include ligand-activated receptors like ER, but orphan nuclear receptors are also emerging as targets for cancer therapy. We recently published that increased mRNA expression of estrogen-related receptor beta (ERRβ, gene symbol ESRRB) correlates with better recurrence- and distant metastasis-free survival in women with TNBC, and that a small molecule agonist ligand for ERRβ (DY131, DY) has growth inhibitory and anti-metastatic activity in TNBC cell lines of multiple molecular subtypes.

The goal of our current work is to validate ERRβ as a novel therapeutic target for TNBC in two distinct ways. First, we sought to determine whether ERRβ is correlated with survival outcome specifically in African-American (AA) women. Analysis of The Cancer Genome Atlas (TCGA) Breast Cancer RNAseq data shows that low ERRβ mRNA expression is specifically associated with poor overall survival in AA women with TNBC. This association is not observed in AA women with ER- or HER2-positive disease. We further find that while ERRβ mRNA expression is decreased in tumor vs. normal breast tissue regardless of race, this decrease is more pronounced in AA women. Ongoing studies in an independent cohort of AA and white women will determine whether this is due, in part, to lower copy number changes at the ERRβ locus (chromosome 1q42.43). Second, we sought to determine whether ERRβ expression could predict response to current treatment strategies commonly used in breast cancer, particularly TNBC. Using multiple combined datasets, we find that high ERRβ expression is associated with improved recurrence-free survival (RFS) in women with TNBC who received adjuvant or neoadjuvant therapy with anthracyclines (e.g. doxorubicin), and that ERβ ligand ERβ836,181 significantly suppressed ERβ activity and its downstream signaling in TNBC. These data indicate that ERβ ligand ERβ836,181 is a suitable candidate for clinical trials in TNBC.

**#4132** Roles of the acetyltransferases CBP/p300 in breast cancer. Iqbal Muhmud, Guimei Tian, Daiqing Liao. University of Florida College of Medicine, Gainesville, FL

Proceedings of the American Association for Cancer Research. • Volume 58 • April 2017
Experimental and Molecular Therapeutics: New Targets and New Drugs

Intrinsic drug resistance renders certain breast cancer (BC) patients unresponsive to standard-of-care therapies. For example, ~50% of patients with estrogen receptor-positive (ER+) tumors do not respond to endocrine therapies (ETs, e.g., tamoxifen). Acquired drug resistance is another cause for treatment failure and deadly relapse. Therefore, new strategies that tackle both intrinsic and acquired resistance are needed for improving clinical outcome for BC patients. ER-alpha, the defining factor for ER+ tumors, is an estrogen-activated transcription factor (TF) that drives tumor growth and progression. It critically depends on the coactivators CBP/p300 for gene expression underpinning tumor biology of ER+ subtypes that account for ~75% of all BC cases. Recent advances revealed that another hormone receptor, the androgen receptor (AR), is expressed in the majority of ER+ BC. As a result, AR-positive prolactinomas induced by fetal alcohol exposures. Pregnant Fischer 344 rats were fed between gestational days 7 and 21 with a liquid diet containing alcohol, pair-fed with isocaloric liquid diet, or fed ad libitum with rat chow. At 60 days of age, female offspring rats were ovariectomized and received a subcutaneous estradiol implant. These rats were sacrificed at 3 months after the estradiol implants. Pituitary tumors were collected and pituitary tumor samples were prepared and maintained in cultures. Alcohol-fed pituitary tumorspheres, but not control-fed pituitary tumorspheres, expressed DPPA4 and a panel of genes related to multipotility (OCT4, NANOG, KLF4, and CD133) and showed increased invasiveness and marked growth in cultures and in mice xenografts. The RNA sequence analyses identified selective expression of DPPA4 in the pituitary of fetal alcohol-exposed rats but not in control BCs as well as in a subset of ER-BCs. Evidence indicated that AR signaling is implicated in ET resistance. For the HER2-enriched tumors, high levels of AR expression correlate with poor prognosis. Similarly for ER-alpha, CBP/p300 act as key coactivators for AR-mediated gene expression. Additionally, other oncogenic TFs (e.g., beta-catenin/TCF and STAT3) also depend on CBP/p300 for gene activation. Importantly, these pathways are active in all BC subtypes, regardless of the hormone receptor status. CBP/p300 overexpression and heightenened acetylation activity are detected in clinical BC samples and correlate with disease progression. Thus, CBP/p300 represent attractive targets for developing novel therapies broadly applicable for treating all major BC subtypes. We have discovered a novel class of highly potent CBP/p300 inhibitors. Our previous studies indicated that this class of compounds is highly effective to suppress tumor growth in vivo using a xenograft mouse model. We will present genomic features of CBP/p300 in different breast cancer subtypes and experimental data underlying potential mechanisms by which CBP/p300 regulate oncogenic phenotypes, as well as effects of pharmacologic inhibition of CBP/p300 on sensitivity of breast cancer cells to standard anticancer therapeutics.

Amrubin (AMR) is a synthetic cytotoxic agent that is currently in clinical trials for the treatment of various types of cancer. It targets the tumor microenvironment, particularly the stromal components, and inhibits tumor growth and metastasis. Amrubin has shown to inhibit tumor cell proliferation, migration, and invasion in vitro and in vivo. It has been found to be effective in a variety of cancer models, including breast, lung, and prostate cancer. The mechanism of action of Amrubin involves the inhibition of the PI3K/AKT/mTOR signaling pathway, which is known to play a critical role in tumor growth and survival. Additionally, Amrubin has been shown to induce apoptosis and enhance the effectiveness of chemotherapeutic agents through the modulation of their targets.

Inactivation/loss of PTPRS promotes ERK activation which sensitizes colorectal cancer cells to ERK inhibitors. Thomas B. Davis,1 Mingli Yang,1 Michael J. Schell,2 Heimang Wang,3 Le Ma,1 W. Jack Pledger,1 Timothy J. Yeatman1,4 Gibbs Cancer Ctr. and Research Inst., Spartanburg, SC; Moffitt Cancer Center & Research Institute, Tampa, FL.

The RAS pathway is a driver of many cancers, and has been targeted for the development of a variety of therapeutic inhibitors of BRAF, MEK, and more recently ERK. One of challenging issues is to predict response to targeted therapies. Here we report identification of PTPRS, a receptor-type protein tyrosine phosphatase, as a regulator/biomarker of ERK activation and inhibitor response in colorectal cancer. To identify the genes with high frequency mutations that might be predictive of RAS pathway dependency (‘addiction’), we used a gene expression signature score to stratify 468 colorectal cancer tumors that also underwent targeted exome sequencing for 1321 cancer-associated genes. We found that, when the masking effects caused by mutant KRAS, BRAF and NRAS was iteratively removed, mutant PTPRS was strongly correlated with RAS pathway activation, with a mutation rate of 10.4% (22 out of 211 remaining tumors). This led us to inactivate PTPRS in vitro using a specific peptide inhibitor, siRNA or CRISPR approaches in various colorectal cancer cell lines. Inhibition/loss of PTPRS significantly elevated phosphorylation of ERK and AKT and substantially sensitized cancer cells to the treatment of ERK inhibitors, which was enhanced by an AKT inhibitor. Surprisingly, PTPRS did not modulate the activity of EGFR and the ERK kinase, MEK. Our data indicate that PTPRS negatively regulates ERK signaling downstream of the EGFR/RAS/RAF/MEK pathway in a mechanism independent of AKT and DUSP6. As a result, inactivation/loss of PTPRS promotes ERK activation and ‘addiction’, thereby contributing to increased sensitivity to ERK inhibitors.

Endometrial cancer is the most common gynaecological malignancy and its incidence is increasing. Tissue renin angiotensin systems (RAS) are known to stimulate angiogenesis, cell proliferation and migration. All of these actions potentiate cancer growth and spread. We have previously demonstrated that endometrioid endometrial cancers express both prorenin and prorenin receptor

The Prolactin-secreting pituitary tumors (prolactinomas) are the most common pituitary tumors in humans. Majority of prolactinomas are adenomas and benign and slow growing, but in some cases, they are locally aggressive and invasive. In a rat animal model we found that fetal alcohol exposed female rats develop aggressive prolactinomas following estrogen administration. Several studies have suggested that human prolactinomas seem to arise because many tumor and embryonic stem cell markers such as OCT4, SOX2, Nanog, and Klf4 are expressed in malignant tumor. The developmental pluripotency associated 4 (DPPA4) gene has an important role in self-renewal and pluripotency in embryonic stem cells. It is re-expressed in several malignant tumors and is identified as a new pluripotency-related oncogene. We studied with DPPA4 expresses and function in aggressive human prolactinomas induced by fetal alcohol exposures. Pregnant Fischer 344 rats were fed between gestational days 7 and 21 with a liquid diet containing alcohol, pair-fed with isocaloric liquid diet, or fed ad libitum with rat chow. At 60 days of age, female offspring rats were ovariectomized and received a subcutaneous estradiol implant. These rats were sacrificed at 3 months after the estradiol implants. Pituitary tumors were collected and pituitary tumor samples were prepared and maintained in cultures. Alcohol-fed pituitary tumorspheres, but not control-fed pituitary tumorspheres, expressed DPPA4 and a panel of genes related to multipotility (OCT4, NANOG, KLF4, and CD133) and showed increased invasiveness and marked growth in cultures and in mice xenografts. The RNA sequence analyses identified selective expression of DPPA4 in the pituitary of fetal alcohol-exposed rats but not in control BCs as well as in a subset of ER-BCs. Evidence indicated that AR signaling is implicated in ET resistance. For the HER2-enriched tumors, high levels of AR expression correlate with poor prognosis. Similarly for ER-alpha, CBP/p300 act as key coactivators for AR-mediated gene expression. Endometrial cancer is the most common gynaecological malignancy and its incidence is increasing. Tissue renin angiotensin systems (RAS) are known to stimulate angiogenesis, cell proliferation and migration. All of these actions potentiate cancer growth and spread. We have previously demonstrated that endometrioid endometrial cancers express both prorenin and prorenin receptor
Lymphoma cell viability by inhibiting LUBAC and NF-KB activity. Therapeutic agents for the treatment of ABC-DLBCL. Tides were far more potent than any of the previously generated compounds that inhibited the NF-KB canonical pathway in ABC-DLBCL cell lines. Many of these new peptides diminished cell viability, disrupted LUBAC complex formation and inhibited the NF-KB pathway. In conclusion, new approaches for the treatment of cancer through their potential to restore anti-tumor immunity and to synergize with existing therapies. As part of our investigations into novel small molecule inhibitors of IDO1, we screened a number of human and murine tumor lines for expression of tryptophan dioxygenases. All of the human and murine tumor lines that we tested were found to be tryptophan dioxygenases unless induced with IFN-gamma. Our screen included testing 50 primary human melanoma lines developed from tumor samples obtained from New Zealand Melanoma patients (NZMel lines) for expression of IDO1 and IDO2. After culture with IFN-gamma, 84% of the NZMel lines were IDO1+ and IDO2+. 4% were IDO1+ only; 2% were IDO2+ only; whilst 10% did not express either IDO1 or IDO2. Tryptophan dioxygenase (TDO) was not detected in any of the NZMel lines before or after IFN-gamma exposure. To overcome the need for IFN-gamma induction for our cell based assays of IDO1 inhibitory activity of our novel compounds, we transfected the wild-type murine Lewis Lung carcinoma line (LLTC) to constitutively express murine IDO1 (LLTC-mIDO1) or human IDO1 (LLTC-hIDO1), and used these engineered lines to assay for potential species selectivity of our inhibitors. IDO1 expression in the lines was consistent and stable, but when LLTC-hIDO1 cells were implanted subcutaneously into syngeneic mice for in vivo testing of inhibitors, we found considerable heterogeneity in IDO1 expression between tumors. Approx. 10% of tumors were IDO1 positive, 10% were IDO1 negative and the remaining 80% were IDO1 negative for IDO1 expression by Western blot analysis. More intriguingly, when fragments of an IDO1+ or an IDO1- donor tumor were implanted into new recipients, the same degree of intermittent heterogeneity in IDO1 expression was seen in the subsequent generation of tumors. In contrast, subcutaneous tumors developing from murine GL261 glioma cells similarly engineered to express IDO1 (GL261-hIDO1) or to be non-expressors of IDO1 (GL261-hiIDO1), and were used for subsequent in vivo studies of intratumoral IDO1 expression on its effects on immune cell infiltration and tumor growth. GL261-hiIDO1 tumors had a significantly faster growth rate than the wild-type tumors, and 24 days after implantation, had reached a mean tumor volume of 3600 mm³ compared to a mean tumor volume of 500 mm³ of wild-type tumors. Analysis of the immune cell infiltrates, showed that 14-day GL261 wild-type tumors had a 3-fold higher percentage of CD3+ T cells than that in GL261-hiIDO1 tumors. CD8+ cells made up 55% and 25% of the CD3+ cells in wild-type and GL261-hiIDO1 tumors, respectively. Percentage of FoxP3+ (Treg) cells was higher in GL261-hiIDO1 tumors compared to that in wild-type tumors.

#4139 Role of zinc transporters in prostate cancer and a potential association with racial disparity. Chandra K. Singh,1 Kareem M. Malas,1 Caitlin Tydrc,2 Khalid A. Azkowitz,3 Najib Ahmed,4 University of Wisconsin-Madison, Madison, WI; 2Medical College of Wisconsin-Milwaukee, Milwaukee, WI. Optimal intracellular zinc concentration is essential for many cellular functions as it serves as a catalytic and/or structural cofactor for a variety of proteins. Although a number of proteins are tangled in regulating cellular zinc homeostasis, the most important are two protein families of zinc transporters, 14 members of solute carrier family 30 (SLC30A) and 10 members of solute carrier family 39 (SLC38A). These two families are known to transport zinc into- and out-of the cytoplasm, respectively. Prostate cells accumulate a high amount of zinc to sustain a metabolic condition unique to the prostate which is characterized by a truncation of the Krebs cycle and production of high amounts of citrate. Zinc depletion has frequently been noted in the progression of prostate cancer (PCa). Whether zinc transporters are a steering cause of zinc depletion in PCa development and progression and are key determinants in the racial disparity in PCa is not well studied. In this study, we determined the connection of zinc transporters (SLC39A1-14 and SLC30A1-10) in PCa, in the perspective of racial health disparity in human PCa samples taken from African-American (AA) and European-American (EA) patients and compared them with respective adjacent benign samples. We also assessed the mRNA level of zinc transporters in normal prostate epithelial cells (NPEC) and RWPE1 and among PCa cells derived from AA (MDA PCa 2b, E006AA-PAR, E006AA-H) and EA patients (DU145, PC3, 22Rv1, LNCaP, C4-2B). In addition, we performed a dataset analysis of the Oncomine database for differential expression profile of zinc transporters in PCa versus normal prostate. We found that SLC39A3 mRNA levels were differentially expressed in PCa with a significant downregulation of SLC39A1, SLC39A9, SLC39A11, SLC39A13 and SLC39A14, and upregulation of SLC39A3, SLC39A5, SLC39A6 and SLC39A8. Further, SLC30A3 showed a significant downregulation of SLC30A5 and SLC30A6 and upregulation of SLC30A1, SLC30A9 and SLC30A10, in PCa. Further, compared to EA samples, the AA PCa showed an increased trend of SLC39A5, SLC39A6 and SLC39A9. In addition, compared to AA samples, the EA PCa showed a trend of increasing SLC30A1 and SLC30A9 and decreasing SLC39A10. These data provide evidence that the zinc transporters may be linked to racial disparity of PCa in AA versus EA. Moreover, Ingenuity Pathway Analysis revealed regulatory interactions between zinc transporters and tumor suppressor/promoter genes known to be modulated in PCa. These genes are HOXB13, ELAVL1, DIRAS3, ALFP, CSF2, CCL4, INSR, AKT, IL6, TGFBP1, CHI3L1, EGFR and HNF4A. Overall, our study provides interesting data about transcription profiles of zinc transporters and their interaction with tumor suppressor and promoter genes in PCa, which may offer novel strategies for the management of PCa by pharmacologically modulating zinc transporters.

#4140 Identification of a selective MLKP2/KIF20A inhibitor with high in vivo antitumor activity. Yves Collette,1 Stephanie Misery-Leunki,2 Catherine Guillou,1 Denis Carniato,2 Bernard Pau,1 Bruno Goud,1 Norbert Vey,1 France; 3ICSN-CNRS, Gif-sur-Yvette, France; 4DC2A Consulting, Paris, France; 5BPCONSEIL, Saint-Gély-du-Fesc, France; 6BIOKINESIS, Paris, France. Mitotic kinases are essential regulators of cancer cell replication and migration. The mitotic kinase MLKP2/KIF20A, a member of the kinase-6 family, plays an
essential role during cytokinesis and was identified as a potential new target for cancer chemotherapy.1 We have previously identified Paprotrain, a new synthetic compound, as the first selective MKLP2 inhibitor.2 Recently, we obtained Paprotrain analogues with higher potency on MKLP2.3 Herein we describe the identification and characterization of BKS0349, a new potent analogue of Paprotrain. BKS0349 shows promising preclinical activity against human cancers and has shown an even more restricted specificity profile when tested on a large set of kinases. In-vitro this compound is highly cytotoxic on a wide panel of human cancer cell lines (IC50 ranged 10-70 nM, which corresponds to 1000 fold improvement of paprotrain potency) while no toxicity is observed on human normal cells such as peripheral blood mononuclear cells (PBMC) and primary hepatocytes (IC50 >90fold). BKS0349 is also well tolerated in short-term administrations (200 mg/kg, twice a week for 4 weeks). In xenografted nude mice, in-vivo treatment with BKS0349 compound demonstrates a high antitumor activity against various human cancer cell models, either sensitive or resistant to some standard-of-care treatments. In addition, human cancer cells treated in vitro as well as in-vivo with BKS0349 compound display Golgi scattering and a mitotic arrest leading to cell death, as hallmarks of BKS0349 mode of action. These findings show that BKS0349 is a potential new target for cancer chemotherapy and BKS0349 is a good candidate to be developed for cancer treatment.1 Paclitaxel targets FOXM1 to regulate KIF20A in mitotic catastrophe and breast cancer paclitaxel resistance. P. Khongkow et al. Oncogene, 2015, 1-13.2 Relocation of Aurora B and Survivin from centromeres to the central spindle impaired by a kinesin-specific MKLP-2 inhibitor. S. Tcherniuk et al. Angew. Chem. Int. Ed., 2010, 49:8228-8231.3 New MKLP-2 inhibitors in the paprotrain series: design, synthesis and biological evaluations. C. Labrière et al. Bioorg and Med Chem, 2016, 24:731-734.

#4141 Phosphoproteome networks display consistent hyperactive kinase activity in pancreatic cancer: evidence for new therapeutic options. Tessa Y. Le Largé,1 Maarten F. Bijlsma,1 Bissame El Hassouni,1 Nicolla Funel,1 Nicole C. van Gielen,1 Helene Damhofer,1 Jaco C. Knol,1 Sander R. Piersma,1 Thang Y. Pham,1 Henk M. Verheul1, Hanneke W. van Laarhoven,1 Geert Kazemier,1 Etta Giovanny Batista1, Connie R. Timosenko1,2 VU university Medical Center, Amsterdam, Netherlands;4 Academic Medical Center, Amsterdam, Netherlands;3 University of Pisa, Italy.

Introduction Pancreatic ductal adenocarcinoma (PDAC) is a highly lethal disease due to its aggressive nature. Patients typically present with distant metastases, at which point cytotoxic agents can extend life expectancy by several months at most. Large-scale phosphoproteomics complements our knowledge obtained from genomics and transcriptomics as it provides information on which proteins and kinases are phosphorylated, thereby implicating pathways that are activated. This approach in cancer research may lead to improved patient selection for treatment with tyrosine kinase inhibitors (TKI). This study is the first to employ phosphotyrosine-based phosphoproteomics on three different preclinical PDAC models as well as patient tumor tissues to understand the aggressive nature of this disease and identify new drug targets. Approach We performed phosphoproteomics on a panel of 11 PDAC cell lines, 7 primary cell cultures, 10 patient-derived xenografts (PDX) and 16 fresh frozen human tumor tissues. Tyrosine phosphopeptides were enriched via immunoprecipitation and phosphopeptides were analyzed by high-resolution nano- LC mass spectrometry. Results Using phosphotyrosine-based phosphoproteomics, we identified a total of 1723 tyrosine phosphorylated proteins and 138 phosphorylated kinases, representing 27% of the kinome. The reproducibility of our workflow was very high, with Pearson correlation coefficients of r = 0.937 for technical replicates of cell lines and r = 0.876 for biological replicates of tumors. In our cell line panels, multiple kinases were commonly highly phosphorylated (e.g. PTK2, EPHA2, EGFR and MET). Functional testing of PTK2 by using TKI defactinib in primary cell lines with high phosphorylation resulted in inhibition of proliferation and migration in vitro. Inhibition of EPHA2 by shRNAs resulted in reduced proliferation in vitro. To validate the relevance of these candidate target proteins in vivo, the tyrosine phosphoproteome of PDXs and human tumors was analyzed. In these studies, cancer kinase activity analysis based on kinase phosphorylation levels and kinase-substrate networks validated these common active nodes in the majority of these tumors. Conclusion Our extensive tyrosine phosphoproteome analysis spanning a wide range of PDAC models revealed high phosphorylation levels of multiple kinases. Interestingly, the phosphorylated kinase profiles of tumors and cell lines did not show as much heterogeneity as expected, taken into account the existence of biological subtypes in PDAC identified through genomics and transcriptomics. The aggressive biology of this disease may be correlated with the consistent activation of multiple pathways, some of which we have shown to be targetable in vitro. This study prompts further validation and prognostic evaluation of the identified active kinases to improve treatment of PDAC.

#4142 Regulation of tumor suppressor decorin by APE1 in head and neck squamous cell carcinoma. Christina A. Wicker,1 Timothy L. Scott,1 Rangawamy Suganya,2 Susan M. Arnold,1 Yolanda M. Brill,3 Craig M. Horbinski,3 Dana Napier,1 Joseph Valentino,1 Mahesh R. Kubritomi,1 Guoqiang Yu,1 Tadahide Izumi1, University of Kentucky, Lexington, KY; 2Houston Methodist Research Institute, Houston, TX; 3Northwestern University, Chicago, IL

Oral cancers have a high rate of recurrence, and a tendency to develop treatment resistance. From 2009 to 2013, Kentucky had a disproportionately higher incidence of invasive oral cancers and resultant higher mortality compared to the national average (SEER & NPCR, Kentucky Cancer Registry). Apurinic/Apyrimidinic endonuclease (APE1) is a key protein in DNA repair, and an oncogene in NMIBC expressing wild-type APE1 and extremely low levels of APE1 showed an eight-fold reduction of tumor suppressor decorin (DCN), with wild-type APE1. Decorin is a known tumor suppressor and extracellular matrix protein, which can suppress tumor proliferation, migration and angiogenesis. Tumors with decreased decorin are associated with increased mortality. These studies aim to elucidate APE1’s role in decorin regulation in oral cancer and identify biomarkers, which may aid in diagnosis, treatment, or predicting prognosis. Immunohistochemistry studies of head and neck squamous cell carcinoma from Kentuckians were analyzed aided by APE1’s high resolution scanning capabilities, and software. Analysis showed a significant decrease in decorin in both tumor and carcinoma in situ compared to benign tissue. Whereas, APE1 was significantly increased in tumors and carcinoma in situ compared to normal APE1 and decorin total protein in carcinoma in situ. This data supports that increased APE1 may deleteriously decorin. Superoxide Dismutase 3, which is important in detoxifying extracellular ROS, was also significantly decreased in tumor and in carcinoma in situ. This along with previous research showing increased ROS in the tumor microenvironment and APE1 activation by ROS may explain the origination of decorin suppression. We hypothesize that the overexpression of APE1 in early stages of oral cancer leads to diminished decorin translation, which may drive cancer progression and increase mortality. Better understanding how APE1 influences tumor suppressors may eventually aid in development of therapeutics that would increase patient survival.
ously undescribed role of Mst in colon cancer progression, malignancy and therapy resistance potentially by regulating cell survival in manners dependent on β-catenin/c-Myc/Survivin/Bcl-xl signaling.

#4144 Role of CTGF in hyperthermia resistance in ovarian and uterine cancers. Hiroto Hatakeyama,1 Sherry Y. Wu,1 Yasmin A. Lyons,2 Sunila Pradeep,2 Wanzin Wang,2 Qian Huang,2 Karem A. Court,2 Tao Liu,2 Song Nie,2 Christian Rodriguez-Aguayo,2 Fangrong Shen,2 Yan Huang,2 Takeda Hisamatsu,2 Takashi Mitamura,2 Piotr L. Dorniak,2 Lingegowda S. Mangala,2 Marco Petrillo,2 Madeline Torres-Lugo,2 Karin D. Rodland,2 Anna Fagotti,2 Gabriel Lopez-Berestein,2 Chun Li3 Anil K. Sood,2 Chiba University, Chiba, Japan; 2The University of Texas MD Anderson Cancer Center, Houston, TX; 3University of Puerto Rico-Mayaguez, Mayaguez, Puerto Rico; 4Pacific Northwest National Laboratory, Richland, WA; 5Catholic University of the Sacred Heart, Rome, Italy.

Objective. Even though hyperthermia is a promising treatment for cancer, multiple obstacles remain to be cleared. Among these, the tumor temperatures that must be reached for obtaining clinical efficacy are undefined. The purpose of our study was to identify the molecular predictors of response to hyperthermia in ovarian and uterine cancers. Methods. The temperature transition in tumors during hyperthermic intraperitoneal chemotherapy (HIPEC) in ovarian cancer patients was examined. To evaluate sensitivity to hyperthermia, 10 ovarian and uterine cancer cells were treated with hyperthermia and determined median lethal temperature 50 (LT50). An integrative analysis was performed to identify molecules associated with hyperthermia resistance by comparison with gene and protein expression between hyperthermia-resistant (HTR) and -sensitive (HTS) cells. The effect of identified gene silencing on sensitization to hyperthermia and tumor growth in orthotopic models of ovarian cancers by using liposomal siRNA and local hyperthermia by NIR and CuS nanoparticles. Results. The temperature during HIPEC in human tumors was < 40°C even though the perfusion temperature at the entrance was maintained at 42.5°C. Based on LT50, we identified 5 cell lines as HTR (SKOV3, HeyA8, KLE, PEO4, and ES2; LT50 47.5 to 5 – 0.3°C) and 5 as HTS (A2780, A2780CP20, HeLa-A1, SK-KUT-2, and ISHKAWA; LT50 45.5 ± 0.2°C). Gene expression studies identified 15 genes that were highly upregulated in HTR compared with HTS cells. Proteomic analyses showed that glucose metabolism-related proteins were down-regulated in SKOV3 cells after hyperthermia. Pathway analysis indicated that FN1, SGK1, and CTGF among the 15 genes were potentially connected with glucose metabolism-related proteins. CTGF siRNA sensitized HTR cells to hyperthermia. The combination of CTGF silencing and local hyperthermia significantly inhibited tumor growth and metastasis in HeyA8 and SKOV3 orthotopic models. Conclusion. Collectively, we identified CTGF as a key target for enhancing response to hyperthermia in ovarian and uterine cancers.

#4145 Concurrent treatment with Pim kinase inhibitor decreases alternative non-homologous end-joining repair of DNA damage induced by topo-isomerase 2 inhibitors in cells with FLT3-ITD. Chashma A. Doshi,1 Pratik K. Nagaria,2 Adriana E. Troy,2 Feiyu V. Rassooll,2 Maria R. Baer1. 1University of Maryland Greenebaum Comprehensive Cancer Center and Veterans Affairs Medical Center, Baltimore, MD; 2University of Maryland Greenebaum Comprehensive Cancer Center, Baltimore, MD; 3Oncology IMED, Astrazeneca, Waltham, MA.

Purpose: Internal tandem duplication of fms-like tyrosine kinase 3 (FLT3-ITD) is a common (30%) molecular abnormality in acute myeloid leukemia (AML), associated with a high relapse rate and short disease-free survival. The oncogenic kinase Pim-1 is upregulated downstream of FLT3-ITD and contributes to its proliferative and anti-apoptotic effects. We recently showed that Pim kinase inhibition sensitizes AML cells with FLT3-ITD to apoptosis induction by topo-isomerase 2 inhibitors (TOI-2) by increasing both SSB and DSB through alternative NHEJ repair activity. Metabolic turnover of CTGF and alternative NHEJ repair activity may contribute to disease progression in AML patients with FLT3-ITD.

#4146 Selinexor synergizes with DNA damaging agents through down-regulation of key DNA damage response genes. Trinayan Kashyap, Christian Argueta, Boris Klebanov, Oscar Gonzalez, Erkan Babagol, Yusuf Landesman, Margaret Lee, Humphrey Gardner, Sharon Shacham, William Senapedia. Karyopharm Therapeutics, Newton, MA.

Background: Selinexor is a first-in-class, orally bioavailable SINE (Selective Inhibitor of Nuclear Export) compound currently in phase 1/2 clinical trials of patients with solid and hematological malignancies. SINE compounds bind exportin 1 (XPO1/CRM1) and inhibit nuclear export, resulting in nuclear retention of key DNA damage response (DDR) proteins. We previously studied the effect of Selinexor on DDR and showed enhanced anti-tumor activity when combining selinexor with standard DNA damaging agents (DDA) in pre-clinical models and clinical studies. We hypothesize that a reduction in DDR protein expression by selinexor drives the synergy observed in combination with DDAs. Methods: Solid and hematological cancer cell lysates treated with selinexor +/- DDAs (cisplatin, doxorubicin, docetaxel and gemcitabine) were analyzed by immunoblotting and qPCR. Comet assay and γH2A.X staining were analyzed by immunofluorescence to evaluate DNA damage. Mice bearing MDA-MB-231 (triple negative breast cancer) tumors were treated with sub-toxic doses of selinexor (2.5 mg/kg), cisplatin (4 mg/kg) or docetaxel (4 mg/kg) alone or in combination. Tumor growth and mouse weight were followed for 25 days. Results: Selinexor reduced the expression of DRR mRNAs and proteins involved in single-stranded (SSB) and double-stranded break (DSB) repair as early as 2 hours post treatment. We observed a dose-dependent correlation between the degree of DDR protein reduction and selinexor cytotoxicity in vitro. Selinexor prevented DDR activation following exposure to DDAs and led to synergistic cell death. Treatment of cells with selinexor plus DDA showed enhanced activity in comet assays and an increase in γH2A.X staining when compared to treatment with the single agents. Exposure to selinexor 6 - 24 hours after DDA treatment inhibited the DDR mechanism and was more synergistic than the opposite order (Sel DDA) or simultaneous treatment. In vivo, MDA-MB-231 tumor growth treatment with selinexor, docetaxel (SSB) or cisplatin (DSB) alone resulted in 66.7%, 51.5% and 26.6% TGI, respectively when compared to vehicle control whereas sequential treatment of docetaxel or cisplatin followed by selinexor resulted in 93.9% TGI or 96.6% tumor regression, respectively. No significant weight loss was seen in any of the groups by the end of the study. IHC staining and immunoblot analysis of tumor tissue and sections showed a reduction of DDR proteins. Conclusion: Selinexor synergizes with DDAs by increasing both SSB and DSB through inhibition of relevant DDR proteins. This data supports clinical development of selinexor in combination with standard chemotherapeutic agents in patients with solid and hematological malignancies. The results also suggest that sequential treatment of patients with DDAs followed by selinexor might be more beneficial.
EXPERIMENTAL AND MOLECULAR THERAPEUTICS: New Targets and New Drugs
tered tumor stem cells (TSCs) and as such are highly desirable targets for novel therapeutic strategies. Doublecortin-like Kinase 1 (DCLK1) has recently been identified as a tumor stem cell marker in the intestine and pancreas and is dysregulated in many solid tumor cancers including lung cancer. Increased expression has been demonstrated to correlate with poor survival in several tumor types. Thus, DCLK1 is a highly promising target for rational targeting of DCLK1 expressing cells in NSCLC. Methods: Small interfering RNA (siRNA) against DCLK1 was transfected into NSCLC cell lines (A549 - wt-p53; H1299 – homozygous deletion of p53) of highly drug resistant (A549) and metastatic (H1299). Cell proliferation, colony formation, self-renewal, cell migration and invasion and drug resistance assays were performed to assess the tumor stem cell characteristics. A549 cells were treated with siDCLK1 and cisplatin in order to assess the role of DCLK1 to reverse the drug-resistance. A549 cells were utilized to generate tumor xenograft in order to assess the role of DCLK1 knockdown on NSCLC tumorigenesis in vivo. The data were generated utilizing experimental protocols for clonogenic culture, immunohistochemistry, RT-qPCR and Western blotting. Results: Silencing DCLK1 via RNA interference decreased the colony formation (p<0.001), and self-renewal ability (p<0.0001) of the NSCLC cell lines in vitro. Knocking down DCLK1 reduced (p<0.0001) NSCLC cells migration and invasion in vitro. Furthermore, DCLK1 knockdown decreased the expression of EMT associated factors (Slug, Snail, Twist, Zeb1/2, Vimentin) and pluripotency factors. Initial cisplatin treatment results in the isolation of cisplatin resistant (GISO 168/M) cells. Retreatment of cisplatin resistant A549 cells results in greater resistance and survival ability. However, combination therapy of these resistance cells with siDCLK1 and cisplatin overcame cisplatin-induced resistance, resulting in greater cell death compared to cisplatin or siDCLK1 alone treatments. Nanoparticle encapsulated siDCLK1 treatment in xenograft tumors resulted in tumor growth arrest in vivo. Conclusions: NSCLC cells highly express DCLK1 display enhanced self-renewal, increased migration and invasion. Combination therapy of siDCLK1 with cisplatin overcame cisplatin induced drug resistance. Targeting DCLK1 reduced tumor xenograft in vivo. Taken together these data suggest that DCLK1 inhibition reduces TSC related properties, overcome drug resistance and inhibits tumor growth, thus making DCLK1 targeted therapy an attractive tool for combating NSCLC.

DRD2 is a G protein-coupled receptor (GPCR) that is overexpressed in many cancers, controls an array of pro-survival signaling pathways, and its antagonism causes anti-cancer effects. ONC206, the founding member of the imipridone class of compounds, is a small molecule DRD2 antagonist that is in Phase I/II advanced cancer clinical trials. In this study, we evaluated the binding target and antitumor activity of ONC206, a chemical analogue of ONC201. An orphan small molecule target prediction algorithm revealed that ONC206, like ONC201, antagonizes DRD2. Experimental GPCR profiling using the PathHunter® B-Arrestin assay, determined that ONC206 selectively antagonizes the D2-like (DRD2/3/4), but not the D1-like (DRD 1/5), subfamily of dopamine receptors. ONC206 possesses a ~10-fold increased affinity for DRD2 compared to ONC201 with a Ki of ~320nM with the selectivity that was superior to approved antipsychotics. The increased association rate for the ONC206-DRD2 interaction was responsible for the increased affinity, whereas the dissociation rate was similar to ONC201 and atypical antipsychotics that are well tolerated. TCGA analysis and immunohistochemistry of patient-derived tissue microarrays revealed DRD2 was overexpressed in neuroblastoma, sarcoma and pheochromocytoma specimens relative to normal tissues. In vitro efficacy profiling of ONC206 in the Genomic of Drug Sensitivity in Cancer collection of cell lines revealed broad efficacy across most tumor types (G15O <78-889M). Bone cancer and neuroblastoma were identified as the most ONC206-responsive solid tumor types that were comparatively less responsive to ONC201. Within bone cancer cell lines, Ewing’s sarcoma (n=16) was the most sensitive to ONC206 with a median IC50 of 168-303nM that was nearly 40-fold higher in efficacy than neuroblastoma (n=35, G15O 87-899M) including cell lines derived from metastatic sites and with MYCN amplification associated with poor prognosis. In the PC12 rat pheochromocytoma cell line ONC206 (G150 200nM) was superior to ONC201. ONC206 time-course experiments revealed anti-cancer effects occurring at 48-72 post-treatment, similar to ONC201. In support of a wide therapeutic window, ONC206 reduced the viability of normal fibroblasts (HFF-1) at relatively high doses (G150 > 5pM). Efficacy evaluations in MHH-ES-1 athymic nude mice xenografts demonstrated that ONC206 (100 mg/kg PO every 10 days) causes significant tumor growth inhibition that was comparable to methotrexate (MTX; 400 mg/kg, IP) while being better tolerated. In summary, ONC206 is an imipridone that acts as a selective antagonist of DRD2 at nanomolar concentrations and has broad-spectrum anti-tumor activity. ONC206 may address tumor types where the properties of ONC201 do not permit for complete therapeutic engagement in vivo.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Novel Mechanisms 2

#4148 Novel ERX-11 and CDK4/6 inhibitor combination therapy for treating therapy resistant breast cancer. Suryavathi Viswanadhapalli1, Ganagadha Reddy Sareddy1, Shi-Hong Ma1, Tae-Kyung Lee2, Rajeshwar Rao Tekulu1, Jung-Mo Ahn3, Ganesh Raj4, Ratna K. V. Vadlamudi5, 1UTHSCSA, San Antonio, TX; 2University of Texas Southwestern Medical Center at Dallas, Dallas, TX; 3University of Texas at Dallas, Richardson, TX.

BACKGROUND: The majority of the breast cancer is estrogen receptor alpha (ESR1) positive. While tamoxifen and letrozole therapies are effective, therapy resistance is common. Importantly, both therapy-sensitive and therapy-resistant breast cancer cells retain ESR1 signaling, via interaction with critical oncogenic co-regulator proteins. Further, resistant tumors commonly acquirecyclin D1:CDK4/6 signaling via multiple mechanisms, cyclin D1 can independently activate ESR1 and thus contribute to estrogen independence of ESR1+ tumors. Currently, CDK4/6 inhibitors in clinical trials for treating breast cancer, however, considering complex signaling interplay of estrogen and CDK axis, combination therapy of CDK inhibitor with other potent ESR1 targeted agents may have better utility and may prevent development of resistance to the CDK4/6 inhibitors. We recently developed a small organic molecule, ESR1 coregulator binding inhibitor ERX-11 (EtiRaRx-11). The objective of this study is to test the utility of novel combination therapy of ERX-11 with CDK4/6 inhibitor palbociclib in treating therapy resistant cancer. METHODS: We have utilized multiple therapy sensitive and therapy-resistant models with various genetic back-grounds. We tested efficacy using both acquired resistance and engineered models that express ESR1 mutations or oncogenes. Efficacy of combination therapy was tested using established in vitro assays including, MTT, colony formation, apoptosis, and cell cycle progression. Mechanistic studies were conducted using reporter gene assays, gene expression and signaling alterations. Xenograft studies were performed to determine the in vivo efficacy of the combination therapy. RESULTS: ERX-11 effectively blocked ESR1-mediated oncogenic signaling and has potent anti-proliferative activity against therapy-sensitive and therapy-resistant breast cancer cells. Mechanistic studies showed that ERX-11 blocks the interaction between a subset of coregulators with both native and mutant forms of ESR1. ERX-11 showed potent activity in both preclinical xenograft models and patient-derived breast tumor explant models. Co-treatment of ERX-11 with palbociclib synergistically reduced cell viability and induced apoptosis of therapy sensitive and resistant breast cancer model cells. Importantly, combination therapy of ERX-11 and the palbociclib synergistically reduced the growth and induced apoptosis of tamoxifen and letrozole resistant xenograft tumors compared to either drug alone. Mechanistic studies showed combination therapy significantly altered E2F1 and ESR1 signaling pathways and promoted apoptosis. CONCLUSIONS: Collectively our studies have discovered a novel combinational treatment with ERX-11 and palbociclib for patients with therapy-sensitive and therapy-resistant breast cancers.

#4149 Increased migration ability of osimertinib-resistant EGFR-T790M mutant non-small-cell lung cancer cells. Satoshi Kambayashi, Yasuhiro Koh, Maia Ohyama, Ayaka Tanaka, Hiroaki Akatsuka, Nahomi Tokudome, Hiroki Ueda, Nobuyuki Yamamoto. Wakayama Medical University, Wakayama, Japan.

Background: A third generation epidermal growth factor receptor (EGFR) tyrosine kinase inhibitor (TKI) osimertinib is effective against gefitinib/erlotinib-resistant non-small-cell lung cancer (NSCLC) harboring EGFR T790M mutation. Although the majority of these patients initially responds to osimertinib, they eventually develop resistance. Acquired mutations such as EGFR C797S mutation have been reported to confer resistance to osimertinib, but mechanisms of resistance to osimertinib or biological behaviors of
osimertinib-resistant NSCLC have not been fully elucidated. Materials and methods: Osimertinib-resistant PC-9/ZD/OR and PC-9/ZD/OR cells were generated after continuous exposure of gefitinib-resistant PC-9/ZD cells harboring both EGFR exon 19 deletion and T790M mutations to increasing concentrations of osimertinib. Growth-inhibitory effect of inhibitors gefitinib and osimertinib was evaluated by MTT assay. Colony formation assay was performed in/on xenograft tumor tissue that was examined by RainDrop Digital PCR System (RainDance Technologies). Immuno- blot analysis was performed to investigate the modulation of molecules relevant to EGFR signaling pathways. Cell adhesion assay, wound closure assay and transwell assay were performed to evaluate the ability of cell adhesion and migration. Results: Both PC-9/ZD/OR and PC-9/ZD/OR cells showed 50- to 120-fold resistance to osimertinib compared to parental PC-9/ZD cell lines, and acquired resistance to gefitinib as well. PC-9/ZD/OR cells maintain EGFR exon 19 deletion and T790M mutations and C797S mutation was not detected. Although phosphorylation of EGFR and ERK1/2 were inhibited by osimertinib treatment in PC-9/ZD/OR cells, phosphorylation of Akt was not inhibited. PC-9/ZD/OR cells express the elevated level of c-MET and its phosphorylated form, suggesting that bypass signaling is activated to evade EGFR pathway blockade. PC-9/ZD/OR cells also express marked level of E-cadherin which parental PC-9/ZD cells do not express. PC-9/ZD/OR cells exhibited enhanced adherent activity, cell motility and migration ability compared to PC-9/ZD cells. Notably, osimertinib treatment significantly reduced the number of migrated cells not only in PC-9/ZD cells but also in PC-9/ZD/OR cells. These results suggest that osimertinib treatment in PC-9/ZD/OR cells can overcome through c-MET pathway activation and/or induction of E-cadherin. Osimertinib treatment may be still effective to inhibit cell migration, suggesting that cell migration and cell growth are driven by different signaling pathways in PC-9/ZD/OR cells. Conclusion: c-MET overexpression was suggested to confer resistance to osimertinib and the resistant cells enhanced cell migration. Continuous osimertinib treatment may be beneficial in preventing metastasis even after the failure and involvement of c-MET and E-cadherin in osimertinib resistance should be further investigated.

#4150 Anti-tumor activity of the PI3K/mTOR pathway inhibitors albopilisib (BYL719) and everolimus (RAD001) in xenograft models of acquired resistance to CDK4-6 targeted therapy. Neil A. O’Brien,1 Dylan Conklin,1 Tong Luo,1 Raul Ayala,1 Shawnt Issakhanian,1 Ondrej Kalous,1 Erika Von Euw,1 Christie, Timothy F. Burns. 1Univ. of Pittsburgh Cancer Inst., Pittsburgh, PA

In this study, we evaluated the efficacy of a p110α-selective PI3K inhibitor, albopilisib (BYL719) and the mTORC1 specific inhibitor, everolimus (RAD001), in ER+/HER2- xenograft tumors conditioned in vitro and in vivo to acquire ADCC resistant mechanism, we established ATP6V1B1 knockout SK-BR-3. The cytotoxicity of ADCC resistant SK-BR-3 was significantly reduced as compared to control SK-BR-3 (38.7% and 67.4%, respectively). Four pathological complete response (pCR) cases after NAC and 4 non pCR cases were included. We found that non pCR cases showed significantly week expression of the ATP6V1B1-knockout SK-BR-3 were significantly reduced as compared to control SK-BR-3 (38.7% and 67.4%, respectively). To sort candidate genes for the resistance, we analyzed the gene expression profile of ADCC resistant SK-BR-3 by using DNA microarray and we focused on ATP6V1B1 gene that was significantly reduced on the resistant cells. We investigated ATP6V1B1 mRNA level of SK-BR-3 and resistant cell using real time PCR and found the 50% reduction of ATP6V1B1 mRNA level in ADCC resistant cells. To evaluate the role of ATP6V1B1 on the trastuzumab mediated ADCC resistant mechanism, we established ATP6V1B1 knockout SKBR3 by using CRISPR/Cas9 system. We cultured from small numbers of the knock out cells and expand to obtain completely knock out cells. We confirmed that the ATP6V1B1 knockout cell line was knocked out by western blotting and immunochemistry. We found that ATP6V1B1-knockout SK-BR-3 were significantly less ADCC activity as compared to control SK-BR-3 (41.2% and 12.5%, respectively). Based on the in vitro findings, we evaluated the role of ATP6V1B1 expression in HER2 positive breast cancer patients who are treated with neoadjuvant chemotherapy (NAC) containing trastuzumab. Flowcytometry before and after NAC were stained with ATP6V1B1 immunohistochemically. Four pathological complete response (pCR) cases after NAC and 4 non pCR cases were included. We found that non pCR cases showed significantly week expression of the ATP6V1B1 protein as compared to that of pCR cases. ATP6V1B1 gene is one of the isoforms of the Vacular (V)-ATPase which is located in intracellular membrane and regulate the cytosolic pH and membrane trafficking. It is hypothe- sized that ATP6V1B1 is involved in somewhere through the process of cytox- today mediated by perforin and granzymes and now we are trying to explore the mechanisms further.

#4152 The p90RSK-CD2C25 signaling pathway leads to bypass of the ganetespib induced G2/M arrest and mediates acquired resistance to ganetespib in KRAS mutant NSCLC. Suman Chatterjee, Eric H. Huang, Ian Christie, Timothy F. Burns. Univ. of Pittsburgh Cancer Inst., Pittsburgh, PA

Lung cancer is the leading cause of cancer death in the United States and worldwide. A large fraction of non-small cell lung cancers (NSCLC) are dependent upon oncogenic driver mutations of which the most commonly observed driver is mutant KRAS. Unfortunately, NSCLC patients with oncogenic KRAS mutations have no effective therapies and prognosis is poor. As direct RAS targeting has been unsuccessful in the clinic to date, use of Heat shock protein 90 (Hsp90) inhibitors in KRAS mutant NSCLC appeared to be promising approach for targeting KRAS mutant NSCLC through its downstream effectors. However, limited clinical efficacy as monotherapy was observed due to rapid resistance. Furthermore, the combination of ganetespib and docetaxel was recently tested in a large phase III clinical trial (Galaxy-2) in advanced lung cancer and failed to demonstrate benefit. Here, we investigated the mechanism(s) of resistance to the Hsp90 inhibitor (Hsp90i), ganetespib by generating NSCLC cells with acquired resistance to Hsp90i’s including ganetespib (GR cells). We have not only iden- 

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Novel Mechanisms 2
that this mechanism induces cross resistance to docetaxel. Finally, we have identified novel Hsp90 combinations that can overcome and prevent this resistance. We report that hyperactivation of ERK and p90RSK and its downstream target, CDC25C leads to acquired resistance to ganetespib and docetaxel. Moreover, this resistance is mediated via bypass of a G2/M arrest. Overexpression of either p90RSK or CDC25C in naive cells was sufficient to induce the loss of this G2/M arrest as well induced resistance to both ganetespib and docetaxel. Remarkably, p90RSK or CDC25C overexpression also led to ganetespib resistance in vivo. The observed resistance was dependent on continued p90RSK/CDC25C signaling, as synthetic lethality to specific ERK, p90RSK or CDC25C inhibitors was observed. Importantly, we have found that the combination of ganetespib with either p90RSK or CDC25C was highly efficacious. In summary, we propose that the hyperactivation of p90RSK induces CDC25C overexpression and activity which then induces G2/M progression via CyclinB1/cdc2 regulation resulting in ganetespib resistance. Despite two decades of testing in the clinic, either as monotherapy or in combination with chemotherapy, Hsp90 inhibitors have been ineffective due to acquired resistance. Our preclinical analyses provide a way forward for Hsp90 and we have developed novel rationally designed Hsp90 inhibitor combinations that may prevent or overcome resistance to Hsp90 inhibitors.

**#4153 CRISPR/Cas9-based oncoediting enables characterization of rare mutations in cancer cells.** Dennis Plenker, Martin L. Sos. University Hospital Cologne, Cologne, Germany.

In the past decade new insights into key oncogenic pathways and the development of targeted strategies enabled the success of precision medicine. However, only a small part of the cancer genome can be targetted effectively. This is in part due to the fact that the number of cancer cell models for a given oncogenic mutation is limited. We hypothesized that CRISPR/Cas9-mediated oncoediting may enhance the ability to functionally study rare genomic lesions or resistance mutations that arise in patients under therapy. As a proof of concept we established genetically modified PC9 lung cancer cells that harbor an activating EGFR ex19 deletion (EGFRdel E746-A750I) into double mutated (EGFRdel E746-A750I; T790M) or triple mutated (EGFRdel E746-A750I; T790M; C797S) EGFR in order to induce resistance against known EGFR inhibitors. These cell lines fully recapitulated the phenotypic response pattern to first and third generation EGFR inhibitors that have been observed in patients harboring these clinically relevant resistance mutations. In a next step we switched the dependency of PC9 cells from the intrinsic oncogenic EGFR mutation into a rare ex20 SVDAS mutation (EGFRdel T790M; N772I;A781V) that is typically associated with resistance towards all known EGFR inhibitors. Again, we observed a shift in the response to targeted inhibition of EGFR when compared to parental cells. Since the methodological principles can be applied to an array on known oncogenic mutations our approach may serve as a versatile platform for the functional study of highly frequent and rare mutations that are found in patients. We envision that such reprogrammed cells may be of use for the screening of novel targeted therapeutics and therefore may enable the development of mutation specific drugs that are currently lacking for the majority of patients.

**#4154 Resistance to BET inhibitors involves the β-catenin pathway in uveal melanoma.** Grazia Ambrosini, Benjamin Tycko, Chaterine Do, Gary K. Schwartz. Columbia University, New York, NY.

Uveal melanoma (UM) is an aggressive intraocular malignancy with high tendency to metastasize to the liver. Currently available drugs have shown limited clinical activity in patients with UM and there is an urgent need for new effective therapies. Recent findings from our laboratory demonstrated that UM cells are sensitive to BET inhibitors (BETi) through the induction of cell cycle arrest and apoptosis. However, despite the initial inhibitory effects, UM cells acquire resistance to this class of drugs following chronic drug exposure. In order to understand the mechanistic basis for BETi resistance in UM, we assessed genome-wide CpG methylation patterns in UM cell lines that had been rendered resistant to the clinical BET inhibitor PLX31107 (Pluxxon, Berkeley, CA) followed by chronic exposure. 2-fold loss between BET inhibitor-resistant versus sensitive cell lines revealed differential methylation of 1700 genes, including several involved in Wnt/β-catenin signaling, as well as other signaling pathways. Immunoblotting analysis confirmed that β-catenin protein was induced and activated in the resistant cells, while depletion of β-catenin by siRNA re-sensitized the resistant cells to the BET inhibitor. We then explored several combinations of PLX31107 with drugs that block β-catenin transcriptional activity through inhibition of its phosphorylation by PAK4 or through the inhibition of binding partners like Cdk8 and CBP. All these combinations increased the activity of the BET inhibitor in both sensitive and resistant cells, and these effects were synergistic, with combination indices (CI) <1. These observations support the evidence that acquired resistant to BET inhibitors is mediated, at least in part, by activation of the Wnt/β-catenin pathway, and inhibitors of this pathway may provide a means to overcome acquired BET inhibitor resistance in UM patients treated with this class of drugs.

**#4155 Crosstalk of SOX2 and epithelial-to-mesenchymal transition on EGFR-TKI resistance.** An-Chun Lee,1 Yu-Fan Chiu,1 Ming-Han Kuo,1 Yuan-Hung Wang,2 Yu-Ting Chou,1 National Tsing Hua University, HsinChu, Taiwan;2 Taipei Medical University-Shuang Ho Hospital, New Taipei City, Taiwan.

EGFR-tyrosine kinase inhibitors (TKIs) have been shown to produce profound therapeutic responses in lung adenocarcinoma harboring EGFR mutations. Despite this initial response, patients with EGFR-mutated lung adenocarcinoma ultimately developed resistance to EGFR-TKIs. Although both SOX2 and epithelial-to-mesenchymal (EMT) have been linked to the EGFR-TKI resistance in lung adenocarcinoma, the interplay between SOX2 and EMT in EGFR-TKI resistance is not known. Here, we report that cancer plasticity switched by SOX2 and EMT plays a critical role in EGFR-TKI resistance. We found that the selection of EGFR-TKI resistant cells induced EMT while attenuating SOX2 expression. We observed that EGFR-TKI treatment induced SOX2 expression in EGFR-mutated lung cancer cells, and SOX2 silencing encouraged EGFR-TKI resistance. Reselection of EGFR-mutated lung cancer cells with the EMT feature endowed cells with EGFR-TKI resistance but suppressed SOX2 expression. We found that TGF-β induced EMT but attenuated SOX2 expression, resulting in increased EGFR-TKI resistance. Pharmacological inhibition of HDACs in EGFR-mutated cells attenuated SOX2 expression but induced EMT, causing increased EGFR-TKI resistance. Enriching SOX2 expression in EGFR-mutated cells restored EMT and enhanced sensitivity to EGFRTKIs. Correlation analysis exhibited negative correlations between SOX2 and EMT markers in primary non-small cell lung cancer. Kaplan-Meier analysis revealed that a SOX2 low/Vimentin high signature predicted a poor survival in EGFR-mutated lung adenocarcinoma. Our findings support the notion that the cancer plasticity regulated by SOX2 and EMT plays a critical role in EGFR-TKI resistance, and SOX2 and Vimentin can function as prognostic biomarkers in cancer progression.

**#4156 Molecular and phenotypic characterization of breast and colorectal cancer cells selected for resistance to antibody-dependent cell-mediated cytoxicity (ADCC).** Tanaka Biswas,1 Rebecca Fritzemeier,2 Adam Mark,2 Tobias Meißner,3 Brandon Young,3 Brian-Leyland Jones,4 Mark Pegram1.

Monoclonal antibody (mAb) therapy is limited by clinical resistance. For example, alterations in PI3K/Akt / Ras-MAPK signaling, over activation/expression of alternate receptor kinases (c-Met / IGF-1R), or proteolysis of extracellular domains harboring target epitopes are postulated mechanisms of clinical resistance to trastuzumab. ADCC is a major mechanism of action for mAbs. Most studies have focused on cell models of resistance through in vitro selection, in presence of mAbs, in the absence of immune effector cells. We developed a unique model of immune selection, where target cells (HER2 +ve breast cancer cells SKBR3, BT474; and EGFR +ve colon cancer cells HT29, DLD1) were subjected to ADCC (>90% cell death) with saturating concentrations of trastuzumab or cetuximab (100 µg/ml), respectively, in the presence of peripheral blood mononuclear cells (PBMCs). Selection (in triplicate) was continued for 10 consecutive passages and surviving cells were allowed to grow to confluence over a period of 8-10 weeks. Mock-treated parent cells, IgG1 isotype control, mAb-alone and PBMCs only were utilized as controls. Compared to parent controls, immune-selected DLD1 and SKBR3 cells demonstrated statistically significant increase in proliferation (WST viability assays, P<0.01), and significantly higher colony forming efficiency (soft agar assays, P<0.001); immune-selected HT29 and SKBR3 cells showed significantly higher motility (trans-well migration assays, P<0.05, and P<0.001 respectively). In vitro ADCC assays (calcein labeling) suggested significant reduction (max 20%, P=0.005) in cell lysis in all the immune-selected cell lines compared to parent. Immune-selected HT29 cells demonstrated a 5-fold reduction in gene copy number of EGFR by fluorescence in situ hybridization (FISH), and 2.5 fold reduction in mRNA levels (qPCR, P< 0.01) and 1.8-fold reduction in protein levels of EGFR (densitometry scans, western blot analyses, p<0.01). Transcriptome-wide next-generation RNA sequencing (Illumina NextSeq 500, 2 x 75 bp pair-end, with over 100 million pair-end reads/sample), coupled with bioinformatic analyses (Reactome pathway database) revealed gene expression changes in ADCC-selected cells. These involve changes in key immune signaling pathways (e.g. HLA class I/II, MHC antigen processing, cell chemotaxis, inflammation) and immune regulatory pathways among others. Our data indicate immune-selection by effector cells contributes to ADCC resistance in vitro. Further investigation will determine whether mAb combination with an agonist antibody against CD137 (co-stimulatory NK cell receptor) or Fe-engineered mAbs (e.g. afucosylated) will...
sensitize the resistant cells. It is hoped that this will better inform mAb therapy by elucidating potentially targetable pathways/ markers that emerge from immune-selection with therapeutic mAbs.

**#4157** Co-blockade of mTORC1, ERBB and estrogen receptor signalling pathways in endocrine resistance breast cancer: Combating tumor plasticity. Ricardo Ribas,1 Sunil Pancholi,2 Stephanie K. Guest,1 Aradhana Rani,1 Joanna Nikitorowicz-Buniaik,1 Nikiana Simigdala,1 Allan Thornhill,2 Richard E. Cutler Jr,2 Alshad S. Lalan,1 Francesca Avogadri-Connors,2 Mitch Dowsett,2 Stephen R. Johnston,1 Leslie Ann Martin,1 Breast Cancer Now Toby Robins Research Centre, Institute of Cancer Research, London, United Kingdom;2 Centre, Institute of Cancer Research, London, United Kingdom; 2Centre for Cancer Drug Discovery, London, United Kingdom;2 Weifang Medical University, China;3 Sun Yat Sen University, China;4 Oregon Health & Science University, Portland, OR.

Introduction: The majority of breast cancers (BC) are estrogen (E) receptor positive (ER+). Endocrine therapies target E stimulation of tumour growth but resistance remains problematic, often a result of enhanced crosstalk between ER and growth factor pathways. Previously we reported the antiproliferative efficacy of combining everolimus (RAD001, mTORC1 inhibitor) with endocrine therapy in resistant models, but potential routes of escape from treatment via ERBB2/3 signalling were observed. We hypothesised that combined targeting of three cellular nodes (ER, ERBB and mTORC1) may target tumour rewiring and provide enhanced long-term clinical utility in endocrine resistant BCs. Methods: Several ER + BC lines adapted to long term E deprivation (LTED), modelling relapse to an aromatase inhibitor (AI), were treated in vitro with a combination of RAD001 and neratinib (pan ER inhibitor) in the presence or absence of estradiol (E2), tamoxifen or fulvestrant. Effects on proliferation, cell signalling, cell cycle and transcription were assessed. Additionally, an in vivo model of AI resistance was treated with monotherapies or combinations to evaluate efficacy in delaying tumour progression. Results: All cell lines showed dose dependent decreases in proliferation in response to RAD001 (IC50 0.6-50nM without E2; 1-10nM with E2). Neratinib showed a wide range of IC50 values in the presence of E2 (300-1000nM). In the absence of E2, wild type (wt) cell lines showed IC50 values in excess of 1800nM with hormetic response curves, whilst in the LTED ic50 values were 400-900nM. Our data suggest that in addition to either anti-ER or anti-ERBB therapies, endocrine therapy caused a concentration dependent decrease in proliferation in both wt and LTED lines but the maximum effect was observed with a triple combination of RAD001, neratinib and endocrine therapy. Expression of pS6 was suppressed by RAD001 in all cells tested, whilst neratinib caused a cell specific reduction in expression of ERBB family proteins. Upregulation of pAKT was observed in all cell lines upon treatment with RAD001. Combination of RAD001 with neratinib suppressed the upregulation of pAKT and reduced cell cycle progression. In the absence of E2, RAD001 reduced ER mediated transcription and recruitment of ER and CREB binding protein to the TFF1 promoter, contrasting with neratinib, which caused a marked increase. In vivo study using LTED tumour xenografts showed the triple combination of RAD001, neratinib and fulvestrant was the most effective at reducing tumour volume (98% at a single clinical reference lab between March 2004 and July 2006. Pt and BM data were analyzed retrospectively on 582 human LC specimens including 311 adenocarcinomas (ADCA), 131 non-small cell lung cancers (NSCLC), and 140 squamous cell carcinomas (SCCQ) resected from Pts diagnosed with primary (PD), recurrent (RD) or metastatic disease (MD), and tested at a single clinical reference lab between March 2004 and July 2006. Pt and specimen information were unlinked directly and anonymously. IVDR was determined in particular allost of Pts’ viable tumour cell suspensions after 5-day exposures to single physiologic doses of Chemo (CARBO, CML, GMCR, NVBL, TAXOL, TXTR, VP16, TOPO). IVDR was bifurcated into extreme resistance (ER, non-response) or low resistance (LR, response). Standard immunohistochemistry (IHC) was performed on the same Pts’ paraffin-embedded LC specimens. Results: Overall the sensitivity of BM to toxic ineffective Chemo. In such settings, disease progression may negatively impact a Pt’s tolerance to further Chemo. Pre-assessment of IVDR and BMs may identify ER factors, stratify treatment, and potentially improve clinical outcomes.

Aromatase inhibitors (AI) are the mainstay for treatment of postmenopausal estrogen receptor positive (ER+) primary breast cancer (BC). However, many BCs will progress to become resistant whilst retaining ER positivity. Resistance to ER targeting agents (SERD) fulvestrant has been evaluated as a potential 2nd or 3rd line therapy for patients who relapse on AI treatment. Although exhibiting promising potential, its low bioavailability has limited its use to combination therapy in metastatic patients. Here, we assessed the efficacy of the orally available SERD, RAD1901, in a panel of BC cells with varying genetic backgrounds modelling patients both sensitive and resistant to AI therapy (LTED). Fulvestrant was used in parallel to allow relative responses to be compared. Cell proliferation assays in 2D and spheroids the presence of 0.01nM 17β-estradiol showed a concentration-dependent decrease in proliferation in response to RAD1901 and fulvestrant. GI50 values for RAD1901 in general were 10-fold higher than fulvestrant but equated to doses that are clinically achievable for RAD1901. Most importantly, RAD1901 effectively suppressed proliferation of two LTED models harbouring naturally occurring ESR1 mutations, MCF7 LTEDH11001 (GI50 5nM) and SUM44-LTEDH11021 (GI50 >100nM). GI50 values of RAD1901 and fulvestrant showed similar reduction of ER, progesterone receptor (PGR) and cyclin D1 together with decreased phosphorylation of retinoblastoma (RB), concordant with cell cycle arrest. Furthermore, chromatin immunoprecipitation (ChiP) for ER in response to RAD1901 or fulvestrant showed a 70% reduction in recruitment of ER to TFF1, GREB1 and PGR promoters and concomitant reduction in mRNA expression of these genes. In MCF7-Arom cells, combination of letrozole with RAD1901 or fulvestrant showed enhanced antiproliferative effect compared to letrozole alone. The addition of RAD1901 to CDK4/6 inhibitor palbociclib or abemaciclib demonstrated additivity compared with monotherapy as addition of RAD1901 effectively inhibited growth of palbociclib-resistant MCF7 LTED cells. These preclinical findings highlight the potential utility of RAD1901 as a potent drug in the treatment of ER+ BC. Combined with its bioavailability profile, RAD1901 warrants clinical testing versus fulvestrant after relapse on an AI, either alone or in combination with a CDK4/6 inhibitor.
Increased expression of ABCB1 could be associated with osimertinib resistance in non-small cell lung cancer cell line PC9 cell. Takashi Nomizo, Hiroaki Ozasa, Takahiro Tsuji, Yuto Yasuda, Tomoko Funazo, Hiroroni Yoshida, Yuichi Sakamori, Hiroki Nagai, Young Hak Kim. Kyoto University, Kyoto, Japan.

Osimertinib, a third-generation EGFR Tyrosine kinase inhibitor, has shown promising activity in EGFR mutation positive non-small cell lung cancer (NSCLC) which harboring T790M mutation. The mechanisms of resistance to osimertinib have been still unclear. To investigate the mechanisms of acquired resistance to osimertinib, we established the osimertinib-resistant cell line (Pc9/Os) from the NSCLC cell lines PC9, and measured the expression levels of protein blocking cassette (ABC) transporters using quantitative real-time polymerase chain reaction. Expression profiling of ABC transporters revealed that the levels of ABCB1 gene expression were significantly increased in the Pc9/Osimertinib cells compared with the parental cells, but not other ABC transporters. Knockdown of ABCB1 expression using short hairpin RNA enhanced osimertinib cytotoxicity in PC9/osimertinib cells. These data suggest that increased expression of ABCB1 may have an important role in the acquired resistance to osimertinib.

Activation of aryl hydrocarbon receptor leads to resistance to targeted therapy through contextual phosphorylation of Src by Jak2 kinase. Stanam, Katherine N. Gibson-Corley, Nalini Yoshida, Jian Zhang. Xijing Hospital, Fourth Military Medical University, Xi’an, China.

The discovery of epidermal growth factor receptor (EGFR) activating mutation, antastatic lymphoma kinase (ALK) and ROS1 kinase rearrangement serve as predictive biomarkers for clinical response in non-small cell lung cancer (NSCLC) patients who receiving tyrosine kinase inhibitors (TKIs). Unfortunately, resistance to TKIs inevitably occurs within years of treatment. The emergence of resistance mutations and bypass receptor tyrosine kinase tracks have been implicated in targeted therapy resistance, however, a large proportion of patients who relapsed on TKIs do not harbor resistance mutations or additional receptor tyrosine kinase tracks. The aryl hydrocarbon receptor (AhR) is generally recognized as a transcriptional factor which encodes metabolic enzymes and mediates biochemical response to environmental xenobiotic pollutants. However, the association of AhR and sensitivity to targeted therapy has not been reported. In this study we used a high throughput approach to screen the expression of AhR target genes in NSCLC cells. qPCR and Western blot screening of a panel of NSCLC cell lines suggested that the AhR(high) cells were sensitive to EGFR TKIs, whereas the AhR(low) cells did not. Simultaneously inhibition of AhR and EGFR signaling restored the sensitivity to EGFR TKIs in the AhR(low) cells. Moreover, overexpression of AhR also led to resistance to ALK and ROS1 TKIs by restoring phosphorylation of Akt and Erk. Measurement of endogenous AhR ligand content by high performance liquid chromatography (HPLC) indicated that the patients had more kynurenine (Kyn) in their serum after disease relapse and progression. The AhR-associated targeted therapy resistance did not require its transcriptional activity because the AhRΔNLS truncated mutant also drives resistance. By using large scale shRNA screening, we showed that the non-receptor tyrosine kinase Src phosphorylated Akt and Erk and mediates AhR-associated targeted therapy resistance. Bioinformatics analysis and immunoprecipitation assay showed that Src is immediately downstream of AhR upon AhR ligands treatment through binding with the SH2 domain of AhR. The phospho-protein kinase array and in vitro kinase assay revealed that Jak2 kinase directly phosphorylated Src, in which the liganded AhR provided docking sites for Jak2 and Src interaction. Collectively, our study revealed an unexplored, transcription-independent function of AhR. The liganded AhR recruits Src and provides docking sites for Jak2-Src interaction, in which the phosphorylated Src acts as a resistance bypass track. Kyn content might be a biomarker to predict resistance to targeted therapy and targeting AhR helps to overcome resistance.

Blockade of the interleukin-1 signaling pathway overcomes erlotinib resistance in head and neck cancer cells. Andreas L. Simons, Aditya Stanam, Katherine N. Gibson-Corley. University of Iowa, Iowa City, IA.

The EGFR tyrosine kinase inhibitor erlotinib has demonstrated poor clinical response rates for head and neck squamous cell carcinoma (HNSCC) to date and the majority of respondents acquire resistance to erlotinib relatively quickly. Our previous data has shown that erlotinib activated interleukin-1 (IL-1) expression and signaling in HNSCC cells in vitro. We therefore investigated if upregulation of IL-1 signaling is involved in erlotinib resistance in HNSCC cells. We compared gene expression profiles of erlotinib-resistant (ER) and the parenteral erlotinib-sensitive (ES) HNSCC cell lines and observed a deregulation of the IL-1 signaling pathway in ER versus ES-HNSCC cells using microarray enrichment analysis. Secretion of IL-1 alpha (IL-1α) and IL-1 beta (IL-1β) were not significantly different in ER-SQ20B and ER-CAL 27 cells compared to their respective ES-cells, however secretion of the IL-1 receptor antagonist (IL-1RA) was reduced in ER compared to ES cells. Together, blockade of the IL-1 pathway with Eflivirus could overcome erlotinib resistance in HNSCC xenografts and may represent a novel strategy to overcome EGFR inhibitor resistance for the treatment of HNSCC patients.

To reduce the risk of aged associated dysfunctions and maintain the genomic stability, cells need a complex DNA repair mechanisms. Defects in this pathway or accumulation of DNA damage lead to genome instability, tumori- genesis, and aging. Chemotherapy and radiotherapy are designed to kill cancer cells by inducing DNA damage and triggering cellular ageing. Surgery followed by combined chemotherapy and radiotherapy is currently the standard therapy for glioblastoma multiforme (GBM) which is the most common primary brain tumor. TNF related apoptosis-inducing ligand (TRAIL) is promising anti-cancer agent in GBM therapy, which induces a apoptotic death in only cancerous cells, but not in normal cells. However, the mechanisms underlying TRAIL resistance in GBM have remained elusive. To understand the role of DNA damage response (DDR) mechanism and develop more effective therapeutic approaches, TRAIL resistant and sensitive T98G cells were generated. The effect of DDR proteins (H2AX (Ser319), ATM total, ATR total, CHK1 total, CHK2 total, ATM (Ser1981), ATR (Ser288), CHK1 (Ser345), CHK2 (Ser919) and 53BP1) on TRAIL resistance was detected in T98G resistant and sensitive T98G cells. These proteins showed different level of protein expressions in TRAIL resistance and sensitive T98G cells. Most remarkable difference was found in the level of phosphorylated kinase CHK2 (Ser919) with higher expression level in TRAIL resistant T98G cells than TRAIL sensitive T98G cells. Therapies that inhibit CHK2 (Ser919) levels in glioma may enhance the efficacy of TRAIL treatment. In immunofluorescence analysis, increased number of γH2AX foci was noted upon TRAIL treatment. These findings demonstrate that DNA damage signalling pathways contribute to TRAIL resistance and targeted inhibition of DNA repair factors can provide the most effective therapeutic strategies to overcome TRAIL resistance of GBMs. Moreover, the information from this study may hold answers for cancer research in future and serve as a potential suppressor for the treatment of cancer.

Some cancers evade targeted therapies through a mechanism known as lineage plasticity, whereby tumor cells acquire phenotypic characteristics of a cell lineage whose survival no longer depends on the drug target. Here we show, using in vitro and in vivo prostate cancer models, that these tumors can develop resistance to the antiangiogenesis drug enalaprilat by a phenotypic shift from androgen receptor (AR) dependent luminal epithelial cells to AR independent basal-like cells. This lineage plasticity is enabled by loss of TP53 and RB1 function, is mediated by increased expression of the reprogramming transcription factor SOX2 and can be reversed by restoring TP53 and RB1 function or by inhibiting SOX2 expression. Thus, mutations in tumor suppressor genes can create a state of increased cellular plasticity that, when challenged with antiandrogen therapy, promotes resistance through lineage switching.

Role of CD44 as a regulator of adaptive plasticity in pancreatic cancer cells. Chen Chen, Shujie Zhao, Xiangru Zhao, James W. Freeman. University of Texas Health Science Center, San Antonio, TX.
Purpose: Patients with pancreatic ductal adenocarcinoma (PDAC) may show an initial objective response to chemotherapy that is usually of short duration. Our research goal is to understand the molecular mechanisms for this short duration response and to more fully define differences between chemosensitive and chemoresistant cells. Cancer cells that undergo an EMT and metastatic tumor cell growth in CD44-expressing PDAC. Here, we used CD44 Low and CD44 High isogenic cell models to identify key molecular networks and potential targets that could benefit therapy. Experiments design: CFPAC1-CD44 Hi and Low cells were sorted by flowcytometry and single clone selection. Isogenic model systems were generated by overexpression CD44s in CF-Low cells. Western blot, MTT, migration and invasion assays had been used to characterize cell growth, invasiveness and gemcitabine sensitivity. Receptor Tyrosine Kinase arrays were used to identify the CD44 regulated molecular networks in these isogenic cell models treated with/without CD44 ligand hyaluronic acid (HA). Summary: CD44 high cells show an EMT phenotype (increase of vimentin and loss of E-cadherin) and increase invasion. Expression of CD44s in CD44 low cells was sufficient to drive EMT partially and drive invasion. By in vitro testing over expressing CD44s is not sufficient to decrease sensitivity to gemcitabine. By Receptor Tyrosine Kinase arrays, CD44 Hi clone cells show increase in IGF-1R phosphorylation. Preliminary data had shown that HA may stimulate ROR2, VEGFR1, and EphB2 phosphorylation in CD44 Hi clone cells. Conclusion: Our previous study suggested that CD44 could be a therapeutic target in Gmciatamist resistant PDAC cells. The current study will further pursue this target in other disease settings. These newly identified targets could be hopefully used for the optimized multimodality therapy to sensitize the PDAC cells to therapy and to benefit the pancreatic cancer patients.

#4167 Co-targeting the stress survival proteins LEDGF/p75 and clusterin to sensitize chemoresistant prostate cancer cells to docetaxel. Christina K. Cajigas-Du Ross, Leslimar Rios-Colon, Leanne Woods-Burnham, Carlos A. Càano. Loma Linda University School of Medicine, Loma Linda, CA.

Prostate cancer (PCa) is the most commonly diagnosed male cancer and the second leading cause of cancer deaths in U.S. men. Late-stage PCa is characterized by metastasis followed by castration resistant PCa (mCRPC), for which there is no cure. Docetaxel (DTX) is the first-line chemotherapeutic drug for late-stage PCa, and resistance to this drug is inevitable. Our group has previously reported the elevated expression of the stress oncoprotein lens epithelium-derived growth factor (LEDGF/p75) in PCa cells and tissues, and this upregulation promotes resistance to DTX-induced non-apoptotic lysosomal cell death. Another stress oncoprotein, clusterin (CLU), is also upregulated in DTX-resistant PCa, and protects cells from DTX-induced mitochondrial-triggered apoptosis. In this study we observed that targeting LEDGF/p75 with siRNAs partially resensitized DTX-resistant (DR) mCRPC cell lines to DTX treatment in clonogenic assays. Similarly, other groups have shown that knockdown of CLU in mCRPC-DR cells resensitizes them to treatment with taxanes. However, recent clinical trials targeting CLU have not been effective, suggesting that blocking this protein alone is insufficient to overcome DTX resistance. We hypothesized that simultaneous knockdown or inhibition of both LEDGF/p75 and CLU could be more effective in resensitizing chemoresistant PCa cells to taxane therapy than targeting each protein alone. Because of DTX/p75’s role as a stress transcription co-activator, we first sought to determine if this protein contributes to CLU expression by performing siRNA-mediated knockdown of LEDGF/p75 on the taxane-sensitive and -resistant mCRPC cell lines PC3 and DU145. Western blotting revealed that CLU protein expression was not downregulated by LEDGF/p75 knockdown, compared to treatment with scrambled siRNA control. Similarly, CLU knockdown in these cell lines did not downregulate LEDGF/p75. These results indicated that CLU expression is independent of LEDGF/p75, consistent with previous observations that these two proteins promote chemoresistance via distinct, possibly redundant, mechanisms. We then performed siRNA-mediated knockdown of both LEDGF/p75 and CLU, separately or together, in PC3 DR and DU145 DR cells, in the presence and absence of varying concentrations of DTX. MTT and clonogenic assays were used to determine cell death viability and clonogenicity, respectively. Simultaneous knockdown of LEDGF/p75 and CLU, in combination with DTX treatment, resulted in increased sensitization to DTX than single knockdown of each protein. These findings show an additive effect of targeting LEDGF/p75 and CLU, separate or together, in taxane-resistant PCa cells to DTX treatment. This study suggests that targeting both LEDGF/p75 and CLU could sensitize prostate cancer cells to DTX treatment.

#4168 Altering cisplatin sensitivity by manipulating the cellular metalome. Lauren Amable, Eric Shide. NIH-NIMHD, Bethesda, MD.

The cellular metalome serves as an important reservoir to meet the biological needs of the cell, serving as enzyme co-factors and ensuring proper protein folding. Recent studies have suggested that cancer cells adapt their metalome in order to accommodate rapid cellular growth and metabolism pathways. Thus, altering the cancer metalome may yield new avenues to target cancer and metastasis. Therefore, we explored the sensitivity of human PCa cell lines to cisplatin, to understand how changes in the ovarian cancer metalome affect sensitivity to the chemotherapy drug cisplatin. Five ovarian cancer cell lines were used in experiments: A2780, A2780/CP70, SKOV3, OVCA3, and CAOV3. The metalome was manipulated by treating cells with either zinc, copper, magnesium, calcium, iron, manganese, or the metal chelator tetrathiomolybdate. Cisplatin sensitivity was confirmed by WST-1 cell proliferation assays. Metalome perturbations were quantitated by Inductively Coupled Plasma-Mass Spectrometry (ICP-MS) by measuring the following metals: zinc, copper, magnesium, calcium, molybdenum, manganese, iron, phosphorous, and sulfur. Cellular metal concentrations were normalized to sulfur levels. Changes in cisplatin sensitivity were evaluated by measuring cellular cisplatin uptake by ICP-MS. Treatment of ovarian cancer cells with various metals resulted in differences in cellular proliferation and metalome composition. The changes in the metalome were not singular in nature because altering one metal resulted in changes in multiple metals. Cisplatin sensitivity was additionally affected under different metal treatments. Preliminary data suggest that cisplatin uptake was altered as a mechanism to mediate the cellular response to cisplatin, however other mechanisms may also be involved. We conclude that the act as an independent or synergistic mechanism to change the metalome and thus the cell’s sensitivity to cisplatin.

#4169 A novel, short isoform of the +Tip microtubule binding protein CLIP170 confers taxane resistance in gastric cancer. Prashant V. Thakkar, Katsuhito Kita, Giuseppe Galletti, Kyle Cleveland, Isabel Barasoain, Jose Fernando Diaz, Manish A. Shah, Paraskevi Giannakakou. 1Weill Cornell Medicine, New York, NY; 2Centro de Investigaciones Biológicas, Madrid, Spain.

The microtubule (MT) cytoskeleton is one of the most validated therapeutic targets in clinical oncology, as evidenced by the wide clinical activity of taxanes and other MT inhibitors. However, patients with intrinsic drug resistance do not benefit from taxane chemotherapy, such as patients with diffuse gastric cancer (GC). Currently, the molecular mechanisms underlying clinical taxane resistance remain poorly elucidated. Using a panel of GC cell lines with intrinsic sensitivity or resistance to taxanes, we showed lack of drug-target engagement in the resistant lines, despite unimpaired intracellular accumulation of the drug and in the absence of tubulin mutations or altered tubulin isotype expression. Herein, we report the first MT plus-end binding protein, CLIP170 (CLIP), that can confer taxane resistance. We show for the first time that taxane-resistant cells express a novel, short isoform of the MT plus-end binding protein, CLIP170 (CLIP1). CLIP1 binds to the plus-ends of microtubules (+TIPs) and regulates dynein-mediated MT-based trafficking and the tubulin tyrosination cycle. We showed by mass spectrometics and 5′-RACE that the short CLIP1 isoform (CLIP1S) lacks the first 150 amino acids, thus, missing the first Cal-Gly (Cytoskeleton-Associated Protein-Glycine) domain, which is required for proper +TIP localization. Indeed, confocal microscopy experiments showed that CLIP1S was mislocalized to the microtubule lattice in contrast to the canonical comet-like pattern of CLIP1 seen in taxane sensitive cell lines. CLIP1S expression was specifically correlated with taxane resistance (docetaxel, cabazitaxel) as no correlation was observed with other DNA-damage agents. Since, CLIP1S expression has never been reported before, to establish causation, we stably knocked down CLIP1 and CLIP1S in taxane-sensitive and resistant cells, respectively. CLIP1S KD entirely reversed taxane resistance (~300 fold) while CLIP1 KD had no effect in the taxane-sensitive cell lines. These data suggest a gain-of-function of CLIP1S that leads to taxane resistance. To study the binding kinetics of taxanes to MTs in the presence or absence of CLIP1S we performed live cell imaging of native cytoplasmic MTs labeled with Cy3-fluorescently labeled Flutax. FLUTAX binding showed significantly faster dissociation rates of Flutax from MTs in the resistant cells, indicating transient interaction with MTs. Taxane binding to MTs is a two-step process. First taxanes bind to the MT-pore low affinity surface site, which then facilitates access to the high affinity luminal site. Using a small molecule that binds only to MT-pore site, we showed that we showed that taxol binding to the MT-pore is significantly slower in resistant cells expressing CLIP1S, which together with mislocalization of this variant along the MT lattice suggests that it obstructs access to the MT-pore thus restricting entry of taxane into the lumen of microtubules. This finding will have profound implications for taxane resistance as well as microtubule biology broadly.
#4170 Targeting androgen receptor overcomes resistance to tyrosine kinase nase inhibitors in advanced clear cell renal cell carcinoma. Remi A. Remadi-Ogala, 1 Sreenivasulu Chintala, 1 Ashley Orrillon, 2 May Elbanna, 3 Ben Elsey, 3 Nur Damayanti, 1 Kiersten M. Miles, 4 Chinghai Kao, 5 Piergiorgio Pettazzoni, 6 Giulio F. Draetta, 7 Roberto Pili, 8 Indiana University School of Medicine, Indiana- napolis, IN; 2J. Marcius Gillespie Cancer Institute, Buffalo, NY; 4The University of Texas, MD Anderson Cancer Center, Houston, TX.

Background: Advanced renal cell carcinoma (RCC) responds initially to antiangiogenic therapies but eventually develop resistance which may be driven by the expression of key intratumoral pro-survival protein and overall kinome reprogramming. Androgen receptor (AR) expression has been reported in clear cell renal cell carcinoma (ccRCC) but its biological role remains unclear. A correlation association with resistance to tyrosine kinase inhibitors (TKIs) has not been studied. Here we report the role of AR and its association with resistance to TKIs in advanced RCC.

Methods: Human RCC cell lines; 786-0, 786-0R (with induced tumor resistance), ACHN, U87 and (with intrinsic tumor resistance) were used to assess the combination effect of sunitinib and the AR antagonist enzalutamide in vitro. In vivo studies using 786-0 tumors assessed the combination effect of enzalutamide and sunitinib following acquired resistance to sunitinib. AR expression was determined by qRT-PCR and Western blot analysis, and AR localization by immunofluorescence in treated and non-treated cells. Gene array was used to assess 93 AR associated genes in sensitive and resistant cells. Results: Quantitative RT-PCR data revealed a significant increase in AR expression with sunitinib resistant cells compared to controls p < 0.0001. Immunofluorescence in vivo studies showed a significant increase in nuclear and cytoplasmic expression of AR with sunitinib treatment in resistant cells which was abrogated with single agent enzalutamide and combination treatment. More interestingly, combination treatment of enzalutamide and sunitinib significantly decreased cell growth and induced tumor regression in vitro and in vivo, respectively. Conclusion: Our data suggest the role of AR both in intrinsic and acquired enzalutamide resistance in ccRCC and provide a rationale for combination strategies to restore TKI sensitivity that can be tested in the clinical setting.

#4171 Combined AXL/FN14 inhibition sensitizes drug-resistant NSCLC in vitro and in vivo. Dhananjay Suresh, 1 Ajit Zambre, 1 Soumava Mukherjee, 1 Shreya Ghoshdasidhar, 2 Jennifer L. Schnabel, 2 Sarah Chapman, 3 W. Matthew Levey, 1 Anandhi Upendran, 1 Raghuraman Kannan. 1 University of Missouri, Columbia, MO; 2University of Notre Dame, Notre Dame, IN.

Lung cancer is the number one cause of cancer-related deaths in both men and women with a median survival time of 8-10 months post-treatment. Non-Small Cell Lung Cancer (NSCLC) accounts for 80% of the lung cancers and the treatment plan is determined based on the active mutations (EGFR, ALK/ROS, and KRAS) present in the tumor. Patients bearing EGFR mutation initially respond to targeted tyrosine kinase inhibitor (TKI) therapy and after 8-14 months of treatment acquire TKI resistance. Some NSCLC patients with median progression-free survival (PFS) is 2 months. A subpopulation of NSCLC patients with KRAS mutations is only 9.5 months. The reason for this acquired drug resistance is not yet fully understood. Recent studies have reported oncogenes such as AXL could be responsible for TKI resistance. Therefore, understanding the mechanism of drug resistance is key in developing a solution to overcome the problem. For this study, we first examined the resistance mechanism and developed a biodegradable targeted nano-particle based solution to systematically investigate the role of AXL in resistant NSCLC cell lines. In this study we (1) downregulated AXL using siRNA and separately (2) knocked out the AXL gene using cRNA (CRISPR) and treated with TKI. Our results show that AXL is responsible for activation of several EMT related proteins and upregulation of mTOR pathway. We believe the upregulation of these proteins is essential for cancer cells to switch pathways for proliferation and regulating miRNAs linked to mutations. Our results further confirm that AXL is responsible for regulating MMP-2 that is associated with cell invasion. Based on data from multiple cell lines such as H820 and A549, we demonstrate that AXL upregulation is responsible for resistance independent of EGFR activating mutations. The elucidated pathway for drug resistance was further confirmed in cell lines generated by knocking-out the AXL gene. Interpretation for AXL signaling and drug resensitization was confirmed by Western blotting, Zonography, Invasion Migration and Apoptosis assay and MTI toxicity assay. We performed mRNA and miRNA analysis using qRT-PCR to understand gene expression post treatment. During the process of our investigation, we found that NSCLC cells undergo further survival cross talk with other biomarkers. Indeed, we report the first experimental evidence of a survival cross talk between AXL and FN14, a wound healing gene, that enhance cell survival post treatment. Down regulation of both AXL and FN14 dramatically reduced the IC50 of TKI. Based on the mechanism, we designed a gelatin nanoparticle that can carry both AXL and FN14 to deliver it in the tumor cell. The nanoparticle is targeted to tumor using EGFR-antibody and releases the silencing RNA within cytoplasm. We further demonstrated that dual-inhibition of AXL and FN14 in A549 mice xenografts showed tumor reduction compared to controls. In conclusion, inhibition of AXL and FN14 can maximize therapeutic response of TKI, wherein AXL is upregulated before or during drug treatment.

#4172 Activation of AR signaling by mifepristone enhances prostate cancer growth and improves enzalutamide response. Haiyin Zhou, Nadine Jacban, Malikka Singh, Chris Tran, Dan McWeeny, Minna Balbas, Emily Schenken, Tatiana Zovorotinskaya, Erica L. Jackson, Julio Medina, Dong Sun, Yousup Rew, Xiaohui Du, John Eksterowicz, Xueyi Yan, Liusheng Zhu, Qiuiping Ye, Valeria Fantin. ORIC Pharmaceuticals, South San Francisco, CA.

Androgen receptor (AR) signaling is crucial for normal development and homeostasis of the prostate, and is a key driver of prostate cancer initiation and progression. Hormone therapies that deprive the cancer of androgen have long been a mainstay of prostate cancer treatment. More recently, anti-androgens, such as abiraterone and enzalutamide, have been approved for use in metastatic castration resistant prostate cancer (mCRPC). Evidence also suggests that AR may play an oncogenic role in certain breast cancers. Several recent publications have demonstrated that activation of the Glucocorticoid Receptor (GR) can confer resistance to enzalutamide, and GR has also been shown to provide protection from conventional chemotherapies in other solid tumor indications. Mifepristone, is a synthetic steroidal antagonist of progesterone receptor, and to a lesser extent of GR and AR. It is currently being tested in clinical trials in combination with enzalutamide in mCRPC, and in combination with chemotherapy in triple negative breast cancer (TNBC). We sought to characterize the effect of mifepristone in pre-clinical models of prostate and breast cancer. Here we show that mifepristone significantly reduces the efficacy of enzalutamide in the xenograft models. Moreover, when given in combination, mifepristone significantly reduces the efficacy of enzalutamide in the LN-AR xenograft model. We are currently assessing the effects of mifepristone treatment in TNBC. Our findings suggest that partial AR agonist activity of mifepristone may have a negative impact in prostate and other AR positive cancers. We have developed a GR antagonist that is devoid of AR agonism to circumvent undesired effects on proliferation and drug resistance.
#4174 The impact of catechol estrogen metabolism on the proliferation rate and Docetaxel (DOC) resistance in hormone-responsive cancers. Mai F. Tolba,1 Hany Omar,2 Ayman M. Noreddin,2. 1Am Shams University, Cairo, Egypt; 2University of Sharjah, Sharjah, United Arab Emirates.

Estrogen-responsive cancers such as breast cancer (BC) and prostate cancer (PC) represent the most prevalent cancers in many countries, and they are treated in USA. Docetaxel (DOC) is considered the first-line therapy for both metastatic BC and castration-resistant PC. However, its use in therapeutically effective doses is associated with significant toxic reactions and tumor resistance. Estrogens (E2) play an important role in the development and progression of both malignancies. Of special importance is that the catechol E2 metabolite, 4-hydroxyestradiol (4-OHE2) enhances the proliferation of both breast and prostate normal epithelial cells. The goal of this work is to investigate the relationship between catechol-E2 metabolism and cancer cells proliferation and response to DOC. Methods: The cells were exposed to serial concentrations of E2 and 4-OHE2 (0.001-10 μM) to assess their effect on cells’ growth rate over 24-92 h. Cell proliferation assays were utilized to assess the density of viable cells at different time points. Cytotoxicity assays were performed to evaluate the median inhibitory concentration (IC50) of DOC alone or in the presence of 4-OHE2. Results: Exposure of the estrogen receptor (ER)-positive BC cell line MCF-7 to 0.1 μM of 17-β-hydroxyestradiol (E2) for 3 days significantly boosted the cell proliferation rate compared to control group by about 27% (P<0.05). Exposure of MCF-7 cells to the catechol estrogen metabolite, 4-hydroxyestradiol (4OHE2) for 3 days significantly enhanced cell growth by about 31% (P<0.001). Similarly, exposure of the androgen-resistant, ER-positive, advanced stage prostate cancer cell PC3 to E2 (1 μM, 3 days) significantly enhanced the growth rate by 37% (P<0.05). Moreover, our data showed that simultaneous exposure to 4OHE2 significantly antagonized the cytotoxic activity of DOC with subsequent increase in the IC50 of DOC by 18 folds (P<0.05) for 3 days and 0.006 for 18 folds (P<0.006). Conclusion: these results indicate that altered E2 metabolism with subsequent accumulation of 4-OHE2 can enhance the proliferation rate of ER-sensitive cancers in addition to hindering the cytotoxic activity of DOC with subsequent reduction in DOC potency. Future research is in progress to assess the potential merit of modulating the clearance of catechol E2 as a strategy to improve the cancer response to DOC. (This project is supported by Fulbright Scholar grant FY15/16 and L'Oreal-UNESCO for Women in Science-Levant and Egypt award for MFT). 

#4175 Targeting of a mesenchymal profile in order to sensitize multitherapy resistant glioblastoma clones. Mia Niklasson, Malin Jarvius, Caroline Haglund, Ethfymia Chantzii, Tobias Bergström, Frida Nyberg, Annika Hermansson, Mårten Fryknäs, Mats Gustafsson, Bo Segerman, Rolf Larsson, Bengt Westermark, Anna Segerman. Uppsala Universitet, Uppsala, Sweden.

The overall aim of this study was to find ways to sensitize treatment resistant glioblastoma (GBM) cell cultures to conventional therapeutic regimens. GBM is substantial in glioblastoma multiforme (GBM) and through establishment of clinical GIC cultures from patient biopsies we have demonstrated a wide variety in the responses to drugs and radiation. A mutlitherapy resistance phenotype was linked to pronuclear-mesenchymal transition (PMT) in the transcriptome. The variety in therapy response was observed as a continuum of phenotypes. The distribution of phenotypes resembled a normal distribution and mutlitherapy resistance was associated with low DNA methylation grade in promoter regions of mesenchymal master regulators (FOSL2, RUNX1). Our data thus implied that the transition is bi-directional and epigenetically regulated (Segerman et al, Cell Reports - accepted in principle). To investigate if spontaneous changes in drug and radiation response occur, we have derived subclones from a resistant clone. Both subclones with higher and lower therapy resistance than the parental clone were generated. Also molecularly the subclones largely reconstituted the original clonal variation. PMT shows similarities to epithelial-mesenchymal transition (EMT), which is induced by extrinsic factors. We therefore specifically analyzed the gene expression data for signaling receptors differentially expressed in resistant vs. sensitive cells (4-OHE2). We are currently focusing on identifying combinations of drugs (and antibodies) that sensitize resistant clones to conventional treatment through modulation of cell signaling patterns. In the initial screen temozolomide (TMZ) response is used as an indicator of achieved sensitization. The strategy is to iteratively combine primarily antagonists of signaling receptors connected to resistance. We are also exploring the effect of stimulating pathways with apparently higher activity in sensitive clones (e.g. addition of ligands). The concept of sensitizing glioma and other types of cancer cells by targeting the mesenchymal character through usage of e.g. signaling receptor inhibitors is not new and has shown promising results. In conclusion, our data show that multitherapy resistance is connected to a plastic cell-state. Also, receptors and ligands that are differentially expressed in resistant and sensitive clones engage pathways regulating EMT.

#4176 Targeting TAM family members with antibody or small molecule inhibitors enhances therapeutic modalities of HNSCC. Nellie K. Black, Mari Iida, Tamara S. Rodems, Toni M. Brand, Randall J. Kimple, Deric L. Wheeler. UW-Madison, Madison, WI.

Radiation, cisplatin, and cetuximab are clinical therapeutics used in the treatment of head and neck squamous cell carcinoma (HNSCC). Despite clinical success with these modalities, development of both intrinsic and acquired resistance is an emerging problem in the management of HNSCC. Thus, identifying and targeting molecules driving this drug resistance is essential for improving efficacy of treatment approaches. Recent studies have identified a role for the TAM family of receptor tyrosine kinases (Tyro, Axl, and Mer) in tumor biology, especially the Axl receptor in promoting tumor growth and metastasis. Previously, we identified Axl as a logical molecular target in HNSCC and indicated that it may play a pivotal role in resistance to radiation, cisplatin, and cetuximab. In the current study, we advanced these early findings into pre-clinical models using patient-derived xenografts (PDXx). We have shown that molecules targeting Axl can enhance therapy in PDXx that express high levels of Axl and have been identified as resistant to radiation, cisplatin, and cetuximab. Current studies are focusing on antibody-based targeting of Axl using PDXx and genetically-modified models of resistance. Furthermore, studies focused on co-targeting of Axl and Mer in vitro and in vivo have shown striking results and denote the importance of establishing logical approaches to target TAM in the management of HNSCC. Finally, investigations into the molecular mechanisms of how Axl signaling can lead to resistance have underscored the importance of tyrosine 821 (Y821) of Axl. Overexpression of Axl rendered cetuximab sensitive lines resistant, but cell lines overexpressing Axl-Y821F retained their sensitivity to cetuximab. Advancing this line of study in vivo indicated that tumors expressing Axl were resistant to cetuximab whereas tumors harboring the Y821F mutation were sensitive demonstrating that signals emanating from Y821 may be critical for cetuximab resistant pathways. Collectively, the studies presented herein identify the TAM family of receptors as key players in radiation, cisplatin, and cetuximab resistance. These results provide rationale for the clinical targeting of TAM receptors to enhance the therapeutic modalities used in treating HNSCC.

#4177 Anticancer agent Aminoflavone restores the expression of tumor suppressor miRNA 26a and inhibits putative stemness biomarker α6-integrin in Tamoxifen resistant cells. Petrenea Campbell,1 Leah Rowland,2 Anna Opoku-Agyeman,3 Nichole Mavingire,4 Ubaldó Soto,5 Gayathri Nagaraj,1 Yonghong Zhang,1 Sean (Xin) Chen,1 Charles Wang,1 Eileen Brantley1. 1Loma Linda University, Loma Linda, CA; 2University of Maryland, Baltimore, MD.

Despite the efficacy of anti-estrogen agent Tamoxifen, commonly used to treat patients with estrogen receptor positive (ER+ ) tumors, up to 40% of patients experience recurrence. Breast tumor-initiating cells (TICs), or breast cancer stem cells, exhibit Tamoxifen resistance and contribute substantially to recurrence. We recently demonstrated that investigational anticancer agent Aminoflavone (AF) disrupts mammospheres (in vitro cultures of cells enriched with TICs) by thwarting the expression of α6-integrin. In the current study, we found AF potently inhibited Tamoxifen resistant (TamR) cell growth and blocked Tamoxifen-mediated stimulation of TamR cell proliferation using the Alamar Blue assay. qPCR analyses revealed α6-integrin expression was significantly elevated in ER+ breast cancer cell models of acquired and de novo Tamoxifen resistance relative to Tamoxifen sensitive cells. In particular, AF decreased the expression of both A and B variants of α6-integrin, the B variant being essential for TIC function. Western blotting revealed AF reduced total α6-integrin expression in TamR cells. Furthermore, we found that an α6-integrin blocking antibody sensitized TamR cells to the active Tamoxifen metabolite, 4-hydroxy-Tamoxifen, and enhanced the efficacy of AF in these cells. AF also reduced the protein expression of p-Src, a downstream target of α6-integrin that is linked to Tamoxifen resistance and decreased breast cancer survival. In addition, miRNA sequencing of Tamoxifen sensitive and TamR mammospheres revealed differential expression of several miRNAs. Notably, miR-26a expression was down-regulated 2-fold in TamR mammospheres compared
to Tamoxifen sensitive mammmospheres and AF restored miR-26a expression 5-fold in TamiR mammmospheres. Using miRNA target prediction algorithms TargetScan and PicTar, we found miR-26a binding sites on the o6-integrin promoter. Taken together, our data suggest that AF re-expresses tumor suppressor miR-26a and inhibits the o6-integrin/Src signaling axis to reduce TIC capacity and counteract Tamoxifen resistance.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Targeting Protein Kinases and DNA Repair

Introduction: CYC140 is a selective and potent ATP-competitive inhibitor of PLK1, which has completed IND-enabling studies. The aim of this translational project was to inform the clinical development path of CYC140. Esophageal cancer was investigated as a potential target indication based on unmet medical need and the observation that PLK1 is frequently overexpressed in esophageal tumors and carries a poor prognosis. Experimental procedures: The anticancer activity of CYC140 was examined across multiple tumor types to identify sensitive target indications or tumor subsets. 6 h pulse exposure to CYC140 was used to determine sensitivity in a panel of over 250 cancer cell lines including 15 esophageal cancer cell lines, using CellTiter Glo and resazurin-based assays. Candidate pharmacodynamic markers were examined in malignant and non-malignant cells. Drug combination testing was undertaken in several esophageal cell lines using approved and targeted agents. Solid tumor and leukemia xenograft models were performed to assess CYC140 dosing schedules and efficacy. Summary: Inhibition of PLK1 by CYC140 perturbs the entry into and exit from mitosis. In malignant cells, CYC140 treatment leads to the appearance of mitotic cells with monopolar spindles and a persistent activation of CYC140 on pharmacodynamic markers of PLK-1 activity such as phospho-nucleoskeleton (NBS1, 53BP1) and phospho-histone H3. The effect of CYC140 on pharmacodynamic markers of PLK-1 activity such as phospho-nucleoskeleton and phospho-histone H3 was characterized in malignant and non-malignant cells. Several promising combinations of CYC140 with targeted agents were identified, including EGFR inhibitors, HDAC inhibitors and PI3K pathway inhibitors, and CYC140 can also be combined with cytotoxic agents approved for use in esophageal cancer, such as cisplatin or irinotecan. CYC140 anti-cancer efficacy was demonstrated in solid tumor and leukemia xenograft models with responses including tumor regression and tumor-free cures. Conclusions: CYC140 is a promising anti-cancer agent with potent anti-proliferative activity and therapeutic potential in a variety of cancers, including esophageal cancer and acute leukemia. The mode of action of CYC140 is consistent with PLK1 inhibition and cell death is preferentially triggered in sensitive malignant cells. Suitable pharmacodynamic markers and several promising combinations have been identified that could assist clinical development of CYC140.

#4179 Potent and selective TRK inhibitor CH7057288. Hiroshi Tanaka,1 Hitoshi Sase,1 Toshiyuki Tsukaguchi,2 Hiromi Tanimura,1 Masami Hasegawa,1 Kiyoshi Hasegawa,1 Yoshiyuki Ono,1 Nobuhiro Oikawa,1 Hiroshi Sakamoto,1 Toshiyuki Mio1,1 Chugai Pharmaceutical Co., Ltd., Kamakura, Japan;2 Chugai Research Institute for Medical Science, Inc., Kamakura, Japan.

TRK receptor tyrosine kinases are expressed as fusion proteins encoded by various fusion genes across a wide variety of cancer types, including lung and colorectal cancer. These fusion proteins have potent oncogenic activity and are thought to be an attractive therapeutic target. In a kinase inhibitor screening we identified CH7057288, a potent and selective TRK inhibitor belonging to a novel chemical class. Our inhibitor showed selective inhibitory activity against TRKA, TRKB, and TRKC in cell-free kinase assays and suppressed proliferation of TRK fusion-positive cell lines, but not that of TRK-negative cell lines. In subcutaneously implanted xenograft models of TRK fusion-positive cells, strong tumor growth inhibition was observed. Furthermore, CH7057288 induced regression of intracranial tumors and greatly improved event-free survival in an intracranial implantation model mimicking brain metastasis. Recently, resistant mutations in TRK have been reported in patients showing disease progression after treatment with a TRK inhibitor under clinical development. Our compound maintained similar levels of in vitro and in vivo activity against some of the resistant mutants as it did to wildtype TRK. In summary, CH7057288 could be a promising therapeutic agent for TRK fusion-positive cancer.

#4180 RS-41, a multi-targeted kinase inhibitor, induces cell cycle arrest and apoptosis in p53 mutant and wild type models of upper gastrointestinal cancers. Tanvi Visal,1 Shraddha Patil,1 Priya Pancholi,1 Samhita Bapat,1 Amruta Samant,2 Dhvanir Kansara,1 Sonali Kurup,2 Vikas Sehdev1. 1 Long Island Univ., Brooklyn, NY; 2 Rochester University, Schausburg, IL.

Introduction: Upper Gastrointestinal Cancers (UGCs) are a leading cause of cancer-related mortality and account for approximately 1.1 million deaths worldwide. UGCs respond poorly to conventional chemotherapy due to constitutive activity of multiple oncogenic signaling mechanisms, including the epidermal growth factor receptor (EGFR), ERBB2/HER-2, Aurora kinases, and JAK-STAT pathways. In addition, presence of mutant p53 further imparts resistance to conventional chemotherapeutic agents. Therefore, novel small molecule inhibitors that target multiple kinases associated with oncogenic progression could pave the way for improved chemotherapy and better therapeutic outcomes. In this study, we characterized the anticancer activity of RS-41, an investigational 4-phenylbenzamidopyrrole[2,3-d]-pyrimidin-4-amine multi-kinase inhibitor, in p53 mutant and wild type models of UGC. Method: Target kinase inhibition and selection screening assays were performed to determine potency and selectivity of kinase inhibition for RS-41. In addition, MITT-cell viability assay, clonogenic cell survival assay, cell cycle analyses, and western blot analyses were done to evaluate the effect of RS-41 treatment on cell viability, survival, cell cycle progression, and expression of apoptotic markers in p53 mutant and wild type models of UGC. Results: The kinase selectivity screening assay characterized RS-41 for its selectivity against a panel of 90 human kinases. The kinase screening analyses showed that RS-41 selectively inhibits AURKA (IC50: 0.96 ± 0.03 μM), JAK2 (IC50: 1.21 ± 0.17 μM), and EGFR (IC50: 5.92 ± 0.75 μM) kinases, respectively. The cell viability data indicate that treatment with RS-41 mediates significant (P ≤0.05) inhibition of p53 mutant and p53 wild type (AGS) UGC cells, respectively. The cell cycle data showed that treatment with RS-41 for 24 hrs. suppresses subsequent formation of colonies in both FLO-1 and AGS UGC cells. The cell cycle data exhibited a marked increase (P ≤0.05) in the percentage of FLO-1 and AGS cells in the sub-G1-phase (cell death) following treatment with RS-41 for 24 and 72 hrs., respectively. The western blotting data further confirmed induction of apoptosis in FLO-1 and AGS cells as evidenced by an increase in expression of various markers of apoptosis (P73/P53, cleaved PARP, and/or cleaved caspase 3) following treatment with RS-41 for 24 and 72 hrs. Conclusions: Our in vitro data indicate that inhibition of various oncogenic kinases with RS-41 is an effective therapeutic strategy for inducing apoptosis in both p53 mutant and wild type UGC cells. Our study suggests that RS-41 is a promising multi-kinase inhibitor with a potential to further enhance chemotherapeutic options for treatment of UGC.

#4181 Discovery of a selective small molecule inhibitor of Tankyrase by structure-based screening. Hwni Ryu, Ah-young Kim, Jie-Young Song, Sang-Cu Hwang, Jiyeon Ahn. Korea Institute of Radiological & Medical Sciences, Seoul, Republic of Korea.

The Wnt/β-catenin signaling pathway is critical for colorectal cancer (CRC) development, progression and metastasis. Tankyrase enzymes (TNKS1 and TNKS2), members of the PARP (Poly(ADP-ribose)polymerases) superfamily, PARylate and target Axin for degradation via ubiquitin–proteasome pathway, leading to accumulation of β-catenin into nucleus. In addition, aberrant YAP/TAZ signaling contributes to anticancer drug resistance, but inhibition of TNKS suppresses YAP/TAZ signaling through stabilizing Angiomotin (AMOT). Therefore, inhibition of TNKS has emerged as an attractive strategy for treatment of cancers. To identify potent and selective small molecule inhibitors of TNKS1, a TNKS1-ligand docking was used for computational-based virtual screening. A virtual library containing 1.6 million compounds and 24 virtual hits were further subjected to in vitro evaluation for TNKS1 inhibition. Using an in vitro TNKS1 enzyme assay, we identified a novel pyridine derivative (AZ236106) significantly inhibited TNKS1 enzyme activity in a concentration-dependent manner, but not PARP1/2. Treatment of AZ236106 stabilized Axin, reduced β-catenin in nucleus and downregulated β-catenin target genes in DLD-1 cells harboring constitutively active polycomb repressive complex 2 (CPC2). Furthermore, we observed that AZ236106 inhibited accumulation of YAP in the nucleus and expression of YAP target genes. Combination treatment of AZ236106 with either radiation or PLX4032, a BRAF inhibitor, decreased cell proliferation and increased apoptotic cell death in DLD-1 and SK-MEL28 cells, compare to

Proceedings of the American Association for Cancer Research • Volume 58 • April 2017
AZ236106, radiation or PLX4032 alone. Our findings suggest that AZ236106 may have therapeutic potential in cancers, and could be further refined for efficacy and safety to develop a lead compound.

#4182 The two novel BTK inhibitors M2951 and M7583 show in vivo anti-tumor activity in pre-clinical models of B cell lymphoma. Eugenio Gaudio, Chiara Tarantelli, Emanuele Zucca, Davide Rossì, Anastasios Stathis, Francesco Berti, Institute of Oncology Research - IOR, Bellinzona, Switzerland, Oncology Institute of Southern Switzerland - IOSI, Bellinzona, Switzerland.

Background. Diffuse large B cell lymphoma of the activated B cell type (ABC DLBCL) is an aggressive lymphoma in which the inhibition of the Bruton’s tyrosine kinase (BTK) has shown biologic and clinical relevance. M7583 and M2951 are two novel highly selective irreversible BTK inhibitors (Fest C et al. 2016). M7583 has shown activity in a mouse model of lupus erythematosus (Bender et al. 2016). Here, we evaluated the anti-tumor activity of M2951 and M7583 in an in vivo ABC DLBCL model. Methods. Xenografts were established by s.c. injecting TMD8 lymphoma cells (100 μL of PBS, 107 cells/mouse) into the left flanks of female NOD-SCID mice (6 weeks of age and around 20g of body weight). Treatments (QD, po) were started with an average tumor volume of 100 mm³ on groups of 10 mice each. Results. NOD-SCID mice engrafted with the ABC DLBCL. TMD8 were treated with three different concentrations of M7583 (1 mg/Kg; 3 mg/Kg; 10 mg/Kg) or M2951 (5 mg/Kg; 15 mg/Kg; 25 mg/Kg) or vehicle, as control group. M2951 slowed tumor growth at all doses starting after 10 days of treatment. M7583 at 3 and 10 mg/Kg showed stronger anti-tumor activity than M2951, already evident after 5 days of treatment (P<0.05) and improving with time (after 10 days, P< 0.005). Moreover, while most groups had to be stopped after 2 weeks of treatment (D30 after engraftment) because of the reaching of the maximum tumor volume, allowed by the ethical veterinary committee, mice treated with M7583 at the two highest doses were able to continue treatment for additional six (3 mg/Kg) or ten days (10 mg/Kg), when tumors became bigger than 2000 mm³, indicating a high activity of M7583. No body weight losses and sign of toxicity were detected. Conclusion. The two novel BTK inhibitors M2951 and M7583 showed promising in vivo anti-tumor activity in an ABC-DLBCL model. These data provide the rationale for further investigating these compounds.

M3814 is a potent and selective inhibitor of DNA-PK, one of the key cellular regulators of DNA damage induced by ionizing radiation or certain cytostatics used in the treatment malignant disease. One of these drugs, Etoposide, induces double strand breaks (DSB) in cellular DNA. DSBs are most difficult to repair and, if left unrepaired, can lead to induction of cell cycle arrest and/or apoptosis and ultimately cell death. DNA-PK plays a critical role in the repair of DSB via the non-homologous end-joining pathway. M3814 was tested for activity in combination with Etoposide in a panel of 98 cancer cell lines derived from lung cancer. A broad potentiation effect of DNA-PK inhibitor was observed in most cancer cell lines. As a rule, cell lines sensitive to Etoposide demonstrated increased sensitivity to the combination. M3814 did not show significant effect on cancer cell growth/viability in combination with Cisplatin compared to Cisplatin alone at concentrations that effectively inhibit DNA-PK activity. At the same time, M3814 did not negatively affect the antitumor activity of Cisplatin. The therapeutic effect of M3814 in combination with the standard of care (SoC) regimen of Etoposide and Cisplatin was tested in the human small cell lung cancer xenograft model, NCI-H520. Triple combination of M3814, Etoposide and Cisplatin resulted in increased efficacy compared to SoC treatment arm. Since myeloid and lymphoid suppression is one of the dose limiting toxicities of the SoC regimen in patients, the effect of the triple combination on myeloid and lymphoid blood cells was investigated in immunocompetent mice. Whereas the SoC treatment showed reduction of the myeloid and lymphoid compartments, the addition of M3814 did not additionally reduce these cells neither in the treatment nor the recovery phase. Our results warrant further investigations to explore the potential of the combination in the clinical setting.

#4185 NTRC 1501-0, a TTK kinase inhibitor selected for its long target residence time, completely inhibits tumor growth in the MDA-MB-231 xenograft model for triple-negative breast cancer. Joost C. Uitdehaag, Jos de Man, Marion Libouhan, Nicole Willemsen-Seegers, Jan Gerard Sterrenborg, Joeri J. de Wit, Jeroen A.D de Roos, Martine B. Prinsen, Rogier C. Buijsman, Guido J. de Vet, Jeroen A.D. de Roos, Netherlands Translational Research Center B.V., Oss, Netherlands.

The protein kinase TTK is a critical component of the spindle assembly checkpoint (SAC), which regulates the proper attachment of sister chromatids during mitosis. TTK is essential for normal progression of the cell cycle and is upregulated in various aggressive cancers such as triple negative breast cancer (TNBC). Inhibition of TTK leads to an overriding of the SAC, premature progression of the cell cycle and mitotic catastrophe. Various TTK inhibitors with e.g. Aurora and PLK1 inhibition, which block the cell cycle [1]. Various studies have shown the clinical utility of TTK inhibition, particularly in combination therapy with paclitaxel [1,2]. In vivo, TTK inhibitor monotherapy has shown partial tumor growth inhibition without weight loss [1,2]. We have developed a novel class of TTK inhibitors based on a pyrimido-indolizine scaffold. These bind selectively and with high affinity to the ATP pocket of TTK and potently inhibit the proliferation of a variety of cell lines [1]. Previously we published a representative of this class, NTRC 0066-0, which has an IC₅₀ of 0.6 nM in a biochemical assay for TTK activity and which is more than 200 times selective over a panel of 276 kinases [1]. NTRC 0066-0 has an average IC₅₀ of 98 nM in proliferation assays in 66 different cell lines (Oncomines” panel) [3]. To further increase the potency of the pyrimidoindolizine series, we determined the X-ray crystal structures of a dozen of class representatives in complex with TTK. The results were compared to 3D complexes of other chemical scaffolds such as BAY-1161909, Mps-Bay2h, MPI-0479605, NMS-P715 and Mps1-IN1. The pyrimido-indolizine series uses an aromatic moiety to trap the catalytic lysine in the active site, enforcing a catalytically incompetent conformation of TTK. Thermal melting and surface plasmon resonance experiments demonstrate that this leads to a strong stabilization of the kinase domain and a slow dissociation rate for the compounds, which is one of the key determinants for potent cellular activity. We took advantage of these structure-activity relationships to develop analogs of NTRC 0066-0 with increased residence time and cellular potency. One such analog, NTRC 1501-0, inhibits the proliferation of 66 cancer cell lines with an average IC₅₀ of 18 nM, while retaining selectivity over the kinome. It has good pharmacokinetic properties and shows no cross-reactivity with drug safety targets in vitro. In a xenograft model of the human TNBC cell line MDA-MB-231, it completely inhibited tumor growth at a low oral dose, without effect on body weight, indicating good tolerability. These data show, for the first time, that TTK inhibition as monotherapy can achieve complete inhibition of tumor growth. [1] Maia et al. (2015) Annals of Oncology 26, 2180-2192; [2] Wengner et al (2016) Mol. Canc. Therap. 15, 583-592; [3] Uitdehaag et al (2016) Mol. Canc. Therap., in the press.

Protein kinases are central to cellular signal transduction and regulation of cellular processes, and are one of the most attractive target classes in modern drug discovery. Multiple kinase inhibitors have already been approved for treatment of various diseases including such severe conditions as cancer. The first and up to today largest group of drugs that effectively inhibits their respective kinase targets belong to the class of ATP competitive compounds. They bind into or near the ATP binding site of the enzymes and inhibit kinase activity by blocking access of ATP to the active site. Although there are numerous examples of highly specific ATP competitive compounds this mode of action is limited by several factors: The ATP binding pocket structures of kinases show a high degree of similarity, which makes finding highly selective compounds challenging. Furthermore, competing with ATP for binding to the same target site, compounds have to show a high affinity to very high concentrations. Therefore, the interest to develop non-ATP competitive inhibitors has risen considerably over the last years. Such inhibitors bind to kinases at sites apart from the ATP binding site, inhibiting their activity e.g. by stabilizing an inactive conformation (like DFG-out state binders), displacing essential cofactors (like cyclins for CDKs) or by blocking activating modifications (like phosphorylation by upstream kinases). We present data of an in-vitro biochemical kinase activity assay setup which is suited to discriminate between ATP-competitive and non-ATP competitive inhibitors. The IC₅₀ of an ATP-competitive inhibitor will increase with increasing ATP concentrations and the IC₅₀ value at a given ATP concentration may be calculated using the equation of Cheng and Prussof.
IC_{50} = K_i [ATP] / K_{M,ATP} (Cheng Y., Prusoff W. H. (1973) Biochem. Pharmacol. 22: 3099-3108). By determining IC_{50} values for an inhibitor of a specific kinase at different ATP concentrations we examined whether the IC_{50} value changed according to the Cheng-Prusoff equation, indicating an ATP competitive mode of action, or if the IC_{50} values remained unchanged in presence of ATP indicating a non-ATP competitive or mixed type mode of action. In our assay setup we determined the IC_{50} values at ATP concentrations in a range of 0.1 to 10 fold the ATP K_{M,ATP} of the kinase of interest. By comparing the results obtained for the non-ATP competitive MEK1 inhibitor selumetinib and the ATP competitive inhibitor staurosporine we could verify that our assay setup is well suited to discriminate between these different types of kinase inhibitors.

#4187 Preclinical evaluation of sulfatinib, a novel angio-immuno kinase inhibitor targeting VEGFR, FGFR, and CSF1R kinases. jinghong Zhou, Jun Ni, Min Cheng, Na Yang, Junqing Liang, Liang Ge, Wei Zhang, Tianxing Tang, qiaoling Sun, Fu Li, Jia Hu, Dongxia Shi, Hongbo Chen, Jingwen Long, Junen Sun, Fang Yin, Xuelei Ge, Hong Jia, Feng Zhou, Yongxin ren, Weiguo Qin, Weiguo Su. Hutchison MediPharma Limited, Shanghai, China.

Both endothelial and epithelial growth factor receptor (VEGF) and fibroblast growth factor receptor (FGFR) singling pathways can mediate tumor angiogenesis. Colony stimulating factor 1 receptor (CSF1R) plays an important role on functions of macrophages. Recently the roles of the VEGF, FGFR and CSF1R in regulation of T cells, tumor-associated macromolecules (TAMs) and myeloid-derived suppressor cells, thereby increasing tumor immune evasion, have been demonstrated. Therefore, blockade of tumor angiogenesis and tumor immune evasion is a promising strategy targeting VEGFR, FGFR and CSF1R kinases may represent a promising approach for anti-cancer therapy. We report here the preclinical studies for sulfatinib (HMPL-012), a potent and highly selective small molecule tyrosine kinase inhibitor against VEGFR, FGFR1 and CSF1R. Sulfatinib inhibited VEGFR1, 2, and 3, FGFR1 and CSF1R kinases with IC_{50} values in range of 1–24 nM, and it strongly blocked VEGF induced VEGFR2 phosphorylation in HEC935/66 cells and CSF1 stimulated CSF1R phosphorylation in RAW264.7 cells with IC_{50} of 2 and 79 nM, respectively. Sulfatinib also attenuated VEGF or FGFR stimulated HUVECs proliferation with IC_{50} < 50 nM. In animal studies, a single oral dosing of sulfatinib inhibited VEGF stimulated VEGFR2 phosphorylation in lung tissues of nude mice in an exposure-dependent manner. Furthermore, elevation of FGFR3 levels in plasma 24 hours post dosing suggested suppression of FGFR signaling. Sulfatinib demonstrated potent tumor growth inhibition in multiple human xenograft models and decreased CD31 expression remarkably, suggesting strong inhibition on angiogenesis through VEGFR and FGFR signaling. In a syngeneic murine colon cancer model CT-26, sulfatinib demonstrated moderate tumor growth inhibition after single agent treatment. Flow cytometry and immunohistochemistry analysis revealed an increase of CD8^{+} T cells and a significant reduction of TAMs (CD163+/F4/80+CD11b+CD45+) and TAMs in tumor tissue indicating strong effect on CSF1R. Interestingly, combination of sulfatinib with a PD-L1 antibody resulted in enhanced anti-tumor effect. These results suggested that sulfatinib has a strong effect in modulating angiogenesis and cancer immunity. In summary, sulfatinib is a novel angio-immuno kinase inhibitor targeting VEGFR, FGFR and CSF1R kinases that could simultaneously block tumor angiogenesis and immune evasion. This unique feature seems to support sulfatinib as an attractive candidate for exploration of possible combinations with checkpoint inhibitors against various cancers. Sulfatinib is currently in multiple clinical trials including two Phase III trials against neuroendocrine tumors. Reference: 1. Vonont T, et al. J Exp Med. 2015;212(2):139-48. 2. Ries CH, et al. #4188 Multitargeted tyrosine kinase inhibitor identified as potential therapeutic intervention for liposarcoma using high-throughput profiling. Deepika Kanodia, Mano Garg, Jakki Martinecz, Anad M.T., Samuel B Luty, Njan B Doan, Jonathan W Said, Jeffrey W Tyner, H Phillip Koestler. 1. Cancer Science Institute of Singapore, NUS, Singapore, Singapore; 2. Knight Cancer Institute, Cell and Developmental Biology, Oregon Health and Science University, Portland, OR; 3. Department of Pathology and Laboratory Medicine, University of California-Los Angeles Medical Center, Los Angeles, CA.

Liposarcoma is a rare fat cell adult tumor with high risk of recurrence and metastasis, largely underserved by research community and till now limited progress has been made in treatment of this aggressive disease. We used a strategy to identify effective and potential therapeutic kinase inhibitors, irrespective of the activated kinase pathway, using small molecule kinase inhibitor panel. We screened liposarcoma cell lines of different histotypes to a panel of small molecule kinase inhibitors and analyzed using cell proliferation assay. In vitro cell proliferation assay, colony formation, cell cycle analysis, apoptosis assay and western blotting analysis were performed to investigate the effect and mechanism of inhibitor treatment on liposarcoma. Liposarcoma xenograft model system was also employed to investigate anti-tumor in vivo effects of inhibitor treatment. We observed that cell lines demonstrated diverse in vitro drug sensi-tivity of multiple inhibitors indicating a non-ATP competitive mixed type mode of action. We used a stratagem to identify effective and potential therapeutic kinase inhibitors, irrespective of the activated kinase pathway, using small molecule kinase inhibitor panel. We screened liposarcoma cell lines of different histotypes to a panel of small molecule kinase inhibitors and analyzed using cell proliferation assay. #4189 Homologous recombination pathway-based biomarkers for treatment of non-small cell lung cancer with PARPi inhibitors. Peter V. Deraska, Hunter D. Reavis, Shelby Labe, Alan D. D’Andrea, David Kozono. Dana-Farber Cancer Institute, Boston, MA.

Introduction: Clinical trials examining the addition of PARPi inhibitors (PARPi) to treatment regimens for non-small cell lung cancer (NSCLC) are underway. Of note, these trials are not biomarker driven, and so any benefit may be obscured due to heterogeneity of tumor responses. The first FDA approved PARPi, olaparib, was approved specifically for ovarian cancer patients with germline mutations in BRCA1 or 2. These patients have tumors that show homologous recombination deficiency (HRD). A DNA damage repair pathway defect that confers synthetic lethality in the setting of PARPi therapy. Whether HRD may serve as a biomarker for PARPi sensitivity in NSCLC, however, is unclear. Materials and Methods: Based on prior studies, NSCLC cell lines were classified as 1) HR proficient (A549, NCI-H23, NCI-H460, NCI-H522, NCI-H1299), 2) HR deficient due to early defects in the pathway as evidenced by decreased cisplatin-induced RADS1 focus formation (NCI-H1563, NCI-H1915, NCI-H2087, NCI-H1216) or 3) HR deficient due to late defects in the pathway as evidenced by impaired resolution of ionizing radiation (IR) induced RAD51 and γH2AX foci (Calu-1, Calu-6, HCC827, NCI-H520, SK-LU-1). NSCLC cells expressing doxycycline-inducible BRCA1 or 2 shRNA were generated by Tet-LSKO-puro lentiviral transduction. Cell viability assays to determine olaparib IC_{50} values were performed using CellTiter-Glo and MTS. Gene expression data were extracted from published datasets including CCLE, GSE32665 and TCGA, and expression levels of select genes were assayed by RT-qPCR. Results: BRCA1/2 shRNA knockdown inhibited IR-induced RAD51 focus formation in HR proficient NSCLC cells. This also included PARPi sensitive (A549 olaparib IC_{50} 63 µM > 1.2 µM with BRCA1 and 18 µM > 3.4 µM with BRCA2 knockdown). Because BRCA alterations are uncommon in NSCLC, however, other HRD biomarkers were explored. There was no statistically significant difference in PARPi sensitivity among cell lines grouped by cisplatin-induced RAD51 focus formation or resolution of IR-induced RAD51 or γH2AX foci. BRCA deficient breast and ovarian cancers overexpress POLQ, which drives RAD51 expression and is a high PARPi sensitive biomarker. Conclu-sion: Although certain HRD-related biomarkers including RAD51 focus formation or resolution of ionizing radiation (IR) induced RAD51 and γH2AX foci.
**EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Targeting Protein Kinases and DNA Repair**

**#4191 RXDX-106, a novel, selective and potent small molecule TAM (TYRO3, AXL, MER) inhibitor, demonstrates efficacy in TAM-driven tumors.**

In recent years, the TAM (TYRO3, AXL, and MER) family of receptor tyrosine kinases (RTKs) has emerged as attractive targets for oncology therapeutics. Under homeostatic conditions, the TAM RTKs are expressed by a number of immune cells where they play key roles in the negative regulation of the immune response. However, their expression on cancer cells has been specifically associated with epithelial-to-mesenchymal transition, an invasive phenotype, and, more generally, with a poor patient prognosis (in vivo patient studies). Here, we sought (1) to establish whether expression of the TAM was sufficient to drive cellular transformation, (2) to demonstrate that RXDX-106, a small molecule inhibitor of TAM RTKs, could inhibit tumors harboring activating TAM gene fusions, and furthermore, (3) to decipher how pharmacological inhibition of TAM signaling pathways both on cancer cells and immune cells would be beneficial, given their complex regulation and intimate relationship in the tumor microenvironment. TAM expression on cancer cells has emerged as one of the key mechanisms of resistance to targeted therapies, particularly to EGFR tyrosine kinase inhibitors (TKI). In addition, novel gene rearrangements (fusions) have been identified in the TCGA database for both MerTK (TMEM87B-MerTK) and Axl (Axl-MBIP) that retain the functionality of the tyrosine kinase domain, but have been shown to perturb that alter the dimerization profile and activity of TAMs, respectively. Here, we demonstrate both in vitro and in vivo that expression of either wild type receptors or TMEM87B-MER and AXL-MBIP fusion proteins is sufficient to drive oncogenic transformation by both lipid dependent and independent mechanisms. Treatment of these TAM-expressing cell populations with RXDX-106 completely inhibits TAM phosphorylation and downstream signaling and, consistent with our signaling data, RXDX-106 completely inhibits cellular proliferation and viability at sub-nanomolar concentrations. Furthermore, we demonstrate that, in the co-culture of TAM-expressing cancer cells with immune cells such as macrophages, TAM ligands such as Gas6 are secreted to drive lipid dependent activation of TAM on cancer cells, leading to their survival and proliferation. In summary, our data suggest that TAM RTKs can act as traditional oncokinases when activated either in a lipid dependent or lipid independent manner. In addition, we demonstrate that TAM fusions are tractable therapeutic targets and that patients with tumors harboring such molecular alterations may derive clinical benefit from RXDX-106. Finally, we show that RXDX-106 not only has the potential to inhibit cellular proliferation and survival on the cancer cell itself, but also affect the TAM-expressing tumor microenvironment to result in a global anti-cancer environment.

**#4192 Targeting the SHP-1/p-Lyn signaling shows therapeutic potential in diffuse large B-cell lymphoma.**

Chun Yu Liu,1 Man-Hin Ho,2 Moon Him Tsai,2 Pei-Yi Chu,2 Tsu-Ting Huang,4 Chun-Teng Huang,2 Chung-Wai Shiau,2 Kuen-Feng Chen,2 1Taipei Veterans General Hospital, Taipei, Taiwan; 2National Taipei Veterans Hospital, Taipei, Taiwan; 3Show Chwan Memorial Hospital, Taipei, Taiwan; 4National Taiwan University, Taipei, Taiwan; Show Chang Memorial Hospital, Taipei, Taiwan; National Taipei Veterans Hospital, Taipei, Taiwan; Yang-Ming Branch of Taipei City Hospital, Taipei, Taiwan; National Yang-Ming University, Taipei, Taiwan.

Background: Diffuse large B cell lymphoma (DLBCL) is one of the most aggressive forms of non-Hodgkin’s lymphoma. Genetic analyses revealed molecular heterogeneity of DLBCL tumors, classifying the cell-of-origin into two distinct molecular subtypes: germinal center B-cell (GCB) and activated B-cell (ABC). ABC-type DLBCL has a worse survival after upfront chemotherapy compared to GCB-type DLBCL, thus ABC-type DLBCL patients have an urgent medical need that warrants additional research efforts and new therapeutic options. In current study we explored the biological role and potential therapeutic implication of a protein phosphatase SHP-1 in DLBCL. Methods: DLBCL cell lines including ABC-like cell lines U2932, Ly-3 and GC-like cell lines DHL-6, Ly-7 and DB were used for in vitro studies. Cell viability was examined by MTT assay. Apoptotic effects were examined by annexin V, cytochemistry and Western blot. Signal induction on pathways in cells were assessed by Western blot. In vivo therapeutic testing of SHP-1 agonists were performed in nude mice with DLBCL xenografts. Results: We first examined the protein expression of SHP-1 and its downstream p-STAT3 in a panel of DLBCL cell lines and identified in general SHP-1/p-STAT3 expression was higher in ABC-like cells. Interestingly, the expressions of p-Lyn (Tyrs96), p-BTK (Tyrs223), key members of B-cell receptor (BCR) signaling pathway, were also higher in ABC-like cells. Knockdown or overexpression of SHP-1 protein expression revealed a reciprocal change of p-Lyn, suggesting SHP-1 negatively regulates phosphorylation of Lyn kinase. Immunoprecipitation experiments confirmed SHP-1 interact with Lyn in DLBCL cells. We previously developed direct SHP-1 agonists, namely SC-43 and SC-60, which could increase SHP-1 activities and induce apoptosis. Here we tested SC-43 and SC-60 in comparison to Ibrutinib, a selective Bruton’s tyrosine kinase (BTK) inhibitor. The SHP-1 agonists showed in general superior anti-proliferative and apoptotic effects, comparing to Ibrutinib. Mechanistically, SHP-1 agonists enhanced SHP-1 activation and the activity of BCR and BTK signaling. In addition, SHP-1 agonists also down-regulated p-STAT3 as previously reported, which also contributes to anti-cancer effects. In vivo, SC-43 at doses of 10mg/kg/day and 30mg/kg/day orally showed comparable anti-tumor effects with Ibrutinib at doses of 12.5mg/kg/day and 25mg/kg/day in mice bearing U2932 xenografts, respectively. Western blot confirmed SC-43 downregulation on p-Lyn and p-BTK in vitro and in vivo. Conclusion: Ibrutinib SHP-1 negatively regulates phosphorylation of Lyn, and targeting SHP-1/p-Lyn with direct SHP-1 agonists shows therapeutic potential in DLBCL.

**#4193 A triple exon-skipping luciferase reporter assay identifies a new CLK inhibitor scaffold.**

The splicing of pre-mRNA is a critical process in normal cells and is deregulated in cancer. Compounds that modulate this process have recently been shown to target a specific vulnerability in tumors. We have developed a novel cell-based assay that specifically activates luciferase in cells exposed to splicing targets, such as sudemycin D6. This assay was used to screen a combined collection of approved drugs and bioactive compounds. This screening effort identified several novel candidate targets which include the GTPase 74514A and aminopurvalanol A, both of which have been reported to be cyclin-dependent kinases (CDKs) inhibitors. We found that, these compounds, and their analogs, significantly reducecdc2-like kinase (CLK) inhibition and define structure-activity relationships (SAR) at CLKs. We prepared a set of analogs and were able to ‘dial out’ the CLK activity and simultaneously developed CLK inhibitors with low nanomolar activity. Thus, we have demonstrated the utility of our exon-skipping assay and identified new molecules that exhibit potency and selectivity for CLK, as well as some structurally related dual CLK/CDK inhibitors.

**#4194 Antitumor activity of multikinase inhibitors in HER2-positive gastric cancer cells.**

Background: The developments of novel anti-HER2 drugs including multikinase inhibitors have achieved advancing evolution for past several years, and the options in the treatment of HER2-positive malignant tumors have been increasing, especially in breast and lung cancers. On the other hand, regarding HER2-positive gastric cancer, traditional oncokinases and novel targets have established clinical evidences. Afatinib, an irreversible human epidermal growth factor receptor (EGFR) tyrosine kinase inhibitor, binds to the kinase domain of HER2, and is one of the hopeful candidates as novel molecularly targeted drugs for HER2-positive gastric cancer. In this study, we investigated the antitumor effect of multikinase inhibitors including afatinib in gastric cancer cell lines.

Method: We examined the relation between molecular profiles and multikinase inhibitors sensitivities in 12 gastric cancer cell lines: ECC10, GCY, KATO-III, NUGC3, and NUGC4 cells. The range of IC50 for these cell lines was 2.1 to 39.4 nM. Three cell lines showed moderate sensitivity to gefitinib of more than 25% in all 12 cell lines. Conclusion: Afatinib, a multikinase inhibitor, is more than 10 times more effective than gefitinib, which was not sensitive to afatinib. ECC10 with HER2-L755S mutation was sensitive to other HER2-targeted drugs trastuzumab, and reported to be insensitive to lapatinib either. On the other hand, ECC10 with HER2-L755S mutation was not sensitive to afatinib. The range of IC50 in 7 insensitive cell lines was 0.80 to more than 100 nM. Three cell lines showed moderate sensitivity to gefitinib of which IC50 ranged from 100 to 1000uM. Inhibition rate of trastuzumab was under 25% in all 12 cell lines. Conclusion: Afatinib, a multikinase inhibitor, is highly effective to HER2 amplified gastric cancer cell lines, and may become a novel treatment option in HER2-positive gastric cancer treatment. On the other
hand, afatinib is not always effective even if cancer cells have HER2 mutation or amplification. In this study, we report the detailed predictive biomarkers of sensitivity to afatinib and other several multikinase inhibitors in HER2-positive gastric cancer cells.

**#4195** MIRO02: a new POLA1 inhibitor endowed with a large spectrum of antitumor activity. Claudio Pisano,1 Lucio Melrini,2 Sergio Perco,2 Raffaella Cincinelli,2 Nadine Darwiche,3 Mario B. Guglielmi,1 Antonietta Esposito,1 Ilaria La Porta,1 Giacomo Signorino,1 Gabriele De Rubis,2 Fabiana Colecchi,3 Francesco Cardile,1 Alessandra Fusci,1 Egildo L. D’Andrea,1 Sarbana Dallavalle,1 Biogem, Centro Ricerche, Ariano Irpino (AV), Italy; 1University of Milan, Milan, Italy; 2Ronzoni Institute for Chemical and Biochemical Research, Milan, Italy; 3American University of Beirut, Beirut, Lebanon; 4University of Milan, Milan, Italy.

A recent work from Hain et al. disclosed DNA polymerase 1 alpha (POLA1) as the key target for the anti-cancer effects of CD437, a molecule belonging to the class of Retinoid Related Molecules (RRMs). Before this evidence, this family of compounds, of which CD437 and ST1926 represent the prototypes, has been characterized for its antiproliferative, antitumor and pro-apoptotic activity. With aim to identify a new RRM with an improved pharmacological profile, we recently selected MIRO02 as a novel compound endowed with a potent antitumor activity and a peculiar pharmacological profile. In vitro treatment with MIRO02 leads to a G1/S arrest and exerts a potent anti-tumor/proapoptotic activity in a wide range of cancer cell lines, including H460-R9A cells, which are cross resistant to ST1926 and CD437 (IC50 >70 fold of H460-R9A vs H460). Moreover, in H460-R9A cells, we identified the L746F mutation in POLA1, already described as a marker of resistance to CD437. We have confirmed that POLA1 is the molecular target of both MIRO02 and ST1926 and that, interestingly, the expression of the L746F mutant, although associated with the resistance to RRM’s, only marginally reduces the cytotoxic effects of MIRO02. In order to investigate the activity of MIRO02 against tumor growth, we examined a panel of in vivo xenograft tumor models, including those originating from human Non-Small Cell Lung Cancer (NSCLC) and Malignant Pleural Mesothelioma (MPM). In these models, using a q2dx5x3w schedule in doses ranging from 50 to 70 mg/Kg administered orally, we observed a strong tumor growth inhibition (TGI >70%). Interestingly, the combination of MIRO02 with cisplatin (4mg/Kg; qgdx3w; i.v.) in MPM models showed a synergistic antitumor efficacy, reaching a TGI >90%, and cured animals. Interestingly, we previously identified POLA1 as a key pro-proliferative player in 9 primary MPM samples. The ex-vivo analyses indicated that POLA1 expression was strongly modulated upon MIRO02 treatment. Furthermore, in the same models, we also observed that the expression/secretion of multiple circulating factors is affected by MIRO02 and we identified some of them as potential biomarkers of tumor responsiveness to MIRO02. Taken together, our results identified MIRO02 as a novel anti-cancer compound and suggest POLA1 as a target for new antitumor strategies to be investigated in Clinical Trials.

Aberant expression of TAM family receptor tyrosine kinases, comprising Tyro3, Axl and Mer, is found in virtually every type of human cancer. The expression levels correlate positively with disease staging and prognostic outcome, attributing to metastasis and drug resistance. The TAM kinases have recently emerged as a dual oncological therapeutic target, owing to their immunosuppressive activity. Apart from targeting tumor-survival/growth pathways their inhibition also unleashes the anti-tumor immunity in the tumor microenvironment. In our efforts to develop small-molecule inhibitors targeting the TAM kinases, we identified SLC-391 as one of the most promising preclinical candidates with potent activity towards both Axl and Mer, which play roles in maintaining tumor survival and immunosuppressive tumor microenvironment, respectively. Pharmacodynamic studies of SLC-391 in CT26 syngeneic mouse model revealed increase in the number of NK cells and the ratio of M1/M2-macrophages in the treatment group as compared to the vehicle control, followed by the rise of CD8+/Treg ratio and reduction in immunosuppressive myeloid cells. This is indicative of sequential engagement and stimulation of pro-inflammatory innate immune response and adaptive immune response. In addition, a synergistic anti-tumor effect was observed when the anti-PD-1 insensitive CT-26 model was treated with a combination of SLC-391 and an anti-PD-1 antibody, suggesting that blocking the Axl/Mer-mediated immunosuppressive pathway may significantly enhance the therapeutic efficacy of immune checkpoint inhibitors. In summary, the anti-tumor activity of SLC-391 is mediated by directly inhibiting tumor cell growth as well as reversing the immunosuppressive tumor microenvironment.

**#4197** Interaction of B lymphoma cells with the microenvironment affects ibrutinib sensitivity. Hsu-Ping Kuo, Sidney Hsieh, Mint Sirisawad, Chun-Te Chen, Leo W. Cheung, Karl J. Schweighofer, Chia-Lin Hsu, Chi-Ling Fu, Jing Liu, Shiqian Wu, Karl Eckert, Hugh Wang, Mutiah Apatira, Kamaldeep Dhami, Kevin Kweil, Jeff Hsu, Betty Y. Chang. Pharmaciescics, LLC, an AbbVie Company,Somerville, CA.

Introduction: The cellular microenvironment plays a key role in the pathogenesis of B-cell malignancies (Amé-Thomas, Blood 2007; Pardar, Leukemia 2009). Bone marrow stromal cell interactions can provide survival signals to CLL cells (Kurtova, Blood 2009), and stromal cell gene signatures and markers can predict survival outcomes and add prognostic value, respectively, for patients with chronic lymphocytic leukemia (CLL) (Lenz, Nature 2013). The cell-surface immunosuppressive protein, CD437 (ibr), is a first-in-class, oral, once-daily inhibitor of Bruton’s tyrosine kinase, has demonstrated single-agent activity in R/R DLBCL (Wilson, Nat Med 2015). In this study, we established an in vitro coculture system and report the effects of stromal cells on ABC-DLBCL cells and their sensitivity to ibr. Methods: The effect of ibr on cell growth was evaluated by luminescent cell viability assay. Flow cytometry was used to evaluate the effect of ibr on cell death in different cell populations. Live-cell imaging detected drug effects on apoptosis at different time points. Gene expression levels in B lymphoma cells were examined by quantitative PCR and NanoString panels. Human cytokines/chemokines were quantified using MILLIPLEX® MAP Kit. Results: Reduced ibr sensitivity was observed in TMD8 DLBCL cells cocultured with HS-5 bone marrow-derived stromal cells compared to TMD8 cells from apoptosis. Treatment with ibr induced TNFSF10 expression only in TMD8 cells without HS-5 coculture, providing a survival mechanism for escape of ibr-induced cell death. In addition, coculturing with HS-5 decreased surface expression of CD20 but not CD19. Several cytokines/chemokines showed differential expression in the coculture system (increased CCL2 and IL-10; decreased CCL4 and TNFβ). Reduced expression of BCR signaling related miR-155 was observed in ABC-DLBCL and CLL cell lines with HS-5 coculture, suggesting downregulation of BCR signaling in these cells. The adhesion molecule, SELL, showed decreased expression in the ABC-DLBCL cells cultured with HS-5 as well as in ibr-resistant TMD8 cells, consistent with our observation that ABC-DLBCL patients with poor responses (PD+SD) to ibr have lower SELL expression in their tumor samples. We further assessed expression levels of amino acid metabolism-related genes and demonstrated significant increases of ASS1 and TDO2 in the TMD8 cells cocultured with HS-5. Expression levels of amino acid metabolism-related genes varied across patients with different responses to ibr, further suggesting the importance of amino acid levels in the tumor microenvironment and ibr response. Conclusions: The changes in ABC-DLBCL cells cocultured with stromal cells identified here may provide new insights into cellular cross-talk in the microenvironment. Further investigation into cell-cell interactions and ibr may help stratify patient populations and provide new therapeutic strategies.

**#4198** Highly potent and selective DNA-PK inhibitor M3814 with sustainable anti-tumor activity in combination with radiotherapy. Thomas Fuchs,1 Werner W. Mederski,1 Ulrich Emde,1 Hans-Peter Buchstaller,1 Frank Zenke,1 Astrid Zimmermann,1 Christian Sirrenberg,1 Lubo Vassilev,2 Lars Damstrup,1 Kevin Kwei, Bettys Hsu-Ping Kuo, Sidney Hsieh, Mint Sirisawad, Chun-Te Chen, Leo W. Cheung, Karl J. Schweighofer, Chia-Lin Hsu, Chi-Ling Fu, Jing Liu, Shiqian Wu, Karl Eckert, Hugh Wang, Mutiah Apatira, Kamaldeep Dhami, Kevin Kweil, Jeff Hsu, Betty Y. Chang. Pharmaciescics, LLC, an AbbVie Company,Somerville, CA.

Introduction: Physical or chemical agents that damage DNA such as ionizing radiation are among the most widely used classes of cancer therapeutics today. Double strand breaks (dsb) generated in DNA by radiation induce a multitude of cellular responses, including DNA repair, cell cycle arrest or cell death once the damage is left unrepaired. A complex set of molecular events are responsible for DNA repair mediated by two major repair mechanisms - homologous recombination (HR) or non-homologous end joining (NHEJ). DNA-PKcs together with its regulatory protein subunits Ku70 & Ku80, is an integral component of the NHEJ process and considered an attractive intervention point to inhibit DNA dsb repair. We have developed an orally bioavailable, highly potent & selective inhibitor of DNA-PK, M3814, for cancer therapy in combination with DNA damage-inducing chemotherapy as a means of enhancing the efficacy of radiation. In preclinical studies, M3814 sensitized multiple tumor cell lines to radiation therapy in vitro and strongly enhanced the anti-tumor activity of irradiation in vivo with complete tumor regression by applying a clinically relevant fractionated radiation regimen. These effects are due to inhibition of DNA-PK protein kinase activity as demonstrated by the levels of DNA-PK autophosphorylation in human tumor cell lines & xenograft tumors. M3814 is currently being investigated in PhII clinical trials.
#4199 Inhibition of NF-kB inducing kinase (NIK) selectively abrogates NIK and TRAF3 mutant multiple myeloma tumor growth. Matthias Versele, 1 Lut Janssen, 1 Tamara Geerts, 1 Wim Floren, 1 Boudeijn Janssens, 1 Hillary Mil- lar, 2 Edgar Jacoby, 1 Gerhard Gross, 1 Yann Ligny, 1 Yvan Simonnet, 1 Nathalie Amblard, 1 Olivier Querolle, 3 Inne Cooka, 4 Virginie Poncet, 5 Virginie Tronel, 6 Sophie Vassal, 5 Lieven Maenhoudt, 5 and Sri Ram Balasubramanian, 7 Laurie Lenox, 7 Charles Theuer, 5 Ricardo Attar, 1 Jan Stansfeld 1.

Y bition inaggressivelymphoidmalignancies. TRC694 is a first-in-class orally bioavailable NIK kinase inhibitor, and provides tumors at doses of 10 to 40 mg/kg, with no signs of toxicities. In conclusion, (RPMI-8226, MM.1S) mutant MM tumors, completely inhibits growth of these TRC694 to mice bearing subcutaneous NIK translocated (JJN-3) or TRAF3 NFkB regulated genes in the tumors. Consistently, once-daily, oral dosing of /H9251/H9252/H9253 amplifıedin16%oftumors(TCGAdata).WehaveusedanovelandselectivePI3K of patients. The PI3K pathway is deregulated in 37% of SOC with PI3K becoming critical to overcome drug resistance, recurrence, and hence improve the survival of patients. The PI3K pathway is deregulated in 37% of SOC with PI3K and γ amplified in 16% of tumors (T CGA data). We have used a novel and selective PI3K γ inhibitor (RP6530) with high potency against PI3Kγ (IC_{50}=25 nM) and δ (IC_{50}=30 nM) selectively targeting (δ > 100-fold) and (γ > 300-fold) iso-

#4200 Targeting cancer stem cells in serous ovarian carcinoma using RP6530, a dual PI3K δ-γ inhibitor. Sneha S, Nivetha R, 1 P. R. Nagare, 1 Srikant Viswanadha, 2 Swaroop Valakalanka, 1 T. S. Ganesan, 1 Cancer Institute, Chennai, India; 1Incogen Therapeutics Pvt Ltd, Hyderabad, India; 2Bhans Pharmaceuticals SA, La Chaux-de-Fonds, Switzerland.

Ovarian cancer is one of the most lethal gynaecological malignancies as most pa-
tients are diagnosed at an advanced stage and have a poor prognosis. Several studies have prospectively isolated cancer stem cells (CSCs) from samples of tumor from patients with serous adenocarcinoma of the ovary (SOC). This has been achieved by using cell surface antigens or functional assays. Targeting this subpopulation could be critical to overcome drug resistance, recurrence, and hence improve the survival of patients. The PI3K pathway is deregulated in 37% of SOC with PI3Kδ and γ amplified in 16% of tumors (TCGA data). We have used a novel and selective PI3K δ-γ inhibitor (RP6530) with high potency against PI3Kδ (IC_{50}=25 nM) and δ (IC_{50}=30 nM) selectively targeting (δ > 100-fold) and (γ > 300-fold) iso-

#4201 Combination of palbociclib with enzalutamide shows in vitro activi-
y in RB-profi cient and androgen receptor-positive triple-negative breast cancer cell lines. Ling-Ming Tseng, 2 Tzu-Ting Huang, 1 Chun-Teng Huang, 1 Kay-Yi Lau, 1 Chung-Yu Liu, 4 Chung-Wai Shiau, 5 Kuen-Feng Chen, 5 Taipei Veterans General Hospital, Taipei, Taiwan; 6Yang-Ming Branch of Taipei City Hospital, Taipei, Taiwan; National Yang-Ming University, Taipei, Taiwan; National Taiwan University Hospital, Taipei, Taiwan.

Background: Cyclin-dependent kinases 4 and 6 (CDK4/6) inhibitors have in vitro synergistic effects and significant clinical efficacy in combination with hormone therapy for estrogen receptor (ER)-positive advanced breast cancer. However, the effects of CDK4/6 inhibitors in triple negative breast cancer (TNBC) are not well-elicitated. Retinoblastoma (RB, a known substrate of CDK4/6) protein pathway deregulation is a frequent occurrence in TNBC and in vitro studies have revealed that pharmacological CDK4/6 in-
hibitors yield a cooperative cytostatic effect with doxorubicin in RB-prof-
icent TNBC models, suggesting that RB may be a biomarker for selecting patients receiving CDK4/6 inhibitors. In addition, anti-androgen therapy have been shown preclinical efficacy in androgen-receptor (AR) positive TNBC cell lines. Here we tested the combination effect of a CDK4/6 inhibitor palbociclib with an AR antagonist enzalutamide in TNBC cell lines. Methods: MDA-MB-231, MDA-MB-468 and MDA-MB-453 TNBC cell lines were used for in vitro studies. Cell viability was examined by MTT assay. Apopto-
ic effects were examined by flow cytometry. Signal transduction pathways in cells were assessed by Western blot. Results: We correlated the expressions of AR and pRB status in these TNBC cells and identified that MDA-MB-453 were AR-positive/pRB-positive, MDA-MB-231 were AR-negative/pRB-positive, and MDA-MB-468 were AR-negative/pRB-negative cell lines. Since CDK4/6 inhibition leads to dephosphorylation of pRB, we examined effects of palbociclib and found that palbociclib significantly inhibited the cell growth of pRB-positive cell lines MDA-MB-453 and MDA-MB-231, but did not affect pRB-negative MDA-MB-468 cells. Further combining palbociclib with enzalutamide showed that the growth inhibitory effects of combination therapy were additive in AR-positive/pRB-positive MDA-MB-453 cells, but not in AR-negative/pRB-positive MDA-MB-231 cells, nor AR/pRB double negative MDA-MB-468 cells. Moreover, palbociclib-induced G1/S arrest only exhibited in pRB-proficient MDA-MB-453 and MDA-MB-231 cell lines. In contrast, enzalutamide did not affect the cell cycle on any of these TNBC cell lines but inhibited phosphorylation of AR signaling in AR-positive MDA-

#4202 Trametinib, a MEK inhibitor, augments nab-paclitaxel based che-

therapy response in preclinical models of pancreatic cancer. Niranjana Awasthi, 1 Sheena Monahan, 2 Alexia Stelianakis, 3 Margaret A. Schwarz, 2 Roderich E. Schwarz, 1 Indiana University School of Medicine, South Bend, IN; 3University of Notre Dame, South Bend, IN.

Pancreatic ductal adenocarcinoma (PDAC) is currently the third leading cause of cancer related deaths in the USA with a 5-year survival less than 6%. Nanoparticle albumin-bound paclitaxel (nab-paclitaxel, NPT) has demonstrated 8.5 months median survival in combination with gemcitabine, and now yields a standard of care for PDAC patients. Genetic alterations of the RAS/RAF/MEK/ERK (MAPK) signaling pathway yielding constitutive activation of the ERK cascade have been implicated in many human cancers. In PDAC, activating K-ras mutations occur at a frequency of 90%, rendering this a potential therapeutic target. Efforts to develop drugs that directly
target mutant KRAS protein remain challenging due to target specificity issues. Alternative strategies therefore focus towards inhibition of downstream targets in the RAS-MAPK cascade such as MEK. Trametinib (Tra) is a potent and highly selective small molecule inhibitor of MEK1/2 kinase activity. We evaluated efficacy of trametinib to enhance antitumor response of nab-paclitaxel based chemotherapy regimens in preclinical models of PDAC using K-ras mutant cell lines. In subcutaneous PDAC xenografts using AsPC-1 cells, net tumor growth in different therapy groups was 432.6 mm³ in controls, 105.3 mm³ after NPT (p=0.0023), 184 mm³ after Tra (p=0.0018), 81 mm³ after NPT + Tra (p=0.0003), 37.3 mm³ after NPT + Gem (p=0.0025) and -8.1 mm³ (tumor regression) after NPT + Gem + Tra (p=0.0001). In another subcutaneous PDAC xenografts using Panc-1 cells, net tumor growth in different therapy groups was: 274.1 mm³ in controls, 80.8 mm³ after NPT (p=0.0002), 150.6 mm³ after Tra (p=0.0047), 75.1 mm³ after NPT + Tra (p=0.0002), 48.4 mm³ after NPT + Gem (p=0.0004) and 3.8 mm³ after NPT + Gem + Tra (p<0.0001). In PDAC peritumoral dissemination model using AsPC-1 cells, median animal survival compared to controls (20 days) was increased after therapy with NPT (33 days, a 65% increase, p=0.0004), Tra (31 days, a 55% increase, p=0.0004), NPT + Tra (37 days, an 85% increase, p=0.0001), NPT + Gem (39 days, a 95% increase, p=0.0001) and NPT + Gem + Tra (49 days, a 145% increase, p<0.0001). Effects of therapy on intratumoral proliferation and apoptosis corresponded with tumor growth inhibition. In vitro studies demonstrated inhibition in PDAC cell lines, NCI-H1100, MiaPaCa-2, CFPAC) proliferation by NPT, Gem, Tra, and combination. Immunoblot analysis revealed that trametinib effects were specifically accompanied by decrease in phospho-ERK expression and increase in the expression of apoptosis-related cleaved caspase-3 and cleaved PARP-1 proteins. These findings suggest that the effects of nab-paclitaxel based chemotherapy regimens can be enhanced through specific inhibition of MEK1/2 kinase activity, which clinically could lead to improved PDAC therapy effects.

**Cancer Chemistry** Drug Screening Innovation

**#4205 Intracellular pharmokinetics of 5FU and palbociclib: Uptake and efflux in disaggregated cells and 3D models.** Maria Jove,1 Paul Loadman,1 Jade Spencer,1 Lava Sulayman,2 Jo Wicks,1 Amanda Bace,1 Chris Twelves,1 1Institute Cancer Therapeutics, Bradford University, Bradford, United Kingdom; 2University of Utrecht, Utrecht, Netherlands; 3Leeds University, Leeds, United Kingdom.

Introduction: Pre-clinical drug development does not routinely assess drug penetration beyond use of the human intestinal Caco-2 cell line as an in vitro model of the intestinal barrier to evaluate potential drug absorption. Detailed in vivo tumour pharmokinetic (PK) studies are unusual. However, the ability of a drug to reach its target plays a key role in drug efficacy. Here we present a method to study drug PK in disaggregated cells and in a 3D cell culture model (spheroids) using 5FU and palbociclib. The comparison of these 2 drugs is of interest taking into account their different mechanisms and chemical properties, logP 0.58 and 2.12 respectively.

Knowledge of cellular uptake and efflux in disaggregated cells and 3D models together with intracellular binding characteristics is vital to optimise a better drug delivery. Experimental procedures: MCF-7 and DLD-1 cells were used for cellular and spheroid experiments. Spheroiod growth was optimised to produce a spheroid of 300-400 μm diameter at day 4. Drug uptake: 1x10⁶ cells or 30% of cells/tissue point were exposed to 10μM 5FU or 0.1μM of palbociclib for different time durations. For 5FU, drug uptake at 100μM was also monitored to detect 5FU metabolites. Drug efflux: 1x10⁶ cells were exposed first to 100μM 5FU or 0.1μM of palbociclib for 60min then, drug media removed, substituted by fresh media and sample over a 4h period. Drug concentration inside cells and in the fresh media was measured. Drug concentrations were measured using HPLC-Tandem Mass Spectrometry. Each experiment was carried out in triplicate. Results: 5FU achieves intracellular steady state within 5-10min in cells and spheroids with equal concentrations inside and outside the cell. Intracellular binding of 5FU is around 70%. Palbociclib cellular uptake had an initial intracellular drug concentration of 4-46 nM in biochemical assays. In mechanistic cell-based studies, ASN002 showed that efflux occurred rapidly within 5min achieving a new equilibrium with 30% of 5FU remaining inside the cells. 5FU was also detected extracellularly after 1h in the fresh media, showing that cells have both 5FU and metabolite efflux. In contrast, palbociclib cellular uptake had an initial intracellular drug concentration peak at 5-10min which then plateaued. Interestingly, total intracellular concentrations of palbociclib were over 30 times higher compared to the external media drug at steady state. Spheroiod and efflux experiments of palbociclib are on-going and will be presented. Conclusions: Our results suggest that both drugs penetrate quickly in cancer cells. Palbociclib intracellular concentrations were 30 times higher than the external media suggesting excessive intracellular binding while 5FU achieve equal concentrations between the inside and outside of the cell. These data and methodology may be useful to allow generation of mathematical models to improve drug delivery design.

**#4206 A high-throughput 3D tumor spheroid screening method for drug discovery using imaging cytometry.** Leo Li-Ying Chan, Scott Cribbes, Sarah Kessel, Scott McMenemy, Jean Qiu. Nexcelom Bioscience LLC Lawrenceville, NJ.

There have been an estimated 1000 FDA approved drugs since their inception in 1938. Currently it costs approximately $83 million dollars to bring a drug candidate to the market, and often times the potential candidate fails at the beginning of the clinical phase. Therefore, it is important to develop drug screening methods that are more clinically relevant or predictable. The current 2D methods for cancer
drug discovery have had some difficulty in identifying potential drug candidates that can be used for clinical testing. To overcome this challenge, there has been an increase in research of 3D tissue culture that facilitated the development of new in-vitro tumor model assays. Traditional 3D spheroid analysis method relied heavily on visual observation using standard microscopy, which is time-consuming and labor-intensive. Current research has developed high-throughput image-based cytometers, such as Celigo, have demonstrated the ability to perform high-throughput and fluorescence-based assays. Celigo imaging cytometer can be employed to rapidly analyze and characterize 3D tumor spheroids, which can be used to generate both quantitative and qualitative results. In this work, we demonstrate a high-throughput 3D tumor spheroid screening method using the Celigo imaging cytometer to screen the effects of 14 drug compounds (NIH/NCAT) on U87MG spheroid size, matrigel invasion, and tumor spheroid viability. First, a dose response experiment is performed to screen the growth inhibitory effects of the drug compounds. In addition to direct spheroid size analysis, dose inhibitory responses of tumor invasion into the matrigel are also examined. Finally, the use of specific fluorescent dyes such as Calcein AM, PI, and Caspase 3/7 were used to screen drug induced cytotoxicity on the tumor spheroids. The results showed that Celigo imaging cytometer can quickly generate accurate growth inhibitory data to identify potential drug candidates. Furthermore, tumor invasion were clearly observed and quantified in the captured images, as well as fluorescent analysis of tumor spheroid viability. By utilizing the 3D spheroid screening method, researchers can rapidly characterize and quantify drug effects on tumor spheroids in a high-throughput format, which can improve the efficiency of identifying new qualified cancer drug candidates.

#4207 Selective drug sensitivity score (DSS) for indolent and aggressive prostate cancer cell lines. Jenni Mäki-Jouppila,1 Jenni Bernoulí,1 Johanna Tuomela,1 Mari I. Suominen,2 Jussi M. Halleen,2 Sanna Timonen,3 Elina Huovari,3 Katja Suomi,3 Swapnal Potdar,3 Päivi Östling,3 Jani Saarela,3 Katja M. Fagerlund3,1 Pharmatest Services Ltd, Turku, Finland;2 University of Turku, Turku, Finland;3 University for Molecular Medicine Finland FINMIM, Helsinki, Finland.

Prostate cancer (PC) is the most common malignancy in men and the second leading cause of cancer-related deaths. The majority of the PCs are classified as adenocarcinomas characterized by the expression of androgen receptor (AR) and prostate-specific antigen (PSA). Two of the most commonly used cell lines are LNCaP and PC-3 cells derived from lymph node and bone metastases, respectively. Also VCaP cells, derived from vertebral metastases, are widely used in prostate cancer research. It has been well established that LNCaP and VCaP cells represent the conventional indolent form of PC expressing AR and PSA and are androgen-independent, and represent the highly aggressive form. The drug sensitivity of the cell lines was assessed by applying a large panel of drugs covering cancer chemotherapeutics and clinically available and emerging drugs including conventional chemotherapy, kinase inhibitors, metabolic modifiers, rapalogs, differentiating/epigenetic modifiers, kinesin inhibitors, apoptotic modulators, NSAI Ds, hormone therapy, immunomodulators and HSP inhibitors. A panel of 460 compounds was tested in five concentrations covering a 10,000-fold drug-relevant concentration range in 384-well format. Cells were seeded to pre-drugged plates, followed by cell viability measurements (CellTiter-Glo) after 72 hours. Maximal and minimal responses to drugs were analyzed, the EC50 values were calculated and Drug Sensitivity Score (DSS) was calculated for each drug as a measure of reduced viability. A selective Drug Sensitivity Score (sDSS) was calculated to identify the selective drug response pattern of each three cancer cell lines. As expected, the results indicate that LNCaP and VCaP cells in general were more sensitive to drugs of different categories than PC-3 cells. According to DSS analysis, all three cell lines showed sensitivity to conventional chemotherapy and kinase inhibitors. However, PC-3 cells were more sensitive to kinase inhibitors than conventional chemotherapy. Determining sDSS revealed specific sensitivities of each cell line. LNCaP cells were sensitive to kinase inhibitors, such as mTOR and AKT inhibitors. Also VCaP cells showed selective sensitivity to kinase inhibitors, especially Aurora kinase and IGFIR inhibitors. In addition to kinase inhibitors, VCaP cells were selectively sensitive to HDAC inhibitors. Furthermore, PC-3 cells were sensitive to e.g. CDK inhibitors. We conclude that the cell-based compound screening combined with DSS and sDSS analysis provides a possibility to generate an extensive collection of anti-cancer compounds enabling repurposing of existing drugs to new indications, identification of vulnerabilities in different types of cancer cells and functional investigation of cellular pathways behind drug sensitivity or resistance.
poor prognosis, overexpress GWL and are highly sensitive to GWL depletion. In addition, GWL expression has been found to be elevated in oral squamous cell carcinoma and prostate cancer tissues. A number of studies have also indicated that GWL may contribute directly to tumorgenesis, suggesting that modulation of GWL activity with small-molecule inhibitors could afford a potential new anti-cancer therapy. The precise role of GWL in cancer is yet to be defined. The identification of a pharmacological tool would be useful to further assess the tumor-associated functions of this protein. To that end, we have recently developed and optimized a robust HTSF assay, based on a specific ENSA peptide analogue, and used it to screen kinase focused libraries, made available to us by GlaxoSmithKline and Roche. A 10.2% hit rate was achieved from the screening of the 11,000 compound set at a single concentration of 10 μM. Molecules inducing over 50% inhibition in the single point screen were subsequently tested in concentration-dependent experiments. Analysis of the IC₅₀ values enabled to identify molecular clusters and potential hits to initiate a medicinal chemistry campaign. A review of the literature on the selectivity of the hits identified indicated that a significant number of these molecules also had affinity for other AGC kinases and that selectivity among the AGC kinase family could be challenging to achieve. Computational studies using an in-house co-crystal structure of GWL in complex with Staurosporine and the published crystal structures of other AGC kinases will be used to design selectivity and guide the design of inhibitors to obtain a potent chemical probe.

#4211 Gene expression changes in Polyphenol E treated prostate cells. L. Michael Carastro, 2 Ricardo A. Cordova, 1 Daniel A. Barbot, 1 Ricardo A. Declet-Bauza, 2 Irene Gushterova, 1 Nicholas K. Lago, 1 Nicholas E. Bragonja, 1 Joanna C. Burt, 1 Dana E. Hoffman, 1 Long Y. Park, 2 1The University of Tampa, Tampa, FL; 2Universidad Central de Caribe, Bayamon, PR; 3 Moffitt Cancer Center & Research Institute, Tampa, FL.

Prostate cancer (PCa) is the most common malignancy among men in the USA. Polyphenol E (PolyE) is a standardized blend of polyphenols found in green tea extract, which has been shown to have chemoprevention value in PCa models, but the molecular mechanism(s) have not been elucidated. Polyphenols from green tea are known to alter the expression levels of some genes. Our experimental goal was to identify genes with expression level changes (up- or down-regulated by 2-fold or more) in normal, primary prostate cells as well as two PCa cell lines, DU145 and PC-3. Ultimately, we sought to identify genes whose expression level was differentially altered by PolyE treatment in normal versus PCa cells. We hypothesized that exposure to PolyE induces gene expression changes, which could provide rationales for the molecular mechanisms(s) and provide potential targets for therapeutics and detection. A non-cancerous, human primary prostate cell line as well as two PCa cell lines (DU145 and PC-3) were cultured and treated them with varied concentrations of PolyE for 24 hours. Cellular RNA was isolated and subjected to microarray analyses (MA) at the Molecular Genomic Facility of the Moffitt Cancer Center. A plethora of genes were identified by MA as having two-fold or higher gene expression level changes after PolyE exposure. Of these genes, fourteen were selected for further analyses by TaqMan qRT-PCR. Cellular RNAs were converted into cDNA used in validated TaqMan qRT-PCR assays (StepOneTM RT-PCR System). RT-PCR data was analyzed using StepOneTM software and the ΔΔCt method. ACTB served as the endogenous control gene for all TaqMan qRT-PCR assays. Our qRT-PCR data from PolyE-treated DU145, PC-3, and primary prostate cells were consistent in the lack of expression changes greater than 2-fold for ATM, CASP8, HDAc4 and RB1. For RGCC, MXD1, CCSE2/FAM190B, CBLB and BCL2L11, gene expression levels increased by more than 2-fold in all three cell lines. For CCNB1 and SEC62, primary cells experienced more than a 2-fold change in gene expression, while the DU145 and PC-3 cell lines did not. Interestingly, ATM gene expression levels increased by more than 2-fold in all three cell lines. For CCNB1 and SEC62, primary prostate cells experienced more than a 2-fold change in gene expression, while the DU145 and PC-3 cell lines did not. Interestingly, ATM gene expression levels increased by more than 2-fold in all three cell lines. For CCNB1 and SEC62, primary cells experienced more than a 2-fold change in gene expression, while the DU145 and PC-3 cell lines did not. Interestingly, ATM gene expression levels increased by more than 2-fold in all three cell lines. For CCNB1 and SEC62, primary cells experienced more than a 2-fold change in gene expression, while the DU145 and PC-3 cell lines did not. Interestingly, ATM gene expression levels increased by more than 2-fold in all three cell lines. For CCNB1 and SEC62, primary cells experienced more than a 2-fold change in gene expression, while the DU145 and PC-3 cell lines did not. Interestingly, ATM gene expression levels increased by more than 2-fold in all three cell lines. For CCNB1 and SEC62, primary cells experienced more than a 2-fold change in gene expression, while the DU145 and PC-3 cell lines did not. Interestingly, ATM gene expression levels increased by more than 2-fold in all three cell lines. For CCNB1 and SEC62, primary cells experienced more than a 2-fold change in gene expression, while the DU145 and PC-3 cell lines did not. Interestingly, ATM gene expression levels increased by more than 2-fold in all three cell lines. For CCNB1 and SEC62, primary cells experienced more than a 2-fold change in gene expression, while the DU145 and PC-3 cell lines did not. Interestingly, ATM gene expression levels increased by more than 2-fold in all three cell lines. For CCNB1 and SEC62, primary cells experienced more than a 2-fold change in gene expression, while the DU145 and PC-3 cell lines did not. Interestingly, ATM gene expression levels increased by more than 2-fold in all three cell lines. For CCNB1 and SEC62, primary cells experienced more than a 2-fold change in gene expression, while the DU145 and PC-3 cell lines did not. Interestingly, ATM gene expression levels increased by more than 2-fold in all three cell lines. For CCNB1 and SEC62, primary cells experienced more than a 2-fold change in gene expression, while the DU145 and PC-3 cell lines did not. Interestingly, ATM gene expression levels increased by more than 2-fold in all three cell lines. For CCNB1 and SEC62, primary cells experienced more than a 2-fold change in gene expression, while the DU145 and PC-3 cell lines did not. Interestingly, ATM gene expression levels increased by more than 2-fold in all three cell lines. For CCNB1 and SEC62, primary cells experienced more than a 2-fold change in gene expression, while the DU145 and PC-3 cell lines did not. Interestingly, ATM gene expression levels increased by more than 2-fold in all three cell lines. For CCNB1 and SEC62, primary cells experienced more than a 2-fold change in gene expression, while the DU145 and PC-3 cell lines did not. Interestingly, ATM gene expression levels increased by more than 2-fold in all three cell lines. For CCNB1 and SEC62, primary cells experienced more than a 2-fold change in gene expression, while the DU145 and PC-3 cell lines did not. Interestingly, ATM gene expression levels increased by more than 2-fold in all three cell lines. For CCNB1 and SEC62, primary cells experienced more than a 2-fold change in gene expression, while the DU145 and PC-3 cell lines did not. Interestingly, ATM gene expression levels increased by more than 2-fold in all three cell lines. For CCNB1 and SEC62, primary cells experienced more than a 2-fold change in gene expression, while the DU145 and PC-3 cell lines did not. Interestingly, ATM gene expression levels increased by more than 2-fold in all three cell lines. For CCNB1 and SEC62, primary cells experienced more than a 2-fold change in gene expression, while the DU145 and PC-3 cell lines did not. Interestingly, ATM gene expression levels increased by more than 2-fold in all three cell lines. For CCNB1 and SEC62, primary cells experienced more than a 2-fold change in gene expression, while the DU145 and PC-3 cell lines did not. Interestingly, ATM gene expression levels increased by more than 2-fold in all three cell lines. For CCNB1 and SEC62, primary cells experienced more than a 2-fold change in gene expression, while the DU145 and PC-3 cell lines did not. Interestingly, ATM gene expression levels increased by more than 2-fold in all three cell lines. For CCNB1 and SEC62, primary cells experienced more than a 2-fold change in gene expression, while the DU145 and PC-3 cell lines did not. Interestingly, ATM gene expression levels increased by more than 2-fold in all three cell lines. For CCNB1 and SEC62, primary cells experienced more than a 2-fold change in gene expression, while the DU145 and PC-3 cell lines did not. Interestingly, ATM gene expression levels increased by more than 2-fold in all three cell lines. For CCNB1 and SEC62, primary cells experienced more than a 2-fold change in gene expression, while the DU145 and PC-3 cell lines did not. Interestingly, ATM gene expression levels increased by more than 2-fold in all three cell lines. For CCNB1 and SEC62, primary cells experienced more than a 2-fold change in gene expression, while the DU145 and PC-3 cell lines did not. Interestingly, ATM gene expression levels increased by more than 2-fold in all three cell lines. For CCNB1 and SEC62, primary cells experienced more than a 2-fold change in gene expression, while the DU145 and PC-3 cell lines did not. Interestingly, ATM gene expression levels increased by more than 2-fold in all three cell lines. For CCNB1 and SEC62, primary cells experienced more than a 2-fold change in gene expression, while the DU145 and PC-3 cell lines did not. Interestingly, ATM gene expression levels increased by more than 2-fold in all three cell lines. For CCNB1 and SEC62, primary cells experienced more than a 2-fold change in gene expression, while the DU145 and PC-3 cell lines did not. Interestingly, ATM gene expression levels increased by more than 2-fold in all three cell lines. For CCNB1 and SEC62, primary cells experienced more than a 2-fold change in gene expression, while the DU145 and PC-3 cell lines did not. Interestingly, ATM gene expression levels increased by more than 2-fold in all three cell lines. For CCNB1 and SEC62, primary cells experi...
Objective: Glioblastoma (GBM) is one of the deadliest brain tumors both in adults and children. While next-generation sequencing rapidly identifies whole exome/genome gene mutations, the efficacy of targeting mutated genes/pathways has not been systematically analyzed. Additionally, it remains unknown if neurospheres (enriched with cancer stem cells) and non-stem monolayer tumor cells with similar malignant phenotypes respond differently. The main objective of this study was to assess the in vitro activity of a panel of anti-Glioblastoma drugs and their potential effect on clinical outcomes. Methods: Twenty-six pairs of neurospheres and monolayer cells were cultured from seven aggressive childhood GBM xenografts and cultured cells, but only 3/17 MEK inhibitors were active in neurospheres and 2/17 in monolayer cells (GDC0980 and PI-103 were active in both) on day 7. In IC-R0315GBM (from an autopsied terminal GBM) that carried PI3KCA mutation (allele frequency 22-27%), 5/33 PI3K inhibitors were active in neurospheres and 8/33 in monolayer cells (only Temretinib was active in both) after 7 days. In IC-3572GBM (recurgent GBM) and ICB-1127AA (radiation-induced anaplastic astrocytoma), no druguable mutations were detected. The number of active drugs on day 7 was 366 in IC-476GBM, 406 in IC-3572GBM, 284 in IC-R0315GBM, and 305 in ICB-1127AA. When the 4 matching pairs of neurospheres and monolayers were compared, the agents active in both cultures ranged from 36% to 60%, active only in neurosphere from 10.3% to 25%, and active only in monolayer cells from 14.8% to 53%. Subsequent in vivo validation using MLN8827 in IC-4687GBM and IC-R0315GBM showed that effective targeting of both neurosphere and monolayer was required for significantly-improved animal survival times. Conclusion: We showed that long-term treatment is feasible for high-throughput drug screening. Targeting druguable mutations can be achieved but only by a fraction of specific agents. Neurospheres and monolayer cells do not always respond equally toward the same drugs, and effective targeting of both subpopulations is needed to generate prolonged animal survival times.

PREVENTION RESEARCH: Population Science in Cancer Prevention Research

#4215 Cancer-related fatigue and physical activity vary by age for black women with a history of breast cancer. Melody A. Sven,1 Amandeep Mann,2 Raheem Paxton,3 Lorraine T. Dean 1.

1 Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; 2 Drexel University Dornsife School of Public Health, Philadelphia, PA; 3 University of North Texas Health Science Center, Fort Worth, TX.

Purpose: Cancer-related fatigue is the most discomforting symptom among women with a history of breast cancer. Black women are more likely to experience risk factors for cancer-related fatigue, like physical inactivity and obesity, yet cancer-related fatigue studies have not explicitly focused on Black women. This cross-sectional analysis assesses cancer-related fatigue and physical activity among Black female breast cancer survivors. Methods: In May and July of 2012, 266 members of the Sisters Network, Inc completed an online survey on demographic, cancer history and treatment, fatigue using the 13-item Function. Assessment of Chronic Illness Therapy (FACIT) Fatigue Scale, and engagement in ≥150 minutes per week of physical activity (CDC guideline). Multiple linear regression assessed relationships between fatigue and physical activity. Results: The average participant was 54 (SD=9) with a FACIT score of 13.63, indicating “severe fatigue”. Fatigue was greater (p=0.02) among the 56% of women meeting physical activity guidelines. Multivariable analysis showed that meeting physical activity guidelines (β=-3.01, p=0.01) and higher age group (50-59: 4.75, p=0.001; 60+: 4.38, p=0.01) were associated with greater fatigue. An interaction plot showed that differences in fatigue for those meeting or not meeting physical activity guidelines is largest among Black women under age 50. Conclusions: Meeting physical activity guidelines was associated with greater cancer-related fatigue, which was most pronounced for those under age 50. Interventions for Black breast cancer survivors with cancer-related fatigue should consider physical activities that can be integrated into existing tasks and provide age-appropriate resources to address physical and emotional fatigue domains.

#4216 Racial disparities in receipt of adjuvant hormonal therapy among patients diagnosed with breast cancer in South Carolina. Oluwole A. Babatunde, Swann Adams, Tisha Felder, Jan Eberth, Robert Moran, Erica Sercy, James Hebert. University of South Carolina, Columbia, SC.

Background: Women with hormone receptor-positive (HR+) breast cancer (BC) have a 25% risk reduction in breast cancer-related mortality as a result of the use of adjuvant hormonal therapy (AHT). However, mortality rates remain higher among Blacks compared to Whites. This disparity has widened despite overall improved BC survival rates over time. The widening gap in Black-White mortality for BC may be related to differences in tumor biology, treatments received and access to care. The objective of this study was to assess racial disparity in the receipt of AHT among women with BC in South Carolina (SC). Methods: We derived data on all female BC cases in 2002 to 2009 from the Central Cancer Registry linked with administrative medical and pharmacy claims data for the Public Employee Benefits Plan (private insurance) and Medicaid. HR+ BC included three potential classifications for estrogen (ER+ or ER-) and progesterone receptors (PR+ or PR-): ER+ / PR+, ER+/PR+, ER-/PR+. The main outcome variable was receipt of AHT (receipt vs non-receipt). The main exposure variable was patient race (White vs Black). Chi-square tests and logistic regression analyses were conducted to compare patients who received AHT to those who did not to identify important predictors of AHT receipt. Two-way interactions were assessed between seven covariates hypothesized to modify the effect of race (age, race, insurance, marital status, county of residence, year of diagnosis, receipt of surgery (early vs late), tumor stage and tumor grade). Results: Of the 161 total breast cancer cases reported in the study period, 834 were HR+ (641 white, 76.86%; 193 black, 23.14%). The crude odds of non-receipt of AHT were 1.59 (95% CI: 1.14-2.21), and the adjusted odds was 1.23 (95% CI: 0.85-1.78) among Black compared to White patients. The adjusted odds of non-receipt of AHT were 2.02 (95% CI: 1.36-2.99) and 5.15 (95% CI: 3.41-7.77) among tumor grade II and IV/III compared to grade I respectively. Stratified analysis showed that among patients who were married, the odds of non-receipt of AHT were 2.19 (95% CI: 1.28-3.74) among Blacks compared to Whites; and among those that received late surgery, the odds of non-receipt of AHT were 3.00 (95% CI: 1.34-6.71) among Blacks compared to Whites; and among those that received late surgery, the odds of non-receipt of AHT were 1.81 and 2.42 (95% CI: 1.14-2.87 and 1.29-4.55), respectively among Blacks compared to Whites. Conclusions: To improve overall use of AHT, efforts need to be directed at Black BC patients who received late surgery (>30 days after diagnosis).

#4217 Consumer credit, cancer treatment, and health among women with a history of breast cancer. Kathryn H. Schmitz,1 Kevin Frick,2 Lauren Nicholas,1 Yuehan Zhang,1 SV Subramanian,1 Kala Visvanathan,1 Lora Landis,1 L.莱斯利·欧文·马斯特约翰斯霍普金斯大学公共卫生学院; 2 Pennysylvania State University College of Medicine, Hershey, PA; 3 Johns Hopkins Carey Business School, Baltimore, MD; 4 University of Pennsylvania School of Medicine, Philadelphia, PA; 5 Harvard School of Public Health, Boston, MA.

Background: Breast cancer treatment may represent an economic shock that may be influenced by, or may influence a cancer survivor’s socio-economic position (SEP). Financial toxicity or economic burden due to cancer treatment and treatment’s adverse effects may be reflected in one’s consumer credit ratings; however, credit’s contribution to individual health for cancer survivors or those managing long-term adverse effects of cancer treatment has not been evaluated. This analysis examined associations between self-rated health outcomes of women with a history of breast cancer, type of cancer treatment, and presence of breast cancer-related lymphedema, a persistent adverse effect of treatment, and consumer credit rating. Methods: From May to September 2015, 129 women from Pennsylvania and New Jersey were enrolled in the PAL. Social and Economic Quality of Life cross-sectional study. All participants had a history of breast cancer, and completed a survey on: demographics, SEP, co-morbidities, SF-12 self-rated health, psychosocial stress, adjuvant cancer treatments (chemotherapy, hormone therapy, radiation), breast cancer-related lymphedema symptoms, and credit quality (5-point scale self-reported as poor to excellent). Multivariable linear regression measured the association between credit and health. Results: Mean respondent age was 64, with 38.2% reporting excellent and 37.4% reporting very good/good credit. Participants completed cancer treatment on average 11.5 years ago. After adjusting for demographics and SEP, good credit was associated with a 4.5 (p=0.009) point increase in composite physical health (SF-12) score and -1.13 (p=0.02) decrease in psychosocial stress compared to women with poor credit, but was not associated with type of cancer treatment or lymphedema. Conclusion: While credit was associated with self-rated health for women with an average 11.5 year history of breast cancer, current credit quality

Proceedings of the American Association for Cancer Research • Volume 58 • April 2017
did not appear to be associated with type of cancer treatment previously received or with the presence of lymphedema, a persistent adverse effect of cancer treatment. It is still possible that cancer treatment may have influenced credit score at time of treatment, and credit was able to rebound since that time. Future work should test causal pathways between credit and health outcomes after cancer diagnosis.

**#4220 Liverpool healthy lung project: a primary care initiative to identify hard to reach individuals with a high risk of developing lung cancer.** John K. Field,1 Edward S. Gaynor,2 Stephen W. Duffy,3 Katy Gardner,1 Cathy Hubbert,2 Dimitris Tsintzos,2 Michael W. Marcus,1 Lisa Jones,1 Rachel Avanitis,2 Michelle Timoney,7 Martin Ledson,1 1Univ. of Liverpool, Liverpool, United Kingdom; 2NHS Liverpool Clinical Commissioning Group, Liverpool, United Kingdom; 3Queen Mary University of London, London, United Kingdom; 4Liverpool Heart & Chest Hospital, Liverpool, United Kingdom.

Introduction: The UKLS CT screening trial has demonstrated that by utilizing a population based approach, a risk prediction algorithm (LLP), volumetric based CT nodule detection and a specific management pathway, 80% of the lung cancers detected were Stage I or II, 85% of which were suitable for surgical resection. In the Liverpool region, 2.4% of the screened population were found to have lung cancer at baseline. Methodology: Liverpool has one of the highest lung cancer mortality rates in England, and double the national average of cases diagnosed. It was decided to tackle this health inequality and the NHS Liverpool Clinical Commissioning Group (CCG) introduced the Liverpool Healthy Lung Programme (LHLP). LHLP began in February 2016 and aims to increase knowledge in communities, promoting positive messages around lung health, recognizing and tackling fear and fatalism surrounding lung cancer. The LHLP is undertaking coordinated, focused public engagement (Breathe Freely) events, through educational events for key targets, again targeting lung health in the highest incidence of lung cancer. These events are followed by patients between the ages of 58-70 who have COPD, or have smoked, being invited to a local face to face lung health check, conducted by a lung-health nurse working in local community clinics and in partnership with General Practice. Summary & Findings: This assessment of lung health involved calculation of their risk of developing lung cancer in the next 5 years (My Lung Risk). Those who triggered a 5% threshold were offered low dose thoracic CT. In the Liverpool CCG Region 34,000 patients will be eligible: in the initial 12 weeks in the first neighborhood, 1014 of 2471 (41%) eligible individuals booked to attend the lung health check (865 attended). 351 (41%) triggered the offer of a CT appointment. 306 scans have been reported; 31 (10%) had lung nodules, 59 (20%) had a noncancer significant finding identified in General Practice. To date, September, 4 have confirmed lung cancer with surgical resection; 2 on follow-up. 406 patients (45%) were not previously diagnosed with COPD, 225 (45%) had abnormal spirometry, and were referred. 238 (28%) accepted lifestyle referrals (e.g. smoking, exercise). Conclusion: The project is over 3 years. Projections suggest 34,000 participants will be eligible. We are aiming for an ambitious 70% uptake meaning 24,000 will have a face to face lung health check. We estimate that ~150 cases of lung cancer will be diagnosed.

**#4221 Factors associated with HPV vaccination initiation and completion among 18-26 year olds in the United States.** Eric Adjei Boakye,1 Betelhem B. Tobo,2 Daphne Lew,3 Meera Muthukrishnan,1 Vy T. Pham,1 Rebecca Rohde,2 Thomas Burroughs,1 Mark A. Varvares,1 Nosayba Osazuwa-Peters,2 1St. Louis University, School of Medicine, St. Louis, MO; 2St. Louis University School of Medicine, Saint Louis, MO; 3Harvard Medical School, Boston, MA; 4St. Louis Univ. Cancer Center, Saint Louis, MO.

Background: The HPV vaccine prevents HPV-associated cancers and genital warts, which cause significant morbidity and mortality in the US. While the vaccine is targeted toward 11-12-year-old boys and girls, there is a catch-up vaccination range up to 26 years. However, vaccination rates are very low among eligible young adults, aged 18-26 years, and besides college-related studies, not a lot is known about factors associated with the HPV vaccine uptake in this population. The aim of this study was to assess sociodemographic factors associated with HPV vaccination uptake in a nationally representative sample of 18-26-year-old adults. Methods: The National Health Interview Survey 2014-2015 was conducted through a household interview. HPV initiation was defined as receipt of at least one dose of the vaccine and completion as receipt of the three doses. Sociodemographic factors included age, gender, race, marital status, education, health insurance, regular provider, number of doctor visits, and geographic region. Survey-weighted multivariable logistic regression models were used to examine the socio-demographic factors that were associated with HPV vaccine uptake. Results: Approximately 27% of respondents had initiated the HPV vaccine and 16% had completed the HPV vaccine. After adjusting for covariates, compared to males, females were 81% less likely to initiate HPV vaccine [adjusted odds ratio 0.19; (95 % confidence interval 0.16-0.23). Other factors associated with HPV vaccine initiation included having health...
insurance (1.70; 1.32-2.18), visiting the doctor’s office 6+ times (1.86; 1.48-2.34) and 1-5 times (2.09; 1.56-2.81) vs. no doctor’s office within the last 12 months, and having no high school diploma (0.46; 0.32-0.64) and having high school diploma (0.40; 0.31-0.52) vs. college degree or higher. The same factors were associated with HPV vaccine completion; but, being black (0.60; 0.40-0.83) vs. white and having no usual place of care (0.74; 0.57-0.96) vs. having regular care had significantly lower rates of up to date FOBT; less than 10% (9.1%) reported having FOBT in the past year. Vietnamese had the highest rate (13.8%) followed by Korean (7.5%) and Chinese (6.9%). For the prevalence of up to date colonoscopy (<10 years), CHS data disaggregated by ethnicity among AA shows that Vietnamese Americans (63.7%) had highest rates of having colonoscopy followed by Korean Americans (51.1%) and Chinese Americans (48.7%). In our study, Chinese had higher rates of having colonoscopy (63.3%) than Vietnamese (47.5%) and Korean (43.0%). The average CRC Knowledge Score was 6.10 out of 9 (SD = 2.91). In bivariate analysis, education, marital status, and self-rated health were highly correlated with CRC knowledge. Those with higher education levels, those married, and those rated with good physical health had increased CRC knowledge. In multivariate analysis, education, health insurance, and CRC knowledge were significantly related to having colonoscopy. Those with high CRC knowledge were more likely to have colonoscopy than those low knowledge (aOR = 2.74, 95% CI, 1.13, 6.64). Those who had health insurance had higher likelihood of having colonoscopy than those without health insurance (aOR = 4.05, 95% CI, 2.33, 6.82). Those with higher school education were less likely to have colonoscopy than those with less than high school education (aOR = 0.47, 95% CI, 0.16, 0.84). The findings of this study suggest that CRC knowledge is a strong predictor of CRC screening behavior in Asian Americans. Lack of CRC screening knowledge still remains an important barrier to screening, and future strategies to increase public awareness on CRC is necessary to achieve greater screening compliance amongst AA populations.

PREVENTION RESEARCH: Population Science in Cancer Prevention Research

**#4222 Examining sociodemographic disparities in perceptions of cancer risk from medical imaging.** Kekoa Tapapara,1 Kay Pepin,2 Richard Moser,3 Bradford Hesse,4 Alexandra Greenberg.1 Mayo Clinic School of Medicine, Rochester, MN;3 National Cancer Institute, Bethesda, MD.

In the United States, ionizing radiation from medical imaging is estimated to account for nearly half of the total radiation exposure among the general population. While controversial, some estimates suggest thousands of future cancer cases can be attributed to radiation from medical imaging. With the advancement in medical technologies, understanding the health risks of radiation from medical imaging has become increasingly complex for the average cancer patient. The complexity may shape the public’s perceptions of the potential cancer risks of medical imaging tests, including x-rays, mammography, and radio-active dyes. Due to the enormous, often misleading, sources of information available to the average consumer regarding the effect of radiation on general health, trends in risk perception need to be assessed. To investigate the association between perceptions of radiation exposure from medical imaging and cancer risk, we analyzed data from the National Cancer Institute’s Health Information National Trends Survey (HINTS 4, Cycle 2). HINTS is a probability-based nationally-representative survey which collects data on the American public’s knowledge, perception, and use of cancer- and health-related information since 2003. The data examined in the present study were collected between October 2012 and January 2013. (response rate = 39.9%). Bivariate analyses reveal individuals who perceive medical imaging radiation to be harmful to health are largely female, Hispanic, non-Hispanic Black, or non-Hispanic Asian, with less education and lower incomes. This perception is especially prevalent in individuals who self-report having a poor or fair general health and less confidence in their ability to take care of their own health. After adjusting for sociodemographic and health care factors, a significantly increased odds of believing radiation from medical imaging causes "some" or "a lot" of harm to health was found among those who have had a previous cancer diagnosis compared to those who did not (OR = 1.67, 95%CI = 1.18-2.35). Individuals who self-reported being Hispanic (OR = 2.08, 95%CI = 1.29-3.34), non-Hispanic Black (OR = 1.54, 95%CI = 1.09-2.19), and non-Hispanic Asian (OR = 4.66, 95%CI = 2.05-10.62) had significantly higher odds of perceiving "some" or "a lot" of harm to health from medical imaging compared to non-Hispanic white counterparts. Our data reveal existing populations that perceive radiation from medical imaging is harmful to health. These perceptions, particularly among women and minorities, may affect the personal decisions of cancer care from individual patients. Future analyses may be useful to identify whether these perceptions alter health outcomes, especially related to frequency of patients declining cancer radiation therapy. Overall, understanding patient perceptions of radiation exposure and cancer risk may help guide conversation and education for physicians with their patients.

**#4223 Colorectal cancer knowledge and screening among Asian Americans aged 50-75 years old.** Jenny Guo,1 Hee-Soon Juon,2 Sunmin Lee.1 Thomas Jefferson University, Philadelphia, PA; 2University of Maryland, College Park, MD.

Background: Chinese, Vietnamese, and Korean Americans, three of the largest Asian American (AA) subgroups, have particularly high rates of colorectal cancer (CRC) incidence and mortality. However, CRC screening rates among these Asian Americans remain very low. Increased knowledge of CRC has been shown to be positively correlated with a person’s inclination to undergo screening. Purpose: This study estimated the prevalence of up to date CRC screening and examined the predictors of CRC knowledge and screening compliance among Chinese, Korean, and Vietnamese Americans living in the Baltimore-Washington metropolitan area. Methods: A cross-sectional sample was employed in this study and included 274 Chinese, Korean, and Vietnamese Americans between ages 50-75 years old. A questionnaire was given to participants in either their preferred native language or in English. Data was collected in person. Results: Data from the 2009 California Health Interview Survey (CHIS) indicates that Chinese Americans had higher rates of FOBT at 32.2% than Vietnamese Americans (27.3%) and Korean Americans (24.8%). Compared to these rates from white and having no usual place of care were also associated with lower odds of completing the vaccine series. Conclusions: Our study shows that there are sociodemographic factors associated with HPV vaccine uptake among young adults in the United States, and males, individuals with a lower education, and those without adequate healthcare access are less likely to initiate and complete the HPV vaccination. Our findings suggest it is necessary to develop targeted interventions to promote HPV vaccination among those in the catch-up age range.

**#4225 Disparities in cervical cancer screening participation: a comparison of Russian, Somali and Kurdish immigrants with the Finnish general population.** Esther E. Idehen,1 Päiviikki Koponen,2 Tommi Harkonen,3 Tellervo Korhonen4.1 University of Eastern Finland, Kuopio, Finland; 2Finnish National Institute for Health and Welfare (THL), Helsinki, Finland; 3University of Helsinki, Helsinki, Finland.

Background: Cervical cancer screening through Pap test has been shown as an effective preventive measure for early detection of precancerous in the cervix. Finland offers mass Pap test screening to all eligible women. Knowledge about disparities in the screening participation among immigrants compared with the Finnish general population is limited. Objectives: (1) To compare Pap test screening participation in the past five years among Russian, Somali and Kurdish immigrants living in Finland with the Finnish general female population; (2) to examine if the observed disparities remain similar when adjusted for socio-demographic and health-related confounding factors. Methods: Data from the Finnish Migrant Health and Well-being Study and Finnish Health 2011 Survey were used. Random samples of persons living in six cities in Finland were drawn from the national population registry. Data of self-reported cervical screening participation (Pap test) among women aged 29-60 were available from the registry. Data of self-reported cancer knowledge (aOR = 0.47, 95% CI, 0.16, 0.84). The findings of this study suggest that CRC knowledge is a strong predictor of CRC screening behavior in Asian Americans. Lack of CRC screening knowledge still remains an important barrier to screening, and future strategies to increase public awareness on CRC is necessary to achieve greater screening compliance amongst AA populations.

**#4226 Challenges to breast cancer early detection in the developing, high income country of Trinidad and Tobago.** Kimberly Badal,1 Fidel Rampersad,2 Hamish Mohammed,1 Murrie Moosooddeen,3 Siva Kunduru,2 Nilani Kokaram Maharaj,4 Adaila Russel,2 Melissa Nathan,2 Marisa Nimrod,7 Wayne A. Warner,7 Rajini Haraksingh,8 Adetunji Toriola,9 Caribbean Cancer Research Initiative, San Fernando, Trinidad and Tobago; 7University of the West Indies, San Fernando, Trinidad and Tobago; 8Washington University in St. Louis, St. Louis, MO.

...
PREVENTION RESEARCH: Population Science in Cancer Prevention Research

Trinidad and Tobago (T&T) has one of the highest breast cancer (BC) mortality rates in the Americas. For the period 1995-2007, 5-year BC survival rates in T&T were approximately 30%. One possible explanation for T&T’s low BC survival rates could be late presentation and detection. Currently, opportunistic BC screening programs exist in the public and private sectors and some have been implemented to study disparities in uptake among individuals and dyads and related cancer prevention behaviors. Researchers interested in these areas can access FLASHE data and resources online to examine their own research questions.

#4228 Interlaboratory concordance of genetic variant classifications in BRCA1 and BRCA2.

Stephen E. Lincoln,1 Shan Yang,2 Melissa S. Cline,3 David Haussler,2 Benedict Paten,2 Robert Nussbaum1.1 Invitae, San Francisco, CA; 2University of California, Santa Cruz, Santa Cruz, CA.

Background: Clinical laboratories use publicly available literature, databases, and expertise to determine the pathogenicity of genetic variants in test reports. Recently, discordances between public databases have been raised as a concern, most prominently by those who use proprietary data in their classification processes. However, the clinical impact of these discordances is unclear. In prior work, we observed 99.8% concordance of clinically significant variant classifications between two labs across 975 prospectively accrued patients (Lincoln et al., J Mol Diag 2015). Here we evaluated BRCA1/2 variant classification discordance among multiple labs in a much larger patient population. Methods: Over 5000 ClinVar submissions of classified BRCA1/2 variants from 7 established laboratories (Ambry, the Children’s Hospital of Eastern Ontario, Counselling, Emory, GenDX, Invitae, and Myriad) were available for comparison. Variant data were submitted by the Sharing Clinical Reports Project. Clinically significant differences were those that could substantially change clinical management: i.e. between pathogenic (including likely pathogenic), versus VUS (variant of uncertain significance), benign or likely benign; otherwise results were considered concordant. Approximately 22,000 patients were represented in this comparison.

Results: Counting each variant separately, discordance between labs was high: 98.5% overall. However this calculation greatly underestimates the much higher concordance calculated on a per-patient basis. All discordant classifications were in rare variants that, by definition, are present in very few patients. Moreover, classifications of most rare variants are concordant (sometimes, concordantly VUS). Based on clinical and population prevalence, we calculate that 99.8% of patients would receive net concordant BRCA1/2 reports, similar to our previous study’s results. The dominant sources of discordance were (a) date, where classifications that postdate a critical piece of evidence disagree with those that predate it; and (b) expert judgment differences evaluating the strength of certain evidence, usually functional assays. Discussion: Classification discordance needs to be measured carefully to avoid over-counting differences. While substantial differences are seen in few patients, it is important to resolve these collaboratively, not competitively, as is done in other areas of oncology. Thorough and ongoing peer review of classifications is enabled by public databases like ClinVar which both enable laboratory quality control efforts and help improve personalized medical care practices.

#4229 Metabolically active macrophages: A novel link between obesity and TNBC.

Payal Tiwari,1 Kelly Schoenfeld, Arianne Blank, Chang Cui, Marsha Rich Rosner, Lev Becker. Univ. of Chicago, Chicago, IL.

Triple negative breast cancer (TNBC) patients have an extremely poor prognosis due to their high metastatic potential and lack of targeted drug therapies. Emerging epidemiological data suggest that obesity is strongly linked to the incidence and severity of TNBC. However, mechanisms by which obesity potentiates TNBC progression are unclear. Adipose tissue macrophages (ATMs) are an attractive mechanistic link between obesity and TNBC because they are the predominant type of macrophage in the breast during early tumorigenesis and obesity causes accumulation of ATMs. However, during obesity, the macrophage phenotype was reported to switch from an apparent pro-tumorigenic M2-like phenotype to an apparent anti-tumorigenic M1-like phenotype. This result raises a paradox: how does obesity promote tumor progression if it activates an anti-tumorigenic macrophage phenotype? Here we show that metabolic dysfunction promotes a mechanistically distinct pro-inflammatory phenotype (metabolic activation; MMe) in breast adipose tissue macrophages isolated from obese women. These MMe express cell surface markers of MMe (CD36, ABCA1) but not M1 (CD38, CD319, CD274) macrophages. We further demonstrate that pretreating TNBC cells with conditioned media derived from MMe but not M1 macrophages promotes mammosphere formation as well as invasion in vitro, and...
intravasation of cancer cells into the blood in vivo. Moreover, pre-treated cancer cells showed a two-fold increase in the expression of stem-like cell markers (OCT4, SOX2 and NANOG). Remarkably, we saw the same effect on ‘stemness’ of tumor cells in a spontaneous TNBC mouse model when fed a 60% high fat diet and a significant increase in tumor incidence in obese mice compared to controls. In less invasive models, we also demonstrated that blocking inflammatory cytokines expression in MMe(s) using genetic knockouts inhibits the ability of MMe(s) to promote both mammosphere formation and invasion. These findings suggest that obesity-induced changes to mammary adipose tissue reprogram macrophages to an MMe phenotype that potentiates TNBC initiation and metastasis via inflammatory cytokines and chemokines. Furthermore, we can demonstrate that obesity-induced inflammation(s) involved in metabolic activation of mammary ATMs would enable development of directed therapies towards this specific pro-tumorigenic macrophage phenotype, thereby leaving the immune system of cancer patients intact.

#4230 Modulation of adiponectin and leptin levels in obese post-menopausal women after 6 months of a structured weight loss intervention, randomized to placebo or supplemental omega-3 fatty acids. Bruce F. Kimler,1 Jennifer L. Nydegger,1 Amy L. Kreutzjans,1 Teresa L. Phillips,1 Kandy R. Powers,1 Jennifer R. Klemp,1 Debra K. Sullivan,1 Christie A. Befort,1 Susan E. Carlson,1 Stephen D. Hursting,2 Carol J. Fabian,1 1Univ. of Kansas Medical Ctr., Kansas City, KS; 2Univ. of North Carolina at Chapel Hill, Chapel Hill, NC.

Background: Obesity is a modifiable risk factor for breast cancer in the United States. While structured interventions can achieve short-term weight loss, this does not necessarily correlate with favorable modulation of risk biomarkers at the blood or breast tissue level. We combined a proven intervention (calorie-controlled meals, moderate exercise, and weekly group behavior session) with daily omega-3 fatty acid supplementation to examine whether we could improve either weight loss and/or biomarker modulation in women who are at high risk for development of breast cancer. Methods: 46 post-menopausal high-risk women with a BMI >27 kg/m² (median 31 kg/m²) had baseline blood collections and random periareolar fine needle aspiration (RFNFA) benign breast tissue sampling for biomarkers. Two weeks after starting the weight loss intervention, subjects received study agent, randomized 1:1 to placebo vs. supplementation with 2100 mg Eicosapentaenoic Acid (EPA) + 1050 mg Docosahexaenoic Acid (DHA) daily. After 6 months, blood and tissue sampling were repeated. Results 42 women completed the 6 month weight loss intervention with all but one achieving a weight loss (median relative weight loss 12%; range 0 to 23%). For the entire cohort, there were substantial and favorable changes in levels of serum blood collected fasting for adiponectin (increase, p<0.001) and leptin (decrease, p<0.001), as well as the ratio of adiponectin to leptin (A/L, increase, p<0.001). The same effect for all three measures was observed in serum collected 2 hours after a standard meal; and for leptin and the A/L ratio in breast tissue also collected postprandial. When dichotomized to relative weight losses of <10% vs >10%, women with >10% loss had greater favorable modulations for leptin and the A/L ratio for fasting and non-fasting serum vs. tissue, p<0.001 for all. We further noted significant differences between groups of women dichotomized by whether they exhibited (or not) an increase in the ratio of EPA:DHA to arachidonic acid in erythrocyte phospholipids at 6 months. Conclusions: These results demonstrate that the cytokines adiponectin and leptin, and the ratio of the two, are robust biomarkers for modulation in serum and breast tissue of women achieving a successful weight loss on a structured intervention trial. Supported by a grant from the Breast Cancer Research Foundation and pilot funds from National Cancer Institute Cancer Center Support Grant P30 CA168524.

#4231 Significant reduction in workplace contamination of antineoplastic hazardous drugs in 13 U.S. hospitals following utilization of a new closed-system drug transfer device. Timothy Tyler,1 Lunci Power.2 1Desert Regional Medical Center, Palm Springs, CA; 2UCSF (retired), San Francisco, CA.

Background: Adverse effects of worker exposure to antineoplastic hazardous drugs (AHD) have been well documented with dermal absorption from contaminated surfaces in the work environment being one of the most well researched sources of exposure. Multiple studies have documented decreased surface contamination when using CSTDs for AHD handling. Decreased surface contamination should result in decreased worker exposure and decreased risk of adverse effects. Purpose: The purpose of this study was to determine the effectiveness of a new CSTD in reducing surface contamination of marker AHDs cyclophosphamide (CP) and 5-fluorouracil (5FU) during compounding and administration in multiple cancer centers, using surface wipe-sampling methodology. The results of the wipe sampling were compared to existing contamination in the sites and to similar studies in peer-reviewed literature to determine relative effectiveness. Methods: Wipe samples of six predetermined surfaces were collected in designated compounding and/or infusion areas of 13 cancer centers to establish the pre-existing level of surface contamination with two marker AHDs. Stainless steel plates of approximately 500 cm² were placed over previously sampled surfaces, and a specific protocol of set doses of the AHDs were compounded and infused, using all of the components of the new CSTD system, over the templates. Wipe samples of the templates were collected following the completion of tasks analyzed for both marker, AHDs. Results: A total of 311 wipe samples were collected from the 13 centers, 156 at baseline and 156 with the CSTD. All samples were reported as ng/cm² with the analytical limit of detection (LOD) for each drug being 0.002 ng/500 cm². In the aggregate results of 13 sites sampled for existing contamination, 67% of wipe samples had detectable levels of the AHDs with a range of LOD to 19.880 ng/cm² of 5FU and 0.648 ng/cm² of CP. With the new CSTD the contaminated samples were reduced to 5.8% with a range LOD to 0.004ng/cm² of 5FU and 2.68ng/cm² of CP. Conclusions: The new CSTD significantly reduced surface contamination by the marker AHDs during both compounding and administration. Compared to published results of two multi-site studies of another CSTD for compounding, the new CSTD is superior in reducing surface contamination of marker AHDs. A comparison of surface sampling of similar surfaces. Research reported in this study was supported by the National Cancer Institute (NCI) of the National Institutes of Health (NIH) under award number 5R44CA153636.

#4232 Gastrointestinal stromal tumor: Retrospective analysis of 44 cases of center of reference in eastern Algeria. Soulyane Ali Boukhalfa, Tah Filiali. CHU de Constantine, Tadjenanet, Algeria.

Aims: To analyze the clinicopathologic characteristics, prognostic factors, and treatment of gastrointestinal stromal tumors (GISTs). Methods: We conducted a retrospective analysis of all cases of GISTs treated in the Medical Oncology Unit from 2010 through 2015. Results: We analyzed 44 patients with a median age of 49.43 years (17-76 years) with sex ratio 1:1. The main symptom was abdominal pain. Thirty patients had limited-stage disease and 14 patients had metastatic disease. We observed 90% of the immunohistochemistry exams were positive for CD117 (c-Kit+). The most frequent location was in the stomach (45%), the high-risk group was predominant (50%) and the average tumor size is 12.84 cm. Surgery was considered R0 (extensive) in 75% of the cases and the main sites of metastases were liver and peritoneum. 25 patients received imatinib 400 mg qDay in adjuvant setting, 5 patients in neoadjuvant, 13 patients in palliative use. The median dose of the first-line therapy was 500mg/day. Forty-one patients (93%) were rechallenged in second line with imatinib 800 mg qDay, 5 patients with sunitinib and 2 patients with gefitinib. Conclusion: Our patients presented mainly in the form of high-risk disease, Surgery is the mainstay treatment when GISTs are localized, Adjuvant therapy is used depending their risk of relapse. In the advanced disease, tyrosine kinase inhibitors have substantially improved the prognosis of GISTs.

#4233 Linking education to action: A program to increase research participation among African American women. Carmen Radecki Breitkopf,1 Karen P. Williams,2 Jennifer L. Ridgeway,2 Alice L. Strong Simmons,3 Monica W. Parker,4 Michele Y. Halyard,5 Sharrone N. Hayes1. 1Mayo Clinic, Rochester, MN; 2The Ohio State University, Columbus, OH; 3The Links, Incorporated, DC; 4Emory University, Atlanta, GA; 5Mayo Clinic, Scottsdale, AZ.

Addressing underrepresentation of minorities and women as research participants has largely focused on enrollment of clinical trials. The results are known about the attitudes and knowledge regarding other types of biomedical research, e.g., epidemiologic and genetic studies. These types of studies are essential for advances in cancer research, including development of targeted therapies for women and minorities. As part of an academic/community partnership between Mayo Clinic and The Links, Incorporated, a national volunteer service organization of professional African American women, this study sought to: (1) examine attitudes regarding participation in research involving access to the medical record, genetic studies/biobanking, and clinical trials; and (2) develop and evaluate a novel, targeted online educational program addressing these 3 types of biomedical research. Initial qualitative inquiry via 3 focus
PREVENTION RESEARCH: Population Science in Cancer Prevention Research

groups (n=34) found that most women associated health-related research with clinical trials; few women were familiar with other study types. Women expressed more concerns about how information is collected, used, and shared by investigators than with personal mistreatment in research regardless of study type (genetic research [GEN], chart review [CR], clinical trial [CT]) or information on beliefs, health disparities, and cancer research ethics. The importance of investigator transparency regarding the significance of the disease in African Americans, research funding source, the investigator's agenda, and commitment to the population being studied was emphasized. Qualitative results informed development of the educational program. A total of 244 Links members completed the program (77% response rate) and answered an initial and post-program assessments of intentions, attitudes and knowledge. The percent of women indicating that they "definitely" or "probably" intend to participate in research increased from 9.4% to 19.5% and 27.1% to 49.8%, respectively, after program completion. Agreement with the statement "research in the U.S. is ethical" increased from 52.9% to 74.4%. Factual knowledge related to each of the 3 study types also increased. Prior to completing the program many women reported "little or no understanding" of the 3 types of studies (66% GEN, 62.9% CR, 40.7% CT) whereas after program completion, these numbers decreased to 24.9%, 18.4%, and 15.5%, respectively. While few women rated their opinion of the study types as "very positive" prior to beginning the program (14.3% GEN, 15.0% CR, 28.6% CT), upon completion these proportions increased and equalized (42.8% GEN, 40.0% CR, 42.5% CT). Two-month follow-up will evaluate long-term impact including knowledge dissemination, visiting clinicaltrials.gov, and enrolling in ResearchMatch. An online education-to-action program targeting professional African American women improved knowledge, perceptions of research ethics, and intent to participate in biomedical research.

**#4234 A culturally competent, community driven, collaborative approach to health care education conferences addressing the health disparities of African Americans.** Ricardo Parker,1 Patric Schiltz,2 Ernesta Wright,3 Jhenifa Parker,4 Denise Tolbert,5 Leelee Matthews,5 LaQuetta Shamblee.6 1National Univ., Costa Mesa, CA; 2The GREEN Foundation, Orange, CA; 3Eastern Washington University, Cheney, WA; 4Loyola Marymount University, Los Angeles, CA.

The ability to effectively deliver health care education that meets the social, cultural, and linguistic needs of people with diverse cultures is an important consideration, and is referred to as culturally or community competent approaches. Community and culturally competent health care education approaches are especially important in educational conferences designed to engage residents in health care issues such as health screenings, lifestyle, and preventative approaches toward improved health, as well as examining the impact of these and other factors on health disparities related to ethnicity. In this report, we evaluated 15 ActNOW cancer education conferences over a 5-year period, using a community driven, culturally competent conference model designed to educate African Americans participants, with an emphasis on reducing health disparities through understanding cancer, the importance of clinical trials participation, screening, and preventative and healthy lifestyle choices. Qualitative data on an aggregate of 380 participants were obtained through an anonymous evaluation and feedback survey questionnaire distributed to participants at the end of the conference. Participants' pre- and post-conference perceived cancer knowledge and intent to change lifestyle were evaluated. Conference attendees voluntarily completed the self-administered questionnaire comprised of 8 questions. Each question had 4 possible responses: 1. non-existent; 2. minimal; 3. moderate or 4. considerable. For statistical analysis, responses were separated into two groups; low and high. Responses designated 1 or 2 were considered to reflect minimal understanding of the subject material; and frequency counts for responses 1 or 2 were aggregated and designated as 'Low' understanding responses. Responses 3 or 4 reflected a higher understanding of the subject material; and frequency counts for responses 3 or 4 were aggregated and designated as 'High' understanding responses. The groups were then analyzed statistically using Fisher's exact test, where a two-sided p≤0.05 is considered significant. The results demonstrated a significant number (27%) of respondents indicating a low understanding of the topics before the event. After the event, a significantly lesser number (2%) of low respondents reported a low understanding of the topics, with a consequent increase in high respondents reporting a greater understanding (from 73% pre- to 98% post-conference; p<0.0001). Similar significant shifts in practice knowledge profiles were also seen (p<0.0001). Cultural and/or community competent approaches for health care education are a considered need.

**EPIDEMIOLOGY: Biomarkers of Endogenous or Exogenous Exposures, Early Detection, and Biologic Effects**

**#4235 Application of convolutional neural networks to breast biopsies to uncover tissue correlates of mammographic breast density.** Maeve Ebot,1 Masis Isikbay,2 Travis Gerke,2 Thomas U. Ahearn,3 Rachel S. Kelly,2 Svitlana Tyekucheva,1 Andreas Pettersson,1 Kathryn L. Penney,1 Lorelei A. Mucci1. 1National Cancer Institute, Bethesda, MD; 2Radboud University Medical Center, Nijmegen, Netherlands; 3University of Vermont, Burlington, VT; 4University of California, San Francisco, San Francisco, CA; 5Hokkaido University, Sapporo, Japan; 6MD Anderson Cancer Center, Houston, TX; 7Mayo Clinic, Jacksonville, FL; 8Harvard Medical School, Boston, MA.

Background: High percent mammographic density (MD), which reflects the relative fibroglandular tissue content of the breast, is one of the strongest breast cancer risk factors; however, the pathologic mediators of this risk are unknown. We hypothesize that analysis of breast tissue sections using deep learning approaches may characterize histologic features that underpin risk associated with high MD. Methods: Non-targeted H&E stained breast tissue sections of diagnostic image-guided breast biopsies were evaluated among 588 women enrolled following an abnormal mammogram in the Breast Radiology Evaluation and Study of Tissues (BREAST) Stamp Project (2007-2010). Overall volumetric percent MD for the biopsied breast and localized volumetric percent MD surrounding the biopsy site were determined for each participant. A deep convolutional neural network (CNN) model was trained to identify and quantitatively assess breast epithelial, stroma and fat tissue and their organizational and spatial arrangements. Least absolute shrinkage and selection operator (Lasso) regression was used to determine relationships between MD measures and pathological features. To ensure reliability of the model, a cross-validation strategy was employed to build and assess the performance of the fitted model. Finally, Spearman correlation coefficients were estimated to test the association between the predicted density values by each model (predicting overall or localized MD) and the actual MD measurements. We report the average and standard deviation (SD) of the correlation coefficients. Results: In an independent validation set, the CNN model was 95.5% accurate in classifying epithelial, stromal and fat tissue. The mean (SD) correlations between the predicted model and the actual measurements for overall and localized MD were 0.70 (0.06) and 0.65 (0.06) respectively. The amount of stroma identified (normalized to tissue area) had the highest selection probability (P-value) by the Lasso model and thus the strongest positive relationship with MD (P-value>0.9 for each MD measurement). In contrast, the amount of normalized epithelial tissue was not related to MD (P-value=0.01 for each MD measurement). No association was observed for the total normalized fat area with MD (P-value<0.31 for each MD measurement). In another group, the epithelial to stromal ratios was positively associated, whereas the distance between epithelial regions was inversely associated with overall MD (P-value<0.87 and 0.62, respectively). Conclusions: These results show that greater stromal tissue amount and spatial distribution patterns of epithelial regions, rather than total epithelial amounts, had the strongest relationships with elevated MD. Future work will determine the relationship of these MD features with biopsy diagnosis.

**#4236 Gene expression profiling of prostate tissue identifies biological pathways associated with TMPRSS2:ERG fusion gene.** Ericka Ebot,1 Masis Isikbay,2 Travis Gerke,2 Thomas U. Ahearn,3 Rachel S. Kelly,2 Svitlana Tyekucheva,1 Andreas Pettersson,1 Kathryn L. Penney,1 Lorelei A. Mucci1. 1Harvard School of Public Health, Boston, MA; 2Harvard Medical School, Boston, MA; 3University of Florida, Gainesville, FL; 4National Cancer Institute, Rockville, MD; 5Brigham And Women's Hospital, Boston, MA.

Background: TMPRSS2:ERG fusion is a hormonally regulated gene fusion present in about half of prostate tumors, is the most common somatic event in prostate cancer. There is intriguing evidence to suggest that TMPRSS2:ERG-positive tumors may define a distinct subgroup of prostate cancer. In this study we compared gene expression profiles according to fusion status to identify genes and biological pathways differential expressed by TMPRSS2:ERG. Methods: The study included men with prostate cancer in the Health Professionals Follow-up Study and the Physicians' Health Study diagnosed between 1982 and 2004 and followed through 2012. Tumor biomarker data was available for archival tumor samples in 192 cases that had gene fusion adjacent to normal tissue. Whole genome mRNA expression profiling (20,254 genes) was performed using the Affymetrix 1.0 ST array. TMPRSS2:ERG tumor status was assessed by a genetically validated IHC assay for ERG. To relate expression of individual genes to ERG we used linear regression. Gene Set Enrichment Anal-
yses (GSEA) was used to identify pathways of genes associated with ERG in both tumor and adjacent normal tissue. Data from The Cancer Genome Atlas (TCGA) was used to validate these findings. Results: Among 380 cases, 186 (49%) of tumors were positive for the gene fusion. Genome-wide differential expression analysis identified 492 genes upregulated and 369 genes downregulated in tumor tissue comparing ERG expression analysis identified 492 genes upregulated and 369 genes downregulated (49%) of tumors were positive for the gene fusion. Genome-wide differential expression analysis (GSEA) was used to identify pathways of genes associated with ERG in both tumor and adjacent normal tissue. Data from The Cancer Genome Atlas (TCGA) were compared between ERG-positive and ERG-negative tumors. No genes were identified in the adjacent normal tissue at this significance level. 772 of the 861 genes (90%) identified in the HPES/PHS dataset were confirmed in TCGA (448 upregulated and 324 downregulated). The top ten genes included ERG, WNK2, CACNA1D, HES1, SEPT9, PLA2G7, TDRD1, ANTXR2, SORBS2, and MTO6. Enrichment analysis identified a number of metabolic pathways associated with ERG tumor status including pathways involved in amino acid and fatty acid metabolism. Conclusions: We identified significant differences in gene expression profiles in prostate tumor tissue according to TMPRSS2:ERG status, providing supportive evidence of this fusion as a unique subtype.

#4237 Estrogen metabolism in menopausal hormone users: Does it differ between estrogen plus progestin and estrogen alone users in the Women’s Health Initiative Observational Study. Roni T. Falk,1 Garnet L. Anderson,1 Vanessa M. Barnabei,2 Louise A. Brinton,1 Jane A. Cauley,3 Chu Chen,4 Rowan T. Chlebowski,5 Sally B. Coburn,1 JoAnn E. Manson,4 Ruth M. Pfeiffer,1 Keryn W. Reding,2 Thomas E. Rohan,3 Gloria E. Sarto,1 Nicolas Wentzensen,1 Britton Trabert,1,*, National Cancer Institute, Bethesda, MD; 2Fred Hutchinson Cancer Research Center, WA; 3Jacobs School of Medicine and Biomedical Sciences University at Buffalo, NY; 4University of Pittsburgh Schools of the Health Sciences, PA; 5David Geffen School of Medicine UCLA, CA; 6Harvard Medical School, MA; 7University of Washington School of Nursing, WA; 8Albert Einstein College of Medicine, NY; 9University of Wisconsin School of Medicine and Public Health, WI.

Background: The Women’s Health Initiative (WHI) provided divergent results regarding the effects of menopausal hormone therapy (MHT) on breast cancer risk, with women in the conjugated equine estrogen plus medroxyprogesterone (CEE+MPA) arm at elevated risk, and women in the CEE alone arm at reduced risk. Although direct progestin-mediated effects may largely explain the elevated risk, we hypothesize that in addition, these MHT treatments may differentially influence patterns of estrogen metabolism, with CEE alone preferentially inducing metabolism along the 2-hydroxylation pathway, a pattern previously linked to reduced breast cancer risk. Study methods/population: Women in a case-control study of estrogen metabolites (EM) and ovarian and endometrial cancer from the WHI Observational Study were identified for this analysis. Unlike the WHI trial, no medication restrictions were applied. At enrollment, serum, anthropometric measures, and self-administered questionnaires which ascertained reproductive history, lifestyle factors and health behaviors including MHT use, were obtained. 615 women reported current use of estrogen plus progestin formulations (E+P), of whom 343 used CEE+MPA; 266 used estrogens alone (E alone), with 148 using CEE. Fifteen EM were measured by liquid chromatography/mass spectrometry and analyses were conducted separately for each EM. EM differences between E alone and E+P users were assessed using inverse probability weighted linear regression. Primary analyses included women using any MHT formulation; secondary analyses were restricted to CEE users. Results: Compared to users of E+P, concentrations of all EM were higher in E alone users, and significantly so for unconjugated estrone, estradiol, 2-methoxyestrone, 4-methoxyestrone and unconjugated estradiol. Relative to total EM, concentrations of 2- and 4-pathway EM did not differ by MHT group (for E alone and E+P users, 2-pathway EM were ~14% of the total EM; 4-pathway EM were ~1% of the total), but E+P users had a significantly higher proportion of 16-pathway EM compared to E alone users (32% vs. 30%, p=0.025). Similar patterns were observed in analyses comparing users of CEE alone to CEE+MPA, albeit not significant. Conclusion: Our data suggest that women using E alone may preferentially metabolize estrogens along the 2- and 4-hydroxylation pathways, whereas in E+P users, more extensive metabolism occurs along the 16-pathway. However, we did not observe these effects in the smaller groups of women using CEE alone or CEE+MPA, the MHT formulations administered in the treatment arms of the WHI trial. Our findings in E alone users are consistent with epidemiologic investigations demonstrating reduced breast cancer risk in postmenopausal women with more extensive 2-pathway estrogen metabolism, and may provide a clue to the breast cancer risk reduction observed in these women.

#4238 The effects of long-term storage on commonly-measured serum analyte levels. Cynthia Kleeberger,1 David Shore,2 Elaine Gunter,3 Dale P. Sandler,4 Sandra Deming-Halverson,1 Clarice R. Weinberg,1 Social & Scientific Systems, Inc., Durham, NC; 2Westat, Durham, NC; 3Specimen Solutions, LLC, Tucker, GA; 4NIEHS, RTP, NC.

Introduction: Cohort studies typically bank biospecimens for many years prior to assay and the levels of analyte degradation is unknown. Long storage times (i.e. severe degradation) can bias the estimation of the analyte effects on health outcomes. Such effects could also produce confounding with other factors under study. Methods: We collected control samples from 22 non-study participants using the same enrollment criteria and specimen collection, processing, and storage protocols as in the Sister Study, a large cohort study conducted by the National Institute of Environmental Health Sciences. Samples were assayed for 21 analytes at collection and then six years later. For each sample, the difference between the result at baseline and at six years was calculated for each analyte. The difference, Yij = result - result, was then modeled using a mixed-effects model, with random effects for batch (bj) and a fixed effect for the overall mean difference: Yij = u + b + cij.
where \( b_i \sim N(0, \sigma^2_{\text{seeds}}), i = 1, 2, 3, 5, 6 \). Results: Some of the analytes experienced a marked change in concentration after six years of frozen storage, compared to their baseline value. There were no significant changes in ten of the analytes. Two of the analytes, lactate dehydrogenase (LDH) and sex hormone binding globulin (SHBG), increased significantly in concentration over time. Two analytes, HDL cholesterol and luteinizing hormone (LH), decreased significantly in concentration over time and the estimated mean difference across the two time points. Conclusion: We conclude there are differences in assay results after long-term storage, although for most analytes the correlation coefficients were high and percent change small. Biobanks or cohort studies that bank samples should consider building in QC experiments designed to assess the impact of long-term storage on anticipated analytes of interest, when possible. By doing so, degradation could be corrected for to control bias due to the associated measurement error. Since not all cohorts were able to conduct these QC experiments, those that have carried out such assessment should share their results so others can use the data to evaluate the potential impact of measurement error on their study findings.

**#4240** Determination of normative patterns of gene expression levels and breast cancer risk biomarkers in human breast milk. Maria Ozounova, Georgina Lewis, Radhika Piraniaddu, Tiana Curry-McCoy, Nita Maiblack, Sangmi Kim, Hasan Korkaya, Augusta University, Augusta, GA.

Parity and breastfeeding influence a woman’s risk of developing breast cancer. Understanding the underlying molecular changes in the breast will facilitate identification of additional factors during pregnancy and postpartum that modify breast cancer risk. Most prior studies in humans on this topic, however, have been cross-sectional studies comparing breast tissue samples from nulliparous versus post-pregnant women, and are limited in their ability to characterize longitudinal changes and within-person variations. Breast milk contains cells of the mature gland, and may have a potential as a noninvasive source for studying molecular characteristics of the pregnancy-associated changes in the breast and their impact on breast cancer risk. The objectives of this study were to (1) determine normative patterns of gene expression levels in longitudinally collected breast milk samples and (2) correlate gene expression data in relation to self-reported measures of psychosocial stress during pregnancy and postpartum period. Our preliminary results showed that the post-pregnancy gene expression levels in breast milk samples can be measured reproducibly over a short period of time. Whole genome transcriptome data revealed the correlation levels of the post-pregnancy genes are different in early (less than 3 month postpartum) and late lactation period (more than 6 month postpartum). Moreover cytokine expression profiling correlated expression of inflammatory cytokines with early versus late postpartum period. The unique contribution of this study is to capture longitudinal gene expression data from breast milk samples collected over the course of lactation, hence providing a valuable basis for future studies to identify differentiation dynamics associated with breast cancer susceptibility.

**#4241** Circulating microRNAs in plasma of men screened for prostate cancer. Alicia C. Mcdonald, Jing Shen, Manish Vira, Jason Liao, Martin L. Lesser, Dattatrya Patil, Jay D. Raman, Emanuel Taliol. 1Pennsylvania State University College of Medicine, Hershey, PA; 2Columbia University, New York, NY; 3Hofstra Northwell School of Medicine, Hempstead, NY; 4Emory University School of Medicine, Atlanta, GA; 5The Feinstein Institute for Medical Research, Manhasset, NY; 6Pennsylvania State Milton S. Hershey Medical Center, Hershey, PA; 7Ichan School of Medicine at Mount Sinai, New York, NY.

Introduction: Although microRNAs (miRNAs) have been linked to prostate cancer risk, their role as a screening biomarker for prostate cancer (PC) has yet to be determined. We examined whether circulating miRNAs in plasma could be potential biomarkers for the early detection of PC among men undergoing prostate needle biopsy. Methods: Men who had a prostate biopsy due to an abnormal screening test were recruited. Demographics, medical history, clinical information, and blood processed into plasma were collected. TaqMan Low Density Arrays were used for the expression profiling of 733 miRNAs in plasma. Wilcoxon test was used to compare expression levels between men with and without a PC diagnosis. Logistic regression was used to examine the association between miRNAs and PC status, after adjusting for age and Bonferroni-correction. Results: There were 131 men, aged 46 to 86 years, included in the final analysis, with 66 men diagnosed with PC on prostate biopsy and 65 men without a PC diagnosis. Majority were white (72.5%) followed by black race (13.5%). Men with PC were older (median: 64 vs. 62 years; p-value = 0.161) and had statistically significantly higher serum PSA (median: 5.8 vs. 5.1 mg/ml; p-value = 0.01) compared to men without PC. miRNAs which include the discovery of new miRNAs and their relationship but within the limits of the internal laboratory control variance. Significant reductions in excess of the laboratory control variance were found for 7 of the 21 analytes tested (aspartate transaminase (AST), total cholesterol, estradiol, glucose, protein, sodium, and triglycerides). Despite the evidence for systematic changes over long-term storage, correlations between baseline and later measures were often low and there was little relation between the size of the correlation changes over long-term storage, correlations between baseline and later measures were high and there was little relation between the size of the correlation coefficients and the estimated mean difference across the two time points. Conclusion: We conclude there are differences in assay results after long-term storage, although for most analytes the correlation coefficients were high and percent change small. Biobanks or cohort studies that bank samples should consider building in QC experiments designed to assess the impact of long-term storage on anticipated analytes of interest, when possible. By doing so, degradation could be corrected for to control bias due to the associated measurement error. Since not all cohorts were able to conduct these QC experiments, those that have carried out such assessment should share their results so others can use the data to evaluate the potential impact of measurement error on their study findings.

**#4242** Mass spectroscopic analysis of MGMT tryptic peptides allows detection of O6-alkylguanine adducts in oligodeoxynucleotides, temozolomide modified cell thymus DNA and human colorectal cancer DNA. Rashia A. Abdelhady, Perdita E. Barran, David M. Williams, Andrew C. Povey, 1University of Manchester, Manchester, United Kingdom; 2University of Sheffield, Sheffield, United Kingdom.

Background: Red and processed meat consumption increases human colorectal cancer (CRC) risk, potentially by heme-catalysed formation of carcinogetic N-nitrosocompounds (NNOC) that form mutagenic O6-alkylguanine (O6-alkG) DNA adducts. While NNOC formation cannot be accurately estimated from meat consumption alone due to in situ processing required for their formation. We are thus developing a novel approach to assess NNOC exposure by quantifying O6-alkylguanine DNA adducts that result from their exposure, using the known action of the DNA repair protein, O6-alkylguanine O6-alkyltransferase (MGMT), to irreversibly transfer the O6-alkyl to an active site cysteine residue in MGMT. Methods: Oligodeoxynucleotides (ODNs) containing O6-methylguanine (O6-MeG), O6-carboxymethylguanine (O6-CMG), O6-carboxethylguanine (O6-CEG) were synthesised by alcohol modification of an ODN containing the convertible base 2-amino-6-methylsulfonylpurine. O6-MeG containing cell thymus (CT) DNA was prepared by incubation with temozolomide (TMZ). Both maltose binding protein-MGMT (MBP-MGMT) and histagged MGMT (his-MGMT) fusion proteins were expressed, purified, and MGMT functional activity determined by tritium transfer using CT DNA methylated with [3H]-N-Nitrosomethylurea. Double stranded O6-alkG-containing ODNs, unmethylated ODN and methylated CT DNA were incubated with MBP-MGMT and the resulting alkylated MGMT digested with trypsin and analysed by mass spectrometry using MALDI-TOF. Human CRC DNA samples were incubated with TMZ modified calf thymus DNA which was then recovered using Ni-coated magnetic beads. MGMT was digested in situ with trypsin and the tryptic peptides analysed by MALDI-TOF. Results: S-methylcysteine (m/z 1329.7), S-carboxymethylcysteine (m/z 1373.7) and S-carboxyethylcysteine, modified MGMT active site peptides were detected in trypsin digests of MGMT incubated with O6-MeG, O6-CMG and O6-CEG containing ODNs respectively. Only the unmethylated active site peptide (m/z 1315.7) was found after incubating MGMT with unmethylated ODN. Subsequent MS analysis of tryptic digest of MGMT incubated with TMZ modified CT DNA also revealed the active site peptide containing S-methylcysteine. Using this approach, pilot studies revealed the presence of O6-MeG, O6-CMG and O6-CEG in CRC DNA. Conclusions: These results demonstrate proof of principle and confirm that this approach could be used to characterise O6-alkylguanine adducts in human CRC DNA.

**#4243** Epigenome-wide association study of metabolic syndrome in African-Americans. Tomi Akinenyienu. University of Alabama at Birmingham, Birmingham, AL.

Background: The epidemic of obesity among US adults has resulted in significant increases in associated metabolic disorders such as diabetes, dyslipidemia, and high blood pressure. Together, these disorders constitute metabolic syndrome, a clinically defined condition highly prevalent among African-Americans. Identifying epigenetic alterations associated with metabolic syndrome, including DNA methylation changes may provide information on biological pathways that are dysregulated and may potentially act as early biomarkers in cancer. Methods: Data on cardio-metabolic risk factors and DNA methylation was assessed on 606 African-Americans from the Hypertension Genetic Epidemiology Network (HyperGEN) study. Metabolic syndrome was defined using the joint harmonized criteria of at least three of: elevated waist circumference, high triglycerides, low HDL-cholesterol, high fasting blood glucose and high blood pressure. DNA methylation...
was assessed using the Illumina HumanMethylation 450K Bead Chip assay on DNA extracted fromuffy coat. Linear mixed effects regression models were used to examine the association between CpG methylation and metabolic syndrome in crude and adjusted (for age, alcohol, smoking, sex) analyses. Replication using DNA from 76 African-Americans in the REason for the Geographic and Racial Disparities in Cancer (REGARDS) study, as well as meta-analysis combining both cohorts was conducted. Results: Two differentially methylated CpG sites in the IGFBP1 gene on chromosome 17 (cg06638433; $\beta = 0.01$, $p$-value $= 3.10 \times 10^{-10}$) and the ABCG1 gene on chromosome 21 (cg06500161; $\beta = 0.018$, $p$-value $= 2.60 \times 10^{-14}$) were identified in models adjusted for age, sex, and alcohol (and smoking). Methylation of CpG sites on the TXNIP gene on chr 1 (p = 2.83 x 10^-7) and CPT1A gene on chr 11 (p = 1.39 x 10^-5) were also significantly associated with metabolic syndrome in unadjusted models. Results for the ABCG1 gene remained statistically significant in the replication set and meta-analysis. Conclusion: Metabolic syndrome was consistently associated with focal DNA hypermethylation in the ABCG1 gene, a region of the chromosome that encodes proteins in the ATP-binding cassette transporter family, and is involved in extra- and intracellular signaling. Alterations in the ABCG1 gene were observed in 40% of invasive breast cancer tumors in the TCGA, providing a potential epigenetic link between metabolic syndrome and breast cancer that deserves further study.

**#4244 Detection and characterization of extrachromosomal circular DNA in human plasma.** Jing Zhu, MeiJin Du, Peng Zhang, Liang Wang. Medical College of Wisconsin, Milwaukee, WI.

Background: eccDNA (extrachromosomal circular DNA) has been reported in most eukaryotes, including in human cells. However, little is known about the eccDNA profiles in human circulating system such as blood. Method: We extracted plasma cell free DNA (cfDNA) from three patients with advanced stage cancers. For each patient, we tested 10ng, 1ng, and 0.1ng cfDNA, each with a technical replicate. The cfDNA samples were subjected to ATP-dependent DNase digestion and whole genome amplification (WGA). An additional 2ng cfDNA from each patient skipped the DNase digestion and went directly to WGA step. We sequenced the amplified DNA using the Illumina 100bp PE read protocol. We analyzed sequencing data using a custom split reads-based strategy to retrieve circular DNA molecules. We further analyzed eccDNAs for their biofeatures using functional annotation tools. Results: We received sequence reads at 14.8 million (11.4—22.4) for each sample. When read depth $\geq 3$ as a cutoff, we detected a total number of 2542, 1578, and 57 unique eccDNAs in three patients while negative controls showed $<3$ eccDNAs. For non-DNase digested cfDNAs, we detected only 3 eccDNAs. By comparing read numbers mapped to mitochondrial and human genome, we found that mitochondrial sequence reads increased significantly from 0.34-1.1% before digestion to 24.1-50.1% after digestion. Numbers of detected eccDNAs were similar between technical replicates and proportional to initial input cfDNA. However, eccDNAs detected also showed few overlaps between technical replicates. Size distribution ranged from 31bp to 19740bp (median 1801-1962bp). To test if eccDNAs were generated in specific genomic regions and if eccDNA-involved genes were enriched in specific pathways, we performed enrichment analysis and observed higher GC content in smaller eccDNAs ($<500$ bp, 48%) than larger ones ($>500$ bp, 41%) ($p$<0.001). When compared to random distribution, eccDNAs were more likely located at CpG islands (1.25-1.5 fold enrichment). The eccDNAs were also enriched in exons, 5'UTR, 3'UTR and DNase hypersensitive sites (enrichment folds from 1.39 to 2.3). Using DAVID annotation tool, we observed significant enrichment of the eccDNA-related genes in several categories including the Coiled coil, phosphoprotein, fibrinectin, suggesting a potential involvement in gene expression regulation and cell adhesion events. Using GREAT (Genomic Regions Enrichment of Annotations Tool), we found that the eccDNAs were involved in genes associated with inflammatory and immune cells expression regulation ($p<0.001$). Conclusion: Human plasma contains an abundant number of eccDNAs. Distribution of these eccDNAs is nonrandom event and is likely enriched in genomic regions with known functional consequences and genes that play a role in gene regulations. Further characterization of circulating eccDNAs in peripheral blood will facilitate understanding of their molecular mechanisms and potential clinical utilities.

**#4245 Serologic markers of infection and risk of non-Hodgkin lymphoma in a pooled prospective study of three Chinese cohorts.** Bryan A. Bassig,1 Angelica Michel,1 Xiao-Ou Shu,3 Woon-Puay Koh,4 Yu-Tang Gao,5 Lesley M. Butler,3 Mark Purdue,1 Yong-Bing Xiang,2 Jennifer Adams-Haduch,1 Renwei Wang,3 Nicole Brenner,6 Tim Waterboer,7 Martina Willhaus-Fleckenstein,8 Liang Wang,9 Zhiqin Chen,9 JunPing Zhang,9 Wei Hu,9 Gong Yang,9 Hong-Ou Chow,9 Michael Pawlita,2 Wei Zheng,1 Jia-Min Yuan,1 Jing Lan,6 Nathaniel Rothman,1 1NCI-DECG, Rockville, MD; 2German Cancer Research Center (DKFZ), Heidelberg, Germany; 3Vanderbilt University School of Medicine, Nashville, TN; 4Duke-NUS Graduate Medical School, Singapore; 5Shanghai Cancer Institute, Shanghai, China; 6University of Latvia; 7Paganygh, PA; 8German Cancer Research Center, Heidelberg, Germany; 9Shanghai Jiaotong University School of Medicine, Shanghai, China; 10Albert Einstein College of Medicine, New York, NY; 11The University of Texas MD Anderson Cancer Center, Houston, TX.

Background: Infections with some viruses, including HIV and Epstein-Barr Virus (EBV) in immunocompromised individuals, are known risk factors for specific subtypes of non-Hodgkin lymphoma (NHL). Epidemiological studies have also provided evidence that hepatitis viruses, and EBV in immunocompetent individuals, may also be associated with NHL. There are limited population-based prospective studies with pre-diagnostic blood samples that have comprehensively evaluated viral biomarkers and NHL risk in East Asians, in whom the descriptive characteristics of NHL and the prevalence of certain viral infections differ compared to Western populations. Methods: We conducted a nested case-control study with a nested case-control study of 214 NHL cases and 214 controls from three population-based prospective cohorts in Shanghai and Singapore. Cases and controls were individually matched by age, sex, date of blood draw, and cohort. Antibodies to 21 antigens associated with the evaluated viruses (herpesviruses, Hepatitis B (HBV) and C (HCV), and polyomaviruses) were measured in plasma/serum using fluorescent bead-based multiplex serology. Conditional logistic regression was used to evaluate associations between viral antibody levels measured as median fluorescence intensity and NHL. Results: For herpesviruses, an increased risk of NHL was observed for higher compared to lower early antigen diffuse (EA-D) ($OR = 2.2, 95\% CI = 1.2-4.1$) and BZLF1-encoded replication activator (ZEBRA) ($OR = 2.2, 95\% CI = 1.0-4.9$) antibodies ($\text{OR} = 1.9, 95\% CI = 1.0-3.9$, $p = 0.03$) associated with EBV. An increased risk of NHL was also observed among those seropositive for the intermediate-early 1A antigen ($OR = 1.9, 95\% CI = 1.0-3.3$, $p = 0.03$) with EBV antibodies ($\leq 0.2$) associated with human herpesvirus-6 (HHV-6). For hepatitis viruses, a significant NHL risk was observed for higher compared to lower antibodies to the HBV-associated core (HBc) antigen ($OR = 1.8, 95\% CI = 1.1-3.1$), and this risk was particularly apparent in those with the highest HBC and EBV EA-D antibody levels ($OR = 4.2, 95\% CI = 1.4-12.7$) compared to the lowest. Seropositivity to HCV was low (1.4% cases; 0.9% controls). No associations with NHL were observed for individual polyomaviruses (BK, JC, TSV, MCV). Discussion: Our study of serologic markers of infection and NHL risk in three prospective population-based studies of Chinese individuals suggests a role of specific viral agents in lymphomagenesis. The findings for EBV are consistent with some data from Western cohorts and indicate that EBV reactivation may be associated with NHL risk in the Chinese general population. HHV-6 is a lymphotropic virus that has been observed in some retrospective studies to be associated with lymphoma, but to our knowledge has not previously been associated with NHL prospectively in the general population. HBV is endemic to regions of East Asia, including China, and our data suggest that high levels of antibodies to the HBc antigen may be a marker for NHL risk.

**#4246 Associations of Epstein-Barr virus (EBV)-positive gastric cancer with circulating mediators of inflammation and immune response.** M. Constanza Carmago,1, Armanda Sivina,2 Sergeijs Isaevs,3 Dace Rudzite,4 Margaret Gulley,5 G. Johan Offerhaus,4 Marcis Leja,2 Charles S. Rabkin1.

1National Cancer Inst., Bethesda, MD; 2University of Latvia, Latvia; 3University of North Carolina, Chapel Hill, NC; 4University Medical Center, Utrecht, Netherlands.

Epstein-Barr virus (EBV) positivity defines one of four major molecular types of gastric cancer in The Cancer Genome Atlas (TCGA). However, viral status is currently determined in the last study determined and therefore is not gener-}

ally collected in epidemiologic research. Histologically, EBV-positive gastric cancer is characterized by prominent inflammatory infiltrate. In molecular analyses from TCGA, EBV-positive gastric cancer had significantly higher expression of several chemokines, chemokine receptors and programmed death-ligand 1 (PD-L1) as compared to other molecular types combined. We hypothesized that EBV tumor status may also be reflected in profiles of circulating chemokines and other markers of immune response. We have therefore evaluated pre-treatment EDTA plasma samples of gastric cancer patients from Latvia, including 28 with EBV-positive (as assessed by EBV RNA in situ hybridization) and 34 with EBV-negative tumors, frequency-matched by age, sex, an-
Adiposity, change in adiposity during adulthood and mammographic density in premenopausal women. Aliya Alimujjaid, Graham Colditz, Catherine Appleton, Adetunji T. Toriola. Washington Univ. School of Medicine, St. Louis, MO.

Background: Body mass index (BMI) is inversely associated with mammographic density among premenopausal women, but few studies have evaluated this in premenopausal women. Further, there is limited data on the associations of weight change during adulthood with mammographic density. To address these, we investigated the associations of current adiposity measures, BMI at ages 18, 30, and changes in BMI at these age periods with volumetric mammographic density measures in 314 premenopausal women who underwent screening mammograms at the Northwestern University Breast Center, Women's Health Program, St. Louis, MO. Methods: Study participants completed a questionnaire with information on breast cancer risk factors. Weight at ages 18 and 30 were self-reported. Current weight, height, waist, and body fat percent (%), were assessed by trained research personnel. BMI's were calculated as weight at each age/current height squared (kg/m²). We calculated weight change from: (i) age 18 to 30, (ii) age 18 to current age, (iii) age 30 to current age. Volpara was used to determine volumetric mammographic density measures. We investigated age-adjusted correlations between adiposity measures and mammographic density measures using Pearson correlation coefficients. We used multivariable linear regression models (adjusted for age, at menarche, parity, age at each birth, family history of breast cancer, race, and education) to evaluate the associations of adiposity measures with mammographic density. Adiposity measures, adiposity change and BMI were subjected to non-linear model tests, with no non-linear associations observed.

Results: Participants had a mean age of 50 (range: 23-78) years. The proportion of non-Hispanic white women was 51%, and 45% of the sample were overweight or obese at age 18. The average current BMI was 25.4 (range: 17.7-41.8). Adiposity measures and BMI were strongly inversely correlated with MV and BV. A 1 kg/m² increase in BMI was associated with a 0.14% decrease in MV and a 0.18% decrease in BV. Odd ratios (OR) and p-values were calculated for tertiles of BMIs across adulthood, with ORs adjusted for age, menarche, parity, age at each birth, family history breast cancer, race, and education.

Conclusions: These findings show that BMI and weight change are associated with changes in mammographic density. Further work is needed to identify potential interventions to increase mammographic density and improve cancer risk.
An APOBEC3-associated variant was defined as a variant having one of the eight possible motifs (5’ [CT]/C-T/W 3’) out of 96 potential motifs of 3 base-pairs. Using logistic regression, we compared the number of APOBEC3-associated variants in cases and controls, among HPV16 variant lineages, and among genome regions of the virus. We discovered that there is evidence of APOBEC3 activity predicting the viral non-coding upstream regulatory region. We observed a 74% increase in HPV16 A lineage infection with more APOBEC3-associated variants compared to those with a non-A lineage infection (OR = 1.35, p-value = 0.02). After controlling for the number of APOBEC3 variants, we observed that the tissue from women with early menarche had upregulation of genes associated with defense against oxidative stress later in life. Women with early menarche and breast cancer development. Methods: To test our hypothesis we used the early and late menarche cohort. Our findings point to a possible interplay between telomere and mitochondrial dysfunction, and epigenetics in carcinogenesis. Additional studies should also examine these associations in larger cohorts with greater racial/ethnic, gender, and socioeconomic diversity to validate these findings.

A possible link between telomeres, mitochondria, and cancer incidence. Jacob K. Kresovich,1 Tao Gao,2 Brian T. Joyce,3 Pantel Vokonas,4 Joel Schwartz,4 Ananda K. Voinov,5 Minho Shong,6 Jiri Zavadil,4 Arthur P. Grollman 1.

Background: PGC1A and PGC1B encode transcriptional factors that regulate mitochondrial biogenesis and have been implicated in the early age at menarche as a breast cancer risk factor and advance research for women’s health and public health risk linked to carcinogenic herbal medicines. Shuhan Wang,1 Daeun Choi,2 Jaesung Lim,3 Kathleen G.Dickman,4 Magali Olivier,4 Viktoriya S. Sidorenko,1 Maude Ardin,4 Byong H. Yun,5 Robert J. Turesky,6 Minho Shong,7 Jiri Zavadil,4 Arthur P. Grollman 1.

Methods: To test our hypothesis we used the resources available at the Susan G. Komen Tissue Bank at the Indiana University School of Medicine, Indianapolis, IN.

#4250 Molecular alterations in the breast associated with early menarche.

Maria L. Johnson,1 Natascia Marino,2 Anna Maria V. Storniolo,3 Bradley A. Hancock,4 Milan Radovich,5 George E. Sandusky6.

Komen Tissue Bank at the Indiana University Simcon Cancer Center, Indianapolis, IN; Indiana University School of Medicine, Indianapolis, IN.

Background: Menarche, the onset of the female menstruation, is a marker of pubertal timing. Age at menarche varies widely between girls and is highly dependent on nutritional status and body fat accumulation. The occurrence of menarche at an early age is linked to an increased risk of several adverse health conditions later in life, such as obesity, type-2 diabetes, breast and endometrial cancer, and cardiovascular disease. Indeed, for every one year decrease in age at menarche (from an average age at menarche of 12.5 years), breast cancer risk is increased by 5%. Several genome wide association studies (GWAS) have identified genetic variants (i.e. in the LIN28B gene) that are associated with early age at menarche, however little is known about the changes occurring in the breast tissue of women with early menarche. We hypothesize that early age at menarche results in permanent molecular alterations in the breast tissue and that those abnormalities may contribute to the tissue’s susceptibility to carcinogens and breast cancer development. Methods: To test our hypothesis we used the resources available at the Susan G. Komen Tissue Bank at the Indiana University Simon Cancer Center (KTB). We selected histologically normal breast tissue from healthy, young women with either early (age ≤ 10 years) or late menarche (age ≥ 15 years), and matched for age, race, BMI, and menstrual phase. Breast tissue biopsies from these women were microdissected to isolate the breast epithelium and next generation RNA-sequencing was used to generate a transcriptome profile for each sample. Differential expression was performed using DESeq2 in R. The tissue samples were also evaluated using immunostaining.

#4251 DNA methylation of mitochondrial biogenesis regulating genes: A possible link between telomeres, mitochondria, and cancer incidence.

Jacob K. Kresovich,1 Tao Gao,2 Brian T. Joyce,3 Pantel Vokonas,4 Joel Schwartz,4 Ananda K. Voinov,5 Minho Shong,6 Jiri Zavadil,4 Arthur P. Grollman 1.

Background: PGC1A and PGC1B encode transcriptional factors that regulate mitochondrial biogenesis and have been implicated in the interplay between telomere and mitochondrial dysfunction, and epigenetics in carcinogenesis. Additional studies should also examine these associations in larger cohorts with greater racial/ethnic, gender, and socioeconomic diversity to validate these findings.

Results/Conclusions: Preliminary data show significant differences when comparing the transcriptome profiles of the microdissected breast epithelium from the early and late menarche cohort. Specifically, we observed that the tissue from women with early menarche had upregulation of genes associated with defense against oxidative stress and/or infectious bacteria (lactoferrin [LTF], ceruloplasmin [CP]), cell adhesion, (ITGα1, ITGα2, ITGα3, ITGα4, ITGβ2), immune response (CARD9, LAIR1), and had downregulation of ubiquitination pathways (USP40, AMFR) and lipoprotein metabolism (OSBPL1A, LIPH, PIGN). Immunohistochemical evaluation of markers of oxidative stress (LTF, CP), cell proliferation (Ki67), and immune infiltrates (CD45, CD20, CD8, CD68) is underway. Together, this information will give us the opportunity to better understand early age at menarche as a breast cancer risk factor and advance research for women’s health.

#4252 New molecular evidence associating exposure to aristolochic acid with urothelial cancers in South Korean patients: Implications for global public health risk linked to carcinogenic herbal medicines.

Shuhan Wang,1 Daeun Choi,2 Jaesung Lim,3 Kathleen G. Dickman,4 Magali Olivier,4 Viktoriya S. Sidorenko,1 Maude Ardin,4 Byong H. Yun,5 Robert J. Turesky,6 Minho Shong,7 Jiri Zavadil,4 Arthur P. Grollman 1.

Animal studies have shown that loss of PGC1A protects against cancer as a possible link between telomeres, mitochondria, and cancer incidence. Further evaluation is underway.
adduct analysis, can address exposure to AA in extended UTUC case series, thereby assisting in the design of preventive measures against this global public health funding. IARC: SW is Recipient of research support from the Drs. Martin & Dorothy Spatz Charitable Foundation; Henry and Marsha Lauder grant to KGD, VSS, APG.

#4255 Associations of coffee consumption and caffeine intake with mammographic breast density. Lusine Yaghjian, 1 Graham Colditz, 2 Bernard Rosner, 3 Aleksandra Gasparova, 1 Rulla Tamimi, 4 Univ. of Florida, Gainesville, FL; 5Washington University in St. Louis, MO; 6Channing Division of Network Medicine, Department of Medicine, Brigham and Women's Hospital and Harvard Medical School, Boston, MA.

Purpose: Previous studies suggest that coffee consumption and caffeine intake may be associated with reduced breast cancer risk which may result from stimulating effect of coffee on estrogen metabolism enzymes and subsequent changes in bioavailable estrogen. We investigated the association of coffee consumption and caffeine intake with mammographic breast density by woman’s menopausal status and, in postmenopausal women, by hormone therapy (HT) Method: This study included 4,130 cancer-free women within the Nurses’ Health Study and Nurses’ Health Study II cohorts. Percent breast density (PD), absolute dense and non-dense areas were measured from digitized film mammograms using a computer-assisted thresholding technique; all measures were square-root transformed for the analysis to improve normality. Diet was assessed with a semi-quantitative food frequency questionnaire, average cumulative coffee/caffeine consumption was calculated using data available from all the questionnaires preceding the mammogram date. Information regarding breast cancer risk factors was obtained from baseline or biennial questionnaires closest to the mammogram date. We used generalized linear regression to quantify associations between exposures and breast density measures, adjusted for potential confounders. Associations were adjusted separately for regular coffee, decaffeinated coffee, total coffee, and energy-adjusted caffeine intake. Results: In multivariable analyses, decaffeinated coffee was positively associated with PD in premenopausal women (2 cups/day: β = 0.23, p-trend = 0.03). In postmenopausal women, decaffeinated and total coffee were inversely associated with PD (decaffeinated coffee 2 cups/day: β = −0.24, p-trend = 0.04; total coffee 4 cups/day: β = −0.17). These associations appeared to be driven by the inverse associations of these exposures with absolute dense area. Among current HT users (n = 980), regular coffee and caffeine intake were inversely associated with PD (regular coffee 4 cups/day: β = −0.29, p-trend < 0.01; caffeine 4th vs. 1st quartile: β = −0.32, p-trend < 0.01). Among past users (n = 430), decaffeinated coffee was inversely associated with PD (2 cups/day β = −0.70, p-trend = 0.02). Conclusions: Our findings suggest that among current HT users, regular coffee and caffeine intake are inversely associated with mammographic percent breast density.

#4256 Impact of diesel engine exhaust exposure on the airway transcriptome. Eduard I. Drizik, 1 Seena Cybergett, 2 Roel Vermeulen, 3 Yuxin Meng, 3 Debra Silverman, 4 Nathaniel Rothman, 4 Marc Lenburg, 4 Danzhi Ren, 4 Huawei Duan, 5 Yong Niu, 5 Jun Xu, 5 Wei Fu, 5 Kees Mielisefiet, 6 Baosen Zhou, 7 YuFang Yang, 7 Meng Ye, 7 Xiaowei Jia, 7 Tao Meng, 7 Ping Bin, 7 Yuxin Zheng, 7 Debra Silverman, 4 Nathaniel Rothman, 4 Avrum Spira, 7 Qin Lan, 7 Boston University, Boston, MA; 8Utrecht University, Utrecht, Netherlands; 9Chinese Center for Disease Control and Prevention, Beijing, China; 10National Cancer Institute, Rockville, MD; 11Chao Yang Center for Disease Control and Prevention, Chao Yang, China; 12Hong Kong University, Hong Kong, Hong Kong.

Rationale: Recent epidemiological studies show that Diesel Engine Exhaust (DEE) exposure is associated with lung cancer, however the mechanism by which this occurs is not well understood. The goal of this study was to assess the transcriptomic alterations in the nasal epithelium of DEE exposed workers from factories where diesel engines are utilized. Methods: Nasal epithelium brushings were obtained from 41 subjects who work in a factory with DEE exposure, and 38 comparable control subjects who work in factories without any DEE exposure. The median Elemental Carbon (EC) levels of exposed individuals was 60.7 µg/m³, with a range of 17.2–105.4 µg/m³, respectively. RNA was isolated from nasal epithelial cells, and profiled for gene expression using Affymetrix microarrays. Linear modeling was used to detect differential expression between DEE exposure and controls. Pathway enrichment in differentially expressed genes was assessed using GO Biological Process and KEGG terms via EnrichR. Results: We found 234 genes that were differentially expressed between samples derived from DEE exposed participants versus controls at FDR < 0.25. Within this set of genes, we observed a higher expression of genes involved in oxidative stress, and in cell proliferation, cellular transcription, and regulation of apoptosis. In addition, we found that genes involved in ion transport, such as CFTR, were expressed at lower levels in DEE exposed samples. Conclusions: Chronic DEE exposure associates with changes in the airway transcriptome,
with increased stress response as a major effect of DEE exposure. The transcriptomic alterations we identified may help provide insight into the underlying mechanisms of DEE carcinogenicity.

#4257 Dietary nutrient intake, ethnicity, and epigenetic silencing of lung cancer genes detected in sputum in New Mexican smokers. Shuguang Leng, Maria Picchi,1 Piotr Filipczak,2 Frank Gilliland,3 Steven A. Belinsky.1 Lovelace Respiratory Research Inst., Albuquerque, NM; 4University of Southern California, CA.

Promoter hypermethylation of lung cancer (LC) genes detected in sputum assesses field carcinization and predicts LC risk. Hispanic smokers have greater risk for methylation than non-Hispanic Whites (NHW). We aimed to identify novel dietary nutrients affecting methylation of LC genes in sputum and determine the degree of ethnic disparity explained by diet. A cross-sectional population-based study was conducted with dietary intake assessed using a validated Harvard food frequency questionnaire in 327 Hispanics and 1502 NHWs from the Lovelace Smokers cohort (LSC). Twelve LC genes with diverse cellular functions whose concomitant methylation strongly predicted LC risk were studied. A global association was identified between dietary intake and gene methylation (Fperm=0.003). Seventeen nutrient measurements were associated with methylation with magnitude greater than seen for folate and these nutrients together accounted for 36% of the variance in methylation. Six protective nutrients were identified and their insufficient intake in Hispanics explained approximately 42% of ethnic disparity in methylation. Functional validation of protective nutrients that also explained ethnic disparity was provided by showing an effect of a red wine supplement on LC methylation in a mouse model. We conclude that understanding of the biological mechanisms underlying the observed epidemiologic associations are needed to guide the development of intervention strategies and the most effective public health messages for breast cancer prevention.

#4259 The relation of childhood diet to the timing of puberty in boys: Results from the Longitudinal Studies of Child Health and Development. Alya Alimujigaj,1 Graham A. Colditz,2 Catherine S. Berkey,3 Siobhan Sutcliffe.1 Washington University School of Medicine, Saint Louis, MO; 2Harvard Medical School, Boston, MA.

Background: Although accumulating evidence from different disciplines supports an early-life contribution to prostate cancer (PCa) risk, few studies have focused on this life stage. One major reason for this dearth of research is the decades-long span of time between early-life exposures and PCa onset, making traditional epidemiologic study designs challenging. To overcome this challenge, we took advantage of several well-supported or recently observed PCa risk factors - age at peak height velocity (APHV), height at age 13, and adult height - to shorten the time required to study early-life exposures and to improve exposure classification by using these risk factors as markers of future PCa risk. We focused our analysis on childhood diet because it influenced APHV in a similar study of girls, and because of its strongly suspected role in PCa development. Methods: We analyzed data from the Longitudinal Studies of Child Health and Development, which followed 67 Caucasion boys from Boston from birth through adolescence in the 1930–40s. At each biannual (or annual) visit, study staff measured participants’ height and weight, and assessed their diet by dietary history interviews. We used these data to estimate age- and energy-adjusted nutrient intake, diet scores (combining information on fat and protein intake), and information on vegetable protein from ages 1-10 into a healthy diet score), age-specific height-2-scores, body mass index, peak height velocity (PHV), and APHV. We investigated crude associations between dietary and anthropometric measures by Pearson correlation coefficients, and multivariable-adjusted associations by linear regression. Results: Childhood consumption of a Western diet (as measured by our fat-animal protein score) was positively associated with height at age 13 (beta coefficient β=0.08, P<0.001) and adult height (β=0.05, P=0.013), and inversely associated with APHV (β=−0.06, P=0.014). In contrast, childhood consumption of a healthy diet (as measured by our vegetable protein score) was inversely associated with height at age 13 (β=−0.09, P=0.008). No notable associations were observed for diet and PHV. After controlling for height at ages 1-2 as a marker of genetic growth potential, only the association between Western diet and height at age 13 remained significant (β=0.08, P<0.001). Our findings suggest that consumption of a Western diet during childhood (1-10 years of age) is associated with greater height at age 13, a possible marker of both earlier onset of puberty and greater height. As this measure was recently associated with later PCa risk/mortality in a large Danish cohort study, our findings may point towards an early dietary contribution to PCa risk. Future studies should explore this possible association further for its potential to inform primary PCa prevention strategies.

#4258 Influence of lifestyle factors on adipocyte size in human breast tissue. Kristin L. Campbell,1 Nagarajan Kannan,2 Sarah E. Neil-Sztramko,3 Connie J. Eaves,4 Jonathan P. Little,5 Itona Ciszmadia,6 David Zhu,7 Sarah Sayyari,1 Kelcey Bland,1 James D. Johnson.1 Univ. of British Columbia, Vancouver, British Columbia, Canada; 2Mayo Clinic, Rochester, MN; 3McMaster University, Hamilton, Ontario, Canada; 4Terry Fox Laboratory, Vancouver, British Columbia, Canada; 5Univ. of British Columbia, Kelowna, British Columbia, Canada; 6University of Calgary, Calgary, Alberta, Canada.

Background: Accumulating epidemiological studies positively associate healthy body mass index (BMI) and higher physical activity with lower risk of postmenopausal breast cancer. Many of the proposed biomarkers underlying these associations, such as insulin, inflammatory markers, steroid hormones, and adipokines, are produced or regulated by adipose tissue. However, the biological impact of lifestyle factors at the level of the breast tissue, particularly adipose tissue in the breast, is unclear and may play a role in the etiology of breast cancer. Using a cross-sectional approach, we examined the impact of demographic and lifestyle factors on histological features of breast adipose tissue.

Results from the Longitudinal Studies of Child Health and Development. Kristin L. Campbell, 1Nagarajan Kannan, 2Sarah E. Neil-Sztramko, 3Connie J. Eaves, 4Jonathan P. Little, 5Itona Ciszmadia, 6David Zhu, 7Sarah Sayyari, 1Kelcey Bland, 1James D. Johnson. 1Univ. of British Columbia, Vancouver, British Columbia, Canada; 2Mayo Clinic, Rochester, MN; 3McMaster University, Hamilton, Ontario, Canada; 4Terry Fox Laboratory, Vancouver, British Columbia, Canada; 5Univ. of British Columbia, Kelowna, British Columbia, Canada; 6University of Calgary, Calgary, Alberta, Canada.

Background: Genetic alterations are considered to be accumulated in normal tissues at extremely low levels by exposure to various carcinogenic factors, and the degree of accumulated alterations, namely mutation burden, is likely to be associated with prostate cancer (PCa) risk. Few studies have focused on this life stage. One major reason for this dearth of research is the decades-long span of time between early-life exposures and PCa onset, making traditional epidemiologic study designs challenging. To overcome this challenge, we took advantage of several well-supported or recently observed PCa risk factors - age at peak height velocity (APHV), height at age 13, and adult height - to shorten the time required to study early-life exposures and to improve exposure classification by using these risk factors as markers of future PCa risk. We focused our analysis on childhood diet because it influenced APHV in a similar study of girls, and because of its strongly suspected role in PCa development. Methods: We analyzed data from the Longitudinal Studies of Child Health and Development, which followed 67 Caucasian boys from Boston from birth through adolescence in the 1930–40s. At each biannual (or annual) visit, study staff measured participants’ height and weight, and assessed their diet by dietary history interviews. We used these data to estimate age- and energy-adjusted nutrient intake, diet scores (combining information on fat and protein intake), and information on vegetable protein from ages 1-10 into a healthy diet score), age-specific height-2-scores, body mass index, peak height velocity (PHV), and APHV. We investigated crude associations between dietary and anthropometric measures by Pearson correlation coefficients, and multivariable-adjusted associations by linear regression. Results: Childhood consumption of a Western diet (as measured by our fat-animal protein score) was positively associated with height at age 13 (beta coefficient β=0.08, P<0.001) and adult height (β=0.05, P=0.013), and inversely associated with APHV (β=−0.06, P=0.014). In contrast, childhood consumption of a healthy diet (as measured by our vegetable protein score) was inversely associated with height at age 13 (β=−0.09, P=0.008). No notable associations were observed for diet and PHV. After controlling for height at ages 1-2 as a marker of genetic growth potential, only the association between Western diet and height at age 13 remained significant (β=0.08, P<0.001). Our findings suggest that consumption of a Western diet during childhood (1-10 years of age) is associated with greater height at age 13, a possible marker of both earlier onset of puberty and greater height. As this measure was recently associated with later PCa risk/mortality in a large Danish cohort study, our findings may point towards an early dietary contribution to PCa risk. Future studies should explore this possible association further for its potential to inform primary PCa prevention strategies.

#4260 Increased mutation burden in normal-appearing lung tissues with high cancer risk. Emi Kubo,1 Hideyuki Takeshima,2 Noriko Motoi,2 Toshikazu Ushijima1. 1National Cancer Center Research Institute, Tokyo, Japan; 2National Cancer Center Hospital, Tokyo, Japan.

Background: Genetic alterations are considered to be accumulated in normal tissues at extremely low levels by exposure to various carcinogenic factors, and the degree of accumulated alterations, namely mutation burden, is likely to be associated with cancer risk. In lung tissues, smoking is a well-known carcinogenic factor, and is considered to be involved in accumulation of mutation burden. However, due to the limitation of detection methods of such extremely low frequency mutations, the presence of mutation burden in normal human lung tissues has been unclear. To overcome this limitation, we recently developed a new method to detect mutations with extremely low frequency by sequencing 100 DNA molecules using a next generation sequencer[Yamashita, submitted]. Aim: We aimed to reveal 1) the presence of mutation burden in normal lung tissues, and 2) its association with cancer risk. Methods and results: The presence of somatic mutations was analyzed in 55 cancer-related genes (totally 15,724 bp) in normal lung tissues (n = 11) obtained from background tissues of lung metastasis of cancer patients, without smoking history, other than those with lung cancers (“entirely normal lung tissues”) and non-cancerous lung tissues (n = 11) of lung cancer patients with smoking history (“smoking-exposed normal tissues”). The mutation frequency in smoking-exposed normal tissues (2.7 ± 0.8×10−7/bases) was significantly higher than that in entirely normal
tissues (1.8 ± 0.5×10^7/bases) (p= 0.0189). C to T transition was most frequent in both smoking-exposed normal tissues (60% of detected base substitutions) and entirely normal tissues (61%), but the fractions were not different between the two groups. In contrast, C to A transversion, the signature mutation of smoking, was more frequent in smoking-exposed normal tissues (4%) than in entirely normal tissues (0.8%). In some malignant tissues, higher levels of somatic mutations occurred at the C to A transversion at a loci of SN (`OR = 3.75% (95% CI = 0.54-26.06%)). Conclusion: It was shown, for the first time, that somatic mutations were accumulated in normal lung tissues with high cancer risk, possibly by exposure to tobacco smoking.

**EPIDEMIOLOGY: Biomarkers of Endogenous or Exogenous Exposures, Early Detection, and Biologic Effects**

**Epidemiology**

**Background:** The World Trade Center (WTC) collapse occurred on September 11, 2001. Among those working or living near the WTC, a new cancer syndrome (WTC cancer) has emerged. This cancer is characterized by the presence of a high number of tumors in the pleura, thorax, and lymph nodes. The etiology of WTC cancer remains uncertain, and the role of environmental factors in its development is still under investigation.

**Methods:** A case-control study with 600 participants was conducted, including 300 cases with WTC cancer and 300 controls without WTC cancer. The study was nested within the New York City Health Department's Health Insurance Plan (HIP) database. The primary outcome was the presence of WTC cancer. Participants were matched by age, sex, and race.

**Results:** The risk of WTC cancer was significantly higher among individuals who worked at the WTC or lived in the immediate vicinity during the attack compared to those who did not. The risk was also higher among individuals who had respiratory symptoms or were exposed to fine particulate matter. The risk was lower among individuals who had received radiation therapy or chemotherapy.

**Conclusion:** The study provides evidence for the role of environmental factors in the development of WTC cancer. Further research is needed to identify the specific environmental factors that contribute to this cancer syndrome.
endogenous E2 and total T levels in current OC users and non-users was thus observed. Therefore, history of OC use needs to be incorporated in studies on associations between smoking and breast cancer risk.

#4264 Smoking exposure and quantitative levels of estrogen-receptor expression in ER+ breast tumors. Ebonee N. Butler, John A. Baron, Jeanette T. Bensen, Mengjie Chen, Kathleen Conway, Andrew F. Ollhan, Melissa Troester, University of North Carolina at Chapel Hill, Chapel Hill, NC.

Introduction: Smoking is a suspected risk factor for breast cancer and has been linked to increased risk of estrogen-receptor positive (ER+) disease in some epidemiologic studies. Cigarette smoke has also been shown to have antieigenetic effects, leading to a potentially contradictory hypothesis that smoking would lead to decreased ER expression driven by smoking-induced DNA damage. ER status and breast tumors with respect to ER may mask quantitative associations between smoking and ER expression. Methods: Using data from the Carolina Breast Cancer Study (CBCS), we examined relationships between smoking and quantitative levels of ER expression from tumors of 1,297 women with ER+ disease (i.e., > 10% of tumor cells ER+ by immunohistochemical analysis). We used unweighted logistic regression to estimate associations between categorical measures of smoking and quartiles of ER protein or ER$^*$ mRNA expression, represented by odds ratios (OR) and 95% confidence intervals (95%CI). We also examined associations between smoking and quantitative ER levels among women with ER+ breast tumors, stratified by menopausal status. Multivariate regression models include adjustment for age, race, stage, grade, and tumor size. Results: Quantitative ER$^*$ was positively associated with any history of smoking (i.e., current at time of diagnosis or former smoking) (OR=1.96 and 95% CI: 1.24 to 3.10). In addition, smoking more than 1 pack of cigarettes per day was associated with high ER$^*$ expression (OR=3.19 and 95% CI: 1.29 to 7.91) as smoking duration of > 20 years (OR=2.08 and 95% CI: 1.16 to 3.74). Among former smokers, we observed higher ER$^*$ expression among those who quit 5–10 years prior to diagnosis. The magnitudes of association between smoking and quantitative ER expression were similar for both pre- and post-menopausal women, but were not reflected in similar association on the protein level. Conclusions: Among women with ER+ breast cancer, smoking dose and duration was positively associated with elevated ER$^*$ mRNA levels, regardless of menopausal status. Absence of this association for protein suggests that ER$^*$ RNA merits further consideration, but may suggest that ER$^*$ RNA more sensitively captures biological differences than ER protein expression.

EPIDEMIOLOGY: Familial and Hereditary Cancers

#4265 Risks of familial breast cancer associated with known and proposed breast cancer susceptibility genes. Kara N. Maxwell, 1 Thomas Paul Stulik, 1, 2 Jena M. Lallyquist, 3 Joseph Viji, 4 Susan L. Neuhausen, 1 Steven N. Hart, 1 Vi gnesh Ravichandran, 5 Tinu Thomas, 4 Ann Maria, 1 Kasimtian A. Schrader, 6 Raymond Moore, 3 Chunling Hu, 3 Brad Wubbenhorst, 1 Brandon M. Wenz, 1 Jenna M. Lilyquist, 3 Joseph Vijai, 4 Susan L. Neuhausen, 2 Steven N. Hart, 3 Vijalette Delong, 1 John Hopper, 6 Katherine L. Nathanson, 1 Fergus J. Couch, 3 Jeffrey N. Weitzel 2, John L. Hopper, 1 Mark A. Jenkins, 1 Roger L. Milne, 2 Graham G. Giles, 15 Dallas R. English, 1 Finlay A. Macrae, 5 Amanda B. Spurde, 1 Ingrid M. Winship, 6 Christophe Rosty 1, 1 University of Melbourne, Parkville, Australia; 2 Cancer Council Victoria, St. Kilda, Australia; 3Queenland Institute of Medical Research Berghofer, Herston, Australia; 4University of Melbourne, Carlton, Australia; 5Royal Melbourne Hospital, Parkville, Australia.

Background: Tumour mismatch repair (MMR) deficiency, determined by immunohistochemical (IHC) loss of MMR protein expression, is used diagnostically to identify individuals with Lynch syndrome. A high proportion of colorectal cancers (CRCs) and endometrial cancers (ECs) that demonstrate tumor MMR-deficiency are categorised as having “Lynch-like syndrome” due to the absence of MSH6 or MLH1 methylation and germline MMR gene mutations after standard screening approaches. The aim of this study was to investigate somatic causes of tumor MMR-deficiency in patients with Lynch-like syndrome. Methods: Population-based participants with incident MMR-deficient colorectal (n=193; ACCFR and MCCS) or endometrial cancer (n=197; ANECs and MCCS) were categorised as either Lynch syndrome, MLH1 methylated or Lynch-like after screening for germline MMR gene mutations and for tumor MLH1 gene promoter hypermethylation. Lynch-like tumors were tested for somatic MMR gene mutations (point mutations and loss of heterozygosity) using AmpliSeq Ion Proton custom capture sequencing and for MSH2 or MSH6 gene promoter methylation. Overall survival for molecularly defined subgroups of Lynch-like CRCs were compared to Lynch syndrome related CRCs using cox regression models to estimate hazard ratios (HR) and 95% confidence intervals adjusting for age at CRC diagnosis, sex, AJC stage and grade. Results: Lynch-like tumors comprised 32% (63/193) and 23% (45/197) of the MMR-deficient CRCs and ECs, respectively compared with 27% and 15% for Lynch syndrome and 41% and 62% for MLH1 methylated CRCs and ECs, respectively. Two somatic mutations were identified in the MMR gene indicated by the pattern of MSH6 and MLH1 methylation and germline MMR gene mutations after standard screening approaches. The proportion of tumors with double somatic alterations was highest for both CRC and EC tumors showing MSH2 deficiency (40% and 64.3%). The mean age at diagnosis for the Lynch-like CRCs with double somatic mutations was 49.7 ± 15.8years which was not significantly different from the Lynch syndrome CRCs (n=52; 45.4 ± 11.3years; p=0.2) but was younger than the Lynch-like CRCs with different classification of the MLH1 mutation (n=83; 70 ± 8.9years;p=0.0001). The adjusted HR for double somatic Lynch-like CRCs was 2.58 (95% CI, 0.77-8.67) compared with Lynch syndrome CRCs (p=0.01). No evidence of tumor MSH2 or MSH6 gene promoter methylation was identified in either (5% MSH2-deficient or MSH6-deficient Lynch-like CRCs or ECs tested (n=34 and n=12, respectively). Conclusions: Double somatic mutations in the MMR genes represent a significant proportion of the unexplained Lynch-like MMR-deficient subtype for both population-based CRC and EC. Triaging strategies used to identify Lynch syndrome for both CRC and EC should include tumor testing for somatic mutations in the MMR genes.

#4267 Association of polygenic risk scores and family history with the risk of chronic lymphocytic leukemia (CLL). Geffen Kleinstern, 1 Silvia de Sanjose, 1 Nicola Camp, 1 Claire M. Vajdic, 1 Timothy G. Call, 2 Dennis Robinson, 3 Neil E. Kay, 4 Julie Cunningham, 4 Yolanda Benavente, 5 Alain Monereau, 1 John Spinelli, 1 James R. Cerhan, 4 Susan L. Slager 1, Mayo Clinic, Rochester, MN; 2Hospital de Llobregat, Barcelona, Spain; 3University of Utah, Salt Lake City, UT; 4University of NSW, Sydney, Australia; 5Sorbonne Paris Cité Cen tre, Paris, France; 6BC Cancer Research Center, Vancouver, British Columbia, Canada.

Background: Thirty-four single nucleotide polymorphisms (SNPs) are associated with CLL risk to-date. Moreover, family history (FH) of hematological malignancy has been consistently found to be associated with CLL at this time. Larger cancer control studies are needed to fully evaluate the cancer risks associated with moderate penetrance and proposed breast cancer susceptibility genes.

Case-control analysis demonstrated significant associations with FBC for ATM, PALB2, and TP53 mutations (OR>3.0, p<10^-4), BARD1 mutations (OR=3.2, p=0.012), and CHEK2 truncating mutations (OR=1.6, p=0.041). Our results therefore demonstrate that only approximately 4% of BRCA1/2 negative FBC patients have mutations in genes definitively associated with breast cancer at this time. Large case-control studies are needed to fully evaluate the breast cancer risks associated with moderate penetrance and proposed breast cancer susceptibility genes.

EPIDEMIOLOGY: Biomarkers of Endogenous or Exogenous Exposures, Early Detection, and Biologic Effects

#4268 Smoking exposure and quantitative levels of estrogen-receptor expression in ER+ breast tumors. Ebonee N. Butler, John A. Baron, Jeanette T. Bensen, Mengjie Chen, Kathleen Conway, Andrew F. Ollhan, Melissa Troester, University of North Carolina at Chapel Hill, Chapel Hill, NC.

Introduction: Smoking is a suspected risk factor for breast cancer and has been linked to increased risk of estrogen-receptor positive (ER+) disease in some epidemiologic studies. Cigarette smoke has also been shown to have antieigenetic effects, leading to a potentially contradictory hypothesis that smoking would lead to decreased ER expression driven by smoking-induced DNA damage. ER status and breast tumors with respect to ER may mask quantitative associations between smoking and ER expression. Methods: Using data from the Carolina Breast Cancer Study (CBCS), we examined relationships between smoking and quantitative levels of ER expression from tumors of 1,297 women with ER+ disease (i.e., > 10% of tumor cells ER+ by immunohistochemical analysis). We used unweighted logistic regression to estimate associations between categorical measures of smoking and quartiles of ER protein or ER$^*$ mRNA expression, represented by odds ratios (OR) and 95% confidence intervals (95%CI). We also examined associations between smoking and quantitative ER levels among women with ER+ breast tumors, stratified by menopausal status. Multivariate regression models include adjustment for age, race, stage, grade, and tumor size. Results: Quantitative ER$^*$ was positively associated with any history of smoking (i.e., current at time of diagnosis or former smoking) (OR=1.96 and 95% CI: 1.24 to 3.10). In addition, smoking more than 1 pack of cigarettes per day was associated with high ER$^*$ expression (OR=3.19 and 95% CI: 1.29 to 7.91) as smoking duration of > 20 years (OR=2.08 and 95% CI: 1.16 to 3.74). Among former smokers, we observed higher ER$^*$ expression among those who quit 5–10 years prior to diagnosis. The magnitudes of association between smoking and quantitative ER expression were similar for both pre- and post-menopausal women, but were not reflected in similar association on the protein level. Conclusions: Among women with ER+ breast cancer, smoking dose and duration was positively associated with elevated ER$^*$ mRNA levels, regardless of menopausal status. Absence of this association for protein suggests that ER$^*$ RNA merits further consideration, but may suggest that ER$^*$ RNA more sensitively captures biological differences than ER protein expression.
not been an evaluation of the interactive effects among genetic factors and FH with CLL risk. Methods: We pooled data from 8 CLL case-control studies within the InterLymph Consortium (1499 CLL cases and 2601 controls). We computed a polygenic risk score (PRS), a weighted average of the number of risk alleles across the 34 SNPs, with the weights being the log of the previously reported odds ratio for the SNP. We categorized the PRS by tertiles using the cutoff points based on the distribution of all InterLymph controls (N=8228). Self-reported FH data was available for 60% of cases and 73% of controls. FH was defined as any hematological malignancy in one or more first-degree relative. Logistic regression was used to estimate ORs and 95% confidence intervals (CIs) adjusted for age, sex, socioeconomic status and study. Results: The median age at diagnosis in FH cases and controls was 67 years and median interval between diagnosis and controls was 67% were male in CLL cases and 57% in controls. As expected, FH was associated with CLL risk (OR= 2.14, CI = 1.60-2.86). The median PRS in the cases was 0.40 and in the controls was -0.36 with the frequency of CLL cases in the upper PRS quintile as 48% while in the lowest quintile only 6%. The PRS was strongly associated with CLL risk (OR= 2.90, CI = 2.35-3.56 for upper versus middle quintile). When jointly modeling FH with PRS, a significant interaction was observed (P =0.03). When stratifying by FH, the upper quintile of the PRS had an 11.8-fold (CI = 3.97-34.8) increased risk relative to those in the middle quintile in the FH+ strata, while a 3.11-fold (CI = 2.35-4.10) increased risk was observed in the FH- strata. Conclusions: Our data suggest that the PRS has a strong association with CLL risk and this association varies with FH status. A two-point linkage analysis between the disease and each marker was performed using TwoPoint-QLinkage. A regional-based linkage analysis was performed using MERLIN. We identified five loci that corresponded to a gene or a portion of a gene. Two-point linkage analyses were then performed on the risk of CLL for those markers using TwoPoint-QLinkage. The final signal on 14q13 was NAP153, a transcription factor that is a tumor suppressor in brain tumors. It should be noted that all previous evidence linking these genes to cancer was based on somatic mutations; this is the first time any of these genes has been shown to be significantly linked to germline disease risk in a family-based study. We plan to perform targeted sequencing on the linked regions to elucidate the exact causal variant.

#4269 Risk of different cancers among first-degree relatives of pancreatic cancer patients and impact of probands’ germline mutation on sibling cancer risk. Samuel O. Antwi,1 Sarah E. Fagan,2 Kari G. Chaffee,3 William R. Bamlet,3 McWilliams R. Robert,4 Ann L. Öberg,5 Gloria M. Petersen,1 *Epidemiology, Mayo Clinic, Rochester, MN;1 Epidemiology, Tulane University, New Orleans, LA;1 Biomedical Statistics and Informatics, Mayo Clinic, Rochester, MN;2 Medical Oncology, Mayo Clinic, Rochester, MN.

Background: There have been varying reports on risk of different cancers, other than pancreatic cancer (PC), among first-degree relatives (FDRs) of PC patients. Because the pattern and scope of aggregation of PC with other malignancies in families of PC patients are not entirely clear, we investigated risk of 15 common malignancies among FDRs of unselected PC probands. Methods: The study included 17,181 FDRs with more than 336,000 person-years at risk. The FDRs were identified through sequentially enrolled PC probands (n = 2,305) in the Mayo Clinic prospective pancreatic cancer patient registry from 2000-2016. Data on family history of cancer were provided by the probands at the time of enrollment in structured risk factor questionnaires. Standardized incidence ratios (SIRs) and 95% confidence intervals (CIs) were calculated by comparing cases of each cancer type observed among the FDRs with those expected using data from the Surveillance Epidemiology and End Results Program (SEER). Stratified analyses were performed among the FDRs of probands on whether the related proband tested positive for a mutation in ATM, BRCA1, BRCA2, CDKN2A, CHEK2, MUTHY, BNN, PALB2, or PMS2; or tested negative for mutation in a total of 25 sequenced cancer susceptibility genes. Results: Compared to the SEER reference population, risk of PC was two-fold higher than expected among the FDRs (SIR = 2.04, 95% CI: 1.78-2.31) and 12-fold higher than expected among FDRs with FH of PC in at least two blood relatives (SIR = 11.99, 95% CI: 10.48-13.64). Siblings of mutation-positive probands had higher risk of PC (SIR = 13.57, 95% CI: 6.19-25.76) than siblings of mutation-negative probands (SIR = 8.91, 95% CI: 6.73-11.57). For other cancer types, primary liver cancer was elevated among female FDRs (SIR = 2.10, 95% CI: 1.34-3.12), whereas breast (SIR = 3.16, 95% CI: 1.63-5.32) and ovarian (SIR = 6.61, 95% CI: 1.33-19.31) cancers were elevated only among siblings of the mutation-positive probands. There also were suggestions of lower than expected risk of other malignancies, such as bladder, colorectal and prostate cancers, among the FDRs as compared with the SEER population. Conclusions: These findings confirm familial aggregation of PC with breast and ovarian cancers, and further suggest a potential aggregation of PC and primary liver cancer among female FDRs of PC probands. The elevated risks of breast cancer and ovarian cancer among siblings of the mutation-positive probands suggests a strong influence of genetic susceptibility shared with the related proband, possibly due to an inherited mutation in BRCA1, BRCA2, or PALB2. These findings lend support to genetic counseling and targeted screening of certain cancers in high-risk families.

#4270 Family history in first degree relatives and risk of gastric cancer in the alpha-tocopherol, beta-carotene cancer prevention study. Min'kong Song, Maria Constanza Camargo, Stephanie J. Weinstein, Demetrius Albanes, Charles S. Raskin. National Cancer Institute, Bethesda, MD.

Background: Studies of the familial associations of gastric cancer risk have largely been limited to case-control approaches which are susceptible to recall bias and cannot distinguish temporality. Furthermore, associations with family history could be explained by shared exposure to Helicobacter pylori infection, the most important environmental risk factor for gastric cancer. Notably, the risks of early onset disease and diffuse-type tumors are thought to have a different genetic component. We therefore examined in a prospective study the associations of gastric cancer risk with history of gastric cancer in first degree relatives, controlling for H. pylori infection. Methods: We selected 605 incident gastric cancer cases and 4,129 controls with known H. pylori serology status from the Finnish Alpha-Tocopherol, Beta-Carotene Cancer Prevention (ATBC) Study among male smokers aged 50-69 at baseline. Odds ratios (ORs) and 95% confidence intervals (95% CIs) were calculated using logistic regression with adjustment for H. pylori and other potential confounders. All statistical tests were two-sided. Results: Family history of gastric cancer was associated with increased risk (OR = 1.84, 95% CI = 1.32-2.58). The association appeared stronger with gastric cancer in siblings (OR = 2.87, 95% CI = 1.64-5.03) than with gastric cancer in parents (OR = 1.53, 95% CI = 1.05-2.24). Distinguishing cases by anatomic subtype, the family history association was significant for noncardia gastric cancer (n = 305; OR =2.15, 95% CI =1.50-3.07), but not for cardia cancer
Population-wide vs. carrier-probability-based BRCA1/2 mutation testing in the Washington Ashkenazi Study. Ana F. Best, Margaret A. Tucker, Hormuzd A. Katki. National Cancer Institute, Division of Cancer Epidemiology and Genetics, Bethesda, MD.

Background: Currently, women are referred for BRCA1/2 mutation testing if their family history of breast and ovarian cancer indicates they have sufficient probability of carrying mutations. In contrast, calls have intensified for population-wide testing for BRCA1/2 founder mutations among Ashkenazi Jews, due to relatively high mutation prevalence (2.5%) and decreasing genotyping costs. However, population-wide testing would strain genetic counseling resources and incur costs from testing mostly mutation-negative women. We compared the performance of population-wide vs. carrier-probability-based BRCA1/2 testing in the community-based Washington Ashkenazi Study (WAS). Methods: BRCA1/2 carrier-probabilities based on reported family histories were calculated using BRCAPRO for 4589 probands (102 BRCA1/2 mutation-carriers) in WAS. For each carrier-probability threshold, we compared the percent of mutations found (sensitivity) vs. the percent of women requiring mutation testing, overall and by proband age. At example carrier-probability thresholds, undetected and detected carriers’ attributes were compared using nonparametric tests. Results: A 1.2% carrier-probability threshold identified 80% of BRCA1/2 mutations in the 35% of women with highest carrier-probability. For women under age 40, 94% of BRCA1/2 mutations were identified in the 58% of women with highest carrier-probability. Compared to identified mutation-carriers, missed mutation-carriers had no personal cancer history, no affected first- and second-degree relatives (p<0.0001), more unaffected first-degree relatives (p=0.0002), and were older (p=0.012; median age=53). Conclusion: Carrier-probability-based BRCA1/2 mutation testing identified large differences in mutation-carriers and would have avoided testing for many mutation-negative women. Missed mutation-carriers were older and cancer-free and would gain minimal benefit from risk-reducing interventions. A cost-effective carrier-probability threshold should acceptably tradeoff identifying BRCA1/2 mutation-carriers before they get cancer while testing as few women as possible.

Mutations in BRCA1 and BRCA2 and associated with hereditary pancreatic cancer. Sahar Nissim, 1 Ignaty Lechchin, 1 Joseph D. Mancias, 1 Matthew B. Greenblatt, 2 Ophelia Maertens, 1 Christopher A. Cassa, 1 Jill A. Rosenfeld, 1 Andrew G. Cox, 1 John Hedgepeth, 1 Julia Wücherpfennig, 1 Andrew J. Kim, 1 Jake E. Heidel, 2 Xiao-Xu Yamagami, 1 Nobuyuki Susumu, 1 Hitoshi Tsuda, 3 Daisuke Aoki1. 1 Brigham and Women’s Hospital, Boston, MA; 2 Broad Institute of MIT and Harvard, Cambridge, MA; 3Graduate School of Biomedical Sciences, Saitama, Japan

Pancreatic ductal adenocarcinoma (PDAC) is one of the deadliest solid cancers with limited treatment options despite intensive research efforts. Familial predisposition to PDAC is thought to occur in ~10% of cases, but causative genes have not been identified in most of these families. Uncovering the genetic basis for PDAC susceptibility has immediate prognostic implications for families and can provide precious mechanistic clues to PDAC pathogenesis. Here, we perform whole-genome sequence analysis in a family with high incidence of PDAC and identify a germline nonsense mutation in the member of RAS oncogene family-3 (RAB3) gene that has never before been directly associated with hereditary cancer. The truncated mutant allele (RAB3_p.Ser36*) co-segregates with cancer occurrence. To evaluate the contribution of the RAB3 mutant allele in hereditary cancer, we generated a Rab3 heterozygous mutant zebrafish and found increased susceptibility to cancer formation in two independent cancer models. Complementary unbiased approaches implicate RAB3 in LFS pathway regulation. RNA-Seq and genome-set enrichment analysis of juvenile rab3 mutants reveals a KRAS upregulation signature. Furthermore, affinity-purification mass-spectrometry for proteins associated with RAB3 or RAB3_p.Ser36* identifies RAP1 GTPase-GDP Dissociation Inhibitor 1 (RAP1GDS1, SmgGDS), a chaperone that regulates prenylation of RAS GTPases. Indeed, in vitro studies demonstrate that RAB3_p.Ser36* accelerates KRAS prenylation, and this impact is lost in the absence of H/N/KRAS proteins. Whereas heterozygous rab3 mutant zebrafish exhibit abnormal craniofacial, skeletal, and growth defects consistent with human RASopathies, and these defects are partially rescued with the MEK inhibitor trametinib. Our findings support a gain-of-function rather than a null function typically associated with premature protein truncations. The discovered causative RAB3 germline mutation provides new diagnostic opportunities for genetic testing in other cancer families and uncovers an alternative mechanism for dysregulated RAS signaling in development and cancer.

Variant reclassifications in hereditary cancer genetics and their implications for clinical care. Thomas P. Slavin, 1 Stacy W. Gray, 1 Lily R. Van Tongeren, 1 Ilana Solomon, 1 Christina Rybak, 1 Bita Nehoray, 1 Lili Kuzmich, 1 Mariana Niell-Swiller, 1 Kathleen R. Blazer, 1 Kai Yang, 1 Julie Culver, 1 Sharon Sand, 1 Danièle Castillo, 1 Josef Herzog, 1 Jeffrey N. Weitzel 1. 1 City of Hope, Duarte, CA; 2 University of Southern California Norris Comprehensive Cancer Center, Los Angeles, CA.

BACKGROUND: Clinicians who provide genetic cancer risk assessment (GCRA) are dependent on laboratory reporting of germline results to inform cancer screening and treatment recommendations. Efforts to enhance variant classification and harmonization, such as ClinVar, will lead to an increase in the number of variant reclassifications. As the rate of variant reclassification on care is unknown, we evaluated the frequency and clinical impact of variant reclassification on individuals seen for GCRA. METHODS: We retrospectively evaluated data on 7,356 participants enrolled through the Clinical Cancer Genomics Community Research Network (CCGCRN) at City of Hope and Olive View Medical Center from September 1996- October 2016. RESULTS: 4,969 commercial genetic tests yielded a total of 1,610 variants of any category, of which 181 unique variants in 20 genes were reclassified. BRCA1 and BRCA2 (BRCA) and mismatch repair genes comprised 73.5% and 5.5% of the genes reclassified. Compared to initially reported variants, reclassified variants were older (p=0.0001), more unaffected first-degree relatives (p=0.0002), and were older (p=0.012; median age=53). Conclusion: Variant reclassification may change clinical care. Thirteen variants carried by 15 individuals were upgraded from a variant of uncertain significance (VUS) to likely pathogenic or pathogenic (10 BRCA, 3 MLH1 or MSH2). These reclassifications prompted additional prophylactic surgical interventions (i.e., bilateral salpingo-oophorectomy), specialist referrals, and surveillance recommendations for at-risk patients and family members. Three variants (NRB p.Arg215Trp, PSEN p.Ala79Thr, and MET c.1200+2T>G) were downgraded from likely pathogenic or pathogenic to VUS. Prior to downgrade to VUS, 2 cases had unnecessary surveillance procedures. CONCLUSIONS: Since many genetic variants will be reclassified over time, it is critical that laboratories deliver prompt notification of reclassifications, and that providers involved in GCRA discuss the possibility of variant reclassification with patients and family members and collect patient/proxy information during informed consent so that re-contact is possible. Given the non-trivial effort required for variant reclassification and patient/participant re-contact, system-level interventions are needed to facilitate genomic reinterpretation and the return of results to individuals over time.

The contribution of deleterious germ-line mutations of susceptibility genes to ovarian, fallopian tube, and peritoneal cancers in Japanese. Akira Hirasaawa, 1 Issei Imoto, 1 Takuya Naruto, 1 Tomoko Akahane, 1 Wataru Yamagami, 1 Nobuyuki Susumu, 1 Hitoshi Tsuda, 1 Daikusu Aoki 1. 1 Keio University School of Medicine, Tokyo, Japan; 2Graduate School of Biomedical Sciences, Tokushima University, Tokushima, Japan; 3National Defense Medical College, Saitama, Japan.

Different ethnic groups present specific morphological features in ovarian cancer (OC). High-grade serous OC is more frequently found in Caucasian women, in contrast clear cell OC is more frequently found in East Asian women. Although inherited mutations of BRCA1 or BRCA2 (BRCA1/2) and other genes are known to predispose to OC, the contributions of these inherited mutations on disease burden is not well characterized in Japanese OC patients. Using a comprehensive genetic testing panel, the aim of our study was to identify the prevalence of pathogenic germ-line mutations of candidate genes associated with OC. 1093
with genetic predisposition to OC in Japanese patients with ovarian, fallopian tube, or peritoneal cancer. Samples from 236 individuals with unselected ovarian, fallopian tube, or peritoneal cancer, which were obtained from the Keio Women’s Health Biobank (KWB) from the School of Medicine at Keio University (Tokyo, Japan), were used for this study. Germ-line DNA was enriched using the SureSelect XT Target Enrichment System (Agilent Technologies) designed for 75 or 79 genes as a custom OC panel, followed by sequencing using MiSeq (Illumina). Detected variants, including point mutations, small indels, and a gross deletion, were classified according to the American College of Medical Genetics and Genomics (ACMG) recommendations. Furthermore, BRCA1/2 variants were interpreted using resources from Myriad Genetic Laboratories. Forty-two (17.8%) OC patients had germ-line mutations of cancer predisposition genes. BRCA1/2 pathological germ-line mutations were found in 27 cases (11.4%) while six cases (2.5%) had a mutation in a mismatch repair gene (MLH1, MSH2, MSH6, or PMS2). Furthermore, ten cases (4.2%) had germ-line mutations in the RAD51D, ATM, MRE11A, FANC, or GABRA2 genes. Of patients with a BRCA1/2 mutation (n=27), we found that the most common histological subtype was high-grade serous OC, but we also found two cases with clear cell carcinoma. Of 42 cases with an inherited mutation, we found that 25% (6/24) had no family history of cancer, and 78% (31/41) were under 60 years old at diagnosis. We found that approximately 18% of unselected Japanese patients with ovarian, fallopian tube, or peritoneal cancer were associated with inherited mutations of cancer-predisposing genes. Our study demonstrates that comprehensive genetic testing is informative for all women with fallopian tube and peritoneal cancers to establish personalized clinical management and genetic counseling, irrespective of the patient’s histological subtypes, ages or family histories.

**#4275 Pathogenic germline variants in Mexican patients with hereditary breast and ovarian cancer syndrome.** Felipe Vaca-Paniagua, Rosalía Quezada-Urban, Clara Díaz-Velásquez, Rina Gitler, Gabriela Torres-Mejía, Luis Ignacio Terrazas, Patricia Rojo-Castillo, Max Sirota-Toporek, Andrea Figueroa-Morales, Oscarilyhistories.

neticcounseling, irrespective of the patient’s histological subtypes, ages or family histories.

- **#4276 Oral contraceptive use and breast cancer risk: a cohort study of BRCA1 and BRCA2 mutation carriers.** Liesa H. Schrijver, Hakon Olsson, Antonis Antoniou, Roger Milne, Kelly Phillips, Nadine Andrieu, Douglas Easton, David Goldgar, Christophe Engel, Karin Kast, Marie-Jose Blom, Thea Moolt, John Hopper, Floor Van Leeuwen, Mary-Beth Terry, Matti Perheentupa, IBCCS, BCER, Netherlands Cancer Institute, Amsterdam, the Netherlands; Lund University, Lund, Sweden; University of Cambridge, Cambridge, United Kingdom; University of Melbourne, Cancer Council Victoria, Melbourne, Australia; University of Melbourne, Peter MacCallum Cancer Centre, Melbourne, Australia; Institute Curie, PSL Research University, INSERM, Paris, France; University of Utah Salt Lake City, UT; University of Leipzig, Germany; Greywater and the Netherlands Cancer Institute, University Hospital Carl Gustav Carus, Dresden, Germany; University of Melbourne, Melbourne, Australia; Columbia University, New York, NY.

Background: BRCA1 and BRCA2 mutation carriers are at high risk of breast and ovarian cancer. Oral contraceptive preparations (OCPs) may reduce ovarian cancer risk, but its effect on breast cancer risk remains unclear. Methods: Combined data from three cohorts of 5705 BRCA1 and 3521 BRCA2 mutation carriers (IBCCS, BCER and kConFab) were analyzed using age-dependent Cox regression models stratified for study and birth cohort. We conducted the first prospective analyses on this topic. Our additional main retrospective analyses were left-censored 5 years preceding date of baseline questionnaire to control for survival bias. The full-cohort retrospective analyses, without left-censoring, was performed using Cox proportional hazard model. Results were considered most valid, while retrospective analyses were most powerful. Results: For BRCA1 mutation carriers we found no association between ever OCP use and risk of breast cancer in the prospective analyses (HR=1.08, 95% CI 0.75-1.56), but 23% and 27% increased risks for ever OCP use in the left-censored and full retrospective analyses, respectively. Prospectively, an increasing trend for longer duration of use, especially before first full-term pregnancy (FFTP) was found (left-censored analyses: &lt5 years HR 1.05 (95% CI 0.84-1.33), 5-9.9 years HR 1.15 (95% CI 0.92-1.44), &gt10 years HR 1.41 (95% CI 1.10-1.81), p-trend=0.001 for duration of use before FFTP). For BRCA2 mutation carriers we found a positive association between each OCP use and risk of breast cancer prospectively (HR=1.73, 95% CI 1.03-2.97), but retrospectively findings were inconsistent (HR=1.06, 95% CI 0.85-1.33 and HR=1.52, 95% CI 1.28-1.81 for the left-censored and full analyses, respectively). Conclusion: For BRCA1 mutation carriers the discrepancy between results of prospective and retrospective analyses may be explained by time since last OCP use before FFTP. Thus, a temporal increased risk of breast cancer following longer duration of OCP use before FFTP cannot be ruled out. The discordant findings between prospective and retrospective analyses for BRCA2 carriers could not be explained. Because of the lack of scientific clarity it is too early to give an unequivocal advice on OCP use with respect to breast cancer risk to BRCA1 and BRCA2 mutation carriers.

**#4277 Clinicopathological significance of endometrial cancer with MSH2 deficiency.** Junko Haraga, Takeshi Nagasaka, Keiichiro Nakamura, Tomoko Haruma, Takeshi Nishida, Akihito Nyuya, Kazuya Yasui, Hisashi Masuyama, Yoshiyoshi Fujiwara, Yuji Hiramatsu. Okayama University Graduate School of Medicine Dentistry and Pharmaceutical Sciences, Okayama City, Okayama, Japan.

Background: Endometrial cancer accounts for the second percentage of Lynch syndrome related tumors following colorectal cancer. Inactivation of MSH2 was frequently observed in endometrial cancer with microsatellite instability (MSI) or mismatch repair complex deficiency (dMMR). With respect to MSH2 deficiency (dMSH2), not like MLH1 deficiency, most of dMSH2 were caused by germline mutations in the MSH2 gene or germline EpCAM deletions. Meanwhile, heritable germline epimutations in MSH2 have been reported in a few Lynch syndrome families that lacked germline mutations in the MSH2 gene. We previously provided evidence for frequent MSH2 hypermethylation in Lynch syndrome colorectal tumors with dMSH2 and MSH2 methylation may serve as the “second hit” at the wild-type allele. Materials and Methods: In the study, we analyzed MSH2 promoter hypermethylation status and methylation status, and expression status of the mismatch repair proteins (MLH1, MSH2, PMS2, and MSH6) by immunohistochemistry in a cohort of 138 endometrial cancer tissues surgically resected at Okayama University Hospital. DNA was extracted from formalin-fixed, paraffin-embedded tissue, analyzed MSI status by four mononucleotide markers and both MLH1 and MSH2 promoter methylation status by a fluorescent quantitative bisulfite PCR assay. Results: Endometrial cancers displaying MSI or dMMR were observed in 40 (29.0%) or 41 cases (29.7%), respectively. Endometrial cancers with MSH2 deficiency were observed in eight (5.8%) of 138 tumors (19.5% of dMSH2). MSH2 promoter methylation was present in 7 cases (5.1% in 138 tumors), and significantly cor-
related with dMSH2 (P = 0.0041, Fisher’s exact probability test). Then, we also examined the family history of first-degree relatives retrospectively. In this cohort, although patients with MMR deficiency were significantly associated with family history of Lynch syndrome related tumor (P < 0.001), patients with this family history of Lynch syndrome related tumor are more frequently observed in patients with prostate cancer (P = 0.0347). Intestinal polyposis syndromes associated with familial history of Lynch syndrome related tumor (P = 0.002), though patients with MLH1 methylation were not (P = 0.0878). Conclusions: In this study, we demonstrated that MSH2 methylation significantly correlated with dMSH2 and may have strong relation with family history of Lynch syndrome related tumor, taking a role as “second hit” to the MSH2 gene.

#4278 Screening for BRCA1 founder mutation in Mexican population: an accessible approach. Rosa M. Alvarez, Jose Velazquez, Verónica Fragoso, Julieta Domínguez, Paulina Nuñez, Talía Wegman, Yuliana Sanchez, Silvia Vidal, Enrique Bargallo, Dolores Gallardo, Abelardo Meneses, Luis A. Herrera, National Cancer Institute, Mexico, Mexico City, Mexico; National Institute of Pediatrics, Mexico City, Mexico.

Aim: To implement an accessible strategy for detection of the Mexican founder mutation NG_005905.2:g.118973_133629del, located in BRCA1, which deletes exons 9-12 (BRCA1 ex9-12del), as part of the health care setting of patients with hereditary breast and ovarian cancer (HBOC), from the National Cancer Institute (Mexico). Material and methods: We designed a polymerase chain reaction (PCR) based method, for the targeted detection of the deletion of exons 9 through 12, of the BRCA1 gene. The method was validated previ- ously verified results of the deletion by multiplex ligation-dependent probe amplification assay (MLPA), or deep sequencing of the region. Finally, the technique was used for the detection of BRCA1 ex9-12del mutation in a group of 302 HBOC patients, in whom the existence of BRCA1 and BRCA2 point mutations had been ruled by pyrosequencing. Results: The concordance of our method, with previously reported BRCA1 ex9-12del mutation results, was 100%. Also, we provided a profile of the clinical and familial characteristics of 302 Mexican patients with clinical suspicion of HBOC, in whom the detection of BRCA1 ex9-12del mutation was performed. In this way, 21 patients (6.95%) were identified as BRCA1 ex9-12del mutation carriers. Among whom, a higher proportion of triple negative breast cancer was found (73% versus 21%, p = 0.0005; two sided Fisher’s exact test). Conclusions: A feasible molecular diagnostic strategy for the detection of BRCA1 ex9-12del mutation was established in Mexican patients, with HBOC. In this way, we identified 21 (21/302) carriers of the dele- tion, who represented the 6.95%. Related to the clinical features, triple negative breast cancer carriers stood out. It had been reported that large genomic rearrangements in BRCA1 are associated with an increased frequency of high risk features. This type of approach is appropriate in populations where a founder effect is recognized. For its simplicity and effectiveness, it can be transferred to other laboratories, for the benefit of a greater number of Mexican patients and with the aim of minimize costs of testing. Because of the frequency of BRCA1 ex9-12del mutation, this method has been implemented as the first line of BRCA1 clinical genetic analysis in patients with suspected HBOC, at National Cancer Institute (Mexico).

Background: Familial PDAC constitutes of 5-10% of all PDAC, and germline mutations in BRCA1 and BRCA2 are associated with increased risk of PDAC. Although previous studies showed the prevalence of BRCA1 and BRCA2 germline mutations in patients with PDAC ranged between 3% and 21%, these data have been mostly based on the Western patient population. Considering ethnic differences in the prevalence of the mutations in these genes, we performed prospective evaluation to analyze the prevalence of BRCA1 and BRCA2 muta- tions in PDAC patients with Asian ethnicity. Methods: Between November 2015 and May 2016, all consecutive PDAC patients with locally advanced unresect- able or metastatic disease who were referred for systemic chemotherapy in Asan Medical Center, Seoul, Korea were included. Mutation analysis for germline BRCA1 and BRCA2 were performed for patient with one or more first- or sec- ond-degree relatives with breast or ovarian cancers, or past medical history of these diseases. Germline DNA was extracted from 10 cc of whole blood and analyzed for 23 coding exons of BRCA1 and 26 coding exons of BRCA2 using Sanger sequencing. Results: A total of 175 potential participants with locally advanced unresectable or metastatic PDAC were identified during the study period. Among them, 10 (5.7%) patients met the criteria for further analysis of germline BRCA1 and BRCA2 mutations. Six (60%) patients had family history of breast or ovarian cancers and four (40%) patients had previous medical history of breast cancer. The median age was 60 years (range 49-72) and 5 patients (50%) were male. Pathogenic germline BRCA2 mutation (7480C>T) was iden- tified in one male patient (10%) with family history of breast cancer. Two pa- tients had germline BRCA2 mutations (687>T>A and 1744A>C), which were regarded as the variants of uncertain significance (VUS). Conclusion: Germline BRCA mutations, potentially clinically meaningful, were identified in 1.7% (3/ 175) of overall patients with locally advanced or metastatic PDAC and 30% (3/10) of patients with past or family history of breast or ovarian cancers. Our results indicate that the prevalence of BRCA mutation in Asian PDAC popula- tion is lower than Western patients. Risk category used in this study (past med- ical history or one more first- or second-degree relatives with breast or ovar- ian cancers) may be the feasible criteria for germline BRCA mutation analysis in PDAC patients with Asian ethnicity.

#4280 FH (rs367543046, chr1:241661227 A/ATTT) heterozygous carrier status does not confer risk to hereditary leiomyomatosis and renal cell cancer (HLRCC) and prostate cancer. Michael F. Walsh, Diana Mandelker, Joseph Vijay, David Musheyne, Jennifer Kennedy, Zoila Stadler, Yelena Kemel, Sabine Topka, Karen Cadoo, Maria Carla, Marc Ladanyi, Mark Robson, Kenneth Ofit, Liying Zhang, Memorial Sloan-Kettering Cancer Center, New York, NY; Sloan Kettering Institute, Memorial Sloan-Kettering Cancer Center, New York, NY.

Fumurrate Hydratase (FH) mutations underpin the autosomal recessive syn- drome Fumarate Hydratase deficiency and the autosomal dominant syndrome Hereditary Leiomyomatous and Renal Cell Carcinoma (HLRCC). The variant rs367543046, a duplication leading to p. Lys477_Asn478inslys, in FH has strong evidence for risk towards fumarate hydratase deficiency when occurring in trans to another germline alteration in the FH gene. In addition, this variant in the heterozy- gous state has been reported in ClinVar to predispose to the autosomal dominant condition HLRCC, given other heterozygous mutations have shown to be patho- genic. Population level data is sparse to determine the variant’s impact in the heterozygous state. Here, we show in a series of 1375 cancer cases the (rs367543046, chr: 241661227 A/ATTT), variant detected in 7 (0.5%) individuals with cancer. One patient with bladder cancer had a history of uterine leiomyomas, but the immuno- histochemistry for 25C was negative, suggesting that the leiomyomas were not associated with HLRCC. None of the other 6 carriers of this variant had any features of HLRCC. Notably, this variant was not detected in any of the patients with renal cancer (n = 178) participating in the study. Since 4/7 prostate cancer patients of Ashkenazi ethnicity harbored this variant, we performed a genetic epidemiology study using 856 Ashkenazi Jewish prostate cancer patients. The allele frequencies were compared with 557 Ashkenazi Jewish non-cancer controls. A fisher’s two sided exact test showed that the variant is not associated with prostate cancer in Jews (P = 1. OR 1.12(CI 95% 0.21-7.25). Our findings suggest that the variant, which is patho- genic for autosomal recessive fumarate hydratase deficiency does not confer patho- genicity in the heterozygous form for Hereditary Leiomyomatous and Renal Cell Carcinoma or prostate cancer.

#4281 Identification of putative cancer susceptibility genes through whole exome sequencing of a family presenting hereditary colorectal cancer. Gio- vana T. Torrezan, Anna Smirnova, Felipe C. Silva, Erika M. Santos, Renan Valieris, Jorge E. de Souza, Samuel Aguilar, Benedito M. Rossi, Sandro J. de Souza, Dirce M. Carrao, A. C. Camargo Cancer Center, Sao Paulo, Brazil; Sírio-Libanês Hospital, Sao Paulo, Brazil; Instituto de Bioinformática e Biotec- nologia – Zbió, Sao Paulo, Brazil; Universidade Federal do Rio Grande do Norte, Sao Paulo, Brazil.

Germline mutations in known colorectal cancer (CRC) predisposing genes accounts for less than half of the genetic cause of hereditary CRC cases. The absence of mutations in the remaining patients suggests that other yet unknown CRC predis- posing genes might exist. However, recently studies with large cohorts probably discounts the existence of major unknown genes and it is thought that rare or even family private variants and genes may contribute to familial CRC. Thus, the aim of our study was to identify novel CRC susceptibility genes by whole exome sequencing (WES) of a family presenting hereditary CRC. The studied family fulfilled Amster-
The mean age at presentation was 52 years. Out of the 279 individuals, 206 had ovarian cancer, 36 had breast cancer, 26 had double primary ovarian/breast cancer, and 11 had no cancer. Fifty five individuals had family history of ovarian/breast cancer in first degree relatives. Sixty three patients (22.6%) tested positive for a BRCA mutation (45 BRCA1, 18 BRCA2). The mean BRCAPRO and MYRIAD scores were significantly higher for patients who tested positive for a BRCA mutation (30.4% vs. 6.3%, P < 0.001, 12.1% vs. 7.7%, P < 0.001, respectively). The area under the receiver operating characteristics curves were 0.762, and 0.751 for all patients for the BRCAPRO and MYRIAD score to predict the risk of carrying a BRCA mutation. Conclusion: BRCAPRO and MYRIAD appear to be valid risk assessment tools for determining the risk of carrying a BRCA mutation in Korean ethnicity.

#4284 Gate keeping role for endometrial cancer about Lynch syndrome by surgeon.

Min Kyu Kim,1 Min Jung Kwon,2 Min Jeong Yun3. 1Sungkyunkwan University of Medicine, Samsung Changwon Hospital, Changwon-Si, Republic of Korea; 2Sungkyunkwan University of Medicine, Samsung Medical Center, Seoul, Republic of Korea.

Background: It is well known that Lynch syndrome increases risk of endometrial and colorectal cancer. There is not much study about detecting Lynch syndrome patient fast among Korean population by gynecologic oncology surgery. We undertook this study to investigate this. Methods: A review of endometrial cancer patients who was counseled about Lynch syndrome in Department of Obstetrics and gynecology at Samsung Changwon Hospital by single surgeon was done. Clinical information was extracted from the medical record including age, family and personal history of cancer, immunohistochemistry (IHC), microsatellite instability test (MSI), and gene sequencing results. Risk management and posttest education after result were offered about risk reducing options and cascade testing for affected individual Results: App patient was 16. There were two germline mutations (both MSIH) (c.253C>T (p.Thr84Met), c.187delG (p.Val63*). Both were negative for MSIH IHC, but no patient matched criteria of Amsterdam. Four variation of unknown significance (VUS) was found (Three MSIH and One MLH1). Among those were all abnormal in IHC and there was only one Amsterdam criteria matched patient. There were two unstable MSI patients, one was MSIH germline mutation and the other was MSH2 VUS. Median age was 57 (41-76). Seventy five percent were stage I (12/16). Conclusion: Two MSIH germline mutation patients among this population was found. Gynecologic oncology surgeon can be adapted to develop the ability to assess and evaluate genetic risk among endometrial cancer.

#4285 Impact of subsidies on cancer genetic testing uptake in Singapore.

Shao Tzu Li, Jeanette Yuen, Ke Zhou, JOANNE NGEOW. National Cancer Centre, SINGAPORE, Singapore.

Purpose: Previous reports cite high costs of clinical cancer genetic testing as main barriers to patient’s willingness to test. We report findings of a pilot study that evaluates how different subsidy schemes impact genetic testing uptake and total cost of cancer management. Methods: We included all patients who attended the Cancer Genetics Service at the National Cancer Centre Singapore (January 2014-May 2016). Two subsidy schemes, the blanket scheme (100% subsidy to eligible patients), and the varied scheme (patients received 50%-100% subsidy dependent on financial status) were compared. We estimated total spending on cancer management from government’s perspective using a decision model. Results: 445 patients were included. Contrasting against the blanket scheme, the varied scheme observed a higher attendance of patients (34 vs 8 patients per month), of which a higher proportion underwent genetic testing (5% vs 38%), while lowering subsidy spending per person (S$1098 vs S$1161). The varied scheme may potentially save cost by reducing unnecessary cancer surveillance when first-degree relatives uptake rate is above 36%. Findings: Provision of subsidy leads to a considerable increase in genetic testing uptake rate. From the government’s perspective, subsidising genetic testing may potentially reduce total costs on cancer management. Understanding and overcoming barriers for cascade testing in first degree relatives can improve cost-savings.

#4286 What have we learned from pancreatic cancer patients undergoing multigene panel testing.

Holly LaDuca,1 Chunling Hu,2 Hermela Shimelis,2 Eric Polley,3 Jenna Liliquist,2 Mary Helen Black,4 Brigitte Tippin Davis,5 David G. Goldie6 Debra Peck,1 Keri Parcel,7 Fereus J. Cooney,8 Ambra Benetti,9 Also Viejo, CA; 1Mayo Clinic, Rochester, MN; 2University of Utah, Salt Lake, UT.

Purpose: The relevance of inherited pathogenic variants in cancer predisposition genes to pancreatic cancer (PC) is not well understood. Several small studies have identified pathogenic variants in 4% to 14% of unselected PC pa-
patients using multigene panels of predisposition genes, but only BRCA2, ATM, and PALB2 have been clearly implicated in this disease. We aimed to assess the clinical and molecular characteristics of PC patients referred for hereditary cancer genetic testing, and to estimate the risk of PC associated with pathogenic variants in panel-based cancer predisposition genes. Methods: PC patients (n=3,189) were ascertained from a large cohort of over 14,000 patients undergoing multigene panel testing (MGPT) of predisposition genes between March 2012 and June 2016 at a single diagnostic laboratory. Clinical histories and molecular results were reviewed and summarized. Gene-level variant frequencies among PC cases were compared to those from the Exome Aggregation Consortium (ExAC) to calculate gene-specific pancreatic cancer risk ratios. Results: PC patients were predominantly Caucasian (76.5%) and female (58.9%), with a median age at diagnosis of 61 years (51.7). Of these, 33.5% reported additional cancer primaries, and 44.8% reported a family history of PC. Overall, 15.4% of PC patients were found to have at least one pathogenic/likely pathogenic variant in panel-based predisposition genes. Genes with the highest frequencies of pathogenic/likely pathogenic variants included BRCA2 (3.9%), ATM (3.6%), CHEK2 (excluding p.Ile157Thr) (2.0%), PALB2 (1.5%), VHL (1.4%), CDKN2A (1.2%), BRCA1 (0.8%), and MSH6 (0.8%). 21.8% of BRCA1 and BRCA2 carriers did not meet BRCA1/2 testing criteria and 61.5% of MSH6 carriers did not meet Lynch syndrome testing criteria. No CDKN2A families met diagnostic criteria for familial atypical multiple mole melanoma syndrome, and 44% did not report any personal or family history of melanoma. To estimate associations between pathogenic/likely pathogenic cancer predisposition genes and PC, case ascertainment was compared to non-Finnish European, non-TGCA ExAC reference controls. Pathogenic variants in ATM, BRCA2, CDKN2A, MSH6, and PALB2 were significantly associated with high PC risks. Pathogenic variants in BRCA1 were associated with a moderate risk of PC (RR = 2.7). Conclusions: These findings shed light on the spectrum of mutations that can be expected for PC patients referred for cancer predisposition testing. The results confirm the associations of CDKN2A and BRCA2 variants with PC, and expand on the phenotypic spectrum associated with these variants. Furthermore, these results suggest that ATM, PALB2, and MSH6 may be high-risk PC genes, warranting further investigation in case-control and family-based studies.

#4288 HABP2 p.G534E variant in patients with family history of thyroid and breast cancer: Maisa Pinheiro,1 Sandra A. Drigo,1 Fabio A. Marchi,2 Renatta Tonhosolo,2 Sonia C. Andrade,3 Igor Jurisica,4 Luiz P. Kowalski,2 Maria Isabel CNPq(481132/2012-0).

Background. Familial Papillary Thyroid Carcinoma (PTC) has been recently associated with the HABP2 p.G534E mutation. In this study we evaluated the putative association of the HABP2 p.G534E mutation and familial history of PTC and Breast Carcinoma (BC) in the Brazilian population. Methods. Germline mutations of twenty unrelated individuals with personal and/or family history of PTC and/or BC were identified by whole exome sequencing (WES), using Nextera Exome Enrichment kit and HiSeq2000 platform (Illumina). Two cases were positive for p.G534E. Family members from both positive cases (seven from Family 1 and three from Family 2) were recruited for segregation analysis. An additional patient and three relatives (Family 3) with history of PTC and BC were included for validation. Fifty frozen PTC tumor samples and 170 healthy Brazilian individuals were also screened for the HABP2 variant. Confirmation and validation were performed by Sanger sequencing. Results. Interestingly, Family 1 reported a consanguineous history, reflected in two homozygous cases: the proband (PTC) and his unaffected sister. Also, only one (BC) out of eight tested members was negative for p.G534E. In the Family 2, the only patient diagnosed with PTC was negative for the mutation, while three relatives were positive for the same loci. Both index cases (PTC and BC) bore the wildtype for HABP2 and three relatives tested were positive carriers. In PTC tumor samples the Allele Frequency (AF) was 0.04: two heterozygous and one homozygous for p.G534E. Among 170 healthy individuals, five were heterozygous for the variant, representing an AF of 0.0147. The two index patients evaluated by WES also presented interesting pathogenic variants in genes potentially associated with deregulation of the extracellular matrix organization pathway (CTSB, TNXB, COL4A3, COL16A1, COL24A1, COL5A2, NID1, LOXL2, MMP11, TRIM24 and MUSK) and DNA repair function (NBN and MSH2). Conclusion. Our findings suggest that HABP2 is not a predisposition gene involved in familial PTC and BC. Financial Support: FAPESP (2013/01867-8 and 2014/03983-8) and CNPq (481132/2012-0).

#4289 Whole-exome sequencing study of neurovial basal cell carcinoma syndrome (NBCCS) families to identify disease-causing exonic mutations: Mathew Gianferante,1 Alisa Goldstein,1 Mingyi Wang,2 Bin Zhu,2 Belynda Hicks,2 NCI DCEG Cancer Genomics Research Laboratory, Lisa Mirabello1. 1National Cancer Institute, Rockville, MD; 2Cancer Genomics Research Laboratory, Frederick, MD.

NBCCS is an autosomal Dominant disorder with nearly complete penetrance and variable expression. Clinical findings include multiple basal cell carcinomas, keratocysts of the jaw, pits of the palms and/or soles, and more rarely medulloblastoma. The PTCH1 gene is the major NBCCS susceptibility gene; it regulates the sonic hedgehog (SHH) pathway. Here, we are evaluating mutations in unselected NBCCS families to identify potential disease-causing mutations. Our study included specimens and clinical data from 21 NBCCS families. PTCH1 targeted sequencing and CGH array were previously performed. We subsequently whole-exome sequenced (WES) affected family members with no mutation detected from prior targeted analyses (N=9). We focused our analyses on rare variants of PTCH1, genes that directly interact with PTCH1, SHH pathway genes, and cancer predisposing genes. Variants were considered rare if minor allele frequency (MAF) was less than 1% in publicly available databases (ESP, ExAC, and 1000 genome). In-house population cancer-free controls, and an in-house database of approximately 2,000 familial samples that underwent WES in parallel with our NBCCS families. We used in-silico prediction models, variant impact on the protein (i.e., nonsynonymous, nonsense, frameshift, splice site), and public mutation databases to assess pathogenicity. Rare variants in PTCH1 were considered pathogenic if they were (a) previously reported as disease-causing in NBCCS, or (b) predicted high impact (i.e., frameshift, nonsense mutation), or (c) predicted damaging by at least five of seven in-silico prediction programs (CADD, PolyPhen 2, SIFT, Assessor, Mutation Taster, IRT, FATHMM). Ten families (N= 17 individuals) without a PTCH1 mutation were assessed with WES. WES identified PTCH1 mutations in six families. Overall,
only one PTCH1 variant was previously reported (p.S732fs) in HGMD or ClinVar databases. Six novel variants were identified: three frameshifts, p.Y92fs, p.S732fs and p.T212fs; one nonsense, p.W862*; one non-synonymous variant, p.E835K; and, one splice site variant, c.2716-2A>C. The non-synonymous variant was a heterozygous C to T transversion (chromosome 9, position 98 229 452) and predicted damaging. In the four families without a PTCH1 mutation, two separate families had a rare nonsynonymous variant in the same gene that directly interacts with PTCH1. Both variants had a MAF of less than 0.1%, but only one was predicted damaging. Another family had a rare nonsynonymous variant in a known lung cancer predisposing gene that was deleterious in five of seven silico prediction tools and found in both the proband and affected mother. Overall, in the 93 families, 81% had PTCH1 mutations detected with targeted sequencing, aCGH, or WES. Additionally, WES detected two potentially new disease-associated genes that we are currently evaluating further.

#4290 A study in locus heterogeneity: Targeted sequencing analysis of 6q reveals multiple significant loci as the source of a previous linkage peak in familial lung cancer. Anthony M. Musolf,1 Claire L. Simpson,2 Bilal A. Moiz,3 Candace Middlebrook,3 Mariza de Andrade,4 Diptasi Mandal,5 Colette Gaba,5 Ping Yang,3 Yafang Li,5 Ming You,5 Elena Y. Kupert,5 Marshall W. Anderson,5 An G. Schwartz,6 Susan M. Pinney,6 Christopher I. Amos,6 Joan E. Bailey-Wilson,6 1NIH NHGRI, Baltimore, MD; 2University of Tennessee Health Science Center, Memphis, TN; 3Mayo Clinic, Rochester, MN; 4Louisiana State University Health Sciences Center, New Orleans, LA; 5University of Toledo Dana Cancer Center, Toledo, OH; 6Dartmouth College, Lebanon, NH; 7Medical College of Wisconsin, Milwaukee, WI. Cancer Research Institute, Dana-Farber Cancer Institute, Boston, MA; 8University of Cincinnati Cancer Center, Cincinnati, OH; 9University of Cincinnati College of Medicine, Cincinnati, OH.

Lung cancer is the leading cancer-related cause of death in the United States. We had previously performed multipoint linkage analysis on families with a strong family history of lung cancer and found significant linkage to the 6q25 region. In order to find the source of that linkage signal, we performed targeted sequencing 6q23-6q27 on 75 individuals from the 9 most highly linked families. We performed two types of parametric linkage analysis, using an autosomal dominant mode of inheritance with 10% penetrance for carriers and a 1% phenocopy rate using a disease allele frequency of 1%. The first type was a two-point analysis using an Elston-Stewart algorithm. This approach did not lead to any genome-wide significant results but demonstrated significant heterogeneity throughout the nine families. In an effort to recover the power from the original multipoint analysis, we performed a regional linkage analysis using SEQlinkage and MERLIN. SEQlinkage built regional haplotypes that corresponded to a gene or an intergenic region - the regions were based on a customized map of our design. The regional markers were multiallelic which allowed for greater information content and were similar to the microsatellites that were used in the original multipoint analysis. The regional markers were then analyzed in a two-point linkage analysis via MERLIN. This allowed us to identify two genome-wide significant signals at PACRG-AS1 at 6q26 (HLOD = 3.4) and SAMD5 at 6q24 (3.3). The PACRG-AS1 is novel, though it is associated with the known lung cancer gene PARK2. SAMD5 may be involved in lung cancer cell proliferation. The heterogeneity of the two signals was particularly interesting. The PACRG-AS1 region was driven primarily by two families. The SAMD5 marker was not being strongly driven by any of the families and appears to be a small cumulative effect across the nine families. In addition, several families have large, but non-significant LOD scores at other loci across the region. This further reinforces the locus heterogeneity within the region, and it is likely that our two significant signals here are not the only variants affecting the phenotype. We further attempted to localize the signals by running SEQLinkage using a custom map where genes are broken into exons and introns. Though this resulted in no significant markers, the highest signal was located in the intronic region of SAMD5 (HLOD = 3) and several other suggestive signals were localized to intronic regions of good candidate genes like SASH1 and ARID1B. Examination of predicted effects of the candidate regulatory variants using eQTL databases is ongoing. This is a region full of promising candidates, and it is likely that the two significant signals found here are just part of many that could be affecting lung cancer risk. We plan to do further analysis within the individual families to elucidate any more genes affecting this signal.

Introduction: The purpose of this study was to investigate potential associations between body composition and current smoking in young healthy women from high-risk families. Cigarette smoke contains >7000 chemicals of which 69 are established carcinogens and smoke also acts as an aromatase inhibitor. Smoking is now recognized as a carcinogen for the breast and influences both risk and prognosis. However, the underlying mechanisms need to be better elucidated. One study showed that breast cancer patients who smoked were younger, had a lower body mass index (BMI), smaller breast volumes, but a higher waist-to-hip ratio (WHR) than non-smokers. However, smoking was also associated with prior oral contraceptive (OC) use. Since breast cancer development starts long before the tumor is clinically detectable, we aimed to study the impact of cigarette smoke on anthropometric factors. Material and methods: Between 1996 and 2006, 269 healthy women were included in a study on the impact of lifestyle factors in women <40 years from high-risk breast cancer families. Thirty-six participants who had missing height or with prior OC use were excluded. Overall, in 21 families, 81% had undergone previous breast surgeries, who were currently breast-feeding or who were current users of hormonal contraceptives other than combined E + P OCs or had missing smoking status were excluded, leaving 233 women of which 35 were known BRCA1/2 mutation carriers. Height, weight, waist- and hip circumference, and total breast volume were measured in a standardized way by a research nurse 5-10 days before predicted onset of the next menstrual period. Weight, BMI, breast volume, and waist circumference, were not normally distributed and were transformed using the normal logarithm to obtain a better distribution. Multivariable linear regression was used to obtain P-values, adjusted for age, nulliparity, and current OC use. Means and geometric means for smokers and non-smokers were standardized at age 29 years, nulliparity, and non-current OC use. Results: The median age was 29 years (IQR 24-35) and the median year of birth was 1970. Forty-two percent had ever smoked, 23% were current smokers, 28% were current OC users, and 54% were nulliparous. Current smoking was not associated with height, BMI breast volume, or hip circumference (all \( \beta \)s > 0.18). However, current smokers had significantly larger standardized waist circumference (78 vs 74 cm; \( \beta \) = 0.02), and higher standardized WHR (0.79 vs 0.76; \( \beta \) = 0.003) compared with non-smokers. Conclusion: Current smokers had significantly larger waist circumference and higher WHR, but similar BMI and breast volume compared with non-smokers, although most women had anthropometric measures within WHO’s recommended limits. The difference in fat distribution towards more abdominal fat, suggests that current smoking is associated with a more inflammatory and/or androgenic profile at the age when breast cancer is initiated.

MOLECULAR AND CELLULAR BIOLOGY / GENETICS: Cell Death in Cancer

#4292 Indole-3-carbinol (I3C) enhances efficacy of Gemcitabine in leiomyosarcoma. Sujit Suwal, Alexandra Moran, Ana Paz-Mejia, Lorena Flor, Omar Picado, Basem Azab, Jonathan Trent, Fiorella Pendola, Alan S. Livingstone, Danny Yakoub. University of Miami-Miller School of Medicine, Miami, FL.

Introduction: Adjuvant Gemcitabine have recently been shown to improve progression free survival in some types of leiomyosarcoma. Adequate cellular uptake of the drug remains a challenge. We aimed to evaluate the role of nucleoside transporter activator (I3C) in increasing the in vitro efficacy of gemcitabine in combination with non-smokers. Conclusion: Current smokers had significantly larger waist circumference and higher WHR, similar BMI and breast volume compared with non-smokers, although most women had anthropometric measures within WHO’s recommended limits. The difference in fat distribution towards more abdominal fat, suggests that current smoking is associated with a more inflammatory and/or androgenic profile at the age when breast cancer is initiated.
Siraimesine and lapatinib induce ferroptosis in glioblastoma and lung adenocarcinoma cells. Anna R. Blankstein,1 Shumei Ma,2 Spencer B. Gibson1.

Ferroptosis, a morphologically and biochemically distinct cell death pathway, is characterized by the production of reactive oxygen species (ROS) within the cell. The combination of siraimesine, a lysosome disruptor, and lapatinib, a dual tyrosine kinase inhibitor, has been shown to synergistically induce cell death in breast cancer cells. This cell death was blocked by the ferroptosis inhibitor ferrostatin-1 (Fer-1) and the iron chelator deferoxamine (DFO). The objective of the present study was to determine whether lysosome disruptor and tyrosine kinase inhibitors, in combination, induced synergic cell death via the ferroptotic pathway in additional types of cancer. U87 (glioblastoma) and A549 (lung adenocarcinoma) cells were treated with various lysosome disruptors (siraimesine or desipramine) in combination with tyrosine kinase inhibitors (lapatinib or sorafenib), and the amount of cell death was measured by trypan blue exclusion. We found that these combinations synergistically induced cell death in U87 and A549 cells. To determine whether ferroptosis was the mechanism of cell death, cells were pretreated with either Fer-1 or DFO (inhibitors of ferroptosis), or with exogenous iron chloride (an inducer of ferroptosis) before treatment with the combination of siraimesine and lapatinib. Pretreatment with Fer-1 or DFO decreased cell death by approximately 35%. Pretreatment with iron chloride increased the effect of the drug combination. Targeting DPD2 and DPD5 by interfering one of the therapeutic strategies was an increase in intracellular iron accumulation following treatment with the combination of siraimesine and lapatinib. Collectively, these data show that in U87 and A549 cells, the combination of lysosome disruptors and tyrosine kinase inhibitors, specifically siraimesine and lapatinib, induces ferroptotic cell death. Therefore, inducing ferroptosis in tumor cells is a potential strategy for therapy in these cancers with limited treatment options.

Preclinical evaluation of imipridone ONC201 in triple negative breast cancer identifies predictive biomarkers and combinatorial opportunities. Bora Lim, Jangsoo Lee, Huey Liu, Troy Pearson, Larry Coffer, Debu Tripathy, Naoto T. Ueno. UT MD Anderson Cancer Ctr., Houston, TX.

Background: Triple negative breast cancer (TNBC) lacks effective targeted therapy, leaving chemotherapy as the only therapeutic option. Metastatic TNBCs eventually develop resistance to chemotherapy via several mechanisms including apoptosis evasion, hence representing an urgent unmet need for novel therapies. ONC201 is a first-in-class imipridone that induces caspase-mediated apoptosis in multiple cancers including TNBC, selectively antagonizing dopamine D2-like receptors (DRD2) resulting in inhibition of Ras signaling and cell death. Selective antagonism of D2-like receptors has been shown to induce cell death in cancer cells via the same signaling pathways engaged by ONC201. To translate these early findings for breast cancers patients, more studies to prove death. Selective antagonism of D2-like receptors has been shown to induce cell death in breast cancer cells. This cell death was blocked by the ferroptosis inhibitor ferrostatin-1 (Fer-1) and the iron chelator deferoxamine (DFO). The objective of the present study was to determine whether lysosome disruptor and tyrosine kinase inhibitors, in combination, induced synergic cell death via the ferroptotic pathway in additional types of cancer. U87 (glioblastoma) and A549 (lung adenocarcinoma) cells were treated with various lysosome disruptors (siraimesine or desipramine) in combination with tyrosine kinase inhibitors (lapatinib or sorafenib), and the amount of cell death was measured by trypan blue exclusion. We found that these combinations synergistically induced cell death in U87 and A549 cells. To determine whether ferroptosis was the mechanism of cell death, cells were pretreated with either Fer-1 or DFO (inhibitors of ferroptosis), or with exogenous iron chloride (an inducer of ferroptosis) before treatment with the combination of siraimesine and lapatinib. Pretreatment with Fer-1 or DFO decreased cell death by approximately 35%. Pretreatment with iron chloride increased the effect of the drug combination. Targeting DPD2 and DPD5 by interfering one of the therapeutic strategies was an increase in intracellular iron accumulation following treatment with the combination of siraimesine and lapatinib. Collectively, these data show that in U87 and A549 cells, the combination of lysosome disruptors and tyrosine kinase inhibitors, specifically siraimesine and lapatinib, induces ferroptotic cell death. Therefore, inducing ferroptosis in tumor cells is a potential strategy for therapy in these cancers with limited treatment options.

AZ'5576, a selective CDK9 inhibitor, demonstrates in vitro and in vivo activity in diverse preclinical models of non-Hodgkin lymphoma. Justin Cidado,1 Theresa Proia,1 Gareth Gregory,2 Izabela Todorovski,3 Scott Boiko,3 Maryann San Martin,5 Ricky Johnstone,1 Lisa Drew1. AstraZeneca, Weltham, MA;2Peter MacCallum Cancer Centre, Victoria, Australia.

Cyclin-dependent kinase 9 (CD9) is a serine/threonine kinase that regulates elongation of transcription through phosphorylation of RNA polymerase II at serine 2 (pSer2-RNAPII). Transient inhibition of CDK9 results in modulation of genes with short-lived transcripts and labile proteins, thereby representing a potential therapeutic opportunity in tumors dependent upon oncogenes fitting these criteria. McII, an anti-apoptotic protein that has been linked to increased cell survival and chemotherapy resistance in various cancers, is a proto-oncogenic transcription factor that coordinates diverse transcription programs and is over-expressed, amplified, or translocated in many cancers, are two such oncogenes. AZ'5576 is a potent, highly selective, and orally bioavailable inhibitor of CD9 that inhibits CDK9 enzyme activity with an IC50 <5 nM and decreases phosphorylation of Ser2-RNAPII in cells with an IgG of 96 nM. In sensitive cell lines, short-term treatment with AZ'5576 led to a rapid dose- and time-dependent decrease in pSer2-RNAPII with concomitant loss of McII and Mcy mRNA and protein, resulting in the cleavage and activation of caspase 3 and loss of cell viability. Using cell potency and magnitude of caspase activation to define sensitivity, we previously reported that AZ'5576 demonstrates broad in vitro and in vivo activity across hematological malignancies. Initially focusing on acute myeloid leukemia, we expanded our preclinical model to encompass non-Hodgkin lymphoma (NHL), which includes diffuse large B-cell lymphoma (DLBCL), Burkitt's lymphoma (BL), mantle cell lymphoma (MCL), and Waldenstrom macroglobulinemia (WM). In vitro screening assays reveal about half (19/35) of NHL cell lines undergo cell death in response to AZ'5576, demonstrating a potency <50 nM and a maximum caspase activation >50% after 6 hour treatment. Combining AZ'5576 with a BTK inhibitor further enhances cell death compared to that observed with either single agent alone in BTK inhibitor-sensitive ABC-DLBCL cell lines. Consistent with the in vitro data, significant anti-tumor activity was associated with short-term reduction of pSer2-RNAPII tumor levels after intermittent dosing of AZ'5576 in a mouse xenograft model of ABC-DLBCL cell line OCIY10. Similarly, combining AZ'5576 with a BTK inhibitor in vivo drove tumors into regression (combination =199% TGI) compared to the partial TGI from either single agent alone (AZ'5576=79% TGI, Acalabrutinib=58% TGI) in the OCILY10 xenograft model. Finally, in an aggressive Eμ-Myc transgenic mouse model of B-cell lymphoma, AZ'5576 treatment results in potent induction of apoptosis in vitro and a greater than 50 day increase in median overall survival in vivo. Together, these results highlight the therapeutic potential for selective CDK9 inhibition in the treatment of patients with non-Hodgkin lymphoma.

A real-time annexin V annexin V framework for monitoring programmed cell death. Kevin Kupcho,1 Andrew Niles,1 John Shultz,1 Jamison Grauler,1 Wenhui Zhou,1 Robin Hurst,1 Jim Hartnett,2 Terry Russ,2 Dan Lazar,1 James Cali1. Promega Corporation, Madison, WI;2Promega Biosciences LLC, San Luis Obispo, CA.

Efficacious and durable anti-cancer responses are driven by both the selective death of malignant cells and the induction of immunostimulatory activities. Limited but promising clinical evidence suggests that provocation of an unknown balance of inflammatory- and non-inflammatory cell death may be key for orchestrating these positive outcomes. Therefore, identifying and characterizing new clinically useful small molecules and biologic inducers (or combinations thereof) which promote a spectrum of programmed cell death in vitro screening environments remains critically important. Unfortunately, current screening methods are either insufficiently robust, cost- or resource-prohibitive, or provide no means for initial characterization of the kinetics of programmed cell death. To address this unmet need, we developed a real-time, live cell assay method that utilizes a fully homogeneous, bioluminescent annexin V reagent. The method does not require laborious washing and sample preparation steps associated with conventional assays and is compatible with plate-based multimodal signal detection systems. The system contains two annexin proteins which have been engineered to contain separate and distinct complementing domains of a binary luciferase. Additionally, the system contains a novel time-released luciferase substrate and a cell impermeable, fluorogenic DNA dye for monitoring necrosis. Because the annexin-luciferase fusion pairs have only modest affinity for each other, luminescence remains low until phosphatidylserine exposure, a hallmark of the programmed cell death phenotype, brings annexin monomers into close proximity facilitating complementation of the luciferase sensor. The assay reagent can be applied at dosing for real-time measurement of the dose-dependency and magnitude of programmed cell death.

MOLECULAR AND CELLULAR BIOLOGY / GENETICS: Cell Death in Cancer

Proceedings of the American Association for Cancer Research • Volume 58 • April 2017
progression. This work describes our efforts to characterize and validate the performance of the bioluminescent annexin assay using relevant cell death induction models. First, the assay was shown to be functionally concordant with a flow cytometry annexin method in a dose-response model with bortezomib at exposure periods known to produce both early and late-apoptosis (with necrosis) phenotypes. Next, we assessed the performance of the assay using a limited training set of small molecule and biologic inducers of programmed cell death that utilize different mechanisms of action (i.e., apoptosis and necroptosis) and by using a number of diverse but representative cancer cell lines. We conclude that the bioluminescent annexin method provides a new kinetic approach to efficient and effective detection of programmed cell death mechanisms in real time in a convenient homogeneous format.

#4297 ADCs inhibiting the all-powerful omotic transducer. James R. Prud- dent,1 David Marshall,1 Fabio Malavasi,2 Antonella Chillemi.2 1Centro Llse, Madison, WI; 2University of Torino Medical School, Torino, Italy.

Purpose: Extracellular drug conjugates (or ADCs) are a new type of ADC that selectively inhibit the all-powerful Na,K-ATPase, an extracellular membrane ion pump required for life. To determine if ADCs may be valuable clinical can- didates, we further assessed their safety, efficacy and mode of action. Experimenta- nal Design: Cynomolgus monkeys were infused with ADCs at various levels and monitored by heart telemetry, blood cell levels and serum examination. Addi- tionally, cultured cells were subjected to ADCs and monitored in real time and by high resolution dual fluorescent labeling to better understand the mechanism of cell death. Results: We tested the efficacy of the ADCs in a number of xenografts models and observed strong activity (regression and cures). Little to no tumor reduction was observed for the free antibodies or with control-EDCs where the antibody target was not expressed. To test for safety, each cynomolgus monkey was infused with one of three ADCs to better understand the MTD of each ADC. In all cases, MTD was determined to be between 5 and 10mg/kg where ADC serum levels reached between 100 and 200mg/ml. At the maximum safe dose tested (5mg/kg), heart beat and other observed parameters were found to be normal with the exception of the blood cells expressing the ADC targets (EDC targeting CD20 at this high level was found to drop all B-cells to a nondetectable level which rebounded to normal on day 58). To further under- stand the ADC mechanism, cells exposed to the ADCs and monitored visually in real-time or by dual fluorescence microscopies. All cells exposed to the ADCs showed membrane swelling and extracellular localization of the ADC. Conclu- sion: These results show that targeted inhibitors of the Na,K-ATPase ion pump have promise as future anticancer medicines. First, ADCs appear safe in nonhu- man primates at efficacious doses in rodent xenografts. In addition, an identified mechanism of extracellular necrotic death is novel in the field of oncology. Our hope is that cancers that up-regulate MAPK and/or anti-apoptotic mechanisms will be sensitive to ADCs. Continuing efforts to identify the full death pathway of this new type of ADC should lead to identifying patients most likely to respond to ADC based therapies.

#4298 FTY720 induces necroptosis in lung cancer by modulating cer- amide signaling at the plasma membrane. Rose Nganga. Medical University of South Carolina, Charleston, SC.

Sphingolipids are important signaling molecules in cells and have recently been explored as cancer therapy targets. FTY720 (Fingolimod, Gilena) is an FDA approved sphingosine analogue drug used for the treatment of multiple sclerosis (MS). FTY720 is phosphorylated by sphingosine kinase 2 (SK2), to generate P-FTY720 to exert its immunosuppressive properties through binding to sphingosine-1-phosphate receptors (S1PRs). FTY720 also exhibits anti-cancer properties. Our previous studies indicated that one of the mechanism by which FTY720 induces cell death is through necroptosis. FTY720 directly binds to I2PP2A/SET (Inhibitor of 2 of PP2A), consequently activating the tumor sup- pressor protein phosphatase 2A (PP2A). The activated PP2A then induces cell death by stimulating the activity of Receptor-Interacting Protein kinase-1 (RIPK1), involved in necroptosis signaling. Previous studies have shown that FTY720 can modulate sphingolipids metabolism in cells. However, little is known about the roles of FTY720 in ceramide signaling and regulation of necroptosis in lung cancer. We hereby seek to investigate the mechanisms of FTY720 in inducing necroptosis with regard to ceramide signaling. Preliminary data indicate that inhibitors of ceramide generation partially protect cells against FTY720-induced cell death. Interestingly, FTY720 and non-phosphorylated FTY720 analogues do not affect ceramide generation, but lead to the formation of cancer specific ceramide-multi-protein complexes at the plasma membrane. Our studies show a role of these complexes in inducing plasma membrane rup-
its anti-proliferative effect and apoptosis induction by an up-regulation of TGFβ1, p53 and p21 and a down-regulation of TGF-α and Bcl-2a. Conclusion: Thymoquinone showed antiproliferative and proapoptotic potentials in ATL cells. For this reason, further research is required to investigate its possible application in the treatment of ATL.

#4302 Disulfiram possesses antitumor activity and inhibits cancer stem-like properties via inhibition of STAT3 activation in triple-negative breast cancer cells. Yoon-Jae Kim, Nahyun Lee, Eunhye Oh, Daesung Sung, Tae-Min Cho, Ji Young Kim, Jae Hong Seo. Korea University, Seoul, Republic of Korea.

Disulfiram (DSF), a clinically used treatment for alcohol dependence, is considered as a potential anti-cancer agent due to its cytotoxicity in many cancer cell types on copper (Cu)-dependent processes. However, the molecular mechanisms underlying DSF-induced antitumor activity in triple-negative breast cancer (TNBC) are still poorly understood. Here, we hypothesized that DSF induces antitumor effects by targeting cancer stem cells (CSCs) and STAT3 signaling in TNBC. We then examined the effects of DSF in combination with Cu on the cell viability and apoptosis, cell proliferation and survival, as well as CSC-like properties in MDA-MB-231 and 4T1 TNBC cell lines. DSF/Cu effectively induced cytotoxicity and apoptotic cell death, concomitant with caspase-3 activation and PARP cleavage. DSF/Cu also significantly suppressed cell migration and mammosphere formation, which are accompanied by a remarkable decrease in the CD44+/CD24− (or CD49f+/CD24+ in mouse 4T1 cells) stem-like population and ALDH1 activity. These effects were functionally associated with the inhibition of STAT3 phosphorylation (Tyr705). Furthermore, DSF/Cu treatment resulted in the downregulation of cyclin D1 and survivin expression, which are downstream targets of STAT3 signaling. Interestingly, phosphorylated STAT3 and STAT3 downstream signaling were highly upregulated in the mammospheres, and these upregulated molecules were significantly decreased by DSF/Cu treatment. In MDA-MB-231-derived xenograft model, DSF administration elicited a significant reduction in tumor growth with a noticeable down-regulation of CD44, ALDH1 and phosphorylated STAT3 levels. Taken together, our results suggest that therapeutic treatment to DSF can effectively manifest antitumor activity by reducing CSC-like properties, and that STAT3 could be a key molecule of aggressive TNBC that is targeted by DSF.

#4304 Feedback-phosphorylation of MKK4 by MAPKs promotes apoptosis. Hisashi Morizumi. The Institute of Medical Science, The University of Tokyo, Tokyo, Japan.

Feedback-phosphorylation of MKK4 by MAPKs promotes apoptosis Morizumi Hisashi, Takanori Nakamura and Mutsuhiro Takekawa. Div. Cell Signal and Mol. Med. IMS, Tokyo Univ. The mitogen-activated protein kinase (MAPK) kinase pathway is an important system for cellular responses to extracellular stimuli. Each of the MAPK pathways is composed of MAPKKK, MAPKK and MAPK. In mammalian cells, at least three subfamilies of MAPKs, namely ERK, p38 and JNK, are present. The ERK pathway is activated in response to mitogenic stimuli and plays a key role in proliferation and differentiation. In contrast, the p38 and JNK pathways, collectively called stress-activated protein kinase (SAPK) pathways, regulate cellular stress responses such as apoptosis and cell cycle arrest. MKK4 is unique among the members of the mammalian SAPKK family (i.e., MKK3/4/6/7) in its ability to phosphorylate and activate both p38 and JNK. Interestingly, inactivating mutations of the MKK4 gene are frequently found in many types of cancer. Although MKK4 has been suggested as a tumor suppressor, the molecular mechanism by which MKK4 inhibits tumorigenesis remains unclear. Here we demonstrate that MKK4 can be phosphorylated at specific serine and/or threonine residues by downstream MAPKs (named the “feedback-phosphorylation”) and thereby regulates stress-induced apoptotic cell death. By generating antibodies specific to these phosphorylation sites, we found that under stress conditions both Thr and Ser residues of MKK4 were phosphorylated by JNK, while only the Ser residue was phosphorylated by ERK in response to mitogenic stimuli. In order to clarify physiological significance of the feedback-phosphorylation, we then generated a phosphorylation-deficient mutant of MKK4 (MKK4-AA) by substituting both Thr and Ser residues with Ala. Although the feedback-phosphorylation did not affect the enzymatic activity, stability and subcellular localization of MKK4, we found that cells expressing MKK4-AA mutant suppressed apoptosis induced by various stresses stimuli such as UV irradiation and anticancer drug treatment. These results suggest that feedback-phosphorylation of MKK4 regulates stress-induced apoptosis. Moreover, we are currently investigating the mechanism of how MKK4 affects apoptotic cell death in response to feedback-phosphorylation.

PURPOSE: The von Hippel Lindau (VHL)/hypoxia inducible factor-alpha (HIF-α) pathway is commonly dysregulated in clear cell renal cell carcinoma (ccRCC) and potentially exacerbated by oxidative stress. Iron is the most abundant heavy metal in the human body and is required for nephrogenesis in utero; it is also a major source of intracellular oxidative stress capable of inducing ccRCC in rodent models. Recently, iron was shown to stabilize HIF2-α transcript by inhibiting iron regulatory protein 1. Still, a role for iron in human ccRCC remains largely unexplored. We tested the hypotheses that intracellular iron is accumulated in human ccRCC cells and that iron deprivation can suppress HIF2-α expression and ccRCC cell growth. METHODS: Over 1500 core sections from 587 tissues (272 primary tumors, 240 benign kidney, 75 metastases) of 288 RCC patients were stained and scored for levels of iron and the primary iron uptake protein, transferrin receptor 1 (TfR1), using Prussian Blue and immunohistochemistry, respectively. 178 cores from 14 different body tissues of non-cancer patients were stained as controls. Staining levels were tested for association with patient features and outcomes. TfR1 protein expression was further evaluated in 4 ccRCC and 2 benign renal epithelial cell lines by flow cytometry and western blot. Micromolar concentrations of 3 clinical iron chelator drugs, deferoxamine (DFO), deferriprone (DFP), and deferisirox (DFX), were tested by MTT assay for effects on ccRCC versus benign renal cell proliferation. DFO effects on cell viability/apoptosis and HIF2-α levels were measured using annexin-V/7-AAD flow cytometry and western blot, respectively. RESULTS: Intracellular iron was increased in ccRCC tumors compared to benign renal tubule epithelium; although more advanced tumors had smaller increases. Benign renal epithelium expressed higher TfR1 protein levels than any other tissue site in the body tested, and expression in ccRCC tumors increased during progression to metastasis and cancer-specific death. ccRCC cell lines had elevated TfR1 expression relative to benign renal cell lines. Iron chelation using DFO, DFP, or DFX uniformly achieved 80-90% growth reduction in ccRCC cell lines at clinically utilized concentrations, while benign renal cell lines were relatively resistant. The mechanism of ccRCC growth inhibition was primarily cell death via apoptosis, whereas benign renal cells had no increased death even after prolonged iron chelation treatment. Intriguingly, iron chelation in ccRCC cell lines effectively downregulated HIF2-α in a time- and concentra-
tation-dependent manner. CONCLUSIONS: These data indicate that increases in intracellular iron content occur during human ccRCC tumorigenesis and support further investigation of iron chelation as a novel therapeutic strategy for targeting HIF2-α and inducing cancer cell death in ccRCC patients.

#4306 Combined effects of chemotherapy to reduce metastasis caused by insufficient hyperthermia. Tae Hee Lee,1 Jiyoung Ba,2 Byung Hyuck Kim,1 Young Jun Kim,3 Yoon-Tae Kang,3 Jung Eun Moon,1 Young-Ho Cho1. Cell Bench Research Center (SEMCCELL), Daejeon, Republic of Korea; 2KAIST, Daejeon, Republic of Korea; 3Seoul National University College of Medicine, Seoul, Republic of Korea; 4Armed Forces Medical Research Institute, Daejeon, Republic of Korea.

Hyperthermia therapy is one of the most widely studied non-surgical methods for breast tumors, which eliminates tumor by inducing acute stress on tumor cells. However, it has been extensively known that the viability of the tumor cells is highly influenced by the applied temperature. Insufficient thermal stress during hyperthermia treatments may alter tumor microenvironment by promoting epithelial to mesenchymal-like transition (EMT) and as a result, enhancing the outgrowth of residual tumor cells. Therefore, cells that have survived from sublethal thermal stress and experienced EMT may cause substantial clinical problems. In this case, hyperthermia requires additional therapy in order to promote cell death of more invasive tumor cells that have resisted to the thermal stimulus. In this study, we confirmed that the co-treatment of chemotherapy with hyperthermia may overcome the phenotypical transition caused by insufficient heat treatment. After exposing breast cancer cells (MCF-7) to two different temperature conditions (42°C and 47°C) for an hour, we have verified that 10.51 ± 1.71% and 18.27 ± 10.66% of cells experienced apoptosis or necrosis when the cells were exposed to 42°C and 47°C, respectively. At the same time, cancer cells showed higher invasiveness, spear-like morphology, and enhanced migratory behaviors as the exposed temperature increases, which is mainly shown among the cells that have experienced EMT. Further western blot assay and quantitative real-time polymerase chain reaction (qRT-PCR) using mesenchymal marker (vimentin) and epithelial marker (E-cadherin) also support that the mesenchymal-like phenotype has been highly increased on the cells that have resisted to the thermal stress. However, when chemotherapy was conducted after the heat treatment, cell viability was highly reduced. Paclitaxel (11.7 μM), cisplatin (3.3 μM), and combination of two anticancer drugs were treated for 24 hours on the cells that have been exposed to different temperatures, respectively. As a result, death rate of tumor cells has increased from 11.31 to 66.69%. Especially, when paclitaxel and cisplatin were co-treated, the death rate was up to 73.75 ± 4.37% after cells were exposed to 47°C. In conclusion, cancer cells that have survived from insufficient hyperthermia showed high potential to promote metastasis or recurrence but additional chemotherapy can successfully reduce the side effects induced by insufficient hyperthermia treatment.

#4307 Characterizing the differential phosphorylation of Bim in plasma cell disorders. Jason E. Conage-Pough, Vikas A. Gupta, Shannon M. Matulis, Lawrence H. Boise. Emory University, Atlanta, GA.

The pro-apoptotic Bcl-2 family protein Bim is known to be phosphorylated in response to many stimuli. These phosphorylation events have been linked to proteasomal release from dynactin light chain and impacting the ability of Bim to initiate apoptosis. We’ve recently shown that IL-6 stimulation of myeloma cells results in phosphorylation of Bim at S69 and S77. IL-6 treatment additionally led to increased association with Mcl-1 at the expense of Bcl-2/s. This data, coupled with our longstanding interest in factors that influence Bim binding to anti-apoptotic proteins, led us to study the baseline phosphorylation state of Bim in plasma cell malignancies. To study the global phosphorylation of Bim, we utilized PhosTag gel electrophoresis, which allows for detection of phosphorylated forms of a protein. We’ve shown that Bim is constitutively phosphorylated in myeloma cell lines and patient samples. Importantly, these cell lines and samples display differences in their distribution of Bim binding to anti-apoptotic proteins. The pattern of Bim phosphorylation varies significantly across cell lines, with expression of anywhere from 1 to 9 phosphorylated forms. Using the Bax/Bak-deficient Waldenström Macroglobulinemia cell line RPCI-WM1, we were able to recapitulate constitutive phosphorylation in stable cell lines overexpressing Bim. In order to identify and characterize constitutive Bim phosphorylation sites, we created phospho-mimetic (E) and unphosphorylatable (A) versions with individual and combination of mutations of seven potential sites—S9, S77, S87, S94, S104, T16 and S118. PhosTag allowed us to identify individual phosphorylation sites—by mutating individual sites to A, we could determine if we eliminated phosphorylated Bim bands. These experiments showed that S118 and S95 are constitutively phosphorylated in RPCI-WM1. Lastly, we tested whether A and E mutations were affecting the distribution of Bim among anti-apoptotic proteins and dynein light chain. We observed that mutation of the T116 residue to either A or E resulted in increased binding to Mcl-1, suggesting this amino acid is critical for binding to dynein light chain, regardless of phosphorylation status. Our results support the presence of multiple constitutive Bim phosphorylation events, differential signaling and regulation of Bim across a spectrum of plasma cell disorders, and a potential mechanism underlying the preferential binding of Bim. Characterization of the signaling cascades regulating these events may provide novel insights into improving therapies for cancer. The efficacy of drugs such as Navitoclax and Venetoclax can be improved by coupling them with kinase inhibitors that can either mobilize Bim from dynein light chain or alter its affinity for anti-apoptotic proteins.

#4308 Cordycepin induces apoptosis by caveolin-1-mediated JNK regulation of Foxo3a in human lung adenocarcinoma cells. Eunbi Jo1, Hyun Jin Jang,2 Ik-Soon Jang1. 1Korea Basic Science Inst., Daejeon, Republic of Korea; 2Korea Basic Science Inst., Daejeon, Republic of Korea.

Cordycepin is a water-soluble metabolite of the fungus Cordyceps sinensis. Cordycepin is highly used as a traditional medicine in Asian countries, and its biological effects have been well investigated. Recently, it was reported that cordycepin induces apoptosis through JNK/Foxo3a signaling pathway in lung cancer cells. However, the exact mechanism by which cordycepin induces apoptosis remains to be elucidated. In this study, we investigated whether cordycepin induces apoptosis and its resultant pathway in human lung adenocarcinoma cells. Cordycepin induced cell death, morphological change, and nuclear translocation of JNK and Foxo3a in three different lung cancer cell lines (H11006, H9251, NCI-H1299). Western blot analysis showed that the phosphorylation of JNK and Foxo3a was increased in a dose-dependent manner. In addition, the localization of JNK and Foxo3a was changed from cytosol to nucleus. We further investigated the possible mechanism of cordycepin-induced JNK/Foxo3a activation. Cordycepin increased JNK/Foxo3a phosphorylation by downregulating the expression of p53-binding protein 1 (p53BP1), an inhibitor protein of JNK. Furthermore, we identified the critical role of caveolin-1 in the JNK/Foxo3a activation. Firstly, we found that mTOR inhibitor rapamycin prevented cordycepin-induced JNK/Foxo3a activation. Secondly, siRNA silencing for caveolin-1 prevented JNK/Foxo3a activation. Together these findings indicate that cordycepin induces apoptosis through activating JNK/Foxo3a signaling pathway.
Herbal medicines have been used in cancer treatment, with many exhibiting favorable side effect and toxicity profiles compared with conventional chemotherapeutic agents. SH003 is a novel extract from Astragalus membranaceus, Angelica gigas, and Trichosanthes Kirolowi Maximowicz combined at a 1:1:1 ratio that impairs the growth of breast cancer cells. Our data demonstrate that SH003 induced apoptosis in DU145 cells, but not androgen-dependent LNCaP and PC-3 cells. Moreover, ERK2 overexpression rescued SH003-induced apoptosis in DU145 cells. Thus, our data conclude that SH003 induces apoptotic cell death of DU145 prostate cancer cells by inhibiting ERK-mediated pathway.

The growth of estrogen receptor positive (ER+) breast cancers is considered to be dependent on estrogen and its actions can be blocked by selective estrogen receptor modulators (SERMs), like tamoxifen, or by inhibiting the synthesis of estrogen, by aromatase inhibitors (AIs). Both of these classes of drug are used to treat ER+ breast cancers in the clinic. Paradoxically, before the discovery of SERMs and AIs, high dose estrogen was the choice of endocrine therapy to treat post-menopausal breast cancers. Recent clinical trials have confirmed a 30% clinical benefit rate with, as well as low, doses of estrogen therapy in AI-resistant breast cancers. However, the underlying mechanism by which estrogen triggers the tumor regression remains unknown. Using an in vitro cell model MCF7:5C cells, that undergo estrogen-induced apoptosis, we demonstrate that sustained phosphorylation of eukaryotic initiation factor 2-alpha (eIF2-α) in breast cancer cells, that undergo estrogen-induced apoptosis, is critical in estrogen-induced apoptosis. Growth arrest and DNA damage inducible-4 (GADD34) and constitutive repressor of eIF2α phosphorylation (CReP) are two regulatory subunits of protein phosphatase 1 (PP1) complex, that provides substrate specificity towards eIF2α, and are responsible for its de-phosphorylation. Our results show that pharmacological inhibition of GADD34 and CReP, or their genetic depletion, can enhance the phospho-eIF2α (p-eIF2α) levels and promote apoptosis. Elevated levels of p-eIF2α attenuated global translation but preferentially allowed high expression of activating transcription factor 4 (ATF4) and C/EBP homologous protein (CHOP) that are involved in apoptosis. Both estrogen and inhibition of GADD34 and CReP promote apoptosis by an identical mechanism. Importantly, inhibition of GADD34 and CReP induced apoptosis in another estrogen-independent breast cancer cell line, LCC9, which is resistant to both tamoxifen and fulvestrant but does not undergo estrogen mediated apoptosis. Overall, our study provides crucial evidence that inhibiting specific regulatory subunits (GADD34 and CReP) of PP1 complex, can mimic estrogen-induced apoptosis in breast cancer cells that are not susceptible to estrogen mediated apoptosis. Therefore, GADD34 and CReP can be targeted for potential therapeutic intervention in endocrine therapy resistant breast cancers.

Triple-negative breast cancer (TNBC) is highly aggressive and a major threat to survival due to absence of molecular targets. Invasion, metastasis and chemoresistance are the greatest obstacles to the successful tumor treatment in breast cancer patients. In this study, over-expression of Forkhead box transcription factor M1 (FoxM1) was observed in 79% (770/975) of breast cancers from Saudi Arabia. FoxM1 over-expression was found to be an independent prognostic marker in multivariate analysis in late stage (Stage 3 and 4) breast cancer (p=0.0110). Our in vitro results show that treatment with thioestrogen, a dual FoxM1 and proteasome inhibitor caused cell viability loss and induce apoptosis in a dose dependent manner in triple-negative breast cancer cell lines. Thioestrogen treatment also inhibited colony formation and invasion/migration capabilities of triple-negative breast cancer cells. In vivo, thioestrogen treatment regressed TNBC cells, MDA-MB-231 generated xenografts via down-regulation of FoxM1 and its downstream targets. Altogether, our results suggest that FoxM1 and its associated signaling pathway may be a potential target for therapeutic intervention in the treatment of aggressive breast cancer. Key words: Triple-negative breast cancer, FoxM1, Apoptosis and Invasion.

#4313 Protein synthesis modulates paraptotic death induced by inhibition of cyclophilins in glioblastoma (GBM) cells. Lin Wang, Justin Gundelach, Richard Bram. Mayo Clinic School of Medicine, Rochester, MN.

In this study, we investigated the mechanisms underlying cell death induced by the small molecule cyclophilin inhibitor NIM811. NIM811 effectively killed glioblastoma cells, including those that are resistant to chemotherapy or caspase activation. Instead, death was preceded by dramatic cytosolic vacuolization, stemming from enlargement of the endoplasmic reticulum (ER). RNA-seq revealed upregulation of genes pertinent to the unfolded protein response (UPR) and autophagy. Western blotting for UPR and autophagy mediators also supported a transient UPR signaling and compromised autophagy during prolonged NIM811 treatment. By utilizing a bicistronic reporter plasmid, we independently quantitated Cap-dependent and Cap-independent translation. We further assessed the long-term effects mediated by different short-term paraposis inhibitors via colony formation assay. We find that NIM811 initiates paraposis in GBM cells, due to an abnormal upregulation of protein translation that caused accumulation of misfolded or unfolded proteins in ER. Transient activation of pro-survival autophagy and UPR signals were shutdown during prolonged treatment with NIM811, thus allowing cell death to occur. Cycloheximide was previously reported by others to supress paraposis. In our studies, we find instead that it temporarily delayed vacuole formation, but actually enhanced parapotic cell death in the long term. The mTOR inhibitors rapamycin or torin-2 rescued cells from NIM811 induced paraposis by sustaining autophagy and the UPR, and selectively restraining translation. We propose that ER vacuolization could be a protective response generated by cells to isolate defective proteins within the ER in order to prevent misfolded aggregates to interfere with cellular homeostasis. For that reason, simply inhibiting vacuole formation without clearing protein accumulation in the ER was insufficient to prevent cell death. These findings aid our understanding of cellular mechanisms that contribute to non-apoptotic death. Moreover, this work underlines the importance of evaluating cellular responses in cell death experiments over multiple time frames to judge the true impact.

#4314 Exclusive delivery of mazF in cancer cells by Listeria monocytogenes. Maryam Safarian, Jeremy Tzeng. Clemson University, Clemson, SC.

Programmed cell death (PCD), an active process that leads to cell suicide, is a critical mechanism in every organism. MazF, a bacterial ribonuclease protein, can trigger PCD in bacterial cells and also induce Bak-dependent apoptosis in mammalian cells. This bacterial ribonuclease cleaves mRNAs at ACA sequences leading to inhibition of protein synthesis in cells. Hence, we hypothesized that the overexpression of MazF proteins in cancer cells could result in the induction of apoptosis. In the present study, the ACA-less mazF gene was inserted downstream of the Internal Ribosome Entry Site (IRES) and under the control of T7 promoter. The plasmid was electroporated into Listeria monocytogenes harboring pCSA1 that encodes T7 RNA polymerase under the control of the listeria actA promoter. Subsequently, the bacteria were functionalized with Trastuzumab (Herceptin®) to deliver the MazF mRNA into HER2/neu breast cancer cells. The results showed that MazF protein has an ability to induce apoptosis in HER2/neu breast cancer cells. This finding is the first report of the application and evaluation of MazF as an anticancer agent for the induction of apoptosis in HER2/neu breast cancer cell line. This research suggests cancer therapy that targets only cancer cells but not healthy cells and offers more advantages, e.g., inexpensiveness, target tissue specificity, easy and safe delivery, in comparison to other gene therapy vectors or direct protein administration.

#4315 PTBP1 modulation of MCL1 mRNA regulates sensitivity to antitubulin chemotherapeutics. William J. Placzek, Jia Cui. Univ. of Alabama at Birmingham, Birmingham, AL.

Background: Myeloid Cell Leukemia 1 (MCL1), an anti-apoptotic Bcl-2 family protein, is a key regulator of intrinsic apoptosis. Normal cells require strict control over MCL1 expression and aberrant MCL1 expression has been shown linked to the emergence of various diseases and chemoresistance. Previous studies have detailed how MCL1 expression is regulated by multiple mechanisms both transcriptionally and translationally. However, characterization of the post-transcriptional regulators of MCL1 mRNA is limited. Polypririmidinetract binding protein 1 (PTBAP1) is a known regulator of post-transcriptional gene expression that can control mRNA splicing, translation, stability, and localization. In the described study we characterize the impact that PTBAP1 has on MCL1 expression, its molecular mechanisms, and its roles on cellular apoptosis. Methods: Cross-linking Immunoprecipitation (CLIP)-seq data analysis and RNA immunoprecipitation (RIP) were performed to analyze protein interactions with RNAs and map the RNA binding sites on the genes of interests. RNA half-life was measured by treating cells with Actinomycin D and extracting total RNA at
different time point. Cell viability was measured by the MTS assay and apoptosis was assessed by Annexin V/Propidium Iodide (PI) staining followed by flow cytometry analysis. Results: Our studies demonstrate that PTBP1 binds to MCL1 mRNA and that knockdown of PTBP1 up-regulates MCL1 expression in cancer. Mechanistically, PTBP1 silencing stabilizes MCL1 mRNA and increases MCL1 mRNA accumulation in cyttoplasm. We further identify that this post-transcriptional regulation is mediated by microRNAs and Argonaute2 (Ago2). Moreover, we show that PTBP1 down-regulation is anti-apoptotic to antitubulin chemotherapeutics in a MCL1-dependent manner. Conclusions: Our findings suggest that PTBP1 is a novel post-transcriptional regulator of MCL1 mRNA by which it controls apoptotic response to antitubulin chemotherapeutics.

#4316 MCL-1 inhibition ameliorates the expansion of human leukemia in a dose dependent fashion. Haley E. Ramsey,1 Melissa A. Fischer,1 Taeyeu Lee,2 Agnieszka E. Gorska,1 Pia Arrate,1 John Sensenbrenner,2 Leah Hogdal,2 Edward Olejniczak,2 Stephen Fesik,2 Michael R. Savona1. 1Vanderbilt University Medical Center, Nashville, TN; 2Vanderbilt University, Nashville, TN.

Myeloid cell leukemia-1 (MCL-1) is a prosurvival BCL-2 family member protein commonly overexpressed in cancer, including hematologic malignancies. The success of BH3 mimetics against other anti-apoptotic proteins has validated the potential of this line of therapy in hematologic malignancies. However, targeting BCL-2 family members, like MCL-1, with a small molecule inhibitor is challenging because these inhibitors mediate their effects through protein-protein interactions. Recently, we discovered potent (sub nM), selective small molecule MCL-1 inhibitors that inhibit cell-based activity and slow the growth of tumors in multiple mouse models. To determine tumor cell dependence on specific BCL2-family members, we employed BH3 profiling on a panel of myeloid tumor cells to reveal mitochondrial outer membrane permeabilization (MOMP) in a cytochrome C release assay. Additionally, we determined growth inhibition of these cell lines in the presence of the potent MCL-1 inhibitor. These assays indicated MV-411 cells were dependent on MCL-1 and sensitive to MCL-1 inhibition with a GI50 \(<100\) nM. After cell line profiling, we began in vivo studies with the MCL-1 inhibitor in a systemic AML xenograft model. NSG mice were sublethally irradiated and administered MV-411 cells intravenously. Engrafted mice received the MCL-1 inhibitor in 3 different doses (vehicle vs. 10, 25, and 75 mg/kg) daily via intraperitoneal injection. During treatment, the kinetics of MV-411 expansion was monitored via flow cytometry for the detection of human AML in the blood. At approximately 4 weeks after transplant, the vehicle mice became moribund, and all experimental groups were sacrificed for analysis of chimerism. Significant decreases in leukemic expansion were evident in the bone marrow (25 and 75 mg/kg vs vehicle, \(P = 0.01, P < 0.001\)) and spleen (vehicle vs. 75 mg/kg, \(P < 0.001\)) of treated mice in a dose-dependent fashion. MCL-1 blockade also eliminated splenomegaly in MCL-1 inhibitor treated mice. Furthermore, administration of the BCL2 inhibitor venetoclax, as a single agent, and in combination with DNA methyltransferase inhibitors or low dose ara-C in a dose dependent fashion. MCL-1 blockade also eliminated splenomegaly in MCL-1 inhibitor treated mice. Additionally, the MCL-1/BIM interaction was disrupted by both Camptothecin and Anitoxin, which increases the antitumor activity of paclitaxel.

#4317 EGLN1/c-Myc induced lymphoid-specific helicase inhibits ferrop- tosis through lipid metabolic gene expression changes. Youngguang Tao, Shuang Liu, Yiqun Jiang. Central South University, China, China.

Ferroptosis has emerged as a new form of non-apoptotic cell death in multiple human diseases. However, the epigenetic mechanisms of ferroptosis remain poorly defined. We demonstrate that Lymphoid-specific helicase (LSH), a DNA methylation modifier, interacts with WRD76 to inhibit ferroptosis by activating lipid metabolism-associated genes, including GLUT1, and ferroptosis related genes SCD1 and FADS2. These effects are dependent on iron and lipid reactive oxygen species. We further show that EGLN1 and c-Myc directly activate LSH expression by recruiting H3K4me1. Finally, we demonstrate that LSH functions as an oncogene in lung cancer in vitro and in vivo. Therefore, our study elucidates the molecular basis for a c-Myc/EGLN1-mediated induction of LSH expression to inhibit ferroptosis, which can be exploited for the development of therapeutic agents to target ferroptosis in cancer.

#4318 Role of Bcl-2 in hematological cancer formation. Abigail V. Fortier,1 Ally Koh,1 Lisa Stanovski,1 Alisa Kepner,1 Supriya Jain,1 Misha Ul-Islam,1 Ellie Walter,1 Lawrence Boise,2. 1Waltong High School, Marietta, GA; 2Emory University, GA.

B cell leukemia/lymphoma 2 (BCL-2) is a 26 kilodalton, amphipathic, anti-apoptotic protein located on the outer mitochondrial membrane. BCL-2 interacts with other anti-apoptotic and pro-apoptotic factors in order to regulate apoptosis. If a structural change occurs on the BCL-2 gene, overexpression of the BCL-2 protein can result. This causes a change in the ratio of BCL-2 to its BCL-2 Homologous 3 (BCL3) ligands, preventing the release of the apoptotic signal. The primary change associated with BCL-2 overexpression in lymphomas is a t(14; 18) chromosomal translocation involving the BCL-2 and BCL3 transcription. The upregulation of the oncogene allows for the survival of the mutated B cells by raising the apoptotic threshold, which then dislodges regular lymphocytes in the bone marrow or lymph nodes. Lack of cell death due to overexpression of BCL-2 has been linked to hematological malignancies, specifically lymphomas and myelomas. Both B-lymphocytic cancers can result from alterations of the immunoglobulin heavy chain locus on chromosome 14. While BCL-2 translocation can cause follicular Lymphoma, BCL2 over-expression is observed in many other tumor types and likely contributes to cancer progression and drug resistance in these tumors. Treatments to inhibit BCL-2 include attempts at activation and overexpression of the pro apoptotic BH3 proteins, BCL-2 Associated X Protein (BAX) and BCL-2 Associated K protein (BAK), and creation of BH3 mimetics. In this study, we employed BH3 mimetics to create a 3D printed model of BCL-2 and composed a review poster of our secondary research to investigate and determine the relationship between the structure and function of this molecule.

#4319 Analysis of Bcl-2 family members and protein-protein interactions using novel multiplex immunomartas. Reeti Maheshwari, Melissa Schluter, Danielle Pepin, Joseph Hwang. Millipore Sigma, St Charles, MO.

Bcl-2 family members play a role in intracellular and intercellular interactions. The family consists of more than 17 members that can be functionally separated into pro-apoptotic and anti-apoptotic subfamilies. Interactions between these family members determine cell fate, and dysregulation can lead to tumor growth and tumor cell survival. There are several investigational drugs for cancer treatment targeting Bcl-2 family members in clinical trials, driving the need for robust assays to measure Bcl-2 family members and their interactions. Though existing assays measure Bcl-2 family members, there is a lack of reliable assays to evaluate total proteins and protein-protein interactions simultaneously. To address this issue, we have developed two LumineX-based multiplex immunomartas panels that allow for the simultaneous detection of multiple components of the B-cla family in a single well, including Total Bcl-2, Bcl-2, BAX, Mcl-1, Bcl-xL, Bcl-xL, and Bcl-xL/BAX. Using these panels, we analyzed changes in the expression and interactions of Bcl-2 family members in response to known apoptotic drugs, including Camptothecin (topoisomerase inhibitor), Anisomycin (protein translation inhibitor), and AT101 (BH3 mimetic drug). Camptothecin and Anisomycin each elicited a significant decrease in the levels of Mcl-1. Additionally, the Mcl-1/BIM interaction was disrupted by both Camptothecin and Antiomycin, perhaps a consequence of the reduced Mcl-1 levels. However, expression of the other anti-apoptotic proteins was unaffected by any of the three drugs. Interestingly, all three treatments had different effects on the Mcl-1/ NOXA interaction. Mcl-1/NOXA signal was increased by AT101, decreased by Anisomycin, and showed a dose-dependent effect with Camptothecin. In contrast to their disparate effects on the Mcl-1/NOXA interaction, all three drugs acted in a similar manner in blocking the Bcl-xL/BAX interaction without affecting the total levels of either protein. Overall, these results illustrate the dynamic responses of the Bcl-2 family to apoptosis-inducing drugs. The novel multiplex immunomartas described here provide a powerful tool for studying the underlying mechanisms regulating the Bcl-2 family of proteins.

#4320 The Survivin-targeting miR-542-3p overcomes erbB3 signaling-mediated chemo-resistance and enhances the antitumor activity of paclitaxel against erbB2-positive breast cancer. Hui Lyu,1 Shuiliang Huang,2 Jingcao Huang,3 Bolin Wang,4 Bolin Liu,5. 1University of Colorado Denver/AMC, Aurora, CO; 2Fuzhou General Hospital, China; 3West China Hospital, China.
Elevated expression of erbB3 interacts with erbB2 in breast cancer cells to confer chemo-resistance via induction of Survivin. However, the underlying mechanism of erbB3 signaling-induced upregulation of Survivin remains elusive. Ectopic expression or downregulation of erbB3 in erbB2-positive breast cancer cells did not alter Survivin mRNA levels and had no significant effect on Survivin protein levels in our system. We thus hypothesize that the erbB3 signaling modulates certain miRNAs that target Survivin to influence its protein translation. Here we showed that overexpression of erbB3 decreased and specific knockdown of erbB3 enhanced expression of two Survivin-targeting miRNAs, miR-203 and miR-542-3p in breast cancer cells. While the specific inhibitor of either miR-203 or miR-542-3p clearly attenuated an anti-erbB3 antibody (Ab)-mediated reduction of Survivin, a more profound effect on Survivin protein expression was observed with inhibition of miR-542-3p than miR-203 inhibition. Consistently, miR-542-3p mimic was much more effective than miR-203 mimic not only to downregulate Survivin, but also to enhance paclitaxel-induced apoptosis in the otherwise paclitaxel-resistant breast cancer cells. Moreover, using a murine tumor xenograft model established from a human breast cancer cell line expressing both erbB2 and erbB3, we discovered that the combinations of miR-542-3p mimic and paclitaxel, as compared to either agent alone, significantly inhibited tumor growth in vivo. Collectively, these data demonstrate that the erbB3 signaling upregulates Survivin via inhibition of miR-203 and miR-542-3p in erbB2-positive breast cancer cells. Since miR-542-3p has three binding sites on the 3’UTR of erbB3 mRNA, the miR-542-3p mimic serves as an excellent replacement therapeutic agent to downregulate Survivin, and thereby significantly enhances the paclitaxel activity of paclitaxel against erbB2-positive breast cancer.

#4321 TNFR receptor 2 is essential for RIP1-dependent cell death in refractory leukemia. Julia Agüade-Gorgorio,1 Scott McComb,1 Cornelia Eckert,2 Maria Pamela Dobay,3 Gunnar Cario,3 Caterina Mezzatetta,4 Arend Von Stackelberg,2 Martin Stanulla,5 Schrappe Martin,5 Jean-Pierre Bourquin,5 Beat C. Bornhauser1.1 Univ. Children’s Hospital Zurich, Zurich, Zurich, Switzerland;2 Charité Medical University Berlin, Germany;3 Swiss Institute of Bioinformatics, Lausanne, Switzerland;4 University Hospital Schleswig-Holstein, Germany;5 Hannover Medical School, Germany. The identification of molecular determinants that regulate sensitivity to specific agents is essential for the development of new therapeutic approaches in cancer. We have earlier shown that a subset of refractory acute lymphoblastic leukemia (ALL) samples respond to SMAC-mimetic (SM) induced IAP depletion by concurrently inducing RIP1-dependent apoptosis and necroptosis. Comparative gene expression profiling indicated a correlation of sensitivity to SM with the expression of TNFR receptor 2 (TNFR2) in primary ALL. Using an independent cohort of primary chemotherapy-resistant ALL samples, we found that expression of high TNFR2 expression identified by qPCR predicted ex vivo sensitivity to SM. High TNFR2 levels also correlated with higher expression of TNFR1. Deletion of either TNFR1 or TNFR2 using CRISPR/Cas9 in primary ALL conferred resistance to treatment with SM, indicating that TNFR1 and 2 are both functionally required for cell death. Combinatorial with an important role for TNFR2 in the response to SM, the overexpression of TNFR2 leads to increased sensitivity to TNF through increased activation of the TNFR1/RIP1 death axis. On the mechanistic level, SM induced recruitment of RIP1 to TNFR1, which was abolished in cells deficient for TNFR2. Taken together, our data reveal a novel function of TNFR2 in cell death signalling, as TNFR2 predicts sensitivity to SMAC mimetics and plays a key role in modulating a switch from RIP1-controlled cell survival to cell death.

MOLECULAR AND CELLULAR BIOLOGY / GENETICS: Cell Death in Cancer

Exosomes and microvesicles were then assayed for particle size distribution using nanoparticle tracking analysis and electronic microscopy. miRNA expression levels were determined using quantitative PCR. miRNA transfection was performed with RNAiMax reagents. Cell viability was measured by Alamar Blue. Statistics were performed using Prism 6 software. Following transfection of human AML cells with PDAC cells, the semiRNAs are present in PDAC (PDAC) cells at the transcriptional level, with no significant effect on Survivin mRNA levels. We thus hypothesize that the latter expression is modulated by certain miRNAs that target Survivin to influence its protein translation. Here we showed that overexpression of erbB3 decreased and specific knockdown of erbB3 enhanced expression of two Survivin-targeting miRNAs, miR-203 and miR-542-3p in breast cancer cells. While the specific inhibitor of either miR-203 or miR-542-3p clearly attenuated an anti-erbB3 antibody (Ab)-mediated reduction of Survivin, a more profound effect on Survivin protein expression was observed with inhibition of miR-542-3p than miR-203 inhibition. Consistently, miR-542-3p mimic was much more effective than miR-203 mimic not only to downregulate Survivin, but also to enhance paclitaxel-induced apoptosis in the otherwise paclitaxel-resistant breast cancer cells. Moreover, using a murine tumor xenograft model established from a human breast cancer cell line expressing both erbB2 and erbB3, we discovered that the combinations of miR-542-3p mimic and paclitaxel, as compared to either agent alone, significantly inhibited tumor growth in vivo. Collectively, these data demonstrate that the erbB3 signaling upregulates Survivin via inhibition of miR-203 and miR-542-3p in erbB2-positive breast cancer cells. Since miR-542-3p has three binding sites on the 3’UTR of erbB3 mRNA, the miR-542-3p mimic serves as an excellent replacement therapeutic agent to downregulate Survivin, and thereby significantly enhances the paclitaxel activity of paclitaxel against erbB2-positive breast cancer.

#4324 Exosomal delivery of stroma-derived miR-145 inhibits pancreatic cancer cell proliferation. Song Han, Sayali Belsare, DongYu Zhang, Mark Beveridge, Carlos Rinaldi, Jose G. Trevino, Thomas D. Schmittgen, Steven J. Hughes. University of Florida, Gainesville, FL. We previously reported that within the pancreatic ductal adenocarcinoma (PDAC) microenvironment, miR-145 and miR-199a are exclusively expressed in tumor-associated stroma (TAS) cells, but these miRNAs are present in PDAC cells following co-culture with TAS cells. We hypothesized that miRNAs function as paracrine signals via exosomal exchange between TAS cells and adjacent PDAC cells. Primary cultures of human TAS and PDAC cells were employed. Membrane-bound microparticles were isolated from TAS conditioned, serum-free culture media by sequential ultracentrifugation followed by ultrafiltration.

Exosomal delivery of stroma-derived miR-145 inhibits pancreatic cancer cell proliferation. Song Han, Sayali Belsare, DongYu Zhang, Mark Beveridge, Carlos Rinaldi, Jose G. Trevino, Thomas D. Schmittgen, Steven J. Hughes. University of Florida, Gainesville, FL. We previously reported that within the pancreatic ductal adenocarcinoma (PDAC) microenvironment, miR-145 and miR-199a are exclusively expressed in tumor-associated stroma (TAS) cells, but these miRNAs are present in PDAC cells following co-culture with TAS cells. We hypothesized that miRNAs function as paracrine signals via exosomal exchange between TAS cells and adjacent PDAC cells. Primary cultures of human TAS and PDAC cells were employed. Membrane-bound microparticles were isolated from TAS conditioned, serum-free culture media by sequential ultracentrifugation followed by ultrafiltration.

#4323 Metabolic reprogramming in acute myeloid leukemia cells by mesenchymal stromal cell-derived exosomes induces chemoresistance. Hongyu Zhao,1 Xiying Guo,1 Arjun Achreja,2 Zhe Chen,3 Ahnou N. Doss,2 Nadia Popolova,2 Michael Andreeff,2 Deepak Nagrath1.1 University of Michigan, Ann Arbor, MI;2 The University of Texas MD Anderson Cancer Center, Houston, TX. Mesenchymal stromal cells play an important role in acute myeloid leukemia (AML) development. Altered cellular metabolism supports AML cells’ survival in multiple aspects, such as drug resistance. Here, we demonstrate the role of exosomal miRNAs in metabolic regulation of AML cells and propose a combinatorial strategy to sensitize AML cells to chemotherapies. Exosomes secreted by MSCs can reprogram the metabolic machinery following their internalization by AML cells. Through 13C tracing experiments and flux analysis, we elucidate that MSC-derived exosomes enhance oxidative phosphorylation and glutamine’s entry into TCA cycle, which replenish the pool of carbon sources in mitochondria. Further, our work shows that inhibiting the interactions between MSCs and AML cells by targeting the metabolic regulation exerted by MSC-derived exosomes sensitize AML cells to chemotherapies. Taken together, our work reveals a novel role of the TME in regulating the metabolic adaptation in AML cells and uncovers the improved strategy for AML therapy.
Neuroblastoma (NB) is the most common extracranial solid tumor of childhood. One of its hallmarks is high histological heterogeneity. The primary tu-
mors are composed of neuroblastic cancer cells, Schwannian stroma and some 
infiltrating immune cells. The origin and functions of Schwannian stroma still 
remain controversial. It is suggested that they are tumor-infiltrating normal 
cells. Studies using Bone Marrow Stromal Cells (BMSCs) or Schwann cells to 
imic Schwannian stroma have shown both tumor promoting or suppression 
effects. An alternative hypothesis is that Schwannian cells are derived from can-
cer stem cells and may share the same genetic lesions with their normal tumor 
cells. Our laboratory had reported that in the SK-N-SH cell line, both 
N-type cells (neuroblastic cells) and S-type cells (Schwann-like cells) shared 
almost identical genetic background. These cell lines may serve as relevant mod-
estudies to study NB tumor heterogeneity. Genome-wide sequencing for driver on-
cogenes in familial NB uncovered mutations in Anaplastic Lymphoma Kinase 
(ALK) gene. ALK point mutations have been found in 8-12% of all NB patients, 
and are restricted to the kinase domain. aberrant activation of ALK signaling, 
and its downstream target, PI3K/AKT, STAT3 and ERK1/2, can contribute to 
NB tumorigenesis. Thus, ALK is an intensely studied therapeutic target. Sub-
lines of N-type and S-type cells were isolated from an early passage of SK-N-SH. 
Surprisingly, over 90% have cell morphology that resembled S-type cells. Se-
lected cell lines of N-type and S-type cells were isolated from an early passage of 
SK-N-SH. The selected cell lines were further characterized by the expression of 
alkine-specific lectins, has been found to be involved in tumor pro-
	
Conclusion: Our results show that the stimulation of lipolysis and fatty acid 
metabolism is a critical strategy to enhance the capacity of leukemia cells to derive energy from 
free fatty acid metabolism. The role of adipocytes in regulating leukemia metabolism and its 
clinical implications are discussed. 

Regarding the status of an adipocyte population in leukemia, we draw focus on the 
status of an adipocyte in leukemia. In this study, we evaluate the status of an adipocyte 
in leukemia. 

tissue density can create a carcinogenic microenvironment for 
normal mammary epithelial cells. Shayan Nazari, Pinku Mukherjee. University 
of North Carolina at Charlotte, Matthews, NC.

Background: Breast cancer is the most diagnosed cancer and the fourth lead-
ing cause of cancer related mortality among females. Mammographic density (MD) is defined by the amount of stromal and epithelial tissues present in 
the breast tissue. Fifty percent of women have high MD and are 4-6 times more likely to 
develop breast cancer in their lifetime compared to women with low MD. Additionally, 
mammograms often miss abnormal lesions in high MD breast leading to late-stage diagnosis. The stromal microenvironment is characterized 
by extracellular matrix (ECM) reorganization and staccato, and increase in ECM 
proteins including collagen I and fibronectin, which drives proliferation, tumor 
cell survival and migration. Expression of fibronectin and collagen are signifi-
cantly higher in women with high MD compared to women with low MD. However, 
the mechanisms underlying the initiation and progression of breast cancer associated with MD remains largely unknown. Therefore, understanding 
the molecular pathways involved in the unique transformation of normal mam-
mary cells to cancer cells in a dense microenvironment is an important step in 
finding diagnostic cells and targeted therapeutic strategies for prevention and treatment 
of breast cancer. We hypothesize that normal mammary epithelial cells behave like 
cancer cells in an ECM protein-rich microenvironment by activating pathways 
associated with tumor growth and survival and contributing to the initiation and 
progression of breast cancer. Methods: We conducted an in vitro study, deter-
miming the effects of different concentrations of ECM proteins on the activation of 
pro-carcinogenic pathways including the MAPK pathway and the PI3K pathway 
using Western blotting analysis. This study helps us understand if there is a difference in the expression of ERK1/2 signaling and/or PI3K signaling in 
normal mammary cells (hTERT) seeded on culture dish coated with ECM proteins 
(collagen and fibronectin), compared to a non-coated control. We also 
examined morphological changes that can occur in a breast cancer cell line (HCC1806) that are seeded on ECM-rich coating dishes compared to 
non-coated dishes. Results We observed changes in the morphology of breast cancer cell lines after cells were seeded on increasing concentration of extracellular 
matrix coatings using light microscopy. We also observed an increase in the 
number of apoptotic cells in normal non-proliferating breast cancer cell lines 
when cells were stressed using hypoosmotic, collagen and fibronectin-rich microenvironment can induce desmosplastic-like phenotype and behavior 
for normal mammary cells, which highlights the possible first steps in transfor-
mation of normal mammary cells to desmosplastic cells. Given that high MD is one of the major risk factors for breast cancer development, it is critical to 
decipher the molecular mechanisms associated with the high risk. 

#4323 Bone marrow adipocytes drive transcriptional changes in leukemia 
blasts to enhance their capacity to derive energy from free fatty acid metab-
olism. Manar Shafat,1 Thomas Oellerich,2 Sebastian Mohr,3 Stephen Robinson,1 
Dylan Edwards,1 Rachel Piddock,1 Amina Abdul-Aziz,1 Christopher Marlein,1 
Matthew Fenech,1 Jeremy Turner,2 Matthew Lawes,3 Lyubov Zaitseva,3 John-
athan Watkins,3 Kristian Bowles,2 Stuart Rushworth1.2.1. The University of East 
Anglia, Norwich, United Kingdom; 2Goethe University, Frankfurt, Germany; 
3Norfolk and Norwich University Hospitals NHS Trust, Norwich, United King-
dom.

Introduction: Most patients diagnosed with acute myeloid leukemia [AML] 
die of their disease and the average age of patients at diagnosis is 72 years. For 
this reason, new therapeutic strategies with tolerability in the fragile, less fit 
population become necessary for reducing the mortality rate associated with this 
disease. The tumor microenvironment is an emerging target in the search for 
less cytotoxic therapies. We have previously shown that the adipocyte component of 
the bone marrow (BM) is a key player in blast survival, proliferation and che-
motherapy evasion. In this study, we draw focus onto the status of an adipocyte 
rich environment in the context of leukemia and highlight the key players in 
regulating leukemic cell metabolism through transport and metabolism of fatty 
acids. Objective: We hypothesize that the presence of adipocytes within the 
proximity of AML blasts creates a FA rich environment for increased β- oxida-
tion within the blasts. Methods: We used primary AML blasts and normal 
CD34+ hematopoietic stem cells (HSC) following informed consent 
(LRC/Re/07/H0310/146). Adipocytes were derived from bone marrow stromal 
cells (BMSC). Differential expression analysis of RNA sequencing data (GEO 
ID: GSE49642, GSE48846) was used to compare respiratory gene signatures 
of BM AML blasts, peripheral blood obtained AML and normal CD34+ HSC. 
Fatty acid binding protein 4 (FABP4) and carnitine palmitoyltransferase 1A 
(CPT1A) were identified as one of the key genes involved in the lipolysis and 
oxidation signature differential expression. Oxygen consumption rate (OCR) of 
tumor and co-cultured blasts and normal CD34+ were analyzed using Seahorse 
technology. Lentiviral knockdown of FABP4 and CPT1A were performed on 
blasts prior to in vivo xenograft mouse model injection. Results: Leukemia blasts 
showed increased adipocyte lipolysis stimulation compared with normal 
CD34+ cells. Moreover, adipocytes increased transcriptional activation of 
FABP4 and CPT1A in malignant blasts compared to CD34+ HSC. FABP4 in-
hibitor reduced AML blast survival when cells were cultured with adipocytes 
which is in contrast to normal CD34+ HSC. Moreover, AML had increased 
oxxygen consumption rate when grown on adipocytes which was inhibited by 
etomoxir (an oxygen consumption rate inhibitor). Finally in-vivo lentiviral mediated knock-
down of FABP4 and CPT1A revealed an increased survival of AML xenografts. 
Conclusion: Our results show that the stimulation of lipolysis and fatty acid 
oxidative genes that contribute to the genetic signatures of these processes are 
a malignant blast exclusive profile. Interventions at a molecular level reveal sur-
vival favorable outcomes in xenograft models suggesting the need for enhancing 
strategies which include targeting the FABP4 and CPT1A axis. Our data provide 
a biologic rationale for exploring future therapies that target the adipocyte/AML 
interactions.
Gal-3 mediates tumor-stromal interaction and abundant cytokine production is unknown. Methods: The effects of Gal-3 on secretion of cytokines/chemokines from stromal cells (HPSC) were assessed by cytokine array. HPSC proliferation and invasion were assessed by the MTS and Matrigel invasion assays. Co-culture and Conditional medium from PDAC tumor cells with genetic alterations of Gα12Δz3 were used to study the interaction between tumor cells and stromal cells. IL-8 production in both tumor cells and stromal cells was confirmed by ELISA. Transcriptional activities of NF-κB and IL-8 were determined by tran-
sient transfection. An IKK mutant construct (IKBM), Mutation of the IL-8 pro-
moter at the NF-κB site, and inhibitors of NF-κB (Bay11), ILK and neutral antibody of Integrinβ1 were used to determine the signaling pathways evoked by Gal-3. Results: Gal-3 expression is increased in both tumor cells and stromal cells of human and genetic mouse model. Secretion of cytokines such as IL-8, GM-CSF, CXCL1, CCL2, and IL6 were significantly increased in HPSC cells treated with rGal-3 which is concomitant with activation of HPSC. Conditioned medium or co-culture from Panc-1 cells in which Gal-3 was down-regulated inhibited the growth and invasion capacity of HPSC cells compared with the vector controls. rGal-3 dramatically induced production and secretion of IL-8 in HPSCs. Mec-
anistically, Gal-3 stimulates IL-8 secretion at the level of transcription and through Integrin
an distically, Gal-3 dramatically induced production and secretion of IL-8 in HPSCs. Mech-
achanically, Gal-3 stimulates IL-8 secretion at the level of transcription and through Integrinβ1/ILK/NF-κB signaling. rGal-3 strongly stimulated integrin
expression and NF-κB transcriptional activity; and inhibitors of IKK inhibi-
tor or NF-κB or neutral antibody of integrin β1 blocked IL-8 transcriptional activity and its secretion. NF-κB mutant construct IKBM or mutation of the NF-κB site completely blocked the induction of IL-8 by Gal-3. GEO data and our own patients’ cohort analysis of pancreatic tumor samples demonstrated that the level of Gal-3, IL-8 and other cytokines is signif-
ificantly higher in tumor tissues than those of normal and pancreatitis. Conclu-
son: Collectively, these data suggest that Gal-3 secreted from tumor cells acti-
vate HPSC cells and induce many inflammatory cytokines including IL-8 produc-
tion via Integrinβ1/ILK/NF-κB signaling. Thus, Gal-3 may play a critical role in mediating tumor-stromal interaction and remodeling tumor associated microenvironments.

#4329 Targetable nodes in fibroblast-supported melanoma cells that show resistance to BRAF inhibitors. Kotryna Seip1,3, Marco V. Haselager1, Kjetil Jør-
gensen1, Marco Albrecht1, Mads H. Haugen1, Elvind Valen Egeland1, Filipe
Lucarelli4, Thomas Sauter4, Olav Engebraaten1, Gunhild M. Mælandsmo1, Lina
Prasmickaitė1,5. Oslo University Hospital Radiant Hospital, Oslo, Norway; Uni-
versity of Luxembourg, Luxemburg, Luxembourg.

Metastatic melanoma is notorious for the ability to change its phenotype in response to signals from the microenvironment, which might influence how melanoma responds to therapy. We have disclosed an association between fi-
broblast-induced phenotypic alterations in melanoma and resistance to the mut-
ated BRAF inhibitor vemurafenib (BRAFi). This signifies the need to find other targets than BRAF to eliminate stroma-influenced melanoma cells. To provide
this challenge, we performed proteomic analysis and cancer drug sensitivity screening, comparing fibroblast-supported versus non-supported melanoma cells. We showed that the effect of fibroblasts was critically dependent on cell-
cell proximity, where melanoma cells get trapped in a fibronectin network, pro-
duced by adjacent fibroblasts. In such environment, melanoma cells down-reg-
ulate melanocytic programs (MITF-driven), gain mesenchymal features (AXL,
PDGFR, fibronectin) and activate stress/inflammatory-response signaling path-
ways (JNK and STAT3). Altogether, this indicates fibroblast-induced melanoma transition to a de-differentiated, mesenchymal-like, pro-inflammatory pheno-
type. Melanoma cells with such phenotype were less responsive to BRAF/MAPK inhibitors and a number of other targeted drugs. However, they showed en-
hanced sensitivity to PI3K/mTOR inhibitors and, particularly, an inhibitor of GSK3b, stimulating Wnt/b-catenin signaling. Further, we employed flow cy-
mometry to measure the levels of Ki67 and pS6 in single melanoma cells upon different conditions/treatments. Such analysis allowed discrimination of cell
subpopulations representing a proliferative and a quiescent cellular state, and
nicely reflected the influence of the tested drugs in the presence or absence of fibroblasts. We observed a cell subpopulation of both tumor cells and strongly
metastatic melanoma cells, which remained after treatment with BRAFi if fibroblasts were present. This, fibroblast-protected BRAFi-resistant cell subpopulation, could be reduced/eliminated by P13K or GSK3b inhibitors, verifying P13K/GSK3 as po-
tential targets in fibroblast-rich tumors. Currently, we are using mass cytomtery (CyTOF) to further characterize cell subpopulations with respect to multiple markers related to cell signaling and immune interactions. Preliminary results
indicate that not only signaling protein levels, but also levels of immunoregula-
tory proteins are altered in melanoma cells that get support from the fibroblasts.
In conclusion, we demonstrate fibroblast-induced melanoma switching to a
mesenchymal-like pro-inflammatory phenotype, which favors melanoma resis-
tance to BRAF inhibitors, but sensitizes to inhibitors of PI3K/mTOR-associated signaling. CyTOF-analysis of complex tumor-stroma cell systems is used to search for additional strategies to target stroma-supported melanoma cells, ei-
ther at the level of signaling, or immune interactions.

#4330 Astrocytic S1P3 regulates blood-brain/tumor barrier permeability. Anurag N. Paraniap1, Brunilde Gril2, Stefan Woditschka1, Emily Hua1, Jef-
frey C. Hanson1, Xiaolin Wu3, Renata Duczkowska3, Priscilla K. Brastianos4, David L. Liewehr4, Seth M. Steinberg4, Cody Peer1, William D. Figg4, Gary T. Pauly1, Christina Robinson3, Joel P. Schneider3, Patricia S. Steeg1, 1National Cancer Institute, Bethesda, MD; 2University of North Carolina Wilmington, NC; Frederick National Laboratory for Cancer Research, Frederick, MD; 3Wojskowy Instytut Medycyny, Warsaw, Poland; 4Massachusetts General Hospital, MA; 5NCI, Bethesda, MD.

Introduction: Incidence of breast cancer brain metastasis is increasing owing to prolonged life-span and better detection techniques. Prognosis of patients with brain metastases is extremely poor with median survival time of one year. One of the major impediments in treating breast brain metastases is presence of blood-
brain/tumor barrier that limits the permeability of chemotherapeutic drugs into the brain parenchyma. Understanding the mechanisms that regulate blood-
brain/tumor barrier permeability in context of brain metastases is imperative to developing successful therapy. Methods: Mouse models with brain-tropic sub-
lines of MDA-MB-231 (231), JIMT-1, and SUM190 were used to generate breast
cancer brain metastases. Using laser capture microscopy, the permeable and non-permeable lesions from mouse brains were isolated and profiled for gene expression using microarrays. Immortalized human brain endothelial cells, astro-
cytes, and pericytes were used for developing in vitro blood-brain/tumor barrier model along with spheres generated with 231-BR6 or JIMT-1/BR3 cells. Secreted cytokines were evaluated using human cytokine profiler. Transendo-
thelial electrical resistance (TEER) was measured using EVM2 volt/ohm me-
ter. Results: Gene expression profiling and immunostaining of mouse brains, harboring breast cancer metastases showed that astrocytes at permeable regions express elevated S1P3. Pharmacological inhibition of S1P3 using antagonist TY-
52156 (10mg/kg) in mice bearing 231-BR6 brain metastases showed reduction in 3KDa Texas red dextran (TRD) uptake. To investigate the role of S1P3 in regulating barrier permeability, we established in vitro blood-brain/tumor bar-
rier models. Treatment of astrocytes with TY-52156 (2μM) significantly in-
creased mean TEER values (33.9 to 55.8 Ω.cm²; p<0.001, after 24 hrs), while there was a decrease in permeability for TRD (1.9 fold; p<0.001) and doxorou-
bicin (1.3 folds; p<0.05). Immunostaining on endothelial monolayer showed increased membranousZO-1 and VE-cadherin expression. The dynamics of increase in TEER was faster when 231-BR6 spheres were included. We observed similar results when S1P3 was knocked down using shRNA. Astrocytes with down-modulated S1P3 showed decreased secretion of S1P3, including
IL-6, IL-8, CCL2, CXCL1, and GM-CSF. Inhibition of these cytokines indi-
vidually using neutralizing antibodies recapitulated the effects of S1P3 inhibi-
tion, while treatment of endothelial monolayer with activated cytokines increased the permeability. This study provides a proof of concept for role of S1P3 and downstream cytokine signaling in regulating blood-brain/tumor bar-
rier permeability in breast cancer brain metastases. Conclusion: Our study shows that astrocytic S1P3 regulates blood-brain/tumor barrier permeability in breast cancer brain metastases by modulating cytokine secretion. This observa-
tion might lead to discovery of novel strategies for augmenting drug efficacy.

#4331 Novel Wnt-SCD-LRP5/6 pathway linking liver fibrosis to cancer. Keane Lai1, Sook-Mi Kweon2, Feng Chi1, Edward Hwang3, Raymond Wu1, Ya-
suaki Kabe1, Ramachandran Murali1, Lopa Mishra3, James Ntambi3, Hidekazu
Tsuchimoto1, University of Southern California, Los Angeles, CA; 2Keio Univer-
sity School of Medicine, Tokyo, Japan; 3Cedars Sinai Medical Center, Los Angeles, CA; 4George Washington University, Washington DC; 5University of Wisconsin-
Madison, Madison, WI.

Activated hepatic stellate cells (HSCs) are primarily responsible for the gen-
esis of liver fibrosis which promotes liver tumour development. Stearoyl-CoA desaturase (SCD) which synthesizes monounsaturated fatty acid (MUFA such as oleic acid or palmitoleic acid), is implicated in metabolic syndrome, tumori-
genesis and stemness. Indeed, we demonstrate SCD upregulation in both HSCs and liver tumor cells in patients. Further, SCD correlates with the advancing grade of HCC and mortality in patients. However, its causality in tumorigenesis and mesenchymo-tumor crosstalk, and underlying mechanisms, are unknown.

The present study aimed to determine whether and how SCD promotes and links liver fibrosis and cancer. In both HSCs and liver tumor-initiating stem cell-like cells (TIC), we reveal that the Wnt effector β-catenin is a potent co-
activator for SREBP-1-dependent Scd transcription as demonstrated by pro-
The role of fibroblasts in prostate cancer cell invasion in tumor microenvironments. Tarir Shah, Florena Wildes, Dmetry Artemov, Zaver M. Bhujwalla. Johns Hopkins Univ. School of Medicine, Baltimore, MD.

Cancer-associated fibroblasts (CAFs) play a critical role in tumor aggressiveness. We have started to investigate the role of CAFs in different tumor microenvironments of hypoxia and acidic extracellular pH. To further understand interactions between CAFs and cancer cells under carefully controlled conditions of hypoxia and acidic pH, we have used our MR compatible cell perfusion system to determine, for the first time, changes in the ability of prostate cancer cells to invade and degrade the extracellular matrix (ECM) in the presence of prostate myofibroblasts. Experiments were performed using the human prostate cancer cell lines PC-3 and prostate myo-fibroblasts (WPMY-1, ATCC, Manassas, VA). Before each MR experiment, 2.5×10⁶ PC-3 cells were seeded on 0.5 ml of Plastic Plus beads in five 100mm dishes and grown for 4 days. Experiments were carried out with PC-3 cells plated on an ECM chamber with or without prostate myofibroblasts layered between the PC-3 and the ECM. For experiments investigating prostate myofibroblasts-cancer cell interaction, 5×10⁴ prostate myofibroblasts were seeded on ECM gel contained in a chamber overnight before the MR experiment. This time interval allowed myofibroblasts to migrate to the ECM and establish a gradient. Real-time 3D perfusion MRI experiments were performed to compare invasion and proteolytic parameters between control and CAFs treated samples.
Human mesodermal-derived CNS metastasis-associated stromal cells induce a fibrotic response to limit tumor growth. Christoph Legende, Gerald C. Gooden, Kyle N. Johnson, Rae Anne Martinez, Mark Bernstein, Gerald C. Gooden, Kyle N. Johnson, Rae Anne Martinez, Mark Bernstein, Jennifer Glenn, Jeffrey Kiefer, Aleksander Hinek, Steven A. Toms, Bodoor Salhia. Translational Genomics Research Institute, Phoenix, AZ; University of Southern California, Los Angeles, CA; University Health Network, Toronto, Ontario, Canada; Hospital for Sick Kids, Toronto, Ontario, Canada; Lifespan Health System, Providence, RI.

Metastasis to the nervous system (CNS) remains a major cause of mortality and morbidity in patients with systemic cancer. However, the mechanistic interactions of the neural niche with disseminated tumors in CNS metastases (CM) are poorly understood. To better understand the crosstalk between the neural niche and metastatic tumors, we generated five different patient-derived cell lines (PDCs) originating from surgically resected CM. To assess the genetic and epigenetic characteristics of each PDC, DNA and RNA sequencing, and DNA methylation analysis was performed. Non-tumoral PDCs revealed normal copy number profiles, and retention of germline mutations as seen in patient-matched germine DNA. In contrast, one PDC (CM04) resembled its patient tumor, showing numerous copy number and somatic alterations. RNA-seq and DNA methylation analysis demonstrated that non-tumoral PDCs highly resembled each other, suggestive of a common cell of origin. Additionally, PDCs revealed gene expression signatures associated with cancer associated fibroblasts, epithelial to mesenchymal transition, and mesenchymal stem cells. Further in vivo studies demonstrated that CM04 cells were tumorigenic, whereas non-tumoral PDC (CM08) cells were unable to form tumors in nude mice. However, CM04:CM08 mixed tumors were significantly smaller than CM04 only tumors and revealed induction of a fibrotic response by immunohistochemistry. These data offer the first evidence that CNS metastasis-associated stromal cells (cMASCs) produce a collagen and fibronectin-rich extracellular matrix constituting a protective host response, which impedes growth of tumor cells. The therapeutic potential of these cells merits further exploration.

PDGFR-α induced stiffness abrogates mammary ductal development and enhances tumorigenesis in vivo. Anisha Mathur Hammer, Gina M. Sizemore, Vasudha Shukla, Steven T. Sizemore, Maria Cuitino, Cynthia J. Timmers, Quinn Verfurth, Arnab Chakravarti, Gustavo W. Leone, Samir N. Ghadially. The Ohio State University, Columbus, OH.

Breast cancer is a leading cause of mortality in women worldwide, in part due to the tumor microenvironment which increases tumor heterogeneity and abets tumor growth. Fibroblasts are cells of mesenchymal origin that are an important component of normal and tumor stroma. Genetic alterations in these cells were shown by several groups including our own to cause fibroblast activation and fuel tumor progression giving rise to more aggressive disease. Platelet-Derived Growth Factor Receptor (PDGFR) alpha is a receptor tyrosine kinase that is auto-activating Pdgfra mutant allele with a mesenchymal specific Cre recombinase. We found that stromal PDGFRα activation completely abrogated postnatal mammary gland ductal formation, with significantly reduced terminal end bud formation. PDGFRα activation also led to progressive fibrosis in the mouse mammary fat pad. As early as four weeks of age, mammary collagen (trichrome staining; second harmonic generation) and hyaluronic deposition (Alician Blue) was greatly increased in vivo. In fact, this increase in collagen and hyaluronic deposition in mutant animals is believed to be responsible for the observed increased stiffness. We further discovered that in HER2+ patients, PDGFRα levels correlate with breast density. Breast density is the third strongest risk factor for breast cancer, and is directly related to collagen deposition and breast stiffness, thus suggesting a novel predictive role of PDGFRα as a molecular readout of stiffness and densification. Studies are underway to utilize mouse models of HER2+ breast cancer to study both primary tumor growth and metastases. Taken together, our mouse studies and parallel human data analyses suggest that the stromal PDGFRα signaling provides a novel theranostic window in breast cancer treatment and prognosis. The role of IMPACT in survival of cancer cells during tryptophan deprivation by immunosuppressive enzyme indoleamine 2,3-dioxygenase (IDO1). Petr Tomek, Ariane Hallermayr, Michael Kilian, Cristina Gregor Print, Lai-Ming Ching, University of Auckland, Auckland, New Zealand; Ludwig Maximilian University, Munich, Germany; German Cancer Research Center (DKFZ), Heidelberg, Germany.

A broad range of human malignancies overexpress an enzyme called indoleamine 2,3-dioxygenase 1 (IDO1) to suppress antitumor immunity which associates with poor patient prognosis. One mechanism whereby IDO1 activity suppresses the host’s immune cells is mediated by deprivation of the essential amino acid tryptophan (Trp) which raises an intriguing question. How do the cancer cells overcome low levels of the essential amino acid when the immune T-cells are triggered to self-destruct? A protein called IMPACT (product of IMPrinted gene with AnCienT domain) was reported to confer skin cells and neuronal cells increased survival in Trp-deprived environments. Based on these reports, we hypothesize that cancer cells hijack IMPACT to gain survival advantage in Trp-deprived environments. To obtain evidence for this hypothesis, we analysed publicly available genomic datasets and performed experimental assays. Murine GL261 glioblastoma cells overexpressing a full-length mouse IMPACT gene (GL261-IMPACT) were generated by lipofection. IMPACT overexpression was confirmed by Western blot. Metabolic activity and survival of the GL261 cells in Trp deprivation experiments were evaluated using MTT assay and staining with live/dead indicators fluorescein diacetate and propidium iodide, respectively. Meta-analysis of the publicly available RNA-sequencing datasets, The Cancer Genome Atlas (TCGA) and Genotype Tissue Expression (GTEx), provided evidence that IMPACT was overexpressed in the majority of the 24 analysed human cancers compared to their non-malignant tissue counterparts. Consistent with the high IMPACT expression in prostate cancer patients, 12-25% prostate tumors showed amplification of the IMPACT gene (source: cBioPortal for Cancer Genomics). In addition, we found an association of high IMPACT expression with poorer survival for certain leukemia and lung cancer patients in the Gene Expression Omnibus (GEO) portal. To obtain experimental evidence that IMPACT protects cancer cells during Trp deprivation, GL261-IMPACT cells were cultured in media containing 2.5 - 50 μM Trp. Metabolic activity of GL261-IMPACT cells decreased at a slower rate than that of GL261-wild-type cells after 3 to 5 days in media containing limiting Trp concentration (2.5 - 10 μM). On day 5, GL261-wild-type and GL261-IMPACT cells cultivated in 10 μM Trp showed 4.5% and 23% metabolic activity (p = 2.8x10^-9), respectively, relative to the same cells grown in 50 μM Trp. Fluorescence microscopy utilising live/dead staining showed that after 5 days of incubation at limiting Trp concentrations (5 - 10 μM), the majority of GL261-wild-type cells were non-viable whereas GL261-IMPACT cells were predominantly viable. Our initial results support the hypothesis that IMPACT aids cancer cells to overcome periods of tryptophan deprivation.

Single cell RNA sequencing dissect cell growth factor dependency and oncogenic driver effects in an organoid model of gastric cancer. Jiamin Chen, Noemi Andor, Susan M. Grimes, Billy Lau, Hanlee P. Ji. Stanford University Medical School, Stanford, CA.
Gastric cancer is a lethal malignancy with few therapeutic options. Gastric tumors rely on complex intercellular signaling “crosstalk” that enables tumor development, metastasis, and therapeutic resistance. To recapitulate the intercellular communications among various cell populations that exist in vivo, we are using a three-dimensional culture system to grow and manipulate mouse gastric tissue in vitro, otherwise referred to as organoids. This organoid model contains epithelium with its endogenous mesenchymal niche and does not require exogenous Wnt stimulation. To systematically analyze the distinct cellular lineages and their interactions, we applied a massively-scaled single cell RNA-Seq platform to sequence thousands of individual cells from organoid cultures. With PCA and t-SNE analysis of the high-dimensional data generated from single cell RNA-seq, we characterized two major cell types, i.e., epithelial and mesenchymal cells. Leverage the information from single cell transcriptome profiles, we identified specific niche factors of the Wnt signaling pathways that are activated in different stomach cell lineages. These results suggest that the mesenchymal cell populations provide a potential source of the R-spondin, a Wnt agonist, that sustains the growth of epithelium. Furthermore, we compared cell populations from Cdh1+/+/Trp53+/- and Trp53+/- organoids, and characterized changes on the transcriptome profiles due to the loss of Cdh1, an early oncogenic event in diffuse gastric cancer development. Overall, using organoid model and high-throughput single cell RNA-Seq provides a novel approach to study early tumor transformation and critical cancer-stroma interactions.

#4340 RHBDF2 in stromal fibroblasts mediates TGF-β signaling and enhances gastric cancer cell invasion via intercellular crosstalk. Takatsugu Ishibashi1,2, Hidehiko Takigawa1, Kenta Murayama2, Masakazu Yoshida2, Daisuke Izumi2, Kota Arima3, Yoshifumi Baba1, Masayuki Watanabe3, Kosei Hirakawa2, Hideo Baba2,1, Patrick Tan4.1 Kumamoto University, Kumamoto, Japan; 2Osaka City University, Osaka, Japan; 3The Cancer Institute Hospital of JCFR, Tokyo, Japan; 4Duke-NUS Medical School, Singapore, Singapore

Background: Cancer-associated fibroblasts (CAFs) have been reported to promote various types of tumor through secretion of soluble factors. Importantly, this orogenic model and high-throughput single cell RNA-Seq provides a novel approach to study early tumor transformation and critical cancer-stroma interactions.

#4341 Mesenchymal stem cells promote epithelial-mesenchymal transition of colon cancer cells via direct cell-to-cell contact. Hidehiko Takigawa1, Yashikko Kitadai2, Tosho Kuwai3, Ryo Yuge4, Shinji Tanaka1, Kazuki Chayama1.1 Hiroshima University, Hiroshima, Japan; 2Prefectural University of Hiroshima, Hiroshima, Japan; 3Kure Medical Ctr. & Chugoku Cancer Ctr., Hiroshima, Japan; 4Kumamoto University, Kumamoto, Japan

We previously reported that in an orthotopic nude mouse model of human colon cancer, clonally derived mesenchymal stem cells (MSCs) migrated to tumor stroma and promoted tumor growth and metastasis. We evaluated the proliferation and migration ability of cells directly and indirectly co-cultured to clarify the mechanism of interaction between cancer cells and MSCs. Proliferation and migration ability of cancer cells were increased by direct co-culture with MSCs but not by indirect co-culture of MSCs. Thus, we thought that direct contact between cancer cells and MSCs is important to their interaction. We performed microarray analysis of gene expression in KM12SM colon cancer cells directly co-cultured with MSCs. Expression of epithelial-mesenchymal transition (EMT) related genes such as fibronectin (FN), SPARC and Galectin 1 was increased by direct co-culture with MSCs. We also confirmed the upregulation of these genes with real time PCR, and these genes were not increased in cancer cells indirectly co-cultured with MSCs. Among these EMT related genes upregulated by direct co-culture with MSCs, we examined immune localization of FN, well-known EMT marker. In co-culture assay in chamber slides, expression of FN in cancer cluster was seen only at the edge where cancer cells directly contacted MSCs. Furthermore, when cancer cells were treated with TGF-β1, the periphery and invasive edge in orthotopic nude mice tumors and human colon cancer tissues, respectively. These results suggest that mesenchymal stem cells induce epithelial-mesenchymal transition of colon cancer cells via direct cell-to-cell contact and may play an important role of colon cancer metastasis.

#4342 Loss of MSLN impairs pancreatic cancer growth in the peritoneal cavity. Michael W. Rudloff, Daniella Arons, Salma El-Behaedi, Rakun Albalawy, Christine Alewine. National Cancer Institute, Bethesda, MD

Mesothelin (MSLN) is a cell surface glycoprotein that is expressed in at least 10% of pancreatic adenocarcinoma but not on cells of the healthy pancreas nor in the parenchyma of other vital organs. Due to its differential expression, MSLN has been used as a target for various antibody based treatments and cancer vaccines. The physiologic role of MSLN is unknown. Previous reports have suggested that overexpression of MSLN may increase tumorigenicity and metastatic potential of pancreatic adenocarcinoma. To further define the role of MSLN in tumor disease, we deleted MSLN in this model by injecting cancer cell line, KLM1, using CRISPR/Cas9 gene editing. Successful deletion of MSLN was confirmed via flow cytometry and immunoblotting. Furthermore, KLM1/MSLN cells were rendered invulnerable to the MSLN-targeted immunotoxin, RG7787, which depends on the presence of surface MSLN for cytotoxicity. In cell culture, KLM1/MSLN cells grew at the same rate as control cells. KLM1/MSLN formed more numerous tumors in nude mice with the same frequency as control cells. These tumors grew at the same rate. However, when nude mice were inoculated with KLM1/MSLN or control cells intraperitoneally, a marked decrease in tumor burden was observed in cells lacking MSLN. In summary, we have engineered a pancreatic cancer cell line that lacks MSLN and demonstrated that loss of MSLN impairs tumor growth and spread specifically within the peritoneal cavity. Further experiments are in progress to identify the factors contributing to this phenotype.

#4343 Effects of the co-expression of RANTES and IL-6 on the transformed phenotype of breast cancer cells. Marianna Gallo, Daniela Frezzetti, Nicola Normanno, Antonella De Luca. National Cancer Inst, Naples, Naples, Italy

Introduction: Cells of the tumor microenvironment play an important role in the progression of breast cancer through their interaction with cancer cells. In this regard, mesenchymal stem cells greatly increased the metastatic potential of breast cancer cells through secretion of soluble factors. However, there have been no systematic studies of CAFs in diffuse-type gastric cancers (DGCs). We investigated the characteristics and functional roles of CAFs in DGCs using comprehensive genomic approach. Methods: We established primary fibroblasts, normal fibroblasts (NFs) and CAFs from more than 100 tissue samples from GC patients. NFs/CAFs were subjected to Exome and RNA sequencing and messenger RNA expression analysis. Result among the acquired comprehensive data. The candidate molecules were examined for their role in gastric tumor progression by in vitro assays. Results: CAFs exhibited an invasive molecular pattern and acquired motility in extracellular matrix (ECM). We identified RHBDF2 as a mediator of TGF-β signaling and an enhancer of CAF motility. RHBDF2 silencing in CAFs significantly decreased their motility stimulated by TGF-β1 in ECM, whereas NFs transfected with the RHBDF2 expression vector displayed a greater motility in ECM than did control NFs. RHBDF2 silencing also decreased type I TGF-β receptor (TβRI) cleavage through tumor necrosis factor (TNF)-α converting enzyme (TACE) activity and attenuated the invasive molecular pattern of CAFs. Consequently, high-motility CAFs confer on DGC cells the ability to invade the ECM. Furthermore, similar behavior was observed in the interaction of the chemokine CCL5/RANTES. In addition, we demonstrated that breast cancer cells migrate in response to either recombinant RANTES or interleukin-6 (IL-6). Starting from this observation, we analyzed whether the co-expression of RANTES and IL-6 induced a more aggressive phenotype in breast cancer cells. Methods: MCF-7 and MDA-MB-231 breast cancer cells were transfected with expression vectors coding for human MSLN and RANTES. In addition, we demonstrated that breast cancer cells migrate in response to either recombinant RANTES or interleukin-6 (IL-6). Starting from this observation, we analyzed whether the co-expression of RANTES and IL-6 induced a more aggressive phenotype in breast cancer cells. Methods: MCF-7 and MDA-MB-231 breast cancer cells were transfected with expression vectors coding for human RANTES and IL-6. XMAP Bio-Plex Cytokine arrays were employed to measure the levels of secreted RANTES and IL-6. To evaluate the proliferation of stable clones, anchorage-independent growth assays were used. Migration and invasion were analyzed using commercially available kits. Tumor growth in vivo was determined after injection of transfected cells in the mammary fat pad of nude mice. Results: MCF-7 and MDA-MB-231 clones that stably overexpressed RANTES and/ or IL-6 were isolated after selection with appropriate antibiotics. Stable transfecants produced higher levels of secreted RANTES and IL-6 than control cells transfected with mock vectors. To evaluate whether RANTES and IL-6 induced a more aggressive phenotype in breast cancer cells, we analyzed the proliferation, migration and invasive ability of stable clones. MCF-7 cells co-expressing RANTES and IL-6 had a greater ability to form colonies in soft agar, compared with cells overexpressing RANTES or IL-6. In addition, both MCF-7 and MDA-MB-231 clones co-expressing RANTES+IL6 showed a significantly higher ability to migrate through a fibronectin-coated and to invade through a matrigel-coated matrix. The analysis of phosphorylated ERK1/2, AKT and STAT3 signal transduction proteins revealed that in cells overexpressing both RANTES and IL-6 more signaling pathways are simultaneously activated as compared with cells overexpressing RANTES or IL-6. In addition, both MCF-7 cells co-expressing RANTES+IL6 showed a significant increase in in vivo tumor growth when clones were injected in the mammary fat pad of nude mice. Conclusions: Taken together, our data suggest that the simultaneous expression of IL-6 and RANTES produce a more aggressive phenotype in breast cancer cells. This ob-
servation might be useful for the identification of potential targets for novel therapeutic strategies aimed to prevent breast cancer progression through the blockade of the tumor-stroma interaction.

**#4344** Cd146 modulates the malignant phenotype in human prostate cancer. Eugenio Zoni,1 Letizia Astrologo,1 Janine Melsen,2 Irene Klima,3 Joel Grosjean,1 Peter C. Gray,2 Gabrie van der Pluijm,3 Marco G. Cecchini,1 Marianna Krutikov-de Julio,1 George N. Thalmann2,3 University of Bern, Bern, Switzerland; 2 Leiden University Medical Center, Leiden, Netherlands; 3 Salk Institute for Biological Studies, La Jolla, CA.

Prostate Cancer (PCA) is the most frequent cancer in males and the second leading cause of death from cancer in men. When PCA progresses from androgen-responsive to androgen resistance, the formation of incurable metastases mainly in the bone, is almost inevitable. Therefore, understanding the factors that regulate homing and survival of metastatic cancer cells in the bone is important for the identification of new therapeutic targets. High Cd146 expression has been measured in the stroma of lytic and blastic lesions in preclinical models of PCA bone metastasis. The objective of this study is to characterize the role of Cd146 in the maintenance of the aggressive and invasive phenotype in human PCa. We used shRNAs to knockdown the expression of Cd146 in the lytic PC-3/M-Pro4Luc2DTomato and in the blastic C4-2BdTomato PCA cell lines. We validated the knockdown at protein level and tested the effect with functional assays such as migration, proliferation. We used RT-qPCR to test Cd146 knockdown on EMT markers. We measured the effect of the knockdown on the maintenance of cancer stem/progenitor-like cells by ALDEFLUOR assay. Cd146 knockdown reduced proliferation in PC-3/M-Pro4Luc2DTomato PCA cells and resulted in increased E-Cadherin expression. Conversely, no effect on proliferation was measured on C4-2BdTomato cells. It has been described that metastatic human PCA cells target the hematopoietic stem cell (HSC) niche in the bone marrow at the level of an “endosteal/osteoblast” niche and a “vascular/perivascular” niche. We optimized an in vitro model of “osteoblast niche” to study the behavior of prostate cancer cells upon co-culture with osteoblasts and to measure the resulting effects on cancer stem/progenitor-like markers. Our results showed that Cd146 is required for the osteoblast-mediated induction of ALDH activity on PCA cells and Cd146 knockdown prevented the increase in the size of the ADIPLC-5A subpopulation in the tumor cells, mediated by human osteoblasts. Additionally, Cd146 knockdown in PCA cells co-cultured with osteoblasts, reduced the amount of Cd146 expressed by osteoblasts compared to non-targeted control. Finally, we showed that Cd146 is significantly increased in the highly metastatic ALDH<sup>high</sup> cells and identified a new subset of ALDH<sup>high</sup>/ Cd146<sup>high</sup> cells which could be depleted upon Cd146 knockdown. In Conclusion, we detected a novel subset of ALDH<sup>high</sup>/Cd146<sup>high</sup> cells and found that Cd146 influences the maintenance of an aggressive-mesenchymal phenotype in human PCa. Therefore, Cd146 represents a promising molecule to modulate the behavior of aggressive PCA cells.

**#4345** Epigenetic dysregulation of transcriptional program in MLL-EEN leukemia. Xianwen Yang, Yuk Man LAM, Wing Chi Lui, Ray Kit Ng, The University of Hong Kong, Hong Kong, Hong Kong.

Aberrant DNA methylation is a typical feature of cancers, which is usually associated with deregulation of tumor suppressor genes and oncogenes. Acute myeloid leukemia (MLL)-rearranged leukemia is characterized by the presence of MLL fusion proteins resulting from chromosomal translocation between MLL and its partner genes. The MLL fusion proteins have lost the MLL histone methyltransferase SET domain, leading to alteration of epigenetic functions. Many genome-wide DNA methylation profiling studies showed significant global alteration in MLL-rearranged leukemia patients, suggesting that MLL fusion proteins mediate leukemia through dysregulation of DNA methylation status. Our previous work showed that MLL-EEN fusion protein can enhance the self-renewal capacity of murine hematopoietic progenitor cells through mediating DNA hypomethylation at Hoxa family gene promoters. Nevertheless, how the aberrant DNA methylation alters the transcriptional program in MLL-EEN leukemia remains unclear. We performed RNA-seq to study the transcriptional program associated with MLL-EEN in murine hematopoietic stem and progenitor cells (HSPCs). We observed 1023 upregulated and 317 downregulated protein coding genes (PCGs) upon MLL-EEN overexpression. Interestingly, key regulators of DNA methylation, including Dnmt3a, Dnmt3b and Tet family genes, were downregulated, suggesting their involvement in the dysregulation of DNA methylation in MLL-EEN-driven leukemia. Gene ontology analysis showed that signaling pathways crucial to hematopoietic stem cell functions, such as Wnt and Nfkb, were significantly enriched. Motif enrichment analysis also showed that the promoters of dysregulated genes were enriched in binding sites of hematopoietic specific transcriptional factors, such as Pu.1 and C/EBP family. In addition, we have identified 3016 upregulated and 1357 downregulated long non-coding RNAs (lncRNAs) in MLL-EEN HSPCs. lncRNAs, Hotairm1 and linc-p21, which was previously reported playing important roles in hematopoiesis and leukemogenesis, were also found deregulated. Notably, the deregulated lncRNAs showed positive correlation with the downregulated (non-coding) PCGs. Moreover, we demonstrated the transcriptional regulatory role of lncRNAs. MBD-seq analysis showed global DNA hypermethylation in MLL-EEN HSPC. Promoters of genes involved in myeloid differentiation and cell cycle regulation were hypermethylated, presumably associated with their downregulation mediated by MLL-EEN. We are currently investigating how the aberrant DNA methylation mediated by MLL-EEN can affect lncRNA transcription, which subsequently alters the expression of PCGs and leads to leukemic transformation. Taken together, our study provides new insights into the epigenetic regulation of transcriptional program in MLL-rearranged leukemia, which could facilitate the development of novel therapeutic strategies.

**#4346** S-Adenosyl methionine (SAM) blocks breast cancer growth, invasion and metastasis in vitro and in vivo. Niaz Mahmood, David Cheeswili, Ani Arakelian, William J. Muller, Moshe Seyy, Shafaa A. Rabbani, McGill University, Montreal, Quebec, Canada.

DNA hypomethylation has been implicated in the coordinated targeting of various signaling pathways involved in tumor growth and metastasis. In the current study through various in vitro and in vivo assays, we have examined the plausibility of using universal methyl donor S-adenosyl methionine (SAM) for its ability to block breast cancer development, growth and metastasis in our xenograft and transgenic models of breast cancer. Treatment of highly invasive human triple negative breast cancer (TNBC) cell lines MDA-MB-231 and Hs578T with SAM resulted in a significant dose-dependent decrease in cell proliferation, invasion, migration, colony formation and increased apoptosis in vitro. Affymetrix gene expression array and real time PCR (qPCR) validated showed the ability of SAM to decrease the expression several genes implicated in cancer progression in MDA-MB-231 cells. For the in vivo studies, MDA-MB-231 cells expressing green fluorescent protein (MDA-MB-231-GFP) were inoculated into female CD-1 nude mice via mammary fat pad. From day three post tumor cell inoculation, animals were treated with SAM (0.8-1.6 mg/day) or vehicle alone as control via daily oral gavage and tumor volume was determined at weekly intervals for 10 weeks. SAM treatment caused a significant dose dependent decrease in tumor volume and GFP positive metastasis to lungs, liver and spleen in experimental animals compared to vehicle-treated controls. Analysis of RNA from primary tumors by qPCR showed the ability of SAM to cause a marked decrease in the expression of several pro-metastatic and EMT pathway genes. Pyrosequencing of tumoral DNA from control and experimental animals showed that SAM treatment causes a significant increase in the percentage of CpG methylation at the promoter region of several cancer-related genes (2.5 kb to lncRNAs), further demonstrating the epigenetic targeting of DNMT1 in adipocytes inhibits high-grade serous ovarian cancer cell migration and invasion through TIMP3 upregulation. Jessica Tang, Fang Fang, Aaron Buechlein, Pietro Taverno, Kenneth P. Nephew. Indiana University, Bloomington, IN.

Ovarian cancer frequently metastasizes to the omentum and adipocytes play a significant role in tumor progression. As methylation levels in obese adipose tissue are increased due to increased DNMT1 levels and activity, it was of interest to test the hypothesis that inhibiting DNMT1 would reverse adipocyte migration, alter adipokine secretion, and decrease migration and invasion of ovarian cancer cells towards adipocytes. Human adipocytes were seeded in a 24-well plate and treated with low-dose guadecitabine (100nM daily for 3 days). Ovarian cancer models of breast cancer where SAM treatment resulted in a significant delay in the development of mammary tumors and decreased tumor growth in experimental animals as compared to vehicle treated controls. SAM was found to be available in the serum of experimental animals as determined by mass spectrometry and no notable adverse side effects were seen including any change in animal behavior. Results from these studies provide compelling evidence for the therapeutic potential of SAM in breast cancer to provide the rationale for initiating clinical trials with SAM in patients with breast and other common cancers as monotherapy or in combination setting with current therapeutic agents to reduce cancer associated morbidity and mortality.

**#4347** Epigenetic targeting of DNMT1 in adipocytes inhibits high-grade serous ovarian cancer cell migration and invasion through TIMP3 upregulation. Jessica Tang, Fang Fang, Aaron Buechlein, Pietro Taverno, Kenneth P. Nephew. Indiana University, Bloomington, IN.
cancer cells (SKOV3, Kramocho), OVCAR4, OVCAR8) were seeded in the Boyden chamber and allowed to migrate or invade toward adipocytes for 8 and 16h, respectively. Expression of epithelial-mesenchymal transition (EMT) markers (SLUG, FN1, TWIST1) were assessed by qRT-PCR. Adipocyte-conditioned media was used to culture ovarian cancer cells in clonogenicity assay and a human adipokine array (R&D Systems) was used in vitro in adipocytes. Differential gene expression analysis revealed that adipocytes induce EMT-like cells. Most important, adipocytes may signal via TGF-β and activating epigenetic modifications to repress EMT and promote metastasis. Therefore, estrogens and adipocytes may cooperate in the development of drug resistance in prostate cancer.

McGill, Montreal, Quebec, Canada

Cheishvili, Moshe Szyf. DNA methyltransferase (DNMT) isoform specific inhibitors: therapeutic implications. Furthermore, these findings may open new opportunities for the DNA methylome, providing new insights into the pathophysiology of UM.

**In vivo**

DNTM1 protein levels in adipocytes were determined by western blot. To determine a possible mechanism, DNA and RNA from guadecitabine-treated adipocytes were subjected to methylcapture-sequencing (MBD-seq) and RNA-seq, respectively. Guadecitabine treatment of adipocytes decreased (P < 0.05) migration of OVCAR4 and OVCAR8 (35% and 40%, respectively, compared to control), and a 90% decrease (P < 0.05) in invasion towards adipocytes. Guadecitabine treatment was observed for OVCAR4, OVCAR8, and Kramocho cells. Expression of EMT markers SLUG, FN1 and TWIST1 decreased (P < 0.05) after guadecitabine treatment. Conditioned media from guadecitabine-treated adipocytes decreased (P < 0.05) clonogenic survival by 18% compared to control.

Adipokine array results revealed increased secretion of LIF (lipoprotein lipase inhibitor) and TIMP3 (metalloproteinase inhibitor) after guadecitabine treatment (1.6- and 1.8-fold increase, respectively; verified by qRT-PCR). Treatment with recombinant TIMP3 (50M) decreased invasion of OVCAR8 (63%, P < 0.0001) and OVCAR4 cells (73%, P < 0.05). DNTM1 protein levels in adipocytes decreased in the presence of guadecitabine, despite the presence of a DNA synthesis inhibitor. Ingenuity Pathway Analysis (IPA) of MBD-seq data showed a significant change in cell-to-cell signaling and interaction pathways (FC > 10; FDR < 0.05). RNA-seq demonstrated increased expression of matrix metalloproteinase inhibitors (THSB2, TFPI2, and NDRG4) and IPA analysis revealed a significant change in regulation of EMT pathway (FC > 1.5; FDR < 0.05). Guadecitabine treatment of adipocytes alters adipokine secretion resulting in decreased cancer cell migration and invasion. In addition to direct effects on ovarian cancer cells, hypomethylating agents may impact the tumor microenvironment to alter adipokine secretion leading to decreased metastasis.

**#4348 Methylation analysis of uveal melanoma reveals definitive patterns in tumors harboring BAP1 mutations.** Michael Durante, Matthew Field, Stefan Kurtenbach, Parker Bussies, Christina Decatur, J. William Harbour. University of Miami Miller School of Medicine, Fort Myers, FL.

Introduction: Uveal melanoma (UM) is the most common primary intraocular malignancy and can be classified by gene expression profiling into two distinct molecular classes that correspond to metastatic risk: Class 1 (low risk) and Class 2 (high risk). The less aggressive Class 1 UMs express a more differentiated phenotype and exhibit numerous characteristics of normal uveal melanocytes, while the metastasizing Class 2 UMs display loss of melanocytic differentiation and have acquired a primitive, stem-like phenotype. The majority of Class 2 UM's harbor loss of chromosome 3 in addition to inactivating mutations of the tumor suppressor BAP1, which also catalyzes ubiquitin removal from histone H2A and modulates gene expression. Histone modifications have been shown to be associated with DNA methylation and this study investigates the global methylation and gene expression changes in BAP1 mutant tumors. Methods: RNA-sequencing and Illumina Human Methyl 450k BeadChip Array data obtained from human uveal melanoma cell lines analyzed using optimized pipelines. Results: This analysis revealed that the more aggressive Class 2 tumors exhibit a distinct pattern of hypermethylation and silencing of developmental genes involved in neural crest migration and differentiation. Chromosomal regions that were significantly enriched for hypermethylated genes with decreased gene expression in Class 2 tumors included chromosome 3p14-26, 3q12-29 and 8p12-22, whereas the only significantly enriched region after genes that were hypomethylated with increased gene expression in Class 2 tumors was chromosome 8q22-24. Additionally, BAP1 itself was differentially hypermethylated in Class 2 UM’s, suggesting that it may regulate its own transcription. Conclusions: Class 2 UM’s harboring BAP1 mutations displayed distinct regional changes in DNA methylation compared to Class 1 UM’s. In these tumors, the most significantly hypermethylated regions occurred on chromosome 3 and in regions that were enriched for genes encoding neural crest guidance cue proteins that regulate homing, migration and invasion. These findings suggest that BAP1 mutations are associated with marked reorganization of the DNA methylome, providing new insights into the pathophysiology of UM.

**#4349 Adverse & anticancer activities of 5-azaCdr & DNA methyltransferase (DNMT) isoform specific inhibitors: therapeutic implications.** Cheishvili, Moshe Szyf, McGill, Montreal, Quebec, Canada.

Activation of methylated and silenced promoters of genes that suppress tumorigenesis has been the rationale behind the clinical use of DNMT family inhibitor 5aza for treating cancer. However, the adverse effects of general DNA methylation inhibition on tumors through activation of tumor promoting and prometastatic genes as well adverse effects on normal cells have limited the clinical development of DNMT inhibitors. Our data needs to be considered for further clinical development of DNMT inhibitors.

**#4350 Cell-origin differentiation stages define methylation-based subtypes of human colorectal cancer.** Felix Bormann, 1 Manuel Rodriguez-Paredes, 1 Yehudit Bergman, 2 Heinz G. Linhart, 3 Frank Lyko. 1 German Cancer Research Center, Heidelberg, Germany; 2 Institute for Medical Research Israel-Canada, Hebrew University Medical School, Jerusalem, Israel; 3 Asklepios Klinik Lindau, Lindau, Germany.

Introduction: Colorectal cancer accounts for a significant fraction of cancer-related mortalities, but has proven to be surprisingly refractory to consensus pathological and molecular subclassification. Similarly, little is known about the molecular profiles of colorectal cancer cells-of-origin. DNA methylation is an important epigenomic marker of cellular identity and can therefore be used to infer cancer cells-of-origin. Methods: Infinium 450k data from colorectal cancer samples provided by “The Cancer Genome Atlas” was applied to a consensus clustering algorithm. The identified epigenetic subtypes were tested for features including well established clinical parameters or subgroup specific gene expression. Additionally, the subgroups were compared with Infinum 450k data of non-malignant colorectal adenomas. Finally, clinical significance was addressed by testing for subgroup specific overall survival rates. Results: Analysis of the TCGA dataset defined 5 distinct epigenetic subtypes of human colorectal cancer. These subgroups showed an overlap to the microsatellite instability phenotype and the CpG island methylator phenotype. Gene expression analysis revealed that the subtypes also form a continuum of epigenetic program reflecting various intestinal crypt cell differentiation stages. Patient survival correlated with the differentiation stage, with a particular poor prognosis for patients with stem cell-related signatures. Interestingly, its prognostic potential outperformed a recently established gene expression-based classifier. Finally, non-malignant colorectal adenomas could be classified into the same epigenetic subtypes, suggesting their shared cell-types of origin with carcinomas. Conclusion: Our results establish a novel and clinically relevant approach for colorectal cancer classification and illustrate how differences in the cell-type of origin shape the tumor methylome.

**#4351 Effects of epigenetic agents on methylation of DNA in vitro and in vivo, as measured with stable isotopically labeled methionine.** Lawrence Anderson, 1 Eva Majerova, 2 Kimberly D. Hill, 3 John Carter, 2 Jessie Stottlemeyer, 2 Howard Stotler, 3 Melinda G. Hollingshead, 4 Jerry M. Collins, 4 NCI, Frederick, MD; 5 FNLCR Leidos Biomedical Research Inc., Frederick, MD.

Background: Modulation of cytidine methylation in DNA continues to be actively investigated as a target for chemotherapy. The primary source of methyl groups is methionine, via S-adenosyl-methionine (SAM) as the direct methyl donor. However, the primary source of methyl groups is methionine, via S-adenosyl-methionine (SAM) as the direct methyl donor.
donor for DNA methyltransferases, e.g., DNMT1. Methods were developed using stable isotypes and mass spec detection to examine the flux of the DNMT reaction and modification to this flux by cytidine analogs such as decitabine, an established hypomethylating agent, and 5-aza-4'-thio-2'-deoxy-cytidine (AzATdC), currently under development at NCI. Methods: For in vitro studies; A549, H460, HEL, LNCaP, and OVCA433 cells were grown in RPMI supplemented with 10% FBS were exposed to D3-methionine(20uM) and either decitabine or AzATdC (NSC775806) at 0 to 5uM in the media for 0 to 48hr. For in vivo studies; mice were maintained under standard ACUC protocols and practices. Tumors were grown SC in the flank area. Stable labeled methionine, decitabine and AzATdC were administered as oral bolus. At set times, mice were sacrificed and tumors, tissues and plasma samples collected. DNA was isolated and purified from cells and tissues using PureLink Genomic DNA kits (Invitrogen) according to manufacturer’s instructions. The purified DNA was digested to nucleosides for analysis. The isotopic enrichment in 5-methyl-deoxy-cytidine (mdc) was determined by analysis using HPLC coupled to a Qq mass spectrometer (Thermo Scientific). Results: D3-methionine was found to be an efficient precursor via SAM for the methylation of cytidine in DNA. Fortification of basal media (100uM methionine) with 20uM D3-methionine yielded D3-mdc enrichment of 5-15% in 24 hr, depending on cell line. All cell lines were found to have some enrichment. Treatment of cells with either decitabine or AzATdC caused a concentration dependent reduction of the enrichment for mdc in DNA. In mice, after an oral dose of D3-methionine, enrichment of methionine and SAM in plasma peaked within 1hr and fell to 5% of peak levels within 5hrs. Methionine and SAM enrichment in tissues followed similar time curves. At 50mg/kg of D3-methionine, no perturbation was observed for endogenous levels of either methionine or SAM. Enrichment of mdc in DNA was detectable in 1hr, maximal in 3hr, and remained constant for up to 48hr. When mice were treated with 1-2 mg/kg of either decitabine or AzATdC along with D3-methionine, the level of enrichment of mdc in DNA was reduced by 20-70% in tumors, bone marrow and intestine. Conclusions: Stable labeled methionine can be efficiently used to monitor the flux of methyl groups into mdc in DNA, both in vitro and in vivo. Changes in the flux of the methylation reaction can be used to assess the extent and time course for inhibition caused by cytidine analogs. These techniques may have relevance for improvement of doses and schedules to produce epigenetic modulation. Funded by NCI Contract No. HHSN261200800001E

#4352 Identification of ZFP42/REX1 as a regulator of cancer stemness in CD133+ liver cancer stem cells by genome-wide DNA methylation analysis
Steve Tin-Chi Luk,1 Man Tong,1 Kai Yu Ng,1 Kevin Yuk-Lap Yip,2 Xin Yuan Guan,1 Stephanie Ma,1 1The University of Hong Kong, Hong Kong; 2The Chinese University of Hong Kong, Hong Kong.

The cancer stem cell (CSC) subset is well established in hepatocellular carcinoma (HCC). This subset can be characterized by its CD133+ expression. Since the discovery of this marker, studies have revealed deregulated pathways and epigenetic alterations associated with this subset, but few have focused on changes in DNA methylation. This study aims to fill this research gap by discovering aberrant DNA methylation patterns governing CD133+ CSC-driven HCC. Results from Infinium HumanMethylation450 BeadChip (HuMet450 BeadChip) have led to the discovery of differential methylation patterns between CD133+ liver CSCs and matched CD133- differentiated samples. ZFP42/REX1 is one of the top-ranking differentially methylated candidates. Protocols corresponding to its promoter are extensively hypermethylated in the CD133+ samples. To explore the hypothesis that promoter DNA hypermethylatation modulates REX1 expression, REX1 mRNA levels were first validated to be down regulated in sorted CD133+ HCC cell lines (n=2) and HCC samples (n=46, p<0.05) by RT-qPCR. Upon 5-AZA treatment, only low REX1-expressing cells re-expressed REX1. By in silico prediction, a CpG island of interest derived transfection domain is transfected into cancer cells. This coincided with tumor suppressor function in cancer. We selected tumor suppressor gene SEMA3A as a regulator target for further investigation. As array data indicated, resveratrol led to reduction in methylation of SEMA3A promoter region. The 18% decrease in methylation of SEMA3A was confirmed by pyrosequencing in MCF10CA1a breast cancer cells. This coincided with 23% up-regulation of SEMA3A expression. In addition, analysis of the effects on DNA methyltransferases (DNMTs) demonstrated that resveratrol decreases expression of DNMT3. Furthermore, ChIP indicated decreased occupancy of DNMT3A on SEMA3A, active histone mark, H3K9ac, was significantly increased and repressive histone mark, H3K27me3, was significantly decreased after resveratrol treatment, indicating an open, more transcriptionally active chromatin state. These results demonstrate a role for polyphenol-mediated epigenetic modifications in reactivation of tumor suppressor genes in cancer cells and pave the way for further studies on the mechanism driving these changes. This study was supported by the PCCR, Indiana CTSI (UL1TR001108), Women’s Global Health Institute, and USDA National Institute of Food and Agriculture (Hatch project 1005656) granted to B5.

#4354 Methylation-mediated silenced PYCARD plays a key role in human prostate cancer.
Shinichi Fukushima, Toshiya Miyauchi, Tepppei Okubo, Koji Mitsuzuka, Yoichi Arai, Akira Horii, Tohoku Univ. Graduate School of Medicine, Sendai, Japan.

Epigenetic gene silence by aberrant DNA methylation leads to loss of key cellular pathways in tumorigenesis. In order to analyze effects of DNA methylation in prostate cancer, we constructed LNCaP-derived human prostate cancer cells that can induce global reactivation of hypermethylated genes by the methyl-CpG targeted transcriptional activation (MeTa) method. In MeTa, a cassette driven methyl-CpG binding domain (MBD) with NfKBe-2 transcriptional activation domain is transfected into cancer cells. Then 2 MBD2-derived methyl-CpG binding domain (MBD) with NfKBe-2 transcriptional activation domain is transfected into cancer cells. Then, in a cassettespecifically binds to the hypermethylated promoter regions, and NfKBe-2 transcriptional activation domain recruits p300/CREB-binding protein (CBP) and reactivates hypermethylated silenced genes. A cell proliferation assay indicated that MeTa suppressed the growth of LNCaP cells. Furthermore, both flow cytometry and TUNEL assays demonstrated that MeTa-induced apoptosis. In order to search genes responsible for apoptosis, we performed gene expression microarray analysis of MeTainduced and -repressed LNCaP cells. These genes encoding apoptosis-inducing factors upregulated two-fold or more in accordance with the induction of MeTa; PYCARD (PYD and CARD domain containing), TNFRSF25 (tumor necrosis factor receptor superfamily 25), HKR (harakiri, BCL2 interacting protein), BIK (BCL2 interacting killer), and CIDEA (cell death-inducing DFFA-like effector a). These genes also contained CpG islands (CGIs) within ± 1,000-bp of the
to matched, normal thyroid tissue. A similar trend was also observed in about 500 PTC samples in the TCGA database, compared with 60 normal thyroid samples. Methylation was explored as a cause for the down-regulation of the AR mRNA in disease pathogenesis, using in-silico methods such as Wanderer, a Maplab tool for TCGA RNA data visualization, and MethyPlotter. A methyl-
ylation-mediated silencing of PYCARD contributes to escape from apoptosis in human prostate cancer, and MeTA may provide important clues to analyze changes in cancer cell phenotypes by DNA methylation alterations.

#4357 ESRP1 overexpression and its role in ovarian cancer. Mi Jeong

#4358 The immunomodulatory anticancer agent RRx-001 induces a vac-

transcription start site. We focused on PYCARD and TNRFSE25 because these two genes upregulated 10-fold or more in accordance with the induction of MeTA. We found that both genes were hypermethylated and showed low expression levels in LNCaP prostate cancer cells, whereas only PYCARD was unmethylated in RWPE-1 normal prostate epithelial cells. We further analyzed primary subcutaneous tumor samples and found the AR gene was methylated in the expression of PYCARD in 53.8% (7/13; P < 0.01). These results suggest that methylation-mediated silencing of PYCARD contributes to escape from apoptosis in human prostate cancer, and MeTA may provide important clues to analyze changes in cancer cell phenotypes by DNA methylation alterations.

Prior candidate gene studies have shown that methylation-induced silencing of tumor suppressor genes in breast milk is related with history of breast biopsy, an established risk factor for breast cancer. To further establish the utility of breast milk as a tissue-specific biospecimen for investigations of carcinogenesis we measured genome-wide DNA methylation in breast milk from women with and without a diagnosis of breast cancer. Breast milk provides a source of cells without invasive procedure that is available during a window of increased breast cancer risk. Actively lactating women were enrolled and consented through the University of Massachusetts Amherst breast milk study targeting high risk subjects. Participants completed a questionnaire to provide demographic and breast cancer risk factor data. Genome-wide DNA methylation levels were quantified using the Illumina 450K HumanMethylation array. Data was processed in R using RnBeads. Beta-values were normalized (FUN-
norm), low quality probes were filtered and transformed to M-values. Linear mixed effects models were fit including a random effect for subject and adjusted for history of breast biopsy, age, body mass index, age of the baby, and estimated cell type proportions, an interaction term for time of diagnosis was included. DNA methylation in women with breast cancer (n=9), was compared with women without a history of breast cancer (n=22). Among women with a diagnosis of breast cancer there were two groups: those diagnosed within one year of donating breast milk, and those diagnosed more than one year before sample collection. Four women in the control and five women in the cancer group provided bilateral breast milk samples at recruitment and both samples were included in the analysis. CpGs with significant differential methylation were tested for enrichment in gene pathways using the KEGG database. We identified 215 differentially methylated CpG sites in women diagnosed within one year of sample donation compared with women without a diagnosis of breast cancer (Q<0.05). The top sites were in ATRE3 (an adaptively responsive gene linked to epithelial mesenchymal transition), and COL5A3 (an extracellular matrix gene related to metastasis potential). In addition, among women with a breast cancer diagnosis more than one year before sample donation we identified 8148 differentially methylated CpG sites compared with women without a breast cancer diagnosis (Q<0.05). Five sites were in OT05 (a calcium-sensing protein in cancer), high risk subgroups differentially methylated sites were significantly enriched in relevant pathways such metabolic (Q=3.12E-116), and cancer pathways (Q=2.08E-58), PI3K-Akt signaling pathway (Q=7.05E-40), and transcriptional regulation in cancer (Q=1.41E-29). Future studies are needed to validate our findings in independent subjects and to investigate the utility of breast milk as a biospecimen for understanding the molecular basis of disease risk and prospec-
tive risk assessment.

Methylation and expression of androgen receptor in Papillary Thy-
roid Cancer. Anvita Gupta,1 Tommy O’Connell,1 Melanie Jones,1 Karnika Singh,1 Monica Schwarz,1 JK Rasamny,1 Dorota Halicka,1 Jianguang Li,1 Codrin Iacob,1 Nina Suslina,1 Stimson Schantz,2 Edward Shin,1 Zbigniew Darzynkiewicz,2 Raj Tiwari,1 Jan Gielebien.1 1New York Medical College, Valhalla, NY; 2New York Eye and Ear Infirmary, New York, NY.

Papillary Thyroid Cancer (PTC) accounts for the vast majority of thyroid cancers and comprises more than 90% of neoplasms in the endocrine system. In the last 30 years, the incidence and prevalence of PTC has dramatically risen in developed countries, with a three-fold higher incidence in women than in men. With an overall five-year survival rate of 98.1%, early stage PTC has a favorable prognosis. However, PTC exhibits increased aggressiveness with poor prognosis in men diagnosed with the disease. These striking observations led us to explore the role of androgen and androgen receptor (AR) in this disease. We found an approximately 70% decrease in median AR RNA expression (p<0.0001) in 24 PTC patient tissue samples (from New York Eye and Ear Infirmary), compared

The immunomodulatory anticancer agent RRx-001 induces a vac-
cine-like interferon response through epigenetic induction of viral mimicry. Susan J. Knox. Stanford University School of Medicine, Stanford, CA.

RRx-001, sourced from the aerospace industry and currently in phase II clinical trials, is a novel anti-cancer agent that mediates immunomodulatory effects, either directly through polarization of tumor associated macrophages or indi-
rectly through vascular normalization and increased T-lymphocyte infiltration. With multiple additional mechanisms of action including upregulation of oxid-
ative stress, depletion of GSH and NADPH, anti-angiogenesis and epigenetic modulation, RRx-001 is being studied as a single chemotherapeutic agent to sensitize tumors to prior therapy and to prime tumors to respond to radiation, chemotherapy and immunotherapy in combination therapy studies. In this study, we identified another mechanism, viral mimicry, which refers to the ‘un-
veiling’ of epigenetically silenced viral genes that provoke an immune response and may contribute to the anti-cancer activity of RRx-001. Specifically, RRx-001 inhibited the growth of human colon cancer cells (HCT 116) and decreased levels of the DNA methyltransferases Dnmt1 and Dnmt3a in a time and dose-dependent manner. Treatment of HCT 116 cells with 0.5 μM RRx-001 for 24 hours significantly increased transcripts of inter-
feron (IFN) responsive genes and this induction was sustained for up to 4 weeks after transient exposure to RRx-001. ELISA assays showed that RRx-001 in-
creased secretion of type I and III IFNs by HCT 116 cells, and these IFNs were confirmed to be bioactive. Transcription of endogenous retroviruses was in-
duced by RRx-001 through demethylation of the promoter of endogenous ret-
roviruses as determined by methylation-specific polymerase chain reaction and combined bisulfite restriction analysis. Immunofluorescence staining with J2 antibody confirmed induction of double-stranded RNA. In conclusion, transient exposure of HCT 116 cells to low-dose RRX-001 induced transcription of silenced retroviral genes present in the cancer cell DNA with subsequent synthesis of this “pseudo-pathogenic” stimulus, mimicking an antiviral defense. RRX-001-mediated IFN induction may have the potential to improve the efficacy of immunotherapies as well as radiotherapy, standard chemotherapy and molecularly targeted agents when used in combination.

There is no doubt that testing for disease specific methylation changes can guide disease risk assessment, facilitate detection of the disease, support prognostication and personalization of treatment as well as guide post treatment patient care (1). Nevertheless, the use of methylation biomarkers in standard patient care is still marginal. Difficulties in implementation of methylation biomarker testing in standard in-vitro diagnostics are mainly attributed to challenges in establishment of the systematic approach allowing for efficient discovery and subsequent validation of clinical utility of potential disease specific methylation biomarkers. We have combined state-of-the-art genome wide methylation screening technologies (including: newest Illumina Methylation-EPIC 850K BeadChip) enabling methylation biomarker discovery with the cost and time efficient locus specific technologies to streamline the development, validation and implementation of methylation biomarkers for clinical disease management. With the use of technologies that in an affordable fashion enable screening for genome wide methylation changes in a substantial number of clinical samples, we were able to discover clinically relevant disease specific methylation signatures e.g. in CLL. The high technical complexity of the genome wide screen technologies prevents them for being straightforward applicable in diagnostic settings. Thus we used techniques such as Methylation-Sensitive High Resolution Melting (MS-HRM) (2) to develop assays fulfilling the requirements for diagnostic applications. Subsequently, we evaluated the clinical relevance of the most promising biomarker candidates in chronic lymphocytic leukemia, breast and lung cancers, using these assays (3, 4).

**#4360 Epigenetic alteration at HBV integrants is associated with methylation at-flanking human genome.** Yoshiyuki Yamamoto, Fumio Itoh, Hiroyuki Yamamoto, Fumio Itoh, St. Marianna Univ. School of Medicine, Kawasaki, Japan.

Integration of DNA viruses into the human genome plays an important role in various types of tumors, including hepatitis B virus (HBV)-related hepatocellular carcinoma. However, the molecular details and clinical impact of HBV integration on either human or HBV epigenomes are unknown. Here, we show that methylation of the integrated HBV DNA is related to the methylation status of the flanking human genome. We developed a next-generation sequencing-based method for structural methylation analysis of integrated viral genomes (denoted G-NaVI). This method is a novel approach that enables enrichment of viral fragments for sequencing using unique baits based on the sequence of the HBV genome. We detected integrated HBV sequences in the genome of the PLC/PRF/5 cell line and found variable levels of methylation within the integrated HBV genomes. Allele-specific methylation analysis revealed that the HBV genome often became significantly methylated when integrated into highly methylated host sites. After integration into unmethylated human genome regions such as promoters, however, the HBV DNA remains unmethylated and may eventually play an important role in tumorigenesis. The observed dynamic changes in DNA methylation of the host and viral genomes may functionally affect the biological behavior of HBV. These findings may impact public health given that millions of people worldwide are carriers of HBV. We also believe our assay will be a powerful tool to increase our understanding of the various types of DNA virus-associated tumorigenesis.

**#4361 An integrated genome-wide methylation analysis with gene expression in normal breast tissues identifies differentially methylated CpG loci associated with obesity.** Daniel Y. Weng, Min-Ae Song, Theodore M. Brasky, Catalin Marian, Renny S. Lan, Adana A. Llanos, Scott L. Spear, Bhaskar V. Kallakury, Jo L. Freudenheim, Peter G. Shields.

**#4363 Bisulfite DNA sequencing analyses to detect methylation patterns in the p73 gene promoter in prostate cancer cell lines.** Nicholas E. Bragance, L. Michael Carastro, Johannes J. Schabot, Jong Y. Park.

**Acknowledgement:** We thank National Cancer Institute for funding this study. Background: Non-small cell lung cancer (NSCLC) accounts for approximately 85% of all lung cancers. NSCLCs are mainly classified adenocarcinoma and squamous cell carcinoma. It seems more and more obvious that specific molecular analyses are necessary to elucidate the complexity of clinically relevant phenotypes which determine the lung carcinogenesis. This includes the role of microRNAs (miRNAs) in the disease, involved in the complexity of gene expression regulation. Different modulator mechanisms are involved in the biogenesis and function of miRNAs, one of them is DNA methylation. Alterations in these mechanisms may contribute to the tumor genesis and progression. The purpose of this study was to assess miRNA methylation patterns in patients with NSCLC to study the potential of coordinate regulation of miRNAs as a relevant mechanism involved in this pathogenesis. Materials and Methods: DNA methylation of gene clusters was analyzed by Illumina 70 subjects. The samples were divided into two cohorts. A first cohort constituted from 47 patients who had undergone surgical resection for clinical early stage NSCLC. A second group from 23 subjects was used as health cohort. DNA was extracted using the QIAamp DNA Mini Kit. For each assay, 500 ng of DNA was treated with sodium bisulfite using EZ DNA Methylation “Kit and cleaned with ZR-96 DNA Clean-up Kit”, before standard Illumina amplification, hybridization, and imaging steps. Methylation data were processed using the RnBeads R package. Results: We identified two clusters clearly correlated by methylation in lung cancer, involving 49 miRNAs differentially hypomethylated in tumor samples compared to control tissue. Some of these miRNAs have been implicated in several pathways in cancer. Conclusions: Our results strongly imply hypomethylation of two miRNA clusters, which represent key targets in unravelling of the mechanism of lung tumorigenesis.
rather reversible modifications, e.g., CpG methylation. The CpG islands in tumor suppressor gene promoters are often hypermethylated, thus down regulating their expression. The p73 gene is a member of the p53 tumor suppressor family of proteins, and like p53, has a bifurcated promoter. The p73 P1 promoter transcribes a full-length mRNA, which then translates into the truncated pro-apoptotic p73. The promoter is therefore a good candidate for demethylating agents. Methods. Hypermethylated DLD-1 human colorectal cancer cells were cultured for three days and treated daily with demethylating agents 5-azacytidine (AZA) or RRX-001 across a dose range (0.5 μM to 5 μM). Standard tests of population doubling (RPD) and cytotoxicity (trypan blue) were performed across the dose range for each compound. Treated cells were subjected to a 500 μm gel-insert scratch migration assay and video microscopy was used to record time-to-convergence (TC). Methylation specific PCR was performed on harvested cells across the dose range and compared to controls for eight genes associated with CIMP (SOCS1, MINT-1, hMLH, NEUROG1, THBD, HAND1, ADAMTS1, IGFBP3). Results. 5-azacytidine and RRX-001 both demonstrated >50% reduction in RPD at a dose of 2 μM, with a linear dose-dependent retardation of population growth from 0.1 μM to 1.0 μM. Trypan blue test also demonstrated linear increase in cytotoxicity for both agents up to 1 μM. Mean TC was 38.6hrs +/- 2.4hrs (1SD) for control, solvent control (DMSO), and 0.5μM AZA & RRX-001. Mean TC for 1.0μM and 2.0μM AZA was 52.0hrs +/- 3.75hrs, respectively (p<.0001). Mean TC for 1.0μM and 2.0μM RRX-001 was 57.0hrs +/- 2.0hrs and 96.0hrs +/- 5.0hrs, respectively (p<.0001). DLD-1 cells were treated with a concentration range of 0.5μM to 5μM of 5-azacytidine and RRX-001 and observed over 8 Cpg islands across the dose spectrum. hMLH, SOCS, and IGFBP3 were resistant to demethylation for both compounds at all doses. MINT, HAND, and THBD were partially demethylated by both agents, but ADAMTS1 was demethylated by AZA only. In each of the genes that demonstrated CpG island demethylation the demethylation was incomplete, with strong methylated bands present despite an additional demethylated band also being demonstrated. RRX-001 demonstrated a dose-dependent demethylation of NEUROG1 and THBD as integrated density of demethylated bands decreased against increasing dose of drug. Conclusions. This study demonstrates the demethylation ability of both agents against the methylene of 5 out of 8 genes associated with CIMP, which is a known to be associated with EMVI; an independent risk factor for poor prognosis in rectal cancers. The biological and demethylating effects occur at doses below those that may be considered cytotoxic, suggesting that demethylation itself is reducible the rate of cell division and migration of cancer cells. Further work is required to quantify the effects of both agents on the methylene of DLD-1 cells, and to explore the mechanisms of action of both compounds.

#4364 Establishment and validation of a breast cancer panel using targeted next generation bisulfite sequencing (INGBS). Matthew L. Poulton,1 Ryan Drennan,2 Andrew Miller,3 Andrew Miller,3 Ann Meyer,3 Garth H. Rauscher,7 Liying Yan1,2 EpigenDx, Inc., Hopkinson, MA;2University of Illinois at Chicago, Chicago, IL.

Aberrant DNA methylation (e.g., global reduction in DNA methylation and differential methylation of promoter regions) is a hallmark of cancer and may function in various ways to influence transcription. We developed a panel of bisulfite specific methylation sequencing assays in order to assess the methylation status of large number of genes using pyrosequencing. By combining these pyrosequencing assays into a targeted NextGen bisulfite sequencing panel, we can screen both a large number of genes and a large number of samples simultaneously. We first assembled the 40 pyrosequencing assays and sensitivity and reproducibility were analyzed on pilot DNA samples isolated from FFPE tissue. Assays were specifically designed to work in highly fragmented and cross-linked DNA from formalin-fixed, clinical samples. Initial pyrosequencing on the pilot samples showed that 24 of the 40 assays gave quality validation and sample results. Reasons that some assays were not successful may be due to the A/T or G/C content within the amplicon, PCR Bias, low amplification efficiency, or strong cross-linking from fixation within the assay to name a few. The initial 40 assays were next assembled in a combination of 7 multiplex PCRs in which gradient PCRs were performed and analyzed for optimal multiplex amplification using a bioanalyzer. Final assay multiplexing combinations were established and PCR bias testing was performed by INGSB on a sample set high of low methylated DNA mixed at different ratios. Assays with an R-square of less than 0.9 between the expected and generated methylation from this mixing were removed, leaving us with 21 validated assays in our panel (9 of 24 assays that were previously validated in pyrosequencing and 12 of 19 assays that could not be validated in pyrosequencing). In the present study we looked at DNA methylation changes in breast cancer development using paired adjacent normal and in situ tissue from a 30 patients with breast cancer as well as 11 various normal tissues other than breast, and 12 cell lines for a total of 83 samples in a panel of 21 genes. The results of the INBS were compared with the pyrosequencing results. This process of panel development, where small amounts of bisulfite treated DNA can be amplified in a target specific manner, prior to sequencing, makes investigating a large number of samples on a large panel of genes possible in a small amount of time. We observed a high correlation between the pyrosequencing and INGSB sequencing results, and we show that there is several genes that are either hypermethylated or hypomethylated in tumor tissue when compared to adjacent normal tissue.

#4365 Epigenetic and biological effects of 5-azacytidine and RRX-001 on DLD-1 colorectal cancer cell lines. Rory Kokeelaar, Huw Jones, John Beynon, Dean Harris, Gareth Jenkins. ABMU / Swansea University, Swansea, United Kingdom.

Introduction. Extramural vascular invasion (EMVI) in rectal tumours is an important risk factor for disease recurrence and death. Recent studies have demonstrated CpG island hypermethylation phenotype (CIMP) to be an independent risk factor for developing EMVI. This study investigates the cellular processes linking hypermethylation with EMVI by an in vitro model of rectal cancer, and assess the biological and epigenetic effects of known and putative demethylating agents. Methods. Hypermethylated DLD-1 human colorectal cancer cells were cultured for three days and treated daily with demethylating agents 5-azacytidine (AZA) or RRX-001 across a dose range (0.5 μM to 5 μM). Standard tests of population doubling (RPD) and cytotoxicity (trypan blue) were performed across the dose range for each compound. Treated cells were subjected to a 500 μm gel-insert scratch migration assay and video microscopy was used to record time-to-convergence (TC). Methylation specific PCR was performed on harvested cells across the dose range and compared to controls for eight genes associated with CIMP (SOCS1, MINT-1, hMLH, NEUROG1, THBD, HAND1, ADAMTS1, IGFBP3). Results. 5-azacytidine and RRX-001 both demonstrated >50% reduction in RPD at a dose of 2 μM, with a linear dose-dependent retardation of population growth from 0.1 μM to 1.0 μM. Trypan blue test also demonstrated linear increase in cytotoxicity for both agents up to 1 μM. Mean TC was 38.6hrs +/- 2.4hrs (1SD) for control, solvent control (DMSO), and 0.5μM AZA & RRX-001. Mean TC for 1.0μM and 2.0μM AZA was 52.0hrs +/- 3.75hrs, respectively (p<.0001). Mean TC for 1.0μM and 2.0μM RRX-001 was 57.0hrs +/- 2.0hrs and 96.0hrs +/- 5.0hrs, respectively (p<.0001). DLD-1 cells were treated with a concentration range of 0.5μM to 5μM of 5-azacytidine and RRX-001 and observed across the dose spectrum. hMLH, SOCS, and IGFBP3 were resistant to demethylation for both compounds at all doses. MINT, HAND, and THBD were partially demethylated by both agents, but ADAMTS1 was demethylated by AZA only. In each of the genes that demonstrated CpG island demethylation the demethylation was incomplete, with strong methylated bands present despite an additional demethylated band also being demonstrated. RRX-001 demonstrated a dose-dependent demethylation of NEUROG1 and THBD as integrated density of demethylated bands decreased against increasing dose of drug. Conclusions. This study demonstrates the demethylation ability of both agents against the methylene of 5 out of 8 genes associated with CIMP, which is a known to be associated with EMVI; an independent risk factor for poor prognosis in rectal cancers. The biological and demethylating effects occur at doses below those that may be considered cytotoxic, suggesting that demethylation itself is reducible the rate of cell division and migration of cancer cells. Further work is required to quantify the effects of both agents on the methylene of DLD-1 cells, and to explore the mechanisms of action of both compounds.
whereas positive correlation was observed in CHG and CHH1 context. mRNA and serum protein expressions of IFNγ, IL4, IL6, IL10, IL2, TNFα were not correlated with promoter methylation status of MGMT and RUNX3 genes. Smoking habit was associated with IFNγ, IL6 and TNFα for mRNA expression and IL2 for protein expression. Alcohol consumption was statistically associated with TNFα for mRNA expression and IL10 for protein expression. Betel nut consumption was significantly correlated with IL4 and IL6 for mRNA expression and IFNγ, IL4, IL6, TNFα were with protein expression. Tobacco consumption was correlated with only protein expression of IL2 and IL6. Smoked food consumption was statistically associated with IFNγ, IL4, TNFα for mRNA expression and IL6 and IL10 for protein expression. Conclusions: Promoter methylation of MGMT was correlated with mRNA expression but RUNX3 was not. Both RUNX3 and MGMT promoter methylation was not found to be associated with alteration of cytokine expression whereas they were associated with different life style factors in EC cases from North-East India.

**#4367** LOX expression, LINE 1 DNA methylation and prognosis in oesophageal cancer. Rebecca T. Kalikale, Yoshihumi Baba, Yuki Kitano, Kensuke Yamamura, Keisuke Miyake, Kenichi Nakamura, Hideo Baba. Kumamoto University, Kumamoto, Japan.

Background: In cancer cells, DNA methylation may be altered in two principle ways; global DNA hypomethylation and site-specific CpG island promoter hypermethylation. Since Long interspersed element-1 (LINE-1 or L1) constitutes a substantial portion (approximately 17%) of the human genome, the extent of LINE-1 methylation is regarded as a surrogate marker of global DNA methylation. In previous studies, we demonstrated that LINE-1 hypermethylation was strongly associated with a poor prognosis in oesophageal cancer, supporting its potential role as a prognostic marker. Lysyl oxidase (LOX) is an extracellular matrix remodelling enzyme and its upregulation has been associated with poor prognosis in various cancers since it has been reported to promote malignancy. We conducted this study to examine the correlations between LOX expression, LINE-1 methylation and the clinical pathological features in patients with oesophageal cancer. Methods: We examined LOX expression in 8 oesophageal cancer cell lines by quantitative reverse-transcriptase polymerase chain reaction (RT-PCR) and Western blotting. The expression levels of LOX in 150 oesophageal cancer tissues and adjacent normal mucosa was measured by RT-PCR and immunostaining. Results: Our Gene Expression Microarray revealed that LINE-1 hypomethylated oesophageal tumours presented higher expression level of LOX compared with LINE-1 hypermethylated tumours. Similar results were observed in the comprehensive analyses using public array data of oesophageal cancer cell lines. In cell lines, LOX mRNA was expressed at a high level in TE-6, TE-11, TE-14 and at a low level in TE-1, TE-4 and KYSE 30 and similar expression patterns for catalytically active LOX were observed in Western blot analysis. In immunohistochemical study, LOX was predominantly identified in the cytoplasm of oesophageal cancer cells. LOX expression was significantly associated with LINE-1 methylation levels (P < 0.034). LOX expression was significantly associated with invasion depth, tumour stage and venous invasion. Overall and cancer-specific survival rates of high LOX expression group were significantly lower than those of low LOX expression group (P = 0.012 and 0.008 respectively). In multivariate analysis high LOX protein expression was an independent prognostic factor in oesophageal cancer. Conclusions: The expression of LOX is up-regulated in oesophageal cancer cell lines and resected tumour specimens and its controlled epigenetically. Our findings suggest that LOX can serve as a useful prognostic biomarker in oesophageal cancer patients and might be potential therapeutic target.

**#4368** The clinicopathological significance of glutathione S-transferase P1 hypermethylation in breast cancer, a meta-analysis and literature review. Mingli Liu. Morehouse School of Medicine, Atlanta, GA.

Background: Glutathione S-transferase P1 (GSTP1) has been reported to function as a tumor suppressor gene in various types of human cancers including breast cancer (BC). However, the association and clinicopathological significance between GSTP1 hypermethylation and BC remains unclear. The purpose of this study is to conduct a meta-analysis and literature review to investigate clinicopathological significance of GSTP1 methylation in BC. Method: A detailed literature search was made in PubMed, EMBASE, Web of Science and Google Scholar databases. The data were extracted and assessed by two reviewers independently. Odds Ratios (OR) with 95% confidence corresponding intervals (CIs) were calculated. A total of twenty four relevant articles were available for meta-analysis. Results: The frequency of GSTP1 hypermethylation was significantly increased in BC than in benign breast disease, the pooled OR was 7.09, p < 0.00001. The rate of GSTP1 hypermethylation was significantly different between early stage I/II and later stage III/IV, OR was 2.05, p < 0.0001. In addition, the rate of GSTP1 hypermethylation was also significantly different regarding the node involvement status. The rate of GSTP1 hypermethylation in node positive BC was higher than that in node negative BC, OR was 1.77, p = 0.006. However, GSTP1 hypermethylation was not significantly associated with ER, PR and HER2 status. Conclusion: In summary, our meta-analysis indicated that the frequency of GSTP1 hypermethylation was higher in BC than in benign breast disease. The rate of GSTP1 hypermethylation in late stages of BC was higher than that in early stages. Our data suggested that GSTP1 hypermethylation could be a risk factor and a diagnostic biomarker of BC carcinogenesis. GSTP1 hypermethylation may have a role in the progression of BC. GSTP1 is a potential drug target for development of demethylation treatment for patients with BC.

**MOLECULAR AND CELLULAR BIOLOGY / GENETICS: Genomic Landscape of Head and Neck and GI Cancers**

**#4370** ASNS and other significant mutations in head and neck squamous cell carcinomas: mutational landscape in a South Asian population. Sadiq Rehmani,1 Sana Abdul Razzaq,2 Sarah Madhani,1 M Kamran Azim,2 Rashida Ahmed,3 Mumtaz Khan,3 Kusloom Ghias3. 1Mount Sinai St. Luke’s Hospital, Icahn School of Medicine at Mount Sinai, New York, NY; 2University of Karachi, Karachi, Pakistan; 3Aga Khan University, Karachi, Pakistan.

Head and neck cancers are the sixth most common cancer type globally and contributing significantly to the burden of disease in South Asia. Specifically in Pakistan, they are the most commonly diagnosed cancer in males and the second most common in females. The increasing burden of head and neck squamous cell carcinoma (HNSCC) in the region along with a unique set of risk factors merited a deeper investigation of the disease at the genomic level. Whole exome sequencing of HPV-negative HNSCC samples and matched normal genomic DNA (n = 7) was performed. Smoking, oral tobacco use and alcohol were identified as among the most commonly affected pathways in all the samples. This data is the first of its kind from the Pakistani population. The results of this study can guide a better mechanistic understanding of HNSCC in the population, ultimately contributing new, rational therapeutic targets for the treatment of the disease.

**#4371** Genomic characterization of oropharyngeal squamous cell carcinoma in Korean population. Jee soo Chae,1 Weon Seo Park,2 Dongwan Hong,2 Jong-II Kim,3 Yuh-Seog Jung3. 1Seoul National University, Seoul, Republic of Korea; 3National Cancer Center, Goyang, Republic of Korea.

Objective: Oropharyngeal squamous cell carcinoma (OPSCC) is a subtype of head and neck squamous cell carcinoma (HNSCC). Environmental risk factors such as tobacco, alcohol, and especially, human papillomavirus (HPV) are known to be associated with HNSCC. Also, large-scale sequencing studies identified several HNSCC-associated genes such as TP53, EGFR and PIK3CA. However, still the initiation and progression of OPSCC and mutational profiles of OPSCC in Korean population are unclear. Methods: Frozen tumor mucosa, tumor tissues and blood were collected from nine OPSCC patients; 6 HPV positive and 3 negative. Adjacent non-tumor tissues were obtained about 1 cm apart from the tumor tissue and were histologically confirmed as non-neoplastic. We then performed whole exome sequencing with Agilent SureSelect Human All Exon Kit v4+ UTR, yielding average on-target coverage of 100X. Results: First, we compared somatic alterations of adjacent non-tumor and tumor tissue to understand the genomic status of non-tumor mucosa. Comparison of genome-wide copy number alterations (CNA) between non-tumor and OPSCCs showed that majority of somatic CNA (SCNA) was occurred after tumor progression. Also, non-tumor mucosa rarely harbored genomic changes, showing average nonsilent mutations rate of 0.07 per Mb. In contrast, OPSCC showed 1.0 mutation per Mb with few shared mutations with non-tumor. These results indicate occurrence of new distinct subclones after tumor progression. Second, somatic mutations and CNA analysis of 9 OPSCC identified two distinct groups divided by the HPV status of tumor. HPV (+) tumors showed lower mutation burden than HPV(-) tumors (0.63 and 1.73 mutations per Mb, respectively). And TP53
and CDKN2A mutations were detected exclusively in HPV(-) group, accounting for 66.6% of HPV(-) tumors. Furthermore, HPV(-) tumors showed greater degree of chromosomal alterations compared to HPV(+) tumors. Conclusions: Although there are many studies to understand the relationships between pre-malignant and malignant tissue, there is a lack of understanding for genetic changes function on non-epithelial mucosa. Our data show that genomic picture of normal crypt mucosa rarely changes and tumor develops in distinct sub- clones. This would provide a glimpse into the fundamental cellular changes of non-tumor cells of tonsillar crypts and oral cavity. Also, we provide a mutational landscape in HNSCC of Korean population. Although our OPSCC showed recurrent mutations and copy number alterations of genes related to RTK/Pi3K- AKT/mTOR signaling pathways, similar as western, mutation burden in tumors was relatively lower, and somatic mutations on well-known HNSCC-associated genes such as PIK3CA, FAT1 and HRAS weren’t detected. Further investigation and molecular experiments are required to understand the mechanism of carcinogenesis and to discover early driver mutations of HNSCC.

#4374 Chromosome 3q22-29 amplification is linked to increased expression of multiple genes in key pathways deregulated in head and neck squamous cell cancers and cell lines. Hui Cheng,1 Xiping Yang,1 Han Si,1 Anthony Saleh,1 Jamie Coupar,1 Robert L. Ferris,1 Wendell G. Yarbrough,2 Mark E. Prince,3 Thomas E. Carey,4 Carter Van Waes,1 Zhong Chen1. National Institutes of Health, Bethesda, MD; 2University of Pittsburgh Cancer Institute, Pittsburgh, PA; 3Yale School of Medicine, New Haven, CT; 4University of Michigan, Ann Arbor, MI.

As part of the Cancer Genome Atlas (TCGA) Network, our comprehensive genomic analysis of 279 head and neck squamous cell carcinomas (HNSCCs) found frequent chromosomal copy number variation (CNV) and mutations of potential biologic and therapeutic importance. This underscored an urgent need to identify cell line models that harbor genomic alterations representative of HNSCC. We performed whole exome DNA and transcriptome RNA sequencing on 15 human papillomavirus HPV(-) and 11 HPV(+) HNSCC cell lines. HNSCC lines harbored chromosome gains (3q, 5p, 7q, 8q, 11q) and losses (3p, 5q, 8p, 18q), consistent with those found in HNSCC tumors by TCGA and previous karyotype studies. Integrative genome-wide analysis of CNV with gene expression uncovered over 1500 genes that display significant correlation between CNV and gene expression in both TCGA tumors and cell lines. Ingenuity Pathway Analysis revealed multiple genes that converge on key pathways and functions deregulated in HNSCC, including PI3K/AKT/mTOR, NF-kB, RAS/ MAPK, TP53, death receptor signaling, inflammation, and differentiation. Intriguingly, 103 genes displaying significant amplification and increased expression were predominantly located on chromosome 3q22-29. These genes encode components involved in the PI3K/AKT/mTOR, Hippo, TGF-beta and Wnt/beta-catenin pathways, cell cycle, translational and post-translational regulation, and mitochondrial biosynthesis. Fisher’s exact test and survival analysis showed significant co-occurrence and worse overall survival of 3q26.3 amplification and TP53 mutation in HNSCC patients from TCGA datasets; 3q26.3 encompasses 53 genes including PIK3CA, PLD1, AXL, CDK4 and SOX2. HNSCC cell lines also harbor common mutations found in TCGA, such as TP53, FAT1 and NOTCH1, and novel and rare tumor suppressor genes, such as MYH9. Our findings suggest that these cell lines could serve as models for mechanistic studies and pharmacologic screening, and investigation of genomic and expression alterations as potential biomarkers for precision diagnosis and prognosis of HNSCC.

#3179 Network analysis of karyotype study data identifies distinct genomic signatures of Barrett's esophageal adenocarcinoma (EAC). Dunfa Peng,1 Yan Guo,2 Heidi Chen,2 Jun Eul Hwang,2 Kyung Hee University, Seoul, Republic of Korea; 3Chonnam National University, Gwangju, Republic of Korea.

Purpose: Numerous studies have indicated that Sex-determining region Y-box 2 (SOX2) is involved in many squamous cell carcinomas. However, the role of SOX2 in head and neck squamous cell carcinoma (HNSCC) remains unclear. Therefore, we investigated whether activation of SOX2 is significantly associated with prognosis in HNSCC. Methods: Gene expression signature reflecting SOX2 activation was identified in HNSCC cohort, and patients were stratified into two groups according to this signature: SOX2-high group or SOX2-low group. Validation of the signature was sought in two independent patient groups. The association between the signature and prognosis of patients was assessed. Results: The SOX2-low group was associated with poor prognosis for HNSCC in three independent patient cohorts. In a multivariate analysis, the impact of SOX2 signature on overall survival (OS) was independent of other clinical variables [hazard ratio (HR), 1.45; 95% confidence interval (CI), 1.09 - 1.92; P=0.01]. In patients who received radiotherapy (RT), SOX2-low group had significantly poor OS than those in SOX2-high group. Conclusions: SOX2-low signature is associated with poor prognosis in patients with HNSCC and could be used to predict patients who would benefit from RT.

#4375 Complex interactions between genomic and epigenomic alterations in esophageal adenocarcinoma. Dunfa Peng,1 Yan Guo,2 Heidi Chen,2 Jun Eul Hwang,2 Kyung Hee University, Seoul, Republic of Korea; 3Chonnam National University, Gwangju, Republic of Korea.

Backround: The incidence of Barrett’s-related esophageal adenocarcinoma (EAC) is rapidly rising in the USA and the Western countries. However, the interaction between genomic and epigenomic alterations in regulating gene expression networks in EAC is poorly understood. Results and Discussion: We carried out an integrative analytical approach to identify DNA copy number, promoter DNA methylation and gene expression in a panel of esophageal adenocarcinomas, using chip-based technologies. Our analysis displayed significant differences between EAC and normal samples in DNA copy numbers, gene expression, and DNA methylation profiles. Our results identified remarkable incidence of DNA copy number (CN) alterations showing that 90% of probes had a copy number aberration (gain or loss) in at least one tumor, suggesting a vast chromosomal instability in EAC. Integrative analysis indicated that altered expression of 1755 genes was associated with changes in CN or methylation. We found that expression alterations in 84 genes (56 overexpressed and 28 down regulated) were associated with changes in both CN and methylation. These data suggest a strong interaction between genetic and epigenic events to modulate gene expression in EAC. Of note, we detected a prominent K-RAS signature in EAC. Network analysis predicted activation of several important transcription factor networks in EAC, including beta-catenin, MYB, TWIST1, SOX7, GATA3 and GATA6. 56 genes were overexpressed in EAC with simultaneous promoter
hypo-methylation and gene amplification, including CDH17 and GATA6. Not-
tably, several genes associated with inflammation such as COX2, IL8 and IL23R
were over-expressed and hypomethylated in EAC, a reaffirmation of the under-
lying inflammatory process in Barrett’s tumorigenesis and a suggestion of an
epigenetic regulation of these genes. Conclusions: In summary, our integrative
analysis suggests that epigenetic alterations in EAC demonstrates a complex
interaction between molecular mechanisms in EAC and provides several novel
insights for future studies.

#4376 Next-generation sequencing of gastric cancer samples from Rw-
da: a feasibility study. Mary D. Chamberlin, Francine B. De Abreu, Torrey L.
Gallagher. Geisel School of Medicine at Dartmouth, Lebanon, NH.
Background: Gastric cancer is associated with high morbidity and mortality
around the world. In developing countries, patients often present with advanced
disease creating a challenge for effective treatment. Next generation sequencing
is identifying mutations in more than 50% of gastric cancers in developed coun-
tries. Chronic infections and other geographic differences may lead to variations
in somatic mutations that could lead to different approaches to treatment. In this
pilot study we sought to determine if an overseas collaboration between the
University of Rwanda College of Medicine and Health Sciences and the Geisel
School of Medicine at Dartmouth was feasible and effective at determining mol-
ecular profiles of gastric cancer. Methods: Patients referred for endoscopy at
University Teaching Hospital of Kigali, Rwanda were consented to participate
prior to the procedure. Biopsy tissues were processed for routine pathologic
assessment. Those determined to be gastric adenocarcinoma were included. Formal-
alin-fixed paraffin embedded tissues, H&E stained slides and tissue blocks
were transported from Rwanda to New Hampshire, USA by visiting professors
participating in the Human Resources for Health Program between May 2015 and
July 2016. DNA and RNA from 39 samples were extracted using at least 7 FFPE
unstained slides according to AllPrep RNA/DNA FFPE Kit Protocol. Library
preparation was performed using 5 ng DNA using KilpaLLAMA MampSTM Lung and Colon Hot Spot Panel. Library quantification was per-
formed using Qubit, and samples with at least 4 nM were normalized, pooled
and sequenced on the v3 cartridge on the Illumina’s MiSeq system. For data
analysis, FASTq files were uploaded to Pillar Biosciences, where sequence align-
ment, annotation, and variant classification were performed. Results: Eighteen samples had insufficient tissue for nucleic acid extraction. Of the 39 samples
processed for sequencing, 17 had low library quantification due to low DNA
concentration or poor quality. Mutations were detected in 9/22 samples (41%).
One sample contained 3 mutations while the majority of mutated cases had 1-2
mutations identified. A total of 12 mutations were identified: TP53 (4), SMAD4 (2), ERBB4 (2) (S341L and D228N), PTEN (2) (K267RfsTer9 and C136Y), PRW7 (1) and KRAS (1). Conclusions: Overseas collaboration for next gen-
eration sequencing of gastric cancer samples is feasible. Quality control is a com-
mon challenge and may improve with larger sized biopsies or tissue blocks.
Frequency of mutations is lower than expected. ERBB4 mutations identified are
not known to be pathogenic. The PTEN mutations observed are considered
pathogenic and this may be a feasible target for therapy. A fusion panel and
amplification profiling may be more effective in identifying potential targets for
therapeutic trials. Limitations: Small sample size. Panel limited to mutations.

#4377 EBV associated gastric cancer in Korean. Woochan Lee. Seoul Na-
tional University, Seoul, Republic of Korea.
Gastric cancer was the third leading cause of death worldwide and most prev-
alent malignant cancer in Korea, comprising 20.8% of all cancers. The Cancer
Genome Atlas (TCGA) divided gastric cancer to four subgroups; EBV (Epstein-
Barr Virus infected, 9%), MSI (Microsatellite instability, 22%), GS (Genomically
stable, 20%), CIN (Chromosomal instability, 50%). We sequenced transcrip-
tomes of 11 gastric cancers associated with EBV infection (EBVaGC) tissues, 11
gastric cancers not associated with EBV infection (EBVnGC) tissues and 22
matched normal gastric mucosa for find unique features of Korean EBVaGC.
We compared RNA expression, EBV gene expression, germline mutations, and
somatic mutation between EBVaGC and EBVnGC. We found IKKBE gene, which
is taking an essential role in regulating antiviral signaling pathways, ex-
pressed higher on EBVaGC tumor than EBVnGC tumor (p-value = 1.73 x 10^-10).
While most EBV genes appeared to be similar, BMRF1,2 genes made distinct
patterns compared to previous TCGA report in expression of EBV which inte-
grated into human cells. The BMRF-2 gene is associated with cell-to-cell spread
of EBV, which is major infection mechanism of EBV. We found novel germline
mutations on PAPPC3, PGA3, and C4A,B in almost every samples, which are can-
didate for Korean specific mutations.

#4378 Gastric cancer organoid culture shows preserved genomic stability
in long-term passage. Sarah Siu Kuen Yue, Helen Hoi Ning Yan, Ho Cheong
Siu, Siu Lun Ho, Wai Yin Tsui, Desy Chan, Annie Shuk Yee Chan, Bernard Ch
Hang Lee, Anthony Kin Wang Chan, Suei Yi Leung. Department of Pathology,
The University of Hong Kong, Hong Kong.
In recent years, techniques, normal epithelial and tumor cells can be directly cultured from clinical specimens in vitro and expanded long-term with a very high success rate. Thus, this constitutes a good
platform for various mechanistic functional studies and clinical applications. A
previous karyotyping and gene expression profiling study has indicated that
organoid culture of normal epithelial cells can be propagated for long periods of
time without any genomic alterations. However, data on the genomic stability
of tumor organoids in long-term culture are not yet available. We have successfully
established organoid cultures derived from either primary tumor or lymph node
metastasis from 4 gastric cancer patients. For each sample, we performed long-
term culture for at least 6 months. DNA was extracted from blood, as well as the
early and late passes of these organoids, and submitted for whole-exome se-
quencing (WES), achieving a mean coverage approach across 90X. Somatic muta-
tions detected in early versus late passage gastric cancer organoids were com-
pared. Furthermore, we examined the organoids for copy number variations
based on the coverage and loss of heterozygosity (LOH) information derived
from exome sequencing. We detected between 80 to 228 somatic mutations in
the 4 early passage organoids, in which over 84-99% of them were retained
after 6 months of culture. We detected 18 new 31 and 38 new mutations in the 4
long-term organoids, respectively. The one case with a substantial large number
of new mutations (n=98) appeared to have emerged from a subclone of TP53
wild-type cells in a TP53 mutant tumor. Notably, the C=T mutation was the most
dominant mutation spectrum in this case, constituting 48%. Despite the
presence of frequent long segment LOH and chromosomal aberrations in early
passage organoids, indicating the presence of chromosomal instability, these
patterns of aberrations were stably maintained in long-term passage. Overall,
with the current organoid culture protocol, tumor genomes are mostly stably
maintained with the accumulation of only a small number of new mutations.
Our results indicate that this is a reliable and stable in vitro cell culture model
for various cancer-related and clinical studies.

#4379 Somatic exomic landscape of small intestinal adenocarcinomas.
Ulrika A. Hanninen,1 Riku Katainen,1 Jiri Hamberg,1 Jukka-Pekka Mecklin,2
Linda Forsström,1 Esa Pitkänen,1 Netta Mäkinen,1 Lauri A. Aaltonen3. Ge-
nome-Scale Biology Research Program, Research Programs Unit, University of
Helsinki & Department of Medical and Clinical Genetics, Medicum, University of
Helsinki, Finland, 2Department of Surgery and Education & Science, Jyväskylä
Central Hospital and University of Eastern Finland, Jyväskylä, Finland,
3Gastroenterology, Charles University Hospital, Prague, Czech Republic.
Small intestinal adenocarcinoma is a rare cancer with a high mortality rate. The
small intestine makes up less than 1% of the gastrointestinal tract, how-
never, small intestinal tumors constitute less than 5% of gastrointestinal tumors.
Of small intestinal tumors, around one third are aggressive adenocarcinomas
with poor outcome (5-year survival rate is approximately 30%). Reasons for
their rarity are still unclear. Predisposing factors include Crohn’s disease,eliac
disease, hereditary genetic syndromes such as familial adenomatous polyposis
(FAP) and hereditary nonpolyposis colorectal cancer (HNPCC), and dia-
tary factors. Due to the low incidence of small intestinal adenocarcinomas
(SIAs), the number of genetic studies remains insufficient. Since there are lim-
ited data available to guide the therapeutic decisions, our aim is to characterize
the somatic mutational landscape of SIAs in a population-based material using
exome sequencing. We collected information on all patients diagnosed with
SIA in Finland between the years 2006-2011 utilizing the Finnish Cancer Regis-
try. This registry maintains a nation-wide database on all cancer cases diagnosed
in Finland since 1953. From these we selected all cases with 1) confirmed small
intestinal primary tumor, 2) available tumor material, and 3) the tumor content of
at least 50%. In order to focus solely on small intestinal tumors, we excluded
tumors of the papillary region since they might also have arisen from the pan-
tes or the biliary tract. Altogether 107 tumors representing all three parts of the
small intestine were selected for exome sequencing. The tumor data was filtered
against the ExAC and SISU databases to remove germline variations. In addi-
tion, Sanger sequencing of the corresponding normal tissue will be used to verify
the somatic origin of the most interesting observed mutations. The data analysis
is ongoing. The average number of mutations in a tumor was 358 (range 40
- 1666). Preliminary findings show that 10-20% of those tumors representing all
three parts of the small intestine were selected for exome sequencing. The most
frequent mutations, map against the current organoid culture protocol, tumor genomes are mostly stably
maintained with the accumulation of only a small number of new mutations. Our results indicate that this is a reliable and stable in vitro cell culture model for various cancer-related and clinical studies.

#4380 Molecular and cellular biology / Genetics: Genomic landscape of head and neck and gi cancers

Proceedings of the American Association for Cancer Research • Volume 58 • April 2017 1119
MOLECULAR AND CELLULAR BIOLOGY / GENETICS: Genomic Landscape of Head and Neck and GI Cancers

between the discovered mutations and patients’ survival time. This comprehensive characterization of the molecular basis of SIAs will provide better insight on how these tumors arise and possibly how they should be treated.

We performed an integrated clinical and bioinformatic analysis of colorectal cancers (CRCs) genotyped at our institution from 4/2014–7/2016 to comprehensively characterize genomic alterations in metastatic CRC (mCRC). We analyzed 1008 samples (474 primaries, 534 metastases) from 985 mCRC patients and 128 early stage CRCs sequenced with MSK-IMPACT, a hybridization capture next generation sequencing assay. Metastatic CRCs were divided into 3 groups by mutation burden and MSiSensor algorithm score: microsatellite stable (MSS) (n=939; 95%), microsatellite-high (MS-H) (n=41; 4%), and ultra-mutated (n=5; 1%). Early stage CRC were enriched for MSI-H due to clinical selection and were 53% MSS, 44% MS-H, and 4% ultra-mutated. Ultra-mutated tumors exhibited >100 mutations and harbored hotspot mutations in POLE in 8 cases and a potential novel POLE alteration in 1 case. We evaluated the frequency of oncogenic alterations in MS-H and MSS mCRCs. The frequency of the resistance biomarkers KRAS and NRAS did not vary between MS-H and MSS mCRCs (46% vs 41%, p=0.6). Potentially actionable alterations were enriched in MSI-H tumors (78% vs 33%, p<0.001). Metastases did not have more actionable alterations than primary tumors. We classified clinically relevant targets using the OncoKB classification as level 2B (FDA-approved target in another disease type), 3A (target with compelling early clinical evidence in CRC), and 3B (target with compelling early clinical evidence in another disease type). Twelve percent (109/939) of MSS mCRCs had a level 2B target: BRAF V600E (5%), ERBB2 amplification (AMP) (4%), MET AMP (1%), BRCA1/BRCA2 alteration (1%), TSC1/TSC2 mutation (1%), EGFR mutation (<1%), RET fusion (<1%); there was significant enrichment of BRAF V600E (24%) and BRCA1/BRCA2 alterations (29%) in MSI-H versus MSS mCRC (p<0.001). NTRK fusions, the main 3A alteration identified, occurred in 7% of MSI-H and <1% MSS CRC (p<0.001). Level 3B alterations at ≥ 1% in MSS CRC included PIK3CA (15%), NRAS(3%), AKT1 (1%), MAP2K1 (1%), and ERBB2 (1%) mutations and FGFR1 AMP (2%). PIK3CA and PTCH1 mutations were both enriched in MSI-H versus MSS mCRC (32% vs 1%, p<0.01; 27%, v <1%, p<0.001, respectively). Analysis of mutation frequencies in 3 MSS CRC disease states - early stage resected primary (The Cancer Genome Atlas, TCGA), primary site of mCRC, and metastatic site - found significant depletion of IDH2 MT mutations in metastases. We also found significant and progressive enrichment of TP53 alterations (58% TCGA, 73% primaries of mCRC, 79% metastases) and BRAF mutations (4% TCGA, 9% primaries of mCRC, 10% metastases) in advanced disease, suggesting a role of these genes in aggressive disease. One third of the BRAF mutations in our cohorts were not V600 but known to be oncogenic. In this large cohort of mCRC subjects, significantly more patients harbored unique mutations in MSI-H and MSS CRC have a similar frequency of resistance biomarkers, MSI-H CRC more commonly harbor actionable alterations.

#4381 The mobile genome of colorectal cancer: Characterization of retrotransposon insertions in 202 colorectal cancer whole genomes. Tatiana Ca-juo, Paivi Sulo, Riku Katainen, Ulrika Hänninen, Tomas Tanskanen, Johanna Kondelin, Jiri Hamberg, Niko Välälä, Kimmo Palin, Outi Kilpiövaara, Esa Pitkänen, Lauri A. Aaltonen. Genome-Scale Biology Research Program, Research Programs Unit and Department of Medical and Clinical Genetics, Medicinum, University of Helsinki, Helsinki, Finland.

The aim of this study is to characterize the landscape of retrotransposon insertions in 202 colorectal cancer whole genomes. We performed an integrative analysis of colorectal cancer patients using next-generation sequencing approaches. We found that retrotransposon insertions can contribute to genomic variation, which may be associated with the development of colorectal cancer. Furthermore, these insertions may be associated with the resistance to chemotherapy and the risk of recurrence. Our study highlights the importance of integrating molecular and clinical data to better understand the biology of colorectal cancer.

#4382 Genomic events associated with metastasis of colorectal cancer by whole-genome sequencing. Yi Pan, Joanna Tong, Johnny Kwan, Kwok Wai Lo, Anthony Chan, Ka Fai To. Prince of Wales Hospital, The Chinese University of Hong Kong, Hong Kong, Hong Kong.

Background: The diversity of the genomic landscape in colorectal cancer (CRC) is understood to be due to the accumulation of mutations in primary tumors and metastatic spread of cancer cells to other organs. Genetic alterations in primary tumors may be different from those in metastatic tumors, suggesting a heterogeneity in the genetic landscape of CRC. The aim of this study was to investigate the genetic alterations associated with metastatic spread of CRC.

Methods: We performed whole-genome sequencing of 257 CRC patients, including 100 patients with primary tumors and 157 patients with metastatic tumors. We used a hybridization capture approach to enrich for exonic regions and performed sequencing on the Illumina HiSeq 2000 platform with 100 base-pairs paired-end reads. Each sample was sequenced to a minimum of 40x median coverage. To detect retrotransposon insertions we utilized TraFiC (Transposome Finder in Cancer). To identify retrotransposon-mediated translocations that were not identifiable using TraFiC, we utilized DELLY and the European database of L1-HS retrotransposon insertions in humans (euL1db).

Results: We identified a total of 5085 somatic insertions. 2% of these insertions were located in exons, whereas 45% were in introns. We identified several genes with recurrent insertions, some of these loci being known fragile sites. However, we identified 13 known cancer genes with two or more insertions. Furthermore, we identified two patients with insertions in exon 16 of APC, suggesting that these insertions could be initiating tumorigenic events. To conclude, we found retrotransposon insertions in the clinical setting and further suggest that these insertions could be contributing to metastasis of CRC.

#4383 Novel fusion transcripts in colorectal cancer patients revealed by next-generation RNA sequencing. Yury Choi,1 Chae Hwa Kwon,1 Hee Ji Park,2 Yeo-Jin Won,3 Do Youn Park.1,2 Pusan National University, Busan, Republic of Korea;3 Pusan National University Hospital, Busan, Republic of Korea.

Background: Colorectal cancer (CRC) is the second most common cancer in the world, with an estimated 9 million new cases and 1.7 million deaths. The genetic landscape of CRC is complex, with mutations in various genes leading to the development of CRC and its progression. The identification of novel fusion transcripts in CRC can provide new insights into the molecular mechanisms underlying CRC development and progression.

Methods: We performed next-generation RNA sequencing on 257 CRC patients, including 100 patients with primary tumors and 157 patients with metastatic tumors. We used a hybridization capture approach to enrich for exonic regions and performed sequencing on the Illumina HiSeq 2000 platform with 100 base-pairs paired-end reads. Each sample was sequenced to a minimum of 40x median coverage. To detect retrotransposon insertions we utilized TraFiC (Transposome Finder in Cancer). To identify retrotransposon-mediated translocations that were not identifiable using TraFiC, we utilized DELLY and the European database of L1-HS retrotransposon insertions in humans (euL1db).

Results: We identified a total of 5085 somatic insertions. 2% of these insertions were located in exons, whereas 45% were in introns. We identified several genes with recurrent insertions, some of these loci being known fragile sites. However, we identified 13 known cancer genes with two or more insertions. Furthermore, we identified two patients with insertions in exon 16 of APC, suggesting that these insertions could be initiating tumorigenic events. To conclude, we found retrotransposon insertions in the clinical setting and further suggest that these insertions could be contributing to metastasis of CRC.
quencing and were not found in another cohort. Overexpression of these fusion genes, except B4GALT1-BAG1, increased proliferation of CRC cells. In addition, overexpression of NAGLU-IKZF3 enhanced migration of CRC cells. These results reveal novel fusion transcripts and their tumorigenic effects in CRC. Ultimately, it could illuminate a genomic-driven strategy to develop personalized medicine. Key words: fusion transcript, colorectal cancer, RNA-seq.

#4384 Targeted sequencing reveals distinct and rare pathogenic variants in Caucasians with colorectal cancer. Pooneh Mokarram,1 Sudhir Varma,2 Hamed Azimi,3 Hasti Olumi,1 Ali reza Safarpour,1 Michael Nickerson,4 Hassan Brim,1 Hassan Ashktorab1, Shiraz University, Shiraz, Islamic Republic of Iran; 2Hihura, Washington, MD; 3Howard Univ., Washington, DC; 4NIH, Bethesda, MD.

PURPOSE: Next-generation sequencing (NGS) is currently used to establish mutational profiles in many multigene diseases such as colorectal cancer (CRC) which is on the rise in many parts of the developing world including in the Middle East. Little is known about its genetic hallmarks in these populations. AIM: To identify variants in 15 CRC-associated genes in patients of Iranian descent. METHODS: CRC specimens from 63 patients were used to establish the variants’ profile on an Ion Torrent platform by targeted exon sequencing. To rule out technical artifacts, the variants were validated in 13 of these samples using an Illumina NGS platform. Validated variants were annotated and compared to variants from publically available databases. An in-silico functional analysis was performed. MSI status of the analyzed samples was established. RESULTS: There were 51 validated variants distributed on 12 genes: 22% MSH3 (n = 11/51), 10% MSH6 (n = 5/51), 8% AMER1 (n = 4/51), 8% APC (n = 10/51), 2% BRAF (n = 1/51), 2% KRAS (n = 1/51), 12% PIK3CA (n = 6/51), 8% TGFBR2A (n = 4/51), 2% SMAD4 (n = 1/51), 4% SOX9 (n = 2/51), 6% TP53 (n = 3/51). Most known and distinct variants were in mismatch repair genes (MMR, 32%) and APC (20%). Among oncogenes, PIK3CA was the top target (12%). MSH3 variants were more frequent and predominantly homozogous in the analyzed population. CONCLUSION: These results illustrate for the first time CRC mutational profile in Iranian patients. MSH3, MSH6, APC and PIK3CA genes seem to play a bigger role in the path to cancer in this population. This is especially true for MSH3 variants that were very frequent and predominantly homozogous as these will associate with the EMAT phenotype that has prognostic implications. These findings will potentially lead to informed genetic diagnosis protocol and targeted therapeutic strategies.

#4385 Landscape of driver gene mutations in stage II and stage III colorectal cancer. Yoshikage Inoue,1 Nobuyuki Kikuchi,1 Kenichi Yoshida,1 Yusu Shiozawa,2 Yuichi Shiraishi,3 Kenichi Chiba,4 Keisuke Kataoka,4 Hiroko Ueno,1 Hiroko Tanaka,1 Satoshi Nagayama,2 Satoru Miyano,3 Yoshishiro Sakai,2 Seishi Ogawa1.

Introduction: Colorectal cancer (CRC) is the second leading cause of cancer death in Japan. The overall survival rate is approximately 85% and 70% for stage II and stage III CRCs, respectively, where over 45,000 deaths were ascribed to recurrence or metastasis. Survival benefit of adjuvant therapy is well defined only among stage III CRC patients, whereas that for stage II CRC patients remains modest, or according to recent reports, might be even deleterious among those with microsatellite instability (MSI). In an attempt to reveal the landscape of driver mutations in CRC and their association with clinical outcomes, we conducted targeted-capture sequencing of known driver mutations in stage II and III CRCs. Methods: A total of 248 patients with stage II (n = 145) and stage III (n = 103) CRC were enrolled. All patients were treated at a single institute between 2004 and 2016 and clinically well-annotated. Targeted-capture sequencing was performed using RNA baits designed for detection of oncogenic variants in 128 known driver genes in CRC. Additional baits for 1,605 SNPs, 7 introns and 18 microsatellites were also included to assess genome-wide copy numbers, fusion genes and MSI, respectively. Results: The median age at diagnosis was 64 (32-95) with a median observation period of 1,460 days. Of the 101 patients with recurrence, 59 and 42 patients had stage II and III diseases, respectively. Sixty percent of stage III patients received adjuvant chemotherapy, whereas only 10% of stage II patients received adjuvant chemotherapy. The average depth of the targeted-capture sequencing was 909x. In total, 2,243 somatic mutations (median 5 percent, range 0-106) were detected in 243 patients (97.9%). VTI1A-TCF7L2 translocation was identified in one sample. Except for a modest overrepresentation of TP53 mutations, frequency distribution of mutations was similar to those reported in previous reports, where APC (83%), TP53 (79%), KRAS (45%), and PIK3CA (18%) represented the most frequent mutational targets. Although none of these mutations were significantly associated with tumor recurrence or overall survival, we found that FBXW7 mutations had a positive correlation with tumor free survival. Twenty-one patients had more than 20 mutations, suggesting the presence of defects in DNA repair and/or replication. In fact, analysis of 18 microsatellites suggested that 22% of stage II MSI patients and 12% of stage III MSI patients had hypermutated cancer were explained by somatic mutations in POLE gene. Conclusions: We revealed the landscape of driver mutations in Japanese patients with stage II and III CRC with their implication in clinical outcomes. Hypermutated samples accounted for 8% of the whole cohort, which were explained by MSI or replication errors due to somatic POLE mutations. Our findings help to understand the relationships between driver mutations and recurrence for CRCs after curative resection.

#4386 Identification of clinically relevant colon cancer genes predictive of improved relapse free survival. Marie J. Parsons. The Walter and Eliza Hall Of Medical Research, Parkville, Australia.

Colorectal cancer (CRC) is the third most common cancer worldwide, affecting over 15,000 individuals in Australia each year. While CRC is often detected at a stage where resection of the primary tumour is possible, approximately 50% will relapse and die from metastatic disease. Prognostication is mainly determined by tumour depth (T), lymph node stage (N) and the extent of cancer spread (M). However, clinical outcomes of patients with the same TNM stage can be heterogeneous. Therefore, there is a need to identify markers to better predict prognosis and stratify patients for treatment regimes. A panel of 113 candidate CRC genes were identified as significantly mutated in whole genome and whole exome sequencing studies from 361 MSS colon cancers and 63 CRC cell lines. Custom ampiclon panels for target enrichment were designed for use with the HaloPlex™ target enrichment system. Sample libraries were prepared for 274 patients with stage II/III CRC using the automated Bravo liquid handling platform followed by next-generation sequencing (NGS) on the Illumina Next-Seq 500. Analysis of the 113 candidate genes identified 31 genes recurrently mutated above 10 percent in our discovery cohort. We identified 4 genes previously reported as colon cancer genes (APC 68%, TP53 60%, KRAS 30% and PIK3CA 20%), confirming APC, TP53 and KRAS as the most frequently mutated genes in CRC. To identify novel and clinically relevant genes, the 31 genes in our discovery cohort were tested for association with clinical features of CRC. In the discovery cohort, 24/31 genes were significantly associated with right sided CRC, 10/31 with mucinous CRC, 9/31 with stage II CRC and 7/31 with improved relapse free survival (RFS). Of these significantly associated genes, 10/24 genes were validated as significantly associated with right sided colon cancer, 3/9 with stage II and 3/10 with mucinous CRC in the validation cohort. Five of these genes were selected for further investigation as they were significantly associated with improved RFS, together with one or more clinical feature of CRC. Identification of novel recurrently mutated genes is key to a better understanding of the molecular mechanisms of CRC and development of novel therapeutics.

#4387 The clonal composition of colorectal cancer cell lines is defined by the maintenance of specific genomic imbalances, not by ongoing chromosomal instability. Darawalee Wangsa,1 Madison Schiefer,1 Daniel Bronder,1 Hesed Padilla-Nash,1 Irianna Torres,1 Lidia Warner,1 Yue Hu,1 E Michael Gertz,2 Russell Schwartz,2 Alejandro A. Schäffer,2 Daniela Hirsch,4 Timo Gaiser,2 Rüdiger Meyer,1 Jordi Camps,1 Kerstin Heselmeyer-Haddad,1 Thomas Ried1,3.

Keywords: fusion transcript, colorectal cancer, RNA-seq. Ultimately, it could illuminate a genomic-driven strategy to develop personalized medicine. Key words: fusion transcript, colorectal cancer, RNA-seq.
propagated in the single cell derived lines. These analyses were complemented by gene expression profiling of the single cell derived clones and the parental cell lines using the Nanostring technology which measures expression levels of 770 cancer-associated genes. The SW-480 clones separated into two distinct clusters that reflect discrete ploidy levels that were also present in the parental line. We then explored whether mutations of the BRAF (H1179Y) and KRAS (SW-480) genes observed in the parental lines were maintained in the derived clones; this was the case in all instances. Finally, we reconstructed phylogenetic trees of tumor evolution using a specifically developed algorithm, termed FISHTrees. Our meticulous analysis of the cloning distribution of these colorectal cancer models shows that, despite a certain degree of chromosomal instability, specific genomic imbalances are maintained.

The results of our investigation of genomically stable cell lines underline the importance of the gut microbiome and associated inflammation in predicting CRC progression. To date however, these insights have not led to significant changes in the treatment paradigm because efforts continue to be focused on the later stages of disease. We believe CRC presents a unique opportunity for disease intervention but to design effective interventional strategies, the exact sequence of molecular events underlying progression needs to be better defined and understood. To address these needs, we have assembled a clinically annotated sample database encompassing all stages of CRC (healthy colon, adjacent mucosa, adenomas, high-grade dysplasia, primary CRC and liver metastases), including samples from the conventional, microsatellite stable subtype, as well as from the serrated, microsatellite instable pathway. The progression status of each sample was characterized using standard pathology criteria. In addition, molecular progression was determined by targeted mutation profiling and targeted copy number profiling, as well as genome-wide expression profiling. This analysis confirms previous observations of early mutational events at the adenoma stage, including known tumor suppressor and oncogene driver mutations, e.g. KRAS G12 and G13 are mutated in 15% of the conventional adenomas but not in all colorectal cancers, as well as in 23% of the colorectal tumors. Copy number aberrations were observed at the adenoma and carcinoma stage, but with a lower prevalence then somatic mutations. Furthermore, genome wide expression analysis indicates that several pathways known to be affected in colorectal cancer are already disregulated at the adenoma stage. These pathways include Wnt signaling, mucosal barrier defects, biofilm formation, and several genes of the innate immune system, pointing at the interplay between local inflammation, the microbiome, and epithelial events. In addition, we observed that while genetic events are very dissimilar between the serrated/MSI and conventional/MSS pathway, the transcriptional regulation has many similarities, indicating at a possibility at targeting these disease subtypes using the same therapeutics. These initial findings provide rational avenues to intercept CRC at the adenoma stage and efforts are now focused on exploring the added role of the colonic microbiota and immune system modulation. A more comprehensive and integrated view of the changes associated with disease initiation will lead to the identification of new targets for prevention, interception and cure.

#4388 Characterisation of molecular events across the colorectal cancer progression axis. Joke Reumers,1 Liesbeth Van Wesenbeck,2 Eric Claeyssens,2 Gerald Chu,2 Stan Gaj,1 Emanuele Palescandolo,1 Carl Van Hove,1 Karin Verstraeten,1 Gary Borzillo,2 Dianna Wu,2 Pieter Poeters,2 Janine Arnts,1 Janssen R&D, Beere, Belgium;2Janssen R&D, Spring House, PA;3LabConnect LLC, Seattle, WA.

Uniquely amongst the major tumor types, the premalignant state in colorectal cancer (CRC) is readily detectable and diagnosable. Indeed, a multi-step process of CRC genesis was defined by the seminal work of Vogelstein et al, who described the mutational evolution of adenomas to adenocarcinomas. In addition to genetic aberrations, recent evidence has highlighted the importance of the gut microbiome and associated inflammation in predicting CRC progression. To date however, these insights have not led to significant changes in the treatment paradigm because efforts continue to be focused on the later stages of disease. We believe CRC presents an exceptional opportunity for disease intervention but to design effective interventional strategies, the exact sequence of molecular events underlying progression needs to be better defined and understood. To address these needs, we have assembled a clinically annotated sample database encompassing all stages of CRC (healthy colon, adjacent mucosa, adenomas, high-grade dysplasia, primary CRC and liver metastases), including samples from the conventional, microsatellite stable subtype, as well as from the serrated, microsatellite instable pathway. The progression status of each sample was characterized using standard pathology criteria. In addition, molecular progression was determined by targeted mutation profiling and targeted copy number profiling, as well as genome-wide expression profiling. This analysis confirms previous observations of early mutational events at the adenoma stage, including known tumor suppressor and oncogene driver mutations, e.g. KRAS G12 and G13 are mutated in 15% of the conventional adenomas but not in all colorectal cancers, as well as in 23% of the colorectal tumors. Copy number aberrations were observed at the adenoma and carcinoma stage, but with a lower prevalence then somatic mutations. Furthermore, genome wide expression analysis indicates that several pathways known to be affected in colorectal cancer are already disregulated at the adenoma stage. These pathways include Wnt signaling, mucosal barrier defects, biofilm formation, and several genes of the innate immune system, pointing at the interplay between local inflammation, the microbiome, and epithelial events. In addition, we observed that while genetic events are very dissimilar between the serrated/MSI and conventional/MSS pathway, the transcriptional regulation has many similarities, indicating at a possibility at targeting these disease subtypes using the same therapeutics. These initial findings provide rational avenues to intercept CRC at the adenoma stage and efforts are now focused on exploring the added role of the colonic microbiota and immune system modulation. A more comprehensive and integrated view of the changes associated with disease initiation will lead to the identification of new targets for prevention, interception and cure.

#4389 TSC1/2 mutations define a molecular subset of HCC with aggressive behavior and treatment implication. Daniel Wai Ho,1 Lo Kong Chan,1 Yung Tuen Chiu,1 Iris Ming Xu,1 Ronnie Poon,1 Tan To Cheung,2 Chung Ngai Tang,2 Victor Tang,2 Irene Lo,2 Polly Lam,2 Derek Yau,2 Miao Xin Li,2 Chun Ming Wong,2 Irene O. L. Ng,1 Univ. of Hong Kong, Pokfulam, Hong Kong;2Pamela Youde Hospital, Hong Kong;3Queen Elizabeth Hospital, Hong Kong.

We investigated the mutational landscape of mTOR signaling cascade in hepatocellular carcinomas (HCCs) with chronic hepatitis B (HBV) background, aiming to evaluate and delineate mutation-dependent mechanism of mTOR hyper-activation in hepatocarcinogenesis. We performed next-generation sequencing on human HCC samples and cell line panel. Systematic mutational screening of mTOR pathway-related genes was undertaken and mutant genes were evaluated based on their recurrence. Protein expressions of TSC1, TSC2 and pRPS6 were assessed by immunohistochemistry in human HCC samples. Rapamycin sensitivity was estimated by colony formation assay in HCC cell lines and the treatment was further tested using our patient derived tumor xenograft (PDTX) models. Results: We identified and confirmed multiple mTOR in HCC cohorts. We performed sequence variants of TSC1/2 in HCC samples from Asian populations. This analysis identified frequent (16.2%, n = 18/111) mutations of TSC1 and TSC2 genes in the HCC samples. The spectrum of TSC1/2 mutations likely disrupts the endogenous gene functions in suppressing the downstream mTOR activity through different mechanisms and leading to more aggressive tumor behavior. Mutation disruption of TSC1 and TSC2 was also observed in HCC cell lines and our PDX model of HCC. We found that the mTOR pathway was hyper-activated upon rapamycin treatment. With the use of the biologically relevant TSC2 mutant PDTXs, we demonstrated the therapeutic benefits of the hyper-sensitivity towards Rapamycin treatment. Taken together, our findings suggest the significance of previously undocumented mutation-dependent mTOR hyper-activation and frequent TSC1/2 mutations in HBV-associated HCCs. They define a specific molecular subset of HCC having genetic mTOR signaling, with potential significance of effective specific drug therapy.

#4390 The Thailand initiative in genomics and expression research in liver cancer: Race related common molecular subtypes among Asian hepatocellular carcinoma and cholangiocarcinoma identified by integrated genomics. Anuradha Budhul,1 Jittiporn Chaisaingmongkol,2 Hien Dang,1 Siritida Rabibhadana,2 Benjarath Pupacdi,2 So Mee Kwon,3 Marshonna Forgues,4 Yotsawat Pomyen,5 Vajarabhongsa Bhudhisawasdi,6 Nirush Lertprasertsuk,7 Chaisiri Pakskul,7 Chansuk Tangtrakul,7 Nirit Thawornsri,8 Thanaya Sricharunrun,8 Kannika Phornphutkul,9 Suleeporn Sangrajrang,9 Maggie Cam,10 Ping He,11 Stephen M. Hewitt,1 Xiaolin Wu,1 Snorri S. Thorgerisson,1 Joshua J. Waterfall,1 Yuelin J. Zhu,1 Jennifer Walling,1 Holly S. Stevenson,1 Daniel Edelman,1 Paul S. Meltzer,1 Christopher A. Loffredo,1 Robert H. Wiltrout,1 Curtis C. Harris,1 Chulahborn Mahidol,1 Mathiuos Ruchirawat,1 Xin W. Wang,1 National Institutes of Health, Bethesda, MD;2Chulabhorn Research Institute, Thailand;3Khoa Kao University, Khon Kaen University, Khon Kaen, Thailand;4Chulabhorn Hospital, Thailand;5Rajavip Hospital and Lampong Cancer Center, Thailand;6National Cancer Institute, Thailand;7FDA, Silver Spring, MD;8Georgetown University Medical Center, Washington, DC.

Hepatocellular carcinoma (HCC) and intrahepatic cholangiocarcinoma (ICC) are two distinct histologic liver cancers. They are clinically and biologically heterogeneous and highly resistant to treatment, making liver cancer the second most lethal malignancy in the world. In Thailand, liver cancer represents the primary cause of cancer-related death and is a major health problem. While HBV and HCV are major etiological factors for HCC globally, liver fluke infection (O. viverrini) is a major etiological factor for ICC in Thailand, especially in parts of northern Thailand where O. viverrini is endemic and approximately 70% of liver cancers are ICC. These unique risk factor patterns provide an opportunity to study cancer heterogeneity and unique liver tumor biology. The Thailand Initiative in Genomics and Expression Research for Liver Cancer (TIGER-LC) consortium was established to identify genomic and expression factors that may modify HCC and ICC susceptibility and progression. Here, we determined molecular subtypes and features of HCC and ICC through systems integration of genomic, transcriptional and metabolic profiles. We performed genome wide profiling of 398 surgical specimens derived from 199 Thai liver cancer patients. We employed the Affymetrix Human Transcriptome Array 2.0, the Affymetrix Genome-Wide Human SNP Array 6.0, Metabolon’s DiscoveryHD4 platform and Exome Sequencing to examine transcriptome profiles, somatic copy number alterations (SCNA), cancer metabolic profiles and mutation patterns, respectively. The results were validated in 847 independent Asian or Caucasian HCC or ICC cases. Transcriptomic analyses revealed that Thai HCC consisted of 3 stable subgroups (C1-C3), while Thai ICC contained 4 stable subgroups (C1-C4). Interestingly, HCC-C1 and ICC-C1 subtypes shared a similar gene expression matrix, as did HCC-C2 and ICC-C2, which correlated with patient survival. The molecular subtypes were similar in independent Asian HCC and ICC cohorts, but not in Caucasian patients, and were associated with tumor biology rather than etiology. GSEA revealed that the C1 subtype is enriched for mitotic checkpoint anomalies, while the C2 subtype is related to cytokine and chemokine signaling. We found that the C1 subtype encompassed a higher degree of SCNA when compared to the C2 subtype, suggesting an association with a genomic instability phenotype. Further analysis showed that the C2 subtype is linked to an increased body mass index, inflammatory responses and unique tumor metabolic activities. HCC and ICC from Asian populations, while clinically treated as separate entities, share common subtypes with similar actionable targets which can be targeted to improve precision therapy.
Expression of constitutively activated mutant FOXOs induced by PMPCB knockdown-mediated ROS productions suppressed gene expression in the liver cancer cell is regulated still remain to be delineated. In this study, we identified candidate genes critical for the maintenance of EpCAM positive hepatocellular carcinoma (HCC) cells using a global RNAi screening method. HCC cells were infected with pools of ~200,000 lentiviral shRNA library, then they were sorted to EpCAM positive or negative group. The abundance of shRNA in each group was analyzed using a microarray hybridization method. As a result, 76 candidate shRNAs with significantly different expression between EpCAM positive and negative populations were identified by class comparison analysis. Unsupervised clustering analysis of these genes in 247 HCC samples clearly separated EpCAM positive HCC cases from negative cases. Furthermore, we found that the EpCAM-dependent gene signature can predict survival in epithelial-like HCC cases. We focused on shRNA for PMPCB gene, which has an important role for processing mitochondrial protein, since it ranks as the top differentially altered shRNA-targeted gene between EpCAM positive and negative cells. PMPCB shRNA efficiently reduced EpCAM positive population and effectively inhibited cell proliferation both in vitro and in vivo. Interestingly, PMPCB shRNA specifically induced cell death in EpCAM positive HCC cells, but not in EpCAM negative cells. These data suggest that EpCAM positive cells functionally depend on PMPCB expression. On the other hand, we confirmed that PMPCB shRNA induced physiological dysfunction of mitochondrial function, leading to the increase of reactive oxygen species (ROS) production. We found that PMPCB shRNA significantly reduced TCF4 activity as well as the expression level of c-myc and cyclin D1, which are the downstream molecules of Wnt/β-catenin pathway. Although total β-catenin levels in the cytosol and nuclei fractions were not affected by PMPCB knockdown, overexpression of constitutively activated mutant β-catenin partially rescued the cells from PMPCB-induced apoptosis. Forkhead box O (FOXO) is known to be induced by the ROS production, bind β-catenin and decrease TCF activity, leading to the induction of apoptosis. We found that the nuclear translocation of FOXO family members, such as FOXO1 and FOXO3, were facilitated by PMPCB shRNA in EpCAM positive cells. These results suggest that the activation of FOXO's induced by PMPCB knockdown-mediated ROS production suppressed the activity of Wnt/β-catenin pathway, leading to the death of EpCAM positive HCC cells. In conclusion, we discovered a novel candidate target molecule of EpCAM positive HCC cells using a genome-wide RNAi screening method. Our study shed light on the mechanisms how EpCAM positive HCC cells are maintained and identified a new target molecule that has therapeutic vulnerability in EpCAM positive HCC cells.

#4392 Genetic diagnosis of multiple hepatocellular carcinoma. Yutaka Midorikawa,1 Shigo Yamamoto,1 Kenji Tatsuno,1 Hiroki Ueda,2 Shingo Tsuchi,3 Genta Nagae,3 Tadatoshi Takayama,1 Hiroyuki Aburatani2.

Multiple hepatocellular carcinoma (HCC) is categorized into two types; multicentric hepatocarcinogenesis (MC) and intrahepatic metastasis (IM). Although discrimination of the types of multiple HCC is of clinical importance, it is quite difficult to determine it correctly even after histological diagnosis. In order to determine multiple HCC as MC or IM, we compared pairs of multiple HCC samples from 40 patients with multiple HCC and 2 patients with pairs of primary HCC and extrahepatic metastasis such as adrenal gland and lung metastasis with regard to molecular aberrations. Exome sequence showed that more than 7% of somatic mutations were common in the pairs of IM, which were consistent with the result of a pair of primary HCC and extrahepatic metastasis, while no common somatic mutations was detected in genomic-MC (gMC) pairs. Notably, more than 60% of clinically monochromatic-MC cases were diagnosed as genomic-IM (gIM) due to the concordance of mutation and shows significantly frequent tumor thrombus, suggesting that gIM pairs developed from the common ancestor. In addition, cell-free DNA was analyzed using exome sequence in five patients with recurrent HCC, and found that somatic mutations of cell free DNA were similar to the primary HCC only in gIM not in gMC cases. Taken together, comparison of mutations in a pair of HCCs makes it possible to classify multiple HCCs into MC and IM, which is difficult to be correctly determined in clinical practice. Furthermore liquid biopsy for mutation analysis is available to make treatment plans for multiple HCC patients.

In introduction: Liver cancer is the second cause of cancer-related mortality worldwide. Currently, there are only two systemic agents able to increase survival in patients at advanced stages (i.e. sorafenib and regorafenib). Median survival of these patients is still poor, which highlights the need for new therapies. Our aim is to identify key regulatory genes with oncogenic properties amenable for therapeutic intervention through 1) integration of gene expression and DNA methylation data from human liver cancer by 2) functional validation in mice using shRNA screens. Methods: DNA methylation (Illumina HM450) and mRNA expression (Affymetrix human genome U219) data of 215 human HCC samples (Villanueva, Hepatology 2015) were analyzed to identify key gene regulatory networks. A causality test interrogated the impact of cis and trans regulation of promoter methylation on gene expression (Yoo, PLoS Genet 2015). A key regulator gene was defined when it regulated a substantial number of downstream genes (more than 2 standard deviations from the mean predicted trans-regulated downstream genes). Data analysis includes differential gene expression, topological overlap clustering (hierarchical, non-negative factorization [NMF]), and gene annotation. The tumorigenic potential of candidate tumor suppressors was experimentally validated through a positive selection of shRNA screening in human immortalized liver cell line H9252. Furthermore, we found that the EpCAM-dependent gene signature can predict survival in epithelial-like HCC cases. We focused on shRNA for PMPCB gene, which is a key regulator in the liver cancer cell is regulated still remain to be delineated. In this study, we identified candidate genes critical for the maintenance of EpCAM positive hepatocellular carcinoma (HCC) cells using a global RNAi screening method. HCC cells were infected with pools of ~200,000 lentiviral shRNA library, then they were sorted to EpCAM positive or negative group. The abundance of shRNA in each group was analyzed using a microarray hybridization method. As a result, 76 candidate shRNAs with significantly different expression between EpCAM positive and negative populations were identified by class comparison analysis. Unsupervised clustering analysis of these genes in 247 HCC samples clearly separated EpCAM positive HCC cases from negative cases. Furthermore, we found that the EpCAM-dependent gene signature can predict survival in epithelial-like HCC cases. We focused on shRNA for PMPCB gene, which is an important role for processing mitochondrial protein, since it ranks as the top differentially altered shRNA-targeted gene between EpCAM positive and negative cells. PMPCB shRNA efficiently reduced EpCAM positive population and effectively inhibited cell proliferation both in vitro and in vivo. Interestingly, PMPCB shRNA specifically induced cell death in EpCAM positive HCC cells, but not in EpCAM negative cells. These data suggest that EpCAM positive cells functionally depend on PMPCB expression. On the other hand, we confirmed that PMPCB shRNA induced physiological dysfunction of mitochondrial function, leading to the increase of reactive oxygen species (ROS) production. Our study shed light on the mechanisms how EpCAM positive HCC cells are maintained and identified a new target molecule that has therapeutic vulnerability in EpCAM positive HCC cells.
#4395 Somatic genomic alteration of 412 cancer-targeted genes of periampullary and pancreatic ductal adenocarcinoma in Indian patient population. Nilabja Sikdar,1 Gourab Saha,1 Richa Singh,1 Dhira Archinda,2 Paromita Roy,2 Supriyo Ghatak,2 Sudeep Banerjee,2 Sumit Gulati,2 Shibayoti Ghosh1,3
1Indian Statistical Institute, Kolkata, India; 2Calcutta Medical College, Kolkata, India; 3Tata Institute of Fundamental Research, Mumbai, India.

Introduction: Pancreatic Ductal Adenocarcinoma (PDAC), the most common primary malignant disease of the pancreas and the periampullary region, accounts for about 75% of all nonendocrine tumors arising in this region. It is 1st most lethal malignancies. The 5 year survival rate is below 5%. At the beginning of the 21st century, the estimated number of PC worldwide was 110,000, with an estimated global mortality rate of 98%. Incidence of periampullary adenocarcinoma (PACs) is low, approximately 0.5-2% of all gastrointestinal malignancies and 20% of all tumors of the extrahepatic biliary tree. Aims & Objectives: To identify the somatic single nucleotide variants (SNVs) in 412 cancer related genes in PDAC & PAC’s. To identify possible altered biological pathways enriched in these cancers. Methodology: DNA samples from Tissue and blood were sequenced for exom sequencing of 412 cancer related genes (NMIBLNGE panel, Custom). Raw fastq files processed using GATK tools and variants identified by Varscan2, & MuTect. Altered pathways identified by KEEG. Result: A total 105 somatic exonic Single Nucleotide Variants (SNVs), 9 somatic exonic Indels, 22 LOH mutations (both Indel and SNV’s) were identified in our sample set. Among the candidate genes of PDAC somatic SNV’s were found in TP53, SMAD4 in some patient whereas frequency of KRAS mutation was less frequent. Fourteen SNV’s were reported in cosmic database which includes 5 pathogenic variants, whereas 91 SNV’s were novel. A total 75 non-synonymous, 6 stopgain, and 24 synonymous SNV’s were observed among 105 SNV’s. Fifty eight percent of transversion and 52% of transition observed from all SNVs. Among all transversion fifty five percent SNV’s were C>T, G>T. PI3-Akt, Proteoglycans in cancer, Transcription misregulation, Rap1, ErbB, Neurotrophin pathways were found to be most commonly enriched in our patient population. Our data strongly suggest PI3-Akt, Proteoglycans in cancer pathways play a critical role in the disease. Conclusion: This study implicates a landscape of somatic SNV’s in PDAC’s and PAC’s and alteration of biological pathways in our patient population. We also observed EBBB2 and KMT2C genes are predominantly altered in PDAC’s and PAC’s. PI53, KRAS and SMAD4 are the known mutated genes counterparts which contribute very similar mutation pattern.

#4396 Multiclonics assessment of the cancer and stromal compartments of patient-derived pancreatic xenografts reveals clinically-relevant subtypes and novel targeted therapies. Remy Nicolle,1 Yuna Blum,2 Laetitia Marisa,3 Celine Loncle,4 Odile Gayet,5 Vincent Moutardier,5 Olivier Turriu,6 Marc Giovannini,7 Benjamin Blanc,8 Martin Bigonnet,2 Marion Rubis,2 Nabila Elarouci,1 Jean-Luc Raoul,4 Veronique Secq,3 Stephane Garcia,3 Philippe Grandval,5 Martin Bigonnet,2 Marion Rubis,2 Nabila Elarouci,1 Jean-Luc Raoul,4 Veronique Secq,3 Stephane Garcia,3 Philippe Grandval,5 Martin Bigonnet,2 Marion Rubis,2 Nabila Elarouci,1 Jean-Luc Raoul,4 Veronique Secq,3 Stephane Garcia,3 Philippe Grandval,5

#4397 Deciphering the diversity of somatic alterations and Salmonella infection in gallbladder cancer by whole exome sequencing. Prajash Sundaram Iyer,1 Nilesh laxman Gardi,1 Malika Ranjan,1 Bikram Sahoo,1 Pratik Chandran,1 Pawan Upadhyay,2 Mukta R. Ramadwar,2 Shailesh V. Shirkhande,2 Amit Dutt1,3
1ACTREC, Mumbai, India; 2Tata membrane Centre, Mumbai, India.

Background: Gallbladder cancer is fifth most common cancers among the gastrointestinal cancers with the majority of patients presented at an advanced state of the disease. In India, gallbladder cancer is a major problem in the northern part of the country with its highest incidence of 22/1,00,000 women and risk factors ranging from gallstones, female gender, ethnicity. Salmonella infections and genetic alterations. Despite its high incidence in our country, there is only few candidate gene based studies and systematic genomic-wide studies are far in dismal. Hence there is an unmet need to understand the genomic landscape of Indian Gallbladder cancer genome. Materials and methods: We interrogated the cancer regions of gallbladder cancer genome of 27 samples (10 paired and 7 unpaired tumors) using whole exome sequencing at an average coverage of 100X and above. Further, we validated our findings from whole exome sequencing in an extended cohort of 27 FFPE (Formalin fixed paraffin embedded) samples using other sequencing technologies. In addition we used a computational subtraction tool to identify Salmonella DNA sequences in the whole exome sequencing data. Results: We identified 383 somatic alterations across 17 tumors, which includes an average 112 synonymous, 245 missense, 8 nonsense, 8 indels and 8 splice site changes. The average mutation rate considering the paired tumors is about 14 mutations/Mb. We found recurrent alterations in TP53, CTNNB1, SF3B1, ATM, AKAP11 and other genes by exome sequencing analysis. In addition, we examined our exome sequencing data for identifying Salmonella sequences as well as presence of 143 HPV types using computational subtraction based on HPVDetector. In our analysis we found association of typhoidal Salmonella strains in 11 of 26 gall bladder cancer samples and non-typhoidal Salmonella species in 12 of 26 sample, 6 samples were co-infected with both. Moreover, we observed co-occurrence of TP53 alterations in 4 of 16 Salmonella positive samples while we did not observe TP53 alterations in Salmonella negative samples. Conclusion: Taken together, we present the landscape of somatic alterations in Indian gallbladder cancer genome and identification of non-typhoidal Salmonella species along with co-occurrence of TP53 alterations could aid in the treatment of gallbladder cancer.

#4398 Identification of bile duct cancer specific fusion genes in patient tissues. Kahee Kim,1 Dawoon Esther Jung,2 Mi-kyoung Seo,2 Sang-Woo Kim,3 Si Young Song3
1ACTREC, Mumbai, India; 2Tata membrane Centre, Mumbai, India; 3Yonsei University College of Medicine, Seoul, Republic of Korea; 4Yonsei University College of Medicine, Seoul, Republic of Korea.

Gene fusion occurs when a part of one gene fuses with or attaches to a part of another gene by genome rearrangement and the result in gene fusion may possess oncogenic properties; fused gene may be translated into a unique protein that may promotes cancer properties. Bile duct cancer are one of the most lethal cancer types with low 5-year survival rates, but lack of proper diagnostic or prognostic markers. Our aim was to investigate bile duct cancer specific fusion genes found in patient’s specimens. We extracted total RNA from five bile duct cancer tissues and normal tissues from the same patients. We performed RNA sequencing and the result data was analyzed using ChimeraScan, Jaffa or Fusionchacker softwares to detect gene fusion. To identify the cancer somatic fusion gene, the fusion occurred in normal tissues and previously reported fusion genes found in normal tissues were excluded and the fusion occurred in coding region was included. As a result, we found 52 bile duct cancer tissue specific fusion genes. We analyzed the expression of selected fusion genes in 30 bile duct cancer patients and cancer cell lines by qRT-PCR. As a result we observed two novel bile duct cancer specific fusion genes. We cloned one of the fusion genes and transfected into the bile duct cancer cell lines SNU-1196 to assess, and increase in cell motility was observed in vitro. These findings indicate the presence of novel fusion genes as well as its possible application for the early diagnosis or prognosis of bile duct cancer.
MOLECULAR AND CELLULAR BIOLOGY / GENETICS: Metabolic Regulation and Cancer Therapy 1

#4399 MUC13 induced NF-κB activation regulates metabolic reprogramming by promoting its crosstalk with GLUT-1 receptor. Sonam Kumari,1 Sheema Khan,2 Subash C. Gupta,3 Vivek K. Kashyap,4 Murali M. Yallapu,5 Subhas C. Chauhan,1 Meena Jaggi,1 *Univ. of Tennessee Health Science Center, Memphis, TN, 2Banaras Hindu University, Varanasi, India.

Objective: Pancreatic cancer (PanCa) is the fourth most common cause of cancer-related deaths in the US. MUC13, mucin is aberrantly expressed in PanCa and promotes tumor growth and progression. Herein, we investigate the fundamental role of MUC13 in glucose metabolism and delineate the molecular interplay of various molecules governing MUC13 mediated metabolic reprogramming that may be involved in pancreatic tumor maintenance. Methods: MUC13 expressing (Panc-1) and knockdown PanCa cells (HPAF-II) were generated for the study. Immunoblotting and qRT-PCR assays were performed to assess the expression of protein and mRNA levels, respectively, of key signaling molecules involved in glucose metabolism of PanCa. MUC13 and Glut-1 interaction was studied using co-immunoprecipitation, immunofluorescence, proximity ligation, Western blotting, co-capping assays in cell lines. Lactate and glucose assays were performed using commercially available kits. In vitro functional assays using wound healing scratch assay (migration), and cell Matrigel assay (invasion) were performed in presence or absence of Lactate and 2DG supplementation. Results: Our results demonstrate that MUC13 expression leads to the TNF-induced activation/nuclear translocation of NF-κB which in turn upregulates additional key proteins, Glut-1, c-Myc, Bcl-2. This recruits the Glut-1 to MUC13, wherein MUC13 functionally interacts with Glut-1 and stabilizes it, initiating downstream events that result in altered glucose metabolism. MUC13 expression in PanCa cells increases glucose uptake, lactate secretion which is reduced upon MUC13 knockdown. Additionally, MUC13 mediates increased cell migratory and invasion potential which can be potentiated by supplementing the culture media with lactate, an end product of aerobic glycolysis. However, treatment of cells with NF-κB inhibitor, Sulfasalazine, inhibits the MUC13 and Glut-1 interaction and abrogates all these events associated with glucose metabolism. Conclusion: These outcomes from our study suggest that MUC13 plays an important role in metabolic reprogramming of PanCa cells metabolism to induce cancer growth and enhanced cellular invasion and motility. NF-κB acts downstream of MUC13 to coordinate the events leading to its interaction with Glut-1 and metabolic reprogramming. Overall, these findings illustrate mechanism by which MUC13 coordinates the shift in metabolism to sustain cancer growth and invasion in PanCa.

#4400 Targeting lactate dehydrogenase-A promotes docetaxel induced cytotoxicity predominantly in castration-resistant prostate cancer cells. Hiroiyo Muramatsu,1 Makoto Sumitomo,1 Shingo Morinaga,1 Hiroshi Sakai,1 Ikuo Kobayashi,1 Keishi Kajikawa,2 Geyna Nishikawa,3 Yoshiru Kato,1 Masahito Watanabe,1 Kent Kanao,1 Koenja Nakamura,2 Kauzihiro Yoshikawa.1

Introduction & objectives: It is well known as Warburg effect that anaerobic glycolytic pathway is activated in various type of advanced cancers including prostate cancer (PC). Lactate dehydrogenase-A (LDH-A) controls the conversion of pyruvate to lactate and plays an important role in glucose metabolism. Since LDH-A pathways have been implicated in chemoresistance in various cancers, we investigated whether inhibition of LDH-A pathway could mediate the sensitivity to docetaxel (DOC) in human PC cells. Materials and Method: Four PC cell lines (PC3, DU145, LnCaP, LN-SS) were used. LN-SS is one of the LnCaP-derived castration-resistant PC (CRPC) cell lines established in our laboratories. Sodium oxamate (SO) was used as a specific LDH-A inhibitor. The protein expression was detected by western blot analysis using specific antibodies. Cell growth and survival were evaluated by WST-1 assays. Cell cycle progression and apoptotic inducibility were evaluated by flow cytometry using propidium iodide and Annexin V. The cytotoxicity of SO/DOC combination on PC cells was evaluated using the Chou-Talalay combination index (CI) method which offers quantitative definition for additive effect (CI = 1), synergistic (CI < 1), and antagonism (CI > 1) in drug combinations. Result: Western blot analysis showed that LDH-A protein was highly expressed in LN-SS cells compared with other PC cell lines including the parental LnCaP. WST-1 assays showed that treatment with SO (50 mM) for 72 hours increased growth inhibition (PC3: ~30%, DU145: ~55%, LnCaP: ~20%, LN-SS: ~55%), while SO has little growth inhibitory effects on normal lymphocytes in the concentrations between 1-100 mM. IC50 to DOC in PC cells were showed to be 4 nM, 1 nM, 1 nM and 4.5 mM in PC3, DU145, LnCaP and LN-SS, respectively, suggesting that both PC3 and LN-SS were relatively resistant to DOC compared with DU145 and LnCaP. Synergistic cytotoxicity was observed after the combination therapy with DOC and SO in LN-SS (CI: 0.5) but not in PC3 (CI: 1.9), DU145 (CI: 2.0), or LnCaP (CI: 6.5). Cell cycle analyses revealed that the combination with DOC and SO for 72 hours resulted in the accumulation of cells in G2-M phase followed by sub-G1 accumulation in LN-SS cells. Annexin V assays showed that 43% apoptosis was induced by the combination therapy in LN-SS cells, while only 12% by DOC only in LN-SS cells. Conclusion: Our results strongly suggest that LDH-A plays an important role in DOC resistance in advanced PC cells and inhibition of LDH-A promotes DOC-sensitivity especially in CRPC cells. Our study may provide valuable information for the future development of targeted therapies in patients with CRPC.

#4401 Role of estrogen signaling in colon microenvironment during obesity. Amena Archer,1 Linnea Petterson,2 Marcela Gonzalez-Granillo,3 Chris-tina Sava,2 Marion Korach-Andre,2 Cecilia Williams,2 KTH SciLifeLab, Stockholm, Sweden; 2Karolinska Institutet, Stockholm, Sweden.

Recent epidemiological studies highlight the strong association between high body mass index (BMI) and enhanced risk of colon cancer. This association appears stronger in men than in women, indicating a possible protective role of estrogens in this context. The biological action of the estrogens is mediated by specific transcription factors, the estrogen receptors (ERs). ERβ is the main ER in the intestine; and it is expressed in both epithelial cells and immune cells. Anti-tumorigenic and anti-inflammatory effects of ERβ in colon associated neoplasia have been demonstrated. Several rodent models for obesity show an impaired intestinal epithelial barrier function and an increase of pro-inflammatory markers in the colon. Moreover, in murine colitis models, high fat diet (HFD) exacerbates colonic inflammation. However, the specific molecular mechanisms linking obesity to increased colon cancer development, where estrogen signaling may be involved, is not clear. We hypothesize that ERβ-selective agonists can oppose the HFD-mediated inflammatory pro-tumorigenic colonic signaling in a gender-specific manner during obesity, and thereby protect against colorectal cancer. Our study is focused on the initiation of colon inflammation during obesity and aims to investigate the impact of ERβ activation in this context. To address this question, male and female mice were fed a HFD for 6 weeks and treated with an ERβ-selective agonist for 3 weeks prior sacrifice. Stool pellets were regularly collected. Animals were sacrificed; colon samples and caecal contents were collected for further analysis. We show that the expression pattern of inflammatory genes in colon is modified by the ERβ-selective agonist in HFD fed mice. Moreover the ERβ-selective agonist appears to induce gender-specific changes of the microbiota of HFD-fed mice. Our results show that an ERβ-selective agonist can modulate the colon microenvironment during obesity in mice and will provide a better comprehension of the molecular mechanisms leading to obesity-associated colonic inflammation.

#4402 CHTM1, a novel protein linked to cellular metabolism and human malignancy. Mansi Babbar,1 Ying Huang,5 Saeed Sheikh. SUNY Upstate Medical University, Syracuse, NY.

Several lines of emerging evidence indicate that alterations in metabolism are linked to pathogenesis of human malignancies. However, more studies are needed to completely understand the link between tumorigenesis and metabolism. In this context, we have characterized a novel protein named CHTM1 (Coliled-coil Helix Tumor and Metabolism 1) that appears to be associated with cancer and cellular metabolism. Per our findings, CHTM1 was present in cytosal as well as mitochondria. CHTM1 knockdown in human cancer cell lines caused oxidative stress, and decrease in cellular oxygen consumption and mitochondrial ATP levels, suggesting mitochondrial dysfunction. In view of the importance of mitochondria to nutrient stress, the effect of CHTM1 deficiency on human cancer cells in glucose-deprived conditions was also analyzed. The results indicated that CHTM1-deficient cells became more sensitive to glucose deprivation and exhibited altered cellular metabolism involving down regulation of PKC-CREB-PGC1 alpha signaling events. CHTM1 expression was also found to be increased in patient samples representing breast, colon and lung cancers when compared to their respective matching normal tissues. Based on these findings, we propose CHTM1 to be a novel tumor marker that can also be developed as a target for novel therapeutics particularly those that exploit cellular metabolism to mediate their effects.

#4403 EDG uptake in human lung adenocarcinoma associated with invasion through the hexosamine biosynthesis pathway. WeiRong Zhang,1 Gina Bouchard,2 Alice Yu,1 Majid Shafiq,1 Mehran Jamali,1 Joseph Shrager,1 Kelsey Ayers,1 Viswam S. Nair,1 Andrew Gentes,2 Maximilian Diehn,1 Andrew Quon,2 Sandy Napel,3 Sylvia Plevritis,3 Stanford University, Stanford, CA; 4UCLA, Los Angeles, CA.

MOLECULAR AND CELLULAR BIOLOGY / GENETICS: Metabolic Regulation and Cancer Therapy 1

Proceedings of the American Association for Cancer Research • Volume 58 • April 2017

1125
Introduction: Metabolic reprogramming is a cancer hallmark that is not fully understood. Moreover, increasing evidence suggests that metabolic dysregulation is histology-specific, particularly in the case of non-small cell lung cancer (NSCLC). In this study, we investigated the differences in glucose metabolism between the two major histology subtypes of NSCLC, namely adenocarcinoma (AD) and squamous cell carcinoma (SQ). We performed transcriptomic association with FDG-PET SUV
\textsubscript{max} (maximum standardized uptake value), a common clinical marker of glucose uptake in cancer. Methods: We identified metabolically-associated differentially expressed genes (DEGs) by histology subtypes using RNAseq data from selected tumors in our study cohort of 127 NSCLC patients (96 AD and 31 SQ) and validated the DEGs on The Cancer Genome Atlas. We identified gene-enriched cellular processes correlated with SUV
\textsubscript{max} separately for AD and SQ. We validated our findings in public domain cell line microarray data. In a separate cohort of 40 NSCLC patients (20 patients overlap with study cohort) whose tumors were sorted by cell type (cancer, endothelial, fibroblast and immune cells), we identified specific cell types where the genes of interest were expressed. Results: Metabolically-associated DEGs in AD were enriched in the hexosamine biosynthesis pathway (HBP), which is involved in glycosylating proteins related to invasion. SUV
\textsubscript{max} correlated genes in AD were enriched for epithelial-mesenchymal transition (EMT) and extracellular matrix remodeling. In particular, GPT2 (the rate-limiting gene in HBP) and 4-EMT-related glycoprotein genes were highly correlated with SUV
\textsubscript{max}, suggesting potency of HBP for EMT related glucose metabolic reprogramming. We validated DEGs on cell line microarray data (GSE49644) before and after TGF-\beta induced EMT, showing that many genes in HBP increased after induced EMT, while genes in the glycolysis pathway and the pentose phosphate pathway (PPP) were unchanged or reduced. HBP genes and many SUV
\textsubscript{max} correlated EMT genes were most highly expressed in tumor-associated fibroblasts compared to other cells in the tumor microenvironment. In SQ, metabolically-associated DEGs were enriched in the glycolysis pathway and PPP. SUV
\textsubscript{max} correlated genes were enriched for cell death. Conclusion: An integrative analysis of PET-RNAseq showed that in AD glucose uptake was related to invasion through metabolic reprogramming of HBP. In SQ, glucose uptake was associated with glycolysis and higher proliferation potential. Our work confirms that metabolic dysregulation in NSCLC is histology-specific and extends the finding to identify cellular processes associated with FDG uptake that differ in histology as well. Understanding histology-specific differences of tumor metabolism provides new insights into tumor behavior that can have implications for anti-cancer therapy.

Novel approach to circumvent cisplatin resistant lung cancer by targeting metabolism. Medhi Wangsaipichit, 1 Chunjing Wu, 2 Ying Ying Li, 3 Lynn G. Feun, 2 Macus T. Kuo, 1 Niramol Savaraj. 1 Univ. of Miami/VAMedical Cir., Miami, FL; 2VA Medical Cir., Miami, FL; 3University of Miami, Miami, FL; MD Anderson Cancer Ctr., Houston, TX.

For the past three decades, there are no drugs which could reverse cisplatin resistant or selectively kill these resistant cells. We have discovered that cisplatin resistant (CR) lung cancer shares one common factor which is increase in reactive oxygen species (ROS). Decreased intracellular thioredoxin-1 (TRX1) due to excessive secretion was found in vitro and in vivo, as well as in patients’ serum which could be a primary contributory factor to higher mitochondria-Ros levels. Furthermore, CR cells possess significantly increased number of mitochondria and consume higher rates of oxygen. Key glycolytic enzymes (HKII and LDHA) and lactate production were decreased in CR cells which suggests rewiring of tumor metabolic pathways. NAD\textsuperscript{+}, crucial co-factor of all redox systems, is significantly reduced in all CR cells. Importantly, treatment with riluzole (the FDA approved drug that interferes with cystine/glutamate exchange) thoroughly negativates the increase in ROS levels (wt)) resulted in completely disappeared in wild type mice and were significant reduced in KRAS mutant mice (n=5 per treatment group; p<0.002). Repurpose of riluzole should be considered for future treatment of CR lung cancer patients. Supported by Department of Veterans Affairs, CDA2 award (1K28BX001289) and Woman Cancer Association Fund.

Pancreatic cancer is a deadly disease with only 6% of patients living more than 5 years. Even if the disease is diagnosed when it is localized, the 5-year survival rate is approximately 19%. A characteristic of cancer cell metabolism is a shift from oxidative phosphorylation to aerobic glycolysis known as the Warburg effect. It is well known that calorie restriction (CR) is a powerful intervention that suppresses tumorgenesis in animal models by targeting glycolysis and oncogenic signaling pathways. Recent studies have shown that the metabolic responses characteristic of CR can be obtained with the use of energy restriction mimetics (ERM). The purpose of this study is to evaluate a new ERM, OSU-CG5 in altering growth of pancreatic cancer cells and nutrient-sensitive signaling pathways. Pancreatic tissues including those of the pancreas have uncontrolled proliferation necessitating increased fuel demands by increasing glucose availability and altering metabolic signaling pathways. Since ERM have been reported to target glucose transport, we evaluated whether OSU–CG5 alters glucose transport (Glut) proteins and glucose uptake. Glut1, but not Glut2, 3, 4, and 6, were overexpressed in Panc-1 cells with a 6-fold higher expression compared to HPNE cells. Glut proteins were not altered in MiaPaca cells. OSU-CG5 did not alter Glut1 protein expression in either cell line. Silencing Glut1 also had no effect on the cytotoxicity of OSU-CG5. OSU-CG5 did not alter glucose uptake when measured in different concentrations of glucose in the media. Cell survival, as measured with Pico green, was decreased after OSU-CG5 treatment with an IC \textsubscript{50} of 3\textsuperscript{um} when cultured in physiological concentration of 5 and 10mM of glucose. FOXM1 is unregulated in pancreatic cancer and a promoter of the Warburg effect. We found that OSU–CG5 significantly decreased expression of FOXM1 in Panc1 and MiaPaca cells. Our findings indicate that OSU-CG5 does not inhibit the growth of Panc1 and MiaPaca pancreatic cancer cells by decreasing glucose uptake but may target the FOXM1 signaling pathways.
expression and lipid synthesis in lung cancer. These results also revealed that negative regulation of ALCY and lipid synthesis is a novel and critical mechanism for CUL3 in tumor suppression.

Purpose: Cancer cells exhibit altered glucose metabolism, termed glycolysis which is described by the increased uptake of glucose and the conversion of glucose to lactate in cancer cells under adequate oxygen tension. Alternating glucose transporters (GLUTs) expression was detected in the cancer specific metabolism to adapt to the rapid growth and tumor microenvironment in diverse malignant tumors. In this study, GLUTs profiling of ESCC patients, the relation between proliferation and GLUT1 expression using siRNA for GLUT1 were analyzed. Furthermore, the prognostic features according to GLUT1 expression was evaluated on esophageal squamous cell carcinoma (ESCC) patients. Methods: The ratio of the 11 GLUTs (GLUT1- GLUT14) expression between tumor and normal tissue (T/N) were analyzed in silico (GDS3838). GLUT1 expression was down-regulated using 3 siRNAs in vitro. Immunohistochemical staining of GLUT1 was performed using paraffin sections of tissues obtained from 145 resectable ESCC patients without preoperative treatment. Results: Expression of GLUT1 (T/N 2.44; 95% confidence interval (CI): 1.78-3.34, P = 0.001) and GLUT3 (T/N 1.96; 95%CI: 1.23-3.13, P = 0.01) and GLUT6 (T/N 1.31; 95%CI: 1.12-1.54, P = 0.01) were significantly higher in ESCC tissues than normal tissues. In vitro, TE-1 and TE-8 cells were treated with 3 siRNAs for GLUT1 and control siRNA for 72 hours in vitro. The proliferation of TE-1 and TE-8 cells after siRNAs for GLUT1 compared with control siRNA decreased 72.9-84.5% and 44.8-53.3%, respectively. GLUT1 expression was evaluated with 145 ESCC patients. GLUT1 positivity was observed in 41 patients (28.2%) and associated with depth of invasion (odds ratio (OR) =2.984; 95% CI: 1.208-7.371; P = 0.018) and vascular invasion (OR =2.771; 95% CI: 1.118-6.871; P = 0.028) in multivariate analysis. GLUT1 positivity was a significant disadvantage to both relapse-free survival (hazard ratio (HR) =2.021; 95% CI: 1.100-3.712; P = 0.023) and esophageal cancer-specific survival (HR =2.223; 95% CI: 1.121-4.411; P = 0.022) in univariate Cox hazard analysis. Conclusions: GLUT1 expression was altered in ESCC patients and GLUT1 expression was most up-regulated among the 11 GLUTs. Growth assay with siRNAs for GLUT1 revealed that GLUT1 played a curial role of ESCC cells proliferation. High expression of GLUT1 was associated with depth of invasion and poor prognosis of ESCC patients. These findings provide evidence of the significance of GLUT1 expression as a biomarker and GLUT1 may be therapeutic target in ESCC patient.

### 4408 Metabolic alterations induced by ibrutinib in CLL cells as a basis for drug combinations to enhance ibrutinib therapeutic activity. Helene Pelicano, Li Feng, William G. Wierda, Michael J. Keating, Peng Huang. UT MD Anderson Cancer Ctr., Houston, TX.

The use of ibrutinib, which targets the Bruton tyrosine kinase, has signified improved the therapeutic outcome for patients with chronic lymphocytic leukemia (CLL), especially in cases with chromosome 17p deletion, which usually results in poor responses to conventional chemotherapy. However, CLL is highly resistant to current therapeutic options, and this resistance is incompletely curative, and a small portion of CLL patients exhibit resistance. The main objectives of this study were to investigate the effect of ibrutinib on CLL mitochondrial metabolism and to develop novel strategies to enhance the therapeutic activity of ibrutinib. Ibrutinib-induced changes in mitochondrial functions were analyzed by measuring oxygen consumption rate (OCR) as an indicator of mitochondrial respiration and extracellular acidification rate (ECAR) as a parameter of lactate production from glycolysis using an extracellular flux analyzer. In a primary CLL cell-stromal cell co-culture system (which maintains long-term CLL cell viability), ibrutinib induced little change in OCR and ECAR during the first 48-72 h. However, prolonged drug exposure (up to 7 days) in vitro caused a consistent and significant decrease in OCR compared to that in untreated cells, and in untreated cells ibrutinib treated in tumor tissue was prepared with normal tissue. Treatment with ibrutinib for 7 days also had significantly decreased OCR compared to pre-treatment samples from the same patients, suggesting that the impact of ibrutinib on mitochondrial functions occurred in vivo and was clinically relevant. On western blot analysis, ibrutinib induced decreases in expression of certain respiratory chain components associated with AMPK activation. On electron microscopy, CLL cells treated with ibrutinib in vitro for 6 days exhibited lower numbers of mitochondria than untreated cells, which was confirmed by flow cytometry analysis of cells stained with Mitotracker Green. Functional analysis showed that ibrutinib caused CLL cells to take up less glutamine but did not affect glucose uptake, suggesting that ibrutinib has a preferential impact on glutamine metabolism. On testing the possibility that the metabolic alterations and mitochondrial dysfunction induced by ibrutinib render CLL cells vulnerable to compounds that affect mitochondria or inhibit glutamine metabolism, we found that combinations of ibrutinib with metformin (inhibitor of mitochondrial OXPHOS) or with C968 (glutaminase inhibitor) resulted in synergistic activity against CLL cells and in vivo murine leukemia cells in comparison to either drug alone. Notably, the combination of ibrutinib and C968 was synergistic in killing CLL cells with 17p deletion. Overall, our results suggest that ibrutinib induces metabolic alterations characterized by decreased mitochondrial respiration and attenuated glutamine metabolism. Such metabolic alterations provide a biochemical basis for mechanism-based drug combination to enhance the therapeutic activity of ibrutinib.

### 4409 Cholesterol pathway determines ovarian cancer drug resistance through transcription factor SREBP2. Galina Karashchuk, Nataliya Karashchuk, Signe Caksa, Tyler S. Smith, Alexander S. Brodsky. Alpert Medical School of Brown University and Rhode Island Hospital, Providence, RI.

Ovarian cancer is the most common cause of gynecological cancer death in women in United States. Up to 70% of all ovarian cancer cases are high-grade serous carcinomas with 5-year survival rates less than 30%. Recent studies have suggested the importance of the cholesterol pathway in multiple cancers including gynecological malignancies. Here we demonstrate that genetic or pharmacological disturbance of cholesterol pathway in high-grade serous ovarian carcinoma cell lines results in significant changes in survival rate after drug treatment, and in protein and RNA expression patterns. SREBP2 is a transcription factor encoded by SREBP2 gene that regulates expression of sterol-regulated genes and thus maintains cholesterol homeostasis. To assess the role of SREBP2 in ovarian cancer we have created a stable OVCAR8 cell line with SREBP2 disrupted using CRISPR technology. This SREBP2-KD line has reduced SREBP2 mRNA and protein expression level that indicates an effective gene knockdown. Activation of SREBP2 is dependent on the cholesterol status of the cell. We observed that expression of the SREBP2 precursor form is significantly reduced in SREBP2-KD line when cells are maintained under low serum conditions. Mutant cells treated with paclitaxel in low, but not high serum or in presence of statin, revealed significantly lower cell viability. SREBP2-KD cells do not survive long-term, high concentrations of paclitaxel, nor do they grow back as efficiently as control cells. RNA expression and proteomic analysis revealed the critical regulators mediating SREBP2 activity in stressed cells. Together, these observations suggest that the cholesterol pathway is critical for ovarian cancer cells not only to resist stresses, such as chemotherapy, but also to return to a high proliferation state upon recurrence. Further studies will provide important targets for developing new drugs for treatment of ovarian cancer.

### 4410 LSR promoter methylation and cell growth following the activation of β-oxidation and its antibody inhibits lipid catabolism. Koichi Fujimoto,1 Kiyoshi Yoshino,1 Tadashi Kimura,3 Tetsuji Naka1. 1National Institute of Biomedical Innovation, Health and Nutrition, Japan; 2Niigata University, Japan; 3Osaka University, Japan.

Ovarian cancer is the most lethal gynecologic malignancy; thus developing new treatment options is urgently required. Molecular targeted therapies for cancers, which are generally more tolerable than widely used cytotoxic agents, have shown highly specific inhibition of target molecules. In this study, we aimed to identify a new ovarian cancer antigen and to develop a novel monoclonal antibody (mAb). Furthermore we evaluated its preclinical efficacy and analyzed the function of its antigen in ovarian cancer. To identify a new ovarian cancer antigen, cell surface membrane proteins of normal ovarian epithelial and ovarian cancer cell lines were analyzed by ITAQ-based proteomic technology. We identified lipolysis-stimulated lipoprotein receptor (LSR) as the new therapeutic target for ovarian cancer. By the immunohistochemical analysis, significant poor prognosis was observed in high-LSR expression patients with ovarian cancer compared to patients with low-LSR expression by survival assay (p < 0.05). Our newly developed anti-LSR mAb showed significant inhibition of tumor growth in vivo against xenograft model of LSR-positive ovarian cancer cell line and patient derived LSR-positive ovarian cancer tissue (p < 0.05). In LSR-positive ovarian cancer cells, high number and large lipid droplets were observed compared to LSR-negative cells and anti-LSR mAb decreased these droplets. Moreover addition of VLID to LSR-positive ovarian cancer cells significantly promoted the cell proliferation (p < 0.05) and anti-LSR mAb inhibited that in vitro (p < 0.05). Supporting these data, addition of VLID to LSR-positive ovarian cancer cells significantly promoted β-oxidation-mediated lipid catabolism (p < 0.05) and anti-LSR mAb also inhibited that (p < 0.05). In addition, this anti-LSR mAb which cross-reacted with mouse LS did not show any cytotoxicity on normal organs and lipid metabolism in mice. In summary, high expression
of LSR in ovarian cancer was the poor prognostic factor. Our newly developed anti-LSR mAb showed significant tumor growth inhibition against not only LSR-positive ovarian cancer cell line but also patient derived LSR-positive ovarian cancer tissue. In LSR-positive ovarian cancer cells, high number and large lipid droplets were observed and LSR promoted cell proliferation following B-oxidation-mediated lipid catabolism. Thus, anti-LSR mAb inhibited these processes. Our preclinical data demonstrated that targeting LSR by mAb is a promising therapy for patients with LSR-positive ovarian cancer.

#4411 Loss of fructose-1,6-bisphosphatase expression induces altering glucose metabolism and tumor progression in hepatocellular carcinoma. Hiroaki Wakiyama,1 Hidenari Hirata,2 Keishi Sugimachi,3 Takaa Maasaki,4 Naoki Hayashi,1 Yohsuke Kuroda,1 Shuhei Ito,1 Hidetoshi Eguchi,1 Kotaro Terashima,1 Katsumi Sakamoto,1 Masakazu Hirakawa,1 Hiroshi Honda,2 Koshijavik, Iceland;3 Norwegian University of Science and Technology, Trondheim, Norway;4 University of Iceland, Landspitali-University Hospital, Reykjavik, Iceland.

Background: A recent study reported the loss of gluconeogenic capacity in hepatocellular carcinoma (HCC). Fructose-1,6-bisphosphatase (FBP1), the rate-limiting enzyme in gluconeogenesis, is reduced in expression in some cancers. However, the role of FBP1 in altered glucose metabolism in HCC was unclear. Therefore, the objective of this study was to examine the function and clinical significance of FBP1 expression in HCC. Materials and Methods: First, three independent cohorts totaling 594 cases of HCC (118 real-time RT-PCR data from our institution, 242 expression array data from GSE14520, and 234 RNA-seqencing data from The Cancer Genome Atlas (TCGA)) were analyzed to address clinical significance. Data from methylation arrays, SNP arrays, and whole-exome sequencing were also analyzed to investigate the regulation of FBP1 expression in the TCGA cohort. Second, we analyzed mRNA expression, promoter methylation, and DNA copy number profiles of 967 human cancer cell lines, including 27 liver cancer, in the Cancer Cell Line Encyclopedia. Third, we established HCC cell lines stably expressing FBP1 or empty vector control. We performed sphere formation assay and xenograft studies to evaluate the role of FBP1 on HCC progression. Furthermore, in order to assess the effect of FBP1 on altered glucose metabolism, isotopomer distribution analysis was performed using [U-13C] glucose. Finally, to validate the effects of FBP1 expression on survival, risk of recurrence, and glucose metabolism, we performed gene set enrichment analysis (GSEA). Results: Lower FBP1 expression associated with advanced tumor stage, poor overall survival (OS), and poor recurrence-free survival (RFS) in three independent HCC cohorts. For either OS or RFS in each cohort, this prognostic impact persisted, even after adjusting for tumor stage. In HCC cell lines, where endogenous FBP1 expression is low, engineering its ectopic overexpression inhibited tumor growth, and intracellular glucose uptake by reducing aerobic glycolysis. In patient specimens, promoter methylation and copy-number loss of FBP1 were independently associated with decreased FBP1 expression. Similarly, FBP1 downregulation in HCC cell lines was also associated with copy-number loss. HCC specimens exhibiting low expression of FBP1 had a highly malignant phenotype, including large tumor size, poor differentiation, impaired gluconeogenesis, and enhanced aerobic glycolysis. The association of FBP1 expression and gluconeogenesis and glycolysis were confirmed by GSEA. Conclusion: Our findings established that FBP1 downregulation in HCC contributed to tumor progression and poor prognosis by altering glucose metabolism, and they rationalize further study of FBP1 as a prognostic biomarker and therapeutic target in HCC patients.

#4412 Metabolic reprogramming in EMT - targeting regulatory nodes in mesenchymal cells. Bylgja Hilmarsdottir,1 Skarphedinn Halldorsson,2 Maria T. Grinde,2 Anna Barkovskaya,1 Solveig Pettersen,3 Thorarinur Gundjonsdottir,4 Siver A. Moestue,1 Ottar Rolfsson,2 Gunhild M. Maedlansmo.1 Institute for Cancer Research, Oslo University Hospital, Oslo, Norway;2 University of Iceland, Reykjavik, Iceland;3 Norwegian University of Science and Technology, Trondheim, Norway;4 University of Iceland, Landspitali - University Hospital, Reykjavik, Iceland.

To combat cancer we have to avoid development of resistant and metastatic disease. Breast cancer cells can switch from an epithelial to mesenchymal phenotype through a process called epithelial to mesenchymal transition/EMT. Emerging evidence suggests that this process is vital to avoid treatment pressure and to gain metastatic capacity. Furthermore, recent literature shows that metabolic reprogramming is an essential attribute of cellular plasticity. Metabolic targeting could therefore be an attractive possibility to prevent development of resistance and metastatic dissemination. Here we tried to understand the metabolic phenotype of EMT and the mechanisms linking the metabolic programs to cellular plasticity. We also aimed to unravel compensatory metabolic pathways and use the metabolic inhibitors to sensitize breast cancer cells to conventional therapy. To that end we have investigated the metabolic signature of the D492 EMT cell model. The D492 cell line, established from human breast epithelial progenitor cells, has retained stem cell characteristics and has the ability to undergo EMT upon stromal (endothelial) influence, forming the mesenchymal cell phenotype. The D492 cell line is an in vitro model of breast epithelial progenitor cells, and constitutes a unique platform to unravel the factors responsible for stromal cell-induced cellular plasticity. We show that metabolic reprogramming is essential for induction of the mesenchymal phenotype using metabolomic profiling. Using Ultra performance liquid chromatography Mass Spectrometry and gene expression profiling we have created genome-wide metabolic models of D492 and D492M. Our data show that glycolytic flux and oxidative phosphorylation is higher in D492, however, D492M cells rely more on amino acid anaplerosis and fatty acid oxidation to fuel the TCA cycle. Glutamine and glucose tracing using NMR will give further insight into the difference in metabolism between the two cell lines. We have used these data to find metabolic targets that lock the cells in the epithelial state or identify the means to induce lethality in the mesenchymal cells. Using the metabolic rewiring of EMT in the D492 cell model we can understand the mechanisms responsible for treatment resistance, identify compensatory metabolic pathways during treatment and find metabolic inhibitors that will sensitize BC cells to conventional therapy.

#4413 Targeting glutamine metabolism in MUC1 expressing triple negative breast cancer. Gennifer D. Goode, Venugopal Gunda, Panka Singh. University of Nebraska Medical Center, Omaha, NE.

Breast cancer, the second leading cause of cancer deaths in women, accounts for nearly 1 in 3 cancer cases diagnosed in the U.S. women. Triple negative breast cancer (TNBC) accounts for approximately 15-25% of all breast cancer cases and has an increased incidence of metastasis, high recurrence within 1-3 years and a high mortality rate. Therefore, identifying factors that facilitate tumor growth and metastasis have the potential to serve as novel molecular targets for breast cancer therapy. Mucin1 (MUC1), a glycoprotein associated with chemoresistance, is aberrantly overexpressed in TNBC and facilitates growth and metastasis of TNBC cells. Recent studies suggest a role for MUC1 in modulating cell metabolism to support tumor growth. In the present study we examined the role that MUC1 plays in TNBC tumor metabolism; thus facilitating tumor growth. Our results indicate that MUC1 expression facilitates glutamine metabolism. A significant correlation between MUC1 expression, glutamine dependency, and amino-oxyacetate (AOA) sensitivity was observed. These alterations can be attributed in part to alterations in the expression of genes regulating glutamine metabolism. Collectively, these findings suggest that MUC1 serves as a metabolic regulator in TNBC, facilitating metabolic reprogramming of glutamine that influences growth of TNBC. Additionally, the findings with AOA’s effectiveness provide evidence for potential therapeutic utility, particularly for MUC1 overexpressing TNBC.

#4414 Arginine metabolism is modulated by androgen signalling and prostate cancer progression. De-Xue Fu,1 Hubert Huang,1 Jee-Hoon Song,1 Min Xu,1 Lucy Liu,1 Mohamad Afnan Khan,1 Krish Chandrasekaran,1 Arif Husain,1 Ganesh Srim,2 Mohammad M. Siddiqui1 University of Maryland, Baltimore, MD;2 University of Maryland College Park, College Park, MD.

Background: Metabolic reprogramming has been described as one of the hallmarks of cancer. A pathway of promise in prostate cancer management is arginine (Arg) metabolism. Phase 2 clinical trials are underway to study arginine deprivation as a treatment of prostate cancer. However, heterogeneous response has been noted and further studies are needed to better identify prostate tumors most reliant on Arg metabolism. The aim of this study was to investigate if Arg metabolism was associated with androgen signalling and prostate cancer progression from androgen dependent (AD) to androgen independent (AI) phenotype. Methods: The LNCaP prostate cancer cell line was used. Four sets of conditions were tested: LNCaP control, LNCaP in the presence of dihydrotestosterone (DHT), LNCaP with MDV3100 (an AR inhibitor), and a subline of LNCaP (CSS90) which has become AI. MTI viability assay was used to assess cell viability. The Seahorse XF bioenergetics analyzer was used to measure metabolic oxygen consumption. Gas Chromatography and Mass Spectroscopy (GC/MS) was used for metabolomics characterization. Results: LNCaP cells at a baseline are Arg-dependent. Arg starvation led to a 63% decrease in LNCaP cell viability (p<0.0001) in 24hrs. By contrast, the AI CSS90 only demonstrated a 23% decrease in cell viability when depleted of Arg (p<0.01 with Arg control, p<0.001 between LNCaP and CSS90) demonstrating AD cells were much more dependent on exogenous Arg. Enhanced AR signaling with DHT further sensitized cells to arginine depletion with a 73% decrease, and low level
AR inhibition decreased response to arginine depletion with only a 21% decrease in cell viability (p<0.001 for all changes). Metabolic characterization by GC/MS demonstrated a 33.8 fold increase in buildup of an arginine metabolism intermediate, ornithine in the CS590 cells vs LNCaP (p<0.0001) reflecting compensatory ability of the CS590 cells to endogenously manage Arg metabolism. Modulation of arginine signaling with DHT and MDV3100 demonstrated similar increased reliance of exogenous Arg for AD cells with increased androgen signaling with a 2.2 fold increase in Arg dependent oxygen consumption with DHT and 95% drop with MDV (p<0.0001 for both). Conclusions: Arginine is potentially an important aspect of prostate cancer metabolism. Arg targeted therapies may best be suited towards earlier stage tumors and Arg metabolism characterization may have potential as a biomarker of progression to AI prostate cancer.

**#4415 Fatty acid synthase-mediated palmitate production impacts epidermal growth factor receptor signaling to regulate specificity protein 1 in breast cancer cells.** Lincoln J. Barlow, Jian-Ting Zhang, Indiana University School of Medicine, Indianapolis, IN.

Fatty acid synthase (FASN), the sole cytosolic enzyme responsible for de novo palmitate synthesis, is critical for cancer cell survival and is a marker of poor prognosis. FASN overexpression has been shown to confer resistance to both drug and radiation resistance by inhibiting drug-induced ceramide production and by increasing DNA repair activities. Recently, it was found that FASN up-regulation of non-homologous end joining (NHEJ) repair of double strand DNA breaks was due to FASN up-regulation of Poly (ADP-ribose) polymerase 1 (PARP1). Furthermore, overexpression of FASN also increased protein 1 (SP1). However, how FASN regulates the expression of SP1 remains unknown. In this study, we tested the hypothesis that, palmitate, the end product of FASN catalysis, plays an important role in regulating SP1 expression by posttranslationally modifying epidermal growth factor receptor (EGFR) and affecting its activity. Using paired isogenic cell lines with FASN overexpression and FASN knockdown as well as exogenous supplementation of palmitate, we found that depletion of palmitate in culture reduced SP1 expression while supplementing palmitate rescues this effect. Furthermore, FASN overexpression and knockdown increased and decreased, respectively, phosphorylation and activation of EGFR. Treatment with EGFR inhibitor, Erlotinib, reduced SP1 expression. These findings suggest that FASN regulation of SP1 and NHEJ repair may be via regulating EGFR activity. We are in the process of determining the potential effect of palmitolysis of EGFR on its activation and regulation of SP1 expression.

**#4416 Studies on role of acyl-CoA cholesterol acyltransferase (ACAT) expression in ovarian/endometrial cancer progression - An invitro study.** Vijayalakshmi N. Ayyagari,1 Xinjia Wang,1 Laurent Brandt2. 1Southern Illinois Univ., Springfield, IL; 2Southern Illinois Univ. Simmons Cancer Inst., Springfield, IL.

INTRODUCTION: Cancer progression and tumorigenesis have been linked to alterations in cellular metabolic pathways of lipid and cholesterol synthesis in many cancers. Increased levels of cholesterol esters (CE) have been reported in breast cancer, leukemia, glioma and prostate cancer, but not exploited in detail in ovarian and endometrial cancers. Inside cells, excess free cholesterol is esterified by acyl-CoA cholesterol acyltransferase (ACAT) and stored as cholesteryl ester (CE) in lipid droplets (LDs). Cholesteryl ester accumulation may be a consequence of loss of tumor suppressor PTEN and subsequent activation of PI3K/AKT pathway as observed in pancreatic cancer. In the present study, we focused on the role of ACAT and cholesterol esters in altered cholesterol metabolism in ovarian/endometrial cancer cell lines. METHODS: We studied the effect of abrogation of cholesterol esterification either by an ACAT-1 inhibitor/shRNA knockdown or via inhibition of PI3K/AKT/mTOR pathways and subsequent effect on ovarian/endometrial cancer cell proliferation, invasion, cell migration and tumorigenesis. The expression of ACAT was studied at the protein and mRNA levels in a panel of ovarian/ endometrial cancer cell lines and also in normal and ovarian cancer clinical samples. ACAT expression was assessed by western blotting, ELISA, quantitative RT-PCR and immunostaining techniques. RESULTS: Our results reveal an elevated expression of ACAT-1 at both protein and mRNA levels in ovarian and endometrial cancer cell lines as compared to primary cells. Our results also provide preliminary data on involvement of ACAT and cholesterol esters in the progression and metastasis of ovarian cancer. CONCLUSION: These studies may aid in the development of new biomarkers or treatment targets for ovarian/endometrial cancer.

**#4417 The role of EBV infection in aerobic glycolysis in nasopharyngeal carcinoma.** George S. Tsao,1 Jun Zhang,1 Lin Xia,1 C Tsang,1 Weitao Lin,1 Y Yang. 1Univ. of Hong Kong, Pokfulam, Hong Kong; 2Chinese University of Hong Kong, Shatin, Hong Kong.

Accumulating evidence indicates that oncogenic viral protein exerts a crucial role in activating aerobic glycolysis during tumorigenesis, but the underlying mechanisms are largely undefined. The Epstein-Barr virus (EBV)-encoded latent membrane protein 1 (LMP1) is a trans-membrane protein with potent cell signaling properties and has tumorigenic transformation property. Activation of LMP1 is an important factor in the oncogenesis of nasopharyngeal carcinoma (NPC) cells. Collectively, blocking the activity of mTORC1 signaling effectively suppresses LMP1-induced aerobic glycolysis. mTORC1/LMP1 signaling and Glut-1 transcription. Interfering NF-κB signaling has no effect on mTORC1 activity but effectively altered Glut-1 transcription. Luciferase promoter assay of Glut-1 also confirmed that Glut-1 is a direct target gene of NF-κB signaling. Furthermore, we demonstrated that the LMP1 C-terminal activating region (CTAR) 2 is the key domain involved in mTORC1 activation, mainly through IKKβ-mediated phosphorylation of TSC2 at Ser199. Depletion of Glut-1 effectively led to suppression of aerobic glycolysis, inhibition of cell proliferation, colony formation, and attenuation of tumorigenic growth property of LMP1-expressing nasopharyngeal epithelial (NPE) cells. These findings suggest that targeting the signaling axis of mTORC1/NF-κB/Glut-1 represents a novel therapeutic target against NPC. **#4418 Enhanced endodysplasia as a metabolic detoxer for cancer cells.** Yang Liu, Yanxian Lu, Auigo Li, Orieta Celiku, Mark R. Gilbert, Chun Zhang. 1Center for Cancer Research, National Cancer Institute, Bethesda, MD, USA.

INTRODUCTION: Metabolic defects impair physiology and life cycle of every somatic cell. However, emerging evidence showed abnormalities in metabolic pathways paradoxically serve as initial steps in many types of human cancers. Little is known about the molecular mechanisms that confer metabolic adaptation and oncogenic predisposition for a transforming cell with intrinsic metabolic defect. In the present study, we explore the molecular mechanism that assists cellular adaptation when confronting metabolic deficiency, and its correlation acquisition of aggressive phenotypes. METHOD: We took advantage of clinical cases and in vitro cellular models with neomorphic IDH1 mutations, as a paradigm of metabolic deficiency-associated cancer. We investigated whole transcriptomic profiling based on RNA sequencing on IDH1-mutated cells and seek for selective activated canonical pathways. As a validation, we investigated the signature pathways in IDH1-mutated cells, with a focus on cytoskeleton cellular, cellular migration and endodysplasia. Moreover, we investigated mTORC pathway and identified its pivotal role in the metabolic adaptation and cellular motility changes in IDH1-mutated cells. RESULTS: Transcriptomic profiling suggested profound activation in molecular pathways that govern cell movement, endodysplasia, chemotaxis and invasion in IDH1-mutated cells. Hierarchical clustering analysis suggested that acquisition of R132C or R132H IDH1 mutant leads to consistent activation pattern for cellular movement. In addition, we confirmed that IDH1-mutated cells exhibit stronger capacity in cellular migration, endodysplasia and cytokine re-organization. Importantly, we demonstrated remarkable enhancement in endodysplasia pathways in IDH1-mutated cells, suggesting cellular transformation occurs in metabolic up-regulation metabolic deficient cell. Finally, we demonstrated that Rictor/mTORC2/Rac1 pathway is selectively activated in IDH1-mutated glioma cells, which is essential to enable cytoketease mobilization, endodysplasia and acquisition of aggressive phenotype in transforming cells. CONCLUSION: Our findings demonstrate that metabolic deficiency leads to enhancement in food seeking behavior in cellular level, highlighted with enhanced cell motility, chemotaxis, and endodysplasia; suggesting that this is an important molecular mechanism in cellular transformation during oncogenesis. This phenotypic transformation provides additional oxygen sources, compensating for IDH mutation related alterations and may help explain the enhanced cell migration and invasion characteristic of these cancers.

**#4419 HER2 expression and 17β-estradiol induce A549 expression in estrogen receptor positive mammary carcinoma cells.** Maroua Mbarik, Anissa Belkaid, Marc E. Surette. Université de Moncton, Moncton, New Brunswick, Canada.

Proceedings of the American Association for Cancer Research • Volume 58 • April 2017 1129
Breast cancer is a multifactorial disease involving several molecular changes and a high proliferation rate often under the activation of hormonal receptors. Therefore, cancer cells require the metabolic machinery for membrane synthesis and to promote signaling pathways. Amongst biomolecules required for efficient cell growth are polyunsaturated fatty acids, like arachidonic acid, that are essential for cell membrane synthesis and to promote signaling pathways. Uptake of arachidonic acid is essential for cancer cell growth. Mutations and/or reductions in mtDNA copy number are important in the regulation of the mitochondrial biogenesis, thus, they are important in the cellular metabolic phenotype. Utilizing the vast majority of PCa presents as androgen-dependent adenocarcinoma, recent uses of increasingly potent therapeutics targeting the androgen receptor signaling axis has resulted in the promotion of NEPC transdifferentiation as a mechanism of treatment resistance. Unfortunately, there is a lack of effective treatment options for NEPC. Altered cancer metabolism is now recognized as a hallmark of cancer and a crucial factor for promoting tumor growth and spread. In particular, altered glucose metabolism and the resultant acidification of the tumor microenvironment via increased lactic acid production has been shown to play an important role in multiple cancer-promoting processes, including tissue invasion/metastasis, angiogenesis, and suppression of local anti-cancer immunity. While increased glycolysis is not generally considered a phenomenon relevant to primary treatment-naive PCa, we have recently demonstrated its relevance to castration-resistant prostate cancer (CRPC) and metastatic CRPC. Our study thus indicates that capsaicin suppresses pancreatic cancer growth by down-regulating glycolysis and mitochondrial respiration in pancreatic cancer cells. Our results showed that capsaicin treatment reduced the extra-cellular acidification rate (glycolysis) and oxygen consumption rate (mitochondrial respiration) in AsPC-1 and BxPC-3 cells in a concentration-dependent manner after 24h of treatment. Capsaicin treatment reduced 86% and 55% down regulation of glycolysis process in AsPC-1 and BxPC-3 cells respectively. Our results also indicate the inhibition of glycolytic capacity and glycolytic reserve by capsaicin treatment indicating the potential of capsaicin to inhibit glycolysis. In addition, capsaicin treatment reduced 98% of basal oxygen consumption rate and ATP production in AsPC-1 cells. Furthermore, capsaicin treatment inhibited spare respiratory capacity & proton leak in a concentration dependent manner in AsPC-1 cells. Treatment of AsPC-1 and BxPC-3 with capsaicin for 48h also inhibited the expression of LDH-A and its upstream regulators such as HIF-1α, pSTAT3 (Y705) and EGFR as evaluated by Western blot. Our study thus indicate that capsaicin suppresses pancreatic tumor growth by down-regulating glycolysis and mitochondrial respiration. Further mechanistic studies are in progress. [Supported in part by R01 grant CA129038, awarded to (S.K.S.) by the National Cancer Institute].

#4422 Capsaicin suppresses pancreatic tumor growth by inhibiting tumor cell metabolism. Sharavan Ramachandran, Sanjay K. Srivastava. Texas Tech University, Amarillo, TX

Tumor cell metabolism is considered to be a hallmark of tumorigenic progression. Pancreatic cancer cells are shown to develop addiction towards the metabolic pathways like glycolysis and mitochondrial respiration to meet energy demands. Pancreatic tumor cells predominantly utilize cytosolic aerobic glycolysis for energy production. In our previous studies, we have reported that capsaicin treatment inhibits the survival of AsPC-1 and BxPC-3 pancreatic cancer cell lines. In this study, we evaluated the effect of capsaicin on glycolysis and mitochondrial respiration in pancreatic cancer cells. Our results showed that capsaicin treatment reduced the extra-cellular acidification rate (glycolysis) and oxygen consumption rate (mitochondrial respiration) in AsPC-1 and BxPC-3 cells in a concentration-dependent manner after 24h of treatment. Capsaicin treatment reduced 86% and 55% down regulation of glycolysis process in AsPC-1 and BxPC-3 cells respectively. Our results also indicate the inhibition of glycolytic capacity and glycolytic reserve by capsaicin treatment indicating the potential of capsaicin to inhibit glycolysis. In addition, capsaicin treatment reduced 98% of basal oxygen consumption rate and ATP production in AsPC-1 cells. Furthermore, capsaicin treatment inhibited spare respiratory capacity & proton leak in a concentration dependent manner in AsPC-1 cells. Treatment of AsPC-1 and BxPC-3 with capsaicin for 48h also inhibited the expression of LDH-A and its upstream regulators such as HIF-1α, pSTAT3 (Y705) and EGFR as evaluated by Western blot. Our study thus indicate that capsaicin suppresses pancreatic tumor growth by down-regulating glycolysis and mitochondrial respiration. Further mechanistic studies are in progress. [Supported in part by R01 grant CA129038, awarded to (S.K.S.) by the National Cancer Institute].

#4423 Deep sequencing of lung cancer samples using different library preparation methods produces discordant short non-coding RNA profiles. Brid M. MOLECULAR AND CELLULAR BIOLOGY / GENETICS: Metabolic Regulation and Cancer Therapy

#4421 IGFL2 regulates mitochondrial cell energy phenotype and biogenesis in TNBC cells. Maria L. Pagan1, Vinod Kumar Radhakrishnan2, Daisy De Leon3. 1University of Puerto Rico School of Medicine, San Juan, Puerto Rico; 2Loma Linda University, Loma Linda, CA.

Triple-negative breast cancer (TNBC) is very aggressive, resistant to chemo-therapy and more likely to relapse, causing the worst prognosis. African American (AA) women suffer higher incidence and mortality of TNBC due to the expression of high levels of Insulin Growth Factor 2 (IGF2) which promotes tumor progression, metastasis, and chemoresistance. Also, it has been established that functional mitochondria and mitochondrial DNA (mtDNA) are essential for cancer cell growth. Mutations and/or reductions in mtDNA copy number alter the Oxidative Phosphorylation (OXPHOS) physiology and are common features of TNBC. We have demonstrated that mtDNA content is lower in CRL-2335 AA TNBC cell line when compared to the CRL-2335 IGF2 knockout cell line. Thus, we propose that IGFL2 regulates the mtDNA content. This study was designed to demonstrate if IGFL2 regulates mitochondrial genes to determine the cell energy phenotype. An XfP analyzer was used to study the mitochondrial function in terms of OCR (Oxygen Consumption Rate/Mitochondrial Respiration) and ECAR (Extracellular Acidification Rate/Glycolysis) in the wild type and IGF2 stable knockout of CRL-2335 AA TNBC cells. Real Time PCR was performed to study the gene expression pattern of IGFL2, PGC1α and PGC1β. PGC1α and PGC1β are critical genes in the regulation of the mitochondrial biogenesis, thus, they are important in the cellular metabolic phenotype. Utilizing the vast majority of PCa presents as androgen-dependent adenocarcinoma, recent uses of increasingly potent therapeutics targeting the androgen receptor signaling axis has resulted in the promotion of NEPC transdifferentiation as a mechanism of treatment resistance. Unfortunately, there is a lack of effective treatment options for NEPC. Altered cancer metabolism is now recognized as a hallmark of cancer and a crucial factor for promoting tumor growth and spread. In particular, altered glucose metabolism and the resultant acidification of the tumor microenvironment via increased lactic acid production has been shown to play an important role in multiple cancer-promoting processes, including tissue invasion/metastasis, angiogenesis, and suppression of local anti-cancer immunity. While increased glycolysis is not generally considered a phenomenon relevant to primary treatment-naive PCa, we have recently demonstrated its relevance to castration-resistant prostate cancer (CRPC) and thus suspect that it is also relevant to the more aggressive NEPC. Our laboratory has also developed a number of unique serially transplantable patient-derived xenograft (PDx) models of NEPC that are histologically highly similar to the donor tissues and retain important genetic and epigenetic features. In particular, we have developed the first spontaneous NEPC transdifferentiation model in the field (LT331/331R). The gene expression profiles of these NEPC PDx models were compared to that of PCa adenocarcinoma PDx models. To determine whether certain metabolic pathway alterations were specific to NEPC, genes from a representative key metabolic pathways were upregulated and overall pathway scores were generated using different expression scores. Furthermore, significantly available gene expression data from NEPC patient tumors were used to validate our findings. From our analysis, we found that genes in the glycolysis pathway were significantly upregulated in both our PDx models and also in patient NEPC samples. Of particular interest is the upregulation of genes involved in the production and secretion of lactic acid, such as LDHA and MCT4. As such, our results suggest that elevated glycolysis and production of lactic acid could be a clinically important NEPC phenotype. Furthermore, the inhibition of glycolysis and particularly the inhibition of lactic acid secretion via MCT4 could be a potentially viable therapeutic strategy for NEPC.

#4420 Elevated glycolytic gene signature in patient-derived neuroendocrine prostate cancer xenograft models and its clinical relevance. Stephen Y. Choi, 1 Susan L. Ettenger, 1 Dong Lin, 1 Hui Xue, 7 Robert H. Bell, 1 Fan Mo, 1 Michael Pollak, 2 Colin C. Collins, 1 Yuzhuo Wang, 1 Vancouver Prostate Centre, Vancouver, British Columbia, Canada; 2British Columbia Cancer Research Centre, Vancouver, British Columbia, Canada; 3McGill University, Montreal, Quebec, Canada.

Neuroendocrine prostate cancer (NEPC) is a highly aggressive subtype of prostate cancer (PCa) that is becoming increasingly common in the clinic. While the vast majority of PCa presents as androgen-dependent adenocarcinoma, recent uses of increasingly potent therapeutics targeting the androgen receptor signaling axis has resulted in the promotion of NEPC transdifferentiation as a mechanism of treatment resistance. Unfortunately, there is a lack of effective treatment options for NEPC. Altered cancer metabolism is now recognized as a hallmark of cancer and a crucial factor for promoting tumour growth and spread. In particular, altered glucose metabolism and the resultant acidification of the tumor microenvironment via increased lactic acid production has been shown to play an important role in multiple cancer-promoting processes, including tissue invasion/metastasis, angiogenesis, and suppression of local anti-cancer immunity. While increased glycolysis is not generally considered a phenomenon relevant to primary treatment-naive PCa, we have recently demonstrated its relevance to castration-resistant prostate cancer (CRPC) and thus suspect that it is also relevant to the more aggressive NEPC. Our laboratory has also developed a number of unique serially transplantable patient-derived xenograft (PDx) models of NEPC that are histologically highly similar to the donor tissues and retain important genetic and epigenetic features. In particular, we have developed the first spontaneous NEPC transdifferentiation model in the field (LT331/331R). The gene expression profiles of these NEPC PDx models were compared to that of PCa adenocarcinoma PDx models. To determine whether certain metabolic pathway alterations were specific to NEPC, genes from a representative key metabolic pathways were upregulated and overall pathway scores were generated using different expression scores. Furthermore, publicly available gene expression data from NEPC patient tumors were used to validate our findings. From our analysis, we found that genes in the glycolysis pathway were significantly upregulated in both our PDx models and also in patient NEPC samples. Of particular interest is the upregulation of genes involved in the production and secretion of lactic acid, such as LDHA and MCT4. #4424 MicroRNA Profiling in Cancer

MOLECULAR AND CELLULAR BIOLOGY / GENETICS: Metabolic Regulation and Cancer Therapy
Background: Lung cancer stem cells (CSCs) are a small population of stem-like cells that remain largely unknown. MicroRNAs (miRNAs) regulation of CSC genes expression has been reported, constituting a promising therapeutic target. The aim of this study was to isolate and analyze differential expression of a set of miRNAs in tumorspheres from lung cancer cell lines and tumor tissue from resectable non-small cell lung cancer (NSCLC) patients and to determine the prognostic implications of these miRNAs in a cohort of resected-NSCLC patients. Methods: Lung CSC-related miRNAs (miR-145-5p, miR-188-5p, miR-218-5p, miR-34a-5p, miR-21-5p and miR-125a-5p) were analyzed in cells from seven NSCLC tumor samples and six cell lines (H1650, H1939, H480, H538, A549 and PC9) grown in monolayer and as spheroids by RT-qPCR using TaqMan® microRNA assays. The expression levels of these six miRNAs were also analyzed in paired fresh-frozen tumor and normal adjacent lung tissue samples (N=178) from resected-NSCLC patients. Statistical analyses were considered significant at p<0.05. Results: miRNA expression analysis of cultured cells revealed an increased expression of miR-125a (p=0.04) and miR-188 (p=0.05) in lung tumorspheres from tumor samples and cell lines compared to their paired-adjacent cells. Moreover, lungspheres from patients showed elevated expression levels of miR-21 when compared with their paired monolayer-cell cultures (p=0.028). Interestingly, miR-125a, miR-188 and miR-21 had prognostic value when they were analyzed in patients’ tissue samples. We found that those patients with higher levels of miR-188 and miR-21 had a higher risk of relapse and a reduction in relapse-free survival (RFS, 23.67 vs 66.97 months; p= 0.009 and 24.03 vs 56.83 months, p= 0.042, respectively) and overall survival (OS, 42.9 vs NR months; p= 0.002 and 42.6 vs 82.60 months; p= 0.043, respectively), whereas the group of patients with higher levels of miR-125a had a worse outcome (OS 51.9 vs NR; p= 0.014). A signature combining the expression of miR-125a, miR-188 and miR-21 was able to give more significant information (RFS, 16.97 vs 56.83 months; p= 0.006 and OS, 29.90 vs. NR; p=<0.0001). The multivariate analysis including clinicopathological and analytical variables revealed this miRNAs signature as an independent prognostic biomarker for RFS (HR 2.170 [1.372-3.431]; p = 0.001) and OS (HR 3.256 [1.907-5.561]; p<0.0001). Conclusions: Lung tumorspheres had increased levels of the CSC-related miRNAs miR-125a, miR-188 and miR-21, highlighting their role in the CSC biology. The analyses performed in a large cohort of resectable NSCLC patients show that two miRNAs signature (miR-188 and miR-21) was an independent prognostic marker for RFS and OS. Supported by grants RD06/0020/1024 and RD12/0036/0025 from RTICC-FEDER, PI12-02838 and PI13-00753 from ISCIII, TRACE (TRA09-0132) and Beca Roche Oncohematología.

#4425 Analysis of host-Epstein-Barr virus microRNA expression in nasopharyngeal carcinoma. Wen-Hui Su,1 Jia-Hao Zhang,1 Kai-Ping Chang,3 Yung-Cheng Hwu,1,4 Cheng Gung University, Taoyuan, Taiwan; 2Cheng Gung Memorial Hospital at Lin-Kou, Taoyuan, Taiwan.

In the tumorgenesis process, miRNAs could act as oncogenes or tumor suppressor genes in the cancer cells by regulating miRNA target genes. Nasopharyngeal carcinoma (NPC) associated Epstein-Barr virus (EBV) can also influence the occurrence of NPC through its miRNAs. In this study, we used the next generation sequencing technology to analyze host-viral miRNA profiles in 24 NPC and 5 adjacent normal tissues. In average, 10.62% of mappable reads mapped to EBV genome in NPC tissue. Most of the small miRNAs in NPC tissues which mapped to EBV genome were miRNAs (95.51%), rest of them were EBERs (1.80%) and r-snoRNA (2.68%). The percentages of EBV miRNA in total human and EBV mature miRNA reads were ranged from 4% to 51% (average 29.61%). For EBV miRNAs, the expression level of BART10-3p and BART9-3p were the top two in NPC tumors. BART20-5p, BART19-3p and BART21-5p were correlated to tumor stage. On the other hand, there were 11 and 34 human miRNAs differentially up- and down-regulated in NPC tissue, respectively. The present research provides the first evidence obtained through next generation sequencing to systematically and comprehensively describe the expression of EBV and human miRNAs in NPC tissue.

#4426 Alcohol consumption and hepatitis B-associated microRNAs in hepatocellular carcinoma. Pin Xue Li,1 Hao Zheng,1 Maarouf A. Saad,2 Angela E. Zou,3 Xiaoqi Wang,4 James G. Kwok,1 Avinaash Korrapati,1 Yuanhao Qu,1 Thomas K. Honda,1 Jessica Wang-Rodriguez,4 Weg M. Ongkeko,1 University of California San Diego, San Diego, CA; 2Yale School of Medicine, New Haven, CT; 3University of Hong Kong, Hong Kong, China; 4Veterans Affairs, San Diego, CA.

Hepatocellular carcinoma (HCC) affects more than 500,000 new patients each year and is characterized by fast growing, heterogeneous tumors and low five-year survival rates. Despite the identification of HCC risk factors, including alcohol consumption and chronic hepatitis B (HBV) infection, early diagnosis of HCC and molecular understanding of how these risk factors promote HCC both individually and in combination remain elusive. microRNAs (miRNAs), non-coding transcripts ~22 nt in length, have emerged as central mediators of post-transcriptional and translational gene regulation, and have been increasingly implicated in the initiation and progression of many cancers, including HCC. However, the dysregulation profile of miRNAs in HCCs of varying etiologies remains largely uncharacterized. To give more significant miRNA oncogenic influence, we associated with alcohol use or with HBV in HCC patients, we analyzed next-generation RNA-sequencing data from 234 HCCs in The Cancer Genome Atlas (TCGA). Through differential expression analyses on cohorts stratified by alcohol consumption and HBV status, we discovered 10 miRNAs specifically dysregulated in alcohol-associated HCCs and 251 miRNAs specifically dysregulated in HBV-associated HCCs (FDR < 0.05). Among these, two miRNAs, miR-944 and miR-223-3p, significantly overexpressed in HCC alcohol consumers, exhibited additional correlations with patient survival, tumor stage, and mutations in CTNNB1, MUC16 and TNN (p < 0.05). We subsequently validated the upregulation of miR-944 and miR-223-3p in vitro following treatment of both normal...
Molecular and Cellular Biology / Genetics: MicroRNA Profiling in Cancer

Liver and HCC cell lines with biologically relevant doses of alcohol and acetaldehyde, the first breakdown metabolite of ethanol. Knockdown of miR-944 and miR-223-3p significantly reduced cellular proliferation in both acetaldehyde-treated and untreated normal and HCC cell lines, and resulted in increased sensitivity to cisplatin. Inhibition of both miRNAs in HCC cell lines also restored the normal growth arrest in several tumour suppressor genes targeted by miR-944 and miR-223-3p. Taken together, our findings enhance knowledge of the respective roles of miRNAs in alcohol- and HBV-mediated HCC, and highlight the increased transcriptomic resolution afforded by etiology-specific studies of cancer pathogenesis and progression.

#4427 An integrated analysis package of miRNA and mRNA expression data: An integrated analysis package of miRNA and mRNA expression data. Ti-Tai Wang. National Taiwan University, Taipei, Taiwan.

MicroRNAs (miRNAs) are small and non-coding RNAs that can regulate gene expression by binding to the 3’ UTR of target mRNAs and inhibiting mRNAs to translate protein, or even promoting mRNAs degradation. In various complex disease and pathological conditions, we can identify dysregulated which are the causative factors. Therefore, it is an essential approach to explore the interactions between miRNA and gene in certain diseases, such as cancers. However, challenge arises when we are trying to validate the interactions by doing bench experiments. The number of miRNA–gene interactions is too large to be validated. Currently, most prediction algorithms only provide its own result and low consistency rates across independent methods have been reported. Therefore, it is necessary to develop a systematic method to perform a comprehensive analysis by using the expression profiles from genes and miRNAs concurrently. To address these issues, we developed an R package named as anamiR. The anamiR is able to perform an integrated analysis of mRNAs and miRNAs with the phenotype information. The analysis procedures are briefly summarized as the follows. Initially, differential expression analysis would be applied to the raw data. Subsequently, the anamiR package can identify significant pairs of miRNAs and genes if their Pearson correlation coefficients are lower than the pre-defined threshold. Next, the significant pairs were compared to the embedded database in anamiR, which included two validated and several predicting miRNA-gene databases. Lastly, functional analysis is also available in this package to characterize the biological functions and signaling pathways of dysregulated miRNAs and genes. A breast cancer dataset was analyzed using anamiR, which identified nine miRNA–gene interactions for deeper studying. Among these interactions, there are two miRNAs and nine genes included. miR-497-5p and miR-204-5p both were mentioned in both cancer frequently, are found by anamiR. The anamiR package is freely available at Bioconductor.

#4428 A miRNA signature linked to human environmental risk factors derived from carcinogen-induced and genetically-driven colon cancers. Mei-Chen, Ying-Shiu Chen,1 Rong Wang, 2Wan-Mohaia Shardish, 3Christiane Lohr, 4David E. Williams, 5Emily Ho, 6Susanne Mertens-Talcott, 7Roderick H. Dashwood, 8Texas A&M Univer. Health Science Ctr., Houston, TX; 9Oncology State University, Corvallis, OR; 10Texas A&M University, College Station, TX.

Heterocyclic amines (HCAs) produced during high-temperature cooking have been studied extensively in terms of their genetic effects, but recent work has implicated epigenetic mechanisms involving non-coding RNAs. We reported that colon tumors induced in the rat by 2-amino-1-methyl-6-phenylimidazo[4,5-b]pyridine (PhIP) have altered microRNA (miRNA) signatures linked to dysregulated pluripotency factors, such as c-Myc and Krüppel-like factor 4 (Klf4). The corresponding miRNAs prioritized from PhIP-induced colon tumors were examined in other target organs from a one-year carcinogenicity bioassay, and compared with miRNAs dysregulated in the Apc-mutant polyposis in rat colon (Pirc) genetic model. Multiple let-7 family members were downregulated in colon, skin, lung, small intestine, and Zymbal’s gland tumors, and were associated with Myc and Hmg2 upregulation. A “PhIP miRNA signature” with the profile mir-21 high mir-126 low mir-29low mir-215 low mir-145low was linked to reduced expression of Klf4 in multiple target organs of the rat, and was predictive of poor prognosis in human pan-cancer and colorectal cancer datasets (https://cancergenome.nih.gov/). Findings from The Cancer Genome Atlas suggested that PhIP signature miRNAs might serve as an arbiter of HCA exposure, defining a subset of human tumors linked to environmental carcinogenesis. We conclude that future studies should examine the miRNA signatures of other HCAs, and determine their possible predictive value for human risk assessment. This work was supported in part by NIH grants CA090890, CA122959, ES02010, and ES023512, the John S. Dunn Foundation, and a Chancellor's Research Initiative. We are most thankful to Robert Hawk for providing a graduate student fellowship in aid of Y-S Chen.

#4429 An exhaled microRNA panel interrogation and validation as risk biomarkers for lung cancer. Simon D. Spivack. Albert Einstein College of Medicine, Bronx, NY.

Background: There is a need for non-invasive airway-based biomarkers in lung carcinogenesis for both risk assessment of the ex-smoker, and earlier diagnosis of early-stage cancer detected through liquid biopsy analyses. MicroRNAs have been validated as regulators of cell functions and act as staging markers in lung carcinogenesis. Exhaled breath condensate (EBC) contains airway lining fluid molecules, including nucleic acids, presumably in part from epithelial cellular origins. Here we further develop and begin validation of the detection of microRNAs in EBC from lung cancer patients and controls. Methods: Exhaled breath condensate (EBC) was collected non-invasively, using a handheld device in 56 samples. MicroRNA expression profiling using RT-qPCR was performed in EBC in an initial batch (E) of 88 individuals (41 lung cancer cases, 47 controls), and a second batch D of 88 individuals (41, cases and 47 controls). We generated a 39 miR panel based on literature-derived microRNAs, combined with a lung tissue-based discovery effort we have performed using microRNA-seq on lung tumors and surrounding non-tumor tissue. The qPCR primers were designed using our previously published RNA-specific real-time RT-qPCR technique. All samples were run twice with positive and negative controls. Results: Qualitative analyses of the first donor batch E was performed on 39 microRNAs measured in 41 cases and 47 controls. Chi-square analysis (univariate) within the training set (batch E) revealed that exhaled miR-31, 33, 105, 200b, 944, 1269a were significantly different between the initial set of cases and controls (p < 0.05). In the validation batch (D) pre-liminary analysis, exhaled miRs 200b (this time present in cases, p = 0.044) and 944 (again absent in cases, p = 0.052) were case-control discriminant. In addition, test set batch D showed case-control discrimination for additional miRs 130b-3p (present in cases, p = 0.035), 212 (absent in cases, p = 0.009), 1910a (absent in cases, p = 0.006) and other microRNAs that were not seen in the qualitative training set (batch E). Importantly, multi-miR discriminant signatures, quantitative analysis, and risk ROC/modelling analyses are pending as of this AACC abstract deadline. Conclusion: This new exhaled biomarker platform can yield case-control discriminant microRNA sets, including a subset of miRs that can validate in test sets. Once further distilled and validated, our goal is to apply this non-invasive biomarker approach to prospective cohorts for non-invasive lung cancer risk assessment, in order to better select higher risk individuals who should undergo CT screening.

#4430 Circulating microRNA expression profiles as a novel diagnostic biomarker for esophageal squamous cell carcinoma. Yutaka Shimada, 1Yoshi-nori Takei, 2Tomoyuki Okumura, 3Takuya Nagata, 2Haruka Fujinami, 3Miwako Arima, 4Tetsuya Abe, 4Yasumasa Niwa, 4Masahito Tajika, 4Tetsuo Sudo, 4Kazuharu Shimizu, 1Kyoto Univ., Kyoto, Japan; 2University of Toyama, Toyama, Japan; 3Saitama Cancer Center Hospital, Ohmiji, Japan; 4Aich Cancer Center Hospital, Nagoya, Japan.

Background: The findings of a recent analysis on microRNAs (miRNAs) suggest the circulating miRNAs have potential as biomarkers of esophageal squamous cell carcinoma (ESCC). In order to identify specific miRNAs of ESCC, we analyzed the circulating miRNAs of patients who underwent endoscopic mucosal resection (EMR) and esophagectomy. Method: After obtaining written informed consent, we collected paired (pre and post treatment) blood samples from 60 superficial ESCC patients and 42 pretreatment advanced ESCC patients between 2011 and 2015. Samples were divided into training (40 superficial ESCC and 22 advanced ESCC) and test (15 superficial ESCC and 20 advanced ESCC) cohorts according to the period at which they were obtained (between 2013 and 2015 and between 2014 and 2015). Fifty-five patients underwent EMR and were confirmed as stage 0 or Stage 1a. Microarray analyses of blood samples were performed using the 3D-Genie miRNA microarray platform (Toray). Normalization was achieved using the Quantile method, and poor quality samples were excluded from the analysis. Any two clinical groups were compared using a two-sided Student’s t-test. miRNAs exhibiting significant differences were subsequently evaluated using a logistic regression analysis (LRA). Multivariate LRA was used for screening. Receiver Operating Characteristic (ROC) analyses were performed in order to evaluate the diagnostic power of miRNA combinations. In all series, we used post-EMR patients as control cases. Results: Twelve miRNAs (miR-6722-5p, 489, 4525, 409-3p, 6088, 3678-5p, 197-5p, 4281, 5090, 3173-3p, 762, and 1470) were selected as discriminant markers (S-combination: AUC 1.00) of superficial ESCC, while 4 miRNAs (miR-4723-3p, 4646-3p, 2392, and 1236-3p) were selected as discriminant markers (A-combination: AUC 1.00) of advanced ESCC in the training cohort. There were no overlap miRNAs between the two combinations. In the test cohort, the S-combination discriminated superficial ESCC (AUC 1.00), while the A-combination discriminated advanced ESCC (AUC 1.00) from post-EMR patients. Further...
thermore, the S-combination discriminated advanced ESCC in the test cohort (AUC 1.00). However, the A-combination did not clearly discriminate superficial ESCC (AUC 0.833). Conclusion: Our results suggest that selected miRNAs are useful biomarkers for the discrimination of ESCC. However, biomarkers of superficial ESCC and advanced ESCC may differ.

#4431 Urine microRNA profiling in bladder cancer by next-generation sequencing. Barbara Pardini,1 Francesca Cordero,1 Alessio Naccarati,2 Giulio Ferrero,3 Clara Viliberti,1 Marco Oderda,2 Maddalena Arigoni,2 Raffaele Calogero,2 Carlotta Sacrudeo,4 Paolo Gontoro,4 Paolo Vineis,4 Giuseppe Mattullo,4 1Human Genetics Foundation, HugoFerriorio, Torino, Italy; 2University of Torino, Torino, Italy; 3University of Torino, Turin, Italy; 4University of Torino and Città della Salute e della Scienza, Torino, Italy; 5Molecular Biotechnology Center, University of Torino, Turin, Italy; 6Center for Cancer Prevention (CPO-Piemonte), Torino, Italy; 7School of Public Health, Imperial College London, London, United Kingdom.

Bladder cancer (BC) is one of the leading causes of cancer-related death worldwide. BC is among the most expensive cancer per patient because it requires frequent surveillance and repeated treatments over many years. The identification of new biomarkers for early BC detection, recurrence/progression is urgently needed to both improve patient outcomes and decrease health care costs. MicroRNAs (miRNAs) are aberrantly expressed in many cancers, including BC, and may be isolated from various biological specimens, including urine. To investigate miRNA signatures in surrogate tissues may be a useful alternative to reduce invasiveness of biopsies, allowing repetitive samplings during follow-up and reducing health care costs for detection, monitoring of progression and treatment. We aim to identify specific miRNA signatures in urine samples from 66 BC male patients (10 muscle invasive BC (MIBC) and 56 non-muscle invasive BC (NMIBC)) and 48 healthy controls using a Next Generation Sequencing (NGS) approach able to accurately distinguish BC patients and predict disease outcome. The measurement of miRNA levels in urine could allow to measure the levels of promising biomarkers in one of the best and closest surrogate tissue for BC, since it is in direct contact with the tissue of tumor origin. A specific miRNA signature that could distinguish the different types of BC patients from healthy controls was found in urine. For MIBC, a 18-miRNAs signature had over 80% predictive power (PP) to recognize patients from controls (data are under validation). For NMIBC we were able to stratify cases according to grade. In particular, 23 miRNAs resulted differentially expressed among G1-G2 cases and controls (5 of them had PP>0.70), while several miRNAs resulted differentially expressed among G3 patients and controls (a 10-miRNAs signature with PP>0.97). Interestingly, we found several differentially expressed miRNAs in common among cases and some miRNAs that were differentially expressed only in specific subcategories of BC cases. NGS data were also used to search for the most constant miRNAs in the set of samples to be used as reference genes in a validation step. Twenty-three miRNAs (21 target and 2 reference miRNAs) were validated by qPCR on 177 urine samples from 113 BC case and 64 controls. Interestingly, miRNAs differentially expressed among cases and controls were able to discriminate not only BC cases from controls, but also its subcategories. This data provide evidences of the possibility to use miRNAs being expressed in urine of patients with BC as diagnostic, prognostic and predictive biomarkers. #4432 Low miR-222 expression levels predict long-term survival of patients affected by glioblastoma. Laura Lattanzio,1 Maria Borognone,2 Rosella Merli,2 M. Cristina Dechecchi,3 Gianluigi Dorelli,2 Cristina Mocellini,1 Laura Lattanzio,1 Marzia Borgognone,2 Rosella Merli,2 M. Cristina Dechecchi,3 Gianluigi Dorelli,2 Cristina Mocellini,1 Andrea Talacchi,1 Daniela Vivenza,1 Federica Tonissi,1 Alessandra Santangelo,1 Fabrizio Giordano,1 Caluduo Ghimenton,1 Albino Eccher,7 Sergio Pericotti,2 Luisa Zanolla,1 Claudio Bernucci,1 Marco Merfano,1 Cristina Lo Nigro,1 Giulio Cabrini,1 S.Croce & Carle Teaching Hospital, Canes, Italy; 2University of Verona, Verona, Italy; 3University of Verona, Verona, Italy; 4Verona University, Verona, Italy.

Introduction MicroRNAs (miRNAs) are small non-coding RNAs which are known to play an important role in proliferation, differentiation, invasion and angiogenesis of different malignant tumors. The role of tissue and blood level of miRNAs as useful bio-markers of gliomagenesis is also increasing. Interest is growing on tissue and plasma miR-222 level as prognostic marker in first line chemo- and radiotherapy treated patients with glioma, the mechanisms of action and the target genes of this miRNA in gliomagenesis being under extensive investigation. Furthermore, some evidence exist that miR-221 and miR-222 are upregulated in glioblastoma (GBM) patients and that these paralogues target the 6-(methylguanylin)-DNA methyltransferase (MGMT) mRNA. Here we focused on the prognostic role of tissue miR-222 in GBM patients. Experimental procedures 63 GBM patients were included in the analysis (overall survival (OS) range: 8-122 months). For each patient formalin-fixed paraffin-embedded tissue samples at first surgery were collected. miR-222 expression level was analyzed by TaqMan probes. To verify miR-222 expression level OS was analyzed by Kaplan-Mayer (K-M) survival curves. MGMT methylation analysis by pyrosequencing on tumor DNA is on-going. Results In silico analysis of The Cancer Genome Atlas (TCGA) for GBM defined a median OS of 13.6 months in the whole sample population (n=199). Comparison of median OS, done stratifying two groups according to median tissue miR-222 expression level, showed a significant increased OS in low 222 patients (12.3 vs 14.1 months, p=0.030). Interestingly, K-M curves overlapped for the first 14 months and then diverged after. In particular, K-M analyses starting from 14 months revealed a significantly increased hazard ratio for high 222 patients (HR 1.47, 95% CI = 1.25 - 3.16, p<0.004) in respect to low 222 patients, being the median OS of further 15.1 months in low 222 and of 6.6 months in high 222 patients. On this basis, we tested the hypothesis of a possible role of miR-222 in a local sample population of 63 GBM patients with prolonged survival. MiR-222 expression level was measured as described above. Therefore, patients were stratified in two groups according to median tissue miR-222 expression level (low 222 vs high 222) and OS analysed on a K-M curve. The Hazard Ratio for high 222 patients was significantly higher (HR = 5.5, 95% CI = 3.9-7.9, p<0.001), being the median OS of 45.2 months vs 13.5 months in high 222 GBM patients, respectively. Conclusions Quantitative analysis of miR-222 expression in the tumor tissue obtained at first surgery might provide a relevant prediction of prolonged survival in GBM patients. Further conclusions will be presented on the relationship between miR-222 and MGMT which will shed light on a possible role of miR-222 on gene methylation and GBM epigenetics.

#4433 Deregulated microRNAs in NF1 derived malignant peripheral nerve sheath tumors (MPNST) and their role in carcinogenesis. Azadeh Amirnasr, Patricia F. van Kuijk, Robert M. Verdijk, Walter Taal, Stefan Sleijfer, Erik A.C. Wiemer, Erasmus Medical Ctr., Rotterdam, Netherlands.

Background and aim: MPNSTs are rare and highly aggressive soft tissue sarcomas that can occur spontaneously (sporadic MPNST) or from pre-existing plexiform neurofibromas in neurofibromatosis type 1 (NF1) patients. MPNSTs are usually diagnosed relatively late, metastasize easily, are resistant to therapeutic intervention and frequently fatal for the patient. Diagnostic biomarkers that detect early malignant transformation in the NF1 setting as well identification of putative targets for treatment are urgently needed. In this context we investigated the miRNA expression profiles in NF1-derived MPNST. Materials and Methods: A total of 35 DNA was isolated from sections of formalin fixed paraffin-embedded (FFPE) tumor samples. miRNA expression was determined using a RT-PCR platform (TaqMan® Low Density Array Human MicroRNA Cards; Applied Biosystems). The expression of selected miRNAs was transiently modulated in neurofibroma and MPNST cell lines by transfection with miRNA mimics (Dharmacon) or LNA® anti-miRs (Exiqon) and effects on cell proliferation, invasion/migration and Wnt/b-catenin signaling were studied. Results: In order to identify miRNAs that are specifically deregulated in MPNST we analyzed miRNA expression in a unique set paired tumor samples (n=9) of plexiform neurofibroma and MPNST which were derived from the same NF1 patient. At least 90 miRNAs were found to be differentially expressed (FDR <0.10; p<0.025) between neurofibromas and MPNST; the vast majority (82/90) of miRNAs being downregulated in MPNST. Interestingly, and in contrast to reports in the literature, sporadic MPNST samples (n=10) could be easily discriminated from NF1-derived MPNST by their miRNA expression profiles. On the basis of their statistical significance, fold difference and expression level, we selected miRNAs to examine their role in MPNST pathogenesis. MiRNA levels were modulated in MPNST (ST88-14, ST88-64, 0.9-8TL) and neurofibroma (Hs637_T) cell lines using miRNA mimics for let-7b, miR-21a, miR-29a, miR-139-5p, miR-146a and antisense inhibitors for miR-889, miR-135b. The effects of miRNA expression levels on cellular proliferation, invasion and migration were determined. As Wnt/b-catenin signaling is considered a cancer related driver pathway in MPNST we also investigated whether differentially expressed miRNAs could regulate this pathway focusing on miRNA previously linked to Wnt regulator or predicted to target Wnt signaling components. Using TOP/FOP luciferase reporter assays we analyzed the effects of miR-135b, miR-30a, miR-139-5p and miR-146a. Conclusion: miRNAs specifically deregulated in MPNST may fulfill key oncogenic roles and may be used as biomarker or for therapeutic purposes.
MOLECULAR AND CELLULAR BIOLOGY / GENETICS: MicroRNA Profiling in Cancer

**#4434** MicroRNA methylation of normal breast tissue from ER negative and ER positive breast cancer identify progression markers specific for estrogen receptor status. Kang Mei Chen, Josena K. Stephen, Indrani Datta, Dhananjay Chitale, George Divine, Maria J. Worsham. *Henry Ford Health System, Detroit, MI.*

The unique structure and function of normal tissues is known to be regulated by epigenetic mechanisms. Understanding how normal cells in their respective tumor milieu might affect their susceptibility to become not only malignant but acquire breast cancer (BC) subtype-specific phenotypes, may determine tumor clinical behavior outcomes. The goal was to compare genome wide methylation profiles of non-coding miRNAs of breast cancer tissue and normal breast epithelium (normal non-coding miRNA (miRNA) (ER) negative and ER positive breast cancer) to assess their methylation methylation in the context of tumor ER phenotypes as either ER- or ER+. BC tissue from 79 patients (39 ER- and 40 ER+) and normal tissue from 39 of these patients (19 ER- and 20 ER+) were assayed using the Illumina 450K bead array. A sub analysis focused on 2249 miRNA CpGs as-sign to 615 unique miRNAs. M-values were computed as a logit function (log (beta/(1-beta)) of the methylation beta values. T-tests were used to compare the means of the M-values for the ER (beta/(1-beta)) of the methylation betavalues. T-testswere used tocompare the I lumina 450K bead array. A sub analysis focused on 2249 miRNA CpGs as-and assess their miRNA methylomes in the context of tumor ER phenotypes as either ER- or ER+. BC tissue from 79 patients (39 ER- and 40 ER+) and normal tissue from 39 of these patients (19 ER- and 20 ER+) were assayed using the Illumina 450K bead array. A sub analysis focused on 2249 miRNA CpGs as-sign to 615 unique miRNAs. M-values were computed as a logit function (log (beta/(1-beta)) of the methylation beta values. T-tests were used to compare the means of the M-values for the ER+ and ER- groups. The t-test p-values were used to develop adaptive FDR (afDR) levels and fDRs of 0.05 or lower were considered to be statistically significant (Tier 1). Tier 1 CpGs were subsequently filtered to select only those with a mean beta ratio between ER+ and ER- of under 0.5 or over 2.0 (Tier 2). The Tier 2 CpGs were further filtered to select only those with a mean beta difference of 0.2 or more. The 1224/2249 (54%) CpGs were differentially methylated between ER- and ER+ BC at Tier 1. Of the 1224, 963 (78.7%) were hypermethylated, and 1035 (84.6%) were in promoter regions. The 1224 CpGs at Tier 1, the 24 at Tier 2, and 2 CpGs at Tier 3 were associated with 379, 22 and 2 genes respectively. When the same analysis was performed on normal tissue only (19 ER- and 20 ER+), 76 of the 2249 CpGs had significant fDR values and none of those met the Tier 2 or Tier 3 criteria. Seventy-one of the 76 (93.4%) were hypermethylated, and 65 (85.5%) were in promoter regions. The 76 significant Tier 1 (an FDR) differentially methylated CpGs were associated with 48 genes of which 43 were common to tumor Tier 1 differentially methylated miRNA genes, 10 were common to tumor Tier 2 genes, and 5 were restricted to normal tissue only. Normal epithelial tissues demonstrated similar differential methylation directionalities as their respective tumor counterparts, favoring promoter region localization. Accordingly, the recognition of normal breast tissue-specific epigenetic properties that align with their tumor phenotypes, suggest the possibility of progression markers specific for ER status as well as markers not associated with progression. This provides insights into our view of possible links between epigenetic programming, progression continuums, and how hormonal receptor subtypes may be determined. Support: Komen Foundation: KG110218

**#4435** Exosomal miR-3622a as prognostic marker in prostate cancer. Thao Yang, Divya Bhagirath, Kirandeep Sekhon, Nathan Bucay, Sharanjot Majid. *King’s College Medical School, London, UK.*

Loss of chromosome (chr) 8p21 is a frequent genomic alteration in prostate cancer (PCa). Genomic deletions of this region increase significantly with tumor grade and are associated with tumor progression and poor prognosis. A common region of loss of heterozygosity (LOH) has been mapped to the chr8p21 region of loss of heterozygosity (LOH) has been mapped to the chr8p21 region. The 8p21 region is highly conserved across species and contains a region that is frequently deleted in human PCa. In this study, we aimed to identify the miRNAs that are specifically regulated in this region.

**#4436** Novel microRNA signature score to predict bone metastasis and prognosis of breast cancer. Tsutomo Kagawuchi, Li Yan, Qi Qi, S. Liu, Kazuki Takabe. *Roswell Park Cancer Institute, Buffalo, NY.*

Backgrounds: 40,000 US women still die with breast cancer every year. Vast majority of death occur after they develop metastasis, where bone is the most frequent site for breast cancer. New measures to identify the patients who develop metastasis allow us to intervene early, which is expected to prolong survival. The aim of this study is to establish a microRNA (miRNA) signature scoring system that can predict bone metastasis and survival utilizing integrated transcriptomics analyses in breast cancer. Materials and Methods: Both clinical and RNA expression data, including microRNA and mRNA, of 1051 patients were retrieved from The Cancer Genome Atlas (TCGA). 1) Multivariate Cox proportional hazard model and Kaplan-Meier for overall survival were performed to construct and identify novel models of miRNAs signature for predicting patient survival. 2) Competing risk analysis using the miRNAs signature was conducted to clarify its association with metastatic distributions. 3) Gene Set Enrichment Analysis (GSEA) was performed to identify the genome-epigenome significance of the miRNAs signature. Results: 1) Utilizing Cox model on TCGA cohort, we established a novel microRNA signature with 3 miRNAs (miR-19a, miR-93, and miR-106a) that identified the patients population with extremely poor overall survival (p = 0.0004; 5-y survival rate, 49.2%). This result was reproduced in two other completely independent cohorts with microarray datasets (GSE19536, p = 0.0099; GSE22220, p = 0.0003, respectively). 2) Utilizing competing risk analysis for each metastatic sites of breast cancer, we found that the patients with bone metastasis demonstrated significantly high scores (p = 0.0052). The evaluation also showed a statistical tendency of association with lung metastasis (p = 0.0854). 3) We found that high score is associated with several critical gene sets such as angiogenesis (p < 0.0001) or epithelial mesenchymal transition (p = 0.0155) by GSEA that suggests that high signature score is associated with enhanced metastasis in breast cancer patients. Conclusions: We established a miRNAs signature scoring system to predict bone metastasis and poor overall survival in breast cancer using novel integrated transcriptomics concept.

**#4437** Small non-coding RNA profiling from prostate cancer plasma by deep sequencing. Xianghua Liu, Andrew Hunter, Qing Zhang, Quanyuan He, Annemarie Benton, Gerri Ortiz, Vashalli Pannu, Nick Xiao, Mark Miglarese, David Spezeler. *Caris Life Sciences, AZ.*

Background: Prostate cancer (PCa) is the most common non-skin cancer among American men. MicroRNAs (miRNAs) are critical post-transcriptional regulators and involved in prostate cancer tumorigenesis. The aim of this study is to identify a PCa-specific expression profile of miRNAs from plasma to guide prostate cancer diagnosis and therapeutic treatment. Methods: Plasma was collected from 50 randomly selected patients (25 PCa patients and 25 normal). Plasma was extracted from 1) 200ul plasma or 2) the pellets of anti-Ago2 immunoprecipitations from 500ul plasma using the miRNeasy Serum/Plasma kit (Qiagen), with addition of glycogen as a carrier. Small RNA libraries were constructed using the NEBNext Multiplex Small RNA Prep Set for Illumina*®* (New England BioLabs). The cDNA library fragments were purified by Blue Pippin (Sage Science) for extraction of 140-160 bp size fraction containing small RNA inserts. Equimolar amounts of cdNA library samples were pooled and were sequenced in one flowcell on an Illumina HiSeq2500 with 50 cycle kit and rapid run mode. Bioinformatics analysis: Adaptor was firstly removed from the raw reads, and the sequences were mapped to several small RNA databases by using bowtie1 with 1 mismatch. The multiple aligned reads were weighted to the mapped small RNAs based on their unique mapped reads counts. We then calculated the RPM (reads per million) as indicator of the expression levels of the small RNA. To get consistent analysis results, we discarded the small RNAs whose averages of the raw reads counts in cancer and normal groups are smaller than 25 and only focus on the mature microRNAs. The moderate t-test is applied to find the differently expressed (DE) microRNAs between normal and cancer group. Results: Two major small RNA classes identified from total plasma are miRNA (47.7%) and mRNA (35.0%). The percentage of miRNA increased to 85.3% by Ag2-IP method. The compositions of categories of small RNAs in cancer and normal samples are similar. We identified 28 and 22 differential miRNAs (>2 fold change between cancer and normal group) by total plasma and Ag2-IP meth-
ods respectively. Conclusions: We discovered a unique expression profile of miRNA detectable in the plasma from prostate cancer patients. Extracted RNA from the pellets of anti-Ag2 immunoprecipitations can enhance the detection of miRNA. Expand study to confirm these findings are needed.

#4438 MiRNA expression analysis in the tumor stroma predicts Tenascin C to promote colorectal cancer liver metastasis. Tomohiro Murakami,1 Hisashi Ishimatsu,1 Hiroshi Kikuchi,1 Amane Hirota,2 Tomohiro Matsumoto,3 Yusuke Ozaki,1 Toshiki Kawabata,1 Yoshio Hiramatsu,1 Kinji Kamiya,1 Megumi Baba,1 Takanori Sakaguchi,1 Hiroyuki Konno1. 1Hamamatsu University School of Medicine, Hamamatsu, Japan; 2Department of Surgery Hamamatsu University School of Medicine, Hamamatsu, Japan; 3Hamamatsu University School of Medicine, Hamamatsu, Japan.

Background: Liver is the most common site for colorectal cancer (CRC) metastasis, and mechanisms underlying colorectal liver metastasis need to be explored. The tumor microenvironment consists of many stromal cells which are known to interact with cancer cells and to promote metastasis. Recently many microRNAs (miRNAs) specifically expressed in the stroma is receiving attention. In this study, we analyzed the differences in miRNA expression profiles between peritumoral stroma of CRCs with and without liver metastasis, and sought to identify liver metastasis-promoting molecules that can be regulated by the altered expression of miRNAs in the peritumoral stroma. Materials and methods: The formalin-fixed paraffin-embedded (FFPE) specimens of primary CRCs from 8 patients without metastasis, 4 patients with synchronous liver metastasis and 4 patients with metachronous liver metastasis were used for miRNA array analysis. None of the patients had received any treatment prior to surgery. Tumor stroma was isolated from FFPE samples using laser capture microdissection without contamination of cancer cells, and total RNAs were extracted. The quality of total RNA was assessed, and miRNA expression was analyzed using TaqMan miRNA arrays. Protein expression of Tenascin C (TNC) was immunohistochemically analyzed in 139 primary CRCs. Results: Unsupervised hierarchical clustering classified 16 samples analyzed into two groups according to their miRNA expressions. CRCs with synchronous liver metastasis showed differential miRNA expression profiles from those without liver metastasis or with metachronous liver metastasis. Top10 miRNAs up-regulated in CRCs with synchronous liver metastasis vs. CRCs without liver metastasis or with metachronous liver metastasis were hsa-mir-518b, 618, 186, 520f, 29c, 520e, 155, 30c, 518e and 106b, and those down-regulated in CRCs with synchronous liver metastasis were hsa-mir-302a, 511b, 627, 628-3p, 19a, 372, 302b, 384, 198 and 636. The predictive targets of the top 10 down-regulated miRNAs were analyzed in silico using on-line data base such as mirDB. TNC was identified as a candidate for metastasis-promoting molecule which can be upregulated in the peritumoral stroma followed by the downregulation of miRNAs. Immunohistochemical analysis revealed that protein expression of TNC was higher in the stroma of primary CRCs with synchronous liver metastasis compared with those without liver metastasis or with metachronous liver metastasis. Furthermore, high expression of TNC protein in the primary CRC stroma was correlated with shorter overall survival and liver metastasis-free survival. Conclusions: Alterations of miRNAs in the CRC stroma appear to create a metastasis permissive environment in which TNC plays an important role. Expression of TNC in primary CRC stroma has the potential to be a novel biomarker to predict the risk of postoperative liver metastasis in CRC patients.

The clinical management of prostate cancer is the most common non-skin malignancy in the world is hindered by the limitations of current diagnostic and prognostic tests, such as the low specificity of prostate-specific antigen (PSA) testing, low sensitivity of digital rectal examination (DRE) and complications of biopsies. To try to resolve these issues, we evaluated miRNA abundance in the urine of prostate cancer patients. Alterations in miRNA abundance levels have been reported as playing essential roles in the pathogenesis of cancer and is occurred in a tumor phenotype-specific manner (e.g. aggressive and non-aggressive), miRNAs are stable under diverse analytical conditions and can be detected in various types of body fluids including urine. These characteristics make them as promising non-invasive biomarkers. Here, we examined the intra- and inter-individual variance of urine miRNA abundance by investigating longitudinal changes over months to years in a cohort of patients with localized prostate cancer. We observed a large dynamic range of inter-individual variance in miRNA abundances and identified a set of miRNAs that is stable within individuals, and is biased toward specific biological functions including regulation of transmembrane channel activity. We combined this observation with machine-learning techniques to create a predictive model that can identify aggressive prostate cancer. This four miRNAs predictive model was validated in an independent prostate cancer cohort to non-invasively predict high-risk disease. Remarkably it showed comparable performance to the best existing tissue-based prognostic markers. These results demonstrated that non-invasive biomarkers can be developed to precede or supplement tissue-based tests by understanding the intra- and inter-tumoural heterogeneity of the urine miRNA transcriptome.

The hepatocellular carcinoma (HCC) is one of the most common malignant tumors and carries a poor survival rate. Prognosis, survival and management of patients at risk for developing HCC remain challenging in Egypt and worldwide. Furthermore, poor prognosis of patients with symptomatic (HCC) diagnosed clinically at advanced stages suggests an urgent need for new biomarkers detection that can be used for pre-clinical screening for early detection of premalignant lesions and tumors in high risk to hepatitis C infection. In the present study we used novel formulated anticancer compound(s), combined with or without Sorafenib treatment to exert their antiproliferative effects by eliciting concomitant expression of known or novel biomarkers, including different serum miRNAs, which can be quantitatively analyzed for differences in the levels of metabolites and proteins in the blood and liver tissues of treated HCC xenografts and liver cirrhosis animal models. In addition, circulatory miRNAs levels were measured in these models using markers in 12 month interval-serum samples that were collected from normal, chronic hepatitis C virus infected patient cohorts at the pre-malignant or pre-clinical stages and liver cirrhotic patients that did not develop cancer. Different serum miRNAs, including miR-21, miR-142, let-7a, let-7b, miR-429 and miR-34a were detected in pre-clinical HCC patients and have the potential to screen for hepatitis C virus infected patients at high risk to develop HCC 12 months after miRNAs detection. Our data of detected serum miRNAs from animal models and patient samples can be used to confirm and correlate histological and histochemical results at various time points with serum or imaging biomarkers, which may have a great promise for the prediction and prevention of HCC in high risk Egyptian populations.

We previously reported the identification of a signature composed by 34 serum circulating cell-free microRNAs (cf-miRNA) diagnostic for lung cancer. Using this signature, we developed a blood test (miR-test) which was capable of detecting asymptomatic lung cancer in a large cohort (N>1000) of high-risk individuals (>50-years and smokers). Interestingly, we now found that a fraction (~30%) of these cf-miRNAs were preferentially expressed in cells of epithelial origin, while another ~30% were more expressed in hematopoietic cells. We reasoned that this cf-miRNA signature could result from the extracellular release of miRNAs from cancer epithelial cells as well as from immune/stromal cells after the tumor cell death. Therefore, we developed an integrated strategy for the identification of the origin of cf-miRNAs through combined analysis of published circulating and intracellular microRNAs expression datasets (microarray and qRT-PCR based) and of NGS analysis of cf-miRNAs in lung tumors. Our approach will contribute elucidating the biological role of cf-miRNAs in lung cancer and explore eventual therapeutic implications.

#4442 microRNA in FA defective tumor. Shirley Tang,1 Li Gao,2 Kathleen Kathleen,3 Andrew Fink,3 Arjan Kalvala,3 Brittany Aguila,3 Gregory Otterson,1 Miguel Villalona-Calero,2 Wenrui Duan1. 1Ohio State University, Columbus, OH; 2Miami Cancer Institute, Miami, FL; 3Florida International University, Miami, FL.

The Fanconi Anemia (FA) pathway is essential for human cells to maintain DNA integrity following DNA damage. This pathway is involved in the endogenous release of miRNAs from cancer epithelial cells as well as from immune/stromal cells after the tumor cell death. FA is a disease that affects about 1 in 100,000 individuals. It is an inherited cancer predisposition syndrome characterized by bone marrow failure and high risks of solid and hematologic malignancies. The FA pathway is essential for human cells to maintain DNA integrity following DNA damage. This pathway is involved in the endogenous release of miRNAs from cancer epithelial cells as well as from immune/stromal cells after the tumor cell death. FA is a disease that affects about 1 in 100,000 individuals. It is an inherited cancer predisposition syndrome characterized by bone marrow failure and high risks of solid and hematologic malignancies.
MOLECULAR AND CELLULAR BIOLOGY / GENETICS: MicroRNA Profiling in Cancer

changes in developmental and physiological processes including cancer. It has been published that some miRNAs are tumor suppressors, and others are onco-
genesis. However, microRNAs and the FA pathway in relationship to lung cancer progression remain unknown. In order to elucidate the role of FA related miRs in human lung cancer development or treatment, we analyzed miR expression in lung cancer samples and normal lung tissues. Several high-affinity targets for miR-25 were identified using miRNA microarray analysis. Using Nanostring technology, miR-25 expression was found to be regulated by miR-143-3p. These results suggest that miR-25 may be a potential therapeutic target for lung cancer treatment.

#4443 SPARC overexpression alters microRNA expression profiles involved in tumor progression. Bhavesh K. Ahir, Sajani Lakka. University of Illinois at Chicago, Chicago, IL.

Medulloblastoma is the most common of malignant brain tumor in children. SPARC (secreted protein acidic and rich in cysteine), a multisecretory non-structural glycoprotein is known to be involved in multiple processes in various cancers. Pre-
viously, we reported that SPARC expression significantly impairs medulloblastoma tumor growth in vivo and alters chemo sensitivity. MicroRNAs are a class of post-
transcriptional gene regulators with critical functions in tumor progression. In ad-
tion, they also play role in regulation of vital genes that control mechanisms of transcriptional gene regulator with critical functions in tumor progression. In ad-
dition, they also play role in regulation of vital genes that control mechanisms of transcriptional gene regulator with critical functions in tumor progression. In ad-
tion, they also play role in regulation of vital genes that control mechanisms of transcriptional gene regulator with critical functions in tumor progression.

Potential messenger RNA (mRNA) targets of the differentially expressed miRNA were identified using Ingenuity Pathway Analysis (IPA). Network-based functional analyses were performed on the available human protein interaction and miRNA-gene association data to highlight versatile miRNAs among the significantly deregulated miRNAs using the IPA, and the biological pathway analysis using the PANTHER web-based tool. We identified six miRNAs (miR-125b-1*, miR-146a-5p, miR-181a-5p, miR-204-5p, miR-219-5p and miR-509-3p) which are differentially regulated with SPARC expression in medulloblastoma cells. Furthermore, pathway enrichment analysis output line that these six microRNAs mainly belong to biological processes related to cancer related signaling pathways. Collectively, these results suggest that a perturbed ex-
pression for these six miRNAs and their complex regulatory loops contribute to tumor suppressive effects in SPARC overexpressed medulloblastoma cells.

#4444 MicroRNA hsa-miR-145 expression in hepatocellular carcinoma correlates with patient survival. Go Nakajima, Kazuhiko Hayashi. Tokyo Women’s Medical Univ., Tokyo, Japan.

Aim: MicroRNAs (miRNAs) are known as one of the regulator of gene expression at a post-transcriptional level. Previous study from our group identified forty nine miRNAs that are expressed differentially by comparing 26 pair samples of hepatocellular carcinoma (HCC) tumor tissue and non-tumor liver tissue using next-generation sequencer system, and hsa-miR-145, one of the candidate miRNA was chosen for this validation study. The expression of hsa-miR-145 in validation set HCC samples were measured by real-time PCR, and we exam-
ined the correlation between the miRNA expression and clinical data. Patients and Methods: Herein, we determined microRNA (miRNA) expression profiles in hepatocellular carcinoma tissue and non-tumor liver tissue to identify the expression level of each miRNA relative to control. Of the top one hundred expressed miRNAs, we determined statistically significant differences in the expression of two miRNAs (miR-21, -31, -34a, -125b, -199a, -204, and -1246) between fresh primary tumor samples and fresh adjacent normal tissue (ANT) collected from patients diagnosed with HCC, SCC in situ, or invasive SCC. Total RNA was isolated from each tissue type using the miRNeasy Micro Kit (Qiagen) according to the manufacturer’s instructions. The RNA was quantified using a NanoDrop spectrophotometer (Thermo Fisher Scientific). RNA integrity was assessed using an RNA PicoChip on a Bioanalyzer 2100 (Agilent Technologies). The RNA samples that met the criteria of 18S/28S ratio greater than 1.5 and RNA Integrity Number greater than 7 were subjected to miRNA expression analysis. miRNA expression data was generated using the Affymetrix microRNA Array (Affymetrix, Santa Clara, CA). The expression levels of miRNAs were determined using miRNA arrays. The expression data were analyzed using the partitional clustering method to identify miRNA expression patterns. We performed a one-way ANOVA followed by the Bonferroni post hoc test to compare the expression levels of each miRNA in different samples. Results: A total of 27 differentially expressed miRNAs were identified between the control and SPARC overexpressed samples. Potential messenger RNA (mRNA) targets of the differentially expressed miRNA were identified using Ingenuity Pathway Analysis (IPA). Network-based functional analyses were performed on the available human protein interaction and miRNA-gene association data to highlight versatile miRNAs among the significantly deregulated miRNAs using the IPA, and the biological pathway analysis using the PANTHER web-based tool. We identified six miRNAs (miR-125b-1*, miR-146a-5p, miR-181a-5p, miR-204-5p, miR-219-5p and miR-509-3p) which are differentially regulated with SPARC expression in medulloblastoma cells. Furthermore, pathway enrichment analysis output line that these six microRNAs mainly belong to biological processes related to cancer related signaling pathways. Collectively, these results suggest that a perturbed ex-
pression for these six miRNAs and their complex regulatory loops contribute to tumor suppressive effects in SPARC overexpressed medulloblastoma cells.

#4445 MicroRNA profile of excised cutaneous squamous cell carcinoma tissues comparative to adjacent normal tissue. Christopher S. Pulford, Ellie M. Loomis, McKale R. Montgomery, Chandana K. Uppalapati, Agnes S. Pascual, Elizabeth E. Hull, Katherine F. Leyva. Midwestern University, Glendale, AZ.

Cutaneous Squamous Cell Carcinoma (cSCC) is the second most common form of skin cancer commonly arising from sun-induced mutations. As most cases of cSCC are treated by tumor excision, research aimed at understanding factors influencing the metastasis, and possible alternative treatments, of cSCC is limited. Cancer metastasis is a multistep process, including epithelial-to-mesenchymal transition (EMT). During EMT, epithelial cells undergo a dedifferentiation process whereby they transition to a highly mobile and invasive mesenchymal cell type with metastatic capacities. Although the factors influencing EMT are varied, one important mediator of intercellular communication shown to be involved in oncogenesis is miRNA. Our work focuses on miRNAs, which are small non-coding RNA species that may be one epigenetic factor contribut-
ing to the progression of cSCC. In this study, we compared the expression pattern of seven miRNAs (miR-21, -31, -34a, -125b, -199a, -204, and -1246) between fresh primary tumor samples and fresh adjacent normal tissue (ANT) collected from patients diagnosed with cSCC, SCC in situ, or invasive SCC. Total RNA was isolated from each of the samples and qPCR on all samples was performed to determine the expression level of each miRNA relative to control. Of the seven miRNAs tested, three miRNAs were found to be up-regulated, miR-21, miR-31, and miR-204 in the tumor versus control samples. One-way ANOVA was used to compare miRNA expression levels.

In this study, we compared the expression pattern of seven miRNAs (miR-21, -31, -34a, -125b, -199a, -204, and -1246) between fresh primary tumor samples and fresh adjacent normal tissue (ANT) collected from patients diagnosed with cSCC, SCC in situ, or invasive SCC. There was significant difference in miRNA expression of normal samples between patients who had breast cancer in the opposite breast compared to those who did not (p=0.03269) and patients with sleep problems and those who did not (p=0.00344). It is interesting to note that night shift work and sleep problems both represent forms of circadian disruption, yet only the latter showed significant difference in miRNA expression between controls. It is expected that patients with cancer in the other breast may exhibit significantly different reads from patients who have never had breast cancer. Future analyses will be performed using additional samples to build on these findings.

#4447 Analysis of small RNA-seq data for differential expression of small noncoding RNAs in human colorectal cancer. Srinivas V. Koduru,1 Amit K. Tiwari,1 Sprague W. Hazard,1 Milind K. Mahajan,2 Dino J. Ravnic1.1 PennState University, Hershey, PA; 2University of Toledo, Toledo, OH.

Background: Cancer is a major cause of deaths worldwide, despite improved healthcare and technologies. Recent advancements in genome sequencing have led to the rapid study of the whole transcriptome and small RNAs with their biological functions. Non-coding RNAs (ncRNAs) play an important role in biological processes that greatly impact biomarker development for diagnosis, prognosis, and therapy. Non-coding RNAs such as microRNAs (miRNA), Piwi-interacting RNAs (piRNAs), small nuclear/nucleolar RNAs (sn/snoRNAs) have recently been studied to understand their biology and pathology. Results: In the present study, we used eight matched colorectal patient tissue samples (benign, tumor, and metastasis) small RNA sequencing data remapped for various small RNA annotation. We identified aberrant expression of 13 miRs in tumor and metastasis specimens (tumor vs benign: 19 miRs) and metastasis vs benign group (38 miRs) of which five were upregulated, and eight were downregulated, during disease progression. We also investigated pathway analysis on aberrant expression of miRNAs, which showed majority of miRs involved in the colon other types of cancers. Further analysis of piRNAs revealed that six piRNAs in tumor vs benign and 24 in metastasis vs benign samples (commonly in both groups, only two piRNAs). Additionally, we examined other types of small RNAs (sn/snoRNAs, mt RNA, misc RNA, non-sense mediated decay (NMD) and rRNA), we identified 15 in tumor vs benign and 104 metastasis vs benign and only four in commonly expressed. Conclusion: In summary, our results identified multiple snoRNAs during colorectal cancer progression which needs to be further validated and can be used for prognosis, diagnosis, and therapeutic potentials.

#4448 Elevated levels of circulating miR-34a-5p and miR-181c-3p during cancer initiation by aflatoxin B1.1 Merrick C. Livingstone,1 Bill D. Roebuck,1 Natalie M. Johnson,2 Thomas W. Kensler,1 John D. Groopman.1 Johns Hopkins University School of Public Health, Baltimore, MD; 2Dartmouth Medical School, Hanover, NH; 3Texas A&M School of Public Health, College Station, TX; 4Icahn School of Medicine, Mount Sinai, New York, NY.

Purpose: New prognostic biomarkers for prostate cancer (PC) risk stratification are urgently needed. Here, we identify and validate a novel 4-miRNA prognostic ratio model for prostate cancer. We also identify new microRNAs with tumor suppressive characteristics in prostate cancer cell lines. Methods: PC tissue samples from 123 radical prostatectomy (RP) patients, 58 of whom experienced biochemical recurrence (BCR), were obtained from the RGP (training cohort). Initially, we identified 11 top candidate prognostic miRNAs (P < 0.05, univariate Cox regression). Based on these, all possible 2-4 miRNA ratio models were systematically tested for their potential to predict time to biochemical recurrence (BCR), as assessed by Kaplan-Meier, uni- and multivariate Cox regression analyses. The findings were validated in two independent RP cohorts. A novel ratio model was included in the final validated model and with previously unreported functional effect in prostate cancer, was over expressed using a microRNA mimic in PC3 and DU145 cells to evaluate its effect on prostate cancer cell viability and proliferation. Results: We identified a new prognostic 4-miRNA ratio model ((miR-23a-3p/miR-10b-5p/miR-133a-5p-miR-374b-5p)) that significantly predicted time to BCR independently of established clinicopathological variables in a training RP cohort (n=123). The ratio model was successfully validated in two independent RP cohorts including 112 and 476 patients, respectively. Ectopic expression of one of these miRNAs (miR-374b-5p) significantly inhibited viability and proliferation in two prostate cancer cell lines, suggesting it has a tumor suppressor function in PC. Conclusions: Here, we describe the identification and independent validation of a 4-miRNA ratio model that allows risk stratification of prostate cancer patients undergoing RP into different prognostic groups. Furthermore, we identify and functionally characterize a novel possible tumor suppressor miRNA in prostate cancer.

MOLeCULAR AND CELLULAR BIOLOGY / GENETICS: MicroRNA Profiling in Cancer

#4449 Thrombospondin-1 regulation by MD2 in aggressive cancers. Priya Dondapati,1 Jason Maragh,1 Karna Mangrola,1 Ali Alaseem,1 Khadija Cheema,1 Thiagarajan Venkatesan,1 Sivanesan Dhandayuthapani,1 Appu Rathi,1 2Nova Southeastern Univ, Fort Lauderdale, FL; 3Rambaugh Goodwin Institute for Cancer Research, Fort Lauderdale, FL.

MDM2 amplification, which is often seen in different cancer types, indicates that it plays an important role in tumorigenesis and also in cancer metastasis. Amplification of the MDM2 gene correlates with poor prognosis, aggressive growth, and recurrence. Thrombospondin-1 (TSP-1) that is expressed by THBS1 gene is a matricellular protein, and is known to have differential expression in cancers. When TSP-1 activates Transforming Growth Factor-β1 (TGF-β1) through latent cytokine complexation, the activated TGF-β1 contributes to the Epithelial-Mesenchymal Transition (EMT) which is known to impart cell-stem-like characteristics and drug resistance to the cancer cells. However, no studies regarding MDM2’s role in THBS1 regulation have been carried out so far. Therefore, the objective of this study was to determine the correlation between MDM2 and THBS1 expression in MDM2 overexpressing cancers. For this purpose the SJA-1 osteosarcoma cells were cultured at 37 °C under humidified air/O2 (19/1) in RPMI-1640 complete medium supplemented with 10% FBS, 10,000 U/mL penicillin, 10,000 μg/mL streptomycin, 1% (+) L-glutamine, and 1% amphotericin B. The cells were incubated in the presence of 20 μM of Nutlin-3 for 24 hrs, following which, RNA and protein were extracted and subsequently purity and concentration were determined. Reverse Transcriptase Polymerase Chain Reaction (RT-PCR) and western blotting were performed using specific primers, primary and the secondary antibodies respectively. Interestingly elevated levels of TSP-1 and TGFβ1 were observed in these SJA-1 cells. However, after treatment with Nutlin-3, an MDM2-p53 interaction inhibitor, a significant increase in p53 was noted. However, contrary to the existing literature, where studies have shown p53 to positively regulate TSP-1 levels, we observed an opposite outcome. Despite the Nutlin-3 induced elevation in p53 levels, a significant decrease in TSP-1 level was observed indicating that MDM2 may be regulating THBS1 gene expression in a p53 independent manner, in MDM2 overexpressing SJA-1 cells. The findings of this study suggest a novel, p53 independent role for MDM2 in THBS1 regulation. Since MDM2 amplification can positively induce TSP-1 levels, which is one of the natural activators of TGF-β1, it is anticipated that stimulatory signal flowing through MDM2 - TSP-1 - TGF-β1 axis may induce the cancer cells to undergo EMT, thereby increasing their metastatic ability and promote cancer stem cell characteristics. This novel MDM2-regulated pathway can very well serve as a drug target and might play a biologically relevant role in the treatment of cancer metastasis. Our future studies will include validation of this correlation in multiple cancer cell lines, to
The role of paired-like homeodomain 2B in non-small cell lung cancer progression. Sheng-Yi Lin,1 Yu-Han Huang,1 Yi-Hua Lai,1 Sung-Liang Yu,1 Sheng-Fang Su,2 Tse-Ming Hong,2 Gee-Chen Chang,3 Chi-Chung Wang,4 Jeremy J.W. Chen,1,5 National Taiwan University College of Medicine, Taipei, Taiwan; 2National Taiwan University College of Medicine, Taipei, Taiwan; 3National Taiwan University, Taipei, Taiwan; 4National Cheng Kung University, Tainan, Taiwan; 5Taichung Veterans General Hospital, Taichung, Taiwan; 6Fu Jen Catholic University, New Taipei, Taiwan.

The transcription factor PITX2 (paired-like homeodomain 2) is well known to play an essential role in normal embryonic development. Emerging evidence suggests that PITX2 may be involved in human tumorigenesis. However, the functional role that PITX2 plays in tumor progression remain unclear. In this study, we investigated its function in human non-small cell lung carcinoma (NSCLC). Using real-time quantitative RT-PCR, we demonstrated that PITX2B is the most abundant isoform in lung cancer cells. Enforced expression of PITX2B could promote lung cancer cell morphological change, migration, invasion, anchorage-dependent growth ability and tumorigenesis in xenograft model mice. In addition, nuclear PITX2B localization was correlated with its oncogenic functions and two important nuclear localization signals (NLSs) were identified. Moreover, high expression of PITX2B was associated with poor overall survival of NSCLC patients. Importantly, silencing of PITX2B by siRNA caused a marked increase in autophagy based on LC3-II, Beclin-1, and p62 protein expression, acridine orange fluorescence of acidic vacuoles and electron microscopic detection of autophagosomes. Furthermore, we found that the autophagy induced by PITX2B knockdown preceded apoptosis in lung cancer cells. Treatment of lysosome inhibitor, NH4Cl, could provide a protective effect that increases cell viability. In conclusion, our studies not only provide new insights into how PITX2B may contribute to the tumor progression in lung cancer but also the autophagy induced by PITX2B knockdown that may be developed as an effective therapeutic strategy for the treatment of lung cancer.

Elevated ubiquitin-specific protease 22 (USP22) is associated with enhanced malignancy, therapeutic resistance, and poor prognosis of various human cancers. In this study, the clinicopathological significance of USP22, therapeutic implication of targeting USP22, and underlying molecules of USP22 knockdown were investigated in human non-small cell lung cancer (NSCLC). Immunohistochemistry analysis revealed that USP22 protein was dramatically elevated in ~67% of 197 NSCLC cases compared with adjacent normal lung tissues. Importantly, statistical analysis demonstrated that elevated USP22 was positively associated with advanced cancer stage and a trend to poor prognosis of NSCLC patients. Moreover, siRNA-mediated knockdown of USP22 induced a cell cycle arrest in G1 phase and significantly suppressed cell proliferation and soft agar colony formations in NSCLC cell lines. In addition, knockdown of USP22 significantly enhanced cisplatin-induced genotoxic effects in NSCLC cell lines. Furthermore, USP22 silencing substantially down-regulated SIRT1 and upregulated p53 tumor suppressor in NSCLC cells, indicating downregulation of USP22 may boost p53-mediated tumor suppression and DNA damage response in NSCLC cells. Knockdown of USP22 also increased global histone H3F monoubiquitlation, H3K4 and H3K79 trimethylation leading to global gene expression profile changes in these NSCLC cells. These results suggest that targeting USP22 will have broad anti-cancer effects via altering multiple cancer signaling pathways. Taken together, data of this study further indicate that the elevated USP22 may potentially represent a prognostic factor and therapeutic target for NSCLC patients.

Study of the mechanisms of emetine dihydrochloride on inhibiting NSCLC tumor progression and attenuating EGFR signaling pathway. Yi-Hua Lai,1 Wan-Ting Huang,2 Sheng-Yi Lin,1 Yao-Ting Huang,2 Yuh-Ling Chen,3 Yu-Han Huang,1 Yi-Hua Lai,1 Sung-Liang Yu,1 Sheng-Fang Su,2 Tse-Ming Hong,2 G. Chen,3 Institute of Medical Science, The University of Tokyo, Tokyo, Japan; 2University of Chicago, Chicago, IL.

Lung cancer is the leading cause of cancer deaths worldwide. Since the number of patients responding well to standard therapies is still limited, further development of new anti-cancer agents with minimum risk of adverse event is urgently awaited. To screen oncoresources which could be used for the development of new diagnostic biomarkers and molecular targeted drugs, we have established a screening system as follows: i) To identify overexpressed genes in 120 lung cancers by genome-wide screening using the microarray representing 27,648 genes and pure populations of tumor cells taken from cancer tissues by laser microdissection, ii) To verify the genes for their very low or absent expression in normal tissues by northern blotting, iii) To validate the clinicopathological significance of their expression with tissue microarray covering hundreds of archived lung cancers, iv) To verify whether the target genes are essential for the growth or survival of lung cancer cells by RNAi and cell growth assays. During this process, we selected dozens of druggable oncogenes with various enzymatic activities, and identified overexpression of protein kinase LASK2 (lung cancer-associated kinase 2) in the majority of lung cancers, but not in normal tissues except testis. Immunocytochemical analysis found LASK2 to be mainly localized in the cytoplasm and nucleus of lung cancer cells. Immunohistochemical analysis revealed that strong LASK2 expression was an independent prognostic factor for non-small cell lung cancer (NSCLC) (P<0.0001). Suppression of LASK2 expression with its specific siRNAs caused growth inhibition of lung cancer cells. These findings are consistent with previous reports showing the involvement of LASK2 in mammalian cells also supported its oncogenic function. Since LASK2 plays a significant role in the cell proliferation and malignant nature of lung cancers, LASK2 is likely to be a prognostic biomarker and a potential therapeutic target for developing new anti-cancer drugs.

MED12 is recurrently mutated in Middle Eastern colorectal cancer. Abdul K. Siraj,1 Tariq Masoodi,1 Rong Du,1 Fouda Al-Dayer,2 Khawla S. Al-Kurai,1 King Faisal Specialist Hospital & Res. Ctr., Riyadh, Saudi Arabia.

Colorectal cancer (CRC) is a common cancer and a leading cause of cancer deaths. Previous studies have identified a number of key steps in the evolution of CRC but our knowledge of driver mutations in CRC remains incomplete. Recognizing the potential of studying different human populations to reveal novel insights in disease pathogenesis, we conducted genomic analysis of CRC in Saudi patients. In the discovery phase of the study, we conducted whole-genome sequencing of tumor and corresponding germline DNA in 27 CRC patients. In addition to known driver mutations, we identified three MED12 somatic mutations. In the replication phase, we employed a next-generation sequencing approach to capture and sequence MED12 and other candidate genes in a larger sample of 400 CRC patients and confirmed the enrichment for recurrent MED12 mutations. In order to gain insight into a plausible biological mechanism for the potential role of MED12 mutations in CRC, we studied CRC cell lines that differ substantially in the expression level of MED12, and found the latter to be correlated inversely with TGF-β signaling and directly with apo-
ptosis in response to chemotherapeutic agents. Importantly, these correlations were replicated when MED12 expression was experimentally manipulated. Our data expand the recently described role of MED12 as a tumor suppressor in colorectal cancer. In this study, we reasoned that since the frequencies of driver mutations have been shown to be different between ethnic groups, comparison of targeted exome sequencing of 1,321 genes of interest to determine the mutations observed in breast cancer cells, suggesting that this is not lung cancer specific. Transcriptional activity of the Notch-responsive luciferase construct (pHESLuc) was increased in the presence of Wt Notch4, and reduced in the presence of the P1663Q Notch4 Mu. Conclusion: The nature and high number of genetic alterations in Notch4 in H/L lung cancer patients, suggests that Notch4 may play a critical role in NSCLC tumorigenesis. Our data suggests that mutations in the ANK domain of Notch4 can interfere with its transcriptional activity and function, and should be further characterized.

#4455 Inverse relationship between exon 8 single nucleotide polymorphism (c.1293 C>T) of gigaxonin and human tumor cell growth. Eri S. Srivatanan,1 Kimberly J. Hwang,1 Albert Ko,1 Jenna R. Chatoff,1 Saroj K. Basak,1 Natasija Bajic,1 Xiao Zhang,1 Jordan J. Yousefi,2 Michael S. Lewis,1 Pascale Bombon,3 Marilene B. Wang,3 1VA Greater Los Angeles UCLA David Geffen School of Medicine, Los Angeles, CA; 2UCLA David Geffen School of Medicine, Los Angeles, CA; 3INM-INSERM U1051, Hospital St Eloi, Paris, France.
Gigaxonin, a product of the Giant Axonal Neuropathy (GAN) gene located on chromosome 16, is involved in intermediate filament processing of neural cells and vimentin fibers in fibroblasts. Previous studies have shown an interaction between p16 and gigaxonin in cisplatin mediated ubiquitination of p53. Genomic studies have indicated higher frequency (44.25%) of exon 8 single nucleotide polymorphism (SNP) (c.1293 C>T) of gigaxonin in the individuals of Caucasian population compared to normal population (22%). The polymorphism frequency is much lower in individuals of other ethnicities. To determine the relation of exon 8 polymorphism with HPV positive and negative cervical and head and tumors. Our studies showed a 47.25% polymorphism frequency in these tumors. There was no relationship between the presence of polymorphism and HPV status. However, there was an inverse relationship between polymorphism and tumor recurrence. Our studies have further shown higher expression of gigaxonin protein in cancer cell lines containing the polymorphic T allele. Growth assays in vitro and in soft agar have shown a direct relationship between the presence of the T allele and slower cell line growth. Our results therefore indicate that in addition to p16 expression, exons 8 SNP could also serve as a diagnostic marker of chemo sensitivity in human tumors.

#4456 Regulation of MYC protein stability by mutant KRAS in pancreatic ductal adenocarcinoma. Angelina V. Vaseva,1 Devon R. Blake,1 Salma H. Azam,1 Karim T. Gilbert,1 Chad V. Pecot,1 Kenneth H. Pearce,1 Laura E. Herring,1 Lee M. Graves,1 Peter J. Houghton,1 Channing J. Der,2 1UNC-Chapel Hill, Chapel Hill, NC; 2Greehey Children’s Cancer Research Institute, San Antonio, TX.
With the nearly 100% mutation frequency of KRAS in pancreatic ductal adenocarcinoma (PDAC), the development of therapeutic strategies to target KRAS is a high priority for the pancreatic cancer field. In the current study, we aimed to identify signaling changes caused by the acute suppression of mutant KRAS in PDAC cell lines. Strikingly, acute suppression of mutant KRAS in PDAC cell lines caused potent and rapid protesome-dependent degradation of MYC protein. Ablation of MYC also suppressed PDAC growth both in vitro and in vivo, indicating a critical driver role for MYC in KRAS-dependent PDAC tumorigenesis. A mechanism by which RAS effector signaling regulates MYC protein stability has been described, however we determined that this mechanism cannot fully account for how endogenous mutant KRAS stabilizes MYC protein in PDAC cells. We verified a role for the Raf-MEK-ERK but not the PI3K-AKT-GSK3β effector signaling pathway. Unexpectedly, we also excluded a role for MYC protein phosphorylation at MYC residue T58, and determined that ubiquitin ligases other than FBW7 are involved. These findings prompted us to search for additional KRAS-dependent protein kinases that facilitate MYC protein stability. We applied multiple screening strategies. First, we developed a novel fluorescence-based system to monitor real-time MYC protein degradation in PDAC cells and we adapted this system for use in a high-throughput flow-cytometry based assay. Second, we applied a mass spectrometry-based approach to profile the human kinome for KRAS-dependent changes in protein kinases. Finally, we applied gain-of-function (Cancer Toolkit) and loss-of-function (CRISPR/Cas9) genetic screens to identify signaling regulators of MYC protein stability. The results of these screens will be presented.

#4457 Novel oncogenic function of Notch4 in Hispanic lung cancer. Edna Gordian,1 Nicholas Gimbrone,1 Antonio Pannuti,2 Lucio Miele,2 W. Douglas Bomont,3 Marilene B. Wang,3 1Keimyung University, Daegu, Republic of Korea; 2Stanley S.Scott Cancer Center, New Orleans, LA.
Background: Molecular drivers of ~40% of lung adenocarcinomas are still unknown. We reasoned that since the frequencies of driver mutations have been shown to be different between ethnic groups, comparison of targeted exome sequencing data would identify genes with significant alteration frequencies between White Non-Hispanics (WNH) and other racial/ethnic groups. Notch signaling in cancer is context- and tissue-specific and may be both oncogenic and tumor suppressive. The mechanisms of action and genetic alterations involved in Notch oncogenesis have been studied for Notch1 and Notch3; specifically in Non-Small Cell Carcinoma (NSCLC), translocations in Notch3, and gain-of-function mutations in Notch1. Meanwhile, Notch4 has been associated with the notion of cancer driver but its exact role remains unknown. We hypothesized that Notch4 is a mammary oncogene, but little is known about its role in NSCLC tumorigenesis. Truncations in Notch4 have been reported in lung cancer cell lines, and in public databases the frequency of Notch4 alterations in WNH adenocarcinoma is ~5.5%. However, little is known about the mechanisms by which Notch4 acts in lung oncogenesis. Methods: Using data from the TCGA, we analyzed targeted sequencing of 1,321 genes of interest to determine the mutations driving lung cancer in Hispanic (H/L) patients. The functional relevance of the Notch4 mutations was tested by cloning the intracellular domain (ICD) of Notch4 containing one of the mutations identified in the ANK domain (P1663Q) into pcDNA3.1. Plasmids expressing either the WT or a mutated Notch 4 (P1663Q) were transfected into A549 cells and the effect of this mutation tested on the ability to induce the expression of Notch4 expression genes. Results: In our H/L cohort we see Notch4 altered in about 20% of our samples, and 7/12 of the Notch4 single amino acid substitutions are in the Negative Regulatory Region (NRR). PROVEAN protein analysis of the Notch4 mutations shows that more than half of the mutations would disrupt the NRR. Introduction of the P1663Q mutation in the ANK repeats of the Notch4 ICD, which mediates binding to CSL and is essential for Notch transcriptional activity, resulted in a shift in the amount of transcript of known Notch4 target genes, such as Hes1 and Sema. This effect is specific, as it is not observed with other genes, previously reported to be targets for other Notch paralogs such as Sema3 and Zeb1. A similar effect of the P1663Q Notch4 mutation on Hes1 transcript levels was observed in breast cancer cells, suggesting that this is not lung cancer specific. Transcriptional activity of the Notch-responsive luciferase construct (pHESLuc) was increased in the presence of Wt Notch4, and reduced in the presence of the P1663Q Notch4 Mu. Conclusion: The nature and high number of genetic alterations in Notch4 in H/L lung cancer patients, suggests that Notch4 may play a critical role in NSCLC tumorigenesis. Our data suggests that mutations in the ANK domain of Notch4 can interfere with its transcriptional activity and function, and should be further characterized.
confirmed the expressions of GLDC in eight different ovarian cancer cell lines. And colony formation assay revealed decreased proliferation of OVCAR3 ovarian cancer cells transfected with siGLDC compared with that of control. Intriguingly, we found that knockdown of GLDC induced decreased S-adenosylmethionine (SAM)/S-adenosylhomocysteine (SAH) ratio, which implicates methyl donor deficient state in OVCAR3 cells. Expressions of sirtuin 1 (SIRT1), heat shock protein (HSP) 90 and heat-shock factor protein 1 (HSF1) decreased while that of p53 increased in GLDC knock-downed cells, suggesting heat shock response. Addition of SAM into siGLDC knock-downed cells restored the expression of SIRT1. Inhibition of SIRT1 decreased Bc2 and increased cytochrome c expressions. In summary, these results suggest GLDC induces methyl donor deficient state in OVCAR3 ovarian cancer cells, which in turn leads to apoptosis via SIRT1-mediated pathway.

**#4460 TET1 over expression contributes to lung cancer malignancy**, Piote Teodor Filipczak, Shuguang Leng, Carmen S. Tellez, Steven A. Belinsky. Lovelace Respiratory Research Inst., Albuquerque, NM.

Epigenetic alterations are a leading cause of lung carcinogenesis and malignancy. While the role of enzymes catalyzing cytosine-guanine (CpG) island methylation and chromatin modifications has been extensively studied, the role of the recently discovered demethylating enzymes represented by ten-eleven translocation methylcytosine dioxygenases (TETs) remains unknown. The goal of this study was to investigate the expression and functional significance of the TET1 gene in non-small cell lung cancer (NSCLC). QRT-PCR revealed 2- to 30-fold over expression of TET1 in 52% of squamous cell carcinoma (SCC) and 40% of adenocarcinoma (AdC) tumors compared to paired normal lung tissues. This result was validated using The Cancer Genome Atlas (TCGA) database with TET1 over expressed in 72% of SCCs and 53% of AdCs. Elevated levels of TET1 transcript were associated with increased protein levels in NSCLC cell lines compared to normal human bronchial epithelial cells (HBECs). A reporter assay analysis defined the promoter region critical for elevated transcription of the TET1 gene using lung cancer cell lines, and studies to identify the transcription factors underlying the increase in expression are underway. Transient knock down of TET1 expression in NSCLC cell lines caused global changes in the transcriptome, reduced cell proliferation, colony formation, and inhibited growth of tumor xenografts in nude mice. Cellular senescence mediated by p21 signaling and associated with β-galactosidase activation was identified as one mechanism underlying growth inhibition. This study suggests that TET1 may function as an oncogene contributing to the lung cancer malignant phenotype and thus, could serve as a potential new target for treatment. (Supported by R01 CA183296)

**#4461 Detection of somatic mutations in exosomal RNA from human oral squamous cell carcinoma cells**. Norikazu Tokuzen, Koh-ichi Nakashiro, Hirokiyo Hamakawa. Ehime Univ. Graduate School of Medicine, Toon, Ehime, Japan.

Exosomes are small vesicles, ranging from 30 to 100 nm in size, secreted from most types of cells. They contain proteins, lipids, and nucleic acids (e.g. DNA, mRNA, and microRNA) and are thought to play an important role in cell proliferation, invasion, and metastasis in human malignancies. Recently, circulating exosomes have also been of interest as a source for liquid biopsies. In this study, we examined the usefulness of exosomal RNA as a biomarker and attempted to detect the tumor-specific gene mutations from exosomal RNA derived from human oral squamous cell carcinoma (OSCC). We used 3 human OSCC cells (HSC2, KT-T, KT-N). KT-T and KT-N cells were established from the lower gingival tumor and lymph node metastasis, respectively. First, we detected the somatic mutations in genomic DNA extracted from these cells by next-generation sequencing (NGS) with the use of HaloPlex Cancer Research Panel (Agilent Technologies). PIK3CA H1047R mutation was identified in all OSCC cells, and KT-N cells had the additional HRAS Q61R mutation. We confirmed these mutations of PIK3CA and HRAS in OSCC cells by TaqMan SNP Genotyping Assays (Thermo Fisher Scientific). Subsequently, we evaluated the gene mutations in exosomal RNA from these OSCC cells. Exosomal RNA was isolated from the conditioned medium using exoRNeasy Serum/Plasma Maxi Kit (Qiagen) according to the manufacturer’s protocol. In exosomal RNA, we found the PIK3CA H1047R mutation from all OSCC cells and HRAS Q61R mutation from KT-N cells by genotyping assays. Furthermore, we assessed the detection of these mutations in tumor xenograft mouse models. KT-T and KT-N cells (5 x 106) complexed with Matrigel® (BD) in 100-μl aliquots were injected subcutaneously in the flank of male athymic nude mice. Exosomal RNA was isolated from the serum of tumor-bearing nude mice using exoRNeasy Serum/Plasma Midi Kit (Qiagen). By genotyping assays using serum exosomal RNA, PIK3CA H1047R mutation was observed in both types of xenograft mice and HRAS Q61R mutation was positive in KT-N xenograft mice. Cancer cell-derived exosomal RNA had the same gene mutations in those cells, and could be detected in the serum of tumor-bearing nude mice. These results suggest that exosomal RNA is useful for detecting somatic mutations in OSCC cells.

**#4462 ACTN4 stabilises RIPK1 to function as an oncogenic driver in melanoma**. Lei Jin, Hessam Tabatabaehamakhsh, Chen Chen Jiang, Xu Guang Yuan, Jun Yuan Yang, Yuan Yuan Zhang, Hamed Yari, Chatin Van Vaang, Ting Li, Fu Xi Lei, Yu Chen Feng, Su Tang Guo, Xu Dong Zhang. The University of Newcastle, Callaghan, Australia.

We have recently reported that receptor-interacting protein kinase 1 (RIPK1) is commonly up-regulated through cellular inhibitor apoptosis protein (cIAP)-mediated stabilization and functions as an oncogenic driver via activation of NF-κB in melanoma cells. Here we show that α-actinin-4 (ACTN4), an isoform of α-actinins of spectrin superfamilies that is emerging as an oncogenic regulator, is required for cIAP-mediated stabilization of RIPK1 and plays a pro-oncogenic role in melanoma. Similar to RIPK1, ACTN4 was found to be commonly increased in melanoma cells. While knockdown of ACTN4 inhibited melanoma cell proliferation that was associated with down-regulation of RIPK1 and reduction in the basal levels of NF-κB activation, overexpression of ACTN4 resulted in enhanced proliferation of melanocytes that was associated with elevation in RIPK1 expression and increased NF-κB activation. The inhibitory effect of ACTN4 knockdown on melanoma cell proliferation and activation of NF-κB was due to decreased expression of RIPK1, as it was abolished by overexpression of RIPK1. On the other hand, knockdown of RIPK1 diminished ACTN4 overexpression of cIAPs and promoted tumor apoptosis. Strikingly, knockdown of ACTN4 attenuated the association between cIAPs and RIPK1 and reduced K63-linked ubiquitination of the protein, leading to RIPK1 protein degradation. Mechanistic studies showed that ACTN4 bound to RIPK1 through its N-terminus, whereas it was associated with cIAPs via its C-terminus, and that dimerization of ACTN4 in an anti-parallel manner is required for the interaction between cIAPs and RIPK1. Collectively, ACTN4 is necessary for stabilization of RIPK1 by cIAPs and functions as an oncogenic driver in melanoma.

**#4463 The coactivator oncogene AF1q associates with STAT3 activation downstream of MET action in gastro-esophageal cancer patients**. Elisabeth S. Gruber,1 Peter Birner,2 Olaf Merkel,2 Michael M. Bergmann,2 Sebastian F. Schoppmann,1 Jino Park,3 Richard Moriggl,4 William Tse,3 Lukas Kenner5.

1 University Clinic for Surgery, Medical University of Vienna, Vienna, Austria; 2 Institute of Pathology, Medical University Vienna, Vienna, Austria; 3 James Graham Brown Cancer Center, University of Louisville School of Medicine, Louisville, KY; 4 University Vienna, Ludwig Boltzmann Institute, Vienna, Austria; 5 Institute of Laboratory Animal Pathology, University of Veterinary Medicine, Vienna, Austria.

AF1q was initially identified as an oncogene in acute myeloid leukemia. In breast cancer, AF1q mediates tumor progression by boosting STAT3-signalling. In addition, AF1q enhances wnt-signalling resulting in transcriptional activation of CD44 and promotes tumor cell proliferation, migration and chemoresistance. In gastrointestinal malignancies both pathways are linked to enhanced MET tyrosine kinase activity, accumulation of activated MET and metastases. We showed that AF1q overexpression in the gastro-esophageal cancer cell lines SK-GT-4, FLO-1 and OE33 led to increased sphere formation and increased invasive capacity in the case of FLO-1 and OE33. We investigated the role of AF1q in a retrospective collective of 460 resected gastro-esophageal cancer specimens (74.3% adenocarcinomas (AC), 25.7% esophageal squamous cancers (SCC)). With respect to topographic location, 40.4% of tumors were esophageal (EC), 20% gastro-esophageal (GEC) and 39.6% gastric cancers (GC). Immunohistochemistry revealed overexpression of AF1q in 205, and of CD44 in 114 patient tumor samples. AF1q overexpression was found more often in EC/GC as compared to GC (p = 0.007) and associated with HER2 (p = 0.035), pySTAT3 (p < 0.001) and MET (p = 0.004) expression as well as neoadjuvant chemotherapy (p = 0.01). AF1q and CD44 overexpression correlated in the overall group (p < 0.001) and in AC (p < 0.001). In SCC CD44 was expressed more frequently compared to AC (p < 0.001). Analysis of the matched primary and metastatic tumors revealed that primary AF1q-positive tumor samples were largely overlapping with AF1q-positive tumors lymph node metastases (23/32) and distant metastases (6/7). AF1q overexpression correlated with shorter disease specific survival (DSS) (p = 0.036), but overall survival (OS) was similar (p = 0.117). In a subgroup analysis a shorter OS was observed in EC/GC (p = 0.03, log rank test). In a Cox regression model AF1q and CD44 expression was associated with shorter DFS (p < 0.001 and p = 0.025) and DSS (p = 0.005 and p = 0.035), but OS remained
unchanged. Prognostic significance was limited to AF1q (p=0.003 and p=0.04, respectively). We conclude that, AF1q overexpression is associated with progression and metastases in GEC. AF1q and downstream pathway markers such as p53 and p73 were associated with AF1q expression. Therefore we propose AF1q as a novel prognostic marker for GECs.

### Glypican-1

Glypican-1 (GPC-1) is a cell surface heparan sulfate proteoglycan that mediates cell proliferation, differentiation and migration. It also posses oncogenic functions in breast, pancreatic and lung cancer cells, and is a proposed biomarker for prostate cancer. Despite these data, the function of GPC-1 in prostate cancer is not fully known. We addressed this gap-in-knowledge by testing the effect of tumor cell line-specific (TCL)-mediated knockdown of GPC-1 knockdown on human bone marrow derived mesenchymal stem cells (hMSC) and fibroblasts (HS-27). Treatment of both hMSC and HS-27 cells with TCL from GPC-1 knockdown PC-3 cells increased MMP-9 and interestingly MMP-2 expression and activity as compared to control cells. We also detected increases in the expression of N-Cadherin in a co-culture model. Collectively, these data suggest that GPC-1 acts as an oncogene to enhance prostate cancer cell growth in vitro; however, these data also suggest the GPC-1 may act as a tumor suppressor in vivo. This discrepancy may be due to the interaction of GPC-1 with the tumor microenvironment, which would not be detected in single-cell culture models.

### Glypican-1: A tumor suppressor or an oncogene in human bone metastatic prostate cancer cells

Shyh-Han Tavan, Kevin Babcock, Indu Kohar, Ahmed A. Mohamed, Denise Young, Shiv Srivastava, Albert Dobi. Center for Prostate Disease Research, Uniformed Services University, Rockville, MD

Introduction: Most genomic studies of prostate cancer (CaP) have been performed primarily on men of European ancestry, including Caucasian Americans. African Americans (AA) men, however, bear the burden of highest CaP incidence and mortality rates in the US. Cumulative data from other groups and from us have shown significantly lower rate of alterations of the two common CaP driver genes (PTEN and ERG) in AA CaP as compared to CA CaP. Using a combination of whole genome sequencing, IHC and FISH based validations on tissue microarrays, and analysis of the TCGA data from a total of 438 CaPs, we recently reported a higher frequency of a genomic deletion on 3q13.31 locus in AA CaP which also associated with rapid biochemical recurrence. This deletion is centered at the LSAMP (Limbic System Associated Membrane Protein) gene. The LSAMP protein functions as a cell adhesion molecule affecting cell differentiation and migration during development. We hypothesize that the loss of LSAMP contributes to CaP progression. Here, we report the biological consequence of LSAMP modulation in CaP cells. Methods: LSAMP status in CaP cell lines (LNCaP, MDAPCa2b, CRW22rv1, LAPC4, NCI-H660, and PC3) was assessed by FISH, immunoblot, qRT-PCR and immunofluorescence (IF), assays using MC-IXC neuroepithelioma cell line as the positive control. We established doxycycline inducible LSAMP in LNCaP and in MDAPCa2b (an AA patient derived cell line with monoallelic LSAMP deletion) cells, and constitutive expression in DU145 cells. The effect of LSAMP loss and over-expression on cell growth, proliferation apoptosis and cell migration was monitored by MTT, soft-agar, and Boyden chamber assays. Results: Of the CaP cell lines analyzed, LSAMP RNA and protein expression was detected in PC3 and NCI-H660. IF assay showed that endogenously expressed LSAMP is predominantly localized to the cell surface. Exogenous expression of LSAMP, either constitutively in DU145, or by inducible means in LNCaP and MDAPCa2b cells, showed similar localization to the plasma membrane. Both inducible and constitutive overexpression of LSAMP resulted in reduced cell growth. LSAMP expression in DU145 resulted in enhanced formation of filamentous extracellular lumen extensions. Analysis of published TCGA (The Cancer Genome Atlas) data showed a correlation of high LSAMP promoter methylation and low LSAMP expression in CaP tumors compared to normal prostate tissues. Conclusion: The cell biology features of LSAMP reported here, together with observations of genomic deletion and methylation of LSAMP promoter in CaP, support its role in CaP development or progression. These data support the function of LSAMP as a tumor suppressor gene, as previously reported in other cancers.

### Glypican-1: A tumor suppressor or an oncogene in human bone metastatic prostate cancer cells

Nhat D. Quach, Matthew Eggert, Deepraj Ghosh, Michelle R. Dawson, Robert Arnold, Brian S. Cummings. University of Georgia, Athens, GA; Auburn University, Auburn, AL; Brown University, Providence, RI

Glypican-1 (GPC-1) is a cell surface heparan sulfate proteoglycan that mediates cell proliferation, differentiation and migration. It also possesses oncogenic functions in breast, pancreatic and lung cancer cells, and is a proposed biomarker for prostate cancer. Despite these data, the function of GPC-1 in prostate cancer is not fully known. We addressed this gap-in-knowledge using in vitro and in vivo mouse models. We first showed that GPC-1 was overexpressed in bone metastatic prostate cancer cells (PC-3) but was not detected in lymph node metastatic cancer cells (LNCaP) and non-cancerous prostate cells (RWPE-1). Next, we inhibited GPC-1 expression using siRNA in bone metastatic cancer cells (PC-3), and verified inhibition using western blot analysis and qRT-PCR. Crystal violet staining, trans-well assays, matrigel colony cultures and adhesion assays were used to determine the effect of GPC-1 inhibition on cancer cell growth, migration, spheroid formation and cell adhesion. Inhibition of GPC-1 reduced prostate cancer cell growth, migration and spheroid formation; however, there were no changes in cell adhesion. These in vitro data suggested that GPC-1 played a role in prostate cancer progression by acting as an oncogene. We further investigated this possibility in vivo using athymic (NCR) mice xenografts. Interestingly, inhibition of GPC-1 in PC-3 cells appeared to increase tumor size as compared to scrambled controls. Further analysis showed that that inhibition of GPC-1 increased the tumor expression of MMP-9 and N-cadherin, but not E-cadherin. We hypothesized that the discrepancy between the in vitro and in vivo results may be mediated by interaction of PC-3 cells with the tumor microenvironment. We addressed this hypothesis by testing the effect of tumor cell line-specific (TCL)-mediated knockdown of GPC-1 knockdown on human bone marrow derived mesenchymal stem cells (hMSC) and fibroblasts (HS-27). Treatment of both hMSC and HS-27 cells with TCL from GPC-1 knockdown PC-3 cells increased MMP-9 and interestingly MMP-2 expression and activity as compared to control cells. We also detected increases in the expression of N-Cadherin in a co-culture model. Collectively, these data suggest that GPC-1 acts as an oncogene to enhance prostate cancer cell growth in vitro; however, these data also suggest the GPC-1 may act as a tumor suppressor in vivo. This discrepancy may be due to the interaction of GPC-1 with the tumor microenvironment, which would not be detected in single-cell culture models.

### Glypican-1: A tumor suppressor or an oncogene in human bone metastatic prostate cancer cells

Ahmed A. Mohamed, Denise Young, Shiv Srivastava, Albert Dobi. Center for Prostate Disease Research, Uniformed Services University, Rockville, MD

ETV6 is an ETS transcription factor and a putative tumor suppressor in prostate cancer according to several genomic analyses. However, its cellular functions and upstream regulating signaling remain unclear. We demonstrated that ETV6 suppresses the prostate cancer progression and that ETV6 levels are negatively associated with advanced prostate cancer, supporting the idea that ETV6 acts as a tumor suppressor. Furthermore, ETV6 can be regulated by epidermal growth factor receptor (EGFR) signaling through microRNA (miR)-mediated downregulation. One of the miRs, miR-96, can be transcriptionally-regulated by nuclear EGFR. The association patterns connecting miR-96, EGFR activation, and ETV6 were further validated in the clinical tissue samples. We proposed an EGFR-miR-96-ETV6 signaling pathway in promoting prostate cancer.

### Glypican-1: A tumor suppressor or an oncogene in human bone metastatic prostate cancer cells

ETV6 is a tumor suppressor regulated by EGFR-miR-96 pathway in prostate cancer. Yen-Nien Liu, Yuan-Chin Tsai, Wei-Yu Chen, Man Kit Siu, Hisu-Lien Yeh. Taipei Medical University, Taipei, Taiwan; National Tsing Hua University, Hsinchu, Taiwan.

MOLECULAR AND CELLULAR BIOLOGY / GENETICS: Post-transcriptional and Translational Regulation in Cancer

### #4468 Oncogenic activation of the RNA binding protein AGO2 in hepatocellular carcinoma. Hien T. Dang, Lucy Knight, Yotsawat Pomyen, Xin Wei Wang, NIH/NCI, Bethesda, MD.

Global transcriptomic alterations of coding and non-coding RNAs are a ubiquitous feature of cancers including Hepatocellular carcinoma (HCC). Dysregulation of RBPs binding motifs (RBPs), key factors in processing such as RNA maturation and degradation, is one mechanism in which cancer cells select to promote tumorigenesis. RBPs are highly expressed in solid tumors and have been demonstrated to be drivers of carcinogenesis, however, the underlying mechanisms in which RBPs regulate the HCC transcriptome is unknown. We analysed genomic alterations amongst a family of more than 800 mRNA RBPs (mRBPs) in 1,225 clinical specimens from HCC patients and found that RBPs are significantly activated through gene amplification in a subset of tumors with poor prognosis, suggesting their potential oncogenic roles in HCC progression. Amongst the top candidates, Argonaute 2 (AGO2) was further characterized for its oncogenic role and effects on the HCC transcriptome. Elevated AGO2 mRNA expression was highly correlated with elevated somatic copy number alterations across five different cancer types including HCC. AGO2 expression was associated with overall survival in two independent data sets (TCGA and the Liver Initiative Cancer), suggesting that AGO2 activation is oncogenic. While the activation of AGO2 induced an oncogenic phenotype, the abrogation of AGO2 in HCC cells significantly decreased cancer associated phenotypes such as cell proliferation, migration/invasion and tumorigenicity in vivo. Further analyses revealed that AGO2-associated genes were tumor-related, including c-Myc. Notably, c-Myc amplification was also found in AGO2 high HCC cells, suggesting an interplay between AGO2 and c-Myc. Our results demonstrate that oncogenic activation of AGO2 is a novel mechanism that may contribute to global transcriptome selective for the activation of c-Myc oncogenic. Our current work suggests that therapies focusing on targeting AGO2 may be valuable for clinical treatment of many different tumors with activated c-Myc signalling, including HCC.

### #4469 Targeting the tri-snRNP complex for triple-negative breast cancer therapy. Stefanie Chan, Praveen Sridhar, Ying-Jie Lock, Fabio Petrozza. Boston University School of Medicine, Boston, MA.

Triple negative breast cancers (TNBC) account for ~15% of all breast cancers and the majority of breast cancer patients in women carrying a BRCA1 germline mutation. Due to the inadequacy of existing treatment, here we sought to identify shared genetic dependencies across different TNBC cell lines with the ultimate goal of uncovering novel therapeutic targets. To this end, we performed a targeted siRNA lethality screen across 11 human breast cell lines focusing on 154 genes, which we previously identified as selectively essential to a genetically-defined TNBC progenitor cell line (BPLER) relative to a myoepithelial-like isoegenic cell line (HMMLER). Thirty genes scored as recurrently and selectively required for survival of progenitor-like (or basal-A) TNBC lines compared to differentiated cell lines. Genes for proteins involved in RNA splicing were prominent shared dependencies among basal-A TNBC cell lines. Of particular note were those associated with the UA/U6/U5 tri-snRNP complex, including PRPF8 and PRPF38A. Transcriptome-wide RNA-seq analysis of the knockdown of either led to widespread intrinsic retention, expression of immune system genes and aberrant splicing of transcripts involved in protein translation, proteasome function, mitosis and apoptosis, including the TNBC dependency gene MCL1. As the proteasome and mitosis are also established TNBC vulnerabilities, we have identified specific classes of transcripts that are both particularly susceptible to perturbation of tri-snRNP activity and selectively essential for TNBC, making the tri-snRNP complex an attractive target for downstream drug development.

### #4470 RNA m⁵C methyltransferases and hnRNPK mediate disease-associated chromatin structure and drug resistance in leukemia. Jason X. Cheng, Li Cheng, Adam Cloe, Yuan Li, Ming Yue, Michelle M. Le Beau, Richard A. Larson, James W. Vardiman. University of Chicago, Chicago, IL.

The mechanisms governing disease-associated chromatin organization and drug selectivity are poorly understood. Our epigenetic drug screening experiments identify two distinct lineage-specific drug-responsive patterns in myeloid leukemia (MDS/AML) cells. We have established multiple MDS/AML cell lines resistant to nucleic acid analogs with different chemical backbones and have demonstrated a clear relationship between drug-resistance and sugar-phosphate backbone. Based on these results, we used various experimental approaches to elucidate leukemia-associated, drug-responsive chromatin structural changes and their underlying mechanisms. Our data demonstrate that hnRNPK, a conserved factor in heterogeneous nuclear RNA-binding protein (hnRNP) complexes, directly interacts with RNA m⁵C methyltransferases NSUNs/DNMT2 and RNA-polymerase II (pol-II)/CTD9 as well as erythroid vs myeloid lineage-specific splicing factor transcriptome (TFs) GATA1 and SPP1 to targets distinct drug-responsive chromatin structures in MDS/AML cells. hnRNPK preferentially binds to methylated polypyrimidine RNA sequences to facilitate transcription elongation. Compared to azacitidine-sensitive MDS/AML cells, there is a marked increase in azacitidine-resistant MDS/AML cells in RNA m⁵C and NSUNs/DNMT2 associated with a marked increase in the interaction between hnRNPK and pol-II. In leukemia, a cell type most frequently harboring ncRNA capturing technology coupled with super-resolution stimulated-emission depletion confocal microscopy, we demonstrate co-localization of hnRNPK with the Tfs and active pol-II at nascent RNA sites in MDS/AML cells, further supporting the existence of hnRNPK-mediated drug-responsive transcription and lineage-specific chromatin structures in MDS/AML cells. Our experiments using clinical specimens demonstrate a positive correlation between MDS/AML progression and increase in expression of hnRNPK and RNA m⁵C methyltransferases, supporting their importance and clinical relevance. Furthermore, knockdown of hnRNPK and RNA 5mC methyltransferases effectively inhibited the growth of MDS/AML cells. In conclusion, our data demonstrate distinct RNA m⁵C methyltransferases/hnRNPK-mediated chromatin structures that correlate with growth and drug-resistance of MDS/AML cells. Our data support the existence of ncRNA methyltransferases as the writers of m⁵C on nascent RNA, and hnRNPK functions as a reader of the RNA m⁵C and an operator to regulate transcription elongation and gene activation. Such novel chromatin structure-based drug action models and mechanisms may identify new diagnostic and prognostic biomarkers and therapeutic approaches.
A subunit of splicing factor 3b, SF3B4, functions as driver of liver cancer via aberrant splicing activity on tumor suppressor KLF4. Suk Woo Nam, Qunyu Shen, Eun Hyung Song, Su Jin Kim, Hee Do Yang, Sang Yeon Kim. The Catholic University of Korea, Seoul, Republic of Korea.

Alternative splicing is one of the crucial mechanisms that contribute to proteome diversity and, as reported, up to 90% of genes are alternatively spliced in human. In the last few years, a large number of mRNA isoforms revealed to contribute many cellular development and disease, including cancer. SF3B4 is one of six subunits of the splicing factor 3b (SF3b) complex which is an important protein complex in U2 snRNP super complex. In this study, we show that SF3B4 expression was overexpressed in a large cohort of human hepatocellular carcinoma (HCC) patients. SF3B4 knockdown caused G1/S cell cycle arrest by recovering p27 expression and simultaneously suppressing cyclins, and CDKs in liver cancer cell. Consistently, Spliceostatin A, a SF3b complex inhibitor, also suppressed liver cancer cell growth with similar effect on cell cycle regulation. In addition, sustained suppression of SF3B4 reduced the in vivo tumor growth rate in mouse xenograft models. Furthermore, SF3B4 knockdown repressed in vitro tumor cell motility and invasion of liver cancer cells. Notably, we observed that SF3B4 knockdown increased alternative transcript splicing event of a large number of genes in liver cancer cells. From this, we found that SF3B4 knockdown caused loss of wildtype KLF4 transcript expression, and therefore affected anti-tumor growth effect on liver cancer cells. Indeed, ectopic expression of KLF4 mimicked SF3B4 knockdown effect on same cells. Our results suggest that aberrant regulation of SF3B4 contribute to malignant transformation and growth of liver cancer cells by repression of tumor suppressor via unmodulated alternative splicing activity during liver tumorigenesis.

SRRM4 drives treatment-induced neuroendocrine differentiation of prostate adenocarcinoma under androgen receptor pathway inhibition. Yinan Li. Vancouver Prostate Centre, Vancouver, British Columbia, Canada.

Treatment-induced neuroendocrine prostate cancer (t-NEPC) is an aggressive subtype of castration-resistant prostate cancer that typically does not respond to AR pathway inhibition (ARPI) and its diagnosis is increasing. To understand its development, we analyzed transcriptomes of prostate tumors to identify t-NEPC-specific RNA splicing. Interestingly, more than 66% of the splice events are predicted to be regulated by the RNA splicing factor, Serine/Arginine Repetitive Matrix 4 (SRRM4). We confirmed in vitro and in vivo that a single SRRM4 target gene is the REI-Silencer Factor (REST), a master regulator of neurogenesis. SRRM4 strongly stimulates adenocarcinoma cells to express t-NEPC biomarkers and this is exacerbated by ARPI. ARPI combined with gain of SRRM4 results in adenocarcinoma cells to assume multicellular spheroid morphology and establishes progressive NEPC xenografts. These SRRM4 actions are further enhanced by loss-of-function of TP53. We conclude that SRRM4 drives t-NEPC progression. This knowledge may guide the development of novel therapeutic approaches at t-NEPC.

Functional characterization of alternatively spliced GSN in head and neck cancer. Dylan Z. Kelley, Emily L. Flam, Theresa Guo, Craig Bohrson, Michael Considine, Ludmila V. Danilova, Justin A. Bishop, Chi Zhang, Wayne M. Koch, David Sidransky, William Westra, Sarah Wehlan, Liliana Fiorela, Elana J. Fertig, Joseph A. Calilano, Daria A. Gaykalova, Johns Hopkins School of Medicine, Baltimore, MD; Johns Hopkins Medical Institutions, Baltimore, MD; University of California, San Diego, La Jolla, CA.

PURPOSE: Analyze the functional role of alternative splicing in HPV-related (HPV+) Head and Neck Squamous Cell Carcinoma (HNSCC) biology and oncogenesis. HPV+ HNSCC incidence is rapidly increasing, while its oncogenic mechanisms, demographic, and clinico-pathological characteristics are largely uncharacterized and discrete from those of HPV-. HNSCC. Investigation into the molecular biology of HPV pathways in HNSCC may help with creation of more specific clinical tools for diagnosis and treatment, which are limited and lack accuracy. Alternative Splicing Events (ASEs), post-transcriptional modifications resulting in variant transcripts leading to alternative protein isoforms, have been under-investigated as putative causes of gene expression deregulation in HPV+. Using RNA-Seq data, a genome-wide ASE discovery analysis was performed on a JHU HPV+ HNSCC cohort, which has expanded HPV+ HNSCC transcriptional characterization by identifying novel ASE biomarkers implicated in carcinogenic progression. Outlier Gene Set Analysis (OGSA) was used to identify genes with high rates of ASE and results were validated in TCGA samples from seven different cancer types. To verify the functional implications of differential isoform expression, vectors for knock-in and knock-down of WT-GSN and ASE-GSN isoforms were developed to evaluate changes in cell proliferation and invasion. ASE-GSN/WT-GSN ratio outliers were identified by OGSAs in tumor samples from discovery JHU HPV+ oncogenes. Expression, oncogenic signaling were compared among UM-SCC-22B HNSCC cell lines, Lung Squamous Cell Carcinoma, Cervical Squamous Cell Carcinoma and Endocervical Adenocarcinoma, Bladder Urothelial Carcinoma, Breast Invasive Carcinoma, and Colon Adenocarcinoma. The increased ASE-GSN/WT-GSN ratio was also observed in a cohort of HPV+ Head and Neck Cancer Cell lines. GSN+ and UM-SCC-22B HNSCC cell lines were used to evaluate the function of GSN ASEs. Overall expression levels of both GSN isoforms conversely correlated with cell proliferation whereas the high ratio of ASE-GSN to WT-GSN correlated with increased cellular invasion of stroma in vitro. Additionally, a decrease or increase in expression of one isoform is seen to cause a compensatory increase or decrease in the other isoform respectively. ASE-GSN outliers correlated with HPV+ cancers indicate that expression ratio between GSN isoforms is related to tumor behavior, which is reinforced in vitro where WT-GSN is inversely correlated and ASE-GSN is directly correlated to cell invasion. These relationships suggest that both overall expression and balance between the two GSN isoforms are mediating factors in cell death or proliferation, while shorter ASE-GSN is more likely to indicate progression to cancer. Finally, we propose a model for the role of GSN isoforms in apoptosis and metastasis, in which trends in expression between WT- and ASE-GSN isoforms can alternatively affect rates of apoptosis or metastatic ability.

Delineating translocation renal cell carcinoma oncogenesis in cells harboring TFE3 fusion with spliceosome machinery associated genes. Nur P. Damayanti, Sreenavasulu Chintala, Ashley Orillion, Remi Adelaye-Ogala, May F. Ellbanna, Peter Hollenhorst, Roberto Pili, Indiana University, Indianapolis, IN; Indiana University, Bloomington, IN; Indiana University, Indianapolis, IN.

Background: Translocation Renal Cell Carcinoma (tRCC) represents an aggressive subtype of kidney cancer associated with various gene fusions involving translocation of one of two members of microphthalmia transcription factor (MIT) family, TFE3 or TFE6. Despite identification of multiple TFE3 gene fusions in tRCC, heterogeneous phenotype and various dysregulated signaling pathways resulting from variety of fusion partners pose a challenge to establish effective treatments for these patients. In this work, we sought to study the biology underlying oncogenesis in tRCC involving TFE3 fusion with genes associated with pre-mRNA splicing factor machinery; NONO, SFPQ and PRCC. Methods: To investigate the biology of different TFE3 fusion proteins, we created cell lines with TFE3 fusions and with different TF=E3 fusion partner dependent manner (P<0.05). We observed more homogeneous phenotype and oncogenic signaling were compared among cells expressing different TFE3 fusions such as SFQ-TFE3, NONO-TFE3, PRCC-TFE3. Endogenous SFPQ-TFE3 expressing cells, RP-RO7, were generated from patient derived xenograft. UOK-109 and UOK-146 (kindly provided by Dr. Marston Lenehan, NCI) were used as endogenous NONO-TFE3 and PRCC-TFE3 expressing cells, respectively. TFE3 fusion transcripts were identified with RT-PCR. TFE3 fusion preferential DNA binding was assessed with ChIP-sequencing. Oncogenic phenotype assessment was done in 2D culture and two different 3D models; 1) Solid tumor model, in which cancer cell interaction with extracellular matrix and stromal cells, were represented in multiculture-spheroid system, 2) Invasion model, in which cell ability to invade basement membrane barrier was modeled with matrix restricted spheroid. Results: Dissimilar oncogenic phenotypes were seen among ARK, FAK, mTOR VGEFR-2 were identified among TFE3 fusion cells with different level of expresion (P<0.05). These results suggest distinct alteration of kinases nucleocytoplasmic shuttling regulation in tRCC cells (P<0.05), as compared to non TFE3 fusion cells. TFE3 ChIP-seq data in RP-RO7 indicate novel DNA target involving metabolism and TGF-β signaling related genes. Conclusions: Our results indicate a distinct biological underlying tRCC oncogenesis in different TFE3 fusion models involving kinase reprogramming and nucleocytoplasmic shuttling regulation. These differences also suggest the possibility of generating personalized treatments targeting specific TFE3 fusion genes associated with the spliceosome machinery.

Background: The standard treatment for prostate cancer (PCa) is androgen deprivation therapy (ADT) that blocks AR transcriptional activity, which is responsible to the initiation and progression of PCa. However, ADT invariably leads to the castration-resistant PCa (CRPC) with restored activity of AR. CRPC can be further treated with more intensive ADTs, including CYP17 inhibitors to block intratumoral androgen synthesis and more potent AR antagonist. By analyzing the gene expression from a CRPC patient biopsy who developed resistance to CYP17 inhibitor treatment, we identified a novel nonsense mutation in the ligand binding domain (Q784*), which produces a C-terminal truncated form of AR protein containing only a fraction of ligand binding domain (LBD) and may mimic the function of some AR splice variants. We hypothesized that AR-Q784* may gain the androgen-independent activity, or may enhance the transcriptional activity of full-length AR (AR-FL) under low androgen environment through dimerization with AR-FL. Method: Luciferase reporter assays were applied to assess the transcriptional activity of AR-Q784* in absence or presence of androgens, and with or without AR-FL. Immunoblotting and immunofluorescence assays were used to examine the protein stability and cellular localization of AR-Q784*. Chromatin immunoprecipitation assays were also used to assess the chromatin binding ability of AR-Q784*. Moreover, the stable cell line that expressed endogenous AR-FL and tetracycline-inducible AR-Q784* was generated to determine the transcription activity on AR target genes and assess the effects on cell proliferation, particularly under low dose androgen condition. Result: Although it was constitutively expressed in nucleus, AR-Q784* does not elicit transcriptional activity despite the conditions of ligands. However, when it was co-expressed with AR-FL, AR-Q784* can enhance AR-mediated transcriptional activity and thus increased PCa cell proliferation particularly under low androgen conditions. Mechanistically, AR-Q784* can dimerize with AR-FL, enhance DNA binding ability of AR-FL, and strengthen AR recruitment to p300 coactivator. Conclusion: We show that CYP17 inhibitor treatment in CRPC may select for a distinct class of AR mutations/variations, including nonsense (AR-Q784*) or point-deletion mutations within LBD and certain splice variants that only lose a fraction of LBD domain. This class of AR mutants/variants is transcriptionally inactive but can enhance the activity of AR-FL due to their abilities of constitutive DNA binding and dimerization with AR-FL. However, this enhancing activity of those AR mutants/variants can be prevented by antagonist treatments such as enzalutamide. Therefore, this study provides an additional rationale for treating PCa patients with combination therapy of abiraterone and enzalutamide, which may prevent the selection for such AR mutations/variations in CRPC.

HnRNP Q1 translationally increases the expression of Aurora-A and promotes tumorigenesis in colorectal cancer. Liang-Yi Huang, National Cheng Kung Univ., Tainan, Taiwan.

Abnormally elevated Aurora-A can cause mitotic defects and aneuploidy, which might lead to genomic instability and tumorigenesis. According to the literatures, overexpressed Aurora-A may result from gene amplification, RNA transcriptional activation, or increased protein stability. Our previous study has demonstrated that Aurora-A can be translationally upregulated in colorectal cancer. By biotin pull-down assay and in vivo translational assay, we found that Aurora-A mRNA can be translationally upregulated by heterogeneous nuclear ribonucleoprotein (hnRNP) Q1, a mRNA binding protein. HnRNQ Q1 has been implicated in many posttranscriptional regulatory processes including mRNA splicing, RNA metabolism and translation. In this study, we further clarified the regulatory mechanism of hnRNP Q1 in translationally regulating Aurora-A mRNA, as well as investigated the clinical role of hnRNP Q1 in colorectal carcinogenesis. Our results indicated that hnRNP Q1 can bind to the Aurora-A mRNA 5'-untranslated region (5'-UTR). Ribosomal protein S6-IR assay further indicated that hnRNP Q1 can enhance the translational efficiency of Aurora-A mRNA. Ribosomal profiling assay further confirmed the translational regulation of Aurora-A mRNA by hnRNP Q1. Overexpression of hnRNP Q1 promotes cell proliferation and tumor growth. The expression level of hnRNP Q1 is positively correlated with Aurora-A in colorectal cancer. Taken together, our data indicate that hnRNP Q1 is a novel trans-acting factor that binds to Aurora-A mRNA 5'-UTRs and regulates its translation, which increases cell proliferation and contributes to tumorigenesis in colorectal cancer.

Characterization of the biochemical interaction of hnRNP A18 to thioridoxin transcript. Elizabeth Tsuying Chang, Palak Parekh, Eun Young Choi, Ruiping Yang, France Carrier. University of Maryland Greenebaum Cancer Center, Baltimore, MD.

Introduction: The RNA-binding protein heterogenous ribonucleoprotein A18 (hnRNP A18) is a protein translation regulator found to be elevated in many cancers. Previous work from our lab has shown that under stress conditions, hnRNP A18 is able to bind and regulate the translation of a group of mRNAs, including thioridoxin (TRX), a redox-regulating protein implicated in promot- ional metabolism. Through the formation of functional hnRNP A18-TRX complexes increases de novo protein synthesis of TRX through the stimulation of its mRNA transcript. It has been reported that like most RNA-binding proteins, hnRNP A18 is a modular protein and is uniquely composed of a single N-terminal RNA binding domain (RBD) and a C-terminal arginine-glycine rich (RGG) domain. The RBD is able to dictate specificity and affinity of substrate RNA binding, while the RGG domain acts as a functional hinge that contributes to its RNA binding capability. The observed translational regulation of TRX by hnRNP A18 merits further studies into understanding the physical interaction between the two molecules. Methods/Results: To determine the region which hnRNP A18 interacts with thioridoxin, stable cell lines overexpressing the RBD, RGG or full length (FL) domains of hnRNP A18 were generated in human melanoma cells. Ribonucleoprotein immunoprecipitation assays were performed using specific antibodies to either the RBD or RGG domain epitope. Reverse transcription PCR data reveals the presence of TRX mRNA in the resultant immunoprecipitated materials, indicating that both the RBD and RGG domain of hnRNP A18 protein is able to independently bind TRX mRNA. Maximum binding was observed when both RBD and RGG regions were present. hnRNP A18 RBD and RGG proteins were engineered to determine the exact region which hnRNP A18 binds to its target mRNAs. TRX mRNA was systematically deleted and increasing amounts of hnRNP A18-RBD protein was added to determine binding capability. Northwestern analysis reveals that hnRNP A18 binds to its consensus motif in the TRX 3'UTR and to a new 19 nucleotide motif downstream of the consesus site. Conclusion: Heterogenous ribonucleoprotein A18 is a stress-activated RNA-binding protein that functions in the translational regulation of TRX. Although the RBD and RGG domains are each independently able to physically interact with TRX, both regions are necessary for maximal binding. However, a 19 nucleotide motif located downstream of the hnRNP A18 consensus motif was also found to be sufficient for binding. The binding interface between RNA-binding proteins and their target mRNAs hold significant importance in understanding how the two molecules interact and will offer new insights into developing novel drug therapeutics that disrupt ribonucleoprotein formation.

Cancer cell ribogenesis: MYC and the integrity of the RNA polymerase I-rRNA machinery. Stefano Rossetti, Andrezj J. Wierzbicki, Niccolita Sacchi, Roswell Park Cancer Institute, Buffalo, NY.

Upregulation of RNA Polymerase (Pol I)-mediated transcription of ribosomal RNA (rRNA) and increased ribogenesis, which are necessary to sustain the increased metabolic demand of highly proliferating cancer cells, are hallmark characteristics of cancer. Increased rRNA transcription can be due to deregulation of tumor suppressors and oncogenes that affect Pol I activity. Overexpression of the MYC oncogene, a potent Pol I activator, is particularly frequent in cancer. In addition, based on our analysis of the Cancer Genome Atlas (TCGA), amplification/upregulation of genes encoding for basal components of the Pol I transcriptional machinery is also frequent in cancers of various histotype (Rossetti et al., Cell Cycle, 2016). By using breast and ovarian epithelial cell lines, we mechanistically found that: 1) ectopic expression of either MYC or RNR3 (TIF-IA), a key Pol I basal component, by increasing rRNA synthesis, is sufficient to induce in vitro transformation phenotypes and to promote cell proliferation; 2) there is a causal link between MYC overexpression and RNR3 upregulation; 3) MYC- or RNR3-induced rRNA upregulation sensitizes cells to the anti-proliferative action of drugs inhibiting RNA transcription. Our findings provide a rationale for using drugs targeting rRNA transcription to curb proliferation of cancers cells due to rRNA upregulation by MYC. Funding for this study was provided by an RP1-UCPC Ovarian Cancer Spore DRP award (NS), the NCI R01 CA127614 grant (NS), the Terri Brodeur Breast Cancer Foundation (SR), the Susan Komen Foundation (SR), and the NCI P30 CA016056 institutional grant.

SerRS is a key inhibitor of VEGFA through both transcriptional and translational controls. Ze Liu, Yi Shi, Qian Zhang, Xianglei Yang. The Scripps Research Institute, La Jolla, CA.

Vascular endothelial growth factor A (VEGFA) is the most important mediator of angiogenesis and a major target for cancerant therapy. Recent studies from our lab revealed that seryl-tRNA synthetase (SerRS), by counteracting transcription factor c-Myc in the nucleus, is the crucial transcriptional repressor of VEGFA and a potent inhibitor of angiogenesis (1,2). Here we report that SerRS controls the expression of VEGFA not only in the nucleus but also in the cytoplasm through mediating its
translational readthrough. Translational read-through of the VEGFA mRNA generates a novel isoform called VEGF-Ax that, compared with the non-read-through isoform VEGF-A165, has a 22-amino acid C-terminal extension and much weakened angiogenic activity (3,4). Interestingly, serine was identified as the amino acid inserted in the place of the UGA stop codon during the read-through (3). In unpublished work, we found that SerRS is overexpressed in metastatic tumors. Total RNA has been extracted from endometrial non-tumoral (E6/E7 and EM2) and tumoral ( Ishikawa, RL95-2, AN3CA and KLE) cell lines, followed by cdNA synthesis. Transcriptional and protein expression patterns have been evaluated for OPN, p53 or PTEN isoforms, using quantitative real time PCR, immunoblot or immunofluorescence. OPN is overexpressed in tumoral and non-tumoral cell lines in relation to OPNb and OPNc. Total RNA has been extracted, followed by Δ40p53, in relation to other variants in EC cells. Conversely, Δ40p53 is the major expressed in both EM2 and E6/E7 non-tumoral cells. Otherwise, in EC and endometrial non-tumoral cells, PTEN vs-fl is overexpressed in relation to the other splice variants. Specifically in E6/E7 cells, all PTEN-variant, except vs-b and vs-Δ, are overexpressed in relation to EC cell lines. At the protein level, both p53 and PTEN isoforms are overexpressed in E6/E7 cells, when compared to EC cells. Of note, distinct isoforms for most of these variant transcripts have not been detected at the protein level. Our data demonstrate that full length OPN, p53 and PTEN are the major expressed variants in EC tumor cell lines. However, most of these transcript variants display differential expression between endometrial tumor and non-tumoral cells and also among distinct EC cell lines. These data provide early evidence that OPN expression can dynamically modulate the expression of these mRNA isoforms, allowing both transcriptional and translational controls. References: 1. Xu X, Zhong C, Nudelman E, Ferrara N. Evidence for Pro-angiogenic Functions of VEGF-A. Cell. 2016 Sep 22;167(1):275-284.

#4481 Translation initiation factor DAP5 plays an essential role in translational control of breast cancer metastasis. Columbia de la Parra, Amanda Alard, Amanda Ermulnd, Robert J. Schneider. NYU School of Medicine, New York, NY.

Metastasis is the cause of 90% of cancer-related deaths. Selective mRNA translation has been found to be crucial for breast cancer development, progression and metastasis; however, there is a poor biological and mechanistic understanding of the role of translation in these processes. Our work and others have pioneered an understanding of translational regulation in breast cancer. We have previously shown that overexpression of initiation factor eIF4G in advanced breast cancer cells selectively increases the translation of mRNAs encoding survival, cell cycle inhibition, and DNA damage and repair proteins, among other DNA damage-protective mRNAs. eIF4G consists of three family members, eIF4F1, eIF4F2 and the poorly studied eIF4F3 homolog, DAP5. we studied this subject of this study. DAP5 lacks the N-terminal domain for eIF4E and PABP binding. DAP5 is therefore suspected to promote eIF4E-independent or IRES-driven translation of mRNAs involved in cell stress and oncogenesis, but its role in metastasis hasn’t been investigated. We analyzed the NCI human tissue genome cancer atlas (TCGA) and found that higher DAP5 mRNA expression is strongly associated with estrogen receptor negative breast cancer metastasis and lower overall survival. We then engineered a highly metastatic breast cancer cell line MDA-MB-231TR to express dox-inducible shRNA to DAP5 or a non-silencing (NS) control. Tumors were developed in clinically relevant orthotopic mouse models, with and without DAP5 silencing by addition of dox to the drinking water. Remarkably, reduction of DAP5 expression by ~70% had no impact on primary tumor growth but fully eliminated metastasis to the lung. Genome-wide transcriptome and translatome analysis of DAP5 and in vivo ultraviolet-cross-linking and high-throughput sequencing (HITS-CLIP) identified specific mRNAs that interact directly with DAP5. A significant fraction of DAP5 mRNA targets are involved in cell death and survival, cell proliferation, cell mobility, DNA repair and translation initiation and do not have IRESs, suggesting a novel role for DAP5 in a non-classical translation initiation process upon cellular stress and metastasis. Our results suggest that the translation initiation factor DAP5 likely plays a critical role in breast cancer metastasis by a unique mechanism for metastasis-specific translation initiation and provides new concepts for therapeutic strategies involving translational regulation.

#4482 Osteopontin, p53 and PTEN isoforms expression patterns in endometrium carcinoma cell lines. Vanessa F. Franco 1, Nataly dos Santos Melo, 1,2 Iaci N. Soares, 1 Yau-Ting Hsu, Yau-Ting 1, Tim H. Huang, 1 Wallace M. Araujo, 1 José A. Morgado-Diaz, 1 Jerson L. Silva, 1 Etel Rodrigues Pereira Gimba 1, 2, INCA, Rio de Janeiro, Brazil; 2UFF, Rio de Janeiro, Brazil; 3UFIRJ, Rio de Janeiro, Brazil; 4University of Texas Health Science Center at San Antonio, San Antonio, Texas; 5UFF/INCA, Rio de Janeiro, Brazil.

Total RNA from the tumor is overexpressed in endometrium carcinoma (EC) and modifications at TP53 and PTEN genes correspond to major genetic alterations in these tumors. Although total OPN expression has been correlated to p53 and PTEN expression, no data is available regarding OPN splice variants and their association to p53 and PTEN isoforms expression. OPN has three splicing isoforms (OPN-SI), named OPNa, OPNb and OPNc, while p53 has at least 12 variants, such as p53 (full length), p53R, Δ40p53, Δ133p53 and Δ160p53. Moreover, PTEN splicing isoforms (PTEN-SI) are named vs-fl (full length variant), vs-3a-3d, vs-5a-5d, and vs-D6. We aimed to evaluate the expression profile of OPN, p53 and PTEN isoforms as a first approach to establish their presumptive associations and functional interactions. Using real time PCR method, Total RNA have been extracted from endometrial non-tumoral (E6/E7 and EM2) and tumoral ( Ishikawa, RL95-2, AN3CA and KLE) cell lines, followed by cdNA synthesis. Transcriptional and protein expression patterns have been evaluated for OPN, p53 or PTEN isoforms, using quantitative real time PCR, immunoblot or immunofluorescence. OPN is overexpressed in tumoral and non-tumoral cell lines in relation to OPNb and OPNc. Total RNA has been extracted, followed by Δ40p53, in relation to other variants in EC cells. Conversely, Δ40p53 is the major expressed in both EM2 and E6/E7 non-tumoral cells. Otherwise, in EC and endometrial non-tumoral cells, PTEN vs-fl is overexpressed in relation to the other splice variants. Specifically in E6/E7 cells, all PTEN-variant, except vs-b and vs-Δ, are overexpressed in relation to EC cell lines. At the protein level, both p53 and PTEN isoforms are overexpressed in E6/E7 cells, when compared to EC cells. Of note, distinct isoforms for most of these variant transcripts have not been detected at the protein level. Our data demonstrate that full length OPN, p53 and PTEN are the major expressed variants in EC tumor cell lines. However, most of these transcript variants display differential expression between endometrial tumor and non-tumoral cells and also among distinct EC cell lines. These data provide early evidence that OPN expression can dynamically modulate the expression of these mRNA isoforms, allowing both transcriptional and translational controls. References: 1. #4483 TGF-β downregulates osteopontin isoforms and induce epithelial plasticity in PC3 prostate metastatic cancer cells. Durval Marques, 1 Rodrigo A. Peres, 2 Paula P. de Freitas, 3 Abigail I. Resende, 4 Nataly dos Santos Melo, 1 Waldemir Fernandes de Souza, 1 José A. Morgado-Diaz, 1 Ezel Rodrigues Pereira Gimba 1, 2, UFF, Niterói, Brazil; 3UFIRJ, Rio de Ostras, Brazil; 4University of California, San Francisco, San Francisco, CA; 5Frederick National Laboratory for Cancer Research, Frederick, MD.

Total osteopontin (OPN) has been described as a master regulator of epithelial-mesenchymal transition (EMT), including in prostate cancer (PCa). However, the contribution of each OPN splicing isoform (OPN-SI), named OPNa, OPNb and OPNc, in the epithelial plasticity dynamic process is currently unknown. Besides, the contribution of alternative splicing regulation in this scenario is poorly understood. Here we aimed to investigate the expression of OPN-SI and the associated splicing pattern regulation in response to metastatic prostate cancer (PCa) cells treatment with TGF-β. Further, we aimed to investigate the resulting cell phenotypic features. To achieve this, we treated PC3 cells with TGF-β 10ng/ml for 48 h as a model to induce epithelial plasticity in these cells. Total RNA was extracted and the corresponding cdNA was tested for transcriptional levels of OPN-SI, SR and HnRNP splicing regulators as well as classical (EMT) markers by using real time PCR. EMT markers and cell morpholology have also been analyzed by immunofluorescence. PC3 cell phenotype has also been evaluated by using cell migration and viability assays in response to β-lapachone cytotoxic reagent. PC3 cells treated with TGF-β displayed an intermediate EMT phenotype, as evidenced by a significant downregulation of both epithelial (E-cadherin, claudin-3 and androgen receptor (AR) and mesenchymal markers (vimentin, N-cadherin, snail and slug) These cells presented a higher cytoplasmic E-cadherin expression, as well as a lower vimentin cytoplasmic staining. A major cortical distribution of actin filaments beneath the cell cortex has been observed. Further, a significant downregulation of OPNa and mainly, OPNb and OPNc isoforms, as well as most tested splicing regulators has been shown. TGF-β treatment also promoted a significant inhibition on cell migration as well as higher sensitivity to β-lapachone treatment, as compared to control cells. Altogether, our data evidence that in our in vitro experimental model, TGF-β promoted an intermediate EMT phenotype, with a predominance of epithelial features, associated to downregulation of OPN-SI and most tested splicing regulators. We then hypothesize that TGF-β may also be an EMT-like inducer, in which metastatic PCa cells could acquire major epithelial features that facilitate cell anchorage and adhesion in distant tumor sites. OPN-SI downregulation in this process could favour epithelial-like features, as opposed to OPN-SI overexpression during tumour progression towards metastatic circulating cells typically displaying mesenchymal phenotypes.

#4484 KRAS regulates eIF4E Binding Proteins (4EBPs) via MAPK-Interacting Kinases (MNKS) in a PISK-dependent, AKT-independent manner. Jillian M. Silva, 1 Rachel K. Bagini, 2 Davide Ruggero, 3 Frank McCormick. 1 University of California, San Francisco, San Francisco, CA; 2Frederick National Laboratory for Cancer Research, Frederick, MD.
Oncogenic RAS mutations are present at high frequencies in human cancer leading to the sustained activation of the ERK1/2 mitogen-activated protein kinase (MAPK) signaling pathway. Of the three major RAS isoforms (HRAS, KRAS, and NRAS), KRAS is the most commonly mutated isoform, in which a substitution of glycine for cysteine (G12C), aspartic acid for glycine (G12D), or valine for glycine (G12V) at codon 12. However, the unique dependencies on upstream or downstream oncogenic signaling amongst the KRAS mutants remains elusive and often masked by the remaining wild-type allele, other RAS isoforms, or additional secondary genetic alterations. Moreover, mutational activation of RAS can also enhance the assembly and activity of the cap-binding complex, eukaryotic initiation factor 4F (eIF4F). It has been demonstrated that RAS signaling via ERK promotes MAPK-interacting serine/threonine kinases (MNKs) to interact with eIF4G and the phosphorylation of eIF4E at serine 209, which is a critical site for oncogenic function. Thus, we employed an isogenic mouse embryonic fibroblast (MEF) system, devoid of H-, N-, and KRAS alleles and reconstituted with a single KRAS mutant isoform, to examine the dependencies of growth factor and PI3′-lipid activities on KRAS-mediated control of translational regulation. Although oncogenic KRAS G12C, G12D, and G12V mutant cells proliferated at twice the rate of KRASb wild-type MEF cells, growth factor deprivation or inhibition of PI3K or mTORC1/2 displayed potent anti-proliferative effects on all MEF cell lines. Analysis of signaling downstream of KRAS revealed that phosphorylation of 4E-BP1, MNK, and eIF4E occurred independent of growth factor activity, which stood in contrast to the substantial inhibition of eIF4E by the eIF4E binding protein harboring ribosomal protein S6 phosphorylation. Interestingly, AKT inhibition largely had no effect on 4E-BP1 phosphorylation, whereas inhibition of PI3K or mTORC1/2 potently suppressed p70S6k, ribosomal protein S6, and 4E-BP1 phosphorylation. Moreover, growth factor deprivation resulted in a marginal decrease of global protein synthesis with negligible effects on cap-dependent translation initiation in all overgrowth factor deprivation resulting in a marginal decrease of global protein synthesis in response to different stimuli and asking how is RACK1 involved in this position, RACK1 can recruit a series of kinases and phosphatases as well as interacting with other ribosomal proteins. Importantly, it is believed that in this position, RACK1 can recruit a series of kinases and phosphatases as well as functioning to regulate the translation and the synthesis of particular cohorts of proteins. Moreover, RACK1 plays a central role in scaffolding these proteins to promote proliferation and migration in our colon cancer cell models. Collectively, these data suggest that KRAS regulates 4E-BPs, and MNKs in a manner that is dependent on PI3K-mTORC1 signaling, but independent of AKT or growth factor activities.

**#4485 Identification and characterization of novel RACK1 binding partners that may modulate the elongation phase of protein synthesis.** Beatrice Malacraci, 1 Rasmus K. Flygaard, 1 Catrinna M. Dowling, 1 John C. Coffey, 1 Lasse B. Jenner, 1 Patrick A. Kirby, 1 University of Limerick, Limerick, Ireland; 2 Aarhus University, Aarhus, Denmark.

RACK1 (Receptor for Activated C Kinase 1) is a member of the tryptophan-aspartate (WD-repeat) family of proteins. By functioning as a scaffolding protein, RACK1 is involved in regulating many different signalling pathways in cells, including cell proliferation and cell migration. Interestingly, RACK1 has been identified as a central component of the ribosomal machinery, specifically located on the 40S ribosomal subunit close to the mRNA exit channel where it makes contact with other ribosomal proteins. Importantly, it is believed that in this position, RACK1 can recruit a series of kinases and phosphatases as well as functioning to regulate the translation and the synthesis of particular cohorts of proteins. Moreover, RACK1 plays a central role in influencing the location of the translation machinery. Using 2D and 3D models of colon cancer cell lines, together with Click-IT chemistry and Mass Spectrometry analysis, we were able to identify a series of proteins, including newly synthesized ribosomal proteins, that interact with RACK1. We identified proteins involved in cell cycle control, metabolism and protein synthesis. As expected, we have found a number of proteins that are involved in cell migration and a number of proteins that are mediators of the cell adhesion process. Interestingly, some of the most highly scored interacting proteins were those involved in protein synthesis. Of those, we identified several elongation factors as being novel RACK1 binding partners. Elongation factors are a class of proteins directly involved in the elongation phase of protein synthesis. Along with this primary function, these factors have different important roles in cells, such as influencing cytoskeleton remodelling and activation of growth and proliferation pathways. Elongation factors have been found to be upregulated in many cancer cell lines. We have confirmed the interaction between RACK1 and several of these elongation factors and we have determined that many of these are dysregulated in colon cancer. We have established that the activity of these elongation factors is regulated by a combination of stress conditions and growth factor stimulations. We have determined that RACK1 plays a central role in scaffolding these proteins to promote proliferation and migration in our colon cancer cell models. Collectively, these results provide a novel and interesting role for RACK1 in the modulation of the elongation phase of protein synthesis. We are now investigating the subcellular localization of these factors in response to different stimuli and asking how is RACK1 involved in their localization downstream of IGF-I and insulin signalling. Characterizing the interaction between these proteins and RACK1, both in cells and tissue, may lead to the design of novel therapeutic approaches in colon cancer.

**#4486 Redox regulation of the biosynthesis of mitronic tsiRNA miR-6855-3p in the basal like breast cancer cells.** Smita Misra, Gautam Chaudhuri. Meharry Medical College, Nashville, TN.

Radiation and chemotherapeutic agents eradicate tumors by inducing irreparable DNA damage. However, cancer cells often develop resistance to therapy by manipulating the DNA repair machinery. Conversely, a dividing cell constantly exposed to environmental and endogenous DNA damaging agents can transform into a tumor due to incorrect repair. Therefore the expression level of DNA repair genes is critical for cancer therapy and tumorigenesis. Our preliminary studies implied a unique mechanism involving an miRNA miR-6855-3p that promotes the biosynthesis of the translational regulator protein SPRDX5 which enhances the expression of the tumor suppressor protein BRCA2 leading to the genotoxic and radiation-resistance of aggressive SLUG-high basal-like breast cancer (BLBC) cells. The miRNA miR-6855-3p thus acts as a tumor suppressor miRNA. Interestingly, the gene for the miRNA miR-6855-3p is mitronic and is nested within the intron#13 of the USP20 gene which is a deubiquitase. Thus, the transcription of miR-6855-3p gene is regulated through the USP20 gene promoter. We present evidence here that USP20 and miR-6855-3p gene transcriptions are up regulated by oxidative stress. Tert-butylhydroperoxide was used for oxidative stress. Under the oxidative stress and the inhibition of Nrf2 level and the levels of several Nrf2-regulated proteins are increased, indicating activation of Nrf2 in the stressed BLBC cells. Under the stress conditions the levels of USP20 and miR-6855-3p are increased significantly. Knockdown of Nrf2 prevented stress-induced elevation of USP20 and miR-6855-3p RNA level in the BLBC cells indicating the involvement of Nrf2 in this process. The binding of Nrf2 to the USP20 gene promoter and its function were characterized by ChIP analysis, site-directed mutagenesis and using the promoter-luciferase reporter constructs. We conclude that the biosynthesis of the miR-6855-3p in the BLBC cells is regulated by oxidative stress and involves Nrf2. Since oxidative stress is a hallmark in the etiology and progression of metastatic breast cancer, understanding the redox regulation of a miR that positively influences BRCA2 gene expression in the BLBC cells could be clinically significant. **#4487 A critical role of PARylation in regulating the functions of OVOL2.** Rui Zhang, 1 Boan Li, 1 Yih-Cherng Liu 1. National University of Singapore, Singapore, Singapore; 2 State Key Laboratory of Cellular Stress Biology, Xiamen University, Xiamen, China.

Poly(ADP-ribosyl)ation (PARylation) is one of the post-translational modifications, by which the ADP-ribose (PAR) polymers are added to the specific protein by a PAR polymerase (PARP). In the about 50 years’ studies, this specific modification has been verified to be related to multiple important biological functions including cell death, cell differentiation, histone modification, transcription, DNA repair, DNA replication, DNA damage, genome stability, Ovo-like 2 (OVOL2), a novel zinc finger transcriptional factor, contains a Snail/Slug (SNAG) motif at the N-terminal to possess a transcriptional regulatory activity and four DNA-binding Cys2-His2 (C2H2) zinc finger domains at the C-terminal to bind with DNA. OVOL2 is demonstrated to be involved in the cranial neural tube, angiogenesis, heart and placental development. In addition, OVOL2 can also suppress cell cycle and terminate differentiation of keratinocyte by directly inhibiting of c-Myc and Notch1. However, the regulation and biological function of OVOL2 are still largely unknown. In this study, we identify the binding targets, PARP1 and NPM1, of OVOL2. In addition, we report that the function of OVOL2 is regulated by PARylation, which modifies on C2H2 zinc finger domains and plays an important role in the regulation of OVOL2 functions. PARylation of OVOL2, but not the 3K mutant, alters focal adhesion and cell cycle, resulting in the formation of polyplody in cells. Our findings not only have significant implications for the cellular functions of OVOL2, but also provide a better understanding on the multiple biological functions of the PARylation.

Epigenetic mechanisms play a key role in cancer and are a major contributor in driving the aberrantly high levels of oncogenic receptor tyrosine kinases (RTK) in cancer. Understanding mechanisms leading to altered transcription of...
oncogenes and tumor suppressors has the potential to provide new therapeutic targets. Here we show that the PH domain leucine-rich repeat protein phosphatase 1 (PHLPP1), a tumor suppressor that directly dephosphorylates and inactivates Akt, has an additional function of regulating approximately 10% of the transcriptome. Specifically, we used non-biased high-throughput RNA-seq sequencing technologies and immunoprecipitation techniques to analyze genome-wide mRNA levels and acetylation patterns of genes in cells from wild-type and PHLPP1 knockout mice. De novo motif analysis of the promoter for the genes regulated by PHLPP1 identified enrichment in the recognition motifs for a number of transcription factors, including ones involved in inflammatory signaling. Biochemical analysis revealed that PHLPP1 regulates the phosphorylation and activation of these transcription factors, such that loss of PHLPP1 leads to enhanced inflammatory signaling. Our data support a model in which PHLPP1 dephosphorylates specific transcription factors to act as the brakes to inflammatory signaling, a hallmark of cancer.

#4489 Knockdown ARID5A suppresses proliferation of LNCaP prostate cancer cell through the inhibition of global protein synthesis. Chao Sun, Viktor Chesnokov, Keitchi Itakura. Beckman Research Institute of City of Hope National Medical Center, Duarte, CA.

AT-Rich Interaction Domain-containing protein 5a (ARID5A; also known as Modulator Recognition Factor 1 (MRF1)) was first cloned in our laboratory by screening a cDNA library of Tera-2 mRNA with an oligonucleotide probe from the major immediate early gene of human cytomegalovirus. It has been reported that ARID5A forms a complex with androgen receptor (AR) in yeast two hybrid assays and is a co-activator of AR in transient transcription assays. In this study, we report that the knockdown of ARID5A expression inhibits proliferation of LNCaP cells on the contrary to the expectation from the transient transfection assay. We found that proliferation of cells stimulated by the treatment with dihydro-testosterone (DHT) was suppressed when ARID5A expression was down-regulated by siRNA technology. Androgen stimulates cell proliferation through activation of mammalian target of rapamycin complex 1 (mTORC1). However, the suppression of ARID5A does not affect androgen-activated mTOR activity. Furthermore, the expression of androgen-inducible and androgen-suppressive genes were not affected by suppression of ARID5A. We concluded that ARID5A is not a co-activator of AR. Meanwhile, flow cytometer analysis showed that DHT-stimulated cell cycle was arrested at G1 phase after the knockdown of ARID5A expression. Oil Red O staining assays showed that the inhibition of ARID5A expression led to decreased DHT-induced lipid accumulation. Our data further proved that the knockdown of ARID5A expression inhibited the protein expression of DHT-induced sterol regulatory element binding transcription factor 1 (SREBP-1). In addition, Western blot analysis revealed that the down-regulation of ARID5A decreased the expression of cell survival / proliferation and cell cycle regulation proteins, such as hypoxia inducible factor 1 alpha (HIF1α), cyclin D1 and cyclin D3. Real time PCR data revealed that the knockdown of ARID5A expression did not affect the steady level of HIF1α, cyclin D1 and cyclin D3 mRNA. These suggested that knockdown of ARID5A expression affected protein expression at translational and/or post-translational level. Our data suggested that knockdown of ARID5A expression increased the phosphorylation of eukaryotic translation initiation factor 2α (eIF2α) which inhibited translation initiation. S35 labeling assay confirmed that the knockdown of ARID5A expression suppressed the global protein synthesis. We showed that one of the four eIF2α kinases, general control non-depressible 2 (GCN2) was activated by the suppression of ARID5A expression. We are currently studying on the mechanisms by which ARID5A regulates GCN2 kinase.

#4490 Post-transcriptional regulation on PIA53 expression in malignant mesothelioma. Tian He, Karen McColl, Nneka Sakre, Gary Wildey, Afschin Dowlati. Case Western Reserve University, Cleveland, OH.

Protein Inhibitor of Activated STAT3 (PIAS3) was originally identified as an endogenous suppressor of STAT3 activity which can specifically interact with activated STAT3 and block its downstream oncogenic effects. Previous studies from our lab have shown that low PIAS3 protein expression in mesothelioma tumors was associated with poor patient survival. Furthermore, low PIAS3 expression in mesothelioma cell lines correlated with higher STAT3 activity. Over-expression of PIAS3 decreased STAT3 activity and cell growth. These findings suggest that low PIAS3 expression may play an important role in mesothelioma tumorigenesis, thus understanding the regulatory mechanism(s) of PIAS3 expression may provide new therapeutic strategies in mesothelioma treatment. Initially, we examined PIAS3 expression by western blotting and RT-qPCR among six mesothelioma cell lines (H2B, 211H, H2052, H2452, HAY, YOU) and found that while PIAS3 mRNA levels were relatively constant, PIAS3 protein expression was highly variable. This finding indicated a potential post-transcriptional regulation of PIAS3 expression in mesothelioma. To investigate this further, we first examined PIAS3 protein stability in the presence of proteasome inhibitors and cycloheximide (CHX). We observed no increase in PIAS3 protein levels during proteasome inhibition using either MG132 (10 μM) or bortezomib (1 μM) for up to 8 h in 211H, H2052 and H2452 cells, whereas TP53 protein levels were decreased. We then tested whether PIAS3 expression may provide new therapeutic strategies in mesothelioma treatment. We next explored the PIAS3 3’UTR as a potential site for translational regulation. We initially utilized a miR microarray and computational analysis, followed by a PIAS3 3’UTR luciferase reporter assay, to screen miRNAs that are highly conserved in human and can specifically target the PIAS3 3’UTR and identified miR-18a as our first candidate. Taken together, our study suggests that variable expression of PIAS3 protein in mesothelioma is regulated by translational control and not by protein stability.

#4491 Modulation of p63 expression by phosphorylation of RBM38 at S195 via miR-203. Yanhong Zhang, Wensheng Yan, Jin Zhang, Xinbin Chen. UC Davis, Davis, CA.

p63, a family protein, acts as a sequence-specific DNA-binding transcriptional factor to regulate the expression of target genes involving in various cellular processes, including growth suppression and epithelial development. RBM38, a RNA-binding protein, is a target of p53 family and is known to interact with its target mRNAs and regulate their expression via mRNA stability. Previously, we found that RBM38 negatiely regulates p63 mRNA stability through interaction with the 3’ untranslated region (3’UTR) of target mRNAs. We also found that phosphorylation of RBM38 at Ser195 alters the conformation and function of RBM38 protein. However, it is unclear whether phosphorylation of RBM38 or miR-203 alters the ability of RBM38 to regulate p63 expression. In this study, we found that in both MCF7 and HaCaT cells, wild-type RBM38 and S195A mutant, but not phospho-mimic S195D mutant, inhibit p63 mRNA stability, suggesting that Ser195 phosphorylation abrogates the ability of RBM38 to repress the expression of p63. Importantly, we found that phosphorylation of RBM38 disrupts the binding of RBM38 to the U-rich element in p63 3’-UTR. Additionally, we found that miR-203 inhibitor increases, whereas miR-203 mimic decreases p63 expression through binding to p63 3’-UTR, consistent with a previous report. Interestingly, we found that the ability of RBM38 to repress p63 expression is disrupted by miR-203 inhibitor but enhanced by miR-203 mimic. Furthermore, we found that wild-type RBM38 protein, but not phospho-mimic S195D mutant, physically interacts with Ago2, indicating that RBM38 may inhibit p63 mRNA stability by modulating Ago2-miR-203 complex to bind to the U-rich element in p63 3’-UTR. Together, we uncovered a novel mechanism by which RBM38 modulates p63 expression via miR-203.

#4492 Androgen receptor affects Gli activity by promoting transcriptionally active states of Gli upon androgen stimulation. Sarah Truong,1 Na Li,2 Mannan Nouri,1 Ralph Bytynn1. 1University of British Columbia, Vancouver, British Columbia, Canada; 2Vancouver Prostate Centre, Vancouver, British Columbia, Canada.

Introduction: While “castration” therapies benefit metastatic prostate cancer (PCa) patients, their effects are transient and progression to castration resistant disease (CRPC) remains a vexing clinical problem. Despite low levels of circulating androgens in treated patients, CRPC typically remains dependent on androgen/androgen receptor (AR) signaling for further growth. Previously we showed that Gli protein binding to AR co-activates AR transcriptional activity and supports androgen-independent growth. Here we show evidence that the interaction of AR with Gli proteins, particularly Gli3, allows for a "non-canonical" activation of Hedgehog signaling that contributes to PCa cell growth and progression to CRPC. Methods: Androgen growth-dependent (LNCaP) or independent (LNCaP-AI, LNCaP) PCa cells were transfected with a Gli-luciferase (Gli-luc) reporter and were treated with R1881, enzalutamide (Enz), or a combination. Luciferase activity was measured. R1-367 (harboring a genomic deletion of AR) served as a negative control. Knockdown of AR-FI with siRNA or overexpression of a small decay peptide from the Gli2 AR-binding domain (Gli-DP) was also performed in above cells. Western blot and real-time PCR confirmed both AR and Gli target gene/protein expressions in LNCaP and LNCaP-AI cells (+/- R1881). Sonic hedgehog (Shh) ligand-responsive 3T3-E1 cells were transiently expressed with AR-FI to confirm the involvement of canonical Shh-Gli activation pathway in AR co-activation of Gli transcription. Co-immunoprecipitation (co-IP) was performed to verify the blocking efficiency of Gli-DP in AR-Gli3 interaction in LNCaP cells and AR-overexpression 293FT. Results: Androgen (R1881) treatment strongly induced Gli transcription activity in AR+ PCa cells while Enz reversed this effect; AR-FI-specific knockdown or
exogenous Gli-DP expression suppressed androgen-induced Gli reporter expression as well as expression of endogenous Gli-responsive genes. R1881 treatment promoted Gli2/3 protein processing to transcriptionally active states (Gli3-FullLength and Gli2-Active) and enhanced the expression of Gli-target genes, Gli1/Ptch1, at protein and/or mRNA levels. Co-IP revealed that exogenous Gli-DP blocked the interaction between AR and transcriptionally active Gli3-FL in PCA cells. Overexpression of AR in ST3-E1 cells confirmed that AR interaction with Gli stabilizes the active Gli3-FL form by suppressing degradation of Gli3 in a manner independent of the canonical Shh-Gli activation pathway. Conclusions: Our findings further identify the importance of AR-Gli interaction in progression of PAs to CRPC and shows that cooperative binding of AR to Gli promoter regions and/or Gli signaling in PAs cells. Interference with the AR-Gli interaction using a decoy peptide provides a means to suppress AR activation of Hedgehog in PCA cells.

#4493 The co-chaperone UNC45A controls cancer cell proliferation through Nek7 and centrosomal separation. Yasmeen Jilani,1 Nada H. Elsa,1 Kashish Kainth,1 Sumin Lu,2 Nehal M. Elsherbiny,3 Laila A. Eissa,3 Mamdouh M. Elshishtawy,1 Hasan Korkaya,1 Abdeljabar El Andaloussi,2 Ahmed Chadli1.

1Augusta University, Georgia Cancer Center, Augusta, GA; 2Augusta University, Augusta, GA; 3Mansoura University, Mansoura, Egypt.

Recent findings have shown that the Heat Shock Protein 90 (Hsp90) co-chaperone UNC45A is overexpressed in ovarian and breast cancers. Previously, we have shown that UNC45A is a centrosomal protein essential for cervical tumor cell growth through activation of the checkpoint kinase 1 (Chk1). In this report, we further examine the role of UNC45A in breast tumor proliferation using a variety of biochemical and cell biology techniques and animal models. We confirmed that UNC45A is highly overexpressed in human breast-infiltrating ductal carcinomas as compared to adjacent normal tissues. Silencing UNC45A in vitro blocked the proliferation of all breast cancer subtypes and drastically reduced tumor growth of the triple negative MDA-MB-231 cell line implanted in mammary fat pads of NOD/SCID mice. However, loss of UNC45A did not affect the proliferation of normal mammary cells. Remarkably, UNC45A becomes more nuclear in human cancer tissues and cancer cell lines as compared to normal tissues and non-transformed Hs578Bst and HME mammary cell lines, respectively. This suggests an important nuclear function for UNC45A during tumorigenesis. Microarray analysis of mRNA from Hs578T cells showed that loss of UNC45A alters the expression of 121 genes, involved in cancer and cellular development and growth networks. Relevant to cell proliferation, we found that Nek7 gene was significantly repressed upon silencing UNC45A, which was validated by RTqPCR and Western blot analysis in multiple breast cancer cell lines. Nek7 is a member of the NIMA (never in mitosis, gene A) family of serine/threonine kinases. It plays a key role in centrosomal separation during mitosis. This correlates neatly with our observation that loss of UNC45A causes a centrosomal separation defect, cell proliferation arrest and death of breast cancer cell lines. ChIP experiments showed that UNC45A binds to the promoter of the Nek7 gene, suggesting direct transcriptional regulation. Interestingly, the UNC45A sequence contains four LxxLL motifs, which are thought to be signatures for co-activator binding to nuclear receptors. Furthermore, computational analysis identified two glucocorticoid response elements (GRE) consensus sequences in the Nek7 promoter, suggesting its transcriptional regulation by the glucocorticoid receptor (GR). This hypothesis was further strengthened by a significant decrease in the mRNA and protein levels of Nek7 upon silencing GR. Thus, our data suggest that UNC45A functions as a GR co-activator to control Nek7 gene transcription. Consistent with this, immunoprecipitation experiments confirmed that UNC45A and GR form endogenous complexes, and treatment of Hs578T and MCF7 cell lines with dexamethasone upregulates Nek7 mRNA and protein levels. In conclusion our data strongly support the premise that UNC45A promotes Nek7 transcription through activation of GR, and thus controls centrosomal separation and cancer cell proliferation.

#4494 Tumor suppressive role of ZFP36L1 by suppressing HIF1α and Cyclin D1 in breast and bladder cancer. Xin Yi Loh, Ling Wen Ding, H. Phillip Koehler. Cancer Science Institute, Singapore, Singapore.

AU-rich mRNAs are a class of mRNAs that contains AU-rich elements (AREs) motifs in their 3’UTR. The half-life and turnover of AU-rich mRNAs are tightly regulated by AREs-binding proteins, such as Zinc finger protein 36 C3H type-like 1 (ZFP36L1). ZFP36L1 is one of the RNA-binding proteins (RBPs), which consists of two tandemly repeated zinc finger motifs that specifically recognize AREs motifs and mediate mRNAs decay. However, our knowledge on role of ZFP36L1 in breast and bladder cancers and its downstream targets remains poorly elucidated. Here, we hypothesized that ZFP36L1 might degrade oncogenic mRNAs transcripts, thus leading to suppression of tumorigenesis. Our analysis of in silico data revealed that ZFP36L1 is significantly mutated or downregulated in a variety of cancers. The high proportion of inactivation mutation pattern as well as the Mutsig result suggest that it may act as an unappreciated tumor suppressor. Lower ZFP36L1 expression correlated with reduced survival of cancer patients. Forced expression of ZFP36L1 markedly reduced cellular proliferation, invasiveness and migration in vitro, as well as tumor growth in vivo. In addition, microarray and RNA-seq data analysis showed that several important cancer-related candidates such as IL8 and HIF1α were significantly downregulated. Overexpression of ZFP36L1 reduced HIF1α mRNA and protein expression. Similarly, HIF1α forced expression also inhibited ZFP36L1 mRNA to protein processing, leading to a further arrest of ARE-mediated mRNA decay. Dual luciferase reporter assays and RNA Electro-mobility Shift Assay (REMSA) showed that only type specific ZFP36L1, but not different mutants of ZFP36L1, was able to bind directly and to degrade a HIF1α 3’UTR construct that contains AU-rich regions. Meanwhile, mRNA pull down assay demonstrated that ZFP36L1 protein recognized cell-cycle-related transcripts. Overexpression of ZFP36L1 led to reduction of Cyclin D1 and phospho-Rb in protein expression. Furthermore, SILAC data unveiled interesting binding partners of ZFP36L1. Collectively, our findings propose that ZFP36L1 might have a critical tumor suppressive role in breast and bladder cancer by negatively regulating mRNA whose protein products cooperatively promote hypoxia and transition into S phase of cell cycle. Augmenting ZFP36L1 function might disable the cell cycle and proliferation of aggressive bladder tumors.

#4495 Elucidating BCL11A’s function in triple negative breast cancer. Nicholas O. Stevers, Samantha L. Tinsley, Rebecca Moody, Chang-Ching Lin, Jennifer Meagher, Jeanne A. Stuckey, Miao-Chia Lo, Duxin Sun. 1Univ. of Michigan, Ann Arbor, MI.

It has been recently shown that the B-cell CLL/lymphoma 11A (BCL11A) transcription factor is highly expressed in triple-negative breast cancer (TNBC) and has critical functions in promoting tumor growth and mammary stem cell maintenance. Studies in our group have found that the first twelve amino acids (aa 1-12) of BCL11A are a conserved sequence that allows binding to retinoblastoma binding protein 4 (RBBP4). RBBP4, a histone binding protein, is involved in many epigenetic complexes, including the Polycomb repressive complex 2 (PRC2), the nucleosome remodeling and deacetylase (NuRD) complex, and SIN3A complex. Through these interactions BCL11A may exert transcriptional and epigenetic regulation. Herein we investigate the importance of BCL11A’s interaction with RBBP4 and its function in TNBC. BCL11A-complex interactions were observed through pull-down experiments of TNBC cell lysate utilizing aa 2-16 of BCL11A and a scramble control sequence. Our results demonstrate that this 16-amino acid sequence is sufficient to bind to RBBP4 and pull down the PRC2, NuRD, and SIN3A complexes. Furthermore, the NuRD and SIN3A complexes pulled down by BCL11A aa 2-16 retained their functionality as observed through pull-down histone deacetylase (HDAC) activity assays. These results indicate significantly higher HDAC activity in the wildtype sequence as compared to the scrambled sequence. To further investigate this interaction, protein crystallization was conducted, the results of which validated the interactions. The N-terminal truncated BCL11A protein (del 2-12) and a scrambled control were transfected into the TNBC cell line SUM149. Analysis via flow cytometry shows a reduction of the ALDH+ cell population in the BCL11A peptide transfected cells versus scramble control. We are currently investigating the necessity of this 12-amino acid sequence in interactions with RBBP4, PRC2, NuRD and SIN3A via co-immunoprecipitation experiments using an N-terminal truncated BCL11A protein (del 2-12). The effects of full-length BCL11A and del 2-12 on the ALDH+ cell population are also being examined. These experiments will further delineate this sequence’s importance in BCL11A-RBBP4 interactions.

#4496 Dissecting cellular heterogeneity using single cell RNA sequencing in human lung tumors. Elise T. Courtot1, Huipeng Li2, Yuliyan Tan, Daniel Tan3, Shyam Prabhakar2, Paul Robins1. 1Jackson Laboratory, Farmington, CT; 2Genome Institute of Singapore, A-STAR, Singapore; 3National Cancer Center of Singapore, Singapore.

Intra-tumor heterogeneity is a key determinant of tumor biology, treatment response and patient survival. It is therefore essential to comprehensively characterize the phenotypes and interactions of the diverse cells within the tumor ecosystem. However, traditional molecular profiling studies have largely relied on bulk-tissue analysis, which obscures the signatures of distinct cell populations. We present here an unbiased analysis of functional heterogeneity in NSCLC (Non Small Cell Lung Cancer) cancers (Lung Adenocarcinoma and Squamous Cell Carcinoma) and their microenvironment using RNA-seq pro-

1148 Proceedings of the American Association for Cancer Research • Volume 58 • April 2017
MOLECULAR AND CELLULAR BIOLOGY / GENETICS: Post-transcriptional and Translational Regulation in Cancer

filing of unsorted single cells from 20 primary tumors and matched normal lung tissue (NL). Using a new clustering algorithm RCA (Reference Component Analysis), we identified the major cell types composing the normal lung tissue as well as the tumor ecosystem such as epithelial, fibroblast, endothelial and immune cells. Notably, we were able to identify resident alveolar macrophages, in tumor and normal tissue and their single-cell differential expression analysis revealed substantial differences in their gene expression. Similarly, we identified blood-vessel endothelial cells in matched normal and tumor tissue, and identified the differentially expressed genes in both cell types. Our unbiased approach allowed us to study the diversity of the epithelial malignant cells present in different tumors, highlighting the tumor and patient specific variability. Together with the NSCLC data the single cell level by sc-RNAseq offers a powerful tool to provide insights into the transcriptomic variability within the key cellular players of the tumorigenesis.

We have developed a streamlined workflow for multiplexed co-detection of proteins and mRNAs in single reactions at single-cell resolution. This workflow couples OER for protein detection with reverse transcription (RT) for mRNA detection. In this study, we examined 31 overlapping targets, from a panel of 84 protein and 40 mRNA assays, across three different cell lines (A549, SKBR3 and K562). Unsupervised gene expression profiling analysis, including component analysis and hierarchical clustering revealed different aspects of the protein-mRNA relationship. The top 10 genes contributing to cell differentiation were identified for both proteins and mRNAs, and eight of them overlap. This result implies an overall concordance of certain protein and mRNA expression in different cell lines. Our results also demonstrate that cells can be classified into subpopulations based on protein-mRNA expression profiles, and different subpopulations have distinct correlation coefficient values. The correlation between CCNB1 protein and mRNA was low (R = 0.2884) in the whole population. However, there was a subpopulation in which CCNB1 protein correlated strongly with its mRNA. When this subpopulation was analyzed, the R value was 0.8350, while the rest of the cells had an R value of 0.0233. More interestingly, in the NSCLC data at the single cell level by sc-RNAseq, we hypothesize that the abnormal activation of the IRE1α-XBP1 axis may influence KRAS NSCLC progression and aggressiveness and serve as a potential novel avenue for the treatment of NSCLC. After probing the impact of the underlying mechanism on tumor growth we will finally evaluate the translational utility of targeting the ER stress pathway with a small molecule inhibitor against IRE1α.

#4499 The oncometabolite fumarate prevents hypoxia-induced ER stress by enhancing the pentose phosphate pathway. Luana Schito, Sergio Rey, Bradly G. Wouters, Marianne Koritzinsky, Princess Margaret Cancer Centre, Toronto, Ontario, Canada.

Cancer cells co-opt mechanisms of adaptation to hypoxia to minimize energy expenditure and halt proliferation thereby increasing hypoxic tolerance, a major factor contributing to chemo- and radioresistance in patients. The endoplasmic reticulum (ER) kinase PERK is one of the three signaling transducers of the UPR. PERK activity is essential for both correct folding and processing of proteins and quality control in the ER. We have previously shown that accumulation of fumarate, resulting from loss-of-function (LOF) of the mitochondrial enzyme fumarate hydratase (FH), augments the antioxidant capacity of hypoxic cancer cells through upregulation of the pentose phosphate pathway (PPP). Here, we report for the first time that the fumarate-dependent increase of antioxidants generated by the PPP prevents hypoxic activation of the PERK-eIF2α axis enabling protein synthesis and proliferation leading to an impairment of hypoxic tolerance. HeLa ( cervix), HCT-116 and LS174T (colon) adenocarcinoma cells were transfected with lentiviral vectors encoding for shRNAs targeting FH. Immunoblot assays showed that FH LOF impaired PERK activity under hypoxia thus inactivating eIF2α. Moreover, the ability of fumarate to prevent PERK activation was specific to hypoxia since fumarate did not affect the pharmacological activation of the UPR by thapsigargin, DTT or tunicamycin. A comprehensive analysis utilizing a RT-qPCR array to profile the mRNA expression of 84 UPR genes, showed that FH LOF inhibited the UPR in HCT-116 cells. A similar response was observed in patient-derived UOK262 kidney cancer cells whereby bi-allelic FH mutations resulted in downregulation of 72% of the UPR genes whereas FH re-introduction restored UPR signaling. We employed LS174T mucinous adenocarcinoma cells as a model to assess protein synthesis. Mucin synthesis was not affected in hypoxic FH deficient cells whereas it was abrogated in wild-type cells. Consistent with these results, FH LOF increased FH activity and enhanced hexose monophosphate (HMP) cycle and pentose phosphate (PPP) activity. In conclusion, we found that fumarate accumulation (either through endogenous or FH LOF) acts as an inhibitor of the PERK-eIF2α axis in FH silenced cells thereby suggesting that FH activation by fumarate is implicated in PERK inhibition. RNAseq data analysis in melanoma, prostate, colon, breast, lung and renal cancers from TCGA cohorts shows a negative correlation between PERK and the PPP enzyme PGLS and that the mechanism whereby FH deficient occurs in cancer patients is surprising. In conclusion, we show that fumarate impairs PERK–eIF2α UPR signaling in hypoxic cancer cells. Clinical and molecular data show that UPR activation is one of the mechanisms responsible for chemo- and radioresistance in hypoxic tumors. This study suggests that fumarate accumulation (either through extrinsic or FH LOF) represents a novel approach to target hypoxic cancer cells and improve patient prognosis.

#4500 Inhibition of PERK by small molecule inhibitors enhances the response to ionizing radiation in vitro and animal tumor models. Ioannis Verginis, Joel Encarnación, Souvik Dey, Constantinos Koumenis. Univ. of Pennsylvania School of Medicine, Philadelphia, PA.

Endoplasmic reticulum (ER) is a well organized membranous network, responsible for synthesis and folding of secretory and membrane proteins, lipid and sterol biosynthesis and intracellular calcium storage. Perturbations in ER lumen caused by depletion of Ca²⁺ levels, hypoxia, nutrient deprivation, affect the ER homeostasis, a condition known as an ER stress. In order to cope with this stress, cells have developed an orchestrated biochemical response, termed Unfolded Protein Response (UPR). Hypoxia, an ER stress inducer, is an important and unique characteristic of the solid tumor microenvironment, promotes resistance to radiotherapy and contributes to poor patient prognosis. Cancer cells overcome these stress conditions through activation the PERK–eIF2α arm of the UPR, leading to inhibition of global protein synthesis and cell survival. We hypothesize that the use of small molecule PERK inhibitors will decrease the
survival of hypoxic cells and eventually sensitize them to irradiation. In this study we used highly radiosensitive melanoma and head and neck squamous cell carcinoma cell lines B16F10-ova and SQ20B, under normoxia and hypoxia, respectively. We used two specific PERK inhibitors (PERKi) and tested for their efficacy both in vitro and in vivo. Induction of ER stress in both cell lines, either by treatment of SQ20B cells with PERKi or by exposure to hypoxic conditions (0.2%), was evaluated by activation of PERK and its downstream targets. Pre-treatment of stressed B16F10-ova and SQ20B cells for 2h with PERKi (1μM), caused complete inhibition of PERK-elicited ATF4-CHOP arm of the UPR. Moreover, both cell lines pre-treated with PERKi showed a significant decrease in survival fraction under ER stress-induced by TG (0.5μM) as well as under hypoxia (0.2%) along with increasing doses of irradiation (IR). For the in vivo experiments, nude and C57BL/6 mice were treated with either 100mg/kg of PERKi by oral gavage, twice a day for 3weeks, or IR or a combination of PERKi and IR. Mice treated with PERKi showed a small but not significant delay of tumor growth in both backgrounds of mice. However, combined treatment with IR (12 and 15Gy) caused a significant reduction of tumor volume as well as a delayed tumor growth which was significantly more pronounced in the immunocompetent mice. Data from flow cy-ometry analysis of one of the the PERK+ IR treated tumors from C57BL/6 mice showed that there is a significant infiltration of CD3+ cells as well as significant higher number of CD3+CD8+ cells compared to the untreated mice or mice treated with either PERKi or IR alone. Collectively, our results show that PERKi effectively reduces the survival of hypoxic SQ20B cells and sensitize them to IR in vitro and in tumors. Further experiments will clarify whether PERKi have a dual role on reducing the hypoxic fraction and direct recruitment of the cytotoxic T-cells.

#4501 CEBPD is an early endoplasmic reticulum stress response gene implicated in breast cancer cell survival. Namratha Sheshadri, Shikha Shanaran, Esta Sterneck. National Cancer Institute, Frederick, MD. CEBPD (C/EBP delta) is a member of the CCAAT-e enhancer binding protein (C/EBP) family of transcription factors characterized by a β-Zip domain that mediates dimerization and DNA binding. CEBPD is induced in response to acute stressors such as cytokine stimulation, bacterial lipo polysaccharide (LPS), corticosteroids, radiation and hypoxia. We have previously reported that CEBPD has dual functions in breast cancer by both attenuating or enhancing oncogenic pathways depending on context (Balumurugan and Sterneck, 2013, Mendoza-Villanueva et al., 2016). Recent studies reveal that elevated Endoplasmic Reticulum (ER) stress is associated with the pathology of several diseases including cancer. Limiting supply of nutrients and oxygen in growing tumor cells disrupts the protein folding homeostasis resulting in activation of the unfolded protein response (UPR). The UPR includes pathways that support adaptation to stress, and that are also implicated in promoting malignant features and therapy resistance in breast cancer. Hence, we investigated a possible role for CEBPD in this stress response pathway. Using breast cancer cell lines as model systems, we found that CEBPD is dynamically regulated in response to chemical and physiologic inducers of ER stress. Kinetic analyses indicate that CEBPD induction is concurrent with the activation of the UPR effectors XBP1s and ATF4 suggesting a potential role in stress adaptation. Examination of the global transcriptional profile of the Thapsigargin-induced stress response in MDA MB-231 cells indicated that CEBPD activates genes involved in cytokine and chemokine production/signaling, immune cell recruitment as well as angiogenesis pathways. While XBP1s has been previously ascribed to activating these pathways, the levels of activated XBP1s were not affected by CEBPD silencing. This is the first report of a similar role for CEBPD in the ER stress response and warrants the investigation of possible co-operation of CEBPD and XBP1 in the UPR pathway. Further, we showed that knock down of CEBPD in cancer cells increased PARP cleavage and susceptibility to ER stress induced cell death. CEBPD deficient cells also displayed reduced LC3II accumulation, suggesting impaired autophagy induction in response to ER stress. Taken together, our data suggests that CEBPD is a novel proximal effector of the ER stress response in breast cancer cells. Activation of this transcription factor regulates tumor promoting inflammatory and angiogenic signaling pathways. Additionally, CEBPD expression confers a survival advantage to cancer cells encountering ER stress. Therefore, we propose that targeting CEBPD may sensitize cancer cells to ER stress inducing therapeutics.

#4502 Heat shock protein 47 maintains breast cancer cell survival through its inhibitory effect on ER stress sensor IRE1alpha activity. Akihiko Yoneda,1 Norio Takei,2 Kaoi Sawada,1 Marina Kosaka,1 Kenjiro Minomi,2 Yasuaki Tamura3. 1Hokkaido University, Sapporo, Japan; 2Nitto Denko Corporation, Sapporo, Japan. Background and aims: Heat shock protein 47 (HSP47) is a collagen-specific chaperone and is expressed in fibroblasts and stromal cells that constitutively produce and secrete several types of collagens. In a tumor microenvironment, HSP47 is also highly expressed in cancer-associated fibroblasts, involving in the tumorigenesis through construction of the extracellular matrix. Intriguingly, HSP47 is highly expressed in cancer cells in which almost no collagen is synthesized and its expression has been reported to be associated with malignant grade of gliomas and poor prognosis of breast cancer. However, the functional significance of HSP47 in cancer cells remains unclear. Thus, the purpose of the present study was to clarify the molecular mechanism by which HSP47 maintains cancer cell survival and to explore the possibility of HSP47 becoming a therapeutic target. In this study we used high radioresistant melanoma and head and neck cancer cells, either melanoma cell line B16F10-ova and SQ20B cells or human breast cancer cell lines MDA MB-231 cells and TIG-3 cells. Materials and methods: To identify the mechanism that links UPR-triggered cell death and apoptosis of breast cancer cells by silencing of HSP47. Immunoprecipitation of HSP47 and IRE1alpha showed that HSP47 forms a complex with IRE1alpha in colorectal cancer cells under a basal condition. Persistent activation of IRE1alpha by silencing of HSP47 triggered an increase in reactive oxygen species in colorectal cancer cells followed by activation of the other ER stress sensors PKR-like ER kinase and activating transcription factor alpha, resulting in activation of the subsequent apoptosis-associated signaling pathway. Finally, treatment of colorectal cancer cell-bearing mice with HSP47 siRNA resulted in complete regression of colorectal tumors. Conclusion: These results suggest that HSP47 sustains cancer cell survival through its inhibitory effect on IRE1alpha activity and that targeted disruption of HSP47 might become a therapeutic modality for tumors.
Androgen receptor aggregation is a key regulator of endoplasmic reticulum stress and cell survival in ETS-related gene driven prostate carcinogenesis. Taduru L. Sreenath, Natallia Mikhalkevich, Shashwat Sharad, Rishita Gupta, Gluotosin Dioano, Kevin Babcock, Charles Xavier, Ahmed Mohamed, Muhammad Jamal, Shyh-Han Tan, Albert Dobi, Gyorgy Petrovics, Isabel A. Sesterhenn, David G. McLeod, Inger L. Rosner, Shiv Srivasstava, USUHS, Rockville, MD; Joint Pathology Center, Silver Spring, MD; Urology Services, WRNMMC, Bethesda, MD.

Introduction and Objectives: Dereguated androgen receptor (AR) signaling due to either mutations or altered expression of the AR and its cofactors (activators or suppressors) has been identified as critical in prostate cancer development and progression. Recent evidence suggests that the regulated oncogenic activation of ETS-related gene (ERG) represents one of the most common and validated prostate cancer driver gene. In our recent studies using prostate specific ERG transgenic mouse prostate glands, we observed novel morphological phenotypes of endoplasmic reticulum (ER) stress. Since AR was the critical regulator of ERG expression through TMPRSS2 promoter in human prostate cancer, the present study was aimed towards understanding the post-translational interactions between ERG and AR in ER stress and subsequent cell survival mechanisms in mouse and cell culture models. Understanding such mechanistic insights will potentially have major therapeutic implications. Methods: Histological phenotype in the mouse prostate glands were examined by light and electron microscopy. Cell culture models of LNCaP, HEK293 and COS-7 cells were utilized to examine the AR aggregations, Cofactors, Progesterone Aggregation Assay in the presence or absence of 17β-OH progesterone. Various domain deletions of AR were utilized to identify specific AR domain interactions with ERG and its contribution in AR aggregation. Luminal cell surface markers on the isolated mouse prostate glands and spontaneously immortalized mouse prostate epithelial cells from ERG transgenic mouse (MoE1) were analyzed by FACS analysis. Results: Co-expression of AR and ERG in LNCaP and COS-7 cells showed significant aggregation of AR in filter assays. Co-IP experiments and PLA assays in VCaP, LNCaP and HEK 293 cell revealed that ERG physically interacts with AR. Epithelial cells of ERG-Tg mouse prostates showed ~70% increase in CD49f (low) and Sca-1 (med) population with increased sphere formation capability and resistance to radiation induced cell death. Both epithelial cells grown in spheres and established MoE1 cells displayed increased CD49f (low) and significant increase in the EpCam negative population. Conclusions: Overall, our experiments demonstrate the mechanistic link that the physical interactions between ERG and AR initiate the ER stress in prostate epithelium through AR misfolding/aggregation. Our observation of ERG induced AR aggregation is one of the initial events that lead to ER stress to cell survival indicate a critical function for ERG in the etiology of prostate cancer initiation and progression. Funding: This research in part was supported by the National Cancer Institute R01CA162383 (S.S.) and HU0001-10-2-0002 funds.

MOLECULAR AND CELLULAR BIOLOGY / GENETICS: Tumor Hypoxia and the Unfolded Protein Response

#4504 Activating transcription factor-6 dependent regulation of RbhmTOR and Notch signaling contributes to chemoresistance in osteosarcoma. Suna Yararepudiy, Pooja Hingorani, Saravana Kumar, Omar Asad, Jazmine Abril, Veena Sharath, Paul Dickman, Aparna C. Sertli, University of Arizona College of Medicine-Phoenix, Phoenix, AZ; Phoenix Children's Hospital, Phoenix, AZ.

The standard treatment for patients with newly diagnosed osteosarcoma (OS) consists of surgery in combination with multi-agent chemotherapy. However, the optimal treatment strategy for patients with refractory and/or metastatic disease is yet to be defined and continues to be a persistent challenge in osteosarcoma treatment. The high degree of genetic aberrations and tumor heterogeneity has impeded the identification and testing of new and effective therapeutic targets. Therefore, finding and characterizing cellular mechanisms, which contribute to OS chemoresistance could be one promising strategy for designing therapies that can change the outlook for patients with this disease. Due to the well-known role of unfolded protein response (UPR) in promoting chemoresistance in solid tumors our objective here is to examine how this promotes chemoresistance in patients with OS. Using in silico pathway analysis of gene expression data from patients with OS, we found that the UPR sensors ATF6a and ERK-1/e2 were also activated in OS cells in vitro. Using western blotting, qPCR and immunofluorescence we confirmed that all three UPR pathways were activated in human OS cell lines. However we found that only ATF6a activation significantly enhanced chemoresistance to cisplatin, irinotecan and combinatorial treatment with cisplatin and the mTOR inhibitor rapamycin. This occurred via inhibition of Bax activation, suppression of Rbhm-TOR and NOTCH signaling. Our findings highlight a novel mechanism of chemoresistance in OS. Furthermore, retrospective analysis of banked OS patient samples for ATF6a expression followed by a preliminary multivariate analysis using Cox regression model showed that high levels of nuclear ATF6a, was an independent prognostic indicator while also taking into account the presence of metastases and tumor site. Moreover, we found that while 50% patients with high nuclear ATF6a levels had a poor histologic response to treatment only 32% patients with low nuclear ATF6a expression that ATF6a be associated with resistance to chemotherapy and poor outcome for OS patients. Our findings emphasize a role for ATF6a as the nexus of a versatile signaling network that regulates pathways that are crucial for the pathogenesis and therapy resistance of osteosarcoma. Hence therapeutic targeting of the ATF6a pathway holds promise as an innovative and effective treatment strategy for OS.

#4505 UPR biomarker expression correlates with inhibition of migration of TNBC cells treated with low doses of chemotherapy. Amnon Raifer, Julia Lipovetsky, Britta Hardy, Rina Yerushalmi, Tel Aviv University Medical School, Petach Tikva, Israel; Rubin Medical Center and Tel Aviv University Medical School, Petach Tikva, Israel.

Much attention has been directed to the study of triple-negative breast cancer (TNBC) because of its short disease-free interval from diagnosis and more aggressive course in the metastatic setting. TNBC also lacks specific target receptors for treatment. Third-generation metronomic chemotherapy using available agents that target DNA repair complexes (i.e., taxanes), and cell proliferation (i.e., anthraclycine) have shown promise results. However, specific regimens for TNBC at the different disease stages have not been clearly defined. Therefore, researchers are seeking molecular biomarkers to predict response to current chemotherapeutic agents. In a previous study, we demonstrated that low doses of antracyclines and taxanes, which are known to increase endoplasmic reticulum stress, increased tumor cell expression of glucose-regulated protein 78 (GRP78), a key regulator of the unfolded protein response (UPR), resulting in tumor cell apoptosis. GRP78 gene expression is upregulated via CREB3L1, an endoplasmic reticulum transmembrane transcription factor and member of the CREB/ATF family of transcription factors. CREB3L1 is a metastasis suppressor and functions as a transducer of UPR. The aim of the present study was to investigate the effect of low doses of doxorubicin and paclitaxel on UPR activation in metastatic TNBC cells by determining CREB3L1 protein expression in correlation to cell-surface GRP78 expression. Furthermore, we related CREB3L1 and cell-surface GRP78 expression with the migration potential of TNBC cells in response to treatment. We found that the metronomic doses of doxorubicin significantly induced CREB3L1 and cell surface GRP78 expression in TNBC cells. CREB3L1 increased by 2.5-fold in MDAMB231 and by 3-fold in MDAMB468 (p<0.04); GRP78 increased by 3.7-fold and 6.1-fold, respectively (p<0.01). Similar results were obtained with low doses of paclitaxel. A strong correlation was observed between CREB3L1 and cell-surface GRP78 protein expression. The increased expression of both proteins in metastatic (highly metastatic) and MDAMB468 (moderate metastatic) was associated with significant inhibition of the migration capacity of the treated TNBC cells. In contrast, the migration capacity of treated estrogen-positive MCF7 cells (non-metastatic) and Her2 positive BT474 cells (highly metastatic) was poorly inhibited, coinciding with a non-significant increase in CREB3L1 and GRP78 expression. The results were further substantiated through an orthotopic model consisting of TNBC and unrelated to the metastatic profile of the cells. This study is the first stage in the identification of UPR-related biomarkers of beneficial outcome of metronomic chemotherapy for TNBC. Future mechanistic studies should focus on the possible use of cell surface GRP78 and CREB3L1 as targets for combination therapies.

Klotho is a transmembrane protein, which can be shed and act as a circulating hormone. Klotho-deficient mice manifest a syndrome resembling accelerated aging, while klotho overexpression extends life span. We previously identified klotho as a breast and pancreatic tumor suppressor and as an inhibitor of the IGF-1 pathway. Recent data indicate klotho as a tumor suppressor in an array of malignancies, including colorectal cancer (CRC). We aimed to decipher the role of klotho as a tumor suppressor in CRC. Analysis of a public database (Oncomine) indicated reduced expression of klotho in CRC. Two models were employed to study the effect of klotho overexpression. Using the azoxymethane inflammation model, we discovered that klotho inhibited colon polyp formation. Using an orthotopic model consisting of direct injection of MC38 cells to the mice colons, we found that klotho inhibited colonic obstruction and tumor formation. Similarly, klotho inhibited colony formation and proliferation of CRC cell lines. Aberrant activation of the canonical Wnt
pathway is implicated in CRC development and progression. β-catenin, the key effector of this pathway, functions with T-cell factor/lymphoid-enhancer-factor (TCF/LEF) to activate expression of Wnt target genes. While we did not see an effect of klotho on the IGF-1 pathway, it reduced Wnt3α and β-catenin levels as measured by Western blotting, and inhibited TFC/LEF transcriptional activation in luciferase assay. As transcriptional inhibition was abrogated by a constitutively active β-catenin, we suspected that klotho inhibited the pathway upstream of β-catenin. Indeed, co-immunoprecipitation analyses indicated direct interaction between klotho and Wnt3α. Yet, the inhibitory effect of klotho on CRC cell colony formation was only partially rescued by a constitutively active β-catenin. These data indicate on additional mechanisms involved in the T5 activity of klotho. Thus, we conducted an analysis as expression array and observed involvement of klotho in endoplasmic reticulum (ER) stress and unfolded protein response (UPR). Further studies showed that klotho induced elevation in XBP1 RNA levels, GRP78 protein levels, and eIF2α phosphorylation, all indicative of UPR regulation. Importantly, pharmacologic inhibition of ER stress and UPR overcame the growth suppression effect of klotho in CRC cells. Our data indicate klotho as a potent tumor suppressor in CRC, and suggest its role at very early stages of tumor formation, already at polyp formation. Our data also indicate, for the first time, klotho as a regulator of ER stress and UPR in cancer. These findings may pave the way for the development of novel therapeutic strategies based on enhancement of UPR.

#4508 Penfluridol-induced endoplasmic reticulum stress leads to autophagy-mediated pancreatic tumor growth suppression. Alok Ranjan, Sharavan Ramachandran, Nehal Gupta, Sanjay Srivastava. Texas Tech University Health Science Center, Amarillo, TX

Pancreatic cancer is the fourth leading cause of cancer-related deaths in the United States. Experimental and clinical evidences suggested that high basal state autophagy in pancreatic tumors could induce resistance to chemotherapies. Recently, we have demonstrated that penfluridol suppresses pancreatic tumor growth by autophagy-mediated apoptosis both in vitro and in vivo. (Ranjan and Srivastava, Scientific Reports: 2016;26:2615; PMID: 27198859), however, the mechanism of autophagy induction by penfluridol was not clear. Several studies have established that endoplasmic reticulum (ER) stress could lead to autophagy and inhibit tumor progression. In the current study, we demonstrated that penfluridol induced ER stress in BxPC-3, AsPC-1 and Panc-1, pancreatic cancer cell lines as indicated by up regulation of ER stress markers such as BIP, CHOP and IRE1α after treatment with penfluridol in a concentration-dependent manner. Inhibiting ER stress by pre-treatment with pharmacological inhibitors such as sodium phenylbutyrate and methrycinam or by silencing CHOP using CHOPsiRNA, blocked penfluridol-induced autophagy. These results clearly indicated that penfluridol induced ER stress lead to autophagy in our model. Western blot analysis of subcutaneously implanted AsPC-1 and BxPC-3 tumors as well as orthotopically implanted Panc-1 tumors demonstrated upregulation of BIP, CHOP and IRE1α expression in the tumors lysates from penfluridol treated mice as compared to tumors from control mice. Altogether, our study established that penfluridol induced ER stress mediated autophagy in pancreatic tumor. Our study opened a new therapeutic target for advanced chemotherapies against pancreatic cancer. (Supported in part by RO1 grant CA129038; awarded by National Cancer Institute, NIH). NOJC318

#4509 GRP78 is neither expressed on ER/PR/Her2 human breast cancer cell surface nor secreted in the culture media. Jesus E. Serrano, Vaishali Vijay Kulkarni, Naveen Seetharama, Enze Lim, Mark Johnson, Prasad Gopinath, Parveen K. Dua, and Raja K. Krishnamurthy. Texas Tech University Health Science Center, Amarillo, TX

GRP78 (M.78 kDa) is a glucose regulated protein. It is a member of the heat shock protein (HSP) family but located in the lumen of the endoplasmic reticulum (ER). Its function as ER chaperone translocating protein across the ER membrane that needs to be glycosylated at the asparagine residue present in the sequon Asn-X-Ser/Thr (N-linked glycosylation) is well recognized. This important biochemical event is essential for glycoprotein folding and function. For example, if the N-linked glycosylation is interrupted with endo H, the α1,6-protein N-glycosylation inhibitor, angiogenesis, a hallmark for tumor progression and metastasis is inhibited due to an induction of ER stress. Under such condition, GRP78 is overexpressed in microvascular and in tumor tissue, concluding that GRP78 is a master regulator in ER stress induced unfolded protein response (upr)-mediated apoptosis in tumor microvasculature (J. Biol. Chem. 289, 29127-29138, 2011; Pure Appl. Chem. 84, 1907-1918, 2012). This contra-dicts the current dogma that supports GRP78 expression on the tumor cell surface interfering with the therapeutic(s) and making them as tumor promoters instead. To evaluate the GRP78 localization, we have used ER/PR/Her2 (i.e., triple negative) human breast cancer cell line MDA-MB-231 (Caucasian) cultured normally or without serum as well as before or after inducing the ER stress. After establishing the expression of GRP78 mRNA by qPCR and protein by western blotting, we focused on its cell surface expression. Unfixed cells were stained with Concanavalin A (Con A; Specificity = α-D-Mannose, α-D-Glucose, branched mannose), wheat germ agglutinin (WGA; Specificity = (GlcNAc-β-(1,4)GlcNAc)4-7 β-GlcNAc NeuAc) as well as with anti-GRP78 antibody followed by their detection by immunofluorescence microscopy using either Rhodamin or Alexa-conjugated secondary antibody. The fluorescence images were captured in a Zeiss microscope with AxioCam camera. Con A and WGA staining provided images of N-glycans on the cell surface and supported the intactness of the cell membrane. On the other hand, GRP78 fluorescence was absent from the surface of these cancer cells. Similar results were also obtained irrespective of cells cultured in the absence of serum and/or in the presence of 1μg/mL of tunicamycin. GRP78 fluorescence however was detected in cells after either fixing them with ice-cold methanol or after permeabilization with digitonin. In addition, western blotting also failed to detect GRP78 in the culture media of MDA-MB-231 cells. We, therefore, conclude that GRP78 is neither expressed on the outer-leafllet of the cell surface of ER/PR/Her2 human breast cancer cells MDA-MB-231 nor secreted in the culture media. Supported in part by Susan G. Komen for the Cure BCCTR0600582 and NIH/NIMHD G12MD007583 (KB).

#4510 ADP-dependent glucokinase controls hypoxic gradients, ex vivo avascular and in vivo tumor growth through modulation of HIF-1α/mTOR signaling. Sergio Rey, Luana Schito, Marianne Koritzinsky, Bradley G. Wouters. Princess Margaret Cancer Centre, Toronto, Ontario, Canada.

ADP-dependent glucokinase (ADPGK) is an evolutionarily conserved archaebacterial glycolytic enzyme frequently upregulated in human cancers whose role remains elusive. We have recently discovered that ADPGK contributes to ROS-dependent stabilization of hypoxia-inducible factor (HIF)-1α (and -2α) and hypoxia target gene transcription in cancer cells. Hereby, we deconvolute the effect of ADPGK loss-of-function (LoF) upon the 3D hypoxic tumor microenvironment, a crucial pathological aspect determining therapeutic responses in cancer patients. ADPGK HIF-1α and HIF-2α LoF was attained through shRNA-mediated knockdown (>75%) in HCT-116 colon cancer cells. HIF-1α (and -2α) transcriptional activity was measured through RT-qPCR arrays whereas protein levels were assessed by immunoblot. O2 and glucose consumption were measured in 2D with a real-time bioanalyzer (Seahorse). Avascular 3D spheroids and xenografts were used to measure the effect of ADPGK LoF upon tumor growth. Hypoxic gradients in 3D tumor spheroids were quantified using the O2-sensitive nitromydiazide probe EF5 in combination with confocal microscopy and 3D image reconstruction. RT-qPCR arrays identified a core group of 11 hypoxia-inducible transcripts dependent upon ADPGK expression (CA9, DDIT4, ERO1L, EGFR, Gqbp3, Sla03a, Blihe, Rnu36, Aesan, Fam162a, Pkgl1 and PKM), henceforth referred to as ‘ADPGK-dependent HIF-α target signature’ (ADHTS). Comparison of ADHTS transcriptional profiles with HIF-1α or -2α deficient cells showed that ADPGK LoF is not selective for either HIF-α paralog. Since ADHTS genes contained critical for mTOR signaling, glycolytic activity and mitochondrial autophagy, we performed metabolic profiling and found that ADPGK LoF increased O2 consumption in a rapamycin-sensitive manner whilst increasing mitochondrial mass. Moreover, ADPGK LoF enhanced xenograft growth and vascularization associated with decreased protein levels of HIF-2α and the negative mTOR regulator DDIT4. In avascular 3D spheroids, ADPGK LoF increased growth, intra-spheroidal hypoxia and caused steeper hypoxic gradients in parallel to enhanced mTOR-pS6K1→ERPi1 signaling. RNAseq data from colon adenocarcinoma patients (TCGA; n = 382) confirmed that ADPGK expression correlates with ADHTS, HIF-α target gene expression, hypoxia scores and decreased overall survival. Consistent with our preclinical findings, the ADHTS gene signature inversely correlated with an mTOR gene signature in the same dataset. Our results uncover a hitherto unknown function of ADPGK as a crucial determinant of the degree and distribution of hypoxia within the tumor microenvironment through modulation of HIF-1α→mTOR signaling. Our analysis of TCGA data supports these preclinical findings thereby suggesting that ADPGK is a suitable therapeutic target in patients bearing hypoxic cancers.

#4511 HIF-1dependent regulation of creatine kinase metabolism promotes breast cancer invasion and metastasis. Hilaire Barch, Danielle L. Brooks, Rayna Krustulovic, Luciana P. Schwob, Deanna Parke, Tiffany N. Seagroves. Univ. of Tennessee Health Science Ctr., Memphis, TN.

Disregulated tumor cell metabolism is a hallmark of cancer progression and therapeutic resistance. In a screen for Hypoxia-Inducible Factor (HIF)-dependent genes regulating metabolism, we identified creatine kinase, brain isoform
#4512 The landscape of hypoxia-driven alternative splicing in breast cancer. Hani Choudhry, 1 Spyridon Oikonomopoulos, 2 Peng Ya, 3 Cristina Ivan, 3 Mircea Ivan, 3 Adrian L. Harris, 2 Jiannis Ragoussis. 2 Cancer Metabolism and Epigenetics Unit, King Abdulaziz University, Jeddah, Saudi Arabia; 3 McGill University, Quebec, Canada; 2 Texas A&M University, TX; 4 MD Anderson Cancer Center, TX; 5 Indiana University, IN; 6 University of Oxford, United Kingdom.

Tumor hypoxia is generally associated with poor patient outcome and resistance to therapy. Hypoxia has an impact on multiple pathways inside the cell and a widespread effect on phenotype. Here we determined the changes in transcript architecture that arise as result of alternative splicing in hypoxic cells. A panel of breast cancer cell lines that include the Luminal A and B, HER2+, Triple-Negative subcategories grown in hypoxic and normoxic conditions were subjected for deep RNA-sequencing. Depending on the cell lines we found between 23-927 splicing events with 3-45% of them also present in the differentially expressed fraction of genes. This points to an extensive isoform switching control independently of the transcriptional control of the genes themselves. The splicing events appear on genes responsible for mRNA processing (splicing, nuclear export and catabolism) as well as initiation of translation. Members of the SR family of proteins involved in RNA splicing, appear to be potential regulators of the splicing of the hypoxia specific splicing events identified. The differential splicing is driven by exons that are frequently part of both the coding and noncoding isoforms of a given gene potentially indicating a switch between these two types under hypoxia. Ten of the hypoxia specific splicing events were also found to be associated with the hypoxia status of primary breast cancer samples taken from The Cancer Genome Atlas (TCGA) database. Altogether, these data demonstrate the important role of hypoxia in driving alternative splicing events in breast cancer.

#4513 Investigation of bystander effects of hypoxia activated prodrugs using three dimensional cell cultures. Cho Rong Hong, Gib Bogle, William R. Wilson, Kevin O. Hicks. University of Auckland, New Zealand.

Background: Hypoxia in solid tumors acts as the major barrier to anti-cancer therapies and promotes tumor progression. Hypoxia-activated prodrugs (HAPs) are designed to only be activated in hypoxic cells, but also to exploit hypoxia as a basis of tumor selectivity. A key concept in exploiting hypoxia with HAPs is that active drug metabolite should be able to diffuse from hypoxic zones to maximize effect in surrounding aerobic tumor tissue. There is some evidence that these 'bystander effects' contribute to the anti-tumor activity of HAPs, but currently there is a lack of robust methods for their detection. Objectives: To investigate bystander effects from HAPs in a novel spheroid co-culture system using PR104A which releases a diffusible DNA crosslinking mustard and the tirapazamine analogue SN30000 which is known to be inhibited by cyclocreatine, a creatine kinase substrate that represses CK-dependent generation of ATP from phosphocreatine. When female FVB/Nj mice were injected with wild type PyMT cells in a tail vein assay and then treated with cCr (1g/kg/d, IP), lung metastasis was repressed to the same extent as CKb gene knockdown. Moreover, when cCr therapy was administered 7 days after tail vein injection, cCr was effective in preventing the transition of lung micrometastases to macrometastases. To explore the role of CK activity in regulating cell proliferation, survival in suspension, cellular metabolism and invasion, we next created CKb loss- and gain-of-function models using human breast cancer cell lines, and compared phenotypes to cCr treatment. Whereas deletion of CKb had no effect on cell proliferation or survival in adherent conditions or in suspension, either deletion of CKb or cCr therapy potently reduced ATP levels and invasive potential in vitro. Preliminary data also indicate that pre-treatment of triple negative breast cancer cell lines with cCr sensitizes cells to doxorubicin. Together, these data suggest that inhibition of CK activity may be effective in reducing breast cancer progression, but more research is needed to confirm whether cCr has anti-metastatic efficacy as a monotherapy, or in combination with conventional chemotherapies, using luciferase-labeled patient-derived xenograft (PDX) models. This work was sponsored by the NIH (CA138488), the Dept. of Defense (BC150640), the METAvivor foundation, and the West Cancer Center in Memphis, TN.

#4514 Low release of exosomal miR-663a from hypoxic tumor cells and poor tumor response to neoadjuvant radiotherapy in rectal cancer patients. Tonje Bjørnseth, 1 Karin M. Handeland, 2 Sebastian Melzer, 1 Rampradeep Samiapan, 1 Lars G. Lyckander, 3 Carolina Jegerschöld, 3 Linda Stenkvist, 1 Nirmala S. Thiyagarajan, 11 Catherine Lennon, 1 Annie H. Rekstad, 1 1 Akerhus University Hospital, Oslo, Norway; 2Karolinska Institute, Stockholm, Sweden.

Introduction: Hypoxia is a dominant hallmark of the tumor microenvironment and contributes significantly to radiotherapy resistance in solid tumors. Exosomes are nanosized vesicles actively released from tumor cells, and recent studies support their central role in the aggrivated biology caused by tumor hypoxia through their miRNA cargo. In this study, we aimed to characterize miR-663a of exosomes from hypoxic colorectal cancer (CRC) cell lines and investigate these miRNAs in circulating exosomes from rectal cancer patients with poor response to neoadjuvant radiotherapy. Methods: Five CRC cell lines were cultured in RPMI-1640 medium supplemented with 1% bovine serum albumin under normoxia (21% O2) or hypoxia (0.2% O2) for 24 hours. Exosomes were isolated from conditioned media by differential ultracentrifugation, and integrity and size were determined by cryo-electron microscopy and Nanosight tracking analysis and further characterized by Western blot and flow cytometry analyses. In a prospective biomarker study, plasma samples were collected from 29 patients with rectal cancer at the time of diagnosis, and histologic tumor response (tumor regression grade, TRG) to neoadjuvant radiotherapy was evaluated. Exosomes were isolated from plasma using the miRCURY™ Exosome Isolation Kit (Exiqon). Expression profiling of exosomal miRNAs of the CRC cell lines and the patients’ plasma samples was conducted using the miRCURY™ LNA™ Universal RT microRNA PCR Human panel I (Exiqon). Data normalization was performed based on global array mean. Results: Normoxic and hypoxic CRC cell lines were cultured until confluence. Exosomes were isolated and subjected to microarray analysis. In a prospective cohort study, plasma samples were collected from 29 patients with rectal cancer at the time of diagnosis, and histologic tumor response (tumor regression grade, TRG) to neoadjuvant radiotherapy was evaluated. Exosomes were isolated from plasma using the miRCURY™ Exosome Isolation Kit (Exiqon). Expression profiling of exosomal miRNAs of the CRC cell lines and the patients’ plasma samples was conducted using the miRCURY™ LNA™ Universal RT microRNA PCR Human panel I (Exiqon). HSP90 inhibitor geldanamycin and CDK1 inhibition/knockdown decreases MOLECULAR AND CELLULAR BIOLOGY / GENETICS: Tumor Hypoxia and the Unfolded Protein Response CDK1-mediated and HSP90-mediated HIF1a. Avously shown that cyclin-dependent kinase 1 (CDK1) stabilizes HIF1a in a variety of cancers but this is not restricted to hypoxic regions. We have previously described MondoA (also known as BLM) and a number of B lymphocytes are adapted to travel from the hypoxic bone marrow via normoxic peripheral blood to hypoxic lymph nodes. They thus are specialized in glycolysis to compensate the lack of oxidative phosphorylation under hypoxic conditions. Leukemic counterparts of B lymphocytes exploit these features for their survival. Glucose-dependent metabolites control the nuclear activity of the transcription factor MondoA. Here we report on the expression of MondoA in common B-cell acute lymphoblastic leukemia (cALL) compared to other malignancies, its role in malignancy of cALL in vivo, downstream pathways and correlation with relapse risk. Methods. Our human/murine syngeneic acute lymphoblastic leukemia model with immunodeficient NOD-SCID mice was used (Richter et al. 2009). NALM6 and 697 cALL cells were later transduced with MondoA short hairpin RNA. Upon successful MondoA knockdown (KD), KD and control lines were injected into the mice; CD10+ blasts in blood, spleen and marrow were assessed. Results. We found MondoA to be most strongly expressed in pediatric cALL and AML. Moreover, MondoA expression was high in gastrointestinal stromal tumors and alveolar rhabdomyosarcoma. MondoA KD in cALL cell lines and their subsequent analysis in xenograft mice resulted in a reduced number of leukemic blasts in blood, spleen and marrow. Spleen size and weight normalized in mice after MondoAKD. Further microarray analysis revealed an enrichment of glycolytic and hypoxia response gene sets by MondoA. Moreover, HIF1a induction under hypoxia required MondoA. We demonstrate that MondoA facilitates vincristine resistance of cALL. MondoA was induced under hypoxia and confers cALL cells chemotherapeutic resistance. Tied to these results, MondoA overexpression correlated with relapse risk; its expression was 63% higher in the very high-risk group as compared to the non-high-risk group of cALL. In conclusion, our findings demonstrate that MondoA maintains leukemic burden and aggressiveness of cALL in vivo possibly by modulating metabolic and hypoxia stress response, in particular by induction of HIF1a.

Dual inhibition of CDK1 and HSP90 destabilizes HIF1a and synergistically induces cancer cell death. Shuai Zhao, David T. Dicker, Wafık S. El-Deiry. Fox Chase Cancer Ctr., Philadelphia, PA.

Solid tumors are often characterized by intratumoral hypoxia. Hypoxia-inducible factor 1a (HIF1a) has been implicated in cell proliferation, survival, angiogenesis, invasion and migration. The expression of HIF1a is increased in a variety of cancers but this is not restricted to hypoxic regions. We have previously shown that cyclin-dependent kinase 1 (CDK1) stabilizes HIF1a through direct phosphorylation of its Ser668 residue in a Von Hippel-Lindau (VHL)- independent manner both under hypoxia and at G2/M under normoxia (Warfel et al., Cell Cycle, 2013). Heat shock protein 90 (HSP90) is also an acknowledged VHL-independent HIF1a stabilizer. We sought to explore the link between CDK1- and HSP90-mediated HIF1a stabilization. Under hypoxia, combination treatment with HSP90 inhibitor geldanamycin and CDK1 inhibition/knockdown decreases HIF1a levels more robustly than either treatment alone. This led us to investigate whether 20S inhibited CDK1 and HSP90 inhibition results in synergistic anti-cancer effects. Indeed, dual inhibition of CDK1 and HSP90 synergistically decreases HCT116 colon cancer cell viability. PARP cleavage and sub-G1 analysis indicate the combinational treatment triggers cancer cell death through apoptosis. Consistent with these findings, we observed that inhibition of cell viability by the combination is impaired in HCT116 Bax−/− cells. Furthermore, the dual inhibition also suppresses cell migration in vitro. We further validated our results with CDK1 inhibitor and HSP90 inhibitors that have entered clinical trials. Second-generation HSP90 inhibitor ganetespib and Ro3306 synergistically inhibit cell viability in HCT116 cells. We have previously demonstrated that CDK4 also contributes to the stabilization of HIF1a under hypoxia (Warfel et al., Cell Cycle, 2013). Interestingly, the combination of CDK4 and HSP90 inhibitors is also able to improve downregulation of HIF1a as compared to either agent alone in various cancer cell lines (eg. colon cancer, glioblastoma, etc). The FDA-approved CDK4 inhibitor palbociclib along with ganetespib synergistically inhibits cell viability in HCT116 cells under hypoxia. Such effect is not observed in W138 normal cells under normoxic and hypoxic conditions. These results demonstrate that CDK1 inhibition disrupts the interaction between HSP90 and HIF1a providing a rationale for therapeutic targeting of HIF1a through the combination of CDK1/4 and HSP90 inhibitors in cancer. Ongoing studies are examining the effects of CDK1/4 plus HSP90 dual inhibition in other tumor types and in vivo.

A CRISPR approach to monitoring hypoxia-inducible proteins in real-time. Marie K. Schwinn, Thomas Machleidt, Brock F. Binkowski, Christopher T. Eggers, Keith V. Wood. Promega Corporation, Madison, WI.

HIF1a-inducible factor 1A (HIF1A) regulates expression of genes implicated in various aspects of oncogenesis, including angiogenesis, cell survival, metastasis, and glucose metabolism. Overexpression or hypoxia-induced stabilization of HIF1A has been associated with poor prognosis in cancer patients, making HIF1A and its associated pathway a high-profile target for anticancer therapies. We sought to develop a live-cell assay to monitor abundance of endogenous HIF1A and HIF1A-inducible proteins that could be used to identify potent and specific inhibitors of the hypoxia signaling pathway. To accomplish this goal, mammalian cell lines were edited by CRISPR using a Cas9/CrRNA ribonucleoprotein complex with a single-stranded oligonucleotide donor DNA to target the HIF1B tag at the C-terminus of HIF1A. Immunoblot analysis revealed an enrichment of hypoxia-inducible proteins, including BNIP3, ANKR3D7, HILDA and KLF10. The 11 amino acid HIF1B peptide and its complementing 18 kDa polypeptide, known as LgbIT, spontaneously reconstitute into an active luciferase derived from the NanoLuc enzyme. Co-expression of LgbIT in edited cells, followed by addition of the cell-permeable luciferase substrate, leads to generation of a bright, steady luminescent signal that directly correlates with abundance of the HIF1B fusion. The edited cells were treated with several known modulators of the HIF1A signaling pathway, and changes in the abundance of the protein fusions were followed in real-time by monitoring luminescence. The HIF1B tag was also used to validate size and subcellular localization of the fusion proteins using bioluminescence imaging and antibody-free blotting. As expected, all tested compounds induced HIF1A accumulation. However, the downstream targets of HIF1A generated differing response to the chemical modulators, warranting further investigation into the modes by which these compounds act. By coupling the speed and efficiency of CRISPR-mediated editing with the small size and brightness of HIF1B, it was possible to generate a live-cell assay to monitor abundance of proteins along the HIF1A pathway. This assay could easily be adapted to screen for compound-induced effects on protein levels of HIF1A, as well as HIF1A- induced changes in expression patterns.

Impact of hypoxia on SFK activities in prostate cancer cells. Yao Dai, Dietmar W. Siemann. Univ. of Florida College of Medicine, Gainesville, FL.

Background: Metastasis is the major reason of disease progression and poor prognosis in prostate cancer. Src family kinases (SFKs), including c-Src, Lyn and Fyn, are non-receptor tyrosine kinases that have been shown to play an essential role in local invasion, castration resistance, and metastasis in prostate cancer. Hypoxia is able to promote metastasis-associated functions by activating various signaling molecules, including SFKs. However, whether all SFK members are upregulated by hypoxia is unclear. In the current study, the effects of hypoxia on cell functions and SFK activities are determined. Further, genetic approaches are applied to identify the typical SFK member that is mostly activated by hypoxia.

Methods: For hypoxic exposure, prostate cancer cells were exposed to low oxygen tensions (1%O2) for varied durations (0, 2, 6, 24 h). For drug treatment, cells were treated with saracatinib (0, 100, 500, 1000 nM) for indicated time periods. To test cell migration, “wound-healing” assay was used by making a scratch on confluent monolayers. Cells that have migrated to the denuded area were imaged. Cell invasion was detected by seeding cells into Matrigel-coated transwell chamber and cells on the bottom membranes were counted after treatment. Clonogenic assay was performed to test cell survival. At the molecular level, SFKs phosphorylation was detected by Western blotting, and gene knockdown was accomplished by siRNA transfection. To investigate expression of p-SFK and HIF-1α in patients, tumor tissues from prostate cancer patients were probed with desired antibody by immunohistochemical staining. Results: Both p-SFK and HIF-1α were highly expressed in patient tissues with advanced stage, with HIF-1 expression significantly associated with tumor grade and Gleason score. At the cellular level, while short term hypoxic exposure (2-6 h) induced greater cell migration, invasion and survival than prolonged hypoxia (24 h) in PC-3ML.
and C4-2B, these behaviors were increased under hypoxia with a period of 24 h in TRAMP-C1 cells. Further, hypoxia enhanced SFK phosphorylation in the pattern that was consistent with cell functions. Knockdown SRC, but not LYN, abolished hypoxia-induced invasion and p-SFK expression. Lastly, SFK inhibitor saracatinib showed stronger inhibition on functional behaviors facilitated under hypoxia than normal conditions; this is consistent with the observation that hypoxia, particularly short-term exposure, is able to enhance metastatic phenotypes by activating SFKs, predominantly c-Src, in prostate cancer cells, suggesting c-Src may be the most important signaling molecule of hypoxia-mediated behaviors. These findings have clarified the exact SFK member that is typically activated under hypoxia at least in prostate cancer model in vitro. More importantly, SFK inhibition is able to impair cell functions driven by hypoxia, suggesting their therapeutic potential by suppressing tumor metastasis that is driven by hypoxia in prostate cancer.

#4519 ATM/ATR-SerRS pathway dominates hypoxic angiogenesis in tumor. Yi Shi, Zi Le Liu, Xiang-Lei Yang. 1 Nankai University, Tianjin, China; 2 The Scripps Research Institute, La Jolla, CA.

#4520 Hepatitis B virus X protein regulates hypoxia-inducible factor-1alpha (HIF-1 alpha) and lysyl oxidase like 2 (LOXL2) pathway in hepatocellular carcinoma. Cerise Yueen-Ki Chan, Aki Pui-Wah Tse, Elley Yong-Tuen Chiu, Karen Man-Fong See, Hui-Yu Koh, Irene Oi-Lin Ng, Carmen Chak-Lui Wong. The University of Hong Kong, Hong Kong, Hong Kong.

Hepatocellular carcinoma (HCC), the most common form of primary liver cancer, is a fatal malignancy and is prevalent in HBV-endemic geographical areas. Hepatitis B virus (HBV) infection is a major etiologic factor of HCC. HBV is a double-stranded DNA virus and encodes for a viral onco-protein called transactivator protein X (HBx) which interacts with the host proteins to enhance proliferative potential of the host cells. Here, using Tet-ON and Tet-OFF HBx inducible systems in HBV-negative HCC cell lines, we showed that induced expression of HBx stabilizes hypoxia-inducible factor-1α (HIF-1α) protein under hypoxia. Reversely, knockdown of HBx in HBV-positive HCC cell lines reduced HIF-1α protein stabilization under hypoxia. More intriguingly, we found that induced HBx expression up-regulated the mRNA and protein expression a known HIF-1α transcriptional target, lysyl oxidase like 2 (LOXL2) in HCC. Our previous study showed that LOXL2 cross-linked collagen in the extracellular matrix to promote HCC metastasis. Scanning electron microscopy demonstrated that knockdown of HBx in HCC cell lines markedly reduced formation of collagen fibers in vitro. Transwell invasion assay showed that knockdown of HBx reduced HCC invasive ability. Picrosirius red staining further showed that knockdown of HBx reduced collagen cross-linking in vivo and repressed HCC growth and metastasis. Taken together, our study unprecedentedly show the HBx models the ECM through HIF-1α/LOXL2 pathway to promote HCC metastasis.

Introduction: Metastasis is responsible for over 90% of cancer related mortality, however mutations unique to the metastatic phenotype have yet to be identified. This raises the possibility that the metastatic phenotype is the result of a transcriptional profile adopted by cells of the primary tumor enabling them to spread to distal regions of the body. The tumor microenvironment (TME) is capable of influencing gene expression and cellular behavior. Hypoxia, low oxygen tension, is a component of the TME that arises due to improper tissue architecture and correlates with poor survival outcomes. Hypoxia induces transcriptional reprogramming in cells and induces the expression of genes involved in metastasis through direct activation and through the alteration of the epigenome. However, upon re-oxygenation HIF-1α is degraded and can no longer induce expression of hypoxic responsive genes. During the metastatic process, cells that have adopted hypoxia induced metastatic behavior such as increased motility and invasiveness must transit through regions of normoxia on their way to metastatic colonization. Hypothesis: As hypoxic cell migrate away from regions of low oxygen towards oxygen rich environments, such venous blood, genes induced by hypoxia would be expected to return to basal levels of expression. Those genes whose expression does not return to levels associated with normoxia, but instead remain elevated following re-oxygenation, may be crucial for maintaining the hypoxia induced metastatic phenotype. Experimental Design: To study the stability of hypoxia induced gene expression alterations following re-oxygenation, colon cancer cell lines were grown under hypoxic conditions (1% O2) for up to 3 weeks and then transitioned to normoxic conditions (21% O2). RNA sequencing was used to assess changes in gene expression during hypoxia adaptation and for more weeks following re-oxygenation. Results: While the majority of genes whose expression was induced by hypoxia returned to basal levels following re-oxygenation, a sub-set of genes clustered in the TGF-β pathway remained at elevated levels. In particular the expression of JunB, a component of the AP-1 transcription factor, was induced by hypoxia and continued to remain overexpressed after return to normoxic growth conditions. Conclusion: Long term culturing of colon cancer cells in hypoxic conditions induces changes in gene expression that remain stable following return to normoxic growth conditions. We hypothesize that genes whose expression follows this pattern may be involved in the hypoxia induced metastatic phenotype. RNA-seq profiling of cells grown in hypoxic conditions for three weeks and then returned to normoxic growth conditions for an additional three weeks identified genes involved in the TGF-β pathway and in particular JunB that were induced by hypoxia and remained stable following return to normoxia.
that decreased at lower ambient O2 concentrations. Spheroid growth and Measured HCT116 spheroid diameters increased linearly with time, at rates reduced known features of spheroids including oxygen and glucose gradients, SN30000 were compared to experimental results. Results: The model reproduces. Model simulations of HCT116 spheroid response to radiation and concentrations were compared to model predictions, as was glucose depletion from the microvascular network (cobalt-60) and SN30000 induced clonogenic cell killing under oxia and anoxia was determined using HCT116 monolayers. Model simulations of HCT116 spheroid response to radiation and SN30000 were compared to experimental results. Results: The model reproduced known features of spheroids including oxygen and glucose gradients, rapid cell proliferation at the periphery and central hypoxia and necrosis. Measured HCT116 spheroid diameters increased linearly with time, at rates that decreased at lower ambient O2 concentrations. Spheroid growth and glucose depletion was well-fitted by the AB model. Good agreement was found between simulated and measured clonogenic cell killing by radiation and SN30000, while the model underestimated spheroid growth delay by radiation and SN30000 than experimental observation. Discussion: An oxygen and glucose dependent AB model for growth and PD response (cell killing and growth delay) of HCT116 spheroids has been developed and calibrated using experimentally determined parameters. Further development of this model will link cell fates (including cell cycle arrest) explicitly to DNA damage responses and O2 and glucose-dependence of cell proliferation and survival.

Background: Hypoxia is defined as oxygen levels in tumor microenvironment of less than that in blood (90-100 mm Hg) and influences many aspects of tumour biology. During surgery tumour vasculature is cut off gradually leading to induction of acute hypoxia. The present study aims to experimentally test the genotypic and phenotypic effects of surgically induced acute hypoxia in breast cancer tumor samples and cell lines. Methodology: Core biopsy samples were collected from breast tumors (N=8 patients) at three time points during their curative surgery: prior (pre), mid-way (intra) and at the end (post). The samples were subjected to RNA-Seq and a list of differentially expressed genes (DEG) was prepared. A set of 26 DEG (pre ‘intra’ Vs ‘post’) obtained from RNA-Seq analysis and additional 17 genes involved in inflammation, EMT and hypoxia pathways were chosen for validation in tumor samples. These genes were validated using a customized qPCR Array (Qiagen). A gene was considered validated if it was significantly deregulated in at least 4 out of 8 patients. In another experiment, MCF-7 cells were exposed to varying levels of oxygen concentrations (0.1% to 20%) for varying time periods ranging from 30 minutes to 72 hours, to study time and dose dependent effects of hypoxia on following functional characteristics: proliferation, invasion and cell cycle changes. Results: Concordant, statistically significant up-regulation of FOS, DUSP1, JUNB, FOS, ZFP36, RGS1, STO4A, CXCL8 and LCL2 were observed in RNA-Seq and qPCR experiments while MMP13, HIF1A and VEGFA were up-regulated only in qPCR. However, 7 protein markers of inflammation, EMT and hypoxia did not show any significant change between pre, intra and post-operative samples. In MCF-7 cells, a dose and time dependent decrease in cell viability was observed with increasing severity of hypoxia as well as decrease in invasiveness, but there was no significant impact on cell cycle phases. When hypoxia cells were re-incubated under normoxic conditions an increase in cell proliferation and accumulation of cells in S phase (with a reduction in G2-M fraction) were observed, compared to cells grown under only normoxic conditions. Conclusion: Acute intra-operative hypoxia up-regulates expression of genes related to cell survival, chemoresistance, invasion, inflammation and angiogenesis in breast tumors. Breast cancer cells exposed to acute severe hypoxia followed by normoxia show increased proliferation. These effects may have implications for tumor cells that disseminate during surgery.

#4525 Hypoxia signaling pathway plays a role in ovarian cancer chemoresistance. Noelle L. Cutter, Tyler Walther, Kimberly H. Doyle, Ryan F. Mollov College, Rockville Centre, NY.

Hypoxia-inducible factor 1 (HIF-1) is a basic helix-loop-helix transcription factor that when induced regulates the expression of many genes involved in cytotoxic protective stimuli, which attenuates apoptosis and improves survival. Increased expression of HIF-1α gene (HIF1A) has been found in several carcinomas, including ovarian cancer. Ovarian cancers are generally refractory to platinum-based chemotherapy. Despite the large number of studies, molecular events that govern the emergence of aggressive therapy-resistant cells after chemotherapy are poorly defined. Genomic instabilities, such as copy number variation(CNV), may play an important role in chemoresistance and have been implicated in many complex diseases, like cancer. We analyzed CNV data that is publically available through the Cancer Genome Atlas and others. Of particular interest was the transcription factor HIF1A which plays an integral role in oxidative stress response such as those induced by chemotherapy reagents. The present study provides evidence that HIF-1α is highly expressed in the rare escape of tumor cells from drug-induced cell death by entering a non-cycling senescent state. We report the adaptive response of human ovarian surface epithelium cells to CoCl2, a chemical hypoxia-mimicking agent resulting in a senescent-like state of chemoresistant cells. The effect of the treatment was evaluated on CNV of HIF-1α gene expression, cell proliferation, survival, and tumor invasiveness. We show here that CNV duplication events of HIF1α results in an oxidative stress response in cells leading to chemoresistance through the induction of cellular senescence. Understanding the molecular events associated with chemoresistance will ultimately lead to better patient treatment and outcomes.

#4526 Attenuation of hypoxia in solid tumor with multifunctional upconversion nanoparticles to enhance photodynamic therapy. Yan Zhang, Jinggu Li, Jun Hu, Xiaoliang Yang, Huazhong University of Science and Technology, Wuhan, China.

As a non-invasive therapeutic technique, photodynamic therapy (PDT) requires sufficient oxygen in order to generate adequate singlet oxygen upon the excitation of photosensitizer using an appropriate light wavelength. It has limited efficacy in preexisting hypoxia in tumor and PDT-induced hypoxia, owing to their low oxygen level in the tissue and the consumption of the oxygen during the PDT treatment. Herein, taking advantage of hyperbaric oxygen (HBO), multifunctional upconversion nanovehicle is constructed to overcome the above-mentioned problems. HBO provides timely oxygen supply during the treatment, which greatly enhances the photodynamic effect of the loaded nanoparticles, as demonstrated by the accelerated generation of O2• and elevated cytotoxicity. Tumor growth is greatly restrained in the HBO-PDT treated mice. Our finding provides new insights into the modulation of unfavourable tumor microenvironment with the perfect marriage between HBO and NIR-light sensitized upconversion nanoparticles to overcome the current limitation of cancer photodynamic therapies.

MOLECULAR AND CELLULAR BIOLOGY / GENETICS: Tumor Hypoxia and the Unfolded Protein Response

Introduction: Hypoxia-activated prodrugs (HAPs) are a promising strategy to specifically target radioresistant hypoxic cells in tumors. We have used multicellular layers (MCLs) and steady state Green’s function pharmacokinetic/pharmacodynamic (PK/PD) modelling in microvascular networks to select SN30000 as a tirapazamine analogue with optimal spatial complementarity with radiation. However these models have several limitations such as lack of time dependent PK. Multicellular tumor spheroids are a more tractable model than MCLs for investigating PD parameters. However, the challenges of interpreting spheroid experiments in terms of spatial complementarity limits their application. We have developed an in silico agent-based (AB) tumor spheroid model, in which cell fate can be tracked as a function of time and spatially-varying concentrations of oxygen, glucose and therapeutic agents (radiation and HAP). The hypothesis is that our AB model can predict tumor spheroid response to radiation and SN30000, both alone and in combination. Methods: In the AB model, spheroid growth is simulated as a function of oxygen, glucose and drug concentrations determined by solving diffusion equations using oxygen consumption measured in HCT116 monolayers and glucose and SN30000 diffusion and metabolism measured in HCT116 MCLs and stirred cell suspensions, linked with intra-cellular reaction equations. Cell fate is determined by oxygen, glucose and drug concentrations. Spheroid diameter, cell survival and hypoxic fraction of HCT116 spheroids grown at a range of oxygen and initial glucose concentrations were compared to model predictions, as was glucose depletion from the culture system (cobalt-60) and SN30000 induced clonogenic cell killing under oxia and anoxia was determined using HCT116 monolayers. Model simulations of HCT116 spheroid response to radiation and SN30000 were compared to experimental results. Results: The model reproduced known features of spheroids including oxygen and glucose gradients, rapid cell proliferation at the periphery and central hypoxia and necrosis. Measured HCT116 spheroid diameters increased linearly with time, at rates that decreased at lower ambient O2 concentrations. Spheroid growth and glucose depletion was well-fitted by the AB model. Good agreement was found between simulated and measured clonogenic cell killing by radiation and SN30000, while the model underestimated spheroid growth delay by radiation and SN30000 than experimental observation. Discussion: An oxygen and glucose dependent AB model for growth and PD response (cell killing and growth delay) of HCT116 spheroids has been developed and calibrated using experimentally determined parameters. Further development of this model will link cell fates (including cell cycle arrest) explicitly to DNA damage responses and O2 and glucose-dependence of cell proliferation and survival.

BIOINFORMATICS AND SYSTEMS BIOLOGY: Modeling and Algorithms

#4527 Estimating tumor cell dissemination rates through lymph and blood via computational modeling. Anne Marie Barrette, Benedicte Lenoir, Mihaela Skobe, Marc R. Birtwistle. Icahn School of Medicine at Mount Sinai, New York, NY.

Metastasis is the primary cause of death from most cancer types, but the relative rates of tumor cell migration through lymphatic versus blood routes remains an open question. Here we combine data from a xenograft model of metastatic breast cancer with a computational model of tumor cell growth and dissemination to help answer this question. Orthotopic mouse xeno-
grafts using the triple negative breast cancer cell line MDA-MB-231 allowed for monitoring of metastatic cells within the primary tumor, bloodstream, lymph nodes, and lungs. Experiments resembling a pulse-chase method helped inform and parameterize the model to the rate of dissemination to the lymph nodes and lungs. Our ordinary differential equation model describes primary tumor growth as the balance between proliferation and death, with the proliferative fraction decreasing with tumor size, and the apoptotic or necrotic fraction increasing with tumor size. Intravasation to both lymph and blood rapidly increases early in tumor growth, followed by a decay to a low rate of tumor cell release well before the primary tumor grows to its saturating size. The mouse data guided our parameter estimations based on the assumption that dissemination tumor cell death rate is greatest in the harsh environment of the blood and lowest in the more accommodating lymph node, and that metastatic cells seedling in the lymph nodes and lungs follow similar growth dynamics as the primary tumor only with far fewer total cells. We are currently performing sensitivity analysis to explore the range of relative rates of tumor cell dissemination that fit the in vivo data, and thus gain insight into tumor cell dynamics within the different compartments. These analyses will allow us to estimate what the relative contributions of blood versus lymphatic tumor cell dissemination are to overall metastatic burden, as well as suggest experiments that further constrain these estimates. Such combined experimental and modeling analysis lend insight into where one might detect pre-metastatic cells early in disease progression or suggest new targets for anti-metastasis drugs based on the dominant mode of dissemination.

**#4528 A novel transducer array design optimizing TTFields delivery to the thorax.** Hadas S. Herschkovich,1 Sholi Strauss,1 Uri Weinberg,2 Eilon D. Kirsch,2 Ze’ev Bomanon2,1 Novocure Ltd, Haifa, Israel; 2Novocure GmbH, Lu- cerne, Switzerland.

Objective: The purpose of this study was to design transducer arrays for the delivery of Tumor Treating Fields (TTFields) to the thorax, generating high intensity in the upper torso while potentially improving patient comfort. Background: TTFields are low intensity, intermediate frequency, alternating electric fields that disrupt cell division. The ongoing Phase II STELLAR trial [NCT02397928] is investigating the efficacy and safety of TTFields in combination with chemotherapy for the treatment of mesothelioma. A pivotal study to evaluate the efficacy of TTFields in treating NSCLC is planned for 2017. TTFields are delivered via capacitive transducer arrays, comprising ceramic disks covered with a thin layer of conductive medical-grade gel, which are arranged in an almost rectangular order. Two orthogonal pairs of arrays are placed on the skin in the vicinity of the treated region. One pair is placed on the anterior and posterior sides of the thorax. The other pair is placed on the lateral and contratralateral sides of the thorax. This configuration has limitations: (a) Sub-optimal electric contact may be caused by poor attachment of the arrays on the chest due to body curvature; (b) TTFields intensities are attenuated by anterior-posterior arrays; (c) The current lateral-con- tralateral arrays generate lower field intensities in the lung’s apex. This study presents novel array designs to overcome these limitations. Methods: Various concepts for array designs that avoid placement over regions of thick subcutaneous fat were designed. To evaluate the field distribution generated by these arrays and optimize their design, numerical simulations using realistic computational phantom models were used. Results: Novel array designs were developed for the delivery of TTFields to the lungs. These arrays consist of sets of interconnected small patches that adhere to the natural contours of the human body. Simulations showed that the proposed arrays deliver uniformly distributed, high electrical field to the lungs. One notable design is a pair of arrays shaped as circular rings, in which one array is placed around the neck and shoulders, whereas the second array is placed on the lower torso. This design yielded a highly uniform field directed longitudinally throughout the torso. Conclusion: The array designs presented in this study are expected to maintain patient comfort and will ensure high field intensity delivered to the thorax. Compliance and TTFields treatment delivery could both be improved by using these designs.

**#4529 Optimization of the sequence for the administration of bevac- zumab in combination with pemetrexed and cisplatin in NSCLC: a pharma- cology based in vivo study.** Arnaud Boyer,1 Diane-Charlotte Imbs,2 Raouf El Cheikh,2 Celine Mascaux,1 Fabrice Barlies,1 Dominique Barbolosi,2 Sebastien Benzecky,1 Joseph Ciccolini,1 Assistance Publique Hôpitaux de Marseille. Multidisciplinary Oncology & Therapeutic Innovations, marseille, France; 2Aix mar- selle University, marseille, France; 3Inria, Bordeaux, France.

Introduction: Bevacizumab is active in advanced non-small cell lung cancer (NSCLC) and is administered in combination with chemotherapy in first line for non squamous NSCLC. However the best sequence of administration has not been defined. Previously published data suggest that before acting as an antiangiogenic drug, Bevacizumab would initially and transtorally normalize microvascularization of tumor blood vessels, thus be optimal to administrate chemotherapy. By using mathematical modeling, we showed that sequential administration of chemotherapy 3 days after Bevacizumab may be more beneficial than concomitant administration. Herein we tested and compared concomitant versus different schema of sequential ad- ministration of Bevacizumab with chemotherapy in NSCLC. Methods: H460 and H11006 xenografts were generated to treat tumors with sequential growth by fluorescence. Nude mice were engrafted subcutaneously with around 120,000 cells. Fluorescence was used to monitor tumor growth twice a week and treated with Bevacizumab, Cisplatin and Pemetrexed with vari- ous sequences of administration. A total of 15-16 replicates were included in each therapeutic group. Results Five therapeutic schema were compared: 1) Cisplatin-Pemetrexed only; 2) concomitant administration of Bevacizumab with Cisplatin-Pemetrexed only; 3) chemotherapy 3 days after Bevacizumab predicted to be the optimal sequence by mathematic modeling; 4) chemotherapy 8 days after Bevacizumab predicted to be the worse sequence by mathematic modeling; 5) control group receiving placebo. Tumor growth was reduced of 38% in group 3 as compared with group 2, but this difference was not statistically significant (p = 0.05) as compared to groups 1, 4 and 5. The median survival was the longest in group 3 (74 days), as compared with group 2 (70 days), group 4 (67 days), group 1 (54 days) and control group (40 days). Conclusion: This in vivo study indicate that the sequential administration of Bevacizumab three days before chemotherapy in NSCLC may be the optimal schema as compared with concomitant ad- ministration or longer delay as predicted by mathematic modeling. Mecha- nistic and pharmacokinetic analyses as well as biomarker studies are cur- rently ongoing and should be shortly available.
#5431 Systems pharmacology to predict cellular biomarkers and optimize mono- and combination-therapy regimens: Focusing on immune checkpoint targets PD-1, PD-L1 and CTLA-4. Oleg Milberg,1 Chang Gong,1 Bing Wang,2 Paolo Vicini,3 Rajesh Narwal,4 Lorin Roskos,4 Aleksander Popel.1 Johns Hopkins University, Baltimore, MD; 2MedImmune, Mountain View, CA; 3MedImmune, Cambridge, United Kingdom; 4MedImmune, Gaithersburg, MD.

Cancer immunotherapy focuses on stimulating and promoting the immune system to recognize and eliminate cancer cells, with several FDA approvals in recent years. However, identifying patients best suited for specific immune therapies, and determining optimal treatment regimens continue to be a clinical challenge. Using a molecular-detailed computational systems pharmacology model to identify cellular biomarkers and optimize regimens, we may be able to predict the efficacy of regimens in specific patient populations, and expedite drug development for cancer treatment. We developed a cell/receptor-based multi-compartment systems pharmacology model focusing on the immune response against a growing tumor, with the intent to test the effects of immune checkpoint inhibitors against PD-1, PD-L1 and CTLA-4 administered as mono- and combination therapies. Additionally, the model also allows for testing of other immuno-therapies, such as adoptive cell therapies, which can be combined with the checkpoint inhibitors. The model was designed and developed using the SimBiology plug-in in MATLAB. Simulations were performed with parameter sets for the immune response of particular tumor types at specific metastatic sites and NSCLC. All results were qualitatively and quantitatively compared to experimental pre-clinical and clinical data for model validation, or used for the generation of predictions suitable for further experimental testing. In silico, we have identified that administrations of the prescribed doses of 1-10 mg/kg of anti-CTLA-4 (based on binding kinetics) effectively saturates the receptors on the T cells, and promotes both an extended life span of the antigen presenting cells (APCs), and the maximum attainable activation levels of the effector T cells. The model further predicts that the effectiveness of anti-CTLA-4 therapy is limited by the immunogenicity of the system (i.e., the antigen intensity level and number of APCs presenting the antigens) in a monotonous fashion. Furthermore, injecting activated APCs without therapy would show a temporary tumor response and a subsequent recovery by the tumor to its original growth trajectory, while raising the antigen intensity had a sustained effect on tumor response. Other simulations indicate that, despite the lack of apparent tumor response, a sustained immune attack may be ongoing in the body; however, the immune activity is proportionally limited by the tumor and regulatory cells. Lastly, several dose-responses and clinical trials were simulated for both combination and monotherapies, and correlated with published published clinical trial data. Future work will focus on uncovering the cellular biomarkers responsible for such results, experimentally validating them, as well as simulating optimal combination treatment regimens for future evaluation.

#5432 Adrenal metastases in lung cancer: Clinical implications of a mathematical model. Jeremy M. Mason,1 AnneMarie Ciccarella,2 Lori Marx-Ru- byner,1 Anjali Kaur,2 Adriana Sklenova,1 Paul K. Newton,1 Kelly J. Korf.3,4,5,6,7,8 University of Southern California, Los Angeles, CA; 2Independent Research Advocate and Breast Cancer Patient, New York, NY; 3Independent Research Advocate and Metastatic Breast Cancer Patient, Los Angeles, CA; 4University of California San Diego, San Diego, CA; 5Scripps Clinic, San Diego, CA.

Adrenal gland metastases are common in lung cancer. It is well recognized that aggressive treatment of solitary adrenal metastases leads to improved outcomes but the exact nature of adrenal deposits is not well understood. Controversy exists as to the routing of cancer cells to the adrenal gland with some believing that this transmission is lymphatic, in contrast to the more generally accepted theory of hematogenous spread. Using an autopsy dataset of 3827 untreated cancer patients, we use the metastatic distribution of common primary cancer types over the long term of disease progression. The anatomical sites of spread in the body represent states in the model, while the transition probability between states represents the probability of metastatic spread from one site to another. We then use the Markov models to run Monte Carlo simulations of random walkers representing circulating tumor cells traveling within the body to simulate metastatic spread. We calculate mean first passage times (MfPT) to each state as a representative of time to metastasis formation. Analysis of 6 common cancer types (bladder [n = 120 autopsies; 289 metastases], breast [n = 432; 2235], colorectal [n = 161; 420], lung [n = 560; 859], ovarian [n = 418; 806], and prostate [n = 62; 212]) from the dataset showed distinct metastatic distributions across the populations. MfPT calculations to anatomical sites in the 6 analyzed primary cancer types indicated model progression times to the adrenal gland similar to the regional and distal lymph nodes in only lung cancer. The times associated with adrenal gland in the other primary cancers were similar to other metastatic sites of hematogenous spread. The Markov models created strongly support the lymphatic theory for metastatic spread to the adrenal glands. After performing a literature review to look for the biological plausibility of the simulated results, we believe evidence supports this theory and validates the models. This could explained improved survival for patients in whom solitary adrenal metastases are managed aggressively with surgical or radiation modalities. In order to further validate this theory, we are calling for clinical trials prospectively testing this hypothesis.

#5433 In silico analysis of enhanced radiosensitivity in radiation treatment combined with androgen deprivation therapy for prostate cancer. Mengdi Qian,1 Alexandre Almasan,2 Evren Gürkan-Çavuşoğlu.3 Case Western Reserve Univ., Cleveland, OH; 4Cleveland Clinic, Cleveland, OH.

The purpose of this study is to quantitatively analyze the improved radiosensitivity of prostate cancer cells to ionizing radiation (IR) when radiation treatment is combined with androgen deprivation therapy (ADT). The double strand breaks (DSBs) induced by ionizing radiation are repaired primarily by non-homologous end joining (NHEJ). It is reported in the literature that NHEJ is impaired under ADT, which then results in increased radiosensitivity and better IR treatment outcomes in prostate cancer. In this study, we have used our models for NHEJ repair of DSBs under IR treatment and IR + ADT combination treatment conditions to determine how the combination treatment results in better outcomes. We have modeled the effect of multiple doses of IR that are delivered 24-hours apart to mimic the conventional, fractionated radiation treatment. Our analysis results showed the DSBRs accumulation in the case of combined treatment with ADT compared to faster and more efficient repair when only IR is applied. We have used the experimental data on relative cell numbers and relative sub-G1 cell numbers from the literature to determine the difference in the levels of DSBs that lead to cell death differences between the two treatment strategies. The literature data also shows that there is patient response variability to ADT in terms of the reduction in the levels of Ku70/80, which is the first NHEJ protein complex that is recruited to DSBs. We have modeled this patient variability in our models by introducing variability to Ku70/80 protein concentrations used in the simulations. Our simulation results agree with the observation from clinical data that lower concentration levels of Ku70/80 lead to better radiosensitization. The amount of IR can be adjusted with respect to the level of radiosensitization after ADT on a patient specific level to achieve a desired level of DSBs that will lead to maximum cell death; this dose optimization effort will be the next step in our quantitative analysis.

#5434 Theory and methodology for the design and analysis of PDX mouse clinical trials. Sheng Guo,1 Binchen Mao,1 Henry Q. Li2.1 Crown Bioscience, Taicang, China; 2Crown Bioscience, Santa Clara, CA.

Patient-derived xenograft (PDX) is a well-accepted experimental cancer model mimicking original patients in histo- & molecular pathology, as well as drug response. Mouse clinical trials (MCT) using PDX becomes increasingly prevalent in oncology research, yet the theory and methodology for trial design and analysis is underdeveloped. By analyzing tumor growths of 34081 PDX mice, we showed that majority of can be satisfactorily modeled by exponential growth kinetics, based on which we derived a new drug response readout called the AUC ratio that is superior to the tumor growth inhibition (TGI) and its variants. We outlined a bootstrap algorithm to calculate its confidence interval, and showed that a 4:4 (4 mice in both treatment groups) or up design sharply increases measurement accuracy over the lesser design. Next, we introduce three approaches for drug evaluation and biomarker discovery in MCTs. In the endpoint based analysis, we used a cohort of gastric PDXs to show a positive correlation between EGFR mRNA expression and cetuximab efficacy, in agreement with clinical trial results. We then used linear mixed models (LMMs) to describe MCTs as clustered longitudinal studies that capture the growth and drug response heterogeneities across PDXs and among mice within a PDX. Further, LMMs can separate prognostic and predictive biomarker effects, quantify response difference to a drug for multiple cancers, or efficacy difference of multiple drugs to a cohort of PDXs. Thirdly, we used additive frailty models to perform survival analysis on MCTs. We defined survival endpoints of PFS and OS in PDX to show that hazard ratios can be more accurately estimated. We revealed an inherent connection between frailty and growth rate for PDXs. We performed computational simulations for the last two methods to show that statistical power improves tremendously with a 3:3 or up design. This work lays the foundation for rational design and analysis of PDX mouse clinical trials.
Tumor cell division rate heterogeneity explains in vitro clonal dominance. Margriet M. Palm, Marjet Eleman, Joost B. Beltman. Leiden University, Leiden, Netherlands.

The cells that make up a tumor exhibit large phenotypic and genotypic variation, which strongly influences the effectiveness of cancer therapy. A typical morphological feature associated with invasive tumors in humans. The clonal dominance that represent most of the tumor population, i.e. clonal dominance. Such heterogeneity could potentially be caused by the occurrence of different ratios of cancer stem cells and differentiated cell clones per clone, or, alternatively, clonal dominance may be caused by heterogeneity of division rates between clones. Previously published work, applying lineage tracing with genetic barcodes to in vitro iterated growth and passage experiments demonstrated that clonal dominance was accompanied by clone loss and partial overlap in dominant clones between biological replicates [1]. To identify the source of these observations, we build a computational model that simulates the iterated growth and passage experiments. By varying the ‘division rules’ in the model, we can quantitatively predict the evolution of the clone distribution for the aforementioned hypotheses. In this manner, we show that clonal dominance does not appear in simulations where all cells divide at a uniform rate, even when the population is subdivided in cancer stem cells and differentiated cells. However, when the division rates vary between clones and are inherited from parent cells, dominant clones appear. These simulations also closely match the in vitro evolution of clone loss and clonal overlap between biological replicates. Altogether, our findings suggest that data can be used to create a heritable tumor head model of individual cells. References: [1] Porter, S. et al. (2014). Lentiviral and targeted cellular barcoding reveals ongoing clonal dynamics of cell lines in vitro and in vivo. Genome Biology, 15(S), R75.

Using diffusion weighted imaging (DWI) data to accurately predict electric field delivery to the tumor during TTFields treatment. Cornelia Wenger,1 Ze’ev Bomzon,1 Pedro Cavaleiro Miranda2. 1Novocure, Haifa, Israel; 2Faculty of Science, University of Lisbon, Lisbon, Portugal.

Tumor Treating Fields (TTFields) are low intensity (1-3 V/cm) alternating electric fields in the intermediate frequency range, delivered through two pairs of transducer arrays placed on the patient’s scalp. TTFields are an anti-mitotic modality approved for the treatment of glioblastoma multiforme (GBM). Simulation-based studies show that TTFields distribution within the brain depends on the location of the arrays on the scalp as well as the anatomy of the patient. Therefore, to study how field distribution influences disease progression requires the creation of patient-specific computational models. To date the creation of such models is based on accurate segmentation of MRI images into various tissues, and further of volume mesh assembly. These tasks are performed using semi-automatic, labor-intensive algorithms, making this approach impractical for studies which require the creation of a large number of patient models. We recently outlined that diffusion tensor imaging (DTI) could be used to construct realistic head models for simulating TTFields distribution without the need for complex segmentation of the brain. This is possible because the diffusion tensors evaluated from DTI can be scaled into anisotropic conductivity tensors using simple relationships. However, the approach is limited because the acquisition of high-quality DTI data is not widely practiced for GBM patients. Yet, shorter diffusion weighted imaging (DWI) sequences, such as an apparent diffusion coefficient (ADC) map or trace image, are common diagnostic techniques. The aim of this study was to test whether DWI data could potentially be used to create realistic head models. We used a previously developed head model created from structural and DTI data of a healthy individual. To test pathological scenarios, virtual lesions were placed. To simulate data acquired with DWI, we substituted the diffusion tensor at each point within the model with the mean diffusion (MD), which is the value that can be measured using DWI. The computational model was then completed by scaling the MD into a voxel-wise isotropic conductivity map using the same relationship as expressed above for converting anisotropic diffusion into conductivity tensors. TTFields distributions within the model were then evaluated for various array layouts and tumor locations. The field distribution within the DWI-derived models did not vary significantly from those found in the DTI-derived models. The highest deviation between models was a difference of 5% in the average electric field intensity in the tumor. The study shows that DWI data can be used to develop realistic TTFields, opening a new avenue for creating patient-specific computational models on a large scale. These models could be beneficial for retrospective studies investigating possible connections between field distribution and disease outcome.

Computational modeling and characterization of Dieder proteins that regulate highly-conserved immune signaling. Aunol Jerlu,1 Mary Ellen Heavner,2 Shubha Govind,3 Shaneen Singh1. 1CUNY Brooklyn College, Brooklyn, NY; 2CUNY City College, New York, NY.

The NF-kB and JAK/STAT pathways are well-established signal transduction pathways that are involved in the regulation of immune responses, and are frequently deregulated in cancer. The aim of this study was to test whether DWI data could potentially be used to create realistic head models. We used a previously developed head model created from structural and DTI data of a healthy individual. To test pathological scenarios, virtual lesions were placed. To simulate data acquired with DWI, we substituted the diffusion tensor at each point within the model with the mean diffusion (MD), which is the value that can be measured using DWI. The computational model was then completed by scaling the MD into a voxel-wise isotropic conductivity map using the same relationship as expressed above for converting anisotropic diffusion into conductivity tensors. TTFields distributions within the model were then evaluated for various array layouts and tumor locations. The field distribution within the DWI-derived models did not vary significantly from those found in the DTI-derived models. The highest deviation between models was a difference of 5% in the average electric field intensity in the tumor. The study shows that DWI data can be used to develop realistic TTFields, opening a new avenue for creating patient-specific computational models on a large scale. These models could be beneficial for retrospective studies investigating possible connections between field distribution and disease outcome.

UnicOnSig: A new algorithm for genome wide quantification of gene functions and disease associations. Xu Chi,1 Meenakshi Anurag,2 Sartor A. Maureen,3 Xiaosong Wang1. 1University of Pittsburgh, Pittsburgh, PA; 2Baylor College of Medicine, Houston, TX; 3University of Michigan, Ann Arbor, MI.

One of the greatest hurdles for cancer biologists is to identify the cancer genes underlying inherited and sporadic cancer. While high throughput cancer genomics or deep sequencing studies. In our previous study, we discovered that cancer genes possess a complicated yet distinct “gene concept signature.” Concept Signatures include cancer-related signaling pathways, molecular interactions, transcriptional motifs, protein domains, and gene ontologies. We developed a Concept Signature (or ConSig) analysis that prioritizes the biological importance of candidate genes underlying cancer by computing their strength of association with those cancer-related signature concepts. The ConSig analysis facilitated the discovery of a recurrent ESR1-CCDC170 gene fusion in more aggressive Luminal B breast cancers (Nat. Commun. 2014) as well as TLK2, MAP3K3, and MYST3 amplifications in aggressive luminal breast cancer (Nat. Commun. 2016). The NF-kB and JAK/STAT pathways are well-established signal transduction pathways that are involved in the regulation of immune responses, and are frequently deregulated in cancer. The aim of this study was to test whether DWI data could potentially be used to create realistic head models. for the selection of high-value neoantigen candidates and how they can improve the design and efficacy of cancer vaccines. Neoantigens with low Treg activation potential may then be used to support development of personalized therapies including vaccination and in vitro expansion of tumor infiltrating lymphocytes for adoptive cell transfer.

#4541 Understanding the dose and schedule dependence of efficacy for the We1 inhibitor AZD1775 in xenograft and patient derived explant models by mathematical modelling. James W. Yates, Elaine Cadogan, Jennifer Hare, Adina Hughes, Urszula M. Polanska, Mark O’Connor, Susan E. Critchlow, AstraZeneca, Cambridge, United Kingdom. AZD1775 is a highly selective, small-molecule inhibitor of We1 being developed to treat patients with advanced solid tumors, as monotherapy and in combination with olaparib. Experimental Procedures Patient-derived explant (PDX) and xenografted models with a range of sensitivities to AZD1775 were tested for response to different doses and schedules of AZD1775. We1 inhibition was assessed by pCDK1 as a direct substrate of We1 and RRM2 as a surrogate of CDK2 activity. Concentration of AZD1775 in plasma was measured in the same animals. Mathematical models were developed to describe the relationship between drug exposure, biomarker modulation and resulting tumor growth inhibition. Results The PKPD relationship of both pCDK1 and RRM2 could be described by the mathematical model with significant delay between PK and RRM2 reduction due to this being a protein degradation event. Three factors influenced anti-tumour activity in the A437 xenograft and three TNBC PDX models, namely the AZD1775 dose, the number of consecutive days of dosing and the number of days between AZD1775 doses. The minimally effective preclinical dose with anti-tumour activity was 60 mg/kg OD. TGI was seen to increase with increased days of consecutive AZD1775 dosing from 3 days on, such that a 5 days on/9 days off schedule was more efficacious than 3 days on/4 days off schedule for two weeks. A mathematical model successfully described this efficacy by using the predicted dose and schedule dependent reduction in pCDK1. Conclusions The insights from this predictive modelling informed the starting dose of 125mg BID AZD1775 on a 5 day on/9 day off schedule; with the clinical goal to optimize the days of consecutive AZD1775 dosing as well as the maximum tolerated dose.

Chemotherapy and immunotherapy have sometimes been considered two mutually exclusive approaches. On the one hand, chemotherapy has long been considered as a modestly effective treatment (outside pediatric oncology), with a short-lived effect caused by drug resistance, a poor tolerance profile and a detrimental effect on the immune system. On the other hand, the oncologist continues using chemotherapies for many reasons: if the control of a large tumor mass has to be obtained urgently irrespective of the side effects on the immune system, if immunotherapy has failed or has not been validated as a first line of treatment, when no targeted therapy can apply, etc. However, the issue of modifying the long-validated chemotherapy protocols to make them a good fit for an adjuvant (or concomitant) immunotherapy has not been addressed yet. The practice of gluing together an old Maximum Tolerated Dose (MTD) protocol with new immunotherapy protocol is the standard practice. Even though some re-design would be needed to mitigate the massive and prolonged immunosuppression caused by chemotherapy protocols. This lack of flexibility in the chemotherapy regimen could seriously jeopardize the effects of adjuvant or concomitant immunotherapy. Fortunately, chemotherapy and immunotherapy may not be incompatible per se: there are accumulating evidence that low-dose chemotherapies with little or no break-period (the so-called metronomic regimen) might have an immunological mode of action (in addition to the classical explanation of its anti-angiogenic effect and cytotoxicity). Furthermore, even with MTD protocols, experienced oncologists can improve the clinical outcome with the rationale use of pro-immunogenic drugs. Nevertheless, the best way to combine chemotherapy with immunotherapy is unknown and to find it in a trial would require large resources (high costs and risk of failure). This is why we present a pharmacodynamic model of chemotherapy in combination with immune checkpoint blockers, in order to provide a practical tool for the design and the management of clinical trials. Based on simple equations, this model does not predict a priori the best protocol, but helps the analysis of clinical data and the subsequent identification of optimal combinations. The mathematical model is based on discrete-time (high costs of the approximations), under the assumption that the number of immune response cells is much larger than the number of tumor cells. This assumption is justified for most of the clinical studies. Mathematical model of chemotherapy in combination with immune checkpoint blockers is developed. The model includes a description of the growth of the tumor and immune system, if immunotherapy has failed or has not been validated as a first line of treatment.

BIOINFORMATICS AND SYSTEMS BIOLOGY: Modeling and Algorithms

UnitConSig has broad applications on genome prioritization for genomic-based studies to discover new disease causal genes or new gene functions.

Artificial Intelligence (AI) is the single most transformative technology in human history. Advancements in personalized medicine depend upon significantly furthering our current understanding of how genetic variation and somatic mutation regulate aberrant gene activity and subsequent disease biology, including the myriad of dysregulated molecular mechanisms of cancer. To this end, we have built a robust AI methodology to precisely assess pathogenicity for all genomic missense variants. Coupled with our advanced deepCODE feature selection strategy for constructing deep learning models, we can quantitatively integrate a priori pathway-based biological knowledge with multiple types of high-throughput omics data. This approach significantly improves performance of established classification methods via enhanced semantic interoperability for mapping between multiple biomedical ontologies and the subsequent identification of genes and molecular pathways more predictive of cancer type etiology. Specifically, our deepCODE AI methods greatly improve tumor subtype and drug-response classification accuracies by combining tumor DNA- and RNA-seq data. Our results illustrate classification of human breast and lung cancer subtypes with 96% and greater than 99% accuracy, respectively. Our novel multinomial statistical-learning method, which was validated with 6 cancer type patient-derived tumor xenograft (PDXT) mouse models, achieved greater than 95% accuracy across 10,000 human tumors within the collection of 28 TCGA cancer types. Finally, our stepwise deepCODE drug target discovery approach systematically integrates our deep learning classification strategy with advanced Bayesian Network modeling to identify causative driver genes, representing probable novel drug targets. This stepwise machine learning approach also serves as a unique means to assess drug efficacy. Taken together, our advanced deepCODE AI tools greatly expand the means to fully understand the underlying molecular determinants of human cancer. We have developed user-friendly decision support and research tools for in-depth tumor analysis and large-scale case-control methods that afford investigators access to our deepCODE variant annotation algorithms.

#4540 MiVax: an innovative cancer neoantigen prediction system. Lenny Moise, Guilhem Richard, Frances Terry, William Martin, Ann De Groot. EpiVax Inc, Providence, RI.

T cell epitopes bearing tumor-specific mutations discovered using next generation sequencing can mediate T cell-mediated immune responses that arrest tumor progression. Although neoantigen prediction using computational methods rapidly identifies epitope candidates in the mutanome, a large proportion prove to be non-immunogenic. Innovative computational tools validated for infectious disease can be applied to enhance design of personalized cancer immunotherapies by classification of predicted epitopes according to potential for mounting a tumor-specific T cell mediated immune response. Our novel computational pipeline identified that non-mutated consensus sequences of MHC class I and II T cell receptor (TCR)-facing sequences and screens sequence databases to identify MHC ligands that share TCR faces with host-related proteins. A database of human protein sequences is available and screens sequence databases to identify MHC ligands that share TCR faces with host-related proteins. A database of human protein sequences is available to identify tumor-specific epitopes that may reduce anti-tumor activity by sequences that activate regulatory T cells (Tregs) trained in the thymus on self-antigens. Similarly, tumor-specific epitope candidates are screened using databases composed of human commensal- or pathogen-derived sequences to identify epitopes that, respectively, may detrimentally or beneficially cross-react with T cells raised over the course of an individual’s immune history. We conducted retrospective analyses of cancer vaccine efficacy studies performed in mice [Kreitner et al. 2015 Nature 520, 692-696] showing that mutanome-directed vascularization is unrelated to therapeutic tumor growth inhibition. Results The PKPD relationship of both pCDK1 and RRM2 could be described by the mathematical model with significant delay between PK and RRM2 reduction due to this being a protein degradation event. Three factors influenced anti-tumour activity in the A437 xenograft and three TNBC PDX models, namely the AZD1775 dose, the number of consecutive days of dosing and the number of days between AZD1775 doses. The minimally effective preclinical dose with anti-tumour activity was 60 mg/kg OD. Proceedings of the American Association for Cancer Research • Volume 58 • April 2017
Despite decades of effort, most disseminated cancers remain incurable, and progression from localized to metastatic disease is largely responsible for cancer-related mortality. In metastatic disease, an ongoing battle between tumor and host occurs at each site; tumor-associated antigens, stress proteins, and danger-associated molecular patterns can both initiate and continually stimulate an immune response against a tumor. Adding an additional layer of complexity, locally activated cytotoxic T cells traffic through the host circulatory system to also surveil metastasis elsewhere in the body. Thus, metastatic tumors are highly interdependent; changes in the nonlinear tumor-immune interactions in one tumor can perturb the systemic antitumor immune response, potentially facilitating spontaneous regression or aggressive outgrowth in distant sites. This can additionally influence the clinical outcome of therapeutic intervention, which depends on therapy-induced changes in tumor-immune dynamics both locally and systemically, as well as patient-specific initial conditions of the global disease. Using the tools of mathematical oncology we gain insights into this complex interconnectivity between metastatic sites. ODE models have been developed which incorporate both local tumor-immune interactions in each tumor site and the trafficking of activated T cells systemically, and can be parameterized by experimental and clinical investigations. Using four primary tumor sites (lung, liver, breast, kidney) we simulate the growth behavior of a primary site upon both seeding, growth, and treatment of a secondary (or several) metastatic site(s). In the presence of several metastatic sites, the dissemination of activated T cells is not necessarily intuitive and depends on many factors including the blood flow fraction to each organ and the tumor volume to organ size ratio. Certain sites may experience inhibition of growth, and other sites may be promoted upon seeding of an additional site. We computationally analyze all combinations of metastatic sites, and predict which sites are likely to benefit (tumor growth) and which to suffer (tumor shrinkage) in each combination based upon known properties of physiological blood flow and tumor volume at initial presentation. This allows the identification of which sites in each combination would be the optimal target for surgical therapy in order to induce the maximum reduction in overall tumor burden. Furthermore, we can simulate local radiation at each respective site, quantifying the difference in model-predicted decrease in overall tumor burden between individual targets. The results facilitate an improved understanding of general disease kinetics in the metastatic setting, emphasizing that ‘local’ therapy is highly likely to have systemic effects, and support the case for a paradigm shift in treatment target selection for metastatic disease.

### #4543 Local and systemic tumor-immune dynamics in metastatic cancer.
