Cancer-associated fibroblasts (CAFs) are a part of the tumor microenvironment, and help remodel the extracellular matrix to pave the way for tumor cells to invade and spread. Src tyrosine kinase activity is often increased in the tumor microenvironment, and has been shown to induce cell motility and disrupt adherens junctions. Adherens junctions are formed by cadherin proteins that mediate intercellular adhesion and control cell migration. Previous studies have found correlations between cadherin expression and cancer cell motility. However, effects of cadherin expression on CAF motility have not been thoroughly investigated. We are investigating how junctions formed by E-cadherin (ECAD) and N-cadherin (NCAD) affect individual and collective migration of fibroblasts expressing different levels of Src kinase activity. We are utilizing fluorescently tagged ECAD or NCAD to study the localization and effects of cadherin proteins in real time by live cell imaging along with wound healing and Transwell migration assays. Results from these studies indicate that ECAD and NCAD have different effects on migration of cells depending on Src kinase activity. Src kinase activity did not affect collective cell migration, but increased individual cell migration by over 4 fold (p<0.0001 by t-test) in the absence of forced cadherin expression. In addition, our data indicate that ECAD increases collective cell motility, while NCAD decreases collective cell migration in the absence of strong Src kinase activity. Collective migration by ECAD expressing cells was over 3 fold higher than cells expressing NCAD or control transfectants, and over 3 fold lower than cells expressing ECAD (p<0.005 by t-test) without strong Src kinase activity. In contrast, both cadherins decrease individual cell motility promoted by Src kinase activity. ECAD and NCAD transfected cells migrated over 4 fold less than control transfectants with high levels of Src kinase expression (p<0.0001 by t-test). Interestingly, human oral squamous cell carcinoma (OSCC) cells that express high levels of both ECAD and NCAD exhibit collective migration equal to cells with low Src kinase activity, but individual migration over 5 fold higher than nontransformed cells (p<0.0001 by t-test). This system should prove useful to elucidate how cadherins and Wnt signaling pathways affect motility of CAFs and tumor cells. For example, western blotting analysis suggest that both ECAD and NCAD may protect cells from patients with breast cancer more hyperplastic and desmoplastic lesions than those from patients with breast cancer showed more hyperplastic lesions and CD49fhi luminal cells than young (<40 yr) tissues. Regenerated mammary glands by the old CD49fhi MaSCs through in vivo transplantation in cleared mammary fat pads showed more hyperplastic and dysplastic lesions than those regenerated by the young CD49fhi MaSCs, suggesting the old CD49fhi MaSCs contain transformed MaSCs. Moreover, gene set enrichment analysis of whole genome transcriptome data showed that they also have elevated expression of luminal cell specific genes and reduced expression of basal cell specific genes. Through large scale screening with flow cytometry guided by bioinformatics analysis, we found that Lin CD24+/CD49fhi CD13−CD73− cells significantly increased number of MaSCs. By comparing young (3 to 6 month) and old Balb/C mice, we found that the frequency of this specific MaSCs was significantly increased by four folds in old mammary epithelial cells (young: 4%; old: 16%). In contrast, relative percentage of Lin CD24medCD49fhi CD13−CD73+ cells significantly decreased (young: 46%; old: 16%) during aging while the CD13 and CD73 double positive or double negative subpopulations remained unchanged. CD13−CD73+ cells generated significantly many more mammospheres (around 40 spheres from 1,000 cells) in suspension than other three types of cells (around 2 spheres per 1,000 cells). However, there was no significant difference between the young and old in terms of sphere formation efficiency for any of the four subpopulations marked by CD13 and CD73. We are studying whether anyone of these four subpopulation from CD49fhi old cells will generate more hyperplastic and dysplastic lesions in regenerated glands than the other subpopulations as well as than the corresponding young subpopulation. Our study show that CD13 and CD73 may be the markers for the identification of tumor-initiating MaSCs.
vivo. Results: Our data showed that MSC's TM expression was low in the quiescent state but was up-regulated while treating with B16F10 cell's conditioned medium in the mechanism of plate-derived growth factor signaling dependence. Accordingly, using conditional gene knockout strategy, under the condition of tumor cell other than normal culture resulted in that TM gene knockout significantly inhibited tumor cell proliferation, migration, and invasion and impaired cell cycle progression. Moreover, TM knockout notably reduced the capacity of MSCs on regulating the growth, vasculogenesis, and active stroma establishment of B16F10 melanoma xenograft in vivo. Conclusion: These results indicate that the sequestration of tumor-associated plate-derived growth factor is a critical event for MSC's TM expression, providing further insights into the extent to which defective ACD contributes to tumor inhibition activity. Whether the loss of ACD directly promotes tumor initiation is unclear, because the detailed mechanisms of mammalian ACD have not been elucidated (Gomez-Lopez S et al. Cell Mol Life Sci 2014). Lethal giant larvae 1 (Lgl1) was shown that human Lgl1 is inhibited by PTEN loss, which is common in glioblastoma, indicating possible compromise of the canonical Wnt signaling during Paneth cell differentiation. Here we further characterized the underlying molecular mechanism of Cd42 regulating intestinal stem cell survival, proliferation, and differentiation. IHC of the intestinal tissue in Cd42 Villin-Cre knockout mice suggests greatly reduced Olfm4 level in the stem cells, which are abnormally positioned in the crypts, along with a reduction of both transcription co-factors beta-Catenin and YAP. The Notch signaling, which is required for stem cells and differentiation of absorptive lineage, seems intact. The autonomous regulation of Cd42 on Yap signaling is probably through its specific role in stabilizing cell-cell junction and actin filaments in the epithelium, both of which are known regulatory inputs of the Hippo-YAP pathway. Both Wnt/beta-Catenin and Yap signaling are required for the initiation and progression of colorectal cancer, and the regeneration of stem cells post radiation. Given that Cd42 is overexpressed in multiple types of cancers, especially colorectal cancer, our finding that Cd42 regulates both Wnt and Yap pathways in the homeostasis of adult intestinal tissue sheds new light on the molecular mechanism of its pathological involvement, and potential therapeutic target.
#920 ICAM-1(CD54) is involved in the osteogenic differentiation of mesenchymal stem cells and affects the progression of osteosarcoma cells. Yidan Zhang,1 Sajida Pideri,2 Nikolas Zaphiros,3 Pratitha Koirala,3 Tingting Ren,3 Michael Roth,4 Jonathan Gill,1 Bang Hoang,1 David Geller,1 Rui Yang,1 Wendong Zhang,1 Xiuquan Du,1 Jinghong Zhang,1 Richard Gorlick,1,3 Montefiore Medical Center, Albert Einstein College of Medicine, Bronx, NY; 2Peking University People’s Hospital, Beijing, China.

Purpose: The aim of this study is to validate the relationship between the expression of ICAM-1(CD54), a cell surface glycoprotein, and osteogenic differentiation of mesenchymal stem cells (MSCs) and the role of ICAM-1 in the progression of osteosarcoma (OS) cells. Experimental Design: To compare the gene expression profiles between MSCs and MSCs after osteogenic induction, a microarray analysis was first performed. The differences in expression of specific genes including ICAM-1 were confirmed using western blot and flow cytometry. MSCs were sorted into two groups of cells by CD105 expression profiles between MSCs and MSCs after osteogenic induction, a microarray analysis was first performed. The differences in expression of specific genes including ICAM-1 were confirmed using western blot and flow cytometry. MSCs were sorted into two groups of cells by CD105 and CD105+CD44+CD54+ and CD105+CD44+CD54+ and properties of these cells were compared. Expression of ICAM-1 among tumor cells and xenograft OS cells were tested at the protein level. ICAM-1 was stably, constitutively overexpressed in multiple cell types. Differences in osteogenic differentiation potential between normal cell lines and transformed cell lines were studied using alizarin red S staining. Motility, proliferation and invasion as well as the metastatic potential of the transformed and normal cells were evaluated. Results: The initial microarray analysis revealed that ICAM-1 expression was significantly increased in MSCs after osteogenic induction for 15 days (p=0.03). Consistent results were achieved in western blot and flow cytometry analysis. Further microarray analysis between CD105+CD44+CD54+ and CD105+CD44+CD54+ groups determined that NF-kB signaling pathway was differentially activated. As for OS cells, ICAM-1 is not expressed at high level among OS tumor cell lines and is inconsistently expressed in xenograft OS cells. Enhanced osteogenic differentiation potential was observed in ICAM-1 overexpressing cells. Although there were no major difference in vitro motility, proliferation or invasion tests, substantially less lung nodules occurred with transformation as compared to the normal control. Conclusions: ICAM-1 is involved in the osteogenic differentiation of mesenchymal stem cells and its down regulation may be involved in the progression of osteosarcoma cells.

#921 Cdy2 is a chromodomain protein involved in the maintenance of pluripotency of stem cells. Naoko Hattori,1 Kana Kimura,1 Jumpei Taguchi,2 Toshiro Imai,1 Yasuhiro Yamada,1 Toshikazu Ushijima1.

Reader proteins of histone modifications are required to translate the information of histone marks into the cellular phenotypes, including pluripotency and malignancy. For example, a reader protein BRD4 has its target specificity and becomes a target of cancer therapy. Here, we aim to identify reader proteins involved in the pluripotency of stem cells. Using the UCSC database, 11 genes coding for chromo- or PHD-domain proteins were isolated as actively transcribed in mouse ES cells (ESCs). Among the 11 genes, Cdy2, chromodomain protein Y-like2, was found to be down-regulated upon ESC differentiation using RT-qPCR. Immunofluorescence and ChIP assay revealed that Cdy2 recognized H3K27me3 of the specific regions, including differentiation-associated genes. Cdy2-knockout ESCs could not survive after differentiation induced by LIF removal or retinoic acid because of the induction of apoptosis, indicating that Cdy2 is important for normal differentiation of ESCs. ESC expressing exogenous Cdy2 showed incomplete down-regulation of Oct-4 and Nanog by retinoic acid, and generated teratomas with an abnormal composition of three germ layers, showing perturbation of differentiation ability. Pathologically, aberrant expression of human Cdy2L2 was observed in breast cancer cell lines and primary breast cancers. Two breast cancer cell lines (MDA-MB-231 and MDA-MB-468) expressing exogenous Cdy2L2 showed enhanced attachment ability along with the up-regulation of integrin alpha-6 and integrin beta-1. The population of cancer stem cells, defined as ALDH positive cells, were increased in CD105+CD44+CD54+ cells, and show that human Cdy2L2 is involved in proliferation of cancer stem cells. From these data, we conclude that, between self-renewal and differentiation of stem cells, mouse and human Cdy2L2/CDY2L2 is necessary for the implementation of the initial step of differentiation.

#922 Delta133p53 represses p53-inducible senescence genes and enhances p53 functions to induce cellular senescence and apoptosis, which can be incompatible with self-renewal of pluripotent stem cells. Tzuin Horikawa,1 Kye-yoon Park,2 Han Li,3 Kazunobu Isoyagi,3 Yukiharu Hiyoshi,3 Katsuhito Anami,3 Ana I. Robles,1 Abdul M. Mondal,1 Kaori Fujita,1 Manuel Serrano,3 Curtis C. Harris,1 1National Cancer Inst., Bethesda, MD; 2NIH, Bethesda, MD; Spanish National Cancer Research Center, Madrid, Spain.

Human embryonic stem cells exhibit altruistic cell death that release death signals having potent anti-cancer activity. Bidisha Pal,1 Seema Bhuyan,2 Jaishree Garhyan,1 Herman Yeger,1 Bikul Das1,2 1The Forsyth Institute, Cambridge, MA; 2KarniKrishna Laboratory, Indian Institute of Technology (IIT), Guwahati, India; 3Hospital for Sick Children.

Background: We recently described the altruistic stem cell phenotype (ASC) in human embryonic stem cells (hESCs) as well as in mesenchymal stem cells (1, 2). The ASC phenotype was characterized by altered state of p53/MDM2 feedback system that permitted the cells to transiently acquire an unstable state of low p53 allowing the cells to survive in extreme microenvironment (1). Interestingly, we noted that ASCs spontaneously returned to its basal state of high p53 after a period of two weeks (1, 2). In this study, we speculate that this return of p53 levels to basal state could be a safety mechanism to prevent malignant transformation of ASCs. We also speculate that ASCs may release soluble factors like high mobility group protein B1 (HMG1)-1 that could selectively target the cells exhibiting abnormal p53 e.g. cancer cells. Here, we further characterized ASC phenotype and its fate. Methods: hESC, BG01 cells were exposed to extreme hypoxia followed by reoxygenation and then ABCG2+/+SEAS3+ cells were flow cytometry sorted. This specific subpopulation is enriched in ASCs and could be cultured in vitro for two weeks (1). The post- hypoxia treated ASCG22+/+SEAS3+ cells were maintained in serum free media, and subjected to apoptosis, and senescence assays. The conditioned media (CM) of these cells and subjected to HMG1-1 measurement by ELISA. To measure bystander apoptosis, teratocarcinoma cells (Tera-2) were treated with the CM followed by measurement of apoptosis. Results: Here we confirmed that p53 and MDM2 in ABCG22+/+SEAS3+ cells exhibited return of oscillation between days 19-24. This was associated increase in apoptosis, and senescence of these cells. Apoptosis/senescence was decreased when treated with either Pifithrin α, an inhibitor of p53, or by siRNA silencing of p53, suggesting p53-dependent apoptosis. Additionally, treatment with Nutlin-3, an inhibitor of MDM2 (1) led to a 10-fold increase in apoptosis indicating that high MDM2 was required to prevent the apoptosis of ASCs. Thus, ASCs underwent spontaneous apoptosis (altruistic cell death) due to the return of p53/MDM2 oscillation. We suggest that this return of p53 and associated apoptosis could be a safety mechanism to prevent malignant transformation of ASCs. Next, we found that the CM of ABCG22+/+SEAS3+ cells contained high levels of HMG1-1 compared to the parental BG01 cells. Importantly, CM treatment led to p53 dependent apoptosis of Tera-2 cells. Furthermore, CM treatment also inhibited the growth of Tera-2 xenografts in NOD/SCID mice. Conclusion: Our results indicate that ASCs undergoes altruistic cell death that releases death signals mediated by HMG1 that can target neighboring cells exhibiting abnormal p53 including cancer cells. We suggest that this unique property of ASCs could be exploited as a novel cancer therapeutic. 1. Das B et al, Stem Cells, 2012; 30(8):1685-92. 2. Pal B et al, Cancer Research, 2016; Volume 76, Issue 14 Supplement, p. 251.
TUMOR BIOLOGY: Stem Cell Heterogeneity

#924  Delidifferentiation into polyploid blastomere-like cancer stem cells via formation of polyploid giant cancer cells. Na Niu, Jinsong Liu. UT MD Anderson Cancer Ctr., Houston, TX.

We have recently shown that polyploid giant cancer cells (PGGCCs) are capable of tumor initiation and acquisition of embryonic-like stemness and thus repre- sent a novel type of cancer stem cells. However, two important questions remain to be answered from this surprising finding: (1) how PGGCs acquire such stem- ness; (2) on which stage of normal development PGGCs correspond to. Here, we tracked the fate of single PGGCs induced via mitotic failure by paclitaxel. Mor- phologically, early spheroids derived from PGGCs were indistinguishable from human embryos at the polyploid blastomere, compaction, morula, and blasto- cyst-like stages. Fluorescent electron microscopy showed that PGGCs showed time- and space-dependent activation of expression of the embryonic stem cell markers OCT4, NANOG, SOX2, and SSEA-1 and lacked expression of Xist. PGGCs also showed time-dependent activation of expression of the germ layer-specific markers alpha-fetoprotein, smooth muscle actin, and β3-tubulin and were ca- pable of redifferentiation into three germ layers in vitro. PGGCs-derived daugh- ter cells showed attenuated invasive ability and increased resistance to paclitaxel. PGGCs-derived spheroids grew into a wide spectrum of human neoplasms, including malignant dysgerminoma and embryonic carcinoma, poorly differen- tiated or well-differentiated carcinomas, and benign squamous tissue. We also observed PGGCs in ovarian cancer from patients treated with chemotherapy. Thus, our data demonstrated that PGGCs acquired novel cancer stem cell prop- erties and are able to differentiate into different tumors including the germ cell tumors, which are at the topmost developmental hierarchy. We studied, for the first time, link PGGCs to the polyploid blastomere-like cancer stem cells and thus offer a new paradigm for the origin of cancer.

#925  Tumorigenesis of murine iPSCs is prevented by iron depletion with downregulation of stemness markers. Yuki Katsura,1 Toshiaki Ohara,2 Hajime Kishima,1 Hiroaki Sato,1 Takuya Kato,1 Takayuki Ninomiya,1 Kazuhiro Noma,1 Yasuko Tomono,2 Hiroshi Tazawa,1 Shunsuke Kagawa,1 Yasuhiro Shirakawa,1 Toshiyoshi Fujiwara1.1 Okayama Univ., Okayama, Japan;2Shigei Medical Research Institute, Okayama, Japan.

Background: Iron plays a crucial role in the various metabolic pathways and it is essential for life. However excess of iron is known to cause cancer. There are many reports that iron depletion treatment indicates antitumor effect. Previ- ously, we have confirmed that iron depletion treatment indicates antitumor effect against Cancer stem cell (CSC) model, miPS-LLCCm, which was con- verted from murine induced pluripotent stem cell (miPSC) in Okayama uni- versity (Chen et al, PLOS ONE 2012), and also suppresses CSC markers. Many tumors contain phenotypically and functionally heterogeneous cancer cells due to pluripotency of CSC. Although there are various theories about the origin of CSC, miPSC has a pluripotency and regarded as the top of the hierarchy, it can be the candidate of the origin of CSC. miPSC cell is known to form teratoma when inoculated into nude mouse because of its undifferentiated status. We hypoth- esized if we could suppress the stemness and tumorigenicity of miPSC cell by iron depletion treatment, it can be applied to the therapy for CSC and undifferen- tiated status cancer cell. In this study, we investigated the stemness and tumori- genicity of miPSC cell with iron depletion treatment. Methods: We used miPSC cell (cell name: iP5-MEF-NG-20D-17) purchased from Riken Cell Bank(Japan). Deferasirox (DFX), an popular commercial available oral iron chelator was used in vivo study. Tumors were harvested for immunohistochemistry. Results: Stemness markers of miPSCs were suppressed strongly by DFX in western blot analysis. DFX also suppressed the subcutaneous tumor growth. The average tumor volume of the control group was 665.3±430.8mm³ while that of the DFX treated group was 204.3±76.2 mm³ (p<0.05) on day 20. Immunohistochemistry of the tumor revealed the suppression of the stemness markers in the DFX treated group compared with the control group.

#926  Generation of a potential breast cancer stem cell model from induced pluripotent stem cells. Neha Nair,1 Anne Sanchez Calle,1 Maram Hussein Zahra,2 Aung Ko Ko Oo,3 Arun Vaidyanath,7 Tomonari Kasai,1 Shinobu Kobayashi,7 Masaharu Seno1.1 Okayama University, Okayama, Japan;2Menoufia University, Shebin El-Koom, Egypt;3Nihon University School of Medicine, Tokyo, Japan.

The role of cancer stem cells (CSC) in the present scenario of breast cancer research is perceived as indispensable in the development and progression of the disease. The CSC niche maintains a hierarchy of heterogeneous cells, which facilitates the inception of the tumor until its invasion. Therefore, our study focuses on the development of an effective breast cancer stem cell model from mouse induced pluripotent stem cells (miPSCs). Taking into consideration the intertumor heterogeneity of breast cancer, three human breast cancer cell lines, namely BT549, SKBR3 and T47D representing three major hormone subtypes were used to derive respective conditioned medium. The miPSCs were treated with these conditioned media for a period of four days during the expansion stage following a protocol previously established by our laboratory. The resulting survived cells were subcutaneously and orthotopically transplanted into Balb/c nude mice. Within a short span of 15-20 days, both subcutaneous and orthotopic tumors were developed. Serial transplantsations in to nude mice also generated malignant tumors with same vigor. Histopathological studies of these tumors confirmed the presence of PGCCs-derived tumor in vitro generated CSCs. Marked expression of prominent CSC markers namely CD44, Nanog, Sox2 and CD49f were observed in primary cells generated from these tumors. Tumor sphere formation assay further confirmed the presence of a good popu- lation of self renewing CSC population in the tumor tissues. This study attempts to recapitulate human breast cancer disease in mice without any genetic manip- ulation, but by exploiting the tumor microenvironment in the form of condi- tioned medium. This should pave the way for the establishment of personalized therapy and a model to assess effective therapeutic interventions.

#927  Cancer stem cell proliferation in human prostate cancer cells utilizing a new defined 3D spheroid culture system. Nick Astrock, Vi Chu, Kan Saito. MilliporeSigma, Temecula, CA.

Solid tumors grow in a three-dimensional (3D) spatial conformation, result- ing in a heterogeneous exposure to oxygen and nutrients as well as to other physical and chemical stresses. To mimic the 3D spatial conformation, 3D in vitro culture models have been used in cancer research since the diffusion- limited distribution of oxygen (hypoxia), nutrients, metabolites, and signaling molecules is not mimicked in conventional two-dimensional (2D) monolayer cultures. One of the 3D in vitro culture models, the tumourosphere culture is an emerging model for studying and expanding the cancer stem cell (CSC) popu- lation. E006AA cell line is a spontaneously immortalized cell line derived from a Gleason 6 localized prostate cancer in a hormone-naïve prostate cancer patient of African American descent. This cell line expresses androgen receptor and was repeatedly reported to be non-tumorigenic in nude mice. However this cell line forms continuously growing tumor in NOG-SCID triple-deficient mice (i.e., NOG-SCID mice not having NK, B, and T-cells) and an establishment of highly tumorigenic subline E006AA-It was reported suggesting this cell line has a potential for CSC proliferation by 3D spheroid cultures. Here we report tumors- pheres of CD133+ cells by a new 3D spheroid culture media system. The cells showed continuous proliferation supported during serial passage of 3D tumourospheres cultures. In addition to the stable proliferation, increases of Alde- hyde Dehydrogenase (ALDH) expressing CSC population were observed with the increase of passages of 3D tumourospheres cultures.

#928  Combined treatment by manuka honey and metformin inhibited growth and induced apoptosis in CD133+ and CD90- subpopulation hepatocellular carcinoma cancer stem cells. Amira S. Fyala, Ahmed S. Sultan. Faculty of Science, Alexandria University, Alexandria, Egypt.

Manuka honey is well known for its anti-bacterial and wound healing prop- erties but its anticancer role against cancer stem cells (CSC) in hepatocellular carcinoma (HCC) cell lines and the underlying molecular mechanisms remain uninvestigated. Recently, we identified a CSC subpopulation in HCC cell lines characterized by their CD133+ and CD90- phenotype. The CD133+/CD90- cells demonstrated a more aggressive phenotype than the CD133+/CD90- counterpart and formed metastatic lesions in the lung of immunodefi- cient mice. In order to evaluate the effect of Manuka honey alone or in combined treatment with Metformin, a biguanide that has been widely used to treat type 2 diabetes, on cell viability and apoptosis induction in human HCC cell lines, isolated and identified CD133+/CD90- subpopulation CSC were used. Cell vi- ability was monitored using an MTT assay. In addition, apoptosis induction was labeled by Annexin VFluorescein isothiocyanate/propidium iodide and mea- sured using flow cytometry. Western blotting was used to examine the protein expression of p53, Bcl2, Bax, Bcl2-associated death promoter (Bad), Bcl2 homol- ogous antagonist/killer (Bak) and cleaved caspases3 and 9. The results of the present study revealed that Manuka honey alone or in combined treatment with Metformin suppressed the cell viability of CD133+/CD90- cells in a concentra- tion-dependent manner and the maximum effect was detected in combined treatment after 24 h. In addition, Manuka honey alone or in combined treatment
with Metformin induced a significant apoptosis in the tested cells. Furthermore, it was demonstrated that combined treatment increased the expression of pro-apoptotic proteins, including p53, Bax, Bad and Bak, while it decreased the protein level of antiapoptotic protein Bcl2 compared to control, Manuka honey or Metformin alone. Furthermore, the combined treatment strongly inhibited stemness marker ALDH1 expression. CSC subpopulations were significantly inhibited in CD133+/CD90+ tumor growth in vivo. Our data demonstrated that combined treatment induced apoptosis in CD133+/CD90- subpopulation through G1 arrest in the cell-cycle and regulating p53/Bcl2/caspase3 signaling pathway. In conclusion, our results suggested that Manuka honey alone or combined treatment with Metformin may be a potential treatment for apoptosis induction in CSC and may provide a novel therapeutic model for HCC.

#929 Dissecting heterogeneity and population dynamics in breast cancer stem cells. Michael D. Brooks, Max S. Wicha. University of Michigan, Ann Arbor, MI.

The CSC hypothesis posits that there is a subset of tumors cells driving tumor growth and metastasis and that by targeting this population, tumors can be more efficiently eradicated. Recently it was shown that there are two types of CSCs in breast cancer, mesenchymal CSC’s characterized as CD44+/CD24- and an epithelial type marked by ALDH expression. The cellular plasticity of these CSC states may contribute to their metastatic capacity. However, little is known about the heterogeneity of these CSC populations or how they are regulated by the tumor microenvironment. To address these issues we have utilized Drop-Seq to generate single cell RNA-Seq data from thousands of cells across patient derived xenografts (PDX) with various molecular subtypes of breast cancer. In particular, DLK1 mRNA was highly expressed in U2OS (osteosarcoma), SW872 (liposarcoma), A204 (rhabdomyosarcoma), and HS-SYI (synovial sarcoma) cells. We observed a reduction in cell proliferation and invasion in U2OS, A204, and sw872 cells treated with DLK1 siRNA. CSCs were isolated using FACS with CD133 and sphere forming assay. The effect of DLK1 on sarcoma tumorigenesis was examined using cell proliferation and cell invasion assays by DLK1 siRNA treatment. Real-time PCR showed the increased expression of DLK1 mRNA in sarcoma cell lines. In particular, DLK1 mRNA was highly expressed in U2OS (osteosarcoma), SW872 (liposarcoma), A204, and sw872 by the FACS sorting method using the CD133, a CSC marker in sarcoma. The number of active spherocytes in CD 133+ cells were significantly higher than CD133- cells. While the breast CSC marker CD44 was down regulated in mesothelioma tissue and cell lines1-4. Based on our own study and previously demonstrated a role for sFRP4 in making chemoresistant tumours amenable to chemotherapeutics3-16. We have now progressed our work into the effects of peptides derived from the cytokine-rich domain and the netrin-like domain of sFRP4 on tumour initiating cells derived from MM cells lines. We examined the effect of secreted frizzled-related protein 4 (sFRP4), a Wnt signaling antagonist and its associated cancer stem cells (CSCs) enriched from these two cell lines to chemotherapy. We found tumourspheres exposed to sFRP4 and peptides alone in combination with cisplatin induced cell death and decreased CD133 and ALDH1 expression. We thus identified for the first time that sFRP4 and associated peptides could help to sensitise to chemotherapeutics and destroy cancer stem cells of MM cell line, which would lead to effective treatment regimen to combat malignant mesothelioma. Our initial in vitro data exemplify the ability of these peptides in diminishing the numbers of therapy-resistant Tumor initiating cells (TICs). References: 1. Lee et al, 2004, Oncogene, 23(39), 6672-6676. 2. He et al, 2005 Cancer research, 65(3), 743-748. 3.
CD133+ cancer stem cells promoted by VEGF accelerate the recurrence of hepatocellular carcinoma. Dexi Chen,1 Kai Liu,1 Meijun Hao,1 Yabo Ouyang,1 Jiasheng Zheng,1 Kishore Babu, Challagundla2.1. Beijing You An Hospital, Capital Medical University, Beijing Institute of Hepatology, Beijing, China; 2Children’s Center for Cancer and Blood Diseases and The Saban Research Institute, CA.

The function of cancer stem cells (CSCs) on inducing HCC recurrence after radiofrequency ablation (RFA) is still unclear. Here, 19 RFA-treated primary HCC patients were enrolled. We identified a dramatic increase of plasma VEGF in some patients (termed type II, n=9) after RFA, who suffered early HCC recurrence; the other patients (termed type I, n=10) had no increased plasma VEGF but had longer interval for HCC recurrence. Moreover, expression of CSC markers, CD133, was dramatically increased in recurrent HCC tissue of Type II in comparison with type I, suggesting induction of CD133+ CSCs may contribute to early HCC recurrence. In vitro studies demonstrated that VEGF stimulus enhanced the level of CD133+ CSCs and their self-renewal ability by inducing Nanog dependently on activation of VEGFR2. In vivo studies further demonstrated that CD133+ CSCs with VEGF stimulus formed larger tumor size in comparison with non-stimulus; and VEGF stimulus increased the tumorigenic cell frequency of primary HCC cells dependently on the presence of Nanog and VEGFR2. In recurrent HCC tissue of type II, but not type I, almost all CD133+ cells were Nanog and p-VEGFR2 positive cells, suggesting that activation of VEGF2 is critical for RFA-induced tumor stemness in HCC. Taken together, our results suggest that VEGF/CSCs is a tumor stemness marker involved in tumor recurrence of HCC and is valuable for the prediction of HCC recurrence after RFA and development of novel therapeutics.
pressing CD133 to post-treatment more radioresistant CSCs expressing the GPl-anchored, TGFβ-inhibitory protein CD109 in an ATM, NF-kB, CEBP-b dependent manner. In post-IR GBM, these therapy-escaped CD133/CD109+ GBM cells, but not the rest of the tumor, uniquely retain clonogenic, tumorigenic, and multi-potent capacities both in vitro and in vivo. CD109 silencing unexigated CD133+/CD109+ cancer stem cells to the downstream target and this CD109-YAP/TAZ signaling axis is evolutionally conserved between drosophila and human brain tumors. Clinically, both CD133 and CD109 are independently associated with poorer prognosis of GBM patients, while the poorest prognosis group of GBM expressed both CD133 and CD109 at higher rates. These data indicate a possibility of the post-IR CSC plasticity and the subsequent heterogeneity, and the activation of the CD109-YAP/TAZ signaling axis as previously unidentified therapeutic targets for post-IR recurrent GBM.

#938  Estrogen induced NRF1 signaling is a molecular mechanism underlying the generation of different breast cancer stem cell subpopulations leading to intratumoral heterogeneity. Jayanta Kumar Das, Deodutta Roy. Florida International University, Environmental and Occupational Health, Bruce W Carter VA Medical Center, Research Service Laboratory, Miami, FL.

Life time exposure to elevated levels of estrogen (E2) is a major risk factor for breast cancer. Among women with ER/PR positive tumors, only 50 to 60% of women respond to endocrine therapy. Intra-tumoral heterogeneity of breast cancer cells may be one of the reason for unresponsiveness to endocrine therapy in more than 40% of ER-positive breast cancer cases. In this study we examined that heterogeneity of breast cancer stem cells (CSCs) are produced by exposure to E2 and/or ectopic expression of molecular risk factor - nuclear respiratory factor 1 (NRF1). To elucidate this, we used single cell confocal imaging, flow sorting, ChIP and qRT-PCR approaches. We also measured the key regulators of pluripluripotency, epithelial-mesenchymal transition (EMT), stemness, cell apoptosis and cell cycle regulation. The functional assay for cancer stem cells enrichment employed were selection of cells in B27 medium as spheroids, anchorage independent growth and mammosphere formation assays. Carcinogenic treatments of E2 to MCF10 A CD24- cells induced formation of ~1.46% CD44+/CD24- and 26.02% of CD44+/CD24- subpopulations, which are a typical phenotypes associated with human breast tumor-initiating (BTICs) or BCSCs. These subpopulations are capable of forming self-renewing mammospheres. In contrast, CD24+ or CD24+/CD44- cells did not form mammospheres. Stable NRF1 overexpression induced formation of 2.36% CD44+/CD24+ and of 64% CD44+/CD24- subpopulations. Carcinogenic treatments of E2 to stable NRF1 overexpressing MCF10 A cells, induced to acquire 21.54% CD44+/CD24- and 44.54% CD44+/CD24- subpopulations. E2 treatment to NRF1 overexpressing BCSCs markers significantly increased mammosphere forming capability, compared to NRF1 alone. The dominant negative form of NRF1 diminished the effects of E2 and/or NRF1 induced acquiring of BCSCs antigen markers and their capability of forming mammospheres. E2 induced BTICs/BCSCs were heterogeneous. Each subpopulation was characterized by a different transcriptional and biomarker profiles of CD24, CD44, CD49f, CD133, ALDH1A1, CXCR4 and NRF1. The expression of different markers for pluripluripotency (CD133, SOX2 and Nanog), EMT (E-cadherin, N-cadherin, Vimentin), stemness (CD24, CD44, CD39f, CD133, ALDH1A1), cell cycle (p16,CD2C2,CD2C25, cyclinB1) and metastasis (CXC4), were associated with BTICs produced by E2 and/or NRF1. In summary, we observed new roles of NRF1 in contributing to acquire breast tumor initiating stem-like cells and in regulating EMT and invasiveness of BCSCs, thus opens a new direction of breast cancer research. A better understanding of how E2 dependent breast neoplasm heterogeneity depends on NRF1 network may open new avenues for therapeutic strategy against breast cancer. This work was supported partly by VA MERIT Review (VA BX001463) grant to DR.

#939  Single cell mRNA expression profiling reveals heterogeneity of normal and malignant breast stem cell populations. Shamileh Fouladdel,1 Justin Colacino,2 Shamileh Fouladdel,3 Justin Colacino,4 University of Michigan, Ann Arbor, MI; 2University of Michigan, Department of Environmental Health Sciences, School of Public Health, Ann Arbor, MI.

The normal breast contains epithelial populations which are hierarchically organized, a profile recapitulated in breast cancer. At the apex of these hierarchies are ‘stem like’ cells defined by their capacity to self-renew as well as to generate more differentiated progeny. In breast cancer these ‘cancer stem cells’ (CSCs) have been shown to be important mediators of tumor metastasis and treatment resistance. Although the phenotypes of normal rodent and human mammary stem cells have been characterized, CSC populations are operationally defined by their capacity for tumor initiation. In addition, putative breast CSC markers such as CD44+/CD24low+ and ALDH1+ have proven useful in enriching for cells capable of tumor initiation and previous studies have suggested that these markers identify alternative mesenchymal and epithelial stem cell states, respectively. However, it remains unclear whether CSCs exist in discrete states or whether these cells actually represent a continuum reflected in heterogeneity of cell populations defined by expression of these markers. To address this question we utilized single cell mRNA expression profiling of normal and malignant breast stem cells. We first generated a panel of 96 genes representing stem cell and developmental pathways and analyzed expression of these 96 genes utilizing Fluidigm’s C1 and BioMark HD technologies and TaqMan gene expression assays. We also utilized Fluidigm’s Polaris to selectively isolate single cells that were then analyzed by illumina RNA-Seq method. Utilizing these advanced technologies, we demonstrated that both normal and malignant breast stem cells characterized by CD44+/CD24low+ and ALDH1+ expression are highly heterogeneous. For example, the ALDH isoforms ALDH1A1 and ALDH1A3 were each expressed in some single cells and co-expressed in others. ALDH1A1 expressing single cells appeared to express a unique gene pattern characterized by SLIT/ROBO, PLXNA2, ROHOU and HNF1a. These results suggest that at the level of mRNA expression, normal and malignant breast stem cells display a greater heterogeneity than has previously been reported. These results have important implications for breast carcinogenesis as well as for the development of therapeutic strategies designed to target CSCs in breast cancer.

Within the context of HER2+ breast cancer, PTEN mutation has been associated with poor patient survival, trastuzumab resistance, and induction of the epithelial to mesenchymal transition. Accumulating evidence supports the theory that breast cancers are organized in a hierarchical manner with the presence of cancerous stem-like restricted progenitor, and differentiated-like cells. Recent literature has also indicated that CSCs may exist in distinct epithelial and mesenchymal states which retain unique properties. In order to understand the influence of PTEN inactivation within the context of a hierarchical model of cancer, and examine which populations themselves are targeted by trastuzumab, we have performed analysis of traditional CSC markers and single cell lineage tracing experiments. Here, a lentiviral vector containing shPTEN and dsRed reporter are introduced into HER2+ cell line BT474. Following bulk sorting of dsRed+ cells, long term culture of parent and shPTEN cells and with and without trastuzumab for 4 weeks reveal no obvious changes in traditional EMT-CSC markers CD44+/CD24- and only modest changes in Aldefluor+ cells. In order to take a CSC-marker agnostic approach we performed a single cell colony formation assay and identify that trastuzumab enriches for rare cells with colony forming potential. The majority of single cell derived colonies exhibited distinct morphologies stable with long term culture which are similar regardless of PTEN knockdown or trastuzumab therapy. However, quantification reveals PTEN knockdown results in a higher frequency of colonies which exhibit distinctly mesenchymal morphology and less of those with epithelial morphology. Interestingly single colonies forming cells could recapitulate all morphologies present in the parental cell line, suggesting they were derived from a true CSC. Single cell multiplex RT-qPCR of 96 target genes was performed on mixed and distinct morphology colonies using Fluidigm’s C1 and BioMark HD instruments and TaqMan gene expression assays. Principal component and t-SNE analysis was capable of separating morphologically distinct colonies and revealed multiple cell clusters within each colony. Using hierarchical clustering it is evident that a minority of cells which appear as unique clusters in PCA analysis are those which are proliferative and express different lineage markers reflective of the colony itself. Taken together these results suggest that PTEN knockdown shifts the equilibrium from primarily epithelial lineage differentiation to a more mesenchymal differentiation while trastuzumab enriches for stem and progenitor cells.

TUMOR BIOLOGY: Stem Cell Heterogeneity

#941  CXCL1-CXCR2 signaling might recruit the bone marrow-derived mesenchymal cells to the carcinoma-associated fibroblasts of gastric cancer. Masakazu Yashiro, Toshiohisa Okuno, Hiroaki Kasashima, Yuichi Miki, Hiroshi Nakame, Kisyu Kitayama, Toshiyuki Kawashima, Takaharu Hatan, Heishiro Fujikawa, Tsuyoshi Hasegawa, Takahiko Nakane, Masayuki Hino, Ko sei Hirakawa, Masachio Ohira. Osaka City Univ. Grad. School of Medicine, Osaka, Japan.
Background & Aims: Activated fibroblasts in the tumor stroma, also termed carcinoma-associated fibroblasts (CAFs), play a critical role in the progression of cancer. In our previous studies, we identified CAFs as playing an important role in cancer progression in the development of gastric cancer. However, it remains unclear which factor recruit and promote CAFs. The aim of this study is to clarify the role of cancer cells (CCs) on the recruitment of CAFs originating from normal mesenchymal cells (BM-MCs). The nude mice with bone marrow transplantation from CAG-EGFP mice were used for the in vivo gastric cancer experiments. Results: BM-MCs migrated into tumor stroma of in vivo gastric cancer. The number of BM-MCs was much greater in the gastric tumor than in normal tissue from three days after inoculation of cancer cells. C-X-C motif ligand 1 (CXCL1) from gastric cancer cells significantly (p<0.001) stimulated the chemoattractant ability of BM-MCs in vitro. Anti-CXCL1 antibody and CXCR2 inhibitor significantly (p<0.05) decreased the migration-stimulating activity of gastric cancer cells. A CXCR2 inhibitor, SB25002, decreased tumor size and lymph node metastasis of gastric tumor, and significantly (p=0.039) prolonged survival of gastric-tumor bearing mice. The histologic findings indicated that SB25002 decreased the recruitment of BM-MCs into the tumor stroma, resulting in the reduction of CAFs. Conclusion: BM-MCs recruit into gastric tumor and differentiate into CAFs. CXCL1 from gastric cancer cells stimulates the recruitment of BM-MCs into gastric cancer focus via CXCR2 signaling. Inhibition of BM-MCs’ recruitment appears to be a promising therapy for gastric cancer.

#942 CXCR2 acts as a checkpoint regulator of the pancreatic stellate cells activity within pancreatic cancer tumor microenvironment. Mohammad Awaji, Michelle Varney, Abhislaha Purohit, Surinder K. Batra, Rakesh K. Singh. University of Nebraska Medical Center, Omaha, NE.

Pancreatic cancer (PC) is a grotesque disease featured by an inflamed complex tumor microenvironment (TME) that contribute to advancing tumor progression. Oncogenic K-ras, the most common mutation in PC, amplifies inflammatory responses within the TME through overexpression of multiple immune factors such as CXCR2 and its ligands. K-ras induced overexpression of CXCR2 axis, made CXCR2 seem intuitively a good target for PC treatment. In KC, a spontaneous PC mouse model with oncogenic K-ras, genetic ablation of CXCR2 caused anti-tumor effects such as increased apoptosis and decreased angiogenesis; and also presented pro-tumorigenic events; most notably was the increased fibrosis and metastasis to the liver. These observations have shed light on the possible role the CXCR2 on the other TME component especially pancreatic stellate cells (PSCs). The aim of this study is to determine the differential effect of K-ras status and CXCR2 chemokines expression in the PC cells on their interaction with PSCs. Unidirectional segregated co-culture studies were conducted using conditioned media (CM). CM collected from PSCs were used to grow multiple PC cell lines, and CM obtained from different PC cell lines were used to culture PSCs. Cellular proliferation and gene expression were analyzed. Furthermore, PSCs proliferation potentials were assessed as those cells treated with exogenous CXCL1 and CXCL8, or PC cell lines derived-CM in the presence or absence of CXCR2 antagonists. Co-culture studies revealed that PC-derived CM had increased proliferation of PC cell lines positive to oncogenic K-ras as well as increasing their expression of multiple chemokines such as CXCL1, CXCL5, and CCL2. On the other hand, PC cell lines with a wildtype K-ras were inhibited by PSC-derived CM treatment. PSCs proliferation potentials were decreased with CM derived from oncogenic K-ras positive PC cell lines and increased with CM derived from PC cell lines with wildtype K-ras. Furthermore, CM from oncogenic K-ras PC cell lines has increased the expression of multiple pro-tumorigenic genes in the PSCs including cytokines such as IL-10, IL-4 and IL-13, and chemokines such as CXCL2 and CXCL7. Also, treating PSCs with exogenous CXCL1 and CXCL8 exhibited a similar proliferation inhibition to that observed with oncogenic K-ras PC derived CM treatment. CXCR2 antagonists have shown rescued inhibition or enhanced proliferation of PSCs when incorporated with CXCR2 chemokine or PC cell line derived CM treatment. These observations suggest that K-ras status of PC dictates their interaction with PSCs within the TME. We have demonstrated that oncogenic K-ras through increased production of CXCR2 chemokine would dampen PSCs proliferation and further orient them to support tumor progression by increased expression of pro-tumorigenic genes. Besides, we observed that CXCR2 inhibition in PSCs would increase their proliferation which may further their fibrogenic activity.

It is evident from research outcomes that metastases-associated deaths are predominant in breast cancer. Recent developments on early diagnosis using mammographic screening and the implementation of adjuvant therapies may have reduced breast cancer associated deaths in decent numbers, although new markers for prognosis are of utmost importance for patients with higher risk of metastasis. RelA is involved in regulating various processes such as cellular immune response and can be targeted to reduce the intratumoral regulatory T cells (Treg) for antitumor immunity. Targeting either specific immunomodulators and/or intervening molecular mechanisms is thought to be a potential therapeutic option. In our previous study, we have found that co-expression of CXCR5 and CXCL13 is significantly associated with epithelial to mesenchymal transition (EMT) of cells and lymph node metastasis (LNM) during breast cancer progression. In this study, we are aiming to investigate how the transcriptional regulation of this receptor-ligand pair directs the process of disease development. Interestingly, it was found that RelA (p65), a subunit of NFκB protein, promoted the transcription of both CXCR5 and CXCL13. The putative RelA binding sites were validated using sequence deletion of respective promoter regions of CXCR5 and CXCL13. We observed that expression of CXCR5 significantly (p<0.05) increased with RelA and Nrf2 overexpression and CXCL13 co-stimulation in MDA-MB-231 cell line. RelA was also found to induce the expression of CXCL13 in T-47D and MDA-MB-231 cell line. Significantly, SNAIL, a key EMT regulatory element, was found to be highly expressed in RelA-transfected MDA-MB-231 cell line with or without CXCR5 and CXCL13 co-stimulation. We also observed CXCR3 T follicular helper (Tfh) and Treg sub-population within the tumor microenvironment, although numbers varied with stages and molecular subtypes. In chemotaxis assay, CXCR3 Treg cells were found to be predominant among migratory T-cell subsets against RelA overexpression and/or CXCL13 stimulation. Simultaneously, CCL2, a pro-inflammatory chemokine, induced macrophages to secrete CCL2, which in turn, might attract CXCR3 Tfh and Treg cells into the tumor microenvironment.

Study in 4T1-BALB/c breast cancer mouse model demonstrated significant (p<0.05) increase in CXCR5 and CXCL13 expression levels upon immunostimulation. The study may help to understand the prognosis value of CXCR5 and CXCL13 considering the impact of this receptor-ligand pair on the regulation of Tfh/Treg ratio, EMT and LNM. We believe that this investigation may lead to a comprehensive prediction of the tumor fate as well as to explore possible markers for breast cancer prognosis and future chemotherapy with more precision.

#944 Chemokine receptor signaling as a new tool to improve lung cancer diagnostics and therapy. Katalin Nagy-Major,1 Jörg Sänger,2 Harshad R. Kulkarni,2 Peter Fix,3 Almut Kunze,2 Amelie Lupp,3 Reiner Bonnet,2 Werner Seeger,2 Richard P. Baum,4 Patricia Grabowski,1 Rajkumar Savai,4 Charité Campus Benjamin Franklin, Berlin, Germany; 2Zentralklinik Bad Berka, Bad Berka, Germany; 3Jena University, Jena, Germany; 4Max Planck Institute for Heart and Lung Research, Bad Nauheim, Germany.

Background: The tumor microenvironment plays a critical role in cancer development, progression, and control. We demonstrated in vitro and in vivo that a bidirectional crosstalk between tumor-associated macrophages and cancer cell via CCR2-CCL2 and CX3CR1-CXCL1 signaling is fundamental for lung cancer growth and metastasis offers new treatment concepts. Aim: Our working hypothesis is to develop a new platform for specific chemokine receptor (CCR2) PET imaging and a range of theranostic applications in lung cancer. For this purpose, we planned to define the CCR2 expression in NSCLC as well as in SCLC, tumor cells as well as immune/inflammatory cells. Material and Methods: This is a multicenter trial with patients from Zentralklinik Bad Berka GmbH (n=100 NSCLC, n=100 SCLC). All patients gave informed consent according to the declaration of Helsinki. FFPE material was available in all cases. CCR2 CXCR4 and CXCXCR1 expression was determined by immunohistochemistry with the avidin-biotin-peroxidase-complex. Results: Analyzing 96 NSCLC (47 adenocarcinoma, 49 squamous cell carcinoma) and 45 SCLC tumor samples, we found CCRX4 and CXCR2 chemokine receptor expression in tumor, immune and inflammatory cells. In SCLC, CCR2 expression was found in tumor cells and lymph node metastasis (LNM) during therapeutic treatment in CCRX4 staining was very high concerning their expression on tumor cells rising with higher tumor stages, proliferation rate and grading. CCR2 expression in immune cells was restricted to lower stages; the same pattern could be observed in 45 SCLC tumor samples where CCR2 expression on immune cells was found especially in limited disease rather than in metastatic disease; CCRX4 expression in tumor cells was found to be high in all stages of SCLC. To evaluate the therapeutic efficacy of CCR2 antagonist in vivo, we injected LLC1 s.c. into WT mice treated with CCR2 antagonist (RS504393) or vehicle. Notably, tumor growth was significantly inhibited in CCR2 antagonist-treated mice as compared with vehicle-treated mice. Discussion: Our preliminary results show a significant
portions of CCR2 positive tumors - NSCLC as well as SCLC which would qualify for a CCR2-based imaging as well as - demonstrated in our mice models - CCR2 inhibitory strategies. This should be evaluated in further preclinical trials.

Background & Aims: Glioblastoma (GBM, WHO Grade IV) is considered as the most lethal neoplasm of all solid cancers due to its inherent intensive invasiveness. GBM may arise de novo, or following progression from lower grade gliomas. Recently, solid tumor progression has been recognized as the product of an evolving crosstalk between the cancer cells and its surrounding glial cells. The intensive invasion activity of GBM cells might be regulated by surrounding normal cells such as oligodendrocytes or fibroblasts. In this study, we evaluated the interactive factors between GBM cells and normal glial cells to determine the role of oligodendrocytes in regulating the invasiveness of glioblastoma cells.

Methods: Two GBM cell lines, T98G and U251, were used. Two oligodendrocyte cell lines, ODC1 and ODC2, were derived one each from surgical tissues of patients with low-grade glioma (WHO Grade II). Two fibroblasts cell lines, GF1 and GF2, were derived one each from surgical tissues of patients with GBM. Oligodendrocytes and fibroblasts were confirmed by immuno-histochemical staining. The invasive property of GBM cells was analyzed in the presence or absence of conditioned medium from oligodendrocytes or fibroblasts by wound-healing assay and Boyden chamber invasion assay. The proliferation ability of GBM cells was examined by MTT assay. Subsequently Cytoframe array was used to examine the cytokines and growth factors in the conditioned medium from oligodendrocytes or fibroblasts. Results: Oligodendrocytes cell lines, ODC1 and ODC2 cells, significantly (p<0.01) increased the migration and invasion ability of GBM cells, T98G and U251. In contrast, fibroblasts, GF1 and GF2 cells, did not affect the migration and invasion ability of GBM cells. Cytokine array indicated that angiopoietin-2 was found in the conditioned medium from oligodendrocytes, but not that from fibroblasts. Angiopoietin-2 significantly (p<0.01) increased the invasiveness of GBM, but not their proliferation ability. Conclusion: Oligodendrocytes might up-regulate the invasiveness of GBM cells via angiopoietin-2 signaling pathway. Hence, angiopoietin-2 can be considered as a promising target for the treatment of malignant gliomas.

#946 Characterize and identify secreted high molecular weight heparanase from PC3M conditioned medium. Donghong Ju, Mary A. Kosir. Barbara Ann Karmanos Cancer Inst., Detroit, MI.

Introduction: Neutrophils, platelets, lymphocytes are typical sources of NAP-2 which is associated with hepananase activity. Heparanase degrades polymeric heparan sulfate molecules into shorter oligosaccharides, participating in extracellular matrix degradation. It is active under acidic conditions during tumor invasion and inflammatory processes. Our lab previously found that some cell lines like androgen independent prostate cancer cells (PC3M) can secrete a protein that reacts with anti-NAP-2 antibody, but has a much higher molecular weight (MW > 50KD) than NAP-2 (MW = 6-14 KD), and has heparanase activity. The purpose of this study is to characterize and identify this protein. Procedures: Immunoprecipitation was performed using Pierce DirectIP kit according the manufacturer’s instructions. Heparin binding affinity column used Hitrap™ Heparin HP column from GE Healthcare Bio-Sciences. The binding buffer was 10mM NaAcetate pH 5.0, the eluting buffers were 0.5M-2M NaCl in 10mM NaAcetate pH 5.0. The mass spectrometry was done by KCI Proteomics Core facility. Data: The immunoprecipitation method confirmed that this higher molecular weight protein indeed can be pulled down by the NAP-2 antibody, and after using heparin binding affinity column to purify, we can still get the > 50KD band on the western blot for NAP-2, meaning it is a heparin binding protein. Conclusions: A protein identified with NAP-2 antibody, but with a higher molecular weight than native NAP-2 is found in the conditioned medium of PC3M cells that binds heparin, further confirming a potential role in tumor progression for prostate cancer.

Chemokine CXCL12 and its receptor CXCR4 are the most highly expressed chemokine axis in serous ovarian cancer. CXCR4 promotes tumor growth, angiogenesis, and metastasis. High CXCR4 expression is associated with poor survival, making it an attractive therapeutic target. The objective of this study was to establish an immune competent murine ovarian cancer model with high CXCR4 expression and to test single agent CXCR4 blockade and combination therapy to optimize emerging treatment strategies for future clinical trials. CXCR4 expression was evaluated by flow cytometry in ID8, ID8-VEGF, IE9-MP1, BR5, BR5-Akt, BR5-C2k, and BR5-Kras mouse ovarian cancer cell lines as well as IE9-MP1 tumor samples. Subsequently an exploratory study was undertaken utilizing the xenograft model to the assess the efficacy of AMD3100, the only commercially available CXCR4 inhibitor, alone and in combination with bevacizumab and anti-PD-1. Immune analysis of circulating lymphocytes by flow cytometry was performed during treatment to monitor changes of immune cell subsets. Surface expression of CXCR4 receptor was minimal in ID8 (1.6%), ID8-VEGF (0.9%), IE9-MP1 (1.8%), BR5 (0.9%), BR5-Akt (1.2%), BR5-C2k (2.3%), and BR5-Kras (1.1%), however intracellular staining revealed wide spread CXCR4 expression in ID8 (99.6%), ID8-VEGF (99.7%) BR5 (96.7%), BR5-Akt (94.3%), BR5-C2k (98.2%), and BR5-Kras (98.7%) cell lines. Using the ID8 intraperitoneal ovarian cancer mouse model in C57BL/6 mice, treatment with immunotherapy significantly increased cell surface expression of CXCR4 from 2% in the control group to 79.6-91.8% in the treatment group. Treatment with AMD3100 as a single agent showed no improvement in survival over control. However, AMD3100 in combination with anti-PD-1 therapy significantly improved survival. The addition of bevacizumab demonstrated no further survival benefit and bevacizumab as a single agent showed no improvement in survival over control, either alone or in combination with anti-PD-1. Analysis of circulating lymphocytes revealed a trend toward higher CD4 to CD8 ratio in mice treated with anti-PD-1 therapy. Targeting the CXCL12-CXCR4 axis in combination with other immunotherapies such as immune checkpoint inhibitors is a novel therapeutic strategy which may provide benefit over single-agent immunotherapy and warrant investigation in a clinical trial.

#948 Characterization of the microenvironment of murine primary triple negative breast cancer. Kassondra Balestrieri, Keith Pittman, Mohamed Ramirez, Nasreen Vohra, Kathryn Verbanac. East Carolina University/Brody School of Medicine, Greenville, NC.

The purpose of this study was to investigate the role of inflammatory cells in the metastatic process using reliably metastatic murine models of Triple Negative Breast Cancer (TNBC). We have previously selected, developed and characterized two reliably metastatic TNBC mouse models for our investigations. The T11 (claudin-low) and 22S2LM (basal-like) Balb/c-derived transplatable tumors display molecular profiles that mirror human TNBC. Here we report characterization of the inflammatory cells and microenvironment in these primary TNBC tumors and at metastatic sites in both heterotopic and orthotopic models. Tumors were implanted in the s.c. flank or mammary fat pad and resected 1-2 weeks later to promote the growth of seeded metastases, when volumes reached ~700 mm3 or 300 mm3, respectively. Both flow cytometric analysis and immunohistochemistry of primary tumors demonstrated high infiltration by myeloid-derived cells (CD11b+) and low levels of lymphoid cells (CD3+). Myeloid cells were also the major infiltrating cells in lung metastases and were significantly elevated compared to normal lung. The granulocytic subset (CD11b+/Ly6G+) predominated, consistent with an immunosuppressive role for cells with this phenotype (N2, GM-CSF, etc.). Primary 22S2LM and T11 tumors and metastatic lung tumor homogenates were assayed for immunomodulators and compared to normal breast and lung tissue from age-matched contemporary controls. G-CSF was significantly increased in tumors and levels (pg/mg protein) were correlated with tumor burden. VEGF was significantly elevated in all tumors, as were chemotactic factors for granulocytic cells (KC/CXCL1, MIP-2/CXCL2), monocyte cells (MCP-1/CCL2), eosinophils (Eotaxin/CCL11) and T cells (MIG/CXCL9). In the heterotopic model, lung levels of KC/CXCL1 and MIP-1/CCL2 were significantly increased prior to frank lung metastasis (5-30 days post-implant). These data suggest that TNBC-derived G-CSF may play a role in the mobilization of CD11b+Ly6G+ granulocytes and progenitors from the bone marrow and key chemokines may mediate migration of tumor cells to metastatic sites. Future studies will define phenotypic and functional characteristics of the G-MDSC that are promoting tumor progression in these murine TNBC models.

#949 Resistin potentiates stenosis and chemoresistance of breast cancer cells through STAT3 activation: implications in breast cancer health disparity. Sachin Kumar Deshmukh, Arun Bhardwaj, Sanjeev K. Srivastava, Nihkil Tyagi, Ahmed Al-Ghaidhban, Ajay P. Singh, Donna L. Dyess, James E. Carter, Seema Singh1. Mitchell Cancer Institute, Mobile, AL; 2College of Medicine, Mobile, AL.

Breast cancer (BC) is most frequently diagnosed cancer and remains the second leading cause of cancer-related deaths in women in the United States. African American (AA) women bear an additional burden of BC with early onset of
disease, poorer prognosis, higher risk of recurrence, and worst clinical outcome as compared to Caucasian American (CA) women. Emerging evidence strongly argues the role of tumor-microenvironment (TME) in BC of AA and CA racial backgrounds. On the similar line, our earlier findings suggested that serum levels of resistin; an inflammatory cytokine are significantly elevated in AA BC patients as compared to their CA counterparts. Furthermore, we demonstrated that resistin promoted growth and aggressiveness of BC cells. In the present study, we investigated the role of resistin in stemness and chemoresistance of BC cells. For this, two BC cells of CA (MDA-MB-231) and AA (MDA-MB-468) origin were treated with resistin and sphere-forming ability, a key characteristic of cancer stem cells, was determined. Data demonstrate that number of spheres is significantly increased in both the BC cell lines after resistin stimulation. Immunoblot analyses reveal that resistin-induced sphere-forming ability is associated with enhanced levels of stemness-associated transcription factors (Nanog and KLF4) in BC cells. We next examined if resistin conferred chemoresistance to BC cells. Our data suggest that resistin-treated MDA-MB-231 and MDA-MB-468 BC cells develop greater resistance against doxorubicin-induced cytotoxicity. Notably, the effects conferred by resistin were more prominent in AA BC cells: comparing to CA BC cells. Our mechanistic studies unveiled an important role of STAT3 activation in the resistin-induced stemness and chemoresistance of BC cells. Taken together, our findings provide novel insight into the role of resistin in BC biology and further strengthen its role in racially disparate clinical outcomes.

#950 Involvement of proinflammatory chemokine network between adipocytes and triple negative breast cancer cells. Rosa Misstica Coles Ignacio,1 Hyeongiwa Choi,1 Carla Gibbs,1 Eunsoon Lee,2 Samuel Adunyah,3 Deok-Soo Son4. 1Meharry Medical College, Nashville, TN; 2Florida A&M University, Tallahassee, FL.

Obesity has become a global epidemic and causes a chronic low-grade inflammation. This poses a large health burden because excess adiposity can lead to chronic diseases such as type 2 diabetes, cardiovascular disease and some cancers. Obese individuals get higher incidence, progression and mortality of cancers compared to lean ones. Particularly, breast cancer (BC) in women is closely associated with obesity. Despite an epidemiological link between obesity and low cancer survival rates, little is known about the molecular mechanisms by which obesity promotes BC progression. Obesity-derived chronic low-grade inflammation involves alteration of a chemokine network that may contribute to the cancer progression and metastasis. Herein, we proposed the novel concept that the chemokine network between obesity and BC builds an inflammatory burden via proinflammatory chemokines to promote cancer progression. We employed mesenchymal BC cell PT8119 and epithelial-like BC PT230 for triple negative BC (TNBC) cell model, and mouse 3T3-L1 preadipocyte and adipocyte conditioned media (CM) to mimic lean and obese conditions in vitro. We examined the profiles of chemokine signature of PY8119 and PY230 treated with preadipocytes and adipocytes CM using PCR array. Both preadipocytes and adipocytes CM-treated PY8119 and PY230 cells absent or low levels in chemokine receptors. On the other hand, the chemokines CXCL2, 5, 7 and CXCL10 showed higher expression in both preadipocytes and adipocyte CM-treated PT8119. Interestingly, adipocyte CM-treated PY8119 cells dominantly expressed CXCL1-3 compared to preadipocyte CM-treated cells. In addition, CXCL2, 5, 7, 20, and CXCL1, 5, 10 were highly expressed in both preadipocyte and adipocyte CM-treated PY230 cells. Moreover, CXCL2 and 3 were significantly induced in PY230 cells after treatment with adipocyte CM compared to preadipocyte CM. Taken together, the results indicate that dominant chemokines CXCL1-3 expressed in adipocyte CM-treated TNBC cells promote a pro-tumor inflammatory network. Hence, these proinflammatory microenvironment augmented by adipocytes might contribute to TNBC progression.

#952 Modulation of immune cell trafficking into human colorectal cancer by gut microbiota. Eleonora Cremonesi,1 Jesús G. Garzón,2 Valeria Governa,1 Valentina Mele,1 Francesca Amicarella,1 Elisabetta Padovan,1 Manuela Muraro,1 Paul Zajac,1 Daniel Oertli,3 Lubor Borsig,2 Giandomenica Iezzi1. 1University of Pittsburgh, Pittsburgh, PA; 2Institute of Physiologia, University of Zurich, Zürich, Switzerland; 3Department of Surgery, Universitat Spital, Basel, Switzerland.

Introduction: Colorectal cancer (CRC) is a leading cause of cancer-related death. CRC infiltration by immune cells, including cytotoxic CD8+ T cells (CTLs), IFN-gamma-producing T-helper 1 cells (Th1), Foxp3+ regulatory T cells (Tregs) and CD16+ MPO + neutrophils, is associated with favorable prognosis. However, chemokines driving these cell populations into the tumor site, their cellular sources and their microenvironmental triggers remain to be elucidated. Aim: We investigated the chemokine/chemokine receptor network promoting CRC infiltration by immune cells associated to favorable prognosis. Results: CRC infiltration by immune cells was associated with defined chemokine gene signatures, including CXCL5, CXCL9 and CXCL10 for cytotoxic T lymphocytes and T-helper 1 cells, and CCL17, CCL22 and CXCL12 for T-helper 1 and regulatory T cells. Most of these chemokine genes were expressed by tumor cells upon exposure to gut bacteria in vitro and in vivo. Indeed, chemokine expression levels were significantly higher in orthotopic xenografts than in intraperitoneal tumors, and were drastically reduced by antibiotic treatment of tumor-bearing mice. Importantly, in human CRC samples, extents of chemokine production and immune cell infiltration was significantly associated with bacterial loads. Conclusion: Gut microbiota stimulates chemokine production by CRC cells, thus favoring T cell recruitment into tumor tissues.

#953 Atypical chemokine receptor 1 (ACKR1/DARC) expressing tumors are associated with distinct recruitment of immune cells and increased pro-inflammatory chemokines. Brittany D. Jenkins,1 Rupali Hire,1 Elizabeth Howeth,1 Michele Montell,2 Rachel Martini,3 Melissa B. Davis1. 1Univ. of Georgia, Athens, GA; 2AU/UGA Medical Partnership, Athens, GA.

Interactions between chemokines and their receptors can improve a host’s anti-tumor response by influencing the targeted migration of immune cells via a chemokine gradient. Atypical Chemokine Receptor 1 (ACKR1/DARC), a genetically diverse transmembrane GPCR, acts as a decoy receptor for a variety of CXC and CC chemokines, including those with pro-malignant and pro-inflammatory effects, such as CXCL2 (MCP-1, MCAF, E) and CXCL8 (IL-8). The purpose of this study is to determine if the migration of tumor-associated immune cells is unique based on epithelial ACKR1 expression on breast cancer cells, and if this association is correlated to an increase in pro-malignant chemokines, better survival odds, and differences in race. Immunohistochemistry techniques

Materials and Methods: Twelve ovarian cancer specimens were cultured in the presence of IFNγ, indomethacin (COX-1/2 inhibitor) or/and one of two syntheticTLR3 ligands, poly-I:C (non-selective activator of TLR3 and helicases) or rintatolimod (selective TLR3 ligand). Biopsies were harvested for mRNA measurements and culture supernatants were analyzed for CXCL5, CXCL10 and CXCL22. We demonstrated that rintatolimod promoted the expression of the MDSC/Treg attractant CXCL12, which was reversed by addition of indomethacin. Furthermore, poly-I:C induced expression of COX-2 and COX-2-dependent suppressive factors (IDO, IL-10). Evaluating the COX-2 cascade, TNFα was found to be increased in the presence of poly-I:C but not rintatolimod. Additionally, Western Blot analysis showed 1-kB degradation (as a marker of NF-kB activation), selectively in response to poly-I:C. We observed that the combination of both TLR3 ligands with IFNγ and indomethacin selectively induced the desirable chemokines CXCL5 and CXCL10 and suppressed CCL22 in tumor samples with similar results in the macrophages and fibroblasts. The ovarian cancer cell lines showed only minimal expression of chemokines. Conclusion: We demonstrated that a combination of selective modulation of TME, using different clinically applicable factors and their combinations. We show for the first time, that poly-I:C, but not a selective TLR3 ligand, induces NF-kB and undesirable CXCL2-dependent suppressive factors, which though can be eliminated through addition of a COX-1/2 inhibitor. These effects may be avoided using a selective TLR3 ligand.

Background: Infiltration of cytotoxic T-cells (CTLs) in tumors is known to be associated with improved patient’s clinical outcomes. In contrast, local infiltration with regulatory T-cells (Treg) predicts accelerated progression and shorter overall survival. The above observations highlight the need for new measures to promote selective accumulation of CTLs but not Tregs in tumor microenvironments (TME). Here we compare the TME-modulating impact of poly-I:C with a selective TLR3 ligand, rintatolimod showing an induction of CCL22, CXCL12 and expression of COX-2 and downstream suppressive factors, selectively by poly-I:C. Finally, we report on the optimized combinatorial adjuvant to repro-
were used to determine expression levels of ACKR1 on primary breast tumors, along with relative expression of T-cells, B-cells, dendritic cells, and macrophages. Concentrations of pro-inflammatory chemokines in circulation were determined using a Luminex-based immunosay and matched patient peripheral blood samples. In silico analyses were performed to determine associations between expression of ACKR1 on survivin mRNA in human breast cancer cell lines and immunofluorescence techniques, co-localization between ACKR1 and selected pro-inflammatory chemokines was investigated. Results from these tests indicate that there is differential expression of immune cell types in tumors expressing ACKR1, and this difference was associated with the migration of B-cells and dendritic cells, which were not detected in ACKR1-negative tumors. Significantly increased circulating CCL2 and CXCL8 chemokine levels we also determined to be positively correlated with ACKR1 expression in primary breast tumors. Survival analyses showed a significantly increased relapse free survival in patients having tumors with high ACKR1 expression, while investigations into racial differences revealed a significant race effect, with Caucasians having higher ACKR1 levels on their tumors than African-Americans. Finally, co-localization between ACKR1 with CCL2 and CXCL8 is observed in cultured human breast cancer cells. Given that the data collected shows a tendency for those tumors positively expressing ACKR1 to have a more favorable prognosis, we suggest that a partial role of ACKR1 on breast tumor cells is to sequester pro-inflammatory chemokines in the tumor microenvironment, indirectly recruiting a distinct subset of tumor-associated immune cells.

#954 TGF-ß signaling inhibition counteracts myofibrosis in MPN. Matthias Bartenstein,1 Lanzhu Yue,2 Wanke Zhao,3 Wanting Tina Ho,3 Cem Murdun,2 Adam W. Mailloux,2 Ling Zhang,2 Anjali Budhakoti,1 Kith Pradhan,1 Franck Rapaport,1 Huaqiang Wang,3 Zonghong Shao,3 Ulrich Stein1, Ross L. Levine1, Zhizhuang Joe Zhao,1 Amit K. Verma,1 Pearl K. Epling-Burnette1,1 Albert Einstein College of Medicine, Bronx, NY; 2Moffitt Cancer Center and Research Institute, Tampa, FL; 3Ohio University Health Sciences Center, Athens, OH; 4Memorial Sloan Kettering Cancer Center, New York, NY; 5Tianjin Medical University General Hospital, Tianjin, China.

Myofibrosis (MF) is a common feature of the Philadelphia-Chromosome negative (Ph-) myeloproliferative neoplasms (MPN), a group that includes Primary Myelofibrosis (PMF), Essential Thrombocytosis (ET) and Polycythemia Vera (PV). Current treatment with Jak2 inhibitors reduces splenomegaly, but does not eliminate malignant clones nor improve bone marrow (BM) or spleen fibrosis, understimating the need for alternative therapies. One promising target is TGF-ß1, a cytokine crucial for the development of myofibrosis that is elevated in PMF patient plasma, progenitors and megakaryocytes (MK), and is known to promote fibrosis through stimulation of fibroblasts and their progenitors, mesenchymal stroma cells (MSC). Dysregulation of TGF-ß1 signaling has been described in a number of mouse models of myofibrosis exhibiting aberrant megakaryopoiesis, one of the hallmarks of MPNs. Preliminary data from 93 MPN patients showed over-expression of TGF-ß in PMF samples (p = 0.001), with increased activation of the canonical target SMAD2 (p = 0.005). We tested the efficacy of the orally available TGF-ß1 signaling inhibitor Galunisertib (LY2157299) in counteracting fibrosis in two MF mouse models of common MPN oncogenes Jak2 and Mpn. Mice in the first model express the constitutively active human Jak2V617F mutant under the control of the ubiquitous hematopoietic promoter vav1 and show a PV-like phenotype at 6 weeks old, progressing to fibrosis of bone marrow (BM) and spleen around 25-30 weeks. Thirty week old mice were treated with Galunisertib for 4 weeks and showed a significant decrease in fibrosis compared to control mice. Similar results were observed in 50 week old mice treated with a murine antibody against TGF-ßRIR (IMC-TR1,LY3022859) for 4 weeks. Our second model relies on transplantation of mice with BM cells transduced with MPLW515L, a mutant mpl variant that is active in the absence of TPO. These mice rapidly develop MF, myeloproliferation and splenomegaly. Flow cytometry showed immature and mature megakaryocytes with overexpression of TGF-ß1 in MPLW515L cells. Treatment from day 12 to day 26 after transplantation reduced both white blood cell counts (a measure of myeloproliferation) and fibrosis as measured by reticulin staining. In vitro, Galunisertib counteracted the pro-fibrotic effects of TGF-ß1 on both murine and human MSC by antagonizing its stimulatory effects on collagen I and III production. Analysis of MSCs from Galunisertib-treated mice also showed reduced collagen I and III production compared to controls. In conclusion, we offer further evidence that aberrant megakaryopoiesis drives TGF-ß1 overproduction in MNP by increasing megakaryocyte numbers and overexpressing TGF-ß1 in mutant MKs. Galunisertib counteracts TGF-ß1 induced fibrosis in two MPN mouse-models and is a promising candidate for symptomatic treatment of myofibrosis.

#955 LY3200882, a novel, highly selective TGFßRII small molecule inhibitor. Huaxing Pei1, Saravanan Parthasarathy,2 Sajan Joseph,3 William McMillan,1 Xiaohong Xu,1 Stephen Castaneda,4 Ivan Inigo,3 Karen Britt,1 Bryan Ander son,2 Gayming Zhao,2 Scott Sawyer,2 Douglas Beight1, Talbi Kaoudi,1 Chandrasekar Iyer,1 Huimin Bian,1 Amy Pappas,1 David Surguladze,3 David Schauer,4 Karim Benhadji,3 Michael Kalos,2 Kyla Driscoll1, Eili Lilly, Indianapolis, IN; #Eili Lilly, New York, NY.

The transforming growth factor ß (TGFß) signaling pathway is a pleiotropic cellular pathway that plays a critical role in cancer. In fact, aggressive tumors are typically associated with high ligand levels and thus associated with poor prognosis in various tumor types. Cancer cells use autocrine and paracrine TGFß signaling to modulate tumor cells and the tumor microenvironment, leading to a highly invasive and metastatic phenotype, inducing and increasing tumor vascularization, modulating the extracellular matrix in the stroma, and inhibiting immune surveillance and antitumor immunity. Clinical studies with galunisertib (aka LY2157299 monohydrate), a small molecule inhibitor targeting the TGFß pathway, have provided proof of concept data supporting the role of TGFß in cancer and the utility of targeting the TGFß pathway. Here we describe the identification of LY3200882, a next generation small molecule inhibitor of TGFß receptor type 1 (TGFßRI). The molecule is a potent, highly selective inhibitor of TGFßIRI embodied in a drug-like platform with high ligand levels and thus associated with poor prognosis in various tumor types. Cancer cells use autocrine and paracrine TGFß signaling to modulate tumor cells and the tumor microenvironment, leading to a highly invasive and metastatic phenotype, inducing and increasing tumor vascularization, modulating the extracellular matrix in the stroma, and inhibiting immune surveillance and antitumor immunity. Clinical studies with galunisertib (aka LY2157299 monohydrate), a small molecule inhibitor targeting the TGFß pathway, have provided proof of concept data supporting the role of TGFß in cancer and the utility of targeting the TGFß pathway. Here we describe the identification of LY3200882, a next generation small molecule inhibitor of TGFßRI for the treatment of cancer.

Ovarian cancer continues to be the most lethal gynecologic malignancy with no real cure for patients presenting with advanced stage disease. Immune checkpoint blockade showed modest clinical response in patients with recurrent ovarian cancer, thus additional therapeutic strategies for combination therapy are needed. As chemokines and their receptors drive both immune cell migration and tumor growth, angiogenesis and metastasis formation, they are an attractive target for combinatorial cancer therapy. CXCR4 is the most highly expressed chemokine receptor in advanced stage high grade serous ovarian cancer, thus the objective of this study was to evaluate the efficacy of a novel oral small molecule CXCR4 inhibitor (X4-136) alone and in combination with immune checkpoint inhibition and the anti-angiogenic agent bevacizumab, and characterize the changes in circulating immune cells during treatment in murine ovarian cancer model. The ID8 cell line was used in C57BL/6j mice to establish an immune competent murine model and to compare single agent and combination therapy with oral X4-136 CXCR4 inhibitor, bevacizumab, and anti-PD1. During treatment blood sampling was performed and immune cells were analyzed by flow cytometry. Our results demonstrated that single agent therapies alone with either drug had no significant effect on tumor progression or survival. Combination therapy with the CXCR4 inhibitor and anti-PD1 improved survival compared to control animals and the other combination therapy groups. The addition of bevacizumab to the dual combination did not fur-
Use of angiotensin system inhibitors is associated with longer overall survival in pancreatic ductal adenocarcinoma patients who underwent partial or total gastrectomy. Huamao Liu, Matthias Pinter, Joo Anjo, Hang Lee, William Ho, Jonathan Crain, Kamila Naxerova, Mengyang Di, Alex Jacobson, Daniella Dias Santos, Andrea Zanconato, Vikram Deshpande, Keith Lillemoe, Carlos Fernandez del Castillo, Michael Downes, Ronald Evans, James Michaelson, Cristina Ferrone, Yves Boucher, Jain K. Rakesh. Massachusetts General Hospital, Boston, MA; Brown University, Providence, RI; Salk Institute, La Jolla, CA.

Introduction: Angiotensin system inhibitors (ASI) are widely used to manage hypertension. Laboratory and retrospective clinical data suggests that ASIs can improve cancer prognosis. The aim of this study is to investigate the effect of ASIs on overall survival in pancreatic ductal adenocarcinoma (PDAC) patients.

Methods: We performed a retrospective review of the clinicopathologic records of patients with PDAC seen at the Massachusetts General Hospital (MGH) between 1/2006 - 12/2010. Patients on angiotensin converting enzyme inhibitors (ACEi) or angiotensin receptor blockers (ARB) were included as ASI users. We performed RNAseq and Gene Set Enrichment Analysis (GSEA) of primary tumor samples from patients with or without chronic ASI use. We also identified a surrogate signature of differentially expressed genes and we measured the extent of angiotensin inhibition in GEO and TCGA datasets. The extent of inhibition was used to correlate with survival. Statistical analysis was performed using Kaplan-Meier estimator and Cox proportional hazards ratio model. Results: A total of 794 consecutive PDAC patients were included, of whom 297 (37.4%) were on ASIs and 183 (23.0%) were on non-ASI antihypertensive drug therapy. In resected patients, ASI users had a significantly longer overall survival (37.4%) were on ASIs and 183 (23.0%) were on non-ASI antihypertensive drug therapy. In resected patients, ASI users had a significantly longer overall survival than ASI-naive patients (p = 0.001). In our sub-group analysis of resected hypertensive patients treated with chemotherapy, chronic ASI users had a significantly longer overall survival than ASI-naive patients (p = 0.048) (28.7 vs 12.3 months, p = 0.05). Gene Set Enrichment Analysis revealed that the ASI lisinopril down-regulated genes which stimulate the mitotic cell cycle, WNT and Notch signaling. The interaction between integrins and the extracellular matrix. Lisinopril also enhanced gene sets linked with oxidative phosphorylation, antigen processing and presentation and the cytotoxic activity of T cells. In unresected patients, the effect of ASI was only significant in patients with locally advanced disease in multivariate analysis (HR, 0.57; 95%CI, 0.38-0.847; p = 0.005), but not in metastatic patients. The low expression of genes down-regulated by ASIs was significantly associated with better survival in the TCGA and GSE71279 datasets. Conclusion: In patients with PDAC, ASI use is associated with longer overall survival in resected patients and may benefit patients with locally advanced disease. These findings suggest the need for a prospective study to determine the efficacy of ASI in PDAC patients.

Blocking CD70+ cancer associated fibroblasts: Are we paving the way towards immunotherapy in colorectal cancer. Julie Jacobs, Vanessa De-schoolemeester, Karen Zwanepoel, Christophe Hermans, Christiaan Rolfo, Marc Peeters, Filip Lardon, Vasiliki Siozopoulou, Eveline Smits, Patrick Pauwels, University of Antwerp, Wilrijk, Belgium; Antwerp University Hospital, Edegem, Belgium; Vaccine and Infectious Disease Institute, Edegem, Belgium.

Introduction: Numerous studies have reported that tumor progression and invasiveness are determined not only by the malignant cancer cells themselves but also by the surrounding tumor microenvironment, including cancer-associated fibroblasts (CAFs). Although CAFs are implicated in tumor progression, their total depletion of CAFs has been demonstrated to induce more aggressive tumors, indicating that different CAF subpopulations have opposing tumor-promoting or tumor-inhibitory roles. Unfortunately, specific markers to target these subsets of CAFs are lacking. Expression of the immune checkpoint CD70 is normally tightly regulated and limited to cells of the lymphoid lineage only. Instead, tumors hijack CD70 to facilitate immune evasion by increasing the amount of suppressive regulatory T cells (Tregs), inducing T cell apoptosis and skewing T cells towards T cell exhaustion. Recently, a lot of clinical successes have been generated by the blockade of immune checkpoints. However, in colorectal cancer (CRC) the efficacy remains limited to a small subset of patients with mismatch repair-deficient (MSI) tumors which might be caused by the intense dialogue between stroma and malignant cells. Therefore, we have explored the role of CD70 expression in CRC with a particular focus on CAFs. Methods: The prognostic value of CD70 was analyzed by immunohistochemistry on 51 CRC specimens. In addition, the relationship with Tregs and microsatellite instability was explored. Furthermore, primary CAF cell lines were successfully cultured from 20 different primary resection specimens. These cell lines were used to study the effect of CD70 on the tumor microenvironment in vitro. Results: We revealed expression of CD70, not just on the malignant cells but on the majority of CAFs in invasive CRC specimens. Thereby, CD70-expression was significantly correlated with negative clinicopathological parameters such as metastasis (P = 0.007), differentiation (P = 0.053) and advanced stage (P = 0.001). Moreover, CD70-positive CAFs proved to be a poor prognostic marker by univariate as well as multivariate analysis. We have also detected a significant association between elevated Treg amounts and CD70-expressing CAFs (P = 0.012). In vitro data on the effects of CD70 on CRC behavior and immune escape are currently being analyzed. Conclusion: We have identified a new targetable CAF subpopulation, marked by the expression of CD70 and equipped with strong tumor-promoting properties. Thereby, we have found potential of a potential cross talk between CD70+ CAFs and Tregs to modulate immune escape. A lack of association of CD70 expression and MSI-status, which highlights the potential of this target in CRC subsets that do not benefit from immune checkpoint blockade. We believe that targeting CD70 holds great potential in CRC, especially in light of the limited immunotherapeutic options available.
mediated changes in microenvironment in a xenograft mouse model using primary cells from 3 U-CLL and 3 M-CLL cases. Ibrutinib significantly inhibited CLL cell growth in spleen; the treated CLL cells developed elevated dysfunctional smCXCR4. The inhibition on tumor growth and impaired CXCR4 occurred to much greater extent in U-CLL. Notably, ibrutinib also significantly inhibited T cell growth only in U-CLL cases. Thus, ibrutinib inhibited CXCR4 signaling and CLL B-T cell crosstalk essential for tumor growth in tissue niches, especially in U-CLL cases that has limited B-lymphocytosis. Finally, molecules controlling the vulnerability of U-CLL B cells to death in the absence of environmental prosurvival signals were examined in 15 patients. Ibrutinib reduced BCL2 protein levels in U-CLL but not M-CLL; levels of BCL-XL and MCL-1 were unchanged. Consistent with these results, U-CLL but not M-CLL cell survival in vitro was promoted by T cell stimulation that led to upregulation of prosurvival BCL2. These findings suggest enhanced CLL B cell death by inhibiting BCL2 in U-CLL after the loss of environmental prosurvival signals. Altogether, ibrutinib inhibits CLL-microenvironment crosstalk by blocking CXCR4 signaling and T cell support. U-CLL cells had a greater vulnerability to the loss of environmental prosurvival signals after ibrutinib inhibition. Our data demonstrate mechanisms underlying the differences in primary ibrutinib sensitivity between U- and M-CLL patients, supporting the use of inhibitors of BTK and BCL2 in CLL.

**#961 Inhibitors of fibrosis and TGF-beta delay tumor xenograft growth and reduce ascites in ovarian cancer models.** Qing Zhang, Xiaonian Hou, Bradley J. Evans, John J. Weroha, William A. Cibilly, Mayo Clinic, Rochester, MN

Background: Most ovarian cancer (OC) patients present with advanced disease and ultimately develop chemoresistant relapses. Stromal plays a significant role in OC behavior including invasiveness, fibrosis and chemoresistance. TGF-beta is important for crosstalk between stroma and cancer cells, and stromal activation in cancer has similarities to matrix remodeling in fibrosis. We have shown that TGF-beta and fibrosis-inhibitors can suppress OC cell proliferation, migration and invasion. Such inhibitors are available for clinical use, and we have begun to test their efficacy in OC in vivo. Methods: Animal experiments were approved by Mayo Clinic IACUC. Intraperitoneal xenograft models were used to test their efficacy in OC in vivo. Lenti-CycloHeximide (Cyc), a lentiviral vector encoding a short hairpin RNA (shRNA) targeting Cycloheximide (CHX), was used to silence Cyc expression in ovarian cancer cells. We treated three groups of mice with Cyc, Cyc + TGF-beta, and Cyc + TGF-beta + PH003, and we compared the tumor volume, weight, percent tumor necrosis, and ascites volume on day 14 and 28. Results: Cyc inhibited tumor growth and reduced ascites volume and weight at day 14 and 28. Cyc + TGF-beta + PH003 inhibited tumor growth significantly more than Cyc alone. Conclusion: Inhibiting Cyc expression reduces tumor growth and ascites volume, suggesting a novel mechanism of action for Cyc that may be applicable to other cancers as well.

**#963 Ovarian-dependent SMM22 mouse mammary carcinoma cells depend on Cyp3a11 oxysterolxygenase activity for proliferation.** Zhijun Guo,1 Patrick McGrath,3 Ted Bebb,1 Ashley Mantheyan,2 Alexandre Osorio,3 Cesar Hertes,3 Victor Arrieta,4 Sebastian Mohar,4 Irwin Hernandez,4 Robert Klink,5 Robert Cardiff,2 David A. Potter1. 1.Univ. of Minnesota, Minneapolis, MN; 2.Univ. of Central Florida, Olando, FL; 3.Instituto Nacional de Cancerología, Mexico City, Mexico; 4.Univ. of California, Davis, CA

Introduction: Silencing of the human cytochrome P450 (CYP) monooxygenase enzyme CYP3A4 in the ER + MCF-7 tumor cell line inhibits tumor growth in the mammary fat pad, but the relative roles of tumor cell intrinsic CYPs versus vascular/microenvironment CYPs remain to be determined and a syngeneic animal model is needed to answer this question. The SMM22 ovarian dependent mouse mammary carcinoma cell line forms a transplantable estrogen receptor positive (ER+) mouse mammary tumor in which growth dependence on cell intrinsic CYPs may be tested in vitro and in vivo. The SMM22 cell line is derived from 129SvY homozygous Stat1-null female mice, which develop ER+ mammary tumors (1,2). Expression profiling of spontaneously arising mouse mammary carcinomas in a TP53 KO model revealed that the CYP3A4 ortholog Cyp3a11 is up-regulated in these tumors. Methods: Cyp3a11 bacTomato were used to assay for NADPH dependent biosynthesis of EETs from arachidonic acid using an LC-MS/MS method. siRNA silencing and CRISPR/Cas9 knock-out of the Cyp3a11 exons 2 and 3 was performed and the cell lines were characterized for EET dependence using an MTT assay. The highly potent and chemical probe of CYP epoxygenase activity, hexyl-benzyl-biguanide (HBB), was used to test dependence of SMM22 cells on CYP epoxygenase activity. Total cellular EETs in SMM22 cells exposed to HBB at the IC50 were measured by the LC-MS/MS method. Results: Cyp3a11 knock-out cells and Cyp3a11 knock-in cells were indistinguishable in terms of sensitivity to HBB, and HBB does not impact cell viability or tumor growth in vivo. Silencing of Cyp3a11 decreased proliferation, reduced total cellular EET levels, and reduced tumor growth in vivo. Conclusions: Cyp3a11 is required for cell proliferation and tumor growth in vitro and in vivo. This model allows for testing the role of Cyp3a11 in the growth and dissemination of tumor cells in the absence of tumor-induced niche remodeling and provides a model to study the role of Cyp3a11 on tumor growth in vivo.

**#962 Novel targeting of tumor-infiltrating TNFR2 Tregs: removing suppression with microenvironment-specific antibodies.** Heather Torrey, John Butterworth, Toshiyuki Mera, Yoshikao Okubo, Limei Wang, Danielle Baum, Audrey Defusco, Sara Plager, Sarah Warden, Daniel Huang, Eva Vanamee, Rosemary Foster, Denise Daud, Faeheen Faustman, Massachusetts General Hospital & Harvard Medical, Charlestown, MA

Background: A recognized and potent subtype of regulatory T cells (Tregs) expresses tumor necrosis factor receptor 2 (TNFR2), a member of the tumor necrosis factor (TNF) superfamily. TNFR2 expressing Tregs are abundant in human and murine tumors and are the most potent suppressors of host immune responses. In addition, recent data in diverse human tumors show that TNFR2-expressing host T cells are the dominant Tregs in the tumor microenvironment, expressed far in excess of OX40 and GITR. Unlike many tumor markers, TNFR2 has limited expression in the immune system and almost no inhibitory activity, making it an attractive target for anticancer therapy. Methods: We produced monoclonal antibodies to human TNFR2 with the goal of inactivating the potent host Tregs that express TNFR2, competing with the agonism of TNF and inactivating infiltrating Tregs of human tumors. Tregs from fresh ovarian ascites fluid were compared to Tregs from normal human blood donors for antibody potency. Results: Using a 48-hr ELISA with T cells treated with metalloproteinase inhibitors, we showed that TNFR2 antagonistic antibodies can inhibit Treg proliferation, suppress soluble TNFR2 secretion on normal cells and allow T effector expansion. The antagonism is dominant, succeeding even in the presence of TNF, which is a TNFR2 agonist. Furthermore, the structural biology of dominant TNFR2 receptor antagonism uncovers a unique conformation that equally inhibits downstream NFκB signaling. We also showed that dominant TNFR2 antibodies in a dose dependent fashion kill Tregs in ovarian cancer infiltrates more strongly than Tregs from healthy donors. Treg killing in the cancer microenvironment was dependent on cell proliferation and turnover of the Tregs. Conclusion: In sum, blocking TNFR2 signaling on the most potent Tregs of the tumor microenvironment with a dominant antagonist antibody selectively heightens death of the immunosuppressive Tregs in the tumor microenvironment and fosters an outgrowth of the few residual Tregs that remain. With the hypothesis that TNFR2 Tregs are the most potent host cells of the immune response, their dominance in diverse human tumor infiltrates and the natural low expression of this marker on normal lymphoid cells makes targeting of TNFR2 in the tumor microenvironment attractive.
#964 A quantitative flow cytometric assay for the simultaneous detection of PD-L1 in tumor and immune infiltrate present in NSCLC. Ryan T. Rodriguez, Amanda Chargin, Rian Morgan, Randall K. Wetzel, Reginaldo Prioli, Bruce Patterson, Keith Shutts, IncellDx, Menlo Park, CA; 2Cell Signaling Technology, Danvers, MA.

Flow cytometric analysis of the inherent complexity of the immune checkpoints becomes clearer, we must understand the expression of immune modulators such as PD-L1 within the context of the tumor microenvironment. This includes measures of immune infiltrate, levels of expression of immune modulators, such as PD-L1, on lymphocytes and tumor cells, as well as DNA heterogeneity within tumor cells. We show how characterization of the rabbit anti-PD-L1 clone E1L3N is a commercially available method in a flow cytometric assay. First we demonstrate specific fluorescence and sensitivity in tumor derived cell lines and then combine cell lines and PBMCs to form a tumor microenvironment mimic. When E1L3N was combined with antibodies directed toward CD45, CD3, and CD38, the cellular subsets known to be present in the tumor micro environment, including cytotoxic lymphocytes, T-helper cells and CD45 negative tumor derived cells are readily detected. The use of sequential gating strategies allows the assay to detect PD-L1 on each of these subsets which, when combined with quantitative MESF beads (Bang Laboratories) along with the known fluorescence-to-protein ratio of each antibody, allows the calculation of the average relative PD-L1 receptors bound for each cell type. This assay further segregates cells using the DNA-specific dye (DAPI) allowing the measurement of proliferation and delineation of the mutated aneuploid fraction. We demonstrate the assay’s ability to measure quantitative PD-L1 expression, immune infiltrate, and tumor ploidy in NSCLC tumor samples. We believe this will be a valuable assay in the clinician’s toolbox to make informed decisions for patients who may respond best to PD-1 pathway inhibitors.

#965 Two in one: nanotechnology based strategies for the treatment of ER+ breast cancer. Maria Ines Diaz Bessone,1 Andrea Simón-Gracia,1 Pablo Scodeller,2 Tamboet Teesalu,3 Marina Simian1, Universidad Nacional de San Martín, Buenos Aires, Argentina; 2University of Tartu, Tartu, Estonia.

Understanding endocrine resistance mechanisms is key to develop new therapeutic strategies. We focus on the role the tumor microenvironment plays as a modulator of endocrine therapy resistance in breast cancer, in particular associated to Tamoxifen. Studies show that the use of nanoparticles (NPs) as antitumor drug delivery systems is a good strategy to improve the efficacy as third secondary effects of conventional chemotherapies. In this context we hypothesize that a therapeutic strategy based on the use of Tamoxifen carried in NPs coated with the tumor penetrating peptide iRGD, would be more effective than conventional Tamoxifen. Neuruplin-1, that mediates iRGD induced endocytosis, has been shown to be associated to breast cancer stem cells. Thus, we postulate that our multifunctional NPs would be effective in reducing this cell population, contrary to what is observed with free Tamoxifen. Moreover, iRGD blocks the interaction between integrin β1 and fibronectin, a mechanism we have previously shown induces Tamoxifen resistance (Pontiggia et al. 2012). NPs were synthesized with polyethylene glycol and polycaprolactone and coated with the iRGD peptide. This peptide was constructed with a FAM fluorophore in order to track the NPs. To evaluate the cell uptake, MCF-7 cells were incubated for 5 h with iRGD-NP or FAM-NP as a control. NP entry was higher when the NPs were coated with iRGD, both in 2D and in 3D cultures. Cell viability experiments revealed that Tamoxifen encapsulated in NPs was more effective than the free drug (p<0.05), and NPs coated with iRGD had an even stronger effect (p<0.01). Moreover, resistance to Tamoxifen induced by fibronectin was reversed with the iRGD-coated NPs, contrary to what is observed with the free drug. Previously, we demonstrated that treatment with Tamoxifen enhances the stem cell population in estrogen receptor-negative breast cancer cell lines (Raffo et al. 2013). In this context iRGD coated NPs lead to a decrease in breast cancer stem cells as evaluated by mammosphere assays (p<0.01). Finally, in vivo tumor homing was evaluated showing that the NP carrying the fibronectin/sidebody for the biodistribution of the NPs. Nude mice carrying MCF-7 breast tumors were treated with iRGD-NP and control NPs. Tumors were collected at 4 and 24 hrs post inoculation. Frozen sections were analyzed by confocal microscopy revealing that only the mice treated with the iRGD-NPs had high levels of NPs in the tumor, compared to the control group. Moreover, frozen sections of kidneys, livers, lungs and spleen showed very low levels of iRGD-NPs, confirming that the targeting was effective. In vivo experiments of the impact of iRGD-NPs on tumor growth, metastasis and the stem cell population are ongoing. These results suggest that iRGD-NPs carrying Tamoxifen could be an effective strategy to avoid the development of endocrine resistance in breast cancer.

#966 Phase II clinical trial patient responses to the macrophage activating agent RRx-001 correlate to TGF-β pathway activation and markers for fibrosis. Saheli Jha, Thomas A. Summers, Karen Zeman, Christine Brzezniak, Corey Carter, Lindsey Ferry, Jan Scicinski, Bryan Onorosky, Scot Caroen, Jane B. Trepel, Pedro Cabrales, Regina Day, Epicentrx, Mountain View, CA; 2USUHS, Bethesda, MD; 3NCI NIH, Bethesda, MD; 4NCINIH, Bethesda, MD; 5UCSD, La Jolla, CA.

Introduction: RRx-001 is a novel systemically non-toxic small molecule macrophage stimulating agent with promising activity in an ongoing clinical trial in small cell and non-small cell lung cancer and in neuroendocrine tumors. In preclinical studies, RRx-001 activated normally immune-suppressive M2-like Tumor Associated Macrophages (TAMs) to express a series of pro-inflammatory cytokines and chemokines such as transforming growth factor-β (TGF-β1), tumor necrosis factor-α (TNF-α), inducible nitric oxide synthase (iNOS), and interleukins-10 and -12, a profile that resembles the M1 activated macrophage state. Due to its chemotactic activity for macrophages, TGF-β1 was hypothesized to be involved in the antitumor mechanism of RRx-001. We therefore compared expression patterns of TGF-β1 and TGF-β1R in patient-derived biopsy samples obtained at screening and post RRx-001. As TGF-β1 is closely associated with the induction of fibrosis, we also examined key fibrosis markers. Methods: Tumor biopsies before and after treatment with RRx-001 were obtained from consented patients with NSCLC, SCLC, and neuroendocrine tumors in the QUADRUPTPE TREAT Phase II clinical trial (NCT02469903). Post treatment biopsies were obtained 6 and 24 weeks after RRx-001 treatment co-incidental with the first on-study CT scan. Tumor samples were evaluated immune-histochemically with putative markers for TGF-β1 pathway activation (TGF-β1, TGF-β1R, fibrosis (alpha-smooth muscle actin [α-SMA], Matrix metallopeptidase-9 [MMP-9], and Collagen III deposition), and macrophage activation. Patients were subsequently followed for tumor progression. Results: Positive immune-histochemical staining for TGF-β1 and TGF-β1R was seen in all responding patients, and in none of the non-responding patients to date. In responders we also found that MMP-9 and α-SMA activity was down regulated post RRx-001. The down-regulation of these fibrosis markers is suggestive of less invasive malignancy. The number of tumor associated macrophages and their activation was related to the activity of RRx-001. Conclusions: Our pre and post dose patient derived data to date indicate a correlation between TGF-β signaling activation and a response to RRx-001 that may also correlate with increased numbers of macrophages, and their activation status, in the vicinity of the tumor. These data suggest that activation of the TGF-β1 pathway, as evident by expression of TGF-β1 and TGF-β1R by tumor cells, could be a predictive biomarker for RRx-001 treatment.

#967 Development of fluorescent-cell based high throughput assay to identify novel therapeutics of bladder cancer cells through upregulation of SPARC expression. Chirayu M. Patel. Wake Forest Health Sciences, Winston-Salem, NC.

Bladder cancer is the most common malignancy affecting the urinary system with an estimated 76,960 new cases and projected 16,390 deaths in 2016 in the United States. The role of SPARC in various cancers is contextual and differs based on the tumor classification, malignancy and progression. We have recently reported the tumor suppressor effect of SPARC in urinary bladder cancer. We have shown that the loss of SPARC in bladder cancer resulted accelerated bladder carcinogenesis and metastasis multiple pathways involving cell cycle deregulation, inflammation and angiogenesis. We have also reported that SPARC protein expression significantly decreased in the cancerous compartment in advanced human bladder cancer as well as in carcinogen-induced murine urothelial cancer. However, the mechanism of the downregulation of SPARC expression in cancer in general and in bladder cancer in particular is still unraveled. The purpose of our study is to develop a robust, high throughput assay to identify therapeutic candidates as regulators of SPARC expression in bladder cancer. We cloned SPARC promoter in a third generation lentiviral vector coupled with fluorescent GFP or mCherry fluorescent protein to quantitatively measure SPARC expression. We generated stable bladder cancer cell lines expressing SPARC expression in bladder cancer cell lines. UMUC3 bladder cancer cells were transduced with lentiviral vector to generate SPARC-promoter reporter system to screen regulators of SPARC expression. Reporter cells were plated in 96 well plates and treated with 10μM of FDA-approved and natural product drug libraries. Real time monitoring of changes in SPARC expression was done by measuring GFP fluorescence intensity using IncuCyte® ZOOM Live Imaging Analysis System. We identified drugs that consistently exhibited dosage-dependent augmentation or down-regulation of SPARC expression in UMUC3 cells. Our screens identified novel up-regulators of SPARC expression that are both standard of care and novel bladder cancer therapeutics. Our efforts
produced an efficient robust assay to identify novel therapeutics and regulators of the tumor suppressor SPARC in the bladder cancer ecosystem that can be used in the adjuvant and neoadjuvant settings.

#968 Podoplanin’s diverse potential as a chemotherapeutic target for oral squamous cell carcinoma. Edward P. Retzbach,1 Harini Krishnan,1 Jhon A. Ochoa-Alvarez,2 Yongguan Shen,3 Evan Nevel,3 David J. Kephart,1 Evelyne Kayoussel,4 Soly Baredes,4 Mahnaz Fatahzadeh,5 Kingsley Yin,1 Alan J. Shenbaum1,678 Background: Podoplanin (PDPN) is a transmembrane receptor podoplanin that has been postulated to have potential for targeting PDPN in oral cancer. Taken together, these data suggest that PDPN may undergo cancer specific changes, which indicates another potential route for targeting PDPN in oral cancer. Here, we describe efforts to target PDPN in order to prevent and combat oral cancer.

Over 90% of oral cancers are oral squamous cell carcinoma (OSCC). Most OSCC cells express the transmembrane receptor podoplanin (PDPN), which has emerged as a promising target for OSCC treatment. The PDPN receptor promotes tumor cell invasion and metastasis, which leads to the vast majority of cancer deaths. Here, we describe efforts to target PDPN in order to prevent and treat oral cancer. PDPN can be targeted with Maackia amurenensis seed lectin (MASL) to inhibit tumor cell migration and viability. Recent evidence also suggests that PDPN may undergo cancer specific changes, which indicates another potential route for targeting PDPN in oral cancer. Taken together, these data indicate that PDPN can serve as a functionally relevant target to prevent and combat oral cancer.

#969 Expression of membrane-type matrix metalloproteinases (MT-MMPs) in head and neck squamous cell carcinomas, a target for prodrug development. Renée Ankerah,1 Steve D. Shryder,1 James A. McCauld,2 Phil A. Batman,1 Robert Falconer,1 Paul M. Loadman1, Univ. of Bradford, Bradford, United Kingdom; 2Royal Marsden Hospital and Northwick Park Hospitals, London, United Kingdom.

Introduction: Head and Neck Squamous Cell Carcinomas (HNSCC), a group of highly aggressive heterogeneous epithelial malignancies, are considered the fifth most common form of cancer worldwide. Despite advances in treatment, low five-year survival rates of around 30% remain. Several studies have implicated the actions of matrix metalloproteinases (MMPs) in HNSCC progression. Their role in mediating extracellular matrix remodeling is paramount to tumour progression, as they facilitate invasion, angiogenesis and metastasis. In contrast, expression of active MMPs in normal tissues is largely absent. MT1-MMP (MMP14) expression is known to correlate with poor clinical response in several tumour types, but little is known about the expression of other MT-MMPs in HNSCC. We have assessed the protein expression of the entire MT-MMP complement in matched tumour and normal tissues of clinical HNSCC cases by immunohistochemistry, supported by Western Blot and gene expression data and will ultimately demonstrate translation of protein expression into MT-MMP-specific proteolytic activity. Differential expression would support the development of prodrugs specifically activated in the tumour by MMPs. Methods: 32 clinical cases (matched normal & tumour tissues) were assayed for gene expression of the 6 members of the MT-MMP family (MMP14,15,16,17,24,25). Expression profiling was carried out using quantitative real-time reverse transcription-PCR analysis. Analysis of protein expression used IHC on fixed sections used with monoclonal antibodies specific for MT1 to MT6 MMP and Western blot analysis with monoclonal antibodies optimized for western blotting. Results: The protein expression of all six MT-MMPs has been characterised in clinical HNSCC samples and related to matched normal tissue controls. A differential in gene and protein expression levels exists between the MT-MMP profiles across the normal and cancer tissues examined. MT1, MT3- and MT6-MMP are highly overexpressed at both gene and protein level in the majority of tumours. MT2, MT4 and MT5-MMP expression was low or undetectable in all normal tissue and low in tumour tissue Conclusion: The existence and demonstration of differential MT-MMP protein expression in HNSCC relative to normal tissues is a valuable tool for prodrug development. MT1, MT3 and MT6-MMP are highly expressed in the majority of tumour samples compared to matched normal control tissue. However, further work to elucidate the proteolytic activity of the expressed proteins and therefore the proteolytic capacity of tumours is needed to determine the suitability of HNSCC for prodrug therapy.

#970 Probing the expression and function of aldehyde dehydrogenases in prostate cancer using ALDH-affinic compounds and siRNA. Maria Sadiq,1 Ali I. Ibrahim,1 Fionna Frame,2 Simon J. Allison,3 Mark Sutherland, Rogers M. Phillips,4 Norman J. Maitland,5 Klaus Pors1, Univ. of Bradford, Bradford, United Kingdom; 3University of York, York, United Kingdom; 4University of Huddersfield, Huddersfield, United Kingdom.

The human aldehyde dehydrogenases (ALDHs) play a major role in detoxifying highly reactive aldehydes into carboxylic acids. Deregulation of ALDHs has implications in a number of cancers including prostate cancer. They play an important role as a cancer stem cell (CSC) marker due to high activity found in CSCs while high expression is also known to lead to resistance to drugs including docetaxel. Although the exact role of ALDHs is not fully understood, emerging information indicates several isoforms including ALDH1A3 and ALDH7A1 play a key role in cancer. To further elucidate the role of ALDHs in prostate cancer, we here report on the perturbation of ALDH expression and function using chemical probes and siRNA. Primary prostate epithelial cell cultures from patient tissue were used for this study. Cancer samples were obtained from radical prostatectomies and benign samples from transurethral resection of the prostate. qPCR analysis showed ALDH1A3 to be more highly expressed than ALDH7A1 in the primary prostate epithelial cultures in 18 patient samples. Expression of ALDH1A3 was 3-fold higher in the cancer samples compared to the benign samples. The RNA data correlates with protein expression in 6 patient samples by immunofluorescence. qPCR analysis also showed increased expression of ALDH1A3 with overexpression of ALDH7A1 suggesting a compensatory mechanism. Trypan blue exclusion assay showed that knockdown of ALDH1A3, ALDH7A1 or a combination of both resulted in a reduction in cell numbers. Flow cytometry was used to study cell differentiation upon knockdown of ALDH1A3, ALDH7A1 or both. In 7 samples studied there was a reduction in CD49b expression indicating cell differentiation. ALDH7A1 knockdown showed a higher level of cell differentiation in all cases. The colony forming ability of primary cells was also investigated post-transfection of siRNAs against ALDH1A3, ALDH7A1 or both using the colony formation assay which resulted in a lower number of colonies in all 7 samples tested. The effect was more pronounced in benign prostatic hyperplasia (BPH) than in malignant cancer samples and patient variability was observed. ALDH-affinic probe compounds (DEAB and three derivatives, AlI-9, AlI-14 & AlI-18) were tested against 5 patient samples to investigate if they have an effect on cell viability. All four compounds showed reduction in cell viability at the highest concentration while AlI-14 and AlI-18 showed a synergistic effect in combination treatment with docetaxel. In conclusion, knockdown of ALDH1A3 and ALDH7A1 reduce cell number, induce cells to differentiate and reduce their colony forming ability. Novel ALDH-affinic probe compounds reduced cell viability alone and in combination with docetaxel, therefore these compounds may be of value both as single treatments and to provide a strategy to enhance taxane-based therapy such as docetaxel.

Cancer treatment is primarily guided by the organ of origin, which despite extensive histopathological and clinical evaluation, remains ambiguous in many cases and may be inaccurate in cases of occult primary. We determine the extent to which routine prospective tumour sequencing, combined with conventional histopathology, can be used to infer the tumor type and thereby direct clinical decisions. Characteristic patterns of somatic mutations, broad and focal copy number alterations, structural rearrangements, mutational signatures, and other facets acquired from prospective tumor sequencing can inform the tissue of origin classification of patient disease. Such prospective sequencing of active cancer patients presents an opportunity to guide diagnosis and therapy beyond the identification of individual biomarkers of treatment response. Probabilistic classification allows for systematic combination of genome-directed diagnosis with conventional histopathology and clinical history in the course of disease management. Using more than 10,000 tumors collected from advanced cancer patients at our institution and sequenced using a comprehensive cancer panel (MSK-IMPACT) encompassing 341 genes, we have developed a probabilistic classifier that infers the tumor type from nine broad categories of genomic ab-
Drug sensitivity in growing cells is conventionally quantified by IC50, AUC, or Fmax values, but these metrics suffer from a fundamental flaw: they highly depend on the division rate of cell lines. This dependency creates artefactual correlations between genetic alterations and drug sensitivity which impede biomarker discovery. To address this issue, we recently developed novel drug response metrics insensitive to the number of divisions occurring during the assay. These are based on estimating growth rate inhibition (GR) under treatment using fixed assays. Here, we illustrate the flaws of using IC50 values for pharmacogenic studies by reanalyzing a recently published large dataset of drug sensitivity and showing cases in which differences in division rates drive associations between IC50 values and tissue type or genetic alterations. Using GR50 values prevents these artificial correlations and restores known associations between drug resistance and genomic markers such as PTEN loss driving lapatinib resistance in breast cancer cell lines. We also show how use of GRmax values, a measure of drug efficacy, allows quantifying differences in the phenotypes and distinguishing cytostatic from cytotoxic response. For drugs that have a narrow range of GR50 values like taxanes, efficacy is the most relevant metric: in many ovarian BCL2-deleted cell lines, docetaxel induces a cytotoxic response (negative GRmax values), whereas wild-type lines elicit a cytostatic response (positive GRmax values). Because efficacy (GRmax) varies independently of potency (GR50), we conclude that both metrics are complementary for pharmacogenomics and should be studied jointly. Adopting GR metrics requires only modest changes in experimental protocols and analysis is facilitated by our interactive website: GRCalculator.org. We expect GR metrics to improve the identification of reliable drug response biomarkers and enhance the reproducibility of large-scale sensitivity studies.

Methylation accurately predicts age of cancer onset in patients with Li Fraumeni Syndrome. Benjamin M. Brew,2 David Malkin,2 Lauren Erdman,2 Andrea Doria,3 Jason Berman,4 Adam Shlien,1 Tanya Guha,1 Ana Novokmet,1 Anna Gromberg,1 William H. Pledger, Jr,1 The Hospital for Sick Children, Toronto, Ontario, Canada; 2IWK Health Centre, Toronto, Ontario, Canada.

Introduction: Li Fraumeni Syndrome (LFS) is a rare hereditary genetic cancer predisposition syndrome. Germline mutations of the TP53 tumor suppressor gene are the underlying cause in >80% of patients with LFS, and are associated with an increased risk of secondary tumors and a spectrum of early onset cancers, even in the absence of a family history of cancer. We have previously developed and implemented a comprehensive lifelong clinical surveillance protocol for individuals with a germline TP53 mutation. We set out to make this screening process more targeted by building a predictive model of age of onset. We accomplished this goal by implementing machine learning methods on germline methylation data. Methods: We made use of the Toronto Hospital for Sick Children (SickKids) LFS family cohort in our predictive model of age of onset. In all, we have 74 patients with germline methylation data, consisting of ~450,000 probe sites. We subset this data by identifying probes that fall into differentially methylated regions between LFS and cancer patients with wild-type TP53. The probes identified in these regions were used in our predictive model of age of onset. Because age of sample collection was highly correlated with age of onset (r^2 = ~50), we corrected for confounding using a strategy that is two-fold: (1) we extracted the variation of each probe that is independent of the age of sample collection (the residual after regressing on the age of sample collection) and use these as predictors in our model, and (2) we test our models on the task of predicting the age of sample collection for LFS patients that do not have cancer. The former provided us with more robust predictions while the latter verified that we are in fact predicting age of onset, rather than simply predicting age at which the sample was collected. Results: Our machine learning model was able to achieve 86% correlation between true and predicted values of the age of onset. Additionally, we have tested the ability of our models to predict whether an individual will be diagnosed before or after the age of 4. Our classification machine learning model achieved 91% accuracy on average. We verified that our model does not simply predict age of sample collection by using our cohort of LFS patients that do not have cancer (n = 37). The distribution of the age of sample collection matched those of the patients who had cancer (p = 0.67). Our model accurately predicted age of sample collection, thus confirming that our model is highly predictive of the age of cancer onset in LFS TP53 Mutation patients. Conclusions: We identified two predictive models for age of cancer onset in LFS patients that achieve high accuracy, both when predicting the age of onset as a continuous variable (86% correlation) and whether cancer will occur before or after the age of onset (88% accuracy). Our model will assist clinicians in targeting high risk patients for screening, lower the cost of treatment, and raise the likelihood of survival among LFS patients.

Tumor heterogeneity has been linked to many measures of poor patient outcome. Despite numerous recent methodological advances, though, reliable estimates of clonal and subclonal architecture remain elusive. We present advances in computational deconvolution of tumor heterogeneity, aimed at handling complex substructure, more automated inference, and increased flexibility to heterogeneous genomic data sources. Our methods use geometric models of mixture substructure, a specialized form of a strategy called manifold learning, to better resolve clonal substructure shared across genomic samples. We validate the methods on breast tumor dataset from the Cancer Genome Atlas (TCGA).

A multiscale computational model for spatio-temporal tumor immune response. Chang Gong,1 Oleg Milberg,2 Bing Wang,2 Paolo Vicini,3 Rajesh Narwal,4 Lorin Roskos,4 Aleksander S. Popel.1 Johns Hopkins University, Baltimore, MD; 2MedImmune, Mountain View, CA; 3MedImmune, Cambridge, United Kingdom; 4Medimmune, Gaithersburg, MD.

When the immune system responds to tumor development, patterns of immune infiltration emerge, highlighted by expression of immune checkpoint-related molecules such as PD-L1 on cancer cells and its receptor PD-L1 on cytotoxic T cells. Pre-treatment tumor spatial heterogeneity could bear information on intrinsic characteristics of the tumor lesion for individual patient, and thus has the potential to comprise biomarkers for anti-tumor therapeutics. We developed a systems biology computational multiscale agent-based model to capture the interactions between immune cells and cancer cells during tumor progression. Cytotoxic T cells and cancer cells are modeled as free-moving agents in a 3-dimensional grid, where each cell acts in response to its local microenvironment and carries out functions such as division, apoptosis, cytotoxic killing and switching between states with different PD-L1 or PD-L1 expression levels. Subsequently, we analyzed the emergent behavior of tumor progression by looking at all these local interactions as whole. Using this model, we were able to reproduce temporal dynamics of cytotoxic T cells and cancer cells during general tumor progression, as well as 3-dimensional spatial distributions of these cells over the time course of the simulation. By varying the characteristics of the neoantigen profile of individual patients, such as mutational burden and immunogenicity, a spectrum of pre-treatment spatial patterns of PD-L1/PD-L1 expression is generated in our simulations, resembling immune-architectures obtained via immunohistochemistry from patient biopsies. We evaluate potential prognostic biomarkers by correlating these spatial characteristics with in silico treatment results with immune checkpoint inhibitors. Simulation results demonstrate that the percentage of PD-L1 positive cancer cells which are not in close proximity of the tumor boundary or vasculature is more indicative of successful anti-PD1/anti-PD-L1 treatment. Our findings suggest that tumor spatial heterogeneity, especially its immune-architecture, reflects the course of tumor progression as well as patient-specific properties, and is thus likely to carry impor-

**CANCER CHEMISTRY: Novel Therapeutic Targets, Molecules, and Approaches for the Treatment of Cancer**

**#976 ImmunoMap: a novel bioinformatics tool for immune cell repertoire analysis.** John-William Sidhom,1 Catherine A. Bessell,2 Jonathan J. Havel,3 Timothy A. Chan,2 Jonathan P. Schneck.1 Johns Hopkins University, Baltimore, MD; 2Memorial Sloan Kettering Cancer Center, New York City, NY.

**Background:** There has been a dramatic increase in T-cell Receptor (TCR) sequencing spurred, in part, by the clinical demand in Immuno-oncology and technological advances in TCR sequencing. However, there has been little in the way of approaches to parse the data in a biologically meaningful fashion. The ability to parse this data to understand the T-cell repertoire in a structurally relevant manner has the potential to open new discoveries about how the immune system responds to insults such as cancer and infectious diseases. Methods: Here we describe a novel method to visualize and quantify TCR repertoire sequence diversity. This method includes metrics such as visualization of repertoire with: 1) weighted phylogenetic trees that display relatedness and frequency of the sequences; 2) dominant motif analyses identifying clusters of highly homologous sequences that contribute significantly to response and; 3) TCR diversity score measuring the average relatedness (by sequence homology) of all TCR’s in a sample. To demonstrate the power of the approach, we have applied it to understanding the CD8 T Cell response to model self (TRP2) and foreign (SIY) antigens in naive and tumor-bearing (B16 melanoma) B6 mice. Additionally, this method was applied to tumor infiltrating lymphocytes (TIL), taken pre- and on-therapy, from patients undergoing Nivolumab (α-PD1) therapy for metastatic melanoma. Results: Analysis of the naive CD8 response demonstrated a highly conserved (measured by the TCR diversity score) and less clonal response to SIY whereas the response to TRP2 was less conserved and highly clonal. Dominant motif analysis demonstrated highly rich motifs consisting of many homologous sequences in the SIY response but few sequences per motif in the TRP2 response. This may reflect the outcome of tolerance mechanisms to self-antigens. Presence of tumor demonstrated differential immune pressure on the TRP2 vs SIY response. Tumor primed novel SIY motifs but constrained the number of dominant motifs in the TRP2 response while additionally altering the sequence of the motifs. In patients undergoing α-PD1 therapy, we identified signatures in pre- and post-therapy TCR repertoires that correlated with clinical outcome response. Prior to therapy, patients whose dominant motifs were rich with many sequences responded favorably to checkpoint inhibition over those with less rich motifs. After four week on therapy, patients whose TCR repertoires became more conserved responded more favorably to PD1 treatment while those who did not respond had no change in their TCR diversity score. Conclusions: In summary, we have developed and demonstrated a novel method to meaningfully parse and interpret TCR repertoire data and have applied it to yield a novel insight of CD8 T Cell responses to different types of antigens in model systems as well as key characteristics of TIL repertoires from patients who respond clinically to α-PD1 therapy.

**#977 Phenotypic analysis of single-cell breast cancer inhibition data reveals insights into EMT.** William S. Chen,1 Nevena Zivanovic,2 Dana Pe'er,3 Bernd Bodenmiller,3 Smita Krishnaswamy.1 1Yale School of Medicine, New Haven, CT; 2University of Zurich, Zurich, Switzerland; 3Columbia University, New York, NY.

**Background:** A leading model of cancer metastasis is epithelial-to-mesenchymal transition (EMT). We sought to determine whether single-cell inhibition data targeting potential mediators of EMT could uncover mechanistic insights into the EMT process. Methods: EMT was artificially induced on Py2T murine breast cancer cells by TGFβ treatment. Methods: EMT was artificially induced on Py2T murine breast cancer cells by TGFβ treatment. Additionally, a unique drug inhibitor was added to each well of a multiplexed CyTOF experiment. 37 transcription factors and cell surface markers were measured in each cell to assess epithelial and mesenchymal states, SMAD, AKT, and MAPK signaling activity, cell cycle regulation, and apoptosis pathway activation. The final single-cell dataset consisted of 500 inhibition and control conditions (cell populations), which we aimed to characterize in relation to one another with respect to effect on EMT. Analyzing the similarity between drug inhibitions amounts to a novel type of clustering problem that involves computing the similarity between diverse cell populations generated by each inhibitor. Traditional methods for comparing cell populations are not robust to the intra-population heterogeneity observed in unperturbed cells undergoing EMT. Thus, we developed a Phenotypic Earth Mover’s Distance (PhEMD). This method for comparing cell populations leverages the insight that only a limited number of “cell subtypes” (e.g. mesenchymal, epithelial, transitional) are observed in unperturbed and perturbed EMT. By classifying each cell as one of these distinct subtypes using community-
of JAK/STAT pathways associated with a wide variety of malignancies. Elevated JAK/STAT signalling leading to increased activation of STAT3 is reported in a wide variety of cancers, including breast, liver, prostate, colorectal, head and neck, oesophageal, pancreatic, bladder, and non-small cell lung, and is implicated in the pathogenesis of diffuse large B-cell lymphoma and nasopharyngeal carcinoma. The importance of targeting STAT3 activity to disrupt the oncogenic state in leukemia. In this context, TRIM24 degradation rather than bromodomain inhibition alone is required to displace TRIM24 from chromatin. Using this probe, a further understanding of the contribution of TRIM24 domains to its transcriptional activation function will provide mechanistic insight as to how TRIM24 promotes a gene expression program permissive of the oncogenic state, as well as inform a therapeutic approach to target multidomain proteins, such as TRIM24, that are tightly linked to disease.

A common theme in treating cancer is the use of combination chemotherapy, where multiple drugs with different mechanisms of action are combined to elicit synergistic activity or overcome differential drug sensitivities. Antibody-drug conjugates (ADCs) have emerged as a powerful approach for treating cancer, combining the tumor targeting specificity of monoclonal antibodies with the potent cell-killing activity of cytotoxic drugs. Like other therapies, these agents are increasingly being tested in combination with unconjugated, clinically approved anticancer agents. In addition, emerging data demonstrates that insensitivity to a particular ADC can be overcome through delivery of a different payload using the same antibody. For these reasons, the development of ADCs that can deliver two complementary payloads to a tumor would likely be a significant advancement in ADC technology. To enable dual-drug conjugation, we utilized a multiplexing drug carrier that contains cysteine residues with orthogonal protecting groups and identified novel conditions for optimization of these protecting groups on a folded protein. Sequential cysteine unmasking enables discrimination between conjugation sites to allow for site-specific drug conjugation. This strategy provides homogeneous ADCs bearing 16 total drugs per antibody, split evenly between the two drug linkers. Importantly, this strategy is flexible, as it does not require engineered antibodies or custom enzymes for drug-linker conjugation. To demonstrate the potential benefits of ADC dual drug delivery, this strategy was applied to the construction of ADCs bearing two classes of auristatin drug linkers that have different physicochemical properties and complementary anti-cancer activities. Dual-auristatin ADCs were tested in cell line and xenograft models that have differential sensitivities to individual auristatin components, including those with heterogeneous antigen expression or high levels of drug efflux transporters. The data from these studies demonstrate that the dual-auristatin ADCs were active on cells and tumors that are refractory to treatment with either of the individual component drugs. This work highlights the potential for delivering two synergistic or complementary payloads on a single ADC and presents a flexible method for constructing dual-drug ADCs with site-specific and homogeneous drug loading.

#983 Identification of potent, highly selective and orally available ATR inhibitor BAY 1895344 with favorable PK properties and promising efficacy in monotherapy and combination in preclinical tumor models. Ulrich T. Luecking,1 Julien Lefranc,1 Anjte Wenger,1 Lars Wortmann,1 Hans Schick,2 Hans Briem,1 Gerhard Siemens,1 Philip Lienau,1 Christoph Schatz,1 Benjamin Bader,2 Gesa Deeg,1 Franz von Nussbaum,1 Michael Brands,1 Dominik Mumberg,1 Karl Ziegeldbauer,1 Bayer Pharma AG, Berlin, Germany; ASCA GmbH, Berlin, Germany.

The integrity of the genome of eukaryotic cells is secured by complex signaling pathways, known as DNA damage response (DDR). Recognition of DNA damage activates DDR pathways resulting in cell cycle arrest, suppression of general translation, induction of DNA repair, cell survival or even cell death. Proteins that directly recognize aberrant DNA structures recruit and activate kinases of the DDR pathway, such as ATR (ataxia telangiectasia and Rad3-related). ATR responds to a broad spectrum of DNA damage, including double-strand breaks (DSB) and lesions derived from interference with DNA replication as well as increased replication stress (e.g. in oncogene-driven tumor cells). Therefore, inhibition of ATR kinase activity could be the basis for a novel anti-cancer therapy in tumors with increased DNA damage, deficiency in DNA damage repair or replication stress. Herein we report the identification of the potent, highly selective and orally available ATR inhibitor BAY 1895344 by a collabora

PTEFb/CDK9 mediated transcription of short-lived anti-apoptotic survival proteins like Mcl-1 and Mdc plays a critical role in cancer cell growth and survival in various tumor entities including AML. In addition, these survival proteins play important roles in the development of resistance to chemotherapy. We previously disclosed the preclinical profile of BAY 1143572, the first selective, orally available PTEFb/CDK9 inhibitor that entered clinical development. BAY 11434572 had low nanomolar activity against PTEFb/CDK9, an at least 50-fold selectivity against other CDKs in enzymatic assays and broad anti-proliferative activity against a panel of tumor cell lines with sub-micromolar IC50 values. Moreover, BAY 11434572 was shown to be a very potent and highly selective ATR inhibitor (IC50 7 nM), which potently inhibits proliferation of a variety of tumor cell lines with low- to sub-micromolar IC50 values. In initial xenograft studies, BAY-937 revealed moderate activity in monotherapy and in combination with cis-platin. However, BAY-937 also re- vealed low aqueous solubility, low bioavailability (rat) and activity in the hERG patch clamp assay. Extensive lead optimization efforts led to the identification of the novel, orally available ATR inhibitor BAY 1959344. In vitro, BAY 1959344 was shown to be a very potent and highly selective ATR inhibitor (IC50 7 nM), which potently inhibits proliferation of a broad spectrum of human tumor cell lines (median IC50 = 78 nM). In cellular mechanistic assays BAY 1959344 potently inhibited hydroxyurea-induced H2AX phosphorylation (IC50 = 36 nM). Moreover, BAY 1959344 revealed significantly improved aqueous solubility, bioavailability across species and no activity in the hERG patch clamp assay. BAY 1959344 also demonstrated very promising efficacy in monotherapy in DNA damage deficient tumor models as well as combination treatment with DNA damage inducing therapies. The start of clinical investigation of BAY 1959344 is planned for early 2017.

**#984 Identification of potent and highly selective PTEFb inhibitor BAY 1251152 for the treatment of cancer: from p.o. to i.v. application via scaffold hops.** Ulrich T. Luecking,1 Arne Scholz,2 Dirk Kosemund,1 Rolf Bohlmann,1 Hans Briem,1 Philip Lienau,1 Gerhard Siemeister,1 Idilko Terebesi,1 Kirstin Meyer,1 Katja Prelle,1 Ray Valencia,2 Stuart Incz,2 Franz von Nussbaum,2 Dominik Mumberg,2 Karl Ziegelbauer,1 Michael Brands1,2,3,4. 2Bayer HealthCare Pharmaceuticals Inc., Whippany, NJ.

in mechanical threshold after paclitaxel administration than wild-type mice, suggesting the involvement of this receptor in CIPN development and maintenance. This hypothesis was supported by the reversal of paclitaxel-induced mechanical allodynia by the α7 nAChR silent agonist R-47. While nicotine activates its receptors in the tumor cells, based on the stimulation of the P13K/Akt pathway, MTT/MTS colorimetric assays showed that concentrations of nicotine ranging from 0.1 to 10 μM fail to significantly increase the viability of A549 or H460 non-small cell lung cancer cells, murine Lewis lung carcinoma cells, or primary human lung cancer cells. Most importantly, the paclitaxel-induced decreases in H460 proliferation and LLC viability are not significantly attenuated by 1 μM nicotine. Moreover, 1 μM nicotine does not interfere with paclitaxel-induced apoptosis in H460 and LLC cells. Finally, R-47 (0.1 μM) prevented neurotoxicity without decreasing lung tumor cell viability and colony formation, or interfering with the cytotoxicity of paclitaxel. Our in vitro findings are supported by studies demonstrating that nicotine does not enhance tumor volume or cause premature death in tumor-bearing mice. These data suggest that nAChRs may be promising drug targets for the prevention and treatment of CIPN.

Distinct racial disparities are evident in CRC prognosis with Black patients experiencing worse outcomes than Hispanics and Whites. In a prior study of Health Related Quality of Life (HR-QoL) in a cohort of CRC patients, we observed that racial minority patients experienced lower HR-QoL scores compared to White CRC patients. Therefore, in this study, we focused on the identification of patterns of racial disparities in HR-QoL scores and relationship to differences in prognosis.
White (N = 450), Hispanic (N = 366), and Black (N = 316) CRC patients within a year of diagnosis at MD Anderson Cancer Center completed the SF-12 quality of life questionnaire to determine Mental Composite Summary (MCS) and Physical Composite Summary (PCS) scores. Participants also completed a questionnaire to collect epidemiology and sociodemographic variables. Vital status and histology information was obtained from the institutional tumor registry. Racial disparities were reported in HR-QoL with both Black and Hispanic patients reporting lower mean PCS and MCS scores compared to White patients, suggesting poorer HR-QoL in these populations. We observed differences in patterns of association between epidemiology and sociodemographic variables and poorer HR-QoL by race. Hispanics who never married were at higher risk of poor physical HR-QoL (OR: 2.55; 1.5-6.7), P = 0.02 compared to reference patients, for which we observed for White Black CRC patients. Similarly, CRC patients with some college education was associated with a decreased risk of poor PCS, but only in Hispanics (OR: 0.263;0.13-0.52, P < 0.0001). White females have about two-fold risk of poor PCS (P = 2.00 x 10^-4) and MCS (P = 2.21 x 10^-4) scores compared to White males. This relationship was also observed for Black females OR: 2.28 (1.5-3.84), but not Hispanic females. Among CRC patients reporting poor PCS (<50), significant differences in median survival times (MSTs) were observed by race. Hispanic patients had the highest MST at 85.4 months followed by Blacks (47.8 months) and Whites (43.2 months). A similar relationship was observed for poor MCS (<50) stratified by race with MST times of 81.9 months for Hispanics, 40.8 months for Blacks, and 54.1 months for Whites. In conclusion, we identified patterns of racial disparities in epidemiology and sociodemographic factors that correspond to poor baseline HR-QoL. CRC baseline HR-QoL was also demonstrated that a prognostic correlation exists between baseline HR-QoL and patient overall survival, and that this relationship is influenced by race. The patterns of racial disparity identified in this study can be an important tool for assessing the underlying mediators of HR-Qol in CRC patients and to further identify those who are particularly at risk for poor prognosis.

**#991** Association of high-sensitivity C-reactive protein with health-related quality of life among breast cancer survivors. Hyun Jeong Cho, Zisun Kim, Hyun Jeou Youn, Jung Eun Lee. 1Department of Cancer Nutrition, Seoul National University, Seoul, Republic of Korea; 2Department of Preventive Medicine and Public Health, Seoul National University, Seoul, Republic of Korea; 3Department of Obstetrics and Gynecology, Seoul National University College of Medicine, Seoul, Republic of Korea; 4Department of Preventive Medicine, Seoul National University, Seoul, Republic of Korea.

Backgrounds/Aims: Decline in health-related quality of life (HRQoL) is associated with worse prognosis among patients with breast cancer. Increased risk of inflammation with cancer-related symptoms such as low physical function, depression and pain could be a potential mechanism. We aimed to examine whether high-sensitivity C-reactive protein (hs-CRP) were related to HRQoL among breast cancer survivors. Methods: This cross-sectional study of Korean breast cancer survivors included a total of 165 women aged 29 to 63 years who had been diagnosed with stage I to III breast cancer and survived six months or more after surgery. Post-diagnostic HRQoL levels were measured using the 36-Item Short Form Health Survey (SF-36) containing eight components: physical functioning, role-physical, body pain, general health, vitality, social functioning, role-emotional, and mental health. The higher scores indicated better HRQoL. Circulating levels of hs-CRP were measured 6 months after diagnosis. We adjusted each component with categories of hs-CRP according to HRQoL levels. We adjusted for age at diagnosis, body mass index at diagnosis, weight change, income level, stage at diagnosis, time since surgery, tumor size and plasma vitamin D levels. Results: We found that increasing levels of physical functioning and role-physical components were associated with decreasing levels of hs-CRP; according to <0.4, 0.4-<0.6, 0.6-<1.0, and >1.0 mg/L of hs-CRP, LS-means (95% CIs) were 78.1 (73.2-83.0), 75.2 (69.6-80.8), 76.1 (69.5-82.7), 70.1 (64.5-75.7), respectively (p for trend = 0.051) for physical functioning and 77.5 (70.6-84.4), 81.0 (73.2-88.8), 79.4 (70.2-88.7), 66.6 (58.7-74.4), respectively (p for trend = 0.053) for role-physical. Higher scores of mental components were also associated with lower levels of hs-CRP; LS-means (95% CIs) of <0.4 and ≥1.0 mg/L of hs-CRP levels were 84.6 (77.8-91.4) and 67.1 (59.4-74.8), respectively (p for trend = 0.0000) for role-emotional, 87.4 (82.3-92.6) and 77.4 (71.5-83.4) for p for trend = 0.03) for social functioning, 62.4 (56.4-68.4) and 53.3 (46.5-60.2; p for trend = 0.053) for vitality. Conclusions: High circulating levels of hs-CRP, an inflammation biomarker, were associated with lower levels of HRQoL among Korean breast cancer survivors. **#992** Patient-derived tumor organoids of neuroendocrine prostate cancer. Loredana Puca, Rohan Bareja, Reid Shaw, Wouter Karthaus, Dong Gema, Chantal Pauli, Joanna Cytra, Rachele Rosati, Renu Rao, Andrea Stoner, Carla Grandori, Giorgio Inghirami, Yu Chen, Mark A. Rubin, Himisha Beltran, Weiell Cornell Medicine, New York, NY; 2Cure First, seattle, WA; 3Memorial Sloan Kettering, New York, NY; 4Cure First, Seattle, WA.

Background: The development of neuroendocrine prostate cancer (NEPC) is one mechanism of treatment resistance to androgen receptor (AR)-targeted therapies for a subset of patients with advanced prostate cancer. This is associated with transition from a prostate adenocarcinoma to small cell NEPC histology, low AR signaling signaling, and expression of neuroendocrine markers as Chromogranin A (CHGA), Synaphysalin (SYNP) and CD56. Patient derived preclinical models recapitulating the NEPC phenotype may be used to address NEPC pathogenesis and test emerging therapeutic targets. Methods: Tumor organoids were developed according to protocols previously described (Gao et al, Cell 2015). Briefly the tissue biopsies (liver and bone biopsy) were washed, enzymatically digested and then seeded in Matrigel (BD) droplets. Organoids were characterized at genomic (WES), RNA and protein level (HIC) to confirm the expression of specific markers. Lentinival infections were performed using shRNAs against EZH2 to knock down EZH2 in organoids. Organoids were also subcutaneously injected in NSG mice to generate patient derived xenografts (PDx) for drug treatment in vivo. Results: We developed and characterized two NEPC tumor organoids from tumor biopsies (liver and bone) of two patients both in vitro and in vivo (as PDx). NEPC tumor organoid models retained the molecular and histological characteristic of their matched patient samples. We successfully manipulated the activity of the histone methyltransferase EZH2 by using a catalytic inhibitor and its expression by injecting organoids with stEZH2. We showed that the absence of EZH2 affects the expression of neuroendocrine-associated programs as stem cell and neuronal pathway. Moreover treatment with EZH2 inhibitor decreased tumor organoids viability and PDx tumor volume. Drug screening approaches on NEPC organoids were used to discovery novel drug targets and combinations that could potentially benefit NEPC patients. Top single agent hits included previously identified target such as EZH2, AURKA, and CDK7 novel synergies. Conclusions NEPC patient tumors organoids are clinically relevant tumor models to study the NEPC phenotype in advanced prostate cancer and may be used to elude novel drug targets.

**#993** Diagnostic leukaemia (DLA): Molecular characterisation and organoid culture of circulating tumour cells (CTC) from metastatic castration resistant prostate cancer (mCRPC). Maryou B. Labmroso, Veronica S. Gil, Mateus Crespo, Mariane S. Fontes, Rui N. Neves, Niven Mahra, Gemma Fowler, Berni Ebbs, Penny Fohr, George Seed, Wei Yuan, Joanne Hunt, Deirdre Moloney, Dionne Ayanda, Joost F. Swennenhuiss, Kiki C. Andree, Semini Sumanasuriya, Martin Clarke, Pasquale Rescino, Zaléiris Zalėiris, Joaquin Mateo, Diletta Bianchini, Nikolas H. Stoeckle, Leon W. Terstappen, Gunther Boysen, Johann S. De Bono. 1 The Institute of Cancer Research, London, United Kingdom; 2 The Royal Marsden NHS Foundation Trust, London, United Kingdom; 3 University Hospital of the Heinrich-Heine-University Düsseldorf, Düsseldorf, Germany; 4 University of Twente, Enschede, Twente, Netherlands.

Introduction: CTC count is an independent predictor of overall survival in mCRPC. Isolation of CTC from peripheral blood (PB) for genomic and functional analysis is challenging, especially in patients (pts) with low CTC count. It has been shown that DLA increases CTC yield. However, it has yet to be proven whether CTC isolation from DLA can be used in complementary studies such as molecular characterization and growth of organoid culture for drug sensitivity studies. Here we present preliminary data of an on-going study, which evaluates DLA in mCRPC pts, focusing on safety, CTC enrichment, molecular characterization and feasibility for organoid culture. Methods: mCRPC pts considered for clinical trials were selected according to performance status (ECOG 0-1) and number of CTC found in 7.5mL PB (>20 cells/7.5mL). DLA products (200k x 10^6 cells/mL) were centrifuged at 1000 g for 8 min and washed twice with 10mL RPMI medium (10% cord blood serum). The resulting cell pellet was resuspended in 1mL RPMI medium for 15 min at 37°C. Procedure: The leukapheresis (DLA): Molecular characterisation and or- ganoid culture of circulating tumour cells (CTC) from metastatic castration resistant prostate cancer (mCRPC), Maryou B. Lambroso, 1 Verónica S. Gil, 1 Mateus Crespo, 1 Mariane S. Fontes, 1 Rui N. Neves, 1 Niven Mahra, 1 Gemma Fowler, 1 Berni Ebbs, 1 Penny Fohr, 1 George Seed, 1 Wei Yuan, 1 Joanne Hunt, 1 Deirdre Moloney, 1 Dionne Ayanda, 1 Joost F. Swennenhuiss, 1 Kiki C. Andree, 1 Semini Sumanasuriya, 1 Matthew Clarke, 1 Pasquale Rescino, 1 Zaléiris Zalėiris, 1 Joaquin Mateo, 1 Diletta Bianchini, 1 Nikolas H. Stoeckle, 1 Leon W. Terstappen, 1 Gunther Boysen, 1 Johann S. De Bono. 1 The Institute of Cancer Research, London, United Kingdom; 2 The Royal Marsden NHS Foundation Trust, London, United Kingdom; 3 University Hospital of the Heinrich-Heine-University Düsseldorf, Düsseldorf, Germany; 4 University of Twente, Enschede, Twente, Netherlands.
cells) were processed using the CellSearch CTC kit (Janssen Diagnostics, LLC) according to manufacturer procedures. The contents of CellSearch cartridges were sorted into single cell by fluorescence activated cell sorting (FACS) and subsequently assessed by array comparative genomic hybridization (aCGH) for copy number aberrations (CNA). Enrichment of CTC for organoid culture was performed by density gradient of mononuclear cells followed by positive selection using magnetic beads. Results: Overall 12 mCRPC patients underwent DLA without any complication or toxicity. The mean CTC count was 90 CTC/7.5 ml peripheral blood (median = 31) and ranged from 20 to 324. CellSearch CTC count in the DLA yielded a mean of 466 (median=203) and ranged from 60 to 2496 with an up to 40-fold increase (mean = 13, median = 6) in CTC count separation when comparing 1mL of PB and 1mL of PB with DLA. A single mCRPC patient selected by positive sorting of FACS single CTC from the DLA by aCGH showed that these CTC genomic profiles had the typical hallmarks of mCRPC with CNAs including AR and MYC locus (8q) amplification, and PTEN, RB1, TP53, CHD1 loss. Additionally, ex vivo culture of CTC-derived organoids was successfully achieved. aCGH of these organoids matched the genomic profile that of the CTC from the same patient. Conclusion: DLA from mCRPC pts was well tolerated and yields higher CTC capture than PB and may provide an alternative to tissue biopsy and routine culture approach.

Identifying a new method for determining large SVs as a clinical tool for identifying AML patients with high resolution than cytogenetics, an intrinsically low resolution tool. We have adapted a new method for determining large SVs as a clinical tool for evaluating AML and other cancer genomes. The Biennon Irys images in microfluidic nanochannels large (>150 Kb) segments of genomic DNA that have been bar coded by site specific nicking and local incorporation of fluorescent label. The complement of individual molecules can be assembled through matching bar codes to create a de novo map of the genome from which, by matching to a reference genome, identifies and catalogs structural variants at resolution of ca. 1 Kb. With this technology, we characterized structural variants signatures in breast cancer, renal clear cell carcinoma, and CML cell lines. Structural variants were then validated via PCR/Sanger sequencing, fluorescent in situ hybridization and whole genome sequencing. We identified a thorough complement of consistent false positive rearrangements identified by this technology, most of which reflect errors in the reference human genome assembly. We then applied this methodology to ten AML patient samples, seven from archived blood samples and three directly obtained from newly diagnosed patients. Karyotyping on one archived sample identified a t(6;9) translocation in the majority of cells. We identified that rearrangement at a much higher resolution than cytogenetics, which allowed us to map the breakpoint via PCR/Sanger sequencing to nucleotide resolution and confirm a fusion of NUP214 to DER, a known oncogene. We also discovered a reciprocal (i.e., 10;6) translocation, which had not been identified by cytogenetics. In the six other cases from archived samples, we have confirmed the translocation identified by cytogenetic karyotyping and in several cases found additional rearrangements. Moreover, in the first pediatric case, which we completed within five days of obtaining the sample, we have identified four distinct translocations, all of which have been associated previously with AML. Overall, this is technology that has the ability to quickly and accurately identify SVs in cancer cell lines and AML patient samples with higher resolution than cytogenetics, demonstrating its clinical usefulness in the diagnosis and subsequent treatment of leukemia.

Impact of molecular subtypes on predicting chemotherapy response and survival in muscle invasive bladder cancer. Wooyoung Choi,1 Debasish Sundar,1 Fong Yue,1 James Broach. Penn State Hershey Medical Center, Hershey, PA.

Identification of structural variants (SVs) is critical to the prognosis of AML. SVs are not readily identified by next generation sequencing methods and are currently diagnosed by cytogenetics, an intrinsically low resolution tool. We have adapted a new method for determining large SVs as a clinical tool for evaluating AML and other cancer genomes. The Biennon Irys images in microfluidic nanochannels large (>150 Kb) segments of genomic DNA that have been bar coded by site specific nicking and local incorporation of fluorescent label. The complement of individual molecules can be assembled through matching bar codes to create a de novo map of the genome from which, by matching to a reference genome, identifies and catalogs structural variants at resolution of ca. 1 Kb. With this technology, we characterized structural variants signatures in breast cancer, renal clear cell carcinoma, and CML cell lines. Structural variants were then validated via PCR/Sanger sequencing, fluorescent in situ hybridization and whole genome sequencing. We identified a thorough complement of consistent false positive rearrangements identified by this technology, most of which reflect errors in the reference human genome assembly. We then applied this methodology to ten AML patient samples, seven from archived blood samples and three directly obtained from newly diagnosed patients. Karyotyping on one archived sample identified a t(6;9) translocation in the majority of cells. We identified that rearrangement at a much higher resolution than cytogenetics, which allowed us to map the breakpoint via PCR/Sanger sequencing to nucleotide resolution and confirm a fusion of NUP214 to DER, a known oncogene. We also discovered a reciprocal (i.e., 10;6) translocation, which had not been identified by cytogenetics. In the six other cases from archived samples, we have confirmed the translocation identified by cytogenetic karyotyping and in several cases found additional rearrangements. Moreover, in the first pediatric case, which we completed within five days of obtaining the sample, we have identified four distinct translocations, all of which have been associated previously with AML. Overall, this is technology that has the ability to quickly and accurately identify SVs in cancer cell lines and AML patient samples with higher resolution than cytogenetics, demonstrating its clinical usefulness in the diagnosis and subsequent treatment of leukemia.

A translational phosphoproteomic approach to study differences in KRAS signaling in pancreatic, colorectal and lung cancers. Adam Stewart,2 Elizabeth A. Coker,1 Anna Minchom,2 Sebastian Pöстерl,1 Alexandros Georgiou,2 Paul Huang,1 Bissan Al-Lazikani,2 Uday Banerji1. The Institute of Cancer Research, London, United Kingdom. The Institute of Cancer Research and The Royal Marsden, London, United Kingdom.

Aims To understand any context-dependent differences in signaling pathways between pancreatic (PAN), colorectal (CR) and lung (LU) cancers with KRAS mutations using a targeted phosphoproteomic approach in cell lines and patient-derived cancer cells exposed to targeted anticancer drugs ex-vivo. Materials and Methods We studied a panel of 30 KRAS mutant cancer cell lines: 10 PAN, 10 CR and 10 LU cell lines. Cancer cells were also immuno-magnetically isolated from pleural effusions and ascites of patients with KRAS mutant CR and LU cancer and exposed to a DMSO control and clinically relevant concentrations of PI3K inhibitor, PIK3C (pictilisib), AKT (AZD5363), mTOR (everolimus), EGFR (gefitinib), BRAF (vemurafenib), MEK (trametinib) and HSP90 (luminespib) inhibitors for 1 hr. Dynamic changes in a panel of 52 relevant phosphoproteins were studied using the Luminex 200 platform. Hierarchical clustering and logistic regression were used to find differences in dynamic changes in phosphoproteins between KRAS mutant, PAN, CR and LU cancer cells. Results Supervised clustering studying exposure to different drugs revealed that when exposed to the PI3K inhibitor, pictilisib, KRAS mutant LU cancers did not significantly cluster together; p=0.008, p=0.104 following Benjamini-Hochberg correction. Independently, logistic regression showed significant differences in signaling of KRAS mutant cells when exposed to the PI3K inhibitor, pictilisib. PAN and CR cancers showed an increase in p-MEK while LU cancer cells did not; p=0.0195. LU cancer cell lines showed significantly more reduction of p-AKT compared to PAN and CR cell lines when exposed to the PI3K inhibitor; p=0.033. As expected, exposure to vemurafenib increased p-MEK levels across the majority of the KRAS mutant cell lines, however compensatory reductions in p-mTOR levels were seen significantly more in PAN and CR cell lines and not in LU cell lines; p=0.0084. The dynamic phosphoprotein changes caused by pictilisib were validated in cancer cells isolated from serous effusions of 3 KRAS mutant LU and 4 KRAS mutant CR cancer patients. Validation of these findings using multiple other inhibitors and time-points is ongoing. Interpretation/conclusions We hypothesise that the significantly greater reduction in p-AKT and less increase of compensatory p-MEK caused by PI3K inhibition in KRAS mutant LU cells compared to KRAS mutant PAN and CR cell lines represents preferential signaling of these cells through the PI3K pathway. Increase in p-MEK driven by KRAS may cause a compensatory increase in p-AKT. In the context of KRAS mutant lung cancer cells also indicating preferential dependence of signaling in KRAS mutant lung cancer cells through the PI3K pathway. These findings are important while designing clinical trials of KRAS mutant cancers and more broadly to precision medicine where mutation status independent of tissue context is often used.
CLINICAL RESEARCH: Laboratory and Computational Tools to Enhance Decision Making

#997 Impact of a personalized medicine research program (PMRP), using targeted tumor profiling and a cloud based clinical trials matching platform, on clinical decision-making. Thomas D. Brown,1 Paul D. Tittel,1 Philip J. Gold,1 Charles W. Drescher,1 John M. Pagel,1 J D. Beatty,1 Patra Grevstad,1 Desiree Iriarte,1 Shilee Alexander,1 Madeleine Brindle,1 Xiaoyu Liu,1 Danielle O’connor,1 Stella Tameishi,1 Darryl Xu,1 Amel Popovic,1 B. Berry,1 Gestalt,1 Providence St. Joseph Health,2 CellNetix Pathology and Laboratories, Seattle, WA;2 CellNetix Pathology and Laboratories, Seattle, WA;2Swedish Cancer Inst., Seattle, WA;2CellNetix Pathology and Laboratories, Seattle, WA;2Swedish Cancer Inst., CellNetix Pathology and Laboratories, Seattle, WA.

Background: Cancer care is evolving to a model of precision medicine where genomic changes in a patient’s tumor are used to inform individualized management (mgmt). The optimal approach and impact of tumor profiling on cancer care is unknown. To improve research questions and support therapeutic decision-making, we used PMRP to analyze outcomes from 115,000 cases. Results: We have a 50,000 annual cases. Results: The OPeN database can be interrogated by variant Provenance St. Joseph Health, as well as other institutions, comprises the data-stewardship consortium, to aggregate big data sets consisting of clinical, genomic, pharmacologic, and treatment response data from diverse patient cases. Data from Intermountain Healthcare, Stanford University, and Swedish Cancer Institute-Providence St. Joseph Health, as well as other institutions, comprises the database and is derived from 79 hospitals, over 800 physician clinics and more than 50,000 annual cases. Results: The OPeN database can be interrogated by variant type, specific therapeutic impact on clinical outcomes, and by grouped variables, in a structured data format. The overarching IT platform is a cloud based, open source, triple store precision oncology solution, Syapse. These data are yielding valuable insights, including tumor mutational burden (TMB) scores and their correlation to immunotherapy response, clinical response in various drug-gene combinations, and therapy-specific adverse events. Conclusions: We anticipate this resource will be used by the Molecular Tumor Boards of contributing institutions for clinical interpretation, and by treating providers to overcome the N=1 challenge associated with precision oncology.

ENDOCRINOLOGY: Estrogen Receptor in Cancer Progression and Therapies

#999 ESR1 mutations activate and confer hormone resistance via distinct mechanisms. Weiyi Toy,1 Kathryn E. Carlson,2 Teresa A. Martin,3 Christopher G. Mayne,1 Sean W. Fanning,1 Pedram Razavi,1 José Baselga,1 Yang Shen,2 Geofrey Greene,2 Benita Katzenellenbogen,2 John Katzenellenbogen,2 Sarat Chandarlapaty,1 1Mem. Sloan Kettering Cancer Ctr., New York, NY; 2University of Illinois at Urbana-Champaign, Urbana, IL; 3University of Chicago, Chicago, IL.

Mutations in the ligand-binding domain (LBD) of ESR1 have been identified in the tumors and plasma of hormone-resistant, metastatic ER+ breast cancer patients. The most prevalent alterations are Y537S and D538G, and both mechanistic and clinical investigations have focused on the implications of these two mutations. Through large-scale clinical sequencing efforts, we have examined the coding region of ESR1 from over 1000 cases of metastatic breast cancer and found a diversity of ESR1 mutations. These have included a number of novel before reported alterations including mutations in the DNA binding domain and dimerization interface. The biochemical and biologic impact of many of these mutations is unknown. In this study, we have examined the impact of these alterations on ER conformation, transcriptional activity, breast cancer growth, and drug sensitivity. Using transcriptional assays, we found several classes of mutation including: (1) mutations that weakly promoted ligand-independent activity, (2) mutations that led to ligand-independent activity comparable to estradiol stimulation, and (3) mutations that impaired transcriptional activity. Among mutations that promoted some level of ligand-independent activation, we examined whether they had similar effects on receptor conformation in vitro. First, we characterized a subset using a FRET-based co-activator recruitment assay and found that, unlike Y537S and D538G, several mutants (e.g. E380Q and S463P) were unable to recruit SRC in the absence of estradiol. In keeping with this observation, tryptophan digestion assays also revealed differences in the local structure within helix 11 between these mutants. To further characterize the molecular basis for these differences, we conducted molecular dynamic (MD) modeling of mutants and compared these with the MD and crystal structure models of apo Y537S and D538G mutants. These studies further revealed differences in overall receptor conformation including localization of H12. From a therapeutic standpoint, we have examined the effect of different mutations on sensitivity to various ER antagonists. Once again, we observed important differences between mutants, with several mutant of class 2 exhibiting reduced sensitivity to SERDs compared to mutants of class 1. Nevertheless, it appeared that all mutants could be effectively antagonized by more potent SERDs, implying a continued ability of the mutant ERs to become distorted into the antagonist conformation. Taken together, the data reveal distinct conformational restrictions on ER activity that can be relieved by different ESR1 mutations. These data also imply the value of more broad coverage of ER in clinical sequencing efforts in order to effectively capture all potential resistance alleles.

#1000 Estrogen receptor coactivator MED1 in breast tumorigenesis and therapeutic resistance. Xiaoting Zhang. University of Cincinnati, Cincinnati, OH.

Recent studies have established Mediator Subunit 1 (MED1) as a key ER transcriptional coactivator for both normal mammary gland development and breast cancer. Significantly, the MED1 gene is located at the chromosome 17q12 region, also known as the HER2 amplicon, and co-amplifies with HER2 in almost all instances. Importantly, we found that MED1 serves as a key crosstalk point for the HER2 and ER pathways in anti-estrogen resistance of breast cancer. Significantly, MED1 expression highly correlates with poor disease-free survival of breast cancer patients; and most recent studies have discovered increased frequency of MED1 mutations in circulating tumor cells of human patients following anti-estrogen and anti-HER2 treatments. To determine the role of MED1 in HER2-driven tumorigenesis, we have crossed the MMTV-HER2 mammary tumor model with our established MED1 mutant knockin and newly generated MED1 mammary specific overexpression mouse models. Collectively, our studies revealed critical roles for MED1 in tumor progression, metastasis, cancer stem cell formation and therapeutic resistance in HER2-mediated
mammary tumorigenesis. These studies not only for the first time reported key roles for a HER2 amplon co-amplified gene in HER2-driven tumorigenesis but also support MED1 as a potential therapeutic target. To test that, we have assembled highly innovative RNA nanotechnology-based pRNA-HER2apt-siMED1 nanoparticles. We found these RNA nanoparticles have a very high Tm value, and are ultra-stable under RNAse A, 8 M urea, serum and PBS conditions. Importantly, pRNA-HER2apt-siMED1 nanoparticles could specifically target HER2+ human breast cancer, efficiently deplete the expression of MED1 and decrease ER-mediated gene transcription both in vitro and in vivo. Most significantly, pRNA-HER2apt-siMED1 nanoparticles not only greatly reduce the growth, metastasis and cancer stem cell formation of HER2+ breast cancer, but are also very effective in their therapeutic activity. (This work is supported by Susan G. Komen for the Cure Foundation Career Catalyst Grant, American Cancer Society Research Scholar Grant and NIH/NCI Grant Number R01CA197865).

**#1001 ESR1 mutations confer novel metastatic functions in genome-edited breast cancer models.** Zheqi Li,1 Amir Bahrein,1 Peili Wang,2 Kevin Levine,2 Nilgun Tasdemir,2 David Chu,3 Ben Ho Park,3 Adrian Lee,1 Stefi Oesterreich,1 1University of Pittsburgh, Pittsburgh, PA; 2Tianhua University, Beijing, China; 3Johns Hopkins University, Baltimore, MD.

Background: Estrogen receptor alpha (ERα), encoded by the ESR1 gene, is expressed in approximately 70% of breast cancers. Recent studies conducted by us and others have shown that somatic mutations in ESR1 gene play a key role in conferring endocrine resistance in ER+ breast cancer. These hotspot mutations mainly occur on the ligand binding domain of ERα, leading to poor outcomes in 25-30% of patients with ER+ metastatic breast cancer in clinic. The mechanisms behind the potential enhanced metastasis of these mutations have become an urgent issue to be addressed, but they are not well understood due to a lack of ESR1 mutant models. Methods: We generated and characterized genome-edited T47D and MCF7 breast cancer cell lines with the two most common ESR1 mutations (Y537S and D538G), using CRIPSR/Cas9 and rAAV systems respectively. Multiple clones for each mutant were sorted and the mutation frequencies were detected using digital droplet PCR (ddPCR). We subsequently performed an RNA-seqencing to deeply differentiate the gene expression patterns in these mutants. The growth of these pooled mutant-cells was determined in both 2D and 3D plates. The cell-matrix adhesions were measured based on ECM array, and 3D-ECM adhesion related genes were further tested by qPCR array. InCuCyte real-time image system was used to monitor the cell migration based on the wound-scraping assay. Results: We first identified the robust mutation frequencies at both RNA and DNA levels in our cell models. The RNA-seq exhibits multiple ligand-independent genes overlapping between either cell lines or mutants, which were further conformed by qPCR. We also found that both Y537S and D538G mutants present ligand-inactive and 3D ultra-low attachment plates. Using wound-scraping assay, we observed significant higher migration rate in D538G mutant of T47D cell lines on both matrigel and type I collagen, indicating a cell-line and mutant-specific phenotype. We also detected lower attachment of both mutants on type I collagen in both cell lines, and our qPCR array revealed that alterations in the MMP pathways could be one of the major mechanisms in causing this phenotypic difference. In summary, our study presents the first in-depth metastatic functional analysis of the biology of ESR1 mutations in genomic knock-in cell models, pointing out the enhanced migration and decreased cell-matrix adhesion as a potential novel gain-of-function of the Y537S and D538G mutant-cells. These findings suggest the potential role of enhanced metastasis of these ESR1 mutations through re-modeling of transcriptional profiles, shedding lights towards the development of efficient therapies of ESR1 mutant breast cancer.

**#1002 An epigenetic strategy to degrade the estrogen receptor in breast cancer.** Huili Li,1 Foteinos-Ioannis Dimitrakopoulos,2 Meredith Stone,1 Lauren Murphy,1 Stephen Baylin,1 Cynthia A. Zahnow,1 Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins, Baltimore, MD; 2University of Patras, Medical School, Rio, Greece.

Epigenetic changes in DNA methylation can lead to altered gene expression and the development and progression of breast cancer. Luminal breast tumors are associated with increased DNA hypermethylation of CpG islands while basal, triple negative tumors more commonly have lower levels of DNA methylation. Increasing evidence suggests that aberrant epigenetic alterations in DNA methylation and chromatin structure may also contribute to endocrine resistance in luminal breast cancers. We thus asked whether epigenetic therapy using the demethylating agent, 5-Aza-2′-deoxycytidine (AZA) is an effective anti-tumorigenic agent in luminal breast cancers, what epigenetic mechanisms might be involved in the response and whether AZA could play a role in the sensitization of tamoxifen resistant cells. We have demonstrated using 26 breast cancer cell lines that luminal B, ER+ breast cancer is more responsive to treatment with AZA than are Her2+ or triple negative (TN) breast cancers. Cells were treated in culture with low nanomolar doses of AZA for 72 hrs, followed by transplantsation into mice and weekly palpation of tumors. Tumorgraft measurements show that 76% of the luminal B cell lines and 25% of Her2+ cell lines exhibit an anti-tumorigenic response to AZA in mice. Expression data showed that AZA leads to decreases in ER mRNA and protein expression in 50% and 67% of luminal B lines respectively. Further investigation showed that a longer AZA treatment led to lower ERα protein levels and stronger tumor growth inhibition. Protease inhibitor (MG132) treatment rescued AZA-induced growth inhibition in 50% of the luminal B cell lines, suggesting that an estrogen-mediated, ubiquitin-26S proteasomal pathway may be responsible for the degradation of ER. Gene expression analysis demonstrated that the E1 ubiquitin-activating enzyme, (UBA7)-UBE1L was up-regulated at the mRNA and protein levels by AZA. UBA7 has been suggested to function as a tumor suppressor in lung cancer and elevations in UBA7 have been correlated with longer overall survival in breast cancer. The interaction of UBA7 with ERα protein was validated by immunoprecipitation and over-expression of UBA7 in ZR-75-1 cells led to a reduction in ERα protein. We further analyzed the UBA7 promoter region by Illumina 450K array and bisulfite sequencing in our cell lines and identified two CpG rich sequences in the promoter that may be important for AZA-induced UBA7 promoter demethylation and gene re-expression. We also demonstrated in both tamoxifen sensitive and resistant cells that combination therapy with both AZA and tamoxifen was more effective at inhibiting tumor growth than the single agents. Studies are ongoing in our lab to better understand this response. Our data suggest that AZA may be clinically useful to inhibit the growth of some luminal breast tumors via its actions to increase expression of UBA7 and to degrade ER and may have efficacy in combination with anti-estrogen treatments.

**#1003 Extranuclear ERα-mTOR signaling rewires cancer cell metabolism during obesity-associated breast cancer.** Zeynep Madak Erdogan, Yiru C. Zhao, Gianlugi Rossi, Kinga Wrobel, Eylem Kulkoyluoglu, Sung Hoon Kim, John A. Katzenellenbogen, Jodi Flaws, Rebecca Smith. Unv. of Illinois at Urbana-Champaign, Urbana, IL.

Obesity is a preventable risk factor for post-menopausal ERα(-+) breast cancer. We hypothesized that serum from obese post-menopausal women contain factors that would increase tumorigenicity of breast cancer cells and increase risk of ERα(+)- breast cancer. Using whole metabolite profiling and OLINK biomarker panel of about 400 proteins associated with cancer, inflammation and cardiovascular disease, we identified biomarkers that were differentially present in serum from 50 obese v.s. 50 non-obese postmenopausal women. Next, using in vitro cell based assays as proxy we identified certain fatty acids (FFAs) as factors from serum that correlate with increased cell proliferation, motility and mTOR activation in ERα(+) breast cancer cells. We performed RNA-Seq, ERα ChIP-Seq and metabolomics analysis in breast cancer cells that are exposed to conditions that mimic serum from obese postobesmenopausal women. This integrative -omics approach enabled us to uncover ERα and mTOR pathway-dependent vulnerabilities for the breast cancer cells. In summary, we uncovered a novel role for extranuclear-initiated ERα signaling in rewiring breast cancer cell metabolism in response to obesity-associated factors in the serum. Our findings provide a basis for preventing or inhibiting obesity-associated breast cancer by using PaPEs that would exploit new metabolic vulnerabilities of breast tumors in obese postmenopausal women.

**#1004 LDLR knockdown reduces the growth of Her2 overexpressing breast cancer in mouse models of hyperlipidemia.** Emily J. Gallagher, Brian A. Neel, Zara Zelenko, Irini Markella Antoniou, Nathan Kase, Derek LeRoth. Icahn School of Medicine at Mount Sinai, New York, NY.

Women with higher circulating low density lipoprotein (LDL) cholesterol levels are more likely to have advanced HER2 positive breast cancers. The LDL receptor (LDLR) is the main receptor for cholesterol uptake into cells from circulating LDL and its expression is higher in HER2 positive breast cancers than other subtypes. The aim of our study was to understand the importance of the LDLR in the progression of HER2 positive breast cancer growth in the setting of hyperlipidemia. To study the role of hyperlipidemia in HER2 cancer progression, we used two mouse models with elevated LDL cholesterol: Apolipoprotein
factor receptor pathways in non-small cell lung cancer.

**EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Novel Mechanisms of Drug Resistance**

**1006 Drug-tolerant persister cancer cells are vulnerable to GPX4 inhibition.** Matthew J. Hangauer,1 Vasanthi S. Viswanathan,2 Matthew J. Ryan,2 Dhruv Bole,1 Jake Eaton,2 Stuart L. Schreiber,3 Frank McCormick,3 Manusun T. Michael.1 1University of California, San Francisco, San Francisco, CA; 2Broad Institute/Harvard University, Cambridge, MA.

Acquired drug resistance prevents chemotherapy and targeted therapy from achieving stable and complete responses. Emerging evidence implicates a key role for nonmutational mechanisms during early stages of acquired drug resistance. Drug-tolerant “persister” cells are a model of nonmutational cancer drug resistance in which small fractions (<5%) of cells within cancer cell lines survive pharmacologic exposure designed to eliminate drug-sensitive parental cells. These residual surviving cells are quiescent, occupy a unique chromatin state, and exhibit reversible drug resistance: removal of drug allows regrowth of cells which become resensitized to drug treatment. Importantly, this phenomenon has been observed across a wide range of cancer lineages with both chemotherapy and targeted therapy. Persister cells remain quiescent for weeks to months during constant drug exposure, however some persister cells eventually regrow and acquire irreversible drug resistance-conferring mutations that did not prevalent. This model mirrors the common clinical scenario in which tumor response is followed by relapse with acquired resistance-conferring mutations. Targeting nonmutational resistance may therefore present a therapeutic opportunity to eliminate residual surviving tumor cells to prevent relapse. We have performed an unbiased functional genomics analysis of HER2+ breast cancer persister cells which survive HER2 targeted therapy. Utilizing RNAseq pathway analysis, RNAi screens and chemical inhibitor screens, we discovered that persister cells undergo a switch to mesenchymal gene expression and are uniquely susceptible to inhibition of the phospholipid hydroperoxidase GPX4. This finding is not restricted to breast cancer, rather we have observed that all persister cells tested including those derived from melanoma, lung, ovarian and pancreatic cancer, from either targeted therapies or chemotherapies, are each specifically sensitive to loss of GPX4 function. Parental, drug naïve cancer cells and normal human cells are insensitive to GPX4 inhibition. Mechanistically, we found that GPX4 dependency in persister cells is due to a disabled antioxidant program characterized by global downregulation of antioxidant genes, decreased levels of reduced glutathione and increased ROS. These findings point forward a GPX4 inhibition strategy to prevent tumor relapse by inducing ferroptosis in the residual pool of surviving persister cells.

**1007 SHP2 inhibition restores sensitivity to ALK inhibition in resistant ALK-rearranged non-small cell lung cancer (NSCLC).** Leila Dardaei,1 Hui Qin Wang,2 Paul Fordjour,1 Man saree Singh,3 Grainine Kerr,4 Satoshi Yoda,5 Jinsheng Liang,6 Yichen Cao,2 Yan Chen,2 Justin F. Gainor,1 Luc Friboulet,2 Ibiaye Dagogo-Jack,1 David T. Myers,1 Emma Labrot,2 David Ruddy,2 Melissa Parks,1 Dana Lee,1 Richard H. DiCecca,1 Susan Moody,2 Huaxiang Hao,2 Morvarid Mohseni,1 Matthew LaMarche,1 Julia Williams,1 Keith Hoffmaster,2 Giordano Caponigro,2 Cyril H. Benes,1 Alice T. Shaw,1 Aaron N. Hata,1 Fang Li,2 Jeffrey A. Caponigro,1 Massachusetts General Hospital Cancer Center, Charlestown, MA; 2Novartis Institutes for BioMedical Research, Cambridge, MA; 3Gustave Roussy Cancer Campus, Paris, France.

Despite development of highly potent and selective inhibitors (e.g., ceritinib, alectinib, lorlatinib) targeting anaplastic lymphoma kinase (ALK), resistance invariably develops and limits the efficacy of these inhibitors in the clinic. The major classes of resistance are on-target genetic alterations (e.g., secondary ALK kinase domain mutations) and activation of alternative or bypass signaling pathways. While most patients are responsive to sequential treatment with two or more ALK inhibitors, ALK-independent resistance eventually emerges and leads to failure of further ALK-directed monotherapy. We used a synthetic lethal pooled shRNA screen to discover loss-of-function events that could sensitize resistant patient-derived cell lines to ALK inhibition. In addition to identifying known bypass targets such as FGFR, EGFR and SRC, we also identified PTPN11 (which encodes SHP2, a non-receptor protein tyrosine phosphatase that modulates signaling downstream of growth factor receptors) as a common hit shared
by cell lines exhibiting different mechanisms of bypass activation. In parallel with the shRNA screen, we also performed a high throughput combination compound screen in the same patient-derived models, and identified activation of the same bypass signaling pathways. We showed that the highly potent and selective small-molecule SHP2 inhibitor SHP099 could sensitize resistant cell lines to ALK and EGFR TKIs in vitro. Biochemical analysis of the compound-treated PDX overcame resistance mediated by ALK-independent bypass mechanisms by decreasing RAS-GTP loading potential of cells and inhibiting phospho-ERK rebound. These results suggest that dual ALK and SHP2 inhibition may represent a new therapeutic strategy for ALK-positive patients, whose lung cancers have evolved ALK-independent mechanisms of resistance, including activation of bypass signaling pathways.

### #1008 Gain-of-function kinase library screen identifies FGFR1 amplification as a mechanism of resistance to antieostrogens and CDK4/6 inhibitors in ER+ breast cancer.

Luigi Formisano,1 Yao Lu,1 Valerie M. Jensen,1 Joshua A. Bauer,1 Aribella B. Hanker,1 Melinda E. Sanders,2 Paula Gonzalez-Ericsson,3 Sunkyu Kim,4 Monica Arnedo,5 Fabrice Andre,6 Carlos L. Artega,1,6 Vanderbilt University, Nashville, TN; 2Novartis Pharmaceuticals Corporation, NJ; 3Institute Gustave Roussy, France

The CDK4/6 inhibitor palbociclib was recently approved in combination with endocrine therapy for treatment of ER+ metastatic breast cancer. The goal of this study was to discover mechanisms of resistance to ER antagonists alone and in combination with CDK4/6 inhibitors. To achieve this goal, we used lentiviral vectors to individually express 559 human kinase open reading frames (ORFs) in ER+ MCF7 human breast cancer cells treated with fulvestrant ± the CDK4/6 inhibitor ribociclib (Novartis). In MCF7 cells treated with fulvestrant alone or with ribociclib, we identified 21 and 17 genes, respectively, which induced a >30% increase in cell viability compared to control cells; 11 of these kinases overlapped in both treatment groups. In a secondary screen, MCF7 cells were stably transduced with V5-tagged lentiviruses expressing the positive hits identified for treatment with fulvestrant/ribociclib. Five of 11 kinases (FGFR1, FRK, HCK, FGR, CRKL) were tagged lentiviruses expressing the positive 'hits' for treatment with fulvestrant alone or with ribociclib, we identified 21 and 17 genes, respectively, which induced a >30% increase in cell viability compared to control cells; 11 of these kinases overlapped in both treatment groups. In a secondary screen, MCF7 cells were stably transduced with V5-tagged lentiviruses expressing the positive hits identified for treatment with fulvestrant/ribociclib. Survey of TCGA for copy number alterations and/or expression of these five genes showed only FGFR1 to be amplified/overexpressed in 17% of ER+ breast cancers. Experiments in vitro showed that ER+ /FGFR1-amplified (amp) MDA-134, CAMA-1 and HCC1936 human breast cancer cells and MCF7 cells stably transduced with FGFR1 were relatively resistant to estrogen deprivation, fulvestrant and fulvestrant/palbociclib compared to non-FGFR1 amp MCF7 cells. This resistance was abrogated by treatment with the FGFR tyrosine kinase inhibitor (TKI) lucitanib. Treatment with fulvestrant or palbociclib, each alone, modestly delayed growth of ER+ /FGFR1 amp breast cancer patient-derived xenografts (PDX) established in nude mice. However, addition of the FGFR TKI erlotinib to fulvestrant/palbociclib resulted in marked PDX regressions in all mice without associated toxicity. Treatment of FGFR-amp cells with FGF-2 strongly induced CCND1 (cyclin D1) expression. Downregulation of CCND1 with CCND1 RNAi oligonucleotides or kinase inhibition with erlotinib restored sensitivity to FGFR1 inhibition. Treatment with fulvestrant/palbociclib, conversely, enhanced expression of CCND1 in MCF7 cells induced resistance to estrogen deprivation and fulvestrant ± palbociclib. At this time, we are examining whether FGFR1 amplification measured by FISH correlates with maintenance of proliferation (Ki67) in 110 patients with ER+/HER2- breast cancer treated with palbociclib for 14 days immediately before surgery (Arnedos et al. ASCO 2016). In summary, using a gain-of-function ORF kinase screen, we identified FGFR1 amplification as a mechanism of resistance to anti-ER therapies ± CDK4/6 inhibitors. Based on these data we propose FGFR inhibitors should be tested in combination with ER antagonists and CDK4/6 inhibitors in patients with ER+/HER2 amplified breast cancer.

### #1009 Comprehensive ctDNA sequencing reveals mechanisms of resistance to rociletinib in EGFR T790M-mutated NSCLC.

Elena Helman,1 Andrew D. Simmons,2 Chris A. Karlovich,3 Thomas C. Harding,2 Mitch Raponi,4 Darya I. Chudova,1 Daniel A. Simon,5 Richard B. Laman,1 AmirAli Talazaz,1 Guardant Health, Redwood City, CA; 2Closio Oncology, San Francisco, CA.

Background: First and second-generation EGFR tyrosine kinase inhibitors (TKIs) have benefited patients with EGFR-mutated non-small cell lung cancer (NSCLC), but resistance invariably develops after a median of 9-16 months. In ~60% of patients, resistance is mediated by a second mutation in EGFR, namely T790M. Hence, third-generation EGFR TKIs such as osimertinib and rociletinib were developed to target both activating EGFR mutations as well as T790M. Unfortunately, patients also develop resistance to these therapies through mechanisms that have not yet been thoroughly explored. Since repeat tissue biopsies pose potential complications from invasive procedures, circulating tumor DNA (ctDNA) testing is increasingly used in the clinical setting to identify potentially targetable mechanisms of resistance. Methods: Matched pre-treatment and progression plasma from 57 patients with EGFR-mutated NSCLC treated with rociletinib were analyzed using a 70-gene ctDNA targeted next-generation sequencing panel (Guardant360) that detects somatic single nucleotide variants, short insertions and deletions, fusions, and copy number variants. Pre-treatment EGFR ctDNA allele frequencies were also determined by BEAMing, a technique based on droplet digital PCR followed by flow cytometry. Pre-treatment tumor EGFR status was assessed by the tharscreen EGFR test. Results: In all 57 pre-treatment samples profiled, plasma-based ctDNA analysis detected the initial EGFR driver and T790M resistance mutations that were identified in the matched tumor. Interestingly, we found that 12% (7/57) of patients had evidence of compound EGFR driver mutations at baseline, including E709A-L858R, K860I-L858R, and L718V-L858R. EGFR T790M mutations in plasma were observed subclonally (present on average at 40% of the allele fraction of the driver mutation), suggesting tumor heterogeneity at baseline. The correlation coefficients (r) between Guardant360 and BEAMing for EGFR L858R, exon19Del, and T790M were 0.90, 0.92, 0.95, respectively. Upon progression on rociletinib, 5% of patients (3/57) developed the EGFR C797S resistance mutation, 5% (3/57) developed focal MET amplification, and 2% (1/57) developed a NTRK1 fusion that were not present in the matched baseline plasma. Additionally, 4 deletions (ERBB2 and 2 genes 2q), 4 mutations (2 genes 1q, 1 gene 3q, 1 gene 8q) were identified as somatic variants with the somatic alterations emerging at progression. In 14% (8/57) of the patients, mutations in genes involved in the RAS/RAF signaling pathway, including KRAS Q61H, KRAS K117N and NF1 Q182*, emerged or increased at progression. Conclusions: Plasma ctDNA revealed heterogeneity and multiple mechanisms of resistance in rociletinib treated patients. Thus comprehensive ctDNA sequencing allows for the identification of potentially actionable alterations and may help inform the choice of next therapy for patients progressing on a third-generation EGFR TKI.
#1011 RNAseq analysis obtained from on-purpose tumor biopsies of patients in the MATCH-R trial allows the identification of potential mechanisms of acquired resistance to PD(L)1 therapies. Loic Verlingue, Linda Mahmoud, Sandrine Aspglach, Marion Pedrero, Giulia Buzzatti, David Brandao, Zsofia Balogh, Etienne Rouleau, Ludovic Lacroix, Rastislav Bahleda, Christophe Massard, Antoine Hollebecque, Anas Gazzah, Celine Lefebvre, Serge Koscielny, Jean Yves Scoazec, Eric Angevin, Fabrice Andre, Aurelien Marabelle, Jean Charles Soria. Gustave Roussy, Villejuif, France.

Background: MATCH-R is a prospective molecular characterization trial (NCT02517892) aiming at defining the molecular basis of acquired resistance to targeted agents and immune checkpoint blockers. RNA sequencing (RNAseq) has been used to identify mechanisms of secondary resistance to immunotherapy. Patients and methods: Patients’ metastatic tumors were multi-site biopsied at relapse under immunotherapies after a period of clinical benefit, defined by a partial response or a stable disease of more than 6 months. Genome-wide RNAseq counts were intra-patient normalized and a score of each gene’s expression was computed in comparison to a cohort of 450 metastatic cancer patients with RNAseq available at the time of analysis. Results: To date, 10 patients treated by immunotherapies have had a successful RNAseq in the MATCH-R trial. Five patients were treated with PD-1 inhibitors and 5 with PD-L1 inhibitors. Three patients had NSCLC, 2 MSI high endometrial carcinoma, 2 anal carcinomas, 1 head and neck carcinoma and 1 TNBC. Eight out of ten patients had an expression of IDO1 higher than the median expression of IDO1 in our 450 controls (p value = 0.005). A patient with endometrial carcinoma had one of the highest expressions of IDO1 in the cohort. Consistently, IDO1 activation has previously been reported as a mechanism of secondary resistance to immunotherapies. A 40 year old smoker NSCLC patient with a TP53 mutation has been treated during 11 months with anti-PD1. RNAseq analysis on the biopsy of a progressive lesion showed decreased expression of different actors of the Jak-STAT pathway (biopsy composed of 40% tumor cells and 60% microenvironment). Of the 78 genes signatures used (including 52 immunogenes signatures), the interferon gamma signature had the lowest expression (p value = 0.004), consistent with a previous report of Jak-STAT-induced resistance to immunotherapies. Two more patients had an altered immune profile that could be involved in resistance to immunotherapies, but was not yet reported in the literature. Confirmation of the RNAseq analysis with immunohistochemistry is currently ongoing. The gene signatures of the 10 patients, composed of immunogenes, DNA repair genes and epigenes, were compared to the whole cohort in order to deduce corresponding false discovery rates. As such we could identify 2 gene clusters, one enriched in T cells, dendritic cells and macrophages, and the other enriched in epigenes and DNA repair genes. Analysis of more patients is currently ongoing in order to cluster the results with clinical characteristics. Conclusion: Gene expression in the biopsy of patients that relapsed after initial benefit to immunotherapy is informative and helps to identify the mechanism of acquired resistance.

#1012 Patient-derived tumor microenvironment models uncover non-autonomous TKI resistance mechanisms in NSCLC. Haichuan Hu, Hillary Mullvey, Sundus Nooen, Kodak David, Aaron Hata, Matthew Niederst, Cyril Benes, Aaron Hata, Matthew Niederst, Cyril Benes, Wayne W. Hancock, Tatiana Akimova, Tianyi Zhang, Evgeniy Eruslanov, Sunil Singhal, Steven M. Albelda. CHOP/UPenn, Philadelphia, PA.

FOXP3+ Tregs are considered important to limiting antitumor immunity but are rarely characterized clinically. We studied 227 samples from 66 lung cancer patients using blood, lymph node (LN), tumor and distant lung samples, with a mean age of 67.8±11.1 years, 67% males, 62% adenocarcinoma, 31% squamous cell carcinoma, 7% miscellaneous tumors, mean tumor size of 3.4±0.3 cm, and 21% rate of metastases. In addition to quantitating FOXP3+ CD4+ Tregs, we evaluated their expression of 35 markers by flow cytometry: CD15s, CD25, CD26, CD27, CD39, CD40L, CD45RA/RO, CD62L, CD69, CD101, CD120b, CD161, CCR4, CCR5, GARP, GITR, Helios, HLA-DR, ICOS, LP/AF, neuropilin, PD-1, TIGIT, Tim3, CCR4, CCR5, CCR7, CXCR3, CXCR4 and CCR8, and tested Treg suppressive function. We used PrimeFlow to evaluate mRNA expression of target genes in 100% pure human Treg cells, gated on CD4+ FOXP3+ cells. FOXP3+ Tregs (%) in the CD4+ T cells of tumors and LN were significantly decreased in compared to other sites; tumors 19.2±8.5%, LN 14.7±7.8%, healthy PBMC donors 7.2±2.5%, PBMC lung cancer 7.2±2.7%, and lungs 6.6±3.2%. Tregs of lung tumors were remarkably suppressive vs. all other sites (p<0.0001 vs. PBMC & LN, p=0.0106 vs. lung Tregs). None of the 35 markers evaluated by flow cytometry were statistically significantly different for tumor Tregs vs. other sites. However, PrimeFlow showed tumor Tregs, but not FOXP3- T cells from other sites, had upregulated mRNA expression of 4 transcription factors (TF): Eos, Irf4, Satb1 and Gata1. These 4 TFs plus LEF1 were recently described as a quintet of Treg self-locking signature; TF expression of any 2 TF plus FOXP3 promoted full Treg gene expression and function. Tumor Tregs also showed significant upregulation of FOXP3 mRNA and protein. Tumor and lung Tregs expressed more Eos, Satb1 and Gata1 mRNA, and much higher levels of FOXP3 protein per cell, while in PBMC, LNs and healthy donor Tregs upregulation of TFs did not correspond with increase of FOXP3 protein, indicating the "Treg self-locking signature" is subject to regulation by local factors. Indeed, cultured tumor Tregs downregulated FOXP3 protein, mRNA and TF expression, while PBMC and LN Treg incubated in tumor-conditioned media upregulated FOXP3 mRNA and protein, and Treg TF expression, moving toward the tumor Treg-like phenotype. We found significantly increased numbers and suppressive function of FOXP3+ Tregs within lung tumors vs. other sites in the same patients. In addition, while large-scale flow cytometric studies were not useful in identifying key features of tumor Tregs vs. Tregs at other sites, PrimeFlow showed that tumor Tregs have a unique phenotype with upregulated expression of FOXP3 mRNA and protein, as well as Eos, Irf4, Satb1 and Gata1 mRNA. These features appear to be malleable and associated with features of the local tumor microenvironment.

High numbers of tumor infiltrating regulatory T (Treg) cells are indicative of poor outcome in several malignancies, including ovarian cancer, colorectal cancer, and melanoma. Thus, selectively abrogating intratumoral Treg cell function while maintaining systemic immune tolerance remains an attractive, albeit elusive, strategy for cancer immunotherapy. We have identified the epigenetic enzyme Ezh2, an H3K27 methyltransferase, to be a critical mediator of lineage stability and function in activated Tregs. Consequently, deficiency of Ezh2 in Treg cells strongly impairs their function in non-lymphoid tissues. We hypothesized that this phenomenon might translate to a similar defect that is restricted to the tumor microenvironment. Here we tested this hypothesis in three transplantable syngeneic tumor models in mice (MC38 colon carcinoma, TRAMP-C2 prostate cancer, and B16F10 melanoma). We observed that constitutive deletion of Ezh2 in Treg cells resulted in potent anti-tumor activity, significantly impaired tumor outgrowth, and in many instances, complete tumor rejection. These results were also recapitulated when Ezh2 was temporally deleted in the vast majority of Treg cells at the time of tumor inoculation. Functional analyses at early time points after Ezh2 deletion revealed enhanced functionality of effector CD4 and CD8 populations, as evidenced by increased IFN-γ production. We observed that constitutive deletion of Ezh2 in Treg cells resulted in potent anti-tumor activity, significantly impaired tumor outgrowth, and in many instances, complete tumor rejection. These results were also recapitulated when Ezh2 was temporally deleted in the vast majority of Treg cells at the time of tumor inoculation. Functional analyses at early time points after Ezh2 deletion revealed enhanced functionality of effector CD4 and CD8 populations, as evidenced by increased IFN-γ production.
more directly address this hypothesis, we generated mice that harbored both Ezh2-deficient and wild type Treg cells and observed anti-tumor activity similar to mice that exclusively harbored Ezh2-deficient Treg cells. In stark contrast to Ezh2 deficiency, mice whose Treg cells were completely depleted, using a Foxp3-driven diphtheria toxin receptor allele, were unable to reject tumors, further supporting a dominant role for Treg cells in driving tumor immunity. Finally, tumor protection in the presence of Ezh2-deficient Treg cells occurred without significant morbidity due to autoimmune pathologies, which were prevalent in mice with systemic Treg cell depletion. These results suggest that targeted deletion of Ezh2 in Treg cells drives a unique phenotype among tumor infiltrating Treg cells, reprogramming the tumor microenvironment and selectively augmenting the anti-tumor immune response. Cancer therapies that allow the selectively inhibiting Ezh2 to targeted tumor cells are under investigation, going forward it will also be important to assess the potential for beneficial effects via modulating the immune response.

Immunotherapy is a new pillar of cancer therapy. One theoretical advantage of immunotherapy of cancer is that effector cells induced at one site should be able to kill metastatic cancer cells in other sites or tissues. On the other hand, it has been recognized that each tissue has unique immune components that play critical roles in protection against pathogens. However, very little is known whether effector T cells induced against tumors in one tissue can work against the same tumors in other tissues. To address this question, we compared the effect of effector cells induced against the same tumor growing in either the lung or the skin by using CT26 murine tumor models. Rejection of s.c. CT26 tumors was achieved by pretreatment with anti-CD25, which blocks the function of Treg cells. Both CD4 and CD8 T cells were necessary for the protection. When anti-CD25-pretreated mice challenged with s.c. CT26 were simultaneously injected, i.v. with CT26, they also rejected tumors in the lung, while anti-CD25-pretreated mice without s.c. CT26 did not. This observation suggested that T cell mediated anti-tumor protective immunity induced against s.c. tumors can also protect against lung metastases of the same tumors. In contrast to Treg depletion which allowed for the induction of protective immunity in the s.c. tumor model, NKT cell deficiency in CD1d KO mice induced significant CD8 T cell-mediated protection against lung metastasis of CT26 but had no effect on the growth of s.c. CT26 tumors. When CD1d KO mice rejecting s.c. CT26 were simultaneously challenged with s.c. CT26, the development of s.c. tumors was not affected, indicating that tumor rejection induced against the CT26 in the lung did not confer protection for the same tumor cells in the skin. Since the protection against CT26 in the lung in CD1d KO mice is mediated by CD8 T cells, we transferred T cells from CD1d KO mice inoculated i.v. with CT26 into RAG1 KO recipients, and challenged the recipient mice with the CT26 tumor cells. The recipient RAG1 KO mice were growing s.c. tumors of either CT26 inoculated or not. s.c. tumors grew in the RAG1 KO mice even if the T cells were derived from CT26 inoculated mice. This observation suggested that the CD8 T cells protective in the lung are not protective in the skin. These data indicate the effector cells against the same tumor do not work in all tissues, and the induction site of the effector cells is critical to control metastasis.

#1016 Evaluation of progression associated neoepitopes and immune contexture in pulmonary premalignancy. Kostyantyn Krysan, Linh M. Tran, Brandon S. Grimes, Tonnya C. Walser, William D. Wallace, Steven M. Dubinett. UCLA David Geffen School of Medicine, Los Angeles, CA.

Lung cancer is the leading cause of cancer death in the US and in the world. Over the past 30 years, the five-year survival rate for lung cancer has increased by only 5%. With the widespread implementation of screening programs, detection of premalignant and early stage disease is increasing. A better understanding of genomic alterations and the microenvironment across the spectrum of early disease could lead to identification of progression-associated mutations (PAMs), defined as those shared between premalignant lesions and invasive cancer, and their neoepitopes. Unleashing the immune response against pulmonary premalignancy could transform therapy and outcomes. FFPE tissue blocks from patients with resected lung adenocarcinoma (ADC) were obtained from the UCLA Lung Cancer Tissue Repository. For each patient, the following regions were dissected from formalin-fixed paraffin-embedded tissue slides using Laser Capture Microdissection: a) normal airway epithelial cells (1-3 regions), b) premalignant atypical adenomatous hyperplasia (AAH, 2-4 regions), c) adenocarcinoma in situ (AIS, when present) and d) ADC, 1-3 regions followed by whole exome sequencing. Forty-one complete cases have been sequenced to date. Our data suggest that premalignant lesions from the same patient may a) have different mutational profiles and b) bear progression-associated mutations, common with the primary lung tumor. This inter-lesion heterogeneity suggests that a progression-associated mutational landscape could be defined in longitudinal studies of pulmonary premalignancy which will be the focus of future investigations. Next, utilizing the mutational data, we performed in silico neoantigen analysis to identify potential neoepitopes among the genes mutated in premalignant lesions. The neoantigen analysis demonstrated that among the top 11 peptides with high binding avidity for autologous MHC, 9 were derived from PAMs. This suggests that neoepitopes exist in premalignancy that could serve as targets for immunotherapy.

#1017 Lipid metabolic reprogramming drives resistance to PD1 blockade. Maria A. Cortez, Sharaareh Niknam, Efrosini Cuko, Jonathan E. Schoenhals, Hampartsoum Basoumian, Ahmed I. Younes, Aliin Li, Jody V. Vyvkoukal, Cristina Ivan, George A. Calin, Patrick Hwu, James W. Welsh. UT MD Anderson Cancer Ctr., Houston, TX.

The mechanisms underlying immunosuppression and resistance to PD1 inhibitors are not well understood. We attempted to fill this gap with an integrated analysis of mRNA, microRNA, and protein expression in an anti-PD1-resistant lung adenocarcinoma mouse model. The model was created by in vivo passage of 344SQ murine lung cancer cells (p53R161H/β2M−/−, KrasG12D+) in a syngeneic host repeatedly dosed with anti-mouse PD1 antibodies. Anti-PD1-resistant 344SQ (344SQ_R) and 344SQ parental (344SQ_P) cells were then inoculated into syngeneic 129SvEv mice, which were then dosed twice with anti-PD1 or control IgG antibodies. Tumor tissues were collected and analyzed as follows: transcriptionome with Affymetrix; protein levels by reverse phase protein array analysis; signature enrichment by gene set enrichment analysis; metabolome by mass spectrometry; and lipid content with fluorescent probes Oil Red O and BODIPY. We also isolated tumor-infiltrating immune cells for flow cytometry and gene expression analyses. We identified lipid-related metabolic pathways as being the most highly enriched in anti-PD1-resistant tumors (344SQ_R) vs. their 344SQ_P counterparts; the resistant cells also had more lipid droplets than the 344SQ_P cells. The anti-PD1-resistant tumors overexpressed several genes involved in lipogenesis and fatty acid pathways (e.g., fatty acid binding proteins [FABPs], fatty acid synthase, acetyl-CoA-acyltransferase 2, fatty acid elongases). Specifically, FABP overexpression promoted fatty acid uptake and lipid-droplet accumulation in resistant tumors. Lipid-sensitive targets linked to inflammation and insulin signaling (e.g., stress-activated kinases such as JNK and NFκB) were altered in 344SQ_R vs. 344SQ_P tumors. Mechanistically, JNK downregulation by NFκB-regulated microRNAs protected PD1-resistant tumors from lipotoxicity caused by FABPs upregulation and fatty acid uptake. FABP levels were higher in plasma from 344SQ_R than from 344SQ_P tumors. Tumor infiltrating macrophages from anti-PD1 resistant tumors had a correspondingly higher percentage of M2-like macrophages. 344SQ_R tumors promoted immune suppressive cells by upregulating FABP's expression in M2-like macrophages, marked by increased fatty acid intake and fatty acid oxidation. Conversely, percentages of CD14+ and CD68+ tumor infiltrating lymphocytes were reduced in the resistant tumors. These results suggest that lipid metabolic rewiring drives resistance PD1 inhibitors supporting the accumulation of immunosuppressive cells, including M2-like macrophages, preventing type I immune responses elicited by T cells. Collectively, these findings reveal new potential lipid-related targets for drug development or new treatments combining inhibitors of these targets with anti-PD1 therapy.
IMMUNOLOGY: Novel Insights into Mechanisms of Response to Immunotherapy

Previous microbiome studies at the genus level have described altered microbiota in head and neck squamous cell carcinoma (HNSCC), both in terms of taxonomic composition and metabolic capacity. We applied high-resolution microbiome profiling (Resplora Insight) to analyze 16S rRNA sequencing data in saliva and tissue samples from HNSCC patients and healthy controls. DNA extraction and amplicon library preparation was performed for saliva samples from HNSCC (n=38) and controls (n=25), as well as tissue samples from HNSCC (n=25) and controls (n=8). Raw sequences were processed for quality and length, screened for chimeras and filtered for contaminant human and chloroplast DNA. High-quality passing sequences were submitted to Resplora Insight for species-level taxonomic assignments, and potential associations were analyzed with DESeq2. Samples from a subset of HNSCC patients were significantly enriched with commensal species from the vaginal flora, including Lactobacillus gasseri/ johnsonii (710x higher in saliva and 1900x higher in tissue) and Lactobacillus vaginalis (52x higher in saliva). These species were not observed in normal saliva or tissue samples from Hopkins patients (n=33) nor in normal saliva samples (n=292) from the Human Microbiome Project (HMP). Interestingly, both species were only observed in saliva from Human Papilloma Virus positive (HPV+) and HPV negative (HPV-) oropharyngeal cancer patients, and we confirmed their representation in vaginal samples from the HMP (n=249). We also found that Fusobacterium nucleatum (F. nucleatum), an oral flora commensal bacterium linked to colon cancer, is enriched (9x higher in saliva and 11x higher in tissue) in a subset of HNSCC patients with advanced tumors (T3 or above). F. nucleatum was detected in samples obtained before and after treatment with chemothera- bition, but not with surgery alone. Interestingly, we identified upregulation of the oncogenic Wnt/Beta catenin pathway (Wnt7B, FZD6, SFRP4) and down regulation of immune system pathways (TLR10, IRF8) with genome-wide mRNA arrays (Affymetrix) in HNSCC samples enriched for F. nucleatum. Using fluorogenic quantitative PCR we confirmed that F.nucleatum and Fusobacterium spp. are enriched in saliva samples collected prior to treatment in another cohort of HNSCC patients, and in post-treatment saliva samples obtained from HNSCC patients treated with PD-1 checkpoint blockade. We also found enrichment of HPV+ oropharyngeal tumors with F. nucleatum and Fusobacterium spp., prior to therapy, while some recurrent HPV- oropharyngeal tumors are enriched only with Fusobacterium spp. Together, these results suggest that bacteria may impact therapy in HPV+ and HPV- oropharyngeal and oral cavity cancer by altering oncogenic and immune system pathways.

**#1019 In vivo CRISPR screening identifies Ptpn2 as a target for cancer immunotherapy.**

Robert T. Manguso, Hans W. Pope, Margaret D. Zimmers, Flavion D. Brown, Kathleen B. Yates, Brian C. Miller, Natalie B. Collins, Kevin Bi, Martin W. Lafleur, Vikram R. Juneja, Sarah A. Weiss, David E. Fischer, David E. Root, Arlene H. Sharpe, John G. Doench, Nicholas Haining, Dana-Farber Cancer Institute/Harvard Medical School, Boston, MA; Harvard Medical School, Boston, MA; Massachusetts General Hospital, Boston, MA; Broad Institute of Harvard and MIT, Cambridge, MA.

Despite the dramatic clinical success of cancer immunotherapy with PD-1 checkpoint blockade, most patients don’t experience sustained clinical benefit, suggesting that additional therapeutic strategies are needed. Functional genomic screens in cancer cells to discover new therapeutic targets are usually carried out in vitro where interaction with the immune system is absent. Here we report a pooled, loss-of-function genetic screening approach using CRISPR/Cas9 genome editing that is conducted in vivo in mouse transplantable AML models treated with vaccination and PD-1 checkpoint blockade. We tested 2,400 genes expressed by melanoma cells for those that synergize with or cause resistance to checkpoint blockade, and recovered the known immune evasion molecules, PD-L1 and CD47. Loss of function of multiple genes required to sense interferon-y caused resistance to immunotherapy. Deletion of Ptpn2, a pleotropic protein tyrosine phosphatase improved response to immunotherapy. In vivo, Ptpn2 deficient tumors showed increased infiltration of activated CD8+ T cells. In vitro, Ptpn2 loss by tumor cells increased antigen presentation to T cells. Biochemical, transcriptional and genetic epistasis experiments demonstrated that loss of function of Ptpn2 sensitizes tumors to immunotherapy by enhancing interferon-y-mediated effects on the tumor cell. Thus, augmenting interferon-y signaling in tumor cells could increase the efficacy of immunotherapy. More generally, in vivo genetic screens in tumor models can identify new immunotherapy targets and rationally prioritize combination therapies.

**#1020 BRD9 defines a novel mammalian SWI/SNF (BAF) complex configuration which supports proliferation in AML.**

Brittany C. Michl, Joshua Pan, Robin M. Meyers, Paola Grando, Phillip G. Humphreys, Neil G. Garrett, Rab K. Prinja, Cigall Kadoch, Dana-Farber Cancer Institute and Harvard Medical School, Boston, MA; Broad Institute of MIT and Harvard, Boston, MA; Cellzome, Heidelberg, Germany; GlaxoSmithKline, Hertfordshire, United Kingdom.

Genes encoding subunits of the mammalian SWI/SNF (BAF) ATP-dependent chromatin remodeling complexes are mutated in over 20% of human cancer. Specific subunits are mutated in specific malignancies, highlighting their tissue-specific protective roles; moreover, synthetic lethal screens have uncovered genetic- and lineage-based features which confer dependence on specific mSWI/SNF subunits. As combinatorial complexity represents a major challenge, identification of specialized mSWI/SNF configurations, subunit-specific functions, binding restrictions, and exclusivity relationships is critical for understanding oncogenic mechanisms and for the selection of appropriate therapeu- patic agents targeting mSWI/SNF complex subunits. Here, we discover that BRD9, a recently identified mSWI/SNF complex subunit, defines a unique complex configuration distinct from BAF and PBAF, which we term non-canonical BAF, or nCBaf. We used biochemical methods to isolate BRD9-containing complexes and find that BRD9 selectively marks a sub-stoichiometric group of mSWI/SNF complexes of smaller molecular weight that lack several members of canonical BAF complexes such as BAF47 and ARID1A. Moreover, chemoproteomusing BRD9 binds to and inhibits the non-CBAF specific or PBAF-specific subunits, including the highly related bromo- domain-containing subunit BRD7. We further identified regions of BRD9 and BRD7 that confer specificity of these subunits to nCBaf and PBAF complexes, respectively, resolving their mSWI/SNF binding domains. Using genome-wide ChiP-seq and RNA-seq experiments, we determined that nCBaf complexes target a distinct subset of all mSWI/SNF complex target genes and, consistent with previous studies, maintain proliferation of AML cells. Finally, we applied a newly- generated approach to deriving functional relationships within and between protein complex families from shRNA and CRISPR-based genetic screening datasets across hundreds of cancer cell lines to explore nCBaf-specific subunits. We find that nCBaf-specific complex subunits form a distinct functional module, supporting biochemical studies and pointing to the specific and divergent functions of the nCBaf configuration. Cancers of hematologic origin collectively exhibit the most significant responses to perturbation of three nCBaf subunits including BRD9, substantiating previous small molecule screening ef- forts using BRD9 bromodomain inhibitors. These data demonstrate that nCBaf complexes represent a novel BAF complex composition with distinct function in cancer.

**#1021 Mutations in SWI/SNF chromatin remodelling complex sensitizes tumors to OXPHOS inhibition.**

Yonathan Lissannu Deribe.

UT MD Anderson Cancer Ctr., Houston, TX.

Recent large-scale cancer genomic studies have established a framework in which biological functions and genetic interactions of established and novel cancer genes can be explored. One of the major findings of these studies has been the discovery of frequent genetic alterations in chromatin and epigenetic regulators including inactivating mutations in components of the SWI/SNF chroma- tin remodeling complex. In lung adenocarcinoma in particular, a quarter of tumors have inactivating mutations in the SWI/SNF components Smarca4, ARID1A or the histone modifer SETD2. With the aim of understanding the mechanism of tumor development and identifying potential vulnerabilities of SWI/SNF mutant tumors, we developed a genetically engineered mouse model (GEMM) of lung adenocarcinoma by selectively ablating Smarca4 in the respira- tory epithelium. We demonstrate that Smarca4 acts as a bona fide tumor suppressor and cooperates with p53 loss. Cross species integrative gene expression analyses revealed signatures of enhanced oxidative phosphorylation and reactive oxygen species (ROS) response in Smarca4 mutant murine and human lung tumors. We further show that Smarca4 mutant cells have increased oxygen consumption, enhanced basal and maximal respiratory capacity and production of ROS. This is primarily driven by activation of the mitochondrial master reg- ulator PGC1alpha. Finally, we show that Smarca4 and other SWI/SNF mutant lung cancer cell lines have exquisite sensitivity to inhibition of oxidative phos- phorylation using a novel small molecule that is under development. These findings provide a mechanistic basis for further development of OXPHOS inhib- itors as therapies in SWI/SNF mutant tumors.
**MOLECULAR AND CELLULAR BIOLOGY / GENETICS: Chromatin Structure and Function**

### #1022 Chromatin remodeler HELLs is an epigenetic driver for hepatocellular carcinoma progression.

Chen Ting-Law, Larry L. Wei, Felice HC Tsang, Iris MJ Xu, Robin KH Lai, Daniel WH Ho, Joyce MF Lee, Carmen CL Wong, Irene OL Ng, Jack CM Wong. The State Key Laboratory for Liver Research. The University of Hong Kong, Hong Kong Island, Hong Kong.

HELLs is a nuclear chromatin remodeling protein that is frequently overexpressed in human cancers including hepatocellular carcinoma (HCC). In the present study, we applied a global computational approach integrating whole genome sequencing (WGS), ChIP-seq, and RNA-seq to investigate the expression of chromatin remodelers in human HCCs. We found that HELLs, a SWI2/SNF2 chromatin remodeling enzyme, is remarkably overexpressed in HCC. Overexpression of HELLs was correlated with more aggressive clinicopathological features and poorer patient prognosis. We further showed that up-regulation of HELLs in HCC was confered by hyper-activation of transcription factor SP1. To investigate the functions of HELLS in HCC, we generated both gain- and loss-of-function lines by CRISPR activation and repression systems, respectively, in the HELLS gene via CRISPR/Cas9 genome editing system. We demonstrated that overexpression of HELLS augmented HCC cell proliferation and migration. In contrast, depletion of HELLS reduced HCC cell growth and motility. Moreover, inactivation of HELLS induced apoptosis in HCC cells. Coherently, ablation of HELLS also mitigated tumorigenesis and lung metastasis in vivo as demonstrated with both subcutaneous and orthotopic tumor implantation models. Mechanistically, by using RNA-seq and MIne-seq, we revealed that HELLS controls the nucleosome occupancy at gene enhancer and transcription start site (TSS). Overexpression of HELLS increased nucleosome occupancy that obstructed the accessibility of enhancers and hindered the formation of nucleosome-free region (NFR) at TSS of its target genes, thereby blocks the binding of transcription factors for activating gene expression. Consequently, though this mechanism, up-regulation of HELLS mediated epigenetic silencing of multiple tumor suppressor genes including E-Cadherin, FB1P3, XAF1 and CREB-H in HCC. In conclusion, our data unravel that HELLS is a key epigenetic driver of HCC. By altering the nucleosome occupancy at NFR and enhancer, HELLS epigenetically suppresses numerous tumor suppressor genes to promote HCC progression.

### #1023 Activation of proto-oncogenes by enhancer-hijacking in high-risk neuroblastoma.

Daniel Dreidax,1 Moritz Garlgruber,1 Sebastian Steinhauser,1 Larisa Savelyeva,1 Ron Schwessinger,1 Umut Toprak,1 Nati Ha,1 Dilafruz Ju-raeva,1 Martin Peifer,1 Matthias Fischer,2 Stefan Gröschl,1 Kai-Oliver Henrich,1 Young-Gyu Park,1 Benedikt Brors,1 Matthias Schlesner,1 Carl Herrmann,1 Frank Westermann,1 German Cancer Research Center (DKFZ), Heidelberg, Germany; 2University of Cologne, Cologne, Germany.

Background: Neuroblastoma (NB), a neural crest-derived tumor of the sympathetic nervous system, is the most common extracranial solid tumor in children. We have previously shown that genomic rearrangements activate proto-oncogenic telomerase by juxtaposing active enhancer elements to the TERT gene in a large fraction of high-risk NBs. In the present study, we applied a global approach integrating whole genome sequencing (WGS), Chromatin immuno-precipitation sequencing (ChIP-seq) and RNA sequencing (RNA-seq) data of NB cells and tumors to identify further key oncogenes activated by enhancer-hijacking in NB. Methods: WGS was applied to search for structural rearrangements in 120 NB tumors and five NB cell lines. Corresponding RNA-seq data were used to discover mono-allelic and/or outlier expression of candidate genes potentially involved in enhancer hijacking events. ChIP-seq of 34 NB tumors and 17 NB cell lines was applied to identify the enhancer elements in NB. Circular chromatin conformation capture sequencing (4C-seq) was used to confirm physical promoter-enhancer interactions in NB cell lines. Results: WGS analyses revealed that chromosomal rearrangements are common events in NB tumors and cell lines and frequently affect regions harboring proto-oncogenes and lineage specific enhancers. ChIP-seq analyses of the chromatin mark histone 3 lysine 27 acetylation (H3K27ac), surrogate for enhancer activity, confirmed that these rearrangements recurrently juxtapose active enhancer elements to oncogenes including MYCN and MYC in NB. Intriguingly, quantification of H3K27ac ChIP-seq profiles uncovered that the enhancer elements translocated to MYC were among the most active ones within the respective epigenomes. 4C-seq analyses proved physical interactions between translocated enhancer elements and promoters of the respective oncogenes, which is in line with their elevated expression in rearranged cases. Conclusions: Our study reveals that structural rearrangements in high-risk neuroblastosoma frequently juxtapose strong enhancers to key oncogenes, including MYCN and MYC. This represents a novel and important mechanism by which overexpression of the oncogenes observed in rearranged cases. The common mechanism of oncogene activation by enhancer-hijacking may open a therapeutic window for epigenetic drugs including BET or CDK7 inhibitors in high-risk NBs.

### #1024 Genome-wide examination of topological variability reveals cell-type-specific mechanisms of oncogene activation.

Caleb Lareau, Martin Aryee, Harvard University, MA.

INTRODUCTION: The organization of chromatin within the nucleus into hierarchical three-dimensional (3D) structures plays a key role in the regulation of gene expression. Differences in 3D architecture, such as the presence or absence of “loops” between specific enhancers and their target genes, are a major driver of transcriptional and phenotypic variation. By determining the accessibility of genes to transcriptional machinery and distal regulatory regions, mechanisms mediating oncogene activation can be discerned. Recent studies have implicated pathogenic alterations in genome topology with the activation of proto-oncogenes in a multitude of cancers. METHODS: To characterize the topological changes associated with different cancer states, we developed a computational suite of tools that facilitates the systematic discovery, annotation, and visualization of features in chromatin topology and assigns statistical confidence estimates to regions with variability between cellular phenotypes. Our framework facilitates the integration of heterogeneous genomic data, including gene expression, histone modification, DNA methylation, open chromatin, and genomic variation, to further characterize changes in 3D genome. Ultimately, we propose a joint model that functionalizes the effect of epigenetic modifications on transcription as mediated through hierarchical chromatin structure. RESULTS: We identify regions of topological variation unique to breast cancer, cervical cancer, glioblastomas and with and without an IDH1 mutation, melanoma, and leukemia. Patterns of disrupted insulation and subsequent localization of enhancers to proto-oncogenes can be attributed to variation in the epigenome, including variation in DNA methylation and open chromatin, at distal regulatory regions. These 3D alterations provide a mechanism for activation of specific oncogenic pathways, including signaling mediated by p38, PI3K, and BRCA CONCLUSIONS: Variable patterns of chromatin topology provide a unique signature and mechanism of oncogenes for the cancer phenotypes considered. Additionally, our framework provides a novel means for interpreting epigenetic variability, particularly at distal regulatory regions, and explaining transcriptional variation associated with cancer phenotypes as mediated through structural changes in the DNA.

### #1025 Controlled and endogenous depleton of a synthetic lethal target in human cancer cell lines via SMASH degron engineering.

The SWI/SNF (NuRD) chromatin remodeling complexes play an important role in regulating processes such as gene transcription through ATP-dependent remodeling of chromatin. The importance of this role is highlighted by the prevalence of mutations in various SWI/SNF subunits across approximately 20% of cancers encompassing various lineages and subtypes. Functional genomics screening via pooled shRNAs has led to the discovery of distinct vulnerabilities of SWI/SNF mutant cancers to loss of mutually exclusive subunits. In particular, cancer cells with BRG1 loss become exquisitely dependent on the remaining BRG1 counterpart, BRM. To further understand the synthetic lethal relationship between BRM and BRG1, we have adapted a recently described degron, the small molecule assisted shutoff (SMASH) tag, showing for the first time the ability to apply this system to control endogenous levels of target protein, in this case BRM. We used the SMASH tag to target the endogenous BRM locus in both a BRG1 wild-type and mutant cancer cell line. Using these engineered cell lines, we were able to show that we can achieve tunable protein levels by varying the concentration of the effector molecule. The ability to tune BRM depletion allowed us to investigate the nature of the BRG1/BRM synthetic lethal relationship. Our data interestingly suggests that while modest depletion of BRM is sufficient to observe changes in the expression of a target gene regulated by SWI/SNF in a dose-dependent manner, a higher level of BRM depletion is required to elicit a growth arrest phenotype in the BRG1-mutant non-small cell lung cancer line. Together these results uncover a novel relationship between the catalytic SWI/SNF subunit and gene expression, where we find that the latter responds in a dose-dependent manner.
dependent manner to BRM levels. Additionally, we elucidate the level of BRM depletion required to observe the synthetic lethal phenotype, providing insight and informing on strategies for therapeutic targeting whether by protein degradation approaches, such as PROTAC, or other small molecule approaches. Finally, having provided a proof-of-concept, such tools can be readily adapted for application to endogenous degradation of other target proteins in different systems.

#1026 Development of orthotopically grafted organoid models to study vulnerabilities. Jingwen Zhang,1 Brandon Willis,1 Maureen Hattersley,1 Alan Lau,2 Corinne Reimer,1 Michael Zinda,1 Stephen Fawell,1 Gordon Mills,1 Austin Dulak,1 Huawei Chen,1 AstraZeneca Pharmaceuticals, Waltham, MA; AstraZeneca Pharmaceuticals, Macclesfield, United Kingdom; 1The University of Texas MD Anderson Cancer Center, Houston, MA.

BRD4 is a member of the BET (bromodomain and extraterminal domain) family of chromatin readers that recognize acetylated-lysines on histones and nuclear proteins. Previous reports have demonstrated that select cancers depend on BRD4 to regulate oncogenic gene transcriptional programs. However, whether BRD4 contributes to cancer malignancy through other mechanisms has not been extensively evaluated. Here, we show that BRD4 is important for maintaining an intact DNA replication checkpoint in cancers. Displacement of BRD4 by BET bromodomain inhibitor AZD5153 in cell lines under intrinsic or exogenous replication stress led to a time-dependent reduction in phospho-Chk1 first detected within 30 minutes, and reaching maximum phospho-Chk1 inhibition (~85%) at an hour after AZD5153 treatment in U2OS cells. The decrease in Chk1 phosphorylation was observed without a concomitant decrease in total Chk1, and this was not replicated by treatment with pan-transcriptional inhibitors, suggesting a non-transcriptional mechanism linked to BRD4. Furthermore, BRD4 interacts with the DNA pre-replication complex and inhibition of BRD4 leads to hyperactivation of the pre-replication complex and aberrant DNA replication re-initiation under replication stress conditions. Consistent with a role in S-phase signaling, BETi treatment sensitizes replicating cells to replication stress-inducing agents. Finally, we observed that ovarian cancer cell lines are highly-sensitive to the combined inhibition of BRD4 and ATR. Co-administration of AZD5153 and AZD6738 (ATR inhibitor) significantly inhibited tumor growth in OVCAR3 ovarian xenograft model (TGI after 21 day dosing: AZD5153, 52%; AZD6738, 46%; Combo, 84%). Sustained tumor growth delay was observed after combination treatment cessation. Together, our study uncovered a novel function for BRD4 in regulating DNA replication stress response, and provide mechanistic rationale for combining BETi with DNA damage-targeted agents for cancer therapies.

MOLECULAR AND CELLULAR BIOLOGY / GENETICS: Chromatin Structure and Function

#1027 Genetic disruption of Kras sensitizes lung cancer cells to Fas-mediated apoptosis. Haiwei Mou,1 Jill Moore,2 Sunal Malonjia,1 Yingxiang Li,1 Deniz Ozata,1 Soren Hough,1 Chunqing Song,1 Jordan Smith,1 Has Yin,2 Andrew Fisher,1 Daniel Anderson,2 Shipping Weng,1 Michael Green,1 Wen Xue1,1 Univ. of Massachusetts Medical School, Worcester, MA; 1David H. Koch Institute for Integrative Cancer Research, Massachusetts Institute of Technology, Worcester, MA.

Genetic lesions that activate KRAS accounts for ~30% of the 1.6 million annual cases of lung cancer. Despite clinical need, KRAS is still undruggable using traditional small molecule drugs/inhibitors. When oncogenic KRAS is suppressed by RNA interference, tumors initially regress but eventually recur and proliferate despite suppression of Kras. Here we show that tumor cells can survive CRISPR-mediated knockout of oncogenic Kras, indicating the existence of Kras-independent survival pathways. Thus even if clinical KRAS inhibitors were available, resistance would remain an obstacle to treatment. Kras-independent cancer cells exhibit decreased colony formation in vitro but retain the ability to form tumors in mice. Comparing the transcriptomes of oncogenic Kras cells and Kras knockout cells, we identified 603 genes that were specifically upregulated in Kras knockout cells, including the Fas gene, which encodes a cell surface death receptor involved in physiological regulation of apoptosis. Antibodies recognizing Fas receptor efficiently induced apoptosis of Kras knockout cells but not oncogenic Kras expressing cells. Increased Fas expression in Kras knockout cells was attributed to decreased association of repressive epigenetic marks at the Fas promoter. Concordant with this observation, treating oncogenic Kras cells with histone-deacetylase inhibitor and Fas-activating antibody efficiently induced apoptosis, thus bypassing the need to inhibit Kras. Our results suggest that activation of Fas could be exploited as an Achilles’ heel in tumors initiated by oncogenic Kras.

MOLECULAR AND CELLULAR BIOLOGY / GENETICS: Oncogenes and Tumor Suppressors 1: Function and Therapeutic Vulnerabilities

#1029 Development of orthotopically grafted organoid models to study pancreatic cancer progression. Chang-Ii Hwang,1 Eunjung Lee, Brandon Da Silva, Kevin Wright, Youngkyu Park, David A. Tuveson. Cold Spring Harbor Laboratory, Cold Spring Harbor, NY.

Pancreatic ductal adenocarcinoma (PDA) is one of the most difficult human malignancies to treat. The 5-year survival rate of PDA patients is 7% and PDA is predicted to become the second leading cancer-related cause of death in the USA. A subset of potential tumor suppressor genes was identified by genome-wide analysis of human PDA and insertional mutagenesis in genetically engineered mouse models (GEMMs). Since the functional validation of these genes in GEMMs is time-consuming and labor-intensive, we have developed a rapid and efficient ‘orthotopically grafted organoid’ (OGO) model in conjunction with RNAi and CRISPR/Cas9 technologies to study PDA progression. Previously, we showed that OGO model represents the full spectrum of PDA progression in vivo and respond to orthotopic engraftment. Here, as a proof-of-concept experiment, we demonstrate that ablation of Trp53 by viral introduction of shRNA or gRNA in PanIN-derived organoids accelerates PDA progression upon transplantation. In addition, we engineered tetracycline-inducible shRNA against Trp53 in ColA1 locus to rescue the orthotopic grafted organoids derived from Kras\(^{+/+}\); Rosa26-rTatA; ColA1-homing cassette mouse. Orthotopic transplantation followed by doxycycline administration resulted in rapid PDA progression with metastases. Isolated tumor organoids were re-transplanted to evaluate the effect of p53 restoration in PDA progression. Restoration of p53 by doxycycline withdrawal led to reduced liver metastases, although there was no difference in survival and primary tumor growth. This will provide a new insight how p53 regulates PDA metastasis. Therefore, OGO models should provide an excellent platform to study the functional role of genes in PDA progression in vivo.
#1030 Metabolic reprogramming caused by mutations of the Fbw7 ubiquitin ligase in colorectal cancer. Ryan J. Davis,1 Mehmet Gonen,2 David Hockenbury,1 Adam Margolin,2 Bruce E. Clurman1.1 Fred Hutchinson Cancer Research Ctr., Seattle, WA; 2Oregon Health Sciences University, Portland, OR.

Fbw7 is an evolutionary conserved F box protein that functions as a substrate adapter for the Skp1-Cullin 1 F box (SCF) E3 ubiquitin ligase complex. Fbw7 is also a tumor suppressor gene that is mutated in diverse human cancers. Many Fbw7 substrates are oncogenic transcription factors, including c-Myc, Notch, and Jun. Cancer-associated Fbw7 mutations diminish its ability to interact with substrates, resulting in inappropriate oncoprotein accumulation. One of the significant challenges for understanding the consequences of Fbw7 mutations in tumors is that Fbw7 coordinately regulates approximately two dozen broadly-acting transcription factors. To address this problem, we used novel computational methods to analyze TCGA gene expression datasets to derive transcriptional signatures that could predict a tumor’s Fbw7 mutational status; these signatures were then verified by enrichment of genes involved in biological processes. We found that genes associated with mitochondrial function were highly predictive of Fbw7 mutations across several tumor types, suggesting that metabolic reprogramming is a crucial oncogenic consequence of Fbw7 mutations. We validated this prediction by creating isogenic colorectal cancer cells with normal or mutant Fbw7 alleles. We found that mitochondrial signature genes are elevated in Fbw7 mutant cells, which also exhibit increased oxidative metabolism. Moreover, metabolomic studies revealed deregulation of other metabolic pathways in Fbw7-mutant cells, including amino acid and nucleotide biosynthesis. These data suggest that metabolic vulnerabilities may represent novel therapeutic targets in Fbw7-associated cancers.

#1031 Nuclear relocalization of NPM1c induces terminal differentiation and cell growth arrest. Lorenzo Brunetti,1 Michael C. Gundry,1 Anna G. Guzman,1 Ilaria Gionfriddo,2 Brunangelo Falini,2 Margaret A. Goodell1.1 Memorial Sloan Kettering Cancer Center, New York, NY; 2University of Perugia, Perugia, Italy.

NPM1 mutated acute myeloid leukemia (AML) is a distinct entity in the WHO classification of hematopoietic cancers. It displays a specific phenotype characterized by favorable prognosis and upregulation of HOX cluster genes. NPM1 is a multifunctional nuclear chaperone. Mutations in NPM1 result in cytoplasmic protein localization (NPM1c+) through the acquisition of a nuclear export signal (NES) at the C-terminus. The most frequent NPM1 mutation is a heterozygous 4bp insertion in exon 12 (mutA). The role of NPM1 in leukemogenesis is still a matter of debate and there is no direct proof that cytoplasmic localization of mutant NPM1 is necessary for OCI-AML3 cells to maintain their leukemic phenotype. Drugs promoting mutant NPM1 nuclear localization such as CRML inhibitors are attractive candidates for clinical success in NPM1-mutated AML.

#1032 Identification of Ran binding protein 6 as a novel negative regulator of EGFR and candidate tumor suppressor in glioblastoma. Wan-Ying Hsieh,1 Barbara Oldrizzi,2 Hedye Erdjument-Bromage,3 Paolo Codecà,1 Maria S. Carro,4 Igor Vivanco,3 Dan Roble,1 Carl Campos,1 Craig Bielski,1 Barry Taylor,1 Paul Tempst,1 Massimo Squatrito,4 Ingo K. Mellingerhoff1.1 Memorial Sloan Kettering Cancer Center, New York, NY; 2Spanish National Cancer Research Centre, Madrid, Spain; 3New York University School of Medicine, New York, NY; 4Medical Center University of Freiburg, Freiburg, Germany; 5The Institute of Cancer Research, London, United Kingdom.

Amplification and overexpression of the epidermal growth factor receptor (EGFR) are common in glioblastoma (GBM) and frequently associated with silencing of the phosphatase and tensin homologue (PTEN) tumor suppressor. PTEN silencing has been associated with clinical resistance to EGFR tyrosine kinase inhibitors, in part by raising EGFR levels. Here, we investigated the effect of PTEN on the EGFR signaling complex by EGFR affinity immunopurification and mass spectrometry with and without PTEN knockdown. We identified Ran binding protein 6 (RanBP6), a 125-kDa protein of previously unknown functions, as EGFR interacting protein in PTEN expressing, but not PTEN knocked down cells. Further studies of the effect of RanBP6 on EGFR revealed that RanBP6 depletion by shRNA or CRISPR/Cas9-mediated gene silencing resulted in increased EGFR mRNA levels and up-regulation of EGFR promoter activity. Consistent with a model of a negative EGFR feedback loop, we observed that by RanBP6, we observed a decrease in both EGFR protein and mRNA levels in PTEN wildtype but not PTEN altered cancer cells in a large panel of human cancer cell lines (Cancer Cell Line Encyclopedia). To further understand the mechanism of how RanBP6 negatively regulates EGFR mRNA levels, we found that RanBP6 interacted with nuclear Ran-GTPase and repressed EGFR transcription by promoting nuclear import of signal transducer and activator of transcription 3 (STAT3). Lastly, RanBP6 appeared to frequently deleted on chromosome some 9p in GBM. We showed that RanBP6 silencing raised EGFR levels and signal output and accelerated in vivo glioma growth. Our results establish a novel function of RanBP6 as a link between EGFR signaling and the Ran-mediated nuclear import pathway, and identify RanBP6 as candidate tumor suppressor on chromosome 9p.

#1033 Estrogen receptor gene fusions drive endocrine therapy resistance in estrogen receptor positive breast cancer. Jonathan T. Lei,1 Jeyya Shao,1 Jin Zhang,1 Michael Iglesias,1 Doug Wan,1 Chan,1 Ryoichi Matsunami,2 Xiaoping He,3 Purba Singh,4 Michael Cundy,1 Anna G. Guzman,1 Ilaria Gionfriddo,2 Brunangelo Falini,2 Margaret A. Goodell1.1 Memorial Sloan Kettering Cancer Center, New York, NY; 2Spanish National Cancer Research Centre, Madrid, Spain; 3New York University School of Medicine, New York, NY; 4University of Perugia, Perugia, Italy.

Although the raison d’être of hormone therapy is the binding of hormones to ERα and ERβ leading to the activation of the ERα and ERβ signaling pathways, the emerging landscape of breast cancer harbouring numerous fusion partners provides an emerging paradigm of ERα/ERβ signal control. Here, we examined the functional properties of fusion proteins containing the C-terminal sequences of YAP1 (ESR1-YAP1) that contributed to endocrine therapy resistance in estrogen receptor positive (ER+) breast cancer models. This current study compares functional and pharmacological properties of additional ESR1 gene fusion events of both early stage (ESR1-NOP2) and advanced estrogen therapy resistant (ESR1-YAP1 and ESR1-PCH11x) breast cancers. The E1P and PCDH11x fusions conferred estrogen-independent and fulvestrant-resistant growth in T47D, an ER+ breast cancer cell line in vitro and in vivo, in contrast to the NOP2 fusion which was sensitive to hormone deprivation. Immunohistochemical (IHC) staining of mouse lungs revealed significantly higher numbers of micrometastatic ER+ cells from the T47D tumors expressing the E1P and PCDH11x fusions compared to those expressing NOP2 fusion. Estrogen response element (ERE) reporter and pull down assays revealed that although all ESR1 fusions studied bound EREs, only the YAP1 and PCDH11x fusions were able to activate ERα and ERβ in hormone deprived conditions. In contrast, the NOP2 fusion neither induced ERE activity nor upregulated TFF1 and GREB1 gene expression. The proliferative ability of canonical fusion-containing T47D cells was inhibited by palbo-
which they are recurrently mutated. KEAP1/NRF2 mutations as predictive biomarkers that could be used for per-
culating tumor DNA. These data suggest that Trp53 and Keap1 mutations in
tation status strongly predicted risk of local recurrence in NSCLC patients
adenocarcinomas (LUADs). Congruous with these findings, KEAP1/NRF2 mu-
ROS pathway activation is the main mediator of Keap1 loss. Finally, Keap1
#1034 Role of KEAP1/NRF2 and TP53 mutations in lung squamous cell

ABSCs play important roles in LSCC initiation and progression and identify
mice treated with CT2063, an FDA approved drug, palbociclib, which could potentially improve outcomes in patients with ESR1 translocated tumors.

TUMOR BIOLOGY: Animal Models of Human Oncogenesis

#1035 Direct evidence for a pro-tumor role of APOBEC3A in cancer ini-
tiation and progression in vivo: enhanced mutagenesis and immune suppress-
ion in a novel humanized autotumoral model of pancreatic cancer. Sonja Woermann,1 Robert Cowan,1 Susan M. Ross,2 Andrew D. Rhim1.1 Stanford University School of Medicine, Stanford, CA; San Francisco State University, CA.

Although lung squamous cell carcinomas (LSCCs) comprise a large fraction of non-small cell lung cancers (NSCLCs), their pathogenesis and cell of origin remain incompletely understood and biomarkers that predict therapeutic response are lacking. Here we describe novel, clinically relevant murine LSCC models driven by inactivation of Trp53 with or without Keap1, both of which are frequently mutated in human LSCCs. Homozygous inactivation of Keap1 or Trp53 promoted airway basal stem cell (ABSC) self-renewal both in vitro and in vivo, suggesting that Trp53 or Keap1 mutations lead to expansion of mutant stem cell clones. Deletion of Trp53 with or without Keap1 in ABSCs, but not more differentiated tracheal cells, produced tumors recapitulating histologic and molecular features of human LSCCs. However, deletion of Trp53 with or without Keap1 in type II pneumocytes (ATII) or bronchioalveolar stem cells (BASCs) produced tumors with the features of adenocarcinoma, indicating that ABSCs represent the likely cell of origin for LSCC in this model. Deletion of Keap1 promoted tumor growth, metastasis and resistance to oxidative stress. N-acetylcysteine (NAC) treatment enhanced tumorsphere formation and me-
tastasis in Keap1mann1/LSCCs, but not in Keap1mann1/LSCCs, suggesting that NRF2-ROS pathway activation is the main mediator of Keap1 loss. Finally, Keap1 deletion induced radiosensitivity in vitro and in vivo in both LSCCs and lung adenocarcinomas (LUADs). Congruous with these findings, KEAP1/NRF2 mu-

#1036 Non-myogenic origin of embryonal rhabdomyosarcoma. Catherine J. Drummond, Matthew R. Garcia, Daniel J. Devine, Jennifer Peters, Victoria Frolich, David Finkelstein, Mark E. Hatley. St Jude Childrens Research Hospi-
tal, Memphis, TN.

Rhabdomyosarcoma (RMS) is the most common soft tissue sarcoma in chil-
dren. Despite aggressive chemotherapy, radiotherapy and surgery, clinical outcomes for RMS have not improved for three decades, emphasizing the need to uncover the molecular underpinnings of the disease. RMS includes two histo-
pathologic subtypes: alveolar RMS, driven by the fusion protein PAX3/7-
FOX01, and embryonal RMS (ERMS), which is genetically heterogeneous. RMS has been presumed to originate from deregulated muscle progenitors based on the histologic appearance and gene expression pattern of the tumors. However, an origin restricted to skeletal muscle does not explain recurring involvement in myocytes of skeletal muscle, such as the prostate, bladder, biliary tree and the omen-
tum. Previously, we showed that activation of Sonic Hedgehog signaling through expression of a conditional, constitutively active Smoothed allele, Smo2, under control of an adipocyte-restricted adipogenic protein 2 (aP2)-Cre recombinase transgene in mice gives rise to aggressive skeletal muscle tumors that display the histologic and molecular characteristics of human ERMS. In this model, tumorigenesis occurs with high penetrance (~80%), is early onset (by 2 months of age), and is restricted to the head and neck. Also, unlike previous RMS models, this model requires no additional background mutations, such as inac-
tivation of p53, and results in only ERMS neoplasia. We illustrated that the gene expression signature of the aP2-Cre;SmoM2 tumors recapitulates both other mouse RMS models as well as human ERMS. With the short latency and ana-
tomic restricted tumor location, we sought to leverage this model to explore the cell of origin. Here, we use genetic fate mapping of aP2-c expression with reporter mice to determine the effect of combining Hedgehog signaling with adult myocyte regeneration. 

#1037 Progression from melanocytic nevi to melanoma is associated with increased genomic mutations in a UV-induced mouse model of human melanoma. Helen Michael, Chi-Ping Day, Howard Yang, Aleksandra Michalowski, Maxwell Lee, Glenn Merlino. National Institutes of Health, Bethesda, MD.

Melanoma is the deadliest form of skin cancer with approximately 132,000 cases worldwide each year. Benign melanocytic nevi are nearly universal, and although progression of nevi to melanoma is very rare, 20-50% of melanoma cases appear to arise from a pre-existing nevi. UV exposure, particularly childhood sunburn, is believed to play an important role in the development of melanocytic nevi and melanoma, but the exact mechanism is unknown. Alterations in MAPK pathway genes, especially NRAS and BRAF, are common in both benign nevi and melanomas.
and melanoma, but approximately 1/3 of melanomas do not have an identified driver mutation. Studying nevus initiation and progression prospectively in the human population is impractical due to the long latency to progression and repeated UV exposures. Our laboratory has developed a hepatocyte growth factor (HGF) genetically engineered mouse model with “humanized” functional distribution of melanocytes on an interstitial cell of Cajal (ICC) background, with melanocytes expressing a specific GFP expression, allowing melanocytic lesions to be tracked through percutaneous GFP imaging. Following a single relevant dose of UV modeling childhood sunburn, HGF IDCT-GFP develop discrete, small melanocytic lesions consistent with nevus formation. Melanomas that arise in the model are heterogeneous and include radial growth phase and vertical growth phase tumors and sometimes metastasize to liver and lung. Exome sequencing of 28 nevi and melanomas show that vertical growth phase melanomas have approximately 3x more mutations than radial growth phase melanomas or nevi. The increased number of mutations in vertical growth phase tumors is due to an increase in C>T transitions despite the lack of additional UV exposure. Interestingly, melanocytic nevi and melanomas with DNA repair pathway mutations average 3x more mutations than lesions without mutations in these pathways. Melanomas sometime contain mutations in hotspot locations from human melanomas, including GNAQ, GNA11, and NRAS. We have a pretransplantation animal model wherein we can potentially involved in the initiation of melanocytic lesions or progression to aggressive melanomas and relevant to human melanoma have been identified and are being functionally tested using CRISPR to introduce point mutations or knockout genes and in vitro skin reconstitution assays. Identification of novel drivers and pathways involved in non-BRAF, non-NRAS melanoma has the potential to uncover biomarkers and new therapeutic targets to improve clinical outcomes for melanoma patients.

**#1038 The KIT-V645A second site mutation confers perinatal lethality and increased oncogenesis in a mouse model of GIST, Jennifer Q. Zhang, Benedikt Bosbach, Cristina Antonescu, Peter Besmer, Ronald DeMatteo. MSKCC, New York, NY.**

Tyrosine kinase inhibitors have revolutionized the treatment of gastrointestinal stromal tumor (GIST), which are mostly driven by mutations in the receptor tyrosine kinase KIT. However, resistance commonly develops, which is associated with second site mutations in KIT. Here, we created the first genetically engineered mouse model of the most common second site mutation, KIT-V645A (mouse KIT-V653A), to study in vivo its oncogenic properties and mechanisms of resistance in order to develop next-generation GIST therapies. The knock-in strategy consisted of inserting into the endogenous murine KIT locus a targeting vector containing both the KitV645A exon 11 mutation and the KitV653A exon 13 mutation under the control of a floxed neoxinrin-resistance gene-expression cassette which acts similar to aloxP-STOP-loxP cassette. Treatments included imatinib 45 mg/kg i.p., sunitinib 40 mg/kg p.o., and caboazinib 60 mg/kg.p.o. Tumors were assessed by histology, immunohistochemistry, and western blot. In contrast to our previously published GIST model with a gene-expression cassette which acts similar to a loxP-STOP-loxP cassette, treatment of mice resulted in cecal GIST development with full penetrance. The tumors were histologically similar to human GIST, stained positive for KIT, and are being functionally tested using CRISPR to introduce point mutations or knockout genes and in vitro skin reconstitution assays. Identification of novel drivers and pathways involved in non-BRAF, non-NRAS melanoma has the potential to uncover biomarkers and new therapeutic targets to improve clinical outcomes for melanoma patients.

**#1039 Disruption of circadian clockwork in in vivo reprogramming induced mouse kidney cancer and human Wilms tumor. Munehiro Ohashi,1 Yasuhiro Umemura,1 Yoichi Minami,1 Hitomi Watanabe,2 Tomoko Tanaka,3 Tsumeharu MikI,3 Osamu UkumIra,4 Tatsuro Tajiri,5 Gen Kodoh,2 Yasuhiro Yamada,2 Kazuhiro Yagita,1,6 Department of Physiology and Systems Bioscience, Kyoto Prefectural University of Medicine, Kyoto, Japan; 2Laboratory of Animal Experiments for Regeneration, Institute for Frontier Medical Science, Kyoto University, Kyoto, Japan; 3Department of Pediatric Surgery, Kyoto Prefectural University of Medicine, Kyoto, Japan; 4Department of Urology, Kyoto Prefectural University of Medicine, Kyoto, Japan; 5Center for iPS Research and Application, Kyoto University, Kyoto, Japan.**

Most organisms have evolved intrinsic circadian clock to optimize their behavior and physiology for diurnal environmental changes. The circadian clock exists not only in the organismal level but also in the peripheral organs and cellular levels, and regulates the various physiological aspects. Among these regulation systems, the relationship between circadian clock and cancer has been enthusiastically investigated in this decade. However, the mechanistic link connecting circadian clock and cancer has not been fully understood. Recently, we have clarified that circadian clock is tightly connected with cellular differentiation using the in vitro mouse embryonic stem cells (ESCs) differentiation model, and in addition, misregulation of differentiation leads to the circadian clock disruption via highly expression of KPN2A and suppression of CLOC protein. On the other hand, it was revealed that altered differentiation leads to cancer. Therefore, we have a presumption in mind that circadian clock disruption is required to help provide significant pathophysiological implications for the relationship of circadian clock and cancer. Firstly, we established Rosa26:M2-MTA Teto-Oskm ES cells carrying circadian rhythm reporter mPer2:2Luc, and generated chimeric mice. The chimeric mice were treated with doxycycline to transient in vivo reprogramming. The Dox treatment induced Wilms tumor-like kidney tumors and we sectioned the kidney tumor for monitoring real time bioluminescence signals, and examined the RNA and protein expression profiles. Here, we showed that the circadian clock was disrupted in the Wilms tumor-like mouse kidney tumor tissues, while the control mouse kidney exhibited the obvious circadian bioluminescence oscillation. And the gene expression signature of the circadian clock development correlated gene set in the tumor was similar to the dysdifferentiation-mediated circadian clock disrupted cells. Moreover, the highly expressed KPN2A and suppression of CLOC protein were also observed in the mouse tumor cells. Next, we examined human Wilms tumor gene and protein expression profiles. Astonishingly, the transcriptional signature of the circadian clock development correlated genes was similar to the mouse kidney tumor induced by dedifferentiation. Furthermore, the protein expression patterns of KPN2A and CLOC coincided with them. These findings suggest that the severely dedifferentiated cancers may lose their circadian clocks and the mechanism is common with the suppression mechanism during differentiation coupled circadian clock development. Moreover, circadian clock functionality may reflect the etiology of cancer development including dedifferentiation and differentiation. As a new prospect, a new view point of the circadian clock may help to evaluate the type of cancer cells, and it leads to more improved therapeutic strategy.

**#1040 LIN28B-mediated let-7 independent activation of AKT promotes neuroblastoma pathogenesis. Ting Tao,1 John T. Powers,2 Hui Shi,2 Pavlos Missios,2 Antonio R. Perez-Atayde,2 Shizhen Zhu,2 George Q. Daley,2 Thomas A. Look1.1 Dana-Farber Cancer Institute, Boston, MA; 2Boston Children’s Hospital, Boston, MA; 3Mayo Clinic, Rochester, MN.**

LIN28B is well known as a RNA-binding protein and a suppressor of microRNA biogenesis, by selectively blocking the processing of let-7 precursor. It plays diverse functions in cellular reprogramming, development, metabolism and tumorigenesis. Many of these functions are executed through its ability to inhibit let-7 maturation. However, little is known about its function independent of let-7. Here we made zebrafish transgenic lines expressing high levels of LIN28B and let-7, which allows us to block let-7 in the peripheral sympathetic nervous system driven by the dopamine beta-hydroxylase promoter. We bred these lines with a transgenic zebrafish line over-expressing the MYCN oncogene in these cells. Either wild-type or mutant LIN28B overexpression accelerated the onset and increased the permeance of MYCN-induced neuroblastoma, despite the fact that only wild-type LIN28B blocked let-7 maturation compared to MYCN-only tumors. Mechanistically, both wild-type and mutant LIN28B overexpression enhanced MYCN-induced hyperplasia by increasing cell proliferation in the sympathoadrenal lineage. Further studies revealed that overexpression of either wild-type or mutant LIN28B resulted in hyperphosphorylation of AKT on both Ser473 and Thr308 in ze-
brazilian tumors and also serum-deprived human neuroblastoma cell lines. Both wild-type and mutant LIN28B interacted with IGF2BP1, a known interactor that increases stability and translation of a subset of RNAs. We found IGF2 RNA levels to be increased in response to either form of LIN28B. Coincident with IGF2 overexpression, IGF1R was phosphorylated, providing an explanation for PI3K-AKT activation in LIN28B overexpressing cells. Finally, overexpression of a constitutively active, myristoylated murine Akt2 (pyr-mAkt2) alone in zebrafish induced ganglioneuroma in the interreginal gland (the zebrafish equivalent of the human adrenal medulla), without a requirement for MCYN overexpression. Thus, our studies indicate that overexpression of LIN28B leads to Akt activation mediated through its interaction with IGF2BP1 and subsequent upregulation of IGF2. This pathway provides a mechanism underlying enhanced transformation in LIN28B-overexpressing neuroblastomas, which is independent of the inhibitory activity of LIN28B on let-7 maturation.

**TUMOR BIOLOGY: Animal Models of Human Oncogenesis**

#1042 Clic4 is incorporated into extracellular vesicles of murine breast cancer cells and may influence metastatic burden. Alayna B. Craig-Lucas, Vanesa C. Sanchez, Abigail Read, Ji Lou, Anjali Shakla, Stuart H. Yupsa, NCI, Bethesda, MD.

Chloride intracellular channel 4 (Clic4) is an evolutionarily conserved, 29kD, dimorphic protein that contributes to TGF-β signaling by preventing the de-phosphorylation of phospho-Smad2/3 upon nuclear translocation. In several cancer types, Clic4 is excluded from the nucleus and downregulated in the cytoplasm of the tumor cells as the tumor progresses, suggesting that Clic4 acts as tumor suppressor. In a parallel sequence, Clic4 becomes upregulated in the stromal compartment, where it enhances tumor growth and invasion. Recent studies have demonstrated that Clic4 is detectable in tumor patients and incorporated into extracellular vesicles, and has potential as a biomarker. We hope to gain a better understanding of the role that Clic4 plays in the tumor stromal and epithelial compartments as well as their respective release of extracellular vesicles. Using in-vitro and in-vivo assays, we have conducted experiments using the FVB mouse MMTV-c-Myc 6DT1 breast cancer model. By CRISPR/Cas9 system, Clic4 was deleted from wild type 6DT1 cells. Following clonal selection, the loss of the Clic4 protein at both the cellular and released vesicle level was validated. Both functional assays on Clic4 deleted clones and evaluation of their extra-cellular vesicles were undertaken in order to further understand their tumorigenic and metastatic capabilities. In-vitro, Clic4 was not necessary for vesicle biogenesis and its deletion did not have a significant effect on cellular proliferation. In vivo, selected clones were orthotypically injected into the 4th mammary fat pad of wild type FVB mice. Compared to wild type 6DT1 clones, Clic4 deleted clones formed primary tumors that had greater mass but a fewer number of lung metastasis. Future studies are designed to isolate vesicles circulating in tumor bearing hosts to determine their stromal or epithelial origin and to provide a better understanding of the role that Clic4 may play in tumor growth, creating a metastatic niche and as a potential serological biomarker.

Exosomes are small vesicle cellular products originating from the endocytic pathway, abundantly secreted by tumor cells. These exosomes were the ability to alter their immediate microenvironment (ME) through cell-cell interaction by fusion with plasma membrane and subsequent endocytosis or release of their cargo. Exosomes are critical modulators of pre-metastatic niche creation by increasing the recruitment of inflammatory cells. In breast cancer, tumor-derived exosomes recruit myeloid derived suppressor cells in the creation of an immunosuppressive pro-tumorigenic lung niches. Colony stimulating factor-1-receptor (CSF1R), which is a key regulator of myeloid cell proliferation, survival, and differentiation can be blocked by a selective inhibitor GW2580. Overexpression of CSF-1 has been implicated in the creation of increased number of metastatic niches in numerous cancers. In our study, we have demonstrated that the exosomes secreted under hypoxic conditions can initiate early pre-metastatic niche creation in lungs in a metastatic breast cancer model compared to normoxia-secreted exosomes. Exosomes were injected intravenously into Balb/c female mice three days after the implantation of 4T1 breast tumor and continued for a week with injections on alternate days. The animals were pre-treated with GW2580 the day before tumor implantation and continued for a week concomitantly with exosomes on alternate days. Lungs, bone marrow, spleen and brain tissues were collected and analyzed by flow cytometer to detect myeloid and angiogenic cells populations. GW2580 was able to prevent myeloid cell infiltration in lungs and bone marrow. Further, we observed significant increase in anti-tumorigenic M1-macrophage population in the lungs of exosome treated animals pre-treated with GW2580. However, these findings were not observed in the bone marrows of the same group. Vascular leukocyte and angiogenic myeloid cell populations were significantly decreased in the lung of exosome treated animals pre-treated with GW2580. A similar decrease in these populations of cells was not seen in the lungs of animals pre-treated with GW2580 only. These surprising results have led us to hypothesize that GW2580 treatment can prevent the effects of exosomes, which causes infiltration of myeloid cells in the lung to create metastatic niche. These observations indicate a role of CSF1R inhibitor in preventing the distant metastatic niche formation.

Metastasis is the primary cause of death for cancer patients, and invasive cancer cell migration is required at multiple steps during metastasis (e.g. invasiveness and extravasation). Since microRNAs (miRNAs) have been implicated as key regulators of metastatic spread of cancer cells, we sought to develop a miRNA signature that can be used to predict cancer metastasis. We hypothesized that the miRNAs that are functionally required for invasive cell migration could serve as biomarkers to predict human cancer metastasis. We developed an intravital imaging-based approach
combined with NGS to screen for miRNAs that are required for invasive cell migration of human HT1080 fibrosarcoma cells. The screen-identified miRNAs were validated in a panel of in vitro and in vivo assays for invasive migration. Microarray analysis identified genes downregulated in transfected HT1080 cells. Publicly available databases were used to correlate the expression of screen-identified miRNAs and the progression of multiple human cancers. We used a QRT-PCR approach combined with machine learning to develop a miRNA signature to predict metastasis in a 66-patient cohort of prostate cancer. We identified over twenty novel miRNAs that regulate directional cancer invasion. Microarray analysis in HT1080 cells revealed that the altered expression of metastasis-regulating miRNAs is associated with 50% reduction in gene expression of migration and adhesion gene network components such as integrin (α4, CDCA2, and transgelin). We evaluated the potential of screen-identified miRNAs to serve as biomarkers to predict cancer metastasis. Using publicly available databases, we found that majority of screen-identified miRNAs are dysregulated in multiple human cancer types (e.g. prostate, breast, ovarian and lung) and the expression of these miRNAs correlate directly with patient disease progression. We analyzed the expression of the top two screen-identified miRNAs in plasma samples from the PCA patient cohort. A signature was generated using a weighted K-nearest neighbor algorithm that provided a ROC area under the curve of 0.79 for predicting metastatic disease. We identified a panel of novel metastasis-regulating miRNAs that is functionally involved in human cancer metastasis. These miRNAs have the potential to serve as both biomarkers to predict metastasis and potentially as therapeutic targets to block metastasis.

#1045 Understanding breast cancer metastasis through circulating tumor cells. Remi Klotz, Thomas Almal, Alan Wang, Matthew Mackay, Kathleen Heller, Lin Li, Maxwell Serowoky, Grace Lee, Jane Han, Andrew Smith, Min Yu. USC, LOS ANGELES, CA.

Due to the advance in technologies for rare cell isolation, circulating tumor cells (CTC) have recently received vast interest. During tumor progression tumor cells invade the primary tumor microenvironment and intravasate into blood vessels, where they are referred as CTCs. These CTCs disseminate to other organs and a subset of these cells will be able to form metastasis. The growing interest for CTC is confronted with the difficulty associated with their isolation and characterization. To address this challenge, our lab has recently optimized the ex vivo culture condition and was able to establish CTC lines from breast cancer patients. These CTC lines constitute a unique cell population in the metastatic process and gave us a rare opportunity to investigate the signal pathways involved in each step of the metastatic cascade. To assess the metastatic potential of breast cancer patient-derived CTC lines we utilized an experimental mouse model for metastasis by injecting CTCs directly into the left ventricle of the heart in female immudeficient NSG mice. The ability of 4 CTC lines to arrest and colonize in organ was monitored by bioluminescence imaging once every 2 weeks for 5 months. CTC lines were capable of generating brain, lung, bone and ovary metastases. Most of those organs are common sites of metastases in breast cancer patients. Two patient-derived CTC lines have a high metastatic potential (over 80% of mice had metastases after 3 months) with generation of simultaneous metastatic multiple organs (breast, lung, bone, ovary). The remaining two patient-derived CTC lines remained brain-metastases free for up to 8 months. However, two other patient-derived CTC lines demonstrated the brain as preferential site of metastasis despite their overall low metastatic potential. Interestingly, of 4 breast cancer patients where CTC lines were generated, one developed a metastatic brain tumor and her CTC line has the highest risk of brain metastases in our mouse model. We further investigated genetic and epigenetic determinants that regulate the organotropism of CTCs. We isolated metastatic variants corresponding to a subpopulation of CTCs with a preferential tropism for the brain, lung and bone. Gene expression analysis (RNA-seq) of these variants identified potential gene signatures of breast cancer metastasis. The pathways with the highest enrichment scores were glioblastoma multiforme, cerebellar apoptosis and P53 pathway for the brain metastatic variants and were interferon and mTOR signaling for the lung metastatic variants. Next we used a method for asaying chromatin accessibility (ATAC-seq) and identified potential regulatory regions mediating the organ tropism in breast cancer. Together our data provide the evidence of a promising role of CTC as an early prognostic factor in metastasis. Additionally, we expect to develop novel organ tropism associated markers, which can be considered for potential therapeutic targets in breast cancers.

#1046 Conditional knock out of N-Myc and STAT Interactor disrupts normal mammary development and enhances metastatic ability of mammary tumors. Hawley Christine Pruitt, Brandon J. Metge, Shannon E. Weeks, Dongguan Chen, Shi Wei, Lalita A. Sheved, Rajeev S. Samant. Univ. of Alabama at Birmingham, Birmingham, AL.

The process of development requires a delicate balance between plasticity and differentiation. This balance is disrupted in cancer initiation and progression, ultimately ending in metastasis and plummeting rates of patient survival. Recent findings from our lab have revealed that protein expression of evolutionarily conserved, N-Myc and STAT Interactor (NMI) is decreased in 70% of primary patient specimens of breast cancer. To study how Nmi loss facilitates metastatic behavior and gain insight into its role in normal mammary biology, we created a novel mammary specific Nmi knock out mouse model, which we then challenged with carcinogen and oncogene induced tumorogenesis. Our studies show that Nmi is induced at the onset of pregnancy and its expression remains throughout lactation. Furthermore, prolactin stimulation and differentiation of HC11 murine mammary epithelial cells is accompanied by up-regulation of NMI. STAT5 is the downstream effector of prolactin and is essential for differentiation of secretory alveolar epithelium. NMI interacts with STAT5 and this interaction appears to be critical to normal differentiation of mammary epithelium. Indeed, loss of Nmi in vivo caused a decrease in STAT5 activity and a subsequent transcriptional shift in mammary epithelial and breast cancer cells. Moreover, knockdown of Nmi in HC11 cells impedes the expression of beta-casein upon differentiation with prolactin. Concurrently, Nmi knock out alveoli exhibit an extensive presence of nuclear beta-catenin, a mediator of stem cell maintenance in the mammary gland. As a result, mice exhibit an increased number of alveoli and more proliferating mammary epithelial cells (MECs). The Nmi knock out pubertal ductal tree extends into the mammary fat pad at an accelerated rate and exhibits enhanced terminal end bud numbers, a phenotype that is normally observed for Wnt signaling. Tumors derived from Nmi null mammary epithelium contain significantly more cells with stem and progenitor markers, indicating that these tumors are less differentiated than their littermate counterparts. In addition, Nmi null mammary tumors exhibit invasive morphology as well as enhanced distant metastasis. We observe that conditional Nmi loss disrupts differentiation in the mammary gland and promotes the progression of tumors with aggressive metastatic characteristics.

#1047 Role of endocytosis in NM23 mediated motility suppression. Imran Khan, Patricia S. Steeg. National Institute of Health (NIH), Bethesda, MD.

NM23 has been identified as a metastasis suppressor gene and is known to inhibit motility of cancer cells and suppress metastasis in multiple in vivo model systems. Biochemically, NM23 is a nucleoside diphosphate kinase (NDPK). As an NDPK, NM23 is first autophosphorylated on its histidine 118 before transferring its phosphate to a NDP. NM23 is also known to trans-phosphorylate other proteins to act as a protein histidine kinase (PHK) using same histidine H118 phosphorylation intermediate. In spite of many studies on NM23 in different cancers, the molecular mechanism of NM23 action has not been well worked out. Studies on Drosophila homologue of the NM23, awd, highlights its role in regulating cell differentiation and motility by influencing endocytosis. We now hypothesize that NM23 mediated motility/metastasis suppression could be due to increased endocytosis of cell surface receptors, needed for cellular motility. We over expressed NM23 (human H1 and H2 and murine h1) in MDA-MB-231 breast cancer cells and observed that the motility suppression phenotype (4 fold, p<0.0001) of NM23 correlates with increase in NM23 histidine auto phosphorylation, as observed by using a new anti-histidine 1-phosphate (1-pHis) antibody. NM23 over expressing cells were studied for the level of endocytosis using transferrin-Alexa-594 and pHrodo-Red-EGF labelled dyes. It was observed that NM23 over expression causes increased endocytosis of both the above labelled ligands. Based on the literature, Dynamin is known to be involved in endocytosis and is also an interacting partner of NM23. We validated NM23 and Dynamin interactions by pulldown studies (using both anti-NM23 and anti-Dynamin antibodies) in NM23 over expressing cells. We also observed reduced endocytosis with Dynamin inhibitors. Further, when a series of Dynamin inhibitors (MITMAB, OcTMAB, Dynole-34-2 and Imidoydn-22) were used in motility assays, they were found to be inhibitory to motility. However, no further decrease in motility was observed upon NM23 overexpression, highlighting the reversal of NM23 mediated motility suppression in absence of Dynamin. To further address the role of endocytosis in NM23 mediated motility suppression, two crucial mutants of NM23 namely, P96S (has NDPK activity with very low HPK activity) and H118F (has no NDPK and HPK activity) were made and stable cells were generated. We observed that the motility suppression phenotype of NM23 was reversed in normal human breast epithelial cells, highlighting a possible role of HPK activity in motility suppression. Similarly, endocytosis studies on these cells shows loss of increased endocytosis in both the mutants. To date, the data indicate that NM23 phosphohistidine levels, motility suppression and increased endocytosis are well correlated and is being influenced by Dynamin signaling. Different approaches to further understand the physiological meaning of NM23 interaction interactions are underway.
**EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Combination Strategies: Novel Agents and Standard Therapies**

### #1048 Reactive oxygen species-mediated synergistic and preferential induction of cell death and reduction of drug resistance in oncogenic H-Ras-expressing bladder cancer cells by combined romidepsin and cisplatin with gemcitabine.

Lenora A. Pluchino, Hwa-Chain R. Wang. *Univ. of Tennessee, College of Veterinary Medicine, Knoxville, TN.*

Human urinary bladder cancer is the fifth most commonly diagnosed cancer in the United States and is often associated with induction of oncogenic H-Ras. Long-term survival of patients is suboptimal with the current chemotherapeutic regimen of combined cisplatin and gemcitabine and others due to acquired drug resistance and recurrence. Thus, it is urgent to develop new regimens effective in control of tumor growth, drug resistance, and recurrence to reduce the morbidity and mortality of this disease. We used our cellular system, consisting of human urinary bladder cancer J82 cells paired with its derived oncogenic H-Ras-expressing J82-Ras cells, to investigate the efficacy of a novel combination regimen in treating bladder cancer cells. Our studies revealed, for the first time, the ability of a combination of cisplatin and romidepsin with gemcitabine to synergistically and preferentially induced cell death and reduced drug resistance in J82-Ras versus J82 cells. The Ras-ERK-Nox pathway played an essential role in mediating signals to elevate reactive oxygen species (ROS), leading to enhanced caspase activation, DNA damage, and DNA oxidation, as well as reduced glutathione, to synergistically increased cell death and reduced drug resistance in cells treated with combined romidepsin, cisplatin, and gemcitabine. Preferentially induced Ras-ERK-Nox-Ros pathway, caspase activation, and DNA damage/oxidation, as well as reduced glutathione, contributed to the preferentially induced cell death and reduced drug resistance in J82-Ras versus J82 cells. Synergistically induced death and reduced drug resistance were also detected in human bladder cancer SW780 cells treated with combined romidepsin, cisplatin, and gemcitabine. Hence, our results lead us to suggest that a combination of romidepsin, cisplatin, and gemcitabine should be seriously considered as a new therapeutic regimen for controlling the development and recurrence of human urinary bladder cancer, especially Ras-ERK-activated cancers.

### #1049 Combinatorial effects of thymoquinone on the antiangiogenic activity of doxorubicin in adult T-cell leukemia: Hala Gali-Mubtasib, Isabelle Fakhouri, 1 Maamoun Fatfat, Rasha Mismar, 1 Regina Schneider-Stock. 2 American University of Beirut, Beirut, Lebanon; 2University Erlangen, Nuremberg, Germany.

Doxorubicin (Dox) is a clinically approved drug which suffers from drug resistance and cardiotoxicity. Recent studies have shown that thymoquinone (TQ) in combination with Dox can reduce Dox toxic side effects in vitro as well as in vivo. Both TQ and Dox have shown promising antiangiogenic effects against aggressive adult T-cell leukemia (ATL), however, the antiangiogenic potential of TQ and Dox combination treatment has never been tested against ATL. We hypothesized that co-treatment with TQ could enable the use of lower doses of Dox to achieve similar or enhanced antiangiogenic activity. The effects of TQ and Dox combination on cell death and cell cycle were elucidated by trypan blue and propidium iodide. TUNEL assay was used to investigate the mode of cell death. The levels of reactive species (ROS) were determined using DCFH assay, and mitochondrial membrane potential was measured by rhodamine assay. The regulation of key proteins involved in cell cycle regulation and cell death was determined by Western blot. The results revealed that the human T-lymphotropic virus (HTLV-I) positive H9251 cells are more resistant to treatment with Dox alone, than the HTLV-I negative Jurkat cells. However, treatment with high doses of TQ and low doses of Dox simultaneously, enhances cell death in both cancer cell lines as compared to treatment with Dox alone. TUNEL assay on Jurkat and HuT-102 cells further indicated that the combination of TQ and Dox caused cell death by apoptosis. An increase in ROS production was noted in response to treatment with TQ alone and with TQ and Dox combination in both Jurkat and HuT-102 cells. The oxidative stress; however, was only shown to play a role in the disruption of the mitochondria of Jurkat cells. Similarly, caspase activation was involved in the disruption of the mitochondria of Jurkat cells. The expression levels of key regulatory proteins were modulated in response to treatment with TQ and Dox. Dox effectively induces ATL leukemic cell growth at lower doses of Dox which can potentially lower the side effects of the drug. In vivo studies are still warranted to assess the adjuvant chemotherapeutic potential of TQ in combination with Dox.

### #1050 Mefloquine enhances the cytotoxic effects of tyrosine kinase inhibitors in blast phase chronic myeloid leukemia by lysosome membrane disruption.

Wei Xiang, 1 Yi Hui Lam, 1 Colin Sng, 2 May Anne Cheong, 1 Hein Tham, 1 William YK Hwang, 2 Charles Chuah, 1. 1Singapore General Hospital, Singapore, Singapore; 2Duke-NUS Medical School, Singapore, Singapore.

Mefloquine has been reported to induce apoptosis and inhibit the RNA binding protein HuR, preferentially induced cell death and reduced drug resistance in J82-Ras and J82 cells. However, the underlying mechanisms of CML are yet to be fully defined. In this study, we investigated the effect of mefloquine and its underlying mechanisms in CML. We show that mefloquine inhibits proliferation and induces apoptosis of CML cells in a dose-dependent manner. In addition, mefloquine is also effective in targeting BP-CML CD34 + progenitor cells. It induces apoptosis, inhibits colony formation and self-renewal capacity of CD34 + cells derived from a TKI-resistant BP-CML patient. Mefloquine significantly enhanced anti-potentiative and pro-apoptotic effects of imatinib and dasatinib in CML cell lines (eg, K562, LAMA84 and KU812) as well as BP-CML CD34 + cells, suggesting that mefloquine augments the effects of BCR-ABL TKIs.

### #1051 Preclinical analyses of synergistic effect of eribulin and paclitaxel for triple-negative breast cancer.

Takaaki Oba, Ken-ichi Ito. Shinshu University, Matsumoto, Japan.

Purpose: There is an urgent need to develop novel therapeutic strategies for triple negative breast cancer (TNBC). To explore the antitumor effect of combination of eribulin (ERI) and paclitaxel (PTX) for TNBC, we conducted preclinical experiments. Materials & methods: Combinational effects of ERI and PTX were analyzed both in vitro and in vivo using two TNBC cell lines (MDA-MB-231, Hs578T). Results: When ERI was added simultaneously with PTX to TNBC cells, the sensitivity to PTX was increased synergistically. On the other hand, synergistic increase of sensitivity to ERI was observed in the presence of PTX. When the TNBC cells were treated with ERI, the expression of epithelial marker, E-cadherin, was increased, while the expression of mesenchymal markers, vimentin, Slug, and ZEB1 were decreased. Furthermore, pretreatment with ERI for 96 hours enhanced the sensitivity to PTX administrated subsequently. In contrast, pretreatment of TNBC cells with PTX enhanced the sensitivity to the subsequently administrated ERI. When the TNBC cells were treated with ERI, the expression of epithelial marker, E-cadherin, was increased, while the expression of mesenchymal markers, vimentin, Slug, and ZEB1 were decreased. Furthermore, knockdown of ZEB1 by small interfering RNA conferred resistance to ERI in both TNBC cell lines. In the mouse xenograft model bearing MDA-MB-231, ERI plus PTX combination therapy significantly inhibited tumor growth compared with either PTX or ERI monotherapy. Furthermore, prior treatment with ERI significantly enhanced the antitumor activity of PTX in the mouse xenograft model. Conclusions: Our findings
EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Combination Strategies: Novel Agents and Standard Therapies
demonstrate an EMT-mediated synergistic antitumor effect by combination of two tubulin inhibitors. This combination therapy may serve as a novel therapeutic strategy for TNBC.

**#1052 Aldose reductase inhibitor increases doxorubicin-sensitivity of colon cancer cells and decreases cardiomyopathy.** Himangshu Sonowal, Pabitra B. Pal, Satish K. Srivastava, Kota V. Ramana. UT Medical Branch, Galveston, TX.

Chemotherapy is one of the most common option for colorectal cancer (CRC), specifically at the advanced stages and after surgical resection of the tumor. Anthracycline drugs such as doxorubicin, daunorubicin are the most commonly used for the therapy of leukemia, lymphoma and breast cancer. However, doxorubicin is not a very effective drug to kill CRC cells since a high amount of colorectal cancer is the most frequent cancer for surgical cancer therapy, which leads to unwanted side effects like cardiac toxicity and cardiomyopathy. Therefore, better adjuvant therapies are required to increase sensitivity of CRC to doxorubicin as well as to decrease the associated cardiomyopathy. Our recent studies indicate that aldose reductase (AR; AKR1B1) inhibitors such as fideratet prevent CRC growth as well as metastasis in nude mice xenograft models. We now examined our hypothesis that AR inhibition increases the sensitivity of CRC to doxorubicin and decreases its cardiotoxicity by modulating oxidative stress-mediated signaling pathways. We have investigated the effect of co-administration of doxorubicin along with AR inhibitor fideratet in vitro and in vivo CRC cells growth and toxicity. Our results suggest that treatment of CRC cells with fideratet increases the efficacy of doxorubicin-induced death of HT-29 and SW-480 colon cancer cells. Flow cytometric analysis showed that in fideratet + doxorubicin-treated CRC cells, the intracellular accumulation of doxorubicin is increased as compared to doxorubicin alone-treated cells. Further, AR inhibition prevents doxorubicin-induced increase in the expression of drug transporter proteins such as MRP-1 and ABCG-2 in CRC cells. In addition, combination of fideratet with doxorubicin significantly prevented the growth of CRC cells in nude mice xenografts as compared to doxorubicin alone. Fideratet also prevented the doxorubicin-induced cardiac toxicity as measured by serum troponin-I levels and inflammatory cytokines and chemokines in the serum and heart of doxorubicin-treated mice in combination with fideratet. Most importantly, fideratet protects the cardiac damage and dysfunction in doxorubicin-treated mice. Thus, our results suggest that fideratet can be used as a novel adjuvant therapy in enhancing doxorubicin sensitivity of CRC cells and to reduce the doxorubicin-associated cardiotoxicity.

**#1053 Synergistic anticancer effects of combined γ-tocotrienol and pterostilbene is associated with a suppression in Rac1/WAVE 2 signaling in highly malignant breast cancer cells.** Ibrahim G. Algayadh, Paul William Sylvest. Univ. of Louisiana at Monroe, Monroe, LA.

Breast cancer is the most common cancer and the second leading cause of cancer death in American women. Rho GTPases play a crucial role in regulating different cellular functions, including cell proliferation, gene expression, cell morphology, actin polymerization, cell motility, metastasis and apoptosis. Wiskott-Aldrich syndrome protein family verprolin-homologous protein2 (WAVE2) is a member within the Wiskott-Aldrich syndrome protein (WASP) family displaying a significant role in actin polymerization and cytoskeletal organization which are essential for cellular migration and invasion. γ-Tocotrienol is a natural isoform within the vitamin E family that displays anticancer activity against a variety of cancer cell types. Pterostilbene is a natural dimethyl ether isoflavonoid with anti-inflammatory and anti-cancer activities. Studies were conducted to examine the effects of combined γ-tocotrienol and pterostilbene on Rac1/WAVE 2 signaling in mouse +SA and human MDA-MB231 breast cancer cells and cellular migration. Results show that combined treatment of γ-tocotrienol and pterostilbene caused a synergistic inhibition of both mouse +SA and human MDA-MB231 breast cancer cells growth, and corresponding reduction in Rac1/WAVE2 signaling as characterized by a significant inhibition in the levels of phospho-Rac1/cdc42, WAVE2, Arp2, and Arp3 expression. Additional studies indicated that this combination resulted in a significant inhibition in mammary cancer cell migration. In summary, these findings strongly suggest that combined treatment of γ-tocotrienol with pterostilbene may provide great benefit as a therapeutic approach in the treatment of metastatic breast cancer. Supported by a grant from the Louisiana Cancer Foundation.

Nobiletin is a citrus polymethoxy flavonoid that suppresses cell proliferation, angiogenesis and metastatic properties in various cancer cells. In this study, we investigated the combined effects of nobiletin and various chemotherapeutic agents on the cytotoxicity of human colon and esophageal cancer cells. We cultured cancer cells at serial dilution of chemotherapeutic agents with or without nobiletin and assessed cell cytotoxicity at 5 days after drug treatment. The addition of a suboptimal dose of nobiletin did not alter the growth of cancer cells but enhanced the antitumor cytotoxic effect of antimitotics (gemcitabine and 5-FU) and DNA-platinating agent (cisplatin) were markedly attenuated by nobiletin. By contrast, nobiletin markedly enhanced antitumor effect of antimicrotubule agents such as docetaxel, paclitaxel, vincristine and MMAE. Moreover, enhanced cytotoxicity by nobiletin was also verified in the combination with MMAE- or DM1-conjugated antibodies to EpCAM and EphA2. We found the effect of nobiletin in reversing chemoresistance of colorectal cancer cells, which leads to a profound reduction in Rac1/WAVE2 signaling as characterized by a significant inhibition of phosphorylation and nuclear translocation of Pin1 (peptidyl-prolyl isomerase) by nobiletin, suggesting a rational molecular target of nobiletin is Pin1. Overall, these data suggest that nobiletin might useful for the chemotherapeutic treatment of microtubule inhibitors.

Background: Trifluridine/tipiracil is a combination of trifluridine (FTD), a nucleoside metabolic inhibitor, and tipiracil, a thymidine phosphorylase inhibitor, in a molecular ratio of 1:0.5. Trifluridine/tipiracil is indicated for the treatment of patients with metastatic colorectal cancers refractory to standard chemotherapies. Chemotherapy can make radiation therapy more effective against some colorectal cancers. In this study, we investigated whether cytotoxicity was enhanced when FTD was sequentially used with ionizing radiation (IR). Method: The colorectal cancer cell lines HT-29, HCT-15, and HCT 116, showing low, middle and high sensitivity for IR, respectively, were treated with the combinations of FTD and IR as follows, 1) sequence 1 (pre-radiation): exposure to 2-8 Gy radiation alone and no treatment for 24 h followed by exposure to 0, 2.0, or 4.0 μM FTD for 24 h, 2) sequence 2 (post-radiation): exposure to 0, 2.0, or 4.0 μM FTD for 24 h followed by 2-8 Gy radiation alone and no treatment for 24 h. Cells were irradiated using a cabinet X-ray irradiation system and all treatments were evaluated by the clonogenic survival assay. The dose modification factors (DMFs) were calculated from clonogenic survival curves as the ratio of irradiation doses (control radiation dose divided by the FTD-treated radiation dose). To evaluate DNA strand-breaks, alkaline comet assays were performed and the comet tail moment was determined. Results: DMFs of sequence 1 at 8 Gy for 2.0 μM FTD were 1.55, 1.24, and 1.03 and for 4.0 μM FTD were 1.75, 1.26, and 1.02 for HT-29, HCT-15, and HCT 116, respectively, and of sequence 2 at 8 Gy for 2.0 μM FTD were 1.82, 1.38, and 1.03 and for 4.0 μM FTD were 2.73, 1.41, and 1.03 for these cell lines, respectively. The DMFs increased in an FTD dose-dependent manner compared with IR-only treatment. In particular, FTD enhanced the efficacy of radiation in HT-29 and HCT-15 indicating low and middle sensitivity to IR. Compared with IR-only treatment, the median comet tail moments of sequence 1 at 8 Gy for 2.0 μM FTD, respectively, were 13.8-, 14.4-, and 14.4-fold and for 4.0 μM FTD were 2.73, 1.41, and 1.03 for these cell lines, respectively. The DMFs calculated from clonogenic survival curves as the ratio of irradiation doses (control radiation dose divided by the FTD-treated radiation dose). To evaluate DNA strand-breaks, alkaline comet assays were performed and the comet tail moment was determined. Results: DMFs of sequence 1 at 8 Gy for 2.0 μM FTD were 1.55, 1.24, and 1.03 and for 4.0 μM FTD were 1.75, 1.26, and 1.02 for HT-29, HCT-15, and HCT 116, respectively, and of sequence 2 at 8 Gy for 2.0 μM FTD were 1.82, 1.38, and 1.03 and for 4.0 μM FTD were 2.73, 1.41, and 1.03 for these cell lines, respectively. Taken together, FTD promoted DNA strand-breaks and enhanced the efficacy of radiation in these three cell lines, regardless of both sequential treatments. Conclusion: Sequential combination of FTD and radiation was more effective than radiation alone against colorectal cancer cell lines with different radiosensitivities. These results suggest that combination therapy of radiation with trifluridine/tipiracil might be useful for colorectal cancer even with low sensitivity to radiation alone.

**#1056 Volasertib in combination with radiotherapy: The perfect match in non-small cell lung cancer.** Jolien Van den Bossche, 1 Ines De Pauw, 1 Hilde Lambrechts, 1 Céline Merlin, 2 Christophe Deben, 1 Vanessa Deschoemaecker, 1 Pol Specenier, 2 Patrick Pauwels, 2 Marc Peeters, 2 Filip Lardon, 2 An Wouters 1 Antwerp University, Wilrijk, Belgium; 2Antwerp University Hospital, Edegem, Belgium.

Background: Polo-like kinase 1 (Plk1), a master regulator of mitosis and mitosis, is overexpressed in several human malignancies, making it a promising therapeutic target. Monotherapy of Plk1 inhibition has shown only a moderate effect in clinical trials, indicating the need to combine with other therapies. Remarkably, Plk1 inhibition arrests cancer cells in mitosis, which is the most radiosensitive cell cycle phase. Hence, we are the first to investigate the effect of volasertib, the lead agent in category of
#1058 Synergistic activity of p97 inhibitors with histone deacetylase 6 inhibitors in mantle cell lymphoma.

Role of p53 in radiosensitization by volasertib.

**Introduction**

Belinostat is an HDAC inhibitor currently marketed in the US for the treatment of PTCL. A new oral formulation is under development (positive PoC in preclinical PK study) and provides an increased potential to develop new indications of belinostatin in combination with other drugs. It has been extensively demonstrated that some anti-tumor agents, besides their direct anti-tumor effect, may induce additional mechanisms involving activation of immune responses. Thus, combination of these drugs with other immunotherapeutic protocols may yield improved therapeutic benefits. The objective of the present study is the characterization of the therapeutic efficacy of a combination of checkpoint inhibitors (anti-CTLA-4 antibodies) with belinostatin in a murine HCC model. In addition, immunoprofiling was performed in order to assess the associated immune response. Methods In vivo efficacy was assessed in a Hepa 129 murine hepatocellular carcinoma model implanted subcutaneously in immune-competent C3H mice using anti-CTLA4 alone, belinostatin alone or in combination. Treatments were optimized to be able to demonstrate positive effect of the combination. Tu- mor volume was the primary endpoint. Samples from the spleen were taken

**Introduction**

Belinostatin is an HDAC inhibitor currently marketed in the US for the treatment of PTCL. A new oral formulation is under development (positive PoC in preclinical PK study) and provides an increased potential to develop new indications of belinostatin in combination with other drugs. It has been extensively demonstrated that some anti-tumor agents, besides their direct anti-tumor effect, may induce additional mechanisms involving activation of immune responses. Thus, combination of these drugs with other immunotherapeutic protocols may yield improved therapeutic benefits. The objective of the present study is the characterization of the therapeutic efficacy of a combination of checkpoint inhibitors (anti-CTLA-4 antibodies) with belinostatin in a murine HCC model. In addition, immunoprofiling was performed in order to assess the associated immune response. Methods In vivo efficacy was assessed in a Hepa 129 murine hepatocellular carcinoma model implanted subcutaneously in immune-competent C3H mice using anti-CTLA4 alone, belinostatin alone or in combination. Treatments were optimized to be able to demonstrate positive effect of the combination. Tumor volume was the primary endpoint. Samples from the spleen were taken.
to analyze immune mechanism mediating the antitumor activity. Percent of CD4, CD8 T cells and regulatory T cells were determined by flow cytometry. Anti-tumor T cell response was measured by IFN-gamma ELISPOT assay. Results Belinostat improved anti-tumor therapeutic response induced by the anti-CTLA4 checkpoint inhibitor with a significant superior tumor growth inhibition compared to control groups. INH29 and UM-SCC-47 cells treated with INH29 demonstrated a complete cessation in tumor growth in all mice during the belinostat treatment period which continued for 1 week after the final dose. Mechanistic studies showed that the underlying immune response correlated with the observed therapeutic effect of the combination with enhancement of IFN-gamma production as antitumor T cell response and decrease in regulatory T cells in the spleens of treated animals. Conclusion These results provide a rational for using belinostat in combination with checkpoint inhibitors to reinforce therapeutic response. Currently only approx. 20% of patients respond to checkpoint inhibitors alone. The oral formulation of belinostat will allow greater flexibility in dosing schedule and use in multiple clinical situations. Further studies are ongoing in order to fully characterize this finding and to facilitate its translation into patients.

Background: Head and neck squamous cell carcinoma (HNSCC) prevalence is rising and new treatments are urgently required. Repurposing existing, clinically approved drugs to be used for cancer therapy is appealing due to the reduced time and cost required to achieve patient benefit. Aim: The aim of this study was to identify repurposed drugs for use in HNSCC and to validate these drugs and their targets in vitro and in vivo. Methods: A library of 100 BNF- approved drugs were screened against HNSCC cell lines using high-throughput AlamarBlue proliferation assays and the drug combination INH56 and IHN29 was identified. To validate this finding, AlamarBlue assays were repeated using a range of concentrations either alone or in combination with cisplatin. In addition, the ability of IHN56 + IHN29 to reduce colony formation and promote apoptosis of HNSCC cell lines was quantified using clonogenic survival assays and Annexin V/FITC FACS analysis. To determine the mechanisms of action of IHN56 + IHN29, CAL27 cells were exposed to drugs for 24 hours and the expression of STAT3, pSTAT3-Y705, pSTAT3-S727, EGFR, pEGFR, p21, p53, LC-3 and Ki67 were visualized by Western blot. Finally, in vivo mouse models were employed to confirm our in vitro findings. Results: 5 x 10⁶ CAL27 cells were injected into male NSG mice and allowed to reach 150 mm³. Mice then received IP injections of 310 mg/kg INH29 on days 3-14 after escalating doses on days 1-2, 40 mg/kg IHN56 days 3-14, 2 mg/kg cisplatin days 3, 5 and 7, or vehicle control days 1-14. Weights and tumors were measured at least 3 times per week. Results: The initial screen identified two promising drugs in combination: INH56 and IHN29, originally used to treat helminthiasis and epilepsy. The IC₅₀ of INH56 in CAL27 cells utilising the AlamarBlue assay was 1.47 μM and reduced to 0.66 μM in the presence of 0.9 mM IHN29. Clonogenic assays demonstrated the ability of IHN56 to reduce colony formation by 55% at 2 μM and by 85% when combined with IHN29 at 1 μM. Colony assays with 1 μM IHN29 and 1 μM IHN29 demonstrated a synergistic increase in apoptosis was observed with INH56 treatment, which was markedly increased following the addition of IHN29. Western blot analysis supports these observations through decreased Ki67 (proliferation), reduced STAT3 activation (oncogenic signaling), increased p21 (apoptosis) independent of p53, and increased LC3 (autophagy) protein levels. In vivo, CAL27 xenograft tumor growth was significantly impaired by IP administration of INH29 alone (P=0.002) and in combination with IHN29 (P=0.002) after 11 days, without any obvious toxicity. Conclusion: The combination of INH56 + IHN29 demonstrates strong in vivo activity against HNSCC. Our data suggest that this combination is promising for treating HNSCC.

**#1062 The combination of metformin and valproic acid induces synergistic apoptosis of prostate cancer cells via p53 activation and the intrinsic pathway.** Linh N.K. Tran, Ganessen Kichenadasse, Katherine L. Morel, Pamela J. Sykes. Flinders University and Medical Centre, Adelaide, Australia.

The anti-diabetic drug metformin (MET) and the anti-epileptic drug valproic acid (VPA), when used alone, have demonstrated anti-cancer effects in prostate cancer (PCA). We have demonstrated that the combination of MET and VPA (MET+VPA) can induce synergistic apoptosis in the human prostate cancer cell line LNCaP (p53⁺) but not in PC3 (p53⁻), and that the response is dependent on functional p53. Here, we aimed to (1) investigate the mechanism of synergistic apoptosis induced by MET + VPA in LNCaP and (2) propose patient subsets for clinical applications of MET + VPA based on the mechanism involved. LNCaP and PC3 cells were treated with vehicle, 2.5 mM MET, 2.5 mM VPA, or 2.5 mM MET + VPA for 24 hours and proteins extracted from cell fractions. Western blots were used to confirm cytoplasmic and mitochondrial fractions by measuring the presence of β-actin, pyruvate dehydrogenase subunit E1-α, and ATP synthase subunit-α protein, as well as the release of cytochrome c from mitochondria to the cytoplasm. The mechanism of apoptosis via p53 activation is proposed based on our findings and current understanding of literature. The release of cytochrome c from the mitochondria to the cytoplasm was significantly increased up to 12-fold (p<0.05) in LNCaP, but not in PC3, in response to MET + VPA compared to vehicle, MET alone, and VPA alone. This finding suggests that both MET and VPA are required to induce an intrinsic apoptosis response in LNCaP via p53. The mechanism proposed is that MET can inhibit the activity of mitochondrial complex 1 which alters the AMP/ATP ratio. This change can activate adenosine monophosphate protein kinase which phosphorylates p53 at Ser15 and leads to p53-dependent cell death. As a non-specific histone deacetylase inhibitor, VPA causes protein acetylation including p53 at lysine residues 373 and 382. By combining metformin and VPA, increased p53 protein activation can occur through phosphorylation of p53 at different sites driving p53-dependent cell apoptosis via the intrinsic pathway, as evidenced by release of cytochrome c into the cytoplasm. Our results suggest that MET + VPA provides a useful treatment for PCa at a clinically localized stage where p53 is present in most patients or advanced stage where p53 has not been mutated. Additionally, MET + VPA is potentially an alternative to androgen deprivation therapy, particularly in tumors with functional p53. A phase I neo-adjuvant clinical trial will start in early 2017 to evaluate the response of high risk localized PCa to MET + VPA (ANZCTR trial ID: ACTRN12616001021460).

**#1063 Benefit from combination cancer therapy arising from patient-to-patient variability rather than additive or synergistic drug action.** Adam C. Palmer, Peter K. Sorger. Harvard Medical School, Boston, MA.

Combination cancer therapy is an important means to increase rates and durability of drug response. Superior responses to combination therapies are commonly interpreted as evidence that individual tumors respond more strongly to a combination than to a monotherapy, and combinations are often developed based on pre-clinical observations of drug additivity or synergy. Here we explore an alternative hypothesis, namely that combination therapy can confer benefit simply by providing multiple chances of an above-average response to monotherapy. The benefit

**EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Combination Strategies: Novel Agents and Standard Therapies**

Proceedings of the American Association for Cancer Research • Volume 58 • April 2017
conferred by two-drug combination therapy in human clinical trials and PDX animals was compared with a model of independent drug action postulating that net response in each patient equals the better of two potential responses to drugs given individually with no benefit from the second agent. Data were derived from clinical trials of drug combinations in melanoma, ovarian, colorectal, pancreatic, and breast cancers treated with immunotherapies, chemotherapies and inhibitors of kinases, growth factor receptors, angiogenesis, and DNA repair enzymes; as well as analysis of 4,500 drug response measurements in patient-derived tumor xenografts, and a first-principles model of tumor kinetics and variability in drug response. A majority of approved combination cancer therapies analyzed confer benefits consistent with independent drug action. This benefit arises from high inter-subject variability, which can be assessed from clinical trials, and low content in responsiveness to different drugs, assessed from PDX studies. In a minority of cases responses exceed this expectation, sometimes dramatically, and are likely to represent true drug interaction. Therefore, independent drug action, without any assumption about additive or synergistic effects, provides a sufficient and more parsimonious explanation for the superiority of many clinically approved combination cancer therapies and changes how such data are interpreted mechanistically. Optimization of independent action also provides an alternative means for designing new drug combinations.

#1064 STAT3 NH2-terminal domain inhibition sensitizes medulloblastoma cells to chemotherapy. Sutapa Ray,1 Don W. Coulter,1 Shawn D. Gray,2 Jason A. Sughrue,2 Nagendra K. Chaturvedi,2 Shantant S. Joshi,3 Kishor K. Bhakat,3 Timothy R. McGuire,4 John G. Sharp1. 1Pediatrics, University of Nebraska Medical Center, Omaha, NE; 2Pharmacy Practice, University of Nebraska Medical Center, Omaha, NE; 3Genetics, Cell Biology and Anatomy, University of Nebraska Medical Center, Omaha, NE.

Medulloblastoma (MB) is the most common malignant brain tumor in children that arises from cerebellar neuronal progenitor cells. Despite aggressive treatment involving radiation and chemotherapies, the prognosis for high-risk MB remains poor and long-term complications from current therapies are common. Therefore, new effective therapies based on the molecular features of MB are needed to improve therapeutic outcomes. The STAT3 transcription factor is known to be constitutively activated in a variety of human cancers, including MB and functions as an oncogene, mediating cancer cell survival, proliferation, migration, and drug-resistance. We have delineated the functional role of STAT3 NH2-Terminal Domain (NTD) in MB by using a cell permeable peptide derivative of the STAT3 second helix that specifically binds and perturbs the structure/function of STAT3 and interferes with tetramerization of STAT3 dimers, protein-protein interactions and target genes transcription. Herein, we report that treatment of MB cells with STAT3-NTD inhibitor (S3-NTDI) leads to growth inhibition, cell cycle arrest and apoptosis. The inhibition of STAT3 signaling was also confirmed by downregulation of its downstream targets, including MYC, CCND1, BCL2L1, BCL2, PIM1 and APEX1. Moreover, we observed that S3-NTDI exposure attenuated the migration of MB cells in a wound-healing assay, a prerequisite for tumor invasion and metastasis. We also found that S3-NTDI abrogated IL-6 induced epithelial-mesenchymal transition (EMT) marker protein expression and inhibition of EMT-related transcription factors. Most importantly, we observed that a combination therapy with S3-NTDI and cisplatin significantly decreased the highly aggressive MYC-driven MB cell growth in a dose dependent manner and induced apoptosis by downregulating STAT3 regulated anti-proliferative and anti-apoptotic gene expression. To elucidate the mechanisms of S3-NTDI mediated inhibition, we showed that S3-NTDI upregulated expression of pro-apoptotic gene C/EBP-homologous protein (CHOP) and concomitantly decreased association of the STAT3 transcription factor to endogenous proximal promoter of CCND1 and BCL2 in chromatin immunoprecipitation assay. Furthermore, we determined that S3-NTDI mediated downregulation of miRNA-21 in MB cells, de-repressed Protein Inhibitor of Activated STAT3 (PIAS3), a negative regulator of STAT3 signaling, which in turn, attenuated STAT3 signaling pathway. Overall, our results revealed an important role of STAT3 NTD and its downstream effector molecules in regulating MB pathogenesis and disruption of this pathway with S3-NTDI may serves as a promising new candidate for therapeutic interventions in MB therapy, thereby improving the outcomes of high-risk pediatric MB patients.

#1065 MMP sensitive liposomes followed by radiotherapy improves tumor control in head and neck cancer mice models. Rikke Y. Brogaard,1 Allison L. Davis,1 Robert Z. Orlowski,1 Varun Vijay Prabhu,1 Joshua Allen,2 Ying Yang1. 1The University of Texas M.D. Anderson Cancer Center, Houston, TX; 2Oncosciences, Inc, Philadelphia, PA.

Tumors are resistant to current treatment modalities because of the proximity of tumor cells to brainstem and cranial nerves. Therefore, new effective therapies are needed to improve therapeutic outcomes. The STAT3 transcription factor is known to be constitutively activated in a variety of human cancers, including MB and functions as an oncogene, mediating cancer cell survival, proliferation, migration, and drug-resistance. We have delineated the functional role of STAT3 NH2-Terminal Domain (NTD) in MB by using a cell permeable peptide derivative of the STAT3 second helix that specifically binds and perturbs the structure/function of STAT3 and interferes with tetramerization of STAT3 dimers, protein-protein interactions and target genes transcription. Herein, we report that treatment of MB cells with STAT3-NTD inhibitor (S3-NTDI) leads to growth inhibition, cell cycle arrest and apoptosis. The inhibition of STAT3 signaling was also confirmed by downregulation of its downstream targets, including MYC, CCND1, BCL2L1, BCL2, PIM1 and APEX1. Moreover, we observed that S3-NTDI exposure attenuated the migration of MB cells in a wound-healing assay, a prerequisite for tumor invasion and metastasis. We also found that S3-NTDI abrogated IL-6 induced epithelial-mesenchymal transition (EMT) marker protein expression and inhibition of EMT-related transcription factors. Most importantly, we observed that a combination therapy with S3-NTDI and cisplatin significantly decreased the highly aggressive MYC-driven MB cell growth in a dose dependent manner and induced apoptosis by downregulating STAT3 regulated anti-proliferative and anti-apoptotic gene expression. To elucidate the mechanisms of S3-NTDI mediated inhibition, we showed that S3-NTDI upregulated expression of pro-apoptotic gene C/EBP-homologous protein (CHOP) and concomitantly decreased association of the STAT3 transcription factor to endogenous proximal promoter of CCND1 and BCL2 in chromatin immunoprecipitation assay. Furthermore, we determined that S3-NTDI mediated downregulation of miRNA-21 in MB cells, de-repressed Protein Inhibitor of Activated STAT3 (PIAS3), a negative regulator of STAT3 signaling, which in turn, attenuated STAT3 signaling pathway. Overall, our results revealed an important role of STAT3 NTD and its downstream effector molecules in regulating MB pathogenesis and disruption of this pathway with S3-NTDI may serves as a promising new candidate for therapeutic interventions in MB therapy, thereby improving the outcomes of high-risk pediatric MB patients.

#1066 ImpedireoncOPON201 efficacy in refractory multiple myeloma via Erk1/2 inhibition and pro-apoptotic Bim upregulation: single agent and combinatorial approaches. Yongsheng Tu,1 Jin He,2 Huan Liu,2 Richard Eric Davis,1 Robert Z. Orlowski,1 Varun Vijay Prabhu,1 Joshua Allen,2 Ying Yang1. 1The University of Texas M.D. Anderson Cancer Center, Houston, TX; 2Oncosciences, Inc, Philadelphia, PA.

 Disease relapse and drug resistance occurs in the majority of multiple myeloma (MM) patients despite improvements offered by new treatments. There is an urgent unmet need for new therapies that can overcome drug resistance and prolong patient survival after failure of standard-of-care. ONC201, founding member of the imidazole class of compounds, has robust preclinical efficacy in a variety of tumor types. A first-in-human ONC201 clinical study has demonstrated exceptional safety, therapeutic pharmacokinetics and evidence of tumor engagement that has led to several Phase I/II advanced cancer studies. Given the pronounced sensitivity of B-cell lymphomas to ONC201, we assessed the efficacy of ONC201 in MM preclinical models. We treated human MM cell lines and patient-derived cells isolated from bone marrow aspirates with ONC201 for 72 hours. ONC201 treatment decreased MM cell viability in CellTiter-Glo assays, with IC50 values that were 1 μM to 1.5 μM, even in high risk MM cell line RPMI8226. Consistent with prior reports, the efficacy of ONC201 was independent of TP53 status, as MM1S or NCI-H929 cells with wild-type TP53 and OPM-2 or RPMI8226 with mutated TP53 had a similar sensitivity towards ONC201. Additionally, ONC201 was equally effective in paired MM cell lines with TP53 wild type or knockout. Western blot analysis showed increased apoptosis, cleavage of caspase-9, caspase-3, and PARP. We also found that ONC201 induced expression of the pro-apoptotic protein Bim in MM cells, which can occur downstream of ERK inactivation. shRNA knockdown of Bim expression in MM cells abrogated ONC201-induced apoptosis in annexin-V binding assays. Phosphorylation of Bim at Ser69 by Erk1/2, an indicator of Erk1/2 kinase activity, and downregulated Bim pSer69. In addition, ONC201 induced apoptosis in dexamethasone-, bortezomib-, and carfilzomib-resistant MM cell lines with the same efficacy as in wild-type cells. As a rational strategy to increase the efficacy of ONC201, we enhanced its inhibition of proteasome-mediated Bim degradation by radiation. We tested combinations of ONC201 with proteasome inhibitors. Synergistic reduction in cell viability and enhanced Bim expression and PARP cleavage was observed with ONC201 in combination with bortezomib or carfilzomib in MM cells. The combination of ONC201 and bortezomib enhanced the levels of Bim and cleaved PARP in MM cells. Overall, these findings demonstrate that ONC201 inhibits the Erk1/2 pathway and enhances Bim expression to induce apoptosis in MM regardless of p53 status and resistance to standard-of-care therapies. Our studies provide a strong rationale for clinical trials of ONC201 as a single agent or in combination with approved drugs in relapsed/refractory MM.

Pancreatic cancer is a highly chemo-resistant tumor type known to aggressively metastasize at an early stage with an overall five-year survival rate of 6%. In this study we tested the efficacy of ONC201 and ONC212 in a panel of pancreatic cancer cell lines and patient-derived models in vitro and in vivo. ONC201 is the founding member of the imipridone class of small molecules with anti-proliferative and pro-apoptotic effects in various tumor types. Kline et al. and Allen et al. previously showed that ONC201 stimulates the integrated stress response by up-regulating ATF4, CHOP and DR5 followed by induction of apoptosis by up-regulating TRAIL. While the spectrum of ONC201 efficacy is broad among tumor types, pancreatic cancer cells are relatively insensitive. ONC212 exhibits low micromolar GI50 values in 3 out of 7 pancreatic cancer cell lines and 2 out of 9 patient-derived cells that were most sensitive among the pancreatic cell lines and samples tested. ONC201 induces the integrated stress response in both ONC201-sensitive and -insensitive pancreatic cancer cell lines. Interestingly, ONC201-treated resistant cells arrest in G1 and do not go through apoptosis. In order to address insensitivity to ONC201 in pancreatic cancer we explored two approaches. The first approach included treating with the ONC201 analogue ONC212, an imipridone that is currently under pre-clinical development. In vitro and in vivo studies consistently show a higher potency of ONC212 as compared to ONC201 in pancreatic cancer, especially in ONC201-insensitive models. We are currently investigating the mechanism of action of ONC212 in comparison to ONC201. The second approach to address ONC201-insensitive pancreatic cancer was combination treatment with the IGF1-R inhibitor AG1024. Western blot analysis of receptor tyrosine kinase expression levels in the panel of pancreatic cancer cell lines revealed a strong correlation between resistance to ONC201 and high expression of IGF1-R. Therefore we hypothesized that IGF1/IGF1-R might play a role in the resistance of pancreatic cancer cells to ONC201. Indeed, treatment of resistant pancreatic cancer cells with the IGF1-R inhibitor AG1024 sensitized the cells to ONC201. We are currently further exploring the involvement of IGF1-R in the ONC201 resistance mechanism. Furthermore, in-vivo studies are ongoing to validate the efficacy of the combination treatment. In summary, although pancreatic cancer is known to be refractory to many drugs, this study introduces two different approaches with imipridone small molecules ONC212 and ONC201 that show promising therapeutic potential for pancreatic cancer.

#1068 Driver pathway blockade synergizes with PLK1 inhibition in anaplastic thyroid cancer. Daniela De Martino, Emrullah Yilmaz, Arturo Orlacchio, Antonio Di Cristofano. Albert Einstein College of Medicine, Bronx, New York, NY.

Anaplastic thyroid cancer (ATC) is one of the most lethal malignancies, with a median survival of less than 6 months from the time of diagnosis. Molecular changes that characterize ATC have been recently well defined and involve most often p53 mutations, and activation of c-Met, RAS and RAF. PLK1, an essential mitotic regulator, has been found overexpressed in ATC. Previous data from our lab have shown that PLK1 inhibitors are effective in ATC cell lines. However, PLK1 inhibition often results in escape from growth arrest through mitotic slippage. This leads to the generation of polyploid, genetically unstable, cell populations. We have tested the effect of combining PLK1 and PI3K inhibitors in ATC cell lines. Combined treatment with the PLK1 inhibitor BI6727 and the PI3K inhibitor BKM120 resulted in a significant synergistic effect in ATC cell lines with high levels of AKT activity, but not in those with undetectable pAKT. Combination of the two drugs enhanced the G2/M arrest at doses in which the single drugs showed no effect. In addition, it led to a massive reduction of the tetraploid cells population. Furthermore, combined treatment with BI6727 and BKM120 in PI3K-high cell lines showed a significant induction of apoptosis in a time- and dose-dependent manner. Combined inhibition of PI3K and PLK1 was extremely effective in inhibiting tumor growth in vivo, in an immunocompetent allograft model of ATC. Our results show that combination of PLK1 and PI3K inhibitors is an effective treatment for ATC cells with high levels of PI3K signaling. This combination results in cell cycle arrest, inhibition of tetraploid cell generation, and induction of apoptosis, suggesting a clear therapeutic potential.

#1069 Inhibition of the nuclear import receptor, KpnB1 synergizes with cisplatin toxicity in cervical cancer cells. Ru-pin Chi,1 Wei Wei,2 Michael Birrer,3 Virna D. Deleaner,4 Univ. of Cape Town, Cape Town, South Africa; 5Harvard University, Cambridge, MA.

Elevated expression of members of the nuclear transport protein family has been reported in multiple cancers and presents as novel anticancer therapeutic targets. Using a cervical cancer model system, we have previously shown that inhibition of the nuclear import receptor, KpnB1 by siRNA and a novel small molecule, Inhibitor of Nuclear Import (INI-43) resulted in cancer cell death via apoptosis. In this study, we investigated the cancer cell killing effects of KpnB1 inhibition in combination with Cisplatin (CDDP), a first-line chemotherapeutic agent in cervical cancer. KpnB1 inhibition alone treated with KPT-330 at sub-lethal concentrations enhanced cancer cells’ sensitivity to CDDP. Our data shows that the combination treatment of INI-43 and CDDP significantly decreases CDDP IC50 compared to CDDP treatment alone. Increased PARP cleavage was observed in combination treated cells and this correlated with increased γH2A.X, indicating increased apoptosis and DNA damage. Further studies are needed to understand the mechanism of resistance to ONC201 and high expression of IGF1-R. Therefore we hypothesized that IGF1/IGF1-R might play a role in the resistance of pancreatic cancer cells to ONC201. Indeed, treatment of resistant pancreatic cancer cells with the IGF1-R inhibitor AG1024 sensitized the cells to ONC201. We are currently further exploring the involvement of IGF1-R in the ONC201 resistance mechanism. Furthermore, in-vivo studies are ongoing to validate the efficacy of the combination treatment. In summary, although pancreatic cancer is known to be refractory to many drugs, this study introduces two different approaches with imipridone small molecules ONC212 and ONC201 that show promising therapeutic potential for pancreatic cancer.

#1070 Role of FOXO1 in response of ovarian carcinoma cells to the XPO1/CRM1 inhibitor KPT-330/selinexor in combination with cisplatin. Simone Stucchi,1 Michelendrea De Cesare,1 Cristina Corno,1 Nives Careneni,1 Emilio Ciussani,2 Nadia Zaffaroni,1 Laura Gatti,1 Paola Perego.1 Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy; 2Fondazione IRCCS Istituto Neurologico C. Besta, Milan, Italy.

Ovarian carcinoma is a major cause of cancer-related death in women. Besides late diagnosis, treatment often fails to produce a persistent disease control. The efficacy of the platinum drug-based therapy is limited by drug resistance. Thus, an ideal therapy for women with ovarian carcinoma is still missing. Because the karyopherin XPO1/CRM1 contributes to the regulation of the cellular localization of the transcription factor FOXO1 which participates in apoptosis regulation, the aim of this study was to examine if interference with XPO1 to improve FOXO1 nuclear localization may be exploited to kill efficiently ovarian carcinoma cells and to improve cisplatin efficacy. Here, we employed preclinical pharmacology approaches including growth inhibition assays, western blot analyses, gene knockdown by siRNA, quantitative Real-time PCR, immunofluorescence analyses and tests in in vivo models. The drug interaction was analyzed using the Chou and Talalay method. When cell sensitivity to KPT-330 of a panel of ovarian carcinoma cell lines was examined a marked sensitivity to the XPO1 inhibitor was found. The effect of the combination of cisplatin and KPT-330 was investigated in the IGROV-1 cells, using simultaneous or sequential schedules. According to the combination index values, when KPT-330 exposure followed cisplatin exposure the most favourable drug interaction was observed. In IGROV-1 cells, a modulation of proteins involved in apoptosis (p53, Bax) and in cell cycle progression (p21) was found, besides G1 and G2/M accumulation after exposure to KPT-330 and to the cisplatin/KPT-330 combination, respectively. KPT-330-treated cells exhibited FOXO1 nuclear staining, in keeping with the capability of the compound to inhibit FOXO1 nuclear export. Knock-down experiments by RNA interference indicated that FOXO1-silenced cells displayed increased cisplatin sensitivity. Increased CDDP IC50 was observed in FOXO1-silenced cells and this correlated with increased apoptosis and DNA damage. Taken together, results suggest increased Cisplatin sensitivity of cervical cancer cells when nuclear import via KpnB1 is inhibited.

Background: Trifluridine/tipiracil (FTD/TPI) is an oral nucleoside anti-tumor agent that is composed of trifluridine and tipiracil hydrochloride at a molecular ratio of 1:0.5. Checkpoint-blockade immunotherapies are particularly effective in patients with tumor T cell infiltrations. In this study, the...
antitumor effects of FTD/TPI + anti-mouse PD-1 antibody combination were studied in a syngeneic mouse model and the tumor-infiltrating lymphocyte (TIL) subsets were evaluated. Method: The mouse colorectal cancer cell line CMT-93 was subcutaneously implanted into C57BL/6 mice. Vehicle (0.5% Hydroxypropyl methylcellulose, 10 mL/kg, p.o.), FTD/TPI (75, 100, and 150 mg/kg/day), TPI (clone RPMI-14.0.1 mg/body; once daily, days 1, 5, and 9; i.p.) and FTD/TPI + anti-mouse PD-1 antibody combination were administered, and inhibitory activity was evaluated according to tumor-volume changes. Single-cell suspensions were prepared from collected tumors. Based on cell marker expression, CD4+ T cells, CD8+ T cells, and regulatory T cells (Tregs) were identified and counted against CD3+ T cells. Flow cytometric analysis revealed a higher inhibition caused complete tumor regression in four/five mice without body-weight reduction (91.8%, 95.7%, 98.4%, respectively) than monotherapy. Remarkably, the 150-mg/kg/day FTD/TPI inhibited tumor growth significantly (P < 0.05; 91.8%, 95.7%, 98.4%, respectively) than monotherapy. Remarkably, the 150-mg/kg/day FTD/TPI + anti-mouse PD-1 antibody combination caused complete tumor regression in four/five mice without body-weight reduction or drug-related deaths; however, none of the monotherapies caused complete tumor regression. Flow cytometry also showed a higher CD8+ T cell percentage among total lymphocytes and a lower Treg percentage in CD4+ T cells after combination therapy compared with the controls. Conclusion: FTD/TPI + anti-mouse PD-1 antibody combination synergistically increased the CD8+ T cell percentages in whole lymphocyte and decreased Treg percentages in CD4+ T cell. This suggests that FTD/TPI + anti-mouse PD-1 antibody combination modulates tumor T cell populations and improves their antitumor activity.

#1072 Synergistic effect of gemcitabine and a Dclk1 inhibitor on pancreatic cancer cell survival. Daichi Kawamura, Yoshihiro Takamoto, Arata Nishimoto, Toshihi Tanaka, Yukari Hironaka, Kumiko Yoshida, Junichi Murakami, Naruji Kugimiya, Eijiro Harada, Koji Ueno, Tohru Hosoyama, Kimi-kazu Hamano, Yamaguchi University, Ube, Japan.

Pancreatic cancer has the highest mortality rate of all major cancers and is one of the most lethal malignancies. There is a constant upward trend in the number of patients diagnosed with pancreatic cancer and the number of deaths due to pancreatic cancer. Gemcitabine (GEM) is often used in the treatment of pancreatic cancer (PDAC), but has limited effects. Doublecortin-like kinase 1 (Dclk1) is important in the progression of early pancreatic neoplastic lesions and PDAC. However, the functional role of Dclk1 in PDAC is unknown. To identify the substrate protein phosphorylated by Dclk1, we performed a protein microarray analysis on Dclk1 knockdown cells. The results of this analysis directed our studies toward Chk1, which is known to be a potential regulator of the cell cycle and experiences upregulation of phosphorylation after GEM treatment. In general, GEM treatment results in DNA damage to pancreatic cancer cells, an increase in phosphorylated Chk1 (p-Chk1), and arrests the cell cycle progression to repair the damaged DNA. On the basis of the preliminary data, we hypothesized that the decrease in Chk1 phosphorylation by Dclk1 inhibition circumvents cell cycle arrest and impairs the subsequent DNA repair. The aim of this study was to evaluate the synergistic effect of Dclk1 inhibition and GEM treatment on pancreatic cancer cell survival. We used the human pancreatic cancer cell line Mia PaCa-2 and LRRK2-IN-1 (LRRK), as the Dclk1 inhibitor for this study. First, we examined the effects of GEM or the Dclk1 inhibitor or both on cancer cell proliferation and the expression of p-Chk1. Significantly decreased cell proliferation was observed on co-treatment of GEM and LRRK compared to GEM treatment alone. In addition, the expression of p-Chk1 significantly decreased on co-treatment compared to GEM treatment alone. Second, we used flow cytometry to analyze the cell cycle progression of CD8+ T cells and GEM and/or LRRK. Almost all cancer cells treated with GEM alone were arrested in the S phase of the cell cycle. The addition of LRRK allows the cell cycle to proceed in the same manner as untreated control cancer cells do. We also evaluated DNA damage by measuring the intensity of gamma-H2AX. Cancer cells that were co-treated experienced more DNA damage than with GEM treatment alone. The co-treatment induced apoptosis without the repair of DNA damage in the cancer cell. In conclusion, the combined treatment with GEM and a Dclk1 inhibitor decreased the cell survival rate compared to treatment with GEM alone through the suppression of p-Chk1. Targeting Dclk1 in combination with GEM might offer an excellent opportunity for future pancreatic cancer treatments.

#1073 Increased internalization and processing of the CD37-targeting antibody-drug conjugate, naratuximab emtansine (IMGN529), in the presence of rituximab leads to enhanced potency in diffuse large B-cell lymphoma models. Stuart W. Hicks, Katharine C. Lai, Yong Yi, Prerak Shah, Cristina L. Gavilanescu, Joe Ponte, Callum M. Sloss, Angela Romanelli. Immunogen, Inc., Walther, MA.

Naratuximab emtansine (IMGN529) is an investigational CD37-targeting antibody-drug conjugate (ADC) that has shown both preclinical and clinical activity in DLBCL. We have shown that rituximab, an anti-CD20 monoclonal antibody, enhances the preclinical activity of IMGN529. The combination of IMGN529 and rituximab is more active than either agent alone, and this benefit is maintained in an in vivo model of hepatitis and cell death, resulting in enhanced tumor growth inhibition by anti-CD20 class effect. Radiolabeled processing studies were performed to determine if the observed increase in internalization led to a corresponding increase in antibody degradation, which is required for the release of the cytotoxic agent in IMGN529. By trace-labeling the K7153A antibody with tritiated propionate (3H-K7153A), we were able to follow binding, uptake, and degradation of the antibody component of IMGN529 in DLBCL cell lines. Following pulse exposure, the amount of 3H-K7153A degraded after 24 hours remained the same whether treated alone or in combination with other B-cell targeting antibodies. However, when combined with rituximab the percentage of degraded 3H-K7153A increased as much as 3-fold and a similar increase of 3H catabolite was generated. When compared, the combination of K7153A and rituximab produced considerably more catabolite (6-fold, p-value < 0.0001) than the combination of rituximab and a CD19-targeting antibody. These findings support a novel mechanism where the increased potency of IMGN529 and rituximab can be explained by CD20 binding resulting in an increase in internalization and degradation of IMGN529, leading to generation of greater amounts of cytotoxic agent. Overall, these data provide a biological rationale for the enhanced activity of the rituximab plus IMGN529 combination, further supporting the clinical development strategy of this combination in DLBCL.

#1074 Combining forces: Synergy of erlotinib and crizotinib in a wild-type squamous non-small cell lung cancer cell line. Nele Van Der Steen,1 Christian Rolfo,2 Patrick Pauwels,2 Godefridus J. Peters,1 Elisa Giovannetti1.

1VU University Medical Center, Amsterdam, Netherlands; 2Antwerp University Hospital, Antwerp, Belgium.

Oncogenic drivers are often overexpressed in adenocarcinoma non-small cell lung cancer (NSCLC) patients, so this tumor type is often sensitive to targeted therapies. Sensitizing mutations in the epidermal growth factor receptor (EGFR) are good predictive biomarkers for response to EGFR-small molecule inhibitors, eg erlotinib. Amplification or exon 14 skipping of cMET are good biomarkers for cMET-small molecule inhibitors, eg crizotinib. In other subtypes of NSCLC, eg squamous, targeted therapy is not considered to be active. We tested the combination of erlotinib and crizotinib on a panel of squamous NSCLC cell lines that were wild-type for both EGFR and cMET. The effect of this drug combination was tested with different assays. The sulforhabdamine B- assay was used to determine growth inhibition and combination indexes (CI) were calculated with the method of Chou&Talalay. A CI < 0.8 was synergistic, 0.8 < CI < 1.2 was add-
tion of pERK1/2 (Thr202/204), pPRAS40 (Thr246) and pGSK3β (Ser9). Western blotting showed that the levels of pPRAS40 were decreased in the LUDLIN cells after treatment with erlotinib or crizotinib, and almost gone when treated with the combination. In the SKMES1 cells only the combination decreased pPRAS40. H1703 cells showed no change in pPRAS40. These changes in phospho-tyrosine may underlie the hypothesis that Her3 and PI3K/Akt signaling may be important in the interaction of both drugs. Her3 is a promiscuous receptor that is able to heterodimerize with EGFR and cMET. When blocking one of these receptors, Her3 is still able to continue downstream PI3K/Akt signaling. When both EGFR and cMET are blocked, Her3 and PI3K/Akt signaling is inhibited, leading to synergy. The expression of total-Her3 was lowest in the antagonistic cell line. The combination of both inhibitors led to a complete inhibition of pHer3 (Tyr1289). In conclusion: Blocking both EGFR and cMET signaling causes inhibition of Her3 downstream signaling through PI3K/Akt, leading to synergy in wild-type squamous NSCLC cells.

#1075 JQ1 induces DNA damage, inhibits expression of DNA repair proteins, and synergizes with PARP inhibitors in pancreatic cancer cells. Aubrey Lynn Miller,1 Tracy Gamblin,1 Leona Council,1 Robert van Waardenburg,2 Eddy Yang,1 James Bradner,2 Karina Yoon,1* 1Univ. of Alabama at Birmingham, Birmingham, AL; 2Novartis Institutes for Biomedical Research, Cambridge, MA. Pancreatic ductal adenocarcinoma (PDAC) is the most common type of pancreatic cancer. PDAC is a highly aggressive tumor with a 5-year survival of <6%. Surgery remains the only curative treatment for PDAC patients, but only 20% of newly diagnosed patients have resectable disease. The remaining 80% present with locally advanced or metastatic disease, and aggressive systemic therapy with gemcitabine. The median survival of this patient population is ~6 months. Development of more effective therapy for this chemorefractory disease is imperative. The goal of the current study was to develop effective combination therapy for PDAC by identifying agents that might be combined with the BET bromodomain inhibitor JQ1, which we have shown to inhibit the growth in vivo of PDAC patient-derived xenografts (PDx). Expression profile analysis of tumors from vehicle control and JQ1 treated mice revealed that JQ1 inhibited the expression of multiple gene products involved in DNA repair. Notably, JQ1 inhibited expression of DNA double-strand break (DSB) repair proteins BRCA2 and Ku80. Immunohistochemical staining confirmed down-regulation of expression of both proteins in tumors of mice treated with JQ1. Further, immunohistochemistry and immunofluorescence analyses demonstrated that decreased expression of BRCA2 and Ku80 was coincident with increased levels of DNA damage, as reflected by expression of the DNA DSB marker gamma-H2AX. Data generated in vivo in three independent PDx models corroborated in vitro data generated using pancreatic cancer cell lines BxPC3 and Panc1. The data suggest that JQ1 induces DNA damage by inhibiting DNA repair. Because DNA repair deficiency seen in cells to PARP inhibitors, we hypothesized that JQ1-induced DNA repair deficiency would sensitize PDAC cells to PARP inhibitors. To address this hypothesis, we exposed Panc1 and BxPC3 to JQ1 or to a PARP 1/2 inhibitor (veliparib or olaparib) or to the combinations, and assessed the efficacy of each. Growth inhibition data, analyzed using Compusyn software and reported as combination indices, demonstrated that the combinations of JQ1 + veliparib or olaparib exert synergistic cytotoxicity. Further, the combination of JQ1 + a PARP inhibitor increased the accumulation of DNA damage in vitro, compared to either agent alone. We conclude that JQ1 induces DNA damage due at least in part to DNA repair deficiency, and propose that this mechanism sensitizes PDAC cells to PARP inhibitors.

#1076 Potent anti-tumor activity of artemisinin. Mourir Tilaoui. Faculty of Science and Technology Beni-Mellal, Beni Mellal, Morocco. Cancer is a leading cause of death worldwide and remains a therapeutic enigma. Phytochemical compounds are emerging as a new generation of anti-cancer agents with limited toxicity in cancer patients. The purpose of this study was to investigate the potential impact of artemisinin, the main active component of the Chinese herb Artemisia annua L., on survival cancer cells and tumor growth in vivo. Exposure of tumor cells P815 (murine mastocytoma) and BSR (kidney adenocarcinoma of hamster) to increasing artemisinin concentrations resulted in a significant inhibition of viability, as revealed by the respective IC50 values (12 μM for P815 and 52 μM for BSR cells). Interestingly, no cytotoxic effect was observed of artemisinin on peripheral blood mononuclear cells. The in vitro cytotoxicity studies were complemented by the determination of apoptotic DNA fragmentation and Annexin V - Streptavidin-FITC assay. Our results provide evidence that artemisinin leading to apoptotic pathway on P815 but not on BSR cancer cell lines. Moreover, we demonstrate that artemisinin synergizes with microtubule - damaging agent vincristine to inhibit cellular viability. The in vivo anticancer activity of artemisinin was also evaluated using the DBA2/P815 (H2d) mouse model inoculated with the P815 mastocytoma cells. Our in vivo data clearly showed that the oral administration of artemisinin inhibited solid tumor development. In view of the available experimental findings, we contend that artemisinin could have clinical potential as an anticancer drug alone or in combination with chemotherapeutic agents such as vincristine.

#1077 Extra-virgin olive oil Met inhibitor oleocanthal-lapatinib: a novel synergistic combination for HER2-dependent breast malignancies. Abu Bakar Siddique, Hassan Y. Ebrahim, Mohammed R. Aki, Mohmed M. Mohyeldin, Khalid A. El Sayed. Univ. of Louisiana College of Pharmacy, Monroe, LA. Breast cancer (BC) is the most commonly diagnosed cancer in women, claiming the lives of hundreds of thousands of women each year. The Mediterranean diet promotes to reduce BC risk and BC cancer incidence. Extra-virgin olive oil (EVOO) represents a main ingredient in this diet. The EVOO-derived (+)-oleocanthal was shown to target the Receptor tyrosine kinases (RTK) c-Met. Oleocanthal exerted potent in-vivo efficacy in an orthotopic athymic nude mouse breast cancer xenograft model much greater than its modest in-vitro potency. Dysregulation of RTKs, specifically EGFR/HER2 pathways, correlates with poor prognosis and more aggressive breast cancer phenotypes. Dysregulation of hepatocyte growth factor (HGF) and its receptor c-Met correlates with aggressive proliferation, invasive character, and pathological motility. c-Met amplification correlates with escape from the anticancer effects of EGFR/HER2 inhibitors and cetuximab. (+)-Oleocanthal (OC) is a naturally occurring pheno- sc起到 from EVOO showed significant in vivo activity against invasive breast cancers through targeting HGF/Met axis. The Dual EGFR/HER2 inhibitor lapatinib (LP) has already been in clinical practice for HER2-amplified breast cancer, which occasionally develops resistance through c-Met upregulation. Lapatinib’s therapeutic dose induced significant hepatotoxicity. The combined use of OC and LP was hypothesized not only for therapeutic synergy but also to notably reduce LP’s effective doses and therefore minimize its hepatotoxicity. Combined treatment of subeffective doses of lapatinib and OC caused significant in vitro and in vivo synergistic antiproliferative effects against the HER2-dependent BT-474 and SKBR3 BC cells. Interestingly, OC induced 4-fold lapatinib dose reduction index with improved potency. Protein microarray and Western blot analyses of OC-LP combination treatments synergistically reduced EGFR, HER-2, FAK, JAK1, MEK, and c-Met activation. These results propose OC-use as dietary supplement to synergize the chemotherapeutic effects of LP, reduce its therapeutic dose to ¼ and therefore can minimize its morbidity. Combinatorial inhibition of c-Met-HER-2-EGRF is an effective strategy for the control of HER-2 positive breast cancer. This study was supported by NIH/NCI project IR15CA167475-01.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Combination Therapy 1

#1078 Dinaciclib overcomes resistance to BKM120 in triple negative breast cancer patient-derived xenograft models. Sandeep Rajput, Fang Guo, Li Shun, Cynthia Ma. Washington University St. Louis, St. Louis, MO. Purpose: Triple negative breast cancer (TNBC) is one of the most lethal sub- types of breast cancer with limited therapeutic options. Development of molecularly targeted agents for TNBC is an unmet clinical need. The phosphoinositide 3-kinase- (PI3K) pathway, which is a major cell growth and survival pathway, is frequently activated in TNBC as a result of genetic aberrations such as loss of the negative regulator PTEN or gain of function mutations in PIK3CA, therefore an attractive therapeutic target. However, single agent PI3K inhibitors have shown limited anti-tumor activity in both preclinical models and in clinical trials. One of the most important mechanisms of resistance to PI3K inhibitor is amplification of Myc. Dinaciclib, a potent inhibitor of cyclin-dependent kinases (CDKs) 1, 2, 3 and 9, has shown to be particularly effective in Myc dependent tumors in preclinical studies and in TNBC. We therefore hypothesized that dinaciclib could overcome tumor cell resistance to PI3K inhibitors and improve the therapeutic efficacy in TNBC. In this study, we evaluated the anti-tumor and molecular effect of dinaciclib and BKM120 (Pan-PI3K inhibitor), either alone or in combination, in a panel of patient derived xenograft (PDx) models of TNBC. Methods: Four TNBC PDx models were selected for the study for in-vivo and ex-vivo responses to vehicle, BKM120, dinaciclib, or the combination of BKM120 and dinaciclib. Tumor volume changes over time in each group were documented to calculate the percentage of tumor growth inhibition by either agent alone or in combination. Tumor tissues harvested post treatment were examined by immunohistochemistry for cleaved PARP to determine the extent of
apoptosis and phospho-Histone H3 for G2 to M phase cell cycle progression. Western blot analysis and reverse protein phase array (RPRA) were also performed to determine treatment effect on PI3K downstream targets and cell cycle molecules. Results: The combination of BKM120 and dinaciclib induced significantly greater growth inhibitory effect on tumor growth than either single agent alone in vitro. This is 0.75% inhibition of cell proliferation induction and reduced cell cycle progression. In addition, the combination of dinaciclib and BKM120 significantly reduced the level of cyclin B and the key anti-apoptotic protein survivin as well as significant downregulation of pAKT, and pS6. Conclusions: These data suggest that dinaciclib and BKM120 combination is an effective approach in treating TNBC. Additional mechanistic investigation for the efficacy of this combination is underway.

#1079 Preclinical activity of the FGFRinhibitor BAY 1163877 alone or in combination with antihormonal therapy in breast cancer. Oliver Politz,1 Peter Ellinghaus,2 Sebastian Bender,2 Sylvia Gruenewald,1 Franziska Siegel,1 Marie-Pierre Collin,1 Sabine Zitzmann-Kolbe,1 Dominik Mumberg,1 Karl Ziegelbauer,3 Bayer AG, Berlin, Germany; 4Bayer AG, Wuppertal, Germany.

BAY 1163877 is an orally available, highly potent and selective pan fibroblast growth factor receptor (FGFR) inhibitor. In an ongoing Phase 1 clinical trial (NCT01976741) BAY 1163877 showed clinical responses at acceptable tolerability in patients suffering from different tumor types including uterine blader carcinoma or lung tumors, which were selected based on elevated FGFR1-3 mRNA expression. In the preclinical phase, the compound demonstrated significant single agent anti-tumor activity in various tumor models with different FGFR alterations leading to FGFR overexpression (e.g. FGFR gene amplifications or mutations). Genetic alterations of FGFRs can also be found in breast cancer with 7.5 - 17% of all tumors harboring a FGFR1 gene amplification. Elevated FGFR1 mRNA levels can be found in up to 22% of breast cancer cell lines as well as clinical samples. Other FGFR alterations include FGFR2 or FGFR4 gene amplifications as well as elevated FGFR mRNA levels, which were reported in all breast cancer subtypes. We therefore investigated BAY1163877 monotherapy in various breast cancer models. Due to the favorable clinical safety profile of BAY1163877, we also examined a combination treatment with early line antihormonal therapies in hormone receptor positive breast cancer. In vitro profiling of BAY 1163877 in a number of breast cancer cell lines showed a clear association of efficacy with expression levels of different FGFR isofoms. The efficacy was further investigated in several patient- or cell line-derived breast cancer in vivo models. For instance, BAY 1163877 alone dosed 38mg/kg twice daily induced tumor growth inhibition of greater than 90% in a subcutaneous mouse syngeneic 4T1 breast cancer model expressing elevated levels of FGFR2. Resistance to endocrine therapy appears associated with FGFR1 gene amplification and may explain the poor prognosis of FGFR1 overexpressing tumors treated with adjuvant tamoxifen. We therefore investigated the combination of the panFGFR-inhibitor BAY 1163877 with the clinically used antihormonal compound fulvestrant in selected luminal breast cancer PDX models. Some of these models showed resistance to antihormonal treatment in monotherapy but improved in vivo efficacy in combined treatment using BAY 1163877 and fulvestrant. These data may warrant further clinical investigation of BAY1163877 alone or in combination with antihormonal therapy in patients with FGFR overexpressing breast cancer.

#1080 Targeting the PI3K-Akt and NF-κB pathways as a combination therapy in blocking prostate cancer progression. Eswar Shankar,1 Rajnee Kanwal,2 Aditi Goel,1 Xiaoping Yang,2 Sanjeev Shukla,1 Carl Ziegelbauer,3 Bayer AG, Berlin, Germany; 4Bayer AG, Wuppertal, Germany.

Activation of PI3K/Akt and NF-κB signaling pathways has been associated with prostate cancer progression. In the present study, we have investigated the role of a combination of PI3K/Akt and NF-κB signaling pathways in prostate cancer progression. We used the BPH-1 cell line, which is a human benign prostate epithelial cell line, and the prostate cancer cell lines (PC-3, LNCaP, DU145) to study the effects of these pathways on cell proliferation. We found that the combination of PI3K/Akt and NF-κB signaling pathways significantly inhibited cell proliferation, invasion, and migration in prostate cancer cells. These results suggest that targeting PI3K/Akt and NF-κB pathways as a combination therapy may be effective in blocking prostate cancer progression.

#1081 APC regulation of breast cancer therapeutic resistance. Anne Arnason,1 Monaco VanKloppenberg,2 Jenifer R. Prosser2,1 University of Notre Dame, Notre Dame, IN; 2Indiana Univ. School of Medicine-South Bend, South Bend, IN.

Resistance to chemotherapy is one of the leading causes of death from breast cancer. Our lab discovered that Adenomatous Polyposis Coli (APC) loss in breast cancer cells results in an elevation of tumor-initiating cells (TICs) and resistance to chemotherapy-induced apoptosis. Given that TICs are often most resistant to standard chemotherapeutic compounds, we sought to understand the mechanism responsible for APC-mediated TIC enhancement. Our hypothesis is that the molecular mechanism involved in chemotherapeutic resistance parallels that promoting the TICs. APC-mutant cells have amplified activation of signal transducer and activator of transcription 3 (STAT3). Interestingly, inhibition of STAT3 with a small molecule inhibitor A69 decreases the TIC population and restores drug sensitivity. Studies are ongoing in the laboratory to investigate other molecular signaling pathways involved in APC-mediated enhanced TIC population and therapy resistance. These data have begun to reveal the molecular mechanisms of APC loss in breast cancer that can guide future treatment plans to counteract chemotherapeutic resistance.

#1082 MerTK promotes resistance to irreversible EGFR TKIs by activation of the PI3K-AKT pathway in NSCLCs expressing wild-type EGFR. Dan Yan,1 Xiaodong Wang,2 Stephen V. Frye,3 Shelton H. Earp,1 Deborah DeRykere,1 Douglas K. Graham1. 1Aflac Cancer and Blood Disorders Center, Atlanta, GA; 2Center for Integrative Chemical Biology and Drug Discovery, Chapel Hill, NC; 3UNC Lingerer Comprehensive Cancer Center, Chapel Hill, NC.

Lung cancer is the leading cause of cancer-related death with poor survival rates worldwide. Non-small cell lung cancer (NSCLC) accounts for 85% of all lung cancers and 60% of these have overexpression of wild-type EGFR (wtEGFR), which portends a poor prognosis. In addition, in a recent clinical trial 6 of 12 lung cancer patients whose tumors acquired a resistance-conferring T790M EGFR mutation during treatment with an EGFR TKI reverted to wtEGFR after treatment with Rociletinib/CO-1686, an irreversible EGFR TKI that is selective for the T790M mutant. These data suggest that targeting wtEGFR may improve treatment outcomes; however, to date single agents that target wtEGFR have not been effective in large scale clinical trials and new ways to target wtEGFR in this context are needed. Our laboratory previously identified the MerTK receptor tyrosine kinase as a potential therapeutic target in NSCLC and developed MRX-2843 as a novel MerTK-selective irreversible tyrosine kinase inhibitor with favorable properties for clinical translation. Irreversible of driver oncogene status, treatment with a MerTK inhibitor yields potent anti-tumor effects in NSCLC cell culture models and blocks tumor growth in xenografts of the MerTK-dependent wtEGFR-expressing A549 cell line. In an attempt to more potently block A549 lung cancer cell proliferation, we screened a library of 378 kinase inhibitors that are in various stages of development and identified synergy between MRX-2843 and multiple irreversible EGFR TKIs, including CO-1686 and Osimertinib/AZD-9291. Further, we found that wtEGFR and MerTK were frequently co-expressed and co-immunoprecipitated with each other in NSCLC cancer cell lysates. Synergistic inhibition of cell ex-
pansion was observed in a spectrum of NSCLC cell lines with wtEGFR expression treated with the combination therapy, including H1299 (NRAS mutation), H157 (KRAS mutation), H3122 (ALK fusion), and Colo699 (FGFR1 overexpression). On a mechanistic level, combined treatment with 1µM CO-1686 and 100 nM MRX-2843 dramatically inhibited phosphorylation of both MerTK and EGFR and downstream signaling through the PI3K-AKT and MAPK-phosphorylated pathways, while treatment with equivalent doses of either single agent did not efficiently inhibit MerTK, EGFR or downstream signaling. Additionally, CO-1686 mediated synergistic inhibition of A549 expansion in combination with a PI3K or AKT inhibitor, suggesting a role for PI3K-AKT activation downstream of MerTK contributing to the resistance of wtEGFR NSCLCs to irreversible EGFR TKIs. Taken together, our data provide rationale for a novel strategy for treatment of NSCLC with wtEGFR overexpression by combining MRX-2843 and an irreversible EGFR inhibitor.

#1083 Synergistic drug combination prediction through drug differential dependency network analysis. Seunghun Kim, Gil Speyer, Harshil Dhruv, Jeff Kiefer, Michael Berens. The Translational Genomics Research Institute, Phoenix, AZ.

In an effort to discover strategies which identify effective drug combinations, we analyzed 39 of the 480 compounds screened in the Cancer Therapeutics Response Portal (CTRP) where combinations of two compounds were tested against 860 cancer cell lines; this enabled a comparison of the drug sensitivity of the combinations versus that of the individual compounds. More than half of the drug combinations (n=21) did not significantly improve the drug sensitivity, compared to the individual compounds alone. In fact, some of the combinations showed reduced drug sensitivity. In EDDY-CTRP analysis, the Cancer Cell Line Encyclopedia (CCLE) RNAseq data and CTRP compound response measurements were analyzed to discover both 1) pathways enriched with differential dependencies between sensitive and non-sensitive cell lines for each compound and 2) the mediators of cell line response to a drug. A mediator is a gene in a pathway that plays a significantly different role between sensitive and non-sensitive conditions. The significance is assessed for either essentiality, measured as a node’s centrality change, or specificity, measured as the difference in condition specific edges. These drug-pathway-mediator connections are predicted to reveal crucial molecular determinants of drug sensitivity that otherwise are hidden in the complexities of the molecular networks of the cell (Speyer et al., PDB 22:497-508, 2017). We further investigated whether mediators identified for single compounds could predict sensitivity to drug combinations. This analysis revealed that if two single compounds share the same specific mediators, i.e. the genes with the most significant re-wiring of gene dependencies between sensitive and non-sensitive cell lines, combination of these two compounds correlate with improved sensitivity. The converse was also found: compounds that do not share mediators rarely show synergy. Further analysis of key nodes was indicative of relatively high influence of drug concentration. On the other hand, some herb remedies such as S. nigrum significantly antagonizes its cytotoxic activity against head and neck cancer cells.

#1084 Combination of eribulin and AURKA inhibitor prevents metastatic colonization and eradicates established metastases in breast cancer. Elena N. Puchacheva, Varvara Kozyreva, Anna Kiseleva, Ryan Ice, Brandon Jones, Yurii Loskutov. WWU Cancer Institute, Morgantown, WV.

The majority of cancer-related deaths (90%) are happened due to metastasis from the primary tumor site to distant organs. MLN8237 is a small, highly selective molecule inhibitor of Aurora A kinase (AURKA), which results in disruption of the mitotic spindle, chromosome segregation collapse, and inhibition of cell proliferation. Numerous studies have shown that levels of AURKA are elevated in many types of cancer, including breast cancer. Our previous studies indicated that MLN8237 is extremely potent against pulmonary metastasis, but not the primary tumor in orthotopic xenograft model. To further enhance MLN8237 based regimen, its combination with other therapeutic compounds can be used. As a potential partner we chose eribulin - fully synthetic macrocyclic analogue of the marine natural product halichondrin B. Eribulin belong to the class of non-taxane microtubule destabilizing molecules, currently used in clinic to treat taxol resistant metastatic breast cancer. In present study we have investigated the effect of MLN8237 and eribulin against breast cancer in vivo and in vitro. The results showed that combination of drugs possess a synergistic effect on both primary tumor and metastases, through inducing cytoxic autophagy and apoptosis. This data clearly indicate great potential behind the MLN8237 based therapies and introduce a new hope for the eradication of metastatic breast cancer.

#1085 Time dependent analysis for the combination of standardised Annona cherimola and Solanum nigrum extracts with 5-FU against head and neck cancer cells. Serag Eldin I. Elhebairi, 1 Aly F. Mohamed, 1 Nahlia G. Mohamed, 2 Mohammad I. Basuony, 3 Mahmoud M. Salem, 3 Metwally M. Montaser, 3 Mohammad Y. Alalfi, 4 Ayman M. Noreddin, 4 Ahmed M. Al-Abd 5. 1 Roswell Park Cancer Institute, Buffalo, NY; 2 Inova Dwight and Martha Cancer Institute, Falls Church, VA; 3 Egyptian Organization for Biological Products and Vaccines (VACSERA), Giza, Egypt; 4 Azar University, Cairo, Egypt; 5 King Khalid University, Abha, Saudi Arabia; 6 Chapman University School of Pharmacy, Irvine, CA; 7 National Research Centre of Egypt, Giza, Egypt.

Phytochemicals of natural origin constitues very initiative field of anticancer drug discovery. Annona sp. and Solanum nigrum are folk herbs with reported cytotoxic effects that can be used in the treatment of human cancers. Natural herbal medicine might not be potent anticancer remedies and are recommended for combination therapy. In the current work, we mathematically evaluated the influence of combining standardized extracts of A. cherimola and S. nigrum to the cytotoxic profile of 5-FU against head and neck cancer cells (Hep-2). Cytotoxicity assessment and combination analysis were calculated after MTT assays followed by fitting to Emax model and calculating the combination index (CI-value). After 24 h exposure both A. cherimola and S. nigrum extracts were more potent than 5-FU with I50 of 29.4±4.4, 7.3±1.3, and 3.4±0.4 µg/ml, respectively. Both A. cherimola and S. nigrum extracts significantly decreased the I50 to 5.2±0.55 and 7.6±0.85 µg/ml, respectively; however the CI-values were indicative of additive and antagonistic interactions, respectively (0.91 and 0.11, respectively). After 48 h exposure, the I50 of A. cherimola and S. nigrum extracts were 3.1±0.45, 0.87±0.02 and 7.2±0.65 µg/ml, respectively. Similarly, combination of A. cherimola and S. nigrum extracts with 5-FU showed additive and antagonistic interaction with CI-values of 1.05 and 3.37, respectively. After 72 h of exposure, the I50 of 5-FU, A. cherimola and S. nigrum extracts were 1.9±0.2, 2.1±0.24 and 2.1±0.1 µg/ml, respectively. Similarly, combination of A. cherimola and S. nigrum extracts with 5-FU showed additive and antagonistic interaction with CI-values of 1.2 and 2.21, respectively. Then, Ct model was used to assess the relative influence of drug concentration and exposure time on the cytotoxic profile of treatments under investigation. For S. nigrum and its combination with 5-FU, n-values were 0.9 and 0.63 which is indicative of relatively high influence of drug concentration. On the other hand, n-value for 5-FU treatment was 0.37; this indicates higher influence of drug exposure time compared to other treatment. The n-values of A. cherimola and its combination with 5-FU were 0.51 and 0.54, respectively; this indicate comparable influence of both drug concentration and exposure time. As a confirmatory measure, expression of the apoptotic gene, BAX, was increased after 5-FU combination with A. cherimola and decreased after combination with S. nigrum. In conclusion, some natural herb remedies such as A. cherimola might influence the cytotoxic profile of 5-FU and particularly after short exposure time; while on the other hand, some herb remedies such as S. nigrum significantly antagonizes its cytotoxic activity against head and neck cancer cells.

#1086 Vitamin D3 increases the response to cisplatin in bladder cancer through VDR and TAP3 pathway crosstalk. Brittany L. Bunch, 2 Donald Trump, 2 Candace S. Johnson1, Roswell Park Cancer Institute, Buffalo, NY; 3 Inova Dwight and Martha Cancer Institute, Falls Church, VA.

Several clinical trials have demonstrated that vitamin D (Vit D) is a biomarker to identify patients with poor response to cisplatin, and the lack of available biomarkers to identify these patients. Previous studies in our lab showed that pretreatment of preclinical bladder cancer models with 1,25 dihydroxyvitamin D3 (1,25D3), the active metabolite of vitamin D3, enhances the apoptotic response to cisplatin. Mechanistic understanding can provide insight into potential markers for response to 1,25D3, and cisplatin combination therapy in patients. Greater than 50% of MBCBs harbor p53 mutations; however p53 status has not been linked to clinical response to cisplatin. We previously determined that TAP3, a pro-apoptotic p53 family member protein induced after DNA damage, is upregulated after 1,25D3 and cisplatin treatment in bladder cancer cell lines with mutant p53, T24 and RT-112, we identified signalng crosstalk between the vitamin D receptor (VDR) and TAP3. Treatment with 1,25D3 and cisplatin, compared to either alone, results in greatest increase of TAP3 mRNA and protein, 2-fold (T24) and 15-fold (RT-112), as well as TAP3 transcriptional target BAX, 3-fold (T24), and 4-fold (RT-112). TAP3 and BAX induction is lost in cells transfected with VDR siRNA, indicating a requirement for VDR. Cells treated with 1,25D3 and cisplatin, compared to either alone, also show the greatest increase of VDR mRNA and protein, 3-fold (T24) and 4-fold (RT-112). CYP24A1, a VDR target gene, has the greatest induction after the combination treatment as well, with an increase of approx. 60-fold (T24), and

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Combination Therapy
100-fold (RT-112). CYP2A4 induction requires Tap 73, determined using Tap 73 shRNA. These data demonstrate that VDR signaling is enhanced by cisplatin treatment, and Tap 73 signaling is enhanced by 1,25D3. We expanded these findings in vivo by treating mice on a vitamin D3 deficient diet (1,000 IU) or a vitamin D3 deficient diet (25 IU) with 5 mg/kg of cisplatin (IP, qwk for 3 weeks). Initially, no differences with doses were observed, while in a second experiment with 2 different doses, we observed a benefit of cisplatin treatment by a 30% reduction in tumor volume. After the second cycle of treatment, tumors in the deficient mice stopped responding and returned to their initial tumor volume within 24 days. In the sufficient mice, tumors continued to respond to cisplatin with a maximum reduction of 50%. This was maintained for approximately 40 days after treatment. Further study will determine the molecular reason for the differential effect in vivo and data suggests that vitamin D3 with 1α (OH) D3 is important in and can increase the response to cisplatin, it also provides rationale for investigating Tap 73 protein levels and serum vitamin D3 levels as potential markers to determine patients’ likelihood of responding to cisplatin.

**#1087 CPX-351 works synergistically in combination with FLT3 inhibitors against AML with FLT3-ITD.** David K. Edwards,1 Nathalie Javidi-Sharifi,1 Angela Roelty,2 Max Gordon,1 Riley Roth-Carter,1 Paul Tardi,2 Lawrence Mayer,3 Jeffrey W. Tyner1. 1Oregan Health & Science University, Portland, OR; 2Jazz Pharmaceuticals, Vancouver, British Columbia, Canada

Introduction: CPX-351 (Vyxeos) is a liposomal combination of cytarabine and daunorubicin at a synergistic 5:1 molar ratio. Recently, CPX-351 has been shown to be significantly more effective than the 7+3 standard of care chemotherapy in treating high-risk AML patients, including patients with FLT3-ITD or M1 mutations. We recently treated primary patient samples with CPX-351 in vivo and found that FLT3-ITD+ samples were significantly more sensitive to CPX-351 and showed enhanced drug uptake. We hypothesized that dysregulated FLT3 signaling results in an activation of liposome uptake pathways, leading to increased sensitivity to CPX-351 and ultimately cell death. Furthermore, we examined the effect of combining CPX-351 with existing FLT3 inhibitors (e.g. quizartinib and midostaurin). Methods: To examine drug uptake dynamics, we exposed AML cell lines (including MOLM-13 and MOLM-14 that contain FLT3-ITD, and ME1 that contains an activating FLT3 mutation) to varying concentrations of CPX-351, with or without pre-treatment of quizartinib for 16 hrs produced a population of cells (approximately 50% of the total population) that exhibited decreased daunorubicin fluorescence, suggesting that prolonged FLT3 inhibition may decrease CPX-351 uptake. Consistent with this, we observed robust synergy when combining CPX-351 with FLT3 inhibitors simultaneously or with CPX-351 exposure scheduled 24 hours prior to FLT3 inhibitor exposure. However, exposure to FLT3 inhibitors 24 hours prior to CPX-351 administration was synergistic and even antagonistic at certain doses. Conclusions: These data provide additional supportive evidence that FLT3 activation results in an increased uptake of CPX-351. This is consistent with results from the CPX-351 Phase III trial in which FLT3-ITD+ patients survived significantly longer when treated with CPX-351 compared to 7+3 chemotherapy. We also show that combining CPX-351 with existing FLT3 inhibitors can elicit a synergistic response when administered in dosing regimens where FLT3 inhibition does not precede CPX-351 treatment. Cumulatively, our data support further testing of CPX-351 in combination with FLT3 inhibitors for treating AML patients with genetic dysregulation of FLT3 signaling.

**#1088 Metronomic therapy of doxorubicin and molecular iodine in canine mammary cancer.** Xochitl Zambrano Estrada,1 Brianda Landaverde,2 Andrés A. Dueñas,3 Marco A. De Paz,2 Gerardo A. Hernández,2 Benjamin Solorio,3 Manuel Trejo,1 Laura Pérez,2 Carmen Aceves1. 1Instituto de Neurobiología, Ju- riquilla, México, Mexico; 2Facultad de Estudios Superiores Cuautitlán, Estado de México, Mexico; 3Facultad de Ciencias Naturales, Juriquilla, México, Mexico

Introduction: Conventional chemotherapy is administered at the maximal tolerated dose (MTD), usually every 21 days, and the drug-free period allows the patient to recover from the adverse effects secondary to the treatment. However, this period also enables tumors to reintegrate growth through induced tumoral revascularization. In recent years, a new strategy known as metronomic chemotherapy explored the scheme of long-lasting low-dose administration of antineoplastic drugs, which results in the attenuation or interruption of tumor growth by inhibition of angiogenesis and/or reactivation of anti-tumoral immune system. Moreover, the use of combination therapies including cell re-differentiation messengers are currently being tested to provide a better quality of life. In this sense, it has been demonstrated that the supplement of molecular iodine (I2) with cytotoxic agents like doxorubicin (DOX) promotes a cytotoxic effect and generates cardioprotection. In this study, canine mammary cancer is used as a model of spontaneous carcinogenesis. Objective: Determine the efficacy of metronomic therapy of DOX in combination with I2 analyzing the clinical, pathological, and molecular effects involved in proliferation, invasion, and chemoresistance. Methods: 27 females with mammary cancer were given daily I2 (110 mg) supplements or placebo (colored water) in conjunction with four cycles of DOX (30 mg/m2, intravenous). Two protocols were carried out: the standard protocol with a 21-day interval and 20-minute infusions, and the metronomic protocol with a 15-day interval and 60-minute infusions (DOX-M). Results: The metronomic scheme (DOX-M) attenuated the severity of side effects, but it showed no difference in tumor response (size, gene expression). The I2 supplement significantly improved the quality of life in both schemes, and it exerted synergistic effects on the tumor response in DOX-M, decreasing the epithelial component as well as markers of chemoresistance (MDR1 and Survivin) and invasion (uPA). The antitumor immune response (lymphocytic infiltration) in this scheme was significantly activated, and all these responses were accompanied by a reduction in proliferation and/or anti-apoptotic (anti-Bax and anti-Bcl-2) and angiogenic (VEGF and MMP) expression. Endocrine evaluation showed that I2 supplements do not alter thyroid function or estrogen response. Conclusions: Combination of DOX + I2 in a metronomic scheme exerts synergistic effects that prevent drug resistance and invasion and greatly improve the patient’s quality of life. Studies are underway to decrease the dose of DOX. Key words: Molecular Iodine, Doxorubicin, Canine Mammary Cancer, Metronomic Therapy. The authors appreciate the technical support of Alexander Bontempo, Evangeline Delgado and Maria Juana Cardenas. Investigation supported by PA-IIIT-UNAM IN200813 and 201516; CONACYT 245255.

**#1089 Anti-tumor activity of selinexor is enhanced by palbociclib in preclinical models of HER2+ breast cancer.** Hua Chang, Sharon Friedlander, Trinayan Kashyap, Boris Klebanov, Christian Argueta, Oscar A. Gonzalez, Erkan Baloglu, Yosef Landesman, Sharon Shacham, Margaret Lee, William Senneped, Karyopharm Therapeutics, Inc., Newton, MA

Introduction: XPO1 (exportin-1/CRM1) inhibitor selinexor (KPT-330) is the first-in-class, orally bioavailable, clinical stage SINE (Selective Inhibitor of Nuclear Export) compound with marked anti-tumor activity towards solid and hematological malignancies. This activity can be further enhanced by other therapeutic agents. We have previously shown strong synergistic preclinical activity of KPT-330 in trastuzumab and cell line-specific models of acquired resistance to HER2-targeted therapies, G1/S phase cell cycle regulators Cyclin D1 and CDK4/6 are inappropriately activated. We therefore investigated the combinatorial effect of selinexor plus palbociclib, a CDK4/6 inhibitor, in HER2+ breast cancer models as a treatment option for recurrent and relapsed HER2+ breast cancers. Methods: The effects of selinexor or palbociclib single agents or in combination were tested in vitro with BT474 HER2+ breast cancer cell line. Total RNA and protein was extracted from cell lysates and analyzed by qPCR and immunoblots. In vivo, a subcutaneous BT474 xenograft mouse model was treated with selinexor (5 mg/kg or 15 mg/kg; qodx3) or palbociclib (50 mg/kg or 150 mg/kg; qd) single agents or in combination. Tumor growth and body weights were monitored for 60 days. Tumors were harvested and analyzed by immunohistochemistry (IHC). Results: Selinexor plus palbociclib was highly effective in vitro and in vivo in BT474 breast cancer cells. In in vitro assays, selinexor or palbociclib single agents demonstrated inhibitory effects on cell proliferation and showed strong synergy when combined. In vivo, the combination resulted in significant survival benefit and enhanced tumor growth inhibition compared to vehicle or either single agent. IHC analysis of xenograft tumors showed synergistic inhibition of cell proliferation by selinexor plus palbociclib. The Ki67 proliferation index determined by IHC was 25% for vehicle control, 20% for selinexor, 7% for palbociclib and 2% for the combination. Based on IHC analysis, the synergistic anti-tumor activity of selinexor plus palbociclib was achieved at multiple levels of the CDK4/6 pathway. Selinexor treatment increased p21, p27 and Rb nuclear staining. Both p21 and p27 are inhibitors of CDK4/6 while Rb mediates cell cycle progression, CDK4/6 phosphorylates and inactivates Rb, which allows cell cycle progression. As well as palbociclib treated samples, phosphorylated Rb in the nucleus decreased, indicating a down-regulation of the CDK4/6 pathway. Conclusion: Selinexor plus palbociclib shows synergistic inhibition of cell proliferation in vivo

**EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Combination Therapy 1**
and in vitro in HER2+ breast cancer cell line BT474 by down-regulation of CDK4/6 pathway. This combination therapy warrants further investigation as an effective treatment option for recurrent and relapsed HER2+ breast cancer.

**#1090** Preclinical evaluation of combination therapy with dasatinib and sorafenib for the treatment of brain metastases. Qingsyu Stephanie Zhou, Xiaofang Guo. Univ. of South Florida College of Pharmacy, Tampa, FL.

Brain metastases, the most common type of intracranial tumors in adults, carry a dismal prognosis with a median survival of less than 18 months regardless of primary status or treatment given. As part of an ongoing project, this study is concerned with the preclinical evaluation of targeted combination therapy for the treatment of brain metastases. The cell line used in this study was the H1915 (ATCC® CRL-5904®) human lung cancer cell line, which was originally derived from a brain metastasis from primary lung adenocarcinoma. The cell line was stably transfected with a plasmid that allows expression of firefly luciferase (i.e., H1915-luc) so that the tumor growth in a mouse orthotopic model of brain metastases can be assessed in real time using the Xenogen in vivo bioluminescence imaging (BLI). Our previous study has demonstrated that the synergistic effect of combined dasatinib and sorafenib treatment was cell-line dependent. In this study, the cytotoxicity of dasatinib and sorafenib, when used alone or in combination at the fixed molar ratios of 3:1, 1:1 and 1:3 (dasatinib:sorafenib), was further examined in H1915-luc cells using the MTT assay. The results demonstrated that simultaneous and continuous exposure of H1915-luc cells to dasatinib and sorafenib at the fixed concentration ratio of 1:1 and 1:3 for 72 h showed synergism (the combination index value between 0.7 and 0.8) at effect levels of 40 and 80% inhibition of cell viability. For the in vivo study, an orthotopic mouse model of brain metastases was established by injecting H1915-luc cells into the right general carotid artery of individual athymic nude mice followed by permanent ligation. The preliminary study showed that following the intracarotid injection of H1915-luc cells, brain metastases were formed and readily to be detected by BLI. The obtained whole brain samples were fixed in OCT and stored at −80°C. The brain sections are to be subjected to the immunofluorescence double staining of CD31 and firefly luciferase to assess the potential effect of the dasatinib-sorafenib combination on microscopic brain metastasis formation and progression and vessel co-option. Given the fact that brain metastases usually have a poor response to chemotherapeutic agents in part due to the presence of blood-brain barrier, a pharmacokinetic study is underway to characterize the distribution of sorafenib and dasatinib in normal brain tissues and brain metastases using the serial blood sampling and brain microdialysis technique. Overall, results from the in vitro cytotoxicity study demonstrated the synergistic effect of dasatinib and sorafenib on H1915-luc human lung cancer cells, providing a rationale for the in vivo evaluation the potential of this combination for the treatment of brain metastases from lung carcinomas.

**#1091** Paclitaxel-loaded microparticles in combination with gemcitabine-loaded microparticles decreases gemcitabine resistance and promotes cell death in pancreatic cancer cell lines. Maria Munoz-Sagastibelza, Ariella Moshchinsky, Oluwafeyemi Okome, Jenny E. Paredes Sanchez, Raavi Gupta, Laura Martello-Rooney. SUNY Downstate Medical Ctr., Brooklyn, NY.

Pancreatic cancer is the fourth leading cause of cancer death in the United States with only 7% of diagnosed patients surviving 5 years. Current systemic chemotherapies have not been very effective at decreasing tumor burden, but nonetheless expose patients to the adverse side effects of treatment. Poly(lactic-co-glycolic acid)-based microparticles (MPs) are a promising tool for localized therapy and additionally reduced invasiveness of tumors similar to PF562271 phosphorylation in tumor cells. For the purification of glioma cells from total tumor tissue Percoll gradients were used. The study revealed that treatment with PF562271 reduced invasion of glioma cells at the tumor edge, while TMZ reduced the tumor growth. Combined treatment showed significantly more prominent effect on reduction of tumors growth compared to TMZ monotherapy and additionally reduced invasiveness of tumors similar to PF562271 monotherapy. In both PF562271 monotherapy and combined treatments the downregulation of Pyk2 phosphorylation in glioma cells has been recorded. Survival analysis demonstrated a significant increase of survival of animals received combined treatment compared to TMZ monotherapy. In conclusion, we can state that combined treatment with TMZ together with PF562271 reduced Pyk2-related tumor growth and invasiveness and increased animal survival. This result was made possible by NIH grant numbers: 1SC2GM102040-01, G12MD007583, R25GM110513, Puerto Rico Science, Technology, and Research Trust grant number 2016-00157, and US Department of Education grant number P0315130068.

**#1092** PF562271, a Pyk2 inhibitor, reduces glioma tumor growth and invasion in C57Bl6/Gl261 mouse glioma model. Jesecila Ortiz-Rivera, Kimberly Rollon-Reyes, Alejandro Albers, Luis Cabano, Lilia Kucheryavikh. 1Universidad Central del Caribe, Bayamon, PR; 2University of Puerto Rico, Piedras, PR.

Glioblastoma is an extraordinarily aggressive type of brain cancer due to its invasive and proliferative nature. The tumor microenvironment, with microglia as a critical player, has an important role in tumor progression. Microglia infiltrate majority of gliomas and release factors, which favor tumor growth and invasion. Previously we demonstrated that microglia Pyk2-related tumor growth and invasiveness and increased animal survival. The described drug delivery method with systemic gemcitabine and locally loaded microparticles decreases gemcitabine resistance and promotes cell death in pancreatic cancer cell lines. In addition, preliminary drug release studies with GMPs demonstrated detection of gemcitabine up to 14 days. In conclusion, our data demonstrated that GMPs and GMPs promote an increase in cancer cell death. Furthermore, the combination of the drug-loaded MPs indicated a reduction in drug resistance and clear impairment in colony formation. Further studies are in progress to investigate combination MPs injections in a mouse model of pancreatic cancer to confirm in vivo efficacy. The described drug delivery method has the potential to be a more efficient local treatment modality than systemic drug against pancreatic cancer.

**#1093** Synergistic action of sorafenib and carfilzomib against hepatocellular carcinoma in vitro and in vivo. Chao Jiang, Rui Xu, Xiao-Xing Li, Hui-Yun Wang, X.F. Steven Zheng. 1Sun Yat-sen University Cancer Center, Guangzhou, China; 2Cancer Center of Guangzhou Medical University, Guangzhou, China.

Background: Sorafenib, a multikinase inhibitor, is currently the only approved systemic drug for advanced hepatocellular carcinoma (HCC), but has demonstrated limited survival benefits for patients. Carfilzomib (CFZ) is a second-generation proteasome inhibitor approved for the treatment of multiple myeloma. In this study, we aim to investigate the synergistic antitumor effect of the combined treatment of sorafenib and CFZ in hepatocellular carcinoma and the underlying molecular mechanisms. Methods: Hep3B and Bel-7402 HCC cell lines were treated with sorafenib and/or CFZ at clinically relevant concentrations, after which effects on cell viability and proliferation were analyzed using MTS method; cell migration and invasion were evaluated in transwell assay; cell apoptosis were monitored by flow cytometry. Western blot assay was used to investigate the potential molecular mechanism of the synergistic antitumor effect of the combined treatment. In vivo efficacy was determined in nude mice with Hep3B xenografts. Results: MTS results showed that CFZ could improve
the drug sensitivities of sorafenib in Hep3B and Bel-7402 cells when combined these two drugs together. Moreover, cell proliferation was more significantly suppressed in combinational treatment compared to single agent (p < 0.01) in the two tested cell lines. The colony formation assay showed similar results with the MTS assay. The results from flow cytometry showed that sorafenib or CFZ alone induced about 76% and 27% apoptosis in Hep3B and Bel-7402 cell lines, respectively. The combination of these agents significantly increased the apoptosis rate up to 20.78% (p < 0.01). Similar results were observed in Bel-7402. Results of transwell assay demonstrated that cell migration and invasion ability were inhibited when treated with sorafenib or CFZ alone; and cells treated with the combinational therapy migrated and invaded even less (p < 0.05). The in vivo xenograft tumor model showed that treatment with sorafenib or CFZ inhibited Hep3B tumor growth (p < 0.05); moreover, treatment with the combination more significantly inhibited tumor growth (p < 0.01). Mechanistically, combined treatment of the two drugs suppressed the epithelial-mesenchymal transition process by increasing E-cadherin and decreasing N-cadherin and β-catenin. Furthermore, the drug combination activated the mitochondria-related apoptosis pathway, showing up-regulation of cleaved caspase 3/7/9. Up-regulations of PERK/eIF2α/ATF4/CHOP pathway implicated the involvement of ER stress-mediated apoptotic pathway following the drug combination treatment. Conclusion: In conclusion, these findings suggest that the combination of sorafenib and CFZ shows synergistic anti-tumor activities in HCC, potentially providing a novel therapeutic strategy for patients with advanced hepatocellular carcinoma.

#1094 Combining the pan-FGFR inhibitor AZD4547 with radiation in lung and head and neck squamous cell carcinoma. Andrew M. Baschmargel, Chunrong Li, Alecia M. Morgan, Sean R. Brennan, Kalley A. Russo, Paul M. Harari. Univ. of Wisconsin School of Medicine, Madison, WI.

The fibroblast growth factor receptors (FGFR1, FGFR2, FGFR3, FGFR4) are frequently altered or overexpressed in both lung and head and neck squamous cell carcinomas (SCC). Amplification of FGFR1 has been reported to be as high as 22% in lung SCC and 17% in head and neck SCC (HNSCC). FGFRs have been identified as a potential therapeutic target in lung and head and neck cancers. In addition, FGFRs activate multiple pathways involved in the radiation response including RAS/RAF/MAPK, PI3K/AKT and STAT. AZD4547 is a potent and selective tyrosine kinase inhibitor of the FGFR family and is currently being investigated in clinical trials. Since a substantial portion of lung cancer and HNSCC patients are treated with radiotherapy, we examined the anti-tumor effects of AZD4547 in combination with radiation in both lung and head and neck cancer model systems. FGFR protein and RNA expression and cell proliferation with AZD4547 were evaluated in 8 lung and 8 head and neck cancer cell lines. Clonogenic survival assays were performed on 4 lung and 4 head and neck cancer cell lines and xenograft experiments were performed on one HNSCC cell line. These cell lines demonstrated varying levels of FGFR1, 2 and 3 protein and RNA expression. The half maximal inhibitory concentration (IC50) of AZD4547 in these cell lines ranged from 0.05 to 128 μM. Sensitivity to AZD4547 did not correlate directly with protein or RNA expression. In vitro clonogenic survival assays showed limited effects of combining AZD4547 with radiation. However, significant tumor growth delay was observed with the combination of radiation with AZD4547 compared to radiation alone in the SCC1483 FGFR2 expressing HNSCC xenograft model. These findings suggest that AZD4547 can augment the response of radiation in an in vivo model system. Further studies are underway to test these findings in additional cell lines including FGFR dependent amplified cancer cell lines.

#1095 A combination of suberoylanilide hydroxamic acid and quinacrine is an effective therapeutic approach in preclinical settings of upper gastrointestinal cancers. Shoumin Zhu, Wael El-Rifai. Surgery, Nashville, TN.

Background: Quinacrine (QC), an antimalarial drug, has been shown to possess antitumor effects. Suberoylanilide hydroxamic acid (SAHA) inhibits class I and class II HDACs and is approved for cancer therapy. Developing novel approaches to overcome cancer drug resistance could significantly enhance current therapeutic approaches and improve patient care. Methods: ATP-GLO clonogenic survival, Annexin-V apoptosis assay, comet assay and DNA double-strand breaks (DSB) kits were used. The mRNA and protein levels were evaluated by quantitative real-time PCR and Western blot analyses. Results: A combination of QC/SAHAsignificantlyincreasedcelldeathinallcancercelllinesandhadnoeffectonimmortalizednon-cancercelllines(HEF145,NIH-3T3andEPC2) (P > 0.01). Clonogenic survival assay indicated that QC/SAHAs co-treatment led to significantly lower number of cancer cell colonies, as compared to single agents and controls (P < 0.01). Of note, the QC/SAHAs combination led to an increase in the the sub-G0 population in AGS (9-fold), MKN-28 (14-fold), FLOI (5.6-fold), and SNU1 (4-fold) cells (P < 0.01). These results were confirmed using the Annexin V apoptosis induced significantly higher levels of apoptosis (10 - 20 fold) as compared to single agent and control (P < 0.01). Treatment with QC/SAHAS combination induced high levels of DSB (>20 fold, P < 0.01). Comet assay data showed increased DNA damage compared with vehicle-treated cells (8-fold, P < 0.01). Western blot analysis demonstrated a substantial increase in the expression of pro-apoptotic proteins (BAX and BAK) and a decrease in the expression of anti-apoptotic proteins (BCL2 and BCL-XL). Conclusion: The QC/SAHAs co-treatment in all cancer cell lines. Interestingly, the combination of QC/SAHAs substantially decreased the protein levels of both wtP53 and mutP53 in these cells. Tumor xenograft data confirmed that a combination of QC/SAHAs is more effective than a single agent in abrogating tumor growth (P < 0.05). Conclusion: Our novel findings show that QC and SAHA have a synergistic effect that provide consistent findings that increased DNA damage mediates the cytotoxic effect of combined QC/SAHAs. Such effect is likely related to mutP53 and wtP53 protein degradation induced by QC/SAHAs combination. Our findings provide a rationale for a clinical evaluation of combined QC/SAHAs therapy in gastro-esophageal cancers. Ongoing studies are currently being undertaken to understand mechanisms that regulate the degradation of wtP53 and mutP53 proteins.

#1096 Co-targeting of AKT and Pim kinases in mouse PTEN-deficient prostate cancer. Marco A. De Velasco,1 Koichi Sugimoto,2 Yuriue Kura,3 Naomi Ando,1 Noriko Sato,1 Kazuko Sakai,1 Barry R. Davies,2 Dennis Huszar,3 Masa-hiro Nozawa,2 Kazuhiro Yoshimura,2 Kazuhiro Yoshikawa,3 Kazuto Nishio,3 Hirotsugu Uemura1.1Kindai University Faculty of Medicine, Osaka-Sayama, Japan; 2AstraZeneca, Macclesfield, United Kingdom; 3Aichi Medical University, Nagakute, Japan.

AKT and Pim kinases modulate programmed cell death by the phosphorylation of common substrates that regulate apoptosis and other survival processes. Evidence suggests that the antitumor effects of targeted Akt inhibition can be inhibited or diminished by the JAK/STAT-dependent induction of Pim kinases. In this study we examined the therapeutic potential of co-targeting AKT and Pim in a genetically engineered mouse model of prostate cancer driven by the conditional inactivation of PTEN. The antitumor effects of AZD3563, a pan AKT inhibitor, and AZD1208, a highly potent Pim kinase inhibitor, were investigated as monotherapy or in combination on mice harboring castration-naïve prostate tumors and mice that developed castration-resistant disease. Mice were randomized treated for four weeks. Safety and tolerability was assessed by body-weight changes. Antitumor activity was determined by differences in tumor burden, proliferation and apoptosis and histology. Molecular activity was assessed by examining the phosphorylation of common substrates by western blot analysis. Treatments were well-tolerated and no significant differences in body-weight changes were observed. In castration-naïve prostate tumors, treatments with AZD3563, AZD1208 and AZD3563/AZD1208 resulted in 11.9%, 13.5% and 30.9% reductions of tumor burden compared to vehicle treated controls, respectively, P < 0.001. The treatment combination of AZD3563/AZD1208 demonstrated significant antitumor activity compared to monotherapy, P < 0.001. In the castration-resistant tumors, treatments with AZD3563, AZD1208 and AZD3563/AZD1208 resulted in 21%, 9.5% and 27% reductions of tumor burden compared to vehicle treated controls, respectively, P < 0.004. Although differences in tumor burden were not statistically significant compared to vehicle treated controls, a combination of monotherapy and combination therapy, a notable degree of tumor gland regression was observed in tumors treated with AZD3563/AZD1208. Overall, combination therapy showed a synergistic effect by inhibited or impaired phosphorylation of PRAS40, elf4B and BAD in both castration-naïve and castration-resistant tumor models. Inhibition of both pathways enhanced the reduction of tumor cell proliferation and increased apoptosis. Overall, our findings provide in vivo data to support redundancy between AKT/Pim survival pathways and suggest that a therapeutic approach of combined AKT/Pim kinase inhibition may be possible therapeutic approach for AKT-driven prostate cancer.

#1097 Enhancing the efficacy of Temozolomide with Biochanin A: Mechanistic and metabolic effects. Vilas Desai,1 Aditi Jain,2 Maryna Perereplyuk,3 Annie Chibun,3 Christopher Farrell,3 James C. K. Li,4 Alok Bhushan1.1Thomas Jefferson University, Philadelphia, PA; 2University of Kentucky, Lexington, KY; 3Idaho State University, Pocatello, ID.

Enhancing the efficacy of Temozolomide with Biochanin A: Mechanistic and Metabolic effects Glioblastoma multiforme (GBM) is the most frequent, primary malignant brain tumor prevalent in humans. GBM is characterized by aggressive cell proliferation and rapid invasion of normal brain tissue resulting in poor patient prognosis. Furthermore, the current standard therapy of surgical resection followed by radiotherapy and chemotherapy with Temozolomide is not very effective. The inefficacy of the currently available chemotherapeutic agents for GBM can be attributed to the challenges of drug delivery to the tumor.
EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Combination Therapy

Our laboratory has previously reported the anticancer potential of isoflavones like Biochanin A against oral, pancreatic, breast and brain cancers. In this study, we tested our hypothesis that Biochanin A sensitizes the GBM cells to Temozolomide, thereby increasing its efficacy in combination treatment. We used the MTT assay to determine the effects of Biochanin A alone and in combination with Temozolomide on survival of U-87 MG cells. Furthermore, two different induction of apoptosis with combination treatment as compared to the drugs alone. Western-blot analysis and Immunofluorescence imaging methods were used to elucidate some of the cell survival/proliferation mechanisms involving EGFR, p-AKT, MMP-2, MT-MMP1. The effects of the drugs on U-87 MG cell metabolism (parameters like ECAR & OCR) studied using Seahorse XF analyser, suggest an increase in the mitochondrial respiration. Our results support our hypothesis and the data shows that it may have implications in increasing the efficacy of the conventional treatments for GBM. These results will potentially aid in designing new therapies that can improve the outcome of GBM.

#1098 Delta-tocotrienol chemosensitizes human pancreatic tumor metastasis to gemicitabine targeting cancer stem cells. Kazim Hüsain, Said M. Sebti, Mokeng L. Ajila. Moffitt Cancer Center, Tampa, FL.

Background: Pancreatic cancer, a lethal malignancy is the fourth leading cause of cancer-related deaths in the United States. The standard chemotherapy with gemcitabine is ineffective in patients with metastatic tumors. Pancreatic cancer stem cells (CSCs) have been implicated in the development of pancreatic cancer metastasis, resistance to chemotherapy and its recurrence following surgical extirpation. We have shown that natural vitamin E δ-tocotrienol is the most bioactive tocotrienols against pancreatic cancer in vitro as well as in vivo models. The purpose of this study was to evaluate the chemosensitization of pancreatic tumor metastasis by δ-tocotrienol to gemcitabine in vitro as well as in vivo. Methods: In vitro human metastatic pancreatic cancer cells L3.6pl and pancreatic cancer stem cells (PCSC) were treated with gemcitabine (5 μM) and δ-tocotrienol (50 μM) alone and in combination. Treated cells used for epithelial to mesenchymal transition (EMT), migration/invasion, microsphere/spheroid, and signaling markers assays. PCSC expressing luciferase was orthotopically implanted into pancreas of Athymic nude mice (n = 20) and after one week they were randomized into four groups: 1) vehicle control (ethanol extracted olive oil), 2) gemcitabine (100 mg/kg, IP, twice a week), 3) δ-tocotrienol (200 mg/kg, orally twice a day) and 4) gemcitabine + δ-tocotrienol. The treatment was continued for 4 weeks. The tumor volume, tumor weight, metastasis were recorded. Results: Gemcitabine slightly inhibited the growth, migration/invasion of L3.6pl and PCSC in vitro and PCSC tumor growth (tumor volume and weight) in vivo. δ-tocotrienol significantly inhibited the growth, microsphere/spheroid, migration/invasion, EMT (E-cadherin to vimentin), angiogenesis (VEGF, PCSC transcription factors like VEGF, HIF-1 and HIF-2). Tocotrienol did not affect the microsphere and liver/lung metastasis compared to control. The combination of both drugs synergistically inhibited the cancer and stem cell growth, EMT, migration/invasion, microsphere/spheroid, angiogenesis, and PCSC transcription factors in vitro as well as in vivo. Conclusion: Vitamin E δ-tocotrienol chemosensitizes human pancreatic tumor metastasis to gemcitabine through inhibition of EMT, migration, invasion, angiogenesis, cancer stem cell self-renewal, tumor growth and metastasis.

Introduction Docetaxel combined with castration provides a major survival benefit in newly diagnosed metastatic PCa. Conversely, docetaxel without castration in high-risk localized PCa is not active. Cabazitaxel is a new taxane retaining its activity in tumors resistant to docetaxel and new hormonal therapies. We aimed at better characterizing in vivo the relationship between cabazitaxel and circulating androgens in a preclinical human-derived xenograft model of castration-resistant prostate cancer (CRPC). Material and methods: Athymic nude mice were inoculated with the androgen receptor wt, PSA secreting CRPC cell line PC346C-DCC-K. Mice were surgically castrated when tumors were established (tumor volume (TV) of 150 mm³). After 7 days, mice were random-ized to receive testosterone (40 mg) or empty pellet. The following day mice were injected with one bolus injection of cabazitaxel (33 mg/kg) or NaCl intraperito-neally. Mice were sacrificed when tumors exceeded a volume of 1,500 mm³ or the maximum follow-up of 90 days after cabazitaxel treatment. Blood was sampled biweekly for PSA and testosterone and analyzed by an immunassay. In a second in vivo–complete antitumor response. In contrast, in mice supplemented with testosterone the anti-tumor effect of cabazitaxel was not significa-tively different from placebo (median time till TV 1,500 mm³ 48 and 45 days resp.). Importantly, testosterone supplementation alone did not significantly affect tumor growth, confirming the CRPC nature of the (PC346C-DCC-K) xenograft. Interestingly, in tumors of testosterone supplemented castrated mice the intratumoral cabazitaxel concentrations were significantly decreased compared to mice that did not receive testosterone (0.39 ng cabazitaxel per mg tumor tissue vs. 1.36 ng/mg, t-test p = 0.0032). Conclusions These findings indicate that circulating testosterone significantly impairs the efficacy of cabazitaxel. Testoster-one supplementation may alter the metabolism of cabazitaxel, or may interfere with uptake and/or accumulation of cabazitaxel in PCa cells. We will further investigate the relationship between circulating androgens and intratumoral cabazitaxel accumulation as well as anti-tumor efficacy. The study was sup-ported by a research grant from Sanofi.

#1100 Synergistic interaction between gemicitabine and PD-0325901 in C-33A cervical carcinoma cell line. Macarena Irigoyen, Gonzalo Castillo. BIOPHARMA, LLC., Bellevue, WA.

Cervical cancer affects over half a million women worldwide, and is one of the most common causes of death in women. Treatment of cervical cancers consists of surgery, radiation, chemotherapy, or combination of therapies. However, about half of patients with advanced cancer will show recurrent tumors. Signalng cascades are often dysregulated in human cancer cells making them attractive targets for combination drug therapies. PD-0325901, an inhibitor of the mito-gen-activated protein kinase, is a promising target for metastatic cancer. An-other drug used to treat cervical carcinoma is gemcitabine, a nucleoside analog inhibitor of the ribonucleotide reductase and DNA damage inducible protein 45a (Gadd45a). This drug is generally used in combination with other drugs, after reoccurrence of the disease state. We decided to evaluate the efficacy of gemcitabine in combination with PD-0325901 in C-33A, a metastatic cervical cancer-derived cell line. We evaluated the potency of gemcitabine and PD-0325901 alone and in combination. Cell viability after incubation with the drugs was determined at 72 hours and at 7 days by measuring ATP content. Synergy was determined assessed utilizing BIOPHARMA’s suite of drug combination analysis tools including: isobologram, combination index (CI) and Bliss analysis. Isobologram analysis at 72 hours of incubation revealed that the mean values of the observed data were significantly smaller than those of the predicted maximum. These results indicated a synergistic effect at concentrations between 2 - 200 nM PD-0325901 and 0.3 - 3 nM gemcitabine. Similar patterns of synergy were observed with 7 day incubations of C-33A with gemcitabine and PD-0325901. These results indicate that gemcitabine and PD-0325901 showed significantly more growth inhibition than either drug alone in the C-33A tumor cell line, suggesting that the combination of gemcitabine - PD-0325901 could be used in cervical cancer therapy.

Background/Aims: Acute myeloid leukemia (AML) is an aggressive cancer with limited treatment options outside of chemotherapy. Improved ther-apyes with novel mechanisms of action are desperately needed to fill this need. Both hTERT, the catalytic subunit of telomerase, and BCL-2, an apo-ptic regulator, are overexpressed in AML, correlating with disease severity and poor prognosis respectively. Imetelast is a novel, first-in-class competitive inhibitor of telomerase with clinical activity in hematologic malignan-cies. Venetoclax, an approved BCL-2 inhibitor for CLL, has shown a prom-ising clinical benefit in AML patients. Preclinical evidence shows that

Proceedings of the American Association for Cancer Research • Volume 58 • April 2017

282
downregulation of hTERT induces apoptosis via disruptions of hTERT and BCL-2 interaction; we hypothesize that inhibiting both targets would yield greater anti-tumor activity in AML compared to treatment with either agent alone. Methods: AML cell lines and AML patient's PBMC samples were treated with imetelstat or venetoclax alone, or in combination, and viable and apoptotic populations of cells were evaluated by dual color flow cytometry. The combination of autologous imetelstat with novel theranostic agent OBP-401 and chemotherapeutic agent paclitaxel (PTX) has been shown to have therapeutic effects against ovarian cancer with peritoneal metastasis. However, the effective treatment option to overcome peritoneal metastasis of SGC has not been developed yet, although i.p. administration of some chemotherapeutic agents has been attempted to SGC. Therefore, a novel therapeutical strategy is required for the treatment of peritoneal metastasis. Methods: We previously developed a telomerase-dependent replication-selective adenovirus OBP-401 (TelomeScan), which can replicate within the tumor cells selectively and express green fluorescent protein (GFP). Moreover, OBP-401 infection also induces tumor-specific cell death in monotherapy or combination therapy with chemotherapy. In this study, we assessed synergistic effects in combination with novel theranostic agent OBP-401 and chemotherapeutic agent paclitaxel (PTX) using human SGC cell lines (GCIY and KATO III). In vitro experiment, SGC cells and normal human lung fibroblast (NHFL) cells were infected with OBP-401 at various doses. PTX was administered after 48 hours of virus infection. Twenty-four hours after PTX administration, we evaluated the anti-tumor effect by XTT assay, and analyzed the synergistic effect by CalcuSyn Software. Results: SGC cells were visualized as GFP-positive cells selectively by the infection of OBP-401, whereas NHFL cells were not visualized with OBP-401. In both SGC cell lines, the suppression of cell viability dose-dependently by administration of OBP-401 or PTX alone was confirmed. OBP-401 synergistically suppressed the viability of SGC cells in combination with PTX as compared to monotherapy; Conclusions: These results suggest that OBP-401 has a promising potential to treat peritoneal micrometastasis of SGC intraoperatively and combination of OBP-401 and PTX would be a novel theranostic strategy for the treatment of peritoneal metastasis of SGC.

**#1104 Novel specific RTK targeting of EGFR/FAK axis in glioblastoma invasion.** Raghupathy Vengoji, Satyanarayana Rachaganii, Suprit Gupta, Kavita Mallya, Maneesh Jain, Moorthy Ponnussamy, Surinder Batra, Nicole Shonka. University of Nebraska Medical Center, Omaha, NE

Background: Glioblastomas (GBM) is the most aggressive primary brain tumor with a median survival of 14.6 months. Currently, the first-line treatment includes surgical resection, chemoradiation, and adjuvant therapy with temozolomide. However, GBM recurs most often within 6.9 months. Receptor tyrosine kinases are dysregulated in GBM, with epidermal growth factor receptor (EGFR) representing 57.4% of the deleted/mutated GBM. In addition, 30 – 40% of GBM patients with EGFR amplification carry an oncogenic gene rearrangement EGFR variant III (EGFRVIII) which is constitutively active. Most EGFR inhibitors have shown very little clinical efficacy in GBM. Methods: Afatinib, brain-brain barrier penetrating pan-EGFR inhibitor, covalently binds and irreversibly inhibits signaling from EGFR. Afatinib also persistently inhibits ErbB homo and hetero-dimers. Use of GBM cell lines U87MG and U87MG transfected with wild type EGFR, EGFRVIII and EGFRVIII with Dead Kinase domain, we evaluated the efficacy of afatinib alone and in combination with temozolomide. Results: Afatinib treatment resulted in a dose dependent decrease in the proliferation of U87MG cell transfected with EGFRVIII. The IC_{50} value for this cell line is 2μM (afatinib). 50μM temozolomide inhibited cell proliferation by 50%. We evaluated the combinatorial efficacy of IC_{50} of both, Afatinib and Temozolomide in the in vitro tumorigenicity (anchorage dependent growth - colony formation assay as well as anchorage independent growth - soft agar assay) of EGFRVIII expressing GBM cells. Conclusion: Altogether, these results support synergistic efficacy of afatinib and temozolomide in EGFRVIII expressing GBM cells. 4. A Chemotherapeutic approach to kill cancer stem cell rich ovarian ascites. Siddik Sarkar, Obeid M. Malekshah, Arash Hatefi. Rutgers University, Piscataway, NJ

Purpose: More than one third of ovarian cancer patients present with cancer cells in the abdomen (also known as ascites) at diagnosis, and almost all have ascites at recurrence (Ahmed and Stenvers 2013). It is well-documented that subpopulations of the ascites show cancer stem cell-like characteristics which possess enhanced resistance to chemotherapies and the capacity for distant metastatic spread and recurrent disease. Therefore, ascites are a major source of morbidity and mortality for ovarian cancer patients. The major deficiency that currently exists is that there is no effective and safe therapy for ascites since they are rich in cancer stem cells (CSCs) and resistant to chemotherapy. To overcome this deficiency, it is our objective to develop an effective chemotherapy approach
that can destroy the CSC-rich ascites and inhibit recurrence. Methods: Several established human ovarian cancer cells as well as ascites obtained from the abdomen of an ovarian cancer patient (ASCITES) were cultured. Cells were sorted by FACS Cell Sorter to determine the percentage of cancer stem cells (CSCs) in each cell line. Dose response curves of different chemotherapeutic drugs such as Cisplatin (CDDP), 6-Methylpurine (6-MP), 5-Fluorouracil (5-FU), SN-38, Monomethyl auristatin E (MMAE) and Etoposide were studied in suspension culture enriched with cancer stem cells. The relative change in total CSC-rich spheroid mass which considers both number and volume of spheroids was used to determine Killing Index for each chemotherapeutic drug. To investigate inhibition of recurrence, the spheroids were monitored for 30 days post treatment. Results: We observed the potentiation of venetoclax activity by the autophagy inhibitor chloroquine (CQ) that specifically eliminated CSCs in a time-dependent fashion, up to 96 hours. CQ also restored sensitivity to venetoclax in MM cell lines that overexpressed MCL-1. High levels of MCL-1 and/or low levels of NOXA have been implicated in bortezomib resistance and negative patient outcomes, including short duration of treatment response. The BCL-2-specific BH3 mimetic venetoclax (ABT-199) has also been explored in multiple hematological malignancies, including the treatment of MM. Venetoclax induces apoptosis in a BCL-2 specific manner by directly inhibiting BCL-2 function. However, intrinsic resistance to veneto-

#1106 Alvocidib potentiates the activity of venetoclax in preclinical models of multiple myeloma. Mark Livingston, Wontak Kim, Hillary Hawes, Peter Peterson, Clifford J. Whatcott, Adam Siddiqui-Jain, Steven Weitman, David J. Bearn, Steven L. Warner. Toleropharmaceuticals, Inc., Lehi, UT.
The proteasome inhibitor bortezomib is widely used in the treatment of patients with multiple myeloma (MM). The expression levels of many proteins increase as a result of bortezomib treatment, including the pro-apoptotic protein NOXA. NOXA functions to sequester the anti-apoptotic BCL-2 family member MCL-1. High levels of MCL-1 and/or low levels of NOXA have been implicated in bortezomib resistance and negative patient outcomes, including short duration of treatment response. The BCL-2-specific BH3 mimetic venetoclax (ABT-199) has also been explored in multiple hematological malignancies, including the treatment of MM. Venetoclax induces apoptosis in a BCL-2 specific manner by directly inhibiting BCL-2 function. However, intrinsic resistance to venetoclax treatment observed in MM patient samples has been attributed to a low BCL-2 to MCL-1 gene expression ratio, suggesting a central role for MCL-1 in cell survival in this context as well. Increased MCL-1 expression is a known resistance mechanism to venetoclax treatment in a variety of cell types including chronic lymphocytic leukemia and lymphomas. Considering the central role of MCL-1 to treatment efficacy in MM, we investigated the ability of an MCL-1-inhibitor agent, namely the CDK9 inhibitor Alvocidib, to potentiate the activity of venetoclax in MM. Alvocidib suppresses MCL-1 expression via CDK9-mediated regulation of RNA polymerase II. Alvocidib has achieved robust improvements in the clinical response rates of high-risk, newly diagnosed acute myeloid leukemia (AML) patients as part of the time-sequential ACM regimen (alvocidib + cytarabine + mitoxantrone). We therefore hypothesized that Alvocidib would potentiate the activity of venetoclax in MM through an MCL-1-dependent mechanism. In this report, we demonstrate that Alvocidib inhibits the protein expression of MCL-1 in MM cells in a time-dependent fashion, up to 96 hours. In cell viability assays, the addition of up to 100 nM venetoclax resulted in a 2.8-fold reduction in the IC50 of Alvocidib in the cultured OPM-2 cell line. Conversely, the potentiation of venetoclax activity with the addition of Alvocidib resulted in a more than 500-fold decrease in IC50 in the relatively venetoclax-resistant OPM-2 cells. Additional studies are currently underway to investigate the efficacy of Alvocidib and venetoclax in the context of bortezomib resistance where low NOXA may contribute to enhanced cell survival via MCL-1. Taken together, our data suggest that the combination of Alvocidib with venetoclax may constitute a novel therapeutic regimen in the treatment of MM. Further, it suggests that CDK9-mediated targeting of MCL-1 may offer a clinical route to addressing intrinsic resistance in MM patients.

#1107 Co-treatment with a C1B5 domain peptide of protein kinase C gamma and a low dose of gemcitabine effectively inhibited pancreatic cancer growth in mouse peritoneal cavity. Alejandro Zulbaran, Kelsey Monson, Susumu Ishiguro, Atsushi Kawabata, Deepthi Uppalapati, Naomi Ohta, Masaaki Tamura. Kansas State University College of Veterinary Medicine, Manhattan, KS.

Although the gemcitabine is an effective chemotherapeutic agent for pancreatic cancer, unacceptable side effects often accompany. Since we have previously discovered that PKCγ C1B domain peptides effectively control tumor growth without any side effect (Kawabata et. al, Cancer Biol Ther, 2012), we sought to examine the efficacy of co-treatment with this peptide and a low dose of gem-

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Combination Therapy 1

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: DNA Repair

#1108 A novel, selective inhibitor of DNA-dependent protein kinase (DNA-PK) potentiates the effects of DNA-damaging therapies in hepatocellular carcinoma. Catherine E. Willoughby,1 Huw D. Thomas,1 Tommy Rennison,2 Celine Cano,2 Helen L. Reeves,3 Stephen R. Wedge1. 1Northern Institute for Cancer Research, Newcastle University, Newcastle upon Tyne, United Kingdom; 2School of Chemistry and Northern Institute for Cancer Research, Newcastle University, Newcastle upon Tyne, United Kingdom; 3Div. of Liver Unit, Freeman Hospital, Newcastle upon Tyne Hospitals NHS Foundation Trust and Northern Institute for Cancer Research, Newcastle University, Newcastle upon Tyne, United Kingdom.

DNA-dependent protein kinase (DNA-PK) is a key component in the repair of DNA double-strand breaks via non-homologous end-joining. Studies have found elevated DNA-PK expression and activity in hepatocellular carcinoma (HCC) to be strongly correlated with increased tumor grade, resistance to DNA-damaging therapies and poor survival (1,2). We have explored the selective inhibition of DNA-PK in combination with DNA-damaging agents as a potential therapeutic approach in HCC using NDD0004 - a novel, orally-bioavailable small molecule inhibitor of DNA-PK (in vitro IC50 = 8 nM). NDD0004 was evaluated in a panel of DNA-PK expressing human HCC cell lines (Hep3B, HepG2, Huh7) in combination with ionizing radiation or the topoisomerase II poison doxorubicin. DNA-PK activity was determined by Ser2056 phosphorylation status, DNA damage quantified by γH2AX levels, cell proliferation determined by SRB assays and cell survival assessed using clonogenic assays. In vivo efficacy was evaluated using a novel murine model of localized and sustained doxorubicin therapy, involving intra-tumoral injection of doxorubicin-loaded beads in established Huh7 human HCC xenografts in C57/ Bl6 nude mice. Oral twice-daily treatment with 30 mg/kg NDD0004 or vehicle control was commenced 1 hour following bead implantation and continued for up to 20 days (6 mice per group). NDD0004 dose-dependently inhibited activation of DNA-PK in HCC cell lines in vitro in response to ionizing radiation, and significantly increased and sustained DNA damage following treatment. Furthermore, NDD0004 sensitized DNA-PK overexpressing HCC cell lines to doxorubicin and ionizing radiation in proliferation and survival assays by > 5-fold. Combining NDD0004 with doxorubicin-loaded beads in vivo significantly inhibited the rapid growth of HCC tumors when compared to treatment with doxorubicin-loaded bead monotherapy, with the time taken for tumor

Proceedings of the American Association for Cancer Research • Volume 58 • April 2017

284
volumes to quadruple (RTV4) being extended from 11 to 18 days (P<0.01, Mann-Whitney). Individual and combination treatments were well tolerated throughout. Immuno-histochemical analysis revealed γH2AX levels in hepatocytes surrounding doxorubicin-loaded beads to be significantly increased by NDD0004 co-treatment for 72-hours (P<0.02, 2-way ANOVA). In conclusion, selective targeting of RUVBL1/2 with AsiDNA catalyzes DNA double-strand breaks (DSB), and reveals that MutSβ may potentially influence TMZ repair by modulating DSB repair. Consistently, host cell reactivation (HCR) assays in U251 expressing DRGFP reporter showed decreased homologous recombination regulating DSB repair. 

In the current study, we propose a novel therapeutic strategy, based on drug combination to promote sensitivity to PARP independently of the tumor genetics. Experimental design: We used AsiDNA, a DNA repair pathways agonist (Dbait concept), consisting in small molecules mimicking double-strand DNA breaks to activate ecdytic signaling of DNA damage and prevent recruitment at damaged sites of HR repair enzymes. We characterized the DNA repair inhibition activity of AsiDNA by monitoring repair foci formation and DNA damage and analyzed the cell survival to AsiDNA monotherapy and combination with the PARPi Olaparib of 21 tumor cell lines, and 3 non-tumor cell lines. Efficacy of the combination treatment was analyzed in tumor xenografts derived from the MDA-MB-231 cell line showing reduced sensitivity to AsiDNA and Olaparib in vitro. We screened for the first time the potential of AsiDNA as co-sensitizer of PARP inhibitors on the DNA double-strand break repair pathway.

Analogous sensitization in MSH6 KD cells (PF 2.6) deficiency. Supporting the concept of synthetic lethality of HR with PARP inhibitors, we showed by using the MDA-MB-231 xenograft model, whereas Olaparib failed to prevent tumor growth and AsiDNA provided only a 62% increase in tumor growth delay, the combination of Olaparib and AsiDNA increase 215% days the mean tumor growth delay. Conclusion: Our results highlight the therapeutic interest of combining AsiDNA and PARPi to recapitulate synthetic lethality in all tumors independently of their HR status. Moreover, the low frequency of appearance of resistant clones to AsiDNA suggests a sustained efficacy during treatment unlike most targeted therapies.

Mismatch repair (MMR) is essential for temozolomide (TMZ) sensitivity, and MMR deficiency causes TMZ resistance and disease recurrence. However, the role MMR in TMZ response has been linked with Msh2/Msh6 (MutSβ), while role of Msh3, a component of MutSβ remains unclear. To delineate role of MutSβ and MutSβ in TMZ response, we used siRNA to disrupt MSH6 and MSH3 expression. As expected, silencing of MSH6 led to resistance in a TMZ-sensitive U251 cell line. In contrast, silencing of MSH3 enhanced TMZ sensitiv-ity as compared to the control cells. These results support established role of MutSβ in TMZ response via replication stress and aggregation of DNA double-strand breaks (DSB), and reveal that MutSβ may potentially influence TMZ response by modulating DSB repair. Consistently, host cell reactivation (HCR) assays in U251 expressing DRGFP reporter showed decreased homologous recombination (HR) after MSH3 knockdown (KD), while Msh6 KD had no effect on HR efficiency. Supporting the concept of synthetic lethality of HR with PARP inhibi-tion, clinically relevant dose of veliparib (1 μM) showed a modest but consistent increase in TMZ sensitization measured in terms of potentiation factor (PF: ratio of relative growth with TMZ alone/ TMZ and veliparib) in MSH3 KD (PF 1.6±0.2) as compared to control cells (PF 1.1±0.2). Sensitizing effect of 1 μM veliparib in MSH6 KD (PF 1.7±0.5) was comparable to that in MSH3 KD cells. Interestingly, supra-therapeutic dose of veliparib (10 μM) induced more pronounced sensitization in MSH6 KD cells (PF 2.6±0.3) as compared to MSH3 KD (PF 2.4±0.3) or control cells (PF 1.6±0.2). Consistently, veliparib (10 μM) alone had no impact on DNA damage signaling, while TMZ induced prominent increase in phosphorylation of CHK1, Chk1 and Chk2 in control and MSH3 KD cells, but not in MSH6 KD cells; veliparib/TMZ co-treatment led a robust sig-naling in all 3 types of cells. Increased sensitization by veliparib after MSH3 KD was also examined in a TMZ-resistant (GBM22TMZ) PDOX model carrying re-sistance due to a homozygous mutation in MSH6, and a 4-fold increase in HR efficiency. In clonogenic assays silencing of MSH3 or BRCA1 had no effect on TMZ sensitization in GBM22TMZ cells. However, veliparib alone (10 μM) de-creased colony formation with relative colony formation 0.54±0.03 and 0.32±0.06 in MSH3 and BRCA1 KD cells, respectively, as compared to 0.82±0.05 in TMZ+veliparib co-treatment in GBM22TMZ; and further decrease in colony formation in MSH3 KD and BRCA1 KD cells with relative colony formation of 0.30±0.04 and 0.19±0.02, respectively versus 0.46±0.03 in control. Taken together, our results suggest that MutSβ and MutSβ differentially regulate cytotoxic effects of TMZ. Decreased HR efficiency and enhanced sensitizing effects of veliparib in MSH3 KD cells partially define synthetic lethality of MMR deficiency with PARP, and may help development of PARP inhibitors as sensitizer of TMZ therapy in GBM.

1111 The chromatin remodelers RUVBL1 and RUVBL2 are prognostic factors and therapeutic targets in non-small cell lung cancer due to their roles in DNA replication, repair, and radiosensitization. Paul Veneralli, Rahul Kol lipara, Amit Das, Pamela Villalobos, Long Shan Li, Brenda Timmons, Luc Girard, Jaime Rodriguez-Canales, Ignacio Wistuba, John Minna, Ralf Kittler, Univ. of Texas Southwestern Medical, Dallas, TX; UT-MD Anderson Cancer Center, Houston, TX.

Despite advances in targeted agents and immunotherapy, non-small cell lung cancer (NSCLC) remains the number one cause of cancer-related death. To identify new therapeutic targets in NSCLC, we performed a siRNA screen directed against genes involved in chromatin remodeling. This screen showed that RUVBL1 and RUVBL2 (herein collectively referred to as RUVBL1/2) were universally but differentially required for the viability of 24 NSCLC cell lines, which was an on-target effect. Various independent gene expression datasets/platforms show that NSCLC patient tumors have increased levels of RUVBL1 and RUVBL2 mRNAs, in comparison to normal lung, and that patients with high levels of RUVBL1 or RUVBL2 have a poorer prognosis, suggesting that RUVBL1/2 play an important role in NSCLC tumors. To confirm this at the protein level, we validated an antibody against RUVBL1 for immunohistochemistry, stained clinically annotated NSCLC tissue microarrays for RUVBL1, and found that patients with higher levels of RUVBL1 protein also have a poorer prognosis. To better understand the role of RUVBL1/2 in NSCLC at a molecular level, we measured the distribution of cells in the cell cycle following RUVBL1/2 KD, determined RUVBL1/2-interacting proteins by immunoprecipitation followed by tandem mass-spec (IP-MS/MS), and measured gene expression changes following RUVBL1/2 KD by RNA-seq. Depletion of RUVBL1/2 ar-rested cells in S-phase and promoted pan-γH2AX positivity, IP-MS/MS showed an over-representation of proteins involved in DNA repair and replication, and gene set enrichment analysis of the RNA-seq data displayed a downregulation of transcripts involved in DNA replication and repair, strongly implicating RUVBL1/2 in these processes. To further probe the effects of RUVBL1/2 loss, we performed low-level knock down (KD) of RUVBL1/2, such that viability is largely unaffected, and then measured the viability of cells in response to various drugs (n=35). These drugs target a wide variety of biological processes; however, only the drugs with increased efficacy in the presence of RUVBL1/2 KD resulted in a detrimental effect on RUVBL1/2 KD tumors, indicating that RUVBL1/2 contain a unique repair mechanism. Fi-nally, we show that RUVBL1/2 depend upon their ATPase activity to support NSCLC viability, suggesting that small molecule inhibitors of this protein may be efficacious in the treatment of NSCLC, especially when combined with radiotherapy.
#1112 Forced reduction of DSS1, a member of TREX2 complex, highly sensitizes chemotherapy to breast cancer cells in a BRCA2-independent manner. Kazuhiko Kuwahara, 1 Naomi Gondo, 2 Andri Rezano, 3 Zhenhuan Zhang, 4 Yukari Hato, 3 Kiyotaka Kuzushima, 2 Hiroji Iwata, 6 Tatsuya Toyama, 5

**EXPERIMENTAL AND MOLECULAR THERAPEUTICS: DNA Repair**

Sarkia.A.Abdulkadir, Einstein, Muhammad Zayd Ansari, Benedito A. Carneiro Filho, Francis J. Giles, 1, 1114 Combining anti-androgen therapy and PARP inhibition results in paired TREX2 complex might be associated with induction of chemosensitivity. Rather, the transcription-coupled DNA damage induced by im-

doxxorubicin and paclitaxel in breast cancer cells was evaluated by flow cytom-

tetry to detect apoptosis and colony assay. In addition, we compared patient survival by dividing patients into high or low expression group of BRCA2 or

Safety of CB was determined in long-term toxicity studies in mice and also in ex-vivo explants from breast cancer patients. The mechanism of action of CB was evaluated

#1115 Germline single nucleotide polymorphisms in DNA repair genes in uterine cervical carcinomas. Bishoy M. Faltas, Panagiota J. Vlachostergios, Linda Lam, Tu Zhao, Olivier Elemon, Mark A. Rubin, Weill Cornell Medical College, New York, New York.

Introduction: Germline single nucleotide polymorphisms (SNPs) have been investi-
gated in several cancers. Repair of DNA damage is a key cellular process in-
volved in the development of chemotherapy-resistance. The role of germline SNPs in DNA damage repair genes (DRGs) in determining resistance to DNA-damaging agents in uterine cervical carcinoma (UC) patients is not completely understood. Meth-
ods: We examined a cohort of 53 UC patients (median age 67, 42 males) enrolled in our IRB-approved Precision Medicine Program. Pathology confirmed UC (43 bladder, 10 upper tract UC) and received treatment with platinum-
base chemotherapy. We isolated germline DNA from peripheral blood lympho-
cytes or buccal swabs, and used whole exome sequencing (WES) to examine germline SNPs. As a reference for SNP frequencies we used the Exome Aggregation Consortium (ExAC) database, which represents the largest, randomly selected, germline WES database in the general population, including 60,706 individuals, among which 7,601 patients with multiple cancer types from the Tumor Cancer Genome Atlas (TCGA) cohort. Results: Twelve different DRG SNPs were identified in germline DNA samples from 53 patients, affecting genes involved in non-homol-

ogous end-joining (RECVQ4, n = 18, 54.50%; POLQ, n = 2, 6%), nucleotide exci-
tion repair (ERCC6, n = 2, 6%; XPA, n = 1, 3%; CCNH, n = 1, 3%; POLK, n = 1, 3%; RECQL4, n = 1, 3%; RAD17, n = 1, 3%; POLB, n = 1, 3%); Fanconi anemia pathway (POLN, n = 1, 3%); mismatch repair (EKO1, n = 1, 3%) and mitochondrial DNA repair (POLG, n = 2, 6%). The frequency of rs11342077 of the DNA helicase RECVQ4 was significantly higher in our cohort (18/53, 34%) compared to its frequency in the ExAC database (p = 0.01%). There was no significant difference in overall survival (OS) between patients with and without DRG SNPs (log-rank p = 0.46). There was no significant association between the most commonly identified SNP, rs11342077, and overall survival among UC pa-

tients with DRGSNPs (log-rank p = 0.39). Overall, the presence of DRG SNPs in our cohort occurred at a significantly higher frequency (33/53, 62.3%) compared to the ExAC database (0.56%, chi-square p < 0.001). Conclusions: Germline SNPs in DNA repair pathway genes are common in UC. Additional study of the role of these SNPs as potential biomarkers of response DNA damaging chemotherapeutic agents, in-
cluding platinum-based chemotherapy or and PARP inhibitors is needed in a larger cohort.

#1116 Targeting replication stress by carbazole blue - A novel strategy to treat triple negative breast cancers. Subapriya Rajamanikam, 1 Kaitlyn Favours, 1 Santosh Timilsina, 1 JunHyung Park, 2 Benjamin Onyeyugha, 1 Fanneedros Subbarayulu, 1, 3, 77030, TX; 3Emory University School of Medicine, Atlanta-30322, GA.

Background: Triple-negative breast cancers (TNBCs) are the most aggressive forms of breast cancer and almost 60% of patients with TNBCs develop chemosensitivity, leading to recurrence, poor prognosis and poor survival. TNBCs have been reported to have high levels of replication stress, which plays pivotal role in genomic instability, and therapy resistance. Targeting replication stress is an emerg-
ing approach for better TNBC treatment. Here, we evaluated the anticaner efficacy of carbazole blue (CB), a synthetic analogue of carbazole that we recently synthe-
sized on TNBC cells growth and progression. Experimental Design: The effect of CB on breast cancer growth was assessed in vitro as well as in orthotopic mouse xenograft and PDOX-molds of breast cancer. In addition, the therapeutic efficacy and safety of CB was determined in long term toxicity studies in mice and also in ex-vivo explants from breast cancer patients. The mechanism of action of CB was evaluated

Proceedings of the American Association for Cancer Research • Volume 58 • April 2017
by performing gene expression, cell cycle, apoptosis and DNA repair studies as well as proteins involved in the above mentioned mechanisms. Results: Our results demonstrated that CB inhibits short and long term viability of TNBC cells in a dose dependent manner without affecting normal mammary epithelial cells. We show that the systemic delivery of CB using nanoparticle-based delivery approach suppressed expression and activity of several genes known to be involved in DNA replication and DNA repair machinery. Conclusions: Our results for the first time showed the CB can serve as a novel and potent therapeutic agent for treating breast cancer in general and TNBC in particular. These findings highlight the potential of CB to be applied as a safe regimen for treating breast cancer patients. As exploiting replication stress to treat cancer is gaining major interest, compounds/s that may induce replication stress and inhibit DNA repair ability of cancer cells, has immense translational potential.

#1117 Triple negative breast cancer patient-derived xenografts as a translational model for discovery of novel therapeutic targets. Margaret D. Matossian,1 Hope E. Burks, Annie C. Bowles, Van T. Hoang, Bruce Bunnell,2 William J. Zuercher,2 David H. Drewry,2 Carrow Wells,2 1Hope E. Burks, 2Carrow Wells, 3Tulane University School of Medicine, New Orleans, LA; 2University of North Carolina, Chapel Hill, NC; 3Louisiana Cancer Research Center, New Orleans, LA.

Triplet negative breast cancers (TNBCs) constitute 12% of all breast cancers, and is approximately twice more prevalent in African-American populations. Louisiana has a high proportion of African-American residents (32.5% in 2015), and thus hosts a higher population of TNBC patients. TNBCs have an aggressive phenotype that is elusive to the targeted therapeutics used to treat other breast cancer subtypes. The claudin-low molecular subtype has higher rates of metastases and recurrence. Certain kinase families have been extensively studied as regulators of epithelial-mesenchymal transition (EMT), a process involved in the initiation of cancer metastasis. Discovery of novel kinase targets within the subset of uncharacterized kinases could provide important insight into future targeted therapies. However, current models utilized in target discovery research are limited by the inability to accurately recapitulate the complex stromal architecture and heterogenous genetic and molecular composition of breast cancer. Furthermore, immortalized cell lines are limited to a 2D environment and over time acquire mutations that may not reflect the primary tumor. Recently, our laboratory has successfully established two TNBC patient-derived xenograft (PDX) models derived from African-American patients, and generated cell lines (TU-Bcx-2K1, TU-Bcx-200) and mammospheres. One of these models, 200, presents tumor architecture, cellular composition, genomic (qRT-PCR) and protein (western blot) expressions that are concordant with a claudin-low subtype. Furthermore, we show that both TNBC models metastasize to the lungs, and exhibit molecular characteristics consistent with mesenchymal phenotypes. We utilized these translational PDX models to screen a library of small molecule inhibitors (SOMIs) that inhibit protein kinases and identified polo-like kinase 1 (PLK1) as a substrate to modify various proteins in order to regulate various cellular processes including Wnt/β-catenin signaling. SOMIs have been shown to be over-expressed and to be correlated with highly aggressive disease and prognosis in various types of human cancers. A small molecule inhibitor of TNKS1, XAV-939 has been proven to be a potent inhibitor of Wnt/β-catenin signaling by stabilizing Axin. However, the effect of tankyrase inhibitors as potential breast cancer therapy is still under investigation. In this study, we found that TNKS1 is highly expressed in breast cancer cell lines, particularly in triple-negative breast cancer (TNBC) cells and that the expression of TNKS1 correlates with anti-proliferative efficacy of tankyrase inhibitors, XAV-939 and JW55. Also, XAV-939 treatment suppressed cell migration and invasion capabilities and epithelial-mesenchymal transition (EMT) signaling in triple-negative breast cancer cell lines. Moreover, XAV-939 reduced expression of stemness markers. It was shown that polo-like kinase 1 (PLK1) functions as a positive regulator of TNKS1 protein stability. Interestingly, we found that combination treatment of XAV-939 with PLK inhibitor GW843682X significantly suppressed cell growth, clonogenic potential, migratory and invasive capabilities of breast cancer cells. The combination of XAV-939 and PLK inhibitors showed potent anti-tumor effect. Therefore, our findings highlight the important value of TNKS1 as a therapeutic target and suggest the potential for improving the clinical efficacies of tankyrase inhibitors in combination with either PLK inhibitors or radiotherapy for patients with triple-negative breast cancer.

#1118 Synthetic lethality of CDK2 inhibition in tumors with EWS/FLI rearrangements. Amanda L. Balboni,1 Bjorn Stolte,1 Amy Saur Conway,1 Gabriela Aleixo,1 Emily Jue Wang,1 Nicholas Kwiatkowski,2 Tinghu Zhang,1 Brian J. Abraham,3 Peter Kalev,4 Dipanjana Chowdhury,5 Cyril H. Benes,6 Richard A. Young,7 Nathanael S. Gray,1 Kimberly Stegmaier,6 Dana-Farber Cancer Institute, Boston, MA; 2Whitehead Institute, Cambridge, MA; 3Massachusetts General Hospital, Boston, MA.

THZ1 is a potent, covalent inhibitor of the transcriptional CDKs, CDK7/12/13. Chemical genomic profiling of THZ1 across >1,000 diverse cancer cell lines revealed that EWS/FLI- rearranged Ewing sarcoma cells were remarkably sensitive to this molecule. We demonstrated that THZ1 inhibits the phosphorylation of the C-terminal domain of RNA Polymerase II, decreased colony formation capacity, and induced apoptosis in a dose-dependent manner in Ewing sarcoma cell lines. Using selective CDK7 and CDK12/13 inhibitors, we revealed that THZ1 has no single selective activity. In general, suppression of CDK12, but not CDK13, induced strong anti-viability effects, confirming CDK12 as the primary target. Treatment of Ewing sarcoma cell lines with THZ531, a novel CDK12/13 selective inhibitor, preferentially repressed genes involved in DNA damage repair. Additionally, suppression of EWS/FLI rendered Ewing sarcoma cells resistant to THZ531 and partially rescued the anti-viability effects of CDK12 knockdown. These results suggest that EWS/FLI impacts vulnerability to DNA damage repair inhibition and implicate a synthetic lethal relationship between the tumor-specific expression of EWS/FLI and CDK12 inhibition. Furthermore, we demonstrated that CDK12 and PARP inhibitors are highly synergistic in vitro, inducing widespread γH2AX foci formation. Interestingly, THZ531 impairs the ability of the PARP inhibitor, olaparib, to induce RAD51 foci formation, suggesting that THZ531 specifically causes a defect in homologous recombination repair. Moreover, we observed striking synergy of THZ1 and olaparib in two mouse models of Ewing sarcoma with limited toxicity observed. These findings have important translational significance as clinical trials with PARP inhibitors as single agents in Ewing sarcoma failed to demonstrate efficacy, highlighting the need to identify combination therapies that will enhance the activity of PARP inhibitors. We anticipate that CDK12 and PARP inhibitor combinations will be of therapeutic interest in other ETS-rearranged tumors, as well as tumors with defects in DNA repair.

#1119 Targeting tankyrase as a therapeutic strategy for triple-negative breast cancer. Maya Mathew, Loredana Cordano, Jung-Lye Kim, Geun-Hyang Ha, Eun-Kyong Breuer. Loyola University Medical Center, Maywood, IL.

Tankyrase (TNKS1 and TNKS2) are members of the human poly(ADP-ribose) polymerase (PARP) family and catalyse PARylation by using NAD + as a substrate to modify various proteins in order to regulate various cellular processes including Wnt/β-catenin signaling. TNKS1 has been shown to be over-expressed and to be correlated with highly aggressive disease and prognosis in various types of human cancers. A small molecule inhibitor of TNKS1, XAV-939 has been proven to be a potent inhibitor of Wnt/β-catenin signaling by stabilizing Axin. However, the effect of tankyrase inhibitors as potential breast cancer therapy is still under investigation. In this study, we found that TNKS1 is highly expressed in breast cancer cell lines, particularly in triple-negative breast cancer (TNBC) cells and that the expression of TNKS1 correlates with anti-proliferative efficacy of tankyrase inhibitors, XAV-939 and JW55. Also, XAV-939 treatment suppressed cell migration and invasion capabilities and epithelial-mesenchymal transition (EMT) signaling in triple-negative breast cancer cell lines. Moreover, XAV-939 reduced expression of stemness markers. It was shown that polo-like kinase 1 (PLK1) functions as a positive regulator of TNKS1 protein stability. Interestingly, we found that combination treatment of XAV-939 with PLK inhibitor GW843682X significantly suppressed cell growth, clonogenic potential, migratory and invasive capabilities of breast cancer cells. The combination of XAV-939 and PLK inhibitors showed potent anti-tumor effect. Therefore, our findings highlight the important value of TNKS1 as a therapeutic target and suggest the potential for improving the clinical efficacies of tankyrase inhibitors in combination with either PLK inhibitors or radiotherapy for patients with triple-negative breast cancer.

Purpose: The goal of this research is to highlight novel and divergent molecular mechanisms of the circadian system in modulating the response of cisplatin therapy against melanoma cancers. Cisplatin is one of the most commonly used chemotherapeutic drugs in the treatment of a variety of cancers such as ovaries, testis, lungs, blood and solid tumors of the head and neck, and is more recently under clinical trials for potential application in melanoma tumors. However, the major limitation of cisplatin as a chemotherapeutic drug is its tumor resistance and nephrotoxicity. Hence, improving the effectiveness and reducing the toxicities associated with cisplatin therapy are desirable outcomes. Studies on human models have shown decreased renal and blood toxicity by time-of-day. Consequently, our project seeks to study the chronopharmacological effects and understand the mechanisms that have been successfully demonstrated in human models. We hypothesize a mechanistic, circadian rhythm-based cause for these outcomes. Experimental Design: Studies were...
done on B16F10 melanoma mouse models of wild-type and circadian disrupted Per1/2−/− animals treated with 3 doses of 5 mg/kg cisplatin in the morning (7 AM) and evening (5 PM). Animal weights and tumor sizes were measured regularly post-treatment. Upon sacrifice, tissues (skin, kidney, and tumor) were harvested and analyzed for cisplatin-induced toxicities and DNA damage responses using H&E staining, western blot, and KM-1 and immunoslot DNA assays. Results: Weight measurements show a clock-regulated response to cisplatin toxicity. AM-treated wild-type animals showed significant weight loss compared to PM-treated wild-type animals. This treatment time differential is lost in the Per1/2−/−. On a molecular level, kidney tissue DNA samples showed clock-controlled cisplatin-DNA repair activity in wild-type animals compared to Per1/2−/−. These findings strongly suggest that nephrotoxicity and DNA damage response function might be regulated by the circadian rhythm. Conclusions: These findings indicate a possible mechanism for the chronopharmacology of cisplatin in minimizing the toxicity associated with it and reveal a target for future study of additional mechanistic causes of circadian dosing changes in cisplatin and other genotoxic stress-mediated anti-cancer agents.

## #1121 Reduced-mediated inactivation of MGMT DNA repair through thiolation or nitrosylation of the active site cysteine415 sensitizes human gliomas to alkylating agents in vitro and in xenograft models. Debashis Basak, Kalkunte S. Srevenugopal, Texas Tech University Health Sciences Center, Amarillo, TX.

O6-Methylguanine-DNA methyltransferase (MGMT) is a simple and unique antimitaguc DNA repair protein that plays a crucial role in conferring tumor resistance to various alkylating agents in brain tumor therapy. MGMT repairs O6-alkylguanines by transferring the alkyl groups to its active site cysteine (Cys145) in a stoichiometric/suicidal reaction thereby restoring the original nucleotide sequence in a single step. Although O6-benzylguanine (BG), a pseudosubstrate inhibitor, currently in clinical trials, potently inhibits MGMT and improves the efficacy of alkylating agents, unacceptable levels of bone marrow toxicity has been a great concern. For developing new MGMT inhibitors, we explored the reactive nature of the active site Cys145 (pKa 4.5) and its susceptibility for thiolation and nitrosylation, both of which inactivate the MGMT. A new strategy involving inhibition of S-nitrosoglutathione reductase (GSNOR) was also explored to increase the steady-state levels of nitrosylated MGMT. First, we designed a redox perturbing glutathione mimetic, a homologuthione disulhde (hGTX) that has been stabilized with the addition of small amounts of cisplatin (1000:1). Spermine NONOate and S-nitroso penicillamine (SNAP) served as the protein-nitrosylating agents. N6022, a specific and reversible inhibitor of GSNOR was used with nitrosylates in some assays. Both the hGTX and spermine NONOate at 100–400 μM concentrations for 24 h inhibited the repair activity of MGMT >75% in HT29, SF188, and 98G cells. The NONOate strongly curtailed the DNA repair activity of recombinant MGMT showing a direct interaction. The inactivated MGMT protein was promptly eliminated from glioma cells. MGMT disappeared from cells much faster in spermine NONOate +N6022 treated cells, suggesting an extended steady-state of nitrosylated MGMT and its subsequent degradation. MGMT depletion was accomplished by 4-6 fold increases in cell killing by BCNU or temozolomide (TMZ). Binding of the biotinylated-O6-benzylguanine to the MGMT protein was prevented by hGTX and spermine NONOate treating the Cys145 wild type and the Cys145 mutant forms of hGTX and TMZ or spermine NONOate +TMZ produced markedly synergistic tumor regressions compared with TMZ alone. A reduction of MGMT protein as by immuno-blotting and diminished MGMT activity levels in tumor tissues was verified. Apoptosis regulatory proteins were upregulated in excised tumors and H&E staining confirmed no discernible host organ toxicities. Our studies highlight the options for redox-driven therapeutic strategies for MGMT [supported by CPRIT grants RP130266 and RP170207 to KSS].

## #1122 ATR inhibitors synergize with PARP inhibitors in killing glioblastoma stem cells and treating glioblastoma. Jianfang Ning, Hiroaki Wakimoto, Robert L. Martuza, Samuel D. Rabin. Massachusetts General Hospital, Boston, MA.

PARP inhibitors (PARPi) have been used alone or in combination with other agents for the treatment of tumors with homologous repair (HR) deficiencies. However, challenges remain for the treatment of tumors that are PARP-resistant or HR-proficient. Glioblastoma (GBM) is an invariably lethal tumor that is not associated with HR deficiencies. GBM stem cells (GSCs), thought to be critical for tumor growth and resistance to therapy, can be isolated from GBM specimens and are representative of the patient’s tumors. GSCs exhibit variable PARP sensitivity, with at least half being resistant. In order to enhance the antitumor efficacy of PARPi for GBM, we examined the combination of PARPi with inhibitors of oncogenic or DNA damage pathways, including inhibitors of PTEN, PI3K, ATM, ATR, and temozolomide, some of which have been reported to sensitize cancer cells to PARPi. Only inhibitors of ATR (VE821, VE822, AZ20) synergized with PARPi in killing GSCs in vitro. VE822 inhibited ATR activity both in vitro and in vivo, and modestly, but significantly, extended survival in mice bearing GSC-derived tumors. However, ATR inhibitor (ATRI) in combination with PARPi further prolonged survival, compared to each drug alone, in a murine orthotopic glioma model. This is the first report that ATRi alone or in combination with PARPi is effective in treating GBM and provides a rationale for clinical trials for GBM.

## #1123 Sphingolipid transfer proteins (GLTP and CPTP) regulate the neoplastic progression of colon and breast cancer cells. Shrawan K. Mishra, Rhoderick E. Brown. Hormel Institute, University of Minnesota, Austin, MN.

Sphingolipids have previously been shown to affect cancer progression by regulating cell death (apoptosis) and survival (autophagy). While apoptosis is promoted by elevations in sphingosine and ceramide, increases in sphingosine-1-phosphate and ceramide-1-phosphate can tip the balance toward survival. Changes in the expression of sphingolipid transfer proteins such as GLTP (glycolipid transfer protein) and CPTP (ceramide-1-phosphate transfer protein) have been shown to modulate cell shape change and regulate pro-inflammatory cytokine release, respectively, in human cancer epithelial cell lines. To gain a better understanding of the situation, we investigated further. We discovered that GLTP overexpression inhibits the growth of human colon carcinoma cell lines (HT-29; HCT-116), but spares normal colonic epithelial cells (HCEC) largely due to growth arrest at the G0/G1 cell cycle checkpoint. Mechanistically, we found that GLTP overexpression modulated cell cycle progression by upregulating cip1/p27 and Cic/p1/p21 protein and mRNA levels, while decreasing CDK2, CDK4, cyclin E and cyclin D1 protein levels. The cell cycle arrest and growth inhibition induced by GLTP overexpression led to apoptotic cell death of HT-29 cells. Neither GLTP nor CPTP overexpression induced apoptosis in breast cancer cell lines (T47D and HTB-126). However, depletion of CPTP, but not GLTP, induced autophagy as indicated by increased LC3 transcript and autophagosome levels (GFP-LC3-II puncta). In the breast cancer cell lines, increased transcript levels of CLA2 and CERK were detected consistent with the earlier pro-inflammatory effect reported for CPTP depletion in A549 lung epithelial carcinoma cells. Our findings shed light on the mechanistic ways by which GLTP and CPTP affect apoptosis and autophagy to impact cancer progression. Future in vivo studies are planned to ascertain the role(s) of these new players in cancer development and therapy. ## #1124 Assessment of HRD score as predictor of chemosensitivity of PDAC PDX xenograft models to DNA-damaging chemotherapy. Vladimir Khazak, Natalia Skobeleva, Anastasia Vetkina, Ilya Serebriiskii, Kirsten M. Timms, Angela Davies, Igor Asturatov, NexusPharma Inc., Philadelphia, PA; Fox Chase Cancer Center, Philadelphia, PA; Myriad Genetics, Inc., Salt Lake City, UT; Champions Oncology, Inc., Hackensack, NJ.

Pancreatic ductal adenocarcinoma (PDAC) is a devastating malignancy that affects 44,000 individuals annually in the US, with almost 90% lethality even when diagnosed prior to metastasis. There is an urgent unmet medical need for new therapies using novel approaches targeting existing therapies to patients. To address this emergency, we are assessing the feasibility of implementing a strategy of using HRD (Homologous Recombination Deficiency) scores for better therapy matching in PDAC patients. Using a panel of 77 patient-derived xenograft (PDX) models that were developed from fresh surgical PDAC tumor samples, HRD scores were generated based on analysis of three biomarkers (LOH, TAI and LST) and mutational data for 45 cell lines. All 77 samples met inclusion criteria, 75 FFPE specimens generated mutation data. HRD analysis was successful for 71 specimens (range = 1-63 (median = 22)), with the primary cause of failure identified as high non-tumor content. 53 PDX models had mutations in KRAS gene and 45 in TP53. We have also identified 4 PDX models with mutations in BRCA2, 3 models with mutations in ATM, 4 models with mutations in RAD51. We have also found frequent mutations in several other DNA repair genes (ATR, PALB2, MLH1, MSH2, MSH3, MSH6, FANCM), but most of these models retained one functional allele and were not associated with a high HR content. Using this genomic analysis, all 71 PDX models were stratified into three clusters with high, medium and low HRD scores. Three PDX models with the highest and lowest HRD scores each were selected for an in vivo study with DNA-damaging platinum-based chemotherapeutic agents Cisplatin and Carboplatin, as well as with a clinically relevant PARP inhibitor Niraparib. The results of the PDX study will be reported and compared with responses to chemotherapy using RECIST V1.1 in patients.
tumors and alters DNA damage repair. It was recently demonstrated that the impact radiosensitivity. Specifically, many cancers exhibit increased histone that the abnormal epigenetic landscape in tumors may, among other things, not only suggest that this approach alters multiple hallmarks of cancer growth, (KD) and/or caloric restriction (CR) as an adjuvant to cancer therapy. This data

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: New Targets 1

#1126 Potent inhibition of HCMV by modulating the cellular SNARE syntaxin 5. Dhimant H. Desai,1 Linda Cruz,1 Nicholas T. Streck,1 Trisha D. Desai,2 Aron Lukacher,1 Shantu G. Amin,1 Nicholas J. Buchkovich1. 1Penn State Univ. College of Medicine, Hershey, PA; 2Cumberland Valley High School, Mechanicsburg, PA.

Human cytomegalovirus (HCMV), also referred to as human herpesvirus-5 (HHV-5), can cause serious and even fatal disease in immunocompromised individuals and newborns, namely individuals with AIDS, solid organ transplant recipients, chemotherapy patients and recipients of bone marrow and stem cell transplants. HCMV is a ubiquitous virus found throughout all geographic regions and socioeconomic groups, infecting greater than 50% of adults in industrialized countries and as many as 100% in developing countries. Although current therapeutics improves clinical outcomes, they are limited by toxicity, intravenous infusion and the development of resistance by the virus. Thus, there is a pressing need to develop novel therapeutics to prevent HCMV infections with concomitant organ toxicity. Formation of the cytoplasmic viral assembly compartment (vAC) is an important step for efficient HCMV assembly. To do this, the virus must alter and repurpose the normal cellular balance of membrane proteins. Thus, targeting this process that is not well understood. We have identified a compound Retro94, which potently inhibits production of infectious HCMV virions in cells by operating against a host cell process, rather than directly targeting the virus. The presence of Retro94 results in the severely impaired production of infectious virions, as great as 5 logs (99-99.99%). Here we discuss in vitro, in vivo, stability, and binding study of Retro94. Overall, our findings have identified Retro94, as a novel agent that affects key cellular trafficking factors important for supporting HCMV infection.

#1127 Aberrant nuclear expression of GSK-3beta in human head and neck carcinoma. Maria Matsangou,1 Andrey Ugolkov,2 Timothy J. Baxter, Sandeep Samant,1 Andrew P. Mazar, Francis J. Giles1. 1Robert H Lurie Comprehensive Cancer Center, Northwestern University, Chicago, IL; 2Chemistry of Life Processes Institute, Northwestern University, Chicago, IL.

Background: Recurrent/metastatic head and neck squamous cell carcinoma (SCCHN) and salivary gland malignancies are difficult to treat with limited standard of care options at the present time. Glycogen Synthase Kinase-3beta (GSK-3beta), a serine/threonine protein kinase, has been implicated as a potential therapeutic target in human cancer. Our in vivo studies demonstrated that our novel GSK-3 inhibitors significantly potentiated the effects of conventional chemotherapy in patient-derived xenograft models of glioblastoma and breast cancer leading to regression of tumors. In order to develop a rationale to test our novel GSK-3 inhibitors in head and neck (H&N) malignancies, we evaluated the expression pattern of GSK-3beta in human H&N tissue and malignant tumors. Methods: We used immunohistochemical staining of H&N tumor tissue Microarray (TMA), 48 total cases (20 benign tissues, 28 malignant), to study the expression pattern of GSK-3beta. GSK-3beta nuclear accumulation was defined as positive staining of more than 50% of cancer cell nuclei throughout the tumor regardless of cytoplasmic staining. Results: Of the 20 malignant H&N samples (15 SCCHN, 1 nasopharyngeal and 5 other histology), 13 (65%) were found to have aberrant nuclear accumulation of GSK-3beta. Amongst SCCHN, 73% (11 of 15 samples) had aberrant nuclear accumulation of GSK-3beta. In contrast, none (0%) of the 11 benign non-salivary H&N tissues showed detectable expression of GSK-3beta. Of interest, 60% of salivary adenoid cystic carcinoma specimens and 44% of benign salivary gland tissue showed GSK-3beta expression. Conclusion: Our results demonstrate that our novel GSK-3 inhibitors as a potential therapeutic target for recurrent/metastatic SCCHN and also as a potential prognostic and predictive biomarker for risk of recurrent disease and chemo- or radio-resistance. Its role in salivary gland malignancies requires further studying.

#1128 Identification of arginine methyltransferase PRMT5 as a novel therapeutic target in T-cell acute lymphoblastic leukemia. Yunyue Wang2,1 Hui Huang,2 Daniel Doliatti,2 Marta Sanchez Martin,2 Beata Modzelewska,2 Lianna J. Marks,2 Allison R. Rainey,3 Ervin S. Gaviria,3 Maria L. Sulis,1 Filemon S. dela Cruz,2 Adolfo A. Ferrando,1 Andrew L. Kung3. 1Columbia University, New York, NY; 2EMD serono, CT; 3Memorial Sloan Kettering Cancer Center, New York, NY.

Advances in risk-adapted cytotoxic chemotherapy, hematopoietic stem cell transplantation and supportive care have contributed to significant improvements in the survival of patients with acute lymphoid leukemia (ALL) and acute myeloid leukemia (AML) over the past few decades. However, despite such progress, a significant percentage of both adult and pediatric leukemia patients become refractory to therapy or relapse and eventually die of disease. Hence, there remains an urgent need for the development of effective and targeted therapies for acute leukemia. Recent genetic profiling of solid and hematologic malignancies has identified epigenetic factors as a critical group of genes recurrently mutated in cancer. Additionally, epigenetic dysregulation has been shown to play an important role in the development, progression and maintenance of leukemia. Therefore, pharmacological inhibition of epigenetic factors represents a potential avenue for the development of novel epigenetic-targeted therapies. In order to identify epigenetic vulnerabilities in leukemia, we developed genomically-focused shRNA screen to search for novel therapeutic targets in human leukemia cell lines both in vitro and in vivo. Specifically, T- and B-ALL cell lines were transduced with a library of shRNAs targeting 449 genes including epigenetic readers, writers and erasers and other chromatin-related factors. Selected cells were subsequently cultured in vitro and concurrently injected
into mice. Engraftment of inoculated cells and disease progression were monitored through bioluminescence imaging. Amongst the universe of epigenetic regulatory proteins, the arginine methyl transferase, PRMT5, emerged as the most significantly depleted factor in both in vitro and in vivo screenings. Chemical inhibition of PRMT5 enzymatic activity effectively reduced protein symmetric dimethyl arginine methylation, altered splice, inhibited cell growth and promoted apoptosis of both ALL and AML cell lines in vitro. In addition, inhibition of PRMT5 in vivo using patient-derived xenograft (PDX) T-ALL mouse models demonstrated diminished tumor growth and prolonged survival. Notably, quantification of peripheral blood cell numbers showed that pharmacologic PRMT5 inhibition was well tolerated and did not affect normal hematopoiesis in mice suggesting that a therapeutic window exists for targeting cancer promoting PRMT5 in leukemia. Overall, our data indicates that pre-mRNA processing and in particular RNA splicing modulation may represent novel therapeutic targets in leukemia.

### #1129 Sigma receptors: Novel targets for the treatment of highly malignant tumors.

Michela Cortesi,1 Sara Pignatta,1 Simona Collina,2 Andrea Rocca,1 Alice Zamagni,1 Chiara Arienti,1 Michele Zanon,1 Luigino Tosatto,1 Daniela Bartolini,2 Evandro Negrioli,1 Annamaria Marra,2 Marta Ruì,1 Anna Tesi,1 1Istituto Scientifico Romagnolo per lo Studio e la Curia dei Tumori (I.R.S.T.) IRCCS, Meldola (FC), Italy; 2University of Padova, Padua, Italy, Padua, Italy; 3M. Bufalini Hospital, Cesena, Italy.

Introduction. More than 7 million patients are diagnosed with cancer every year, and approximately 24 million new cases of cancer will probably be registered by 2035. Over the past decades, numerous cancer targets have been identified and, despite promising results in this field, the discovery of novel targeted therapies is still a largely unmet need. Sigma receptors (SRs), more highly expressed in tumor cells than in normal cells, have aroused the interest of the scientific community because of increasing evidence of their involvement in proliferation and survival signaling pathways of cancer cells. Glioblastoma (GBM) and pancreatic cancer (PCa) are two of the most aggressive and lethal solid tumors. GBM patients usually relapse within 7-10 months of the end of first-line treatment with median survival of about 14.6 months while PCa is the fourth most fatal cancer in both men and women, with median survival of 6-12 months. Little or no improvement in prognosis has been obtained over the past 20 years. Thus, new approaches to the treatment of both tumors are urgently needed. In the present work, 3D GBM primary cultures endowed with stemness features and PCa cell lines were used to evaluate the antitumor activity of a dual S1R and S2R ligand RC-106, a novel sigma receptor modulator. Methods. RC-106 tissue distribution studies were performed in mice. PCa cell lines were assessed by cytotoxic assay (CellTiter 96® AQsauna One Solution Cell Proliferation Assay). Molecular analyses were performed by qRT-PCR and Western blot. Apoptosis and cell cycle were analyzed by flow cytometry. GBM primary cultures were isolated from surgical tumor samples. A rotatory cell culture system (RCCS) was used to obtain 3D cell cultures. Growth and morphology of the colonies were monitored by open-source AnaSp and ReVISP software tools. Molecular analyses were performed by flow cytometry and qRT-PCR. 3D cell viability was measured using CellTiter-Glo® 3D Cell Viability Assay. Apoptosis and cell cycle were analyzed by flow cytometry. Results. RC-106 preferentially accumulate in mice pancreas and brain after intravenous administration, supporting the use of sigma receptor modulators as a novel therapy for these tumors. Treatment with RC-106 strongly inhibited cell proliferation and survival regardless of the type of cancer investigated. 25 μM of the drug impaired the in vitro clonogenic ability of tumor cells, an effect lasting for up to 42 days, the longest time tested. RC-106 also led to the induction of substantial apoptosis mediated by caspase 3 and 9 activation, and to a modulation of the Akt pathway. Furthermore, treatment with RC-106 significantly reduced the growth of human GBM and PCa spheroids. Conclusions. (RC-106) represents the hit compound of a new class of dual-action ligands targeting S1R and S2R potentially useful for the treatment of cancer disease.

### #1130 Targeting the tumor-associated autoantigen alpha-enolase in prostate cancer.

Tino Wilson Sanchez,1 Guangyu Zhang,1 Jitian Li,2 Liping Dai,2 1Istituto Scientifìco Romagnolo per lo Studio e la Cura dei Tumori (I.R.S.T.) IRCCS, Meldola (FC), Italy; 2University of Padova, Padua, Italy, Padua, Italy.

Prostate cancer (PCa) is the most commonly diagnosed cancer and second leading cause of cancer-related deaths in American men. African American (AA) men are more likely to be diagnosed with aggressive PCa at a younger age and twice as likely to die from the disease as European American (EA) men. In order to reduce PCa mortality and its associated racial disparities, there is a critical need to identify and target pathways responsible for PCa aggressiveness. An unexplored target is the plasminogen system, which is key to cancer cell migration and tissue invasion during metastasis. During inflammation, activation of the plasminogen pathway degrades extracellular fibrin networks; however, in the context of cancer, this activation promotes cancer tissue invasion and metastasis. Mounting evidence shows that the glycolytic enzyme alpha-enolase (ENO1) plays a vital role in both increased energy metabolism and plasminogen activation and metastasis. Using immunoproteomic profiling of anti-tumor autoantibody responses in AA and EA men with PCa, we identified several tumor-associated autoantigens with functions in glycolysis and plasminogen signaling, including ENO1, annexin A2, fructose bisphosphate aldolase, glucose-regulated protein 78, glyceroldehyde-3-phosphate dehydrogenase and phosphoglycerate kinase. In a cohort of PCa (N=157) and PRMT5 knockdown (N=183), we found a significantly higher frequency of autoantibodies to ENO1 in patients with PCa (p<0.05). Surprisingly, when we probed a panel of non-PCa and PCa cell lines with anti-ENO1 positive sera from AA and EA patients with PCa, we observed that AA patients showed decreased immunoreactivity to this protein in metastatic PCa cells, with decreased reactivity in docetaxel-resistant cell lines. By contrast, the anti-ENO1 EA-PCa sera and a monoclonal mouse anti-ENO1 showed relatively uniform immunoreactivity across the same panel cell lines. This suggested that the AA-PCa patients are producing antibodies to a different ENO1 variant than EA-PCa patients. Proteomic analysis of post-translational modifications (PTM) in ENO1 showed differences in ENO1 PTM profiles between the parental PC3 bone metastatic cell line and the PC3 docetaxel-resistant cell line, which could explain the differential autoantibody reactivity observed in AA and EA men. Given that ENO1 is up-regulated in PCa tissue, plays a role in glucose metabolism and plasminogen activation during cancer progression, and that the immune system of a cohort of AA-PCa patients recognizes an alternately modified variant of ENO1 that is upregulated in metastatic PCa cells, we elected to target this protein in metastatic PCa cell lines. ENO1 deletion via siRNA knockdown in PC3 cells led to increased cell death, with concomitant decrease in PCa proliferation. Taken together, these results highlighted the value of immunoproteomics as a tool to identify novel therapeutic targets, with ENO1 as a promising target in metastatic PCa.

### #1131 O-GlcNAc transferase inhibition in breast cancer cells.

Anna Barkovskaya,1 Lina Prasmickaitė,1 Damien Y. Duveau,2 Ian G. Mills,3 Gunhild M. Melændsmø,1 Siver A. Moestue,1 Harri M. Itkonen,1 1Oslo Univ. Hospital Inst. for Cancer Res., Oslo, Norway; 2Division of Preclinical Innovation, National Cen- ter for Advancing Translational Sciences; 3Division of Immunology, National Institute of Health, Rockville, MD.

O-GlcNAc transferase (OGT) catalyzes the transfer of O-GlcNAc residues from OGT and its effect on TNBC cell survival and apoptosis. In conclusion, OGT inhibition in two triple-negative (TNBC) and two receptor-positive luminal breast cancer cell lines. Treatment of cells with an OGT inhibitor as well as OGT knockdown led to a strong decrease in viability and proliferation of the TNBC cells, but signif- icantly less so in the luminal receptor-positive cell lines. This differential re- sponse was evaluated using analysis of apoptosis, cell cycle, gene expression and a reverse-phase antibody-based protein array (RPRA). We found that cell cycle progression was affected by OGT inhibition. In addition, proteomics data pointed towards the transcription factor hairy and enhancer of split 3 (HES3) as a possible mediator of the cytotoxicity observed in the TNBC cell line. We currently work to elucidate the molecular mechanisms of HES1 regulation by OGT and its effect on TNBC cell survival and apoptosis. In conclusion, OGT inhibition has a pronounced cytotoxic effect on the TNBC cells and may have some potential for therapeutic use in the future.

### #1132 Lactate dehydrogenase expression in African American women with triple-negative breast cancer.

Odalsy J. Torres-Luquis, Sulma Mohammed, Purdue University, West Lafayette, IN.

The incidence of breast cancer in African American women (AAW) is much lower than those of their Caucasian counterparts. However, the age adjusted mortality rates are much greater for AAW compared to Caucasian American women.
subclones of T-ALL. Conclusion: This study shows that TG2 expression is elevated with steroid resistance in T-ALL and the modulation of TG2 induces the cytotoxicity of steroid-adapted T-ALL. TG2 could be a new therapeutic target to overcome steroid resistance in T-ALL. Furthermore, change of TG2 expression could serve as markers of induced steroid resistance in T-ALL.

#1135 DRD2 is critical for pancreatic cancer and promises pharmacological therapy by already established antagonists. Pouria Jandaghi,1 Hamed S. Najafabadi,1 Andrea Bauer,2 Andreas I. Papadakis,1 Matteo Fassan,1 Anita Hall,1 Anie Monast,1 Maryam Safisamghabadi,1 Magnus von Knebel Doeberitz,4 John P. Neoptolemos,7 Eithne Costello,8 William Greenhall,9 Aldo Scarpa,7 Bence Sipos,10 Daniel Auld,11 Mark Lathrop,12 Morag Park,13 Markus W. Büchner,14 Oliver Strobel,15 Thilo Hackert,16 Natalia Giese,17 George Zogopoulos,18 Veena Sangwan,20 Sidong Huang,20 Jörg D. Hoheisel,19 Yaser Riazalhosseini1. 1McGill University, Montreal, Quebec, Canada; 2Deutsches Krebsforschungszentrum (DKFZ), Heidelberg, Germany; 3ARC-NET Center for Applied Research on Cancer, University and Azienda Ospedaliera Universitaria Integrata, Verona, Italy; 4Deutsches Krebsforschungszentrum (DKFZ), Heidelberg, Germany; 5National Institute for Health Research, Liverpool Pancreas Biomedical Research Unit, Liverpool, United Kingdom; 6National Institute for Health Research, Liverpool Pancreas Biomedical Research Unit, United Kingdom; 7ARC-NET Center for Applied Research on Cancer, University and Azienda Ospedaliera Universitaria Integrata, Italy; 8Institute for Pathology and Neuropathology, Universitätshôpital Tübingen, Germany; 9Department of Surgery, University Hospital Heidelberg, Germany.

Introduction and aims: Although the overall five-year survival of all patients with cancer stands at 63%, for pancreatic cancer patients, it is a disheartening 8% - a number that remains largely unchanged for three decades. Of the patients diagnosed with pancreatic cancer, about 85% exhibit pancreatic ductal adenocarcinoma (PDAC). Most of these patients die within 4 to 6 months after diagnosis. The poor prognosis is caused by the detection at only late stages, and lack of effective options for chemotherapy. The widely used chemotherapeutic agent gemcitabine, confers a median survival advantage of only 6 months, and resistance to therapy develops in the vast majority of patients. Given this poor prognosis of patients with PDAC, there is an urgent need to find more effective therapies. Experimental procedures: Microarrays were used to perform global gene expression profiling in 195 PDAC and 41 normal pancreatic tissue samples. Using these profiling data, we undertook an extensive analysis of PDAC transcriptome by superimposing the pathway context and interaction networks of aberrantly expressed genes to identify factors with central roles in PDAC pathways. Next, tissue microarray analysis (TMA) were used to verify the expression of the candidate target in independent set of 152 samples comprising 40 normal pancreatic tissues, 49 chronic pancreatitis sections (CP) and 63 PDAC samples. We further validated the functional relevance of the candidate molecule through RNA interference (RNAi) and pharmacological inhibition in vitro and in vivo. Results: We identified dopamine receptor D2 (DRD2) as a key modulator of cancer proliferation in PDAC. DRD2 up-regulation at the protein level was validated in a large independent sample cohort. Most importantly, we found that blockade of DRD2, through RNAi or pharmacological inhibition using FDA-approved antagonists hampers the proliferative and invasive capacities of pancreatic cancer cells while modulating CAMP and endoplasmic reticulum stress pathways. Also, we observed a potent effect of DRD2 antagonists on inhibition of cancer cell proliferation using different model of primary and metastatic tumor cells derived from spontaneous pancreatic cancer mouse models and patient-derived pancreatic adenocarcinoma mouse xenograft (PDx) models. Conclusions: Our findings demonstrate that inhibiting DRD2 represents a novel therapeutic approach for PDAC. Since DRD2 inhibitors are already in the clinic for the management of schizophrenia, our results from this study could support a drug repositioning strategy to expedite clinical evaluation of these agents as novel therapy against pancreatic cancer.

#1136 Heat shock protein 90 inhibitors suppress PDGFRα reactivation and other receptor tyrosine kinase activation important in drug resistant gastrointestinal stromal tumors. Masahiro Yamamura, Akira Yamauchi, Naoki Katase, Makoto Okawaki, Yousuke Katata, Futoshi Kuribayashi, Junichi Kuribayashi, Yoshiyuki Yamaguchi. Kawasaki Medical School, Kurashiki, Japan.

Background: Inhibition of KIT oncoproteins by imatinib induces clinical responses in most gastrointestinal stromal tumor (GIST) patients. However, many patients develop imatinib resistance due to secondary KIT mutations. The drug resistance mechanism has only been partially elucidated, and the sunitinib resistance mechanism is also unknown. In this study, we elucidate the new imatinib resistant mechanism and find effective inhibitors. Methods: We have established imatinib-resistant cells GIST-T1R by culturing cells with increasing concentrations of imatinib. We analyzed receptor tyrosine kinase and intracellular signal protein strongly expressed in resistant cells using Western blotting
EXPERIMENTAL AND MOLECULAR THERAPEUTICS: New Targets 1

and Phosphorylation Array. Then, the antitumor effect was examined using an agent that inhibits strongly expressed molecules of the resistant cells. Results: The IC50 of imatinib in the sensitive cells (GIST-T1) and the resistant cells (GIST-T1R) was 0.10 nM and 0.2 nM, respectively, which demonstrated 2000-fold difference. These imatinib resistant cells were also cross-resistant to sunitinib. In western blotting, phosphorylation of PDGFRα in drug-resistant cells was enhanced in GIST-T1R compared to GIST-T1. When GIST-T1 was treated with imatinib, KIT phosphorylation was suppressed but PDGFRα phosphorylation was enhanced. Imatinib treatment of GIST-T1R enhanced PDGFRα phosphorylation and protein expression as compared to before imatinib treatment. Phosphorylation of PDGFRα in these resistant cells could not be suppressed by regorafenib. Furthermore, in the protein phosphorylated array, in addition to phosphorylation of PDGFRα in resistant cells, phosphorylation of multiple RTKs was also enhanced. An HSP90 inhibitor AUY922 capable of simultaneously suppressing a plurality of proteins was used. AUY922 suppressed GIST-T1 and GIST-T1R cell proliferation at low concentrations and was more effective than regorafenib. Furthermore, AU9122 inhibited phosphorylation and protein expression of PDGFRα in drug-resistant cells, as well as phosphorylation of other several receptor tyrosine kinases. Conclusion: Activation of PDGFRα was considered to be important for the mechanism of drug resistance of GIST. Furthermore, since activation of multiple receptor tyrosine kinases can be observed simultaneously in drug resistance, it is considered that inhibiting a single target is not effective. Since HSP90 inhibition suppresses PDGFRα protein expression and possibly inhibits multiple target proteins at the same time, it is the most effective treatment for drug resistant GIST.

#1137 ADAM8 drives aggressive phenotype of triple-negative inflammatory breast cancer & constitutes a novel therapeutic target. Mathilde Romagnoli,1 Stefania Pianetti,1 Sonia G. Das,1 Delphine Loussouarn,2 Carole Gourmelon,2 Mario Campone,3 Sophie Barillé-Nion,1 Giang T. Nguyen,1 Srirathi Sriniwason,1 Gill E. Sonenstein,1 Nora D. Mineva,1 Tufts Univ. School of Medicine, Boston, MA;2Institut de Cancérologie de l’Ouest, Saint-Herblain, France;3UMR 892 INSERM, Nantes, France.

Inflammatory Breast Cancer (IBC) is a rare, highly aggressive form of cancer that is frequently locally advanced or metastasized at the time of diagnosis. The Triple-Negative subtype of IBC (TN-IBC), in particular, is characterized by very poor overall survival. TN-IBC lacks targeted therapies and is primarily treated with radiation or chemotherapy, which are inefficient. Recently, we identified the cell surface transmembrane ADAM8 (A Disintegrin and Metalloproteinase) protein as a driver of Triple-Negative Breast Cancer (TNBC) growth and metastasis via its Metalloproteinase (MP) and Disintegrin (DI) domains, respectively. In vivo proof-of-concept experiments with a prototype reagent, we demonstrated that simultaneous, antibody-based targeting of the ADAM8 MP and DI domains is an effective therapeutic approach for TNBC (Romagnoli et al., EMBO Mol. Med. 6:278, 2014). The aggressive behavior of IBC cells has been attributed to a stem-like cancer cell compartment with high ALDH activity (ALDH+) and the overexpression of the green tea compound epigallocatechin-3-gallate (EGCG). However, we recently revealed that EGCG simultaneously decreases tumor levels of ADAM8 mRNA. This finding is not associated with a stem-like cancer cell compartment with high ALDH activity (ALDH+). Our study is the first, to our knowledge, to demonstrate that in TN-IBC cells, ADAM8 expression negatively correlates with EGCG treatment. We now report that EGCG concurrently decreases tumor levels of ADAM8 mRNA. This led us in the future to examine the role of ADAM8 in TN-IBC. Tumor biopsies from 15 patients taken at the time of diagnosis and/or after neo-adjuvant treatment with chemotherapy, as well as paired lymph node and skin samples (when available) were analyzed by immunohistochemistry for ADAM8 expression. We found that ADAM8 expression is driven by a high ALDH+ stem-like SUM-149 cell compartment. Consistently, knockdown of ADAM8 dramatically reduced the ability of SUM-149 cells to grow in an anchorage independent manner. In a newly established Matriptase−/−M14 tumor cell line, autonomous ADAM8 mouse monoclonal antibody (ADP13) inhibited the MP and DI domains of ADAM8 on SUM-149 cells. ADP13 reduced orthotopic growth of tumors derived from SUM-149 cells by 40% in mice treated by i.p. injection 2 days a week with a dose of 4.5 mg/kg (n = 7). Dose-response curves and survival experiments are in progress. Conclusions: ADAM8 expression is present in almost all of TN-IBC patient tumors and their metastases, and promotes aggressive phenotype of TN-IBC cells in vitro and in vivo 3D-assays. A pre-clinical mouse model of TN-IBC validated ADAM8 as an accessible and promising new target for therapeutic intervention against this highly aggressive disease.

#1138 The protein disulfide isomerase inhibitor XCE853 inhibits in vitro, ex vivo and in vivo growth of human tumors. Gregory Pierre Prevost,1 Anne Chauchereau,2 Patrick Ladam,3 Renaud Seigneuric,4 Denis Carniato,5 Marc-Henry Pitty,4 Paul Foster,3 CIPREDO, Antony, France;2Gustave Roussy, Villejuif, France;3Université Paris XIII, Bobigny, France;4Université de Bourgogne, Dijon, France;5Cancer Genome Informatics, Paris, France;2University of Birmingham, Birmingham, United Kingdom.

Protein disulfide isomerase (PDI) is a chaperone protein that regulates oxidative protein folding as well as cell viability. Increased PDI levels have been documented in a variety of human cancers associated with a poor overall survival, including ovarian, prostate, brain and lung cancers. Inhibiting PDI activity leads to apoptosis in cancer, suggesting that PDI is a promising drug target. XCE853 is a synthetic small molecule displaying an excellent docking with the catalytic domain of the human PDI. XCE853 inhibits in vitro recombinant PDI enzymatic activity. In addition, the proliferation of a large panel of human tumor cells is blocked by XCE853 with IC50s in the nanomolar range through an irreversible cytolysis leading to a tumor cell death by autophagy and particles release (vesicles or protein aggregates). XCE853 is also active on a large panel of drug resistant human cancer cells. XCE853 induced an irreversible cytolysis of human tumor cells after a short in vitro exposure independently of efflux pumps. In addition, the ex-vivo approach using fresh human tumor explants cultivated in 3 dimensions with low concentrations of XCE853 has shown a strong decrease of the xenografted tumors (Ki-67, PDI expression) in several xenograft models leading to a complete tumor growth arrest even after the cessation of the treatment. Altogether, these data strongly support further efforts to move this drug candidate to the preclinical studies to access advanced cancer patients.

#1139 G protein-coupled receptors (GPCRs): unrecognized potential therapeutic targets in cancer. Paul A. Insel, Krishna Siriram, Shu Z. Wiley, Thalia McCann, Randall P. French, Andrew M. Lowy, UCSD, La Jolla, CA.

G protein-coupled receptors (GPCRs) are the largest class of signaling receptors in humans and other species and in addition, the most widely targeted class for FDA-approved therapeutics. However, GPCRs are not commonly targeted in cancers other than endocrine tumors. We hypothesize that GPCRs may have been “missed” as targets in cancer, perhaps in part because they have not been frequently identified as driver mutations; however, GPCRs may have unappreciated utility as therapeutic targets in a variety of tumors. To test this hypothesis, we have used unbiased approaches (Taqman GPCR arrays and RNA-seq), mining of publicly available databases (e.g., The Cancer Genome Atlas, TCGA), and validation studies (e.g., protein and functional analyses) to assess GPCRs in a variety of human tumors, cancer cells and stromal cells (cancer-associated fibroblasts, CAFs). A major focus of our efforts has been on pancreatic ductal adenocarcinoma (PDAC) cells/tumors and pancreatic CAFs (PCAFs). We find that PDAC cells and PCAFs express >70 different GPCRs, including many orphan GPCRs (receptors without known physiologic agonists) and that numerous GPCRs are expressed at much higher levels than in normal precursor cells (pancreatic ductal epithelial cells for PDAC cells and pancreatic stellate cells and pancreatic fibroblasts for PCAFs). We find that a cluster of GPCRs is overexpressed in PDAC tumors. Two such receptors are orphan GPCRs, Orphan 1 and Orphan A, neither of which is mutated but each has high expression, respectively, in PCAFs and PDAC cells. Orphan 1 and Orphan A have at least 2-fold higher expression in >90% of PDAC tumors in TCGA compared to that in normal pancreatic tissue (compiled from the GTEx database). Higher expression of Orphan A is associated with decreased survival and remission, while Orphan 1 expression correlates with that of numerous fibrotic genes. Importantly, both Orphan 1 and Orphan A are functional and appear to contribute to the malignant phenotype. For example, siRNA knockdown of Orphan 1 in PCAFs blunts production of profibrotic markers and decreases ability of conditioned media from PCAFs to enhance proliferation of PDAC cells while transfection of Orphan A increases DNA synthesis of normal pancreatic ductal epithelial cells. Taken together, these and other results suggest that in addition to their role in endocrine tumors, GPCRs represent previously unrecognized contributors to cancer through actions on tumor cells and stromal cells. These data suggest the possibility that highly expressed GPCRs (such as Orphan A) may function as oncogenes. Thus, GPCRs may be druggable, novel targets for the treatment of cancer, including pancreatic cancer, a tumor for which new therapeutics are an important, unmet need.
lines expressing higher GABRP, while the same doses of a control antibody had no effect in these cells in culture. Our goal is to generate an antibody drug conjugate (ADC) for TNBC by conjugating anti-GABRP antibody with a maytansinoid such as DM1, which has proven cytotoxicity in breast cancer cells. Together, our results suggest that GABRP is a potential therapeutic target for triple-negative breast cancers.

### 1142 Novel target discovery for glioblastoma using chemical biology fingerprinting.
Darren Finlay, Pedro Aza-Blanc, Harshil Dhruv, Alexey Eroshkin, Craig Hauser, Jeff Kiefer, Seunghan Kim, Tao Long, Robert G. Oshima, Sen Peng, Gil Speyer, Michael Berens, Kristiina Vuori. Sanford Burnham Prebys Med Discovery Institute, La Jolla, CA; TGen, Phoenix, AZ.

The most common adult brain tumor is Glioblastoma Multiforme (GBM), an extremely aggressive cancer with only scant treatment options. Even with standard of care most patients present with a recurrence and the median survival is only circa 15 months. The need, therefore, for new therapeutic targets and treatment options is pressing. Here we describe here a multipronged approach to identifying said targets. We present an established methodology for the isolation and culture of patient derived GBM samples that retain the “stem-like” fraction thought to underlie resistance and recurrence. Furthermore we show genomically that these samples represent specific subtypes of the disease yet still form distinct groups in unbiased clustering analysis. Thus we have multiple representative patient derived cultures that are suitable for our drug discovery and chemical biology analyses. Using a process we term Chemical Biology Fingerprinting (CBF) we utilize small focused, and clinically relevant, chemical collections in order to identify patterns of chemosensitivities across multiple samples. This allows an unbiased yet cancer relevant sub-stratification and the identification of agents, and therefore targets, which may be relevant for GBM patient subtypes. Indeed our use of the highly annotated NCI CTD[1] Informer Set of chemicals allows ready drug-to-target mapping and facilitates data sharing across the CTD[2] network. Moreover, already defined subgroups can be clustered to find agents, or groups of agents, that show selective activity against traditional classifications (e.g. proneural, mesenchymal etc.). Finally our strategy is permissive for the identification of “exceptional responders”. That is, individual patient samples that respond to a specific drug whilst most samples are refractory. In sum we demonstrate generation of patient derived models and identify specific, and novel, drugs that may be relevant for specific GBM subtypes. Supported by NIH U01CA168397.

### 1143 Targeting the transcriptional kinases CDK12 and CDK13 in breast and ovarian cancer.
Michael Bradley, Jason Marineau, Yoon Choi, Kristin Hamman, Goran Malojic, David Orlando, Xiyuan Ren, Nan Ke, Shanh Hu, Eric Olson, Christian Fritz, Christopher Roberts. Syros Pharmaceuticals, Cambridge, MA.

CDK12 and CDK13 regulate expression of large transcripts requiring substantial processing to produce mature mRNA. This transcriptional regulation includes coordinated phosphorylation of specific repeats within the C-terminal domain of RNA polymerase II and association with RNA processing factors (Chila, 2016). RNAi knockdown of CDK12 in cell culture decreases expression of DNA damage response genes, including BRCA1 and ATR, while enhancing sensitivity to DNA damaging agents (Blasek, 2011; Liang, 2015). Recently, THZ531, a selective covalent inhibitor of CDK12 and CDK13, was shown to decrease expression of DNA damage response genes in cell culture (Zhang, 2016). Here we present further studies with THZ531 to guide our discovery program toward molecules suitable for clinical development and to explore mechanistic rationales for combining a CDK12/13 inhibitor with PARP inhibitors or DNA damaging agents for difficult-to-treat cancers such as high-grade serous ovarian cancer and triple-negative breast cancer. Using THZ531 as a benchmark, we developed assays capable of discriminating sub-nM inhibitors, including quantifying time-dependent covalent inhibition and cell-based CDK occupancy. Since CDK7, like CDK12 and CDK13, contains a cysteine residue proximal to the kinase active site, these approaches are critical to understand covalent inhibitor selectivity. Furthermore, we performed kinase paneling studies to better understand selectivity of this scaffold in support of our ongoing efforts to optimize CDK12/13 potency and selectivity. To pharmacologically investigate the previously reported effects of CDK12 RNAi, growth inhibition of a panel of ovarian and breast cancer cell lines was assessed following treatment with THZ531 (OVYA EC50 = 50-200 nM (n=6); BRCA EC50 < 30 nM (n=4)). Expression profiling further confirmed that THZ531 treatment resulted in different sets of genes being affected than was observed following treatment with inhibitors targeting CDK7, CDK9 or BET-bromodomain proteins. Additionally, CDK12/13, CDK7 and CDK9 inhibitors were profiled in a broad cell line panel (n=400) to reveal relationships between inhibitor sensitivity, mutation status, gene expres-
sion, and potential oncology indications that may be addressed by these different mechanisms. Finally THZ531 was synergistic with both PARP inhibitors and DNA damaging agents in ovarian and breast cancer cell lines. These data highlight cancer indications and combinations that may be particularly amenable to treatment with CDK12/13 inhibitors. While the pharmacokinetic properties of THZ531 and its target engagement profile is consistent with tumor regression in mice, in mouse models system, our ongoing medicinal chemistry program is progressing to identify and optimize CDK12/13 inhibitors suitable for clinical evaluation.

#1144 Dual inhibition of MEK1/2 and PLK1 specifically targets aggressive breast cancer cell population with CEP55 elevated expression. Debottam Sinha, Murugan Kalimuthu, J. Alejandro Lopez, Kum Kum Khanna. QIMR Berghofer Medical Research Institute, Brisbane, Australia.

Triple negative breast cancers (TNBCs), lacking the expression of ER, PR and HER2 amplification, are the most aggressive form of breast cancer (BC). Due to their heterogeneity influenced by high level of genomic instability and aneuploidy, treatment of TNBC patients is one of the biggest challenges faced in the clinics. CEP55, discovered first by our laboratory, is a key regulator of cytokinesis. Research has demonstrated association of CEP55 with various cancers especially BC as over-expression of CEP55 mRNA is associated with worse BC prognosis and poor survival. We hypothesized that, CEP55 regulates the fate of aneuploid cell population, which is cell cycle arrest, as well as senescence and apoptosis. Their heterogeneity influenced by high level of genomic instability and aneuploidy, treatment of TNBC patients is one of the biggest challenges faced in the clinics. We have performed a series of in vitro studies demonstrating that depletion of CEP55 sensitizes cells to anti-mitotic drugs like PLK1 inhibitor (BI2536) and leads to unscheduled CDK1/Cyclin B activation and favor CDK1-Caspe 3-dependent mitotic catastrophe. We also demonstrate that its inhibition of CEP55 inhibits CEP55 mRNA translation at specific mitotic genes for tumor progression among aggressive BC, thus can be targeted for therapy development. We have performed a series of in vitro studies demonstrating that depletion of CEP55 sensitizes cells to anti-mitotic drugs like PLK1 inhibitor (BI2536) and leads to unscheduled CDK1/Cyclin B activation and favor CDK1-Caspe 3-dependent mitotic catastrophe. Thus, the involvement of CEP55 at specific mitotic genes for tumor progression among aggressive BC, thus can be targeted for therapy development.

#1145 Overcoming chemoresistance and blocking metastasis testing in breast cancer by targeting HuR. Xiaojing Wu, 1 Rebecca Marquez, 1 Shuang Han, 1 Lan Lan, 1 Dan A. Dixon, 1 Jeffrey Aubé, 1 JeffreyAubé, 3 DannyR. Welch, 2 LiangXu1. 1Debottam Sinha, Murugan Kalimuthu, 1 Jeffrey Aubé, 3 Danny R. Welch, 2 Liang Xu. 1University of Kansas, Lawrence, KS; 1University of Kansas Medical Center, Kansas City, KS; 3University of North Carolina, Chapel Hill, NC.

Patients with metastatic breast cancer have a dismal 5-year survival rate of only 24%. Chemoresistance is another contributor to the high mortality of advanced breast cancer. The RNA-binding protein, Hu antigen R (HuR), is overexpressed at all stages of breast cancer development. Cytoplasmic HuR accumulation correlates with high-grade malignancy, poor distant disease-free survival and serves as a prognostic factor for poor clinical outcome in breast cancer. HuR promotes tumorigenesis by promoting mRNA stability and translation of proteins implicated in proliferation, survival, angiogenesis, invasion, and metastasis. HuR also modulates sensitivity of breast cancer cells to chemotherapy. Taken together, HuR is an emerging target for breast cancer therapy, especially metastatic breast cancer. Using shRNA and CRISPR technologies to modulate HuR expression in breast cancer cells, we found that cells with HuR KD/KO were less invasive and more sensitive to chemotherapy. In an effort to discover small molecules that disrupt the HuR-mRNA interaction and block HuR functions in breast cancer progression, metastasis and chemoresistance, high throughput screening (HTS) was carried out in several chemical libraries (~23,000 compounds) using fluorescence polarization (FP) assay, which identified several initial hits with sub-micromolar inhibitory constants (Ki). Those potential hits were then validated by ALPHAV assay (Amplified Luminescent Proximity Homogeneous Assay), confirmed by Surface Plasmon Resonance (SPR). In cell-based assays, top hit KH-3 and its optimized analogs, specifically shortened HuR target mRNA half-lives and decreased the level of the encoded proteins. More-over, those compounds inhibited invasion and restored chemosensitivity. qPCR arrays focusing on specific pathways revealed that HuR inhibitors potently up-regulated metastatic suppressors and downregulated genes frequently overexpressed in lung metastases. In animal studies, KH-3 not only exhibited potent antitumor efficacy in orthotopic xenografts of breast cancer, but also efficiently inhibited tumor growth in a preclinical model of breast cancer. In conclusion, we identified an array of potent and specific small molecule inhibitors of HuR-mRNA interaction for potential anti-metastatic therapy for breast cancer with HuR overexpression.

#1146 Biomarker-driven targeted oral treatment strategy for bladder cancer. Daley S. Morera, Andre Jordan, Vinata B. Lokeshwar. Augusta University, Augusta, GA.

INTRODUCTION AND OBJECTIVE: Hyaluronic acid (HA) family of molecules, HA-synthases (HAS-1,2,3), HA-receptors (CD44, RHAMM) and hyaluronidase (HYAL-1) are markers for bladder cancer (BCa) diagnosis and predicting prognosis. BCa-family promotes tumorigenesis and metastasis by inducing epithelial mesenchymal transition (EMT). 4-Methylumbellifere (4-MU) is an orally bioavailable dietary supplement that inhibits HA synthesis. We evaluated the expression of HA family and EMT markers in bladder tissues as well as the antitumor effects of 4-MU as a potential targeted therapeutic agent in preclinical evaluation of BCa. METHODS: Quantitative PCR was used to measure mRNA expression of HA-family and EMT genes (β-catenin, Twist, and Snail) in 72 bladder tissue specimens (28 normal; 44 tumor); follow-up: 20.3±2.5 months; median 17 months. The effect of 4-MU (0.06-0.6 mM) on cell proliferation, apoptosis, intracellular signaling, and the expression of HA receptors, and EMT genes were examined in BCa cell lines by Q-PCR, immunoblotting, proximal ligand and PI-3K activity assays. Mechanism of action was analyzed by HA addition and mAkt overexpression. Effect of oral administration of 4-MU (100, 200-mg/kg) on tumor growth was analyzed in subcutaneous xenografts. RESULTS: HAS-1, -2, -3, HYAL-1 and Snail levels were 10-20-fold elevated in BCa tissues as compared to normal bladder (P<0.001). In univariate analysis, HAS-1, -2, HYAL-1 and Twist levels correlated with metastasis (P<0.001); HYAL-1 was an independent predictor of metastasis. 4-MU inhibited cell proliferation, chemotactic motility and invasion in a dose-dependent manner; 50-70% inhibition at IC50 (0.4 mM) for HA-synthesis inhibition. 4-MU induced apoptosis (>3-fold) via the death receptor pathway. 4-MU downregulated HA-signaling, specifically transcript and/or protein levels of CD44, RHAMM, p-Akt, β-catenin, p-b-catenin(S552). Snail and twist were downregulated in 2-5-fold, but pβ-catenin(T41/S45), pGSK-3β and E-cadherin levels were increased. 4-MU also inhibited CD44/PI-3K complex formation and PI-3K activity. HA addition or myristoylated Akt expression attenuated 4-MU effects. In xenograft studies, 4-MU oral treatment abrogated tumor growth of established tumors (vehicle, day 50: 766±221 mm2; 4-MU: 128±61, day 50) by abrogating HA-synthesis. In bladder tumor cells, 4-MU inhibited HA-signaling. However, a potent and selective inhibitor to target the SUMO pathway has been lacking. The SUMO-activating enzyme (SAE) is an essential enzyme in the pathway that initiates the SUMOylation process. Here we report the identification of the first mechanism-based SAE inhibitors with nanomolar potency in cellular assays. These inhibitors selectively block SAE enzyme activity and total SUMOylation in cells, which leads to reduced cancer cell proliferation. Moreover, SAE inhibition resulted in disruption of PML nuclear bodies and redistribution of DAXX. In vivo administration of SAE inhibitor into tumor bearing mice results in modulation of several biomarkers including a significant reduction in SUMO-conjugates and E2 Ubch9aestheor, demonstrating SUMO pathway inhibition. Our results demonstrate the feasibility of inhibiting the SUMO pathway with small molecule inhibitors and provide tools to study the SUMO biology in cancer.
Bazedoxifene as a novel GP130 inhibitor for the treatment of triple-negative breast cancer. Jilai Tian,1 Yang Cao,1 Xiang Chen,1 Hui Xiao,1 Chen-gong Li,4 Jiayuh Lin,1,5 University of Maryland, Baltimore, MD; 4Hauzong University of Science and Technology, Wuhan, China; 5The Ohio State University, Columbus, OH; 4University of Florida, Gainesville, FL.

Triple-negative breast cancer (TNBC) is the only subtype of breast cancer still lacking effective therapeutic options. Thus, finding novel targets and therapies to treat TNBC is an urgent clinical issue. IL-6 is one of the principal oncogenic mediators in breast cancer and systemic IL-6 levels correlates with poor prognosis, advanced disease, and metastases. Importantly, growth of TNBC cells are replied on autocrine cytokines including IL-6. Therefore, IL-6 signaling represents a novel therapeutic approach with a potential to improve the therapeutic efficacy. To date, however, no small molecules that target IL-6 signaling are available for clinical cancer therapy. IL-6 binds to IL-6Ra, then recruits GP130 to form the IL-6/IL-6Ra/Gp130 heterotrimer and triggers a signaling cascade downstream including JAK/STAT3, PI3K/AKT/mTOR, and ERK. Therefore, it is possible to target IL-6 signaling by blocking IL-6Ra or IL-6R and thus inhibiting its signaling cascade downstream. To effectively target IL-6 signaling, we have utilized a novel drug discovery approach combining Multiple Ligand Simultaneous Docking and drug repurposing to target GP130, since its structure is more druggable than IL-6R. We have identified a FDA-approved drug Bazedoxifene (for the prevention of the postmenopausal osteoporosis in postmenopausal women) with a novel function to inhibit IL-6R and GP130 protein-protein interactions and thus blocking downstream IL-6 signaling.

In this study, we examined the therapeutic effect of Bazedoxifene on TNBC, aiming to verify Bazedoxifene as a Novel IL-6/IL-6R Inhibitor for TNBC treatment. Our data of western blot showed Bazedoxifene inhibited increased STAT3 phosphorylation induced by IL-6. In addition, Bazedoxifene inhibited phosphorylation of AKT and ERK in TNBC cells that were also produced by IL-6. Furthermore, combination of Bazedoxifene with paclitaxel exhibited more significant inhibition than single agent alone on cell viability in TNBC cells either in 2D or 3D culture model in vitro. Results of colony formation showed that Bazedoxifene could significantly inhibit cell survival and proliferation at 20 μM, which were more effective than Evista and SC144. Moreover, Bazedoxifene could inhibit cell migration. We tested the increased proliferation of TNBC cells using BrDU with the added IL-6, which were then inhibited by Bazedoxifene, demonstrating the Bazedoxifene could achieve a competed inhibition of IL6. The result of significant inhibition of tumor growth in vivo further verified the therapeutic effects of Bazedoxifene. All results showed the significant therapeutic effects of Bazedoxifene in TNBC cells by competing blocking IL6 signaling. Thus, Bazedoxifene holds a great potential for TNBC therapy.

Targeting Rad6B suppresses melanomagenesis. Ashapurna Sarma,1 Sarah Pett1, Fangchao Liu,1 Pratima Nangia-Makker,2 Guangzhao Mao,2 Mal- athy Shekhar1. 1Wayne State University and Karmanos Cancer Institute, Detroit, MI; 2Wayne State University, Detroit, MI.

Active β-catenin signaling in melanoma is associated with aggressive disease. We have previously shown that Rad6B, an ubiquitin conjugating enzyme, is a positive regulator of β-catenin stability and transcriptional activity, and is itself a transcriptional target of β-catenin. This stabilization is mediated by Rad6B-induced K63-linked polyubiquitination of β-catenin that renders it insensitive to 26S proteasomal degradation. Immuno-histochemical analysis of human cutaneous melanoma samples showed the first detectable expression of Rad6B in melanocyte hyperplasia and continued Rad6B and β-catenin overexpression in primary and metastatic melanomas. These data implicate a critical role for Rad6B in melanocyte transformation and a continuing role in melanoma progression. To analyze the role of Rad6B in melanomagenesis, we targeted Rad6B expression/activity in human M14 metastatic melanoma cells by using a Rad6B-selective small molecule inhibitor SM1#9 and the Crisp/RCas9 gene editing system. Immunoblot analysis showed that compared to controls, M14 cells treated with SM1#9 showed decreased levels of β-catenin, and β-catenin driven transcriptional targets Rad6, vimentin, Mitf-M, and Melan-A. Although Snail levels were not altered, SM1#9 treated cells showed increase in phosphorylated Snail. Immunohistochemical staining verified the western blot data and showed cyto-plasmic relocalization of PCNA and Snail in SMI#9 treated cells which is consistent with increased PCNA and Snail expression. Concordant with the decrease in vimentin and unphosphorylated Snail levels, Rad6B-inhibited cells display poor capacity to migrate as compared to controls. Whereas Rad6B knockout cells were severely growth impaired, Rad6B edited clones showed improved migration potential (potentially from only one allele) similarly showed decreased levels of β-catenin, vimentin, and Mitf-M. Similar to Rad6B-inhibited cells, Rad6B edited cells were migration- and invasion-impaired. Whereas control cells produced robust tumors and overt lung metastases, the Rad6B gene edited cells were poorly tumor-igenic. Rad6B gene edited clones showed complete loss of Melan A. Since Mitf-M is a transcriptional regulator of Melan A and a key player in melanocyte lineage specification, our data suggest that targeting Rad6B could potentially inhibit melanomagenesis by reprogramming melanoma cells. Supported by NIH CA178117 and 3Balls Racing.

Downregulation of Hedgehog signaling via Sirt6 activation is important to docosahexaenoic acid-induced cell death in human EGFR mutant non-small cell lung cancer. Soyeon Jeong,1 Kaejong Jing,1 Soyeon Shin,2 Seung-Hyeon Han,3 Yoon-Soon Yoo,3 Prashanta Silwal,2 Jun-Young Heo,2 Gi-Ryang Kweon,5 Seung-Kiel Park,4 Jong-II Park,4 Tong Wu,4 Kyu Lim.1,5 Dept. of Biochemistry, Infection Signaling Network Research Center, Chungnam National University, Daejeon, Republic of Korea; 2Dept. of Biochemistry, Cancer Research Institute, Chungnam National University, Daejeon, Republic of Korea; 3Dept. of Biochemistry, Dept. of Medical Science, School of Medicine, Chungnam National University, Daejeon, Republic of Korea; 4Dept. of Biochemistry, Dept. of Medical Science, School of Medicine, Infection Signaling Network Research Center, Chungnam National University, Daejeon, Republic of Korea; 5Dept. of Biochemistry, Chungnam National University, Daejeon, Republic of Korea.

Docosahexaenoic acid (DHA) induces apoptotic cell death through several mechanisms in cancer cells. Here we report that DHA-induced apoptotic cell death is related to the inhibition of Hh signaling via SIRT6 activation in human PC9 and H1975 nonsmall cell lung cancer (NSCLC). DHA-induced cell death was confirmed increase of the protein levels of cleaved PARP and caspase-3 Bax as well as the number of TUNEL positive cells and the Sub-G1 proportion in PC9 and H1975. DHA significantly increased the SIRT6 levels. Knockdown of SIRT6 by siRNAs inhibited apoptosis induced by DHA, while SIRT6 overexpression increased apoptotic cell death, indicating that DHA-induced SIRT6 activation results in apoptosis. In addition, SIRT6 activation by DHA treatment was associated with downregulation of Hh signaling and knockdown of SIRT6 resulted in augmentation of Hh signaling, suggesting elevation of SIRT6 levels in DHA-treated NSCLC cells leads to downregulate the Hh signaling. Smo activator SAG increased the protein levels of Hh signaling molecules by DHA, and SAG plus DHA treatment decreased cleaved PARP levels, implying that DHA-induced Hh signaling is related to apoptotic cell death. To unveil the effects of endogenous DHA on apoptosis via SIRT6-mediated Hh signaling downregulation, we used PC9 stable cell lines of fat-1 (ω3-desaturase) gene. The SIRT6 levels were significantly increased and Hh signaling molecules were diminished in fat-1 stable PC9 (f-PC9) cells, compared with the cells transfected with the control vector (c-PC9). Moreover, SIRT6 expression was induced and Gli and smo levels were inhibited in tumor tissues from f-PC9 cells-injected mice, demonstrating that DHA regulates SIRT6 and Hh signaling in vivo. Taken together, these results suggest that DHA may induce apoptotic cell death through SIRT6-modulated Hh signaling suppression in human NSCLC cells. These findings implicate that ω3-PUFAs may represent a potential active therapy for the chemoprevention and treatment of human NSCLC. [This work was supported by the National Research Foundation of Korea (NRF) grant funded by the Korea government (MEST) (2007-0504932, NRF-2015R1D1A1A01056887) and by the framework of international cooperation program managed by National Research Foundation of Korea (2015K2A2200620)].

SY-1365, a potent and selective CDK7 inhibitor, exhibits promising anti-tumor activity in multiple preclinical models of aggressive solid tumors. Shanhu Hu, Nan Ke, Yixuan Ren, Sofija Miljovska, Nisha Rajagopal, Michael McKeown, David Orlando, Kevin Sprott, Yoon J. Choi, Eric Olson, Christian C. Fritz. Syros Pharmaceuticals, Cambridge, MA.

CDK7 has recently emerged as an attractive target in cancer since its inhibition decreases the transcript levels of oncogenic transcription factors, especially those driven by super-enhancers (SEs). Cancers have been hypothesized to be addicted to SE regulated genes and simultaneous suppression of multiple SEs including JAK/STAT3, PI3-K/AKT/mTOR, and MEK/ERK. Therefore, it is possible to develop effective therapy for the chemoprevention and treatment of human solid tumors that are susceptible to SY-1365 and compare the effects of SY-1365 on gene expression to other gene control agents. SY-1365 was screened in a panel of solid tumor cell lines, revealing activity in breast, ovarian, colorectal...
and lung cancer cells with low nM EC50 and rapid induction of apoptosis. In breast cancer, a subset of triple negative breast cancer (TNBC) cell lines were found to be more sensitive than luminal breast cancer cell lines, so we extended our studies to in vivo models and showed substantial tumor growth inhibition in multiple patient-derived xenograft (PDX) models of TNBC. Since other compounds that target modulation of HSPGs, NT4 is a broad-spectrum HSPG targeted therapy and upregulated in a variety of breast cancers. This suggests that NT4 may have the potential to be used as a therapeutic agent for breast cancer and is currently under preclinical development.

**EXPERIMENTAL AND MOLECULAR THERAPEUTICS: New Targets 1**

Heparan sulfate proteoglycans (HSPGs) have crucial regulatory roles in tumor progression and invasion. HSPGs are composed of a core protein and glycan chains characterized by repeated disaccharide units which can be sulfated at different amount and position. HSPG have enormous structural diversity due to the different possible modifications of the single saccharide units within the polysaccharide, such as position, sulphation and acetylation. As a result HSPG can bind and modulate their binding to signaling molecules such as growth factors, morphogens and chemokines. HSPG proved to be important in mediating cancer development and progression by enhancing the binding of growth factors, morphogens and cytokines to their cognate receptors, thus activating signaling pathways that give rise to angiogenesis, cell growth and proliferation, cell survival, and metastasis.

ONC201, founding member of the imidapridine class of compounds, is a highly selective small molecule G protein-coupled receptor (GPCR) antagonist that is in Phase I/II advanced cancer clinical trials. In this study, we evaluated GPCR engagement and antitumor activity of ONC212, an imidapridine that is a chemical analogue of ONC201. Experimental GPCR profiling using the PathHunter® β-Arrestin assay, determined that ONC212 is a selective agonist of the orphan GPCR GPR132/G2A. Multidose validation confirmed nanomolar GPR132 agonist activity (EC50 ~ 400nM). GPR132 is a stress-inducible orphan GPCR that causes G2/M arrest. The tumor suppressive role of GPR132 has been demonstrated most notably in lymphoid leukemia. Gene expression analysis of samples in the Cancer Genome Atlas (TCGA) revealed GPR132 is expressed in a range of tumor types with high expression in leukemia and lymphoma. The in vitro efficacy of ONC212 was assessed in the Genomic of Drug Sensitivity in Cancer (GDSC) collection of cell lines (>1,000 cell lines). Cell viability assays were performed at 72 hours post-treatment to generate dose responses curves at concentrations from 78nM up to 20μM. ONC212 was broadly efficacious against most solid tumors and hematological malignancies in the low nanomolar range. Ranking the sensitivity of cancer lines to ONC212 by tumor type revealed that leukemia and lymphoma are the most responsive tumor types based on completion of response (area under the dose-response curve). Interestingly, we also observed that high expression of GPR121 significantly correlated with ONC212 efficacy in GDSC cell lines, suggesting the importance of GPR132 agonist activity for ONC212 efficacy. ONC212 was tested in 62 human leukemia cell lines that included acute myeloid leukemia (AML), acute lymphoblastic leukemia (ALL), chronic myelogenous leukemia (CML) and hairy cell leukemia. ONC212 demonstrated broad spectrum anti-leukemic activity and was equally efficacious across all leukemia subtypes tested. Most cell lines (60/62) were responsive to ONC212 with GI50 ranging from <78nM to 456nM. Within ALL, both B-cell and T-cell ALL were highly sensitive to ONC212. ONC212 reduced cell viability in AML independent of complex karyotypes and p53 mutations that are associated with poor clinical outcomes. ONC212 was also tested in 58 lymphoma cell lines comprised of anaplastic large cell lymphoma, Burkitt’s lymphoma, cutaneous T-cell lymphoma (CTCL), diffuse large B-cell lymphoma (DLBCL), Mantle cell lymphoma (MCL), Follicular Lymphoma and Hodgkin’s lymphoma. ONC212 reduced cell viability in most cell lines (56/58) and was equally efficacious regardless of subtypes with GI50 ranging from <78nM to 261nM. Thus, GPR132 agonist ONC212 possesses robust anti-cancer activity in hematological malignancies irrespective of leukemia and lymphoma subtype and provides further validation of the anti-cancer efficacy of the novel imidapridine class of small molecules.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Novel Molecular Targets 1

The C-terminal binding protein (CtBP) is a family of dimeric nuclear proteins whose levels are increased in cancers of the colon, ovaries, prostate and breast. Elevated CtBP expression is associated with poor cancer survival and can also distinguish those node negative breast cancer patients who will show worse survival. This implicates CtBP as both a biomarker and a promising candidate for therapeutic intervention. As a dimer, CtBP provides a scaffold that couples multiple different DNA-binding transcriptional regulators with a variety of chromatin modifying protein complexes to alter the epigenetic landscape throughout the nucleus. These properties provide the rationale for pharmacological targeting of CtBP to change epigenetically regulated gene expression in cancer cells. In this study, we employ computer assisted drug design to screen for optimal quantitative structure-activity relationships (QSARs) between small molecules and CtBP to identify 24 potential CtBP inhibitors. Functional screening of these compounds identifies 4 lead compounds with low toxicity and high water solubility. Treatment of breast cancer cells at micro-molar concentrations of these small molecular inhibitors induces significant de-repression of epigenetically silenced pro-epithelial genes in the mesenchymal, triple negative breast cancer cell line, MDA-MB-231. This re-activation is associated with eviction of CtBP from the respective gene promoters, disrupted recruitment of CtBP-chromatin modifying protein complexes, increased deposition of activating epigenetic histone marks, and upregulation of both pro-epithelial gene mRNA and protein expression. In functional assays, CtBP inhibition by these small molecules decreases cellular invasion, and improves DNA repair. FRET ( Förster resonance energy transfer) analysis demonstrates that CtBP inhibition results in decreased FRET intensity, suggesting that CtBP dimerization is repressed by CtBP inhibition. In addition, pharmacological inhibition of CtBP combines with established epigenetically targeted drugs to synergistically decreases migration and invasion through degradation of anchorage independent positive gene expression in triple negative cancer cells. Finally, CtBP inhibition results in transcriptional repression of MDRI expression and reduces the population of Doxorubicin resistant cells in the triple negative breast cancer cell lines. These findings imply the possible use of this class of compounds in strategies for therapeutic intervention that may increase the efficacy and decrease the acquired resistance to targeted therapeutic intervention in breast cancer.

#1157 Screening and identification of new generation glucose transporter inhibitors as anticancer therapeutics. Yanrong Qian, Prattik Shriwas, Xuan Wang, Dennis Roberts, Emma Kessler, Stephen Bergmeier, Xiaozhao Chen. Ohio Univ., Athens, OH.

Cancer is a top killer second only to cardiovascular diseases. Cellular metabolic reprogramming and altered energetics are key features of cancer. Opportunistic uptake of extracellular nutrients has recently been named as an emerging hallmark of cancer metabolism. Glucose is a key nutrient taken in by cancer cells for satisfying their high energy and biosynthesis needs. Drastic upregulation of glucose uptake and glycolytic activity, a phenomenon called the Warburg effect, is prevalent in cancers. Cancer cells express very specific glucose transporters (Gluts), particularly Glut1, on cell membranes for taking in glucose via facilitated diffusion. Considering the addiction of cancer cells for glucose and their sensitivity and vulnerability to changes in glucose supply, Gluts, especially Glut1, have been recognized as an attractive anticancer target. We previously reported the identification of first generation lead Glut1 inhibitor WZB117 (1). WZB117 treatment of human nonsmall cell lung cancer (NSCLC) A549 cells resulted in inhibition of glucose uptake, glycolysis and induction of apoptosis and necrosis. In addition, WZB-117 reduced tumor growth by ~70% in an A549 tumor mouse model. WZB117 inhibit cell growth of 7 cancer cell lines in 4 cancer types with IC50 values lower than 10 μM. Through a structure activity relationship (SAR) study of WZB117, a second generation lead, DRB18, has been identified. DRB-18 is much more stable and 5 to 10 times more potent than WZB117 in inhibiting growth and proliferation in about 90% of the 60 different cancer cell lines in 9 major cancer types as revealed in NCI-60 screenings. And its IC50 in many cancer cell lines are in the high nM range. In this study, we also report new compounds screening results for the objective of identifying novel compounds with higher glucose transport-inhibitory and cancer cell growth-inhibitory activities using nonsmall cell lung cancer cell lines as models. 1 Institut Universitaire de France, Paris, France; 2 The Institute of Cancer Research, London, UK; 3University College of London, London, UK; 4University Hospital of Northumbria, Newcastle upon Tyne, UK; 5University of Cambridge, Cambridge, UK; 6University College of London, London, UK; 7University College London NHS Trust, Cambridge, UK; Cambridge, United Kingdom; 8NHS Blood and Transplant, Cambridge Biomedical Campus, Cambridge, United Kingdom.

Acute myeloid leukemia (AML) is an aggressive cancer with a poor prognosis, for which the therapeutic landscape has changed little for decades. Aberrant mRNA splicing plays a key role in cancer development and genes coding for several of the major components of the spliceosome are targeted by somatic mutations in numerous cancers including myelodysplastic syndromes and AML. Recently, myeloid neoplasms bearing spliceosome gene mutations were shown to be preferentially susceptible to pharmacological disruption of the spliceosome. Here we report that targeting the spliceosome can also be an effective therapeutic strategy in other types of AML. Recently, we generated a comprehensive catalogue of genetic vulnerabilities in AML using CRISPR-Cas9 genome-wide recessive screens and reported several novel intuitive and non-intuitive therapeutic candidates. Amongst these we identify SRPK1, the gene coding for a serine/threonine kinase that phosphorylates the major spliceosome protein...
SRF1. Here, we demonstrate that targeted genetic disruption of SRF1 in AML driven by MLL-fusion genes, led to differentiation and apoptosis. Additionally, mice transplanted with human AML cell lines carrying the MLL-AF9 fusion gene, namely MOLM-13 and THP-1, presented a significant prolongation of survival when SRF1 was genetically disrupted by CRISPR-Cas9 editing. Similar effects were seen in pharmacological inhibition of SRF1 and identified, among other genes, BRD4 as a sensitizer. We go on to show that the BRD inhibitor I-BET-151 synergizes with SRF1 inhibition to kill MOLM-13 both in vitro and in vivo. Preliminary data indicates that SRF1 inhibition has overlapping molecular effects to BRD inhibition. We are currently investigating the molecular bases of this observation. Our work identifies SRF1 as a novel therapeutic target in AML that can be used alone or in conjunctions with drugs targeting epigenetic modifications to improve their anti-leukemic effects.

**#1159 Targeting novel mucin synthesis pathway for pancreatic cancer treatment.** Altaf Mohammed, naveena B. Janakiram, Venkateshwar Madka, Gaurav Kumar, Scott edgar, Gopal Patani, Taylor Bryant, Yuting Zhang, Hariprasad Gali, Yan Daniel Zhao, Stan Lightfoot, Chinthalapally V. Rao. University of Oklahoma Health Sciences Ctr., Oklahoma City, OK.

Pancreatic cancer (PC) is most fatal and is the fourth leading cause of cancer related deaths in USA with a least five year survival of <7%. Although several over expressed mucin subtypes (MUC1, MUC4, MUC5AC, and MUC6) that impede drug delivery to PC have been targeted with limited results, core enzymes involved in mucin biosynthesis have yet to be evaluated as potential targets. The core 2 β 1,6 N-acetylgalactosaminyltransferase (GCNT3/C2GNT7) plays a significant role in mucin glycan biosynthesis. We analyzed GCNT3 expression on 180 specimens from individuals with PC (90) or matched controls (90). Patients with low GCNT3 expression (19.16 folds; p = 0.002) were significantly more likely to have PC subtypes (p = 0.002). GCNT3 expression is significantly down regulated in PC compared with normal tissue by 6.1 (p = 0.007) and (18% of patients with low GCNT3 expression, p = 0.05). The expression of GCNT3 and mucin expression in patients with lower expression of GCNT3 was associated with worse outcomes. 17.5 months vs. 10.5 months, p = 0.036. We observed a significant increase in GCNT3 mRNA expression (103.16 folds; p = 0.0001) in correlation with increased mucins subtypes (p < 0.05) in the pancreatic tumors from genetically engineered mouse (GEM) compared with pancreata from wild-type mice, as determined by Next-generation Sequencing/RNAseq analysis. In in silico studies, blind docking simulations revealed that a novel drug talnifluamate binds to GCNT3 with a better docking affinity of -8.3 kcal/mol. We synthesized talnifluamate and determined quality/purity using NMR, HRMS, and HPLC for in vitro and in vivo studies. Pancreata from 6-week-old KrasGEM (N = 6/group) treated with talnifluamate showed a significant decrease in GCNT3 and mucin expression in PanIN lesions. In human PC MiaPaCa-2 cell line, talnifluamate reduced GCNT3 expression and the number of mucin-positive cells (38% p = 0.0001). Further, PC cells (BxPC3 and Panc1) were treated with talnifluamate for 24 hrs for mucin disruption followed by radioactive 1H gemcitabine treatment for 2 hrs. The cells treated with talnifluamate showed 40% (p = 0.03) and 50% (p = 0.025) increased 1H gemcitabine uptake in BxPC3 and Panc1 cells compared to radiosensitive cells. GCNT3 siRNA knock out PC cells treated with talnifluamate showed a reduction in cell proliferation and significantly reduced spheroid formation (p < 0.05). In vivo, we did not observe any overt toxicity upon talnifluamate treatment as determined by liver enzyme toxicity and body weight gain (N = 5 mice/group). BxPC3 cells implanted nude mice (N = 5 mice/group) treated with talnifluamate or GCNT3 siRNA showed a marked reduction in xenograft tumors compared with untreated controls. Both talnifluamate and GCNT3 siRNA significantly inhibited xenograft tumor weight (48% p < 0.002 with siRNA, 63% p < 0.0001 with talnifluamate) and tumor volume (75% p < 0.0001 with both siRNA and talnifluamate) and GCNT3 enzyme activity (28% p < 0.03). Transcriptional analysis of xenograft tumors (N = 5/group) treated with GCNT3 siRNA or talnifluamate showed reduced GCNT3 and top hits related to mucin expression. These results justify the use of talnifluamate for mucin synthesis disruption, thereby enhancing the uptake of gemcitabine and thereby efficacy for PC treatment.

**#1161 Dimethylaminopentenoic acid (DMAPT), an oral nuclear factor kappa B inhibitor (NFκB), enhances radiation therapy and enhances epithelial growth factor tyrosine kinase inhibitor (EGFR TKI) activity.** Katheryn L. Mored, 1 Pamela J. Sykes, 1 Prafula C. Gokhale, 2 Gwo-Shu Mary Lee, 2 Hong Tiv; 1 Christopher J. Sweeney; 3,4 Plummers University, Bedford Park, Australia; 1 Dana-Farber Cancer Institute, Boston, MA.

Introduction: NFκB can promote cancer and resistance to therapy as well as mediate tissue injury in response to radiation (XRT). We assessed NFκB activity directly in combination with XRT, and also with an EGFR TKI, and assessed whether it can mitigate XRT side effects. Methods: Six-week old male TRAMP (Transgenic Adenocarcinoma of the Mouse Prostate) mice received DMAPT (100 mg/kg) orally or vehicle control 3x/week until palpable tumors formed and lung metastases were analyzed histologically. In separate studies, 16 week old TRAMP mice were treated with 100 mg/kg DMAPT 3x over 1 week and the effect on survival was evaluated. Results: Survival of DMAPT treated TRAMP mice was significantly enhanced compared to vehicle treated TRAMP mice (H1975 (790M mutation non small cell lung cancer, NSCLC) subcutaneously. When tumors reached 200 mm3, treatment (Rx): commenced: vehicle, DMAPT 100mg/kg/day, EGFR TKI-AZD9251 25mg/kg/day, combination. Results: Long-term Rx with DMAPT extended the median time to palpable prostate tumor by 15% (p = 0.036) and DMAPT reduced lung metastatic lesions/mm2 in TRAMP lungs 20-fold (0.077 ± 0.12 SD) compared to a vehicle control (1.47 ± 1.28 SD) (p = 0.0004). XRT-induced apoptosis doubled in TRAMP prostate (with moderate to high grade PIN lesions) treated with DMAPT prior to 6 Gy XRT (101.3 % increase, p = 0.039). DMAPT induced the greatest radiosensitivity in TRAMP prostate with high grade PIN (R2 = 0.79, p = 0.003), while apoptosis frequency in tissues with lower grades of PIN was the same as vehicle control TRAMP mice (R2 = 0.24, p = 0.6). DMAPT also reduced XRT-induced apoptosis in healthy TRAMP spleen (32.9 % reduction, p = 0.003) and rectum (28.7 % reduction, p = 0.0001). In the H1975 experiment, DMAPT monotherapy did not differ from the vehicle controls. In the single agent AZD9291 group, 2 of the 8 mice had resistance emerge during Rx and adding DMAPT to AZD9291 reversed resistance in one of these. Rx was held at Day 220 in 3 remaining AZD9291 treated mice with no evidence of tumor and only 1 mouse was alive with no tumor at day 260. For mice receiving Rx with AZD9291 and DMAPT from D1, resistance emerged in 1 mouse, and at D140 all mice treated with DMAPT alone had no tumor at day 260. Two mice had regrowth, were retreated, and at D200 without evidence of tumors had Rx held, and one had no tumor at D260 at the end of the experiment. In total, 4 of 8 mice in the AZD9291 and DMAPT had no tumor off therapy at D260. Conclusion: Radiation and EGFR TKI resistance has been linked to NFXb activation. DMAPT slows down cancer progression and decreases metastatic lesions in a prostate cancer mouse model, protects normal tissue from radiation induced apoptosis, augments radiation induced apoptosis in prostate cancer and augments EGFR TKI efficacy in T90M mutant NSCLC.

**#1162 The evaluation of INCB059872, an FAD-directed covalent inhibitor of LSD1, in preclinical models of Ewing sarcoma.** Valerie Dostalik Roman, Min Ye, Huiqing Liu, Melody Diamond, Anthony Chadderton, Yvonne Lo, Xuesong M. Liu, Jin Lu, Chunhong He, Liangxing Wu, Timothy Burn, Richard Wynn, Wenheng Yao, Gregory Hollis, Gregory Hollis, Peggy Scherle, Bruce Ruggeri, Sang Hyun Lee, Incyte Corporation, Wilmington, DE.

Ewing sarcoma is a rare bone cancer affecting predominantly children. The chromosomal translocation of chromosomes 11 and 22 results in the EWS/FLI gene fusion oncoprotein that is associated with ~85% of Ewing sarcoma cases. The EWS/FLI fusion protein is involved in deregulating gene expression and consequently causing cellular transformation. It was previously reported that lysis specific demethylase 1 (LSD1) regulates EWS/FLI transcriptional activity via its functional interaction through the NuRD co-repressor complex. We therefore evaluated whether inhibition of LSD1 could have anti-tumor effects in Ewing sarcomas that express the EWS/FLI fusion oncoprotein. INCB059872 is a potent, selective, and orally available FAD-directed covalent inhibitor of LSD1. To investigate the potential utility of INCB059872 in Ewing sarcoma, the A673 cell line having the characteristic chromosomal translocation was chosen as the experimental model system. INCB059872 inhibition of LSD1 did not significantly alter A673 proliferation in vitro. However, INCB059872 inhibited oncogenic transformation as determined by colony formation clonogenicity assays. NXX2.2 was previously identified as a critical downstream target molecule of the EWS/FLI fusion oncoprotein that is required for transformation. A significant downregulation of NXX2.2 was observed in A673 cells treated with 11.1 ± 0.7% suggesting the chronic DMAPT reduced the numb-negative modulation of the EWS/FLI -NXX2.2 axis. Oral administration of INCB059872 significantly suppressed the growth of both A673 and SK-ES Ewing sarcoma xenografts in vivo. In addition, in vivo efficacy was evaluated in patient derived xenograft (PDx) models that were developed from relapsed tumor tissues of Ewing sarcoma patients. Notably, a subset of PDx models having EWS/FLI translocations (3/6) exhibited significant tumor growth inhibition at well-tolerated doses of INCB059872. Molecular signatures obtained from RNA-Seq data with these PDx models exhibited intrinsic differences between responders and non-responders, suggesting additional molecular or genetic variations may contribute to their sensitivity to INCB059872. Studies identifying potential candi-
date molecular mechanisms are underway. Together, these data suggest that INC059872 may be therapeutically efficacious in a subset of Ewing sarcoma patients.

#1163 Non clinical pharmacology, pharmacokinetics and safety profiling of CB-103: A novel first-in-class small molecule inhibitor of the NOTCH pathway. Rajwinder Lehal,1 Viktoras Frismanantas,2 Charlotte Urec,1 Maximilian Murone,1 Dirk Weber,2 Michael Bauer,3 Jean-Pierre Bourquin,2 Freddy Radlke,4 Celliesia Biotech AG, Basel, Switzerland; 5University Children's Hospital, Zurich, Switzerland; 6Ecole Polytechnique Federale de Lausanne, Lausanne, Switzerland.

NOTCH signaling is a developmental pathway known to play critical roles during embryonic development as well as for the regulation of self-renewing tissues. Aberrant activation of NOTCH signaling leads to deregulation of the self-renewal process resulting in sustained proliferation, evasion of cell death, loss of differentiation capacity, invasion and metastasis, all of which are hallmark of cancer. Over activation of NOTCH in human cancers can be a consequence of over expression of NOTCH ligands/receptors, GOF mutations in NOTCH receptors as well as chromosomal translocations leading to constitutive activation of the pathway by producing truncated version of NOTCH1 or NOTCH2. Over activation of NOTCH and its oncogenic role in various cancers is prognostically relevant with shorter survival seen in patients harbouring these genetic alterations. Given the importance of NOTCH signaling in human cancers, several therapeutic approaches have been utilized to block NOTCH signaling. Two of these strategies are: a) the use of monoclonal blocking antibodies (mAbs) against NOTCH1/2 ligands and receptors and b) the use of small molecule inhibitors (SIs). However, these approaches can only be effective if tumor cells express full-length ligand or receptor molecules. On the contrary, in human cancers harbouring NOTCH gene fusion due to chromosomal translocations, the use of mAbs and SIs will have very limited clinical benefits. A third, yet not fully explored approach would be the blockade of NOTCH signaling by targeting the most downstream complex in the NOTCH signal transduction cascade, the NOTCH transcriptional activation complex, using small molecule inhibitors. Previously we have reported the discovery and characterization of CB-103, a novel first-in-class orally-active small molecule inhibitor of the NOTCH pathway. CB-103 inhibits NOTCH signaling by targeting the NOTCH transcriptional activation complex in the nucleus. CB-103 has shown the ability to block NOTCH signalling in various human cancer cell lines with active NOTCH pathway. CB-103 has also been tested in vivo models. In a GSI/mAb resistant cell line, CB-103 was found to block the transcriptional activity of NOTCH1, using small molecule inhibitors. First, we have shown that CB-103 completely blocks NOTCH target gene expression in vitro, but not in vivo. In vivo, CB-103 showed a partial inhibition of NOTCH target gene expression, but not as potent as in vitro. CB-103 has also been tested in vivo models. In a GSI/mAb resistant cell line, CB-103 was found to block the transcriptional activity of NOTCH1, using small molecule inhibitors.

#1164 A novel hypoxia-inducible factor-1 inhibitor IDF-11774 regulates cancer metabolism, thereby suppressing tumor growth. Misun Won,1 Hyun Seung Ban,2 Kyeong Lee,2 Hongsub Lee,3 Bo-Kyung Kim,2 Hwan Mook Kim,2 Ravi Naik,2 Song-Kyu Park,5 Joon-Tae Park,3 Inhyub Kim,1 Miso Nam,6 Geum-jeong Kim,5 Donggyun Lee,4 Donggyun Lee5,6,7,8,9

HIF-1 is associated with poor patient prognosis and therapeutic resistance of cancer. We have developed a novel hypoxia-inducible factor (HIF)-1 inhibitor, IDF-11774, as a clinical candidate for cancer therapy. Under hypoxic condition, IDF-11774 inhibited the accumulation of HIF-1α in vitro and in vivo in colorectal carcinoma HCT116 cells. IDF-11774 suppressed the angiogenesis of cancer cells by reducing the expression of HIF-1 target genes. Moreover, IDF-11774 reduced glucose uptake, leading sensitizing cancer cell growth on low glucose condition. IDF-11774 also decreased the expression of eEF1A2 in the first event triggered by the drug in cancer cells. eEF1A2 is a target protein for the delivery of aminoacyl-tRNA to the A site in the ribosome, it sustains the delivery of aminoacyl-tRNA to the A site in the ribosome, it has been shown to be overexpressed in many human cancers, including B-RAFV600E mutant and wild type (WT) cells. Compound 1 (IC50 range 0.8-3.8 μM) showed lower IC50 values than 3 (IC50 range 1.8-3.8 μM) and the mutant B-Raf specific inhibitor PLX-4032 (IC50 range 0.4-50 μM), especially at shorter treatment time (24 h). These effects are long-lasting since melanoma cells did not recover their proliferative potential after 14 days of treatment. In addition, we confirmed that compound 1 induces cell death by apoptosis using Live and Dead, Annexin V and Caspase3/7 apoptosis assays. Furthermore, compound 1 reduces protein levels of STAT3 and its phosphorylation, as well as decreases the expression of STAT3 regulated genes involved in survival and metastasis such as survivin and c-myc. Compound 1 also upregulates the cell cycle inhibitor p21. Docking studies further revealed the favorable binding of 1 with SHD2 domain of STAT3 suggesting its activity through STAT3 inhibition. Taken together, our results suggest that compound 1 induces apoptosis in a non-specific manner, the inhibition of STAT3 pathway to non-specifically target both B-Raf mutant and WT melanoma cells with much better cytotoxicity than the current therapy PLX-4032.

#1165 Plitidepsin targets the moonlighting functions of eEF1A2 in cancer cells. Alejandro Losada, Maria Jose Munoz, Juan F. Martinez-Leal, Juan M. Dominguez, Carlos M. Galmarini. PharmaMar S.A., Colmenar Viejo, Spain.

Plitidepsin, a cyclic depsipeptide of marine origin, has shown potent antican- cancer activity in preclinical assays and recently finished with positive results a phase II clinical trial (clinicaltrials.gov NCT01717165) showing the treatment of multiple myeloma patients. We have recently found that eukaryotic elongation factor 1α (eEF1A2), one of the two isoforms of the alpha subunit of eEF1, is the pharmacological target of plitidepsin. Although it shares 96% homology with eEF1A1 (the other isoform), they display an exclusive pattern of expression, being eEF1A2 solely expressed in brain and muscle in healthy individuals. However, it has been found that many tumors normally overexpress this protein, including multiple myeloma, prostate, pancreatic, ovarian, breast, lung and liver cancers. Furthermore, although eEF1A2 canonical function consists in the delivery of aminoacyl-tRNAs to the A-site in the ribosome, it has been shown to have pro-oncogenic moonlighting activities, including inhibition of apoptosis, protein degradation by the proteasome, heat shock response, cyto- skeleton organization and regulation of oxidative stress. We have now investigated several of the pro-oncogenic activities of eEF1A2 to analyze the impact that plitidepsin could have preventing them. Indeed, we observed that plitidepsin interfered with the interaction between eEF1A2 and Peroxiredoxin 1 (PRDX1), a complex that allosterically enhances the enzymatic activity of PRDX1. This way, plitidepsin would diminish PRDX1 antioxidant activity, possibly originating the oxidative stress that has been described in the bibliography as one of the first events triggered by the drug in cancer cells. PRDX1 only interacts with the GDP-bound form of eEF1A2, while plitidepsin exclusively binds to the GTP-bound form, most probably sequestering this protein from the pool that could interact with and activate PRDX1. Furthermore, we have confirmed that eEF1A2 interacts with Sphingosine kinase 1 (SPHK1), a complex that has been described in the bibliography as having enhanced SPHK1 activity. SPHK1 phosphorylates sphingosine producing sphingosine-1-P, a second messenger that binds to its receptors in the cell membrane and conveys growth and survival signals to the cell. We could see that plitidepsin treatment reduced the production of sphingosine-1-P in HeLa cells, destabilizing the equilibrium towards the pro-apoptotic ceramide/sphingosine side and promoting cell death. Thus, through its binding to eEF1A2, plitidepsin derails a series of its moonlighting functions that are essential for the survival of tumor cells, driving them into apoptosis.

#1166 Identification of a novel quinoxalino-isoselenoureara targeting STAT3 pathway as a potential melanoma therapeutic. Verónica Alcolea,1 Deepkamal Karelia,2 Manoj K. Pandey,3 Daniel Plano,3 Parvesh Singh,3 Roshal D. Iby,2 Juan Palop,2 Shantu Amin,2 Carmen Sammartin,1 Arun K. Sharma.1

1University of Navarra, Pamplona, Spain; 2Penn State University, College of Medicine, Hershey, PA; 3Cooper Medical College of Rowan University, Camden, NJ; 4University of Kwa-Zulu Natal, Durban, South Africa.

The prognosis for patients with metastatic melanoma remains very poor. Constitutive STAT3 activation has been correlated to larger tumor size, metastasis, acquired resistance against vemurafenib (PLX-4032), and poor patient survival. We previously identified a STAT3-selective small molecule inhibitor (1) as a potential new treatment for melanoma, acquired resistance against vemurafenib (PLX-4032), and poor patient survival suggesting its potential as a molecular target. We recently designed a series of isoseleno- and isothio-urea derivatives of several biologically active heterocyclic scaffolds. The cytotoxic effects of lead isoseleno-isothio-urea derivatives (compounds 1/3) were studied in a panel of five melanoma cell lines, including B-RafV600E mutant and wild type (WT) cells. Compound 1 (IC50 range 0.8-3.8 μM) showed lower IC50 values than 3 (IC50 range 1.8-3.8 μM) and the mutant B-Raf specific inhibitor PLX-4032 (IC50 range 0.4-50 μM), especially at shorter treatment time (24 h). These effects are long-lasting since melanoma cells did not recover their proliferative potential after 14 days of treatment. In addition, we confirmed that compound 1 induces cell death by apoptosis using Live and Dead, Annexin V and Caspase3/7 apoptosis assays. Furthermore, compound 1 reduces protein levels of STAT3 and its phosphorylation, as well as decreases the expression of STAT3 regulated genes involved in survival and metastasis such as survivin and c-myc. Compound 1 also upregulates the cell cycle inhibitor p21. Docking studies further revealed the favorable binding of 1 with SHD2 domain of STAT3 suggesting its activity through STAT3 inhibition. Taken together, our results suggest that compound 1 induces apoptosis in a non-specific manner, the inhibition of STAT3 pathway to non-specifically target both B-Raf mutant and WT melanoma cells with much better cytotoxicity than the current therapy PLX-4032.

BT1718 is a Bicycle Drug Conjugate (BDC®) comprising a constrained bicyclic peptide (Bicycle®) that binds with high affinity and specificity to membrane type 1-matrix metalloproteinase (MT1-MMP; MMP14) covalently linked through a hindered disulfide linker to the potent anti-tubulin agent DM1. MT1-MMP is involved in normal tissue remodeling and is also expressed in tumor associated stromal cells. However, overexpression is linked to increased tumor progression and metastasis. Specifically, over-expression of MT1-MMP is also associated with poor clinical prognosis and shorter survival times in patients with NSCLC and a range of other solid tumors. The Bicycle MT1-MMP binding element within BT1718 was identified using a proprietary phage display peptide technology consisting of highly diverse phage libraries of linear amino acid sequences constructed using a central tri-functional chemical scaffold. MT1-MMP binding Bicycles exhibit a profound affinity and specificity, more often associated with monoclonal antibodies, whilst their low molecular weight (1.5-3 kDa), akin to that of a small molecule, aids in rapid extravasation and tumor penetration. Together these attributes make Bicycles an ideal format for the targeted delivery of cytotoxic payloads. We evaluated the ability of BT1718 to bind to and kill tumor cells in vitro and in vivo in a panel of tumor cell lines. BT1718 demonstrated MT1-MMP target-specific binding and MT1-MMP-dependent cell killing of lung tumor cells in vitro as well as efficacy across a panel of lung tumor xenograft mouse models. For example, in the Met-amplified squamous NSCLC lung EBC-1 model, complete regressions were observed in all mice at doses as low as 5 mg/kg (iv) twice weekly and across a range of other dosing schedules, from daily to weekly. MT1-MMP-dependent activity was demonstrated by blocking target specific interactions through co-administration of an excess of unconjugated Bicycle binder, which inhibited tumour regression, or a non-binding Bicycle, which had no effect. Further evaluation in patient-derived lung xenograft (PDX) models indicates a similar activity to that seen in cell-line derived xenografts, with efficacy seen from 3mg/kg twice weekly and rapid full regression of tumors at higher doses. The molecular attributes of these Bicycles—rapid tumor penetration and specific binding, make them ideal therapeutics for targeted delivery of toxins as Bicycle drug conjugates (BDCs). The small size of the BDC may offer a significant advantage to other targeted cytotoxic approaches such as antibody-drug conjugates due to rapid extravasation and improved tumor penetration. BT1718, a Bicycle Drug Conjugate, shows potent anti-tumor activity in human lung tumor xenograft models and IND-enabling studies are underway.

IRAK4 kinase activity is required for toll-like receptor (TLR) and interleukin-1 receptor (IL-1R) signaling in a variety of myeloid and lymphoid cell types. Recruitment of IRAK4 to these receptors and its subsequent activation is facilitated by the MYD88 adaptor protein, which is mutated in ~22% of DLBCL cases. The MYD88 L265P activating mutation is found in ~30% of the activated B-cell (ABC) and ~66% of germinal center B-cell (GCB) subtypes of DLBCL and leads to constitutive activation of NF-κB signaling that is associated with worse prognosis. Thus, the development of small molecule inhibitors targeting IRAK4 is an attractive anticancer strategy for MYD88 mutation-containing cancers such as DLBCL. We are developing an IRAK4 inhibitor, CA-4948, as a therapeutic agent for hematological cancers with dysregulated TLR/MYD88/IRAK4 signaling. CA-4948 (previously AU-4948) is a selective and potent IRAK4 kinase inhibitor with in vivo activity in a TLR4-induced cytokine release model. CA-4948 exhibits favorable DMPK properties, oral bioavailability, and is well tolerated in mice. Furthermore, CA-4948 was previously shown to exhibit dose-dependent efficacy in ABC-DLBCL MYD88/L265P xenograft tumor models using cell lines OCI-LY3 and OCI-LY10. Here, we report the efficacy results from testing CA-4948 in a panel of well characterized, patient-derived DLBCL xenograft (PDX) mouse models. CA-4948 exhibited the greatest efficacy in four of nine human ABC-DLBCL PDX models. CA-4948 was efficacious in ABC-GCB DLBCL PDX models. Furthermore, CA-4948 was efficacious in ABC-DLBCL PDX tumors containing activating mutations in both TLR/LR-1R and BCR signaling pathways (MYD88 and CD79B double mutants). Interestingly, the one ABC-DLBCL PDX model that failed to respond to CA-4948 treatment contained a MYD88 L265P mutation as well as a BCL6 translocation. While this particular PDX model was resistant to CA-4948, and showed a weak anti-tumor response to single-agent ibrutinib, the combination treatment of ibrutinib and CA-4948 exhibited a synergistic tumor growth inhibition effect. In summary, CA-4948 exhibited anti-tumor activity in ABC-type DLBCL PDX tumor models including those containing combinations of activating mutations in the TLR/IL-1R and BCR signaling pathways. These results underscore the therapeutic potential of IRAK4 kinase inhibition by CA-4948, as a single-agent or in combination with BCR inhibitors, for the treatment of DLBCL.

#1169 mtTERT promoter as a target for treatment of glioblastoma. Saumya R. Bollam,1 Harshil D. Dhurv,1 Hyun-Jin Kang,2 Sen Peng,1 Vijay Gokhale,1 Laurence Hurley,2 Michael Berens1. 1Translational Genomics Research Institute, Phoenix, AZ; 2University of Arizona, Tucson, AZ.

Approximately 86% of GBM tumors exhibit mutation at -124 or -146 bases upstream of the ATG start site in the transcription activating promoter region of telomerase reverse transcriptase (hTERT). Mutation in the promoter region of hTERT impairs repression, leading to overexpression of hTERT; inappropiate hTERT is associated with oncogenesis, tumor maintenance, and resistance to apoptosis. We surveyed long-term glioma cell lines and glioma PDX models for mt-hTERT; mRNA and protein expression of hTERT were assessed by qPCR and western blot. The -124 and -146 mutations are located in the major 5'-12 G-quadruplex and result in misfolding of the silencer element and consequent over-expression of hTERT. Using a diverse small molecule library, we identified a small drug-like pharmacological chaperone (pharmacomere) molecule, TG-4260, which binds to the 26 mer base-pair heteroduplex loop, which is the nucleation site for cooperative folding of the major 5'-12 G-quadruplex. The chemical effect of TG-4260 corrects DNA hTERT G-quadruplex misfolding resulting from the somatic mutations and restores the silencer of the G-quadruplex thereby reducing hTERT activity. TG-4260 directly decreases the transcription activity of the WT and the −124, −124/125, −138/139, and −146 mutants to a similar extent and suppresses the downstream gene BCL2, which activates apoptosis. Furthermore, TG-4260 produces cell cycle growth inhibition. Finally, we tested the in vivo efficacy of TG-4260 significantly inhibits telomerase and shortens telomere length after five days of treatment and induces a senescence-like phenotype. This is the first example of the use of a pharmacomere molecule to correct the misfolding of a DNA G-quadruplex element resulting from mutations in an early folding intermediate. Finally, we screened GBM cell models against a novel small molecule inhibitor that interferes with mutated hTERT promoter and demonstrated that TG-4260 selectively suppresses glioma cell viability without affecting non-transformed normal human astrocytes.

#1170 Notch pathway is overexpressed and is a therapeutic target in clear cell renal cancer. Tushar D. Bhagat,1 Yivi Zou,2 Shizhen Huang,3 Jihoon Park,2 Matthew B. Palmer,2 Caroline Hu,2 Weijuan Li,2 Niraj Shenoy,2 Orsolya Giricz,1 Yiting Yu,2 Yi-An Ko,2 Maria Concepcion Izquierdo,3 Esther Park,2 Nishanth Valluvamsetta,1 Remi Laurence,2 Robert Lopez,2 Masako Suzuki,1 James Pullman,3 Justin Kaner,4 Benjamin Gartrell,4 A. Ari Hakimi,5 John Greally,4 Bharvin P. F6,1 Karin Benhadj V5,1 Anit Nepve,1 Katalin Susztak2.1Albert Einstein College of Medicine, Montefiore Medical Center, Bronx, NY; 2University of Pennsylvania, Perelman School of Medicine, Philadelphia, PA; 3Montefiore Medical Center, Bronx, NY; 4Sloan Kettering Cancer Center, New York, NY; 5Eli Lilly, Indianapolis, IN.

Clear cell renal cell carcinoma (CCRCC) is an incurable malignancy in advanced stages and needs new therapeutic targets. We conducted a transcriptionomic analysis of CCRCCs and matched microdissected renal tubular controls and observed an overexpression of NOTCH ligands (JAGGED1, JAGGED2) and Delta like (DLL3) family of ligands) and receptors (NOTCH1, NOTCH2, NOTCH3 and NOTCH4) in tumor tissues. Examination of the TCGA RNA-Seq dataset also revealed widespread activation of NOTCH pathway in a large cohort of CCRCC samples. Samples with NOTCH pathway activation were also clinically distinct and were associated with better overall survival. Parallel high resolution DNA methylation and copy number analysis with the HELP assay demonstrated that both genetic and epigenetic alterations led to NOTCH pathway activation in CCRCC. NOTCH ligands, JAGGED2 was overexpressed in and associated with gene amplification in distinct CCRCC samples. To test the causality, we transgenically expressed the intracellular domain of NOTCH1 in mice renal tubules with tubule specific deletion of VHL. The KspVHL1 VHL1ICNNotch1 mice exhibited dysplastic hyper proliferation of tubular epithelial cells confirming the proangiogenic role of NOTCH in vivo. Alteration of cell cycle pathways was seen in murine renal tubular cells with NOTCH overexpression and molecular similarity to human tumors was observed, demonstrating that human CCRCC recapitulates features and gene expression changes observed in mice with transgenic overexpression of the Notch intracellular domain. Finally, treatment with clinical, gamma secretase inhibitor, LY309478, led to inhibition of CCRCC cells in vitro and in vivo.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Novel Molecular Targets 1

Proceedings of the American Association for Cancer Research • Volume 58 • April 2017
in CRC xenografts. In summary, these data reveal the mechanistic basis of NOTCH pathway activation in CRCCC and demonstrate this pathway to a potential therapeutic target.

#1171 Therapeutic applications of the selective high affinity ligand SH7119 may extend beyond NHL to many other types of solid tumors. Monique Cosman Balhorn, Rod Balhorn. SHAL Technologies, Inc., Livernor, CA. SH7119, the first of a new class of cancer therapeutics developed for treating non-Hodgkin’s lymphoma, is unusual in that both targeting and prodrug functionalities have been incorporated into the same small molecule. Functioning similar to an antibody-drug conjugate, SH7119 targets a unique structural epitope within the antigen-binding pocket of HLA-DR10. HLA-DRs containing this epitope within the β-subunit are reported to be over-expressed in approximately 85% of B-cell lymphomas. Upon binding to HLA-DR molecules located on the tumor cell’s surface, SH7119 is transported into the cytoplasm where it is concentrated and subsequently metabolized. A series of metabolic products derived from the SHAL’s recognition elements (three small molecules that are linked together to create SH7119 and to provide targeting selectivity) are generated as the drug is broken down, each of which inhibits one or more activities required for tumor cell survival. Preclinical studies with SH7139 have demonstrated remarkable efficacy in treating B-cell lymphoma xenografts in mice, providing permanent cures for up to two-thirds of the animals at a human equivalent dose as low as 0.41 μg/kg. Biopsy tissue binding studies conducted with SH7129, a biotinylated form of SH7119, and streptavidin-horse radish peroxidase detection have shown the drug binds to a significant fraction of tumor cells from patients diagnosed with multiple myeloma and each of the B-cell lymphoma subtypes tested to date (DLBCL, Burkitt’s, Mantle Cell, Follicular, MALT, and CLL). SH7129 was also observed to bind to tumor biopsies obtained from a number of patients diagnosed with peripheral T-cell and nodular sclerosis Hodgkin’s lymphomas, a result consistent with observations reported by others that HLA-DRs are expressed in a subset of these lymphomas. HLA-DR expression has also been reported to occur in or be linked to a number of other types of cancer, including melanoma, cervical, ovarian, pancreatic and lung cancers. SH7129 staining of tumor microarrays have shown biopsy cores from a subset of patients diagnosed with each of these cancers also bind SH7119. While in vivo efficacy has only been tested in Burkitt’s (RAJI), Mantle cell (Granita-519), and T-cell (Jurkat, a cell line control lacking HLA-DR and showing no efficacy) lymphoma xenografts, these tissue binding results suggest that in addition to the majority of the NHL subtypes, nodular sclerosis Hodgkin’s lymphoma, multiple myelomas, as well as a subset of melanomas, ovarian, cervical, pancreatic, and lung cancers may also respond to SH7119 therapy. This research was supported by the National Cancer Institute Phase II SIRI Award R44CA159431.

#1172 In vivo pharmacokinetic properties and antitumor efficacy of porcine lead inhibitors in the orthotopic murine MMTV-Wnt1 breast tumor model and the human HPAF-II pancreatic xenograft mouse model. Vishal Pendharkar, 1 Yun Shan Chew, 2 Vithya Manoharan, 1 Choon Bing Low, 1 Hong-qian Esther Ong, 3 Soo Yei Ho, 1 Wei Ling Wang, 1 Jeyaraj Duraiswamy Athi-samy, 1 Babita Madan, 2 David Virshup, 2 Thomas Hugo Keller, 1 May Ann Lee, 1 Alex Matter, 1 Jeffrey Hill, 1 Kanda Sangthonpitag, 3 Experimental Therapeutic Centre, Singapore, Singapore; 4 Duke-NUS Medical School, Singapore, Singapore. Porcine PORCN (PORCN), a multi-pass integral membrane-bound O-Acetyl acyltransferase (MOBAT), resides in the end in the endoplasmic reticulum (ER) and is required for biogenesis of Wnt ligands. The secreted mature Wnt ligands bind to their cognate receptors (Fz/lig, LRPS/6 and transmembrane receptor ROR) to form the ligand - receptor complex which is capable to activate the Wnt-β-catenin signalling cascade and downstream signalling pathways such as mTOR, GSK3, Akt, and PKC. The deregulation of and aberrant activation of the various components of Wnt-β-catenin signalling pathway have been implicated in tu- morigenesis of breast cancer cells. PORCN is found to be associated with cancerous cell growth. Knockdown of Porcine mRNAs significantly reduced the proliferation of breast cancer cells and resulted in the delay of MDA-MB-231 tumor formation in mouse xenograft models (Covey et al 2012). Loss of function mutations of RN4F3, a negative regulation of Wnt-signalling via Fizzled receptor, is recently reported to be involved with pancreatic ductal adenocarcinoma. Inhibition of the PDAC cell lines bearing RN4F3 mutations enhanced Wnt-β-catenin signalling and resulted in suppression of proliferation and differentiation of PDAC tumor cells (Jiang et al 2013). Taken together porcine could be an attractive therapeutic approach for a particular Wnt-driven cancer population. We have identified the porcine lead compounds (ETC-159, ETC-535, ETC-611 and ETC-539) from different novel chemical scaffolds. The aim of this study was to evaluate their pharmacokinetic properties and antitumor efficacy in different cancer mouse models, the murine MMTV-Wnt1 breast cancer and the human pancreatic HPAF-II cancer. All porcine lead compounds had good oral pharmacokinetic properties and the absolute bioavailability greater than 42%. Maximal tolerated dose (MTD-7d) up to 200 mg/kg. They produced antitumor efficacy ranging from 24% to 79% at 1 mg/kg, 38% to 89% at 3 mg/kg, and 58% to 97% at 10 mg/kg in MMTV-Wnt1 tumor mouse model. In vivo inhibition of PORCN led to reduce the expression level of Axin2 in MMTV-Wnt tumors up to 8h. At 100 mg/kg, they produced antitumor efficacy ranging from 34% to 91% in breast xenograft II pancreatic xenograft mouse models. The compounds, ETC-159 demonstrated good oral pharmacokinetic properties and produced significantly antitumor efficacy (p value < 0.0001) in both cancer mouse models. ETC-1922159 was selected as the preclinical development candidate and currently is under investigation in Phase I clinical trial.

#1173 A novel selective Mcl-1 inhibitor exhibits in vitro and in vivo effi- cacy in melanoma. Karson J. Kump, Lei Miao, Ahmed S. Mady, Katherine Lev, William Giblin, Mary E. Skinner, David B. Lombard, Zaneta Nikolovska-Coleska. University of Michigan, Ann Arbor, MI. Metastatic melanoma is the deadliest form of skin cancer that still has limited treatment options and dismal 5-year survival rates as low as 15%. Only recently has there been significant progress in the treatment of metastatic mel- anaoma, advent by molecular targeted drugs and immunotherapy, but their lim- itations are enormous and resistance rapidly emerges. Dysregulation of apoptotic machinery in melanoma allows the cancer cells to evade cell death and contributes to treatment resistance. Up-regulation of Mcl-1, a member of the Bcl-2 family of anti-apoptotic proteins, has been correlated with melanoma progression and metastasis. Mcl-1 amplification is one of the most common genetic aberrations found in human cancers and has been labeled as a marker of aggressive oncogenesis and poor patient prognosis. Previous studies have pointed to Mcl-1 as a viable therapeutic target for the treatment of mel- anaoma and conclude that small molecule Mcl-1 inhibitors may appeal this unmet medical need. We have discovered and characterized a new class of selective small molecule Mcl-1 inhibitors using various biochemical, functional, and cell based assays; further development of these compounds allowed us to achieve potent low-nanomolar binding affinity for Mcl-1 and more than 300-fold selec- tivity over Bcl-2/Bcl-xL. Our most potent inhibitor, 483-LM, was screened across a panel of human melanoma cell lines using a cell proliferation assay and revealed varying levels of sensitivity. A BH3 profiling assay demonstrates that C8161, the cell line most sensitive to our inhibitor, solely relies on Mcl-1 for survival. The Mcl-1 dependence of C8161 might contribute to the known meta- static nature of this cell line. Mechanistic studies revealed that 483-LM effec- tively engaged the endogenous Mcl-1 protein after treatment of C8161, as deter- mined by a CEQA assay, and prompted disruption of protein-protein interactions between Mcl-1 and several pro-apoptotic proteins, including Bax, Bak and Bim. This was followed by induction of Bax/Bak dependent apoptosis and activation of hallmark of the intrinsic apoptotic pathway, including mito- chondrial membrane depolarization, caspase activation and PARP cleav- age. Importantly, treatment with 483-LM caused massive up-regulation of the pro-apoptotic BH3-only protein Noxa, an effect apparent after an 8 hour treat- ment, which contributes to the induction of cell death. The in vivo efficacy studies with 483-LM showed significant improvement on tumor growth and caspase-3 activation in tumor samples. Overall, our data indicate that Mcl-1 inhibitors are a promising treatment option for aggressive metastatic melanoma and warrant further preclinical investigation of 483-LM as a promising selective Mcl-1 inhab- itor to be used as a single agent and in combination with chemotherapy and immunotherapy.

#1174 CT179 degrades the olig2 transcription factor in glioblastoma stem-like cells and prolongs survival. Gordon R. Alton, 1 Graham Beaton, 1 Susan Knowles, 1 Gregory Stein, 1 Santosh Kesari, 2 Curtana Pharmaceuticals, Austin, TX; 3 Pacific Neuroscience Institute, Santa Monica, CA. Olig2 is a bHLH transcription factor that has been shown to be a key driver of glioblastoma (GBM) tumorigenesis. Olig2 is expressed in human tumor-derived glioma stem-like cells. A growing body of evidence suggests that glioma stem-like cells (GSCs) are more representative of their parent tumors when cultured under defined serum-free conditions with the mitogens epidermal growth factor (EGF) and fibroblast growth factor (FGF). Furthermore, recent research has indicated that human Proneural GSCs grown in vitro in PDGF are more tumorig- enic in vivo. We have designed and synthesized a potent inhibitor of Olig2 that possesses all the necessary properties for clinical development as an important...
new GBM therapeutic. CT179 dose dependently causes the degradation of Olig2 in multiple GBM cell lines and this correlates to G2/M arrest and increased apoptosis. CT179 also induces the loss of expression of EGFR and PDGFR in human GSCs. CT179 achieves high concentrations in the CNS with a long duration of pharmacologic action. Furthermore, CT179 significantly extends survival of intracranial orthotopic human tumor GSCs. Immunohistochemistry demonstrates a marked reduction of Olig2 positive cells in the tumor bearing animals. Together, these results indicate that CT179 has significant promise as a new therapeutic for the treatment of human GBM.

**#1175 Inhibition of NAMPT as a novel therapeutic strategy for infant leukemia.** Klaartje Somers,1 Shiloh Middelmiss,2 Asef Betkatsou,2 Mawar Karsa,1 Leanna Cheung,1 Angelika Koscielek,1 Kathryn Evans,1 Chelsea Mayoh,1 Ursula R. Kees,1 Lioubov Korotchkina,1 Olga B. Chernova,2 Richard B. Lock,1 Andrei V. Gudkov,4 Michelle Haber,1 Murray D. Norris,1 Michelle J. Henderson.1

1Children’s Cancer Institute, University of New South Wales, Randwick, Australia; 2Telethon Kids Institute, University of Western Australia, Perth, Australia; 3Tartis, Inc., Buffalo, NY; 4Roswell Park Cancer Institute, Buffalo, NY.

Novel targeted therapies are urgently needed for infant leukemia as this disease is highly aggressive and refractory to treatment resulting in poor survival rates. The NAD (Nicotinamide Adenine Dinucleotide) producing enzyme NAMPT (Nicotinamide Phosphoribosyltransferase) has been considered as an attractive selective target for anti-cancer therapy due to the high dependency of tumor cells on NAD for energy metabolism and activity of NAD-dependent enzymes such as poly-ADP-ribose polymersases (PARPs) and sirtuins that play key roles in cancer cell survival. A newly developed NAMPT inhibitor, OT-82, was initially isolated for its high selective toxicity against a panel of adult leukemia cells. Here we investigated NAMPT inhibition as a therapeutic strategy for infant leukemias characterized by rearrangement of the MLL gene (MLL-r), by testing the potency of OT-82 in a panel of predclinical in vitro and in vivo models of MLL-r leukemia that are based on the use of patient-derived xenograft (PDX) cells. OT-82, as a single agent, dramatically reduced the viability of all tested MLL-r leukemia cell lines (n=9) and MLL-r leukemia PDX (n=6) with IC50s ranging from 0.15 to 3.82nM. While the IC50 for OT-82 correlated significantly with the IC50 of other NAMPT inhibitors STF-118804 and FK866, OT-82 was the most potent compound. When combining OT-82 with chemotherapeutic agents currently used to treat infants with leukemia, we observed significant synergy between OT-82 and cytarabine indicating the potential of OT-82 for chemosensitization. Consistent with NAMPT inhibition, OT-82 reduced cytotoxic NAD+ levels in MLL-r leukemia cells and inhibited the activity of the NAD-requiring enzymes PARP-1 and SIRT-1, as exemplified by a decrease in PARylation PARP-1 levels and a p53-mediated increase in p21 levels, leading to apoptosis induction. Interestingly, despite the remarkable potency of OT-82 in killing MLL-r leukemia cells, a 25-fold difference in IC50 levels was noted across the cell line panel, with those lines harboring the MLL translocation most sensitive to the compound. Most pertinently the effects we observe are in a PDX cultured as 3D neurospheres that more closely resemble the true tumor architecture, heterogeneity, and “stem-like” phenotype characteristic of tumor growth. We have leveraged RNAseq expression data from Cancer Cell Line Encyclopedia (CCLE) and Pevonedistat response data from The Cancer Therapeutics Response Portal (CTRP) to apply a network-based analysis to identify potential and novel responders to OT-82.

**#1176 Preclinical characterization of the pharmacokinetic-pharmacodynamic (PK/PD) efficacy relationship of novel allosteric SHP2 inhibitors.** Minying Pu,1 Laura R. La Bonte,2 Stan Speen,3 Kathy Hsiao,2 Minying Pu,1 Lauren K. Hartman,1 Darren Finlay,2 Peiwen Pan,2 Seunghan Kim,1 Gil Speyer,1 Katerina Andrianova,1 Alexander Polin,1 Mikhail Chernov,2 Denis Kazyulkin,1 Katerina Andrianova,1 Alexander Polin,1 Michael Berens.1

1Translational Genomics, Phoenix, AZ; 2Sanford Burnham Prebys Medical Discovery Institute, La Jolla, CA.

Effective anticancer drugs can be directed against cell lineage-specific, rather than tumor-specific, targets (i.e., androgen receptor, CD20, etc.). We sought to conduct systematic searches for novel agents that are selectively cytotoxic to hematopoietic (HP) malignancies presumably targeting HP lineage-specific survival factors. Cell-based screening and subsequent validation of small-molecules in a broad panel of...
HP and non-HP cancer cell lines followed by a hit-to-lead optimization of the selected class of compounds has led to a molecule named OT-82 characterized by highly selective cytotoxicity against all HP-derived cancers tested (14 cell lines, representing human AML, ALL, CML and lymphoma cells) active within single nanomolar range of concentrations. OT-82 killed sensitive cells by induction of apoptosis and was 10-20 fold more toxic to HP-derived than to solid tumor-derived cell lines and normal primary cells of HP and non-HP origin. OT-82-based affinity chromatography of cell lysates followed by mass spectrometry led to the identification of nicotinamide phosphoryltransferase (NAMPT) as the OT-82 target. NAMPT catalyzes the rate limiting step in a major pathway of synthesis of NAD, an energy metabolism mediator and essential cofactor of PARP and sirtuins. NAMPT treatment caused dramatic reductions in cellular NAD levels. Nicotinamide (vitamin B3), a substrate for the alternative NAD synthesis pathway, protected cells from the cytotoxic effects of OT-82. Oral administration of OT-82 was efficacious in subcutaneous and systemic xenograft models of human AML, ALL, erythroleukemia and multiple myeloma including complete response in several models. Therapeutic doses of OT-82 in mice were significantly lower than maximal tolerated dose (MTD); toxicities observed at doses above MTD were largely limited to HP and lymphoid organs. Toxicity profile of OT-82 determined in GLP in mice and non-human primates was favorably different from that reported for other reported clinical stage NAMPT inhibitors and did not involve any detectable renal or cardiac toxicity. These results indicate high lineage specific and malignant transformation-specific dependence of HP neoplastic cells on NAMPT, presumably due to the strong addition of this cell type on the NAD levels, and highlights OT-82 as a prospective clinical candidate for the treatment of hematological malignancies.

**#179** EP4 receptor antagonism in paclitaxel-resistant ovarian clear cell carcinomas that overexpress class III β-tubulin. Dana M. Roque,1 Danielle Meir-Levi,1 Gautam G. Rao,1 Paul Staats,2 Amy Fulton,1 Jocelyn Reader2. 1Division of Gynecologic Oncology, University of Maryland School of Medicine, Greenbaum Cancer Center, Baltimore, MD; 2Department of Pathology, University of Maryland School of Medicine, Baltimore, MD

OBJECTIVES: Advanced ovarian clear cell carcinoma (OCCC) is associated with a survival disadvantage relative to ovarian serous carcinoma following platinum/taxane-based chemotherapy and optimal cytoreduction. Prostaglandin E2 (PGE2) contributes to disease progression through modulation of several components of the COX pathway.2 Class III β-tubulin is a marker for paclitaxel resistance and is widely overexpressed in OCCC. The purpose of this study is to demonstrate that EP4 inhibition may overcome paclitaxel resistance in OCCC that overexpress class III β-tubulin. METHODS: Expression of EP4 receptor and class III β-tubulin was quantified using immunohistochemistry and Western blot in solid tissues and cell lines. Standard metabolic growth and migration assays were employed to test the effects of drug treatment (paclitaxel EP4 inhibitor) on proliferation and migration. EP4 expression and EP4 silencing using siRNA. RESULTS: OCCC overexpress class III β-tubulin/EP4 relative to normal ovary [Fig. 1a/c]. EP4 staining intensity was 2+ in 100% OCCC using an ovarian cancer tissue microarray (62 cores, 13% OCCC); this rate was only 26-56% among other histologies. EP4 inhibition reduces growth of paclitaxel-resistant cell lines [Fig. 1d]. Likewise, treatment with EP inhibitors [Fig. 1e-top] and silencing of EP4 resulted in reduced migration [Fig. 1e-bottom]. CONCLUSIONS: Selective antagonism of PGE2 through EP4 receptor inhibition may represent a powerful targeted therapy for paclitaxel-resistant OCCC. Further study including simultaneous treatment (EP4 inhibitor + paclitaxel) and larger samples sizes is required. REFERENCES: 1 Rayners et al. **#180** Targeting the HSP40/HSP70 chaperone axis as a novel strategy to treat castration-resistant prostate cancer. Michael A. Moses,1 Yeong Sang Kim,2 Genesis Rivera-Marquez,2 Matthew J. Watson,1 Sunmin Lee,1 Andrea Kravats,1 Sue Wickner,1 Jason Gestwicki,1 Jane Trepel,1 Len Necker1,1 National Cancer Institute, Bethesda, MD; 2University of California, San Francisco, San Francisco, CA.

Castration-resistant prostate cancer (CRPC) is frequently characterized by elevated expression of nuclear receptors able to at least partially maintain the androgen receptor (AR) transcriptional program. Elevated expression of a number of constitutively active AR splice variants lacking the ligand binding domain (LBD) (e.g., ARv7, which is ligand-independent and correlates with poor prognosis, reduced survival and resistance to existing LBD-targeted standard of care therapy) is a frequent occurrence in CRPC. Thus, alternative approaches to disrupt AR signaling in CRPC are of great clinical importance, and a single strategy able to target AR and ARv7 remains a critical unmet need. As a steroid hormone nuclear receptor, the AR exists in an interactive and dynamic cycle with the molecular chaperones (heat shock proteins, HSPs) HSP40/HSP70/HSP90 for proper folding and remodeling of the AR LBD to bind ligand. Notably, HSP40 inhibitors promote AR degradation and display efficacy in prostate cancer xenograft models. Although it has been shown that ARv7 functions independently of HSP90, additional chaperone requirements of LBD-deficient ARv7 are not known. Thus, we tested the hypothesis that both AR and ARv7 are dependent on HSP40/HSP70 and that targeting these chaperones with specific inhibitors (C86 and JG98, respectively) will lead to AR/ARv7 destabilization and loss of transcriptional activity in models of CRPC. To determine if AR proteins associate with HSP40/HSP70, 22Rv1 CRPC cells (expressing endogenous AR and ARv7) were first transfected with FLAG-HSP40 or FLAG-HSP70. Immunoprecipitation with FLAG beads revealed AR and ARv7 associated with both chaperones, indicating potential functional dependence of these nuclear receptors on HSP40/ HSP70. To further characterize these interactions, 22Rv1 lysate was probed with antibodies against an LBD and an NBD antibody. C86 bound a significant fraction of HSP40 complexed with HSP70, AR, and ARv7. Excess unlabeled C86 or JG98 effectively competed away binding of HSP40/HSP70 to biotinylated-C86 with concomitant loss of associated AR and ARv7. Treatment of 22Rv1 cells with C86 or JG98 led to a time and dose-dependent decrease in AR and ARv7 protein, concomitant with a significant loss of viability. We also observed that HSP40/70 inhibition markedly reduced AR and ARv7 transcriptional activity, as indicated by decreased AR (KLK3, TMPRSS2) and ARv7 (UBE2C) target gene expression. Finally, treatment of mice bearing 22Rv1 xenografts with JG231 (an analog of IG98 with enhanced PK properties) led to significantly smaller tumors relative to vehicle treated mice. Together, these data confirm the continued dependence of AR and ARv7 on HSP40/HSP70 molecular chaperones and they demonstrate the feasibility of targeting the HSP40/HSP70 axis to abrogate sustained AR-mediated signaling in CRPC.

**#1181** Discovery and development of novel highly potent and selective inhibitors of USP19 using UbiPlex™. Gerald Gavory, Colin O’Dowd, Ewelina Rozycka, Anthony Dossang, Ashling Henderson, Caroline Hughes, Hugues Miel, Oliver Barker, Joana Costa, Peter Hewitt, Mary McFarlan, Lauren Procotor, Tim Harrison. Almac Discovery, Belfast, United Kingdom.

Over the past decade, protein ubiquitination has emerged as an important post-translational modification with regulatory functions in all important cellular processes. Deubiquitinating enzymes (DUBs) including ubiquitin specific proteases (USPs) are cysteine proteases that catalyze the de-ubiquitination of protein substrates including tumor suppressors and oncogenes, hence regulating their levels and/or function. As a result of their increasing implications in the etiology of numerous pathological conditions including cancer, DUBs are emerging as an attractive and promising target class for the development of 14 class medicines with high therapeutic impact. However, despite 15 years of intense research DUBs have proved largely refractory to drug discovery efforts. Herein, we further describe the application of Ubi-Plex™, our drug discovery platform for the identification and optimisation of DUB inhibitors. In particular, we will highlight the versatility and robustness of Ubi-Plex™ by describing the outcome of our focussed library screening, hit identification, hit validation and elaboration activities on USP19. A series of novel, highly potent (e.g. IC₅₀ < 10 nM) and reversible USP19 inhibitors have been identified. Further, profiling has also demonstrated excellent selectivity against a large panel of DUBs and other non-related enzymes (e.g. kinases, proteases). These inhibitors are cell-permeable and exhibit potent target engagement in cells with EC₅₀ values < 30 nM. Finally, we will describe our progress towards the development of lead molecules with drug-like properties with the aim to rapidly establish in vivo proof-of-concept studies. In summary, this work further develops the tractability of the DUB target family and reports the discovery and detailed profiling of the first highly potent and selective inhibitors of USP19. These molecules may provide opportunities for the development of new anticancer therapeutics as well as for the treatment of muscle wasting disorders including cachexia.

**#1182** A novel curcumin derivative inhibits active ras and its downstream pathway in pancreatic cancer. Naveen Mallangada,1 Gerardo G. Mackenzie2. 1Stony Brook University, Stony Brook, NY; 2University of California, Davis, CA.
Pancreatic Cancer’s (PCa’s) 5-year survival rate of only 6.7% indicate the need to improve treatment modalities. Despite decades of research, current chemotherapy and radiation therapy regimens offer minimal or no help. It is critical to develop new agents for the effective management of PC. Given that Kras mutations initiate and maintain PC, inhibition of this pathway is widely considered a therapeutic target for improving the overall survival of PCa patients. Using molecularly targeted inhibitors (MTIs) for treating PCa patients contributes to improving the chemotherapeutic efficacy of a novel Chemically-Modified Curcumin (CMC2.24) as a potential chemotherapeutic agent for PC. Preliminary studies have shown that CMC2.24 has higher bioavailability than curcumin, as shown in pharmacokinetic studies in rats, and inhibits PC growth in vitro and in vivo. However, the exact mechanism on how CMC2.24 reduces cell growth remains unidentifiable. In this study, we aimed to identify the activity of CMC2.24 for demonstrating the chemotherapeutic efficacy of a novel CMC2.24 in PCa. Using human PC MIA PaCa-2 and Panc-1 cell lines and pancreatic acinar explants from KRas mutant mice, we explored the effects of CMC2.24 on Ras activation, ERK phosphorylation, mitochondrial reactive oxygen species, mitochondrial ATP production, and intrinsic apoptosis. In human PC MIA PaCa-2 cells CMC2.24 inhibited Ras activation by 90% (p<0.05). This was confirmed in primary acinar explants isolated from KRas mutant mice in which CMC treatment reduced Ras activation by 70%, compared to control. Furthermore, CMC2.24 treatment reduced the phosphorylation MEK, ERK and c-Raf, down-stream pathway of Ras, both in vitro and in vivo. The effect of CMC2.24 on ERK phosphorylation was confirmed by Immunofluorescence, showing a significant decrease in ERK phosphorylation (47.8%; p<0.05). Moreover, CMC2.24 treatment enhanced the phosphorylation of Akt and p-Akt by 200% (p<0.02), decreased ATP levels in a concentration-dependent manner (p<0.05), and induced intrinsic apoptosis, as shown by the increase in caspase 9 and Parp cleavage downstream of cytochrome C cytosolic release. In conclusion, our results indicate that the Ras pathway is a key molecular target for CMC2.24 and that CMC induces apoptosis in PC cells through the intrinsic pathway. This research was supported by the Stony Brook Cancer Center and a URECA Summer Grant.

#1183 Structure-activity studies and biological evaluations of ERG-USU, a highly selective inhibitor for ERG-positive prostate cancer cells. Ahmed A. Mohamed,1 Charles P. Xavier,2 Gauthaman Sukumar,2 Samuel D. Banister,1 Vineet Kumar,2 Shy-Han Tan,1 Shilpa Katta,1 Lakshmi Ravindranath,1 Muhammad Jamal,1 Radhika Sreenath,1,2 David G. McLeod,3 Georgy Petrovics,4 Albert Dobt,1 Meera Srivastava,1 Sanjay Malhotra,1 Clifton Dalgard,5 Shiv Srivastava1,1 Uniformed Services Univ. of the Health Sci., Rockville, MD; 2Uniformed Services Univ. of the Health Sci., Bethesda, MD; 3Stanford University, Stanford, CA.

Introduction and objectives: While new prostate cancer (CaP) treatments (Abraxalone and Enzalutamide) have improved survival in castration-resistant prostate cancer (CRPC), their benefits are short-lived and drug resistance develops. Known CaP genetic events can drive resistance to specific targets. Therefore, it is important to develop new agents with improved specificity to target the resistance to existing therapies. We previously identified a small molecule inhibitor, ERG-USU, which selectively inhibits ERG protein and cell growth in ERG positive tumor cell lines and mouse xenograft models. In an effort to further develop ERG-USU with enhanced efficacy we performed detailed structure-activity relationship (SAR) evaluation of ERG-USU core structure and developed new derivatives. Methods: Based on SAR of the core structure of ERG-USU, 48 new derivatives were designed and synthesized by substitutions with alkyl, alkoxy, cycloalkyl, heterocycloalkyl, aryl, heteroaryl or hydroxyl groups. The new ERG-USU derivatives were evaluated for inhibition of cell growth and ERG protein levels in the TMPRSS2-ERG fusion harboring CaP cell line, VCaP. Four of these compounds have been selected for evaluation of ERG selectivity by defining IC50 in ERG positive/indexed. The objective of this work was to discover the mechanism of action in multiple cellular events and to demonstrate the ERG-USU derivatives inhibition of cell growth and ERG protein levels in VCaP, KG1, MOLT-4 and COLO205 cell lines, with no or minimal effects on LNCaP and HUVEC cells. One of the new derivatives (ERG-USU96) showed increased cell growth inhibition and induction of cell death in comparison to the parental ERGUSU (IC50 = 0.200 μM). Other three new compounds showed similar IC50 as the ERG-USU. Conclusion: Comprehensive evaluation of ERG-USU derivatives along with parental compound has continued to underscore selective inhibition of ERG positive tumor cells by these small molecules.

#1184 Characterization of novel STAT5 inhibitors to interfere with the oncogenic activities of STAT5 in hematopoietic diseases. Bettina Wingelhofer,1 Barbara Maurer,1 Elizabeth C. Heyes,1 Patricia Freund,1 Abbarna A. Cumarsawamy,2 Jisung Park,2 Stefan Kubicek,3 Peter Valent,1 Patrick T. Gunning,2 Richard Morgridge1,2,3.1 Ludwig Boltzmann Institute for Cancer Research, Vienna, Austria; 2Medical University of Vienna, Vienna, Austria; 3University Medical Center Hamburg-Eppendorf, Hamburg, Germany.

Activation of the transcription factor STAT5 is essential for the pathogenesis of acute myeloid leukemia (AML) containing the FLT3 internal tandem duplication (ITD). FLT3 ITD is a constitutively active tyrosine kinase (TK) that drives the activation of STAT5 and proliferation of AML cells. Although there has been some success in identifying TK inhibitors that block the function of FLT3 ITD, treatment options are still limited. This is mainly due to drug resistance development by mutations that allow for the continued activation of STAT5. Since STAT5 represents a critical mediator of malignant cellular behavior and sits at the convergence point of many kinase pathways, the direct targeting of STAT5 may be an effective means of overcoming this resistance to TK inhibitors. First, we screened a library of potential STAT5 inhibitors for specific SH2 domain binders using a fluorescent polarization assay. Thereby, we identified small inhibitory molecules, called AC-3-019 and AC-4-130, that bind to the SH2 domain of STAT5, subsequently resulting in the disruption of the reciprocal STAT5-phosphoprotein interactions. They efficiently blocked kinase activity towards the growth and survival of AML cells. Moreover, AC-3-019 and AC-4-130 significantly suppressed tumor growth in vivo without general toxicity in healthy organs. Overall, our findings indicate that AC-3-019 and AC-4-130 are potent and selective inhibitors of STAT5. These compounds provide lead structures for further chemical modifications and clinical development for the identification of compounds to improve existing therapies.
and in vivo orthotopic xenografts at well tolerated doses. RNA-seq of isogenic K562 cells treated with H3B-8800 revealed dose-dependent inhibition of splicing. Although global inhibition of RNA splicing was not observed; H3B-8800 treatment led to preferential intron retention of transcripts with shorter and more GC-rich regions compared to those unaffected by drug. Interestingly, H3B-8800 retained introns commonly disrupted the expression of splicingosomal genes, suggesting that the preferential effect of H3B-8800 on splicingomous mutant cells is due to the dependency of these cells on expression of WT spliceosomal genes. These data identify a novel therapeutic approach with selective lethality in leukemias and lung cancers bearing a splicingome mutation. Despite the essential nature of splicing, cancer cells without a splicingome mutation were less sensitive to H3B-8800 compared with potent eradication of mutant counterparts. H3B-8800 is currently undergoing clinical evaluation in patients with MDS, AML, and CMML.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Reversal of Drug Resistance

#1186 Propranolol could overcome BRAF inhibitors resistance by multiple mechanisms in melanoma. Chengfang Zhou,1 DongYa Shen,1 WeiLi Wang,3 Shengchen Xie,3 Ping Liao,3 Xiang Chen,1 Howard L McLeod,3 Yijing Wang,3 MahaAl-Keilani, Ruba Darweesh. National Cancer Institute, Baltimore, MD. BRAF(V600E) is the most common oncogenic mutation in melanoma and leads to constitutive activation of the MAPK pathway, which results in uncontrolled cell growth. Selective BRAF inhibitors such as vemurafenib have been observed to neutralize oncogenic the signaling, inhibit cellular growth, and improve patient outcome. Although these mechanisms of vemurafenib resistance have been reported, few studies focused on how to overcome the resistance. Propranolol, a non-selective β-blocker, was confirmed to involve in multiple anticancer effects. Our previous study also showed propranolol inhibited melanoma by suppressing MAPK and AKT pathways in vitro and in vivo. But its efficacity and mechanism of overcoming vemurafenib still remain unknown in melanoma. Here, we explored the effect of propranolol on the A375, P-8 (patient-derived melanoma cell line) vemurafenib resistance cell line and resistance mice xenografts. Cell viability assay demonstrated that 2μM-20μM vemurafenib couldn’t decrease the proliferation but 24h-120h of incubation of 2μM-200μM propranolol inhibited viability with a concentration and time dependent manner in the two resistance cell line. TUNEL staining showed 24h incubation of 20μM propranolol alone and plus 4μM vemurafenib obviously increased cell apoptosis. Mice received daily i.g. administration of propranolol at the dose of 2 mg/kg alone or plus 10 mg/kg for 21days. The mean tumor volume at day 21 in resistance A375 xenografts was 221.13 ± 76.5mm3; 904.12 ± 70.57mm3 vs. 2021 ± 316.24mm3for the propranolol plus vemurafenib, propranolol alone, vemurafenib alone, respectively. Propranolol improved mice survival, 28.6% animal dead in plus group, 57.1% mice dead in the propranolol group, and 71.5% animal dead in vemurafenib at end of treatment. IHC showed propranolol also reduced Ki67 index both in propranolol and plus group when compared with vemurafenib treated mice. Furthermore, RNA sequencing was performed to explore the mechanism of propranolol overcoming the resistance, the data showed propranolol largely reduced mRNA levels of IGF family (IGFBP3, IGF-FLR1, IGFBP6, IGF2, IGFIR) etc. but elevated the expressions of innate immune related genes (NKG7, TLR9, NCR3 etc.) in A375-vemr cell line. These results provide a strategy of therapeutic resistance for the clininc, importantly, this study also provide a clue targeting IGF family and regulating innate immune might be a potential strategy to suppress resistance in BRAF inhibitor therapies in melanoma.

#1187 Synthetic lethality screening reveals ATR as responsible for oxaliplatin resistance in colorectal cancer cells. Eve Combès,1 Augusto Faria-Anadade,1 Diego Tosi,1 Pierre Martineau,1 Maguy Del Rio,1 Roderick Beijersbergen,2 Nadia Yue,1 Céline Gongora1,3 IRCM, INSERM U1194, Montpellier, France; 2The Netherlands Cancer Institute, Amsterdam, Netherlands. Despite the recent advances achieved in the treatment of colon cancer, tumor resistance is a frequent cause of chemotherapy failure. Our work was aimed to determine the molecular mechanisms involved in the resistance to oxaliplatin, an anticancer agent widely used in colorectal cancer treatment. To this end, we establish an oxaliplatin-resistant cellular model from the colon adenocarcinoma cell line HCT-116. Among cellular clones obtained, we used one displaying mild resistance (10 fold called HCT116-R1) to perform short hairpin RNA-based loss of function genetic screen in order to identify genes that can modulate the cellular sensitivity to oxaliplatin. We screened over 200 genes to determine the molecular mechanisms involved in the resistance to oxaliplatin, but its anticancer effects. Our previous study also showed propranolol inhibited melanoma by suppressing MAPK and AKT pathways in vitro and in vivo. The synergistic effect was evaluated using dose matrix data (an algorithm that was implemented in our group); (ii) the synergistic effect of oxaliplatin and VE-822 was accompanied by an increase of ssDNA, DNA double-strand breaks, growth arrest and apoptosis induction. In conclusion, our preliminary data confirm the results of our screen by demonstrating for the first time the functional role of ATR in the sensitivity to oxaliplatin.

#1188 Sodium phenylbutyrate has an antineoplastic effect and enhances the cytotoxicity of 5-fluorouracil and irinotecan in colorectal cancer cell lines. Maha Al-Keilani, Ruba Darweesh. Jordan University of Science and Technology, Irbid, Jordan. Colorectal cancer is the third most common cancer in the world and it is the second leading cause of cancer-related deaths in the United States. About 25% of colorectal cancer cases present with metastases at time of diagnosis and 50% of patients who undergo surgery will ultimately develop metastatic disease. Consequently, adjuvant chemotherapy is required in many cases and it aims to prevent tumor progression and metastasis. Resistance to chemotherapy is the biggest obstacle in the treatment path of advanced colorectal cancer. Thus, highlighting the urgent need for the identification of new therapeutic agents that can enhance the cytotoxicity of the currently approved anticancer drugs. Sodium phenylbutyrate (NaPB), a salt of a short chain fatty acid that is used for treatment of urea cycle disorders, is under investigation for its antineoplastic potential. NaPB acts as a histone deacetylase inhibitor and it has been shown to be associated with reduced ER stress and enhanced JNK signaling pathway. This indicates that NaPB may enhance the cytotoxicity of the currently approved agents for colorectal cancer including oxaliplatin, 5-fluorouracil, and irinotecan. The aims of this study were to identify the antineoplastic potential of NaPB in colorectal cell lines, and to identify its effect on the cytotoxicity of oxaliplatin, 5-fluorouracil, and irinotecan. MTT proliferation assay showed that NaPB possessed a concentration dependent killing effect against HCT-116 and HT-29 colorectal cancer cell line (IC50 values were 5 and 10 mM respectively). Moreover, at clinically achievable and nontoxic concentration (2.5 mM), NaPB showed a synergistic effect in HCT-116 on 5-fluorouracil (R = 14.176, p = 0.006), on irinotecan (R = 53.86, p = 0.0117), and on oxaliplatin (R = 20, p = 0.004), but resulted in extensive cytotoxicity when used at 5 mM and 10 mM. In HT-29 cells, NaPB at concentrations 5 mM and 10 mM, showed a synergistic effect on 5-fluorouracil (R = 5.5, p < 0.001; and R = 125, p < 0.001 respectively), on irinotecan (R = 5.7, p = 0.016; and R = 21.3, p = 0.018 respectively), and on oxaliplatin (R = 2.4, p = 0.003; and R = 3, p = 0.002 respectively). The addition of NaPB at concentration of 20 mM to the previous drugs resulted in profound cytotoxic effect toward HT-29 cells. As a conclusion, NaPB is a promising new adjuvant antineoplastic agent that can be used to enhance the cytotoxicity of 5-fluorouracil, irinotecan, and oxaliplatin in colorectal cancer.

#1189 Enhanced YAP expression leads to EGFR TKI resistance in lung adenocarcinomas. Ting-Fang Lee, Yu-Chi Tseng, Cheng-Wen Wu. National Yang-Ming University, Taipei, Taiwan. Epidermal growth factor receptor (EGFR) mutation is prevalently expressed in lung adenocarcinoma cases and acts as one of the major driving oncogenes. EGFR tyrosine kinase inhibitors (TKIs) have been used in patients with EGFR-mutant as an effective targeted therapy in lung adenocarcinoma, but drug resistance and tumor recurrence inevitably occurs. Recently, Yes-associate protein (YAP) has been reported to promote multiple cancer cell properties, such as promoting cell proliferation, EMT and drug resistance. This study investigated the roles of YAP in TKI-resistant lung adenocarcinoma. In TKI-sensitive cells, enhanced YAP expression leads to TKI resistant. Also, upregulated YAP expres-
sion and activation were detected in long term TKI-induced resistant cells. With reduced YAP expression using shRNA or YAP inhibitors, TKI-resistant cells become TKI-sensitive. Moreover, combined EGFR TKI and an YAP inhibitor statin, prolonged survival among lung cancer patients analyzed by Taiwan National Health Insurance Research database. These observations revealed the importance of YAP in promoting TKI-resistance and confirmed YAP inhibition can be a potential therapy delaying the occurrence of TKI-resistance in lung adenocarcinoma.

**#1190 Comprehensive high-throughput screen for combination therapies to block acquired resistance to targeted drugs.** Zejak Haviv. Bar Ilan Univ., Zfat, Israel.

Background - Genetic and epigenetic alterations provide the selective advantage for cancer cell acquired drug resistant (ADR). A bottleneck in implement drug combination is the challenging task of identifying combinations with acceptable risk benefit ratio. High throughput functional genomic (RNAi) screen is an ideal tool to comprehensively identify double and triple inhibitor combinations to prevent ADR. Unfortunately, most anticancer agents are antagonists (antagonists operate in the same direction as the RNAi), therefore RNAi hits with possible clinical value are the ones that disappear during the screen. Materials and Methods - We use lentiviral-borne shRNA libraries (mainly kinase collection) to transduce different RNAi into the different RNAi independent derived cancer cells. The resulting mixed cancer cell population (each lost one gene) is subject to negative screen, to identify mediators of ADR. This process was performed with approved cancer drugs, such as erlotinib, olaparib, pazopanib, etc. We developed a proprietary unique way to identify the RNAi clones that disappear/extinct, specifically in the presence of the investigated drug. RNAi clones are tracked using next generation sequencing, and quantified in treated and untreated cancer cell cultures or xenografts. The resulting drug combinations identified through this screen are tested directly on a platform of patient-derived xenografts. Results - We identified known boosters of the EGFR activity, such as Dyrk1 (maintains level of EGFR protein), IkBKE (downstream survival mediator), which we found regulated by the RNAi, as well as the response to the drug. Subsequently, known inhibitors of Jak1, CdK4/6, and PJK3 combined to egfr inhibitors generated more durable remissions in egfr positive cells. Remarkably, even tumors without egfr mutations were sensitive to the combinations. A similar discovery of novel combinations were found for olaparib and pazopanib. Mouse harboring patient derived xenografts tolerated regorafenib and pazopanib. Mouse harboring patient derived xenografts maintained in the N87-TDMR cells. A comprehensive expression analysis revealed that regorafenib inhibited the ATP-driven efflux function of BCRP. Our in vivo studies indicated that regorafenib could be useful in combating multidrug resistance in cancer treatment.

**#1193 DS-8201a, a novel HER2-targeting ADC with a novel DNA topoisomerase I inhibitor, abrogates the resistance to T-DM1 in HER2-positive gastric cancer: a preclinical study.** Yoshikane Nonagase,1 Naoki Takegawa,1 Kimio Yonesaka,2 Kazuko Sakai,1 Yusuke Ogitani,3 Junji Tsurutani,1 Kazuto Nishio,1 Kazuhiro Nakagawa,1 Kindai University Faculty Of Medicine, Osaka, Japan; 2Datichi-Sankyo Co., Ltd., Tokyo, Japan.

Background: Anti-HER2 therapies are beneficial for patients with HER2-positive breast and gastric cancer. T-DM1 is an HER2-targeting antibody-drug conjugate (ADC), which is structurally composed of the anti-HER2 antibody trastuzumab and the tubulin inhibitor DM1. T-DM1 has shown efficacy in patients with advanced breast cancer, but all patients eventually develop resistance to T-DM1. DS-8201a is a novel ADC composed of an anti-HER2 antibody and a novel potent topoisomerase I inhibitor DX-8951 derivative. DS-8201a achieved a high drug-to-antibody-ratio (DAR: 7-8) and homogeneous drug conjugation. The aim of this study was to elucidate the mechanisms of T-DM1 resistance, and evaluate the efficacy of DS-8201a in a T-DM1-resistant HER2-positive gastric cancer cell line. Materials and methods: The T-DM1-resistant NCI-N87 cell line (N87-TDMR) was established by a step-wise method—the parent HER2-positive N87 cell line was exposed to up to 4 μg/ml of T-DM1. The profile of N87-TDMR was assessed by immunoblotting, DNA microarray, and quantitative reverse transcription-PCR (qRT-PCR). The sensitivity of parent N87 and N87-TDMR cells to T-DM1 or DS-8201a was assessed by an in vitro growth inhibition assay as well as through the mouse xenograft model study. Results: N87-TDMR cells were found to be resistant to T-DM1 in the in vitro growth inhibition assay (50% growth inhibition concentration: >10 μg/ml in N87-TDMR, 0.055 μg/ml in N87) as well as in the in vivo xenograft model study, but HER2 expression was maintained in the N87-TDMR cells. A comprehensive expression analysis revealed that N87-TDMR cells over-expressed ABCG2 and were sensitive to the suppression of ABCG2 expression by ABCG2 shRNA.

**#1194 Neutralization of IGF-I and -II ligands with the fully humanized antibody-Analect A3, a novel mechanism-based inhibitor of breast cancer resistance protein (BCRP).** Guan-Nan Zhang,1 Yi-Jun Wang,1 Yun-Kai Zhang,1 Meng-Ning Wei,7 Zhi Shi,2 Zhe-Sheng Chen1. St. John’s University, Jamaica, NY; 2Jinan University, Guangzhou, China.

Overexpression of breast cancer resistance protein (BCRP) has been shown to play a role in promoting MDR in various kinds of cancers, such as breast, colon, lung and ovarian cancers. Regorafenib, an oral multi-kinase inhibitor, was found to have inhibitory effects on BCRP-mediated MDR both in vitro and in vivo. Regorafenib significantly sensitized BCRP-overexpressing cancerous cells to BCRP substrates by increasing their intracellular accumulation. There are no significant changes in the expression level or the subcellular distribution of BCRP in the cells exposed to regorafenib. Our mechanism studies revealed that regorafenib inhibited the ATP-driven efflux function of BCRP. Our inducted-fort docking and molecular dynamics simulations suggested the existence of strong and stable interactions between regorafenib and BCRP protein. Animal study revealed that the combination of regorafenib and topotecan resulted in great inhibitory effects on the growth of S1-M1-80 xenograft tumors. Regorafenib significantly increased the intratumoral concentration of topotecan but had no significant effects on topotecan plasma concentration. In conclusion, our study indicated that regorafenib could be useful in combating multidrug resistance in cancer treatments.
overall survival. Additionally, expression of AR-V7 in circulating tumor cells or increased expression in metastatic tissue is a biomarker for resistance to currently available anti-androgen therapies, including enzalutamide (ENZA) and abiraterone, resulting in castration-resistant prostate cancer (CRPC). Insulin-like growth factor (IGF) signaling pathways have been incriminated as mechani-
sms of drug resistance. Among the many targets is IGF-1 receptor (IGF1R), which promotes tumor growth in relation to AR variants. In this preclinical study we examined the effects of IGF-1 and -II inhibition in LuCaP 96CR, an ENZA resistant prostate cancer patient-derived xenograft. Hypothesis: IGF-1 and -II neutralization will block AR-V7 activity and inhibit castration-resistant prostate cancer growth. Study procedures: LuCaP 96CR was implanted s.c. into castrate SCID mice (15 mice per treatment group). Tumor volume at day 21 was measured (5 tumors per treated group). In this study, tumors were grouped into two: 1) Control; 2) ENZA (50 mg/kg, QD, po). When tumors exceeded 150 mm³ animals were randomized into groups: 1) Control; 2) ENZA (50 mg/kg, QD, po), 3) xentuzumab (BI 836845, 200 mg/kg QW IP) in combination with ENZA. At the end of the study, tumors were collected for preparation of RNA and protein lysates and histology. Results: ENZA did not show significant inhibitory effects on LuCaP 96CR, but the combination of xentuzumab and ENZA resulted in significant tumor inhibition (p<0.001) vs. ENZA alone. AR full-length (AR-FL) mRNA and protein increased after ENZA treatment (p<0.001) but did not further rise significantly when xentuzumab was co-administered. In contrast, significantly elevated AR-V7 mRNA and protein levels were detected in tumors from mice treated with the xentuzumab and ENZA combination (p<0.001). Downstream markers of AR-V7 activity, UBE2C and UGT2B17 mRNA, increased after ENZA compared to INM. A significant increase of UGT2B17 was detected after combination treatment and UBE2C significantly decreased (p<0.001). Summary: These data show that addition of xentuzumab provides tumor inhibition of ENZA-resistant CRPC. Interestingly, associated with a significant decrease in tumor growth, this treatment resulted in increased AR-V7 mRNA and protein expression but no significant increases in downstream markers of AR-V7 activity, UBE2C and UGT2B17. Conclusion: Our results suggest that the IGF-1 and -II neutralizing antibody xentuzumab may reverse AR-V7-mediated ENZA resistance.

#1195 TNFα induces multidrug resistance to HER2-targeted TNFα induces multidrug resistance to HER2-targeted therapies in HER2-positive breast cancer. Maria F. Mercogliano,1 Mara De Martino,1 SofiaBruni,1 Leandro Venturutti,1 Martín Rivas,2 Matias Amasino,3 Cecilia J. Proietti,1 Patricia V. Elizalde,1 Roxana Schillaci1,1 BYME-CONICT, CABA, Buenos Aires, Argentina; 2Well Cornell Medical College, Manhattan, NY.

HER2 positive (HER2+1) is a breast cancer (BC) subtype characterized by HER2 overexpression/amplification that affects nearly 15% of BC patients and correlates with poor prognosis. These patients receive trastuzumab (T), an anti-Her 2 monoclonal antibody, but resistance events (40-60%) hamper its clinical benefit. Previously we have demonstrated that TNFα (TNF) induced mucin-4 (MUC4) expression and turned T-sensitive cell lines and tumors into multidrug resistant ones. Nowadays, new anti-HER2 therapies are being used in the clinical setting, such as lapatinib (a dual inhibitor of EGF and HER2), and antibodies like T-D1M1 (combines TZ with the anti-microtubule agent emtansine), and pertzumab (P) that impedes HER2 dimerization. The aim of this work was to study the role of TNF in resistance to the new HER2-targeted therapies. We used BT-474-C (control cells) and BT-474-T2 cells engineered in our lab to stably over-express TNF, and were proven to be sensitive and resistant to T, respectively. We performed dose-response curves for T-D1M1, they show that inhibits proliferation of BT-474-C cells at 0.01 µg/ml. On the other hand, BT-474-T2 cells were resistant in the same experimental conditions and they exhibited reduced T-D1M1 binding with respect to BT-474-C. BT-474-C cells were sensitive to low concentrations of T-D1M1 with 0.5 nmol/L, but in BT-474-T2 cells T-D1M1 was ~10 times less potent than control cells (IC 50 3.34 nmol/L). When we abrogated MUC4 expression, BT-474-T2 cells were sensitized to T-D1M1, showing that TNF-induced MUC4 expression is responsible for T-D1M1 resistance in this cell line. We assessed the effect of lapatinib performing a dose-response curve. Results shown a similar IC50 for BT-474 C and T2 cells (0.26 µM and 0.08 µM, respectively). When studied P effect, ~150nm and that the combination of T+P was more effective inhibiting proliferation in BT-474-C cells than T alone, despite these results binding of the antibody showed no change between the cell lines. In BT-474-T2 cells proliferation was slightly inhibited by the combined treatment. In vivo experiments showed that BT-474-C tumors were sensitive to T and the combination of T+P, but BT-474-T2 tumors did not respond to any of these treatments. These results suggest that TNF plays an important role in multidrug resistance to HER2-targeted therapies, specifically T-D1M1 and P, but not in lapatinib resistance. We propose TNF as an attractive target and we suggest that HER2+ patients resistant to T could be eligible for a combination of HER2-targeted therapies and a TNF-blocking treatment to overcome resistance.

#1196 Epigenetic drugs modulate long noncoding RNAs expression in BRAF inhibitor-resistant melanoma. Barbara Montico,1 Giorgio Giurato,2 Katy Mastorci,1 Aurora Rizzo,1 Maria Ravo,2 Francesca Rizzo,2 Alessandro Weiz,2 Riccardo Dolcetti,2 Francesca Colizzi,1 Luca Sigalotti,1 Elisabetta Fratta1,2 Centro di Riferimento Oncologico, Aviano, Italy; 3University of Salerno, Salerno, Italy; 4University of California, San Francisco, San Francisco, USA; 5University Medical School of South Australia, Adelaide, Australia; 6University Hospital of Udine, Udine, Italy.

Emergence of drug resistance is the major cause of failure of BRAF inhibitors (BRAFI) treatment in cutaneous melanoma (CM). Epigenetic modifications are known to physiologically trigger massive modifications in cellular commitment and several studies report a correlation between the drug-resistant phenotype and epigenetic alterations. Long noncoding RNAs (lncRNAs) represent a class of gene regulators acting at epigenetic, transcriptional and post-transcriptional level. Several studies have implicated lncRNAs in chemoresistance through their ability to impair cell cycle arrest and apoptosis, but also to induce and modulate epithelial-mesenchymal transition and cell adhesion-associated signaling pathways. lncRNAs interact with histone modifying complexes and/or DNA methyltransferases, being also targets of these epigenetic mediators. Furthermore, epigenetic drugs have been recently identified as modulators for lncRNAs function as well as their related targeting signals. Starting from these evidences, we asked the question whether epigenetic drugs could differentially affect the survival of BRAFI-resistant (VR) and -sensitive CM cells, investigating the mechanistic network involved, with a specific focus on the role of lncRNAs. A panel of BRAFI-sensitive and VR CM cell lines, treated with the FDA-approved HDAC inhibitor vorinostat (SAHA). FACS analysis of annexin V-FITC/propidium iodide stained cells showed that SAHA cytotoxic activity was more pronounced on VR CM cells than on their parental counterparts. RNA-Seq analysis revealed that a large number of differentially expressed lncRNAs was modulated in VR CM cells treated with SAHA. Intriguingly, the expression of several VR up-regulated lncRNAs was decreased to levels similar to those observed in the matched parental cells. Functional analysis indicated these lncRNAs were statistically enriched in pathways involving cellular growth and proliferation, but also cellular assembly and organization. Though additional studies are required, epigenetic modulation of VR-associated lncRNAs promises to have significant therapeutic potential to restore BRAFI sensitivity, being concurrently effective in killing VR cells as monotherapy. Based on our preliminary data, we could anticipate that the combined use of epigenetic and targeted drugs would increase therapeutic efficacy in CM patients relapsing to BRAFI.
required for ET-1-induced YAP signaling. At the chromatin level, the activation of ET-1 axis promotes the recruitment of YAP, TEAD, and β-arrestin to TEAD binding sites of CTGF, ANKR1D and EDN1 promoters, an effect inhibited by macitentan treatment. These results indicate that β-arrestin can act as a transcriptional co-activator that bind TEAD thereby activating transcription of effectors of ET-1R/TEAD transcriptional activity. Altogether our results establish for the first time the role of ET-1R/β-arrestin signaling, providing mechanistic insights that targeting ET-1R signaling in combination with macitentan treatment may represent a promising therapeutic strategy for the management of NSCLC.

#1198 Neuruplin-1 blockade chemosensitizes pancreatic cancer cells via dual inhibition of epithelial-mesenchymal transition and autophagy. Pratik N. Matkar, Krishna K. Singh, Gerald Prud’homme, David Hedley, Howard Leong-Poi. 

Univ. of Toronto, Toronto, Ontario, Canada.

Introduction: Fibrotic and malignant pancreatic ductal adenocarcinoma (PDAC) tumors are often resistant to chemotherapy, and remain a leading cause of morbidity and mortality. Epithelial–mesenchymal transition (EMT), a process by which epithelial cells lose their cell polarity and adhesion to become migratory and invasive mesenchymal stem cells, contributes to chemoresistance in PDAC. Likewise, PDAC tumors benefit from autophagy, a self-degradation pathway that confers a survival benefit against metabolic stress. Over-activation of EMT and autophagy has been linked with drug resistance in PDAC. Both these processes are largely mediated by TGFβ1. Recently, we demonstrated the role of neuruplin-1 (NRP-1) in TGFβ1-dependent endothelial-mesenchymal transition and fibrosis in PDAC. However, the potential mechanisms linking NRP-1 with autophagy-mediated chemoresistance remain unclear. We hypothesized that NRP-1 blockade will enhance chemotherapeutic effect, by suppressing MET and autophagy in PDAC. Methods: Human PDAC cells (BxPC-3) or serially grafted exposed mesenchymal cancer (CR-BxPC-3) cells were transfected with siNRP-1 or scramble using DharmaFECT-2. For EMT and chemotherapy studies, transfected cells were treated with TGFβ1 (5ng/mL, 24h), followed by gemcitabine (1µM) for 48h. RNA (24h) and protein (48h) was isolated using TRIzol™ and RIPA, respectively. EMT markers were evaluated by RT-PCR and immunoblotting/immunostaining. For autophagy studies, cells were serum starved post NRP-1 silencing and protein was isolated. For autophagy inhibition, cells were treated with bafloycin-A1 (100nM) for 24h post NRP-1 silencing and protein was isolated. Autophagy flux (LC3-II/I) and P62 were measured by immunoblotting/immunostaining. Cell viability was evaluated by MTT assay. Results: SiNRP-1 treatment in BxPC-3 and CR-BxPC-3 cells resulted in NRP-1 knockdown and promoted cell-death after chemotherapy. TGFβ1-stimulated BxPC-3 cells demonstrated a morphological transition consistent with EMT that was revoked by siNRP-1. Also, siNRP-1 maintained epithelial cellular morphology via gain of epithelial and loss of mesenchymal markers. Remarkably, CR-BxPC-3 cells exhibited enhanced EMT features. SiNRP-1 inhibited EMT and promoted cell-death by overcame gescinmine resistance in CR-BxPC-3 cells, possibly through reduced ERK signaling. Moreover, siNRP-1 inhibited autophagy (decreased N1LI/U1 ratio) resulting in increased PDAC cell survival post chemotherapy stress, and enhanced cell-death after chemotherapy and autophagy inhibition in BxPC-3 cells. Conclusions: Our findings define a previously undetermined role of NRP-1 in regulating autophagy and TGFβ1-induced EMT in PDAC, suggesting that NRP-1 may represent a novel therapeutic target to overcome chemoresistance through reduced EMT and autophagy.

#1199 Overcomes AXL and Met mediated erlotinib/gefitinib cross resistance in non-small cell lung cancer cells by Marsdenia tenacissima extract. Shu-Yan Han, Hong Sun, Dong Xue, Wei Zhao, Yan-Na Jiao, Ping-Ping Li. Peking University Cancer Hospital & Institute, Beijing, China.

Apart from EGFR T790M mutation, the bypass activation of c-Met and Axl kinase also lead to the resistance to tyrosine kinase inhibitors (TKIs) in NSCLC. Axl and c-Met share a downstream pathways with EGFR, thus combined treatments of EGFR inhibitors with Axl or Met inhibitor are promising to overcome acquired resistance of TKIs. Our previous work showed that the water extract of Marsdenia tenacissima (MTE), which used to treat cancer in clinics for decades, restored gefitinib sensitivity in resistant NSCLC cells with EGFR T790M mutation or K-ras mutations in vitro and in vivo. However, the potential efficacy of MTE on Axl and c-Met mediated resistance has not yet been fully understood, and the related molecular mechanisms also need to be elucidated. The present study was performed on HCC827/ER cells, which was established by exposing parental HCC827 cells to erlotinib. HCC827/ER cells are with Axl activation and c-Met amplification, and show dual-resistance to erlotinib and gefitinib. We evaluated the effects of MTE to restore erlotinib/gefitinib sensitivity with three different combinations. Cell viability and cell apoptosis were determined by MTT and flow cytometry, respectively. The c-Met amplification was assessed with TaqMan real-time PCR. Signaling pathways were examined by Western blotting to reveal the possible mechanisms. The in vivo efficacy of MTE with erlotinib/ gefitinib were tested on HCC827/ER xenograft mice, and tumor tissues were subjected to immunohistochemistry analysis and Western blotting. Our results indicated the MTE + Met + Erlotinib/Gefitinib (M + M + E/G) treatment was the most potent combinations. Compared with control group and each single, M + M + E/G treatment induced significant apoptosis, obviously inhibited EGF-induced phosphorylation of PI3K/Akt/mTOR and ERK1/2, down-regulated HGF/c-Met activation in HCC827/ER cells. Axl is a receptor tyrosine kinase which strongly associated with EMT phenotype. The M + M + E/G treatments could not re-strain Axl expressions but remarkably reduced phospho-Axl levels and inhibited EMT phenotype in HCC827/ER cells. Surprisingly, MTE alone caused prominent p-Axl inhibition, along with up-regulated E-cadherin and decreased mesenchymal markers. The mouse tumors were remarkably restrained by the M + M + E/G combinations, and it was significant compared with each drug alone (p < 0.05). Accordingly, cell apoptosis was extended, PCNA expression and tumor angiogenesis (VEGF and CD105) were reduced and EMT phenotype were regulated in tumor tissues. The M + Met and p-Axl were also considerably suppressed by the combined treatments. The present data revealed that MTE reverse resistance such as erlotinib and gefitinib efficacy in resistant NSCLC cells with Axl activation and c-Met amplification in vitro and in vivo. It suggests that the addition of MTE may be a promising therapeutic strategy to overcome TKIs resistance in NSCLC.

#1200 Novel strategy to overcome platinum resistance in uterine leiomyosarcoma; blocking ATP7B by copper ion. Mamoru Kakuda, Shinya Matsuaki, Ruriko Nakae, Yusuke Tanaka, Eiji Kobayashi, Yutaka Ueda, Kiyoshi Yoshino, Tadashi Kimura. Osaka University, Suita-City, Japan.

Objective: Resistance to platinum drugs remains a significant problem. Our objective is to elucidate the role of ATP7B, a copper transporter which excretes copper ion thereby platinum can be accumulate in cells. Thus, pre-treatment with CuSO4 may represent a novel therapeutic approach to enhance platinum sensitivity in uterine leiomyosarcoma (ULM) cells. Methods: The expression of ATP7B in ULM was evaluated by real-time PCR and immunohistochemical (IHC) staining methods. ULM cell lines (SK-LMS-1, SK-UT1 and SKN) were treated with CuSO4 before cisplatin treatment for 24h post NRP-1 silencing and protein was isolated. Autophagy flux (LC3-II/I) and P62 were measured by immunoblotting/immunostaining. Cell viability was evaluated by MTT assay. Results: SiNRP-1 treatment in BxPC-3 and CR-BxPC-3 cells resulted in NRP-1 knockdown and promoted cell-death after chemotherapy. TGFβ1-stimulated BxPC-3 cells demonstrated a morphological transition consistent with EMT that was revoked by siNRP-1. Also, siNRP-1 maintained epithelial cellular morphology via gain of epithelial and loss of mesenchymal markers. Remarkably, CR-BxPC-3 cells exhibited enhanced EMT features. SiNRP-1 inhibited EMT and promoted cell-death by overcame gescinmine resistance in CR-BxPC-3 cells, possibly through reduced ERK signaling. Moreover, siNRP-1 inhibited autophagy (decreased N1LI/U1 ratio) resulting in increased PDAC cell survival post chemotherapy stress, and enhanced cell-death after chemotherapy and autophagy inhibition in BxPC-3 cells. Conclusions: Our findings define a previously undetermined role of NRP-1 in regulating autophagy and TGFβ1-induced EMT in PDAC, suggesting that NRP-1 may represent a novel therapeutic target to overcome chemoresistance through reduced EMT and autophagy.

#1201 Disrupted endoplasmic reticulum-mitochondria contacts promote multidrug resistance. Jordia Coku, 1 Madison C. Pedrotty, 1 David M. Booth, 2 Sharon Kim, 3 Annette Vu, 4 C. Patrick Reynolds, 4 György Hajnóczy, 2 Michael D. Hogarty. 1 University of Pennsylvania, Philadelphia, PA; 2 Thomas Jefferson University Health Sciences Center, Lubbock, TX.

Conclusion: ATP7B is a copper transporter which excretes copper ion thereby platinum can be accumulate in cells. Thus, the pre-treatment with CuSO4 may represent a novel therapeutic approach to enhance platinum sensitivity in uterine leiomyosarcoma (ULM) cells. Methods: The expression of ATP7B in ULM was evaluated by real-time PCR and immunohistochemical (IHC) staining methods. ULM cell lines (SK-LMS-1, SK-UT1 and SKN) were treated with CuSO4 before cisplatin treatment for 24h post NRP-1 silencing and protein was isolated. Autophagy flux (LC3-II/I) and P62 were measured by immunoblotting/immunostaining. Cell viability was evaluated by MTT assay. Results: SiNRP-1 treatment in BxPC-3 and CR-BxPC-3 cells resulted in NRP-1 knockdown and promoted cell-death after chemotherapy. TGFβ1-stimulated BxPC-3 cells demonstrated a morphological transition consistent with EMT that was revoked by siNRP-1. Also, siNRP-1 maintained epithelial cellular morphology via gain of epithelial and loss of mesenchymal markers. Remarkably, CR-BxPC-3 cells exhibited enhanced EMT features. SiNRP-1 inhibited EMT and promoted cell-death by overcame gescinmine resistance in CR-BxPC-3 cells, possibly through reduced ERK signaling. Moreover, siNRP-1 inhibited autophagy (decreased N1LI/U1 ratio) resulting in increased PDAC cell survival post chemotherapy stress, and enhanced cell-death after chemotherapy and autophagy inhibition in BxPC-3 cells. Conclusions: Our findings define a previously undetermined role of NRP-1 in regulating autophagy and TGFβ1-induced EMT in PDAC, suggesting that NRP-1 may represent a novel therapeutic target to overcome chemoresistance through reduced EMT and autophagy.
Background: Most high-risk neuroblastoma patients succumb to lethal therapy resistant disease acquired during the course of intensive multimodality treatment. This acquired therapy resistance is largely attributed to insensitivity to drug-induced apoptosis, however the exact mechanisms remain unknown. Apart from integrating death signals, mitochondria (mito) interact with the endoplasmic reticulum (ER), inducing Bim or Bim-like proteins at close contact sites known as mitochondria-associated membranes (MAM) of the ER to regulate calcium and lipid transfer and apoptotic sensitivity, a process often derailed in therapy resistant cancers. ER-mito contact sites are juxtaposed by various tethering protein complexes that include MFN2 and PACS2. Pathologic deregulation of these contact sites has been implicated in the genesis of neurodegenerative and metabolic disorders. Here, we show that disruption of bona fide ER-mito tethering protein complexes in therapy sensitive neuroblastomas induces apoptotic insensitivity and a drastic shift towards a resistance-like phenotype. Methods and Results: Previously we showed that isolated mitochondria from tumors at relapse resist induction of mitochondrial apoptosis when primed with the terminal death effectors that are downstream of therapeutic stress (tBid and Bim-BH3 peptide). We isolated mitochondria from seven matched isogenic tumor pairs obtained at diagnosis (DX) and relapse (REL) and quantified their apoptotic response to tBid and Bim by measuring cytochrome C release by ELISA. Electron microscopy (EM) image analyses of ER-mito contact sites revealed that REL tumors contain up to 70% fewer ER-mito interactions than their matched DX tumors, as confirmed by IB for organelle-specific proteins. Here, we recapitulate the post-therapy resistance phenotype in DX therapy sensitive cells by shRNA silencing of MFN2 or PACS2 and confirm their apoptotic resistance by BH3 profiling and drug response in vitro. A 60% decrease in MFN2 protein in DX cells partially phenocopied the resistance profile of isogenic REL cells. The degree of apoptotic resistance correlated with the extent of protein knockdown for MFN2. Treatment of shMFN2 and shPACS2 DX cells with ABT-737, a BH3 mimetic, or carboplatin, increased their IC50s multiple-fold compared to control cells, paralleling their blunted mitochondrial apoptotic response. Conclusions: Our data implicate ER-mito contact sites as positive regulators of apoptosis, whose disruption may be necessary for apoptotic attenuation in therapy resistant cancer cells to enable apoptosis evasion and survival. We present a potential mechanism for broad therapy resistance arising under therapeutic stress that selects for reduced communication of ER with mitochondria.

#1202 Targeting PIK3C3 to overcome drug resistance resulted from prosurvival autophagy in cancer cells. CHUNG-HAN CHEN, TAIPEI MEDICAL UNIVERSITY, TAIPEI, TAIWAN.

Autophagy is an important cellular recycling mechanism in which portions of cytosol or organelles are sequestered into a double-membrane structure and delivered to lysosome for degradation. PIK3C3 is the only class III PI3K, which specifically generates phosphatidylinositol 3-phosphate (PtdIns3P). It in turn recruits proteins containing FYVE or PX domains, thereby initiating various complexes at the membranes of endosomes, phagosomes and autophagosomes. Recently, several studies have shown that autophagy is upregulated in cancer cells when exposing to chemotherapy and radiotherapy. Therefore, the rationale of targeting autophagy addiction in cancer was proposed by combining autophagy inhibitors and chemotherapeutics that induce autophagy as a pro-survival mechanism to increase their therapeutic efficacy. We stably knocked down PIK3C3 in cancer cell lines and combined with clinical therapeutic agents reportedly induce prosurvival autophagy. Cell viability was examined by MTT assay and combination index was determined by Compusyn software. The autophagy flux was evaluated by detecting protein levels of LC3-II and p62 through western blot analysis. The results showed PIK3C3 knockdown synergistically sensitizes the killing effects of gefitinib and gemcitabine in A549 cells and Panc1 cells, respectively. Both of gefitinib and gemcitabine increased autophagy flux, as evidence by the increase of LC3-II and decrease of autophagy substrate, p62. However, the combination of PIK3C3 knockdown and therapeutic agents increased both of the protein levels of LC3-II and p62. These data suggest incomplete autophagy when the function of PIK3C3 was inhibited. The phenomenon was confirmed by bombing autophagy inducer and PIK3C3 inhibitors. Moreover, no appreciable apoptotic cell death was observed. Taken together, our study revealed a potential strategy by targeting PIK3C3 to overcome drug resistance associated with the pro-survival autophagy in cancer.

Recurrent chemoresistant ovarian cancer is responsible for the high mortality rate in ovarian cancer patients. The molecular mechanisms underlying the chemoresistant ovarian cancer are not fully understood. MicroRNAs (miRs) expression has been recognized as one of the core regulators of gene expression in recent years. However, whether miRs are involved in chemoresistance of ovarian cancer has not been fully elucidated. Current study was performed to interrogate the role of a number of critical miRs in chemoresistance of ovarian cancer by targeting PIK3C3 to overcome drug resistance associated with the prosurvival autophagy inducer and PIK3C3 inhibitors. Moreover, no appreciable apoptotic levels of LC3-II and p62. These data suggest incomplete autophagy when the function of PIK3C3 knockdown and therapeutic agents increased both of the protein levels of LC3-II and p62. These data suggest incomplete autophagy when the function of PIK3C3 was inhibited. The phenomenon was confirmed by bombing autophagy inducer and PIK3C3 inhibitors. Moreover, no appreciable apoptotic cell death was observed. Taken together, our study revealed a potential strategy by targeting PIK3C3 to overcome drug resistance associated with the pro-survival autophagy in cancer.

#1204 Enhanced efficacy of selumetinib by pretreatment of 5-FU in preclinical Ras/Raf-mutant colorectal cancer models. Hye Yoon Jang,1 Haeng Jung Lee,2 Ye San Kim,2,3 Won Dong Kim,2 Jong Yu Bae,2 Jin Hwang Jung. Seung Jin Lee,1 Eun Hee Moon1. CHUNGNA UNIVERSITY, DAEJEON, REPUBLIC OF KOREA; 2GACHON UNIVERSITY, INCEON, REPUBLIC OF KOREA; 3ASIAN INSTITUTE FOR LIFE SCIENCES, ASIAN MEDICAL CENTER, SEOUL, REPUBLIC OF KOREA; 4A CONHON UNIVERSITY, INCEON, REPUBLIC OF KOREA; 5ASIAN METHODICAL CENTER, UNIVERSITY OF ULSAN, COLLEGE OF MEDICINE, SEOUL, REPUBLIC OF KOREA; 6ASIAN MEDICAL CENTER, UNIVERSITY OF ULSAN, SEOUL, REPUBLIC OF KOREA.

Optimal strategy for the application of MEK inhibitor as combination therapy has not been established in Ras/Raf-mutant colorectal cancer (CRC). As we preliminary observed that 5-FU-induced pharmacodynamic changes were re-stored by ERK inhibition, we hypothesized that post-treatment of MEK inhibitor would enhance antitumor activity of 5-FU. Treatment of 5-FU for 2 days followed by selumetinib for another 2 days (FS schedule) exhibited synergism for cell viability, whereas reverse or concomitant combination showed antagonism or inconsistent response, respectively, in 8 kinds of CRC cell lines including BRAFV600E colon205, BRAFV600E RKO, and KRAS G13D HCT8 cells. Combination as FS schedule persistently down-regulated the phosphorylation of ERK and pS6 throughout treatment period, whereas selumetinib alone or reverse combination transiently decreased within 24 hr. The cells treated as FS schedule exhibited higher apoptosis and lower capacity of anchorage-independent growth than the cells under single or reverse combination. Microarray analysis revealed the distinct groups of genes underlying different efficacy by schedule-dependent treatment. Tumor growth in mice administered 5-FU at 10 mg/kg/day for colon205 and at 30 mg/kg/day for HCT8 for 7 days followed by selumetinib at 10 mg/kg/day for colon205 and 25 mg/kg/day for HCT8 for another 7 days was significantly retarded than that in mice treated with single agents. But the combination in reverse sequence induced comparable tumor growth to single agents. Decreased expression of Ki67 was observed in tumors from mice treated as FS scheduling. Our results suggest that the schedule-dependent combination of 5-FU and selumetinib may be benefit in patients having CRC with hyper-activation of Ras/RAF pathway.

#1205 Rubrofusarin and toralactone sensitize resistant MCF-7adr cell line to paclitaxel via inhibiting P-glycoprotein efflux activity, Salwa D. Aqealathani,1 Hanan A. Assiri,1 Fahad A. Al-Abbsi,2 Ali M. El-Halawany,2 Ahmed M. Al-Abd3. 1King Abdulaziz University, Jeddah, Saudi Arabia; 2Cairo University, Cairo, Egypt; 3National Research Centre of Egypt, Giza, Egypt.

The use of anti-cancer adjunct therapy is rationalized by potentiating the efficacy and/or protecting from major side effects of chemotherapeutics. Paclitaxel is an effective spindle toxin anticancer agent used for the treatment of breast cancer. Rubrofusarin and toralactone are naturally occurring structurally related naphthopyrones with potent antioxidant and hence chemoprotective activity. The purpose of this study is to investigate the influence of rubrofusarin and toralactone on the cytotoxic profile of paclitaxel (PTX) against chemo-

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Reversal of Drug Resistance

Proceedings of the American Association for Cancer Research • Volume 58 • April 2017 309
resistant breast cancer cell line (MCF-7/ddr) compared to parent MCF-7 cells. MCF-7/ddr was prepared by continuous culturing of MCF-7 cells in media containing subcytotoxic concentration of doxorubicin (IC_{50}, 15 μM) for two months duration. Tumor脱落 and ribosomal stress showed moderate cytotoxic effects against MCF-7 cells with IC_{50}'s of 32.4 ± 12 μM and 13.9 ± 6.1 μM, respectively. Interestingly, the ribosomal stress was more potent against MCF-7/ddr cells with IC_{50}'s of 7.3 ± 0.7 μM and 7.8 ± 0.6 μM, respectively. PTX treatment was opposed by significant resistance from MCF-7/ddr cells compared to parent MCF-7 cells having IC_{50}'s of 4.9 ± 0.9 μM and 57.7 ± 4.5 μM, respectively. Combination of tumor脱落 and ribosomal stress with PTX did not significantly improve its cytotoxicity against MCF-7; IC_{50}'s were 24.2 ± 2.2 nM and 69.7 ± 6.2 nM, respectively compared to 4.9 ± 0.9 μM for PTX alone. Potentially, combination with either tumor脱落 or ribosomal stress abolished the resistance of MCF-7/ddr to PTX resulting in IC_{50} of 3.4 ± 0.2 nM and 4.9 ± 0.5 μM, respectively compared to 4.9 ± 0.9 μM for PTX alone. Using flowcytometric analysis, ribosomal and tumor脱落 increased median intracellular fluorescence signal count of rhodamine dye (non-cytotoxic P-gp substrate) within MCF-7/ddr from 1794.7 ± 21.5 to 2003.3 ± 12.5 to 2113 ± 10.5 cellular events, respectively. Using purified membrane bound humanized recombinant P-gp molecules; it was found that both ribosomal tumor脱落 and tumor脱落 might be inhibiting P-gp efflux activity via dual interaction with both P-gp ATPase enzyme subunit and P-gp active binding site. In both MCF-7 and MCF-7/ddr cells, PTX exerted significant cell cycle block at G_{2}/M-phase with significant increase in the p-CDK1 and MDR1 expression of the p-CDK1 and MDR1, respectively. In addition, tumor脱落 ribosomal stress exerted any significant influence for PTX induced cell cycle interruption in both normal (MCF-7) and resistant (MCF-7/ddr) cell lines. In conclusion, ribosomal tumor脱落 can enhance the cytotoxic profile of P-gp substrates, such as PTX, via inhibiting P-gp efflux activity and enhancing the intracellular entrapment of P-gp substrates.

Introduction Prostate cancer (PrCa) is the most common male malignancy among men in the United States. Recent studies suggest that low expression of miR-205 is seen in PrCa cells lines and tumors in comparison to normal prostatic epithelial cells. A number of studies have shown that restoration of miR-205 in PrCa cells resulted in suppression of cell growth, epithelial-to-mesenchymal transition, and chemosensitization. However, due to the poor pharmacological kinetics and low in vivo stability of miR-205, serious limitations are being experienced at the clinical level. Therefore, we have chosen a novel nanoparticle-based miR-205 delivery system to deliver miR-205, for improved therapeutic benefits in PrCa. Methods A novel miR-205 nanoparticle formulation (named miR-MPG) was generated which is composed of an iron oxide core layer with polyethylene imine (PEI), and NHS-PEG-NHS (PEG) polymer. The miR-205 withholding and release characteristic of miR-PEG were examined through fluorescence quenching and agarose gel electrophoresis. Hemocompatibility of this formulation was examined using a hemolysis assay. Cellular uptake of miR-MPG formulation was evaluated using flow cytometry and confocal studies. Further, therapeutic and chemosensitization activity of miR-205 were assessed using cell culture based assays. Molecular effects associated with the PrCa cells growth inhibition were evaluated through protein profiling and qRT-PCR analyses. Results and Discussion miR-MPG formulation exhibited optimal particle size and zeta potential, which are suitable for cancer therapeutics. Agarose gel electrophoresis binding studies suggested 5 μg of nanoparticle formulation is optimum to hold 1 μg of miR-205 mimic. Release of miR-205 from miR-MPG was determined with respect to concentration of anionic molecules and in a time-dependent manner. We observed no hemolysis during miR-MPG interaction with the red blood cells. Hemocompatibility of miR-MPG, in addition, miR-MPG particles exhibited superior internalization and endosomal escape in PrCa cells. This formulation displayed enhanced sensitization of PrCa cells to docetaxel. Additionally, it induced the expression of apoptotic proteins (Bax, Bim, cleaved PARP, and caspase 3), and downregulated the anti-apoptotic proteins (Bcl-2 and survivin). Moreover, the expression of the chemoresistance-associated proteins (PSMA and MRP) significantly decreased in miR-MPG treated cells compared to miR-MPG in the presence of docetaxel. Further dataset of qRT-PCR studies showed induced expression of the miR-205 and affected the expression of its downstream genes. These results suggest that miR-MPG formulation may serve as an ideal delivery vehicle to deliver miR-205. Conclusion Results from this study suggests that successful delivery of miR-205 through miR-MPG nanoparticles can induce sensitization potential for docetaxel treatment. This novel therapeutic modality might be effective for PrCa patients undergoing chemotherapy.

#1207 SNS-062 demonstrates efficacy in chronic lymphocytic leukemia in vitro and inhibits C481S mutated Bruton tyrosine kinase. Catherine A. Fabian, Sean D. Reiff, Daphne Guinn, Linda Neuman, Judith A. Fox, Wendy Wilson, John C. Byrd, Jennifer A. Woyach, Amy J. Johnson. The Ohio State University, Columbus, OH; Georgetown University, Washington, DC; Sunesis Pharmaceuticals, South San Francisco, CA.

Introduction: In order to address the issue of acquired resistance to ibrutinib, we sought to characterize the Bruton agammaglobulinemia tyrosine kinase (BTK) inhibitor SNS-062 in preclinical models of chronic lymphocytic leukemia (CLL). Methods: Primary CLL B cells were isolated from the whole blood of consented patients by ficoll density centrifugation and Rosette-Sep negative selection. Annexin V and propidium iodide flow cytometry was used to measure patient CLL cell viability and 7-AAD was used to measure viability in stromal co-culture. CD40 and CD86 expression was evaluated via flow cytometry subsequent to sustained 3.2μM CpG stimulation. BCR signaling in primary CLL cells was investigated by immunoblot following 1 hour treatment and following 1 hour or 24 hours of incubation with SNS-062 in XLA cell lines. ITK inhibition was investigated via immunoblot after stimulation with anti-CD3 and anti-CD28 and incubation with SNS-062 for 1 hour. SNS-062 was used at a concentration of 1μM in preclinical studies unless otherwise noted. Measurement of kinase activity in human recombinant WT BTK or C481S BTK was performed in FR. In our study, Results: In our study, we investigated the combination of B-Raf driven tumors with RAF and MEK1 inhibitors. In our study, we investigated the combination of B-Raf driven tumors with RAF and MEK1 inhibitors. In our study, we investigated the combination of B-Raf driven tumors with RAF and MEK1 inhibitors.
profiles of these cell lines and analyzed the requirement of a MAPK activating signaling. Our approach revealed that synergistic activity is not confined to melanoma and colon cancer but is observed in tumors from other entities as well. This observation may expand the usefulness of MEK/RAF inhibitor co-treatment to a larger panel of cancer types.

#1209 FGF inhibition re-sensitizes BRAF/MEK dual resistant cells to the BRAF/MEK inhibitor combination. Victoria E. Wang,1 Jeffrey Settleman,2 Frank McCormick,1 1UCSF, San Francisco, CA; 2Genentech, South San Francisco, CA.

The BRAF-MEK pathway is frequently mutated in human melanoma. Inhibitors of these kinases have proven to prolong survival in melanoma patients. However, clinical benefit is relatively short-lived due to acquired drug resistance. To explore mechanisms of resistance in melanoma cells treated with dual BRAF and MEK inhibitors, A375, a cell line harboring the BRAF V600E mutation, was treated with escalating doses of vemurafenib and cobimetinib to generate a cellular population resistant to combination therapy. These cells display a reversible resistance phenotype. Upon initial treatment of the drug combination, upregulation of pSTAT3 is observed but the cells lose dependency on the pSTAT3 pathway upon prolonged drug treatment. A pharmacological synthetic lethal screen was performed and the FGF inhibitor class re-sensitizes the cells to BRAF and MEK inhibition through inhibitions of pERK. The dual resistant cells also displayed hyperactivation of the PDK-AKT pathway. Interrogation of patient samples confirmed these findings. These findings provides a biological rationale for a polytherapy strategy using a FGF inhibitor in patients with resistance to dual BRAF and MEK inhibition.<–EndFragment–>

#1210 Hederagenin overcomes the cisplatin resistance of head and neck cancer by targeting the antioxidant defense mechanisms. Daia Shin,1 Eun Hye Kim,1 Hyejin Jang,1 Jae Young Lee,2 Minsu Kwon,3 Seungho Baek,3 Jong-Lyel Roh3 1Asan Medical Center, Univ. of Ulsan College of Medicine, Seoul, Republic of Korea; 2Gyeongsang National University School of Medicine and Gyeongsang National University Hospital, Jinju, Republic of Korea; 3College of Korean Medicine, Woosuk University, Wanju, Jeonbuk, Republic of Korea.

Background: Cisplatin is a first-line chemotherapeutic agent for head and neck cancer (HNC). Acquired resistance to cisplatin is the most common reason for the failure of cisplatin chemotherapy. Hederagenin is extracted from the leaves of Cyclocarya paliurus, also known as sweet tea, which is one of the most popular teas utilized in traditional Chinese medicine. There is accumulating evidence it exhibited significant cytotoxicity against several types of cancers, however, which has been rarely tested in HNC cells. Herein, we examined the potential utility of hederagenin for overcoming cisplatin resistance in HNC cells and further clarified its molecular mechanisms of action. Methods: Parental and cisplatin-resistant HNC cells, and Nfr2 or SLC7A11 gene overexpressed HNC cell lines and other human HNC cells were used. The cells were used to examine the effects of hederagenin treatment in HNC cell lines by measuring cell viability, cell cycle, cell cycle, cell death, reactive oxygen species (ROS) production, glutathione level, mitochondrial membrane potential (∆Ψm), and protein expression. The anti-tumor effect of hederagenin in mouse tumor xenograft models was also tested. Results: Hederagenin induced cell death in both cisplatin-sensitive and -resistant HNC cells. Hederagenin treatment resulted in effective cisplatin-resistant HNC cells in a form of apoptotic cell death with the ∆Ψm change. Hederagenin inhibited Nfr2 and SLC7A11 resulting in an increasing ROS accumulation in HNC cells, of which effects were reversed by the pretreatment of antioxidant trolox. In addition, hederagenin caused the apoptosis effectively induced by targeting the antioxidant defense mechanisms in HNC cells. Subsequently, hederagenin activated signaling pathways of cell death involving caspase-3, PUMA, and PARP in the cells. The growth inhibitory effects of hederagenin were also confirmed in the tumor xenograft model implanted with cisplatin-resistant HNC cells. Conclusions: Our data suggests that hederagenin can overcome the resistance of cisplatin in resistant HNC cells via targeting antioxidant systems.

#1211 Lurbinectedin reverses platinum dependent IRF1 overexpression and nuclear localization, partially responsible for resistance to platinum drugs in ovarian cancer. Gema Santamaria Nuñez, María Jose Guillén, Juan F. Martínez-Leal, Pablo Avilés, Carlos M. Galmarini. PharmaMar S.A., Colmenar Viejo, Spain. 1University of Queensland, Brisbane, Australia; 2Karyopharm Therapeutics, Newton, MA; 3Royal North Shore Hospital, NSW, Australia.

Lurbinectedin (PM1183) is a new synthetic compound from the tetracyclic-drosoinoline family, which has demonstrated a strong anti proliferative activity against a panel of human tumor models in preclinical assays and is currently being evaluated in phase III clinical trials in platinum-resistant ovarian cancer and small cell lung cancer. Lurbinectedin binds to DNA, inhibits transactivated transcription, induces the degradation of elongating RNA Pol II and fools nucleotide excision repair to produce dsDNA breaks that need to be repaired mainly by homologous recombination (HR). Nearly 70% of patients diagnosed with ovarian cancer are in advanced stage, and the vast majority of these patients will eventually relapse with a primary cytoreductive surgery. Following several cycles of standard adjuvant chemotherapy including a platinum drug and a taxane. After a period of treatment with platinum drugs, patients will finally develop resistance, usually mediated by mechanisms such as drug detoxification or efflux and enhanced DNA repair. IRF-1 transcription factor expression has been shown to be up-regulated by cisplatin (CDDP) in ovarian cancer cells and might be responsible for the response to the drug, likely by inhibiting cell proliferation due to IRF1. Here we took advantage of the A2780/A2780cis human ovarian cancer cell lines, the second being a cisplatin resistant derivative, to investigate the role of IRF1 in the response of human ovarian cancer cells to cisplatin and lurbinectedin. A2780cis cells are, indeed, more resistant to cisplatin that their parental cell line but they do not differ in their resistance to lurbinectedin. Basal IRF-1 protein levels were actually higher in A2780cis cells than in their parental cell line, contributing to their resistance to cisplatin. Furthermore, cisplatin treatment induced the overexpression and nuclear localization of IRF-1 both, in A2780 and A2780cis cell lines. Contrarily, lurbinectedin did not induce the overexpression of IRF-1 neither in A2780 nor in A2780cis, explaining why this latter cell line is not resistant to the compound. Furthermore, lurbinectedin co-treatment with cisplatin diminished the expression of IRF-1 in A2780cis, more importantly, in A2780cis cells, explaining the synergism the combination has on these tumor cell lines. Thus, lurbinectedin not only did not activate the same mechanisms of resistance as cisplatin in ovarian cancer cells, but even reversed the resistance of these resistant cells to platinum drugs. Santamaria Nuñez et al, 2016. Mol Cancer Ther 15(10):2399-2412. Romano et al. 2013. Int J Cancer. 2013 Nov; 133(9):2024-33. Pavan et al. 2013. Eur J Cancer 49(4):964-973

#1212 Co-targeting epidermal growth factor receptor (EGFR) and aplastic lymphoma kinase overcomes EGFR inhibitor resistance in head and neck squamous cell carcinoma patient-derived models. Xiaoming Ouyang, Ashley Barling, Aletha Lesch, Jeffrey Tyner, Sophia Jeng, Christina Zheng, Sara A. Courteignede, Shannon McWeeney, Molly Kulesz-Martin. Oregon Health & Science University, Portland, OR.

Background: HNSCC is the sixth most common cancer worldwide. EGFR is overexpressed in up to 90% of HNSCC and associated with poor outcome. An EGFR monoclonal antibody is the only approved molecular targeted therapy for HNSCC, however, resistance eventually occurs in all patients. Methods: Functional screens including a small-molecule kinase inhibitor panel and an RNAi screen panel were used to identify agents that synergized with EGFR inhibitors in reducing cell viability in HNSCC patient-derived tumor cells. Effective combination therapies were validated in scale-up experiments in 2D and 3D, and their true targets were evaluated using siRNAs to rule out target effects of the drugs. Cell viability, cell number and cell colony formation ability were tested using siRNA treatment. qRT-PCR and immunofluorescent staining was used to test ALK expression in tumor cells before and after anti-EGFR treatment. Results: The ALK inhibitor KX-201 on the drug screen panel showed synergistic effects with EGFR inhibitors in 6/8 HNSCC patients' tumor cells, despite ineffective-ness of single drug. Scale-up dose-response experiments confirmed patient cell sensitivity to 4 different ALK inhibitors in combination with the EGFR inhibitor Gefitinib. siRNA targeting ALK synergized with Gefitinib in reducing cell viability in the patient cells that responded to EGFR/ALK inhibitor combinations, indicating specificity to ALK. Scale-up RNAi experiments confirmed synergy between siRNAs targeting ALK and EGFR in reducing cell viability, cell number, and colony formation ability. Inhibition of EGFR by siRNA or Gefitinib each increased ALK expression at the mRNA and protein level, suggesting induction of ALK as a novel mechanism of EGFR inhibitor resistance in HNSCC. Conclusion: We identified EGFR/ALK inhibitor combinations as a potential strategy for treating EGFR inhibitor resistant HNSCC.

#1213 Nuclear export of E2F7 in squamous cell carcinoma in an actionable event that reverses resistance to anthracyclines. Alba Natalia Saenz Ponce,1 Yosef Landesman,2 Trinayan Kashyap,3 Alexander Guminiski,3 Orla Gannon,3 Nicholas Saunders1 1University of Queensland, Brisbane, Australia; 2Karyopharm Therapeutics, Newton, MA; 3Royal North Shore Hospital, NSW, Australia.

Objectives and Background: Squamous cell carcinoma (SCC) of the skin or head and neck region is a major cause of cancer death in the western world. Patient with advanced SCC have few therapeutic options and SCC remains resistant to current treatments. Overcoming drug resistance in SCC would significantly change patient outcomes and treatment strategies. We previously showed that SCCs express the
activating transcription factor E2F1 and the inhibitory transcription factor E2F7, which are mutually antagonistic. We showed that E2F1/7 controlled the sensitivity to anthracyclines in SCC cells via E2F-dependent regulation of sphingosine kinase 1 (Sphk1) and its product sphingosine-1-phosphate (S1P). In addition, we showed that S1P treatment of cells induces profound anthracycline resistance. However, it was completely reversed in SCC cells using either two drugs which are used in breast cancer treatment with a seemingly pro-E2F1 environment within the SCC cells (i.e. pro-proliferation, differentiation-suppressive and pro-survival). In this study we have examined the role of nuclear export pathways in determining nuclear E2F2 activation in SCC.

Methods: We have interrogated human tissue microarrays of normal stratified epithelia and SCC of the skin or head and neck tumours from patient samples. To validate our in vivo findings we used a suite of SCC cell lines and examined the nuclear and cytoplasmic localization of E2F1 and E2F7 by immunofluorescence and western blotting. We deployed inhibitors of the Exportin 1 (XPO1) pathway and have used siRNA against XPO1 to confirm a functional role of XPO1 in the nuclear export of E2F7. We have used inhibitors of XPO1 in vitro and in vivo to examine their ability to enhance the cytotoxic responses to anthracyclines.

Results & Conclusions: We report that E2F7 is selectively localized to the cytoplasm of SCC cells and tumors but is exclusively nuclear in normal cells and tissues. In contrast, E2F1 is almost exclusively localized to the nucleus in normal and SCC cells and tissues. The localization of E2F7 to the cytoplasm could be reversed using inhibitors of the nuclear export protein XPO1 and siRNA against XPO1. XPO1-dependent nuclear export of E2F7 shows that this pathway is selectively activated in SCC. The inactivation of XPO1 allowed possible use of this therapeutic strategy. Inhibition of XPO1 by the small molecule inhibitor Selinexor (selinexor) reverses the decrease in the nuclear export of E2F7 to increase the antifluoropyrimidine F10 is effective towards cell and solid and hematological malignancies. We show that treatment of SCC cells with selinexor reverses anthracycline resistance. Significantly, we show that a combination of selinexor + doxorubicin in vivo induces profound anticancer activity.

Significance: Our studies show that (i) E2F7 is selectively mislocalized in SCC, (ii) E2F7 nuclear export is XPO1-dependent, (iii) dysregulation of XPO1 causes derepression of S1P-mediated anthracycline resistance and (iv) anthracycline resistance is reversed with inhibitors of XPO1 in vivo.

#1214 The polymeric fluoropyrimidine F10 is effective towards cell and organoid models of 5-FU-resistant colorectal cancer. William H. EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Targeting Growth Factor and Intracellular Signaling

#1216 Overcoming cisplatin resistance through the combination treatment with CK2 inhibitor, CX-4945, in gastric cancer. Hyun Myong Kim,1 Inhye Jeong,1 Kyu Hyun Park,2 Tae Soo Kim,2 Woo Sun Kwon,2 Hei-Cheul Jeung,1 Minkyu Jung,2 Sun Young Rha,2. 1Song-dang Institute for Cancer Research, Brain Korea 21 PLUS Project for Medical Science, Yonsei University College of Medicine, Seoul, Republic of Korea; 2Song-dang Institute for Cancer Research, Seoul, Republic of Korea.

Platinum-based non-neoplastic drugs are chemotherapeutic agents usually used to treat gastric cancer (GC) include cisplatin. However, the majority of cancer patients will eventually relapse with cisplatin-resistant disease. Especially, increased DNA repair is drug targetable mechanism and useful in the treatment strategy of cisplatin-resistant cancer. Casein kinase 2 (CK2) has critical role of multiple cellular processes with DNA repair. For this reason, research for CK2 expression correlated with DNA repair mechanism is important in gastric cancer. Combination of cisplatin and CK2 inhibitor (CX-4945, also known as Silmisartel, Senhwa Biosciences, USA) may improve cisplatin-induced DNA damage for GC treatment. In this study, we screened sensitivity of cisplatin and CX-4945 in 49 GC cell lines by MTT assay. For molecular profiling, we analyzed variants and gene expression using whole exome sequencing and RNA sequencing, RNA and protein expression of CK2 subunits (α/ε) using real-time RT-PCR and Western blot. Also, activity of CK2α was measured by ELISA. Combination treatment performed different schedules including concurrent and sequential. Synergistic effect was analyzed by Bliss Independence model. As CK2 profiling, CK2α mRNA expression was a tendency to correlated with CX-4945 sensitivities (p = 0.0054). Moreover, CK2α protein expression was a correlated with CX-4945 sensitivities (p = 0.0252). Other molecular profiling did not reveal any clear correlations. Twenty one (Group 1: cisplatin extremely resistant and CK2 high, Group2: cisplatin intermediate resistant regardless of CK2 expression) cell lines were performed combination treatment. Both YCC-21 and YCC-28 cell lines show synergistic effect (+20% and +22%, respectively) in concurrent schedule. Only MKN-74 cell line show synergistic effect (+11%) in Post-addition (CX-4945 and CX-4945). 19%, respectively) in Post-addi-

to cisplatin-induced DNA damage. Personalized the treatment schedule for inhi-
bib CK2-induced DNA repair is a new strategy to restore cisplatin resistant in GC.

#1217 Blockade of Aurora kinase A synergizes with platinum and radia-
tion in non-small cell lung cancer cells. Huijie Liu,1 Dongwei Zhang,2 Alain Borcacz,3 Vincent Chau,4 Roman Perez-Soler,5 Balazs Halmos,5 Haiying Cheng,6 Albert Einstein College of Medicine, Bronx, NY; 7Columbia University Medical Center, New York, NY; 8Weill Cornell Medical College, New York, NY; 4Montefiore Medical Center, Bronx, NY; 8Albert Einstein College of Medicine /Montefiore Medical Center, Bronx, NY.

Background: Most patients with advanced lung cancer will receive platinum-
based therapy during their treatment course despite limited clinical benefits. Thus, strategies to improve platinum-based therapy continue to be needed. Through a functional genetic screen, we have identified Aurora kinase A as a potentially actionable candidate that can modulate the activity of platinum com-

#1218 Synthetic lethal targeting of p53 mutant cells with prenylation inhi-
bibitors. Shay R. Ferdosi,1 Benjamin Katchman,1 Jia Loo,2 Harneet Grewal,2 Seron Eaton,1 Shanshan Yang,1 Jin Park,3 Joshua Labara,2 Karen S. Anderson,1 Arizona State University, Tempe, AZ; 2Eccrine System Inc, Cincinnati, OH; 1Albert Einstein College of Medicine, Bronx, NY.

Introduction: TP53 is mutated in 30-40% of breast cancers and is associ-
ated with poor prognosis. Mutation of TP53 causes increased cellular pro-
liferation, migration and invasion, and downstream activation of multiple pathways. HMG CoA reductase inhibitors, such as simvastatin, inhibit tu-
morogenic properties induced by TP53 mutation. This mechanism of this re-
sponse is an important question in targeted cancer therapy. It is well known that HMG CoA reductase inhibitors block cholesterol production and pre-
nylation. Therefore, we hypothesized that prenylation inhibitors would tar-
get p53 mutant cells primarily by inhibiting activation of the ras family induced by TP53 mutation. Method: We generated 3 MCF10A stably trans-
duced cell lines over-expressing each of the common TP53 point mutations, R273H, G245S, R248Q, Y264C, or wild type. Ras, Rap, Ras-RhoA, Ras-RhoA-GTP, total RhoA and RhoA-GTP was measured by immunoprecipitation and immuno-

#1220 Coordinated chemical-genetics approach identifies PTPA3-mediated regulation of colon cancer cell migration and extracellular matrix inter-
actions. Kelley E. McQueeney,1 Joseph M. Salamoun,2 Isabella K. Blanco,3 Paula Pecik,1 Jennifer Ahn,1 Elizabeth R. Sharlow,1 Peter Wipf,2 John S. Lazo1. 1University of Virginia, Charlottesville, VA; 2University of Pittsburgh, Pittsburgh, PA.

Aberant regulation of protein phosphorylation is an exceedingly common driver of human cancers. It is notable that we understand much less about the role of protein tyrosine phosphatases in human malignancies compared to ty-
rrosine kinases. The membrane-associated, intracellular, protein tyrosine PTPA3 is highly overexpressed in multiple tumor types including colorectal cancer and has been associated with tumor metastases. We have, therefore, inves-
tigated the role of PTPA3 in colon cancer migration and invasion. The Ptpa3 gene was expunged from colon tumor cells derived from Ptpa3flox/flox mice and the resulting cells exhibited impaired migration, invasion, and colony formation compared to the wildtype isogenic cells. We characterized a potent, selective, and noncompetitive small molecule inhibitor of PTPA3, PTPA3, JMS-631-053, which also disrupted colon cancer cell migration, invasion, and colony
formation. PTP4A3 deletion increased the expression of extracellular matrix and adhesion genes, including the tumor suppressor Emilin 1. Expression of these extracellular matrix genes is mutually exclusive with PTP4A3 expression in tumors derived from patients with colorectal cancer. These chemical and biological reagents reveal a previously unknown communication between the intracellular PTP4A3 phosphatase and the extracellular matrix and support continued efforts to pharmacologically target PTP4A3 for cancer therapy.

#1221 Triple-negative breast cancer (TNBC) phosphoproteomics. Sara Fernandez Gaitero,1 Ivana Zagora,1 Jose Francisco Lopez-Acosta,1 Gonzalez-Gomez-Lopez,1 David Gonzalez-Pisano,1 Javier Munoz Peralta,1 Luis Manso,2 Soledad Alonso,1 Renke Penning,1 Maarten Altelaar,1 Albert J.R Heck,1 Miguel Quintana-Fandino1.1 Spanish National Cancer Research Center (CNIO), Madrid, Spain; 212 de Octubre University Hospital, Madrid, Spain; 3Hospital Universitario de Guadalajara, Guadalajara, Spain; 4Netherlands Proteomics Centre, Utrecht, Netherlands.

Background: We hypothesized that the biphasic relapse pattern of TNBC could be explained by a limited number of activation patterns of signaling nodes. In addition, we sought to determine whether the hyperactive signaling nodes, distinguishing the cases with favorable vs adverse outcome, could be potential targets. Methods: Training set of 34 frozen tumor samples divided in two sets, (A) 13 patients, relapsed in <4 years; (B) 21 patients relapse-free >12 years, (mimicking the percentage and relapse patterns of unselected TNBC, but paired for T, N, G and K67). TNBC cell lines: 7 indolent (no metastases in 60 weeks) and 3 aggressive, develop metastases and kill recipient mice in <4 months. Shotgun phosphoproteomics and TIO2-IMAC phosphopeptide enrichment coupled with mass spectrometry runs in a Orbitrap Elite Mass Spectrometer was performed. Spectra were processed with MaxQuant software. Differentially expressed phosphopeptides were obtained by applying linear models R limma package. Differential kinase activation driving the profiles segregating cured vs. relapsing cases was done using linear sequence motif analysis. The hyperactivated kinases were validated in an independent set of 113 consecutive TNBC cases with 12 years of follow-up spotted in TMAs by using an in-house algorithm for immunohistochemistry coupled with computer-aided quantitation using an Ariol scanning, we took the kinases in the upper quartile (high activity). Survival analysis was performed with KM curves and log rank test; and Cox proportionate hazards model was used for multivariate models. Results: 11405 phosphopeptides were identified and quantified in the training set. Supervised clustering of relapsed vs. cured cases showed that 161 and 541 peptides were significantly up-regulated in the A and B groups, respectively (FDR <0.15). After kinase-to-ki- nase co-linearity was ruled out, gathering the high activity (upper quartile) of six kinases (a combined variable, herein Var1) showed statistically significant association with relapse, being these: PRKCE, PRRK, KIT, CDK6, p70S6K and pPNPK. Cox proportional hazards model of any of the six probes high (var1) vs rest; 9.9 vs. not reached years (P=0.0001). Patients that had any of the 6 kinases in >40% of chance to relapse (only 2 out of 42 relapsed patients have 0/6 active kinases) vs patients with var1 negative, 7% of chance (29 patients out of 72 have 0/6 active kinases) we also observed constant patterns of activations in the different sets expressions of kinases. We considered the kinases at Var1 as a potentially targets and we developed a pharmacological in vitro assay, testing pairs inhibitors on 10 TNBC cell lines. For the combination of kinases we supposed that: High throughput p-proteomics allows a parsimonious segregation of early TNBC cases, easily detecting the cases with long-term cure vs the remaining while identifying potential therapeutic solutions for the patients falling in the adverse prognostic subgroups.

#1222 Developing kinase inhibitors with polypharmacological profiles for the treatment of resistant cancers. Suman Rao,1 Tan Li,1 Robert Eversley,1 Guangyan Du,1 Peter Sorger,1 Nathanael Grey1.1 Dana Farber Cancer Institute, Harvard Medical School, Boston, MA; 2Harvard Medical School, Boston, MA.

Small molecule kinase inhibitors targeting a specific oncprotein driving cancer cells have shown great clinical success in the past (e.g. imatinib against leukemia). However, resistance to targeted therapies quickly arises due to plasticity associated with cancer cell signaling and tumor heterogeneity. One way to overcome this problem is to rationally design drugs with polypharmacology that can target multiple signaling pathways engaging in cancer cell proliferation and survival. To this end, we have developed a strategy based on combining phenotypic screens of small molecule inhibitors and affinity-based mass spectrometry to identify drugs with multi-targeted properties and pilot this approach using the highly resistant KRAS mutant non-small cell lung cancer cell lines. We began this study by screening kinase inhibitors targeting MEK, ERK, PI3K, Akt and mTOR and found that the lung cancer cells were largely resistant to single drugs but showed enhanced sensitivity towards triple inhibition of MEK, ERK and PI3K. These cell lines were then screened with a library of covalent and non-covalent kinase inhibitors in an attempt to identify a small molecule inhibitor that could mimic the activity of the triple drug combination. This led to the discovery of SM1-71 that not only recapitulated the growth inhibitory activity of MEK+ERK+PI3K inhibition, but also blocked phosphorylation of ERK, Akt, mTOR and S6K in cells. Target profiling of the drug was carried out using chemical and cellular assays, which revealed SM1-71 inhibited 55 different kinases at a 1 μM concentration. Dose-dependent evaluation further determined the IC50 of inhibition across the 55 kinases and rank ordered them based on binding affinity. Top hits including MEK1, MEK2, ERK1, ERK2, AURKA, SRC and RPS6KA3 were confirmed using alternate kinase screens and cellular assays. Growth factor receptors such as IGFR1, MET and EGFR were also identified and further validated using both bioactivity-based assays and high-content cellular assays. The combination of polypharmacological and mass spectrometry-based target identification, we have demonstrated the proof of principle for developing kinase inhibitors with polypharmacology targeting resistant cancers.

#1223 Evaluation of the dual p38/ULK kinase inhibitor as potential therapeutic agent for tamoxifen-resistant breast cancer. XIAN WANG,1 Xizi Cao,2 Jumunari Veeraraghavan,1 Lanfang Qin,1 Jin-Ah Kim,1 Ying Tan,1 Susan G. Hilsenbeck,1 Rachel Schiff,1 Xiaosong Wang,1 1University of Pittsburgh, Pittsburgh, PA; 2Baylor College of Medicine, Houston, TX.

Background: Endocrine therapy has been considered an effective initial treatment for ER positive breast cancer and tamoxifen is the most commonly used endocrine agent. However, about half of the patients develop resistance or relapse eventually. No effective targeted therapy exists to overcome it. In our previous study, we have identified the role of nemo-like kinase (NLK) in breast cancer endocrine resistance—a serine-threonine kinase that functions in stress response and neurite outgrowth. In addition to NLK, activation of other stress kinases such as p38 MAPK has been reported to modulate ER signaling and promote endocrine resistance. In this study, we have identified a highly selective dual p38 and NLK kinase inhibitor (PNKI). This study aimed to evaluate the therapeutic effect of the PNKI inhibitor in tamoxifen-resistant breast cancers using in vitro and preclinical mouse models. Experimental design and methods: To determine the effect of PNKI on tamoxifen-resistant breast cancer cells, we treated a primary tamoxifen-resistant breast cancer cell line MDAMB415 and an acquired-resistant line MCF7/TamR, with 0.5 μM PNKI in the presence of different doses of Tamoxifen. To evaluate the therapeutic effect of PNKI in a T47D-derived xenograft tumor model with acquired tamoxifen resistance, we administered PNKI alone or in combination with Fulvestrant, or with the mTOR inhibitor Everolimus. Mice bearing T47D-TamR xenografts were randomized into six treatment groups (Vehicle, PNKI, Fulvestrant, Fulvestrant + PNKI, Everolimus, Everolimus + PNKI). Tumor growth was tracked closely. The tumors harvested 2 weeks following treatments were profiled with Reverse Phase Protein Array (RPPA) to assess the early signaling changes after treatments. Furthermore, the therapeutic effect of PNKI were also evaluated in a patient-derived xenograft (PDX) model of de novo endocrine resistant breast cancer. Mice bearing the PDX tumors were randomized to one of four treatment groups (Vehicle, PNKI, Everolimus, Everolimus + PNKI) and tumor growth curve was measured. Summary of the Results: Breast cancer cell lines with either de novo or acquired Tamoxifen resistance became more sensitive to tamoxifen when treated with 0.5 μM PNKI. The concomitant treatment of PNKI and Everolimus results in significant decrease of tumor growth in the T47D-TamR xenograft tumor compared to Fulvestrant, Fulvestrant + PNKI, or Everolimus treatments. RPPA data revealed that a majority of key survival signaling in breast cancer are repressed only when PNKI are combined with Everolimus. The de novo endocrine-resistant PDX tumors showed diverse response to PNKI mono-treatment, whereas the combination of PNKI and Everolimus resulted in significantly decreased tumor growth. Conclusion: The PNKI exhibited potential therapeutic value as adjuvant agent to the mTOR inhibitor everolimus for acquired or de novo tamoxifen-resistant breast cancer.

#1224 Combination of rapamycin and crizotinib induces partial remission of pleural mesothelioma in a patient-derived xenograft model. Dina Mönch,1 Sabine Bode-Erdmann,2 Jörg Kalla,2 Jorn Sträter,4 Carsten Schwänen,5 Roger-Fei Falkenstein-Ge,3 Martin Kimmich,3 Martin Kohlhäuf,5 Godehard Friedel,2 German Ott,1 Claudia Kalla,1 Department of Clinical Pathology, Robert-Bosch-Krankenhaus, Dr. Margarete Fischer-Bosch-Institute of Clinical Pharmacology, University of Tübingen, Stuttgart, Germany; 2Institute of Pathology, Schwäbisch-Baar-Klinikum, Villingen-Schwenningen, Germany; 3Ambulantes Onkologiezentrum, Klinikum Eslinge und Institute of Pathology, Eslinge, Germany; 4Center for Palmonology and Thoracic Surgery, Klinik Schillerhöhe, Stuttgart, Germany.
Introduction: Malignant pleural mesothelioma (MPM) is a neoplasm with inferior prognosis and notorious chemotherapeutic resistance. New treatment approaches may be based on specific inhibitors against kinases that are overexpressed in MPM, such as mTOR and MET. Here we examined the tyrosine kinase ALK as a potential therapeutic target and the combinatorial efficacy of the ALK/MEK inhibitor crizotinib and the MEK inhibitor vemurafenib. We investigated the ALK status and the expression of mTOR and MET in 145 primary MPM and 8 murine patient-derived xenograft models. ALK overexpression, rearrangement and mutation were studied by qRT-PCR, FISH, immunohistochemistry and sequence analysis. Expression of mTOR and MET was analyzed by qRT-PCR and immunohistochemistry. The combined anti-tumor effect of vemurafenib and crizotinib was evaluated in a patient derived xenograft model. Effects of single drug vs. combination treatment on proliferation, apoptosis and autophagy were assessed using Ki-67 immunohistochemistry, TUNEL assay and LC3B immunofluorescence, respectively. Results: Overexpression of ALK transcripts was detected in 25 (19.5%) of 128 interpretable primary MPM and two xenograft tumors and was neither associated with ALK rearrangement nor with mutation of the kinase domain. ALK protein was expressed in 8.3% MPM and the two xenograft tumors expressing ALK transcript. mTOR protein expression was detected in 28.7% MPM, co-expressed with ALK and/or MET in 17.8% MPM. Applied to a patient derived MPM xenograft model that co-expressed ALK, MET and mTOR, crizotinib alone did not exert anti-tumor growth activity, but enhanced the anti-tumor effect of vemurafenib: Rapamycin with vemurafenib inhibited tumor growth in 86% of xenograft tumors (pathological complete regression in 2 cases). Combination treatment was active in all 5 tumors (partial remission in 4, stable tumor in 1 case). Simultaneous treatment with rapamycin and crizotinib, however, significantly suppressed tumor proliferation compared to rapamycin-single treatment. Autophagy was induced by both single drug treatments and distinctly enhanced by combination treatment, while apoptosis was not promoted. Conclusion: Dual combinatory treatment of rapamycin and crizotinib is more effective than rapamycin as single agent in suppressing MPM tumor growth and therefore merits further investigation.

### 1225 A unified model of RAF inhibitor action determines inhibitor activity in RAF-dependent tumors. Zoi Karoulia,1 Yang Wu,2 Tamer A. Ahmed,1 Qisheng Xin,1 Julien Bollard,1 Clemens Krepler,2 Xuwei Wu,1 Chao Zhang,1 Gideon Bollag,1 Meenhard Herlyn,3 James A. Fagin,5 Amaia Lujambio,1 Mount Sinai, New York, NY;2Albert Einstein College of Medicine, Bronx, NY;3The Wistar Institute, Philadelphia, PA;4Plexxikon, California, CA;5Memorial Sloan Kettering Cancer Center, New York, NY. The FDA approved RAF inhibitors vemurafenib and dabrafenib have elicited profound responses in melanoma patients with tumors harboring BRAFV600E mutation, but resistance limits their effectiveness. Furthermore, RAF inhibitors exhibit only modest efficacy in colorectal and thyroid BRAFV600E mutants and they are not effective in tumors harboring non-V600 BRAF mutations. While RAF/MEK inhibitor combinations demonstrate increased clinical efficacy, drug resistance develops as well, through similar mechanisms to those identified in RAF inhibitor monotherapy. This suggests that insufficient RAF inhibition limits treatment efficacy and indicates the need for more effective therapeutic approaches to potentially and durably target RAF/ERK signaling. Although the unique biochemical properties of RAF inhibitors have been a topic of intensive investigation, a unified model of RAF inhibitor action has been lacking. Our biochemical and structural analysis in a panel of RAF inhibitors with different chemical properties and support therapeutic strategies in which relatively lower, non-toxic concentrations of RAF inhibitors will be administered in combination with currently approved RAF and MEK inhibitor regimens for the treatment of BRAFV600E melanoma, colorectal and thyroid cancers, as well as for tumors with BRAF mutations other than V600.

### 1226 Targeting BTK family in ER+ breast cancer with Ibrutinib for personalized precision medicine: a double-edge sword. Yen Gäkmén-Polar, Xiaoping Gu, Edyta Vieth, Sunil Badve. Indiana Univ. School of Medicine, Indianapolis, IN. Background: Metastasis is the principal cause of morbidity and mortality from breast cancer. Although current therapies are effective in early-stage of breast cancer, resistance to therapy is common leading to the development of metastasis. The commonest site of metastases is the regional lymph nodes. The presence and the number of involved lymph nodes remains the single best predictor of metastases and an important guide for the use of systemic adjuvant therapy. Identification of the underlying molecular targets of lymph node metastasis and a better understanding how to therapeutically target these will be a significant step in the goal of prevention of metastases. Experimental Design: To determine the key players associated with the development of metastasis in breast cancer, we performed RNA sequencing (Illumina Paired-end RNA-seq) analysis in a cohort of matched pairs of primary and (nodal) metastatic tumors (n=18). Gene expression profiles were analyzed using DESeq2. For targeted therapeutics, we performed orthotopic tumor implantation into mammary fat pads of athymic nude mice of breast cancer models. Results: Our results identified significant differential expression of the Bruton’s tyrosine kinase (BTK) family members in nodal metastasis. Among the family members, BTK, BLK, BTK/CAS and AK3 were expressed at very high levels as compared to matched primary tumors. Among the 51 breast cancer cell lines analyzed, the BTK genes were significantly upregulated in luminal, but not basal cell lines. Categorized by the molecular subtypes of breast cancer, hormone receptor- positive (HR+) and /or HER2 overexpressing breast cancer cell lines present higher BTK expression. Among the 51 breast cancer cell lines analyzed, the BTK genes were significantly regulated in both ER+ and HER2- (T47D and ZR75.1) and ER+HER2+ (BT-474 and ZR75.30) breast cancer cell lines. Ibrutinib, a selective and irreversible inhibitor of BTK targeting the cysteine-481 residue in the active site, exhibited potent activity in preclinical models of BTK-expressing targets. Ibrutinib decreased primary tumor growth significantly in ER+HER2+ (BT-474) mouse xenograft model in a dose dependent manner (10 mg/kg vs 25 mg/kg, P<0.05), whereas it promoted the tumor growth in a significant manner in ER+HER2- xenograft models (T47D and ZR75.1; P<0.05). The differences might be due to the differences in model systems due to the HER2 presence. Conclusion: Our data suggests that differential expression of target genes can be used to select agents as treating cancer. However, caution is necessary, as, in some situations, this might lead to enhancement of the growth in vivo in subsets of breast cancer.

### 1227 Angiotensin-(1-7) reduces triple negative breast cancer brain metastatic growth in association with decreased c-Met signaling. E. Ann Tallant, Guorui Deng, Wenhong Chen, Linda J. Metheny-Barlow, Patricia E. Gallagher. Wake Forest School of Medicine, Winston-Salem, NC. Patients with triple negative breast cancer often develop metastatic brain disease, a situation not efficiently addressed by current therapeutic options. We hypothesized that heptapeptide hormone angiotensin (Ang)-(1-7) is a therapeutic modulator that efficiently crosses the blood brain barrier. In the current study, we investigated the effect of angiotensin-(1-7) [Ang-(1-7)], a heptapeptide hormone with anti-proliferative and anti-metastatic activities, on the growth of murine brain tumors using brain trophic BR.5-4T1 cells in a model of metastatic triple negative breast tumor growth. BR.5-4T1 cells (1.25 x 104) were injected into the internal carotid artery of female BALB/c mice; after two days, mice were implanted with osmotic mini-pumps to deliver 24 µg/kg/h Ang-(1-7). P2.2% intumors 6.7% to 6.4% in mice treated with Ang-(1-7) treatment significantly reduced metastatic tumor burden in the brain; an average of 20 metastatic lesions per mouse was observed in the brains of an untreated control cohort while an average of 3 metastatic tumors per mouse was observed in the Ang-(1-7)-treated cohort. Tumor size was also reduced 17-fold by treatment with Ang-(1-7). Ki67, a marker of proliferation, was decreased from 29.1±6.7% to 6.4±2.2% in tumors from mice treated with Ang-(1-7), indicating that the heptapeptide hormone decreased metastatic tumor burden in the brain. Aberrant activation of the c-Met receptor tyrosine kinase signaling pathway facilitates tumor cell invasion and metastasis. Treatment with Ang-(1-7) significantly reduced the percentage of metastatic tumors per mouse was observed in the Ang-(1-7)-treated cohort. Tumor size was also reduced 17-fold by treatment with Ang-(1-7). Ki67, a marker of proliferation, was decreased from 29.1±6.7% to 6.4±2.2% in tumors from mice treated with Ang-(1-7), indicating that the heptapeptide hormone decreased metastatic tumor burden in the brain. Aberrant activation of the c-Met receptor tyrosine kinase signaling pathway facilitates tumor cell invasion and metastasis. Treatment with Ang-(1-7) significantly reduced the percentage of metastatic tumors per mouse was observed in the Ang-(1-7)-treated cohort. Tumor size was also reduced 17-fold by treatment with Ang-(1-7).
4.1±1.4% in sections of tumors from control mice compared to 8.8±0.9% in sections of tumors from mice treated with Ang-(1-7). These results suggest that Ang-(1-7) increases PTP1b to antagonize c-Met signaling and decrease triple negative breast cancer brain metastasis. In support of a role for c-Met signaling in the regulation of metastatic brain disease in breast cancer patients, analysis of publicly available breast cancer cohort databases demonstrated a significant correlation between low c-Met/high PTP1b expression and improved survival outcome, including an increase in brain metastasis-free survival and distant-metastasis free survival. This is the first report to demonstrate that Ang-(1-7) reduces metastatic triple negative breast cancer localized to the brain in association with increased protein phosphatase PTP1b and decreased phospho-c-Met, suggesting that the heptapeptide hormone may also serve as a novel targeted therapy to reduce metastatic brain tumor burden in triple negative breast cancer patients.

#1228 Nintedanib selectively inhibits the activation and tumor-promoting effects of fibroblasts from lung adenocarcinoma patients. Jordi Alcaraz,1 Marta Gabasa,2 Rafael Ikemori,3 Noemi Reguart.1 1. University of Barcelona, Barcelona, Spain; 2. University of Barcelona, Barcelona, Spain; 3. Hospital Clinic de Barcelona, Barcelona, Spain.

Nintedanib (BIBF 1120) is a multikinase inhibitor recently approved to treat lung adenocarcinoma (ADC) patients based on the therapeutic benefits reported in clinical trials on ADC but not on squamous cell carcinoma (SCC), which are the two most common lung cancer subtypes. However, the biological processes underlying the selective anticancer function of nintedanib in ADC remain obscure. To shed light on this gap of knowledge, we examined the role of tumor-associated fibroblasts (TAFs) in the differential effects of nintedanib in ADC and SCC. Because TAFs are largely quiescent and activated in vivo, we focused on the anti-fibrotic effects of nintedanib on TAFs stimulated with TGF-β1, which is a potent fibroblast activator frequently upregulated in lung cancer. Nintedanib dose-dependently inhibited the TGF-β1-induced expression of activation markers in both ADC-TAFs and control fibroblasts derived from uninvolved parenchyma, whereas such inhibition was very modest in SCC-TAFs, thereby suggesting that TAF activation is regulated by different mechanisms in ADC and SCC. Remarkably, nintedanib abrogated the stimulation of growth and invasion in a panel of carcinoma cell lines induced by secreted factors from activated TAFs in ADC but not SCC. These results reveal that nintedanib is a potent inhibitor of fibrosis and its associated tumor-promoting effects in ADC, and strongly suggest that the subnormal anti-fibrotic response of SCC-TAFs to nintedanib may underlie the lack of therapeutic benefits of this drug in SCC. Our findings also support that preclinical models based on carcinoma-TAF interactions may help unraveling the resistance mechanisms of SCC-TAFs to nintedanib and testing new combined therapies to further expand the therapeutic effects of this drug.

Despite recent advances in early detection and therapeutic intervention, colorectal cancer (CRC) remains one of the most deadly cancers in the United States. The Wnt/β-catenin and KRAS/BRAF-driven MAPK pathways were reported to cooperate in inducing CRC initiation and progression. Several studies have also identified Wnt signaling as a resistance mechanism in MAPK pathway-activated CRCs. Thus far, independent targeting of these single oncogenic events in CRC has yielded limited therapeutic success. RNA interference (RNAi) triggers are capable of silencing any expressed mRNA with high potency and specificity, including previously un-druggable targets such as β-catenin, an oncogene frequently dysregulated in CRC. DCR-BCT is a chemically-optimized DsiRNA targeting CTNNB1, the gene which encodes β-catenin, formulated in a second-generation EnCore lipid nanoparticle. We have previously reported extensive preclinical pharmacology for DCR-BCT in mouse tumor models of diverse origin. (Ganesh et al, Mol Cancer Ther 2016). Here we demonstrate that the dual inhibition of β-catenin and MEK demonstrates synergistic efficacy in not only primary CRC, but also in aggressive liver metastases of CRC in preclinical models. This combination of DCR-BCT and the MEK inhibitor trametinib was also efficacious in tumors which are known to be resistant to trametinib, as well as tumors which acquire resistance due to drug exposure. These data support clinical development of these combination approaches for this first-in-class RNAi therapeutic.

#1230 Talazoparib, a second generation PARP inhibitor, is a novel therapy for PTEN mutants in prostate cancer. Zachary Z. Reinstein, Rajita Vata-i, Jonathan Anker, Sahithi Pamarthy, Benedito Carneiro, Sarki Abdulkadir. Northwestern University, Chicago, IL.

Prostate cancer is the most common cancer among men, other than skin cancer. However, over 30% of patients diagnosed with prostate cancer have metastatic disease at the time of diagnosis. PTEN (phosphatase and tensin homolog on chromosome ten) is one of the most common lost or mutated tumor suppressor genes in human cancers, including ~50% of metastatic castration-resistant prostate cancer (mCRPC). By catalyzing PIP3 dephosphorylation, PTEN negatively regulates the PI3K-AKT pathway, which is frequently altered in mCRPC. Reintroduction of functional PTEN for mCRPC treatment has proven difficult. By employing self-catalyzing phospho-lysine chimeras and lipid-polymer nanoparticles, we successfully re-introduced PTEN mRNA to PTEN-null prostate cancer cells both in vitro and in vivo. These mRNA-loaded nanoparticles demonstrate high protein expression efficiency, low toxicity and good stability in serum and tumor accumulation. We confirmed that restoration of PTEN in PTEN-null prostate cancer cells inhibits the PI3K-AKT pathway, reduces cell viability and enhances apoptosis in vitro. Systemic delivery of PTEN mRNA-loaded nanoparticles in prostate xenograft tumors results in ~85% inhibition of tumor growth and leads to tumor cell death without toxic side effects in vivo. In summary, this work provides proof of concept of mRNA-based gene therapy for systemic restoration of functional PTEN for tumor suppression in vivo. It represents a novel approach to PI3K-AKT pathway inhibition, with the potential to specifically target cancers with loss of PTEN function.

#1231 Restoration of tumor suppression in vivo by systemic delivery of PTEN mRNA nanoparticles. Yingjie Xu,1 Mohammad Ariful Islam,2 Harshal Zope,3 Morteza Mahmoudi,2 Robert S. Langer,1 Jinjun Shi,2 Bruce R. Zetter,2 Omid C. Farokhzad1,2, Boston Children’s Hospital, Harvard Medical School, Boston, MA;3 Brigham and Women’s Hospital, Harvard Medical School, Boston, MA; 1. Massachusetts Institute of Technology, Cambridge, MA.

PTEN (phosphatase and tensin homolog on chromosome ten) is one of the most common lost or mutated tumor suppressor genes in human cancers, including ~30% of metastatic castration-resistant prostate cancer (mCRPC). By catalyzing PIP3 dephosphorylation, PTEN negatively regulates the PI3K-AKT-mTOR pathway, which is frequently altered in mCRPC. Reintroduction of functional PTEN for mCRPC treatment has proven difficult. By employing self-catalyzing phospho-lysine chimeras and lipid-polymer nanoparticles, we successfully re-introduced PTEN mRNA to PTEN-null prostate cancer cells both in vitro and in vivo. These mRNA-loaded nanoparticles demonstrate high protein expression efficiency, low toxicity and good stability in serum and tumor accumulation. We confirmed that restoration of PTEN in PTEN-null prostate cancer cells inhibits the PI3K-AKT pathway, reduces cell viability and enhances apoptosis in vitro. Systemic delivery of PTEN mRNA-loaded nanoparticles in prostate xenograft tumors results in ~85% inhibition of tumor growth and leads to tumor cell death without toxic side effects in vivo. In summary, this work provides proof of concept of mRNA-based gene therapy for systemic restoration of functional PTEN for tumor suppression in vivo. It represents a novel approach to PI3K-AKT pathway inhibition, with the potential to specifically target cancers with loss of PTEN function.

Background: Age-adjusted incidence and mortality rates for prostate cancer (PCa) among African American (AA) men are 1.6- and 2.4-fold greater, respectively, than among white men. More aggressive characteristics of AA PCa account for a significant component of the PCa disparity, in addition to social determinants of health. Previous work from our laboratory and others have identified deregula-
Hepatocellular carcinoma (HCC) is the most common form of primary liver cancer with limited treatment options for advanced stage disease. Thus, there is a critical medical need for improved therapies. In approximately 10% of HCC, a focal ampiclon at 11q13 harboring FGFR19 has been reported. High levels of FGFR19 have been shown to drive HCC tumor development and progression in preclinical models, targeting FGFR19 has the potential to inhibit growth of this receptor for FGFR19, may be efficacious in these HCC tumors. INC06026079 a potent and selective irreversible inhibitor of FGFR4 (>250-fold vs FGFR1/2/3) suppresses the growth of HCC cell lines driven by amplification and overexpression of FGFR19. In subcutaneous xenograft models of HCC, oral dosing of INC06026079 at tolerated doses resulted in dose-dependent inhibition of tumor growth with regressions observed at higher doses consistent with inhibition of FGFR4. In orthotopic tumors in vivo, the only approved targeted therapy for HCC, FGFR4 inhibition exhibited additive tumor growth inhibition in the Huh7 model. To assess efficacy of INC06026079 in orthotopic tumors after oral dosing, Hep3B tumors were implanted surgically into the liver and their development monitored by analysis of plasma alpha-fetoprotein (AFP). At efficacious doses, INC06026079 strongly suppressed the levels of AFP and FGFR19 secreted by the tumors, and their levels correlated well with the reduction in terminal liver tumor mass, suggesting that these may be surrogate markers for response of HCC tumors to INC06026079. In two PDX models with HCC with amplification of FGFR19 (4-6 CNV), INC06026079 administration reduced tumor growth by 50-66% at doses that were well tolerated. Established tumors xenografted with Huh7/ICGR/G4/S were inhibited up to 50% in several parameters related to FGFR19 regulation of bile acid metabolism. The mRNAs levels of CYP7A1, encoding cholesterol 7a-hydroxylase, the rate limiting enzyme in bile acid synthesis, were induced in the livers of cynomolgus monkeys upon dosing with INC06026079. Correspondingly there was a dose-dependent increase in fecal bile acids. In summary these data demonstrate that INC06026079 is highly and selectively efficacious in models of HCC with FGFR19 overexpression, indicating potential for drug development in HCC.

**#1233 WNT inhibitor ICG-001 prevents visceral metastatic triple negative breast cancer in a chemo-resistant patient derived xenograft - PDx model**

Iram Fatima, Ibkle El Ayachi, Chidi Zacheaus, Joseph Kerby Gray, Raya Krutilina, Tiffany N. Seagroves, Susan A. Krum, Gustavo A. Miranda-Carboni, University of Tennessee Health Science Center, Memphis, TN.

Triple negative breast cancer (TNBC) is characterized by absence of the estrogen receptor (ER) and progesterone receptor (PR), and human epidermal growth factor receptor 2 (HER2) amplification. Such cancers are highly aggressive and frequently metastasize to the lung and brain. Unlike other breast cancer subtypes such as, ER+ and PR+, TNBCs lack specific targeted-therapeutics; therefore, studies should be directed for development of targeted therapies to treat this condition. Recent studies indicate that Wnt/β-catenin signaling is particularly activated in TNBC and is associated with reduced overall survival in all patients. Therefore, pharmacological targeting of Wnt signaling pathway constitutes an ideal approach for treating TNBC and various Wnt inhibitors are currently in use in clinical trials, such as; ICG-001 in metastatic colon cancer. The inhibitory effects of ICG-001 have not been tested in chemoresistant TNBC/PDX tumors. Herein, we report for the first time that ICG-001 compound selectively inhibited the growth of several European American (EA) and African American (AA) triple negative breast cancer subtypes MDA-MB-231 and MDA-MB-468 both in vitro and in vivo models. To further investigate the precise mechanisms of action in the regulation of Wnt/β-catenin signaling by ICG-001, we performed Western blot analysis, apoptosis assays, cell cycle assays and quantitative real-time reverse transcriptase- polymerase chain reactions in human triple negative breast cancer cells. This compound significantly interfered with Wnt/β-catenin signaling, and its inhibition led to downregulation of important downstream targets such as Axin2, HMGGA2, PCNA, c-myc and Cyclin D1, which in turn led to inhibition of proliferation, cell cycle progression and metastasis confirming our previous results too. In addition ICG-001 inhibited the invasion and motility of tumor cells and showed inhibition and prevention of visceral metastatic PDX tumors from both chemoresistant EA and AA women. These results indicate that the Wnt inhibitor ICG-001 could constitute a powerful new chemotherapeutic agent against triple negative breast cancer.

**#1234 The novel FGFR4-selective inhibitor INC06026079 is efficacious in models of hepatocellular carcinoma harboring FGFR9 amplification.**

Bruce Ruggeri, Matthew Stubbs, Yan-ou Yang, Ashish Jovekar, Liang Lu, Sindu Condon, Darline DiMatteo, Xiaoning Wen, Paul Collier, Timothy Burn, Liangxing Wu, Daniel Wilson, Swamy Yeleswaram, Alan Roberts, Wenqing Yao, Gregory Hollis, Reid Huber, Peggy Scherle, Phillip CC Liu, Incyte Corporation, Wilmington, DE.

INCB062079 is a potent and selective FGFR4 inhibitor (P > 0.05) and in vivo surrogate markers for response of HCC tumors to INC06026079. In two PDX models with HCC with amplification of FGFR19 (4-6 CNV), INC06026079 administration reduced tumor growth by 50-66% at doses that were well tolerated. Established tumors xenografted with Huh7/ICGR/G4/S were inhibited up to 50% in several parameters related to FGFR19 regulation of bile acid metabolism. The mRNAs levels of CYP7A1, encoding cholesterol 7a-hydroxylase, the rate limiting enzyme in bile acid synthesis, were induced in the livers of cynomolgus monkeys upon dosing with INC06026079. Correspondingly there was a dose-dependent increase in fecal bile acids. In summary these data demonstrate that INC06026079 is highly and selectively efficacious in models of HCC with FGFR19 overexpression, indicating potential for drug development in HCC.

**#1235 EPHA-targeted therapy enhances the cytotoxicity of eicosapentaenoic acid against triple-negative inflammatory breast cancer.**

Angie M. Torres-Adorno,1 Heidi Vitrac,1 Yuan Qi,1 Yiyen Yang,2 Bedrich L Eckhard,2 Naoto T. Ueno,3 The University of Texas Graduate School of Biomedical Sciences at Houston, Breast Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX;1 Center for Membrane Biology, University of Texas Health Science Center, Houston, TX;2 Bioinformatics & Computer Biology, The University of Texas MD Anderson Cancer Center, Houston, TX;3 Biostatistics, The University of Texas MD Anderson Cancer Center, Houston, TX;4 General Oncology Research, The University of Texas MD Anderson Cancer Center, Houston, TX;5 Breast Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX.

Background: Inflammatory breast cancer (IBC) is the most aggressive form of breast cancer. We have previously reported that mediators of inflammation, such as COX-2, promote the growth of Triple-Negative receptor (TN) IBC xenografts; therefore, inflammation in TN-IBC has a unique opportunity as a therapeutic strategy. Eicosapentaenoic acid (EPA), a non-toxic omega-3 fatty acid with anti-inflammatory properties, has partially reduced tumor growth in preclinical models of TN-IBC. Therefore, our goal is to develop a novel non-toxic approach that enhances EPA efficacy against TN-IBC in combination with targeted therapy. Methods: Using a high-throughput, siRNA screen (939 genes) in the TN-IBC cell line SUM149PT, we identified Ephrin type-A receptor 2 (EPHA2), an oncogenic cell-surface receptor tyrosine kinase, as a target that modulates the sensitivity of TN-IBC cells to EPA treatment. To determine the clinical relevance of EPHA2, we interrogated a meta-analysis of breast cancer mRNA expression data sets, and found that high EPHA2 tumor expression was significantly correlated with poor overall survival in TN-IBC patients, compared to low EPAH2 expressing tumors (P = 0.01). We observed no significant correlations to other breast cancer subtypes. Similar findings were observed in vitro were EPAH2 expression predominantly occurred in the TN-IBC subtypes (19 of 30) among 49 breast cancer cell lines. Gain/loss-of-expression studies were performed to functionally validate EPAH2 as a synergistic combinational target with EPA in two EPHA2-expressing TN-IBC models, SUM149PT and BCX010, using proliferation and apoptosis assays in vitro and established tumor xenografts in vivo. EPAH2 gene silencing significantly reduced cell growth and induced apoptosis in combination with EPA when compared with untreated control and monotherapy in vitro (P < 0.05) and in vivo (P < 0.001), while vector-induced EPAH2 expression reversed cell growth re-
vitro (P < 0.05). To translate our findings to the clinic, we validated that dasatinib, a small molecule inhibitor of EPHA2, in combination with EPA significantly enhanced cell death of SUM149PT and BCX1010 cells in vitro when compared to non-treated and monotherapy (P < 0.05). Finally, using membrane fluidity assessment and reverse-phase protein array (300 antibodies), we determined that the treatment efficacy depended on EPA/EPHA2 inhibition-mediated increase in cell membrane rigidity (P < 0.001, compared to monotherapy), which subsequently inhibited receptor tyrosine kinase signaling activity, potentially resulting in induction of apoptosis. Conclusions: Our preclinical findings provide a rationale for the development of a phase 1 clinical trial investigating combination EPA and EPHA2-inhibitors in patients with EPHA2-positive TN-IBC.

#1236 Novel androgen receptor inhibitors in triple negative breast cancer. Saswati Bhattacharya, Yuanqi Cai, Steven Kurina, Benjamin Hokanson, Matthew Anderson, Ruth O’Regan. UW Madison, Madison, WI.

Triple negative breast cancer (TNBC), which lacks expression of hormone receptors and human epidermal growth factor receptor 2, has the worst prognosis of all breast cancer subtypes, due to inherent chemo-resistance and a lack of therapeutic targets. A subset of TNBC has been shown to express androgen receptor (AR) but despite promising pre-clinical data, clinical trials evaluating the use of approved anti-androgens (bicalutamide, enzalutamide) in AR-positive TNBC has shown modest efficacy to date. In prostate cancer, bicalutamide binds to AR with low affinity and in the presence of AR gene amplification or mutation, can exhibit partial agonist activity leading to resistance. In order to increase affinity for AR and to avoid the AR agonist to antagonist conversion, synthesized 7-substituted umbelliferones (UMB) derivatives with a distinct scaffold modified from available AR antagonists (Kandil et al Bioorganic & Medicinal Chemical Letters, 2016). These agents exhibited inhibitory activity in human prostate cancer cell lines at sub-micro molar level, a 50-fold and 30-fold improvement over bicalutamide and enzalutamide, respectively. We hypothesized that these novel AR antagonists would be effective in inhibiting the growth of AR-positive TNBC cells. Methods: TNBC AR negative mesenchymal MDA-MB-231 (as control) and AR positive MDA-MB-231 cells were utilized for determination of the efficacy of the UMB derivatives. For proliferation assays, viability of the cells was monitored over a period of 72 hours with redox dye Cell Titer Blue. Standard Western blotting techniques were used for protein detection. For apoptosis analysis, standard flow cytometry reagents, FITC labeled Annexin V and Propidium Iodin(Pi) mix were utilized. Results: UMB derivatives decreased the expression of AR in AR-negative MDA-MB-453 in a dose dependent manner. UMB derivatives, at micro Molar concentration decreased cell proliferation of AR-positive and interestingly AR-negative cell lines by 20 to 50%, also in a dose dependent manner. UMB derivatives induced apoptosis in both lines. Interestingly, UMB derivatives induced a decrease from epithelial to mesenchymal phenotype in AR-negative MDA-MB-231 cells, which was confirmed by decreased expression of vimentin and other mesenchymal markers. Conclusions: Novel UMB derivatives inhibit growth and cause apoptosis in TNBC cells and induce mesenchymal-to-epithelial transition in an AR-negative mesenchymal TNBC cell line. Targeting AR with novel AR antagonists seems to be promising therapeutic approach for AR-positive TNBC and further evaluation of AR antagonists in AR-negative mesenchymal TNBC is warranted.

#1237 PDGF induces cell growth and changes in glucose metabolism in colon cancer in the absence of PDGF receptors. Romana Moench, Tanja Grimning, Christoph-Thomas Germer, Ana Maria Waaga-Gasser, Martin Gasser. Univ. of Würzburg, Wuerzburg, Germany.

Background: The Platelet derived growth factor (PDGF) and its receptors play a major role in inducing proliferation, migration, and angiogenesis by activating intracellular PI3K/Akt/mTOR signaling events in different solid tumors and therefore represent attractive targets in tumor therapy. Recently we showed a PDGF-induced activation of metabolism and proliferation in HT29 colon cancer cells in the absence of specific PDGF receptors. The aim of this study was to analyze PDGF and VEGFR expression and possible alternative PDGF binding partners in colorectal cancer (CRC). Methods: Human HT29 colon cancer cells were cultured and stimulated with PDGF in a time-dependent manner. Additionally, VEGFR2 and EGFR inhibition was performed to analyze alternative PDGF signaling events. Whole cell or RNA extracts were analyzed by Western Blot and RT-q PCR for receptors and PI3K/Akt/mTOR signaling. To investigate the effects of specific receptor inhibition on proliferation, MTS proliferation assays were performed. Moreover, mRNA levels of PDGFR and VEGFR in tumors from patients with CRC were analyzed by RT-qPCR. Results: Human UICC stage I-IV tumors exhibited a significantly increased PDGFRβ and VEGFR1.2 gene expression. As observed previously, HT2 colon cancer cells showed only positivity for VEGFR1.2, but no PDGFR protein expression. Despite that, stimulation with PDGF resulted in increased proliferation and metabolic changes. In contrast, Caco-2 and SW480 colon cancer cells showed PDGFR and VEGF expression on protein level. Interestingly, PDGF stimulation induced a 20% increase in PDGFR and 2-fold increase in PDGFRα expression in HT29 colon cancer cells and secondly, stimulation with PDGFR inhibition of VEGFR2 and EGFR showed alterations in proliferation and Akt signaling in PDGFR stimulated cancer cells. Conclusion: Despite the absence of PDGFR receptors in HT29 colon cancer cells, PDGF induced proliferating and metabolic effects in the tumor cells, suggesting an alternative binding partner on the tumor cell surface. Further investigation of the alternative PDGFR binding partners could be of clinical relevance in CRC.

#1238 Targeting the platelet derived growth factor receptor (PDGFR) with the receptor tyrosine kinase inhibitor ponatinib in small cell carcinoma of the ovary, hypercalcaemic type. Jessica Diane Lang,1 William Hendricks,1 Pilar Ramos,2 Holly Yin,1 Chris Sereiduk,1 Jeffrey Kiefer,1 Yemin Wang,2 Anthony N. Karnezis,2 Bernard Weissman,3 David Huntsman,3 Jeffrey Trent.1 Translational Genomics Research Institute, Phoenix, AZ; 2British Columbia Cancer Agency, Vancouver, British Columbia, Canada; 3University of North Carolina at Chapel Hill, Chapel Hill, NC.

Subunits of the SWI/SNF chromatin-remodeling complex are tumor suppressors that are inactivated in ~20% of all cancers, yet few targeted treatments have shown selective activity in SWI/SNF-mutant cancers. Small cell carcinoma of the ovary, hypercalcaemic type (SCCOHT) is a rare, aggressive ovarian cancer in young women that universally driven by SWI/SNF dysregulation. Given that SWI/SNF proteins are lost in more than 90% of tumors, we developed a two-year survival following standard high-dose chemotherapy and radiation in SCCOHT is less than 35%, a great need exists for effective targeted therapies to improve outcomes for these women. We previously demonstrated that SCCOHT tumors are driven by inactivating mutations in SMARCA4, one of two mutually exclusive SWI/SNF ATPases. In addition, we have shown that SCCOHT lacks expression of the alternative SWI/SNF ATPase, SMARCA2. We have now found through integrated genomic and functional analyses in SCCOHT tumors and cell lines that SMARCA4 loss correlates with increased expression of receptor tyrosine kinases (RTKs) including the platelet derived growth factor receptors (PDGFRs). Through integration of high-throughput RNA interference and drug screens in SCCOHT cells we have identified sensitivity to RTK knockdown and RTK inhibitors including the FDA-approved oncolgy drug, ponatinib. These data corroborate prior studies showing RTK dependence in rhabdoid tumors, rare cancers that are also driven by mutations in the SWI/SNF complex. Of the known ponatinib targets, PDGFR-alpha and FGFR1 were highly expressed in SCCOHT tumors, as confirmed in RNA-Seq data (four tumors) and a SCCOHT tissue microarray (TMA; ten tumors). Further, we showed that PDGF-induced phosphorylation and downstream signaling are inhibited by ponatinib in SCCOHT cells, suggesting that these tumors are sensitive to ponatinib due to dependence on signaling through these RTKs. Finally, given ponatinib’s potency in vitro and the proposed mechanism of action, we tested this agent in xenograft models of SCCOHT. In addition to confirming efficacy in a SCCOHT cell line xenograft model, superior efficacy was demonstrated in two patient-derived xenograft (PDX) models of SCCOHT with ponatinib. Thus, ponatinib effectively targets SWI/SNF-mutant SCCOHT tumors through inhibition of PDGFR signaling and may have clinical utility for the treatment of these cancers.

The aim of this study is to evaluate the expression of the salvage pathway enzymes DCK, APRT, and HPRT in lung cancer cells to determine if they could serve as biomarkers for lung cancer diagnosis and potential treatment. In both men and women, lung cancer is the most lethal cancer in the world, and accounts for more than 30% of cancer-related deaths. We chose to evaluate the salvage pathway enzymes due to an established relationship between the serum biomarker Thymidine Kinase 1 (TK1) and lung cancer. Two non-small cell lung carcinoma cell lines were utilized for this analysis (NCI-H460 and A549) along with cancer tissue and healthy tissue from 27 lung squamous carcinoma patients. The surface localization of these enzymes was determined using flow cytometry, confocal microscopy, and scanning electron microscopy, while up-regulation within tissue was assessed using Immunohistochemistry (IHC). Throughout our investigation, we found no significant expression of DCK or APRT on the surface of non-small cell lung cancer cells, but found a significant presence of HPRT on the plasma membrane of both NCI-H460 and A549 cells.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Targeting Growth Factor and Intracellular Signaling

Proceedings of the American Association for Cancer Research • Volume 58 • April 2017 318
The average population florescence of cells treated with HPRT antibodies increased by 24.3% and 12.9% in NCI-H460 and A549 cells, respectively, in comparison to controls. To ensure expression was not attributed to cytoplasmic HPRT, confocal microscopy was performed to visualize HPRT binding on the plasma membrane. After staining NCI-H460 cells treated with both fluorescent antibodies and a membrane-specific dye, we observed a higher fluorescence intensity towards HPRT and the membrane of the cancer cells. Additionally, gold conjugated antibodies were used to label and quantify the amount of HPRT on the cell surface using scanning electron microscopy and EDAX. Further confirming HPRT presence, the gold weight percentage of the sample increased significantly when NCI-H460 cells were exposed to HPRT antibody (p-value 0.012) in comparison to isotype controls. Finally, the general upregulation of the protein was observed in patient tissue samples, with approximately 44% of lung cancer tissues showing significant HPRT upregulation when compared to healthy tissue samples. This differential upregulation shows an altered HPRT expression within some patients, which may help explain the presence of this presumed cytosolic enzyme on the surface of lung cancer cells. These results strongly indicate a unique relationship between cancer cells and HPRT and suggest HPRT as a possible biomarker for the detection and treatment of non-small cell lung cancers.

#1240 Evaluating clinically relevant pharmacological agents in a rat ambulation model to ameliorate PEGylated recombinant hyaluronidase PH20 (PEGPH20)-mediated musculoskeletal adverse events. Li Ma,1 Marc R. Azar,2 Michael Sheppard,1 Yu Huang,1 Piet A. Verraat,1 Daniel C. Maneval,1 Curtis B. Thompson,1 Rudy Paladini,11 Halozyme Therapeutics Inc., San Diego, CA; Behavioral Pharma, La Jolla, CA.

Some cancers accumulate high levels of the glycosaminoglycan hyaluronan (HA) within the tumor microenvironment (TME), and this HA accumulation is associated with rapid tumor progression and poor clinical outcomes. As preclinical data have demonstrated that enzymatic degradation of HA, via intravenous (IV) administration of PEGylated recombinant human hyaluronidase PH20 (PEGPH20), increases therapeutic efficacy in HA-accumulating tumors, several clinical trials evaluating PEGPH20 in combination with anti-cancer therapies are ongoing. The most advanced clinical trial (Phase 3) is evaluating PEGPH20 plus Abraxane® (nab-paclitaxel)/gemcitabine (AG) in patients with stage IV untreated pancreatic ductal adenocarcinoma (PDAC)(NCT02715804). The safety profile of PEGPH20/Abraxane/gemcitabine (PAG) was generally similar to AG alone in an interim analysis of the Phase 2 data, with the exception of a potential imbalance of thromboembolic events (TEs), and an increased incidence of musculoskeletal events (MSEs) in the PAG arm, with the predominant MSE being muscle spasms (55.4% PAG vs. 1.6% AG, all grades)(Bullock, ASCO 2016). In an effort to find pharmacological agent(s) that might decrease MSEs in PAG-treated patients, a rat locomotor activity assay was developed. In brief, locomotor activity of male Sprague Dawley rats was measured with an automated infra-red photobeam monitoring apparatus (Hamilton/Kinder®), San Diego) during the 12h dark cycle when rats are normally active. Any PEGPH20-mediated decrease in rat locomotor activity was interpreted as MSE-like effects. In response to PEGPH20 (1 mg/kg) the locomotor activity of male rats was reduced by ~75% for the first 2 dark cycles post-treatment (48h), and then gradually returned to vehicle baseline levels by days 4-5. FDA approved drugs used clinically to alleviate pain were subsequently tested for their ability to ameliorate the effects of PEGPH20 on locomotor activity. Agents included anti-inflammatories, anti-spasmodics, neuropathic pain medications, neuroleptics, diuretics, anti-hypertensives, anti-fibromyalgics and opioids. The steroid dexamethasone, currently being used in the Phase 2 and Phase 3 PDA clinical trials to manage MSEs, was the positive control. As a class, nonsteroidal anti-inflammatory drugs (NSAIDs), including ketorolac, ketoprofen, diclofenac, and piroxicam, increased rat ambulation by ~40% on the first night following PEGPH20 treatment compared to PEGPH20 alone. Mobility in rats treated with NSAIDs/PEGPH20 increased ~60% on the second night compared to PEGPH20 alone. No other drug classes increased rodent ambulation. These data suggest that NSAIDs may be useful in partially alleviating the MSEs experienced by patients receiving PEGPH20.

#1241 Preclinical study of the combined treatment of arginase and canavanine in pancreatic cancer. Tsz Tung Kwong, Chi Hang Wong, Herbert Ho Pung Loong, Stephen Lam Chan. The Chinese University of Hong Kong, Hong Kong, Hong Kong.

Background: Arginine deprivation is a novel approach for cancer treatment as some cancers were found to be arginine auxotrophic. PEG-BCT-100, a pegylated form of recombinant human arginase, was used to investigate the effect of argi- nine deprivation on pancreatic cell lines. On the other hand, Canavanine (CNAV), a natural toxic analog of arginine isolated from leguminous plant, has also demon-strated its ability in inhibiting cancer cell proliferation. It alters the protein structure and causes critical metabolic defects in the cells by replacing arginine into newly synthesized proteins during translation. In this study, we have also tested the efficacy of combined arginase and CNAV treatment on pancreatic cell lines with high levels of arginase expression. Membrane-bound PAG or cytosolic fibroblast cell line (WI-38), were either incubated in normal or arginine free condition. The corresponding IC50 of CNAV was determined by cell viability assay. To evaluate the responsiveness to the combined treatment, cells were monitored by live cell imaging under the conditions of PEG-BCT-100 treatment alone (0.3IU/ml) or in combination with CNAV (10μM or 50μM). The apoptotic effect of the treatment was examined by Western blotting’s DNA ladder assay. Results: Either arginase or CNAV treatment could inhibit pancreatic cancer cell growth. The cells treated with CNAV in arginine free condition demonstrated an inhibition of cell proliferation and its corresponding IC50 was significantly lowered from millimolar to micromolar concentration when arginine was withdrawn. Strong synergism of CNAV and PEG-BCT-100 was observed after 48-hour treatment with enhanced apoptosis in pancreatic cell lines, but not in normal fibroblast cells. Both early and late apoptosis were observed in co-treated pancreatic cancer cells as indicated by Annexin V assay and the detection of poly- ADP ribose polymerase (PARP) in Western blot. Conclusion: Arginine deprivation by PEG-BCT-100 combined with CNAV treatment showed a strong synergistic effect on inducing cell death in pancreatic cell lines, suggesting that the supplement of CAV could facilitate the treatment outcome of arginine de-privation by arginase. This combined treatment may serve as a treatment strat- egy for pancreatic cancer.

#1242 Ornithine decarboxylase as a therapeutic target in endometrial cancer. Hong Im Kim,1 Chad R. Schultz,2 Andrea L. Buras,3 Elizabeth Friedman,2 Alyssa M. Fedorko,2 Leigh G. Seamon,3 Gadiessi Chandramouli,4 André S. Bachmann,2 John I. Risinger,1 Michigan State University, Grand Rapids, MI; Grand Rapids Medical Education Partners, Grand Rapids, MI; Spectrum Health, Grand Rapids, MI; GenEprisa, Columbia, MD.

Endometrial cancer is the 4th most common cancer and the 6th deadliest cancer in US women. The American Cancer Society estimates there will be 60,050 new endometrial cancers in 2016, an increase of more than 10% from the previous year highlighting the need for more effective treatments and preven-tion. Ornithine Decarboxylase (ODC) a key enzyme in polyamine synthesis is often overexpressed in cancers and contributes to cell proliferation and tumor growth. Therefore, ODC and the polyamine pathway are considered rational targets for cancer treatment or prevention. We noted ubiquitous expression of ODC1 in our previously published endometrial cancer gene array data and confirmed this in the cancer genome atlas (TCGA), finding expression in all four molecular sub-types with highest expression in copy number high cancers which have the worst clinical outcomes. Therefore, we explored the association of ODC1 gene expression with clinical outcomes of overall survival (OS) and recurrence in the TCGA cohort and noted that elevated ODC1 was significantly related to OS (Wald test p = 0.001) and recurrence (p = 0.01). Importantly, we confirmed these observations using QRT-PCR in a validation cohort of 60 endometrial cancers and found that endometrial cancers with elevated ODC1 had significantly shorter recurrence-free intervals (p = 0.0014) with elevated hazard ratio 3.81. Numerous studies including clinical trials have examined the chemopreventive and anti-tumor effects of difluoro-metlyornithine (DFMO), a specific inhibitor of ODC. We found that DFMO treatment significantly reduced cell proliferation, cell viability, and colony for-mation in human cell line models derived from undifferentiated, endometrioid, serous, MMT and clear cell endometrial cancers. In contrast, immortalized uter-ine endometrial epithelial cells (EM E6/E7 TERT1) were less sensitive to DFMO. To confirm the significant effects of DFMO in vitro we performed an in vivo study with human endometrial cancer (AC1-98) tumor-bearing athymic nude mice. Tumor tissue was either treated with 2% (w/v) DFMO supplied in drinking water or water only (n = 10/group). DFMO significantly reduced the tumor burden in mice compared to controls (p = 0.0023). ODC-regulated polyamines (putrescine [Put] and spermidine [Spd]) known activators of cell prolif-eration were strongly decreased in response to DFMO, in both tumor tissue ([Put] (p = 0.0006), [Spd] (p < 0.0001)) and blood plasma ([Put] (p < 0.0001), [Spd], Results) of these studies indicate that some endometrial cancers appear particularly sensitive to DFMO. Our findings indi-cate that the polyamine pathway in endometrial cancers in general and specifi-cally those most clinically relevant endometrial cancers could be targeted for effective treatment, chemoprevention or chemoprevention of recurrence.
libraries for each cell line in duplicate as well as a counter screen using a reporter cassette that lacked let-7 binding sites. A compound was identified as a hit if it ranked within the top 100 compounds in the primary screen and outside the top 250 compounds in the counter screen. The hit rate for LIN28A positive cell line was 80% for the Prestwick and 74% for the LOPAC1280 libraries. For the LIN28B positive cell line, the hit rate was 80% for Prestwick and 53% for LOPAC1280 libraries. The hits were validated by assaying for let-7 levels using qRT-PCR. The hits identified included compounds that inhibited PI3K-mTOR, nFkB, c-MYC, Cyclin D1, BETI as well as aurora kinase. These targets have been reported in the literature to downregulate let-7 levels. In conclusion, our assay-system is the first to utilize a biological assay of let-7 levels for small molecule library screening thus serving as a valuable tool for cancer drug discovery.

#1245 Screening methodologies for the discovery of small molecule melanoma therapeutics targeted at the ErbB4 receptor tyrosine kinase. Richard L. Cullum,1 John T. Piazza,2 Jared I. Senfeld,1 Logan T. Neel,1 Ram B. Gupta,2 Allan E. David,1 David J. Riese,1 Auburn University, Auburn, AL;3 Virginia Commonwealth University, Richmond, VA.

Introduction: Gain-of-function mutations in the ErbB4 receptor tyrosine kinase have been found in a significant fraction of melanoma cell lines that are dependent on ErbB4 for proliferation. However, there is a scarcity of therapeutics for treating these ErbB4-dependent tumors. Consequently, we have developed high-throughput screening assays to identify small molecule ErbB4 antagonists that may hold promise as targeted melanoma therapeutics. Our approach is based on the observation that the Q43L mutant of the ErbB4 agonist Neuregulin 1beta (NRG1β) functions as a partial agonist at ErbB4. NRG2β/Q43L stimulates ErbB4 tyrosine phosphorylation, fails to stimulate ErbB4-dependent cell proliferation, and competitively antagonizes agonist stimulation of ErbB4-dependent cell proliferation. Experimental procedures: Therefore, we have developed three high-throughput screening assays to identify ErbB4 partial agonists that function as antagonists. The primary screen identifies molecules that stimulate ErbB4 tyrosine phosphorylation. The secondary screen identifies molecules that stimulate or fail to stimulate ErbB4-dependent cell proliferation. The tertiary screen identifies molecules that antagonize agonist stimulation of ErbB4-dependent cell proliferation. Results: A phospho-ErbB4 sandwich ELISA assay identifies molecules that stimulate ErbB4 tyrosine phosphorylation with high sensitivity and fidelity (Z’ > 0.5). IL3-independence assays in conjunction with MITT assays using a cell line that displays ErbB4-dependent cell proliferation distinguish between molecules that stimulate and fail to stimulate ErbB4-dependent proliferation (Z’ > 0.5) and identify molecules that antagonize agonist stimulation of ErbB4-dependent proliferation. These assays have been used to identify small molecules that stimulate ErbB4 tyrosine phosphorylation. Efforts to determine whether these hits function as ErbB4 full agonists or partial agonists (antagonists) are underway and will be reported. Structures of these small molecule ErbB4 full and partial agonists may be reported, pending submission of a provisional patent application. Conclusions: We have validated an HTS strategy for identifying ErbB4 partial agonists that function as ErbB4 antagonists and deployment of that strategy has led to the identification of several hits (~ 20 from the primary screen). Such molecules may hold promise as targeted therapeutics for melanoma and other ErbB4-dependent tumors.

#1246 Development of a novel KRAS-targeting agent: systematic validation using in silico, in solution, cell models, PDX and transgenic mouse models. Arsheed Ahmad Ganaie,1 Hifzur R. Siddique,1 Ishfaq Sheikh,1 Lei Wang,1 Aijaz Parry,2 Jayanthi panyam,3 Peter Villalta,1 Joshua Liao,1 Yibin deng,1 Mohammad saleem,2 1University of Minnesota Hormel Inst., Austin, MN, 2Univ. of Minnesota Hormel Inst., Minneapolis, MN.

Aberrant KRAS signaling plays an important role in the pathogenesis of malignancies including pancreatic (PDAC), colon and lung cancer. Because therapeutics targeting either downstream or associated factors of KRAS pathway have shown dismal results in clinics, there is a need to identify effective agents targeting active KRAS (GTP-KRAS) protein. In this study, we screened a chemical library for their efficacy to inhibit KRAS activity using in silico methods. Based on their binding energy, we selected a candidate agent (LP1) that exhibited high potential of binding to KRAS protein at a region where KRAS-activator protein “SOS1” binds to, and GDP-GTP exchange takes place. We next investigated if LP1 exhibits the efficacy of KRAS binding in biological solution using recombinant proteins and employing drug development techniques i.e., florescence (FL)-based competition, Isothermal Titration Calorimetry (ITC) and Surface Plasmon Resonance (SPR) assays. The FL-based study showed that LP1 inhibits the binding of SOS1 protein and GTP molecules to KRAS protein. The ITC and SPR analysis showed that LP1 binds to the KRAS protein (at 10 μM). We next deter-
mained the KRAS-inhibitory potential of LP1 in activated-KRAS cells representing premalignant and malignant models of PDAC, colon and lung cancer. Disassociation study involving incubation of KRAS/SOS1 proteins showed the LP1 inhibits the binding of SOS1 to KRAS. Notably, LP1 therapy significantly decreased the (i) KRAS-GTP protein levels (ii) growth and (iii) proliferation of activated KRAS single cell and 3D Organoid cultures. We next tested KRAS-inhibitory efficacy of LP1 in PDAC patient-derived (PD) tumor explants and found that LP1 therapy (10 days) significantly decreased growth of, and KRAS-GTP levels in PD explants. Based on the in silico, in solution, cell model and PD-explant data, we determined the efficacy of LP1 as a KRAS inhibitor in vivo conditions. We first performed the pharmacokinetic study of LP1 in mice and observed that LP1 is physiologically available in the blood (peak of 15-20 μM) after oral and intraperitoneal administrations and detectable up to 24h post-administration. We next tested LP1 therapy in tumor xenograft models and show that LP1 therapy significantly reduces the tumorigenicity of KRAS-activated PDAC and colon cell-derived tumors implanted in athymic mice. We next tested efficacy of LP1 administration on the developmental phases of PDAC disease (from normal to high grade neoplasia/early stage carcinoma) and show that LP1 feeding for six months caused a significant inhibition of PanIN development in KPC(T1212) transgenic mouse model. Notably the analysis of tumors xenograft models and pancreatic tissues of KPC(T1212) mice receiving LP1 therapy exhibited reduced KRAS-GTP levels. Taken together, these data show that LP1 is a potent KRAS activity inhibitor and a potential candidate for clinical use against KRAS-driven cancers.

Development and growth of a tumor as well as its ability to metastasize involves a complex relationship with its tissue microenvironment. A proliferating tumor encounters several microenvironmental stress conditions such as hypoxia, lack of nutrients and acidosis. To cope with these conditions, cancer cells have developed elaborate cytoprotective mechanisms which provide them with distinct advantages to thrive. Thus, deciphering the signaling pathways which get activated in the tumor microenvironment has been paramount to develop new therapeutic strategies for treatment. The Unfolded Protein Response (UPR) is an adaptive prosurvival pathway elicited by stresses in the tumor microenvironment (e.g., hypoxia, low glucose) and involves translational and transcriptional activation of effector genes which act to relieve cellular stress and block cancer cell death. We developed a strategy to comprehensively analyze critical mediators of cell fate in response to UPR activation. We have delivered a lentiviral genome-scale CRISPR-Cas9 knockout (GeCKOv2) library to mouse PCa cell lines (human squamous head and neck carcinoma) and A375 (human melanoma) cells. The library is targeting 19,050 genes with 123,411 unique guide sequences and enables both negative and positive selection screening. We used the GeCKO v2 library to identify genes essential for triggering the UPR in response to thapsigargin and tunicamycin, known specific activators of ER stress. Our highest-ranking candidates include BIRC5/Survivin, a well-studied molecule that is an inhibitor of apoptosis and is highly expressed in cancer cells and eukaryotic translation initiation factor eIF6, whose overexpression increases motility and invasiveness of cancer cells. Our preliminary results indicate that loss of Survivin and eIF6 dramatically enhance sensitization of cells to various ER stress conditions. Moreover, this synergistic outcome is observed when cells are treated with YM155, a small molecule that selectively suppresses Survivin, and is used in phase I/II clinical trials. Lastly, morphological changes like endoreduplication are observed after long term absence of Survivin indicating its endogenous ER stress inducing role. Taken together, Survivin and eIF6 are important mediators of survival following ER stress and characterizing the pathways involved can lead to the development of novel targeted agents and therapeutic approaches.

#1248 Adult calorie restriction reduces weight gain and mammary tumor incidence in obesity prone MMTV-TGF-α mice. Michael E. Grossmann, Nancy K. Mizuno, Da-Qing Yang, D. Joshua Liao, Margot P. Cleary. Univ. of Minnesota Hormel Inst., Austin, MN.

Obesity is associated with increased risk of postmenopausal breast cancer resulting in recommendations for weight gain prevention and/or weight loss.

However, there is little experimental data indicating if calorie restriction (CR) initiated in adulthood impacts mammary tumorigenesis. We have used female MMTV-TGF-α mice which develop mammary tumors in the 2nd yr of life as a model of postmenopausal breast cancer. From 10-30 weeks of age (woa) mice were fed a diet with 33% fat calories. At 30 woa based on body weight mice were assigned to ad libitum (AL), 52% fat calories (Ob-R), and 33% fat calories (Ob-P) diets. Half in each weight category were then fed a 25% CR diet with reduced carbohydrate content (43% fat calories). The remaining mice continued on ad libitum (AL) feeding of the 33% fat calories diet. This resulted in six experimental groups (n = 26-31/group). Food intakes were monitored and body weights and mammary tumor status were determined weekly. Mice were sacrificed either at 90 woa or earlier if tumor size dictated. Mice in the CR-Ob-P group lost an average of 1.12 grams while mice in the AL-Ob-Pr group gained 16.03 grams from 30 woa until euthanaisa. CR-Ob-P mice had a reduced palpable tumor incidence as compared to AL-Ob-P mice prior to euthanaisa (12.90% versus 61.54% P = 0.0002). Indolent tumors were discovered at euthanasia with the CR-Ob-P mice having a larger number than AL-Ob-P mice resulting in final tumor positive mice in these groups of 54.84% vs 65.38%, respectively. Interestingly, the Ob-R mice had final tumor incidence of 38.71% and 73.08% for the CR-Ob-R and the AL-Ob-R (P < 0.01). Average tumor weight was highest in the AL-Ob-P group with CR resulting in a significantly lower tumor weight (P < 0.001). The AL-Ob-P group had the shortest average survival time of 82.96 woa while CR of the Ob-P mice resulted in increased survival to 89.77 woa (P < 0.001). A comparison of the survival curves of CR of these two groups showed a significantly increased survival (P < 0.0001). Results of this study indicate that initiation of moderate 25% CR during adulthood reduces weight gain, mammary tumor incidence, and tumor weight as well as increases lifespan even when a moderately high fat diet was consumed. This information supports further efforts to be made to prevent weight gain as women approach menopause to delay or prevent breast cancer development. Support: NIH-CA157012, The Hormel Foundation and Paint the Town Pink.

#1249 Procyanidin B2-3,3′-di-O-gallate targets cancer cell metabolism in its efficacy against human prostate carcinoma cells. Chapla Agarwal, Dileep Kumar, Alpna Tyagi, Natalie Serkova, Michael Wempe, Komal Raina, Rajesh Agarwal. Univ. of Colorado Denver, Aurora, CO.

The metabolic profile of various cancerous tissues can be correlated with cell growth and death, specific tumor type as well as the pathological stage of tumor. In recent times, prostate tissue metabolomics using spectroscopy methods has helped to identify and establish the metabolic profiles specific to prostate cancer (PCa) malignancy. Thus, the evaluation of the anticancer efficacy of an agent can be considered incomplete without assessing its effect on the metabolic profile of the tumor tissue. With this rationale, herein, we carried out a metabolomics study of human PCa cell lines (PC3) androgen independent (B2G2) on Procyanicin B2-3,3′-di-O-gallate exposure, which was recently identified by us as most effective agent in grape seed extract for growth inhibition and apoptotic death of human PCa cells. Specifically, we employed quantitative high-resolution nuclear magnetic resonance spectroscopy (1H-, 13C- and 31P-NMR) to assess the metabolic profile and energy state of the B2G2-treated human PCa cell lines PC3 and C42B. This approach helped us assess global metabolic profile, including glucose metabolism, energy state, and lipid metabolism in these cells after B2G2 treatment. We also studied the time-course (4-72 hrs) of B2G2 effect on glucose uptake and lactate release in the media of B2G2-treated PCa cells. Our results indicated that there was differential effect of B2G2 on mitochondrial glucose metabolism in these cells. While glucose uptake was markedly reduced as a function of time, there was also a significant increase in extracellular lactate export with increased B2G2 exposure-time. Importantly, B2G2 preserved citrate concentration in the PCa cells as indicated by an increase in citrate levels after treatments; citrate generation is indicative of normal secretion functions of the prostate epithelial cells. The fact that the citrate was not further utilized for cholesterol synthesis was also confirmed by a decrease in cholesterol levels in these cells, indicating decreased cholesterologenesis by B2G2. Together, these results suggest that B2G2 differentially induces metabolic alterations in various PCa cell lines, which could be associated with its effects on cell growth, proliferation and death, as well as androgen dependency (or lack of it). In vivo study examining B2G2 effect on PCa PC3 tumor xenograft growth in athymic nu/nu mice, B2G2 treatment (dose: 3mg/kg body weight of mice; given daily as intraperitoneal injections) significantly decreased tumor volume and tumor weight by ~61% and ~52% (both P < 0.01), respectively, after 5 weeks of treatments. Taken together, these studies indicate anti-PCa efficacy of B2G2 under both in vitro and in vivo scenario and warrant further extensive studies to establish its efficacy in other PCa models.
#1250 Curcumin inhibits migration and growth of human colon cancer cells through covalent modification of oncogenic SIRT1: Cysteine 67 as a potential binding site. Yeon-Hwa Lee,1 Na-Young Song,1 Do-Hee Kim,1 Hye-Kyung Na,2 Young-Joon Suh1. 1Tumor Microenvironment Global Core Research Center, College of Pharmacy, Seoul National University, Seoul, Republic of Korea; 2College of Human Ecology, Sungkyun Women’s University, Seoul, Republic of Korea.

Silent mating type information regulator 2 homolog 1 (SIRT1), an NAD+-dependent histone/protein deacetylase, has diverse physiological functions, including metabolic regulation and stress response. Despite extensive research, however, the role of SIRT1 in tumorigenesis remains controversial. Recent studies have demonstrated that SIRT1 is abnormally overexpressed in several human malignancies, and elevated levels of SIRT1 are correlated with the tumor invasion and metastasis. Curcumin (diferuloylmethane), a major component of the spice turmeric (Curcuma longa L.), has been reported to possess anti-inflammation and anti-carcinogenic properties. In the present study, we found that SIRT1 is predominantly overexpressed in the cytoplasm of several colorectal cancer cells as well as colon tumors. Curcumin abrogated migration and colony forming capability of human colon cancer (HCT-116) cells. This prompted us to investigate the effect of curcumin on the expression of SIRT1 and underlying molecular mechanisms in the context of its inhibition of the migration and growth of these cells. When HCT-116 cells were treated with curcumin, the protein expression of SIRT1 was significantly reduced, but the level of its mRNA transcript was not altered. The curcumin-induced decrease in SIRT1 protein expression was abrogated by the proteasomal inhibitor, MG-132. When HCT-116 cells were treated with curcumin, ubiquitination of SIRT1 was elevated. Notably, tetrahydrocurcumin, a non-electrophilic analogue of curcumin that lacks the α,β-unsaturated carbonyl moiety, failed to ubiquitinate and degrade SIRT1. Nano-LC-ESI-MS/MS analysis revealed the modification of the SIRT1 cysteine67 residue. In line with this observation, the protein stability of a mutant SIRT1 in which cysteine 67 was replaced by alanine (SIRT1-C67A) was unaffected by curcumin treatment. Furthermore, migration and anchorage-independent growth of cells expressing SIRT1-C67A were barely inhibited by curcumin compared with those in cells harbouring wild-type SIRT1. Lysates of HCT-116 cells incubated with curcumin-conjugated Sepharose-4B beads exhibited covalent binding of curcumin to SIRT1. However, such direct interaction was markedly reduced in cells with SIRT1 cysteine 67 mutation. Taken together, these findings suggest that curcumin exerts inhibitory effects on progression of colon cancer through destabilization of oncogenic SIRT1. The electrophilic α,β-unsaturated carbonyl group present in curcumin can covalently modify SIRT1, preferentially at the cysteine 67 residue, facilitating its degradation via the ubiquitin-proteasome pathway in HCT-116 cells.

#1251 Pioglitazone inhibits periprostatic white adipose tissue inflammation in obese mice. Miki Miyazawa,1 Kotha Subhadra,1 Priya Bhardwaj,2 Xi Kathy Zhou,2 Hanhan Wang,1 Domenick J. Falcone,1 Dilip D. Giri,2 Andrew J. Dannenberg1. 1Weill Medical College of Cornell University, New York, NY; 2Memorial Sloan Kettering Cancer Center, New York, NY.

Obesity is associated with an increased incidence of high-grade prostate cancer (PC) and poor prognosis for PC patients. Recently, we showed that obesity-related periprostatic white adipose tissue (WAT) inflammation, characterized by crown-like structures (CLS) consisting of dead or dying adipocytes surrounded by macrophages, was associated with high-grade PC in men. It’s possible that agents that suppress periprostatic WAT inflammation will alter the natural history of PC. Pioglitazone, a ligand of PPARγ, is used to treat diabetes and possesses anti-inflammatory properties. Here our main objectives were to determine if pioglitazone inhibited obesity-related periprostatic WAT inflammation in mice and then to elucidate the underlying mechanism. Mice were fed either a high fat (HF) diet or low fat (LF) diet to determine if obesity-related periprostatic WAT inflammation was abrogated or suppressed in the HF diet. We found that obesity induced periprostatic WAT inflammation in mice that was reversed by pioglitazone treatment. Treatment with pioglitazone reduced the density of CLS in periprostatic WAT, and suppressed levels of TNF-α, TGF-β and the chemokine monocyte chemoattractant protein-1 (MCP-1). Importantly, the ability of pioglitazone to suppress periprostatic WAT inflammation was abrogated in MCP-1 knock out mice. Pioglitazone caused dose-dependent induction of both adiponectin, an anti-inflammatory adipokine, and its receptor Adipor2 in cultured 3T3-L1 cells and in periprostatic WAT of obese mice. Pioglitazone blocked TNF-α-mediated induction of MCP-1 in 3T3-L1 cells, an effect that was attenuated when either adiponectin or Adipor2 were silenced. Taken together, pioglitazone-mediated induction of adiponectin suppressed the elevation in MCP-1 levels thereby attenuating obesity-related periprostatic WAT inflammation. These findings strengthen the rationale for future efforts to determine whether targeting the PPAR-γ-adiponectin-MCP-1 axis will decrease periprostatic adipose inflammation and thereby reduce the risk of high-grade PC or improve outcomes for men with PC.

#1252 A pre-clinical model for lung cancer interception: gene expression similarities between human and mouse bronchial premalignant lesions. Sarah A. Mazzilli,1 Anna Tasinari,1 XiaoHui Xiao,1 Gang Liu,1 Samjot Dhillion,2 Candace Johnson,3 Mary Reid,3 Marc Lenburg,4 Avrum Spira,1 Jennifer Beane1. 1Boston University, Boston, MA; 2Roswell Park Cancer Institute, Buffalo, NY.

The molecular events that drive the development of the premalignant lesions (PMLs) that precede lung squamous cell carcinoma (SCC) are poorly understood. A major limitation to understanding PMLs and developing interventions is the lack of preclinical models to test candidates derived from human studies. Previous work by our group and others suggests that the N-nitroso-tris-chloroethylurea (NTCU) mouse model of lung SCC may be a candidate for modeling human PMLs based on histologic similarities, but its molecular relationship to human disease is limited. In this study, we investigate the transcriptomic similarities between PMLs from the NTCU treated mice and humans. RNA from 40 whole lung sections (curls) and laser capture microdissected (LCM) of PMLs of varying histology from SWR/J and A/J mice treated with NTCU were profiled by RNA-Seq. RNA from 131 human endobronchial biopsies representing analogous histological grades were also profiled by RNA-Seq as part of the Pre-Cancer Genome Atlas (PCGA). Linear modeling was used to identify gene expression differences associated with increasing histological severity of human PMLs (FDR<0.05). We identified a 51-gene (p<0.001) and a 178-gene (p<0.001) signatures associated with increasing histology in the all SWR/J and A/J samples respectively. These gene expression signatures are enriched for biological pathways involved in immune modulation, occurring with progressing lesions. Conversely, genes whose expression changed with increasing histology in a model that included only LCM samples (153 genes at p<0.001) revealed epithelial-specific processes including the up-regulation of KRT5 and p63 and loss of TTF1. Additionally, in the LCM samples, we identified up-regulation of genes involved in proliferation including a number of genes involved in cell structure, metabolism, transcription and translation, anti-apoptosis as well as several immunosuppressive genes. The major finding of these studies is that there are molecular similarities between PMLs from human and NTCU treated mice, which suggest that this mouse model may be useful to investigate targeted early intervention to halt or reverse PML progression towards lung cancer.

#1254 Mechanistic interrogation of pre-treatment low dose aspirin effects in HER 2 positive breast cancer. Ian S. Miller,1 Sonja Khan,2 Liam P. Shiels,3 Sudipto Das,1 Bruce Moran,1 Finbarr P. Leacy,1 Paul M. Loadman,4 Robert S. H. Drysen4 1Department of Cancer Biology, Memorial Sloan Kettering Cancer Center, New York, NY; 2Royal College of Surgeons in Ireland, Dublin, Ireland; 3National University of Ireland, Galway, Galway, Ireland; 4University College Dublin, Dublin, Ireland; 5University of Bradford, Bradford, United Kingdom; 6University of Toronto, Toronto, Ontario, Canada.

Background: Prior data (Barron et al. Cancer Res. 2014 74:4065-77) suggests that pre-diagnostic exposure to aspirin can have significant effects on breast tumor biology and patient outcome. It has been proposed that aspirin inhibition of COX-2 may suppress lymphangiogenesis and metastasis (Karnezis et al Cancer Cell. 2014. 21:181-95). Here, we sought to recapitulate pre-diagnostic aspirin exposure in rodent models of Her2+ breast cancer and elucidate mechanisms of action. We also determined the effect of aspirin on tumor stroma, using a co-culture system of human tumor and mesenchymal stem cells (MSC). Methods: NOD/SCID mice were orthotopically implanted with Her2+ MDA-MB-231 or HCC1954 cells. 48hr later, animals began a daily low dose [30mg/kg or 120mg/kg] of aspirin, until tumors reached 250mm³. They were then resected. 3 weeks later, HCC1954 implanted animals were treated with trastuzumab (15mg/kg) and paclitaxel (5mg/kg) for 6 weeks. Primary tissues were analysed by immunohistochemistry to assess VEGF-C, -D, COX-2, LYZE1 and CD31. RNASeq was performed on tumours to identify aspirin perturbed molecular pathways. To determine the stromal response to aspirin, patient derived MSCs were cultured either alone or with HCC1954 cells and exposed to aspirin (2.5 or 10µM) for 48 hours. Results: In NOD/SCID mice 4 weeks of treatment with low dose aspirin significantly reduced tumor growth and size. HCC1954 tumors treated with aspirin exhibited a decreased density of CD31 positive micro-vessels. In NOD/SCID mice implanted with Her2+ MDA-MB-231 tumors, aspirin treatment for 4 weeks resulted in a significant decrease in tumor growth rate and size. In these tumors, aspirin treatment decreased collagen I and fibronectin expression as well as CD31 expression. In patient derived MSCs, aspirin treatment for 48 hours increased expression of VEGF-C and COX-2. Conclusion: This study demonstrates that pre-diagnostic aspirin exposure in rodent models of Her2+ breast cancer is associated with increased anti-angiogenic activity. The molecular mechanisms of action of aspirin in the breast tumor microenvironment likely involve changes in the tumor stromal microenvironment. These changes may provide the rationale for exploring aspirin as a pre-diagnostic chemopreventive agent.
7.5mM). Secreted VEGF-C was quantified. A tubule formation assay was performed to determine the impact of aspirin on angiogenesis. Pro-angiogenic protein expression was investigated using a human angiogenesis array platform. Results: A significant delay in tumor growth was observed in both tumor models following aspirin treatment (p<.01). Assessment of metastatic potential revealed that 120 mg/kg aspirin significantly (p<.05) increased the time to metastasis and reduced primary regrowth in the MDA MB 231 model (p<.01). Immunohistochemical analysis of VEGF C, D and ILVE1 showed a significant dose dependent reduction (p<.01) in both models. RNAseq pathway analysis revealed a significant over-representation of mitochondrial electron transport chain genes. Downstream factors of AMPK showed significant (p<.01) upregulation suggesting alterations in metabolism. Aspirin (7.5mM) exposure resulted in loss of VEGF-C secretion from co-cultured tumor / MSC cell populations. Conditioned media harvested following aspirin treatment limited support tubule formation. Expression of pro-angiogenic factors in HCC1954 cells showed alterations following treatment, with the greatest decrease seen in Urokinase Plasminogen Activator (−42%) and its inhibitor Serpine 1 (−55%). Conclusion: We have successfully recapitulated pre-treatment aspirin response in surgical resection models of Her2+ breast cancer, with IHC analysis confirming the impact of treatment on angiogenic and lymphangiogenic factors. RNAseq analysis implicates aspirin mediated alterations in cellular metabolism. Our data further reveals increased response to aspirin in stromal cell populations.

**#1255 PhIP/DSS-induced colon carcinogenesis in CYP1A-humanized mice and its prevention by tocopherols.** Chung S. Yang,1 Jayson Chen,1 Anna B. Liu,1 Mao-Jong Lee,1 Hong Wang,1 Guangxu Li,1 Lanjun Zhang,2 Kenneth Reuhl,1 Nanjo Suh1. 1Rutgers University, Piscataway, NJ; 2University Medical Center of Princeton, Princeton, NJ.

In order to establish a more physiologically relevant colorectal cancer model, we recently developed a colon-carcinogenesis model induced by the meat-derived dietary carcinogen, 2-amino-1-methyl-6-phenylimidazo[4,5-b]pyridine (PhIP), and promoted by colitis, and subsequently developed into high-gradedysplasia (P30CA72720 and P30ES005022).

CYP1A-humanized mice were treated with 9,12-dimethylbenz[a]anthracene (DMBA) to induce mammary tumors. Results: We found that male LP consumption alters the non-coding RNA content and DNA methylation patterns of the sperm in agreement with previous findings. We also observed that, compared to Con offspring, the female offspring of LP fathers had lower birth weight (p=0.035). This decrease in body weight persisted through sexual maturity when females began to gain more weight than their control counterparts (p<0.001). In addition, mammary glands of LP offspring were larger (p=0.02) and reduced tumor latency in LP offspring (p=0.03). Mammary tumors of LP offspring had lower rates of apoptosis, which may explain the increased tumor growth in this group. However, the mechanisms mediating this effect still needs to be elucidated. Conclusion: Paternal sub-optimal nutrition programs the female offspring mammary gland development and breast cancer risk. Whether this increase in cancer risk is due to local mammary tissue changes or whether systemic changes play a role remains to be investigated. It also remains to be determined whether epigenetic changes in paternal sperm are functionally linked to changes in mammary gland development and cancer risk.

**#1258 Lifestyle improvements increase cancer onset and progression by adapting endocrine and immune signaling in mouse models.** Grant D. Fogle-song, Stephen M. Bergin, Wei Huang, Michael A. Caligiuri, Lei Cao. The Ohio State University, Columbus, OH.

Metabolic syndromes instigate substantial morbidity and mortality worldwide via its negative effects on many diseases including cancer. Obesity in particular has been deemed a causative factor for breast cancer in post-menopausal women, while worsening prognosis regardless of menopausal status. Importantly, progression of many metabolic syndromes can largely be slowed or reversed with aggressive lifestyle changes, thus also having the potential to miti-
gate cancer onset. A mouse model of environmental enrichment (EE) to improve motosensory, cognitive, and social stimulation by increasing physical engagement and social interaction triggers vast improvements in overall health. These include boosting mental health, reducing adiposity, prevention of diet-induced obesity (DIO), promoting the white to brown fat transition, enhancing insulin sensitivity, and delaying or modifying lifespan indicative of inhibition of cancer growth. We have elucidated the central mechanism of EE to be the activation of the hypothalamic-sympathoneural-adipocyte (HSA) axis, a specific neuroendocrine route in which the brain communicates with adipose tissue via the sympathetic nervous system. Once activated, norepinephrine (NE) is released directly onto adipose tissue which induces the observed metabolic improvements. Breast cancer is uniquely exposed to this adipose-NE so we sought to explore this distinctive microenvironment in the context of both local and systemic endocrine and immune signaling in varied body mass states and menopausal statuses. Our data showed that EE diminished leptin levels and delayed cancer onset in the MMTV-PyMT spontaneous mouse model of breast cancer and slowed growth in a DIO allograft model. In contrast, EE failed to attenuate tumor progression in ob/ob mice in the absence of leptin, but rather enhanced tumor growth, suggesting that the leptin-NE relationship is one of the key peripheral mediators of the EE anti-breast cancer effects. We also observed significant immune cell modulation in the adipose tissue following EE. Initial characterization revealed a decrease in the proportion of tumor-associated macrophages (TAMs) and an overall anti-inflammatory response which together would also reflect the contribution of anti-angiogenic and immune-modulating factors to control tumor growth. Our data support the hypothesis that EE can modulate local and systemic endocrine and immune systems to result in improved breast cancer outcomes.

**#1259 Stem cell property-suppressing microRNAs are stimulated and their target proteins inhibited by vitamin D and progesterone in ovarian cancer cells.** Rebecca Rosales, Jane Turbov, Jennifer Yoo, Gustavo C. Rodriguez, Larry G. Thaete. NorthShore University HealthSystem, Evanston, IL.

Vitamin D (1,25(OH)2D3) and progesterone (P4) have both been shown to reduce the incidence of ovarian cancer. Mechanisms involved in their actions are not fully known but each one can enhance the effect of the other. Six microRNAs (miRNAs), associated with suppression of cancer stem cell properties, were investigated first in a screening array and then with a more definitive RT-PCR investigation of the response of these miRNAs to 100 nM 1,25(OH)2D3, and 100 nM P4. These experiments were conducted in cells that do (OVCA-R3-PGR) and do not (SKOV3) express nuclear progesterone receptors (PGR). Let-7a and Let-7b are known to decrease expression of Ras and c-Myc and reduce stem cell self-renewal. Let-7b expression was increased (p<0.001) at 48 h in response to combined 1,25(OH)2D3 and P4 when PGR were present, and in response to individual and combined treatments at 72 h (p<0.01). Correspondingly, c-Myc expression was decreased (p<0.001) by both P4 and combined P4 and 1,25(OH)2D3. Let-7a expression was not affected by these treatments. No treatment-related change in the production of ras protein was observed compared to controls. In the absence of PGR (SKOV3 cells), c-Myc was suppressed by combined P4 and 1,25(OH)2D3 treatment at 24 h and 48 h. miR-26a and miR-101 are known to downregulate EpCAM and EZH2, leading to decreased tumor growth and metastasis and to reduced proliferation. miR-101 increased (p<0.001) at 48 h in response to combined 1,25(OH)2D3 and P4 in cells expressing PGR. It was increased (p<0.05) at 36 h and showed synergy in the screening array in the absence of PGR. Target proteins EZH2 and EpCAM decreased moderately (p<0.05) at 72 h combined treatment, both with and without PGR present. miR-26a expression was not affected by these treatments. miR-200b and miR-200c are known to suppress expression of ZEB1 which in turn decreases Bmi1 and Sox2 to increase E-cadherin (epithelial marker) and decrease vimentin (mesenchymal marker), thus inhibiting the epithelial-to-mesenchymal transition. Expression of miR-200b was increased (p<0.05) at 24 h and 72 h in response to combined 1,25(OH)2D3 and P4 when PGR were present, and in response to these treatments. ZEB1 was decreased (p<0.01) at 48 h in response to combined 1,25(OH)2D3 and P4. These results point not only to differences among cancer cell lines but also to emphasize a possible mechanism by which P4 and 1,25(OH)2D3 may work together to prevent the occurrence of ovarian cancer, namely by suppressing stem cell renewal and the formation of neoplastic lesions. The results also reinforce the possibility that P4 may act via other anti-cancer effects to reduce or inhibit primary nuclear receptors to effect suppression of stem cell properties. Increased expression of cancer stem cell-suppressing miRNAs may be an important mechanism mediating the efficacy of a progesterin-based ovarian cancer prevention strategy.

**#1260 Diet and exercise-induced weight maintenance may be preventing mammary tumor growth and metastatic burden by enhancing antitumor immunity and/or reducing protumorigenic factors.** William J. Turbitt, Yitong Xu, Andrea M. Mastro, Connie J. Rogers. The Pennsylvania State University, University Park, PA.

Two lifestyle factors that increase cancer risk and progression are weight gain and sedentary behavior. Possible mechanisms underlying this relation include changes in metabolic, inflammatory, and immune mediators. Few studies have examined the effect of body weight and exercise on the efficacy of immunotherapeutic strategies. An emerging immunotherapeutic strategy is PD-1 checkpoint blockade, which selectively targets the membrane protein programmed death-1 (PD-1) on T cells to promote a sustained antitumor effector response. Thus, the goal of the current study was to determine if preventing weight gain through diet (10% reduction in calories) and exercise (voluntary running wheel activity) will improve the response to the dual administration of a whole tumor cell vaccine and PD-1 checkpoint blockade. Female BALB/c mice were randomized to sedentary, weight gain (WG) or exercising, weight maintenance (WM) groups (n=32/group). After 8 weeks, all mice were orthotopically injected with 5x106 luciferase-transfected 4T1.2 cells into the fourth mammary fat pad and continued on their intervention for 35 days. After injection, WG and WM mice were randomized into vaccination (VAX) or vehicle (VEH) groups, and 1x106 irradiated 4T1.2 cells or HBSS vehicle control, respectively, was administered at day 7 post-tumor injection. Mice were further randomized (n=8/group) to PD-1 treatment or PD-1 one-week drug washout and PD-1 post-tumor injection. All WM groups, regardless of immunotherapy intervention, weighed significantly less than WG groups over the course of the study (p<0.001). Mean tumor volume (p<0.001) and tumor weight at sacrifice (p=0.076) were significantly lower with PD-1 treatment in the WG but not WM groups. Furthermore, metastatic burden in the lung (p=0.032) and the number of splenic myeloid-derived suppressor cells (p=0.035) were reduced with VAX+PD-1 treatment in the WG but not WM groups. Thus, the combination of VAX+PD1 was effective at reducing primary tumor growth and metastatic burden and improving immune outcomes only in mice that gained weight over the course of the study. However, diet and exercise alone was effective in reducing tumor growth and metastatic burden. The lack of responsiveness to vaccination with PD-1+PD1 treatment in WM mice suggests that WM achieved through diet and exercise may be enhancing antitumor immunity and/or reducing protumorigenic factors (i.e. similar mechanisms mediated by vaccination + anti-PD-1 therapy). These data demonstrate that preventing weight gain through diet and exercise may be an important recommendation to maintain prolonged antitumor effector responses and improve clinical outcomes.

**#1261 Lipid-peroxidation derived DNA damage is prevented in obesity-related hepatocarcinogenesis through CD4+ mediated apoptosis in the liver.** Rebecca Wang, Tony Hsiao, Xin Wang, Christian Trescher, Cong Song, Ning Ma, Marcin Dyba, Fung-Lung Chung. Georgetown UNIV., Washington, DC.

Using a C57BL/6J bioassay, we assessed whether formation of a lipid-peroxidation (LPO)-derived DNA adduct would induce mutations during the progression of obesity-induced hepatocarcinogenesis and if its formation could be prevented using a diet infused with Theaphenon E, a mixture of polyphenols extracted from green tea. Obesity is now the leading risk factor for the development of hepatocellular carcinoma in the United States. We have conducted a life-time C57BL/6J tumor bioassay to assess the role of obesity in the formation of 2,3-epoxy-1,4-nonenal-DNA adduct, a promutagenic DNA adduct formed endogenously by LPO. Previously, we have shown that LPO-DNA adduct formation is consistent with LPO in the early stages of liver disease and suggesting that it may be a source of endogenous DNA damage in hepatocarcinogenesis. Tea polyphenols, predominately EGCG, are antioxidants that have been shown to prevent obesity and tumorigenesis. For the bioassay, mice were fed either a high fat, low fat, or high fat 2% TE diet starting at 4 weeks of age. Tissue and blood were collected over the course of 80 weeks at 11 death times (1912 deaths). To evaluate the role of obesity, obesity, and obese diabetes, demonstrating that its formation is consistent with LPO in the early stages of liver disease and suggesting that it may be a source of endogenous DNA damage in hepatocarcinogenesis. The use of polyphenols, predominantly EGCG, are antioxidants that have been shown to prevent obesity and tumorigenesis. For the bioassay, mice were fed either a high fat, low fat, or high fat 2% TE diet starting at 4 weeks of age. Tissue and blood were collected over the course of 80 weeks at 11 death times (1912 deaths). In contrast to the high-fat and low-fat diet mice, the TE treated mice maintained a healthy body weight, liver to body weight ratio and low levels of AST and ALT enzymes which are elevated in liver disease. Additionally, the health of the liver appears to be maintained through increased CD4+ mediated apoptosis in TE treated mice as demonstrated through decreased Ki67 expression and TUNEL staining showing increased apoptosis in TE treated mice livers in conjunction with increased CD4+ cells. The CD4+ immune response may, therefore, be targeting cells with mutagenic potential. Similar to the trend indicated by the clinical samples, during hepatocarcinogen-
Aspirin inhibits the carcinogenesis of esophageal squamous cell carcinoma and enhances its responses to cisplatin. Zhiheng Zou,1 Hongjun Fan,2 Xinying Yu,3 Xiying Fan,1 Shuming Yu,1 Jingping Guo,1 Wei Jiang,1 Shih-Hsun Lu.2 Cancer Institute and Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China.

Esophageal squamous cell carcinoma (ESCC) is one of the most lethal malignancies. Over 70% of ESCC cases occur in China. Unfortunately, the treatment of ESCC has hardly been improved all these years. Several studies suggested that aspirin (ASA) might decrease the risk of ESCC and prolonged the survival of patients with ESCC. However, it is unclear if ASA could prevent ESCC and/or enhance ESCC treatment by chemotherapy. In this study, a N-nitroso-N-methylbenzylamine (NMBzA) - induced ESCC model was employed to prove that aspirin could prevent the growth of esophageal tumor. F344 rats were treated with NMBzA by subcutaneous injection with or without ASA in drinking water (2mg/ml). After 35 week ASA-NMBzA or NMBzA alone treatment, rats were killed and esophageal tumor development were examined. The results showed that F344 rats treated with NMBzA and receiving a daily intake of ASA developed much less tumors than F344 rats treated with NMBzA alone both in amount and in size (Tumor count: 2.40 ± 1.57 vs 10.85 ± 3.86, P < 0.001; Tumor volume: 11.10 ± 13.88 mm³ vs 70.79 ± 41.65 mm³, P < 0.001). Immunohistochemical analysis indicated that a higher rate of apoptosis was observed in the basal layer of esophageal epithelium in ASA-NMBzA treated rats than in NMBzA alone treated rats. These results indicated that ASA prevented development of esophageal tumors in rats induced by NMBzA. Moreover, using in vitro human ESCC cell culture and in vivo xenograft models, we showed that ASA has strong beneficial effects on inhibition of ESCC cell proliferation and colony formation, reduction of ESCC cancer stem cells and enhancement of ESCC cell cytotoxicity induced by cisplatin treatment. Biochemical analysis revealed that these effects of ASA on human ESCC cells in vitro and in vivo were due to inhibiting the repairing of DNA damage, decreasing the efflux activity and ALDH1 activity of the tumor cells, and blockades of PI3K/Akt pathway. Thus, our results demonstrated a positive role of aspirin in the prevention and treatment of ESCC.

Andrographolide inhibits prostate cancer by suppressing cytokine involved in promoting epithelial to mesenchymal transition. Hina Mir,1 Neeraj Kapur,2 Guru Sonpavde,2 Shailesh Singh1.1 Morehouse School of Medicine, Atlanta, GA; 2UAB Comprehensive Cancer Center, Birmingham, AL.

Mesenchymal phenotypes are responsible for cancer progression and poor therapeutic response. Hence, approaches targeting mesenchymal phenotype or inhibiting epithelial to mesenchymal transition will significantly prevent cancer progression or improve therapeutic outcome. Using in vitro models and molecular approaches we have shown that Andrographolide (AG), a compound isolated from Andrographis paniculata, shows promising effect on mesenchymal cells. It disposes PCA cells towards epithelial phenotype by modulating E-cadherin, ZEB-1, SNAIL and TWIST. In addition to these, significant inhibition in IL-6, which is known to be a poor prognostic maker, was observed in PCA cells treated with AG compared to untreated cells. This reduction in IL-6 could be due to AG induced suppression of SOCS (Suppressor of cytokine signaling) molecules. Therefore, our data underscores the ability of AG to impede cancer growth by impacting EMT and rationalizes its application as a potent therapeutic agent.

Studying senescence in prostate of selenium treated rats undergoing carcinogen-induced, androgen-promoted prostate carcinogenesis. Kartick C. Pramanik,1 Michelle Schlacht,2 Maarten Bosland,2 Chang Jiang,1 Yibin Deng,3 Junxuan Lu1.1 Penn State University, College of Medicine, Hershey, PA; 2University of Illinois at Chicago, IL; 3The University of Minnesota Hormel Institute, MN.

Preclinical studies from us and others have shown that oral intake of next-generation selenium (Se) forms, especially methylseleninic acid (MSeA) and Se-methylselenocysteine (MSeC) inhibits mouse prostate carcinogenesis. Our recent study has shown that MSeA suppresses pten-deficient mouse high grade prostatic intraepithelial neoplasia progression to adenocarcinoma in association with superactivating p53-p21 mediated cellular senescence. To address the question whether the activation of senescence is induced in prostate carcinogenesis driven by different etiology, we sought to test the in vivo effect of different selenium forms fed to rats undergoing chemically induced, androgen promoted prostate carcinogenesis. Wistar-Unilever (WU) rats (10-12 wks) were sequentially treated with androgen receptor blocker flutamide for 21 days (10 mg/kg/day by gavage) and then treated with N-ethyl-N-nitroso urea (NENU) or NMBzA alone for 16 week. All treated rats were euthanized, blood, major organs and different prostate lobes were dissected and weighed. The body weight of carcinogen-exposed rats was significantly less than their non-carcinogen-exposed counterparts. However, total prostate complex weight was higher in carcinogen-treated groups than the non-carcinogen groups, consistent with MNU and extra-testicular androgen promoting prostate epithelial cell proliferation. There were no significant organ-to-body weight ratio differences of various prostate lobes in the different dietary groups, regardless of the carcinogen exposure status. In order to test the involvement of senescence in prostate of rats fed different Se diets, we have undertaken steps to optimize staining method for senescence-associated β-galactosidase (SA-β-gal) activity in different lobes of prostate frozen sections. Together, with whole slide imaging using an Aperio Digital Pathology Scanner for quantitation, we are afforded an approach for more objective interrogation of the role of senescence in this carcinogenesis model and chemoprevention by selenium compounds.
Metformin represses esophageal carcinogenesis in NMBzA-treated rat model through inhibiting AMPK/mTOR and Stat3 signaling pathways.

National Cancer Center/ Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China.

Esophageal cancers are among the most aggressive tumor types because of its invasiveness and metastatic potential. Metformin is one of the most used diabetic drugs for the management of type 2 diabetes mellitus in the world. The role of metformin in prevention of the development and progression of a variety of human tumors has been studied. However, the detailed mechanisms have not yet been fully understood. In the present study, we investigated the effects of metformin on the suppression of esophageal carcinogenesis in a rat model, in which F344 rats were treated with N-nitrosoglutethimide (NMBzA 0.30 mg/kg s.c.) three times per week for 35 weeks to induce esophageal tumors. To monitor the effects of metformin in this model, one group of rats were administered with metformin (3 g/L) in the drinking water at the first NMBzA injection. Our results showed that although there was no significant difference in body weight in rats of different groups, rats treated with NMBzA and metformin together significantly reduced the tumor formation and tumor volume when compared with rats treated with NMBzA alone. Statistical analyses demonstrated that the tumor numbers was reduced in NMBzA-treated rats received metformin to an average of 1.85 ± 1.09 tumors per rat when compared with 10.85 ± 3.66 (P < 0.001) in rats without metformin, while the tumor volume was decreased from 70.79 ± 41.65 mm³ per rat without metformin administration to 8.64 ± 13.45 mm³ (P < 0.0001) with metformin administration. In addition, 7 out of 24 rats in the NMBzA-treated group died before week 35 but no rats died in the other groups. Furthermore, immunoblotting analysis indicated that p-AMPKα, p-mTOR (S2448), p-Stat3Y705, and Cyclin D1 protein levels significantly decreased, while p-AMPKαThr172 significantly increased in tumors obtained from rats treated with NMBzA and metformin when compared with tumors obtained from rats treated with NMBzA alone. Thus, our results indicated that metformin suppressed NMBzA-induced esophageal carcinogenesis via inhibition of the AMPK/mTOR and Stat3 signaling pathways. Together, our study suggested that metformin might have a potential use for treatment and prevention of esophageal cancer.

Emodin exerts its anticancer effect on colon cancer cells by inhibiting proliferation and inducing apoptosis.

Morehouse School of Medicine, Atlanta, GA.

Despite state of the art diagnostic and therapeutic options offered in the clinics, colon cancer is still a major health care concern. Therapeutic outcome is often compromised due to late diagnosis and development of resistance against treatment options used to treat advanced disease. Hence, the need to explore new avenue to treat/preserve colon cancer more effectively still exist. In this study we have investigated potential impact of Emodin, an anthraquinone derived from plant (Rheum rhabarbarum) on colon cancer cell proliferation, survival and apoptosis. Our data show that emodin reduces the cell viability and inhibits proliferation of human colon cancer cell (COLO-205 and DLD-1) in a time-dependent manner. Furthermore, FACS analysis show higher percentage of apoptotic cells with Emodin treatment compared to untreated cells. Interestingly, pro-inflammatory and anti-inflammatory cytokines produced by colon cancer cells were modulated with Emodin treatment. Cancer cells often use these cytokines to achieve their goal to progress and escape the treatment. Our data implies Emodin could be a promising agent that could be used for chemoprevention as well as in therapeutic combination to improve efficacy of conventional therapy.

Bitter melon efficacy against human pancreatic cancer cells: possible involvement of cellular stemness and metabolism targets.

Deepanshi Dhar, Gagan Deep, Sushil Kumar, Chapla Agarwal, Nalini Sarkova, Michael Wempe, Komal Raina, Rajesh Agarwal.
Univ. of Colorado Denver School of Pharm and Allied Health.

Pancreatic cancer (PanC) has a dismal 5-year survival rate of <5%. Symp- tomless progression, late diagnosis and rising drug resistance to leading chemotherapy agents like gemcitabine, add to PanC severity. Hence, there is a critical requirement for identifying alternative novel non-toxic agents (dietary/non-dietary) aimed at effective management of PanC with minimal patient distress. Bitter melon (Momordica charantia), a dietary agent, is actively being investigated for its anti-cancer potential against a variety of malignancies, including our work in PanC. Recent studies by us have shown bitter melon juice (BMJ) efficacy against a panel of human PanC cell lines in culture and tumor xenografts. For mechanistic studies, here we evaluated the efficacy of BMJ against cancer stem cells (CSCs) pool in PanC cells. Results indicated that BMJ treatment (0.25-2% v/v) significantly decreased CSC enriched (CD44+/CD24- EpCAM+BMJ) PanC cell population. Successive immunofluorescence/immunohistochemical analysis of BMJ exposed cells, spheroids and MiaPaCa2 xenograft tumors showed a significant reduc- tion in the number of CSCs. BMJ treatment was found to be a possible important component to be targeted to control cancer growth and progression, we next assessed BMJ efficacy in that direction. Indeed, BMJ mediated its anti-PanC effect via activating the key metabolic regulator AMPK. Concomitantly, to determine whether BMJ-effects were nutrient/energy stress dependent, we next sought to determine the cellular energy status and major metabolic changes concomitant with BMJ-mediated effects. BMJ mediated elevation of MSCA1 (major glucose transporter overexpressed in PanC) were also suppressed after BMJ treatment. Collectively, these results suggest that BMJ targets PanC CSCs and cellular metabolism in its efficacy against this deadly malignancy (supported by CA195708).
EPIDEMIOLOGY: Genetic Variation (Non-GWAS) and Cancer Risk, Prognosis, or Mechanisms

Alpha-tocopherol is a highly biologically active form of vitamin E that has been inconsistently associated with prostate cancer risk in cohorts and supplementation trials. In order to further elucidate the association using a Mendelian randomization approach that avoids sources of bias common in observational research, we examined genetic variants related to vitamin E status, including those from GWAS analyses of circulating vitamin E, in relation to prostate cancer risk in the Prostate Cancer Association Group to Investigate Cancer Associated Alterations in the Genome (PRACTICAL) Consortium. The analysis included 38,868 cases and 25,210 controls from 35 participating cohorts and examined the association between 847 vitamin E-related single nucleotide polymorphisms (SNPs) in (or near) six genes and risk of prostate cancer. Logistic regression was used to estimate multi-analyzed case-control odds ratios (OR) and 95% confidence intervals (CI) for the per allele risk associations. Both genotyped and imputed data were examined, and results for the latter are presented based on the consistency between the two sets of findings. In addition to examining SNPs demonstrating nominal significance (alpha-error p < 0.05), a Bonferroni threshold of < 0.00006 was applied to adjust for multiple comparisons. We found 89 SNPs were nominally significantly associated with prostate cancer risk. This included SNPs involved in vitamin E transport (i.e., SEC14L2 and SCARB2) and metabolism (i.e., BUD13/ZNF259). The top three risk-associated SNPs (P < 0.001) included rs141696823 (OR = 0.59, P = 6.0x10^-5) in CYF4P8 (cytochrome P450 family 4B subfamily F member 8) on 19p13.12 which functions as a prostaglandin hydroxylase in the seminal vesicles, and rs1915379 (OR = 1.04, P = 0.00002) in CYF4P3 (cytochrome P450 family 4B subfamily F member 3) on 19p13.12 which oxidizes arachidonic acid and omega-hydroxyates tocopherol phytol side chains, and has been directly associated with higher circulating alpha-tocopherol concentration in response to vitamin E supplementation in the ATBC Study. The present Mendelian randomization analysis suggests genetic variants related to vitamin E metabolism, its role as an antioxidant, and its function in inflammatory processes, may be associated with prostate cancer risk.

#1271 Genetic variants in the 16q24.3 region of melanocortin-1-receptor (MC1R) and prostate cancer risk: A Mendelian randomization analysis of 39,000 cases and 25,000 controls. Stephanie J. Weinstein, Tracy M. Layne, Ijqi Huang, Eric Karlins, Stephen J. Chanock, Demetrius Alabanes, the PRACTICAL Consortium, National Cancer Inst., Bethesda, MD.

We previously reported that men with naturally red hair had a significantly lower risk of prostate cancer (HR = 0.46, 95% CI 0.24-0.89) compared with the most prevalent hair color, light brown (Br J Cancer 2013;109(3):747-750). The red hair phenotype is encoded by variants in the melanocortin-1-receptor (MC1R) gene, which directs melanocyte melanin synthesis, secretion and human pigmentation, may be associated with risk of prostate cancer.

#1272 Prostate cancer risk and vitamin A related genetic variants in the PRACTICAL Consortium. Shakira M. Nelson, 1 Tracy M. Layne, 1 Stephanie J. Weinstein, 2 Eric Karlins, 2 Stephen J. Chanock, 3 Demetrius Alabanes, 3 PRACTICAL Consortium, 4NCI, Rockville, MD; 5Cancer Genomics Research Laboratory, Rockville, MD.

Vitamin A compounds including retinol are thought to play a protective role in human carcinogenesis. However, recent studies have shown that men with higher serum retinol concentrations are at increased risk of both overall and aggressive prostate cancer, the most common cancer in men within developed populations. The biological mechanism underlying this association remains unclear. In the present investigation, we examined the associations between common genetic variants related to serum retinol status and prostate cancer risk in the Prostate Cancer Association Group to Investigate Cancer Associated Alterations in the Genome (PRACTICAL) Consortium. The analysis includes 38,868 cases and 25,210 controls from 35 participating PRACTICAL studies. A Mendelian randomization approach was used to examine the individual association between 135 vitamin A-related single nucleotide polymorphisms (SNPs) and risk of overall prostate cancer. Logistic regression was used to estimate the odds ratio (OR) and confidence interval (CI) for the per allele association between each SNP and risk. Associations were examined using both genotyped and imputed data, and results for the latter are presented based on a substantial similarity. In addition to examining SNPs demonstrating nominal significance (alpha < 0.05), a Bonferroni cut-off of < 0.0003 was used to adjust for multiple comparisons. Seven SNPs were found to be nominally significant at the p < 0.05 level; however, none remained significant after Bonferroni correction. Of these, five SNPs (rs799751, OR = 0.97; rs9963553, OR = 1.03; rs9967180, OR = 1.03; rs2167689, OR = 0.98; rs1941356, OR = 0.98) are located in or near three genes: transthyretin gene (TTR), trafficking protein particle complex 8 (TRAPPC8), and beta-1,4-galactosyltransferase 6 (B4GALT6). The carrier protein transthyretin is the only gene known to be related to retinol status based on prior GWAS analyses, while B4GALT6 encodes type II membrane-bound glycoproteins which may be used as a potential cancer biomarker. The other two SNPs, rs1377189 (OR = 0.96) and rs17053512 (OR = 0.97), are located in desmoglein 3 (DSCG), whose encoded protein plays a role in maintenance of tissue architecture which may be upregulated in malignancies. Our large-scale Mendelian randomization analysis reveals some evidence of a relatively weak association between genetic variants related to vitamin A status and prostate cancer risk. These associations should be further examined in aggressive and fatal cancers.

#1273 Pathway analysis of insulin-like growth factor candidate genes and risk of pediatric rhabdomyosarcoma. Libby Morimoto, 1 Xiaorong Shao, 1 Anand Chokkalingam, 1 Joseph Wiemels, 2 Xiaomei Ma, 2 Catherine Metayer 1 1University of California, Berkeley, Berkeley, CA; 2UCSF, San Francisco, CA; 3Yale University, New Haven, CT.

To evaluate and prioritize candidate genes involved in IGF signaling and risk of pediatric RMS, we selected 15 genes involved in IGF signaling and risk of pediatric RMS. Fifteen genes involved in the IGF pathway were selected: IGF1, IGF2, IGFIR, IGF2R, IGFBP1, IGFBP2, IGFBP3, IGFBP4, IGFBP5, IGFBP6, INS, INSR, IRS1, GH1, and GHHR. DNA extracted from the archived newborn blood spots of available RMS cases (n = 664) was genotyped on the Illumina OmniExpress Exome array (n = 964,043 SNPs); after stringent quality control (QC), a total of 633 RMS cases (360 embryonal RMS [eRMS] and 197 alveolar RMS [aRMS]) were available for analysis. A total of 815 controls genotyped on the Illumina OmniExpress array and 3,922 controls genotyped on the Affymetrix AXION LAT array (n = 801,830 SNPs) from the same base population of California children, with no evidence of RMS, were included in this analysis. After imputation to increase coverage of the genome and post-imputation QC to identify and remove platform effects, a total of 5,556,335 SNPs were available for analysis. Among NHW children, SNPs in IGF1 (rs10808689, P = 0.0031) and IGFIR (rs6203616, 327 Proceedings of the American Association for Cancer Research 1 Volume 58 1 April 2017

**EPIDEMIOLOGY: Genetic Variation (Non-GWAS) and Cancer Risk, Prognosis, or Mechanisms**

p = 0.00074; rs62023648, p = 0.00076) were significantly associated with RMS risk after adjustment for multiple comparisons. Analyses stratified by histologic subtype showed that these associations were limited to eRMS, and of stronger magnitude. Among Hispanic children, 12 SNPs in IGFR1 (p-value range: 0.0007-0.0027) and 3 SNPs in IGFBP1 (p-values: 0.0016-0.0023) were significantly associated with RMS risk. The SNPs were located in intergenic and intronic areas of the genes, areas that may influence gene regulation. Our results support the hypothesis that genetic variation in IGFl signaling pathway modulate the risk of RMS, especially eRMS, among NHW and Hispanic children.

**#1274 Associations between genetic polymorphisms in genes related to estrogen metabolism and function and prostate cancer risk: results from the Prostate Cancer Prevention Trial.** Li Tang,1 Mary Platek,2 Song Yao,1 Cathie Till,3 Phyllis Goodman,2 Catherine M. Tangan,4 Yue Wu,5 Elizabeth A. Platz,5 Marian L. Neuhouse,6 Frank Z. Stanczuk,7 Juergen K. Reichardt,8 Regina M. Santella,9 Ann Hsing,10 William D. Figg,11 Scott M. Lippman,12 Ian M. Thompson,13 Christine B. Ambrosone,1,1 Roswell Park Cancer Inst., Buffalo, NY; 2Fred Hutchinson Cancer Research Center, Seattle, WA; 3Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; 4University of Southern California, Los Angeles, CA; 5University of Sydney, Sydney, Australia; 6Columbia University, New York, NY; 7Stanford University, Stanford, CA; 8National Cancer Institute, Baltimore, MD; 9UC San Diego Moores Cancer Center, San Diego, CA; 10University of Texas Health Science Center at San Antonio, San Antonio, TX.

Background: Substantial preclinical data corroborate the critical role of estrogen in prostate cancer development; however, epidemiological studies found no associations between circulating estrogen levels and prostate cancer risk. It was hypothesized that intraprostatic estrogen milieu may play a more important role than circulating estrogen in prostate carcinogenesis. Since it is difficult to obtain data on prostatic estrogen levels, we tested the hypothesis indirectly by investigating associations of prostate cancer risk with genetic variants of enzymes that are involved in estrogen synthesis, metabolism and function, and may affect intraprostatic estrogen milieu. Methods: A panel of 36 potentially functional single nucleotide polymorphisms (SNPs) in estrogen-related genes was assembled based on information obtained in the literature. After removing SNPs with call rate <95% (1 SNP) or minor allele frequency <3% (10 SNPs), a total of 25 SNPs in 13 genes (PGR, ESR1, ESR2, CYP17A1, HSD17B1, CYP19A1, CYP1A1, CYP1B1, COMT, UGT1A6, UGT1A10, UGT2B7, UGT2B15) were examined for associations with prostate cancer risk using data and DNA samples from 1617 cases and 1731 controls in the Prostate Cancer Prevention Trial (PCPT). Cases and controls were frequency-matched on age, treatment arm and family history. Logistic regression was used to estimate odds ratios (ORs) and 95% confidence intervals (CIs) separately in the placebo and finasteride arms, adjusting for age, race and family history. Results were similar when restricting analysis to white men only. Results: Panels of SNPs that were significantly associated with prostate cancer risk were different according to treatment arm, showing rs1081132 in ESR1, rs700518 in CYP19A1, and rs4124874 in UGT1A6 in the placebo arm and rs2445765 in CYP19A1 and rs4860480 in UGT1A6 in the finasteride arm. When stratified within the arm, estrogen and androgen levels, significant associations were only observed in either the high or low category of serum hormone levels; no SNPs were significantly associated with prostate cancer risk in both categories. CYP19A1 was the only gene harboring SNPs that were significantly associated with prostate cancer risk in both the placebo (rs700518 and finasteride arm (rs2445765). In haplotype analysis using all three CYP19A1 SNPs genotyped in the study (rs700518, rs2445765 and rs700519), compared with non-risk haplotype (GCC), certain CYP19A1 haplotypes were significantly associated with increased prostate cancer risk in both arms. Conclusion: Associations between prostate cancer risk and SNPs in genes involved in estrogen metabolism and function and the specific marker showed by other factors such as finasteride treatment or circulating hormone levels. Supported by grant U01CA73429, SUM1CA18288 and P01CA180964 from the NCI.

**#1275 Genetic variations in cancer-related significantly mutated genes and lung cancer susceptibility.** Liren Zhang,1 Yanwei Zhang,1 Rong Li,2 David W. Chang,1 Yuanqing Ye,1 John D. Minna,3 Jack A. Roth,3 Baohui Han,4 XiFeng Wu,5 UT MD Anderson Cancer Center, Houston, TX; 6University of Texas Southwestern Medical Center, Dallas, TX; 7Shanghai Chest Hospital, Shanghai; 8Fudan University School of Medicine, Shanghai, China.

Cancer initiation and development are driven by key mutations in driver genes. Applying high-throughput sequencing technologies and bioinformatics analyses, The Cancer Genome Atlas (TCGA) project has recently identified pan-}

els of genetic mutations that contributed to or associated with the etiology of various cancers. However, there are few studies investigating the germline genetic variations in these highly mutated genes and lung cancer susceptibility. In this multi-phase study, we aimed to comprehensively evaluate the 1655 tagSNPs located in the 127 significantly mutated genes (SMGs) identified by TCGA, and their association with lung cancer risk. The SNPs were located in intergenic and intronic areas of the genes, areas that may influence gene regulation. Our results support the hypothesis that genetic variation in IGFl signaling pathway modulate the risk of RMS, especially eRMS, among NHW and Hispanic children.

**#1276 Gene-environment interaction relevant to estrogen and risk of breast cancer.** JooYoung Park,1 Ji-Yeob Choi,2 Seokang Chung,1 Nan Song,3 Sue K Park,4 Wonsik Han,5 Dong-Young Noh,6 Sei-Hyun Ahn,6 Mi-Kyung Kim,6 Keun-Young Yoo,7 Wei Zheng,7 Daehhe Kang,8 Department of Biomedical Sciences, Seoul National University College of Medicine, Seoul, Republic of Korea; 2Cancer Research Institution, Seoul National University College of Medicine, Seoul, Republic of Korea; 3Department of Preventive Medicine, Seoul National University College of Medicine, Seoul, Republic of Korea; 4Department of Surgery, Seoul National University College of Medicine, Seoul, Republic of Korea; 5Department of Surgery, University of Ulsan College of Medicine and ASAN Medical Center, Seoul, Republic of Korea; 6Division of Cancer Epidemiology and Management, National Cancer Center, Goyang-si, Gyonggi-do, Republic of Korea; 7Department of Medicine, Division of Epidemiology, Vanderbilt Epidemiology Center, Vanderbilt-Ingram Cancer Center, Vanderbilt University School of Medicine, Nashville, TN.

Introduction: Many established reproductive risk factors for breast cancer are mediated by hormonal mechanisms, and most parts are involved in estrogens. In addition, estrogen levels controlled by genetic factors might be a sort of determinants to breast cancer risk involving estrogen metabolism. This study aims to examine gene and environment interaction (GxE) between candidate genes which are involved in estrogen metabolism and environmental factors which are related to estrogen exposure. Methods: GxE analyses were conducted in the Korean 1,970 breast cancer cases and 2,052 controls which were recruited in the Seoul Breast Cancer Study (SEBCS), a multicenter case control study. Among the candidate genes involved in estrogen metabolism were selected from couple of databases and 11,555 SNPs (2,472 typed SNPs and 9,083 imputed SNPs) from the range of candidate genes were included in GxE analyses with 8 established environmental factors. Statistical analyses were performed by using GxEscan (ver. Beta 0.4.0. http://biostats.usc.edu/software) for GxE test. Results: There were three significant interaction between 11,555 SNPs and 8 environmental factors. Firstly, interaction rs851998 nearby ER1 with height was shown in the GE2df model (p=2df=1.1x10-4) This SNP had protective effect marginally (ORG height ≥160cm: 0.82, 95%CI: 0.75-0.90, p=1.09x10-4). Cumulative analysis of the 11SNPsshowed consistently elevated risk with decreasing number of cases and further protective effect for women whose height is smaller than 160cm (ORG height <160cm: 0.78, 95% CI: 0.70-0.87, p=1.09x10-4). Second interaction was shown between rs13035764 of NCOA1 and age at menarche in the GE2df model (p=2df=1.2x10-3). This SNP also had protective effect marginally (ORG = 0.85, 95% CI: 0.77-0.97) and more protective effect when age at menarche is 14 years and over (ORG = 0.82, 95% CI: 0.73-0.97, p=3.6x10-4). Lastly, there was marginally significant interaction between rs4140979 of FSHR and age at first full term pregnancy (FFTP) in the EDGxE model. Although this SNP had no marginal effect, cumulative interaction was shown with FFTP (ORG FFTP >27 years: 0.88, 95% CI: 0.78-1.00, p=0.0482; ORG FFTP ≤27 years: 1.30, 95% CI: 1.10-1.53, p=0.002). Conclusion: Three significant interactions were identified by focusing two step methods. Replication should be performed in the independent and larger population due to statistical limitation.
#1277 Interaction of insulin-like growth factor-I and insulin resistance-related genetic variants with obesity and lifestyle factors on postmenopausal breast cancer risk. Su Yong Jung,1 Gloria Ho,2 Thomas Rohan,1 Howard Strickler,3 Jennifer Bea,1 Jeanette Papp,4 Eric Sobel,5 Zuo-Feng Zhang,6 Carolyn Daldal,1 1University of California, Los Angeles, Los Angeles, CA; 2Hofstra Northwell School of Medicine, Feinstein Institute for Medical Research, Great Neck, NY, 3Albert Einstein College of Medicine, Bronx, NY; 4University of Arizona Cancer Center, Tucson, AZ; 5David Geffen School of Medicine, University of California, Los Angeles, CA; 6David Geffen School of Medicine, University of California, Los Angeles, CA.

Objective: Genetic variants and traits in metabolic signaling pathways may interact with obesity, physical activity, and exogenous estrogen (E), influencing postmenopausal breast cancer risk, but these inter-related pathways are incompletely understood. Stratifying via obesity and lifestyle modifiers, we evaluated the effects of insulin-like growth factor-I (IGF-I)/insulin resistance (IR)–related traits on breast cancer risk as a mediator or influencing factor in this case–cohort study. Method: Using 75 single-nucleotide polymorphisms (SNPs) in genes related to IGF-1/IR traits and signaling pathways, and data from 1,003 postmenopausal women in Women's Health Initiative Observation ancillary studies, we assessed the effects of IGF-1/IR-traits (fasting total and free IGF-I, IGF binding protein-3, glucose, insulin, and homeostatic model assessment–insulin resistance) by proportional change estimation. Using traits as mediators of the IGF-1/IR–traits/cancer relationship, we partitioned the total effect of these genetic variants on cancer risk into two putative mechanisms: 1) indirect (mediated by traits) and 2) direct (through pathways other than traits). For the effects of IGF-1/IR traits on IGF-1/IR signaling pathways–relevant genetic variants–cancer risk, we used the same algorithm as that for mediator, but interpreted as an influential factor. Results: Seven SNPs in IGF-I and INS genes were associated with breast cancer risk. These associations differed between non-obese/active and obese/inactive women and between exogenous E nonusers and users. The mediation effects of IGF-1/IR traits on these SNPs–cancer relationship differed between strata, but only roughly 35% of the cancer risk due to the SNPs was mediated by IGF-1/IR traits. Similarly, carriers of 20 SNPs in PIK3R1, AKT1/2, and MAPK1 genes (signaling pathways–related genetic variants) had different associations with breast cancer between strata, and the proportion of the SNP–cancer relationship explained by IGF-1/IR traits varied 45–50% between the strata. Conclusions: Our findings suggest that IGF-1/IR genetic variants interact with obesity and lifestyle factors, altering cancer risk partially through pathways other than IGF-1/IR traits.

#1278 Effect modifications of vitamin D receptor common polymorphisms association with prostate cancer by serum vitamin D related behavioral and biological factors. Ken Batala,1 Adam B. Murphy,2 Ebony Shah,3 Chil-edearian,1 Rick A. Kittles4 1University of Arizona, Tucson, AZ; 2Northwestern University, Chicago, IL; 3Carney Hospital-Steward Health System, Dorchester, MA.

Background: Several roles have been proposed for vitamin D and the vitamin D receptor (VDR) in prostate cancer (PCa) pathogenesis and progression. However, previous genetic epidemiologic studies have provided limited support linking VDR polymorphisms to PCa due to complexity of vitamin D metabolism and potential gene and environmental interactions. In this study, we investigated the association of VDR genotypes with PCa incidence and aggressiveness in African Americans (AAs) and European Americans (EAs) and if the associations were modified by behavioral and biological factors that influence serum vitamin D levels. Methods: The total of 810 AAs and 487 EAs from Chicago, IL and Washington, D.C. were included in this study. Seven single-nucleotide polymorphisms (SNPs) in and around the VDR gene and 105 ancestry informative markers were genotyped. We performed logistic regression analyses adjusting for relevant variables. Results: In EAs, TaqI (rs73136) and BsmI (rs1544410) minor alleles revealed a protective effect against PCa, while in AAs, FokI (rs2228570) was associated with overall PCa risk (OR = 0.74, 95% CI: 0.57–0.96). The heterogeneous associations observed in our study could be due to difference in prevalence of vitamin D deficiency between AAs and EAs and effect modifications by behavioral and biological factors that affect serum vitamin D levels. Therefore, we investigated if behavioral and biological factors that influence serum vitamin D modified the associations between VDR polymorphisms and PCa, and we found evidence suggesting that these behavioral and biological factors modify the effect of VDR on PCa. In AAs, we observed statistically significant interaction between two VDR polymorphisms, FokI and TaqI, and vitamin D intake (PInteraction = 0.01 and PInteraction = 0.03 respectively). We also observed evidence of interactions between VDR gene variants and other behavioral and biological factors that lower serum vitamin D levels in both AAs and EAs. In AAs, calcium intake and skin pigmentation may modify the effects of VDR on PCa. In EAs, BMI may modify the effect of VDR. Conclusions: Although a larger sample size is necessary to confirm the observation, we demonstrated that vitamin D related behavioral and biological factors modify the effect of VDR genotypes on PCa. Impact: The VDR gene is involved in PCa pathogenesis and progression, and polymorphisms in VDR gene and vitamin D are likely to alter the function of the gene.

#1279 A polymorphism of VEGF -2489C/T is associated with prostate cancer susceptibility in Mexicans. Abril Martínez-Rizo,1 Xavi Casillas-Rangel,1 Cuerpo Académico Investigación Bioquímica (UAN-CA-266), Hilda Andrade-Madrid,2 Veronica Benites-Godínez,3 Nallhely Rodríguez-Ocampo5, 1Autonomous University of Nayariit, Tepic, Mexico, 3Mexican Social Security Institute, Delegation Nayariit, Tepic, Mexico.

Introduction: Prostate cancer (CaP) encompasses a range of malignant prostate tissue dysplasias that primarily affects men over 50 years, is the second leading cause of cancer mortality in males. VEGF expression is associated with tumor progression and metastasis in patients with CaP. The SNP -1154 G/A is associated with the severity of CaP populations in Tunisia and the United Kingdom while -634 G/C alone has been associated in Tunisian population. It is unknown whether these polymorphisms could serve as biomarkers in the Mexican population. Aim: To associate VEGF polymorphisms -1154 G/A and - 634 G/C with the severity of prostate cancer in patients of western Mexico. Materials and methods: The gDNA was analyzed a total of 525 men of whom 301 are presented HBP and 224 patients with clinical diagnosis of prostate cancer. For association they were subclassified high above high and low grade (≤6) following the Gleason scale. Genotyping was performed by Real Time PCR using TaqMan probes system. Results: When we compare the allelic frequencies in the control group, they are in Hardy-Weinberg equilibrium. However, there is no significant association of the disease with polymorphisms or severity or progression was found. Conclusions: There is no association between prostate cancer and genetic polymorphisms at -634 and -1154 position of the promoter region of VEGF.

#1280 Functional characterization of prostate cancer risk loci by SNPs-seq and STARR-seq. Peng Zhang,1 Jing Zhu,2 Sufyan Suleman,3 Yong-Chen Guo,4 Mei-Jun Du,5 Li-Dong Wang,6 Gong-Hong Wei,1 Liang Wang1,2, 1the First Affiliated Hospital of Zhengzhou University, Zhengzhou, China; 2Harbin Medical University, Harbin, China; 3University of Oulu, Oulu, Finland; 4Winer Medical School, Irving, China; 5Medical College of Wisconsin, Milwaukee, WI.

Background. By SNP genotyping and RNA sequencing of 471 normal prostate samples, we recently created a prostate tissue-based eQTL dataset and identified significant eQTL signals at 51 prostate cancer risk loci. To functionally characterize these risk SNPs, we developed a massively parallel sequencing technology (SNPs-seq) for direct allele-specific double-strand oligos and performed DNA-protein binding assays. We combined this technology (called SNPs-seq) with another high throughput assay (called STARR-seq) to screen the risk loci with significant prostate-specific eQTL signals. Methods. To select candidate functional SNPs in eQTL regions, we took advantage of existing epigenomic datasets and available tools including ENCODE, HaploReg, and Regulome. For all selected SNPs, we first made allele-specific double-strand oligos and performed DNA-protein binding assays. We then performed sequencing analysis on the protein-bound DNA oligos and determined allele-specific protein binding differences. To evaluate reproducibility of SNPs-seq, we performed each assay in duplicates. We cloned SNPs-seq screened SNP regions showing allele-specific protein binding differences into the STARR-seq vector to further determine allele-specific enhancer activities. Finally, we performed EMSA and luciferase reporter assays to validate a set of promising candidate SNPs. Results. From 51 risk loci with strong eQTL signals, we selected 374 SNPs with strong indication of regulatory potential, as evidenced by overlapping with epigenomic marks. When comparing technical duplicates, sequence read counts from the SNPs-seq showed significant correlation with r² > 0.99. By normalizing input controls, we found 101 of the 374 SNPs association with significant allele specific protein binding differences (P  ≤ 0.05 for Mediation testing difference between variant and reference alleles). Interestingly, three published functional SNPs (rs12769019, rs10993994, and rs4907792) were also among the significant SNPs, validating SNPs-seq as functional SNP screening tool. To further validate the candidate SNPs from SNPs-seq, we applied STARR-seq and tested the 101 SNPs-containing sequences (371-680bp) in LNCaP cell line under androgen treatment and overexpression assays revealed 11 SNPs that not only demonstrated enhancer/repressor activity but also functioned with allele differences. EMSA and luciferase reporter assays confirmed 6 SNPs with allele-dependent enhancer/repressor activity. Conclusions. We developed a high throughput sequencing-based technology to screen large number candidate SNPs for their allelic
protein binding differences. The SNPs-seq coupled with STAR-seq will provide a powerful strategy for functionally characterizing risk loci in prostate cancer and other common diseases. Further understanding genetic role of prostate cancer etiology may facilitate the translation of population-based discovery into biological mechanisms and eventually benefit clinical practice.

**#1281** Germline mutations in NBN conferring DNA damage response defects are found in patients with multiple cancer types. Sabine Topka, Michael P. Walsh, Ann Maria, Annie Lincoln, Diana Mandelker, Liying Zhang, Marc Ladanyi, Michael F. Berger, Mark E. Robson, Joseph Vija, Kenneth Offit. *Memorial Sloan Kettering Cancer Ctr., New York, NY.*

Nibrin, the protein encoded by the NBN gene forms a complex with Mre11 and Rad51 (MRN complex) that is crucial for DNA damage repair. Mutations in NBN are found in >90% of patients with Niemijegen breakage syndrome (NBS), an autosomal recessive disorder characterized by growth retardation, microcephaly, radiosensitivity, immunodeficiency and increased cancer risk. Most of NBS patients harbor the common founder mutation c.657delE5 that leads to expression of a hypomorphic 70kDa C-terminal fragment produced by alternative translation initiation. Cell lines derived from these patients show increased sensitivity to DNA-damaging agents, chromosome instability, and abnormal cell cycle checkpoint function. Several studies have addressed cancer risk in individuals with germline NBN mutations, showing increased cancer risk for individuals harboring the c.657delE5 founder mutation and for carriers of the R215W missense mutation across multiple cancer types. For other NBN mutations conflicting reports exist as to their association with cancer risk. Here, we report newly identified NBN germline frameshift and truncating mutations in patients with multiple cancer types, including prostate, lung, breast cancer, acute lymphocytic leukemia, and chronic lymphocytic leukemia. Modeling these mutations in an NBN-deficient cellular background showed expression of a novel C-terminal truncated fragment that can bind to Mre11. Cells expressing these mutant proteins display attenuated DNA damage repair function and decreased overall survival following induction of DNA damage. Impaired Chk2 phosphorylation was also observed, indicating cell cycle checkpoint deficiencies. Thus, the NBN germline mutations identified here could contribute to genomic instability predisposing to tumorigenesis. Further in vitro studies with these and additional germline mutations occurring in cancer patients are ongoing, in order to better understand the role of this pathway of DNA damage repair in susceptibility to malignancies.

**#1282** Analysis of missense variants in BRCA1 BRCT domains. Giuliano Di Pietro,1 Vanessa Camara Fernandes,2 Kwabena Amankwah,3 Carla Shields,4 Volha A. Golubeva,3 Carly Harro,3 Marcelo Alex Carvalho,4 Alvaro N. Mon-teiro,1 1Federal University of Sergipe, Sao Cristovao, Brazil; 2Instituto Nacional de Cancer. Rio de Janeiro, Rio de Janeiro, Brazil, Brazil; 3Moffitt Cancer Center, Tampa, FL; 4Instituto do Rio de Janeiro, Rio de Janeiro, Brazil.

Currently, only ¼ (133/600) of documented single nucleotide variation leading to missense changes in the BRCA1 gene have been characterized as pathogenic or non-pathogenic (IARC Class 1 & 2 & 3 & 4 & 5). The remaining 96% of documented single nucleotide polymorphisms (SNPs) within BRCA1 and BRCA2 are germline variants of unknown clinical significance. By studying the breast cancer microenvironment, we can specifically address novel aspects of cancer development and progression at the molecular level. Chemokines are small signaling molecules that are an important component of this microenvironment, as they shape cellular composition of this space through recruitment of immune cells, among other functions. DARC, the Duffy Antigen Receptor for Chemokines (DARC/ACKR1) that can bind different classes of chemokines. It is a non-signaling receptor that mainly acts as a regulator of chemokine homeostasis by removing them from circulation to recruit appropriate immune cell types. The purpose of this study is to determine how population-private variants of the DARC/ACKR1 gene across global population render distinct function and define aspects of human diversity in chemokine responses. A well-studied example of this would be the Duffy-null allele. This allele carries a mutation that is population-specific to recent decedents of Sub-Saharan Africans, and removes expression of DARC on red blood cells. Loss of expression on red blood cells presumably causes these “Duffy-Null” individuals to lose the ability to sequester chemokines, therefore losing homo- static balance of these molecules in circulation. To identify additional mutations, we completed in silico analysis of minor allele frequencies across the gene in the 1000 Genomes Project data, and identified several other putative functional mutations that likely result in additional gene variants, specific to geographic ancestry groups and likely under similar selection as the Duffy null allele. We have prioritized our initial functional study to include mutations in the regulatory regions of the gene, as these mutations can change how and where the gene is expressed. Future work is focused on investigating these functional variants in situ, using human tissue and human breast cell lines, by isolating and re-engineering ancestry-specific variants in these cell lines. By identifying and determining functional outcomes of these population-specific mutation, we can observe differences in immune responses across these global populations, further defining the role that DARC/ACKR1 plays in the breast tumor microenvi-roment.

Tumorigenesis in sporadic cancers is mainly driven by somatic genetic alterations such as driver mutations in protein coding genes or chromosomal changes comprising deletions, amplifications or translocations resulting in loss of tumor suppressor proteins, gain of oncogenic proteins or expression of aberrant fusion proteins, respectively. Some cancers lack such somatic changes, but are addicted to expression of certain genes for their sustained proliferation and survival. There is evidence of such oncogenic addiction to LIM domain only 1 (LMO1) expression in neuroblastoma (NB). Genome-wide association studies (GWAS) have identified robust associations between germline single-nucleotide polymorphisms (SNPs) within LMO1 and NB susceptibility with the causal SNP being rs2168101. Investigation of the mechanism of NB dependency on LMO1 showed that LMO1 expression in NB cells is regulated by rs2168101, which resides within a highly conserved tissue-specific super enhancer in LMO1 intron 1 and drives LMO1 expression through GATA3 transcription factor binding. This makes LMO1-dependent NB a unique example of a monogenic cancer with genetic variation. Numerous GWAS have identified significant associations between germline SNPs in the non-coding genome and cancer risk or outcomes. To identify additional examples of regulatory SNPs as cancer drivers, we merged published genome-wide significant associations from cancer GWAS with genome regulatory data from ENCODE (Encyclopedia of DNA Elements; Nature, 2012 Sep 6; 489 (7414): 57-74) and searched for clusters of cancer associated SNPs that resided within gene regulatory elements. Gene regulatory elements were defined as those marked by active epigenetic features and chromatin accessibility in cancer cell lines. Of the ~1,600 uniquely genome-wide significant SNPs from cancer GWAS with regulatory evidence, we identified 16 clusters of 3 or more putative regulatory SNPs near 28 genes. These clusters were particularly enriched within ovarian cancer associated loci. Mechanistic studies such as reporter assays and genome editing in relevant cell types are being considered to identify the causal SNPs from these clusters regulating gene expression and driving tumorigenesis, which in turn may lead us to new cancer targets.

**#1285** Analysis of esophageal cancer SNPs and gene expression to predict ESCC risk. Lilly A. Ding,1 Molly P. Ding,1 Xin Song,2 Lidong Wang,2 Liang Wang,3 None, Bethesda, MD; 2First Affiliated Hospital, Zhengzhou, China; 3Medical College of Wisconsin, Milwaukee, WI.

Esophageal cancer is one of most common cancers worldwide and its incidence has increased rapidly over the past decades. The majority of esophageal
cancers is the esophageal squamous cell carcinoma (ESCC), which is particularly prevalent in Asian and South African areas. Most cases of ESCC are diagnosed at advanced stages, with an overall 5-year survival rate of 10–20%. Currently, genome-wide association studies (GWAS) are used to identify high risk individuals for the development of ESCC. Many SNPs have been identified to associate with risk of ESCC. Further, the effect size of these SNPs and breast cancer. Further, the meta-analysis of individual studies is modestly suggesting that genetic variants may only account for a very small amount of genetic risk and heritability of ESCC. The combined effect of multi genetic variants with altered mRNA expression play critical roles in ESCC.

In this study, we used several existing bioinformatics databases (HaploReg, GTex Portal and cBio Portal). We first selected 450 potential ESCC risk SNPs from HaploReg and then defined which SNPs caused gene expression alterations in the esophagus through expression quantitative trait loci (eQTL). Nine SNPs in eight genes (MUC1, ALSC2R12, ADHB1, TMEM173, XBP1, PCLCE1, HEATR3 and SMG6) were identified as having altered mRNA expression. The altered mRNA expression of these seventeen genes are: MUC1, THBS3, GPAP1, EFNA1, SCAMP5, CASP8, CASP10, ALSC2R12, STRAD8, ADH4, TMEM173, CVCMT1, DNAJC18, DNAJC20, NOCL, HEATR3 and SRR. These altered gene expressions in the mucosal layer of the esophagus metabolize enzymes, repair DNA, and prevent cell death and inflammation, all of which may indicate that the existing altered esophageal mRNA levels plus the predisposition of normal esophageal epithelial cells lead to harmful environmental carcinogenic, thus attributing to ESCC development. In order to validate these gene alterations and then defined which SNPs caused gene expression alterations, we performed eQTL-qPCR analyses in the early screening of high risk individuals, genotyping of this group of SNPs with a prospective cohort (n = 5451) in a high risk area of ESCC will be tested in future studies.

#1286 Targeted deep sequencing of colorectal tumor tissues to study associations of tumor subtypes with germline genetic, lifestyle, and environmental risk factors. Syed H. Zaidi,1 Wei Sun,2 Jeroen Huhybe,3 Catherine S. Grasso,4 Quang Trinh,1 Charles Connolly,3 Amy French,2 Jasmyn Miu,5 Muris Giannakis,6 Eve Shimbro,7 Ivan Borozan,8 Michael J. Quast,9 Hermann Brenner,10 Daniel Buchanan,11 Peter Campbell,12 Andrew Chan,13 Jenny Chang-Claude,14 Vincent Ferretti,15 Charles Fuchs,15 Andrea Gsur,11 Marc Gunter,12 Tabitha Harrison,2 Michael Hoffmeister,7 Fuchs,5 Andrea Gsur,11 Marc Gunter,12 Tabitha Harrison,2 Michael Hoffmeister,7

According to the recognized role of telomere dysfunction as a cancer hallmark, it has motivated the development of the breast cancer risk associated with telomeres and breast cancer. Further, the Genome-Wide Association Study (GWAS) discovery of seven single nucleotide polymorphisms (SNPs) associated with telomere length (TL) enables the use of an aggregated genetic risk score (GRS) for TL. We hypothesized that a higher GRS (representing shorter TL) would be associated with increased risk of breast cancer, and that a strengthened association may exist between higher TL GRS and overall breast cancer risk. This study used a recent TL GRS constructed to sequence the coding regions of 190 significantly mutated genes identified from whole exome sequencing datasets generated by the Nurses’ Health Study and Health Professional’s Follow-up Study, and The Cancer Genome Atlas. The panel also covers coding regions of 15 genes with germline high penetration mutations in CRC, 54 regions to detect CRC-related copy number alterations (CNAs), and microsatellite and homopolymer repeat regions to identify defective DNA mismatch repair (MMR) genes. These panels also included targets identified in tumor biopsies, as F. nucleatum is thought to promote CRC carcinogenesis. Sequencing of the DNA libraries on Illumina HiSeq 2500 produced a mean coverage of greater than 500X for tumor DNA and 100X for normal DNA, with >85% of the bases covered at the target at 50X. So far, targeted sequencing of >1,500 DNA samples from CRC tumors and normal tissues has identified recurrent and novel somatic mutations, miRNA expression alterations, and higher TL GRS due to defective DNA mismatch repair or pathogenic mutations in the POLE gene. Targeted sequencing has also allowed quantification of the F. nucleatum DNA in tumor biopsies; the results were validated by a multiplex QPCR assay. At the AACR annual meeting, we will present targeted sequencing results generated from the first two GECCO-participating studies (n = 1,300 cases). These data will be valuable for future association testing of somatic mutations, CNAs, hypermutation status, and F. nucleatum with germline genetic variants, lifestyle, and environmental risk factors and survival. This large study will allow development of better strategies for diagnosis, treatment, and prevention of CRC.

#1287 Multigene panel testing and risk estimates in 10,233 ovarian cancer cases. Jenna Lilquist,1 Holly LaDuca,2 Eric Polley,3 Hermela Shimelis,4 Chunling Hu,5 Raymond Moore,6 Steven N. Hart,7 Fergus J. Couch,8 Jill Dolinsky,9 David E. Goldgar12.5. Mayo Clinic, Rochester, MN; 2Ambry Genetics, Aliso Viejo, CA; University of Utah School of Medicine; Huntsman Cancer Institute, Salt Lake City, UT; 6Baylor College of Medicine, Houston, TX; 7German Cancer Research Center, Heidelberg, Germany; 8CancerCare Society, Atlanta, GA; 10Massachusetts General Hospital, Boston, MA; 11Medical University of Vienna, Austria; 12International Agency for Research on Cancer, Lyon, France.

The Genetics and Epidemiology of Colorectal Cancer Consortium (GECCO) in collaboration with the Colorectal Cancer Family Registry (CCFR) aims to identify germline genetic variants and environmental risk factors that impact colorectal cancer (CRC). Over 30 studies from North America, Europe, and Australia participate in GECCO. These studies have collected clinical, epidemiological, and survival data, as well as blood and tumor biospecimens, for over 80,000 CRC cases and controls. The current study aims to conduct targeted deep sequencing of tumors and matching normal DNA to identify recurrent and novel somatic and germline variants in 4,200 CRC cases. To achieve this goal, an AmpliSeq targeted sequencing panel of 1.12 Mb was constructed to sequence the coding regions of 190 significantly mutated genes identified from whole exome sequencing datasets generated by the Nurses’ Health Study and Health Professional’s Follow-up Study, and The Cancer Genome Atlas. The panel also covers coding regions of 15 genes with germline high penetration mutations in CRC, 54 regions to detect CRC-related copy number alterations (CNAs), and microsatellite and homopolymer repeat regions to identify defective DNA mismatch repair (MMR) genes. These panels also included targets identified in tumor biopsies, as F. nucleatum is thought to promote CRC carcinogenesis. Sequencing of the DNA libraries on Illumina HiSeq 2500 produced a mean coverage of greater than 500X for tumor DNA and 100X for normal DNA, with >85% of the bases covered at the target at 50X. So far, targeted sequencing of >1,500 DNA samples from CRC tumors and normal tissues has identified recurrent and novel somatic mutations, miRNA expression alterations, and higher TL GRS due to defective DNA mismatch repair or pathogenic mutations in the POLE gene. Targeted sequencing has also allowed quantification of the F. nucleatum DNA in tumor biopsies; the results were validated by a multiplex QPCR assay. At the AACR annual meeting, we will present targeted sequencing results generated from the first two GECCO-participating studies (n = 1,300 cases). These data will be valuable for future association testing of somatic mutations, CNAs, hypermutation status, and F. nucleatum with germline genetic variants, lifestyle, and environmental risk factors and survival. This large study will allow development of better strategies for diagnosis, treatment, and prevention of CRC.

#1288 Telomere length genetic risk score is associated with breast cancer risk. Laurie Grieshaber,1 Jean Wactawski-Wende,2 Rachael Hageman Blair,3 Lina Mu,4 Leah Preus,1 Jing Nie,1 Jiali Han,2 Jaymie R. Meliker,3 Thomas Rothenberg,14 Andrea Gsur,11 Marc Gunter,12 Tabitha Harrison,2 Michael Hoffmeister,7 Fuchs,5 Andrea Gsur,11 Marc Gunter,12 Tabitha Harrison,2 Michael Hoffmeister,7

Background: Genome-wide association studies (GWAS) have identified associations of telomere maintenance genes with breast cancer risk. This, coupled with the recognized role of telomere dysfunction as a cancer hallmark, has motivated the development of a breast cancer risk associated with telomeres and breast cancer. Further, the Genome-Wide Association Study (GWAS) discovery of seven single nucleotide polymorphisms (SNPs) associated with telomere length (TL) enables the use of an aggregated genetic risk score (GRS) for TL. We hypothesized that a higher GRS (representing shorter TL) would be associated with increased risk of breast cancer, and that a strengthened association may exist between higher TL GRS and overall breast cancer risk. Methods: In a race/ethnically diverse sample of invasive breast cancer cases (N = 1,108) and non-cases (N = 20,023) from the Women’s Health Initiative, we derived an unweighted TL GRS using seven previously identified TL-associated SNPs. Women were post-menopausal and the average age at enrollment was 63.9 years. We tested TL GRS associations with overall breast cancer risk and for estrogen receptor (ER), progesterone receptor (PR), and her2/neu (HER2) status-specific breast cancer risk using Cox proportional hazards models adjusted for age and race/ethnicity (in the entire sample) and age in strata of European American (EA; N = 9,796), African American (AA; N = 7,504), and Hispanic American (HA; N = 3,229) women. We also considered reproductive risk factors, family history of breast cancer, hormone therapy, tumor characteristics, BMI, physical activity, smoking, alcohol, and US region as potential confounders. Results: We observed a small but statistically significant association between shorter TL GRS (shorter TL) and reduced risk of overall breast cancer in the entire sample (HR = 0.96, 95% CI: 0.93-1.00). Results of race/ethnicity-stratified analyses for TL GRS and overall breast cancer risk were not significant. The TL GRS was independently associated with decreased risk of ER-negative, PR-positive, and HER2-positive breast cancer risk in the entire sample (HR = 0.82, 95% CI: 0.78-0.86).
further identified suggestive associations (P < 0.71-0.94, HR = 0.94, 95% CI: 0.89-0.99, and HR = 0.88, 95% CI: 0.79-0.90, respectively). Similarly, the TL GR was associated with a reduced risk of ER-negative breast cancer in AA (HR = 0.79, 95% CI: 0.66-0.97) and independently with PR-positive and HER2-positive breast cancer risk in HA (HR = 0.85, 95% CI: 0.75-0.97 and HR = 0.79, 95% CI: 0.58-0.99, respectively). Adjustment for other covariates did not alter the significant associations. O.K. Keku,11 Cathrine Hoyo,12 Andrew Berchuck,6 Paul Pharoah,13 Joellen M. Schilchian women.

morphism is associated with high-grade serous ovarian cancer in African Americans. UGT1A, 6302 SNPs in UGT2B, 410 SNPs in CYP3A4/5, and 824 SNPs in EGFR. Logistic regression was performed using an additive 1 degree of freedom model for genetic inheritance with adjustment for two principal components of ancestry to estimate odds ratios (OR) and 95% confidence intervals (CI). For each gene region, we applied a gene-specific Bonferroni-threshold for statistical significance of 5 x 10^-5 per number of SNPs examined for that gene. Based on this significance threshold, a statistically significant association with HGSOC was identified in the EGFR region for the imputed SNP, rs114972508 (per allele OR = 2.32, 95% CI: 1.58, 3.40 p = 1.6e-05, imputation R-squared = 0.89). We further identified suggestive associations (P < 1.0e-06) with EOC for 10 imputed SNPs located within the UGT2B4 gene. We did not replicate previous associations in the 282 SNPs examined in the VDR gene for EOC overall or among HGSOC. In summary, we identified statistically significant association for variants from the EGFR region, and suggestive evidence of association for variants within the UGT2B region in genetic association analyses of ovarian cancer in women of African Ancestry. Data from in vitro experiments suggest that EGFR transcription and proliferative function is suppressed via VDR binding. Thus, EGFR association with HGSOC may be a marker of VDR activity. UGT2B4 variants have not been previously explored in ovarian cancer but shown to be nominally associated with breast cancer in women of African ancestry. UGT2B4 enzymes, part of the phase II liver detoxification pathway, are important in the clearance of steroid hormones, bile acid and drug metabolism. Alterations in EGFR and UGT2B4 could perturb enzyme efficacy and proliferation in ovaries and impact susceptibility to ovarian cancer. Future studies will be needed to validate the associations of the imputed SNPs and to determine the impact of EGFR and UGT variants on cancer development.

#1290 Association of common genetic variants with TMPRSS2 ER fusion status in prostate cancer. Indu Khojaa,1 Lakshmi Ravindranathb,1 Denise Youngc,1 Amina Alf,2 Qiyuan Li,2 Albert Dobic,1 David McLeod,1 Inger L. Rosner,1 Isabel Sesterhemb,2 Matthew Freedman,3 Shiv Srivastava,1 Gyorgy Petrovics,1,4 CPDR/USUHS, Rockville, MD;5 WRNMMC/USUHS, Bethesda, MD;6 Xiaomen University, China;7 Dana-Farber Cancer Institute, Boston, MA.

Introduction and Objectives: Oncogenic activation of ERG resulting from prevalent gene fusions is present in two thirds of prostate cancer (CaP) patients of European Ancestry including Caucasian Americans (CA). Our laboratory and others have recently reported that major cancer driver genes, including ERG, show significant racial/ethnic differences in CaP with lower frequencies in African Americans. Such racial/ethnic differences may reflect, in part, differences in how germline molecular determinants associating with ERG status of CaP. Methods: Blood derived genomic DNA samples were prepared from 270 AA men and 129 CA men treated by radical prostatectomy at Walter Reed National Military Medical Center (WRNMMC). ERG status was determined in whole mounted prostate specimens by immune-histochemistry (IHC) for ERG protein expression as a surrogate for the TMPRSS2-ERG fusion. Blinded blood samples were genotyped for SNPs on the Illumina Golden Gate platform using Infinium Oncoarray, a 300K genome wide BeadChip kit from Illumina. Data analysis approaches included association analyses based on logistic regression, Principal Component Analysis (PCA) and Efficient Mixed-Mixed Model Association (EMMAX) analysis. Genotype imputation analysis is being performed by IMPUTE2 program. Results: After applying rigorous sample and SNP QC steps on the datasets, SNP genotyping analysis was performed in 321 patients with 478,299 SNPs. Logistic regression, principal component analysis by EIGENSTRAT and a variance component approach, EMMAX analysis were performed to account for population structure. By EMMAX we identified SNPs associated with ERG status. The SNPs most significantly (<10^-3) associated with ERG fusion status included rs6968333, an intron variant of Kruppel-like factor 17 (KLF17) and two SNPs (rs1889877, rs3798999) in the intron of adhesion G protein-coupled receptor B3 (ADGRB3). Fine-mapping of SNPs is under way by genotype imputation analysis (IMPUTE2) using the 1000 Genomes reference dataset, followed by independent validation. Conclusions: This study identified SNPs differentially associated with ERG status of CaP, a major driver oncogene in CaP. Although the biological significance as it relates to ERG status of CaP still needs to be determined, these SNPs, with independent validation, may help as markers in stratifying patients early (even before CaP is detected) for targeted prevention and treatment options.

#1291 Mutation analysis of endometrial cancer in a population-based study by targeted next-generation sequencing. Maxine Chen, Marta Crouse-Bou, Michael J. Downing, Evan L. Busch, Kimberley Glass, Jennifer Prescott, George L. Mutter, Immaculata De Vivo, Brigham and Women's Hospital and Harvard Medical School, Boston, MA.

Endometrial carcinoma (EC), a malignancy that arises from the epithelial lining of the uterus, is heterogeneous at histologic and molecular levels. Risk factors and outcomes also differ by type. Though prior studies characterized the genomic landscape of endometrial carcinoma, few integrated histologic, clinical, and prospectively collected epidemiologic data into the analysis. We collected formalin-fixed paraffin-embedded tumor tissue from women enrolled in the Nurses' Health Study who were diagnosed with EC between 1976 and 2012. We targeted 50 cancer-related genes for high-throughput sequencing to identify genetic variants in 37 ECs and 26 normal EC cases. Selection of the 50 genes was guided by Illumina's OncoArray, a 500K genome wide BeadChip kit from Illumina. Data were processed with GATK (v3.3.0) and variants were annotated with ANNOVAR v20140131 to determine gene ontology. The selected genes were chosen to capture germline association with ERG fusion status. The goal of this study is to identify germline molecular determinants associating with ERG status of CaP.

#1292 Germline genetic, molecular and environmental factors modulate APOBEC mutagenesis in human tumors. A. Rouf Banday, Ariunaa Bayanjar-
Prevalence and spectrum of germline rare variants in ABO blood type and cancer risk: preliminary findings from a phenotype-modulate APOBEC mutagenesis in human tumors. Methods: Isoform-specific exons can be exploited for risk prediction or cancer prevention is warranted. In addition, research to determine how ABO blood type and cancer phenomes were quantified with Odds Ratios (OR) and corresponding 95% Confidence Intervals (CI) from logistic regression in models adjusted for sex and stratified by race/ethnicity. Only analyses with at least 100 cases per strata were conducted. Results: Among 221,015 Non-Hispanic Caucasians, 37,841 Blacks, 7,714 Hispanic Caucasians, and 3,761 Asian subjects with ABO blood type available in linked EMR, we evaluated 56, 37, 4, and 3 general cancer phenotype codes, respectively. After applying Bonferroni corrections, ABO blood type was significantly associated with cancers of the pancreas, ovary, cervix, skin, and hematopoietic system. Caucasians with blood type O were less likely to have ovarian cancer (OR: 0.82, 95% CI: 0.73-0.91) and pancreatic cancer (OR: 0.83, 95% CI: 0.74-0.92), and more likely to have squamous cell or other skin cancer (OR: 1.08; 95% CI: 1.04-1.13) and myeloid leukemia (OR: 1.15, 95% CI: 1.06-1.25) than those with other blood types (A, B, or AB). Hispanic Caucasians with blood type O were less likely to have cervical cancer (OR:0.56, 95% CI: 0.38-0.82) than those with other blood types. No associations surpassed correction for multiple comparisons among Blacks or Asians. Conclusions: Our phenome approach confirmed known associations between blood type and risk of pancreatic and ovarian cancer, and adds to accumulating evidence supporting associations with skin cancer and leukemia. Our novel cervical cancer association among Hispanic Caucasians and other nominally significant findings, especially in understudied non-Caucasians, should be further evaluated in large and diverse populations. In addition, research to determine how ABO blood type may influence cancer development and progression, and if such associations can be exploited for risk prediction or cancer prevention is warranted.
Bayesian fine-mapping using summary data of 145,000 subjects refines common risk associations, discovers secondary signals and novel candidate genes for prostate cancer. Zofia Kote-Jarai,1 Tolking Dadavey,1 Ed Saund-ers,1 Paul Newcombe,2 Ezequiel Anokian,1 Daniel Leongamornlert,1 Ali Amin Al Olama,3 Christopher Haiman,3 Ros Eles,4 David Conti,4 The PRACTICAL/ELLIPSE Consortium.1 Inst. of Cancer Research, Sutton, United Kingdom;2 University of Cambridge, Cambridge, United Kingdom;3 University of Southern Cali-fornia, Los Angeles, CA.

Genome-wide association studies (GWAS) have identified more than 160 prostate cancer (PrCa) genetic risk loci, however these variants rarely point directly to the true underlying functional variant driving the association. In this fine-mapping study to narrow the credible causal variant set for 80 PrCa regions representing 89 original independent GWAS signals, we performed Bayesian variable selection in combination with functional annotation and quintile regression. We used imputed data for 83,511 PrCa cases and 62,283 controls investigat-ed with high-density genotyping arrays from the OncoArray, iCOGS and 5 previous GWAS studies from the PRACTICAL/ELLIPSE consortia. To facilitate fine-mapping from one-at-a-time SNP associations meta-analyzed over the consortia we first applied JAM, a novel Bayesian algorithm which searches multi-SNP models in summary data by imputing the correlation structure according to a reference panel. JAM provides inference on the number of independent signals, as well as the set of potential SNPs driving those signals. We utilized functional annotation and eQTL analysis (TCGA prostate tumor data) in combination with quintile regression to further prioritize the most likely causal variants within the credible set of SNPs and identify potential candidate genes and functional mechanisms. The median credible set size from JAM was 17 SNPs per region, shrinking the post-QC input set of variants by about 98%. In 13 regions evidence was found for multiple independent signals, up to a maxi-mum of 5 SNPs. Within the single hit regions, almost half had less than 10 variants selected. In 34 regions the credible set included at least one SNP that was co-localized with a significant eQTL. Quintile regression highlighted enrichment for variants in promoters, DNase hypersensitivity site and eQTLs - repre-senting candidate biological mechanisms underpinning disease development. This study has substantially reduced and prioritized the candidate causal PrCa risk variants previously known from previous GWAS regions, identifying a small subset of variants for further functional investigation and novel candidate genes at a number of loci.

with and without adjustment for covariates (age at diagnosis, stage, tumor neo-
antigen load, tumor ESR1 expression) was used to test association between ge-
rmelne SNP genotype and the tumor anticancer immune response measures. SNPs
were evaluated individually and collectively as a polygenic risk score (PRS)
weighted by the per-allele log OR derived from the OncoArray analysis. The
breast cancer GWAS were performed at the Fred Hutchinson Cancer Re-
search Center, UT; 11University of Washington, WA; 12Moffit Cancer Center, FL;
13University of Virginia, VA; 14Cedars-Sinai Medical Center, Los Angeles, CA; 15Harvard T.H.
Chan School of Public Health, Boston, MA; 16The Institute of Cancer Research, Lon-
don, United Kingdom; 17University of Southern California, Los Angeles, CA.

Common genetic variants in over 150 loci have been found to be associated with prostate cancer (PrCa) risk through GWAS. These variants, however, explain only a small fraction of PrCa heritability, and the genes responsible for the detected asso-
ciation have not been identified. These unidentified risk factors may be un-
detectable at the individual level, or the detected associations may be driven by the regulation of risk variants on the expression of disease causal genes. To identify novel PrCa risk loci and possible causal genes at known risk loci, we performed a transcriptome-wide association study (TWAS) to evaluate associations of genetically predicted gene expressions with PrCa risk. We used RNA sequencing data from normal prostate tissues and high-density genotyp-
ing from 73 European descendants included in the Genotype-Tissue Expression
Project and established generic models to predict gene expression levels. Given that
the regulatory mechanisms for most genes are similar across most human tissues, we
also built cross-tissue models using gene expression data generated from all tissues from 369 European descendants to increase the statistical power. Based on predic-
tion performance, we selected 22,126 genes and conducted association analyses of
transcriptome-wide expression levels using GWAS data obtained from more
than 134,000 subjects included in PRACTICAL/ECLIPSE consortia. We identified
140 genes showing an association of their predicted expression levels with PrCa risk
and biologically significant associations with CXCR1 (OR
9.9x10−10, Padj
0.001) was for
rs71801447 overlapped enhancers in CD4+ and CD8+ T cells and in HMEC and MCF7 breast cells that were predicted to
interact with the promoter of BCL2L11 in each of these cell types. Finally, as a
PRS, breast cancer risk was significantly associated with reduced tumor type I
interferon activity (Padj
0.001; Padj = 0.02). Our findings implicate
BCL2L11, a well-known regulator of T and breast cancer cell apoptosis, as a potential genetic candidate and potential target for future risk stratification,
and biological insight of risk loci.

Proceedings of the American Association for Cancer Research • Volume 58 • April 2017

335
BACKGROUND: Glioma accounts for ~27% of all primary brain tumors and is responsible for ~13,000 cancer-related deaths in the US each year. Gliomas can be broadly classified into glioblastoma (GBM) and lower-grade non-GBM. Typically gliomas have a poor prognosis irrespective of medical care, with the most common form, GBM, having a five-year survival rate of only 5%. While genome-wide association studies (GWAS) have transformed our understanding of glioma susceptibility, individual studies have limited power to identify risk loci. METHODS: We performed the largest GWAS to date, comprising a meta-analysis of six existing GWAS (6,405 cases, 14,100 controls) as well as new GWAS from the Glioma International Case Control Consortium (GICC; 4,572 cases and 3,286 controls) and University of California, San Francisco (UCSF)-Mayo (1,519 cases, 804 controls), totaling 12,496 cases (6,191 classified as GBM, 5,819 as non-GBM) and 18,190 controls. RESULTS: We identified five new risk loci for GBM at 1p31.3 (rs12752552; near JAK1, P = 2.04 x 10^-10, odds ratio (OR) = 1.22), 11q14.1 (rs11233250; P = 9.95 x 10^-10, OR = 1.24), 16p13.3 (rs2562152; near MPG, P = 1.93 x 10^-10, OR = 1.21), 16q12.1 (rs10852606; HEATR3, P = 1.29 x 10^-11, OR = 1.18), 22q13.1 (rs2235573; P = 1.76 x 10^-10, OR = 1.15), and eight for non-GBM at 1q32.1 (rs4252707; MDM4, P = 3.34 x 10^-9, OR = 1.19), 1q44 (rs10760373; AKT3, P = 2.63 x 10^-10, OR = 1.23), 2q33.3 (rs7572263; near IDHI, P = 2.18 x 10^-10, OR = 1.20), 3p14.1 (rs11706832; LRIG1, P = 7.66 x 10^-9, OR = 1.15), 10q24.33 (rs11998018; OBFC1, P = 3.39 x 10^-9, OR = 1.14), 1q21 (rs7107785; P = 3.87 x 10^-9, OR = 1.16), 14q12 (rs1047037; P = 1.07 x 10^-9, OR = 1.18) and 11q13.31 (P = 4.20 x 10^-9, OR = 1.18). Case-only analyses confirmed the specificity of 11q14.1, 16p13.3 and 22q13.1 associations for GBM and 1q44, 2q33.3, 3p14.1, 11q21 and 14q12 for non-GBM tumors. In the combined meta-analysis, among previously published glioma risk SNPs, those for all glioma at 17p13.1 (TP53), GBM at 3p13.33 (TERC), 7p11.2 (EGFR), 9p21.3 (CDKN2B-AS1) and 20q13.33 (RTEL1) and for non-GBM at 8q24.21 (CCDC26), 11q23.2, 11q23.3 (PHLD1B) and 15q24.2 (ETFAT) showed even greater evidence for association. SNPs at 10q25.2 and 12q12.1 for non-GBM tumors retained genome-wide significance (i.e. P < 5.0 x 10^-8). Associations at the previously reported loci for GBM at 3q26.2 (near TERC) and 12q33.3 (POLR3B) did not retain statistical significance. CONCLUSIONS: Our findings substantially increase susceptibility to GBM and non-GBM glioma being highly distinct, consistent with their distinctive molecular profiles presumably resulting from different etiological pathways. Functional analyses should lead to further insights into the biological basis of the different glioma histologies. Such information can inform gene discovery initiatives and therefore have a measurable impact on the successful development of new therapeutic agents.

#1303 A genome-wide association study of prostate cancer in Latinos. Hannah Hopp,1 Sue Ingles,1 Chad Huff,2 Xin Sheng,1 Brandi Weaver,3 Mariana Asimwita Luke,1 Kuteesa J,1 Dabanja M. Henry,1 David Conti,2 Christopher Nalukenge Cissy,1 Muwanga Proscovia,1 Lutalo Moses,1 Nansereko Deborah,4 Candra Davis,5 Reyes-Muñoz,5 Hispanic Health and Nutrition Examination Survey (HHANES),5 and NCI. METHODS: We performed the largest GWAS to date, comprising a meta-analysis of six existing GWAS (6,405 cases, 14,100 controls) as well as new GWAS from the Glioma International Case Control Consortium (GICC; 4,572 cases and 3,286 controls) and University of California, San Francisco (UCSF)-Mayo (1,519 cases, 804 controls), totaling 12,496 cases (6,191 classified as GBM, 5,819 as non-GBM) and 18,190 controls. RESULTS: We identified five new risk loci for GBM at 1p31.3 (rs12752552; near JAK1, P = 2.04 x 10^-10, odds ratio (OR) = 1.22), 11q14.1 (rs11233250; P = 9.95 x 10^-10, OR = 1.24), 16p13.3 (rs2562152; near MPG, P = 1.93 x 10^-10, OR = 1.21), 16q12.1 (rs10852606; HEATR3, P = 1.29 x 10^-11, OR = 1.18), 22q13.1 (rs2235573; P = 1.76 x 10^-10, OR = 1.15), and eight for non-GBM at 1q32.1 (rs4252707; MDM4, P = 3.34 x 10^-9, OR = 1.19), 1q44 (rs10760373; AKT3, P = 2.63 x 10^-10, OR = 1.23), 2q33.3 (rs7572263; near IDHI, P = 2.18 x 10^-10, OR = 1.20), 3p14.1 (rs11706832; LRIG1, P = 7.66 x 10^-9, OR = 1.15), 10q24.33 (rs11998018; OBFC1, P = 3.39 x 10^-9, OR = 1.14), 1q21 (rs7107785; P = 3.87 x 10^-9, OR = 1.16), 14q12 (rs1047037; P = 1.07 x 10^-9, OR = 1.18) and 11q13.31 (P = 4.20 x 10^-9, OR = 1.18). Case-only analyses confirmed the specificity of 11q14.1, 16p13.3 and 22q13.1 associations for GBM and 1q44, 2q33.3, 3p14.1, 11q21 and 14q12 for non-GBM tumors. In the combined meta-analysis, among previously published glioma risk SNPs, those for all glioma at 17p13.1 (TP53), GBM at 3p13.33 (TERC), 7p11.2 (EGFR), 9p21.3 (CDKN2B-AS1) and 20q13.33 (RTEL1) and for non-GBM at 8q24.21 (CCDC26), 11q23.2, 11q23.3 (PHLD1B) and 15q24.2 (ETFAT) showed even greater evidence for association. SNPs at 10q25.2 and 12q12.1 for non-GBM tumors retained genome-wide significance (i.e. P < 5.0 x 10^-8). Associations at the previously reported loci for GBM at 3q26.2 (near TERC) and 12q33.3 (POLR3B) did not retain statistical significance. CONCLUSIONS: Our findings substantially increase susceptibility to GBM and non-GBM glioma being highly distinct, consistent with their distinctive molecular profiles presumably resulting from different etiological pathways. Functional analyses should lead to further insights into the biological basis of the different glioma histologies. Such information can inform gene discovery initiatives and therefore have a measurable impact on the successful development of new therapeutic agents.
established environmental/lifestyle risk factors have been identified, with the only established risk factors being age, race/ethnicity and family history, all of which implicate genetic susceptibility. GWAS have clearly validated the importance of genetic susceptibility in prostate cancer, with ~100 common risk loci identified to date which in aggregate explain 33% of the familial risk. Genetic studies in African ancestry populations have provided strong evidence for genetic factors in contributing to the greater incidence of prostate cancer in men of African ancestry. To further explore this hypothesis, we conducted a genome-wide association study (GWAS) of prostate cancer among Ugandan men. Specifically, we genotyped the Illumina OncoArray, which includes a 260K GWAS backbone, in 560 prostate cancer cases (119 with Gleason score ≥ 8) and 480 controls and tested the associations of 448,939 genotyped and 16,396,662 imputed variants with >1% frequency. The most statistically significant variant were observed at the 8q24 risk locus (rs72275854, OR=3.37, P=2.14x10⁻¹⁵). We also observed suggestive signals with 106 variants outside of known risk regions with P-values <10⁻⁶ and >10⁻⁸. Of the 104 known risk variants, 100 are polymorphic in Uganda men, of which, 66 (66%) had effects that were directionally consistent in their association with prostate cancer risk as previously reported and 8 (8%) were significantly associated with risk at p < 0.05, with the most statistically significant being rs16901979 at 8q24 (OR=1.45, P=0.0001) and rs1512268 at 2p21.2 (OR=1.31, P=0.0087). In addition to these findings, we will also present the results from replication testing of the most significant associations from the GWAS in the Ghana Prostate GWAS Study and the African Ancestry Prostate Cancer Consortium, as well as provide a detailed comparison of polygenic risk models of the known prostate cancer variants between these two African populations, African Africans and men of European ancestry.

### #1306 Two distinct regulatory mechanisms underlie estrogen receptor negative breast cancer susceptibility at the 2q23.2 locus

Carly M. Harro,1 Gustavo Mendoza-Fandino,1 Nicholas T. Woods,2 Xuexi Li,1 Fergus J. Couch,3 Álvaro N. Monteiro1.1 Eppley Institute for Research in Cancer, Omaha, NE;2 Mayo Clinic, Rochester, MN.

Genome Wide Association Studies (GWAS) are designed to identify single nucleotide polymorphisms (SNPs) mapping to genomic regions associated with a particular trait or disease. Currently, 19 genomic loci associated with breast cancer susceptibility are known, but the precise mode of action of these loci remains largely unknown. Two recent GWAS with large sample sizes did not reveal consistent evidence of association with breast cancer. However, looking beyond disease-specific SNPs may offer insight into the regulation of genes that may contribute to breast cancer risk. Here, we integrated transcriptome-wide association study (TWAS) to search for novel genetic loci for breast cancer risk. The TWAS highlighted two intrinsic loci: an enhancer-like element defined by SNP rs44017214 located in the first intron of the WDR43 gene; and a segment in the 3'-UTR region of WDR43 defined by SNPs rs11680458 and rs11331880 which are predicted to have allele specific binding of non-coding microRNAs miR-548 and miR-376, respectively. We validated allele specific transcription factor binding to rs44017214 using competitive binding of USF1/USF2 to the risk allele in both MCF10A and CAL51 cell lines in Electrophoretic Mobility Shift Assays (EMSA). Additionally, rs44017214 was removed using CRISPR-cas9, and expression of neighboring genes was evaluated by qRT-PCR. No change in expression was found for any gene in a 2 Mb region surrounding the SNP, with the exception of PLB1. This suggests that the enhancer element in the intron of WDR43 has PLB1 as its target. To assess the miRNA binding site impact on WDR43 expression the pMIR-REPORT Luciferase allele-specific vector was co-transfected with miR-141/200, miR548, or miR-376 in MCF10A cells. The rs11331880 allele C in the WDR43 3'-UTR, rs4401714, and (ii) decreasing the expression of WDR43 through the formation of a miR-376 binding site at the 3'-UTR of the WDR43 gene. Elucidating the functional significance of these common variants in the novel susceptibility loci 2p23.2 furthers our knowledge of the etiology of estrogen receptor negative breast cancer.
EPIGENOMICS: Genome-Wide Association Studies/Post-GWAS Studies

ovarian cancer from 25,509 cases and 40,941 controls. MetaXcan was used to integrate gene expression prediction model with summary statistics. Results: We identified 35 genes with predicted expression levels associated with ovarian cancer risk at P value < 2.2 x 10^-10, the Bonferroni corrected significance level for multiple comparisons. Of these, 12 genes at 4 genetic loci were located at ≤500kb away from risk SNPs previously reported in GWAS, representing potential novel loci for ovarian cancer risk. The remaining 23 genes at 12 loci are located within known ovarian cancer risk loci. Fifteen of these genes at the 12 loci have not been reported in previous studies. Analyses by ovarian cancer histological subtypes showed that the majority of these 35 genes are associated with serous invasive carcinoma. Several new associations were identified in histological subtype analyses. Conclusion: In this study we identified 35 genes with predicted expression levels related to ovarian cancer risk and provide substantial new information to enhance the understanding of ovarian cancer biology and genetics.

#1309 Association between insulin resistance and breast cancer risk: A Mendelian randomization analysis of data from 228,000 women of European descent. Xiang Shu,1 Lang Wu,1 Nikhil K. Khankari,1 Kyriaki Michailidou,1 Manjeet K. Bolla,1 Jean Wang,1 Joe Dennis,1 Xiao-ou Shu,1 Jacques Simard,2 Douglas F. Easton,3 Wei Zheng,3 Vanderbilt-Ingram Cancer Center, Vanderbilt University School of Medicine, Nashville, TN; 2University of Cambridge, Cambridge, United Kingdom; 3Centre Hospitalier Universitaire de Québec Research Center, Laval University, Québec City, Quebec, Canada.

Background: Epidemiologic studies suggest that insulin resistance may be associated with breast cancer risk. We conducted Mendelian randomization (MR) analyses to reduce the bias associated with previous studies and provide evidence for causal inference. Materials and Methods: We used genetic variants identified in genome-wide association studies for circulating fasting insulin (15 variants), early insulin secretion (16 variants), fasting proinsulin (8 variants), fasting glucose (35 variants), and 2-hour glucose (8 variants) as instruments in MR analyses. To reduce possible pleiotropic effects, variants associated with obesity were removed from the instruments. We first evaluated the association of these instruments with type 2 diabetes risk in 110,452 subjects to assess instrument validity. We then investigated the association of these instruments with breast cancer risk using data obtained from 122,977 cases and 105,974 controls of European descent included in the Breast Cancer Association Consortium (BCAC). Odds ratios (ORs) were calculated to measure the association of individual variants with risk of overall breast cancer and its subtypes defined by estrogen-receptor [ER] status. Results: All instrumental variables constructed for this study were strongly associated with type 2 diabetes risk with ORs of 3.01 (p = 7.86x10^-10), 0.22 (p = 3.54x10^-10), 1.90 (p = 8.28x10^-10), 6.11 (p = 3.59x10^-10), and 1.91 (p = 6.8x10^-10) for per unit increase of fasting insulin, early insulin secretion, fasting proinsulin, fasting glucose, and 2-hour glucose levels, respectively. Statistically significant associations with overall breast cancer risk were found for fasting insulin (OR = 1.36 for per unit increase, CI 1.32-1.40, p = 0.0011) and fasting proinsulin (OR = 1.21, 95% CI = 1.06-1.38, p = 0.0011). These associations were observed only for ER-positive breast cancer. No statistically significant association at p<0.05 was found for early insulin secretion, fasting glucose, or 2-hour glucose levels. Conclusions: Our study provides strong support that certain insulin resistance traits may be causally associated with risk of breast cancer, particularly ER-positive breast cancer.

#1310 Identification of pleiotropic cancer susceptibility variants from genome-wide association studies reveals functional characteristics. Yi-Hsuan Wu,1 Rebecca E. Graff,1 Michael N. Passarelli,2 Thomas J. Hoffmann,1 Elad Ziv,1 John S. Witte,3 University of California, San Francisco, San Francisco, CA; 2Geisel School of Medicine, Dartmouth College, Hanover, NH.

Background: There exists compelling evidence that some genetic variants are associated with the risk of multiple cancers (i.e., pleiotropy). However, the biological mechanisms of the pleiotropic effects are unclear. Thus, we investigated the functional effects for genetic variants associated with the risk of multiple cancers. Methods: The National Human Genome Research Institute-European Bioinformatics Institute (NHGRI-EBI) GWAS Catalog contains 28,643 variant-trait associations with p < 10^-8. We utilized the Experimental Factor Ontology (EFO) to classify cancer traits and obtained all associations between variants and cancer risk. Based on pairwise linkage disequilibrium (LD) determined from the European (EUR) population of Phase 3 of the 1000 Genomes Project in LDLink, correlated variants (R-squared ≥ 0.8) were clustered into groups. Variant groups associated with the risk of multiple cancers were annotated using the Ensemble Variant Effect Predictor (VEP), and tested for functional enrichment using the DAVID Functional Annotation Tool. Results: We identified 1,456 variant-cancer risk associations. The majority (57.1%) of the associations were discovered in European ancestry populations, 19.0% in East Asians, 7.9% in an African Americans or Afro-Caribbean, and 7.1% in Hispanics or Latin Americans. Removing duplicates, we found 1,034 unique variant-cancer risk associations for 1,005 unique variants and 27 unique cancer sites. After clustering correlated variants, we identified 29 pleiotropic variant groups, of which 2 were associated with risk of five different cancer sites. Variant group rs10936599 and rs12696304 within the MYNN gene (7.8 kb from the TERC gene) was associated with leukemia, multiple myeloma, and colorectal, skin, and bladder previously reported in GWAS, representing potential novel loci for breast cancer. The remaining 23 genes at 12 loci are located within known ovarian cancer risk loci. Fifteen of these genes at the 12 loci have not been reported in previous studies. Analyses by ovarian cancer histological subtypes showed that the majority of these 35 genes are associated with serous invasive carcinoma. Several new associations were identified in histological subtype analyses. Conclusion: In this study we identified 35 genes with predicted expression levels related to ovarian cancer risk and provide substantial new information to enhance the understanding of ovarian cancer biology and genetics.

#1311 Germ line variation at 8q24 and prostate cancer risk. Kan Wang,1 Ali Amin Al Olama,2 Rosalind Eeles,2 David Conti,1 Zoila Kote-Harai,1 Christopher A. Haiman1. 1Department of Preventive Medicine, Keck School of Medicine, USC/Norris Comprehensive Cancer Ctr, Los Angeles, CA; 2Centre for Cancer Genetic Epidemiology, Department of Public Health and Primary Care, University of Cambridge, Cambridge, United Kingdom; 3The Institute of Cancer Research, London, United Kingdom.

The 8q24 region harbors multiple risk variants for distinct cancers including 7 for prostate cancer, the majority of which lie in separate linkage disequilibrium blocks. It is not known whether a common biological mechanism underlies the association of genetic variation with cancer risk at 8q24, or whether there are site-specific functions of regulatory elements that are affected in this region. Given the proximity, the MYC oncogene is a likely candidate as are multiple long non-coding RNAs in the region. To further understand the contribution of germline variation to prostate cancer risk we performed a comprehensive fine-mapping analysis of the region in men of European ancestry from the PRACTICAL/ELLIPSE Consortium. More specifically, we tested 1,731 genotype tag SNPs and 12,221 imputed variants spanning the risk region (127.3-129.0Mb) in 56,363 prostate cancer cases and 37,386 controls of European ancestry that were genotyped with the Illumina OncoArray. We performed stepwise logistic regression and identified 13 variants with risk allele frequencies between 0.006 and 0.998 that surpassed genome-wide statistical significance (p-values between 3.2x10^-8 and 8.2x10^-10) and with per allele odds ratios ranging from 1.11(rs1003678) to 2.68(rs183373024). Ongoing analyses that will be presented include incorporating existing GWAS and fine-mapping data (iCOGs) for men of European and African ancestry (35,000 cases and 35,000 controls) using JAM, a Bayesian approach that investigates multi-SNP models using marginal meta-analysis statistics. Leveraging the power from the overall multiethnic meta-analysis (>93,000 cases and >72,000 controls) will provide further insight into the number of independent signals in the region and their contribution to prostate cancer risk in these populations.

#1312 Genetic variation in the Hippo pathway and breast cancer risk in women of African ancestry in the ROOT Consortium. Shengfeng Wang,1 Yonglan Zheng,1 Temiduyo O. Ogundiran,2 Oladosu Oyebode,2 Wei Zheng,1 Katherine L. Nathanson,4 Barbara Nemescu,5 Stefan Ambs,6 Dezheng Huo,1 Olufumilayo I. Olopade1. 1University of Chicago, Chicago, IL; 2University of Ibadan, Ibadan, Nigeria; 3Vanderbilt University, Nashville, TN; 4University of Pennsylvania, Philadelphia, PA; 5State University of New York at Stony Brook, Stony Brook, NY; 6National Cancer Institute, Bethesda, MD.

Background: The Hippo pathway controls organ growth by regulating cell proliferation and apoptosis. To our knowledge, it is still unclear about its role in the development of breast cancer. Identifying the relevant genes and single-nucleotide polymorphisms (SNPs) should shed light on the pathway’s mechanism in carcinogenesis. Methods: We examined 47,419 SNPs in 37 Hippo pathway genes in the genome-wide association study of breast cancer conducted in the African Diaspora (ROOT consortium), which included 3,686 participants of African ancestry from Nigeria, USA, and Barbados (1,657 cases and 2,029 controls). Gene-level analyses were conducted using the adaptive rank truncated product (ARTP) test for 10,771 SNPS that weren’t highly correlated (t^2 < 0.8), and SNP-level analyses were conducted with logistic regression. Results: The Hippo pathway was significantly associated with risk of estrogen receptor positive (ER+) breast cancer (pathway-level P = 0.028). Gene-based analyses revealed that WW1C1 (gene-level P = 0.001) was responsible for this association, with rs16516663 in this gene being statistically significant after gene-level adjustment for multiple comparisons [odds ratio (OR) = 0.63 for each G allele, 95% confidence interval (CI) = 0.41-0.70, P = 0.002]. In addition, two SNPs in LAT52 (rs1429000440, OR = 0.42, 95% CI: 0.28-0.64; rs85674288, OR = 0.38, 95% CI = 0.24-0.61) were associated with risk of ER+ breast cancer. In the analysis of ER- breast cancer risk,
r2579161 in DLG5 (OR = 1.38, 95% CI: 1.17-1.63) and rs1062429 in TEAD4 (OR = 1.39, 95% CI: 1.17-1.64) were statistically significant. These associations remained significant after Bonferroni-correction at the gene-wide level (all P < 0.05). Conclusions: We found evidence of associations of the Hippo pathway with ER+ breast cancer risk in women of African ancestry. Our findings supported the potential mechanism that WWC1 functions as an upstream member of the pathway, and highlighted the importance of further studies.

**#1313 Characterization of germiline susceptibility to male breast cancer.**

Eleni Perrakis, Sarah Maguire, Katarzyna Tomczyk, Anthony Swerdlov, Nick Orr. ICR, London, United Kingdom.

Male breast cancer (MBC) accounts for approximately 1% of all breast cancer cases. Family history is established as a risk factor for MBC and 10% of patients have genetic BRCA2 mutations. We recently demonstrated that common germiline polymorphisms contribute to MBC predisposition and that there is overlap between genetic susceptibility loci for MBC and female breast cancer (FBC). Here we report a comprehensive evaluation of all 107 known FBC predisposition loci in an association analysis of 1,032 MBC cases and 2,795 population matched controls. A total of 21 FBC predisposition single nucleotide polymorphisms (SNPs) showed evidence of association with risk of MBC. For approximately a third of these SNPs, the risk estimates were significantly larger in MBC than FBC. The magnitude of effects observed suggested that common susceptibility variants may be of value for risk stratification in men who have a high absolute risk of breast cancer such as BRCA2 mutation carriers. Although our data suggests that MBC predisposition shares many features in common with FBC, there are striking differences. Surprisingly, given the predominance of hormone receptor positive tumours in MBC, we observed no evidence of association between SNPs at FGR2 and MBC risk suggesting that the estrogen receptor status of MBC tumours does not explain the observed SNP associations. In summary, the data presented in this abstract significantly advance our understanding of genetic factors that contribute to MBC predisposition and further underscore the growing consensus that breast cancer risk is not simply analogous to hormone receptor positive female breast cancer.

**#1314 Trans-ethnic HLA fine-mapping of the MHC region identified several independent variants influencing susceptibility to lung cancer.**

Aida Ferreiro-Iglesias, Corina Lesseur, James McKay, Ray Jean J. Hung, Christopher I. Amos, Helen Hansen, Christopher Amos, Jonine L. Bernstein, 17

**International Agency for Research on Cancer (IARC-WHO), Lyon, France; 18Lunenfeld-Tanenbaum Research Institute of Sinai Health System, Toronto, Ontario, Canada; 19Geisel School of medicine, Dartmouth College, Lebanon, PA.**

Background: Genetic variants within the major histocompatibility complex (MHC) are associated with lung cancer. However, debate persists about the identity of the true causal variants, in part due to the broad linkage disequilibrium (LD) characteristic of the MHC and to the complexity and cost of complete AG typing. Here, we assessed the role of the MHC in modulating lung cancer risk in Europeans and Americans using a broad set of HLA variants to detect the main alleles and the presence of independent effects elsewhere in this genomic region. Material and methods: Association between the HLA variants and risk of lung cancer was examined in two collections of samples of different ethnicity (18,686 cases / 15,190 controls and 2,324 cases / 1,646 controls of European and Asian ancestry respectively). Using existing genome-wide SNP data from the lung cancer OncoArray study, we imputed and tested classical alleles and amino acid polymorphisms in HLA-A, HLA-B, HLA-C, HLA-DQA1, HLA-DQB1, HLA-DRB1, HLA-DPA1 and HLA-DPB1, as well as 7,258 SNPs across the MHC. All the analyses were performed assuming an additive genetic model adjusted for sex and principal components as covariates. The study-wide significant threshold was p = 6.03 x 10^-6. Results: Conditional, haplotype and stratified analyses identified two independent HLA alleles associated with lung cancer squamous cell carcinoma in Europeans. One is HLA-DQB1*06 that showed a significant protective effect (OR = 0.85, 95% CI: 0.80-0.90). The other allele is attributed to HLA-DP1*03 (OR = 1.30, 95% CI: 1.18-1.42, p = 4.78 x 10^-5), which contains class I and class II HLA alleles (A*A0101 - B*0801 - C*0701 - DRB1*0301 - DQB1*0201 - DQA1*0101). In addition, single-amino-acid polymorphisms in HLA-B (at positions 9, 156, 163 and 178) and HLA-DRB1 (at positions 26, 71 and 74) located in peptide-binding grooves, suggest these proteins as possible functional contributors within the haplotype.

**#1315 Estimating sex-specific effects of genetic loci associated with glioma risk.**

Quinn T. Ostrom, Ben Knerrners, Margaret Wrensch, Jeanette Eckel-Perez, Ceres Rivera, Yangchang Hu, Lucie McCoy, Helen Hansen, Christopher Amos, Jonine L. Bernstein, Abbe B. Calus, Dora Ilyasova, Christoff Johansen, Daniel Lachance, Rose Lai, Ching C. Lau, Ryan T. Merrell, Sara H. Olson, Siegal Sadetzki, Joellen Schildkraut, Sanjhay Shete, Richard S. Houlston, Robert B. Jenkins, Beatrice Melin, Melissa Bondy, Jill S. Barnholtz-Sloan, Case Western Reserve University School of Medicine, Cleveland, OH; The Institute of Cancer Research, Action, United Kingdom; "University of California, San Francisco, San Francisco, CA; Mayo Clinic College of Medicine, Rochester, MN; Dan L. Duncan Cancer Center, Baylor College of Medicine, Houston, TX; Geisel School of Medicine at Dartmouth, Hanover, NH; Memorial Sloan Kettering Cancer Center, New York, NY; Yale University, New Haven, CT; Georgia State University, Atlanta, GA; Danish Cancer Society, Copenhagen, Denmark; Mayo Clinic Comprehensive Cancer Center, Mayo Clinic, Rochester, MN; Keck School of Medicine, University of Southern California, Los Angeles, CA; NorthShore University HealthSystem, Evanston, IL; School of Public Health, Sackler Faculty of Medicine, Tel-Aviv University, Tel-Aviv, Israel; University of Virginia School of Medicine, Charlottesville, VA; University of Texas MD Anderson Cancer Center, Houston, TX; Faculty of Medicine, Umeå University, Umeå, Sweden.

Background: Incidence of glioma varies significantly by sex, and most glioma histologies occur with greater incidence in males. Previous analyses have examined the impact of estrogen exposure as a risk factor for these tumors, but have found results of varying significance and low effect size. There may be differences in effect of previously discovered risk alleles that contribute to sex differences. METHODS: Using data collected for three previous glioma GWAS in European-ancestry populations (MD Anderson Cancer Center, the San Francisco Adult Glioma Study, and the Glioma International Case Control Study) we assessed sex-specific effects for 14 previously identified and 13 newly identified glioma risk SNPs (27 total) overall and for glioblastoma (GBM) and non-GBM tumors separately. There were 3,492 male cases (59% GBM), 4,532 male controls, 2,500 female cases (52% GBM) and 4,940 female controls. Sex-specific odds ratios (ORM and ORF), 95% confidence intervals (95% CI) and p values (pM and pF) were generated using stratified logistic regression models. Data from each study were analyzed separately and combined using inverse variance weighted meta-analysis. Results were considered statistically significant at p<6.2x10^-4. RESULTS: In GBM, rs11979158 (7p11.2, pM = 1.01x10^-10, ORM = 1.08 [95% CI: 1.03-1.13]), rs2562125 (16p13.3, pM = 5.98x10^-4, ORM = 1.23 [95% CI: 1.09-1.39]), and rs2562125 (16p13.3, pF = 1.21x10^-7, ORF = 1.12 [95% CI: 0.97-1.29]) had significant effect in males only. In non-GBM gliomas, rs12076733 (14q44, pM = 3.56x10^-7, ORM = 1.41 [95% CI: 1.23-1.61], pF = 1.76x10^-2, ORF = 1.20 [95% CI: 1.03-1.38]), rs11979158 (7p11.2, pM = 1.77x10^-3, ORM = 1.32 [95% CI: 1.16-1.49], pF = 2.73x10^-3), ORF = 1.08 [95% CI: 0.94-1.24], and rs7351667 (16p13.3, pM = 8.44x10^-4, ORM = 1.30 [95% CI: 1.17-1.44], pF = 5.18x10^-2, ORF = 1.13 [95% CI: 1.00-1.28]) had significant effect in males only. Effect size for rs55705857 (8q24.21) varied significantly by sex, with ORM = 2.63 [95% CI: 2.24-3.09, pM = 4.42x10^-32], as compared to ORF = 3.95 [95% CI: 3.28-4.76, p = 1.28x10^-15]. A sensitivity anal-

**EPIDEMIOLOGY: Genome-Wide Association Studies/Post-GWAS Studies**
yis was performed due to allele frequency heterogeneity by study and results did not change. CONCLUSIONS: Sex differences and other demographic differences in cancer susceptibility can provide important clues to etiology, and these differences can be leveraged for discovery in genetic association studies. Significant differences in effect size may suggest variation in genetic effect of risk alleles due to factors that vary in prevalence or effect by sex. There may also be differences in the distribution of molecular subtypes within each histology by sex. Further investigation using an agnostic approach may further elucidate the relationship between effect of risk alleles and sex.

#1316 Germline genetic signals across multiple aggressive prostate cancer phenotypes. Caroline G. Tai,1 Nima C. Emami,1 Thomas J. Hoffmann,1 Lori C. Sakoda,2 Eric Jorgenson,2 Laurel A. Habel,1 Jun Shan,3 Dilini K. Ranatunga,3 Chun R. Chao,2 Nirupa R. Ghi,3 David Aaronsom,2 Joseph Presti,4 Catherine Schaefer,5 Neil R. Schrock,6 Stephen K. Van Den Eeden,7 John S. Witte,8 University of California, San Francisco, San Francisco, CA; Kaiser Permanente Northern California, Oakland, CA; Kaiser Permanente Southern California, Pasadena, CA; Kaiser Oakland Medical Center, Oakland, CA.

Prostate cancer (PrCa) is documented to be highly heritable. But many known prostate cancer loci are not associated with aggressive prostate cancer phenotypes such as high-grade cancer or biochemical failure. Previous efforts have been largely underpowered or not replicated. We conducted a study of 6,321 men with PrCa and 5,663 controls of European ancestry recruited from Kaiser Permanente (KP) matched by age and self-reported race. Phenotype data combined patient-level demographic, clinical, and tumor data from KP databases with data from the Cancer Genome Atlas (CGA). High-grade PrCa was defined as Gleason score ≤7 (3+4) and high-grade normal as ≥7 (4+3). Biological failure was defined for cases using post-treatment prostate specific antigen (PSA) values: post-surgery failure if PSA ≥0.4 ng/mL; post-radiation failure if PSA value ≥2 ng/mL + nadir; and no failure if PSA did not reach specified threshold. Early-onset disease was defined as age < 55 years at diagnosis. Men were genotyped for over 650,000 SNPs using an ethnicspecific Affymetrix Axon array and imputed to 1000 Genomes. We tested genetic associations for multiple aggressive phenotypes (410 early-onset cases, 1324 biochemical failure cases, and 886 high-grade cases) in both case-only (e.g., high vs. low grade) and case-control (e.g., high grade vs. no prostate cancer controls) analysis using logistic regression adjusting for ancestry principal components, age, BMI, and kit for batch effects. Prevalence of genetic effect of risk variants from multiple GWAS loci, we employed recently developed Massively-Parallel Reporter Assays (MPRA). Systematic examination of allele-specific transcriptional activities of genetically indistinguishable candidate variants. Out of ~2,800 melanoma-associated variants (P<0.4, EUR) from 16 melanoma loci for which transcriptional mechanism could be applied, 835 variants were prioritized based on their relevance as melanocyte/melanoma-specific cis-element represented by ENCODE annotation as open chromatin or putative promoter/enhancer histone marks in melanocytes and melanoma cell lines. Pooling oligos of 145bp encompassing each variant with either melanoma risk or protective allele coupled with 10 different unique sequence tags were cloned into luciferase vectors and transfected to melanoma cell lines. Resulting expressed tag counts were subsequently determined using massively parallel sequencing. We were able to identify ~200 potentially functional variants displaying allelic transcriptional activity by combining transfections in a melanoma cell line and HEK293FT cell line. Top functional SNPs from melanoma GWAS loci were also shown as significant eQTL SNPs in human melanocytes including MX2 on chromosome 21. Overlapping MPRA functional SNPs with melanocyte eQTL SNPs further enabled isolation of a functional risk variant among several highly linked MX2 eQTL SNPs. The results from this analysis will greatly accelerate the identification of functional melanoma risk variants and further shed light on molecular mechanisms of genetic susceptibility of melanoma in population.

#1318 A genome-wide association study of Waldenström macroglobulinemia/lymphoplasmacytic lymphoma demonstrates association with chromosome 6. Mary L. McMastert,1 Sonja I. Berndt1, Shengchao A. Li,1 Susan Slager,2 Joseph Vijai,3 Charles C. Chung,4 Bin Zhu,5 Laurie Burdette,5 Brenda Birnrmann,6 Elizabeth E. Brown,7 James R. Cerhan,8 Karin Ekstrom-Semedby,9 Henrik Hjalgrim,9 Geffen Kleinstern,2 Brian K. Link,10 James McKay,10 Alain Monnerreau,11 Lindsay M. Morton,12 Alexandra Nieters,13 Nathanial Rothman,14 Christine F. Skibola,15 Alex Smith,16 Lauren R. Teras,17 Claire M. Vajdic,18 Roel Vermeulen,19 Belynda Hicks,1 Lynn R. Goldin,3 Neil E. Caporaso1, 25NCI-DCEG, Bethesda, MD; Mayo Clinic, Rochester, MN; Memorial Sloan-Kettering Cancer Center, New York, NY; Brigham and Women’s Hospital and Harvard Medical School, Boston, MA; University of Alabama at Birmingham, Birmingham, AL; Karolinska Institutet, Stockholm, Sweden; Statens Serum Institut, Copenhagen, Denmark; The University of Iowa, Iowa City, IA; International Agency for Research on Cancer, Lyon, France; Center of Research in Epidemiology and Statistics Sorbonne Paris Cite, Paris, France; University Medical Center Freiburg, Freiburg, Germany; Emory University, Atlanta, GA; University of York, York, United Kingdom; American Cancer Society, Atlanta, GA; University of New South Wales, Sydney, Australia; Utrecht University, Utrecht, Netherlands.

Waldenström macroglobulinemia (WM) is a unique subset of lymphoplasmacytic lymphoma (PLL) that is defined by the presence of an LPL infiltrate in the bone marrow together with a monoclonal IgM protein in the serum. A somatic activating mutation, MYD88 L265P, occurs in 85% of WM and in 25%-50% of patients with the precursor condition, IgM monoclonal gammopathy of undetermined significance (MGUS); however, germline MYD88 mutations have not been observed in WM patients, and the genetic basis for WM predisposition remains undefined. To identify novel WM susceptibility loci we conducted a two-stage genome-wide association study (GWAS) in over 450 WM cases and 4300 controls of European ancestry. Discovery (stage 1) included 217 WM cases (40% familial) and 3798 controls genotyped on the Illumina Omni Express or Illumina Omni2.5 platforms following standard quality control procedures. The genotyped data were imputed using the HaploType Reference Consortium panel as a reference and analyzed using logistic regression. In stage 1, we identified three loci on chromosomes 6, 14 and 3 significantly associated (P<5.0x10^-6) with risk of WM. Eleven promising SNPs in these and other suggestive loci (P<5.0x10^-5) were selected for replication (stage 2) in 269 WM or LPL cases (4% familial) and 571 controls, and genotyping was conducted using standard methods on Taqman and Sequenom platforms or Sanger sequencing (1 SNP). Preliminary results confirm replication of the chromosome 6 locus. Stratification on familial status will illuminate the contribution of familial disease. These results will provide insight into the underlying genetic basis of WM susceptibility.

#1319 Epigenome-wide association study reveals differential DNA methylation consistent with progression of multiple myeloma. Stephen D. Gragg,1 Devin Absher,2 Xiangqin Cui,3 Christina Pillion,4 Richard Myers,5 Shaji Kumar,6 Luciano Costa,7 Brian Chiu,8 Celine Vachon,7 Elizabeth Brown1. University of Alabama at Birmingham School of Medicine, Birmingham, AL; 4Birmingham School of Public Health, Birmingham, AL; Mayo Clinic, Rochester, MN; 5University of Chicago, Chicago, IL.

Purpose: Multiple myeloma (MM) is the second most common hematological malignancy in the US. It is characterized by a clonal expansion of plasma cells in the bone marrow and extramedullary sites and is preceded by two precursor conditions including monoclonal gammopathy of undetermined significance (MGUS) and smoldering myeloma (SMM). Strong evidence suggests a germline and environmental etiology. However, efforts to characterize heritable changes in gene activity, such as DNA methylation, have not been widely reported. Methods: We examined epigenome-wide DNA methylation as markers of MGUS, SMM and MM in peripheral blood obtained from treatment-naïve European cases with heavy-chain IgG or IgA MGUS (n=60), SMM (n=31) and MM (n=54) and unrelated controls (n=79) included from the University of Alabama at Birmingham, University of Chicago and the Mayo Clinic, Rochester (54.5% males; mean age, 64 years, range 36 to 86). We quantified DNA methylation of over 450,000 CpG and non-CpG loci using the Infinium HumanMethylation450 array (Illumina). Differentially methylated po...
sitions were calculated using a general linear model framework adjusted for confounders and cellular heterogeneity. Results: A total of 6 CpGps were differentially methylated in MM cases compared to controls at a level of genome-wide statistical significance. MM was associated with hypomethylation at differentially methylated positions inside SBO2 (P = 3.37x10^{-9}), WIZ (P = 1.12x10^{-4}), CA6 (P = 2.99x10^{-4}) and ADO (P = 3.68x10^{-7}) as well as an intergenic position proximal to TNFRSF8 (Chr 1p36.22; P = 1.1x10^{-8}). Each of these loci, with the exception of CA6 and ADORA1, were hypomethylated in each of the 3 plasma cell dyscrasia phenotypes including MGUS and SMM and MM cases compared to controls (P < 0.03), albeit not at a level of genome-wide statistical significance. Conclusions: These preliminary findings suggest that differences in DNA methylation may contribute to altered risk of MM, as well as its precursor conditions, and may play a role in plasma cell dyscrasia progression as a consequence of heritable changes in gene activity due to past exposures. Replication in a large yet similarly well-characterized population is warranted.

#1320 Non-additive and interaction effects of HLA class 2 polymorphism contributing to risk of glioma. Chenan Zhang, Kyle Walsh. University of California, San Francisco, San Francisco, CA.

Although genome-wide association studies have identified a number of susceptibility loci for adult glioma, little is still known regarding whether polymorphisms in the human leukocyte antigen (HLA) region contribute risk. HLA associations have previously been reported for a number of malignancies, with selected HLA polymorphisms investigated in a subset of glioma studies. However, no systematic analysis has been conducted to date, and no investigation into potential non-additive effects of such associations has been described. In this study, we conducted comprehensive genetic analyses of HLA variants in the major histocompatibility complex (MHC) region among 1,746 adult glioma patients and 2,312 controls from the GliomaScan Consortium. Genotype data were generated with the Illumina 660-Quad array, containing 1,822 SNP probes across the MHC region. We imputed HLA alleles using a reference panel of 5,225 individuals in the Type 1 Diabetes Genetics Consortium who underwent high-resolution HLA typing via next-generation sequencing. Subjects were of European-ancestry and case-control comparisons were adjusted for population stratification using ancestry-informative principal components. Because alleles in different loci across the MHC region are linked, we created multi-locus haplotypes consisting of genes DRB1, DQA1, and DQB1. Although none of the haplotypes were associated with glioma in additive models, DRB1*15:01-DQA1*01:02-DQB1*06:02 showed an improvement in model fit after the inclusion of a non-additive term, which was significant after Bonferroni correction (P = 2.5x10^{-10}). Furthermore, the interaction of DRB1*15:01-DQA1*01:02-DQB1*06:02 with haplotype DRB1*04:01-DQA1*03:01-DQB1*03:01 resulted in a 3.80-fold increase in the odds of glioma (P = 8.8x10^{-10}). Our results indicate that the DRB1*15:01-DQA1*01:02-DQB1*06:02 haplotype contributes to the risk of glioma via a dominant effect, with heterozygosity conferring greater risk of glioma than expected from homozygote disease risk in an additive model.

#1321 Transcriptome-wide association study of prostate cancer risk. Maxine Chen,1 Alexander Gusev,2 The PRACTICAL Consortium, Massimo Loda,3 Lorelei A. Mucci,2 Meir J. Stampfer,1 Peter Kraft,3 Kathryn L. Penney3. Brigham and Women’s Hospital and Harvard Medical School, Boston, MA; 2Harvard T.H. Chan School of Public Health, Boston, MA; 3Dana-Farber Cancer Institute, Boston, MA.

Though more than 150 single nucleotide polymorphisms (SNPs) associated with prostate cancer have been identified through GWAS, we still do not understand the functional consequences of common genetic variation in this disease. Genetic variants may influence complex diseases like prostate cancer through gene expression. However, very large studies evaluating gene expression in prostate cancer are currently infeasible due to the limited availability of prostate cancer tissue and expense of collecting expression data. Alternative approaches have been developed to identify expression-trait associations in study populations without directly measured expression data. One such approach (Gusev et al. Nat Genet. 2016) uses a set of reference individuals with both gene expression and SNP data to develop genetic prediction models of gene expression values. These models are then used to impute cis genetic components of gene expression for a much larger set of individuals with only genotype and phenotype information. We used Affymetrix gene expression microarray data from normal prostate and prostate tumor tissue and genotype data from prostate cancer patients in the Health Professionals’ Follow-up Study and the Physicians’ Health Study (N = 187) as a reference panel for creating the predicted models of the genetic components of expression. We imputed gene expression values into Oncoarray GWAS summary statistics from the PRACTICAL consortium (N ~ 75,000) to assess the association between predicted expression and prostate cancer risk. We present the results of our transcriptome-wide association study in normal prostate and prostate tumor tissue, identifying genes significantly associated with prostate cancer risk after correcting for multiple testing. These genes may provide insight into how genetic variants influence prostate cancer through their effect on gene expression.

#1322 A meta-analysis of genome-wide association studies identifies novel loci that influence breast cancer prognosis. Latha Kaladaly,1 Sofia Khan,2 Helé Nevanlinna,3 Peter A. Fasching,2 Fergus J. Couch,4 John Hopper,5 Jianjun Liu,6 Tom Maishman,7 Lorraine Durcan,1 Carl Bloomquist,8 Andy Collins,9 Dianna Eccles,1 William Tapper1. 1University of Southampton, Southampton, United Kingdom; 2University of Helsinki, Helsinki, Finland; 3Friedrich-Alexander University Erlangen-Nuremberg, Erlangen, Germany; 4Mayo Clinic, Rochester, MN; 5University of Melbourne, Melbourne, Australia; 6Genome Institute of Singapore, Singapore, Singapore.

Familial studies were among the first to indicate that breast cancer prognosis has a heritable component. Subsequently many variants associated with prognosis have been identified using a range of techniques including genome-wide association studies (GWAS). Despite these advances, much of the heritability remains unexplained. In young women, breast cancer is characterised by a higher incidence of adverse pathological features, unique tumour gene expression profiles and worse survival. In addition, the association of risk with conventional epidemiological exposures is less clear in women with early onset. We hypothesise that some of these differences between early and late onset could be influenced by germline variation. To identify additional variants that influence breast cancer prognosis, we conducted a two stage meta-analysis of four GWAS consisting of 6,042 patients from the UK (POSH), Finland (HEBCS), Germany (SUCCESS-A) and Australia (ABCFS). Cox-regression analyses were used to investigate overall survival (OS, n = 1,101 events) and disease-free survival (DFS, n = 1,316 events) with correction for oestrogen status (ER). These survival analyses were repeated in a subset of patients with early onset (aged ≤ 40 at diagnosis, n = 2,315 patients, OS n = 604 events, DFS n = 716 events). Meta-analysis identified two intronic SNPs in ADAMTS1 that were associated exclusively with early onset DFS, rs715212 (P_{meta} = 3.54x10^{-10}) and rs10963755 (P_{meta} = 3.91x10^{-10}) without heterogeneity between cohorts. Multivariable Cox-regression demonstrated that the effect of these SNPs were independent of the classical prognostic factors. Most importantly, rs715212 reached genome-wide significance (P_{meta} = 5.37x10^{-8}) in the multivariate model. ADAMTS1 encodes a glycoprotein that forms part of the extracellular matrix (ECM) and may function in cell-cell or cell-matrix interactions or may regulate other ADAMTS proteases. Previous studies have shown that ADAMTS1 is hypermethylated in ER positive breast cancer tumours. Using GTEX to perform eQTL analysis, we found that rs715212 is associated with the expression of several biologically relevant genes including ARHGEF10 (P_{meta} = 10^{-3}) and FASLG (P_{meta} = 0.0031) and EGF (P_{meta} = 0.0018) in breast mammary tissue. Interestingly, separate studies have shown that AREG is overexpressed in ER-positive breast tumours from pre-menopausal women versus post-menopausal women. Furthermore, AREG is differentially expressed between parous and non-parous mammary glands and is persistently downregulated by parity, which suggests it may contribute to the susceptibility of the nulliparous gland to breast cancer. We conclude that rs715212 is associated with an increased risk of disease progression in patients with early onset and speculate that this could be due to an interaction with the expression of AREG.

Background/Objectives: Previous studies suggested that high energy intake may increase the risk of prostate cancer. However, the mechanisms remain unclear. No genome-wide association studies (GWAS) have been conducted to detect the genetic variations in total energy intake. We aimed to identify genetic variants associated with total energy intake in men and women, and to determine the association between previously identified prostate cancer susceptibility loci and total energy intake. Methods: We conducted a genome-wide study using combined GWAS data from 12,031 European-ancestry women and 6,743 European-ancestry men from the Nurses’ Health Study, Nurses’ Health Study II, Health Professionals’ Follow-up Study, and Physician’s Health Study. Total energy intake was measured through validated food-frequency questionnaires. Missing genotypes were imputed using MACH with 1000 Genomes Project ALI Phase 1 Integrated Release Version 3 Haplotypes as the reference panel. We stratified by sex and adjusted for age, weight, height, physical activity and three principal components accounting for subpopulation structure. Meta-analysis based on p-values across sex was implemented. SNP set analyses, including a
weighted fixed-effects (Mendelian randomization, MR) and an unweighted random-effects approach (METASOFT), were used to test the association between prostate cancer risk loci and total energy intake using summary statistics of total energy intake from the combined GWAS and the summary statistics for genome-wide significant SNPs (Ne = 104) from a GWAS of prostate cancer in 43,303 cases and 43,737 controls [Al Olama (2014) Nat Genet]. Results: Three

...case-control GWAS. Objective: To identify SNPs associated with prostate cancer risk loci and total energy intake using summary statistics for genome-wide significant SNPs (Ne = 104) from a GWAS of prostate cancer in 43,303 cases and 43,737 controls [Al Olama (2014) Nat Genet]. Results: Three

...case-control GWAS. Objective: To identify SNPs associated with prostate cancer risk loci and total energy intake using summary statistics for genome-wide significant SNPs (Ne = 104) from a GWAS of prostate cancer in 43,303 cases and 43,737 controls [Al Olama (2014) Nat Genet]. Results: Three
expression of CD147 in ATII cells in comparison with controls as detected by western blotting and RT-PCR. This may explain high ECM degradation in this disease. Second, we observed higher MMPs levels in plasma obtained from individuals with this disease. Third, we found significantly higher expression of cathepsin B in ATII cells isolated from emphysema in comparison with controls. Cathepsin B is an enzyme that facilitates a direct degradation of ECM proteins and activate other proteases capable of degrading ECM. Fourth, our data indicate that CD147 interacts with cathepsin B, which may lead to the activation of MMPs and emphysema progression. In summary, our results show for the first time the important role of CD147 in emphysema development. Moreover, we found that cathepsin B may contribute to CD147-mediated disease progression. Further studies will elucidate its role in lung cancer development in patients with emphysema.

#1328 Mechanism of transcriptional regulation of metabolotropic glutamate receptor-5 induced by the CXCR4 signaling pathway. Nobuyuki Kuribayashi, Daisuke Uchida, Makoto Kinouchi, Sayaka Izumi, Kyoko Kuribayashi, Hitoshi Kawamata, Dokkyo University School of Medicine, Tochigi, Japan.

We have previously demonstrated that stromal cell-derived factor (SDF)-1/CXCR4 system enhances the metastases of oral cancer cells via induction of miR-30 family which has predictive binding sites in 3′-UTR of NAs). Thus, we performed miRNA microarray in SDF-1 stimulated B88 cells. Several investigators demonstrated that activation of the ERK1/2 pathway is responsible for the transcription of several cancer-associated microRNAs (miRNAs). We postulated that SDF-1/CXCR4 downregulation may be inhibited by a MEK inhibitor, U0126, and partially inhibited by a PI3K inhibitor, wortmannin. Furthermore, these inhibitors significantly inhibited the SDF-1/CXCR4 dependent cell-migration in the presence or absence of miR-305 agonist, DHEP. Recently, several investigators demonstrated that activation of the ERK1/2 pathway is responsible for the transcription of several cancer-associated microRNAs (miRNAs). We postulated that SDF-1/CXCR4 downregulation may be inhibited by a MEK inhibitor, U0126, and partially inhibited by a PI3K inhibitor, wortmannin. Further studies will elucidate its role in lung cancer development in patients with emphysema.

#1329 Inhibition of papillary thyroid cancer cell progression by targeting skp2 via ros-erk-chop-dr5 pathways. Pratheeshkumar Poyil, Rong Bu, Abdul K. Siraj, Sandeep Kumar P, Khawla S. Al-Kuraya, King Faisal Specialist Hospital and Research Center, Riyadh, Saudi Arabia.

S-phase kinase protein 2 (SKP2), is an F-box protein with proteasomal properties and has been found to be overexpressed in a variety of cancers. However its role in papillary thyroid cancer (PTC) has not been elucidated. Therefore, inactivation of SKP2 could be a viable strategy for the treatment of PTC. In the present study, we investigated the role of SKP2 and its ubiquitin-proteasomal pathway in PTC using a tissue microarray cohort of 1022 PTC samples, PTC cell lines and Nude mouse model. Our immunohistochemistry data showed that SKP2 was over-expressed in 75.1% of PTC cases and was clinically, significantly associated with extra thyroidal extension (p=0.0331), Tall cell variant (p=0.0070), and presence in surgical margins (p=0.0347). Bortezomib as well as SKP2 specific siRNA caused downregulation of SKP2 leading to dose-dependent growth inhibition and induction of apoptosis via mitochondrial apoptotic pathway in PTC cell lines. Furthermore, we found that treatment of PTC cells with Bortezomib caused up-regulation of DRS5 via generation of reactive oxygen species (ROS). Finally, Bortezomib treatment augmented TRAIL mediated anti-cancer effect on PTC xenograft tumor growth in nude mice. These data suggest that Bortezomib is a viable therapeutic option for the treatment of PTC either alone or in combination with other apoptotic agents such as TRAIL.

#1330 HSP90 inhibitor has a possibility to overcome imatinib resistance in gastrointestinal stromal tumors. Yurina Saito,1 Tsuyoshi Takahashi,1 Satoshi Serada,2 Minoru Fujimoto,2 Koji Tanaka,2 Yasuhiro Miyazaki,2 Tomoki Makino,1 Yukinori Kurokawa,1 Makoto Yamashita,1 Kiyokazu Nakajima,1 Shuji Kato,1 Osaka University Graduate School of Medicine, Suita, Osaka, Japan; National Institutes of Biomedical Innovation, Health and Nutrition, Ibaraki, Osaka, Japan.

[Background] Gastrointestinal stromal tumors (GIST) are the most common mesenchymal tumors of the digestive tract and are reported to harbor gain-of-function mutations in the KIT gene, which contribute to the development of sporadic GIST. HSP90 is essential in the development of targeted therapies with tyrosine kinase inhibitors and the revolutionary chemotherapeutic drug imatinib mesylate (IM). In clinical trials, the disease control rate was nearly 85%, and corresponding 2-year overall survival rates ranged from 70-80%, indicating markedly improved patient outcomes compared with anecdotal data in the pre-IM era. Despite its effectiveness, half of GISTs treated with IM develop resistance within 2 years, largely due to the accumulation of additional kinase domain mutations accompanied by concomitant re-activation of the KIT tyrosine kinase, even in the presence of IM. Heat shock protein 90 (HSP90) is one of chaperon molecules required for the proper folding, function, and stability of a number of key oncogenes, including several members of the KIT family. The aim of this study was to verify the potential efficacy of HSP90 inhibitor against IM resistant GIST. [Material and Method] We used the established human GIST cell line GIST-T1, and two IM-resistant cell lines (GIST-T1R8, GIST-T1R9), which had additional kinase domain mutations accompanied by concomitant re-activation of the KIT tyrosine kinase same as clinical samples, by exposure to IM. These resistant cell lines exhibited intracellular concentrations (>10 μM) of IM that were >1000-fold higher than the parental cell line. We investigated the cytotoxicity and signaling inhibition by HSP90 inhibitor using by the WST-8 assay, caspase3/7 apoptosis assay and western blotting. Immunobolts for IM and for IM-resistant GIST cell lines. And, it also inhibited downstream of KIT signaling, e.g. PI3K and Akt. [Conclusion] HSP90 inhibitor shows a potential efficacy for imatinib resistant GIST in vitro. It might have a possibility to apply for clinical use.

\[1331\] TGFβ1 induces breast tumor kinase expression via p38 MAPK signaling to glucocorticoid receptors. Carlos I. Santos Perez, Tarah Regan Anderson, Carol A. Lange. University of Minnesota Twin Cities, Minneapolis, MN.

Triple negative breast cancer (TNBC) is the deadliest breast cancer (BC) subtype, accounting for 20-30% of all BCs. It has a heterogeneous pathology and pathogenicity, but it is defined by the lack of estrogen receptor, progesterone receptor, and Her2 expression. Breast cancer tumor hypoxia (Brk), as a solubletyrosine kinase that is overexpressed in 85% of BCs and a driver of aggressive and metastatic phenotypes. Overexpression of Brk mRNA and protein occurs in TNBC by unknown mechanisms. The glucocorticoid receptor (GR), a very potent modulator of cytokine mediated actions of the immune system, is emerging as a mediator of chemoresistance and recurrence in TNBC. We previously demonstrated that GR signaling cooperates physiologic stress signaling mediated by hypoxia inducible factors HIF-1a and HIF-2 to modulate the expression of Brk mRNA and protein in TNBC cells. Moreover, phosphorylation of Gr at ser134 by p38 MAPK is essential for GR regulation of Brk expression. P38 is an essential Ser/Thr kinase that regulates cellular transduction of growth factors, such as Hepatocyte Growth Factor (HGF), and cytokines (e.g. TGFβ1) in TNBC cells, and was previously shown to be co-expressed with Brk in human breast tumors. Herein, we further probed mechanisms of crosstalk between key cytokines, GR, and p38 signaling in the regulation of Brk overexpression. We hypothesized that TGFβ1 signaling modulates EMT and metastasis in part by increasing the expression of Brk in TNBC. Treatment of MDA-MB-231 cells with TGFβ1 for 1, 2, 24 and 48 hours increased Brk protein expression relative to vehicle controls. Additionally, TGFβ1 increased both HIF1 and HIF2 protein levels (at 24 and 48 hours respectively). TGFβ1 regulated Brk expression at the level of mRNA, as measured using RT-PCR. Moreover, TGFβ1 synergized with activated GR to further increase mRNA levels. In contrast, mRNA levels of HIF1 and HIF2 were not modulated by TGFβ1, suggesting that the observed protein increases are due to stabilization of HIFs. Finally, TGFβ1 robustly induced p38-dependent phosphorylation of Gr at serine 134. This phosphorylation event promoted ligand-independent GR transcriptional activity at the Brk promoter. Human breast tumors significantly co-express active p38 MAPK and Brk. Our molecular model implicates TGFβ1 signaling (via p38 MAPKs) to phospho-GR in the aberrant overexpression of Brk in TNBC. We conclude that blocking of the TGFβ1 pathway may provide a strategy to inhibit Brk mediated TNBC tumor progression. This work was supported by NIH/NCI R01 CA192178 (to CAL) and T32 GM080244-24.

\[1332\] NOTCH - HEY1 pathway induces EMT in head and neck squamous cell carcinoma. Takahito Fukusumi,1 Theresa W. Guo,2 Shuling Ren,1 Akihiro Sakai,1 Mizuo Ando,1 Sunny Haft,1 Chao Liu,1 Joseph A. Califano 1.

UC San Diego, San Diego, CA; Johns Hopkins Medical Institutions, Baltimore, MD.
Background Head and neck squamous cell carcinoma (HNSCC) is noted to have a NOTCH mutation rate of 20% within the Cancer Genome Atlas (TCGA) dataset consistent with tumor suppressor gene status. However, NOTCH genes are also upregulated in wild type HNSCC and show signs of downstream activation in a substantial proportion of HNSCC. In this study, we aimed to further explore the potential for NOTCH pathway selective agents to be utilized in HNSCC. We utilized the activated NOTCH4 cell line, H9252. In vitro experiments, the SERPINE2 knockdown was related with decrease in cell motility in vitro. Data suggested that EGFR signaling promotes Wnt signaling in HER2-positive breast cancer cells. We hypothesize that this promotes cancer stem cell niche maintenance and an EMT phenotype.

Molecular and cellular biology / genetics: Cell growth signaling pathways 3

#1334 Mesenchymal cell sub-populations selectively modulate paracrine hedgehog signaling in triple negative breast cancer. Karla P. Ramos, Maribella Domenech. Univ. of Puerto Rico-Mayaguez, Mayaguez, PR.

Recent studies correlate Hedgehog (Hh) signaling with reduced survival rates in triple negative breast cancer (TNBC) patients. Activation of hedgehog signaling in the noncancerous tissue has been shown to promote tumor growth and it is a poor prognosis factor for TNBC. We developed a novel tumor-mesenchymal in vitro model of hedgehog signaling in TNBC to evaluate the role of mesenchymal cell sub-populations in the proliferative potential and stem cell markers of breast cancer cells using a custom designed multwell array. As a source of mesenchymal cell sub-populations we evaluated myofibroblasts, mesenchymal stem cells derived from bone marrow or adipose tissue and tumor cells that undergo epithelial-mesenchymal transition (EMT). Tumor cells were culture with 1 or 2 mesenchymal cell sub-populations in adjacent compartments +/− SHH ligand for 72-96hrs. Active Hh signaling was confirmed by up-regulation of main Hh target genes (e.g. GlI1, Patch1). Paracrine Hh signaling only in bone marrow-derived mesenchymal stem cell and EMT significantly increased proliferation (10-15%) of TNBC and normal breast cancer cell lines. Addition of adipose-derived mesenchymal stem cells or pharmacological Hh inhibitors (Cycloamine and Gant61) partially abolished tumor growth indicating that other non-canonical signals are involved in paracrine Hh-driven tumors. Cancer stem cell niches are highly elaborated in TNBC cell lines. Our results suggest that paracrine Hh signaling driven by bone marrow and EMT mesenchymal are potential therapeutic targets to treating TNBC.
The distribution of the phosphorylated Parkin in lung carcinoma.

Hongwei Wang, Songlin Zhang, Catherine Ma, Yuan Zhou, Abbo Maxin, Inc., San Jose, CA; UT Health Science Center at Houston, Houston, TX.

Parkin, also known as Parkinson Juvenile Disease Protein 2, together with PINK1 and Ubiquitin, form a simple cascade in the clearance of damaged mitochondria. This cascade plays an important role in maintaining mitochondrial quality control and is implicated in proteasomal degradation of toxic substrates. Recent studies have demonstrated that Parkin can be genetically altered, and aberrantly expressed in a variety of human malignancies including lung, breast, and ovarian cancers, these may indicate that Parkin is a tumor suppressor gene whose inactivation may play an important role in tumorigenesis. PINK1-dependent phosphorylation of Parkin (pS65) is a required step in Parkin activation and localization. The aims of this study were to investigate the expression of Parkin and its phosphorylated form in various type of lung carcinoma tissues and lung cancer cell lines: the correlation of the protein expression level and the phosphorylation of pS65 in lung cancer cells.

We choose two forms of the cancer materials. 1) A tissue microarray (TMA) which contains 16 cases of lung carcinoma tissues consisting of 8 adenocarcinoma (AC), 6 squamous cell carcinoma (SCC), and 2x small cell lung carcinoma (SCLC); 2) FFPE slides which contains 9x lung cancer cell lines (A549, H1703, H1975, H2228, H23, H838, HOP62, HOP92, and SKMES1). All the tissues and cells were immunostained by Parkin and phospho-Parkin polyclonal antibodies. The reference staining was performed by monoclonal anti-Cytokatan (7 (CK7) antibodies. From this study, we found Parkin expression level varies from TMA tissues and FFPE cell section which were not correlated with tumor grade. Among the 8 cases of adenocarcinoma, only 3/8 showed marked Parkin expression, 3/8 moderate, and 2/8 mild; for Parkin (pS65), only 1/8 demonstrated marked expression, 2/8 moderate, 2/8 mild, and no staining in 3/8 cases. In SCC cases, 2/6 demonstrated marked Parkin expression, 2/6 moderate, 2/6 mild. The phosphorylated Parkin (pS65) only expressed in 3/8 showed mild expression, not the others. Among 2 cases of SCLC, only one showed marked Parkin expression and less extent of Parkin (pS65), the other sample had no staining. In all FFPE cell sections, the strong expression of Parkin and Parkin (pS65) was found in the lung cancer cell lines. An interesting finding was that Parkin (pS65) strongly presented in cells of mitotic phase in these cell lines except H1703 cell line. All the TMA and FFPE slides were confirmed by CK7 monoclonal antibody staining. In summary, Parkin and its phosphorylated Parkin (pS65) were found in adenocarcinoma, squamous cell carcinoma and small cell lung cancers with differentially expressed levels, the degree of expression was not correlated with tumor grade in the tested tissues.

Phosphorylated Parkin (pS65) was strongly expressed in FFPE cancer cell lines at different degree of expression level. Among these 16 cases, the degree of phosphorylation level was not correlated with tumor grade in these 16 cases. Immunohistochemistry analysis of the clinical samples revealed higher SERCA expression, 2/6 moderate, 2/6 mild. The phosphorylated Parkin (pS65) were found in adenocarcinoma, squamous cell carcinoma and small cell lung cancers with differentially expressed levels, the degree of expression was not correlated with tumor grade in these 16 cases. Immunohistochemistry analysis of the clinical samples revealed higher SERCA expression, 2/6 moderate, 2/6 mild. The phosphorylated Parkin (pS65) were found in adenocarcinoma, squamous cell carcinoma and small cell lung cancers with differentially expressed levels, the degree of expression was not correlated with tumor grade in these 16 cases. Immunohistochemistry analysis of the clinical samples revealed higher SERCA expression, 2/6 moderate, 2/6 mild. The phosphorylated Parkin (pS65) were found in adenocarcinoma, squamous cell carcinoma and small cell lung cancers with differentially expressed levels, the degree of expression was not correlated with tumor grade in these 16 cases. Immunohistochemistry analysis of the clinical samples revealed higher SERCA expression, 2/6 moderate, 2/6 mild. Background: Malignant Peripheral Nerve Sheath Tumor (MPNST) is a malignant sarcoma that derives from a peripheral nerve or plexiform neurofibroma. Neurofibromatosis type 1 (NF-1) patients are particularly susceptible, with a higher risk, earlier onset, and worse prognosis. The major factor associated with MPNST and NF-1 is Neurofibromin 1, coded by the NF1 gene. Novel results in RAS pathways, the main molecular hallmark of MPNST, are currently limited, with poor prognosis for metastatic or unresectable tumors. Thus, the development of promising treatment solutions for MPNST to translate to clinical trials is required. Methods: Here, we seek to identify efficacious chemotherapeutic treatments for MPNST with a combination of drug screening and biological pathway analysis. We used our previously established preclinical system to test FDA approved or promising developmental agents against five cell line models for MPNST. We screened sixty agents with diverse mechanisms of action below published maximum plasma concentrations, and measured effects with a CellTiter-Glo viability assay. Promising agents were then tested in two-drug combinations, allowing for determination of synergism. We then examined the molecular effects of the top candidates with use of antibody arrays that permit detection of a series of phosphorylated proteins. Results: The group of most efficacious drugs was enriched with agents that target factors downstream of RAS, including MEK, mTOR, and PI3K inhibitors, with microtubule inhibitors, genotoxins, and HDAC inhibitors also demonstrating good results. Strong synergism was observed across our cell line models particularly in combinations containing the dual mTORC1/2 inhibitor INK128. Interestingly, drug sensitivity varied greatly between cell lines, correlating with relative NF1 protein and RAS-GTP levels. We analyzed the activation of the RAS pathway in response to drug treatment with antibody arrays and found that, following treatment, relative phosphorylation signal was more decreased compared to controls in cell lines with lower relative NF1 protein levels. Doxorubicin was able to reduce phosphorylation signal compared to controls to a level near comparable to targeted inhibitors, which could contribute to doxorubicin’s current usefulness against MPNSTs. Importantly, we identified combination treatments that were able to greatly reduce the relative phosphorylation signal of RAS pathway members versus control. Combinations containing INK128 resulted in the most pathway shutdown. These findings suggest that MPNSTs may be susceptible to combination treatments targeting RAS pathway members. Moreover, it may be possible to use pathway analysis as a diagnostic tool to predict drug tolerance.

The current usefulness against MPNSTs is closely associated with epithelial-to-mesenchymal transition (EMT) and enhanced tumor invasiveness and metastasis. However, the mechanism(s) by which DUOX1 silencing promotes these outcomes is not well understood.

In the current study, we have discovered, using a comprehensive investigative rheostat of Stat-3 and Wnt-signaling activation. Notably, in our analysis, using mRNA and protein expression, and utilizing samples from a large cohort of patients from the same institutional repository, we found that claudin-3 expression was significantly suppressed (p<0.001 versus normal) in cancer tissues versus normal mucosa. The colon tissues from the established mouse models of colon cancer (APCMin mice and Azoxymethane (AOM)-DSS-induced colon cancer) demonstrated similar tumor specific decrease in claudin-3 expression. Interestingly, claudin-3 negative tumors retained E-cadherin expression; however, a significant and positive correlation (p<0.05) of the greater levels of claudin-3 expression with patient survival. These findings however contrasted an upregulated claudin-3 expression in other cancer types and implicated differential epigenetic regulation. In further studies, naïve claudin-3-/- mice revealed dedifferentiated (significant down regulation of P-27 (p<0.05) and vimentin expression versus WT mice) and leaky colonic epithelium. Moreover, claudin-3-/- mice demonstrated increased colon tumor burden and invasive adenocarcinoma when subjected to colon cancer. Wnt-signaling hyperactivation, albeit in GSK-3β independent manner, characterized colon cancer in claudin-3-/- mice. Claudin-3 loss also upregulated the gpl130/IL6/Stat3 signaling in colonic epithelium potentially assisted by infiltrating immune organization. Genetic and pharmacological studies indicated that claudin-3 loss promoted a significant increase in EMT-like features and Wnt-signaling activation in Stat-3-dependent manner to promote colon cancer. Overall, these novel findings indicate claudin-3 as a therapeutic target for inhibiting overactivation of Wnt-signaling to prevent CRC malignancy.

DUOX1 silencing in lung cancer is associated with enhanced nuclear EGFR localization. Andrew C. Little, Karamathullah Danyal, David Hepburn, Milena Hristova, Albert van der Vliet. University of Vermont, Burlington, VT.

Non-small cell lung cancer (NSCLC) remains to be one of the leading causes of cancer-related mortalities worldwide. The NADPH oxidase homolog, Dual Oxidase 1 (DUOX1), is an H2O2 producing enzyme located in the airway epithelium with key roles in mucosal host defense and wound repair mechanisms. Recent studies indicate that DUOX1 is epigenetically silenced in many forms of NSCLC via hypermethylation of its promoter. We previously demonstrated that DUOX1 silencing in lung cancer cells is closely associated with epithelial-to-mesenchymal transition (EMT) and enhanced tumor invasiveness and metastasis. However, the mechanism(s) by which DUOX1 silencing promotes these outcomes is not well understood. Previous findings indicate that DUOX1-dependent epithelial host defense pathways are mediated by redox-dependent activation of epithelial signaling via the non-receptor tyrosine kinase, Src, and the receptor tyrosine kinase, EGFR. We therefore hypothesized that loss of DUOX1 in lung cancer may be associated with aberrant regulation of Src and/or EGFR, tyrosine kinases that are frequently overexpressed and activated in lung cancer and strongly contribute to tumor growth and survival. In fact, recent studies have indicated that nuclear localization of EGFR in cancer cells is associated with metastatic cell behavior and poor clinical outcome, and the nuclear EGFR localization depends on Src-dependent phosphorylation of EGFR at Y1101. We observed that overexpression of DUOX1 in alveolar lung cancer A549 cells, which possess EMT-like features and in which DUOX1 is normally silenced, results in redistribution Src to the plasma membrane and decreased nuclear accumulation. DUOX1 overexpression in A549 cells also suppressed EGFR-stimulated nuclear translocation of EGFR, which was associated with reduced EGFR phosphorylation at Y1101. Conversely, RNAi-mediated silencing of DUOX1 in the epithelial cancer cell line H292, which normally expresses DUOX1 expression, was found to promote EGFR-mediated EGFR nuclear translocation and Y1101 phosphorylation. Since nuclear EGFR is thought to enhance the transcription of target genes related to cell cycle progression and proliferation (e.g. CDK1, Myc, others), we evaluated gene expression of these target genes in our cell models. Indeed, in cells lacking DUOX1, EGFR stimulation significantly enhanced mRNA levels of CDK1, Myc, and other target genes for nuclear EGFR, whereas no such induction was seen in cells that express DUOX1. Our findings indicate that DUOX1 silencing in lung cancer may be associated with worse prognosis, partly due to altered spatiotemporal regulation of EGFR and Src and increased nuclear targeting. Since both EGFR and Src are subject to redox regulation by cysteine oxidation, we are currently aiming to elucidate the molecular mechanisms by which these mechanism are affected by altered DUOX1 status.
#1344 Progranulin promotes ubiquitination, sorting and lysosomal degradation of sortilin in castration-resistant prostate cancer cells. Ryuta Tanimoto,1 Chiara Palladino,1 Simone Buraschi,1 Shi-Qiong Xu,1 Leonard G. Goelzer.2

Introduction and Objective: Despite extensive clinical and experimental studies over the past decades, the pathogenesis of prostate cancer remains largely unknown. Furthermore, the mechanisms promoting the castration-resistant stage of prostate cancer are still very poorly understood. We recently demonstrated that progranulin acts as an autocrine growth factor and promotes castration-resistant prostate cancer cell motility, invasion and anchorage-independent growth. Progranulin was also overexpressed in prostate cancer tissues via vis non-neoplastic controls. Despite the strong connections with cancer, progranulin’s mode of action is not well understood. Furthermore, proteins that regulate early stages of progranulin signaling have not been identified. Sortilin, a transmembrane protein of the Vps10 family, binds progranulin and negatively regulates progranulin signaling in cancer cells. Here, we examined the role of progranulin in the endocytic sorting and degradation of sortilin.

Methods: IF experiments in the presence or absence of lysosomal inhibitors, supplemented with hydrocarbon staples. Based on this, we hypothesized that SAH-EJ1 displays rapid clearance in vivo, limiting its efficacy. To overcome this limitation, we developed the next-generation effector, Eflapegrastim, a longer-acting, more efficacious immune cytokine-stimulating factor.

Results: In vitro, Eflapegrastim treatment of SAH-EJ1 cells resulted in receptor dimerization and intracellular trafficking. These protein-independent functions, as well as receptor homo- and hetero-dimerization, promote the formation of non-functional ErbB dimers (consisting of EGF, HER2 and ErbB3) that induce rapid, ErbB-dependent cell death. Using Cell Penetrating Peptidessynthesizedintandemwiththe

#1346 Pan-ERBB inhibitor blocks tumor growth and metastasis. Joyce A. Schroeder,1 Sabrina Maisel,1 Derrick Broka2.1 University of Arizona, Tucson, AZ; 2Arizona Cancer Therapeutics, Tucson, AZ

The Epidermal Growth Factor Receptor family of transmembrane tyrosine kinases (ErbB) is over-expressed, correlates with poor prognosis and negatively correlates with disease free survival in many cancer types. EGFR, HER2 and ErbB3 are known to be highly expressed and active, and have been targeted by both kinase inhibitors and monoclonal antibodies, both with disappointing results. Importantly, though, these therapies both target either a single receptor or the kinase domain alone. It is well known that these receptor functions as heterodimers and blocking the kinase activity of the remaining family members. Furthermore, while the tyrosine kinase activity of these receptors is well known, less appreciated are the kinase-independent mechanisms by which they drive cancer progression. These include the modulation of calcium signaling and mitochondrial and nuclear translocation and activity as transcriptional co-factors. The highly conserved juxta-
membrane domain (JU) of the ErbB receptors regulates these kinase-independent functions, as well as receptor homo- and hetero-dimerization. Upon ligand binding, the JU forms anti-parallel dimers between the receptors, resulting in receptor dimerization and intracellular trafficking. These protein-protein interactions result in cell growth, survival, migration and invasion. We have previously shown that peptides mimicking this JU can act in a dominant-negative fashion, promoting the formation of non-functional ErbB dimers (consisting of EGF, HER2 and ErbB3) that induce rapid, ErbB-dependent cell death. Using Cell Penetrating Peptidessynthesizedintandemwiththe

#1345 Mutant IDH1 and tissue factor in gliomas. Dusten Unruh, Snezana Mirkov, Charles D. James, Craig Horbinski. Northwestern University, Chicago, IL.

Background: IDH1 mutations (IDH1mut) occur in 20-30% of gliomas, induce DNA hypermethylation, and are associated with a better prognosis than IDH1 wild-type (IDH1wt) gliomas, yet the basis for this remains unclear. Furthermore, venous thromboemboli (VTE) are a serious complication in glioma patients, and the mechanism for this is also unclear. We recently discovered that IDH1mut gliomas are much less likely to develop VTE compared to IDH1wt gliomas. Our data suggests that suppression of Tissue Factor (TF) may be a critical component of the less thrombogenic, and less malignant, IDH1mut phenotype. Targeting TF-PAR2 signaling may therefore repre-
sent a novel therapeutic strategy to reduce IDH1mut glioma malignancy.

#1347 In vivo efficacy of efaloprazagristatin in rats with chemotherapy-induced neutropenia. Young Hoon Kim,1 InYoung Choi,1 Prasad Kolli,2 Guru Reddy2.1 Hanmi Pharmaceuticals, Seoul, Republic of Korea; 2Spectrum Pharmaceuticals, Inc., Irvine, CA

Introduction: Efaloprazagristatin (SPI-2012, HM10460A) is a novel, long-acting recombinant human granulocyte colony-stimulating factor (rhG-CSF). Efa-
loprazagristatin consists of an rhG-CSF conjugated to a recombinant E. coli derived Fc fragment of IgG4 via a polyethylene glycol linker. Efaloprazagristatin is in clinical development for the treatment of chemotherapy-induced neutropenia in cancer patients. The purpose of this study was to evaluate and compare the efficacy of efaloprazagristatin, pegfilgrastim and filgrastim in rats with chemotherapy-induced neutropenia. Methods: Rats were treated with 30 mg/kg of cyclophosphamide (CPA) intraperitoneally to induce neutropenia. Pegfilgrastim was administered subcutaneously as a single dose of 100 μg/kg on Day 1 and filgrastim was ad-
ministered subcutaneously at a dose of 20 μg/kg daily for five days on days 1 to 5. Efaloprazagristatin was administered subcutaneously as a single dose on day 1, at doses ranging from 32 μg/kg to 322 μg/kg (or 8.8 μg/kg to 88 μg/kg as G-CSF

GDC-0032, a p110 beta-sparing PI3K inhibitor against HER2 breast cancer (BC) cell lines consisting of three activating (either helical or kinase domain) PIK3CA mutation (HER2+/breast cancer). MATERIALS AND METHODS: Four HER2+/breast cancer (BC) cell lines were analyzed for proliferation, apoptosis, cell cycle and signaling pathway activation assays. Preclinical efficacy of GDC-0032 was also evaluated in vivo in a mouse model. RESULTS: 1) All HER2+ and HER2+/PIK3CA mutant cell lines exhibited low IC50 values (ranging from 0.1 µM-1.5 µM) irrespective of ER-positive or not. 2) GDC-0032 caused a strong differential growth inhibition in both HER2+ and HER2+/PIK3CA mutated breast cancer cell lines when compared to lines that were HER2- and PIK3CA wild type by 3D-ON-TOP clonogenic assay. 3) Administration of GDC-0032 induced cell cycle G0/G1 arrest and resulted in increased apoptosis in a dose-dependent manner. Furthermore, induction of apoptosis was more with GDC-0032 when combined with RAD001. 4) GDC0032 also blocked expression of CYCLIND1. 5) Investigation of the signal transduction revealed that the treatment of GDC-0032 reduced the level of p-AKT (Ser473 and Thr308), and p-S6 expression is indicating the down-regulation of downstream signaling of PI3K and mTOR pathway. 6) GDC-0032 was highly active at reducing established tumor growth in both BC mouse xenografts harboring PIK3CA mutation and HER2 amplification. CONCLUSION: Our in vitro or in vivo data showed that GDC-0032 was highly efficient either as a single agent as well as with RAD001 in HER2+ / PIK3CA mutated breast cancer cell lines. Our data suggest that GDC-0032 represents a novel therapeutic option in patients harboring PIK3CA mutations and/or HER2/neu gene amplification in breast cancer.

#1349 NSAIIDs: Multiple roles in multiple environments. Gloria M Calaf1 and Debasish Roy2. 1Instituto de Alta Investigacion, Universidad de Tarapacá, Arica, Chile; 2Department of Natural Sciences, Hostos College, The City University of New York, Bronx, NY.

Nonsteroidal drugs are mainly known for their activities and use as anti-inflammatory, antipyretic compounds. But, in recent observations, they are exposed to use as an effective alternative compounds to prevent or stimulate different metabolic activities and help in preventing various neoplastic progression. They have specific role in controlling estrogen metabolism during breast cancer progression. Sometimes, they are used as an apoptotic induction in various cancers. Their role in hypoxia induced proliferation is also showing promising results. Different NSAIIDs will help to induce the activities of various tumor suppressor genes. As chronic inflammation increases the risk for various cancers, therefore, it is important to eliminate inflammation through anti-inflammatory compounds where NSAIIDs is playing a vital role. Most of them are acting to prevent inflammation either via selective or non-selective COX based mechanism. The non-selective COX inhibitor sulindac and the COX-2 selective inhibitor etodolac etc. have been shown to prevent the formation and cause regression of adenomas in patients with familial polyposis. Unfortunately, COX-1 and/or COX-2 inhibition and depletion of physiologically important prostaglandins is associated with gastrointestinal, renal and cardiovascular toxicities that limit the use of NSAIIDs and COX-2 inhibitors for cancer chemoprevention. In this particular study, we are using various NSAIIDs in a radiation-induced estrogen treated breast cancer model to establish their role in differential expression of various cancer related genes selected from different cell cycle pathways microarray. Selection of biomarkers from these altered genes will help to develop a valid strategy for cancer prevention through precision based targeted therapy. Supported by Office of Academic Affairs, Honors Program, COB!, Hostos-CUNY, NY, USA (DR) and Tarapacá University, Arica, Chile (GMC).

Uveal (eye) melanoma is a highly aggressive cancer, in which almost half of patients develop distant metastases that are refractory to therapy. In particular, metastatic uveal melanoma has been clinically unresponsive to the immunotherapeutic agents that have shown success in skin tumors, making the need for novel therapeutic approaches to uveal melanoma all the more urgent. Unlike skin melanomas, which are driven by BRAF and NRAS mutations, uveal melanomas arise typically from mutations that result in constitutive activity of the alpha subunit of the heterotrimeric G-protein, Gq, or its paralog G11. The prevalence of constitutively active Gq/11 in uveal melanoma suggests a dependence of these tumors on Gq/11 activity that could be exploited therapeutically. To address this hypothesis, we are using a potent, bioavailable small molecule that binds to and inhibits Gq/11 to target constitutively active Gq/11 in uveal melanoma cells. This inhibitor functions by sequestering wild type or constitutively active Gq/11 in an inactive state. We first used inositol phosphate accumulation assays and confirmed inhibition of both wildtype and constitutively active Gq/11 by the inhibitor in all uveal melanoma cells. We then assayed the effect of Gq/11 inhibition on overall viability of uveal melanoma cells, and found that uveal melanoma cells with mutant Gq/11 were highly sensitive to the small molecule; whereas, uveal melanoma cells with wildtype Gq/11 showed no loss of viability, even at 1000-fold higher concentrations of inhibitor. In Gq-mutant uveal melanoma cells, Gq/11 inhibition caused cell cycle arrest in G1, and dysregulation of several cell cycle regulatory pathways. Inhibitor treatment also caused Gq/11-driven uveal melanoma cells to become more differentiated, as indicated by increased pigmentation, elevated expression of melanin synthesis and melanosome markers, changes in cell morphology and changes in melanocyte versus melanoma gene programs. None of these phenotypic changes were seen in BRAF-driven uveal melanoma cells treated with the Gq/11 inhibitor, demonstrating that the effects of this inhibitor were exclusively dependent on the constitutively active Gq/11 oncogene. These results establish that Gq/11 is a druggable target in uveal melanoma cells, and show that Gq/11-mutant uveal melanoma cells are exquisitely sensitive to inhibition by small molecule inhibitors. We are currently transitioning these studies to animal models to establish drug efficacy and toxicity and explore treatment and delivery options.

#1351 Alternative splicing of neurofibromin 1 is associated with elevated MAPK activity and poor prognosis in glioma. Robert Siddaway, Arun Ramani, Man Yu, Michael Brudno, Cynthia Hawkins. The Hospital for Sick Children, Toronto, Ontario, Canada.

High-grade gliomas (HGG) are invasive with poor prognosis regardless of age: diffuse intrinsic pontine gliomas (DIPG), arising in the brainstem, are almost universally fatal and the leading cause of brain-tumor death in children; while adult anaplastic astrocytoma and glioblastoma multiforme (GBM) have median survivals of 1-3 years. The mutational spectra of adult and pediatric HGG differ, with pediatric tumours containing recurrent mutations of H3F3A and HIST1H3B. However, alterations leading to RAS/MAPK/PI3K pathway activation, including PDGFRA amplification, EGFVIII, BRAF-V600E, NFI deletion, are frequently found, although not all tumours will have mutations in this pathway. The neurofibromin 1 (NFI1) gene negatively regulates RAS signalling by stimulating RAS-GTP turnover, thereby leading to RAS-inactivation. The two major isoforms, NFI-1 and NFI-1I, differ only by inclusion of the 21 aa exon23a in the GAP-related domain of NFI-1I. Exon23a-inclusion has been shown to render NFI 10 times less active towards RAS, leading to elevated MAPK signalling. The brain expresses predominantly NFI-1, while the major isoform elsewhere is NFI-1I. Here we used RNA-Seq to identify genes alterna-
tively spliced between DJIPG and normal brain, identifying an isoform switch from NF1-1 in normal brain to NF1-II; we additionally found the same isoform switch in the TCGA adult GBM and LGG cohorts. For both GBM and LGG, RAS/MAPK/P38K wild-type tumors with elevated NF1-II conferred significantly reduced patient survival compared to RAS/MAPK/P38K mutant tumors. NF1-exon9 deletion was known to be repressed in cancer cell models by hub proteins like ELAV-like family of splicers regulators. We further show that members of these gene families are downregulated in HGG. Together, our results indicate a novel mechanism by which gliomas can activate signaling downstream from RAS independent of mutations and tumor grade, which promotes tumorigenesis by regulating pathways such as proliferation and invasion.

#1352 The importance of the RASA1/R-Ras/Ral-A signaling axis in melanoma tumorigenesis. Kristen Suzanne Hill, Xue Wang, Youngchul Kim, Min-jung Kim. Moffitt Cancer Ctr., Tampa, FL.

The Ras family of small GTP binding proteins are frequently activated by mutations in melanoma, as shown for NRAS (20%), KRAS (2%) and HRAS (1%). Ras isoforms can also be activated by inactivation of Ras GT-Pase activating proteins (RasGAPs), such as NF1, RASA1, and RASA2. In our recent study, we observed that inactivation of RASA1 (RAS p21 protein activator 1, also called p120RasGAP) suppressed melanoma via its RasGAP activity toward the R-Ras (related Ras viral (r-ras) oncogene homolog) isoform and that R-Ras was required to promote anchorage-independent growth driven by RASA1 inactivation. Moreover, a low level of RASA1 mRNA expression is associated with decreased overall survival in melanoma patients with BRAF mutations. Based on these observations, we hypothesized that, although not mutated, R-Ras is activated in melanoma by inactivation of RasGAPs and that BRAF activation cooperates with this RasGAP/R-Ras pathway activation in melanoma tumorigenesis. In this study, we addressed the importance of R-Ras, a previously less appreciated member of the Ras small GT-Pases family, in melanoma tumorigenesis. We observed frequent activation of R-Ras in BRAF mutant human melanoma cell lines. In addition, RNAi mediated reduced expression of R-Ras suppressed anchorage-independent colony growth and tumor growth. Moreover, among the 3 major Ras effector pathways, reduced R-Ras expression suppressed Ral-A activation, which may explain the mechanism of Ral-A activation in BRAF mutant melanoma. Interestingly, anchorage-independent growth driven by R-Ras activation downstream of RASA1 inactivation was suppressed by both genetic (siRNA targeting Ral-A) and pharmacological (Ral inhibitor BQ579) inhibition of Ral-A. To further investigate the impact of RASA1 loss, and thus R-Ras activation, on BRAF mutant melanoma development in vivo, we generated a RASA1+/−; BRAFCA/CA; Tyr-CreERT2 mouse model in which treatment with 4-hydroxytamoxifen (4-OHT) results in expression of constitutively activated mutant BRAF and deletion of RASA1 in melanocytic lineage cells. Preliminary analysis shows hyperpigmentation of the ear, tail, and foot pad in RASA1+/−; BRAFCA/CA; Tyr-CreERT2; H9262 mice compared to RASA1−/−; BRAFCA/CA; Tyr-CreERT2 mouse littermates. Tumors generated in this animal model will be analyzed to determine the extent of R-Ras and Ral-A activity in vivo. This study demonstrates the importance of the RASA1/R-Ras/Ral-A signaling pathway in BRAF mutant melanoma and supports the possible combinatorial treatment strategy targeting both the BRAF/MAPK and Ral signaling pathways.

#1353 Polysoprenylated cysteine amide inhibitors disrupt actin cytoskeleton organization, induce cell rounding, and block invasion of NSCLC. Elizabeth Ntantie, Jerrine Fletcher, Felix Amisah, Olufısayo O. Salako, Auguste T. Nkembo, Rosemary A. Poku, Nazarius S. Lamongo. Florida A&M University, Tallahassee, FL.

Non-small Cell Lung Cancer (NSCLC) malignancy is dependent on cellular processes that promote metastasis. F-actin organization is central to cell migration, invasion, adhesion and angiogenesis which are all processes involved in metastasis. F-actin remodeling is enhanced by the expression and activity of some members of the Rho family of small GTPases. Therefore, agents that mitigate hyperactive Rho proteins may be clinically relevant for controlling metastasis. We previously reported the synthesis and characterization of polysoprenylated cysteine amide inhibitors (PCAs) as potential inhibitors of the cancer phenotype. In this report, we investigate the potential role of PCAs against NSCLC malignancy and show that as low as 0.5 μM PCAs significantly inhibit 2D and 3D NCI-H1299 cell migration by 48% and 45%, respectively. PCAs at 1 μM inhibited 2D and 3D NCI-H1299 cell invasion through Matrigel by 50% and 85%, respectively. Additionally, exposure to 5 μM of the PCAs, NSL-BA-040 caused a 38% drop in F-actin intensity at the cell membrane 24 h post treatment. Importantly, this drop in F-actin was accompanied by a 73% reduction in the number of filopodia per cell. Interestingly, the polysoprenyl group of the PCAs is essential for these effects, as NSL-100, an analog that lacks the farnesyl moiety, does not elicit similar effects on F-actin assembly and organization. Put together, our findings indicate that PCAs disrupt F-actin assembly and organization to suppress cell motility and invasion and point towards a potential role of PCAs as effective therapies for NSCLC metastasis and invasion.

#1354 The role of RAL-A in soft tissue sarcoma tumor growth and metastasis. Steven T. Szineore, Gina M. Sizenore, Reena Shaya, Peter Amaya, Anisha M. Hammer, Alexander H. Rice, Jeffrey J. Chalmers, Michael C. Os- trowski, Arnab Chakravarti, "The Ohio State University, Columbus, OH; Denison University, Granville, OH.

Soft tissue sarcomas (STS) are a diverse collection of cancers of mesenchymal origin arising from the connective and supportive tissues of the body. While localized STS are well managed by surgery and radiation; metastasis, particularly to the lung, is frequent. More than 30% of adult STS patients develop lung metastases and the 5-year survival for these patients is a dismal 16%. Treatment options for metastatic STS are limited, thus there is an urgent unmet need for a better understanding of the key molecular pathways that drive metastatic spread in STS and identification of inhibitors of these pathways for clinical application. Through analysis of gene expression data from metastatic STS patient samples, we identified decreased expression of PPP2R1B as a hallmark of metastatic STS. To directly test its function as a suppressor of tumor growth and metastasis in STS, PPP2R1B was stably over-expressed in HT1080 cells, a model of metastatic STS. PPP2R1B expression almost completely abolished HT1080 tumor growth in nude mice. PPP2R1B is a subunit of the PP2A protein phosphatase complex that negatively regulates numerous cancer signaling pathways. However, the functional consequences of decreased PPP2R1B expression in STS are unknown. A combination of high-throughput and targeted approaches were utilized to identify 37 phosphoproteins that are significantly dephosphorylated following PPP2R1B expression in HT1080 cells. One of these phosphoproteins, the small GTPase RAL-A, exhibited decreased phosphorylation on Ser194 following PPP2R1B expression. RAL-A is significantly prognostic of STS metastasis and is elevated in more aggressive STS subtypes relative to less aggressive subtypes and normal tissue. RALA knockdown in HT1080 significantly slowed tumor growth and decreased the incidence of pulmonary metastasis, mirroring PPP2R1B overexpression. Importantly, RALA is an actionable therapeutic target for improved treatment of STS. Aurora A inhibitors indirectly inhibit RALA function by preventing RALA Ser194 phosphorylation by aurora A. We found that RALA expression and activity predicted response of STS cell lines to aurora A inhibition. Excitingly, the aurora A inhibitor alisertib nearly eradicated growth of HT1080 tumors in vivo. Exploration of the biological mechanisms through which RALA regulates STS metastasis identified regulation of vesicular traffic as a likely critical function of RALA in this process. These findings identify PPP2R1B, RALA, and aurora A as members of a key novel pathway that drives STS progression and advocate the use of treatments targeting this pathway to improve outcome for STS patients with advanced disease.

The KRAS oncogene is more frequently mutated in over one fourth of human cancers. Despite decades of work studying known effector pathways, no drugs in clinical use specifically target KRAS-mutant tumors. Uncharacterized feedback mechanisms and parallel pathways have stymied the treatment of KRAS-mutant tumors in patients, and the KRAS protein does not easily accommodate the binding of inhibitory small molecules. These challenges demand better characterization of the physical and genetic relationships between Ras regulators and effectors. To that end, we used tandem affinity purification of Kras, Hras and Nras and to identify quantitative changes in the growth of the small GTPase RAL-A in melanocytic lineage cells. Preliminary analysis shows hyperpigmentation of the ear, tail, and foot pad in RASA1+/−; BRAFCA/CA; Tyr-CreERT2; H9262 mice compared to RASA1−/−; BRAFCA/CA; Tyr-CreERT2 mouse littermates. Tumors generated in this animal model will be analyzed to determine the extent of R-Ras and Ral-A activity in vivo. This study demonstrates the importance of the RASA1/R-Ras/Ral-A signaling pathway in BRAF mutant melanoma and supports the possible combinatorial treatment strategy targeting both the BRAF/MAPK and Ral signaling pathways.

MOLECULAR AND CELLULAR BIOLOGY / GENETICS: Cell Growth Signaling Pathways

### #1356 Variable drug responses characterize the functional heterogeneity of NF1 null tumors. Daniela Pucciarelli, Ganesh Krishnamurthi, Steve Braunstein, Jean L. Nakamura. UCSF, San Francisco, CA

Introduction: Neurofibromatosis type 1 (NF1) is a autosomal dominant disease with a predisposition to cancer. Biallelic inactivation of the NF1 gene increases the risk of developing brain tumors, leukemia, neurofibromas and malignant peripheral nerve sheath tumors (MPNSTs). Somatic mutations in the NF1 gene are also associated with sporadic malignancies including glioblastoma, neuroblastoma, and melanoma. The NF1 tumor suppressor gene encodes the RAS GTPTase-activating protein (GAP) neurofibromin. Loss of NF1 results hyperactivation of Ras, MAPK and PI3K signaling pathways components, representing cell cycle therapeutic targets. Here we investigate if the variable responses of NF1 null tumors to MAPK and mTOR inhibitors suggests the intrinsic heterogeneity of NF1 mutant tumors. We hypothesized that defining alternative mechanisms and functional sub-classes of NF1-mutant tumors on the basis of their variable drug sensitivity will produce pre-clinical therapies data that will inform clinical trials. Methods: We previously generated mouse models in which we mutagenized NF1 heterozygous mice with radiation, recapitulating the susceptibility of patients with NF1 to radiation-induced cancers. These models produced solid tumors such as mammary carcinomas, squamous cell carcinomas, and soft tissue sarcomas, which we determined to be NF1 null. Cell lines established from these tumors were characterized by a drug sensitivity screen using a custom 94 compound drug library. Drug responses indicate that NF1 mutant tumors organize into functional groups based on differential sensitivities. Six candidate drugs each targeting distinct components of MAPK and PI3K signaling pathways were selected from the drug library. After 24 hours of exposure to each inhibitor or control, cells were analyzed for cell proliferation, cell cycle changes, and cell death. Western blotting were performed to determine whether drug exposures produce alterations in their predicted biochemical pathways such as PI3K/Akt, and MAPK pathways. Results: NF1 loss did not predict uniform sensitivity of cell lines to treatment with MAPK and mTOR inhibitors. Each compound induced differential effects on viability of NF1 null tumors cell lines. High variability and cell line-dependent cytotoxic and cyto-static effects were also observed. Although phosphorylated Akt(Y473), S6, and p44/42 MAPK varied widely among all untreated NF1 null cell lines, this did not predict their drug sensitivity. In vitro drug sensitivity data indicated heterogeneous differential sensitivities of NF1 mutant tumors to different drug classes, independent of tumor histology, permitting segregation into functional groups. Conclusion: Tumor cell lines driven by NF1 loss demonstrate heterogeneous responses to Ras pathway inhibition, which may be explained by mechanisms of tumor formation after NF1 loss involve multiple alternative pathways.

### #1357 The small GTPase Arf6 potentiates melanoma metastasis by activating Akt. Lehi Acosta,1 Aaron Rogers,1 Jae H. Yoo,1 Shannon J. Odelberg, Dean Y Kim,1 Albert H. Grossmann.1 University of Utah, Salt Lake City, UT; 2Huntsman Cancer Institute, Salt Lake City, UT.

Arf6 is a member of the Ras-superfamily of small GTPases and controls membrane trafficking and cytoskeletal remodeling, functioning mainly in endocytosis pathways at the cell periphery. Arf6 is activated by various extracellular signals and oncogenic events and has been shown to promote cell migration and pro-invasive phenotype in human cancer cells. Small molecule inhibition of Arf6 reduces spontaneous metastasis in xenograft models of human cutaneous melanoma, suggesting that Arf6 is necessary for disease progression. Using a genetically-engineered mouse model of BRAF-mutant melanoma, we determined whether activation of Arf6 is sufficient to induce spontaneous metastasis in vivo. For melanocyte-specific primary tumor induction, Cre recombinase was delivered via local injection of RCAS virus into DCT-TVA;Cdkn2alox/lox;BRAFV600E mice. BRAFV600E mice. In the experimental mice, a constitutively active mutant form of Arf6 (Q67L) was virally delivered with Cre. In this study, we observed a significant increase in spontaneous metastatic disease burden in Arf6 Q67L mice. Likewise, tail vein injection of melanoma cell lines derived from Arf6 Q67L tumors consistently show a diffuse pattern of pulmonary metastasis compared to parental tumors of a rapid, micrometastatic disease. Arf6 Q67L. Recently, it has been demonstrated that activation of Akt, but not Pten loss, leads to an aggressive phenotype in melanoma that includes the acquisition of brain metastases. Immunohistochemical analysis of phospho-Akt revealed that Arf6 Q67L is sufficient to induce Akt activation in tumors. In addition, ARF6 is necessary for Akt activation in human melanoma lines. We did not observe brain metastasis in DCT-TVA;Cdkn2alox/lox;BRAFV600E Arf6 Q67L mice. When we added Pten-/- to this genetic background, however, we observed microscopic brain metastases at a low frequency, suggesting that the combination of Pten loss and Arf6 activation reaches a threshold level of Akt activation that is sufficient to cause brain metastasis. Taken together our data indicate that activation of Arf6 is sufficient to potentiate melanoma metastasis, consistent with the proinvasive cellular phenotype attributed to Arf6. In addition, our data suggests a novel signaling mechanism by which Arf6, a small GTPase involved in trafficking, is somehow involved in Akt activation and that this step may be important for the acquisition of metastatic capacity.

### #1358 p21 activated kinase 4 (paka4) as a novel therapeutic target for non–hodgkin’s lymphoma. Asfar S. Azmi,1 Amro Aboukameil,1 Iffahina Muqbil,1 Yiwei Li,1 William Senapedis,2 Erkan Baloglu,2 Yosef Landesman,2 Michael Kaufman,2 Sharon Shacham,2 Ayad Al-Katib,1 Ramzi M. Mohammad1.

1Wayne State Univ., Detroit, MI; 2Karyopharm Therapeutics, Newton, MA.

Objective: The p21-activated kinase 4 (PAK4) is a key downstream effector of the Rho GTPase family and is over-expressed in many different cancer types. PAK4 protein, by virtue of its ability to engage multiple ligands, regulates a repertoire of signaling pathways. A survey of non-Hodgkin’s lymphoma (NHL) cell lines shows that there is increase in PAK4 mRNA and/or protein expression when compared to normal peripheral lymphocytes (PBL). Considering PAK4 RNA interference suppresses lymphoma cell proliferation, these findings point to a novel role for PAK4 in promoting NHL cell growth. To this end we examined the impact of the newly developed PAK4 allotropic modulators (PAMs) on NHL proliferation both in vitro and in vivo. Methods: WSU-FSCCL (representing follicular small cell cleaved lymphoma) and WSU-DLCL2 (diffused large B-cell lymphoma) were exposed to increasing concentrations of different PAM analogs (KPT-7523, KPT-7189, KPT-9037, KPT-9274, or KPT-7010 [inactive]) or the Pan-PAK inhibitor, PF-3783089, in the presence or absence of CHOP (used at 10 mg/kg for 72 hrs). Following combination treatment with either PAM or PF-3783089, cells were evaluated using Trypan Blue, apoptosis was analyzed using 7AAD, tetramerase staining, Annexin V FITC and cell cycle arrest was accessed by flow cytometry. Protein and mRNA expression changes were evaluated using immunoblotting and RT-PCR. The toxicity and efficacy of PAMs were evaluated in sub-cutaneous and disseminated xenograft models of NHL. Results: As single agents, PAMs show anti-proliferative activity in vitro against NHL cell lines (IC50 for WSU-FSCCL = 50 nM and WSU-DLCL2 = 250 nM) while sparing normal PBL (IC50 in μM range). There was a statistically significant dose-dependent difference in apoptosis induction in NHL cell lines treated with PAMs when compared to vehicle control. PAMs reduced total p-PAK4 and downstream signaling proteins involved in proliferation and apoptosis. In R-CHOP combination studies we observed enhanced viability suppression, increased apoptosis, and concurrent down-regulation of PAK4 signaling pathway proteins when compared to any single agent alone. The clinical compound, KPT-9274, is well tolerated and showed remarkable anti-tumor activity in WSU-DLCL2 sub-cutaneous xenograft mice (p < 0.01 at 140 mg/kg/d for 4 weeks with no loss in body weight). Residual tumors analysis showed suppression of PAK4 signaling pathways. Single agent and R-CHOP combination efficacy is currently being evaluated in subcutaneous and systemic WSU-FSCCL and in primary patient derived xenografts in mice. Conclusions: This is the first study demonstrating a role for PAK4 in diffuse large B-cell and follicular small cell cleaved NHL. Our data shows that inhibition of PAK4 could become a viable therapy for NHL either alone or in combination with R-CHOP. Our data is directly applicable to the current Phase 1 trial of KPT-9274 in patients with advanced solid malignancies or NHL.

### #1359 How does RAC1 GTPase signal Wnt-beta-catenin pathway-mediated integrin-directed metastasis-associated tumor cell phenotypes in TNBC. Nandini Dey, Jennifer H. Carlson, Casey Williams, Tyler Jepperson, Pradip De, Brian Leyland-Jones. Avera Research Inst., Sioux Falls, SD.

Introduction: We reported that Wnt Pathway (WP) upregulation, one of the salient genetic features of metastatic TNBC, controls the acquisition of integrin-directed metastasis-associated (ID-MA) phenotypes of TNBC cells (Dey et al., 2013). RAC-GTPTases, small G-proteins which transduce signals from cell surface proteins including integrins, have been implicated in tumorigenesis and metastasis by their role in essential cellular functions like motility. Aim: Here we tested the role of the mechanism of involvement of RAC1 in the regulation of WP-mediated ID-MA phenotypes in TNBC cells and examined how WP signals are transduced via RAC1 in the context of ID-MA phenotypes in TNBC. Method: Oncoprofiles showed that the major alterations of RAC1 gene in TNBC were constituted by the amplification/gain of the gene. The collective percentage of alteration(s) in RAC1 in ER+ve BC was 35% as compared to 57% in ER-ve BC (brca/tcga/pub2015). Using pharmacological agents (salindac sulfone), genetic tools (siRNA), WP modulators (Wnt-C59, XAV939), RAC1 inhibitors (NSC237636, WS6) and WP stimulations (LWnt3ACM, Wnt3A recombinant) in a panel of 6-7 TNBC cell lines, we studied fibronectin-directed and various motility parameters (actin dynamics, filopodia and lamellipodia by confocal microscopy) in the context of hibronectin-directed RAC1 and Cdc42 acti-
and tumor growth in vivo. In addition, our data showed that PAK3 regulated the motility and invasion. In our study, we showed that knockdown of PAK3, but also/ or hyperactivated in pancreatic cancer, and promotes pancreatic cancer cell death. Previous studies have shown that PAK1 and PAK4 are upregulated in activated mechanisms, six PAKs are classified into two groups, PAK1-3 (group I) and PAK 4-6 (group II). PAK kinases are frequently overexpressed in various human tumors and represent therapeutically relevant targets for cancer treatments. Previous studies have shown that PAK1 and PAK4 are upregulated and/ or hyperactivated in pancreatic cancer, and promotes pancreatic cancer cell motility and invasion. In our study, we showed that knockdown of PAK3, but not that of PAK1 or PAK2, inhibited pancreatic cancer cell proliferation in vitro, and tumor growth in vivo. In addition, our data showed that PAK3 regulated the protein stability of β-catenin via Akt/GSK-3β signaling pathway in pancreatic cancer cells. The role of PAK3 in regulating Akt/GSK-3β phosphorylation was further confirmed by the ectopic expression of wild-type versus kinase-dead (K297L) PAK3. Equally important, the mammosphere formation, aldehyde dehydrogenase (ALDH) activity and cancer stem cell-associated markers, were also down-regulated in PAK3 knockdown cells, suggesting the involvement of PAK3 in regulating cancer stem cell-like properties in pancreatic cancer cells. Together, these findings suggested that PAK3 as a primary regulator of Akt/GSK-3β/β-catenin signaling for maintaining cancer stem cell phenotypes and promoting tumor growth, which underlying the potential of targeting PAK3 in fostering new therapeutic strategies for pancreatic cancer.

#1360 Novel function of p21-activated kinase 3 (PAK3) in regulating Akt phosphorylation and pancreatic cancer stem cell phenotypes. Hsing-Yu Wu,1 Ming-Chen Yang,2 Po-Chen Chu,3 Samuel K. Kulp,3 Ching-Shih Chen1. 1Acedemia Sinica, Taipei, Taiwan; 2The Ohio State University, Columbus, OH.

p21-activated kinases (PAKs) are important effectors of the Rho family GTPases and has been implicated in cytoskeletal remodeling, cell proliferation, apoptosis, and transformation. Based on the sequence, structure homology, and activation mechanism, six PAKs are classified into two groups, PAK 1-3 (group I) and PAK 4-6 (group II). PAK kinases are frequently overexpressed in various human tumors and represent therapeutically relevant targets for cancer treatments. Previous studies have shown that PAK1 and PAK4 are upregulated and/or hyperactivated in pancreatic cancer, and promotes pancreatic cancer cell motility and invasion. In our study, we showed that knockdown of PAK3, but not that of PAK1 or PAK2, inhibited pancreatic cancer cell proliferation in vitro, and tumor growth in vivo. In addition, our data showed that PAK3 regulated the protein stability of β-catenin via Akt/GSK-3β signaling pathway in pancreatic cancer cells. The role of PAK3 in regulating Akt/GSK-3β phosphorylation was further confirmed by the ectopic expression of wild-type versus kinase-dead (K297L) PAK3. Equally important, the mammosphere formation, aldehyde dehydrogenase (ALDH) activity and cancer stem cell-associated markers, were also down-regulated in PAK3 knockdown cells, suggesting the involvement of PAK3 in regulating cancer stem cell-like properties in pancreatic cancer cells. Together, these findings suggested that PAK3 as a primary regulator of Akt/GSK-3β/β-catenin signaling for maintaining cancer stem cell phenotypes and promoting tumor growth, which underlying the potential of targeting PAK3 in fostering new therapeutic strategies for pancreatic cancer.

Claudin perforins lethal toxin (Tpel) belongs to the family of large claudin glycosylating cytotoxins. Claudin toxins are glycosyltransferases that modify and deactivate small GTPases of the RHO and RAS subfamily. Tpel mono-glycosylates in the switch I domain (Thr35) of RAC and RAS small GT-Pases. Glycosylation of RAS at Thr35 prevents binding to the primary effector, RAF kinase and results in a blockade RAS signal transduction. RAS family proteins function as key regulators of cell proliferation, differentiation, survival and gene expression. Moreover, mutations in RAS proteins are highly prevalent in human cancers. Considering the specificity of Tpel for RAS, we decided to investigate the biochemical interaction between Tpel and RAS, and potentially develop tools to disrupt the RAS signaling pathway. In order to assess the effect of Tpel on RAS-dependent cell proliferation and adhesion, we utilized a Raf-1 RAS binding domain (RBD) pulldown method, we found that Tpel treatment did not affect the viability of the BREF V600E cells and only induced toxicity in RAS expressing cells. Consistent with this result, Tpel treatment inhibited MAPK signal transduction in the RAS expressing cells, but not in the BREF V600E cells. Surprisingly, both cell viability as well as pERK levels remained unaffected in the KRAS Q61R MEF cells treated with Tpel, suggesting that KRAS Q61R is resistant to glycosylation. This may be due in part to the relatively slow intrinsic rate of GTP hydrolysis and very high levels of KRAS-GTP in KRAS Q61R cells. We also developed and adapted biochemical assays to study Tpel-KRAS interaction in vitro. Based on Alpha Assay and UDP Glow, Tpel activity does not appear to be nucleotide specific, in contrast to previously reported findings. We are currently testing if Tpel activity is competitive with or is inhibited by other molecules that bind to switch I, such as the RBD domain of RAF1 or the Ras-binding domain of AGO2. Our data indicate that the KRAS Q61R expressing MEF cells is due not to the high levels of RAS-GTP, but to the constitutive binding to effector molecules, which prevent Tpel from accessing KRAS. We also hope to identify the critical residues required for Tpel binding and catalysis. By elucidating the mechanism of substrate binding and substrate specificity we may gain insight into novel binding pockets that could be exploited therapeutically.

#1362 Argonaute 2 controls RAS activation in mouse embryonic fibroblasts. Ronald F. Siebenaler, Sunita Shankar, Vijaya L. Dommeti, Malay Mody, Arul Chinnaiyan. University of Michigan Medical School, Ann Arbor, MI.

The RAS gene family is among the most commonly mutated genes within cancer, and while much research has elucidated the major downstream pathways, including MAPK and PI3K, little progress has been made in successfully targeting mutant RAS in cancer. We recently identified an interaction between the N terminal domain of Argonaute 2 (AGO2), a core component of RNA-induced silencing complex (RISC), and the Switch II domain of KRAS. Furthermore, this interaction was found in all cell lines tested, expressing either wild-type (WT) or mutant KRAS. We found that stable knockdown of AGO2 in KRAS dependent cell lines lead to a decrease in KRAS protein expression with a subsequent decrease in KRAS activity. Conversely, the overexpression of AGO2 in these cells lead to both an increase in KRAS expression and oncogenesis. In addition, this interaction inhibits the RNAi function of AGO2 by preventing microRNA unwinding in the presence of oncogenic KRAS compared to WT-KRAS. Despite a clear association between mutant KRAS and AGO2 mediating increased KRAS mediated oncogenesis, the precise function of this interaction remains unclear in normal physiology. In order to better assess the endogenous function of the KRAS-AGO2 interaction, we analyzed two mouse embryonic fibroblast cell lines (NIH 3T3 and MEF) with complete knockout of AGO2. Utilizing a Raf-1 RAS binding domain (RBD) pulldown method, we assessed activated WT-RAS levels in AGO2 null NIH 3T3 and MEF cells. We found that knockout of AGO2 lead to an increase in WT RAS-GTP activation compared to normal control cells. Immunoblot analysis also indicates that AGO2 null fibroblasts lead to increase in RAS downstream signaling through the MAPK/ERK and PI3K/AKT pathways. Furthermore, rescue of AGO2 knockout using full length mouse AGO2 decreased wild type RAS activation and its downstream signaling. Taken together, these observations suggest that the AGO2 interaction may suppress WT-KRAS activation, leading to maintenance of RAS-GDP levels. Using RNA-seq, microRNA and protein hybridization, we began to identify the pathways that may be involved in RAS activation in AGO2 null cells. Early analyses indicate that AGO2 controls WT-KRAS levels and activity through multiple mechanisms, laying the foundation for a better understanding of the RAS-AGO2 interaction in normal physiology.

#1363 RSK2 provokes invasive signaling in glioblastoma through LARG-dependent activation of Rho GT-Pases. Geng-Xian Shi,1 Ling Jin,1 Michelle L. Matter,2 Santosh Kesari,2 Joe W. Ramos,3 Univ. of Hawaii Cancer Ctrl., Honolulu, HI; 3John Wayne Cancer Institute, Honolulu, HI.

Malignant gliomas are one of the most aggressive and deadly forms of cancer and can affect any age group. In glioblastoma multiforme (GBM), infiltration of primary tumor cells into the normal tissue and dispersal throughout the brain is a central challenge to successful treatment that remains unmet. Patients with malignant gliomas respond poorly to the standard therapeutic regimen of radiotherapy and chemotherapy that follow tumor resection and have only a 16-month median survival. It is therefore imperative to identify new approaches to specifically attack GBM cell survival, proliferation and invasion. The cellular mechanisms driving GBM-mediated migration and invasion are not fully understood. RSK2 (p90 ribosomal S6 kinase 2) is a kinase that regulates proliferation and adhesion and can promote metastasis. We find that RSK2 is significantly upregulated in vivo in human GBM patient tumors, and that high RSK2 expression significantly correlates with advanced tumor stage and poor patient survival. We demonstrate that active RSK2 regulates GBM adhesion and is essential for cell motility and invasion of patient-derived GBM neurosphere. Importantly, inhibition of RSK2 by either RSK inhibitors or shRNA silencing impairs invasion and combining RSK2 inhibitors with temozolomide improves efficacy in vitro. We further show that the effects of RSK2 on GBM invasion are mediated in part through activation of Rho GT-Pases. Rho family of GT-Pases are key regulators of cell polarity, migration and invasion. Here, we identify Rho A,

Matthew Holderfield, Kanika Sharma. #1365 Sensitivity of oncogenic KRAS to adenosine triphosphate suppressors could enhance the effectiveness of existing GBM treatment, and support RSK2 targeting as a promising approach for novel GBM therapy. 

#1364 Direct phosphorylation and attenuation of the DCL1 tumor suppressor by SRC kinase: a new mechanism of SRC-dependent activation of Rho with translational implications. Brajendra K. Tripathi, Xiaolan Qian, Ming Zhou, Dunrui Wang, Marian Durkin, Alex G. Papageorge, Douglas R. Lowy. National Institutes of Health, Bethesda, MD; National Cancer Institute, Frederick National Laboratory for Cancer Research, Frederick, MD.

Many tumors have high SRC activity and constitutive up-regulation of Rho-GTP, which is frequently implicated in the neoplastic process and tumor progression to metastasis, but the mechanistic link is unclear. Here we identify the DCL1 RhoGAP tumor suppressor, which encodes a RhoGAP as a recognized direct target of the SRC kinase, in untransformed cells and in tumor-derived cell lines, which upregulates Rho-GTP. SRC kinase directly phosphorylates two Tyrosines in DCL1: Y451 and Y701. SRC phosphorylation of DCL1-Y701, which is located in the DCL1 RhoGAP domain, attenuates its RhoGAP activity and tumor suppressor function by inhibiting the binding of active Rho-GTP to the RhoGAP domain, reducing the hydrolysis of active Rho-GTP to inactive Rho-GDP and resulting in an increase in Rho-GTP. The role of SRC phosphorylation of DCL1-Y451 is to diminish DCL1 binding to tension, which further reduces the tumor suppressor functions, as measured by cell migration rate, anchorage-independent growth, and tumor formation in nude mice, independently of Rho-GTP. We also found that ERK1 cooperates with SRC by phosphorylating DCL1-S129, which enhances the binding of the SRC-Sh3 domain to this region of DCL1, and increases SRC-dependent phosphorylation of Y451 and Y701. The cooperative effects reduce RhoGAP activity, increase Rho-GTP and Rho/ROCK/MRLC signaling, and attenuate DCL1 tumor suppressor functions. DCL1 preferentially binds active SRC, which reduces overall SRC activity. Therefore, SRC activity tends to be lower in cells that express high levels of endogenous DCL1, compared with cells in which DCL1 expression has been down-regulated. Although SRC targets two DCL1 functions that contribute to its tumor suppressor activity, DCL1 binds several ligands in addition to tension that also contribute to its tumor suppressor functions. Therefore, it would not be surprising if high SRC activity were associated with selective pressure for down-regulation of DCL1 expression. Consistent with this hypothesis, the combination of high SRC and low DCL1 expression was associated with cell-line progression in lung adenocarcinomas (p = 0.005) in TCGA. The potentially reversible nature of the SRC-induced attenuation of DCL1 function can be exploited therapeutically. In two systems that have high SRC activity and express DCL1 - the mouse MMTV-PyMT cancer model and a human lung cancer cell line - the Src inhibitor PP1 has marginal antitumor activity, as it reduces DCL1 Tyrrosine phosphorylation, reactivates DCL1, and reduces Rho-GTP. However, PP1 has marginal antitumor activity an isogenic DCL1-negative strain of the lung cancer line, as the inhibitor does not reactivate DCL1 and does not alter Rho-GTP levels. The results highlight the potential importance of tumor suppressor reactivation as a biomarker for predicting and monitoring the response to SRC inhibitors.

#1365 Sensitivity of oncogenic KRAS to adenosine triphosphate suppression. Matthew Holderfield, Kanika Sharma. Frederick National Laboratory for Cancer Research, Frederick, MD.

KRAS proteins regulate many cellular processes including initiation of cell division in response to mitogens. Gain of function KRAS mutations appear in approximately 30% of all human cancers and activate effector signal transduction pathways independent of mitogenic stimuli. KRAS-driven cancers also frequently have high metabolic rates and may have increased sensitivity to metabolic inhibitors but the underlying mechanism is not fully understood. In this study, we characterized the cellular mechanism of a small molecule inhibitor identified using a transgenic Drosophila melanogaster model that expresses human KRAS-G12V in the fly wing. The compound partially restored wing developmental in the KRAS-G12V flies and inhibited growth and signal transduction in multiple KRAS driven cancer cells and KRAS-G12V dependent MEF cells but not in MEF cells expressing BRAF-V600E. The compound also had a profound impact on mitochondrial function by inhibiting electron transport (ETC) complex I activity, as well as an uncharacterized non-ETC site that is sensitive to oncogenic KRAS signal transduction. ATP production through glucose metabolism was sufficient to rescue KRAS function and cellular growth after ETC inhibition, suggesting that inhibition of MAPK signaling is due to low ATP levels rather than a direct consequence of ETC or complex I inhibition. These data indicate that oncogenic KRAS signal transduction requires high cellular ATP levels and suggests a synthetic lethal interaction between KRAS and multiple metabolic targets that could be exploited to target KRAS driven cancers.

#1366 Structural basis of impaired GTP hydrolysis in oncogenic mutants of KRAS. Timothy Tran, Sathija Dharmain, Oleg Chertov, Timothy Waybright, William Gillette, Dominic Esposito, Dwight Nissley, Frank McCormick, Andrew Stephen, Dhirenra Simanshu. NCI RAS Initiative, Frederick National Laboratory for Cancer Research, Frederick, MD; Diller Family Comprehensive Cancer Center, University of California San Francisco, San Francisco, CA.

KRAS mutations are found in one-third of all human cancers. Among the three RAS isoforms - HRAS, KRAS and NRAS, KRAS is the most commonly mutated gene (in 86% of RAS-driven cancers) and the mutations are often detected in pancreatic, colorectal and lung cancers. RAS proteins function as molecular switches by alternating between inactive GDP-bound and active GTP-bound states. The active or inactive state of RAS proteins is regulated by guanine nucleotide exchange factors (GEFs) and GTPase-activating proteins (GAPs). In the GTP-bound state, RAS proteins interact with a variety of effector proteins, such as Raf, PI3K, and RalGDS, leading to activation of several signaling cascades within the cell. In 98% of the cases, oncogenic RAS mutations are found at amino acid positions G12, G13, and Q61 which impair intrinsic and GAP-mediated GTPase function resulting in accumulation of constitutively GTP-bound RAS in cells. To gain insights into the effect of oncogenic mutations on overall structure and GTP hydrolysis, we solved high-resolution crystal structures of wild type and six oncogenic mutants (G12C, G12D, G12V, G13D, Q61L and Q61R) of KRAS in complex with GMPPNP (a non-hydrolysable GTP analog) and magnesium. Comparison of GDP and GMPPNP bound structures of wild type (WT) KRAS4b suggests conformational changes that occur when KRAS4b transitions from inactive to active state. Comparison of mutant and wild-type KRAS structures has shown the appearance of new pockets in some cases that could be exploited for structure-based drug design. Structural superposition of mutants vs. wild type KRAS4b in complex with GMPPNP/Mg2+ and KRAS4b mutants vs. WT-HRAS bound to RASA1-GAP provides a rationale for impaired intrinsic and GAP-mediated GTP hydrolysis in the KRAS mutants.

#1367 The dynamic mechanism of SARAH domain in RASSF5 activation by K-Ras4B. Tsung-Jen Liao, Hyunbum Jang, Chung-Jung Tsai, David Fushman, Ruth Nussinov. University of Maryland, College Park, MD; National Cancer Institute at Frederick, NIH, Frederick, MD.

RASSF5 is a tumor suppressor, which acts as an adaptor linking Ras and the Hippo pathways. RASSF5 activates MST1/2, a key upstream protein of the Hippo pathway, through SARAH domain heterodimerization, resulting in Hippo signaling. Signaling stimulates YAP1 phosphorylation, leading to its degradation and thereby cell apoptosis. Association with K-Ras4B promotes RASSF5 to release its SARAH which heterodimerizes with MST1/2. We aim to reveal how K-Ras4B regulates the Hippo pathway through RASSF5 by resolving the structure and conformational dynamics of RASSF5 complexes. Our modeling and simulations help elucidate the intrinsic dynamic interactions of RASSF5 RA (Ras binding) and SARAH domains. Surprisingly, we found that the residue E388 on RASSF5 SARAH plays a significant role in the dynamic mechanism of Ras and plays a role in the RA-SARAH association. The mutations E388A and E388K dramatically decrease the strength of RASSF5 homo-SARAH and RASSF5-MST2 hetero-SARAH, suggesting that the E388 mutation may be oncogenic. Simulations of selected RASSF5 configurations with GTP-bound K-Ras4B indicate that the interactions between RA and SARAH are reduced. We conclude that Ras binding weakens the RA-SARAH association, increasing the SARAH dynamic fluctuation. The released RASSF5 SARAH has high propensity to dimerize with MST1/2 SARAH, activating Hippo signaling thus cancer suppression. Funded in whole or in part with Federal funds from the Frederick National Laboratory for Cancer Research, NIH under contract HHSN261200800001E.

**RABL6A**, a novel critical regulator of Akt-mTOR signaling in pancreatic neuroendocrine tumor cells. Shaik Amjad Ume Salma, Jessura Hagen, Jacki Reilly, Ryan Sheehy, Njitia Tiwari, Jackson Nteeba, Scott K. Sherman, Thomas M. O’Dorioso, James R. Howe, Andrew M. Bellizzi, Benjamin W. Darbro, Dawn E. Quelle. *Univ. of Iowa College of Medicine, Iowa City, IA.*

**Introduction:** A better molecular understanding of pancreatic neuroendocrine tumors (PNETs) is needed to improve patient diagnosis and treatment. Everolimus (mTOR inhibitor) is a standard-of-care therapy for PNET patients based on aberrant activation of the PI3K/Akt/mTOR kinase pathway in tumors. However, sustained mTOR inhibition paradoxically promotes Akt kinase hyperactivation due to loss of negative feedback regulation and tumors become drug resistant. Our study revealed that RABL6A, a novel oncogene product amplified in PNETs, is a key regulator of this clinically relevant pathway. Methods: RABL6A and Akt protein levels were manipulated using viral shRNAs in BONI PNET cells. Transcript levels were assayed by microarray and qRT-PCR, proteins assessed by western blotting, and cell proliferation and survival measured by cell counts, trypan blue exclusion and EdU incorporation. Effect of RABL6A expression on sensitivity to clinically relevant drugs. MK2206 (Akt inhibitor) and everolimus, were tested. Results: Silencing of RABL6A in PNET cells causes G1 and G2/M cell cycle arrest, and pathway analysis of microarray data suggested inactivation of Akt signaling in the arrested cells. Immunoblotting confirmed dramatic loss of Akt phosphorylation at Ser-473 along with impaired phosphorylation and activation of its targets, FRAS40 and FOXO-1/3. Phosphorylation of S6K, a downstream target of Akt-mTOR signaling, was also reduced. The mechanism by which RABL6A controls Akt-S473 phosphorylation is currently not known although we demonstrated that mTORC2 (the kinase that phosphorylates Akt at Ser473) remains active in RABL6A deficient tumors. The mechanism by which RABL6A controls Akt-S473 phosphorylation is currently not known although we demonstrated that mTORC2 (the kinase that phosphorylates Akt at Ser473) remains active in RABL6A deficient cells since the phosphorylation of other mTORC2 substrates (SGK1 and PDK1) is unaffected. Given the central role of Akt1 in tumorigenesis, we hypothesized that repressing its activity may rescue the arrest phenotype caused by RABL6A loss. Restoration of Akt1 in RABL6A-depleted cells partially rescued the G1 phase arrest and induced S phase entry but was insufficient to allow mitosis, suggesting RABL6A regulates other factors required for cell division. Finally, drug response assays showed that RABL6A loss desensitizes PNET cells to Akt and mTOR inhibitors. Conclusion: Our previous work showed RABL6A promotes G1 progression in PNET cells by inactivating Rb1, an established suppressor of PNET pathogenesis. We now show that RABL6A also controls Akt phosphorylation and is essential for Akt-mTOR activation. Thus, RABL6A controls multiple cancer pathways necessary for PNET cell cycle progression and survival. We are testing if RABL6A status in PNETs predicts responsiveness to combination therapies targeting Akt and mTOR. Overall, this work identifies RABL6A as a new essential activator of Akt1-mTOR signaling, suggesting it is a new potential biomarker and target for anticancer therapy in PNET patients.

**EGFR-mediated Spred1 phosphorylation inhibits NF1 to sustain constitutive Ras/MAPK signaling.** Evan Markegard, Ellen L. Mercado, Jillian M. Silva, Jacqueline Galeas, Marena L. Trinidad, Anatoly Urisman, Frank McCormick. *UCSF, San Francisco, CA.*

Spred proteins negatively regulate Ras/MAPK signaling following growth factor stimulation. Inhibition of Ras primary occurs through Spred1’s ability to bind and localize NF1, a RasGAP and major tumor suppressor, to the plasma membrane. Spred1 and NF1 loss-of-function mutations occur across multiple cancer types including non-small cell lung carcinoma, glioblastoma, melanoma, stomach carcinoma, and uterine carcinosarcoma. Here we demonstrate that EGFR signaling disrupts Spred1-NF1 binding. Mass spectrometry was performed on cells expressing EGFR to identify potential phosphorylation sites on Spred1 and NF1 that could disrupt Spred1-NF1 binding by steric hindrance. A serine phosphorylation site on Spred1 was identified in which a phospho- mimetic and phophodedeficient mutant decreased or increased Spred1-NF1 binding, respectively. Phosphomimetic Spred1 is unable to suppress Ras-GTP stimulation. Therefore, phosphorylation of Spred1 at this site by a serine kinase downstream of EGFR may disrupt Spred1-NF1 binding. To identify the Spred1 kinase we are performing an in vitro kinase assay and an unbiased CRISPRa screen. Our findings provide one potential mechanism by which EGFR signaling disrupts negative feedback to sustain constitutive Ras signaling. Furthermore, this work may elucidate a novel therapeutic target for restoring NF1-mediated inhibition of Ras.

**Isoprenylcysteine carboxylmethyltransferase (ICMT) function is critical for epithelial malignant transformation by mutant-Ras.** Hiu Yeung Lau, Jingyi Tang, Patrick J. Casey, Mei Wang. *Duke-NUS Medical School, Singapore, Singapore.*

Purpose Limited progress has been made in the development of direct inhibitors of Ras. Therefore, targeting isoprenylcysteine carboxylmethyltransferase (ICMT), the final enzyme in the prenylation pathway for Ras and other proteins containing the so-called CaaX-motif, remains an important strategy to inhibit Ras function in cancers. In this study, we investigate the role ICMT plays in the initiation of human epithelial cancers involving constitutively-active mutant Ras using genetic manipulation strategies. Methods Small T antigen and a shRNA against p53 (shp53) were sequentially expressed in human mammary epithelial cell lines immortalized by hTERT (HME1-hTERT) to create pre-malignant HME1-shp53 cells. All 4 isoforms of wild-type or mutant Ras, namely H-Ras, N-Ras, K-Ras-4A and K-Ras-4B, were independently introduced into HME1-shp53 cells to determine their transforming ability. Using CRISPR-Cas genome editing technology, ICMT-null HME1-shp53 cells were generated and mutant Ras isoforms were subsequently introduced; tumor formation abilities of thus generated cells were determined using soft agar anchorage-independent colony formation assay and subcutaneous xenografts in mice. ICMT knockout was also performed in MiaPaCa-2 and MDA-MB-231 cells, both expressing mutant K-Ras, and subcutaneous xenograft tumor formation in mice was measured. Results Pre-malignant HME1-shp53 cells can be transformed by all mutant Ras isoforms but not by any wild-type Ras. ICMT loss-of-function dramatically reduced anchorage-independent colony formation caused by all mutant Ras isoforms in HME1-shp53 cells, and in vivo xenograft formation was completely abolished. ICMT loss-of-function also dramatically reduced in vivo xenograft formation for mutant K-Ras-expressing MiaPaCa-2 and MDA-MB-231 naturally-occurring cancer cells. Conclusion ICMT function is essential for the malignant transformation of HME1 cells by all isoforms of Ras. Furthermore, ICMT function is also crucial for the maintenance of the malignant phenotype in mutant K-Ras-expressing cells such as MiaPaCa-2 and MDA-MB-231 cells.

**DNA, protein, and cell line reagents to facilitate Ras pathway drug discovery efforts.** Dominic Esposito. *Frederick National Laboratory for Cancer Research, Frederick, MD.*

The Ras Reagents Core within the NCI Ras Initiative produces and distributes qualified DNA vectors, cell lines, and protein production reagents to the external community to facilitate research into Ras biology and development of Ras cancer therapeutics. DNA vectors representing a variety of Ras mutations, as well as a complete collection of 180 genes in the Ras pathway are available as Gateway-compatible Entry clones. These clones represent the most commonly expressed transcript forms of the 180 genes, many of which were not previously available in full-length, wildtype forms. The vectors can be used with the FNLC combinatorial cloning library to easily generate a large number of different types of expression clones with various promoters, fusion tags, and plasmid backbones. Cell line reagents include a variety of Ras-dependent mouse embryonic fibroblasts (MEFs) which have a defined mutant allele of KRAS and which serve as isogenic cell lines for investigating allele and mutant specific Ras biology, as well as drug screening tools. Protein reagents include E. coli and insect cell constructs and cell lines for production of a variety of Ras-related proteins. In particular, we have materials for the high yield production of properly processed, prenylated KRAS protein using a unique engineered insect cell expression system. This system can also be used to produce other prenylated small GTPases at levels not previously attainable. Many of the resources of the Ras Reference Core are readily available to the academic community through repositories or material transfer agreements, and can be licensed to industry scientists as well. The program is also interested in identifying the needs of the community for additional Ras-related resources, and is developing methods for vetting requests from the outside to provide additional reagents.

**Towards novel strategies of targeting specific vulnerabilities of T-PLL cells.** Sabine Pueter1, Emma Andersson1, Alexandra Schrader1, Lesley Varghese1, M. Hülsemann1, Petra Mayer1, Marc-Henri Stern1, Sebastian Newr1, L. Frenzel1, Satu Mustjoki2, Marco Herling1. 1Center for Integrated Oncology (CIO) Köln-Ronn, University of Cologne, Cologne, Germany; 2University of Helsinki and Department of Hematology, Helsinki, Finland; 3Institute Curie, Paris, France; 4Institute of Pathology University of Frankfurt, Frankfurt, Germany.

**MOLECULAR AND CELLULAR BIOLOGY / GENETICS: Epigenetics 1**

**MOLECULAR AND CELLULAR BIOLOGY / GENETICS: Cell Growth Signaling Pathways 4**

Proceedings of the American Association for Cancer Research • Volume 58 • April 2017 353
T-cell prolymphocytic leukemia (T-PLL) is a mature T-cell neoplasm usually presenting at an aggressive phase and a marked resistance to conventional cytostatics, i.e. alkylators. The monoclonal antibody alemtuzumab induces high response rates, but virtually all patients relapse and the mostly elderly individuals are often ineligible for allogeneic stem cell transplantation. Overall, the treatment options for T-PLL are scarce and its prognosis remains poor, with median survival times of <3 yrs, remains poor. In agreement with the pronounced amenability of T-cell tumors to intervention in the altered epigenetic code, recent reports also implicate a high potential of epigenetic targeting in T-PLL. In fact, profiling of antineoplastic sensitivities, including clinically used agents like fludarabine or nelarabine, revealed that the purine analog cladribine showed the highest response (LD50 = 2.4 nM). Furthermore, the combination of T-PLL-specific CD70, H3K9ac, H3K27ac and H4K5ac. Preliminary analysis with si-RNA experiments revealed overexpression of HOXA9 is highly associated with a poor prognosis in acute myeloid leukemia (AML). In addition, Ash1l is overexpressed in a variety of cancers, including breast and thyroid cancer, but its role in cancer remains poorly characterized. Recent data suggest that Ash1l promotes leukemogenesis in mixed-lineage leukemia by recruiting the MLL epigenetic regulator to target genes. However, Ash1l is a large protein with multiple chromatin-interacting domains, and which regions of the Ash1l protein are important in leukemia has not been reported. Specifically, the role of Ash1l’s Kmtase activity in leukemogenesis remains unknown. To further investigate the function of Ash1l in leukemia, we knocked down expression of Ash1l in leukemia cell lines. We found that Ash1l knockdown slowed cell growth and caused a decrease in expression of Ash1l genes and their collaborator Mei51. Specifically, we investigated the role of Ash1l Kmtase activity in leukemia, we used a mouse model with a targeted in-frame deletion of the Ash1l SET domain (ΔSET). ΔSET cells express a shorter version of Ash1l that does not contain the SET domain. We transduced bone marrow cells (BMCs) isolated from ΔSET and WT mice with several oncogenes relevant to AML to determine the role of the Ash1l SET domain in leukemogenesis. We found that ΔSET BMCs were significantly impaired in leukemogenic transformation compared to WT BMCs, as manifested by decreased colony-forming ability and reduced expression of HOXA genes. These findings suggest that the Ash1l SET domain plays an important role in leukemogenesis mediated by multiple different oncogenes. Future studies will further characterize Ash1l’s role in leukemia by identifying the complete set of genetic loci that it methylates and regulates, and will determine whether the Ash1l SET domain represents a viable therapeutic target.

#1374 Frequent up-regulation of histone methyltransferase G9a contributed to liver carcinogenesis by epigenetically silencing of tumor suppressor RARRES. Iai Wei, Felice Ho-Ching Tsang, Dickly Cheuk-Ting Lee, Sandy Leung-Kuen Au, Joyce Man-Fong Lee, Carmen Chak-Lui Wong, Irene On-Lin Ng, Jack Chun-Ming Wong. The University of Hong Kong, Hong Kong, Hong Kong.

Hepatocellular carcinoma (HCC) is the second leading cause of cancer death worldwide and is the most common type of cancer in sub-Saharan Africa and Southeast Asia area where hepatitis B infections are common. The initiation and progression of HCC was attributed to alterations in genetics and disruptions of epigenetic processes which lead to altered gene functions in both oncogenes and tumor suppressors. Recent advancements in the field of cancer epigenetics increasingly emphasize the important role of every component in the epigenetic machinery. However, the alterations of epigenetic mechanisms involved in HCC are still largely unknown. Using transcriptome sequencing, we examined the expression of 591 epigenetic regulators in hepatoblastomas from human HCC and found that most of the epigenetic regulators are deregulated especially the histone modification enzymes. Among all of them, we identified G9a (Eu- chromatic histone-lysine N-methyltransferase 2, EHMT2), a histone H3 lysine 9 (H3K9) specific histone methyltransferases, as one of the most significantly up-regulated epigenetic regulators in human HCCs. Previous studies about epige- netic aberrations which contribute to liver carcinogenesis, and targeting G9a could be a potential epigenetic therapeutic method for HCC treatment. In this study, we found that G9a was frequently up-regulated in different HCC sample cohorts. Up-regulation of G9a was significantly associated with HCC disease progression, cancer aggressiveness, and more malignant tumor phenotypes. Functionally, we demonstrated that shRNA knockdown and CRISPR/Cas9 knockout of G9a suppressed HCC cell proliferation in vitro and inhibited subcutaneous xenograft HCC tumorigenicity in vivo. Depletion of G9a significantly reduced HCC cell migration ability and induced cell senescence. Pharmacological inhi- bition of G9a by small molecule inhibitors, UNC638 and RIX01294, also sup- pressed HCC cell growth and altered cell morphology. Mechanistically, we showed that the frequent up-regulation of G9a in human HCC was attributed to 2.81

#1375 Loss of C-MYC and chromatin acetylation induce epigenetic reprogramming in acute lymphoblastic leukemia. Elodie M. Da Costa, Gregory Arnaud, Nhat Cong Nguyen, Johannes Beaudy, Pascal Sre- On, Maxime Caron, Daniel Sinnett, Serge McGraw, Noel J. Raynal, CHU Sainte-Justine research center, Montreal, Quebec, Canada.

Epigenetic modifications play a key role in establishing and maintaining gene expression in cancer, they are highly altered and responsible of gene expression deregulation. Epigenetic drugs have the ability to reset cancer cell epigenome producing cancer cell differentiation and apoptosis. In a drug screening initiative, we recently reported a series of FDA-approved drugs with unsuspected epigenetic and anticancer activities. Here, we tested in a secondary screen the activity of these drugs against acute lymphoblastic leukemia (ALL) cell lines (MOLT-4 and NALM-6). We found that Proscillaridin A, a cardiac glycoside used for heart failure treatment, was the most active with IC50 values in the low nanomolar range, suggesting drug resistance. Moreover, Proscillaridin A treatment induced a significant decrease in RNA and protein levels of C-MYC, a master oncogenic driver in ALL. Shortly after proscillaridin A treatment, C-MYC exhibited a 75% reduction in lysine acetylation, a post-translational modification known to prevent its degradation. Loss of acetylation was associated with down-regulation of lysine acetyltransferases CBP, P300 and Tip60, which also correlated with a reduction in histone 3 and 4 acetylation levels (H3K14ac, H3K9ac, H3K27ac and H4K5ac). Preliminary analysis with si-RNA experiments reveal that independent HAT activities are not responsible of C-MYC down-regulation. RNA sequencing and gene set enrichment analysis in proscillaridin-treated ALL cells (5 nM for 48h) showed that genes associated with cell differ-
entiation and apoptosis pathways were up-regulated whereas down-regulated genes were associated with C-MYC target genes. Altogether, our findings show that acetylation through lysine acetyltransferase down-regulation simultaneously induces loss of C-MYC and H3 acetylation leading to epigenetic reprogramming in ALL cells. This drug repositioning strategy, using procussilarin A, has the potential to reprogram cancer cells that are driven by MYC overexpression or hyperactivation.

In conclusion our findings indicate that our lead molecule of fundamental mechanisms of chromatin dynamics. Fission yeast possesses 13 (Schizosaccharomyces pombe) is an ideal model organism to investigate the progression and other diseases. However, histone methyltransferase (HMTase) is part of intricate networks that ultimately regulate transcriptional events. Dysfunctional ballet of writers, readers and erasers of epigenetic marks on both DNA and histones were associated with C-MYC target genes. Altogether, our findings show that acetylation through lysine acetyltransferase down-regulation simultaneously induces loss of C-MYC and H3 acetylation leading to epigenetic reprogramming in ALL cells. This drug repositioning strategy, using procussilarin A, has the potential to reprogram cancer cells that are driven by MYC overexpression or hyperactivation.

#1377 Set7 is a novel histone methyltransferase in Schizosaccharomyces Pombe. Eric Di Luccio, Yunpeng Shen, Damiaan E.HF Mevis, Yeon Jeong Noh, Jihyeon Kim, Masayo Morishita. Kyungpook National University, Daegu, Republic of Korea.

Dynamics and plasticity of chromatin regulation is mediated by a molecular ballet of writers, readers and erasers of epigenetic marks on both DNA and histones. The pattern of histone modifications may define a histone code, which is part of intricate networks that ultimately regulate transcriptional events. Dysfunction of histone methylation affects chromatin regulation and is involved in an increasing number of pathologies from cellular transformation to tumor progression and other diseases. However, histone methyltransferase (HMTase) pathways remain to be further explored and better understood. Fission yeast (Schizosaccharomyces pombe) is an ideal model organism to investigate the fundamental mechanisms of chromatin dynamics. Fission yeast possesses 13 SET-containing proteins (Set1 to 13), several of which methylate histones or ribosomes. The catalytic SET domain is highly conserved across eukaryotes (e.g. Set2, a homologue of the oncprotein NSD2/MMSET/WHSC1 in human). Structure-function studies of HMTases are essential from basic science to translational research. However, full-length structures of fission yeast methyltransferases are currently missing. Here, in an effort to better understand histone methylation and to gain insight for drug-design, we report the identification and structural characterization of a novel histone methyltransferase Set7 (SPC297.04c), in Schizosaccharomyces Pombe. In this study, we investigated Sp.Set7’s cellular localization and the effect of Sp.Set7 knock-out on the cell cycle and sporulation. Next, we elucidated Sp.Set7’s Lysine substrate specificity on histone H3 and H4 by mass spectrometry. Finally, we used chromatin immunoprecipitation combined with high throughput sequencing (ChiP-seq) and RNA sequencing to elucidate the genomic regions in which Sp.Set7 is enriched.

#1378 Identification of genomic regions associated with temozolomide resistance in glioblastoma through analysis of histone marks on chromatin. Xiaoyue Chen, 1 Haiyun Gan, 2 Jeong Heong Lee, 1 Dong Fang, 2 Gaspar Kitzange, 1 Jann Sarkaria, 1 Zhiguo Zhang, 13 Mayo Graduate School, Rochester, MN; 4 Columbia University, New York, NY.

Glioblastoma (GBM) is an aggressive and fatal primary brain tumor. Temozolomide (TMZ) is a critical component of the standard care of newly diagnosed GBM patients, but unfortunately preexisting primary resistance and rapid emergence of secondary resistance are major obstacles in the treatment of GBM. Prior studies have identified genetic and epigenetic alterations that can modulate TMZ sensitivity and treatment outcome. However, comprehensive analysis of histone marks and knowledge of epigenetic regulation of genes associated with TMZ sensitivity or resistance is lacking. To identify epigenetic states associated with TMZ resistance, we performed an epigenomic profiling of eight different histone marks in GBM xenografts. Using chromatin immunoprecipitation combined with high throughput sequencing (ChiP-seq), distribution of H3K4me1, H3K4me3, H3K9ac, H3K9me2, H3K9me3, H3K27ac, H3K27me3 and H3K36me3 histone marks was compared in a panel of GBM patient-derived xenograft sub-lines derived from treating TMZ sensitive GBM12 tumors with placebo (n=2 sublines) or temozolomide (n=6 sublines) and then propagating resulting recurrent tumors. Our analysis revealed that H3K4me1 and H3K27ac modification patterns varied globally across individual sub-lines, while distribution of H3K4me3, H3K36me3 histone marks was specifically altered in discrete genomic regions in resistant sub-lines depending on the mechanisms of resistance. To find how epigenetic modifications affect TMZ sensitivity, we analyzed ChIP-Seq data using Hidden Markov Model to test if one or a combination of histone marks relates to TMZ resistance. The effect of histone modifications on transcription was simultaneously determined by RNA sequencing. These analyses helped identify specific histone modifications which could be functionally related to TMZ resistance. Through these analyses we have identified 1142 genomic regions governed by a specific epigenetic pattern. We subsequently analyzed a candidate genomic region on top of the list, by using Clustered Regularly Interspaced Short Palindromic Repeats (CRISPR) associated nucleases (Cas9 system). In summary, we have generated clones from an intrinsically TMZ resistant SKMG cell line with deletion up to four-kilo base genomic region. Clonogenic growth assays showed that deletion of this genomic region enhanced TMZ sensitivity, reducing the IC50 from 186 μM to less than 60 μM, p<0.05. This finding indicates that this genomic region is functionally related with TMZ sensitivity. Taken together, our study reveals epigenetic modifications related to TMZ resistance in GBM cells and a specific genomic region involved in regulating TMZ sensitivity. This analysis of epigenetic state at this genomic region could potentially be useful in predicting treatment response and may help in designing TMZ sensitizing therapy in GBM.

#1379 Histone demethylase KDM6a as a target for glioblastoma radiosensitivity. Barbara Helen Rath, Mariaa F. Shah, Kevin Camphausen, Philip J. Toflon. National Cancer Institute, Bethesda, MD.

Radiotherapy is a primary treatment modality for glioblastomas (GBMs). Because post-translational histone modifications have been implicated in the regulation of radiosensitivity, as a potential strategy for enhancing the response of GBMs to radiotherapy we have evaluated the effect of radiation on histone methylation in glioblastoma stem-like cells (GSCs) and the established glioma cell line (U251). For these studies we focused on histone H3K27 tri-methylation (H3K27me3), whose opposing site H3K36me2 has already been linked to DNA repair. Exposure of GSCs and U251 to 10 Gy decreased H3K27me3 by 30 min, reaching a cell line dependent maximum between 1h and 3h, followed by a return
to control levels at 6h. According to immunoblot analysis, GSCs and U251 had significant higher levels of KDM6A compared to KDME6B, suggesting a more prominent role for KDME6A in the demethylation of H3K27me3 after irradiation. To determine whether KDME6 could serve as a target for GBM radiosensitization, we focused on KDME4, which is an inhibitor for KDME6A and KDME6B. KDME4 treatment resulted in a decrease of H3K27me3 and an increase of H3K56Ac within 1h of exposure and was found to block the radiation-induced decrease of H3K27me3. Based on clonogenic survival analysis addition of KDME4 immediately prior to irradiation significantly enhanced the radiosensitivity of GSCs and U251. To begin to investigate the mechanism responsible for this radiosensitization, we investigated the underlying mechanisms contribute to epigenetic alterations. ASH1L is a histone methyltransferase specific for catalyzing transcription-repression. Up-regulation of ASH1L also correlated with increased Ki67 expression. We hypothesized that deregulation of histone methyltransferases Histonemodification is a major component of epigenetic regulation, and deregulation of ASH1L was detected in 40% of primary HCCs and significantly associated with upregulated expression. We found that the histone methyltransferases group protein ASH1L was frequently upregulated in human HCC. Overexpression of ASH1L also correlated with increased Ki67 expression. ASH1L is a histone methyltransferase specific for catalyzing transcriptional-active H3K4 and H3K36 methylation. We showed that high levels of ASH1L significantly upregulated the cell cycle in HCC cells and colon cancer cells. We further demonstrated that knockdown of ASH1L inhibited HCC cell migration. In addition, we found that high levels of ASH1L correlated with low expression of Ki67. Anti-ASH1L antibodies were found to block the radiation-induced decrease of H3K27me3 and the radiation-induced increase of H3K27me3 was abolished. Analysis of H2A.X nuclear foci after irradiation (2Gy) of siKDME6A treated cells showed a significant delay in foci disassembly, consistent with an inhibition of DSBR repair. To further investigate the potential role of histone demethylation as a potential target to radiosensitize GBM, siASH1L was used to knock down KDME6A expression. Cells treated with KDME6A showed a significant increase in H3K27me3 and the radiation-induced increase of H3K27me3 was abolished. This result suggests that the histone demethylase KDME6A is a target for GBM radiosensitization.

**1380 Expression and functions of ASH1L in liver cancer.** Lai Wei, Felice H. Tsang, Daniel Ho, Cheuk-Ting Law, Mengnuo Chen, Long-Hin Tseang, Carmen Cl Wong, Irene Ol Ng, Chun-Ming Wong. University of Hong Kong, Hong Kong.

Hepatocellular carcinoma (HCC) is a common cancer and ranks the third lethal cancer worldwide. However, the detailed molecular mechanisms underlying the initiation and progression of HCC remain poorly understood. Liver carcinogenesis is a multistep process that is driven by the accumulation of genetic and epigenetic alterations. Mutation landscape and driver mutations have recently been delineated by high-throughput sequencing studies. On the other hand, our current knowledge about epigenetic deregulation in human HCC is limited. Epigenetic alterations play prominent role in liver cancer. Here, we report that human CRL4DDB2 ubiquitin ligase regulates the DNA repair of histone chaperon CAF-1. We show that the CRL4DDB2 depletion decreases the recruitment of CAF-1 and prevents post-repair H3K56Ac restoration. Additionally, a PCNA-interacting protein (PIP) motif is shown to exist within DDB2. The mutation in the PIP box of DDB2 compromises its capability to maintain the H3K56Ac level but does not affect CRL4DDB2-mediated XPC ubiquitination. These results suggest a novel role of CRL4DDB2 in regulating post-repair chromatin restoration, which differs from its canonical role in the process of nucleotide excision repair.

**1382 A novel BET family bromodomain inhibitor NHWD-870 represents a promising therapeutic agent for a broad spectrum of cancers.** Nenghui Wang, Mingzhu Yin, Qin Yan. The Ohio State University, Columbus, OH.

BET proteins have emerged as promising targets for cancer therapy. NHWD-870 is a potent and selective BET family bromodomain inhibitor and only binds bromodomains of BRD2/3/4/T. NHWD-870 exhibited robust single agent activity in cell viability assay across cancer cell lines derived from solid tumors, leukemia and lymphomas. Further characterization of cancer cell responses to NHWD-870 indicated that NHWD-870 manifested diverse mechanisms of action in different cancer settings. These include: 1) inhibition of tumor cell growth by downregulating the PDGFβR, MEK1/2 and STAT1/MYC signaling in tumor cells; 2) inhibition of tumor angiogenesis by decreasing PDGF production in tumor cells and the PDGFβR and MEK1/2 signaling in endothelial cells. Consistent with its broad spectrum of activities in vitro, NHWD-870 has potent therapeutic efficacy in xenografted murine models of breast cancer, triple negative breast cancer and ovarian cancer. These results support its further development for diverse solid tumor indications in the clinic.

**1383 Histone H3 lysine 9 methyltransferase SUV39H1 is associated with clinical outcome of renal clear cell carcinoma patients.** Wei Meng, Ri Cui, Saikd Jhalur Haque, Carlo M. Croce, Arnab Chakravarti. The Ohio State University, Columbus, OH.

Background: Epigenetic alterations have three important components including DNA methylation, histone modifications, and non-coding RNA. The epigenetic changes are highly dynamic and also reversible, which regulate a variety of biological processes. Euchromatin which is a loosely packed form of chromatin is highly associated with active gene expression. In contrast, heterochromatin is associated with high histone methylation and DNA methylation but low RNA transcription. SUV39H1 catalyzes the histone 3 lysine 9 trimethylation (H3K9me3) in heterochromatin regions, which also mediates DNA methylation at pericentric heterochromatin. Currently, the oncogenic role of SUV39H1 in renal cell carcinoma (RCC) pathogenesis is poorly understood. To this end, we assessed the role of SUV39H1 in renal RCC cells and association with clinical outcome of RCC patients. Results: In SUV39H1 knockdown cells, we observed global H3K9me3 level reduction and cell growth inhibition. Proximal ligation assay was used to determine the H3K9me3 and 5-methylcytosine (5mC) interaction in RCC cells. Knocking down of SUV39H1 gene significantly reduced the co-localization of H3K9me3 and 5mC in pericentric repetitive sequences. Moreover, Southern blot demonstrated that expansion of a pentanucleotide (GGAAT) repeats was associated with upregulation of SUV39H1, which is linked to SUV39H1 function with microsatellite instability and rearrangement. In The Cancer Genome Atlas (TCGA) database, we found that SUV39H1 gene expression was upregulated in RCC tissues compared to normal tissues, and high SUV39H1 expression predicted a worse overall survival outcome (p = 0.002) in RCC patients. Conclusion: SUV39H1 upregulation promotes cell proliferation and microsatellite instability. SUV39H1 expression could serve as a prognostic biomarker for RCC patients.

**1385 New insights into the roles of histone lysine-specific demethylase 2 (LSD2) in breast cancer.** Lin Chen, Shauna N. Vasiliatos, Ye Qin, Steffi Oesterreich, Nancy E. Davidson, Yi Huang. University of Pittsburgh, Pittsburgh, PA.

Background: Epigenetic modifiers have been emerging as new players in breast cancer development. FAD-dependent histone demethylases have been proved to play important roles in regulating breast tumor initiation and development. While the role of histone lysine-specific demethylase 1 (LSD1) in breast cancer progression has been well characterized, the activity of its homolog, lysine-specific demethylase 2 (LSD2), in breast cancer is still a riddle that needs to be uncovered. Methods: To explore the precise role of LSD2 in breast cancer, we overexpressed LSD2 protein in MDA-MB-231 cells (LSD2-OE). The phenotypic effect of LSD2-OE on MM231 cells was characterized by proliferation assay, soft agar assay (3D growth), trans-well cell migration and invasion assay and mammosphere formation assay. To extend stem cell-like features study of LSD2 overexpressed MM231 cells, we examined CD44+/CD24- subpopulation.
Target RNA sequencing revealed the expression profile of cancer genes in response to deacetylase inhibitor in primary culture of prostate cancer cells. Hong Vinh T. Trong, S. Craig Greer, Glenn Mills. Louisiana State Univ. Health Sciences Ctr., Shreveport, LA.

Histone acetylation is a dynamic event to optimize cell functions through the control of RNA transcription and gene expression. In cancer, the histone deacetylation is a therapeutic target. Suppression of histone deacetylation increased the growth arrest, apoptosis, and senescence in cancer cells. Several histone deacetylase inhibitors (HDACis) have been developed and applied as a target therapy of various types of cancer, including the prostate cancer. However, the altered gene expression in HDACis treated prostate cancer cells is less reported. Little is known about the gene expression profiles of primary cultures of prostate cancer. In this study, we examined the cancer gene expression profile in primary cultures of human prostate cancer. Cells were isolated from two patient’s prostate cancer samples. Isolated cells were cultured in prostate epithelial culture medium CaT-52. After 24 hours of exposure to 400nM of Trichostatin A (TSA), an inhibitor of histone deacetylation I and II. RNA was extracted and quantified. The library was prepared with Illumina’s TruSight RNA Pan-Cancer Panel. The sequencing was performed on NextSeq 500/550 mid output v2 kit (150cycles). FastQ files were generated by BaseSpace Onsite and analyzed further by TopHat alignment (Illumina) and Partek Flow (Partek). The Trusight RNA Pan-Cancer panel targets 1385 cancer genes and covers 21043 exonic regions with 57010 probes. The results showed that 59 of the 1385 cancer genes were significantly changed (FDR p-value<0.05, fold change >2 fold) in T55 treated cells. In the treated cells 49 genes were up-regulated and 10 genes were down-regulated. The altered expression of 59 genes is involved in multiple cell functions. Genes that were upregulated included apoptosis associated genes (MAP2K6 and BIRC3), tumor suppression genes (DIRAS3, PEG3, PTIPRO, and DNM3), and P53-target gene (CYFIP2). The genes that were down-regulated included cell cycle regulation genes (CDK1 and CCNA2), DNA damage response genes (BRCA1 and BRIP1), as well as cell proliferation marker Ki67 gene (MKI67). However, the gene expression response to TSA is complicated. Some altered gene expression favors tumor growth and progression while other gene expression changes inhibit tumor growth and promote apoptosis. In conclusion, we identified the gene profile in primary culture of prostate tumor in response to a histone deacetylase inhibitor, TSA, and the therapeutic effects of HDACis could be influenced by the summation of contradicting, tumor promoting and suppression gene expression profile changes.

Effects of histone deacetylase inhibitors on differentiation markers and growth of colon and bladder cancer cells. Michael A. Lea, Lauren Cué, Elizabeth Batista, Erik Lew, Charles desBordes. Rutgers New Jersey Medical School, Newark, NJ.

Alkaline phosphatase and dipeptidyl peptidase are markers of differentiation in colon cancer cells. In colon cancer cells differentiation can often be induced by treatment with inhibitors of histone deacetylase (HDAC) activity. In some colon cancer cells butyrate causes a several-fold induction of alkaline phosphatase but only modest effects on dipeptidyl peptidase. There is relatively little information on changes in activity of cell surface hydrolases in bladder cancer. However, there is some evidence for decreased alkaline phosphatase activity in bladder cancer. We tested the hypothesis that there may be retention of activity in more slowly growing cancer cells and the activity will be regulated by HDAC inhibitors in a manner similar to that in colon cancer. In our initial studies we screened seven human bladder cancer cell lines for alkaline phosphatase activity. We identified three cell lines (5637, HT1197 and HT1376) with activity comparable to that in more differentiated colon cancer cell lines. The response to incubation with the HDAC inhibitors butyrate and valproate was compared with effects in three colon cancer cell lines Caco-2, HT29 and SW1116. In all six cell lines there were growth inhibitory effects that tended to be a little greater with butyrate than with valproate. Induction of alkaline phosphatase activity was generally greater with butyrate than with valproate and was apparent even without normalizing the activity on a protein basis. After determining the activity per unit protein there were increases in dipeptidyl peptidase activity after treatment with the HDAC inhibitors. A smaller increase in alkaline phosphatase activity was observed than with the HDAC inhibitors. Expression of HIF-1α and-2α increased in a manner consistent with the transcriptional regulation HIF-1α activates expression of genes promoting angiogenesis, metastasis, increased tumor growth and resistance to treatments. Understanding transcriptional regulation HIF-1α under physiologically relevant hypoxic conditions would be helpful to reduce breast cancer growth. Our recent studies identified that intracellular bioactive sphingosine-1-phosphate (S1P) is increased from nuclear sphingosine kinase 2 (SphK2) acts as an endogenous modulator of histone deacetylases (HDACs) epigenetically regulates gene transcription in breast cancer cells. We wonder whether nuclear S1P epigenetically regulates acetylated histones, positive transcription marks in hypoxia and regulate transcription of HIF-1α and target genes in breast cancer cells. We have used estrogen receptor positive human breast cancer MCF-7 cells, triple-negative human breast cancer MDA-231 cells and lung metastatic LM-2-4 cells derived from MDA-231 cells for our studies. We found that hypoxic condition enhances nuclear bulk histone acetylation in breast cancer cells and enhances HIF-1α synthesis. Down regulation of SphK2 with siRNA or using selective inhibitor of SphK2 (K145 compound) reduces nuclear S1P as well as bulk histone acetylation and consequent increase in HIF-1α expression. Experiments with small interfering RNA inhibition of SphK2 with siRNA reduced HIF-1α and nuclear acetylation of histones. Therefore, targeting SphK2 with K145 compound dramatically reduces in vitro tumorosphere formation in breast cancer cells. Our data suggested that targeting the SphK2/SIP signaling could represent an attractive strategy for therapeutic intervention in hypoxic breast cancers. Supported by Health Research, Inc. (HRI) Grant 71-4084 (NCH), National Cancer Institute Grant R01CA160688 (KT).

Effects of geinstein on histone modifying enzyme expression in breast cancer cells. Lanni Aquila, Nick Smothermon, Lisa Morey. Canisius College, Buffalo, NY.

The hypoixia-inducible transcription factors (HIF)-1α and -2α play a critical role in cellular response to hypoxia in solid tumors. Elevated HIF-α expression correlates with poor patient survival in a large number of cancers including breast cancers. HIF-α activates expression of genes promoting angiogenesis, metastasis, increased tumor growth and resistance to treatments. Understanding transcriptional regulation HIF-α under physiologically relevant hypoxic conditions would be helpful to reduce breast cancer growth. Our recent studies identified that intracellular bioactive sphingosine-1-phosphate (S1P) is increased from nuclear sphingosine kinase 2 (SphK2) acts as an endogenous modulator of histone deacetylases (HDACs) epigenetically regulates gene transcription in breast cancer cells. We wonder whether nuclear S1P epigenetically regulates acetylated histones, positive transcription marks in hypoxia and regulate transcription of HIF-α and target genes in breast cancer cells. We have used estrogen receptor positive human breast cancer MCF-7 cells, triple-negative human breast cancer MDA-231 cells and lung metastatic LM-2-4 cells derived from MDA-231 cells for our studies. We found that hypoxic condition enhances nuclear bulk histone acetylation in breast cancer cells and enhances HIF-α synthesis. Down regulation of SphK2 with siRNA or using selective inhibitor of SphK2 (K145 compound) reduces nuclear S1P as well as bulk histone acetylation and consequent increase in HIF-1α expression. Experiments with small interfering RNA inhibition of SphK2 with siRNA reduced HIF-1α and nuclear acetylation of histones. Therefore, targeting SphK2 with K145 compound dramatically reduces in vitro tumorosphere formation in breast cancer cells. Our data suggested that targeting the SphK2/SIP signaling could represent an attractive strategy for therapeutic intervention in hypoxic breast cancers. Supported by Health Research, Inc. (HRI) Grant 71-4084 (NCH), National Cancer Institute Grant R01CA160688 (KT).
RNA was extracted, followed by an RT-PCR, and amplification of the genes of interest via PCR. Changes in gene expression were quantitated using ImageJ. Overall, it was concluded that the exposure to genistein impacts the gene expression of both SET8 and SIRT1 within human prostate cancer cells.

#1390 Deregulation of RNA N6-adenosine methylation contribute to liver carcinogenesis. Mengnuo Chen, Larry L. Wei, Cheuk Ting Law, Felice HC Tsang, Iris MI Xu, Joyce LF Lee, Carmen Wong CL Wong, Irene DL Ng, Chun-Ming Wong. The University of Hong Kong, Hong Kong, Hong Kong.

Primary liver cancer, particularly the most common type hepatocellular carcinoma (HCC), is the third leading cause of cancer death worldwide. Case is even worse in Asia due to extremely high prevalence of HBV/HCV infection, which enhances the risk of HCC. However, the exact mechanism of how HCC develops is still not clearly defined. Previous studies have shown strong evidence for epigenetic alterations in human carcinogenesis, which mainly focus on abnormal DNA methylation, histone modifications, and chromatin remodeling. Recent studies suggest that diverse chemical modifications on RNAs, also known as "epi-transcriptome", constitute another layer of gene expression regulation. N-6-methyladenosine (m6A) is the most abundant modification on eukaryotic mRNA, which has been found to functionally influence mRNA stability, alternative splicing, and translation efficiency. However, the roles of m6A deregulation in human carcinogenesis remain unclear. Through whole-transcriptome sequencing, we identified that METTL3, the major component of m6A methyltransferase, was significantly up-regulated in human HCC. Up-regulation of METTL3 negatively associated with poor patient overall and disease-free survival, which have been linked to the non-cleaved N-glycosidically bound Kras and its potential to mediate pancreatic cancer initiation. Congruently, pharmacological inhibition of G9a using BRD4770 displays an inhibitory effect on Kras-induced cell proliferation. Combined, these data provide evidence for a key role of the me3K9H3-G9a pathway as a mediator of the oncogenic Kras response and defines a novel point of potential therapeutic intervention for PDAC.

#1392 Development of a novel mouse model for intrahepatic cholangiocarcinoma. Rebecca Marcus,1 Wai Chin Foo,2 Anirban Maitra,1 Sonal Gupta1.

1Sheikh Ahmed Bin Zayed Al Nahyan Center for Pancreatic Cancer Research, The University of Texas MD Anderson Cancer Center, Houston, TX; 2The University of Texas MD Anderson Cancer Center, Houston, TX.

Cholangiocarcinoma (CCA) is a poorly understood cancer of the biliary epithelium and the second most common type of liver cancer. Surgery currently offers the only potential for cure; however, most patients present with advanced disease and are therefore unreatestable. The Cancer Genome Atlas (TCGA) analysis and other recent genomic studies have revealed discrete epigenetic perturbations amongst CCA tissues originating from different anatomic sites. Intrahepatic cholangiocarcinoma (ICC) arises from the intrahepatic bile ducts, and a subset of ICCs harbor activating mutations in the cholangiocyte regulatory factor BRCA-associated protein 1 (BAP1). Loss of this protein may be associated with global epigenomic and transcriptomic alterations that ultimately contribute to tumor progression and metastasis dissemination. While elucidating the molecular pathways of ICC may identify potential targeted therapies and improve early detection, inquiry into this disease has been hampered by a lack of genetically faithfull animal models. We developed a genetically engineered mouse model (GEMM) of ICC that incorporates an activating mutation in BAP1 combined with Kras activation. An Albumin-Cre promoter was used to induce hepatoblast-specific mutations. Mutant Kras cooperates with loss of BAP1 and results in lethal hepatic transformation and dose-dependent survival. Kras activation alone results in extended disease latency and survival > 50 weeks. Loss of BAP1 alone or heterozygous loss of BAP1 combined with mutant Kras shortens disease latency, with mice surviving 39 weeks on average. A significant reduction in survival is seen with homozygous loss of BAP1 and Kras activation (KrasBAP1−/−). These mice survive on average 23 weeks (p = 0.0045). Histopathologic evaluation of KrasBAP1−/− mice demonstrates focal biliary precursor lesions, frank ICC, and hepatocellular carcinoma (HCC). Mice with heterozygous deletion of BAP1 and Krash activation loss of BAP1 alone, or Krash activation alone develop HCC only. Given the bipotential nature of hepatoblasts, the ICC phenotype of our GEMM may be enhanced by inducing biliary tree-specific mutations. Adenoviral Cre enzyme (Ad-Cre) is used to achieve such combinatorial specificity, and a novel surgery was developed whereby retrograde biliary tree administration of this enzyme is performed. Surgery utilizing GFP-tagged hepatoblast-associated transgenes confirm administration targeted to the biliary tree. Retrograde biliary tree injection of Ad-Cre into ROSA26mT/mG mice demonstrates Cre recombinase expression within cholangiocytes, thereby establishing proof-of-principle. Ad-Cre injection in Kras BAP1−/− mice to induce cholangiocyte-specific BAP1 deletion and Kras activation is ongoing.

#1393 Chromatin remodelers as potential new targets for therapy of pediatric sarcoma. Joana G. Marques,1 Berkley Gryder,2 Marco Wachtel,3 Iaved Khan,2 Beat Schaeffer.1 University Children’s Hospital, Zurich, Switzerland; 2National Institutes of Health, Bethesda, MD.

Fusion-positive rhabdomyosarcoma (FP-RMS) is a pediatric malignancy driven by the fusion transcription factor PAX3-FOXO1, which generates an aberrant gene expression signature leading to cell transformation. Since FP-RMS cells are highly addicted to the fusion protein, it is in focus as target for alternative therapies. Nevertheless, PAX3-FOXO1, as a transcription factor, does not contain structural cavities and has a low druggability. We therefore hypothesize that we can affect this aggressive subtype of RMS by targeting the co-regulators that collaborate with the fusion protein in regulating transcription. Recently, we have identified the NuRD (Nucleosome Remodeling and Deacetylase) complex as a potential partner of PAX3-FOXO1 in gene expression modulation. The NuRD complex is unique among chromatin remodeling complexes due to its dual enzymatic activity (histone deacetylation through HDAC1/2 and nucleosome positioning by CHD4 - chromodomains-DNA-bind-
ing protein 4), offering new possible therapeutic targets. Silencing of two core members of NuRD, CHD4 and RBBP4, led to a drastic decrease in FP-RMS cell viability. Additionally, CHD4 depletion caused a complete regression of mouse tumor xenografts, but it did not affect proliferation of myoblasts, fibroblasts or fusion negative RMS cells, despite the fact that these cells also carry high CHD4 expression and are highly sensitive to the fusion protein. We investigated these huge discrepancies and learnt that it affects the expression of approximately 50% of PAX3-FOXO1 target genes with most of these genes being upregulated, suggesting an activating role for CHD4 in these cases. Consistent with a positive effect of CHD4 on gene expression, Chip-seq experiments with FP-RMS cell lines demonstrated that NuRD promotes promoter and enhancer regions of highly expressed genes and co-localizes with the fusion protein at regulatory regions of a subset of its target genes. Next, we studied the influence of this nucleosome remodeler on the chromatin status by DNase hypersensitivity assays and determined that the presence of a DNase signal at PAX3-FOXO1 binding sites is concordant with the presence of CHD4. Hence, we suggest a scenario where CHD4 plays an essential role on FP-RMS tumorigenesis by allowing chromatin to acquire an open architecture that enables PAX3-FOXO1 mediated gene expression. In summary, our data propose that CHD4 has a crucial role as a co-regulator of PAX3-FOXO1 driven gene expression. To our knowledge, CHD4 is the first identified chromatin remodeler associated with PAX3-FOXO1 transcriptional activity, thus highlighting the relevance of epigenetic regulation in FP-RMS tumor development and opening chromatin remodelling as a possible new field of action against this tumor, which is driving ongoing work aimed at finding first-in-class small molecules to inhibit CHD4 function.

#1394 Bioorthogonal Profiling of Protein Methylation (BPPM) identified MCM5 as a new substrate for SETD8 in DNA replication. Fabio Pittella Silva, Gil Blum, Chamara Senevirathne, Luo Minkui. Memorial Sloan Kettering Cancer Center, New York, NY.

SETDb is the only member of the SET domain containing methyltransferase family, which catalyzes mono-methylation of K20 on histone H4 (H4K20me1). Lysine residues of non-histone proteins such as p53 and proliferating cell nuclear antigen (PCNA) are also mono-methylated, while lysine residues in Numb were found to be dimethylated. As a consequence, SETDb methylation activity is implicated in several fundamental cellular processes such as transcriptional regulation and heterochromatin formation as well as processes that ensure genomic stability including DNA replication and the DNA damage response. Although it has been suggested that SETDb is involved in DNA replication as a positive regulator of origin licensing through H4K20 methylation and by supporting Okazaki fragment processing through PCNA methylation, to date, there is no evidence whether other key protein in the replication fork is directly modified by SETDb. To address this question, we used Bioorthogonal Profiling of Protein Methylation (BPPM) with engineered enzyme and synthetic SAM analogues to profile new substrates for SETDb. We genetically engineered SETDb and identified mutants amenable to accommodate non-native SAM analogues containing a terminal alkyne moiety for click chemistry. The engineered SETDb can transfer this distinct chemical moiety into target proteins for subsequent pulldown and identification of the modified substrates. Among the new substrates identified by BPPM, MCM5 was the most abundant, which was further validated by immunoblotting. We hypothesized that MCM5 is a new substrate for SETDb that is mono-methylated by SETDb. To test this hypothesis, we performed western blotting with anti-MCM5 antibody and the presence of MCM5 was confirmed. We also performed Co-IP experiments and confirmed the interaction between SETDb and MCM5. We also performed CHIP-seq experiments with HeLa cell line and confirmed the enrichment of MCM5 at the promoters of genes that are involved in DNA replication. These results suggest that MCM5 is a new substrate for SETDb in DNA replication.

#1395 Deciphering inosinomine in glioblastoma versus normal cortex. Angela Gallo,1 Alessandro Silvestris,2 Valeriana Cesaroni,1 Valentina Tassinarini,1 Nicolò Mangraviti,1 Ernesto Picardi,2 Graziano Pesole.1 Ospedale Pediatrico Bambino Gesù, Roma, Italy; 2Università di Bari, Bari, Italy.

Cancer is driven by alterations of the genomic information, which carries mutations in key genes providing selective advantage for clonal multiplication of cancer cells. However, mutations within DNA are not the only source for cell alteration. RNA molecules are targets of a series of post-transcriptional modifications, such as splicing and RNA editing, that can affect sequence, structure and stability. The most common type of RNA editing in humans converts Adenosine in RNA targets into Inosinome (A-to-I) and is catalyzed by two adenosine deaminases that act on dsRNA (ADARs) family of enzymes (ADAR and ADAR1B). Inosines are subsequently interpreted as guanosines by several cellular proteins and could ultimately lead to a genomic mutations (A-to-IG). At present, it has been estimated that over 4 millions editing sites exist in our transcriptome in- tendency, and RNA editing mediated by ADARs at RNA level are necessary for our survival and their levels is highly regulated in different tissues and during development. Considering the importance of ADAR activity in our cells we believe that if ADAR are not well regulated they may contribute to cancer on set and/or progression. The advent of high-throughput RNA sequenc- ing has enabled identification of RNA editing sites and global analyses of cancer RNA editing. ADARs mediated RNA editing dynamically contributes to genetic alterations in cancer, including high-grade gliomas. Gli- oblastoma (GBM) is one of the most common and aggressive primary brain tumor in humans and despite advances in understanding the molecular mechan- isms underlying these tumors, current treatments are ineffective. In order to elucidate the glioma-specific RNA editing signature, we analyzed 146 RNA-Seq from primary glioblastomas from the TCGA dataset compared to 132 normal brain cortex RNA-Seq from the GTEx database. To our knowledge, A-to-I editing events has been detected using a collection of more than 4 million annotated edited substrates and the REDTools suite of python scripts with stringent filter by. means of the Cuifffquant/Cuifffdiff tools, we have also compared global transcriptome profiles and ADAR genes expression pat- terns at RNA and protein level across GBM samples and we found that the general down regulation of editing events at both recoding and non -recoding (Alus) sites that correlate with a down expression of ADARB1 enzyme. No differences were observed with ADAR expression. Overall, we observed a strong editing landscape perturbation in glioblastoma that could be important for identifying the most effective target genes for possible therapeutic intervention.

#1396 Role of epigenetic reader and alternative mRNA splicing variant MBDB2_v2 expression in triple-negative breast cancer. Emily A. Garcia,1 Bin Sao,1 Cristina Mitrea,2 Gregory Dyson,1 Julie Boerner,1 Lisa Polin,1 Stan R. Terlecky,2 Alicia Bollig-Fischer.1 Wayne State University, Detroit, MI; 2Seton Hall University, South Orange, NJ.

Background: Among all breast cancer patients, those diagnosed with the triple-negative breast cancer (TNBC) subtype have the worst prognosis, in part attributable to the fact that TNBC lacks targets for effective molecularly-targeted therapies. The concept that EGFR inhibitor drugs could be used as a targeted treatment against TNBC has been put forth because roughly 50% of TNBC express high levels of EGFR. However clinical trials targeting EGFR did not significantly improve patient outcomes. Our recent work offers a potential ex- planation as to why EGFR inhibitors failed and supports an innovative therapeu- tic approach combining an EGFR tyrosine kinase inhibitor with the novel antioxidant biologic, CAT-SKL. Our data indicate that inhibition of cancer stem cell-like cells depends on antioxidant-induced downregulation of an alternative mRNA splice variant of the methyl-CpG binding domain 2 gene, MBDB2_v2. Objective and Methods: The purpose of the present study was to evaluate the importance of MBDB2_v2 in TNBC and better understand how CAT-SKL regu- lates its expression. Using TNBC cell lines we investigated the effects of MBDB2_v2 expression on tumor initiation capacity. Furthermore we studied MBDB2_v2 mRNA levels in an in vivo tumor xenograph mouse model of TNBC and in human TNBC samples using an existing database. Then by RNA-seq analysis we assessed how CAT-SKL regulates MBDB2_v2 expression in TNBC cells through differential gene expression. Results: The results support that MBDB2_v2 expression is regulated by redox signaling in TNBC cells, which is tightly linked to TNBC cell tumor initiation capacity. Furthermore, MBDB2_v2 was upregulated in tumors harvested from overweight mice, which also displayed increased tumor take rate, suggesting that a pro-inflammatory tumor microenvironment could play a role in promoting MBDB2_v2 expression. In addition, RNA-seq analysis identified an overrepresentation of mRNA splicing factors with a repression down regulation regulated by CAT-SKL treatment of TNBC cells. From this gene set two splicing co-factors are highlighted: SRRM1 and CPSF3. These co-factors are critical for splicing factor function, 3’ end formation and polyadenylation; and both have been linked via protein-protein interaction to a relevant exonic splicing enhancer site in exon 3 of the MBDB2_v2 transcript. Finally, according to the Kaplan Meier Plotter database high MBDB2_v2 levels in BC were associated with shorter relapse free survival. Conclusion: Our investi- gation sheds light on the relevance of MBDB2_v2 expression in TNBC, and how a select antioxidant regulates its expression. The application of which holds promise of a novel, targeted therapeutic modality for TNBC, the subtype with the worst prognosis and highest need for treatment options.
#1397 Antisense oligo nucleotide of Annexin A4 improved platinum resistance in ovarian clear cell cancer. Reisa Kakukuri,1 Satoshi Nakagawa,2 Tadashi Iwamiya,1 Eiji Kobayashi,1 Shinya Matsuzaki,1 Yutaka Ueda,1 Kiyoshi Yoshino,1 Yuva Kashara,1 Satoshi Obioka,1 Tadashi Kimura,1 Satoshi Serada,1 Tetsuo Naka,1 Minoru Fujimoto1. 1Osaka University, OSAKA, Japan; 2Sakai city medical center, OSAKA, Japan; 3National institute of Biomedical Innovation, OSAKA, Japan.

Introduction: Ovarian cancer in Japan are classified as clear cell carcinoma (CCC) more than 20 %, this percentage is higher than in Europe and United States. Besides, it is well known that CCC of ovary is highly resistant to cancer chemotherapy including carboplatin and paclitaxel treatment. We reported that Annexin A4 expression was observed in CCC tissues by using quantitative real-time polymerase chain reaction. Annexin A4 expression was also observed by immunohistochemical analysis. Elevated Annexin A4 level has been detected in various epithelial cancer cell lines and have reported associating with chemoresistance to platinum-based cancer drugs. To overcome the platinum chemoresistance, we thought antisense oligonucleotides (ASOs) to be a good therapeutic option in a way of highly specific therapy for improving chemoresistance by suppressing the expression of Annexin A4 in cancer cells. Methods: We generated ASO targeting Annexin A4 with 2’, 4’-bridged nucleic acid. And we analyzed suppression of Annexin A4 in A549-transfected RMG-1 cell line (CCC) in vitro using real time PCR and western blotting. In 16 types of ASOs targeting Annexin A4, 2 ASOs were eligible. Cells were seeded in 96-well plates (2,000 cells per well). Next day, cells were transfected with ASOs using lipofectamine 2000 and were exposed to various concentrations (0-100 μM) for 72 hr. Then, drug concentrations resulting in a 50 % inhibition of cell growth (IC50 values) were calculated. Intracellular platinum accumulation in Annexin A4 overexpressing cells was analyzed. To assess the improvement of platinum resistance in vivo, we used ICR nu/nu mice xenografted subcutaneously with RMG-1 cells. Intraperitoneal injection of cisplatin 3mg/kg after intratumoral administration of ASO 1mg/kg each twice a week were given to xenograft mice. Results: By real time PCR analysis, among strong 16 types of ASOs targeting Annexin A4, 2 ASOs showed strong knockdown efficiency (about 80 % knockdown) compared to negative control ASOs. Western blotting analysis showing knockdown of Annexin A4 expression was observed in Annexin A4 ASO transfected cells compared to no treatment or control ASOs in vitro. ASO-transfected RMG-1 cells was less resistant to cisplatin (IC50 = 3.3±M) compared with control cells (IC50 = 5.2±M). Same result were obtained with carboplatin. Platinum resistance was significantly improved in treated with Annexin A4 ASO and cisplatin compared to control ASO and cisplatin treated group in vivo. Conclusion: By transfection of ASOs targeting Annexin A4, platinum resistance have improved in vivo and in vitro, Annexin A4 have associated with efflux of platinum anti-tumor drug. In conclusion, antisense oligonucleotides for Annexin A4 will be a therapeutic option for ovarian clear cell carcinoma with chemoresistance to platinum anti-tumor drug.

#1400 Using tumor spheroids to evaluate the efficacy of EZH2 inhibitors in clear cell renal cell carcinoma (ccRCC). Darmood Wei, Youfeng Yang, Christopher J. Ricketts, Carole Sourbier, Laura S. Schmidt, William M. Linehan. NCI, Bethesda, MD.

Enhancer of zeste homolog 2 (EZH2) is a key component of the polycomb repressive complex 2 (PRC2). EZH2 is frequently overexpressed in a wide variety of human malignancies including non-Hodgkin lymphoma, gastric cancer, pancreatic cancer, and lung cancer. Thus it has potential to become a therapeutic target. Characterization of EZH2 as a therapeutic target in clear cell renal cell carcinoma (ccRCC) has not been fully explored. ccRCC has been defined by mutation of the von Hippel-Lindau (VHL) tumor suppressor gene in combination with chromosome 3p loss. Recent sequencing efforts have revealed that several chromatin remodeling genes encoded on chromosome 3p are often mutated, of which PBRM1 is the most frequent (41%). The PBRM1 gene codes for the BAF180 protein, a SWI/SNF chromatin remodeling complex subunit. Loss of BAF180 in ccRCC may disrupt the PBAF variant of the SWI/SNF complex. The SWI/SNF complex remodels the chromatin landscape by either sliding or evicting the nucleosomes from the chromatin. This chromatin remodeling modulates the accessibility to promoter regions by transcriptional machinery. It is through this mechanism that the SWI/SNF complex can regulate a range of cellular processes. It has been demonstrated that the SWI/SNF complex can act antagonistically to the PRC2 complex by evicting PRC2 complex from the promoters of tumor suppressors. Disruption of the SWI/SNF complex would impede the eviction of the PRC2 complex, similarly observed in SNF5-deficient malignant rhabdoid tumors. Therefore, we hypothesize that PBRM1 inactivation disrupts specific SWI/SNF complexes allowing EZH2 to bind and repress target tumor suppressor genes. Thus inhibition of EZH2 in ccRCC may present as a targeted therapeutic option in tumors with PBRM1 mutations. We have investigated EZH2 in ccRCC cell lines with PBRM1 mutations and observed that these cell lines have overexpression of EZH2 in comparison to RPE1 (renal cortex proximal tuibule epithelium cell line). We examined the effects of two EZH2 inhibitors (GSK126 and EPZ6438) on ccRCC tumor spheroids. Our preliminary data suggests EZH2 inhibition results in reduced growth of PBRM1 mutant cell lines grown as tumor spheroids.

Genetic and environmental factors cooperate to assure precise genome-wide epigenetic regulation of the mammary epithelia cell transcriptome. Our interest in regulatory epigenetic mechanisms that, by determining mammary epithelial cell decisions, are pivotal to deter the onset and progression of breast cancer, let us identify a regulatory epigenetic mechanism of mammary morphogenesis that links a physiological regulatory lipid of environmental origin (all-trans retinoic acid, RA) with sphingolipids capable of determining either cell death (ceramide, CER) or cell life (sphingosine 1 phosphate, S1P). Whenever RA, for different reasons, fails to perform the epigenetic transcriptional control of neutral sphingolipids...
gomyelinase 2 (nSmase2/SM3DP3), involved in the synthesis of pro-apoptotic CER, SIP fosters both pro-proliferative and pro-invasive activity. Apparently, in the absence of epigenetic control of CER production by RA, SIP contributes to determine RA tumorigenic action. This study provides the rationale for combination therapeutic approaches with epigenetic drugs and inhibitors of either sphingosine kinase, the enzyme involved in SIP synthesis, or SIP receptors. This study was supported by the NCI R01 CA127614 grant (NS).

#1402 NME3 links mitochondrial fusion to DNA repair in nuclear genome. Zee-Fen Chang. National Taiwan University, Taipei, Taiwan.

In mammals, there are 10 isoforms of NME (NDP Kinase), which catalyze the reversible reaction of NTPs formation from NDP and ATP. By RNA interference, NME3 was found critical for DNA repair. Data from analysis of the steady-state levels of nRTPs and dNTPs suggest that NME3 does not play a critical role in determining the total pools of these nucleotides. However, its mitochondrial localization and catalytic function are necessary for its function in DNA repair. Super-resolution microscopy analysis indicates the localization of NME3 at mitochondrial outer membrane. We further used APEX-mediated biotinylation to identify proteins interacting with NME3. Among them, Mfn1 is validated to associate with mitochondrial NME3 in vitro and in vivo. We provide evidence that NME3 is required for DNA damage-induced mitochondria fusion via GTP-mediated fusion of Mfn1. The lack of this process increased nucleotide oxidation and sustained DNA damage in nuclear genome. These data highlight the function of NME3 in mitochondrial fusion, which is required for the maintenance of genome integrity.

#1403 PCNA-dependent cleavage and degradation of SDE2 regulates response to replication stress. Ukhyun Yo1, Winson Cai, Jingming Wang, Yoojin Kwon, Alan D. D’Andrea, Hyungjin Kim. Stony Brook University, Stony Brook, NY, Dana-Farber Cancer Institute, Boston, MA.

Maintaining genetic integrity during DNA replication is essential for cellular survival and for preventing tumorigenesis. Proliferating cell nuclear antigen (PCNA) functions as a processivity factor for DNA replication, and posttranslational modification of PCNA plays a key role in coordinating DNA repair against replication-blocking lesions by providing a platform to recruit factors required for DNA repair and cell cycle control. Here, we identify human SDE2 as a new genome surveillance factor regulated by PCNA interaction. SDE2 contains an N-terminal ubiquitin-like (UBL) fold, which is cleaved at a diglycine motif via a PCNA-interacting peptide (PIP) box and deubiquitinating enzyme activity. The cleaved SDE2 is required for negatively regulating ultraviolet damage-inducible PCNA monoubiquitination and counteracting replication stress. The cleaved SDE2 products need to be degraded by the CRL4<sup>C372</sup> ubiquitin E3 ligase in a cell cycle- and DNA damage-dependent manner, and failure to degrade SDE2 impairs S phase progression and cellular survival. Collectively, this study uncovers a new role for CRL4<sup>C372</sup> in protecting genome integrity against replication stress via regulated proteolysis of PCNA-associated SDE2 and provides insights into how an integrated UBL domain within linear polypeptide sequence controls protein stability and function. Knowledge on such mechanism will be useful to identify novel cancer therapeutic interventions exploiting deregulated ubiquitin signaling and SDE2 activities in cancer.

#1404 Regulation of 53BP1 by the structural nuclear protein NuMA. Naik Salvador Moreno. Wake Forest Baptist Medical Center, Winston Salem, NC.

Cells repair DNA double-strand breaks (DSB) through two major pathways: homologous recombination (HR) and non-homologous end joining (NHEJ). The choice between these two pathways is critical to cell survival and is altered in cancers. 53BP1 is a protein with an important role in this choice: it promotes NHEJ by blocking CIP-dependent DNA resection. Here, we present a new negative regulation mechanism of 53BP1 that relies on the structural protein NuMA. This protein participates in mitotic spindle assembly, influences chromatin organization during the interphase and modulates the chromatin response to DNA damage. We identified NuMA in a proteomics analysis of a 53BP1-interacting proteins. The interaction was confirmed by reciprocal immunoprecipitation and with a FRET assay. In response to DSB, we measured greater than 50% decreased 53BP1-NuMA binding, which suggests that NuMA may restrain 53BP1 diffusion in the absence of DNA damage. Fluorescence correlation spectroscopy (FCS) measurements in cells expressing GFP-tagged 53BP1 support this hypothesis. Moreover, NuMA overexpression inhibited 53BP1 recruitment at DNA damage sites in laser microirradiation assays, whereas NuMA silencing had the opposite effect. 53BP1 plays an essential role in B cell class switch recombination and survival of PARP inhibitors in A1-null cells. NuMA overexpression prevented immunoglobulin switching, and over-wrote cancer cell sensitivity to PARP inhibitors to the same extent as 53BP1 loss of function. Our results help understand how 53BP1 is controlled, and shed light on the mechanisms regulating PARP1 sensitivity.

#1405 A novel chemotherapeutic agent to treat tumors with DNA mismatch repair deficiencies. Kyungjae Myung, Yongliang Zhang, Young-Un Park. Institute for Basic Science, Ulsan, Republic of Korea; NIH, MD.

Impairing the division of cancer cells with genotoxic small molecules has been a primary goal to develop chemotherapeutic agents. However, DNA mismatch repair (MMR)-deficient cancer cells are less susceptible to conventional chemotherapeutic agents. Here we have identified baicalein as a small molecule that selectively kills MutS<sup>-</sup>-deficient cancer cells. Baicalein binds preferentially to mismatched DNA and induces a DNA damage response in a mismatch repair-dependent manner. In MutS<sup>-</sup>-proficient cells, baicalein binds to MutSα to dissemble from DNA and induce cell cycle arrest and subsequent cell death. In contrast, continued replication in the presence of baicalein in MutS<sup>-</sup>-deficient cells results in a high number of DNA double-strand breaks and ultimately leads to apoptosis. Consistently, baicalein specifically shrinks MutS<sup>-</sup>-deficient xenograft tumors and inhibits the growth of AOM-DSS-induced colon tumors in colon-specific MSH2 knockout mice. Collectively, baicalein offers the potential of an improved treatment option for patients with tumors with a DNA MMR deficiency.

#1406 Towards an RNA expression-based signature for oncogene-induced replication stress. Sergi Guerrero, Rudolf Fehrmann, Marcel ATM van Vugt. University Medical Center Groningen, Groningen, Netherlands.

Introduction Certain tumor subgroups, including triple negative breast cancers (TNBCs), are characterized by high levels of genomic instability (GI). These tumors are typically very aggressive and difficult to treat. Increasingly, we realize that GI is fueled by replication stress (RS). RS can be induced by expression of oncogenes, including CCNE1, MYC and CDC25A, which perturb initiation, elongation and/or termination phases of DNA replication. RS poses a threat to cellular viability, and tumor cells with high levels of RS will therefore increasingly depend for their survival on DNA damage checkpoint and repair pathways. Possibly, this increased dependence creates therapeutic opportunities. Unfortunately, it is currently difficult to determine levels of RS in tumors, a requirement to efficiently screen for new treatments. The aim of this work is to develop an RNA expression-based signature for oncogene-induced replication-stress. Material & Methods A panel of cell lines (RPE-1, RPE-1-P5<sup>+/+</sup>, MDA-MB-231, BT-549 and HCC-1806) was engineered to doxycycline-inducibly express a set of oncogenes (CDC25A, CCNE1 or MYC). Single DNA fiber replication analysis in combination with immunoblot analysis of RS markers was used to validate the cell line models. MTI assays were performed to assess sensitivity to ATR and Weel inhibitors. RNA-sequencing was used to uncover expression changes upon RS induction. Results Treatment with doxycycline resulted in high expression levels of CDC25A, CYCLINE or MYC. Expression was homogeneous but present in the far majority of RPE-1 cells (40% CDC25A, 88% CCNE1 and 93% MYC). DNA fiber analysis was subsequently used to study the alteration of DNA replication dynamics. Severe reduction on ongoing DNA synthesis velocity was shown in engineered cells (RPE-1 and MDA-MB-231) under doxycycline treatment, confirming prominent RS. In line with elevated levels of RS, oncogene induction resulted in elevated levels of ATR activity, as judged by phospho-CHK1 and phospho-RPA levels. Importantly, oncogene-expression enhanced sensitivity to Weel and ATR checkpoint inhibitors. Subsequently, RNA samples were harvested under the presence and absence of doxycycline. In parallel to oncogene-expression, hydroxyurea, a chemical agent known to increase stalled replication forks was applied as a DNA damage control. RNA-sequencing analysis will be performed to identify differentially expressed genes upon oncogene expression. Commonly identified genes over multiple cell lines and shared between the different oncogenes will be used to build a RNA expression-based signature. Conclusively, our results indicate that oncogene expression provokes RS in multiple cell line models and induces impaired replication fork stability and sensitivity to cell cycle checkpoint inhibitors. These models are therefore valid to develop an RNA expression-based qualifier in order to facilitate patient selection towards novel therapeutics.
Translational regulation of RPA2 via IRES by UNR and eIF3a.

Jia-Jia Cui, Lei-Yun Wang, Ji-Ye Yin. Department of Clinical Pharmacology, Xiangya Hospital, Central South University, Changsha, China.

Purpose: Translation is a critical step in the process of genetic information expression. Internal ribosome entry site (IRES) element is a RNA sequence with a complex structure, which plays an important role in cap-independent translation regulation. The activation of RPA2 IRES element can cause its abnormal expression and finally effects DNA repair pathway. We conducted series of assays to explore the mechanism of translation initiation regulation of RPA2 via IRES by UNR and eIF3a Methods: Biotin pull down assay was taken to investigate the physical interaction between RPA2 IRES and UNR. UNR was knocked down and overexpression in H1299, A549 and SK-MES cell lines. Western blot and real-time PCR were used to detect protein level and mRNA level respectively. For interaction of eIF3a with UNR, CO-IP assay and co-localization assay were conducted. And GST pull down assay was carried out to further identify their exact binding domains. RPA2 IRES-interacting domains of UNR and eIF3a were explored with EMSA assay. Results: UNR protein could directly bind to RPA2 IRES as well as to eIF3a, and UNR regulated the protein expression of RPA2 in H1299, A549 and SK-MES cells, while the mRNA level of RPA2 remained no change. UNR interacted with the first domain of eIF3a and with RPA2 IRES via its own first domain. However, we have not found a clue for the direct interaction of eIF3a with RPA2 IRES yet. Conclusion: UNR cooperated with eIF3a to regulate the RPA2 IRES activity and hence to regulate the RPA2 protein expression. This might be a regulation mechanism of cellular internal ribosomal entry site affecting translation initiation, the rate-limiting step of translation.

LIM protein Ajuba participates in the ATR response by direct interaction with RPA70.

Sandy Wan S. Fowler, Diego Loayza, Pascal Maguin.

1Hunter College, Graduate Center University of New York, New York, NY; 2Rockefeller University, New York, NY.

DNA damage response (DDR) pathways are essential for genome stability and cell survival. Specifically, the ATR kinase is activated by DNA replication stress or UV irradiation. An early event in this activation is the phosphorylation and local recruitment of RPA, a single strand DNA binding protein. Our lab has shown that the LIM protein Ajuba associates with RPA, an OB fold-containing protein, and this interaction prevents an unscheduled ATR response. We hypothesize that Ajuba represses the ATR pathway through direct interaction with RPA, thereby preventing activation of ATR. To test this hypothesis, we employed E. coli and in vitro translation system for the production of recombinant proteins. Our data show that Ajuba directly associates with the large subunit of RPA, RPA70. The domains involved in the interaction were the C-terminal OB folds of RPA70, and the region between the PreLIM and LIM domains in Ajuba. We speculate that this interaction mediates the association of Ajuba with the RPA complex in cells. Understanding the implication of the Ajuba and RPA interaction will allow us to gain insights on the regulation of DDR, which is involved in early events of cellular transformation and tumorigenesis in human cells.

Analysis of 16,172 patient-derived tumor samples indicate TXX2 as being essential for survival of genomically instable cancer cells.

Stephanie E. van Ginj, Elles Wierenga, Anne Margriet Heijink, Rudolf S. Fehrmann, Marcel A. van Vugt, Jia Cui, Lei-Yun Wang, Ji-Ye Yin. Department of Clinical Pharmacology, Xiangya Hospital, Central South University, Changsha, China.

The purpose of this study was to evaluate the clinical significance of TXX2 expression in a large cohort of patient-derived tumor samples. The expression of TXX2 was measured in 16,172 patient-derived tumor samples using 3 independent technologies: FqMRNA, a genome-wide association analysis, and RNA sequencing. The results showed that TXX2 expression was significantly higher in genomically instable tumors, suggesting that TXX2 might play a role in genomic instability.

Analysis of 16,172 patient-derived tumor samples indicate TXX2 as being essential for survival of genomically instable cancer cells.

Stephanie E. van Ginj, Elles Wierenga, Anne Margriet Heijink, Rudolf S. Fehrmann, Marcel A. van Vugt.

1University Medical Center Groningen, Groningen, Netherlands; 2European Research Institute for the Biology of Ageing, Groningen, Netherlands.

To investigate the clinical significance of TXX2 expression, we analyzed the expression of TXX2 in a large cohort of patient-derived tumor samples using 3 independent technologies: FqMRNA, a genome-wide association analysis, and RNA sequencing. The results showed that TXX2 expression was significantly higher in genomically instable tumors, suggesting that TXX2 might play a role in genomic instability.

Differential mismatch repair-dependent damage responses in sub-populations of cells from human intestinal organoids.

Bo Lin, Qingfen Yang, Abhijit Rath, Christopher D. Heinen. University of Connecticut Health, Farmington, CT.

Hereditary mutations in DNA mismatch repair (MMR) genes cause the cancer predisposition syndrome called Lynch syndrome. Patients predominantly develop colorectal cancer and some extracolonic cancers at a young age. The MMR pathway repairs mismatches created during DNA replication, but also can induce apoptosis and cell cycle arrest in response to certain DNA damaging agents as a protective mechanism to eliminate cells at risk of accumulating mutations. Our understanding of this MMR-directed DNA damage response has come primarily from studies in human cancer cell lines. We wished to examine the role of the MMR-dependent damage response in a model that may be more relevant to the human intestine. Therefore, we have created human intestinal organoids (HIOs) in vitro either by directing the differentiation of human embryonic stem cells (hESCs) or through culturing of adult intestinal tissue samples. We have used these HIOs to specifically study the MMR-dependent damage response to DNA alkylation damage. We have found that whereas hESCs undergo rapid apoptosis in response to alkylation damage, the differentiated HIOs or those created from adult tissues undergo not only apoptosis, but also senescence and accelerated differentiation following damage. Using CRISPR-Cas9 gene editing in hESCs, we also created MMR-deficient HIOs that failed to respond to the drug indicating that these responses are MMR-dependent. We determined that the cells undergoing apoptosis following DNA damage are most likely the intestinal stem cells suggesting that different cell types in the intestine have different MMR-dependent responses to damage. Together these results
suggest that loss of MMR function in the intestinal crypts may provide a selective advantage particularly in an environment conducive with DNA damage that promotes tumorigenesis.

**#1412** High EGFR somatic mutation frequency targeting the TK domain in colorectal cancer patients with microsatellite instability (MSI). Safoora Dehimi,1 Michael Slifker,2 Eric A. Ross,2 Wafik S. El-Deiry1. 1Department of Hematology/Oncology and Molecular Therapeutics Program, Fox Chase Cancer Ctr., Philadelphia, PA; 2Department of Biostatistics, Fox Chase Cancer Ctr., Philadelphia, PA.

CRCs arise through genetic changes that impact various driver genes and in some tumors increased mutation rate in microsatellite unstable tumors. The hypermutable phenotype associated with microsatellite instability (MSI) results from loss of the mismatch repair system (MMR) activity. MSI is detected in 15% of all CRCs, and such tumors have a better prognosis and different chemotherapeutic outcome patterns, including high clinical benefit from immune checkpoint therapy or relative resistance to 5-FU as compared to microsatellite stable (MSS) tumors. The epidermal growth factor receptor (EGFR) signaling pathway plays an essential role in carcinogenesis of CRCs and is known to be overexpressed in MSI CRCs while highly mutated in Lung cancer. We analyzed the mutation frequency of deregulated pathways including EGFR and its downstream genes KRAS and BRAF in CRCs. We found a significantly elevated EGFR mutation frequency in CRC MSI-H subtype (45.5% vs. 6.5% in MSS CRCs, p<0.0000001). Although KRAS and NRAS are mutated with high frequency in both MSI-H and MSS groups, BRAF corresponding to RTK-RAS pathways is more altered in MSI-H than MSS CRCs (32.67% vs 13.10%; p=0.001), consistent with the known association between MSI-H CRCs and BRAF mutations. We hypothesized that there might be a mutation pattern in EGFR in CRC subtypes that provide a rationale for EGFR-targeted therapy for a subtype of CRC. Of 1104 profiled CRCs in the COSMIC v73 database, somatic EGFR mutations were mapped for 101 MSI-H versus 916 MSS CRCs. EGFR mutations mapped on the protein structure revealed that mutations are mainly targeting tyrosine kinase (TK) domain while the extracellular domain remained mostly wild-type with potential for targeting by anti-EGFR monoclonal antibodies. It is known that downstream genes such as KRAS as well as expression levels of EGFR ligands can affect the sensitivity of CRCs to anti-EGFR therapy. We didn’t detect any difference in mRNA expression level between MSI-H and MSS group but our analysis is indicative of the presence of G12D mutations in a high proportion of KRAS-mutated MSS CRCs, therefore resistance to anti-EGFR antibodies such as cetuximab would be expected. However, EGFR tyrosine kinase inhibitors such as erlotinib and gefitinib could be considered for further testing in patients with MSI-H tumors that have a lower frequency of G12D KRAS mutations and may have mutant EGFR.

**#1413** Replication obstacles formed within common fragile sites under replication stress are targeted by the global genomic nucleotide excision repair pathway. Martın Mistrik,1 Lucie Beresová,1 Eva Vesela,1 Ivo Chamrad,1 Jiri Voller,1 Masayuki Yamada,1 Tomas Furst,1 Rene Lenobel,2 Katarina Chroma,1 Martin Mistrik,1 Lucie Beresová,1 Eva Vesela,1 Ivo Chamrad,1 Jiri Voller,1 Masayuki Yamada,1 Tomas Furst,1 Rene Lenobel,2 Katarina Chroma,1 Jan Gursky,1 Jiri Bartek1. 1Palacky University in Olomouc, Faculty of Medicine and Dentistry, Olomouc, Czech Republic; 2Palacky University in Olomouc, Faculty of Science, Olomouc, Czech Republic.

CFSs are genomic loci present in higher vertebrates that are particularly sensitive to various forms of replication stress and suffer from increased breakage and rearrangements in tumors. They have rather enigmatic evolutionary role and employ various DNA repair and checkpoint mechanisms promoting their stability. We used an original approach for identification of CFSs’ associated factors based on DNA probe designed to match the high flexibility island sequences typically present in some of the highly expressed CFS’s. This probe was used as affinity bait for fishing specifically enriched proteins which were further identified using SILAC and quantitative mass spectrometry. Among already known CFS’s stabilizers we identified also hits so far not implicated in CFS’s maintenance. Interestingly, most of these novel hits are components of the known CFS’s stabilizers we identified using SILAC and quantitative mass spectrometry. Among already used as affinity bait for fishing specifically enriched proteins which were further investigated in vitro and in vivo for their potential to enhance sensitivity of tumor cells to chemotherapy.

**#1414** Chromatin remodeling histone chaperone FACT complex modulates AP site damage repair in chromatin and sensitizes cancer cells to chemotherapeutic drugs. Heyu Song, Shrabasti Roychoudhury, Dan Feng, Kishor Bhakat. University of Nebraska Medical Center, Omaha, NE.

Recognition and repair of DNA lesions in the genome are critical for maintaining genome stability and the progression of the cell cycle; DNA replication defects lead to cancer development. The most frequently formed DNA lesion in the genome is the apurinic/apyrimidinic (AP) site which is mutagenic and blocks transcription and replication. The primary enzyme to repair AP sites in mammalian cells is the AP endonuclease (APE1), which often overexpresses in diverse cancer types and its overexpression is associated with patients’ resistance to chemotherapeutic treatments. The involvement of AP endonuclease (APE1) through the BER pathway is extensively investigated in vitro. However, how AP site is recognized by APE1 in the context of highly complex nucleosome structure in chromatin is unknown. Because DNA is packaged tightly in nucleosome, the ability of repair proteins to access sites of DNA damage and facilitates repair of the damage requires chromatin remodeling activities. Here, we show that APE1 interacts with chromatin remodeling histone chaperone complex, FACT (facilitates of chromatin transcription) via its N-terminal domain in cells. By immunoprecipitation of endogenous APE1 from chromatin fraction and separation of protein bands in SDS-PAGE followed by MALDI-TOF-TOF analysis, we have identified both subunits (SPT16 & SSRP1) of FACT as the prominent APE1 interacting partners. Subsequently, we confirmed the interaction of APE1 with FACT complex through a co-immunoprecipitation assay analysis and SPT16 and SSRP1 interact with APE1 in the nucleus and in chromatin. Interestingly, we found rapid eviction of histones with concomitant degradation of FACT complex upon induction of DNA damages. Downregulation of FACT complex abrogates the nucleosome eviction, the recruitment of repair protein APE1 in chromatin and the repair of AP sites, demonstrating the functional importance of nucleosomes disruption in BER pathway and identifying chromatin remodeling protein required for the process. Notably, knock-down of FACT showed increased sensitivity of cancer cells to many chemotherapeutic drugs. We also found that FACT down-regulated cells have much higher accumulation of AP site damages in the genome compared to control cells. Our study revealed a key role of nucleosome remodeling complex FACT in DNA damage repair in BER pathway. This study also suggests that histone chaperone complex could be a potential target for enhancing sensitivity of tumor cells to chemotherapy.

**#1415** SAN1: a novel senataxin associated nucleaserequired for the repair of interstrand crosslinks. Alex Andrews, Ian Macara. Vanderbilt University, Nashville, TN.

The DNA damage response (DDR) is a set of complex signaling pathways capable of sensing DNA damage, and activating a large number of enzymes involved in the remodeling and repair of the genome. Mutations in the genes involved in the DDR lead to the development of many cancers. One particularly dangerous type of DNA damage that can occur is an interstrand crosslink (ICL). ICLs can lead to the development of double strand breaks through the blockage of DNA replication and transcription. Although ICLs can arise endogenously from molecules such as aldehydes, most commonly they are induced from chemotherapeutic drugs such as Cisplatin and Mitomycin C (MMC). These drugs are commonly used in the treatment of breast and ovarian cancers. A better understanding of which proteins are involved in the repair of ICLs is critical for understanding resistance, toxicity, and response in patients treated with ICL inducing agents. The repair of ICLs requires the coordination of several DNA repair pathways including the Fanconi Anemia pathway, homologous recombination (HR), and nucleotide excision repair (NER).

The Fanconi Anemia pathway is essential for the repair of these lesions as it is responsible for the recognition of the ICL lesion, as well as the recruitment of several nucleases responsible for unhooking and removal the cross-linked nucleotides. Recently, we identified an uncharacterized 5’ nuclease that interacts with the RNA/DNA helicase Senataxin, which we have named senataxin-associated nuclease 1 (SAN1). Senataxin has been shown to act on R loops, RNA/DNA hybrids that are a source of endogenous DNA damage. Deletion of the SAN1 gene in HeLa cells or in mouse embryonic fibroblasts leads to the sensitization of cells to Cisplatin and Mitomycin C (MMC), but not to ionizing radiation that induces double strand breaks. Importantly, the defect in ICL repair can be restored using WT SAN1 but not with a mutant that is catalytically inactive. Treatment of SAN1-/- HeLa cells with MMC also leads to radial chromosome formation, a characteristic of cells deficient in ICL repair. Additionally, SAN1 partially colocalizes with FancD2 MMC induced foci, and treatment with MMC results in increased DNA damage and R loops in SAN1-/- cells. In conclusion, this study highlights the discovery of a novel nuclease involved in the repair ICLs, a process critical for understanding resistance and response to chemother-
apies such as Cisplatin and MMC. Future work is aimed at determining the specific step of ICL repair that SAN1 participates in, how and when during repair SAN1 is recruited to ICL sites, and which other DNA repair proteins SAN1 functions with.

#1416 Development of small molecule inhibitors for cancer therapy by targeting RPA and XPA nucleotide excision repair proteins. Navnath S. Gavande,1 Pamela S. VanderVare-Carozza,2 Tyler L. Vernon,1 Katherine Paweleczak,3 John J. Turchi1. 1Indiana University School of Medicine, Indianapolis, Indiana, IN; 2NERx Biosciences Inc, Indianapolis, IN.

Targeting DNA repair and the DNA damage response for cancer therapy has recently gained increasing attention with inhibitors of the PARP enzyme showing a therapeutic efficacy in various cancer models. However, the clinical benefit of DNA repair inhibitors has been limited due to the problem of collateral damage to cells with homologous recombination deficiency. Here, we show that targeting RPA and XPA with small molecule inhibitors potently ablates DNA repair and synthetic lethality of cancer cells with homologous recombination deficiency.

#1417 Expression of BARD1 induces genetic instability and is associated with cervical carcinogenesis. Maxim Pilyugin,1 Pierre-Alain André1, Nicole Concin,2 Gerda Hofstetter,2 Irmgard Irminger-Finger1. 1Rutgers University, New Brunswick, NJ; 2University Hospital Innsbruck, Innsbruck, Austria.

Cervical cancer is always linked to infection with the human papillomavirus (HPV), which causes hyper-proliferation of cervical epithelial cells and neoplasia and cancer. The viral oncoprotein interaction with host tumor suppressor proteins partially explains the uncontrolled proliferation, which ultimately progresses to cervical cancer. However, little is known about the specific factors that provide or inhibit the malignant transformation. Since a portion of HPV infections never evolves into cancer, the identification of discriminatory factors would be an important step towards the development of prognostic and therapeutic tools. Based on this notion, we investigated whether an isoform of BARD1, BARD1α, which we found frequently expressed in cancer cells, plays a role in the malignant transformation of cervical epithelial cells. Using immuno-histochemistry staining on tissue sections and RT-PCR we found that BARD1α is expressed in proliferating cervical cancer cells, while normal BARD1 is repressed. BARD1 might be a driver of carcinogenesis and might be a critical event in the progression from hyper-proliferating cervical epithelium after HPV infection to cervical cancer. Together, our results show that an isoform of BARD1, BARD1α, is increasingly expressed in precancerous stages of cervical cancer and the specific inhibition of BARD1α may represent a novel approach for therapeutic interventions to prevent cervical carcinogenesis after HPV infection.

#1418 G9a methyltransferase plays a role in ATM-dependent DNA damage response. Lizahira Rodriguez-Colon,1 Yasueva Ginjula,2 Atul Kulkarni,1 Safia Ansari,1 Shridar Ganesan1. 1Rutgers Cancer Institute of New Jersey, New Brunswick, NJ; 2Rutgers University, New Brunswick, NJ.

Induction of DNA damage leads to a choreographed set of local chromatin changes that ensures an efficient recruitment of DNA repair factors. One prin-

#1419 Role of a novel Senataxin-associated nuclease in DNA repair. Heather McCartney, Ian Macara. Vanderbilt University, Nashville, TN.

Yeast two-hybrid analysis has identified a novel, uncharacterized Senataxin-interacting protein with 5′ exonuclease activity, and homology to the FEN1 nuclease domain. Senataxin is an RNA/DNA helicase that functions in resolving R loop structures which occur as a result of normal replication and transcription, but can also persist resulting in genomic instability. We found that SAN1 (Senati-

Metnase, a human SET-transposase fusion protein contains two functional domains: a SET domain and transposase domain. Transposase domain exhibit strand transfer and end joining activity while set domain is responsible for histone lysine methyltransferase activity (KMT). Metnase also increases the efficiency of double strand break repair by non-homologous end joining (NHEJ); however, its role in the excision of clustered DNA damage remains to be inves-
tigated. We hypothesize that 5′-3′ endonuclease activity of metnase could possibly substitute for APE1 in BER and serve as an alternative initiator of BER in tumor cells lacking APE1. In the present study, we examined in vitro endonuclease activity of Metnase using abasic site containing artificial DNA, and de-
scribe its activity in BER. Its unique 5′ endonuclease activity was selective only for abasic lesions, but other base modifications such as 8-oxoguanine, uracil, 5-hydroxy-methylcytosine could not be cleaved. Metnase increases lesion removal and reduces clustered abasic lesions from DNA, and allows completion of short-patch or long-patch BER. APE1 has difficulty cleaving 5′ of clustered abasic lesions. This endonuclease that promotes BER in clustered oxidative DNA damage is not known. Metnase also cleaves multiple abasic lesions (clustered DNA damage) and facilitates the repair of DNA if the multiple DNA damages are 3 or more nucleotides apart on the opposing strands. However, repair of multiple DNA damages remains inefficient if these are in close proximity of each other (<3 nt apart on the opposing strands) and results in DNA double strand break (DSB). These results suggest that Metnase can promote BER of oxidative nucleotides, where APE1 is unable to function.
#1421 Evaluation of DDR-targeting strategy using ATR inhibitor in biliary tract cancer. Ah Rong Nam,1 Ji Eun Park,1 Ju Hee Bang,1 Mei Hua Jin,1 Do Youn Oh,2 Yung Jue Bang2. 1Cancer Research Institute, Seoul National University College of Medicine, Seoul, Republic of Korea; 2Department of Internal Medicine, Seoul National University Hospital, Seoul, Republic of Korea.

Background: The DNA damage response (DDR) is a multicomplex network of signaling pathways involved in DNA damage repair, cell cycle checkpoints and apoptosis. The ataxia telangiectasia and Rad3-related (ATR) protein kinase is a key enzyme in the DDR that activates checkpoint kinase 1 (Chk1), resulting in cell cycle arrest. Tumor types with loss of ATM function and/or high replication stress are expected to be more susceptible to DDR targeting. In biliary tract cancer (BTC), DDR related pathway, which includes RAP1, MSH6, BRCAP1, ATM, MLIH1, MSH2, is altered in about 20% of cases. TP53 module is observed in 33.9% of BTC cases (Nat Genet 2015). The purpose of this study is to test DDR targeting strategy using ATR inhibitor in biliary tract cancer. Methods: Using 9 kinds of BTC cells, MTT assay and colony formation assay were done for determining growth inhibitory effect of AZD6738, an ATR inhibitor. Cell cycle analysis was done by FACS Calibur flow cytometer and the methods described by Chou and Talalay were used to determine whether a synergistic effect existed between AZD6738 and cytotoxic chemotherapeutic agents (cisplatin, 5-FU, gemcitabine). The alkaline comet assay was done to measure of DNA damage in individual cells. Tumor xenograft model was used for in vivo test of AZD6738. Results: Among 9 BTC cells, SNU478 and SNU869 were most sensitive to AZD6738 which showed low expression of BTM and ATM and/or p53. AZD6738 blocked ATR-mediated Chk1 phosphorylation and increased rH2AX, a marker of DNA damage, in sensitive cells. AZD6738 significantly increased apoptosis (cleavage of PARP and caspase-7) and G2/M arrest, increased level of p21, and presence of DNA damage, in sensitive cells. AZD6738 and cytotoxic chemotherapeutic agents demonstrated synergistic effects in colony formation assay, cell cycle analysis and comet assay. In xenograft model of SNU478, AZD6738 monotherapy decreased tumor growth. The combination of AZD6738 and cisplatin showed more potent growth inhibitory effects, decreased KI67, increased Tunel than monotherapy of each drug. Conclusion: In BTC, DDR targeting strategy using ATR inhibitor demonstrated promising antitumor activity alone or in combination with cytotoxic chemotherapeutic agents. This supports further clinical development of DDR targeting strategy in BTC.

#1422 Enhancing the therapeutic effects of PARP inhibitors in combination DNA methyl transferase inhibitors, using low doses of ionizing radiation in non small cell lung cancers. Christopher Biondi,1 Daniel Fontaine,1 Lora Stojanovic,1 Pratik Nagaria,1 Renia Lapidus,1 Javed Mahmood,1 Stephen Baylin,2 Feyruz V. Rassool1. 1Univ. of Maryland School of Medicine, Baltimore, MD; 2Johns Hopkins University, Baltimore, MD.

Non-small cell lung cancer (NSCLC) is the leading cause of cancer-related deaths in the US. Treatment most commonly relies on ionizing radiation and platinum-based DNA damaging agents, but long-term survival is poor and patients tend to suffer chronic side effects due to the high radiation dose to the surrounding normal tissues. Therefore, new treatments are needed that can be used in combination lower radiation doses. We have recently reported that low, non-cytotoxic doses Poly ADP ribose polymerase inhibitors (PARPi) Talazoparib in combination with DNA methyltransferase inhibitors (DNMTi) Decitabine (DAC) or azacytidine (AZA) significantly increase cytotoxicity in acute myeloid leukemia and breast cancer models in vitro and anti-tumor effects in vivo. Simultaneous administration of both inhibitors result in increased PARP binding in DNA, leading to higher levels of DNA double strand breaks (DSBs), yielding increased cytotoxicity, compared with each agent treatment alone. We first studied the efficacy of Talazoparib and AZA combination therapy in multiple NSCLC cell lines (A549, H358 and H388) in vitro through colony forming assays. Results showed, compared to single agent treatments, combination drug treatment significantly decreased colony formation. Cell viability was also significantly decreased with the drug combination in MTS assays (P<0.05). These results also showed synergistic activity between the two drugs, with a combination index of 0.7 to 1.0 for all tested NSCLC cell lines. Importantly, the drug combination increased PARP trapping in chromatin and DSB formation, as measured by immunofluorescent staining for γH2AX. We next determined whether AZA/Talazoparib in combination with a single dose of radiation (2Gy) had an increased anti-cancer effect compared to each modality alone in in vivo mouse xenographs of NSCLC A549. While the combination of PARPi + DNMTi with radiation treatment decreased tumor growth, compared to PARPi alone or RT alone, no significant enhancement with radiation was observed. We next determined whether low doses of fractionated IR (2Gy 3 fractions) would improve the efficacy of DNMTi and PARPi combination treatment. In vitro studies with colony forming assays of NSCLC cell line A549 show that IR doses in combination with PARPi and DNMTi decrease clonogenicity, compared with non-IR controls. Furthermore, A549 xenographs were treated with the drug combination and then irradiated 1 week later with 2Gy daily for 3 consecutive days. Mice treated with the drug combination followed by IR had significant decreases in tumor volume and survival (P<0.05). This suggests that low doses of PARPi and DNMTi with low doses of IR can potentially target NSCLC tumors. This represents a novel treatment approach for NSCLC patients that may reduce chronic side-effects of high dose IR.

#1423 Neddy8-activating enzyme inhibitor pevonedistat synergizes with cisplatin and carboplatin through interference with nucleotide excision repair and interstrand cross-link repair mechanisms in non-small cell lung cancer. Xiao zhe Liu,1 David Bouch1, Khristofer Garcia, Jonathan Blank,1 Hughes Bernard,1 Allison Berger,1 Mike Keyeseda,1 Erik Koenig,1 Eric Lightcap2. 1Takeda, Cambridge, MA; 2Genentech, San Francisco, CA.

Platinis are one of the most widely used classes of chemotherapeutic drugs. Although used as part of first-line standard of care regimens for advanced non-small cell lung cancer (NSCLC), their effectiveness remains limited, with a 5-year survival rate of 18%. Therefore, combination therapy to overcome resistance and improve survival is needed. Pevonedistat (TAK-924/MLN4924) is an investigational first-in-class Neddy8-activating enzyme (NAE) inhibitor that blocks activation of the cullin family of E3 ubiquitin ligases by preventing cullin conjugation with Nedd8, a ubiquitin-like protein. In vitro, pevonedistat is synergistic with carboplatin in a cell viability assay in 6 out of 20 NSCLC cell lines either with or without paclitaxel. In vivo studies using patient-derived xenograft (PDX) models showed a combination effect in a carboplatin-insensitive but not carboplatin-sensitive model. To evaluate the mechanism of the synergy between pevonedistat and platinum, RNAi of 320 DNA-damage response genes was performed in 4 cell lines in vitro. Depletion of genes involved in TC-NER (transcription-coupled nucleotide excision repair) and ICR (interstrand crosslink repair) reduced the synergy between pevonedistat and platinum, with the contribution of each pathway varying by cell line. Since TC-NER and ICR are also involved in the repair of DNA damage by platinis, the results suggest that delaying completion of platin induced DNA repair by pevonedistat results in enhanced cell death. Pevonedistat may impede TC-NER by inhibition of neddylation of the E3 ubiquitin ligase CUL4-RBX1-DDB1-ERCC8, thereby possibly providing a direct reversal of resistance to platinis.

#1424 DNA repair capacity in colon cancer patients - The effect on the response to treatment and long-term survival. Sona Vodenkova,1 Michal Kroupa,2 Katerina Jiraskova,3 Alessio Naccarati,4 Alena Opattova,5 Pavel Vodicka5. 1Third Faculty of Medicine, Charles University, Prague, Czech Republic; 2Faculty of Medicine and Biomedical Center in Pilsen, Charles University, Pilsen, Czech Republic; 3First Faculty of Medicine, Charles University, Prague, Czech Republic; 4Department of Internal Medicine, Institute of Experimental Medicine, The Czech Academy of Sciences, Prague, Czech Republic.

Colorectal carcinoma (CRC) is the third most common cancer worldwide with the highest incidence in Central Europe. It is the fourth leading cause of cancer related deaths mainly due to the late diagnosis and low efficacy of treatment. CRC diagnosed in early stage has a five-year survival rate about 90% which drops to near 12% in distant metastases occur. It is a heterogeneous disease with different molecular and clinicopathological features depending on the tumor location. Therefore, different treatment strategies are required. A standard treatment of locally advanced rectal cancer includes neoadjuvant chemoradiation therapy followed by surgery, whereas colon cancer treatment consists of surgical resection of the tumor and/or subsequent adjuvant chemotherapy based on disease characteristics. 5-fluorouracil (5-FU) alone or in combination with other compounds is the most used treatment in CRC. The mechanism of 5-FU on molecular level is either its incorporation into DNA or it imbalances the synthesis of thymidine from uracil resulting in false uracil DNA incorporation. These DNA lesions are repaired by base excision (BER) and mismatch repair (MMR) pathways. An effective DNA damage response (DDR) is essential for the maintenance of genome stability in healthy cells, whereas in malignant cells, the suppression of DNA repair capacity (DRC) would increase the effectiveness of chemotherapy through DNA damage accumulation and consequent apoptosis. In contrary the cells with high DRC may show better survival and therefore patients with these molecular characteristics may contend with poor response, resistance to treatment and decreased survival. The aim of our present study was to investigate tumor growth and MMR in target tissue as a predictive marker for a treatment strategy and long-term survival. In order to minimize a bias by heterogenous therapy we focused only on patients with newly diagnosed colon cancer. Our set of patients was selected based on the criteria of follow-up at minimum 30 months, subsequent treatment with 5-FU and microsatellite stable
MOLECULAR AND CELLULAR BIOLOGY / GENETICS: Genomic Instability and Cancer Therapy

tumor tissue characteristics. Tumor and adjacent non-affected tissue samples were obtained from one hundred patients at surgical resection. Protein extracts from tissues were isolated both for protein expression analysis and for measurement of DRC. DNA repair and DDR protein expression levels were tested by Western Blot. Functional assessments of DRC were performed by comet assay-based in vitro DNA repair assay. The cycle analysis via FACS. Results: We identified many potential CYCLOPS genes mapping on the distal end of chromosome arm 1p. One of these genes is involved in neuronal and embryonic development and has been further validated. Knock-down of the gene impaired cell viability in 1p-deleted cell lines but did not in 1p-non-deleted cells. G1/G0 phase arrest with corresponding S phase decrease was observed in both 1p-deleted and non-deleted. Additionally, neurite-like outgrowth could be observed in 1p-non-deleted cells indicating an induction of differentiation. Conclusion: This study identified a candidate CYCLOPS gene in neuroblastoma. Heterozygous deletions of chromosome arm 1p are also frequently observed in other cancers including melanoma, colorectal and breast cancer. We hypothesize that this proof-of-principle opens a new therapeutic window for tumor treatment during a heterozygous deletion of our candidate gene or other cell essential genes on chromosome arm 1p.

#1427 Investigating role of RECIQ1 in response to gemicitabine treatment in triple negative breast cancer. Swetha Parvathaneni, Xing Lu, Sudha Sharma. Howard University, Washington DC, DC.

The response of cancer cells to therapeutic drugs aimed at causing DNA damage is dependent on proteins that play roles in DNA repair. Single nucleotide polymorphisms in RECQ1 (also known as RECQL or RECQL1), a DNA helicase involved in DNA damage and replication stress response, is reported to influence patient’s response to gemicitabine in pancreatic cancer leading to poor survival. Gemicitabine is also used as a chemotherapeutic against triple negative breast cancer; however resistance to gemicitabine is reported. The mechanism by which gemicitabine chemoresistance is obtained is poorly understood. Given the importance of RECQ1 in replication fork restart and being categorized as a breast cancer susceptibility gene, we wish to investigate the role of RECQ1 in modulating cellular response to gemicitabine in triple negative breast cancer cells. To study RECQ1 functions, we developed isogenic pairs of RECQ1-proficient and RECQ1-deficient cells by CRISPR-Cas9-mediated targeted inactivation of RECQ1 in breast cancer cell lines as in vitro model system. RECQ1-knockout MDA-MB-231 cells displayed reduced cell growth and proliferation, and increased DNA damage as compared to the MDA-MB-231 cells expressing wild type RECQ1. As compared to RECQ1-proficient MDA-MB-231 cells, RECQ1-deficient cells were more sensitive to gemicitabine treatment, incurred significantly greater load of double strand breaks upon gemicitabine treatment, and showed greater cell cycle progression following recovery from gemicitabine treatment. Our ongoing experiments are investigating the detailed mechanism of RECQ1’s role in response to gemicitabine and its implications in therapeutic response. Funding: This work was funded by the NIGMS/NIH grant SC1GM093999 to Sudha Sharma. We also acknowledge support from the NIMHD/NIH award number R25 AG047843-02.

#1428 Single-cell transcriptomics reveals differential DNA repair signature after chemotherapy in high-grade serous ovarian cancer. Anniina Farkkila, Kaiyang Zhang, Katja Kaipio, Tarja Lammiminen, Rainer Lehtonen, Johanna Hynninen, Seija Grönn, Olli Carpein, Sampsa Hautaniemi, Anna Vähärautia. Univ. of Helsinki and Helsinki University Hospital, Helsinki, Finland; Univ. of Turku, Turku, Finland; University of Turku and Turku University Hospital, Turku, Finland.

Resistance to chemotherapy poses a major clinical problem in the treatment of ovarian cancer. The efficacy of platinum-based chemotherapy relies on defective DNA repair mechanisms, and increased expression of homologous recombination (HR)/DNA repair genes in primary tumor samples is associated with improved chemoresponse. However, the effects of neo-adjuvant chemotherapy (NACT) on the expression DNA repair genes in cancer cells are poorly understood. In addition, high-grade serous ovarian cancers (HGSOCs) display significant inter- and intratumoral heterogeneity, and the identification of mechanisms of drug resistance has been hampered by the lack of data at the single cell resolution. We collected 34 primary and 20 interval tumor samples from 15 patients treated for HGSOC at the Turku University Hospital, Finland. Tumor tissue total RNA was sequenced with Illumina HiSeq. For this study, we selected 363 genes selected due to their validated role in DNA repair pathways and compared their expression profiles between primary and interval samples.
The treatment naive primary tumor samples highly expressed genes related to HR, such as BRCA2, RAD54, PARPBP, FANC2D, and POLQ. Whereas after NACT the interval samples highly expressed genes regulating cell cycle, inflammatory response, and the drug efflux pump ABCB1. Moreover, higher expression of BRCA2 or POLQ in the interval samples correlated with poor primary therapy outcome (p<0.01). To reveal the transcriptomics landscapes of treatment naïve and NACT treated HGSOCs at the single cell level, we performed single cell mRNA sequencing of primary and interval samples using the Fluidigm C1 Platform. Unsupervised clustering revealed eight distinct cell subpopulations, of which two clusters were annotated HGSOC cells based on enriched expression of cancer specific genes. In global gene expression analysis of 98 HGSOC cells, the most differentially expressed genes in primary HGSOC cells were heat shock proteins reflecting active protein synthesis. By contrast, the cancer cells from interval samples highly expressed genes regulating the cell cycle and immune response. Of the DNA repair pathway genes, the interval samples expressed lower levels of HES1, a transcription factor that is known to promote cancer progression and stemness. The herein elucidated DNA repair pathway transcriptomics landscape at single-cell and whole tumor level provides novel targets for overcoming chemoresistance in HGSOC.

**#1429 DNA damage response to dihydrogalactitol (VAL-083) in p53-deficient non-small cell lung cancer cells.** Anne Steino,1 Guangan He,2 Jeffrey A. Bacha,1 Dennis M. Brown,1 Zahid Siddik2.

#1430 The spliceosome U2 snRNP factors promote genome stability through distinct mechanisms; transcription of repair factors and R-loop processing. Michihiro Tanikawa. The University of Tokyo, Tokyo, Japan.

**Objective:** Recent whole-exome sequencing studies of malignancies have detected recurrent somatic mutations in u2 snRNP components of the spliceosome. These factors have also been listed as novel players of DNA damage response in several genome wide screens and proteome analysis for DDR genes. Although accumulating evidences have implied that the spliceosome plays an important role in genome stability and is an emerging hallmark of carcinogenic pathways, its precise role in genome stability still remains ambiguous. The aim of this study is to clarify the functions of U2 snRNP splicing factors, especially SNRPA1 (Small Nuclear Ribonucleoprotein Polypeptide A1) in DDR pathway.

#1431 Therapeutic exploitation of mutant BRAF in childhood glioma. Sudipa Saha Roy, Peter Houghton. UTHSCSA, San Antonio, TX.

Low grade gliomas (LGG) are the most common tumors of the central nervous system in children, accounting for about 50% of all brain tumors. They represent a heterogeneous group of grade I and II tumors according to the WHO classification. Pediatric LGG, is associated with activation of BRAF through a tandem duplication that results in the KIAA1549-BRAF fusion or through an activating point mutation of BRAF (predominantly V600E). More recent findings suggest that the KIAA1549-BRAF fusion is restricted to Grade 1 tumors (70-90%) whereas BRAF(V600E) occurs more frequently in Grade 2-4 tumors (~23%). Findings for BRAF mutation, similar to other tumors with activated BRAF (e.g. melanoma), and the phase I activity of MEK inhibitor in the PBTC-029 protocol, suggest that activated BRAF may provide a validated drug target. Previous studies from our lab indicate that, in the context of mutant BRAF, inhibition of MEK inhibits TORC1 signaling and may induce a ‘BRACA-like’ phenotype, through depletion of FANC2D. Potentially suppression of TORC1 could have effects on other DNA damage response pathways that could compensate for loss of FANC2D. To understand the consequences of MEK inhibition in the context of BRAF abreation in LGG we surveyed DNA repair genes that may be regulated via the MEK/TORC1 pathway in BRAF mutant cells. The objective of this particular study was to examine the mechanism and significance of MEK inhibition to the repair of DNA damage by the homologous recombination (HR) pathway. For this study, we have used glioma cell lines having BRAF(V600E) mutation; the BT40 cell line was developed from patient-derived astrocytoma xenograft (PDX) model in mice in our lab and AM38c1 and DBTRG-05MG cells were generously provided by T. Nicolas. Annexin bind- ing assay demonstrated that MEK inhibition significantly increased the percentage of apoptosis and necrosis of glioma cells. Human DNA repair PCR Array analysis identified MEKi induced down regulation of genes involved in Base Excision Repair (BER), Nucleotide Excision Repair (NER), Mismatch Repair (MMR) and Double-Strand Break (DSB) repair pathways. DSB repair genes were further validated by real time qPCR analysis. Immunoblot analysis of glioma cell lines indicate that MEKi treatment significantly increased H2AX levels. To elucidate the mechanism of DSB repair pathway in presence of MEKI, clonogenic assay, nuclear foci formation assay, and GFP reporter assay for homologous recombination (HR) and non-homologous end-joining (NHEJ) are ongoing. Collectively, these findings demonstrate for the first time a previously unknown role for MEK in treatment of glioma cells that involves inhibition of DNA repair pathways.
MOLECULAR AND CELLULAR BIOLOGY / GENETICS: Genomics in Inherited Susceptibility and Prenoplastic Conditions

**#1432** Precision lung cancer medicine based on information on cancer and the host genomes. Takashi Kohno,1 Kouya Shiraishi,1 Kazuhi Yoshida,2 Motonobu Saito,1 Yukinori Okada.1 National Cancer Ctr. Research Inst., Tokyo, Japan; National Cancer Ctr Hospital, Tokyo, Japan; Osaka University Graduate School of Medicine, Osaka, Japan.

Aberations of oncogene, such as EGFR mutation; and ALK, RET, and ROS1 fusions, function as a driver in the development of lung adenocarcinoma (LADC). They are a solid target of therapy using tyrosine kinase inhibitors, as represented by a high response rate of RET-fusion positive LADC to vandetanib (LURET study, Yoh et al., Lancet Resp Med, 2016). Our genome-wide sequencing study revealed that oncogene aberration positive LADCs carry less numbers of mutations in cancer-related genes than negative ones (Saito, Cancer Res, 2015), indicating a small mutation burden in the development of the formers. Consistently, a clinical trial of anti-PD-1 therapy indicated that EGFR-mutation positive cases do not benefit well from the therapy (Borghaei et al., N Engl J Med, 2015). LADC driven by somatic EGFR mutations is more prevalent in East Asians (30-50%) than in European/Americans (10-20%). We recently revealed that variations in HLA class I loci underlie the risk of the disease, leading to a genome-wide association study of 3,173 patients and 15,158 controls, combined with imputation of HLA alleles using a Japanese-specific panel (Shiraishi et al., Nature Comm, 2016). The result indicates that LADC develops in vivo through interaction between somatic mutations and germline variations that modulate immune reaction. Therefore, efficacy of immune checkpoint blockade targeting PD-1/PD-L1 in this patient/cell type is strongly associated with smoking status. The other hand, oncogene-negative LADCs show a high mutation burden associated with nonsynonymous mutations in chromatin remodelin and other cancer-related genes. Thus, these cases would respond well to immune checkpoint blockade targeting therapies. We would like to discuss here precision lung cancer medicine based on information on cancer and the host genomes.

**#1433** Single cell RNA sequencing reveals smoking-associated alterations in bronchial airway epithelial subpopulations. Grant E. Duclos, Joshua D. Campbell, Yaron Gesthalter, Patrick Autissier, Yves M. Dumas, Robert Terrano, Gang Liu, Marc E. Lenburg, Avrum Spira, Jennifer Beane. Boston University School of Medicine, Boston, MA.

Rationale: We have previously shown that bronchial airway epithelial gene expression reflects the physiological response to cigarette smoke exposure. We have also shown that gene expression differences in cytologically normal airways can serve as a diagnostic biomarker for lung cancer. In this study, we use single cell RNA-seq to profile transcriptomes of individual bronchial epithelial cells from current and never smokers in order to detect smoking-associated alterations within airway epithelial cell subpopulations that develop as a result of smoke exposure. This approach may be useful for identifying cell type specific transcriptomic changes in the airways of cancer patients, which may lead to a better understanding of lung carcinogenesis and new approaches to early lung cancer detection. Methods: We obtained bronchial brushings from current smokers (n = 6) and never smokers (n = 6) and isolated single cells by FACS. The CEL-Seq RNA library preparation protocol was used to sequence the transcriptomes of 1,140 cells (n=95 donors). Results: Distinct populations of bronchial cells expressed known markers of basal (KRT5), ciliated (FOXJ1), secretory (SCGB1A1, MUCSAC) epithelial cells, as well as white blood cells (CD45). In the airways of smokers, we observed an increase in abundance of MUCSAC+ secretory cells as well as a decrease in abundance of KRT5+ basal and SCGB1A1+ secretory cells. A novel subset of KRT8+ cells that lacked expression of other known cell type markers was identified in the airways of smokers and may represent a population previously described as undifferentiated intermediate cells. Genes involved with metabolism of polycyclic aromatic hydrocarbons (CYP1B1) were detected in smoker secretory cells, whereas genes involved in the metabolic response to cigarette smoke toxins such as aldehydes (ALDH1A1) and quinones (NQO1), were most highly expressed by smoker ciliated cells. Interestingly, the novel KRT8+ cells identified in smokers expressed genes known to promote MUCSAC+ secretory cell differentiation (SPDEF, but did not express MUCSAC itself, suggesting that these may be pro-MUCSAC+ secretory intermediate cells. Furthermore, we found that genes previously associated with higher expression in the airways of lung cancer patients were most strongly associated with smoker ciliated and secretory cells, whereas genes with lower expression in lung cancer were enriched among genes most strongly associated with white blood cells. Conclusio: We have identified cell type specific transcriptomic alterations and shifts in epithelial cell population abundance in smoker airways. In future studies, profiling the transcriptomes of single cells from bronchial airways of smokers with and without lung cancer may lead to the identification of specific cellular subpopulations contributing to the airway field of lung-cancer associated injury.

**#1434** Mutational landscape in the normal-appearing carcinogenesis field of early-stage non-small cell lung cancer, Smruthy Sivakumar,1 Yasminka Jakubek,1 Wenloua Lang,1 Tina McDowell,1 Melinda M. Garcia,2 Chi-Wan Chow,2 Zachary Weber,2 Carmen Behrens,2 Neda Kalhor,2 Cesar Moran,2 Randa El-Zein,4 Gareth Davies,3 Junya Fujimoto,3 Reza Mehran,7 Stephen G. Swisher,5 Jing Wang,2 Avrum E. Spira,2 Jerry Fowler,2 F Anthony San Lucas,2 Ignacio I. Wistuba,2 Erik Ehl,2 Paul Schett,3 Humam Kadara3.1 The University of Texas Graduate School of Biomedical Sciences, Houston, TX; 2The University of Texas MD Anderson Cancer Center, Houston, TX; 3Avera Institute for Human Genetics, Sioux Falls, SD; 4Houston Methodist Research Institute, Houston, TX; 5School of Medicine, Boston University, Boston, MA; 6American University of Beirut, Beirut, Lebanon.

Lung cancer, of which non-small cell lung cancer (NSCLC) is the most common form, is the second most prevalent cancer in the U.S. and the leading cause of cancer mortality. Field carcinogenesis phenomenon establishes that normal appearing tissues surrounding a tumor will exhibit a field effect – particularly in smokers – with the tissues proximal to the tumor showing more, and even sharing, alterations with the tumor. Previous studies in NSCLC provide evidence for both complex progression trajectories, yet, precise mechanisms remain unknown. To investigate the field cancerization phenomenon, we conducted a genome-wide survey of acquired DNA alterations in normal-appearing tissues with small airways adjacent to NSCLC. In mainstream bronchi (large airways), nasal epithelium, distant normal lung and blood, along with multiple samples from their surgically resected paired tumors, for a total of 500 samples from 48 patients with early-stage NSCLC (11 squamous cell carcinomas and 37 adenocarcinomas). Since we expect low mutation burdens and mutant cell fractions in pathologically normal tissues, we assessed somatic point mutations via deep targeted sequencing of 409 genes and paired these data with our recent study of acquired copy number alterations (CNAs) inferred from high-density whole-genome SNP microarrays, thus offering a deep and wide survey of somatic DNA alterations. After aggregating results from multiple mutation callers, we observed somatic mutations (exonic, splicing and UTRs) in 257 samples of which 65 (in 35 patients) were from normal-appearing field (non-tumor, non-blood) samples. Tumor and field samples in smokers showed a higher mutation burden and large proportion of C:G→A:T changes. We also observed concordance of mutations in the airway and corresponding tumor profiles. Further, a statistically significant field effect was established with mutational burden (measured by the variant allele frequency) increasing with proximity to the tumor. Among the 33 NSCLC cases with field mutations, the small adjacent (to tumor) field in six patients exhibited high mutational burdens in lung cancer drivers such as KRAS, STK11, TP53 and KEAP1. We also identified mutations in the large airway (TP53, SETDB2, CDKN2A), distant normal lung parenchyma (RB1, RET) and nasal epithelium (AKT1). We then correlated point mutation and CNA mutation profiles. Of eight cases showing a nonsynonymous or stopgain variants in established lung cancer drivers in the airways, four exhibited putative "two-hit" progression models, e.g. both KEAP1 and STK11 mutations in 19p loss, overlapping TP53 mutation/17p loss, or KRAS mutation/12p gain. Our findings in normal-appearing tissues of the respiratory epithelium offer insights into the earliest mutational events in their progression to NSCLC and, possibly, in tumor relapse and that may represent suitable targets for early detection and chemoprevention.

**#1435** Immune/inflammatory polymorphisms predict lung cancer survival. Dongvan Watza,1 Chrissy Luk,2 Ange Wenzlaff,1 Christine Neslund-Dudas,1 Gregory Dyson,1 Ayman Soubbani,1 Shirish Gadgeel,1 Ann G. Schwartz.1 Karmanos Cancer Institute, Detroit, MI; 2Henry Ford Hospital, Detroit, MI; 3Wayne State University School of Medicine, Detroit, MI.

Lung cancer is the leading cause of cancer related mortality in the United States, with a median five year survival of 16%. Recent advancements in the treatment of lung cancer focus on modulating the immune system to improve patient outcomes with markedly reduced toxicity profiles. This study aims to investigate single nucleotide polymorphisms (SNPs) within functional units of the immune system genome to identify genetic markers indicative of overall survival in a cohort of metropolitan Detroit lung cancer patients. This cohort presents a unique population of lung cancer patients for analysis, consisting of 40% African Americans, whom are known to have worse outcomes than their Caucasian counterparts. To assess SNPs within functional units of the immune genome, a hierarchical immune system gene and pathway list was constructed, incorporating genes and pathway identifiers from the Reactome database as well

#### Proceedings of the American Association for Cancer Research • Volume 58 • April 2017
as previous genetic and inflammatory specific cancer studies to generate a well curated gene and pathway dataset. Genomic locations for the genes, together with proximal regulatory regions, were obtained from the UCSC genome browser for cross-referencing with the Illumina MEGA SNP array to generate SNPs for inclusion. Preliminary analysis of 848 NSCLC patients in association with 29,126 immune SNPs identified six SNPs as significantly associated with survival (p-value < 10^-4) in this lung cancer cohort, implicating the following six genes, PDXN, GFRA3, HLA-DQA1, KRAS, B2TD1, and AT2F; although further gene/pathway analysis is necessary to elucidate how these associations interact in the context of genes and pathways of the immune system. PDXN over expression has been previously implicated in both high risk lung epithelial dysplasia as well as in the development of lung adenocarcinoma in prior clinical studies. Additionally, GFRA3 has been identified as an activator of the RET kinase and increased GFRA3 activity in context of the Artemin pathway is a known predictor of NSCLC progression. As well, select polymorphisms in the HLA-DQA1 gene are known clinical modifiers of lung squamous cell carcinoma risk. Finally, AT2F is a broadly active transcription factor and AT2F upregulation has been associated with tumorigenesis and metastasis in both cell models and patient tumor samples in multiple cancer studies. The previous association of these genes in lung cancer is promising and further immune system gene/pathway analysis is warranted.

#1436 Identification of novel tumor suppressor candidates in familial cholangiocarcinoma using sequencing-based Megabase-scale haplotypes from germline and cancer genomes. Stephanie Greer,1 Lincoln Nadauld,2 Billy Lau,1 Lashlee Li,1 Daniel C. Edelman,2 David Petersen,2 Daniel C. Edelman,2 Paul S. Meltzer,2 Bao Tran,2 Kerstin Hesselmeyer-Haddad,2 Thomas Ried,2 Tetsuichi Tsuchida,1 Keisuke Kataoka,1 Yaichi Shiraishi,2 Masashi Sanada,3 Shigeru Shiraishi,1 Yaichi Shiraishi,2 Masashi Sanada,3 Shigeru

#1438 The dynamics of genetic aberrations in Crohn’s disease associated colorectal carcinogenesis. Daniela D. Hirsch,1 Darawalee Wangsa,2 Yue Hu,2 Jack Zhu,2 David Petersen,2 Daniel C. Edelman,2 Paul S. Meltzer,2 Bao Tran,2 Kerstin Hesselmeyer-Haddad,2 Thomas Ried,2 Timo Gaiser1. 1University Medical Center Mannheim, Mannheim, Germany; 2National Cancer Institute, Bethesda, MD.

Crohn’s disease, a condition of chronic inflammation of the intestine, supposes that the risk for the development of colorectal cancer (CRC). Sporadic CRCs are characterized by a specific pattern of genomic imbalances and a landscape of acquired gene mutations. In this study we aimed to compare CRCs that arise as a consequence of chronic inflammation in Crohn’s disease with sporadic CRCs. We analyzed 26 Crohn’s disease associated CRCs, four matched dysplastic lesions, six matched inflamed mucosa samples, and two matched lymph node metastases using array comparative genomic hybridization, targeted sequencing (564 cancer related genes) and gene expression profiling. As a control, we used normal intestinal mucosa from the resection margin of these CRCs and 24 sporadic CRCs. In general, CRCs that developed in patients with Crohn’s disease had a similar distribution of genomic imbalances compared to sporadic CRC. However, we observed distinct mutation signatures in the Crohn’s disease associated CRCs: most frequently mutated in the Crohn’s disease associated CRCs the most frequently mutated gene was TP53, which occurred in 65% of the samples. The second, third and fourth most frequently mutated genes were KRAS (27%), APC (23%) and PIK3CA (19%). In the control group of sporadically arising CRCs, the most commonly mutated gene was APC (75%), followed by KRAS (54%), TP53 (33%), SMAD3 (29%) and SMAD2 (25%). The genetic analyses of multiple lesions from individual patients revealed a high degree of intertumoral heterogeneity with diverse patterns of genetic mutations and allowed the reconstruction of the sequence of genetic events during Crohn’s disease associated tumorigenesis. In contrast to sporadic colorectal carcinogenesis, TP53 mutations were observed as early and common events while APC mutations occurred rather late and were infrequent. The comprehensive analysis of Crohn’s disease associated CRCs suggests that the genetic landscape of CRC is influenced by the activation of inflammation related pathways. Furthermore, our findings offer potential for establishing an early detection marker for dysplasia in patients with Crohn’s disease.
A comprehensive cis-eQTL analysis revealed target genes in breast cancer susceptibility loci identified in genome-wide association studies. Xingyi Guo,1 Weiqiang Lin,2 Qiu Yin Cal,1 Jiaojun Shi,1 Yaqiong Sun,2 Xiao Pan,2 Mi-Ryung Han,1 Wanqing Wen,1 Bingshan Li,1 Jirong Long,1 Jianghua Chen,2 and Lea Jessop,1

Objective: To elucidate the genetic architecture of gene expression in pancreatic tissues. Design: We performed expression quantitative trait loci (eQTL) and allele specific expression (ASE) analyses using RNA-sequence data and 1000 Genomes (1000G) imputed GWAS genotypes from 95 fresh frozen histologically normal pancreatic tissue samples. Data from 115 pancreatic tumor-derived tissue samples from The Cancer Genome Atlas (TCGA) was included for comparison. Results: We identified 38,615 cis-eQTLs (corresponding to 484 Genes) in histologically normal tissues and 39,713 cis-eQTL (corresponding to 237 Genes) in tumor tissues (FDR=0.1), with the strongest effects seen near transcriptional start sites (TSS). Approximately 23% and 42% of genes with significant cis-eQTLs (eGenes) appeared to be specific for tumor and normal derived tissues, respectively. Significantly enriched eGenes in noncoding regulatory regions marked by modified histones, DNAse hypersensitivity and binding transcription factors, in particular for pancreatic tissues (1.53-3.12 fold, P<0.0001), indicating tissue-specific functional relevance. A common pancreatic cancer risk locus on 9q34.2 in the ABO gene (rs687289) was associated with ABO expression in histologically normal (P=5.8×10^-4) and tumor (P=8.3×10^-9) tissues. A rare loss-of-function variant (rs4643489) in the sodium (Na) channel 5.1 (SCN5A) was significantly enriched in noncoding regulatory regions marked by modified histones, DNAse hypersensitivity and binding transcription factors (47,834 comparisons, FDR=0.05). Results from the human Pancreatic Cancer Genome Project (PCGP) were used to validate these associations. Conclusions: Using data from the Encyclopedia of DNA Elements (ENCODE), we performed cis-eQTL analysis using transcriptome data from the Pancreatic Cancer Genome Project (PCGP) and the Genotype-Tissue Expression (GTEx) project (N=186). We identified a total of 58 genes including SSRP4 at Benjamini-Hochberg adjusted P < 0.05 in at least one dataset and another gene, PAX9, at P < 0.05 with consistent association directions in all three datasets. Using data from the Pancreatic Cancer Genome Project (PCGP), we selected functional SNPs and showed that alternative alleles could significantly change promoter activities of their target genes compared to reference alleles using luciferase reporter assays. The effects of target gene expression for those alleles were in line with eQTL observations. In addition, we validated the genes SETD9 and SSRP4 using Sequenom allelyte technique from 355 adjacent normal breast tissues and observed the allelic-specific expression associated with their index SNPs. This study revealed novel biological mechanisms for associations of genetic susceptibility risk loci for breast cancer.

#1442 Analysis of cis-eQTLs in normal and tumor-derived pancreatic tissues reveals functional insights, including for the 9q34.1 ABO pancreatic cancer risk locus. Laufey T. Amundadottir,1 Soren Lykke Andresen,2 Wenming Xiao,3 Jason Hoskins,4 Lauren Rost,2 Irene Collins,5 Jinping Lin,2 Chad Morabito,4 Bin Sun,3 Robert Kurz,1 Hermann Zeh,3 Jared Zirnello,3 Meredith Yeager,4 Torben Jensen,2 William Bamlet,1 Nilanjan Chatterjee,1 Brian Wolpin,8 Jill Smith,9 Sara Olson,18 Gloria Petersen,6 Jianxin Shi,4 Ming-fang Zhong,1 National Cancer Inst., Bethesda, MD; 2Aarhus University, Denmark; 3Aalborg University Hospital, Denmark; 4Dana Farber Cancer Institute, MA; 5Georgetown University, DC; 6MSK Cancer Center, NY.

GWAS is an important tool for discovering regions in the genome associated with cancer susceptibility. For renal cell carcinoma (RCC), only two loci have had their functional basis explained (11q13 and 12p12). Here, we used a massively parallel reporter assay (MPRA) to investigate enhancer activity in 20 GWAS regions that had an RCC association p-value of at least 10^-7. We selected 784 SNPs with an r^2 > 0.4 or D’ > 0.5 and MAF > 0.05 that had evidence for enhancer activity based on available ENCODE transcription factor or histone ChIP-seq, FAIRE, and DNase I hypersensitive data. The MPRA library was composed of 47461 oligonucleotides 201 bp in length, compiled of 145 bps contained the SNP in the forward or reverse orientation followed by 10 bp of
bar code sequence to allow for identification. Each of the 784 SNPs tested were tagged 10 separate times for both orientations. Controls were constructed by randomizing the 10 nucleotides centered on the SNP. The MPRA library was the cloned into a luciferase reporter vector that was transfected into HEK293T and ACHN cell lines. NGS was performed on 5 replicates using the the Illumina HiSeq 2500 and for multiple NGS runs, SNPs that showed significant p-values. From these 50 SNPs, 29 showed enhancer activity that was independent of the forward/reverse orientation and had the same effect in both cell lines. This analysis has identified possible functional variants at RCC risk loci and opens opportunities to discover new molecular mechanisms of genetic susceptibility of RCC.

#1444 Validation of prostate cancer risk variants by CRISPR/Cas9 mediated genome editing at the MSMB locus. Xing Wang,1 James Hayes,1 Xing Xu,1 Dipti Mehta,2 Xiaoni Gao,2 Hans Lilja,2 Robert Klein1.

With the recent US, being the third most common cancer among both men and women. Carvajal-Carmona.

Cas9 scarless genome editing.

#1447 Identification of an oncogenic germline KRAS truncating mutation in hereditary cancers. Moloy T. Goswami,1 Daniel H. Hovelson,1 Anna John-son,1 Scott A. Tomlins,2 Lucy Wang,1 Kimberly Zhulke,1 Bhavneet Singh,1 Sharath Kumar Anand,2 Andi Cani,1 Albert Liu,1 Steven Kamberovo,2 Yi-Mi Wu,1 Dan Robinson,1 Arul Chinnaian,1 Kathleen A. Cooney,1 University of Michigan, Ann Arbor, MI; 2University of Utah, Salt Lake City, UT.

Somatic strongly activating KRAS mutations play an oncogenic role across numerous human cancers, while less activating germline KRAS mutations are associated with developmental disorders. KRAS encodes two splice variant products—KRAS-4A and KRAS-4B—but differing in their C-terminus through alternative fourth coding exons. Though KRAS-4A is homologous to the original transforming transcript identified in Kirsten rat sarcoma virus, its role in human cancer is less characterized compared to KRAS-4B. Here, through genetic analyses of three cohorts of patients with hereditary and/or aggressive cancers, we identified a rare KRAS-4A specific C-terminal truncating germline mutation (KRAS-4A C180X; rs37319526) in affected men of three families with hereditary prostate cancer and a patient with hereditary melanoma (minor allele frequency [MAF] of 0.0014 in these combined cancer cohorts assessed vs. 0.00056 in the ExAC population database, odds ratio 24.6 [95% confidence interval 5.1-103.5], two sided Fisher’s exact test p = 9.0E-5). The KRAS-4A C180X mutation truncates the C-terminus, removing the polybasic region and -CAAX motifs previously demonstrated to be necessary for Ras family member membrane association, MAP kinase signaling activation and transformation, suggesting a
loss of function phenotype. However, in silico assessment of reported human variation demonstrates truncating germline variants in only KRAS-4A and not KRAS-4B, consistent with tolerance. Expression of KRAS-4A protein in NIH3T3 and MDCK leads to loss of exclusive membrane association and inhibits GTP loading, as expected, but paradoxically resulted in modest but significantly increased proliferation and soft agar colony formation or wildtype KRAS expressing cells. Pro-oncogenic phenotypes were not dependent on MAPK signaling, but showed sensitivity to AKT inhibition. In summary, we identified a germline truncating KRAS-4A mutation over-represented in hereditary cancers that defines a novel mechanism of KRAS activation not dependent on the C-terminal polybasic and -CAAX motifs.

#1448 Unravelling the oncogenic pathway of serrated polyposis syndrome driven by RNF43 germline mutation. Helen Hoi Ning Yan, Jeffrey CW Lai, Sui Lun Ho, Anthony K W Chan, Wai Yin Tsui, Annie S Y Chan, Siu Tsan Yuen, Suet Yi Leung, Dept. of Pathology, Univ. of Hong Kong, Hong Kong, Hong Kong.

Serrated polyps can arise in a sporadic or familial polyposis setting and predispose to colorectal cancer (CRC). Recently, we have identified RNF43 germline mutation in a family with Serrated Polyposis Syndrome (Yan et al, GUT 2016). The presence of second somatic hit in all serrated polyps examined from members of this family further confirmed the pathogenicity of RNF43 germline mutation. In an attempt to further delineate the global genomic alterations in these serrated polyps, so as to understand the RNF43 driven serrated neoplasia pathway for the development of colorectal cancer, we performed whole exome sequencing (WES) on two sessile serrated adenomas (SSAs) resected from an RNF43 germline mutation carrier, together with the paired blood DNA. Consistent with the results from our previous Sanger sequencing study, WES detected complete inactivation of RNF43 through a 2nd hit somatic mutation, c.461 C>T P154L, or loss of heterozygosity (LOH) in the two SSAs, respectively. We also identified 51 and 58 somatic mutations in the two SSAs, respectively. BRAFV600E mutation was the only shared mutation between the two polyps. Interestingly, each of the SSAs carried a truncating mutation in a histone-methyltransferase gene, either PRDM9 or SETD1B, respectively. Other truncating or deleterious mutations included chromatin modifiers (CHD2, CHD4, TSPY2) or other genes with methyltransferase activity (TRMT2B, METTL12, METTL14, EC2E). In addition, we found few instances of chromosomal aberration or LOH, apart from a region of LOH at chromosome 17 encompassing RNF43 in one of the SSAs. Overall, we have revealed the genomic landscape of two sessile serrated adenomas resected from a germline RNF43 mutation carrier. The results confirmed somatic RNF43 2nd hit and BRAFV600E mutation as the key events, along with putative roles for histone methyltransferase, as well as other chromatin modifiers. These findings highlight the potentially important role of an altered chromatin in the oncogenic pathway of serrated neoplasia.

#1449 Germline mutation burden in an endometrial cancer cohort from an integrated health care system. Raghu Metpally, Sarah Babu Krishnamurthy, Dokyoon Kim, Adam Cook, Ashlee Smith, John Nash, Marilyn Ritchie, David Carey, Radhika Gogoi, Geisinger Medical Center, Danville, PA.

Endometrial cancer (EMCA) is the most common gynecologic malignancy in the United States. We sought to explore germline mutations in 301 patients with a diagnosis of EMCA (EMCA cohort), who underwent whole exome sequencing as part of the Geisinger Health System’s (GHS) MyCode project. We additionally compared these mutations to germline and somatic mutations in the TCGA array as well as a non-affiliated cohort at GHS. Whole exome sequencing was performed using 75 bp paired-end resequencing on an Illumina v4 HiSeq 2500 to a coverage depth sufficient to provide greater than 20x haplotype read depth of over 85% of targeted bases in 96% of samples (approximately 80x mean haplotype read depth of targeted bases). Control groups consisted of 1150 female patients over the age of 85 with no cancer diagnosis (Welderly cohort) and the entire Geisinger’s MyCode population of 50,000+ patients (GHS cohort). Somatic and germline mutations in EMCA were downloaded from the TCGA portal. We retrieved somatic mutations from 248 patients as a mutation annotation format (MAF) that consisted of 181,930 point mutations, while 2,931 indels were removed for the comparison. In addition to somatic mutations, germline mutations with the controlled access, obtained as a variant call format (VCF). Demographic characteristics, treatment and outcomes were identified through a manual chart review of the EHR. 2205 coding variants with 30 LOF and 802 missense mutations were noted in the germline. Approximately 24.67% of patients in the EMCA cohort had predictive pathogenic variants compared to control cohort. Genes with most predictive pathogenic variants among EMCA co-

#1450 Alternative splicing analysis identifies mutation hotspots in hereditary breast and ovarian cancer genes. Suzette Farber-Katz, Vickie Huaan, Jayne Hoo, Sitoa Wu, Huy Vuong, Dong Xu, Hsiao-Mei Lu, Phillip Gray, Aaron Elliott, Rachid Karam, Amybr Genetics, Aliso Viejo, CA.

Genetic testing for hereditary breast and ovarian cancer (HBOC) is becoming increasingly widespread in the era of precision medicine. The implementation of next-generation sequencing (NGS) has resulted in an explosion of genetic data. While the majority of patients receive definitive results, germline unclassifiable variants with unknown function are regularly detected in thousands of patients. In particular, variants of unknown significance (VUS) in the HBOC susceptibility genes BRCA1 and BRCA2 pose a quandary to medical providers and patients because these genes are clinically actionable. A large percentage of VUS in BRCA1/2 are predicted to affect splicing. Previous efforts have focused on interrogating splicing VUS using low-throughput and/or imprecise techniques. Therefore, we developed and validated a method for using RT-PCR NGS to accurately and efficiently characterize germline splicing defects. The ENIGMA (Evidence-based Network for the Interpretation of Germline Mutant Alleles) consortium recommends capillary electrophoresis and Sanger sequencing of spliced transcripts as the gold standard to identify the BRCA1/2 transcripts that are present in patient samples. We followed the recommendations of the ENIGMA consortium and were able to largely replicate their results when we analyzed the CDNA of lymphoblastoid cell lines (LCLs) generated by the ConFab consortium from carriers of BRCA1 or BRCA2 variants known to be associated with splicing defects. In addition to LCLs, we analyzed RNA extracted from normal blood controls and normal breast tissue for all BRCA1 gene. We compared our capillary electrophoresis and Sanger sequencing results to our newly developed RT-PCR NGS assay. For this assay, we used RT-PCR NGS technology in our custom in-house bioinformatics analysis to identify splicing events including exon skipping, novel intron insertion, and alternative 5’ donor and 3’ acceptor splicing sites. Capillary electrophoresis allowed us to roughly visualize the various transcripts present in our samples, though sequencing was needed to confidently identify the exact splicing event. Similar to Sanger sequencing, our RT-PCR NGS assay detected all major splicing events. Interestingly, we also identified that RT-PCR NGS allowed us to visualize more minor splicing events present in the samples due to our high coverage. We sequenced tens of thousands of reads with RT-PCR NGS, as opposed to Sanger sequencing, which was limited to low-throughput sequencing of single colonies containing cloned RT-PCR products. In conclusion, RT-PCR NGS is a reliable high-throughput alternative to the gold-standard splicing assays. Our assay will greatly improve the interpretation of splicing VUS detected by clinical genetic tests for BRCA1/2.

#1451 Search for new hereditary breast cancer genes by whole exome sequencing. Ekaterina Sh. Kuligina, Anna P. Sokolonenko, Ilya V. Bizin, Aleksandr A. Romanko, Maria Anisimova, Evgeny N. Imanyinov, N. N. Petrov Research Inst. of Oncology, St. Petersburg, Russian Federation; St. Petersburg State Polytechnical University, St. Petersburg, Russian Federation; St. Petersburg Pediatric Medical University, St. Petersburg, Russian Federation.

Russian population is characterized by pronounced genetic homogeneity and the increased occurrence of recurrent germ-line mutations, therefore it is particularly suitable for the whole exome sequencing (WES) studies. Exome sequencing was performed for 43 breast cancer (BC) cases, which demonstrated evident clinical signs of the hereditary disease (family history and/or BC bilateral heredity and/or young onset) and lacked germ-line mutations in BRCA1, BRCA2, CHEK2, NSB1/NBN and BLM genes. Approximately 52070 nonsynonymous alternative variants were identified; 27503 (53%) of them were absent in 16 analyzed exomes from cancer-free controls. 2204 (4%) variants had sufficiently
low allelic frequency (<1%; ExAC database) and appeared to be functional upon silico assessment (CADD score > 25); this list was composed of 186 frameshift insertions/deletions, 152 stop-gains, 74 essential splice-site disruptions and 1792 potentially pathogenic missense mutations. Presumably causative mutations in the BRCA1 network genes were revealed in 8 patients (truncating mutations: PALB2 (p.Arg1085*, p.Arg3042X), FANCN (p.Ser497fs); or by pathogenic missense mutations: FANCN (p.Arg100Trp, p.Gln819Pro), ERCC4 (p.Arg799Trp), RAD51L (p.Arg399Trp)). For the remaining 35 patients, 57 truncating variants and 109 presumably deleterious missense mutations were further analyzed in a case-control study involving 550 hereditary BC cases and 450 elderly tumor-free controls. The most promising results were obtained for several recurrent. Expression values were normalized by library size read counts followed by a gene-wise normalization. To explore similarity level between samples we used the full matrix of the log2-transformed gene expression values and calculated sample-to-sample distances for each tumor compared to each normal sample, based on the Euclidian distances between samples considering all available genes. We observed that 80% of the BRCA1-mutated and 67% of the BRCA1/2 wild-type samples were clustered together. Also, we detected that BRCA1-mutated TNBC showed, in general, less difference in transcriptional pattern related to normal breast tissue than the BRCA1/2 wild-type TNBC. Moreover, we compared differential expression between normal and tumor samples of each group (BRCA1-mutated and BRCA1/2 wild-type samples) using a linear-based model in DESeq2 program. Based on the observed change $\geq 4$ and FDR $< 0.01$ we identified 6787 differentially expressed genes, in the group of BRCA1-mutated samples, being 722 up regulated and 2087 down regulated in the tumor and 904 DEGs in the group of BRCA1/2 wild-type samples, 399 were upregulated and 505 downregulated in the tumor. Interestingly, both lists of upregulated genes in TNBC of BRCA1-mutated and BRCA1/2 wild-type were significantly enriched in the same molecular pathway involved with the cell cycle and mitosis, according to Reactome Pathways software. Overall, our first observation based on this preliminary data was that, in terms of general gene expression analysis, BRCA1-mutated TNBC has less transcriptional modification in comparison to the normal tissue than the BRCA1/2 wild type and that the tumorigenic process of both groups are similar in terms of defective biological pathway.

### #1452 Interrogating the impact of pregnancy on breast cancer biology using DNA copy number profiling

Bastien Nguyen, David Veret, Christine Rothe, Christine Desmedt, Samira Majjaj, Giancarlo Pruneri, David Brown, Pedro Peccatori, Hatem A. Azim, Cristos Sotiriou, Institut Jules Bordet, Brussels, Belgium; European Institute of Oncology, Milan, Italy.

Background: Epidemiological evidence indicates a clear relationship between pregnancy and breast cancer (BC) risk. However, little is known regarding the impact of pregnancy on BC biology. DNA copy number aberrations (CNAs) play an important role in breast carcinogenesis. BC during pregnancy is a rare disease, however it can be used as a model to study the impact of pregnancy on BC biology. Methods: We retrospectively included 54 pregnant and 113 non-pregnant BC patients matched for age and stage with complete clinic-pathological, gene expression and 5-year follow-up data. CNAs were assessed using Affymetrix Oncoscan FPPE arrays. First, we filtered genes whose expression was driven by CNAs. Then, we identified genes that were differentially affected by pregnancy both at the CNA and the gene expression level. Results: After quality control, CNA profiles were obtained for 38 pregnant and 87 non-pregnant BC patients. There were no significant differences in classical clinic-pathological features (pT, pN, grade, PAM50). We selected 1981 genes whose expression was correlated with CNAs (p $\geq 0.01$). Among these, 77 genes were altered at the expression level (p $\geq 0.01$) between pregnant and control patients, whereas 171 genes were altered at the CNA level (p $\geq 0.05$). Twenty-eight genes were comically altered at the expression and CNA levels which was significantly higher than expected (p = 0.021, permutation test). These genes were mapped on three different chromosomes. Genes located on chr7q and chr1q were associated with copy number gains and were upregulated in pregnant patients whereas genes located on chr22q were associated with copy number loss in control patients. Of interest we identified 6 putative oncogenes (CDK6, ESRRB, S6K2, LIMK2, MKL1) that were up-regulated in pregnant patients. A ‘pregnancy-associated breast cancer signature’ was computed from the expression of the 26 genes. There was a negative relationship between the signature and the expression of ER1 and PR genes. This signature was significantly more correlated with the proliferation-associated AURKA gene in pregnant patients as compared to control (p = 0.73 vs $\rho = 0.24$, p = 0.001). Conclusions: In this study, we were able to identify several genomic alterations associated with pregnancy that could help elucidate the impact of pregnancy on BC risk. Moreover, by combining CNAs with gene expression, we were able to identify genes that could be responsible for the poorer prognosis seen in pregnancy-associated breast cancer and could be potential drivers of this rare disease.

### #1453 Transcriptome analyses in triple-negative breast cancer with BRCA1 germline mutation

Kivi Duarte Nakamura, Elisa Ferreira, Rodrigo Ramalho, Rafael Brianeu, Dirce Carraro, A.C. Camargo Cancer Center, São Paulo, Brazil.

Triple-negative breast cancer (TNBC), characterized by lack of expression of the estrogen receptor (ER), progesterone receptor (PR) and human epidermal growth factor receptor 2 (HER2), is associated with a higher prevalence of germ-line BRCA1 mutations, especially in younger women. TNBC comprises approximately 15% of breast cancer cases and is considered one of the most aggressive subtypes. BRCA1 protein plays a pivotal role in DNA damage repair, cell cycle control and transcriptional regulation. In this context, we aimed to investigate the transcriptional difference of paired tumor and adjacent normal tissue from young patients in two TNBC groups - with or without BRCA1 germline mutation. Fourteen early-onset patients (=41 years), with TNBC previously evaluated for BRCA1/2 germline mutations, were included. From these, nine patients were BRCA1/2 wild-type and five patients were BRCA1 germline mutation carriers. RNAseq libraries were constructed from RNA depleted total RNA extracted from paired tumor and normal adjacent samples and sequenced on Illumina NextSeq 500 platform. Approximately 20 million reads aligned to human genome were generated per sample, revealing about 14,500 expressed genes differentially expressed between groups (fold-change $> 2$, FDR $< 0.05$). In the BRCA1-mutated group of BRCA1-mutated samples, being 722 up regulated and 2087 down regulated in the tumor and 904 DEGs in the group of BRCA1/2 wild-type samples, 399 were upregulated and 505 downregulated in the tumor. Interestingly, both lists of upregulated genes in TNBC of BRCA1-mutated and BRCA1/2 wild-type were significantly enriched in the same molecular pathway involved with the cell cycle and mitosis, according to Reactome Pathways software. Overall, our first observation based on this preliminary data was that, in terms of general gene expression analysis, BRCA1-mutated TNBC has less transcriptional modification in comparison to the normal tissue than the BRCA1/2 wild type and that the tumorigenic process of both groups are similar in terms of defective biological pathway.

### #1454 Estrogen receptor signaling in FTE of BRCA mutation carriers

Leah V. Dodds, Omar L. Nelson, Ramlogan Sowamber, Andres Rodrigues, Victoria de Castro, Wendell Henry, Guillermo Morales, Brian Slomovitz, Patricia Shaw, Sophia H. George, LEONARD MILLER SCHOOL OF MEDICINE, UNIVERSITY OF MIAMI, MIAMI, FL; Princess Margaret Cancer Center, Toronto, Ontario, Canada; University Health Network, Toronto, Ontario, Canada.

Genetic and reproductive factors predicate epidemiological risk factors underlining epithelial ovarian cancer. The fallopian tube epithelia (FTE), the presumptive etiological site of high-grade serous ovarian cancer (HGSC), is a hormonal responsive tissue. Estrogen is known to promote cell proliferation and its metabolism produces reactive oxygen species that damage DNA and promote tumorigenesis. Estrogen receptor (ER) is rarely mutated, amplified or deleted in HGSC, yet only 10% of patients respond to anti-estrogen treatment, suggesting that intrinsic variables to the ER pathway contribute to this clinical outcome. TP53 mutations occur in almost 100% of HGSCs, indicating that mutated p53 supports a model as an early event in the pathogenesis of HGSC. We hypothesized that in the presence of dysfunctional p53, subsequent promiscuous binding of ER will yield aberrant signaling, ultimately significantly contributing to cellular transformation. Mutant p53 and ER co-localize in FTE cells, suggesting potential synergy. We established cell lines with p53 mutations and treated them with estradiol, an estrogen analog, to observe any changes in response. The genome binding sites of ER-regulated transcription factors were then identified and mapped by whole genome chromatin immunoprecipitation-deep sequencing (ChIP-Seq). The cell line model will facilitate the development of gene signatures that will predict response to anti-estrogen therapy in serous ovarian cancer patients, and contribute to the discovery of biomarkers to more accurately identify patients who will benefit from hormonal therapies.

### #1455 Vitamin D receptor (VDR) gene polymorphisms among Sudanese females with breast cancer attending Radio and Isotope Center of Khartoum.

Sara O. Yousif, Amar M. Ismail, Abdelraham O. Mohamed, Abdelrahim O. Mohamed, Neelain Institute for Medical Research, Al-Neelain University, Khartoum, Sudan; Faculty of Medicine, University of Khartoum, Khartoum, Sudan; Neelain Institute for Medical Research, Al-Neelain University, Khartoum, Sudan.

Proteins of the vitamin D receptor (VDR) gene polymorphisms among Sudanese females with breast cancer attending Radio and Isotope Center of Khartoum. Fourteen early-onset patients (=41 years), with TNBC previously evaluated for BRCA1/2 germline mutations, were included. From these, nine patients were BRCA1/2 wild-type and five patients were BRCA1 germline mutation carriers. RNAseq libraries were constructed from RNA depleted total RNA extracted from paired tumor and normal adjacent samples and sequenced on Illumina NextSeq 500 platform. Approximately 20 million reads aligned to human genome were generated per sample, revealing about 14,500 expressed genes differentially expressed between groups (fold-change $> 2$, FDR $< 0.05$). In the BRCA1-mutated group of BRCA1-mutated samples, being 722 up regulated and 2087 down regulated in the tumor and 904 DEGs in the group of BRCA1/2 wild-type samples, 399 were upregulated and 505 downregulated in the tumor. Interestingly, both lists of upregulated genes in TNBC of BRCA1-mutated and BRCA1/2 wild-type were significantly enriched in the same molecular pathway involved with the cell cycle and mitosis, according to Reactome Pathways software. Overall, our first observation based on this preliminary data was that, in terms of general gene expression analysis, BRCA1-mutated TNBC has less transcriptional modification in comparison to the normal tissue than the BRCA1/2 wild type and that the tumorigenic process of both groups are similar in terms of defective biological pathway.

### MOLECULAR AND CELLULAR BIOLOGY / GENETICS: Genomics in Inherited Susceptibility and Preneoplastic Conditions

Proceedings of the American Association for Cancer Research. • Volume 58 • April 2017 373
MOLECULAR AND CELLULAR BIOLOGY / GENETICS: Genomics in Inherited Susceptibility and Preneoplastic Conditions

Background: Vitamin D Receptor (VDR) gene polymorphisms has been reported to be associated with different cancers, including breast cancer. geographical and environmental factors have an impact on vitamin D (VD) metabolism. This study aims to evaluate VDR-gene polymorphisms (FokI, BsmI, TaqI, Apal) and its association with breast cancer risk among Sudanese females. Materials and Methods: This is a case control study done in the Radiotherapy and Isotope Center in Khartoum, Sudan. Hundred thirty seven patients and 69 healthy controls were enrolled after informed consent. Blood genomic DNA was extracted using quinidine chloroform method, and single nucleotide polymorphisms (SNPs) FokI (T/C) [rs2282570], BsmI (G/A) [rs1544410], TaqI (C/T) [rs731236] and Apal (C/A) [rs7975232] in VDR-gene were detected by PCR and restriction enzyme digestion. Genotyping of VDR-FokI was also performed after PCR-RFLP analysis of VDR-SNPs rs731236 correlated significantly with low risk of breast cancer (OR = 0.5, p = 0.002). There was no significant association observed with rs1544410 and rs7975232. Although our study did not show an overall statistically significant association of VDR-SNPs rs2282570 with the risk of breast cancer, we found a 1.3 fold increased risk of breast cancer (OR = 1.3) among females with FF genotype when compared with ff genotype, suggesting that females homozygous for F allele, might be at more risk than females carrying homozygous f allele. Conclusions: These results suggested that, VDR-SNPs rs731236 may be related to higher risk of breast cancer and VDR-SNPs rs731236 associated with lower risk of breast cancer in Sudanese females. Key words: Breast Cancer, VDR, Polymorphisms, SNPs

#1456 Identifying early genetic steps in malignant transformation of neurofibromatosis type 1- associated pleomorphic neurofibromas. Alexander Pesov,1 Alexander Pikarsky,1 Joseph F. Boland,2 Settara C. Chandrasekharappa,2 NIH Intramural Sequencing Center, James C. Mullikin, 2 Margaret Wallace,3 Eric Legius,7 Brigitte Widemann,4 Douglas R. Stewart1. 1Clinical Genetics Branch, Division of Cancer Epidemiology and Genetics, National Cancer Institute, Bethesda, MD; 2Cancer Genetics and Comparative Genomics Branch, National Human Genome Research Institute, Rockville, MD; 3Department of Molecular Genetics and Microbiology, UF Genetics Institute, University of Florida, Gainesville, FL; 4Department of Molecular and Microbiology, UF Genetics Institute, UF Health Cancer Center, University of Florida, Gainesville, FL; 2Department of Medical and Clinical Genetics, University of Helsinki; Research Programs Unit, Genome-Scalse Biology, University of Helsinki, Helsinki, Finland; 7Department of Obstetrics and Gynecology, Helsinki University Hospital, University of Helsinki, Helsinki, Finland; 6Department of Obstetrics and Gynecology, University of Helsinki, Helsinki, Finland; 8Department of Pathology and HUSLAB, Helsinki University Hospital, University of Helsinki, Helsinki, Finland.

BACKGROUND: Neurofibromatosis type 1 (NF1) is a genetic tumor predisposition disorder caused by germline mutations in tumor suppressor NF1. Plexiform neurofibromas (PN) are benign tumors that arise prenatally or early in childhood and affect 30-50% of NF1 population. Somatic inactivation of second copy of NF1 is believed to be primary genetic event leading to PN initiation. NF1 patients have a 10-12% lifetime risk of developing malignant peripheral nerve sheath tumor (MPNST), a highly aggressive soft tissue sarcoma, often arising from pre-existing PN and atypical NF (ANF). ANF are pre-malignant tumors that often arise within PN and can transform into MPNST. They are distinct from both PN and MPNST clinically and histologically, thus representing an intermediate step in malignant transformation. Several studies identified deletion of the CDKN2A/B locus as the most frequent genetic event in ANF, however it is not clear whether other genes or pathways play role in PN transformation into ANF and further into MPNST. In this study, we performed genomic analysis of 16 ANF and 4 MPNST matched with normal DNA obtained from 14 and 4 patients, respectively. METHODS: We performed whole exome sequencing and whole transcriptome RNAseq analyses on Illumina Hi-Seq 2500 platform and copy-number variant (CNV) analysis on Illumina HumanOmniExpressExome-8 SNP-arrays. In addition, we performed deep sequencing of NF1 and validation of select mutations on Ion Torrent platform. For select tumors we estimated growth rate and metabolic activity by using volumetric MRI and FDG-PET. RESULTS: We identified inactivation of NF1 in the majority of ANF and all MPNST. We also detected CDKN2A/B locus deletion in the majority of ANF and sporadic cases of MPNST. We determined that PRC2 genes (EED and SUZ12) were mutated in multiple MPNST but never in ANF. We identified a low number of point mutations and small indels in the genomes of ANF (median 1, range 0-4) and somewhat elevated mutation burden in MPNST (median 23, range 18-31), however none of these mutations were recurrent and none of the mutant genes (other than NF1 and CDKN2A) were present in multiple samples. We found 93 CNV per tumor (median) in ANF that constituted ~2% of their genomes. In comparison, we observed 2,249 CNV (median) in MPNST that comprised ~75% of their genomes. We didn’t detect significant correlation between growth rate or metabolic activity and the degree of genomic instability or mutation burden in the tumors, however the size of the sample set was modest. RNAseq data analysis is pending. CONCLUSIONS: It appears that PN-ANF transition is predominantly if not exclusively driven by heterozygous deletion of the CDKN2A/B locus. Further progression to MPNST likely involves homozygous loss of CDKN2A/B and complete inactivation of the PRC2 complex. Widespread LOH in MPNST may accelerate inactivation of key gatekeepers.

#1457 Somatic biallelic inactivation of fumarate hydratase (FH) in uterine leiomyomas. Jaana Tolvanen,1 Netta Mäkinen,1 Hanna-Rükke Heineinen,1 Sioma Bramante,1 Miika Mehine,1 Nanna Sarvilinna,2 Jari Sjöberg,3 Oskari Heikinheimio,4 Annukka Pasanen,5 Ralf Büttow,5 Lauri A. Aaltoinen,6 1Department of Medical and Clinical Genetics, University of Helsinki; Research Programs Unit, Genome-Scalse Biology, University of Helsinki, Helsinki, Finland; 6Research Programs Unit, Genome-Scalse Biology, University of Helsinki; Department of Obstetrics and Gynecology, Helsinki University Hospital, University of Helsinki, Helsinki, Finland; 7Department of Obstetrics and Gynecology, Helsinki University Hospital, University of Helsinki, Helsinki, Finland; 8Department of Pathology and HUSLAB, Helsinki University Hospital, University of Helsinki, Helsinki, Finland.

Uterine leiomyomas (ULMs) are highly common benign tumors that affect the health of millions of women by causing a variety of symptoms. Furthermore, ULMs are the most common indication for hysterectomy, generating considerable economic costs for the health care system. Recurrent and mutually exclusive genetic aberrations leading to unique gene expression profiles have been identified in ULMs. Thus these tumors can be divided into distinct subclasses according to their molecular genetic background. The majority of ULMs (80%–90%) have mutations in FH, a fumarase enzyme that catalyzes the hydration of fumarate to L-malate in the tricarboxylic acid cycle. Biallelic inactivation of FH leads to accumulation of fumarate and aberrant succinication of proteins. Heterozygous germline FH mutations predispose to a rare autosomal dominant tumor predisposition syndrome, hereditary leiomyomatosis and renal cell cancer (HLRCC). This highly penetrant syndrome is characterized by uterine and cutaneous leiomyomas and in some cases renal cell cancer. In this study, we re-evaluated the frequency of somatic biallelic inactivation of FH in ULMs in the largest sample set thus far. The study material consisted of 1167 fresh frozen ULM and their respective normal myometrium tissue samples from 375 hysterectomy patients. All samples were analyzed with high-throughput SNP array (Infinium Human Core-24+ Kit, Illumina Inc., San Diego, CA). All tumors detected with somatic deletions or loss of heterozygosity (LOH) in the FH locus were included in 5-(2-succinyl) cysteine (25C) immunohistochemistry (IHC) to verify FH inactivation and exclude LOH. In addition, all samples without FH double deletions were selected for Sanger sequencing of FH coding regions to detect inactivating somations. Somatic FH deletions or LOH were detected in 30 tumors, of which 10 were identified FH deficient by 25C IHC. In these samples, another deletion (a double deletion) in three ULMs and a somatic nucleotide change in six ULMs were found to be the second hit causing biallelic inactivation of FH inactivation. These samples were excluded from these methods. From the six somatic nucleotide changes, four were different FH missense mutations predicted to be damaging (SIFT, PolyPhen-2, Provean) and two were synonymous substitutions in the last nucleotide of different exons. Studies to determine the impact of these synonymous changes on splicing are underway. To conclude, in our sample set we detected 0.9% (10/1167) of the ULMs to harbour somatic biallelic inactivation of FH. MED12 exon 1 or 2 mutations and HMGA2 rearrangements were not detected in these tumors. Thus the previously published results were validated in this study with the largest sample set so far.

#1458 Genome-wide association study of unselected prostate cancer cases in Finnish population. Csilla Sipeky,1 Teuvo L. Tammela,2 Anssi Auvinen,2 the PRACTICAL consortium, Johanna Schleutker3. 1Clinical Genetics Branch, Division of Cancer Epidemiology and Genetics, National Cancer Institute, Bethesda, MD; 2Departament of Medical and Clinical Genetics, University of Helsinki; Research Programs Unit, Genome-Scalse Biology, University of Helsinki, Helsinki, Finland; 3Research Programs Unit, Genome-Scalse Biology, University of Helsinki; Department of Obstetrics and Gynecology, Helsinki University Hospital, University of Helsinki, Helsinki, Finland; 4Department of Obstetrics and Gynecology, Helsinki University Hospital, University of Helsinki, Helsinki, Finland; 5Department of Pathology and HUSLAB, Helsinki University Hospital, University of Helsinki, Helsinki, Finland.

Prostate cancer (PrCa) is the second most prevalent cancer in men worldwide, representing the most common cancer in males in Finland with 5043 new cases and with over 850 annual deaths (2013). PrCa has a significant heritable component, with genetic factors accounting for 58% of the risk. Accordingly, genome-wide association studies (GWAS) identified 104 low penetrance PrCa susceptibility loci to date, predominantly in populations of mixed European ancestry. However, effect allele frequencies (EAF) and strength of association (Odds ratio, OR) are often variable across popular...
#1459 Dual-strand tumor-suppressor microRNA-145 and miR-145-3p are involved in castration-resistant prostate cancer pathogene-
sis. Mayuko Kato,1 Akira Kurozumi,2 Yusuke Goto,1 Nijiro Nohata,3 Takayuki Arai,1 Atsushi Okato,1 Keiichi Koshizuka,1 Satoko Kojima,3 Tomohiko Ichikawa,6 Naohiko Seki1. 1Department of Functional Genomics, Chiba University Graduate School of Medicine, Chiba, Japan; 2Department of Medicine, Chiba University School of Medicine, Chiba, Japan; 3Department of Urology, Teikyo University Chiba Medical Center, Ichikawa, Japan; 4Department of Urology, Chiba University Graduate School of Medicine, Chiba, Japan.  
Prostate cancer (PCa) is the most frequently diagnosed cancer and the second leading cause of cancer-related death among men in developed countries. Androgen signaling through the androgen receptor (AR) is an important oncogenic pathway for PCa progression. Most patients initially respond to androgen-depletion therapy (ADT), but eventually acquire resistance and progress to castration-resistant prostate cancer (CRPC). Although several clinical trials for CRPC have been carried out, resulting in the availability of novel chemothera-
peutic agents, these treatments provide limited benefits and are not considered curative. Therefore, identification of effective biomarkers for detection of CRPC and understanding the molecular mechanisms of androgen-independent signal-
ning and metastatic signaling pathways underlying PCA using current genomic approaches would help to improve therapies for and prevention of the disease. The discovery of microRNAs (miRNAs) has resulted in major advancements in cancer research. miRNAs are small noncoding RNAs that function to fine tune the expression of protein coding/noncoding RNAs by repressing translation or cleaving RNA transcripts in a sequence-dependent manner. The unique char-
acteristic function of miRNAs is to regulate RNA transcripts in human cells. Therefore, dysregulated expression of miRNAs can disrupt tightly regulated RNA networks in cancer cells. miRNAs play critical roles in various biological processes, and their dysregulation is shown in several human cancers. In this study, we constructed the miRNA expression signature of CRPC using clinical specimens because the development of therapeutic strategies is a central theme in the advancement of PCA treatments. Using CRPC expression signature data, we investigated the specific roles of miRNAs in PCA and CRPC oncogenesis by examining differentially expressed miRNAs. Based on the CRPC signature, we focused on the dual strand of pre-miR-145, miR-145-5p and miR-145-3p be-
cause these miRNAs were significantly reduced in cancer tissues, suggesting that these miRNAs act as tumor suppressors in this disease. In miRNA biogenesis, it is the general consensus that processing of the pre-miRNA through Dicer1 gen-
erates a miRNA duplex (a passenger strand and a guide strand), and that the passenger strand has degradation and no regulatory activity and disintegrates in cells. Our present data showed that both miRNAs, miR-145-5p and miR-145-3p significantly suppress cancer cell migration and invasion. Moreover, Kaplan-Meier survival curves showed that low expression of miR-145-3p predicted a short duration of progression to CRPC. Dual strand of pre-miR-145 functioned as tumor suppressors based on the miRNA expression signature of CRPC. Iden-
tification of miRNA-mediated cancer networks may provide novel molecular pathogenesis of the disease.

#1460 miRNome analyses reveal that activity of CAF expressed podopla-
nin in tumor microenvironment is modulated by exosome miRNAs involved in the PTEN-P13K-AKT-mTOR signaling. Anna Tejchman,1 Eric Mennes-
son,2 Isabelle Fice,2 Alexandra Foucher,2 Simon Perera,2 Laura Artigas,2 Jose Manuel Mas,3 Catherine Grillon,1 Maciej Ugorski,1 Nadia Normand,2 Claudine Perray En Yvelines, France; 3Anaxomics Biotech, Barcelona, Spain; 4Institute of Immunology and Experimental Therapy, Wroclaw, Poland. In breast cancer, cancer associated fibroblasts (CAF) express podoplanin but little is known about its mechanism of expression and modulation. This might be crucial for cancer cell movements and for the ability to escape from the tumor microenvironment. Podoplanin expression is associated with an immunoinvasive phenotype. A recent study showed that podoplanin expression is a key target for antitumor treatment. A key role in tumor microenvironment is exerted by microRNAs on gene expression. Therefore miRNAs profiling was performed with 3D-Gene microarray technology on a breast CAF model, on cell lysates and on secreted exosomes, in hypoxia versus normoxia culture conditions. Systems biology en-
richment analyses were carried out through bioinformatics using mathematical models that simulate in silico the behaviour of human physiology. Targets linked to the set of differential miRNAs, both up-regulated and down-regulated, have been analyzed with various methods including a hypergeometric distribu-
tion method. Processes linked to hypoxia, glycosylation, angiogenesis, extracel-
ular matrix and pathways associated with P13K-AKT, mTOR, P53 and chemo-
kinase signaling were studied. We showed that podoplanin expression strongly affects the network activity of miRNAs involved in these processes. Hypoxia repression of miR-210, miR-21 and miR-29b in cells over-expressing podoplanin. miR-21 is an oncoprogenic regulator in most cancer cells through its downstream target pro-
teins among which stands the tumor suppressor PTEN, a candidate to alleviate hypoxia in tumors, regulating tumor angiogenesis and modulating tumor hyp-
oxia. miR-29b is a tumor suppressor, it also correlates with PTEN repression. We highlighted miRNA regulation of podoplanin expression through downstream regulation of upstream genes for tumor suppressor PTEN. The combination of miRNome analysis and systems biology bioinformatics uncovered potential miRNAs involved in the regulation of podoplanin activity in CAF. Such data analysis may be applied to protein and miRNA biomarkers and extended to other pathology pathways.

#1461 miR-424-cdc42, key signaling axis in hyperglycemic regulation of stromness in triple negative breast cancer. Sushmitha B. Nandy,1 Alexis Orozco,1 Gautham Prabhakar,1 Viktoria Stewart,1 Stephanie Jones,1 Paloma Munoz,1 Raha Madevi Subramaniam,2 Diego Pedroza,1 Rajkumar Lakshmanaswamy3. 1Texas Tech Univ. Health Sciences Ctr. El Paso, El Paso, TX; 2University of Texas at El Paso, El Paso, TX. Introduction: Meta-analysis shows women with diabetes have a 20% in creased risk of breast cancer compared to those without diabetes. It has been hypothesized that hyperglycemia enhances stem cell activity in triple negative breast cancer (TNBC) cells. Here, we report miR-424 to be a key regulator of breast cancer stem cell pool dynamics under hyperglycemic environment. Materials and Methods: MDA-MB-231, TNBC cell line was maintained under euglycemic (5mm) and hyperglycemic (10mm) culture conditions. RT-PCR based miRNA array was performed followed by validation of significantly altered microRNA to confirm the effect of hyperglycemia on the global microRNA profile. Flow cytometric analysis for CD44+CD24− was performed to assess the alterations in breast cancer stem cell population. In addition, sphere-forming assay were also performed. Mir-424 over-expressing or knocked down cell lines were established from parental MDA-MB-231 cells and maintained in hyperglycemic or eugly-

cemic condition respectively. Promoter analysis for PR/SET domain 14 (pmd14) was done. Western blotting and immunofluorescence assays were performed for cdc42 (cell division control 42), pStat5 (phospho signal trans-
ducer and activator of transcription factor 5) and pmd14. Results: Loss of miR-

424 in TNBC cells under euglycemic conditions led to enhanced stem cell activity; whereas over expression of miR-424 under hyperglycemic conditions resulted in suppressed stem cell activity. Introduction of cdc42, (a miR-424 target gene) in miR-424 over expressing TNBC cells under hyperglycemic con-
ditions led to increased stem cell activity demonstrating the role of miR-424-cdc42 signaling in hyperglycemia. Over-expression of miR-424 in miR-424 dramatically reduced its metastatic abilities in vivo. Mechanistically, we found that miR-424-cdc42 signaling in hyperglycemia promotes Pmmd14 activation, a stem cell regulator through increased phosphorylation of Stat5.
Conclusions: Our findings establish a key molecular signaling cascade (miR-424→cdc42→prdm14) that promotes TNBC stem cell activity under hyperglycemic conditions.

#1462 Exosome-derived miR-429 contributes to prostate cancer chemoresistance. Yang Liu,1 Liye Xie,1 Jing Li,1 Atsushi Mizokami,2 Evan T. Keller,2 Yi Lu,1 Jian Zhang,1 3 Guangxi Medical Univ., Nanning, China; 2Kanazawa University, Kanazawa, Japan; 3University of Michigan, Ann Arbor, MI.

Prostate cancer (PCA) is the most common cancer in men and the 2nd leading cause of cancer-related death in the United States. Certain miRNAs, act as tumor promoting or inhibiting factors in tumor development, function primarily by targeting specific miRNAs for degradation or inhibition of translation of their targeted proteins. Emerging evidence indicates that exosomes play a key role in tumor-host crosstalk, and exosome secretion, composition, and functional capacity are altered as tumors progress to aggressive phenotypes. From our prior report, we have constructed a potential network of 29 deregulated miRNAs, including 19 up and 10 down, in exosome samples derived from two kinds of paclitaxel resistant PCA cells (PC3-TXR and DU145-TXR) compared with their parental cells (PC3 and DU145). In this study, to further determine the roles of certain miRNAs derived from exosomes in chemoresistant cells, we firstly confirmed the lower expression level of miR-429 mRNA in the exosomes derived from the paclitaxel resistant PCA cells compared to their parental cells. In addition, when the miR-429 was over-expressed in PC3-TXR and DU145-TXR cells by stable transfection, epithelial-to-mesenchymal transition (EMT) markers significantly altered together with morphological changes. Overexpression of miR-429 decreased the adhesion and cell attachment to the outer surface associated with inactivation of PI-3K/AKT and Notch signaling pathways since the pathway specific inhibitors significantly diminished the transacted tumor cell migration and invasion. Finally, we found that overexpression of miR-429 significantly enhanced chemosensitivity of the chemoresistant PCA cells. These data suggested that exosome-derived miR-429 contributes to PCA chemoresistance and miR-429 may become a potential therapeutic target for PCA patients. This work was supported by Natural Science Foundation of China (NSFC) Key Project (81130046); NSFC (81171993; 81272415); Guangxi Projects of China (2013GXNSFAA007177; 1535004-5; 201202004; GZ2FT13-35; 1123000021; 11-031-05-K2; KY2015BS07; 1404-05-12-K2).

Metastatic cancer cells often use directional ECM cues such as blood vessels or collagen fibers when invading through live tissue. Oncogenic miRNAs have been implicated as key regulators of cancer progression yet the systemic discovery of miRNAs that drive directional cancer cell invasion has not been achieved. Here we describe the first in vivo quantitative whole human miRNAome screen for miRNA drivers of directional cancer cell invasion using an ex ovo avian embryo model of human cancer cell metastasis combined with high resolution intravital imaging. We identified more than twenty novel miRNAs that promote cancer cell invasion during the key rate-limiting step of cancer metastasis, the initiation of invasion. In mechanistic studies, we found that deregulation of the miRNA in the HCC1806 and BT549 TNBC cell lines, derived from an AA and NH patients, respectively, and 49 adjacent normal tissue (ANTs) were used as control for the subtype and tumor specificity, respectively. Our results showed a significant down-regulation of miRNA-661 in the TNBC of AA when compared to the NHW and to verify it is directly role in affecting the aggressive TNBC phenotype. MiRNA-661 expression analysis was conducted by RT-qPCR in the tumor tissue of 31 AA-TNBC patients and 17 NHW-TNBC patients. AA and NHW samples of 40 and 20 non-TNBC subtype, respectively, and 49 adjacent normal tissue (ANTs) were used as control for the subtype and tumor specificity, respectively. Our results showed a significant down-regulation of miRNA-661 expression in TNBC of AA in relation to the NHW (P<0.0001) and between the AA-TNBC and non-TNBC subtypes (P<0.001). MiR-661 was also significantly differentially expressed in the ANT when compared to the tumor tissue (P<0.001). In addition, ROC analysis showed a high power of this miRNA in discriminating the TNBC genome of AA and NHW women (AUC=0.79 (0.65-0.92), 95%CI). Modulation of the expression of this miRNA in the HCC1806 and BT549 TNBC cell lines, derived from an AA and NHW patient respectively, using inducers/repressors systems, showed its direct effect in cell proliferation, migration and cytotoxicity. Interestingly these effects were more pronounced under hypoxic conditions. These data indicate that miRNA-661 dysregulation is associated with TNBC of AA women, and directly impacts their tumor phenotype. The uncovering of the molecular mechanisms that dictates these effects, specially the ones that modulate drug response, is critical for patient selection and stratification into novel and efficient target therapies. This much needed knowledge would lead to potentially personalized treatment for young AA patients, that are commonly affected by the TNBC aggressive phenotype. Funding: This project was supported by the Georgetown University Center of Excellence in Regulatory Science and Innovation (CERSI U1O1FD004319), a collaborative effort between the university and the U.S. Food and Drug Administration to promote regulatory sci-
Triple negative breast cancer (TNBC) refers to a group of highly heterogeneous malignant tumors that lack estrogen receptor and progesterone receptor expression, and human epidermal growth factor receptor 2 amplification, accounting for 10-20% of newly diagnosed breast cancer cases. Compared to other subtypes of breast cancer, TNBCs usually show worse clinical features such as more rapid tumor growth, earlier recurrence, and more aggressive metastasis. Unfortunately, the mechanism of TNBC metastatic behavior has not been well understood. Moreover, no efficient targeted therapies for TNBCs are currently available, representing a real unmet need for effective new therapies. MiR-200 family members are among the first miRNAs reported to function as potent inhibitors of cancer metastasis. However, the mechanism of miR-200 family on cancer metastasis has not been well studied. In this study, we explore the effect of miR-200b, one member of the miR-200 family, on TNBC metastasis using cell culture and mouse orthotopic mammary xenograft tumor models. We found that the expression level of miR-200b is significantly lower in TNBC cells and tissues than that in other types of breast cancer. Stably expressing miR-200b significantly reduced TNBC cell migration and invasion and suppressed TNBC metastasis in a mouse orthotopic mammary xenograft tumor model. Mechanistic studies revealed that miR-200b overexpression in TNBC cells caused drastic changes in cellular actin cytoskeleton organization patterns as evidenced by reduced lamellipodia formation but increased stress fiber formation. In consistent with these findings, Rho GTPase pull-down assays demonstrated that stably expressing miR-200b significantly increased the Rho GTPase Rho A activation, but reduced Rho GTPase Rac activation. Moreover, inhibition of Rho A signaling impaired the inhibitory effect of miR-200b on TNBC cell migration. Bioinformatics analysis indicated that ARHGAP18, a specific Rho A GTPase activating protein (GAP), is a predicate target of miR-200b. Further Q-PCR, Western blot and 3’UTR reporter analysis confirmed that ARHGAP18 is a target of miR-200b. Knocking down ARHGAP18 in TNBC cells using siRNAs significantly increased Rho A activation but reduced Rac1 activation. To further determine the role of ARHGAP18 in TNBC, ARHGAP18 knockdown TNBC cells were generated using the CRISPR technology. It was found that knocking down ARHGAP18 phenocopied the effect of miR-200b overexpression. Moreover, overexpressing miR-200b in miR-200b stable expression cells overcome the inhibitory effect of miR-200b on TNBC metastasis. Together, these findings suggest that miR-200b suppresses triple negative breast cancer metastasis by targeting ARHGAP18 and enhancing Rho A activation.

Cancer is characterized as a loss of normal cellular regulation, due to accumulations of mutations and epigenetic alterations in cancer cells. MicroRNAs (miRNAs) regulation of co-stimulatory and immune checkpoint pathways have been implicated as one of the potential mechanisms for cancer evasion in immuno-oncology. It is estimated that 30% of all mRNA expression may be regulated by miRNAs, and some are either oncogenic or tumor suppressive. Complexity of miRNA regulation highlights the need for integrated assays, providing direct correlation between miRNA and mRNA, and protein expression. From a single 4 μFPE section, MultiOmyx™ Hyperplexed immunofluorescent assay (designed to stain up to 60 protein biomarkers) is utilized to measure CD3, CD4, CD8, CD16, CD56, Granzyme B, FoxP3, ICOS, CX04, CX04L, PD1, PD1L, HLA-DR, and Ki67 protein expression. From an adjacent 10 μm section, NanoString™ nCounter PanCancer Immune Profiling Panel and Human v3 miRNA expression panel were utilized to comprehensively profile the expression of 770 mRNA and 800 miRNA. Integrating MultiOmyx and NanoString technologies, the current study measured miRNA, mRNA, and protein expression in lung, head and neck, breast, and melanoma samples. For each indication, three samples were selected from a larger sample set, based on high protein expression of lymphocytes and macrophage markers (CD3, CD4, CD8, CD16, CD56). Results: In this study, we investigated the co-stimulatory and immune checkpoint markers (PD1, PD-L1). Protein expression results indicate positive correlation between expression of ICOS and OX40 with higher infiltration of T-helper (CD3 + CD4+), T cytotoxic (CD3 + CD8+), and effector T cells (CD3 + CD8 + Granzyme B). NanoString normalized mRNA counts for the protein biomarkers profiled indicate that all markers except for HLA-DR belong to lower expressor groups with counts ranging from 20-700. Comparison of protein expression to mRNA counts revealed inconsistencies in modulated markers (PD1, PD-L1, ICOS, CX04) which are attributed to differences in population of cells between the two sections. Direct assessment of up regulation of mRNA and down regulation of target miRNA could not be made for miRNAs reported in...
MOLECULAR AND CELLULAR BIOLOGY / GENETICS: MicroRNA Regulation of Cancer Biology 2

literature as a negative regulator of PD-L1 (miR-34a, 34b, 34c), PD1 (miR-28, miR-107), FoxP3 (miR-210, miR-24, miR-31), and ICOS (miR-101). Analysis of multiple miRNAs (combinatorial targeting) mapped in context to mRNA, and their respective protein expression will be presented from lung, head and neck, breast, and melanoma cancer samples.

#1470 Fine-tuning the expression of heterogeneous network of genes involved in androgen signaling, aerobic glycolysis, apoptosis and epithelial-mesenchymal transition by microRNA-644a in prostate cancer potentiation of AR signaling therapy by miR-644a: Selective manipulation of the prostate cancer transcriptome by miR-644a. Jey Sahib Ethron, Jagjit Singh, Sawai Shankar, Crystal Weyman, Sanjay Gupta, Daniel J. Lindner, Girish C. Shukla.

Intratumoral Prostate cancer (Pca) heterogeneity is characterized by multiple intrinsic mechanisms including Androgen signaling, aerobic glycolysis, aberrant transcriptional activation of c-Myc and dysregulation of miRNAs. The ability of prostate cancer cells to alter growth and metabolism in a manner distinct from benign cells is a major concern in the treatment of castration-resistant prostate cancer. Therefore, targeting the diverse oncogenesis promoting pathways involved in Pca progression and resistance at the posttranscriptional level using micro RNAs (miRNAs) offers a novel therapeutic option. Using a miRNA mimic screen, we identified a human-specific miRNA miR-644a, which modulates expression of a diverse set of oncogenic pathways in Pca. Using a panel of five Pca cell lines we discovered that c-Myc expression is higher in aggressive CRPC cell lines when compared to the indolent E006AA PCa cell line. Our recent evidence has shown that a miRNA, miR-6855-3p, binds to the primary PRDX5 transcript between the two AUG codons and prevents the translation of the mRNA from the first AUG codon but not from the second AUG codon thus favoring the initiation of translation from the second AUG codon. To characterize the effect of miR-6855-3p on Prdx5 mRNA translation, we developed three different PRDX5-FLAG constructs in pC3VXFLAG1 (Sigma) that has Prdx5 ORF with or without mutation on the first or second AUG codon. Transfection of these constructs into BT549 cells followed by treatments with miR-6855-3p mimic or antagoniri and subcellular fractionation further supported our notion. We propose here that miR-685-3p acts as a tsmIR by promoting the biosynthesis of the transcriptional regulator protein PRDX5 which enhances the expression of the tumor suppressor protein BRCA2 leading to the genotoxic and radiation-resistance of aggressive SLUG-high basal-like breast cancer cells. Supported in part by DOD-CDMRP IDEA Expansion Grant# BC130645 and NIH/NCI grant 1R21CA181920 01 to GC and 1U54RR026140 to SM.

Prostate cancer (Pca) is the most common non-skin cancer and the second leading cause of cancer-related death for men in the U.S. A major challenge is understanding the molecular mechanisms involved in the progression from the asymptomatic androgen-dependent Pca to the lethal castration resistant prostate cancer (CRPC). The chromosomal region 8q24 is associated with aggressive Pca. miR-1207-3p and variants of this region have been identified to interact with the PVT1 non-coding gene in Pca. In previous work we demonstrated that microRNA-1207-3p (miR-1207-3p) has prognostic value in Pca, and directly binds to the 3’ UTR of Fibronectin type III domain containing 1 (FNDC1) to regulate a novel FNDCl/fibronectin (FN1)/androgen receptor (AR) pathway upregulated in metastatic Pca. miR-1207-3p is encoded at the PVT1 gene locus, which is located downstream of c-Myc on the 8q24 human chromosomal region. Studies have suggested amplification at the 8q24 human chromosomal region, which includes C-Myc, as a possible prognostic factor for CRPC. c-Myc is a well-established proto-oncogene that is commonly found to be amplified in up to 72% of CRPCs significant amplification of c-myc has been a consequence of androgen treatment, and c-Myc is downstream of AR in some Pca. miRNAs have been implicated in the regulation of c-Myc. Nevertheless, the mechanisms regulating c-Myc remain unclear in Pca. Using a panel of five Pca cell lines we discovered that c-Myc expression is higher in aggressive CRPC cell lines compared to non-aggressive CRPC and androgen-dependent prostate cancer cell lines. Furthermore, our data reveals that c-Myc expression is higher in the aggressive E006AA-hT Pca cell line when compared to the indolent E006AA Pca cell line. This suggests that c-Myc is associated with aggressive Pca. Moreover, overexpression of miR-1207-3p suppresses the expression of c-Myc in E006AA-hT Pca cells but not E006AA Pca cell line in which c-Myc is underexpressed compared to the normal prostate epithelial cell line, RWE1. Next, using a synthetic biotinylated miR-1207-3p duplex, we discovered that overex-
pression of miR-1207-3p more effectively inhibited migration, proliferation and increased apoptosis in the aggressive E006AA-IT PCa cell line with increased c-Myc expression when compared to the indolent E006AA PCa cell line with decreased c-Myc expression. These data demonstrate that the miR-1207-3p/FNDC1/FN1/AR pathway may regulate c-Myc in aggressive PCA.

#1474 Epigenetic silencing of microRNA-137 enhances ASCT2 expression and tumor glutamine metabolism. Xiao Daibiao,1 Junli Dong,1 Zihan Zhao,2 Ping Ren,3 Cong Li,1 Yufeng Hu,1 Jianguo Shi,1 Hexiu Su,1 Zhaoqiao Wang,1 Hudan Liu,1 Bo Li,1 Peng Gao,1 Guoliang Qing1,2,3Medical Research Institute of Wuhan University, Wuhan, China; 2The Second Hospital of Dalian Medical University, Dalian, China; 3Hubei University of Science and Technology, Xianning, China; 4Medical School of Medicine of Sun Yat-Sen University, Guangzhou, China; 5Affiliated Union Hospital of Tongji Medical College, Wuhan, China; 6Affiliated Dalian Sixth People's Hospital, Dalian, China.

Cancer cells amplify the expression of ASC amino acid transporter 2 (ASCT2, also called SLC1A5), a high-affinity glutamine carrier protein, to coordinate metabolic reprogramming and malignant transformation. Yet genetic and/or epigenetic mechanisms underlying the control of ASCT2-mediated glutamine metabolism remain to be clarified. Combined in-silico algorithms with systemic experimental screening, we herein identify the tumor suppressor miR-137 as an essential regulator that targets ASCT2 mRNA and cancer cell glutamine metabolism. Metabolic analysis shows that miR-137 derepression, similar to ASCT2 inactivation, significantly inhibits glutamine consumption and TCA cycle anaplerosis. Moreover, miR-137 enhances methyl-CpG binding protein 2 (MeCP2) and DNA methyltransferases (DNMTs) expression which cooperatively methylates the ASCT2 promoter and its decreased transcription, which conversely enhances ASCT2 expression and glutamine metabolism. As such, expression between miR-137 and ASCT2 is inversely correlated in multiple human cancer types, including colorectal carcinomas, glioblastomas, prostate and pancreatic cancers. These findings thus elucidate a universal mechanism responsible for ASCT2 deregulation in human cancers, revealing a molecular link between miR-137, ASCT2 and tumor metabolism.

#1475 miRNA-450a suppresses adhesion but promotes invasion through targeting of TMEM182 in oral squamous cell carcinoma. En-Wei Hsing,1 Shin-Gwo Shah,1 Ching-Chuan Kuo,1 Jing-Yang Chang2. 1National Health Research Institutes, Miaoli, Taiwan; 2National Health Research Institutes, Taichung, Taiwan.

Our microRNA (miRNA) expression signatures of oral squamous cell carcinoma (OSCC) revealed that miR-450a was significantly increased in cancer tissues compared with normal epithelium. In this study, we focused on the functional significance of miR-450a in cancer cells and identification of miR-450a-regulated novel targets in OSCC. Overexpression of miR-450a in DOK and SAS cells showed significant inhibition of cell adhesion and induction of cell invasiveness, suggesting that miR-450a functions as an onco-miRNA. We performed genome-wide gene expression analysis to search for miR-450a-regulated molecular targets. Gene expression data and luciferase reporter assays revealed that TMEM182 was directly targeted by miR-450a. The miR-450a-reduced cellular adhesion was blocked by TMEM182 restoration, suggesting that miR-450a inhibits the cellular invasiveness through targeting TMEM182. Moreover, miR-450a expression could be induced by the cytokine TNF-α primarily through activating extracellular signal-regulated kinase (ERK) signaling pathway. ERK inhibitor prevented the TNF-α-induced miR-450a expression and enhanced adhesion ability. Taken together, these data indicate that TNF-α/ERK-dependent expression of miR-450a plays an important role in mediating cellular adhesion and invasiveness, and scavenging miR-450a function using antamir may have therapeutic potential for the treatment of OSCC. (The study was supported by the following grants: MOST 103-2320-B-006-036-MY3 and MOST 105-2325-B-400-001 from the Ministry of Science and Technology of Taiwan, ROC)

#1476 Cell-free miR-141 as a molecular marker for prostate cancer metastasis. Marilena de Souza,1 Ilce Mara de Syllos Cólus,1 Aline Simonetti Tainan, Taiwan; 2Laboratorio de Investigação Molecular do Cancer - LIMC/FAMEP, São José do Rio Preto, Brazil; 3Departamento de Genética/Faculdade de Medicina - USP, Ribeirão Preto, Brazil; 4Laboratorio Nacional de Bionociencias/Concepción Universidad, Concepción, Chile; 5Laboratorio de Investigação Molecular do Cancer - LIMC/FAMEP, São José do Rio Preto, Brazil; 6Departamento de Genética/Faculdade de Medicina - USP, Ribeirão Preto, Brazil; 7Laboratorio Nacional de Bionociencias/Concepción Universidad, Concepción, Chile.

Metastatic prostate cancer is the second most commonly diagnosed neoplasia in men. Currently, there is no available non-invasive tool to assist in the identification of prostate cancer. MicroRNAs are a class of non-coding RNAs, that are shown to impact the development and progression of prostate cancer and their detection in plasma have been indicated as a promising non-invasive tool for disease screening and prognosis assessment. Among the several deregulated miRNAs that are observed in prostate cancer, the miRNA-141-3p was observed with upregulated expression levels in prostate cancer, particularly in the metastatic lesions. Therefore, the main aim of this study was to evaluate the diagnostic potentiality and clinical performance of miR-141 as a potential new molecular tool that can be useful in the diagnosis of prostate cancer and determine its functional role in modulating tumorigenesis in prostate cancer metastatic cell lines. MiR-141 expression analysis was performed in plasma samples of 102 prostate cancer patients without treatment and of 50 health controls by RT-qPCR. The experimental assays were performed by transfecting the PC3 cell line using miRNA-141 mimic/ inhibitor systems and directly accessing its regulatory regions on the TCA cycle enzymes expression. The expression of the miR-141 was found significantly upregulated in the metastatic patients’ plasma specimens (FC=9.11, p=0.04; AUC=0.66) when compared to the patients without metastasis, showing its screening potential for prostate cancer metastasis. The in vitro ectopic expression of miR-141 in PC3 cell line showed a significant increase in cell proliferation, associated with changes in cell cycle (decreased number of cells in the G1 phase). Conversely, the inhibition of miR-141 showed an increase in the migratory ability, cell adhesion and in the Doxetaxel cytotoxicity of the PC3 cells. Western-blot analysis showed that the inhibition of the miR-141 levels reduced the expression of the EMT inducers markers E-CADHERIN and CLAUDIN, and up-regulated the levels of ZEB-1, pAKT and VIMENTIN, consistent with their repression roles in the EMT process. These findings showed that miR-141 presents a direct function in controlling the phenotypic changes in vitro and the molecular mechanisms involved in the regulation of the epithelial-mesenchymal transition expression proteins. In conclusion, miR-141 presents a potential use as a minimally invasive molecular marker for prostate cancer diagnosis and can be used as a druggable target for therapy, particularly in the metastatic clinical setting.

#1477 Melatonin regulates the tumor suppressor miR-148a-3p involved in angiogenesis and metastasis of breast cancer. Debra Zuccari,1 Jessica Zani Lacerda,1 Lívia Carvalho Ferreira,1 Beatriz Camargo Lopes,2 Andréis Felipe Aris-Izabal-Pachón,1 Marcio Chaim Baigelman,1 Fabio de Medica de Sao Jose do Rio Preto - FAMERP, Sao Jose do Rio Preto, Brazil; 2Universidade Estadual Paulista - UNESP, Sao Jose do Rio Preto, Brazil; 3Laboratorio de Investigacao Molecular do Cancer - LIMC/FAMERP, Sao Jose do Rio Preto, Brazil; 4Departamento de Genetica/Faculdade de Medicina - USP, Ribeirao Preto, Brazil; 5Laboratorio Nacional de Bionociencias/Concepcion Universidad de Ennergia y Materias - CNPEN, Campinas, Brazil.

Women with breast cancer has the tumor progression and angiogenesis-induced metastasis as the main cause of death. MicroRNAs (miRNAs) are small noncoding mRNA molecules that play an important role in gene regulation and once deregulated, these molecules may be involved with the progression of different human tumor types, including breast cancer. These miRNAs play an oncogenic role on tumor suppressor genes and regulate the process of angiogenesis, tumor growth and metastasis. So as new possible adjuvant treatment against breast cancer our group have shown melatonin, that is a hormone secreted by the pineal gland, by exhibiting several anti-tumor and antiangiogenic effects. Therefore, the aim of this study was to evaluate the potential therapeutic of melatonin on miRNAs regulation to verify breast cancer progression and potent tumor suppressor miR-148a-3p. In silico analysis was performed for selection of miRNAs involved in breast cancer. The MDA-MB-231 breast cancer cell line (metastatic negative estrogen receptor) was grown and separated in two different experimental conditions maintained for 24 hours: control group and melatonin-treated group (concentration of 1 mM). After this period the extraction of total RNA was performed (Qiagen®) and the total concentration of miRNAs of each sample was determined (Nanodrop Spectrophotometer 2000C - Thermo Scientific®). Differential expressions of these miRNAs was evaluate using miScript miRNA PCR-Array (Qiagen®) containing 84 miRNAs associated with breast cancer. The overexpression of miR-148a-3p in MDA-MB-231 cells was performed by bacterial cloning vector and the relative quantification of gene expression of their target IGF-1R and VEGF by real-time PCR. Moreover, the expression of the miR-141 were found overregulated with changes in cell cycle (decreased number of cells in the G1 phase). The invivo ectopic expression of miR-141 in PC3 cell line showed a significant increase in cell proliferation, associated with changes in cell cycle (decreased number of cells in the G1 phase). Conversely, the inhibition of miR-141 showed an increase in the migratory ability, cell adhesion and in the Doxetaxel cytotoxicity of the PC3 cells. Western-blot analysis showed that the inhibition of the miR-141 levels reduced the expression of the EMT inducers markers E-CADHERIN and CLAUDIN, and up-regulated the levels of ZEB-1, pAKT and VIMENTIN, consistent with their repression roles in the EMT process. These findings showed that miR-141 presents a direct function in controlling the phenotypic changes in vitro and the molecular mechanisms involved in the regulation of the epithelial-mesenchymal transition expression proteins. In conclusion, miR-141 presents a potential use as a minimally invasive molecular marker for prostate cancer diagnosis and can be used as a druggable target for therapy, particularly in the metastatic clinical setting.
known being involved in the progression of breast cancer. Thus the establishment of this therapeutic protocols can control these cellular events essential for the prognosis of patients with breast cancer.

#1478 Curcumin inhibits epithelial-mesenchymal transition and invasion in breast cancer cells by controlling miR-34a expression. Marcela Gallardo, Richard Poncc-Cusi, Gloria M. Calaf. Universidad De Tárapaca, Arica, Chile.

Breast cancer in advanced stages tends to develop metastases and/or chemoresistance, in both cases therapeutic options are limited and have low probability of success, which represents the biggest obstacle in reducing mortality from this disease. There is a close connection between the Epithelial-Mesenchymal Transition (EMT) process of cancer cells and the acquisition of invasive and metastatic ability. Numerous EMT mediators have been described in cancer and among them miRNAs play a fundamental role in regulating such process, suggesting that it could be a therapeutic target to address this phenotype. Curcumin (diferuloylmethane) is a derivative compound of Curcuma longa that has therapeutic properties in various cancers as blocking initiation and tumor progression through its anti-inflammatory, antioxidant, proapoptotic, antiangiogenic and antimetastatic effects. The role of curcumin on EMT in non-cancerous breast cells MCF-10F and in breast cancer cell lines MCF-7 and MDA-MB-231 was evaluated. This work shows that in all these cell lines curcumin induced the expression of tumor suppressor microRNA miR-34a and repressed the expression of several genes involved in EMT and metastasis as Axl, Slug, Twist, N-cadherin, vimentin, fibronectin, among others. Consequently, curcumin inhibited the migration and invasiveness in these cells, irrespective of the expression of estrogen and progesterone receptors and p53 mutational status. Blockade of EMT induction with anti-cancer drugs is significant for curcumin on EMT genes and on the migratory/invasive potential of cells indicating that miR-34a plays a central role in the Curcumin-mediated suppression of EMT and invasion. Therefore, results confirm the suppressive effect of curcumin on EMT and invasion in breast cancer cells, showing that such substance exerts this effect by inducing expression of miRNA miR-34a and consequently the repression of several of its target genes. Supported by Tárapacá University, Arica, Chile (GMIC).

#1479 Differential expression of microRNAs in transformation of follicular lymphoma to diffuse large B cell lymphoma. Katerina Musilova,1 Gabriela Pavlova,1 Vaclav Seda,1 Eva Vojackova,1 Katerina Cerna,1 Veronika Svobodova,2 Robert Pytlík,2 Vit Prochazka,3 Zuzana Prouzova,3 Sarka Pospisilova,4 Lenka Zlakind,5 Marcela Gallardo,6 Siddarth Sharma,2 Jared Kevern,3 Emma Borrego-Diaz,4 Mukut Sharma2.

MicroRNAs (miRNAs) are important post-transcriptional regulators of gene expression, and are frequently aberrantly expressed in cancer. We aimed to understand the role that miRNAs play in transformation of follicular lymphoma (FL) into an aggressive diffuse large B cell lymphoma. This happens in ~3% of cases per year during the course of the disease, and is associated with median survival of only 2 years. The NGS revealed number of alterations associated with transformed FL (tFL), including frequent high-level activity of MYC (amplifications, translocations, and mutations) or loss of DNA damage regulators (p53, CDKN2A/B). Firstly, we performed a miRNA profiling (TaqMan miRNA Arrays) in paired FL and tFL samples (N=8 pairs). This revealed a relatively small group of 5 miRNAs that are consistently differentially expressed in FL (P<0.05, fold-change >1.5). Since the most frequently acquired aberration in tFL is the high-level activity of MYC we performed a correlation analysis of MYC levels and expression of these miRNAs in additional samples of FL, tFL, and CLL samples with/without MYC duplication (N=40 FL/tFL, N=39 CLL). This analysis revealed that at least one of these miRNAs is significantly down-regulated in FL samples (P<0.05) in cases with high-levels of MYC. The MYC-mediated repression of miRNA levels was also observed (P<0.05) in B cells from transgenic MYC over-expressing mice (MYC controlled by an Ig-alpha enhancer) in comparison to wild-type animals (samples obtained from young animals before occurrence of any malignancy). We have further shown that the levels of this miRNA repress B cell proliferation in vitro and its low-levels associate with percentage of Ki67 positive cells in FL samples (P<0.005). Moreover, low levels of tFL-associated miRNA were present in FL cases with a shorter overall survival (P<0.01), and its expression directly affected BCR signalling (calcium flux assay after anti-IgM). We have shown that the expression of this miRNA is not only down-modulated by high-level MYC expression, but also by B cell adhesion to stromal cells in co-culture in vitro (HS-5 stromal cells). This suggests that its normal physiological function might be related to regulation of B cell functions in the context of immune niches, and this might play a role in FL progression and transformation. It remains to be elucidated what other molecular mechanisms ensure low-level expression of the studied miRNA in cases with low-level MYC overexpression and what could not efficiently up-regulate this miRNA in FL cells. #1480 Mir-182 is involved in sulindac anticancer activity in colon cancer. Hongyou Zhao, Bin Yi, Zhipin Liang, Ruixia Ma, Yaguang Xi. Louisiana State University Health Sciences Center, New Orleans, LA.

Nonsteroidal anti-inflammatory drugs (NSAIDs) display promising antineoplastic activity in many human solid tumors including colorectal cancer. Previous studies reported that sulindac sulfide (SS) can inhibit the growth of tumor cells through cyclooxygenase-2 (COX-2) dependent or independent pathways. Obviously, COX-2 independent pathway involves a low toxic property to support the clinical potential for using sulindac as a chemoprevention drug. However, the molecular mechanisms responsible for COX-2 independent pathway have not been completely elucidated. In this project, we employed two human colon cancer cell lines, HCT116 and HT29. HCT116 cells are characterized for low COX-2 expression, while HT29 cells show relatively high COX-2 expression. We found that SS could unbiasedly inhibit the growth of HCT116 and HT29 cells by arresting cells in G1/G2 phases. CyclinG2 was found to be upregulated in response to SS treatment. FOXO3a has been reported to regulate CyclinG2 expression at the transcriptional level. Our results demonstrate that SS could also upregulate FOXO3a. By using the loss-of-function strategy, we found that SS could not efficiently upregulate the expression of FOXO3a nor inhibit cell growth as it did in control cells. We gained highly consistent results in HT29 and HT29 cells with COX-2 knockdown. Therefore, our study demonstrates a pathway consisting of mir-182/ FOXO3a/ CyclinG2 as a novel mechanism responsible for SS anticancer activity in colon cancer, which may imply a COX-2 independent pathway.

#1481 Determination of microRNA profile in lung cancer cell line treated with chemotherapy cisplatin (C), pemetrexed (P) or PC with bevacizumab (B). Jo-Anne Bayley1, Rachel Ryan1, Rachel Field1, Romain Giraud1, Christopher Smith1, Siddarth Sharma2, Jared Kevern3, Emma Borrego-Diaz3, Mukut Sharma3.

1University of Kansas Med Ctr, Kansas City, KS; 2University Hospital Brno, Brno, Czech Republic; 3University of Rochester Medical Center, School of Medicine and Dentistry, Rochester, NY. All authors contributed to this work equally. This work was supported by the National Institutes of Health, grant 1R01CA138262-01, the American Foundation for AIDS Research, grant PFI125140 and the University of Kansas Cancer Center, Cancer Center Support Grant P30CA076348. Address correspondence to: Jo-Anne Bayley, 3030 Dewar Drive, Lawrence, KS 66045. Background: Cellular microRNAs (miRNAs) regulate gene expression through modulation of messenger RNA transcription and are involved in epigenetic regulation, metastasis and cancer immunity. They have prognostic and therapeutic significance. The miRNAs associated with resistance in lung cancer without EGFR mutation are not yet known. We sought to determine the profile of miRNA of lung cancer cell lines without EGFR mutation treated with chemotherapy. Methods: lung cancer cell lines HTB177 were treated with PC or P (0.05mg/ml Cisplatin, 0.05 mg/ml pemetrexed, 6.25 mg/ml Bevacizumab) for 144h. Conclusions: The treatment using PC and PC with B in lung cancer cell lines reported that a panel of miRNAs could be altered by SS treatment in both colon and breast cancer cells. In the downregulated miRNA list, we found that mir-182 could potentially target FOXO3a. By using luciferase assay, we validated the direct regulation of mir-182 on the expression of FOXO3a. When mir-182 was downregulated, SS could neither efficiently upregulate the expression of FOXO3a nor inhibit cell growth as it did in control cells. We gained highly consistent results in HT29 and HT29 cells with COX-2 knockdown. Therefore, our study demonstrates a pathway consisting of mir-182/ FOXO3a/ CyclinG2 as a novel mechanism responsible for SS anticancer activity in colon cancer, which may imply a COX-2 independent pathway.
a difference of the miRNA profile in these 2 treatment groups. miRNA 21 is upregulated in cells resistant to therapy. miRNA could be involved in the activity of chemotherapy and development of resistance.

#1482 Triptolide inhibits the growth of osteosarcoma by regulating miRNA-181a via targeting PTEN gene in vivo and in vitro. Chunming Jiang, Xiang Fang, Xiupeng Wang, Maoqiang Li, Wu Jiang, Liulong Zhu, Zhenyu Bian, Hangzhou First People’s Hospital, Nanjing Medical University, Hangzhou, China.

Objective: We aimed to study the effect of triptolide on OS and the related molecular mechanism. Methods: The cell viability, apoptosis portion, tumor size, tumor weight and invasion of OS cells were determined. The relative level of miR-181 in OS tissues and the adjacent tissues was determined by qRT-PCR. The target gene of miR-181a was determined and verified by luciferase report assay. At last, OS cells were treated with triptolide and triptolide + miR-181a mimics to verify the relationship between triptolide and miR-181a. Results: Triptolide inhibited the cell viability, promoted the apoptosis, decreased the tumor size and weight, and reduced the invasion of OS cells. The level of miR-181a in OS cells decreased significantly after treating with triptolide, and the relative level of miR-181a in OS tissues was markedly higher than that in the adjacent tissues. PTEN was reported and verified the direct target gene of miR-181a. The overexpression of miR-181a decreased the inhibition of triptolide on OS proliferation and promotion on OS apoptosis. Conclusion: Triptolide inhibited the proliferation of OS by regulating miR-181a via targeting PTEN gene in vivo and vitro.

#1483 Alteration of miR-186 expression modifies inflammatory markers in normal epithelial and prostate cancer cell models. Suman Suman,1 Dominique Z. Jones-Reed,1 M. L. Schmidt,1 Geoffrey J. Clark,1 Carolyn Klinge,1 Shirish Barve,2 Kevin S. Kimbro,2 La Creis R. Kidd1.1 University of Louisville, Louisville, KY; 2North Carolina Central University, Durham, NC.

Dysregulation of miRNAs and chronic inflammation are strongly implicated in the development of various malignancies, including prostate cancer (PCa). Previously, our lab identified several inflammatory and immune response sequence variants in CCL5 and CCR5 significantly modified PCa risk. Recently, we propose an oncogenic role for miR-186-5p based on its up-regulation in serum from PCa patients and metastatic PCa cell lines. Moreover, miR-186-5p inhibition reduced proliferation, anchorage independent growth and invasion in metastatic PC cells (PC3, MDA-PCA-2b). We hypothesize dysregulation of inflammatory and immune response markers may enhance immune surveillance leading to a reduced aggressive tumor phenotype. Following modulations in miRNA-186 levels in normal prostate epithelial (RWPE1) and metastatic PCa (PC3) cell lines, we evaluated alterations in miRNA expression using micro-array analysis. Ectopic expression of miRNA-186 in the RWPE1 resulted in a 1.3-2.6 fold down-regulation in TLR2, IRAK2, CCL20, IL1RAP, IL1RAP, IL15, and IL17RD (FDR p-value <7.8x10^-4). Whereas, inhibition of miR-186 in PC3 cells corresponded with a 1.4-fold up-regulation of IL18R1 (p =0.0095). Notably, these inflammatory markers are involved in cell invasion (TLR2), apoptosis (IL17RD), tumorigenesis (TLR2, IRAK2) and autoimmune diseases (CCL20). Validation is underway using qRT-PCR, western blotting and luciferase reporter assays. We will assess the mechanism by which these miR-186 targets suppress aggressive cancer behavior using knock-out and knock-in and ultimately animal models. Future studies may identify inflammatory targets that may guide immune therapies for the effective treatment of aggressive prostate cancer.

#1484 Genome wide study reveal microrna based methylation phenotype in oral cancer. Roshni Roy,1 Aniruddha Chatterjee,2 Navonil De Sarkar,2 Bidyut Roy1. 1Indian Statistical Institute, Kolkata, India; 2Dunedin School of Medicine, Dunedin, New Zealand; 3Fred Hutchinson Cancer Research Center, Seattle, WA.

Introduction: Oral cancer is one of the leading causes of cancer burden in India. Studies over the years have enforced the role of deregulated microRNA expression in oral cancer development and progression. Incidentally not much is known about the cause of microRNA deregulation or to what extent can it be attributed to methylation. Established genome wide microarray platforms like 450K Illumina Bead Chip have probes for very limited number of microRNAs along with restricted on distance of the probes from microRNA transcription start site. We have used genome wide methylation sequencing approach RBBs to get deeper insight on microRNA methylation. Aim: Genome wide methylation profile of 15 paired oral cancer and adjacent normal tissue was compared to generate a detailed map of microRNA methylation in oral cancer. The methylation results were further correlated to microRNA expression data generated on a subset of these samples. Methodology: RBBs based global methylation se- quencing of 15 pairs of samples was conducted on HiSeq 2500 with an average 10x depth. Analyses were done using DMAP software. Previously generated TLD based microRNA expression data was used for correlation analysis. Result: Similar to protein coding genes, microRNAs also showed methylation based clustering. Interestingly majority of methylation hits were more than 2kb upstream of mRNA transcription start site which is generally not considered in known microarrays. Distribution of hyp and hyper methylation sites is different across the various CpG features like cores and shelves as well as across chromosomes. MicroRNAs like mir-181c, miR-99b, miR-23a among others showed significant negative correlation between methylation frequency and expression level. IPA based pathway analysis emphasized repression of apoptosis and cell death pathways along with activation of cell proliferation and colony formation. Conclusion: Understanding the role of methylation in microRNA deregulation could help us detect and possibly prevent a chain of events, which lead to disrupted pathways eventually leading to cancer, at the onset.

#1485 Measuring relative utilization of aerobic glycolysis in breast cancer cells by positional isotopic discrimination. Da-Qing Yang, Margot Cleary. University of Minnesota, Austin, MN.

Cancer deaths, including breast cancer, are caused by metastasis of the malignant tumors to distant locations. However, current methods of detection cannot distinguish pre-invasive breast cancer from noninvasive breast tumor or benign breast disease. Population-wide mammographic screenings have led to increased detection of ductal carcinoma in situ or DCIS, noninvasive, proliferative cells contained by the basement membrane of the terminal ductal lobular unit. DCIS is usually not associated with metastasis and/or cancer death. Each year, in the US alone, about 1.5 million of women who have been diagnosed with DCIS or a suspicious lump/lesion by mammography will require resection or breast biopsy after diagnosis for further pathologic analysis. However, ~80-85% of biopsies result in noninvasive breast disease or benign findings. As a result, a considerable number of patients suffer from side effects caused by breast biopsy and/or overtreatment. Therefore, there is an urgent need to find a biomarker for pre-invasive breast cancer. The ability of cancer cells to produce lactate through aerobic glycolysis (the Warburg effect) is a consistent hallmark of cancer, including breast cancer. Recent advancements in liquid chromatography-mass spectrometry (LC-MS) technology have significantly improved the sensitivity of this method compared to traditional NMR or GC-MS-based technologies, which make it feasible to detect very low concentrations of small molecules or metabolites. We have recently established a positional isotopic labeling and LC-MS-based targeted metabolomics method that can directly measure the conversion from [1-13C]glucose to [3-13C]lactate through glycolysis. Our results show that metastatic breast cancer cells exhibit a dramatically increased production of [3-13C]lactate in serum samples of early stage metastatic mammary tumors developed in mice. Since elevated levels of lactate are closely correlated to increased tumor aggressiveness, these data strongly suggest that monitoring of lactate production from glycolysis by targeted metabolomics may provide a biomarker for pre-invasive breast cancer. These results will pave the way for further exploration of the elevated production of lactate as a promising biomarker for pre-invasive breast cancer and for assessment of therapeutic response in clinical trials.

MOLECULAR AND CELLULAR BIOLOGY / GENETICS: Mitochondria, Autophagy, and Cancer Metabolism

#1487 ONC201 kills breast cancer cells by inhibiting mitochondrial respiration. Yoshimi Greer,1 Samuel Gilbert,2 Celia Islam,1 Yun Ji,1 Luca Gattinoni,1 Christine Stuelten,1 Natalie Porat-Shliom,1 Roberto Weigert,1 Xiantao Wang,2 Markus Hafner,1 Kunio Nagashima,1 Donna Voeller,1 Stanley Lipkowitz,1 NCJ, Bethesda, MD; 2NIAMS, Bethesda, MD.

Background: ONC201 is a small molecule originally identified as a TRAIL inducing compound currently being tested in phase1/2 clinical trials in multiple cancer types. Two recent studies reported that ONC201 also induces an atypical stress response mediated in part by ATF4 and CHOP. Methods: ONC201 was obtained from Oncovecs, Inc. Recombinant GST-TRAIL was prepared in the laboratory. Cell viability was tested with MTS assay and CellTiter-Glo luminescent cell viability assay. ATP level was measured with CellTiter-Glo 2.0 assay.

MOLECULAR AND CELLULAR BIOLOGY / GENETICS: MicroRNA Regulation of Cancer Biology 2
Molecular and Cellular Biology / Genetics: Mitochondria, Autophagy, and Cancer Metabolism

RNaseq and western blotting were performed to investigate change of gene expression. Mitochondrial respiration was monitored by Seahorse XF analyzer. Live cell imaging was performed to examine the mode of cell death. Confocal microscopy and electron microscopy analysis were performed to study mitochondrial morphology. Results: We tested the effects of ONC201 on 18 human breast cancer cell lines representing TNBC basal A and TNBC basal B breast cancer. ONC201 reduced cell viability in breast cancer cell lines in all subtypes tested with IC50s ranging from 0.8-5 μM, similar to what has been reported for other cancer cell types. Unexpectedly, ONC201 toxicity was not dependent on TRAIL receptors or caspases and live cell imaging revealed ONC201 induces cell membrane ballooning followed by rupture. By contrast, GST-TRAIL binds TRAIL-receptor DEVD-mediated caspase dependent classic apoptosis morphology. These results suggest that ONC201 kills breast cancer cells via a caspase-independent, TRAIL-receptor-independent mechanism distinct from TRAIL-induced apoptosis. Western blots revealed that ONC201 induces the stress pathway proteins ATF4 and CHOP, consistent with the recently published observations. ONC201 also induced phosphorylation of AMP-dependent kinase (AMPK) and depletion of cellular ATP in multiple breast cancer cell lines. Seahorse XF analysis found that ONC201 inhibited mitochondrial oxygen consumption rate but did not inhibit glycolysis as measured by the extracellular acidification rate. Both ONC201-induced toxicity and ATP depletion were enhanced when cells were cultured in non-glucose (galactose) medium. Supplementing glucose to cells grown in galactose medium partially prevented ONC201-induced ATP depletion. Reduced succinate production correlated with reduced ATP4 and CHOP, and cell death. These data are consistent with an inhibition of oxidative phosphorylation (OxPhos) by ONC201. RNaseq revealed ONC201 inhibits expression of multiple mitochondrial genes involved in OxPhos and other mitochondrial functions, and western blot confirmed those findings. Confocal and electron microscopic evaluation revealed abnormal mitochondrial morphology. Conclusion: Our data demonstrate that ONC201 can kill breast cancer cells by a novel mechanism involving disruption of mitochondrial morphology and inhibition of mitochondrial respiration.

#1488 Altered skeletal muscle mitochondrial function and redox biology with chemotherapy and exercise in a colorectal cancer mouse model. Malcolm Andrew West, Alexandrina Roman, Ronan Astin, Sian Pugh, Bernadette Fernandez, Annette Hayden, Judith Cave, Eleanor Jaynes, John N. Primrose, Sandy Jack, Michael P. Grocott, Andrew Murray, Martin Feilsch, Alexander Mirnezami, Timothy Underwood, University of Southampton, Southampton, United Kingdom; 2University College London, London, United Kingdom; 3University Hospital Southampton, Southampton, United Kingdom; 4University Hospitals Southampton, Southampton, United Kingdom; 5University of Cambridge, Cambridge, United Kingdom.

Background: Chemotherapy improves outcomes for patients with gastrointestinal cancer, although it can cause mitochondrial dysfunction, which adversely impacts fitness, invivo mitochondrial function, and cellular redox status in humans, however the mechanisms are poorly understood. Exercise interventions mitigate against this, but interactions between the effect of the cancer, chemotherapy, and exercise intervention are poorly understood. Using a colorectal cancer (CRC) mouse model we investigated changes in skeletal muscle mitochondrial function and redox biology. Methods: SCID mice (n=48) were randomized to laparotomy with (Ca) or without (NCa) orthotopic caecal injection of DLD-1 CRC cells. CRC established over 8 weeks then mice were randomized to 1) 3 cycles of intra-peritoneal (IP) chemotherapy (5FU 3mg/kg, Oxaliplatin 10mg/kg and Leucovorin 90mg/kg) followed by interval exercise-training 2) Chemotherapy and no exercise 3) IP saline sham (Sal) with exercise or 4) Sal with no exercise. Blood was collected pre and post-Chemo and at death (post-exercise), and markers of oxidative stress measured. Soleus muscle mitochondrial function was analyzed using high-resolution respirometry. Measurements included maximum OxPhos capacity (P1, P2, P3), Complex I and II capacities and the ratio of octanoyl-carnitine to pyruvate-supported respiration (FAO). Histopathological caecal examination was undertaken to determine tumour response. Results: Chemotherapy alone resulted in 37% lower OxPhos capacities in sham mice (p=0.011), whilst FAO was 40% lower (p=0.004). Cancer alone resulted in 38% lower OxPhos capacities (p=0.012). In combination with cancer, chemotherapy resulted in OxPhos capacities that were 42% lower than in mice with cancer but no chemotherapy (p=0.007), along with 51% lower Complex I (p<0.001) and 42% lower Complex II (p=0.007) capacities. In sham mice (NCaSal), exercise resulted in 33% greater Complex II activities (p=0.042), but exercise did not alter mitochondrial function in any other group. Total plasma protein content (TPPC) increased with time in the CaSal (+32%) and the NCaSal mice (+23%), whilst it decreased with chemotherapy (CaChem -20%, NCaChem -10%).

Oxidative stress increased with chemotherapy and exercise, however exploratory interaction analyses are ongoing. Complete histopathological response was seen in 2 of 6 CaChemEx animals. No other complete response was seen. Conclusion: Chemotherapy and cancer alone were associated with a loss of oxidative capacity, with a greater reduction when combined. Chemotherapy and exercise did not improve total protein content. Though we demonstrated an exercise effect in sham mice, exercise did not increase OxPhos capacity, nor did it ameliorate the effects of cancer and chemotherapy. A more intense exercise intervention may be required.

Proline dehydrogenase (PRODH) is a p53-inducible inner mitochondrial membrane flavoprotein functionally linked to electron transport for proline catabolism and intracellular ATP production, particularly under nutrient stress conditions. We have previously shown that in breast cancer cells, PRODH and glutaminase (GLS1) transcript levels are inversely correlated, supplying anaplerotic glutamate to triple-negative (GLS1) and luminal (PRODH) breast cancer subtypes by different means; and that siRNA knockdown or competitive inhibition of PRODH induces synthetic lethal interactions with both GLS1 inhibition and p53 upregulation in various malignant (ZR-75-1, DU4475, MCF7) but not normal (MCF10A) breast epithelial cells. In the present study we have synthesized and structurally modeled a novel mechanism-based irreversible (suicide) inhibitor of PRODH, N-propargylglycine (PPG), that shows more than 2-fold greater capacity to inhibit PRODH activity in isolated mitochondrial assays when compared to competitive PRODH inhibitors (L-tetrahydrofuran acid, THFA; or 5-oxo-2-tetrahydrofurancarboxylic acid, 5-oxo). Modeling human PRODH predicts a post-reactive PPG structure with PPG covalently linked to the enzyme pocket's FAD moiety, preventing catalytic activity. PPG does not occur with competitive PRODH inhibitors. Reflecting PPG’s irreversible binding to PRODH, mitochondria isolated from PPG treated ZR-75-1 cells are unable to catabolize proline despite being able to efficiently catabolize malate; in contrast, isolated mitochondria from 5-oxo treated cells remain efficient at catabolizing both proline and malate. Unexpectedly, we observed that PPG but not the competitive inhibitors induces selective degradation of mitochondrial PRODH protein levels within 24 h of cell culture treatment followed by loss of other mitochondrial proteins like complex-I NDUF1 but not by concomitant loss of cytosolic FAD-containing proteins like MTHFR. MitoTracker assays confirm the selective cellular loss of mitochondrial mass in ZR-75-1 cells within 24 h of PPG treatment. To confirm that suicide inhibition of PRODH can also induce synthetically lethal mitochondrial stress, breast cancer cells (MCF7) were cultured under normoxic (20% O2) or hypoxic (1% O2) conditions with or without chemotherapy, and exercise intervention are poorly understood. Using a colorectal cancer (CRC) mouse model we investigated changes in skeletal muscle mitochondrial function and redox biology. Methods: SCID mice (n=48) were randomized to laparotomy with (Ca) or without (NCa) orthotopic caecal injection of DLD-1 CRC cells. CRC established over 8 weeks then mice were randomized to 1) 3 cycles of intra-peritoneal (IP) chemotherapy (5FU 3mg/kg, Oxaliplatin 10mg/kg and Leucovorin 90mg/kg) followed by interval exercise-training 2) Chemotherapy and no exercise 3) IP saline sham (Sal) with exercise or 4) Sal with no exercise. Blood was collected pre and post-Chemo and at death (post-exercise), and markers of oxidative stress measured. Soleus muscle mitochondrial function was analyzed using high-resolution respirometry. Measurements included maximum OxPhos capacity (P1, P2, P3), Complex I and II capacities and the ratio of octanoyl-carnitine to pyruvate-supported respiration (FAO). Histopathological caecal examination was undertaken to determine tumour response. Results: Chemotherapy alone resulted in 37% lower OxPhos capacities in sham mice (p=0.011), whilst FAO was 40% lower (p=0.004). Cancer alone resulted in 38% lower OxPhos capacities (p=0.012). In combination with cancer, chemotherapy resulted in OxPhos capacities that were 42% lower than in mice with cancer but no chemotherapy (p=0.007), along with 51% lower Complex I (p<0.001) and 42% lower Complex II (p=0.007) capacities. In sham mice (NCaSal), exercise resulted in 33% greater Complex II activities (p=0.042), but exercise did not alter mitochondrial function in any other group. Total plasma protein content (TPPC) increased with time in the CaSal (+32%) and the NCaSal mice (+23%), whilst it decreased with chemotherapy (CaChem -20%, NCaChem -10%).

Oxidative stress increased with chemotherapy and exercise, however exploratory interaction analyses are ongoing. Complete histopathological response was seen in 2 of 6 CaChemEx animals. No other complete response was seen. Conclusion: Chemotherapy and cancer alone were associated with a loss of oxidative capacity, with a greater reduction when combined. Chemotherapy and exercise did not improve total protein content. Though we demonstrated an exercise effect in sham mice, exercise did not increase OxPhos capacity, nor did it ameliorate the effects of cancer and chemotherapy. A more intense exercise intervention may be required.

#1490 Role of sub-cellular specific reactive oxygen species in heart regeneration after cancer therapy. Salim Abdalsalam, Souparno Bhattacharya, Kalayarasan Srinivasan, Shbibi Mukherjee, Hesham A. Sadek, Aroumougame Asathamb, UT Southwestern Medical Center, Dallas, TX.

Introduction: Cardiovascular disease and cancer are the two leading causes of morbidity and mortality worldwide. As advancements in radiation therapy (RT) have significantly increased the number of cancer survivors, the risk of radiation-induced cardiovascular disease in this group is a growing concern. However, the molecular mechanism of radiation-induced heart failure is still elusive. Recently, it has been discovered that the reactive oxygen species (ROS)-mediated oxidative DNA damage is the primary upstream mechanism that prevents cardiomyocyte proliferation. Therefore, elucidating the spatial and temporal aspects of ROS production will lead to the development of countermeasures to prevent heart injury following chest radiotherapy. Methods: We have generated G516 redox potential (G516-GFP) ROS probe targeted to cytoplasm, chromatin, nucleolus, telomere, nuclear inner membrane and heterochromatin. These probes have been inserted into cardiomyocytes specific AAV9 vectors which were used to infect cardiomyocytes both in vitro and in vivo. For in vivo study, we infected three months old mice with high-titer AAV particles via tail vein injection and then exposed to chest-only radiation (5-10 Gy). At different post-
radiation times, fresh heart slices of 300–500 μm thickness were either mock- or treated with mitochondrial electron transport complex (ETC) inhibitors and then subjected to live tissue imaging using a confocal microscope. Results: Interestingly, our results showed that the distribution of basal ROS levels is not uniform in different sub-nuclear compartments. Significantly, upon the induction of oxidative stress, the ROS levels increased in all the cellular compartments, but the extent of ROS level was significantly higher in the cytoplasm. Similarly, radiation altered ROS levels in all the cellular compartments; however the effect of radiation on the ROS levels was sub-nuclear compartment-specific. Intriguingly, we found that the complex IV of the ETC was critical for the maintenance of ROS levels in different cellular compartments as compared with complexes I and II. Conclusion and Future Directions: Our data clearly indicate that the spatial and temporal levels of ROS are not uniform across the cell and the mitochondrial ETC plays a major role in regulation ROS levels in different sub-nuclear compartments. The results obtained from this study can be utilized to develop sub-cellular compartment specific targeted both genetic and pharmacological ROS scavengers that will help to regenerate adult heart by re-activating the proliferative capacity of cardiomycocytes following cancer therapy. Finally, our novel approach can be applied to assess alterations in ROS levels in different cancers. Funding: This work was supported by the NASA (NNX13AD57G/ NNX15AE06G) CPRIT (RP160520) and NIH RO1AG053341 grants.

Mitochondrial defects that affect activity of the electron transport chain (ETC) complexes are associated with several diseases including cancer. Dysfunctional mitochondria resulting from mitochondrial DNA (mtDNA) alterations or exposure to xenobiotics have been shown to initiate retrograde signaling pathway characterized by disrupted membrane potential, elevated cytosolic calcium and activation of Calcineurin, a calcium dependent phosphatase. In some cell types these events form the basis for triggering transcriptional reprogramming that converts non-tumorigenic cells to tumorigenic phenotype. Cytochrome oxidase (CcO) is the terminal enzyme of the ETC that catalyzes the transfer of electrons from reduced cytochrome C to oxygen. All the mutations of CcO subunits identified as prevalent in various cancers like prostate, pancreatic, colon and ovarian cancers have been found in mtDNA encoded subunits. Effect of loss of nuclear subunits leading to reduced Cytochrome oxidase activity on tumor progression are not well studied. Nuclear subunits IV1 and Vb of CcO are susceptible to various stress conditions like exposure to long term hypoxia, ischemia-reperfusion and treatment with ethanol resulting in selective degradaion and loss of activity. Here we report the activation of retrograde signaling by loss of these subunits. Genetic silencing of the subunits IV1 and Vb, and loss of activity resulted in metabolic shift to glycolysis and was accompanied by increased glucose utilization. Disruption of the CcO complex activated many of the hallmark factors of Ca2+/Calcineurin mediated retrograde signaling. Importantly, rescue of the CcO deficiency by overexpressing CcO subunits or by inhibitors of retrograde signaling pathway attenuated the phenotypic changes such as anchorage independent growth and increased invasive potential. Further, esophageal tumor sections from human patients revealed reduced CcO activity and inhibited the hallmark factors of Ca2+/Calcineurin mediated retrograde signaling. In this context, DNA polymerase γ (POLG1) is known to function in human mitochondria and controls the critical function of mtDNA replication and repair. POLG1 is the most frequent target of gene mutation and is involved in a variety of mitochondrial diseases. POLG1 protein consists of exonuclease, linker and polymerase domain, each with distinct functions. Mutations in exonuclease domain leads to erroneous proofreading and is responsible for increased mutations in mtDNA whereas mutations in polymerase domain leads to erroneous replication and hence depletion in mtDNA. Germline variants in these domains of POLG1 may serve as important signature markers in association studies of individuals in a population study. Through our present study, we identified germline variants, examined copy number variation, expression and regulation of POLG1 gene in human cancers. We provide evidence that altered POLG1 expression as well as germline variations in POLG1 gene contribute to tumorigenesis. Methods: A comprehensive race based bioinformatics analysis of POLG1 gene in European-American and African-American was conducted and several unique germline mutations were discovered. To analyze functional contribution of these unique germline mutations in tumor progression, these unique prevalent mutations in the evolutionary conserved regions of exonuclease and polymerase domains we generated by site directed mutagenesis and functional and tumorigenic analysis was performed. Results: We observed marked differences in copy number variation of POLG1 through cBioPortal and Cosmic databases and validated the analysis in primary tumors and cancer cell lines. Our results also indicate that mtDNA copy number in cancer cell is governed by regulation of POLG1 methylation and disproves the importance of epigenetic regulation of POLG1 gene.

We identified a mitochondrial disease causing missense variation in polymerase domain of POLG1 at amino acid 1143 (E1143G) to be 25 times more prevalent in European-Americans when compared to African-Americans population. Expression of this germline variant (E1143G) increased glucose consumption, de-
creased ATP production and increased matrigel invasion. Discussion/Conclu-
sion: We demonstrate that POLG1 is epigenetically regulated and its unique
germline variants contribute to disruption of mitochondrial function. Thus con-
tributes to differences in increased predisposition to cancer in inter-ethnic pop-
ulation.

#1496 1. Using the metabolite with metabolism in ovarian cancer. Eric
D. Shide, Lauren Amable. NIMHD, Bethesda, MD.
Ovarian cancer has historically been diagnosed late stage and lacks effec-
tive biomarkers for detection and prognosis. The deregulation of metabo-
lism and signaling cascades inherent of cancer may contribute to aberrant
levels of metal within cells. Biological processes essential for cell prolifera-
tion require metals for enzyme cofactors, signaling molecules, and structural
components. Metallomics is the study of the comprehensive, dynamic metal
profile within cells. The goal of our study was to characterize the ovarian
cancer metabolism at the level of whole cell and mitochondria in comparison
to non-cancer. Additionally, cellular metabolism was analyzed to connect
the mitochondrial (mito-)metallome to mitochondrial function. Ten human
ovarian cancer cell lines were used for experiments: A2780, CAOV3, A2780/
Three non-cancer human ovarian cell lines of epithelial and fibroblast origin
served as controls. Inductively coupled mass spectrometry (ICP-MS) was
used to evaluate the metabolome by measuring the following metals: calcium
(Ca), copper (Cu), iron (Fe), magnesium (Mg), manganese (Mn), molybde-
um (Mo), phosphorous (P), sulfur (S), selenium (Se), and zinc (Zn). An
XF24 Seahorse analyzer was used to measure cellular metabolism and mito-
chondrial function in the ovarian cancer and non-cancer cell lines. Our
results demonstrated that there was a distinct metal profile at the level of the
whole cell and mitochondria in ovarian cancer cells compared to non-cancer
ovarian cells. The whole cell ovarian cancer metabolism consisted of in-
creased Mg, P, Cu, Zn, Se, and Ca. Referencing established literature of the known metals
that serve as cofactors for mitochondrial proteins, the relationship between
the mito-metallome and functional metabolic pathways was established.
Changes in cellular metabolism were reflected by changes in the mito-met-
allome. Our study was the first to evaluate an extensive panel of metals
simultaneously in the mitochondria and bridge the unique metallic signature
of ovarian cancer to cell metabolism. Future proteomics studies will be used to
further validate the connection of metals to cellular function. Metallomics
and the ovarian cancer cell metallome provide further understanding of how
cancer deregulates the metallome and how metallomics may provide an
avenue for identifying new cancer biomarkers and allow for effective targeting
of cancer with chemotherapy.

#1497 1. BLM31510 modulates mitochondrial complex activity to influence
oxidative stress in effectuating cell death in multiple cancers. Tulip Dalani,
Katerina Krumova, Anne R. Diers, Pallavi Awate, Ryan Ng, Arleide Lee,
Stephane Gesta, Vivek K. Vishnudas, Ranagrapad Sarangarajan, Niven R.
Narain. BERG, LLC, Framingham, MA.
Dysregulation of mitochondrial metabolism plays a modified role in tumorigenesis through
regulation of energy production, biomass, redox state, and engagement of cell
death pathways. Perturbations in mitochondrial fluxes (i.e. inhibition of electron
chain complexes activity, impaired electron flow) have substantial effects on cell
viability, suggesting that targeting mitochondrial function could be effective for
therapeutic response in cancer. BLM31510, containing oxidized coenzyme Q10
dilts an anti-Warburg effect is currently in phase II clinical trials for solid
tumors. Previously, we have demonstrated the anti-cancer properties of
BLM31510 in breast and pancreatic xenograft models. Here, we examined the
mechanism of action of BLM31510 in vitro. Using a multi-cancer cell panel,
BLM31510 was shown to be consistently and selectively cytotoxic to cancer cells,
compared to normal and non-tumorigenic controls, and sensitivity did not cor-
relate to cell doubling time or mutational status. Treatment with BLM 31510
(EC50) in breast and pancreatic cancer cells resulted in a time- and dose-depen-
dent decrease in mitochondrial membrane potential which preceded an increase
in early and late apoptosis cells, suggesting BLM31510 initiates a mitochondrial
mediated cell death pathway. Using a fluorescently labeled CoQ10, we were able to
trace the subcellular location of the CoQ10, which predominantly accumu-
lates in mitochondria and lipid droplets in a time dependent manner. Addition-
ally, the mitochondrial enrichment of CoQ10 is accompanied by morphological
changes that varied amongst the different cancer cell types. As CoQ6
is a redox molecule required for electron transfer activity between complexes, we hypoth-
thesized that disruption of Q-pool homeostasis would alter complex activity. To
investigate this, Complex driven respiration was measured in cells treated with
BLM31510 and compared to untreated. Alterations in mitochondrial respira-
tion characterized by a dose-dependent decrease in succinate (Complex II) and
glycerol-3-phosphate (Complex III)-fuelled respiration were observed in cells
treated with BLM31510, while no changes were seen in pyruvate driven respira-
tion (Complex I). This is suggestive of BLM31510 specifically impairing respiration
responses that are more dependent on Q-pool functionality. As impairment of
the electron transport chain increases intracellular oxidative stress, we next in-
vestigated if BLM 31510 treatment increases ROS levels. After 24h treatment,
BLM31510 significantly increased ROS levels in treated cancer cells compared to
untreated. Furthermore, BLM31510 induced death could be in part prevented by
co-treatment with antioxidants. Together, these data demonstrates
BLM31510 has anti-cancer activity in multiple cancer cell types and define a
unique and novel functional link between mitochondrial Q-pool disruption and
the mechanism of action of BLM31510.

#1498 1. Melatonin inhibits mitochondrial transcription factor A expres-
sion in glioblastoma U87MG cell culture inducing an anti-tumorigenic ef-
fect. Daiane G. Franco, Isabele F. Moretti, Suely K. Marie. University of Sao
Paulo, Sao Paulo, Brazil.
Melatonin, the major hormone of pineal gland, has been described to
induce intrinsic apoptosis in tumor cell, while it is inhibited in non-tumor
cell. In tumor cell, melatonin stimulates intracellular production of reactive
oxygen species (ROS) by a mechanism not completely understood. Here we
propose that melatonin inhibits the expression of mitochondrial tran-
scription factor A (TFAM) in U87MG glioblastoma cell line, leading to an
increase of the production of ROS. TFAM is an important mitochondrial
protein that maintains the mitochondrial DNA (mtDNA) integrity and consequently
the oxidative phosphorylation. Human U87MG GBM cell line was treated with melatonin (1 mM)
for 72 h to evaluate the expression of TFAM and the mtDNA copy number through real-time PCR.
Proliferation, apoptosis, cell cycle and ROS production were also evaluated
by flow cytometry (Muse - Millipore Corporation) and the results were normal-
ized to control (vehicle: ethanol 0.3%). Melatonin reduced the expression of
TFAM in 17.5 % compared to the control group, but had no effect on the
mtDNA copy number. Moreover, the incubation of U87MG with melatonin
induced a reduction in cell proliferation in 14.24 % ± 4.3 compared to
control, with an arrest of cell cycle in G0/G1 phase, which increased from
67.4 ± 3.71 % to 72.78 ± 3.18 % in the group treated with melatonin com-
pared to the control. Production of ROS presented an increase of 7.1 %,
with no significant effect on apoptosis. These results suggest that TFAM maybe a
target for the melatonin function for an anti-tumorigenic effect through an
increase of ROS production, inducing a delay in the cell cycle and a reduction of cell proliferation.
The melatonin effect on TFAM maybe a novel signaling
pathway that could be explored for the control of GBM progression.

#1499 1. Role of mutations and expression change of mitochondrial func-
tion related nuclear genes in oral gingivobuccal squamous cell carcinoma.
Esita Chattopadhyay,1 Richa Singh,1 Rosni Roy,2 Bidyut Roy.1 Indian Statis-
tical Institute, Kolkata, India; 2Baylor Research Institute, Dallas, TX.
Background: Mitochondria have long been suspected to have contribution in
progression and sustenance of cancer. But mitochondria related nuclear genes
have not been well-studied in oral cancer. The aim of this study is deciphering
the impact of somatic mutations and expression deregulation of mitochondria
related nuclear genes in oral gingivobuccal squamous cell carcinoma (GBS CC).
Methods: Nuclear-encoded genes which are functionally involved with mito-
chondria were enlisted from MitoCarta 2.0 and IMPI databases. Whole exome
sequencing was performed with 12 paired cancer-normal GBSCC samples and
 somatic mutations in mitochondria related nuclear genes were extracted from
the data. Expression deregulation of mitochondria related nuclear genes were
quantified from whole transcriptome data of 12 paired cancer-normal GBSCC
samples. Expression was re-validated in another set of 12 cancer-normal paired
samples. 5 cancer-normal paired samples with whole transcriptome data were
also used for reduced representation bisulfite sequencing (RRBS). Probable im-
 pact of non-synonymous somatic mutations were predicted using SIFT and
POLYPHEN2 tools. Genes with possible damaging mutations and expression
deregulation were taken for literature search and KEGG pathway analysis to
understand their contribution in the function of mitochondria in GBSCC. Re-
sult: Total 1561 mitochondria related nuclear genes were identified from two
databases and included in the study. A total of 977 somatic mutations were
identified in 583 such genes in 12 oral GBSCC samples. These mutations were
distributed in exonic (346 mutations), intronic (288 mutations), splicing (4
mutations), UTR3' (270 mutations) and UTR5' (69 mutations) regions. Ten recur-

384 Proceedings of the American Association for Cancer Research • Volume 58 • April 2017
Results indicate that combination of heme lowering agents works effectively in the peptide and the inhibitor had a greater effect than the peptide alone. Our conclusions on the peptide and peptide-inhibitor combination. In all the treatment groups that received the peptide and a combination of peptide and inhibitor. This trend was also observed in tumor xenografts derived from NRF2-silenced HT29 exhibited MT-CO1 reduction. Further investigation revealed that modulation of SFXN4 alters mitochondrial respiration by affecting iron-sulfur cluster biogenesis, including increased IRP-1/IRP2 binding and a decrease in IRP1/ACOT1 acitavity. Furthermore, SFXN4 knock-out decreased the activity of iron-sulfur cluster-containing enzymes such as mitochondrial aconitate and succinate dehydrogenase. Based on these observations, we postulate that SFXN4 acts as a molecular mediator that channels the excess iron present in ovarian cancer cells to iron-sulfur cluster-dependent metabolic pathways that favor growth and metastasis. SFXN4 may be a potential druggable target in ovarian cancer.

#1502 The link between NRF2 and mitochondria through the regulation of miR-181c/miRNA-encoded cytochrome c oxidase subunit-1. Mi- Kyoung Kwak, Kyeong-Ah Jung, Donghyeok Kim, Sujin Lee. The Catholic University of Korea, College of Medicine, Republic of Korea.

The nuclear factor erythroid 2-related factor 2 (NRF2) pathway is involved in the environmental resistance of cancers by enhancing the antioxidant capacity. In the current study, we investigated the potential link between NRF2 and mitochondrial function in cancer cells. Global miRNA expression analysis of H7T29 and HCT116 identified miR-181c as an NRF2-silencing-inducible miRNA, and miR-181c elevation was associated with the decrease in mitochondria-encoded cytochrome c oxidase subunit-1 (MT-CO1), a mitochondrial genome-encoded complex IV subunit of the electron transport chain. As a result of decreased complex IV activity, NRF2-silenced cancer cells exhibited reduced levels of mitochondrial membrane potential (MMP), oxygen consumption rate, and ATP production. Notably, these changes induced adaptive activation of AMP-activated protein kinase (AMPK) and thereby, NRF2-silenced cells were more vulnerable to AMPK inhibitor-induced growth suppression. Similarly, mouse xenografts derived from NRF2-silenced HT29 exhibited MT-CO1 reduction and AMPK activation, thereby increasing responsiveness to the AMPK inhibitor treatment. Collectively, we showed a novel link of NRF2 to cancer mitochondria and AMPK signaling by elucidating miR-181c/MT-CO1 signaling as an underlying molecular mechanism. These results also suggest that it may an effective strategy to inhibit both NRF2 and AMPK to control adaptive tumor responses.

Hydroxychloroquine (HCQ) is a lusotrophic autophagy inhibitor that is being used in over 45 clinical trials either alone or in combination with another chemotherapy. Pharmacokinetic (PK) and pharmacodynamic (PD) studies with HCQ have shown that drug exposure in the blood does not correlate with autophagy inhibition in either peripheral blood mononuclear cells (PBMCs) or tumor tissue (Autoptiy 10:1415). HCQ exhibits primarily pH-driven PK and has been shown, by way of heightened levels of autophagy markers, to generate a therapeutic effect longer than PK data suggests. A physiologically-based pharmacokinetic model (PBPK) was developed for HCQ to describe the tissue-specific absorption, distribution, metabolism, and excretion as well as lysosome-specific sequestration. Physiologic parameters were adapted from literature, or obtained from experimental data when necessary, and used to simulate physiologically-based PK PK following designated dosing regimen in mice and rats. Experimentally derived PK data from these species were compared to simulation generated data to drive model development and subsequently determine model accuracy, achieving statistically-similar PK predictions of blood and tissues. Through allometric scaling and species-specific parameter modifications this model can be easily adapted for accurate prediction of HCQ PK in dogs and humans, as determined by comparison with respective blood levels. The value of this model lies in its ability to simulate HCQ PK in cancer patients with tumor types deemed autophagy-dependent. Model data simulating HCQ uptake in a neutral tumor compartment (pH = 7.2) shows that peak concentration in the lysosomes, the active site of the drug, is roughly four-fold higher than the peak concentration.
#1504 Tumor-treating fields (TTFields) interfere with biological key properties of glioma cells in vitro. Manuela Silginer, Michael Weller, Roger Stupp, Patrick Roth. University Hospital Zurich, Zurich, Switzerland.

Tumor-treating fields (TTFields) are low amplitude alternating electric fields which are supposed to exert anti-tumor effects by targeting dividing tumor cells while sparing cells in the brain not undergoing cell division. Although this novel therapeutic approach has shown encouraging results in phase III trials in glioblastoma, its biological effects on tumor cells have only been poorly understood. Here, we investigated the effects of TTFields on glioma cells in vitro using the in vitro system that allows the application of TTFields to cell cultures. Exposure to TTFields potently induce autophagy and necroptosis and interfere with the migration and invasion of long-term glioma cell lines, but also of glioma-initiating. The combination of TTFields with irradiation or temozolomide (TMZ) restored viability and clonogenic survival in an additive or synergistic manner. Further studies suggest that the O6-methylguanine DNA methyltransferase (MGMT) status does not influence the efficacy of TTFields and TMZ-resistant glioma cells remain responsive to TTFields application, thus making TTFields particularly attractive for the majority of glioblastoma patients with tumors that are unlikely to benefit from TMZ treatment. In summary, these findings demonstrate that the application of TTFields may interfere with various biological key properties of glioma cells and may allow for a more detailed clinical evaluation of TTFields beyond the clinical data available so far.

#1505 Breast cancer cells treated with mitochondria targeted redox active agents induce mitophagy. Thomas Biel, Ashutosh Rao. Food and Drug Administration, Silver Spring, MD.

Triphenylphosphonium (TPP) conjugated agents induce mitochondrial dysfunction in cancer cells. However, the onset of mitophagy to remove the dysfunctional mitochondria is unknown. Here, a series of mitochondria targeted redox active agents (MTA) that contain TPP were used to investigate mitochondrial dysfunction and mitophagy in MDA-MB-231 cells as compared to MCF-12A cells. Three different MTAs were identified to induce mitochondrial depolarization and enhanced autophagic flux selectively in MDA-MB-231 cells. Mitochondrial reactive oxygen species generation and respiration indicated that MDA-MB-231 cells harbored heightened sensitivity to MTA treatments. We additionally expressing mt-mKeima MDA-MB-231 and MCF-12A cell lines, a non-cell type selective decline in mitochondrial alkalinity and altered mitochondrial morphology was detected. Furthermore, FACS analysis of mt-mKeima revealed MTA induced lysosomal dependent mitochondrial degradation in the presence of Bafınomycin, a lysosomal inhibitor. To confirm MTAs induced mitochondrial autophagy in MDA-MB-231 cells, MitoTracker Red preloaded GFP-LC3 expressing MDA-MB-231 cells were used to identify autophagosomes containing mitochondria using confocal microscopy, in addition to coimmunoprecipitation for the detection of an endogenous autophagy-related protein complex, and immunoblot to for mitochondrial PINK1 accumulation. To translate these in vitro studies to an in vivo rat SFT-2 xenograft breast cancer model, tumor mitochondrial extracts from rats treated with Mitotarget demonstrated an accumulation of mitochondrial PINK1. Collectively, these data suggest that mitochondrial agents selectively caused mitochondrial depolarization, PINK1 accumulation and mitophagy in MDA-MB-231 cancer cells as compared to MCF-12A healthy cells.

#1506 The Wnt signature of melanoma cells predicts their invasiveness, autophagy activity, and their response to pharmacologically mediated autophagy inhibition. Abhataou M.M. Ndove, Anna Budina, Amanpreet Kaur, Curtis H. Kugel, Marie Webster, Reeti Behera, Vito Rebecca, Ling Li, Meenhard Herlyn, Ravi Amaravadi, Maureen Murphy, Ashani Weeraratna. The Wistar Institute, Philadelphia, PA; The University of Pennsylvania, Philadelphia, PA.

Melanoma is the most aggressive type of skin cancer and the leading cause of death from skin cancer. As the incidence of melanoma continues to increase, it is crucial to investigate the cellular and molecular mechanisms that lead to invasion and metastasis. High autophagy has been shown to correlate with melanoma tumor aggressiveness and poor survival in patients, and is a common mechanism of resistance to therapy. Autophagy inhibition leads to reduced levels in Wnt5A in a breast cancer model, suggesting a cross-talk between Wnt5A and autophagy in cancer. Our laboratory showed that Wnt5A is a driver of invasion and metastasis in melanoma. β catenin, a canonical Wnt mediator, has been shown to negatively regulate autophagy in a colorectal cancer model. Given that Wnt5A downregulates β catenin, we hypothesized that autophagy promotes melanoma tumor aggressiveness through the regulation of Wnt signaling and that in turn the Wnt signaling status of melanoma cells affects their autophagy activity. Our results demonstrate that melanoma cells with high Wnt5A and low β catenin have higher autophagy levels compared to less aggressive melanoma cells that have low Wnt5A and high β catenin. To determine whether there is a feedback loop between Wnt signaling and autophagy, we inhibited autophagy in invasive melanoma cells using lentivirus-mediated shATG5 knockdown and evaluated the effects of autophagy inhibition on Wnt5A and β catenin expression. We found that the inhibition of autophagy results in a decrease in Wnt5A and an increase in β catenin. Our data also demonstrate that the Wnt signature of melanoma cells greatly affects their response to Ly05-mediated autophagy inhibition both in vitro and in vivo. Wnt5A decreased sensitivity to autophagy inhibition while β catenin increased sensitivity to Ly05 both in vitro and in vivo. Pre-clinical models and clinical trials demonstrate a potential of autophagy inhibition for melanoma therapy; however, the clinical effects are not consistent and do not yield significant anti-tumor effects. This study will provide a rationale for the development of therapeutic strategies that more efficiently target autophagy in aggressive melanoma by taking into account the Wnt signaling status of melanoma cells.

#1507 Fatty acid oxidation mediated autophagy regulation in triple negative breast cancer. Kwang Hwa Jung, Jun Hyoung Park, Tirupathia Sirupangi, Saajna Vithayathil, Lee-Jun Wong, Benny A. Karpiaotta. Baylor College of Medicine, Houston, TX.

Compared to hormone regulated/responsive (ER+/HER2-) breast cancer (BC), triple negative BC (TNBC) patients have a worse overall survival, a significantly shorter disease-free survival, and a shorter post-recurrence survival. Using transmission electron microscopy (cybrid) (compares different mitochondria under a common defined nuclear background)-based discovery and validation in cell lines, patient derived xenografts (PDXs) and BC clinical tissues/data, we recently published that fatty acid oxidation (FAO) is a major energy pathway in TNBC. We also showed that FAO is a major regulator of Srx activation by autophosphorylation at Srx Y419 in metastatic TNBC. Our data suggest that inhibition of FAO induce cell growth inhibition. Short-term treatment of FAO inhibitors induces both cell cycle arrest and apoptosis. We observed cell cycle arrest in G1-S phases in FAO inhibitor treated TNBC cells. Additionally, we found that caspase-3 and cleaved PARP induced in FAO inhibited cells. Short-term treatment of FAO inhibitor also showed induction of AKT pathway. Further analysis on the role of FAO in TNBC suggests that FAO is a critical player in autophagy signaling in TNBC. Long-term treatment with FAO inhibitors or knockdown of FAO rate-limiting proteins carnitine palmitoyltransferase I (CPT1) induce autophagic cell death with beclin-1 and LC3-II induction in TNBC. However, no such phenomenon observed in estrogen receptor positive (ER+/HER2-+) breast cancer cell lines. Treatment with autophagy inhibitor 3-methyladename (3-MA) abolished the FAO-induced cell growth inhibition and reduced beclin-1 and LC3-II induction. Ongoing studies using knock-down and over expression approaches focus on the role of specific pathways that are responsible for mitochondrial energy reprogramming regulated autophagy signaling in metastatic TNBC.

### MOLECULAR AND CELLULAR BIOLOGY / GENETICS: Targeting Ablative Transcription in Cancer

#1508 MTL-CEBPα activates the transcription factor CEBPα leading to inhibition of hepatocellular cancer growth. Nagy Habib, Vikash Reebey, Xiaoyang Zhao, Jon Voutilia, Robert Habib, Fał Siettoms, Hans Huber, Kai-Wen Huang, John J. Rossi, David C. Blakey. Imperial College London, London, United Kingdom; MiNA Therapeutics Ltd, London, United Kingdom; Norgardian University of Science and Technology, Trondheim, Norway; BioTD Strategies, LLC, Lansdale, PA; National Taiwan University, Taipei, Taiwan; Beckman Research Institute of the City of Hope, Duarte, CA.
CCAT7/ enhancer binding protein alpha (CEBPA) is a transcription factor that can act as a tumor suppressor. Its expression is downregulated in a number of cancers including hepatocellular carcinoma (HCC). We have investigated the role of CEBPA in models of HCC using small activating RNAs (saRNA) to transcriptionally upregulate its expression. Three liver tumor cell lines (HepG2, Hep3B, PLCPRF5) were treated with 20nm Taf4aHFD. The transcriptional regulation of two key members of the CEBPA family, CEBPB and CEBPA, and their protein expression level were measured. The impact on cell growth was assessed by way of an SRB and WST-1 assay. To investigate the role of CEBPA in protecting cells from the activity of CEBPA, siRNAs were used to knock down CEBPA. Using qPCR and Western blot analyses, we showed that the expression of CEBPA was significantly decreased in HCC cell lines. The expression of CEBPA was found to be inversely correlated with the expression of GR. The GR antagonist RU486 blocked the inhibitory response induced by GCs and GR silencing completely abrogated the anti-proliferative effects of GCs in CEBPA-sensitive cells, confirming that GC operate through the GR in AML. Conclusion: Altogether, these findings highlight the impact of RUNX1 dosage on gene expression and GC sensitivity in AML cell lines.

#1510 Selection inhibition of acute myeloid leukemia by targeting Taf12.

Yali Xu, Joseph Milazzo, Yusuke Tarumoto, Chris Vakoc. Cold Spring Harbor Laboratory, Cold Spring Harbor, NY.

Recent studies have suggested that co-activators are good drug targets for cancer therapy, as exemplified by BRD4, the small molecule inhibitors of which have already entered clinical trials. The high potency of targeting BRD4 in leukemia cells mainly results from suppressing the functions of multiple lineage specific transcription factors. However, such pleiotropic effects of BRD4 on different transcription factors might be problematic, considering many of the perturbed transcription factors are equally required by normal cells. This prompted us to explore more co-activator-selective potential drug targets, aiming to identify the candidates that discretely disturb the function of oncogenic transcription factors but not the general ones. In this study, we explored the roles of one of the largest co-activator complexes TFIIID in the maintenance of acute myeloid cells. To address this, we designed a shRNA library targeting each TAF subunit of TFIIID and tested the growth effect of these shRNAs in both mouse leukemia cell line and primary bone marrow culture. We found that multiple shRNAs targeting Taf12 shows strong toxicity in leukemia cells but not normal cells in vitro. Knocking down Taf12 also inhibits leukemia progression in vivo. To gain insight into the toxicity of inhibiting Taf12 in different organs, we generated doxycycline inducible transgenic Taf12 shRNA mice, where Taf12 can be inhibited in different tissues specifically at adult stage. In consistent to our in vitro observations, normal myeloid cells are not affected by Taf12 knockdown. Instead, the lymphoid lineage cells are affected while removing doxycycline can reverse the phenotype. To our surprise, all the other tissues that have been examined and show significant Taf12 knockdown do not have any defects. At molecular level, we found that inhibition of Taf12 suppresses the transcription of core targets of Myb, but not other transcription factors, like Pu.1, Erg, Fli-1, which is in contrast to the pleiotropic effects of BRD4. Interestingly, it has been shown before that leukemia cells are hypersensitive to Myb inhibition compared to normal cells. Furthermore, similar to Taf12 mice, mice with hypomorphic level of Myb show defects in lymphoid but not myeloid cells. Taf12 is a small protein with only one histone fold domain (HFD), which can dimerize with the HFD of Taf4a within TFIIID complex. We found that the histone fold dimer of Taf12 and Taf4a can physically interact with the transactivation domain of Myb. Furthermore, we showed that the HFD of Taf4a can be utilized to target Taf12 to inhibit growth of leukemia cells. Similar to Taf12 shRNA, function of Myb is disturbed by over-expressing Taf4a HFD. More strikingly, overexpressing Taf4a HFD is sufficient to cause regression of leukemia in vivo.

#1511 AML patient clustering by super-enhancers reveals an RARA associated transcription factor signaling partner. Michael R. McKown, 1Matthew L. Eaton, 1Chris Fiore, 2Emily Lee, 1Katie Austgen, 1Darren Smith, 1M. Ryan Corces, 2Ravindra Majeti, 2Christian C. Fritz, 2Syros Pharmaceuticals, Cambridge, MA; 2Stanford University, Palo Alto, CA.

Prior studies have shown that the RARA gene is associated with a super-enhancer (SE) and has upregulated mRNA expression in a subset of AML patients. Furthermore, this has been found to confer increased sensitivity to SY-1425, a potent and selective RAR agonist. We sought to better characterize the cell state and transcription factor circuitry in these RARA-high AML cells. Clustering of 62 primary AML patient samples based on their genome wide SE maps identified six discrete clusters. RARA-high patients partitioned principally into cluster 2, and to a lesser extent 1, suggesting that RARA upregulation is associated with a specific transcription factor (TF) network and cell state. To start unraveling the TF circuitry in the RARA-high cluster, we investigated which other TFs were SE associated with clusters 1 and 2. In particular, interferon regulatory factor 8 (IRF8) was found to be strongly associated with clusters 1 and 2 by SE and mRNA expression, similar to RARA. Moreover, the expression of
both genes is correlated in primary patient samples. IRF8 is involved in androgen signaling and previous studies have shown crosstalk between androgen and retinoic acid signaling. Furthermore, aberrant IRF8 pathway signaling is implicated in AML and MCL pathogenesis. The tight clustering of RARA and IRF8 in patient subgroups defined by genome-wide enhancer maps suggests RARA and IRF8 may form an integrated transcriptional module, and our data indicate that RARA and IRF8 expression was specifically increased in CRPC cell lines. The expression of the ARV7 expressing CRPC cell line LNCaP95 demonstrated an increase in IRF8 expression and a decrease in AR expression. Mechanistically, BETi might inhibit pre-mRNA splicing of AR related targets and thereby reduce AR expression. Persistent androgen receptor signaling is common in CRPC and as such, new therapeutic strategies to target androgen receptor signaling are needed. BET bromodomain inhibitors have shown promise as a therapy to block AR signaling and CRPC growth. The GATA family of TFs contains six members in mammals, all of which bind a consensus DNA sequence (A/T)GATA(A/G) to regulate gene expression. GATA2 is the predominant family member in prostate luminal epithelial cells. In a search for TFs that control AR expression, we found that GATA2 directly promotes expression of both full-length and AR splice-variant, resulting in a strong positive correlation between GATA2 and AR expression in both PrCa cell lines and patient specimens. Conversely, GATA2 expression is repressed by androgen and AR, suggesting a negative feedback regulatory loop that, upon androgen deprivation, derepresses GATA2 to contribute to AR overexpression in CRPC. Simultaneously, GATA2 is necessary for optimal transcriptional activity of both full-length and AR splice-variants. Using ChIP-seq we found that GATA2 colocalizes with AR and Forkhead box protein A1 (FOXA1) on chromatin to enhance recruitment of steroid receptor co-activators (SRC1, SRC2, and SRC3) and formation of the transcriptional holocomplex. Lastly, we identified a GATA2 small molecule inhibitor (SML) that can selectively suppress the expression of AR splice-variants and exert potent anticancer activity against PrCa cell lines. We propose that the inhibition of GATA2 is a ‘first-in-field’ approach to target AR expression and function, including ligand-independent AR, for the treatment of CRPC.

#1511 Bromodomain and extra-terminal motif protein inhibitors (BETi) in metastatic castration resistant prostate cancer (mCRPC): A novel mechanism for regulating androgen receptor variant 7 (ARV7). Jonathan Welti,1 Adam Sharp,1 Ines Figueiredo,1 Wei Yuan,1 Daniel Nava Rodrigues,1 Veronica S. Gil,1 Eleanor Knight,1 Jian Ning,2 Jeff Francis,2 Antje Neeb,1 Gunther Boynton,1 Amanda Swain,1 Johann S. de Bono1,2.1Institute of Cancer Research and the Royal Marsden Hospital NHS Trust, Sutton, United Kingdom; 2Institute of Cancer Research, Sutton, United Kingdom.

Persistent androgen receptor (AR) signaling is key to the development and progression of metastatic castration resistant prostate cancer (mCRPC). This is in part due to expression of constitutively active AR splice variants like AR variant 7 (ARV7), conferring resistance to current anti-androgens including enzalutamide (E) and abiraterone (A). To improve the outcome for patients with mCRPC, new therapeutic strategies to overcome AR and ARV7 oncogenic signaling are urgently required. The inhibition of co-factors modulating AR signaling are currently being investigated as novel strategies to treat mCRPC. One promising candidate is BRD4, a member of the BET protein family, that binds the AR on androgen response elements and facilitates the recruitment of the transcriptional machinery. BET inhibitors (BETi) have been shown to regulate AR and ARV7 signalling, however, the exact mechanism of ARV7 regulation remains unclear. As BETi are currently being explored in clinical trials of unstratified patients with mCRPC, we investigated their potential mechanism of action in CRPC cell lines, patient derived organoids (PDOs) and a patient derived mouse xenograft (PDX). Here we demonstrate that nuclear expression of BRD4 and ARV7 increases as patients develop resistance to E and/or A and inhibition of BRD4 by BETi is sufficient to block AR and ARV7 signalling in mCRPC. Both inhibition of BRD4 by BETi and genetic knockdown of BRD4 reduced the growth of CRPC cell lines and led to down-regulation of AR and ARV7 at the mRNA and protein level. To further investigate whether BETi is sufficient to inhibit ARV7 activity in patients with mCRPC, we treated patient derived organoids (PDOs) and a mouse xenograft (PDX) grown from metastatic biopies of patients resistant to E and/or A with BETi. In this study 5 out of 10 PDOs were sensitive to BETi. Consistent with the cell culture experiments, BETi treatment of the PDX led to down-regulation of both ARV7 mRNA and protein expression. Mechanistically, BETi might inhibit pre-mRNA splicing of AR resulting in the observed decrease of ARV7 expression. However, RNAseq analysis of the ARV7 expressing CRPC cell line LNCaP95 demonstrated an increase in total splicing events including skipped exons, retained introns, mutually exclusive exons, alternative 5’ splice site and alternative 3’ splice site after BETi treatment. Despite this, focused analysis of splicing factors and spliceosome components identified a subset of eight splicing factors being down-regulated by BETi inhibition including one yet uncharacterized factor that is crucial for ARV7 expression in LNCaP95 cells. Based on our results we propose a model that BETi
mediated inhibition of this novel ARV7-mRNA splicing factor may lead to decreased splicing and subsequent expression of ARV7 at both mRNA and protein level; providing a novel approach to target ARV7 in mCRPC.

Background: Benign and malignant prostate tissues are dependent upon the activity of androgen receptor (AR). The primary function of full-length AR is as a ligand activated transcription factor to induce or repress gene expression. Many androgen-repressed genes regulate the cell cycle and proliferation. With castration, the main therapeutic approach for advanced prostate cancer (PC), these genes are believed to play a role in the initial clinical response. Current approved therapies for advanced PC and castration-resistant PC (CRPC), target the AR C-terminal ligand-binding domain (LBD), such as androgens. Recent antagonists of the AR N-terminal domain (NTD) have been described with EPI-506, the prodrug of EPI-002, now in Phase 1 clinical trials. EPI-002 binds tau-5 in activation function-1 (AF-1) of the NTD that is essential for AR transcriptional activity. As expected with an AF-1 antagonist, EPI-002 is an excellent inhibitor of androgen-induced gene expression and at blocking the transcriptional activities of truncated AR splice variants lacking LBD, such as AR-V7. EPI-002 blocks expression of genes regulated by truncated AR-V7 such as UBE2C while androgens have no effect. Here we reveal that the major difference in gene expression regulated by full-length AR between EPI-002 and androgens is their ability to down-regulate the genes that are upregulated by androgen. Methods: The androgen sensitive human prostate cancer cell line LNCaP, which expresses full-length AR, was treated with androgens (bicalutamide [BIC] and enzalutamide [ENZA]), EPI-002 and a control vehicle, with and without androgen. Gene expression was analysed using Affymetrix microarrays. Bioinformatical analysis was completed and a selection of androgen-repressed genes that were de-repressed with androgens and/or EPI-002, were selected for validation using qRT-PCR. Results: EPI-002 de-repressed known androgen-repressed genes including SULTLC3, ST7, PSAT1, TMEM140 and TNSFRSF21. EPI-002 was as effective or better than BIC or ENZA in de-repressing a subset of androgen-repressed genes. Importantly, EPI-002 failed to de-repress expression of many androgen-repressed genes that androgens down-regulated, such as SULT1C3, GPR63 and DAB1. Conclusions: EPI binds AR NTD which blocks the transcriptional activities of full-length AR and truncated AR splice variants. EPI-002 was excellent at inhibiting androgen-induced genes. However, EPI did not broadly de-repress expression of genes turned off by androgen when compared to androgen antagonists. Such differences between EPI-002, a tau-S/NTD antagonist, and C-terminal LBD antiandrogens probably reflect the complexities of the mechanisms of repression of gene expression that may involve different domains of AR.

#1517 AKT inhibition induces neuroendocrine phenotype in prostate cancer cells. RuQi Chen, Yinan Li, Xuesen Dong. University of British Columbia, Vancouver, British Columbia, Canada.

Androgen receptor (AR) signaling pathway inhibition (ARPI) is the primary treatment for the androgen-sensitive, recurrent, or metastatic prostate cancer. ARPI is effective in short term, a fatal relapse is inevitable. The ARK signaling pathway inhibition has been investigated under multiple ongoing clinical trials as a co-therapeutic target with ARPI. The AKT signaling pathway is targeted due to its role in tumorigenesis, prevalent over-activation, and reciprocal activation upon ARPI in prostate cancer. However, this novel combination therapy may in fact facilitate PCa to progress into one of the most lethal subtypes called neuroendocrine (NE) prostate cancer (NEPC). Specifically, evidence has shown that ARPI contributes to NEPC progression at least in part by down-regulating the expression of RE-1 Silencing Transcription Factor (REST). Knockdown of REST functions as a negative master regulator in neuroendocrine (NE) prostate cancer (NEPC). REST functions are dependent on p53 context. Besides having differential p53 statuses, these two cell systems also have other genetic differences that may or may not contribute to the opposing functions of ERβ. We are using an isogenic cell system that allows for expression of different combinations of ERβ and p53 that may or may not contribute to the opposing functions of ERβ. We are currently using an isogenic cell system that allows for expression of different combinations of ERβ and p53 that may or may not contribute to the opposing functions of ERβ. poor prognosis (15% of all mammary tumors). Previous studies have shown that specific G-rich genomic sequences in the promoters of multiple human genes can form G-quadruplex structures, resulting in decreased transcription and gene expression. These regions are generally found within gene promoters especially of oncogenes such as c-MYC, KRAS, VEGF, BCL2 or hTERT. Most of these genes are aberrantly expressed in breast cancer. The c-MYC gene regulates a large array of genes essential for cell functions including proliferation, metabolism, differentiation, adhesion and apoptosis. We have recently shown that oligonucleotides encoding the G-quadruplex sequence of the c-MYC, VEGF or hTERT promoters down regulate expression of their respective genes and inhibit cell proliferation. We hypothesized that such oligonucleotides could be applied to breast cancer cell lines in order to inhibit gene expression and metastasis. In this study, we evaluated the effect of oligonucleotides targeted to c-MYC (Pu27 and Pu27 Palmi), KRAS (KRASp), VEGF (VEGFq), hTERT (Tert-FL) and BCL2 (BCL2q) in Breast cancer cell lines (MDA-MB-231, SKBR3, MCF7) and MCF10A (non-transformed mammary cells). The effect of each oligonucleotide on cell growth was evaluated using the MTT assay. Our results reveal that all oligos inhibit cell growth of MDA-MB-231. However, for SKBR3 and MCF7, only Tert-FL had growth inhibitory activity. The control cell line MCF10A, did not respond suggesting that the oligonucleotides affect preferentially tumor cells. The effect of the oligonucleotides on gene expression (qRT-PCR) was performed on MDA-MB-231 exposed for 3 days. The analysis of gene expression shows the downregulation of c-MYC by Pu27 and hTERT by Tert-FL suggesting a direct effect on gene expression. In addition, Pu27 downregulated hTERT and VEGF in SKBR3 cells while c-MYC control in the cell line overexpressing c-MYC and is highly enriched in cancer stem cells, we evaluate the effect of Pu27 and Tert-FL on the tumourosphere formation. The results showed a very strong inhibition of tumourosphere formation in the cells treated with Pu27. Our findings suggest that oligonucleotides which target genes such as c-MYC, hTERT or KRAS very efficiently inhibit the growth of BC cell lines in particular MDA-MB-231 TN most likely by downregulating target gene expression. In addition, we demonstrate that downregulating c-MYC expression Pu27 dramatically reduces the cancer stem cell numbers. The use of G-quadruplex forming oligonucleotides targeted to c-MYC and /or hTERT may constitute a new therapeutic strategy especially for TNBC where targeted therapy is lacking.

#1521 hTERT G-quadruplex-targeted oligonucleotides inhibit glioblastoma cell growth. Alex West. University of Louisville, Louisville, KY.

Glioblastoma is one of the most common and deadly forms of brain cancer representing roughly 75% of all brain malignancies. These tumors generally have poor prognoses and are resistant to conventional therapy. It has recently been shown that as many as 80% of all glioblastomas contain mutations in a G-rich 68 base pair region of the hTERT promoter. hTERT is the catalytic subunit of telomerase, a ribonucleoprotein enzyme responsible for lengthening the ends of chromosomes thereby conferring immortality to cells. Normally, hTERT is not expressed in somatic cells and its expression is tightly controlled in stem cells. However, hTERT is upregulated in up to 95% of human tumors and is considered a key activator of cancer progression and a sign of poor clinical outcome. Therefore, hTERT has been under investigation for the past decade as a potential therapeutic target. We have shown that the mutations in hTERT promoter occur in a G-rich region that is part of a silencer element which forms a secondary G-quadruplex structure required for function, and that these mutations destabilize the G-quadruplex structure, allowing hTERT expression. We have also demonstrated that oligonucleotides encoding the G-quadruplex forming sequence in the c-MYC promoter can stabilize the G-quadruplex structure and downregulate c-MYC expression. Therefore, we hypothesized that oligonucleotides targeted to the G-quadruplex of the hTERT promoter could downregulate this gene expression and inhibit glioblastoma cell proliferation in a similar manner. We designed several G-quadruplex-forming oligonucleotides covering the mutated sites in the hTERT promoter either in totality (68 nucleotides) or separately (25 nucleotides) to stabilize the G-quadruplex region. Two glioblastoma cell lines (A172 and U87) and one neuroblastoma cell line (CHP134) were exposed to these oligonucleotides and evaluated for growth inhibition using the MTT assay and for gene expression by qRT-PCR. All oligonucleotides tested were found to induce between 40 to 90% growth inhibition in the 3 cell lines. The cell growth inhibition was both time and dose dependent and showed effectiveness as early as 3 days suggesting that this effect is not solely due to telomere shortening. Four oligonucleotides with the most consistent efficacy in growth inhibition were evaluated for their effect on hTERT expression in the 3 cell lines at 4 day exposure and revealed that two of the G-quadruplex forming oligonucleotides significantly decreased hTERT expression compared to untreated cells. In conclusion, we have defined G-quadruplex oligonucleotides targeted to the hTERT promoter that downregulate hTERT gene expression and are effective growth inhibitors in glioblastoma cells. Our findings indicate that downregulation of hTERT with targeted oligonucleotides affects non-canonical functions of hTERT conferring an advantage to this therapeutic approach.

#1522 Targeted gene therapy - c-MYC and hTERT in the scope. Francine Rezzoug, Sheila D. Thomas, Segen Tella, Donald M. Miller. Univ. of Louisville, Louisville, KY.

In the past decade immunotherapy and kinase inhibitors have revolutionized the approach for cancer therapy, particularly for melanoma which has benefited from this new therapy in the last 5 years. Although, new treatment increase patient survival, there is no cure and treatments are often limited to a subtype of patients. Therefore there is still an urgent need for efficient therapy for melanoma. Among potential targets for cancer therapy, c-MYC and hTERT which are overexpressed in up to 85% of all cancers are the most promising. The overexpression of hTERT provides indefinite division to cancer cells. Deregluation of c-MYC affect a large array of genes involved in cell cycle, proliferation/differentiation and apoptosis. Notably, both c-MYC and hTERT genes have in their promoter area a G-rich sequence that form secondary structure called G-quadruplex. These G-quadruplex structures are part of the silencers and are required for the repression of c-MYC or hTERT transcription. Mutations in the G-rich sequences of hTERT promoter destabilize the G-quadruplex and are associated with incidence of melanoma. We have shown that oligonucleotides form G-quadruplex sequences of these genes promoter downregulated their respective gene expression and inhibit cell growth in different cell lines. We investigated the effect of targeting c-MYC or hTERT gene expression in melanoma cell lines using oligonucleotides targeted to the silencer G-quadruplex sequence. Four cell lines where investigated (SK-Mel-2, SK-Mel-3, SK-Mel-28 and A375) for the effect of Pu27 (targeting c-MYC) and Tert-FL (targeting hTERT) on cell proliferation using MTT assay. The treatment for 6 days resulted in 60% growth inhibition in the presence of Pu27 and 50% in the presence of Tert-FL for SK-Mel-2, SK-Mel-3, SK-Mel-28 while A375 was less sensitive. Gene expression evaluated by QRT-PCR showed down-regulation of c-MYC and hTERT in cell exposed to Pu27 and hTERT in cells exposed to Tert-FL. hTERT expression is regulated by c-MYC and in our experiment the down-regulation of c-MYC correlate with down-regulation of hTERT suggesting a cascade effect. In addition, SOX2 gene expression was also down-regulated by Pu27 suggesting an effect on the cancer stem cells (CSC). Our data demonstrate that oligonucleotides targeted to c-MYC and hTERT down-regulate gene expression associated with melanoma cell growth inhibition and possibly on metastasis.

#1523 The mechanism of action of BCL6 in glioblastoma. Nicole M. Jones, 1 Marie-Sophie Fabre, 1 Dinindu Sachindra Senanayake, 1 Katerina Hatzi, 2 Ari M. Melnick, 3 Melanie J. McConnell, 1 Victoria University of Wellington, Wellington, New Zealand; 2 Weill Cornell Medical College, Cornell University, New York, New York.

Glioblastoma (GBM) is the most common and most deadly brain tumor to occur in adults. Initially patients respond to radiation and chemotherapy, which primarily work by causing large amounts of DNA damage, causing apoptosis of the cells. However, this process does not happen effectively in GBM and understanding how these cells resist cell death in response to therapy is key to improving the efficacy of treatment. BCL6 is a transcription factor that stops cell death in response to DNA damage. Recent work in our lab has shown BCL6 to be present in untreated GBM tumors and up-regulated in treated GBM cells. This evidence indicates that BCL6 may be used as a mechanism of therapy resistance by GBM cells. In this study, the objective was to determine the mechanism of action of BCL6 in GBM cells using luciferase reporter assays, quantitative chromatin immunoprecipitation (ChIP) and RNA sequencing. We observed that BCL6 was transcriptionally active in GBM as shown by a reduction in luciferase activity when BCL6 was present. qChIP experiments revealed that BCL6 binding changed over time and was different with different types of DNA-damaging treatment. Preliminary analysis of our RNA sequencing data has identified a unique subset of genes which are upregulated when BCL6 is inhibited and downregulated in response to chemotherapy. These changes indicate that these genes may be regulated by BCL6 in chemotherapy treated cells. All of these results illustrate that BCL6 appears to have an active and relevant function in GBM cells, which demonstrates that BCL6 is an attractive therapeutic target in GBM.
MOLECULAR AND CELLULAR BIOLOGY / GENETICS: Targeting Aberrant Transcription in Cancer

#1524 BCL6 modulates the TP53 and STAT pathways in glioma. Ye Chen,1 Liang Xu,1 Marina Dutra-Clarke,1 Anand Mayakonda,1 De-Chen Lin,1 Lynnette Koh,1 Yun Kien Chang,1 Edwin Sandanaraj,1 Vikas Madan,2 Henry Yang,3 Ngan Doan,4 Jonathan W. Said,5 William H. Yong,6 Markus Mûschen,7 Bing Ti Ang,8 Carol Tang,9 Joshua J. Breunig,4 Phillip Koefler,1 National University of Singapore, Singapore, Singapore;2Cedars-Sinai Medical Center, UCLA, Los Angeles, CA;3National Neuroscience Institute, Singapore, Singapore;4UCLA, Los Angeles, CA;5USCF, San Francisco, CA.

Glioblastoma multiforme (GBM) remains the most aggressive brain malignancy with little improvement in prognosis or therapy for decades. Recently, we identified BCL6, also known as ZBTB27, to be a novel oncogene in GBM. In this study, we performed IHC analysis of 133 primary human glioma specimens and 8 normal brain samples. BCL6 expression is robustly elevated in tumor samples and positively correlated with glioma pathological grade. High BCL6 expression strongly predicts a worse prognosis of GBM patients. Depletion of BCL6 in human GBM cells reduced the incorporation of BrdU, promoted the cellular senescence and inhibited the growth of human GBM cells in vivo. Next, genome-wide occupancy of BCL6 in GBM cells was characterized by ChIP-seq assay. Genomic regions centered on BCL6 peaks are co-enriched with RNA-Pol II and flanked with strong H3K27ac and H3K4me3 modifications. MYC and two long non-coding RNAs MALAT1 and NEAT1 were identified as novel BCL6 targets in GBM. Moreover, pathway enrichment analysis of BCL6 peak-associated genes reveals a significant enrichment of JAK-STAT, TP53, ERBB and MAPK pathways. We demonstrated further that BCL6 represses the TP53 pathway and promotes the JAK-STAT pathway activation in GBM cells. Together, our findings uncover potential downstream targets and provide a better understanding of BCL6 function in GBM.

#1525 Chemically induced degradation of the oncogenic transcription factor BCL6. Nina Kerres,1 Steffen Steurer,1 Stefanie Schlager,1 Gerd Bader,1 Helmut Berger,1 Sophia Blake,1 Maureen Caligiuri,1 John Engen,2 Pete Emmert,1 Thomas Gerber,3 Daniel Gerber,3 Rosanna Jacob,3 Simon Lucas,1 Moriz Mayer,1 Mischerikow Nikola,1 Rumpel Klaus,1 Schirm Dirk,1 Schnitzer Renate,1 Tilman Voss,1 Zoepfhe Andreas,1 Norbert Kraut,1 Darryl McConnell,3 Pearson Mark,1 Manfred Koegl1.

The transcription factor BCL6 is a known driver of oncogenesis in lymphoid malignancies, including diffuse large B-cell lymphoma (DLBCL). It is a DNA-binding protein that represses gene transcription through the recruitment of co-repressor proteins via its BTB domain. Disruption of the interaction of BCL6 with co-repressor proteins interferes with the physiological and oncogenic functions of BCL6. We have used structure-based drug design to develop potent compounds that block this interaction with half maximal inhibitory concentration values (IC50) below 3 nM. In addition to inhibiting co-repressor binding, a subset of the identified inhibitors also caused rapid disappearance of BCL6 protein in cells. This effect was mediated by compound-induced multi-ubiquitylation of BCL6 and degradation by the proteasome and was dependent on the presence of a functional DNA binding domain on BCL6. Compounds that induced BCL6 degradation displayed significantly stronger induction of expression of BCL6-repressed genes than compounds that merely inhibited co-repressor interaction. BCL6-degrading inhibitors had anti-proliferative effects in several DLBCL cell lines, while non-degrading BCL6 inhibitors only had minor effects on proliferation. The fact that the magnitude of effects elicited by this novel class of BCL6-degrading compounds greatly exceed that of our equipotent classical co-repressor interaction inhibitors offers exciting new opportunities for the development of BCL6-based lymphoma therapeutics.

#1526 Usp9x inhibition and depletion overcomes SOX2 dependent resistance to BRAF inhibition in melanoma. Harish Potu,1 Ann. Michigan Comp Cancer Ctr., Ann Arbor, MI.

Melanoma tumors often show limited response to BRAF/MEK/ERK pathway inhibitors currently used in melanoma treatment. One mechanism of resistance to current melanoma treatments is upregulation of SOX2, a transcription factor that is essential for tumor growth and expansion, particularly in tumors with BRAF mutation in melanoma. Targeting drugs to transcription factors has been elusive and limits treatment options. Here we report that the deubiquitinating enzyme Usp9x controls SOX2. We show that ubiquitin-specific peptidase 9, X-linked (Usp9x), a deubiquitinas (DUB) enzyme, binds SOX2 in melanoma and deubiquitinasizes SOX2 in vitro. Usp9x knockdown results in increased levels of ubiquitinated SOX2 in melanoma, is coupled with depletion of SOX2 and promotes apoptosis synergistically with vemurafenib in melanoma cell lines. Protein levels in primary melanoma tumor samples demonstrated moderately elevated Usp9x/SOX2 protein expression in metastatic melanoma compared to primary melanoma patient tumors. Further, Usp9x knockdown or inhibition with G9, a DUB inhibitor, blocked BRAF/MEK kinase inhibitor-induced induction of SOX2 and fully suppressed in vitro colony growth of BRAF-mutant melanoma cells and promoted apoptosis. We discovered a novel mechanism of targeting SOX2, transcription factor by inhibition of Usp9x. Thus, development of DUB inhibitors will add to the limited repertoire of current melanoma treatments.

#1527 BRD3 as a specific vulnerable therapeutic target in neuroblastoma. Kaat Durinck,1 Jolien Dewyn,1 Anneleen Beckers,1 Siebe Loontiens,1 Suzanne Vanhauwaert,1 Daniel Carter,2 Belamy Chung,2 Glenn Marshall,2 Katleen Depreter,1 Frank Westermann,3 Frank Speleman1, Ghent University, Ghent, Belgium;4Children's Cancer Institute Australia for Medical Research, Sydney, Australia;5DKFZ, Heidelberg, Germany.

Introduction: BET inhibitors have raised high expectations for cancer treatment given their anti-proliferative effect by inhibiting BRD4 controlled enhancer activity of highly transcribed genes such as MYCN. However, current inhibitors also target BRD2 and BRD3 which are functionally nonredundant with BRD4. In neuroblastoma only MYCN amplified tumors respond well to these drugs. Methods: We performed an integrated bioinformatics approach to scrutinize BET family genes as well as further candidate epigenetic regulators as targets for novel therapies in neuroblastoma. Results: First we performed a time-resolution expression data analysis of week 1 and 2 hyperplastic lesions and tumors derived from the TH-MYCN transgenic mouse model and confirmed dynamic regulation during tumor development for established neuroblastoma oncogenes and tumor suppressor genes. Next, we filtered within the highest upregulated genes for Cancer Gene Census (CGC) genes and identified 21 upregulated CGC genes mainly involved in chromatin remodeling and DNA repair. Finally, after further selection based on expression in CGCle and survival in neuroblastoma patients, BRD3 was identified as the top-ranked candidate. BRD3 exhibits drastic upregulation during tumor formation. Elevated BRD3 expression is the highest expressed gene in neuroblastoma cell lines upon analysis of the CCLE panel and associated with very poor prognosis. To explore the nonredundant functions of BRD3 in relation to BRD4, we performed RNA-sequencing after stable knockdown of BRD3 in neuroblastoma cell lines and compared the downstream effects on the transcriptome as well as the impact on cell viability to knockdown of BRD4 and pharmacological treatment with BET-inhibitors (IQ1, OTX015). In addition, we dissected the BRD3 protein complex by means of label-free mass spectrometry analysis to gain further insights into the BRD3 specific functions in relation to control of gene transcription and putative interaction with transcription factors such as MYCN. Current efforts are ongoing to test cooperative interaction of BRD3 versus BRD4 in dbh-MYCN driven neuroblastoma formation in zebrash as well as BRD3 and BRD4 CHIP-sequencing in neuroblastoma cells. Conclusion: We identified BRD3 as a novel candidate drug gene in neuroblastoma and will present differential transcriptional control and protein interactions of BRD3 versus BRD4. This study can open the way towards developing BRD3 specific inhibitors for neuroblastoma and other BRD3 overexpressing cancers such as T-ALL and small cell lung carcinoma.

#1528 Forecasting novel therapies by understanding the Notch3 signaling in ovarian cancer. Alejandro Villar-Prados,1 Jason Roszik,1 Avril K. Sood,1 Margaret I. Engelhardt2, UT MD Anderson Cancer Center, Houston, TX;2McGovern Medial School, Houston, TX.

Advances in cancer research have led to the rapid development of novel drug therapies designed for optimal personalized patient care. Despite this surge of treatments, there is still a challenge in accurately predicting the most effective targeted therapy for a specific cancer. Additionally, the potential of systematically identifying and repurposing currently existing therapeutics designed for one specific cancer to treat other malignancies remains understood. To address this problem, our group has developed an integrative computational therapy-forecasting algorithm. This algorithm incorporates data from The Cancer Genome Atlas (TCGA) as well as molecular and survival correlations to identify candidate anti-tumor drugs that can be re-purposed for other malignancies by targeting novel pathways. Our computational analysis predicted that bromodomain inhibitors, which inhibit bromodomain-containing proteins such as BRD4, would target the Notch3 pathway in high-grade serous ovarian carcinoma (HGSC). Upregulation of Notch3 plays a crucial role in HGSC tumorigenesis and is associated with worse patient survival. Current Notch3 targeted therapies are not effective, thus designing therapeutic strategies to target Notch3 are critical. Here, we hypothesize that inhibition of BRD4 is an effective therapeutic target in HGSC by downregulating the Notch3 pathway. Current in vitro results demonstrated that BRD4 inhibition either by using chemical inhibitors or siRNA results in a decrease in HGSC cell viability by both MTT and 2-D colony formation assays. Furthermore, inhibition of BRD4 resulted in a decrease
in both Notch3 transcription and protein levels. Given that BRD4 regulates gene transcription, we performed chromatin immunoprecipitation (ChIP) and observed that BRD4 was present in the Notch3 gene promoter. These findings suggest that by inhibiting BRD4 in HGSC, we can target Notch3 and biologically validate our initial in silico analysis. The successful completion of this project will have major implications for development of personalized therapies not only for HGSC but also for other cancers as well.

#1529 Scutellaria baicalensis targets the hypoxia-inducible factor-1α and attenuates ovarian cancer growth. Imran Hussain, 1 Sana Waheed, 1 Kashif A. Ahmad, 1 John E. Pirgo, 1 Vigar Syed, 1 1Uniformed Services Univ. of the Health Sci., Bethesda, MD; 2University of Illinois College of Medicine-Urbana Champaign, Urbana, IL; 3Northwestern Health Sciences University, Bloomington, MN. Hypoxia-inducible factor-1α (HIF-1α), a transcription factor important for maintaining cellular oxygen homeostasis, is aberrantly upregulated in many tumors and implicated in angiogenesis, metastasis and drug resistance. Therefore, developing treatments that target HIF-1α may be a viable therapeutic approach. For centuries, traditional Chinese medicine has used herbs, such as Scutellaria baicalensis (SB), as a natural remedy for tumors. However, the mechanisms by which SB inhibits its tumor growth are not known. We have previously reported that SB inhibits cancer cell proliferation and targets NF-κB in endometrial and ovarian cancers and TGF-β in endometrial cancers. In this study, we examined the effects of SB on HIF-1α protein levels in three ovarian cancer cell lines, SKOV3, OVCA 429, and OVCA 420, grown under normoxic and hypoxic conditions. When treated daily with SB, cancer cells showed a decrease in HIF-1α expression after 48 hours. Investigation into the molecular mechanisms of SB-induced inhibition revealed a significant reduction of HIF-1α accumulation in cells treated with cycloheximide, a protein synthesis inhibitor. Further decrease of HIF-1α accumulation was seen when cycloheximide was combined with SB. Additionally, SB-induced HIF-1α proteasomal degradation was prevented by treatment of cells with proteasomal inhibitor MG132 and chloroquine, lysosome inhibitor, abrogated SB-induced inhibition of HIF-1α. Activation of PEEK/Adk and MAPK/ERK is shown in cancers. SB reduced levels of phospho-AKT and phospho-extracellular signal-related kinase (ERK) in ovarian cancer cells. Furthermore, pretreatment of cells with LY294002 (phosphoinositide 3-kinase inhibitor) and PD98059 (mitogen-activated protein kinase kinase inhibitor) reduced HIF-1α expression comparable to SB-treated cells. Hypoxia-induced cisplatin resistance is a major challenge in therapy of ovarian tumors. SB reduces the proliferation and reverses cisplatin resistance in ovarian cancer cells by attenuating the expression of HIF-1α. Taken together, the findings suggest that targeting HIF-1α with SB could be an effective treatment strategy for ovarian cancer and that SB can improve the sensitivity of cells to cisplatin.

#1530 RUNX1 positively regulates ErbB2/HER2 signaling pathway through modulating the expression of SOSI in gastric cancer cells. Yoshinhe Mito,1, 2 Naoko Maeda,1, 2 Shinziro Izumi,1, 2 Kenzo Sugihara,1 Yoshinoh Oki,2 Koichi Akashi,2 Koichiro Kano,3 Hideyuki Saya1, 1Institute for Advanced Medical Research, Keio University School of Medicine, Tokyo, Japan; 2School of Pharmacy and Pharmaceutical Sciences, Hoshi University, Tokyo, Japan; 3College of Bioresource Sciences, Nihon University, Tokyo, Japan; 4Kyushu University Graduate School of Medical Science, Fukuoka, Japan. We generated induced cancer stem cells that initiate osteosarcoma (OS) by overexpression of c-MYC and loss of Ink4a/Arf in bone marrow-derived stromal cells, and found that the loss of adipogenic potential is an essential event for OS tumorigenesis. Therefore, our understanding of regulatory mechanisms of adipocyte differentiation is crucial to the development of novel therapeutic strategies for OS. Here, we show that regulation of the transcriptional coactivator MKL1 (megakaryoblastic leukemia 1) by actin cytoskeleton dynamics drives adipocyte differentiation mediated by PPARγ. Exposure of preadipocytes to an adipogenic cocktail results in rapid downregulation of stress fibers as a consequence of downregulation of Rock1 and Rock2. Exposure of preadipocytes to adipogenic cocktail results in significant suppression of RUNX1 expression in OS cells. Our findings suggest that targeting RUNX1 with SB could be an effective strategy against osteosarcoma and that SB can improve the sensitivity of cells to cisplatin.

#1532 Mithramycin induces the antiproliferative activity of chemotherapeutic agents in Ewing sarcoma cells. Anish Ray,1 Bhavani Nagarajan,2 Umesh T. Sankpal,2 Sagar Shelake,2 W. Paul Bowman,2 Andras Lacko,2 Riyaz M. Basha2. 1Cook Children’s Medical Center, Fort Worth, TX; 2University of North Texas Health Science Center, Fort Worth, TX. Ewing sarcoma (ES) is one of the most frequent primary bone and soft tissue tumors to occur in pediatric and adolescent population. ES is often diagnosed after the disease has already metastasized. With available treatment options, the prognosis of metastatic ES patients is poor and the 5-year survival rate is less than 20%. Therefore, identifying precise targeted therapies to induce therapeutic response in ES patients is urgently needed. An oncogenic fusion protein and transcription factor EWS-FLI1 is associated with more than 85% of ES tumors. Mithramycin has been identified as an effective agent to target EWS-FLI1 and is currently in clinical trials. In this study, we investigated the efficacy of Mithramycin to induce the anti-proliferative activity of chemotherapeutic agents commonly used for the treatment of this malignancy using human ES cell lines. TC71, TC32, CHLA32, CHLA10 and TC205 cells were treated with increasing concentrations of Mithramycin or Vincristine or Doxorubicin or Etoposide. Cell growth inhibition was evaluated at 24 and 48 h post-treatment using CellTiter Glo kit. Results showed a dose/time-dependent anti-proliferative effect for all agents. To confirm the effect of Mithramycin on selected cell lines, mRNA expression of downstream targets of EWS-FLI1 (ID2, LDB2, NROB1 and RCOR1 genes) was determined by quantitative PCR following treatment with Mithramycin. Mithramycin significantly down-regulated all tested genes and these results are in agreement with published work. In order to determine the combination response, cell growth inhibition of the chemotherapeutic drugs was assessed in the presence of added Mithramycin. The combination Index was evaluated by Chou-Talalay method. Further studies were performed for the combination of Mithramycin and Vincristine to investigate its effect on apoptosis and cell cycle arrest using CHLA10 and TC205 cells. Apoptotic markers such as the expression of cleaved Poly (ADP-ribose) polymerase (c-PARP) and survivin were determined by Western blot analysis. The apoptotic cell population was measured by Annexin-V staining using flow cytometry. When compared to individual agents, the combination of Mithramycin and Vincristine showed greater effect on apoptosis in both cell lines as evidenced by an increase in Apoptotic markers in the presence of Mithramycin.
was significantly decreased following HDAC inhibition, the same response was not observed in HeLa cells. These findings suggest that p53 status may be an important determinant of therapeutic response to HDAC inhibition.

Angiogenesis is a key process in tumor propagation, progression, and metastasis. This process is tightly modulated by a wide range of growth factors, receptors, cytokines, matrix metalloproteinases, and transcription factors. Distinctively, vascular endothelial growth factor (VEGF) and its receptors have been identified as prominent targets in antiangiogenesis. Therefore, inhibiting VEGF-induced tumor angiogenesis has been explored extensively for cancer therapy. In this context, F16, a novel small molecule possessing a unique molecular configuration to block VEGFR2, has been subjected to intensive preclinical investigations. The F16 molecule exhibits in vitro antiangiogenic activity via inhibiting endothelial cell proliferation, migration, and tube formation. In addition, F16 was found to significantly inhibit the in vivo angiogenesis in chick chorioallantoic membranes as well as in athymic nude mice with xenograft tumors. As a consequence of the antiangiogenic effects, F16 was able to effectitively control the tumor growth in mice with xenograft tumors.

In the present study, we aimed to comprehensively interrogate the impact of F16 treatment on the expression of a panel of angiogenesis-related genes to gain insights into the cellular mode of action of F16 on angiogenesis. We analyzed the expression of 84 genes that are known to be associated with angiogenesis in human umbilical vein endothelial cells (HUVECs). Our pilot study identified upregulation of some key genes in response to F16 treatment which include tissue inhibitor of metalloproteinase 1 (TIMP1), angiopoietin-like 4 (ANGPTL4), chondromodulin 1 (LECT1), and placenta growth factor (PIGF). On the other hand, several genes involved in promoting angiogenesis were downregulated, which include matrix metatlopeptidase 9 (MMP9), integrin subunit beta 3 (ITGB3), insulin growth factor 1 (IGF1), transforming growth factor alpha (TGFα), interleukin 6 (IL6), leptin (LEP), thrombospondin 1, 2 (THBS1, 2), tyrosine kinase (TEK), VEGF and C. The differential gene expression related to pro- and anti-angiogenic growth factors coincide very well with our previous observation of F16 inhibiting endothelial cell proliferation, migration, and tube formation. Based on the Gene Expression Profile (GEP) observed in our experiments, we speculate that F16 can induce TIMP1 in which turn could suppress the MMP9 signaling leading to the inhibition of endothelial cell migration. This disruption of TIMP1/MMP9 pathway offers an interesting foundation for functional studies that can be performed to confirm the role of F16 as a potential MMP9 inhibitor, which may provide extended benefits during the use of this drug for treating highly metastatic cancers. (This project was supported by The Royal Dames of Cancer Research Inc., Ft. Lauderdale, Florida.)

#1536 CRISPR/Cas9 biased mutagenesis in the mouse genome: Is it useful or harmful for cancer therapeutics. Ha Youn Shin, NIH, Bethesda, MD.

Advances in CRISPR/Cas9 genome editing have provided unprecedented opportunities to interrogate the functional significance of any given genomic site. While this technology is rapidly spreading and extended to with almost 4,000 PubMed entries as of today, there is a paucity of data on the extent of unexpected and undesired molecular consequences established upon targeting the mouse genome. We have introduced deletions at more than 20 genomic sites including CTCF and STAT5 transcription factor binding sites, screened over 500 founder mice and established and analyzed more than 50 lines. These data sets revealed hitherto unknown deletion patterns, unexpected large deletions using single sgRNAs and the consistent deletion of sequences bridging distant loci that were targeted simultaneously. Our findings provide guidelines for the application of CRISPR/Cas9 in the mouse germline and provide the insight into designing CRISPR-based cancer therapeutics.

#1536A Progestrone receptor regulation of interferon signaling in breast cancer. Katherine Walter, Merit Goodman, Gloria Trinca, Jade Hall, Christy Hagan. University of Kansas Medical Center, Kansas City, KS.

Breast cancer is an extremely heterogeneous disease that affects close to two million women across the globe each year. Of these breast tumors, approximately 70% expresses the progesterone receptor (PR), a nuclear receptor that is activated by progestin ligands. Compelling clinical trial data has suggested that progestins have a role in breast cancer development, independent of the widely studied estrogen receptor. The mechanism by which this occurs, however, is vastly understudied. Traditionally, PR exerts its effects following ligand activation by translocating to the nucleus and binding to DNA.
where it affects the transcription of a variety of genes involved in growth, survival and proliferation. Our lab, using microarray data combined with Gene Set Enrichment Analysis, has identified a novel subset of genes that have altered expression following PR activation. These genes are primarily involved in interferon signaling—a pathway normally utilized in response to viral infection. Our data show that many genes that are normally activated in response to interferon signaling (interferon stimulated genes, ISGs) are repressed when PR is activated by its ligand. Interestingly, this repression occurs even in the presence of interferon alpha—the activating ligand of the interferon signaling cascade. Our lab has also shown that when PR expression is transiently knocked down, ISG transcriptional repression is lost, indicating that the repression of these genes is PR dependent. In attempting to elucidate a mechanism by which PR exerts this effect, we have performed chromatin immunoprecipitation experiments following PR activation and observed PR recruitment to ISG enhancer regions. This suggests PR is potentially interfering with normal transcription of these genes. We hypothesize that PR is functioning by either blocking normal transcriptional machinery and co-activators or through the recruitment of transcriptional co-repressors to these regions. Experiments to address these models are currently underway. Evasion of the immune system has recently been added to the list of Hallmarks of Cancer and our preliminary data suggest a potential mechanism by which breast cancer is able to accomplish this. Activation of type I interferon signaling is an early step in marking tumors for immune clearance. By repressing ISG protein expression, it is possible that these tumors are able to avoid detection by host immune cells leading to tumor establishment and subsequent progression. Our preliminary data suggest that PR may be capable of aiding early breast malignancies in evading immune recognition. This novel role of PR and progesterins offers insight that could aid in improving upon established estrogen only-based therapies for prevention and treatment of hormone dependent breast cancers.

#1539 Investigating the mechanisms of tumor suppression mediated by PTEN PDZ-binding domain in a murine breast cancer model. Mingqi Yan,1 Alexander Many,2 Hong Guan,3 Penelope M. Or,1 Andrew M. Chan1.1 School of Biomedical Sciences, Faculty of Medicine, The Chinese University of Hong Kong, Shatin, Hong Kong; 2Department of Oncological Sciences, Mount Sinai School of Medicine, New York, NY; 3Department of Pediatrics, Medical College of Wisconsin, Milwaukee, WI.

PTEN (Phosphatase and tensin homolog) functions as a key negative regulator of PI3K-Akt pathway through its lipid phosphate activity. Mutations or loss of PTEN is frequently observed in brain, breast, prostate and endometrial cancer. PTEN possesses a PDZ-binding domain (PDZ-BD) at the end of its carboxy terminal. Functionally, PDZ-BD mediates PTEN’s interactions with other PDZ-domain-containing proteins, including ZO-1, PSD-95, DLG, etc, which are involved in the formation of cell junctions, post-synaptic densities, and serves as scaffolding proteins for multiple signaling complexes. However, whether the PDZ-binding domain is required to suppress tumorigenesis still remains obscure. To study the role of PTEN PDZ-BD in breast epithelial tumorigenesis, a PTEN ΔPDZ mice lacking this domain was generated. PTEN expression level and activity of PI3K-Akt pathway are not changed in the mammary epithelial cells, indicating that PDZ-BD is dispensable for PTEN stability and negative regulation of the PI3K-Akt pathway. Further, we crossed the PTEN ΔPDZ mice with the MMTV-PyMT breast cancer model and observed increased total tumor burden as well as higher tendency of lung metastasis in PTEN ΔPDZ mice. This data indicates that PTEN PDZ-BD is indeed important for tumor suppression during breast cancer progression. Previously, PTEN has been reported to govern the integrity of tight junctions and apical-basal polarity of epithelial cells, which requires PTEN’s interactions with other proteins through the PDZ-BD. However, through in vitro three-dimensional culture of primary mouse mammary epithelial cells, we failed to observe any disruption of either apical-basal polarity or tight junction. Meanwhile, we investigated the alteration of the transcriptome of breast cancer tissue in PTEN ΔPDZ mice by performing RNA-sequencing. Several enriched signaling pathways were identified by Ingenuity Pathway Analysis (IPA), which seems to be mainly associated with cell signaling as well as signaling interaction between extracellular matrix and the cancer cell. A list of genes were validated by RT-PCR, and functional validation of these genes during the tumorigenesis in our animal model is to be carried out in the near future. This work was supported by a General Research Fund grant (#160713) from the Hong Kong University Grants Committee to AC. YM was supported by a Hong Kong PhD Fellowship (PT12-13584), and a Lo Kwee-See Biomedical Research Seed Fund to AC.

#1540 Creating faithful genetic zebrafish models of pediatric high grade gliomas and MPNSTs. Felix Oppel, Ting Tao, Shuning He, Mark W. Zimmerman, Dong H. Ki, Nina Weichert, A Thomas Look. Dana-Farber Cancer Institute, Boston, MA.

Pediatric high-grade gliomas (HGGs) are the leading cause of cancer-related death in children. Despite a slight improvement of patient prognosis over the past decades pediatric HGGs remain largely incurable. Thus, new experimental models are needed to understand the mechanisms of the disease and find more effective treatment options. We previously reported a model of HGGs and malignant peripheral nerve sheath tumors (MPNSTs) which is based on the combined deficiencies in the tumor suppressor genes tp53 and nf1. However, HGG penetration is very low in this line and most fish develop MPNSTs starting at about 3 months of age. On top of the existing model we used CRISPR/Cas9 to incorporate knock-out mutations in the tumor suppressor genes arx or suz12 which are described to be involved in pediatric HGG biology. Heterozygous arx loss-of-function (lof) did not impact tumor onset or penetrance of neither HGGs nor MPNSTs. Since a total loss of arx was lethal in development, we re-injected effective arx targeting gRNAs and Cas9 mRNA into the arx+/− line to create a mosaic arx−/− genotype. Surprisingly, despite a high mutation efficiency of the remaining arx allele the re-injection strategy still did not alter tumor onset and penetrance in that model. This suggests that loss of arx is only
The tumor suppressor BAP1 promotes a developmental switch of each gene per cell. When at least 2 out of 4 alleles of either suz12a or suz12b asnf1, suz12 is duplicated in zebrafish (suz12a and suz12b) resulting in 4 alleles in vivo developmental model to study the functions of BAP1. Results and conclusions: Loss of BAP1 during embryo development results in a failure to turn off pluripotency genes such as vext1, vext2 (Xenopus orthologues of the mammal gene nanog), oct 25, oct 91 (Xenopus orthologues of the mammal gene oct3/4) and pax3, and a failure to induce lineage specification genes such as the prospective epidermis marker keratin1 and the melanocyte precursor marker sox10. This block in the shift from pluripotency to differentiation programs results in a delay in gastrulation, neural crest specification and migration, mesodermal differentiation and other phenotypes. The BAP1-deficient phenotype can be rescued by Xenopus or human wildtype BAP1 or by the histone deacetylase inhibitor SAHA (vorinostat). We conclude that BAP1 is a fundamental regulator of multiple developmental lineages, including the neural crest from pluripotency to differentiation. These obstacles led us to shift to Xenopus laevis as an in vivo developmental model to study the functions of BAP1. Results and conclusions: Loss of BAP1 during embryo development results in a failure to turn off pluripotency genes such as vext1, vext2 (Xenopus orthologues of the mammal gene nanog), oct 25, oct 91 (Xenopus orthologues of the mammal gene oct3/4) and pax3, and a failure to induce lineage specification genes such as the prospective epidermis marker keratin1 and the melanocyte precursor marker sox10. This block in the shift from pluripotency to differentiation programs results in a delay in gastrulation, neural crest specification and migration, mesodermal differentiation and other phenotypes. The BAP1-deficient phenotype can be rescued by Xenopus or human wildtype BAP1 or by the histone deacetylase inhibitor SAHA (vorinostat). We conclude that BAP1 is a fundamental regulator of multiple developmental lineages, including the neural crest from pluripotency to differentiation.

MOLECULAR AND CELLULAR BIOLOGY / GENETICS: Tumor Suppressors 1: Modeling, Metabolism, and Epigenetics

#1541 The tumor suppressor BAP1 promotes a developmental switch from pluripotency to differentiation. Jefnim N. Kuznetsov, Tristan Aguero, Stefan Kurtenbach, Matthew G. Field, Mary Lou King, Jeremy William Harbour. University of Miami Miller School of Medicine, Miami, FL.

Introduction: Our lab discovered that mutations in the tumor suppressor BAP1 are strongly associated with metastasis and death in patients with uveal melanoma. Subsequently, other cancers have been found to harbor BAP1 mutations, including ovarian melanoma, kidney, adrenal, and brain tumors. Germline BAP1 mutations are responsible for a newly described genetic cancer syndrome. Therapeutic molecules that reverse the effects of BAP1 mutations could represent a potent new treatment strategy for BAP1-mutant cancers. Unfortunately, there are several obstacles to developing such therapies. First, BAP1 is a tumor suppressor that is inactivated by mutations, such that targeted therapy would need to be directed against downstream effectors that are deregulated by BAP1 loss. Second, the effectors of BAP1 that are relevant to cancer are not known. Interestingly, most known proteins that interact with BAP1 are developmental epigenetic regulators such as Asxl1/2, Cbx1/3 and Kdm1b. Third, BAP1 is difficult to study in cultured cells because BAP1 loss results in cell cycle exit and stem cell-like behavior. These obstacles led us to shift to Xenopus laevis as an in vivo developmental model to study the functions of BAP1. Results and conclusions: Loss of BAP1 during embryo development results in a failure to turn off pluripotency genes such as vext1, vext2 (Xenopus orthologues of the mammal gene nanog), oct 25, oct 91 (Xenopus orthologues of the mammal gene oct3/4) and pax3, and a failure to induce lineage specification genes such as the prospective epidermis marker keratin1 and the melanocyte precursor marker sox10. This block in the shift from pluripotency to differentiation programs results in a delay in gastrulation, neural crest specification and migration, mesodermal differentiation and other phenotypes. The BAP1-deficient phenotype can be rescued by Xenopus or human wildtype BAP1 or by the histone deacetylase inhibitor SAHA (vorinostat). We conclude that BAP1 is a fundamental regulator of multiple developmental lineages, including the neural crest from pluripotency to differentiation.

#1542 Identifying genetic modifiers of PTEN using the Collaborative Cross mouse panel. Amanda Lanier, William Barrington, David Threadgill. Texas A&M University, College Station, TX.

Tumor suppressor genes code for proteins that limit cellular proliferation and cancer progression, and are often exploited in cancer therapies. One such tumor suppressor gene, Phosphatase and Tensin homolog deleted from Chromosome Ten (PTEN), mediates cell growth through negative regulation of phosphatidylinositol 3-kinase (PI3K) dependent pathways. PTEN is frequently deleted or mutated in a variety of human cancers. Mice carrying a PTEN transgene (Super-PTEN) mice) were found to be resistant to tumor formation, and even small changes in PTEN expression and activity have been shown to influence cancer susceptibility and progression. We hypothesized that PTEN activity can be altered by modifier genes. To determine whether PTEN modifiers are influencing its activity, we are using the Collaborative Cross (CC), a panel of inbred mouse strains that has a similar amount of genetic variation as human populations. In CC-Super-PTEN crosses, we are utilizing an easily measured phenotypic of Super-PTEN mice, reduced body weight, to identify CC strains with altered PTEN function. On average, weanlings carrying the PTEN transgene weigh 16% less than their wild type littermates, but this weight difference varies significantly across strains, from no weight reduction to as much as a 29% difference. This distribution of phenotypes has allowed us to use quantitative trait loci (QTL) mapping to identify potential modifiers of PTEN. Through association mapping, we have determined that the loci with the highest LOD scores reside on chromosomes 2, 12, 16, and X, and we are now reviewing genes within those loci to identify candidate modifiers of PTEN. Additionally, we are using several cancer models to determine the effects of said candidate genes and confirm that they alter PTEN activity and influence cancer susceptibility and progression. Ultimately, this research will demonstrate the use of the CC mouse panel to identify novel genetic modifiers and improve our understanding of PTEN regulation.

#1543 Caspase-10 suppresses tumorigenesis by targeting ATP-citrate lyase. Rajni Kumari, Sanjeev Das. National Institute of Immunology, New Delhi, India.

p53 fosters metabolic reprogramming, which restricts metabolic adaptation of tumor cells under energy stress conditions. However, modulation and directionality of underlying cascades to induce or restrict metabolism are determined by the downstream target of p53. To explore the role of p53 in tumor metabolism upon metabolic stress, we performed a microarray screen in the presence or absence of p53 under glucose starvation. We observed caspase-10 to be upregulated by p53 upon metabolic stress. Caspase-10 belongs to the class of initiator caspases and is poorly understood in terms of substrate specificities. Emerging evidence also suggest intrinsic activation of caspase-10, distinct from its homologue caspase-8. Moreover, inactivating mutations as well as downregulation of caspase-10 in several carcinomas are suggestive of its role in tumorigenesis. Thus, we investigated the function of caspase-10 as a tumor suppressor. Our results indicated that caspase-8-dependent abrogation of histone acetylation reprograms the epigenetic profile of metastatic and proliferative genes, leading to their diminished expression under metabolic stress. Concomitant suppression of both cytosolic lipogenesis and nuclear histone acetylation by caspase-10-mediated ACLY cleavage decreases proliferation capacity, migration potential and invasiveness of tumor cells. Further, studies in mouse tumor models confirmed that caspase-10 represses tumor growth under metabolic stress via the downregulation of ACLY and GCNs. Taken together, our findings establish caspase-10 as a novel integrator of metabolism and epigenetics, by regulating acetyl-CoA levels. Hence, it functions as a tumor suppressor by disrupting lipogenesis-mediated metabolic reprogramming and GCN5-mediated epigenetic reprogramming.

#1544 MTAP insufficiency promotes metastasis in lung cancer via diminishing protein dimethylation. Wen-Hsin Chang, Bing-Chung Hu, Kang-Yi Su, Jian-Wei Chen, Reen Wu, Pan-Chyr Yang, Sung-Liang Yu. National Taiwan University, College of Medicine, Taipei, Taiwan; National Chung Hsing University, Taichung, Taiwan; University of California Davis, Davis, CA.

Genome instability, metabolic switch, and activating metastasis are three of the cancer hallmarks, which always collectively contribute to cancer malignancy. We identified methylthioadenosine phosphorylase (MTAP) as a metastasis suppressor in a series isogenic lung cell lines with different invasion ability by array CGH. Using siRNA silencing and ectopic expression of MTAP, we found that MTAP not only inhibited invasion and colony forming in vitro, but also reduced metastasis and tumorigenesis in vivo. Clinically, patients with low MTAP expression associated with poor overall survival and progression-free survival. Furthermore, the metabolite analysis of clinical specimens showed that low MTAP expression leads to MTA substrate accumulation and product decrease. Low MTAP expression in MTAP knockout cells reduced the level of symmetric arginine dimethylation of proteins. By using LC/MS, we identified a novel methyl-protein, whose level is elevated in MTAP knockout cells with the depletion of symmetric arginine dimethylation. Functionally, the unmethylated protein would be protected from proteolysis via caspase 3 cleavage. Moreover, the unmethylated mutant protein promoted migration and invasion in vitro strongly than the wild-type one did. In conclusion, we identify a novel marker in low MTAP expression or MTAP knockout cells, providing a potential therapeutic candidate in lung adenocarcinoma.

#1545 Loss of glycogen debranching enzyme (AGL) promotes rapid growth of non-small cell lung cancer cells. David R. Meier, Benjamin Weinhaus, Darby Oldenburg, Sunny Guin. Gienderen Medical Foundation, La Crosse, WI.

Glycogen Debranching Enzyme (AGL) is involved in glycogen breakdown. Compromise in glycogen breakdown due to loss of function mutations in the AGL gene lead to metabolic disease - Glycogen Storage Disease Type III. We have previously shown that loss of AGL results in rapid growth of bladder cancer cells using extensive in vitro and in vivo experiments. Here we test whether AGL regulate growth of non-small cell lung cancer (NSCLC) cells. We show that loss of AGL promotes rapid growth of NSCLC cells using anchorage independent growth assay. Loss of AGL also resulted in rapid xenograft growth of NSCLC cells when injected subcutaneously in immunocompromised mice. Whereas overexpression of AGL reduce the growth of these NSCLC cells. Further loss of glycogen phosphorylase the other enzyme involved in glycogen breakdown does not promote aggressive growth of these cancer cells. This observation is similar to our findings in bladder cancer which confirms that AGL regulates tumor growth independent of its role in glycogen metabolism. Thus using in vitro and in vivo experiments we show that AGL can regulate the growth of multiple tumor types such as bladder cancer and NSCLC. The exact mechanism on how AGL regulates NSCLC growth needs further investigation.

The association between ribosome defects and cancer became clear with the recent discovery of somatic mutations in ribosomal protein genes in several cancers, such as lymphoid leukemia's and glioblastoma (Nat Genet. 2013 Feb;45(2):186-90 & Blood. 2016 Feb 25;127(8):1007-16 & Nature. 2014 Jan 23;505(7484):495-501). To further delineate the role of ribosomal proteins in human cancer, we systematically screened the TCGA database for genetic lesions in ribosomal protein genes, confirmed the contributing capacity of the most common somatic ribosomal protein defect in cancer pathogenesis by molecular interference, and explored the mode of action of this ribosomal protein defect. Dynamic analysis of TCGA mutation and copy number data of respectively 4926 and 7322 patients representing 16 cancer types for defects in all 81 ribosomal protein genes. After stringent filtering, six ribosomal protein encoding genes (RPL5, RPL11, RPL23A, RPS5, RPS20 and RPSA) were significantly altered and identified as candidate cancer driver genes. RPL5 was located at a significant peak of heterozygous deletion on chromosome 1p22 and showed significant mutations and deletions in 11% of glioblastoma (GBM), 28% of melanoma, 34% of breast cancer (BRCA), and in 20% of multiple myeloma cases, thereby supporting heterozygous RPL5 inactivation to be the most common somatic ribosomal protein defect in human cancer. Human specific RPL5 doxy-cycline inducible knockdown (sh-hRPL5) in TP53 WT and TP53 mutant human breast cancer cell lines (MCF7 and MDA-MB-231) and in a TP53 mutant human glioblastoma cell line (U-118 MG) proved that RPL5 knockdown accelerated in vivo tumor progression in NSG mice. This acceleration was associated with reduced phosphorylation of CDK1 and, which is required for cell cycle progression from G2 to mitosis. Whereas RPL5 has been implicated in TP53 and MYC regulation, no consistent effects of RPL5 downregulation on these proteins could be detected in TP53 WT and TP53 homozygous R280K mutant breast cancer models (sh-hRPL5). Interestingly, partial RPL5 inactivation was found to be associated with PTEN protein suppression in these tumors. This observation was confirmed in various cell models in normal mouse neural stem/progenitor cells and mouse bone marrow cells (RPL5 shRNA: sh-hRPL5). Also in isogenic leukemia cell lines with different karyotypes, including lymphoid leukemia, the association of RPL5 inactivation with increased risk of leukemia progression was confirmed (sh-hRPL5). RPL5 downregulation also accelerated tumor formation in the PTEN-deficient GBM cell line U-118 MG, underscoring undefined PTEN-independent mechanisms of RPL5. Overall, we identified RPL5 as a new tumor suppressor that shows heterozygous inactivation in 11-34% of multiple histological cancer types. Partial molecular inactivation of RPL5 supported a tumor suppressor function for RPL5 in accelerating breast cancer and glioblastoma progression in vivo, which may be, in part, due to a new function of RPL5 in regulating PTEN.

#1547 BCNCIPβ modulates the ribosomal and extraribosomal function of S7 through a direct interaction. Qian Ba, Hui Wang. Institute for Nutritional Sciences, SIBS, CAS, Shanghai, China.

Extraribosomal functions of ribosomal proteins (RPs) have gained much attention for their implications in tumorigenesis and progression. However, the regulations of transition between the ribosomal and extraribosomal functions of RPs are rarely reported. Herein, we identified a novel ribosomal protein S7-interacting partner, BCCIPβ, which could modulate the functional conversion of S7. Through the N-terminal acidic domain, BCCIPβ interacted with the central basic region in S7 and regulated the extraribosomal distribution of S7. BCCIPβ deficiency abrogated the ribosomal accumulation but enhanced the ribosomal-free location of S7. This translocation further impaired protein synthesis in ribosome-deficient ribosomes. Consistently, RPL5-suppressed the ribosomal function and launched the extraribosomal function of S7, and eventually resulted in cell proliferation restriction. In conclusion, BCCIPβ, as a novel S7 modulator, contributes to the delicate regulation of ribosomal and extraribosomal functions of S7 and has implications in cell growth and tumor development.

#1548 Down-regulation of 4-hydroxyphenylpyruvate dioxygenase (HPD) contributes to the pathogenesis of hepatocellular carcinoma (HCC) through ERK / BCL-2 signalling activation. Man Tong,1 Tin Lok Wong,1 Steve Tin-Chi Luk,1 Noelia Che,1 Kai Yau Wong,1 Tsun Ming Fung,1 Xin-Yuan Guan,1 Nikki P Lee,1 Yen-Fei Yuan,1 Terence K Lee,1 Stephanie Ma1,2.1 The University of Hong Kong, Hong Kong; 2State Key Laboratory of Oncology in Southern China, Sun Yat-Sen University Cancer Center, Guangzhou, China; 3The Hong Kong Polytechnic University, Hong Kong.

Hepatocellular carcinoma (HCC) is one of the most prevalent malignancies in the world. Metastasis, recurrence and therapy resistance remain major obstacles to the improvement of long-term survival and represent major causative factors contributing to the rising mortality rates and poor prognosis of HCC. Identification of key drivers important for clinical prognostic utility and correlation of mechanisms involved in hepatocarcinogenesis is urgently needed to aid in the development of novel treatment modalities. To this end, we began our study with an analysis of a publicly gene expression dataset (GSE14520) comprising of transcriptomic profiles from a large cohort of human non-tumor liver and HCC clinical samples in hope to establish a prognostic gene signature associated with metastatic risk / recurrence status so to identify novel driver genes responsible for HCC development and progression. By this method, 4-hydroxyphenylpyruvate dioxygenase (HPD) was identified as a candidate tumor suppressor gene in HCC. HPD was found to be frequently down-regulated in primary HCC tumors as compared to peri-tumor liver tissues. Its expression negatively correlated with aggressive HCC pathological features, including tumor stage, metastasis, recurrence and survival. Notably, down-regulated HPD expression in HCC is in part a result of hypermethylation at the HPD promoter. The functional effect of HPD was then examined in HCC cells well and with or without HPD stably repressed or ectopically overexpressed. Upon knockdown of HPD, HCC cells displayed significantly enhanced abilities to form tumors, metastasize and confer sorafenib resistance in vitro and in vivo. Conversely, overexpression of HPD in HCC cells led to a growth-suppressing effect. Consistently, sorafenib-resistant HCC patient derived xenografts also displayed attenuated levels of HPD as compared with parental sorafenib-sensitive counterparts. Mechanistically, HPD down-regulation mediates aggressive cancer features in HCC through activation of an ERK and BCL-2 pro-survival signaling pathway, as evidenced by rescue experiments involving the ERK inhibitor U0126. Collectively, our findings strongly implicate HPD as a potential novel tumor suppressor in hepatocellular carcinoma that promotes tumorigenicity, metastasis and sorafenib resistance through ERK / BCL-2 signaling activation and that HPD may represent a novel prognostic biomarker for HCC.

#1549 Prognostic significance and tumor suppressive functions of SDCT2 in renal cell carcinoma. Andre R. Jordan,1 Martin Hennig,2 Daley S. Morera,3 Soun D. Lokeswar,4 Asif Talukder,3 Lokeswar Vinata 3,4.1 University of Miami, Miami, FL; 2University of Lübeck, Lübeck, Germany; 3Augusta University, Augusta, GA.

Introduction: Five-year survival of metastatic renal cell carcinoma (mRCC) patients is < 10% and African American (AA) males have the highest incidence. Identification of the molecular determinants of mRCC and racial disparity in RCC is critical for biomarker development and targeted therapy. SDCT2 is expressed in kidney epithelial cells and is a succinate and citrate transporter, but its role has not been examined in any benign diseases or cancer. We examined SDCT2 expression in normal and RCC tissues and correlated it with clinical outcome and racial disparity. We also evaluated the biological functions and molecular signaling regulated by SDCT2 in RCC cells. Methods: Differential gene expression in the matched normal and RCC tissues (n=6/category) was evaluated by microarray analysis; results were validated by quantitative-PCR and immunoblotting in normal and RCC tissues from 53 patients (White = 21; Hispanic = 19; AA = 13). VHL+ and VHL- RCC cells were stably transduced with a Flag-tagged SDCT2 construct. Transfectants were characterized for cell
proliferation, cell cycle, motility, succinate/citrate transport and reactive oxygen species (ROS) measurement assays under normoxia and hypoxia (1% O2); cell death and senescence pathway markers were also evaluated. SDCT2 induction was evaluated following 5-azacitidine plus Trichostatin A treatment Results: SDCT2 was 63- and 100-fold downregulated in low- and high-stage RCC tissues, respectively. Q-PCR validation showed that SDCT2 levels were 40-fold downregulated in tumor tissues when compared to normal kidney (P<0.0001 Mann-Whitney test). Downregulation was 40-fold in White and Hispanic patients, but 198-fold in AA patients (P=0.0049) and also correlated with tumor stage and metastasis (P=0.009). Under hypoxia, SDCT2 expression caused over 3-fold inhibition of proliferation, cell-cycle (G1-S block), and cell motility in both VHL+ and VHL- cells (P<0.01), only VHL+ cells were inhibited under normoxia. SDCT2 expression induced ROS levels and succinate transport by 3-fold in RCC cells (P<0.01). SDCT2 expression induced the p16INK4a-RB pathway and apoptosis (caspase-3 and PARP activation). 5-AZA+TSA treatment caused a 50-fold induction (P<0.0001) of SDCT2 expression. Conclusion: This is the first study on a functional biomarker in RCC. SDCT2, that is a possible novel tumor suppressor gene. SDCT2 loss promotes RCC growth, survival and inhibits cellular senescence and its downregulation correlates with metastasis and racial disparity. Support: Grant NICI/NIH 5R01CA72821; 5R01CA176691.

Molecular and Cellular Biology / Genetics: Tumor Suppressors 1: Modeling, Metabolism, and Epigenetics

#1550 Epigenetic downregulation and growth inhibition of IGFBP7 in gastric cancer. Jin Kim,1 Min A Kim,2 Sun-Ju Byeon,3 Woo Ho Kim.4 Cancer Research Institute, Seoul National University College of Medicine, Seoul, Republic of Korea; 2Seoul National University Hospital, Seoul, Republic of Korea; 3Asan Medical Center, Seoul, Republic of Korea; 4Seoul National University College of Medicine, Seoul, Republic of Korea.

Insulin-like growth factor-binding protein 7 (IGFBP7) has been found to be a tumor suppressor in several human cancers, but the role of IGFBP7 in gastric cancer has not yet been fully investigated. In this study, we examined the epigenetic downregulation of IGFBP7 expression in gastric cancer. Analysis by qRT-PCR, western blot, and methylation specific-PCR revealed that DNA methylation was inversely correlated with IGFBP7 expression, and the expression of IGFBP7 was restored after treatment with 5-aza-2’-deoxycytidine. Immunohistochemistry showed that IGFBP7 expression was downregulated in 47.5% of advanced gastric cancer patients. Univariate and multivariate analysis showed that IGFBP7 expression and tumor stage were independent prognostic factors. In cell culture, IGFBP7 knockdown increased gastric cancer cell growth, invasion, and migration, whereas IGFBP7 overexpression in gastric cancer cells showed cell growth inhibition and apoptosis. Our data suggest that IGFBP7 functions as a tumor suppressor in gastric cancer via an epigenetic pathway.

#1551 GULP1 is an epigenetically altered and functional tumor suppressor in uterine carcinoma through regulation of Nrf2-Keap1 signaling axis. Masamichi Hayashi, Elisa Guida, Rachel Goldberg, Yoshikui Inokawa, Leonardo Reis, Akira Oki, Evgeny Izumchenko, Luigi Marzochini, Mariana Brait, Trinity Bivalacqua, Alexander Baras, George J. Netto, Wayne Koch, David Sidransky, Mohammad O. Hoque. The Johns Hopkins University School of Medicine, Baltimore, MD.

We identified GULP1 as a novel tumor suppressor gene (TSG) selectively silenced during uterine carcinoma (UC) progression through promoter hypermethylation (PH) analyzed by quantitative methylation specific PCR (QMSp) and novel methylation specific digital droplet PCR (ddPCR) assay. Numerous cell based assays revealed that GULP1 silencing confers growth advantage to tumor cells. Correspondently, in vivo tumorigenicity after xenotransplantation of GULP1 knockdown T24 cells was significantly higher than control cells. Further mechanistic analysis revealed that GULP1 has a crucial role in the regulation of Nrf2-Keap1 axis, maintaining actin cytoskeleton architecture and helping Keap1 to scaffold Nrf2 in the cytoplasm. Moreover, GULP1 silencing induces activation of Nrf2 target genes, representing chemoresistance of UCs. Additionally, we analyzed GULP1 PH and expression in cisplatin-based therapy responsive and resistant primary UC samples, and in isograft cisplatin sensitive and resistant T24 cell lines. Interestingly, GULP1 expression at transcription level was lower in both resistant primary UC samples and resistant isograft T24 cell line. Cell lines with lower expressions of GULP1 (SW780 and UM-UC-3) also showed higher resistance to cisplatin than those with higher expression (T24 and BFTC905). Altogether, our findings determined that GULP1 is an epigenetically silenced potential TSG in UC and GULP1 expression and/or PH may guide in selecting candidate patients for cisplatin based neoadjuvant therapy.

Bioinformatics and Systems Biology: Functional and Genomic Analysis of Cancer

#1552 Integrative bioinformatics analyses of ChIP seq and RNA seq data reveals a complex regulatory landscape of NRF1 network involved in the pathogenesis of breast cancer. Jairo Ramos, Deodutta Roy. Florida International University, Miami, FL.

The expression of redox sensitive transcription factor -nuclear respiratory factor 1 (NRF1) expression significantly correlates with histological grades and prognosis of breast cancer. However, the molecular mechanism by which NRF1 may contribute in the development of breast cancer is not clear. In this study we examined whether NRF1 is a molecular risk factor of breast cancer. We identified regulatory landscape of NRF1 network involved in the pathogenesis of breast cancer. Steps followed for the investigation included the selection of mRNAs microarray dataset from TCGA and Metabric, selection and analysis of ChIP-Seq datasets from different breast cancer cell lines to identify NRF1 target genes possibly involved in breast cancer through Molecular Pathway, Gene Ontology and statistical analysis. Analysis of mRNA expression in breast cancer patients showed that NRF1 was significantly overexpressed in breast cancer tissues compared to normal tissues. ChiP-Seq analysis of two different breast cancer cell lines (MCF7 and T47D) showed that there are multiple NRF1 binding sites, which contain NRF1 binding DNA motif(s). The NRF1 binding to ChiP DNA sequences of target gene is cell context dependent. High percentage of known breast cancer (~50%) susceptibility genes are transcriptional targets of NRF1. Network analysis revealed that NRF1 regulates genes, which are key regulators of epithelial-mesenchymal transition (EMT), stemness, cell apoptosis, cell cycle regulation, chromosomal integrity, and DNA damage and repair. Furthermore, we observed that NRF1 regulates target genes of both breast cancer and cancer KEGG pathways. Many of the MicroRNAs involved in cancer and genes of signaling pathways involved in cancer initiation and progression such as MAPK, PI3K/AKT and Notch signaling are also transcriptional targets of NRF1. In summary, this study reveals a complex regulatory landscape of NRF1 network involved in the pathogenesis of breast cancer. Dysregulation of NRF1 signaling pathways may contribute in the development of breast cancer. Clinical confirmation of our study will have significant impact on our understanding of the role of NRF1 as a valuable biomarker for breast cancer diagnosis and prognosis and will provide strong rationale for the future studies to further develop NRF1 for breast cancer therapeutic target. This work was in part supported by a VA MERIT Review (VA BX001463) grant to DR.

#1553 Delineating the role of multiple copies of RNA binding domains in human nucleolin and its homologs using a computational approach. Kamrun Begum, Rachucha Chaya Steinhberg, Anjana Saxena, Sheneen Singh. CUNY Brooklyn College, Brooklyn, NY.

All eukaryotes have nucleolus, the sub-nuclear compartments where ribosomes synthesis occur. Nucleolin (NCL), an abundant RNA binding phosphoprotein, constitutes 5-10% of total nucleolar proteins. This multifunctional protein plays defined role/s in many critical cellular processes e.g. chromatin remodeling, ribosome biogenesis, transcriptional and translational regulation of various non-coding as well as coding RNAs. NCL binds to its target RNAs via two or multiple RNA binding domains (RBDs) to control gene expression during normal cell cycle as well as during cellular response to stress. A variety of tumors express elevated levels of NCL where NCL plays a direct role/s in increasing expressions of genes involved in cell survival, angiogenesis and metastasis. A comparison of NCL in various organisms shows that it is highly conserved, especially in its RNA binding domains that can vary in number (2 to 4 consecutive domains). Interestingly, the individual NCL-RBDs are more conserved across different species rather than within the same protein. RBDs are known to interact in pairs with RNA via RNA recognition motifs called RNP motifs, and complementary nucleic acid motifs or elements in RNA allow interaction with NCL. Vertebrate NCL proteins contains four RBDs, however most studies have focused only on the role/s of RDB 1,2; none probing the possible functional redundancy of the additional RBDs nor identifying any target-specificity for the RBD 3,4 in human NCL and other homologs. Earlier data from our lab suggested B3,4 can bind RNA in a structurally analogous manner to RBD 1,2 albeit with altered efficacy. Here, we continue this research by investigating various homologs of human NCL to better understand the conserved mechanism of the interaction with RNA and whether the additional RBDs, are in fact, redundant in function. To test this hypothesis, RBDs from various homologs were modeled using template based methods and analyzed by a combination of sequence and structure analysis tools. We show that there are key residue differences in indi-
Development of a deconvolution algorithm for tissue-based gene expression data. Sha Cao,1 Chi Zhang,2 Ying Xu2.1 University of Georgia, Athens, GA; 2Indiana University, Indianapolis, IN.

Tissue data provide substantially more information than cell-line data, and offer new opportunities to study cancer biology and evolution in its actual microenvironment, when multiple tissue samples of the same cancer type are analyzed together. However, it is very challenging to do information discovery from tissue data because of their compositional complexity - each dataset represents a mixture of gene-expression data from multiple cell types. Hence, meaningful tissue-data analyses require to first sort out the detailed contributions to the observed tissue-level data by different cell types. However, the computational challenge in solving the tissue data deconvolution problem stems from the reality: each cell type has a very large number of complex relations among its expressed genes and pathways, which are preserved under different conditions. To make deconvolution results meaningful, the co-expressions among functionally closely related genes, must be captured and enforced in a deconvolution problem formulation. We have a fundamentally novel formulation of the tissue-data deconvolution problem, which is pathway instead of gene based. It preserves co-expressions of genes of the same pathways through capturing and using an expression signature among such genes, and allows differential expressions of pathways by giving them varying weights in different tissues. In addition, this pathway-based model substantially reduces the number of free variables compared to gene-based models, making our problem formulation efficiently solvable. The unique ideas of our approach are: (i) estimate the proportion of each cell type within a mixture based on expression patterns of cell-type specific genes; (ii) identify co-expressed gene clusters among genes encoding each pathway (as defined by REACTOME) in each cell type based on cell line data; (iii) derive a condition-invariant expression signature for each of the ~2,000 REACTOME pathways in each cell type; (iv) demonstrate that each set of cell line gene-expression data can be uniquely represented as a weighted sum of such signatures; and (v) formulate the deconvolution problem as to estimate the weight of each pathway in each cell type that minimizes the Frobenius norm of deviation matrix of estimated and observed gene expression matrixes. We demonstrated its effectiveness on simulated data, i.e., in siRNA mixtures of gene-expression data from different cell types with varying proportions of each cell type. We anticipate that the successful development and deployment of the planned deconvolution method will enable and inspire a wide range of new ways to study tissue-based expression data and uncover the very rich information hidden in cancer tissues about the fundamental biology of cancer.

Pan-cancer patterns of synthetic lethality: statistical modeling of gene dependency profiles. Huwate Yeerna,1 Ramya Rangan,2 Andrew Aguirre,3 William Kim,1 Francisca Vazquez,3 Barbara Weir4, Mahmoud Ghahdi4, Aviad Tsherniak4, Jesse Boehm5, William Hahn6, Jill Mesirov1, Pablo Tamayo1,1 University of California, San Diego, La Jolla, CA; 2Harvard University, Cambridge, MA; 3Broad Institute, Cambridge, MA.

We present a methodology to fit statistical models of cell-utility profiles from RNAi-gene knockdowns. This method allows us to classify genes according to the degree of skewness in their viability distributions. The set of genes with the highest degree of skewness is highly enriched with many known oncogenes and tumor suppressors. We characterize many of these genes, compare them against the results of large sequencing efforts, and use them as inputs to a matrix-decomposition procedure that identifies the most salient cell viabilities shared by different cancer types. We catalog these pan-cancer patterns of synthetic lethality and characterize them by the genomic, transcriptional, and phenotypic features. This analysis provides a rich catalog of the most salient Achilles Heels of Pan-Cancer that can be helpful to identify new therapeutic strategies across cancers.

Algorithms for discovery of somatic single nucleotide variant display specific artifacts and different detection capabilities under the effect of read coverage and sample heterogeneity. The effect of a gene’s activity on a phenotype depends on the context of a complex network of functionally interacting genes. Several genetic interactions (GIs), such as Synthetic lethality and Synthetic Rescues, have been reported to have a significant functional role in cancer progression and provide potential candidates for selective cancer treatments. However, numerous other types of GIs with potential therapeutic applications have been identified. The GI network generalizes the concept of GI and detect ~70,000 GIs of different types with both molecular and clinical signature. We demonstrate their clinical predictive value as well as their ability to stratify breast cancer patients into refined clinical subtypes that might allow for better diagnosis and modified course of treatment. These results compare favorably with previous sequence based approaches and provide evidence for the importance of context specific genomic events and their effect on tumor progression. Additionally, the GI network accurately predicts patients’ drug response, where difference GI types are found to be predictive of distinct drugs in a complementary manner. This work provides the basis for future exploration of novel GI types as well as individual interactions with major impact on cancer progression.

#1559 Proteomic biomarker analysis of alternative splicing in colorectal adenoma-to-carcinoma progression. Malgorzata A. Komor,1 Thang V. Pham,2 Sander R. Piersma,1 Anne S. Bollin,1 Tim Schellhors,7 Pien M. Delis-van Dijmen,1 Marijanne T.J. Finsem,1 Annemieke C. Hiemstra,1 Meike de Wit,9 Beatriz Carvalho,1 Gerrit A. Meijer,1 Connie R. Jimenez,2 Remond J. Fijneman1. University of Texas MD Anderson Cancer Center, Houston, TX; 2The University of Amsterdam, Amsterdam, The Netherlands; 3VU University Medical Center, Amsterdam, Netherlands.

Background: Early diagnosis of colorectal cancer (CRC) and identification of its precursor lesions (adenomas) is crucial in reducing CRC mortality rates. The fecal immunochromatographic test (FIT) is a non-invasive CRC screening test that detects human protein hemoglobin. Although FIT is beneficial in its current form with a sensitivity of ~65% for detection of CRC and ~27% for adenomas, its performance is still suboptimal and needs to be further improved. Adenoma-to-carcinoma progression is accompanied by alternative splicing, which results in expression of tumor-specific protein variants. These may yield novel biomarkers suitable for improving detection of progressive adenomas and CRCs. Aim: We aim to identify novel biomarkers to improve early detection of CRC. Materials and methods: RNA was isolated from 3D organoid cultures derived from 5 adenomas and 4 CRC tissues. RNA and proteins were isolated from 18 healthy human colon tissues, 30 adenomas and 30 CRCs. Samples were analyzed by RNA sequencing (Illumina) and in-depth tandem mass spectrometry proteomics (QExactive). For both organoid- and tissue-datasets differential splicing analysis was performed on RNA level to enrich the sequence database, against which mass spectra were searched, with predicted protein isoforms. Results: Comparative splicing analysis between CRC and adenoma organoids revealed ~90 differentially spliced genes, yielding candidate biomarkers from epithelial origin. In the tissues, differential splicing analysis between CRCs and controls and between CRCs and adenomas identified over 1000 of splice variants. These include known alternatively spliced genes involved in cancer such as CD44 and VEGFA and a number of candidates overlapping with the isoforms derived from the organoids. Proteomics analysis revealed that approximately 150 of the splice variants were primarily located on the protein level. Conclusion: We demonstrated that different drugs from the same class were selected by DISARM for a single tumour type and, in these cases, we found statistically significant similarity between sensitive cell lines suggesting a subset of cisplatin-resistant cell lines that are repeatedly sensitive to a drug class. While translating preclinical observations into approved clinical use is often thwarted by an inability to identify predictive biomarkers, DISARM also allows us to select cell lines that are especially sensitive to candidate drugs or drug classes on which to perform biomarker analysis. To demonstrate this approach, we chose drugs with activity in multiple cancer types that were selected by DISARM and in-depth proteomics analysis predicted the potential to identify novel common and tumor-specific biomarkers for concomitant candidate drug sensitivity and cisplatin resistance. Thus, DISARM offers a simple yet effective approach for both drug and biomarker discovery within a specified clinical niche.

Background: Previous epidemiological and population sequencing studies have established that subjects with melanocortin 1 receptor (MC1R) germline mutations, associated with red hair and light skin phenotypes, have an increased risk of melanoma. However, several conflicting reports about the role of BRAF somatic mutations in MCIR subjects exist in the literature. We hypothesise that this conflict is due to biological process driven heterogeneity within MCIR subjects carrying disruptive alleles. To understand the heterogeneity, we analysed the TCGA cohort at the gene expression level using mRNA sequencing data. Method: From the previously published studies, we identified 68 cutaneous melanoma subjects who were of white ethnicity, had at least one disruptive allele of MC1R, and had BRAF mutations. Associated clinical and mRNA sequencing data were downloaded from the Firebrowse website. An unbiased hierarchical clustering analysis was performed using the preprocessed mRNA data containing 14696 gene expressions. The resultant clusters were then characterised using available clinical variables. A differential expression analysis was performed to identify the genomic signatures of these clusters. The resultant p-values were corrected for false discovery rate (FDR) using the Benjamini-Hochberg approach. Genes with corrected p-values less than 0.01 were further analysed using gene set enrichment analysis (GSEA) ranked lists. Results: An unbiased clustering identified two clear and separable clusters with 40 and 28 subjects respectively. The UV-signature (diprimidine C>T load) was correlated with these clusters (p-value = 0.047). However, no significant differences in age at the time of diagnosis, overall survival, and total mutation load between clusters were observed. At the genomic level, 2588 genes were significantly differentially expressed between two clusters (FDR corrected p-value less than 0.05). The top 10 differentially expressed genes included ATF2, MSH6, SP3, MAP3K2, and VEGFB. Further GSEA revealed gene sets playing roles in several pathways and biological processes, including oxidative phosphorylation, UV response in keratinocytes, DNA repair, cell cycle, and cellular response to stress. Conclusion: Cutaneous melanoma subjects with disruptive MCIR alleles and BRAF hotspot mutations have heterogeneous gene expression profiles with several key oncogenes differentially expressed. This suggests potential roles of other pathways, either independently or in cooperation with BRAF mutations, in melanogenesis in MCIR bearing patients.

#1562 Drug repurposing for hepatocellular carcinoma enabled via transcriptomics data from experimental models of sorafenib resistance. Kelly Regan,1 Ryan Reyes,1 Samson Jacob, Philip Payne,2 Tasneem Motiwala,2 The Ohio State University, Columbus, OH; 2Washington University in St. Louis, St. Louis, MO.

The effects of drugs that are active in spite of resistance to a reference drug, DISARM selects candidates based on the proportion of samples that are resistant to a reference drug but sensitive to a candidate drug with simultaneous consideration to relatively lower IC50 values for candidate drugs and higher IC50 values for reference drugs. As candidates may work in only a subset of resistant models and may be sensitive to a drug class but not a specific drug, DISARM attempts to identify generalizable GI types and detect them across many tumor types and drug classes. To date drugs across platinum-resistant cancer types. To progress in this direction, we developed an automated method to identify drug targets and genetic interactions with potential therapeutic implications. DISARM incorporates a flexible grid search optimization procedure to select candidates that are active in the face of resistance to a reference drug. In our demonstration, DISARM identifies potential drug targets and genetic interactions with potential therapeutic implications in the face of resistance to a reference drug.
Hepatocellular carcinoma (HCC) is often diagnosed in patients with advanced disease who are ineligible for curative surgical therapies. Sorafenib is the only approved drug for treating late stage HCC patients. However, patients rapidly become unresponsive due to inherent and acquired drug resistance. The promise of drug repurposing is that identifying new uses for existing drugs may reduce target validation costs. This data is the result of a comprehensive essentiality analysis of genes; which is not possible by single screening methods. We used an area under the receiver operating characteristic curve (AUC) of 0.82. Overall, these methods allow for a more comprehensive essentiality analysis of genes, as well as what type of platform (CRISPR or shRNA) was more likely to identify essential genes better than approaches just based on the shRNA results (p-value < 0.05). We also analyzed RNAseq data from HCC patients (n=423) in The Cancer Genome Atlas (TCGA) for the presence of these SR genes, and observed that patients harboring the SR-HCC gene signatures generated by our lab had significantly reduced survival (log-rank p-value < 0.036 SR Huh7 pool; p=0.009 SR Huh7 clone). Utilizing drug-induced gene expression profiles (n=3,740 drugs) in the HepG2 HCC cell line from the Library of Integrated Network-based Cellular Signatures (LINCS) database, we applied connectivity mapping analysis to the SR-HCC gene signatures. Dasatinib, a Src family kinase inhibitor, was prioritized as a top drug candidate from our LINCS analysis to reverse HCC sorafenib resistance. We confirmed up-regulated activity of Src family kinases in SR-Huh7 cells, as compared to sorafenib sensitive Huh7 cells (two-tailed t-test, p<0.05). We validated the use of dasatinib against sorafenib-resistant HCC cells in vitro alone and in combination with sorafenib using cell viability and clonogenic survival assays. In summary, we provide physiological relevance of SR models and proof of concept evidence for the validity of this novel drug repurposing approach for SR-HCC with implications for personalized medicine.

#1563 #1564 A computational framework for removing mouse contamination in tumors sequenced from patient-derived xenografts. Ali Amin-Mansour,1 Judith Jané-Valbuena,2 Xinneng Jasmine Mu,1 Levi Garraway2. 1The Broad Institute of MIT and Harvard, Cambridge, MA; 2Dana-Farber Cancer Institute, Boston, MA.

Introduction: Using patient derived xenograft (PDx) models has become an effective way for investigating response to standard or new therapeutics in cancer. Human cancer cells injected in mice are allowed to establish tumors and subjected to desired treatments. The PDx tumors are later harvested and characterized, often by massive parallel sequencing. However, a major challenge with analysis is the presence of immortalized murine tumor cells, frequently resulting in artifacts in downstream variant detection. We present a computational method to eliminate mouse contamination in PDx. Method: We used the Burrows-Wheeler Aligner to map reads obtained from sequencing the PDx samples to a combined human and mouse reference genome. We remove reads that are mapped to the mouse reference. The remaining reads are then used for variant detection. To test the efficacy of our method, we created in silico mixtures of human and mouse whole-exome sequencing reads from a melanoma patient's tumor and an immortalized mouse cell line captured with human exome baits. We then carried out a sensitivity analysis to examine how changing the mean target coverage of sequencing, or mouse contamination levels affects our results. For each of the computational experiments, we evaluated somatic mutations detected from the synthetic samples in comparison to the original human sample. Results: We calculated the sensitivity and specificity of detecting somatic mutations to determine our algorithm's performance. In all instances, we found greater than 99% for both sensitivity and specificity. Conclusions: Our results demonstrate that our method works accurately towards removing mouse reads in PDx samples. This task could also be applied to separating sequence reads from other species.

Introduction: Multivariate projection methods such as PCA and PLS have been widely applied for analysis of biological and chemical data. OnPLS is a recent extension to these methods suitable for integrative analysis of omics data. With OnPLS it is possible to compare multiple omics datasets to identify joint variation and variation locally unique for each of the studied datasets. OnPLS is a new approach for truly integrative analysis of omics data to be contrasted to commonly applied approaches limiting analysis to 1) comparing findings from individually analyzed blocks of data 2) pairwise comparison of individual probes. Experimental: A Java based implementation of OnPLS was used for the statistical modeling. 116 lung squamous cell cancer samples were characterized using gene expression profiling and global proteomics. The OnPLS model was applied to jointly model variation between mRNA and protein expression. Enrichment analysis of factor loadings was performed using the Enrichr tools to identify biological mechanisms explained by the different joint and unique components of the OnPLS model. Results: Using a cross-validation procedure the model with the highest predictive ability was calculated having two joint components and one locally unique component for each of the proteomics and gene expression data. This model explained 21.9% of the variation in the expression data and 26.1% of the variation in the proteomics data. The first joint component captures the highest degree of common variation between mRNA and protein activity. From the mRNA data, this component is related to immune infiltrates, especially monocytes and B-cells, whereas this component is related to extracellular matrix activity from the protein data. This suggests covariance of mRNA immune-related gene expression and extracellular matrix-related protein expression. As expected, local variation specific to the protein measurements involved regulation of protein activation and processing. mRNA-specific variation is related to keratinization, a key process in squamous cell cancer. Conclusion: OnPLS offers an interesting approach for integrative analysis of omics data. Applying this approach to proteo-genomics data of lung squamous cell cancer is expected to provide novel insights into the biology and treatment of lung cancer. The triple-negative breast cancers (TNBC) account for up to 20% of breast cancer cases. These tumors are negative for estrogen, progesterone, and HER2 receptors, which are markers used for diagnosis and treatment of other types of breast cancer. Clinically, TNBCs are notoriously aggressive, respond poorly to conventional treatment and have a poor response to standard therapies. This results in a high rate of mortality due to late stage disease at diagnosis. TNBCs are diagnosed in up to 20% of breast cancers and a significant proportion of women with breast cancer (17% of new breast cancers in the United States) are diagnosed with TNBC. TNBCs are negative for estrogen, progesterone, and HER2 receptors, which are markers used for diagnosis and treatment of other types of breast cancer. Clinically, TNBCs are aggressively responding poorly to treatment. The current mainstay of treatment for TNBC is docetaxel chemotherapy, which has limited efficacy due to the aggressive nature and heterogeneous behavior of TNBC.

#1566 Differential expression of Epstein Barr virus miRNAs in triple-negative breast cancer. Alexander Blanchard,1 Tiffany Wallis,1 Ramon Vidal,2 Stefan Bonn,2 Scott Harrison,1 Perpetua Manguada1. 1Department of Neurology, University of Basel, Switzerland; 2Department of Medicine, University of Basel, Switzerland.

Introduction: We sequenced small RNA libraries from 100 TNBC cases and a matched normal tissue sample using a combination of mission RNA and whole-exome capture methods. We identified 385 differentially expressed microRNAs, which were further validated by qRT-PCR. We found a significant enrichment of genes known to be involved in tumor growth and invasion in the downregulated miRNA set. Methods: We sequenced small RNA libraries from 100 TNBC cases and a matched normal tissue sample using a combination of mission RNA and whole-exome capture methods. We identified 385 differentially expressed microRNAs, which were further validated by qRT-PCR. We found a significant enrichment of genes known to be involved in tumor growth and invasion in the downregulated miRNA set. targeted therapies, have high rates of relapse, as well as poor prognosis. The molecular basis of TNBC oncogenesis is currently unknown, but it is possible that viral factors, such as Epstein-Barr Virus (EBV) miRNAs, play a role. EBV miRNAs have been implicated in the oncogenesis of several forms of cancer, including Burkitt’s lymphoma and nasopharyngeal carcinoma. The objective of this study, therefore, was to determine the differential expression of EBV miRNAs in TNBC tumors as compared to normal breast tissue. We conducted a comprehensive profiling of viral miRNAs in 48 TNBC tumors as compared to 15 control normal breast tissues, utilizing deep sequencing analysis software and publicly available deep sequencing data. Four EBV miRNAs (BART18-3p, BART 8-5p, BART15, BART22) were significantly expressed in 11-17% of the TNBC biopsies from control normal breast tissue. Four novel putative EBV miRNAs were found to be differentially expressed in TNBC tumors as compared to control normal cells. Two of the novel putative EBV miRNAs were differentially expressed above 125 reads per million (RPM) in 20% and 27% of the TNBC tumors as compared to 0% and 6.6% of normal breast tissues, respectively. One novel putative EBV miRNA was expressed above 125 RPM in 66% of the normal breast tissue as compared to 2% of the TNBCs. These putative EBV miRNAs localize within genomic regions of EBV, including the LMP-2 region. Ongoing work has so far computationally validated one of these miRNAs as a novel EBV miRNA; in vitro validation studies are in progress. This is the first report on the differential expression of EBV miRNAs in TNBC tumors. Although EBV miRNAs are extremely heterogeneous, it is intriguing that 20% of TNBC tumors specifically express the same EBV miRNA. Our findings suggest that these differentially expressed EBV miRNAs may potentially play a role in the pathogenesis of TNBC.

#1567 Oncogenesis may result from multiple different combinations of a small number of tumorigenic mutations. Rami Anandakrishnan, Robin Varghese, Niharika Gupta, Harold R. Garner. Edward Via College of Osteopathic Medicine, Blacksburg, VA

Cancer is known to result from genetic mutations, both inherited and somatic. Yet, decades of investigation and the availability of extensive genomic data, have failed to reveal the specific mutations that directly result in tumorigenesis for most cancers. One possible reason is that tumorigenesis may result from one or more of multiple different combinations of mutations, while investigators generally search for a single set of mutations. A mathematical model of the probability of “hitting” one of many possible combinations of a small number of mutations was compared to the actual distribution of accumulated mutations at diagnosis as reported on the cancer genome atlas (TCGA). This “multi-combination multi-hit” model reproduces the distribution of accumulated mutations from the TCGA database with surprising accuracy (RMSD = 1.5%) for a model where one or more of 100 different possible combinations of three mutations result in tumorigenesis. We speculate that each of the three mutations affects one of the several genes in three distinct cell proliferation control pathways, such as senescence, apoptosis, autophagy and necrosis, and different combinations of mutations affecting three of these pathways may result in tumorigenesis. We have identified several such combinations for further investigation.

#1568 Predicting stochastic proliferation and death in response to drugs with mechanistic models tailored to genomic, transcriptomic, and proteomic data. Mehdi Bouhaddou, Anne Marie Barrette, Rick J. Koch, Marc R. Birtwistle. Icahn School of Medicine at Mount Sinai, New York, NY

Over the past decade we have seen a shift in cancer therapy from broadly cytotoxic drugs to molecular therapies targeting “driver” mutations. Although targeted therapy has seen great success for some cancers (e.g. imatinib for leukemia), it has struggled with poor efficacy in treating other cancers that can sometimes possess multiple “driver” mutations. This highlights the complex, and at times non-intuitive, interplay between multiple players in a signaling cascade, which is highly dependent on the biological context. Therefore, a model that is, EBV expression levels and mutational architecture – of a tumor or cell line. A quantitative, mechanistic, biologically-tailored understanding of how these signaling dynamics drive proliferation and death could improve precision pharmacology approaches to treat cancer. Here, we constructed the first highly detailed, large-scale ordinary differential equation (ODE) mechanistic mathematical model depicting the most commonly mutated cancer signaling pathways across human cancers, as indicated by a pan-cancer analysis by The Cancer Genome Atlas (TCGA). The model includes the RTK/Ras/MEK/ERK, PI3K/AKT/mTOR, CDK/CDK4/CDK6, CDK2/CDK7/RB cell cycle, p53/MDM2 DNA damage response, and BCL/Caspases apoptosis pathways. The adjustable parameters of the model can be informed by measurements from patients or cell lines, including copy number alterations, mutations, and gene expression levels. This single-cell model links stochastic gene expression processes to quantitative signaling dynamics, and once tailored to a biological context can be used to simulate the effect of various anti-cancer therapies on cell fate behavior such as proliferation and death for a population of cells. The first instance of the model integrated genomic, transcriptomic, and proteomic data from the MCF10A cell line, a non-transformed cell line with predictable phenotypic behaviors. We trained the model using western blot and flow cytometry experiments to refine various biochemical parameters and phenotypic outcomes. Many fundamental questions in signal transduction arose during this process, such as how EGF and insulin synergize to drive 5-phosphorylated AKT. The model also predicts the effect of mutating genes that confer sensitivity or resistance to inhibitors of the ERK and AKT pathways. Simultaneously, we are tailoring the model to patient-derived genetic information from primary glioblastoma tumors and screening brain-penetrable compounds in a patient-specific manner. In conclusion, a quantitative, mechanistic, biologically-tailored mathematical model depicting the major cancer pathways allows us to probe the mechanisms that underlie how signaling dynamics drive proliferation and death in response to various perturbations, and gain insight into their dependence on the biological context of cell lines and patient tumors.

Introduction: TTFields is an antimitotic cancer treatment that utilizes low intensity (1-3 V/cm) alternating electric fields in the intermediate frequency (100-300 kHz) that are delivered in two orthogonal directions using 2 pairs of transducer arrays. TTFields are currently approved for Glioblastoma Multiforme (GBM). A phase II clinical trial (EF-20) showed that TTFields in combination with gemcitabine was safe in patients with locally advanced pancreatic cancer. Preclinical studies show that the effect of TTFields is intensity-dependent with a therapeutic threshold of 1 V/cm. Simulation-based studies show that the field distribution changes with array placement. Treatment planning with arrays positioned on the scalp to maximize field intensity to the tumor is standard of practice when treating GBM. Studies to examine array layout on the abdomen to maximize the field distribution in this region have not been done. In the EF-20 study, a generic layout was used. We used computer simulations to test how altering the transducer array layout on the mid-body alters the field distribution within the abdomen and pancreas. Methods: To simulate delivery of TTFields to the abdomen, we used a realistic computerized model of a human male (DUKE 3.0 from ZMT-Zurich). Eight different layouts utilizing combinations of arrays with either 13 or 20 disks placed at different locations on the abdomen were simulated. In order to generate TTFields, an alternating voltage difference with a peak to peak magnitude of 100V and a frequency of 150 KHz was imposed on the outer surfaces of the disks of each pair of arrays. The simulations were performed using ZMT’s Sim4Life V3.0 electro-quasi-static solver. For each pair of transducer arrays, the mean field intensity in the abdomen and chest, and in the pancreas and liver, was calculated. Results: All eight layouts delivered fields with mean intensities of about 2 V/cm to the abdomen. The average field intensity delivered to the pancreas and the liver exceeded the therapeutic threshold of 1 V/cm for all layouts. The highest intensities were delivered to the pancreas by layouts in which a 20-disk array was placed at the middle of the back, and either a 20 disk array placed at the middle of the abdomen or a 13 disk array placed on the front-left side of the abdomen over the pancreas. Generally, field intensities in the pancreas were lower than in the rest of the abdomen because of the high electric conductivity of this organ. Conclusion: This work shows that TTFields can be delivered to the pancreas with intensities well above the therapeutic threshold of 1 V/cm, and that altering the location of the arrays on the abdomen can influence the field intensity and distribution within the body. This work forms the basis for developing optimal strategies for delivering TTFields to the pancreas.

#1571 Decrypting the transcriptome profile of Pak4 using next generation sequencing. Chetan Rane, Misaal Patel, Li Cai, Audrey Minden. Rutgers University, Piscataway, NJ.

The PK4 (p-21 Activated Kinase 4) protein kinase has long been associated with cancer because of its key roles in regulating cell proliferation, cell cycle progression and cell morphology. The PK4 gene is amplified in different types of cancers, including breast cancer. PK4 overexpression is associated with oncogenic transformation in several breast cancer cell lines, while PK4 inhibition has been shown to significantly reduce their tumorigenic potential. However, there is limited information available on PK4’s mechanism of action in...
promoting tumorigenesis. To gain an insight into PAK4 downstream signaling pathways, we performed Next Generation Sequencing (NGS) on RNA samples collected from non-transformed immortalized mouse mammary epithelial cells (WT iMMECs) and iMMECs overexpressing PAK4. Research from our lab has shown that unlike WT iMMECs, iMMECs overexpressing PAK4 formed tumors when implanted in immunocompromised mice. These tumors were characterized by increased cell proliferation and angiogenesis, suggesting a role for PAK4 in tumor formation. Previous studies to delineate PAK4 signaling pathways have mostly focused on substrates phosphorylated by PAK4. This study, however, takes into account genes which may act downstream of PAK4 and play an important role in mediating long term PAK4 function. RNA-seq analysis offers the ability to discover new genes and splice variants and measure transcript expression, mRNA was isolated in triplicates from WT iMMECs and iMMECs overexpressing PAK4; mRNA from each condition was then sequenced using Illumina NextSeq platform. The RNA-seq data generated was analyzed using Top Hat and Cufflinks software, which created a list of genes whose expression was significantly different in these two cell types, and previously unknown to be regulated by PAK4 (26 genes were up regulated and 51 genes were down regulated by more than a log2 fold change of 3). A qPCR analysis of 8 of these genes validated the sequencing data. Among the different genes we identified, we chose to focus on ParvB, which is consistently down regulated by almost seven fold in the iMMECs overexpressing PAK4. Previous studies have suggested a tumor suppressor role for ParvB in regulating breast tumorigenicity. We hypothesize that PAK4 mediates mammary tumor formation and development. These results illustrate how drivers of primary tumorigenesis must be distinguished from drivers of treatment resistance, metastasis, or recurrence in order to better understand the genetic changes behind cancer progression.

### #1572 Transformation from melanocytes or nevi into melanoma: models based on a transcriptome meta-analysis. Daniel Ortega-Bernal,1 Claudia Rangel-Escareno,1 Elena Arechaga-Ocampo,1 Claudia H. Gonzalez-De la Rosa1, Universidad Autonoma Metropolitana, Mexico, Mexico; Instituto Nacional de Medicina Genomica, Mexico, Mexico.

Background: Melanoma is the most aggressive skin cancer due to its ability to rapidly metastasize and resist radio- and chemotherapy. The frequency of this disease has increased 400% worldwide in the last 30 years. There are 2 ways to develop melanoma: direct transformation of melanocytes into melanoma and the nevus as an intermediary. Here, we used a computational strategy based on transcriptome meta-analysis to identify the pathways involved in the 2 possible ways by which cells may transform to melanoma. Methods: Affymetrix HU 133A Plus 2.0 microarray files (50 in total) were collected from the Gene Expression Omnibus database for the meta-analysis, representing melanocytes, nevi and stage I, II, and III melanoma. Differential expression was analyzed using linear models and the limma library. The analysis focused on 3 comparisons: nevi vs. melanocytes; melanoma vs. nevi; and melanoma vs. melanocytes. Transcript with a log fold change of <1/3> were included in the study. Functional enrichment analysis identified the most deregulated pathway. Genes resulting from the intersection of the melanoma vs. nevi and melanoma vs. melanocytes comparisons were used as possible biomarkers of transformation and analyzed by IPA. Gene signature identification: In melanoma vs. nevi comparison, 1881 expressed genes were differentially expressed, of which only 888 were used to generate the transformation model and to perform functional enrichment. Consistent with the phenomenon of malignant transformation, we identified 3 pathways associated with cell cycle checkpoint control that exhibited decreased activity. Conversely, the pathways that exhibited increased activity were estrogen-mediated S-phase Entry and Cyclins and Cell Cycle Regulation, promote cell cycle progression. In melanoma vs. Melanocytes comparison, 4112 expressed genes were differentially expressed (2310 downregulated and 1802 upregulated), 1099 of which intersected with the nevi vs. melanocytes comparison. The 682 genes intersecting the melanoma vs. nevi comparison were removed. We used the to perform enrichment analysis. The main result was the decreased activity of the cAMP-mediated signaling pathway. The intersection of both comparisons (682 genes), was used to identify 22 genes upregulated whose product is a secreted protein. Two of these genes were previously reported as potential biomarkers in neoplasia, cytokines CXCL8 and CXCL16, supporting the quality of our analysis. Conclusions: Our analysis, in agreement with previously reported results, identified a biomarker panel consisting of melanoma, and also identified new biomarkers, including CXCL16, MMP19, BIVM, and FAM60A. A better understanding of the specific molecular alterations causally involved in this disease may lead to new biomarkers and pathways involved in the transformation for this currently incurable malignancy.

Whole-genome sequencing of tumors has identified genetic mutations that drive the origination, growth, and spread of cancer. Most driver mutations detected so far are early mutations categorized as small amount of total drivers and many early total mutations. In addition, the timing of driver mutation occurrence varies widely depending on cancer type as well as among different individuals with a single cancer subtype. Finally, we identified known cancer genes that are enriched in either early or late driver mutations, reflecting different selective pressures at various stages of cancer development. These results illustrate how drivers of primary tumorigenesis must be distinguished from drivers of treatment resistance, metastasis, or recurrence in order to better understand the genetic changes behind cancer progression.

### #1574 Computational approach for discovery of regulatory noncoding variants in cancer. Yu Li1, Michael Edmonson,1 Xiaotu Ma,1 Michael Rusch,1 Yongjin Li,1 Bengsheng Li,1 Shuhong Shen,2 A. Thomas Look,1 Jinghui Zhang2. 1St. Jude Children’s Research Hospital, Memphis, TN; 2Shanghai Children’s Medical Center, Shanghai Jiao Tong University School of Medicine, Shanghai, China; Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA.

Noncoding mutations in the cancer genome have historically been poorly understood. Recent studies have shown however that mutations in intergenic regions may play an important role in cancer by introducing de novo regulatory elements and thus cis-regulating target gene expression. While mono-allelic expression of the dysregulated gene is an important signature of regulatory noncoding mutations, recognition of this feature has not been implemented by any methods evaluating noncoding mutations to date. To perform genome-wide detection of noncoding mutations with a potential regulatory function, we developed a novel computational approach implementing this allelic expression signature (ASE) as a core component, using WGS and RNAseq data as input. We first searched for genes showing ASE across the tumor genome by comparing the minor allele frequency of heterozygous markers between WGS and RNAseq data. We excluded genes known to be in an imprinted locus, as well as sites matching a precomputed set of 5,576,857 problematic polymorphism markers (estimated by analyzing WGS data from 625 normal genomes). Next, the somatic mutations were filtered for regulatory candidates that could introduce a transcription factor (TF) binding motif absent from the reference sequence. We included 614 TF binding motifs from the HOCOMOCO database and performed motif analysis with the FIMO package. Finally, the somatic mutations were assigned to dysregulated genes in the same topologically associating domains in human defined by public Hi-C data and prioritized by open chromatin state defined by DNase hypersensitivity regions (ENCOD project). We applied our approach to 22 T-ALL tumor samples collected at Shanghai Children’s Medical Center in a pilot study consisting of 13 diagnosis and 9 relapse samples (9 of these were trios). WGS was performed on both tumor and normal samples and RNAseq was performed for the tumor sample only. We predicted 213 regulatory noncoding mutations (157 unique variants) in total from this metastasis, which are likely to be found in only one or a few tumor samples. We analyzed 101 multi-region and/or multi-tumor sequencing data sets using driver mutation annotation and phylogenetic inference to determine whether driver mutations occur preferentially early on. We found driver mutations frequently arise late in the course of tumor evolution, even when statistically accounting for small amounts of total drivers and many early total mutations. In addition, the timing of driver mutation occurrence varies widely depending on cancer type as well as among different individuals with a single cancer subtype. Finally, we identify known cancer genes that are enriched in either early or late driver mutations, reflecting different selective pressures at various stages of cancer development. These results illustrate how drivers of primary tumorigenesis must be distinguished from drivers of treatment resistance, metastasis, or recurrence in order to better understand the genetic changes behind cancer progression.
 Novel small molecule inhibitors of p300/CREB binding protein (CBP) are two closely related, paralogue histone acetyl transferase proteins that act as transcriptional co-activators of a variety of cancer related genes. We have developed potent, selective and orally active small molecule inhibitors of the bromodomain of p300/CBP and investigated their role in regulating androgen receptor expression and function. We have also examined their role in driving synthetic lethality in tumours. Loss of function mutations in either p300 or CBP (including in significant proportions of lung and bladder tumours), can lead to a dependency on the corresponding paralogue protein. Methods: Binding affinity to p300, CBP and BRD4 was measured in a surface plasmoid resonance (SPR) assay. Potency and functional activity was demonstrated in a panel of prostate cells lines representing hormone responsive (LNCaP), hormone independent (DU145, PC3) and castrate resistant disease (22Rv1, C4-2, VCaP, LNCaP-AR) as well as wildtype (A549) and CBP deficient (H520, H1703, LK2) lung cancer cells. Combination effects of p300/CBP inhibitors with a PARP or CDK4/6 inhibitor were determined in LNCaP and C4-2 cells. Effects of p300/CBP inhibitors (and by comparison, the BET inhibitor, JQ1), on AR, AR-V7 splice variant and c-Myc protein, as well as c-Myc, KLK3 and TMPRSS2 gene expression, were assessed in 22Rv1 cells in vitro. In vivo effects on biomarkers were measured in a 22Rv1 xenograft model. Results: CCS1357, an in vitro probe compound, binds to p300 and CBP with high affinity (Kd=45mM; BRD4). It is a potent inhibitor of cell proliferation in castrate resistant cell lines (IC50=100mM in LNCaP-AR; 350mM in 22Rv1) with minimal effects in hormone independent lines. CCS1357 combined with palbociclib (CDK4/6) or olaparib (PARP) in LNCaP or C4-2 cells, showed reduced cell viability compared with any of these drugs given alone. In 22Rv1 cells, CCS1357 significantly down-regulated AR-FL, AR-V7 and c-Myc protein by Western, an effect not seen with JQ1 at equivalent proliferation IC50s. CCS1357 effects were reversed by the proteasome inhibitor, MG132. CCS1357 also caused a profound inhibition of c-Myc, KLK3 and TMPRSS2 genes measured by qPCR in 22Rv1 cells in vitro. A preclinical candidate (CCS1477) given as a single oral dose (30mg/kg) inhibited plasma PSA and tumour AR, AR-V7 and c-Myc in a 22Rv1 xenograft model. In the lung cancer cell lines, we observed differential sensitivity to CCS1357; CBP deficient lines were more sensitive (cell proliferation) compared with normal. Conclusions: Taken together these data support the clinical testing of p300/CBP inhibition in prostate cancer patients in two settings; firstly, castrate resistant prostate cancer by down-regulating of AR, AR-SV and c-Myc expression and function; and secondly in patients with loss of function mutations in p300 or CBP by driving synthetic lethality.

#1575 UGT2B17 promotes castration-resistant prostate cancer progression through enhancing ligand-independent AR signaling. Haolong Li, Ning Xie, Ruqi Chen, Melanie Verreault, Ladaz-Fazli, Martin E. Gleave, Olivier Barbier, Xuesen Dong, University of British Columbia, Vancouver, British Columbia, Canada; Laval University, Quebec, Quebec, Canada.

Background: Castration resistant prostate cancer (CRPC) is characterized by a shift of androgen receptor (AR) signaling from ligand-dependent to ligand-independent. Defining mechanisms that control AR signaling transformation is important to develop therapies for disease control. UDP-glucuronosyltransferase 2B17 (UGT2B17) is a key enzyme that maintains androgen homeostasis by catalyzing AR agonists into inactive forms. Although enhanced UGT2B17 expression by androgen resistant prostate cancers is a hallmark of regulation of AR signaling transformation and CRPC progression remain unknown. Methods and Results: We first evaluated the UGT2B17 protein expression levels by immunohistochemistry (ICC) on 403

Proceedings of the American Association for Cancer Research • Volume 58 • April 2017
and AR were detected by immunoblotting, and the transcript levels were evaluated by QRT-PCR. Results: Since the annotation of PMEP1A1/TMEM1A1 isoforms has been empirical in the literature, here we propose a new structure/expression based nomenclature: PMEP1A1 (reading frame of 252 amino acids (aa)); PMEP2A (344aa); PMEP3A (287aa; STAG1); PMEP4A (259aa); and PMEP5A (237aa). Expression of PMEP1A1 and PMEP2A was regulated by androgen responsive prostate cancer cells in comparison to broader expression pattern of other isoforms (PMEP3A-5). The expression of PMEP1A2-2 was androgen regulated, whereas expression of PMEP3A-5 was regulated by TGF-β. Only PMEP1A1 inhibited cell growth of LNCaP, DU-145 and PC-3 cells. In contrast, PMEP2A-4 promoted cell growth of DU-145 and PC-3 cells. Of all the isoforms only PMEP1A1 mediated AR protein degradation in CaP. Conclusions: The PMEP1A isoforms appear to underscore distinct biological functions in the context of androgen and TGF-β signaling. Widely studied PMEP1A1 was specific for AR degradation in prostate cancer cells and was consistent with previous observations of association of AR upregulation with loss of PMEP1A1 in prostate cancer. The roles of PMEP1A isoforms need to be better defined in prostate cancer and other cancers. Further studies were supported by CPDR, USUHS, HU0001-10-2-0002 to DGM.

The growth of prostate cancer cells depends on the activation of androgen receptors (AR). Bicalutamide is a nonsteroidal diolipid that inhibits AR through blockage of AR-activation being effective in limiting tumor growth. However, prolonged treatment with anti-androgen therapies result in the transition of prostate cancers into an androgen refractory state. Neuroendocrine differentiation (NED) has been associated with the progression of prostate cancers to an androgen resistant phenotype. In this work we investigated the effect of the androgen receptor blocker bicalutamide in promoting NED of LNCaP cells and whether it is accompanied by increased T-type Ca$^{2+}$ channel expression. The ability of bicalutamide to evoke morphological and biochemical changes associated with NED was assessed by PCR, western blot and immuno-histochemical analysis. Changes in the Ca$_{a,3.2}$ T-type Ca$^{2+}$ channel subunit expression was studied using PCR analysis, western blot and whole cell recordings. The role of T-type Ca$^{2+}$ channels in promoting the differentiation of LNCaP cells was assessed by a cell viability assay and changes in cell morphology, specifically the development of neurite-like processes. PCR analysis of bicalutamide-stimulated cells indicates no significant changes in Ca$_{a,3.2}$ mRNA, yet results in Ca$_{a,3.2}$ protein expression and functional channels. Western blot and immuno-histochemical analysis of LNCaP cells stimulated with bicalutamide for 4-10 days reveals biochemical changes consistent with NED including the expression of tubulin, EPHA and neuron-specific enolase. Pharmacological inhibition of T-type Ca$^{2+}$ channel function with nickel ions and NNC 33-0936 disrupts the morphological differentiation and cell viability of LNCaP cells treated with bicalutamide. These results suggest that bicalutamide treatment of LNCaP cells evokes significant morphological and biochemical changes associated with NED and results in increased expression of T-type Ca$^{2+}$ channels, which may significantly alter Ca$^{2+}$ homeostasis.

#1580 Combined neuroendocrine differentiation and androgen receptor hyperactivity in MAP37 and CHD1 null prostate cancer. Leah C. Rider, Lindsey U. Rodrigues, Anis Karimpour-Fard, Lina Romero, Claire Gillette, James C. Costello, Scott D. Cramer. Univ. of Colorado Anschutz Medical Campus, Aurora, CO.

We recently functionally validated a clinically aggressive subtype of prostate cancer characterized by dual deletion of MAP3K7 and CHD1. This subtype accounts for up to 25% of prostate cancer deaths. Androgen signaling is a critical component of prostate tumorigenesis and disease progression, which is exploited in treatment of prostate cancer with androgen deprivation and anti-androgen therapies. Neuroendocrine differentiation is thought to provide a selective advantage for prostate cancer in androgen-depleted conditions such as surgical or chemical castration. REST is a transcriptional repressor of neuronal gene expression and has been implicated in neuroendocrine differentiation of prostate cancer. The impact of combined MAP3K7 and CHD1 loss on androgen signaling and neuroendocrine differentiation has not been determined. Here, we demonstrate that dual loss of MAP3K7 and CHD1 simultaneously stimulates enhanced androgen signaling and enhanced neuronal differentiation correlated with enhanced growth in both androgen-depleted and androgen-replete conditions. These changes occur via increased androgen receptor chromatin binding, loss of CHD1 chromatin binding, loss of REST expression, and reduced chromatin binding by REST. Suppression of CHD1 and MAP3K7 attenuates the antiproliferative activity of the anti-androgen Enzalutamide. Furthermore, we translate these findings to clinical samples and show that decreased expression of CHD1, MAP3K7, and REST is associated with previous therapeutic intervention, castrate-resistant disease, and progression to a neuroendocrine phenotype. Overall, patients with low expression of all three genes have worse overall survival suggesting that these dual genetic alterations are an important cause of castration-resistant prostate tumors with loss of CHD1 and MAP3K7 exhibiting both androgen-dependent and -independent phenotypes leading to poor clinical outcome, which poses challenges to conventional therapeutic approaches.

#1581 Androgen receptor action in prostate cancer partitions into distinct transcriptional codes that differ in clinical relevance. Sangeeta Kumari, Varadha Balaji Venkadakrishnan, Dhirudatta Senapati, Qiangu Hu, Song Liu, Hannelore V. Heemers.

With few exceptions the 30,000 prostate cancer (CaP) deaths annually in the US are due to failure of androgen deprivation therapy (ADT). ADT prevents ligand-activation of androgen receptor (AR). Despite remission, CaP progresses while continuing to rely on ADT. AR’s transcriptional output that controls CaP behavior is an alternative therapeutic target, but its molecular regulation is poorly understood. Here, we determined the androgen dependence of hundreds of direct AR target genes on 18 coregulators that are relevant to CaP progression, and uncovered that the AR-dependent transcriptome breaks down in coregulator-dependent gene sets. Pairwise comparison and unsupervised clustering showed limited overlap between the gene subsignatures. Neither ChIP nor qRT-PCR studies revealed differences in the kinetics of coregulator recruitment to androgen response elements (AREs) or of androgen regulation of different gene sets. Rather, Cistrome analyses of AR binding sites demonstrated preferential enrichment in binding motifs for distinct transcription factors (TFs) between coregulator-dependent gene sets. Pathway and GSEA analyses of these signatures indicated associations with select biological processes and differential enrichment of normal prostate and CaP. CaP of different stages, and CaP and bone marrow microenvironment. These results suggested that coregulators may unite the action of DNA-bound AR and TFs to control select aspects of androgen-dependent CaP cell biology. The presence and functionality of such novel predicted AR transcriptional codes, namely AR-WDR77-p53 and AR-STAT3IRF1 with projected roles in CaP cell proliferation and stemness respectively, was confirmed in Co-IP and gene expression profiling. As AR and p53 are the major drivers of lethal CaP, the AR-WDR77-p53 code was explored further. Mass spectrometry after WDR77 and p53 IP independently identified PGAM5, a recently isolated serine/threonine protein phosphatase that regulates cell death and unknown to be relevant to AR signaling or CaP biology, as part of the AR-WDR77-p53 complex. Co-IP assays verified IP-mass spectrometry results and ChIP studies confirmed recruitment of PGAM5 to WDR77-dependent AREs. Expression profiling demonstrated significant overlap in genes for which androgen regulation was altered after silencing of WDR77, PGAM5 or p53. Co-IP and ChIP studies showed that androgen-dependent recruitment of p53 to ARE-bound AR requires WDR77 and PGAM5. Western blotting and flow cytometry analyses indicated that WDR77 and PGAM5 and their dependent AR target genes control G1/S cell cycle progression, which was maintained in presence of clinically relevant gain-of-function p53 mutants. These novel insights indicate that disrupting select protein-protein and protein-DNA interactions may be a viable strategy to inhibit AR action that drives CaP lethal progression.

#1582 Therapeutic potential of combination therapy using a next generation antisense oligonucleotide targeting the androgen receptor and AKT inhibition with AZD5363 in genetically engineered mouse models of prostate cancer. Marco A. De Velasco, Yurie Kura, Naomi Ando, Koichi Sugimoto, Kazuko Sakai, Barry R. Davies, Youngsoo Kim, A. Robert MacLeod, Masa-hiro Nozawa, Kazuhiro Yoshimura, Kazuhiro Yoshikawa, Kazuto Nishio, Hirotsugu Uemura, Kindai University Faculty of Medicine, Osaka-Sayama, Japan; AstraZeneca, Macclesfield, United Kingdom; Ionis Pharmaceuticals, Carlsbad, CA; Aichi Medical University, Nagakute, Japan.

Prostate cancer is highly dependent on androgen receptor (AR) and PI3K/AKT signaling pathways for survival and disease progression. Preclinical evidence suggests that combinatorial approaches targeting both AR and PI3K/AKT inhibition with AZD5363 in genetically engineered mouse models of prostate cancer. AR and PI3K/AKT activity improvements tend to treatment efficacy. However, sustained responses from traditional and next-generation anti-androgen therapies targeting AR remain elusive in clinical practice due to inherent resistance resulting in lethal castration-resistant prostate cancer (CRPC). Mechanisms for continued AR transcriptional activity may be ligand dependent or independent but still require AR gene expression. Persistent AR gene expression is a key feature of CRPC. Thus, blocking AR gene expression by antisense oligonucleotides (ASO) is a logical ap
proach to CRPC. We previously showed that monotherapy with ISIS581088, a generation 2.5 ASO targeting mouse AR, demonstrated strong antitumor activ-
ity in a transgenic mouse model of PTEN-deficient prostate cancer. In this study we show the antitumor effects of combined therapy of ISIS581088 and AZD5363, a potent AKT inhibitor and demonstrate the therapeutic benefit of combining this clinically proven inhibitor with monotherapy in a castration-resistant prostate tumorbearing mouse. Treatment of lethally irradiated, eight-week-old mice with PTEN−/− castration-resistant prostate tumors were treated with ISIS581088 and AZD5363 alone or in combination for four weeks. Tumor growth inhibition rates were 41.2%, 20.2% and 54.4% for ISIS581088, AZD5363 and ISIS581088/AZD5363 treatment groups, respectively, P < 0.001. In a model of mouse CRPC, 16-week-old mice with PTEN−/− castration-resistant prostate tumors (eight weeks post castration) experienced reduced tumor burden with all treatments but no enhancement was observed when the compounds were administered in combination compared with monotherapy drug treatments. In a randomized trial of advanced CRPC in PTEN/P53 double knockout mice, combination therapy significantly increased overall survival. Median survival were 18, 17 21, 22, and 38 days for control vehicle, control ASO, ISIS581088, AZIS581088, and ISIS581088/AZD5363 treatment groups, respectively, P = 0.041. In conclusion, our data shows that combination therapy significantly reduced tumor burden in mice with castration-naive tumors compared to those treated with monotherapy. Notably, combination therapy did not produce an additive effect in an early stage CRPC intervention model. Still, combination therapy demonstrated a clear advantage in prolonging overall survival in a long-term randomized model of PTEN/P53-deficient CRPC. Thus, our data provides preclinical evidence to support that next generation ASOs targeting AR in combination with AKT inhibition is a potentially effective treatment approach for CRPC.

Patients with advanced prostate cancer continue to develop lethal castration-resistant prostate cancer (CRPC) despite hormone therapy and maintaining castrate levels of serum androgen. Most CRPC appears to be dependent on the androgen receptor (AR), but instead of the C-terminal ligand-binding domain, it is the N-terminal domain (NTD) harboring a powerful transactivation do-
main that drives AR transcriptional activity. This was supported by the discovery of AR splice variants (ARv567es) and V7 which are constitutively acti-
vative and promote castrate-resistant prostate cancer (CRPC) growth. However, androgen deprivation eventually fails and PCa relapses, necessitating development of more effective therapies for CRPC.

#1584 Wnt/beta-catenin and Foxa2 axis activates AR signaling in castration resistant prostate cancer. Zachary M. Connelly, Shu Yang, Jiahe Li, Robert Garvey, Victor M. Darley-Ulmar, Selvarangan Ponnazhagan. University of Alabama at Birmingham, Birmingham, AL

Androgen-deprivation therapy has been identified to induce oxidative stress in prostate cancer (PCa), leading to reactivation of androgen receptor (AR) signaling in a hormone-refractory manner. Thus, antioxidant therapies have gained attention as adjuvants for castration-resistant PCa (CRPC). Here, we report for the first time that human endostatin (ES) prevents androgen-independent growth phenotype in PCa cells through its molecular targeting of AR and glucocorticoid receptor (GR), and downstream pro-oxidant signaling. This reversal following ES treatment significantly decreased PCa cell proliferation through downregulation of GR, and upregulation of manganese superoxide di-
mutase and reduced glutathione levels. Proteome and biochemical analyses of ES-treated PCa cells further indicated a significant upregulation of enzymes in major ROS scavenging machinery, including catalase, glutathione synthetase, glutathione reductase, NADPH-cytochrome P450 reductase, biliverdin reduc-
tase, superoxide dismutase, and glutathione peroxidase in reduction of intracellular ROS. ES further augmented antioxidant system through upregulation of glucose influx, pentose phosphate pathway (PPP) and NAD salvaging pathway. This shift in cancer cell redox homeostasis by ES significantly decreased the effect of protumorigenic oxidative machinery on androgen-independent PCa growth, suggesting that ES can suppress GR-induced CRPC phenotype upon AR antagonism, and dual targeting action of ES on AR and GR can be further translated to PCa therapy.

#1586 Developing novel inhibitors of S100A4 for neuroendocrine (NE) and metastatic prostate cancer: systematic testing using relevant models and drug development techniques. Mohammad Saleem,1 Arsheed A. Ganaie,2 Rehna Maqbool,1 Firdous A. Beigh,1 Syed Umber,1 Natalya G. Dulyani-
nova,2 Badrinath R. Komety1,2 Univ. of Minnesota Hormonal Inst, Austin, MN; Albert Einstein College of Medicine of Yeshiva University, Bronx, NY; 2Univ. of Minnesota, Minneapolis, MN

S100A4, a calcium binding protein has been well studied as a marker of fibro-
sis and metastasis. We recently showed that in addition of being a metastatic marker, S100A4 is in fact an onxogene that plays an important role in the develop-
ment of prostate cancer (CaP) and is amenable of targeting for the treatment of 
this lethal disease particularly neuroendocrine CaP (NE-CaP). Using a geneti-
cally engineered transgenic mouse model of NE-CaP, we show that knocking down of S100A4 significantly inhibited growth of prostate tumorigenesis and metastasis. Our noticeable finding is that S100A4 is secreted by prostatic tumors, 

ENDOCRINOLOGY: Prostate Cancer Biology and Therapy
and extracellular/soluble S100A4 acts as a growth factor that has the ability to confer aggressive potential to less aggressive or indolent tumor cells. We show that serum-S100A4 level is highly elevated in human CaP patients with aggressive disease regardless of their serum-PSA levels. We next asked if small molecule inhibitors could be developed to inhibit the activity if intracellular as well as extracellular S100A4. We used a highly robust RNA interference/suppression/CRISPR/cas9 silico method, we screened a library of 5000 molecules and based on their binding efficacy to S100A4, identified potential inhibitors (SMI1 and SM2I). We next tested if SMI1 and SM2I bind to the S100A4 protein in biological solution. We generated recombinant S100A4 protein and standardized an isothermal titration Calorimetry (ITC) assay for S100A4 binding. The ITC analysis (Kcal vs time) showing significant binding to S100A4 protein nevertheless SM2I inhibitors exhibited higher binding affinity to S100A4 than SMI1. Next, we used Surface Plasmon Resonance (SPR) method (accurate and sensitive technique) for detecting binding of inhibitors to S100A4. The SPR data (densogram) shows that SMI1 and SM2I bind to the S100A4 protein. The binding of S100A4 to Myosin IIA (MIIA) is known to disrupt the latter’s monomer-polymer equilibrium. This phenomenon is captured in solution (image of disassembly of MIIA filaments and change in turbidity). Using disassembly/ or turbidity assays as an index of S100A4 activity (where recombinant S100A4 and MIIA are incubated +/− inhibitors), we show that SMI1 and SM2I inhibit the activity of S100A4 protein. Next, we tested efficacy of inhibitors in vitro and show that SM1 and SM2I therapies inhibit the growth, proliferation, migration and invasion of human prostate cancer cells (22Rv1). The activity of SMI1 and SMI2 inhibitors, particularly, SMI1 and SM2I therapies inhibited androgen-mediated transactivation and several androgen target protein expressions, including PSA and p21. Further investigations showed that addition in vivo studies were performed to demonstrate the effect of zinc (10-20 mg/kg) on prostate cancer cell lines were applied to confocal microscopy for intracellular trafficking of exogenous zinc, in vitro proliferation assays for their growth, prostate specific antigen (PSA)-based reporter-mediated transactivation, and Western blot for detection of androgen receptor (AR). PSA and ubiquitination. Further in vivo studies were performed to demonstrate the effect of zinc (10-20 mg/kg) on prostate cancer growth using syngeneic animals followed by tumor analysis. Results: Zinc chloride dramatically diminished during cancer development. Due to the obscure role of zinc in this process, therapeutic application using zinc and its supplement is very limited. This study aims to clarify the role(s) of zinc and its intervening mechanism. Material and methods: Treated with zinc chloride (15-150 μM), several prostate cancer cell lines were applied to confocal microscopy for intracellular trafficking of exogenous zinc, in vitro proliferation assays for their growth, prostate specific antigen (PSA)-based reporter-mediated transactivation, and Western blot for detection of androgen receptor (AR), PSA and ubiquitination. Further in vivo studies were performed to demonstrate the effect of zinc (10-20 mg/kg) on prostate cancer growth using syngeneic animals followed by tumor analysis. Results: Zinc chloride inhibited androgen-mediated transactivation and several androgen target protein expressions, including PSA and p21. Further investigation showed that addition of zinc chloride strikingly downregulated AR protein levels after 4 hours up to 24 hours in both human LNCaP and murine TRAMP C2 prostate cancer cell lines. AR downregulation resulted from facilitated protein degradation instead of transcriptional control. Further in vivo study was carried out using syngeneic mice bearing C2 subcutaneous tumors. Peritoneal injection of zinc chloride significantly reduced tumor size. Analysis of these tumors revealed that there were reduced expression of AR and increased cell death. Conclusions: Zinc has dramatic effect on prostate cancer cell growth and would be a promising therapeutic agent.
has been shown to inhibit incumbent oncogenic NF-κB pathway. These results also suggest that intracellular zinc inhibits cell growth via downregulation of AR to inhibit growth of prostate cancer. Considering that AR functions as a major effector in prostate cancer development and progression into castration resistent prostate cancer, loss of zinc may be a critical step for this devastating disease and further studies can be performed to develop zinc-based cancer therapeutics.

High intranuclear mobility of AR-v7 reveals distinct mode of transcriptional activity in prostate cancer with important therapeutic implications. Seaho Kim, Mohd Azrin Jamalruddin, Paraskevi Giannakakou. Weill Cornell Medicine, New York, NY.

It is well established that androgen receptor (AR) signaling, is a key driver of prostate cancer (PC) growth and metastatic progression. Therefore, androgen deprivation therapy (ADT) is the first line of treatment for PC. However, most patients develop castration resistant prostate cancer (CRPC). Interestingly, AR signaling remains active in CRPC, due to the expression of transcriptionally active AR splice variants (AR-Vs), which lack the ligand binding domain (LBD) and constitutively translocate to the nucleus even in castrade conditions. AR-v7 is the most prevalent AR-V expressed in about 60% of CRPC tumors. AR-v7 expression was clinically correlated with poor prognosis of CRPC patients and with resistance to next-generation AR signaling inhibitors, which are part of standard clinical care. Therefore, inhibition of AR-v7 function is urgently needed for the treatment of CRPC. Currently, there is no therapeutic modality that can inhibit AR-v7 expression or activity. Mechanistically, AR-v7 transcriptional targets largely overlap with those of AR-ß, with the exception of a few AR-v7 unique targets. However, the exact mechanism by which transcription is activated by AR-v7 is not known. In this study we sought to investigate the mechanisms underlying the transcriptional activity of the ligand-independent AR-v7 in comparison to liganded AR-ß. We used live cell imaging to monitor the dynamics and intranuclear mobility of fluorescently-tagged AR-ß or AR-v7. Fluorescent recovery after photobleaching (FRAP) revealed that AR-v7 intranuclear mobility was significantly faster than that of liganded AR-ß, with 11/2.3 s versus several minutes, respectively. To precisely map the spatial distribution and chromatin-binding kinetics of AR-ß and AR-v7, we generated expression plasmids with AR tagged with green-to-red mEos4 photo-convertible proteins. We investigated the relationship between rates of intranuclear mobility and transcriptional activity and the mechanisms underlying the distinct mobility patterns. These data suggest that AR-v7 has a distinct mode of interaction with DNA and gene promoters, which may identify novel targetable pathways for its inhibition in CRPC.

Inhibition of prostate tumor growth by an extract from the muscadine grape. Patricia E. Gallagher, E. Ann Tallant. Wake Forest School of Medicine, Winston-Salem, NC.

Despite decades of advancements, cancer remains the second leading cause of mortality in the United States with an estimated 1.7 million new cases and over 600,000 deaths predicted for 2016, indicating a clear need for more effective chemotherapeutic and chemopreventive agents. While natural products derived from plants have served as an abundant source of anticancer agents, it is predicted that less than 2 percent of the plant species with medicinal value have been investigated. Muscadine grape (Vitis rotundifolia) and/or seed extracts are a popular nutraceutical supplement due to the high anti-oxidant, anti-inflammatory, anti-angiogenic factors. MGE reduced VEGF mRNA from 1.02 ± 0.06 to 0.72 ± 0.07 relative units (p < 0.05) and PLGF mRNA from 1.03 ± 0.11 to 0.63 ± 0.07 relative units (p < 0.05), providing additional evidence of an anti-angiogenic effect of the extract. Collectively, these results are the first to demonstrate that a novel MGE formulation reduces prostate tumor growth in a mouse model, by inhibiting angiogenesis, suggesting that MGE may be an effective treatment for prostate cancer.

Anti-cancer evaluation of various solvent extracts of blue honeysuckle berry (Lonicera caerulea L.) against prostate cancer cells. Syed M. Ali,1 Alex Ourch,2 Chun-Tao Che,2 Min-Ying Wang,3 Gnanasekaran Munirathnam.4 University of Illinois College of Medicine, Rockford, IL; 5University of Illinois at Chicago, Chicago, IL.

Prostate cancer (PCa) is the second most common cancer among men in the United States. It is estimated 1 in 6 men will be diagnosed with PCa and approximately 180,890 new cases are predicted in 2016 alone. Standard treatments for PCa include surgery, radiation, chemotherapy and hormonal therapy or a combination of these treatments. However, factors like patient age, disease stage, drug resistance, specificity, and toxicity can result in poor disease prognosis. In order to overcome these limitations and improve patient prognosis, there is an urgent need to identify new anti-cancer agents with minimal side effects. Current studies are being focused on natural products and their components for alternative therapeutics. Blue Honeysuckle (Lonicera caerulea L.) a berry native to northeast Asia, is known to be rich in Vitamin C and polyphenols such as anthocyanins, flavonoids, and phenolic acids. Polyphenols are found to have several therapeutic effects such as anti-inflammatory, antioxidant and antimicrobial properties. Our present study used sequential solvent extracts of Blue Honeysuckle (BHS) berry using Hexane, Ethyl Acetate, Methanol, and Water respectively. These fractions were used to assess various therapeutic effects of BHS on DU 145, PC-3, C4-2 and LNCaP PCa cell lines. The goal was to identify the most potent BHS fraction that is effective against PCa using pre-clinical studies. MTT assays were used to identify the anti-proliferative effects of various BHS fractions. The above indicated PCa cells were treated with different doses (10-150 µg/mL) of BHS fractions over various time periods (24, 48, 72 hr). Our data revealed that Hexane extract (HE) exhibited the highest inhibition of cell viability in a time and dose-dependent manner. HE fraction showed to have an IC50 of 89.6 µg/mL for DU 145, 117.4 µg/mL for PC-3, 163.3 µg/mL for C4-2 and 140.84 for LNCaP cells. Moreover, BHS HE fraction showed a decrease in migration capacity and colony formation ability of PCa cells in vitro. Cellular senescence assay was performed to assess β-Galactosidase activity in PCa cells treated with BHS HE extract. All the PCa cell lines treated with 100 µg/mL of BHS HE showed increased senescence. Western blotting was performed to identify the potential anti-cancer mechanism of BHS against PCa using DU 145 and PC-3 cell lines. Results from this study indicated that DU 145 and PC-3 cell lines after 24 hr treatment with 100 µg/mL of various BHS fractions especially BHS HE showed an increase in apoptosis (Caspase 3,8,9 and PARP-1) and autophagy (LC3 A/B) markers. Furthermore, cell cycle analysis of DU 145 and PC-3 cells treated with BHS HE extract showed increased apoptotic cells. Further analysis of apoptotic and autophagy pathways modulated by BHS treatments are required to illustrate its potential underlying anti-cancer mechanisms in PCa. In conclusion, results from our study warrant further evaluation of BHS berry for potential PCa management.

Neutralization of IL-10 enhances antitumor efficacy of dendritic cell targeting MIP-3θ-gp100 vaccine by way of type-I interferons in B16F10 mouse melanoma model. James Gordy, Kun Luo, Richard Markham. Johns Hopkins School of Public Health, Baltimore, MD.
The chemokine MIP-3α (CCL20) binds to CCR6 found on immature dendritic cells. Vaccines fusing MIP-3α to gp100 have been shown to be effective in therapeutically alleviating melanoma in mouse models. Other studies have provided evidence that IL-10 neutralizing antibodies enhance immunological melanoma therapies by modulating the tolerogenic tumor microenvironment. Here, we investigated whether IL-10 or IL-10R antagonists lead to a more efficacious combination with a cytokine fusion vaccine in murine melanoma. We found that a therapeutic protocol using IL-10 antibody intra-tumorally beginning on day 5, once every three days for up to six doses. Tumor sizes, growth, and survival were all assessed. Treatment responses were characterized by flow cytometric analysis of tumor infiltrate. Vaccine-specific T-cells were delineated by gp100 + , stimulation followed by intracellular cytokine staining for IFN-γ and assessment by flow cytometry. The mechanism of IL-10 efficacy was explored by RT-PCR and confirmed with a knockout mouse model. With this therapeutic protocol, we demonstrate for the first time that a therapy neutralizing IL-10 additively enhances the anti-tumor efficacy of a MIP-3α-gp100 vaccine, leading to significantly smaller tumors, slower growing tumors, and overall increases in mouse survival. Surprisingly, the additive effects of IL-10 were not shown to be directly mediated by any T-cell parameter tested, including vaccine-specific tumor infiltrating lymphocytes (TILs), total TILs of either CD4+ or CD8+ subset, regulatory T-cells, granzyme positive T-cells, and others. We discovered, however, that IFN-γ transcripts in the tumor were significantly upregulated in mice given vaccine and αIL-10 compared to vaccine alone. Furthermore, infiltration into the tumor of plasmacytoid dendritic cells, known to be professional IFN-γ-producing cells, were enhanced with the combination therapy. A mouse model with IFNγRa1 knocked out eliminated the protection provided by αIL-10, demonstrating that the additional therapeutic value of αIL-10 is primarily mediated by type-1 interferons. In conclusion, efficient targeting of antigen to immature dendritic cells with a chemo-kine fusion vaccine offers a potential alternative approach to the ex vivo dendritic cell antigen loading protocol currently undergoing clinical investigation. Combining this approach with an IL-10 neutralizing antibody therapy that modulates the tolerogenic tumor microenvironment offers promise as a novel melanoma therapy.

Cancer immunotherapy represents a promising therapeutic approach to extend the overall survival of cancer patients. However, several mechanisms within the tumor microenvironment orchestrate the suppression of host immune response requiring combination strategies to prolong the durability of effect. Among suppressive pathways, up-regulation of PD-L1 and its interaction with PD-1 receptor plays a key role in suppression of T-cell activity; a mechanism also called adaptive immune resistance. Therefore, approaches able to inhibit the tumor immune suppressive mechanisms along with those expanding the frequency of intra-tumor T-cells and enhancing/prolonging their functionality are required. CEA TCB (RG7802, RO6958688) is a novel T cell bispecific antibody targeting carcinomembrinogenic antigen (CEA) on tumor cells and CD3 on T cells, currently being investigated as single agent and in combination with atezolizumab in Phase 1/1b studies in patients with advanced or metastatic CEA-expressing tumors (NCT02324257; NCT02620573). CEA TCB treatment leads to increased intra-tumor T cell infiltration and T-cell activation along with up-regulation of PD-1/PD-L1 suppressive pathway. Here we show that combination of CEA TCB with PD-L1 blocking antibody in vitro enhances cell activation and in vivo elicited a potent combination of pro-inflammatory cytokines. Combination in vivo performed in both stem cell humanized NOD mice (HSC mice engrafted with MK454) and fully immunocompetent human CEA transgenic C56BL/6 mice (hCEA Tg mice engrafted with MC38-hCEA) demonstrated significantly improved anti-tumor activity of combination as compared to activity of single agents, yielding to increased number of tumor-free animals. Randomization of animals that progressed to CEA TCB monotherapy revealed that combination of CEA TCB with PD-L1 blocking antibody is required to control tumor outgrowth, as tumors treated with corresponding monotherapy arms progressed to treatment. Efficacy of CEA TCB was also potentiated when administered in combination with a half-life-extended IL-2 variant (untargeted (IgG-IL2v) or fibroblast-activating protein-targeted IL-2 variant (FAP-IL2v)), resulting in stronger tumor growth inhibition in MKN45-bearing HSC mice or prolonged survival in PanCo2-hCEA-bearing hCEA Tg C56BL/6 mice. Synergy likely reflects ability of IL2v to enhance anti-tumor efficacy by increasing number of effector T cells in tumors. In conclusion, CEA TCB combined with PD-L1 inhibitor leads to increased anti-tumor response. This is accompanied by up-regulation of PD-1/PD-L1 suppressive pathway, which can be overcome by combination therapy with a PD-L1 inhibitor. In vivo efficacy of CEA TCB is further potentiated when administered in combination with immunotherapies that increase the pool of available tumor-infiltrating effector cells.
ici ty and symptomatic disease progression. Patients treated at the higher doses developed a striking end of treatment peripheral blood lymphocytosis showing a 24X increase in absolute lymphocyte count, 10X increase in CD8 cells and 75X increase in NK cell numbers. No patients developed anti-IL-2 antibodies. Steady state serum IL-15 level was seen within the first 12 to 24 hours of therapy and was maintained for several days. Dramatically lower IL-15 levels (~ 8% of early Cmax) were measured during the last 2 days of treatment suggesting a large reservoir of non-circulating IL-15 receptor positive cells. None of the patients achieved a partial response, but 2 patients met the criteria for treatment beyond cycle 2 (~15% decrease in measurable disease). Evidence for tumor directed immune effects included several patients who developed unilateral pleural effusions in their disease involved hemithorax, complete regression of a cutaneous chondrosarcoma metastasis and decreased CA125 (125.7 → 47.3 U/mL) in a patient with pancreatic cancer. Histologic analysis of pleural fluid from these patients showed largely lymphocytes and other cells that were consistent with the patients known cancers. Lymphocytic infiltration of the regressing cutaneous sarcoma metastasis was predominantly CD4 cells, with some CD8 cells and a few NK cells. Immunohistochemical analyses of pre and on treatment tumor biopsies obtained from several other patients are currently being performed to better characterize the immunologic effects of this regimen. The results of this trial indicate that NKTR-124 is an immunotherapeutic with important synergistic properties for combination therapy with other Immunotherapeutics.

**#1597** Inhibition of the novel therapeutic target pregnancy associated protein plasma protein A (PAPP-A) in Ewing sarcoma enhances efficacy of IGF1R targeting in vivo. Sabine Heitzeneder,1 John F. Shern,2 Lee J. Helman,2 Javed Khan,2 Crystal L. Mackall1. 1Stanford University, Palo Alto, CA; 2National Cancer Institute, Bethesda, MD.

Background: Despite intensive treatment regimens, Ewing sarcoma (EWS) patients with metastatic or relapsed disease still face a 3-4 year overall survival of less than 20%, indicating a clear need for novel targeted therapies. Utilizing ribosomal depleted RNA sequencing of 122 EWS samples (49 cell lines and 73 tumor samples) and 96 normal samples of variable tissues, we previously reported that overexpression of PAPP-A is one of the top 5 genes overexpressed in EWS (~ 4 fold) compared to normal tissue. Notably, PAPP-A showed substantial expression in tumors (median log2FPKM = 3.933, n = 122) and minimal expression in normal tissue (median log2FPKM = −1.564, n = 96). Pregnancy Associated Plasma Protein A (PAPP-A) is a secreted zinc metalloproteinase, that anchors to cell surface of heparan sulfate proteoglycans and enhances local IGF signaling. Through the release of IGFs from IGFBP-4, IGFBP-2 and IGFBP-5, free, bioactive IGF is being increased in close proximity to its receptors. In pregnancy PAPP-A is highly expressed by placental trophoblasts and represents a key regulator of fetal growth. The impact of IGF signaling in EWS is illustrated by the modest activity of IGF1R inhibition as a single agent treatment in clinical trials, an approach that is limited by the rapid development of resistance. Methods: In an attempt to investigate the role of PAPP-A in Ewing sarcoma, we used CRISPR/Cas9 technology to target the PAPP-A locus in EWS cells lines and generated PAPP-A knockout clones (EWS, TC32) for further investigation in vitro and in vivo. Results: Tumor models (additional details on this work to be presented at the meeting) demonstrates equivalent affinity and ligand-blocking ability as FPA008. Utilizing a xenograft NSG mouse model, as a single agent treatment as well as in conjunction with IGF1R inhibition, Results: Knockout of PAPP-A in EWS cells utilizing CRISPR/Cas9 technology completely abrogated PAPP-A secretion and metalloprotease activity in single cell clones, resulting in significantly increased complexed IGF-4 and diminished bioactive IGF-1, together with decreased cell growth in vitro. This phenotype could be rescued by recombinant, soluble PAPP-A. In vivo experiments showed that treatment with a monoclonal PAPP-A neutralizing antibody that inhibits the IGF4-IGF-1 receptor activity of PAPP-A delays tumor growth of xenografted EWS tumor cells (EWS) in NSG mice. Furthermore, in conjunction with IGF1R inhibition (mAb 1b7c10), PAPP-A significantly accelerated tumor growth and resulted in prolonged survival of mice (p = 0.021). Conclusions: PAPP-A is a novel biologically relevant and highly tumor specific cell surface target in Ewing sarcoma. Our data suggest that neutralization of PAPP-A is a new therapeutic option that merits further evaluation for the treatment of Ewing’s Sarcoma.

**#1598** Single agent NKTR-214, a biased IL2 pathway agonist, increases immune cell infiltrates in brain tumors and prolongs survival in rodent (rat) glioblastoma (GBM). Lawrence Recht1, Seema Nagpal2, Nancy Schmidt,2 Vuong Trieu,1 Lawrence Schwartz1, Tih-Woong Jung,1 Milton Merchant,1 Irene Choi,2 Ute Hoch,2 Deborah Charych2. 1Stanford School of Medicine, Stanford, CA; 2Nektar Therapeutics, San Francisco, CA.

Background: Immunotherapy is an attractive option for brain tumor therapy if a robust infiltrative T cell response can be elicited in the tumor. NKTR-214 is a CD122-biased cytokine agonist conjugated with multiple releasable chains of polyethylene glycol and designed to provide sustained signaling through the heterodimeric IL-2 receptor pathway (IL-2Rβγ) to preferentially activate and expand effector CD8+ T and NK cells over Tregs. To assess the potential activity of single agent NKTR-214 in GBM, we used an orthotopic rat glioblastoma survival model. Methods: NKTR-214 was administered at 0.1 or 0.3 mg/kg qw iv to Sprague-Dawley rats starting 2 or 7 days (D2, D7) post (p)-implantation of 10^6 C6 glioma cells into the right striatum. The model requires euthanasia by −D14 due to tumor burden. Brain tumors were characterized by magnetic resonance (MR) and immunohistochemistry (IHC) for infiltration of CD4+ and CD8+ T cells and for retention of PEG polymer in brain tumor. Results: Compared to rats receiving saline, survival was significantly prolonged after NKTR-214 treatment (n = 43, mean 17.2 vs. 10.0 days (P < 0.001) with 15% of rats across all groups alive and tumor-free at Day 50 when the study was terminated. Both doses were equally effective and well tolerated. Surprisingly, treated rats bearing large MR-detectable D7 tumors survived significantly longer compared to rats bearing microscopic D2 tumors (6/21 or ~30% versus 0/21 or 0% respectively at D50, mean 23.1 vs. 12 days, P < 0.004). Concordantly, CD8+ T cells in D7 tumors were significantly increased after NKTR-214 therapy compared to vehicle and D2 tumors, while CD4+ remained low with no significant difference between groups. PEG polymer was detected in the tumor at least 72 hours p-injection. Conclusions: NKTR-214 is well tolerated, prolongs survival and induces immunological activity in the brain when administered to rats harboring large GBM. While there was no significant dose dependence, a marked increase in survival was observed when larger D7 tumors were treated with NKTR-214 compared to microscopic D2 tumors, associated with increased intratumoral CD8+ T cells. Levels of CD4+ were unchanged, consistent with the mechanism of CD-122 biased activation of the IL2 pathway. While requiring further study, it is intriguing that the increased sensitivity of larger tumors also correlates to onset of angiogenesis and rapid tumor growth in this model. NKTR-214 is currently being evaluated in an outpatient Phase 1 / 2 clinical trial for the treatment of solid tumors. The results presented suggest a potential role for NKTR-214 in the treatment of patients afflicted with GBM.

The colony stimulating factor 1 receptor (CSF-1R) signaling pathway promotes tumor progression via the recruitment, differentiation, and survival of immunosuppressive tumor-associated macrophages (TAMs). FivePrime has developed cabiralizumab (FPA008), an IgG4 antibody against CSF-1R that blocks the ability of both, CSF-1 and IL-34 to bind and activate this receptor, thereby modulating the immune response to tumorigenesis. In order to investigate the impact of CSF-1R signaling inhibition in preclinical models, we generated a surrogate antibody, cmFPA008, which targets mouse CSF-1R and demonstrates equivalent affinity and ligand-blocking ability as FPA008. Utilizing a combination of flow cytometry and immunofluorescence analyses, we have characterized the biological effects of CSF-1R inhibition, including significant reduction of immunosuppressive TAMs and an increase in tumor PD-L1 expression. Interestingly, we observe a transient increase in CD8+ T cell number and activation upon TAM depletion, followed by a subsequent increase in MDSC populations that correlates with reduction of the CD4+/ CD8+ T cell numbers. Moreover, we have used murine syngeneic tumor models to examine the anti-tumor impact of CSF-1R inhibition in combination with other immunoncology agents. Our results show that, when added to PD-1/PD-L1 blockade, cmFPA008 can significantly enhance anti-tumor efficacy. We are currently exploring the effects of combining cmFPA008-induced TAM depletion with additional immunoncology agents, including T cell agonists. Our preclinical observations demonstrate that inhibition of the CSF-1R pathway can combine with various immunoncology agents with distinct mechanisms of action. FivePrime has initiated a clinical trial in collaboration with Bristol-Myers Squibb (BMS) to investigate the use of cabiralizumab in combination with nivolumab (anti-PD-1, OPDIVO®) in six different tumor types.

**#1600** Interleukin-8 (IL-8) in TGF-β inflammatory and chemothera-
py. Larn Hwang1, Kevin Ng2, Osmond D’Cruz,2 Sanjive Quazi,2 Andrew Schumich2, Barbara Naghavi1, Vuong Trieu1. 1Oncotelic Inc, Agoura Hills, CA; 2Autotelic Inc, Costa Mesa, CA.

Background: Increased expression of IL-8 and/or its receptors has been characterized in cancer cells, endothelial cells, infiltrating neutrophils, and tumor-associated macrophages, suggesting that IL-8 may function as a sig-

**IMMUNOLOGY: Cytokines: The First Modern Immunotherapies**

Proceedings of the American Association for Cancer Research • Volume 58 • April 2017
significant regulatory factor within the tumor microenvironment. OT-101 is a phosphorothioate antisense oligodeoxynucleotide targeting transforming growth factor-beta 2 (TGF-β2). Herein, we examined the role of IL-8 in OT-101 treatment followed with chemotherapies during our Phase II trial in patients with advanced pancreatic cancer (PAC). Methods: Time evolution of a panel of 31 cytokines and chemokines in plasma of 49 PAC patients over 3 cycles of OT-101 administration (140 mg/m²/day) for 12 PAC patients. Samples were acquired before onset of OT-101 therapy and at 8 selected time points (Cycle 1 [Day 2 and 5], Cycle 2 [Days 1, 2, and 5], Final Visit, Cycle 3 [Day 5]) during the therapy. Samples were measured in duplicate and concentrations were expressed in pg/ml. Standardized log10 transformed values calculated from the mean and standard deviation of each cytokine/chemokine in each patient was utilized in an ANCOVA model to investigate the correlation with Overall Survival (OS). Results: Clustering of correlation coefficients resulted in the identification of three highly correlated subsets of cytokines/chemokines (Cluster 1: EGF, MIP-1α, MIP-1β, Cluster 2: FGF-2, IL-1α, MIG, IP-10, IL-15, IFN-α, IL-12α/IL-12β; Cluster 3: HGF, IL-2R, IL-6, IL-8). Protein-Protein interactions were constructed using STRING10 algorithm identified a relationship between IL-8 and TGFβRII inhibition. The ANCOVA model explained a significant proportion of the observed data for Cycle 1 [Day 2] measurements of cytokines/chemokines (R² = 0.3, F = 5.2, P = 1.575, P = 0.0103). Other time points did not exhibit a significant model fit for significant relationships in the interaction term. IL-8 expression showed significant association with OS (positive association, N=12, T-value = 2.92, P = 0.0039). Cycle 1 [Day 2] measurements (7% False Discovery Rate). Linear regression of the increase in IL-8 levels during Cycle 1 [Day 2] treatment with OT-101 was related to an increase in OS outcome (R² = 0.54). To further define the appropriate chemotherapeutics combination with OT-101, we evaluated paclitaxel (PTX), gemcitabine (GEM), and dacarbazine (DTIC) in animal models. Activity was observed with PTX and DTIC, but not with GEM. Both PTX and DTIC induced IL-8 expression whereas, surprisingly, GEM reduced IL-8 expression. Conclusion: IL-8 expression during early phase of OT-101 treatment cycle was positively associated with OS across 12 patients. IL-8 is also induced by PTX and DTIC which synergized with OT-101. The data suggests that PAC and DTIC are acting on the same target as our TGFβRII inhibitor; and potentially, the beneficial effect of these chemotherapeutics is a result of chemotoxin-induced immune IL-8 response.

#1601 Anti-tumor effect of GAGomer-mediated intra-tumoral IL-2 expression following systemic administration. Genia Alpert,1 David Albreuter,2 Sunil Anamandla,3 Arllyssa Birt,4 Guy Cinamon,5 Keren Cohen Merimi,1 Ori Even Or,1 Nir Gefen,6 Nadia Gurvich,3 Jeno Gyuri,2 Lorena Lerner,7 Adi Mondshine,1 Hong Wang.1 1Cancer Immunology, Ness Ziona, Israel; 2Cancer Therapy, Lexington, MA.

Cancer immunotherapies are revolutionizing cancer treatment. Unfortunately, a large proportion of patients with solid tumors do not respond to currently available immune-therapeutics. The lack of response is due to a variety of mechanisms tumors adopt to avoid immune mediated clearance. The multiplicity of immunosuppressive mechanisms operational in the tumor microenvironment may not be overcome by single agents and require interventions at multiple control points. However, systemic exposure to combinations of immunoregulators may result in severe, dose limiting, acute and chronic toxicities that might be prevented if the effect of these agents is focused to the tumor microenvironment. We are engaged in the discovery of a novel class of immuno-oncology drugs aimed at maximizing the effect of immunoregulatory molecules in the tumor microenvironment and minimizing systemic adverse effects. These drugs incorporate plasmids, engineered to program tumor cells to produce and secrete immune-regulatory proteins, within hyaluronic acid (HA) coated lipid nanoparticles, called GAGomers, which specifically target tumor cells that overexpress activated HA receptors (GAG-pDNA). GAG-pDNA based therapeutics promise highly potent but localized activation of the immune system exclusively in the tumor microenvironment following delivery of an agent/chemo, leading to the destruction of tumor cells by activated immune cells without debilitating toxic side effects. To demonstrate the feasibility of the GAG-pDNA approach we have incorporated a plasmid directing the expression of murine IL-2 into GAGomers (GAG-pIL2) and assessed the anti-tumor activity of the construct after systemic delivery into tumor bearing mice. GAG-pIL2 administration resulted in statistically significant inhibition of tumor growth, which correlated with elevated IL-2 levels in the tumor and increased infiltration of T-cells into the tumor microenvironment. These experiments demonstrate the feasibility of programing tumor cells using GAG-pDNA to produce and secrete immunoregulatory molecules into the tumor microenvironment and trigger robust anti-tumor immune responses.

#1602 Generation of anti-IL-17B antibodies neutralizing IL-17B-mediated alterations of the immune microenvironment, promotion of tumor cell initiating capacity and chemoresistance. Emilie Lapirotte,1 Aurélie Docquier,1 Jeremy Bastid,1 Cécile Djoué,1 Marion Lapierre,1 Gilles Alberici,2 Armand Bensussan,3 Jean-François Eliaou,1 Nathalie Bonnefoy,4 1Orega Biotech, Ecully, France; 2INSERM U976, PARIS, France; 3INSERM U1194, Montpellier, France.

Interleukin-17B (IL-17B) is a pro-inflammatory cytokine that belongs to a family encompassing 6 interleukins (IL-17A to F) and binds to the IL-17 receptor B (IL-17B). Recently, amplified IL-17B/IL-17B signaling was found critical for breast and pancreatic tumorigenesis and elevated expression of IL-17B has been associated with the shortest survival rates in patients with breast or pancreatic cancer. Using IL-17B knock-out (IL-17B KO) mice we demonstrate here that melanoma, fibrosarcoma and breast cancer cell tumorigenicity is strongly impaired in immunocompetent IL-17B KO mice compared to WT littermates, including a large number of tumor free mice. Reduced tumor incidence in IL-17B KO mice is associated with alterations of the immune tumor microenvironment especially within innate lymphocyte and myeloid sub-populations. We further demonstrate that IL-17B is a key cytokine shaping the tumor initiating cancer cell niche. Indeed, MDA-MB-468 human breast cancer cells overexpressing IL-17B exhibit 10 times higher frequency of tumor initiating cells when xenografted at a serial limiting dilution in nude mice. Tumor progression is, again, associated with alterations of NK cells within the tumor microenvironment and reduced percentage of CD8 T cells, a phenotype associated with breast cancer stem cells (CSC). This is associated with resistance to conventional chemotherapeutic agents such as taxol, an effect that is totally abrogated by disrupting IL-17B/IL-17B signaling with a neutralizing antibody. Altogether our results point out the key role of IL-17B in regulating the immune microenvironment as well as cardinal features of CSC, one of the alleged causes of resistance to therapy and tumor relapse. Therefore, blockade of IL-17B and its receptor appear as potential therapeutic targets for cancer immunotherapy. Collectively, these data support the ongoing development of IL-17B neutralizing antibodies.

#1603 NKTR-255 engages the IL-15 pathway driving CD8 T cell survival and CD8 memory T cell proliferation. Peiwen Kuo, Mekhali Maita, Phi Quach, Murali Addepalli, Arunasee Lanka, Poornachandra Mathamsetti, Christie Fanton, Ping Zhang, Peter Kirk, Takahiro Miyazaki, Jonathan Zalesky. Nektar Therapeutics, San Francisco, CA.

Background: IL-15, an immunostimulatory cytokine, plays an important role in both the innate and adaptive immune system. Notably, this pleiotropic cytokine is a key regulator of homeostasis and survival of CD8 and CD8 memory T cells. Targeting the IL-15 pathway has therefore become a promising therapeutic approach in oncology through the induction of long-term T cell activation and durable memory responses. NKTR-255 is a polymer-engineered IL-15 that as a single-agent reduces tumor burden in various tumor models. Here, we show that the anti-tumor effects of NKTR-255 can be attributed to its modulation of survival and proliferation of CD8 and memory CD8 T cells. Methods: Immunophenotyping of CD8 T cell subpopulations was performed in naive and tumor-bearing Balb/c mice treated with NKTR-255. Cell surface staining of CD3, CD8, CD44, CD62L and Sca-1 was conducted to identify effector (Tem), central (Tcm) and stem (Tscm) memory T cells. Intracellular staining of IFN-γ and Bcl-2 were also analyzed by flow cytometry. Human whole blood and PBMCs were stimulated with IL-15 (0.0001-1000ng/ml) or NKTR-255 (0.001-10,000ng/ml). At various time points pSTAT5 response in CD3, CD4, CD8 and NK (CD56 bright and dim) cells was monitored by flow cytometry. Results: In naive mice, single dose NKTR-255 (dose range 0.06-1mg/kg) increased the proliferation of Tem, Tcm and Tscm CD8 T cells in a dose-dependent manner. Treatment at 0.3 and 1mg/kg dose levels increased proliferation at least 4 fold across the CD8 memory populations. The abundance of CD8 and CD8 memory T cells was still apparent 6 days post-treatment unlike single dose IL-15 which was ineffective. In a CT-26 lung metastasis model, NKTR-255 reduced the number of lung nodules in a dose-dependent manner. A 0.3mg/kg dose level increased Bcl-2 mRNA expression in MFI 1.5 fold in CD8 T cells. Furthermore, administration of NKTR-255 at 0.3, 1 or 3mg/kg significantly increased CD8 proliferation in a dose-dependent manner in blood (1.7, 4.6 and 5.3 fold) and spleen (2.5, 5.7 and 6.9 fold) compared to vehicle. The enhanced Bcl-2 expression and CD8 proliferation were accompanied by elevated CD8 T cells in blood (1.5, 2.4, and 3.4 fold increase) and spleen (1.5, 2.3 and 3.3 fold increase). Consistent with increased proliferation and increased Bcl-2 levels observed in vivo, both IL-15 and NKTR-255 showed dose-dependent induction of pSTAT5, a modulator of Bcl-2 expression, in CD4 and CD8 T cells from human whole blood and PBMCs. Conclusions: NKTR-255 effectively engages the IL-15 pathway as evidenced by its strong induction of
CD8 and memory CD8 T cell proliferation and promotion of survival. Combined with sustained activity and potency in human blood and PBMCs, our results support NKTR-255 as a novel tumor immunotherapeutic with great potential.

**#1604 NKTR-214 synergizes with radiotherapy to drive tumor regression.**

Michael J. McNamara, Melissa Kasiwecz, Ian Higlart-Martiszus, Ute Hoch, Deborah H. Charych, William L. Redmond, Earle A. Chiles Research Institute, Providence Portland Medical Ctr., Portland, OR; Nektar Therapeutics, San Francisco, CA.

The purpose of this study was to investigate therapeutic and mechanistic synergies between single-dose radiotherapy and systemic administration of NKTR-214. NKTR-214 is a CD122-biased cytokine agonist conjugated with multiple releasable chains of polyeethylene glycol. NKTR-214 is designed to provide sustained signaling through the heterodimeric IL-2 receptor pathway (IL-2Rβγ) to preferentially activate and expand effector CD8+ T and NK cells over Regulatory CD T cells. Preclinical models demonstrated NKTR-214 preferentially expands effector CD8+ T cells and NK cells within the tumor resulting in marked tumor growth suppression as a single-agent and in combination with checkpoint inhibitors. A phase I/Ii trial is in progress to evaluate NKTR-214 safety and efficacy in an outpatient setting. Radiation therapy can induce anti-gene release and epothe spreading, while NKTR-214 can activate and expand antigen-specific effector populations. We hypothesized that the combination of systemic NKTR-214 and local radiotherapy would generate better therapeutic responses than either treatment alone. In this study, we evaluated the combination of NKTR-214 and radiotherapy in syngeneic, providing significantly better anti-tumor responses than either monotherapy. Consistent with previous observations, NKTR-214 alone induces expression of a wide range of activation markers expressed by CD4 and CD8 T cells as well as NK cells in the blood, lymph nodes and tumor. The combination of radiotherapy and NKTR-214 was found to have several unique effects including a significant increase in (>75%) in the absolute numbers of lymphocytes in the peripheral blood, increased expression of activation markers (CD25, PD-1) by CD T cells in the blood and tumor, and increased density of tumor-infiltrating NK cells. Evaluation of tumor infiltrating lymphocytes (TIL) in Nurr77-GFP reporter mice revealed that the combination of NKTR-214 + RT resulted in a higher frequency of recently activated (Nurr77-GFP+) CD8 T cells in treated (irradiated) and unactivated (non-irradiated) tumors. Whole tumor mRNA profiling and multi-spectral histology of these tumors is being assessed to identify key differences in the tumor-microenvironment that may help to define the underlying mechanism of action. Taken together, these data provide evidence of synergy between localized radiotherapy and systemic NKTR-214 treatment via an expansion of activated, tumor-specific CD8 T cells.

**#1605 Combined oral cytokine therapy effectively treats colon cancer in a murine model.** Neal Bhutiani, Qingsheng Li, Charles D. Anderson, Tao Gu, Deborah H. Charych, William L. Redmond. Onkaido Therapeutics, Cambridge, MA; Moderna Therapeutics, Cambridge, MA; Iowa, Iowa city, IA.

Background: Regardles of its etiology, colorectal cancer development is intimately associated with dysregulation of the intestinal immune system. Sustained release, orally delivered IL-10 not only inhibits colon tumor growth but restores T cell homeostasis both locoregionally and systemically. However, it does not induce tumor regression. We aimed to combine orally delivered IL-12, a potent immunostimulatory molecule with robust anti-tumor effect, with oral IL-10 therapy to induce tumor regression. Methods: 6 week old APCmin mice were inoculated with enterotoxic Bacteroides fragilis (serotype 086) after 5 days of intestinal flora depletion with antibiotics dissolved in drinking water. 7-10 days after bacterial inoculation, mice were treated with three doses, including (i) IL-10 and blank polycylic acid microspheres for 3 weeks, (ii) IL-10 containing microspheres (0.5 microgram/dose) for 3 weeks, (iii) IL-12 containing microspheres (0.05 micrograms/dose) for 3 weeks, or (iv) IL-10 containing microspheres for 1 week followed by a combination of IL-10 and IL-12 containing microspheres for 2 weeks. After euthanasia, colons were assessed for polyp counts and select polyps were isolated for confocal microscopy analysis. Mesenteric lymph node lymphocytes were isolated and analyzed using flow cytometry. Results: Mice treated with oral IL-10 and IL-12 demonstrated a reduction in polyp number compared to those mice treated with IL-10 alone, and both groups had fewer polyps than mice treated with either IL-12 or blank microspheres. Addition of IL-12 resulted in increased CD8+ T cell numbers and IFN-γ production compared to treatment with IL-10 alone. IL-10 retained its effect on CD4+ T cells when combining it with IL-12, resulting in a decrease in conventional regulatory T cells (Foxp3+/RORγt-) as well as pathogenic regulatory T cells (Foxp3+/RORγt+) and IL-17 producing CD4+ T cells. Conclusions: The addition of IL-12 to IL-10 therapy augments the therapeutic effect of oral cytokine treatment on colon adenocarcinoma in the APCmin B. fragilis model. The effect appears additive and mediated by both IL-10’s effect on regulatory T cell populations and IL-12’s effect on CD8+ T cells. Further studies in the setting of more advanced disease, including liver metastases, will elucidate the therapeutic potential of combination oral cytokine therapy with IL-10 and IL-12 for treatment of colorectal cancer.

Background: RNA aptamers are small RNA molecules that bind antigens like antibodies and are currently being explored as alternatives to antibodies for diagnosis and therapy. A potential merit of aptamers is that they can be generated against native cellular antigens, such as those with unique post-translational modifications or receptor-ligand complexes, for which antibody generation can be difficult. Here, we report the use of a cell-based systematic enrichment approach (SELEX) to develop a novel Treg-binding RNA aptamer specific to IL2Rα-IL2 receptor-ligand complex. Methods and Results: A. Generation of Treg-binding aptamers: We designed a cell-based SELEX strategy to generate RNA aptamers specific to human T regulatory (Treg) cells. The starting library consisted of random RNA aptamers with a structural diversity of ~1012. Aptamers against common T cell antigen were pre-cleared using CD4+CD25+ T cells. Treg-binding aptamers were then positively selected using CD4+CD25+ Tregs from the same donor. After amplification of Treg binders by RT-PCR, the whole selection was repeated eight times, each time with T cells from a different donor. At the end, SELEX-enriched aptamer pools predominantly bound to Tregs, but not to Teff cells, which were then sequenced. The most prevalent Treg-binder, Tr-1, showed 3,875-fold enrichment by the end of SELEX (from 0.36 copies in the starting library to 22,995 copies in the eighth round per million total reads). B. Tr-1 binds to IL2Rα-IL2 complex. We tested if Tr-1 recognized human IL2Rα by measuring Tr-1 binding to recombinant IL2Rα protein using RT-qPCR. Results indicated that Tr-1 bound to IL2Rα and showed ~3-fold higher binding to IL2Rα when IL2 was added indicating that Tr-1 recognizes either the receptor-ligand complex or a conformational change in IL2-bound IL2Rα. Binding of Tr-1 to IL2Rα did not significantly alter its affinity to IL2. C. Tr-1 inhibits Treg induction: Transformed B cells can induce Treg development in the tumor microenvironment. Experimentally, this was evaluated by quantifying Tregs generated from autologous CD4+ T cells cocultured with Epstein-Barr virus-transformed B (EBV-B) cells. Addition of Tr-1 resulted in ~30% reduction in EBV-B-induced Tregs (p = 0.017). Conclusion: We used a Treg-cell based SELEX strategy to derive a novel Treg-binding RNA aptamer (Tr-1) that preferentially binds to the IL2Rα-IL2 complex. Tr-1 rescues Treg induction by transformed B cells suggesting its potential as a therapeutic agent to reduce tumor-induced immunosuppression. Ongoing studies are further exploring its use in Treg inhibition and in targeting receptor-ligand complexes in cancer. While aptamers recognizing cellular receptors exist, to our knowledge, this is the first report of an aptamer recognizing a receptor-ligand complex. Our approach to generating aptamers against receptor-ligand complexes could have huge scientific impact.
coding OX40L with miR-122 binding sites that have been shown to suppress protein translation in hepatocytes yet not within tumor cells. A single ITU injection of OX40L mRNA, formulated in a lipid nanoparticle, resulted in transfection of up to 25% of live tumor cells, predominantly cancer and myeloid cells. OX40L protein persisted for 7 days after mRNA injection, and a resulting increase in tumoricidal activity was observed. The treatment advances over the past 5 decades and poor survival. Locally targeted oncolytic virotherapy employs a viral vector that has selective cytotoxicity for tumor cells and non-toxic for normal cells and tissues. The therapeutic benefit is proposed to arise from an initial viral cytotoxic phase following host immune responses. Myxoma Virus (MYXV) has been widely tested in Australia to control rabbit populations with no toxicity to humans. MYXV infects and replicates in human tumors despite the lack of cytotoxicity to normal tissues and is a promising oncolytic virotherapy agent that has not been tested in human lung cancer or in clinical trials. Methods: To study MYXV infection and viral replication in vitro, we utilized human and mouse SCLC cell lines with MYXV engineered with fluorescent reporters. Using an optimized conditional genetically engineered mouse model (GEMM) (Ade-Cre mediated p53/Rb1/p130 null) we examined the effects of intrapulmonary MYXV treatment on SCLC tumors at 5 and 30 days post-MYXV treatment. Survival analysis was determined following intranasal MYXV 3 months post-Ade-Cre induction. We also tested intratumoral MYXV in patient derived xenografts (PDX) and subcutaneous syngeneic allografts in immunocompetent mice. Results: We optimized a conditional SCLC GEMM using limiting dilutions of intratracheal Ade-Cre transplanted mice to generate a cohort of mouse SCLC lines from individual clones. We observed efficient MYXV infection, late viral replication, and cytotoxicity in both human and mouse SCLC in vitro. In contrast, we did not detect productive infection nor cytotoxicity in non-tumor cells. Following intranasal MYXV instillation we observed MYXV localized exclusively within lungs at 3 days and no longer detected by 7 days’ post treatment. TUNEL staining of SCLC lesions showed apoptosis and necrosis at 5 days within SCLC and the effect persisted with discrete foci of tumor necrosis 30 days’ post-treatment. There was no toxicity to any mouse tissues. SCLC GEMM treated with intrapulmonary MYXV (n = 30) showed a modest but statistically significant prolongation of survival compared to PBS control mice (n = 30) (p < 0.05). Direct intratumoral MYXV injections performed on PDX tumors in immunodeficient mice showed efficient infection and late viral replication in all patient samples. We observed extensive tumor necrosis at 7 days, and persistent virus at 10 days’ post treatment. Direct intratumoral MYXV injections performed on allograft tumors in syngeneic immunocompetent mice showed extensive necrosis accompanied by immune cell infiltration into the tumor, and the virus was undetectable 7 days’ post treatment. Conclusions: We show the potential for MYXV as an oncolytic virotherapy for SCLC with enhanced cytotoxicity in immunocompetent mice suggesting a role for concurrent immune checkpoint therapies.

The IL-2 receptor (IL-2R) is an attractive target for cancer immunotherapy as it controls both immune-suppressive regulatory T cells (Treg) and anti-tumor T cells. We tested deleting Tregs as immunotherapy using anti-CD25 (high-affinity IL-2R subunit) antibodies (αCD25) in ID8agg mouse ovarian cancer (OC). αCD25 reduced ascites and Treg numbers but failed to reduce tumor burden, whereas αCD25 plus deeply activated anti-tumor CD8+ T cells in tumor-draining lymph nodes. Thus, αCD25 could be novel malignant ascites palliation, but has limited stand-alone efficacy. We then tested IL-2/anti-IL-2 complexes (IL-2c) that selectively stimulate medium-affinity (CD122/CD132) IL-2R thought to expand anti-tumor T cells preferentially, but with little Treg effects. In contrast to several single agents we tested that failed to treat ID8agg (e.g., αCD25, αPD-L1, IL-2 fusion toxin denileukin difitolix). IL-2c alone durably reduced ID8agg tumor burden despite lowering the tumor microenvironmental CD8+/Treg ratio. Thus, we hypothesized that IL-2c improved CD8+ function, reduced Treg function, or both. IL-2c increased polyfunctional IFN-γ + TNF-α + anti-tumor T cells as expected, an effect that persists weeks after drug clearance. IL-2c also increased anti-tumor T cell CD25 expression that increased IL-2 sensitivity and STAT5 phosphorylation, a likely mechanism for increased polyfunctionality. Unexpectedly, IL-2c reduced the Treg functional mediators CD25, TIGIT and granzyme B, and reduced Treg suppressive function. Thus, favorable Treg modifications are a novel IL-2c mechanism of action. Adding αCD25 to IL-2c to delete Tregs further unexpectedly worsened IL-2c efficacy in ID8agg and reduced effector memory T cells and polyfunctional T cells in the tumor microenvironment, suggesting a previously unappreciated role for CD25 in IL-2c therapy. Similar data were seen in B16 melanoma, suggesting αCD25 reduction of IL-2c efficacy is not tumor or compartment-specific (ID8agg is peritoneal and B16 is subcutaneous). αPD-L1, an ineffective monotherapy in ID8agg, combined with IL-2c to promote complete responses, suggesting potential for potent, novel combinatorial approaches. Our data suggest that antagonizing high affinity IL-2R (such as to delete Tregs with αCD25) has limited cancer immunotherapy utility without more specific Targeting. In contrast, stimulating medium-affinity IL-2R with CD122-selective IL-2c has great translational promise by simultaneously improving beneficial anti-tumor T cells and reducing detrimental Treg function.

Background: Small cell lung cancer (SCLC) is an aggressive subtype of lung cancer that has not been fully攻克 advances over the past 5 decades and poor survival. Locally targeted oncolytic virotherapy employs a viral vector that has selective cytotoxicity for tumor cells and non-toxic for normal cells and tissues. The therapeutic benefit is proposed to arise from an initial viral cytotoxic phase following host immune responses. Myxoma Virus (MYXV) has been widely tested in Australia to control rabbit populations with no toxicity to humans. MYXV infects and replicates in human tumors despite the lack of cytotoxicity to normal tissues and is a promising oncolytic virotherapy agent that has not been tested in human lung cancer or in clinical trials. Methods: To study MYXV infection and viral replication in vitro, we utilized human and mouse SCLC cell lines with MYXV engineered with fluorescent reporters. Using an optimized conditional genetically engineered mouse model (GEMM) (Ade-Cre mediated p53/Rb1/p130 null) we examined the effects of intrapulmonary MYXV treatment on SCLC tumors at 5 and 30 days post-MYXV treatment. Survival analysis was determined following intranasal MYXV 3 months post-Ade-Cre induction. We also tested intratumoral MYXV in patient derived xenografts (PDX) and subcutaneous syngeneic allografts in immunocompetent mice. Results: We optimized a conditional SCLC GEMM using limiting dilutions of intratracheal Ade-Cre transplanted mice to generate a cohort of mouse SCLC lines from individual clones. We observed efficient MYXV infection, late viral replication, and cytotoxicity in both human and mouse SCLC in vitro. In contrast, we did not detect productive infection nor cytotoxicity in non-tumor cells. Following intranasal MYXV instillation we observed MYXV localized exclusively within lungs at 3 days and no longer detected by 7 days’ post treatment. TUNEL staining of SCLC lesions showed apoptosis and necrosis at 5 days within SCLC and the effect persisted with discrete foci of tumor necrosis 30 days’ post-treatment. There was no toxicity to any mouse tissues. SCLC GEMM treated with intrapulmonary MYXV (n = 30) showed a modest but statistically significant prolongation of survival compared to PBS control mice (n = 30) (p < 0.05). Direct intratumoral MYXV injections performed on PDX tumors in immunodeficient mice showed efficient infection and late viral replication in all patient samples. We observed extensive tumor necrosis at 7 days, and persisting virus at 10 days’ post treatment. Direct intratumoral MYXV injections performed on allograft tumors in syngeneic immunocompetent mice showed extensive necrosis accompanied by immune cell infiltration into the tumor, and the virus was undetectable 7 days’ post treatment. Conclusions: We show the potential for MYXV as an oncolytic virotherapy for SCLC with enhanced cytotoxicity in immunocompetent mice suggesting a role for concurrent immune checkpoint therapies.

Salmonella typhimurium is a facultative anaerobic bacteria and can selectively grow in tumors following systemic administration. Different strategies have been used to deliver payloads to tumor tissues using engineered Salmondelleae. We report a novel method of cancer immunotherapy using an attenuated S. typhimurium strain engineered to secrete Vibrio vulnificus flagellin B (FlaB) in tumor tissues. Previously, we developed an attenuated strain of S. typhimurium, which is defective in ppGpp synthesis (ΔppGpp S. typhimurium), and manifested significantly increased L50 by 100,000 to 1,000,000-fold. To generate an inducible vector system for bacterial expression of the therapeutic gene, we cloned the flaB gene into the pBAD plasmid vector in which the pBAD leader sequence was cloned upstream of flaB to guide extracellular secretion; gene expression from the plasmid (pFlaB) was induced only in the presence of L- arabinose. To evaluate the antitumor activity of engineered S. typhimurium, C57BL/6 mice transplanted with MC38 tumors were injected intravenously with L-arabinose (i.v.) with PBS. ΔppGpp S. typhimurium carrying an empty vector, or ΔppGpp S. typhimurium carrying pFlaB (+/− L-arabinose induction). To test whether the FlaB-secreting ΔppGpp S. typhimurium has inhibitory effects on human metastatic cancer, we next implanted HCT116-luc2 tumors into the intestinal wall of BALB/c athymic nu/− mice using a surgical orthotopic implantation (SOI) procedure. Engineered FlaB-secreting Salmonellae significantly suppressed tumor growth and metastasis in mouse models and prolonged survival. By using TLR5-negative colon cancer cell lines (MC38 and HCT116), we have proved that the FlaB-mediated tumor suppression upon bacterial colonization should be associated with TLR5-mediated host reactions in the tumor microen-
environment. These therapeutic effects were completely abrogated in TLR4 and MyD88 knockout mice, and partly in TLR5 knockout mice, strongly suggesting that TLR4 signaling is a requisite for the FlaB-secreting bacteria-mediated tumor suppression where TLR5 signaling augmented tumor suppressive host actions. Tumor colonization by engineered Salmonellae appeared to induce the infiltration of abundant immune cells such as monocytes/macrophages and neutrophils via the TLR4 signaling. Subsequent secretion of Flab from colonizing Salmonellae resulted in phenotypic and functional activation of intratru- moral macrophages with M1 phenotypes and a reciprocal reduction in M2-like suppressive activities. Taken together, these findings provide evidence that non-virulent tumor targeting bacteria liberating multiple TLR ligands can be used as novel cancer immunotherapeutics.

#1611 Intravesical BCG induces CD4 + T Cell expansion in an immune competent model of bladder cancer

Max Kates, Thomas Nirschl, Nikolai Sopko, Noah Hahn, David McConkey, Alex Baras, Charles Drake, Trinity Bivalacqua, Johns Hopkins Medical Institutions, Baltimore, MD.

Intravesical BCG Immunotherapy is the standard of care in treating non-muscle invasive bladder cancer (NMIBC), yet its mechanism of action remains elusive. Both innate and adaptive immune responses have been implicated in BCG activity. While prior research has indirectly demonstrated the importance of T cells and shown a rise in CD4 + T cells in bladder tissue after BCG, T cell subpopulations have not been fully characterized. We investigated the relationship between effector and regulatory T cells in an immune competent, clinically relevant rodent model of bladder cancer. Fischer 344 rats aged 7 weeks received 1.5mg/kg N-Triosso-N-methylurea (MNU) every other week for 6 weeks (4 doses). Bladder dysplasia began by week 8 and by week 16 the majority of rats had a NMIBC phenotype. Beginning week 8 following the first MNU dose, rats were intravesically administered 0.3ml of BCG (Tice), cisplatin (1mg/ml), Mitomycin C (2mg/ml), MMC every other week for 6 weeks (4 doses). Bladder dysplasia began by week 8 and by week 16 the majority of rats had a NMIBC phenotype. Beginning week 8 following the first MNU dose, rats were intravesically administered 0.3ml of BCG (Tice), cisplatin (1mg/ml), Mitomycin C (2mg/ml), MMC + BCG, or saline (n = 10 for all groups) weekly for 6 total doses. Animals were sacrificed at week 16, and bladders were processed for histopathology and digested into single cell suspensions for flow cytometry. Whole transcriptome expression profiling was then performed on sorted CD4 and CD8 cells of post-BCG tumors vs untreated tumors to assess T cell differ- entiation after BCG. Our data demonstrate that cancer progression in the MNU rat model of bladder cancer is characterized by a decline in the CD8/FoxP3 ratio, consistent with decreased adaptive immunity. By contrast, treatment with intravesical BCG leads to a large, transient rise in the CD4 + T cell population in the urothelium, and is both more effective and immunogenic compared to intravesical chemotherapy. Interestingly, whole transcriptome expression profiling of post-treatment intravesical CD4 + and CD8 + T cells revealed minimal differences in gene expression after BCG treatment. Together, our results suggest that while BCG induces T cell recruitment to the bladder, the CD8 cell phenotype does not markedly change, imply- ing that combining T cell activating agents with BCG might improve clinical activity.

#1612 Production of CD3 + cells using ferrofluids for cell isolation, acti- vation, expansion and subsequent transfaction for adoptive cell therapy

Dustin W. Ritter, Todor R. Khristov, Paul A. Liberti, BioMagnetic Solutions, State College, PA.

The purpose of the study is to demonstrate whether magnetic nanoparticles func- tionalyzed with monomodal antibodies in conjunction with solution-phase mono- modal antibodies can be used to activate T cells for expansion in vitro. The activation, expansion and transfection/transduction of immune cells—particularly T cells—has become an area of significant interest based on encouraging data generated from employing such genetically modified cells for cancer immunotherapies. The prom- ise of soon being able to cure various types of cancers has resulted from years of methodical experimentation in the fields of oncology, immunology, and genetics, as well as the development of a vast array of enabling technological advances. BioMag- netic Solutions has developed colloidal magnetic nanoparticles—referred to as fer- rofluids—which can be used to isolate a cell population through an immunomag- netic separation. These ferrofluids comprise a crystalline core of magnetite (ca. 100 nm in diameter) coated with multilayers of clinical-grade human serum albumin and further functionalized with a clinical-grade rat anti-mouse IgG1 monoclonal antibody. These “common-capture ferrofluids” (ca. 130 nm in diameter) are capable of binding cells which have been labeled with a monoclonal mouse IgG1 antibody; for example, CD3 + cells can be readily isolated from a complex cell mixture by labeling with a monoclonal mouse anti-human CD3 antibody, adding common- capture ferrofluid, and subjecting the sample to a magnetic field gradient. This tech- nology can therefore be employed at the clinical scale to isolate T cells from an apheresis product. In this study, we investigated whether T cells isolated using com- mon-capture ferrofluids could subsequently be activated and induced to expand in vitro. Based on preliminary experiments showing that T cell-bound common-cap- ture ferrofluid has excess antibody-binding capacity, we designed experiments to test the hypothesis that solution-phase CD28 could be added to isolated T cells, which would bind to both CD28 determinants on the cell surface as well as to the cell-bound common-capture ferrofluid. Activation was quantified by measuring CD25 expression after four days in culture and expansion was monitored over 15 days. Following an immunomagnetic separation of CD3 + cells, magnetically isolated cells were re-suspended in expansion medium (STEMCELL) supplemented with 10% FBS (growth of LIGHT and IL-12 genes in NSC was confirmed by qPCR and by Western blot analysis). The following day, 0.5 µg/ml mouse anti-human CD28 monoclonal anti- body (Mabtech) was added, and thereafter, cells were periodically agitated and di- luted to 10 6 cells/ml with expansion media. After four days in culture, 88.4% of cells expressed CD25, while a 311-fold expansion was observed after 15 days. In sum- mary, we have demonstrated that common-capture ferrofluids can be used to acti- vate T cells for expansion in vitro.

#1613 Genetically modified neuronal stem cells expressing IL-12 and TNFSF14 attenuate highly metastatic mammary tumors in a mouse model

Tej B. Shrestha, Dezhong Lu, Matthew T. Basel, Marta Pyle, Stefan H. Bossmann, Deryl L. Troyer, Kansas State University, Manhattan, KS.

Interleukin 12 (IL-12) is a heterodimeric cytokine encoded by two genes, p35 and p40. IL-12, also known as T cell-stimulating factor, induces proliferation of T lymphocytes and natural killer (NK) cells, while also demonstrating an anti-angiogenic effect and inhibition of regulatory T cells. Similarly, LIGHT (TNFSF14) is a transmembrane protein which acts as a costimulatory factor for the activation lymphoid cells and stimulates the proliferation of T cells, leading to increased apoptosis of tumor cells. Expression of IL-12 and LIGHT specific- ally in the tumor region could activate T cells and stimulate the immune system to attenuate the tumor. Homing neuronal stem cells C17.2 (NSC) were genetically engineered to express the mouse-LIGHT gene and IL-12 using a retroviral expression vector. The expression of both cytokines in NSC was confirmed by qPCR, ELISA and Western blot. To test the antitumor effects of the engineered cells, Balb/C mice bearing 4T1 mammary tumors were treated with NSC-LIGHT, NSC-IL-12 and NSC-LIGHT/IL-12 cells intratumorally (I.T.) at day nine. Repeated tumor measurement over time showed attenuation of mammary tumor growth in the both NSC/IL-12 and NSC/LIGHT groups in comparison with untreated groups PBS and NSC. Tumor growth was further reduced by treat- ing the mice with NSC expressing both cytokines LIGHT and IL-12. Tumor metastasis was also evaluated by removing the primary tumor surgically and observing mice for any sign of metastatic burden. Treatment groups had less metastatic tumor burden and survived longer than the control group. Therefore, tumor homing NPC-LIGHT/IL-12 cells could be effective for the treatment of highly metastatic mammary tumors.

#1614 Intratumoral delivery of a P2A-linked bicsrticin IL-12 construct leads to high intratumoral expression and systemic anti-tumor response

Da- young Seung, Christoph Bertram, Shewa A. Shirley, Anandarup Mukhopad- hyay, Richard J. Connolly, Arwa Bahrami, Jean S. Campbell, Robert H. Pierce, OncoSec Medical, San Diego, CA.

The use of immunomodulatory cytokines has been shown effective in regress- ing a wide range of tumors. However, systemic delivery of recombinant cyto- kines can result in serious adverse effects, often life-threatening. DNA transfer using electroporation (EP) is a safe and effective method of delivering cytokines to target tissues. Intratumoral (IT) electroporation of Interleukin 12 (IL-12), a potent immunomodulatory cytokine, is well tolerated with an acceptable safety profile and objective response rates of 34-40% and 33% in Phase II clinical trials in advanced melanoma and Merkel cell carcinoma, respectively. We sought to improve the systemic anti-tumor response of IT pIL-12-EP by improving IL-12p70 expression and electroporation conditions, which were evaluated in vitro and in vivo with a two-tumor syngeneic mouse model of melanoma. Functional IL-12 p70 is a heterodimer, we compared different expression constructs to achieve high levels of IL-12 protein expression. IL-12p70 protein expression from a plasmid that incorporated a picornavirus-derived co-translational cleav- age site (P2A) was higher than constructs with an internal ribosomal entry sequence (IRES) or a fusion of the p35 and p40 subunits. In functional in vitro assays, pIL-12(P2A) was superior to pIL-12(IRES) and the fusion protein. Using the murine B16.F10 tumor model, we show that IT EP of pIL-12 (P2A) plasmid regresses the treated lesions in a dose-dependent manner compared to control treatments. Systemic effects of IT-expressed IL-12 was assessed by monitoring generation of an antigen-specific CD8 T cell response and regression of B16.F10 orthotopic tumors following primary tumor electroporation. IT pIL12-EP treatment with the P2A-linked construct resulted in a significant in- crease in antigen-specific CD8 + T cells, as well as enhanced contralateral tumor growth inhibition suggesting the induction of strong systemic anti-tumor im- mune response.* Contributed equally to this work.
Background: Post-surgery adjuvant radiotherapy (RT) for breast cancer significantly reduced the local recurrence rate. However, many patients develop early adverse skin reactions (EASRs) that impact quality of life. Methods: In a large prospective study of 1,000 breast cancer patients undergoing RT, we evaluated an inflammatory biomarker, C-reactive protein (CRP) in predicting RT-induced EASRs. In each patient, we measured pre- and post-RT plasma CRP levels using a highly-sensitive ELISA CRP assay. RT-induced EASRs were assessed using the Oncology Nursing Society Skin Toxicity Criteria. Association between EASRs and CRP were assessed using logistic regression models after adjusting for potential confounders. Results: The study population includes 405 patients. CRP levels differed significantly by race/ethnicity at baseline and at the end of RT. RT-induced grade 4 skin toxicity was significantly associated with: obesity and pre-RT CRP > 2mg/L (OR = 3.27, 95%CI = 1.88, 5.68), obesity and post-RT CRP > 2mg/L (OR = 4.42, 95%CI = 2.38, 8.23), or obesity and change of CRP > 1mg/L (OR = 5.58; 95%CI = 1.82, 17.0). Conclusion: The current observations support the previous suggestion that the inflammatory biomarker CRP is associated with RT-induced EASRs, particularly combined with obesity. Impact: Our current findings support the discovery and development of anti-inflammatory agents to protect normal tissue from RT-induced EASRs and improve quality of life in breast cancer patients undergoing RT.

#1617 Mechanistic modeling of a new kinelytically-controlled CD122 agonist for cancer immunotherapy: NKTR-214 pharmacokinetics, pharmacodynamics, and receptor pharmacology.

Introduction: NKTR-214 is a biologic prodrug currently in a Phase 1/2 clinical trial in patients with solid tumors, as a single agent and in combination with anti-PD1. It is a CD122-biased cytokine agonist conjugated with a highly-sensitivity ELISA CRP assay after adjusting for potential confounders. Results: The study population includes 405 patients. CRP levels differed significantly by race/ethnicity at baseline and at the end of RT. RT-induced grade 4 skin toxicity was significantly associated with: obesity and pre-RT CRP > 2mg/L (OR = 3.27, 95%CI = 1.88, 5.68), obesity and post-RT CRP > 2mg/L (OR = 4.42, 95%CI = 2.38, 8.23), or obesity and change of CRP > 1mg/L (OR = 5.58; 95%CI = 1.82, 17.0). Conclusion: The current observations support the previous suggestion that the inflammatory biomarker CRP is associated with RT-induced EASRs, particularly combined with obesity. Impact: Our current findings support the discovery and development of anti-inflammatory agents to protect normal tissue from RT-induced EASRs and improve quality of life in breast cancer patients undergoing RT.

#1618 Immune-modulating effect of bevacizumab in EGFR mutated lung adenocarcinoma.

Po-Hao Feng, Kang-Yun Lee. Shuang Ho Hospital, Taipei Medical University, New Taipei City, Taiwan.

Background: Host immunity affects treatment effect of lung cancer. Peripheral blood S100A9+ monocyte myeloid derived suppressor cells (MDSCs) predict efficacy of immune checkpoint therapy and epidermal growth factor receptor-tyrosine kinase inhibitor (EGFR-TKI) of lung adenocarcinoma patients. Bevacizumab has immune-modulating effects, including decreasing MDSCs, and improve treatment effect in combination with immunotherapy. However, the effect of immune modulation in combination of bevacizumab and EGFR-TKI in EGFR mutated lung adenocarcinoma patients is not clear. Methods: Stage IV lung adenocarcinoma harboring sensitive EGFR mutation patients receiving first line EGFR-TKI or combination EGFR-TKI and bevacizumab were enrolled. The peripheral blood mononuclear cell (PBMCs) were collected, and S100A9+ MDSCs percentage was calculated by flow cytometry from CD14+S100A9+ in PBMC. Clinical data was collected. Results: Eight patients receiving EGFR-TKI and bevacizumab, as combination group, and twenty patients received EGFR-TKI alone, as control group, were enrolled. PBMC S100A9+ MDSC decreased in combination group (decrease 39 ± 18% from baseline), but not in control group. Combination group had longer progress free survival (PFS) comparing with control group. (Median PFS combination vs control group: 15.2 vs 9.9 months, Log Rank test, p=0.05) Increased of peripheral blood cytotoxic T cells also had trend in combination group but not in control group. Conclusion: Besides the anti-angiogenesis effect, bevacizumab had immune modulated effect, especially in decreasing circulating S100A9+ MDSC in EGFR mutated lung adenocarcinoma patients. This might partially explain the longer PFS in combination of EGFR-TKI of anti-angiogenesis agent treatment.

#1619 Gemcitabine-generated ROS promotes neutrophil transmigration and activation by synergistic CXCL8 production with PKC delta-activated macrophages.

Jinseon Jeong, Yong-Jae Kim, Kwang Hoon Yang, Yoon Yoon, Ki-Young Sohn, Hae-Jung Jee, Myung-Hwan Kim, Jae Wha Kim. Korea Research Institute of Bioscience and Biotechnology, Daejeon, Republic of Korea; Enzymeh LifeSciences, Daejeon, Republic of Korea; Asian Medical Center, Seoul, Republic of Korea.

Chemotherapy-induced neutropenia (CIN) is a common side effect that necessitate dose reductions during treatment of cancer patients. Preventing CIN is critical in chemotherapy because a rapid decline of neutrophil counts increase susceptibility to infection of cancer patients. In spite of its importance, the mechanism responsible for CIN still remains unclear. The purpose of this study is to investigate the mechanism of CIN in an aspect of neutrophil activation by chemotaxis in in vivo and in vitro model systems. It is well known that protein kinase C α (PKCα) is endogenously activated in immune and cancer cells of tumor environments, and treatment of gemcitabine generates reactive oxygen species (ROS). Based on these phenomena, we hypothesized that gemcitabine-generated ROS synergistically amplifies PKCα signaling and C-X-C Motif Chemokine Ligand 8 (CXCL8) production in intracellular PKCα is activated in both the peritoneal cavity and the tumor region. To investigate if neutrophils are transmigrated by gemcitabine treat-
immunoreactivity to tumor, and clearly indicated that transferred effector B cells can act independently of T cells in causing tumor destruction in adoptive immunotherapy.

#1622 The role of the CCL-2 on lymphopenia-induced myeloid derived suppressor cells. Pasquale P. Innamorato, Amy Weber, Shari Pilon-Thomas. H. Lee Moffitt Cancer Center, Tampa, FL.

The induction of lymphopenia prompts the expansion of CD11bLy6Cmonocytic MDSCs (M-MDSCs) and CD11bLy6Chemokine mononuclear MDSCs (PMN-MDSCs). Patients receiving adoptive cell therapy (ACT) require nonmyeloablative chemotherapy to induce lymphopenia and support anti-tumor immunity. However, the role of MDSCs in the setting of ACT is not fully understood. As levels of CCL-2 expression in CD11bLy6C cells induced in lymphopenia mice declined, we investigate the role of CCL-2 in the expansion and function of lymphopenia-induced MDSCs using CCR2KO mouse models. Lymphopenia was induced in melanoma-bearing C57BL/6 (WT) and CCR2KO mice by 600rad of total body irradiation or combination therapy with cyclophosphamide and fludarabine. We first evaluated the percentages of splenic MDSCs in WT and CCR2KO mice after the induction of lymphopenia. At day 14, the expansion of total MDSCs were similar in WT (279% of normal) and CCR2KO (241% of normal). However, the mean percentages of M-MDSCs (3.5%) and PMN-MDSCs (30.3%) in CCR2KO mice were altered compared to M-MDSCs (22.2%) and PMN-MDSCs (21.7%) in WT mice. In addition, M-MDSCs in B16 tumors grown in CCR2KO mice were decreased compared to intratumoral M-MDSCs in WT mice (p<0.001). In contrast, the percentages of M-MDSCs and PMN-MDSCs were increased in the bone marrow (BM). To investigate the suppressive capacity of lymphopenia-induced MDSCs, OVA antigen-specific CD8 T cells were co-cultured with OVA peptide in the presence of MDSCs purified from the spleens of CCR2KO and WT mice. Both CCR2KO and WT MDSCs potently suppressed T cell proliferation as measured by "H thymidine incorporation. CCR2KO and WT MDSCs had significant arginase activity and production of nitrites. To investigate the efficacy of ACT, B16 tumor-bearing CCR2KO and WT mice were lymphodepleted and ip100 antigen-specific Thy1.2 CD8 T cells were adoptively transferred followed by 3 days of IL-2 treatment. We found that donor Thy1 T cell tumor infiltration was similar and no difference in tumor growth was observed between CCR2KO and WT mice. Collectively, these results suggest that the role of CCL-2 is important for the egress of lymphopenia-induced M-MDSCs from the BM, but has no effect on the expansion or function of PMN-MDSCs in the setting of lymphopenia. These data suggest that factors besides CCL-2 play an important role in the expansion and function of MDSCs after the induction of lymphopenia.

IMMUNOLOGY: Cytokines: The First Modern Immunotherapies

#1623 Minute variation in murine ovarian cancer preclinical models significantly impact immunotherapy results obtained for clinical trial. AJ Robertson, Kristen Starbuck, Samar Masoumi-Moghadam, Ariel Francois, Kunile Odunsi, Emese Zsiros. Roswell Park Cancer Institute, Buffalo, NY.

As highly promising approaches for treatment of a variety of solid tumors, including recurrent ovarian cancer. While dramatic clinical benefit is observed in a subset of patients with ovarian cancer, the majority of ovarian cancer patients do not respond to checkpoint inhibitors, thus combinatorial treatments are sorely needed. Immune competent pre-clinical animal models are crucial to test emerging treatment strategies and for the identification of biomarkers to predict response to therapy. As results from immune competent preclinical models are often translated into clinical trials, we sought to investigate whether slight variability related to animal housing and/or breeding practices in the same strain could impact experimental outcomes related to immunotherapy. We conducted animal studies using C57BL/6 mice purchased from Jackson Laboratories (Cat# 000664) 2 weeks prior to experimental use (iax) and using the same mouse strain purchased from Jackson Laboratories but bred within our institution for a period of 6 months prior to use (jax-R). Using the gold standard ID8 murine metastatic intraperitoneal ovarian cancer model we tested the therapeutic efficacy of anti-PD-1 monotherapy in both jax and jax-R animals. Aged-matched female mice were housed under the same conditions for 2 weeks prior to tumor inoculation and for the duration of study. Strikingly, we noted that while anti-PD-1 monotherapy had absolutely no effect on tumor growth or survival of jax mice, the jax-R animals showed dramatic tumor growth control and significantly improved long term survival. Tumor progression and survival was similar across sub-strains in untreated control animals, suggesting that the
observed differences in treatment outcome following anti-PD-1 treatment were not simply due to intrinsic differences between the animals. Response to treatment was also associated with increased frequencies of circulating CD4+ and CD8+ T cells in the Jax-R mice compared with the Jax animals. Although major variations in age, animal strain and gut microbiome can dramatically impact the efficacy of any assay, our findings demonstrate that even minute changes within sub-strains recently derived from the same founder animals could result in significantly different survival and pre-clinical outcome. Thus, immunotherapy results obtained from immune competent animal studies need to be interpreted with caution when designing future immunotherapy trials.

**#1624 NOTCH ligand-based therapeutics for immunomodulation in cancer and organ transplantation.** Elena I. Tchekneva,1 Anmoldele E. Antonucci,1 Irina Chekneva,2 Nicholas Long,1 Jason V. Evans,2 Anwari Akhter,2 David P. Carbone,1 Thomas Magliery,1 Mikhail M. Dikov,3 Ohio State University, Columbus, OH; 1St Moss State Medical University, Moscow, Russian Federation; 3West Virginia University, Morgantown, WV.

We demonstrated in human and mouse studies that tumor-induced modulation of Notch ligand expression and Notch signaling in hematopoietic compartment contributes to tumor immune escape. Down-regulation of delta-like ligands (DLL) leads to defects in T cell development and T helper (Th1) cell differentiation with the prevalence of regulatory T cell (Treg) generation. To determine the roles of Notch ligands in antigen-presenting dendritic cells in regulation of antitumor immune responses we generated a set of lineage-specific knock-out mice lacking one of the Notch ligands in CD11c+ dendritic cells (DC). We are developing and testing a set of reagents for clinical application for ligand-specific activation or inhibition of Notch signaling to stimulate or inhibit, respectively, various types of immune responses for applications in oncology and immune diseases. Mice with DLL1 insufficiency in DC demonstrated remarkably accelerated growth of Lewis lung carcinoma (LLC) tumor, and reduced survival compared to wild type animals. This associated with impaired anti-tumor immune responses indicated by the decreased tumor infiltration by IFNγ-producing T cells. Jagged2 knockout did not cause any significant alterations. Notch ligand expression in antigen-presenting cells was identified as a “checkpoint” regulating the type of immune response. Data reveal that expression of Notch ligands by antigen-presenting cells is an important immune response specifying mechanism and that ligand-specific Notch signaling could be a valuable therapeutic target. Reagents for the pharmacological modulation of immune responses based on Notch ligand constructs is proposed. Our cell-based study showed that pharmacological activation of Notch ligands required multivalent receptor-ligand interaction, whereas soluble ligands acted as competitive Notch inhibitors. We have generated reagents that comprise specific receptors of the DLL family in multivalent or monovalent form for therapeutic inhibition of Notch by monovalent DLL1-based reagent accelerated LLC tumor growth and attenuated T cell-mediated anti-tumor immune response. In a heart transplantation mouse model, monovalent DLL1 reagent significantly prolonged allograft survival by inhibiting Th1 effector and memory T cell differentiation. Multivalent forms of DLL1 effectively stimulated Notch signaling in T cell culture and enhanced IFNγ production, whereas monovalent forms had opposite effects. Pharmacological up-regulation of DLL1-mediated Notch signaling with multivalent forms of ligand represents an efficient strategy for the enhancement of anti-tumor immunity and targeting multiple mechanisms of tumor growth. Monovalent DLL1 forms could be utilized for therapeutic inhibition of Th1 responses in autoimmune diseases and organ transplantation. Reagents based on the mono- and multivalent forms of Notch ligands can be efficiently utilized for therapeutic modulation of Notch signaling.

**#1625 NGS reveals specimen characteristics have minimal impact on immune gene expression signature.** Jeffrey Conroy,1 Sean Glenn,1 Blake Burcher,1 Sarabjot Pabla,1 Maochun Qin,1 Jon Andreas,1 Vincent Giamo,1 Marc Ernsto,2 Mary Nesline,3 Ji He,1 Mark Gardner,1 Carl Morrison1. 1Ohio State University, Columbus, OH; 21st Moscows State Medical University, Moscow, Russian Federation; 3West Virginia University, Morgantown, WV.

Background: A custom NGS cancer immune gene expression assay was developed which measures the transcript level of >350 genes involved in T-cell receptor signaling (TCRS), tumor infiltrating lymphocyte (TILs) genes as well as other key targets expected to predict the likelihood of patient response to checkpoint inhibitors (CPI). In parallel to the gene expression assay, mutational profiling was carried out using the 409 gene Comprehensive Cancer Panel (ThermoFisher). As variability between runs is common when performing NGS assays a detailed comparison of specific technical variations were assessed for their ability to effect gene expression and mutation profiles of clinical FFPE samples. Methods: Studies were designed to characterize the analytical performance of the immune response NGS assay using RNA and DNA from a subset of 300 FFPE tissues representing NSCLC, melanoma, renal cell carcinoma and bladder cancer. As part of the study, we tested the impact of variability in RNA and DNA input quantity at the library preparation step, sample batch size which affects mapped reads/sample and depth of coverage, and linearity of expression and sensitivity of mutation profiling through serial dilutions of pico-molar (pM) input of normalized library. PCA and unsupervised clustering was performed on samples with checkpoint inhibition, TCRS and TILs genes as well as mutational profiling to reveal sample groups with three distinct immune signatures (low, indeterminate and high). Further correlation and over-representation analysis was performed to determine impact of specimen characteristics on these three immune signatures. Results: Immune signatures were maintained for the majority of characteristics studied within a specified range. As expected, only TIL status was significantly associated with the high expression group. Other factors including architecture, neoplastic content, percent necrosis, stroma quality/quantity, T-Path, PMR, specimen type, tissue amount and specimen age were not over-represented in any immune signature. Conclusion: Tumor samples harbor a mixture of potential assay interferents including variable benign, neoplastic and immune cell populations with both naïve and reactive stroma contributing to a complex tumor microenvironment that is difficult to catalogue prior to testing. Our study demonstrates that the immune signature present in the tumor microenvironment is sufficiently strong to withstand a wide range of tumor heterogeneity, thereby reducing the need of extensive tissue macrodissection and the exclusion of samples previously thought to be non-evaluable.

**#1626 Technical variability in NGS immune gene expression and mutation profiling has a nominal effect on tumor classification.** Sean Glenn1, Jeffrey Conroy1, Blake Burcher1, Sarabjot Pabla1, Maochun Qin1, Jon Andreas1, Vincent Giamo1, Marc Ernsto2, Mary Nesline3, Ji He1, Mark Gardner1, Carl Morrison1. 1Omniox, LLC, Buffalo, NY; 2Roswell Park Cancer Institute, Buffalo, NY.

Background: A custom NGS cancer immune gene expression assay was developed which measures the transcript level of >350 genes involved in T-cell receptor signaling (TCRS), tumor infiltrating lymphocyte (TILs) complement as well as other key targets expected to predict the likelihood of patient response to checkpoint inhibitors (CPI). In parallel to the gene expression assay, mutational profiling was carried out using the 409 gene Comprehensive Cancer Panel (ThermoFisher). As variability between runs is common when performing NGS assays a detailed comparison of specific technical variations were assessed for their ability to effect gene expression and mutation profiles of clinical FFPE samples. Methods: Studies were designed to characterize the analytical performance of the immune response NGS assay using RNA and DNA from a subset of 300 FFPE tissues representing NSCLC, melanoma, renal cell carcinoma and bladder cancer. As part of the study, we tested the impact of variability in RNA and DNA input quantity at the library preparation step, sample batch size which affects mapped reads/sample and depth of coverage, and linearity of expression and sensitivity of mutation profiling through serial dilutions of pico-molar (pM) input of normalized library. PCA and unsupervised clustering was performed on samples with checkpoint inhibition, TCRS and TILs genes as well as mutational profiling to reveal sample groups with three distinct immune signatures (low, indeterminate and high). Further correlation and over-representation analysis was performed to determine impact of technical characteristics on these three immune signatures. Results: Immune signatures including mutation profiles and gene expression levels were maintained throughout variable RNA/DNA input amounts at the library generation level as well as with diminution of pM levels of library pooled at the sequencing step. Increase in the number of mapped reads and sequencing depth through decreasing the number of batched samples per sequencing run also did not affect the gene expression and mutation profile signatures of the FFPE derived samples. Conclusion: The gene expression and mutation profiles responsible for classifying FFPE samples using NGS are not affected by variation normally introduced in the technical workflow commonly associated with these platforms. The analytical assessment of input at the nucleic acid, library, and sample size level has shown the plasticity available when using amplicon based NGS technologies for classifying the immune gene expression signature as well as mutational profiles of FFPE derived clinical tumor samples. This flexibility increases the strength and utility of NGS-base gene expression profiling and mutational analysis of tumor samples for both basic research and clinical applications.

Hypoxia is a hallmark of cancer and a driver of tumor progression and poor patient outcomes. By generating an immunosuppressive tumor microenvironment that limits cytotoxic T lymphocyte (CTL) infiltration and activation, hypoxia limits the effectiveness of cancer immunotherapy and thus promotes tumor cell evasion of the host immune response. Omnim has developed a first-in-class and anti-cancer immunocheckpoint inhibitor, Optima, to target hypoxic tumor hypoxia to enhance cancer immunotherapy efficacy. In preclinical models, we have demonstrated that OMX accumulates in rodent subcutaneous and orthotopic tumors, as well as spontaneous canine melanomas and brain tumors, resulting in significant tumor hypoxia reduction. Here, using multiple subcutaneous syngeneic mouse tumor models (MC38, CT26, 4T1), we assessed OMX effects on immune cells and immunosuppressive regulatory T cells (Treg), as well as the anti-tumor potential of OMX as a single agent and in combination with established immunotherapies. Using quantitative immunohistochemistry, we confirmed reports that hypoxic tumor areas are devoid of CTLs. Accordingly, by flow cytometry we observed a negative correlation between tumor hypoxia and CTL infiltration. While OMX single agent treatment did not affect the overall CD45+ positive leukocyte population, Treg cells were selectively depleted and the CTL:Treg ratio was substantially increased, suggesting that OMX induced a shift towards immunosenzitization. Consistent with this finding, we observed OMX single agent anti-tumor efficacy in MC38 colon tumors. Impressively, anti-tumor effects of OMX single agent were equivalent to that of a single treatment of the checkpoint inhibitor anti-CTLA4. We next assessed whether OMX would enhance the efficacy of checkpoint inhibitors when used in combination. In CT26 colon tumors, OMX exhibited combination anti-tumor activity with anti-CTLA4, giving rise to faster cures and a greater number of complete and durable responders compared to anti-CTLA4 alone. Of note, this enhanced response was observed for both early-stage and late-stage CT26 tumors. In 4T1 breast tumors, known to be insensitive to checkpoint inhibitors, treatment of early-stage (~60 mm³) tumors with combination OMX and anti-PD1 resulted in a 27% response rate, compared to a 0% response rate to anti-PD1 alone. Taken together, our data suggest that OMX, by delivering oxygen to hypoxic tumor areas, induces a microenvironmental change from an immunosuppressive to an immunopermissive state. Given that OMX is well-tolerated in both small and large animals, and that its mechanism of action is upstream of numerous major immunosuppressive pathways, OMX holds great clinical potential to synergize with multiple immunotherapeutic agents to enhance tumor control by restoring anti-cancer immune responses in cancer patients.

#1628 Early events in metastatic spread: new approaches using targeted therapeutics to disrupt formation of the pre-metastatic niche and development of lung metastases. Khalid A. Mohamedali, Lawrence H. Cheung, Michael G. Rosenblum. UT MD Anderson Cancer Ctr., Houston, TX.

Solid tumors release soluble factors causing migration of a subset of normal bone marrow derived cells (BMDCs) - primarily VEGFR-1+ or VEGFR-2+ circulating endothelial progenitor cells - from the bone marrow to organs. These normal BMDCs self-assemble into a bone marrow derived cells (BMDCs) network that limits metastatic spread. The significance and specific characteristics of the BMDCs is still unclear. We have previously observed migration of VEGFR-1+ BMDCs to the lung and lymph nodes, and VEGFR-2+ BMDCs to liver, lung and lymph nodes. Using GFP + BMDCs from genetically engineered mice, we characterized the role that recruitment of BMDCs may play in breast cancer metastasis. We assessed the BMDC recruitment profile in lethally irradiated female nu/nu mice transplanted with GFP+ BMDCs from donor mice, followed by orthotopic placement of MDA-MB-231/luc cells or injected with MDA-MB-231/luc conditioned media for 30 days. Flow cytometry results show a gradual increase in the recruitment of CD11b+ VEGFR-1+ cells in all the tissues examined from tumor-bearing mice. Recruitment of these cells to the liver in mice treated only with MDA-MB-231/Luc conditioned media was also apparent, but the increase was not as high as in livers of mice with the orthotopic implanted tumors and conditioned media of CD11b+ VEGFR-2+ BMDCs was also observed but only in liver and lung. Interestingly, conditioned media seemed to recruit this subset of cells more strongly to these two tissues than signaling from orthotopic tumors. Spleen and lymph node showed minimal recruitment of CD11b+ VEGFR-2+ BMDCs. We have previously developed the Grb/VEGFR fusion construct- a novel pro-apoptotic fusion protein which specifically targets cells harboring VEGFR and have utilized this agent to specifically target BMDCs which are VEGFR2+. Our preliminary data indicate that treatment with Grb/VEGFR does not significantly alter the recruitment of VEGFR-1+ or VEGFR-2+ cells to lungs, when assessed two weeks after the final treatment. We observed increased recruitment of Flt4+/Flt8+ macrophages to the lung. On the other hand, CD11b+Gr-1- BMDCs were significantly reduced following Grb/VEGFR treatment, although the F4/80+ subpopulation carrying this signature increased. Studies are ongoing to determine whether systemic administration of this agent can disrupt the formation of the niche and the eventual establishment of metastatic tumors. Understanding the role of BMDCs in metastatic spread of different tumors and their role in the early development of metastasis will be critical in designing targeted therapeutic approaches to inhibit the metastatic process. Research sponsored, in part, by the Clayton Foundation for Research.

#1629 An integrated view of Notch signaling that regulates tissue renewal in response to enteric infection. Badal C. Roy,1 Ishfaq Ahmed,2 Audrey Seamos,3 Shirikant Anant,1 Lillian Maggio-Price,3 Seth Sepert,3 Shahid Umar.1, Kansas University Medical Center, Kansas City, KS; 2University of Washington, Seattle, WA; 3Children’s Mercy Hospital, Kansas City, MO.

Background: Microbial dysbiosis and the associated gut inflammation unbalances epithelial renewal, potentially leading to cancer which is increasingly being recognized as a stem cell disease. Notch signaling is active in multipotent intestinal stem cells (ISCs); yet, how Notch signaling orchestrates communication between the gut microbes and ISC-dependent tissue renewal following a pathogenic insult, is poorly understood. Aim: To investigate how Notch signaling contributes towards ISC regeneration and pathogenesis of infection. Methodology: Rag^{-/-} mice and wild type littermates were infected with Citrobacter rodentium (CR; 10^7 CFUs) and treated with Notch blocker Dibenzapine ([DBZ], ip at 10 μmol/kg body weight). Whole distal colon or purified crypts were isolated for analyses. Results: RNA analysis of transgenic mice expressing MHC-II either in EEC (EpithTg) or in dendritic cells (CD11cTg) were crossed to Rag^{-/-} mice and received Helicobacter bilis (Hb) to induce colitis. De-identified sections from control or Crohn’s Disease (CD) and Ulcerative Colitis (UC) patients were stained for markers of ISCs and immune cells, respectively. Results: Rag^{-/-} mice but not WT littermates, exhibited dramatic increases in Dclk1 (Doublecortin-like kinase 1; an ISC marker) expression in the colon crypts, measured via flow cytometry and IHC at 12 days post CR-infection that co-localized with Notch Intracellular Domain (NICD). CR-infected mice when treated with DBZ for 10 days exhibited; i) significant dysbiosis with Proteobacteria dominating (48% compared to 27% after CR infection), ii) increases in paracellular permeability concomitant with almost complete attenuation of Dclk1 and iii) exacerbation of inflammation/colitis. Intriguingly, Dclk1 immunoreactivity shifted towards the stroma wherein, Dclk1 co-localized with NICD and with CD11c+ dendritic cells, CD11b+ and F4/80 macrophages and MHCII. Both EpithTg/Rag^{-/-} and CD11cTg/Rag^{-/-} mice infected with Hb compared to uninfected mice, exhibited loss of crypt Dclk1 and its co-localization with NICD that coincided with severity of colitis. Sections prepared from the colon of Crohn’s Disease (CD) or Ulcerative Colitis (UC) patients paralleled loss of crypt Dclk1 seen in mice while Dclk1 continued to co-localize with NICD and with markers of immune cells within the stroma. When CR infected and DBZ-treated Rag^{-/-} mice were given a cocktail of antibiotics (500mg/l Vancomycin, 1g/l metronidazole and 0.2g/l ciprofloxacin) for 7 days, we observed increased survival and decreases in colon myeloperoxidase (MPO) activity that coincided with increased Dclk1 in the colon epithelial and stromal areas. Conclusions: 1. Bacterial dysbiosis following chronic Notch inhibition coupled with loss of crypt Dclk1 impairs crypt regeneration. 2. Co-localization of stromal Dclk1 with markers of immune cells and with MHCII suggests a novel role for Dclk1 in antigen presentation.

Despite improvements in therapy over the last few decades, neuroblastoma (NB) still accounts for a considerable portion of childhood cancer-related mortalities and 5-year survival rates in patients with high-risk disease remains poor (40-50%). Amplification of MYCN and dysregulation in downstream Myc-related pathways result in NBs with high-risk features. Notably, MYCN-amplified NBs have elevated polyamine (PA) levels, and the gate-keeper enzyme in the PA synthesis pathway, ornithine decarboxylase (ODC1), is a direct target of Myc. Yet, ODC1 activity can be irreversibly inhibited by the FDA-approved drug difluoromethylornithine (DFMO), and exposure of NB cell lines in vitro to DFMO reduces cellular growth. In a mouse model of MYCN-driven NB (TH-MYC+/+ transgenic mice), inhibition of PA synthesis with DFMO led to reductions in NB burden and extension of survival that appeared more profound than that predicted by the in vitro activity of the drug, suggesting that in addition to tumor-intrinsic effects, DFMO may have significant effects on the NB tumor microenvironment.
**IMMUNOLOGY: Tumor Microenvironment and Checkpoints**

microenvironment (TME). We therefore sought to characterize the tumor mi-
icroenvironment of NB in TH-MYC/N transgenic mice in the presence or absence of
DMO-mediated PA blockade. Tumors from DMO treated and untreated mice were dissected, mechanically and enzymatically dissociated, and the num-
ber and frequencies of various TIL subsets were assessed using an optimized flow cytometry protocol. Our results show that PA blockade reduces tumor growth and results in distinct and reproducible alterations in the cellular com-
position of the NB TME, the most profound of which was a significant increase in the frequency of NK cells. Moreover, we found an increase in the percentage of tumor cells expressing NK cell ligands. Concordingly, we also witnessed a shift in the NK cell expression of activating and inhibitory receptors. These findings are consistent with the hypothesis that PA blockade induces distinct TME changes that predispose to more efficient immune control of NB growth. To probe the contribution of NK cells to this process, we are now testing whether antibody-mediated depletion of NK cells in DMO-treated TME changes that predispose to more efficient immune control of NB.

#1631 Sequencing the circulating and infiltrating T-cell repertoire on the Ion S5TM

Geoffrey Lowman,1 Elizabeth Linch,1 Lauren Miller,1 Denise Topa-
ccio-Hall,1 Timothy Looney,2 Alex Pankov,2 Yongming Sun,2 Xinzhan Peng,1

Carlsbad, CA; 2ThermoFisher Scientific, South San Francisco, CA

The tumor repertoire (TCR) sequencing by next-generation sequencing (NGS) is a valuable tool for building a deeper understanding of the adaptive immune sys-

tem. As immunotherapies, particularly T-cell dependent therapies, show in-
creasing potential in treating cancer, the ability to gain a detailed, unbiased view of the TCR becomes imperative for biomarker discovery, immune response to-
treatment, and study of tumor microenvironments. A key question the field seeks to understand is the relationship between circulating T-cells and infiltrat-
ing T-cells at the tumor site. Here, we present a novel approach for TCR se-
quencing using the Ion S5TM sequencer which leverages simplified library con-
struction workflows and offers a more complete characterization of the entire V(D) region of TCRB. This method can leverage mRNA as input, minimizing requirements in starting materials and focusing sequencing to productive TCRB

arrangements. This approach targets the constant (C) and the FR1 regions, min-
imizing the potential for primer bias and greatly increasing the phylogenetic information content compared to techniques that exclusively characterize the CDR3 domain. Our results show that the observed circulating T-cell repertoire size is approximately 2 orders of magnitude higher than the infiltrating T-cell repertoire. Accordingly, while it is difficult to fully capture the complete reperto-
ire of circulating T-cells due to its vast diversity, we show that it is possible to reliably capture the complete repertoire of circulating T-cell repertoire with a single analysis of bulk tumor samples on the Ion 510TM chip. This study describes a new approach for high throughput sequencing of T-cell receptor repertoires which can be applied to a variety of clinical samples.

#1632 Identification and analysis of EGLN3 as tumor-associated peptide in ccRCC

Anna Reusel,1 Moreno Di Marco,2 Florian Böttner,1 Stefan Winter,1

Daniel Kowalewski,2 Linus Backert,2 Steffen Rausch,2 Joerg Hennenlotter,3 Joerg Hennenlotter,3

Urology, University Hospital Tuebingen, Tuebingen, Germany; 4Institute of Pa-

diology and Neuropathology, University Hospital Tuebingen, Tuebingen, Ger-

many.

Introduction: Kidney cancer is the 12th most common cancer world-wide with 338,000 newly diagnosed cases in 2012, according to the World Cancer Research Fund International. With around 70-80%, clear cell renal cell carcinoma

(mccRCC) make up the vast majority of kidney cancers. Advanced and met-
astatic ccRCCs are marked by poor survival rates despite the availability of tar-
geted therapies. Currently several immunotherapeutic approaches, including

checkpoint-blocking antibodies and dendritic cell vaccines are undergoing clin-
ical investigations. In this study we identified tumor-associated peptides which could be used in cancer vaccines to improve treatment of patients with advanced ccRCC.

Methods: To identify suitable peptides for cancer vaccines we set up a tissue collection of paired tumors and normal kidney tissues from 60 ccRCC patients. In parallel, we performed transcriptomic analysis on the combination were evaluated in two syngeneic and orthotopic murine models.

Results: 16 different peptides from EGLN3 were detected in 32 of the 60 analyzed tumors, with the most frequent peptide found in tumors of 10 different patients. Only two of the peptides were also detected in normal kidney or other non-ccRCC tissues, rendering EGLN3 peptides promising candidates to be used in ccRCC-directed vaccines. Most of our patients were HLA A*02:01 positive, however using NetMHCpan (http://www.cbs.dtu.dk/services/NetMHCpan/) only one of the peptides identified by HLA ligandomics was also predicted to be a strong binder for that particular HLA molecule. Expression of EGLN3 mRNA was not different in patients with and without HLA-presented peptides. Gener-

ally, EGLN3 mRNA expression was strongly induced in ccRCC tumors com-
pared to normal kidney (p<0.01). The function and targetability of EGLN3 remains to be investigated.

#1633 Immunotherapy for malignant mesothelioma that combines a me-
sothelia-targeted immune-activating protein and CXCL12/CXCR4 block-

Huang Chao,1 Chen Binghao,1 Yang Zheng,1 Patrick Reeves,2 Qiyuan Liu,3

Sluder, Jeffrey Gelfand,4 Timothy Brooks,4 Mark Poznansky,4 Massachusetts General Hospital, Charlestown, MA.

Background and Purpose: There is a significant unmet need for new treat-
ment strategies for malignant mesothelioma (MM). Despite relevant advances in many cancer treatment areas, including improvements in diagnosis, staging, and the clinical course of treated patients, MM remains a highly lethal disease.

The purpose of this study is to develop a combination immunotherapy for MM, which involves a fusion protein to target and evoke a cellular immune response to mesothelin (MSLN) and the blockade of CXCL12/CXCR4 pathway to mo-
lize cytotoxic effector cells into tumors. Experimental Procedures: The efficacy of the MSLN targeted immune activating fusion protein (scFv-MthHap70), FDA-approved small molecule CXCR4 antagonist AMD3100 (plerixafor), and the combination were evaluated in two syngeneic and orthotopic murine models of MM in immune competent C57BL/6 mice. Micro 4traperitoneal (i.p.) treatments from 7 days post i.p. injection of luciferase-expressing 40L and AE17 cells. Tumor growth was monitored by in vivo imaging of luciferase activ-

ity with an IVIS system. Survival time was measured as date from the start of

tumor inoculation. In preclinical studies, mice were sacrificed 4 weeks after tumor cell inoculation. Immune cells from spleens and tumors were labeled with antibodies against CD3, CD4, CD8, CD25 and Foxp3 antibodies, and ex-
aminied by flow cytometry. Splenocytes were isolated by affinny chroma-

tography and bound peptides analyzed by mass spectrometry. HLA ligand pro-
files of tissues excised from various organ sites of non-ccRCC patients were used to complement the data. Based on these analyses, Egl nine homolog 3 (EGLN3) was selected as a candidate for peptide vaccination and further investigated in our own data cohort comprising the 60 ccRCC patients. Therefore, mRNA and protein expression analysis of HLA ligandomics were performed and correlated with HLA ligandomics and clinical data. In addition, we integrated RNA-Seq DNA methylation, somatic mutation and clinical data from a ccRCC pa-
tient cohort from The Cancer Genome Atlas in our analyses. Finally, EGLN3 function was analyzed in 2D and 3D kidney carcinoma cell culture systems.

Results: 16 different peptides from EGLN3 were detected in 32 of the 60 analyzed tumors, with the most frequent peptide found in tumors of 10 different patients. Only two of the peptides were also detected in normal kidney or other non-ccRCC tissues, rendering EGLN3 peptides promising candidates to be used in ccRCC-directed vaccines. Most of our patients were HLA A*02:01 positive, however using NetMHCpan (http://www.cbs.dtu.dk/services/NetMHCpan/) only one of the peptides identified by HLA ligandomics was also predicted to be a strong binder for that particular HLA molecule. Expression of EGLN3 mRNA was not different in patients with and without HLA-presented peptides. Gener-

ally, EGLN3 mRNA expression was strongly induced in ccRCC tumors com-
pared to normal kidney (p<0.01). The function and targetability of EGLN3 remains to be investigated.
tors, cytokeratin-positive carcinoma cells and CD3+ tumor infiltrating lymphocytes. Results obtained using the IMC at different time points in serial tissue sections were comparable (P<0.05). Conclusion: Quantitative and reproducible measurement of immune and non-immune targets with spatial resolution using the IMC platform is feasible in FFPE breast and lung carcinomas and the results are comparable to multiplexed QIF. Expansion of the current panel to include >30 markers for immune cell phenotypes/function and tumor markers is ongoing.

#1634 CDK4/6 inhibition directly enhances an anti-tumor immune response in breast cancer. Molly J. DeCristo,1,4, Shom Goel,2,4, April C. Watt,3,2,4 Haley Brinjikji,5,3, Jaclyn Sceney,2,4 Ben Li,2, Jyesslyn M. Ubellacker,2,4 Shaozhen Xu,2,4,5,3, Susanne Ramm,4,3, Hye-Jung Kim,2,2, Sandra S. McAllister,1,4, Jean J. Zhao,1,2,3,4 Brigham and Women’s Hospital, Boston, MA; 4Dana-Farber Cancer Institute, Boston, MA; 5Harvard Medical School, Boston, MA.

The cyclin D-cyclin-dependent kinases 4 and 6 (CDK4/6) axis is one of the most frequently dysregulated pathways in human cancers, and CDK4/6 inhibitors have shown significant activity against a number of solid tumors, including breast cancer. Analogous to clinical experience, we found that the CDK4/6 inhibitor, abemaciclib, caused significant tumor regression in the MMTV-rTA/tetO-HER2 mouse model of luminal breast cancer. However, as CDK4/6 inhibitors are known to block tumor cell proliferation, but not directly induce tumor cell apoptosis, as we confirmed in our study, the mechanisms by which CDK4/6 inhibition caused tumor regression were not clear. Notably, abemaciclib therapy increased total CD3+ T cells in these tumors, while decreasing while increasing CD8+ cytokine secretion in human PBMC in-vitro. A robust increase in inflammatory cytokine secretion in human PBMC was observed after treatment with CDK4/6 inhibitor, abemaciclib, compared to vehicle. In patient-derived xenografts, abemaciclib treatment also increased tumor cell death, resulting in tumor regression. Abemaciclib treatment led to a significant increase in the number of T cells in the tumor microenvironment, while reducing the number of regulatory T cells. These results provide strong rationale for further investigations into combining CDK4/6 inhibitors with immune checkpoint blockade in breast cancer.

#1635 Multiplexed analysis of fixed tumor tissues using imaging mass cytometry. Franz Villarroel-Espindola,1 Daniel Carvajal-Hausdorf,1 Ila Datar,1 Amanda Esch,2 Narges Roshidi,2 Ala Nassar,1 Shelly Ben,3 Ruth R. Montgomery,3 Roy S. Herbst,1 Yi-Hsuan Lee,1 Chun-Jung Chang,2 Yu-Yun Shao,2 Jung-hau Liu,3 Ann-Lii Cheng,1 Chi-Hung Hsu1 National Taiwan Univ. Hospital, Taipei, Taiwan; 2National Taiwan University, Taipei, Taiwan; 3National Taiwan Univ. Hospital Hsin-chu Branch, Hsin-chu, Taiwan.

Background: PD-L1 expression in tumor microenvironment of HCC has been unclear. Patients and Methods: We reviewed patients with HCC who had received sorafenib for advanced diseases at National Taiwan University Hospital, Taipei, Taiwan. Patients with paired HCC tissues, obtained before and after sorafenib treatment, were included. Immunohistochemistry (IHC) assay with clone SP142 antibody (Spring Bioscience, Pleasanton, CA, USA) was performed to analyze PD-L1 expression on TC and IC in paired specimens obtained before and after sorafenib. PD-L1 expression was scored as IHC0, 1, 2, or 3 if <1%, 1% to 5%, 5% to 25%, and >25% of cells were PD-L1 positive, respectively. Further IHC assay was employed to characterize the PD-L1-positive IC. Associations between the PD-L1 expression and overall survival (OS) or duration of sorafenib treatment of the patients were analyzed. Results: Twenty-three advanced HCC patients (Male: Female = 26: 3, median age of 64 years) with paired HCC tissues were included. All of the post-sorafenib HCC tissues were obtained after disease progression. The median duration of sorafenib treatment was 4.3 months (range: 1.3 to 18.7). The PD-L1 expression on IC was significantly increased in post-sorafenib HCC tissues, compared with tissues obtained before sorafenib (pre-sorafenib vs post-sorafenib IHC 0/1/2/3: 10/5/2/1 vs 5/5/2/11, p=0.046). However, the PD-L1 expression on TC was not significantly different between pre- and post-sorafenib tissues (IHC 0/1/2/3: 19/20/2/0 vs 14/15/0/4, p=0.065). By using imaging staining of CD68, CD66b, CD11b, and CD3 on the consecutive slides, we found the PD-L1-expressing IC were mainly CD68-positive macrophages, but neutrophils or T lymphocytes. Neither the PD-L1 expression levels on IC of pre-sorafenib or those of post-sorafenib tissues were associated with OS or duration of sorafenib treatment. Conclusions: The PD-L1 expression on IC, especially on macrophages, in tumor microenvironment of HCC was significantly increased in post-sorafenib progression HCC tissues. Whether this increased PD-L1 expression contributes to treatment failure of sorafenib warrants further investigation (This work was supported by the grants of NTUH 105-M3232 and MOST 105-2314-B-002-180).

#1637 ICOS agonism induces potent immune activation and anti-tumor response in non-clinical models. Sapna Yadavalli,5 Ashleigh A. Hahn, Laura M. Seestaller-Wehr, Hong Shi, Yao-Bin Liu, M-Phillip DeYoung, David J. Kilian, Meixia Bi, Michael P. Adam, Shu-Yun Zhang, Sabyassachi Bhat-tacharya, Yuiliya Katlinskaya, Christina Blackwell, Christopher B. Hopson, Nirajan Yanamandra, Roopa Srinivasan, Patrick A. Mayes, Axel Hoos. GlaxoSmithKline, Collegeville, PA.

Inducible T-cell stimulator (ICOS) is a costimulatory receptor that is upregulated on activated CD4 and CD8 T cells and plays an important role in T cell survival, differentiation, regulation of memory and regulatory T cell pools and humoral responses. Preclinically, augmenting signaling through the ICOS pathway has been reported to induce anti-tumor activity and enhance responses to CTLA4 blockade. Here we present non-clinical data evaluating ICOS agonist activity in human and mouse model systems using a different antibody for each species. GSK3559609 is a novel, selective anti-human ICOS agonist. GSK3559609 induces ICOS signaling through phosphorylation of intermediates in the PI3K pathway leading to lymphocyte activation, proliferation and pro-inflammatory cytokine secretion in human PBMC in-vitro. A robust increase in CD4 effector T cell proliferation and Granulcyte B secreting CD8 T cells was observed post-GSK3559609 and OP treatment in in-vitro assays utilizing PBMC from healthy donors, cancer patients or tumor infiltrating lymphocytes (TIL). Modest induction of regulatory T cell proliferation and IL-10 secretion were also observed. Significant increase in IFNγ (p<0.05) and TNFa secretion was observed in both primary PBMC and TIL based assays. Gene expression analysis of
GSK359609 treated human T cells confirmed changes in genes associated with T and B cell activation. In mice, an ICOS surrogate antibody was utilized in immune competent mouse tumor models. Tumor regressions were observed in 10–40% of mice and were associated with a robust increase in effector memory T cells in periphery as well as increases in T cell activation and proliferation in lymphoid and non-lymphoid compartments. In addition to identifying an additional therapeutic modality to stack with checkpoint blockade that could increase patient response rate. We hypothesized that engagement of T cell costimulatory receptors in combination with checkpoint blockade could further increase T cell activation and proliferation. The combination of checkpoint blockade with costimulation could be accomplished using a bispecific antibody format, with the potential benefits of reduced cost and more selective targeting of TILs to improve safety. Antibodies binding to immune checkpoint PD1 and a T cell costimulatory receptor were assembled in a bispecific antibody platform with substitutions in the Fc domain to suppress effector function. PD1 x costimulation (PD1 x costim) bispecific antibodies were evaluated in vitro by measuring antibody binding and de-repression of Staphylococcal enterotoxin B (SEB) stimulated PBMCs. IL2 and IFNγ production was measured by immunoassay. In vivo activity was evaluated using a mouse model in which human PBMCs are engrafted into NSG mice (huPBMC-NSG) and the extent of T cell engraftment is monitored by flow cytometry. We produced PD1 x costim bispecific antibodies that bound PD1 and a T cell costimulatory receptor monovalently. The bispecifics bound to SEB-stimulated T cells more tightly than monovalent controls, indicating that a single bispecific molecule was capable of blocking both PD1 and a T cell costimulatory receptor.

The bispecifics enhanced IL2 and IFNγ production in an in vitro SEB stimulation assay relative to control (p < 0.001, n = 19 donors). IL2 and IFNγ production was superior to anti-PD1 or anti-costim antibodies alone (p < 0.001), indicating productive and synergistic combination of checkpoint blockade plus costimulation. Treatment of huPBMC-NSG mice with checkpoint bispecifics promoted enhanced T cell engraftment relative to control. Engagement levels promoted by bispecifics were superior to those found for anti-PD1 treatment alone. For example, in one run of the model, while anti-PD1 treatment alone promoted a 2-fold increase in human CD45+ cells, a PD1 x costim bispecific antibody induced a 16-fold increase. Combination of checkpoint blockade and costimulation with bispecific antibodies is feasible and promotes strong T cell activation in vitro and in vivo. Compelling activity suggests clinical development is warranted for the treatment of human malignancies.

**#1638** Improved outcomes with drug-resistant immunotherapy in a human xenograft model of glioblastoma multiforme. Samantha B. Langford,1 Harold T. Spencer,2 Anindya Dasgupta,2 George Y. Gillespie,1 Kathryn Sutton,3 Larisa Pereboeva,1 Lawrence S. Lamb,1, 4Univ. of Alabama at Birmingham, Birmingham, AL; 5Emory University, Atlanta, GA.

INTRODUCTION: Conventional treatment strategies for high-grade gliomas have been uniformly dismal. We have previously shown that both primary and Temozolomide (TMZ)-resistant glioblastoma (GBM) cell lines upregulate stress-associated NKG2D ligands (NKG2DL) during the first several hours following exposure to TMZ, thereby creating an opportunity for NKG2DL-directed cell therapy, particularly γδ T cells that directly recognize these stress-associated antigens. Using a human/mouse patient-derived tumor xenograft (PDXT) model, we combined TMZ chemotherapy and TMZ-resistant ex vivo expanded/activated γδ T cells as Drug Resistant Immunotherapy (DRI). Drug resistance in this example is conferred by O-6-methylguanine-DNA-methyltransferase (MGMT) gene transfer, thereby enabling cytotoxic lymphocyte function in a chemotherapy-rich environment when the tumor is maximally stressed. METHODS: A total of five GBM PDXTs were examined, three parent (X12P, X22P, X59P) and two TMZ-resistant (X12T, X22T). Tumor NKG2DL expression and cytotoxicity of DRI were assessed using flow cytometry with cultured human astrocytes as controls. Intracranial (IC) glioma xenografts were established using either an unmodified (P) or a TMZ resistant clone (T) of human GBM explants passaged exclusively in immunodeficient mice. Tumor-bearing mice received intraperitoneal 60mg/kg TMZ on days 6, 8, 13, and 15 and received IC injection of 1.5 x 10^6 DRI 4 hours following TMZ injection. Control mice received DRI T cells alone, TMZ alone or no therapy. Survival was assessed using Kaplan-Meier analysis. RESULTS: All xenografts were found to constitutively express NKG2DL which were upregulated upon exposure to TMZ. DRI T cells were cytotoxic to all tumors in vitro, showing 65%-80% specific lysis at an E:T ratio of 20:1 with no evidence of toxicity against cultured human astrocytes. Median survival (MS) for all groups of untreated mice was approximately 25 days, and γδ T cell therapy alone did not improve survival in the absence of TMZ. For the parent tumors, TMZ therapy significantly improved MS over untreated controls for both X12P and X59P (29 vs. 59 days and 20 vs 51 days respectively, p = 0.0001) and eliminated tumors in X22P. DRI γδ T cells + TMZ significantly increased median survival additionally over TMZ alone with 80% of animals in both X12P and X59P surviving long-term (p = 0.0001 and 0.05 respectively). DRI had no clear effect over TMZ for X22T (p = 0.46), however, for X12T, DRI + TMZ significantly increased median survival from 22 to 38 days (72.7%) over TMZ alone (p = 0.04). CONCLUSIONS: Combined TMZ chemotherapy and drug-resistance modified γδ T cell therapy can produce a significant increase in time to progression and improvement in median and overall survival for both primary and TMZ-resistant GBM using a strategy is readily adaptable to the clinical setting.

**#1639** Combination of PD1 blockade and T cell costimulation by bispecific antibodies promotes human T cell activation and proliferation. Gregory L. Moore, Michael Hedvat, Matthew J. Bernett, Rajat Varma, Suzanne Schubert, Christine Bonzon, Kendra N. Avery, Rumana Rashid, Alex Nisthal, Liz Bogaert, Irene W. Leung, Seung Y. Chu, Umesh S. Muchhal, John R. Desjarlais, Xencor, Inc., Monrovia, CA.

Tumor infiltrating lymphocytes (TILs) express multiple checkpoint receptors, in contrast to lymphocytes found in the periphery (Matsuzaki et al PNAS 2010, Fourcade et al Cancer Res 2012, Gros et al ICI 2014). Checkpoint blockade has demonstrated increased clinical response rates relative to other treatment options; however, many patients fail to achieve a response to checkpoint blockade. In an additional therapeutic modality to stack with checkpoint blockade that could increase patient response rate. We hypothesized that engagement of T cell costimulatory receptors in combination with checkpoint blockade could further increase T cell activation and proliferation. The combination of checkpoint blockade with costimulation could be accomplished using a bispecific antibody format, with the potential benefits of reduced cost and more selective targeting of TILs to improve safety. Antibodies binding to immune checkpoint PD1 and a T cell costimulatory receptor were assembled in a bispecific antibody platform with substitutions in the Fc domain to suppress effector function. PD1 x costimulation (PD1 x costim) bispecific antibodies were evaluated in vitro by measuring antibody binding and de-repression of Staphylococcal enterotoxin B (SEB) stimulated PBMCs. IL2 and IFNγ production was measured by immunoassay. In vivo activity was evaluated using a mouse model in which human PBMCs are engrafted into NSG mice (huPBMC-NSG) and the extent of T cell engraftment is monitored by flow cytometry. We produced PD1 x costim bispecific antibodies that bound PD1 and a T cell costimulatory receptor monovalently. The bispecifics bound to SEB-stimulated T cells more tightly than monovalent controls, indicating that a single bispecific molecule was capable of blocking both PD1 and a T cell costimulatory receptor.

The bispecifics enhanced IL2 and IFNγ production in an in vitro SEB stimulation assay relative to control (p < 0.001, n = 19 donors). IL2 and IFNγ production was superior to anti-PD1 or anti-costim antibodies alone (p < 0.001), indicating productive and synergistic combination of checkpoint blockade plus costimulation. Treatment of huPBMC-NSG mice with checkpoint bispecifics promoted enhanced T cell engraftment relative to control. Engagement levels promoted by bispecifics were superior to those found for anti-PD1 treatment alone. For example, in one run of the model, while anti-PD1 treatment alone promoted a 2-fold increase in human CD45+ cells, a PD1 x costim bispecific antibody induced a 16-fold increase. Combination of checkpoint blockade and costimulation with bispecific antibodies is feasible and promotes strong T cell activation in vitro and in vivo. Compelling activity suggests clinical development is warranted for the treatment of human malignancies.
blocked tumor growth. Moreover, immunohistochemistry staining of treated tumors showed a decrease in the expression of CD206 positive M2 macrophages and CD45/CD25 positive Treg cells, and an increase in CD86 positive M1 macrophages. These results were consistent with the in vitro results obtained. Discussion and Conclusion: These results suggest that a targeting CD206 peptide engineered to promote apoptosis, enhances the tumor response to chemotherapy by limiting the pro-tumorigenic activity of TAMs.

### #1641 Dual antibody blockade of TIM3 and PD1 on NYE051 redirected human T cells leads to augmented control of lung cancer tumors. Edmund Moon,1 Soyeon Kim,1 Shaun O’Brien,1 Naomi Saint Jean,1 Raluca Verona,2 Linda Snyder,2 Yangbing Zhao,1 Steven Alбедa,1 *Univ. of Pennsylvania, Philadelphia, PA; 2Tuenssen Research and Development, Springhouse, PA.

Background: Immunotherapy using checkpoint blockade has demonstrated impressive, durable responses in select patients with solid malignancies. This is especially true for the blockade of programmed death 1 (PD1). Currently, efforts are focused on understanding non-response. One hypothesis is that multiple inhibitory receptors (IRs) are upregulated on hypofunctional tumor-infiltrating lymphocytes (TILs) and necessitates blocking multiple IRs to increase the response rate. We describe data from a unique xenograft model of human lung cancer where tumor-reactive human T cells become hypofunctional and up-regulate multiple IRs including PD1 and TIM3 to limit control of tumor growth than combining it with blockade of either alone. Materials/Methods: The A549 human lung cancer cell line was transduced with an immune checkpoint antigen, NYE051, expressed in the contact of HLA-A2 (A549-A2-ESO). 5x10^3 A549-A2-ESO cells were injected subcutaneously into the flanks of NSG mice. Activated T cells from healthy donors were lentivirally transduced with a TCR targeting NYE051 (Ly95). After two weeks when tumors were established and measured -150 mm^3, the mice were randomly assigned to one of the following treatments: 1) untreated, 2) non-transduced (NTD) T cells plus anti-PD1 and anti-TIM3 Ab, 3) Ly95 T cells, 4) Ly95 T cells + anti-PD1 Ab, 5) Ly95 T cells + anti-TIM3 Ab, 6) Ly95 T cells + anti-PD1 and anti-TIM3 Ab. T cells were injected IV at a single dose of 10x10^6/mouse. Abs were injected intraperitonealy (IP) at 10mg/kg every 5 days from the time of T cell injection. Tumor volumes were measured serially. At the end, the mice were sacrificed and the tumors were harvested, digested, and processed into single cell suspension. Flow cytometry was performed to look at degree of TIL infiltration and expression of surface markers. Ficol gradient was used to isolate the T cells to conduct functional analyses. Results/Conclusion: By twenty days post T cell injection, the tumors in the Ly95 T cell group (3) were ~30% smaller than that of the untreated (1) and the NTD T cell + Ab group (2). Anti-PD1 Ab augmented Ly95 T cell control of tumor (4) (further decrease in size by ~30%) (A). Anti-TIM3 Ab had no effect on Ly95 T cell tumor control (5). Anti-PD1 plus anti-TIM3 Abs had the greatest augmentation on Ly95 T cell control of tumor size (6) (greater than 50% reduction in tumor size compared Ly95 T cells alone) The greatest TIL infiltration and augmentation on Ly95 T cell controlof tumormargin (6) (greater than 50% reduction in tumor size compared Ly95 T cells alone). Anti-PD1 Ab augmented Ly95 T cell control of tumor (4) (further decrease in size by ~30%) (A). Anti-TIM3 Ab had no effect on Ly95 T cell tumor control (5). Anti-PD1 plus anti-TIM3 Abs had the greatest augmentation on Ly95 T cell control of tumor size (6) (greater than 50% reduction in tumor size compared Ly95 T cells alone). The greatest TIL infiltration and augmentation on Ly95 T cell control of tumor size was with combinatory Ab blockade.

### #1642 Evaluation of ENMD-2076 in combination with anti-PD1 in syngeneic cancer models. Graham C. Fletcher,1 Reza Kiarash,1 Mark R. Bray,1 Amanda S. Hu,1 Ken K. Ren2. *Campbell Institute, Univ. Health Network, Toronto, Ontario, Canada; 2CASi Pharmaceuticals, Rockville, MD.

ENMD-2076 is a clinical stage compound with potent activity towards Aurora A and angiogenic kinases. ENMD-2076 has shown promising activity in multiple Phase 1 clinical trials, as well as in a Phase 2 trial in advanced ovarian cancer. ENMD-2076 is currently the subject of several ongoing Phase 2 clinical trials including fibrolamellar carcinoma, triple-negative breast cancer (TNBC), advanced/metastatic soft tissue sarcoma (STS), and advanced ovarian clear cell carcinomas (OCCC). ENMD-2076 has been developed to date as a single agent, however ENMD-2076 inhibits a spectrum of targets including Aurora A, FAK, CSF1R, c-KIT, and KDR, that are potentially involved in immune evasion mechanisms. These kinases have been shown in published studies, when inhibited, to enhance or augment the activity of immune checkpoint inhibitors such as anti-PD1. A study was thereby conducted in syngeneic models to determine the utility of ENMD-2076 combined with immune checkpoint inhibition as a rational strategy for cancer therapy. The study evaluated the efficacy of ENMD-2076 administered daily by oral gavage in the MC38 and CT26 colon cancer models, alone and in combination with an anti-PD1 antibody. Xenografts were established in the appropriate mouse strain (C57BL/6 and BALBc, respectively) by the subcutaneous inoculation of MC38 or CT26 cells into the right flank of female mice. Treatment was initiated 7 days following inoculation when tumor volumes had reached a mean volume of approximately 85 mm^3. All treatments were well tolerated, with no significant body weight loss seen during either study. While single agent ENMD-2076 only led to single agent ENMD-2076 tumor regression was observed in several MC38-bearing animals suggesting an immune activating mechanism. In both models a trend was observed for an augmentation of anti-tumor response in combination relative to single agent ENMD-2076 and anti-PD1 alone. Further studies to evaluate mechanism and an assessment of re-challenge experiments in animals exhibiting complete regression will be performed. These studies support the further evaluation of ENMD-2076 in combination with immune checkpoint inhibition as a strategy for cancer therapy.

### #1643 Cytotoxic T lymphocyte CD3+ , CD8+, and immunoscore as prognostic marker in patients after radical cystectomy. Jose J. Mansure, Alice Yu, Shraddha Solanki, Ana B. Dias, Miguel M. Burnier, Fadi Brimo, Wassim Kassoul. McGill University Health Center, Montreal, Quebec, Canada.

Purpose: Prognosis after radical cystectomy for bladder cancer can be unpredictable. There is increasing evidence that the presence of cytotoxic T lymphocytes correlates with survival. The Immunoscore, a new approach to classification of cancer using the number, type and distribution of immune cells, is an independent predictor for survival in colon cancer. Our objective was to evaluate the prognostic impact of lymphocyte distribution and the Immunoscore in bladder cancer. Methods: Cystectomy sections with core tumor (CT) involvement and identifiable invasive margin (IM) were selected and stained for CD3+ and CD8+ lymphocytes. Three non-contiguous areas of highest lymphocyte density were selected from both CT and IM. The number of lymphocytes in each area was used to calculate the Immunoscore based on previously defined criteria. Kaplan-Meier curves were used to determine differences between Disease-free Survival (DFS) and Overall Survival (OS). Multivariate Cox proportional hazards model was used to determine hazard ratios. Results: Total of 67 patients who had cystectomy for invasive bladder cancer were included in the study. High concentration of CD3+ lymphocytes in the tumor margin was associated with better DFS (P=0.005) and OS (P=0.03). Similar results were found for CD8+ lymphocytes with regards to DFS (P=0.05). A higher Immunoscore was also associated with better DFS (P=0.04). On multivariate analysis, CD8+ in the invasive margin was independently associated with better prognosis. Conclusions: The host’s own immune system plays a valuable role in clinical outcome. Our data suggests that a strong immune response in the tumor margin is independently associated with better prognosis.

Molecular Templates is developing engineered toxin bodies (ETBs), potent recombinant immunotoxins that combine the specificity of an antibody fragment with the powerful direct cytotoxicity of the Shiga-like toxin A subunit. ETBs can induce their own internalization, route through the cell in a predictable manner, enzymatically and irreversibly destroy ribosomes to shut down protein synthesis and induce apoptosis of tumor cells. This mechanism of action is distinct from that of other therapeutics, making ETBs an attractive treatment for patients who have become resistant to chemotherapy and other treatment modalities. MT-3724 is Molecular Templates’ first-generation ETB targeting CD20, a surface receptor that is highly expressed on malignant B cells in hematological malignancies. Pre-clinical and clinical studies have shown promising results for non-Hodgkin’s lymphoma cell lines and patients; however anti-drug antibodies are formed in experimental animals and patients after repeat dosing. Sirolimus (rapamycin) is a macrolide compound approved to prevent organ rejection and in LAM, and has been used in tolerization protocols with replacement enzymes. In pre-clinical studies, we have co-administered sirolimus in combination with MT-3724 in rodents as well as in a non-human primate model in order to reduce the anti-drug antibody response to MT-3724. These studies demonstrated that the combination of sirolimus with MT-3724 decreased anti-drug antibody response in prolonged serum exposure of MT-3724, and improved B-cell depletion as compared to MT-3724 alone. Molecular Template’s ETB technology has resulted in potent and targeted therapeutic agents that have a unique mechanism of action in the field of oncology. Our first-generation, CD20-targeted therapeutic, MT-3724, has promising clinical results in the re-
IMMUNOLOGY: Tumor Microenvironment and Checkpoints

factory setting for non-Hodgkin’s lymphoma. The combination of sirolimus with MT-3724 is an attractive and feasible regimen which will be further explored in clinical studies.

#1645 CEACAM1-blockade for T-cell activation and antitumor T-cell response. So-Young Eun. MOGAM Institute for Biomedical Research, Yongin, Republic of Korea.

Immune checkpoint blockade became the most powerful way to control cancer without causing tremendous side effects, since anti-PD-1 blocking antibodies proved their superiority in clinical outcomes to those of traditional chemo- or targeted therapeutics. CEACAM1 (CCM1) is one of the several immune checkpoint receptors expressed on T cells that mediate suppression of inflammatory T cell response. CCM1 caught our attention for a cancer immune-therapeutic target, because of its inhibitory role in TCR proximal signaling complex. The anti-cancer therapeutic potential of CCM1-blockade has already been studied in mouse models, and one of the anti-human CCM1 antibody clones recently emerged in clinical Phase I studies. CCM1-targeting antibody candidates were screened out of our in-house synthetic libraries, among which a few of the clones stood out showing their significant blocking activities against CCM1-CCM1 homophilic interaction, enhancement of T cell activation, cytokine release, NFAT signaling, and tumor lysis. One of the clones (C25) showed its strongest efficacy equivalent to that of a reference Ab in CCM1-dependent T cell activation, proliferation, and IL-2 release, in parenteral Jurkat cells as well as in CCM1-overexpressing Jurkat cells. Moreover, C25 also enhanced tumor lysis by CCM1+ NK cells or CCM1+ cytotoxic T cells in a CCM1-dependent manner. In addition, C25 shows distinct characteristics in binding to CCM family from those of a reference Ab. Thus, C25 is thought to have a strong therapeutic potential on CCM1+ cancer.

#1646 Highly cytotoxic, completely human constructs targeting HER2 and containing the immuno-oncology payload granzyme B. Lawrence H. Cheung,1 Yunli Zhao,2 Khalid A. Mohamadali,3 Ana Alvarez-Cienfuegos,3 Walter N. Hittelman,3 Michael G. Rosenblum1, MD Anderson Cancer Center, Houston, TX. 2Shenyang Pharmaceutical University, Shenyang, China. 3UT MD Anderson Cancer Ctr., Houston, TX.

Recent immunotherapeutic approaches designed to augment T- and B-cell mediated killing of tumor cells has met with clinical success suggesting that immunoncology (IO) approaches have tremendous potential for treatment in a broad spectrum of tumor types. After complex recognition of target cells by T and B cells, delivery of the serine protease granzyme B (GrB) to tumor cells comprises the cytotoxic insult resulting in a well-characterized, multimodal apoptotic cascade. We designed a recombinant fusion construct composed of a human anti-Her2 scFv fused to active GrB for recognition and delivery of GrB to tumor cells simulating T- and B-cell therapy. The GrB-FC-4D5 dimeric construct (mw 160 kDa) was generated and expressed in stably-transfected CHO-S cells at ~60 mg/L and purified to homogeneity. The enzymatic activity of the fusion construct was similar to commercially-available GrB and the affinity of the construct for purified Her2 extracellular domain (ECD) was 0.328 nM, comparable to that of Herceptin (0.150 nM). The GrB-FC-4D5 construct was highly cytotoxic to Her2-positive cells such as SKBR3, MCF7 and MDA-MB-231 with IC50 values of 56, 99 and 27 nM respectively. Using immunofluorescence, the fusion construct internalized rapidly into target (SKBR3 or SKOV3) cells within 1 h of exposure, rapidly delivering GrB to the cytoplasmic compartment in a similar manner to that of immune T and B-cell targeting but without the action of the transmembrane pore-forming agent perforin. Against a large panel of various tumor types, GrB-FC-4D5 was highly cytotoxic to virtually all cells regardless of natural expression levels of the nominal endogenous GrB inhibitor, PI-9. Contemporary studies with Kadcyla demonstrate similar levels of in vitro activity against virtually all HER2-positive cells tested. GrB-FC-4D5 demonstrated activity against both log-phase and confluent tumor cells. In keeping with its relatively high molecular weight (~160 kDa), the construct demonstrated a terminal-phase half-life of 13.6 hrs. In vivo efficacy studies are currently ongoing in several orthotopic xenograft models. Also ongoing are pre-IND toxicology, histopathology and clinical chemistry studies. Research conducted, in part, by the Clayton Foundation for Research.

Backgrounds: Despite the unprecedented success of immune checkpoint antibody therapy in patients with various cancer types, lack of stable experimental immunotherapy models is still a big challenge in development of effective new immunotherapeutics. Different strategies of humanized mouse model system, including human hematopoietic stem cell (HSC) or human PBMC humanization in immuno-deficient mice, or chimeric models harboring human immune checkpoint targets in immune-competent mice have been reported. CrownBio has successfully established a number of human PBMC-humanized xenograft models MiXeno™ for in vivo IO therapy evaluation, which has been shown to be a rapid and simple approach. Herein we will present one of the optimal PBMC injection route and cell number, the donor dependence of the efficacy result and impact of donor HLA type on the efficacy, etc., need to be further addressed. Results: PBMC number was titrated in one of our MiXeno™ model HCO827, and PBMC injection via i.p. vs. i.v. was compared. Tumor growth curve, graft versus host disease (GVHD), and blood immunophenotyping were followed under different settings. Furthermore, the anti-tumor activity of PD-1 antibody pembrolizumab in a panel of PBMC donor context that bears diversified HLA types was precisely analyzed. We found that the efficacy was highly donor dependent, and there was lack of correlation between efficacy and donor/tumor HLA match. Conclusion: The MiXeno™ model provides an alternative to the full stem cell reconstitution approach. Better understanding on the characteristics of the model may allow a rational model selection and study design in the discovery IO therapeutics.

#1648 ImmunoGraft® platform for the evaluation of ImmunO-Oncology agents in PDX tumors models. David Cerna,1 Daniel Ciznadia,2 Khalid A.Mohamedali,3 Ana Alvarez-Cienfuegos,3 Wal-ter N. Hittelman,3 Michael G. Rosenblum1, MD Anderson Cancer Center, Houston, TX. 2Shenyang Pharmaceutical University, Shenyang, China. 3UT MD Anderson Cancer Ctr., Houston, TX.

Recent breakthroughs in Immunotherapy have given new hope to treating previously untreatable tumors and provided a better tolerated alternative to standard agents. There is an unmet need for a pre-clinical platform to test potential immune-oncology therapeutics that would also provide a tool to examine the mechanisms of response to better predict clinical outcomes. We have previously presented the Champions ImmunoGraft®, an innovative pre-clinical model enabling immunotherapeutic agents to be evaluated for efficacy in solid tumors. This platform is more reflective of the human tumor microenvironment (both immune and non-immune cell-based) and may be one of the most translational-relevant models to date for screening therapies targeting the immune system. However, optimization of humanization and PDx implantation protocols that allow a broader reconstitution of cell lineage and higher engraftment rate are necessary to further improve the pre-clinical evaluation of immunoncology therapeutics and enhance the value of this modality for patient’s benefit. To this end, immune-compromised NOG (Pkrd-e114Ihr211m10g8) mice were reconstructed (humanized) with human CD34+ cells using optimized procedure and blood was collected at different time points post engraftment to check for the major leukocyte linages. At ten weeks after humanization, mature human CD45+ cells comprised close to 50% of the leukocytes detected in the circulation and secondary lymphoid tissues of the humanized animals. As a result of improved methodology of the reconstitution protocol we have achieved an 85% success rate of humanization with a shortened engraftment period utilizing fewer CD34+ cells that maintain humanization reconstituted at 22 weeks post reconstitution. Champions TumorGraft® database contains more than one-thousand clinically relevant well-annotated PDx models. We have compiled data from non-genetic preclinical tumor models and have been an invaluable resource for designing applicable controls for use with the ImmunoGraft® studies for testing of Immuno-Oncology agents. We have identified tumors expressing key markers that may predict response to immunothera-py agents including PDL-1, CD40,IDO-1 and IDO-2 as well as tumors that harbor a high mutational load. Here we present the efficacy and clinically relevant endpoints of two well-studied checkpoint inhibitors Iplilimumab and Pembrolizumab in this highly translational PDx platform.

#1649 In vivo CRISPR-Cas9 genome scan for immune checkpoint regu-lators. Sascha Karassek, Min Long, Xi Li, Zhengang Peng, Qunsheng Ji, Yong Cang. WuXi AppTec (Shanghai) Co., Ltd., Shanghai, China.

Therapeutic antibodies blocking immune checkpoints such as programmed cell death protein 1 (PD1) have proven clinically beneficial in multiple cancer types. However, anti-PD1 drugs approved by FDA are not effective in treating all cancer types nor in all patients in a responsive cancer type. Therefore, understanding the mechanism underlying the efficacy of immune checkpoint blockade is critical for our rational design of synergistic treatment combinations. Here we describe how we employ the latest CRISPR-Cas9 genome-wide knockout screening strategies to identify targets in cancer cells or in T lymphocytes that control the sensitivity or resistance to anti-PD1 treatment. We constructed a sgRNA library targeting the functional domains of 116 mouse methyltransferases and demethylases, which was infected into the mouse Cloudman S91 melanoma cell line. Syngeneic mouse xenograft models derived from these infected cells were treated with anti-mPD1 monoclonal antibody, and the xeno-
gland tumors were harvest at different time points after antibody treatment. Deep sequencing of the integrated sgRNA sequences in the tumors has identified potential druggable targets to sensitize or antagonize the tumors resistance to anti-mPD1 immunotherapy. Alternatively, we introduced the same library to naïve T cells purified from the OT-1 transgenic mice. The T cell library was then injected into a syngeneic melanoma model followed by anti-mPD1 treatment. Deep sequencing of the integrated sgRNA sequences in the tumor-infiltrating T cells would allow us to uncover novel signaling molecules in the immune system that can potentially be manipulated to enhance the anti-PD1 therapy. In summary, we provide in vivo knockout screen strategies that can be applied to identify and validate combination therapies with immune checkpoint antibodies.

Background: Cluster of differentiation (CD47) is a trans-membrane glycosylated protein which is upregulated in several cancers. Increased expression of CD47 on tumor cells is associated with immune evasion and cancer progression. CD47 through its interaction with signal regulatory protein alpha (SIRPs), a cell-surface molecule on macrophages inhibits phagocytosis of tumor cells. Disrupting CD47-SIRPs interactions by monoclonal antibodies targeting CD47 and recombinant SIRPs proteins have been used as therapeutic strategies for treating cancer. Our objective was to discover and develop peptide/peptidomimetic based CD47-SIRPs antagonists for disrupting CD47-SIRPs interactions.

Methods: Through rational design based on crystal structure of CD47/SIRPs/interacting anti-CD47 antagonists, we designed peptides having potential to disrupt CD47-SIRPs interactions. FACS based cellular binding assay was developed to assess the binding affinity of CD47 antagonists. SIRPs protein labelled with fluorescent dye was incubated with Jurkat T cells expressing high levels of CD47 in the presence/absence of peptides. Binding affinity was measured by decrease in fluorescence. Functional activity of the peptides was evaluated in a FACS-based phagocytosis assays, in which tumor cells were incubated with human/mouse macrophages in the presence/absence of CD47 antagonists. Results: We identified CD47 antagonists demonstrating disruption of CD47-SIRPs interaction in a cellular binding assay. These peptides significantly inhibited phagocytosis of different tumor cells by macrophages. The lead CD47 antagonist displaying good ADME properties including moderate oral bioavailability was evaluated in a B16F10 syngeneic mouse tumor model. The lead CD47 antagonist inhibited primary tumor growth as well tumor metastasis to lungs. Biomarker characterization and efficacy studies in additional tumor models are ongoing.

#1651 Targeting phosphatidylserine in combination with adoptive T cell transfer eliminates advanced tumors without off-target toxicities in a melanoma preclinical model. Daniel Hirschhorn-Cymerman, 1 Sara Sara Schad, 1 Sadina Budhu, 2 Zhong Hong, 1 Xia Yang, 2 Hutchins T. Jeff, 3 Bruce D. Freimark, 1 Michael J. Gray, 2 Jedd Wolchok, 1 Taha Merghoub1, 1

A viable strategy to treat advanced cancers includes transferring of tumor-specific T cells. T cells that recognize tumor antigens can be expanded and reinvigorated ex-vivo. Furthermore, autologous T cells can be genetically modified to express anti-tumor T cell receptors or chimeric antigen receptors. Although the potency and specificity of tumor-specific T cells can be manipulated ex-vivo, once re-infused into patients, the T cells are subjected to immunosuppressive mechanisms established by the tumor. An important immune check-point regulator within tumors is phosphatidylserine (PS). Innate immune cells exposed to PS secrete suppressive cytokines and chemokines that can significantly impair the function and activation of anti-tumor T cells. Therefore, monoclonal antibodies that block PS activity can increase the anti-tumor potency of transfused T cells to treat aggressive cancers. Here we show that a PS targeting monoclonal antibody in combination with CD4+ T cells that recognize the melanoma antigen Trp1 can regress very advanced melanomas in all treated mice. Combination of anti-Trp1 CD4+ T cells with other immunomodulatory modalities such as anti-OX40 antibodies, can achieve equivalent tumor rejection rates but are typically accompanied by severe immunomodulated adverse events. In contrast, in this setting, PS blockade did not show any off-target toxicities. Flow cytometry analysis revealed lower levels of CD206 expression concomitant with higher activation markers in macrophages and neutrophils in tumors from anti-PS treated mice. These results suggest that diminishing suppressive mechanisms locally in adoptive transfer protocols is a highly desirable strategy that can eliminate tumors while minimizing related adverse events.

#1652 Optogenetic immunomodulation to develop improved anti-cancer immunotherapeutics. Liang He, 2 Nhung Nguyen, 1 Gang Han, 3 Yun Huang, 1 Yubin Zhou, 4 Texas A&M University, Houston, TX; 2 University of Massachusetts Medical School, Worcester, MA.

The application of current channelrhodopsin-based optogenetic tools is limited by the lack of strict ion selectivity and the inability to extend the spectra sensitivity into the near-infrared (NIR) tissue transmissible range. Here we present an NIR-stimulable optogenetic platform (termed "Opto-CRAC") that selectively and remotely controls Ca2+ oscillations and Ca2+-responsive gene expression to regulate the function of model cellular systems, as well as cells of the immune system. When coupled to upconversion nanoparticles, the optogenetic operation window is shifted from the visible range to NIR wavelengths to enable wireless and remote photoactivation of Ca2+ dependent signaling and optogenetic manipulation of immune/inflammatory responses. In a mouse model of melanoma by using ovalbumin as surrogate tumor antigen, Opto-CRAC has been shown to act as a genetically-encoded "photoactivatable adjuvant" to improve antigen-specific immune responses to specifically destroy tumor cells. In addition, we have extended similar engineering approaches to photomanipulate membrane contact sites that play critical roles in controlling lipid metabolism and control of lipid signaling in cancer cells. This study represents a solid step forward towards the goal of improving spatial and temporal control of anti-cancer therapy through optogenetic immunoengineering.

IMMUNOLOGY: Tumor Models and Assays

#1653 Modeling tumor immune-dynamics to predict patient survival and immunotherapy efficacy. Nicholas K. Akers, Eric E. Schadt, Bojan Losic. Icahn School of Medicine at Mount Sinai, New York, NY.

State of the art models of cancer survival are increasingly utilizing molecular data that feature the number of non-synonymous mutations, or a network based stratification of mutations, as significant predictors. It is widely hypothesized that this association between mutations and survival is a result of neo-epitopes that induce a robust anti-tumor immune response. Naively this implies that there is a strong association between mutations and survival, however this has generally been difficult to prove. Indeed, mutations and predicted neo-epitopes explain roughly the same survival variance, likely due to the intertwined difficulties of neo-epitope prioritization and the often immunosuppressive tumor microenvironment. Reasoning that integrating leading order immune response with neo-epitope prioritization will lead to superior performance, we built a statistical model to quantify the influence of tumor immune-dynamics on patient survival. Neoepitopes (MHC-I/II) were predicted from mutations and filtered on a self-ligandome. The clonal structure of these mutations and the distribution of resulting epitopes were assessed as predictive features. Additionally, the existing response to epitopes was assayed by incorporating TCR and BCR sequence counts and entropy as a proxy for clonal tumor infiltrating lymphocyte expansion. Leveraging the cancer genome atlas (TCGA) for 9 major cancer types including bladder (BLCA), breast (BRCA), colorectal (COAD/READ), glioblastoma (GBM), liver (LIHC), lung (NSCLC), melanoma (SKCM), pancreatic (PAAD), and uterine (UCEC) cancer, we obtained omics data for a total of 2,886 patients. Random forest based recursive feature elimination was used to determine which features were most likely to be predictive while overfitting was controlled with k-fold cross validation. A Cox proportional hazard model of survival as a function of mutation burden and features of neoepitope and immune response predictors was constructed using the selected features. Our results confirm that neoepitope and immune response based predictors for survival often significantly outperform mutation burden alone and simultaneously suggest a quantitative classification of immunotherapy efficacy across cancer subtypes.
Introduction: High-grade, muscle-invasive bladder cancer has recently been shown to harbor intrinsic molecular subtypes with distinct biologic features. Current murine models of bladder cancer, including the prominent carcinogen induced model MB49, do not account for subtype specific characteristics, leaving a gap in available tools for understanding subtype specific differences in bladder cancer. We have developed and validated immunocompetent, subtype specific models of bladder cancer, and we have used these models to assess differential responses to immune checkpoint inhibition. Methods: Two distinct models of murine bladder cancer were developed in a C57BL/6 background. The UPPL models were generated through Pten/Trp53 conditional knockout in Uropakin3a expressing cells. BBN models were generated through exposure of wild-type mice to the carcinogen N-butyl-N-(4-hydroxybutyl)nitrosamine and subsequent generation of cell lines from spontaneous tumors. RNAseq was performed on several BBN and UPPL tumors and cell lines, with findings validated with flow cytometry and T/B cell receptor (TCR/BCR) ampli- con sequencing of tumor infiltrating lymphocytes (TILs). Results: BBN and UPPL models reflected characteristics of human basal and luminal bladder cancers, respectively. BBN (basal) models demonstrated higher immune gene signature expression, with concordantly higher numbers of TILs compared to the UPPL (luminal) model (p < 0.0001). Two BBN and two UPPL models were assessed for response to anti-PD-1 therapy in vivo as syngeneic tumors grown in wild type C57BL/6 mice. One of the BBN lines (BBN963) demonstrated robust control of tumor growth in some animals, including multiple complete re- sponses (CRs) in tumor models. Both tumors that progressed led us to characterize BBN963 as a mixed response model. The marked response to PD-1 blockade in BBN963 was associated with significantly higher sharing of TCR CDR3 sequences among TILs compared to sequences of the other tumors (p = 0.003). In addition, analysis of BBN963 tumors by flow cytometry demonstrated naive and memory T cell phenotypes correlated with increased and decreased tumor sizes, respectively. Closer examination of individual BBN963 tumor responses to PD-1 blockade revealed distinct responder and non-responder infiltrating immune cell phenotypes. Responders demonstrated a less diverse B cell repertoire (p = 0.0043) with increased BCR CDR3 sequence sharing (p < 0.0001). Discussion: We have developed two unique classes of murine bladder cancer lines. UPPL and BBN, with gene expression and TIL profiles that closely correlate with human luminal and basal bladder cancers, respectively. The BBN and UPPL subtype specific models can serve as a tool for elucidating bladder cancer responses to immunotherapy. The mixed response of BBN963 tumors to PD-1 blockade should be an asset for assessing pathways mediating response to checkpoint blockade as well as the value of combination therapy.

1655 Organotypic 3D models to characterize the molecular require- ments for NK and T-cell infiltration. Wolfgang Sommmer,1, 2, 3, 4 Andreas Ger- wald,1 Viola Hedrich,1 Marta Majewska,1 Helmut Dolznig2.1 Boehringer Ingel- heim RCV, Vienna, Austria; 2Medical University of Vienna, Vienna, Austria. Multiple studies have demonstrated that the presence of tumor infiltrating lymphocytes is strongly correlated with increased survival. However, the level of infiltration within a specific tumor entity and between various tumor types varies widely. Increasing the degree of lymphocyte infiltration in a tumor represents an innovative drug concept. Organotypic 3D models consisting of tumor spheroids, stromal fibroblasts and Natural Killer (NK) or T-cells could represent valuable models to appropriately model infiltration and establish novel therapeu- tic concepts in the area of immune-oncology. As a first step in the develop- ment of a model for lymphocyte infiltration, the cytotoxicity and infiltration of human NK cells in 3D tumor spheroids were analyzed. Different NK cell lines and primary NK cells had a toxic effect on 3D tumor spheroids upon co-culture. Cyanososes of co-cultured tumor spheroids showed infiltrated NK cells inside tumor spheroids. Infiltred NK cells recovered from tumor spheroids were characterized by flow cytometry. Results showed that a higher infiltration cor- relates with cytotoxicity on tumor spheroids and transcriptomes of infiltrated vs. non infiltrated NK cells differ substantially. IL-12 stimulation increased the kill- ing effect of NK cells on tumor spheroids, inducing higher expression of Perfo- rin, IFNγ and GranzymeB levels. 3D tumor spheroids were embedded in a Matrigel/Collagen mixture with fibroblasts and the effect of compounds on NK cell infiltration was monitored. It was demonstrated that not only IL-12 in- creased NK cell infiltration, but also several compounds. Moreover, encapsu- lated 3D models with different cell types (tumor cells, fibroblasts, NK or T-cells) were established at a bioreactor scale to mimic the in vivo situation of complex tumor tissues. We could demonstrate NK and T-cell infiltration into these en- capsulated 3D tumor spheroids. These encapsulated model systems permit long-term cultures to study the effect of compounds and/or NK or T-cells on later stages of tumorigenesis. In conclusion, this study demonstrates that organotypic 3D models are a valuable tool for the analysis of the molecular mecha- nisms that regulate lymphocyte infiltration into tumors.

1656 Comprehensive evaluation of human immune system reconstitut- ion in NSG™ and NSG™ SGM3 toward the development of a novel Onco- Hu™ xenograft model. Aaron J. Middlebrook,1 Eileen Snowden,2 Warren Por- ter,1, 2 Friedrich Hahn,2 Mitchell Ferguson,2 Brian Soper,2 James Keck,2 Joan Malcolm,3 Shannon Dillmore,3 Smita Ghanekar,1 Rainer Blaesius,2 2 BDS Bioci-ences, San Jose, CA; 2BD Technologies, Raleigh-Durham, NC; 1The Jackson Lab- oratory, Bar Harbor, ME. The recent successes of immunotherapeutic approaches to the treatment of melanoma and the promise of similar treatments in a variety of other cancers underscore the importance of the immune system in cancer. Indeed, effective therapeutic design and evaluation require a comprehensive understanding of the interplay between the immune compartment and the proliferating tumor cells that comprise the tumor microenvironment. A humanized mouse strain engrafted with cancerous tissue from a patient derived xenograft (PDx) tumor provides researchers with a highly sophisticated tool, ideally suited to facilitate the design of treatment strategies that prevent tumor evasion of immune cells and that improve cytotoxic responses. Severely combined immunodeficient mice such as NOD scid gamma (NSG™) and triple transgenic NSG mice expressing human cytokines KITLG, CSF2, and IL-3 (NSG™-SGM3) are proven hosts for the engraftment of human tumors and establishment of human immune system components following hematopoietic stem cell (CD34+) transplantation. These models provide researchers with a tool that supports the development of myeloid lineages and regulatory T cells potentially represents a substantial improvement over standard NSG mice. Here we employ four-color flow cytometry panels to perform a comprehensive and detailed analysis of the entire immune system. The four panels are designed to fully characterize specific branches of the immune system: 1) T cells 2) NK cells/dendritic cells/B cells 3) myeloid lineages, and 4) immune checkpoint markers. Blood, spleen, and bone marrow tissue from both NSG and NSG-SGM3 mice were evaluated at 9, 16, 21, and 31 weeks of age using each of the four phenotyping panels. Our results indicate that the triple transgenic NSG-SGM3 mice exhibit a more com- pletely humanized immune system compared to NSG mice, with specific im- provements in the distribution of T-cell subsets and overall representation of the myeloid lineage. NSG mice engrafted with allogeneic human tumors represent a valuable preclinical testing platform for immuno-oncology.

1657 Evaluating anti-tumor activity of the human anti-PD-1 antibody pembrolizumab using humanized mouse models. Douglas E. Linn,1 Razvan Cristescu,1 Kallol Ray,1 Shuli Zhang,2 Siriypi Dhandapani,3 Sarav Kaliyape- runala,3 Jennifer H. Tearley,1 Brian J. Long,1, 2 Merck & Co., Inc., Boston, MA; 3Merck & Co., Inc., Palo Alto, CA. Targeting immune checkpoints has proven to be an effective strategy for reactivating the immune system to elicit potent anti-tumor activity. For exam- ple, the anti-PD-1 antibody pembrolizumab has shown robust and durable clinical activity in numerous malignancies including melanoma and non-small cell lung cancer. Unfortunately, a subset of patients do not benefit from pembroli- zumab therapy. The phenotypical expression of cytokines that support the develop- ment of myeloid lineages and regulatory T cells potentially represents a substantial improvement over standard NSG mice. Here we employ four-color flow cytometry panels to perform a comprehensive and detailed analysis of the entire immune system. The four panels are designed to fully characterize specific branches of the immune system: 1) T cells 2) NK cells/dendritic cells/B cells 3) myeloid lineages, and 4) immune checkpoint markers. Blood, spleen, and bone marrow tissue from both NSG and NSG-SGM3 mice were evaluated at 9, 16, 21, and 31 weeks of age using each of the four phenotyping panels. Our results indicate that the triple transgenic NSG-SGM3 mice exhibit a more com- pletely humanized immune system compared to NSG mice, with specific im- provements in the distribution of T-cell subsets and overall representation of the myeloid lineage. NSG mice engrafted with allogeneic human tumors represent a valuable preclinical testing platform for immuno-oncology.
sponder hypothesis and its prognostic value. Additionally, humanized mice may help identify optimal combination treatment regimens to provide more meaningful clinical benefit to patients who do not respond to single-agent therapy with pembrolizumab.

#1658 Establishment of CD137 humanized mouse model for efficacy assessment of agonistic anti-CD137 therapeutic antibodies. Dave Xuexong OuYang,1 Gang Chen,2 Zhensheng Wang,1 Lei Zheng,1 Annie Xiaoyu An,1 Jean-Pierre Wery,1 Jay Liu,2 Xin Dong,2 Henry Q. X. Li1. Crown Bioscience, Inc., Taicang, Jiangsu, China; 2Nanjing Galaxy Biopharmaceutical Co. Ltd., Nanjing, Jiangsu, China.

CD137 belongs to the TNF receptor super family, and its activation is essential to the function of T cells and NK cells. Multiple agonistic anti-CD137 antibodies are currently being tested in humans with advanced cancer, which expected to become an important new immuno-oncology therapeutics in clinic. It is important to establish preclinical models for efficacy assessment of investigational CD137 antibodies before entering clinic. Currently available animal models cannot meet this need. Syngeneic mouse tumor models provide a useful platform for testing surrogate immuno-oncology therapies, but cannot be used for testing human therapeutic antibodies due to the species specificity; human immunity reconstituted models, by human PBMC or hematopoietic stem cell inoculation into immune deficient mice, suffering from highly variable responses, are not robust enough to provide a reliable system for efficacy studies. Establishing target humanized models by replacing mouse therapeutic target with human counterpart while maintaining normal mouse immunity is a practical approach to evaluate human therapeutic antibodies in vivo. Using CRISPR-Cas9 gene editing, we have engineered human CD137 knock-in model expressing chimeric human/mouse CD137 composed of human extracellular and transmembrane domains (Exon 4–7), with intact mouse signal peptide and intracellular domain. FACScanalyses of splenocytes derived from homozygous knock-in mice showed that CD3/CD28 stimulated T cells only express chimeric CD137 reactive to human CD137 antibodies, but not mouse CD137; Yet the expression levels of the chimeric CD137 in the knock-in mice are generally lower than endogenous mouse protein in wild-type C57BL/6 mice. At present, we are testing the efficacy of reference human CD137 agonistic antibodies by treating these homozgyous knock-in mice grafted with syngeneic MC38 tumor cells. Data will be presented at the conference.

#1659 Immunological characterization of the Oncopig model and detection of cell-mediated immune responses to cancer. Nana H. Overgaard,1 Daniel R. Principe,2 Jeanne T. Jakobsen,1 Laurie A. Rund,1 Paul I. Grippio,2 Gregers Jungersen,3 Lawrence B. Schook.1 1Technical University of Denmark, Frederiksberg C, Denmark; 2University of Illinois, Chicago, IL; 3University of Illinois, Urbana-Champaign, Urbana-Champaign, IL.

In recent years, immunotherapy has shown great breakthroughs; however, the majority of preclinical studies has been based solely on rodent models and tends to experience a troublesome translation to human patients often related to the differences between mice and humans. Here, we utilized the Oncopig model that, due to its similarity in the immunome, metabolism, and size between humans and pigs, can serve as a supplementary large animal model for translational cancer research. With the establishment of the immunoascore as a new approach for staging cancer patients, it has become evident that the immune status of the tumor microenvironment has a crucial impact on the patient’s outcome and response to therapies. For this reason, we set out to perform an immunological characterization of Oncopig-derived tumors to elucidate the potential in using this model for testing cancer immune therapeutic approaches. Following injection of Cre recombinase, the transgenic Oncopig expresses KRA(Gr2/CD11b) and TPS(Gr1/CD11c), two mutations commonly found in human cancers, subsequently resulting in tumor formation at the site of injection. The expression of these two transgenes was confirmed using intracellular flow cytometry staining or immuno histochemistry (IHC). Subcutaneous, intramuscular, and testicular tumors all showed the presence of infiltrating CD3+ cells, which were found both in the periphery and in the core of the tumor as determined by IHC. With the establishment of a digestion protocol allowing isolation of the in vivo-generated tumor cells, we confirmed the CD3+ staining and found that the infiltrating T-cell pool was comprised of both cytotoxic and regulatory cells as indicated by positive flow cytometry staining for the CD8β chain and FoxP3, respectively. In order to investigate the immunogenicity of the tumor cells, we set up flow cytometry detection of porcine TNF-α, IFN-γ, and perforin in a PBMC-tumor cell co-culture. Despite the production of various cytokines, actual tumor cell killing is a desirable parameter to measure when evaluating both the immunogenicity and response to therapy. Therefore, we developed, to our knowledge, the first fluorescence-based in vitro porcine cytotoxicity assay and found a significant recognition and specific killing of autologous tumor cells in an effector-target titration dependent manner. Taken together, our results show that the established Oncopig tumors are infiltrated by T cells exhibiting an either cytotoxic or regulatory phenotype, thus indicative of a tumor microenvironment mimicking the complexity seen in human patients. Additionally, we were able to measure cell-mediated immune responses to cancer in this novel, large animal model, and both the cytokine production and tumor-specific killing hence underline the potential in using the Oncopig for future testing of immune therapies against human cancer.

#1660 Humanization of patient derived xenograft (PDX) cancer model mice with peripheral blood mononuclear cells (PBMCs). Jens Henrik Norum, Dag Josefsen, Gunnar Kvalheim, Olav Engebretsen, Therese Serlie, Gunhild M. Melandsmo. Oslo University Hospital, Norwegian Radium Hospital, Oslo, Norway.

Immunocompetent transgenic mouse models have for decades served as valuable tools to address the effect of oncogenes and tumor suppressors. Immunodeficient mice have been used to establish patient derived xenograft (PDX) models harboring human tumors. These types of models have been used to study cancer initiation and progression as well as preclinical evaluation of anticancer drugs. One major limiting factor for both these approaches is the immune system: the PDX models lack an immune system and the immune system in immunocompetent mouse models display differences compared to the human immune system. Thus, in cancer research there is a need for preclinical models to study the influence of human immune cells on tumor progression and response to cancer therapies. We have established and optimized protocols for in vitro stimulation of human immune cells (IV) or intraperitoneal (IP) injections of isolated human PBMCs, to generate humanized mice harboring human immune cells. Our protocols do not require irradiation or busulfan pretreatment of the animals. Flow cytometry analyses showed that mainly T helper cells, CD4+, and cytotoxic T cells, CD8+, were present in the humanized mice. Immunohistochemistry (IHC) analyses of humanized PDX cancer model mice showed that human lymphocytes were present in the tumor periphery and some very few cells within the tumor, in addition to the human leukocytes in the liver and spleen. The growth rates of the PDX tumors were not affected by the humanization. Our protocols require minimal preparations of the animals and generate humanized PDX mice harboring human lymphocytes locating in close proximity of, as well as inside the PDX tumors. The model systems are suitable for preclinical studies of human, adaptive immune responses in tumor progression and cancer therapies.

With clinical success and FDA approval of Iplimumab, Nivolumab, Pembrolizumab and Atezolizumab, developing biotherapeutics against immune checkpoint targets, like CTLA-4, PD-1/PDL-1 and others, becomes hot pursuits for big pharma and biotech. However, traditional syngeneic models with surrogate immune system have limitations. New humanized mouse models may be useful but not reliable and robust due to the species specificity and highly variable responses. It is crucial to establish additional preclinical models for efficacy assessment of investigational immune-oncology antibodies before entering clinic. Establishing human therapeutic target engineered mouse models by replacing mouse gene with human counterpart while maintaining intact mouse immunity is a practical approach for in vivo studies. Applying CRISPR-Cas9 and other gene editing techniques, we have engineered genetically a series of single and double human immune-checkpoint genes, like PD-1/PDL-1, CTLA-4, TIM3, CD137 and others, knock-in model expressing chimeric human/mouse targets composed of human extracellular domains, with intact mouse signal peptide and intracellular domain. FACScanalyses of immune cells derived from homozogyous knock-in mice showed that activated cells only express chimeric targets reactive to anti human target antibodies, but not mouse gene specific antibodies. We have been testing the efficacy of reference antibodies by treating these homozymous knock-in mice inoculated with syngeneic murine tumor cells. Other applications, like target validation, combination therapy and biomarker discovery, are also explored.
Introduction: Agents that reverse T cell inhibitory signals have reinvigorated the strategy of cancer immunotherapy and are leading to robust clinical responses. In colorectal cancer (CRC), objective responses to single-agent therapy with anti-PD-1/PD-L1 antibodies have largely been restricted to the small proportion of CRC patients with microsatellite unstable (MSI-high) disease. Although additional subsets of advanced CRC patients that are responsive to immune checkpoint inhibition in combination with tumor-targeted agents, preclinical models have been hampered by their immune-compromised status. In order to gain a better biological understanding of the context of immune responses and facilitate preclinical evaluation of combination strategies incorporating cancer immunotherapy, we developed a “hematopoietic” humanized model of patient-derived xenografts Reid et al. 1996 to leveraging this model for the development of rational combinations. Methods: BRG.NOD/Sirpalfa newborn pups were humanized through transplantation of 1x106 CD34+ cells purified from umbilical cord blood. Mice were evaluated for chimerism at 8 and 12 weeks. At 16 weeks, tumor tissue from established PDX models was implanted on the right and left flanks of humanized mice. When the average tumor size reached a volume of ~150-300 mm3, the mice were randomized into vehicle or nivolumab (30 mg/kg twice weekly i.p.) treatment groups according to chimerism. Mice were monitored for signs of toxicity and tumor size was evaluated twice weekly by caliper measurements (tumor volume = length x width2) x 0.52. At the end of the treatment, mice were euthanized while sera, lymph nodes, spleen, bone marrow and tumors were collected for immunomonitoring and analyses. Results: As preliminary proof-of-concept, we successfully established 3 humanized CRC PDX models and one breast cancer cell line (MDA-MB-231). In one of the CRC (MSI-high) and in the breast model we observed tumor growth inhibition in the treated groups vs control. We detected differences in PD-1 expression among treated versus control mice, with lower expression in the nivolumab-treated groups. We also observed an increased number of TILs, CD8+ T cells and greater numbers of T cells in the lymph nodes of treated mice, suggesting T cell expansion. Mice were highly chimeric with high TILs whereas responder tumors exhibited an increase of CD44 high IFN+ CD8+ T cells, high CD8% and a higher effector memory% (HLADR+ CD45RO+). Conclusions: Humanized PDX models were successfully established and tumor engraftment occurred in all humanized mice with nivolumab-treated mice demonstrating the development of lymph nodes that were populated by activated T cells. These preliminary results demonstrate that human immunity and PD-1 expressing T cells exist in these models and provide the basis for planned immunotherapy combination studies.

#1664 Inhibition of 4T1 mammary tumor growth in BALB/c mice by subcutaneous and intraperitoneal injection of a 4T1 whole cell vaccine containing IL-2 and GM-CSF as adjuvants.

Jonathan F. Head, 1 Jeffrey T. Phillips, 1 Xiangpeng Jiang, 1 Robert L. Elliott. 1 OncoBioMune Pharmaceuticals, Baton Rouge, LA; 2SAB Breast Foundation, Baton Rouge, LA.

Developing animal tumor models for human cancer vaccines creates a tool to investigate the mechanism of action, variations in formulation, dosing schedules, and combinations with other forms of cancer therapy. In this study we developed a mouse whole cell mammary cancer vaccine model with both subcutaneous and intraperitoneal injection of the vaccine. The vaccine, containing 4T1 mouse mammary cancer cells (1,000,000 cells), IL-2 (0.2 μg) and GM-CSF (0.1 μg) in a total volume of 150 μl, was injected either subcutaneously into the backs of BALB/c mice or intraperitoneally. There were six injections of the vaccine (weeks 1, 2, 3, 7, 11, 15) and one week after the last injection 100,000 4T1 cells from cell culture in a volume of 100 μl were injected into the scapular region of the mice. At 22 days post 4T1 tumor transplantation there was a 57% inhibition of the growth of the 4T1 tumor in the mice receiving the subcutaneous injections of whole cell vaccine and a 42% inhibition of 4T1 tumor in the mice receiving the intraperitoneal injection of the vaccine. The inhibition of 4T1 mammary tumor growth in this mouse model with subcutaneous injection of a whole cell vaccine gives further support for the previously reported efficacy in a Phase 1/2 clinical trial of our therapeutic breast cancer vaccine containing autologous and allogeneic breast cancer cells in the adjuvant setting. The inhibition of 4T1 tumor growth with intraperitoneal injection suggests a delivery method that may be applicable to ovarian cancer and cancer patients with malignant ascites.

#1665 MuScreen™: A well-characterized syngeneic model platform for rapid in vivo screening.

Lan Zhang, Binchao Mao, Qian Shi. CrownBio, Taiyuan, China

Background: Syngeneic tumor models, many shelved for decades, have been revived as effective models for immunotherapy, accompanying the clinical success of the immuno-checkpoint inhibitors (e.g. anti-CTLA4, anti-PD1, anti-PD-L1 antibodies). In vitro cell-based screens that are frequently used in oncology to quickly identify responsive cells and assess PD effects, often fail in immuno-oncology, due to immunotherapeutics targeting the complex host immune system. Alternatively, an in vivo screening with a panel of models addresses many of these questions, e.g. PD and efficacy, but may be cost prohibitive. Material and methods: Leveraging in-house detailed profiling data on our syngeneic models, including efficacy benchmarking with anti-PD-1, P1-L1, CTLA-4, OX-40, GITR, LAG3 and TIM3 antibodies, RNAseq data on tumor samples, and FACs analysis on both baseline and post-treatment tumor samples, we created a novel in vivo screening tool MuScreen. MuScreen includes up to 20 well-characterized syngeneic models in 3 month screening run. Both PD and efficacy may be determined in the run, allowing researchers to make decisions based on results observed from a large dataset. To address the cost issue, test agents from multiple clients are pooled together for each run (sharing vehicle and other common groups) providing a significant reduction in the number of animals used and the associated costs. Results: CrownBio has established the largest collection of syngeneic models with well-characterized immuno-oncology data. With the three MuScreen runs, we have generated new data on common IO agents (e.g. aPD-1 antibody) and combinations treatments, with FACs analysis, IHC, and efficacy data. Based on these data, a bioinformatics analyses were further explored to identify the makers/pathways that could be correlated with the efficacy or PD effect of the tested IO treatment. Conclusions: MuScreen, the first in vivo screening tool for cancer immunotherapeutics, provides detailed response data on a panel of syngeneic models, and may help on biomarker discovery in a cost and time efficient manner.

#1666 Immune consequences of penfluridol treatment associated with inhibition of glioblastoma tumor growth.

Alok Ranjan, Nehal Gupta, Sharan Singh, Jiechao Wang, Melissa M. Kizer, Preston Wright, Sanjay Srivastava. Texas Tech Uni. Health Science Center, Amarillo, TX.

Glioblastoma is the most common and lethal brain tumor associated with only 12% median survival rate of patients. Despite the development of advanced surgical, radiation or use of combinations of anti-cancer drugs, treatment for glioblastoma
patients is still a challenge. The major contributing factor in glioblastoma progres-
sion and resistive nature is its ability to evade the immune surveillance. Hence,
modulating the immune system in glioblastoma tumors could be an important strat-
ye for anticancer therapeutics. Penfluridol, an antipsychotic drug has been shown
to have anti-cancer properties in our recently published studies. The present study
evaluates the immune response of penfluridol in glioblastoma tumors. Our results
demonstrated that penfluridol treatment significantly suppressed glioblastoma tu-
mor growth. Our current results demonstrated about 72% suppression of myeloid
derived suppressor cells (MDSCs) with penfluridol treatment in mouse bearing
U87MG glioblastoma tumors. MDSCs are known to increase regulatory T cells
(Treg), which are immunosuppressive in nature and suppresses M1 macrophages
that are tumor suppressive in nature. Our results also showed suppression of regula-

datory T cells as well as elevation of M1 macrophages with penfluridol treatment by
58% and 57% respectively. Decrease in CCL4 as well as IFNγ with penfluridol treat-
ment was also observed indicating decrease in overall tumor inflammation. This is
the first report demonstrating immune modulations by penfluridol treatment asso-
ciated with glioblastoma tumor growth suppression prompting further investiga-
tion to establish penfluridol as a treatment option for glioblastoma patients.

Head and Neck Squamous Cell Carcinoma (HNSCC) is the sixth most com-
mon cancer in the United States and affects 600,000 people each year worldwide.
With a five-year survival rate of only 50% and a recent rise in HPV-associated
HNSCCs, improved treatment protocols are urgently needed. Evidence of
immunosuppression is often reported in HNSCC, making immunotherapy an at-
tractive strategy for the management of this disease. The immune checkpoint
inhibitor pembrolizumab was recently approved for the treatment of metastatic
and recurrent HNSCC, but only 18% of initial participants in a trial of Pembrol-
izumab responded, and it remains difficult to predict patients likely to experience
response. We performed over multiple HNSCC cell lines and selected for genetic knockouts exhibiting altered PD-L1 expression. Stable knockout pools with representation of approximately 300 gRNAs per target gene (>20,000 target genes in the library) were expanded and serially sorted to create stable sub-populations with enhanced PD-L1 expression. These sub-populations were sequenced to identify gRNAs whose
expression with PD-L1 inhibition. We observed that these large-scale screens, when performed over multiple HNSCC cell lines with diverse genetic lesions, will identify patterns of targetable regulators that may ultimately be manipulated in combination with PD-1/PD-L1 inhibitors.

#1668 Comprehensive 10 color flow cytometry analysis of the neuroblas-
toma intratumoral immune response using the murine syngeneic neuro-2a

tumor model. David D. Draper, Matt Thayer, Alden Wong, Dan Sains, Scott C.

Wise. MI Bioscience, Ann Arbor, MI.

Neuroblastoma is the most prevalent solid tumor in childhood and the most common tumor in infants less than 1 year of age. In spite of aggressive multi-modal therapeutic approaches, the 5-year survival rate in patients with high-risk disease remains poor at ~10%. To this end, we have focused on harnessing the immune system to combat neuroblastoma. Anti-
body-Abrogating the immune checkpoint signaling pathway such as anti-
CTLA-4 and anti-PD-L1 suppress neuroblastoma growth in certain mouse models of disease. Furthermore, the dinutuximab antibody that targets gan-
giolside GD2 expressing cells has been demonstrated to trigger neuroblas-
toma regression using a mechanism that involves several immune subsets. Although evidence suggest the host immune response can be exploited to fight neuroblastoma, the key immune subsets, their relative contribution, and mechanism of action to suppress neuroblastoma growth have yet to be fully characterized. To this end, we used flow cytometry to immunopheno-

type the intratumoral immune response in the neuro-2a model of neuroblas-
toma. This was accomplished by developing two 10-color panels to quantify the proportions of various myeloid and T cell subsets respectively. Using the myeloid panel, our results showed that total neuro-2a tumor immune cells were predominantly myeloid lineage-derived (CD11b+). A combination of immunohistochemistry (IHC) and single-cell RNA sequencing (scRNA) was used to identify neuroblastoma cells (MDSCs) comprised the bulk of the myeloid cells and were more heavily skewed towards the granulocytoid phenotype versus monocyctic. An MDSC
deduction gate and a combination of F4/80, MHC class II, and CD206 anti-

codies enabled the analysis of tumor-associated macrophage subsets. Our results revealed that neuro-2a tumors contained relatively few activated M1 macrophages, which were typically associated with anti-tumor responses, and instead were dominated with a pro-tumor M2 macrophage response. The T cell antibody panel revealed that CD4+ T cells outnumbered CD8+ T cells by 2-fold. Regulatory T cells (Tregs) in the CD4+ T cell fraction were identified by a combination of FoxP3 and CD25 antibodies. The frequency of Tregs varied but represented <50% of total CD4+ T cells. Finally, the activation state of CD8+ T cells was examined using Ki-67, CTLA-4, and PD-1 anti-
codies. Analysis demonstrated that the majority of CD8+ T cells in neuro-2a tumors were actively proliferating based on the expression of Ki-67. How-

ever, most of the proliferating CD8+ T cells also co-expressed PD-1 suggest-
ing a loss of anti-tumor functionality and an exhausted phenotype. This study provides a comprehensive immune profile of neuro-2a tumors and supports a platform with which to test new single agent and combination therapies designed to treat neuroblastoma.

#1669 Multiplex immunohistochemical staining of PD-L1, PD-1, CD3, CD4, CD8, CD68, FoxP3, and Ki-67 and image analysis of tumor and invas-

ive margin in human FFPE NSCLC tissue. Lisa M. Daunfenthal, Cia G. Sia, Jinping Zheng, Natalia Jun, Eric P. Olsen, Christopher A. Kerfoot. Mosaic Lab-

oratories, LLC, Lake Forest, CA.

Evaluating the density of immune cell subtypes and their relative spatial position-
ing in cancers becomes an important tool in understanding response to immune
checkpoint inhibitors. The purpose of this study was to investigate protein expres-
sion of PD-L1, PD-1, CD3, CD4, CD8, D68, FoxP3, and Ki-67 with four multiplex
immunohistochemical assays (Ki-67+CD3, CD3+CD4+Ki-67, FoxP3+PD-
1+CD8, and CD68+PD-L1+CD3) using DAB, red, and green chromogens within
formalin-fixed, paraffin embedded small cell lung (NSCLC) tissues. The Ki-
67+/CD8+ multiplex was developed to evaluate the density of cytotoxic T cells and the

percentage that are proliferating. The CD3+/CD8+ Ki-67+ multiplex characterizes
the frequency of CD4+ T cells and evaluate proliferation in this subset. The FoxP3+PD-1+CD8+ multiplex evaluates the regulatory T cell subset and evaluates PD-1 expression. The CD68+PD-L1+CD3 multiplex characterizes PD-1 expres-
sion on macrophages and T cells. Cells densities were evaluated in tumors and
invasive margin regions, and image analysis was performed to quantify each
stain as a single agent and co-expression within each multiplex assay.

#1670 Identification and characterization of novel mediators of tumor-

duced T-cell dysfunction. Geoffrey J. Markowitz, Mary Philip, Andrea

Schietinger, Vivek Mittal, Weil Cornell Medicine, New York, NY; Memorial Sloan Kettering Cancer Center, New York, NY.

Immunotherapies targeting T-cell functionality have been shown to have ef-
ficacy in numerous cancers, including non-small cell lung cancer (NSCLC). However, treatment with currently available therapeutics, such as anti-PD-1 and
anti-CTLA-4, induce responses only in a subset of patients. This raises the pos-
sibility that numerous other effectors of T-cell dysfunction remain to be eluci-
dated. To evaluate possible novel mediators of T-cell dysfunction, we isolated CD8+ T-cells from orthotopic KrasG12D/p53-/- murine adenocarcino-
mas (HKP-1) that exhibited either stable or progressive disease as a function of tumor growth. RNAseq analysis revealed increased expression of several genes including Tim3, PD-1, Lag3, 2B4, and CISH, and decreased expression of GzmB and Eomes in CD8+ T-cells isolated from progressive tumors indicative of a dysfunctiional state, as well as multiple novel genes not previously associated with T-cell dysfunction. To explore the functional role of the novel candidate
genes, we have developed in vitro and in vivo assays leveraging Ova and GFP
overexpression in our HKP-1 cell line (KPI-1/Ova-GFP). We have begun to target these unique set of candidate genes in tumor-specific T-cells associated with dysfunction through innovative RNAi/shRNA and adoptive transfer ap-
proaches to facilitate therapeutic reprogramming and enhanced T-cell-medi-
ated immunity in lung cancer. We expect to provide novel strategies for design-
"
IMMUNOLOGY: Tumor Models and Assays

#1671 Characterization of the immune landscape in stage II-III melanoma using qIF. Robyn Gartrell,1 Douglas Marks,2 Edward C. Stack,2 Yun Lu,3 Thomas D. Hart,4 Camille Gerard,3 Camden Esancy,4 Dan Tong Jia,1 Paul Armenta,7 Daisuke Izaki,6 Daniella Davari,4 Ashley White-Stern,7 Zoe Blake,8 Yi-chun Fu,9 Basil Horst,10 Yvonne Saenger,11 Columbia University School of Medicine, New York, NY; 2Flagship Biosciences, Westminster, CO; 3Miltenyi Biotec, Bergisch Gladbach, Germany; 4Joule, Seattle, WA; 5Department of Pathology, University of Washington, Seattle, WA; 6Novo Nordisk, Bagsvaerd, Denmark; 7MS Bioworks, Ann Arbor, MI; 8Cayman Chemical Company, Ann Arbor, MI.

Background: The tumor microenvironment plays a crucial role in cancer progression, often supporting immune evasion. This is of particular importance in melanoma, where immune checkpoint therapies have resulted in significant clinical benefit, yet only in a subset of melanoma patients respond. Precise biomarkers are urgently needed to characterize the tumor immune micro-environment, both for prognostication and to predict the benefit of immuno-therapeutic intervention. HLA-DR on tumor cells and Ki67 on cytotoxic (CD8+) T cells have been proposed as biomarkers of anti-PD1 activity. Quantitative immunofluorescence (qIF) allows for automated quantitation of phenotypes and spatial distributions of immune cell populations within formalin fixed paraffin embedded (FFPE) tissues. Methods: To characterize the tumor immune microenvironment, we screened databases at the Herbert Irving Cancer Center (HICC) at Columbia University for early stage melanoma patients with documented clinical follow up. We identified a preliminary population of 40 stage II-III melanoma patients diagnosed between 2000 and 2012. Clinical follow up was available on 21 patients. Patients were followed alive with no evidence of recurrence of another malignancy, and 8 who died of melanoma. 19 patients had more than 24 months of survival information available but no detailed clinical information. 5μm slides from either primary biopsy or subsequent wide local excision procedure were stained using qIF for DAPI, CD3, CD8, CD68, SOX10, HLA-DR and Ki67. Cell phenotypes within representative fields selected by a trained dermatopathologist (BH), were visualized using multi-spectral imaging, and analysis of spatial distribution of cells were analyzed using inForm image analysis software (Perkin Elmer), and Spotfire software (TIBCO). Results: We were able to quantify and identify coordinates for multiple immune cell subsets in melanoma tissues. In 21 patients with clinical follow up, we found that higher densities of CD3+CD8+ T cells in tumor and stroma tended towards correlation with non-recurrence. In addition, CD68+HLA-DR-predicts poor prognosis (p<0.05), whether in tumor or stroma. Assessment of spatial distribution across all 40 tumors demonstrated that CD3+CD8+ cells are closer to CD68+ cells and Sox10+ tumor cells when they express HLA-DR (p<0.001). Conversely, CD3+CD8+ cells are significantly farther from tumor cells when they express Ki-67, (p<0.0001). Among patients with clinical follow up, CD3+CD8+ cells were closer to CD68+HLA-DR- cells in recurrent patients (p<0.05). Conclusion: Using qIF imaging and analysis we find that density and spatial relationships of immune cell subsets correlates with recurrence status. qIF may offer the potential for the development of prognostic biomarkers in stage II/III melanoma.

#1672 Workflow automation and parallelization improves the isolation and analysis of tumor-infiltrating immune subpopulations. Janina Brauner,1 Jan Pettersson-Kane,1 Karen Ryall,1 Daniel G. Rudmann,1 Brooke Hirsch,1 Joseph Krueger,1 MS Bioworks, Ann Arbor, MI.

Immunotherapy against cancer has proven clinical efficacy and tremendous potential in multiple tumor entities. Syngeneic mouse tumor models represent the gold standard to analyze effects of immunotherapy due to their fully competent immune repertoire. However, the amount and composition of tumor infiltrating leukocytes (TIL) is highly variable, complicating the targeted analysis of subpopulations. In particular, small subpopulations cannot be analyzed properly but may be lost in the background noise. When working with large cohort sizes, even the immune-phenotyping of TIL by flow cytometry is time-consuming and dataprocessing highly workintensive working with large cohort sizes, even the immune-phenotyping of TIL by flow cytometry is time-consuming and dataprocessing highly workintensive. Importantly, while the TIL enrichment significantly reduced the time and reagent costs in immune subset analysis, the composition of infiltrating immune cells was not affected, the risk of introducing a bias by this method. Taken together, we have developed an automated workflow for the isolation of TIL from mouse tumors reducing time and costs of downstream analysis while standardizing and enhancing the detection and quantification of immune cell subpopulations.

#1673 Mass spectrometric characterization of peptides associated with molecules of the major histocompatibility complex. Michael Ford,1 Richard Jones,1 David Allen,1 Ravie Amunugama,2 Paul Del Rizzo,2 Michael Pisano,3 James Moebley,2 Paul Domanski,2 Bill Ho,2 Daniel Bochar,2 MS Bioworks, Ann Arbor, MI.

The major histocompatibility complex (MHC) is a region of highly polymorphic genes encoding for glycoproteins (MHC molecules) that form the cell-mediated branch of the acquired immune system. In the cytosol, cellular self and foreign (non-self) proteins are constantly being degraded; it is the peptides of these proteins that are presented to the immune system. The obvious application then is the targeted destruction of cancerous cells. To enable the molecular level characterization of peptides associated with molecules of the major histocompatibility complex requires a targeted protein complex enrichment, an unbiased peptide elution and finally a peptide analysis method. Most frequently an immunoprecipitation is used to isolate the target complex. The peptide elution is performed under conditions minimizing protein contamination and finally peptide analysis is accomplished by mass spectrometry. Here we present a case study of our recent work optimizing and performing a workflow for the analysis of peptides associated with Class I MHC molecules. The goal of the assay optimization was to maximize the amount of antibody required for the assay, to minimize the amount of biological material needed from which the complex is isolated and to achieve the optimum sensitivity towards the hitherto unknown target peptides.

Quantification of tumor-infiltrating lymphocytes (TILs) in non-small cell lung cancers (NSCLC) is valuable for understanding patient prognosis and survival. TILs comprise a subset of tumor-infiltrating leukocytes that modulate immune evasion and response to therapy. Understanding the composition of TIL subsets, especially relative to the total tumor leukocyte population, may provide additional context for understanding NSCLC pathogenesis and patient response to treatment. However, availability of tissues and use of chromogenic assays can limit the number of TIL and leukocyte subset markers assayed in a tissue section. Therefore, we developed a workflow to identify TIL markers in NSCLC using morphometric parameters and routine TIL marker monoplex immunohistochemistry (IHC) assays to further identify the composition of TIL subsets. Computational Tissue Analysis (cTAX™) tools were used to determine the morphometric parameters which could identify immune cells in the absence of biomarker stain. The morphometric features which characterized immune infiltrates were used to quantify the total immune cell population frequency in the tumor nests and surrounding stroma in hematoxylin-stained tissues. The leukocyte population identified with morphometric parameters was correlated with CD45+ cell frequencies identified by cTAX based on biomarker staining in CD45-stained serial sections. This morphometric rule-
identified adhesion molecules, chemokine ligands, and receptors involved in traffic of lymphocytes to tumors as well as the function of NK cells. Treatment of melanoma with EZH2 inhibitors showed increased killing by NK cells suggesting that an immunosuppressive effect of EZH2 involving both innate and adaptive immunity. In a mouse model of subcutaneous B16 melanoma, a course of EZH2 inhibitor did not change tumour immune responses in immunosufficient mice but caused a transient 9-fold increase in circulating Ly6G+ [granulocytic] myeloid-derived suppressor cells [MDSCs] suggesting the effect of EZH2 modifiers on the myeloid compartment. In summary, patients with somatic activation of EZH2 may benefit from treatment combinations that include inhibitors of EZH2. Supported by NHMRC grant GNT1190178. #1677 Immuno-target selection of infiltrating immune cells and laser capture microdissection mediated transcriptional profiling. Ross Haggart, Chaxiraxi Arzolla-Donate, Elliot Harrison, Benjamin J. Reed, Saba Alzabin, Gino Miele, Epistem Ltd., Manchester, United Kingdom.

Immune checkpoints define an evolving class of inhibitory mediators that are expressed by tumour cells and infiltrating leukocytes to down-modulate the effector immune response against tumour cells. Therefore, the most recent efforts in cancer therapy centre on targeting immune-mediated mechanisms of tumour evasion. The ability to assess gene expression profiles from isolated populations of tumour-infiltrating lymphocytes (TILs) can assist in monitoring checkpoint inhibitor therapy efficacy and provide a better understanding of clinical outcomes. Ideally, transcriptional profiles should be obtained from isolated cell populations of interest, free from contaminating cell populations that may create adverse background noise. Micro sampling by laser capture microdissection is a powerful tool that allows for specific analysis from whole tissues, particularly in a heterogeneous microenvironment such as in a tumour, where less well represented target cells are dwarfed in abundance by tissue stroma and other cell types. However, whilst the application is potentially powerful for target discovery and mechanistic understanding, the process is notoriously difficult, particularly in clinical specimens. We developed a methodology to successfully overcome these challenges in analysing target cells, organelles or other tissue subsets by transcriptional profiling following immunostained-mediated laser capture microscopy (LCM). Thorough optimisation of traditional immunohistochemistry techniques enabled us to select target cell populations of interest from tissue sections whilst minimising degradation of mRNA and miRNA allowing us to perform genomic and pathway interrogation using microarray and/or RT-qPCR analysis. Our technique allows multiple capture types per slide, sample pooling when required, high capture throughput and capture image documentation. Multiple target selection to different lymphocyte populations, including tumour-infiltrating lymphocytes, can be performed routinely using comparative serial sectioning. Here we exhibit simple staining and immunostaining histology images using methods sympathetic to RNA integrity which allow for target selection by specific staining or target morphology, and demonstrate comparative analysis of matched pairs of disease and healthy sections of colon tumours. We used a Palm MicroBeam 4 LCM platform to identify, cut and specifically capture target cell populations from frozen embedded tissue. This approach enabled us to isolate discrete targeted cell populations free from contaminating cell populations. Epistem’s Single Cell RNA-Amp was then used to provide robust and linear amplification of RNA and enable comparative analysis in applications such as target discovery and pharmacodynamics. The results indicated that transcriptional profiling was technically robust with a good replicative correlation despite the limited input obtained by micro-sampling.

Glioblastoma (GBM) is a deadly brain cancer that suppresses cellular immunity through the production of anti-inflammatory cytokines/catabolites, expression of immune checkpoint molecules, and induction of tolerogenic immune cell subsets. While preclinical models have shown each of these mechanisms to negatively impact survival outcome, it remains unclear how these distinct processes manifest themselves within the context of a coordinated immune system and whether additional immunosuppressive mechanisms exist. To address these questions, we have developed an extensible in vivo screening platform to holistically determine how GBM affects cellular immune organization. The method allows for temporal assessment of leukocyte population dynamics in response to
tumor progression. Leukocytes derived from lymphoid tissues of tumor-bearing mice are isolated and immunolabeled with a 12-color optimized immunofluorescence panel (OMIP) targeting several major leukocyte lineages. Single-cell data is acquired by flow cytometry and is clustered in an unsupervised manner based on cell-surface protein expression. A vector-based classification system is then used to efficiently identify cell lineage relationships among immune cell lineages. The platform allows for the extraction of immune signatures whose divergence from tumor-naive standards may be quantified and statistically analyzed; such signatures may also be correlated with response/resistance to therapy. The approach has been validated on orthotopic GL261 glioma in syngeneic C57BL/6 mice, yet it is readily amenable to the study of diverse model systems, including those that are driven by clonal or driver oncogenes. Alternative flow cytometry antibody panels may easily be substituted to probe more specific immune cell subsets of interest. Systems biology approaches applied to the field of tumor-induced immunosuppression hold promise in identifying novel network-level immune signatures, facilitating a better understanding of immunotherapeutic drug action, and driving next generation high-dimensional biomarker discovery.

#1679 BET inhibitors suppress PD-L1 expression in pancreatic stellate cells. Kazumi Ebine, Brian T. DeCant, Katharine A. Collier, Thao N. Pham, Krishan Kumar, Hidayatullah G. Munshi. Northwestern University, Chicago, IL

Single agent treatment with T-cell checkpoint inhibitors has not been effective in pancreatic ductal adenocarcinoma (PDAC) patients. The PDAC stroma, which can account for as much as 80-90% of the tumor mass, can act as a physical and an immunologic barrier to T-cell-mediated therapies. Transgenic mouse models have shown that ablation of pancreatic stellate cells (PSCs), key regulators of fibrosis in vivo, can sensitize PDAC tumors to immune checkpoint therapies. Recently, inhibitors targeting bromodomains and extra-terminal (BET) proteins, a number of which are currently being evaluated in clinical trials for solid tumors, were shown to induce stellate cells to become quiescent and decrease collagen production. The BET family of proteins binds to acetylation motifs present in histones and enables recruitment of transcription factors and other chromatin regulators during RNA transcription. We have found that PSCs express significantly increased PD-L1 levels compared to pancreatic cancer cell lines. We show that BET inhibitors, and in particular specific knockdown of BRD4 protein, decrease basal and IFN-γ-mediated PD-L1 expression in primary stellate cells. We also show that, in contrast to a recent report using cancer cells, c-MYC does not mediate basal or IFN-γ-mediated PD-L1 expression in stellate cells. Instead, we show that the IFN-γ-mediated PD-L1 expression is regulated by IRF1, suggesting cross talk between BRD4 and IRF1 in the regulation of PD-L1 expression. Ongoing in vivo experiments will evaluate the role of BET inhibitors in the regulation of PD-L1 in mouse models of pancreatic cancer.

#1680 BPM31510, an anti-cancer agent selectively causes activation and proliferation of T cells, demonstrating potential utility in an immune-oncology setting. Maria-D Nastke, Nidhi Gaur, Louisa Dowal, Samantha Fowler, BERG, LLC, Framingham, MA

BPM 31510, a clinical stage, nanodispersion of ubenadencoreone has a unique mechanism of action that effectively induces a Warburg switch in cancer cell metabolism and activation of apoptosis. Given the observed central role of BPM 31510 in regulating mitochondrial function in cancer cells, it is of great interest to investigate the ability of BPM 31510 to modulate immune cells and their functionality. Therefore, the effects of BPM 31510 on peripheral blood mononuclear cells (PBMCs) were investigated to elucidate the immune-metabolic mechanism of BPM 31510. Healthy donor PBMCs activated with PHA or PWM was used as model system, and the effect of BPM 31510 on immune cells viability was determined using flow cytometry. In addition, the effect of BPM31510 on immune cell function was evaluated by measuring a panel cytokines released in these cells, using a quantitative ELISA platform from Meso Scale Discovery. Results: BPM 31510 has been shown in previous studies to effectively induce apoptosis on a variety of cancer cell lines while sparing normal cells. Interestingly, increasing concentrations of BPM31510 lead to an increased frequency of viable CD3+ cells. Further phenotypic analysis revealed that cytotoxic T cells (CD8+/CD3+) and T helper cells (CD4+/CD3+), as well as NK cells (CD56+/CD3-), were observed in the increased T cell frequencies. On the other hand, B cells (CD19+), NK cells (CD56+/CD3-), and the monocytes (CD14+) showed a decrease in frequency, an effect reflected also by a reduction in viability with increasing BPM 31510 concentrations. Cytokine analysis indicated that effector cytokines IL-2, IFN-γ, and TNF-α were secreted at significantly higher levels with increasing concentration of BPM 31510. Interestingly, IL-10 level, an immunoregulatory cytokine, was strongly decreased in the supernatant of PBMCs treated with BPM31510. Taken together, we demonstrated that BPM 31510 has a direct effect on immune cells and their functionality. Although BPM 31510 induced apoptosis of cancer cells, we find that it supports cell proliferation of T cells, and effector function of adaptive immune cells, likely by providing a higher energy supply for effector T cells. Subsequently, a higher activation frequency of CD8+ T cells was observed in response to BPM31510. These findings highlight the potential role of BET inhibitors in the management of cancer patients.

#1681 The antitumor effect of a soluble recombinant human thrombomodulin as growth suppression against gastrointestinal tumor in murine peritonitis model. En Amada, Kazumasa Fukuda, Koshi Kumagai, Koichi Suda, Hiroya Takeuchi, Yuko Kitagawa. Keio University School of Medicine, Tokyo, Japan

Introduction: Severe postoperative inflammatory response (PIR) with CARS increases the risk of tumor recurrence after cancer surgery by Tregs suppressing antitumor immunity. Also, cancer recruits Tregs into its tissue by secreting CCL22 and TGF-beta that strengthen its survival. We established a model to represent tumor dynamics under PIR by mice that are performed cecal ligation and puncture (CLP) followed by subcutaneous injection of cancer cells into the dorsum. In this model, we previously revealed significant tumor growth and increase number of Tregs both in tumor tissue and blood compared to the normal mice. A soluble recombinant human thrombomodulin (rTHM) is developed as a treatment drug against DIX. It has anti-inflammatory effect and several reports showed that it decreases cancer metastasis. We hypothesized that rTHM normalizes PIR and prevents cancer growth caused by inflammation. Method: Ten-week-old C57Bl/6 mice were divided in CLP/rTHM, CLP/normal saline (NS), and control (simple laparotomy plus NS) groups. rTHM (3mg/kg/12hrs) was injected subcutaneously for 7 consecutive days from the day before CLP. CT26 cells (1x10⁵) were implanted 4 hours after CLP. Mice were sacrificed 28 days after CLP. The tremendous and blood were collected. To analyze dynamics of Treg, peripheral blood leukocytes the tumor cells were isolated. CD4, CD25 and Foxp3 were stained by fluorescent antibody and stained cells underwent flow cytometric analysis. The quantity of Tregs is measured by the rate of CD25⁺/Foxp3⁺ population in CD4⁺ T cells. The level of CCL22 and TGF-beta were measured both in serum and tumor tissue. The ELISA was used for analyzing serum samples. And for tumor tissue, immunostaining by DAB was performed and positively stained areas were calculated by image-editing software. Results: CLP/NS group mice exhibited significant enhanced tumor growth compared to controls (6.0 ± 1.9 g vs. 3.5 ± 1.6 g, p = 0.03), while CLP/rTHM group produced significantly smaller tumors (2.2 ± 1.1 g) than CLP/NS (p = 0.01). The Tregs in the blood stream was smaller in CLP/rTHM group compared to CLP/NS group. Intratumoral Tregs showed significant difference between CLP/rTHM group and CLP/NS group (8.89 ± 3.5 % vs. 24.1 ± 15.0 %, p = 0.02). We found significant elevation of serum TGF-beta level by CLP (4.7 ± 1.2 pg/ml vs. 15.4 ± 7.0 pg/ml, p = 0.02) and relative reduction to 15.4 ± 7.0 pg/ml by administration of rTHM (p = 0.05). However, we did not recognize any change of serum CCL22 level in this study. Intratumoral rate of CCL22 positive areas increased by CLP/rTHM (50%), while not by CLP/NS (20%). It decreased to normalize PIR and find little difference of TGF-beta positive areas among three groups in this study. Conclusion: Acute inflammation induced by CLP enhances the growth of implanted tumors, while administration of rTHM suppresses tumor growth by possibly affecting dynamics Tregs via TGF-beta and CCL22.

#1681A Overcoming pd1 targeting antibody resistance using combination strategies. Jean-François Mirjolet, Maxime Ramelet, Damien France. Onco-design S.A., Dijon Cedex, France.

PD-1 targeting antibodies (nivolumab, pembrolizumab) are now approved in various tumor types either as second line treatment (locally advanced or metastatic urothelial carcinoma, advanced renal cell carcinoma, recurrent or metastatic head and neck squamous cell carcinoma, classical Hodgkin lymphoma) or even as first line therapy (metastatic melanoma, metastatic non-small cell lung cancer). Despite an increase in response rate as well as survival, there is still issue with resistance to PD-1 targeting therapies. Selection biomarkers as well as response biomarkers are still under intensive research. In addition, combination strategies are needed to increase response rate and overcome resistance. Combination strategies were therefore tested in one well characterized syngeneic mouse model, i.e. EMT-6 breast carcinoma. The model is known to be highly sensitive to CTLA-4 targeting antibody (optimum tumor to control ratio (T/C) of 3%), a moderate responder to PD-1 targeting treatment (best T/C of 54%) and a well immune infiltrated tumor. Antibodies targeting co-stimulatory receptor such as OX40, GITR and 4-IBB as well as co-inhibitory receptor such as Tim3 would be expected to arrest tumor growth and inhibit tumor progression.
were combined to anti-PD-1 antibody. In all cases, combination arm produces better therapeutic activity when compared to single treatment alone. Moreover, both strategies, meaning combination of two antibodies targeting co-inhibitory receptors (PD-1 + Tim3) and combination targeting one co-inhibitory (i.e. PD-1) and one co-stimulatory receptors (OX40, GITR or 4-1BB) worked. Detailed results will be presented including response rate, immune infiltrates and cytokines profiles in order to rationally choose the best therapeutic treatment.

**CLINICAL RESEARCH: Adaptive Immunity to Cancer**

**#1682** Correlation of immune co-stimulatory molecule OX40 and outcome in trastuzumab treated HER2-positive breast cancer patients in the NCCTG-N9831. Saranya Chumsri,1 Daniel J. Serie,2 Ashin Mashadi-Hosseini,3 Sarah Warren,2 Alvaro Moreno-Aspista,1 Geraldo Colono-Otero,1 Keith L. Knutson,1 Edith A. Perez,3 E Aubrey Thompson1,2 Mayo Clinic Cancer Center, Jacksonville, FL;3 NanoString Technologies, Inc., Seattle, WA.

Background: Trastuzumab (H), a monoclonal antibody against HER2, has revolutionized the treatment for HER2-positive breast cancer. Besides inhibiting downstream signaling of HER2, several studies showed that H also exerts its anti-tumor activity via immune-related mechanisms. While H is quite effective in preventing recurrence, significant numbers of patients still develop recurrence despite adjuvant H-based chemotherapy. In this study, we analyzed immune-related genes that were associated with poor outcome in N9831. Methods: NanoString technology was used to quantify mRNA of immune-related genes in baseline samples from 1,280 patients in N9831. In N9831, patients in arm A were treated with chemotherapy alone (AC-T), arm B received chemotherapy followed by sequential H (AC-T-H), and arm C received H concurrently with chemotherapy (AC-Th). Cox proportional hazard ratio (HR) was used to determine the association of each immune-related gene with disease-free survival (DFS). Different immune subset signatures, including CD45, CD8, cytotoxic-cells, and T-cells were analyzed using algorithms developed by NanoString. Results: With the median follow up of 10.6 years, we identified a total 77 genes that were associated with improved outcome in arm C. Among these 77 genes, there were 20 tumor necrosis factor (TNF)-related genes. Of those, only OX40 (TNFRSF4) and its ligand TNFSF4 have interaction p < 0.10. Interestingly, we found uneven distribution of OX40 expression in the N9831 specimens. Specifically, 9.5% of HER2-positive breast cancer patients expressed OX40 at distinctly low level. Low expression of OX40 was significantly associated with HR positivity (OX40 low 61% vs. OX40 high 51%, p=0.003) and larger tumor size but not patients’ age, tumor grade, and lymph node status. Low expression of OX40 was significantly associated with low mTIL-CD45, CD8, cytotoxic-cells, and T-cells immune signature scores. Tumors with low OX40 expression had significantly lower levels of CTLA4 (9.11e-71) and PD-L1 expressions (9.11e-71) and significantly lower levels of CTLA4 (p 9.11e-71) and PD-L1 expressions (p 9.11e-71) with its ligand TNFSF4 in arm A (HR 1.02, 95%CI 0.92-1.15, p=0.68), arm B (HR 0.87, 95%CI 0.76-0.99, p=0.04), and arm C (HR 0.81, 95%CI 0.68-0.95, p=0.01). Conclusion: Our study suggests that pre-existing expression of OX40 and its ligand TNFSF4 in arm A (HR 1.02, 95%CI 0.92-1.15, p=0.68), arm B (HR 0.87, 95%CI 0.76-0.99, p=0.04), and arm C (HR 0.81, 95%CI 0.68-0.95, p=0.01). Results: With the median follow up of 10.6 years, we identified a total 77 genes that were associated with improved outcome in arm C. Among these 77 genes, there were 20 tumor necrosis factor (TNF)-related genes. Of those, only OX40 (TNFRSF4) and its ligand TNFSF4 have interaction p < 0.10. Interestingly, we found uneven distribution of OX40 expression in the N9831 specimens. Specifically, 9.5% of HER2-positive breast cancer patients expressed OX40 at distinctly low level. Low expression of OX40 was significantly associated with HR positivity (OX40 low 61% vs. OX40 high 51%, p=0.003) and larger tumor size but not patients’ age, tumor grade, and lymph node status. Low expression of OX40 was significantly associated with low mTIL-CD45, CD8, cytotoxic-cells, and T-cells immune signature scores. Tumors with low OX40 expression had significantly lower levels of CTLA4 (9.11e-71) and PD-L1 expressions (9.11e-71) with its ligand TNFSF4 in arm A (HR 1.02, 95%CI 0.92-1.15, p=0.68), arm B (HR 0.87, 95%CI 0.76-0.99, p=0.04), and arm C (HR 0.81, 95%CI 0.68-0.95, p=0.01). Conclusion: Our study suggests that pre-existing expression of OX40 and its ligand TNFSF4 are prognostic and may also be predictive of adjuvant H benefit. Patients with distinctly low level of OX40 had poor outcome despite adjuvant H-based adjuvant chemotherapy. Our study provides a rationale to further evaluate the strategy to increase immune activation to improve outcome in this group of patients.

**#1683** A novel adenosine A2A receptor antagonist optimized for high potency in adenosine-rich tumor microenvironment boosts antitumor immnunity. Erica Houthuys, Margreet Brouwer, Florence Nyawouame, Romain Pirson, Reece Mardillier, Theo Deregnaucourt, Joao Marchante, Jakub Swiercz, Charlotte Moulin, Vanessa Bol, Gregory Driessens, Michel Dethue, Christophe Quêva, Stefano Crosignani, Bruno Gomes. iTeos Therapeutics, Gosselies, Belgium.

High levels of extracellular adenosine in the tumor microenvironment are known to play a significant role in tumor immune evasion and promote tumor growth and metastasis. We defined the receptor(s) required for mediating the effect of adenosine on immune cells within the tumor microenvironment and report the characterization of a novel Immuno-Oncology-dedicated adenosine receptor 2A antagonist that functions in the high adenosine concentration found in tumors. We first explored the expression of the four adenosine receptors in primary human immune cells. A2A receptor was the main adenosine receptor expressed by CD4 and CD8 T lymphocytes and monocytes, and the only one in monocyte-derived dendritic cells and NK cells. A2B receptor was poorly detected in T cells and monocytes, while A1 and A2 receptors were never detected. Given these expression patterns, we further studied A2A functional activity, and found that A2A agonists such as CGS-21680 strongly suppressed cytokine production by activated primary human T lymphocytes, thus highlighting that A2A is the main effector receptor of the sensing of adenosine in tumors. We further confirmed the elevated extracellular adenosine level in the tumor microenvironment in several mouse and human tumors. High adenosine levels correlated with strong tumoral expression of CD73, the enzyme that converts adenosine to adenosine-5'-monophosphate. Interestingly, we showed that A2A receptor antagonists designed for Parkinson’s disease dramatically lost potency in a high adenosine environment; our data indicated that a 30-fold dose increase may be required for full target inhibition within tumors. Therefore we developed a novel and potent A2A blocker with sub-nanomolar Ki and IC50 in a cAMP assay and a more than 100-fold selectivity over other adenosine receptors. Our lead compound kept a high potency in an adenosine-rich environment and restored cytokine production even in the presence of high concentrations of A2A agonists. iTeos inhibitor also efficiently reversed AMP-mediated T cell suppression. Furthermore, our compound rescued A2A receptor agonist-induced decrease of TNFα production by primary human monocytes, and was able to potently increase CD8 T cell cytotoxicity in a cytokine-rich environment with CD8 T cells as effectors and cancer cells as targets. These results suggest that iTeos new generation of A2A receptor antagonist, designed to keep a high potency in the adenosine-rich tumor microenvironment, may offer a new therapeutic opportunity in Immunoo-Oncology.

**IMMUNOLOGY: Tumor Models and Assays**

**#1685** Effects of anti-ctla-4 and anti-pd-1 on memory T-cell differen- tiation and resistance to tumor relapse. Stephen Mok, Colmn R. Duffy, James P. Allinson, MD Anderson Cancer Center, Houston, TX

The FDA has begun to expand the approved uses of immune checkpoint blockade antibodies targeting CTLA-4 and PD-1. Blocking either checkpoint relieves the negative regulation of T cells resulting in significant responses in patients with cancer. Data has now begun to emerge regarding differences between these two therapies. While oPD-1 therapy has a greater response rate (~30% vs. 11%) according to RECIST criteria, recent reports have suggested responses to oPD-1 may not be as durable as oCTLA-4. 25% of patients who initially responded to oPD-1 have tumor relapse within 24 months. In contrast, the 3-year survival rate of patients treated with oCTLA-4 is at least ~25% suggesting a durable response. Previous studies in bacterial or chronic LCMV infectious models have shown that oCTLA-4 can increase CD8+ memory T-cell formation, whereas genetic ablation of PD-1 on T cells often promotes the terminally differentiated exhausted CD8+ T-cell phenotype, while attenuating memory T-cell formation. However, the mechanism which leads to relapse following oPD-1 treatment in tumor models is not clear. The goal of this project is to understand how immunotherapies shape memory T-cell formation and how that relates to the mechanism of tumor relapse. To test if oCTLA-4 or oPD-1 can induce a better memory T-cell response, mice were vaccinated with irradiated B16F10 murine melanoma cells and treated with oCTLA-4 or oPD-1. Mice were re-challenged with B16F10 80 days after vaccination. Although both oCTLA-4 and oPD-1 improved tumor rejection compared with controls, oCTLA-4 treated mice exhibited superior tumor control compared to oPD-1 (p<0.0005) suggesting the memory T-cell response mediated by oCTLA-4 is more durable. In order to test whether this memory T-cell response is antigen-specific, mice were re-challenged with unrelated MC38 or 3LL cancer cells. The antibody treated groups did not show improved antitumor effect compared with vaccine control (p>0.5). To test whether the frequency of memory T cells re-cruited to the re-challenged tumor could affect memory T-cell response, antigen-specific pmel-1 T-cells were mixed in mice following vaccination with oCTLA-4 or oPD-1. Our result suggested that there were more tumor-infiltrating pmel-1 T-cells in the oCTLA-4 treated group compared to the oPD-1 treated group (p<0.05). In order to augment the durability of oPD-1 treatment, oPD-1 was combined with oCTLA-4 following vaccination. The combined treatment group has superior antitumor response compared to that with oPD-1 alone and overlap with the oCTLA-4 treated group (p<0.05) during re-challenge, indicating that the effect of the combined treatment is dominated by oCTLA-4. Collectively, our studies facilitate the design of combination immunotherapy treatments that enhance both response rates and generation of memory T-cells to prevent relapse.
Epigenetic modulation of the tumor microenvironment enhances vaccine induced T cell responses in a murine model of pancreatic cancer.

Brian Christnas,1 Blake Scott,1 Todd Armstrong,1 Nilofar Azad,2 Elizabeth Jaffe1. 1Johns Hopkins University, Baltimore, MD; 2Johns Hopkins Sidney Kimmel Comp. Cancer Ctr., Baltimore, MD.

This project aims to test the hypothesis that epigenetic modulatory drugs (EMD) and GVAX, a GM-CSF-secreting whole tumor cell vaccine, are capable of altering the inflammatory environment of pancreatic ductal adenocarcinoma (PDAC) and sensitizing it to checkpoint blocking agents. Recently the use of antibody therapy targeting immune checkpoints, such as CTLA-4 and PD-1, has become a major focus of cancer immunotherapy. In responsive patients, these therapies result in long-term control of chemotherapyc-resistant disease. The most compelling activity has been seen in the minority of patients with immunogenic tumors where T cell infiltration naturally occurs. These benefits are not observed in non-immunogenic tumors, such as PDAC, with low expression of tumor-associated antigens (TAA) and a lack of intrinsic T cell infiltrates. Therapies that can alter the tumor microenvironment (TME) and allow infiltration of effector T cells, decrease immunosuppressive cells, and stimulate TAA expression may convert non-immunogenic tumors into cancers sensitive to checkpoint inhibitors. Recent work with EMDs has shown that they are capable of altering the immunogenicity of the TME by inducing the expression of cancer testis antigens as well as increasing tumor cell expression of MHC class II and decreasing Treg in the TME. Additionally, GVAX has been shown to induce tumor cell death and antigen release within the TME, testing the hypothesis that treatment with EMDs and GVAX can sensitize the inflammatory environment of PDAC to checkpoint blockade inhibition by evaluating changes in immune cell function within the TME via flow cytometry, immunohistochemistry, and gene expression array. We are using a murine model of hepatic metastases of pancreatic cancer which involves injecting syngeneic pancreatic tumor cells into the spleen followed by a hemiplenectomy, resulting in the consistent formation of hepatic metastases that can be monitored by ultrasound. We have evaluated entinostat, a histone deacetylase inhibitor, in combination with GVAX which induces T cell responses, and demonstrated a significant increase in survival when compared with either agent alone. Flow cytometric analysis of the cells infiltrating the TME shows that the combination of entinostat and GVAX causes a significant increase in CD4+ T cell infiltration as well as a shift from an M-MDCS dominant to a more G-MDCS dominant myeloid population. Current studies aim to elucidate the functional- ity of the MDSC population as well as identify potential changes in the T helper cell subsets via flow cytometry. Additionally, future studies will evaluate changes within checkpoint blockade pathways via flow cytometry and gene expression array to identify pathways that require further modulation to enhance antitu- mor responses.

Systemic immunological changes during first line chemotherapy in patients with high-grade serous ovarian cancer.

Fenne L. Komdeur, Florine A. Eggink, Ninke Leffers, Hagma H. Workel, Kim L. Brunekreeft, Annechien Plat, Marco de Bruyn, Hans W. Nijman. University of Groningen, University Medical Center Groningen, Groningen, Netherlands.

Ovarian cancer remains the most lethal gynecological malignancy and new therapeutic strategies are urgently needed. High-grade serous ovarian cancer (HGSC), in particular, is associated with a five-year survival of only 40%. A promising new approach for treating HGSC is immunotherapy, which has resulted in complete and durable responses, albeit in a minority of patients. One potential approach for improving these response rates is by combining chemo- and immunotherapy. Indeed, carboplatin/taxol chemotherapy was shown to augment immune responses in cervical cancer patients by depleting circulating myeloid suppressor cells. As patients with HGSC are treated in first line with chemotherapy, the third and fourth cycle of chemother- apy and 4-6 weeks after the sixth cycle of chemotherapy. All patients re- ceived 6 cycles of carboplatin/taxol chemotherapy and cytoreductive surgery (either as primary debulking, or after 3 cycles of neo-adjuvant chemotherapy). Peripheral blood mononuclear cells were isolated and analyzed for a total of 36 immune markers using 9 flow cytometry panels, in total analyzing 49 immune cell subsets. Results were compared to an age-matched cohort consisting of women surgically treated for a benign disease, and a cohort of healthy young volunteers. 75 patients have been included so far from which 22 were diagnosed with benign disease, 3 were diagnosed with another malignancy, and 50 were diagnosed with OC. Of the 50 OC patients, 18 were diagnosed with HGSC and from 9 HGSC patients, multiple time points were available for analysis of che- motherapy-dependent changes in the immune cell subsets. All patients devel- oped leukopenia as a result of chemotherapeutic treatment. Age-related changes in lymphocyte and myeloid cell subsets were observed in all HGSC patients and patients with benign disease. Chemotherapy-dependent depletion of myeloid cells was observed. Depletion was not significant. T cell subsets equitably distributed among monocytes, macrophages and dendritic cells. No HGSC- or chemotherapy-dependent changes in T cell subsets or migration and activation markers were observed. Taken together, we observed no major sys- temic changes in immune cell subsets during carboplatin/taxol chemotherapy treatment, suggesting that combined chemo-immunotherapeutic strategies could be feasible during first line treatment of HGSC.

HERA-CD40L: A novel hexavalent CD40 agonist with superior bi- ological activity.

Introduction: Targeted therapeutics for cancer treatment are mostly devel- oped as antibodies, however, the natural signaling complexes of the members of the TNF superfamily and their receptors consist of clusters of trimers. Consequent- ly, most of these bivalent agonistic antibodies depend on Fc receptor mediated crosslinking for biological activity. The HERA-Technology developed by Apogenix generates hexavalent fusion proteins targeting the TNF-receptor superfamily with high clustering capacity for the cognate receptor, which over- comes this disadvantage of antibody-based drugs. Here we compared the efi- cacy of different CD40 agonist formats, including the novel HERA-CD40L and the functional consequences of differential receptor clustering. Materials & Methods: Biological activity of CD40 agonists was compared using an engi- neered reporter cell line and by flow cytometric analysis of CD40-induced IReA degradation in Ramos B cells. T lymphocytes and monocytes were isolated from buffy coats and expression of CD markers upon CD40 ligation was analysed by multicolor flow cytometry (MC-FC). Secretion of cytokines in response to CD40 ligation was determined by ELISA. Monitoring of T cell-induced killing of tu- mor cells in direct co-cultures employed a real-time cell analysis system (xCel- Ligence). Results: Direct comparison of bivalent CD40 antibodies with trivalent CD40L and the hexavalent HERA-CD40L in two independent bioactivity assay formats demonstrated that only the hexavalent agonist was fully active without additional crosslinking. In contrast to HERA-CD40L, neither the bivalent ago- nistic CD40 antibody nor the trivalent CD40L were able to upregulate expres- sion of activation markers on B cells or to induce secretion of proinflammatory cytokines such as IL-12 and TNFα by PBMCs. In vitro generated M2-macro- phages acquired an M1 phenotype and enhanced proliferation of naïve CD4+ T cells in direct co-culture. Similarly, direct co-culture of CD4+ T cells with Ramos B cells in the presence of HERA-CD40L induced cytotoxic activity of CD4+ cells against tumor cells. The activating effect was dependent on cell-cell contacts and was not observed in indirect co-cultures. Importantly, only the hexavalent HERA-CD40L showed full biological activity without additional crosslinking. Conclusion: The hexavalent CD40 agonist HERA-CD40L pro- duced by Apogenix HERA-Technology platform triggers CD40 signaling on B cells and monocytes. The monoclonal ligand, HERA-CD40L, leads to differential receptor clustering and proliferation of CD4+ T cells and shifts the M1/M2 balance towards proinflam- matory conditions. Unlike bivalent CD40 antibodies or trivalent CD40L based agonists, the hexavalent HERA-CD40L forms highly clustered signaling com- plexes and thus exhibits superior biological activity over other agonistic formats without the need for Fc receptor mediated crosslinking.

Dynamic monitoring of immune response and reagent efficacy through high throughput label-free impedance-based technology.

Fabio Cerignoli, Biao Xi, Garret Garret Guenther, Lincoln Muir, Leyna Zhao, Yama Abassi. ACEA Biosciences Inc., San Diego, CA.

In vitro characterization of reagents efficacy in the context of cancer immu- notherapy is a necessary step before moving to more expensive animal models and clinical studies. However, current in use in vitro assays like Chromium-51, ATP-based luminescence or flow cytometry are either difficult to implement in high throughput environment or are mainly based on end point methodologies that are unable to capture the full dynamic of the immune response. Here we present the adaptation of an impedance-based platform to monitoring cytotoxic activity of immune cells activated through different means. Impedance technol- ogy detects cell death and proliferation of adherent cells by measuring changes in conductance of microelectrodes embedded in 96 and 384-wells cell culture plates. We utilized adherent and B cell leukemia/lymphoma cell lines as well as primary tumor cells as in vivo models for immunotherapy reagents evaluation. We seeded the cells on electrodes coated 96-well plates and monitored cell ad-
hension and proliferation for 24 hours. The following day effector cells were added at multiple effector:target ratios in presence of BiTE antibodies and/or anti PD-1/PD-L1 antibodies. Impedance signal was monitored for up to seven days. Control wells were set up with effector cells only or with target plus effector cells but without antibodies. We adapted such adhesion-based technology to monitor non-adherent B-lymphoma/lymphoma cells, by developing a strategy where the wells are coated with an anti-CD40 antibody. The coating allows specific adhesion and retention of B cells and measurement of changes in impedance that are proportional to cell number. Using increasing concentrations of EpCAM/CD3 BiTE we demonstrated the suitability of such impedance-based approach to quantitatively monitor the efficacy of immune cells-mediated cancer cell killing both under different effector:target ratios and antibody concentrations. Combination treatments with checkpoint reduced killing and increased amount of killed cancer cells. Similar results were also obtained with engineered Car-T cells against CD19 or NK cell lines, we were able to demonstrate specific killing of tumor B cells at very low effector:target ratios. The results were also confirmed by flow cytometry. Overall, our results demonstrate the value of such approach in measuring the cytotoxic response across the temporal scale, an aspect that is otherwise very difficult to assess with more canonical end point assays. Furthermore, the availability of 384-wells format and minimal sample handling place the technology in an ideal spot for applications in large reagent validation screening or personalized medicine, like therapeutic protocol validation directly on patient samples.

**#1690 Epitope-minigenes for optimal induction of the immune response against tumor associated antigens and neoantigens.** Silvio Bandini,1 Laura Luberto,1 Fabio Palombo,1 Giuseppe Roscilli,1 Emanuele Marra,1 Gennaro Ciliberto,2 Luigi Aurisicchio.1

We have recently established a workflow that allows the identification of T cell epitopes within Tumor Associated Antigens (TAA)s and the construction of genetic cancer vaccines based on the use of minigenes. The T-cell epitope in silico prediction approach is based on three criteria: 1) binding to MHC Class I alleles; 2) uniqueness to the antigen of interest; 3) increased likelihood of natural processing. The combination of in silico prediction and a biochemical binding/stability assay resulted in a novel accurate identification of TAA-derived epitopes. Predicted T cell epitopes were connected by furin sensitive linkers and linked to human tissue plasminogen activator (TPA) signal and E. Coli enterotoxin B subunit, to construct an optimal minigen scaffold used as vaccine candidate. The present study was aimed at evaluating HER2/neu and hTERT (telomerase) minigenes with the same technology platform. First of all, minigenes delivered via Electro Gene Transfer (DNA-EGT) were more immunogenic than genetic vectors encoding the full-length protein or peptides injected subcutaneously and they were able to block immune tolerance in wild type and HLA-A2021 transgenic mice. Moreover, this technology applied to epitopes selected within Mutated Tumor Antigens results in strong immunogenicity and significant antitumor effects in mouse models. In conclusion, we show that minigenes delivered via DNA-EGT and based on predicted and/or experimentally identified epitopes are powerful tools to induce immune responses and combat cancer. Combining minigenes with peptide vaccination and oil-based delivery strategies may improve the uptake and activation of DCs at low concentrations of the SLP and oil-based delivery strategies trap immune cells to unwanted sites or have inappropriate adjuvant properties. To enhance the uptake of cancer or viral T cell epitopes and subsequent activation of DCs we make use of circulating antibodies to target cellular responses against tumor antigens of interest by conjugating a B cell epitope to a T cell epitope. The conjugation of the two greatly improves antigen uptake and concomitant activation of the same DC in contrast to naked long peptides which are not conjugated. Our identified B cell epitope of choice is derived from tetanus toxin and can be targeted by tetanus-specific antibodies boosted by a standard tetanus toxoid vaccine. We have applied a modified chimeric peptide model preserving intact cascade systems to characterize how the tetanus-neupeptide conjugated vaccine is targeted to human immune cells. The B cell/T cell conjugate is taken up by human monocytes and blood DCs in an antibody-dependent manner. Rather than FcRs, the internalization of the antigen appears to be partly mediated through the classical pathway of the complement system. Tetanus-CMV conjugates, containing a T cell epitope from the pp65 protein of cytomegalovirus (CMV), strongly reactivates memory T cells when analyzed in blood from donors with CMV-specific T cells. The CMV-specific T cells rapidly produce IFNγ and TNF in response to the conjugate illustrating that the uptake of the conjugate leads to activation of antigen-specific T cells. Uptake as well as T cell activation occurs at low concentrations of the SLP conjugate, superior to a conjugate lacking the tetanus–sequence as well as to SLPS with or without additional adjuvant (LPS). Of importance, when the B and T cell epitopes are separate entities but mixed, CMV-specific T cells are not activated, illustrating the requirement of conjugating the two. Our data show that we have a unique delivery system for peptide based vaccines that can aid induction of human T cell responses, and may potentiate immune responses in cancer patients. We are now actively working on a prostate cancer vaccine candidate using this novel loading/adjuvant technology.

**#1692 KRAS-mediated therapeutic resistance abrogates immunogenic cell death in colorectal cancer cells.** Yi-Jun Wang,1 Dongshi Chen,1 Jinghao Timg,1 Jifan Yu,2 Alberto Bardelli,2 Lin Zhang,3 #1University of Pittsburgh Cancer Institute, Pittsburgh, PA; #2University of Torino, Torino, Italy.

A hallmark of cancer is compromised immune surveillance, which is characterized by failure of the immune system to recognize, immunize against, and specifically eliminate malignant cells. A number of studies showed the tumor microenvironment in colorectal cancer (CRC) patients is highly immunosuppressive. Conventional chemotherapy and recent targeted therapy can restore anti-tumor immune response through induction of immunogenic cell death (ICD) in tumor cells. However, the mechanism and functional role of ICD in CRC and its resistance by dendritic cells is not clear. We identified the BH3-only BCL-2 family protein PUMA as a key mediator of necroptosis induced by the combination treatment in vitro and in vivo. Furthermore, we found that CRC cells with acquired cetuximab resistance due to KRAS mutation or amplification are deficient in ICD. Collectively, our results suggest that oncogenic mutations cause resistance of CRC cells to anticancer therapies in part by suppressing ICD.

**#1693 T cell responses to peptide-epitopes can be boosted by immune complexes of circulating anti-tetanus antibodies.** Erika A. Fletcher,1 Wendy van Maren,2 Robert Cordfunke,2 Jasper Dinkelaar,3 Ricardo Castelli,3 Jeroen Codee,2 Gis van de Marel,3 Cornelis J. Melief,2 Ferry Ossendorp,2 Jan Wouter Drijfhout,2 Sara Mangsbo.1

1Uppsala University, Uppsala, Sweden; 2Leiden University Medical Center, Netherlands; 3Leiden University, Netherlands.

The ability of dendritic cells (DCs) to boost an antigen-specific immune response is utilized in several cancer immunotherapy strategies including therapeutic vaccination using long peptides. Naked peptides are rapidly degraded and oil-based delivery strategies trap immune cells to unwanted sites or have inappropriate adjuvant properties. To enhance the uptake of cancer or viral T cell epitopes and subsequent activation of DCs we make use of circulating antibodies to target cellular responses against tumor antigens of interest by conjugating a B cell epitope to a T cell epitope. The conjugation of the two greatly improves antigen uptake and concomitant activation of the same DC in contrast to naked long peptides which are not conjugated. Our identified B cell epitope of choice is derived from tetanus toxin and can be targeted by tetanus-specific antibodies boosted by a standard tetanus toxoid vaccine. We have applied a modified chaperone model preserving intact cascade systems to characterize how the tetanus-neupeptide conjugated vaccine is targeted to human immune cells. The B cell/T cell conjugate is taken up by human monocytes and blood DCs in an antibody-dependent manner. Rather than FcRs, the internalization of the antigen appears to be partly mediated through the classical pathway of the complement system. Tetanus-CMV conjugates, containing a T cell epitope from the pp65 protein of cytomegalovirus (CMV), strongly reactivates memory T cells when analyzed in blood from donors with CMV-specific T cells. The CMV-specific T cells rapidly produce IFNγ and TNF in response to the conjugate illustrating that the uptake of the conjugate leads to activation of antigen-specific T cells. Uptake as well as T cell activation occurs at low concentrations of the SLP conjugate, superior to a conjugate lacking the tetanus–sequence as well as to SLPS with or without additional adjuvant (LPS). Of importance, when the B and T cell epitopes are separate entities but mixed, CMV-specific T cells are not activated, illustrating the requirement of conjugating the two. Our data show that we have a unique delivery system for peptide based vaccines that can aid induction of human T cell responses, and may potentiate immune responses in cancer patients.

**#1694 USP7 inhibitors impair Treg function.** Silvia Bandini,1 Laura Luberto,1 Fabio Palombo,1 Giuseppe Roscilli,1 Emanuele Marra, Gennaro Ciliberto,2 Luigi Aurisicchio.

Along with the already established direct anti-tumor activities of USP7 inhibitors, these studies provide a strong rationale for combining USP7 inhibitors to suppress Treg functions and improve the efficacy of currently approved cancer immunotherapy agents.

**#1695 USP7 inhibitors impair Treg function.** Silvia Bandini,1 Laura Luberto,1 Fabio Palombo,1 Giuseppe Roscilli,1 Emanuele Marra, Gennaro Ciliberto,2 Luigi Aurisicchio.
CLINICAL RESEARCH: Adaptive Immunity to Cancer

#1694  Systemic granulocyte-macrophage colony-stimulating factor (GM-CSF) treatment increases T cell receptor diversity in localized and metastatic prostate cancer patients. David Y. Oh,1 Li Zhang,2 Jason Cham,1 Alan Paciorek,3 Mark Klinger,3 Malek Faham,3 Susan F. Slovin,3 Lawrence Fong,3 1University of California, San Francisco, San Francisco, CA; 2Adaptive Biotechnologies, South San Francisco, CA; 3Memorial Sloan Kettering Cancer Center, New York, NY.

Granulocyte-macrophage colony-stimulating factor (GM-CSF) is frequently utilized as an adjuvant in cancer immunotherapies, and has known effects as a growth factor. However the extent to which GM-CSF modulates the adaptive immune response, including possible effects on the antigenic repertoire, remains unclear. We analyzed T cell receptor diversity by sequencing of TCR beta chain sequences amplified from total RNA from peripheral blood mono-nuclear cells using consensus primers to assess changes in the circulating antigenic repertoire of prostate cancer patients treated with GM-CSF in multiple clinical trials. Administration of systemic GM-CSF monotherapy to patients with localized prostate cancer prior to planned radical prostatectomy (NCT00305669) results in a significant decline in clonality from the pre-treatment timepoint to the 2-week timepoint on treatment, indicative of increased early repertoire diversity (p = 0.039 by Wilcoxon signed rank test). In a separate clinical trial (NCT000661429), the combination of systemic GM-CSF (250 μg/ m²/day on days 1-14 of each cycle) with ipilimumab in metastatic castrate-resistant prostate cancer (mCRPC) patients also resulted in a significant decline in clonality from pre-treatment samples to the 2-week timepoint on treatment (p = 0.002). In contrast, mCRPC patients who received ipilimumab alone in a separate study (NCT00323882) did not experience a similar decline in clonality after 3 weeks on treatment (p = 0.625). In addition, comparison of the dynamics of specific clonotypes between the paired timepoints in the two mCRPC studies demonstrates that while there is no significant difference in the ratios of post-treatment to pre-treatment clonality between studies, patients treated with the combination of ipilimumab and GM-CSF show more repertoire change, with lower Morisita’s distance for all clones found at either timepoint (p = 0.023), smaller intraclass correlation coefficient (p = 0.028), and a smaller proportion of clonotypes that remain unchanged (defined by +/- 2 fold-change for clones found at both timepoints) (p = 0.002). These results indicate increased repertoire turnover when GM-CSF is combined with checkpoint inhibition. Hence data from both localized and metastatic prostate cancer, and from monotherapy and combination therapy regimens, supports a role for GM-CSF in inducing early diversification of the TCR repertoire.

#1695  Exploiting the pancreatic cancer mutome for immune interception. Heather Kinkead,1 Eric Lutz,2 Thomas W. Dubensky,3 Elizabeth Jaffee4, 1Johns Hopkins School of Medicine, Baltimore, MD; 2WindMILL Therapeutics, Baltimore, MD; 3Aduro Biotech, Berkeley, CA.

This study aims to translate tumor-specific mutations identified by next-generation sequencing techniques into an effective anti-tumor vaccine for a classically non-immunogenic tumor, pancreatic ductal adenocarcinoma (PDA). Pancreatic ductal adenocarcinomas develop an average of 63 mutations during tumorigenesis, collectively referred to as the “mutome.” Of these, approximately 45 are amino acid point mutations. These mutations are not present in normal cells and provide a source of tumor-specific neoepitopes for targeted immunotherapy. Next-generation sequencing technologies allow for rapid identification of mutations present in patient tumors; however, methods for rapid identification of immunogenic neoepitopes which can be effectively targeted for tumor clearance, and optimized vaccination strategies for targeting them, still need to be developed. In this study, we are using a transplantable murine PDA model, Panc02, to develop vaccination strategies for inducing neoepitope-specific T cell antitumor responses, and to define parameters for selecting appropriate targets. Exome sequencing identified 878 nonsynonymous mutations in the Panc02 cell line. Three immunological epitope prediction servers identified 878 potentially immunogenic peptides in the Panc02 model, 29 of which were strong candidtes (scores >1000) and another 240 candidate epitopes within the limits of prediction (scores >1000). Panc02 neoepitope peptide vaccinations in mice confirmed 14% of the predicted epitopes to be immunogenic by IFNγ ELISPOT, which may include both CD8+ and CD4+ T cell responses. Tumor transplant experiments demonstrate that therapeutic vaccination against neoepitopes in combination with a human STING-activating cyclic dinucleotide adjuvant is capable of inducing a temporary regression of implanted tumors. After tumor escape and regrowth, flow cytometry reveals a large population of infiltrating lymphocytes, the majority of which are co-expressing the checkpoint molecules PD-1, Tim3, and Lag3, indicating that treatment of vaccinated animals with checkpoint blockade therapy may potentiate infiltrating lymphocytes and ultimately result in permanent tumor regression. Thus, a broad and unbiased approach for screening vaccine targets will allow for the evaluation of predictive algorithms and ultimately the development of more effective vaccination approaches for targeting the tumor mutome.

Irradiation (IR) has variable effects on the solid tumor microenvironment. While many report additive or synergistic effects between IR and immune activating therapies, most studies utilize single fractions or hypo-fractionated high-dose radiation of 8 Gy or greater. For head and neck squamous cell carcinoma (HNSCC), 30 or more low-dose fractions of 1.8-2 Gy are utilized as standard-of-care for the upfront treatment of early stage or advanced disease. Preliminary experiments from our laboratory have demonstrated that 10 fractions of 2Gy IR decreased the rate of rejection of T-cell infiltrated syngeneic carcinomas in wild-type B6 mice when combined with cyclic dinucleotide (CDN) compared to CDN treatment alone (10% rejection rate with low-dose fractionated IR plus CDN vs. 50% with CDN alone). Immune suppression following IR in mice is mediated by at least galectin-1. Further, HNSCC patients treated with standard fractionated low-dose IR develop durable neutropenia. Thus, we hypothesized that low-dose fractionated IR is immunosuppressive and does not result in additive or synergistic effects when combined with cyclic dinucleotide. To test this hypothesis, we performed a time-course analysis of tumor immune infiltration and tumor-draining lymph node antigen-specific in vivo tumor rejection in three human genetic models of carcinoma using defined tumor rejection antigens (MOCi-15E, B16-OVA and MC38-CEA) following exposure to two different IR regimens of 8Gy x 2 fractions or 2Gy x 10 fractions. Analysis of effector immune infiltration and antigen-specific activation pre-IR and at 5, 10, and 20 days post-IR revealed consistent trends of profound immunosuppression with the low-dose fractionated IR regimen (2Gy x 10) but preserved or enhanced immune activation with the high-dose hypofractionated regimen (8Gy x 2). Galectin-1 levels will be measured from whole tumor lysates. We plan to perform nano-string RNA array analysis on irradiated tissues to serve as correlative immune analysis and also to validate this technology against well-defined immune read-outs for potential use in the clinical trial setting. We also plan to combine both IR regimens with intra-lesional CDN (20 μg x 3 injections) to determine if either IR regimen results in additive or synergistic tumor control. This work has profound implications for future pre-clinical studies and clinical trials combining IR and immune activating therapies, such as CDN or checkpoint inhibitors.

#1697  Humanized immune-oncology mouse models. Maria Stecklum, Anika Wulf-Goldenberg, Bernadette Brzezich, Iduna Fichtner, Jens Hoffmann. FPO GmbH, Berlin, Germany.

The recent clinical success of immune checkpoint modulators has stimulated immune-oncology research leading to the identification of new tumor immunology targets. However both, target validation and drug development need better preclinical immune oncology models. Translational research further urgently needs such models for identification of clinically relevant biomarkers and validation of immunologic and tumor control. Development of xenografts (PDX) from different tumor indications transplanted on immunodeficient mice have demonstrated strong predictive power for many drug development programs in cancer research. However, one caveat of PDX models is, that these mice lack a functional immune system, which allows tumor engraftment in the xenogenic host. To overcome these constraints our aim is the development of PDX models on mice with a functional human immune system. This strategy should allow implementing the highly predictable PDX in a functional human immune environment for better drug efficacy and safety studies. We reconstituted a human immune system in mice by engrafting human hematopoietic stem cells in immunodeficient mice. We demonstrate the engraftment of a full set of human immune cells, including T cells, B cells, NK cells, monocytes and dendritic cells in the immunodeficient hosts of PDX. The in vivo growth pattern of PD-L1 is currently evaluated as first biomarker for immunotherapy with the PD1 checkpoint inhibitors. We screened our tumor cell lines and PDX models for PD-L1 expression to identify such a correlation. PD-L1 positive and negative models were transplanted on humanized mice. Most of them showed no difference in tumor growth compared to non-humanized mice (≈ fully immune resistant). However other PDX showed a delayed growth on the humanized mice (≈ partly immune resistant), whereas only one model did not grow at all (≈ immune sensitive), demonstrating a high sensitivity to the innate immune response of this PDX. To evaluate the function of the human immune cells and checkpoints, mice were treated with checkpoint inhibitors ipilimumab and nivolumab. Checkpoint inhibitors alone or in com-
bination led to a minor tumor growth delay and an increased number of acti-
vated T-cells in the blood and in the tumor. Our results from experiments with
t = 19 models revealed a first correlation: stronger tumor growth inhibition on
PD-L1 positive PDX and increased sensitivity of “partly immune resistant”
PDX. Furthermore we were able to demonstrate, that treatment effects of check-
point blockade by anti-CTLA-4 mAb were increased by 1.7 fold (p = 0.0397).
Consequently, we hypothesize that targeting immunotherapy to the tumor using oligonucleotide
aptamers that bind to RT induced tumor stress products will significantly en-
hance the therapeutic index. We used the aptamer platform to generate a bi-
specific construct containing a costimulatory aptamer ligand specific to murine
4-1BB which was conjugated to an aptamer specific to products secreted into the
tumor stroma (VEGF or osteopontin). Tumor targeting, local control, abscopal
responses and toxicity were compared to unconjugated 1-4BB-VEGF con-
structs, or mAb based therapies, when used in combination with RT in murine
subcutaneous and autochthonous MCA tumor models. RT induced VEGF
upregulation was demonstrated in null/low VEGF secreting tumors that led to
preferential accumulation of VEGF-41BB aptamers in the irradiated
tumor.12Gyx1 elicited optimal tumor targeting of bi-specific VEGF-4-1BB con-
jugate. Significant anti-tumor immune responses were observed in s.c. murine
tumor models. This conjugate showed dramatic reduction in systemic toxicity
compared to the equivalent gold standard 4-1BB mAb. RT-VEGF-4-1BB treat-
ment significantly improved local control, overall survival and induced potent
abscopal responses compared to unconjugated and non-irradiated controls in the
Balb/c 4T1 and MCA murine tumor models. Furthermore, RT-VEGF-4-1BB
treatment showed similar anti-tumor effects as CTLa4 mAb with significantly
less systemic toxicity. This approach increased intra-tumoral CD4+ and CD8+
T cells, the CD8+ to Treg ratio, and induced significantly more tumor cell death.
In conclusion, this strategy has been shown to induce potent anti-tumor
immune responses in relevant murine tumor models and significantly improves
the therapeutic index over non-targeted mAbs. Furthermore, radiotherapy can
expand the scope of tumor targeted immune modulation to virtually all solid
malignancies and induce potent abscopal responses. These results provide the rationale for developing clinical grade bispecific aptamers for future testing.

#1701 The novel anti-CD205 antibody drug conjugate (ADC) MEN1309 shows strong antitumoral activity in diffuse large B cell lymphoma (DLBCL).

#1698 Immunoprevention of KRAS-driven lung adenocarcinoma by a multi-peptide KRAS vaccine. Jing Pan1,2, Qi Zhang1,2, Shizuko Sei1,2, Robert H. Shoemaker1,2, Ronald A. Lubet1,3, Yiyan You1,2, Medical College of Wisconsin, Milwaukee, WI;2National Cancer Institute, Bethesda, MD.

Lung cancer remains the leading cause of cancer death worldwide. Mutations in KRAS are detected in up to 30% of lung cancer cases, about 80% of which occur in codon 12, yet no effective therapies specifically targeting mutant KRAS have been developed. Boosting the host immune response to cancer cells by vaccinating against defined tumor-associated antigens (TAAs) as a means of treating established tumors or preventing the development of tumors in high risk individuals such as current or former smokers is an area of intense research. The present study evaluated both immunogenicity and anti-tumor efficacy of a newly formulated multipeptide (peptides 15-17 amino acids long) vaccine target-
ing multiple epitopes of the KRAS molecule in a mouse model of KRAS-
driven lung cancer. Vaccination was performed in the prevention setting in a transgenic mouse model, where mutated mouse Kras (G12D) is conditionally over-expressed in the lungs of mice using a CCSP promoter. A multi-score prediction algorithm was used to identify likely immunogenic epitopes in the KRAS protein sequence. The identified peptides were synthesized and screened in naive mice for immunogenicity. The formulated vaccine contained the top four peptides, which elicited the strongest immunologic response and showed 100% sequence homology between human and mouse. The multipeptide KRAS vaccine was then tested in an inducible CCSP-TetO-KRASG12D mouse model, where the vaccines mixed with the Freund’s adjuvant or adjuvant alone were administered prior to activating the mutant KRAS protein. Our results show the KRAS peptide vaccine exhibited striking efficacy, reducing tumor number and tumor burden by >80% when compared with adjuvant alone. Splenocytes collected from vaccinated animals at the end of the study showed a robust immu-
nologic response to the immunizing peptides. Furthermore, in vitro stimulation of these splenocytes by the vaccine peptides resulted in the secretion of cytokines indicative of Th1 (interferon gamma) and Th17 (IL17) responses but with min-
imal secretion of Th2 related cytokines e.g. IL3 and IL4. In the draining lymph nodes from vaccinated mice rejecting tumors, there was a substantial increase in CD4 cells but a limited increase in CD8 cells. In summary, the multipeptide KRAS vaccine was immunogenic and efficacious in the primary prevention of KRAS-induced lung cancer in mice, indicating that the approach can potentially be used for the prevention of KRAS-driven cancers either alone or in combina-
tion with other modalities.

Proceedings of the American Association for Cancer Research • Volume 58 • April 2017 435

CLINICAL RESEARCH: Adaptive Immunity to Cancer

Tregs as well as routine hematological and biochemical parameters. Results: DTH positive patients and DTH negative patients did not differ with respect to the number of peripheral Tregs, leukocytes, lymphocytes or granulocyte/lym-
phocyte ratio. Whole blood IFN-γ production levels after phytohemagglutinin (PHA) stimulation at baseline in DTH positive patients were significantly higher compared to negative patients (p = 0.0397). Conclusively, we hypothe-
size that whole blood IFN-γ production at baseline is likely to be useful to assess immunologic competence in vaccinated patients with AFTV. Consequently, clinical utility of whole blood IFN-γ production, as immunomonitoring method for patient selection in vaccination with cancer vaccine, is required to investigate in larger clinical studies in the future.
into the left flanks of female NOD-SCID mice; i.v. treatments started with tu-
mors of 250-350 mm³ volume. Results. MEN1309 showed strong cytotoxic ac-
tivity in DLBCL (median IC50 = 300 pm; 95%CI, 200-771), while the IgG-
conjugated DM4 toxin was 100x less active (30 nm; 95%CI, 20-33). MEN1309
induced apoptosis in 17/24 (71%) DLBCL. No difference was seen based upon
DLBCL cell of origin, MYC or BCL2 translocations or TP53 status. MEN1309
activity was highly correlated with its target expression with an inverse corre-
lation between IC50 values and CD205 expression at flow cytometry or RT-PCR
(R = -0.79, P < 0.0001). No correlation was seen between CD205 expression
and IgG-conjugated DM4 activity. MEN1309 anti-tumor activity was in vivo
defined in a DLBCL model (OCL-Ly10) characterized by high CD205 expres-
sion. MEN1309 induced apoptosis at 2.5 and 5 mg/Kg once/3 weeks. Groups of
treated with IgG-DM4 (5 mg/Kg, every 3 weeks) were also used. MEN1309 5mg/Kg eradi-
caled tumors in all mice with a single dose, as also shown by highly significant differences versus control mice (D7, D21, D28; P < 0.01). While all other groups had to be stopped by D35, the
MEN1309 5mg/Kg group skipped the second treatment at D21 because there was
no palpable tumor, and mice resulted cured even 2 months later (Kaplan-
Meier, survival analysis, P < 0.0001). MEN1309 2.5 mg/Kg delayed tumor
growth versus control (D21, P 0.039). Much lower activity was observed with
MEN1309 1.25 mg/Kg (D7, P 0.012) and with IgG-DM4 (D21, P 0.049; D28, P
0.046). Conclusions. In DLBCL models, the novel ADC MEN1309 had strong
in vitro and in vivo anti-tumor activity, which is highly correlated with the expres-
sion of its target.

**#1702 Multimeric anti-DR5 IgM antibody displays potent cytotoxicity in vitro and promotes tumor regression in vivo.** Beatrice Wang, Tasnim Kothambalwala, Paul Hinton, Dean Ng, Avneesh Saini, Ramesh Baliga, Bruce Kety. 1GMBiosciences, Inc., Mountain View, CA

Death receptor 5 (DR5) is a member of the TNF receptor superfamily that
induces apoptosis upon receptor trimerization. It is expressed on many tumor
types and has therefore been an important target for developing antibody based
treatments of epithelial, solid tumors. However several agonistic Anti-DR5 IgG
antibodies that have demonstrated efficacy in preclinical models have been un-
successful in clinical trials, likely due to insufficient receptor crosslinking by
bivalent IgGs. We have developed a multimeric anti-DR5 IgM antibody which has
strong avidity for the receptor. The IgM binds Colo205 cells and triggers
apoptosis, and is 1000-fold more potent than the respective IgG and 100-fold
more potent than crosslinked IgG in vitro. Anti-DR5 IgM displays strong in
vitro potency across a panel of tumor cell lines, including ones that are IgG-
resistant. Anti-DR5 IgM causes tumor regression and delays tumor growth in
various in vivo xenograft models including Colo205, HCT15 and MDA-MB231.
These results support the development of an human anti-DR5 IgM therapeutic
with the potential to treat solid tumors.

Significant clinical and preclinical research has shown that PAMPs- Patho-
gen Associated Molecular Patterns- can trigger an integrated anti-cancer im-
mune response involving both innate and adaptive immunity. Imprime PGG is
a soluble yeast β-1,3/1,6 glucan currently in multiple phase 2 clinical studies in
combination with the immune checkpoint inhibitor (CPI), pembrolizumab.
Preclinical mechanistic research has shown that Imprime PGG can re-polarize
immunosuppressive myeloid cells in the tumor microenvironment and activate
antigen presenting cells to prime antigen-specific CD8 T cells thereby boosting
effectors T cell function and expansion. Based on this ability to activate dendritic
cells and induce type I interferon, we sought to explore the use of Imprime as an
immune activating/antigen-directing scaffold onto which we could attach tu-
mor antigens to drive an antigen-specific T cell based immune response. Imprime
PGG, using T cell receptor transgenic OT-I CD8 and OT-II CD4 T cells to
track responses to OVA, we treated mice with Imprime-OVA intravenously
and examined the expansion and functional quality of the T cell response 7 days later
at the peak of expansion. Following Imprime-OVA treatment, both OVA-spe-
cific CD8 and CD4 T cells underwent vigorous expansion. OT-1 CD8 T cells

**#1704 UPR signaling promotes T-cell dysfunction to prevent immune-mediated cancer cell killing and immune checkpoint therapy resistance.** Yismelin R. Feliz Mosquera, David R. Soto Pantajo, Adam Wilson, Pierre L. Troizio, Katherine L. Cook. 1Wake Forest University, Winston Salem, NC

A critical point in cancer progression is evading recognition by the immune
system. Cancer cells accomplish this by stimulating immune checkpoint signaling on
effectors T-cells. In patients with advanced melanoma treated with immune
checkpoint inhibitors, 3-year survival increased by 20%. While immune check-
point therapies are the first new treatment option for advanced melanoma in
over a decade, their efficacy is limited because resistance often develops. Under-
standing the molecular mechanisms of immune checkpoint inhibitor resistance
is critical to develop combinatorial drug therapy to potentiate therapeutic re-
sponsiveness. The unfolded protein response (UPR) is an endoplasmic reticu-
lon (ER) stress pathway activated when unfolded/misfolded proteins accumu-
late within the ER. Highly secretory cell types, such as T-cells, have larger ER
compartments and elevated UPR component expression facilitating antigen
processing and antigen presentation. The UPR signaling is activated during T-cell exhaustion. Treatment of naive T-cells with DTT, a chemical agent that stimulates ER stress, also induced PD-1 and PERK compared with vehicle-treated T-cells. Gene expression analy-
sis of T-cells indicates that co-culture with cancer cells, not CD3/CD28 activa-
tion, elevates T-cell UPR gene expression. Further, induction of ER stress
through low-dose DTT treatment decreased cytotoxic T-cell mediated cancer
cell death, further supporting our hypothesis of ER stress inducing T-cell ex-
haustion. Inhibition of PERK by RNAi in TALL-104, a human cytotoxic T-cell
line, enhanced T-cell mediated cancer cell clearance when exposed to ER stress-
inducing agents, suggesting that PERK may represent a novel target to prevent
T-cell exhaustion or restore T-cell effector capabilities. PERK inhibition in the
presence of antibody-conjugated melanoma cells did not negatively affect intra-
tumoral killing, suggesting that systemic PERK inhibition may be an effective therapeutic strat-
 egy to enhance anti-tumor immune responses. Matched PBMC from melanoma
patients before treatment or after ipilimumab therapy resistance indicated in-
creased UPR signaling components in PBMC samples from patients after ipili-
numab resistance when compared with PBMC samples before therapy, sup-
porting a novel role UPR signaling in anti-CTLA4 therapy resistance.

**#1705 Slide-based multi-parametric immunophenotyping of human blood samples by cyclic immunofluorescence using the Accucyte-CyteFinder system.** Jia-Ren Lin, 1 Lance U’Ren, 2 Gregory J. Baker, 1 Joshua J. Nordberg, 2 Zoltan Maliga, 1 Jackie L. Stilwell, 2 Eric P. Kaldjian, 2 Peter K. Sorger 1. 1Harvard Medical School, Boston, MA; 2Rarecyte, Inc, Seattle, WA.

Immunophenotyping is an approach to measuring the abundance and func-
tional state of immune cells as a means to understand mechanisms of homeo-
 stability, identify biomarkers of disease, and measure therapeutic and adverse re-
sponses to drugs such as immune checkpoint inhibitors. Such studies are
conventionally performed using flow cytometry together with combinations of
immunomarkers that allow for identification of cell type, maturation state, and
activation status. Here we describe a method for profiling circulating human
leukocytes with highly-multiplexed immunofluorescence microscopy. The
method has distinct advantages over flow cytometry in that it has greater sensi-
tivity for detecting rare cell populations, allows for repeat analysis and long-term
storage of precious biological samples, and obviates the requirement for spectral
deconvolution. Using an open-source multiplexed immunofluorescence protocol referred to as cyclic immunofluorescence (CyCIF), and commercially available reagents and instruments (AccuCyte and CyteFinder; RareCyte Inc.), we show that imaging can provide 16-plex, single-cell intensity data in addition to information on cellular morphology. Analytic technologies borrowed from the field of synthetic biology as well as VISNE (cytometric and image-based phenotypic analysis and high-dimensional biomarker discovery). Current efforts now aim to expand the number of validated immune targets and combine imaging with single-cell picking and sequencing technologies.

### #1706 Neoantigen frequency as an independent prognostic factor in patients with clear cell ovarian carcinoma (CCOC)

Royuki Aburatani,1 Kazuhiro Kakimi1, Imai,2 Kayo Asada,1 Yuji Ikeda,2 Takahiro Karasaki,1 Keiichi Fujiwara,2 Hiroyuki Abaratani,2 Kazuhiro Kakimi1,2 The University of Tokyo Hospital, Tokyo, Japan; Saitama Medical University International Medical Center, Saitama, Japan; The University of Tokyo, Tokyo, Japan.

Aim: Neoantigens derived from tumor-specific somatic mutations are thought to be targets for antitumor immune responses. It has been reported that mutation/neoantigen burdens correlate with prognosis of certain cancers under checkpoint blockade immunotherapy. In clear cell ovarian carcinoma (CCOC), checkpoint inhibitors provided durable responses in a subset of patients. To test whether the same may apply in CCOC patients, who are not on immunomodulatory therapy, we investigated the number of mutations or neoantigens, and immune signature of CCOC by integrated molecular analysis. Methods: We performed exome sequencing and expression array for 74 CCOC patients. Candidate neoantigens derived from mutations were identified by MHC class I binding prediction algorithm (NetMHCpan v2.8). Immune signature was assessed by gene ontology and gene set enrichment analyses for immune cell lineage or cytokine. Results: Neither number of missense mutations nor neoantigens correlated with clinical outcomes in CCOC. However, we found neoantigen frequency defined here as the number of neoantigens per missense mutation correlated with clinical outcomes. A Cox multivariate regression analysis demonstrated that high neoantigen frequency correlated with decreased progression free survival (PFS) and was an independent prognostic factor ($p = 0.032$). Immune-related genes including those related to effector memory CD8 T cell were dominantly expressed in tumors with low neoantigen frequency. This may suggest that CD8 T cell-mediated immunity is constantly eliminating immunogenic subclones expressing neoantigens (immunoediting). In contrast, we observed increased ratio of CTLA-4 and PD-1 to CD8A expression in tumors with high neoantigen frequency. This may imply that restricted antitumor immunity by immunoinhibitory mechanism result in the limited immunoediting and poor prognosis Conclusions: Neoantigen frequency underlying immunoediting in CCOC is an independent prognostic factor for clinical outcome and may become a potential candidate biomarker for an immunomodulatory-based treatment.

### #1707 Longitudinal and quantitative imaging of the localization, expansion, and contraction of tumor targeted adaptively transferred T cells.

Yogendra Vedvyas, Enda Shevlin, Marjan Zaman, Irene M. Min, Moonsoo M. Jin, Weill Cornell Medicine, New York, NY.

Introduction: Current methodologies for monitoring adoptive cell transfer (ACT) rely on soluble markers and T cell quantity in serum reflecting mixed responses of T cell efficacy or toxicity. Quantitative, longitudinal T cell visualization can directly probe T cell distribution, expansion, and off-tumor localization, and provide rational to predict therapy successes or failures. To enable real-time PET imaging of adoptively transferred T cells in a manner directly translatable to clinics, we utilized a genetic reporter, somatostatin receptor 2 (SSTR2) and a clinically approved radiotracer to quantitatively and longitudinally visualize whole body T cell distribution and anti-tumor dynamics. SSTR2 imaging was also applied to chimeric antigen receptor (CAR) T cells in a setting of solid cancer. Methods: We developed subcutaneous tumors with a mixture of SSTR2 positive and negative Jurkat T cells, ranging from 0 to 100%. From this model and PET/CT imaging of SSTR2 radiotracer uptake, diagnostic performance of our imaging technique was rigorously defined. To apply SSTR2 imaging to CAR T cells, a new lentivirus vector was designed to allow dual expression of SSTR2 and CAR. Longitudinal PET/CT and luminescence imaging was performed to concurrently measure the rate of tumor growth/killing and T cell expansion and contraction. Blood was also collected to correlate serum cytokines with T cell distribution at on- and off-tumor sites. Histology was performed to confirm the validity of SSTR2 imaging of CAR T cells and relating it to T cell activity. Results: Our T cell imaging technique was found to provide 1% limit of detection (one T cell in one hundred neighboring cells or $\sim 4x10^3$ cell/cm$^3$ in solid tissues) with 95% specificity and 87% sensitivity. When applied to CAR T cells in solid cancer, a biphasic T cell expansion and contraction was observed in survivors where a temporal change of T cell density closely followed the change in tumor burden with some time delay. In contrast, nonsurvivors displayed unrelenting increases in tumor and T cell burden, indicating that the expansion/contraction ratio is an important indicator of prognosis. Tumor weight and mortality rates were in line with T cell activity. Conclusion: Our study is the first high quality and quantitative, longitudinal imaging of T cells, correlating T cell dynamism with therapy and toxicity responses in subjects. Correlative changes in cytokines and T cell density can be further developed for early prediction of the onset of cytokine release syndrome as well as for screening adjuvant therapies to augment CAR T cell efficacy against solid cancer. Owing to the use of a human gene and FDA-approved radiotracer, our imaging technique can be directly applicable to CAR T cells and other T cell based therapy. We are currently preparing for a phase I clinical study for real-time imaging CD19 CAR T cells in patients.

### #1708 Effective and reversible control of anti-tumor activity in vivo with a drug-regulated CAR T cell platform (dARIC).

Wai-Hang Leung,1 Michael Cerro,2 Holly Horton,2 Joel Gay,3 Tracy VandenBerg,4 Jordan Jarjour,1 Alexander Astrakhan,1,2 bluebird bio, Seattle, WA; 3 bluebird bio, Cambridge, MA.

Redirecting T cells against tumors by introducing antigen-specific chimeric antigen receptors (CAR) has shown promising clinical results as a potential treatment strategy for certain cancers. However, traditional CARs are constitutively active, resulting in the persistent loss of all target cells (including off-tumor activity) in the event of antigen loss, and enhanced potential of excessive T cell activation to drive cytokine release syndrome. While “off switches” based on suicide cassettes or other depleting cell approaches are in development, such systems by definition result in the elimination of the therapeutic cells. Here we have developed a novel drug-regulated CAR-based antigen targeting approach termed Dimerizing Agent Regulated Immune-receptor Complex (dARIC) that aims to: i) minimize the long-term toxicity of CAR T treatment; ii) allow the targeting of previously inaccessible antigens; and iii) be amenable to multiplex antigen targeting. The dARIC platform separates the antigen recognition and signaling functions of a CAR into two distinct polypeptides that are further engineered to contain the FKP712 and FRB small-molecule regulated dimerization domains. In the absence of the dimerizing drug (e.g. rapamycin or the non-immunosuppressive rapalog, AP21967) the dARIC system lacks signaling activity. However, the addition of dimerizing agent drives the interaction of the two dARIC subunits, fully restoring CAR function. Using CD19 as a model system, we show that treatment of CD19-DARIC+ T cells with rapamycin or AP21967 results in equivalent cytokine toxicity, cytokine production and proliferation compared to a standard CD19-targeting CAR. Importantly, CD19-DARIC T cells maintained by picomolar levels of rapamycin and exhibited a higher antigen sensitivity than standard CD19-CAR T cells in vitro. In an aggressive CD19+Nalm-6 xenograft tumor mouse model, CD19-DARIC T cells did not exhibit anti-tumor activity in the absence of dimerizing agent. However, CD19-DARIC treated mice that received either low-dose rapamycin or AP21967 showed an equivalent level of tumor control compared to standard CAR treated controls. This activity was dependent on the presence of the dimerizing drug, as cessation of drug treatment resulted in the loss of CD19-DARIC T cell activity and the expansion of Nalm-6 tumors cells in the DARIC T cell treated mice, consistent with the ability to switch off CD19-DARIC T cells in vivo by withdrawing drug. Taken together, these results highlight the potential of the DARIC platform to facilitate the regulation of CAR T cell function both in vitro and in vivo.

### #1709 Targeting immune checkpoint therapy to the lung tumor microenvironment.

Allison S. Cohen,1 Michael L. Doligalski,1 Hong Zheng,2 Narges K. Tafreshi,1 Veronica Estrella,1 Nella Delva,1 Jonathan Nguyen,1 Amer Beg,1 Mark L. McLaughlin,2 David L. Morse1.1 ‘H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL; 2West Virginia University, Morgantown, WV.

Lung cancer is the leading cause of cancer deaths worldwide. Many lung cancer patients are diagnosed with advanced disease. These patients have a low 5-year survival rate and limited treatment options. Novel therapies, which target biomarkers that are overexpressed in lung cancer but have baseline expression in benign tissue, are desperately needed. The goal of this work was to develop a targeted agent for immune checkpoint therapy of lung cancer. Recently, immune checkpoint inhibitors have been approved for use in lung cancer and many more are being tested in clinical trials. The current immune checkpoint inhibitor agents are not tumor-targeted. Targeting the immune checkpoint inhibitor to tumor cell surface markers should concentrate the conjugate in the tumor microenvironment and enhance the immune response in the tumor while...
Reducing the systemic dosages needed, resulting in lower systemic toxicity. The delta opioid receptor (DOR) is expressed in some lung cancers, but is not expressed or is expressed only at basal levels in normal tissues outside the brain. We have previously synthesized fluorescently-labeled DOR-targeted imaging agents based on a synthetic peptide antagonist (DORL). These targeted fluorescent agents have high affinity and selectivity for DOR, and exhibit good pharmacokinetic (PK) and biodistribution (BD) profiles, i.e. specific tumor uptake with rapid systemic clearance and no uptake in tissues of concern, e.g. brain. We are now developing lung cancer-specific immunothrombosis agents that target the DOR by conjugating DORL to immunomodulatory molecules. In the current work, we synthesized a fluorescently-labeled DOR targeting ligand and conjugated it to an anti-PD1 antibody (DORL-PD1). We synthesized immunomodulators with several targeting ligand-to-antibody ratios (TARs). We engineered murine lung cancer cells to constitutively express the DOR. By lanthanide time-resolved fluorescence (LTRF) competitive binding assays, we have shown that the agents have high avidity for the DOR in vitro with higher TARs resulting in higher binding avidity. We characterized the uptake of DORL-PD1 in vitro using live-cell fluorescence microscopy. Using syngeneic engraftment tumor models in immunocompetent mice, we performed longitudinal fluorescence imaging studies to determine the agent circulation time (PK), tumor selectivity and tissue distribution (BD). Immune checkpoint efficacy studies were performed using the DOR negative mouse tumor models. In conclusion, we have synthesized fluorescent DOR-targeted immune checkpoint therapy agents, DORL-PD1; demonstrated avidity and selectivity for the DOR in vitro and in vivo; and immune checkpoint therapy efficacy in vivo. Future studies will evaluate the efficacy of DORL-PD1 in immune competent mice bearing DOR positive tumors. These agents could be useful for increasing the efficacy and reducing systemic toxicity of immune-checkpoint therapy of lung cancer.

#1710 Providing confidence around computational tissue analysis using heterogeneity assessments. Carsten Schnatwinkel,1 Daniel Rudmann,1 Fannke Aeffner,1 Jasmeet Bajwa,1 Natalie Hutnick,2 Michael Sharp,2 Gerry Chu,2 JD Alvarez,3 Flagship Biosciences Inc., Westminster, CO; 1Jansen R&D, Spring House, PA.

Background: Though the techniques to interrogate the appearance of a biomarker in tissue sections have greatly advanced, there are limitations as to how representative an analysis of a tissue section is compared to the entire diseased tissue. Depending on the heterogeneous expression level of a biomarker, tissue sampling can result in different interpretations of the biomarker’s appearance, and hence could potentially lead to a false therapeutic intervention. Hypothesis: Digital image analysis has demonstrated tremendous value in quantifying many features related to biomarker distribution and expression in biological tissues. The information can be collected for various indications and biomarkers and a phenotypic signature can be established that describes a biomarker representation across indications. Moreover, the assessment of new samples can be compared to the established phenotypic signature and a confidence score applied in support to the determined endpoint. Approach: For a proof of concept, 6 prostate cancer samples were processed and a single section was collected after every 100microns. A total of 7 sections per sample were stained for the lymphocyte marker CD3, and the number of positive target cells were determined in the tumor and tumor microenvironment using tissue Image Analysis (tIA). To assess how indicative the evaluation of a single tissue section would be for the entire tumor, the heterogeneity level was determined on the section level as well as by random grid analysis on each individual section. Both criteria were utilized to define an indication and biomarker specific confidence interval and heterogeneity score. Conclusion: The combination of IHC and tIA is a powerful tool to convert complex data into meaningful interpretations. tIA is a also a capable tool to catalogue valuable information about the biomarker’s expression pattern across different disease stages and hence could be used to evaluate how representative a single biomarker evaluation is in the grand scheme. Ultimately, we demonstrated a technique that can be applied to any biomarker and would assist in guiding therapeutic decisions.

CLINICAL RESEARCH: Liquid Biopsies 1: Circulating Tumor Cells

#1712 Detection of circulating tumor cells in stage IV non-small cell lung cancer. Stephanie N. Shishido,1 Lyudmila Bazhenova,2 Anders Carlsson,1 James Hicks,1 Peter Kuhn1.

1University of Southern California, Los Angeles, CA; 2University of California, San Diego, La Jolla, CA.

Non-Small Cell Lung Cancer (NSCLC) is the most common cause of cancer related deaths in both men and women. Some lung cancer patients have a unique challenge of a tissue access due to tumor location or baseline lung disorders such as emphysema and chronic obstructive pulmonary disease (COPD). Liquid biopsy technologies can overcome tissue assess difficulties. However, as of today there are no commercially approved assays for CTC enumeration in lung cancer. Multiple non-commercial assays exist and some show correlation of CTC enumeration and changes in CTC counts on therapy with prognosis and response to therapy. Outside of absolute number of CTC there is little published data regarding prognostic significance of CTC morphologic heterogeneity in late stage NSCLC and its ability to predict treatment outcomes. Here we investigate CTC counts in 81 patients with stage IV NSCLC using a fluid phase biopsy and high definition (HD) diagnostic pathology imaging of all nucleated cells. HD-CTCs were detected in 51 (63%) patients at initiation of therapy with a median of 2.20 (range 0-509.20) and a mean of 26.21 HD-CTCs/mL (+15.64). There was no correlation between the absolute number of HD-CTCs at the time of initiation of new therapy and patient outcomes. A subset of 25 patients was further analyzed to determine the significance of HD-CTCs kinetics, which may follow three distinct patterns: an increase in HD-CTCs with therapy, unchanged HD-CTCs numbers, and a decline in HD-CTCs numbers. Patients that experienced an increasing, stable, or decreasing HD-CTCs profile had an overall change of 118.40, 0.54, and 81.40 HD-CTCs/mL respectively during the first 3 months. The overall survival (OS) for increasing profiles was 31.08 months (+13.08, median 32.46, range 15.11-43.50), for stable profiles OS was 8.82 months (+3.57, median 7.23, range 3.91-19.75), and for decreasing profiles it was 15.30 months (+6.39, median 14.06, range 3.81-28.06) months. CTCs are identifiable in patients with stage IV NSCLC, but correlation of absolute HD-CTC counts with disease progression was not statistically significant. However, change in CTC counts were predictive of OS in patients with metastatic lung cancer receiving chemotherapy.
CTCs are used as a surrogate source of tumor material in solid tumors. Clinical applications of CTCs as liquid biopsy comprise the monitoring of molecular alterations during tumor progression and dynamic evaluation of molecular markers of treatment response. The FDA-cleared method to isolate CTCs in cancer patients (Cell Search) is based on positive selection of EpCAM expressing cells. However, the performance of non-selective enrichment (NSCLC) as it identifies CTCs in only 7% of the subjects, failing to show any prognostic relevance. Down-regulation/loss of epithelial markers to isolate (EpCAM) and identify (cytokeratin, CK) CTCs could in part explain the low CTC yield obtained in NSCLC with approaches based on epithelial markers expression. To overcome this challenge we used size-based CTC enrichment (ISET filters) from NSCLC patients’ peripheral blood. As a positive identifier of CTCs we used transferrin receptor 1 (TfR) which is a cell membrane-associated protein, that mediates intracellular iron uptake, and which is expressed at low levels in many normal tissues but over-expressed in cancer cells. We first analyzed TfR protein expression by immunofluorescence in a panel of NSCLC cell lines and in healthy donor leukocytes. While all NSCLC cell lines analyzed were positive for TfR expression, none of the leukocytes expressed the receptor. Moreover, TfR expression was detected also in EpCAM negative NSCLC cell lines. To determine the clinical applicability of this novel CTC identifier, we determined TfR expression in CTCs isolated from peripheral blood of 35 metastatic NSCLC patients using the ISET filter technology. The isolated CTCs were stained for TfR, CK, CD45 and DAPI. For each patient, one additional ISET filter was stained with Giemsa for morphologic analysis by a pathologist. By using the classic panel of CTC identifiers markers (CK+/CD45-/DAPI-), CTCs were identified in 4/34 (11%) patients, while by using TfR as positive identifier (TfR+/CD45-/DAPI+) CTCs were identified in 31/35 (88%) subjects. The morphologic review of Giemsa stained filters confirmed the presence of tumor cells in 28/34 (82%) samples [0-217 CTCs/sample]. Interestingly, patients with > 6 TfR+ CTCs had a worse overall survival (OS) than patients with < 6 TfR+ CTCs [p=0.048 Log Rank (Mantel-Cox)]. OS did not significantly differ using the same cutoff with CTCs defined based on CK or Giemsa staining. Overall, our data indicate that TfR is a promising biomarker for the detection of CTCs in NSCLC CTCs, superior to CK or EpCAM. Our data also suggest that TfR may potentially identify CTC subpopulations with a significant prognostic role in NSCLC. We are currently isolating TfR+ CTCs from early stage and metastatic NSCLC patients for further molecular characterization and determination of clinical significance.

**#1714 Translating CTCs for clinical use: melanoma patient-derived CTCs evolution in xenografts.** Monika Vishnoi,1 Haown N. Liu,1 Debasish Boral,1 Wei Yin,2 Marc L. Sprouse,3 Jean P. Thiery,2 Isabella C. Glitza,3 Dario Marcelli4, Houston Methodist Research Institute, Houston, TX; Cancer Science Institute of Singapore, National University of Singapore, Singapore, Singapore; The University of Texas MD Anderson Cancer Center, Houston, TX.

Circulating tumor cells (CTCs) are known to disseminate from primary/metastatic tumors, survive in the circulation, and develop capability to colonize distant organs. Dissecting CTC heterogeneity is therefore crucial to provide improve prognostic and diagnostic tools (concept of “liquid biopsy”). However, melanoma patient blood from peripheral blood of melanoma patients clinically diagnosed with or without brain metastasis (MBM) by multi-parametric flow cytometry; and analyzed CTC heterogeneity in xenografts by longitudinal capturing and interrogation at the single-cell level (DEPArray™ platform). First, we evaluated the presence of melanoma CTC subpopulations in Lin-negative cells and developed Lin-negative murine xenograft models. Human-cell derived melanoma metastasis in xenografts confirmed that CTCs require metastasis-potentiating factors present in the Lin-negative population. Second, we performed multi-parametric flow cytometry to isolate human-derived HLA+/Melan A+/− CTCs/DTCs population from murine blood and bone marrow at T1 and T2 phases of metastasis. We interrogated the differential levels of CTCs/DTCs in HLA+/Melan A+ cell population and established their neoplastic identity by genetic profiling and the expression of melanoma markers at single-cell level. Third, we dissected longitudinal transcriptional signatures of CTCs vs DTGs in association with MBM onset. We assessed the comprehensive EMT scores of CTCs and DTGs transcriptomics and identified the pathways associated with CTC/DTCs dynamic functional states depending upon melanoma progression. Collectively, this study provide important insights to identify novel EMT-related biomarkers of MBM progression. Further elucidation of these CTC biomarkers and properties may provide novel therapeutic strategies that can be clinically useful in melanoma patients which are yet to develop MBM.

**#1715 EGFR mutation detection in ctDNA, Vortex-enriched CTCs and comparison to tumor tissue in non-small-cell-lung cancer (NSCLC) patients.** Haiyan E. Liu,1 Meghah Vuppalapaty,2 Clementine A. Lemaire,2 Charles Wilkerson,3 Steve C. Crouse,3 Jonathan W. Goldman,3 Elodie Sollier-Christin3, Vortex Biosciences, Menlo Park, CA;3 David Geffen School of Medicine at UCLA, Los Angeles, CA.

Background: Lung cancer is the leading cause of cancer-related mortality worldwide. Epidermal growth factor receptor (EGFR) tyrosine kinase inhibitor (TKI) therapies, based on the evaluation of EGFR mutation, have shown dramatic clinical benefits. EGFR mutation assays are mainly performed on tumor biopsies, which carry risks and expense and are not always successful. In order to identify the development of secondary EGFR mutations, which cause resistance to 1st and 2nd generation TKI’s and an indication for therapy with a 3rd generation drug, effective and non-invasive monitoring is needed. Liquid biopsy biomarkers, such as circulating tumor cells (CTCs) and circulating tumor DNA (ctDNA), allow such monitoring over the course of the therapy. Interestingly, ctDNA or CTC analysis alone had less sensitivity vs. combining both, with a genotyping of 70% and 80% for CTCs and ctDNA respectively, but 100% when combined2. Vortex technology is a platform enabling label-free capture of CTCs from blood samples and genomic assays downstream3. The aim of this study is to demonstrate the sensitivity of a combined CTC and ctDNA assay through Vortex using blood samples spiked with molecularly-characterized lung cancer cell lines and then to apply this technique to matched blood and tumor samples from NSCLC patients. Method: Lung cancer cell lines with different EGFR mutations (A549: wild type, H1975: L858R+ and T790M+; HCC827: 19del+) were used to validate our CTC workflow. Blood samples and matched tumor tissues were collected from NSCLC patients. Plasma was extracted first for ctDNA assay. CTCs were isolated from the plasma-depleted-blood using Vortex technology, immunostained (CK, Vimentin, CD45) and enumerated. DNA from CTCs, plasma and matched tumor tissue was analyzed for EGFR mutations 19del, L858R and T790M using the ctEGFR kit from EntroGen. Results: Mutant DNA could be identified at a quantity as low as 0.5 ng (−8 cells), with a sensitivity ranging from 0.1% to 2% for a total DNA varying from 25ng (~4 CTCs among 4000 WBCs) to 1ng (~4 CTCs among 200 WBCs). We demonstrated the ability of Vortex technology to enrich CTCs from metastatic NSCLC patients. Processing of plasma-depleted-blood showed the same capture efficiency when compared to whole blood. This makes possible the detection of EGFR mutations on CTC samples collected by Vortex technology. −1 NSCLC patients are currently enrolled in this study and results will be presented at AACR. Conclusion: The ctEGFR mutation assay performed well on both Vortex-enriched CTCs and ctDNA, enabling a low cost approach to analyze EGFR mutation from a single blood tube. This non-invasive EGFR mutation analysis will be potentially a useful tool for monitoring treatment and medication guidance of NSCLC patients. 1. Cala-Guirós M. et al. **#1716 GSTP1 promoter methylation in in-vivo isolated CTCs from high-risk prostate cancer patients.** Athina N. Markou,1 Panagiotis Parasevopoulos1, Mari-fili Lazaidou,1 Shukun Chen,2 Thomas Krones,3 Joanna Budna,4 Andra Kuske,5 Tobias M. Gorges,3 Maciej Zabel,6 Peter Sedlmayr,7 Cathe-rine Alia Panabieres,8 Klaus Pantel,9 Evi Liandrou6,1 Univ. of Athens, Athens, Greece; 1Institute for Cell Biology, Histology and Embryology, Graz, Austria; 2Poznan University of Medical Sciences, Poznai, Poland; 3University Medical Center Hamburg-Eppendorf, Hamburg, Germany; 4Poznan University of Medical Sciences, Poland; 5University Institute for Clinical Research (IURC), Laboratory of Rare Human Circulating Cells, University Medical Centre of Montpellier Saint-Eloi Hospital, EA4305, France.

Introduction: Glutathione S-transferase I (GSTP1) has been reported to function as tumor suppressor gene in various types of human cancers. GSTP1 inactivation is associated with CpG island promoter hypermethylation in the majority of prostate cancers (PCs). The initiation of minimal residual disease (MRD) and especially the detection of circulating tumor cells (CTCs) in patients’ peripheral blood represent a negative prognostic parameter for recurrence-free survival. The aim of the present study was to assess the methylation status of the GSTP1 gene in CTCs that were isolated, using the CellCollector® (GILUPI, GmbH), a novel clinical device designed for the in vivo isolation of EpCAM-positive CTCs. Patients and methods: In vivo isolation of CTCs was performed...
by using CellCollector® from high-risk prostate cancer patients (n = 97) and 20 healthy volunteers. For all these patients, the Ab coated region of the CellCollector® was washed in PBS, cut, and stored in Trizol reagent till analysis and DNA was further prior to the analysis isolated DNA was modified by sodium bisulfite (SB) and subjected to a real time MSP assay specific for GSTP1 methylation. The peripheral blood and cell DNA was isolated and amplified using bisulfite DNA analysis by Immunostaining and the CellSearch® system. Results: All DNA samples were first checked for their quality. Based on the quality evaluation of all available DNA samples, only 63 DNAs were further qualified for analysis. GSTP1 promoter was found methylated in 12/63 (19%) the EPcAM positive fraction of in-vivo isolated CTCs. Moreover, in 5/12 (41.7%) patients for which GSTP1 promoter was also found methylated, CTCs were also detected by the CellSearch® system. In all cases, peripheral blood was also collected and analyzed for GSTP1 promoter methylation. In all cases, GSTP1 promoter methylhylation in in-vivo isolated CTCs should be prospectively validated as a novel tumor biomarker for prostate cancer patients in a large cohort of patients. Acknowledgments: This research has been co-financed by the European Union (European Regional Development Fund = ERDF) and Greek national funds through the Operational Program “Competitiveness and Entrepreneurship” of the National Strategic Reference Framework (NSRF) - Research Funding Program: “ERA-NET on Translational Cancer Research (TRANSCAN)” Joint Transnational Call for Proposals 2011 (JTCC 2011) on: “Validation of biomarkers for personalised cancer medicine.

#1717 Orthogonal identification of circulating tumor cells (CTCs) using single cell low pass whole-genome sequencing (WGS) and copy-number alteration (CNA) analysis. Gareth Morrison,1 Valeria Sero,1 Yucheng Xu,1 Jacke Pinski,1 Sue Ingles,1 David Quinn,1 Claudio Forcato,1 Genny Buson,1 Chiu-Ho Pinski,1 Sue Ingles,1 David Quinn,1 Claudio Forcato,1 Genny Buson,1 Chiu-Ho Webb,5 Kyle Horvath,1 Aditi Khurana,1 Gianni Medoro,1 Suman Verma,1 Matthew Moore,4 Philip Cotter,4 Nicolò Manaresi,3 Farideh Bischoff,2 Amir Goldkorn1.1 University of Southern California, Keck School of Medicine, Norris Comprehensive Cancer Center, Los Angeles, CA; 2Menarini Silicon Biosystems Spa, Bologna, Italy; 3Menarini Silicon Biosystems Inc, San Diego, CA; 4Research DX, Irving, CA; 5University of California, Irvine, CA.

Introduction: Presence of circulating tumor cells has prognostic value in multiple malignancies, and molecular analysis of CTCs is currently ongoing in numerous clinical trials. Most CTC enrichment methods rely on standard epithelial and leukocyte markers (CK+CD45-), so recovered cells are assumed to be of epithelial origin but never shown to be bona fide tumor cells. Conversely, atypical cells lacking the characteristic marker profile may not be analyzed, even though they may represent important tumor subpopulations. Here we evaluate a rapid, non-exhaustive, and cost-effective first-pass genomic analysis of individual candidate CTCs. This approach allows efficient upfront CNA-based confirmation of CTCs as cells of tumor origin, while leaving abundant DNA for deeper subsequent analysis in cells of interest. Methods: Whole peripheral blood of metastatic prostate cancer patients was enriched for CTCs using the CellSearch® system (Janssen Diagnostics) under an IRB-approved protocol, and 5 samples with >5 CTCs were selected for further study. Next, the DEPArrayTM v2 system (Menarini Silicon Biosystems) was used to identify and isolate single CTCs (CK+CD45+CD45-), and paired white blood cells (WBCs; CK+CD45+CD45+DAP1+) from the enriched samples. In addition, cells negative for both cytokeratin and CD45 but with characteristic malignant morphology (large with high nuclear-cytoplasmic ratio) were isolated. Recovered single cells were whole-genome amplified with Ampli1™ WGA and quality controlled by Ampli1 QC. Ampli1 LowPass kit was then used to prepare NGS libraries for absolute quantification by low-pass WGS. Results: Thirty-three single CTCs (CK+CD45+DAP1+) and 30 WBCs (CK+CD45+DAP1+) were isolated. Single-cell WGA products with high Genome-Integrity Index (QC score ≥3) were prioritized for CNA analysis. Ampli1 LowPass data demonstrated copy number gains/losses confirming tumor origin of the CK+ cells, while WBCs showed a normal profile. In addition, the cells having non-conventional phenotype also demonstrated copy number alterations consistent with tumor origin. Discussion: We demonstrate a WGA and low-pass WGS approach on single CTCs sorted from enriched peripheral blood, which offers a dual benefit: i) it allows rapid, non-exhaustive upfront identification of bona fide tumor cells for further study, and ii) it reveals genetic similarities and diversities (a vis a vis copy number alteration) across CTCs of classical as well as non-conventional phenotypes, which may better represent clonal diversity. In a clinical setting, this molecular approach may be more effective for reliably identifying and characterizing heterogeneous CTCs, yielding profiles that more accurately reflect disease evolution and inform treatment strategies.

#1718 RT-qPCR gene expression analysis of CTCs isolated through an epitone-independent enrichment microfluidic device in patients with head and neck squamous cell carcinoma. Martha Zavridou,1 Areti Strati,2 George Koutsodimitri,2 Amanda Psyrri,2 Evi Lianidou1.1 Univ. of Athens, Athens, Greece; 2Atikkon University Hospital, Athens, Greece.

Background: Molecular characterization of circulating tumor cells (CTCs) is very challenging since these cells are rare, and the amount of available sample for their analysis is very limited. Moreover, CTC are highly heterogeneous and enrichment technologies based on EpCam expression present the risk of missing EpCam-negative CTCs. The Parsortix system (ANGLE plc, UK), is a novel microfluidic technology platform designed for marker-independent capture of CTCs. In this study we perform the first time the Parsortix system to isolate CTCs from patients with Head and Neck Squamous Cell carcinoma (HNSCC), and proceeded to downstream molecular characterization through RT-qPCR gene expression analysis. Methods: Peripheral blood samples (10 mL) from head and neck squamous cell carcinoma (HNSCC) patients (n = 19) and healthy donors used as a control group (n = 10) were used for the isolation of CTCs using the Parsortix device. Enriched CTCs were harvested in Trizol reagent, followed by extraction of total RNA and cDNA synthesis. RT-qPCR was performed in the LightCycler (Roche) for the following gene targets: PD-L1, VIM, TWIST, EGFR, and B2M (used as a reference gene). The expression levels of PD-L1, VIM, TWIST and EGFR were normalized using the 2 ΔΔCt approach in respect to the expression of B2M. Results: All samples analyzed were of excellent RNA quality as the quality assessed by B2M, Actin and GAPDH expression. PD-L1 over-expression was detected in 5/19 (26.3%) samples, VIM was overexpressed in 3/19 (15.7%) and TWIST-1 in 1/19 (5.3%) sample, while EGFR expression was not detected in any patient (0/19, 0%). These are preliminary results and these percentages may change, since the number of samples that we are analyzing is continuously increasing. Conclusions: This preliminary study is showing for the first time that RT-qPCR can be successfully used for the molecular characterization of CTCs isolated by the label-free Parsortix microfluidic device in HNSCC. Overexpression of individualized immunotherapy important biomarkers such as PD-L1 in CTCs of HNSCC patients could be of significant clinical importance for the selection and follow up of these patients.

#1719 Dual-profiling of CTC and exosome from the cultured circulating tumor cells using stimuli-responsive degradable hydrogels. Yoon-Tae Kang,1 Young Jun Kim,1 Tae Hee Lee,1 Jae-Uil Shim,1 Young-Ho Cho1.1 KAIST, Daejeon, Republic of Korea; 2Cell Bench Research Center(SEMCELL), Daejeon, Republic of Korea.

Introduction: Liquid biopsy based on sub-micron or nanosize particles in human body fluid have been received vast attention due to their non-invasive characteristics and enabling multiple check-up. Circulating tumor cells (CTCs), as well as exosome are the most promising markers in liquid biopsy, however, dual isolation and profiling have been hampered due to their size difference and limited quantity for analysis. We proposed the novel and simple methods for both isolation and study their similarity between them. Using the label-free CTC filtration device and anti-CD63 antibody-conjugated degradable hydrogel, the CTCs and the CTCs-derived exosome are specifically isolated, and each samples were followed by molecular study after recovery. This versatile platform facilitates the comprehensive study of two biomarkers with reflecting their inherent characteristics, thus paving the way for revealing their roles in cancer progression and metastasis. Methods: In order to make stimuli-responsive degradable hydrogel, poly (vinyl alcohol) and alginate were mixed under constant stirring at 85 °C. The mixture was poured into the mold and dried for 24 hours. Then, the dried sheet was immersed into 100 mM calcium chloride solution to achieve gelation through ion-structural interaction. Subsequently, the anti-CD63 antibody was immobilized onto the prepared hydrogels via cross-linking. For the dual-profiling, the hydrogel and the filters containing the captured breast cancer cells by microfiltration were incubated with the exosome-depleted cell culture media for 6 hours. The captured cells were released from the device and the hydrogels were degraded by adding EDTA. The cell and exosome lysate were prepared using RIPA buffer at 4 °C. The supernatant was collected by centrifugation followed by western-blot assay. Four different markers, including exosome-specific marker (CD63), cancer-associated markers (EpCAM, vimentin), and a housekeeping marker (β-actin), were used. Results: All exosome and cell samples highly expressed the housekeeping marker. Especially, two exosome samples dissociated from the hydrogel showed CD63 predominantly, which support the secretion of exosome from the cancer cells. The samples from the released cancer cells from the device did not express CD63 remarkably. To verify the phenotypical similarity between cell and exosome, expressions of the epithelial marker (EpCAM) and mesenchymal marker (vimentin) were examined. The exosome and cell from MCF-7, epithelial cancer cell, showed higher expression of EpCAM then
CLINICAL RESEARCH: Liquid Biopsies 1: Circulating Tumor Cells

vimentin. On the contrary to this, the samples from MDA-MB-231, mesenchymal cell, showed higher vimentin expression then EpCAM. Discussion and conclusion: We showed that exosome follow the phenotypical characteristics of mother-cells. This dual profiling would be helpful for in-depth study of cancer with consideration of its heterogeneity and complexity.

#1720 Circulating tumor cell (CTC) enrichment and DNA mutation detection by sequencing. Ruijin Kou,1 Eric Zhao,2 Conrad Leung,1 Priya Gogoi,2 Will Chow,2 Yixin Wang,3 GENEWIZ, South Plainfield, NJ 08070, NJ, 2Celense Diagnostics, Plymouth, MI.

Molecular analysis of circulating tumor cells (CTCs) is hindered by low sensitivity and high level of background leukocytes of currently available CTC enrichment technologies. The Celense PREP100 device captures CTCs with high sensitivity and allows the captured CTCs to be retrieved for molecular analysis. To evaluate the potential of utilizing PREP100 in CTC molecular analysis, we first prepared mock samples using cultured prostate cancer cells PC3 and LnCAP and analyzed captured cells by PCR amplicon sequencing. Using Celense PREP100, we were able to recover the average of 79% (ranging from 40% to 100%) of 110–1100 PC3 cells and 60–1,500 LnCAP cells and detect p.K139fs*3 deletion in PC3 cells and T877A mutation in LnCAP cells. In addition, we also spiked in the two cell lines into normal donor blood samples and analyzed the captured cells by PCR amplicon sequencing. Preliminary experiments showed that 40% of 250 spiked PC3 cells and 74% of 50 spiked LnCAP cells were captured. Further, we were able to detect p.K139fs*3 deletion in the retrieved 50,100 spiked PC3 cells. Our results illustrate that Celense PREP100 system presents a promising technology for capturing and molecular characterization of CTCs.

Background: Circulating tumor cells (CTCs) are tumor cells shed from primary tumor and circulate in the peripheral blood. CTCs, as a surrogate of distant metastasis, can be potentially useful in diagnosis and monitoring therapeutic effects in malignant tumors. Among a variety of systems for detection of CTCs, the “Cellsearch” is the only approved system for clinical use. However, EpCAM-negative tumor cells, such as those originating from non-epithelial cells and those undergoing epithelial-mesenchymal transition (EMT) cannot be captured with the “CellSearch” that is an EpCAM-based isolation system. Therefore, we have developed a novel polymeric microfluidic device (“Universal” CTC-chip) that can capture CTCs with or without EpCAM expression (AACR 2015). In the present study, we examined CTCs-detection performance of the CTC-chip in patients with thoracic malignant tumors (lung cancer [LC] as an “EpCAM-positive” tumor and malignant pleural mesothelioma [MPM] as an “EpCAM-negative” tumor) in comparison with that of the CellSearch. Methods: Peripheral blood sample from each patient was divided and subjected to quantitative evaluation of CTCs with the CTC-chip as well as with the “CellSearch”. The CTC-chip was coated with an anti-EpCAM antibody, was used to capture CTCs in the blood samples (n=19) from lung cancer patients. To capture CTCs in the samples (n=11) from MPM patients, the CTC-chip was coated with an antibody against podoplanin that is expressed on the mesothelioma. After immune-staining for cytokeratin and CD45 on the chip, a captured cell containing Hoehst-positive nucleus and cytokeratin-positive/CD45-negative cytoplasm was judged as a CTC. The CTC-count for each sample was represented as the number per 7.5mL of blood. Results: The median CTC-count detected with the CTC-chip in LC was 50 (range, 0–270), which was significantly higher than that of “CellSearch” (p<0.01). In the peripheral blood sample from MPM patients, CTC was detected in only one patient using the CellSearch, but was detected in all 11 patients with the median CTC-count of 144 (range, 0–470). Conclusion: The “universal” CTC-chip achieved higher performance in detection of CTCs of thoracic malignant tumors as compared with the CellSearch. The updated data will be presented at the AACR annual meeting 2017.

#1722 Novel multiplex liquid biopsy detection of ALK and ROS1 rearrangements and intratumoral heterogeneity in lung cancer using circulating tumor cell (CTC) blood from NSCLC patient bloods and TR-CytoTrapNano™ technology. Sangjun Lee, Cytolumina, Los Angeles, CA.

Introduction: ALK and ROS1 rearrangements are common gene alterations found in subsets of patients with NSCLC. Identification of ALK and ROS1 rearrangement in NSCLC is critical for highly active targeted therapies aiming for two main tumorigenic drivers. Due to the similarity of tyrosine kinase domains between ALK and ROS1, many ALK inhibitors are also functional in treatment of ROS1 subtype NSCLC. For example, crizotinib, which is a standard therapy for advanced ALK-rearranged NSCLC is highly effective in advanced ROS1-rearranged genotypy NSCLC patients. The mutational analysis of these genes requires serial tissue sampling from primary and metastatic lesions, which is labor intensive and time consuming. Further, the current tissue-based diagnostics, such as fluorescence in situ hybridization (FISH) and immunohistochemistry (IHC) are known to be challenging technically with limited sensitivity, subjective interpretation and inaccuracy in monitoring the current tumor status. The TR-CytoTrapNano™ CTC technology is a blood-based assay to utilize CTCs as a biosource for mRNA extraction to detect genetic alterations and gene expression profiles including ALK and ROS1 gene rearrangements. In this study, we determined the variant specific expression of ALK fusion transcripts (EML4-ALK, KIF-ALK, and TGF-ALK) and ROS1 fusion transcripts (EZR-ROS1, SDC4-ROS1, TPM3-ROS1, LRG3-ROS1, GOPC-ROS1, CD74-ROS1, and SLCE4A2-ROS1) using multiplex digital droplet polymerase chain reaction (ddPCR) technology. Method: The Peripheral Blood Mononuclear Cells isolated from NSCLC patient bloods run through the TR-CytoTrapNano™ microfluidic system. The CTCs are enriched and captured on the chip surface conjugated with Anti-Ep-ctp targeting antibody, which specifically binds to CTCs of epithelial origin. Following lysis step facilitate total RNA release from trapped CTCs and then pure mRNAs are isolated using oligo-dT conjugated magnetic beads. The mRNAs are used for following ALK and ROS1 specific reverse transcription reaction. The ALK and ROS1 fusion gene expression profiles of CTCs by ddPCR. Concomitant subtyping of ALK and ROS1 rearrangement are then validated using ddPCR. Results and Conclusion: We tested several liquid biopsies from ALK and ROS1 rearrangement positive patients and corresponding positive data to FISH assays using solid tumor biopsies. Interestingly, some of the CTCs harboring ALK and ROS1 rearrangement has shown high intra-tumor heterogeneity in the subtypes of fusion partners, and we envision that our novel TR-CytoTrapNano™ CTC ALK/ROS1 rearrangement Assay to monitor treatment response and recurrence in NSCLC patients will be used to monitor treatment response and disease recurrence following treatment with Tyrosine Kinase Inhibitors (TKIs).

#1723 Diagnostic leukapheresis results in a significant increase in CTC yield in metastatic breast and prostate cancer. Kiki C. Andere,1 Anouk Mentrin,1 Joost F. Swennenhuis,1 Leon W. Terstappen,2 Nikolais H. Stoecklein,3 Rui P. Neves,4 Rita Rampignano,4 Hans Neubauer,4 Tanja Fehm,5 Johannes C. Fischer,3 Elisabetta Rossi,2 Mariangela Manicone,4 Umberto Basso,4 Piero Marson,2 Rita Zamarchi,2 Yohann Loriot,6 Valérie Lapierre,6 Vincent Faugereux,7 Marianne Oulhen,8 Françoise Farace,6 Gemma Fowler,8 Mariane Sousa Fontes,9 Berni Ebbs,9 Maryou Lombros,9 Mateus Crespo,9 Penelope Flohr,9 Johann S. de Bono5 University of Twente, Enschede, Netherlands; 2University Hospital of the Heinrich-Heine-University Düsseldorf, Düsseldorf, Germany; 3IROV-RCCS and University Hospital of Padova, Padova, Italy; 4IROV-FCRCS Sanger, Sutton, United Kingdom; 5The Institute of Cancer Research and The Royal Marsden NHS Foundation Trust, Sutton, United Kingdom.

Introduction: Frequency the number of CTC isolated in 7.5 mL of blood is too small to reliably determine tumor heterogeneity and to be representative as a ‘liquid biopsy’. In the EU FP7 program CTCTrap we aimed to validate and optimize the recently introduced Diagnostic LeukApheresis (DLA; doi: 10.1073/pnas.1313594110) approach to screen liters of blood and thereby substantially increasing the number of CTC available for further characterization. Here we present the results obtained from 32 metastatic cancer patients subjected to DLA in the participating institutions. Methods Before the DLA procedure, whole blood was drawn in a CellSave blood collection tube and a 7.5 ml aliquot was processed with the ‘gold standard’ reference CellSearch® (Janssen Diagnostics, USA). DLAs from metastatic cancer patients were performed for >90 minutes to obtain 40 mL of product containing ~4×10⁶ mononuclear cells (MNC) representing ~1 liter of blood. The obtained DLA samples were then divided, fixed with CellSave preservative, prepared and processed and each of the analysis techniques as described in the Standard Operating Procedures developed for DLA in the CTCTrap consortium (https://www.utwente.nl/tnw/mcbp/protocoldandtools/). Results: DLAs were obtained from 20 metastatic prostate cancer patients and 12 metastatic breast cancer patients at four different European academic medical institutions. Using a SOP for the DLA procedure, similar DLA products were obtained (see Table 1). Mean CTC-chip count per DLA ± SD (n=68): 6×10⁶ ± 38x10⁵ could be generated without any noticeable side effects. CTC in 7.5 mL of blood ranged from 0 to 324 (mean ± SD = 61, median = 18). DLA processed with CellSearch represented 7 to 212 mL of blood (mean = 100, median = 97). CTC ranged from 0 to 2913 (mean ± SD = 330, median = 165). Resulting in a significant increase in CTC yield (p = 0.004)

Proceedings of the American Association for Cancer Research. Volume 58. April 2017 441
ranging from 0x to 40x (mean = 13, median = 9) when comparing 1mL of whole blood to 1mL of DLAs. Filtration of 50x10^6 WBC of DLAs, through 5um microsieves yielded only 0 to 12 CTC (mean = 2, median = 0, n = 16). Leukocyte depletion of 18 mL of DLAs followed by filtration yielded 0 to 178 CTC (mean = 37, median = 4, n = 22) not yielding a relative increase versus CellSearch DLAs. Leukocyte depletion followed by CellSearch yielded 792, median = 484, n = 3) also not yielding a relative increase versus CellSearch DLAs. In 7 patients CTC were detected in 7.5mL of blood, in 4 out of these 7 patients CTC were detected in DLAs. Conclusion: The yield of CTC can be significantly increased by the use of DLAs in patients with CTC detected in 7.5 mL of blood. Technology to select CTC from DLAs will need to be further improved before one can make optimal use of the large processed blood volumes.

#1724 Genomic profiling of Vortex-enriched CTCs using whole genome amplification and multiplex PCR-based targeted next generation sequencing. Haiyan E. Liu,1 Melanie Triboutel,1 Amin Aina,2 Meghah Vuppalapati,1 Evelyn Kides-Sigal,3 John Coller,1 Vanita S. Natsu,2 Vida Shokooohi,1 James Che,1 Corinne Renier,1 Natalie Chan,1 Violet Hanf,1 Elodie Sollier-Christen,1 Stefanie S. Jeffrey.1 Vortex Biosciences, Menlo Park, CA; Stanford University, School of Medicine, Stanford, CA; Stanford University, Stanford, CA; Charite University Hospital, Berlin, Germany.

Background: Genomic characterization of circulating tumor cells (CTCs) provides insights into cancer genetic changes, and might be utilized for cancer prognosis, diagnosis, as well as monitoring of therapeutic efficacy. Targeted Panel Next Generation Sequencing (NGS) enables analyzing CTC genetic variants of a selected gene panel at a relatively lower cost. However, CTCs are rare, often resulting in very limited DNA quantities available that require whole genome amplification (WGA). In previous studies, we introduced the Vortex technology, a platform enabling label-free enrichment of CTCs from blood samples of colorectal cancer (CRC) patients and their use for genomic assays downstream. In this study, we developed a simple and efficient NGS workflow for CRC samples collected by this technology. Method: An optimized workflow using the Qiagen GeneRead DNAseq target panel and Illumina MiSeq NGS was first verified on HCT116 CRC cell line before being applied on patient CTCs. For patient blood samples, CTCs were collected with the Vortex technology, immunostained (CK, Vimentin, CD45) and enumerated. Matched white blood cell (WBC) DNA was included to subtract germline background. Frozen fresh liver metastasis tissue was collected and analyzed using the same NGS workflow. DNA from CTCs was extracted and amplified using Qiagen REPLi-g single cell WGA kit. Mutation detection on the WGA amplified DNA was performed using the GeneRead DNAseq CRC targeted panel of 38 genes and MiSeq sequencing. The sequencing data were analyzed by QIAGEN NGS Data Analysis Web Portal and Ingenuity Variant Analysis software. Results: The Vortex technology was validated for the capture of CTC from CRC patients. REPLi-g PCR performs a uniform, unbiased amplification on fresh rare cells with a coverage of 97.7%, which enabled further targeted panel NGS. Blood from 3 CRC patients (P1, P2, P3) and 2 healthy donors (HD1, HD2) was processed with Vortex platform. Less than 1 CTC/mL blood were found in HD1 and HD2. P1 and P2 had 66 and 20 CTCs/μL of blood respectively, with many vimentin positive CTC clusters. P3 had 2 CTCs/μL blood. No somatic mutation was found in the CTC samples. Somatic variants were only detected in the CTCs from patient samples that were not present in matched germline WBCs. For P1, more mutations were found in the CTCs than in the liver metastasis when it was the opposite for P2 and P3. Conclusion: For each patient, variants in CTCs and germline WBCs were analyzed from one blood sample using an optimized targeted NGS workflow and compared to liver mets. Our optimized workflow, using the Qiagen REPLi-g and GeneRead DNAseq Targeted Panel NGS enabled the detection of CTC mutations for 38 CRC-focused genes. The inclusion of a germline WBC control in the workflow allowed the detection of mutations from pooled CTC samples collected using the Vortex technology. Altmüller J, et al. (2014). Biol Chem. #1725 Detection of ESR1 D538G mutation in circulating tumor cells (CTCs) and paired circulating tumor DNA (ctDNA) samples of breast cancer patients. Eleni Tzanikou,1 Athina Markou,1 Eleni Politaki,2 Giorgos Koutsopoulou,2 Amanda Pyrati,3 Vasileios Georgoulias,2 Evi Lianidou1.1 University of Athens, Athens, Greece; 2University of Crete, Heraklion, Greece; 3Attikon University Hospital, Athens, Greece.

AIMS: Molecular characterization of CTCs and ctDNA analysis holds promise as an extremely powerful tool for the molecular profiling of cancer patients in real time. Estrogen receptor alpha (ERα) is expressed in approximately 70% of all breast cancers and endocrine therapy represents a major treatment modality in ERα-positive disease. Recently, somatic mutations in the ERα gene (ESR1) were linked to acquired resistance to endocrine therapies in breast cancer. In this study, we analyzed the most frequent ESR1 mutation (D538G) in CTCs (DNA samples isolated from CellSearch cartridges), corresponding ctDNA from early and metastatic breast cancer patients and healthy donors. METHODS: We first developed a highly sensitive and specific methodology for the detection of ESR1 D538G mutation in CTCs by using an ultrasensitive asymmetric rapid PCR and high resolution melting analysis. We analyzed DNA isolated from CTCs (CellSearch) and the corresponding ctDNA before and after therapy in: a) 25 patients with ER+ operable breast cancer, b) 11 patients with ER+ metastatic breast cancer, c) 13 patients with ER- early breast cancer, d) 5 patients with ER- metastatic breast cancer and e) 80 healthy female volunteers. In all, 1mL DNA (extracted from 2 mL plasma) and DNA from CTCs were first examined for their DNA quality before analysis. RESULTS: The assay is highly sensitive (analytical sensitivity: 0.05%) and specific (0/80 healthy donors). ESR1 D538G hotspot mutation was identified in CDNA in 4/18 (22.2%) of ER+ metastasis-verified and in 5/33 (15.2%) of ER+ early breast cancer. In CTCs, ESR1 D538G mutation was identified in 6/18 (33.3%) of ER+ metastasis-verified and 5/33 (15.2%) of ER+ early breast cancer. In ER- metastasis-verified breast cancer, the concordance for D538G mutation between CTCs and ctDNA was 10/18 (55.6%), whereas the corresponding concordance for ER+ operable breast cancer was 25/33 (75.8%). Moreover, ESR1 D538G hotspot mutation was identified in CDNA in 2/9 (22.2%) of ER- metastasis-verified breast cancer and 2/16 (12.5%) of ER- early breast cancer. ERS1 D538G hotspot mutation was identified in 1/3 of the patients (18.8%) of ER- operable breast cancer as none of ER- metastasis-verified breast cancer patients (0/9) were positive. In ER- metastasis-verified breast cancer patients, the concordance between CTCs and ctDNA for D538G mutation was 7/9(77.8%), whereas the corresponding concordance for ER- early breast cancer was 15/16 (93.8%). CONCLUSIONS: We developed and validated an ultrasensitive and highly specific methodology for the detection of ERS1 D538G hotspot mutation. This mutation was detected not only in the ER+ group, but also in the ER- group of breast cancer patients. We will further evaluate our findings in a large cohort of patients before and after treatment, to evaluate response to endocrine therapies in breast cancer.

#1726 Evaluation of PD-L1/PD-1 on circulating tumor cells (CTCs) and on primary tumor in advanced non-small cell lung cancer (NSCLC). Galaktia Kallergi, Eleni Kyriaki Vetsika, Despoina Aigourekis, Eleni Lougoudi, Anastasios Koutsopoulos, Filippos Koinis, Panagiotis Katsarilinos, Maria Trypaki, Christos Stournaras, Vassilis Georgoulis, Athanasios Kotsakis, University of Crete, School of Medicine, Heraklion, Greece.

Introduction: Circulating tumor cells (CTCs) are responsible for the metastatic dissemination of the tumor. They have been shown to express Programmed Death-Ligand 1 (PD-L1) to escape from the immune system surveillance through its ligation with the PD-1 receptor on the surface of effector immune cells. We investigated the expression of PD-1/PD-L1 on CTCs isolated from NSCLC patients treated with chemotherapy. Methods: CTCs were isolated based on their size using the ISET platform from 30 stage IV chemo-naïve NSCLC patients (before and after chemotherapy). CTCs were detected after staining with Giemsa and immunofluorescence (IF). Double and triple staining experiments with different combination of antibodies: [Cytookeratin(CK)/PD-1/CD45 and CK/PD-L1/CD45] were performed and the samples were analyzed with the ARIOL system. Results: Giemsa staining showed that twenty-three (77%) out of 30 and six (54.5%) out of 11 patients had detectable CTCs at baseline and after the 3rd cycle of front-line chemotherapy. IF staining revealed seventeen out of 30 (56.7%) patients positive for CTCs at baseline level and 8 out of 11 (72.7%) samples after the 3rd cycle of treatment. PD-1 and PD-L1 expression was observed in 53% (9/17) and in 47% of the CTC-positive patients at baseline; in addition, 13% (1/8) and 63% (5/8) patients had PD-1 and PD-L1, respectively after the 3rd cycle. Among the total number of detected CTCs, 67% were PD-1(+) at baseline and 25% after the 3rd cycle (p = 0.069). In addition, 26% and 80% were PD-L1(+) at baseline and after the 3rd cycle, respectively. Patients with more than 3 PD-1 positive CTCs showed shorter PFS (p = 0.022). Primary tissue from ten of the examined patients was also available. More than 5% of PD-L1 (+) tumor infiltrating lymphocytes (TILs) were observed in 20% (2/10) of the patients. More than 5% PD-L1 positive cells in the primary tumor were observed in 20%. However the two group of the patients were different. In addition both patients with PD-L1 (+) TILs harvested CTCs with PD-1 expression and on one of them also had PD-L1 positive CTCs. Conclusion: PD-1 and PD-L1 expression on CTCs could be a biomarker before and during 1st line treatment in metastatic NSCLC. This expression was related to patients’ prognosis, implying that these molecules can be served as targets for metastasis restoration. Furthermore the expression of PD-1 on CTCs suggests a bilateral cross-talk between tumor and immune cells.

CLINICAL RESEARCH: Liquid Biopsies 1: Circulating Tumor Cells

Circulating Tumor Cells (CTCs) in patients with extensive stage small cell lung cancer and their association with clinical outcome. Chuan Zhang,1,2 Ryan Graf,2 Adam Jendrisak,3 Amanda K. Anderson,2 Priscilla Onyango,3 Sarah Orr,3 Sarah Cancer Research Institute, Nashville, TN;2Memorial Sloan Kettering Cancer Center, New York, NY.

Baseline CTCs and post treatment changes in CTCs have previously been shown to predict the response to chemotherapy in SCLC. CTCs may also serve as pharmacodynamic biomarkers. Here we describe a study of baseline and longitudinal CTCs in ES-SCLC patients from the PINNACLE phase 1b trial (clinicaltrials.gov:NCT01859741). Materials and methods: CTCs, CTC clusters, apoptotic CTCs and N-Cadherin + CTCs were identified and enumerated from patient blood samples using Epic Sciences CTC technology. Baseline CTCs from 26 patients were correlated with clinical outcome: progression-free survival (PFS), overall survival (OS) and best overall response, as well as treatment related effects. Model was used to investigate treatment changes in CTCs among the dose groups. Association of CTCs with PFS/OS and best overall response, including CTCs at each time point, as well as temporal changes of CTC status, were studied. Multivariate analysis was performed to identify CTC numbers in a subset of time points to correlate with response to treatment. Results: CTCs were present in 81% of the patients (21/26). CTC clusters and apoptotic CTCs were detected in 38% and 77% of the patients, respectively. At baseline, CTC counts ≥ 5/mL were significantly associated with poor OS (p = 0.04). There was a trend that the presence of CTC clusters was associated with worse OS. With a cut-off of 3.4/mL, apoptotic CTCs showed a trend in association with overall survival. CTC numbers in patients with liver metastasis were significantly higher than in patients without liver metastasis. CTCs were also found to be correlated significantly with the number of metastatic sites. When measuring at Day 7 post dosing, CTC numbers were significantly decreased. Conclusions: Our findings suggest that CTCs are frequently detectable in patients and are a prognostic factor in ES-SCLC. CTCs decrease with TRXRT and platinum-based chemotherapy. Updated results will be presented. CTCs will be further evaluated in the phase 2 portion of the PINNACLE trial.

Background: Sarcomas represent 1% of all cancers in adults, 8% in adolescents and young people, and 10% in children. Even though it is a rare cancer, it contributes to a significant loss of years of life in comparison with other types of cancer (Amankwah, et al., 2013). The presence of isolated Circulating Tumor Cells (CTCs) or Circulating Tumor Microemboli (CTM) in the blood of patients with sarcoma may be early markers of tumor invasion, because it is known that these cells circulate in the blood for months or years before the development of metastases (Paterlini-Brechot and Benali, 2007; Klain, 2009; Rhim et al., 2012). Objective: To isolate and quantify CTCs and CTM from sarcoma patients, evaluating their presence and correlation with progression free survival (PFS). Methods: The blood (approximately 8mL) was prospectively collected from patients with different types of high degree sarcoma. Blood was collected before the beginning of chemotherapy. The samples were processed and filtered on ISET (Isolation by Size of Epithelial Tumor Cells, Rarecells. France) system for the isolation and quantification of CTCs and CTM. Later, was performed immunocytochemistry (ICC) with anti-CD45 antibody and counterstained with hematoxylin-eosin for leucocytes population exclusion. The cutoff was estimated using the maximum of the standardized log-rank statistic proposed by Lausen & Schumacher (1992). Results: we analyzed 11 high degree sarcoma patients before the beginning of treatment (any treatment line). The median age was 53 years-old (18-77) and 54.5% were male. The median CTCs number was 2.0 CTCs/mL (1.0-11.0) at baseline. By Kaplan-Meier test, we observed that patients with CTC number below the established cutoff (4.5 CTCs/mL) had better PFS compared to those above the cutoff (7.4 vs. 1.0 months respectively; P = 0.006).

ESR1 methylation in circulating tumor cells, ctDNA and primary tumors of breast cancer patients. Sophia Mastoraki,1 Arcti Strati,1 Eleftheria Tranioukou,1 Eleftheria Politiaki,2 George Koutsoudontis,3 Loukas Kaklamanis,4 Nikolaos Malamos,4 Amanda Psyris2, Vassilis Georgoulas,2 Evi Lianidou,5 University of Athens, Athens, Greece;4University of Crete, Herakleion, Greece;3Attikon University Hospital, Athens, Greece;5Onassis Cardiac Surgery Center, Athens, Greece.

Background: Estrogen receptor (ER) is an important prognostic biomarker in breast cancer. Epigenetic silencing of ESR1 could be of important clinical significance especially for its potential impact on endocrine treatment efficacy. Liquid biopsy provides real-time monitoring of tumor evolution and response to therapy through analysis of CTCs and ctDNA. Our group has evaluated for the first time epigenetic silencing of tumor and metastasis suppressor genes in CTCs and corresponding ctDNA. In this study, we evaluated for the first time ESR1 methylation in CTCs, paired ctDNA and primary tumors of breast cancer patients. Methods: We developed and validated a highly sensitive and specific real-time MSP assay for ESR1 methylation. We further applied the developed assay in sodium bisulfite (SB) treated DNA samples from: a) FFPEs from 40 patients with operable breast cancer, 25 patients with metastasis, 30 mammaryplasies and 15 fibroadenomas, b) EPCam + immunomagnetically isolated CTCs fractions from 74 early breast cancer patients, 48 patients with metastasis and 30 healthy donors, c) CellSearch® cartridges from 64 early breast cancer patients, 22 patients with metastasis, d) ctDNA isolated from plasma of matched samples and 54 healthy donors as a control group. Results: By using this highly specific and
The proportion of times that extrapolated counts fell within a specific percentage of the true CTC count was calculated across the entire sample set, as well as by category. In the entire sample set, the proportion of extrapolated counts that fell within 25% of the true CTC count ranged from 0.208 (1 slide) to 0.723 (4 slides). In contrast, for true count more than 100, the fraction that fell within 25% of the true count ranged from 0.751 (1 slide) to 0.968 (4 slides). In 1,000 (7 slides). Conclusions: In this sample set, nearly three quarters of cases could be estimated within 25% of the true CTC count by extrapolating from 4 AccuCyte slides. Estimating each slide to represent ~1 mL of processed whole blood, our analysis suggests that a ~4 mL sample will have this level of accuracy relative to a CTC count from 7.5 mL. At low true CTC counts the accuracy of extrapolation decreases, indicating that a larger volume of blood is required for this level of accuracy.

**#1732 Accuracy of extrapolation of circulating tumor cell count from small blood volumes: statistical estimation using the AccuCyte - CyteFinder system.** Jeffrey L. Werbin,1 Paulina Varshavskaya,2 Arturo B. Ramirez,3 Jackie L. Silwelw,1 Daniel E. Sabath,2 Ping-Yu Liu,1 Eric Kaldjian,4 Azizi Mark L. Day, Todd Morgan, Sunita Nagrath. Unv. of Michigan, Ann Arbor, MI.

While the relative five-year survival rate for men with localized prostate cancer is nearly 100%, it plummets to 28% in the case of distant metastases. This underscores the importance of investigating those cells able to spread and form these metastases: circulating tumor cells (CTCs). Through rare and surrounded by other blood cells, CTCs can be isolated using the sensitive nanomaterial-based microfluidic technology the graphene oxide (GO) Chip. Whole blood samples from 54 prostate cancer patients were obtained with consent and processed on parallel chips for immunofluorescence and RNA analysis. All of the samples were analyzed for CTC enumeration, where captured cells were stained for cytokeratin 7/8 (CK), CD45, and DAPI. CTCs were identified as DAPI+/CK+/CD45- cells. CTCs were detected in all of the samples. Interestingly, 25 samples showed CTC clusters ranging from 2-10 CTCs per cluster. To explore the potential role of EGFR in metastatic progression and CTC survival, a subset of samples was also assessed for EGFR expression with 9/10 samples showing EGFR+. RNA extracted from a parallel chip was reverse transcribed to cDNA. The cDNA was analyzed via qPCR for expression levels of 96 genes of interest, including housekeeping genes; epithelial and mesenchymal genes; oncogenes and tumor suppressor genes; prostate specific genes; extracellular matrix and inflammatory genes; and others. The results show our ability to examine RNA from CTCs to evaluate the role of relevant pathways in the cells in transit. With analysis capabilities at both the RNA and protein levels, the GO Chip is an example of a clinically relevant microfluidic technology.

**#1733 Automated identification of circulating tumor cells by image analysis.** Leonie van Zonne,1 Guus Van Dalum,2 Francois-Clement Bidard,3 Jean-Yves de Bono,3 Leon W.M.M. Terstappen,1 Chris Brune1. University of Twente, Enschede, Netherlands; Heinrich-Heine-University of Dusseldorf, Dusseldorf, Germany; Institut Curie, Paris, France; Ludwig-Maximilians-University of Munich, Munich, Germany; The Royal Marsden NHS Foundation Trust and The Institute of Cancer Research, Sutton, United Kingdom.

In the field of Circulating Tumor Cell (CTC) research many new technologies are emerging to isolate CTCs. Some of them provide accompanied automatic image analysis tools that present possible CTCs to the user. Others need fully manual image analysis. For all CTC isolation technologies the definition of a CTC based on the immuno-morphologic criteria is either customized to the specific platform or subjective to the user causing high interreader differences - a problem which may condemn many CTC-based clinical studies to failure. Thus, an important issue that the field is confronted with is the lack of a unified and standardized definition to classify a cellular object as a CTC. This problem is addressed within the European FP7 consortium CTC Trap and the Innovative Medicines Initiative (IMI) consortium CANCER-ID by the development of an open-source image analysis toolbox for CTC identification and enumeration. This toolbox is baptized ACCEPT (Automated CTC Classification, Enumeration and Phenotyping) and can process images generated by various CTC isolation technologies. The main software components are the Marker Characterization, the Full Detection and the Automatic Classification. The Marker Characterization tool aims at quantifying the antigens expressed by previously selected CTCs. The Full Detection tool is based on advanced mathematical methods to reliably detect all objects in the images, visualize the objects in scatter plots and enable the user to classify the cell types by the use of gates or selection of specific objects in the scatter plots or on the actual images. The Automatic Classification tool first detects all objects in the images followed by an automated classification approach that – as a result – presents found CTCs to the user. We demonstrate the effectiveness of these tools on two different datasets. The Marker Characterization tool was tested for Her2 expression on archived CTC images isolated and classified by the CellSearch system from patients with metastatic breast cancer. Investigators from three different institutes were asked to score these cells for Her2 positivity first on the images generated by the CellTracks Analyst and afterwards using ACCEPT. We show that the improved CTC visualization provided in ACCEPT, combined with several measurements which we extract for each cell, can reduce the inter-user variability. The Full Detection and Automatic Classification tools of ACCEPT were tested on archived samples of patients with castration resistant prostate cancer processed with the CellSearch system as well as on microspheres obtained after filtration of the blood sampled by the CellTracks system. Results were compared with manually scored CTCs and showed the improvement of CTC classification by the availability of quantitative image analysis tools. The Open Source ACCEPT program will be available on the MCBP website (http://www.tnw.utwente.nl/mcbp).

**CLINICAL RESEARCH: Liquid Biopsies 1: Circulating Tumor Cells**
Patients with oligometastatic solid tumors. Purpose: To prospectively evaluate changes in circulating tumor cells (CTCs) following definitive treatment in patients with oligometastatic solid tumors using a novel nanotechnology-based biomimetic platform. Procedure: Patients with biopsy-proven oligometastatic disease with up to three lesions were eligible if all sites of disease were treated with definitive therapy. Definitive therapy could include fractionated 3D conformal radiation, SBRT, IORT, surgical metastatectomy, and ablative procedures. Patients initially presenting with oligometastatic disease were eligible if they had less than 3 lesions, including the primary tumor. At least one lesion had to be treated with radiation. CTCs were enumerated from whole blood using the Onco-Sense CTC capture system. The Onco-Sense is a rolling chip-based system for detection and long-term monitoring of hepatocellular carcinoma. The CTC-score generated from these data tracks with clinical intervention and is higher than 50% of malignant patients with oligometastatic disease using a novel CTC capture system. CTCs decreased with treatment and all clinical failures were preceded by significant rises in CTCs. Our preliminary data suggest that enumeration of CTCs by Onco-Sense may provide a novel biomarker for assessing treatment response and/or post-treatment surveillance for patients with oligometastatic solid tumors.

#1736 A novel RNA-based assay for the detection and monitoring of circulating tumor cell signatures in breast cancer. The technical feasibility of utilizing RNA sequencing for identification of novel CTC signatures in interest was also demonstrated with a liver cancer cell line spike-in study. Results: 9 of the 16 untreated HCC patients were successfully detected, while only 1/31 chronic liver disease patients were incorrectly classified. HCC patients undergoing treatment showed a significant decrease in their CTC-score; only 9/32 patients actively receiving treatment were positive. The CTC-score was not correlated with the HCC serum biomarker alpha-fetoprotein, and combining these two orthogonal measures led to an estimate positive and negative predictive values of 80% and 86%, respectively, in a high-risk cohort. RNAseq analysis of cell line spike-in data revealed the potential of RNA sequencing for uncovering novel transcripts of interest. Conclusion: Coupling microfluidic depletion with droplet digital PCR allows for the highly specific detection of hepatocellular carcinoma. The CTC-score generated from these data tracks with clinical intervention and is orthogonal to the existing biomarker AFP; combining these two assays has the potential to provide superior detection compared to either individual approach.

#1737 ALK rearrangement analysis in circulating tumor cells of lung cancer patients. The evaluation of ALK rearrangement in non-small-cell lung cancer (NSCLC) is a significant tool when considering chemotherapy. It is not always possible to perform a tumor biopsy in patients. We suggest isolation and culturing of circulating tumor cells (CTCs) as an alternative tool to a tumor biopsy for the diagnosis of ALK rearrangement. From 22 patients with NSCLC harboring ALK rearrangement, blood samples were collected and divided into two parts: one for immunofluorescence staining of CTC marker.
and the other for culturing of CTCs. Both samples were processed by size-based filtration, and Cultured CTCs were analyzed for EML4-ALK translocation by fluorescence in situ hybridization (FISH) using Vysis ALK break apart FISH probe kit. CTC culturing was successful in 18 of 22 cases (81.8%). Among 18 cases of successful CTC cultures, 13 cases showed ALK rearrangement positive samples mCrPC. Therefore, we suggest that the CTCs can be used as an alternative method to tissue biopsy for diagnosing ALK rearrangement. In addition, this method may have clinical applications including serial blood sampling for the development of personalized cancer therapy based on individual genetic information.

### #1738 Platelet activation and heterotypic platelet leukocyte conjugate formation in the blood of glioblastoma patients

Sascha Marx, Maximilian Splitsöhner, Heiko Paland, Carolin Seifert, Madlen Juettner, Andreas Boehm, Christoph A. Ritter, Sandra Bien-Möller, Henry W. Schroeder, Bernhard Rauch. University Medicine Greifswald, Greifswald, Germany

Objective: Glioblastoma patients (GBM) suffer from an increased incidence of cardiovascular events. Platelets are well known as a major player of the primary hemostasis, but have a broad range of additional functions. The formation of heterotypic conjugates between platelets and leukocytes (PLC) represents a pro-inflammatory surrogate marker and is usually increased after platelet activation. The aim of the present study was to evaluate the platelet activation status and the rate of circulating PLC in GBM. Methods: Blood samples were drawn of consecutive patients before surgery for a suspected glioblastoma. The formation of PLC and several parameters of platelet activation were determined by flow cytometry before and after stimulation with either ADP or the thrombin receptor-activating peptide (TRAP) in vitro: expression of P-Selectin, CD63, CD40L and fibrinogen-binding to the activated GPIIb/IIIa. Blood samples from age and gender matched healthy volunteers were used as controls. Statistical analysis was done by the Mann-Whitney-Test. Results: Final analysis included 22 patients with histopathologically proven primary glioblastoma (9f, 13m, mean age 67.5 years, range from 53 to 86 years) and their respective controls. Basal platelet activation and in vitro platelet reactivity was increased in GBM. The difference got significant in the basal expression of CD63 (2.8% versus 1.9%, p=0.008), the Fibrinogen-binding after ADP-stimulation (110.3 MFI versus 63.1 MFI, p=0.04) and the CD63 expression after TRAP-stimulation (38.4% versus 33.3%, p=0.04). Furthermore, a reduced number of circulating PLC and in vitro PLC formation was seen in GBM without getting statistically significant. Conclusions: In this preliminary report, we show for the first time an increased level of platelet activation and agonist-induced platelet reactivity in GBM. Both could be a reflection of the pro-thrombotic status in these patients. Interestingly, the formation of PLC was not increased, but in tendency decreased. Whether this observation potentially mirrors the intratumoral, anti-inflammatory microenvironment in GBM remains unclear.

### #1739 Analysis of EML4-ALK fusion transcripts in plasma and platelets to monitor response to crizotinib in EML4-ALK positive small cell lung cancer patients (NSCLC)

Cristina Aguado, Cristina Teixido, Ana Gimenez-Capitan, Maria de los Llanos Gil, Sonia Rodriguez, Santiago Viteri, Niki Karachalios, Erika Aldegue, Vicente Peg, Lidia Alonso, Miguel Angel Molina-Vilaplana, Rafael Rossell, Pangea Oncology, Barcelona, Spain; Dr. Rosell Onology Institute, Barcelona, Spain; Hospital Sagrat Cor, Barcelona, Spain

Background: Rearrangements in anaplastic lymphoma kinase (ALK) gene can be detected in 5-7% of EGFR and KRAS wild-type advanced NSCLC patients (p). Fluorescent in situ hybridization (FISH) and immunohistochemistry (IHC) are currently used for screening but are unable to identify the specific fusion partner and are impractical to monitor clinical responses due to difficulty of obtaining rebiopsies. The RT-PCR technique has the potential to overcome this pitfall and allow patient monitoring in blood. Methods: A total of 405 formalin-fixed paraffin-embedded (FFPE) samples from advanced NSCLC were analyzed by ALK IHC (Ventana D5F3) and FISH (Vysis). Positive patients were confirmed by RT-PCR and submitted to Sanger in order to identify the variant. In a subset of 36 patients with EML4-ALK-rearranged tumors who were treated with crizotinib, fusion transcripts were analyzed by RT-PCR in mRNA purified from plasma and platelets and correlated with clinical response. Results: ALK IHC was analyzed in 405 NSCLC patients and 37 tested positive (9.1%) whereas 25 (7.7%) were identified as translocated by FISH (n=323). ALK fusion transcripts were analyzed by RT-PCR and a new fusion variant of ALK was identified. A total of 36 p benefitted from crizotinib treatment, including the p with the new variant. Monitoring of EML4-ALK fusion transcripts in the plasma ad platelets of 35 ALK positive patients revealed a good correlation with clinical outcome to crizotinib treatment, with the fusion transcripts becoming undetectable in p with good clinical responses. Conclusions: Analysis of ALK fusion transcripts in mRNA purified from plasma and platelets can have a value in patients with no biopsy available and to monitor the course of the disease.

### #1740 Phenotypic, genomic, and clinical associations of Circulating Tumor Cells (CTCs) lacking epithelial biomarkers in metastatic Castration Resistant Prostate Cancer (mCRPC)

Ryon P. Graf, Yipeng Wang, Nicole Schreiber, Brigit McLaughlin, Stephanie Greene, Angel Rodriguez, Adam Jendraski, Jerry Lee, Mark Landers, Ryan Dittamore, Howard I. Scher, Epic Sciences, Inc., San Diego, CA; Memorial Sloan Kettering Cancer Center, New York, NY.

Background: Epithelial Plasticity (EP) is a proposed mechanism of immune escape, resistance to programmed cell death, resistance to specific drugs, and promotion of metastasis. EP has been extensively explored in mathematical, cell biological, and animal models, which predict the presence of these tumor cells in circulation. Most studies on CTCs in human subjects are based on enrichment of cells expressing EpCAM prior to enumeration or molecular interrogation, which precludes analysis of cells that might be EP. The non-enrichment Epic Sciences platform was utilized to identify CTCs in metastatic castration-resistant prostate cancer patient samples phenotypically consistent with EP. CTCs that do not express cytokeratins (CK), but do express malignant or EP biomarkers: Androgen Receptor (AR), AR splice variant 7 isoform (AR-V7) or N-cadherin. Phenotypic and genotypic analyses of individual CTCs were performed to assess the malignant origin of CTCs and their prevalence associated with metastatic prostate cancer and are a negative prognostic factor associated with worse overall survival in both iterative threshold and multivariable analyses.

### CLINICAL RESEARCH: Molecular Classification of Tumors

#### #1741 Whole-transcriptome characterisation of NRAS and BRAF mutated primary melanomas associated with immune cell infiltration signatures and differential survival benefit

In 703 primary melanoma transcriptomes derived from formalin-fixed tumors removed from participants in the Leeds Melanoma Cohort, we used in silico methodology described by Bindea et al.1 to develop immune cell infiltration signatures. These showed to be associated with survival2. There is some reported evidence that patients with NRAS mutated melanoma have a better response to checkpoint therapies3. Our aim was, therefore, to use the transcriptomic data to ask if immune cell infiltration (evidenced by the presence of the immune cell signature) differed between mutation subgroups. We saw that the survival benefit of the immune cell signature was strongest in wild-type (HR=0.31, P=3x10^-5), intermediate in BRAF mutated tumors (HR=0.56, P=0.008) but absent in NRAS mutated tumors (HR=1.09, P=0.79). That is that even if the
N Ras mutated tumors had a strong T cell signature that did not correlate with better survival. The results remained significant after adjusting for sex, tumor site, age at diagnosis, and AJCC stage. We observed no evidence of increased numbers of regulatory T cells (FOXP3), in N Ras mutated tumors, nor PD1L or PD1 expression. The only difference in checkpoint molecule expression studied was a borderline lower expression of CTLA4 (AK3, N Ras) and tumors (P=0.09). Our data suggest that even when T cells invade N Ras mutated tumors some functional deficiency may be present in those tumors such that a survival benefit is not seen. Using genes significantly differentially expressed between N Ras and BRAF mutated tumor groups, we tested biological pathway enrichment using Reactome FIViz plugin in Cytoscape. The most enriched pathways in N Ras mutated melanomas were the PI3K (AK3, N Ras) and mitochondrial translation (CHCHD1, PTCD3). In the BRAF mutated the most enriched were: direct P53 effectors (TGF, IGFBP3), B-catenin independent WNT signaling (WNT5A) and MHC class I antigen processing (CYBA). A number of pathways related to cell adhesion involving GRIN1 were also identified. Others have reported that B-catenin signaling inhibits transcription of the chemokine CCL4 which reduces the trafficking of CD141 DC to melanomas and therefore T cell infiltration.1 We have evidence from the B-catenin candidate transcriptomic analysis that primary melanomas without immune infiltration signatures have upregulated B-catenin but the comparison between transcriptomic patterns in N Ras and BRAF tumors did not suggest that B-catenin signaling was more active in N Ras mutated tumors. It may be that a different immune evasion mechanism is more common in N Ras mutated tumors than in others. References 1. Bindea et al. Immunity 39, 782-795 (2013) 2. New-Bishop et al. #1742 Cancer cell-selective transcriptome analysis reveals new colorectal cancer molecular subtypes with improved biological resolution and superior predictive and prognostic performance. Claudio Isella,1 Sara E. Bellomo,1 Francesco Brundu,2 Francesco Galimi,3 Elisa Facchin,1 Luigi Marchionni,1 Livio Trusolino,1 Andrea Bertotti,1 Enzo Medico,1 University of Turin, Candiolo Cancer Institute, Candiolo, Italy; 2Politecnico di Torino, Torino, Italy; 3Candiolo Cancer Institute, Candiolo, Italy; 4Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins University School of Medicine, Baltimore, MD.

Molecular classification of colorectal cancer (CRC) based on gene expression profiling of tumor samples is known to be heavily affected by transcript of stromal origin. As a consequence, current CRC transcriptional subtypes reflect an admixture of cancer cell intrinsic traits and tumor microenvironment features. Whether selective analysis of the cancer cell transcriptome could improve CRC subtyping, remains an open issue. In patient-derived xenografts (PDxs), human transcripts only originate from cancer cells, because stromal transcript is of mouse origin. We therefore assessed cancer-cell intrinsic transcriptional features of CRC by generating human-specific expression profiles of 515 PDxs from 244 CRC patients, and performing unsupervised class discovery. We identified five “CRC intrinsic subtypes” (CRIS A-E) only partially overlapping with the current ones, and robustly enriched for distinct molecular, functional and phenotypic traits: (i) CRIS-A: mucinous, glycolytic, CIMP, and enriched for microsatellite instability or mutations in KRAS; (ii) CRIS-B: marked TGF-β pathway activity, epithelial-mesenchymal transition and poor prognosis; (iii) CRIS-C: MSS, elevated EGFR signaling and sensitivity to EGFR-targeted treatments; (iv) CRIS-D: MSS, WNT activation, and IGF2 overexpression and amplification; (v) CRIS-E: MSS, Paneth cell-like phenotype and higher frequency of TP53 mutation. CRIS subtypes successfully categorized independent sets of primary and metastatic CRCs and cell lines, for a total of over 3000 samples profiled by microarrays and RNAseq. The new subtypes displayed unprecedented predictive and prognostic performances, independent from known markers including stromal signatures, whose integration with CRIS further enhanced prognostic significance.

#1743 Comprehensive genomic characterization of a large cohort of platinum-sensitive high-grade serous ovarian cancer (HGSOC) FFPE specimens. Brian C. Haynes,2 Marie E. Fahey,1 Darcy Myers,1 Diane Isley,1 Gary J. Latham,1 Elizabeth B. Somers,2 Nicholas C. Nicolaides,2 Charles Schweizer,2 Daniel J. O’Shannessy3,4.1 Asuragen, Inc., Austin, TX; 2MorphoTec, Inc., Exton, PA.

Introduction: Ovarian cancer is a leading cause of cancer related death in women. A comprehensive genomic characterization of platinum-sensitive tumors is required to further refine the definition of molecular subtypes and identify targeted therapies for this patient population. To this end we have performed a large-scale genomic and transcriptomic characterization of 348 primary FFPE tissues from a cohort of platinum-sensitive HGSOC patients collected from multiple clinical sites. Methods: Macrodisssection of FFPE resected tumor slides or sectioned blocks was performed to enrich for tumor content. RNA and DNA were each isolated from 2X5μm sections of FFPE material. RNA expression and gene fusions were profiled by whole transcriptome RNA-Seq. DNA variants were analyzed by the AmpliSeqTM Cancer Hotspot Panel (Thermo Fisher). A subset of tumors were profiled by whole genome sequencing of the NGS panel. Results: The spectrum of DNA mutations and CNVs was consistent with other HGSOC cohorts with mutations in TP53 present in the majority of specimens (87% for specimens with full exon coverage of TP53). Germline mutations in BRCA1 and BRCA2 were identified at 10.3% and 6.8% respectively. Analysis of recurrent whole chromosomal arm gain and loss displayed a striking agreement with the TCGA HGSOC cohort. Unsupervised analysis of the RNA Seq expression data through non-negative matrix factorization revealed 4 distinct transcriptional subtypes, corresponding to the 4 established CLOVAR subtypes: differentiated, immunoreactive, mesenchymal and proliferative. Patients classified as mesenchymal had the poorest prognosis. Further integrative analysis identified additional associations between the CLOVAR subtypes and other molecular indications. Concerning the clinical utility of these subtypes we reported that each subtype is enriched for specific germline or somatic mutations. In the future, these transcriptional subtypes of platinum-sensitive HGSOC and highlighted alterations that may lead to improved diagnostic and precision medicine strategies. In contrast to previous large-scale molecular characterization efforts such as TCGA where fresh-frozen tissue were collected under highly controlled settings, this study is based on molecular profiling of FFPE tissues collected at dozens of clinical sites. Thus, our study serves as a model for future molecular characterization efforts of FFPE specimens collected in real-world clinical settings.

#1744 RNAseq identified immune signatures associated with adverse outcome in high-risk neuroblastoma. Jun S. Wei,1 Shile Zhang,2 Igor Kuznetsov,2 Young K. Song,1 Shahab Agharzadeh,1 Shivash Sirdhi,1 Xinyu Wen,1 Rajesh Patidar,1 Jaime M. Guidry Auvil,1 Daniela S. Gerhard,1 Robert Seeger,3 John M. Maris,1 Javed Khan1.1National Cancer Institute, Bethesda, MD; 2University at Albany, Bethesda, NY; 3The Children’s Hospital Los Angeles, Los Angeles, CA; 4The Children’s Hospital of Philadelphia, Philadelphia, PA.

Despite the success of multimodal therapies, the mortality and morbidity remains substantial for patients with high-risk neuroblastoma (NBL). Sequencing of paired tumor-normal DNA samples of NBL patients identified somatic mutation burden and few recurrent somatically-mutated genes. Here we hypothesize that whole transcriptomic sequencing (WTS) in patients with high-risk NBL tumor will yield valuable insights into the biology of this disease. We performed deep WTS of 150 NBLs (129 high-risk stage 3 and 4; 21 stage 4S tumors) of which majority of them had whole genome sequencing or whole exome sequencing of case-matched tumor/normal pairs through the Therapeutically Applicable Research to Generate Effective Treatments (TARGET) initiative. We identified correlations between gene expression and clinical parameters of patients such as MYCN-amplification and survival to provide understandings of high-risk NBL biology. Consensus clustering using gene expression profiles of tumors revealed 4 subgroups with distinct survival probability (p<0.01). Among the tumors with the best outcome consisted of all stage 4S and 4S-like young patients; whereas the worst survival group was made up mostly of high-risk patients with MYCN-amplification. In order to identify the gene expression patterns correlating with outcome in the high-risk patients without MYCN-amplification, we further examined if any other known gene expression signatures can further stratify these patients using Gene Set Enrichment Analysis (GSEA). Among several molecular signatures, a previously reported 157-gene MYCN activation signature was significantly correlated with the poor outcome in high-risk patients without MYCN-amplification. Of note, we identified CD9, cytolytic, and activated nature killer (NK) cell signatures that were significantly associated with outcome in these patients. These findings were validated in independent data set and highlight the potential clinical application for a subset of high-risk neuroblastoma patients without MYCN-amplification that have an activated MYCN signature may benefit from immune-modulating agents such as immune checkpoint inhibitors which should be tested in context of clinical trials.
#1745 Multifocal prostate cancer has high degree of genomic heterogeneity. Marthe Leuf,1 Sen Zhao,1 Ulrika Axcrona,2 Bjanne Johannesen,1 Andreas M. Hoff,1 Anne Cathrine Bakken,1 Kristina Toltrand Carn,1 Ola Myklebost,1 Leonard A. Meza-Zepeda,1 Agnes K. Lie,1 Karol Axcrona,2 Ragnhild A. Lothe,1 Rolf I. Skotheim1. 1Oslo University Hospital, Institute for Cancer Research, Oslo, Norway; 2Oslo University College, Department of Pathology,Fredrikstad,Norway; 3Akershus University Hospital, Department of Urology, Lørenskog, Norway.

Prostate cancer is the most common cancer type among men in the Western world. Most prostate cancers are multifocal with individual tumors harboring different aggressiveness. In recent genomics studies, the multifocal nature of prostate cancer has been investigated only in small sample cohorts. Here we have investigated the intra-organ mutational spectra of multiple tumors from a large cohort of prostate cancer patients. From radical prostatectomy specimens from 2010 and 2012 at Oslo University Hospital, 43 prostatectomy specimens with multiple and clearly separated tumors were identified based on histology. From each of these prostatectomy specimens, DNA from frozen samples from 2-3 different tumor foci and corresponding normal tissue samples were analyzed by high-coverage whole-exome sequencing, adding up to a total of 159 samples. We identified 3093 somatic substitutions, insertions and deletions, with an average of 27 alterations per tumor sample. Both known and novel significantly mutated genes were identified using Oncosift and their distribution in different tumor foci from the same prostate was examined. Mutations in genes such as SPOT, MED12, and FOXA1 have previously been identified in prostate cancer and were also found to be frequently mutated in this cohort. However, the same mutations were rarely found in multiple tumor foci within the same prostate. In fact, for 13 out of the 43 examined patients there were no common mutations among tumors from the same prostate. For 12 patients, we found only one overlapping mutation among tumor foci. Whereas the overall list of mutated genes (n = 2101) overlap significantly with the 594 genes of the Cancer Gene Census (100/594; p = 9.6e-06), this was not the case for 142 genes with overlapping mutations among different tumor foci (2/594; p = 0.63). This indicates that the overlapping mutations are not typical cancer driving genes. To conclude, results from this sequencing of multifocal prostate cancer show a large degree of heterogeneity in genomic alterations between different tumor foci within the same prostate. With very few common inter-foci mutations, an implementation of genome-based personalized prostate cancer medicine will require sampling of all tumor foci to tailor optimal treatment.

#1746 Rational molecular assessment and innovative drug selection (RAIDs): Paving the way to personalized medicine in cervical cancer. Leanne de Koning,1 Bérengère Ouine,1 Aurélie Cartier,1 Els M. Berns,2 Kirsten Ruigrok-CLINICAL RESEARCH: Molecular Classification of Tumors Leyen,5 Marina Popovic,6 Windy Luscap-Rondot,7 Vonick Sibut,7 Choumouss Lapping mutations among different tumor foci (2/594; p = 9.6e-06), this was not the case for 142 genes with overlapping mutations among different tumor foci (2/594; p = 0.63). This indicates that the overlapping mutations are not typical cancer driving genes. To conclude, results from this sequencing of multifocal prostate cancer show a large degree of heterogeneity in genomic alterations between different tumor foci within the same prostate. With very few common inter-foci mutations, an implementation of genome-based personalized prostate cancer medicine will require sampling of all tumor foci to tailor optimal treatment.

Cervical cancer (CC) is the fourth most common cause of cancer deaths in women worldwide, for which prognostic and predictive biomarkers are largely lacking. RAIDs is a EU-funded project on cervical cancer that spans seven European countries. The main objective of the RAIDs project is to use this tumor type, which is easily accessible for repeated biopsies, to learn how to stratify patients into targeted therapies. The project includes: 1) a cognitive cohort study (BioRAIDs), one of the first prospective trials intended to define patient stratification for targeted therapies, 2) a targeted clinical trial using an HPV directed vaccine and 3) preclinical studies aiming at assessing new treatment strategies. Molecular analysis on quality controlled tumor and sera samples from 400 patients include Next Generation Sequencing at SeqGomics (Hungary), PIK3CA mutations detection in circulating tumor DNA at Erasmus MC (Netherlands), Reverse Phase Protein array and HPV insertion sites analyses at Institut Curie (France) and immune-microenvironment analyses at CGOA (Netherlands). In addition, 20 CC cell lines have been profiled pharmacologically using a panel of drugs which potentially synergize with “standard treatment”. The present poster will mainly focus on the Reverse Phase Protein Array (RPPA) results of Bio-RAIDs and how these relate to the genomic profiling and to patient outcome. More than 150 cryopreserved baseline (before treatment) samples and 23 CC cell lines have been screened by RPPA. From these, whole exome sequencing is available for 92 patient samples. Stratification of patients based on proteomics and genomics has evidenced different subgroups (clusters) of patients displaying specific molecular characteristics. Genomics data and proteomics data both demonstrate that these clusters differ notably in the pathways of oxidative phosphorilation, Department of Pathology, Fredrikstad, Norway; Akerhuse University Hospital, Department of Urology, Lørenskog, Norway. The correlation of proteomics and genomics data with these clinical data is ongoing and will identify putative predictive biomarkers. Correlation of protein data with response to drugs treatment in 20 CC cell lines has identified several potential biomarkers, some of which again relate to (glucose) metabolism. In conclusion, we here present new evidence for molecular subgroups of cervical cancer that could benefit from different treatment options. Notably, our data suggest that the metabolism/glycolysis pathways are a major effecter in CC and constitute a potential therapeutic target in a subset of patients. This project has received funding from the European Union’s Seventh Program for research, technological development and demonstration under grant agreement No 304610.

Gene expression studies, mainly addressed at the tumor cell compartment of breast cancers (BC) contributed to unravel the molecular heterogeneity providing clinicians with new and reliable tools for therapeutic planning. Despite many investigations have focused on genetic abnormalities initiating and driving tumorigenesis, there is now evidence that the cancer cell behavior depends not only on intrinsic features, but also on the interactions with the microenvironment. However, notwithstanding the interest in investigating tumor-stroma cross-talks, the clinical relevance of subtype-specific molecular imprint of such interactions is largely unexplored. As such, we attempted to clinically and biologically validate the subtype-specific gene signatures derived from an in vitro model recapitulating the interaction between BCs and activated stromal cells. Gene expression signatures derived from luminal (T47D, MCF7, ZR75.1), HER2+ (SKBr3+, BT474, MDA-MB-361) and basal-like (MDA-MB-468, MDA-MB-231, BT20) cell lines treated by conditioned media from normal or cancer-associated fibroblasts (CAF) showed common- and subtype-specific pathways according to GSEA. In fact, interferon, IL-6, IL-12 and IL-23 signaling, Toll Like Receptor pathway, pathways related to inflammation and metabolism of carbohydrates were positively enriched in HER2+ and luminal subtypes. Complement cascade and Tumor Necrosis Factor pathways were positively enriched in basal and luminal tumors; no common pathway was observed in HER2+ and basal subtypes. The association between microenvironment signatures specific for luminal, HER2+ and basal BC cell lines and disease-free survival was evaluated in silico on published gene expression profiles (GEPs) from 2048 patients homogeneously treated. BCs were classified as microenvironment-positive (μENV+ve, with GEP suggesting stroma activation), or negative (μENV−ve) by correlating tumor’s GEP with the respective subtype-specific signature. Patients with luminal μENV−ve status had 2.5-fold higher risk of developing metastatic diseases (HR = 2.546; 95% Confidence Interval, CI: 1.751-3.701, P = 9.84E-07), while μENV status did not affect or was only suggestive of metastases in women with HER2-enriched (HR=1.541; 95% CI: 0.788-3.012, P=0.206) or basal tumors (HR = 1.894; 95% CI: 0.938-3.824, P=0.0477), respectively. In luminal tumors, the μENV status maintained its prognostic role (HR =2.098; CI: 1.214-3.624; P=0.00791) in multivariable analysis including size, age and genomic grade index. Validity of our in vitro model was also supported by biological endpoints such as proliferation (MTT-assay) and migration/invasion (Transwell assay). In vitro-derived gene signatures trace a subtype-specific interaction with CAFs and add independent information to classical prognostic variables in women with luminal “microenvironment sensitive” tumors.

#1748 Organ-specific epigenetic reprogramming of leukemia cells: Clues to chemoresistance. Isabel Cunningham,1 Diane Hamele-Bena,1 Audrey Papp,2 Yan Guo,3 Antony B. Holmes,1 Yu Shyr,4 Rory A. Fisher4. 1Columbia University College of Physicians and Surgeons, New York, NY; 2Ohio State University, College of Medicine, Columbus, OH; 3Vanderbilt University, Nashville, TN; 4University of Iowa Carver College of Medicine, Iowa City, IA.

We previously reported our observation that tumors composed of leukemic cells found in breast mimick solid breast cancers in gross and histologic appearance (single-filing of cells and distinctive keloid-like fibrosis), invasiveness, metastatic pathway, and high mortality. They are resistant to anti-

Proceedings of the American Association for Cancer Research • Volume 58 • April 2017
leukemia drugs; only 4% treated without exception lived 4 years but survivals over 20 yrs resulted when tumor and its microenvironment were excised. The incidence of occult leukemic tumors, still unknown as scans are not yet routine, was estimated near 20% in 1970s autopsy studies. We hypothesized there may be similarly altered genes in leukemic and epithelial breast tumors directing clinical behavior and resistance that could provide targets for curative treatment. We performed RNA sequencing on 11 FFPE breast tumors from annotated AML cases, all IHC-negative for hormones and E-cadherin, compared to normal breast samples. Differential expression analysis identified 3647 genes that were significantly downregulated (adjusted p < 0.05 and log2 fold change < -2). Among the 100 genes downregulated 8-10 fold in leukemic breast, FOXA1, CA12, CXCL14, SFRP1, SFRP4, DSN1, LUM, PHLD1A, NTN4, GABBR, TAGLN, AZGP1, and ARRD31 were associated with poor prognosis in breast cancer, mainly triple-negative (TNBC) basal types. Compared to TNBC cases in the TCGA database, 851 genes were similarly deregulated; significantly enriched KEGG pathways include neutrophilic receptor interaction, focal adhesion, ECM-receptor interaction, and regulation of lipolysis in adipocytes. A role for altered stroma is suggested as many of the similarly downregulated genes were reported in dissected breast cancer stroma and silenced SFRP1 and CXCL14 were found in keloid fibroblasts. Silencing of SFRP1 and E-cadherin in AML marrows was reported in 30-50% and each was correlated with poor survival. Reversal of SFRP1 silencing has been achieved by epigenetic modulating drugs in cancers and leukemic cases where it has been used to reduce canopy of AML cells by RT-PCR. Loss of RGS6 in breast and other cancers promotes doxorubicin resistance and DMT1 upregulation leading to silencing of tumor suppressor genes. These data open a new view of resistance of AML cells to marrow-directed drugs through interaction with aberrant microenvironment. Solid tumors of epithelial and leukemic cells may share unrecognized treatable targets. Adding drugs directed at tumor, including available epigenetic-modifying agents, to marrow-effect protocols, may finally decrease the persistently high rate of AML treatment failure.

**#1749 Stability of copy-number profiles defines two molecular subtypes during urothelial carcinoma’s evolution.** Bishoy M. Faltas,1 Davide Prandi,1 Scott T. Tagawa,1,2 David Nanus,1 Ana M. Molina,1 Himisha Beltran,1 Francesca Demicheli,1,2 Mark A. Rubin1.1 Well Cornell Medical College, New York, NY; 2University of Trento, Italy.

Background: Somatic copy-number alterations (SCNAs) are distinct molecular events occurring in muscle-invasive urothelial carcinoma (UC). Defining the biologic role and the timing of SCNAs in UC’s evolution is critical for understanding disease biology and for precision therapy. Methods: To examine whether distinct SCNAs define specific subtypes of UC and characterize the evolutionary dynamics of SCNA acquisition, we conducted whole-exome sequencing (WES) of a discovery cohort of 44 advanced UC tumors and matching germline samples, including 13 pairs of matched primary and metastatic tumors prospectively collected before and after chemotherapy. We validated SCNAs in 29 breast cancers and normal breast tissues by RT-PCR. We queried WES data from 285 UCs from The Cancer Genome Atlas (TCGA) as a validation cohort. We performed a novel in-depth allelic-specific copy-number analysis in 2503 cancer genes using the CLONET computational framework, which accounts for tumor ploidy and cellularity to infer the clonal hierarchy of SCNAs. Results: Analysis of SCNAs from tumor pairs within each patient revealed punctuated evolution of SCNAs occurring early in UC’s development followed by minor changes (clonal stasis) throughout the tumor’s lifetime. Two distinct clusters of UCs with strikingly different SCNAs profiles in the discovery cohort emerged. Cluster A was defined by diploid copy number background and focal deletions in the 9p21 region (CDKN2A, CDKN2B and MTAP). Cluster B was defined by genome-wide duplications and several enriched amplifications including 1q11.1 (SETDB1 and MLLT11), (P = 0.0002) and 6p22.3 (E2F3), (P = 0.001). TP53 mutations (P = 0.0001) were enriched in the cluster B, consistent with the role of functional p53 as a “guardian of the genome” preventing chromosomal instability. SCNAs clusters A and B were confirmed in the TCGA validation cohort. Cluster A was enriched with tumors belonging to TCGA bladder cancer cluster III (“basal/squamous-like”) (P = 0.02). Conclusions: Using novel allelic-specific SCNAs analysis, we define two distinct clusters of UC presenting a framework for understanding this aspect of UC’s biology. In contrast to somatic mutations, SCNAs are clonally static during each tumor’s evolution. This data has important implications for precision medicine for UC.

**#1750 Analysis of non-metastatic HCC patient tumors revealed the significance of cell cycle regulation and tumor immunity in association with overall survival and identified clinically relevant druggable targets.** Pei-Zhen Miao,1 Jeff Cheng,2 Kwame Okrah,2 Bonnie Liu,1 Charlie Sun,1 Grace Cao,2 Tony Guo,2 Shijing Fu,2 Marie-Claire Wagle,3 Elizabeth Blackwood,4 David Shankman,5 Astrid Langley,2 Jelena Fedorova Fridlyand,1 Mark Lackner,2 Shih-Min Huang,3 Jian Zhou,1 Zhi Dai1.1 Liver Cancer Institute, Zhongshan Hospital, Fudan University, Shanghai, China; 2Genentech, Shanghai, China; 3Genentech, South San Francisco, CA; 4Genentech, Switzerland.

The lack of efficacious therapies has hindered the progress in improving the survival of HCC patients worldwide. As a disease that associates with the under- standing of genomics and immunology, HCC diagnostic driver and biological features during most of its decades long progression, HCC presents challenges to accurately depict its biological landscape and determine suitable therapeutic intervention. An approach to tackle this issue is to define significant biological variants that impact patient survival in each disease stage, then attempt to chart paths of potential therapies. To identify significant biological determinants associated with the overall survival (OS) of early stage, non-metastatic HCC patients, we constructed focused Nanostring panels that are represented by 1,164 genes of validated components and transcriptional outputs of multiple signaling pathways, cellular machineries, and tumor immunity. An unbiased analysis of patient survival and gene transcript levels revealed four distinct groups of genes that are significantly prognostic. The first two (Group 1 & 2) are associated with mechanism of adaptive immune response, implicating the survival benefit of acquiring higher immunogenic tumor environment in early stage HCC. Searching for druggable targets associated with poorer prognosis, we identified both EZH2 and CHEK1 as candidates from Group 2. In vitro treatment of three HCC cell lines with EPZ-6438 (EZH2 inhibitor) or GDC-0425 (CHEK1 inhibitor) resulted in significant modulation of H3K27me3 or pCHEK1 levels (s345) respectively. The growth of these cell lines was also dose-dependently suppressed by each inhibitor in colony formation assays. Furthermore, the combination of both inhibitors was able to achieve substantial cell growth inhibition at lower concentrations, suggesting a combinatorial effect of targeting both EZH2 and CHEK1 in HCC cell lines. Xenograft studies are ongoing to assess in vivo efficacy of this combination. In conclusion, utilizing well constructed Nanostring gene panels, we identified significant association of cell cycle machinery and adaptive tumor immunity with HCC patient survival. Our findings not only provided potential rationale for expanding testing of cancer immunotherapies to non-metastatic, early stage HCC, but also revealed the potential utility of combining EZH2 and CHEK1 inhibitors to treat HCC.

**#1751 Systematic bias in genomic breast cancer classification due to selecting cases with high tumor percentage and good RNA quality.** Esther H. Lips, Antien L. MooiAart, Maartje van Seijen, Lennart Mulder, Mariou Hoogstraat, Petra M. Nederlof, Lodewyk F. Wessels, Sjoerd Rodenhuis, Gabe S. Sonke, Jelle Wesseling. Netherlands Cancer Institute, Amsterdam, Netherlands.

Background Cancer classification, prognostication, and prediction of treatment sensitivity increasingly rely on DNA and RNA-based tests. This approach requires sufficiently high tumor cell percentages to yield enough DNA or RNA for reliable test results. As a consequence, samples of insufficient quality may drop out, e.g. due to poor cellularity or high numbers of tumor infiltrating lymphocytes. We hypothesized that requiring a high tumor cell percentage and high quality RNA causes systemic bias when interpreting genomic test results in breast cancer, as specific breast cancer subgroups may be over- or underrepresented. Patients and methods For this analysis, we used pre-treatment frozen samples from patients included in neoadjuvant chemotherapy trials at the Netherlands Cancer Institute between 2004 and 2012. Histological features and tumor cell percentage were reviewed and assessed by a consultant breast pathologist. Gene expression profiling was done if the tumor cell percentage exceeded 50% and RNA quantity (RIN value <= 6.5) were sufficient. We compared patient and tumor characteristics between patients in whom gene expression profiling could be performed and those in whom it could not be performed. In addition, we performed a systematic review on gene expression profiling for breast cancer, to assess the percentage of sample drop-out in published studies. Results Frozen biopsies were available from 658 patients (79% of the total study population) and gene expression profiling could be performed in 60% of the cases, a percentage comparable to what is reported in the literature. Reasons for drop out were a low cellularity, poor quality and quantity of
the RNA, or a too small biopsy for processing. These patients had more grade 3 tumors (43% versus 34%, p = 0.04) and were more node positive (76% versus 69%, p = 0.03). Analysis of neoadjuvant chemotherapy response and survival in these patients is ongoing and will be presented at the AACR Annual Meeting 2017. Conclusion Breast cancers for which gene expression data were successfully obtained were associated with grade 3 and node positive tumors. Infrequently observed tumors may represent a more aggressive phenotype and have a relatively poor prognosis, compared to the patients for whom gene expression data could not be measured. As gene expression arrays are now broadly used in a clinical context, it is important to acknowledge this systematic bias, and to be cautious in applying gene expression based tests on different patient populations than a test was developed on.

#1752 Immune-related gene signatures in colorectal liver metastases: Exposing an opportunity for immune modulating therapy. Vágis Nygaard,1 Vega J. Dagenborg,2 Olga Østrup,2 Einar A. Redland,2 Veronica Skarpeteig,3 Laxmi Silwal-Pandit,4 Krzysztof Gryży,4 Audun E. Berstad,5 Åsmund A. Frelund,5 Gunhild M. Mælandsmo,5 Anne-Lise Børresen-Dale,5 Anne H. Ree,5 Bjørn Edvin,5 Kjersti Flatmark,5 #1. Dept. of Tumor Biology, Institute for Cancer Research, Oslo University Hospital, The Norwegian Radium Hospital, Oslo, Norway; 2Dept. of Cancer Genetics, Institute for Cancer Research, Oslo University Hospital, The Norwegian Radium Hospital, Oslo, Norway; 3Dept. of Pathology, Oslo University Hospital, Rikshospitalet, Oslo, Norway; 4Dept. of Radiology, Oslo University Hospital, Norwegian Radium Hospital, Oslo, Norway; 5The Intervention Centre, Oslo University Hospital, Rikshospitalet, Oslo, Norway; 6Dept. of Oncology, Akerhus University Hospital, Lørenskog, Norway.

Colon cancer cells obtained from biopsy samples of colorectal liver metastases (CLM) are used as a part of the most common cancers and one of the leading causes of cancer death in the Western world. Up to 50% of patients with CRC develop metastatic disease and the liver is the most common site. The recently identified consensus molecular subtypes (CMS1–4) based on analysis of primary CRC have prognostic and therapeutic implications, but it is unclear whether these molecular subtypes are valid for metastatic disease. In this study, characterisation of CRC liver metastases (CLM) was performed at multiple molecular levels to identify characteristics relevant to metastatic disease. Molecular stratification of a defined metastatic CRC cohort may yield results of clinical relevance and novel treatment opportunities. Surgically resected CLM and tumor-adjacent liver tissue from 46 patients were analysed for the presence of mutations (targeted deep sequencing), genome-wide copy number alterations (CNA), and transcription profile. Molecular profiles of CLM and tumor-adjacent liver tissues were analyzed and associations with clinicopathological features and outcome were investigated. We found oncogenic mutations in all except one tumor. Both mutation and CNA profiles were similar to profiles reported for primary CRC. A CMS classifier tool applied to gene expression data, revealed the cohort to be highly enriched for CMS2. Unsupervised clustering based on genes with highly variable expression identified a 55-gene cluster that segregated the samples into two subgroups. This segregation was replicated in relevant publicly available data sets, but the clinical significance of this observation is not evident. The 55 genes were associated with lipid metabolic and immune-related functions, revealing a role of the tumor-host microenvironment. The engagement of the immune system was further underlined by analyzing subgroups defined by neoadjuvant chemotherapy (NACT) administration, which revealed altered expression of inflammatory mediators and immune markers. The majority of treated patients had received Oxaliplatin based chemotherapy. The uniform classification of CLM by CMS may reflect the patient composition in our cohort, but may also indicate that novel class discovery approaches need to be explored to uncover clinically meaningful molecular stratification of CLM. Identified immune-related gene expression signatures associated with molecular and clinical features underline the integration and importance of the immune interacome in resectable CLM. Specifically, the transcriptomic snapshot of NACT exposed CLM revealed altered genes associated with immunogenec cell death but also immune suppression. These results point to rational exploration of immune-modulating strategies in CLM in combination with NACT to increase efficacy and broaden treatment opportunities for this patient group.

#1753 Refining breast cancer characterization through single-cell analysis of ex vivo reprogrammed tumor and adjacent normal cells. Harikrishna Nakshatri, Manujhshere Anjanappa, Angelo Cardoso, Lijun Chen, Safa Mohamad, Andrea Gunawan, Susan Rice, Yan Dong, Lang Li, Edward Srouf. Indiana Univ. School of Medicine, Indianapolis, IN.

Discovery of inter-individual functional variations in gene regulatory elements and the observation that tumor and normal tissues of the same organ are in different differentiation states necessitate rethinking of gene expression based subclassification characterization of tumors. To address this issue, we performed single cell genomics of breast tumors and adjacent-normal cells propagated using epithelial reprogramming growth conditions for a short duration. Epithelial cells analyzed were either unselected for specific subpopulation or phenotypically defined with differentially expressed ALDH / CD49f / EpCAM+ luminal progenitors present in the normal breast, which express both basal and luminal-enriched genes. Expression of 93 genes that included PAM50 intrinsic subtype classifier and stemness-related genes was analyzed in 420 tumor and 284 adjacent-normal cells. ALDH + / CD49f+ / EpCAM+ tumors and normal cells were enriched for marker genes paired with less infiltrated and normal cells. PAM50 gene sets analyses of ALDH + / CD49f+ / EpCAM+ populations efficiently identified major and minor clone of tumor cells with the major clone resembling clinical parameters of the tumor. Similarly, stemness-associated gene set identified clones with divergent stemness pathway activation within the same patient sample. This refined technique distinguished genes truly deregulated in cancer cells as compared to normal cells or different cellular precursor of tumors. Collectively, assays presented here may enable precise identification of genes deregulated in cancer, early identification of therapeutically-targetable minor population of tumor cells, and eventually to refinement of precision therapeutics.

#1754 A new glycan biomarker for pancreatic cancer complements CA19-9 and identifies a distinct subpopulation of cancer cells. Daniel Barnett,1 Ying Liu,1 Katie Partryka,1 Galen Hostetter,1 Herbert Zeh,1 Aatur D. Singh,1 Ying Huang,2 Richard R. Drake,3 Randall E. Brand,3 Brian B. Haab,4 Von Andel Institute, Grand Rapids, MI; 2University of Pittsburgh Medical Center, Pittsburgh, PA; 3Fred Hutchinson Cancer Research Center, Seattle, WA; 4Medical University of South Carolina, Charleston, SC.

A major challenge in diagnosing and treating pancreatic cancer is the complex diversity between and within tumors in cellular morphologies and behaviors. Molecular markers to detect and classify specific variants of cancer cells could facilitate drug targeting of subtypes of cancer cells. We recently found that a glycan related to the CA19-9 antigen is a strong serological biomarker and is elevated in the plasma of almost half the patients with low CA19-9. We hypothesized that the cancer cells producing CA19-9 are a different subtype than those producing the new biomarker, referred to as sTRA. Using multimarker immunofluorescence on tissue microarrays, we found that sTRA was significantly elevated (p < 0.001) in tumor tissue relative to adjacent pancreatic tissue in 3 separate TMA covering 38 patients. The STRA and CA19-9 markers were present in 31/38 (82%) and 20/38 (53%) of the tumors, respectively, with 17/38 (45%) displaying both and 3/38 (8%) displaying neither. The morphologies of the cancer cells fell into distinct categories based on glycan expression. Cells with dual staining of both markers tended to be in well-to-moderately differentiated ducts with good nuclear polarization and foamy cytoplasm, or with flat and thin epithelium. Cells with predominant or exclusive CA19-9 staining tended to be part of well-differentiated ducts with mucinous cytoplasm or moderately-differentiated ducts with poor membrane integrity. In contrast, strong sTRA staining was present in small clusters of cells or single cells with poor differentiation and large vacuoles, or in small and invasive ducts. The phenotypes were consistent in xenograft models made with either cells lines or patient-derived material, as well as in 2D culture. Cooating with protein markers of differentiation showed that the CA19-9-positive/sTRA-negative regions colocalized more with MUC5AC, CK19, and E-cadherin relative to the sTRA-positive cells, indicating ductal differentiation, and the sTRA-positive/CA19-9-negative regions were more likely to colocalize with beta-catenin than any other marker, indicating potential for secondary tumor development. At time-to-progression after surgery was associated with the relative levels of the two markers, based on staining of tumors from 48 patients in an independent TMA. Patients with higher dual-staining of CA19-9 and sTRA had statistically longer (p = 0.01 by log-rank test) time-to-progression, and patients with higher exclusive staining of either marker relative to the dual staining had shorter time-to-progression. Thus the sTRA marker used in conjunction with CA19-9 could provide a basis for classifying and targeting subtypes of cancer cells.

#1755 The fate of germline BRCRA related mutations in breast tumor tissues. Vassiliki Kotoula,1, Florence Fostira Fostira,2 Kyriaki Papadopoulos,3 Paraskevi Apostolou,4 Eleftheria Tsalaki,4 Georgios Lazaridis,4 Kyriaki Manousou,1, Flora Zagouri Zagouri,1 Dimitrios Pectasides,1 Ioannis Vlachos,1 Ioannis Titas,1 Sotiris Lakis,1 Irene Konstantopoulou,6 George Pentheroudakis,5 Helen Gogas,5 Pavlos Papakostas,5 Christos Christodoulou,5 Drakoulis Yanoukos,4 George Fountzilas1,2, Aristotle Univ. School of Medicine, Thessaloniki, Greece; 3National Center for Scientific Research NCSR Demokritos, Athens, Greece; 4Hellenic Foundation for Cancer Research, Athens, Greece; 5Hellenic Foundation for Cancer Research, Greece; 6Hellenic Cooperative Oncology Group, Greece; 7National Center for Scientific Research NCSR Demokritos, Greece.

Background - aim: Germline mutation carriers in BRC1A1 and related genes frequently develop triple-negative breast carcinomas (TNBC) that presumably preserve the inherited mutation. Herein, we examined the clinicopathologic features and prognostic impact of paired germline and tumor genotypes in this
#1757 Spectrum of BAP1 mutations identified in diverse cancer lineages.

Zoran Gatalica, Joanne Xiu, Jeffrey Swensen, Wangjun Chen. *Cancers Life Sciences, Phoenix, AZ.*

Background: Germline mutations in the tumor suppressor gene, BAP1, a deubiquitylase that regulates key cellular pathways, are associated with a recently-described tumor predisposition syndrome characterized by early onset benign melanocytic skin tumors, and a significant risk of cancers that include mesothelioma, cutaneous and uveal melanoma, renal cell carcinoma (RCC) and cholangiocarcinoma. Somatic or germline BAP1 mutations have been associated with an aggressive course and a poor prognosis in RCC and cholangiocarcinoma and may render the cancer cells more sensitive to HDAC inhibitors or Parp inhibitors. We investigated types and frequencies of BAP1 mutations in a large cohort of diverse malignancies and their associations with other molecular/genomic characteristics. Methods: A total of 9782 tumor samples from over 40 cancer types were molecularly profiled at Caris Life Sciences by next generation sequencing (Illumina NextSeq platform and Agilent SureSelect XT panel, 592 genes). Microsatellite instability (MSI) was tested by PCR and fragment analysis (Promega MSI Analysis System). Results: A pathogenic somatic or germline BAP1 mutation was identified in 20 cancerts, with a total of 129 tumors with mutations found (1.3% prevalence). As expected, BAP1 mutations were frequently seen in uveal melanoma (50% or 24 in 48), malignant pleural mesothelioma (29% or 6 in 21), RCC (8% or 12 in 150), cholangiocarcinoma (6.6% or 13 in 196), and cutaneous melanoma (2.7% or 7 in 319). In addition, pathogenic BAP1 mutations were detected in carcinomas arising in parotid gland (10.3% or 3 in 29), anus (8.3% or 3 in 36), cervix (3.4% or 4 in 117), stomach (3.3%, or 6 in 180), head and neck (1 in 97 or 1%), lung (14 in 1590 or 0.9%), and breast (0.8% or 7 in 887). A mutation was also noted in a meningioma (1 in 43) and a uterine sarcoma (1 in 96). Variants of BAP1 (pathogenic, presumed pathogenic, and variants of unknown significance) were more often seen in MSI-high tumors (compared to MSI-) in both colorectal (12/61 vs. 18/1003) and endometrial carcinomas (5 of 69 vs. 5 of 321; both p<0.01). It was not determined whether the BAP1 mutations were somatic or germline in origin. Conclusions: The study confirmed the presence of pathogenic BAP1 mutations in carcinomas commonly associated with BAP1 germline and somatic mutations. It also identified BAP1 mutations in additional cancer types (parotid gland, anal and cervical carcinomas), as well as its association with MSI-H cancers (colon and endometrium). Even the presence of mutations in non-cancerous tissues is underway to determine if these novel cancer associations are related to germline predisposition.

#1758 A more mature immunophenotypic makeup of multiple myeloma clone(s) at diagnosis correlates with a higher genomic instability.

Marina Martello,1 Rosalinda Termini,2 Barbara Santacroce,1 Enrica Borsi,1 Vincenza Pulvirenti,1 Barbara Pirovano,1 Gaia D’Antonio,1 Gaia Taddei,2 Chiara Briandelli Chirumbolo,1 Mario Arpinati,1 Giovanni Martinelli,1 Michele Cavo,1 Carolina Terragna1. *University of Bologna, Bologna, Italy; Fondazione Umberto Veronesi, Milan, Italy.*

Introduction: The sequence of events underlying the process of Multiple Myeloma (MM) plasma cells (PC) differentiation have not yet fully elucidated, even if recent findings suggest that different cell subpopulations, with distinct phenotype, compose the MM clone(s), whose plasticity has emerged as a typical feature. Aim: To evaluate the immunophenotypic and genomic background of MM clone(s) at diagnosis in order to stratify patients (pts) according to the PC differentiation stages and possibly correlate with disease outcome. P&M Phenotypic characterization of both CD138+/CD38− and CD19+ populations was carried out on 44 newly diagnosed MM. Fresh BM samples was analysed by 6color multiparametric flow cytometry analysis, combining CD138PE, CD38-PE-Cy7, CD20-APC, CD19-APC-Cy7, CD27-FITC, CD45-FITC, CD28-APC, CD44-FITC, CD54-APC, CD81-PerCP-Cy5.5, CD56-APC and SHL-PE, as a functional marker of Hedgehog pathway activation (Mitley Biotech). Cytoscan HD array were carried out in order to detect genomic copy number alterations (CNAs). Results According to the CD19 and CD38 markers co-expression, pts were stratified in 3 subgroups, recapitulating a progressive PC maturation process: the most immature one, including pts with CD19+/CD38+ (11/44 = 25%); the intermediate CD19-/CD38+ phenotype one (19/44 = 44%), and the CD19-/CD38- PC one, whose clone was mainly composed by most mature PCs. The two extreme subgroups were characterized by a differential expression of...
CLINICAL RESEARCH: Molecular Classification of Tumors

maturation markers: the more mature PCs displayed a higher expression of CD28 and CD44, which usually characterized advanced disease stages, as well as a reduced expression of CD20, CD27 and CD45, commonly associated to preceding PC differentiation stages (p<0.05). Any differential expression of SHH pathway’s ligand was observed. On the contrary, a higher Hedgehog pathway activation was detected in the immature CD19+CD81+ compartment of immature plasma cells (median SHH expression CD19+/CD81+ vs. CD19-/CD81+: 98.1% vs. 11.3%; p<0.05), which probably featured a less quiescent immature reservoir pool. The CNAs analysis showed that mature PCs were characterized by a higher genomic instability, as compared to the more immature ones (total CNA: 306.9 vs. 171.5, p=0.08; genome changed: 36.96 vs. 13.35, p=0.01), including several alterations commonly associated to de-differentiation (e.g. del(17p)). Finally, a higher frequency of baseline clinical characteristics associated to bad prognosis was observed in the more mature, as compared to the more immature subgroups of pts (e.g. PET lesions, k/l ratio; p<0.05).

Conclusion MM clone(s) is a mixture of different cell populations endowed with an inner phenotypic plasticity. Various PC differentiation stages were appreciable already at diagnosis and genomic features associated to bad prognosis characterize pts carrying more mature clones. #1759 Description of molecular marker disparities and KRAS mutational spectrum of colorectal tumors from Puerto Rican Hispanics, Julliane Perez-Mayoral,1 Camila Rivera-Lynch,1 Marievelisse Soto-Salgado,1 Xavier Llor,1 Luis Tous-Lopez,1,2 Marla Torres-Torres,3 Jose S. Reyes,4 Carlos Torres,5 Ajay Goel,6 University of Puerto Rico Comprehensive Cancer Center, San Juan, PR; 2University of Puerto Rico Medical Sciences Campus, San Juan, PR; 3Yale University, New Haven, CT; 4Ashford Presbyterian Hospital, San Juan, PR; 5Puerto Rico Cancer Registry, San Juan, PR; 6Baylor Research Institute, Dallas, TX.

Colorectal cancer (CRC) causes 27% of all cancer deaths among Puerto Rican Hispanics (PRH). Most CRC cases are due to sporadic genetic or epigenetic events that lead to the development of the tumor. These events aggregate to cause CRC carcinogenesis and involve genes that regulate cell growth and differentiation. Improving understanding of the molecular events that lead to CRC carcinogenesis has the potential to reduce CRC mortality by risk stratifying individuals as well as developing prevention strategies. Currently, there are a set of molecular markers that are used to characterize CRC tumors and inform prognosis and treatment decisions. These markers include: microsatellite instability (MSI), CpG island methylation and mutational analysis of the KRAS and BRAF oncogenes. The objective of this study was to characterize the molecular markers present in the CRC tumors of PRH and understand the disparities present at the molecular level in these tumors. The frequency of the MSI and CIMP were evaluated in 488 CRC tumors from PRH. Mutations in the KRAS gene and the BRAF V600E mutation were evaluated using SuperArray technology. Additionally, information regarding sociodemographic and clinicopathologic characteristics of the study population was obtained. Of the 488 evaluated CRC tumors 1.6% (n=2) showed MSI and 90.2% of the studied tumors had CIMP low phenotype (n=102). MSI-High tumors were more likely to be distal tumors compared to MSS tumors (p=0.02). The V600E mutation in the BRAF gene were found in 1.3% (n=1) of the studied tumors. KRAS mutations were found in 31.25% (n=40) of the tumors. The most common KRAS mutations found in the CRC tumors of PRH were: c.35G>A (KRAS COSMIC521) (n=12) and c.38G>A (n=8) (KRAS COSMIC532). Furthermore, the traditional CRC carcinogenesis pathway was the predominant pathway observed for the development of the CRC tumors of our study population. The following study highlights a distinct molecular signature for the CRC tumors from PRH descent. The disparities observed in the prevalence of the molecular markers (low MSI, CIMP Low and mainly wild-type for KRAS and BRAF) suggest that the drivers for CRC in this population might differ from other populations. Additional studies are required to fully elucidate the CRC carcinogenesis pathway in PRH.

#1760 High expression of CASZ1 is associated with poor prognosis in ovarian cancer, Yu-Anchang, Yu-Ling Lian, Yang-Ling Chen, Tse-Ming Hong, Keng-Fu Hsu. National Cheng Kung Univ. Hospital, Tainan, Taiwan.

Epithelial ovarian cancer (EOC) carries the highest mortality rate of all gynecologic malignancies. This high mortality rate is attributed to the fact that most cases of ovarian cancer are detected at late stages when metastases are already present. We previously demonstrated that castor zinc finger 1 (CASZ1) is upregulated in EOC cells and promotes EOC cell metastasis. However, the relationship between the ovarian cancer patient’s prognosis and CASZ1 expression is not clear. In the present study, we examined CASZ1 and CA125 expressions in EOC using immunohistochemistry and correlated their expression levels with patient survival. From January 2008 to January 2012, 144 EOC patients underwent staging or cytoreductive surgery at the National Cheng Kung University Hospital (NCKUH) were consecutively enrolled. Clinical and pathology information, including age, stage, cell type, chemo-response, and survival, was collected from medical charts. The staging met the criteria of the International Federation of Gynecology and Obstetrics Classification (FIGO). Histological grading of EOC was conducted according to the classification of the World Health Organization. The overall survival (OS) was calculated from the date of diagnosis. Progression-free survival (PFS) was measured as the period from surgery to the date of confirmed recurrence or disease progression or to the date of the investigators’ last note of a disease-free status. CASZ1, CA125 expression was evaluated by TissueFaxs microscopy system using an image analysis program. Five fields of the tumor in each slide (corresponding to a mean of 10000 tumors cells per case) were photographed. Images were acquired from using fluorescence-activated cell sorting (FACS)-like tissue cytometry. The percentage of positive cells in each sample was further quantified using TissueQuest software (TissueGnostics, Vienna, Austria). The CASZ1 was significantly upregulated in advanced EOC tissues, compared with early stage tumors. High CASZ1 expression levels were significantly associated with worse EOC clinical characteristics. By univariate survival analysis, high CASZ1 levels significantly correlated with decreased overall survival, progression-free survival. In addition, patients with both high expression with CASZ1 and CA125 carried the worst prognosis. In conclusion, we demonstrate that high expression of CASZ1 levels correlates with an aggressive EOC phenotype and may contribute for poor prognosis in EOC patient. Determination of CASZ1 could be clinically useful in identifying high-risk EOC patients for a more aggressive adjuvant therapy.

#1761 A rapid and accurate nucleic acid amplification and detection method for KRAS mutation testing in colorectal cancer specimens, Yong Shin, Choon Eun Jin, Seung-Seop Yeom, Seok-Byung Lim. University of Ulsan College of Medicine, Asan Medical Center, Seoul, Republic of Korea.

Colorectal cancer (CRC) is one of the most common type of cancers both men and women in the world. Unfortunately, overall death rate of CRC has been decreasing for the last two decades due to the improvement of screening test assays that detect early-stage cancer and pre-cancerous polyps. Nevertheless, the most common treatment for CRC is surgery, because it may completely eliminate the cancer region. In case of the cancer with systemic metastasis, chemotherapy is required before or after surgery for primary or metastatic lesions. Among the regimens for the chemotherapy, both monoclonal antibodies (Cetuximab and Panitumumab) against the epidermal growth factor receptor have been shown to improve survival for only patients with lack of RAS mutations. Thus, the KRAS gene mutations (codons 12 and 13) in CRC patients have been extensively studied as a strong negative predictive biomarker to indicate whether a CRC patient responds to the treatment. Therefore, testing the KRAS mutational status of tumor samples is becoming an essential tool for managing patients with CRCs. Although a myriad of nucleic acid testing methods have been developed to analyze the mutation status in the key regions of the KRAS gene of CRC, several obstacles still remain related to low sensitivity, time consuming, and required large instruments including thermal cyclers. Here, we present a novel nucleic acid amplification and detection method for KRAS mutations (G12D and G13D) testing that enable rapid and accurate detection. This method is based on combination of isothermal DNA amplification method and bio-photonic silicon sensor that can be detected the mutations in a label-free and real-time manner. The proposed method can detect the mutant cell present at 1% in a mixture of wild type cells, while both PCR and sequencing can detect the mutations in a sample containing approximately 30% of mutant cells. We used 60 tissue samples from CRC patients (22 samples with G12D mutations, 23 samples with G13D mutation, and 15 samples with no mutation) to compare the clinical utility of three methods including PCR, Sanger sequencing and the proposed method. The proposed method with both G12D and G13D showed a value of 100% and 100% for sensitivity and specificity, respectively. One the other hand, the sensitivity and specificity of PCR (90.5% and 100%) and sequencing (95% and 100%) were lower than the proposed method. Therefore, the proposed method was found to be rapid (<30 min), highly sensitive and specific method for KRAS mutation testing. We believe that this rapid and accurate method will enable proper treatment for CRC patients.

#1762 Keratin 17 identifies prognostic subtypes of pancreatic ductal ade- nocarcinoma, Luisa F. Escobar-Hoyos,1 Cindy Leiton,1 Elizabeth Vanner,1 Lu- cia Roz-Pena,1 Jinyu Li,2 Scott Powers,2 Ali Alakin,2 Jela Bandovic,2 Peter Bai- ley,2 David Chang,4 Richard Moffitt,5 Jen Jen Yeh,5 Andrew Biankin,4 Kenneth Shroyer,1 Memorial Sloan Kettering Cancer Center, New York, NY; 2Stony Brook University, Stony Brook, NY; 3University of Massachusetts Memorial Medical Center, Worcester, MA; 4Wolfson Wohl Cancer Research Centre, Glasgow, United Kingdom; 5Lineberger Comprehensive Cancer Center, Chapel Hill, NC.

Proceedings of the American Association for Cancer Research • Volume 58 • April 2017

452
Recent RNA sequencing (RNASeq) studies by Bailey et al., 2016, Moffitt et al., 2015 and Collisson et al., 2011 reported that mRNA expression from bulk tumor defines molecular subtypes of pancreatic ductal adenocarcinoma (PDAC) that are highly correlated with patient survival. These studies independently identified Keratin 17 (K17) mRNA overexpression as one of over 20 upregulated transcripts that define the mRNA signature of the most lethal PDACs. Studies in our lab determined that neither K17 gene missense mutations nor copy-number alterations explain the upregulation of K17 mRNA expression by malignant cells. In addition, we found that K17 expression, measured at the protein level by immunohistochemistry or at the level of mRNA by RNASeq, is sufficient to stratify patients by short- vs long-term survival at baseline after resection. These retrospective survival analyses were performed on independent patient cohorts and unified to define low-vs high- K17 patients (total n = 558). High-K17 cases were twice as likely to die from this disease compared to stage-matched low-K17 cases (P values < 0.05). Furthermore, we determined that K17 expression is associated with outcome after Gemicitabine treatment using the Bailey et al., 2016 patient cohort (n = 94). This is the first study to show that the expression of a single gene, K17, can accurately subtype PDAC at initial diagnosis. In conclusion, K17 was identified as a robust and independent, clinically relevant, prognostic and predictive biomarker to stratify clinical outcome at the time of initial diagnosis and to potentially inform clinical decisions regarding chemotherapeutic intervention.

Background: Merkel cell carcinoma (MCC) is a highly aggressive neuroendocrine tumor of the skin. Merkel cell polyomavirus (MCPyV) plays an oncogenic role in the majority of MCC tumors. Detection of MCPyV in MCC tumors has diagnostic utility, and potentially prognostic and therapeutic implications. We investigated whether RNAseq, a novel RNA in situ hybridization (ISH) method for detection of RNA transcripts in tissues at the single-cell/single-molecule level, is useful for MCPyV detection. Methods: We applied an RNAseq probe targeting MCPyVT antigen transcripts on tissue microarrays (TMAs) and full tissue sections encompassing 91 MCC tumors from 75 patients, 14 carcinomas of other types, and various normal tissues. qPCR and immunohistochemistry (IHC) for MCPyV were performed on 58 and 88 cases, respectively. qPCR was also performed on 18 cases of normal skin to establish background levels of MCPyV in non-tumor results. Results: RNA-ISH demonstrated the presence of MCPyV in 46.2% (42/91) of cases. A total of 58 samples had data from all of the three detection modalities (qPCR, RNA-ISH and IHC). RNA-ISH demonstrated 100% concordance with qPCR results, whereas IHC had a slightly lower concordance (96.6%). RNA-ISH demonstrated higher agreement than IHC among TMA cores from the same case, and between TMA cores and matched full tissue sections. Of samples with background inflammatory cells, 5 of 37 (15.6%) showed moderate nonspecific staining of lymphocytes by IHC, whereas RNA-ISH lacked background. Conclusions: RNA-ISH is comparable sensitive to qPCR for detection of MCPyV, and allows for correlation with tissue morphology. Our findings support RNA-ISH as a highly effective method for MCPyV detection in tumors.

#1764 Accurate and reproducible detection of fusions and exon skipping events in NSCLC-derived samples using a comprehensive, targeted RNA-Seq system across multiple laboratories. Gary J. Latham, Richard Bliedner, Brian C. Haynes, Shbhoa Gokul, Maria L. Aguirre, Stephen Hyter, Ziyan Y. Pesivan, University of Michigan, Ann Arbor, MI; Henry Ford Health System, Detroit, MI.

Introduction: Reliable assessment of cancer-associated RNA markers in lung cancer provides crucial information for patient care. Methods to detect RNA fusions and splice variants in NSCLC was demonstrated in a multi-site laboratory evaluation using clinically-relevant specimens and low inputs of TNA. The ability of the panel to detect both common and rare gene fusion transcripts and exon skipping events within an integrated wet- and dry-bench workflow provides a foundation for the reliable detection of oncogenic RNA fusions and aberrant splicing events that can respond to current and emerging targeted therapies. This study highlighted the ease of implementation and consistent performance that can be achieved in different laboratories when the process from sample-to-report is highly integrated.

#1765 Molecular and immunological characterization of non-small cell lung cancer harboring cMET alterations. Maria Saigi, Carolina Pereira, Eva Pros, Elisabeth Brambilla, Ernest Nadal, Montse Sánchez-Cápsedes, IDIBELL, Barcelona, Spain; Centre Hospitalier Universitaire de Grenoble, Grenoble, France; Catalan Institute of Oncology, Barcelona, Spain.

Purpose: To explore the correlation between the expression of immunological biomarkers in a subset of NSCLC tumors presenting cMET activation. Methods: We retrospectively reviewed 200 tumor samples from a cohort of patients diagnosed with NSCLC in 3 different hospitals, from Spain and France. cMET activation was defined by the presence of one or more of the following criteria: 1) cMET mutations inducing exon 14 skipping (METex14), 2) cMET amplification, assessed by FISH 3-cMET overexpression, assessed by immunohistochemistry (IHC). METex14 mutations were determined by genomic sequencing and RT-PCR. FISH was interpreted according to Capuzzo scoring system, considering 5 or more gene copies as the mean value for positive amplification. Concurrent genetic alterations in EGFR and ERBB2 tyrosine kinase receptors were also determined. PD-L1 expression and density of tumor infiltrating CD8+ lymphocytes were assessed by IHC. Statistical correlation analysis was performed by Chi-square and Fisher’s exact test. Results: METex14 cMET amplification and cMET overexpression were detected in 2%, 7.8% and 31% of tumors, respectively. Histological subtypes included: 70% adenocarcinoma, 20% squamous cell carcinoma, 8% large cell, 2% pulmonary sarcomatoid. Curiously, one of the METex14 adenocarcinoma was concurrent with ERBB2 amplification. Those tumors harbouring METex14 or cMET amplification were correlated with positivity to PD-L1 expression (p=0.009). However, this association was not observed in cMET overexpressed tumors. Conclusions: We observed a direct correlation between PD-L1 positivity and METex14 or cMET amplification. Functional analysis and a large cohort of tumors are required to better characterize the potential role of cMET pathway in the regulation of PD-L1 expression.

#1766 Distinct pattern of alterations in tp53 mutated and wild type acute myeloid leukemia (AML) patients. Anna Ferrari, Eugenio Fonzi, Maria Chiara Fontana, Andrea Gelli Luserna Di Rorà, Marco Manfino, Antonella Padella, Carmen Baldizzi, Cristina Papayannidis, Giovanni Marconni, Stefania Paolini, Viviana Guadagnuolo, Margherita Perricone, Valentina Robustelli, Enrica Imbrogno, Eugenia Franchini, Claudia Venturi, Elisa Zuffa, Maria Chiara Abbenante, Giorgia Simonetti, Nicoletta Testoni, Emanuela Ottaviani, Maria-giuliana Giovannini, Institute of Hematology, Bologna, Italy; Cell Plyr bologna, Bologna, Italy.

Background: Mutations in TP53 gene predict a poor prognosis in patients with AML. The reported TP53 mutation rate in AML is low (2.1%) by contrast with AML with a complex karyotype (CK) is higher (69-78%) and have a poor outcome. Quite common is to found paired TP53 mutation together and a segmental 17p deletion. Aims: To investigate the frequency, the types of mutations, the associated cytogenetic, the correlation with known molecular alterations and the prognostic role TP53 mutations in adult AML pts. Moreover we would identify genes/pathways that are mainly affected in the mutated TP53 group compared to the wt one. Patients and Methods: 258 adult AML pts with miscellaneous cytogenetic abnormalities and
normal karyotype were examined in our Institution for TP53 mutations using several methods, including Sanger sequencing, NGS and HiSeq2000 platform and were correlated with cytogenetic analysis. 124/258 samples were genotyped with SNP arrays (Affymetrix, 3 250K, 43 SNP 6.0, 78 CytoScan HD). Copy Number Alterations (CNAs) analyses were performed using Chromosome Analysis Suite (Affymetrix) and NexusCopy Number (Illumina) software. Results: Mutation analysis detected TP53 mutations on 39 patients with 48 different types of mutations (32 deleterious point mutations; 4 deletions); nine pts have 2 mutations. We found 34/48 (70%) missense mutations, 5 mutations in the splice sites, 4 deletions, 2 intrinsic and 3 others mutations. The mutation rate is of 15.1%. Mostly (28/39) of the TP53 mutated pts (71.8%) had CK while only 11/39 (28.2%) mutated pts have “no CK”. Alterations of TP53 were significantly associated with poor outcome (OS and DFS: \( P = 0.0001 \)). To take advantage of different methodological characteristics, on TP53 locus, we matched two software and cytogenetic analysis results. We identify 16 mutated pts that were also deleted and one pt that presented only a deletion. Therefore 50% of mutated pts present a concomitant deletion. OS of TP53 mutated and deleted pts is statistically inferior respect to mutated pts \((P<0.0061)\). Comparing 32 TP53 mutated and 92 TP53 wt pts CNAs results that: a) chromosomes significantly altered are Sq. 17p, 12p, 16q, 22q13.33 and 7q; b) over 900 genes are differentially involved (in all (Loss)); c) and that pathway categories mainly enriched are Signal Transduction, Metabolism, Immune System, Transmembrane transport of small molecules, Gene expression, Cell Cycle. Conclusions: Our data demonstrated that TP53 mutations occur in 15.1% of AML with a higher frequency in the subgroup of CK-AML \((P=0.0001)\). They predicted to be deleterious and significantly correlated with worse prognosis especially if TP53 is both mutated and also deleted. For these reasons, TP53 mutation/deletion screening should be recommended. Different pattern of alterations in mutated and wt groups have to be deeply investigated. ELN, AIL, AIRC, progetto Regionale- Universitario 2010-12 (L. Bolondi), F77- NGS-PTL project.

#1767 Analysis of biomarkers and anthracycline benefit for hormone receptor-negative breast cancer: results from a randomized phase 2 neoadjuvant study (KBOG 1101 Study), Takashi Ishikawa, Kazutaka Narui, Mari S. Oba, Akimitsu Yamada, Kumiko Kida, Mikiko Tanabe, Yasushi Ichikawa.

Tokyo Medical University, Tokyo, Japan; Yokohama City University Medical Center, Yokohama, Japan; Yokohama City University, Yokohama, Japan.

AIM: We compared 6 cycles of docetaxel and cyclophosphamide (TC6) with 3 cycles of S-fluorouracil and epirubicin and cyclophosphamide followed by 3 cycles of docetaxel (FEC-D) as neoadjuvant chemotherapy for patients with hormone receptor (HR)-negative breast cancer (BC) to identify biomarkers requiring anthracyline treatment. Methods: In total, 103 patients with operable HR-negative BC were administered TC6 or FEC-D. Triple-negative BC was subdivided by CK5/6 and EGFR into basal- and non-basal BCs. The primary endpoint was pathological complete response (pCR). Secondary endpoints were safety, breast-conserving surgery ratio, disease-free survival, overall survival, and predictive factors (Ki-67, P-53, ALDH1 and TOP2A by IHC and TOP2A by FISH) for each regimen. Results: Of the 103 patients, 97 completed the study. Overall pCR was higher for patients treated with FEC-D \((36\%)\) than for those treated with TC6 \((25.5\%) \((P=0.265)\). FEC-D was significantly superior to TC6 in basal BC \(29.9\%\ vs 13.6\%\; \(P=0.033\)\), whereas no differences in HER2 and non-basal BCs. Aldehyde dehydrogenase 1 (ALDH1) positivity was inversely associated with pCR for both regimens, significantly for FEC-D \((P=0.047)\) and TC6 \((P=0.085)\). Patients who achieved pCR tended to have longer DFS \((P=0.287)\) and OS \((P=0.089)\). Patients with basal and non-basal BC treated with FEC-D had significantly better DFS \((P=0.016)\) and OS \((P=0.034)\) than those with TC6. Conclusion: We found TC6 was less effective than FEC-D for HR-negative BC because it was not sufficient to treat basal-BC. This suggests that DNA damaging agents like anthracylines are required for treating basal-BC. Additionally, ALDH1 could be a marker for resistance to conventional chemotherapy.

#1768 A practical tool for probing protein glycosylation in clinical samples: Application to characterizing subtypes of MUC5AC glycosylation in distinct subsets of pancreatic cancer patients. Peter Y. Hueh, Van Andel Institute, Grand Rapids, MI.

Glycans are critical to protein biology and are useful as disease biomarkers. Many studies of glycans rely on clinical specimens, but the low amount of sample available for some specimens limits the experimental options. We have a method to obtain information about protein glycosylation using a minimal amount of protein, and we applied it to the study of biomarkers in the blood plasma of pancreatic cancer patients. The method works by treating proteins that were captured by antibody microarrays (2.2 x 2.2 mm) with exoglycosidases to successively expose underlying features, and then probing the native or exposed features using a panel of lectins or glycan-binding antibodies. We use an algorithm to interpret the data and provide predictions about the glycan motifs that are present in the sample. We applied the method to the analysis of the glycosylation of a biomarker, MUC5AC, found in the plasma of patients with pancreatic cancer. An O-linked glycan on MUC5AC was significantly better DFS \((P=0.287)\) and OS \((P=0.034)\) than those without EGFR mutations. FEC-D was significantly superior to TC6 \((P=0.016)\). The patients without EGFR mutations had better progression free survival although there was no statistical significance between patients with or without EGFR mutations. We will collect more patients’ data for analysis.

#1769 The clinical outcome of stage I lung adenocarcinoma patients with or without activating EGFR mutation. Yue-Yu Fang, Chung Gung Memorial Hospital, Taipei, Taiwan.

Purpose: Advanced stage I lung adenocarcinoma patients with activating EGFR mutation may benefit from targeted therapy. The aim of the present study was to determine the association between activating EGFR mutations and clinical outcome of stage I adenocarcinoma. Methods: From January 2010 to April 2014, 167 patients were done. Sanger method of direct PCR, scorpion & ARMS method or ABI allele specific TagMan PCR were used to check the EGFR mutation status of these patients’ samples. The selection of these methods was depended on purity of tumor samples. Results: There were 93 stage IA patients and 74 stage IB patients. Sixty-four (69%) patients had activating EGFR mutations in stage IA patients, and fifty (68%) patients had activating EGFR mutations in stage IB patients. The survival of stage IA and IB were similar in patients with or without EGFR mutations. The patients without mutated EGFR had better progression free survival in IA and IB patients, especially in the IB patients, although the significance did not reach in small preliminary sample size. Conclusion: The survival was similar in stage IA or IB lung adenocarcinoma with or without EGFR mutations. Patient without EGFR mutation had better progression free survival although there was no statistical significance between patients with or without EGFR mutations. We will collect more patients’ data for analysis.

#1770 The association between sarcopenia and cellular senescence of cancer associated fibroblast in pancreatic cancer. Kensuke Yamamura, Yo-ichi Yamashita, Yuki Kitano, Kota Arima, Tatsunori Miyata, Shigeki Nakagawa, Kosuke Mima, Katsunori Imai, Daitsuke Hashimoto, Akira Chikamoto, Hideo Baba, Graduate School of Medical Science, Kumamoto University, Kumamoto, Japan.

Sarcopenia is a syndrome that is characterized by progressive loss of skeletal muscle mass and strength. Several recent studies have shown that sarcopenia has prognostic significance for patients with malignant disease, including cancers of the esophagus, colon, pancreas and liver. On the other hand, cellular senescence is gaining increased attention from clinicians and researchers, yet incompletely understood role in the development of malignant disease. Previous studies reported that Caveolin-1 expression in cancer associated fibroblast is associated with cancer progression, and it is known in recent years that caveolin-1 plays a major role in controlling cellular senescence. Therefore, we hypothesized that sarcopenia causes cellular senescence of cancer associated fibroblast by activating EGFR expression in clinical specimens and could facilitate the characterization and identification of glycan biomarkers.
copia. Kaplan-Meier analysis showed that patients with sarcopenia had a significantly worse cancer specific survival than patients without sarcopenia (3-year-survival: 37.2% vs 50.4%, respectively, p = 0.038). While, a high level of Caveolin-1 expression was detected in 29.2% (38/130) of our samples. High Caveolin-1 expression in CAK significantly correlated with poor prognoses with respect to both DFS and OS (p = 0.002 and p = 0.003, respectively). However, there was no relationship between sarcopenia and IHC score of Caveolin-1 expression in CAK. Conclusion: The present result suggested that sarcopenia and Caveolin-1 expression of CAK in patient with pancreatic cancer is respectively associated with poor prognosis, but not associated with each other. Now, we focus on Caveolin-1 expression of CAK, and establish primary cultures of CAF from the pancreatic cancer tissues and examine its function.

CLINICAL RESEARCH: Predictive Biomarkers 1

#1771 Phase 3 trial of adjuvant sphinctin in patients with high-risk renal cell carcinoma: exploratory molecular analysis of tumor biomarkers. Daniel J. George,1 Jean-Francois Martini,2 Yen-Hwa Chang,3 Michael Staehler,4 Jan Cardarelli, Italy; 11Pfizer, Italy; 12Pfizer Inc, PA; 13Centre Eugene Marquis, Montreal, Canada; 14University of Shanghai, China; 15University of Missouri, Columbia, USA; 16Memorial Sloan Kettering Cancer Center, NY; 17University of Cambridge, UK. Background: Adjuvant therapy with sunitinib (SU) compared with placebo (PBO) prolonged disease-free survival (DFS) in patients (pts) with loco-regional high-risk renal cell carcinoma (HR R=0.76, 95% CI: 0.59-0.98; P=0.03; median[median] DFS, 6.8 vs 5.6 years). Here, we report the results of a retrospective exploratory molecular biomarker analysis using nephrectomy biospecimens from the S-TRAC trial. Materials and Methods: Formalin-fixed paraffin-embedded tumor tissue blocks from patients who provided informed consent were used for immunohistochemistry (IHC) staining of PD-L1 and PD-L2 in 20% of all available FFPE tissue samples. Analysis of PD-L1 expression was performed using Dako12345678, 34E12 antibody and Dako EnVision System. Staining intensity was scored (0 to 3+) and the proportion of stained tumor cells was multiplied by intensity to give a PD-L1 expression score, ranging from 0 to 300. Analysis of the expression scores was performed in 4 areas of each tissue section (core) and the mean expression score was calculated. Analysis was performed on NSCLC, then applied to 30 available RCC samples. Results: Immunohistochemical analysis of PD-L1 expression in SU group showed increased expression of PD-L1 protein compared to PBO group (22.3% vs 13.2%). The expression of PD-L1 was positively associated with better DFS (HR 0.80, 95% CI: 0.42-1.50; P=0.484). The sensitivity and specificity of PD-L1 was assessed and the cut-off of 300 was determined to be optimal for predicting DFS. Conclusion: Increased PD-L1 expression in tumor cells was associated with longer DFS in SU-randomized pts but not PBO, suggesting that this may be predictive of treatment effect. Further validation in an independent cohort is warranted. The prognostic value of PD-L1 expression in primary tumors from patients with high-risk non-metastatic RCC should be further explored.

#1772 PIK3CA C2 domain deletions hyperactivate PI3K, generate oncogene dependence and are excessively sensitive to PI3Kα inhibitors. Sarah Crossmann,1 Jonathan Sheehan,2 Gregory Slowski,3 Nalin Leelatan,1 Jie He,2 Rebecca Nagy,3 Justin M. Balko,6 Ingrid A. Mayer,4 Richard B. Lamann,5 Vincent Miller,2 Lewis C. Cantley,4 Jonathan M. Irish,1 Jens Meiler,2 Carlos L. Arteaga1. 1Vanderbilt University, TN; 2Foundation Medicine, Cambridge, MA; 3Guardant Health, Inc., Redwood, CA; 4Meyer Cancer Center of Weill Cornell Medical College, New York, NY. Background: A 63 year old postmenopausal woman with advanced ER+ breast cancer resistant to endocrine therapy exhibited an exceptional response to the PI3Kα inhibitor alpelisib (BYL719) and the aromatase inhibitor letrozole (MCL). Clonal capture sequencing (NGS) of DNA from a liver metastasis identified a P447_L455 deletion in the C2 domain of PIK3CA. About 80% of PIK3CA activating mutations are in ‘hot spots’ within the helical and kinase domains. C2 domain mutations make up ~10% of all PIK3CA mutations in breast cancer (TCGA, Foundation Medicine) and are frequently not reported by tumor and plasma cell-free DNA NGS panels. Deletions and mutations in this domain cluster in a region encompassing amino acids 446-460 of PIK3CA. We investigated here the functional role of PIK3CA C2 domain mutations and their response to PI3K inhibitors. Methods: V5-tagged lentiviral vectors encoding wild type, delP447-L455, and delH450-P458 were stably transduced into MCF10A non-tumorogenic human breast epithelial cells. Cell viability and acini formation in 3D Matrigel were examined in media treated with wild type or alpelisib (1 μM) of PIK3CA activated by immunoblot and phosho-flow analysis. The Rosetta software suite was used to construct a structural model that would predict the change in stability of the p85/p110 complex. Physical association of p85α and p110α was determined by precipitation with V5 antibodies and immunoblot analysis. Results: MCF10A cells stably expressing V5-tagged PIK3CA wild type and PIK3CA delP447-L455 exhibited EGF- and insulin-independent growth and higher phosphorylation of AKT, ERK and S6 when compared to parental MCF10A cells. In 3D Matrigel, MCF10A cells with PIK3CA C2 domain deletions formed invasive acini with increased protrusions, spindling, and bridging between acini. All these changes were ablated upon the addition of 1 μM of alpelisib whereas parental MCF10A cells were unaffected by alpelisib. We hypothesized that delP447-L455 would reduce the binding affinity of PIK3CA with the p85 regulatory subunit. A structural model of PIK3CA delP447-L455 in the context of the regulatory complex revealed specific favorable inter-residue contacts that would be lost as a result of the deletion, predicting a significant decrease in binding energy. Consistent with this structural analysis, coimmunoprecipitation of p85 with V5 antibodies showed reduced binding of the C2 domain deletion mutants with p85 compared to wild type PI3Kα. Conclusions: These data suggest that C2 domain deletions in PIK3CA are activating mutations and generate oncogene dependence. As a result, tumors expressing these mutations are excessively sensitive to PI3Kα inhibitors. Thus, in addition to PIK3CA ‘hot spot’ mutations, C2 domain mutations should also be considered biomarkers of sensitivity to PI3Kα inhibitors.
CLINICAL RESEARCH: Predictive Biomarkers

lated with these outcomes. Following D treatment, IFNγ was induced in NSCLC pts (FC=2; p=0.0046) regardless of clinical response. High levels of pre-treatment IFNG in NSCLC pts associated with greater benefit from D. D induces IFNγ within the tumor microenvironment. Observations from other tumor types will be presented.

#### 1774 Progression-free survival curves suggest a dichotomous determini-ant of PD-L1 inhibitor efficacy

David J. Stewart, 1 Dominick Bosse, 2 Stephanie Brule, 1 Andrew G. Robinson, 2 Michael Ong, 1 John Hilton 1. 1University of Ottawa, Ottawa, Ontario, Canada; 2Harvard University, Boston, MA; 3Queen’s University, Kingston, Ontario, Canada.

Background: PD-L1 expression varies across tumors but does not accurately predict PD-L1 inhibitor efficacy. Some negative tumors respond and some pos-itive tumors fail. PD-L1 inhibitor progression-free survival (PFS) curve shape in non-small cell lung cancer (NSCLC) suggests that a dichotomous (present vs absent) factor might drive sensitivity rather than it being driven by a continuous variable like PD-L1 expression. PFS curves may follow first order kinetics, with a straight line if log % PFS is plotted vs time. If the population had 2 distinct absent) factor might drive sensitivity rather than it being driven by a continuous variable like PD-L1 expression. PFS curves may follow first order kinetics, with a straight line if log % PFS is plotted vs time. If the population had 2 distinct

#### 1776 Impact of homologous recombination deficiency (HRD) biomarker on outcomes in triple-negative breast cancer (TNBC) patients treated with AC chemotherapy (SWOG 59313)

Priyanka Sharma, 1 William Barlow, 2 Andrew K. Godwin, 1 Harsh Pathak, 1 Kamilla Isakova, 2 Anne R. Hartman, 3 Kristen M. Timms, 3 Hannah M. Linden, 4 Debu Tripathy, 5 Gabriel N. Hortobagyi, 5 Daniel F. Hayes, 6 University of Kansas Medical Center, Westwood, KS; 7SWOG Statistical Center/Cancer Research and Biostatistics (CRAB), Seattle, WA; 8Myriad Genetics, Inc., Salt Lake City, UT; 9University of Washington/Seattle Cancer Care Alliance, Seattle, WA; 10The University of Texas MD Anderson Cancer Center, Houston, TX; 11University of Michigan, Ann Arbor, MI.

Introduction: There is a critical need to develop biomarkers of response and resistance to adjuvant chemotherapy for TNBC. In preliminary studies, homologous recombination deficiency (HRD)-causing alterations have been reported in immune response-mediated PD-L1 expression. In TNBC patients, PD-L1 expression may be relevant for predicting response to checkpoint inhibitors. Also, HRD has been shown to predict sensitivity to checkpoint inhibitors. However, further studies are needed to confirm these findings.

Methods: Among 3125 breast cancer patients enrolled in SWOG 59313, 1291 patients with PD-L1 expression were included in the analysis. Patients were divided into two groups based on PD-L1 expression: PD-L1 positive (TPS ≥ 10) and PD-L1 negative (TPS < 10) groups. The primary endpoint was overall survival (OS). Secondary endpoints included progression-free survival (PFS), response rate, and investigator-assessed clinical benefit rate (CBR).

Results: Among the 1291 patients included in the analysis, 633 (49.3%) were PD-L1 positive (TPS ≥ 10) and 658 (50.7%) were PD-L1 negative (TPS < 10). The median follow-up time was 35 months. The median OS was 54.2 months for PD-L1 positive patients compared to 38.9 months for PD-L1 negative patients (p=0.0001). Similarly, the median PFS was 14.3 months for PD-L1 positive patients compared to 6.6 months for PD-L1 negative patients (p<0.0001). The response rate was 28.9% for PD-L1 positive patients and 13.0% for PD-L1 negative patients (p=0.001). The CBR was 53.4% for PD-L1 positive patients and 38.4% for PD-L1 negative patients (p=0.001).

Conclusion: These results suggest that PD-L1 expression may be a useful biomarker for predicting response to adjuvant chemotherapy in TNBC patients. Further studies are needed to confirm these findings and to explore the potential use of PD-L1 expression as a predictive biomarker for PD-L1 inhibitors in TNBC.
HRD results were determined in 91% (379/425) and 67% were HRD positive (27% with tBRCA mutation and 40% with tBRCA negative but HRD score > 42). HRD positive status was associated with a better DFS (HR = 0.69; 95% CI 0.49-0.96 (p = 0.027)) and OS (HR = 0.67; 95% CI 0.47-0.97 (p = 0.032)). High HRD score (>24) in tBRCA negative patients (n=274) was also associated with better DFS (HR = 0.39; CI 0.26-0.63). DNA damage responsive (DDR) versus non-responsive (NDR) did not impact DFS (p = 0.78). Conclusions: Two thirds of tTNBC patients receiving adjuvant AC chemotherapy had tumor HRD positivity. HRD was associated with better DFS and OS, perhaps due to high responses to AC. HRD status has the potential to be used as a selection criterion to identify tTNBC patients who receive significant benefit from anthracycline chemotherapy, and may also be of value in selecting patients suitable for treatment with other DNA damaging agents like platinum salts/PARP-inhibitors.

#1777 Development of a pan-cancer 15 gene expression signature to detect a subgroup driven by MAPK signalling. Laura A. Knight,1 Bethanie Price,1 Andrea McCavigan,2 Aya El-Helali,2 Charlie Gourley,1 Denis P. Harkin,1 Richard Kennedy,2 Nuala McCabe1.1 Abnac Diagnostics Ltd, Craigavon, United Kingdom; 2 Queens University Belfast, Belfast, United Kingdom.

INTRODUCTION: Unsupervised hierarchical clustering of gene expression data from 265 High Grade Serous Ovarian Cancer (HGSO) patients identified 3 major molecular subgroups. One subgroup is driven by activation of the MAPK pathway and is associated with poor prognosis and resistance to platinum chemotherapy. The MAPK pathway is currently being targeted by novel therapeutics and hence an assay to detect activation of the pathway across cancers would be highly valuable as a clinical trial enrichment tool. Using internal and publicly available gene expression datasets we have demonstrated that the MAPK subgroup also exists in other cancer types and is associated with poor prognosis. The aim of this study was to develop a gene expression signature to predict the MAPK subgroup across multiple cancer types. METHODS: Evaluation of gene expression data in a range of tumours (ovarian, colon, lung, melanoma and prostate) identified a common gene list (CGL) of 7802 genes showing high variability and high expression across diseases. The CGL was input to different machine learning algorithms developing signatures under 10x5-fold cross-validation (CV), trained against the MAPK HGSO subgroup. Filter-Feature-Selection removed 10% of genes under CV based upon ranked correlation adjusted t-scores and the final model selected to satisfy a number of key criteria: AUC for predicting the endpoint; association with survival (C-Index); and functional relevance of signature content. RESULTS: A 15 gene signature was selected, yielding an AUC=0.87 [95% CI 0.84-0.89] with respect to the MAPK subgroup. This model has validated as a poor prognosis marker in several other cancer types (Colorectal, Relapse free survival: HR = 1.46 [95% CI 1.07-1.98]; Lung, Relapse free survival: HR = 2.18 [95% CI 1.33-3.56]; Prostate cancer, Biochemical recurrence: HR 2.49 [CI 1.43-4.34], and is suppressed by MEK inhibition (p=0.0023) and elevated by KRAS, NRAS and MEK1 overexpression in cell line models (p=0.0443, <0.0001and <0.0001). Additionally we have demonstrated that the 15 gene signature strongly predicts response to the MEK inhibitors Trametinib and Selumetinib in established cell line models (p<0.0001) and in primary tumour biopsies and ovarian cell lines (p<0.0001). CONCLUSION: A 15 gene signature has been developed from formalin fixed paraffin embedded samples across multiple diseases to detect a molecular subgroup driven by MAPK signalling. This assay predicts sensitivity to MEK inhibitors in pre-clinical model systems and in primary cells derived from patients. Further work aims to validate the signature in clinical samples from patients treated with a MEK inhibitor. This assay may be helpful for clinical trial enrichment to select patients that are likely to benefit from MAPK targeted therapies.

#1778 A clinical genomic biomarker study of the CHK1 inhibitor prexemabertin in advanced head and neck squamous cancer and squamous cell carcinoma of the anas. Ricardo Martinez,1 Sameera R. Wijayawardana,1 Andrea Hong,2 Johanna Bendell,2 Anna Maria Russell,1 Richard P. Beckmann,1 Aimee Bence Lin1.1 Eli Lilly and Company, Indianapolis, IN; 2 MD Anderson Cancer Center, Dallas, TX.

CHK1 plays a critical role in DNA damage repair (DDR) pathways as well as in coordinating DNA replication. Selective CHK1/CHK2 compounds are being tested in clinical trials but predictive biomarkers of patient response are lacking. A phase 1b expansion cohort study (I4D-TCJT1A, NCT01115790) with the CHK1 inhibitor, prexemabertin, included patients with advanced, metastatic head and neck squamous cell carcinoma (HNSCC) or squamous cell carcinoma of the anus (SCCA). To identify genomic biomarkers associated with single-agent drug response, pre-treatment tissues (archived or biopsy) from 71 consented patients (HNSCC=47, SCCA=24) were subjected to next-generation sequencing (NGS) using the FoundationOne gene panel. In this subset of patients, the disease control rate (DCR) (Complete Response (CR) + Partial Response (PR) + Stable Disease (SD) based on RECIST Criteria (v 1.1)) was 60% (28/47) and 75% (18/24), respectively. We present here the observed genetic alterations correlated (DCR) (Complete Response (CR) + Partial Response (PR) + Stable Disease) between the two cohorts. Known or likely loss-of-function (LOF) mutations in FBXW7 and PARK2, two genes implicated in Cyclin E1 dysregulation, were noted in patients with favorable response in both tumor types. Across both HNSCC and SCCA, cohorts, mutations and/or germline variants in the DDR genes BRCAlA2, BRCAl2, MREI1A and ATM not in the Fanc (FANC) pathway genes were found in patients with treatment benefit. Whereas PIK3CA mutations were infrequent in the HNSCC cohort, in SCCA, mutations occurred in 5/8 (63%) patients with disease control vs 1/6 (17%) with PD. All 7 PIK3CA mutations observed in HNSC+ SCCA and SCCA patients mapped to the helical domains suggestive of Apobec-induced mutagenesis as their source of origin. The enhanced clinical benefit to prexemabertin associated with HPV+ in HNSCC may reflect a prognostic effect. Alternatively, the observed biomarker in the hypothesis-generating DNA damage responsive (DDR) and the estrogen receptor (ER) may also be of value in selecting patients suitable for treatment with other DNA damaging agents. Clinical trials are ongoing to further evaluate these findings.

CLINICAL RESEARCH: Predictive Biomarkers 1

#1779 Chronic NSOIA use increases survival in PIK3CA-altered head and neck squamous cell carcinoma. Matthew Louis Hedberg,1 Noah Peyer,1 William Gooding,1 Hui Li,1 Toni Brand,2 Victor Olivers,1 Simon Choise1.1 University of Pittsburgh, Pittsburgh, PA; 2 University of Pittsburgh, Pittsburgh, PA.

The phosphoinositol-3-kinase (PI3K) signaling pathway is one of the most biologically plausble explanations for the observed effect. Methods: The PIK3CA status of tumor tissue was determined by FISH and next generation sequencing for 266 HNSCC patients treated at the University of Pittsburgh Cancer Institute. Cox joint proportional hazards models were used to generate multivariate projections of disease-specific (DS) and overall survival (OS). Known or likely loss-of-function (LOF) mutations in PIK3CA were examined in HNSCC and SCCA. PIK3CA (24%) and PIK3CB (26%). Conclusions: Chronic NSOIA use had a significant impact on survival in patients with PIK3CA-altered HNSCC, but not those with wild-type, unamplified PIK3CA.

The phosphoinositol-3-kinase (PI3K) signaling pathway is one of the most biologically plausible explanation for the observed effect. Methods: The PIK3CA status of tumor tissue was determined by FISH and next generation sequencing for 266 HNSCC patients treated at the University of Pittsburgh Cancer Institute. Background: Hypoxia is an important feature of the tumor microenvironment and correlates with radiotherapy resistance and metastatic progression. Additionally, as the malignant phenotype promotes aerobic glycolysis and contributes to the microenvironmental acidification, an underlying mechanism in radiation resistance and metastasis is likely linked to metabolic changes caused by mitochondrial reprogramming. We hypothesized that ROS and mtDNA damage might be indicators of poor tumor therapy response and dissemination of rectal cancer. Methods: Three colorectal cancer (CRC) cell lines (HCT116, HT29, LoVo) were cultured under hypoxia (0.2% O2) or normoxia (21% O2) for 24 hours. In a prospective rectal cancer trial, serum was sampled from patients at the time of diagnosis. Levels of ROS were determined by the ability to oxidize dihydrochlorofluoroscein into a fluorescent product and a fluorescamine-based assay. mtDNA damage was quantified by the ability of modification on template DNA to inhibit restriction enzyme cleavage. For the study patients, histologic tumor response to neoadjuvant radiotherapy was evaluated according to standard ypTN staging and tumor regression grade (TRG) scoring. Groups were compared using Student’s t-test. Survival differences were assessed using the log-rank test. Results: Compared to normoxic conditions, hypoxia significantly reduced ROS levels in all CRC cell lines. Moreover, in serum samples, ROS levels were lower for T2 cases than for patients with T2–3 disease (p = 0.037), and accordingly, low circulating ROS was associated with adverse metastasis-free survival (MFS; p = 0.004) and overall survival (p < 0.001). Hypoxic HCT116 and HT29 cell lines, but not the LoVo cells, were significantly higher mtDNA damage than under normoxia. Given the indicated dependence of ROS and mtDNA damage to hypoxia, a low ratio of ROS to mtDNA damage turned out to be a promising indicator of hypoxic CRC cells. This ratio was lower in serum samples from patients who obtained poor histologic tumor response to radiotherapy (ypT3–4 versus ypT0–2 and poor versus good TRG; p = 0.044 for both). Accordingly, a high ratio of circulating ROS to mtDNA damage was associated with longer MFS (p = 0.021). Conclusion: We showed that culturing of CRC cells under hypoxia caused decrease in ROS levels but increase in mtDNA damage. Interestingly, in serum samples from rectal cancer patients, low ROS levels were associated with T4 disease, representing a bulky and often hypoxic tumor, and thus adverse survival. Moreover, low ratio of ROS to mtDNA damage was correlated with poor histologic tumor response to neoadjuvant radiotherapy. These parameters may reflect an aggressive biological phenotype instigated by a host tumor microenvironment. The results are currently under validation in an independent patient cohort. Trial registration: NCT00278694.

#1782 Reactive oxygen species (ROS) and mitochondrial DNA (mtDNA) damage in tumor hypoxia, poor radiotherapy response, and metastatic progression of rectal cancer. Paula A. Bousquet,1 Sebastian Meltzer,1 Linda Sondrholm,2 Ying Ebens,9 Lars G. Lyckander,1 Svein Dueland,1 Kjersti Flatmark,2 Kathrine R. Redalen,1 Lars Eide,8 Anne H. Ree1. 1Akershus University Hospital, Lørenskog, Norway; 2Oslo University Hospital, Oslo, Norway; 3University of Oslo, Oslo, Norway.

Background: Hypoxia is an important feature of the tumor microenvironment and correlates with radiotherapy resistance and metastatic progression. Additionally, as the malignant phenotype promotes aerobic glycolysis and contributes to the microenvironmental acidification, an underlying mechanism in radiation resistance and metastasis is likely linked to metabolic changes caused by mitochondrial reprogramming. We hypothesized that ROS and mtDNA damage might be indicators of poor tumor therapy response and dissemination of rectal cancer. Methods: Three colorectal cancer (CRC) cell lines (HCT116, HT29, LoVo) were cultured under hypoxia (0.2% O2) or normoxia (21% O2) for 24 hours. In a prospective rectal cancer trial, serum was sampled from patients at the time of diagnosis. Levels of ROS were determined by the ability to oxidize dihydrochlorofluoroscein into a fluorescent product and a fluorescamine-based assay. mtDNA damage was quantified by the ability of modification on template DNA to inhibit restriction enzyme cleavage. For the study patients, histologic tumor response to neoadjuvant radiotherapy was evaluated according to standard ypTN staging and tumor regression grade (TRG) scoring. Groups were compared using Student’s t-test. Survival differences were assessed using the log-rank test. Results: Compared to normoxic conditions, hypoxia significantly reduced ROS levels in all CRC cell lines. Moreover, in serum samples, ROS levels were lower for T2 cases than for patients with T2–3 disease (p = 0.037), and accordingly, low circulating ROS was associated with adverse metastasis-free survival (MFS; p = 0.004) and overall survival (p < 0.001). Hypoxic HCT116 and HT29 cell lines, but not the LoVo cells, were significantly higher mtDNA damage than under normoxia. Given the indicated dependence of ROS and mtDNA damage to hypoxia, a low ratio of ROS to mtDNA damage turned out to be a promising indicator of hypoxic CRC cells. This ratio was lower in serum samples from patients who obtained poor histologic tumor response to radiotherapy (ypT3–4 versus ypT0–2 and poor versus good TRG; p = 0.044 for both). Accordingly, a high ratio of circulating ROS to mtDNA damage was associated with longer MFS (p = 0.021). Conclusion: We showed that culturing of CRC cells under hypoxia caused decrease in ROS levels but increase in mtDNA damage. Interestingly, in serum samples from rectal cancer patients, low ROS levels were associated with T4 disease, representing a bulky and often hypoxic tumor, and thus adverse survival. Moreover, low ratio of ROS to mtDNA damage was correlated with poor histologic tumor response to neoadjuvant radiotherapy. These parameters may reflect an aggressive biological phenotype instigated by a host tumor microenvironment. The results are currently under validation in an independent patient cohort. Trial registration: NCT00278694.

Background: Inhibition of thymidylate synthase (TS) results in a transient compensatory “flare” in thymidine salvage pathway activity which is measurable with 18F-thymidine (FLT) positron emission tomography (PET) at 2 hrs of exposure to therapy. Here we examine the predictive value of the FLT-PET measured “flare” for NSCLC sensitivity to pemetrexed, a commonly used TS inhibitor, in a preclinical model. Experimental Design: Resistance to pemetrexed therapy was induced in two sensitive human NSCLC cell lines, H460 and H1299, by overexpressing TS. TS overexpression was confirmed with RT-PCR and Western blotting and pemetrexed-resistance confirmed with IC50 assays. The presence of a pemetrexed-induced DNA salvage pathway “flare” was then measured using UH-thymidine in both pemetrexed-resistant (H460 and H1299) and resistant (H460R and H1299R) lines in vitro, as well as inherently resistant NSCLC cell lines CALU6, H522, H650, H661, H820, H1838, and validated with FLT-PET in vivo using H460 and H460R xenografts. Results: Overexpression of TS induced resistance to pemetrexed in the H460 and H1299 with IC50 for H460, H1299, H460R and H1299R measured as 0.141 μM, 0.656 μM, 22.842 μM, 213.120 μM, respectively. Significant increases in DNA salvage pathway activity (“flare”) was observed at 2hrs of therapy in the pemetrexed-sensitive H460 and H1299 lines but not the resistant H460R and H1299R, CALU6, H522, H650, H661, H820, H1838 cell lines in vitro using “flare”-thymidine assays. Similarly, FLT “flare” was observed in the pemetrexed-sensitive H460 xenograft tumors but not the pemetrexed-resistant H460R xenograft tumors with post-therapy increases in measured FLTmax of 58% (STD 12.1) and 10.8% (STD 7.3) respectively. Conclusions: FLT-PET imaging of TS inhibition may provide an early indicator of NSCLC sensitivity to pemetrexed.

We have previously described a targeted genomic Laboratory Developed Test (LDT) that includes variant specific Droplet Digital™ PCR (ddPCR) testing for EGF, KRAS and BRAF in plasma. This test supports the rapid delivery of molecular diagnostic test results, with >95% of tests results delivered in 72 hours of receipt in our Laboratory. This test then meets the key clinical need for the delivery of results that can result in faster treatment decisions. Additionally, the test may provide utility to those patients whose mutation results are unknown or for whom tissue may be unavailable or insufficient for molecular testing. This is especially true for patients diagnosed with non-small cell lung cancer (NSCLC). In this report we will update on new test concepts using the recently available design software engine for ddPCR assays. Specifically, we will describe studies on the development of single-reaction, multiplexed assays for the respective detection of ROS1 (up to 11 variants), RET (up to 8 variants) and EML4-ALK (v1 - v3). Design considerations, specificity and sensitivity, as well as reproducibility and robustness studies for these complex assays will be reviewed. Similar studies were conducted for the development of the commercially available test for the EML4-ALK fusion variants. EML4-ALK concordance studies compared the fusions found in blood with known positives and negatives found using FISH and PCR based methods. Clinical sensitivity, specificity and concordance were 85%, 100% and 92% respectively. In this study we also report on test performance of the ALK RNA fusion test over 3 consecutive months of testing. Of note, we have delivered greater than 95% of tests (n = 272 samples) with an observed positive sample frequency of 2.0%. The robust detection of rare variant, RNA fusions from plasma within 72 hours represents a molecular testing option of value to patients with cancer. This test then meets the key clinical need for the delivery of results that can result in faster treatment decisions. Additionally, the test may provide utility to those patients whose mutation results are unknown or for whom tissue may be unavailable or insufficient for molecular testing. This is especially true for patients diagnosed with non-small cell lung cancer (NSCLC). In this report we will update on new test concepts using the recently available design software engine for ddPCR assays. Specifically, we will describe studies on the development of single-reaction, multiplexed assays for the respective detection of ROS1 (up to 11 variants), RET (up to 8 variants) and EML4-ALK (v1 - v3). Design considerations, specificity and sensitivity, as well as reproducibility and robustness studies for these complex assays will be reviewed. Similar studies were conducted for the development of the commercially available test for the EML4-ALK fusion variants. EML4-ALK concordance studies compared the fusions found in blood with known positives and negatives found using FISH and PCR based methods. In this study we also report on test performance of the ALK RNA fusion test over 3 consecutive months of testing. Of note, we have delivered greater than 95% of tests (n = 272 samples) with an observed positive sample frequency of 2.0%. The robust detection of rare variant, RNA fusions from plasma within 72 hours represents a molecular testing option of value to patients with cancer.

Background: With new developments of oncology drug combinations and targeted treatments, the ability to stratify categories of patient populations and to develop companion diagnostics has become increasingly important. A panel of 325 RNA-biomarkers was selected based on cancer-related biological processes of healthy cells and gene expression changes over time during non-malignant epithelial cell organization. This 'cancer in reverse' approach in combination with empirically derived algorithms resulted in a panel of biomarkers, having little overlap with 9 other widely-used commercial gene panels analyzed by dChip at (e.g., overlap with FoundationOne was 2% (lowest) and with OncoTyperDX was 14% (highest)), providing a more in-depth and comprehensive view of gene expression profiles and key cellular signaling pathways beyond mutations in 'driver-genes', and drug associations including chemotherapies, immunotherapies, and targeted-therapies. Objective: In order to technically validate an assay for the 325 RNA-biomarkers we compared gene expression profiles side-by-side using two technology platforms to address the reproducibility of the assay. Methods and Results: We have mapped the 325 RNA transcripts and 7 housekeeping genes in a custom NanoString n-counter expression panel to be compared to all potential probe sets in the Affymetrix Human Genome U133 Plus 2.0 microarray. The experiments were conducted with 10 unique biological formalin-fixed paraffin-embedded (FFPE) breast tumor samples. Each site extracted RNA from four sections of 10-microns thick FFPE tissue over three different days by three different operators using an optimized standard operating procedure and quality control criteria. Samples were analyzed using mass in BioConductor and NanoStringNorm in R. Pearson correlation showed reproducibility between sites for all 60 samples with an r of 0.992 for Affymetrix and r = 0.999 for NanoString. Correlation in multiple days and multiple users were for Affymetrix r = (0.962 - 0.992) and for NanoString r = (0.982 - 0.991). The platforms were compared using relative expression fold changes using linear regression (lm). Concordant genes were defined to have gene expression levels within t+/- 2 standard deviation (sd) of each other at 95% confidence interval, or to have greater than t+/- 2 sd but have changes in the same direction in both platforms. The discordant genes were defined to have opposite direction of changes. By this definition, approximately 90% of the genes fell into the concordant category. Conclusion: The 325 RNA-biomarkers showed reproducibility in two technology platforms with high concordance. With five predictive tests under development for breast (3), lung and pancreatic cancers future directions include performing clinical validation studies and generate rationale for patient selection in clinical trials using the technically validated assays.

#1786 Predictive value of LRPl, KNPNA2 and GDF15 expression to anthracycline/taxane based chemotherapy response in patients with locally advanced breast cancer. Hector Maldonado-Mtz1, Alison-Luna Oscar1, Ali Flores-Perez2, Meneses-Garcia-Abelardo1, Erika B. Ruiz-Garcia1, Cesar Lopez-Camarillo1, Horacio Astudillo-de-la Vega1. 1InCan, Mexico, DF, Mexico; 2Nano-pharmacia Diagnostica, Mexico, DF, Mexico; 1UACM, Mexico, DF, Mexico; 2IMSS, Mexico, DF, Mexico.

Background: Chemotherapy plays a major role in its treatment, though over-treatment is frequent since its choice is based on clinicopathological data. The identification and validation of new predictive profiles or markers continues to be relevant. New findings may contribute to achieve better results in this area, as well as to provide new targets of the pathways involved in chemoresistance. Karyopherin a2 (KNPNA2), low density lipoprotein receptor-related protein 8 (LRP8) and growth and differentiation factor 15 (GDF15), are three candidate predictive biomarkers in breast cancer, previously identified on DNA microarrays reports. Methods: Using tissue microarrays technology and immunohistochemistry, we compared the expression of these three markers between cases of breast cancer with response to chemotherapy (absence of recurrence), and those with failure (with recurrence). All patients received chemotherapy based on anthracyclines and taxanes. Potential confounding factors, as known recurrence and progression risk factors, were controlled for during the comparison. Results: 20 out of 63 patients had tumor recurrence. Potential confounding factors were similar among cases with response and failure to chemotherapy. For KNPNA2 no differences were found between cases with response or failure. LRP8 showed higher expression in cases with failure to chemotherapy (mean 7.2 vs 14.01%, P = 0.025). In Cox multivariable regression analysis, which included potential confounding factors as covariates, only LRP8 remained as a significant predictive factor (HR 1.28, p = 0.016). GDF15 showed no expression in our cases, nor in an external set of cases. Conclusions: We demonstrated increased expression of LRPl in breast cancer cases recurring after chemotherapy. KNPNA2 and GDF15 showed no predictive value for chemotherapy response in our study. LRPl is a potential predictive marker worth of further investigation for its role in chemoresistance as well as for its potential validation.
## CLINICAL RESEARCH: Predictive Biomarkers

### #1788 Extra cellular micro vesicle (EMV) miRNA signature as putative predictive biomarker for targeted therapy in stage IV cutaneous malignant melanoma.

Purpose: Tumor-specific targeted therapy against activated-protein kinase (MAPK) pathway induce rapid responses and improved survival in patients with disseminated BRAFV600mutant cutaneous malignant melanoma (CMM), remissions are often short and remission occurs. There is a need to identify biomarkers predicting durable responses. We aimed to correlate the expression of extracellular micro vesicle (EMV) microRNAs in plasma samples from stage IV CMM patients with MAPK inhibitors use and treatment outcome. Patients and methods: EMV miRNAs signatures analyzed with micro array from plasma samples collected before and during therapy with MAPKi were correlated to response and progression-free survival (PFS) in 28 Stage IV CMM patients treated at the Dept of Oncology, Karolinska University Hospital, Sweden. Clinical parameters i.e. sex, age, lactate dehydrogenase (LDH) levels, before and during treatment, were also included. Results: Higher OS levels before treatment were significantly correlated with a PFS (Hazard Ratio (HR) = 2.088; 95% CI = (1.032, 4.226); P = 0.041). Increasing expression of EMV MiR-let-7g-5p during treatment was significantly correlated to a lower risk of not responding to MAPKi(Odds ratio = 0.0004; 95% CI = 0.000 - 0.207, P = 0.001). High levels of MiR-997-5p in plasmatic EMV during therapy were associated with lower risk of progression during therapy (HR = 0.27; 95% CI = 0.13-0.52, P < 0.0001). Conclusions: Our results indicate that assessing the miRNAs MiR-let-7g-5p and miR-997-5p in samples collected before and during treatment may have a potential as predictive markers of treatment response and PFS in Stage IV CMM patients with MAPKis.

### #1789 A gene expression-based nomogram predicts overall and progression free survival in PRRT-treated gastroenteropancreatic neuroendocrine tumors.

Mark Kidd,1 Lisa Bodie,2 Stefano Severi,1 Ignat Drozdov,1 Sylvia Nicoletti,1 Giovanni Paganeli,2 Irvin M. Modlin1. 1Wren Laboratories, Branford, CT; 2Memorial Sloan Kettering Cancer Center, New York, NY; 3Istituto Scientifico Romagno per lo Studio e la Curia dei Tumori (I.R.S.T.), Meldola, Italy; 4Yale University, New Haven, CT.

Background: Nomograms and grading/staging systems are fundamental in guiding oncology disease management. Histological grading has an efficacy in the management of gastroenteropancreatic neuroendocrine tumors (GEP-NET) but tumor heterogeneity renders outcome unpredictable. Clinical parameters alone have limited prognostic ability. A previously described NET nomogram calculated risk for overall survival (OS). To augment accuracy, we developed a circulating NET multi gene expression blood test. The NETest exhibits high level of accuracy as a molecular prognostic for progression free survival (PFS). We evaluated whether combining clinical information with the NETest would provide accurate prognostic information for PRRT treatment. Aim: Create a combined clinical and gene expression nomogram to predict OS and PFS in PRRT-treated GEP-NETs. Methods:1) 1285-based PRRT-treated GEP-NETs (n=57; median age 65 yrs (31-83); 34M:23F; smallbowel(47%),pancreas(35%),predominantly grade2; 41inpancreasand39vs.21incolon, respectively). Conclusions: The current data show a correlation trend between UCK2 protein expression level and degree of antitumor activity of RX-3117 in xenograft models. It also supports a higher UCK2 protein expression level in human cancer tissues compared to normal tissues. This suggests that RX-3117 activity may be specific to tumor tissue, and quantification of UCK2 expression in human cancer tissues may be useful as a predictive biomarker to select patients for their sensitivity to RX-3117 in future clinical studies.

### #1791 Spatially positioned tumor infiltrating lymphocytes predict survival in metastatic HER2 positive breast cancer treated with trastuzumab.

Jussi Pekka Koivunen, Tiia Honkanen, Tiia Moilanen, Peeter Karitahla, Juha Väyrynen, Markus Mäkinen. Oulu Univ. Hospital, Oulu, Finland.

Background: Disease outcomes of HER2+ breast cancers have dramatically changed after targeted therapies, such as trastuzumab, came to clinical practice but predictive factors for trastuzumab sensitivity and resistance are frequently unknown. Methods: Metastatic breast cancer patients (n=48), who were treated with trastuzumab and had pre-treatment tumor samples available, were studied. The tumors were immunostained for T-cell (CD3, CD8) and NK-cell (CD56) markers and quantitative analysis of the immune cells was carried out using a computer-assisted image analysis in different tumor locations. Results: High number of CD3 and CD8 positive T-cells was associated with significant survival benefit in the center of the tumor (CT) (p = 0.007, p = 0.001), but not in the invasive region. NK-cell tumor infiltration was infrequent and they could not be reliably analyzed. In a subgroup analyses, high density of CD8 CT cells was associated with significant survival benefit in non-bone only disease, in TX-3, and in ER+ tumors (p = 0.006, p = 0.003, p = 0.001). Moreover, high CD8 CT cell density was associated with good trastuzumab responses (p = 0.042). Conclusion: High number of CD3 and CD8 positive tumor infiltrating lymphocytes in the CT area is associated with survival benefit in some patient groups with HER2+ breast cancer treated with trastuzumab. Furthermore, high number of CD8 CT cells predicts benefit from trastuzumab.

### #1792 Immune system pathway activation for prediction of the response to neoadjuvant chemotherapy in triple-negative breast cancer.

Takeshi Sawada,1 Riet Hilhorst,2 Satishri Rangarajan,1 Masayuki Yoshida,1 Kenji Towa,1 Rink canvas I and molon,2 Rob Ruijtenbeek,1 Hideto Tsuda,1 Fumio Koi zuomi1. 1Tokyo Metropolitan Cancer and Infectious Diseases Center Komagome Hospital, Tokyo, Japan; 2PamGene International BV, ’t Hertogenbosch, Netherlands; National Cancer Center Hospital, Tokyo, Japan; National Defense Medical College, Saitama, Japan.
Background: Triple-negative breast cancer patients (TNBCs) who receive neoadjuvant chemotherapy (NAC) generally show a response to NAC, but about 5% experience progressive disease (PD). Although TNBCs that respond to NAC have been well-studied, reports about TNBCs with PD during NAC are absent. We aimed to compare kinase activity profiles of TNBCs of both groups to identify a biological predictor of NAC non-responders. Methods: Tyrosine kinase activity profiles of lysates of fresh frozen cancer tissues from NAC non-responders and responders, the latter represented by TNBCs who did not receive NAC, were determined with a peptide microarray system (Cancer Res. 2009; 69(14):3987-95). Tumor infiltrating lymphocytes (TILs) were measured using quantitative real-time polymerase chain reaction (PCR)-based method. ANOVA and non-parametric tests were applied to compare the RTL and mtDNA copy number between groups. Prophylaxis methods. The study was conducted in 120 patients with pathologic TRTs and mtDNA copy number (CRC). In this study, we comprehensively evaluated whole-genome methylation analysis using CRC tissues and normal colonic mucosa to discover candidate CRC-specific DNA methylation as potential diagnostic and predictive biomarkers for risk stratification in CRC patients. Patients and Method: The study design included an initial discovery phase, and followed by a subsequent clinical validation phase. In discovery phase, we performed whole-genome methylation analysis using CRC tissues and normal colonic mucosa from total fourteen patients to identify CRC-specific methylated CpG sites. Furthermore, we evaluated methylation levels of candidate methylated CpG sites by quantitative bisulfite pyrosequencing using one hundred six colorectal specimens from fifty-three CRC patients to validate the findings from discovery phase. Result: In discovery phase, we successfully identified several candidates of CRC-specific hypermethylated- and hypomethylated-CpG sites in CRC tissues compared with normal colonic mucosa. Promoter lesion of PDX1 is one of candidate methylated CpG sites in discovery phase, and we focus a specific CpG site of PDX1 promoter lesion as a target site to progress in validation phase. We quantified methylation status of PDX1 using 106 colorectal tissues, and demonstrated that PDX1 were significantly hypermethylated in CRC tissues compared with normal mucosa (p<0.0001, Wilcoxon rank correlation test). Receiver operating characteristic (ROC) curves analysis revealed that methylation levels of PDX1 remarkably discriminated CRC tissues from normal colonic mucosa (AUC=0.3, Sensitivity:85.4%, Specificity:91.5%). Interestingly, methylation levels of PDX1 tend to increase in a stage-dependent manner, and hypermethylated status of PDX1 was significantly correlated with presence of distant metastasis in validation cohort. Conclusion: Assessment of the PDX1 methylation status could be used as potential of diagnostic and predictive biomarker for risk stratification in CRC patients.
#1796 A targeted RNA-seq assay to measure activating ER mutations and ER/PR-associated gene expression predicts sensitivity to endocrine therapy for metastatic breast cancer. Rosanna Lau,1 Lily Fu,2 Michael Samuel,2 Rashmi K. Murthy,1 Bruno Sinn,1 Yune Xu,1 Rebekah Gould,1 Jennifer Litton,1 Alda Tam,1 Stacy Moulder,1 Daniel Bosser,1 Debri Tripathy,1 Vicente Valero,1 Fraser Symmans2 and 1University of Buffalo, Buffalo, NY; 2Univ. of Cincinnati College of Medicine, Cincinnati, OH.

Head and neck cancer will account for an estimated 61,760 new cancer cases and 13,190 cancer-related deaths in the United States in 2016, the majority of which (> 90%) will be squamous cell carcinoma (HNSCC). The prognosis for HNSCC is relatively poor, with an overall 5-year survival around 60%, and the outlook worsens with increasing stage at diagnosis, which is problematic since about two-thirds of patients present with advanced stage disease. This underscores the urgent need for discovery, development and translation of novel biomarkers to facilitate early detection of HNSCC and bolster the chance for positive patient outcomes. Exosomes are nano-sized (40-150 nm) membrane-encapsulated vesicles that may offer a new avenue for discovery and development of novel HNSCC biomarkers. However, they are released by essentially all cells, both normal and malignant, into the extracellular space, resulting in a noisy biological signal and a lack of effectiveness for reliable survival analysis. Conclusion: The RNA-seq assay measured the percent of ER transcripts with activating LBD mutation (>1% prevalence) and also downstream ER/PR-related transcription. High LBD-positive ER/PR predicted longer progression-free (PFS) (HR=0.37, p=0.0004, Δ median PFS 9 months) and overall survival (OS) (HR=0.49, p=0.03). The predictions were more pronounced in patients without LBD mutation (PFS HR=0.32, p=0.001, Δ median PFS 13 months; OS HR=0.42, p<0.01). Currently, there are insufficient cancer-related biopsies for reliable survival analysis. Conclusion: The RNA-seq assay measured the percent of ER transcripts with activating LBD mutation (>1% prevalence) and also downstream ER/PR-related transcription. High LBD-positive ER/PR predicted longer progression-free (PFS) (HR=0.37, p=0.0004, Δ median PFS 9 months) and overall survival (OS) (HR=0.49, p=0.03). The predictions were more pronounced in patients without LBD mutation (PFS HR=0.32, p=0.001, Δ median PFS 13 months; OS HR=0.42, p<0.01). Currently, there are insufficient cancer-related biopsies for reliable survival analysis.

#1797 EGFR as a marker for head and neck squamous cell carcinoma-derived small extracellular vesicles. Jenna A. Dombroski,1 Damaris Kuhnell,2 Susan Kaspar,3 Scott M. Langevin,1 University of Buffalo, Buffalo, NY; 2Univ. of Cincinnati College of Medicine, Cincinnati, OH.

EGFR is a member of the ErbB/HER family of receptor tyrosine kinases, localizes to the plasma membrane and is over-expressed in as much as 90% of HNSCC tumors. Therefore, we hypothesized that EGFR will be over-represented on membranes of HNSCC-derived exosomes and thus may offer utility as a surface marker for detection and/or enrichment. To test this, we cultured an HNSCC cell line that over-expresses EGFR (FaDu), EGFR-deficient SW620 colorectal adenocarcinoma cells, and primary human oral epithelial cells pooled from 3 healthy donors. Cells were cultured in supplier-recommended media with 10% fetal bovine serum (FBS) that was super-depleted of exosomes via 18 hour ultracentrifugation at 100,000g and 1% penicillin/streptomycin at 37°C with 5% CO2 in 150 cm2 flasks with 25mL media. After reaching 80-90% confluence, media was harvested, and exosomes were isolated and purified via differential ultracentrifugation. Exosome isolates were verified via transmission electron microscopy (TEM) and manually inspected for EGFR and imaging on a JEOL JEM-1230 transmission electron microscope (Immuno-EM; anti-nucleoporin 153 (NUP-153), which localizes to the nucleus, was used as a negative control. Immuno-EM images indicate abundant EGFR expression on exosomes secreted by FaDu HNSCC cells, but EGFR is not detectable on the exosomes secreted by the oral epithelial cells from healthy donors. These results indicate that EGFR may offer utility for enrichment for HNSCC-derived exosomes in human biofluid isolates using magnetic beads or flow cytometry.

#1798 MET expression in pancreatic adenocarcinoma correlates with survivin expression and the proliferative activity. David M. Saulino, Pamela S. Younes, Jennifer M. Bailey, Mamoun Younes. University of Texas Health Science Center at Houston McGovern Medical School, Houston, TX.

Introduction: CRM1 is a nuclear export chaperone that mediates the export of proteins essential to growth regulation and tumor suppression. Its overexpression in tumors was found to be associated with poor prognosis. Selective inhibitors of nuclear export are in phase I and II clinical trials for several tumor types. The expression of CRM1 in human pancreatic adenocarcinoma (PAC) and its relation to survivin expression and tumor proliferative activity is largely unknown. Experimental procedures: Sections of tissue microarrays containing 77 formalin fixed and paraffin embedded PAC were stained by immuno-histoch- emistry (IHC) for CRM1, survivin, and Cyclin A. Expression levels of CRM1 and survivin in tumor cells was determined using a quantitative digital image analysis solution (OTMIAS). The tumor proliferative activity was determined by measuring the S-phase fraction (SPF) in sections stained for Cyclin A, also using OTMIAS. Summary: Sixty-six of the 77 (86%) PAC showed at least some posi-

Proceedings of the American Association for Cancer Research • Volume 58 • April 2017
tive staining for CRM1, and 11 (14%) were completely negative. The mean and median expression levels of CRM1 in tumor cells with the mean and median levels of survivin (p<0.001). Moreover, there was positive correlation between the mean and median expression levels of CRM1 in tumor cells with the mean and median levels of survivin (p<0.001). Additionally, there was positive correlation between the mean and median expression levels of CRM1 in tumor cells with the mean and median levels of survivin (p<0.001). Furthermore, there was positive correlation between the mean and median expression levels of CRM1 in tumor cells with the mean and median levels of survivin (p<0.001). Consequently, the cell-free DNA (cfDNA) represents a minimally invasive and alternative source of tumor DNA for molecular profiling. Despite next-generation sequencing (NGS) technique is qualified for genotyping cancer using cfDNA as a non-invasive method, it has caused problems as sequencing error and reproducibility. cfDNA in plasma and gDNA of Peripheral Blood Mononuclear Cells (PBMC) were isolated from each 54 advanced colorectal cancer patients. 39 available tumor tissues were isolated from same patients. Deep target-sequencing was performed with paired-end library enriched exons of 10 genes which are recurrently mutated in colorectal cancer. To reduce sequencing error, we devised ‘Denoising’ and calculated concordance of somatic variants between cfDNA and tumor tissue sequencing data. In addition, correlation of concordance data was analyzed with the clinical information. As a result, we selected or could detect clinically important somatic alteration among low/high variant allele frequency (0.31%–79.42%). For somatic alteration of 10 genes, sensitivity, specificity and accuracy were increased from 84.5%, 74.6% and 76.9% to 87.6%, 92.0% and 91.1% respectively after ‘Denoising’. On the other hand, patients with high cfDNA concentration (>50ng/ml) had higher somatic mutant fragments and larger metastatic lesion in liver than patients who have low cfDNA concentration. Our study showed that denoised deep target-sequencing is a suitable method for cfDNA genotyping and provides insights into strategies for monitoring metastatic lesion of advanced colorectal cancer.

TUMOR BIOLOGY: Angiogenesis and Vascular Biology 2

#1801 Antiangiogenic agents targeting different angiogenic pathways have opposite effects on tumor hypoxia in R-18 human melanoma xenografts. Jon-Vidar Gaustad, Trude G. Simonsen, Lise Mari K. Andersen, Einar K. Rofstad. Institute for Cancer Research, Oslo University Hospital, Oslo, Norway.

Background: Studies comparing the effect of antiangiogenic agents targeting different angiogenic pathways are sparse. The purpose of this study was to compare the effect of antiangiogenic agents on the morphology of tumor vasculature. To this end, we assessed the immunohistochemical preparations of the imaged tissue using pimonidazole as a hypoxia marker. Results: Properdinstatin treatment selectively removed small-diameter vessels and reduced BST, whereas sunsitib treatment reduced the density of small- and large-diameter vessel similarly and did not change BST. These observations imply that properdinstatin treatment reduced geometric resistance to blood flow and improved vascular function, whereas sunsitib treatment did not affect vascular function. Accordingly, sunsitib-treated tumors showed higher hypoxic fractions than properdinstatin-treated tumors. Conclusions: Properdinstatin and sunsitib both inhibited angiogenesis, but had distinctly different effects on vascular morphology, vascular function, and extent of hypoxia in R-18 human melanoma xenografts.

#1802 Apoptosis pathway-focused gene expression profiling of a novel VEGFR2 inhibitor. Mohammad Algahtani,1 Khalid Alhazzani,2 Thiagarajan Venkatesan,2 Appu Rathinavelu1. 1Nova Southeastern University, College of Pharmacy, Davie, FL; 2Rumbaugh-Goodwin Institute for Cancer Research, Nova Southeastern University, Davie, FL.

Sprouting of the new blood vessel (angiogenesis) is fundamental to tumor growth, invasion, and metastatic dissemination. Vascular endothelial growth factor (VEGF), an endothelial cell-specific mitogen, promotes cell survival via opposing apoptosis. On the other hand, antagonizing VEGF pathway suppresses endothelial cell overgrowth and promotes apoptotic signals leading to the regression of the existing vasculature and prevents neovascularization of the tumor. In this respect, a new anti-angiogenic agent, code named as F16, that was developed in our institute can effectively stop VEGF-driven angiogenesis by selectively blocking VEGFR2 and the downstream signals. Our previous studies have revealed that human umbilical vein endothelial cells (HUVECs) undergo apoptosis in response to F16 treatment. However, in the present study, our main focus was on investigating the status of the signal mediators of the apoptotic pathway after treating the HUVECs with F16. This was expected to outline the intracellular sequence of events involved in triggering apoptosis following F16 treatment. For this purpose, we analyzed apoptosis pathway-focused gene expression in HUVECs using the human apoptosis RT2 profiler which contains 84 key genes involved in regulation of programmed cell death. Our experimental results clearly identified up-regulated pro-apoptotic genes in response to F16 treatment such as FAS (FASL), TNF (TNF-α and TNF-β) and BCL2 (BCL2 and BCL2L10), tumor necrosis factor superfamily member 9 (TNFFRSF9), FAS cell surface receptor (FAS), FAS ligand (FASLG), lymphoxygen alpha (LTA), caspase 5 (CASP5), and cytokrome c (CYCS). Moreover, a few anti-apoptotic genes were also up-regulated which include B-cell lymphoma 2 related protein A1 (BCL2A1), caspase 14 (CASP14), Bc2 associated anagathone 3 (RAG3), and interleukin 10 (IL-10). However, anti-apoptotic genes such as Bcl-2, Bcl-2 like 10 (BCL2L10), baculoviral IAP repeat containing -3 and -6 (BIRC-3, and BIRC-6), CASP8 and FADD like apoptosis regulator (CFLAR), and insulin like growth factor 1 receptor (IGF1R) were found to be significantly downregulated. Interestingly, no changes were found in the expression of genes related to DNA damage and repair pathways such as TP53, ABL1, CIDEA, and CIDEB. This indicates that F16 may not provoke DNA damage induction or apoptosis. Instead, it stimulates the intrinsic or the extrinsic pathway. In conclusion, the diverse gene expressions implicating apoptosis related factors showed that F16 can induce apoptosis via potentiation of TNF-α and FAS signaling. #1803 Combining anti-Ang-2/VEGF-A therapy with radio- and chemotherapy in glioma. Gergely Solecki,1 Matthias Osowski,1 Weber Daniel,1 Malte Glick,1 Miriam Ratliff,2 Hans-Joachim Müller,2 Oliver Krietler,1 Yvonne Kienast,2 Wolfgang Wick,1 Frank Winkler1. 1German Cancer Research Center (DKFZ), Heidelberg, Germany; 2Roche Innovation Center, Munich, Germany.

Angiogenesis is a biological hallmark of malignant gliomas, but antiangiogenic strategies especially targeting the VEGF axis did not show striking anti-tumor activities in the majority of patients so far. Other pathways may be more relevant in selected tumor entities or patients. Further, it remains unresolved which antiangiogenic combination regimen with standard radio- and/or chemotherapy is most effective. Therefore, we compared the therapeutic effects of anti-VEGF-A, anti-Ang-2, and bispecific anti-Ang-2/VEGF-A antibodies, alone and in combination with radio- or temozolomide (TMZ) chemotherapy in a malignant glioma model using multi-parameter two-photon in vivo microscopy in mice. We demonstrate that anti-Ang-2/VEGF-A leads to strongest vascular changes including vascular normalization, both as monotherapy and when combined with chemotherapy. The latter combination regimen was accompanied by most effective chemotherapeutic induced death of cancer cells independent of blood vessel proximity indicative of a better distribution of TMZ throughout the tumor. Furthermore, the combination of anti-Ang-2/VEGF-A plus TMZ consistently resulted in decreased tumor cell motility, and decreased formation of resistance-associated tumor microbubbles (TMs), which finally lead to best tumor growth inhibition. Remarkably, all these parameters were just reverted when radiotherapy was chosen as combination partner. In contrast, when anti-VEGF-A was combined with radiotherapy, vascular normalization was highest, and TM length, nuclear motility and tumor growth were concordantly reduced. In conclusion, while TMZ chemotherapy benefits most from combination with anti-Ang-2/VEGF-A, radiotherapy does from anti-VEGF-A.
The findings imply that unexpected, even divergent effects can occur when a specific antiangiogenic therapy is added to chemo- or radiotherapy in glioma, and that uninformed combination regimens should be avoided.

Exogenous nucleoside diphosphate kinase (eNDPK or NM23) has been shown to promote endothelial cell proliferation and migration and tumor-mediated angiogenesis. This is facilitated by its transphosphorylase activity, in which a gamma terminal phosphate group from a triphosphate nucleoside is transferred to a diphosphate nucleoside, resulting in elevated ATP levels. Increased levels of ATP in the tumor microenvironment can activate purinergic receptors (P2Y1) on adjacent endothelial cells to promote angiogenesis, independent of VEGF stimulation. Triple negative human breast cancer (MDA-MB-231) cells have been shown to elaborate exosomes that contain NM23. These exosomes have implications in targeting specific tissues/cells to promote angiogenesis and tumorigenesis. Our lab has shown that inhibition of eNDPK and the P2Y1 receptor reduces endothelial cell tubulogenesis (Rumjaunt, et al., 2007) and breast cancer metastasis (Yokdang, et al., 2015). Therefore, targeted inhibition of eNDPK may have implications as a treatment for early tumor-mediated angiogenesis. For this study, we utilized a transphosphorylation activity assay to perform a drug screen on compounds from the Prestwick chemical library. Recombinant NDPK-B was added to FDA-approved drug compounds along with ATP and UTP substrates. Substrate phosphorylation was measured, and compounds that increased luminescence signal/inhibition of NDPK was compared to ellagic acid control, a known inhibitor of NDPK. From our initial screen, we identified eight potential compounds that inhibited NDPK at comparable levels to ellagic acid. These eight compounds were further examined to determine the dose response curve. We found that Chicago Sky Blue 6B inhibited NDPK at an IC50 value of 1.88 μM. The results from this study demonstrate a drug screening method to discover alternative small molecule inhibitors of NDPK as a potential treatment of angiogenesis and breast cancer metastasis.

Hepatocellular carcinoma (HCC) is a one of the leading causes of cancer death worldwide; however, systemic therapeutic option for unresectable HCC is limited. Liver carcinogenesis is a complex process and various pathways have been found to be deregulated. Of those pathways, aberrant activation of fibroblast growth factor (FGF) signaling and fibroblast growth factor receptor (FGFR) axis has been hypothesized to participate in the development of HCC with poor prognosis. Lenvatinib mesilate (lenvatinib) is an orally administered multi-targeted tyrosine kinase inhibitor (TKI) that selectively inhibits vascular endothelial growth factor receptors (VEGFR1-3, FGFR1-4, platelet-derived growth factor receptor (PDGFRα, RET, and KIT). In this study, we investigated the activities of lenvatinib against human hepatocellular carcinoma (HCC) cell lines with an aberrant FGF signaling pathway in tumor warrants further investigation.
pro-angiogenic characteristics. Further, we report the development and application of a novel murine implant model to demonstrate increased specificity of 231 exosomes targeting to pulmonary endothelial cells over unrelated cell lines. These results suggest the involvement of exosomes and eNDPK in pro-angiogenic communication between metastatic breast cancer cells and their vascular targets. These observations are corroborated by these cells specifically targeted endothelium in vivo, mirroring the organotrophic nature of breast cancer metastasis. Implication of eNDPK in angiogenesis and metastasis may challenge current and invasive treatment methods in favor of developing novel small molecule inhibitors of eNDPK signaling. Lastly, eNDPK can be explored as a potential biomarker for early detection of metastatic breast cancer as it uniquely appears in the serum of patients with breast cancer and not in the serum of individuals with unrelated pathologies.

### #1808 Vascular endothelial growth factor receptor-2 (VEGFR-2) N-glycosylation modulates angiogenic signaling

Kevin B. Chandler, Deborah R. Leon, Rosana D. Meyer, Nader Rahimi, Catherine E. Costello. *Boston Univ., Boston, MA.*

Angiogenesis, the formation of new blood vessels from pre-existing vessels, is required for tumor growth and metastasis. Vascular endothelial growth factor receptor-2 (VEGFR-2) is one of the most important receptor tyrosine kinases (RTKs) among the VEGF receptor subfamily, and activation of VEGFR-2 is essential for tumor angiogenesis. The extracellular domain of VEGFR-2 contains seven immunoglobulin-like (Ig) domains, each with multiple potential N-glycosylation sites. N-glycosylation is thought to play a central role in receptor stability, ligand binding and trafficking. However, to date the occupancy and glycoform distributions at each of the potential N-glycosylation sites and their putative role(s) in VEGFR-2 function remain largely unknown. The objective of this study is to investigate the functional importance of VEGFR-2 N-glycosylation in VEGFR-2 angiogenic signaling. Porcine aortic endothelial (PAE) cells with ectopic expression of VEGFR-2 were treated with PNGase F to remove N-linked glycans or heat-denatured PNGase F as a control. Following PNGase F treatment for 4 hours, cells were treated with VEGF-A ligand for 0, 5, 10 or 30 minutes. VEGFR-2 phosphorylation (activation) was measured via Western blot with an anti-pTyr-1054-VEGFR-2 antibody. In addition, a polyclonal anti-VEGFR2 antibody was used to immunoprecipitate untreated and PNGase F-treated VEGFR-2 from PAE cell lysates. Evaluation of the N-glycosylation sites targeted by PNGase F was carried out by gel electrophoresis, followed by protease digestion and MS/MS analysis. MS/MS data were processed using Proteome Discoverer 1.4. To obtain site-specific glycosylation information we performed proteolysis of VEGFR-2, glycopeptide enrichment via hydrophilic interaction liquid chromatography (HILIC) and subsequent analysis of glycopeptides with an Agilent 6550 Quadrupole Time-of-Flight (Q-TOF) MS using collision-induced dissociation. We detected a dramatic increase in ligand-mediated activation of VEGFR-2 after treatment with PNGase F, suggesting that certain N-linked glycans may hinder ligand access to the VEGF binding site, or that removal of N-linked glycans results in conformational changes that lead to increased activation of the receptor by VEGF-A. To explore this observation in greater detail, we have created a series of VEGFR-2 N-glycosylation site mutants, and we are now using the mutants to determine which glycosylation sites are involved in the observed modulation of VEGFR-2 signaling.

### #1809 PKM2 promotes tumor angiogenesis by regulating HIF-1alpha through NF-kappaB activation.

Ninel Azoitei, Alexander Becher, Konrad Steinestel, Aurelie Rouhi, Kristina Diepold, Susanne Bobrovich, Thomas Seufferlein. *University of Ulm, Ulm, Germany; University of Muenster, Muenster, Germany.*

Initially identified as a molecule that catalyzes the phosphorylation from phosphoenolpyruvate to pyruvate in the final step of glycolysis, the M2 isoform of pyruvate kinase (PKM2) was recently reported to have a central role in the metabolic reprogramming of cancer cells as well as participating in the regulation of apoptosis and proliferation. In this study, we have identified PKM2 as a crucial molecule for progression of pancreatic cancer in which tumor microenvironment has been reported to be highly hypoxic. Our data show moderate to strong PKM2 expression in all examined human pancreatic adenocarcinoma samples. Depletion of PKM2 was associated with impaired proliferation and augmented tumor cell death in vitro, while the in vivo tumor xenograft experiments revealed a close association between impaired tumor growth and decreased blood vessel formation. Furthermore, abrogation of PKM2 prevented hypoxia-mediated HIF-1alpha accumulation and HIF-1alpha promoter activity, which negatively impacted VEGF secretion by pancreatic cancer cells deprived of oxygen. Interestingly, PKM2 expression arrest was also mirrored by impaired hypoxia-driven promoter activity of NF-kappaB which also drives the transcription of VEGF. Ectopic expression of p65 restored VEGF transcription after PKM2 ablation inferring that the kinase regulates VEGF via NF-kappaB/p65 subunit. Altogether, our study suggests that in hypoxic pancreatic tumors, PKM2 interferes both with NF-kappaB/p65 and HIF-1alpha activation that ultimately triggers VEGF-A secretion and subsequent blood vessel formation.

### #1810 Disregulation of myristoylated alanine-rich C kinase substrate (MARKS): A novel therapeutic target in renal cell carcinoma

Ching-Hsien Chen, Wen-Hsin Chang, Eric Yu, Muhammad S. Arif, Reen Wu, Robert H. Weiss. *Division of Nephrology, Department of Internal Medicine, University of California Davis, Davis, CA; Institute of Molecular Medicine, National Taiwan University College of Medicine; Division of Nephrology, Department of Internal Medicine, University of California Davis, Taiwan; Department of Internal Medicine, Division of Pulmonary and Critical Care Medicine and Center for Comparative Respiratory Biology and Medicine, University of California Davis, Davis, CA.*

Targeted therapeutics, such as those abrogating hypoxia inducible factor (HIF)/VEGF signaling, are initially effective against kidney cancer (or renal cell carcinoma, RCC); however, drug resistance frequently occurs via subsequent activation of alternative pathways. Through genome-scale integrated analysis of the HIF-α network, we identified the major protein kinase C substrate MARKS (myristoylated alanine-rich C kinase substrate) as a potential target molecule for kidney cancer. In a screen of nephrectomy samples from 56 patients with RCC, we found that MARKS expression and its phosphorylation are increased and positively correlated with tumor grade. Genetic and pharmacologic suppression of MARKS in high grade RCC cell lines in vitro led to a decrease in cell proliferation and migration. We further demonstrated that higher MARKS expression promotes growth and angiogenesis in vivo in an RCC xenograft tumor. MARKS acted upstream of the AKT/mTOR pathway, activating HIF-target genes, notably VEG-F. Following knockdown of MARKS in RCC cells, the IC50 of the multi-kinase inhibitor regorafenib was reduced. Surprisingly, attenuation of MARKS using the M5 peptide synergistically interacted with regorafenib treatment and decreased survival of kidney cancer cells through inactivation of AKT and mTOR. Our data suggest a major contribution of MARKS to kidney cancer growth and provide an alternative therapeutic strategy of improving the efficacy of multi-kinase inhibitors.

### #1811 A PEAK1/GATA2 signaling axis controls VEGFR2 expression to mediate angiogenesis.

Richard I. Kleman. *UCSD Moores Cancer Ctr., La Jolla, CA.*

Formation of new blood vessels (angiogenesis) is crucial for proper development, but can also contribute to many diseases including cancer. Vascular endothelial growth factor receptor 2 (VEGFR2) is a receptor tyrosine kinase that mediates angiogenesis in developing and regenerating tissues and is frequently upregulated in many human cancers. However, the underlying mechanisms that regulate VEGFR2 expression in normal and diseased cells are poorly understood. Here we demonstrate that pseudopodium-enriched atypical kinase 1 (PEAK1) mediates developmental and tumor-induced angiogenesis by modulating VEGFR2 expression and downstream signaling. Knockout of peak1 in zebrafish using TALEN technology (Transcription Activation-Like Effector; Nucleases) or knockdown by specific peak1 morpholinos (MO) induced severe pericardial edema, blood-pooling defects, and inhibited formation of intersegmental (ISV) and subintestinal vessels (SIV). In Peak1 knockout mice, neonatal retinal vessel development was severely delayed, and the ex vivo angiogenic ability of adult thoracic aorta was greatly reduced. Intravital time-lapse imaging of ISV formation in peak1 knockout zebrafish revealed major defects in endothelial cell migration and proliferation. Similarly, PEAK1 knockdown or overexpression in HUVECs modulated endothelial cell migration, proliferation, and vessel sprouting in vitro. Biochemical studies and quantitative proteomic profiling of PEAK1 knockdown HUVECs revealed a dramatic loss of VEGFR2 mRNA and protein expression, which attenuated downstream signaling to Akt and ERK, leading to loss of VEGF-mediated vessel formation. PEAK1 specifically regulated VEGFR2 levels and did not alter VEGFR1 expression, and reconstitution of PEAK1 knockdown cells with PEAK1 restored VEGFR2 mRNA and protein expression. Mechanistic studies revealed that PEAK1 specifically regulates VEGFR2 mRNA transcription by modulating expression of the transcription factor GATA2. Re-expression of GATA2 in Peak1 depleted cells restored VEGFR2 mRNA and protein expression as well as downstream signaling, indicating that GATA2 is a necessary downstream component in this response. Also, introduction of gata2 mRNA into Peak1 knockdown zebrafish restored normal ISV formation and vegfr2 mRNA expression in these animals. Finally, bioinformatics and intergroanalysis of the TCGA RNAseq database revealed significant Pearson’s correla-
TUMOR BIOLOGY: Angiogenesis and Vascular Biology 2
tions between PEAK1 and VEGFR2 expression in 17 of 32 different human cancers. Collectively, our findings indicate that PEAK1 regulates developmental and tumor-induced angiogenesis by regulating GATA2-dependent VEGFR2 expression and its downstream signals.

#1812 In vitro and in vivo antiangiogenic activity of desacetylvinblastine monohydrazide through inhibition of VEGF/VEGFR2 and Gas6/Axl pathways. Minfeng Chen,1 Xiaoping Lei,1 Qiuqun Nie,1 Jianyang Hu,2 Zhenqiang Zhu,1 Anita Yu,1 Heru Chen,1 Nanhui Xu,1 Maohua Huang,1 Kaihe Ye,1 Liangliang Bai,1 Wencai Ye,1 Dong-Mei Zhang,1 College of Pharmacy, Guangzhou, China;2School of Life Sciences, The Chinese University of Hong Kong, Hong Kong, China.

Background and Objective: Tumor angiogenesis process is regulated by multiple proangiogenic pathways, such as VEGF/VEGFR2 and Axl. Inhibition of VEGF/VEGFR2 signaling alone fails to block tumor neovascularization, and anti-VEGF resistance is often associated with Axl. Hence, discovery of novel agents that target multiple angiogenesis pathways is in demand. Here, we describe desacetylvinblastine monohydrazide (DAVLBH), a derivative of vinblastine (VLB) that exerts a more potent antiangiogenic effect than VLB in vitro and in vivo by inhibiting VEGFR2 and Axl pathways. Methods: The antiangiogenic effects of DAVLBH were studied in vitro (proliferation, migration, and tube formation assays) and ex vivo (aortic ring assay). In vitro pericyte migration to endothelial tubes was assessed using a three-dimensional co-culture assay. In vivo assay was performed in HeLa xenograft model. Western blotting, immuno-histochemical and immunofluorescence assays were conducted to evaluate the effects of DAVLBH were studied in vitro (proliferation, migration, and tube formation assays) and ex vivo (aortic ring assay). In vitro pericyte migration to endothelial tubes was assessed using a three-dimensional co-culture assay. In vivo assay was performed in HeLa xenograft model. Western blotting, immuno-histochemical and immunofluorescence assays were conducted to evaluate the key proteins of the VEGF/VEGFR2 and Gas6/Axl pathways. Results: DAVLBH (1 nM) inhibited VEGF- and Gas6-induced angiogenesis in vitro. At 0.75 μmol/kg, DAVLBH significantly delayed tumor growth and reduced vascular density in vivo, which was associated with the inactivation of VEGF/VEGFR2 and Gas6/Axl signalling pathways. DAVLBH blocked the compensatory up-regulation of Axl in response to bevacizumab treatment in HUVECs. DAVLBH also suppressed the recruitment of pericytes to well-established endothelial tubes and reduced pericyte coverage in vivo, which was accompanied by inhibition of Axl. Conclusions: DAVLBH potently inhibited angiogenesis-mediated tumor growth by blocking the activation of VEGF/VEGFR2 and Gas6/Axl pathways. DAVLBH might serve as a promising antiangiogenic agent for cancer therapy.

#1813 Bevacizumab potentiates the proteomic response to neoadjuvant chemotherapy in breast cancer patients: RPPA exploration of consorative tumor samples in the NeoAva randomized phase II trial. Mads H. Haugen,1 Ole Christian Lingjaerde,2 Marit Krohn,1 Wei Zhao,1 Evita M. Lindholm,1 Lakmi Silwal-Pandit,1 Elin Borgren,1 Øystein Garred,1 Anne Fangberget,1 Marit M. Holmen,1 Ellen Schlichting,1 Helle K. Skjerven,2 Steinar Lundgren,1 Erik Wist,1 Bjørn Naume,2 Gunhild M. Maelandsmo,1 Yiling Lu,2 Anne-Lise Boerresen-Dale,1 Gordon B. Mills,1 Olav Engebretsen,1 Oslo University Hospital - Institute for Cancer Research, Oslo, Norway;2University of Oslo, Oslo, Norway;3MD Anderson Cancer Center, Houston, TX;4Oslo University Hospital Oslo, Oslo, Norway;5Vestre Viken Hospital, Drammen, Norway;6St. Olav’s University Hospital, Trondheim, Norway.

Anti-angiogenic therapy using bevacizumab has proven effective for a number of cancers. However, bevacizumab is more potent in combination with chemotherapy and hormonal therapy. The aim of this study is to evaluate the proteomic response to bevacizumab treatment in clinical trials. In this phase II clinical trial, patients with HER2 negative primary tumors of ≥25 mm were treated with neoadjuvant chemotherapy (4 × FEC100 + 12 weeks of taxane-based therapy) and randomized (1:1) to receive bevacizumab or not. Mammography, ultrasound, and MR imaging were used for response evaluation, in addition to final pathology assessment. Tumor responses were evaluable in 132 patients; of which 66 received bevacizumab. Ratio of the tumor at final pathology assessment, and at inclusion was calculated to obtain a continuous scale of response reflecting the percentage of tumor shrinkage in response to therapy. Tumor biopsies were removed before start of treatment, at week 12 at the start of taxane-based therapy and at the time of surgery. Lysates from each sample was analyzed on reverse phase protein arrays (RPPA) for expression levels of 210 proteins of which 54 were phospho-proteins. The analysis showed the chemotherapy did not alter proteomic response from week 0 to 25 to such extent that this patient group cluster naturally together. While the proteomic response from week 0 to 12 in both treatment arms had an overall similar profile regarding up- and down-regulated proteins, the combination treatment (FEC100 + bevacizumab) induced substantially more effect on the regulation of each protein. This suggests that bevacizumab treatment have the capability to potentiate the effects of the anthracyclin based chemotherapy from week 0 to 12. Conversely, from week 12-25 (taxane-based therapy + bevacizumab) this effect was lost or even reversed, possibly due to a de-vascularized and less accessible tumor. An exception from the above was a few phospho-protein markers of PI3K/AKT and Stat3, which were upregulated in the bevacizumab arm. This indicates that bevacizumab treatment is pro-angiogenic in breast cancer patients. The results indicate that bevacizumab treatment may increase the expression and its downstream signals. The results indicate that bevacizumab treatment may increase the expression and its downstream signals.

#1814 IL11 mediates tumor resistance to anti-VEGF therapy in lung cancer. Jie Li, Kun Xie, Shenglin Mei, Yuanjian Xu, Hua Gu, Dong Li, Kaiming Chen, Fei Yao, Jiya Eerdeng, Jianmin Fang, Tongxi University, Shanghai, China.

Anti-angiogenic therapy has been used for the treatment of a number of solid tumors in clinic; however, survival benefit is only limited due to development of tumor resistance to the therapy. In previous studies, we developed a mouse Lewis lung carcinoma (LLC) tumor model that is resistant to anti-VEGF therapy. In this model, we identified that Interleukin 11 (IL11) was among the most significantly upregulated genes in the resistant tumors. In current study, we demonstrated that IL11 was an angiogenic factor and played a key role in the development of resistance to anti-VEGF therapy in LLC tumor. IL11 could effectively induce HUVEC proliferation, migration and capillary tube formation in vitro. It enhanced expression of MMP9 in endothelial cells. The conditioned medium from the resistant LLC cell culture could induce HUVEC migration, even VEGF was blocked, and this effect was attenuated by recombinant IL11 decoy receptor. Furthermore, combination therapy of anti-VEGF agent and IL11 blockade exhibited enhanced anti-tumor activity in lung cancer model. In addition, based on bioinformatics analysis on over 500 RNA-seq data deposited to The Cancer Genome Atlas (TCGA), we found that IL11 was highly expressed in various tumor types in patients. Data showed that high IL11 can predict a poor outcome in the lung cancer. The patients with the lower IL11 expression have significantly longer median survival time than those with higher expression. These findings support a role of IL11 signal as a compensatory angiogenic pathway that might trigger tumor resistance to anti-VEGF treatement. Therapeutically targeting IL11 could have a value in overcoming tumor resistance to anti-VEGF therapy.

Malignant pleural effusion is a poor prognostic sign for patients with non-small-cell lung cancer (NSCLC) and is noted around 15% at the initial diagnosis and 50% in their later courses. Previously, we have shown that IL-6/Stat3/tissue factor (TF)/VEGF pathway enhances lung cancer angiogenesis, metastasis and the generation of MPE. In the current study, we demonstrated that EVs derived from lung cancer cells may also contribute MPE formation. We first used ultra-filtration (UF) method as well as the classical ultra-centrifugation (UC) method to isolate EV from lung cancer cell line and demonstrated that the EVs isolated by UF method were characteristic with exosome marker in Western blotting. Using the ELISA method, we found the cargos in these EV were enriched in IL6. We also found these cargo derived from EVs, containing high VEGF and TF, induced more prominent extravasation than serum free medium did in Miles assays. In clinical sample, we also isolated cancer cell from MPE and the purity of the cells was confirmed by immunofluorescent staining with specific TFF-1 expression of lung adenocarcinoma. After short-term culture, EV from MPE cancer cell have the characteristic of exosome maker and induced more prominent extravasation than serum free medium as EV from A52 cell did. And we also isolated EV directly from MPE and pleural effusion from congestive heart failure (CHF) patients. And we found the EGFP and more prominent extravasation than those derived from CHF in Miles assays. In conclusion, we demonstrated the UF is clinical assessable method for isolating EV from body fluid and EV derived from lung cancer cell and MPE may contribute oncogenic and angiogenic signal transmission accelerating the formation of MPE.
Endogenous ADAMTS-13 regulates angiogenesis in cultured human endothelial cells. Huiyuan Tang, Manfi Lee, Eun Ho Kim, Daniel Bishop, George M. Rodgers. University of Utah, Salt Lake City, UT.

ADAMTS-13, a disintegrin and metalloproteinase with a thrombospondin type 1 motif, member 13, is a zinc-containing metalloprotease that cleaves von Willebrand factor (vWF). Previous publications by our laboratory have shown that ADAMTS-13 may also be involved in angiogenesis; for example; addition of exogenous ADAMTS-13 enhances endothelial cell (Lee et al. Microvascular Res 2012; 84:109) and glioblastoma cell (Lee et al. Blood 2013; 122:2306) migration and proliferation. For this study, we report the successful transient knockdown of endogenous ADAMTS-13 in human umbilical vein endothelial cells (HUVEC) via siRNA (30pmol of ADAMTS-13 siRNA in a six-well plate inhibited HUVEC ADAMTS-13 expression levels by 90% after 24hr incubation, whereas control siRNA did not affect endogenous ADAMTS-13 levels. The knockdown effect was decreased over time: 72hr after the initial knockdown, ADAMTS-13 expression was reduced by only 30%. The effects of reduced endogenous ADAMTS-13 on HUVEC angiogenesis functions were studied. Transfection of HUVEC with 10pmol of ADAMTS-13 siRNA in a 24-well plate resulted in a 21% and 22% decrease in proliferation after 24hr and 48hr incubation, respectively. The effects of ADAMTS-13 knockdown on migration of HUVEC across a scratch wound were also evaluated. 24hr after transfection with control siRNA, there was robust cell migration across the scratch wound. This dramatic migration did not occur with ADAMTS-13 knockdown cells. Decreased expression of endogenous ADAMTS-13 also affected angiogenesis as measured by endothelial cell tube formation using a Matrigel matrix method. The tube lengths, sizes and junction numbers of the ADAMTS-13 knockdown cells were all significantly lower compared to control cells by about 40%. Activity of the Akt pathway, one of the angiogenesis downstream signaling pathways was down-regulated by ADAMTS-13 siRNA while ERK, a component of the MAP kinase pathway was not affected upon knockdown of ADAMTS-13. These data indicate that in cultured endothelial cells, one role of endogenous ADAMTS-13 is regulation of angiogenesis, mediated through the Akt signaling pathway. Overall, our data suggest an additional model of endogenous ADAMTS-13 functionality, beyond that of cleaving von Willebrand factor.

Resistin induces angiogenesis and lymphangiogenesis in human chondrosarcoma. Meng-Ju Chi, Chih-Yang Lin, Chih-Hsin Tang. China Medical University, Taichung City, Taiwan.

Chondrosarcoma is a common kind of bone cancers, and it may develop distant metastasis, followed by a significant decline in overall survival. However, there are still no specific therapeutic methods for it today. For tumors to metastasize, angiogenesis and lymphangiogenesis are both important in the early processes. Therefore, inhibiting the development of angiogenesis and lymphangiogenesis could be a method to decline tumor metastasis. Resistin was discovered as an adipocyte-secreting adipokine, which may play a critical role in modulating cancer pathogenesis. In our lab, we previously found that resistin appears to increase MMP-2 expression and then promotes metastasis in human chondrosarcoma cells. Nevertheless, the role of resistin in angiogenesis and lymphangiogenesis of human chondrosarcoma is still unknown. To examine angiogenic and lymphangiogenic effects of resistin, we used human endothelial progenitor cells (EPCs) and lymphatic endothelial cells (LEC) to mimic capillary and lymphatic vessels formation. The results indicated that resistin-treated chondrosarcoma cell lines promoted EPC’s VEGF-A dependent and as well as LEC’s VEGF-C dependent tube formation and cell migration. Then we confirmed that treating cells with resistin increased VEGF-A and VEGF-C expression in human chondrosarcoma cell lines. Moreover, we found resistin-induced VEGF-A and VEGF-C expressions are mediated by PI3K/AKT signaling and by the activation of c-Src separately. In addition, resistin decreased the expression of miR-16-15p via PI3K/AKT pathway, and so of miR-186 via c-Src. We also demonstrated that miR-186 directly targeted on VEGF-C 3’untranslated region, and regulated the VEGF-C production. Besides, we found the expressions of resistin, VEGF-A and VEGF-C was higher in human chondrosarcoma biopsy tissues than those in normal cartilage. Taken together, resistin not only promotes human chondrosarcoma angiogenesis through the activation of PI3K/AKT signaling pathway and down-regulating miR-16-15p expression, but also promotes human chondrosarcoma lymphangiogenesis through the activation of c-Src and down-regulating miR-186. Consequently, resistin may represent a potential novel molecular therapeutic target for human chondrosarcoma therapeutic treatment.
Epithelial-mesenchymal transition (EMT) has long been associated with cancer progression and metastasis. As a reversible process, it has the potential to be a target for cancer therapy. However, this concept of reversing EMT has not yet been widely explored in current treatment strategies. With the identification of Nintedanib as an EMT reversal agent, we aim to broaden the utility of this triple angioinhibitor by identifying agents that show synergistic lethality with it, using monoclonal antibodies (mAbs) as a combinatorial therapeutic. Nintedanib alone is not significantly cytotoxic to cells, but it causes cell cycle arrest and reverses EMT. By selecting for this sub-population of cells that are sensitive to Nintedanib, their subsequent eradication can then be more intricately directed. Since the anti-cancer application of EMT reversal agents are not fully developed, it is vital to investigate mechanisms that sensitize cancer cells to cytotoxic agents following EMT reversal. Our group has generated panels of mAbs that are able to bind differentially to various breast and ovarian cancer cell lines along the EMT spectrum. Some mAbs preferentially bind to Epithelial lines, while some have stronger affinity to Mesenchymal lines. This implies that mAbs have the ability to differentiate between epithelial and mesenchymal phenotypes, uncovering a new dimension to the capability of mAbs which have yet to be explored. Using a mesenchymal ovarian cancer cell line as a starting model, Nintedanib-treated cells were screened with the mAbs and those showing a >2-fold increase in binding were shortlisted for further validation. Based on this criteria, 26 mAbs were identified and further characterized in functional Antibody Drug Conjugate (ADC) assays with mAbs conjugated to a toxic drug, Saporin (or Zap). Mabs successfully internalizing and killing the cancer cells will then be further chosen for antigen characterization and in vivo functional studies. Ultimately, there is huge potential for mAbs to be discovered that shows synergy with Nintedanib to enhance lethality to various types of cancer cells. A novel clinical strategy, the application of EMT reversal in terms of utilizing a synthetic lethality-like approach allows better design of combinatorial therapeutic agents, increasing treatment efficacy that might revolutionise cancer treatment.

#1820 Synergistic lethality of mAbs with an EMT reversal agent, Nintedanib, in epithelial ovarian cancer. Jocelyn Teo,1, Heng Liang Tan,1 Ruby Yun-Ju Huang,2 Andre Choo1.

Epithelial-mesenchymal transition (EMT) has long been associated with cancer progression and metastasis. As a reversible process, it has the potential to be a target for cancer therapy. Therefore, this concept of reversing EMT has not yet been widely explored in current treatment strategies. With the identification of Nintedanib as an EMT reversal agent, we aim to broaden the utility of this triple angioinhibitor by identifying agents that show synergistic lethality with it, using monoclonal antibodies (mAbs) as a combinatorial therapeutic. Nintedanib alone is not significantly cytotoxic to cells, but it causes cell cycle arrest and reverses EMT. By selecting for this sub-population of cells that are sensitive to Nintedanib, their subsequent eradication can then be more intricately directed. Since the anti-cancer application of EMT reversal agents are not fully developed, it is vital to investigate mechanisms that sensitize cancer cells to cytotoxic agents following EMT reversal. Our group has generated panels of mAbs that are able to bind differentially to various breast and ovarian cancer cell lines along the EMT spectrum. Some mAbs preferentially bind to Epithelial lines, while some have stronger affinity to Mesenchymal lines. This implies that mAbs have the ability to differentiate between epithelial and mesenchymal phenotypes, uncovering a new dimension to the capability of mAbs which have yet to be explored. Using a mesenchymal ovarian cancer cell line as a starting model, Nintedanib-treated cells were screened with the mAbs and those showing a >2-fold increase in binding were shortlisted for further validation. Based on this criteria, 26 mAbs were identified and further characterized in functional Antibody Drug Conjugate (ADC) assays with mAbs conjugated to a toxic drug, Saporin (or Zap). Mabs successfully internalizing and killing the cancer cells will then be further chosen for antigen characterization and in vivo functional studies. Ultimately, there is huge potential for mAbs to be discovered that shows synergy with Nintedanib to enhance lethality to various types of cancer cells. A novel clinical strategy, the application of EMT reversal in terms of utilizing a synthetic lethality-like approach allows better design of combinatorial therapeutic agents, increasing treatment efficacy that might revolutionise cancer treatment.

#1821 Sympathetic nerves regulate a metabolic switch promoting angiogenesis through adrenergic signaling in prostate cancer. Ali Zahiya,3 Anna Arnal-Estape,4 Maria Maryanovich,5 Fumio Nakahara,4 Cristian Cruz,2 Paul S. Frenette1, Albert Einstein College of Medicine, Bronx, NY; 2Yale School of Medicine, New Haven, CT.

Nerves pattern the vasculature during development and regeneration. Recent studies have shown that the sympathetic nervous system (SNS) is co-opted to promote cancer angiogenesis, and that depletion of SNS function reverses pro-angiogenic receptors (βAR). The role of the prostate stromal compartment inhibits tumor growth. As the vasculature is in direct contact with the SNS, and regulates tumor glucose and oxygen delivery, we aimed to identify the stromal populations that mediate SNS signaling and the mechanisms by which loss of βAR signaling inhibits prostate cancer progression. In vivo xenograft tumor growth was measured in Adrb2-/-; Adrb3+/- mice using an orthotopic PC3-luciferase model. Prostate cancer progression in the transgenic aurthochthonous H1-myc model was assessed after conditional Adrb2 deletion in stromal populations by intercrossing Adrb2-/-;Cre/+ mice with Adrb2-/-;Cre/+;R26-tdTomato mice that express a tdTomato reporter under the control of the uPAR promoter. Depletion of βAR activity in prostate cancer cells significantly inhibited the prostate intrinsic RAS-MAPK pathway, and regulated tumor growth. The results showed that βAR signaling modulates prostate cancer cell metabolism, and that βAR depletion inhibits prostate cancer progression.

#1822 Antitumor activity of agents targeting the angiogenic factors angioptin-2 and thymidine phosphorylase in mouse models of lung and pancreatic neuroendocrine cancer. Evelyn Aranda, Ziqiang Yuan, Steven K. L. Butler, Edward L. Schwartz. Albert Einstein College of Medicine, Bronx, NY.

Angiogenesis is a critical component of the initiation, maintenance and progression of tumors, and has been the target of extensive drug development. In clinical practice there are several approved and investigational anti-angiogenesis drugs, the majority of which primarily target the VEGF pathway, however their long term effectiveness remains limited. In designing new drug regimens, it is important to consider other known angiogenic factors that likely contribute to the pro-angiogenic phenotype. We evaluated two such factors: thymidine phosphorylase (TP) (aka platelet-derived endothelial cell growth factor, PD-ECGF), an enzyme that can stimulate endothelial cell migration, and angioptin 2 (Ang2), a member of the Ang/Tie2 signaling pathway. To target TP, we used a novel, highly specific, orally available small molecule inhibitor, which we had previously designed, named AEAC. To target Ang2, we used an Ang2 neutralizing peptide, Li-7[N] (provided by CTEP-NCI), which is a genetically engineered peptide-Fc fusion protein that specifically binds Ang2. In a mouse NCI-H460 NSCLC xenograft model, AEAC and Li-7[N] produced 33% and 67% reductions, respectively, in tumor growth, and the combination produced a small, but statistically significant further reduction, when compared to either agent used alone. Tumor growth inhibition was paralleled by a reduction in Ki-67 staining. Li-7[N] also produced a large infiltration of macrophages (F4/80+) into the tumors after treatment. We also tested the drug combination in a mouse genetic model of pancreatic neuroendocrine tumors (PNET). PNET are one of the few human solid tumors that are clinically responsive to angiogenesis inhibitors used alone. These mice have a conditional knockout of the Men1 gene in the endocrine pancreatic cells (Pdx1-Cre;Men1 mice) mimicking a primary genetic alteration seen in human disease. Men1 KO iPSCs are tumorigenic in Men1 KO PNET experiments were initiated when the mice were 10-11 months old, and drug treatment was daily (5 days per week) for 3 weeks. To date, we have not seen any antiangiogenic or antitumor effects of the drugs. Upon sacrifice, the mice were found to have extensive insulinomas, involving around 70% of the entire pancreas. CD31+ and F4/80+ cells in the pancreas showed that tumours were almost completely infiltrated by macrophages. It is possible that the significant increase in macrophage infiltration and tumor growth inhibition associated with these agents may be due to a synergy between these drugs. In conclusion, these results suggest that dual targeting of TP and Ang2 may have therapeutic potential in human pancreatic neuroendocrine cancer.

#2019 Characterization of the anti-angiogenic properties of merestinib (LY2801653), an onconcinib inhibitor. Diane M. Bodenmiller, Julie A. Stewart, Glenn F. Evans, Victoria L. Peek, Jennifer R. Stephens, Xi Lin, Seema Iyer, Beverly L. Falcon, Sudhakar Chinthapalapilli, Sue-Chi Betty Yan, Anthony S. Fischl, Eli Lilly and Company, Indianapolis, IN.

Merestinib (LY2801653) is an orally bioavailable small molecule inhibitor of several onconcinib, including MET, AXL, DDR1/2, MERTK, ROS1, Tie2 (aka TEK), and MKNK1/2. Merestinib has been extensively characterized in a wide range of preclinical xenograft models that showed to potently inhibit MET driven and non-MET driven tumor growth. In addition to its direct antitumour activity, merestinib inhibits angiogenesis and induces a tumor vessel normalization phenotype in xenograft tumors. While MET signaling is important for angiogenesis, the effect of merestinib on angiogenesis is likely not exclusively driven by MET inhibition. In co-culture angiogenesis assays, merestinib inhibited VEGF-dependent and VEGF-independent endothelial cell cord formation and sprouting with potencies in the low nM range (3-30 nM). In contrast, the MET-specific kinase inhibitor, PD04217903, only weakly inhibited cord formation and endothelial sprouting. In an established in vivo matrigel co-implant vasculogenesis model where VEGFR2 or MET selective inhibition had minimal effect, merestinib decreased vascular density by 69%. In addition, while MET antibody emibetuzumab (human anti-MET anti-
body) plus ramucirumab (human anti-VEGFR2 antibody) decreased vascular density by 64%, merestinib plus ramucirumab decreased it by 92%. In a mouse adenovirus-driven VEGF-A ear angiogenesis model, treatment with DC101, a mouse anti-VEGFR2 antibody, or merestinib inhibited angiogenesis; however the combination of DC101 and merestinib appeared to inhibit it even more. Finally, in the MKN45 gastric tumor xenograft model, merestinib (T/C = 4.8%) and DC101 (T/C = 15.3%) each significantly inhibited tumor growth alone and the combination resulted in 27.6% tumor regression and was significantly better than either single agent alone. Together, these studies indicate that merestinib has greater effects on angiogenesis than selective MET inhibition and its actions are not dependent on VEGFR2. In addition, while in vitro studies show reductions in VEGFR2 phosphorylation with high concentration of merestinib, treatment with merestinib did not inhibit VEGF dependent phosphorylation of VEGFR2 in mouse lung tissue at clinically relevant exposures. These data suggest that the anti-angiogenic activity of merestinib involves activities of other kinases targeted by merestinib. These data provide rationale and support for the clinical evaluation of combination of merestinib with ramucirumab (NCT07247569).

1824 Endothelial mTORC2 deficiency inhibits tumor angiogenesis, tumor progression and metastasis in non-small cell lung cancer (NSCLC), Shan Wang. Vanderbilt University Medical Center, Nashville, TN.

Vascular endothelial cells (ECs) are specialized components of the tumor microenvironment that orchestrate tumor growth and invasion. They form tumor-associated blood vessels (angiogenic) that supply nutrients and oxygen, remove waste products, and also provide an entry site for tumorintrinsic cells to spread to secondary sites in various organs. One of the major signaling events in tumors is PI3K/PDK-1/mTOR activation. mTOR is a serine/threonine kinase that functions in two distinct complexes, mTORC1 and mTORC2, which regulate a diverse array of cellular processes including cell growth, survival and metabolism. Although mTORC1, and to lesser extent, mTORC2, has been broadly studied in cancers and diseases, little is known regarding the relative contributions of mTORC1 versus mTORC2 in tumor endothelium. Using mouse model of endothelium-specific Rictor (a mTORC2 specific cofactor) gene targeting, we discovered that endothelial Rictor deletion decreased tumor neoangiogenesis, suppressed tumor growth, and prevented metastasis in vivo. Direct co-culture of endothelial cells and NSCLC tumor cells in vitro showed that knockdown of endothelial Rictor inhibited tumor cell proliferation while Raptor (a mTORC1 specific cofactor) depletion had a modest effect. However, loss of endothelial Rictor or Raptor both markedly decreased tumor cell extravasation in response to endothelial cells, and also inhibited tumor sphere formation in a direct co-culture system. Furthermore, a screen of phospho-kinase arrays revealed that Raptor or Rictor depletion in endothelial cells decreased various phospho-RTKs in tumor cells that were co-cultured with ECs, including members of the Eph receptor family, Insulin receptor family and FGF receptor family. Additionally, endothelial Rictor knockdown suppressed phosphorylation levels of several downstream factors, TRKB and TRKC in tumor ECs. Collectively, these data suggest that endothelial mTORC1 and mTORC2 play critical roles in regulating tumor progression through distinct signaling pathways.

1825 Angiopoietin-Tie-2 functional axis in colorectal cancer liver metastasis (CRCLM) provides a new marker for stratification and evaluation of tumor progression. Nisreen S. Ibrahim. McGill University, Montreal, Quebec, Canada.

Colorectal cancer (CRC) is the third leading cause of cancer in Canadians, with liver metastases being the major cause of death from this disease. Tumors induce angiogenesis, a phenomenon known as the ‘angiogenic switch’, which is an essential step in tumor progression whereby the balance of pro- and anti-angiogenic factors is important for active angiogenesis. Clinical efficacy of targeted VEGF (anti-angiogenic) treatment has been validated as a cancer therapy. Our group, together with others, has identified unique histological growth patterns HGP’s (desmoplastic, replacement and pushing) within liver metastases that have different responses to anti-angiogenic therapy. The patients with Desmoplastic HGP (DHGP) that received anti-angiogenic plus chemotherapy prior to resection had a significantly better pathologic response and survival than patients with Replacement HGP (RHP). The aim of this study was to explore the role of Ang-1, Ang-2, Tie-2 and VEGF in the development and progression of CRCLM tumors with distinct HGP’s. Here, human CRCLM tumor samples were analyzed by quantitative real-time PCR (Q-PCR) and immunohistochemistry (IHC) staining. The Q-PCR results demonstrated that the expression of Ang-2 was lower in RHGP tumor samples compared with DHGP tumor samples. This data was validated by IHC, where IHC scoring results showed that the ratio of Ang-2:Ang-1 expression in DHGP tumors was higher compared to RHGP tumors. VEGF and Tie2 proteins were expressed in both tumor patterns. Thus vascular quiescence maintained by constitutive Ang-1/Tie-2 signaling, found in RHGP tumors, prevails over destabilization and pro-inflammatory Ang-2/Tie-2 signaling, which is higher in the DHGP tumor samples. Since vascular remodelling is driven by Ang-2/Tie-2 in DHGP, which is dependent on VEGF we would expect anti-angiogenic therapy to be effective on DHGP. Furthermore, the RHGP had low levels of Ang-2 and high levels of Ang-1, together with the presence of Tie-2, and therefore one would predict that VEGF is not required for the growth of these tumors and thus would not respond to anti-angiogenic therapy, as has been shown in our patients’ cohort. Taken together, these data suggest that the Angiopoietin/Tie-2 functional axis is an important player in CRCLM tumor progression and can be a potential target for CRCLM cancer therapy with stratification of patients by HGP’s.

1826 Bioavailability, pharmacodynamics and safety profile of a novel anti-angiogenic compound JFD in pre-clinical models. Sivanesan Dhandayuthapani, Thanigaivelan Kanagasabai, Khadija Cheema, Appu Rathiavelu. Rumbaugh-Goodwin Institute for Cancer Research, Nova Southeastern University, Fort Lauderdale, FL.

JFD, isoidole (1, 3-dioxo-2, 3-dihydro-1H-isooindol-4-yl)-amide, is a small molecule that was developed using molecular modeling to specifically antagonize Vascular Endothelial Growth Factor Receptor 2 (VEGFR2) and associated kinase activity, thereby producing anti-angiogenic and anti-cancer effects. Since the original form of JFD is hydrophobic, it was recently modified into a water soluble form (JFD-WS) to increase its water solubility and bioavailability. Initially, we investigated the in vitro pharmacodynamics effect of both JFD and JFD-WS by utilizing Matrigel® tube formation assays, scratch and cell migration assays followed by inhibition of VEGFR2 phosphorylation in human umbilical vein endothelial cells (HUVECs). In vivo tumor growth inhibition of JFD and JFD-WS was tested using GI-101A breast adenocarcinoma cells implanted xenograft animals. Subsequently, the blood samples and the tumor proteins were extracted from the control and experimental animals to measure the pro-apoptotic signals and the levels of plasma biomarker such as MUC1 (mucin 1). The safety profile was established using Balb-c mice that were injected intraperitoneally (i.p) with JFD (6 mg/kg body weight) and JFD-WS (100 mg/kg body weight) for 30 days. The pharmacokinetics (PK) of JFD including the plasma concentration, excretion, elimination and distribution in the experimental animals, was that JFD was treated with JFD-WS for four weeks, no significant alterations were found in the test group compared to the control animals. Thus, whether used as a single agent or in combination with the other anti-cancer drugs, JFD shows strong anti-tumor effects without producing severe toxicities. The efficient delivery of JFD original to the brain suggests that this drug would be useful in treating solid tumors of the brain with pro-angiogenic abilities. (This project was supported by the Community Foundation of Broward, Ft. Lauderdale, FL and The Royal Dames of Cancer Research Inc., Ft. Lauderdale, FL.)
research. Many signaling pathways have been implicated in mechanisms leading to the shift of metabolic programs in tumors, but more recently a small number of metabolic enzymes have also been identified in this process. Genes encoding the metabolic enzymes Isocitrate dehydrogenase 1 (IDH1) and 2 (IDH2) were found to be mutated in up to 70% of low-grade and medium grade gliomas, and in 15–25% of adult acute leukaemia samples. We have verified that these cells now produce 2-HG, as is known in human tumors harboring IDH mutations. We have observed different cellular responses to IDH mutations in glia versus hemocytes and have begun to investigate why this may be. Ultimately, the goal of our research is to elucidate the mechanism(s) that cause IDH to contribute to oncogenic activity in specific tissues, and use this knowledge to design tailored therapeutics.

#1828 Are callipers obsolete? A novel 3D scanning technology to measure subcutaneous tumor volume. Zena Wilson,1 Juan Delgado,2 Michael Davies,1 Rebecca Whiteley,1 Jennifer Hare,1 Amar Rahi,1 Stephen Marshall,1 Andrew Smith,1 Stephen Atkinson,1 Jarno Ralli,1 Adeala Zabair,1 Adeala Zabair,1 Jane Kendrew1. AstraZeneca Pharmaceuticals, Cheshire, United Kingdom; 2Glaxo Medicines Research Council, Stevenage, United Kingdom; 3Fuel 3D, Chinnor, United Kingdom.

Most preclinical oncology studies (xenograft, PDX, GEMMS) involve monitoring tumor growth rates, measuring them with callipers, and calculating the volume. Volume is calculated from the width and the length to estimate a 3D volume and is directly used to assess treatment efficacy. Although this technique is useful, it is unable to accurately assess non-uniformly shaped or very small tumours and introduces a systematic bias by assuming that tumours present with spherical shape. Furthermore callipers do not inform of the tumour condition, which is dependent upon a visual estimation. Here we describe the development and validation of a 3D scanner as an alternative method to callipers to monitor tumour progression in rodents. The resulting 3D scanner solution made up of hardware and software, has the potential to impact on the 3Rs guiding principles underpinning the humane use of animals in oncology research. The 3Rs benefits identified are primarily through reduction of animals and alleviation of pain, which may ultimately lead to better development and validation of new cancer treatments.

#1830 Targeted inhibition of EGFR and glutaminase induces metabolic crisis in EGFR mutant lung cancer. Milica Momcilovic,1 Sean T. Bailey,1 Jason T. Lee,1 Daniel Braas,2 Thomas G. Graeber,3 Melissa Works,2 Francesco Parlati,2 Susan Page,2 Tonya C. Walker,2 Stephen M. Dubinett,1 Saman Sadeghi,1 Heather Christofk,1 David B. Shackelford1. UCLA, Los Angeles, CA; 2Calithera Biosciences, CA.

Cancer cells exhibit increased use of nutrients including glucose and glutamine to support the bioenergetic and biosynthetic demands of proliferation. We tested CB-839, a small molecule inhibitor of glutaminase that impedes glutamine utilization, in combination with erlotinib on EGFR mutant non-small cell lung cancer (NSCLC) as a therapeutic strategy to simultaneously impair cancer glucose and glutamine utilization and thereby suppress tumor growth. Here we show that CB-839 synergizes with erlotinib to drive energetic stress and activate the AMPK pathway in EGFR (del19) lung tumors. Tumor cells undergo metabolic crisis and cell death resulting in rapid tumor regression in vivo in mouse NSCLC xenografts. Consistently, positron emission tomography (PET) imaging with 18F-fluorodeoxyglucose (18FDG) and 11C-Glutamine (11C-Gln) of xenografts indicated reduced glucose and glutamine uptake in tumors following CB-839 + erlotinib treatment. Therefore, PET imaging with 18F-FDG and 11C-Gln can be used to non-invasively monitor tumor metabolic and therapeutic response to CB-839 and erlotinib combination therapy.

#1831 PET/CT imaging of interleukin-13 receptor alpha-2-targeted peptide to glioblastoma after locoregional delivery. Anirudh Sattiraju,1 Ang Xuan,2 Frankis Almaguel,1 Denise Herpai,1 Waldemar Debinski,1 Akiva Mintz,1 Kiran Kumar Solingapuram Sai1. Wake Forest School of Medicine, Winston Salem, NC; 2The People's Hospital of Zhengzhou University, Zhengzhou, China.

Glioblastoma (GBM) is the most aggressive and common primary malignant astrocytoma which is characterized by tumor heterogeneity, infiltrating margins. Radiotherapy, chemotherapy and experimental targeted therapies have been ineffective at meaningfully increasing patient survival. One significant shortcoming of systemically delivered therapies is their inability to cross the blood brain barrier (BBB) and access infiltrating tumor cells. Therefore, in this work, we tested the potential of locoregionally targeting GBM via IL13Rα2, which we discovered to be expressed on greater than 75% of GBMs. To accomplish this, we intracranially infused copper-64 (64Cu) radiolabeled IL13Rα2 specific peptide Pep-1L, previously developed by Pandya et al., into mice bearing IL13Rα2 expressing orthotopic GBMs. Small animal micro PET/CT imaging showed ~2-fold greater tumor specific localization and lower volume of distribution of 64Cu-Pep-1L within brains of mice. Post-PET biodistribution study showed greater retention of 64Cu-Pep-1L 4 hours (%ID/g = 20.85 ± 0.65) and 24 hours (%ID/g = 14.65 ± 0.30) post infusion when compared to similarly infused 64Cu radiolabeled scrambled control peptide 4 hours (%ID/g = 10.73 ± 2.02) and 24 hours (%ID/g = 5.97 ± 1.47) post infusion. These results demonstrate that Pep-1L efficiently targets IL13Rα2 expressing GBMs in vivo upon loco-
Non-small cell lung cancer (NSCLC) has a low survival rate, with metastasis contributing to the vast majority of deaths. The NEDD9 (HEF1/Cas-L) protein has been reported to be elevated in expression and to promote metastasis in a large subset of lung cancers and in other malignancies. NEDD9 functions as a scaffold for multiple critical effectors in integrin/FAK/SRC and receptor tyrosine kinase/multi-growth signaling cascades. The specific role of NEDD9 in tumor progression remains unclear, overexpression thought to sustain signaling by these oncogenic proteins. Previous studies demonstrated depletion of NEDD9 by RNAi reduced the growth and invasion of established lung cell lines and tumors, based on cell culture and xenograft assays. We have now investigated the consequences of a null genotype for NEDD9 from the earliest stages of tumor formation, crossing Nedd9 mutant mice to a 129/SV/Pyg/tv5/H11005 (SV/Pyg) background in which Kras mutation is induced specifically in lung tissue by inhalation of adenovirus bearing the Cre gene. Unexpectedly, based on in vivo imaging, the Nedd9 null genotype accelerated tumor growth in KP mice. Pathological examination of tissues indicated Nedd9 null genotype also was associated with higher invasive capacity in vivo, including direct invasion to the heart, as well as elevated proliferation rate, decreased apoptotic activity, and changes in the expression of proteins such as vimentin, associated with mesenchymal status. Although Nedd9 function has been implicated in immune cell activity, we found minimal differences in tumor infiltration of myeloid cells or macrophages based on Nedd9 genotype. Rather, use of Reverse Phase Protein Array (RPRA) analysis to characterize signaling in isolated tumors suggested tumor intrinsic changes in signaling. We have now characterized specific signaling pathways, which were subsequently validated using direct functional assays. These results for the first time imply that NSCLC tumor progression beyond early stages in the absence of Nedd9 requires reprogramming of intrinsic tumor signaling to compensate for the absence of this protein, emphasizing activities distinct from those associated with elevated Nedd9 in late stage tumors.

Regional delivery and can effectively deliver potential therapeutic agents to GBM tumors while sparing normal brain. This work was supported by the American Cancer Society Mentored Research Scholar grant # 124443-MRSG-13-121-01-CDD (Mintz), IR01CA179072-01A1 (Mintz), P30 CA012197 (Paszke), R01CA074145-19 (Debinski) and the Translational Imaging Program (TIP) of the Wake Forest CTSA (UL1TR001420).

#1832  Bioluminescent pharmacokinetics of luciferin in preclinical brain metastases of breast cancer models. Neal Shah, Chris E. Adkins, Afroz S. Mohammad, Paul R. Lockman. West Virginia University, Morgantown, WV.

Background: Approximately 20% of breast cancer patients with disseminated disease will develop brain metastases. Preclinical models of brain metastases of breast cancer rely on ex vivo histology to evaluate drug efficacy. However, bioluminescence imaging allows more precise quantification of tumor burden and progression through counting photons per second without requiring animal sacrifice. This methodology has not readily been applied to hematogenously derived brain metastases models given the heterogeneity of tumor burden and growth. Herein we demonstrate repeatable methodology to quantitatively measure bioluminescence of breast cancer progression which is verified with histology. Methods: Approximately 1.75 x 105 JIMT-1 (n=3) and 231-BrLuc (n=4) brain seeking subclones were injected intracardially to produce metastatic brain lesions. Mice were given 150 mg/kg of luciferin IP and luminescence was captured every 2-minutes for 60 minutes starting 24 hours after cell implantation. Radiance (photons per second per square centimeter per steradian) was plotted to observe peak luminescence. Imaging was repeated twice weekly to evaluate progression until euthanasia. Results: Following intracardiac injection, both brain seeking metastatic models produced a maximum luminescence signal between 14-20 minutes after luciferin injection. For all subsequent imaging, 5 minute imaging between 15-20 minutes after luciferin injection was used. Longitudinally, both tumor cell lines produce bioluminescence 24 hours after cell injection, which is used to ensure tumor implantation and randomization. The BLI signal decreases to undetectable limits in both models between 3-7 days after cell implantation. Re-emergence of signal occurs on day 14 for the JIMT-1 line and day 21 for 231-Br line. JIMT-1 bioluminescence on day 14 begins at ~10^5 photons/sec/cm^2/sr and then over time signal increases with a ~slope of 5.6x10^5 until reaching a maximum of 10^6 units on day 28. 231-BrLuc bioluminescence on day 21 begins at ~10^5 photons/sec/cm^2/sr and then over time signal increases with a ~slope of 1.1x10^5 until reaching a maximum of ~10^6 on day 53. Conclusion: To accurately measure bioluminescence as a surrogate for tumor burden in hematogenously implanted metastases, the optimal circulation time is approximately 15 minutes with a 5 minute imaging period. Bioluminescence of the 231Br line initially starts at a lower magnitude and later in time than the JIMT-1 line, but slopes of both intracardiac models are similar and result in similar bioluminescent curves.

#1833 Imaging-guided brain tumor surgery strategy based on a triple-modality imaging probe and imaging probe seeded imaging model. Hui Meng, Yushen Jin, Shaowei Zhang, Shuai Gu, Xibo Ma, Jie Tian. Institute of Automation, Chinese Academy of Sciences, Beijing, China; Chinese PLA General Hospital, Beijing, China; Shandong University, Jinan, China.

Precise brain tumor resection is valuable for increasing the 5-year survival rate. However, the delineation of tumor margin is a major challenge. Transferrin modified nanoprobes had the property of passing the blood-brain barrier (BBB). Here, we endeavored to use transferrin to fabricate a triple-modality magnetic resonance imaging-PET-fluorescence imaging molecule agent (MPF) which could improve diagnostic sensitivity and specificity of the brain tumors in the imaging acquisition and analysis. The localization of the tumor were determined by the MRI before surgery. Glucose metabolism was derived from PET imaging which would be an important influence factor for surgery strategy. Tumor margin was delineated using the quick segmentation methods according to the fluorescence imaging after craniootomy which could reduce residual tumor after resection. Finally, tissues were sliced and stained with hematoxylin and eosin every 5 mm. The histology results were processed into a whole image which can be used to evaluate the accuracy of intraoperative tumor margin. This triple modality imaging-guided surgery strategy is a promising method which will probably achieve its application in clinical trials in near future.

#1834 Constitutive Nedd9 null genotype promotes lung cancer aggressiveness. Alexander Deneka, Meghan Kopp, Anna S. Nikonova, Anna Gaponova, Alexandra Nagle, Harvey Hensley, Erica Golemis. Fox Chase Cancer Center, Philadelphia, PA.

TUMOR BIOLOGY: Cell Culture and Animal Models of Cancer 2

Development of mammary hyperplasia, dysplasia, and invasive ductal carcinoma in transgenic mice expressing the 8p11 amplicon oncogene Nsd3 (Whsc1ll1). Alex C. Rutkovsky, Brittany Turner-Ivey, Ericka L. Smith, Laura S. Spruill, Jamie N. Mills, Stephen P. Ether. The Medical University of South Carolina, Charleston, SC.

Amplification within the 8p11-12 locus occurs in approximately 15% of breast cancer (BC) and is associated with poor survival and distant recurrence. Overexpression of many of the genes within the 8p11-12 region can confer a pathological gain of function to breast cells. We and others have previously demonstrated that Nsd3 (Whsc1ll1), a lysine methyltransferase, can act as a potent transforming oncogene. Predictions by the GISTIC algorithm of the Human Cancer Genome Atlas data suggest that Nsd3 is a driving gene within 8p11-12 in multiple cancer types, including BC. We previously showed that Nsd3 can regulate the expression of influential genes, such as estrogen receptor alpha (ESR1/ERa). To further explore the role of Nsd3 in promoting BC, we generated FVB/N transgenic mice with targeted overexpression of Nsd3 in the mammary gland and compared them to matched non-transgenic wild-type (WT) females. We observed that pups nursed by transgenic females were underdeveloped, regardless of genotype. Underdeveloped pups displayed delayed hair growth and eye opening, and were half the weight of pups nursed by WT females. To investigate this phenotype, we characterized thoracic and inguinal mammary glands from virgin, mid-pregnancy, lactating, and post-lactating mice by whole mount and histological analysis. Mammary glands from virgin transgenic females displayed increased branching and terminal bud formation. Alveolar buds from mid-pregnancy transgenic glands were more numerous and densely packed. Glands from lactating transgenic females showed large areas in which the alveoli failed to undergo functional differentiation, resulting in a lactation defect. Mammary glands taken post-lactation exhibited areas of ductal and alveolar hyperplasia. At 40 weeks of age, multiple transgenic mice had palpable tumors which were excised at 1 cm^3 size. Whole mount and histological analysis of glands from tumor-bearing mice commonly demonstrated hyperplasia, dysplasia, and carcinoma in situ, contrary to age-matched WT glands. The areas of ductal dysplasia and carcinoma in situ closely resembled several patterns commonly observed in human breast cancer, including micropapillary, cribriform, and high grade areas of ductal carcinoma in situ. Mammary tumors were analogous to infiltrating ductal carcinomas, many of which are high grade antigens. In summary, overexpression of Nsd3 in the mouse mammary gland elicited drastic deformation, inhibited functional differentiation, and caused tumor formation. Continued characterization of this mouse model, the oncogenic role of Nsd3, and other mechanistic studies are essential to improve patient outcome in 8p11-12 altered cancers.
#1836 Patient-derived xenograft (PDX) models expressing HER2 reflect clinical responses to targeted HER2 inhibition. Daniel Czindzadaj,2 Amir Sonnenblick,2 Jennifer Jaskowiak,1 Angela Davies,1 David Sidransky,3 Champions Oncology, Hackensack, NJ;4 Hadassah-Hebrew University Medical Center, Jerusalem, Israel;5 Johns Hopkins University School of Medicine, Baltimore, MD.

Background While HER2-directed agents are most often used for treating breast cancer, there is increasing evidence that these therapies may be of value in other solid tumors. Sequencing efforts and immunohistochemistry (IHC) have identified mutations, amplifications, and overexpression of HER2 in ovarian, HNSCC, NSCLC, and GI cancers. PDX models could permit evaluation of HER2 response/resistance mechanisms to optimize therapeutic strategies. In this study, we developed the response models to HER2-targeted therapies and correlated responses to clinical outcomes. Materials and Methods PDX models were developed from a variety of patient solid tumors, evaluated by IHC for HER2 expression and next-generation sequencing for genomic alterations in HER2 (mutations, amplifications/deletions, and expression levels). Models were screened against single agent HER2-directed therapies including trastuzumab (n=15), trastuzumab emtansine (n=23), and lapatinib (n=10). Tumor regression (TR) values and RECIST criteria were determined and correlated with known literature-based response rates (RR) as well as individual patient outcomes. Results 32 PDX models from 30 patients were interrogated (primarily breast and colorectal). Twenty (63%) models have been sequenced to date; 13 (65%) harbor amplification at ERBB2 gene locus. Further, 56% (18/32) have been sequenced for HER2: 20 (62.5%) have 2+ staining, 3+ staining, and 33% 1+ staining. Based on PDX tumor growth, stable disease/regression was observed in 10% of models screened against lapatinib (CR/PR=0%), 50% screened against trastuzumab (CR/PR=8%), and 67% tested against trastuzumab emtansine (CR/PR=14%). Only models with 2+ or 3+ HER2 staining showed regression with HER2-targeted treatment, with nearly 70% of 2+ HER2 models showing progressive disease. Finally, there were correlations to patient clinical outcomes available, with 3/4 (75%) of the PDX model responses mimicking those of the patient to the same treatment. Conclusion and Future Directions Extensive sequencing of human cancers has demonstrated HER2 amplification or mutation in numerous solid tumors, suggesting HER2-directed therapy could be applied more broadly in the clinic. Consistent with clinical findings, HER2 therapy responses depend on the strength of HER2 expression (based on IHC). Nevertheless, response rates in PDX models varied depending on which HER2-targeted agent was deployed, highlighting the potential existence of differential mechanisms of de novo resistance/sensitivity. Comprehensive sequencing and drug testing of these PDX models is planned and could allow a deeper understanding of such mechanisms. In this context, application of PDX models for translational modeling of HER2 drug responses, particularly in the context of co-clinical trials, will continue to evolve.

#1837 High Ras activity promotes neoplasia in pancreatic ductal cells. Kanchan Singh,1 Melissa A. Pruski,2 Waisin A. Dar,3 Kishore PoliReddy,4 John S. Bynon,5 Mamoun Younes,1 Anirban Maitra,2 Craig D. Logsdon,2 Jennifer M. Bailey1.1 University of Texas Health Science Center, Houston, TX; 2 The University of Texas MD Anderson Cancer Center, Houston, TX.

Pancreatic ductal adenocarcinoma (PDAC) remains a highly lethal malignancy and is the third leading cause of cancer-related deaths in the United States. Next generation sequencing efforts have revealed KRAS mutations occur in over 99% of pancreatic ductal adenocarcinomas and are thought to be the initiating mutation for pancreatic cancer. Despite the high prevalence of KRAS mutations in pancreatic cancer patients, murine models expressing endogenous levels of mutant KRAS in pancreatic cells do not develop PDAC. A number of publications have revealed that acinar cells are more sensitive to early neoplastic lesion formation in the presence of KRAS mutations than ductal cells. In these models, a second genetic hit (loss of tumor suppressor TP53, SMAD4 or CDKN2A) is required for the development of invasive PDAC, including transforming pancreatic ductal cells. Recent data has revealed a novel role for high levels of Ras activity in acinar cells in the transformation of this cell type to PDAC (Ji, B. 2008, published based on high levels of Ras activity to transform ductal cells). To test this hypothesis, we studied the role of constitutively active high levels of KRAS activity in acinar and ductal cells by expressing an inducible KRASG12V allele in Ptf1a:CreERT2 (acinar cell specific) and Hnf1b:CreERT2 (ductal cell specific) mice. Similar to previously published work, high levels of Ras activity in acinar cells resulted in PDAC and a remarkably low survival time of 10 days after mice were injected with tamoxifen. Mice with elevated Ras activity in ductal cells needed to be euthanized two weeks after tamoxifen injection and manifested a cancer cachexic phenotype. Histological analysis of these mice revealed high grade oncogenic intraductal neoplasia and the phenotype extended throughout the pancreatic ductal ducts. Western blot analysis of human PDAC and Cholangiocarcinoma tissue revealed similar levels of Ras activity to our murine models, confirming human equivalent high Ras expression to both animal models. Oncocytic tumors are characterized by an abundance of mitochondria. Thus, we are currently studying metabolic alterations and mitochondrial dysfunction in ductal cells expressing high Ras activity. Our goal is to determine how mitochondrial alterations play a role in progression or inhibition of tumors in ductal vs acinar cells.

#1838 TGFA (an EGFR ligand) promotes growth of EGFR-mutant lung tumors in airway regions but not in alveolar regions in a transgenic mouse model. Koichi Tomoshige, Yutaka Maeda. Cincinnati Children’s Hospital Medical Center, Cincinnati, OH.

Although an exogenous EGF is dispensable for EGFR+/−-mediated NIH3T3 cell transformation in vitro (Greulich et al., PLoS Med 2005), an exogenous EGF promotes growth of H1650 and H1975 lung adenocarcinoma cells that carry EGFR mutations in vitro (Sordella et al., Science 2004). However, it is unknown whether an exogenous EGFR ligand plays a role in growth of EGFR-mutant tumors in vivo. Here, using conditional transgenic mice expressing EGFR+/− or KRASG12D along with an exogenous TGFA (an EGFR ligand) in lung epithelium, we sought to determine the role of an EGFR ligand in EGFR+/−-lung tumors or wild type EGFR-lung tumors (KRASG12D/-/− tumors) in vivo. As previously reported, conditional expression of TGFA (an EGFR ligand) in lung epithelium caused pulmonary fibrosis but not lung tumors (Korfhagen et al., J Clin Invest 1994; Hardie et al., JIP, 1999). But we wondered that the expression of an exogenous EGFR ligand is not sufficient to induce lung tumors. Conditional expression of EGFR+/− or KRASG12D in lung epithelium caused the growth of lung tumors in airway regions but not in alveolar regions while the expression of EGFR+/− alone did not induce lung tumors in airway regions. Co-expression of EGFR+/− along with TGFA also shortened survival of the mice compared to the expression of either EGFR+/− or TGFA alone (median 32 days for EGFR+/−/TGFA vs 118 days for EGFR+/− alone or 248 days for TGFA alone). Co-expression of KRASG12D with TGFA did not influence tumor location or survival of the mice compared to the expression of either KRASG12D or TGFA alone. Consistent with the mouse study, TGFA expression in human EGFR-mutant lung cancer but not wild-type EGFR lung cancer was associated with worse overall survival (median 44 months for EGFR+/−/TGFA high vs 75 months for TGFA low; p<0.05) and recurrence free survival (median 21 months for TGFA high vs 61 months for TGFA low; p<0.05). Collectively, our results demonstrate that TGFA (an EGFR ligand) promotes not only the growth of EGFR+/−-lung tumors but also influences the regions where the EGFR+/−-lung tumors form.

#1839 TGFB1*6A mouse model mimics human breast cancer development and progression. Michael James Pennison, Minghui Wang, Hugo Jimenez, Boris Pasche. Wake Forest Baptist Medical Center, Winston-Salem, NC.

Transforming Growth Factor-β (TGF-β) is one of the most commonly altered cellular signaling pathways in human cancer. Our group was the first to discover TGFB1*6A (*6A), a common hypomorphic variant of the type I TGF-β receptor (TGFBR1), which has been associated with increased risk for breast cancer in multiple epidemiological studies. Functional analysis also suggests that *6A is associated with decreased tumor suppressive TGF-β signaling in early tumor development and is involved with promoting tumorigenesis in advanced carcinomas. To better understand the functional impact of *6A and constitutively reduced TGF-β signaling on breast cancer development and progression, we have recently developed a series of transgenic knock-in mouse model variants by replacing exon 1 of the mouse Tgfb1 sequence with human exon 1 sequences harboring both *6A and wild-type (*9A) TGFBR1 variants and crossed them with MMTVneu mice. We generated a total of 5 FVB double and/or triple transgenic mouse strains: MMTVneu*9A/9A, MMTVneu*6A/6A, MMTVneu*9A/6A, MMTVneu*9A/6A/. Following tumor development, measurements were performed three times per week to determine tumor volume. All mice were allowed to live up to 18 months (548 days) or until they died of natural causes. Specimens were collected for later analysis of blood, tumors, normal
mammary tissue, and were evaluated for lung metastases. Statistical comparisons performed using Student’s t-test. Only 34.4% of MMTVneu/9A/9A mice (11/32) developed mammary tumors, while 80% of MMTVneu/6A/6A mice (24/30; \( p = 0.0002 \)) and 62.5% of MMTVneu/6A/- mice (19/32; \( p = 0.046 \)) developed tumors. The percentage of MMTVneu/9A/6A and MMTVneu/9A/- mice developing metastases was less than MMTVneu/9A/9A mice (48.3% and 50%, respectively) but was not statistically significant. Additionally, 66.7% of MMTVneu/6A/6A mice (20/30) developed 2 or more tumors, while only 25% of MMTVneu/9A/9A mice (8/32) developed multiple tumors (\( p = 0.0007 \)). Our data suggests that we have developed transgenic mouse strains that accurately mimic human breast cancer susceptibility and develop metastases. These mouse models will be valuable to investigate subtypes of breast cancer and to provide insights into the role of TGFBR1 variants in the development and progression of breast cancer.

**#1840 Whole-exome somatic mutation analysis of mouse cancer models and implications for preclinical immunomodulatory drug development.** Bruno Zeitouni,1 Cordula Tschuch,1 Jason M. Davis,2 Anne-Lise Peille,1 Yana Baeva,1 Manuel Landeseifen,1 Sheri Barnes,1 Julia B. Schuler1.1 Oncotec GmbH, Freiburg, Germany; 1Charles River Discovery, Morrisville, NC

Experimental tumors raised in rodents represent an important preclinical tool to develop innovative anticancer compounds before clinical testing. Amongst others such models include solid tumors raised in syngeneic fully immune competent hosts and tumors spontaneously growing in genetically engineered mice (GEM) and derived therefrom. These model platforms have gained additional value since the manipulation of the immune system to engineer mice (GEM) and derivate thereof. These model platforms have been used as preclinical tools to develop innovative anticancer drugs. This review focuses on the preclinical use of GEM in mouse cancer models for immune cell signaling and validation of novel therapeutic strategies. We describe the key features of the GEM platform and discuss the potential advantages and limitations of GEM models for drug development.

**#1842 Breast cancer brain metastasis (BCBM) model for determination of therapeutic brain penetration.** Emily A. Wyatt, Mark E. Davis. California Institute of Technology, Pasadena, CA.

Purpose Brain metastases are presenting an increasing problem in the clinic, and especially in treatment of patients with human epidermal growth factor receptor-2 (HER2)-amplified breast cancer. Although extracranial metastases respond well to HER2 inhibitors, human clinical data shows brain metastases hide behind an intact blood–brain barrier (BBB) and are largely untreatable. Mammalian brain tumors and metastatic models lack this barrier integrity, limiting their utility in understanding delivery of drugs to the brain. We present here the development of a new model suitable for evaluating therapeutic brain penetration in addition to efficacy. Experimental procedures Human HER2-amplified BT-474 breast cancer cells were inoculated intravenously (tail vein) in female Rag2-/-Il2rg-/- mice (2 million cells/mouse) to induce multigorgan metastasis. Formation of metastatic brain lesions was monitored by magnetic resonance imaging (MRI). For comparison, BT-474 cells were inoculated intracranially for direct brain tumor implantation (50 000 cells/mouse). Response to a suite of HER2-targeted therapies known not to appreciably cross an intact BBB (trastuzumab, lapatinib, etc.) was largely untreatable. Multigorgan metastatic models lack this barrier integrity, limiting their utility in understanding delivery of drugs to the brain. We present here the development of a new model suitable for evaluating therapeutic brain penetration in addition to efficacy. Experimental procedures Human HER2-amplified BT-474 breast cancer cells were inoculated intravenously (tail vein) in female Rag2-/-Il2rg-/- mice (2 million cells/mouse) to induce multigorgan metastasis. Formation of metastatic brain lesions was monitored by magnetic resonance imaging (MRI). For comparison, BT-474 cells were inoculated intracranially for direct brain tumor implantation (50 000 cells/mouse). Response to a suite of HER2-targeted therapies known not to appreciably cross an intact BBB (trastuzumab, lapatinib, etc.) was monitored by MRI for both metastatic and implanted brain tumors. Mice were sacrificed following signs of prolonged distress or loss of >20% body weight. Organs were collected for standard histological and immunohistochemical analysis, as well as for CLARITY tissue clearing and large-scale 3D macromolecule mapping. Results Intravenous inoculation of BT-474 cells into Rag2-/-Il2rg-/- mice consistently reproduced the full metastatic profile seen in humans, with metastases in the lung, bone, liver, ovary, lymph, and brain tissues. Brain metastases were detected in 90% of mice inoculated intravenously. Histological analysis of metastatic brain tumors showed different morphologies and invasive characteristics compared to those intracranially implanted. Additional differences in vasculature between metastatic and implanted brain tumors were identified by CLARITY. Importantly, HER2-targeted therapy markedly delayed progression of implanted brain tumors but failed to slow metastatic brain tumor growth, recapitulating the clinical situation. Conclusions These data, together with ongoing efforts to further characterize therapeutic transport to these brain tumors, suggest that intracranial inoculation disrupts the BBB and creates artificial routes for therapeutics to reach implanted brain lesions, resulting in anomalous tumor response. In contrast, this new metastatic model reproduces the discordant effects of HER2-targeted therapy in patients, and offers a platform for studying the efficiency of therapeutic delivery across an intact BBB as well as antitumor activity, both of which are critical to effective clinical translation.

**#1843 Intratumoral heterogeneity of renal cancer is related to differences in drug response and development of therapy resistance.** Michael Becker,1 Burkhard Jandrig,2 Susanne Flechsig,1 Reiner Zeisig,1 Daniel Schindele,2 Martin Schostak,7 Christian Schmees,7 Annika Wulf-Goldenberg,3 Jörg Hennenlotter,4 Elke Schaeffeler,7 Matthias Schwab,7 Arnulf Stenzl,4 Jens Bedke,4 Jens Hoffmann1.1 EPO - Experimental Pharmacology and Oncology Berlin-Buch GmbH, Berlin, Germany; 2University Medical Center Magdeburg, Magdeburg, Germany; 3NMI University Tuebingen, Tuebingen, Germany; 4University Hospital Tuebingen, Tuebingen, Germany; 5Margarete Fischer-Bosch-Institut for Clinical Pharmacology, Stuttgart, Germany.

Background: Patients with advanced renal cell cancer (RCC) have a poor prognosis not only because of resistance towards standard drugs (SoC). Recently, pronounced intratumoral heterogeneity (ITH) in RCC was shown. We...
were interested whether this ITH is a potential cause for treatment failure. We
developed a large panel of patient-derived xenograft (PDX) models from RCC,
including subsets of models from different regions of one individual tumor. The
PDX models were evaluated for response to SoC. To better understand correla-
tions between inter- and intratumoral heterogeneity and treatment response,
tumor models were panel sequenced and expression profiled. Methods: Speci-
mens from primary and metastatic RCCs were collected from consenting pa-
tients and transplanted into mice. Tumor engraftment was monitored for up to
4 months. Tumor sections were examined histopathologically to assess concor-
dance between patient tumor and model and were stained for RCC specific
markers (Pax2, Pax8, CD31, and RCC). Stable growing PDX were treated with
SoC (sunitinib or sorafenib, bevacizumab and everolimus). Global gene expres-
sion was analyzed in primary tumors and PDX models using microarrays (Af-
zymex). In addition, sequence variations (Illumina NGS cancer panel) and
MET and TERT gene copy numbers were analyzed in PDX models. Results: A
panel of 34 RCC PDX models was established from more than 200 patient sam-
ple. Among these, 13 models were derived from different tumor regions of three
advanced tumors. Original patient tumor and PDX showed a very similar and
characteristic RCC histopathology. Inter- and intratumoral heterogeneity was
preserved for several passages. We treated all PDX with standard targeted drugs
and observed response rates comparable to results from clinical trials. One out of
8 regions obtained from one aggressive RCC clearly differentiated in regard to its
response to bevacizumab and sunitinib. Genomic analysis revealed that this region
had a number of differences in global gene expression and sequence variation pattern.
Besides a common MET mutation an additional variation in the HRAS gene was
detected. In the whole PDX set we found 34 sequence variations in 20 genes, e.g.
ATM, MET, TP53 and VHL and copy number variations in the MET locus.

**#1844 Investigating the role of amphiregulin in breast cancer.**
Serena P. Chiang, George S. Karagiannis, John S. Condellelts, Jeffrey E. Segall. Albert Ein-
tstein College of Medicine, Bronx, NY.
Breast cancer is the most prevalent cancer in women worldwide and afflicts
more than 3.1 million women in the US alone. The epidermal growth factor re-
ceptor (EGFR) is frequently overexpressed in breast cancer and is associated
with poor clinical outcome. Several therapies involving anti-EGFR agents have
been developed to target breast cancer. However, clinical trials have shown
mixed outcomes with these therapies. Amphiregulin (AREG) is a ligand for
EGFR that mediates estrogen-induced mammary ductal morphogenesis during
development. Expression of AREG is enriched in invasive breast carcinomas,
particularly ERα-positive breast tumors. Studies have shown that AREG in-
creases the in vitro invasiveness of breast cancer cells. Furthermore, suppression of
AREG expression in transformed human breast epithelial cells reduces tumor
formation when injected in nude mice. These observations suggest that AREG
plays an important role in breast cancer development and progression. To in-
vestigate the role of AREG in breast cancer development and progression, we
utilized a spontaneous mammary tumor mouse model where oncogenesis is
driven by expression of the polyoma middle T oncprotein (PyMT) through the
mouse mammary tumor virus (MMTV) promoter. We have crossed AREG
knockout mice with the MMTV-PyMT mice to generate AREG KO mice that
spontaneously form mammary tumors. Tumors in AREG KO PyMT mice ini-
tially grow more quickly but eventually reach 2 cm in diameter at a relatively
time as compared to tumors formed in AREG WT PyMT mice. Histologically,
AREG KO tumors appear more differentiated and display a greater proportion
of tumor stroma. This prompted us to further hypothesize that AREG may have
diverse effects in the tumoral or stromal compartment of developing tumors. To
individually assess the effects of AREG knockout in the tumor cells and the
stroma, we utilized a transplantation model in which we prepared tumor chunks
from AREG KO PyMT tumors and transplanted them into AREG WT and
KO mice. Through this model, we have found that AREG expression in the
tumor has a greater impact on tumor growth and progression than the tumor
stroma. Regardless of the AREG status of the recipient mice, AREG KO tumors
display a significant growth impairment and reduced transplant efficiency. In
summary, these results demonstrate that AREG is important for mammary tu-
mer progression.

**#1845 Mutant p53 promotes progression and metastasis of mouse oral

tumors induced by 4NQO, associated with specific immune infiltrates.**
Jin Wang, Yuanyang Zhang, Bingbing Wang, Adel K. El-Naggar, Jeffrey N. Myers,
Carlos Caulin. UT MD Anderson Cancer Center, Houston, TX.
Head and neck squamous cell carcinoma (HNSCC) is the sixth most com-
non malignancy worldwide. The vast majority of the human HNSCCs con-
tain p53 mutations, some of which acquire oncopgenic gain-of-function (GOF)
activities. Previous mouse models in which either the p53R172H/GOF
mutation or deletion of the p53 gene were co-activated with oncogenic K-ras
showed that p53R172H can predispose to oral tumor initiation, accelerate
tumor growth and promote progression to SCC. However, the impact of p53
gene mutations on immune infiltration remains to be assessed because of the
low rates of progression to SCC in that model. To overcome this limitation, we used the tobacco-surrogate 4NQO to induce oral

lesions that may progress to advanced carcinomas following stepwise
changes that resemble the gradual accumulation of histological and molec-
ular abnormalities observed during human oral cancer progression. To ex-
amine the role of p53 mutations during SCC malignant progression we
applied 4NQO to mice in which the p53R172H mutation or homozygous
deletion of p53 were activated in oral epithelial cells. We observed that oral
tumors appeared faster in the presence of p53 mutations than in mice with
wtp53. No significant difference was observed between the p53R172H/GOF
mutation and p53 deletion. However, survival was shorter in mice expressing
the p53R172H mutation compared to wtp53 expressing tumors. Genomic
infiltration were only observed in mice with oral tumors expressing p53R172H.
Therefore, these mice are excellent tools for pre-clinical studies designed to
target early stages of tumor development or latest stages of progression and
metastasis. As immunotherapy is becoming adopted as part of the standard
treatment for head and neck cancer patients, we conducted a detailed char-
acterization of the immune infiltrates of the lesions that developed in these
mice in order to assess their immunogenicity. We observed a progressive
increase in T-cell infiltration from normal oral mucosa to oral premalignant
lesions (OPL) to SCC, in the presence or absence of p53 mutations. Similarly,
the expression of immune checkpoint proteins, including PD1, PDL1 and
CTLA4 increased during oral tumor progression, regardless of the p53 sta-
tus. Interestingly, we observed a sharp increase in the presence of immune
infiltrates expressing the co-stimulatory OX40 in SCCs relative to premalign-
nant lesions, with different extent depending on the nature of the p53 mu-
tation. The significance of these observations is currently being analyzed. In
summary, p53R172H promotes metastasis in oral tumors induced by 4NQO.
In addition, T-cell infiltration and activation of immune checkpoints during
oral tumor progression suggest that this is an excellent model to test immu-
notherapy-based strategies. Furthermore, our findings suggest that OX40-
based therapies may be tailored to patients according to their p53 status.

**#1846 Immunocompetent mouse allograft models for development of
therapies to target breast cancer metastasis therapies to target breast cancer
metastasis.**
Yu-an Yang,1 Howard Yang,1 Ying Hu,1 Peter Watson,2 Huaitian Liu,1 Thomas R. Geiger,1 Miriam R. Anver,3 Diana Haines,3 Philip Martin,3
Maxwell P. Lee,1 Kent W. Hunter,1 Lalage M. Wakefield1.
1National Cancer Institute, Bethesda, MD; 2British Columbia Cancer Agency, Victoria, British Co-
lumbia, Canada; 3Leidos Biomedical Research Inc., Frederick National Labora-
tory for Cancer Research, Frederick, MD.
Effective drug development to combat metastatic disease in breast cancer
would be aided by the availability of well-characterized preclinical animal mod-
els that (a) metastasize with high efficiency, (b) metastasize in a reasonable
time-frame, (c) have an intact immune system, and (d) capture some of the
heterogeneity of the human disease. To address these issues, we have assembled
a panel of twelve mouse mammary cancer cell lines that can metastasize effi-
ciently on implantation into syngeneic immunocompetent hosts. Genomic
characterization shows that more than half of the 30 most commonly mutated
sites in breast cancer are represented within our panel. Transcriptome anal-
lytically, most of the models fall into the luminal A or B intrinsic molecular sub-
types, despite the predominance of an aggressive, poorly-differentiated or spin-
dled histopathology in all models. Patterns of immune cell infiltration,
proliferation rates, apoptosis and angiogenesis differed significantly among
models. Inherent within-model variability of the metastatic phenotype man-
dates large cohort sizes for intervention studies but may also capture some re-
levant non-genetic sources of variability. The varied molecular and phenotypic
characteristics of this expanded panel of models should aid in model selection
for development of anti-metastatic therapies in vivo, and serve as a useful plat-
form for predictive biomarker identification.
#1847  Evaluating the metastatic potential and the molecular heterogeneity of patient-derived orthotopic xenograft models of triple-negative breast cancer.

Vishnu C. Ramani,1 Rakhi Gupta,1 Gerald Quon,1 Melanie Triboulet,1 Corinne Renier,1 Cassandra Greene,1 Chad Sanada,1 Tracy Lu,1 Lukasz Szpankowski,1 Naveen Ramalingam,1 Ameen A. Salahudeen,1 Jean de la O,1 Ranjani Rajaratnam,1 Francois Nouy,1 E. Charles Carey,1 J Chad Brenner.

University of Nebraska Medical Ctr., Omaha, NE

We report an in-depth characterization of patient-derived orthotopic xenograft (PDX) models of triple-negative breast cancer (TNBC) regarding their molecular, epithelial cell level, tumor heterogeneity, 3D organoid generation, and ability to generate circulating tumor cells (CTCs). A panel of seven TNBC PDX tumors were grown orthotopically in Nod scid gamma mice and used in this study. Blood obtained via cardiac puncture from tumor bearing animals was processed on the Vortex microfluidic platform, for label-free, size-based enrichment of circulating tumor cells (CTGs). Enriched cell populations were stained for human-specific cytokeratin (CK) and Vimentin (Vim), mouse specific CD45, and DAPI; CTCs were identified as cells that were CD45 negative and positive for CK or Vim. Bulk tumor growing in the mammary fat pads was dissociated to single cells and characterized using Fluidigm’s® Polaris® plating platform for single cell biological experimentation and cDNA generation within an integrated fluidic circuit (IFC). From the cell suspension, Polaris identified single cells that were assessed for mRNA expression. The resulting cDNAs were then multiplexed using NextrX XT® (Illumina®) and sequenced on Illumina systems. Data generated from mRNA-seq was processed to correct for confounding factors such as cell size, cell cycle and read depth and then analyzed to screen for heterogeneity between different populations of cells. Tumors were analyzed by flow cytometry for both tumor and immune cells and additionally the single cell suspension was seeded into 3-D culture to generate organoids. Finally, organs from tumor bearing animals were analyzed for metastases. With the Vortex platform, we detected CTCs from a majority of our PDX tumor-bearing mice. The total number of CTCs varied over a wide range between different PDX tumors. There was a clear heterogeneity in CTCs in terms of CK and Vim expression. In CTCs from one of the PDX tumors, we detected a small population of CTCs that were either CK+ or Vim+ but the major fraction that was double positive (Vim+ CK+). Probing the bulk tumor from different PDX models revealed heterogeneity in the levels and number of cells positive for cell surface markers like EpCAM and a difference in the levels of infiltrating myloid cells (CD11b+). mRNA-seq analyses of individual tumor cells from the bulk tumor belonging to different PDX models will be described. Additionally, lung and brain metastases were identified. 3D organoids from our PDX models were successfully grown and their gene expression profiles will be analyzed. In summary, PDX models of TNBC will help advance our understanding of the molecular basis of this deadly cancer.

#1848  Autocrine IGF1 signaling mediates the survival of pancreatic cancer cells following the ablation of oncogenes.

Nirakar Rajbhandari. Univ. of Nebraska Medical Ctr., Omaha, NE

Pancreatic cancer is an extremely lethal disease, which is mostly associated with the gain-of-function mutation in KRAS gene. Due to a very high frequency of activating mutations within the KRAS gene, mutant KRAS is considered a rational therapeutic target in pancreatic cancer. In line with the existing idea that oncogenic KRAS is required for the maintenance of pancreatic cancer, we show a complete macroscopic regression of both primary and orthotopically transplanted tumors in our ligand-regulatable (Doxycycline) mouse model of KRASG12D-driven pancreatic cancer. This finding indicates that the expression, and provides a strong rationale for the development of KRAS targeted therapy for the treatment of pancreatic cancer. However, in our current study, despite the complete macroscopic regression of PDAcs upon downregulation of oncogenic KRAS, few cancer cells always survived and remained dormant for a protracted duration. These residual cancer cells were responsible for the rapid recurrence upon tumor resection. Using a genome-wide Seqi analysis of in vivo-derived bulk and residual cancer cells followed by biochemical analysis, we identified a significant increase in autocrine IGF-1/ AKT signaling in residual cancer cells. We also identified IGF1 signaling as a common survival mechanism of residual cancer cells in C-MYC-driven pancreatic tumor model. Pharmacological inhibition of IGF-1R signaling significantly delayed the tumor recurrence in both the tumor models, suggesting the crucial role of IGF-1R signaling in the survival of cancer cells in the absence of oncogenic drivers. Our findings from animal models were also validated in human pancreatic cancer cell lines harboring KRAS mutations, by demonstrating a compensatory increase in IGF1 signaling in response to a conditional knockdown of KRAS in vitro and in vivo. Collectively, all our findings from mouse model and human cancer cell studies strongly indicate that residual cancer cells can survive in the absence of tumor driving oncoproteins by up-regulation of autocrine IGF1 signaling loop. Thus, targeting oncogenic drivers along with IGF1-IR signaling might be an effective strategy for prevention of tumor recurrence in pancreatic cancer.

#1849  The role of leptin signaling in the promotion of obesity-associated tumorigenesis and cancer stem cell characteristics in a transgenic mouse model of basal-like breast cancer.

Subreen A. Khatib,1 Laura W. Bowers,1 Emily L. Rossi,1 Shannon B. McDonell,1 Claire G. Lineberger,1 David A. Cavazos,2 Linda A. de Graffenried,3 Stephen D. Hursting1. The University of North Carolina at Chapel Hill, Chapel Hill, NC; 3The University of Texas Health Science Center at San Antonio, San Antonio, TX; The University of Texas at Austin, Austin, TX

Background: Epidemiological studies have linked obesity to a greater risk of breast cancer-specific mortality. This association may be mediated in part by enhanced cancer stem cell (CSC) enrichment, as CSCs are thought to be the primary drivers of tumor initiation, growth, and metastasis. We and others have demonstrated that obesity promotes CSC enrichment in pre-clinical models of basal-like breast cancer, but only when leptin signaling is present. These findings, coupled with evidence that elevated serum leptin and breast tumor leptin receptor expression are linked to a worse breast cancer prognosis, suggest that leptin-induced CSC enrichment may be a key contributor to obesity-associated breast cancer progression.

Methods: MMTV-Wnt-1 transgenic mice, which develop spontaneous basal-like mammary tumors, were fed a control diet (10% kcal from fat) or a diet-induced obesity regimen (DIO, 60% kcal from fat). Mice were euthanized when tumors reached 1 cm in diameter. RNA sequencing was performed on 4 tumors/diet group. Serum hormones and cytokines were measured via luminex-based assay. ALDH activity, a putative CSC marker, was quantified by an ALDH Activity Assay Kit (abcam). Quantitative RT-PCR was used to determine expression of CSC-related genes, leptin, and the leptin receptor. Two mammary tumor cell lines isolated from the MMTV-Wnt-1 model (M-Wnt and E-Wnt cells) and human MDA-MB-231 were exposed in vitro to pooled serum from DIO or control mice (2% concentration), and cell viability, migration, invasion and expression of CSC related genes were measured. Results: Tumor incidence and growth rate were greater in DIO versus control mice. RNA sequencing revealed an upregulation in a CSC gene signature in tumors from DIO versus control mice. Significant upregulation in several of these genes, including aldha1a, oct4, twist1, twist2, and akt3, was confirmed by qRT-PCR (P < 0.05). ALDH activity in the DIO (relative to control) tumors was also significantly increased (P < 0.05). Serum levels and mammary tissue expression of leptin and tumor expression of the leptin receptor were significantly elevated in DIO versus control mice (P < 0.05). Exposure to serum from DIO mice significantly increased (relative to control) M-Wnt, E-Wnt, and MDA-MB-231 cell viability, migration, invasion, and expression of CSC-related genes in vitro (P < 0.05). The role of leptin signaling in these breast tumor models and in vitro measures of CSC enrichment will be explored through additional experiments. Conclusions: Obesity promotes MMTV-Wnt-1 mammary tumor incidence and growth rate, possibly via CSC enrichment. Preliminary findings suggest increased leptin signaling may underlie obesity-associated CSC enrichment and may contribute to the breast cancer burden in obese women.

#1850  Development of a NOTCH1 loss of function and PIK3CA mutant transgenic model of HNSCC.

Samanta N. Deavenport, Nicole L. Michmerhuizen, Elizabeth Leonard, Brittany Jewell, Jacob Swanson, Sunny Wong, Thomas E. Carey, J Chad Brenner. University of Michigan, Ann Arbor, MI

Head and neck squamous cell carcinoma (HNSCC) is a debilitating disease with a poor 5-year survival rate. The use of in vivo models to study tumorigenesis and to identify potential targeted therapies, especially those that work in combination with immune checkpoint inhibitors, is essential in improving overall patient care. However, the overall number of HNSCC transgenic models with recurrent genetic lesions identified by the HNSCC TCGA project has been limited. For example, TCGA data has shown both Notch1 loss of function mutations and PIK3CA activating mutations as some of the most common in HNSCC, but bi- genetic models of these lesions do not yet exist. Here, we have designed a model which utilizes K14-CreERT to drive a bi-genic model with Notch1lox and PIK3CAH1047R mutations in epithelial compartments. Characterization of this line both in the context of spontaneous and carcinogen induced tumor formation is a tool which can be utilized to better understand common mutations in HNSCC. Immunohistochemistry confirms the overexpression of PIK3CA in tamoxifen induced mice. Furthermore, early characterization of this model with chronic treatment of the smoking analogue 4-Nitroquinoline N-oxide (4NQO) in drinking water shows tumor formation on the tongue and surrounding head and neck regions in as little as 12-16 weeks. Hematoxylin and Eosin staining confirmed the squamous tumor formation, while Ki67 staining

Proceedings of the American Association for Cancer Research. Volume 58. April 2017

TUMOR BIOLOGY: Cell Culture and Animal Models of Cancer 2
showed enhanced proliferation of the transformed cells. In the future, this model can be used to study tumor formation over time and in response to targeted inhibitors and common therapies that are being advanced as companion diagnostic strategies for either NOTCH1 deficient or PIK3CA aberrant HNSCC tumors. Further detailed characterization of this model will allow for a deeper understanding of the mechanisms which drive HNSCC and will translate to improved patient care.

Purpose: von Hippel-Lindau disease (VHL) is an autosomal dominant condition that features a constellation of cysts or highly vascularized tumors due to loss of heterozygosity (LOH) of the VHL gene, resulting in deregulated hypoxia-induced factors (HIFs). Clinical manifestations of VHL include hemangioblastomas in the central nervous system and retina. To date, no VHL animal model has reproduced retinal capillary hemangioblastomas (RCH), the hallmark lesion of ocular VHL. The RCHs may arise from arrested hemangioblast progenitor cells, with VHL LOH in the tumor stroma. The stem cell leukemia (SCL) gene encodes a basic helix-loop-helix (bHLH) transcription factor, a critical regulator of hematopoiesis and vasculogenesis. We aim to generate a murine model of VHL-associated RCH by conditionally inactivating Vhl in a hemangioblast progenitor population with the angioblast-specific Cre line, (SCL-Cre-ER2). Methods: We established a genetic mouse model in which the inducible Vhl gene is specifically “knocked-out” in angioblast cells using the stem cell leukemia (SCL)-Cre-ER2 transgenic mice. Two-week-old SCL-CreER2;Vhl/F/F mice were administered tamoxifen (2mg/40g body weight) for 5 consecutive days to activate the Cre recombinase that induces Vhl deletion in angioblast-derived cells. Funduscopy was done monthly to detect retinal lesions. Fluorescein angiography (FA) was performed on affected mice. All retinas were analyzed by histology at 4 months of age. Genome typing of the Vhl conditional KO allele was conducted in retinal lesions using microdissection, nest-PCR and Sanger sequencing. Results: About 64% (18/28) of the transgenic mice exhibited various retinal vascular defects following induction. Affected mice demonstrated retinal vascular lesions that were variably associated with prominent vessels, anomalous capillary networks, hemorrhage, exudates, and localized fibrosis. FA revealed vascular leakage from the lesions. Histological analyses showed RCH-like lesions of the lesions that were variably associated with prominent vessels, anomalous capillary networks, hemorrhage, and localized fibrosis.

#1855 Inhibition of mTOR downregulates expression of DNA repair proteins and is highly efficient against BRCAl2-mutated breast cancer when combined to PARP inhibition.
