Purpose: DNA repair deficiencies and activation of P13K/akt/mTOR pathway are common events in breast cancer. Brca1/2 mutations have been associated with sensitivity to PARPi inhibitors (synthetic lethality), while alterations in component of the PI3K/AKT/mTOR pathway might confer sensitivity to PI3KCA and mTOR inhibitors. Here we explored the therapeutic benefit of combining a mTOR and a PARPi inhibitor in BRCA2-mutated patient-derived xenografts (PDX) with alterations in the PI3KAKT/mTOR pathway. Experimental design: the combination of the mTOR inhibitor everolimus and the PARPi inhibitor olaparib was tested in two BRCA2-mutated PDX established from a luminal B tamoxifen-resistant and a basal-like breast cancers. Both carried alterations in the PI3K/akt/mTOR pathway: PIK3R1 mutation and PTEN loss for the luminal B PDX and PTEN loss for the basal-like PDX. To identify putative crossstalk events between mTOR and DNA repair, a Reverse Phase Protein Array (RPRA) analysis of multiple signaling pathways and DNA repair processes was performed on untreated and treated xenografts. Gene and protein expression changes were confirmed by RT-PCR and Western Blot analyses. The capacity to repair DNA damage was measured by P-H2AX immunostaining. Results: in both PDX, everolimus and olaparib showed marked anti-tumor activity with a growth inhibition comprised between 78% and 86% in the monotherapy setting and 96% in the combination arm, where 100% of mice showed tumor regressions. In the luminal B tumor this combination was more efficient than the combination of everolimus and endocrine therapies (fulvestrant or tamoxifen). In both PDX, the fraction of P-H2AX (marker of unrepaired DNA double-strand breaks) positive cells was increased after everolimus treatment, suggesting a link between mTOR and DNA damage, and strongly increased in the combination setting. RPRA analysis of tumors PhenoProbes alone revealed a marked downregulation of different proteins involved in DNA repair, including FANCID2, RAD50 and SUV39H1, a chromatin compactor factor essential in homologous recombination. In the combination setting, expression of these proteins was almost completely abolished, suggesting convergence of PARP and mTOR in downregulation of DNA repair components. Conclusions: our results support that combining mTOR and DNA repair inhibitors could be a successful strategy to treat a subset of breast cancer with BRCA2 mutation and alterations in the PI3K/akt/mTOR pathway. Further experiments with mTOR and PARPi inhibitors combinations are ongoing in sporadic breast cancer PDX showing a BRCA1-necessity phenotype.

#1854 Generation and characterization of mouse model of Pmepa1 conditional knockout in prostate epithelia. Hua Li, Shashwat Sharad, Talai Bariev, Yingjie Song, Denise Young, Taduru Sreenath, Albert Dobi, Shiv Srivastava. USU/Center for Prostate Disease Research (CPDR), Rockville, MD.

Introduction and Objectives: Prostate cancer (CaP) is the most common non-skin malignancy diagnosed in American men and defunctions of androgen receptor (AR) plays an essential role in prostate tumorigenesis. PMEPA1 is an androgen and TGF-β-induced gene abundant in prostate, which was identified to be associated with prostate tumors via gene expression in prostate cancer cell lines and reduced or loss of expression of prostate cancer. We generated Pmepa1 expression, commonly detected in prostate tumors, led to increased AR protein and activated AR signaling. Pmepa1 inhibited TGF-β receptor 1 mediated signaling by a negative feedback loop. It was reported that loss of Pmepa1 facilitates bone metastasis of CaP through blocking TGF-β signaling. To further investigating the biological function of PMEPA1 gene in CaP tumorigenesis, particularly via AR and TGF-β, we generated Pmepa1 prostate conditional knockout mouse model. Methods: C57BL/6 mice were utilized for generation of Pmepa1 conditional knockout model. Pmepa1 gene was conditionally deleted in mouse prostate epithelium by AAR2PB-Cre-Lox system. Male mice of genotypes of wild-type, Pmepa1 flox/flox and flox/wild-type AAR2PB-Cre, Pmepa1 flox/flox or flox/ARR2PB-Cre were euthanized at the age of 3 months for analysis. The prostate tissue was collected for frozen and formalin fixation for histology analysis, and other major organs including heart, lung, liver, spleen, bladder and testis were also collected for control. The tissue were sectioned and stained with Hematoxylin & Eosin (H&E). Total RNA and protein were harvested by homogenizing tissue. The protein levels of Pmepa1, AR and Nkx3.1 were analyzed by immunohistochemistry (IHC) and immunoblotting, and the transcript levels of these genes were evaluated by in situ hybridization (ISH) and quantitative PCR (Q-PCR). Results: The expression of Pmepa1 protein was found to focus on lateral lobe, consistent with AR protein expression pattern. The data of Q-PCR and ISH showed that transcript level of Pmepa1 was dramatically suppressed in Pmepa1 flox/flox and flox/wild-type AAR2PB-Cre mice. Compared to wild-type ones, Pmepa1 protein was shown significantly decreased in heterogeneous and homogenous knockout mice via immunoblotting and IHC staining. And the protein level of AR was stronger in Pmepa1 conditional deleted mouse. There was no dramatic morphology change in mouse prostate gland by H&E staining. Conclusions: Conditional deletion of Pmepa1 gene in mouse prostate epithelium led to enhanced AR protein and activating AR signaling. The effects of Pmepa1 gene loss in mouse prostate gland on other signaling such as TGF-β and prostate tumorigenesis are needed to be further evaluated. Funding: This study was supported by CPDR, SUHS, HU0001-10-2-0002 to DGM.

Purpose: In order to develop a patient DRation method for hepatocellular carcinoma (HCC), we develop the new protocol using direct injection technique. From January 2015 to June 2016, consent about getting tumor pieces to the patient of hepatocellular carcinoma. The specimens is stored in RPMI1640 and moved from opera-
tion room to research room immediately. For PDOX and PDX to subcutaneous model, 8–10 weeks old NOD SCID and NSG male mouse is used. The tumor pieces cut to the cube size 1mm. For stop the bleeding, inferior vena cava is blocked using Bulldog clamp and the cube is directly injected median lobe to 3 places randomly. After clear the Bulldog clamp, a left lobe is removed using tie and weight. After 3 months, the PDOX mouse is changed for cancer growth using MRI or PET-CT. Successful PDOX or PDX to subcutaneous model is sacrificed and proceeded a generation to another Balb/C-nude male mouse 8–10 weeks old. The rate of success of PDOX model and PDX to subcutaneous model is about 10% respectively. Formed tumor is verified by H&E staining. Based on protocol established, further study plan is required for improving on the rate of success to establish PDOX model and clinical application.

TUMOR BIOLOGY: Imaging for Cancer Diagnosis and Image-Guided Therapy

#1856 Dual-modality immunoPET/fluorescence imaging of prostate cancer utilizing 89Zr- or 124I-Cy5.5-anti-PSCA cys-minibody

Wen-Ting K. Tsai, Anna M. Bhattacharya, UT MD Anderson Cancer Ctr., Houston, TX

Prostate cancer patients can benefit from non-invasive and more accurate diagnosis, as well as improved visualization during surgery. ImmunoPET can provide information on location and extent of the disease, while fluorescent image-guided surgery can distinguish cancerous tissue during resection. Prostate Stem Cell Antigen (PSCA) is upregulated in the majority of prostate cancers and metastases and is therefore a promising target for imaging. Engineered antibody fragments, such as the minibody, exhibit ideal imaging characteristics due to fast blood clearance for high target-to-background images at short imaging times post-injection. A dual-labeled minibody can reveal the whole-body PSCA-expressing tumor burden by PET, followed by intraoperative visualization of margins by fluorescence. The fully humanized anti-PSCA A11 minibody was engineered with a C-terminal cys-tag (A11cMb) for site-specific labeling by thiol-directed chemistry. In order to radiolabel with 89Zr, a metal chelator deferoxamine (DFO) was site-specifically conjugated to A11cMb by maleimide chemistry, while direct iodination was used to label with 124I. Simply labeled 89Zr- and 124I-A11cMb successfully imaged subcutaneous PSCA (+) and (−) 22Rv1 human prostate adenocarcinoma tumors in nude mice, resulting in positive-to-negative tumor ratios of 2.5:1 and 8:1, respectively. Both 89Zr-A11cMb and 124I-A11cMb cleared from blood by 22 hours. As expected for the residualizing radiometal, 89Zr-A11cMb resulted in retention in the organs of clearance (liver and kidneys). For dual-modality imaging, A11cMb was site-specifically conjugated with Cy5.5-maleimide and radiolabeled with 124I PET imaging with 124I-Cy5.5-A11cMb in the subcutaneous 22Rv1 tumor model resulted in a positive-to-negative tumor ratio of 13:1. The PSCA (+) tumors were subsequently visualized by fluorescence in situ and ex vivo with high contrast in comparison to PSCA (−) tumors and tissues. In an orthotopic model, PSCA (+) 22Rv1 cells were implanted in the prostate, and therefore 89Zr was used in order reduce interfering signal from clearance to the bladder. A11cMb was site-specifically conjugated with Cy5.5 and randomly labeled with SCN-DFO, then radiolabeled with 89Zr. 89Zr-Cy5.5-A11cMb successfully imaged the prostate tumor, resulting in a 3:1 tumor-to-blood ratio. Fluorescence imaging clearly distinguished prostate tumor from adjacent tissues including seminal vesicles. In conclusion, a single injection of the dual-labeled A11cMb can visualize tumor burden by immunoPET and fluorescence imaging. This humanized probe has the potential for clinical translation for primary and metastatic prostate cancer detection and surgical guidance that can ultimately enhance treatment success.

#1857 Early detection of pancreatic intraepithelial neoplasms (PanINs) in transgenic mouse model by hyperpolarized 13C metabolic resonance imaging

Phillip Chuong, Yu Zhang, Michelle Zoltan, Marliana Mascaro, Erick Riquelme, Jaelhyuk Lee, Anirban Maitra, Florencia McAllister, Pratip Bhattacharya, UT MD Anderson Cancer Ctr., Houston, TX

Pancreatic cancer, one of the most lethal solid tumors, is an aggressive disease that develops relatively symptom-free. Pre-invasive pancreatic intraepithelial neoplasias (PanINs) have been identified as precursor lesions to pancreatic cancer. While there is growing evidence supporting PI specificity of V7-CMS, Panc1 and S2VP10 cell lines were incubated in cell culture medium at either pH 7.4 or 6.6 followed by treatment with V7-CMS. Particle uptake was determined using near infrared (NIR) fluorescence and tissue phantoms. Finally, for in vivo testing, the same CSMs were injected into mice bearing S2VP10 pancreatic tumors. MSOT imaging was performed 8 hours after CMS injection. Results: TEM images demonstrated successful synthesis of approximately 40 nm V7-CSMs with vermillion pores. On NIR imaging, V7-CSMs demonstrated acidic pH specificity in both S2VP10 and Panc 1 cells at pH 6.6, with particle localization and signal intensity 8-fold and 5-fold higher, respectively, than that observed at pH 7.4. In tissue phantoms, increased pH specificity was also observed in both S2VP10 and Panc 1 cells at pH 6.6. Particle location and signal intensity on MSOT was demonstrated successful synthesis of approximately 40 nm V7-CSMs with vermillform pores. On NIR imaging, V7-CSMs demonstrated acidic pH specificity in both S2VP10 and Panc 1 cells at pH 6.6, with particle localization and signal intensity 8-fold and 5-fold higher, respectively, than that observed at pH 7.4. In tissue phantoms, increased pH specificity was also observed in both S2VP10 and Panc 1 cells at pH 6.6. Particle location and signal intensity on MSOT was demonstrated successful synthesis of approximately 40 nm V7-CSMs with vermillform pores. On NIR imaging, V7-CSMs demonstrated acidic pH specificity in both S2VP10 and Panc 1 cells at pH 6.6, with particle localization and signal intensity 8-fold and 5-fold higher, respectively, than that observed at pH 7.4. Background: Early diagnosis of Invasive lobular carcinomas (ILCs) is clinically challenging due to its histopathologic features making it difficult to detect using mammography. Because of the diffuse infiltration of ILC cells into the surrounding stroma, ILC is also associated with a higher incidence of positive resection margins after breast-conserving surgery. Therefore, there is a significant unmet clinical imaging need to present in early detection, clinical staging and possibly intraoperative imaging to assess surgical margins. We propose to detect mammographically occult ILC by the in vivo detecting of malignant signaling pathways activated in ILC. Heat shock protein 90 (Hsp90) protein is 1-3% of the total cellular protein in most cells and acts as a molecular chaperone for more than 200 reported client proteins. Recently, we developed a series of tethered Hsp90 inhibitors that specifically target a tumor-specific form of Hsp90 associated with poor outcomes. Using near infrared (nIR) probe-tethered Hsp90 inhibitors, we demonstrated that Hsp90 is actively re-internalized and can be used to image murine and human breast cancer in vitro and in vivo. Methods and Results: We tested the imaging efficacy of the nIR-tethered Hsp90 inhibitor, HS196, in ILC models in vitro and in vivo. An inactive structural analog HS199 was used as a control to monitor for non-specific (non-Hsp90 dependent) uptake. Two ILC cell lines, MDA-MB-134 VI and SUM44-PE, and one patient-derived ILC xenograft, HCl-013 EI, were tested. nIR signals of HS196 in vitro and in vivo were detected by Odyssey (LI-COR) and Pearl Trilogy (LI-COR). nIR imaging in vivo imaging was performed on two mice with HCl-013 EI xenograft in SCID-beige mice. After injection of 10 nmol compounds via tail vein, quick and stronger accumulation and longer retention of the HS196 in the ILC xenograft was observed, while HS199 showed significantly weaker accumulation and faster clearance (by 24 h after injection). Significant uptake of HS196 by HCl-013 EI tumors was confirmed by ex vivo imaging of tumors 24 h after compound injection. Histological and flow cytometry analysis of HCl-013 EI tumors showed strong nIR signals in tumor cells. Conclusions: The non-radioactive, nIR imaging strategy, using a novel nIR-Hsp90 inhibitor compound, HS196, was effective in the non-invasive imaging of ILC tumors. This finding suggests that new molecular imaging techniques, not dependent on micro calcifications or architectural distortion, may be a novel strategy to meet the needs of ILC patients to detect, clinically stage and assess margins during surgical resection. Ongoing pre-clinical models will be employed and first in human testing of this approach in planned.

#1860 Direct observation of colorectal cancers using field-emission scanning electron microscopy with a thin polymer membrane, the NanoSuit. Hisakazu Miura, Katsuhiko Sumita, Kinji Kamiya, Takanori Sakaguchi, Yasuharu Takaku, Issa Ohta, Takahiro Hariyama, Hiroyuki Konno. Hamamatsu Univ. School of Medicine, Hamamatsu, Japan.

Background: Field-emission scanning electron microscopy (FE-SEM) enables us to observe nano-sized objects with great depth of focus and high resolution. However, the observation of biological samples including colorectal tissues using an FE-SEM has been difficult because it requires to evacuate its inside to prevent electron scattering, therefore all organisms containing ca. 70% water are rapidly evaporated and consequently caused structural disruption and collapse. To overcome the limitations of the conventional SEM, equipment such as low-vacuum scanning electron microscopy and environmental scanning electron microscope were developed. However, they are not reliable enough to investigate living organisms or wet tissues with high resolution level. We have recently reported that a simple surface modification of a thin extra layer, coined the term ‘NanoSuit®’, can keep organisms alive in the high vacuum (10^-9 to 10^-7 Pa) of the SEM. We now modified the technique and developed a new solution, which enables FE-SEM observations of wet tissues. In this study, we utilized this technique to observe real images of colorectal cancers and their adjacent normal mucosa at high resolution. Materials and methods: Colorectal tissue samples and their adjacent normal mucosa were cut with a scalpel from specimens surgically resected. All patients enrolled in this study provided written informed consent. Observations were carried out with an FE-SEM (S-4800, Hitachi or JEM-7100F, JEOL, Japan) at acceleration voltage of 1.0 kV. The vacuum level of the observation chamber was 10^-3 Pa. The newly developed surface shield enhancer (SSE) solution was used to make NanoSuit® for wet tissue observation. To form the NanoSuit®, the specimens were dipped for 1 min into the SSE solution and blotted briefly thereafter put on dry filter paper to remove excess solution. Specimens were then introduced directly into an FE-SEM to form a NanoSuit® following irradiation of the electron beam. Results: Fine structures of intestinal crypt and villi were successfully observed the real mucosal surfaces and cancer lesions of colorectum, suggesting an invasive front of colorectal cancer. Conclusions: We successfully observed the real mucosal surfaces and cancer lesions of colorectum with high resolution by an FE-SEM using a newly developed vacuum-proof suit, the "NanoSuit®": this novel technique will enable us to investigate further physiopathology of GI tract including cancers.

#1861 LRHH-conjugated magnetite nanoparticles for breast cancer detection and contrast enhancement in MRI. Jingjie Hu1, John Obayemi2, Karen Malatesta3, Derek Adler2, Sean Wang2, Edward Yurkow2, Winston Soboyejo3.

1 Princeton University, Princeton, NJ; 2 Rutgers University, Piscataway, NJ; 3 Worcester Polytechnic Institute, Worcester, MA.

Breast cancer is one of the most frequently occurring types of cancer in women. Furthermore, at the time of initial diagnosis, some tumors may have metastasized. There is, therefore, a critical need for novel procedures for the early detection of breast tumors and their metastases. One of the specific targeting receptors for human breast cancer cells is Luteinizing Hormone Releasing Hormone (LHRH). Approximately 52% of human breast cancers express binding sites for LHRH. Within this context, LHRH-functionalized nanoparticles have been considered for potential applications in cancer detection and treatment. In theoretical studies of the entry of Luteinizing Hormone Releasing Hormone (LHRH)-conjugated Magnetite Nanoparticles (MNPs) into MDA-MB-231 breast cancer cells. The internalization of LHRH-conjugated MNPs into breast cells is studied using confocal fluorescence microscopy. The receptor-mediated entry of nanoparticles into breast cancer cells is also elucidated using the ligand's fluorescence and kinetic models. The trends in predicted nanoparticle entry times and the size range of the engulped nanoparticles are shown to be consistent with the experimental observations. The specific interaction between LHRH receptors and LHRH can be used to enhance the specific targeting of breast cancer cells. Furthermore, LHRH-MNPs demonstrated specific enhancement for in-vivo signal in magnetic resonance imaging (MRI) for breast tumors and their metastases in the body. Lastly, nanoparticle concentration in different organs is presented to show that the conjugated MNPs are accumulated mainly into the tumor sites and their metastasis. While unconjugated MNPs are shown to accumulate in the liver, kidney, spleen and heart. The current results show that LHRH-conjugated magnetite nanoparticles have the potential for the specific targeting and detection/treatment of breast cancer.

TUMOR BIOLOGY: Imaging for Cancer Diagnosis and Image-Guided Therapy

Proceedings of the American Association for Cancer Research • Volume 58 • April 2017

Otali, Gerald Dryden, Nejat Egilmez, Lacey R. McNally. Tomography. Observed when SKOV3 cells were incubated with anti-HER2 NPs, which was unconjugated, PEG NPs regardless of cell number. The highest MRX signal was more, there was little to no MRX signal for all cell samples incubated with controls; p = 0.0004 by MSOT two days after inoculation. These findings were also associated with inflammatory changes observed on histologic analysis. Conclusions: MSOT represents a non-invasive diagnostic modality that effectively identifies colitis in a murine model. With improvements in depth of tissue penetration, MSOT may hold potential as a sensitive, accurate, non-invasive imaging tool in evaluation of both disease status and early detection of malignancy in patients with IBD.

Feasibility of magnetic relaxometry for early ovarian cancer detection: preliminary evaluation of sensitivity and specificity in cell culture and in mice. Kelsey Mathieu, Zhong La, Hailing Wang, Adam Kulp, John Hazle, Robert C. Bust. The University of Texas MD Anderson Cancer Center, Houston, TX; 2UAB, Birmingham, AL.

Introduction: Most ovarian cancers are diagnosed in a late, incurable stage, which has prompted efforts towards earlier detection and more effective screening strategies. To be considered effective, screening must provide sufficient sensitivity and specificity to impact patient mortality while minimizing false positives. Magnetic relaxometry (MRX), which detects binding of targeted iron oxide nanoparticles (NPs) to cancer cells, offers the promise of improved sensitivity and specificity over conventional early detection modalities. Methods: We investigated the sensitivity and specificity of MRX by scanning ovarian cancer cell samples containing 10^5, 10^6, and 10^7 cells incubated with a fixed amount (57 μg Fe₂O₃) of anti-HER2 antibody-conjugated, PEG-coated NPs or unconjugated, PEG-coated NPs (Senior Scientific LLC). To further evaluate specificity, we used cell lines with both high and low expression of HER2 (SKOV3 and HEY, respectively). To assess MRX under in vivo conditions, we subcutaneously injected 10^5, 10^6, and 10^7 anti-HER2 NP labeled SKOV3 cells into nude mice (n = 9) and immediately performed MRX scanning. Prior to performing this study, we verified successful antibody-NP conjugation through an ELISA assay, which confirmed the presence of anti-HER2 antibody in NP pellets. Additionally, we performed flow cytometry to confirm a high level of specific binding between SKOV3 cells and anti-HER2-conjugated NPs. Results: Our in vitro data revealed strong linearity between cell number and MRX signal for both SKOV3 and HEY cells incubated with anti-HER2 NPs (R² = 0.99 and 1, respectively). Furthermore, there was little to no MRX signal for all cell samples incubated with unconjugated, PEG NPs regardless of cell number. The highest MRX signal was observed when 10^7 SKOV3 cells were incubated with anti-HER2 NPs, which was 2.1 ± 0.3 and 15.7 ± 1.4 times higher than when 10^7 HEY cells were incubated with anti-HER2 NPs or when 10^6 SKOV3 cells were incubated with unconjugated PEG NPs, respectively; significantly higher MRX signals (relative to the controls; p < 0.01) were also noted for samples containing 10^5 SKOV3 cells incubated with anti-HER2 NPs. When scanning live mice injected with 10^7 anti-HER2 NP labeled SKOV3 cells, the MRX signal was significantly higher than the signal from the mice prior to the injection (p < 0.001). Additionally, MRX signal versus cell number in the injected mice was highly correlated (r = 0.99) with the MRX data from the corresponding cell sample scans. Conclusion: MRX is sufficiently sensitive to detect 1 million cells in culture or 10 million cells in mice with a high level of specificity. Sensitivity may be improved by using nanoparticles coated with antibodies against antigens that are overexpressed by a larger fraction of ovarian cancers and will be the focus of future work.

Superparamagnetic Relaxometry (SPMR) is combination technology for the early detection of cancer. Conceptually, PEGylated superparamagnetic iron oxide (Fe₂O₃) nanoparticles (NPs) coupled with a targeting monoclonal antibody are systemically administered and target solid tumors by both passive (EPR) and active (receptor targeting) mechanisms. Once bound to the target cells, the NPs are magnetized by a brief, low field magnetic pulse to create magnetic field patterns that are detectable by superconducting quantum interference device (SQUID) detectors. The pattern of decay, known as Néel relaxation, exhibits a difference in latency specific to bound nanoparticles and differs from the Brownian decay exhibited by free/unbound particles. As a proof of concept, we developed PEGylated NPs that are covalently bound to an anti-Her-2 monoclonal antibody. In vitro, the nanoparticles exhibit specific binding to the Her-2 negative BT-474 breast cancer cells, with little to no binding to Her-2 positive MCF-7 cells. Similar patterns of selective targeting were observed in vivo. To improve the specificity of SPMR signals in tumors we developed a novel system that selectively enhances the magnetic signal at tumor sites and reduces the contribution of similar signals at off target sites such as the liver and spleen. For this study, we created phantoms of varying strength to mimic tumor and non-specific signals. We observed that by creating non-homogenous excitation magnetic field patterns, we reduced the contribution of the non-specific signals by an order of magnitude, effectively increasing the signal to noise ratio of the tumor signal. These results are clinically relevant and support the use of SPMR in the detection of small tumors in cancer patients.
TUMOR BIOLOGY: Imaging for Cancer Diagnosis and Image-Guided Therapy

#1867 Near infrared fluorescent imaging of brain tumor with IR780 dye incorporated phospholipid nanoparticles. Shiuling Li,1 Jennifer Johnson,1 Anderson Peck,2 Qian Xie2. 1Van Andel Research Institute, Grand Rapids, MI; 2East Tennessee State University, Johnson City, TN.

Background: Near-IR fluorescence (NIRF) imaging is becoming a promising approach for tumor detection and diagnosis. The intracranial clinic-guided oncological surgery. While heptamethine cyanine dye IR780 has excellent tumor targeting and imaging potential, its hydrophobic properties limit its clinical use. In this study, we developed nanoparticle formulations to facilitate the use of IR780 for the fluorescent imaging of malignant brain tumor. Methods: Self-assembled IR780-liposomes and IR780-phospholipid micelles were prepared. The intracellular accumulation of IR780-nanoparticles in glioma cells were determined using confocal microscopy. The in vivo brain tumor targeting and NIRF imaging capacity of IR780-nanoparticles were evaluated using U87MG glioma ectopic and orthotopic xenograft models and a spontaneous glioma mouse model driven by RAS/RTK activation. Results: The loading of IR780 into liposomes or phospholipid micelles was more stable. In tissue culture cells, IR780-nanoparticles prepared by either method accumulated in mitochondria, however, in animals the IR780-phospholipid micelles showed enhanced intra-tumoral accumulation in U87MG ectopic tumors. Moreover, IR780-phospholipid brain also showed phospholipid intra-cranial tumor accumulation and potent NIRF signal intensity in glioma orthotopic models at a real-time, non-invasive manner. Conclusion: The IR780-phospholipid micelles demonstrated tumor-specific NIRF imaging capacity in glioma preclinical mouse models, providing great potential for clinical imaging and image-guided surgery of brain tumors.

#1868 Molecular imaging of human esophageal cancer for early detection. Xibo Ma, Hui Meng, Jie Tian. Institute of Automation, Chinese Academy of Sciences, Beijing, China.

Esophageal cancer was the sixth common cancer for incidence and ranks fourth for death rate in China, and squamous cell carcinoma is the main histological type. It is usually in an advanced stage at the time of diagnosis, resulting in an overall 5-year survival rate of <15%. Early detection can lead to an improvement in patient outcomes but is limited by non-specific contrast mechanisms. As all we know, antibody and peptides establish a biological basis for image contrast, which could achieve sufficient target-to-background ratio for in vivo detection. In this paper, an EGF antibody (Cetuximab) conjugated with a NIR dye (NIRDye800) was used for early detection of esophageal cancer. We demonstrated our technology could identify esophageal cancer in small size (<1 mm) and high-grade dysplasia from low-grade dysplasia. And 4.2-fold greater fluorescence intensity for esophageal cancer compared with surrounding normal esophageal tissues. No toxicity was observed in our experiments. The results indicated that this targeted, antibody-based imaging agents have great potential in early detection of esophageal cancer and other epidermal cancer.

#1869 Improved image-guided surgical resection of glioblastoma with [18F]fluoroethyltyrosine Cerenkov luminescence imaging. David Y. Lewis,1 Richard Mair,1 Alan J. Wright,2 Kieren Allinson,2 Scott K. Lyons,2 Tom Booth,2 Robert Bielik,1 Dmitry Soloviev,1 Kevin M. Brindle 1, 1University of Cambridge, Cambridge, United Kingdom; 2Addenbrooke's Hospital, Cambridge, United Kingdom.

The ability of a surgeon to completely resect a tumor is directly related to outcome in high- and low-grade gliomas. However current intraoperative navigational tools are useful only in a subset of glioma patients and do not detect the full extent of disease. We modelled orthotopic brain tumors by stereotactically implanting human U87, rat F98 and C6 glioblastoma cells into the forebrains of rats. We show here that a new hybrid PET-Cerenkov luminescence imaging approach using O2- [18F]fluoroethyl-L-tyrosine (FET) can accurately delineate tumor margins pre- and intraoperatively. We demonstrate consistency in the successful localisation and quantification of tumor burden using PET and Cerenkov luminescence imaging. The Cerenkov signal in individual tumors was directly proportional to the signal detected in corresponding FET PET scans (ρ = 1.06 ± 0.01; R2 = 0.98; p < 0.0001 and subsequent autoradiography indicated equivalence between modalities. Cerenkov luminescence was better able to discriminate tumor from healthy brain tissue than the current ‘gold standard’ for intraoperative mapping. 5-ALA (5aminolevulinic acid), indicated by a greater area under the ROC curve in human xenograft (0.968 ± 0.003 vs. 0.893 ± 0.019; p = 0.003) and syngeneic rat glioma models (0.970 ± 0.010 vs. 0.774 ± 0.046; p = 0.006). The quantitative accuracy of Cerenkov luminescence enabled us to determine a threshold of 2.1 x 10^6 p1 sec-1 cm-2 sr-1 MBq-1 that separated U87 human glioblastoma and normal brain tissue, more precisely guiding tumor excision than 5-ALA. At the optimal threshold the specificity for detecting syngeneic rat and human xenograft gliomas was better with FET Cerenkov than 5ALA (91.1 ± 2.7 % vs. 67.2 ± 5.2 %, p = 0.007 and 91.2 ± 1.0 % vs. 67.2 ± 5.2 %, p = 0.0008, respectively). We confirmed these findings at higher spatial resolution on cryosections using FET autoradiography and 5ALA confocal microscopy, with FET demonstrating higher specificity and sensitivity for tumor detection than 5-ALA. FET PET-Cerenkov luminescence imaging has the potential for guiding resections in a much broader range of glioma patients than current approaches. Previous clinical experience with FET offers a facile route for clinical translation of this technology.

#1870 Fluorescence-guided soft tissue sarcoma surgery using a cetuximab-imaging probe conjugate. Nicole K. Behnke, Jason M. Warram, Andrew C. Prince. The University of Alabama at Birmingham, Birmingham, AL.

BACKGROUND: Soft tissue sarcomas (STS) are a heterogeneous group of solid malignancies whose treatment includes margin-negative resection. Large tumor size and anatomic constraints make margin assessment challenging. Fluorescence-guided surgical resection can help delineate intraoperative margins; preclinical studies demonstrate improved oncologic outcomes in other malignancies using cancer-specific imaging probes. Recent literature describes catespin activated probes selective for STS, but no studies using disease-specific chemotherapeutic agents conjugated to imaging probes. This novel strategy has potential to replace unnecessary healthy tissue resection and improve oncologic outcomes by reducing margin-positive resections. Epidermal growth factor receptor (EGFR) is overexpressed in multiple subtypes of STS and is a potential target for fluorescence-guided surgery. Recent studies show fluorescently labeled cetuximab, an FDA- approved, anti-EGFR antibody, to be safe and useful for margin assessment in other malignancies. Our aim was to evaluate its potential for STS, examining tumor-targeting specificity of two drug-probe conjugates, and comparing them to the described catespin-activated probes. We hypothesize the drug-probe conjugates would successfully target STS, with superior tumor specificity. We also aimed to determine the smallest tumor detectable by our conjugate. METHODS: Athymic nude mice with subcutaneous HT1080 fibrosarcoma tumors were injected with one of five probes: IRDye800CW fluorescent probe conjugated to either cetuximab (anti-EGFR) or DC101 (anti-VEGFR2), IRDye800CW conjugated to an isotype control (IGc), or a catespin-activated probe (Integrisense 750 and Prosense 750). Fluorescence imaging was performed daily with open- and closed-field systems. Tumor-to-background ratios (TBR), signal washout times and normalized signal averages were evaluated. On day 9, smallest resectable game evaluation was performed to assess sensitivity for detecting residual post-resection tumor.

RESULTS: At day 9 post-injection, the TBR of the cetuximab-IRDye800CW group (11.1) was significantly greater than Integrisense750 (6.88, p = 0.005), the IgG-IRDye800CW control (4.44, p = 0.0005), Prosense750 (2.35, p = 0.00009), and DC101-IRDye800CW (1.87, p = 0.0003). During in vivo imaging, cetuximab-IRDye800CW outperformed all other agents by several folds of contrast enhancement. The smallest resectable game evaluation demonstrated 1mm3 fragment detection using the cetuximab-IRDye800CW probe. CONCLUSIONS: This study demonstrates superiority of cetuximab-IRDye800CW for disease-specific imaging in a subcutaneous animal model of STS. The novel strategy of coupling improved margin-negative surgical resection with established chemotherapy has considerable translational significance and is an avenue for exploration with other drugs used to treat STS.

#1872 Fluorescence-guided surgery in the tumor microenvironment in a syngeneic mouse model of EL-4 lymphoma. Kosuke Hasegawa,1 Atsushi Suetugu,1 Miki Nakamura,2 Takuro Matsumoto,1 Takahiro Kunisada,1 Masahito Shinizu,1 Shigetoyo Saiji,1 Hisataka Moriwa,1 Michael Bouvet,2 Robert M. Hoffman2. 1Gifu Univ. Graduate School of Medicine, Gifu, Japan; 2University of California, San Diego, CA.

We report fluorescence-guided surgery (FGS) of the tumor microenvironment of the EL-4 RFP lymphoma cells growing subcutaneously in C57BL/6 GFP transgenic mice. Using a portable hand-held Dino-Lite digital imaging system, subcutaneous tumors were resected by FGS. The tumor surface contained both RFP cancer cells and GFP stromal cells. The tumor microenvironment was clearly visualized and resected with the Dino-Lite. Host stromal cells, including adipocyte-like cells and blood vessels with lymphocytes, were observed along the tumor by confocal microscopy in addition to cancer cells by color-coded confocal imaging. Stromal cells were within the tumor and that cancer cells also in-
vaded the TME. Color-coded FGS, which distinguished cancer and stroma, significantly prevented local recurrence, which bright-light surgery or single-color FGS could not.

#1873 Intraoperative assessment of breast tumor margins using multimodal photoacoustic tomography (MarginPAT). Kyle McElyea,1 George Sankey,2 Rui Li,3 Lu Lan,4 Ji-Xin Cheng,5 Linda K. Han,4 Pu Wang,1 Indiana University School of Medicine, Indianapolis, IN;2 Purdue University, West Lafayette, IN;3 Indiana University Health Simon Cancer Center, Indianapolis, IN;4 Virginia Tech, West Lafayette, IN.

Radical mastectomies are progressively becoming a surgery of the past. Women today are increasingly opting for lumpectomies, a less invasive treatment option. Clinical data has shown no difference in survival or clinical outcomes between the two surgical groups in early stages of breast cancer. There is, however, an undesired outcome yet to be adequately addressed. Lumpectomies have, in some cases, failed to remove marginal malignant tumor cells left as a product from surgery. Following surgery, tumor biopsies are analyzed for marginal tumor cells. Biopsies are cut in, fixed, processed in a tissue processor, embedded into a paraffin block, and stained with H&E. After processing, presence of marginal cancerous tissue is determined by a pathologist. This process takes 3-5 days, ultimately requiring the patient to undergo reoperation if a positive margin is discovered. Presently, the reoperation rate is 20-30%. A device capable of imaging removed tissue to determine remaining marginal tumor during surgery would greatly reduce the reoperation rate. Multiple intraoperative imaging tools existing or are emerging for breast tumor margin assessment. 0.7mm spatial resolution in FGS can be achieved in tumor vasculature at an additional curative dose compared with treatment with shells of radiation avoiding hypoxia (anti-boosts) proved tenets of radiation biology: a few surviving hypoxic clonogens cause radiation treatment failure. In response, we implemented rapid 3D printing Tungsten loaded, highly conformal plastic blocks to compare treating ~100% of hypoxic tumor voxels with hypoxia avoidance, treating similar volumes of well oxygenated tumor. Only then did we observe significant (p<0.01) tumor cure differences between hypoxic boost and anti-boosts. This is the first validation of the curative effectiveness of avoiding hypoxia based dose painting in mammalian tumors.

#1875 [18F]HX4 shows potential as a predictive biomarker for the radiosensitizing capacities of metformin in a NSCLC xenograft model. Sven De Bruycker,1 Christel Vangestel,1 Tim Van den Wyngaert,2 Steven Deleye,3 Dominique Vanderghinste,1 Steven Staels,1 Sigrid Stroobants1.2 University of Antwerp, Wilrijk, Belgium;3 Antwerp University Hospital, Edegem, Belgium.

Introduction Metformin (MET) may improve tumor oxygenation and thus radiotherapy (RT) response. However, appropriate imaging biomarkers for patient stratification, critically needed to be able to advance to clinical trials with MET as a radiosensitizer, are still lacking. In this proof-of-concept (POC) study, we first assessed the effect of acute MET administration on NSCLC xenograft tumor hypoxia with PET using the novel hypoxia PET tracer [18F]HX4. Second, we verified the influence of a single dose of MET prior to RT on tumor treatment outcome. Experimental procedures A549 tumor-bearing mice (n=9; animals were inoculated in both hind legs) underwent a [18F]HX4 PET/CT scan to determine baseline tumor hypoxia. The next day, mice were administered 100 mg/kg MET IV. [18F]HX4 was administered IV 30 min later, whereupon a second [18F]HX4 PET/CT scan was performed two days after this second scan, mice were randomized into three groups (n=3/group): a control group (1), a RT group (2), and a MET+RT group (3) with comparable tumor volumes (259±103; 218±81 and 247±121 mm3, resp.). Animals were administered 0.9% saline (groups 1-2) or 100 mg/kg MET (group 3) IV, followed by a single dose of 10 Gy 30 min after administration (groups 2-3). Control animals of group 1 underwent sham RT. During the entire study, tumor growth was monitored triweekly by caliper measurements. Calculation of the relative tumor volumes (RTV) was initiated when tumors reached a mean baseline volume of 100 mm3 with the formula RTV = Vtumor/Vbaseline. Tumor growth inhibition (TGI) was calculated for each tumor in both treatment groups with the formula TGI = 1-(RTVtreated/RTVcontrol). Results MET significantly altered tumor hypoxia, as the mean [18F]HX4 tumor-to-blood ratio (TBR) was reduced from 3.03±0.27 to 2.82±0.25 (p<0.004) after MET administration. The tempering influence of MET on tumor hypoxia improved RT response, as fifteen days after irradiation TGI was 63±7% in the MET+RT group as compared to only 36±5% in the RT group, however significance was not reached. To date, tumors are still being measured triweekly and this will be continued until a volume of 1500 mm3 is reached. Then, tumors will be sacrificed for histological validations on tumor tissue to assess differences in a.o. proliferation and hypoxia. Conclusions Using non-invasive imaging, we showed in A549 xenograft tumors that MET acts as a radiosensitizer possibly by decreasing tumor hypoxia. Our results imply that [18F]HX4 PET imaging holds potential as a predictive biomarker for the beneficial effect of MET in the treatment of NSCLC; however, full proof of this in a POC study did not allow us to draw conclusions. These promising findings will be validated in a larger follow-up study in order to validate [18F]HX4 PET as a predictive biomarker for MET and RT response.

#1875A Preclinical proof of concept for the first Nanocyclix TKI-PET radiotracer targeting activated EGFR positive lung tumors. Philippe Geneste,1 Cyril Berthelot,1 Olivier Raguen,2 Sylvie Chalon,2 Xavier Tison,3 Sophie Sorriere,2 Peggy Provent,1 Marc Hillairet de Boisferon,1 Johnny Verrouaille,2 Celine Mothes,4 Fabienne Gouraud,4 Louisa Barre,5 Denis Guilloteau,6 Petra Blom,7 Jan Hoflack,7 Oncodesign S.A., Dijon Cedex, France;4 INSEM, Tours, France;5 INSERM/ CERRP, Tours, France; Cyclopharma, Saint-Beauzire, France;6 CEA, LDM-TEP, Caen, France.

Background: [18F]HX4 is a positron emission tomography (PET) ligand for EGFR. Progesterone receptor (PR) is a known target of EGFR inhibitors. In vivo, we evaluated the efficacy of HX4 in a xenograft model of the tumor cell line H520. The results were compared with those of [18F]FDG. The biodistribution of both ligands was measured in nude mice after intravenous injection. Results: In the model of the H520 tumor cell line, the uptake of HX4 was higher than that of [18F]FDG, with a statistically significant difference in tumor uptake (p<0.001). The biodistribution of both ligands was similar in the liver, lungs, spleen, and muscles. Conclusion: [18F]HX4 is a promising PET ligand for the detection of EGFR-positive tumors. Future studies will be needed to evaluate the potential of this tracer for the diagnosis and staging of EGFR-positive tumors.
TKI. Methods: New compound ODS2004436 was characterized in vitro for its activity and metabolism. After radiolabeling with $[^{18}F]$, the compound was evaluated in vivo in three clinically relevant lung cancer cell lines (NCI-H441 – EGFR_wild-type (WT); NCI-H3255 – EGFR_L858R; NCI-H1975 – EGFR_L858R/T790M) xenografted in nude rats. Results: The biochemical and cellular profiles were comparable to gefitinib on EGFR_WT and activated EGFR_L858R. The cellular activity was in the nanomolar range ($5 \pm 2$ nM) on NCI-H2355 and weak on NCI-H441 (42 $\pm 27$ nM) suggesting that our compound might inhibit to a lesser extent non activated WT-EGFR. We observed a better biochemical inhibition (254 nM vs 1350 nM) and cellular activity on NCI-H1975, the EGFR double mutant (4.8 $\pm 0.7$ µM vs 18 $\pm 8.7$ µM) of ODS2004436 compared to gefitinib. These data showed that our compound is suitable to bind to in vivo activated EGFR. In vitro binding experiments showed that $[^{18}F]$,ODS2004436 specifically bound to patient tumor samples expressing EGFR. The in vivo experiments in rats showed that $[^{18}F]$,ODS2004436 was rapidly cleared from the blood. Nevertheless the tumor uptake is stable overtime (up to 180 min) with a mean tumor/muscle ratio of 6.5 $\pm 0.9$. The tumor uptake is stable overtime (upto 180 min) with a mean tumor/muscle ratio of 6.5 $\pm 0.9$. Moreover, we observed a good correlation between the radiotracer uptake in the tumors and eEGFR immunostaining, suggesting that $[^{18}F]$,ODS2004436 is a good biomarker of activated EGFR, regardless of the mutation. Conclusions: Based on this study, we proved in vivo that $[^{18}F]$,ODS2004436 binds selectively to activated EGFR, and is a good candidate to evaluate the EGFR activity in NCLS using PET imaging. Clinical evaluation of this novel radiotracer is ongoing (first in-man phase 0/I clinical trial NCT02847377).

TUMOR BIOLOGY: Imaging for Cancer Diagnosis and Image-Guided Therapy

#1876 Cell cycle-dependent front polarized cell migration requires Aurora kinase A. Tony Lok Heng Chou, Lixin Zhou, Jennifer Won, Pooja Mohan, Oksana Nemirovsky, Abbas Fotovati, Torsten Nielsen, Nelly Pante, Christopher Maxwell. University of British Columbia, Richmond, British Columbia, Canada.

PROBLEM: Metastasis accounts for 90% of deaths from carcinomas. BACK-GROUND: To initiate migration, epithelial cells must front-rear polarize and reorganize the microtubule cytoskeleton directed toward the lamellipodia or leading edge. During mitosis, centrosome maturation, duplication, spindle pole assembly and chromosome segregation require Aurora kinase A (AURKA), which is optimally active when complexed with TPX2. Accumulating evidences identify non-mitotic functions for AURKA, such as cell migration and ciliary reorganization. Overexpression of AURKA leads to tumorigenesis in breast cancer. Mechanisms that activate non-mitotic AURKA and promote cell migration as well as metastasis are yet to be uncovered.

RESULTS: In a large breast cancer tissue microarray (n = 3,175), the abundance of phosphorylated RHAMM (a substrate of AURKA) predicted overall and relapse-free survival in ER-negative, basal-subtype, and triple negative breast tumors. We studied the AURKA-TPX2-RHAMM signaling axis in mammary (MCF10A and MUMG-FUCCI) and HeLa cells. In scratch wound assays, migratory cells were found to have front-polarized centrosomes, which correlated with G2 cell cycle phase, phosphorylated AURKA and elevated microtubule nucleation at centrosomes. Small molecule inhibition of Aurora kinase activity impaired centrosome polarity and retarded the kinetics of cell migration. In parallel, silencing RHAMM altered TPX2 localization as indicated by immunofluorescence and immuno-EM, which located TPX2 to the nuclear envelope and nuclear pore basket. Nuclear import of recombinant TPX2 was attenuated in RHAMM silenced cells and nuclear envelope accumulation was elevated.

CONCLUSION: The AURKA-TPX2-RHAMM axis regulates centrosome polarity, microtubule nucleation and directional cell migration while phosphorylated RHAMM predicts survival in aggressive forms of breast cancer.

#1877 Coordination of Rac1 and Cdc42 by centrosomal microtubules in focal adhesion dynamics and directed cell migration. Jean-Cheng Kuo. National Yang-Ming University, Taipei, Taiwan.

Cancer metastasis causes the increase of mortality in most cancer patients, and abnormal cell migration contributes to this disease progression. To control cell migration, the dynamical control of a protein complex within focal adhesions has to be regulated appropriately. It is known that focal adhesions can be regulated dynamically by microtubules. To examine the effects of centrosomal microtubules and non-centrosomal microtubules in regulating focal adhesion dynamics and directed cell migration, we first generated centrosome-deficient cells. We find that centrosomal microtubules and non-centrosomal microtubules control focal adhesion dynamics through modulating focal adhesion composition, which dynamically control the activity of small GTPases Rac1 and Cdc42. Deficiency of centrosomal microtubules significantly disrupts the balance of Rac1 and Cdc42, thereby inhibiting directed cell migration. This study unveils the effects of centrosomal cellular adhesions, and indicates an important role for Rac1 and Cdc42 activation that controls actin polymerization, cell polarization and directed cell migration.

#1878 PDZ-RhoGEF functions as a critical signaling effector for TROY. Zonghui Ding, Alison Roos, Jean Kloss, Harshil Dhruv, Marc Symons, Nhan L. Tran, Joseph C. Loftus. Mayo Clinic Arizona, Scottsdale, AZ; Dr. Translational Genomics Research Institute, Phoenix, AZ; The Feinstein Institute for Medical Research at Northwell Health, Manhasset, NY.

Glioblastoma Multiforme (GBM) is the most common tumor of the CNS with a median survival of approximately 15 months. The highly aggressive invasion of malignant cells into the surrounding normal brain tissue renders complete surgical resection impossible, increases therapeutic resistance, and virtually assures tumor recurrence. We have previously demonstrated that TROY (TNFRSF19) has an important role in GBM invasion and resistance. TROY expression is correlated with glioma grade and inversely correlated with patient survival. Increased TROY expression stimulated cell migration/invasion in vitro and in vivo and confers resistance to both ionizing radiation- and temozolomide-induced apoptosis via activation of Akt and NF-kB. These data indicate that TROY stimulated migration/invasion is associated with signaling pathways that also increase survival and therapeutic resistance, however, the mechanistic basis of this signaling remains unclear. To investigate the mechanism by which TROY induces GBM cell invasion, we performed immunoprecipitation of the TROY receptor coupled with MALDI-TOF and MS/MS analysis and identified PDZ-RhoGEF as a binding partner for TROY. We validated the interaction of TROY with PDZ-RhoGEF by immunoprecipitation and western blotting, and demonstrated that PDZ-RhoGEF can exchange for both RhoA and RhoC in glioma cells and is implicated in GBM cell invasion, proliferation, and survival. In order to assess the specific role of PDZ-RhoGEF in TROY signaling, we examined the effects of PDZ-RhoGEF on TROY-mediated activation of NF-kB. While overexpression of TROY alone strongly stimulated NF-kB transcriptional activity in serum-free conditions, increased expression of PDZ-RhoGEF alone had no effect on NF-kB activity. Co-transfection of PDZ-RhoGEF with TROY synergistically promoted NF-kB activation. Mutation of the TRAF binding domain (TBD) in the cytoplasmic domain of TROY abolished its capacity to activate NF-kB, even in the presence of PDZ-RhoGEF, suggesting that the TBD is important for TROY induced NF-kB activation. Furthermore, knockdown of PDZ-RhoGEF by shRNA attenuated NF-kB activation in TROY expressing cells, blocked TROY mediated invasion of primary GBM xenograft cells and increased sensitivity to temozolomide. Collectively, these data indicate that PDZ-RhoGEF plays an important role in TROY signaling and provides insights into a potential node of vulnerability to limit GBM cell invasion and decrease therapeutic resistance.

#1879 Transcriptional regulation of KAI1 by p73 in colorectal cancer metastasis. Woo Kyun Bae, Kyung Hyun Yoo, Keunsoo Kang, Lothar Hennighausen, Ik-Joo Chung. CUNHL Jeonnam, Republic of Korea; Sookmyung Women’s University, Seoul, Republic of Korea; Dankook University, Cheonan, Republic of Korea; NIH, Bethesda, MD.

Background: p73 is a member of the p53 family transcription factors and known tumor suppressor. However, its transcriptional activity is complex owing to its multiple isoforms, and limited information is available regarding the transcriptional and functional regulation of the p73 gene in colorectal cancer. In this study, we examined the role of p73 in colorectal cancer. Methods: We established a TaP73 overexpressing cell line using the Tet-on inducible expression system and analyzed global RNA expression by RNA-sequencing (RNA-seq) experiments. We studied the effects of TaP73 expression on the expression, invasiveness, and EMT of colon cancer cells. We conducted experiments in animals with liver metastasis of colorectal cancer. To investigate the roles of p73 in colon cancer, we examined the samples from patients who had undergone surgical resection for colorectal cancer between 2009 and 2013. mRNA expression of TaP73 and KAI1 was analyzed in 108 colorectal cancer specimens and adjacent non-cancerous tissues by real-time RT-PCR. Results: RNA-seq showed the association between TaP73 and KAI1 expression. Migration and invasiveness of colon cancer cells were reduced by TaP73 expression, but induced by KAI1 knockdown. TaP73 regulates KAI1 expression in colon cancer cells. TaP73-induced decrease in invasive- ness and epithelial-mesenchymal transition (EMT) was abrogated by KAI1 expression.
knockdown in TAp73 overexpressing cells. Migration ability of TAp73 overexpressing cells was recovered by KA1 knockdown. Hepatic metastases were significantly reduced in mice injected with TAp73 overexpressing cells and increased in those injected with TAp73 overexpressing cells with KA1 knockdown. mRNA expression of TAp73 and KA1 was higher in colorectal cancer cells. Comparing non-cancer- and cancer-expressing cells, the difference between TAp73 and KA1 mRNA expression was detected in early stage primary colorectal cancer, but not in the advanced stage. Conclusions: This study suggests that p73 (TAp73) acts as a tumor suppressor in the progression of colorectal cancer and regulates the expression of KA1, which is a key target of p73 in colorectal cancer liver metastases.

#1880 Bulk lung cancer cell migration is more common than single cell migration and regulated by different genes. Helmut H. Popper, Sylvia Eidenhammer. Medical Univ. of Graz, Graz, Austria.

Introduction: There are two different forms how tumor cells migrate: single or small cell cluster movement as it is seen in small cell carcinoma, and movement by large clusters of organized cells as seen most often in adenocarcinoma or squamous cell carcinoma. This latter migration form is not understood.

Drosophila border cells forming wings migrate in large cell complexes similar to what is seen in the carcinomas and the genes identified in these cells might regulate the same process in carcinomas. Methods: 30 cases of pulmonary squamous cell carcinomas and adenocarcinomas were selected based on the identification of large tumor cell clusters visible within the stroma as well as in blood vessels. Immunohistochemistry was done for receptor of activated C kinase (Rack1), large tumor cell clusters visible within the stroma as well as in blood vessels. Drosophila border cells forming wings migrate in large cell complexes similar to movement by large clusters of organized cells as seen most often in adenocarcinoma or squamous cell carcinoma. In addition immunohistochemistry was also done for Src-kinase, Twist, Snail, and TGFβ1. Tyrosine kinase substrate 5 (Tks5), E-cadherin, SARI (suppressor of AP-1), and vimentin, all known to be associated with epithelial-to-mesenchymal transition (EMT) and formation of invadopodia. Results and Conclusion: Most well differentiated pulmonary carcinomas migrate in large cell clusters, for example acinar adenocarcinomas form nicely structured acini deep within the stroma and even within blood vessels. These carcinomas do not undergo classical EMT. Proteins expressed by the four genes (Rack1, brk, mad, and sax) associated with border cell movement in drosophila could also be identified in pulmonary carcinomas and might coordinate bulk cell movement. Other members of TGF-beta signaling cascade were identified. Inhibition of Src by Rack1 may be important for border cell migration and cluster cohesion maintenance. Proteins usually seen in single tumor cell migration, such as vimentin (a sign of EMT) could not be proven in the tumor cell clusters. Findings of this study show that similar mechanisms are working in pulmonary carcinomas and that bulk cell migration is probably another way of metastasis. Further investigation using cell culture system and genetically designed adenocarcinomas expressing these genes should prove our findings and contribute in understanding migration of carcinoma bulk complexes.

#1881 STIM1 and Orai control non-Hodgkin lymphoma cell migration. Simon Latour,1 Isabelle Mahouche,2 Floriane Cherrier,3 Jean-Philippe Merlio,2 Sandrine Poglio,4 Laurence Bresson Bepoldini.1 INSERM U1218 ACTION, Bordeaux, France.2 INSERM UMR1053 BaRITOn, Bordeaux, France.3 Medical Univ. of Graz, Graz, Austria.

Non-Hodgkin lymphoma is one of the most common cancer in United States representing 4% of all cancer. Diffuse large B cell lymphoma (DLBCL) is the most common and aggressive non-Hodgkin B lymphoma. One of the characteristic features of this disease is the dissemination of the cancer cells, through the lymphatic system in the secondary lymphoid organs and extranodal sites, leading to the death of patients. Chemokines such as the Stromal Derived Factor 1 (SDF1) control the spread and the homing of the cancer cells. It is known that SDF1 activates various signalling pathways involved in cell proliferation, transcription or migration. Moreover, SDF1 induces an increase in intracellular calcium concentration whose role is still unknown in B cells. Store-operated Ca2+ entry (SOCE) is a major Ca2+ influx pathway in this type of cells. By definition, SOCE is activated by Ca2+ release from the endoplasmic reticulum. Two genes are responsible for SOCE activity: Stromal interaction molecule 1 (STIM1), an ER Ca2+ sensor that detects store depletion and ORAI1, the pore-forming subunit of Ca2+ release-activated Ca2+ (CRAC) channel. Several studies performed on adherent cells showed that ORAI1/STIM1 proteins are involved in cancer cell migration. However, the molecular mechanisms involved in cell migration differ widely between adherent and non-adherent cells. We studied the role of both actors of calcium entry: ORAI and STIM1 in DLBCL pathiology and more precisely in basal and SDF1-induced of DLBCL cell migration. Using Tissue MicroArrays approach we revealed that both ORAI and STIM1 are under-expressed in DLBCL tumoral tissue compared to normal lymphoid tissue. Next, using calcium imaging experiments we confirmed that SDF-1 triggered Ca2+ responses in two DLBCL cell lines (SUDHL4 and HLY1) involving intracellular Ca2+ store mobilization and extracellular Ca2+ influx. Based on these observations, we investigated the role of ORAI1 and STIM1 on SDF1-induced Ca2+ influx using pharmacological and RNA interference approaches. The inhibition of ORAI1 by BTP2 as well as the under-expression of ORAI or STIM1 by shRNA, prevented Ca2+ influx induced by SDF1 suggesting the involvement of ORAI and STIM1 in this process. Regarding this results, we studied the role of ORAI1 and STIM1 on DLBCL cell migration in vitro and in vivo. Our results show that basal or SDF1-induced cell migration was significantly inhibited by under-expression of STIM1 or ORAI1 in SUDHL4 and HLY1 cell lines. These results suggest that STIM1 and ORAI1 play a key role in the DLBCL cell migration. The identification of STIM1 and ORAI proteins as key players in the migration of DLBCL cells might provide new therapeutic targets for the treatment of this pathology.

#1882 Tankyrase-binding protein TNKS1BP1 regulates cancer cell invasion. Tomokazu Ohishi,1 Haruka Yoshida,1 Masamichi Katori,1 Toshiro Migita,1 Yukiko Muramatsu,2 Mao Miyake,1 Yuichi Ishikawa,2 Akio Saito,2 Shun-ichiro Iemura,1 Tohru Natsume,4 Hiroyuki Seimiya1.

TNKS1BP1-depleted cells and enhanced cell invasion in a PARP activity dependent manner. Under approval by Institutional Review Board of Japanese Foundation for Cancer Research, we performed immunohistochemical analysis of clinical pancreatic cancer. We found that TNKS1BP1 protein expression is decreased in invasive regions of the tumors. Taken together, these observations suggest that the tankyrase-TNKS1BP1 axis represents a novel post-translational modulator of cell invasion and its aberration promotes cancer malignancy.

#1883 Fibillar 1D tumor microenvironment is the key driver associating high-speed tumor cell motility with nuclear shape in breast cancer. Ved P. Sharma,1 James Williams,2 Edison Leung,3 Joseph Sanders,2 Robert Eddy,1 James Castracane,1 John Condeelis2.

Unlike normal breast stroma, which contains curly collagen fibrils, aligned collagen fibers oriented perpendicular to blood vessels are seen in both human breast tumors and mouse models of breast cancer. These linear collagen fibers provide “highways” for tumor cells to migrate toward blood vessels in a directional migration mode known as tumor cell streaming. Streaming is characterized by tumor cell migration at high speed and directional persistence on 1D collagen fibers. Previous studies utilizing linear ECM substrates have shown that tumor cells adopt elongated morphology and display increased speeds on linear 1D substrates compared to their 2D motility. However, the relationship between 1D geometry of ECM fibers in breast tumor microenvironment and the underlying mechanotransduction mechanism regulating high-speed migration of tumor cells is not well understood. Here, we analyzed in vivo ECM architecture by SHG intravital imaging and found a narrow peak of fiber diameters falling in the range 2-3 μm. These fibers were composed of collagen I and fibronectin. Based on these findings, we developed a high fidelity in vitro nanofiber system to study the molecular mechanisms underlying tumor cell streaming migration. Breast
cancer cells plated on 2 μm ECM-coated fibers showed enhanced motility matching in vivo velocities averaging 1.2 μm/min. We varied 1D fiber diameter (0.7-20 μm) and found that tumor cells move the fastest with highest persistence on smaller fibers within a narrow range of diameters from 0.7-3 μm. High tumor cell speeds correlated with enhanced alignments of F-actin and focal adhesions along the fiber axis. Unexpectedly, we also observed nuclear deformation during carcinoma cell migration on narrow fibers in vitro, similar to nuclear deformation observed in vivo. This was a surprising finding because nuclear deformation in vivo was assumed to be caused by squeezing through ECM pores. Thus, we hypothesized that actomyosin forces not only regulate cell motility parameters, but also nuclear deformation independently of ECM pore size. To test this, we disrupted the transmission of cytoskeletal forces to the nucleus by knocking down LINC complex proteins - SUN1 and SUN2, and found increased nuclear elongation and cell motility parameters, through the upregulation of actin polymerization. These results indicate that in carcinoma cells, F-actin associated forces are shared between the leading edge (to maintain cell speed) and the nucleus (to dynamically regulate nuclear shape). LINC complex disruption releases F-actin forces acting on the nucleus to the cell front, leading to higher tumor cell motility speeds. In summary, our results provide new insights into the interplay between actomyosin contractility and the LINC complex in the regulation of nuclear shape and high-speed tumor cell motility during carcinoma cell metastasis.

Background: Breast cancer (BCa) is a genetically heterogeneous disease and many genes contributing to BCa risk remain to be identified. Genome-Wide Association Studies (GWAS) and subsequent fine-mapping studies (>50) have strongly implicated genetic alterations at the CCDC170/C6ORF97-ESR1 locus (6q25.1) as being associated with the risk of BCa. ESR1, encoding the estrogen receptor, might be a more obvious candidate for influencing risk. Surprisingly, our analysis using genome-wide differential allele-specific expression (DASE), an indicator for BCa susceptibility, suggested that the genetic alterations of CCDC170, but not ESR1, accounts for GWAS-associated BCa risk at this locus. CCDC170 is a coiled-coiled-domain-containing protein of poorly understood function. BCa-specific truncation and missense mutations in CCDC170 also have been detected, with the truncations being implicated in driving Luminal B subtype BCa. Together these findings demonstrate that the CCDC170 gene is involved in BCa, but the underlying molecular mechanisms for its role in tumorigenesis are unknown. Experimental designs and results: By using the approaches of confocal microscopy and cell imaging analysis, here we report for the first time that CCDC170 is associated with the Golgi apparatus and perinuclear microtubules (MTs), and support a role for CCDC170 in the Golgi-associated microtubule network. We have shown that overexpression of CCDC170 triggers Golgi reorganization and stabilizes Golgi-associated MTs, accompanied by dramatically increased acetylation of α-tubulin that is driven by the actin-filament transferase ATAT1. The Golgi-associated MT network has been proposed to regulate cell polarity and migration. In support of this concept, we have shown that CRISPR knockout increases, and overexpression of CCDC170 decreases, BCa directional cell migration in vitro. We also found that the BCa-specific truncations result in mislocalization of CCDC170 and/or diminished stability of Golgi-associated MTs. Lastly, we identified candidate CCDC170 functional binding partners (e.g. MAP4) that are consistent with their localization and proposed function. These partners may serve to mediate the acetylation and stabilization of MTs. Conclusions: Taken together, our findings demonstrate that CCDC170 plays an essential role in Golgi-associated MT organization and stabilization, and provide a mechanism for how perturbations in CCDC170 could alter Golgi-mediated cell polarity, and thereby drive BCa and other abnormalities. This work was partially supported by the Susan G. Komen for the Cure (KG100274), NCI (CA186853), and Eileen Stein Jacoby Fund.

#1885 VEGFA/NRP1 signal contributes to filopodia formation in breast cancer cells. Marina Kiso, Sunao Tanaka, Masakazu Toi, Fumiaki Sato. Kyoto Univ. Graduate School of Medicine, Kyoto, Japan.

Background and objective: VEGF and NRP1 are the ligand and receptor, respectively, for VEGFA/NRP1 signal. VEGF activates the ERK/mTOR pathway to support tumor progression and impaired migration. Exogenous VEGF addition to VEGFA-KO 231 cells recovered WT 231 cell like morphology and induced cell migration. Next, we generated soluble neuropilin-1 (sNRP1) overexpressed 231 cells. sNRP1 traps VEGF to function as an antagonist. sNRP1-231 cells exhibited small and rounded morphology and impaired cell migration similar to that of VEGFA-KO 231 cells. Knock down of NRP1 by using siRNA in 231 cells also caused impaired cell migration. We evaluated the cell morphology using scanning electron microscope. We identified filopodia formation in VEGFA-KO 231 cells compared to WT-231 cells. Exogenous rhVEGF addition to VEGFA-KO 231 cells recovered filopodia formation. Filopodia is a fingerlike protrusion that comes out from the cell periphery by an actin polymerization. Filopodia is required for cell development and functions such as cell migration. Our results indicate, because of the absence of VEGF/NRP1 signal, filopodia formation is abrogated. As a result of diminished filopodia formation, VEGFA-KO 231 cells showed small and rounded shape and reduced migration. Bevacizumab and NRP1 bind VEGF at amino acid motifs from exon 3-4 and exon 7 of VEGF, respectively. Thus, our findings suggested that VEGF could play a role in filopodia formation via NRP1 for 231 cells, and that sNRP1 could not block the VEGF/NRP1 signal. Discussion NRP1 is a receptor of VEGFA, Semaphorine and other growth factors, and expressed in a variety of cancer cells. Intracellular portion of NRP1 lacks kinase domain. Previous study showed that the VEGF stimulated to form a complex between NRP1 and GIPC1/Syt/RhoA, and promoted tumor cell proliferation independently from VEGFRs (Yoshida et al., 2002). The precise downstream regulator, regarding VEGF/NRP1 signaling, is unknown. In conclusion, inhibition of VEGF/NRP1 signaling caused rounded morphology with diminished filopodia formation, which impaired cell migration of 231 cells. These findings would provide profound insights regarding molecular mechanisms in resistance to bevacizumab treatment.

#1886 mGluR1 drives invasion of proneural subtype of glioblastoma cells. Alena Gladwin, Sen Peng, Jeff Kiefer, Seungchun Kim, Michael Berens, Harshil D. Dhruv. TGen (The Translational Genomics Research Institute), Phoenix, AZ.

A major cause for the therapeutic failure and subsequent morbidity and mortality of glioblastoma (GBM) is the aggressive invasion of malignant cells into the surrounding normal brain that effectively renders complete surgical resection impossible and virtually assures recurrent tumor growth. Multi-omic profiling of GBM led to their molecular sub-classification into two distinct molecular subtypes: proneural (PN) and mesenchymal (MES). However, very little is known about shared or distinct invasion processes of cells in these genomically different subtypes. Using Microarray gene expression profiles of microdissected paired stationary core and invasive rim samples from 19 patients, we demonstrated that invasive gene signature of MES subtypes differs from PN. Specifically, using three orthogonal but intersecting bioinformatic approaches, i.e. gene set variation analysis, causal network analysis, and LIFEGOL analysis; we discovered that genes differentially expressed between PN core and rim could, to a meaningful degree, be accounted for based on their annotation as “regulated by the transcription factor REST”. REST functions as a repressor of gene expression. Of the genes repressed by REST, mGluR1 (Metabotropic Glutamate Receptor 1) was significantly overexpressed at the rim of PN glioma cells as compared to the core. Finally, we also investigated the role of mGluR1 in glutamate induced glioma cell migration; our results show that glutamate stimulates migration of proneural-like glioma cells (A127) as compared to non-proneural-like glioma cell (T98G). mGluR1 activation by glutamate has shown to induce activation of Pyk2 and Src in astrocytes; knockout of mGluR1 is not embryonic lethal. In summary, our data demonstrate that glutamate induced glioma cell migration of PN subtype of GBM is dependent on mGluR1 and thus raises the prospect that therapeutic targeting of mGluR1 may be a novel approach to controlling the invasion of this deadly disease.

#1887 Untethering heterochromatin: how loss of HP1α enhances cell invasion by altering nuclear envelope integrity. Tracy K. Hale, Sarah Bond, David Wheeler. Massey University, Palmerston North, New Zealand.

Malignant cell invasion is accompanied by complex changes in nuclear shape and organisation. The onset of invasion correlates with the loss of HP1α in many solid tumours including those of the thyroid, kidney, colon and breast, while in cancer cell lines HP1α suppresses invasive potential. In normal cells HP1α maintains the condensation of transcriptionally silent heterochromatin and seques-
tters it at the inner periphery of the nuclear envelope; an event critical for the maintenance of nuclear stability and envelope rigidity. This role for HP1a leads us to hypothesise that the un-tethering of heterochromatin from the nuclear periphery that would occur after loss of HP1 causes a corresponding disruption to the nuclear periphery that is a weakness of these cells that could be exploited.

#1888 3D matrix confinement triggers vascular mimicry through a conserved migratory and transcriptional response. Daniel Ortiz, Brian Tsui, Tyler Goshia, Colleen Ricker, Hannah Carter, Stephanie I. Fraley. University of California, San Diego, La Jolla, CA.

An initial step in solid tumor metastasis involves the migration of tumor cells through extracellular matrices. Several cancer cell migration strategies exist in vivo, and the local properties of collagen fibrils are implicated in modulating migration behaviors. Yet, individual tumor cells also display heterogeneity in their intrinsic ability to migrate and metastasize. It remains unclear to what extent intrinsic and extrinsic heterogeneity contribute to the emergence of distinct migration phenotypes and whether certain migration phenotypes contribute more to metastasis than others. To study this, we generated 3D collagen matrices of varying densities and monitored single cancer cell migration in these matrices with time-lapse microscopy. We observed a collagen density threshold at 2.5mg/ml, above which 86% of MDA-MB-231 breast cancer cells transition from single mesenchymal migration to collective cell migration, with a 50% increase in persistence after cell division. After seven days, these collectively migrating cells created networks coated with basement membrane molecules resembling a clinical phenotype known as vascular mimicry (VM). The remaining 14% of cells migrated randomly and eventually formed spheroids. HT-1080 fibrosarcoma cells also responded similarly, migrating persistently and forming cellular networks. Next we sought to identify the physical feature of high-density collagen driving VM. Neither hypoxia or matrix stiffness was sufficient to induce VM. However, PtK2 PEG and matrix contraction triggered VM non-specifically. RNA sequencing revealed collectively migrating cells up-regulated a conserved transcriptional program significantly enriched for annotations of vascular development and motility regulation processes. This gene module predicted survival in human tumor transcriptome datasets. Our results suggest that the VM phenotype arises in a subpopulation of cells from a conserved transcriptional and migratory response to confinement in 3D collagen.

#1889 Formation and merger of H69 and H69AR small cell lung cancer (SCLC) tumor cell clusters (TCCs) in vitro. Nico O. Ruprecht,1 Martin Hungerbuehler,2 Philipp Kellmann,2 Nathalie Harder,2 Günter Schmidt,3 Carlos Goshia, Colleen Ricker, Hannah Carter, Stephanie I. Fraley. University of California, San Diego, La Jolla, CA.

A novel migration of tumor cell invasiveness, termed mutual cellular pervasion (MCP), was observed in vitro. It involved TCCs formed by SCLC cells. Suspension cultures of H69 and H69AR cells were grown in flavin-free RPMI 1640 medium with 10% fetal bovine serum as the only source of flavins. Experiments and subcultivations were performed under light with wavelengths above 520 nm. TCC morphology was studied by confocal microscopy and transmission and scanning electron microscopy. Interactions of TCCs were followed by video microscopy in phase contrast and fluorescence modes. Data were analyzed using the Definiens software suite. The interaction of H69AR TCCs with confluent monolayers of human umbilical vascular endothelial cells (HUVEC) was visualized. Freshly subcultivated, singularized tumor cells rapidly formed aggregates. After two days, solid TCCs prevailed whose surface cells were connected by desmosome-like junctions. Apoptosis but not necrosis became obvious in central parts of clusters with diameters above 100 to 150 μm. TCCs enlarged through both cell proliferation and serial cluster formation. In the course of TCC merger, four stages were distinguishable: (1) directed cluster movement leading to contact of clusters, (2) formation of a near circular, symmetric structure termed contact disc. It consists of planar surface areas to which both TCCs involved contribute equally. (3) Merger of TCCs took place in the contact disc, and was accompanied by active movement of adjacent cells. (4) Starting from the merger zone, major surface areas of newly formed clusters were mutually perverted by cells from both participating cell clusters. After numerous merger events, only low numbers of TCCs reaching sizes of up to 2 to 3 mm were present at subcultivation. No spontaneous bursting, shrinkage, degeneration, or decay of TCCs has been observed. However, when TCCs of H69AR cells were confronted with confluent layers of HUVEC, drastic changes occurred in both formations. Formation of intense oscillatory cellular movements were triggered on TCC surfaces, preceding the release of cell aggregates which moved away from TCCs to the HUVEC layer. At the same time, HUVEC were disconnected from each other and started moving either randomly or in an oscillatory fashion. Individual tumor cells attached to the much larger HUVEC and spread on their surface, resulting in full covering which secluded HUVEC from the medium. To our knowledge, neither formation nor merger of malignant TCCs in vitro have been described so far. TCC merger involves movements and remodellings of TCC surface resulting in the invasion of tumor cells into non-tumor tissue, pervasion does not lead to destruction but results in TCC growth. However, key features of tumor cell invasion in vivo, such as chemotaxis, spreading and TCC formation as well as disruption of endothelial layers, manifest under conditions in vitro, thus facilitating related experimental studies.

#1890 PLEK2 contributes to lung cancer progression through upregulation of NDRG1 expression. Yi-Pin Hsieh, Hui-Chia Liu, Hao-Yu Huang, Wan-Jiun Tang, Tai-Lin Lee, Meng-Feng Tsai. Da-Yeh University, Changhua, Taiwan.

PLEK2 is one of the pleckstrin homology domain (PH) domain proteins. Recently studies suggested that PLEK2 may play a critical role in lymphocyte migration through by PI3K/AKT dependent and independent pathways. However, the biological functions of PLEK2 in lung cancer is not clear. We detected the expression of PLEK2 in various lung adenocarcinoma cell lines using quantitative RT-PCR methods. The results indicated that PLEK2 expression significantly positive correlation with cancer cell migration and invasion ability. Forced expression of PLEK2 in lung cancer cells exhibited markedly promoting in the proliferation rate, anchorage independent growth, cell motility and invasion, whereas knockdown of PLEK2 was found to suppress lung cancer cell progression. In addition, we also reported that PLEK2 expression induce lung cancer cell epithelial-mesenchymal transition (EMT) phenomenon, and involve in che- motherapeutic drug resistance through upregulation NDRG1 gene expression. Overexpression of NDRG1 in PLEK2-knockdown cell line restored cancer cell proliferation, migration, and invasion. These results will provide information and help us to understand the roles of NDRG1 in lung cancer cells.

(a) Aim: The purpose of this study is to clarify an unknown function of Annexin A2-binding S100A proteins in tumor growth, cell cycle progression and invasion. Annexin A2 is a membrane bound protein originally identified as-sRc substrate, and often found to be overexpressed in many types of cancers. As a multicompartmental protein that orchestrates a spectrum of dynamic membrane-related events, it is associated with actin cytoskeleton control, vesicle formation and intercellular interaction. (b) Methods and Results: During our proteomics analysis using solid tumor cell lines, we identified both Annexin A2 and S100A proteins in cancer stem cell-rich population. We examined S100A1 and S100A2 proteins expression in several Head and Neck cancer PDX samples. Immunochemical data from in vivo specimens as well as western blots showed that S100A expression abundance was well associated with poor prognosis. Annexin A2 has been indicated to be involved in malignant phenotypes such as invasion and metastasis, and Annexin A2 and S100A form (S100-Annexin A2)x2 dimers, we next examined role of S100A proteins in cancer stem cell-rich population. We examined S100A2-depletion experiments. (c) New Findings: Depletion of S100A from PDX-derived cancer cells resulted in loss of both in vivo tumor formation and invasion. Furthermore, cell cycle progression was inhibited by the depletion, suggesting its potential role in proliferation controls. Similar to the mutant Ras-driven.

tumors. EGFR-overexpression increased S100A gene expression. (d) Conclusion: These results strongly suggest that increased in S100A plays significant roles in cancer cell proliferation and invasion.

**1892** Small molecule NSC59984 prevents cancer cell migration and invasion. Shengliang Zhang, Jessica Wagner, Lanlan Zhou, Wafik S. El-Deiry. Fox Chase Cancer Center, Philadelphia, PA.

Tumor metastasis is one of the main mechanisms leading to mortality of cancer patients. Searching for new therapeutic strategies to prevent tumor metastasis is one of the anti-tumor approaches in cancer therapy. Cell migration and invasion are crucial initial steps in the complex process and progression of tumor metastasis. Mutant p53 has been known as an important factor associated to cancer cell migration. Therefore, targeting mutant p53 is a potential strategy to avoid tumor metastatic spread. We recently reported an anti-tumor small molecule, NSC59984 which degrades mutant p53 and restores p53 pathway via activation of p73. Here we demonstrate that NSC59984 inhibits cancer cell migration and invasion. Treatment with NSC59984 partially attenuates cell migration in various cancer cells based on the scratch assay and Boyden chamber assay. The effect of NSC59984 on cell migration is partially blocked by knockdown of p73, a member of the p53 family, suggesting that restoration of p53 pathway signaling via p73 is required for NSC59984-inhibition of cell migration in cancer cells. We found that NSC59984 induces ERK2-dependent p53 restoration and mutant p53 degradation. To examine the role of ERK2 in the cell migration, ERK2 signaling is blocked by U0126 treatment in cancer cells. The effect of NSC59984 on cancer cell migration is partially inhibited by U0126 treatment, suggesting that NSC59984 inhibits cancer cell migration partially dependent on ERK1/2 pathway signaling in cancer cells. In addition, the gelatin degradation assay shows that NSC59984 inhibits cancer cell invasion. Consistent to the in vitro assays, NSC59984 decreases tumor invasion of xenograft tumors as compared to the xenograft tumors treated with DMSO as control. Our results, taken together, suggest that NSC59984 not only suppresses tumor growth, but also inhibits cancer cell migration and invasion. Our findings provide the potential administration of p53-restoring compound NSC59984 in cancer therapy by blocking tumor metastasis.

**1893** Alpha-tubulin acetyltransferase, MEC-17, regulates cancer cell morphology and migration through epithelial-mesenchymal transition suppression and cell polarity disruption. Cheng-Chee Lee, Chi-Yen Chang, Chi-Min Lin, Jiang-Yang Chang. National Cheng Kung University, Tainan, Taiwan; National Health Research Institutes, Taiwan, Taiwan.

Acetylation of α-tubulin has characterized as a key process for microtubule stabilization, and it can regulate cell spreading and modulate the dynamics of focal adhesion. MEC-17, a newly identified alpha-tubulin-N-acetyl transferase, serves as the major α-tubulin acetyltransferase to promote α-tubulin acetylation in vitro and in vivo. However, the physiological function of MEC-17 in cancer cells and its effect on MT acetylation during cell morphogenesis and migration has remained elusive. In the present study, our results showed that overexpression of MEC-17 induced increment of cell focal adhesion area, suppressed pseudopod formation in three-dimension collagen-embedded cultured environment and inhibited cancer cell migratory and invasive abilities. These changes were further proved to be caused by epithelial-mesenchymal transition (EMT) repression, cell polarity disruption caused by alteration of Golgi orientation and cdc42 activity and the decrease in phosphorylation of extracellular signal regulated kinase 1/2 (ERK1/2). On the contrary, silencing of endogenous MEC-17 by specific shRNA accelerated the pseudopods formation and EMT process, which lead to facilitating the cell migration. Taken together, these results demonstrated that the important role of MEC-17 in the modulation of intrinsic cellular morphogenesis and migratory and invasive functions through regulation of EMT and polarization. (The study was supported by the following grants: MOST 105-2320-B-006-006-MY3 and MOST 105-2325-B-400-001 from the Ministry of Science and Technology of Taiwan, ROC).

The purpose of this study was to clarify the role of BMP inhibitor gremlin 1 in invasive and migration in mesothelioma. Primary mesothelioma cells isolated from patient pleural fluid as well as mesothelioma cell lines were used for in vitro studies. Cells were transfected with siRNAs or transduced with lentiviral expression vectors. Invasive growth was analyzed in 3D Matrigel or collagen I matrices. mRNA expressions were analyzed using a commercial PCR array and quantita-
#1897 The role of nuclear deformation and rupture in breast cancer cell migration. Alexander E. McGregor, Joshua J. Elacqua, Emily S. Bell, Jan Lammersing. Cornell University, Ithaca, NY.

Invasion of tumor cells into the surrounding tissue is a critical step in the metastatic cascade, which is responsible for the vast majority of cancer-related deaths. Recent findings have begun to demonstrate that the biophysical properties of the cell nucleus play a critical role in this process. During invasion, cancer cells must maneuver through tight spaces much smaller than the cell nucleus. While the cell cytoplasm easily maneuvers through confined spaces, the deformability of the nucleus, which is the largest and stiffest organelle, ultimately determines how efficiently a cell can pass through a tight space. Furthermore, as the nucleus deforms to move through a confined space, it can exhibit transient loss of nuclear envelope (NE) integrity, where the nuclear membranes rupture and nuclear and cytoplasmic components interchange. We previously showed that chromatin is exposed to the cell cytoplasm during NE rupture, and cells can incur DNA damage. While this work revealed that cancer cell migration requires nuclear deformation and can involve NE rupture, it is currently unknown whether such events correlate with metastatic potential. We used a panel of human breast cancer cell lines, including claudin-low, basal-like, and lumen-like cells. Cells were stably labeled with a green fluorescent protein fused to a nuclear localization sequence (NLS-copGFP) to investigate whether some cell lines were particularly well suited to migrate through tight spaces, and if any were particularly prone to NE rupture. The cells were loaded into microfluidic devices that were designed to mimic interstitial in vivo space and monitored by time-lapse microscopy. Devices contained constrictions 5 μm tall and 1.2, or 15 μm wide. We found that claudin-low cell lines such as BT-549 migrated through confined spaces (1 ± 2 μm wide constrictions) significantly faster and more efficiently than basal-like HCC70 cancer cells. In contrast, the various cell lines displayed similar migration rates in the 15 μm wide constrictions, which do not require nuclear deformation. Thus, the differences observed between the cell lines reflect specific defects in migration through confined spaces, and not general migration defects. We are currently expanding our studies to a larger panel of cancer cell lines and to mouse breast cancer models. If confirmed, these results could indicate that highly invasive cancer cells may benefit from more deformable nuclei that facilitate movement through tight spaces encountered in the tissue microenvironment.

#1898 MEG3 as a competing endogenous RNA binds with miR-27a to promote PHLP2 protein translation, and consequently impairs bladder cancer invasion. Chao Huang,1 Xin Liao,2 Jingxia Li,1 Chunshu Huang,1,2. New York University School of Medicine and Wuhan Union Hospital, Tuxedo Park, NY,2.

Muscle invasion and metastasis of bladder cancer dramatically decrease survival rate, compared to 77% of 5 year survival rate of all bladder cancer, metastasis bladder cancer is only 5%. This truth implies that one of the therapeutic kernels of bladder cancer is to decrease, even block, its invasiveness. In the current study, we find that MEG3 is significantly downregulated in human muscle-invasive bladder cancer tissues compared with non-muscle invasive tissues. We also demonstrate the MEG3 strongly inhibits human bladder cancer cell invasiveness by acting as a ceRNA. We find that MEG3 competes with PHLP2 mRNA for miR-27a binding, which leads to a decreased miR-27a activity, and subsequently reducing the translation inhibition of miR-27a to PHLP2. The upregulated PHLP2 decreases the c-Jun phosphorylation at Ser63/73, and in turn inhibits the c-myc transcription and its mediated invasiveness of the bladder cancer cells. This is the first demonstration that MEG3 inhibits the invasiveness of human bladder cancer cells via negative regulation of c-Myc as a ceRNA. These findings not only provides a novel insight into understanding the mechanisms behind the MEG3 inhibiting the cancer cell invasion, but also reveals a potential targets for invasive bladder cancer prevention and therapy.

#1899 MKK4/JNK2 down-regulation in NSCLC suppresses tumor growth and metastasis. Tamer Saad Kaoud,1 Nancy D. Ebelt,1 Lili Du,2 Sabrina Van Ravenstein,3 Kenneth Y. Tsai,1 Kevin N. Dalby1. 1UT Austin College of Pharmacy, Austin, TX; 2The University of Texas MD Anderson Cancer Center, Houston, TX; 3UT Austin, Austin, TX.

Mitogen-activated protein kinase kinase-4 (MKK4) has been reported to either enhance or suppress oncogenesis. Evidence of its pro-angiogenic activities in breast, pancreatic, lung and skin cancer have been reported. Although the mechanism of its possible tumorigenic role is still unclear. Recent studies in glioblastoma and lung carcinoma have suggested important roles for the constitutive activation of its downstream substrate JNK2. JNKs require phosphorylation by both MKK4 and MK7 to be fully activated. The JNK2 siRNA shows a unique propensity among the JNKs to autophosphorylate in vitro. Here we show that JNK2 autophosphorylation contributes to the proliferation and migration of NSCLC cells under conditions of low serum through an MKK4-dependent mechanism. This suggests a pro-oncogenic role of MKK4 in NSCLC through a JNK2 autophosphorylation-dependent pathway. Evidence in several cell lines, including mouse embryonic stem cells lacking MKK4 or MKK7 suggests that autophosphorylation alone activates JNK2 weakly in cells. However, JNK2 autophosphorylates on Thr-183, to create a pool of JNK2 primed for activation by MKK4, which phosphorylates JNK2 on Tyr-185 to activate it. Under conditions of low serum the down-regulation/overexpression of MKK4 or JNK2 but not MKK7 or JNK1 suppresses/promotes proliferation of multiple NSCLC cell lines, through STAT3. Under the same conditions, A549 cell migration is inhibited upon down regulation of either MKK4 or JNK2. Further supporting the notion that active JNK2 results primarily from autophosphorylation of Thr-183, pan-JNK ATP competitive inhibitors (JNK-IN-8 and SP600125) showed a dose-dependent dephosphorylation of JNK2 in NSCLC cell lines and inhibited their proliferation under conditions of low serum. Moreover, the downregulation of MKK4 inhibition of JNK2 autophosphorylation by SP600125 inhibited nuclear localization of JNK2 in A549 cells cultured in low serum. To further understand the pro-oncogenic role of MKK4 in the A549 cell line, we investigated tumor growth and lung metastasis in A549 Xenografts in which either JNK2 or MKK4 were stably knocked down. Either JNK2 or MKK4 knockdown showed a similar suppression of tumor growth and lung metastasis if compared to the expression and RNA control. Sequencing of MKK4 in the A549 cells revealed no genomic deletion or somatic mutations. Taken together, the data suggest that MKK4 may exhibit pro-oncogenic properties in NSCLC by activating Thr-183-autophosphorylated JNK2. Targeting this pathway may reduce or block lung tumor progression and/or metastasis.
DNMT1 is involved in esophageal squamous cell carcinoma (ESCC) and self-renewal ability of ESCC-cancer stem cells. Yining Teng, Xiyi Gu, Yin Yuan, Lipeing Guo, Wei Jiang, Shih-Hsin Lu. National Cancer Center/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China.

DNA methylation mediated by DNA methyltransferase 1 (DNMT1) plays an important role in carcinogenesis and self-renewal ability of cancer stem cells (CSCs). However, the function of DNMT1 in esophageal squamous cell carcinoma (ESCC) carcinogenesis, especially self-renewal ability of ESCC-CSCs remains unclear. In this study, we found a high expression of DNMT1 in both side population (SP) cells and sphere formation cells that represented as substitutes for CSCs in KYSE150 and EC109 ESCC cell lines. In addition, the expression of DNMT1 was decreased during the differentiation from SP to None-SP (NSP) in these ESCC cells. These results suggested that DNMT1 might have a role in regulating self-renewal and/or differentiation of ESCC-CSCs. To further investigate DNMT1 in ESCC carcinogenesis and self-renewal ability of ESCC-CSCs, we silenced the expression of DNMT1 in KYSE150 and EC109 ESCC cells using lentivirus-mediated RNA interference (RNAi). Our results showed that ablation of DNMT1 expression in KYSE150 and EC109 ESCC cells resulted in decreased their CSCs by SP analysis and sphere formation assay. Meanwhile, ablation of DNMT1 expression inhibited malignant phenotypes in KYSE150 and EC109 cells, including cell proliferation, colony formation, migration and drug resistance abilities. Treatment of 5-aza-2′-deoxycytidine (5-aza-dC), a DNMT inhibitor that led to the degradation of DNMT1 protein by proteasome, revealed that numbers of CSCs and the malignant phenotypes of KYSE150 and EC109 ESCC cells were repressed significantly, including a dramatic inhibition of self-renewal ability of these ESCC-CSCs. Thus, our results indicated that DNMT1 is involved in ESCC carcinogenesis, especially in the maintenance of ESCC-CSCs, suggesting that DNMT1 could be a potential target for ESCC, especially ESCC-CSCs, therapy.
ous lung metastases resulting in increased survival. CCR10 and its ligands were down-regulated on ALDHhigh D5 CSCs and in lung tissues respectively in animals subjected to ALDHhigh D5 CSC-DC vaccination. Down-regulation of CCR10 by siRNA significantly blocked tumor cell migration in vitro and metastasis in vivo. T cells harvested from ALDHhigh D5 CSC-DC vaccinated animals selectively killed ALDHhigh D5 CSCs as well as the immunolabeled targeting of CSCs. As a result, CSC-DC vaccination significantly decreased the percentage of ALDHhigh cells in residual tumors. These data indicate that, when used in an adjuvant setting, ALDHhigh CSC-DC vaccines effectively inhibit local tumor recurrence, reduce spontaneous lung metastasis, and prolong animal survival; compared with traditional DC vaccines and that simultaneous PD-L1 blockade can significantly enhance this effect.

class of testis-derived proteins which are only expressed in germ cell tumors.
tissues. Thus, SPANX may serve as a selective marker for targeting CSCs. In addition, we demonstrate a functional role for SPANX in mediating CSC phenotype. Knockdown of SPANX decreased the percent of CD24low+ CSCs in TNBC. It also attenuated the proliferation, migration and invasion of CD24+ cells. Radiation treatment increased SPANX expression levels and enriched for SPANX+ cells. Loss of SPANX resulted in decreased number of CD24+ cells after radiation treatment. Hence, we show that SPANX may be promoters of the most aggressive CSC subset of TNBC. Since SPANX is highly immunogenic, our data provide rationale for further testing of combined radiation and immunotherapy approaches in the treatment of this deadly cancer. It also supports the use of protective and therapeutic SPANX vaccines against the most aggressive CSC subset in TNBC.

#1907 Identification of a cancer stem cell-specific function for the histone deacetylases HDAC1 and HDAC7 in breast and ovarian cancer. Abigail E. Witz,1 Corrado Caslini,2 Chung-Wei Lee,2 Tong Iln Lee,3 Diana J. Azzam,3 Bing Wang,4 Fabio Petrocca,5 James Grosso,1 Michelle Jones,1 Evan B. Cohick,2 Adrienne B. Gropper,4 Claes Wahlstedt,4 Andrea L. Richardson,5 Ramin Shiekhattar,6 Richard A. Young,1 Tan A. Tumors are comprised of a highly heterogeneous population of cells, of which only a small subset of stem-like cells possess the ability to regenerates tumors in vivo. These cancer-stem-cells (CSCs) represent a significant clinical challenge as they are resistant to conventional cancer therapies and play essential roles in metastasis and tumor relapse. Multiple signaling pathways involved in the regulation of CSCs have been identified. However, the regulation of CSCs is unlikely the reversible short-term changes in cellular phenotype induced by various extracellular factors, or the permanent changes induced by mutations. The hierarchical differentiation of CSCs to non-stem-tumor-cells (nTCs) is long-lasting over many cell generations but it is also reversible, that is more akin to tissue differentiation of CSCs to non-stem-tumor-cells (nsTCs) is long-lasting over many cell generations but it is also reversible, that is more akin to tissue differentiation. In particular, FGFR1 and FGFR2, which are found in cancer stem cells (CSCs) are sub-population of cells that bear stem-like properties, and are believed to contribute in tissue initiation and recurrence in tumor microenvironment. Understanding role of CSCs in tumorigenesis was limited to immunocompromised nude/SCID mouse models, and should be investigated in immunocompetent mouse model(s) representing clinical conditions. In this study, we have investigated and confirmed CSCs properties in HCC cells lines, and (2) investigated tumor initiation capability of EpCAM positive CSCs in novel immunocompetent mouse model of HCC. Methods: In vitro CSC enrichment was achieved by treating murine (Hepa-1-6) and human (HepG2, Hep3B) HCC cells in serum-free condition. To confirm CSCs, we analyzed CSC biomarkers (EpCAM,CD90,CD44,CD133) using flow-cytometry and Immunocytochemistry (ICC), and functional markers using Aldolase assay and Hoechst-33342 efflux. Drug resistance property of CSCs was studied using Doxorubicin (anthracycline antibiotic) and Sorafenib (multikinase inhibitor) by MTT assay. To study in vivo tumorigenesis, immunocompetent mouse model was established using C57/LI mouse andcopGFP expressing Hepa-1-6 cells. Capability of EpCAM CSCs for tumor initiation was tested in 3 diet induced groups, i.e. control (10% dietary fat), high-fat (60% dietary fat), and NASH (60% dietary fat MCD diet with 0.1% methionine). 2 million FACS sorted EpCAM+/- or EpCAM-/- cells were orthotypically injected into left liver lob. Tumor growth was monitored using high-frequency ultrasound and animals were euthanized after 18 days. Histology and ICC analysis was performed to confirm the tumors and findings. Results: Spheroid forming HCC-CSCs showed significantly higher EpCAM expression and significant higher chemoresistance compared with control HCC cells in vivo findings confirmed that EpCAM+ CSCs required NASH microenvironment. In NASH group mice, EpCAM+/- CSCs have shown significant tumorigenesis compared with no tumors in EpCAM-/- (n=9, p<0.005). Histology analysis of NASH liver tissue confirmed lobular and portal inflammation, hepatocellular ballooning, and fibrosis. Con-
trol and high-fat diet group mice failed to develop tumors. Conclusions: We have developed a novel mouse model to study CSCs to overcome confounding limitations of immunocompromised mouse models for testing functional immune system components. Our findings using immunocompetent mouse model suggest that, in HCC, (1) EpCAM + CSCs cannot initiate tumor by itself within normal liver microenvironment in the presence of functional immune components, (2) NASH microenvironment promotes EpCAM + CSCs mediated tumorigenesis while EpCAM/- non-CSCs subset failed to develop tumor.

#1910 NF-kappaB classical versus alternative pathways support distinct populations of ovarian cancer tumor-initiating cells. Carrie D. House, Christina M. Annunziata. National Cancer Institute, Bethesda, MD.

Ovarian cancer is the most lethal gynecological malignancy in the United States with high morbidity and mortality due to recurrence and chemoresistance. Our data suggest tumor-initiating cells (TICs) play an important role in disease biology. We previously showed that a subset of ovarian cancer cells depends on NF-kappaB signaling, and that expression of NF-kappaB proteins is associated with poor survival. Given that NF-kappaB expression correlates with a poor outcome in ovarian cancer, and NF-kappaB activity supports drug resistance and tumorigenicity, we hypothesize that NF-kappaB supports a TIC program responsible for ovarian cancer relapse. To investigate this pathway in TICs, we designed a novel method to enrich for TICs from cell lines and patient samples by culturing non-adherent, floating cells in stem cell conditions defined by low attachment flasks and serum free media. Preliminary data confirm that these cells have higher stem cell marker expression, are chemoresistant, and are more tumorigenic in nude mice compared to their adherent counterparts. These TIC enriched culture conditions enhance NF-kappaB expression and activity. More specifically, alternative NF-kappaB signaling through the RelB transcription factor supports TIC populations by regulating aldehyde dehydrogenase (ALDH), an enzyme with high activity in TICs. Using an inducible shRNA targeting RelB we show that spheroïd formation, ALDH expression and activity, chemoresistance, and tumorigenesis in both subcutaneous and intrabursal xenograft models, significantly decreased in the absence of RelB. Interestingly, loss of classical NF-kappaB signaling, through a shRNA targeting the RelA transcription factor, was less effective in targeting TICs, but more effective at targeting a proliferative subpopulation with high Ki67 staining. We conclude that classical and alternative NF-kappaB signaling support ovarian tumor cells with distinct phenotypes and the collaboration of these pathways may be critical for supporting tumor repopulation following chemotherapy. Current studies will measure system level changes induced by these shRNAs, and identify a gene signature specific to each NF-kappaB pathway in ovarian TICs. Clarifying the nuances of NF-kappaB signaling in TICs will increase our understanding of ovarian cancer recurrence and further focus therapeutic strategies to prevent relapse.

Intestinal colorectal cancer (CRC) is the third most common cancer diagnosed in both men and women. Dysregulation of the WNT/β-catenin pathway is the most commonly mutated pathway in CRC. R-spondins (RSPO), a family of secreted proteins, are enhancers of WNT signaling. More specifically, alternative NF-kappaB signaling through the RelB transcription factor supports TIC populations by regulating aldehyde dehydrogenase (ALDH), an enzyme with high activity in TICs. Using an inducible shRNA targeting RelB we show that spheroïd formation, ALDH expression and activity, chemoresistance, and tumorigenesis in both subcutaneous and intrabursal xenograft models, significantly decreased in the absence of RelB. Interestingly, loss of classical NF-kappaB signaling, through a shRNA targeting the RelA transcription factor, was less effective in targeting TICs, but more effective at targeting a proliferative subpopulation with high Ki67 staining. We conclude that classical and alternative NF-kappaB signaling support ovarian tumor cells with distinct phenotypes and the collaboration of these pathways may be critical for supporting tumor repopulation following chemotherapy. Current studies will measure system level changes induced by these shRNAs, and identify a gene signature specific to each NF-kappaB pathway in ovarian TICs. Clarifying the nuances of NF-kappaB signaling in TICs will increase our understanding of ovarian cancer recurrence and further focus therapeutic strategies to prevent relapse.

#1912 Actn4, a novel therapeutic target of dietary ellagic acid, promotes breast cancer metastasis via mediating cancer stem cells. Neng Wang,1 Zhiyu Wang,2 Xiaoming Xie,1 Sun Yat-sen University Cancer Center; University of Guangzhou Traditional Chinese Medicine, Guangzhou, China; #1913 SOX9 regulates cancer stem-like cells in non-small cell lung cancer. Muhammad Yousaf,1 Sudjit Luanpitpong,2 Heimo Riedel,1 Yon Rojanasakul1. 1West Virginia University, Morgantown, WV; 2Mahidol University, Bangkok, Thailand.

Lung cancer is the leading cause of cancer death worldwide in both men and women, every year killing more people than breast, prostate and colon cancers combined. Drug/radiation resistance and tumor relapse contribute to low patient survival, which has largely been attributed to the acquisition of stem-like cells (CSCs), or tumor initiating cells. Moreover, conventional therapies are not effective against CSCs. This signifies the need to identify mechanisms of CSC regulation which could lead to the discovery of CSC-specific drug targets and the development of more effective drug therapies. An embryonic transcription factor SOX9 has been implicated in CSC regulation in a number of cancer types, but little is known about its role in non-small cell lung cancer (NSCLC). We demonstrated that high SOX9 expression correlates with poor survival in lung cancer patients by analyzing The Cancer Genome Atlas (TCGA) data. We hypothesized that SOX9 has a key role in tumor progression and chemoresistance by up-regulating CSCs in NSCLC. To test this hypothesis, SOX9 expression was stably or transiently knocked down in NSCLC cells, and their effects on CSC formation and biomarkers, and on drug resistance were investigated. Our results showed that SOX9 knockdown decreased the number of tumor spheres in NSCLC cell lines. Furthermore, SOX9 knockdown downregulated the expression and activity of stem cell marker ALDH1A1 as determined by Western blot and flow cytometric assays. Consistent with this finding, overexpression of SOX9 in non-
TUMOR BIOLOGY: Normal and Neoplastic Stem Cells

cancer lung epithelial Beas-2B cells elevated tumor sphere formation, supporting the role of SOX9 in CSC regulation. Analysis of the soft agar colony formation assay further showed that SOX9 knockdown inhibited anchorage-independent growth in NSCLC cells. More importantly, SOX9 knockdown resulted in an increased sensitivity of the cells to a chemotherapeutic drug cisplatin, with SOX9 knockdown expressing a significantly increased sensitivity. These results indicate an important role of SOX9 in the regulation of CSCs in NSCLC and suggest its potential utility as a drug target for chemoresistant lung cancer.

#1914 GNS561 is a new quinoline derivative with high efficacy on cancer stem cells from colorectal liver metastasis and hepatocellular carcinoma.

Pirsa Bassi,1 Elena Patricia Gifu,2 Sonia Brun,3 Jerome Courcambeck,1 Antoine Beret,1 Jean Marc Pascussi,3 Julie Pannequin,3 Eric Raymond,1 Philippe Hallon,1 Philippe Merle,1 Claude Caron de Fremontel,1 Genovoxis Pharma, Marseille, France; CRCL, INSERM U1052 - CNRS 5286, Université Lyon 1 - Centre Léon Bérard, Lyon, France; *Institut de Génomique Fonctionnelle (IGF), Montpellier, France; CRCL, INSERM U1052 - CNRS 5286, Université Lyon 1 - Centre Léon Bérard, Hospices Civils de Lyon, Lyon, France.

Background: In spite of wide application of sorafenib for advanced hepatocellular carcinoma (HCC) treatment, and systemic chemotherapy cocktails (5-fluorouracil, irinotecan, and oxaliplatin) for metastatic colorectal cancer, the prognostic for both cancers remains poor. In recent years, highly tumorigenic sub-populations of cancer cells named Cancer Stem Cells (CSCs) have been claimed as responsible of some tumor recurrences. Indeed, CSCs are resistant to chemotherapy, and they have the ability to regenerate all the tumor bulk with its heterogeneous latter generations. For this reason, new drugs with original mechanism of action which target CSC properties would likely improve cancer treatment Material and methods: Antitumor activity of GNS561 was tested on a panel of cancer cell lines and primary tumors. GNS561 impact on CSCs subpopulation in patient derived cells from colorectal hepatic metastatic tumors was assessed by flow cytometry (ALDH activity). In HCC, the effect of this drug was evaluated by sphere formation assay as readout to estimate CSC survival. Tolerance and plasma and liver pharmacokinetic were evaluated after single and repeated dosing in mice and rats. In vivo GNS561 activity was tested in orthotopic mouse model Results: GNS561 demonstrated multiple cellular effects such as induction of autophagy, induction of apoptosis and cell cycle modulation. It showed antitumor activity against several human cancer cell lines. Furthermore, GNS561 was effective against a panel of HCC tumors even from patients harboring sorafenib resistance. GNS561 showed nonetheless an original dose-response cytoxic activity against the whole tumor populations but also against a subpopulation displaying high ALDH activity in three CRC patient-derived cell lines established from fresh liver metastasis biopsies. Consequently, on the same model this compound induced a striking decrease of sphere formation. In HCC cell lines GNS561 was seen on both whole populations (mean EC50 2μM) and subpopulations displaying CSC features (Epcam high). In addition, in the opposite of sorafenib, GNS561 decreases the HCC cell capacity to form spheroids. In mouse, GNS561 was found well tolerated and highly selectively trapped in the liver (exposure ratio liver/plasma about 170 animals). In HCC, PDX mouse model, tumor growth was significantly reduced by GNS561 with a dose-response manner, this tumor regression was associated with AFP level decreases (p < 0.002) and 54% with sorafenib (p < 0.046) compared to control Conclusions: GNS561 is a liver selective drug which offers great promise for HCC and liver metastatic tumors treatment. By simultaneously targeting the cancer stem cell subpopulation and tumor bulk, both cell heterogeneity, plasticity and recurrences could be overcome at least in colorectal cancer and HCC. GNS 561 is now aimed to further reach clinical development in patients in 2017.

#1915 Deconstructing cancer stem cells: IL-6, G-CSF and Activin-A as mediators of stroma-orchestrated epithelial cells' dedifferentiation.

Carlos F. Rodrigues,1 Eurico Serrano,2 Marco Cunha,3 Maria I. Patricio,3 Mariana Val,3 João Fonseca,7 Célia Gomes,5 Antero Abrunhosa,6 Filomena Botelho,2 Lina Carvalho,1 Isabel M. Carreira,4 Alpoim Carmen.1 Centro de Neurociências and Cell Biology, Coimbra, Portugal; *Center for Research in Environment, Genetics and Oncobiology (CIMAGO), Coimbra, Portugal; *Nuffield Laboratory of Ophthalmology, NDN & NIHR Oxford Biomedical Research Centre, University of Oxford, Oxford, United Kingdom; 7Cytogenetics and Genomics Laboratory, Faculty of Medicine, University of Coimbra, Coimbra, Portugal; Instituto de Biomedical Imaging and Life Sciences, University of Coimbra, Coimbra, Portugal; Instituto de Nuclear Sciences Applied to Health (ICNANO), Universa, Coimbra, Portugal; Centro Hospitalar Universitário de Coimbra (CHUC), Coimbra, Portugal.

Inter cellular communication in cancer is a deceiving and extremely efficient process through which the corporal machinery is hijacked by a panoply of cellular and molecular strategies turning the entire human body into an evolutionary arena. The extensive crosstalk mediated by cytokines and chemokines overcome the inefficiency of the invasion-metastasis cascade, thus allowing the development of the often-fatal metastatic disease. Cancer stem cells (CSCs) have recently been implicated in major steps of the tumorogenic process, namely in tumor initiation, metastasis formation and tumor relapse following therapy. Yet, despite their relevance, the orchestrated interactions of the intercellular communication process are still unclear. After observing that the malignant human bronchial epithelial RenG2 cells differentiated following culture in the subcutaneous mouse lumbar region, co-cultures of surgically isolated mice lumbar stromal cells with RenG2 cells were established and the conditioned media studied by multiplex and ELISA. Consequently, Interleukin-6 (IL-6), Granulocyte colony-stimulating factor (G-CSF) and Activin-A were identified as the characteristic mediators of the intercellular communication process. Aiming to ascertain the individual role of each cytokine in the de-differentiation process, as well as to access the involvement of exosomes as transport vehicle, the same co-cultures were reproduced in the presence of specific cytokine-communication blockers, either individually or in combinations of up to three blockers, and exosome-mediated communication inhibitors. Finally, exosomes were also collected from control co-cultures and their cargo screened for the target cytokines. ELISA showed that the three cytokines were present inside fibroblasts-secreted exosomes. Moreover, whenever exosomes’ release was blocked, dedifferentiation was abrogated, further proving the role of the aforementioned cytokines and of exosomes in the dedifferentiation process. Additionally, the cytokine-blocking experiments revealed that only IL-6 and Activin-A were endowed with the potential to orchestrate de-differentiation, as at least one of these cytokines was a present population developed inside RenG2 cells. Finally, G-CSF appeared to be decisive in maintaining the undifferentiated phenotype, as a larger pool of CSCs was attained whenever this cytokine and either IL-6 or Activin-A were present. Altogether the attained results implicated IL-6 and Activin-A in the formation of CSCs by de-differentiation, and G-CSF as a potent keeper of the dedifferentiation status. Subsequent studies are now needed to look into the use of these cytokines as therapeutic targets so the tumorigenic process may be abrogated in its initial steps, improving patients’ prognosis and survival. Work sponsored by FEDER, POFC-COMPETE and the FCT grants PTDC/BBB-BQB/2450/2012 and SFRH/BD/33884/2009.

#1916 Peptidylarginine deiminase IV (PADI4) is a novel tumor suppressor that may contribute to regulation of breast cancer stem cell dynamics.

Nellei Moskovich.1 NCITheodosia, MD.

Breast cancer is a global problem that accounts for almost a fourth of all cancers in women. Despite the many therapeutic strategies currently in use, treated patients often suffer from cancer relapse and metastasis due to the presence of a subpopulation of tumorigenic cells capable of self-renewal and termed cancer stem cells (CSCs). To address the properties of this critical sub-population, we utilized our recently developed lentiviral CSC reporter carrying an Oct/ Sox2 response element coupled to a green fluorescent protein (SORE6-GFP) to detect and isolate the CSC population in a low-grade ER+ human breast cancer model, MCF10Ca1h, by FACS. Whole transcriptome sequencing analysis (RNA-seq) on the sorted cells identified Peptidylarginine deiminase IV (PADI4) as differentially expressed between CSCs and non-CSCs. PADI4 was recently shown to regulate citrullination of histone H1, displacing it from chromatin and resulting in global chromatin decondensation and pluripotency in Inhibition was observed in luminal breast cancer. In support of this conclusion, deep deletions of PADI4 were found in luminal breast cancer. In breast cancer CSCs, likely through effects on chromatin structure. We showed PADI4KD. Our findings suggest that PADI4 may function as a tumor suppressor in breast cancer CSCs, likely through effects on chromatin structure. We showed that PADI4 expression is higher in luminal breast cancer cell lines than other subtypes, and we did shRNA knockdown (KD) of PADI4 in the luminal MCF10Ca1h model. PADI4 KD increased tumourosphere formation and clonogenicity indicating increased CSC population/activity. Additionally, MCF10Ca1h cells treated with a PADI4 selective inhibitor showed an increase in CSCs as assessed using the SORE6-GFP stem cell reporter. In vivo limiting dilution studies demonstrate that PADI4 KD increased tumor incidence at low cell inoculum, reflecting a statistically significant 2-4 fold increase in CSCs upon PADI4 KD. Our findings suggest that PADI4 may function as a tumor suppressor in luminal breast cancer. In support of this conclusion, deep deletions of PADI4 locus are found in 1% of human breast cancers in the TCGA datasets. Analysis of the effect of PADI4 KD on chromatin organization in the CSC and non-CSC compartments is ongoing.

#1917 AXL inhibition in ovarian cancer stem-like cells increases chemosensitivity.

Jin-Young Kim, Hyewon Chung, So-Jin Shin, Eunyoung Ha, Chihyun Cho. Keimyung University School of Medicine, Daegu, Republic of Korea.

Cancer stem-like cells (CSCs), a small population of cancer cells with regenerative potential, may lead to the initiation and progression of secondary tumors. Long-term chemotherapeutic drug treatment can also result in the gen-
eration of a drug resistant population of cancer stem cells. In this study we have isolated CD44+ and CD117+ enriched ovarian cancer stem-like cells from primary cultured ascites cells removed from ascites fluid of naïve ovarian cancer patients. AXL, a type I receptor tyrosine kinase family member, is found to be over-expressed in ovarian cancer stem-like cells. Cell viability assays showed that over-expression of AXL was strongly associated with increased cell viability. PI3-kinase/Akt signaling pathway has also been shown to be involved in decreases the cell viability during the inhibition of AXL. This study establishes the role of AXL, a receptor tyrosine kinase, as one of the key factors in decreasing the cell viability during the inhibition of AXL. In conclusion, this study shows that silencing of Twist1 greatly diminishes the tumor sphere-forming potential of breast CSCs. Furthermore, limited dilution assays and stem cell xenotransplantation reveal that knockdown of Twist1 expression decreases the frequencies of CSCs by 72-fold in human TNBC cells. More importantly, we show that silencing of Twist1 blocks Taxol-induced CSC enrichment in residual tumor cells that have survived drug treatment. Together, these results demonstrate a previously unrecognized role for Twist1 in mediating Taxol-induced CSC enrichment in residual tumor cells. Our results strongly support that targeting Twist1 signaling pathway may represent a novel therapeutic strategy to tackle therapy-induced CSC enrichment in breast cancer treatment.

#1918 Gene characterization of lung-tumorspheres for their usage as an in vitro screening platform for testing new therapeutic strategies. Alejandro Herreros-Pomares,1 Ester Munera-Maravilla,1 Silvia Calabuig-Fariñas,2 RutLucas,2 Rosa Farráns,1 Ana Blascoa,1 Susana Torresa,1 Jose Ferria,1 Ricardo Guijarro,1 Miguel Martorell,1 Eileis Jantus-Lewintre,1 Camps Carlos,1 Molecular Oncology Laboratory, General University Hospital of Valencia Research Foundation, Valencia, Spain;2Molecular Oncology Laboratory, General University Hospital of Valencia Research Foundation; Department of Pathology, Universidad de Valencia, Valencia, Spain;3Department of Oncogenic signalling Laboratory, Centro de Investigación Príncipe Felipe, Valencia, Spain;4Department of Medical Oncology, General University Hospital of Valencia, Valencia, Spain;5Department of Pathology, General University Hospital of Valencia, Valencia, Spain;6Department of Pathology, Universidad de Valencia, Valencia, Spain;7Department of Oncology Laboratory, General University Hospital of Valencia Research Foundation; Department of Biotechnology, Universidad Politécnica de Valencia, Valencia, Spain;8Molecular Oncology Laboratory, General University Hospital of Valencia Research Foundation, Department of Medicine, Universitat de Valencia. Department of Medical Oncology, General University Hospital of Valencia, Valencia, Spain.

Background: Lung cancer features like treatment resistance or tumor relapse have been linked to cancer stem cells (CSCs), a population of cells with self-renewal properties, and the ability to grow forming tumorspheres in non-adherent conditions. The aim of this study was to isolate and characterize tumorspheres from lung cancer cell lines and tumor tissue from resectable non-small cell lung cancer (NSCLC) patients and to use them as an in vitro platform for drug screening. Methods: This study was performed on cells from seven NSCLC tumor samples and five cell lines (H1650, H1993, H1395, A549 and PC9) grown in monolayer and as spheroids. The expression of 60 genes, including CSC-markers, pluripotency inducers, cell cycle regulators, invasion promoters and markers of Notch, Wnt and Hedgehog pathways were assayed by qRT-PCR. Drugs commonly used in clinical guidelines (Cisplatin, Paclitaxel, Erlotinib, Gefitinib, Erlotinib, Afatinib, Pemetrexed and Vinorelbine) and specific inhibitors of Wnt and Hedgehog pathways (Iwp2, Xav939, LDE225 and Vismodegib and Saliymin) were tested in triplicates at 4 different concentrations. Cell viability was measured after 48h and 72h using MTS assay, normalized to the respective mock-treated control cells and presented as percentage of control. Statistical analyses were considered significant at p<0.05. Results: Lung tumorspheres had significant increased expression of CSC-related genes EPCAM1, CD44, CCND1, KLF4 and CDKN1A, compared to their paired-adherent cells. Likewise, epithelial to mesenchymal transition (EMT) inducer SNAI1 and integrin ITGA6 were overexpressed in spheroids too. Regarding stemness pathway, Notch pathway ligands JAG1 and DLL4 and receptors NOTCH1, NOTCH2 and NOTCH3 showed higher expression in lungospheres. In Wnt pathway, higher expression levels of WNT3, CTNNB1 and GSK3β were found in tumorspheres. No significant differences were found for the rest of genes. Drugs screening showed classical anticancer drugs, such as Cisplatin, Vinorelbine or Pemetrexed, had mild cytotoxic effects on lungospheres, obtaining significant differences in the expression of some targets. Conversely, inhibitors Iwp2, Xav939, Salminomycin and Vismodegib showed higher cytotoxic effects on spheroids than in cells grown in monolayers. Conclusions: Lung tumorspheres derived from cancer cell lines and primary tumor tissues show increased levels of CSC markers and components of Notch and Wnt signaling pathways compared to the cells grown in adherence. Spheroids showed resistance to classical anticancer drugs, and a greater response to inhibitors of Notch, Wnt and Hedgehog pathways, strengthening its possible use as a short-term culture platform for a simple, and cost-effective screening to investigate novel therapeutic approaches. Supported by grants RD12/0036/0025 from RTICC-FEDER, PI12-02838/P115-00753 from ISCIII and SEOM/2012.

#1919 Twist1 modulates paclitaxel-induced cancer stem cell enrichment in triple-negative breast cancer. Aimin Yang, Xiaoyuan He, Bradley A. Schulte, Steven L. Carroll, Stephen P. Ether, Gavin Y. Wang. Medical University of South Carolina, Charleston, SC.

Triple-negative breast cancer (TNBC), the most aggressive subtype of breast cancer, is highly refractory to chemotherapy and has a high incidence of metastasis and tumor relapse. Targeted therapies for TNBC do not exist because this subtype lacks drugable hormone receptors and HER2 amplification or overexpression. Although Taxane-based chemotherapy is a standard of care for TNBC treatment, paclitaxel (Taxol)-induced cancer stem cell (CSC) enrichment presents a significant challenge to the success of breast cancer treatment. Thus, there is a critical need to understand the mechanisms by which chemotherapy induces CSC enrichment in residual tumors following anticancer therapies. Here we report that Taxol-induced enrichment for CSCs correlates well with a marked upregulation of Twist1 expression in human TNBC cells. Knockdown of Twist1 inhibits the clonogenic capacity of TNBC cells in vitro and TNBC tumorigenesis in vivo. Mammosphere formation assays indicate that silencing of Twist1 greatly diminishes the tumor sphere-forming potential of breast CSCs. Furthermore, limited dilution assays using stem cell xenotransplantation reveal that knockdown of Twist1 expression decreases the frequency of CSCs by 72-fold in human TNBC cells. More importantly, we show that silencing of Twist1 blocks Taxol-induced CSC enrichment in residual tumor cells that have survived drug treatment. Together, these results demonstrate a previously unrecognized role for Twist1 in mediating Taxol-induced CSC enrichment in residual tumor cells. Our results strongly support that targeting Twist1 signaling pathway may represent a novel therapeutic strategy to tackle therapy-induced CSC enrichment in breast cancer treatment.

#1920 Prostaglandin E2 accumulation enhances the expansion of ALDH1-positive cells and Kras-driven tumorigenesis in the pancreas. Koteru Arima,1 Takatsugu Ishimoto,1 Masaki Ohmuraya,2 Reiko Miyake1, Tsugio Eto1, Hirohisa Okabe,1 Yuki Kitan,1 Kunsuke Yamamura,1 Takayoshi Kaida,3 Katsunori Imai,1 Daisuke Hashimoto,1 Akira Chikamot,1 Hideo Baba1.

Background: Chronic inflammation is known to be a risk factor of carcinogenesis and tumor development, and it was demonstrated that oral aspirin reduced cancer-related death including pancreatic ductal adenocarcinoma (PDAC) through inhibiting prostaglandin synthases. On the other hand, cancer stem cells (CSCs) refer to a subset of tumor cells that have self-renewal ability and generate plenty of non-CSC that comprise a tumor. Prostaglandin E2 (PGE2) and inhibition of 15-PGDH, which is an enzyme degrading PGE2, promoted hematopoietic and tissue stem cell fraction, however, little is known about the role of PGE2 accumulation for CSC fraction. A number of CSC marker candidates have been explored to date, and Aldehyde dehydrogenase 1 (ALDH1) was identified as one of CSC markers in PDAC. The aim of this study is to elucidate the functional role of PGE2 in ALDH1 positive CSC fraction during tumor development in pancreas. Methods: The clonogenic growth potential of ALDH1-positive CSCs and that of PGE2 was analyzed by growth assays and sphere formation assays. We next investigated the expression of ALDH1 and self-renewal related genes in PDAC cell lines with PGE2 or 15-PGDH inhibitor treatment. We further conducted functional experiments using sALDH1 in PDAC progression. Furthermore, we examined the effect of PGE2 for pancreatic tumorigenesis using Kras-driven genetic mouse model treated with 15-PGDH inhibitor. Finally, ALDH1 and Ki67 expression was examined by immunohistochemistry in 121 primary surgical specimens of PDAC and analyzed a relationship with clinicopathological factors and clinical outcomes. Results: The number of ALDH1-positive cells was significantly increased by PGE2 treatment, and PGE2 promoted growth and sphere formation potential in PDAC cells. In addition, 15-PGDH inhibitor induced PGE2 accumulation and gave rise to ALDH1-positive cells harboring high proliferating potential in PDAC cells. The growth and sphere formation potential were inhibited by silencing ALDH1 expression in PDAC cells. We next found that the expression of Nanog and Oct-4 genes was regulated by PGE2-ALDH1 signaling. Furthermore, 15-PGDH inhibitor induced ALDH1 expression and promoted PanIN formation in Kras-driven genetic mouse model. Finally, a high level of ALDH1 expression was significantly associated with large tumor size and high Ki67 expression, and poor prognosis in PDAC patients. Conclusion: Current findings suggested that PGE2 positively regulated ALDH1 expression, and the growth and sphere formation potential were promoted by regulating self-renewal related genes expression, resulting in poor prognosis of PDAC patients. Inhibiting PGE2-ALDH1 signaling could lead to the suppression of tumor growth in PDAC patients.

#1921 Stem-like clusters of CD44+ circulating tumor cells seed metastases in breast cancer. Xia Liu, Wenjing Chen, Rokana Taftaf, Huiping Liu. Case Western Reserve Univ., Cleveland, OH.

Background: Circulating tumor cells (CTCs) are cells shed from primary tumor and circulate in the peripheral blood. They are considered the seeds of metastasis. Compared to single CTCs, clusters of multiple CTCs possess 50 times higher metastatic capacity in mouse breast cancer models. However, the mechanisms underlying the metastatic promotion effect of CTC clusters are unclear. Better understanding of CTC clusters properties and what stem cell markers they express have not been determined. Methods: Immunohistochemistry (IHC) was used to detect CTCs in vascular structures, and the stem cell markers in single and clustered CTCs. Lung metastases were either monitored by bioluminescence imaging (BLI) or visualized by fluorescence microscopy. Stem cell properties were examined by cell proliferation in vitro and in vivo. Clustering assay was performed by culturing cells in Poly-HEMA coated plates (for cell lines) or collagen-coated plates (for primary cells derived from patient-derived breast tumor xenografts, PDXs), and then monitored by IncuCyte live cell dynamic imaging. Results: CD44+ enriched circulating tumor cell (CTC) clusters were found in the lung/liver vascular structures in vivo in both metastatic breast cancer patients and PDXs that develop spontaneous lung metastases. Comparing to single CD44+ cells, clustered CD44+ cells formed more mamospheres, increased tumorigenic potential, and promoted lung colonization. Combining siRNA-mediated knockdown and CRISPR/Cas-based knockdout, we found that CD44 is required for breast tumor cell cluster formation and lung colonization upon tail vein seeding. During CD44 knockdout, CD44+ cells were arrested in S phase in vitro, and survival of clustered CTCs. Anti-EGFR antibody mimicked CD44 knockdown to inhibit cluster formation of PDX-derived tumor cells. Administration of EGFR inhibitor Erlotinib efficiently inhibited CD44+ cells-mediated spontaneous metastases to the lungs without affecting primary tumor growth. Conclusions: Our data provide new insights into the cellular and molecular mechanisms of stem-like clustered CD44+ cells-seeded metastasis, and implicate that targeting CD44+ CTC clusters by inhibition of EGFR activity could be a new therapeutic strategy to treat metastatic breast cancer.

#1922 S-SHIP promoter expression identifies a putative cancer stem cell population in C3(1)/Tag murine mammary tumors. Lu Tian,1 Chann Lagadec,2 Eric Adriaenssens,3 Emmanuel Bouchaert,2 Hélène Bauderlique-Le Roy,3 Xufen Lebourhis,3 Roland P. Burette1.1 CNRS UMR 8161 - Institut de Biologie de Lille - SPE5 team, Lille, France; 2Cell Plasticity and Cancer - Insereh U989 - Université Lille 1, Lille, France; 3Plateforme des modèles animaux du SIRICON-Lille, Oncovet Clinical Research, Lille, France; 4BioImaging Center Lille Nord de France - Institut Pasteur de Lille, Lille, France.

Breast cancer is the most common cancer in women worldwide. The isolation and characterization of breast cancer stem cells (CSC) are crucial for understanding cancer biology and revealing potential therapeutic targets. One of the major issues in the study of CSCs is the lack of reliable markers. A transgenic mouse model (Tg 11.5kb–GFP) was generated using the 11.5kb s-SHIP (stem-SH2-containing 5'-Inositol Phosphatase) promoter that specifies expression in mammary gland epithelial cells. We have established a label-free, combined chemical and functional selection strategy that is not accurately performed in conventional 2D cell culture and is inhibited by both cost and time in patient-derived xenografts (PDX).

#1923 Paired isolation and expansion of CSC and CTC from primary small cell lung cancer patient tissue and blood using the 3DKUBE bioreactor platform. Melissa Millard,1 Alina Lotstein,1 Lillia Holmes,1 David Schammel,2 Ki Chung,2 Jeff Edelfien,3 Hal E. Crosswell,1 Tessa Des Rochers1. KITIATEC, Inc., Greenwood, SC; 2Pathology Consultants, Greenville, SC; 3GHS, Greenville, SC.

Surgically resected lung tissue and blood were used for generation of xenografts in the 3DKUBE bioreactor (3DKUBETM). We studied secondary tumors and circulating tumor cells (CTCs) in patient-derived xenografts (PDX) and patients as the majority present with extensive disease at diagnosis. This scarcity of patient samples suitable for research presents a significant road block for the development of SCLC-targeted therapeutics. To address the problem of tissue scarcity, we developed a method for the isolation and expansion of cancer stem cells (CSC) and circulating tumor cells (CTC) from primary tissues and blood of SCLC patients using the 3DKUBE bioreactor. We have established a label-free, combined chemical and functional selection method for the isolation of CSCs from SCLC samples, solid tumor as well as blood, that does not rely upon the bias imposed by marker-based selection. Cells enriched in this manner were further purified and expanded under optimized conditions (growth factors, ECM, scaffolding and oxygen tension) within the 3DKUBE bioreactor. These isolated and expanded CSCs have maintained resistance to cisplatin and etoposide, stabilized the expression of traditional CSC markers, and been validated in vitro through serial spheroid formation assays. These CSCs are currently being characterized and compared to parental tissue through coregicmorphic and phenomic analysis and validated through in vivo tumorigenesis models. These cells will be utilized to generate in vitro models of disease, including drug sensitivity determination that is not accurately performed in conventional 2D cell culture and is inhibited by both cost and time in patient-derived xenografts (PDX).

#1924 Caveolin-1 inhibits mammary carcinogenesis via suppressing c-myc-induced metabolism reprogramming in breast cancer stem cells. Zhiyu Wang,2 Neng Wang,2 Shengqi Wang,1 Yifeng Zheng1, Guangzhou Univ. of Chinese Medicine, Guangzhou, China; Sun Yat Sen University, Guangzhou, China.

Purpose: Caveolin-1 (CAV1), a membrane constituent protein, exhibits tumor suppressor activities in multiple malignancies, whereas the underlying mechanisms remain unclear. The current study aimed to determine the significance of CAV1 in regulating cancer metabolism and its relation to breast cancer stem cells (CSCs). Experimental Design: The anti-carcinogenic function of CAV1 was evaluated by in vitro cell model, CAV1 knockout mice and MMTV-PyMT spontaneous breast cancer xenografts. Glycolysis activity and mitochondrial metabolism were assessed by immunoblotting, oxygen consumption and mitotacker staining analysis. Mammosphere formation, tumorigenic ability, reattachment differentiation and signaling pathways analysis were applied to study the regulation effects of CAV1 on breast CSCs. The clinical significance of CAV1 was also analyzed by human tissue microarray. Results: In both mammary tumorigenic and breast cancer xenografts, CAV1 is found significantly downregulated and positively correlated to increased glycolysis activity and impaired mitochondrial metabolism. CAV1 knockout results in increased ductal hyperplasia, associating with increased stem cell population and glycolysis metabolism. Breast CSCs exhibits glycolytic phenotype and decreased CAV1 expression compared to non-CSC. High expression of CAV1 in mammary and breast cancer xenografts significantly limits CSCs' self-renewal via inhibiting c-myc induced glycolysis. Clinical investigation suggests that high CAV1 expression is revealed with better overall survival and decreased CSCs population. Conclusions: CAV1 loss facilitates mammary carcinogenesis via enhancing glycolytic activity in breast CSCs, and CAV1 based therapy might become a novel strategy for breast cancer prevention.

#1925 Modeling physiologic microenvironments in three-dimensional microtumors facilitates brain tumor initiating cell maintenance. Ashley Gilbert,1 Kiera Walker,1 Anh Tran,2 Yancey Gillespie,2 Raj Singh,2 Anita B. Hjelmeland1. 1Vivo Biosciences, Birmingham, AL; 2Univ. of Alabama at Birmingham, Birmingham, AL.

Development of effective novel anti-tumor treatments will require improved in vitro models that incorporate physiologic microenvironments and maintain intratumoral heterogeneity including tumor initiating cells. Brain tumor initiating cells (BTIC) are a target for cancer therapy because they are highly tumorigenic and contribute to tumor angiogenesis, invasion, and therapeutic resistance. Current leading studies rely on BTIC isolation from patient-derived xenografts followed by propagation as neurospheres. As this process is expensive and time-consuming, we determined whether three-dimensional microtumors were an alternative in vitro method for modeling tumor growth via BTIC maintenance and/or enrichment. Brain tumor cells were grown as neurospheres or as microtumors produced using a human-derived biomatrix HuBioGel® and
maintained with physiologically relevant microenvironments. Percentages of BITCs were determined based on cell surface marker expression (CD133), label retention (carboxyfluorescein succinimidyl ester; CFSE), and tumourosphere formation capacity. Our data demonstrate that expansion of brain tumor cells as hypoxic and nutrient restricted microtumors significantly increased the percentage of BITCs and CFSE+ cells. We further demonstrated that marker positive cells isolated from microtumors maintain neurosphere formation capacity in the in vitro limiting dilution assay and tumorigenic potential in vivo. These data demonstrate that microtumors can be a useful three-dimensional biological model for the study of BTIC maintenance and targeting.

Overview: Head and neck squamous cell carcinomas (HNSCC) are the sixth most prevalent type of malignancy worldwide. Recent reports have demonstrated that nearly every tumor contain a small subpopulation of cells called cancer stem-like cells (CSCs), which are responsible for tumor maintenance, metastasis relapse and therapeutic resistance. Recent studies demonstrate that even established HNSCC cell lines contain a definite sub-population of CSC providing us with the opportunity to discerning their roles in progression, treatment, and relapse of the disease. Background: We have previously demonstrated that a definite subpopulation of CSCs exists in most HNSCC cell lines. Significant differences were seen between the HPV+ and HPV- subtypes, confirmed by analyses of stemness genes and EMT markers. In vivo tumor xenograft formation has established the heightened tumorigenicity of CSCs. We investigated the molecular and functional roles of Beta-catenin in HNSCC CSCs by shRNA knockdown and then subjecting the knocked down (KD) cells to various molecular analysis and in-vivo tumor formations in nude mice. We have also identified SOX2 as a down-stream effector gene that could exert the tumor promoting effects of Beta-catenin. The promoter region of the SOX2 gene was found to contain several putative Beta-catenin binding sites. Methods & Results: After identifying CSCs by in-vitro Sphere Forming (SFA) capabilities and molecular gene signatures, we have knocked down both Beta-catenin and Sox2 in both HPV+ and HPV- HNSCC cell lines (UMSCC47 and UMSCC6). SFA with the Beta-catenin KD-cells depicts a 50% decrease in sphere formation ability. Molecular analyses show lower expression of stemness genes: Sox2 (∼ 3 fold) and Oct4 (∼ 2 fold); metastatic genes: N-cadherin (∼ 2.5 fold), Vimentin (∼ 3 fold), Twist (∼ 4 fold), Snail (∼ 2.5 fold), Slug (∼ 2.5 fold) and Hif-1alpha (∼ 1.5 fold). Two tissue microarrays (TMA) were stained for Oct4, Sox2, and CD44 gene expression by multiplex RNA in situ hybridization. Nearly all tumor cells expressed high levels of aldehyde dehydrogenase (ALDH) and CD44 are critical for metastasis. These ALDH+/CD44+ cells preferentially migrate and/or metastasize to the lung and bone microenvironments, where secondary tumours can severely impede organ function. However, the specific role of the lung and bone marrow (BM) microenvironments in supporting and/or promoting metastasis of ALDH+/CD44+ cells remains poorly understood, and this is the purpose of the current study. Using a 2D ex vivo model, lung and bone marrow (BM) conditioned media (CM) enriched in tissue-specific soluble proteins were generated from murine tissues and utilized in cell culture to assess their ability to influence the stem-like phenotype and behavior of MDA-MB-468 human breast cancer cells. Exposure to lung-CM promoted the generation of a viable, non-adherent (‘floating’) breast cancer cell subpopulation that was not observed in response to BM-CM or basal media (p<0.05). Phenotypic analysis by flow cytometry and gene expression analysis by RT-qPCR revealed notable differences in ALDH/CD44+ phenotype in whole cell populations, adherent subpopulations, and/or non-adherent subpopulations in response to 72 hour exposure to lung-CM relative to basal media. In particular, the non-adherent breast cancer cell subpopulation generated in response to lung-CM demonstrated increased CD44 and ALDH1A3 gene expression and decreased ALDH1A1 gene expression relative to the adherent subpopulation (p<0.05). No significant phenotypic or gene expression differences were observed in MDA-MB-468 breast cancer cells in response to BM-CM. Taken together with our previous studies, these findings suggest that while both the lung and bone microenvironments support breast cancer cell growth, the lung microenvironment may additionally help to even further promote stem-like phenotype and behavior in the secondary metastatic site. Ongoing studies are aimed at elucidating the mechanisms by which aggressive ALDH+/CD44+ breast cancer cells interact with and/or are influenced by the lung microenvironment during metastatic progression.

#1927 The significance of calreticulin in pancreatic cancer: a molecule highly expressed in pancreatic cancer stem-like cells. Satoshi Matsukuma,1 Kiyoshi Yoshimura,2 Atsunori Oga,1 Moeko Inoue,1 Takuya Fujimoto, Atsuo Kuramasa, Masanari Fuse,2 Ryuichi Tsunedomi,1 Hideyoshi Eguchi,1 Hiroto Matsui,1 Shinuke Kaneko,1 Yukio Tokumitsu,1 Shinobu Tomochika,1 Michi-hisa Iida,1 Yoshihiro Tokuhisa,1 Kazukiyo Sakamoto,1 Nobuaki Suzuki,1 Tomoko Furuya-Kondo,1 Hiroshi Itoh,1 Shigeru Takeda,1 Shigeru Yamamoto,1 Shigefumi Yoshino,1 Shoichi Hazama,1 Tomio Ueno,1 Hiroaki Nagano1.

1Yamaguchi University Graduate School of Medicine, Ube, Japan; National Cancer Center of Japan, Tokyo, Japan; 2Osaka University Graduate School of Medicine, Suita, Japan; 3Yamaguchi University Graduate School of Medicine, Ube, Japan; 4Yamaguchi University Hospital, Ube, Japan; 5Yamaguchi University Hospital, Ube, Japan.

Cancer stem-like cells (CSCs) in solid tumors are thought to be resistant to conventional chemotherapy or molecular targeting therapy and to contribute to cancer recurrence and metastasis. In this study, we aimed to identify a biomarker of pancreatic CSCs (P-CSCs). P-CSC-enriched population was generated from pancreatic cancer cell lines using our previously reported method and its protein expression profile was compared with that of parental cells by two-dimensional electrophoresis and tandem mass spectrometry. The results indicated that a chaperone protein calreticulin (CRT) was significantly upregulated in P-CSCs compared to parental cells. Flow cytometry analysis demonstrated that CRT was mostly localized to the surface of P-CSCs and did not correlate with the levels of CD44v9, another P-CSC biomarker. Furthermore, the side population in CRTbright/CD44v9low population is much higher than that in CRTlow/CD44v9high population. CRT expression was also assessed by immunohistochemistry in pancreatic cancer tissues (n = 80) obtained after radical resection and was found to be associated with patients’ clinicopathological features and disease outcomes in the Cox’s proportional hazard regression model. Multivariate analysis identified CRT as an independent prognostic factor for pancreatic cancer patients, along with age and post-operative therapy. Our results suggest that CRT can serve as a biomarker of P-CSCs and a prognostic factor associated with poorer survival of pancreatic cancer patients. This novel biomarker can be useful for detecting P-CSCs independently, which had been detectable by multiple surface markers like CD24, CD44 and ESA. We will present P-CSCs properties of CRTbright population in P-CSCs.

#1928 The lung microenvironment promotes stem-like phenotype and behavior of breast cancer cells. Ashkan Sadri, Alison L. Allan. Western University, London, Ontario, Canada.

Ninety percent of breast cancer-related mortalities result from metastasis, a process whereby the primary tumour disseminates and targets distant secondary organs. We have previously demonstrated that stem-like breast cancer cells expressing high levels of aldehyde dehydrogenase (ALDH) and CD44 are critical for metastasis. These ALDH+/CD44+ cells preferentially migrate and/or metastasize to the lung and bone microenvironments, where secondary tumours can severely impede organ function. However, the specific role of the lung and bone marrow (BM) microenvironments in supporting and/or promoting metastasis of ALDH+/CD44+ cells remains poorly understood, and this is the purpose of the current study. Using a 2D ex vivo model, lung and bone marrow (BM) conditioned media (CM) enriched in tissue-specific soluble proteins were generated from murine tissues and utilized in cell culture to assess their ability to influence the stem-like phenotype and behavior of MDA-MB-468 human breast cancer cells. Exposure to lung-CM promoted the generation of a viable, non-adherent (‘floating’) breast cancer cell subpopulation that was not observed in response to BM-CM or basal media (p<0.05). Phenotypic analysis by flow cytometry and gene expression analysis by RT-qPCR revealed notable differences in ALDH/CD44+ phenotype in whole cell populations, adherent subpopulations, and/or non-adherent subpopulations in response to 72 hour exposure to lung-CM relative to basal media. In particular, the non-adherent breast cancer cell subpopulation generated in response to lung-CM demonstrated increased CD44 and ALDH1A3 gene expression and decreased ALDH1A1 gene expression relative to the adherent subpopulation (p<0.05). No significant phenotypic or gene expression differences were observed in MDA-MB-468 breast cancer cells in response to BM-CM. Taken together with our previous studies, these findings suggest that while both the lung and bone microenvironments support breast cancer cell growth, the lung microenvironment may additionally help to even further promote stem-like phenotype and behavior in the secondary metastatic site. Ongoing studies are aimed at elucidating the mechanisms by which aggressive ALDH+/CD44+ breast cancer cells interact with and/or are influenced by the lung microenvironment during metastatic progression.

TUMOR BIOLOGY: Pediatric Cancer 1: Biomarkers, Preclinical Models, and New Targets

#1929 A novel orthotopic mouse model in sarcomas. Silvia Garcia Monclus, Juan Huertas Martinez, Laura Lagares Tena, Santiago Rello Varona, Olga Almacellas Rabaiget, David Herrero Martin, Roser Lopez Alemany, Oscar Martinez Tirado. IDIBELL, Hospital de Llobregat, Spain.

Pediatric sarcomas are a heterogeneous group of bone and soft tissue malignancies affecting children and young adults. One of the most important prognostic factors of those diseases is the presence of metastasis at diagnosis. In that context, we have developed a novel orthotopic model which consists in injecting Ewing Sarcoma (ES) or Rhabdomyosarcoma (RMS) tumor cells in the gastrocnemius muscle of mice and extracting the tumor at a 10 mm x 13 mm volume. After surgery, animals maintain a complete functional extremity and can live until lung metastasis detection (about 60 days post-injection). Moreover, we have validated the suitability of the model with an Ewing Sarcoma EphA2-low expression cell line. EphA2 is a tyrosine kinase receptor that has been found to be highly expressed in a wide variety of tumors and correlated with malignant phenotype. In this study we report that EphA2 receptor is phosphorylated at S897 in a panel of ES cell lines, which is related to the oncogenic properties of the receptor. Stable silencing of EphA2 in two different ES cell lines resulted in a decrease

Proceedings of the American Association for Cancer Research • Volume 58 • April 2017 495
in the clonogenic, proliferation, migration and invasion capacity in vitro. Moreover, we performed an experimental metastasis assay, injecting tumor cells through the tail vain of mice and observed a reduction in the lung metastasis incidence in EphA2 silenced cells. When we used this new orthotopic metastasis model to validate the impairment in the invasion capacity of EphA2 silenced cells and to use as a base in lung metastasis incidence, indication of the clonogenic role for EphA2 in ES. This novel orthotopic metastasis model is a valuable tool both for the study of spontaneous metastasis and also for evaluating therapeutic index in the onset of metastasis, which can also be applied to the study of other pediatric sarcomas.

#1930 Evaluating the effect of PARP inhibitors in combination with nicotinamide phosphoribosyltransferase inhibitors in Ewing sarcoma. Joshua T. Baumgart,1 Christine Heske,1 Mindy I. Davis,2 Kelli Wilson,2 Xiaoha Zhang,2 Baumann,1 Christine Heske,1 Mindy I. Davis,2 Kelli Wilson,2 Xiaoha Zhang,2 TUMOR BIOLOGY: Pediatric Cancer 1: Biomarkers, Preclinical Models, and New Targets

This new protocol were validated by single cell gene sequencing analysis and osteosarcoma patients using the CSV antibody 84-1. The CTCs captured using asEpCAM because it is only specific to tumor cells and has been demonstrated to have meaningful responses to PARP inhibitors when used as single agents. For this reason, studies combining PARP inhibitors with other agents to enhance their effects in Ewing sarcoma are of particular interest. PARP, an enzyme involved in DNA damage repair, relies on NAD to function. In tumor cells, NAD production occurs primarily through the salvage pathway, in which nicotinamide phosphoribosyltransferase (NAMPT) is the rate-limiting enzyme. Hence, the combination of PARP and NAMPT inhibition would be expected to enhance the activity of PARP inhibition through depletion of cellular NAD. The aim of this study was to assess the synergistic potential of PARP inhibition in combination with NAMPT inhibition in Ewing sarcoma cell lines and xenograft models. Synergistic drug combinations in Ewing sarcoma cells were initially identified using a high-throughput matrix drug screen. In vitro activity was further assessed using proliferation assays of multiple Ewing sarcoma cell lines treated with the PARP inhibitor niraparib and the NAMPT inhibitor GNE-618. In vitro measurement of PAR activity was performed to further understand the mechanism of action of the combination. For in vivo studies, female SCID-beige mice were orthotopically injected with Ewing sarcoma cells and randomized into treatment groups of vehicle, niraparib, GNE-618, or the combination. The initial screen revealed synergy between NAMPT inhibitors and PARP inhibitors using multiple combinations of different agents in each drug class. In vitro assays of the combination of niraparib with GNE-618 confirmed the results of the screen. Assays measuring PAR activity yielded results supporting the hypothesis that dual inhibition of NAMPT and PARP depletes PARP more than PARP inhibitors alone. In vivo studies with short term (5 days) dosing showed no activity of single agent niraparib. In contrast, the combination of niraparib and GNE-618 abolished clonogenicity, clonogenic, proliferation, and migration. However, mice treated with the combination underwent tumor regressions resulting in prolonged survival. When treatments were extended to 2 cycles (5 days each), the effect persisted for longer. Mice tolerated the agents well, with no signs of toxicity. Preclinical data suggest that PARP inhibition in combination with NAMPT inhibition may be a promising therapeutic strategy for Ewing sarcoma patients.

#1931 The first circulating tumor cell detection technique from frozen PBMCs. Heming Li,1 Ihar Singh Battal,2 Xueqing Xia,1 Frank J. Hsu,2 Neeta Somaiah,1 Keila Enitt Torres,1 Ruoyu Wang,3 Shulin Li1.1 National Cancer Institute, Bethesda, MD; 2National Center for Advancing Translational Sciences, Rockville, MD.

Previous research has shown that Ewing sarcoma cells are sensitive to PARP inhibition, but in vivo studies and early phase clinical trials have failed to demonstrate meaningful responses to PARP inhibitors when used as single agents. For this reason, studies combining PARP inhibitors with other agents to enhance their effects in Ewing sarcoma are of particular interest. PARP, an enzyme involved in DNA damage repair, relies on NAD to function. In tumor cells, NAD production occurs primarily through the salvage pathway, in which nicotinamide phosphoribosyltransferase (NAMPT) is the rate-limiting enzyme. Hence, the combination of PARP and NAMPT inhibition would be expected to enhance the activity of PARP inhibition through depletion of cellular NAD. The aim of this study was to assess the synergistic potential of PARP inhibition in combination with NAMPT inhibition in Ewing sarcoma cell lines and xenograft models. Synergistic drug combinations in Ewing sarcoma cells were initially identified using a high-throughput matrix drug screen. In vitro activity was further assessed using proliferation assays of multiple Ewing sarcoma cell lines treated with the PARP inhibitor niraparib and the NAMPT inhibitor GNE-618. In vitro measurement of PAR activity was performed to further understand the mechanism of action of the combination. For in vivo studies, female SCID-beige mice were orthotopically injected with Ewing sarcoma cells and randomized into treatment groups of vehicle, niraparib, GNE-618, or the combination. The initial screen revealed synergy between NAMPT inhibitors and PARP inhibitors using multiple combinations of different agents in each drug class. In vitro assays of the combination of niraparib with GNE-618 confirmed the results of the screen. Assays measuring PAR activity yielded results supporting the hypothesis that dual inhibition of NAMPT and PARP depletes PARP more than PARP inhibitors alone. In vivo studies with short term (5 days) dosing showed no activity of single agent niraparib. In contrast, the combination of niraparib and GNE-618 abolished clonogenicity, clonogenic, proliferation, and migration. However, mice treated with the combination underwent tumor regressions resulting in prolonged survival. When treatments were extended to 2 cycles (5 days each), the effect persisted for longer. Mice tolerated the agents well, with no signs of toxicity. Preclinical data suggest that PARP inhibition in combination with NAMPT inhibition may be a promising therapeutic strategy for Ewing sarcoma patients.

Paediatric glioblastomas (pGBM) are amongst the most common causes of cancer-related deaths in children, and are defined by highly recurrent mutations in H3 histones. Mutations affecting the chromatin remodeling protein ATRX have been reported in 30% of pGBM cases, and are strongly associated with the alternative lengthening of telomeres (ALT) phenotype, but their precise interaction with histone mutations and their role in tumorigenesis remain unclear. We collected sequence data from 262 published and 64 unpublished cases of pGBM and identified somatic ATRX mutations in 54/326 (17%) of cases. ATRX mutations are mainly loss of function mutations, with the majority of frameshift mutations (37/54, 68.5%) found upstream of the helicase domain resulting in truncation of the main functional domain of ATRX. Missense mutations (16/54, 29.6%) reside almost exclusively in the helicase domain (11/54, 20.4%), whereas nonsense mutations are a less common event (7/54, 13%) but present in both the helicase (4/7, 57.1%) and ATRX-defining helicase domains (3/7, 42.9%). ATRX mutations commonly co-occur with H3.3 G34 (16/54) and TP53 (42/54) mutations, and define a subgroup of patients with a longer overall survival (16 months median overall survival in mutant ATRX cases versus 11 months in wild-type ATRX cases, COXPH p = 0.079), though with a greater number of somatic mutations (MWU p = 0.023) and copy number alterations (MWU p = 0.0011) than wild-type cases. We screened a series of 21 primary patient-derived pGBM cell cultures for histone and ATRX mutation status in addition to ATRX protein expression and ALT, and subjected the panel to a high-throughput in vitro cell viability screen of >400 chemotherapeutics and small molecules. We identified a specific genetic dependency for ATRX mutation and sensitivity to distinct PARP inhibitor chemotypes, including olaparib and rucaparib (PARP catalytically trapping PARP inhibitors), and talazoparib (PARP trapper inhibitor). These data were validated using CRISPR-Cas9-engineered ATRX knockout, targeting either the ADD or helicase domain, in SF188 pGBM cells. Gene editing was confirmed by IonTorrent sequencing and Western blot. ATRX mutant clones were also more sensitive to drugs targeting DNA damage response pathways such as bleomycin and mitomycin. Gene expression analysis of ATRX mutant pGBM samples confirmed an intact homologous recombination pathway and overexpression of PARP1, suggesting an underlying mechanism distinct from that observed in BRCA-mutant breast and ovarian cancers. Ongoing work is aimed at unraveling the specific pathways involved, and evaluating the utility of PARP inhibition in orthotopic pGBM xenografts in vivo. These data suggest a synthetic lethality for PARP inhibitors in ATRX-deficient pGBM cells, and may represent a novel therapeutic strategy for these highly aggressive tumours in children.

#1933 Discovery of first-in-class small molecule CD99 inhibitors for targeted therapy of Ewing sarcoma. Haydar Celik,1 Marika Scinder,2 Bess Flaschner,2 Elif Gelmez,2 Nesilhan Kayrakoglu,2 David V. Allegakoen,1 Jeff R. Petro,1 Erin J. Conn,1 Sarah Hour,1 Jenny Han,1 Lalehan Oktay,1 Purushottam B. Tewari,1 Muthu Hayran,2 Maria Cristina Manara,2 Jeffrey A. Toretsky,2 Khatia Scottlandi,1 Aykut Uren,1 Georgeroun University Medical Center, Washington, DC; 2Rizzoli Orthopaedic Institute, Bologna, Italy; 3Hacettepe University, Ankara, Turkey.

Ewing sarcoma (ES) is an aggressive bone and soft tissue malignancy that affects predominantly children and adolescents with a high propensity to metastasize and poor prognosis. CD99 is a transmembrane cell surface protein that is highly expressed on ES cells, and routinely used as a marker for histological diagnosis of ES. We screened small molecule libraries for their binding to recombinant CD99 protein and subsequent selective inhibition of ES cell growth. We identified two structurally similar FDA-approved nucleoside analogues, clofarabine and cladribine that selectively inhibited the growth of ES cells in a panel of 14 ES vs. 28 non-ES cell lines. A significant negative correlation was found in human cell lines between CD99 expression and IC50 values for clofarabine and cladribine. Both drugs inhibited CD99 dimerization and its interaction with downstream signaling components cyclophilin A and PAK-RIs, as well as reduced ROCK2 protein expression and migration in ES cells. A membrane-
impermeable analog of clofarabine showed similar cytotoxicity in ES cells, suggest- ing that it can function through inhibiting CD99 alone without any effect on DNA metabolism. Clofarabine and cladribine led to a significant increase in hypodiploid DNA content of ES cells, which was diminished by suppression of CD99 expression. Both drugs drastically inhibited anchorage-independent growth. The combination of the two drugs was synergistic.

Finally, the screening of a set of chemotherapy drugs revealed a synergy for the combination of anti-CD99 drugs and dasatinib in ES cells, which may translate into increased survival and reduced toxicity. Overall, our findings suggest that clofarabine is a good candidate for early phase clinical trials in children with ES.

**#1934 Retinoic acid and DFMO induce differentiation and inhibit tumor formation in neuroblastoma.**

Austen Vodayoff,1 Ping Zhao,2 Ablin U. Nagan-lapally,2 Jeff Bond,2 Giselle L. Sholler,2 Michigan State University, Grand Rapid- ids, MI; Helen DeVos Children’s Hospital, Grand Rapids, MI.

Background: A key component of high risk neuroblastoma (NB) therapy in-volves cis-retinoic acid (RA) for differentiation of minimal residual disease. DFMO induces differentiation and inhibition of tumor formation through the targeting of cancer stem cell (CSC) pathways via reversal of the Lin28/Let7 axis. Preventative DFMO therapy is currently in a phase II clinical trial at the end of therapy and in a Pilot study in combination with RA and ch14:18 antibody. We hypothesize that the combination of cis-RA and DFMO will induce greater differentiation, inhibition of tumor formation, and reduction of cell prolifera-tion of NB. Methods: NB cell lines MSN-BCR2, B2C and H926 were inoculated in 96 well plates for 24 and 48 hours with low doses of DFMO (2.5 and 5 mM), RA (5 and 10 µM), and the four combinations of dosages. A Calcein AM Cell Viability Assay and BrdU Cell Proliferation Assay Kit were used to deter-mine cell viability and cell proliferation, respectively. Western blot analysis was used to measure protein levels of CSC and differentiation markers. A neurosphere assay was used to assess inhibition of CSCs and tumor formation within wells. Cells were plated 2 cells/well in 96 well plates, drugged with single agents, combination, or DMSO and the percentage of wells per plate that formed neu-roospheres was determined after 1 and 2 weeks. IncuCyte ZOOM Live-Cell Im-aging system was used for kinetic monitoring of neurite length to assess differ-entiation of NB cells. Results: Low dose RA and DFMO combination treatment (2.5-5mM DFMO and 5-10 mM RA) resulted in decreased cell viability as demon-strated through calcein AM. DFMO and RA combination treatments reduced cell viability by 61-71%, 75-78%, and 83-91%, in B2C, H926, and MSN cells, respectively. BrdU incorporation demonstrated a reduction in cell prolif-eration at 48 hours of was 69-70%, 60.2-64.5%, 62.7-71.1% in B2C, H926, and MSN, respectively. Western blot analysis showed that DFMO, RA, and their combination reduced the CSC and increased the differentiation markers at 48 hours compared to control. The combination treatment also decreased tumor formation; the relative reduction in neurosphere formation at 2 weeks was 84.2% with 2.5 mM DFMO, 48% with 5 mM RA, and 73.2% with combination treat-ment. Lastly, differentiation was shown by neurite length increased by a factor of 1.4-1.6 and 5, in MSN and B2C cells, respectively with combination treatment. Conclusion: This study indicates that the combination retinoic acid and DFMO effectively cause a decrease in cell viability with a reduction in cell proliferation. Further, our results in differentiating NB cell lines suggest that targeting CSC pathways and inhibition of tumor formation. Preventative DFMO ther-apy has been initiated with RA in a pilot study for the treatment of high-risk neuroblastoma patients.

**#1935 Molecular characterization of orthotopic patient-derived xeno-graft models of pediatric brain tumors.**

Sebastian Brabetz,1 Susanne N. Gröb-ner,1 Hurrie Seker-Cin,1 Florian Selt,1 Till Müldé,2 David T. Jones,1 Madison T. Wise,3 Jessica M. Rusert,4 Kyle Pedro,3 Olaf Witt,2 Sarah E. Leary,1 Xiao-Nan Li,2 Robert J. Wechsler-Reya,4 James M. Olson,2 Stefan M. Pfister,4 Marcel Kool,1 German Cancer Research Center (DKFZ) and German Cancer Consortium (DKTK), Heidelberg, Germany; 2German Cancer Research Center (DKFZ), German Cancer Consortium (DKTK), Center for Individualized Pediatric Oncology (ZIPO) and Pediatric Brain Tumors, Department of Pediatric Oncology, University Hospital and National Center for Tumor Diseases (NCT), Heidelberg, Germany; 3Fred Hutchinson Cancer Research Center and Seattle Children’s Hospital, Seattle, WA; 4Sanford Burnham Prebys Medical Discovery Institute, Heidelberg, CA; 8Baylor College of Medicine, Houston, TX.

[Introduction: Solid tumors of the nervous system are the most common childhood cancers after leukemias. Even though we might be able to cure more and more patients, survivors still suffer long-term from the intensive treatments. Therefore, new treatment strategies are urgently needed. Orthotopic patient-de-renexograft (PDX) models are an excellent platform for biomarker and preclinical drug development. However, the rarity of pediatric brain tumors and the mul-titude of different sub entities hinder the generation of large collection of PDX models of specific entities within single institutions. In order to generate an overview about existing PDX models in the community, we started collecting established PDX models from various centers all over the world and performed extensive molecular characterization to precisely determine the distinct molecular subgroup and con-current oncogenic drivers. Material and Methods: PDX models were established and main-tained by dissociating tumor material into a single cell suspension and then ortho-topically injecting it into the brain of immunodeficient animals. All PDX models and matching primary tumors (if available) have been analyzed by whole-exome and low-coverage whole-genome sequencing, as well as DNA methylation and gene expression profiling using the the German Cancer Research Center (DKFZ). Results and Discussion: Thus far, we have collected and characterized 70 established PDX mod-els from 6 ATRTs, 8 ependymomas, 16 high-grade gliomas, 38 medulloblastomas, and 2 CNS-PNETs. PDX models always retain their molecular subtype and in the vast majority of cases also the mutations and copy number alterations when com-pared to their primary tumors. Only in rare cases do we observe additional aberra-tions, which most likely represent outgrowths of subclones from the primary tumor. Analysis of our entire cohort identified an overrepresentation of the most aggressive tumor subtypes, but also subtypes which have not been available for preclinical testing before due to lack of genetically engineered mouse models or suitable cell lines, such as Group 4 medulloblastoma. Based on our current analysis, the PDX models within the community are not yet covering the entire heterogeneity within brain tumors. As a next step, we aim to make these models and data accessible in a user-friendly manner so that the community can use them for preclinical research. Conclusion: PDX models of pediatric brain tumors are very rare. Our molecular characterization allows researchers all over the world to find the right models for their specific scientific question. Therefore, this work will provide an unprecedented resource to study tumor biology and pave the way for improving treatment strategies for children with malignant brain tumors.]

**#1936 Epigenetic challenges in derivation of the first cell-based model of Beckwith-Wiedemann syndrome.**

Stella K. Hur,1 Joanne L. Thorvaldsen,1 Suhee Chang,1 Carolyn Lye,1 Alice Yu,1 Moneersa C. Anguera,3 Marisa B. Bartolomei,1 Jennifer M. Kalish,1 2Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA; 1Children’s Hospital of Philadelphia, Philadelphia, PA; 3University of Pennsylvania School of Veterinary Medicine, Philadelphia, PA.

Beckwith-Wiedemann Syndrome (BWS) is a cancer predisposition syndrome that affects at least 1 in 10,500 children. Up to 25% of children with BWS develop tumors, primarily Wilms tumor and hepatoblastoma. BWS is due to genetic or epigenetic changes that affect imprinted loci on chromosome 11 and these same changes are also found in other types of cancer. There are no cell-based models of BWS and most mouse models do not recapitulate the tumor phenotype. To under-stand more about the mechanisms leading to tumor formation in BWS, we devel-oped the first human cell-based model of BWS. Human induced pluripotent stem cell (iPSC) models are commonly used to study disease mechanisms in tissue types that are not normally accessible for study. In the case of BWS, we plan to use such models to study how the genetic and epigenetic changes in BWS lead to tumor formation in hepatic and renal cells. Using skin fibroblasts from four BWS patients, we derived the first iPSC models of BWS. Prior to iPSC derivation, we characterized different tissues available from these four patients, and demonstrated genetic mosaic-ism in different tissue types, including blood, skin, and pancreas. During the derivation process, we demonstrated that both normal and BWS iPSC lines could be derived from the same patient fibroblast sample and the number of clones of each type from each sample approximated the initial level of mosaicism in the original sample. For each patient, these lines are isogenic except for the BWS critical region. The BWS and isogenic normal iPSCs were characterized for pluripotency markers and demonstrated to have normal karyotypes. Following this analysis, BWS and isogenic normal lines were characterized extensively for DNA methylation at spe-cific imprinted loci in both early passage and extended culture. Methylation analysis was performed by both pyrosequencing and COBRA assays. Methylation was main-tained at some imprinted loci but not at others in extended culture. Importantly, relatively stable levels were observed at the BWS critical region (H19/IGF2 and KvDMR), regardless of methods of reprogramming, indi-cating a relatively stable state of DNA methylation in this region. Additionally, nor-mal methylation was seen at the SNRPN locus. In contrast, another imprinted locus, IGF/MEG3, displayed abnormal hypermethylation in iPSCs. These data indicate that reprogramming and extended culture of iPSCs can affect stability of DNA methyl-ation at certain imprinted loci. Therefore caution should be used in interpreting studies using iPSCs as these aberrant methylation states at imprinted loci can affect the downstream functionality of iPSC models. BWS iPSCs and isogenic controls with normal methylation will be used for further study of the mechanism of tumor formation in BWS.
TUMOR BIOLOGY: Pediatric Cancer 1: Biomarkers, Preclinical Models, and New Targets

#1937 Evolution of neuroblastoma patient-derived orthotopic xenografts through space and time. Noémie Braeckeveldt,1 Susanne Fransson,2 Kristoffer von Stedingk,1 Ingrid Ora,3 Rosa Noguera,4 Tommy Martinsson,2 David Gisselsson Nord,5 Sven Påhlman,1 Daniel Bexell1. 1Translation Research Centre, Lund University, Lund, Sweden; 2Department of Clinical Genetics, Sahlgrenska University Hospital, Gothenburg, Sweden; 3Department of Pediatrics, Lund University, Lund, Sweden; 4Department of Pathology, Medical School, University of Valencia, Valenciac Spain; 5Department of Clinical Genetics, Lund University, Lund, Sweden.

Background: Recently, we established orthotopic neuroblastoma patient-derived xenografts (PDXs) which maintain the phenotypic, genomic, and stromal hallmarks of patient tumors. Here we examined how PDXs evolve following years of in vivo growth. Materials and Methods: We established up to eight in vivo generations of neuroblastoma orthotopic PDXs through serial passing in NSG mice. RNA sequencing, exome sequencing and SNP array analysis were used to analyze patient tumors and PDXs from different in vivo generations. Results: Using SNP analysis, we found mostly a remarkable genomic stability at chromosomal level between patient tumors, early and late PDX generations. RNA-seq revealed that patient tumors expressed higher levels of genes involved in immune responses and ECM metabolism compared to PDXs. Different PDX samples clustered correctly into their respective tumor type. PDXs from all early generations did not separate from PDXs from late generations. Thus, gene expression levels are surprisingly often quite stable despite years of in vivo growth. To shed light on neuroblastoma intratumor heterogeneity, we implanted 10 different tumor fragments from a single patient tumor into mice. We classified the 10 mice into three groups based on the time periods required for tumor growth. RNA-seq showed that each of these groups had a distinct gene expression profile and pathways involved in neuroblastoma progression have been identified. Conclusions: Neuroblastoma orthotopic PDXs are often very stable at chromosomal and gene expression levels despite years of in vivo growth. We utilized multiple PDXs to show functional intratumor heterogeneity coupled to distinct gene expression profile.

#1938 Exportin-1 (XPO1) is a novel therapeutic biomarker for patients with neuroblastoma. Basia Galinski,1 Marcus Luxemburg,1 Michelle Ewart,2 Yosef Landesman,3 Daniel Weiser1.1 Albert Einstein College of Medicine, Bronx, NY; 2Montefiore Medical Center, Bronx, NY; 3Karyopharm Therapeutics, Newton, MA.

Background: Half of patients with high-risk neuroblastoma succumb to disease, yet these patients with inferior outcome cannot be identified at diagnosis despite contemporary risk stratification that integrates MYCN copy number status, tumor histology, and patient age. We have shown that overexpression of Exportin-1 (XPO1) (1XPO1) is associated with poor survival in neuroblastoma, affirming what has been identified across a range of malignancies. Selinexor (KPT-330, Karyopharm Therapeutics), an XPO1 inhibitor in early phase clinical trials, inhibits the nuclear to cytoplasmic translocation of tumor suppressor and growth regulatory proteins implicated in oncogenesis. We hypothesized that protein fragments from a single patient tumor into mice. We classified the 10 mice into three groups based on the time periods required for tumor growth. RNA-seq showed that each of these groups had a distinct gene expression profile and pathways involved in neuroblastoma progression have been identified. Conclusions: Neuroblastoma orthotopic PDXs are often very stable at chromosomal and gene expression levels despite years of in vivo growth. We utilized multiple PDXs to show functional intratumor heterogeneity coupled to distinct gene expression profile.

#1939 Loss of MST/Hippo signaling promotes tumorigenesis in a genetically engineered mouse model of fusion-positive alveolar rhabdomyosarcoma. Kristianne Orielian, Lisa E. Crose, Rex Bentley, Nina Kuprasertkul, David G. Kirsch, Corrine Linardic. Duke University, Durham, NC.

While improvement in survival for pediatric cancer patients over the last 40 years has been encouraging, certain cancer types evade cure. One such example is fusion-positive alveolar rhabdomyosarcoma (aRMS), a pediatric soft tissue sarcoma of mesenchymal origin with skeletal muscle features and a 5-year survival rate of <50%. A hallmark of this aggressive malignancy is the t(12;13) translocation fusion protein PAX3-FKHR which drives hyperactive Hippo signaling and inhibits MST1/2/3. We hypothesized that ablating MST/Hippo signaling in an existing genetically engineered mouse model (GEMM) of aRMS would accelerate tumorigenesis and provide insight into the role of this pathway in aRMS. To assess the role of MST/Hippo signaling in aRMS, MST1/2-floxed (SkiCre;Skf4/+) mice were crossed with an established MST1/2 aRMS GEMM driven by conditional expression of Pax3-Foxo1 from the endogenous Pax3 locus and conditional loss of Cdkn2a in Myf6-expressing cells. Statistical analysis revealed that compared to MSTWT aRMS control animals, MSTSmice have significantly accelerated tumorigenesis (median survival 112 vs. 224 days, p < 0.0001) and increased tumor penetrance (76% vs. 27%). MSTsmice developed tumors disproportionately in the head and neck as compared to control, and incurred multiple tumors per animal. Tumors were analyzed via immunohistochemistry for MyoD and myogenin, markers of myogenic lineage and of either positive or negative aRMS phenotypes. MST-derived tumors were positive for positive aRMS markers. MST-derived cell lines were used for in vitro cell-based assays and molecular interrogation. We have identified the MST/Hippo signaling axis as an important tumor suppressor mechanism in aRMS. The rapid onset and increased penetrance of tumorigenesis in this GEMM provides a powerful tool for interrogating RMS biology and screening novel therapeutics.

#1940 Prenatal stress increases malignancy of neuroblastoma tumors in TH-MYCN animal model. Sung Hyeok Hong, Larissa Wietlisbach, Susana Galii, Akanaksha Mahajan, Shuya Zhu, Jason Tilan, Yichien Lee, Olga Rodriguez, Chris Albanese, Joanna Kikutinska. Georgetown University Medical Center, Washington, DC.

Neuroblastoma (NB) is a pediatric malignancy arising due to defects in sympathetic neuron differentiation. NB is a heterogeneous disease, with phenotypes ranging from spontaneously regressing to highly aggressive, incurable tumors. This clinical variability cannot be explained solely by genetic aberrations. Even in families with hereditary NB the penetrance of the disease is incomplete and the same genetic mutation often results in tumors with phenotypes varying from differentiating ganglioneuromas to undifferentiated, highly aggressive NBs. Thus, other, perhaps non-genetic factors can contribute to the development of tumors and modify their phenotype. Strikingly, the two factors promoting de-differentiation of NB cells and their malignant phenotype, hypoxia and glucocorticoids, are elevated in the fetus during maternal stress, suggesting a role for prenatal stress in NB tumorigenesis. Previously, using TH-MYCN mice as a model of aggressive NB, we have shown that an increase in maternal corticosterone levels during pregnancy attenuated by inserting slow release pellets resulted in increased tumor frequency in TH-MYCN offspring. The goal of the current study was to determine the effect of prenatal stress on NB metastasis. To this end, pregnant mice carrying TH-MYCN hemizygous offspring were subjected to chronic stress at embryonic days 10-17, the time of sympathetic neuroblast proliferation and differentiation. Two established stress paradigms were used - chronic unpredictable stress, in which mice were subjected daily to various stressors, and chronic cold stress comprising of daily 30 min exposure to cold. The phenotypes of the disease and its dissemination were compared between offspring of control and stressed mothers. The offspring from both prenatal stress groups presented with more malignant disease, as manifested by the presence of advanced lung metastases disseminating from small primary tumors (<700 mm3). This phenotype was associated with increased mortality in prenatally-stressed TH-MYCN offspring (p < 0.01). In contrast, no advanced lung metastases and no disease-related deaths were observed in TH-MYCN offspring of control mothers despite the presence of large primary tumors (>1,000 mm3). Although not common, lung metastases occur preferentially in NB patients with MYCN amplification and are associated with significantly worse prognosis, as compared to patients with metastatic disease, but no pulmonary involvement (14 vs 43% 3-year event-free survival, respectively). Thus, the profound pulmonary dissemination observed in prenatally-stressed TH-MYCN mice mimics one of the most malignant NB phenotypes observed in human disease. Altogether, our data implicate maternal stress during pregnancy as a potential environmental factor modifying the effects of genetic aberrations and promoting malignant phenotype of NB.

#1941 Cell surface vimentin is a novel marker for CTC detection in neuroblastoma. Izhara S. Batt#1, Heming Li#, Giselle Saulnier Sholler, Shulin Li#. 1UT MD Anderson Cancer Center, Houston, TX; 2Helen DeVos Children’s Hospital, Grand Rapids, MI.

Among children in the United States, brain cancers now account for most neurologic deaths. Neuroblastoma (NB) and sarcoma (SR) are the two most common childhood cancers in the United States. Despite significant progress yielding increased 5-year survival, 1250 deaths are expected this year from childhood cancers and cancer incidence has been steadily increasing. One of the key contributors to cancer mortality is tumor metastasis. It is generally believed that CTCs are shed into the circulation from primary tumors and contain unique information enabling their staging and phenotypic differences. However, detection of CTCs from NB is difficult as there is no direct method. Our lab has developed a monoclonal antibody targeting vimentin on the cells’ surface. Cell surface vimentin (CSV) is only observed in tumor cells; it remains intracellular in normal cells. We have published data demonstrating the superior specificity and sensitivity of our approach in breast, colon, and prostate cancer. Here, we report direct CTC detection using CSV by our mAb. As part of our collaborative effort analyzing NB blood samples from a multicenter Phase II trial, we present novel discoveries regarding treatment of NB with difluoromethylornithine (DFMO) and its effects on CTC release into the circulation in patients under remission. Among our observations, approximately 1/3 patients have low or no CTCs while 1/4 with high numbers of CTCs are responding to DFMO treatment. Our findings show CTC numbers falling with DFMO treatment. DFMO showed a statistically significant decline in CTCs after the beginning of therapy. Ongoing work including whole genome analysis can possibly reveal new insight into CTCs’ entering the circulation. These data demonstrate that our CTC capture using CSV is a novel and unique approach for detection in NB.

#1942 The nicotinamide phosphoribosyltransferase (NAMPT) inhibitor, OT-82, exhibits in vitro and in vivo efficacy against patient-derived xenograft models of high-risk acute lymphoblastic leukemia. Kathryn Evans,1 Tara Pritchard,1 Michelle J. Henderson,1 Kaartje Somers,1 Mawar Karasa,1 Leanna Cheung,1 Raymond Yung,1 Stephen W. Erickson,2 Lioubov Korotchkina,3 Olga Chernova,3 Andrei Gudkov,3 Malcolm A. Smith,2 Richard B. Lock,3 Children’s Cancer Institute, Sydney, Australia; 4National Cancer Institute, MD; 5Oncoartis, Inc., Buffalo, NY; 6Roswell Park Cancer Institute, Buffalo, NY.

Cancer cells are highly dependent on nicotinamide phosphoribosyltransferase (NAMPT) for the biosynthesis of nicotinamide adenine dinucleotide (NAD). Besides its role in energy metabolism, NAMPT influences the activity of NAD-dependent enzymes, including poly (ADP-ribose) polymerase-1 (PARP-1) and sirtuins, and thereby regulates cellular survival and stress response. Disruption of NAD synthesis through NAMPT inhibition represents a potential therapeutic strategy for treating cancer. The aim of this study was to evaluate the efficacy of the novel NAMPT inhibitor OT-82, initially isolated for its selective toxicity against a panel of adult leukemia cell lines, in a diverse panel of leukemia cell lines in vitro and pediatric acute lymphoblastic leukemia (ALL) patient-derived xenografts (PDxX) in vivo, and to identify potential biomarkers predictive of OT-82 response. OT-82 demonstrated low nanomolar IC50 values (0.9 – 3.4 nm) in ALL and 3 acute myeloid leukemia cell lines as determined by resazurin reduction assays. In vivo efficacy of OT-82 (40 mg/kg x 3 days x 3 weeks, p.o.) was evaluated as a single agent against pediatric ALL PDxXs, including B-cell precursor ALL (n = 3), Philadelphia chromosome (Ph) positive ALL (n = 2), Ph-like ALL (n = 2), T-cell ALL (n = 3), and early T-cell precursor ALL (n = 3) in immune deficient (NSG) mice. Response to treatment was assessed by time to event or stringent objective response criteria modeled after the clinical setting. OT-82 was well tolerated, significantly increased event-free survival (EFS) relative to control mice in 11/13 ALL PDxXs, and elicited objective responses in 11/13 (85%) PDxXs [3 Partial Responses, 4 Complete Responses (CRs)] and 4 Maintained CRs (MCRs). Analysis of basal protein expression revealed elevated levels of poly (ADP-ribosylated) (PARylated) PARP1 in 4/5 responders versus 0/3 non-responders. In vitro studies examining various chemotherapeutic agents used for childhood leukemia showed synergy between cytarine (AraC) and OT-82 in an ALL cell line. In an OT-82 sensitive Mixed Lineage Leukemia (MLL) PDxX treatment with AraC (25 mg/kg x 5 days x 2 weeks, i.p.) and OT-82 (40 mg/kg x 3 days x 2 weeks, p.o.) significantly increased EFS compared to OT-82 (P<0.0001) or AraC (P<0.0001) alone. Moreover, the OT-82/ AraC combination elicited an MCR compared to OT-82 and AraC (Progressive Disease) alone. The results herein demonstrate significant activity of OT-82 against leukemia cell lines and a range of pediatric ALL subtypes in vitro, and the potential for PARylated PARP-1 expression as a biomarker for predicting OT-82 response. Moreover, the enhanced activity of OT-82 in combination with AraC over single agent therapy further suggests NAMPT inhibition as an attractive strategy for treating high-risk pediatric ALL. Supported by U01CA199900 from the NCI.

#1943 High-throughput chemical screening identifies Focal Adhesion Kinase and Aurora Kinase B inhibition as a synergistic treatment combination in Ewing sarcoma. Brian Crompton#, Sarah Wang#, Elizabeth Hawang, Rajarshi Gula#, Matthew Boxer,3 Crystal McKnight,2 Min Shen,2 Nicola Melong,3 Channey Veinotte,2 Amy Conway,1 Jason Berman,3 Matthew Hall,2 Mindy Davis,2 Kimberly Stegmaier1, Dana-Farber/Boston Children’s Cancer and Blood Disorder’s Center, Boston, MA; 2National Center for Advancing Translational Sciences, Bethesda, MD; 3D’Alton House University, Halifax, Nova Scotia, Canada.

Ewing sarcoma is the second most common bone malignancy of childhood. Current treatment employs chemotherapy, surgery, and radiation. Although this approach cures approximately 70% of patients with localized disease, treatments are largely ineffective for patients with metastases or relapse. Furthermore, these treatments are associated with an alarming rate of long-term toxicities. New treatment combinations are necessary to improve cures and lower toxicities for these patients. We recently found that Ewing sarcoma is dependent on focal adhesion kinase (FAK) for cell viability and tumor proliferation. In order to identify candidate treatment combinations for Ewing sarcoma, we performed a screen of 1912 compounds to identify those with synergistic anti-angiogenic activity when combined with FAK inhibition. The A673 Ewing cell line was treated with PF-562271, a FAK-specific inhibitor, in combination with compounds from the Mechanism Interrogation PlatE (MIE) 4.0 library. Cell viability was measured after 48 hours of treatment. Multiple computational metrics were used to identify targets with anti-angiogenic activity. More importantly, combinations for synergistic impairment of cell viability. Multiple Aurora kinase inhibitors scored as synergistic with FAK inhibition in this screen. Aurora kinases are important in the regulation of mitosis and are highly expressed in Ewing sarcoma tumors and cell lines. We found that Aurora kinase B inhibitors were synergistic across a larger range of concentrations than Aurora kinase A inhibitors when combined with FAK inhibition in multiple Ewing cell lines. We found that AZD-1152, an Aurora kinase B-selective inhibitor, and PF-562271 when used in combination induced apoptosis in Ewing cells at concentrations that had minimal effect on cell survival when either drug was used alone. We also found that the combination significantly impaired tumor proliferation in zebrafish xenograft models of Ewing sarcoma and prolonged survival in murine xenografts compared to either single-agent treatment alone. Interestingly, treatment with AZD-1152 alone also significantly impaired tumor proliferation and prolonged survival compared to vehicle treatment in a mouse xenograft model of Ewing sarcoma. Our data demonstrate that FAK and Aurora kinase B inhibition synergistically impair Ewing sarcoma cell viability in vitro and significantly inhibit tumor proliferation in vivo. With multiple FAK and Aurora kinase inhibitors in early phase trials for adult malignancies, these results have the potential to be translated into clinical trials for patients with Ewing sarcoma. Previous studies have also suggested a dependency of Ewing sarcoma on Aurora kinase activity; our data further supports a role for Aurora kinase B inhibitors as therapeutic candidates in this disease.

#1944 Tazemetostat displays synergistic antiproliferative activity with backbone therapies in preclinical models of AT/RT and MRT. Christine R. B. Soren#, Richard Sev, Scott Riebs, Alejandra Raimondi, Epizyme, Inc, Cambridge, MA.

Malignant Rhabdoid Tumors (MRT) and Atypical Teratoid Rhabdoid Tumors (AT/RT) are typically pediatric cancers which are rare and aggressive with extremely high unmet medical need. At a molecular level MRT and AT/RT tumors are almost universally characterized by loss of the INI1 protein (also known as SNF5 or SMARCB1), a component of the Switch Sucrose Non-fermentable (SWI/SNF) multisubunit chromatin modifying complex. In many cell types, the SWI/SNF complex and the PRC2 complex have an antagonistic relationship in the regulation of tumor suppressor genes, cell cycle checkpoints, hedgehog and myc pathway genes, among others [Wilson et al, Cancer Cell. 2010 Oct 19;18(4):316-28.]. This explicated the possibility of a novel treatment for patients with INI1-negative MRT and AT/RT tumors, which are largely ineffective for patients with metastases or relapse. Further treatment employs chemotherapy, surgery, and radiation. Although this approach cures approximately 70% of patients with localized disease, treatments are largely ineffective for patients with metastases or relapse. Furthermore, these treatments are associated with an alarming rate of long-term toxicities. New treatment combinations are necessary to improve cures and lower toxicities for these patients. We recently found that Ewing sarcoma is dependent on focal adhesion kinase (FAK) for cell viability and tumor proliferation. In order to identify candidate treatment combinations for Ewing sarcoma, we performed a screen of 1912 compounds to identify those with synergistic anti-angiogenic activity when combined with FAK inhibition. The A673 Ewing cell line was treated with PF-562271, a FAK-specific inhibitor, in combination with compounds from the Mechanism Interrogation PlatE (MIE) 4.0 library. Cell viability was measured after 48 hours of treatment. Multiple computational metrics were used to identify targets with anti-angiogenic activity. More importantly, combinations for synergistic impairment of cell viability. Multiple Aurora kinase inhibitors scored as synergistic with FAK inhibition in this screen. Aurora kinases are important in the regulation of mitosis and are highly expressed in Ewing sarcoma tumors and cell lines. We found that Aurora kinase B inhibitors were synergistic across a larger range of concentrations than Aurora kinase A inhibitors when combined with FAK inhibition in multiple Ewing cell lines. We found that AZD-1152, an Aurora kinase B-selective inhibitor, and PF-562271 when used in combination induced apoptosis in Ewing cells at concentrations that had minimal effect on cell survival when either drug was used alone. We also found that the combination significantly impaired tumor proliferation in zebrafish xenograft models of Ewing sarcoma and prolonged survival in murine xenografts compared to either single-agent treatment alone. Interestingly, treatment with AZD-1152 alone also significantly impaired tumor proliferation and prolonged survival compared to vehicle treatment in a mouse xenograft model of Ewing sarcoma. Our data demonstrate that FAK and Aurora kinase B inhibition synergistically impair Ewing sarcoma cell viability in vitro and significantly inhibit tumor proliferation in vivo. With multiple FAK and Aurora kinase inhibitors in early phase trials for adult malignancies, these results have the potential to be translated into clinical trials for patients with Ewing sarcoma. Previous studies have also suggested a dependency of Ewing sarcoma on Aurora kinase activity; our data further supports a role for Aurora kinase B inhibitors as therapeutic candidates in this disease.
pies for MRT and AT/RT are comprised of cytotoxic chemotherapy which may or may not be administered in the context of stem cell transplant, in addition to surgical resection and radiation therapy. In support of combination clinical scenarios including EZH2 inhibition in this setting, we sought to explore the antiproliferative effects of combining tazemetostatin with current small molecule treatment. Transcriptome models of tumor response to EZH2 inhibition was observed when tazemetostatin was combined with individual components of chemotherapeutic regimens and targeted therapies such as vincristine, doxorubicin, alisertib and HDAC inhibitors. Further, we investigated the effects of ionizing radiation together with tazemetostatin treatment. Application of X-ray irradiation concomitantly or after tazemetostatin treatment, induced robust antiproliferative response and reduction in colony formation compared to individual cell lines tested. Taken together these results suggest that pharmacological inhibition of EZH2 enhances the activity of backbone therapy and may have an advantage over monotherapy in INI1-negative cancers supporting the therapeutic potential of combination regimens that include tazemetostatin in these tumors.

#1945 PPM1D/Wip1, promising new target in childhood cancers neuroblastoma and medulloblastoma. Jelena Milosevic,1 Nina Essler,1 Diana Treis,1 Malin Wickström,1 Susanne Fransson,2 Baldur Sveinbjornsson,3 Ninib Baryawno,1 Subzini Kosala,1 Chandrasekhar Kanduri,2 Kazuya Su Saguchi,3 Tommy Martinsson,3 John Inge Johnsén,3 Per Kogner4 Karolinska Institutet, Stockholm, Sweden; 2University of Gothenburg, Gothenburg, Sweden; 3University of Tromsø, Tromsø, Norway; 4Hokkaido University, Sapporo, Japan.

Background: The most common cytogenetic lesions in the embryonal neural tumors are neuroblastoma (MB) and neuroblastoma (NB) affect chromosome 17, with 17q+ or isochromosome 17q, in approximately one-third of MB with these aberrations being a significant indicator of poor clinical outcome. Similarly, in NB gain of 17q is the most powerful genetic predictor of adverse clinical outcome. 17q+ correlates with poor survival in our population-based material where we found aberrations of chromosome 17 in 85% of primary neuroblastomas, specifically, gain of PPM1D/Wip1 at 17q23. Wip1 is a serine/threonine phosphatase encoded by the gene PPM1D, described as a gatekeeper in the Mdm2-p53 regulatory loop involved in genetic stability, inflammation and a potential oncogene contributing to carcinogenesis. Methods: Comparative genomic hybridization (CGH), immunostaining, mRNA arrays, qPCR, exome- and RNA-sequencing was used to examine PPM1D/ Wip1 in neuroblastoma and medulloblastoma. Genetic and pharmacological inhibition was used to analyze the function of Wip1 in preclinical neuroblastoma and medulloblastoma models. Results: CGH-array analysis detected PPM1D/Wip1 extra copies in all tumors and cell lines containing 17q-gain. Expression arrays and immunostaining showed high expression of Wip1 in neuroblastoma corresponding to poor survival. RNA sequencing confirmed PPM1D-gain and revealed truncated isoforms with oncogenic potential. Exome-seq detected a mutation leading to constitutive PPM1D/Wip1 activation in an aggressive metastatic infant neuroblastoma. Wip1 knockdown experiments showed significant decrease of cell viability, proliferation and colony formation as well as substantial increase of DNA-damage response in neuroblastoma and medulloblastoma cells. Tumor neuroblastoma xenograft development was significantly delayed showing median tumor development (0.10 mL) to be more than doubled (median 15 days, vs. 33 days, p<0.001) after Wip1 downregulation compared to scrambled controls. A novel Wip1 inhibitor, highly potent in cytotoxic/cytostatic effect in neuroblastoma and medulloblastoma cell lines. Furthermore, this Wip1 inhibitor significantly inhibited growth of established human neuroblastomas and medulloblastomas in nude mice after treatment (P<0.001). Conclusions: Our results show that PPM1D/Wip1 is oncogenic in neuroblastoma and medulloblastoma development. We propose three different ways on how PPM1D/Wip1 is activated: due to chromosomal gain, alternative RNA-isosforms and/or DNA-mutation. PPM1D/Wip1 provides a novel therapeutic target in neuroblastoma and medulloblastoma.

#1946 Synergistic effects of the XPO1 inhibitor selinexor with proteasome inhibitors in pediatric high-grade glioma and diffuse intrinsic pontine glioma. John DeSisto,1 Patrick Flannery,1 Trinayan Kashyap,2 Rakheb Lemma, Shelby Mestnick,3 Andrew King,4 Rajeev Vihbhakara,5 Yosef Landesman,6 Adam Green5. University of Colorado Anschutz Medical Campus, Aurora, CO; 5Karyopharm Therapeutics Inc., Newton, MA; 3Rocky Vista University College of Osteopathic Medicine, Parker, CO; 4Memorial Sloan Kettering Cancer Center, New York, NY.

Background: Pediatric high-grade gliomas (HGG) and diffuse intrinsic pontine gliomas (DIPG) account for the majority of pediatric brain tumor deaths and respond poorly to chemotherapy. Selinexor, a nuclear export inhibitor, is effective against HGG and DIPG in in vitro and in vivo models, but resistance to treatment develops. We previously identified the NF-kB pathway as a likely mediator of selinexor’s activity in these tumors. NF-kB transcriptional activity is regulated by an inhibitor, IKR-α, whose levels are in turn regulated by ubiquitination and proteasomal degradation. IKR-α is a client of exportin-1 (XPO1); its nuclear levels are increased by selinexor treatment, leading to inhibition of NF-kB. We subsequently identified proteasome inhibitors as potentially synergistic with selinexor in HGG and DIPG through a screen of all FDA-approved chemotherapy agents. Proteasome inhibition has also been shown to synergize with selinexor treatment in multiple myeloma and osteosarcoma. Methods: We treated HGG cell lines (BT245 and GBM1) and DIPG cell lines (DIPG4, DIPG7 and SF761) for five days with selinexor in combination with each of three proteasome inhibitors, bortezomib, carfilzomib and marizomib, and assayed cell viability at the conclusion of treatment. In each experiment, cells were treated with lower levels of the two drugs at several constant ratios. IC50 values were computed for each drug acting alone, and the combination index (CI) of the two drugs acting together was computed using the Chou-Talalay method. We also treated SF761 cells with a combination of radiation (8 Gy), selinexor, and a proteasome inhibitor. Results: The proteasome inhibitors had widely varying IC50 values in the cell lines tested, ranging from 1 nM to 5 uM. The CI for the combination of selinexor and each proteasome inhibitor was consistently less than 1 (indicating a synergistic relationship) in the cell lines tested. We found that radiation and proteasome inhibition had an antagonistic relationship (CI>1), radiation and selinexor a synergistic relationship (CI<1), and the combination of all three was mixed, with some combinations being synergistic and others antagonistic. Conclusions: Selinexor and proteasome inhibitors promise as a combination therapy for HGG and DIPG. We are conducting in vivo experiments to further explore this combination for subsequent clinical trial use.

#1947 Combination of Vincristine and Clotam induces antiproliferative response in medulloblastoma cells. Shruti V. Patil,1 Don Eslin,2 Robert Sutphin,3 Umesh T. Sanpkal,1 Yazmin Hernandez,1 Areeba Hafeez,1 W.Paul Bowman,1 Riyaz Bashir.2 1University of North Texas Health Science Center, Fort Worth, TX; 2 pediatric Palmers Hospital for Children, Orlando, FL.

Medulloblastoma (MB) is the most common pediatric malignant brain tumor and usually originates in the cerebellum. These tumors have the propensity to disseminate throughout the central nervous system and are often difficult to treat. Chemotherapy is widely accepted as part of the multimodality treatment approach for MB. However, it is associated with debilitating toxicity and potential long term disabilities. Vincristine is a commonly used chemotherapy agent for MB treatment. This drug is known to induce some toxic effects including peripheral neuropathy. The aim of this study was to test a combination treatment involving Vincristine and an anti-cancer non-steroidal anti-inflammatory drug, Clotam (Tolfacenic acid) against MB cell lines. Previously, we showed that Clotam inhibited MB cell proliferation and tumor growth in mice by targeting the transcription factor, specificity protein 1 (Sp1) and an inhibitor of apoptosis protein, BIRC3 (baculoviral inhibitor of apoptosis repeat-containing 5). The overexpression of BIRC5 is associated with aggressiveness and poor prognosis in several cancers. MB cells, DAOY and D283 cells were treated with vehicle (dimethyl sulfoxide) or low dose of Vincristine (DAOY: 2ng/mL; D283: 1ng/mL) or Clotam (DAOY & D283: 10 µg/mL) or combination of Vincristine + Clotam. Cell viability was assessed after 2 days post-treatment using Cell-TiterGlo kit. Flow cytometry was employed to analyze apoptotic cells using Annexin-V staining and cell cycle phase distribution using propidium iodide staining. The activation of apoptotic pathways was further investigated by assessing the levels of effector caspases with CaspaseGlo kit and the expression of apoptotic markers [cleaved Poly (ADP-ribose) polymerase (c-PARP), B-cell lymphoma 2, and BIRC3] by Western blot analysis. The expression of key proteins associated with cell cycle (Cyclin A, B, D, CDK4/6, and p21) was also determined by Western blot analysis. When compared to individual agents, the combination of Clotam and Vincristine increased MB cell growth inhibition which is accompanied by an induction of apoptotic markers and the modulation of Cyclin A, B, D and CDK4/6 down-regulation; p21 up-regulation of proteins associated with cell cycle phase distribution. These results suggest that Vincristine and Clotam combination treatment is effective for inducing anti-proliferative effect in MB cells. The experiments to evaluate the effect of this combination in animal model for MB are currently under study.

#1948 Tumor-specific copy number alterations uncover therapeutic opportunities in osteosarcoma. Leanne C. Sayles,1 Marcus Breese,2 Amanda L. Koch,3 Adam K. Spiller,4 Alex E. Naish,4 Anjaly Shah,5 Krystal Strasser,6 Sheri Spunt,7 Neyssa Marina,8 Damon Jacobson,9 Raffi S. Avedian,2 David G. Mohler,2 Steven DuBois,4 Douglas S. Hawkins,8 and E. Alejandro Sweet-Cordero.1 1UCSF, San Francisco, CA; 2Stanford, Stanford, CA; 3University of Washington, Seattle, WA; 4Dana-Farber Cancer Institute, Boston, MA.

Osteosarcoma (OS) is the most common primary sarcoma of bone accounting for approximately 10% of all bone tumors. Recent advances in the understanding of pathogenesis and genetic changes have propelled new therapeutic strategies. We have previously developed a comprehensive OS-specific copy number alteration (CNA) catalog using high-density aCGH, mRNA and exome sequencing to identify OS-specific genetic alterations. We herein present an integrated OS-specific CNA catalog and clinical annotation, which uncovers novel therapeutic opportunities in OS.

TUMOR BIOLOGY: Pediatric Cancer 1: Biomarkers, Preclinical Models, and New Targets
Osteosarcoma (OS) is a highly malignant cancer for which no targeted therapies are currently available. Current treatment modalities are limited to intensive, highly toxic chemotherapy and surgical resection. OS is characterized by widespread copy number alterations and structural rearrangements. In contrast, no recurrent point mutations in protein-coding genes have been identified, suggesting that OS arises from defined genetic elements which have the potential to lead to tumorogenesis and whose pathways have been altered in OS patient specimens. Serial introduction of the viral constructs hTERT (T), SV40Tag (S), and H-RAS (R), led to spindle cell tumor formation in mice. However, MSC-TSR tumors did not form osteoid, whereas OB-TSR tumors showed only scant production of osteoid. Also the addition of OB-TSR cells to tumors failed to tumorigenesis. Based on these findings, MSC-TS and OB-TS cell lines may be ideal platforms for further analysis of the impact of the genetic transformation of hMSCs and OBs into OS. c-Myc has been shown to be overexpressed in OS cells and hence has been suggested as an oncogene. It has also been suggested as a novel target of RUNX2 through rescue from the apoptosis. MSC-TS and OB-TS cells were transformed with a retrovirus containing human c-Myc. Drug resistant colonies were picked up 21 days after selection to obtain stably transformed cell lines. Quantitative PCR and western blots were carried out to detect both gene and protein expression patterns in transformed cell lines, respectively. Furthermore, in order to determine the expression pattern of c-Myc in OS, quantitative PCR and western blots were also performed on MYCN cancer xenografts and primary tumors. All functional assays outlined below will be performed to determine the tumorigenic properties of transformed cell lines. Six out of seven (86%) osteosarcoma primary samples showed a significantly greater c-Myc gene expression level compared to the positive control cell lines. Selection of stably transformed clones and comparison between cell lines and characterizations are underway. Further ongoing characterization includes: soft agar assays, in-vivo tumorigenic assays, histological examination for osteoid production and other OS specific immunohistochemical markers, proliferation, invasion and migration, and differentiation assays. It is our hope that this study will highlight the model that closely recapitulates the human osteosarcoma phenotype by forming a malignant spindle cell tumor that produces aberrant osteoid, and has the potential for multi-lineage differentiation. 

##1949 Salvaeyes pathway enzyme HPRT as a molecular marker for Burkitt's Lymphoma.

The aim of this study is to investigate the potential of Hypoxanthine phosphoribosyltransferase (HPRT) as a surface biomarker and target for future immunotherapies in Burkitt's B-cell Lymphoma. B-cell malignancies are the most common type of childhood cancer. Development of immunotherapeutics could improve current treatment. HPRT is a cytosolic transferase involved in nucleotide production via the purine salvage pathway. Altered expression of TK1, a salvage pathway enzyme, is an indicator of prognosis and diagnosis in multiple cancer types due to active proliferation of cells and the resulting elevated nucleotide demand. It has previously been reported that some salvage pathway enzymes are found on the surface of Burkitt's Lymphoma cells. HPRT presence on the surface of this B-cell lymphoma subtype could provide a target for adoptive cell transfer and other immunotherapies. The potential surface presentation of HPRT was assessed using flow cytometry, scanning electron microscopy (SEM), and cytoplasmatic staining on both healthy lymphocytes and Burkitt's Lymphoma cells (Raji). Experiments with Raji and Ramos cells and/or antibodies with known surface expression indicated that both cell lines and their subclones expressed HPRT at the cell surface. Co-culture experiments with Ramos cells and HPRT-labeled secondary antibodies show that Raji cells exhibit an 81.4% (p-value.0001) positive fluorescence shift when compared to IgG controls (1.5%). Healthy lymphocytes had a fluorescence shift of 2.38% (p-value.9787). The presence of HPRT on the surface of both Raji cells and healthy lymphocytes was further confirmed using gold-labeled antibodies. Utilizing a scanning electron microscope, the presence of the protein on the surface was evaluated and quantified via increases in gold weight percentage of the sample. When treated with antibodies against HPRT, there was a significant increase in gold binding along with an increase in gold weight percentage. These results suggest a direct relationship between HPRT and the surface of Burkitt's lymphoma cells, indicating HPRT as a potential target for future immunotherapeutic treatment in Burkitt's B-cell lymphoma pediatric patients.

##1950 Introducing c-Myc into transformed human mesenchymal stem cells and osteoblasts to recapitulate the osteosarcoma phenotype.
Sajida Piperdı (Thiem),1 Wendong Zhang,2 Daria Ivenitsky,1 Yidan Zhang,1 Yunja Zhang,3 David S. Geller,3 Bang Haoang,2 Rui Yang,3 Jonathan B. Gill,3 Michael Roth,1 Richard Gorlick1. 1Albert Einstein College of Medicine and The Children's Hospital at Montefiore, Bronx, NY; 2Montefiore Medical Center, Bronx, NY, 152

Osteosarcoma (OS) is the most common primary malignant bone tumor in children and young adults. It remains unclear at what point in the pathway of differentiation between human mesenchymal stem cells (hMSCs) and osteoblasts (OBs), OS originates. Since high grade OS frequently demonstrates histologic variability, as well as the potential for multi-lineage differentiation, some consider the hMSC as the cell of origin in OS, whereas others believe the osteoblast to be the most likely cell of origin. Identifying the primary cell of origin is crucial in understanding the molecular pathogenesis of OS. To address the potential for hMSCs or OBs to transform into OS, we have performed classical mutation analysis and fluorescent-activated cell sorting (FACS) of defined gene subsets which have the potential to lead to tumorogenesis and whose pathways have been altered in OS patient specimens. Analysis of the viral constructs hTERT (T), SV40Tag (S), and H-RAS (R), led to spindle cell tumor formation in mice. However, MSC-TSR tumors did not form osteoid, whereas OB-TSR tumors showed only scant production of osteoid. Also the addition of OB-TSR cells to tumors failed to tumorigenesis. Based on these findings, MSC-TS and OB-TS cell lines may be ideal platforms for further analysis of the impact of the genetic transformation of hMSCs and OBs into OS. c-Myc has been shown to be overexpressed in OS cells and hence has been suggested as an oncogene. It has also been suggested as a novel target of RUNX2 through rescue from the apoptosis. MSC-TS and OB-TS cells were transformed with a retrovirus containing human c-Myc. Drug resistant colonies were picked up 21 days after selection to obtain stably transformed cell lines. Quantitative PCR and western blots were carried out to detect both gene and protein expression patterns in transformed cell lines, respectively. Furthermore, in order to determine the expression pattern of c-Myc in OS, quantitative PCR and western blots were also performed on MYCN cancer xenografts and primary tumors. All functional assays outlined below will be performed to determine the tumorigenic properties of transformed cell lines. Six out of seven (86%) osteosarcoma primary samples showed a significantly greater c-Myc gene expression level compared to the positive control cell lines. Selection of stably transformed clones and comparison between cell lines and characterizations are underway. Further ongoing characterization includes: soft agar assays, in-vivo tumorigenic assays, histological examination for osteoid production and other OS specific immunohistochemical markers, proliferation, invasion and migration, and differentiation assays. It is our hope that this study will highlight the model that closely recapitulates the human osteosarcoma phenotype by forming a malignant spindle cell tumor that produces aberrant osteoid, and has the potential for multi-lineage differentiation.
Children with Down syndrome (DS) are at a 500-fold increased risk for developing acute myeloid leukemia (AML) before they reach five years of age. DS-AML blasts have somatic mutations in the gene encoding the essential hematopoietic transcription factor GATA-1 resulting in hypersensitivity to chemotherapy drugs such as cytarabine and daunorubicin. However, therapy-induced toxicity results in greater morbidity and remains a major barrier in attaining higher survival rate. Thus, alternate therapy approaches to minimize toxicity and increase efficacy are needed. Trisomy 21 and GATA-1 mutations in DS-AML are known to alter the epileptogenic landscape in multiple ways. Therefore, we evaluated the efficacy of epigenetic drugs in comparison to chemotherapy in two patient-derived xenograft (PDx) models of DS-AML. We developed two distinct PDx models by successfully engraftment and serial passage of primary DS-AML cells in NSG-B2m mice. Both PDx lines possessed GATA-1 mutation resulting in the expression of a truncated form of GATA-1. NTPL-60 had a nonsense mutation generating a premature stop codon after the initiation codon, while NTPL-386 had a 136 bp deletion in exon 2 resulting in the loss of the initiation codon. The mouse passaged cells were intravenously injected into 6-8 week old NSG-B2m mice. Once disease establishment was confirmed based on the presence of human cells in mouse peripheral blood, five mice per group were treated with vehicle or DNA methylation inhibitor azacitidine and histone deacetylase inhibitor panobinostat either singularly or in combination at a previously determined maximally tolerated dose of 2.5 mg/Kg each. NTPL-386 xenografted mice treated with azacitidine or panobinostat survived 29 and 21 days longer than the vehicle-treated mice respectively, while the mice treated with the combination survived the longest (35 days). Similarly, azacitidine and panobinostat extended the survival of mice transplanted with NTPL-60 by 48 and 31 days respectively compared to the vehicle-treated mice. NTPL-60 mice treated with the epigenetic drug combination are alive at 57 days. Thus, we observed that the azacitidine-panobinostat combination showed statistically significant (p < 0.0001) differences in leukemic burden and mouse survival compared to treatments with either drug alone in both NTPL-386 and NTPL-60 PDx models. We also tested the efficacy of epigenetic therapy followed by chemotherapy. The inclusion of epigenetic therapy before chemotherapy prolonged survival by 39 days compared to vehicle-treated mice. Taken together, our data indicate that epigenetic therapy may be of benefit for the treatment of children with DS-AML.

Accelerating prediction of pediatric and rare cancer vulnerabilities using next-generation cancer models. Yuen-Yi Tseng,1 Andrew Hong,1 Paula Keskula,1 Shubhroz Gill,1 Jaime Cheah,2 Grigoriy Kryukov,1 Aviad Tsherniak,1 Kelli C. Cheema, Joanna B. Kitlinska. Georgetown Univ., Washington, DC.

Neuroblastoma (NB) is a pediatric malignancy with phenotypes varying from spontaneously regressing to metastatic tumors. Thus, disease stratification and the subsequent treatment decision is of utmost importance for NB patients. The methods, which are currently available for prognosis, require complex genetic analyses and access to the tumor tissue. Thus, there is a need for new prognostic and predictive markers that reflect the NB biology and rely on simple tests and easily accessible material. Serum metabolite profiles reflect a combination of factors released by the tumors and the general metabolic state of the patients. Thus, identifying the differences in metabolites between patients with various tumor phenotypes and responses to treatment may lead to discovery of biologically relevant prognostic biomarkers. The goal of our study was to determine blood-based metabolic signatures characteristic for patients with low and high-risk NB and identify potential biomarkers of high-risk disease. Plasma samples from NB patients at different stages of the disease were obtained from the Children’s Oncology Group. Initially, 50 samples were analyzed by Ultra Performance Liquid Chromatography (UPLC) in conjunction with electrospray-quadrupole-time of flight mass spectrometry (ESI-Q-TOF). A set of 26 independent plasma samples was then used for validation study. Statistically significant differences in metabolic profiles were observed between serum from patients with low and high risk disease, various stages of the disease (stage 1-2 vs stage 3 and/or stage 4), as well as undifferentiated vs. differentiating tumors. For all of the identified metabolites, the metabolic consumption, and synthesis pathways were identified and compared, which significantly differ between the groups exhibited high test sensitivity and specificity (the area under the ROC curves 0.92-1). Metabolites that were disregulated in high risk NBs included those involved in energy and choline metabolism, as well as amino acid and lipid biosynthesis. Of particular interest was a significant increase in serum levels of oxoglutaric acid observed in patients with high-risk disease (p<0.01) and metastatic tumors (p<0.001). As oxoglutaric acid is a key metabolite of the tricarboxylic acid cycle that is involved in regulation of the balance between glutamine and glucose metabolism, as well as lipid synthesis and hypoxia response, these data warrant further investigations into the biological role of these pathways in biology of high risk NB. In summary, using a metabolomics approach we were able to delineate blood based biomarkers that could potentially be used for patient stratification following large scale validation studies.
used this model system and a gene expression based approach to identify that Ewing sarcoma cells are uniquely vulnerable to inhibitors of ribonucleotide reductase (RNR), which impair DNA replication by blocking the synthesis of deoxyribonucleotides. Here we report that the treatment of Ewing sarcoma cells with gemcitabine, an irreversible inhibitor of the RRM1 subunit of RNR, results in impaired DNA replication, cell cycle arrest in G2/M phase, apoptosis in Ewing sarcoma cells. Additionally, we have found that the effect of gemcitabine on the viability of Ewing sarcoma cells is sustained even after removal of the drug from the cell culture medium. Moreover, ataxia telangiectasia and rad3-related protein (ATR) and checkpoint kinase 1 (CHK1) inhibitors increase the toxicity of gemcitabine in Ewing sarcoma cells by blocking the adaptive response to impaired DNA replication. Currently, ongoing work is focused on in vivo testing of gemcitabine, alone and in combination with CHK1 and ATR inhibitors, as a novel therapeutic approach for the treatment of Ewing sarcoma.

TUMOR BIOLOGY: Regulation and Imaging of Tumor Metastasis

#1958 Opposing roles of Sma2 and Sma3 in the regulation of growth and invasion of TNBC through TMEPAI. Prajal K. Singh, Sri lakshmi Pan deswara, Manjeri A. Venkatashamal, Pothana Saikumar. UT Health Science Ctr. at San Antonio, San Antonio, TX.

The dependency of triple negative breast cancers (TNBC) on TGF-β signaling activity for their growth and metastasis is well documented. Breast tumors develop resistance to TGF-β-induced growth inhibition, which helps in tumor progression. Additionally, TGF-β is enriched in the tumor microenvironment and is a key inducer of epithelial to mesenchymal transition (EMT) in breast cancer. In an effort to understand the mechanisms by which TGF-β mediates breast tumorigenesis, we sought to identify the relative individual contributions of Sma2 and Sma3 in mediating cancer cell growth and metastasis by TGF-β. Screening of several TNBC cell lines showed increased Sma3/Sma2 expression ratio compared to normal mammary epithelial cells, which suggested breast cancer cells may escape TGF-β-mediated cell cycle arrest by altering their relative expressions of Sma2 and Sma3. Since overexpression of R-Smads may not always accurately reflect the functional status of the endogenous molecules, we individually downregulated each R-Smad and tested its effect on pro-oncogenic behavior of TGF-β. Although Sma2 deficiency has no effect on breast cancer cell behavior, Sma3 deficiency reduced growth and invasion capacity of breast cancer cells. Interestingly, while Sma2 deficiency was associated with reduced TMEPAI/PMEPAI and EMT gene expressions and increased expression of cell cycle inhibitors, Sma2 deficiency had opposite effect on these regulators. Moreover, decreased growth and invasion associated with Sma2 deficiency were largely reversed by overexpressing TMEPAI in Sma3 knockdown cells, suggesting that Sma3/TMEPAI axis may be involved in subverting growth suppression effects of TGF-β into growth promotion. Compared to control and Sma2 deficient cells, Sma3 deficient cells had markedly elevated PTEN protein levels and suppressed Akt phosphorylation both under basal conditions and TGF-β stimulation. We identified that Sma3 but not Sma2 plays an important role in stimulating TMEPAI expression, growth and EMT in triple negative breast cancer cells by promoting TGF-β dependent non-canonical signaling by decreasing the cellular content of PTEN and p27 in a TMEPAI dependent manner. Taken together, the results demonstrate a novel role for Sma3 in breast cancer transformation and cancer progression through TMEPAI. Current therapeutic strategies are aiming at antagonizing the whole TGF-β signaling pathway thereby completely blocking both Sma2 and Sma3 signaling pathways. Selective targeting of TGF-β-Sma3/TMEPAI axis may be more beneficial in triple negative breast cancer therapy and prevention.

TUMOR BIOLOGY: Pediatric Cancer 1: Biomarkers, Preclinical Models, and New Targets

#1956 ABCE1 regulates the translational profile of neuroblastoma to drive tumor progression. fixuan Gao,1 Klaartje Somers,2 Katherine M. Hannah,1 Jamie I. Fletcher,1 Bing Liu,1 Ross D. Hannan,1 Richard B. Pearson,1 Michelle Haber,1 Murray D. Norris,1 Michelle J. Henderson.1

Neuroblastoma is the most common extracranial solid tumor in children. A key driver of high-risk neuroblastoma is the MYCN transcription factor which fuels neuroblastoma progression by enhancing metabolic processes including protein translation (1). ABCE1, a member of the ATP-binding cassette (ABC) superfamily of transporters, is a translational factor directing up-regulation of MYCN (2). It is thought to dissociate the 80S ribosome into free 40S and 60S subunits so they can re-initiate translation and provide the protein building blocks required for rapid cell growth and migration (3). High ABCE1 expression is associated with poor clinical outcome in neuroblastoma patients (2). Therefore, we hypothesized that ABCE1 suppression may inhibit the aggressiveness of neuroblastoma by disabling protein synthesis. To test this, we suppressed ABCE1 using siRNAs in MYCN-amplified neuroblastoma cell lines, SK-N-BE(2) cells, ABCE1 suppression delayed tumor growth (P<0.001) and metastasis (P<0.001). Mechanistically, when polyribosome analysis was used to monitor the impact of ABCE1 expression on protein translation in SK-N-BE(2) cells, loss of ABCE1 reduced the proportion of actively translating ribosomes (P<0.001), leading to lower global protein synthesis (P=0.018). This is the first report of ABCE1 acting as pro-tumorigenic factor in neuroblastoma. Our data imply that targeting the translational machinery through ABCE1 may be an effective therapeutic approach for the treatment of MYCN-driven cancers. J. Boon, K., Caron, H. N., van Asperen, P., Valentijn, L., Hermus, M. C., van Sluis, P., Roobol, I., Weis, I., Voûte, P. A., Schwab, M. & Versteeg, R. (2001) EMBO J. 20, 1383-1393. 2. Current therapeutic strategies are aiming at antagonizing the whole TGF-β signaling pathway thereby completely blocking both Sma2 and Sma3 signaling pathways. Selective targeting of TGF-β-Sma3/TMEPAI axis may be more beneficial in triple negative breast cancer therapy and prevention.

#1959 MTA1 promotes tumor progression and bone metastasis in prostate cancer via positive regulation of MUC1 and CTSB. Avinash Kumar,1 Swati Dhar,2 Gisella Campaneli,3 Nasir A. Butt,2 Christian R. Gomez,2 Jason M. Schallheim,2 Anait S. Levenson1.1 Long Island University, Brooklyn, NY; 2University of Mississippi Medical Center, Jackson, MS.

About 80% of the time that prostate cancer cells metastasize, they spread to the bones. Metastasis involves activation of invasive programs through genetic and epigenetic alterations, including changes in expression of chromatin remodeler proteins. We have previously identified metastasis-associated protein 1 (MTA1), a chromatin remodeler, as a component of vicious cycle of bone metastasis and confirmed significantly higher expression of MTA1 in bone metastases than in primary tumors. In an attempt to dissect molecular mechanisms of MTA1 action, we performed integrative analysis of our bone metastasis signature data along with MTA1 ChiP-seq data, which revealed mucin 1 (MUC1) and cathepsin B (CTSB) as strong potential candidates responsible for MTA1-driven invasiveness. Here, we show that loss of function studies with MTA1 in PC3M aggressive prostate cancer cells do not affect cell proliferation but leads to decrease in colony forming ability, invasive and migratory property of these cells. When PC3M cells silenced for MTA1 and tagged with luciferase are used to generate subcutaneous or intracardiac xenografts, it leads to reduced tumor progression or decreased metastasis to bone, respectively.
as evident by bioluminescent measurements and histology of tumors. Ongoing experiments aim to validate the role of MUC1 and CTBS in MTA1-driven invasiveness and metastasis in prostate cancer.

**#1960 Upregulation of MCP-1 regulates invasiveness in triple negative breast cancer.** Pranabananda Dutta, Kimberly Paico, Inez Yuwanita, Yanyuan Wu, Marianna Sarkissian, Jaydutt Vadgama. *Charles R. Drew University, Los Angeles, CA.*

Background: Triple negative breast cancer (TNBC) poses a critical problem for targeted therapy due to lack of significant expression of estrogen, progesterone receptor or Her2/neu oncogene. Hence, it is imperative to identify novel therapeutic strategies to target TNBC. Our study is aimed to examine whether Monocyte Chemotactic Protein -1 (MCP-1) is a specific marker for TNBC metastasis. Experimental Design: We employed ELISA to determine secreted MCP-1 in cell conditioned media, as well as Real-time PCR to determine the status of MCP-1 in TNBC cell lines. Boyden chamber assay was used to determine the effect of recombinant MCP-1 on cellular metastasis. Cellular proliferation was measured with MTT assay. Immunofluorescence staining was utilized for protein of interest in breast cancer cells. MCP-1 knockdown was performed using lentiviral vector with shRNA targeting MCP-1 coding regions. Results: Our data show that the key inflammatory chemokine MCP-1 is upregulated in TNBC cell lines both transcriptionally as well as in terms of secretion compared to ER-positive cell line, MCF-7. MCP-1 stimulation in MDA-MB231 and MCF-7 cells does not affect cellular proliferation. However, MCP-1 increases metastatic phenotype of MDA-MB-231 cells along with BT-549 cells. Inhibiting Chemokine receptor 2/4 (CCR2/4), cognate receptor for MCP-1, with small molecule antagonists negatively affects invasiveness in MDA-MB-231 as evidenced by Boyden chamber assay. Knocking down MCP-1 by shRNA decreases cell invasion in TNBC cell line, BT-549 along with downregulation of key epithelial to mesenchymal transition markers, N-cadherin and Vimentin. MCP-1 induced cell invasion in TNBC may involve activation of p44/p42 MAPK Thr202/Tyr204. Conclusion: Our study suggests that high MCP-1 levels in TNBC is driving up metastasis potential in cells. Thus MCP-1 and its mediated pathways could be potential therapeutic targets for the treatment of TNBC.

The epithelial-mesenchymal transition (EMT) is a developmental program that is aberrantly activated in cancer cells, producing an invasive phenotype that can lead to metastasis. Inducers of EMT are largely known and have been widely studied. However, the mechanisms that regulate the link between extracellular stimuli and EMT phenotypes remain poorly understood. Preliminary evidence from our laboratory suggests that downregulation of proteasome activity may be responsible, in part, for driving EMT. Using immortalized human mammary epithelial (HMEE) cells as a model, we show that (1) EMT is associated with decreased proteasome activity and increased polyubiquitinated substrates, (2) pharmacologic inhibition of proteasome activity leads to increased EMT phenotypes and (3) pharmacologic inhibition of proteasome activity leads to increased EMT via stabilization of the TGF-β signaling pathway. Together, these data suggest that proteasome activity may be an unappreciated regulator of EMT.

**#1962 Regulation of invasion by lysine demethylase 5B in non-small cell lung cancer cells.** Elizabeth L. Zoeller, Jessica Konen, Joshua Bell, Emily Summerbell, Jeanne Kowalski, Adam Marcus, Paul Vertino. *Emory Univ., Decatur, GA.*

Histone modifying enzymes are often dysregulated during carcinogenesis and are major contributors to the development of oncogenic features, including proliferation, drug resistance, and metastasis. Given these roles, histone modifiers are promising new targets for oncological therapeutics. One of the enzyme families at the center of this area of research is the lysine demethylase family KDM5, for which several inhibitors are in development. KDM5A and KDM5B are frequently overexpressed or mutated in human non-small cell lung cancer (NSCLC). In overexpression studies, KDM5B promotes invasion and migration of NSCLC cells, whereas invasion and migration of NSCLC cells were decreased following knockdown of KDM5B. Furthermore, in patients with NSCLC, KDM5B is expressed at higher levels in brain metastasis sites when compared to both normal tissues and primary tumors. These findings suggest a role for KDM5B in lung cancer and metastatic spread. However, the precise role of KDM5 family members in lung cancer invasion and metastasis is not known. Recently, we discovered that KDM5B is differentially expressed in cell subtypes within a 3D model of NSCLC collective cell invasion. In this model isolated single cells at the forefront of invasive branches (leader cells) express more 2-4 fold more KDM5B protein than the cells following (follower cells), while KDM5A and KDM5C are evenly expressed across both cell types. KDM5B mRNA expression is similar across cell types suggesting that the differential protein expression is mediated at the posttranscriptional level. Interestingly, global H3K4me3 levels are decreased in leader cells as compared to follower cells, supporting the idea that the lysine demethylases targeting this residue may be expressed at higher levels in leader cells. Collectively, these data suggest that KDM5B could be contributing to initiation of invasion at the primary site and thus, promoting metastasis. Given the rising prominence of therapeutic inhibitors of KDM5 family members, a better understanding how KDM5B contributes to cell invasion may lead to a new approach to the prevention of metastasis.

Background: Advanced gastric cancer (GC) frequently recurs because of undetected micrometastases even when disease is localized and patients undergo curative resection. Moreover, peritoneal metastasis is fatal. We aimed to develop novel diagnostic and therapeutic targets specific for peritoneal metastasis of GC to improve management. Methods: We conducted a metastatic pathway-specific transcriptome analysis to identify candidate biomarkers comprising 340 patients allocated to discovery and validation sets (1:2) to evaluate the diagnostic and predictive value. The mRNA and protein levels in primary GC tissues were compared with patients' clinical characteristics and survival. The effects of siRNA-mediated knockdown on phenotype and fluorouracil sensitivity of GC cells were evaluated in vitro, and the therapeutic effects of siRNAs were evaluated using a mouse xenograft model. Result: Synaptotagmin VIII (SYT8) was identified as a candidate biomarker specific to peritoneal metastasis. SYT8 levels were elevated in the validation set comprising patients with peritoneal recurrence or metastasis. High SYT8 levels were significantly and specifically associated with peritoneal metastasis, and served as an independent prognostic marker for peritoneal recurrence-free survival of patients with stage II/III GC. The survival difference between high and low SYT8 levels was associated with patients who received adjuvant chemotherapy. Inhibition of SYT8 expression by GC cells correlated with decreased invasion, migration, and fluorouracil resistance. Intrapерitoneal administration of SYT8-specific siRNA inhibited the growth of peritoneal nodules and prolonged survival of mice engrafted with GC cells. Conclusions: SYT8 expression represents a promising diagnostic and predictive biomarker for peritoneal metastasis of GC.

**#1965 A novel biocompatible fluorescent nanoparticle enables enhanced live cell tagging and tracking of cancer cells.** Nick Asbrock, Yi Chu, Kevin Su, Ben Zhong Tang, Bin Liu. *MilliporeSigma, Temecula, CA; The Hong Kong University of Science & Technology, Clear Water Bay, Kowloon, Hong Kong, China; National University of Singapore, Temecula, CA.*

Metastasis is the leading cause of cancer mortality. Metastasis is a multi-step process which includes local tumor cell invasion, cell migration into the vasculature, exit of cells from the circulation and colonization at the distal tissue sites. Long-term noninvasive cell tracking by fluorescent probes is of great importance to life science and biomedical engineering. Current methods used to fluorescently tag cancer cells have been limited by short signal duration, high background autofluorescence or lengthy cell line generation using GFP. We have developed a biocompatible fluorescent nanoparticle which relies on Aggregation Induced Emission (AIE) technology that are highly resistant to fluorescent signal quenching. These particles enable highly efficient live cell fluorescent tagging while retaining fluorescent signal for up to 10 days in vitro and 21 days in vivo. These nanoparticles will open new avenues in the development of fluorescent probes for following biological processes such as carcinogenesis.

**#1966 Cell-surface major vault protein is a novel marker for circulating tumor cells with nonepithelial phenotypes in hepatocellular carcinoma.** Hyun Min Lee, Jae Won Joo, Won Tae Kim, Min Kyu Kim, Se Ri Seo, Hong Seo Choi, Hee Jin Chang, Young Joo Jang, Chul Jeuk Ryu. *Sejong University, Seoul, Republic of Korea; Sungkyunkwan University, Seoul, Republic of Korea; National Cancer Center, Goyang, Republic of Korea; Dankook University, Cheonan, Republic of Korea.*

Several recent studies have reported that major vault proteins (MVPs) are involved in a number of biological processes including regulation of proliferation, drug resistance, and metastasis. Given these roles, histone modifiers are promising new targets for oncological therapeutics. One of the enzyme families at the center of this area of research is the lysine demethylase family KDM5, for which several inhibitors are in development. KDM5A and KDM5B are frequently overexpressed or mutated in human non-small cell lung cancer (NSCLC). In overexpression studies, KDM5B promotes invasion and migration of NSCLC cells, whereas invasion and migration of NSCLC cells were decreased following knockdown of KDM5B. Furthermore, in patients with NSCLC, KDM5B is expressed at higher levels in brain metastasis sites when compared to both normal tissues and primary tumors. These findings suggest a role for KDM5B in lung cancer and metastatic spread. However, the precise role of KDM5 family members in lung cancer invasion and metastasis is not known. Recently, we discovered that KDM5B is differentially expressed in cell subtypes in a 3D model of NSCLC collective cell invasion. In this model isolated single cells at the forefront of invasive branches (leader cells) express more 2-4 fold more KDM5B protein than the cells following (follower cells), while KDM5A and KDM5C are evenly expressed across both cell types. KDM5B mRNA expression is similar across cell types suggesting that the differential protein expression is mediated at the posttranscriptional level. Interestingly, global H3K4me3 levels are decreased in leader cells as compared to follower cells, supporting the idea that the lysine demethylases targeting this residue may be expressed at higher levels in leader cells. Collectively, these data suggest that KDM5B could be contributing to initiation of invasion at the primary site and thus, promoting metastasis. Given the rising prominence of therapeutic inhibitors of KDM5 family members, a better understanding how KDM5B contributes to cell invasion may lead to a new approach to the prevention of metastasis.
Hepatocellular carcinoma (HCC) is currently the fifth most common malignancy worldwide and the poor because of frequent metastasis and resistance to chemotherapy. Circulating tumor cells (CTCs) in blood have attracted attention as potential seeds for metastasis and an important indicator of treatment outcome. However, the biological properties of CTCs are largely unknown due to rarity and lack of CTC-specific surface markers. Major vault protein (MVP) is upregulated during malignant progression and drug resistance development in various cancer cells, although it is ubiquitously expressed in many normal tissues. Here, we found for the first time that MVP was expressed on the surface of various cancer cells including HCC cell lines, although MVP has been known as a cytoplasmic and nuclear protein. To investigate the role of cell-surface MVP (csMVP) on HCC cell lines, MVP expression was knocked down in Huh7 cells by small interfering RNA. MVP knockdown decreased cell growth and increased apoptotic cell death. When Huh7 cells were treated with a polyclonal anti-MVP antibody (α-MVP) recognizing csMVP, Huh7 cell proliferation was decreased without apoptotic cell death. Cell sorting revealed that csMVP-positive Huh7 cells showed a higher proliferation and survival rate than csMVP-negative Huh7 cells under the stress of low density seeding. Huh7 cells treated with α-MVP also inhibited cell invasion and migration in vitro. Thus, csMVP is positively associated with HCC cell proliferation, survival, invasion and migration. Analysis of signaling molecules showed that MVP knockdown caused a significant decrease in the levels of phosphorylation of FAK, ERK, AKT and S6K. MVP knockdown also increased E-cadherin but decreased vimentin, indicating that MVP promotes the process of epithelial-to-mesenchymal transition. To further analyze the role of csMVP during HCC metastasis, blood samples from 62 HCC patients and 10 healthy volunteers were stained with csMVP, EpCAM, HSA, EGFR, CK, and/or vimentin antibodies after the depletion of red blood cells and CD45-positive cells. csMVP-positive CTCs were detected in approximately 85.5% (>0.46 CTCs/ml) of patients, and the cell count measured in ml of blood ranged between 0.48 and 37.8. Double staining showed that almost all csMVP-positive cells were panCK-negative while approximately one fifth of csMVP-positive CTCs was HSA-positive. Triple staining further showed that among csMVP-positive cells, EpCAM “Vimentin”, EpCAM “Vimentin”, EpCAM “Vimentin” and EpCAM “Vimentin” cells were approximately 0.0, 49 and 51%, respectively, suggesting that a half of csMVP-positive cells are EMT-phenotype cells and the rest of them are both EpCAM- and vimentin-negative cells. The results suggest that csMVP is a novel marker on CTCs in patients with HCCs, where it is expressed predominantly on EMT phenotypic and EpCAM-“vimentin” intermediate CTCs.

### 1967 A novel 40kDa CPE-ΔN isoform promotes proliferation and invasion in pancreatic cancer cells. Xu Yu Yang, Cong Ling, Hong Lou, Loh Yoke Peng, National Institutes of Health, Bethesda, MD.

Carboxypeptidase E (CPE) is a prohormone processing exopeptidase that cleaves C-terminal basic residues from peptide hormones liberated endopeptidolytically from prohormones. It is identified molecular basis for pancreatic cells and the rest of these effects can be attenuated by Twist1 protein deletion mutants.

### 1968 A novel mechanism of metastasis: Extracellular ATP promotes invasion and metastasis independent of purinergic receptor signaling. Yanyang Cao, Xuan Wang, Xiaohou Chen. Ohio Univ., Athens, OH.

Cancer is one of the top deadliest diseases in the US and worldwide. Metastasis, the dissemination of cancer cells from the primary tumors to distant organs, is responsible for 90% of solid tumor-related deaths. Tumor invasion and metastasis is a multistep process in which loss of cell-cell adhesion, increased proteolysis, and cell motility has been shown to be critical steps. Extracellular ATP (eATP) is released during cellular processes and plays a critical role in tumor cell detachment, motility, invasion and tumor metastasis initiation. It was previously shown that ATP-induced purinergic receptor (PR) signaling is involved in metastasis. Our hypothesis is different in that eATP also mediates invasion and metastasis independent of PR signaling. Various bioassays were used in human non-small cell lung cancer (NSCLC) A549 cells to test our hypothesis. Our results show that eATP treatment led to a substantially increased number of floating cancer cells, and these cells were viable and formed clones in a clonogenic assay. This indicates that eATP induces cancer cell detachment. Moreover, treatment of eATP also induces cell migration in cell woundings and Transwell migration assays. In vitro migration that eATP induced a dose-dependent increase in the invasive capacities of the A549 cells. Western blot analysis indicates that eATP treatment reduced the expression of cell-cell adhesion molecule E-cadherin. PR inhibitors only slightly attenuated these effects. All these suggest novel ATP mechanisms independent of the PR signaling that are unreported before and imply novel targets for inhibiting/preventing metastasis. References 1. Qian et al. Glucose-regulated protein 94 is a novel expression biomarker in esophageal squamous cell carcinoma. Yu-Jia Chang,1 Chien-Yu Huang,1 Taipei Medical Univ., Taipei, Taiwan; 2Department of Surgery, Shuang Ho Hospital, Taipei Medical University, Taipei, Taiwan.

Background: Esophageal cancer is a worldwide health problem with a very poor prognosis as most patients present very late when the disease is advanced and difficult to cure. It is urgent to figure out a diagnostic and therapeutic strategy. Glucose-regulated protein 94 (GRP94) has been found highly correlated with cancer progression. However, the role of GRP94 in the progression and metastasis of esophageal squamous cell carcinoma (ESCC) is still unclear.

Methods: We investigated the GRP94 expression level of ESCC cells and generated GRP94-KD cells by shRNA technique. The proliferation assay, migration, invasion assay were performed. The tissue array was performed to see the correlation of GRP94 and clinical outcomes on ESCC. Mitochondrial bioenergetics were assessed using a Seahorse XF24 flux analyzer. The Transmission Electron microscopy was applied to see the structure of mitochondria.

Results: We found that ESCC specimen that expressed higher GRP94 showed the lower overall survival in tissue array results. The ESCC cells expressed high level of GRP94. Silencing GRP94 reduced the proliferation, migratory and invasion activity. Transmission Electron microscopy revealed the impaired mitochondrial in GRP94-KD cells. GRP94-KD cells also displayed reduced basal respiration, spare oxygen capacity and respiratory control ratio. The changes were analyzed by Mann Whitney U-test. Survival analysis between high and low expression group of the candidate genes was performed by Kaplan-Meier method.

Conclusion: We found that silencing GRP94 in ESCC cells suppressed cancer growth and metastasis ability through COX-2 and EMT molecules expression. In addition, GRP94 may mediate the functional mitochondria in ESCC. GRP94 may be a new target to develop the therapeutic strategy for ESCC.

ITGBL1 is a novel epithelial mesenchymal transition-associated prognostic biomarker in colorectal cancer. Takatoshi Matsuyama,1 Toshiaki Ishikawa,2 Naoki Takahashi,3 Yasuhide Yamada,3 Masamichi Yasuno,2 Tatsu-suyuki Kawano,3 Hiroyuki Uetake,3 Ayaj Goa.1 Baylor Scott & White Research Institute and Charles A Simmmons Cancer Center, Dallas, TX;2Tokyo Medical and Dental University, Tokyo, Japan; 3National Cancer Center Hospital, Tokyo, Japan.

Purpose: Colorectal cancer (CRC) ranks as the third leading cancer worldwide, and its incidence continues to rise gradually, highlighting the need to stratify the risk of recurrence after curative surgery. Recently, several genes have been identified which appear to associate with metastasis, as they mediate epithelial-to-mesenchymal transition (EMT). This study aimed to identify novel EMT and cancer recurrence-associated biomarkers through systematic and comprehensive discovery and validated strategy in multiple, independent CRC cohorts. Experimental Design: Two independent gene expression microarray datasets (n = 173 and n = 307 respectively) were used to identify novel metastasis-recurrence biomarkers for CRC. Following carefully selection and prioritization of biomarkers, we selected a candidate gene and validated its performance as a recurrence marker in a large testing cohort (n = 566), and two independent clinical validation cohorts (n = 201, n = 475, respectively). To confirm the protein expression of ITGBL1 in cancer, immunohistochemistry (IHC) was performed in paired 33 primary CRCs and adjacent normal mucosa, as well as a subset of liver and lung metastases tissues. In addition, we used Gene Set Enrichment Analysis (GSEA) to determine the functional role of ITGBL1 in CRC. Results: During the discovery step, gene expression profiles from differentially expressed genes between recurrence positive and negative primary CRCs, as well as evaluation of the metastatic sites compared with primary CRC, identified ITGBL1 as a most promising candidate biomarker. High expression of ITGBL1 associated with poor overall survival (OS) in stage I-IV patients and worse disease-free survival (DFS) in stage I-III patients. Subgroup validation of these results in two large and independent patient cohorts confirmed these findings and demonstrated that high ITGBL1 expression correlated with shorter DFS in stage II and III CRC patients. In addition, high ITGBL1 expression emerged as an independent prognostic factor for DFS in stage I and II patients. IHC analysis revealed that both early stage CRCs and adjacent normal colonic mucosa displayed low ITGBL1 expression, while ITGBL1 expression gradually increased from tumor surface to the invasive front in late stage cancer, indicating that ITGBL1 may facilitate EMT process and promote a more aggressive phenotype in CRC. Conclusions: High expression of ITGBL1 in primary tumors was associated with tumor recurrence in CRC patients after curative surgery. Collectively, we have identified ITGBL1 as a novel EMT-associated biomarker which could be used for risk stratification for metastatic potential in CRC.

Identification of novel candidate driver genes of colorectal cancer on chromosome 7p. Yuta Koyama,1 Yushi Ogawa,1 Takaaki Masuda,1 Yukihiro Yoshikawa,2 Miwa Noda,1 Hiroaki Wakiyama,3 Kuniai Sato,1 Sho Nambara,1 Qingiang Hu,1 Shinya Kidogami,1 Tomoko Saito,2 Shotoar Sakamura,2 Naoki Hayashi,1 Yohsuke Kuroda,2 Shuhei Ito,1 Hitodetsu Eguchi,1 Koshi Moromi1,3 Kyushu University Beppu Hospital, Japan; 2Showa University Northern Yokohama Hospital, Japan. Japan.

Background: Colorectal cancer (CRC) is one of the most prevalent types of cancer. The high mortality rate of CRC is a serious problem. Hence it is urgently necessary to identify novel molecular target to improve the mortality rate. Amplification of chromosome 7p is frequent in CRC, and it has been considered to harbor driver genes that promote tumorigenesis or tumor progression by the gain of function. The aim of this study is to identify novel candidate driver genes on chromosome 7p and to clarify the clinical significance of their expression in CRC.

Material and Methods: 1. We selected the candidate genes that satisfied the following criteria using CRC data from The Cancer Genome Atlas (TCGA). 1) The DNA copy number and mRNA expression is positively correlated with each other, 2) overexpressed in the tumor tissues compared to the normal tissues. 2. The mRNA expression of the candidate genes was measured in 108 surgically-resected CRC tissues and the paired normal tissues in our hospital by quantitative RT-PCR. The differences of mRNA expression between CRC tissues and normal colon tissues were analyzed by Mann Whitney U-test. Survival analysis between high and low expression group of the candidate genes was performed by Kaplan-Meier method.

Conclusion: We found that the mRNA expression of the candidate genes and the clinicopathological factors were analyzed by Fisher’s exact test. We performed Gene Set Enrichment Analysis (GSEA) in CRC data from TCGA to clarify the correlation between the candidate genes and gene sets that are associated with tumorigenesis or tumor progression. Results: DEAD Box Helicase 56 (DDX56), ATP-dependent RNA helicases involved in several aspects of RNA metabolism including mRNA splicing and transport, transcription and translation, transcriptional and translational remodeling of ribonucleoprotein complexes, was satisfied with the criteria. The expression of DDX56 was significantly higher in CRC tissues than in normal colon tissues (p < 0.005), and it correlated with lymphatic invasion (p = 0.02), and distant metastasis (p = 0.03). The high DDX56 expression group had a significantly poorer prognosis than the low expression group (p = 0.03). On multivariate analysis, high DDX56 expression was an independent prognostic factor affecting OS (p = 0.013) with hazard ratios (95% CI) of 2.32 (1.20–4.48) among clinicopathological factors. GSEA showed that DDX56 expression was positively correlated with mitotic cell cycle progression and splenomegaly. Conclusions: We identified DDX56 as a promising driver gene of CRC on chromosome 7p. DDX56 expression was positively associated with lymphatic invasion and distant metastasis, and was an independent poor prognostic factor. Furthermore, DDX56 may be involved in tumor progression through stimulating cell-cycle. DDX56 could be a therapeutic target as well as a poor prognostic biomarker in CRC.

Novel relationships of expression of methylxanthine alkaloid receptor genes and risk of breast carcinoma recurrence. Seth B. Sereff, Michael W. Daniels, James L. Wittliff. University of Louisville, Louisville, KY.

Consumption of methylxanthine alkaloids such as caffeine, theophylline and theobromine may induce breast pain. Caffeine appears to induce its biological activity by antagonizing adenosine receptors, which have been implicated in breast cancer cell behavior in vitro. Our goal is to evaluate expression of genes for methylxanthine receptors and metabolizing enzymes for assessing risk of breast cancer recurrence. Procedures: De-identified primary cancers previously collected, stored and analyzed under stringent conditions were employed to amass an IRB-approved, de-identified comprehensive Database. Patient-related properties (e.g., nodal status, clinical outcome) and results from estrogen (ER) and progesterin receptor (PR) analyses and gene expression assays guided selection. To decode clinical utility of gene expression profiles, Laser Capture Microdissection (PicCell He164 Arcturus/Thermo Fisher) was used previously to non-destructively collect carcinoma cells. DNA was extracted, amplified and analyzed by microarray (~ 22,000 genes). Results: Gene expression levels of 8 methylxanthine receptors, 8 metabolizing enzymes and various phosphodies- terases were retrieved from microarray results of 247 breast biopsies. Unvariable Cox regressions and Kaplan Meier plots were determined for each candidate gene with R software. Kaplan-Meier plots of PDE4A, CYP2A6 or CYP2E individually indicated lower expression was related to decreased progression free (PFS) and overall survival (OS) while PDE1A over-expression predicted patients with better survival (OS).
TUMOR BIOLOGY: Regulation and Imaging of Tumor Metastasis

FAM83B is a novel oncogene identified by the Jackson Laboratory in a forward genetic screen for drivers of Human Mammary Epithelial Cell (HMEC) transformation. Previous work showed that FAM83B expression is elevated in triple negative breast cancers and that FAM83B also activates key cell signaling pathways (EGFR, MAPK, and PI3K) in breast cancers. Here, we implicate FAM83B as a novel regulator of epithelial-mesenchymal plasticity using a HMEC transformation model. Transformation of primary HMEC by expressing shp16, shp53, c-Myc, and RAS results in the generation of two distinct transformed cell populations. One population retains epithelial characteristics, while an emergent population spontaneously acquires a mesenchymal morphology and a CD24+/CD44+ (CSC) cell surface marker profile. Moreover, isolation of epithelial, CD24+/CD44+ cells (non-CSC) and exposure to Oncostatin M (OSM), an EMT-inducing cytokine, can also generate cells with a mesenchymal/CSC phenotype. Interestingly, FAM83B expression was significantly elevated in the epithelial/non-CSC population compared to the mesenchymal/CSC population. Moreover, treatment of purified epithelial/non-CSC cells with OSM resulted in decreased FAM83B expression levels, indicating FAM83B expression is suppressed as the cells move through EMT. FAM83B expression also correlated with an epithelial phenotype in a panel of breast cancer cell lines. shRNA-mediated knock-down of FAM83B from epithelial/non-CSC resulted in increased spontaneous EMT, concomitant with elevated expression of the mesenchymal marker Vimentin and master EMT transcription factor Zeb1. Following treatment, murine shB3 cells exhibited increased expression of p-ERK, p-STAT3 and p-p70S6K signaling, known contributors to the mesenchymal/CSC phenotype. Conversely, OSM-induced EMT was blunted in epithelial/non-CSC expressing exogenous FAM83B. Thus, FAM83B expression is a determinant in maintaining an epithelial phenotype, while suppression of FAM83B is important during EMT. Future work will seek to define novel FAM83B-mediated signaling pathways important for regulating cellular plasticity.

#1974 Novel function of PCNA in mammary tumor development and distant metastasis through tyrosine phosphorylation. Yuen-Liang Wang,1 Lanie Chang,2 Susan E. Waltz,3 Shao-Chun Wang.1 1China Medical University & Taichung City, Taiwan; 2China Medical University Hospital, Taichung City, Taiwan; 3University of Cincinnati, Cincinnati, OH.

Breast cancer is the most common cancer besides skin cancer and is the second leading cause of cancer-related death in women in the US. Despite intensive study, metastasis and tumor dormancy continue to be major hurdles to eradicate this disease. PCNA forms a heterotrimeric ring encoding the DNA double helix and acts as a sliding platform indispensable for DNA replication, damage repair, and chromatin remodeling. While a positive role of PCNA in oncogenic transformation remains elusive due to the embryonic lethal phenotype in PCNA-deficient mice. We have shown that PCNA is regulated by phosphorylation at tyrosine 211 (Y211) mediated through multiple growth factor-stimulated signaling pathways. Y211 phosphorylation enhances chromatin-bound PCNA to promote cell proliferation and is the embryonic lethal phenotype in PCNA-deficient mice. We have shown that conceivably, how PCNA functions in tumor progression remains elusive due to malignant potential. Further study using syngeneic orthotopic model of transplanting murine breast tumor-initiating cells (TICs) as determined by in vitro and in vivo analysis. Our preliminary findings that the ligand pathways leading to Y211 phosphorylation can also be inhibited by FDA-approved drugs, our results suggest that pY211-PCNA may be a new druggable mechanism to target tumor metastasis.

#1975 FAM83B: A novel regulator of cell plasticity in breast cancer. Courtney A. Bartel, Damon J. Junk, Mark W. Jackson. Case Western Reserve University, Cleveland, OH.

Epithelial to mesenchymal transition (EMT) is an important process in both metastasis and cancer stem cell (CSC) enrichment. Recent studies suggest that instead of simply transitioning from one cell state to another, cancer cells exist along a continuum of epithelial and mesenchymal cell states. Identifying novel regulators of tumor cell plasticity will be critical to fully understand this continuum and to target metastasis and CSC phenotypes in the future. FAM83B is a novel oncogene identified by the Jackson Laboratory in a forward genetic screen for drivers of Human Mammary Epithelial Cell (HMEC) transformation. Previous work showed that FAM83B expression is elevated in triple negative breast cancers and that FAM83B also activates key cell signaling pathways (EGFR, MAPK, and PI3K) in breast cancers. Here, we implicate FAM83B as a novel regulator of epithelial-mesenchymal plasticity using a HMEC transformation model. Transformation of primary HMEC by expressing shp16, shp53, c-Myc, and RAS results in the generation of two distinct transformed cell populations. One population retains epithelial characteristics, while an emergent population spontaneously acquires a mesenchymal morphology and a CD24+/CD44+ (CSC) cell surface marker profile. Moreover, isolation of epithelial, CD24+/CD44+ cells (non-CSC) and exposure to Oncostatin M (OSM), an EMT-inducing cytokine, can also generate cells with a mesenchymal/CSC phenotype. Interestingly, FAM83B expression was significantly elevated in the epithelial/non-CSC population compared to the mesenchymal/CSC population. Moreover, treatment of purified epithelial/non-CSC cells with OSM resulted in decreased FAM83B expression levels, indicating FAM83B expression is suppressed as the cells move through EMT. FAM83B expression also correlated with an epithelial phenotype in a panel of breast cancer cell lines. shRNA-mediated knock-down of FAM83B from epithelial/non-CSC resulted in increased spontaneous EMT, concomitant with elevated expression of the mesenchymal marker Vimentin and master EMT transcription factor Zeb1. Following treatment, murine shB3 cells exhibited increased expression of p-ERK, p-STAT3 and p-p70S6K signaling, known contributors to the mesenchymal/CSC phenotype. Conversely, OSM-induced EMT was blunted in epithelial/non-CSC expressing exogenous FAM83B. Thus, FAM83B expression is a determinant in maintaining an epithelial phenotype, while suppression of FAM83B is important during EMT. Future work will seek to define novel FAM83B-mediated signaling pathways important for regulating cellular plasticity.

#1976 Dried blood imaging and immunoassay: Spot formation, particle migration, and tumor cell detection. Quanxu Shen,1 Bin Hong.2 1The Fifth Central Hospital of Tianjin, Tianjin, China; 2TeloVISION LLC, West Lafayette, IN.

Blood droplet, when dried, forms a structured sedimentation pattern with central flat, corona ring and peripheral rim. This pattern can be fine-tuned with the blood formula. Surfactant is critical to promote the gelation process, eliminate the film cracking and delamination, and hence, suppress the coffee-ring effect. Additionally, surfactant restrains the shrinkage of the dried film. Without surfactant, the contraction was 100–150 μm for 20 μL of blood; decreased with surfactant added; fully stopped at 10% of concentration. Drying at room temperature with surfactant formed a flat disc-shaped deposit, while at 37°C, volca- nic protrusion was developed. The size of the protrusion depended on the concentration of the surfactant primarily, and the anticoagulant type, evapora- tion velocity, and blood volume. To monitor the dynamic desiccation process, video recording of the evaporating drop was employed. It revealed a quick dis- location of the leukocyte-resembling beads to the outer region of the blood spot, reportedly at velocity of 10μm/sec. The use of 1 and 10μm sized beads further demonstrated layered convective flow below the surface. Beads migrated out- ward primarily before gelation, inward slightly during solidification, and ulti- mately settled down across the spot. The movement of beads was found in the range of a few hundred microns to millimeters before and after desiccation for a 50μL drop. Notably, plasma proteins and saline have influenced the bead distri- bution more than the surfactant. After plasma removal and mixing with surfac- tant, the majority of beads were dragged to the periphery, compared with many beads for no plasma and surfactant, some for whole blood with surfactant, and none for whole blood without surfactant. For a thick blood film, detection of embedded cells and beads can be difficult. Experiments showed that beam of longer wavelength, 532nm, was capable of visualizing all fluorescent cells and beads. Dried blood spot (DBS) assay has been widely used for newborn metabo- lic testing and DNA analysis. To detect rare tumor cells in DBS, the dried pattern was optimized to eliminate the artifacts, stabilize the cells, and enrich the targeted cell. DBS assay holds greater potential for cancer detection when the medical resource is limited.
tissue prevalence of tumors in newly diagnosed individuals. Current methods for quantifying tumor burden are mainly qualitative and include measuring the gross weight of the affected organ, counting tumors on the surface of the organ, or evaluating a small sample of the organ using histologic sections. These methods are crude measures of tumor burden and size distribution, and in the case of histologic sectioning, they are time-consuming, difficult, and prone to measurement bias.

Methods: Animal models of metastasis have been useful in identifying genes that regulate susceptibility to the development and progression of metastasis and have helped to highlight potential novel targets for drug development. In particular, several small animal imaging technologies including magnetic resonance imaging, high frequency ultrasound, and optical imaging have been developed to this task. In this report, we describe specific research projects, based on their unique combination of resolution, image acquisition time, animal throughput, and cost-effectiveness, yet none of these modalities adequately address the need for rapid quantification of tumors across the entire organism, nor do they assess therapeutic effectiveness in eradicating cancer in xenograft models. We have developed an Accelerator Mass Spectrometry (AMS)-based high precision quantitative method for assessing the metastatic potential of primary tumors isolated from newly diagnosed patients.

Results: Our AMS-based methodology to study metastasis uses xenograft cancer cells labeled with $^{14}$C-labeled thymidine that are delivered intravenously into NSG mice and allowed to develop metastatic cancer over the course of up to 10 weeks. At the end of the experiment, all vital organs are collected; the DNA is isolated and analyzed using AMS for fluorescent bisphosphonates. The labeling was optimized to achieve sufficient signal such that a tumor derived from a single cell could be detected by AMS, in secondary tumors, in vivo, independent of histological data. Conclusions: Using this approach we have determined that tissue colonization by tumor cells is a very rare event, where most metastatic tumors are initiated by less than 10 cells delivered into NSG mice. Further optimization of these techniques will allow us to explore the metastatic potential of primary tumors, isolated from biopsies and expanded in Avatar mice. This study was supported in part by NIH P41 M021483 and was conducted under the auspices of the USDOE by LLNL. (DE-AC52-07NA27344). IM number: LLNL-678306.

#1978 Identification of the metastatic cell populations in a spontaneous mouse model of melanoma. Xiaoshuang Li, Raul Torres, Lidia Kos. Florida International University, Miami, FL.

Melanoma is the deadliest form of skin cancer due to its high propensity to metastasize and resistance to current therapies. We have created a spontaneous mouse model of metastatic melanoma (Dct-Grm1/K5-Edn3) where metastasis to the lungs is 80% penetrant. The primary tumors of these mice present cellular heterogeneity with cells at varying levels of differentiation. The main goal of this study is to determine the metastatic potential of the primary tumor resident Tyrosinase positive cells and evaluate the dynamic pattern of gene expression as those cells move from the primary tumors to the sites of metastasis. To accomplish this aim we crossed the Dct-Grm1/K5-Edn3 mice to CreERT2/ROSAmTmG mice to indebly label Tyrosinase cell populations within the primary tumor by topical application of 4-hydroxytamoxifen at the tumor site. In vivo lineage tracing and characterization of those labeled cells was performed in the metastatic xenografts. We found that Tyrosinase positive cells present the highest positive cell frequency and dissemination. We performed RNAseq analysis of those cells and tissue pairs to identify genes that are upregulated in cells that are able to metastasize. Overall, we identified a group of genes important for metastatic melanoma.

#1980 Fusion of cancer and stromal cells imaged by color-coded imaging of metastasis. Miki Nakamura,1 Atsushi Suetsugu,2 Kousuke Hasegawa,1 Takuro Matsumoto,1 Hiromi Aoki,1 Takahiro Kunisada,1 Masahito Shimizu,1 Shigeyo Saji,1 Hisataka Moriwaki,1 Robert M. Hoffman 2.

We report here imaging of stroma during the metastatic process. RFP-EL4 lymphoma cells were injected subcutaneously in C57/BL6 GFP transgenic mice. Subcutaneous tumors were resected and immediately transplanted to the abdominal cavity of BALB/c nude mice. Metastases to the liver, periarterial lymph node, ascites, bone marrow and as well as the primary tumor were imaged. Metastases expressed GFP at low magnification. At higher magnification, yellow-remaining cancer cells resulting from fusion of GFP stromal cells and RFP cancer cells were observed. Metastasis contained fusion of cancer and stromal cells which may be a feature of metastasis.

#1981 Tissue engineered bone for longitudinal intravital microscopy of solid tumor growth and therapy response. Eleonora Dondossola,1 Stephanie Alexander,1 Boris Holzapfel,2 Christopher J. Logothetis,3 Dietmar W. Hutmacher,1 Peter Friedl1.

We report here imaging of stroma during the metastatic process. RFP-EL4 lymphoma cells were injected subcutaneously in C57/BL6 GFP transgenic mice. Subcutaneous tumors were resected and immediately transplanted to the abdominal cavity of BALB/c nude mice. Metastases to the liver, periarterial lymph node, ascites, bone marrow and as well as the primary tumor were imaged. Metastases expressed GFP at low magnification. At higher magnification, yellow-remaining cancer cells resulting from fusion of GFP stromal cells and RFP cancer cells were observed. Metastasis contained fusion of cancer and stromal cells which may be a feature of metastasis.
Renal Cell Carcinoma (RCC) is one of the most lethal urological cancers worldwide, with incidence and mortality rates increasing in the past two decades. The disease does not present early clinical symptoms and is commonly diagnosed at the metastatic stage, leaving the 5-year survival rate at ~10-20.

For a wide array of neoplasms, many key molecular determinants involved in mediating the process of tumor cell growth, invasion, and colonization at a secondary site (i.e. metastasis) have been reported. However, few molecular predictors have been identified for RCC, rendering the mechanisms underlying RCC metastases poorly understood. This results in the lack of effective treatment for patients with advanced RCC. G protein-coupled receptors (GPCRs) and their effectors, such as the arr2 proteins, have been implicated in tumor growth, metastasis, and angiogenesis. Arrestin proteins are well known for their function in the desensitization and trafficking of GPCRs, but have also been implicated in unique signaling pathways to regulate fundamental cellular functions, including cell cycle progression, cell migration, and survival. Furthermore, arrestin involvement has been identified in a number of breast, colorectal, lung, and hematological malignancies. However, the role of arrestin proteins in RCC is yet to be determined.

Our preliminary data show that arr2 proteins levels correlate with growth and metastatic potential in several RCC cell lines, including ACHN and SN12C. We hypothesize that arr2 regulates RCC tumor progression, specifically through involvement in proliferation, invasion, and metastatic processes. To test our hypothesis, we used genetic-based loss of function approaches such as interfering RNA and CRISPR/Cas9. arr2 knockdown results indicated a role in RCC malignancy as it significantly decreases the migration and invasion of RCC cell lines in vitro. arr2 knockout (KO) impairs 3D spheroid formation of these cells and induced morphological changes compared to control cells as observed under confocal microscopy imaging. Moreover, epithelial marker E-cadherin expression levels were elevated while mesenchymal markers twist1, twist2 and vimentin levels were decreased in the arr2 KO cells compared to control, indicating a mesenchymal to epithelial transition. In vivo data support our hypothesis that arr2 plays a critical role in tumor growth and metastasis. Our data suggests a role for arr2 in RCC malignancy and present a possible target in development of therapies for patients with advanced RCC.

CD117 expression and activation induce prostate cancer metastasis. Koran Harris, Li Hong Shi, Taylor Peak, Stephanie Sanders, Aleksander Skardal, Bethany Kerr. Wake Forest University School of Medicine, Winston Salem, NC; Wake Forest Institute for Regenerative Medicine, Winston Salem, NC.
Tyrosine kinase receptors have been shown to drive prostate cancer progression and metastasis. In particular CD117-c-kit expression is upregulated during tumor progression with the highest levels being expressed in bone metastases. In addition, the numbers of circulating CD117+ cells is higher in advanced prostate cancer patients. The presence of these cells in patients’ circulation after radical prostatectomy was also associated with biochemical recurrence. Further, the expression of CD117 can be upregulated on prostate cancer cells after repeated culturing in the bone microenvironment. These data indicated that CD117 expression and activation may be associated with bone metastasis. To test this, LNCaP-C4-2 cells were sorted into CD117+ and negative cell populations. Proliferation, matrigel invasion, and gene expression were compared in the two cell populations in the presence and absence of the ligand stem cell factor (SCF) or CD117 and Akt inhibitors. To track cells during coculture and competition experiments, sorted cells were infected to express mCherry (CD117+) or ZsGreen (negative). Using these cells, competition was tracked using an IncuCyte ZOOM live cell imager for in vitro studies and an IVIS imager for in vivo xenograft studies. To better visualize transendothelial migration, a 3D microfluidic metastasis-on-a-chip was developed to track tumor cell migration through the ECM and across an endothelial cell layer. Here, we examine the activation of CD117 in prostate cancer cell progression and migration. CD117 expression was associated with increased proliferation, beta1 integrin expression, and EMT marker expression. Interestingly, treatment with the CD117 ligand stem cell factor (SCF) reduced proliferation but further enhanced invasion indicating that CD117 activation may drive metastasis. CD117 activation stimulated Akt expression and drove the cancer stem cell phenotype as demonstrated by increased Oct4 and Sox2 expression. CD117 expression was associated with increased expression of cancer progression and EMT signaling pathways. Using live cell imaging, competition between CD117+ and negative cells, and analyzed by molecular signatures of proliferation, scratch healing, invasion, trans-endothelial migration, and sphere formation. Xenograft models also demonstrated competition in vivo. Sectioning of tumors demonstrated the localization and composition of co-injected cells. In vivo fluorescent imaging was used to examine tumor initiation capabilities of the two cell populations. Using 3D microfluidics, we have modeled the competition between CD117+ and negative cell populations during transendothelial migration, CD117 expression on prostate cancer cells drives a more aggressive cell phenotype and may be involved in metastasis. Further, CD117+ cells represent a possible cancer stem cell population.

Breast cancer (BrCa) is one of the most important public health problems in the entire world. Metabolic syndrome (MeS) increases the incidence and aggressiveness of BrCa. C-terminal binding protein 1 (CTB1) is a co-repressor of tumor suppressor genes that is activated by low NAD+/NADH ratio. Recently, we generated a MeS-like experimental mouse model by chronically feeding animals with high fat diet (HFD) and we found that CTB1 and MeS modulated breast carcinogenesis and tumor growth. We also showed that CTB1 and MeS decreased BrCa cell adhesion, a crucial event in the beginning of metastasis. Considering metastasis is still the main cause of death, and around 30% of women with BrCa diagnosed at early stages will progress to metastatic stage, it is crucial to understand the impact of non-inherited factors and the mechanisms underlying this process. The aim of this work was to explore CTB1 and MeS role in BrCa cell migration and metastasis. By wound healing assay, we found that CTB1 increased cell migration of MDA-MB-231 and 4T1 BrCa cells. To study CTB1 and MeS effect in tumor progression, MeS nude mice induced by chronically feeding animals with HFD, and control diet fed animals, were injected with CTB1-depleted expression or –control MDA-MB-231 cells. Six weeks post-injection primary tumors were surgically removed. After two weeks, mice were sacrificed and the presence of metastasis in lung, liver and ascites was analyzed by histology and/or quantified by RT-qPCR using specific primers for human GAPDH. Consistently with the onset of metastasis, MeS increased the number of mice that developed neoplastic ascites (20% in MeS vs. 50% in control) with greater size and number of tumors. To confirm the effect of MeS on tumor cell adhesion we generated a MeS-like experimental mice model by chronically feeding animals with high fat diet (HFD) and we found that CTB1 and MeS modulated breast carcinogenesis and tumor growth. Interestingly, human Vimentin mRNA was induced in TC from ascites compared to primary TC; while it was diminished in lung, suggesting the crucial role of EMT/MET processes in metastasis. Finally, we analyzed expression of cell adhesion and EMT-related genes in primary tumor tissue by RT-qPCR. We found that CTB1 and MeS modulated cell adhesion and EMT expression genes: Vimentin, Slug, ITGB4, ITGB6, Col1A7, FABP4 and PRSS2. Altogether, these results suggest a key role for MeS and CTB1 induced BrCa EMT and metastasis.

Tbk1 loss in pancreatic cancer leads to changes in epithelial plasticity. Victoria Haley Burton, Rolf A. Breken, Melissa Gross, Alberto Bremauntz. UT Southwestern Medical Center, Dallas, TX.

Effective therapies are needed to enhance the long-term survival of patients with pancreatic ductal adenocarcinoma (PDA), which is the fourth leading cause of cancer-related deaths in the United States and eighth worldwide. Initial stages of PDA are commonly characterized by an activating mutation in K-RAS, yet direct inhibition of K-RAS through pharmacological means remains a challenge. Higher levels of TANK Binding Kinase 1 (Tbk1) mRNA, a critical downstream effector of mutant active K-RAS in lung cancer, are associated with poorer overall survival in a cohort of human PDA patients. We hypothesize that Tbk1 is an effective mediator of K-RAS driven pancreatic cancer. Here we report that Tbk1 is expressed and more active in human PDA cell lines relative to normal pancreatic ductal epithelial cells. Using RNA sequencing we found that Tbk1 expression levels were highest in PDA cell lines relative to normal pancreatic ductal epithelial cells. Using live cell imaging, we found that Tbk1 expression was induced in PDA cell lines in response to K-RAS activation. To confirm this, we used CRISPR/Cas9 knockdown to inhibit Tbk1 expression in PDA cell lines. We found that Tbk1 knockdown inhibited K-RAS-driven proliferation, scratch healing, invasion, and sphere formation. These data suggest that Tbk1 is an effective mediator of K-RAS driven pancreatic cancer. We hypothesize that Tbk1 is an effective mediator of K-RAS driven pancreatic cancer. Here we report that Tbk1 is expressed and more active in human PDA cell lines relative to normal pancreatic ductal epithelial cells. Using RNA sequencing we found that Tbk1 expression levels were highest in PDA cell lines relative to normal pancreatic ductal epithelial cells. to immortalized pancreatic epithelial lines (HPN) and fibroblasts. We found that human PDA cell lines are sensitive to a small molecule inhibitor of Tbk1 in the low micromolar range. Further mice engineered to express a mutant kinase dead form of Tbk1 (Tbk1<sup>Δ<sub>KD</sub></sup>) are viable and fertile yet display smaller tumors at early time points in a genetically engineered mouse model of PDA. Interestingly, tumors from Tbk1<sup>Δ<sub>KD</sub></sup>-PDA mice are less aggressive and show significantly less collagen deposition compared to Tbk1<sup>+/+</sup>- PDA tumors. Additionally, cell lines isolated from Tbk1<sup>Δ<sub>KD</sub></sup>- PDA tumors are more epithelial in morphology and less migratory and invasive relative to Tbk1<sup>+/+</sup>- PDA tumors. These results further our understanding of Ras signaling in pancreatic cancer and are critical for exploring a new avenue of targeted therapy.

TUMOR BIOLOGY: Tumor Microenvironment

#1986 Determining the signaling pathway of epithelial-IKKα deletion-mediated symbiotic bacterial and fungal infection in carcinogenesis. Naoyuki Song, Jami Willette-Brown, Feng Zhu, Yinling Hu. NCI-Frederick, Frederick, MD.

Bacteria and fungi, two major components of the microbiota, generally share niches and develop both antagonistic and symbiotic relationships, regulating the pathological impacts on the host. The epithelium is where the bacterial-fungal interaction occurs most abundantly, but the relationship between the epithelium, bacteria, and fungi on the pathogenesis, particularly tumorigenesis, is poorly understood. IKKα is one of the crucial factors regulating the homeostasis of squamous epithelial tissues. Recently, our lab has established a mouse model that develops esophageal squamous cell carcinomas associated with IKKα reduction, inflammation and chronic fungal infection. Claudosporium cladosporioides was a major type of fungi identified in this mouse model. Because IKKα deletion in the keratinocytes causes impaired skin barrier, we hypothesized that loss of epithelial IKKα may control fungal colonization through regulating the barrier integrity and inflammation. We generated IKKα<sup>−/−</sup>- mice with inducible K15.Cre (IKKα<sup>−/−</sup>/K15.Cre) specifically expressed in keratinocytes in hair follicles which is considered as skin stem cells. After deleting IKKα in K15 cells in oral mucosa and skin, IKKα<sup>−/−</sup>/K15.Cre mice were orally inoculated with Claudosporium cladosporioides. We found that epithelial IKKα deletion increased bacterial colonization in oral mucosa and skin. Moreover, Claudosporium infection further promoted bacterial and fungal colonization in oral cavity and development of skin tumors. Taken together, our data suggested that epithelial IKKα induces the bacterial-fungal symbiosis in oral mucosa, promoting skin tumors. This study will shed light on the importance of the epithelial-bacterial-fungal interaction in the pathogenesis, proposing epithelial IKKα as a novel regulator of the bacterial-fungal interaction.

#1987 Inhibition of collagen receptor discoidin domain receptor-1 (DDR1) reduces gastric cancer cell motility and metastasis. Ryo Yuge, Y. Suzuki Kimata, Hidetsugu Takigawa, Shinya Tanaka, Kazuaki Chayama, Wataru Yasui, Hiroshima Univ., Hiroshima, Japan; Hiroshima Prefectural Univ., Hiroshima, Japan.

Accumulating evidences suggest that a unique set of receptor tyrosine kinases, known as discoidin domain receptors (DDRs), play a role in cancer progression by interaction with their surrounding collagen matrix. Although abnormal expression of DDRs is reported in some human cancers, little is known about the expression and function of DDRs in gastric cancer progression. In this study, we investigated expression and the role of DDR1 in the tumor progression of human gastric cancer. The expression and distribution of DDR1 was analyzed by immunohistochemistry in 127 human gastric cancer cases, and the expression level of DDR1 in 7 human gastric cancer cell lines was analyzed by RT-PCR and western blotting. Proliferation, migration, invasion, and tube formation assays were conducted in DDR1 silenced gastric cancer cells. The effect of DDR1 on the tumor growth and metastasis were examined in orthotopically implanted nude mice model and a model of liver metastasis. DDR1 was expressed in human gastric cancer cell lines, and expression of DDR1 in human gastric tumor was associated with poor prognosis. Among 7 gastric cancer cell lines, MNK74 expressed DDR1 at highest level. DDR1-silenced MNK74 cells showed unaughterd proliferation activity. In contrast, migration, invasion, and tube formation were significantly reduced. When examined in an orthotopic nude mouse model, DDR1-silenced implanted tumor significantly decreased angiogenesis and lymphangiogenesis, thereby leading to reduction of lymph node metastasis and liver metastasis. We showed that treatment of DDR1 inhibitor also inhibited lymph node metastasis in an orthotopic nude mouse model. These results suggest that DDR1 is involved in GC tumor progression and metastasis. DDR1 could be not only an independent prognostic classifier, but also a promising therapeutic target in patients with GC.

#1988 Exosome-mediated ovarian cancer tumorigenesis mediated by miR1246/Rb/Cav1 axis. Pinar Kanlikilicer, Recep Bayraktar, Mohammed Rashid, Burcu Aslan, George A. Calin, Anil K. Sood, Gabriel Lopez-Berestein. MD Anderson Cancer Center, Houston, TX.

Exosomes are secreted from many cell types and play an important role in the tumor microenvironment. The most impressive breakthrough in exosomes research was that they contain the genetic material of the host cell. However, whether cancer cells use their exosomes to transfer oncogenic material to recipient cells, or to get rid of their tumour suppressor material is not well understood. We previously identified that miR-1246 was hundreds of folds higher expressed in six different ovarian cancer exosomes compared to their originating cells. Here, we showed that miR-1246 co-localized in the exosomes in ovarian cancer cells. miR-1246 act as an oncogenic miRNA and the levels were elevated in ovarian cancer patients compared to health donors. We also demonstrated that miR-1246 inhibited tumor growth in combination with CAV-1, a known anti-tumor gene. This result suggested that miR-1246 significantly inhibited tumor burden in SKOV3-ip1 orthotopic ovarian cancer model. Our results suggest that miR-1246 inhibited RB tumor suppressor protein and regulate CAV-1 and platelet-derived growth factor receptor beta precursor signaling in ovarian cancer. In addition Inhibiting miR-1246 led a significant decrease in exosome release. Together, our findings provide strong evidence that oncogenic miR-1246 can be targeted as a potential novel therapeutic approach in the treatment of ovarian cancer.

#1989 Characterization and integration of mantle cell lymphoma microenvironments are determinant for the development of rational targeted therapies. David Chiron, Celine Bellanger, Antoine Papin, Benoit Tessoulin, Christine Douset, Sophie Maiga, Philippe Moreau, Cyrille Touzeau, Steven Le Gouill, Martine Amiot, Catherine Pellat-deceunynck, CRCNA, INSERM, CNRS, Université de Nantes, Nantes, France; Service d’Hématologie Clinique, Unité d’Investigation Clinique, CHU, Nantes, France.

Mantle cell lymphoma (MCL) accumulates in lymphoid follicles (FL) and disseminates early on in extranodal tissues. Recent effort has been invested on the identification of intrinsic MCL abnormalities but little attention has been paid to the importance of the surrounding cells and soluble factors in this pathology. Further investigations that integrate the key role of the microenvironments are now needed to overcome drug resistance in this incurable malignancy. Despite a significant level of the proliferation index Ki67 in LN, we did not detect any proliferating peripheral blood (PB) MCL cells, suggesting a major role of the tumor ecosystem. To determine whether stromal (hMSC) or lymphoid-like (CD40L) interactions could support survival and proliferation, primary circulating MCL cells were cocultured ex vivo. In all the 21 samples tested, CD40L, but not hMSC, induced cell-cycle progression that was amplified by a MCL-specific cytokine cocktail (Ck). To determine the microenvironment-dependent molecular modulations, RNA-seq in MCL cells from PB or cocultured was performed (n=8) and compared with genes expressed in MCL cells from LN and PB (Geo, PB n=77, LN n=107). More than 65 % of genes induced by “CD40L+Ck” were also upregulated in the LN. Our model recapitulated molecular signatures that are characteristic of MCL i.e., cell cycle, BCR, NFkB, NIK and survival, confirming the relevance of the coculture. We further studied the coculture-induced regulation of the genes belonging to the survival signature. The major regulation was an increase in expression of Bcl-xL protein associated with a striking downregulation of Bcl2 and Bim. Using the functional BH3-profiling assay, we demonstrated that, whereas PB MCL cells were dependent on Bcl2 for survival, Bcl-xL upregulation was responsible for loss of mitochondrial priming and drug resistance. Consequently, whereas clinically available Bcl-xL-mimetic efficiently triggered apoptosis in PB MCL cells, protected by the microenvironment were resistant. We then hypothesized that targeting Bcl-xL could increase treatment efficacy. By integration of microenvironment modulation using our coculture model, we developed efficient targeted strategies (i.e.: BTK inhibitor, Type II anti-CD20), which counteract Bcl-xL overexpression and overcome drug resistance in primary cells ex vivo. This strategy should target cells protected into their niches and our ongoing OAIs Trial (NCT02558816) will rapidly determine in vivo efficacy in MCL. In summary, we reported here the development of a relevant model that provides new insights into the microenvironment-dependent regulation of proliferation and Bcl-2 family expression.
Our increased understanding of intrinsic abnormalities and the integration of extrinsic signaling offer new opportunities to design mechanism-based strategies to overcome drug resistance in MCL and other B cell malignancies.

#1990 Single cell co-expression profiles of immunotherapy targets in the tumor microenvironment of NSCLC samples. Jeffrey Kim, Nan Su, Xiao-Jun Ma, Emily Park. Advanced Cell Diagnostics, Newark, CA.

Cancer immunotherapies have made great strides in recent years, yet identifying key molecules in the tumor microenvironment is necessary to develop improved approaches to achieve more durable responses in a greater number of patients. Obstacles such as adaptive resistance to individual checkpoint marker blockade, such as PD1 and CTLA4, have led researchers down the path of pursuing multiple immune targets that may be upregulated on the same lymphocyte as a consequence of mono-antibody therapies. While several clinical trials taking a combinatorial approach are currently in progress, including targeting multiple checkpoint markers, it is clear that these new strategies may rely on the pre-existing immune system, regardless of being treatment naïve or previously treated. The challenge now is to identify the relevant biomarkers and to stratify patients to provide the most appropriate treatment. As a proof of concept, here we evaluate single cell co-expression profiles of key therapeutic targets in archived tissues of non-small cell lung cancer (NSCLC) samples using the RNAseq® Duplex Assay, an advanced in situ hybridization platform that allows for the visualization of single cell gene expression of mRNA targets directly in tissue. In our investigation of 60 archived formalin-fixed paraffin embedded NSCLC tissues, co-expression profiles of PD1 or PD-L1 coupled with another therapeutic target (IDO1, LAG3, 4-1BB, GITR, and TIM3) were assessed. With an ingenuity that led to slight variations in the tumor microenvironment between tissue samples. These marked differences of co-expressed targets on tumor infiltrating lymphocytes were scrutinized through quantitative image analysis to further reveal both the diversity and degree of individuality between tissue samples. Quantitatively measuring the expression of multiple targets in single cells within intact tissues exposed the distinct milieu of targetable therapeutic molecules, leading to the potential identification of responsive tumors which could help guide in stratifying patients for different combinatorial approaches.

Purpose: Despite improvements in care and advancements in the understanding of ovarian cancer (OC) pathobiology and genetic alterations, the survival rate is disappointingly low when compared to that of other types of cancer. One factor contributing to the poor survival rate is the development of chemotherapeutic resistance and a high rate of recurrent tumor growth in the months and years following primary OC treatment. Our objective was to identify potential new therapeutic targets for prevention of recurrence through examination of changes in gene regulation that occur in recurrent versus matched primary tumors. Procedures: We used 16 primary-recurrent tumor pairs from patients with stage III/IV serous epithelial OC from the Duke Gynecologic Oncology Tissue Bank. Illumina Infinium HumanMethylation450 BeadChips and Affymetrix microarrays were used to assess methylation changes in androgen gene expression, respectively. Expression and methylation of POSTN and COL11A1 were analyzed using an independent OC dataset comprising 38 women with < 3 years survival and 26 women with > 7 years survival, 3 normal ovarian surface epithelium (OSE) and 2 fallopian tube fimbriae epithelium (FITE) samples. siRNA knockdown of POSTN and COL11A1 in OC cells was followed by expression and proliferation assays. Results: Patients with recurrence had significantly higher expression of POSTN and COL11A1, with a 2-fold difference for 13 of the 1,569 significantly differentially expressed genes, seven with increased expression in recurrent OC (POSTN, COL11A1, MMP1, MMP13, TNC, ASFN, and EPYC), and six with decreased expression (GATA6, PEG3, SST, MAOB, TSPAN8, and C7). Interestingly, all seven up-regulated genes are involved in extracellular matrix (ECM) functions, an important component of the microenvironment. Furthermore, changes in androgen gene expression were used to guide in stratifying patients for different combinatorial approaches.

#1992 Changes in gene expression of stromal and epithelial cells during prostate cancer progression. Milos Babic,1 Elliot Imler,1 Peter Shepard,2 Joanne Yeakley,1 Raymond Nagle,3 Bruce Seligmann1. BioSpyder Technologies, Inc., Carlsbad, CA; 2University of Arizona, Tucson, AZ.

Prostatic intraepithelial neoplasia (PIN) is a histologic abnormality which arises within the secretory epithelium of prostate glands, without disrupting the layer of basal cells which separates the epithelium from the surrounding stroma. PINs are generally considered to be a step towards development of prostatic adenocarcinoma (PCA). Molecular steps in the transition from normal glands to PIN to PCA are poorly understood, in part due to the difficulty of accessing and characterizing individual PINs without contami- nation from surrounding stroma. Furthermore, the surrounding stroma surrounding pre-cancerous glands may play an active role in cancer development and progression, but are difficult to profile. We utilized the ultra-sensitive and quantitative TempO-Seq gene expression assay of the whole transcriptome to profile microdissections of stromal vs. epithelial cells in archival prostatectomy FFPE tissue. TempO-Seq is highly insensitive to RNA degradation (measurements of intact RNA RIN = 9.1 to degraded RNA RIN = 3.0 correlate with R² = 0.97) and does not require RNA extraction, allowing measurement of both soluble and insoluble cross-linked RNA. This allowed deparaffinization and H&E staining of prostate sections prior to the assay, so morphologic clarity was clearly visible and subsections could be readily extracted and profiled. Microdissections were performed on individual 5 μm FFPE sections of prostatectomy specimens with regions of 6 containing PIN alongside PCA. We removed an ~300 μm diameter region of stroma surrounding individual normal, PIN, and PCA glands, followed by targeted dissection of the gland epithelium itself which was lysed and assayed separately. Stromata and epithelial samples from 3 adjacent sections of the same glands were pooled together (adding up to ~0.005 mm³ tissue/repli- cate), and then profiled. We compared the whole transcriptome expression profile of stroma vs. epithelium at every stage of progression. Our results indicate that stroma and epithelium undergo separate and distinct changes in gene expression patterns throughout the development of PCA, most notably in genes involved in cell-cell signaling. Specifically, we found that changes in CAMP signaling in stromal cells accompanied the shift from normal glands to PIN. Furthermore, changes in androgen signaling pathways were present in stromal cells as well as in epithelium during the transition from PIN to invasive carcinoma. These results shed light on the molecular progression to PCA and demonstrate the feasibility of profiling gene expression at the level of tissue microstructure to elucidate changes within the tissue microenvironment. Since archival FFPE can be used, studies of progression can be carried out and the findings translated to diagnosis and prognosis as well as to the investigation of new therapeutic approaches.

#1993 Acidic tumor microenvironment stimulation of GPR4 alters cytoskeletal dynamics and migration of vascular endothelial cells. Elizabeth A. Krewson, Li V. Yang, Lixue Dong. East Carolina University, Greenville, NC.

The acidic tumor microenvironment results from aberrant vasculature, insufficient oxygen delivery and aerobic glycolysis of cancer cells. As cancer progresses, the acidic microenvironment can lead to structural changes of endothelial cells (ECs) resulting in increased vessel permeability which may increase metastasis. Extracellular acidification can activate cellular signaling molecules, including G-protein coupled receptor 4 (GPR4), which is prominently expressed in ECs. We have previously reported that acidic activation of GPR4 induces the transcription of several pro-inflammatory and ER-stress related genes in ECs. The purpose of the study is to identify the functional response of acidity-induced GPR4 activity using Human Umbilical Vein Endothelial Cells (HUVECs) as a model system. The expression of GPR4 was overexpressed (HUVEC/GPR4) or knocked down (GPR4 shRNA) using several genetic constructs. HUVECs were treated with media buffered to pH 6.4 or to physiological pH 7.4. Permeability of a HUVEC cell monolayer was assessed by measuring gap formation as one indicator. Cell migration was assessed by wound healing assays. Cytoskeletal changes in androgen gene expression were used to guide in stratifying patients for different combinatorial approaches.

#38 #466 Proceedings of the American Association for Cancer Research • Volume 58 • April 2017 511
Neoadjuvant chemotherapy (NACT) is used in breast cancer to decrease tumor and lymph node burden and the extent of surgery. However, response is variable and prediction poor. Stromal cells are involved in breast cancer progression and drug resistance although very little is known about the mechanisms. Our research aims to characterize breast cancer-associated fibroblasts (CAFs) and peritumoral fibroblasts (PTFs) that predict response to NACT and could be used to influence treatment choices. Pre-NACT core biopsies from cancer-associated and peritumoral tissues were collected under ultrasound guidance. To date, mRNAs from early passage (passage ≤ 5) fibroblasts isolated from cores of 23 matched pairs (CAFs and PTFs) (8 triple-negative (TNBC), 7 ER +Her2+ and 8 ER +Her2-) and an additional 8 PT samples (4TNBC, 1 ER +Her2+ and 3 ER +Her2-) were analysed by whole-genome expression array (Illumina beadchip HT12v4). Data were analysed with Partek® Genom Suite™ 6.6 and Pathway softwares (Partek Inc., St. Louis, MO, USA).

Differentially expressed genes (DEGs) were identified (t-test, p-value ≤ 0.05, fold-change (FC) ≥ 1.3) between CAFs and PTFs and between NACT responders (Residual Cancer Burden (RCB) 0/1) and non-responders (RCB ≥ 2). A significant difference between CAFs and PTFs was seen by principal component analysis and t-test. PTFs showed similar mRNA levels of major myofibroblast markers (e.g. FAP, ASMA) with only FSP1 being lower in PTFs compared to CAFs (FC = -1.4, p-value = 0.023), suggesting that PTFs, like CAFs, are activated myofibroblasts. We then tried to identify a gene signature in CAFs or PTFs that could predict response to NACT. Comparing RCB 0/1 vs RCB 2/3 resulted in very few DEGs due to cancer subtype variation in both CAFs and PTFs.

Similar to other studies, only 2/19 patients in our cohort with ER + tumours achieved RCB 0/1, preventing analysis of these samples. However, 45% (5/11) TNBC responded to NACT and we identified 566 DEGs between RCB 0/1 and RCB 2/3 CAFs, with changes in metabolism, PtSiK/ACT pathway, proteoglycan synthesis or ECM-receptor interaction. For PTFs, 186 DEGs were identified, with changes in Wnt signalling and ECM-receptor pathways. Microarray data from our uniquely large sample set of 23 pairs of CAFs and PTFs from breast cancer patients suggest that PTFs have a similar gene expression profile to CAFs. Although others have demonstrated that CAF phenotype is breast cancer subtype dependent, we are the first to show similar observations in PTFs. Finally, we identified gene signatures from both CAFs and PTFs that relate to RCB response in TNBC. We are currently in the process of confirming the most highly dysregulated genes by qPCR and/or immunohistochemistry analysis.

The omentum promotes ovarian cancer cell survival by increasing cell cycle duration and chemoresistance. Carlos Cardenas, Ayeshas B. Alvero, Mary Pitruzzello, Roslyn Tedja, Gil G. Mor. Yale University School of Medicine, New Haven, CT.

Background: Ovarian cancer is the most lethal of all gynecologic cancers. It is characterized by the presence of carcinomatosis at time of presentation and chemoresistant micrometastatic seedlings at the time of recurrence. The omentum, an adipocyte-rich organ, is a frequent site of ovarian cancer metastasis in patients and the most common site of post-chemotherapy residual disease in animal models. Whereas previous studies have shown how the adipocyte microenvironment can induce metabolic re-programming in cancer cells, it is not clear if it can regulate pathways that affect chemoresistance. The objective of this study is to determine the effect of the adipocyte microenvironment on pathways that control cell cycle and apoptosis. Methods: In vitro: Patient-derived epithelial ovarian cancer cell lines were cultured in the presence of abundance of omentum conditioned-media. Cell growth was determined by measuring culture confluence using Incucyte®. Protein expression was determined by western blot analysis. In vivo: Patient-derived ovarian cancer xenografts were established intra-peritoneally in nude mice. Tumor implants from adipocyte-rich organs such as the omentum, pelvis fat, mesentery and tumor implants from non-adipocyte-rich organs such as liver, ovaries, and GI tract were collected and analyzed independently. Results: Compared to cells cultured in growth media, epithelial ovarian cancer cells cultured in omentum CM demonstrated a more fibroblastic morphology characterized by elongated shape and bipolarity, significantly slower growth kinetics (p < 0.0001) accompanied by upregulation of the cell cycle inhibitor, p27, and enhanced secretion of the proangiogenic factor, VEGF. More importantly, these cells express higher levels of the anti-apoptotic proteins Bcl2 and Mcl-1. Consequently, ovarian cancer cells in growth media treated with Carboplatin had a IC50 of 14.5 μg/ml. In contrast, cells cultured in omentum CM demonstrated enhanced resistance to carboplatin with IC50 of > 50 μg/ml. Analysis of tumor implants in vivo showed similar results as observed in vitro. Thus, tumor implants isolated from adipocyte-rich organs express higher levels of p27, Bcl2, and Mcl-1. Conclusion: We demonstrate a significant effect of the adipocyte microenvironment on chemoresistance in the phenotype of ovarian cancer cell characterized by morphological changes chemoresistance and growth rate. These findings highlight the importance of the adipocyte microenvironment in the progression of ovarian cancer. Further studies that can identify specific therapeutic targets in the adipocyte-educated chemoresistant ovarian cancer cells may aid in the development of novel therapies and improve patient survival.

CXCL12 drives selective expansion of AKT-induced quiescent, preeuroplastic breast cells. Zahra S. Masoud,1 Lisa Kim,2 Kelsey J. Weigel,2 Matthew M. Champion,2 Zachary T. Schafer,2 Cheuk Leung1.1University of Minnesota, Minneapolis, MN; 2University of Notre Dame, Notre Dame, IN.

A critical stage of premalignant development in breast tumorigenesis is the emergence of preeuroplastic cells that carry key oncogenic drivers yet remain quiescent. Preeuroplastic cells maintain a state of quiescence, but may be triggered to proliferate through largely unknown factors. Expansion of these cells is key to driving clonal evolution, which is evident in early lesions and tissue fields surrounding tumors. Although preeuroplastic development is determinant to successful evolution and formation of tumor growth, the cellular mechanisms controlling preeuroplastic development is unclear. Our limited mechanistic understanding of quiescent, preeuroplastic cell outgrowth highlights a major knowledge gap in the early control of tumor development. Advancements in detecting molecular changes in precancerous lesions have provided opportunities for devising early intervention strategies. Aberrant AKT activation has emerged as a founding oncogenic alteration in preeuroplastic cells. While molecular changes predispose these cells to develop tumors and presumably favors their selection during early tumor development, how these alterations contribute to the cellular control of quiescent preeuroplastic cells remains unknown. A major barrier to studying quiescent preeuroplastic cells is the lack of physiologically relevant experimental models. Here, we utilized a novel quiescent, preeuroplastic cell model that reconstructs the molecular and cellular contexts of preeuroplastic breast tissue. We combined a three-dimensional (3D) organotypic cell culture on reconstituted basement membrane with cells that can be induced to activate defined oncogenic pathways. Using this model, we investigated the contribution of aberrant AKT activation in preeuroplastic breast tumor development. We found that aberrant AKT signaling in quiescent, preeuroplastic mammary cells does not stimulate cells to proliferate under normal conditions, but confers cell sensitivity to stroma-derived CXCL12 through upregulating the receptor CXCR4. Using heterotypic co-culture to recapitulate a tumor-promoting environment and quantitative proteomic analysis, we found that stromal-derived chemokine CXCL12 selectively promotes expansion of preeuroplastic cells with hyperactivated AKT signaling. Mechanistically, we showed that AKT signaling induces the expression of the chemokine’s receptor, CXCR4, which confers the selective sensitivity to CXCL12. This CXCL12-CXCR4 axis serves as an entry point for oncogenic signaling through PKA and ERK to drive the downregulation of CDKN1C and promote cell proliferation in AKT-induced preeuroplastic cells. Our studies uncovered a distinct role of AKT signaling in promoting preeuroplastic development. Furthermore, our studies suggest a model of preeuroplastic clonal expansion where oncogene signaling confers quiescent preeuroplastic cell sensitivity to alternate mitogenic stimuli in a permissive tissue microenvironment.

Charting the DNA methylation landscape of prostate cancer associated fibroblasts. Mitchell G. Lawrence,1 Ruth Pidsley,2 Elena Zotenko,2 Birunthi Niranjani,1 Aaron Statham,3 Jenny Song,1 Nicola Armstrong,2 John Pedersen,2 Mark Frydenberg,1 Renea Taylor,1 Clare Stitzer,1 Gail Risbriger,1 Susan Clark.1 1Monash University, Melbourne, Australia; 2Garvan Institute of Medical Research, Sydney, Australia; 3TissuePath Pathology, Melbourne, Australia.

Most studies of the genome and epigenome landscape of tumors focus on the aberrations in epithelial cancer cells. However, the growth and progression of solid tumors involves dynamic cross-talk between cancer epithelium and the surrounding microenvironment, including cancer-associated fibroblasts (CAFs). The molecular landscape of these cells is still poorly understood, so it is important to define the epigenetic features that underpin the functional differences between CAFs and non-malignant prostate fibroblasts (NFs) and influence cancer progression. Therefore, we used whole-genome bisulfite sequencing to chart the epigenome landscape of CAFs at single base resolution. Our data...
revealed that NPFs and CAFs from localized prostate cancer have remarkably different epigenome profiles characterized by locus-specific rather than global changes in DNA methylation. CAFs exhibited more than 7500 differentially methylated regions compared to NPFs. In contrast, no recurrent genomic aberrations were detected in CAFs, emphasizing the importance of epigenome changes in their roles as hallmarks of tumor heterogeneity. Their unique epigenetic modifications in the tumour and its microenvironment. Collectively, these data demonstrate that CAFs are defined by an enduring epigenetic signature that comprises a distinct set of locus-specific DNA methylation alterations in cancer-related regulatory loci. The distinct methylyome of CAFs provides a novel epigenetic hallmark of the cancer microenvironment and promises new biomarkers to improve interpretation of diagnostic samples.

#1998 Transcriptome analysis of hypoxic head and neck cancer cells uncovers intron retention in EIF2B5 as a mechanism to reduce protein synthesis. Lauren K. Brady,1 Hejia Wang,1 Caleb Radens,1 Milan Radovich,2 Amit Maity,1 Cristina Ivan,1 Mircea Ivan,1 Joseph Barash,1 Constantinou Koumenis.1
1University of Pennsylvania, Philadelphia, PA; 2Indiana University, Indianapolis, IN; 3University of Texas, MD Anderson Cancer Center, Houston, TX.
Hypoxia is a key feature of solid tumors that contributes to resistance to therapy and reduced overall survival. Cellular adaptation to the hypoxic tumor microenvironment involves attenuation of energy-consuming processes such as macromolecular synthesis. We have identified RNA processing as another major process which is globally downregulated under hypoxic stress. By sequencing RNA of normoxic and hypoxic head and neck cancer cells, we observed widespread repression of genes that regulate RNA splicing and processing. As a result, we observed over 1,000 changes in relative mRNA isoform expression, including a significant increase in hypoxia-induced intron retention in nearly 100 genes. Genes observed to undergo intron retention in hypoxia included major regulators of RNA processing and protein synthesis, such as the translation initiation factor EIF2B5. Surprisingly, hypoxia-induced intron retention in EIF2B5 creates a premature termination codon, which results in a truncated protein isoform of eIF2Be. We provide evidence that this isoform acts in opposition to the full-length protein to inhibit translation under stringent hypoxic conditions. Moreover, this intron is expressed in solid cancers known to contain hypoxic fractions and is overexpressed in head and neck cancer in a stage-dependent manner compared to normal tissue. To investigate how this intron is retained, we are examining the role of hypoxia-mediated changes in phosphorylation of the C-terminal domain (CTD) of RNA polymerase II. Our data suggest that increased phosphorylation of the CTD may lead to transcriptional pausing and subsequent retention of intron 12 in EIF2B5. Furthermore, distinct sequence features at this locus, such as a weak splice site at the intron12:exon13 junction, may explain how this intron is selectively retained in hypoxic cells. These results implicate mRNA splicing in hypoxia-related mechanisms that are key to cellular adaptation under hypoxia, which in turn contribute to cellular adaptation to stress.

#1999 Cofactor Paragon: a novel tool to analyze the tumor microenvironment using RNAseq. Ryan Bloom, Raman Talwar, Jeff Hiken, Jon Armstrong, Cofactor Genomics, St. Louis, MO.
The impact of cancer immunotherapy on clinical cancer care is growing rapidly. However, there are several mechanisms by which a tumor can avoid recognition and/or elimination by the immune system. Immune recognition, activation, and infiltration are each required for effective clearance of a tumor by the immune system. Impairment of any of these mechanisms requires a different therapeutic strategy or combination of strategies to significantly address. The development of new multi-modal biomarker technologies that have the ability to provide insight into each of these factors in a cost-effective manner is essential to effectively guide treatment choice for patients and to discover new therapeutic targets. We have developed Paragon, which is an RNA sequencing based panel that utilizes novel informatics technologies to provide a comprehensive picture of a tumor’s transcriptomic and immune micro-environment. There are three distinct outputs of Paragon: measurement of the expression levels of ten immune checkpoint genes, quantification of the total mutational burden of the tumor, and the levels of infiltration of 24 different immune cell subtypes within the tumor microenvironment. These outputs collectively inform the various mechanisms that tumors use to evade recognition and clearance by the immune system. We show that Cofactor Paragon accurately reports on gene expression, mutational burden and infiltrating leukocytes compared to gold standard methods from just 20 ng of FFPE tumor RNA. We further analyze the data to show the correlation between mutational burden and infiltrating CD4+ and CD8+ T-cell levels. Finally, we show how Paragon can identify patients with different subtypes of tumors that are more likely to respond with resistance to PD-1 blockade therapy. These results position Cofactor Paragon as a novel tool that can help identify ideal therapeutic strategies in immunoncology.

#2000 Targeted characterization of tumor heterogeneity through RNA-Seq analysis of phenotypically defined subpopulations. Warren Porter, Eileen Snowden, Friedrich Hahn, Mitchell Ferguson, Frances Tong, Shannon Dillmore, Rainer Blaessius. BD Technologies, RTP, NC.
Cancer progression and metastases have been linked to the complex heterogeneity found within many solid tumors. In order to understand the complexities within solid tumors there is a need for in-depth characterization of the tumor and the surrounding microenvironment, including the identification and measurement of the subpopulations found within the diseased tissue. Here we describe a method to interrogate the heterogeneity within patient derived xenograft (PDx) derived solid tumors through tissue dissociation, single cell flow sorting, and expression analysis of the resulting subpopulations. Cell sorting enables the identification and capture of phenotypically defined subpopulations within the tumor microenvironment for additional downstream analysis. Whole transcriptome RNA-Seq was performed on samples collected throughout the workflow to characterize the expression changes in cells during the different steps of the process. Expression differences were measured before and after tissue dissociation, before and after incubation, and before and after cell sorting. Expression differences were also measured between phenotypically defined subpopulations sorted by the CD133 and CD49f surface markers. Several significantly differentially expressed gene combinations between samples were observed. We also found unique pathway characteristics for the different subpopulations sorted based on expression of CD133 and CD49f markers. In contrast, changes induced by the workflow process alone were restricted to a small and well-defined gene subset of immediate early genes (IEGs). Within the workflow, these changes were restricted to the tumor dissociation step and no changes were detected after incubating and/or cell sorting the dissociated cells. Our results indicate that solid tumor dissociation followed by flow cytometric analysis and sorting enables the interrogation of phenotypically defined subpopulations found within solid tumors. Since workflow induced changes are minimal and defined, these methods reveal biological differences between subpopulations within and between cancers. Differential expression of numerous surface marker genes were identified by our method allowing discovery of other candidate surface markers that may extend the subpopulation structure. Once verified these additional surface markers could serve to elucidate the dynamic changes cancer tissue undergoes during progression as well as in response to selective pressures such as drug therapy.

#2001 Preclinical investigation of a 15 gene hypoxia profile in different prostate cancer cell lines. Thomas R. Wittenborn,1 Brita S. Sorensen,1 Morten Buus,1 Mathilde B. Thomsen,2 Steffen Nielsen,1 Michael R. Horssman,1 1Aarhus University Hospital, Aarhus C, Denmark; 2Aarhus University Hospital, Aarhus N, Denmark.
Purpose: Hypoxia is known to reduce the response to radiotherapy and has been found to be a common feature in prostate cancer. Identifying patients with hypoxic tumors will allow us to select those patients that require specific hypoxic modifiers. Previously our department has developed a gene profile consisting of 15 genes, which demonstrated prognostic and predictive impact for hypoxic modification in head and neck squamous cell carcinomas (HNSCC). In the current study we investigated the 15 gene profile in vitro in different prostate cancer cell lines, and subsequently in vivo in the PC3 xenograft model. Methods: For the in vitro experiments the prostate cancer cell lines investigated were PC-3, LNCaP and DU-145. Cell lines were cultured under normoxic (21% O2) or varying hypoxic conditions (0%, 0.5%, 1.0%, 2.0%, and 5.0% O2) for 24 hours, totalRNA was extracted and gene expression levels measured by qPCR. Reference gene references were selected (PMSM4, TBP, NDFIP1) and applied in the normalization of the relative expression levels. For all conditions, the reference gene used previously in the HNSCC study was selected. In vivo experiments, the PC3 cell line was inoculated on the flank of female NMRI nu/nu mice. Two hypoxia-sensitive traces (18F-FAZA and Pimonidazole) were administered in order to determine hypoxic and non-hypoxic regions on excised tumor sections. These regions were isolated by laser-assisted microdissection, after which totalRNA was ex-
trated and gene expression levels measured by qPCR. Results: In the in vitro experiments, all three prostate cancer cell lines had 14 of the 15 genes induced by hypoxia, when comparing the anoxic cells (0% O2) to the normoxic cells (21% O2). The only discrepancy was ALDOA, which was not upregulated in the hypoxic profile in different prostate cancer cell lines, both in vitro and in vivo. An identified induction was observed in both types of experiments, however with a differential gene expression with regard to hypoxia level. From the performed experiments, and looking only at oxygen dependency, it appears that the gene profile could be suitable for prostate cancers as well as HNSCC. Despite the fact that the immunosuppressive tumor microenvironment (ISTME) has long been recognized as a major hurdle that significantly limits the anticancer efficacy of various therapeutic strategies, including T-cell-based immunotherapy, there is currently no effective way to address this challenge. In this work, we prove that sequential photothermal therapy (PTT), mediated with stealthy laser-triggerable nanobombs composed of iron oxide nanoparticles (IONPs) following systemic delivery, can remove both pre-resident and newly triggered immunosuppressor cells in established tumors to enhance the efficacy of T-cell anticancer therapy. Using flow cytometry to study various T-cell populations in tumor tissues 48 h post PTT in a 4T1 mouse model, our data suggest that IONP-mediated PTT could significantly reduce the CD4+FoxP3+ regulatory T-cell population. Our data also suggest that CD8+ cytokine T-cell populations in PTT-treated tumor tissues return to those of non-treated tumors, and are believed to be newly activated at the tumor site or recruited from periphery blood following PTT. Our data further suggest that PTT twice spaced by a 24 h interval has the best anticancer efficacy, compared to PTT once or three times at 24 h increments. This enhanced anticancer effect from the sequential IONP-mediated PTT (twice) is believed to be due to an enhanced ability to eliminate triggered immunosuppressor cells that respond faster than cytokine CD8+ T cells. Furthermore, our Luminescence analysis of chemokine serum concentrations indicates that IONP-mediated PTT can decrease suppressor-cell-attractive protein secretion, such as G-CSF. In addition, our immunohistochemistry data from tumor tissue staining indicate that IONP-mediated PTT down-regulates tumor cell PD-L1 expression to disrupt tumor-cell-mediated immunosuppression. The capability of IONP-mediated PTT to disrupt ISTME can significantly enhance T-cell antitumor efficacy toward both treated established tumors and distal tumor cells. When combining IONP-mediated PTT with anti-CTLA-4 therapy to block CD8+ T-cell inhibition, our data suggest that combination treatment significantly inhibits tumor growth (p < 0.01), while control treatments, including the antibody alone, IONP-mediated PTT alone, and mock treatment, fail to do so. Our data further show that in a metastasis-mimic model, mice (6/6) that had primary tumors treated with PTT/anti-CTLA-4 reject pre-inoculated cancer cells at a distant site. Our data also show that the majority of the PTT/anti-CTLA-4 treatment-cured mice can reject subcutaneously (8/12) or tail-vein injected 4T1 tumor cells (9/9), indicating memory T-cell immune surveillance. In conclusion, this study provides a nanotechnology-based novel strategy to effectively disrupt not only pre-existing but also treatment-induced ISTME to boost T-cell-based cancer immunotherapy.

T cell immunoreceptor with Ig and ITIM domains (TIGIT) is a co-inhibitory molecule containing an immunoreceptor tyrosine-based inhibition motif (ITIM) within its cytoplasmic tail, and is highly expressed on regulatory T cells and activated CD4+ T, CD8+ T, and NK cells. TIGIT competes with CD226, which contains an immunoreceptor tyrosine-based activation motif (ITAM) within its cytoplasmic tail. The clinical candidate, OMP-313M32 binds human TIGIT but not rodent and non-human primate TIGIT. Therefore, a surrogate antibody was generated for pre-clinical assessments in mice. Antibody 313R12 is an anti-mouse TIGIT antibody that can block mouse PVR ligand binding and inhibit TIGIT signaling in a manner similar to the clinical candidate OMP-313M32. 313R12 inhibited the growth of syngeneic colon and kidney tumors in immune competent mice. In some cases, anti-TIGIT antibody 313R12 caused complete tumor regression and a potent anti-tumor immune memory response as demonstrated by the lack of tumor growth upon re-challenge of mice that remained tumor-free after prior anti-TIGIT treatment. Mechanistically, anti-TIGIT antibody 313R12 was shown to induce a Th1 response and increase cytotoxic T lymphocyte (CTL) activity. By in vivo depletion of T cells, we have shown that CD8+ T cell depletion completely abrogated the anti-TIGIT therapeutic effect, whereas CD4+ T cell depletion led to partial reversal of efficacy of anti-TIGIT. Therefore, both CD4+ and CD8+ T cells are critical for anti-TIGIT-mediated immune responses. Using mice reconstituted with human hematopoietic stem cells, we also demonstrated that the clinical candidate OMP-313M32 inhibits patient-derived melanoma tumor growth. Taken together, these data demonstrate that anti-TIGIT therapy suppresses tumor growth and generates long-term immunological memory against multiple tumors.

#2004 Epigenetic targeting of CD26 expression in medulloblastoma. Maehedara R. Guda,1 Jose R. Castellanos,1 Collin M. Labak,2 Ramadevi Sanam,3 David J. Daniels,4 Sarah E. Martin,5 Julian J. Lin,5 Andrew J. Tsung,5 Kiran K. Velpula,6 Swapna Asutkara,6 University of Illinois College of Medicine at Peoria, Peoria, IL; 2GVR Bioscience, Mahwah, NJ; 3MGH Cancer Center, Boston, MA; 4UConnSchool of Medicine, Storrs, CT; 5Hahnemann University, Philadelphia, PA; 6University of Michigan, Ann Arbor, MI.

Medulloblastoma (MB) is the most common malignant brain tumor in children and accounts for 20% of pediatric CNS tumors. Following surgery and treatment with chemotherapy and radiation, MBs recur in a significant proportion of patients. Moreover, survivors experience comorbidities related to the tumor and/or its treatment. New insights into MB tumor pathogenesis is needed for improving the survival and outcome of MB. Epigenetic silencing, including histone modification and DNA methylation, is an important tumorigenic mechanism in MB. However, its role in cancer immunopathology is poorly understood. Using datamining and immunohistochemistry analysis, we show that B7-H3 (CD267), an important immune checkpoint member of the B7 and CD28 families, is highly upregulated in all four molecular subtypes of MB compared to normal tissue. We find that a majority of clinical MB specimens show significant expression of B7-H3 checkpoint blockade (CTLA-4, PD-1, and PD-L1). CD267 appears to be a promising therapeutic target for cancer immunotherapy. Moreover, we observed that increased expression of CD267 correlates significantly with the expression of Enhancer of Zeste Homologue 2 (EZH2), a histone H3-methylating (H3K27me3) catalytic subunit of the human MB specimens. We hypothesize that combined targeting of CD267 and EZH2 may have greater impact on tumor progression and immune cell response in MB. Simultaneously, we performed LC/MS analysis to identify novel interaction partners of CD267 in MB tumor. These findings taken together suggest that CD267 is strongly associated with several epigenetic markers, indicating a strong relationship between cancer immune evasion and epigenetic mechanisms.

#2005 Synergistic effect of phenyl alpha-galactosylceramide C34 and chemotherapy on 4T1-tumor bearing mouse model. Jung-Tung Hung, Jen-Chien Wu, Tsai-Hsien Hung, Jing-Rong Huang, John Yu, Alice L. Yu. Institute of Stem Cell & Translational Cancer Research, Taoyuan City, Taiwan.

Intrinsic natural killer T (iNKT) cells represent a unique subpopulation of innate immune cells which have immune modulatory effects on many immune effector cells such as CD4+ T cells and CD8+ T cells. Alpha-galactosylceramide (a-GalCer) is a well-known iNKT-stimulating glycolipid. Using a-GalCer as a template, we have generated a more potent a-GalCer analog C34, which contains two aromatic rings at the acyl chain and demonstrated its anti-cancer effect on tumor bearing mouse model. It has been reported that NKT cells killed cancer cell
lines treated with chemotherapy agents through TRAIL- and Fasl-mediated pathways. In this study, we evaluated the anti-cancer effects of chemotherapy and C34 on tumor-bearing mouse model. First, BALB/c mice bearing 4T1 breast cancer were injected with various dose of chemotherapy agents weekly x 5 and the sub-optimal dose of docetaxel and doxorubicin was determined to be 0.5 mg/Kg. Subsequently, sub-optimal dose of docetaxel (0.5 mg/Kg) and doxorubicin (0.5 mg/Kg) respectively. In both tumor models, the suboptimal dose of C34 was found to be 0.1 ug per mouse. The treatment schedules of combination of chemotherapy and C34 were examined by administration of C34 at the same day (OD), three days (-3D) and one day (-1D) before chemotherapy and one day (+1D) after chemotherapy. We found that treatment benefit with C34 and docetaxel treatment in 4T1-bearing mice as compared to those treated with the other schedules. Moreover, the survival of mice was significantly prolonged when C34 was injected three days after cisplatin treatment in TCI-bearing mice (median survival: 46 days for cisplatin and 55 days for cisplatin+C34, log-rank test p = 0.041). In the 4T1 tumor microenvironment, we found the number of CD3+CD8+ T cells was significantly greater in mice treated with docetaxel+C34 (23,536 +/- 901.4) than those treated with docetaxel only (2,270 +/- 1,536, t-test p < 0.0001). In addition, the number of PD1+ CD8 T cells was slightly higher, but did not reach statistical significance (t-test p = 0.3), in mice treated with docetaxel+C34 (23.3 +/- 8.5) than in mice treated with docetaxel only (14.6 +/- 10.1). In short, we have established an optimal treatment schedule for the combination of C34 and chemotherapy that showed synergistic anti-tumor efficacy. We also demonstrated that C34 could increase the number of CD8+ T cells in the tumor microenvironment in mice receiving chemotherapy. These results indicate that combination of C34 and chemotherapy against an optimal treatment schedule might have synergistic therapeutic efficacy for patients with lung cancer and breast cancer.

#2006   AMX-513 polyamine depletion therapy inhibits tumor growth and reverses immunosuppression in cancers including MYC-driven neuroblastoma and pancreatic cancer. Mark R. Burns,1 Kathy Fosnaugh,2 Michael G. Palfitreman1, Laura Ganem1,2, Jane Murray,2,3 Sophie Allan1,2, Georgina Green1,2, Sara Sarraf,2 Murray Norris,3 David Ziegler,3 Michelle Haber3,1, Aminex Therapeutics, Inc., Kirkland, WA; 2Aminex Therapeutics, Inc., Kenmore, WA; 3Children’s Cancer Institute Australia, Sydney, Australia.

Tumorigenesis is associated with increased polyamine levels and involves the induction of ornithine decarboxylase (ODC), the initial rate-limiting enzyme in polyamine biosynthesis, and increased uptake of polyamines from the blood and diet. As well as contributing to proliferation, polyamines are reported to exert an immunosuppressive effect. Amplification of the MYC/MYCN oncopgenes has been shown to directly induce ODC activity and inhibition of this enzyme by α-difluoromethylornithine (DFMO) markedly delays tumor development. Aminex Therapeutics is developing a polyamine depletion approach targeting both biosynthesis and transport of polyamines with AMX-513, a combination of the approved ODC inhibitor, DFMO, together with AMXT 1501, an alkylated polyamine mimetic which blocks polyamine uptake. In the syngeneic CT26.CL25 mouse model of colorectal cancer, AMX-513, dosed daily for four weeks, reduced tumor growth > 75% compared to vehicle-treated control in immunocompetent Balb/C mice. There was no effect in athymic nude mice indicating that tumor growth inhibition by AMX-513 is T-cell-dependent. In the induced transgenic K6/ODC squamous tumor mouse model, stable regression was sustained 10 weeks after treatment ended and was accompanied by tumor infiltrate increases in IFNγ and in CD3+ and CD8+ T-cells. Tumor infiltrates from AMX-513-treated KPC pancreatic cancer transgenic mice with tumor regressions showed >90% reductions in myeloid-derived suppressor cells (MDSCs; CD11b+ Gr-1+) but no changes in mature myeloid cells (CD11+ Gr-1+++) by FACS analysis. AMX-513 treatment did not impact the percentage or number of CD4+CD25+FoxP3+ Tregs, but did significantly increase the percentage of activated CD8+ T cells in tumors. Neuroblastoma is an aggressive childhood cancer frequently associated with MYCN and ODC deregulation. We treated subcutaneous neuroblastoma cell lines with AMX-513 and showed synergistic (CI<0.5). Prophylactic treatment of neuroblastoma-prone THY-MYC transgenic mice with AMX-513 significantly extended survival compared to either agent alone (median survival time = 81.0 ±11.8 days versus DFMO alone = 57.1 ±7.1 days; P<0.0001). Treatment of mice with small palpable tumors with AMX-513 in combination with cyclophosphamide/topotecan can significantly improve survival compared to either chemotherapy alone (p<0.001). In conclusion, AMX-513 treatment alone or in combination with other cancer therapies results in significant tumor growth reduction in multiple cancer models and demonstrates novel immunotherapeutic potential. Clinical evaluation of AMX-513 is planned in 2017.

Cancer immunotherapies, e.g. the antibody against programmed death ligand 1 (PD-L1), a checkpoint inhibitor, have witnessed great successes in treating certain cancers in recent years. Recent data have also demonstrated that gut microbiota are important modulators on anticancer immunotherapy1,2. Heterogeneity in patient outcome seems to suggest complex communications between microbiota and host antitumor immunity. To this end, we tested an engineered chimeric MC38 mouse cell line, hPD1-MC38-HuCELL™ via human PD-L1 knock-in procedure, where MC38 CRC syngeneic cell is derived from C57BL/6. After treatment of PD-L1 antibodies (cd7A8 and BMS PD-L1 of different dose regimens), we observed significantly different drug responses among the microenvironment of tumor cells lines. AMX-513 treatment showed no tumor progression after treatment with a variety of doses while no favorable response was observed in mice from Vendor 2 and Vendor 3. To deeply study the gut microbiota of these mice, we performed 16s ribosomal RNA sequencing on untreated mice from three groups (5 replicates for each). Global diversity analysis by Quantitative Insights Into Microbial Ecology (QIIME) tool revealed segregation in the three cultures of mice: the microbiota composition of Vendor 2 and Vendor 1 are relatively closer to each other whereas the Vendor 3 mice are different, suggesting that the main difference seen between Vendor 1/2 and 3 in the original composition of gut microbiota is not the key impact for the observed anti-PD-L1 efficacy, and...
there should be other complex dynamics impacted anti-PD-L1 treatment, which remains unknown. Moreover, a group of 27 taxa were identified with significant difference in abundance (Kruskal-Wallis test, p-value < 0.05) across the groups, such as Bacteroidaceae, Lachnospiraceae, and Ruminococcaceae, which confirmed the previous data\(^1\). In conclusion, intestinal microbiota dynamically facilitate anti-PD-L1 efficacy and reversibly anti-PD-L1 treatment could influence reconstruction of gut microbiota. Reference 1. Sivan A, et al. Commensal Bifidobacterium promotes antitumor immunity and facilitates anti-PD-L1 efficacy. Science 2015;350(6264):1079-84. 2. Vézizou M, et al. Anticancer immunotherapy by CTLA-4 blockade relies on the gut microbiota. Science 2015;350(6264):1079-84. 3. Caporaso JG, et al., QIIME allows analysis of high-throughput community sequencing data. **#2009** CC-90002 (anti-CD47 antibody) in vivo anti-tumor activity is associated with an increase in M1-polarized macrophages. Bing Zheng,1 Piu Wong,1 Wen Qing Yang,2 Rama Narla,2 Michael Burgess,1 Laure Escoubet,2 Heather Raynor,2 Kandasamy Harilaran,2 John Boylan,2 Kristen Hege,2 Victoria Sung,2. 1Cellgene Corporation, San Francisco, CA; 2Cellgene Corporation, San Diego, CA

CD47, also known as integrin-associated protein, is over-expressed in several tumor types, including AML, NHL, breast cancer and multiple myeloma. Elevated expression of CD47 on the cell surface protects tumors from phagocytosis by macrophages through binding to signal regulatory protein alpha (SIRPα) on the surface of macrophages. The CD47-SIRPα interaction triggers events that culminate in the inhibition of the phagocytic process. Macrophages are one of the immune cell types frequently found in the tumor microenvironment and exist as a heterogeneous population that includes both M1 and M2 macrophages. While the spectrum of macrophage subpopulations are likely quite diverse, traditionally, it is thought that M1 macrophages are pro-inflammatory, enhancing immune responses against tumor cells, while M2 macrophages are pro-tumor, since they express a wide array of anti-inflammatory molecules, cytokines and growth factors that promote tumor growth, angiogenesis and an immunosuppressive microenvironment. We evaluated CC-90002 efficacy in the RPMI-8226 multiple myeloma and MDA-MB-231 breast cancer xenograft models and enumerated mouse M1/M2-like macrophage populations within in the tumor before and after CC-90002 treatment. In both RPMI-8226 and MDA-MB-231 models, M2 macrophages were the primary resident macrophage. Our studies show that when mice bearing RPMI-8226 multiple myeloma xenografts were treated with CC-90002 (a humanized anti-CD47 antibody), tumor regression was preceded by infiltration of macrophages into the xenograft. In the MDA-MB-231 breast cancer model, resident macrophages appeared to mediate the CC-90002 anti-tumor efficacy in vivo without additional macrophage trafficking. Interestingly, in both models, M1 macrophages appear to mediate CC-90002 efficacy regardless of whether macrophages infiltrate the tumor or are tumor-resident. In the MDA-MB-231 breast cancer model where CC-90002 did not induce infiltration, it is possible that resident tumor macrophages were re-educated to an M1 phenotype. In in vitro experiments using human M1 and M2 macrophages, both M1 and M2 macrophages are able to promote phagocytosis and additionally, we observed that CC-90002 selectively inhibited migration of M2 macrophages toward tumor cell conditioned media. This would presumably shift the overall balance of tumor-associated macrophages toward the M1 phenotype and suggests that inhibiting CD47 can both promote tumor phagocytosis as well as skew macrophage subpopulations toward an anti-tumor phenotype. CC-90002 is currently being tested in two ongoing Phase I clinical studies in subjects with advanced solid and hematologic cancers (NCT02367196, NCT02641002).

---

Background: BGB-3111 is a novel, irreversible, second generation BTK inhibitor with better selectivity profile and DMPK property compared toibrutinib. It has demonstrated promising anti-tumor activities in patients with advanced B cell malignancies. Given BTK is expressed in all hematopoietic lineages except for T lymphocytes, it is reasonable to explore the immune modulatory effect of BGB-3111. In this study, we sought to investigate the anti-tumor activity of BGB-3111 in solid tumor models. Methods: Cell viability was assessed with Cell Titer Glo® assay and half maximal inhibitory concentrations (IC50) were estimated. In vivo activity was assessed in subcutaneous mouse xenograft models. Treatments were administered by oral gavage and individual body weight and tumor volume was recorded twice weekly. Results: In vivo studies showed that MDAMB-436 cells are insensitive to BGB-3111, which do not express BTK. In both human breast cancer MDA-MB-436 and human A431 epidermoid carcinoma subcutaneous xenograft models, the tumor cells were co-injected with peripheral blood mononuclear cells (PBMCs) of healthy donors. In MDA-MB-436 model, BGB-3111 (15 mg/kg, BID) single agent significantly induced tumor growth inhibition (TGI) of 55%, whereas showed no anti-tumor effect if no PBMCs co-injected. Furthermore, co-treatment of BGB-3111 (15 mg/kg, BID) and anti-PD-1 antibody BGB-A317 (10 mg/kg, QW) demonstrated enhanced therapeutic effect in A431 allogeneic model. Interestingly, in BCLU200 and BCLU654 NSCLC primary tumor xenograft models (without PBMC co-injection), BGB-3111 (15 mg/kg, BID) also demonstrated significant anti-tumor activity.

Conclusions: In summary, BGB-3111 showed interesting activity in solid tumor models, suggesting BTK inhibitor might have potential to be used beyond hematologic malignancies.

**#2012** UVB-induced ULBP1 upregulation in melanocytes depends on HMGB1-mediated activation of NF-κB and IRF3. Zhaohui Wu, Wei Wang. University of Tennessee Health Science Center, Memphis, TN.

Anti-tumor immune surveillance mediated by innate immunity cells such as NK cells plays a critical role in eliminating “danger” cells at pre-cancerous stage and preventing cancer progression. As a key epidemiological factor associated with melanoma, solar UV radiation also elicits immunosurveillance by upregulating ligands for NK cell activating receptor NKG2D. Nevertheless, how UVR upregulates NKG2D in melanocytes is not completely understood. We found UVB exposure induced secretion of damage-associated molecular patterns (DAMPs) in melanocytes, which synergistically enhances NKG2D ligand ULBP1 transcription. Moreover, RAGE is essential for HMGB1-induced activation of NF-κB and IRF3, which serves as the HMGB1 receptor and mediates activation of TBK1. Consistently, HMGB1 deficient melanoma cells are less susceptible to NK cells mediated cytotoxicity. Our study provides a mechanistic link between environmental UV radiation and antimelanoma immunosurveillance induced in melanocytes, which may play a critical role in the early stages of melanogenesis.

---

The matrix metalloproteases (MMPs) are a family of zinc-dependent endopeptidase and have proteolysis activity which found to impact several physiological and pathophysiologic conditions including cancer. In cancer, over 20 types of MMPs promote invasion, angiogenesis, metastasis, and proliferation. For instance, MMP-9 is involved in many processes such as wound healing, tissue remodeling and regulation of inflammation. So far, several studies have also shown that MMP-9 is associated with poor clinical outcome. MMP-9 can facilitate angiogenesis and metastasis by releasing cytokines, pro-angiogenic and pro-metastatic factors. Conversely, the tissue inhibitor of metalloproteases (TIMP-1) is a well-known negative regulator of MMPs which can also modulate other biological functions independent of MMPs regulation. TIMP-1 dysregulation has been shown to impact ECM integrity and potentiate metastatic ability also. Similarly, MDM2 (Murine Double Minute) has been recognized as an important multi-domain protooncogene which is overexpressed in many types of cancer and is associated with poor prognosis in different tumor types including sarcomas and carcinomas. Previously, our group reported that MDM2 overexpression is regulating MMP-9/TIMP-1 axis in LNCaP and LNCap-MST (MDM2 transfected) prostate cancer cells. In order to further analyze the status of MMP in MDM2 overexpressing cancers the fluorescence activity assay and the zymography assay were used for measuring the activity of MMPs including MMP-9. Immunoblotting analysis were also used to correlate the expression levels of MMP2, MMP-9, and TIMP-1 in MDM2 overexpressing cell lines with and without Nutlin-3 (20 μM) treatment. Our results indicated that MDM2 activity is elevated by 97.3 % in LNCap-MST cells compared to LNCaP. This may be possibly due to the near knockdown levels of TIMP-1 that was observed in LNCap-MST cells. However, the Nutlin 3 treatment was able to decrease the MMP-9 levels and activity only marginally, without elevating TIMP-1 levels. This suggests that, in addition to MDM2, the PTEN loss in LNCap-MST cells may also play a role in regulating the levels of TIMP-1 and MMP-9 activity. In conclusion, our findings strongly support our original hypothesis, we analyzed the levels of TIMP-1 in SJSA1 and GI-101A cell lines, which are known to overexpress MDM2 and impart aggressive metastatic abilities. Interestingly, the levels of TIMP-1 were found to be elevated in both SJSA1 and GI-101A cell lines compared to LNCap-MST cells. This finding indicates
that TIMP-1 may paly dual role depending on cancer types and the gene expression status in the tumor microenvironment. Further studies are required to fully delineate the interplay between MDM2 and pro-metastatic mechanisms, including the expression of TIMP-1 and MMP-9. (The financial support from the Royal Dames of Cancer Research Inc., Ft. Lauderdale is gratefully acknowledged).

#2014 Genitourinary cancer-derived cells produce microenvironment proteases that regulate proteinase activated receptors (PARs) to drive oncogenic signaling. Stacy G. Gibson, 1 Koichiro Miura, 2 Andries Zijlstra, 2 Matthew E. Friedman, 1 Morley D. Hollenberg. 1 University of Calgary, Calgary, Alberta, Canada; 2Vanderbilt University, Nashville, TN.

Background: Thrombin-triggered activation of proteinase-activated receptor-1 (PAR-1) is recognized as a key stimulus for driving epithelial malignancies (IUBMB life.63:397, 2011; PMID:21557443). However, the enzymes for regulating PAR1 in the tumour microenvironment are not known. Hypothesis: We hypothesize that prostate (PC) and urinary bladder cancer (UBC) cells can regulate microenvironment signaling to drive cancer progression via the secretion of proteases that cleave/regulate proteinase-activated receptors (PARs). Aims: 1.) Visualize the cleavage status of N- and C-terminally-dual-labelled PARs in receptor-transfected UBC- and PC-derived cells. 2.) Measure PAR cleavage by UBC and PC-secreted proteases. 3.) Identify the UBC & PC-derived proteases that cleave/regulate PAR function. Methods: The cleavage status of dual-label PARs (N-termiinus-mCherry/C-terminus-YFP) expressed in PC & UBC cells was determined by confocal image analysis as already described (JBC 288:32979, 2013; PMID:26957205). Intact receptors look ‘yellow’ and cleaved receptors look ‘green’. The cleavage of PARs in UBC and PC cells was studied for dual-tagged-PAR expressing UBC and PC cells exposed or not to cell-derived culture supernatants, enzyme agonists for PAR1 and 2 (thrombin and trypsin, respectively), and proteinase inhibitors (e.g. for MMPs and other enzymes). The impact of CRISPR-mediated elimination of MMPs from PC3 cells on PAR1 cleavage status was also monitored. Results: UBC- and PC-produced enzymes can cleave PAR1 and 2 efficiently as thrombin, an established PAR1 agonist. None of the UBC cells produce proteases that cleave PAR2. Inhibition of MMP activity partially prevents PAR1 cleavage by UBC cells and completely prevents PAR1 cleavage in PC3-PC cells. Conclusions: We conclude that UBC and PC cells secrete PAR-regulating proteases that can directly regulate PAR1 in the tumour microenvironment so as to drive cancer progression. #2015 Mesenchymal stem cell correlates oral leukoplakia malignant transformation through regulate T cell response. Yichen Chen, Ballin He, Da Ma, Jingjing Song, Xi Wang, Bin Cheng, Zhi Wang. Sun Yat-sen University, Guangzhou, China.

Introduction: Leukoplakia is one of the most common clinically presented oral potential malignant disorders (OPMD). Detailed understanding of leukoplakia-associated molecular or cellular changes would help us better understand about the progress of leukoplakia malignant transformation. In this study, we examined the potential involvement of MSC in this very progress, and demonstrated lesion resident MSCs may favour leukoplakia malignant transformation through its strong immunoregulation on T cells. Methods: Eighteen six-week-old female Sprague-Dawley rats (180-220g) were given 0.05%/lg ANQ in drinking water for 22 weeks for development of lesions. Lesions classified by histological HE staining. MSCs were obtained from single cell suspension of lesions, and cultured with splenocyte to study its immunoregulate ability. Results: 1. MSC-like cells are enriched in carcinogen induced leukoplakia and cancers. Representative results showing the lesions on tongue of rats. And relative proportion of MSC phenotype marker (CD29+, CD31-, CD45-, CD90+) in oral lesions (OMSC) was analyzed by flow cytometry. Demstrated MSCs can regulate the expression of MSCs (N-OMSC) share the similar stemness properties. 2. Cancer lesions have less infiltrating T cells (quantified by IHC and FCM of CD3). Cancer-derived MSCs suppress T cell proliferation, but not promote T cell apoptosis and inhibit T cell migration to the lesions. 4. Higher number of lesion derived MSCs associates with higher proportion of lesion in the tumors. Taken together, these results demonstrated MSCs could migrate to pre-malignant leukoplakia lesions prior to tumor establishment. Further, MSCs play an important role in leukoplakia malignant transformation induced by chemicals, which via its strong immunomodulatory activities.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Cell Death Targets

Head and neck squamous cell carcinoma (HNSCC) is the sixth most common cancer with a five-year survival of ~50%. HNSCC are linked to human papillomavirus (HPV+) or tobacco carcinogenesis (HPV-). The Cancer Genome Atlas recently analyzed 279 HNSCC, revealing that 30% overexpress FADD (Fas-Associated Death Domain), with or without BIRC2/3 genes encoding cellular Inhibitor of Apoptosis Proteins 1/2 (cIAP1/2), which are critical components of the Tumor Necrosis Factor (TNF) Receptor signaling pathways that determine cell death or survival. The frequency of such mutations provides a window for potential therapeutics, as IAP antagonists have been shown to switch cancer cell TNFα signaling from being pro-survival to pro-apoptotic. We recently showed that biranapant, a second mitochondrial activator of caspases (SMAC) mimetic that promotes IAP degradation, sensitizes HNSCC cell to death by TNFα and eradicates tumors in combination with radiation in HPV+ HNSCC modeling advanced head and neck squamous cell carcinoma (HNSCC). However, the enzymes overexpressing FADD/+-BIRC2. ASTX660 (developed by Astex Pharmaceuticals) is a novel dual cIAP1/XIAP antagonist currently in clinical trials for treating advanced solid tumors and lymphomas. The objective of the present study is to determine the therapeutic effects of ASTX660 in HPV+/– HNSCC preclinical models. ASTX660 at nanomolar concentrations was found to potentially inhibit cell proliferation (measured using XTT assays) and induce apoptosis (Annexin/V-AAD flow cytometry), and displayed combinatorial activity with TNFα, TRAIL, or cisplatin in multiple human HPV+/- HN-SSC cell lines. Western blotting showed near complete degradation of cIAP1 expression at nanomolar concentrations in human HNSCC cell lines. Flow cytometry revealed that ASTX660 in combination with either TNFα or cisplatin reduced MHC-I expression and increased PD-L1 expression, suggesting that potential synergistic efficacy could be observed in combination with immune checkpoint inhibitors. Our results demonstrate that ASTX660 is a potential therapeutic agent for both HPV+/- HNSCC. Evaluating the anti-tumor effects of ASTX660 as a monotherapy and in combination with radiation, cisplatin, and anti-PD-1 therapies are ongoing, using both human HNSCC xenograft and syngeneic mouse oral cancer (MOC) models. Supported by NIDCD intramural projects (ZIA-DC-00016, 73 and 74).

#2017 The role of ceramide in the dual cytotoxic and metabolic stimulatory effects of sigma-2 receptors. Cheri Z. Liu, Ellen Sukharevsky, Wayne D. Brownell. Brown University, Providence, RI.

Sigma-2 receptors are highly overexpressed in cancer cells compared to normal cells, as well as in proliferative versus quiescent cells. Sigma-2 receptors have been of interest as an antineoplastic target, as sigma-2 agonists cause cell death via a variety of pathways. Recently, a new class of sigma-2 agonists has been discovered, with ligands such as CM764, that do not induce cell death but that affect cellular metabolism, as shown by increased MTT reduction, increased ATP level, and HIF-1α stabilization. Previously, our lab has shown that treatment of breast tumor cells with sigma-2 receptor agonists CB-184 and BD373 caused dose dependent increases in ceramide and simultaneous decreases in sphingomyelin, suggesting that sigma-2 receptors modulate the sphingolipid pathway. The ceramide pathway has been shown to play both prosurvival and pro-apoptotic roles in cancer cells. Here, we examine the role of ceramide in sigma-2 receptor mediated pathways in human SK-N-SH neuroblastoma cells. A 24 h treatment of SK-N-SH neuroblastoma cells with 20 μm exogenous C6-ceramide caused less than 20% cell death. Interestingly, this compares to over 50% cell death in MCF-7 breast adenocarcinoma cells and PANC-1 pancreatic cancer cells, indicating a differential role of ceramide in cell death pathways across cell lines. SK-N-SH cells were treated with 10 μM of either CM572, a classic sigma-2 agonist that causes cell death, or CM764, a sigma-2 agonist that stimulates metabolism. Fumonisin B1 is a potent inhibitor of ceramide synthesis. Treatment of cells with fumonisin B1 (10 μM) did not significantly alter CM572-induced cytotoxicity. Conversely, treatment with fumonisin B1 did significantly inhibit the cytotoxicity of CM764. Taken together, these results suggest that ceramide formation may play a role in the metabolic stimulatory effect of sigma-2 receptors, as opposed to the cytotoxic effect. Decreased levels of ceramide have been shown to increase cellular resistance to apoptosis. Therefore, it has been of interest to increase intracellular ceramide levels.
in drug resistant cancer cells in order to sensitize the resistant cells to chemotherapy. Multidrug resistance (MDR) in cancer cells is often attributed to the overexpression of particular ABC transporters that effectively pump drugs out of the cells. One such protein is the multidrug resistance-associated protein 1 (MRP1). It has been shown that increased expression of drug efflux pumps also decreases cell sensitivity to chemotherapy. Treatment with CM752 caused a dose-dependent decrease in MRP1 protein levels, while treatment with CM764 had little effect on MRP1. We will examine how modulation of MRP1 affects sensitivity to C6-ceramide. We will also examine whether combination of C6-ceramide with sigma-2 receptor ligands augments the cytotoxicity and/or metabolic stimulative effects of sigma-2 receptors.

#2018 Synergistic interactions between PLK1 and HDAC inhibitors in non-Hodgkin's lymphoma cells occur in vitro and in vivo and proceed through multiple mechanisms, Tri Nguyen,1 Rebecca Parker,1 Elisa Hawkins,1 Victor Yazbeck,1 Akhil Kolluri,1 Maciej Kmiecik,2 Mohamed Rahmani,1 Steven Grant2,3, Department of Internal Medicine, Virginia Commonwealth University and Massey Cancer Center, Richmond, VA; 4Department of Internal Medicine, Biochemistry, Pharmacology, Virginia Commonwealth University and Massey Cancer Center, Richmond, VA.

The mitotic kinase polo-like kinase 1 (PLK1) is over-expressed in neoplastic cells, including non-Hodgkin’s lymphoma (NHL) cells, but not in normal cells, prompting development of PLK1 inhibitors e.g., volasertib (Boehringer-Ingelheim). PLK1 plays key roles in cell cycle progression, mitosis, cytoskeleton, centriole duplication, and the DNA damage response (DDR). Notably, volasertib demonstrated preliminary signs of activity in NHL patients in a phase 1 trial. HDAC inhibitors (HDACi) modify chromatin structure and gene expression, but also induce multiple mitotic abnormalities including mitotic slippage and DNA damage checkpoint disruption. Given these complementary mechanisms, we sought to examine volasertib interactions with the pan-HDACI belinostat (Spectrum Pharmaceuticals) in diffuse large B-cell lymphoma (DLBCL) and mantle cell lymphoma (MCL) cells in vitro and in vivo. Exposure of DLBCL cells to extremely low (e.g., 5-30 nM), minimally toxic belinostat concentrations for 48 hr synergistically increased apoptosis in SU-DHL16, SU-DHL4, SU-DHL8 (GC subtype), HBL-1, U2932 (ABC-subtype), and OCI-LY3; Caravanas (double hit) DLBCL cells. Similar interactions occurred in primary lymphoma cells, Granta-519 and Rec-1 (MCL), SU-DHL4/BR and SU-DHL16/BR (Bortezomib-resistant cells exhibiting up-regulation of the proteasome sub-unit PSMB5 and bortezomib binding site mutation (Ala49Val). In contrast, identical regimes were minimally toxic to normal hematopoietic progenitors. Volasertib/belinostat induced massive M-phase arrest, p-histone H3 up-regulation, a marked increase in mitotic errors, and pronounced M-phase cell death associated with striking DNA damage (γH2A.X formation). Belinostat diminished c-Myc mRNA and protein in DLBCL cells, an effect significantly enhanced by volasertib. Notably, PLK1 knock-down in DLBCL cells significantly increased belinostat-induced M-phase accumulation, phospho-histone H3 accumulation, γH2A.X generation, and apoptosis. Analogously, c-Myc knock-down enhanced volasertib-induced cell death and apoptosis in response to volasertib, arguing that c-Myc down-regulation plays a functional role in lethality. Volasertib/belinostat co-administration dramatically reduced tumor growth in an ABC-DLBCL flank model (U2932) and significantly increased survival (56.2 vs 39.7 days; p < 0.001) without weight loss or other toxicities. The regimen also enhanced survival and reduced tumor cell bone marrow engraftment in a systemic double-hit lymphoma model (OCI-Ly18). Together, these findings indicate that PLK1/HDAC inhibition warrants attention as a therapeutic strategy in NHL. Accordingly, based on these findings, a phase 1 volasertib/belinostat trial in patients with aggressive NHL is planned (NCT02875002).

Although cancer cell genetic instability contributes to characteristics that mediate tumorigenicity, it also contributes to the selective toxicity that some chemotherapy drugs have for cancer cells. This ‘synthetic lethality’ (Nature 434:913, 05) can be enhanced by agents that inhibit DNA repair (Mol Onc 8:1429, 14; Proc AACR 57:3718, 16). To exploit this potential, ‘Achilles heel’, we tested the ability of a small molecule inhibitor of RAD51 to potentiate the cytotoxicity of established chemotherapy drugs. 2-(benzylsulfonyl)-1-(1H-indol-3-yl)-1,2-di-hydroisoquinoline (IBR2) was obtained from Drs. J-W Zhu and W-H Lee (Univ. California - Irvine). IBR2 inhibits RAD51-mediated double-strand DNA break repair, but also enhances induction of apoptosis by the ABL inhibitor imatinib against K562 cells (EMBO Mol Med 3:353,13). There is potential value of such synergistic interaction among other tumor types and with other drugs. IBR2- mediated c-Myc knock-down in non-Hodgkin’s lymphoma cell lines from various tissues (AML, CML, carcinoma of breast, colon, stomach, lung, and head) representing a range of oncogenic drivers (ABL, c-kit, Raf, Ras, ER, mutant p53). Cells were exposed to IBR2 simultaneously with inhibitors of various tyrosine kinase receptors, DNA-damaging agents, or inhibitors of microtubule function. Cells were cultured in 96-well plates, exposed to drugs alone and in combination with dilutions or exposure with combinations of belinostat (Camptosar, Blue or neutral red) 4 days later. Inhibition of proliferation by drug combinations was normalized to that of IBR2 alone. Depending on the drug sensitivity of the cell line, IBR2, at concentrations that inhibited proliferation between 0% and 75% as a single agent, enhanced toxicity of imatinib by up to 80%. IBR2 also greatly enhanced antiproliferative activity of regorafenib (targets RAF, kit, other) and EGFR inhibitors erlotinib, gefitinib, afatinib and osimertinib, and microtubule inhibitor vincristine (VCR). However, IBR2 was antagonistic with VP-16, cisplatin, irinotecan, melphanal, and olaparib. To determine a possible mechanism of the observed synergy, the interaction between IBR2 and imatinib or VCR was compared with that between verapamil, a P-glycoprotein inhibitor, and the latter 2 drugs. The VCR-resistant head and neck cell line HN-5a/V15e (very resistant to imatinib; but IBR2 enhanced their sensitivity in this cell line, its HN-5a parent, and HT-29 by up to 60%, much better than verapamil (up to 40% at similar concentrations, P<0.05). IBR2 enhanced VCR toxicity in these 3 lines to degree similar to verapamil, decreasing the IC50 by up to 90%. IBR2 appears to enhance drug toxicities via mechanisms other than just inhibition of RAD51 and may potentially interfere with microtubule function. The results indicate that this agent may be useful as a clinical adjuvant to numerous cytotoxic drugs.

Urokinase-type plasminogen activator (uPA) system may play a crucial role in cancer cell invasion and metastasis. uPA has been validated as a predictive or prognostic biomarker protein and considered as a therapeutic target in human breast cancer. Mesupron is a uPA inhibitor blocking uPA enzymatic activity to reduce tumor cell invasion, migration and cell growth. Auranozin has been known as an antitherapeutic drug and a thioedrin reducectase inhibitor and recently its anticancer activity in ovarian and breast cancers has also been identified. To study whether cotreatment with mesupron and auranozin shows a significant anticancer activity, the synergistic induction of apoptosis of mesu-pron with auranozin was determined. Auranozin or mesupron alone inhibited cancer cell growth in MCF-7 cells with IC50 of 0.25 μM or 25 μM, respectively. Flow cytometric analysis also showed an increased apoptosis. When cells were treated with mesupron (0.125 μM) in combination with auranozin (10 μM), we found a significant induction of apoptosis although the cytotoxic effects of mesupron or auranozin alone at those concentrations were not quite strong. Interestingly, combined mesupron and auranozin treatment significantly suppressed mitochondrial antiapoptotic proteins including Bcl-2 and Bcl-xL. We also found the increase of caspase-3 and PARP cleavages. The combination index (CI) also indicated the synergistic induction of apoptosis by auranozin and mesupron. Taken together, these data suggest that the use of mesupron and auranozin in combination can be valuable to achieve higher anticancer activity.

#2021 Ablation of caspase-7 promotes solar-simulated light-induced mouse skin carcinogenesis through upregulation of keratin-17. Mee Hyun Lee,1 Do Young Lim,2 Sung Young Lee,3 Jung Hyun Shim,4 Xuejiao Liu,1 Ran Zhao,1 Hai Huang,1 G. Timothy Bowden,5 Young-Soon Surh,3 Yong-Yeong Cho,2 Ann M. Bode,2 Zuzang Dong,1 China-US (Henan) Hormel Cancer Institute, Zhengzhou, China; 2The Hormel Institute, Austin, MN; 3Department of Pharmacy, College of Pharmacy and Natural Medicine Research Institute, Mokpo National University, Mokpo, Republic of Korea; 4University of Arizona Cancer Center, Tucson, AZ; 5Department of Molecular Medicine and Biopharmaceutical Sciences, Graduate School of Convergence Science and Technology, College of Pharmacy, Seoul National University, Seoul, Republic of Korea; 6College of Pharmacy, The Catholic University of Korea, Bucheon, Republic of Korea.

Solar UV irradiation is an environmental carcinogen that causes skin cancer. Caspase-7 is expressed at reduced levels in many cancers. The present study was designed to examine the role of caspase-7 in solar-simulated light (SSL)-induced
skin cancer and to elucidate its underlying molecular mechanisms. Our study revealed that mice with genetic ablation of caspase-7 are significantly susceptible to SSL-induced skin carcinogenesis. Epidermal hyperplasia, tumor volume and tumor numbers were increased in caspase-7 knockout (KO) mice compared with SKH1 wild-type mice irradiated with SSL. The expression of cell proliferation biomarkers Ki-67 and cyclin D1 was increased in SSL-irradiated SKH1 wild-type mice. Immunohistochemical analysis of skin of caspase-7 KO mice compared with those observed in SSL-exposed wild-type SKH1 mouse skin. Moreover, SSL-induced apoptosis was abolished in skin from caspase-7 KO mice. 2-DE gel electrophoresis, followed by matrix-assisted laser desorption/ionization-time-of-flight analysis of skin tissue lysates from SSL-irradiated SKH1 wild-type and caspase-7 KO mice revealed an aberrant induction of keratin-17 in caspase-7 KO mice. Immunohistochemical analysis of skin tumors also showed an increase of keratin-17 expression in caspase-7 KO mice compared with SKH1 wild-type mice. Furthermore the expression of keratin-17 was also elevated in SSL-irradiated caspase-7 KO keratinocytes as well as in human basal cell carcinomas. The in vitro caspase activity assay showed keratin-17 as a substrate of caspase-7, but not caspase-3. Overall, our study suggests that genetic loss of caspase-7 promotes SSL-induced skin carcinogenesis by blocking caspase-7-mediated cleavage of keratin-17.

Background: Bcl-2 family is a group of apoptosis regulators that plays an anti-apoptotic role for cell survival and is known to contribute to induce chemotherapy resistance in small cell lung cancer (SCLC). ABT-737 is an anti-cancer drug that induces apoptosis by selectively blocking the activities of Bcl-2 and Bcl-XL, but not Mcl-1. Consequently, the efficacy of ABT-737 is largely restricted in the presence of Mcl-1. Heat-shock protein 90 (Hsp90) is highly expressed in most tumors and Hsp90 inhibitors induce the proteasomal degradation of Hsp90 client proteins. In addition, Hsp90 inhibitor can reduce Mcl-1 expression, a down-stream of Akt and Erk pathway. Furthermore, Hsp90 inhibitor activates activities of NF-kB by degradation of IKK. Thus, we show that downregulation of Mcl-1 and NF-kB by Hsp90 inhibitor can lead to synergistic pro-apoptotic effects with ABT-737. Materials and methods: The proliferative activity, apoptotic activities, and expression of apoptotic proteins were assessed in SCLC cell lines after treatment with ABT-737, NVP-AUY922, or both drugs. The synergy effects of ABT-737 and NVP-AUY922 were analyzed by cell viabilities with different concentrations in SCLC cell lines, and the combination index values were < 1. In addition, the synergy effects of the drugs were showed with xenograft model with human SCLC cell line in vivo. Results: Here, we show that NVP-AUY922, an Hsp90 inhibitor, can potentiate the pro-apoptotic effects of ABT-737 not only by reducing the levels of Akt but also by inhibiting pNF-kB. ABT-737 induced apoptosis by blocking Bcl-2 activation, and NVP-AUY922 blocked the levels of Hsp90 client proteins, Akt and Erk, ultimately leading to decreased level of Mcl-1. In addition, NVP-AUY922 induced degradation of IKK, and increased IkB-α inhibited activation of NF-kB. And this combination treatment showed higher BIM and BID expression, pro-apoptotic proteins, than single treatment. Furthermore, synergy effects of combination were verified in xenograft model with human SCLC cell line. Conclusions: Consequently, NVP-AUY922 synergizes with ABT-737 to induce apoptosis by reducing activities of Mcl-1 and NF-kB in SCLC. This study suggests that adopting an appropriate combination of drugs can lead to better outcomes compared with monotherapy in SCLC.

#2023 Artemisinins enhanced the antileukemic efficacy of BCL2 inhibitors. Blake S. Moses,1 Jennifer M. Fox,1 Xiaoqun Chen,1 Jeffrey W. Tyner,2 Gary H. Posner,3 Patrick Bailey,1 Curt I. Clevin,1 *University of Maryland Baltimore, Baltimore, MD; 2Oregon Health and Science University, Portland, OR; 3Johns Hopkins University, Baltimore, MD.

More effective, less toxic treatments are needed to improve longevity and quality of life for patients with acute leukemias. Artemisinin (AS), the current WHO-recommended drug for severe malaria, is a semi-synthetic derivative of the natural compound Artemisinin. AS has broad antiepileptic activity in vitro, and is well tolerated, inexpensive, and can be parenterally or orally administered in humans. Both AS and a more potent synthetic derivative, artesiminin-derived trioxane diphosphonate dimer 838 (ART-838), substantially inhibited acute leukemia growth in vivo and in vitro, at doses where normal CD34+ hematopoietic stem-progenitor cell clonogenicity was essentially unaffected. Moreover, AS and ART-838 synergized with several current antileukemic drugs (Fox et al, Oncotarget, 2015). To identify additional potential antileukemic drug combinations, we identified synergistic combinations of AS and ART-838 against 3 acute leukemia cell lines co-treated with a panel of 122 antileukemic compounds (mainly emerging antineoplastic drugs). Both AS and ART-838 showed synergistic or additive growth inhibition with several compounds. Two BCL2 protein family inhibitors demonstrated among the highest levels of synergy. One of these, ABT-199 (venetoclax), was recently approved by the FDA for the treatment of chronic lymphocytic leukemia (CLL). MDA-MB-231 and MDA-MB-231/BRCA2 cell lines exhibited the greatest synergy through designation for acute myeloid leukemia (AML). Therefore, we decided to further investigate the combination of ABT-199 with AS or ART-838. Synergy between AS (or ART-838) and ABT-199 was confirmed across several acute leukemia cell lines with varying sensitivities to each drug. Both leukemia cell proliferation and survival were affected synergistically by exposure to the combination of AS (or ART-838) plus ABT-199. Utilizing in vivo imaging, we assessed changes in growth kinetics of tail vein injected acute leukemia cell lines and primary patient-derived samples constitutively expressing luciferase in mice treated with AS, ABT-199, or the combination. The combination of AS plus ABT-199 had the greatest antileukemic effect. Based on these data, we propose that Artemisinins plus BCL2 inhibitors comprise an antileukemic drug pair with high potential for incorporation into acute leukemia therapeutic regimens.

#2024 Reactivating apoptosis in BFL-1/A1 driven cancer with cysteine-reactive stapled peptide inhibitors. Rachel M. Guerra, Anissma J. Huhn, Edward P. Harvey, Gregory H. Bird, Loren D. Walensky. Dana Farber Cancer Institute, Boston, MA.

BFL-1/A1 is a BCL2 family protein implicated in the progression and chemoresistance of melanoma, lymphoma, and other cancers, yet it remains undrugged. Anti-apoptotic BCL2 family proteins block cell death by trapping the critical α-helical BH3 domains of pro-apoptotic members in a surface groove. Cancer cells hijack this survival mechanism by overexpressing a spectrum of anti-apoptotic members, mounting formidable apoptotic blockades that resist chemotherapeutic treatment. Drugging the BH3-binding pockets of anti-apoptotic proteins has become a highest-priority goal, fueled by the clinical success of venetoclax, a selective BCL2-1 inhibitor, in reactivating apoptosis in BCL2-dependent cancers. A natural juxtaposition of two unique cysteines at the binding interface of the NOXA BH3 helix and BFL-1/A1 pocket informed the development of stapled BH3 peptides bearing acrylamide warheads to irreversibly inhibit BFL-1/A1 by covalent targeting. Here, we describe the development and application of cysteine reactive stapled peptides that, compared to their non-covalent analogs, trigger rapid mitochondrial cytochrome c release, caspase 3/7 activation, and apoptosis induction of BFL-1/A1 driven cancers such as melanoma. Mechanism of action studies demonstrated the exquisite BFL-1/A1 selectivity and mitochondrial localization of the in situ covalent reaction. Given the frequent proximity of native cysteines to regulatory binding surfaces, covalent stapled peptide inhibitors provide a new therapeutic strategy for targeting oncogenic protein interactions.

Purpose Statins, a class of 3-hydroxy-3-methylglutaryl coenzyme A (HMG-CoA) reductase inhibitors, are initially developed as cholesterol-lowering drugs by inhibiting the mevalonate pathway. They have recently gained attention for their potential anticancer properties, but the mechanisms of their anticancer effects remain elusive. This study aims to investigate the antiproliferative effects of statins in breast cancer cell lines. Methods We screened a panel of breast cancer cell lines (Estrogen receptor positive (+): CAMA1, MCF7, T47D, ZR-75-1 and Hcc1428; triple negative (TNBC): MDA-MB-231, MDA-MB-436, BT549, Hs578T and Hcc1806) and assessed the sensitivity of these cells to simvastatin in relation to their hormone receptor status using cell proliferation assays. Next, to elucidate the mechanisms underlying simvastatin sensitivity, we evaluated the (i) expression of key enzymes in the mevalonate pathway using qPCR and western blot analysis and (ii) the role of steroid biosynthesis metabolic inhibitors by exogenously adding these compounds and testing their effects on simvastatin-induced cytotoxicity. Finally, we performed functional assays following siRNA knockdown to identify the key small GTPase involved. Results We found TNBC cell lines to be more susceptible to simvastatin compared to ER+ cell lines (mean IC50 of 7.98µM [95%CI 2.75-13.22] versus 41.74µM [95%CI 6.71-
Evasion of apoptosis represents an essential hallmark in the progression of many cancers. The Bcl-2 family of proteins plays a central role in regulating the apoptotic process. Targeting pro-survival Bcl-2 family members like Mcl-1 with small molecule inhibitors represents a viable therapeutic approach for the treatment of cancer. This study evaluated the in vitro and in vivo activity of AMG 176, a novel, potent and selective Mcl-1 inhibitor currently in Phase I clinical development. AMG 176 binds with high affinity and selectivity to the BH3-binding groove of Mcl-1.

In a cell based split-luciferase complementation assay, AMG 176 disrupted the interaction between Mcl-1 and Bak, leading to downstream activation of the intrinsic apoptosis pathway as measured by increased caspase activity and subsequent effects on viability. Oral administration of AMG 176 to mice bearing OPM-2 multiple myeloma xenografts resulted in a dose-dependent increase in tumor growth inhibition, complete tumor regression at a dose higher than the administered dose and also demonstrated robust tumor growth inhibition with complete tumor regression at an elevated dose. Efficacy in this model was achieved at doses in agreement with those eliciting induction of apoptotic markers. Treatment of tumor cell lines with Compound A, a close structural analog of AMG 176, revealed a dose- and time-dependent increase in Mcl-1 protein levels that was reversible upon compound washout. Subsequent experiments performed with cycloheximide suggested that elevations in Mcl-1 protein levels were due to an increase in Mcl-1 protein half-life, likely driven by the compounds ability to disrupt proteasome-mediated degradation. Compound A was also used to characterize the kinetics of activating apoptosis. These studies revealed a rapid induction of apoptosis and loss of viability in Mcl-1 dependent multiple myeloma and AML cell lines. In cell lines highly dependent on Mcl-1, treatment with Compound A for as little as two hours was sufficient to achieve complete cell killing. Cell line profiling studies (>200 lines) revealed robust effects on cell viability in a subset of solid tumor cell lines and cell lines of hematological origin, including multiple myeloma, acute myeloid leukemia and non-Hodgkin lymphoma. Similar pro-apoptotic effects were found to inhibit the survival gene E2F1 expression and sensitivity to Mcl-1 inhibition. Combination screens with Compound A revealed multiple highly synergistic combinations including compounds targeting the MAPK pathway, standard of care chemotherapeutics and agents targeting additional pro-survival members of the BCL-2 family. In conclusion, AMG 176 is a potent and selective Mcl-1 inhibitor, with significant in vitro and in vivo activity in Mcl-1 dependent cancer models.

#2028 PDE3A modulation for cancer therapy. Xiaoyun Wu,1 Timothy Lewis,2 Luc de Waal,1 Galen Gao,1 Jian Zhang,1 Monica Schenone,1 Colin Garvie,4 Brett Diamond,5 Selena Lorrey,1 Andrew Cherniack,1 Steven Corsello,4 Alex Burgin,5 Todd Golub,6 Stuart Schreiber,7 Matthew Meyerson,4 Heidi Greulich,1,6 Broad Institute, Cambridge, MA; 4C Therapeutics, Cambridge, MA; University of Connecticut, Cambridge, MA; Dana-Farber Cancer Institute, Boston, MA.

In a differential cytotoxicity screen, we identified a novel small molecule modulator of phosphodiesterase 3A (PDE3A) that kills cancer cells expressing elevated levels of PDE3A and SLFN12 (de Waal, Nat Chem Biol, 2016). Treatment with this cell-selective cytotoxic small molecule, DNMDP, induces complex formation between PDE3A and SLFN12, resulting in apoptosis. Inhibition of PDE3A enzymatic activity is not sufficient for cancer cell killing, and expression of both PDE3A and SLFN12 are required. Although the mechanism of signaling to the apoptosis machinery remains unclear, we examined more closely the role of the PDE3A-SLFN12 complex in cancer cell killing mediated by DNMDP. We found that cancer cell lines made resistant to DNMDP by persistent exposure became more sensitive to DNMDP, suggesting that expression of SLFN12 was sufficient to restore sensitivity. Furthermore, ectopic expression of PDE3A and SLFN12 are sufficient to sensitize cancer cells to DNMDP. These data underscore the tight correlation of PDE3A-SLFN12 complex formation and cancer cell killing mediated by DNMDP.

#2028A Glutamine deprivation-elicited sensitization of multiple myeloma to venetoclax is associated with electron transport chain inhibition. Richa Bajpai, Changyong Wei, Mala Shanmugam. Winship Cancer Institute, Emory University, Atlanta, GA.

Cancer cells exhibit altered glucose and glutamine metabolism to sustain survival and proliferation. Altered nutrient utilization also contributes to the development of resistance to apoptosis via regulation of pro- and anti-apoptotic BCL-2 family members. We previously reported that glutamine deprivation enhanced binding of BIM to BCL-2 thereby sensitizing myeloma cell lines and patient samples to Venetoclax (ABT-199). In this study we investigated the metabolites regulated by glutamine withdrawal that contribute to enhanced BIM-BCL-2 association and ABT-199 sensitivity. Metabolite profiling and isotope tracing flux analyses of glutamine deprived myeloma cell lines revealed specific reduction of the TCA cycle metabolism including succinate, that were not maintained by glucose present in the medium. Cellular bioenergetics end points i.e. OCR and ATP were also suppressed upon glutamine withdrawal correlating with a suppression of the TCA cycle and oxidative phosphorylation. Supplementation of cell permeant dimethyl-a-ketogluturate (DMK), a TCA cycle metabolite derived
from glutaminolysis, to glutamine deprived cells reversed sensitivity to ABT-199. This ability of DMK to reverse ABT-199 sensitization in glutamine deprived cells was associated with a replenishment of TCA cycle intermediates without restoration of ATP levels. Therefore, we sought to further interrogate the TCA cycle and electron transport chain (ETC) in facilitating glutamine withdrawal-associated ABT-199 sensitization. TCA cycle metabolites are linked to mitochondrial respiration through ETC complexes. Inhibition of ETC complexes I, II, III or V in myeloma cell lines enforced similar effects as glutamine deprivation and sensitized cells to ABT-199. Among all five complexes, complex II is more explicitly linked with the TCA cycle through succinate dehydrogenase (SDH). SDH facilitates the oxidation of succinate to fumarate in the TCA cycle through SDHB, SDHC, and SDHD, and transfers the released electrons to ubiquinone via its SDHFe, C and D subunits supporting the ETC activity of complex II. Competitive inhibition of succinate dehydrogenase by 3-nitro propionic acid (3NP) induced BIM expression and sensitized myeloma cells to ABT-199, similar to that detected upon glutamine deprivation. Our observations thus narrow down a role for ETC inhibition in facilitating ABT-199 sensitivity and underscore the importance of further interrogation of ways to metabolically perturb and sensitize cancer cells to the highly potent BH3 mimetic ABT-199.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Combination Therapy 2

#2029 Precision therapeutic combinations are synergistic against triple negative breast cancer using compensatory pathways. Jeffrey P. Solzak,1 Brad Hancock,1 Robin Paul,1 Patrick Kiel,2 Todd Skaar,1 Bryan Schneider,1 Milan Radovich,1 1Indiana Univ. School of Medicine, Indianapolis, IN; 2IU Health, Indianapolis, IN.

Introduction: Triple negative breast cancer (TNBC) accounts for 15% of all breast cancer cases in the United States, and despite its lower incidence, contributes to a disproportionately higher rate of morbidity and mortality compared to other breast cancer subtypes. No FDA-approved targeted therapies are currently available. It has been hypothesized that drug combinations could potentially be chosen based on a tumor harboring two or more druggable genomic mutations. However, previously published data has noted that single agent treatment can change the genomic landscape and may be responsible for the lack of synergy of dual genomic drug targeting. Herein we show that targeting a compensatory pathway after treatment with a genomically-directed agent, results in synergistic combinations and can outperform choosing two drugs a priori based on genomic mutations. Methods: Nine TNBC cell lines were chosen based on the presence of two or more clinically actionable genomics targets. Drug combinations based on targeting two genomic mutations were chosen using DNA-seq data from CCLE and a board consisting of oncologists and researchers. Compensatory therapies were found using RNA-seq data from untreated versus single-agent treated TNBC cell lines. The merged transcript RPKMs were transformed and analyzed for differential expression. Statistically significant genes were imported into Ingenuity Pathway Analysis (IPA) to identify therapeutics based on compensatory targets using the Causal Network Analysis and Upstream Regulator functions. Cell viability was assessed via Celltiter-Fluor. Synergy of the combinations was calculated using the Chou-Talalay method. Results: Using two-drug combinations based on genomic mutations alone in all nine cell lines resulted only in additive or antagonistic responses. However, using RNA-seq data of each cell line treated with one genomically-directed agent, IPA analysis identified several compensatory targets that were upregulated or activated. Treating each cell line in combination with one genomically-directed agent plus one compensatory agent resulted in a striking increase in synergy. To understand why targeting compensatory pathways was superior to targeting two genomic mutations, we re-evaluated the RNA-seq data. This analysis revealed that treatment with the first genomically-directed agent, in many cases, resulted in up-regulation or inactivation of the second genomic-target. This may explain the lack of synergy when targeting cells with two drugs based only on genomic mutations. Conclusion: Targeting TNBC cell lines based on drug combinations informed by compensatory pathways results in significant synergy and is superior to choosing drug combinations based on genomic alterations alone.

#2030 Fisetin, a dietary flavonoid for the prevention and treatment of PIK3CA-mutant colorectal cancer. Naghma Khan, Farah Jajeh, Devon Miller, Rachel Van Doorn, Richard B. Halberg, Hasan Mukhtar. 1Univ. of Wisconsin-Madison, Madison, WI.

Colorectal cancer (CRC) is one of the most frequent and deadliest cancers worldwide with patients often diagnosed in advanced stages of the disease. Approximately 15-20% of advanced colorectal cancers harbor activating mutations in PIK3CA, which has been identified as an important oncogene in multiple cancers. Therefore, modeling the effects of this type of mutation in the mamma- lian genome would help elucidate the significance of this oncogene. Fisetin, a flavonoid found in blueberry, persimmon, grape, onion and cucumber, 5-Fluorouracil (5-FU) is the most used chemotherapeutic agent in CRC; however, it has serious side-effects. Therefore, augmentation of the 5-FU therapeutic effect could lead to lower effective doses and subsequently fewer side effects. We conducted in-vitro and in-vivo studies to determine the effect of fisetin, 5-FU and their combination on PIK3CA-mutant colon cancer cell lines (HT116 and HT-29), PIK3CA wild-type colon cancer cells (SW480), and newly developed mouse models. We found that there was more pronounced decrease in cell-viability and number of colonies in PIK3CA-mutant colon cancer cells than PIK3CA wild-type colon cancer cells. Apoptotic genes and proteins are promising targets for cancer treatment as they provide several theoretical basis to influence pathways causing greater tumor cell death. We observed an increase in the protein expression of Bax and decrease in Bcl2 on treatment with combination of fisetin and 5-FU than either agent alone. The full size PARP (116 KD) protein was also cleaved to yield an 85 KD fragment after treatment with cell lines with fisetin, 5-FU and their combination. Apoptotic effects of fisetin and 5-FU combination were also confirmed by flow cytometry in PIK3CA-mutant colon cancer cell lines. The PIK3/AKT pathway is frequently activated in CRC leading to tumorigenesis and the resistance to chemotherapy. Treatment of PIK3CA-mutant colon cancer cells with fisetin and 5-FU caused decrease in the expression of (i) PI3K (p85 and p110), (ii) phosphorylation of Akt (Ser473 and Thr308), (iii) phosphorylation of mTOR, its target proteins, and constituents of mTOR signaling complex. Treatment with fisetin and 5-FU also led to an increase in the phosphorylation of AMPKα. Next, we performed studies to investigate the effect of the treatment of combination of fisetin and 5-FU on colorectal tumorigenesis in 5F3K-ApcMin/+ mice. These animals form tumors in the distal small intestine and colon that have lost APC activity and express constitutively active PI3K as often occurs in humans. Interestingly, the effect of fisetin was much stronger than that of 5-FU and comparable to the fisetin and 5-FU combination. Both fisetin and 5-FU treatment group had significantly lower incidence relative to the control group. We suggest that fisetin could be used as a preventative agent as well as an adjuvant for 5-FU for the treatment of PIK3CA-mutant CRC.
brane potential, and the production increasing of ROS were observed. In HBCx-10 PDX, a trend for antitumor activity of DFX alone was observed (p = 0.09) at the end of the experiment (day 81). A significant difference of Relative Tumor Volume (RTV) was observed since day 18 between the AC group and the DFX + AC group (tumor growth inhibition: 37 to 61%, tumor growth delay: 10 to 14 days, p < 0.04). Similar results in observations of PI3K pathway and hypoxia are involved in this antitumor synergy. Except neutropenia (due to chemotherapy), no other hematologic toxicity was observed in both AC and DFX + AC groups. Conclusions: Iron chelators may increase the effectiveness of conventional chemotherapies for TNBC treatments. This antitumor synergy involves PI3K pathway downregulation, ROS production and decrease mitochondrial membrane potential.

**#2032 Combination of epigenetic regulation via LSD1 inhibition with signal transduction inhibitors significantly enhances anti-tumor activity in models of hematologic malignancies.** Sang Hyun Lee, Matthew Stubbs, Ashish Juvekar, Melody Diamond, Antony Chadderton, Robert Collins, Xiaoming Wen, Holly Koblish, Chunhong He, Liangxing Wu, Richard Wyn, Andrew Combs, Chu-Biao Xue, Wending Yao, Gregory Hollis, Reid Huber, Peggy Scherle, Bruce Buggeri. *Incyte Corporation, Wilmington, DE.*

Combinatorial therapeutic strategies have achieved improved response rates and durability of responses in several malignancies either by selectively targeting distinct and non-overlapping oncogenic signaling pathways (e.g. PARP and phosphoinositide 3-kinase (PI3K) inhibition in subsets of breast and ovarian cancers), or alternatively, inhibiting distinct nodal points of regulation in common oncogenic signaling pathways (e.g. Rb and MEK inhibition in subsets of melanoma). Recent data suggest that deregulated epigenetic modifications may be just as significant as genetic mutations in driving cancer development and growth by inhibition of tumor suppressor activity and activation of oncogenic pathways. We therefore hypothesized that an epigenetic regulator could potentiate the efficacy of a protein kinase inhibitor to result in robust tumor growth inhibition. We previously reported that the potent and selective LSD1 inhibitor INCB059872 potently inhibited tumor growth in multiple tumor xenograft models of AML and SCLC as a single agent and in a combination with standard of care of agents. In this study, we explored the anti-tumor effect of combining INCB059872 and various signal transduction pathway inhibitors, including the PI3 kinase inhibitor INCB059394, the JAK1/2 inhibitor ruxolitinib, or the PI3K delta-selective inhibitor INCB05465 in models of human hematologic malignancies. Each of these therapeutic combinations significantly inhibited tumor growth in the Molm-16 human AML xenograft model. Mechanistic studies suggested that MYC expression levels were downregulated by these combinations both in vitro and in vivo. Treatment with INCB059872 alone or in combination with signal transduction kinase inhibitors significantly downregulated cytokines levels, particularly IL-10, sCD40L, and MCP-1 in Molm-16 tumors. These data suggest that the combination of an LSD1 inhibitor and signal transduction inhibitor can co-regulate key tumor intrinsic and extrinsic pathways involved in paracrine or autocrine signaling in AML. In addition to the improved efficacy observed in AML models, the combination of INCB059872 with the PI3Kdelta inhibitor INCB050465 enhanced tumor growth inhibition in the Will-2 xenograft model (IC50 submicromolar, double hit hit lymphoma), whereas the activity of these single agents were modest in this particular subtype of lymphoma. Our findings support the possibility for more effective ibrutinib-based therapy via manipulation of the MCL cell niche.

**#2034 LSD1 inhibition alone and in combination with chemotherapeutic delay in Ewing sarcoma cell lines.** Darcy Welch, Elliot Kahan, Christopher L. Cubitt, Damon R. Reed. *Moffitt Cancer Center, Tampa, FL.*

Background: Ewing Sarcoma (ES) is the second most common primary bone cancer affecting children and young adults. Despite advances in treatment that have led to survival rates of approximately 73% for localized disease, outcomes for patients with metastatic or recurrent ES remain poor. A distinguishing feature of ES is the presence of the EWS/FLI1 fusion in 85% of cases. The fusion has been shown to alter expression of a number of oncogenic genes. Mechanistic studies have demonstrated that the NuRD co-repressor complex interacts with EWS/FLI1. The associated protein LSD-1 contributes to the repressive function by histone modifications. While reversible LSD1 inhibitors demonstrate single agent activity, in preclinical models, a system to evaluate combinations may be needed for optimizing effect in clinical trials. Methods: Here, we seek to confirm promising single drug activity and evaluate combination therapies using active chemotherapies currently utilized in ES care (4-HC, etoposide, SN-38, vincristine and doxorubicin) along with the LSD1 Inhibitors SP2509 and SP2577 and romidepsin, an HDAC inhibitor. We evaluated these combinations in high-throughput screening platforms and well-established cell line models for ES (A-673, TC-32, RD-ES, TC-71). Taking into consideration past lessons learned from in vitro experiments, we designed stringent screening conditions that bias the held out combination to specifically match clinically relevant concentration and exposure times that mimic the in vivo pharmacokinetics in an effort to maximize the translational potential of these results to the clinical setting. All combinations of agents were studied in two-drug combinations to evaluate for synergy in addition to efficacy. Results: IC50 for SP2509 was found to be in the submicromolar range across cell lines with SP2577 being more potent. A-673 and TC-71 were 5-10 fold less sensitive than RD-ES and TC-32. Agents currently utilized in clinic were universally active at clinically achievable concentrations and exposure times. Combinations showed additivity frequently and demonstrated promising activity that can be used to inform further decision making once LSD1 inhibition toxicities are better known. These findings suggest potentially promising opportunities for developing combination clinical trials to maximize development of LSD1 inhibitors.

**#2035 MGMT inhibition leads to CDK4/6 inhibition and enhances palbociclib and abemaciclib activity in breast cancer.** George C. Bobustuc, Amin B. Kassam, Richard A. Rovin, Deborah L. Donohoe, Maxwell Albiero, Tarun Jella, Olivia Fukui, Cameron Piron, Santhi D. Konduri. *Mayo Clinic, Rochester, WI.*

Background: MGMT (O6-methylguanine DNA methyltransferase), a DNA repair protein leading to chemotherapeutic resistance, is increasingly studied for its cell cycle regulatory functions, also known to control ER expression and function, is overexpressed in a majority of cancers, including breast cancer. MGMT inhibition has been reported to restore ER function and sensitivity to hormonal therapy in tamoxifen resistant breast cancer. CDK4/6 is a cell cycle regulator targeted by a new class of drugs in the treatment of breast cancer in patients who had progressed during prior endocrine therapy. We investigated a potential correlative role between MGMT and CDK4/6 expression/activity. In this therapeutic context MGMT inhibition would have the dual role of increasing/restoring effect of endocrine therapy and facilitate activity of CDK4/6 inhibitors (Palbociclib and Abemaciclib). Methods: We have tested the effect of Antabuse (disulfiram, DSF), as an MGMT inhibitor, at nontoxic doses, on the expression of CDK4/6, or in combination with Palbociclib (PB) or Abemaciclib (LY2835219-LY) on ER+ breast cancer cells. Results: DSF at very low doses (achievable in human serum with standard DSF clinical dosing) decreases ER+ breast cancer cell growth (MCF7, T47D and ZR75) in a dose-dependent manner. DSF further sensitizes breast cancer cells to PB or/and LY and significantly inhibits breast cancer growth without causing unwanted side effects on the normal healthy ER+ breast cells. One dose of concentrations of DSF + LY and moderate synergism for DSF + PB. DSF, alone or in combination with PB (DSF + PB) and/or LY (DSF + LY), significantly inhibits expression of MGMT, CDK4/6, ERα and aldehyde dehydrogenase activity - all involved in breast cancer cell cycle proliferation and tumorigenesis. Furthermore, PB and LY dose dependently decreased MGMT and CDK4/6 expression in breast cancer cells and significantly accumulated breast cancer cells in G1 phase of the cell cycle. DSF, alone or in combination with PB (DSF + PB) and/or LY (DSF + LY) caused significant apoptosis in breast cancer cells. DSF inhibited colony formation which was further enhanced by addition of PB/LY (DSF + PB/LY). Similarly, DSF alone or in combination with PB (DSF + PB) and/or LY (DSF + LY) decreased the metastatic poten-
tant of breast cancer cells. Conclusions: Our findings suggest that DSF as an MGMT inhibitor significantly enhances the antitumor effect of CDDA/6 inhibtors (P8 or LI) in ER+ breast cancer.

**#2036 In vitro and in vivo effect of carbamustine and selenite combination on EGFR signaling in androgen-independent prostate cancer.** Vijayalakshmi Thamilselvan, Mani Menon, Sivagnaan Thamilselvan. Vattikuti Urology Institute, Henry Ford Health System, Detroit, MI.

Introduction: Despite the use of androgen deprivation therapy, the majority of prostate cancer patients will progress to castration resistant disease within 2-3 years, driven by aberrant androgen receptor activation. We have previously shown that combination of carbamustine and selenite effectively induces apoptosis by completely reducing AR and AR-variants in AR-dependent castration resistant prostate cancer cells both in vitro and in vivo. Although studies have demonstrated that AR signaling is a central mechanism of castration resistant prostate cancer progression, the cell growth mediated by AR-independent signaling is also operative. EGFR signaling has been implicated in the survival, invasion, and metastasis of prostate cancer cells in an AR-independent manner. Therefore, in this study, we tested whether the combination of carbamustine and selenite could inhibit EGFR signaling, induce apoptosis, and inhibit growth of AR-independent prostate cancer cells in an in vitro cell culture and in vivo xenograft models.

Methods: AR negative PC-3 prostate cancer cell line was used to study the effect of carbamustine and selenite alone or in combination on EGFR signaling. Cell viability, proliferation, and apoptosis in the presence or absence of EGFR (50ng/ml) were determined. Tissue and tumor cell extracts were used to determine pAkt and pERK1/2 protein expression levels. The combination treatment exhibited a strong inhibitory effect on EGFR stimulated Akt, and ERK1/2 phosphorylation. Combination treatment was able to induce apoptosis even in the presence of EGFR. Consistent with in vitro results, combination treatment for 3 weeks reduced PC-3 xenograft tumors in nude mice by 88% without any toxicity. Wherein individual agent treatment showed only partial effect both in vitro and in vivo. Conclusions: Our pre-clinical data demonstrate that the combination treatment of carbamustine and selenite substantially inhibits EGFR signaling, induces apoptosis, and reduces tumor growth of AR-independent prostate cancer cells in vitro and in vivo. Our novel findings suggest that the combination of carbamustine and selenite is an effective therapeutic agent for successful treatment, survival, and improved quality of life for patients with prostate cancer.

**#2038 Reactive oxygen species-mediated synergism of fenretinide and romidepsin in preclinical models of T-cell lymphoid malignancies.** Monish Ram Makena, Balakrishna Koneru, Min H. Kang, C. Patrick Reynolds. Texas Tech University Health Sciences Ctr., Lubbock, TX.

Introduction: T-cell lymphoid malignancies (TCLMs) are in need of novel and effective therapeutic strategies. Romidepsin is a histone deacetylase (HDAC) inhibitor that achieved FDA registration as 2nd line therapy for peripheral and cutaneous T-cell lymphomas. The cytotoxic retinoid fenretinide achieved durable complete responses against T-cell lymphomas in early-phase clinical trials and T-cell lymphoma patients who failed prior romidepsin treatment responded to fenretinide. Fenretinide is currently being evaluated in a Phase IIa clinical trial for T-cell lymphoma patients (NCT02159515). We propose that fenretinide has potential for using these two agents in combination in TCLMs. Methods and Results: Using the DIMSCAN assay, we demonstrated cytotoxic synergy between romidepsin and fenretinide in fifteen TCLM cell lines at clinically-achievable concentrations that lacked cytotoxicity for non-malignant cells (fibroblasts and blood mononuclear cells). In vivo, romidepsin + fenretinide + ketoconazole (enhances fenretinide exposures by inhibiting fenretinide metabolism) showed greater activity in subcutaneous (COG-LI-317m and TX-LY-183x PDX) and disseminated (COG-LI-317mLuc expressing the luciferase gene) TCLM xenograft models than single agent romidepsin or fenretinide + ketoconazole. Fenretinide + romidepsin caused a reactive oxygen species (ROS, measured by DCFDA dye)-dependent increase in pro-apoptotic proteins (Bim, BID, Bax and Bad) and induced TUNEL positive apoptosis. Unfortunately, both agents lacked antitumor efficacy, which achieved a synergistic increase in histone acetylation. The synergistic cytotoxicity, apoptosis, and histone acetylation of fenretinide + romidepsin was abrogated by antioxidants (vitamins C or E). Romidepsin + fenretinide activated p38 and JNK via ROS, and shRNA knockdown of p38 and JNK1 significantly decreased the synergistic cytotoxicity and apoptosis. Romidepsin + fenretinide also showed synergistic cytotoxicity for B-lymphoid malignancy cell lines, but did not increase ROS, acetylation of histones, activation of p38 + JNK, or cytotoxicity in fibroblasts and blood mononuclear cells. Conclusion: Romidepsin + fenretinide achieved synergistic activity in preclinical models of TCLMs, but not in non-malignant cells, via a novel molecular mechanism. These data support conducting clinical trials of romidepsin + fenretinide in relapsed and refractory TCLMs.

**#2039 The use of self nano-emulsifying drug delivery systems to improve bioavailability of combination therapy in non-small cell lung cancer.** Ebony Nottingham, Vasara Sekar, Arindam Mondal, Mandip Sachdeva. Florida Agricultural and Mechanical University, Tallahassee, FL.

Background: Erlotinib, an EGFR selective reversible inhibitor, improved response of patients diagnosed with non-small cell lung cancer (NSCLC) with 70% in lung cancer showing significant tumor shrinkage upon treatment. Unfortunately, most patients eventually relapse due to development of resistance. Our research goal is to quantify the effects of combination treatment of erlotinib with a gycurrylchecetic acid analogs and to improve the oral bioavailability of this treatment using self nano-emulsifying drug delivery systems. Methods: NSCLC cell lines HCC827, HCC827 (4μM erlotinib resistant), HCC827 Cl4 (second site EGFR mutated), HCC827 BEAS2B, and H1975 (4μM erlotinib resistant) were treated in combination with CDDA-Me, CF-CDDA-Me and Erlotinib. The cell viability assays were performed and combination index (CI) values were calculated by isobolographic analysis. Self nano-emulsifying drug delivery systems (SNEDDS) were formulated and characterized through in vitro and in vivo studies. Results: CI_CDDA and improved efficacy for erlotinib in all cell lines with IC50 values of 6.0μM, 7.21μM, 4.6μM and 4.2:1.56μM for HCC827(RESISTANT), H1975(RESISTANT), HCC827CL4 and HCC827 respectively compared to IC50 values of erlotinib alone (25μM, 21μM, 23μM, and 8μM). This was superior when compared to IC50 values of CDDA-Me combination treatment (6.66μM, 7.32μM, 12.0μM, and 3.45μM respectively). Combination treatment showed strong synergism with a constant concentration of 0.5μM CF, CDDA and CI values of 0.461, 0.548, 0.389, 0.550 for HCC827 4μM, H1975μM, HCC827CL4 and HCC827 respectively and antagonism in HCC827BEAS2B (1.508) cells. This is comparable to the synergism observed at a minimum concentration of 2μM CDDA-Me with CI values of 0.337, 0.67, 0.64, and 0.657 respectively and antagonism CI of 1.175 for HCC827BEAS2B. CF-CDDA Combination therapy showed a 2.5-fold decrease in colony formation making them comparable to wild type. This was comparable to CDDA-Me combination treatment with a 1.46-fold decrease in colony formation. Both combination treatments showed little effect on HCC827BEAS2B. Western Blot analysis showed decrease MET expression and decreased apoptosis inhibiting markers BCL2 and Survivin. SNEDD
formulations increased maximum drug plasma concentrations for Erlotinib (281 ng/ml to 442 ng/ml) and circulating time as well (12 hrs - 21 hrs). Conclusions: Based on the results of these studies, CDDOA-Me and CF,CDDOA have shown to overcome erlotinib resistance in non-small cell lung cancer and when combining these treatments with the use of SNEDDS, they have shown to be a promising treatment regimen.

#2040 Superior therapeutic efficacy of nanoparticle albumin-bound paclitaxel over cremophor-paclitaxel in experimental esophageal adenocarcinoma. Md Sazzad Hassan, Niranjan Awasthi, Roderich E. Schwarz, Margaret A. Schwarz, Urs von Holzen. Indiana University School of Medicine-South Bend, South Bend, IN.

Introduction: Esophageal adenocarcinoma (EAC) has become the dominant type of esophageal cancer in the United States. EAC is the fastest growing cancer in the world and the overall 5 year survival rate of EAC is below 20 percent. Most patients with EAC present with locally advanced or widespread metastatic disease, where current treatment is largely ineffective. Prognosis for EAC patients remains poor even with combination therapies due to high resistance to chemotherapy. Therefore, new therapeutic approaches are urgently needed. Paclitaxel (PTX) has been used in combination with carboplatin (CP) as a standard combination therapy for advanced EAC. PTX required emulsification with solvents to allow intravenous administration which has resulted in hypersensitivity reactions and potentially dramatic side effects in patients. Nanoparticle albumin-bound (nab) PTX is an albumin-stabilized, cremophor-free and water soluble nanoparticle formulation of PTX. Nab-PTX is a novel microtubule-inhibitory cytotoxic agent and the potential role of nab-PTX has not been tested yet in experimental EAC. Methods: We explored the antiproliferative and anti-tumor efficacy with survival advantage following CP, PTX and nab-PTX as monotherapy and in combinations in in-vitro, and in murine subcutaneous xenograft and peritoneal metastatic survival models of human EAC. Results: Nab-PTX inhibited in-vitro cell proliferation with significantly lower IC50 (0.25 μM in OE19 and 49 nM in OE33) than that of PTX (0.74 μM in OE19 and 98 nM in OE33) and CP (5.21 μM in OE19 and 1.05 μM in OE33) in OE19 and OE33 EAC cell lines. Nab-PTX treatment resulted in significantly higher antitumor efficacy and survival benefit compared with PTX or CP treatment. After two-week nab-PTX, PTX, CP, nab-PTX+CP or PTX+CP treatments, the average in vivo local tumor growth inhibition rate was 73, 60, 35, 81 and 68 percent respectively (p=0.025). Nab-PTX treatment increased expression of the mitotic-spindle associated phospho-stathmin, decreased expression of proliferative marker Ki-67 and enhanced apoptosis as confirmed by increased expression of cleaved-PARP and cleaved caspase-3. There was an increase in median animal survival after nab-PTX treatment (65 days) compared to controls (46 days, p=0.002), PTX (57 days, p=0.0004) or to CP therapy (53 days, p=0.034). Conclusions: In conclusion, the present study demonstrates that nab-PTX had stronger antiproliferative and antitumor activity in experimental EAC than the current standard chemotherapeutic agents. This strong antitumor activity supports the rationale for clinical evaluation of nab-PTX as promising microtubule-inhibitory agent in EAC.

#2041 High-throughput chemical screening for sensitization of bladder cancer to gemcitabine and cisplatin chemotherapy. Yuki Kita, Takashi Kobayashi, Ryouchi Saito, Toshinari Yamasaki, Takahiro Inoue, Osamu Ogawa. Kyoto University, Kyoto, Japan.

Introduction and Objectives: Gemcitabine and cisplatin chemotherapy (GC) is the current standard regimen for locally advanced and metastatic bladder cancer (BC). Despite a relatively high initial response rate, some cases do not regress (intrinsic resistance) and the remaining cases often show regrowth after initial shrinkage (acquired resistance). To identify novel therapeutic agents for overcoming these resistances, we applied a high-throughput screening of chemicals administered in combination with GC. Methods As a high-throughput screening, 2100 compounds were administered alone or in combination with GC to human BC cell lines (J82, UMUC-3). Cell viability was determined after 3-day incubation and chemicals that enhanced inhibitory effect of GC were screened. The in vivo effect of disulfiram (DSF) was studied in UMUC-3 cell xenografts, and Western blot, immunofluorescence, induced coupled plasma spectrometry and measurement of reactive oxygen species (ROS) were done in vitro for mechanistic exploration. Results: The initial screening identified 26 compounds and further validation narrowed them into the most synergistic agent DSF, an FDA-approved drug for alcoholism. Combination index assay showed synergistic effects of DSF with cisplatin but not with gemcitabine in J82, UMUC-3, T24, HT1197 and HT1376 cells. Co-administration of DSF significantly increased DNA-platinum adducts by regulating cisplatin efflux transporter ATP7A and enhanced apoptosis by GC treatment in UMUC-3 cells, with significant increase of ROS production. Use of DSF in combination with GC significantly increased tumor growth of UMUC-3 subcutaneous xenograft on athymic mice (by 39% compared with GC alone, p = 0.02). GC regimen was as tolerable as GC and no significant differences were observed in body weight of treated mice between the two regimens. Conclusions: Repositioning of DSF to a chemotherapy sensitizer is a promising treatment strategy, which can be translated rapidly in the future.

**EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Combination Therapy 2**

#2042 Nano-tetaoidothyroacetic acid (NDAT) potentiates gefitinib-induced antiproliferation in colorectal cancer cells by inhibiting EGFR sialylation and PI3K activation. Yu-Tang Chin, Chi-Yu Lin, Chun A. Changou, Jacqueline Whang-Peng, Paul J. Davis, Hung-Yun Lin. Taipei Medical Univ., Taipei, Taiwan; Albany Medical College, Albany, NY.

The resistance of gefitinib has been revealed to complicate cancer therapy. Tetaoidothyroacetic acid (tetra) and its nanoparticle derivative (NDAT, nano-tetra) have been proved in vitro and in vivo xenograft demonstrating anti-proliferative and anti-angiogenic activities. It also indicates that they potentiate anti-cancer agent-induced anti-proliferation in cancer cells. In this study, we investigated the effects of NDAT on gefitinib-induced anti-cancer activities in human colorectal cancer cells. Gefitinib inhibited cell proliferation at concentration 1 μM in K-ras wild type HT29 cell and NDAT enhanced the anti-proliferation-induced gefitinib significantly. Meanwhile, both inhibited proliferative and metastatic genes expression in HT29 cells. On the other hand, 10 μM gefitinib inhibited cell proliferation in K-ras mutant HCT116 cell which was further enhanced by NDAT. Different from results in HT-29 cells, only NDAT inhibited proliferative and metastatic genes expression significantly and enhanced the effect of gefitinib in HCT116 cells. ST6Gal-1 catalyzes sialylation of EGFR and induces gefitinib-resistant in colorectal cancers. In addition, NDAT did reduced not only ST6Gal-1 gene expression, but also its protein expression. However, the inhibition of ST6Gal-1 expression may not be sufficient to induced anti-proliferation in colorectal cancer cells. PI3K inhibitor, LY294002, was able to potentiate the gefitinib-induced anti-proliferation in HCT116 cells suggesting that constitutive activation of PI3K may play a key role on gefitinib-resistance in HCT116 cells. In summary, NDAT potentiated gefitinib-induced anti-proliferation via inhibiting the activity of ST6Gal-1 and PI3K activation in gefitinib-resistant colorectal cancer cells.

#2043 Entinostat in combination with Cladribine synergistically induces apoptosis in multiple myeloma cells. Bolun Wang, Hui Lu, Bolin Liu. University of Colorado Anschutz Medical Campus, Aurora, CO.

Cladribine (2-CDA) is a well-known purine nucleoside analog against lymphoproliferative disorders. Entinostat, a selective class I histone deacetylase (HDAC) inhibitor, exerts anti-tumor activity in various cancers, including multiple myeloma (MM). We sought to determine whether cladribine and entinostat may exhibit synergistic anti-proliferative/anti-survival effects on MM cells. Here we showed that, in cell growth MTS assays, either cladribine or entinostat alone inhibited cell proliferation in a dose-dependent manner. The combination of cladribine and entinostat significantly induced growth inhibition in MM cells tested. The combination index (CI) curves showed a synergistic effect between cladribine and entinostat. An apoptotic-ELISA and western blot analyses of caspase-3 and PARP revealed that entinostat in combination with cladribine enhanced both more potent activity than either agent alone to promote the MM cells undergoing apoptosis in a dose and time-dependent manner. Collectively, our data suggest that combinations of entinostat and cladribine possess synergistic anti-proliferative/anti-survival activity in MM cells. Regimens consisting of entinostat and cladribine may represent novel therapeutic strategies against MM.

**EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Drug Resistance: Other Topics**

#2044 Development of stable and brain-penetrating disulfiram nanopar-

ticles, characterization and efficay in glioma cell culture and xenograft mod-

Blood brain-barrier entry, tumor heterogeneity, need to eliminate the tumor-igenic stem cells and inhibit the DNA repair protein MGMT are all essential considerations in glioma treatment. Previously, we showed that alcohol aersion
ExPERIMENTAL AND MOLECULAR THERAPEUTICS: Drug Resistance: Other Topics

Drug disulfiram (DSF) shares all these properties [Carcinogenesis 35, 692, 2014; Oncotarget 4,502, 2013]. DSF was shown to inhibit the MGMT activity in the same way as ALDH by conjugating with the active-site cysteine 145 and sensitizes brain tumors to alkylating agents. Although DSF exerts significant anticancer effects in vitro, the drug undergoes rapid decomposition and metabolism. To overcome these limitations, we have engineered DSF nanoparticles to deliver the drug in PEG-PLGA polymer by solvent evaporation method. The formulation was optimized for various process formulation variables. The optimized nanoformulation (NP) ranged from 70-80 nm in particle size as confirmed using dynamic light scattering and transition electron microscopy. Drug loading, encapsulation efficiency, in vitro release were also optimized and the particles showed excellent BBB permeability in vitro. The time course of internalization of particles using a cyanine dye (HTIC-1) showed a lysosomal accumulation followed by mitochondria. Live animal imaging after IV injections of HTIC-labeled DSF-NPs revealed a selective accumulation in the brain and subcutaneous tumors. Further, the cytotoxicity elicited by DSF-NPs against SF188, DOAY, UW18, UW28 and T98G brain tumor cells was extended and greater than obtained with the free drug. When combined with DSF-NPs, temozolomide showed an 8-10-fold increased cytotoxicity against glioma cell lines. The DSF-NPs also induced significant degradation of MGMT and other redox-sensitive proteins such as the NF-eB, MDR1 and GSTP1 in a concentration-dependent manner in glioma cells. ROS induction by the encapsulated drug was confirmed through DCF-DA and DHE staining of live cells co-staining these cells with the mitochondrial membrane potential probes JC-1 and Rh123. DOX and DHE were monitored for the altered integrity. GSTP1 inhibition and ROS induction by DSF-NPs led to an activation of JNK/ MAPK pathway, culminating in autophagy and apoptosis as verified by western blotting, FACS and immunofluorescence of appropriate markers. Finally, the antitumor efficacy of DSF-NPs was tested in intracranial glioblastoma developed in nude mice by injecting Luciferase-expressing SF-188 GBM cells. A superior tumor regression was evident in DSF-NP-administered animals compared with the free drug after IVIS bioluminescence and histochemical staining of brain tissue. Collectively, our efforts provide strong evidence that DSF nanoparticles allow for the first time to directly evaluate drug binding to target proteins in a manner associated with the drug mode of action. A specific MDR1 spectral fingerprint (ITDRF) were used to study the relative drug target engagement in glioma spheroids. Modulation of p-glycoprotein altered the spectral response to drugs in a manner associated with the drug mode of action. A specific MDR1 spectral signature was not observed in these experiments but experiments with MDR1 silenced spheroids are underway to identify a possible signature.

#2047 The muscarinic receptor antagonist, benzotropine, blocks the expansion of a temozolomide resistant subpopulation of glioma cells. Damian A. Almiron Bonnin, Joseph M. Howard, Alison L. Young, Mark A. Israel, Matthew C. Havrda. Geisel School of Medicine at Dartmouth, Lebanon, NH.

Virtualy all malignant gliomas become drug resistant and recur after initial treatment, recurrent tumors are fatal within two-years, and no therapies exist that cure gliomas. The recognition that subpopulations of primitive cells with an oligodendrocyte precursor-like (OPC-like) phenotype capable of resisting standard therapy and contributing to recurrence, frames the question of whether adjuvant therapies designed to modify or eliminate OPC-like cells could slow the progression of glioma. Agents that force the differentiation of treatment-resistant OPC-like glioma cells, a phenomenon that requires cessation of proliferation, are compelling candidates for targeting OPC-like GSCs. Recently, it was observed that OPC proliferation was driven by activation of the M1, M3 and M4 muscarinic receptors. In another report, a large-scale drug screen designed to seek drugs to induce OPC differentiation in the context of multiple sclerosis identified a muscarinic receptor antagonist, benzotropine (a.k.a. Cogentin), as a potential new therapeutic differentiated, and cell cycle exit. We have conducted studies in glioma cell lines supporting a role for benzotropine in suppressing the development of drug-resistance to the standard glioma chemotherapeutic temozolomide (TMZ). Upon treatment with TMZ, we identified the emergence of an OPC-like subpopulation of glioma cells identifiable by the co-expression of CD44/CD15/PDGFRα and whether benzotropine will suppress the development of TMZ resistance in animal models of glioma.

#2048 Saturated fatty acids in cell membrane phospholipids play an important role in chemoresistance in colorectal cancer. Takanori Hirota, Takanori Sakaguchi, Satoru Furuhashi, Tomohiro Matsumoto, Yusuke Ozaki, Ryo Kuichi, Makoto Takeda, Yasushi Shibasaki, Yoshifumi Morita, Hirotoshi Kikuchi, Megumi Baba, Mitsutoshi Setou, Hiroyuki Konno. Hamamatsu University School of Medicine, Shizuoka, Japan.

[Background and Aim] Resistance to chemotherapeutics represents the major obstacle to survival in patients with colorectal cancer. Various factors, such as drug efflux, autocrine survival signaling, and alterations in DNA damage repair mechanisms, can contribute to chemoresistance; however, the actual underlying mechanism is yet to be elucidated. The aim of this study was to elucidate the mechanism behind anticancer drug resistance based on lipidomics.

<p>[Materials and Methods] 1) Spheroids were derived from three colorectal cancer patient-derived xenograft models (A, B, and C) that were incubated with chemotherapy agents, such as 5-fluorouracil (5-FU). We analyzed the response rate of spheroids under 5-FU treatment. Global lipid analysis was performed on 5-FU resistance spheroids (A) and sensitive spheroids (C) using a Q Exactive LC-MS/MS treatment platform. An increase in phospholipid was identified with Lipid Search software. 2) We tried to identify genes that were responsible for changes in phospholipid profiles in the cell membrane. 3) To determine phospholipid profile changes in the cell membrane that occur in colon cancer cells (HCT116, SW480) during anticancer drug resistance, the genes responsible for such resistance were knocked down using siRNA. [Results and discussion] 1) Changes in phospholipid composition and cell cycle events were also characterized from different aspects such as epigenetic markers, cell cycle events, oxidative stress and DNA repair capacity. Assays for nucleotide modifications and epigenetic markers in PDT resistant glioblastoma and its parental cell line showed significant higher level of two epigenetic marks including 5-methylcytosine (5-mC) and 5-hydroxymethylcytosine (5-hmC) in U-87R compared to U-87P, before and after PDT. Doubling time of U-87R cells was considerably longer than that of U-87P. Cell cycle analysis showed shorter G1 phase in U-87R cells compared to U-87P. Moreover, accumulation in G2 phase following PDT was observed earlier in resistant cells than in parental line. That suggests the role of early activation of DNA damage response in resistant cells. Resistance cells were found to be sensitive to either BRCA1/2 or RAD51, which are involved in homologous recombination (HR) pathway upstream inhibitor) failed to overcome bortezomib resistance. Only photodynamic therapy. This work was supported by the Polish National Science Centre (NCN) grants: DEC-2012/07/B/NZ1/00008, UMO-2014/15/B/NZ5/0144, UMO-2014/13/N/NZ3/00863.

Background: Triple-negative breast cancers (TNBC) are associated with an extremely poor prognosis due to their aggressive behavior and rapid resistance to chemotherapy. Chemotherapy may select for resistant subclones and lead to tumor recurrence. Although, DNA aneuploidy has been a long known prognostic biomarker in breast cancer, the biological role of aneuploid or polyploid cancer cells in tumorigenesis and chemoresistance is largely undefined. Polyploid cells arise due to repeated rounds of DNA duplication in the absence of mitosis. Chemotherapeutic DNA-damaging agents or mitotic inhibitors can also induce formation of polyploid cells and subsequent senescence. However, recent reports indicate that polyploid cells represent a viable and proliferating subpopulation within a tumor that may escape chemotherapy and contribute to tumor recurrence. Methods: In this study, we examined the prevalence and functional significance of polyploidy occurring de novo or induced by chemotherapeuy in TNBC cell lines. DNA ploidy was analyzed in Hschoest 33342 stained cells using FACS. Cells with greater than 4n DNA content were defined as polyploid. Live-cell imaging was used to observe cell division patterns in polyploid cells using IncuCyte Zoom. Cell proliferation was assessed in the absence and presence of chemotherapy drugs with distinct modes of action (docetaxel and 5-fluorouracil, respectively). Results: Polyploid cells showed formation of mitotic structures suggesting multi-polar cell division. Cell proliferation assay revealed that polyploid cells grow slower than diploid cells and show reduced sensitivity to all four chemotherapy drugs. Docetaxel treatment resulted in induction of polyploidy and drug-induced senescence in parental TNBC cells. Drug-induced polyploid cells were resistant to subsequent docetaxel treatment. Time-lapse imaging showed budding of small daughter cells from polyploid senescent cells. Majority of senescent cells died, some cells survived and regrewed the diploid and polyploid subpopulations similar to those present in parental cells. RNAseq identified differentially expressed genes involved in G1-S and G2-M checkpoint pathways (B2/1, RAD51), cell proliferation (Aurora kinase A/B) and apoptosis (BIM, BIRC3). Conclusions: Above findings indicate that there are molecular and functional differences between diploid and polyploid cells that are both naturally occurring or induced by chemotherapy. In our future studies, we will examine combinatorial approaches to overcome polyploidy-associated chemoresistance.

#2051 LSTRA cell line as a model for large granular lymphocytic leukemia in drug screening. Fu-Shin Chueh,1 Fu-Yu Chueh,2 Chao-Lan Yu2.

Large granular lymphocytic (LGL) leukemia is a rare form of leukemia that is characterized by the presence in circulating lymphocytes of LGL cells. A subcategory of T-LGL leukemia that co-expresses T and NK cell surface markers is a very aggressive and has a very poor prognosis. Current treatment of aggressive T-LGL is based on non-specific immunosuppressive therapy. Lack of model cell lines contributes to slow progress in designing targeted therapy and clinical trials. Our recent studies demonstrate that the mouse T-leukemic cell line LSTRA reproduces some important characteristics of aggressive T-LGL leukemia. This is the first report of a cell line model mimicking the deadly human leukemia and has great potentials for drug screening in treating T-LGL leukemia. Bortezomib is one of the drugs that show promising results in treating LGL leukemia patients in clinical trials. Bortezomib is the first FDA-approved reversible proteasome inhibitor in treating multiple myeloma and mantle cell lymphoma patients. One of the major concerns is that patients develop resistance during the course of treatment and cancers relapse. Therefore, it is important to develop novel strategies in overcoming LGL leukemic cells’ resistance to bortezomib and its derivatives. In our current study, we showed that bortezomib inhibited cell proliferation and induced apoptosis in LSTRA leukemic cells. Partial reversion after 48-72 hr of bortezomib treatment in U-87R suggested development of resistance to bortezomib. We further established bortezomib-resistant LSTRA cells that tolerated significantly higher levels of bortezomib. Both carfilzomib (FDA-approved second generation irreversible proteasome inhibitor) and MLN 9242 (proteasome pathway upstream inhibitor) failed to overcome bortezomib resistance. Only
luteolin, a common flavonoid found in plants, can effectively overcome bortezomib resistance. Metabolic reprogramming has been linked to drug resistance in cancer cells. Indeed, We found that bortezomib-resistant LSTRA cells had smaller cell size as well as reduced rate of glucose uptake, lactate secretion, and mitochondrial respiration. These results suggest that reduced mitochondrial energy metabolism may be an important factor underlying LSTRA cell’s resistance to bortezomib. All together, we identified luteolin as a potential small molecule in overcoming LGL leukemia’s resistance to proteasome inhibitor therapy. Altered mitochondrial activity and cell metabolism in bortezomib-resistant cells provide additional targets in developing novel combined chemotherapy for cancer patients.

#2052 Chemotherapy sensitivity, cytokine IL-8 level, and genetic expression mRNA IL-8 in gastric cancer treatment response prediction. Sirikan Limpakan (Yamada), Chiang Mai Univ. Faculty of Medicine, Chiang Mai, Thailand.

Aims: To determine chemotherapy sensitivity in primary gastric cancer cell isolated from Thai gastric cancer patients against anticancer drugs. To search for the correlation of interleukin-6 and interleukin-8 levels in primary gastric cancer cell culture with single cell isolation technique. The 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) assay was performed to ex vivo examine the chemotherapy sensitivity to three anticancer drug: cisplatin, oxaliplatin, 5-Fluorouracil, and Irinotecan. Biopsy tissues from tumor site were collected before chemotherapy treatment in 63 patient who received neo-adjuvant chemotherapy by FOLFOX IV regimen due to advance stage III and IV in both resectable and un-resectable cases. The IL-8 mRNA gene expression was reported by relative quantitation real time RT-PCR. ELISA technique was performed to investigate the cytokine level from primary cultures taken from 41 gastric cancer patients who undergone biopsy from Maharaj Chiang Mai Hospital during year 2014 to 2016. The clinical data base was parallel collected and analysed in correlation with clinical response and ex vivo response. Results: Each patient has different sensitivity pattern to the standard anticancer drugs. There are no significantly direct correlations or difference between cytokine IL-8 levels or mRNA IL-8 expression, and the chemotherapy sensitivity to the actual drugs that are being used for treatment of gastric adenocarcinoma in individual patients. However, the chemotherapy resistance to all drugs in primary gastric cancer cell culture has trend to increase after the third cycle of chemotherapy treatment when compared to prior cell treatment with fluctuation of cytokine level. Different cytotoxic drug gives the same response result for chemresistance test in this population. The author observed the down regulation of tissue mRNA IL-8 expression and cytokine level in the good responders. Conclusion: The results provide an additional basis of information for primary chemotherapy selection in the individualised treatment for advanced gastric adenocarcinoma patients. Therefore, the author suggest to select the less toxic cytotoxic drug for being primary chemotherapy of choice. Cytokine gene level and mRNA IL-8 gene expression show individually significantly change after chemotherapy treatment in good responder. This result may also useful to find some new targeted therapy or additional treatment for its suppression.

#2053 Mechanisms of resistance to palbociclib and aromatase inhibitors in hormone receptor positive breast cancer. Armina A. Kazi,1 Antony Sare,1 Saranya Chumsri,2 Angela Brodie1. Loyola University MD, Baltimore, MD; Mayo Clinic, Jacksonville, FL; University of Maryland, Baltimore, Baltimore, MD.

Estrogen receptor-positive (HR+) breast cancer is the most common form of breast cancer that is accountable for the majority of breast cancer mortality. Currently, the cyclin dependent kinase inhibitor palbociclib in combination with endocrine therapy represents the new standard first and second line therapy for patients with metastatic HR+ breast cancer. While palbociclib has been shown to significantly improved progression free survival in combination with aromatase inhibitor (AI) and fulvestrant, resistance will inevitably occur in patients with metastatic breast cancer. However, the mechanisms of resistance to the combination of palbociclib and AI remain largely unknown. It is also unclear whether resistance mechanisms would be the same if palbociclib was given as first line treatment in combination with letrozole vs. if palbociclib was given as second line treatment after letrozole resistance had already occurred. To address this, previously well established and well characterized letrozole-sensitive MCF7/Ca cells and letrozole-resistant LTTLTa cells were subjected to continuous, long term treatment with increasing doses of letrozole and palbociclib until resistance to both drugs was achieved (MCF7/Ca+let+palb and LTTLTa+palb, respectively). Preliminary MTT cell viability assays indicate palbociclib IC50s of 750 nM in MCF7/Ca and LTTLTa cells vs. 21 nM in palbociclib and letrozole-resistant cells. First line and second line palbociclib resistance correlated with changes in morphology, protein expression, and cancer stem cell characteristics. Under phase contrast microscopy, first line and second line palbociclib-resistant LTTLTa cells were larger in size, more circular in shape, and tended not to grow in epithelial cell-like groups compared to palbociclib-sensitive MCF7/Ca and letrozole cells, with second-line palbociclib resistant cells exhibiting these characteristics the most. Western blot showed that ER protein expression in ER+/HER2- MCF7/Ca cells decreased with first line palbociclib and letrozole resistance, and that both ER and HER2 protein expression were decreased with second line palbociclib resistance in ErRlow/HER2+ LTTLTa cells. Lastly, mammosphere assays demonstrated increasing percentage of cancer stem cells with letrozole resistance alone (4 per 1000 cells plated MCF7/Ca vs. 58 per 1000 planted LTTLTa) and with palbociclib and palbociclib resistance (317 per 1000 cells plated MCF7/Ca and 202 per 1000 cells plated LTTLTa cells). Overall, these results indicate that 1) resistance to palbociclib, whether as first line or second line treatment has significant effects on breast cancer cells that may be relevant to patient diagnosis and treatment.

#2054 Cervicatatin overcomes the acquired resistance to crizotinib in EML4-ALK positive non-small cell lung cancer by controlling YAP activation. Miran Yun,1 Hun Mi Choi,2 Kyoung Ho Pyo,3 Byoung Chul Cho.1 Jeuk, Seoul, Republic of Korea; 2Yonsei University College of Medicine, Seoul, Republic of Korea.

Crizotinib is highly effective in patients with non-small cell lung cancer (NSCLC) harboring the echinoderm microtubule-associated protein-like 4 (EML4)-anaplastic lymphoma kinase (ALK) fusion. However, its efficacy has been limited by the development of acquired resistance, and the mechanisms of such resistance remain largely unknown. Herein, we investigated a possible candidate for circumventing the acquired resistance to crizotinib. We established a model of acquired resistance to crizotinib (H3122-CR) by exposing EML4-ALK-positive H3122 lung cancer cells to increasing doses of crizotinib, and performed MTT screening using a library of FDA (Food and Drug Administration)-approved drugs composed of a collection of 640 clinically used compounds. Our MTT screening identified that cervicatatin, a drug targeting 3-hydroxy-3-methylglutaryl-CoA (HMG-CoA) reductase, significantly inhibited the cell growth in H3122-CR cells, which was completely restored by addition of geranylgeranyl pyrophosphate (GGPP), a key metabolite of mevalonate pathway. We also found that yes-associated protein (YAP), a major effector of the Hippo tumor suppressor pathway, was robustly accumulated in nucleus with a concomitant decrease of YAP phosphorylation in H3122-CR cells compared to parental cells. Importantly, inhibition of geranylgeranylation (GGylation) by GGTI-298 or cerivastatin markedly increased YAP phosphorylation, led to cytoplasmic translocation of YAP, and subsequently induced YAP inactivation. Moreover, the enrichment of EGFR signaling pathway and cell cycle signature including transcriptional targets of YAP was enhanced in H3122-CR cells, whose induction contributed YAP-mediated resistance to crizotinib. Inhibition of YAP function with siRNA or verapamil as a YAP inhibitor greatly abrogated cell growth of H3122-CR cells, by regulating cell cycle regulation and EGFR activation. Finally, we confirmed up-regulation of nuclear YAP expression in crizotinib-acquired resistant patient derived tumor xenograft (PDXT) models established from EML4-ALK positive NSCLC patients. Collectively, our findings define the GGylation-mediated YAP transcriptional activation as a new mechanism of resistance to crizotinib, providing a rationale for further exploring statins as a possible anticancer agent to overcome the acquired resistance to crizotinib in EML4-ALK positive NSCLC cells.

#2055 Therapeutic resistance to BET bromodomain inhibition in prostate cancer.

Carl G. Engkel, Rohit Malik, Steven Kregel, Irfan A. Ansangari, Kani Wilder-Romans, Xia Jiang, Xuhong Cao, Corey Speers, Arul M. Chinnaiyan. University of Michigan, Ann Arbor, MI.

Prostate cancer is the most common cancer among men and a leading cause of cancer-related death in North America. Current therapies include radical prostatectomy and radiotherapy for localized disease, and androgen deprivation therapy (i.e. surgical or medical castration) for metastatic disease. Recently, we described the use of inhibitors of bromodomain and extraterminal (BET) protein peptides for the treatment of castration-resistant prostate cancer (CRPC), which have since undergone investigation in clinical trials. In anticipation of patients refractory to treatment with BET inhibitors, we explored the development of resistance to a clinical-grade BET inhibitor in four cell line models—VCaP, LNCaP, LNCaP-AR, and 22Rv1—by serially passing cells in increasing concentrations of drug with matched controls in DMSO. All resistance models...
displayed several-fold increased IC50 values relative to control in in vitro cell viability assays. Additionally, we have modeled resistance to BET inhibition in vivo by serially passaging cell line- and patient-derived xenografts in animals treated with BET inhibition. Interrogating these models through traditional molecular techniques and next-generation sequencing, we discovered several putative mechanisms of resistance to BET inhibition that we are currently validating in our laboratory.

#2056 MYC and HIF-2 alpha mediate resistance to Epidermal Growth Factor Receptor (EGFR) antagonism in oral squamous carcinoma cells. Su-Kanya Gayan, Reza Bayat-Mokhtari, Bidisha Pal, Anupam Sarma, Joyeta Talkudder, Sorra Sandhiya, Rashmi Bhuyan, Seema Bhuyan, Jaishree Gar- hyan, Debabrat Basuha, Amal Kataki, Rakesh Bhattacharjya, Herman Yeger, Bikul Das. Forsyth Institute, Cambridge, MA; B. Borodd Cancer Institute, Guwahati, India; KaviKrishna Laboratory, Guwahati Biotech Park, IIT, Guwa- hati, India; Gauhati University, Guwahati, India; Jawaharlal Nehru University, New Delhi, India; Hospital for Sick Children, Toronto, Ontario, Canada.

Background: Oral squamous cell carcinoma (OSCC) is a devastating dis- ease. Recent findings suggest that the EGFR antagonist including erlotinib may induce tumor regression alone or in combination with chemo/radia- tion. Our preliminary clinical study conducted at KaviKrishna laboratory indicates that many poor patients are taking the highly expensive drug Er- lotinib, and or equivalent EGFR antagonists. However, oral cancer lesions are often hypoxic, and the hypoxia-induced cellular mechanisms might con- tribute to drug resistance. Here, we investigated, whether resistance to EGFR antagonist could be enhanced by increased hypoxia.

Results: We used SCC-25 and SCC-9 cell lines, as well patient derived primary oral cancer cells (n=5) for the study. Immunomagnetic sorting was performed to obtain ABCG2+ population. The self-renewal was studied using in vitro clonogenic and in vivo serial transplantation assay in NOD/SCID mice. Results: First, we identified a rare ABCG2+ expressing, highly tumorigenic cell population in SCC-25, and SCC-9 having cancer stem cell (CSC) like characteristics. Second, we found that the ABCG2+ cells exhibited sensitivity to PD158780 (10 μM; 62% inhibition within 48 hours), and AG1478 (10 μM; 56% inhibition within 48 hours), two small molecular inhibitors of EGFR tyrosine kinase. These small molecular inhibitors signifi- cantly inhibited the clonogenic capacity of the ABCG2+ cells. Next, we found that ABCG2+ cells also showed sensitivity to Erlotinib in the in vitro clonogenic assay. Third, the ABCG2+ cells, when exposed to hypoxia (<0.1% O2, 24 hours), exhibited enhanced expression and transcriptional activity of MYC, and HIF-2alpha. The post-hypoxia ABCG2+ cells exhib- ited complete resistance to PD158780, AG1478 and Erlotinib treatment, which could be reversed by siRNA silencing of MYC and or HIF-2alpha. ChIP assay revealed that HIF-2alpha directly binds to MYC in ABCG2+ cells. We found similar results in ABCG2+ cells obtained from primary oral cancer patients (n=5) for the study. Importantly, ABCG2+ cell lines derived from patients exhibited hypoxic phenotype, including the high expression of HIF-1alpha, and HIF-2alpha, as well as resistance to erlotinib. Furthermore, erlotinib enhanced the stemness of ABCG2+ cells by activation of the MYC/ HIF-2alpha self-renewal pathway (1). Conclusion: These data indicate that MYC and HIF-2alpha operate to mediate intrinsic resistance of oral squa- mous cancer cells to EGFR antagonist in the hypoxia microenvironment. (1) Bhuyan et al. Cancer Research, volume 76 (14), abstract 935; 2016.

The high expression of P-glycoprotein (P-gp) is consistently observed in mul-tidrug resistance (MDR) cancer cells. The purpose of our study is to identify conditions that could increase the sensitivity of P-gp-overexpressing drug-resis- tant KBV20C cancer cell line. We have used the commercially available epige- ne library, which includes 128 compounds. Using the cell viability assay test, we also identified that NVP-BSK805 is highly sensitized to KBV20C-resistant cells and vincristine treatment. However, NVP-BSK805-induced sensitization was not observed in vincristine-treated sensitive KB parent cells, suggesting that the effects are specific to resistant cancer cells. Using FACS analysis, western-blots, and Annexin V staining, we identified that NVP-BSK805 sensitized vincristine- treated KBV20C cells via apoptosis and G2 arrest. Furthermore, sensitiza- tion potency of NVP-BSK805 in combination with vincristine was measured in KBV20C cells when comparing with P-gp inhibitor verapamil or another JAK2 inhibitor CEP-33779. We further investigated the mechanisms of NVP-BSK805 against sensitization of vincristine-treated KBV20C cells. The sen- sitization mechanism of NVP-BSK805 was mainly dependent on the inhibi- tion of P-gp. In addition, APTase activity was also conducted to identify its potential role in NVP-BSK805 for P-gp inhibition. Both NVP-BSK805 and CEP-33779 showed high binding affinity docking scores of -9.1 and -7.4, respectively, against the ABCB1 receptor protein. Collectively, inhibition of P-gp by NVP-BSK805 can increase the vincristine-sensitiveness in MDR cancer cells through increased apoptosis and G2 arrest. Our findings indicate that JAK2 inhibitor may be a promising target in the treatment of patients resis- tant to anti-miticot drug.

1 April 2017 528
To overcome resistance, 2nd and 3rd generation covalently binding TKI starget-approximately 70% overall response rate, increased progression free survival,Heymach. conclusion, unlike other EGFR TKIs, thenon-covalentEGFR inhibitors CUDC-ence of 50nM PKC412 and 500nM of CUDC-101. Moreover, PKC412 partiallytriple mutant Ba/F3 cells showed decreased phosphorylation of EGFR in pres-

The sensitization mechanism of XL109 against sensitization of vcinristine-treated KBV20C cells. The sensitization mechanism of XL109 was mainly depends on the inhibition of P-gp. In addition, ATPase activity was also conducted to identify as potential role of XL019 in P-gp inhibition. In the docking modeling, XL019 and CEP-33779 showed high binding affinity docking score against ABCB1 receptor protein by 10nts. Collectively, inhibition of XL109 by XL109 can increase the vcinristine-sensitivity in MDR cancer cells through in-

anaplastic thyroid cancer (Tpo-cre/HrasG12V/p53flox/flox;Hras;p53) with the FTI staexploited clinically. We treated a murinemodel of poorly differentiated andanaplastic thyroid cancer (Tpo-cre/Hras<sup>12V12</sup>/p53<sup>lox/lox</sup>;Hras;p53) with the FTI tipifarnib, and observed sustained tumor regression and increased survival; however, tumors eventually recur. Following HRAS deolocalization by tipifarnib in vitro, ERK phosphorylation was only inhibited transiently in HRAS-mutant cell lines, which was associated with increased GTP loading of wild-type RAS proteins in the setting of RTK ligand stimulation. This adaptive reactivation of RAS-MAPK signaling was aborted by selective RTK (i.e. EGFR, FGFR) inhibitors, or by MEK inhibitors. Importantly, tipifarnib combined with the MEK inhibitor AZD6244 led to improved responses in Hras<sup>p53</sup> mouse tumors, whereas combination with the EGFR/FGFR inhibitors erlotinib and ponatinib did not, suggesting heterogeneity of upstream inputs. In order to identify ac-

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Drug Resistance: Other Topics

The CDK4/6 inhibitor palbociclib is currently being used in combination withendocrine therapy to treat advanced ER positive breast cancer patients. While this treatment has shown great promise in the clinic, about 25% of the patients do not respond, and almost all patients eventually acquire resistance to palbociclib treatment. Hence, understanding the mechanism(s) of acquired resis-
tance to CDK4/6 inhibition is crucial to devise alternate treatment strategies.

The farnesyltransferase inhibitor tipifarnib causes dramatic tumor regression and enhances cancer survival. It was shown that the farnesylation-in activates G9A-cAMP-CREB pathway and decreases expression of G9A, p53, and G9A-binding proteins in pancreatic cancer cells, which was associated with increased GTP loading of wild-type RAS proteins in the setting of RTK ligand stimulation. This adaptive reactivation of RAS-MAPK signaling was aborted by selective RTK (i.e. EGFR, FGFR) inhibitors, or by MEK inhibitors. Importantly, tipifarnib combined with the MEK inhibitor AZD6244 led to improved responses in Hras<sup>p53</sup> mouse tumors, whereas combination with the EGFR/FGFR inhibitors erlotinib and ponatinib did not, suggesting heterogeneity of upstream inputs. In order to identify ac-

#2061 Non-covalent EGFR T790M targeting TKIs inhibit AZD9291 resis-
tant EGFR C797S mutants. Jacqueline P. Robichaux, Monique Nilsson, John V. Heymach. UT MD Anderson Cancer Center, Houston, TX.

Approximately 10-15% of non-small-cell lung cancers (NSCLC) have epider-
mal growth factor receptor (EGFR) mutations resulting in increased sensitivity to 1<sup>st</sup> generation tyrosine kinase inhibitors (TKIs) such as gefitinib and erlotinib. For common mutations in EGFR, treatment with 1<sup>st</sup> generation TKIs results in approximately 70% overall response rate, increased progression free survival, and increased quality of life compared to chemotherapy alone. However, resis-
tance to 1<sup>st</sup> generation TKIs typically develops within ~12 months, and approx-
imately 55% of patients acquire a secondary mutation in EGFR Exon 20, T790M. To overcome resistance, 2<sup>nd</sup> and 3<sup>rd</sup> generation covalently binding TKIs target-
ing T790M mutations have been developed. Recent studies show that approxi-
mately 40% of acquired resistance to 2<sup>nd</sup> and 3<sup>rd</sup> generation TKIs can also occur via a third acquired EGFR mutation at the site of covalent binding, C797S. To date, there are no standard approved targeted therapies for treating EGFR C797S mutant NSCLC. Moreover, we have recently demonstrated the use of covalent inhibitors in the first line setting, C797S mutations are expected to become more prevalent and new strategies to overcome therapeutic resistance will be required. To this end, we have generated stable Ba/F3 and HCC827 NSCLC cell lines expressing C797S mutant EGFR receptors with common mutations in EGFR including, L858R/T790M/C797S, and Ex19del/T790M/C797S. EGFR mutant cell lines expressing C797S were screened against 1<sup>st</sup>, 2<sup>nd</sup>, and 3<sup>rd</sup> generation EGFR TKIs and cell viability was determined using Cell Titer Glo. Triple mutant cell lines containing T790M and C797S mutations were not sensitive to any 1<sup>st</sup>, 2<sup>nd</sup>, or 3<sup>rd</sup> generation inhibitors with IC<sub>50</sub> values of >10μM, 7.0μM, and 7.6μM, respectively. However Ba/F3 and HCC827 cell lines transfected with EGFR triple mu-
tants were inhibited by non-covalent inhibitors: CUDC-101, an EGFR, HER2 and HER3 inhibitor (GSEA) revealed enrichment of immune pathways (interferon alpha and gamma response, immune response) and pathways known to regulate EMT and cancer stem cells (IL-6/Stat3, IL-2/STAT-5, Notch, Wnt) in the resistant cells. Additionally, GSEA analysis revealed deregulation of G2/M checkpoint, estrogen response and DNA repair pathways (double strand break re-

Tumor cells treated with a PBD-based antibody-drug conjugate targeting ST4 develop acquired resistance due to ST4 down-regulation and response to alternate therapeutics. Shenlan Mao,1 Andrew Garcia,1 Tracy Chen,1 Rajanama Chaeradvy,1 Allison M. Marrero,1 Helen Zhaoming2. Dorsin Toader,1 Nazareno Dimasi,1 Maureen Kennedy,1 Philip Howard,2 Changshou Gao,1 Heren Wu,1 Ronald Herbst,1 David Tice,1 Jay Harper1.1 MedImmune, Gaithersburg, MD; 2MedImmune, London, United Kingdom.

Resistance to antibody-drug conjugates (ADC) has been observed in both preclinical models and in the clinic. It has been previously reported that an ADC targeting CD33 with a DNA cross-linking pyrrolobenzodiazepine (PBD) dimer was active in models of multidrug-resistant (MDR) AML, suggesting that PBDs, delivered as part of a molecular-targeted cancer therapy may be effective in MDR settings. However it could still be possible to develop resistance to PBD-conjugated ADCs though other mechanisms that remain unknown. Studies
were conducted to determine if tumor cells have innate resistance to PDs or an anti-ST4 ADC delivering PBd warhead. It was found that both the ADC and its PBd warhead, SG3199, completely eradicat MDA-MB-361 breast cancer cells and CNDI-N87 gastric cancer cells in culture, suggesting a lack of intrinsic resistance in these cell lines. The potential emergence of acquired resistance was investigated using miRNA stability, time-response silencing effect and the therapeutic effect in xenograft OC in vivo model. We demonstrated that siRNA-2'-F-P2x prolong the stability for more than 24 hours and enhance the silencing for more than 96 hours. Moreover, we found that PTGER3-silencing effect can control the expression of CFTR multidrug resistant pump by regulating ERK-ELK1-ETS1-CFTR axis, resulting in an increase of the cisplatin uptake, decreasing the tumors and associated angiogenesis and tumor growth in xenograft OC in vivo model. siRNA-PTGER3-2'-F-P2x modification increase the stability and time-response silencing effect, leading to a synergistic anti-tumor in combination with cisplatin in ovarian cancer models.

#2067 Tumor-infiltrating PMN-MDSCs mediate sorafenib resistance in hepatocellular carcinoma through immune suppression. Chun-Jung Chang,1 Li-Chun Lu,1 Cher-wei Liang,2 Chih-Hung Hsu,3 Ann-Li Cheng 4. Graduate Institutes of Oncology, College of Medicine, National Taiwan University, Taipei, Taiwan; 2Department and Graduate Institute of Pathology, National Taiwan University Hospital, Taipei, Taiwan.

Background: The mechanisms underlying the inherent or acquired resistance to sorafenib in advanced hepatocellular carcinoma (HCC) are not fully understood. We studied the role of myeloid-derived suppressor cells (MDSCs), a subset of peripheral blood monoocytes, in the development of resistance to sorafenib, an inhibitor of receptor tyrosine kinase activity, in murine liver cancer model. Results: Liver tumor-bearing mice were treated with sorafenib (5 mg/kg/d) for 1 week or 3 weeks from the day after tumor cells implantation. For combination therapy, mice were treated sorafenib and anti-IL-6 Ab or its isotype control Ab (500 μg/3 days starting from day 4 for 4 doses). Tumor infiltrating leukocytes (TILs) and leukocytes of other tissues including liver, spleen, peripheral blood, and bone marrow were isolated, and characterized by flow cytometry analysis. Morphological characteristics of MDSCs were determined by cytospin and Liu staining. Pro-inflammatory cytokines were detected by ELISA or mouse inflammatory cytokines beads array (BD). Paired HCC tissues from advanced HCC patients treated with sorafenib (before and post-sorafenib progression tissues) were evaluated for the expression of CD11b, CD15, and CD66b in TILs by immunohistochemistry. Results: In mice treated with sorafenib, the CD11b+/Gr1−Ly6G−/Ly6C− MDSCs were significantly increased in liver tumors, but not in others tissues. Morphologically, these MDSCs were segmented nuclear PMN type cells. The analysis of TILs revealed that the percentage of total immune effectors (CD4+ or CD8+ IFN-γ-expressing T cells versus total immune suppressors (CD10 or TGF-β-expressing CD4+ T cells, FOXP3-expressing CD4+ T cells) was lower in the tumors of sorafenib-treated mice than those of the vehicle-treated mice. The T cell proliferation capability was also significantly decreased in TILs of sorafenib-treated mice versus TILs of vehicle-treated mice. Multiple inflammatory cytokines including VEGF, G-CSF, MCP-1, and IL-6 were significantly increased in mouse liver tumors treated with sorafenib. When combined with sorafenib, anti-IL-6 antibody alleviated the early tumor-infiltration of Ly6G+ MDSCs, restored the proliferative activity of TILs, decreased the levels of pro-inflammatory factors in tumors, and suppressed the liver tumor growth synergistically. In 6 paired human HCC tissues, we found that 3 exhibited higher proportion of CD11b+, CD15, or CD66b+ cells in post-sorafenib progression tissues than their pre-sorafenib treatment tissues. Conclusions: Our data indicate that tumor-infiltrating PMN type MDSCs and associated immunosuppression may be an important mechanism impeding the therapeutic efficacy of sorafenib in HCC. (This works was supported by MOST 105-2314-B-002-180).
to date about p53 turnover through autophagy-lysosome pathway. Here we discover that the activation of p53 autophagic degradation during an oral small molecule receptor tyrosine kinase inhibitor sunitinib in p53 wt cancer cells and normal cells. Mechanistically, the nucleus-to-cytoplasm shift is essential for the autophagic degradation of p53 induced by sunitinib, however, does not require p53 nuclear export signals. The degradation of p53 is achieved by the nuclear-cytoplasm transport of its nuclear binding target HMGB1, shifting the distribution of p53 from the nucleus to the cytoplasm. Then cytoplasmic p53 directly interacts with the autophagy cargo receptor p62 to promote degradation. Importantly, inhibition of HMGB1 sensitizes cancer cell to sunitinib. Taken together, our study identified an alternative p53 protein turnover mechanism induced by sunitinib, thus not only elucidating the underlying mechanisms that limit sunitinib efficacy in cancer therapy but also opening an avenue for expanding the clinical indications of sunitinib.

Sub-clonal heterogeneity and risk of treatment failure in Philadelphia-positive leukemias. Michael W. Schmitt,1 Justin R. Pritchard,2 Lan Beppu,1 J. Graeme Hodgson,2 Victor M. Rivera,2 Lawrence A. Loeb,1 Jerald P. Radich,1 University of Washington, Seattle, WA; ARIAID Pharmaceuticals, Inc., Cambridge, MA; Fred Hutchinson Cancer Research Center, Seattle, WA.

Molecularly targeted therapies have been exceptionally successful in the treatment of some malignancies, most notably chronic myeloid leukemia (CML). However in other cancers, e.g. Philadelphia-positive acute lymphoblastic leukemia (Ph+ ALL), drug resistance is a frequent occurrence. Resistance mutations may pre-exist as a consequence of intra-tumor heterogeneity; thus the extent of heterogeneity may determine the likelihood of treatment failure. Intra-tumor heterogeneity is a challenging problem to quantify, as heterogeneous mutations are likely to occur below the background error rate of conventional approaches for mutation detection. To overcome this limitation and explore the relationship between intra-tumor heterogeneity and drug resistance in Ph+ leukemias, we utilized single-molecule Duplex Sequencing (DS) of the ABL1 gene. DS eliminates sequencing errors by independently tagging the two strands of individual DNA molecules; true mutations are present at the same position in both strands, while PCR and sequencing errors are only present in one strand. DS has an error rate below 0.00001%, and thus enables quantitation of heterogeneous mutations with unprecedented resolution. We find that CP-CML, a disease that is often well controlled with targeted therapy, has an extremely low burden of intra-tumor heterogeneity at the time of diagnosis, with a sub-clonal mutation burden similar to that of normal individuals. Simulations which take into account the low cancer stem cell fraction of CP-CML and the sub-clonal mutation burden we measured reveal that only a minority of CP-CML patients will harbor pre-existing drug resistance, which may explain the unusual success of targeted therapy in this setting. Next, we studied patients with advanced Ph+ leukemias (refractory BP-CML and Ph+ ALL), which have a high rate of treatment failure and poor outcomes. We find that patients with BP-CML and Ph+ ALL have a significantly elevated in sub-clonal heterogeneity relative to those with CP-CML. We demonstrate that the higher extent of intra-tumor heterogeneity correlates with a significantly higher rate of drug resistance mutations and compound resistance (i.e. two concurrent resistance mutations) in patients. Unlike CP-CML, pre-existing mutations conferring resistance to targeted therapy are nearly certain to occur below the background error rate of conventional approaches for mutation detection. Thus, we find that patients with BP-CML and Ph+ ALL have a significantly elevated in sub-clonal heterogeneity and high cancer stem cell fraction. We support this concept by three distinct approaches: (i) detection of pre-existing sub-clones that drive treatment failure; (ii) modeling the growth kinetics of resistant clones; and (iii) extrapolation of the mutation burden measured by DS. Our results suggest that intra-tumor heterogeneity influences the likelihood of resistance to molecularly targeted therapy. Quantitation of sub-clonal mutation load may be broadly applicable in other malignancies for predicting the likelihood of response to targeted therapy and monitoring disease progression.

Combination of CDDOA-Me, a glycyrrhetinic acid derivative, and Erolitinib overcomes chemo-resistance in NSCLC PDX spheroids and 3D bio-printed cells. Arindam Mondal,1 Aragaw Gebebehu1,2 Ebony Nottingham,1 Ar-vind Ragde,1 Subramanian Ramakrishnan,3 Arun K. Rishi,1 Mandip Singh1.

Florida A&M University, Tallahassee, FL; 2Florida State University, Tallahassee, FL; 3Wayne State University, Detroit, MI.

Patient-derived Xenografts (PDx) are considered as relevant preclinical model for anticancer drug development due to original recapitulation of patient genetic profile, gene expression patterns and tissue histology. In this study, we investigated combination efficacy of CDDOA-Me (Methyl-2-cyano-1,11-dioxo-18-olean-1,12-dien-30-oate) and TKI inhibitor Erolitinib (ERL) against lung NSCLC PDX spheroids and 3D bio-printed PDX cells. NSCLC PDX cells (EGFR T790M mutants) were obtained from Dr. Rishi's Laboratory. PDx spheroids were grown in DMEM/F12 media supplemented with L-glutamine, B27 sup-
plement, recombinant human epidermal growth factor (EGF) and recombinant human basic fibroblast growth factor (bFGF). Spheroids were treated with CDODA-Me, ERL alone and in combination. Cell viability was measured by MTT assay. Western blot analysis was used to study the modulation of Bcl-xL, MDR1 and ABCG2 in treated PDX spheroids. For 3D bio-printing of PDX cells, hydrogels were prepared by partial cross-linking of sodium alginate (4.5% w/v) and gelatin (1% w/v) mixture with 40mM CaCl2 solution. PDX Cells were mixed with partially cross-linked hydrogel and printed with Inkredible 3D bio-printer (CELLINK, Sweden). Bio-printed scaffolds were fully cross-linked by 160 mM CaCl2 solution and then incubated overnight with cell culture media. The scaffolds were treated with CDODA-Me and ERL alone and in combination. After 48 h cell viabilities were determined by live/dead assay using fluorescence microscopy. MTT assay showed that approximately 65% and 74% viability was observed at 10 μM ERL and 2.5 μM CDODA-Me respectively. Decreased spheroid cell viability was observed in ERL and CDODA-Me combination treatment. Our western blot studies showed down-regulation of Bcl-xL, MDR1 and ABCG2 in combination group. Further, 81.04 ± 5.65, 78.65 ± 3.98 and 74.35 ± 4.24 percent viable PDX cells were observed in the bio-printed scaffolds after 48, 72 and 96 h respectively. Higher percentage of dead cells (52.62 ± 1.66) were found in the combination group than CDODA-Me (28.39 ± 1.60) and ERL (29.62 ± 4.91) alone. In conclusion, CDODA-Me in combination with ERL was found to be effective against human lung PDX spheroids and bio-printed PDX cells by decreasing the cell viability and overcoming drug resistance. Partially cross-linked sodium alginate-cohacitin hydrogel enhances the possibility of PDX cell bio-printing with high cell survival rate. CDODA-Me can be considered as an effective neo-adjuvant to improve ERL efficacy in human NSCLC.

#2073 A systematic investigation of the effect of scheduling of targeted combination therapies on response and dynamics of relapse in triple negative breast cancer cells. Gauri A. Patwardhan, Vikram B. Walk, Lajos Pusztai, Chris- tos Hatziis, Yale University, New Haven, CT.

Cancer treatment typically involves administration of combination of targeted therapies, but initial response is often followed by disease relapse. The efficacy of a treatment regimen depends on the complex interplay between cancer growth dynamics, drug specificity and kinetics, treatment dose and its scheduling. In standard high-throughput drug screening assays, cells are treated with a single drug cocktail bolus and cell viability is assessed after 2-3 days, thus not considering treatment interactions and long-term effects. Recently we have reported a promising synergistic combination of crizotinib (ALK/MET inhibitor) and ABT-263 (BCL2/BCL-XL inhibitor) against triple negative breast cancer cells. To understand the effect of the sequence and combination doses of crizotinib and ABT-263, we designed a comprehensive experimental plan that involved a total of 567 treatment regimens by varying treatment duration with the first drug (1, 2, or 3 days), followed by drug withdrawal and recovery period (2, 5 or 10 days) and then by a second cycle of treatment and recovery periods over a 26-day period. Cell viability was assessed by the CellTiter-Glo luminescence assay. Interestingly, ABT-263 alone induced higher cytotoxicity than an equivalent dose of crizotinib, but the remaining viable cells recovered much faster after ABT-263 withdrawal than cells after crizotinib withdrawal. Furthermore, cells exposed to higher doses of ABT-263 eventually become less sensitive to crizotinib. Among sequential regimens, crizotinib followed by ABT-263 was significantly more effective than ABT-263 followed by crizotinib, and combinations that in- cluded lower doses of ABT-263 were most effective. Taken together, our results show a significant interaction between the two targeted therapies, and suggest that it may be possible to select treatment scheduling that can delay drug resistance and tumor relapse in vivo.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Drug Resistance: Other Topics

#2076 Targeting the FGFR pathway in androgen receptor negative castration resistant prostate cancer. Colm Morrissey,1 Eva Cory,1 Lisa Brown,1 Ilia Coleman,2 Holland Guyn,1 Michael Schweizer,1 Peter Nelson,1,2 Univ. of Washington, Seattle, WA;2 Fred Hutchinson Cancer Research Center, Seattle, WA.

Metastatic castration-resistant prostate cancer (CRPC) has a poor prognosis and remains a significant therapeutic challenge. The continued importance of androgen receptor (AR) signaling as a growth and survival pathway in the most advanced prostate cancer (PC) has prompted the development of therapeutics directed toward further suppressing AR ligands or the AR itself. However, total androgen blockade can give rise to AR-negative PC and currently there are no effective therapies for AR-negative PC. We have developed two novel patient-derived xenograft (PDX) models from a liver metastasis and a rib metastasis of a patient with CRPC. LuCaP 173.1 (Neuroendocrine; NE) and LuCaP 173.2 (Dou- ble negative: DN (AR-negative and NE-negative)). Using RNA-Seq we observed that both of these lines express high levels of fibroblast growth factors (FGF’s) and downstream effectors. We hypothesized that FGF signaling promotes sur- vival and proliferation of NEPC and DNPC. To determine if blocking the FGFR survival pathway can attenuate the growth of NEPC/DNPC tumors, to charac- terize the molecular response and resistance to FGF signaling inhibition, and to support further evaluation in the clinic, we treated both PDX models with the FGFR inhibitor CH5183284. CH5183284 significantly reduced LuCaP 173.2 tumor volume (TV) (p<0.0001). The reduction in TV in CH5183284-treated ani- mals bearing LuCaP 173.1 tumors was not as significant. To address this difference, we analyzed FGFR1 expression at the transcript and protein levels. Analysis of the FGF’s in the LuCaP 173.1 PDX model revealed a loss of FGFR1 expression. FGFR2 and FGFR3 transcripts were expressed at similar levels in both PDXs. The loss of FGFR1 expression may explain the low efficacy of CH5183284 in the LuCaP 173.1 PDX model. We are currently assessing the molecular pathways impacted by FGFR inhibition and mechanisms of resistance to treatment in these studies. We have demonstrated that FGFR inhibition attenuated tumor growth in FGF[+]/AR-negative PC. We intend to target the FGFR survival pathway in additional NE and DNPC PDX models to investigate tumor heterogeneity in response to therapy and identify mechanisms of resist- ance. This studies will provide translational evidence that FGFR inhibitors could represent a new therapy for CRPC patients with AR-negative PC.

#2077 Selective MET kinase inhibition in MET-dependent glioma models. Corina van den Heuvel,1 Anna Navis,1 Houshang Amir,1 Kiek Vervliet,2 Arnd Hoegers,1 Karen E. de Reus,3 Isabelle Dussaut,2 Sean Caenepeel,5 Angela Coxon,2 Pieter Wesseling,1 William Leenders1. 1Radboudumc, Nijmegen, Netherlands; 2Amen Inc., CA.

Background - Grade 4 diffuse gliomas (glioblastomas) are notoriously difficult to treat. Many studies aim at targeting tumor-specific aberrations, such as mutations in genes encoding oncogenic receptor tyrosine kinases (RTKs). Of high interest as a tumor target in diffuse glioma is the RTK MET, which is amplified in a significant proportion of glioblastomas, and a number of MET inhibitors have been developed. However, most RTK inhibitors available in the clinic today, including those inhibiting MET, are not entirely selective and inhibit additional kinases at the doses used. They therefore may...
induce potentially undesired off-target effects, such as blood-brain barrier normalization in the case of concomitant VEGFR2 inhibition. Methods – We studied the effects of the novel, selective MET-kinase inhibitor (Compound A) and the combined VEGFR2/RET/MET inhibitor cabozantinib on MET activation and proliferation in the MET-amplified E98 astrocytoma cell line in vitro and using brain metastasis models. MET inhibition is known to have effects on AKT phosphorylation in the absence of MET phosphorylation, suggesting in vivo AKT resistance mechanisms. Interestingly, resistance to Compound A was not seen in vitro in an E98 cell line derived from Compound A-resistant tumor xenografts. Conclusions – Compound A is a promising, highly selective MET kinase inhibitor with activity against gliomas with constitutive MET signaling. Selective MET kinase inhibitors may be more suited for treatment of glioma than combined VEGFR2/MET inhibitors, as the latter may induce resistance mechanisms resulting in poor penetration. Similar to clinical experience, E98 tumor-bearing mice ultimately develop resistance to TKIs. Combination therapies targeting both MET and potential resistance pathways may be required to allow long-term tumor treatment.

Patients with non-small cell lung cancer (NSCLC) with activating epidermal growth factor receptor (EGFR) mutations initially respond to small molecule inhibitors of the EGFR tyrosine kinase such as gefitinib and erlotinib. However, secondary mutations in the kinase domain lead to acquired resistance to these inhibitors and limited clinical efficacy, with the EGFR T790M mutation being the most common mechanism of acquired resistance in more than half the patients that experience disease progression. CK-101 (also known as RX518) is a novel, orally administered EGFR kinase inhibitor that specifically targets the mutant forms of EGFR, including T790M, while exhibiting minimal activity toward the wild-type (WT) EGFR. WT EGFR inhibition is believed to drive the commonly observed side effects of skin rash and diarrhea. The 50% inhibitory concentrations (IC50s) of CK-101 and 2 reference compounds, afatinib and AZD-9291, were determined in cell proliferation assays in human cancer cell lines in vitro after incubation for 72 hours. Xenograft studies were conducted in BALB/c nude mice or SCID/Beige mice using once daily oral administration of CK-101 or afatinib for 14 or 21 days. CK-101 selectively inhibited cell proliferation of cell lines expressing the WT form of the receptor (e.g. A431, IC50 < 0.015 μM) and resistance mutations (NCI-H1975, IC50 ≤ 0.005 μM), but was much less potent at inhibiting proliferation of cell lines expressing the WT form of the receptor (e.g. A431, IC50 > 0.5 μM); i.e., CK-101 was over 100 fold less potent against A431 than against NCI-H1975. Single agent CK-101 significantly inhibited tumor growth in EGFR-mutated NSCLC xenograft models, with no activity in a WT EGFR xenograft model. In a xenograft study of PC-9 cells (exon 19 deletion) in SCID/Beige mice, CK-101 inhibited tumor growth by up to 90% (p < 0.001). In a xenograft study of NCI-H1975 cells (L858R/T790M double mutant) in BALB/c nude mice, CK-101 inhibited tumor growth by up to 95% (p < 0.001). The pre-clinical findings from this work strongly supported the clinical development of CK-101, and a first-in-human study of CK-101 was initiated in September 2016.

EGFR exon 20 insertion (Ex20Ins) mutations represent a combination of in-frame insertions and/or duplications that account for 4-10% of all EGFR mutations in non-small cell lung cancer (NSCLC). To date, more than one hundred different Ex20Ins mutations have been identified. With the notable exception of the rare A763_Y764insFQEA insertion (<1%), EGFR Ex20Ins mutations are clinically unresponsive to early generation EGFR inhibitors, the standard of care for NSCLC patients with EGFR Ex20Ins mutations is chemotherapy. Therefore, a significant unmet need remains requiring the development of an EGFR TKI agent that can more effectively target NSCLC with EGFR Ex20Ins mutations. Osimertinib (AZD-9291) was approved for the treatment of advanced NSCLC with EGFR T790M tumors. This work describes the potential of osimertinib and AZS5104, a circulating metabolite of osimertinib, in Ex20Ins tumors. Using CRISPR-Cas 9 genome editing technology, we engineered cellular disease relevant models carrying the most prevalent Ex20Ins mutations, namely Ex20Ins/HCC827, Ex20Ins/NCI-H11021, Ex20Ins/D770_N771delM and Ex20Ins/V790E. Using these models, we show that osimertinib and AZS5104 inhibit signalling pathways and cellular growth of Ex20Ins CRISPR-Cas9 engineered cell lines in vitro. This translates into sustained tumor growth inhibition in vivo in both the Ex20Ins SVD (65%, p < 0.001 & 95%, p < 0.001 respectively at day 14) and Ex20Ins AVS (82%, p < 0.001 & 95%, p < 0.001 respectively at day 14) xenograft models when compared to the control group. Importantly in vivo osimertinib was dosed at exposures consistent with the 80 mg osimertinib clinical dose. Moreover, a dual EGFR blockade strategy combining osimertinib or AZS5104 with cetuximab (an EGFR antibody) improved the anti tumor effect further. We also describe the anti-tumor activity of osimertinib and AZS5104 using a series of patient derived xenograft models harbouring the rarer Ex20Ins H773-V774insNPH and M766-V767insASV mutations. In addition, we performed pharmacodynamic studies to explore the relationship between efficacy and target/pathway modulation. These studies establish a clear relationship between depth and duration of phospho-EGFR inhibition and anti tumor efficacy. Interestingly, we observed that downstream signalling molecules displayed a more transient inhibition than the phospho EGFR signal. Two patients from the AURA Phase 2 osimertinib trials with plasma positive Ex20Ins (concurrent with Ex19del and T790M) had durable PFS responses of 6.4 and 13.9 months, supporting the premise that osimertinib has the potential to be clinically beneficial in tumors harboring Ex20Ins. The work presented herein demonstrates that osimertinib has the potential to improve upon the current treatment options for NSCLC patients whose tumors harbour an Ex20Ins mutation, and warrants its further clinical investigation.

#2080 Polycomb-mediated disruption of an AR feedback loop drives castration-resistant prostate cancer. Ka-Wing Fong, Jonathan Zhao, Jung Kim,1 Shangze Li,1 Angela Yang,1 Bing Song,1 Laure Rittié,2 Ming Hu,3 Ximing Yang,1 Bernard Perbal,4 Jindan Yu1. Northwestern Univ., Chicago, IL;1University of Michigan Medical School, Ann Arbor, MI;2New York University School of Medicine, New York, NY;4Université Côte d’Azur, CNRS, GREDEG, GREDEG, France.

Androgen receptor (AR) is an androgen-stimulated transcription factor that critically promotes prostate cancer development and progression. In addition to its conventional role in transcriptional activation, AR also acts as a transcriptional repressor to directly inhibit target gene expression. Through meta-analysis of androgen-regulated expression microarray data, we nominated CCN5/NOV, a CCN family protein, as one of the top AR-repressed genes in prostate cancer, implicating that CCN5 may play a tumour suppressive role in prostate cancer development. Therefore, we sought to investigate the molecular functions of CCN5 and its roles in prostate cancer progression especially in castration-resistant prostate cancer (CRPC). We first showed that CCN3 protein physically interacts with AR. The CCN3 interaction domain was mapped in the N-terminal domain of AR which is also present in constitutively active AR variants. Using immunofluorescence microscopy as well as subcellular fractionation technique, we demonstrated that CCN3 sequesters AR or AR variants into the cytoplasm to inhibit AR nuclear translocation, which in turn suppresses AR (ph)omatin targeting and transcriptional activation. However, this negative feedback loop between AR and AR-repressed gene CCN3 is disrupted in CRPC through CCN3 persistent epigenetic silencing by the Polycomb group protein EZH2, rendering AR transcriptional activation and CRPC progression. Taking advantage of this repressive mechanism, we restored CCN3 in CRPC cell model, either through ectopic overexpression or treatment with EZH2 inhibitor, which results in strong suppression of CRPC cell proliferation and anchorage-independent cell growth. Consistently, application of EZH2 inhibitor remarkably reduced tumor size in a castrated mice model. Taken together, our data highlight CCN3 as a novel regulator of AR signaling and support the promise of EZH2-targeting agents in treating CRPC.
#2081 Robust activity of BLU-285, a potent and highly selective inhibitor of mutant KIT and PDGFRα, in patient-derived xenograft (PDx) models of gastrointestinal stromal tumor (GIST). Yemarshet K. Gebreyohannes,1 Agnieszka Wozniak,1 Madeleina-Elena Zhai,1 Jasmin Wellens,1 Jasmin Cornillie,1 Erica Evans,2 Alexandra K Gardino,2 Christoph Lengauer,2 Maria Debiec-Rytkönen,3 Raf Sciot,4 Patrick Schöffski1. 1Department of Oncology, KU Leuven, and Department of General Medical Oncology, University Hospitals Leuven, Leuven Cancer Institute, Leuven, Belgium; 2Blueprint Medicines Corporation, Cambridge, MA; 3Department of Human Genetics, KU Leuven and University Hospitals Leuven, Leuven, Belgium; 4Department of Pathology, KU Leuven and University Hospitals Leuven, Leuven, Belgium.

Objective: Patients with advanced and treatment-resistant GIST are treated with tyrosine kinase inhibitors (TKI) such as imatinib (IMA), sunitinib (SUN) or regorafenib (REG). Resistance to these TKI is mainly caused by the emergence of on-target secondary KIT mutations in exons 13 and 17. We tested the activity of BLU-285 (Blueprint Medicines), a potent and highly selective inhibitor of mutant KIT and PDGFRα, in three PDx models of primary and refractory GIST that respond differently to the approved TKI used in the treatment of GIST. Methods: NMRI nu/nu mice (n=93) were transplanted bilaterally with human xenografts UZLX-GIST3 (KIT: exon 11 p.W557/V559delNS; IMA-sensitive), GIST2B (KIT: exon 9 p.A562/565dup, IMA dose-dependent sensitive) and GIST9 (KIT: exon 11 p.P577A; IMA resistant) in both right and left flank. Animals were dosed orally for 16 days. Activity was assessed by tumor volume measurement, histopathology and Western blotting of the KIT signaling pathway (WB). Mann Whitney U test was used for statistical analysis. A p value <0.05 was considered significant. Results: In all models, BLU-285 resulted in a dose dependent reduction of tumor volume, significant inhibition of proliferation (p < 0.05 compared to the control in all models, at all doses tested), and inhibition of KIT signaling as assessed by WB. In two models, BLU-285 led to a higher histologic response (graded as described previously by Antonescu et al. 2005), a significant increase of apoptosis (p < 0.005 compared to the control in both models, at all doses tested), and a pronounced decrease in MAPK phosphorylation as compared to the control. The activity of BLU-285 was similar (GIST3) or better (GIST2B and GIST9) than a standard dose of IMA. In the IMA-resistant model (GIST9), the anti-tumor effects of BLU-285 were significantly better those seen with either IMA or REG. BLU-285 was well tolerated at all administered doses. Conclusions: BLU-285, an investigational agent, has significant anti-tumor effects in GIST PDx models characterized by different KIT mutations and variable sensitivity to established TKI therapies. These data support the therapeutic rationale for the ongoing Phase I clinical trial being conducted by Blueprint Medicines (NCT02588312) and provide further evidence that BLU-285 has the potential to be an important treatment option for patients with PDGFRα or KIT-driven GIST.

#2082 NMS-E668, a potent and selective RET kinase inhibitor characterized by specificity towards VEGF2 and high antitumor efficacy against RET-driven cancers. Elena Ardini, Patrizia Banfi, Nilla Avanzi, Marina Ciomei, Paolo Polucci, Alessandra Ciria, Antonella Ermoli, Ilaria Motto, Elena Casale, Giulia Canevari, Cinzia Cristiani, Sonia Troiani, Federico Riccardi Sirtori, Nadia Amboldi, Dario Ballinati, Francesco Caprara, Eduard Felder, Arturo Galvani, Daniele Donati, Antonella Isachic, Maria Menichincheri. Nerviano Medical Sciences, Nerviano, Italy.

RET, a receptor tyrosine kinase (RTK) expressed mainly in neural crest-derived tissues, plays a role in cell growth and differentiation and its physiological activation depends upon binding to the GDNF family. Genetic aberrations leading to constitutive RET activation are associated to activating point mutations of RET, for example, are present in ca. 70% of medul- lary thyroid carcinoma patients including all hereditary cases, while RET gene rearrangements resulting in production of activated RET fusion proteins occur in approximately 10% of sporadic papillary thyroid carcinomas. More recently, recurring RET gene rearrangements have also been found in 1-2 % of lung adenocarcinomas and subsets of other solid tumors including colorectal and activating point mutations of RET, for example, are present in ca. 70% of medul- lary thyroid carcinoma patients including all hereditary cases, while RET gene rearrangements resulting in production of activated RET fusion proteins occur in approximately 10% of sporadic papillary thyroid carcinomas. More recently, recurring RET gene rearrangements have also been found in 1-2 % of lung adenocarcinomas and subsets of other solid tumors including colorectal and activating point mutations of RET, for example, are present in ca. 70% of medul- lary thyroid carcinoma patients including all hereditary cases, while RET gene rearrangements resulting in production of activated RET fusion proteins occur in approximately 10% of sporadic papillary thyroid carcinomas. More recently, recurring RET gene rearrangements have also been found in 1-2 % of lung adenocarcinomas and subsets of other solid tumors including colorectal and activating point mutations of RET, for example, are present in ca. 70% of medul- lary thyroid carcinoma patients including all hereditary cases, while RET gene rearrangements resulting in production of activated RET fusion proteins occur in approximately 10% of sporadic papillary thyroid carcinomas. More recently, recurring RET gene rearrangements have also been found in 1-2 % of lung adenocarcinomas and subsets of other solid tumors including colorectal and activating point mutations of RET, for example, are present in ca. 70% of medul- lary thyroid carcinoma patients including all hereditary cases, while RET gene rearrangements resulting in production of activated RET fusion proteins occur in approximately 10% of sporadic papillary thyroid carcinomas. More recently, recurring RET gene rearrangements have also been found in 1-2 % of lung adenocarcinomas and subsets of other solid tumors including colorectal and activating point mutations of RET, for example, are present in ca. 70% of medul- lary thyroid carcinoma patients including all hereditary cases, while RET gene rearrangements resulting in production of activated RET fusion proteins occur in approximately 10% of sporadic papillary thyroid carcinomas. More recently, recurring RET gene rearrangements have also been found in 1-2 % of lung adenocarcinomas and subsets of other solid tumors including colorectal and activating point mutations of RET, for example, are present in ca. 70% of medul-

#2083 Development of novel targeted adjuvant therapy for triple negative breast cancer. Nidhi Bansal,1 Eduardo Farias,1 Veronica Gonzalez,2 Garry Nolan,3 Samuel Waxman1. 1Icahn School of Medicine at Mount Sinai, Manhattan, NY; 2Stanford University School of Medicine, Stanford, CA.

There is an unmet clinical need for targeted adjuvant therapy in Triple Negative Breast Cancer (TNBC) to overcome its poor prognosis, short disease-free interval and metastatic dissemination. We previously reported that blocking interactions between the PAH2 domain of chromatin regulator Sin3 and Sin3 interaction domain (SID) containing proteins like PFI and TGIF1 by SID decoys (peptides and small molecule, C16) decreased the cancer stem cell population, invasion, EMT, and metastases. This, programmed upregulation of retinoic signal that sensitized TNBC cells to ADM, a novel clinically available RARα specific agonist. Here we report preclinical investigations on effects of SID decoys and ADM on treatment cells heterogeneity, primary tumors, metastatic dissemination, minimum residual disease (MRD) and host microenvironment. Using CyTOF2, we made single cell measurements of markers of differentiation, proliferation and stemness in CSC-enriched 4T1 tumor spheres. Treatment with SID peptide decreased cell populations expressing nanog, sox2, vimentin and β-catenin with increase in hY2A. Addition of ADM in combination with C16, resulted in populations with increased expression of differentiation marker CD24 with decrease in vimentin, β-catenin and Ki-67. To interrogate the neo-adenovirus effects of C16-ADM80 treatments, primary 4T1 tumors in Balb/c mice were treated with C16 and AM80 alone or in combination. Compared to DMSO, ~40 % decrease in tumor weight, 60% decrease in ALDH activity and 60% decrease in lung metastasis was seen in mice treated with C16-AM80 combination. In post-surgical adjuvant settings, both 4T1 and MMTV- myc xenografts, we observed 100% disease-free survival and absence of macrometastases in mice receiving minimally toxic adjuvant therapy with the C16-AM80 combination for 90 days. However, MRD was found consisting of a small number of single CK8+ cells which failed to form colonies when recovered from the bone marrow and selectively cultured in vitro. Upon stopping the treatments, 20-40% animals developed macrometastases within the first three months. To test the influence of C16-AM80 to condition the host microenvironment to prevent macrometastases mice received only pretreated pC16 and ADM80 followed by 4T1 cell injection in the tail vein. The percentage of parenchyma occupied by metastatic nodules were: DMSO = 50%; AM80 = 25%; C16 >10% and C16-AM = << 10%; the mitotic features were greatly reduce from 0-5 in DMSO to 0-1 per 400x/fi in the C16-AM80 combination. The predominant effects were observed with C16 treatment, which was enhanced to a small degree in combination with AM80. These results suggest that C16 can potently prevent changes in the host microenvironment to prevent the colonization and metastatic growth of cancer cells in TNBC.
**#2084 Conformational activation and allosteric inhibition of SHP2 in RTK-driven cancers.** Michael G. Acker,1 Ying-Nan P. Chen,1 Matthew J. LaMarche,1 Ho Man Chan,1 Peter Fekkes,1 Jorge Garcia-Fortanet,1 Jonathan R. LaRochelle,2 Brandon Antonakos,1 Christine Hiu-Tung Chen,1 Zhuliang Chen,1 Vesselina G. Cooke,1 Jason R. Dobson,1 Zhan Deng,1 Fei Feng,1 Brant Firestone,1 Michelle Fodor,1 Cary Fridrich,1 Hui Gao,1 Huai-Xiang Hao,1 Jaison Kato,1 Samuel Ho,1 Kathy Hsiao,1 Zhao B. Shultz,1 Kavitha Venkatesan,1 Ping Wang,1 Markus Warnmuth,1 Sarah Williams,1 Guizhi Yang,1 Jing Yuan,1 Ji-Hu Zhang,1 Ping Zhu,1 Stephen C. Blacklow,2 Timothy Ramsey,1 Nicholas J. Keen,1 William R. Sellers,1 Travis Stams,1 Pascal D. Fortin1. 1Novartis Institutes for BioMedical Research, Cambridge, MA; 2Dana-Farber Cancer Institute, Boston, MA. The non-receptor protein tyrosine phosphatase (PTP) SHP2 is an important component of RTK signaling in response to growth factor stimulus and plays just upstream of the RAS-MAPK signaling cascade. The first oncophosphatase to be identified, SHP2 is dysregulated in multiple human diseases including the developmental disorders Noonan and Leber syndromes, as well as leukemia, lung cancer and neuroblastoma where aberrant activity of SHP2 leads to uncontrolled MAPK signaling. Cancer-associated activating mutations in SHP2 imparts an “auto-on” state of the enzyme, boosting basal activity by shifting the equilibrium away from the auto-inhibited state. Reduction of SHP2 activity through genetic knockdown suppresses tumor growth, validating SHP2 as a target for cancer therapy. SHP099, a recently reported potent and selective allosteric inhibitor of SHP2, stabilizes the auto-inhibited form of SHP2 through interactions with the N-terminal SH2 and C-terminal PTP domains of the protein. SHP099 suppresses MAPK signaling in RTK amplified cancers resulting in suppressed proliferation in vitro and inhibition of tumor growth in mouse xenograft models. Together, these data demonstrate the therapeutic potential of SHP2 inhibition in the treatment of cancer and other RAS-MAPK-linked diseases.

**#2085 Development of a novel targeted therapy for malignant mesothelioma.”** Takuya Fukazawa,1 Yuitaka Maeda,1 Tomoki Yamatsumi,1 Munenori Takaoka,1 Masakazu Yoshida,1 Naomasa Ishida,1 Miki Iwai,1 Etsuko Yokota,1 Takuro Yukawa,1 Minoru Haisa,1 Noriko Miyake,1 Tomoko Ikeda,1 Nagio Takigawa,1 Jeffery Whitsett,1 Yoshio Naoi1. 1Kawasaki Medical School, Okayama, Japan; 2Cincinnati Children’s Hospital Medical Center, Cincinnati, OH. Malignant pleural mesothelioma is an aggressive tumor of mesenchymal origin and is increasing worldwide as a result of widespread exposure to asbestos. The median survival of patients with mesothelioma from time of diagnosis ranges between 1 and 2 years. The mortality is expected to increase, at least until 2020, which is mainly due to the long latency (30-50 years) of the disease. Since considerable advances in the understanding of its pathogenesis and etiology, malignant mesothelioma remains largely unresponsive to standard modalities of cancer therapy. Thus, there is an urgent need for new therapeutic options for mesothelioma. Midkine (MDK) is a heparin-binding growth factor that is highly expressed in many malignant tumors, including lung cancers. We have previously reported that a MDK inhibitor, iMDK, suppresses non-small cell lung cancer expressing MDK without harming normal cells. Importantly, iMDK inhibits the PI3 kinase / Akt pathway and induces apoptosis in MDK expressing non-small cell lung cancer cells. In the present study, we have investigated the antitumor effect of iMDK against malignant mesothelioma both in vitro and in vivo. 48 hours after treatment, iMDK dose-dependently inhibited cell growth of MDK expressing malignant mesothelioma cells. iMDK also suppressed colony formation of MSTO-211H mesothelioma cells. TUNEL positive cells were significantly increased in MSTO-211H cells 48 hours after iMDK treatment in a dose-dependent manner, confirming the induction of apoptosis in mesothelioma cells by iMDK. Combination treatment of iMDK and Bcl-2 inhibitor ABT-263 is more effective than each drug alone in MSTO-211H mesothelioma cells. Moreover, systemic administration of iMDK significantly inhibited tumor growth in a mesothelioma xenograft tumor in vivo. Inhibition of MDK with iMDK provides a potential therapeutic approach for the treatment of malignant mesothelioma that is driven by MDK.

**#2086 Dominant role of receptor tyrosine kinase in the activation of MAPK signaling in BRAF non-V600 mutant cancers.** Hiromichi Ebi, Hiroshi Kotani, Hidenori Kitai, Yuta Adachi, Seiji Yano. Kanazawa Univ. Cancer Research Inst., Kanazawa, Japan. BRAF mutations are found in ~8% of all cancers. In addition to the commonest mutation in kinase domain at the V600, a wide range of other missense mutations (non-V600) have been reported. Non-V600 mutant BRAF protein was also shown to enhance MAPK signaling, suggesting the effectiveness of MEK inhibitors. However, the existence of feedback mechanism in MAPK signaling in BRAF mutant cancers has not fully been understood. To investigate this, BRAF non-V600 cell lines with intermediate/ impaired kinase activity were treated with MEK inhibitor. RTKs involved in the upregulation of P-MEK following MEK inhibition in BRAF non-V600 mutant cell lines were determined by phospho-RTK arrays. The effect of combinatorial inhibition of RTKs and MEK in BRAF non-V600 cancer was assessed in vitro and in mouse xenograft models. By analyses of data, we found that BRAF non-V600E mutation were less sensitive to MEK inhibition compared with BRAF V600E mutant cell lines and almost comparable to RAS/RAF wild-type cell lines. MEK inhibition did not induce P-MEK suppression and it resulted in significant upregulation of p-MEK compared to BRAF V600E mutant cell lines. Phospho-RTK arrays in the presence or absence of trametinib displayed basal phosphorylation of RTKs including EGFR, MET, and JGFIR, although the phosphorylation level was not consistently changed following MEK inhibition. Among these RTKs, treatment with the EGFR inhibitor erlotinib led to more complete suppression of P-ERK upon trametinib treatment. Furthermore, we found that erlotinib monotherapy downregulated P-ERK in BRAF non-V600 mutant cell lines in contrast that inhibition of RTKs had no effect on MAPK signaling in BRAF non-V600 mutant cells. While erlotinib treatment led to complete suppression of P-MEK in intermediate active and impaired kinase active BRAF mutant cell lines, p-MEK and P-ERK were more strongly suppressed in impaired type BRAF non-V600 mutant cells. The combination of EGFR inhibitor and MEK inhibitor suppressed cell growth and achieved tumor shrinkage in mice xenograft. These results suggest that RTKs, especially EGFR, are dominantly involved in the regulation of MAPK signaling in BRAF non-V600 cancer cells.

**#2087 Pan-HER inhibitor, varlitinib, disrupts HER/ERK signaling and causes apoptosis in triple-negative breast cancer cells.** Chun-Yu Liu1, Tzu-Ting Huang,1 Chun-Teng Huang,1 Hsiu-Ping Yang,1 Ling-Ming Tseng1, Chung-Wai Shiau,1 Kuen-Feng Chen1,2 Taipei Veterans General Hospital, Taipei, Taiwan; 3Yang-Ming Branch of Taipei City Hospital, Taipei City, Taiwan; 4National Yang-Ming University, Taipei, Taiwan; 5National Taiwan University Hospital, Taipei, Taiwan. Background: Triple-negative breast cancer (TNBC), characterized by aggressive behavior and poor prognosis, represents an important clinical challenge because there is no well-established target therapy. Therefore, the identification and validation of a targeted therapy for TNBC is an urgent need. Molecular profiling studies have shown some TNBC tumors harboring aberrant epidermal growth factor receptor (EGFR) or human epidermal growth factor receptor (HER) signaling, suggesting therapeutic potential with EGFR/HER inhibitor. Varlitinib (ASLAN001) is a small molecule reversible pan-HER inhibitor of EGFR (HER1), HER2 and HER4. To date, varlitinib has been extensively investigated in several tumor types, including HER2 positive metastatic breast cancer. TNBC is known to demonstrate expression of EGFR. Since varlitinib also targets EGFR signaling, we hypothesized that it may also have antitumor efficacy in TNBC. Methods: MDA-MB-231 and MDA-MB-468 TNBC cell lines were used for in vitro studies. Cell viability was examined by MTT assay. Apoptotic effects were examined by flow cytometry and Western blot. Signal transduction pathways in cells were assessed by Western blot. Results: We first examined the protein expression of EGFR in a panel of TNBC cell lines. We identified MDA-MB-468 and MDA-MB-231 as EGFR-expressing cell lines. We found that varlitinib significantly inhibited cell viability and induced cell apoptosis in MDA-MB-468 cells but not in MDA-MB-231 cells. MDA-MB-231 cells carry the KRAS G13D mutation that drives downstream ERK signaling. We therefore examined the downstream signaling proteins of EGFR, including PI3K/Akt and MAPK/ERK. Results showed that the protein levels of p-EGFR and p-ERK were decreased in varlitinib-resistant MDA-MB-468 cells, but there was no significant change in these phospho-proteins in varlitinib-resistant MDA-MB-231 cells. Furthermore, we found that ERK inhibition sensitized varlitinib-resistant cells to varlitinib-induced cell death. In addition, ectopic expression of ERK reduced the varlitinib-induced apoptosis in varlitinib-sensitive MDA-MB-468 cells. In addition, MDA-MB-468 cells are known to harbor V600E mutation in the RAF gene of function mutation that may activate EGFR signaling, whether the mutation is associated with varlitinib sensitivity needs further investigation. Conclusions: In this study, we identified TNBC as another tumor type that may be sensitive to varlitinib’s antitumor activity through the inhibition of HER/MAPK signaling and subsequent increase in apoptotic activity.
**EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Growth Factor and Hormone Receptors as Therapeutic Targets**

#2088 The activity of the FGFR selective inhibitor Debio 1347 is correlated with high mRNA expression. Franck Brichory,1 Anna Pokorska-Bocci,1 Paolo Nuciforo,2 Stefania Rigotti,1 Nathalie Lembrecz,1 Grégoire Vuagniaux,3 Corinne Moulon,4 Anne Vaslin1,1 Debiopharm International SA, Lausanne, Switzerland; 2Vall d’Hebron Institute of Oncology, Barcelona, Spain.

Dysregulated growth factor receptor (FGFR) signaling pathway due to receptor overexpression, gene amplification, point mutations or fusions/chromosomal translocations is associated with cancer development and progression. Debio 1347 (CHS183284) is an oral selective FGFR inhibitor (FGFR1,2 and 3) currently in clinical development. The aim of this study was to investigate Debio 1347 activity in patient derived xenograft (PDx) mouse models harboring diverse FGFR alterations in multiple in vivo (TDI) and in vitro (CRL) settings. The trial was conducted in 66 PDx models of diverse histotypes selected according to their FGFR1, 2 and 3 alteration status. Debio 1347 was administered orally once daily at 40 up to 80 mg/kg for 10 to 22 consecutive days (N=3/group). Tumor volume was compared to the vehicle control group and measured by caliper twice weekly. Treatment response was determined by relative treatment-to-control ratios (ΔT/ΔC) of which a responding model was defined as ΔT/ΔC < 0. PDx tumors were collected at the end of the treatment period and extensively characterized using FISH, nCounter Gene Expression and immunohistochemistry (IHC). Effect on downstream Dual Specificity Phosphatase 6 (DUSP6) signaling was also investigated by qPCR and RNA in situ hybridization (ISH). Debio 1347 induced tumor regression in 33% of PDx models that exhibited a gene copy number gain, presence of a gene fusions for tumor gene amplification. In addition, Debio 1347 treatment led to tumor regression in 29% of models that did not harbor any FGFR genetic alteration. In contrast, all models that responded to Debio 1347 were shown to display a high expression level (mRNA) of at least one FGFR gene. These findings suggest that high expression of at least one FGFR might be a better predictor of sensitivity to Debio 1347 than genetic alteration. Furthermore, response to Debio 1347 was associated with a decrease in DUSP6 mRNA levels, suggesting that it could be a reliable pharmacodynamic biomarker in clinical trials. These results provide new mechanistic insights into the predictive sensitivity to Debio 1347 and will help refine patient selection for FGFR-targeted therapy.

#2089 Evaluation of fruquintinib, a potent and selective oral VEGFR inhibitor, in combination with targeted therapies or immune checkpoint inhibitors in preclinical tumor models. Yongxin Ren, Qiaoing Sun, Jingwen Long, Shiming Fan, Renniang Tang, Wei Zhang, Xuelei Ge, Jianxing Tang, Linfang Wang, Dongrui Shi, Hongbo Chen, Min Cheng, Weiguo Qing, Weiguo Su, Hutchison MediPharma Ltd., Shanghai, China.

The development of therapies targeting tumor angiogenesis, tumor driver gene alterations and tumor immune evasion has made tremendous advancement in improving overall survival. However, efficacy may be limited and resistance often develops rapidly when targeting a single axis of tumor growth. Therefore, it is important to explore rational combination of therapies based on tumor-specific features. Fruquintinib is a potent and selective oral VEGFR inhibitor currently in Phase III clinical trials for non-small cell lung cancer (NSCLC) and colorectal cancer (CRC). We report here the evaluation of anti-tumor effect of fruquintinib in preclinical animal tumor models in combination with therapies targeting tumor driver gene alterations such as EGFR and c-MET with immune checkpoints. In NSCLC xenograft models with EGFR activation such as activating mutations, gene amplification or protein overexpression, fruquintinib plus an EGFR tyrosine kinase inhibitor such as gefitinib or thalitabin (HMPL309) was found to be more efficacious than either monotherapy. For instance, in PC-9 subcutaneous tumor model carrying EGFR exon 19 deletion, single agent treatment with fruquintinib at 2 mg/kg and gefitinib at 5 mg/kg produced the tumor growth inhibition (TGI) of 63%, respectively, while the combination treatment resulted in a TGI of 100% and tumor regression was observed in 11 of 16 mice treated with combinational therapy. In multiple xenograft models derived from lung cancer or renal cell cancer with c-MET activation (amplification or over-expression), addition of fruquintinib to a c-MET inhibitor savolitinib (AZD6094, HMPL-304) also improved the tumor growth inhibition substantially. At the end of the efficacy studies, CD131 and phosphorylation of EGFR, c-MET, AKT and ERK were analyzed with immunohistochemistry and western blotting method in tumor tissues. The results suggested that the enhanced anti-tumor effect in combination therapy could be attributed to the simultaneous blockade of cell signaling in tumor cells (EGFR or c-MET) and VEGFR suppression in the tumor microenvironment. Up-regulation of the immune inhibitory checkpoint PD-1/PD-L1 is one of the important mechanisms for tumor cells to escape immune surveillance. In a syngeneic murine tumor model, co-administration of fruquintinib and anti-PD-L1 antibody was found to provide improved anti-tumor effect compared to fruquintinib or anti-PD-L1 single agent alone. Studies to understand the mechanism responsible for the combination effect are under way. All combinations with fruquintinib described above were well tolerated. The efficacy observed in these models suggested that simultaneous blockade of tumor angiogenesis and tumor cell signaling or immune evasion may be a promising approach in improving treatment outcomes.

#2090 Targeting estrogen receptor negative breast cancer cells using diarylhthiourea analogs of ShetA2. Hongye Zou,1 Emily Ginn,2 Sabah M. Francis,3 Shengjuan Liu,4 Maggie Louie,5 Dominican University of California, San Rafael, CA; 2Touro University of California, Vallejo, CA.

Breast cancer is one of the most common cancers that occur in women in the United States. Depending on the expression of estrogen receptor or (ERx), breast cancer can be classified as ER-positive or negative. ER-negative (ER-) breast cancers are often more aggressive and have poorer prognosis compared with the ER-positive (ER+) subtype. Consequently, there is a great need to develop more targeted therapeutic options for ER-breast cancer. One such compound is ShetA2, a flexible tetrahydropyran (J-fluorocycle) that has been shown to exhibit growth of multiple cancer types including breast cancer. However, the clinical utility of ShetA2 is limited by its high lipophilicity (LogP). The goal of this study is to screen eleven 2nd generation analogs of ShetA2 with lower LogP values — SL1-22, 24, 27, 29, 30, 32, 37, 38, 39, and 40 — on different breast cancer cell lines to identify potential lead compounds that show the highest anti-growth activities against ER-breast cancer cells. In vitro, we will further delineate the mechanism by which these compounds affect breast cancer cell growth. Results from this study demonstrate that SL1-38 [1-(3-chloro-4-methyl-phenyl)-3-(4-nitrophenyl)]thiourea] and SL1-39 [1-(4-chloro-3-methylphenyl)-3-(4-nitrophenyl)]thiourea], inhibit ER-negative breast cancer cells (MDA-MB-231, MDA-MB-453 and MDA-MB-468) effectively at micromolar concentrations. In order to understand the mechanisms of action, we evaluated the effects of SL1-38 and 39 on the expression of key cell cycle regulators. Our results show that these two analogs down-regulate the expression of cyclin A, cyclin B, cyclin D1, cyclin E and cdk2 and block S-phase progression. Taken together, these preliminary results suggest that SL1-37 and 39 may be further developed as anti-cancer agents for treating ER-negative breast cancer.

#2091 PRN1371, an irreversible, covalent inhibitor of FGFR1-4 exhibits sustained pathway inhibition in cancer cell lines. Eleni Venetsanakos, Yan Xing, Natalie Loewenstein, J. Michael Bradshaw, Dane Kerr, Jacob LaStant, Philip Nunn, Jin Shu, Abha Bommireddi, Jens Oliver Funk, David M. Goldstein, Stefani Wolff, Ken A. Brameld, Steven G. Gourlay. Principia Biopharma, South San Francisco, CA.

Introduction: Multiple human cancers harbor alterations in FGFRs that drive tumor growth, including mutations, translocations and amplifications. PRN1371 is a potent, highly selective irreversible inhibitor exhibiting sustained inhibition of FGFR1-4 in primary renal proximal epithelial cells. Conclusions: PRN1371 is a potent, highly selective irreversible inhibitor exhibiting sustained inhibition of FGFR which extends well beyond circulating drug concentrations in preclinical models. The duration of inhibition of the FGFR signaling pathway is dependent on protein turnover of FGFR, which may vary depending on the type of FGFR alteration. Thus, we set out to investigate whether the duration of target inhibition differs across cancer cell lines of various lineages harboring different FGFR alterations, including fusions and mutations. Furthermore, as FGFR inhibitors exhibit hyperphosphatemia via on-target pharmacology, we also investigated the duration of target inhibition in primary renal epithelial cells which are wild-type for FGFR. Materials and Methods: Cancer cell lines from several lineages harboring different FGFR alterations were treated with increasing concentrations of PRN1371 in vitro for 1 hour, before washing out the compound. Cells were harvested at various time-points post-washout, protein lysates were generated and assessed for modulation of the downstream signaling pathway by western blot analysis. Results: Dose-dependent inhibition of phospho-ERK was observed in the cancer cell lines tested in response to compound treatment for 1 hour in vitro. Dose dependent partial or full rebound of phospho-ERK back to baseline levels were detected in cancer cell lines after a prolonged period post-washout. In contrast, full rebound of phospho-ERK was observed at 1 hour post washout in response to a non-covalent inhibitor. Studies are on-going to assess duration of pathway inhibition in the primary renal proximal epithelial cells. Conclusions: PRN1371 is a potent, highly selective irreversible inhibitor exhibiting sustained inhibition of FGFR signaling across cancer cell lines harboring different FGFR alterations. The duration of target inhibition differed across cancer cell lines harboring different FGFR alterations, including mutations, fusions and amplification of FGFR and was prolonged when compared to a non-covalent inhibitor. A Phase 1 clinical trial of PRN1371 for the treatment of solid tumors harboring FGFR alterations is ongoing (NCT02608125).
#2092 A potent and selective RET inhibitor with efficacy in RET-driven mouse models of medullary thyroid carcinoma and lung adenocarcinoma.

Mandy Watson,1 Helen Small,1 Ben Acton,1 Habiba Begum,2 Samantha Hitchin,1 Allan Jordan,1 Paul Kelly,1 Rebecca Newton,1 Ian Waddell,1 Gina Paris,1 Donald Ogilvie1. 1Cancer Research UK Manchester Institute, Manchester, United Kingdom; 2ChemoCentryx, Inc., Paris, France.

Background: The aim of this CRUK-MI Drug Discovery project is to deliver a RET-selective inhibitor for the treatment of cancers with RET activating mutations, which include 1-2% of lung adenocarcinomas and medullary thyroid cancers (MTC).

Methods: We have established a robust screening cascade to develop a potent, selective RET inhibitor and developed several in vivo models to evaluate compound PKPD and antitumor efficacy. Tumor growth inhibition and PKPD studies were carried out in BaF3 mouse allograft models overexpressing KIF5B-RET or RETV804M and other disease relevant models, including an MTC xenograft (MZ-CRC-1), a KIF5B-RET lung cancer patient derived xenograft (PDX) model (CTG-0838, Champions Oncology) and a lung cancer control xenograft (Calu-6). Results: Two orally bioavailable compounds displaying nanomolar RET potency and >10 fold selectivity over KDR in cellular assays were selected from the lead series and further evaluated in our in vivo PD and efficacy models. Both compounds demonstrated efficacy in the BaF3 KIF5B-RET model (71% and 103% tumor growth inhibition (TGI), respectively), accompanied by reduced levels of pRET in the tumor tissue. Following further lead optimisation, a compound displaying an improved DMPK profile and additional nanomolar potency versus the gatekeeper mutation (RETV804M) was identified and accelerated through our DMPK/ in vivo cascade. We consider this additional activity versus RETV804M beneficial since mutations at the gatekeeper residue in other tyrosine kinases (e.g. EGFR) have been shown to mediate acquired drug resistance in the clinic. This compound demonstrated significant TGI of 58% and 82% respectively in the BaF3 KIF5B-RET and BaF3 RETV804M allograft models. Moreover, tumor growth in the lung cancer PDX model was strongly inhibited (95% TGI) and tumor regression induced in the MTC xenograft model (109% TGI). As expected, this potent and selective RET inhibitor was not active in the Calu-6 model, which is sensitive to KDR inhibition, whereas vandetanib, a potent KDR inhibitor, significantly inhibited tumor growth (84% TGI). Additional in vitro and in vivo DMPK analyses further support the nomination of this compound as a preclinical candidate. Conclusions: The identification of selective RET inhibitors with significant in vivo activity and minimal toxicity may overcome the limitations of the currently available clinical compounds. We have made considerable progress towards this goal and show here the compelling data supporting our nomination of a preclinical development compound.

#2093 HEC73543 is a novel potent, selective Flt3 receptor tyrosine kinase (RTK) Inhibitor for the treatment of refractory acute myeloid leukemia (AML).

Cliff Cheng. HEC Pharm Group, Dongguan, China.

Background: Adults acute myeloid leukemia (AML) account for ~30% of leukemia and ~40% of leukemia-related deaths. FLT3 is a receptor tyrosine kinase that is normally expressed on immature hematopoietic cells and functions in the development of both stem cells and the immune system. FLT3 is the most frequently mutated gene in AML, with an estimated 30% of AML patients harboring FLT3 mutations. FLT3-ITD is a common mutation in AML and correlates with a poor prognosis and higher risk of relapse of AML patients. Methods and Results: HEC73543 is a potent, orally bioavailable small molecule tyrosine kinase inhibitor (TKI) against FLT3 which has been implicated in acute myeloid leukemia (AML) pathogenesis. In cell-based assays, HEC73543 showed IC50 of ~1.5 and 1.4 nM against MV-4-11 and MOLM-13 cells in proliferation (both cell lines are FLT3-ITD+). Induction of apoptosis following treatment of FLT3-ITD-FLT3 leukemic MV-4-11 cells for 48 h was assayed by flow cytometry. In MV-4-11 cells, a concentration of 10 nM HEC73543 induced 64.8% of the cells to undergo apoptosis and a dose dependent manner. HEC73543 orally (4.5mg/kg) to MV-4-11 tumor-bearing nude mice, HEC73543 potently inhibited the phosphorylation of FLT3 and its downstream signaling kinases STAT5, AKT and ERK1/2 for up to 8 hours in tumor tissues. The antitumor activity of HEC73543 was evaluated using an FLT3-ITD subcutaneous tumor xenograft model (MV-4-11 and MOLM-13) in athymic mice. Groups of 8 tumor-bearing mice were treated with vehicle alone or with HEC73543 administered orally at 0.5, 1.5, or 4.5mg/kg/day. The compound was well tolerated and no significant body weight loss or lethality was observed. The antitumor activity of HEC73543 was dose dependent. At the 1.5 mg/kg/day dose level all animals had a complete regression (CR) in MV-4-11 model, and the CR induced by 4.5mg/kg/day in MOLM-13 model. HEC73543 can significant prolong mice survival time at 1 mg/kg/day dose level in MOLM-13 systemic xenograft model. We have studied cytotoxic interactions of HEC73543 with conventional antileukemic agents cytarabine using two leukemia cell lines carrying FLT3-ITD (MOLM-13, MV-4-11) The combination of HEC73543 with cytarabine produced 40% of synergistic effects in in vitro experiments and the combination of HEC73543 displayed excellent oral bioavailability and desirable drug exposures in mice, rats, dogs and monkeys. Conclusions: Together, HEC73543 exhibits potent target inhibition and efficacy in FLT3-ITD models suggests that this compound may have a therapeutic benefit for patients with FLT3-ITD leukemia.

#2094 Dual inhibition of FLT3 and Src pathways by ON150030, a type 1 inhibitor, as a novel strategy for relapsed and refractory AML therapy.

Hlya Ghaflarian, M.V. Ramana Reddy, Stephen C. Cosenza, Rodrigo Vasques del Carpio, E. Premkumar Reddy. Icahn School of Medicine at Mount Sinai, New York City, NY.

Approximately one third of patients suffering from Acute Myeloid Leukemia harbor a FLT3 Internal tandem duplication mutation (FLT3-ITD). When mutated, this receptor tyrosine kinase increases the activity of pathways for proliferation and blocks apoptosis. Quizartinib is a 2nd generation FLT3 inhibitor that inhibits FLT3-ITD in AML, but has a median duration response of 12.1 weeks. Studies revealed a secondary mutation in FLT3 at the aspartate of codon 835 (D835X) is responsible for relapse. The D835 substitution renders FLT3 constitutively active. Type 2 inhibitors like Quizartinib bind to FLT3 in its inactive state and fail to inhibit FLT3-ITD harboring a D835X mutation. Here, we tested the utility of ON150030, developed by our group, as a novel therapeutic agent to treat AML. Structural studies suggest ON150030 binds to the active form of FLT3 (Type 1 inhibitor) so mutations such as D835X do not affect the inhibitory activity of the compound. In vitro kinase assays demonstrate that ON150030 potently inhibits Wildtype and FLT3-D835Y forms, while Quizartinib fails to inhibit FLT3-D835Y. Additionally, ON150030 demonstrated time and temperature dependent inhibition of FLT3, suggesting that the compound is an irreversible inhibitor of FLT3. Biological studies reveal that ON150030 specifically inhibits the growth of MV-4-11 cells harboring the FLT3-ITD mutation (G150; 10nM). Western blot analysis demonstrates that MAPK and PI3K/ AKT pathways in these cells are inhibited with increasing dose of ON150030. The JAK independent phosphorylation of STATS seen in the context of FLT3-ITD is also reduced in response to ON150030. Future goals are to introduce FLT3 and its various mutant isoforms into the mouse myeloid cells (32Dc3) and examine how it affects proliferation and differentiation, and then compare the effects of ON150030 and Quizartinib. In addition to strongly inhibiting FLT3, ON150030 inhibits SRC, which was shown to induce resistance to targeted therapies in several leukemias including AML. We will introduce SRC into the 32D-FLT3-ITD cell lines sensitive to ON150030 and test whether these cells retain their sensitivity to the drug. Next, we will perform cytotoxicity and biochemical assays on patient-derived primary AML cells using ON150030. We use our genetic model to determine if ON150030 synergizes with standard chemotherapy agents and inhibits cancer progression in vivo. At the conclusion of this project, we hope to demonstrate that ON150030 can be used in combination therapies in all AML patients harboring a FLT3 mutation, and result in sustained remission of disease.

#2095 E7090, a novel and selective FGFR inhibitor, for the treatment of cholangiocarcinoma cells harboring FGFR2-fusion genes.

Sauri W. Miyano,1 Yasuhiito Ara,2 Junji Mitsui,1 Tatsuhiro Shibata3. 1Eisai Co., Ltd, Tsukuba-shi, Ibaraki, Japan; 2Division of Cancer Genomics, National Cancer Center Research Institute, Tokyo, Japan; 3Laboratory of Molecular Medicine, Human Genome Center, The Institute of Medical Science, The University of Tokyo, Division of Cancer Genomics, National Cancer Center Research Institute, Tokyo, Japan.

Genetic abnormalities (gene fusion, mutation and amplification) of fibroblast growth factor receptor (FGFR) family members are known to cause constitutive activation of their signaling pathways, which play an important role in proliferation, survival and migration of cancer cells, as well as tumor angiogenesis. Several recent studies have identified that FGFR2 gene fusions were found in about 10% of intrahepatic cholangiocarcinoma and acted as oncogenes. E7090, an orally available FGFR1, 2 and 3 inhibitor, whose chemical-structure and basic kinase inhibitory profile have been disclosed at AACR2015, is currently under a first-in-human study (NCT02727910). The antitumor activity of E7090 against NIH3T3 and human cholangiocarcinoma cells harboring FGFR2-fusion genes was investigated. NIH3T3 cells stably infected of five FGFR2-fusion genes (FGFR2-AHCYL1, FGFR2-BICC1 type1, FGFR2-BICC1 type2, FGFR2-TXNIP, FGFR2-HCDO1) were used to determine if FGFR2-fusion genes have a therapeutic benefit for patients with FGFR2-fusion genes.
stream pathways of FGFR signaling (MAPK and STAT3) in these cells. Subcutaneous transplantation of FGFR2-BCC1 type2, FGFR2-TXLNA, or FGFR2-KCTD1 expressing cells into immune-deficient mice produced tumor growth, and then oral administration of E7090 at 12.5, 25 and 50 mg/kg showed significant tumor growth inhibition. Finally, antitumor activity of E7090 was examined in a patient-derived xenograft (PDX) model of human cholangiocarcinoma harboring FGFR2-BCC1 fusion gene. E7090 also showed dose-dependent antitumor activity and more than 50% of tumor regression was achieved at a dose of 50 mg/kg. In conclusion, E7090 showed potent antitumor activity against FGFR2-fusion genes found in intrahepatic cholangiocarcinoma both in vitro and in vivo models, suggesting that E7090 may provide therapeutic opportunities for cholangiocarcinoma harboring FGFR2 fusion genes.

**#2096 Bozitinib, a highly selective inhibitor of cMet, demonstrates robust activity in gastric, lung, hepatic and pancreatic in vivo models.** Joe Shih,1 Royu Zhong,2 Hephg Shi,2 David Xue,2 Gavin S. Choy,3 Sanjeev Redkar3. 1Crown Bioscience, Taiyang City, Jiangsu Province, China; 2Beijing Pearl Biotechnology Limited Liability Co., Chaoyang District, Beijing, China; 3GBT Pharmaceuticals, Inc, Santa Clara, CA.

Background: cMET is a receptor tyrosine kinase that is located on the cell surface and is activated by the binding of its ligand, hepatocyte growth factor (HGF). In cancer cells, MET can be aberrantly active and cause abnormal signal transduction, which leads to tumor growth, angiogenesis, and metastasis. In vitro studies have demonstrated that bozitinib (CBT-101, PLB-1001) is a highly selective and specific inhibitor (8 nM) of cMET receptor cell proliferation. Methods: In vivo PD studies of gastric (MKN45), lung (LUM588, LU1901, LU2503), hepatic (LIM0612, LIM0801), and pancreatic (KP4) were evaluated. These models covered the HGF-dependent and HGF-independent mechanisms. Among these models, LUM588, LU1901, LU2503, LIM0612 and LIM0801 are PDX models. In particular, in the LU1901 model, bozitinib (BT) was compared to capmatinib (INC280). Groups included: BT at 1, 3 and 10 mg/kg QD × 21 and INC280 at 1, 3, and 10 mg/kg QD × 21 and 10 mg/kg BID × 21 via IG, CDPP 5 mg/kg, QD × 3 as a positive control via IP and the vehicle control (QD × 21 via IG). Each group (n = 8 mice) and the tumor volume was evaluated on D21. Results: In MKN45, LU2503, LIM0612 and LIM0801, the effect of BT seemed superior than that of crizotinib; in LUM588, its effect was higher than that of erlotinib; in LU1901, its effect was higher than that of crizotinib and INC280. In the LU1901 model, the strongest activity was observed BT at 10 mg/kg with a T/C ratio of 2%, compared to an equi-dose of INC280 (T/C of 22%). All doses of BT and INC280 were well tolerated; no mouse experienced weight loss. In MKN45 model, BT showed a PK/PD correlation and dose-dependence. BT inhibited the phosphorylation of c-Met protein; the rate of target inhibition exceeded 90% at >7 mg/kg. The plasma concentration for BT decreased over time with a significant decline 12 h after its administration, contrasting with at least 1 week of phosphorylation inhibition of the c-Met protein. Conclusions: In conclusion, BT was well-tolerated, with no animal death nor major weight loss. The in vivo experiments demonstrated that BT is a viable candidate with effective anti-tumor activities. BT is currently under evaluation in cMet dysregulated NSCLC (NCT02896231) with additional trials planned.

**#2097 A novel J-series prostamide induces ER stress-mediated apoptosis and upregulates ER oxidoreductase 1 alpha (ERO1α) in human colon cancer cells.** Hussam M. Albasam, Daniel A. Ladin, Rukiyah Van Dross. East Carolina University, Greenville, NC.

Colon cancer is the third most common cancer and the third leading cause of cancer-related death in the United States. The endoplasmic reticulum (ER) is a cellular organelle responsible for protein synthesis and oxidative folding. ER stress occurs when the protein folding load exceeds the protein folding capacity. Low levels of ER stress promote survival while excessive ER stress causes cell death. An important regulator of the cytoplasmic ER stress pathway is the transcription factor, C/EBP homologous protein 10 (CHOP10). It has been shown that CHOP10 regulates the transcription of ER oxidoreductase 1α (ERO1α). ERO1α promotes ER luminal oxidi- zation and under conditions of excessive ER stress releases H2O2 into the cytoplasm, resulting in oxidative stress-mediated apoptosis. Previous studies from our laboratory that showed that 5deoxy, Δ2,4-prostamide 1j (15d PMJ1) induced ER stress-mediated apoptosis, leading to a reduction in cell viability in tumorigenic keratinocytes and melanocytes. In addition, 15d PMJ1-induced ER stress-apoptosis was decreased in the presence of ER stress inhibitors, 4-phenylbutarate (PBA) and salubrinal. However, the specific pathway involved in 15d PMJ1-induced ER stress-apoptosis have not been identified. In this study, we hypothesize that 15d PMJ1 causes ER stress-mediated apoptosis in colon tumor cells by activating CHOP10 and its downstream transcriptional target, ERO1α. To examine the anti-proliferative effect of 15d PMJ1, tumorigenic colon cells (HCT116) and non-tumorigenic colon cells (HFC) were treated with different concentrations of 15d PMJ1 or 10μM shapiggin (TG) for 24 hours and cytotoxicity was measured by lactate dehydrogenase (LDH) assay. A significant increase in cell death was observed in HCT116 cells treated with 5μM 15d PMJ1 and this cytotoxic effect was 3-fold greater in HCT116 compared to HFC cells. Apoptotic measurements showed a significant increase in percentage of apoptosis in the presence of 15d PMJ1 treatment. The expression of CHOP10 was significantly enhanced in the 15d PMJ1-treated group. In addition, 15d PMJ1-induced apoptosis was decreased in the presence of ER stress inhibitors, PBA and salubrinal, suggesting that ER stress is essential for 15d PMJ1-induced apoptosis. Western blot analysis revealed an increase in ERO1α protein expression following 15d PMJ1 treatment. Apoptosis measurements showed a sig- nificant inhibition in 15d PMJ1-induced apoptosis in the presence of ERO1α in- hibitor, EN460, suggesting that ERO1α is important for 15d PMJ1-induced apoptosis. These findings suggest that 15d PMJ1-induced apoptosis is mediated via the ER stress pathway. CHOP10 and its transcriptional target, ERO1α, play a potential role in 15d PMJ1-induced ER stress-apoptosis, suggesting that 15d PMJ1 could be a potential anti-neoplastic agent with a unique mechanism for colon cancer.

**#2098 NVP-FGF401, a first-in-class highly selective and potent FGFR4 inhibitor for the treatment of HCC.** Diana Graus Porta,1 Andreas Weiss,2 Robin A. Fairhurst,3 Markus Wartmann,1 Christelle Stamm,1 Flavia Reimann,2 Alexandra Buhrle,2 Jalueine Kinyamu-Akunda,1 Dario Sterker,2 Masato Murakami,1 Youzhen Wang,4 Jeffrey Engelman,3 Francesco Hofmann,1 William R. Sellers3. 1Novartis, Basel, Switzerland; 2Novartis, East Hanover, NJ; 3Novartis, Cambridge, MA.

Hepatocellular carcinoma (HCC) is the seventh most common cancer world- wide and the third most common cause of cancer-related death. Sorafenib is the only FDA approved targeted agent to show a marginal improvement in overall survival (OS) for patients with advanced HCC. Recent data have implicated aberrant activation of the FGFR1-FGFR4/KLB axis as the driver of certain forms of HCC, making this pathway a novel therapeutic target in this disease. The first evidence for this is the finding that aberrant expression of FGFR1, as a consequence of gene amplification and other not yet known mechanisms, occurs in subsets of HCCs and HCC cell lines leading to constitutive FGFR4 activation. In this setting, conditional knock-down of FGFR1, as well as its receptors FGFR4 and KLB, suppresses proliferation of HCC cell lines, supporting the notion that FGFR1 activates FGFR4 in an autocrine fashion. Secondly, in transgenic mouse models, FGFR1 produced by non-tumor cells at an ectopic site (skeletal muscle) acts in a para- crine fashion on the liver hepatocytes leading to liver dysplasia and HCC. In these mice, tumorigenesis is abolished in an FGFR4 null background, as well as upon treatment with anti-FGF19 and anti-FGFR4 blocking antibodies. Thus, we anticipated that targeted therapies aimed at blocking the FGFR4 pathway might be efficacious in subsets of HCCs. We have identified and developed NVP-FGF401, a first in class, highly selective and potent FGFR4 inhibitor that is currently in Phase I/II clinical testing. NVP-FGF401 binds in a reversible covalent manner to the FGFR4 kinase domain and it inhibits FGFR4 with an IC50 of 1.1 nM. In biochemical assays, it shows at least 1,000 fold selectivity against panel of 65 kinases and in a kinase wide scan, consisting of 456 kinases, FGFR4 was the only target of NVF-FGF401. In xenograft animal models in vivo, NVP-FGF401 showed a consistent pharmacokinetic / pharmacodynamic (PK/PD) relationship with phospho-FGFR4 (pY925/926). NVP-FGF401 binds in a reversible covalent manner to the FGFR4 tumor—robustly inhibited in a dose dependent manner. The data support a lowest observed trough concentration (C trough) driven PD/efficacy relationship. The anti-tumor activity was confirmed across several xenograft animal models, as well as in patient-derived tumor xenografts (PDX) established in mice. The excellent drug-like properties of NVP-FGF401 drove us to test its efficacy in HCC patients in a PhII study, being the first selective FGFR4 inhibitor to ever enter into clinical trials (NCT02325739).

**#2099 In vitro characterization of the effect of nazartinib against non-small cell lung cancer activating clinically relevant EGFR mutants.** Keita Mauszawa, Hiroiyouki Yasuda, Toshiyuki Hirano, Shigenari Nukaga, Hanako Hasegawa, Junko Hamamoto, Katsuhiko Naoki, Kenzo Soejima, Tomoko Bet-suyaku. Keio University, School of Medicine, Shinjuku-ku, Tokyo, Japan.

Purpose: Multiple EGFR-TKIs are available and under development to treat patients with lung cancer harboring EGFR mutations. Nazartinib is one of the 3rd generation EGFR-TKIs targeting EGFR T790M as well as common mutations such as L858R and exon 19 deletions. Today, there is no clear guideline regarding which EGFR-TKIs should be used for which mutations. The purpose of this study is to clarify which EGFR-TKIs including nazartinib are best for each EGFR mutation, especially exon 20 insertion mutations using in vitro modeling. Experimental design: We evaluated drug sensitivity and downstream signaling of human lung cancer cell lines (PC9, H3255, H1975, PC9ER, BID007) and Ba/s3 cells harboring multiple types of EGFR mutations for 1st- (erlotinib), 2nd-
(afatinib) and 3rd- (osimertinib and nazartinib) generation EGFR-TKIs by MTS assay and western blotting. An in vitro model of mutation specificity was created by calculating the ratio of IC50 values between mutated and wild type EGFRs. Results: The model of mutation specificity identified a wide therapeutic window of each EGFR-TKIs for exon 19 deletions and L858R. On the other hand, osimertinib and nazartinib have wide therapeutic windows for other resistance mutations in human cell lines and Ba/F3 cells. In human cell lines and Ba/F3 cells harboring exon 19 deletions or L858R, afatinib dramatically inhibited the phosphorylation of EGFR, AKT, and ERK. Afatinib and 3rd generation EGFR-TKIs, osimertinib and nazartinib, effectively inhibited the phosphorylation of EGFR, AKT, and ERK in T9T0M positive cells. For EGFR exon 20 insertion mutations, although afatinib, osimertinib and nazartinib effectively inhibited the phosphorylation of EGFR, AKT, and ERK in several exon 20 insertion mutations, osimertinib and nazartinib were potent and presented a wide therapeutic window. Conclusion: Nazartinib as well as osimertinib has wide therapeutic windows for exon 19 deletions, L858R, T9T0M and some exon 20 insertions.

#2100 Selective inhibition of FGFR4 by INC062079 is efficacious in models of FGFR9- and FGFR4-dependent cancers. Phillips C.C. Liu, Guang Lu, Kevin Bowman, Matthew C. Stubbs, Liaoxing Wu, Darlin DiMatteo, Sindy Condon, Ronald Klabe, Ding-Quan Qian, Xiaoming Wen, Paul Collier, Karen Gallagher, Michael Hansl, Xin He, Bruce Ruggeri, Yan-ou Yang, Maryanne Covington, Timothy C. Burn, Sharon Diamond-Fosbenner, Richard Wynn, Reid Huber, Wenqing Yao, Swamy Yeleswaram, Peggy Sherfe, Gregory Hollis. Incyte, Wilmington, DE.

Ablation signaling through Fibroblast Growth Factor Receptors (FGFR) has been reported in multiple types of human cancers. FGFR4 signaling contributes to the development and progression of subsets of cancer: in approximately 10 percent of hepatocellular carcinoma (HCC), genetic amplification of FGFR9, encoding an endocrine Fgfr ligand that activates Fgfr4-KLB receptors, has been reported. In models with this alteration, FGFR9-FGFR4 signaling is oncogenic and antagonism of the FGFR9-FGFR4 axis has been shown to be efficacious suggesting that selective targeting of FGFR4 may be an effective strategy for malignancies with FGFR4 activation. We describe the preclinical characterization of INC062079 a potent and selective inhibitor of the FGFR4 kinase. In biochemical assays INC062079 inhibited FGFR4 with low nM potency and exhibited at least 250-fold selectivity against other FGFR kinases and greater than 800-fold selectivity against a large kinase panel. This selectivity derives from the ability of INC062079 to bind irreversibly to Cys552, a residue within the active site of FGFR4 that is non-conserved among other FGFR receptors. Covalent binding of INC062079 to Cys552 was demonstrated using a LC/MS/MS-based proteomic analysis that confirmed specificity for the target Cys. In assays using HCC cells with autocrine production of FGFR9, INC062079 inhibited the autophosphorylation of FGFR4 and blocked signal transduction by FGFR4 to downstream markers of pathway activation. Cancer cell lines that have amplification and expression of FGFR9 are uniquely sensitive to growth inhibition by INC062079 (EC50 less than 200 nM) compared with HCC cell lines or normal cells without FGFR9-FGFR4 dependence (EC50 > 5000 nM) confirming selectivity for FGFR4. In vivo, oral administration of INC062079 inhibited the growth and induced significant regressions of subcutaneous xenograft models of HCC with FGFR4 activity at doses that were well-tolerated (10-30 mg/kg BID) and did not result in a significant increase in serum phosphate levels which is observed with FGFR1/2/3 inhibition. Suppression of tumor growth correlated with pharmacodynamic inhibition of FGFR4 signaling. Collectively, these preclinical studies demonstrate that INC062079 potently and selectively inhibits models of FGFR9-FGFR4-dependent cancers in vitro and in vivo, supporting clinical evaluation in patients harboring oncogenic FGFR4 activation.

#2101 Ormeloxifene suppresses the growth of prostate tumor via inhibition of β-catenin induced AR signaling. Aditya Ganju, Bilal Bin Hafeez, Mohammed Sikander, Vivek Kumar Kashyap, Murali Mohan Yallapu, Subhash C. Chauhan, Meena Jaggi. Univ. of Tennessee Health Science Ctr., Memphis, TN.

Background: Prostate cancer (PrCa) first manifests as an androgen-dependent disease and can be treated with androgen deprivation therapy. Despite the initial success of androgen ablation therapy, resistance to anti-androgen therapy displays by progression to hormone refractory (androgen-independent) advanced stage PrCa which is primary cause of patient’s death. Main underlying cause for the onset of hormone refractory cancer is ligand independent activation of AR signaling in PrCa cells. It has been shown that β-catenin acts as a non-androgen activator of AR which enhances AR transactivation in PrCa cells. Thus, identification of agents with excellent pharmacokinetics and pharmacodynamics parameters that can inhibit ligand independent activation of AR signaling might be highly useful for the treatment of advanced stage PrCa. Herein, we identified a synthetic molecule, ormeloxifene (ORM), which efficiently represses β-catenin mediated ligand independent activation of AR signaling, thus, inhibits growth and metastatic features of PrCa cells. Methods: Androgen-refractory but AR positive PrCa cell (C4-2) was used as an in vitro and in vivo model systems. Effect of ORM on AR and PSA protein levels was determined by Western blot analysis. Effect of ORM treatment was analyzed on AR and PSA luciferase activities by transiently transfecting the C4-2 cells by AR and PSA luciferase construct as was used as an internal control. Nuclear and cytoplasmic lysates were prepared using Active Motif kit. Immunoprecipitation analysis was performed to determine if ORM inhibits physical interaction of β-catenin with AR. Therapeutic efficacy of ORM was evaluated in cell lines and PrCa xenograft mouse models. Results: ORM dose-dependently (10, 15 and 20 μM) inhibited the protein levels of AR and its downstream target protein PSA. ORM (10 and 20 μM) treatment inhibited protein levels of nuclear β-catenin and physical interaction of β-catenin with AR in PrCa cells. ORM administration dose-dependently (intra-peritoneal; 100 and/or 500 μg/mouse; thrice/week) significantly (P<0.01) inhibited growth of C4-2 cells derived xenograft tumors in athymic nude mice. ORM treatment significantly (P<0.01) inhibited the expressions of nuclear AR and β-catenin expressions in xenograft tumor tissues. These ORM treated mice did not show any apparent toxicity in our study. Conclusion: Our study demonstrates that ORM is a potent inhibitor of β-catenin-mediated activation of AR signaling. Based on its safety profile, ORM might be an ideal candidate for repurposing to treat advanced stage PrCa alone or in combination with other therapies.

Androgen receptor (AR) signaling plays a key role in prostate cancer progression; thus Androgen Deprivation Therapy (ADT) is a mainstay therapy for patients with advanced prostate cancer. However, in most cases the tumor becomes androgen-independent and resistant to ADT with patients ultimately progressing to metastatic castration resistant prostate cancer (mCRPC). Constitutively activated AR splice variants (AR-Vs) have emerged as major mediators of resistance to AR-targeted therapy and progression of mCRPC, representing an important therapeutic target for mCRPC. Out of at least 15 AR-Vs described thus far, AR-V7 is the most abundant in prostate cancer and its expression correlates with ADT resistance. Onc201 is the founding member of the imipridone class of small molecules that induces apoptosis in a variety of tumor types tested. It is currently in Phase I/II clinical trials for advanced solid tumors and hematological malignancies, including mCRPC with encouraging activity observed in patients in early clinical testing (Stein et al., ASCO, 2016). We demonstrate here that Onc201 treatment induces apoptosis in both castration-resistant and −sensitive human prostate cancer cell lines. Furthermore, an in vitro synergistic effect is observed with Onc201 and FDA approved drugs for prostate cancer such as enzalutamide, docetaxel and everolimus. Mechanically, we found that Onc201 inhibits both AR and AR-V7 signaling pathways. Analysis of AR+ cell lines stimulated with DHT showed a significant decrease in both RNA and protein levels of AR, AR-V7, PSA and other AR-target genes following Onc201 treatment. Ongoing experiments are aimed at better understanding the molecular and cellular mechanisms that enable Onc201 to inhibit the AR signaling pathway. In-vivo studies with AR-negative hormone refractory prostate cancer xenografts demonstrate single agent Onc201 anti-tumor efficacy. Ongoing studies are further evaluating the in-vivo efficacy of Onc201 as a single agent or in combination with enzalutamide and everolimus using mouse models of both castration-resistant and −sensitive prostate cancer. These preclinical results indicate that Onc201 is well suited to address mCRPC, including tumors that harbor AR-V7, as a single agent that may be combined synergistically with enzalutamide or everolimus. With these observations we envision further development a combination of Onc201 plus everolimus in CRPC with or without enzalutamide resistance.

#2103 NVP-FGF401: Cellular and in vivo profile of a novel highly potent and selective FGFR4 inhibitor for the treatment of FGFR9/FGFR4/KLB+ tumors. Andreas Weiss,1 Diana Graus Porta,2 Flavia Reimann,1 Alexandria Buhles,1 Christelle Stamm,1 Robin A. Fairhurst,1 Jacqueline Kinyamu-Akunda,2 Dario Sterker,1 Masato Murakami,1 Markus Wartmann,1 Youzhen Wang,3 Jeffery A. Engelman,3 Francesco Hofmann,1 William R. Sellers,1 Novartis Institutes for BioMedical Research, Basel, Switzerland; 2Novartis Institutes for BioMedical Research, East Hanover, NJ; 3Novartis Institutes for BioMedical Research, Cambridge, MA.

Hepatocellular carcinoma (HCC) is the most common primary malignancy of the liver and a deadly disease. Treatment options are limited and prognosis
EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Growth Factor and Hormone Receptors as Therapeutic Targets

generally is poor. Aberrant signaling through the fibroblast growth factor 19 (FGF19) - fibroblast growth factor receptor 4 (FGFR4) axis has been implicated in the development of HCC, and recently FGF19 has been determined as a specific driver gene amplification in a subset of liver tumors and cancer cell lines. Here, we describe the cellular and in vivo profile of NVP-FG401, a highly potent and selective, first in class, reversible-covalent small-molecule inhibitor of the kinase activity of FGFR4. NVP-FG401 is exclusively selective for FGFR4 versus other FGFR family members and all other kinases. We show that among the FGF19-amplified liver cancer cells in the cancer cell line encyclopedia (CCLE), only those with concomitant expression of β-klotho (KLB), a co-receptor for FGF19 that facilitates its binding to FGFR4, are sensitive to NVP-FG401. NVP-FG401 has good oral PK properties and shows an excellent in vivo PK/PD relationship. NVP-FG401 has remarkable anti-tumor activity in mice bearing HCC tumor xenografts and PDX models that are positive for FGF19, FGFR4 and KLB. NVP-FG401 is the first FGFR inhibitor to enter clinical trials, and a Phll study is currently ongoing in HCC and other types of solid tumors.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Mechanism of Drug Action

#2104 In vitro drug effects on cancer cell morphology and functional state revealed by multiparameter imaging mass cytometry. Olga Ornatsky, Alexandre Bouzekri, Bedilu Allo, Jessica Watson. Fluidigm Canada, Markham, Ontario, Canada.

Results of in vitro drug testing are correlated with clinical response to chemotherapy: Accuracy to predict clinical drug resistance was found to be as high as 90%. The benefit of using in vitro models lies in the ability to probe cellular response in a controlled closed system, where effects of drug concentrations, treatment duration, drug efflux kinetics and multidrug combinations can be assessed by a variety of cell biology techniques. Cisplatin is a widely used chemotherapy drug that targets genomic DNA of the cells, forming both interstrand and intrastrand cross-links that lead to cell death. One limitation of its clinical use is in predicting the development of resistance and severe side effects in patients. Mechanisms of resistance such as reduced drug accumulation, increased detoxification through cisplatin binding to cellular thiol, reduced DNA platination, and increased DNA repair have been reported, however (tamoxifen enhancement of cisplatin). In vitro models of different cancer types (SKOV3, HeLa, A431, MCF-7) were used to study the effects of cisplatin on cell morphology and phenotypic and functional characteristics with a large panel of metal-tagged antibodies and Imaging Mass Cytometry (IMC) at the single-cell level (1). Proteins involved in DNA damage repair (γH2AX, PP2A, pHistone H3), apoptosis (CD98, caspase-3, cleaved PARP), cell proliferation (cyclin B1, Ki-67), metastasis (vimentin, β-catenin, VEGF, CD63, CD99), substrate adhesion (CD29, CD49e, CD49f, CD51, CD54, CD47), organelle morphology (CD107a, Mito, histone H3), and signaling pathways (STAT3, pERK1/2, pS6) as well as surface receptors (EGFR, HER2, BRCA, MUC1, CD44, EpCAM, CD142, CD39, beta-catenin) and structural markers (CK5, CK8/18, β-actin, β-tubulin), were identified simultaneously in each individual cell with specific metal-conjugated antibodies. S-phase cells were visualized by detection of 127I in 5-ido-2′-deoxyuridine (IdU) added to culture media. Presence of cisplatin in cell nuclei and cytoplasm was registered by IMC of platinum stable isotopes. Combination therapy of cisplatin and paclitaxel is a standard chemotherapeutic regimen to treat recurrent or metastatic cervical cancer. Cell lines from various tumors may develop resistance to cisplatin. Reduced cisplatin uptake has been observed in cervical cancer cells with cisplatin resistance. The cisplatin-resistant HeLa cells and A431 (A431/P) cells show 50% and 77% reduction in cisplatin uptake, respectively, compared with the parental cell lines. Human ovarian cancers (in vitro model SKOV3), for which cisplatin is a mainstay of treatment, develop drug resistance and pose an important clinical challenge. (1) Chang, Q et al. Nature Scientific Reports 6 (2016): 36641.

Besides the progress in the knowledge of cancer biology, the rates of mortality due to this disease are still considerably elevated. Therefore, application of new drugs in antitumor therapies has been constantly studied. However, any of them have achieved a considerable success so far. In this work we evaluated the ability of metformin, a traditional hypoglycemic prescribed to treatment of type II diabetes along decades, over programmed cell death and modulation of metastatic potential in multidrug resistant (MDR) human myeloid chronic leukemia cells (Lucena), through MTT reduction test, flow cytometry, western bloting and gelatin zymography. Metformin was able to reduce the cell viability in a concentration and time-dependent way and was capable of induce Lucena cells to apoptosis or necrosis, though activation of the apoptotic machinery. Indeed, it was not observed activation of caspase 3, in contrast to an expressive activation of PARP. Interestingly, proteins associated to autophagy were over-expressed by Lucena cells, and an arrest of cell cycle was observed after exposition to the drug. Finally, it was verified that metformin was able to modulate activity of MMPs and PARP enzymes associated to the metastatic process. Taken together these results suggest that the hypoglycemic is able to acts over the first steps of cancers in more aggressive stages. Finally, inhibition of MMPs indicates a promissory action of metformin for the treatment of metastatic disease.

#2106 In-depth profiling of the energy depletion-mediated cancer cytotoxicity by passively delivered zinc complexes via PARP1 activation. Jinhyuk F. Chung. 1 Tae Jung Park, 2 Yoko Norihisa 3. 1Xylonix Pte Ltd, Singapore, Singapore; 2Chung-Ang University, Seoul, Republic of Korea; 3Cheonghim International Medical Center, Gyeonggi-do, Republic of Korea.

Disfunctional apoptotic function from impaired p53 tumor suppressor activity leads to poorer prognosis in cancer patients by compromising drug sensitivity and promoting drug resistance development. Activation of the hypoglycemic zinc is a theoretically proposed cytotoxic mechanism for circumventing this problem. Herein we demonstrate that a biodegradable zinc complex is capable of triggering the programmed necrosis via activation of PARP1/PARG/MPTP, which consistently resulted in p53-independent broad spectrum cytotoxicity in vitro across all 20 cancer cell lines tested including many with reported drug resistance phenotypes. Additionally, we investigated its possible interaction with agents that influence p53 for possible antagonism/synergism. Supporting in vivo evidence in both animal models and clinical case studies involving terminal chemo-resistant gastric cancer patients upon oral administration (30 mg Zn/day) are presented. These results implicate macro-molecular biodegradable zinc complexes as promising antitumor agents of simple compositions for overcoming the current hurdles in clinics, and warrant further clinical investigations. We plan to advance the studies through non-invasive small devices reporting real-time blood glucose, blood pressure, microperfusion, and other hemodynamic parameters.

#2107 Tetraarsenic hexoxide induces G2/M cell cycle arrest, apoptosis, and autophagy via p38 MAPK and AKT-mediated pathways in SW620 human colon cancer cells. Won Sup Lee.1 Jeong Won Yun,1 Min Jeong Kim,1 Arulkumar Nagappan,1 Jing Nan Lu,1 Seong-Hwan Chang,2 Jae-Hoon Jeong,3 Jinhyuk F. Chung,1 TaeJung Park, 2 Yoko Norihisa3. 1Gyeongsang National Univ. Hospital, Jinju, Republic of Korea; 2Konkuk University School of Medicine, Seoul, Republic of Korea; 3Cheonghim International Medical Center, Gyeonggi-do, Republic of Korea.

Tetraarsenic hexoxide (As4O6) has been used in Korean folk remedy for the treatment of cancer since the late 1980’s. Evidence suggests that As4O6 show anti-cancer effects, whose mechanisms are different from those for As2O3. However, the detailed anticancer mechanism is still unclear. Here, we investigated the anticancer effects of As4O6 on SW620 human colon cancer cells. As4O6 induced cell death in a dose-dependent manner. Flow cytometry analysis revealed that As4O6 increased the sub-G1 (apoptotic cell population) and G2/M phase population in a dose-dependent manner. Further, nuclear condensation and cleaved nuclei were also observed upon staining with Hoechst 33342 in Hoechst 33342 in As4O6-treated SW620 cells. Western blot revealed that As4O6 significantly down-regulated the cyclin B1,cdc2, pro-caspases -3, -8 and -9, and up-regulated p21 and cleavage of PARP in SW620 cells. In addition, As4O6 increased the expression of death receptor 5 (DR5), suppressed Bcl-2 and XIAP family proteins, and promoted the conversion of LC3-I to LC3-II in a Beclin-1 independent manner. Indeed, it was not observed activation of caspase 3, in contrast to an expressive activation of PARP. Interestingly, proteins associated to autophagy were over-expressed by Lucena cells, and an arrest of cell cycle was observed after exposition to the drug. Finally, it was verified that metformin was able to modulate activity of MMPs and PARP enzymes associated to the metastatic process. Taken together these results suggest that the hypoglycemic is able to acts over the first steps of cancers in more aggressive stages. Finally, inhibition of MMPs indicates a promissory action of metformin for the treatment of metastatic disease.
Glioblastoma (GBM) is the most aggressive and deadliest brain malignancy in adults. Despite of surgical techniques, radiotherapy and chemotherapy, GBM has remained an invariably lethal tumor with a median survival less than 15 months. Although the anticancer mechanisms of omega-3 polyunsaturated fatty acids (ω3-PUFAs) have been reported in several cancers, it is still unclear in brain cancer. Here, we show the anti-inflammatory and anti-metastatic effects of ω3-PUFAs in GBM. Invasiveness using transwell chamber was inhibited by docosahexaenoic acid (DHA) treatment in D54MG and GL261 cells. In zymography, MMP-2 activity was suppressed by DHA in a dose dependent manner. MMP-2 promoter activity was also decreased. DHA inhibited both p-STAT3 and β-catenin levels that contribute to invasion by stimulating pro-invasion factors such as MMP-2. Additionally, fat-1 (ω3-desaturase) stable D54MG cell line was established and the effect of the high level of ω3-PUFAs was investigated endogenously. The invasiveness were significantly inhibited in the fat-1 stable cells compared to control cell. Moreover, the metastasis in vivo was significantly reduced when GL261 mouse glioma cells were injected through tail vein into the fat-1 transgenic mice. In immunohistochemistry, intensity of p-STAT3 and β-catenin in GBM cells. Thus, these findings provide important preclinical evidence and molecular insight for utilization of ω3-PUFAs for the chemoprevention and treatment of human GBM. This work was supported by the National Foundation of Korea (NRF) grant funded by the Korea government (MEST) (2007-0054932, NRF-2015R1D1A1A01056887) and by the framework of international cooperation program managed by National Research Foundation of Korea (2015K2A2A6002008).

#2112 Ciclopirox inhibits tumor cell motility by suppressing protein expression of small GTPases and phosphorylation of paxillin. Shile Huang, Tao Shen, Louisiana State Univ. Health Sciences Ctr.-Shreveport, LA.

Ciclopirox oleamine (CPX), an off-patent antifungal drug, is used for the treatment of superficial mycoses. Recent studies have demonstrated that CPX also possesses potent anticancer activity by inhibiting cell proliferation and inducing cell death in tumor cells. However, it is unknown whether CPX inhibits cell motility. In the present study, we found that CPX potently inhibited cell motility in a concentration-dependent manner in rhabdomyosarcoma (RH30 and RD) cells, which was independent of the reduction of cell viability. As small GTPases (RhoA, Cdc42, and Rac1) and focal adhesion proteins (paxillin) play critical roles in the regulation of cell motility, we further studied whether CPX affects these proteins. Our Western blot analysis revealed that CPX did inhibit cellular protein expression of RhoA, Cdc42 and Rac1. However, by RT-PCR analysis, CPX did not alter the mRNA levels of the small GTPases. As microRNAs (miRNAs) can regulate protein expression at transcriptional and post-transcriptional levels, we investigated the effect of CPX on the expression of miRNAs. Our miRNA PCR array revealed that treatment with 10 μM of CPX for 24 hours upregulated the expression of 27 miRNAs by 2.04-6.10 fold, and downregulated the expression of 7 miRNAs by 2.00-7.89 fold in RH30 cells. Further research is ongoing to identify whether these up/downregulated miRNAs are linked to the reduced expression of small GTPases and potentially more proteins. In addition, we found that CPX inhibited the phosphorylation of paxillin, despite no effect on the total cellular protein expression. The results suggest that CPX inhibits tumor cell motility at least by suppressing the protein expression of small GTPases and the phosphorylation of paxillin. Supported by the Feist-Weiller Cancer Center, LSU Health Sciences Center, Shreveport, LA.

#2110 FoxO3a activation by HDAC class IIa inhibition induces cell cycle arrest in pancreatic cancer cells. Makoto Usami, Shohei Kikuchi, Kohichi Takada, Yusuke Sugama, Yohei Arihara, Naotaka Hayasaka, Hajime Nakamura, Yuki Ikeda, Yusuke Kamihara, Masahiro Hirakawa, Makoto Yoshida, Masayoshi Kobune, Koji Miyamish, Junji Kato. Sapporo Medical University, School of Medicine, Sapporo, Japan.

Pancreatic cancer is highly chemo-resistant associated with oncogenic mutations such as KRAS and/or p53. The effect of conventional chemotheraphy is not sufficient and new target and strategy is urgently needed. The forkhead box (Fox) proteins are multidirectional transcriptional factors strongly implicated in malignancies. Although Fox O (FoxO) protein, and particularly FoxO3a, works as negative regulator of cell proliferation by exressing cyclin proteins and inducing cell cycle inhibitors such as p21 and p53, its expression is consistently suppressed by several oncogenic pathways including phosphatidylinositol-3-kinase (PI3K) / AKT pathway, constitutively activated in pancreatic cancer. Thus, upregulating FoxO3a activity could be a promising target of pancreatic cancer.
treatment without impact of underlying oncogenic mutations. Class Ila Histone deacetylase (HDAC) is a subgroup of HDAC. Though HDAC inhibitors (HDACi) have been extensively investigated as a cancer target, its action mechanism is considered due to histone modification by class I. Biological significance of class Ila HDACs which have minimal histone deacetylation activity have not been elucidated yet. Recent studies show class Ila HDACs act as a transcriptional regulator including FoxO3a. In this study, we investigate the biologic impact of HDAC class Ila inhibition on FoxO3a and anti-tumor effect against pancreatic cancer cell line using selective class Ila HDAC TMP269.

TMP269 treatment showed increased FoxO3a expression in a dose dependent manner with immobiloblotting and modest cell growth inhibition effect at 57.5 μM of dose for 48-hour treatment against AsPC-1 in 3MT. G1/S arrest was observed with cell cycle assay. Upregrulated p21\(^{\text{Waf1/Cip1}}\) and downregulated CDK2 and 4/6 and cyclin D1 and D2 expressions were further observed, consistent with inducing G1/S arrest and transcriptionally activated FoxO3a. Importantly, upregulated p21\(^{\text{Waf1/Cip1}}\) was observed in AsPC-1 p53 null cell line, suggesting independent with p53 pathway. These findings suggest upregulated FoxO3a by HDAC class Ila inhibition activated its transcription and resulted in cell growth inhibition. Because P13K/AKT leads FoxO3a to the ubiquitinylation-mediated proteasome degradation, we examined irreversible proteasome inhibitor carfilzomib (CFZ) combined with TMP269, aiming synergetic FoxO3a upregulating. As expected, FoxO3a expression was further increased in TMP269 combined with CFZ compared with TMP269 or CFZ alone. Following the activation of FoxO3a, expression was upregulated and cell proliferation inhibition was dramatically enhanced. In conclusion, HDAC class Ila inhibition modified FoxO3a transcriptional activation and upregulating FoxO3a by dual inhibition of HDAC class Ila and proteasome is promising target against pancreas cancer.

#2113 Mechanism of action of pixantrone in non-Hodgkin’s lymphoma cells. Serina Ng, Ruben Muñoz, Daniel Von Hoff, Haiyong Han. Translational Genomic Research Institute, Phoenix, AZ.

Background: Pixantrone (PIX), an anthracenedione analog, has shown promising results with reduced cardiotoxicity as compared to structurally similar mitoxantrone and doxorubicin (DOX) in early phase clinical trials in patients with non-Hodgkin’s lymphoma (NHL). The exact mechanisms of action on how PIX induce cell death by targeting DNA replication through intercalating DNA and/or inhibiting Topoisomerase II has not been clearly illustrated. Methods: A short-term cell proliferation assay (3 days treatment) and a long-term clonogenic assay (cells were treated with the drugs for 24 hours and then allowed to grow into colonies for 10-14 days) were used to assess and compare the effects of PIX and DOX on cell growth in three NHL cell lines, OCI-Ly3, Z138, and Raji. Immunofluorescent assays using γH2AX antibodies, and DAPI staining were used to examine the effect of PIX and DOX on the formation of double-strand breaks and micronuclei. Results: In the short-term cell proliferation assay, PIX was not as potent as DOX (\(IC_{50}\) values ranging from 22 nM to 2373 nM for PIX and 2.8 nM to 67 nM for DOX). The two drugs were significantly more potent in the long-term clonogenic assay with \(IC_{50}\) values in low nanomolar range (5.1 nM to 82.8 nM) and the difference between PIX and DOX was much smaller. Cells treated with PIX displayed less increases in DNA double-strand breaks compared to those of DOX as quantified by the number of γH2AX positive foci formed in the cells. Furthermore, PIX treatment significantly increased the formation of micronuclei in a drug concentration and time dependent manner. Conclusions: The findings from the current study indicate that PIX induces DNA damages that impair the chromosomal segregation but do not significantly trigger double-strand breakage checkpoint response. Overall, our results suggest that PIX may exert its antitumor activity via mechanisms that are different from those of DOX.

Sphingolipids influence tumor microenvironment in different malignancies. Estrogen and estrogen metabolites are involved in prostate cancer. Fingolimod is Sphingokinase-1 (SphK1) inhibitor which possesses anticancer properties in various tumor types. The aim of the current study is to investigate the interference of Fingolimod with the cross talk between sphingolipid and estrogen metabolism within prostate cancer cells as a novel therapeutic strategy. The design is based on determining the mutual influence between estrogen metabolism/signaling and sphingolipid metabolism within prostate cancer cells. Cytotoxicity using SRB-U assay; cell cycle analysis using DNA cytometry and intracellular caspase-3 concentration were assessed. Estrogen metabolites and estrogen metabolism-activating enzymes were determined using LC/MS and RT-PCR, respectively.

Estrogen receptor (ERs and ERβ) expression and their downstream signaling (CXCR4 and Cyclin-D1, respectively) were measured using immunocytochemical staining and RT-PCR, respectively. Fingolimod showed antiproliferative/cytotoxic effects against different prostate cancer cells (LNCaP, DU145 and PC3) with \(IC_{50}\) ranging from 3.0±0.3 to 6.8±1.7 μM. Fingolimod induced significant decrease in estradiol, estrone, 4-hydroxyestradiol and 16α-hydroxyestrone concentrations with reciprocal increase in 2-methoxyestrone and 2-methoxyestradiol concentrations. This was mirrored by significant down expression for the enzymes, aromatase, CYP1A1 and CYP1B1 and over expression for the enzyme COMT. Additionally, Fingolimod suppressed the expression of ERs and ERβ within prostate cancer cells as well as their downstream signaling proteins CXCR4 and Cyclin-D1. It was observed that CXCR4 and catechol estrogens induce the expression of SphK1 while methoxylation of catechol estradiol suppresses its expression. Our results give compelling evidence that Fingolimod has therapeutic potential by modulating the estrogenic micromilieu and interrupting its cross talk with sphingolipid metabolism in prostate cancer cells.

#2116 Combining the power of different profiling approaches to better understand the activity of kinase inhibitor drugs. Alastair J. King, Jesse J. Parry, Samantha C. Burkart, Lee R. Cavedine, Alyssa M. Craciuchio, Brogan A. Epkins, Steven M. Garner, Timothy J. Sindelar, Charles R. Wageman, Stephen P. Davies, Andrew Plater, Anna M. Woodward, Usha Warrior. 1. Eurofins Panlabs Inc., St. Charles, MO; 2. Eurofins Pharma Discovery Services UK, Ltd.; 3. King Abdullah University, Jeddah, Saudi Arabia; 4. Faculty of Pharmacy, Ain Shams University, Cairo, Egypt; 5. Faculty of Medicine, King Abdullah University, Jeddah, Saudi Arabia.

Profiling of inhibitors for eventual therapeutic use is an essential part of drug discovery and development. Evaluating the in vitro potency of kinase inhibitors in a wide panel of enzyme assays is critical, not only to guiding SAR knowledge for improving drug design, but also for assessing selectivity, which has long-reaching consequences for both biological activity and safety. Evaluation of the same inhibitors in cellular models yields information on the activity of these inhibitors in a more physiologically relevant environment. However, while some selective kinase inhibitors show predictably selective profiles in cell proliferation assays, others do not. Thus, the biological context in which a kinase inhibitor functions, and the signaling networks influenced by inhibition of both the de-
sired target and off-target activities, help to define how that inhibitor will work in a cellular setting and, ultimately, in a therapeutic application. We demonstrate the power of profiling several well-known kinase inhibitors in complementary panel assays, to predict behavior that has implications for clinical activity. The in vitro profiles of selective (trametinib, vemurafenib) and less selective (dasatinib, sorafenib) inhibitors are shown and compared. With care and precision of their in vitro enzyme activity profiles in Eurofins’ KinaseProfiler™ panel, cellular response profiles in OncoPanel™, and predictive biomarker identification by univariate genomic analysis, a fuller picture of these inhibitors’ biological activity can be generated, and may be applied to predicting the therapeutic potential of such inhibitors. While, in some cases, clinical response is seen as expected, this kind of comprehensive analysis opens up the possibility for expanding clinical utility of an asset by potential repurposing for other indications. Collectively, this demonstrates not only the need to understand an inhibitor’s fundamental activity(ies) at its designated target(s), but also the importance of considering cellular context, when assessing its maximum potential clinical utility.

#2117 TRAIL-induced apoptosis in TRAIL-resistant breast carcinoma.
Jasmine M. Manouchehri, Michael Kalafatis. Cleveland State University, Cleveland, OH.

Recombinant human tumor necrosis factor-related apoptosis-inducing ligand (rhTRAIL), the optimized form of the endogenous death ligand TRAIL, shows therapeutic potential for cancer due to its ability to induce apoptosis in cancer cells independent of p53, while exhibiting minimal toxicity to normal cells. Despite a majority of breast cancers display resistance to single agent treatments, the cotreatment of Q and rhTRAIL enhanced the induction of apoptosis in breast cancer BT-20 cells in a dose-dependent manner. RT-PCR analysis revealed Q’s sensitization was displayed in breast cancer cells and triple-negative breast cancer cells (TNBC) viainduced extracellular secretion of acetylated-APE1/Ref-1 (Ac-APE1/Ref-1) and initiated apoptotic cell death by auto-, paracrine binding to the receptor for advanced glycation end products (RAGE). In the present study, we observed potential therapeutic efficacy of Ac-APE1/Ref-1 in preclinical orthotopic models of TNBC in response to hyperacetylation. The extracellular Ac-APE1/Ref-1 was confirmed by proximity ligation assay in lungs of orthotopic tumor tissue, showing direct binding of Ac-APE1/Ref-1 and RAGE. Treatment of orthotopic TNBC xenografts with acetylating agents induced a strong growth inhibition in the tumor development as observed in computed tomography: it caused an increase of RAGE expression and activation of caspase-3 and PARP. The tumors also exhibited markedly higher count of apoptotic bodies and reduced proliferation index and neovascularization compared with controls. However, Ac-APE1/Ref-1-stimulated apoptotic cell death was remarkably retarded in RAGE knockout tumors even in hyperacetylation compared with RAGE-overexpressed one. The functional role of secreted Ac-APE1/Ref-1 in hyperacetylated TNBC was confirmed in vivo, demonstrating its relevance to the anticancer agent. Our findings suggest that Ac-APE1/Ref-1 protein possesses potent chemotherapeutic efficacy against TNBC, resistant to standard chemotherapeutic agents, warranting further evaluation as an anticancer agent.

#2118 Distinct molecular effects of chemotherapeutic agents on choline phospholipid metabolism of triple-negative breast cancer cells. Menglin Cheng, Zayer M. Bhujwalla, Kristine Glunde, Johns Hopkins University School of Medicine, Baltimore, MD.

The magnetic resonance spectroscopy (MRS)-detected total choline (tCho) signal is a promising non-invasive surrogate marker able to predict chemotherapeutic response in breast cancer patients early on. However, the molecular mechanisms underlying the choline-phospholipid changes are mostly unknown. Here we have employed some widely used cancer chemotherapy drugs such as doxorubicin, paclitaxel, and vinorelbine to treat triple-negative human MDA-MB-231 breast cancer cells to elucidate their molecular effects on choline phospholipid metabolism. High-resolution 1H MRS of water-soluble cell extracts was employed to detect changes to their molecular effects on choline phospholipid metabolism. High-resolution 1H MRS of water-soluble cell extracts was employed to detect changes in the choline metabolite profiles, and quantitative RT-PCR (qRT-PCR) to assess the corresponding changes in the expression levels of choline metabolizing enzymes. After 48 hours of doxorubicin treatment, the GPC levels in MDA-MB-231 cells significantly increased, while PC level decreased, and the tCho concentration remained unchanged. Vinorelbine treatment displayed a comparable effect to doxorubicin, but the GPC increase and PC decrease occurred to a lesser extent. Paclitaxel treatment caused an increased GPC level along with an unaltered PC level, leading to a slightly increased tCho level. In all these cases, the PC/GPC ratio decreased from 3.5 in the control to about 2.0 in paclitaxel- or vinorelbine-treated samples, to about 1.0 in doxorubicin-treated samples. qRT-PCR-detected mRNA expression levels showed that GDPD6 and Chk1 genes were downregulated by doxorubicin, GDPD5, GDPD6, and Chk1 genes displayed a reduced mRNA expression level following vinorelbine treatment, while no significant change in these three genes was detected after paclitaxel treatment. For comparison, the known GDPD6 inhibitor dipryridamole significantly increased cellular GPC levels, but, as expected, did not affect GDPD6 mRNA expression levels as it acts as an enzyme inhibitor. Our study demonstrates that choline-dependent metabolic pathways are sensitive to the type of drug used for breast cancer treatment. However, all tested chemotherapeutic treatments resulted in metabolic alteration away from the ‘cholinic phenotype’, which was caused in some cases by decreases in expression of Chk1, GDPD6, and GDPD5 following drug treatment. The choline metabolite concentrations of GPC and/or

#2119 Acetylated secretory APE1/Ref-1 induces apoptotic cell death in orthotopic xenografts of triple-negative breast cancer. Yu Ban Lee, 1Hee Kyung Joo, 1Eun Ok Lee, 1Myoung Soo Park, 2Byeong Hwa Jeon, 1Sunga Cho1.
Chungnam National University College of Medicine, Daejeon, Republic of Korea; 1Chungnam National University Hospital, Daejeon, Republic of Korea; 2Chungnam National University, Daejeon, Republic of Korea.

The anticancer properties of acetylated secretory apurinic/apyrimidinic endonuclease-1 (APE1/Ref-1) was suggested in triple-negative breast cancer (TNBC) cells; Posttranslational modification, hyperacetylation in MDA-MB-231 cells and extracellular secretion of acetylated-APE1/Ref-1 (Ac-APE1/Ref-1) and initiated apoptotic cell death by auto-, paracrine binding to the receptor for advanced glycation end products (RAGE). In the present study, we observed potential therapeutic efficacy of Ac-APE1/Ref-1 in preclinical orthotopic models of TNBC in response to hyperacetylation. The extracellular Ac-APE1/Ref-1 was confirmed by proximity ligation assay in lungs of orthotopic tumor tissue, showing direct binding of Ac-APE1/Ref-1 and RAGE. Treatment of orthotopic TNBC xenografts with acetylating agents induced a strong growth inhibition in the tumor development as observed in computed tomography: it caused an increase of RAGE expression and activation of caspase-3 and PARP. The tumors also exhibited markedly higher count of apoptotic bodies and reduced proliferation index and neovascularization compared with controls. Moreover, the Ac-APE1/Ref-1-stimulated apoptotic cell death was remarkably retarded in RAGE knock out tumor even in hyperacetylation compared with RAGE-overexpressed one. The functional role of secreted Ac-APE1/Ref-1 in hyperacetylated TNBC was confirmed in vivo, demonstrating its relevance to the anticancer agent. Our findings suggest that Ac-APE1/Ref-1 protein possesses potent chemotherapeutic efficacy against TNBC, resistant to standard chemotherapeutic agents, warranting further evaluation as an anticancer agent.

#2120 Potassium bromate prevents growth and progression phenotypes such as migration, invasion and sphere-forming ability of breast cancer cells. Priyanka Ghosh, Gargi Maity, Snigdha Banerjee, Sushanta Banerjee, Ung Joo,1 Eun Ok Lee,1 Myoung Soo Park,2 Byeong Hwa Jeon,1 Sunga Choi.1 Chonnam National University, Daejeon, Republic of Korea; 1Chonnam National University Hospital, Daejeon, Republic of Korea.

Potassium bromate (KBrO3) is by-product of ozone that has found multi-functional purpose in modern society. It is used as disinfectant in drinking water, a bleaching agent to improve flour, a component of cold-wave hair lotion and an ingredient in the production of fish paste and fermented beverages. Potassium bromate has also been used in America for bread-baking as a safe food additive since 1914. Despite the commercial value of this chemical, some studies suggest that KBrO3 is a carcinogen. During the bread-baking process, Potassium bromate is normally converted into a stable and inert compound, potassium bromide (KBr). However, due to incomplete reduction, the residual KBrO3 remains in the bread, which eventually acts as a potential carcinogen to humans. Interestingly, our studies, in breast cancer cells, found contrasting results. We found that KBrO3 delays growth of ER-negative human MDA-MB-231 breast cancer cells caused insome cases by decreases in expression of Chk1, while exhibiting minimal toxicity to normal breast cancer cells independent of p53, while exhibiting minimal toxicity to normal breast cancer cells. Despite this, a majority of breast cancers display resistance to KBrO3-treatment via targeting multiple molecular signatures in breast cancer cells. The growth inhibition effect of KBrO3 is also documented in a tumor xenograft model. Collectively, our findings provide a rationale for the basic and pre-clinical evaluation of the role of KBrO3 in breast cancer progression and therapy.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Mechanism of Drug Action

#2116 The food additive agent potassium bromate prevents growth and aggressiveness phenotypes by targeting multiple molecular signatures in breast cancer cells. Priyanka Ghosh, Gargi Maity, Snigdha Banerjee, Sushanta Banerjee. VA Medical Center, Kansas City, MO.

Potassium bromate (KBrO3) is by-product of ozone that has found multi-functional purpose in modern society. It is used as disinfectant in drinking water, a bleaching agent to improve flour, a component of cold-wave hair lotion and an ingredient in the production of fish paste and fermented beverages. Potassium bromate has also been used in America for bread-baking as a safe food additive since 1914. Despite the commercial value of this chemical, some studies suggest that KBrO3 could be a carcinogen. During the bread-baking process, Potassium bromate is normally converted into a stable and inert compound, potassium bromide (KBr). However, due to incomplete reduction, the residual KBrO3 remains in the bread, which eventually acts as a potential carcinogen to humans. Interestingly, our studies, in breast cancer cells, found contrasting results. We found that KBrO3 delays growth of ER-negative human breast cancer cells and triple-negative breast cancer cells (TNBC) via inducing apoptosis in a dose-dependent manner. KBrO3-induced apoptosis is mediated via targeting BCL-2/Bax and Caspase-3 signaling pathway. Moreover, aggressive phenotypes such as migration, invasion and sphere-forming ability of breast cancer cells are significantly impaired by KBrO3-treatment via targeting multiple molecular signatures in breast cancer cells. The growth inhibition effect of KBrO3 is also documented in a tumor xenograft model. Collectively, our findings provide a rationale for the basic and pre-clinical evaluation of the role of KBrO3 in breast cancer progression and therapy.
PC and/or the PC/GPC ratio may serve as non-invasive surrogates of therapeutic response in triple-negative breast cancer patients undergoing chemotherapy.

#2121 Deguelin-derivative, L80 suppresses tumor growth and metastasis via inhibition of STAT3 activation in triple-negative breast cancer. Tae-Min Cho, Eunhye Oh, Daeil Sung, Yoon-Jae Kim, Ji Young Kim, Jeewoo Lee, Jae Hong Seo. Korea University, Seoul, Republic of Korea.

Triple-negative breast cancer TNBC is associated with aggressive metastasis and poor clinical outcomes due to a lack of effective treatment options. Therefore, new drugs that effectively target both cancer cell proliferation and metastasis are needed to improve clinical outcomes. The 90-kDa molecular chaperone heat-shock protein, HSP90 has been implicated in cancer progression and metastasis by modulating the stabilization and maturation of many oncoproteins. Our objective was to investigate the mechanism of action of C-terminal HSP90 inhibitor, deguelin-derivative L80 on TNBC proliferation and metastasis in vitro and in vivo. L80 induced apoptosis and suppression of cell viability in TNBC cell lines via inhibition of Akt activation with concomitant nuclear accumulation of p27. L80 treatment also caused a marked suppression of cell migration and invasion. These responses were associated with inhibition of STAT3 phosphorylation (Tyr705) as evidenced by downregulation of STAT3 downstream target genes including cyclin D1 and survivin. The synergetic orthotopic mouse model with 4T1 cells, L80 administration resulted in significant reduction in tumor growth together with decreased number of Ki-67-positive cells and downregulation of phospho-STAT3. Double-label immunofluorescence analysis revealed that L80 inhibited a cell population co-localization and expression of HIF-1α and HSP90 compared to their control groups in vivo. Finally, we observed that L80 administration significantly suppressed lung metastasis, as determined by in vivo bioluminescent imaging system. Our findings suggest that L80 may be potentially effective for the treatment for metastatic TNBC patients.

#2122 Pharmacologic interconversion of EMT to MET for prostate cancer. Zheng Cao,1 Shahriar Koochekpour,2 Stephen E. Strup,1 Natasha Kyprianou.1 1University of Kentucky Medical Center, Lexington, KY; 2Roswell Park Cancer Institute, Buffalo, NY.

Introduction and objection: Dysregulation of transforming growth factor-β (TGF-β) and insulin-like growth factor (IGF) axis has been linked to reactive stroma dynamics in the tumor microenvironment during prostate cancer progression. IGFBP3 induction is initiated by stroma remodeling and represents a potential therapeutic target for advanced prostate cancer. A lead quinazoline-based Doxazosin® derivative, DZ-50, generated in our laboratory (US Patent #7377948), inhibits prostate tumor growth via inducing anoikis and disrupting focal adhesions. Molecular profiling revealed that the process of epithelial-mesenchymal transition (EMT) is targetable by DZ-50. In this study, we investigated the effect of DZ-50 on EMT landscape, EMT to mesenchymal-epithelial-transition (MET) conversion, and invasive properties of prostate cancer cells. Methods: Human prostate cancer cells LNCaP, LNCaP overexpressing TGF-β type II receptor (TβRII), and cancer associated fibroblasts (CAFs) derived from human prostate cancer specimens, were used. The antimorphic effect of DZ-50 against prostate cancer cells and CAFs with and without TGF-β receptor (TβRI) was investigated. Effect of the drug on EMT key regulators (including IGFBP3) was determined using RT-PCR and Western blot analysis. Drug-induced phenotypic conversions of EMT were evaluated by confocal microscopy. Impact of TGF-β from the stroma microenvironment or exogenous cytokine, on prostate tumor cell migration and invasion, was assessed in co-cultures with CAFs. The functional contribution of IGFBP3 to EMT-MET interconversion in response to DZ-50 was assessed using siRNA approaches. Results: DZ-50 induced cell death in prostate cancer epithelial cells and CAFs, in a concentration-dependent manner. DZ-50 downregulated IGFBP3 mRNA and protein expression and promoted MET-MET conversion in both LNCaP and LNCaP/TβRII cells. IGFBP3 knockdown in LNCaP/TβRII cells led to E-cadherin upregulation and MET induction, implicating IGFBP3 as a potential target of DZ-50 to reverse EMT to MET. Moreover, exposure to TGF-β reversed DZ-50-induced MET by upregulating IGFBP3 in LNCaP/TβRII cells. Co-cultures of LNCaP/TβRII cells with CAFs promoted prostate cancer cell invasion via TGF-β and IGFBP3, an effect that was inhibited by the drug. Conclusions: Treatment of prostate cancer cells with the novel agent DZ-50 inhibits cell migration and invasion and causes reversal of EMT to MET by regulating IGFBP3. Our study integrates IGFBP3 as new signaling effector driving the antimorphic action of DZ-50 via targeting the EMT-MET phenotypic landscape in the prostate tumor microenvironment. Ongoing work in pre-clinical models will establish the therapeutic value of this novel compound in advanced metastatic prostate cancer.

#2123 Inhibition of AURKA induces Raf1-independent activation of MAPK pathway in breast cancer cells. Malgorzata Gil,1 Archana Chandrakarma,1 Thaer Khoury,2 Kazuaki Takabe,1 Igor Puzanov,1 Irwin Gelman,1 Antonio D’Assoro,2 Mateusz Oprychal,1 Roswell Park Cancer Institute, Buffalo, NY; 2Mayo Clinic College of Medicine, Rochester, MN.

Aurora A (AURKA) is a mitotic kinase responsible for centromere segregation and mitotic spindle formation. In normal cells, expression of AURKA is highly regulated and is predominantly restricted to G2/M phases of the cell cycle. Unlike healthy cells, cancer cells overexpress AURKA through all phases of the cell cycle resulting in the acquisition of alternate non-mitotic functions. Little is known about cellular functions regulated by AURKA and its interaction with other signaling molecules. Here, we report a novel interaction between AURKA and the mitogen-activated protein kinase (MAPK) pathway in wild type BRAF breast cancer cells as well as demonstrate an additive cytotoxic effect of AURKA- and MEK1/2-specific inhibitors against estrogen positive (ER+) and triple negative (ER−, PR−, HER2+) breast cancer cells. Results: We show that treatment of ER− HER2+ MCF-7, ER− HER2+, SKBR3 and ER− HER2+ BT549 cells with AURKA specific inhibitors alisertib, MK8745 and Aurora A Inhibitor I resulted in over 2-fold increase in the levels of both pMEK1/2 and pERK1/2 compared to the untreated controls. The activation of the MAPK pathway was rapid with changes seen within 5 min after treatment with AURKA inhibitors and was sustained for at least 48 hours. No differences in phosphorylation of MEK1/2 or ERK1/2 were observed in BRAFV600E triple negative MDAMB231 cells. Treatment with AURKA inhibitor resulted in significant re-expression of PAK1 and a significant increase in levels of total AURKA protein. The pull-down assay with Ras-binding domain coated agarose beads followed by western blot analysis with anti-pan-Ras Ab revealed no changes in active GTP-bound Ras in alisertib-treated MCF-7 cells compared to the untreated control. Consistently, no significant changes were observed in Ras-inducible phosphorylation of RAF1 activation site at Ser338 as demonstrated by western blot. Treatment with the pan RAF inhibitor TAK-632 did not diminish alisertib-induced pERK and pMEK1/2. Alternatively, treatment with the MEK1/2 specific inhibitor PD0325901 completely abrogated alisertib-induced phosphorylation of MEK1/2 and ERK1/2. Furthermore, combined treatment of alisertib and PD0325901 in vitro revealed significant additive cytotoxic effect in MCF-7 and BT549 cells when compared to either agent used alone (p<0.008 and p<0.011; <0.004 and p<0.028). Conclusions: Our data suggests that AURKA is a RAF1-independent negative regulator of MAPK activity in breast cancer cells. The in-depth analysis of the AURKA-MEK1/2 interaction is currently under investigation. The results reveal a promising new strategy for the treatment of wild type BRAF, TNBC patients using a combination of AURKA and MEK1/2 inhibitors.

#2124 Differentiation of myeloid and multiple myeloma cell lines by inecalcitol involves a marked decrease in CD44 and CD49d cell surface labeling. Susan Benjamin, Cecilie Planquette, Remi Delansorne. Hybrigenics, Paris, France.

Inecalcitol is a vitamin D receptor (VDR) agonist characterized by a high antiproliferative activity on various cancer cell lines (Okamoto et al., 2012; Ma et al., 2013) and a low calcemic potential as demonstrated by the high maximal antiproliferative activity on various cancer cell lines (Okamoto et al., 2012; Ma et al., 2013) and a low calcemic potential as demonstrated by the high maximal antiproliferative activity on various cancer cell lines (Okamoto et al., 2012; Ma et al., 2013). In addition, recent studies revealed that inecalcitol reproducibly induces CD38 expression (Wang et al., 2004). During a screening of 48 CD biomarkers on 4 human myeloid cell lines (HL-60, U-937, MOLM-13 and THP1) and 4 human multiple myeloma cell lines (MM.1R, MM.1S, L-363 and RPMI-8226) treated for 72 hours at 10 nM, we recently discovered that inecalcitol reproducibly induces CD38 expression (Benjamin et al., 2016), another gain of function. We now report the decrease in CD44 and CD49d cell surface labeling mostly in non-mitotic cell lines (Benjamin et al., 2016). In this study we investigated the effect of inecalcitol on CD44 expression in all 8 cell lines (except CD44 in L-363 cells). This decrease in CD44 expression was observable by flow cytometry after 72 hours of treatment with 10 nM inecalcitol. CD44 is the receptor for hyaluronic acid; it is found on the surface of acute myeloid leukemia stem cells and suspected to favor the spread and relapse of the disease. CD44 is
the integrin αv-subunit involved in the interactions of tumor cells with their microenvironment resulting in their "hiding" and survival. Therefore, decreasing both CD44 and CD49d represents a newly identified potential beneficial pro- 
differentiation effects of ineocalcit." 

#2125 Flavokawain A, a kava chalcone, inhibits growth and invasion of human osteosarcoma cells by targeting Skp2. Yidan Zhang,1 Wendong Zhang,2 Nikolai Zaphiros,2 Xiuquan Du,2 Pratibha Koirala,1 Michael Roth,1 Jonathan Gill,3 Sajda Papideri,1 David Geller,1 Rui Yang,1 Jinhong Zhang,1 Richard Gorlick,1 Xiaolin Zi,3 Tao Ji,4 Bang H. Hoang1.

Purpose: Osteosarcoma (OS) is the most common primary bone malignancy with a high propensity for local invasion and distant metastasis. Flavokawain A (FKA), a major chalcone from kava extract, has been reported to have antitumor effects on multiple cancer cell lines. The consumption of kava-containing beverage has been associated with a low cancer incidence. In a previous report, mice treated with high-dose FKA did not demonstrate any significant major organ toxicity. However, the efficacy and antitumor mechanisms of FKA in OS is still to be elucidated. Experimental Design: OS cell lines were treated with increasing dosage of FKA and tested for cell motility, proliferation, and invasion by Matrigel assay and Matrigel invasion assay. Cell cycle analysis was performed using flow cytometry. We examined Skp2 expression in several OS cell lines using western blot and in patient tissue array by immunostaining. Kaplan-meier analysis and log rank test were used to compare overall survival. Both Skp2-dependent cell cycle progression and Skp2-related RhoA expression were also examined after FKA treatment. The effects of FKA on lung metastasis were evaluated after orthotopic injection of OS cells into the tibia. Results: We show that FKA inhibits its growth and motility of multiple OS cell lines in vitro. Flow cytometry analysis confirms cellular apoptosis and arrest in G2/M phase after FKA treatment, whereas cellular invasion is also inhibited in a dose-dependent manner. Skp2 is expressed in several OS cell lines and is associated with a poor prognosis in OS patients. Skp2 levels in OS cell lines decreased after FKA treatment. The expression of cell cycle regulators including p21 and p27, which are downstream of Skp2, was upregulated. Moreover, Skp2-related RhoA expression is inhibited by FKA and confirmed at protein level. Conclusions: Taken together, the evidence suggests FKA exerts anti-invasive effects in association with Skp2-dependent cell cycle progression and Skp2-related RhoA expression. Since Skp2 is a negative regulator of RhoA and may be an important factor for OS patients, FKA should be investigated further as an alternative therapeutic strategy for OS.

#2126 CA102N, a conjugate of hyaluronic acid (ha) and Nimuselide derivative (H-Nim) interferes with PI3K/Akt/mTOR signaling pathway in colorectal cancer (CRC) cells and inhibits tumor growth in vivo. Esokhie H. Tchaparian, Louis Lin. Holy Stone Healthcare Co., Ltd., Taipei, Taiwan.

Aberrant PI3K/Akt/mTOR signaling pathway is common in several human cancers, including CRC. The pathway regulates many major cellular processes and promotes tumorigenesis and inhibition of apoptosis. Targeting the PI3K/Akt/mTOR network could be important in resistance mechanisms in cancer. CA102N, a conjugate of Hyaluronic Acid (HA) and H-Nim, a nimuselide (COX-2 inhibitor) derivative, currently under investigation for preclinical development in CRC. Studies have suggested that the anti-proliferative effects of COX-2 inhibitors could be attributed to modulation of the PI3K/Akt signaling pathway; therefore, in this study we aimed to examine the overall molecular mechanism of the antitumor activity of CA102N and evaluate its impact on the PI3K pathway proteins. Cell based studies indicated that in addition to cell cycle arrest; the antitumor activity of CA102N is also related to apoptosis. Administration of CA102N to nude mice bearing established HT29 subcutaneous tumor xenografts caused significant tumor growth inhibition with no signs of systemic toxicity. Immunohistochemical analyses of xenograft tumors demonstrated inhibition of VEGFR2 and VEGF expression in CA102N-treated tumors. Disruption of angiogenesis and apoptosis was correlated with a decrease in VEGF and the antiangiopotic protein BCL-2. Suppression of PI3K downstream signaling was a key observation in HT29 cells in vitro and in xenograft tumors treated with CA102N. As compared to untreated vehicle control, a significant decrease in phosphorylation of Akt, mTOR, p70S6K, 4EBP1 and FOXO1 was detected by Western blot analyses. The reduction in PI3K activity observed may be caused by both specific protein dephosphorylation/deactivation and by ubiquitin-mediated proteasomal degradation of pathway proteins. These results suggest that the antitumor activity of CA102N may be at least partly related to the modulation of the PI3K/Akt pathways. CA102N represents a promising antitumor agent with minimal toxicity, the insights provided into the mechanisms of its antitumor activity may be the basis for advancing this candidate into clinic.

#2127 p53-independent Noxa induction by cisplatin is regulated by AT3/F  
ATF4 in HNSCC cells. Kanika Sharma,2 Thien-Trang Vu,1 Mitra Naseri,1 Wa-taru Nakajima,2 Kevin Zhan,1 Hisashi Harada1. 1 VCU Massey Cancer Ctr., Richmond, VA; 2Nippon Medical School, Tokyo, Japan.

Head and neck cancer is the sixth leading cancer worldwide and head and neck squamous cell carcinoma (HNSCC) accounts for more than 90% of incid- 
cent cases. The long-term prognosis of patients with advanced HNSCC has shown little improvement over the last three decades. Induction chemotherapy with platinum-based compounds, taxanes, and 5-fluouracil is beneficial for head and neck cancer patients, but the prolonged use of chemotherapeutic drugs is limited by their toxicity and by the development of resistance. Tumor cell death induced by both conventional and targeted chemotherapy is often medi- ated by the BCL-2 family-dependent mitochondrial apoptotic pathway. How- ever, initiators of this apoptotic pathway, such as p53, are frequently mutated or deleted in HNSCC rendering it refractory to treatment. To counter such resis- tance, direct therapeutic targeting of the BCL-2 family is conceptually appealing. We have investigated the cytotoxic effects of a DNA damaging agent, cisplatin that is used for a standard therapy for locally advanced HNSCC. Cisplatin produces antitumor effects mainly by generating DNA lesions and activating DNA damage response followed by inducing BCL-2 family-dependent mitochondrial apoptosis. In this study, we aimed to evaluate the potential of AT3/FATF4 regulation in cisplatin-induced apoptosis in p53-independent HNSCC cells. AT3/FATF4 induction was regulated at the tran- scriptional level. Thus, we examined the regulation of the Noxa promoter with a series of luciferase reporter assays. We found that the CRE (cAMP responsive element located at -66 to -59 from the transcription start site) on the promoter plays a critical role in Noxa induction. The CRE is known to be regulated by ATF4/CREB transcription factors. Downregulation of AT3/FATF4 by shRNAs clearly reduced Noxa induction. Furthermore, the binding of these transcription factors to the CRE on the Noxa promoter was increased by cisplatin treatment, determined by chromatin-immunoprecipitation assays. In conclusion, AT3 and FATF4 are important regulators for cisplatin-induced Noxa in a p53-independent pathway. The results suggest that modulation of the signaling pathways that activate AT3/FATF4 could be an alternative approach to induce Noxa follow- ed by apoptosis in HNSCC.
Assessing the efficacy of targeting mitochondrial respiration in delaying lung tumor growth by using subcutaneous xenografts in mouse models. Sarada Preeta Kalainayakan, Poorva Ghosh, Sanchareeka Dey, Li Zhang. UT Dallas, Richardson, TX.

Previously, studies have focused mainly on the precept that tumors depend on glycolytic metabolism for growth (Warburg effect). However, such tumors might be dysfunctional in cancer cells. Here, we demonstrate that some cancer cells exhibit elevated mitochondrial respiration. Recent studies in our lab have demonstrated that Non-Small Cell Lung Cancer (NSCLC) cells exhibit intensified mitochondrial respiration and oxygen consumption. We further demonstrated that targeting increased mitochondrial respiration by a therapeutic agent facilitates the proliferation and survival of cancer cells. The results showed that Tan-IIA can induce the proliferation inhibition with time and dose dependent and inhibit the activity of the Ras/Raf/MEK/ERK and Ras/PI3K/Akt/mTOR pathways. The use of Tan-IIA for breast cancer may become a feasible novel therapy option. Further studies are warranted to elucidate its mechanisms fully.

Natural products are important sources for bioactive molecules, which have been developed to treat various human health-related symptoms. In our continuous efforts to search for anticancer agents from natural sources, Psammaplin A (PsA), isolated from marine natural products, was found to be a potential candidate in the growth inhibition of cancer cells. PsA, a unique symmetrical bromotyrosine contained in a number of marine sponges of the order Verongida, has exhibited a variety of bioactivities including antimicrobial activity, cytotoxicity against the leukemia cell line, and inhibitory activity of DNA gyrase and DNA topoisomerase. PsA is also known to be a potent inhibitor of DNA methyltransferase and histone deacetylase with growth-inhibitory activity of cancer cells. However, its underlying mechanism of action and the structure-activity relationship (SAR) with PsA analogs have not been elucidated yet. In the present study, twenty-eight synthetic analogs of PsA were newly synthesized and examined the potential of cytotoxicity against cancer cells. A SAR study revealed that the presence of free oxime and disulfide functional groups was responsible for high cytotoxicity. Furthermore, the bromotyrosine component in PsA was relatively tolerable and hydrophobic aromatic groups preserved the cytotoxicity. The aromatic groups were dependent on their size and spatial geometry. Among them, a β-naphthyl derivative of PsA showed a potential cytotoxicity and was comparable to that of PsA. The compound also exhibited a potential antitumor activity in a nude mouse xenograft model. These findings indicated that free oxime and disulfide linker in the chemical structure play an important role for cytotoxicity and PsA analogs might be provided as potential antitumor agents. This work was supported by the National Research Foundation of Korea (NRF) Grant funded by the Korean Government (MEST) (NRF-2016M3A9B6093499) and also supported by a National Research Foundation of Korea (NRF) Grant funded by the Korean Government (MEST) (No.2009-0083533).

Tanshinone IIA can decrease growth factor receptors expression and dural-block both Ras/Raf/MEK/ERK and Ras/PI3K/Akt/mTOR pathways to inhibit human breast cancer BT-20 cells. Chin Cheng Su. Changhua Christian Hospital, Changhua City, Taiwan.

Background: Tanshinone IIA (Tan-IIA, C19H18O3) with anti-inflammatory activities and antioxidant properties, is one of the diterpine quinones extracted from Salvia miltiorrhiza radix (Danshen). Tan-IIA can inhibit many human cancer cell lines through different molecular mechanisms. The phosphoinositide-3-kinase (PI3K)/Akt/ mammalian target of rapamycin (mTOR) and Ras/RAF/MEK/ERK pathways are two of the most frequently dysregulated kinase cascades in human cancer. Transmembrane tyrosine kinase has been strongly implicated in the proliferation, survival, and metastasis of human tumors. Both pathways represent important signal transduction pathways that facilitate the proliferation and survival of cancer cells driven by growth factor receptors, such as vascular endothelial growth factor receptor (VEGFR), insulin-like growth factor-I receptor (IGF-IR), or epidermal growth factor receptor (EGFR). Targeting both the Ras/Raf/MEK/ERK and Ras/PI3K/Akt/mTOR Pathways for suppressing inhibitor resistant cells is necessary because the individual downstream components of these signaling cascades through epigenetic modification or somatic mutation are also known to be frequently altered in cancer, thus contributing to resistance to anticancer therapies and tumorigenesis. Material and methods: In the present study, the human breast cancer BT-20 cells were treated with Tan-IIA in vitro. The cytotoxicity of Tan-IIA was evaluated by MTT assay. The effects of Tan-IIA on the protein expressions of EGFR, IGF-IR, VEGFR, PI3K, Akt, mTOR, Ras, Raf, MEK and ERK and β-actin in the BT-20 cells were examined by western blot analysis. Results: The results showed that Tan-IIA can induce the proliferation inhibition with time and dose dependent and inhibit the activity of the Ras/Raf/MEK/ERK and Ras/PI3K/Akt/mTOR pathways. In addition, it was showed that Tan-IIA treatment inhibited the protein expression levels of EGFR, VEGFR and IGF-IR significantly. Conclusion: This study indicated that one of the molecular mechanisms for Tan-IIA to inhibit BT-20 cells maybe through inhibiting the protein expression levels of EGFR, VEGFR, IGF-IR and both Ras/Raf/MEK/ERK and Ras/PI3K/Akt/mTOR pathways. The use of Tan-IIA for breast cancer may become a feasible novel therapy option. Further studies are warranted to elucidate its mechanisms fully.
growth inhibition with curcumin in a xenograft model of human castrate resistant PCa cells. Collectively, enzyme-mediated depletion of serum Cys and CysC pool suppresses the growth of prostate tumors, and is very well tolerated. These results suggest that cyst(e)ine inase represents a potentially safe and effective therapeutic modality as a single agent or in combination for the treatment of prostate and possibly other cancers.

**#2133 Pre-clinical studies of EC2629, a highly potent FR targeted DNA crosslinking agent.** Joseph A. Reddy, Melissa Nelson, Christina Dircksen, The resa Johnson, Marilyn Vetzl, Spencer Hahn, Longwu Qi, Iontcho Vlahov, Christopher Leamon. Endocyte, Inc., West Lafayette, IN.

Folate receptor (FR) targeted small molecule drug conjugates (SMDCs) have shown promising results in early stage clinical trials with vintafolide and EC1456. In our effort to develop FR targeted SMDCs with varying mechanisms of action, we have now built EC2629, a folate conjugate of a DNA crosslinking agent based on a novel DNA-alkylating moiety. This agent was found to be extremely potent with an in vitro IC50 shown promising results in early stage clinical trials with vintafolide and EC1456. In our effort to develop FR targeted SMDCs with varying mechanisms of action, we have now built EC2629, a folate conjugate of a DNA crosslinking agent based on a novel DNA-alkylating moiety. **#2134 Use of methionine gamma-lyase-loaded erythrocytes to induce effective methionine depletion in cancer therapy.** Fabien Gay,1 Karine Aguer,2 Karine Senchel,3 Philip Lorenzi,1 Alexander Scheer,1 François Horand,1 Vanessa Bourgeaux1. 1 ERYTECH Pharma, Lyon, France; 2 MD Anderson Cancer Center, Houston, TX.

Methionine (Met) dependence is a cancer-specific metabolic defect that has emerged as a target during the last two decades. The use of methionine gammalyase (MGL; EC number 4.4.1.1), a bacterial Met-catabolizing enzyme, is a promising strategy for treatment of Met-dependent cancers. However, one challenge is that MGL has a very short half-life (~2 hours), resulting in a short-term Met depletion in vivo. Additionally, its cofactor, pyridoxal 5’-phosphate (PLP) is rapidly eliminated from plasma (Yang et al., 2004). MGL-lyase extends the MGL half-life in mice to up to 38 hours. Nevertheless, frequent injections are still necessary for maintaining an effective Met depletion over time (Sun et al., 2003). In addition, the low bioavailability of PLP remains a major hurdle due to both scavenging by plasma proteins and very short half-life (~15 minutes) in the blood stream (Zeppenfeld, 1995). Studies showed that pyridoxine (PN), a vitamin B6 vitamin, can easily cross red blood cells (RBCs) membrane to be rapidly converted to PLP via an enzymatic reactions cascade (Anderson et al., 1971). Considering those particular characteristics of RBCs, we propose that RBC-encapsulated MGL (ERY-MET) will protect the enzyme from degradation/immune reactions and therefore overcome the pharmacodynamic limitations for its use in the treatment of Met-dependent cancers. Pharmacokinetics, pharmacodynamics, and safety parameters of MGL-loaded RBCs were evaluated in healthy mice. In parallel, the role of RBC in PLP biosynthesis from exogenous uptake of PN was investigated in vivo. Finally, we investigated the antitumoral effect of repeated injections of MGL-loaded RBCs combined with daily intragastric administration of PN in two subcutaneous xenografted mouse models for human gastric and glioblastoma tumors. The MGL half-life increased from ~24 hours to ~10 days when encapsulated in RBC, with no toxicity reported after one injection of ERY-MET. Following intragastric administration (3.2 mg/kg), PN was rapidly (15 minutes) converted into PTP within the RBC, resulting in an increase of MGL activity (holoenzyme). Combining a weekly single intravenous injection of ERY-MET for 5 days, in association with daily PN supplementation by gavage led to a sustained Met depletion in plasma and induced a 85% inhibition of tumor growth 45 days following implantation of glioblastoma cells. In the gastric mouse model, tumor growth was inhibited by 72% at the same time point (45 days). This study clearly demonstrated that encapsulation of MGL in erythrocytes both strongly improved the half-life and contributed to provide active cofactor. In parallel, repeated injections of ERY-MET were effective against tumor growth in mouse models. Thus, due to the RBC intrinsic characteristics, ERY-MET represents a new promising treatment against a broad scope of cancers that rely on Met metabolism.

**#2135 Selectivity and specificity of engineered T cells expressing KITE-585, a chimeric antigen receptor targeting B-cell maturation antigen (BCMA).** Gregor B. Adams, Jun Feng, Atfeh Ghougha, Armen Mardiros, Ruben Rodriguez, Tassja J. Spindler, Jed Wiltzius, Tony Polyverino. Kite Pharma, Santa Monica, CA.

Background: Immunotherapy has provided treatment options for cancers that are otherwise refractory to standard approaches. One such technique is to use adoptive transfer of engineered autologous T cells expressing a chimeric antigen receptor (CAR) directed against a tumor antigen. The efficacy of CAR T cells directed against hematological malignancies, particularly CD19-expressing B cell leukemia and lymphomas, has been demonstrated in multiple clinical studies. The success of this approach has prompted development of CAR T cells directed to different tumor antigens for other tumor types. To ensure the selectivity and specificity of the CAR T cells against their intended target, screening methods need to be employed. Multiple myeloma is an incurable malignancy of plasma cells. B-cell maturation antigen (BCMA), also known as tumor necrosis factor superfamily member 17 (TNFRSF17) is nearly ubiquitously expressed on multiple myeloma cells, plasma cells and subsets of mature B cells. Methods: In order to screen for the specificity of novel CAR T cells directed against BCMA, we utilized a cell microarray platform developed by Retrogenix. In this screen, approximately 4500 human plasma membrane proteins (representing up to 75% of the human plasma membrane proteome) are individually expressed in human HEK293 cells. Fluorescently labeled CAR T cells, which showed cytolytic activity against MM cell lines expressing BCMA, were applied to the cell microarray and specific binding of the CAR T cells to target cells was determined. Results: Primary hits were sequenced to confirm identity and secondary specificity screens were performed on the identified hits. Specific binding of both mock transduced and BCMA CAR transduced T cells were confirmed for different plasma membrane proteins expressed from the HEK293 cells. These included known T cell interactors, such as ICOSLG, CD244 and CD86, where binding is proposed to be independent of CAR expression. Subtraction of the hits the mock transduced T cells from the BCMA CAR T cells demonstrated specific binding of the CAR T cells to BCMA. Utilizing the fully human IgGs directed against BCMA from which the single-chain variable fragments (scFv)s of the CARs were derived, we further confirmed specific binding to BCMA in additional secondary screens. Additionally, a lack of off-target binding of the fully human IgGs to normal tissue was demonstrated in a tissue cross reactivity screen. Conclusions: These studies highlight the tractability of this cell microarray approach for determining the specificity of novel CAR constructs expressed in T cell. Demonstrating the selectivity and specificity of anti-BCMA CAR T cells further supports the progression of KITE-585 towards Phase 1 clinical studies in MM patients.

**#2136 Inhibiting cancer growth by targeting the TNFR2 oncogene with TNFR2 antagonistic antibodies.** Heather Torrey, John Butterworth, Yoshiyuki Mera, Yoshiaki Okubo, Limei Wang, Danielle Baum, Audrey Defusco, Sara Plager, Sarah Warden, Daniel Huang, Eva Vannamee, Rosemary Foster, Denise L. Fastman. Massachusetts General Hospital & Harvard Medical, Charlestown, MA.

Background: Although antibody targeting of the HER2 oncogene represents an outstanding clinical treatment and a success story showing direct cancer killing with antibodies, many oncoproteins are intracellular and are not expressed broadly, whether on a single or multiple tumor types. The recently discovered TNFR2 oncogene is broadly expressed on many human tumors. Colon cancer cells, multiple myeloma cells, renal cell carcinoma cells, Hodgkin’s lymphoma cells, ovarian cancer epithelial cells and cutaneous non-Hodgkin’s lymphoma cells can aberrantly express the TNFR2 receptor as an oncogene for growth. For non-cutaneous T cell lymphomas, the genetic basis of the TNFR2 deregulation has recently been tied to constitutive overexpression of TNFR2 from frequent gene duplications or cytoplasmic TNFR2 mutations that confer constitutive agonism, i.e. tumor expansion. These features make TNFR2 an advantageous molecular target for direct tumor targeting. Methods: We designed monoclonal antibodies to target the TNFR2 oncogene and directly kill human tumor cells. TNFR2-directed antibodies were screened for their ability to induce the death of rapidly growing tumor cells, such as ovarian cancer cells (i.e., OVCAR3). Results: Novel dominant anti-TNFR2 antibody candidates (TNFR2 antagonistic antibodies) did not require Fc binding for activity, expressed dominance over TNF-mediated agonism, and hampered intracellular NF-kB activation and phosphorylation obligatory for TNF2 signaling and cell growth of tumor cells. Even low doses of TNFR2 antagonists rapidly and directly killed TNFR2-onco-
gene-expressing ovarian cancer cells. Examination of the structural biology of these dominant TNFR2 antagonist antibodies uncovered a unique and stabilizing
TNFR2 receptor formation, anti-parallel dimeric TNFR2, which inhibits intracellular signaling, cannot bind TNF, cannot be cleaved to create soluble
TNFR2 and is exponentially more active on the dividing cells of cancer. Conclu-
sions: TNFR2 is a unique and broadly expressed human tumor necrosis factor
receptor that potentially can be targeted to directly stop the growth of cancer cells (including ovarian cancer cells) by antibody-induced cell death. The creation of dominant
TNFR2 antagonism provides a unique, non-signaling complex that has implic-
tions for the therapeutic targeting of TNF superfamily receptors, especially
TNFR2.

#2137 JAK2 as a novel therapeutic target in anaplastic thyroid cancer
Nicole C. Pinto,1 Kara Ruiczi,2 Stephanie Prokopiec,3 Karlee Seerle,3 Matthew
Lowerison,3 John Yoo,3 Kevin Fung,3 Danielle MacNeil,3 Hon S. Leong,3 Ales-
sandro Datti,3 Paul C. Boutros,3 John W. Barrett,1 Anthony C. Nichols1.1.
1Western University, London, Ontario, Canada; 2Ontario Institute for Cancer Research, Toronto, Ontario, Canada; 3Lunenfeld-Tanenbaum Research Institute, Toronto, Ontario, Canada.

Introduction: Thyroid carcinoma is the most common endocrine malign-
ancy. Anaplastic thyroid cancer (ATC) is rare (1.3%) and represents arguably the most lethal human malignancy with 1-year survival rates of only 10%. There are currently no effective treatments for the majority of patients, highlighting an urgent need for novel therapeutics to manage this disease. Objective: To validate the functional importance of JAK2 as a therapeutic target in ATC. Methods: In this study, we have used siRNA knockdown to interrogate the JAK2 signaling
pathway as a therapeutic target in ATC. We investigated the mechanism of
action and cell death, and assayed for migration and invasion, in vitro. The chick chorioallantoic membrane (CAM) model was also utilized for drug testing, whereby 1x10⁵ Cal62 ATC cells were on-planted to the chick embryo mem-
brane. Two days post on-plant, CAM models were treated with the vehicle (DMSO) or lestaurtinib to measure outcomes including tumor volume and vac-
cularity. Results: We identified the JAK2 inhibitor lestaurtinib as an inhibitory agent controlling cell line proliferation at submicromolar mean inhibitory
concentrations. Immunoblotting revealed the inhibition of phosphorylation of the downstream signaling molecule STAT5 in a dose-dependent manner. Treat-
ment of Cal62 cells resulted in a decrease in cell migration using the scratch-
 wound assay. The anti-proliferative effective of lestaurtinib did not cause apo-
tosis, autophagy or cell senescence. CAM models treated with a 4 μM dose of lestaurtinib showed a significant decrease in both tumor volume and vacu-
cularity. Conclusions: Lestaurtinib was found to provide potent control of ATC cell prol-
fication and migration, and was also found to decrease tumor growth and vacu-
cularity in a CAM model. Knockout studies are underway to confirm that the anti-cancer effect of this drug is indeed mediated through JAK2 signaling. If validated, JAK2 represents a novel therapeutic target for the treatment of aggres-
sive thyroid cancers.

#2138 Tumor treatment fields downregulate the BRCA1/FA pathway
genesis leading to reduced DNA repair capacity, the inhibition of mitophagy
and enhanced cell death
Narasimha Kumar Karanam, Lianghao Ding, Brock Sisak, Debabrata Saha, Michael D. Story. UT Southwestern Medical Center, Dal-
lus, TX.

The application of new physical cancer treatment modality utilizing alternat-
ing electric fields termed tumor treatment fields (TTFields) has revolutionized the treatment of recurrent and newly diagnosed glioblastoma. This non-invasive exposure to low-intensity, intermediate frequency, alternating electric fields to the region of the tumor has resulted in a significant increase in overall survival when compared to standard therapy with very minimal side effects. Clinical
trials are recruiting or ongoing at additional tumor sites including lung, pancre-
atic, and ovarian cancer. The primary mechanism of TTFields cell killing is thought to be the disruption of mitosis; however, other potential mechanisms are under investigation. Using a panel of five NSCLC cell lines we found that
TTFields treatment alone inhibits cell proliferation, and decreases survival, though the degree of inhibition varies between cell lines. To understand the
molecular mechanisms underlying the biological effects of TTFields exposure we studied temporal gene expression changes in the NSCLC cell lines after TTField treatment. We observed that most differentially expressed genes are part of cell cycle and proliferation pathways which is in agreement with earlier findings. Interestingly we found that the expression of BRCA1 DNA damage repair path-
way genes were significantly downregulated (P < 0.05) upon TTField treatment. We confirmed the downregulation of BRCA1/FA pathway proteins by western blot. When examining the nuclear role of the BRCA1/FA pathway genes we found that TTField treatment slowed the repair of ionizing radiation-induced
DNA damage compared to radiation alone which is evident by an increased
number of DNA double strand break repair foci at any given time. Moreover, we found that TTField treatment increased the incidence of chromatin aberrations.
We also examined the newly identified BRCA1/FA pathway genes cytotoxic role in mitophagy when we observed alterations in mitophagy related gene (PIN1K, DNM2, TPP1, TP53BP1), and DAPK1 expression compared the same at the protein level by western blot. We hypothesized that TTFields disrupt the clearance of damaged mitochondria due to the downregulation of BRCA1/FA pathway play-
ers, causing an imbalance in oxygen metabolism leading to the production of high levels of radical oxygen species (ROS) and as a result, cell death. Using
CellROX dye we found that TTField treatment did result in increased ROS
production suggesting a new mechanism of action for TTField exposure. Novel
chemotherapy agents, particularly PARP inhibitors, in combination with DNA damaging agents like radiation and TTFields may be advantageous through the
conditional vulnerability of down-regulated BRCA1.

#2139 The effects of cyclodipeptide on the transport of doxorubicin
and its cytotoxicity on tumor cell
Ivumi Sugiyama, Yasuyuki Sadzuka. Iwate Medical Univ. School of Pharmacy, Shiwa-Gun, Japan.

Purpose: Chemotherapy using antimetabolite plays an important role in clinical
therapy. Among the treatments involving antimetabolite, the enhance-
ment of antimetabolite activity was observed by combined chemotherapy. We have shown previously that some amino acids included theanine, taurine and anserine et al. as food components, increased doxorubicin (DOX) induced antitumor effect in
vitro and in vivo. These effects by combined amino acids have depended on the increased DOX concentration in the tumor cells. Furthermore, these suppositions
of DOX efflux by theanine and taurine were caused by the inhibitions of glutamate transporter and taurine transporter, respectively. The effect of anserine on
DOX influx might connect with dipeptide transporter. Thus, other amino acid and unique peptides may act to DOX transport. In this study, the effects of cyclodipeptide on the transport of DOX and its cytotoxicity on tumor cell were clarified. Methods: Cylo-
leucine-proline (cyclo-Leu-Pro), cyclo-phenylalanine-proline (cyclo-Ph-Pro) and
cyclo-glycine-proline (cyclo-Gly-Pro) as cyclodipeptide was used in this study. In
transport of DOX, DOX influx or efflux was determined with combined cyclodipep-
tide in M5076 ovarian sarcoma cells or P388 leukemia cells. DOX concentration in
tumor cell was measured using spectrophotometer (Ex. 470 nm, Em. 580 nm). The
cytotoxic study of DOX with combined cyclodipeptide was performed using
WST-8. Results and Discussion: Cyclo-Ph-Pro and cyclo-Gly-Pro did not affect
DOX influx and efflux in M5076 ovarian sarcoma cells and P388 leukemia cells. By combined cyclo-Leu-Pro, DOX influx into both M5076 ovarian sarcoma cells and P388 leukemia cells changed, compared to that of DOX only group. Into M5076
ovarian sarcoma, cyclo-Leu-Pro had strong effect in increased DOX influx in partic-
ular. And cyclo-Leu-Pro showed a tendency to suppress DOX efflux from M5076
ovarian sarcoma. In this studies of influx and efflux, concentration of cyclo-Leu-Pro existed optimum amount for increased DOX concentration in tumor cells. It is
expected that cyclo-Leu-Pro induces the increment of DOX concentration in the
tumor in vivo. DOX had the cytotoxic effects on M5076 ovarian sarcoma cells or
P388 leukemia cells in culture. The combined cyclo-Leu-Pro with DOX increased
cytotoxic effect, compared to that in the DOX alone group. In conclusion, cyclo-
Leu-Pro has increased effect on DOX influx and inhibited effect on DOX efflux, and
DOX induced cytotoxicity. It is expected that the combined cyclo-Leu-Pro will im-
prove cancer chemotherapy by DOX. Moreover, cyclo-Leu-Pro may be help to pre-
vent adverse effect since it will be able to decrease DOX dose.

#2140 Understanding molecular mechanisms underlying he
e function in non-small cell lung cancer
cancers, Sagar Solonoi, Chantal Vidal, Li Zhang. University of Texas at Dallas, Richardson, TX.

Heme is a central molecule for mitochondrial respiration and for all processes
involved in oxygen utilization. Heme serves as a prosthetic group or as a cofactor
for a number of oxidative phosphorylation enzymes and other oxygen-utilizing
hemoproteins. Heme directly regulates the synthesis, translocation and assem-
bly of these enzyme complexes. Most, if not all, human cells can synthesize and
uptake heme from the circulation. A number of epidemiological studies have
shown that high heme intake is associated with increased risk of cancer, includ-
ing lung cancer. To assess the status of heme metabolism in lung cancer cells, we
performed a series of experiments in non-small cell lung cancer (NSCLC) cell
lines such as HCC4017, H1299, A349, H2009, H1395, H460 and Calu-3. We then
compared results with an immortalized normal lung cell line, BHE39K7
and observed significant increase in rates of heme synthesis and heme uptake in
NSCLC cells compared to BHE39K7. Previous studies carried out in our lab
showed intensified mitochondrial respiration and increased levels of heme and
hemoproteins in NSCLCs. We examined the effect of heme depletion on mito-
chondrial biogenesis and function. We observed that mitochondrial functions

548 Proceedings of the American Association for Cancer Research • Volume 58 • April 2017

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: New Targets 2
such as ATP production, NAD/NADH ratios and ROS production are also affected by heme depletion. Proteins involved in mitochondrial biogenesis are significantly affected when cells are grown in heme depleted medium. Studies are currently underway to check how heme depletion affects the interactions of various transcription factors involved in mitochondrial biogenesis and function.

#2141 Development of a novel miR-129 mimic with enhanced therapeutic potential for treatment of resistant colorectal cancer. Andrew T. Fesler,1 Ning Wu,1 Hua Liu,1 Jingfang Ju,1 Stony Brook University, Sound Beach, NY; Stony Brook University, Stony Brook, NY.

Treatment of advanced stage colorectal cancer remains a clinical challenge associated with resistance to fluoropyrimidine based chemotherapy. There is an urgent need to discover and develop new strategies to enhance treatment efficacy in order to improve outcomes for these patients. Non-coding microRNAs (miRNAs) have important functions as oncogenes or tumor suppressor genes in the regulation of cancer development and progression. Recently, miRNAs have emerged as potential therapeutic options. We have previously identified miR-129 as a tumor suppressor miRNA and potential therapeutic candidate in colorectal cancer. The expression of miR-129 is progressively lost in colorectal cancer patients and is an important regulator of apoptosis through the targeting of genes such as BCL-2. miR-129 was also found to enhance 5-fluorouracil (5-FU) cytotoxicity in vitro and in vivo. To further developing miR-129 based novel therapeutics in colorectal cancer, we have designed a modified version of miR-129 to enhance stability and efficacy. The miR-129 mimic is more potent in inhibiting proliferation of a panel of colon cancer cell lines than the native miR-129 precursor, with 79% reduction by miR-129 mimic compared to 38% for native precursor. The miR-129 mimic induces profound cell cycle arrest at the G1/S checkpoint. The G1/S ratio increased 3.8 fold compared to control when cells were transfected with miR-129 mimic. We also demonstrated that the miR-129 mimic retains its target specificity to BCL-2, TS and E2F3. The therapeutic potential of miR-129 mimic was demonstrated in vivo mouse colon tumor models as a potent inhibitor of tumor growth and metastasis. As a result, miR-129 mimic has a great potential to be further developed as a novel therapeutic drug for treatment of advanced colorectal cancer.

## EXPERIMENTAL AND MOLECULAR THERAPEUTICS: New Targets 2

Experimental and molecular therapeutics have established links between occupational exposures to automobile exhaust fumes (AEF) and health hazards. Epidemiological studies have established links between occupational exposures to automobile exhaust fumes (AEF) and lung cancer, the propensity for systemic toxic responses. Street hawking and begging between automobiles, on various highways in Nigeria is on the increase. This occupational hazard is further worsen by dire economic recession in Nigeria, and growing population with limited prospect of improving their economic situation. Ages of vulnerable population ranges: 4 to 60yrs, exposure to AEF and susceptibility to health hazard maybe age related. We examined the effect of AEF exposure on E. coli P37 deoxyribonuclease acid (DNA) damage, cell growth and chromosomal aberration in Allium cepa. The effective concentration of AEF was determined as EC50: 0.43mg/ml from A. cepa root length growth against AEF concentrations. Furthermore, A. cepa exposed to AEF at EC50 (0.43mg/ml), EC25 (0.108mg/ml) and EC10 (0.043mg/ml) for 12, 24 and 48hrs mitotic index and chromosomal aberrations were evaluated at various endpoints. Chromosomal abnormalities were observed in dividing cells and decreases in A. cepa cell growth occurred dose and time dependently. Exposure of E. coli to AEF (EC50: EC25: EC10) resulted in inhibition of SOS inducing potency (SOSIP) with increasing concentration of AEF and compared to the positive control 4-nitroquinoline oxide (4-NQO). Decreases in the SOSIP (at EC50) indicate a threshold beyond which E. coli SOS response gene may have been extensively damaged to produce a response. Taken together we conclude that constituents of AEF are genotoxic in E. coli, induce chromosomal aberration and increases cell growth in A. cepa. We speculate on the possibilities of toxic health outcomes including carcinogenesis in humans persistently exposed to AEF fumes either occupationally or by any other means as observed in both street hawkers and beggars in Nigeria.
like LAT1/S12, Mut1/S2, Sav or Mob. We identified a novel regulation of YAP1 by prolyl hydroxylase PDH2, which is mainly known to regulate HIF1α. PDH2 was found to hydroxylate proline residue(s) in YAP1 in a region between aa 284 to aa 289 as seen by mutational analysis. YAP1 was found to directly bind to PDH2 and depletion of PDH2 or treatment with DMOG which is an inhibitor of prolyl hydroxylase elevated YAP1 protein levels in cancer cells. Further, we identified a putative HIF1α binding site that was co-occupied with HIF1α as detected by co-immunoprecipitation experiments and could enhance HIF1α-mediated induction of the VEGF promoter. Proximity ligation assays performed on TM4 showed enhanced YAP1 and HIF1α interaction in lung tumor tissues compared to normal cells. Our data suggest a novel regulation of YAP1 in hypoxic environments that supports angiogenesis and tumor growth.

Laryngeal squamous cell carcinoma (LSCC) accounts for approximately 30-40% of head and neck cancers. Although tobacco and alcohol consumption are considered the major risk factors for LSCC, various genetic and epigenetic factors have also been associated with LSCC development and progression. Since early detection and diagnosis of LSCC can greatly increase the chance of a successful treatment and survival, several studies have addressed the identification of target genes involved in LSCC pathogenesis. In this study we aimed to identify differentially expressed genes involved in the pathogenesis of LSCC using the GeneFishing technique. As a result of this investigation we identified the SLC22A23 gene as one of the differentially expressed gene. Solute carriers (SLC) comprise the largest family of membrane transport proteins with more than 300 members which have been divided into 52 families. The main functions of these proteins is to transfer a wide range of substrates such as amino acids, lipids, inorganic ions, peptides, saccharides, metal ions, proteins, xenobiotics and drugs. It is well known that cancer cells need extra metabolic requirements during rapid cell cycles. One of the known functions of the SLC proteins is to facilitate the uptake of nutrients and removal of metabolites. SLC22A23 (solute carrier family 22, member 23) belongs to the SLC family of organic ion transporters that are responsible for the uptake or excretion of many compounds including drugs, toxins and endogenous metabolites in a variety of tissues. SLC22A23 is expressed in various tissues but no substrates or functions have yet been identified for SLC22A23. Although the exact function is unknown, single-nucleotide polymorphisms which are located in the SLC22A23 gene have been associated with inflammatory bowel disease, endometriosis-related infertility and the clearance of antipsychotic drugs. On the other hand, SLC22A23 was identified as a prognostic gene to predict the recurrence of triple-negative breast cancer. In this study, to confirm the GeneFishing assay data, we investigated expression of the SLC22A23 gene in laryngeal tissue samples obtained from 83 patients by quantitative RT-PCR. We detected statistically significant upregulation of the SLC22A23 mRNA in laryngeal tumor tissues (55.4%) (p<0.05). However, no significant correlation was found between SLC22A23 expression and clinicopathological parameters including age, sex, stage, histological grade and smoking (p>0.05). To understand the association between the SNPs in SLC22A23 and LSCC we also investigated the frequency of different genetic variants (rs4959235, rs6923667, rs9503518). Currently, experiments to determine the BBB-penetrance of the hydrophilic DMG ester, by itself, was cytotoxic with IC50 values up to 500 µM against brain tumor cell lines, however, when combined at 100 µM with TMZ resulted in a greater synergistic cell killing (generally-9 fold, but 28-fold with UW-18 GBM cells). 0.25 mM DMG inhibited the cellular MGMT activity by ~80%, induced degradation of TET1 protein and highly increased the methylation levels of histones (H1K25me1, me2 and H2BK25me2). Currently, experiments to determine the BBB-penetrance of DMG, its ability to induce genomic and MGMT-specific methylations in glioma cells and GBM regression in intracranial xenograft models developed in nude mice are underway. Collectively, these data reveal that acute treatments of α-KG analogs can alter the cellular epigenetic makeup in a manner ascribed to D-2HG, and open up the much-needed novel and exciting avenues of oncometabolite therapy for brain tumors (supported by CPRIT grants RP130266 & RP170207 to KSS).

#2148 Phenyl butyrate inhibits pyruvate dehydrogenase kinase 1 and contributes to its anti-cancer effects. Wen Zhang, Xin Yip Tam. University of Macau, Macau, China.

In cancer cells, the metabolic features are significantly different from those of normal ones, which are hallmarks of several malignancies. Recent studies brought back the idea of metabolic regulation as a new strategy for cancer treatment by acting on glycolytic tumors while showing minimal side effects on the oxidative healthy organs. Phenyl butyrate (PB) has been proved to decrease PDH phosphorylation level and increase PDH activity by inhibiting PDK1 in fibroblast cells, PDH deficiency zebrafish and wild type mice. PB has also shown efficacy in many cancers and so far, all of its anti-tumor activity has been attributed to the histone deacetylase (HDAC) inhibitor mode of action. As PDK1/PDH controls the critical switch between oxidative phosphorylation and glycolysis in cancer cells, PDK1 is a key target in tumor metabolism for anti-cancer treatment. We hypothesize that the therapeutic effects of PB are mediated through downregulation of PDK1, altering the mitochondrial bioenergetics and inducing apoptosis. In addition to its proposed role as HDAC inhibitor, we showed that PB directly inhibited the kinase activity of PDK1 in a purified system. In several different cancer cell lines, PB reduced the phosphorylation level of PDH, increased the mitochondrial respiration, decreased glycolysis in cytoplasm, reversed mitochondrial hyperpolarization, activated some proteins in apoptotic signalling pathway and then induced the apoptosis of cells. In summary, this is the first study indicated that PB could exert its anti-cancer effects through inhibiting PDK1, altering the mitochondrial bioenergetics and inducing apoptosis.

#2147 IDH1 mutation-inspired α-ketoglutarate acid mimics for epigenetic therapy of higher grade gliomas. Hanumantara Rao Madala, Surendra Reddy Punganuru, Kalkunte S. Srivenugopal. Texas Tech Univ. Health Sciences Ctr., Amarillo, TX.

Mutations at the active site of isocitrate dehydrogenase 1 gene (IDH1; R132H) occur at a high frequency (>70%) early in the oncogenesis of lower grade malignant gliomas, and result in a dramatic accumulation of the oncometabolite D-2-hydroxyglutarate (D-2HG), that effectively replaces the normal metabolite α-ketoglutarate (α-KG) in cell physiology. Surprisingly, IDH1 mutations bestow superior therapeutic responses to alkylating agents and better patient survival. D-2HG, effectively competes with α-KG and potently inhibits various dioxygenase reactions, including the TET1, TET2 DNA-deamethylases and histone demethylases (5m-cytosine to 5-OH cytosine, H3-K-met to H3-K-met-) thereby, re-shaping and reprogramming the epigenetic landscape, and consequent transcriptional silencing; the DNA repair protein O6-methylguanine DNA methyltransferase (MGMT), which confers drug resistance is one major target for such repression. As a novel and innovative strategy of turning the tide against GBMs by exploiting the mechanistic aspects of the oncometabolite, we hypothesized that D-2HG and α-KG derivatives that can replace the natural metabolite in epigenomic dioxygenase reactions will serve as potent anti-glioma drugs either by themselves or in combination with the alkylating agents. To this end, we first synthesized a D-2HG diethyl ester to enhance its cellular uptake and tested its effects on four human brain tumor cell lines (DA0Y, T98G, SF188 and U87MG). 5α-dihydroxy-3α-methyl-4-oxo-3,4-dihydro-2H-chromene-2-carboxylic acid methyl ester (DMG) elevated YAP1 protein levels in cancer cells. Further, YAP1 was found to be associated with HIF1α as detected by co-immunoprecipitation experiments and could enhance HIF1α-mediated induction of the VEGF promoter. Proximity ligation assays performed on TM4 showed enhanced YAP1 and HIF1α interaction in lung tumor tissues compared to normal cells. Our data suggest a novel regulation of YAP1 in hypoxic environments that supports angiogenesis and tumor growth.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: New Targets 2

In a selective series of in vitro experiments, we determined that the hydrophilic DMG ester, by itself, was cytotoxic with IC50 values up to 500 µM against brain tumor cell lines, however, when combined at 100 µM with TMZ resulted in a greater synergistic cell killing (generally-9 fold, but 28-fold with UW-18 GBM cells). 0.25 mM DMG inhibited the cellular MGMT activity by ~80%, induced degradation of TET1 protein and highly increased the methylation levels of histones (H1K25me1, me2 and H2BK25me2). Currently, experiments to determine the BBB-penetrance of DMG, its ability to induce genomic and MGMT-specific methylations in glioma cells and GBM regression in intracranial xenograft models developed in nude mice are underway. Collectively, these data reveal that acute treatments of α-KG analogs can alter the cellular epigenetic makeup in a manner ascribed to D-2HG, and open up the much-needed novel and exciting avenues of oncometabolite therapy for brain tumors (supported by CPRIT grants RP130266 & RP170207 to KSS).

Colorectal cancer is one of the most common cancers in the world, affecting nearly 1.2 million people in the United States alone. The aim of this study is to investigate the salvage pathway enzyme HPRT as a possible biomarker in two colorectal cancer cell lines: HT29 and SW620. HPRT is a transerase in the purine salvage pathway that functions primarily by catalyzing the conversion of hypoxanthine to inosine monophosphate and guanine to guanosine monophosphate. Because of its role in proliferation and cell cycle regulation, we hypothesized an increase in HPRT expression within cancer cells, which could potentially lead to presentation on the surface of the cell. HPRT surface localization was assessed utilizing confocal microscopy, flow cytometry, and scanning elec-
tron microscopy. These techniques allowed us to visualize HPRT on the plasma membrane and quantify expression. There was statistically significant expression of HPRT on the surface of both HT29 and SW620 cells with a 28% and 58% fluorescent shift in the population, respectively. Confocal microscopy images revealed overlap between cells stained with a membrane dye and anti-HPRT FITC antibody, which indicates a direct relationship between HPRT and the plasma membrane of SW620 cells. To visualize the location of HPRT on the plasma membrane, anti-HPRT antibodies were labelled with gold and protein presence was quantified using an electron microscope, which measured the gold elemental weight percentage of each sample. When exposed to anti-HPRT antibody, the gold weight percentage of the samples significantly increased with 12.4% gold in SW14 cells and 11.2% gold in HT29 cells. Also, these cells showed cell cycle arrest at the synthetic phase, activation of Bcl-2, K-ras, pAkt proteins as well as inhibition of p53, PUMA, p21 and BAX proteins. Conversely, knockdown of GAEC1 reduced cell proliferation, migration, decreased the phosphorylation of AKT, and induced apoptosis, G2/M phase arrest and cleavage of poly (ADP-ribose) polymerase (PARP). Co-immunoprecipitation revealed GAEC1’s interaction with p53. In addition ectopic over expression and si- lencing of GAEC1 lead to reciprocal effects of p53 protein expression. Moreover, knockdown of GAEC1 reduced the nuclear translocation of murine double minute 2 protein (mdm2) indicating that GAEC1 is responsible for the degradation of p53 through the direct interaction between mdm2-p53 in nucleus. Furthermore, our in vivo data demonstrate that the loss of GAEC1 inhibits the tumor formation in xenograft model. Conclusion: Collectively, our study demonstrates that GAEC1 exhibits the oncogenic role in colon cancer by reducing expression of p53 through protein-protein interaction which leads to the inhibition of PUMA, p21, BAX, and activation of Bcl-2, K-ras and pAkt protein expression.

The Maternal Embryonic Leucine Zipper Kinase MELK has been described as a genetic dependency in several cancer types, most notably in the highly-aggressive basal subtype of breast cancer; MELK inhibition through the use of both RNAi and small-molecule approaches appears to block the growth of cancer types with such dependency. Based on these results, the MELK inhibitor OTS167 is currently being tested as a novel chemotherapeutic agent in multiple clinical trials. Here, however, we report that mutagenizing MELK with CRISPR/Cas9 has no effect on the fitness of basal breast cancer cell lines or cell lines from other cancer types. Through seven guide RNAs targeting the kinase and kinase-associated domains of MELK, we demonstrate that mutagenesis of MELK causes no defect in proliferative ability or anchorage independent growth in these cancer types. Additionally, cells with mutagenized MELK remain sensitive to OTS167, suggesting that this drug blocks proliferation through an off-target mechanism. Finally, the patient tumor gene expression data that initially identified MELK as being significantly upregulated in patients with poor survival was reexamined. As MELK is thought to play a role in mitosis, we compared MELK expression to a set of well-known cell proliferation markers and show significant correlations of MELK with the proliferation genes; this suggests a role of MELK in representing the mitotic activity of a tumor, rather than possessing a transforming role in itself. In total, our results undermine the rationale for a series of current clinical trials based on MELK inhibition and provide an experimental approach for the use of CRISPR/Cas9 in preclinical target validation that can be broadly applied.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Targeting p53, Apoptosis, and the Cell Cycle

#2150 Oncogenic role of GAEC1 and its potential modulation with p53 in pathogenesis of colon cancer. Riajal Wahab, Farhadul Islam, Vinod Gopalan, Alfred King-Yin Lam. Griffith University, Southport, Gold Coast, Australia.

Introduction: GAEC1 (Gene ampliﬁed in esophageal cancer 1), is frequently ampliﬁed and overexpressed in colon cancer tissues. In the present study, we aimed to unveil the oncogenic potential of GAEC1 in carcinogenesis of colon cancer by studying the underlying cellular functions and molecular interactions by in vitro and in vivo experiments. Method: Transient overexpression of GAEC1 with pcDNA3.1-GAEC1 and silencing with GAEC1-siRNA was performed and several downstream assays were done such as migration, clonogenic and apoptotic assay. Analysis of cell kinetics was done using ﬂow cytometry and cell counting kit-8 was used for cell proliferation assay. Immunofluorescence and Western blot assay were used to determine the expression of diﬀerent target proteins. Co-immunoprecipitation was used to conﬁrm the protein-protein interaction. For xenotransplantation the severely combined immunodeﬁcient (SCID) mice (4 groups, 6 in each group) were injected subcutaneously with GAEC1 shRNA and control shRNA transfected (stable) SW480 and SW48 colon cancer cells. Result: The overexpression of GAEC1 increased cell proliferation, migration, reduced apoptosis in colon cancer cells. Also, these cells showed cell cycle arrest at the synthetic phase, activation of Bcl-2, K-ras, pAkt proteins as well as inhibition of p53, PUMA, p21 and BAX proteins.

#2151 Inhibition of WIP1/PPM1D phosphatase by GSK2830371 potentiates the growth inhibitory and cytotoxic activity of MDM2 antagonists (nullin-3, RG7388 and HDM201) in cutaneous melanoma cells. Chiao-En Wu, Arman Esfahani, Yi-Hsiang Ho, Colin Shepherd, Ahmed Khairallah Mahdi, Erhan Apltullahoglu, John Wen-Cheng Chang, Perry Lovat, John Luneck. 1. Northern Institute for Cancer Research, School of Medicine, Newcastle University, United Kingdom; 2. Division of Hematology-Oncology, Department of Internal Medicine, Chang Gung Memorial Hospital at Linkou, Chang Gung University College of Medicine, Taoyuan, Taoyuan, Taiwan; 3. Dermatological Sciences, Institute of Cellular Medicine, Newcastle University, United Kingdom.

Cutaneous melanoma is the most serious skin malignancy. The current study aimed to investigate the WIP1 inhibitor GSK2830371 and MDM2-p53 antagonists (nullin-3, RG7388 and HDM201) alone and in combination treatment in cutaneous melanoma cell lines and explored the mechanistic basis of these responses in relation to the genotype and induced gene expression profile of the cells. A panel of three p53WT (A375, WM35, C8161) and three p53MUT (WM164, WM35-R5R1, CHL-1) melanoma cell lines were used. GSK2830371 (≤10 µM) alone had no growth-inhibitory or cytotoxic effects on the cells, measured by sulforhodamine B (SRB) and clonogenic assays. In combination treatment GSK2830371 significantly potentiated the growth-inhibitory and clonogenic cell killing effects of MDM2 inhibitors in p53WT but not p53MUT melanoma cells, indicating the potentiation worked in a p53-dependent manner (Table). Western blotting demonstrated GSK2830371 increased p53 stabilization through Ser15 phosphorylation and consequent Lys382 acetylation when it was combined with MDM2 inhibitors. These changes were ATM-mediated, shown by reversal with the ATM inhibitor (KU55933). Furthermore, GSK2830371 was demonstrated to slow down p53 degradation when de-novo protein synthesis was inhibited by cycloheximide. In qRT-PCR, nullin-3 or RG7388 induced p53 transcriptional target genes (CDKN1A, MDM2, BAX, FAS, PUMA, TNFRSF10B, TP53INP1) and GSK2830371 enhanced the induction in p53WT but not p53MUT cells. In conclusion, GSK2830371, a WIP1 inhibitor, acts dose-dependently, growth-inhibitory activity alone, potentiated the growth-inhibitory and cytotoxic activity of MDM2 inhibitors, by increasing phosphorylation, acetylation, and stabilization of p53 in cutaneous melanoma cells in a functional p53-dependent manner. Further studies in vivo are warranted to investigate the efficacy of this combination treatment.

#2152 Protein phosphatase Mg2+ and Mn2+ dependent 1F promotes smoking-induced breast cancer by inactivating phosphorylated p53-induced signals. Li-Ching Chen. Taipei Medical University, Taipei City, Taiwan.

Previously we demonstrated that the activation of α9-nicotinic acetylcholine receptor (α9-nAChR) signaling by smoking promotes breast cancer formation. To investigate the downstream signaling molecules involved in α9-nAChR-induced breast tumorigenesis, we used real-time polymerase chain reactions and Western blotting to assess expression of protein phosphatase Mg2+/Mn2+ dependent 1F (PPM1F), a Ser/Thr protein phosphatase, in human breast cancer samples (n = 167). Additionally, stable PPM1F-knockdown and overexpressing cell lines were established to evaluate the function of PPM1F. The phosphatase activity of PPM1F in nicotine-treated cells was assessed through Western blotting, confocal microscopy, and fluorescence resonance energy transfer. Higher levels of PPM1F were detected in the breast cancer tissues of heavy smokers (n = 7, 12.8-fold) greater than of non-smokers (n = 28, 6.3-fold) (**) = 0.01. In vitro, nicotine induced PPM1F expression, whereas α9-nAChR knockdown reduced the protein expression of PPM1F. A series of biochemical experiments using nicotine-treated cells suggested that the dephosphorylation of p53 (Ser-20) and BAX (Ser-184) by PPM1F is a critical posttranslational modification, as observed in breast cancer patients who were heavy smokers. These observations indicate that PPM1F may be a mediator downstream of α9-nAChR that activates smoking-induced carcinogenic signals. Thus, PPM1F expression could be used for prognostic diagnosis or inhibited for cancer prevention and therapy.

#2153 Elephant p53 (EP53) expression induces apoptosis of human cancer cells. Lisa M. Abegglen,1 Lauren N. Donovan,1 Genevieve Couldwell,1 Rosann len,1 Bryan E. Welm,1 Carlo C. Maley,4 Avi Schroeder,2 Joshua D. Schiffman1.

The goal of our study was to determine if elephant TP53 (EP53) proteins contributing to increased apoptosis and possible cancer resistance in elephants could translate into human cancer cells as a future effective cancer treatment. We previously reported that elephants have a lower than expected rate of cancer. 20 copies of TP53 (1 ancestral gene with introns [EP53-anc] and 19 retrogenes [EP53-retro1-19], and increased p53-mediated apoptosis induced by DNA damage in elephant cells compared to human cells (Abegglen JAMA 2015). For the current study, we expressed various EP53 proteins in human cancer cells with different p53 status, including osteosarcoma (U2-OS, Saos-2), glioblastoma (T98G), and breast cancer (MCF7). Western blot analysis confirmed EP53 expression. We compared apoptosis in the human cancer cells transfected/transduced with negative control vectors vs. epitope or protein-tagged EP53 exposed to doxorubicin (to induce DNA damage). Apoptosis was measured by cell viability, caspase activity, Propidium iodide/Annexin V staining, and fluorescence microscopy. We observed a significant increase in caspase activity (normalized to cell viability) of U2-OS and T98G cells expressing EP53 compared to negative control treated cells as shown in Table 1, and apoptosis with p21 restoration in Saos-2. In U2-OS, which overexpress MDM2, EP53 was more effective at inducing apoptosis compared to human TP53. Taken together, we found that EP53-anc restored p53-mediated apoptosis and EP53-anc / EP53-retro9 enhanced p53-mediated apoptosis. These data suggest for the first time that EP53 functions in human cancer cells to promote cell death. Ongoing efforts are exploring the EP53 mechanism of action that leads to increased apoptosis, including expression of EP53 in additional cancer types (lung, melanoma, colon, prostate, and others) with a variety of genetic backgrounds to characterize its functional context. These results support the further exploration of EP53-based cancer therapeutics.

We recently reported that P01 is a potent p53 pathway-restoring small molecule that acts through increasing levels of TAp73. Further, it also interferes with the p73-mutant p53 protein-protein interaction and by downregulation of ΔNp73 (Tian, Zhang and El-Deiry, abstract# 3830, AACR 2016). P01 is a member of the natural products that have been shown to have potent anti-cancer activity against tumors with mutated p53. Based on the structure of the pharma- copoeia of compound P01, we designed and synthesized new analogs based on published structure-activity relationship and organic synthesis papers. The newly synthesized analogs were potent in reducing both short-term and long-term proliferation in a broad panel of mutant p53 cell lines such as HT29, SW480, DLD-1, MDA-MB-231 and H1975 with EC50 in the range of 0.16 μM to 0.26 μM. We are currently evaluating the anti-cancer effects of three analogs P01, P04 and P06, of which only two of these analogs induce TAp73 as assayed by western blot. We are currently characterizing the analog P06, which is the most potent compound among them. P06 engages the apoptosis pathway by upregulation of pro-apoptotic proteins like PUMA, DR5, and BIM and downregulation of anti-apoptotic markers such as Mcl-1 in a time-and dose-dependent manner in colorectal cancer cell lines. P06 treatment also down-regulates both mRNA and protein level of MET and EGFR in HT29 cells that overexpress MET and EGFR receptors. We are currently investigating the mechanisms of induction of both PUMA and DR5 in mutant p53 cells and determining whether either gene is necessary for the apoptotic effects of P06 in colorectal cancer cells. Our preliminary data indicates that upregulation of DR5 is through the ATF4/CHOP pathway post-P06 treatment. It has been reported that Puma is a target gene of ATF4, CHOP and p73, however, we found that none of them is responsible for P06-induced upregulation of PUMA in p53 mutated DLD1, SW480 or HCT116 p53-null cell lines. Thus, our ongoing in vitro studies are focused on further understanding the mechanism of action of P06 in mutant p53 cells and potentially exploring combinations with FDA-approved therapies. We are also in the process of conducting first-in-animal studies of P06 as single agent or in combination with chemotherapy or targeted therapy.

#2155 Small molecule NSC59984 suppresses cancer cell growth under hypoxia. Shengliang Zhang, Lanlan Zhou, Wafık S. El-Deiry. Fox Chase Cancer Center, Philadelphia, PA.

Hypoxia is one of the main features of solid tumors, contributes to drug resistance and is associated with poor prognosis. We have reported that a small-molecule NSC59984 restores p53 signaling and degrades mutant p53 protein in cancer cells. We find that NSC59984-mediated p53 signaling restoration and mutant p53 degradation is significantly blocked by NAC, an inhibitor of reactive oxygen species (ROS), while, further enhanced by BSO, a chemical compound increasing ROS in cells. These results suggest that ROS is a factor required for the effect of NSC59984 on cancer cells. Cellular ROS is produced by hypoxia in solid...

Mutant p53 protein is highly expressed in most cancer cells due to its protein stabilization. Mutant p53 loses wild-type p53 function but gains new oncogenic functions in driving tumor growth and drug resistance. Depletion of mutant p53 is an attractive strategy for cancer therapy. We reported a small-molecule NSC59984 destabilizes mutant p53 protein via protein degradation (Zhang et al., Cancer Research, 2015). In this study, we demonstrate that the ERK2 pathway plays a specific role in NSC59984-induced mutant p53 degradation via MDM2-mediated ubiquitination. We observe a sustained phosphorylation of ERK1/2 in cancer cells treated with NSC59984. ERK1/2 pathway is negatively regulated by MKP-1. We find that MKP-1 activity is partially inhibited by NSC59984 in a dose dependent manner in vitro. These results suggest that NSC59984 sustains ERK1/2 phosphorylation partially via disruption of the feedback-loop between MKP-1 and ERK2 pathway. Knockdown of ERK2 rescues mutant p53 from NSC59984-mediated degradation, and inhibits NSC59984-restoration of p53 signaling in mutant p33-expressing cells. On the contrary, the effect of NSC59984 on the mutant p53 is not inhibited by the blockage of JNK and p38, two pathways negatively regulated by MKP-1. These results suggest that the ERK2 phosphorylation is specifically required for NSC59984-mediated mutant p53 degradation. We further find that NSC59984 induces ERK2-dependent MDM2 phosphorylation. The effect of NSC59984 on MDM2 phosphorylation is partially inhibited by the blockage of ERK2 signaling (via U0126 treatment or Knockdown of ERK2), not by the attenuation of the JNK pathway. Furthermore, NSC59984-mediated mutant p53 protein degradation is inhibited by MDM2 knockdown, and enhanced by MDM2 overexpression in cancer cells. NSC59984-increased ubiquitination of mutant p53 is attenuated by U0126. Our results suggest that the ERK2 signaling pathway-MDM2 axis is a major determinant of NSC59984-mediated mutant p53 degradation. We further demonstrate that NSC59984 induces cell death via apoptosis, and NSC59984-induced cell death is mainly rescued by inhibition of the ERK2 pathway in mutant p53 cancer cells. Taken together, our results suggest that phosphorylated-ERK2 is an important factor required for NSC59984-mediated mutant p53 degradation which may further contribute to NSC59984-induced cell death in cancer cells.

#2157 P73 isoforms regulate cellular survival and response to treatment in diffuse large B-cell lymphoma. Hesham M. Hassan, 1 Michelle L. Varney, 2 Pamela A. Althof, 2 Gabriel C. Caponetti, 3 Kai Fu, 2 Dennis D. Weisenburger, 4 Rakesh K. Singh, 2 Bhavana J. Dave 2.

We investigated the effect of NSC59984 on p53 pathway and cell death in p53 mutant colorectal cancer (CRC) cells cultured under hypoxia. NSC59984 increases p53 signaling in p53 mutant cancer cells under hypoxia, as it does under normoxia. The effect of NSC59984 under hypoxia is blocked by NAC. Moreover, NSC59984 decreases cancer cell viability in a dose-dependent manner under hypoxia similar to normoxia. Our results suggest that NSC59984 inhibits cancer cell growth under hypoxia. Hypoxia has been known to increase cancer stem cells in tumors, which is one of the reasons causing drug resistance. We then evaluate the effect of NSC59984 on the stem cell growth. NSC59984 significantly reduces colosphere formation of SW480, DLD-1 and HT29 cells. CRC stem cell markers such as CD44 and ALDH are decreased in colospheres upon NSC59984 treatment, suggesting that NSC59984 inhibits stem cell self-renewal or/and growth. Our results provide the rationale for administration of NSC59984 in solid tumors with or without hypoxia and in combination treatment with ROS activators.

The first anti-cancer stapled peptide drug has now been advanced to clinical testing in relapsed human cancers that retain the expression of wild-type p53. A common mechanism for cancer cell suppression of wild-type p53 is overexpression of the negative regulators HDM2 and HDMX, which neutralize p53 through protein interaction. Selective HDM2 inhibitor molecules can effectively reverse the repressive effects of mutant p53 in certain cancers, but the co-expression of HDMX can cause treatment resistance, highlighting the need for dual HDM2/HDMX targeting. We previously developed stapled peptides modeled after the p53 transactivation domain to harness the natural propensity of this alpha-helical motif to engage both targets with high affinity and selectivity. Here, we demonstrate that ALRN-7041, a next-generation, clinical-grade stapled peptide, achieves time-dependent cellular uptake and nuclear localization without membrane perturbation, dose-dependently dissociates p53/HDM2 and p53/HDMX complexes as assessed by real-time protein interaction monitoring in live cells, and impairs the viability of cancer cells bearing wild-type p53 by inducing a surge in p53 protein level. Applying an unbiased statistical approach to determine which biophysical parameters dictate the cellular uptake of stapled peptides, we elucidated the design features of ALRN-7041 that confer intracellular access, providing a roadmap for generating cell-permeable stapled peptides with on mechanism cellular activity for clinical translation. We find that cancer cells exhibiting a signature of HDM2, HDMX, and wild-type p53 co-expression are strikingly susceptible to ALRN-7041, highlighting the therapeutic potential of dual HDM2/HDMX inhibition by a cell-penetrating stapled peptide in human cancer.

#2159 A specific 17-beta-hydroxywithanolide (LG-02) sensitizes cancer cells to apoptosis in response to TRAIL and TLR3 ligands. Poonam Tewary, 1 Alan D. Brooks, 1 Ya-xing Xu, 2 Kittishri E.M. Wijeratne, 2 Leslie A. Gunatilaka, 2 Thomas J. Sayers, 4 Leidos Biomedical Research Inc, Frederick, MD. 2 University of Arizona, Tucson, AZ, AZ.

Recent studies have demonstrated a role of toll-like receptor 3 (TLR3) signal for the initiation of apoptosis in some malignant cells. We have previously shown that, withanolide E (WE), a 17-beta-hydroxywithanolide (17-BHW) natural product derived from the medicinal plant Physalis peruviana was capable of sensitizing tumor cells to tumor necrosis factor-related apoptosis-inducing ligand (TRAIL)-mediated apoptosis by reducing cellular levels of the anti-apoptotic protein cFLIP. Animal studies also revealed that WE sensitized human renal carcinoma cells to apoptosis at concentrations that did not promote apoptosis in normal cells. Thus we further screened a library of 30 natural and semi-synthetic 17-BHWs for their ability to promote death ligand-mediated cancer cell death. Among the 16 compounds tested, LG-02 (physachenolide C) was found to be 4-5 fold more potent than WE in sensitizing some human renal carcinoma and melanoma cells to apoptotic cell death in response not only to TRAIL but also to the synthetic polynucleotide poly (I:C), which is known to mimic anti-viral responses by activating TLR3 signaling. To date there are no withanolides known to have this dual apoptosis sensitizing activity. LG-02 and Poly (I:C) treatment resulted in increased activation of caspase-8, and apoptosis was blocked by the pan caspase inhibitor zVAD-FMK. Poly (I:C)-driven apoptosis signaling was dependent on endosomal acidification, but independent of IRF3 and Interferon α/β signaling. Molecular studies suggested a role for changes in the anti-apoptotic proteins cFLIP, IAPs, and Livin on apoptosis signaling in LG-02 treated cells. Loss of cIAP activity is reported to promote spontaneous formation of an intracellular death-inducing protein platform the ripoptosome, that can activate either apoptosis or necroptosis. Immuno-

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Targeting p53, Apoptosis, and the Cell Cycle

Proceedings of the American Association for Cancer Research  •  Volume 58  •  April 2017 553
EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Targeting p53, Apoptosis, and the Cell Cycle

preincubation of either the TRAIL death-inducing signaling complex (DISC) or the Poly (I:C) ripoptosome, demonstrated enhanced levels of FADD and RIP1 and decreased levels of cFLIP in these macromolecular apoptosis signaling complexes in LG-02 treated cells. Intratumor administration of LG-02 and Poly (I:C) in a xenograft M14 melanoma model provided therapeutic benefit leading to complete tumor regression in 90% of mice as compared to controls. Further studies with active 17-BHWs could lead to the identification of more potent analogues, and novel and common therapeutic targets involved in apoptosis signaling in response to both TNF death receptor family members as well as TLR3 ligands. Funded by FNLCR Contract HHSN261200800001E

Colorectal cancer is a major worldwide health problem owing to its high prevalence and mortality rate. Developments in screening, prevention, bio-marker, personalized therapies and chemotherapy have improved detection and treatment. However, despite these advances many patients with advanced metastatic tumors will still succumb to the disease. New anti-cancer agents are needed for treating advanced stage colorectal cancer as most of the deaths occur due to cancer metastasis. A recently developed novel sulfonamide derivative, 4-((2-(4-(Dimethylamino)phenyl)quinazolin-4-yl)aminobenzensulfonamide (3d) has shown to have potent antitumor effect; however the mechanism under- lying the antitumor effect remains unknown. Our study revealed that 3d treatment significantly reduced the viability of human colorectal cancer cells HT-29 and SW620. This is further evidenced by the induction of p53 and Bax, release of cytochrome c, activation of caspase-9, caspase-3 and cleavage of PARP in 3d treated cells. This compound was found to have significant effect on the inhibition of anti-apoptotic proteins, Bcl2, BclxL and XIAP. The results assessed in apoptosis (cleaved Parp) and cell-viability assays following combined inhibition of PI3K/Akt and BCL-XL, in PTEN-mutant prostate cancer cells results in synergistic apoptosis suggesting a novel therapeutic strategy with translational potential in this important subset of disease. Hypothesis: We hypothesized that synthetic lethality following combinational PI3K/BCL-XL inhibition is conserved across the range of PTEN-mutant cancer cells. Methods: PTEN-mutant cell lines (ATCC), validated for PTEN-loss and -pAkt expression, were assessed in apoptosis (cleared Parp) and cell-viability assays following combined inhibition of PI3K/Akt and BCL-XL, -pAkt induction (1.5x), and SW620. Further studies with active 17-BHWs could lead to the identification of more potent analogues, and novel and common therapeutic targets involved in apoptosis signaling in response to both TNF death receptor family members as well as TLR3 ligands. Conclusions: Synthetic lethality in PTEN-mutant tumor cells with PI3K/BCL-XL inhibition was confined to tumor cells without active MEK signaling. MEK inhibition inconsistently overcomes resistance to therapy suggesting heterogeneity of survival pathways in p-Erk expressing PTEN-deficient tumors. These data have implications for precision medicine approaches in PTEN-deficient tumors as absence of p-Erk expression may predict for a responsive phenotype.

#2163 Combined targeting of MEK and MCL-1 induces apoptosis and tumor regression of KRAS mutant NSCLC. Aaron N. Hata, Faria M. Siddiqui, Maria Gomez-Cardaballo, Samantha J. Bilton, Daria Timonina, Varuna Nangia, Angela Coxon, Sean Caenepeel, Paul Hughes, Massachusetts General Hospital, Charlotte, MA, Amgen, Inc, Thousand Oaks, CA.

There are currently no effective targeted therapeutic strategies for KRAS mutant, non-small cell lung cancer (NSCLC). Single agent MEK inhibitors have demonstrated showed disappointing clinical activity, partly due to inability to induce a robust apoptotic response. Combining MEK inhibitors with BCL-XL/-BCL-2 inhibitors may be effective for a subset of KRAS mutant cancers that are dependent on BCL-XL for survival, however this combination is unlikely to be an effective strategy for cancers dependent on MCL-1. We investigated the effect of combining the MEK inhibitor trametinib with a novel MCL-1 inhibitor (compound A), which possesses potent and selective anti-MCL-1 activity in vitro and in vivo, on KRAS mutant cancers. In contrast to colorectal cancer models, which are largely sensitive to combined MEK + BCL-XL inhibition, a subset of cell line and patient-derived mouse xenograft (PDX) KRAS mutant NSCLC models were significantly more sensitive to MEK + MCL-1 inhibition compared to MEK + BCL-XL. The model-based clinical trial strategies, we tested intermittent dosing regimens and unexpectedly discovered a method strategy for dramatically sensitizing KRAS mutant NSCLC cells to the MEK + MCL-1 combination. These studies provide rationale for the clinical evaluation of combined MEK + MCL-1 inhibitors for KRAS mutant NSCLC.

**#2164** BLID is a novel drug-inducible apoptotic molecule: Identification of an integrative mechanism of chemosensitivity in breast cancer cells. Sivaramakrishna Yadavalli, Rong Hu, Antonina Rait, Xin Li, Esther Chang, Robert Clarke, Usha Kasid. Georgetown Lombardi Comp. Cancer Ctr., Washington, DC.

The triple-negative breast cancer (TNBC) is an aggressive form of breast cancer frequently seen in African American women and BRCA1 mutation carriers. The TNBC tumors often relapse with distant metastases following standard chemotherapy. It is now evident that discoveries of new mechanisms and approaches that explain and target breast cancer biology are urgently needed for durable intervention of metastatic disease. Earlier, we have demonstrated that BLID, Bcl2 containing Insulator, is an important tumor suppressor and apoptosis-related factor in invasive breast cancer. Frequent lack of BLID has been associated with TNBC, African American ethnicity and younger women. Significant correlations exist between BLID negative breast cancer and declines in overall survival, local relapse-free survival and distant metastasis-free survival. Recently, BLID has been shown to inhibit breast cancer cell growth and metastasis. The purpose of this study was to investigate the role of BLID in response of breast cancer cells to chemotherapeutic drugs. In the dose response and time course studies, BLID mRNA expression was found to be induced by chemotherapeutic drugs. Expression of BLID CDNA nanoprecipitate (scBLID) resulted in significant increase in chemosensitivity in SKBr3 and MDA-MB-231 cells, and a comparison of BLID with p53 showed that the chemosensitization effect of BLID was significantly greater than that of p53. More consistently, BLID knockdown led to reduced induced cytotoxicity. In the ChIP-PCR and ChIP-qPCR assays, drug treatment of breast cancer cells resulted in an increased binding of pro-apoptotic transcription factor FOXO3a to the BLID promoter, and the reversal of drug-induced BLID reporter activity was seen in presence of FOXO3a siRNA. Furthermore, siRNA silencing of FOXO3a was found to be associated with decrease in endogenous BLID mRNA expression. Remarkably, we found that expression of central tumor suppressor microRNA miR34a also resulted in increased BLID mRNA expression and drug toxicity in breast cancer cells. Because lack of BLID expression has been associated with poor prognosis in breast cancer patients, we reasoned that the silencing of BLID may reveal as yet unknown changes in gene expression that may drive breast cancer cell proliferation and therapy resistance. In this context, the mRNA array profiling studies showed that BLID knockdown in MDA-MB-231 cells was associated with increased expression of the oncogenic/anti-apoptotic molecules CYP1B1, BIRC3 and CSF1, and decreased expression of the anti-oncogenic/apoptotic molecules AKAP12, DFN5 and CHRD1. Our data suggest that chemotherapeutic drugs induce BLID expression via activation of FOXO3a, and the BLID signaling axis downstream of FOXO3a and miR34a is a novel integrative mechanism of breast cancer response to chemotherapy. SY and RH are equal contributors in this study.

**#2165** Deletion of survivin sensitizes human hepatocellular carcinoma cells to low dose of doxorubicin and induce apoptosis. Joseph George, Nobuhiko Hayashi, Takashi Saito, Kazuaki Ozaki, Nobuyuki Toshikuni, Mariano F. Zacarias-Fluck, Silvia Casascuberta, Erika Serrano del Pozo, Christopher Fiore, Laia Foradora, Matthew Guenther, Eduardo Romero Sanz, Marta Oteo Vives, Cynthia Tremblay, Martin Montagne, Miguel Ángel Morcillo Alonso, Jonathan R. Whitfield, Pierre Lavigne, Laura Soucek, Peptomyc S.L., Barcelona, Spain; Vall d’Hebron Inst. of Oncology (VHIO), Barcelona, Spain; San Raffaele, Milan, Italy; Universita degli Studi di Parma, Parma, Italy; Birmingham Women’s Hospital, Birmingham, UK.

Background and Aims: Hepatocellular carcinoma (HCC) is one of the most common cancers in the world and patients with advanced HCC face a dismal prognosis due to lack of effective therapy. Survivin, a member of the family of inhibitors of apoptosis proteins, is highly upregulated in HCC as well as in experimentally induced intrahepatic tumors. Doxorubicin, the only known chemotherapeutic agent for HCC, is cardiotoxic in addition to several well known side effects. Methods: Survivin gene deletion was established in HepG2, Hep3B, and PLC/PRF/5 human HCC cells using CRISPR/Cas9 system. All the three HCC cells in culture were treated with doxorubicin at various concentrations before and after survivin gene knockout up to 72 hr. TUNEL assay and FACS analysis were performed to demonstrate the induction of apoptosis after doxorubicin treatment. Western blotting was carried out for cleaved fragments of caspase-9 and caspase-3 as well as major apoptotic executioner molecules. Results: Cell viability studies depicted around 20% cell death at 24 h, 50% at 48 h, and 80% at 72 h after treatment with doxorubicin at 1 μM (final concentration in the media). Among the three cell lines studied, Hep3B cells were more susceptible to doxorubicin compared to HepG2 and PLC/PRF/5 cells. After deletion of survivin gene, the dosage of doxorubicin could reduce to five fold (200 nM, final concentration in the media) with the same cytotoxic effect before the knockdown of survivin gene. HCC cells treated with reduced doses of doxorubicin depicted induction of apoptosis that was proved with TUNEL assay and FACS analysis as well as increased levels of cleaved caspases and major apoptotic executioner molecules. Conclusions: Our studies demonstrated that blocking of survivin with effective methods would be a successful approach to treat primary hepatic tumors with low and safe doses of doxorubicin and other anticancer agents.

**#2166** Arsenic trioxide targets BCL6 oncprotein for degradation in BCL6-dependent diffuse large B-cell lymphoma. Lok Man Yue, David Hau Wing Chau, Wenyeng Piao, (Eric) Wai Choi Tse, Yok Lam Kwong. The University of Hong Kong, Hong Kong, Hong Kong.

Diffuse large B-cell lymphoma (DLBCL) is the most common type of non-Hodgkin lymphoma throughout the world. B-cell lymphoma 6 (BCL6) overexpression is frequently observed in DLBCL. Several recent studies have supported that BCL6 is a critical pathogenic oncprotein in DLBCL. BCL6 represses various downstream genes, including ATR, TP53 and CDKN1A, thereby impairing DNA repair leading to derangement of cellular proliferation. Most importantly, a specific small molecule inhibitor targeting BCL6 successfully suppressed growth of BCL6-dependent DLBCL cell lines and primary human DLBCL cells, further suggesting that BCL6 plays an important pathogenetic role. Arsenic trioxide (As2O3) has been reported to target various oncogenic proteins, including PML-RARA in acute promyelocytic leukemia, cyclin D1 in mantle cell lymphoma, NPMc+ in acute myeloid leukemia and NPM-ALK in anaplastic large cell lymphoma, for degradation through ubiquitin-proteasome pathway. In this study we investigated the effects of As2O3 on BCL6 in DLBCL. As2O3 was found to inhibit cell proliferation and induce cell death via apoptosis in DLBCL cells. More interestingly, BCL6-dependent DLBCL cells were found to show higher sensitivity towards As2O3-induced cytotoxicity. BCL6 was found to be degraded by As2O3 at posttranslational level through the ubiquitin-proteasome pathway. Such degradation led to an upregulation of several downstream targets of BCL6, including PRDM1, CD44 and CD99. Moreover, As2O3 synergized with cisplatin to inhibit cell proliferation and enhance apoptosis in BCL6-dependent DLBCL cell lines. Concomitant treatment with As2O3 and cisplatin further enhanced the phosphorylation of Chk1 and γH2AX in these cells. In conclusion, our data suggest that As2O3 is a potential therapeutic agent for the treatment of BCL6-dependent DLBCL. On top of that, new combination therapies can be developed to expand the therapeutic spectrum of As2O3 to other neoplasms.

**#2167** Preclinical validation of an Omomyc cell-penetrating peptide as a viable anti-Myc therapy. Marie-eye Beaulieu, Toni Jautset, Daniel Massi-Valls, Peter Rahi, Sandra Martinez-Martin, Loika Maltais, Jonathan R. Whitfield, Pierre Lavigne, Laura Soucek, 1Peptomyc S.L., Barcelona, Spain; 2Vall d’Hebron Inst. of Oncology (VHIO), Barcelona, Spain; 3Syros Pharmaceuticals, Cambridge, MA; 4University of Sherbrooke, Quebec, Canada; 5Centre de Investigaciones Energeticas, Medioambientales y Tecnologicas (CIEMAT), Madrid, Spain.

Deregulation of the MYC oncprotein promotes tumorigenesis in most, if not all, cancers and is often associated with poor prognosis. However, targeting MYC has long been considered impossible based on the assumption that it would cause catastrophic side effects in normal tissues. Despite this general preconceived notion, we showed that MYC inhibition exerts extraordinary therapeutic impact in various genetic mouse models of cancer, and causes only mild, well-tolerated and reversible side effects. For these studies we employed the systemic and conditional expression of a dominant negative of MYC, called Omomyc, which we designed and validated, and that can inhibit MYC transcription function both in vitro and in vivo. To date, Omomyc has only been considered a proof of principle, with any potential clinical application limited to gene therapy. Here we actually show that the 11 kDa Omomyc polypeptide spontaneously transduces into cancer cells, demonstrating unexpected cell-penetrating ability. Once inside the nuclei, the polypeptide effectively blocks MYC binding to its target DNA sites, interfering with MYC transcriptional regulation and halting cell proliferation. Moreover, intranasal (i.n.) administration of the Omomyc polypeptide in mice results in its rapid and persistent distribution to lungs, as well as to other organs (i.e. intestine, liver, kidneys and brain). Importantly, i.n. treatment of mice bearing either Non-Small-Cell-Lung-Cancer (NSCLC) or glioblastoma (GBM) with the Omomyc cell-penetrating peptide (Omomyc<sup>CPP</sup>) significantly reduces tumor burden compared to their control counterparts, suggesting that Omomyc is accompanied by significant reprogramming of the tumor microenvironment and tumor immune response. In summary, our data indicate that this novel generation of polypeptides represents a new opportunity to potentially inhibit MYC pharmacologically in a variety of malignant diseases.
#2168 Nucleic acid clamp-mediated recognition and transcriptional modulation of MYC oncogenes through the stabilization of G-quadruplexes.

Taisen Hao, Tracy A. Brooks. University of Mississippi, University, MS.

G-quadruplexes (G4s) tend to cluster around biologically important regions such as promoters of DNA, 5'-UTR of mRNA and telomeres. Modulating G4s has been explored in these regions using a clamp-based approach for cancer treatment. MYC proto-oncogene is overexpressed in over 80% of tumor types, contributing to deregulated cancer cell proliferation. Silencing MYC expression has been demonstrated to be an effective approach to inhibit tumor growth. Among all the silencing strategies, stabilizing MYC promoter G4 that serves as an on-off switch for the transcription of MYC has been explored by the targeting non-natural molecules. However, the binding specificity of small molecule retarded the drug development process. Exploring novel MYC G4-targeting strategies is necessary to potentiate the pharmacological specificity of MYC G4 modulation. Here, we adopted a nucleic acid clamp based approach to recognize and stabilize the physiologically predominant MYC G4 with high specificity and to downregulate MYC promoter activity. In the current research, we modified and optimized this clamp to allow for flexibility with labeling and monitoring techniques. The original 18 Å polyethylene glycol phosphate linker connecting the 5’ and 3’ regions of clamp A were substituted with thymine bases of varying lengths; 5 thymines were found to be optimal. The binding effects by clamp B and B-g were confirmed. The activity of the optimized clamp A T5 were confirmed by EMSA and ECD; the G4 stabilizing ability of clamp A T5 was demonstrated by DMS footprinting. The cytoxicity of clamp A T5 was examined by MTS assay on HEK-293 and MCF-7 cells. The intracellular localization of clamp A T5 is being determined microscopically with a 6-FAM-labeled clamp A T5 after being transfected into and incubated with HEK-293 and MCF-7 cells for 48 hr. Nuclear localization is being examined by co-staining with DAPI and MYC promoter localization is being determined by clustering with a MYC FISH probe. The modification of the clamp is both cost-effective, and enables the detailed study of intracellular functions. This clamp has potential as both a diagnostic tool to inform the use of MYC G4-targeted small molecules, and as a nontherapeutic.

#2170 Rb1 suppresses prostate cancer metastasis and lineage plasticity underlying castration resistance.

Sheng-Yu Ku, Spencer Rosario, Yangqing Wang, Ping Mu, Mukund Seshadri, Zachary Goodrich, Maxwell Goodrich, Eduardo Cortez Gomez, Jianmin Wang, Bo Xu, Charles L. Sawyers, Leigh Ellis, David G. Goodrich. Roswell Park Cancer Institute, Buffalo, NY; Memorial Sloan Kettering Cancer Center, New York, NY.

Androgen deprivation therapy (ADT) is an effective treatment for metastatic prostate cancer (mPCa), but patients eventually relapse with ADT resistant disease. Well-characterized mechanisms of ADT resistance include AR amplification, intratumoral androgen synthesis, AR splice variants, and growth receptor bypass. All of these mechanisms function to maintain sufficient AR signaling to drive cancer cell growth and survival. Improved ADT like abiraterone acetate (AA) and enzalutamide (Enza) were developed to combat such resistance mechanisms associated with alterations in androgen receptor or androgen metabolism. While AA and Enza extend survival, clinical benefits are short-lived. A new form of resistance is increasingly appreciated in patients relapsing from AA or Enza, histologic transformation of prostate adenocarcinoma (PADC) to neuroendocrine prostate cancer (NEPC) variants. NEPC is lethal and the survival time is less than a year as effective targeted therapy is unavailable. NEPC typically exhibits reduced AR expression, increased expression of neuroendocrine markers, and visceral metastasis in the absence of rising PSA. Of note, NEPC possesses the similar genome rearrangements with adjacent PADC cells, indicating they share clonal origin. Thus, NEPC may arise by histologic transformation of PADC. Underlying mechanisms of histologic transformation are not understood and experimental models are limited, hindering development of effective remedies. Rb1 loss is common in NEPC, but rare in PADC; genetic profiling shows human NEPC exhibit elevated levels of several epigenetic modifiers. We hypothesize that transdifferentiation from PADC to NEPC in the context of Rb1 loss is due to epigenetic alterations and can be reversed or blocked by epigenetic targeted therapy. We have established several genetically engineered mouse models (GEMMs) to test the role of Rb1, and we find Rb1 loss causes metastatic progression of PADC initiated by Pten deficiency. This Rb1/Pten deficient (DKO) PADC exhibits expression markers for both PADC and NEPC as seen in human patients. Yet, these tumors are sensitive to ADT but relapse with low AR expression and acquired Trp53 mutations. RNA profiling demonstrates the phenotype of DKO tumors is similar to human NEPC. While castration and metastatic PADC is accompanied by increased expression of epigenetic reprogramming factors like Sox2 and Ezh2. Clinically relevant Ezh2 inhibitors GSK126 and EPZ66438 can restore Enza sensitivity by reversing neuroendocrine transformation. This finding has been genetically validated using short-hairpin RNA (shRNA) in vitro. These results uncover genetic mutations driving prostate cancer lineage plasticity and suggest an epigenetic approach for extending the clinical benefits of ADT.

#2171 Multi-CDK inhibition efficiently suppresses AR function and cell growth in prostate cancer.

Brian W. Simons, Maria Ybanez, Emmanuel S. Antonarakis, Jun Luo, Barry D. Nelkin. Johns Hopkins Univ. School of Medicine, Baltimore, MD.

Metastatic castration resistant prostate cancer (CRPC) continues to result in over 26,000 deaths per year in the United States. For 70 years, therapy for advanced prostate cancer has relied on AR-directed therapies. Unfortunately, even with the second generation androgen deprivation compounds, treated cancers commonly progress to castration resistance and lethality. This progression to castration resistance marks the central therapeutic roadblock for advanced prostate cancer. Importantly, in the vast majority of CRPC cases, the tumor still depends on AR signaling, but this signaling becomes androgen independent. The most common mechanisms, including mutation, protein truncation, and alternative splicing, affect the C-terminal domain, suggesting that antagonism of AR function via the N-terminal domain may be a promising target for CRPC therapy. Several groups have shown that CDKs 1, 5 and 9 activate AR by phosphorylation of the N-terminal domain.
domain. Here, we show that the multi-CDK inhibitor ronidocib (BAY1000394) inhibits activation of AR in a panel of prostate cancer cell lines, including several cell lines which exhibit androgen-independent AR signaling via AR-V7 alternative splicing. In vivo, ronidocib inhibited growth of prostate cancer xenografts. Since AR inhibition in prostate cancer has been shown to induce compensatory PI3K signaling, we compared xenografts with a combination of ronidocib and the PI3K inhibitor copanlisib (BAY 80-6946). This combination was especially effective, and was well tolerated by the mice. Our results suggest that a combination of a multi-CDK inhibitor and a PI3K inhibitor may be promising for CRPC therapy.

**#2172 ON 123300, an orally administered novel CDK4/6 + ARK5 inhibitor, exhibits potent antitumor activity in vivo: comparative studies with Palbociclib.**

Shradhita Patel,1 Priya Pancholi,1 Tanvi Visal,1 Amruta Samant,1 Dhyanwar Kansara,1 V. J. Rajadhayaksha,2 Benjamin S. Hoffman,3 Manoj Maniar,3 Vikas Sehdev1,1. Long Island Univ., Brooklyn, NY; 2Onconova Therapeutics Inc., Newtown, PA.

Background: The overexpression of cyclin-dependent enzymes 4/6 (CDK4/6) is known to cause cell cycle dysregulation in certain cancer types, making these cell cycle kinase attractive targets for pharmacological inhibition. The effectiveness of first-generation non-selective cyclin-dependent kinases, such as roscovitine and flavopiridol, was hampered by toxicities, leading to the development of second-generation compounds like IBRANCE®/Palbociclib that specifically inhibit CDK4 and 6. ON 123300 is a third-generation potent CDK4/6 inhibitor that also inhibits ARK5 with low nanomolar potency and has the potential to improve upon second-generation compounds. Previous studies have demonstrated the antitumor activity of single-agent ON 123300 in various pre-clinical cancer models of MM and leukemia. In this study, we investigated the comparative therapeutic potential of ON 123300 as an oral anti-cancer agent and a second-generation inhibitor, Palbociclib, in xenografted Rb+ve mouse models. Methods: MDA-MB-435S xenografted mice were treated once a day for 21 days with ON 123300 (125mg/kg) or Palbociclib (125mg/kg). Tumor volumes were measured and peripheral blood was gathered to evaluate the effect on hematological parameters. Separately, Western blot analyses were performed to determine the effect of CDK4/6 inhibition on p-Rb following intra-tumoral treatment with ON 123300 (2.5µM) or Palbociclib (2.5µM). Results: ON 123300 and Palbociclib reduced tumor growth with an equivalent magnitude during the 21-day treatment period, suggesting that the two compounds were equally effective in this model. Both compounds decreased Rb and platelet counts, however Palbociclib had a more prominent and statistically significant (P<0.05) inhibitory effect on neutrophil counts when compared to ON 123300 (30.70 ± 3.55 vs. 45.10 ± 2.04). Western blot analysis of tumor tissues demonstrated equivalent effects on p-Rb for both compounds. Conclusions: Xenograft data indicates that a third-generation CDK4/6 inhibitor, ON 123300, is as effective as Palbociclib in an Rb+ve xenograft model. Moreover, this study also suggests that ON 123300 may have the added advantage of reduced neutropenia compared to Palbociclib. Prior preclinical data suggest that ON 123300 may be efficacious in Rb-ve tumors, where second-generation compounds have diminished single-agent activity, and our ongoing studies are aimed at further characterizing the in vivo activity of ON 123300 in this setting.

**#2173 Targeting CDK1 and MEK/ERK overcome mutant BRAF-mediated apoptosis resistance in human colorectal cancer cells.**

Hisato Kawakami, Shengbing Huang, Frank A. Sinicrope. Mayo Clinic, Rochester, MN.

BRAFV600E mutation occurs in ~10% of human colorectal cancers (CRC) where it is associated with treatment resistance and poor prognosis. Data from TCGA and a clinical trial cohort identified a distinct subset of BRAF mutant colon cancers with deregulation of the cell cycle and overexpression of CDK1 (Barras D, et al, Clin Cancer Res. 2016). We tested the hypothesis that CDK1 inhibition can enhance apoptosis in BRAFV600E CRC cells. Since BRAF mutant cells show p-ERK activation, combined inhibition of CDK1 and MEK/ERK was evaluated. Using isogenic colon cancer cells, BRAF mutant alleles were shown to confer resistance to the CDK1 inhibitor, R0-3306, in a gene dose-dependent manner that was associated with reduced cleavage of caspase-3 and downstream PARP, and decreased pH2AX (DNA fragmentation marker). Ectopic BRAFV600E or constitutively active MEK mutant also conferred resistance to R0-3306. CDK1 siRNA was shown to increase cobimetinib-induced apoptosis, including annexin V labeling, and increased pH2AX. Furthermore, ERK siRNA or cobimetinib treatment attenuated CDK1 protein expression and increased R0-3306-induced pH2AX. Moreover, treatment with R0-3306 plus cobimetinib significantly enhanced a caspase-dependent apoptosis and markedly reduced colony formation vs either drug alone in two CRC cell lines. Caspase-3 cleavage by R0-3306 + cobimetinib was dependent upon caspase-8. Mechanistically, CDK1 inhibition by R0-3306 suppressed the phosphorylation of prosapase-8 at Ser-387 by shown by R0-3306 withdrawal which restored p-C8-S387 coincident with expression of the mitotic marker, pH3S10. In conclusion, inhibition of CDK1 can significantly augment apoptosis induction by MEK/ERK inhibition in BRAFV600E CRC cells, suggesting a novel therapeutic strategy to overcome mutant BRAF-mediated resistance.

**Apoptosis induction by CDK1 inhibitor (R0-3306) ± MEK/ERK inhibitor cobimetinib.**

**#2174 Inhibition of CDK8 kinase with SEL120-34A allows for a personalized approach in AML.**

Tomasz Rzyszmski,1 Michal Mikula,1 Eliza Zylkiewicz,1 Agnieszka Dreas,1 Katarzyna Wilkik,1 Aniela Golas,1 Katarzyna Wojcik,1 Magdalena Masiczycy,2 Iga Dudzicz,1 Katarzyna Kucwaj,1 Małgorzata Statkie- wiz,1 Krzysztof Goryca,2 Aleksandra Grochowska,2 Aleksandra Cabaj,2 Jerzy Ostrowski,1 Urszula Kukliniska,2 Krzysztof Brzozka,1 Selvita S.A., Krakow, Poland; 3Maria Sklodowska-Curie Memorial Cancer Center, Warsaw, Poland.

Inhibition of oncogenic transcription factors can provide a promising therapeutic strategy. SEL120-34A is a novel inhibitor of Cyclin-dependent kinase 8 (CDK8), which regulates transcription by associating with the Mediator complex. SEL120-34A interacts with the ATP binding site of CDK8 in type I inhibitor fashion and forms several types of interactions, including halogen bonds with the protein’s hinge region and hydrophobic complementarities within its front pocket. Although the full compound was only modestly active in solid tumor cell lines, it repressed phosphorylation of STAT3 Ser726 and could differentially inhibit viability of AML and ALL cell lines in vitro and in vivo, along with other type 1 CDK8 inhibitors. Transcriptomic analysis identified major transcriptional programs altered in responder cell lines, which strongly indicated that apart from repression of survival pathways, CDK8 inhibitors could induce differentiation in cell lines with leukemia stem cell characteristics. Further studies on a large panel of responder and non-responder cell lines identified robust biomarkers which could be used with high confidence for stratification and personalized approach in CDK8-dependent AML cases. Favorable pharmacokinetics, confirmed safety and in vivo efficacy in leukemia models provide the rationale for further clinical development of SEL120-34A.

**#2175 Vietnamese medicinal plant compounds show potent anti-pancreatic cancer activity in vitro.**

medicinal plants show significant pancreatic cancer growth inhibition and induce apoptosis in vitro at concentrations that have minimal effect on normal pancreatic cells and therefore show promise as novel anti-pancreatic cancer therapies.

#2176 Thymoquinone synergizes the anticancer properties of cisplatin against head and neck squamous cell carcinoma and protects normal oral epithelial cells. Abdulwahab Noorwali, 1 Omar Alabo, 1 Safia Al-Attas, 1 Fatheya Zahran, 1 Ahmed M. Al-Abd 2 King Abdullah University, Jeddah, Saudi Arabia, 2 National Research Centre of Egypt, Giza, Egypt.

Cisplatin (CDDP) is potent anticancer agent different tumors such as head and neck cancers. Thymoquinone is a natural compound drawing attention as chemotherapeutic and chemomodulator. Herein, we studied the chemomodulatory effect of thymoquinone to CDDP against squamous cell carcinoma cells. CDDP killed head and neck squamous cell carcinoma cells (UMSCC-14C) with IC50's of 5.2±0.2, 2.6±0.2 and 1.6±0.1 µM after treatment for 24h, 48h and 72h, respectively. On the other hand, IC50's of CDDP against normal oral epithelial cells were 36.4±1.1, 16.3±0.6 and 6.7±1.1 µM after exposure for 24h, 48h and 72h, respectively. Thymoquinone alone exerted considerable cytotoxicity against UMSCC-14C cells with IC50's of 9.0±0.2, 6.9±0.1 and 5.0±0.2 µM after treatment for 24h, 48h and 72h, respectively. While significantly weaker killing effect was noticed for thymoquinone against normal oral epithelial cells (OE) with IC50's of 41.1±0.5, 36.5±2.1 and 26.3±1.2 µM after exposure for 24h, 48h and 72h, respectively. Equitoxic combination of thymoquinone and CDDP showed synergistic interaction against UMSCC-14C cells (Combination index of 0.58) and antagonistic interaction against OE cells (Combination index of 1.12). Using annexin-V/PI staining, it was found that thymoquinone alone (5 µM) increased apoptotic cell fraction in UMSCC-14C cells, as early as after only 6 hours, from 1.7±0.1% to 24.4±0.6% compared to 2.7±0.4 apoptosis induced by CDDP (5 µM). Combination of CDDP with thymoquinone further increased total apoptosis in UMSCC-14C to 39.2±1.5% after 6h, prolonged exposure of UMSCC-14C to thymoquinone (5 µM) alone for 24h resulted in 96.7±1.6% total apoptosis which was increased after combination with CDDP to 99.3±1.2% in UMSCC-14C cells. In contrast to UMSCC-14C cells, thymoquinone did not induce any significant apoptosis in OE and even decreased apoptosis induced by CDDP alone from 4.5±0.3% to 3.4±0.2% after combination for 24h. Using western blot analysis, neither thymoquinone nor CDDP managed to increase the expression level of p53 apoptotic protein; while combination of CDDP with thymoquinone significantly increased p53 expression by 4.5 folds. On the other hand, both CDDP and thymoquinone decreased the expression level of the anti-apoptotic protein Bcl-2 to be 60% and 20% of control level, respectively. Combination of both agents further abolished the level of Bcl-2 to be 10% of control level. Caspase-9 expression was similarly induced by 2 folds and 4.5 folds after treatment with CDDP and thymoquinone, respectively. Combination of CDDP and thymoquinone further increased the levels of caspase-9 to be 6 folds original basal expression level. None of these findings could be detected in normal OE cell line. In conclusion, thymoquinone synergized the anticancer properties of CDDP against squamous cell carcinoma cells and protects from its damaging effect against normal epithelial cells.

#2177 The olive bioflavonoids oleuropein selectively induces apoptosis in pancreatic cancer cells in vitro. Chloe D. Goldsmith, 1 Helen Jankowski,1 Dan-chloe Bond, 1 Judith Weidenhofer,1 Costas Stathopoulou,2 Paul Roach,1 Christopher Scarlett1. 1The University of Newcastle, Ourimbah, Australia; 1University of Abertyer, Dundee, United Kingdom.

Pancreatic cancer is a devastating disease with a 5-year survival rate of less than 5%. Resistance to conventional treatment options and toxicity of current chemotherapy agents (gemcitabine) makes pancreatic cancer a target for the development of novel therapeutic agents. Oleuropein is the most abundant bioflavonoid found in olive products; it has anti-atherogenic and anti-inflammatory properties as well as activity against cancers of the breast, colon and prostate. However, there has yet to be any investigation into the effects of oleuropein on pancreatic cancer cells. Consequently, this study aimed to assess the anti-pancreatic cancer activity of oleuropein in vitro. Two cell lines were investigated: a pancreatic cancer cell line (MiaPaCa-2) and a normal pancreas cell line (HPDE).

The viability of cells after treatment with 0-200µM oleuropein was assessed using the Dojindo CCK-8 viability assay and compared to gemcitabine. The induction of apoptosis was measured by way of caspase 3/7 activation, using a MUSE flow cell analyser, and expression of Bcl-2, Bax and Bcl using Western blot. Cell cycle analysis was conducted using the MUSE flow cell analyser. RNA expression was assessed using Affymetrix GeneChip® Whole Transcript (WT) expression arrays.

The IC50 values for oleuropein against MiaPaCa-2 cells was 48±14 µM. However, importantly, oleuropein did not decrease the viability of HPDE cells within the treatment range. In comparison, 20 µM of gemcitabine did not show selectivity; it reduced the viability of MiaPaCa-2 cells to 21% and of HPDE cells to 2%. An increase in the expression of caspase 3/7 was seen in MiaPaCa-2 cells when treated with oleuropein but it had no effect on the HPDE cells. Furthermore, when treated with oleuropein, an increase in the expression of genes involved in the NRF-2 (oxidative stress) pathway was observed in Mi- PaCa-2 cells, an effect not observed in HPDE cells. Conclusion Oleuropein selectively induced apoptosis in the pancreatic cancer cells (MiaPaCa-2), appearing non-toxic to normal pancreas cells (HPDE) within the treatment range; this is significant, since gemcitabine was comparatively more toxic to HPDE cells. Furthermore, the link between oleuropein and the NRF-2 pathway in Mi-PaCa-2 cells justifies further study into the mechanisms of action of oleuropein and its potential as a novel therapeutic approach for pancreatic cancer.

#2178 Growth inhibition of the crude extracts of Musa basjoo in human colon carcinoma cells. Harutoshi Matsumoto, 1 Saeko Ando, 1 Katsumi Fukamichi, 1 Mitsuru Futakuchi, 1 Kazunori Kimura, 1 Naoki Yoshimi, 1 Masumi Suizu, 1 Department of Molecular Toxicology, Nagoya City University Graduate School of Medical Sciences and Medical School, Nagoya, Japan; 1Department of Clinical Pharmacy, Nagoya City University Graduate School of Medical Sciences and Medical School, Nagoya, Japan; 2Department of Pathology and Oncology, Graduate School of Medicine and Faculty of Medicine, University of the Ryukyus, Okinawa, Japan.

Musa basjoo (MB) is a tropical evergreen tree growing mainly in subtropical or tropical countries. MB has been used globally as a folk medicine such as antipyretic, diuretic, and hemostatic drugs for centuries but evidence-based biological activities and molecular mechanism of action of MB are unknown. Therefore, in the current study we examined whether the crude extracts of MB exert anticancer activity in HT29 and HCT116 human colon carcinoma cell lines. Dried leaves of MB samples were extracted with acetone or methanol. Crude extracts of MB were then dissolved in dimethylsulfoxide (DMSO) and used for the following experiments. Growth inhibition was determined by colony or MTT assays in these cell lines. Cells were treated with increasing concentrations (12.5 to 200 µg/mL in colony assays, 25 to 400 µg/mL in MTT assays) of acetone/methanol extracts of MB in DMEM/S%FBS. Untreated control cells were treated with DMSO alone. Crude extracts of MB inhibited the growth of cells with IC50 values of 118 µg/mL (acetone extract, HT29), 75 µg/mL (acetone extract, HCT116), >200 µg/mL (methanol extract, HT29), 141 µg/mL (methanol extract, HCT116) in colony assays, and with IC50 values of 157 µg/mL (ac- etone extract, HT29), 73 µg/mL (acetone extract, HCT116), 240 µg/mL (methanol extract, HT29), 248 µg/mL (methanol extract, HCT116) in MTT assays. Acetone extract was used in the flowcytometry and western blot analyses because it showed stronger growth inhibition than methanol extract in both cell lines. Flowcytometry analysis indicated that when HT29 and HCT116 cells were treated with 100 µg/mL acetone extract of MB for 96h, the percentage of cells in G1 increased by 5.4% and this was associated with a concomitant decrease of cells in the S and G2-M phases of the cell cycle. Acetone extract of MB induced sub-G1 fraction in either HT29 or HCT116 cell lines. The results indicate that acetone extract of MB causes carcinoma cells to arrest in the G1 phase. Therefore, we performed western blot analysis to determine whether treatment of carcinoma cells with acetone extract of MB alters cellular levels of the G1 cell cycle control proteins cyclin D1, cdk4 and the cell cycle inhibitor protein p21CIP1. When HT29 and HCT116 cells were treated with 50 and 100 µg/mL acetone extract of MB for 96h, there was a marked decrease in the levels of expression of the cyclin D1 and cdk4 proteins and a marked increase in the levels of expression of the p21CIP1 protein. Thus, a decrease in cyclin D1 may cooperate with the induction of p21CIP1 to arrest cells in G1 and thereby further contribute to MB-induced growth inhibition. Taken together, the crude extracts of MB contain active component(s) that exert growth inhibition of human colon carcinoma cells. The current study is the first systematic examination of the anticancer activity of MB and may provide a novel approach to the chemoprevention and/or chemotherapy of human colon carcinoma.

CANCER CHEMISTRY: Drug Delivery

#2179 Targeted delivery of nanoparticulate cytotoxic chrome c into GL361 glioma cells through the proton-coupled folate transporter. Yurty Kucher-yavvkh, 1 Jescelina Ortiz-Rivera, 1 Michael Inyushin, 1 Luis Cubano, 2 Moraima Morales-Cruz, 2 Alejandra Cruz-Montañez, 2 Kai Griebenow, 2 Lilia Kucher-yavvkh, 1 1Universidad Central del Caribe, Bayamon, PR; 2University Of Puerto Rico, Rio Piedras, PR.
These data suggest that TPM-LEP derivatives with optimized hydrophobicity tate adenocarcinoma (PC3), human breast cancer cell line (BT549) and mouse TPM-LEP conjugates and the corresponding non-covalent physical mixtures of DIPEA/DIC in moderate yields. Comparative antiproliferative assays between methoxybenzene or methyl2-methoxybenzoate and 1,3,5-trioxane, followed by derivatives with optimized hydrophobicity were synthesized by the reaction tris(4-methoxyphenyl)methanol (TPM) derivatives with the expectation to end. In this study, a prodrug strategy has been introduced to optimize the hy- activity of LEP by increasing the cellular uptake and retention is a remedy to this sive salivation, paraesthesia and increased dysuria. Improving the biological result in decreased levels of sex hormones to postcastration or menopausal tion(constant concentration of LEP in the blood) pituitary becomes insensitive to the action of GnRH. This reduces the level of gonadotropin in the blood, resulting in decreased levels of sex hormones to postcastration or menopausal levels. In addition to the usual side effects of this agonist analogs of LH-RH, other reported adverse effects include transient hypertension, dry mouth, exces- sive salivation, paraesthesia and increased dysuria. Improving the biological activity of LEP by increasing the cellular uptake and retention is a remedy to this end. In this study, a prodrug strategy has been introduced to optimize the hydrophobicity of LEP by using an appropriate hydrophobic linker attached to tris(4-methoxyphenyl)methanol (TPM) derivatives with the expectation to improve the cellular uptake. In this regard, several LEP conjugates of TPM derivatives with optimized hydrophobicity were synthesized by the reaction of methoxy benzenes (e.g. anisole, 2-fluoroisobenzyl, 2-methylanisole 1.2-di- methoxybenzene or methyl 2-methoxybenzate and 1.3,5-trioxane, followed by the conjugation with LEP and doxorubicin in the presence of HBTU/ DIPEA/DIC in moderate yields. Comparative antiproliferative assays between TPM-LEP conjugates and the corresponding non-covalent physical mixtures of the TPM derivatives and LEP were performed against human Caucasian pros- tate adenocarcinoma (PC3), human breast cancer cell line (BT549) and mouse pre-adjacent (3T3-L1) cells and indicated moderate to high inhibition of the cell proliferation at a concentration of 5-100 μM after 24-72 h of incubation. These data suggest that TPM-LEP derivatives with optimized hydrophobicity can be used to improve the biological activity of LEP.

#2180 Triphenylmethanol conjugates of leuprolin as anti-cancer prod- racks. Youssef Ahamedibehi, Kalhe Kharia, William Boadi. Tennessee State University, Nashville, TN.

Leuprolin (LEP) is a synthetic analogue of gonadotropin-releasing hormone (GnRH), first was approved by the FDA for treatment of advanced pros- tate cancer and endometriosis in 1985. The initial effect of administration LEP is to stimulate the pituitary secretion of FSH and LH. After a prolonged stimula- tion (constant concentration of LEP in the blood) pituitary becomes insensitive to the action of GnRH. This reduces the level of GnRH, resulting in decreased levels of sex hormones to postcastration or menopausal levels. In addition to the usual side effects of this agonist analogs of LH-RH, other reported adverse effects include transient hypertension, dry mouth, exces- sive salivation, paraesthesia and increased dysuria. Improving the biological activity of LEP by increasing the cellular uptake and retention is a remedy to this end. In this study, a prodrug strategy has been introduced to optimize the hydrophobicity of LEP by using an appropriate hydrophobic linker attached to tris(4-methoxyphenyl)methanol (TPM) derivatives with the expectation to improve the cellular uptake. In this regard, several LEP conjugates of TPM derivatives with optimized hydrophobicity were synthesized by the reaction of methoxy benzenes (e.g. anisole, 2-fluoroisobenzyl, 2-methylanisole 1.2-di- methoxybenzene or methyl 2-methoxybenzate and 1.3,5-trioxane, followed by the conjugation with LEP and doxorubicin in the presence of HBTU/ DIPEA/DIC in moderate yields. Comparative antiproliferative assays between TPM-LEP conjugates and the corresponding non-covalent physical mixtures of the TPM derivatives and LEP were performed against human Caucasian pros- tate adenocarcinoma (PC3), human breast cancer cell line (BT549) and mouse pre-adjacent (3T3-L1) cells and indicated moderate to high inhibition of the cell proliferation at a concentration of 5-100 μM after 24-72 h of incubation. These data suggest that TPM-LEP derivatives with optimized hydrophobicity can be used to improve the biological activity of LEP.

#2181 Antibody-conjugated nanoparticles for targeting metastatic triple- negative breast cancer. Vidhi Khanna, Stephen Kalscheuer, Ameya Kirtane, Jayanth sundara, James R. Ewing, Henry Ford Hospital, Detroit, MI.

Early detection and the availability of new treatments have improved the survival rates of patients presenting with local or regional breast cancer to as high as 99% and 85%, respectively. On the contrary, patients with metastatic disease have a dismal 5-year survival rate of 17%. Thus, there is an urgent need for treatment strategies directed towards metastasis. Our lab has developed antibi- odies (Clone 6 and AM6) capable of recognizing tumor cells that have undergo- gone epithelial-to-mesenchymal transition (EMT), a key step in the generation of circulating tumor cells and metastasis. The goal of the current study was to determine whether these antibodies can activate an anti-cancer drug-loaded polymeric nanoparticles to metastatic triple negative breast cancer cells as a novel therapeutic option. Polymeric PLGA nanoparticles loaded with paclitaxel, a chemotherapeutic agent, were functionalized with the antibodies using thiol-maleimide chemistry. We optimized the conjugation re- action in order to achieve maximal cell uptake of nanoparticles without com-promising antibody binding. In vitro studies were carried out in an MDA-MB- 231 derivative cell line with enhanced lung metastatic potential as well as a melanoma metastatic cell line M12. Clone 6 nanoparticles and AM6 nanoparticles showed significant improvement in cellular uptake as well as retention. A competition experiment confirmed target-mediated uptake of nanoparticles. Cytotoxicity studies showed improved cell killing when using Clone 6 nanoparticles and AM6 nanoparticles. Based on these promising in vitro results, we are currently carrying out in vivo studies in mice. The development of a targeted drug delivery system for the treatment of metastatic triple negative breast cancer can signifi- cantly enhance the survival rate for patients who often have a life-expectancy of less than one year.

#2183 Targeted delivery of hyaluronic acid-labeled chitosan nanopar- ticles against CD44 overexpressed endothelial cell for tumor angiogenesis therapy. Daehee Kim, Seung Soo Lee, Sunalee Jayasundara, James R. Ewing, Henry Ford Hospital, Detroit, MI.

Antiangiogenesis therapy VEGF-VEGF receptors (VEGFRs) axis alone or in combination with other therapeutic agents have demonstrated mixed results, with the majority of reports indicating that glioblastoma multiform (GBM) de- veloped resistance against anti-angiogenesis therapy as well as small molecular receptor tyrosine kinase inhibitors. This result is perhaps not unexpected, be- cause angiogenesis is obviously complex, involving dozen of different growth factors that trigger a cascade of subsequent events. Even if a drug effectively blocks one angiogenic growth factor, such as VEGF, blood vessels may still develop via activating alternative pathways. Yet without a sufficient blood supply, cancerous tumors can’t grow larger than the head of a pin and are unlikely to become lethal. Therefore, tumor vascularization is a critical process that deter- mines tumor growth, progression and metastasis. Thus, tumor vascularization has become an emerging target for new chemotherapeutic drugs. Vascular disrupt- ing agents (VADs) for example, combretastatin (CA4), represent a new class of chemotherapeutic agent that targets the newly formed vasculature in solid tum- ors. Preclinical and early phase trials have demonstrated the promising ther- apeutic benefits of CA4. Nevertheless, the clinical translation of CA4 has been significantly hampered due to its poor systemic bioavailability and the non- specific distribution of CA4 throughout the body when administered intra- venously. Thus, it is reasonable to explore novel formulations of CA4 that overcome the limitations mentioned above. To improve bioavailability com- brestastatin phosphate (CA4-P) has been synthesized. But, CA4-P showed short blood half life. We have engineered dendrimer-based nano-sized CA4 conjugate which demonstrates high water solubility. Preliminary intrave- nous (i.v.) delivery of nano-combretastatin in an orthotopic glioma model demonstrated a necrosis at the core of the tumor leaving a rim of viable tissue. The MRI-determined tissue parameters Ktrans, blood flow (CBF), DWI, ADC map, distribution volume and tumor size indicated the effective- ness of nano-combretastatin treatment.
Cross-disciplinary optimization of nano-drug delivery to ovarian carcinoma and glioma cells. Rupin Singh,1 Rana Falahat,2 Eva Williams,3 Joseph O. Johnson,4 Norma Alcantar,5 Aleksandra Karolak,6 Katarzyna Rejniak,7 Marzena Wiranowska,8 University of South Florida Morsani College of Medicine, Tampa, FL; 9University of South Florida College of Engineering, Tampa, FL; 10H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL.

This study describes the optimization of a targeted drug delivery system (DDS) consisting of fluorescent labeled 0.01 μM paclitaxel-BODIPY564/570 encapsulated in non-ionic surfactant vesicles embedded in a thermosensitive cross-linked chitosan hydrogel. This is a multi-tiered DDS that allows for enhanced stability, sustained and controlled drug delivery to tumor sites, and decreased toxicity to normal tissues. We demonstrated that cancer cells of epithelial origin, such as human ovarian epithelial carcinoma OV2008 and highly migratory mouse glioma G-26, overexpress MUC1, a mucin surface antigen, which effectively enhances the specific targeting capacity of chitosan. Utilizing this DDS we found that OV2008 carcinoma cells had ~2 times higher fluorescence intensity level than normal ovarian epithelial IMC3 cells with a statistical significance at 5 min and 24 h incubation times suggesting that this DDS had a higher affinity for tumor cells. Therefore, we hypothesized that there is a difference in PTX diffusion towards epithelial origin tumor cells when compared to normal cells in both distance/location and time. Diffusion and localization of fluorescent labeled PTX was evaluated in vitro using confocal microscopy. The fluorescence intensity captured in the images was quantified with ImageJ software in OV2008 carcinoma cells and compared to IMC3 normal cells at time intervals of 5 min, 1 h, 24 h, 48 h, and 72 h. The fluorescence intensity image data was analyzed in multiple radial line segments separated into three different zones of 24 μm each to represent multiple diffusion distances. Our results showed that fluorescence intensity levels in the zones around the IMC3 normal cells at 5 min and 1 h were significantly higher than in the OV2008 carcinoma cells correlating reciprocally with our finding of intracellular fluorescence intensity in these two cell lines. Therefore, the data evaluating fluorescence levels in the radial zones outside the cells indicated that the migrating DDS-PTX had already been taken up by the tumor cells. Furthermore, the normal cells which showed significantly lower intracellular levels of fluorescence had higher levels of fluorescence in the measured radial zones outside the cells. This PTX fluorescence data from in vitro studies is currently being used for computational modeling in the in vivo intracerebral model of G-26 glioma. It will be integrated with mathematical model simulations that describe the pharmacokinetic and pharmacodynamic (PK/PD) properties of this drug delivery system for the evaluation of its efficacy and to optimize drug delivery in vivo. Computational modelling is being done in Matlab using the treatment scenario of the post-surgical late-stage glioma. The simulation studies will be used to determine optimal drug concentrations, chitosan density, and localization.

Peptide-cleavable maytansimid (ADCs) induce high bystander killing leading to improved anti-tumor activity in vivo. Wayne C. Widdison, Juliet A. Costopoulos, Jose F. Ponte, Leanne Lanieri, Yelena Kovtun, Ravi V. Chari. GenInc., Waltham, MA.

Antibodies targeting surface antigens on cancer cells typically have progressively lower access to tumor cells that are further removed from blood vessels. Also, the antibody will not bind to cells in the tumor mass that do not express antigen, including stromal cells of the tumor, many of which reportedly aid in the survival or metastasis of cancer cells. ADCs can bind to antigen positive cancer cells, after which they are internalized and catabolized to release one or more cytotoxic metabolites that can kill the targeted cell. Metabolites that are membrane permeable may also diffuse into and kill neighboring cells, often called bystander cells, that would normally be less accessible. The goal of this work was to design ADCs that would have increased bystander activity, which could result in greater killing of cancer cells and stromal cells in the tumor environment. We have prepared a new type of peptide-cleavable immotile ADC (P-ADC) that efficiently released cytotoxic maytansimid metabolites upon cleavage of the peptide linker, followed by immolation. Several P-ADCs were prepared that release metabolites having different degrees of hydrophobicity. As the hydrophobicity of the metabolite increased, the P-ADC’s bystander activity also increased. The lead PDI-ADC generally displayed a similar degree of in vitro cytotoxicity as maytansimid ADCs that utilize disulfide linkers, however the PDI-ADC induced significantly more bystander killing. In mice bearing large tumor xenografts (250 mm3) or tumor xenografts that express the target antigen heterogeneously, PDI-ADCs were found to be more efficacious than maytansimid ADCs that use disulfide linkers, as well as our recently reported peptide-para-anilino maytansimid ADCs. The nature of the amino acid residues in the peptide linker of the PDI-ADC was also altered so that the tolerability of the ADCs in mice could be increased without impeding efficacy. In conclusion, we have developed a promising new type of maytansimid ADC, one that provides a high degree of bystander killing, improved activity in homogeneous and heterogeneous tumor models in vivo, and has a different mechanism of metabolite release than current maytansimid based ADCs.

Pro-nanodrug with intratumoral reconstitution and intracellular delivery beyond therapy-resistance molecular pumps. Rong Xu,1 Mauro Ferracci,2 Haifa Shen,3 Department of Pharmacology, School of Basic Medicine, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China; 4Department of Nanomedicine, Houston Methodist Research Institute, Houston, TX.

Tumor metastases to distant organs pose a serious challenge to cancer treatment. The metastatic tumor lesions are less accessible to cancer drugs and the malignant cells often quickly develop therapy resistance. To address both biological and drug transport concerns in cancer treatment, we have developed a novel composite pro-nanodrug to provide sustained intra-tumoral assembly of nanotherapeutics, and tested its anti-cancer efficacy in murine models of breast cancer metastases to the lung and liver. Specifically, large payloads of polymeric doxorubicin (pDox) pro-drug were packaged as single molecules into a porous silicon microparticles that can be enriched in tumor tissue in the forms of vascular and cellular depots. Once inside the tumor, the pDox molecules self-assemble into nanoparticles where they are effectively internalized by tumor cells. The nanoparticles are transported through the vesicular system, and doxorubicin is cleaved from the polymer and released in the immediate proximity of the nucleus beyond the reach of the drug efflux pumps. In vivo efficacy studies demonstrated that the pro-nanodrug was effective in treating metastatic tumors with or without expression of the multi-drug resistant genes.

Targeted delivery of pro-apoptotic peptide using ELP-based carrier for effective cancer therapy in various cancer model. Sarangthem Vijaya, Rupin Singh,1 Rana Falahat,2 Eva Williams,2 Joanne Goldsmith,2 Marzenna Wiranowska,1.

Therapeutic peptides classified as biopharmaceuticals have gained attention as a new generation of cancer therapeutics with enhanced efficiency and diminished toxicity. They often fail to have sufficient effects due to their unsatisfactory pharmacokinetic profiles, which include poor bioavailability, low stability, short half-life, and poor penetration across the biological membrane. Elastin-like polypeptide (ELP)-based drug delivery has been utilized for various applications including cancer therapies for many years. Genetic incorporation of internalization ligands and cell targeting peptides along with ELP polymer enhanced tumor drug accumulation and retention time as well as stability and activities of the drug conjugates. Herein, we described a unique delivery system comprised of genetically engineered ELP incorporated with multiple copies of IL-4 receptor targeting peptide (AP1) periodically and proapoptotic peptide (KLAKLAK), referred to as AP1-ELP-KLAK. It triggered thermal responsive self-assembly into a sphere-nanoparticle-like structure at physiological body temperature and stabilized its helical conformation, which is critical for its membrane disrupting activities. Increased IL-4 receptor specific cellular internalization was associated with the enhanced cytotoxic effect of (KLAKLAK)2 peptide. Additionally, multivalent presentation of targeting ligands by AP1-ELP-KLAK significantly enhanced intratumoral localization and prolonged the retention time compared to ELP-KLAK, non-targeted control. Systemic administration of AP1-ELP-KLAK significantly inhibited tumor growth by provoking cell apoptosis in MDA-MB231 breast cancer and B16F10 melanoma tumor xenograft models without any specific organ toxicity. Thus, our newly designed AP1-ELP-KLAK polymer nanoparticle is a promising candidate for effective cancer therapy and due to the simple preparative procedures of ELPs, this platform can be used as a good carrier for tumor-specific delivery of other therapeutics.

Adhesion and entry of gold nanoparticles into breast cancer cells: Nanoparticles for localized delivery/hyperthermia. Vanessa O. Uzonna,1 John David Obayemi,2 Rupin Singh,1 Rana Falahat,2 Eva Williams,2 Joanne Goldsmith,2 Marzenna Wiranowska,1.

The specific releases of breast cancer cells is important for the early detection and treatment of cancer cells/tumor tissue, hence the drive for the development of nanoparticles. This paper presents results of an atomic force microscopy study on the adhesion between triple negative breast cancer cells (MDA-MB-231 and MDA-MB-468) and biosynthesized gold nanoparticles (GNP) conjugated
with luteinizing hormone releasing hormone (LHRH) which is known to target LHRH receptors that are over-expressed on the surfaces of breast cancer cells. It also estimates time scales for Gold nanoparticle entry into cells by means of an analytical model. The adhesion forces between the LHRH-conjugated gold nanoparticles and the breast cancer cells are found to be about 4-5 times greater than those of their normal breast cell counterparts. LHRH-conjugated gold nanoparticles. The increase in the adhesion of LHRH to breast cancer cells is shown to be associated with an increase in the LHRH receptor density, which is revealed using confocal microscopy. The implications of the results are discussed for localized treatment of breast cancer.

#2190 Theranostic nanoscale metal-organic framework-mediated rapid multiplexed microRNA detection and highly therapeutic efficacy in living oral cancer cells. Pei Yu,1 Zehang Zhuang,1 Guihua Qu,2 Haolin Chen,3 Yuying Zhao,1 Jinxiao Chen,1 Xiqiang Liu,1 2 Guanghua School of Stomatatology, Hospital of Stomatology, Sun Yat-sen University, Guangzhou, China; 3 College of Pharmacology, Southern Medical University, Guangzhou, China.

Oral cancer represents the sixth most frequent cancer in the world, characterized by high poor prognosis and low survival rate due to local relapse and metastasis. MicroRNAs (miRNAs) have been discovered as diagnostic biomarkers in patients with oral cancer. However, one of the major challenges of miRNAs-based theranostical approach is to achieve efficient therapy and safety delivery. Thus, a reliable strategy can be used to detect miRNAs expression levels in living cancer cells is urgently needed. Herein, a novel sensing platform based on nanoscale metal-organic framework (NMOF) conjugated with the fluorophore-labeled single-stranded DNA probe (p-DNA) was fabricated to monitor and inhibit multiplexed miRNAs expression in living oral cancer cells. The flow cytometry and confocal laser scanning microscopy (CLSM) were carried out to evaluate the expression levels of miRNAs in oral cancer cells. The miRNA inhibition efficiency was examined by RT-PCR. The effects of the complexes on tumor cell invasion and migration were assessed by transwell assay and wound healing. The flow cytometry, colony formation assay and CCK8 were used to assess cell apoptosis and proliferation. The results showed that NMOF works as fluorescence quencher of the labeled p-DNA. In presence of the target miRNA (including miR-7, miR-21, and miR-155), p-DNA was able to rapidly hybridize and release from the NMOF leading to the recovery of fluorescence in living cells, which can be detected in real-time. Moreover, RT-PCR results demonstrated that the multiplexed miRNAs could be effectively downregulated after treatment of p-DNA@NMOF, resulting in the simultaneous suppression of oral cancer cell proliferation, anti-apoptosis, migration and invasion in vitro. In summary, our study suggests that p-DNA@NMOF possess great potential for combining early diagnosis and gene therapy of oral cancer.

#2191 Multiple imaging reporter labeled acid-degradable dextran nano- polymer as a COX-2 siRNA carrier for COX-2 specific downregulation. Zhao-hang Chen, Balaji Krishnamachary, Marie-France Penet, Zaver M. Bhujwalla. Johns Hopkins University, SOM, Baltimore, MD.

Cyclooxygenase-2 (COX-2) as a target has attracted interest for multiple degenerative diseases and cancers. COX-2 siRNA provides specific and effective down-regulation of COX-2. However, because artificial cationic polymers can induce proinflammatory agents that increase COX-2 expression, there are no reports about the use of artificial cationic polymers as siRNA carrier to downregulate COX-2 in cancer cells. Here we developed a method to efficiently synthesize a multiple imaging reporter labeled biodegradable dextran to use as an efficient cationic polymer carrier for COX-2 siRNA delivery. Amine function groups were conjugated to the dextran platform through acetal bonds. Acetal bonds were broken at acidic conditions that occur in cancer and endocytosis compartments. Rhodamine was labeled to the amine groups to detect degradation and removal of these groups from the cell, while the dextran scaffold was labeled with Cy5.5. The rapid cleavage and release of amine groups minimized the proinflammatory side-effects of the positively charged amine groups. Cytotoxicity assay of Cy5.5 and rhodamine in different pH buffer indicated that the amine group was cleaved at pH 5.5 buffer but was stable in pH 7.4 buffer. Fluorescence imaging showed that the dextran siRNA nanoplex entered the cells through endocytosis that provided acidic conditions for the breaking of the amine group. For the first time, the intracellular breaking of acetal bonds was clearly visualized by multiple imaging reporters. Because the rapid cleavage and release of amine groups minimized the proinflammatory side-effects, quantitatively reversed transcription polymerase chain reaction (qRT-PCR) assay indicated that this dextran COX-2 siRNA nanoplex could downregulate COX-2 expression efficiently. Prostaglandin E2 level decreased significantly with COX-2 siRNA/dextran treatment. In vivo imaging demonstrated that the COX-2 siRNA/dextran nanoplex accumulated in MDA-MB-231 tumors. QRT-PCR and western blot assays of COX-2 levels in tumor tissue demonstrated that this nanoplex significantly downregulated COX-2 expression in vivo efficiently and within 24h. This dextran nanopolymer can be used as a safe, reproducible, and biocompatible siRNA carrier to effectively reduce COX-2 expression in cancer cells and tumors.

#2192 DFP-10825 IP delivery provides a new effective treatment option to peritoneal disseminated cancers. Cheng Jin,1 Kenzo Iizuka,1 Kokoro Eshima,1 Masakazu Fukushima,1 Tatsuhiro Ishida,1 Cheng-Long Huang,2 Hiromi Wada,3 Kiyoshi Eshima,1 1 Delta-Flu Pharma Inc., Tokushima, Japan; 2Tokushima University, Tokushima, Japan; 3Kyoto University, Kyoto, Japan.

Objective: Peritoneal disseminated ovarian and pancreatic cancers are the most difficult to be treated with conventional cytotoxic or molecular targeted drugs. The treatment option is very limited although an intraperitoneal (IP) paclitaxel has been available and shown to improve a prognosis in patients. Therefore, it is urgent to develop a new IP chemotherapeutic drug regulating the fast DNA synthesis in peritoneal disseminated tumors originated commonly from the ovary, pancreas and stomach. We have developed a unique RNAi molecule consisting of shRNA (55-mer) against TS and a cationic liposome (DFP-10825) and tested its anti-tumor activity and PK profile in peritoneal disseminated ascitic tumor models. Methods: We developed luciferase gene-transfected ovarian cancer (SKOV3-luc) and pancreatic cancer (PANC-1-luc) models in mice. After IP injection of 5x10⁶ cells, DFP-10825 containing 20 μg TS shRNA (20 mg/mouse) was administered in an IP route (q3d x 4) to the tumor-bearing mice. In combination therapy, paclitaxel (10 mg/kg) was also IP administered to SKOV3-luc mice to which the treatment was performed in the same schedule. The anti-tumor effect was assessed by measuring luciferase activity and tumor volume. Furthermore, the TS expression level in both ascetic tumor cells and solid tumors was measured by conventional RT-PCR. For PK study with DFP-10825 (especially TS shRNA), total RNAs were isolated at various time points from ascetic tumor cells and disseminated SKOV3-luc solid tumor models treated with DFP-10825 and TS shRNA levels were determined by Stem-loop RT-PCR. Results: IP DFP-10825 delivery significantly suppressed the growth of ascetic SKOV3-luc and PANC-1-luc tumor cells and extended the survival time of these tumor-bearing mice compared with that of control group. Combination with the IP paclitaxel augmented the efficacy of DFP-10825. After the IP administration, TS shRNA levels derived from DFP-10825 in ascitic fluid were maintained at nM range (0.7 - 4.3-nM) across 24 hours but not detected below 5 pm in the plasma, suggesting that TS shRNA be relatively stable in the peritoneal cavity to be able to exert its anti-tumor activity but not in blood. Also, TS expression (TS mRNA) in ascetic tumor cells was significantly suppressed, supporting the notion that the anti-tumor activity and host survival benefit by DFP-10825 in tumor-bearing mice are through MOA to knock down the TS level in tumors specifically. Conclusion: IP administration of newly developed DFP-10825, the TS shRNA conjugated with cationic liposome is localized stably in the peritoneal cavity and provides a new effective treatment option to the intractable peritoneal disseminated ovarian and pancreatic cancers without any systemic adverse events.

#2193 Structural modification of the chemotherapeutic anandamide: Designing anti-cancer agents and investigating their COX-2 metabolic products. Andrew Norris,3 Eman Soliman,3 Rukiyah Van Dross,1 Colin Burns,1 1 East Carolina University, Greenville, NC; 3Faculty of Pharmacy, Zagazig University, Zagazig, Egypt.

Many epithelial cancers have been shown to overexpress the enzyme cyclooxygenase-2 (COX-2), an enzyme responsible for metabolizing anandamide (AEA) to prostamides. AEA has demonstrated cytotoxicity in COX-2 overexpressing cancers via its metabolism to novel J-series prostamides, namely 15d-PGJ₂. Fatty acid amide hydrolase (FAAH) degrades AEA into arachidonic acid and ethanolamine (EA), limiting the cytotoxic capability of AEA. Cell lines with high FAAH expression have demonstrated resistance to AEA. By understanding the metabolic characteristics of FAAH, we can design AEA analogs which circumvent FAAH breakdown. To examine the effects of altering polarity, steric bulk, and functional groups on AEA-mediated cytotoxicity, we investigated known AEA derivatives which possess these properties. Arvanil, Arachidonoyl Diethanolamine (ADA), Arachidonoyl Serinol (AS), and R1-methanandamide (m-AEA) add steric bulk to the molecule via aromatic rings, extra EA arms and additional alcohol/methyl functional groups respectively. Arachidonoyl glycine (NAGly) substitutes the terminal EA alcohol with a carboxylic acid increasing additional alcohol/methyl functional groups respectively. Arachidonoylglycine (m-AEA) add steric bulk to the molecule via aromatic rings, extra EA arms and additional alcohol/methyl functional groups respectively. Arachidonoylglycine (m-AEA) add steric bulk to the molecule via aromatic rings, extra EA arms and additional alcohol/methyl functional groups respectively. Arachidonoylglycine (m-AEA) add steric bulk to the molecule via aromatic rings, extra EA arms and additional alcohol/methyl functional groups respectively. Arachidonoylglycine (m-AEA) add steric bulk to the molecule via aromatic rings, extra EA arms and additional alcohol/methyl functional groups respectively.
structural modifications improve AEA-mediated cytotoxicity. To determine this, JWF2 tumorigenic keratinocytes were exposed to differing concentrations of the AEA analogs for 24 hours and cell viability was measured by conducting MTS assays. Arvanil demonstrated a 90% reduction in cell viability, NAGly demonstrated a 70% reduction in cell viability, and m-AEA demonstrated a 100% reduction in cell viability. Against the OVCAR-3 and SKOV-3 cell lines, Arvanil demonstrated a 60% reduction in cell viability and Arvanil demonstrated a 100% reduction in cell viability in patient-derived primary melanoma. These findings suggest that modulation and substitue to the core structure of AEA will result in decreased susceptibility to FAAH degradation and enhanced antineoplastic activity.

#2194 Synergistic cytotoxicity of targeted liposomes containing doxorubicin and C6-ceramide against nucleolin-overexpressing ovarian cancer cells is supported by the downregulation of the Akt pathway. Ana Filipa Cruz, 1 Nuno André Fonseca, 1 Susana F. Sampaio, 1 Vera Moura, 1 Ramiro D. Almeida, 1 Sérgio S. Moreira, 1 1CNC - Center for Neuroscience and Cell Biology, University of Coimbra, Coimbra, Portugal; 2CNC - Center for Neuroscience and Cell Biology, University of Coimbra, Coimbra, Portugal; 3TREAT U, SA, Coimbra, Portugal.

The acknowledgment that cancer stem cells (CSC) may originate from non-stem normal cells, overturning an EMT-mediated process has turned these distinct cell subpopulations into two relevant therapeutic targets. Moreover, the PI3K/AKT/mTOR pathway is essential to CSC proliferation and survival and it is often over-activated in ovarian cancer. One of the strategies to target these different tumor cell populations, relies on the combination of conventional chemotherapy drugs (as tumor debulking agents, targeting non-stem cancer cells) with sphingolipids targeting CSC (at the level of PI3K/Akt/mTOR). Nucleolin (overexpression has been demonstrated on the surface of both breast CSC and non-stem breast cancer cells (Fonseca NA, Biomaterials 2015) and endothelial cells from tumor blood vessels. The pH-sensitive lipid-based nanoparticle, functionalized with the nucleolin-binding F3 peptide, was recently modified to encapsulate a synergistic combination of a sphingolipid (C6-ceramide) and doxorubicin (DXR). Following the promising results in breast cancer, the aim of this work was to assess the therapeutic potential of this strategy against nucleolin-overexpressing ovarian cancer cell lines, as well as the underlying mechanism of action at the molecular level. A 12.9-fold increase of association of fluorescently-labelled F3 peptide-targeted liposomes ([F3][L], relative to the non-targeted counterparts, into (bulk) ovarian cancer cell lines (SKOV-3, OVCAR-3 and TOV-112D) was observed by flow cytometry. Importantly, the marked pattern of association by prior CSC-enriched population was demonstrated by a 60% reduction in cell viability and A431 tumorigenic keratinocytes. NAGly demonstrated a 60% reduction in cell viability and Arvanil demonstrated a 100% reduction in cell viability in patient-derived primary melanoma. These findings suggest that modulation and substitue to the core structure of AEA will result in decreased susceptibility to FAAH degradation and enhanced antineoplastic activity.

Oxazaphosphorines (Oxaza) represented by cyclophosphamide (CPA) and ifosfamide (IFO) are still the corner stone of several polychemotherapy protocols as they are widely indicated in the treatment of numerous cancer from soft tissue sarcomas to lymphomas and immune-related diseases. However, Oxaza are prodrugs requiring cytochrome (CYP) P450 bioactivation responsible of their toxicities. In particular, the release of the active metabolite 4-OH-IFO (10%), which generates the active nitrogen mustard displaying DNA cross-links. Associated toxicities of IFO due to acrolein, (urotoxicity) and to chloroacetalddehyde (neuro and nephrotoxicity) have been described. Thus, increasing IFO therapeutic index could be of major interest. To circumvent these toxicities, our team has designed new pre-activated IFO analogs to avoid CYP bioactivation (Skarkhe et al J Med Chem 2015). Among these analogs some have the ability to self-assemble as nanoassemblies (NAS), the others can be encapsulated within nano-lipid capsules (NLCs). These new drug delivery systems (DDS) can take advantage of passive targeting, as stealthiness of these DDS can be provided by PEGylation by using Cholesterol-polyethylene glycol or the use of surfactant. These DDS can also be functionalized by appropriate monoclonal antibodies leading to multi stage DDS with active targeting properties. Regarding CPA, it has been shown and described in literature that low doses of CPA enhance the immunity by promoting differentiation of CD4+ cells toward Th1. As IFO is isomeric form of CPA, it was assumed that IFO could also have such properties. Studies on immunocompetent MCA205 mouse model, an immunogenic fibrosarcoma mouse model, demonstrated a dose-dependent immunomodulation of IFO towards a modulation of the secretion of IFNγ, IL-17A and IL-6 cytokines. The ongoing experiments on mouse model depicted in CD4+ T cells and CD8+ T cells show the antitumor efficacy of IFO 150mg/kg on these immune cells in tumor regression. Both strategies could lead to the design of nano-immuno-conjugates (NICs) which could benefit of the immunomodulatory effects of X-Oxaza combined to their antiproliferative properties targeted through immune checkpoint antibodies. These new functionalized DDS may provide a useful strategy to give specificity to active drugs used for many years in clinical practice. Both DDS could be coated with mAbs which could lead to a new family of DDS aiming to combine antiproliferative and immunomodulatory properties for a dual antitumoral action.

#2196 SDF-1/CXCR4 axis-mediated tumor-tropism of monocyte membrane-coated nanoparticles. Yi-Nan Li, Chien-Wen Chang, Chi-Shiu Chang, National Tsing Hua University, Hsinchu City, Taiwan.

Tumor-associated macrophages are one of the most abundant infiltrating cells in solid tumors. These cells are originated from the bone marrow and circulating in peripheral blood. Through the specific chemoattractant released by the tumor cells or stromal cells, bone marrow-derived monocytes (BMDMs) are able to accumulate at the tumor site by their corresponding receptors. In this study, we utilized the characteristics of tumor-tropism of BMDMs on a nanoparticle-based drug delivery system. We hypothesized that the cellular membrane of BMDMs can provide nanoparticle protection from the mononuclear phagocyte system and the chemokine receptor on the membrane can enhance the tumor-tropism of the nanoparticles. To prove the hypothesis, the cellular membrane-coated nanoparticles were prepared and the tumor-tropism of the membrane-coated nanoparticles was assessed. We also found that the expression of chemokine receptor CXCR4 on the bone BMDMs can be induced following the stimulation of tumor conditioned medium. The tumor targeting effect of the monocyte membrane-coated nanoparticles is diminished against SDF-1 knockdown tumor cells. These results indicate that the SDF-1/CXCR4 axis is contributed to the tumor-tropism of the monocyte membrane-coated nanoparticles toward astrocytoma cell line, ALT1S1C1, and this effect can be boosted by the stimulation of tumor conditioned medium. In conclusion, we established a nanoparticle-based drug delivery platform against brain tumor with the cellular membrane coating technology and maximized the effect of tumor-targeting by tumor conditioned medium stimulation.

#2197 Characterization of immunoliposomes as delivery vehicles for the Rac inhibitor Ehop-016 in HER2 TYPE breast cancer. Michael J. Rivera-Robles, 1 Pablo E. Vivas-Mejia, 1 Linette Castillo-Pichardo, 2 Cornelis Vlaar, 3 Eluid Hernandez, 4 Surangani Dharmawardhane 4, 5 University of Puerto Rico School of Medicine, San Juan, PR; 6University of Puerto Rico, San Juan, PR; 7Universidad Central del Caribe, Bayamón, PR; 8University of Puerto Rico School of Pharmacy, San Juan, PR; 9Surangani Dharmawardhane, San Juan, PR.

Due to the critical need for improved therapeutics against advanced Stage IV breast cancer, we developed and pre-clinically validated the small molecule Ehop-016 as a potential anti-metastatic drug. Ehop-016 is a small molecule inhibitor of the Rac pathway, due to the capability to target nucleolin-overexpressing cancer cells and further inhibit the Akt pathway. Ehop-016 proceeds to the American Association for Cancer Research • Volume 58 • April 2017

b
(GEF) Vav2, which consequently decreases invasive actin structures and cellular migration. In a human epidermal growth factor receptor 2 (HER2) type breast cancer model in nude mice, Ehop-016 inhibits mammary tumor growth, angiogenesis, and metastasis. Moreover, Ehop-016 reduces HER2 + cancer cell viability and migration, or individually in combination with anti HER2 or EGFR directed monoclonal antibodies, with Ehop-016 may adversely affect normal immune system function. Therefore, a strategy was developed for the targeted delivery of Ehop-016 into mammary tumors, using nanoliposomes containing the current breast cancer therapeutic, Trastuzumab, a monoclonal antibody directed at the HER2. We tested various nanoliposome formulations as target delivery systems for Ehop-016. First, the encapsulation efficiency of Ehop-016 loaded liposomes was tested using different drug loading methods. To obtain HER2 targeted liposomes, we prepared Trastuzumab-lipid conjugates and incorporated them into the Ehop-016 containing liposomes. The binding, internalization and selectivity of our HER2 targeted delivery system was verified in human metastatic breast cancer cell lines, by using fluorescence microscopy to assess the co-staining of the lipid bilayer and Trastuzumab, and to evaluate the effectiveness of the targeted liposomes in delivering Ehop-016 and inhibiting Rac activity, pull-down assays were performed to detect active Rac-GTP in cells treated with Ehop-016 alone or Trastuzumab-conjugated liposomes with Ehop-016. Results show that the Trastuzumab-conjugated liposomes are more selective at binding to HER2+ breast cancer cells and inhibiting Rac, than treatment with Ehop-016 alone. In summary, our novel delivery system containing Ehop-016 and Trastuzumab has been shown to be effective in breast cancer cells, and needs to be validated in animal models of metastatic breast cancer. The development of this targeted delivery system has implications, not only in the field of breast cancer therapeutics, but may be adapted for the treatment of other diseases, and used to overcome the side effects of current treatments.

Introduction: Biomimetic nanoparticles (NPs) combining synthetic and biological materials have flexibility and functionality for drug delivery and immunomodulation.1 Red blood cell (RBC) membranes coated poly(lactic-co-glycolic acid) (PLGA) NPs that mimic RBCs and act as nanosponges for toxins were recently described.2,3 Here, we coated cancer cell membranes onto PLGA NPs in a “right-side” out manner, to translocate membrane anchored proteins onto NPs. Cancer cell membrane coated PLGA NPs hold promise for disrupting cancer cell-stromal cell interactions, and for priming the immune system in cancer immunotherapy. Method: Plasma membrane fractions (MFs) of U87 (low CXCR4) and U87-CXCR4 (high CXCR4) cells were isolated upon homogenization, and sucrose density gradient centrifugation. MFs and PLGA NPs were mixed and physically entrapped through a porous membrane to obtain MF-coated PLGA NPs. MFs were probed with antibodies against cell fraction markers, and CXCR4. MFs-coated NPs, MFs and PLGA NPs were characterized on size, morphology, and zeta-potential. The orientation of MFs and MF-coated NPs was investigated by confocal microscopy and flow cytometry. Transwell migration assays were performed to investigate the migration of cancer cells towards human mammary fibroblasts (HMFs). Immune-competent Balb/c mice were immunized with IR700-labeled MFs or MF-coated NPs via subcutaneous injection through hock and imaged in vivo and ex vivo by near-infrared micro- and spectrums. Results: Plasma membrane purity was confirmed from west- ern blot analysis that showed the significant enrichment of Na+/K+ -ATPase, negligible amount of GFP/88 or GAPDH in MFs. PLGA NPs, U87-CXCR4 MFs and U87-CXCR4 MFs-coated NPs had average diameters of 50 nm, 200 nm, and 70 nm, respectively. Z-average diameters and zeta-potential of PLGA NPs, U87-CXCR4 MFs and U87-CXCR4 MFs-coated NPs were 98.6 ± 9.5 nm, 336 ± 14 nm, and -34.3 mV, -24.9 mV and -25.0 mV, respectively. Confocal fluorescence microscopy and flow cytometry detected intense PE fluorescence and higher CXCR4 in U87-CXCR4 MFs and U87-CXCR4 MFs-coated NPs than U87 counterparts, confirming a “right-side” out orientation. When U87 or U87-CXCR4 MFs were added to HMFs in the transwell assay, fewer cancer cells migrated towards HMFs, identifying the unique ability of MFs in disrupting HMF-cancer cell interactions. U87-CXCR4 MFs and MF-coated NPs were observed in the popliteal lymph nodes, and triggered the induction of CD8+ T lymphocytes, identifying a role for MF-coated NPs in providing cancer cell membrane-derived antigens to induce a tumor-specific immune response. **#2199** Magneto-electric nanoparticles for high-specificity treatment of cancer. Sakhrat Khizroev,1 Abhi Nagesetti,2 Tiffany S. Stewart,2 Emmanuel Brumme,1,2 Alex Rodzinski,1 Rakesh Gadara,3 Ping Liang,1 Florida International University, Miami, FL;2 University of Notre Dame, Notre Dame, IN;3 Cell Nanomod, Weston, FL.

Introduction: Delivering a drug specifically into the tumor cell past its membrane and then releasing the drug into the tumor cells without affecting the normal cells remains a formidable challenge. Unlike any other nanoparticles, magneto-electric nanoparticles (MENs) display a non-zero magneto-electric (ME) effect and thus present a unique capability to use external magnetic fields to control intrinsic electric fields associated with cell membranes and the interaction between MENs and therapeutic loads. Because cancer and normal cells of the same type have different electric properties, MENs is used for high-specificity targeted delivery. An a.c. magnetic field is used to trigger drug release off the nanoparticles. Brief Methods: 30-nm CoFe2O4-BaTiO3 core shell MENGs were synthesized and the selective uptake of cancer cells and normal cells was investigated by confocal microscopy, a coercivity of 100 Oe, and a ME coefficient of 10-100 mV cm^2/Oe^3 was prepared with a co-precipitation process. MENs were coated with fluorescein isothiocyanate to monitor their intra-cellular transport through a high-contrast confocal microscopy. Three cancer cell lines including Skov-3 (Ovarian adenocarcinoma), U87-MG (Glioblastoma), and MCF-7 (Breast adenocarcinoma), and two normal cell lines including brain endothelial cells (Brain EC) and ovarian cells (HOMEM) were cultured at 37°C. The transport of MENs loaded with drugs, peptides, and RNAs through the cell membranes and the consequent release of the load under different d.c. and a.c. magnetic fields were studied through confocal microscopy and photoabsorption spectroscopy, respectively. Trypan-blue viability count was used to assess cell growth inhibition under different study conditions. Atomic force microscopy of the cell membranes was conducted to understand the interaction between the nanoparticles and the cells. Summary of new data: Comparison of MENs with purely magnetic iron oxide nanoparticles showed that the penetration through the cancer cell membrane could be achieved only with MENs. It took d.c. fields of 100 Oe and over 1000 Oe to nano--electrode the membranes of SKOV-3 and HOMEM cell lines, respectively. An a.c. magnetic field with a strength of 50 Oe and a near-d.c. frequency of 100 Hz was sufficient to enable release of a therapeutic load off MENs. All the cancer cell lines under study showed membrane penetration threshold d.c. fields at least a factor of ten smaller compared to their normal counterparts. Conclusion: MENs displayed unique capabilities for externally controlled high-specificity targeted anticancer drug delivery and release on demand via application of d.c. and a.c. magnetic fields, respectively. Because MENs rely on a physical mechanism rather than chemical, they can be used for prospective delivery and high-efficiency controlled release of a broad range of therapeutic loads including drugs, peptides, and RNAs to treat many different cancers.

**#2200** Dual carfilzomib and doxorubicin carrying nanoparticles for synergistic efficacy in multiple myeloma. Basar Bilgicer, Tanyel Kiziltape, David Omstead. University of Notre Dame, Notre Dame, IN.

We describe the synthesis and analysis of dual carfilzomib and doxorubicin loaded nanoparticles in their ability to deliver both drugs to multiple myeloma tumor cells at their optimal synergistic ratio. First, to identify the optimal synergistic ratio, various molar ratios of carfilzomib to doxorubicin were screened against multiple myeloma cell lines using the Chou-Talalay method. Both therapeutic agents were then incorporated into liposomes at the identified optimal synergistic ratio of 1:1 to achieve dual drug loaded nanoparticles with a narrow size distribution of ~100 nm and with high reproducibility. Our results established that the dual drug loaded nanoparticles exhibited synergy in vitro and were more efficacious in inhibiting tumor growth in vivo than a combination of free drugs, while at the same time reducing systemic toxicity. In conclusion, this study achieved the preclinical evaluation of dual drug loaded liposomes containing carfilzomib and doxorubicin for enhanced therapeutic efficacy to improve patient outcome in multiple myeloma.

**#2201** Downregulation of NF-kB by nanoconjugates to overcome drug resistance in ovarian tumors. Ajit P. Zambre,1 Sarjukumar Pandhal,1 Alyssa Worland,1 Sarah Chapman,1 Matthew Leevy,1 Anandhi Upendran,2 Raghuraman Kannan.1

CANCER CHEMISTRY: Drug Delivery

Proceedings of the American Association for Cancer Research • Volume 58 • April 2017

563
Ovarian cancer is the fifth leading cause of cancer deaths in women. Globally, around 140k women die from ovarian cancer per year. Recurrence can lead to development of resistance to first line agents such as platinum analogs, taxanes, and doxorubicin. Several studies have shown that decrease of NF-kB expression will inhibit P-glycoprotein maturation and thereby overcome drug resistance. In this context, it is well known that Disulfiram (DSF), a FDA approved drug for anti-alcoholism, has been identified as moderate inhibitor of NF-kB activity. It is also shown that DSF possess mild anti-cancer effects via increased permeability of the outer membrane of mitochondria resulting in leakage of proteins, such as cytochrome C, generation of ROS that simulates the ROS-MAPK pathway leading to apoptosis, and inhibition of P-glycoprotein. As such DSF is not a strong therapeutic agent; however, in combination with copper it showed excellent therapeutic benefit. This effect is mainly attributed to metabolite diethyldithio-carbamate—a proteasome inhibitor that was produced upon complexation of DSF with copper. However, delivery of DSF-Cu complex was not successful in clinical setting. We hypothesized gold nanoparticles can serve as potential delivery vehicle to selectively transfer Cu-DKF to tumor without toxicity. Indeed, cellular studies in drug sensitive (OVCAR) and Adriamycin resistant p-glycoprotein expressing (NCI-ADR/RES) ovarian cancer cells indicated that the gold nanoconjugate exhibit significant cytotoxicity and the IC-50 values was decreased 2.5 fold times compared to the Cu-DSF complex. NF-kB expression was decreased by two folds compared to native Cu-DSF complex. Detailed cellular and mechanistic studies along with the evaluation of [Au(DSF-Cu)] in human multi-drug resistant (NCI-ADR/RES) mouse xenografts will be presented.

**FABPS in urinary extracellular vesicles is a potential biomarker of high Gleason score prostate adenocarcinoma.**  

Ryosuke Matsuzaki,1 Atsunari Kawashima,1 Akira Nagahara,1 Motohide Uemura,2 Yasushi Miyagawa,1 Takeshi Tomonaga,1 Norio Nonomura,1 Osaka Univ. Graduate School of Medicine, Osaka, Japan;2Laboratory of Protein Sciences (The PHOENIX center), Beijing, China; 3Fudan University, Shanghai, China; 4East China Normal University, Shanghai, China; 5Baylor College of Medicine, Houston, TX; 6School of Pharmacy, University of Maryland, Baltimore, MD.

Urinary collected after prostate massage is a promising source of new biomarkers of prostate cancer, and was reported to contain extracellular vesicles (EVs) that are secreted from prostate cancer cells. EVs are microvesicles secreted from various cell types. EVs contain microRNAs, proteins, and mRNAs and play a role in intercellular communications via the mechanisms of exocytosis and endocytosis. We aimed to discover a new biomarker for high Gleason score (GS) prostate cancer (PCA) in urinary EVs via quantitative proteomics. Material and methods: Urine samples after massage were collected from 18 patients before prostate needle biopsy. Six patients had negative biopsy outcomes, 6 had high Gleason score 6 prostate cancer (GS6), and 6 had Gleason score 8 to 9 prostate cancer (GS8-9). Urinary EVs were isolated from urine with ultracentrifugation. Protein extracted from EVs were labeled with 4-plex iTRAQ and liquid chromatography tandem mass spectrometry (LC-MS/MS) was used for proteome analysis. The candidate proteins were quantitated in the independent set by selected reaction monitoring/multiple reaction monitoring analysis (SRM/MRM). Results: Seven proteins increased in patients with PCa compared to those with negative biopsy (ratio > 2.0, p-value < 0.05). Thirteen proteins were chosen for further analysis and verified in 29 independent urine samples (negative [n = 11], PCa [n = 18]) using selected reaction monitoring/multiple reaction monitoring. Among these candidate markers, fatty acid binding protein 5 (FABPS) was higher in the cancer group than in the negative group (p-value = 0.009) and was significantly associated with GS (p-value for trend = 0.011). Conclusions: We applied the proteomic analysis to discover biomarkers in EVs in urine collected after prostate massage. FABPS in urinary EVs could be a potential biomarker of high GS prostate cancer. Additional large-scale studies are warranted to confirm this finding.

**A SRM/MRM based targeted proteomics strategy for absolute quantification of potential biomarkers of TKI sensitivity in EGFR mutated lung adenocarcinoma.**  

Shivangi Awasthi,1 Xu Zhang,2 Tapan Maity,1 Benjamin L. Oyler,2 David R. Goodlett,1 University of Maryland for Environmental Science, Baltimore, MD; 3School of Pharmacy, University of Maryland, Baltimore, MD.

Lung cancer remains the leading cause of cancer-related deaths worldwide. Epidermal growth factor receptor (EGFR) is the primary driver oncogene in 10-30% lung adenocarcinoma. Kinase domain mutations in EGFR (L858R and E746-A750 deletion) provide sensitivity to EGFR-specific tyrosine kinase inhibitors (TKIs). Despite good tumor inhibitory effects, after approximately a year, patients acquire resistance to EGFR TKIs. We have hypothesized that targeted proteomic analysis identifying amino acids in cell culture (SILAC)-based quantitative mass spectrometry (MS) on a Thermo Orbitrap Elite to identify and characterize the dynamics of tyrosine phosphorylation upon TKI treatment of human lung adenocarcinoma cell lines. The degree of inhibition of phosphorylation of several phospho-sites correlated with the extent of TKI-sensitivity. Several kinases and adaptor proteins that were significantly differentially phosphorylated include AKT1, RSK1, JUN, ERK, and DUSP6. We have successfully developed stable isotope labeling with amino acids in cell culture (SILAC)-based targeted MS for these tyrosine phosphorylated peptides in human cancer cell lines. The overall goal of these targeted studies is to develop absolute quantitation assays to precisely and accurately quantify these potential biomarkers in clinical samples.

**A proteomic landscape of diffuse-type gastric cancer.**  

Sai Ge,1 Xia Xia,2 Chen Ding,2 Bei Zhen,2 Quan Zhou,2 Jinwen Feng,1 Jiajia Yuan,1 Ruich Chen,1 Yumei Li,2 Zhongge Ge,1 Jiafu Ji,2 Lianhai Zhang,2 Jiauyan Wang,1 Zhongwu Li,1 Yumei Lai,1 Ying Hu,2 Yilian Li,2 Jing Gao,2 Lin Chen,2 Jianming Xu,1 Chuncho Zhang,2 Sung Yun Jung,2 Mingwei Liu,1 Lei Song,2 Guojun Gao,2 Qiang He,2 Yin Chen,2 Teliu Shi,2 Weimin Shi,2 Yi Yang,2 Fuchu He,2 Lin Shen,1 Jun Qin,2 CNHPP.

University Cancer Hospital & Institute, Beijing, China; 2National Center for Protein Sciences (The PHOENIX center), Beijing, China; 3Fudan University, Shanghai, China; 4East China Normal University, Shanghai, China; 5Baylor College of Medicine, Houston, TX; 6General Hospital of Chinese People’s Liberation Army, Beijing, China; 7Affiliated Hospital of Academy of Military Medical Sciences, Beijing, China.

Gastric cancer is a heterogeneous disease characterized by poor clinical outcomes and limited targeted treatment options. Among them, diffuse-type gastric cancer (DGC) is the subtype with worst prognosis. Here we describe the first proteomic landscape of DGC. We carried out proteome profiling and targeted exome DNA sequencing of 84 DGC samples. We analyzed the 1,008 (168 x 6) raw files together for uniformed quality control and protein identification with 1% global protein false discovery rate (FDR), which resulted in the identification of 11,340 gene products (GP). A SAM (significance analysis of microarray) analysis identified 1,641 proteins as differentially expressed between T (tumor) and N (normal) with statistical significance (FDR q-value<0.01 by SAM and differential expression ratio >2.0 and p-value<0.05), including 80 up-regulated and 430 down-regulated GPs. Gene Ontology annotation indicated that tumor proteomes were significantly enriched in cell cycle, DNA replication, checkpoint, E2F, WNT, p53 signaling, epithelial mesenchymal transition (EMT), and inflammation/ cytokine-receptor interaction pathways, and the proteomes of the nearby tissues are enriched in metabolism pathways, such as fatty acid metabolism, oxidative phosphorylation, and amino acid metabolism. Notably, many gastric makers (ANXA10, VSIG1, CLDN18, CTSE, TFF2, MUC5AC and MUC6) and signature proteins for stomach functions, including digestion, absorption, secretion, and stomach acid generation (PGC, GIF, GAST, and ATP4A), were lost in tumors. Based on proteome profiling alone, DGC can be
subtyped into 3 major classes (PX1-3) that exhibit distinct proteome features and correlate with distinct clinical outcomes (Gehan-Breslow-Wilcoxon P = 0.024). PX1 exhibits proteome stability and the best overall survival; PX2 exhibits its dysregulation in DNA replication and cell cycle, and is most sensitive to chemotherapy; PX3 features hyper-activated immune response and is not responsive to EGFR-TKI treatment. We identified cell lines that were enriched in DGGC patients into these three subtypes, opening a door for proteome subtyping in clinical application and intervention. Furthermore, we nominated drug target candidates taking into consideration both the altered DGGC proteome and association data with patients’ overall survival. This study revealed the altered signaling pathways in DGGC and demonstrated the advantage of proteomic approach in molecular subtyping of cancer.

#2205 Identification of potential biomarker related to EGFR mutation by functional proteome profiling in primary non-small cell lung cancer. Yuan-Ling Hsu, Szu-Hua Pan. National Taiwan Univ., Taipei, Taiwan. Non-small-cell lung cancer (NSCLC) accounts for approximately 85% of lung cancers which the leading cause of cancer-related death worldwide. Recently, epidermal growth factor receptor (EGFR) activating mutations have been proved relevant to NSCLC and let treatment of EGFR tyrosine kinase inhibitors (EGFR-TKIs) become an alternative therapy for NSCLC patients. Despite excellent clinical response to EGFR-TKIs, the intrinsic and acquired resistance to EGFR-TKI created challenges in clinical practice. Although several mechanisms may contribute to solve EGFR-TKIs resistance, there still have 20% to 30% of these patients that how the resistance developed remain unclear. Studies indicated that the increment of membrane efflux may be associated with drug resistance. In this study, we use differential membrane proteomic analysis to identify potential biomarkers for therapeutics of EGFR-TKIs resistance in NSCLC patients. Several primary NSCLC cell lines with different EGFR status were be isolated by our laboratory. Identification of modulators on membrane of primary cancer cells with different EGFR status was analyzed by membrane proteomic assay using LC-MS/MS. The expression patterns of EGFR mutation which would compare with that of wild type group and the potential candidates would be selected by cross the results of interactome profiles of EGFR mutation cell lines. The expression patterns and functional role of these candidates were be examined in NSCLC cells by several molecular, cellular and biochemical analysis, and demonstrated the clinical relevance of these specific targets with EGFR mutation. The expression of 100 modulators up-regulated in EGFR mutation cells compared with that of wild type group. After cross reacted with the 474 interaction proteins of mutated EGFR, 8 proteins were selected as potential candidates that related to EGFR-TKI resistance, especially the expression of a protein we called SHX in EGFR mutation cells. We demonstrated the real expression levels of SHX in different lung cancer cells, and performed network analysis of SHX and EGFR in translational level. The analysis of differential membrane proteomic found several novel biomarkers and potential regulation mechanisms that related to the development of EGFR-TKIs resistance in NSCLC. These identification may provide us new direction for exploring therapeutic strategy for NSCLC treatment in the future.

#2206 Proteome phenotype of stage III metastatic melanoma and response to MEK inhibition. Christoph Krisp,1 Robert Parker,1 Dana Pacsoci,3 James Wilmot,2 John F. Thompson,2 Graham J. Mann,2 Richard A. Scovler,2 Nicholas K. Hayward,2 Mark P. Molloy1. 1Macquarie University, Sydney, Australia; 2University of Sydney, Sydney, Australia; 3QIMR Berghofer, Brisbane, Australia. Introduction: Melanoma accounts for 5% of all skin cancers, yet is the most common form of skin cancer-related deaths, and is the commonest lethal malignancy in young people (1<40yrs). Patients with BRAF mutant melanoma show survival benefit from MAPK pathway inhibition, although response rates vary. We conducted proteomic screening using mass spectrometry to detect cellular processes that might predict response to MEK inhibition more effectively than genotyping alone. Methods: Protein extracts from early passages of ten AJCC Stage III local lymph node metastatic melanoma cell lines with known MAPK mutational status (BRAFmut, NRASmut, MAPKwt) were used. Further, 32 fresh frozen NRASmut or BRAFmut AJCC Stage IIIC metastatic melanoma (lymph node metastases) specimens were obtained from patients with varying survival. Lysed cells and tissue were digested with trypsin and analysed by LC-MS/MS using a TripleTOF 5600/6600 mass spectrometer. Data-independent analysis of SHX and EGFR in translational level. The analysis of differential membrane proteomic found several novel biomarkers and potential regulation mechanisms that related to the development of EGFR-TKIs resistance in NSCLC. These identification may provide us new direction for exploiting therapeutic strategy for NSCLC treatment in the future.

#2207 HSP90 inhibition leads to a differential proteomics profile in non small cell lung cancer cell lines. Angela Marrugal,1 Irene Ferrer,1 Maria Dolores Pastor,2 Alvaro Quintanal,3 Antonio Lucena-Cacace,1 Amancio Carnero,1 Luis Paz-Ares,2 Sonia Molina-Pinelo1. 1CNIO, Madrid, Spain; 2IBIS, Sevilla, Spain. Background: The cancer chaperone, Heat Shock Protein 90 (HSP90), is known for its ability to regulate the stability of different oncoproteins. Thus, its overexpression has been related to unfavorable prognosis in some types of tumors. EGFR and EMLA-ALK, two of the most important drivers in non-small cell lung cancer (NSCLC), are HSP90 clients and extremely depend on it. As a consequence, this chaperone is especially important in NSCLC hence HSP90 inhibition shows a lot of possibilities to future treatments in this tumor type. Nevertheless, to obtain a successful clinical development, will be essential supporting evidence of inhibitory efficacy in several molecularly defined subgroups of NSCLC. Methods: NSCLC cell lines carrying different gene mutations, whose direct (HCC827; EGFR mutated and H3122; EMLA-ALK rearrangement) and indirect (A549; KRAS mutated) relationship with HSP90 has been reported, were used. In these cell lines, along with H1781 (EGFR, KRAS, ALK wild type) as control, the activity of the chaperone studied was interrupted. To this end, pharmacological inhibition of HSP90 was achieved through geldanamycin and resorcinol derivates. First, western blotting was carried out to confirm the effect of this inhibition. Later, to identify a proteomic profile associated with HSP90 inhibition, two-dimensional polyacrylamide gel electrophoresis (2D-PAGE) of selected cell lines were performed. Results: The expression of the oncogenic HSP90 client proteins studied was decreased by the inhibitors in the NSCLC cell lines. The oncoproteins drivers EGFR and EMLA-ALK showed a strong dependence on HSP90 observed through a high sensitivity of the cell lines HCC827 and H1122 to the inhibition. Therefore, the cell lines which were selected from the purpose of identify a proteomic signature linked to HSP90 inhibition by 2D-PAGE. The untreated EGFR positive cell line presented 104 protein spots significantly up-regulated, whereas 80 spots were down-regulated compared to inhibited cell line. Meanwhile, the cell line harboring the EMLA-ALK translocation showed 16 spots up-regulated and 5 down-regulated in the untreated versus inhibited cell line. In addition, we have established an expression signature for each processed cell lines, was detected after treatments. This feedback, previously reported, confirmed HSP90 inhibition in the two cell lines studied. Conclusions: The evidence of treatment response, in the cell lines studied, was showed through oncogenic client proteins reduction as well as HSP70 induction. The proteomic profiles identified, of HSP90 inhibited and untreated tumor cells, revealed several deregulated pathways involved in the tumorigenesis.

#2208 Peptide-mediated ‘miniprep’ isolation of extracellular vesicles is suitable for high-throughput proteomics; method evaluation and application in colon cancer. Meike De Wit,1 Jace Knol,2 Inge de Reus,2 Tim Tim Schelhorst,2 Logan Bishop-Currey,2 Nicole van Grieken, Sander Piersma,2 Thang V. Pham,1 Remond J. Fijneman,3 Gerrit A. Meijer,1 Henk Verheul,2 Connie R. Jimenez2. 1Netherlands Cancer Institute, Amsterdam, Netherlands; 2VU University Medical Center, Amsterdam, Netherlands. Objective: Extracellular vesicles (EVs) are cell-secreted membrane vesicles enclosed by a lipid bilayer derived from endosomes or from the plasma membrane. Since they are released into body fluids, and their cargo includes tissue-specific and disease-related molecules, EVs represent a rich source for disease biomarkers. However, standard ultracentrifugation methods for EV isolation (UC-EV) are laborious, time-consuming, and require high inputs. Method: A recently described isolation method, which can be performed at small 'miniprep' scale, utilizes specific Heat Shock Protein (HSP)-binding peptides to aggregate HSP-decorated EVs (Ghosh et al. (2014), PLoS ONE 9,e110443). The authors

CANCER CHEMISTRY: Proteomics and Mass Spectrometry 2

Proteomics and Mass Spectrometry in Cancer 2017
showed comparable results for their method (abbreviated HSP-EV here) and UC-EV, but a detailed proteomic comparison was lacking. Therefore, we compared both methods using label-free proteomics of replicates EV isolations from HT-29 cancer cell-conditioned medium. Subsequently we applied this technique on secretomes of fresh human colorectal cancer (CRC) (n = 17) and colon adenocarcinoma (n = 8) as well as patient-normalized EVs (n = 4) using the same protocol. Despite a 30-fold different input scale (UC-EV: 60 ml versus HSP-EV: 2 ml), both methods yielded comparable numbers of identified proteins (3115 versus 3085), with reproducible identifications (72.5% versus 75.5%) and spectral count-based quantification (average CV 31% versus 27%). EVs obtained by either method contained established EV markers and proteins linked to vesicle-mediated protein transport. In the EV fraction of the secretomes secretomes 6390 proteins were identified, of which 471 proteins were significantly 5-fold more present in CRC samples than in normal tissue EVs. Gene ontology analysis revealed enrichment of nuclear proteins involved in DNA damage response, chromosome organization and RNA processing in the CRC EVs. Conclusions: The HSP-EV method provides an advantageous, simple and rapid approach for EV isolation from small amount of biological samples, enabling high-throughput analysis in a biomarker discovery setting.

**#2209 Characterization of FABP5 antibodies in prostate.** Dennis A. Otali,1 Denise K. Oelschlager,1 James Kearns,3 Sandra M. Gaston,2 William E. Grizzle.1

1Univ. of Alabama at Birmingham, Birmingham, AL; 2Tufts Medical Center, Boston, MA.

FABP5, a member of a family of small proteins (~15 kDa) that transport lipids, is emerging as an important biomarker because it is differentially expressed in prostate cancers (PrCa) compared to uninvolved prostate glands and lipids are important to the progression of prostate cancer. This study was to select an antibody (Ab) for use in immunostaining (IHC) FABP5 in formalin fixed paraffin embedded (FFPE) tissue and also an Ab for use in Western blotting (WB). A mouse monoclonal antibody (mAb) clone A9 to FABP5 from Santa Cruz (SC) Biotechnology, Inc. and a rabbit polyclonal antibody (pAb) to FABP5 from Abcam (AB) (cat. # ab37267) were tested. Six prostate cell lines (PC3, DU145, 22Rv1, MDA PCa 2b, LNCaP, and normal primary prostate epithelial cells (NH Pri Pro)) were used to study protein and mRNA levels of FABP5. Protein expression of FABP5 was determined by WB of whole cell lysates as well as cytoplasmic and nuclear lysates. GAPDH, a "housekeeping" gene expressed at similar level in most types of cells, was used as a loading control for WB. Cells from the six prostate cell lines also were used in Histogel, processed to FFPE and immunostained. The prostate cells were transfected with FABP5 siRNA for WB with aliquots of the transfected prostate cells processed to FFPE, qrtPCR was performed to measure mRNA levels. The expression of whole cell lysates on WB probed with the AB pAb to FABP5 was NH Pri Pro > PC3 > DU145 > 22Rv1 > MDA PCa 2b > LNCaP and compared to NH-Pri-Pro. PC3 > DU145 > 22Rv1 when probed with the SC mAb. WB of the cytoplasmic fractions from each cell line has a similar pattern. In Histogel sections immunostained with AB pAb, the FABP5 cytoplasmic expression was PC3 > DU145 > 22Rv1 > MDA PCa 2b > NH Pri-Pro > LNCaP. These levels of expression among the cell lines followed a similar trend in evaluation of immunostaining of cell membranes, nuclear, and the perinuclear area.

**#2211 Characterization of monoclonal antibodies specific for HPV-positive head and neck cancer.** Hauan-Chen Liu,1 Fatuluni Parkid,1 Thomas Kraus,2 Thomas Moran,3 Andrew Sikora1.1Baylor College of Medicine, Houston, TX; 2Icahn School of Medicine at Mount Sinai, New York, NY.

HPV-driven head and neck squamous cell carcinoma (HNSCC) are among the fastest growing cancers. Although, HPV-HNSCC patients have an overall favorable prognosis, a significant number of patients relapse post-treatment, and currently there is no specific therapeutic approach targeting the unique biology of HPV-driven HNSCC. Our ongoing efforts to target HPV-HNSCC focus on the identification of cell surface antigens that are upregulated by HPV infection. We have developed an ‘antigen-agnostic’ approach for generating HPV-HNSCC-targeting monoclonal antibodies for cancer diagnosis and treatment that does not rely on prior identification of target antigens. We used HPV-HNSCC membrane fractions to immunize recipient mice and generated HPV-specific hybridomas. We then screened five thousand hybridoma colonies by flow cytometry to test the specificity of binding to HPV-positive cancer cell lines (2HNSCC and 2 Cervical Cancer) and HPV-negative cancer cell lines (4 HNSCC and 1 CC). After primary screening, we narrowed down to forty-four clones; among these hybridoma clones, 6D8 and 6B3 bound preferentially to HPV-positive cancer cell lines. The binding targets of 6D8 and 6B3 were identified by immunoprecipitation and mass spectrometry; their targets are integrin alpha6 (ITGA6) and tissue factor (F3) respectively. Future work will validate the biological function of these mAbs in vitro and in vivo models, and continue identifying more binding target of mAbs. We propose mAbs specifically targeting membrane-expressed antigens on HPV-related cancer cells as a potential approach for early diagnosis and targeted therapy.

**#2212 Protein engineering of the decapping enzyme NudT16 enhances its ability to hydrolyze protein-conjugated ADP-ribose for post-translational site identification via mass spectrometry.** Puchong Thirawatananond, Robert L. McPherson, Jasmine K. Mahli, Anthony K. Leung, Sandra B. Gabelli. Johns Hopkins University, Baltimore, MD.

During nonhomologous end joining of DNA follow double-stranded breaks, one common signaling response is the adenosine diphosphate ribosylation (ADP-ribosylation) of recruiter scaffold proteins. ADP-ribosylation is a post-translational modification (PTM) that occurs on aspartate, glutamate, lysine, arginine and cysteine on proteins and is mediated chiefly by polyadenosine diphosphate ribose polymerases (PARP). Using NAD+ as its substrate, PARP transfers an ADP-ribose onto an acceptor protein, releasing a nicotinamide ring in the process; this modification presents as a mono-ADP-ribosylation (MARylation) or poly-ADP-ribosylation (PARylation). While site identification of MARylated protein can be achieved through tandem MS/MS and searching for peptides whose spectra have been shifted by 541.0611 Da, a similar approach for PARylated protein is confounded by the variable length and branching of its PTM. To this end, ADP-ribosylated protein is normally incubated with a snake venom phosphodiesterase (SVP) to leave a standardized phosphoribose tag of 212.0086 Da. It has been shown that a recombinantly-expressed Nudix protein NudT16 provides a cost-effective alternative to SVP to process ADP-ribosylated protein. NudT16 in the cell normally decays small nucleolar RNA. Our studies here...
sought to utilize the x-ray crystallographic structure of NudT16 in complex with ADP-ribose in guiding rational design mutations to enhance binding of our desired ADP-ribose substrate and to widen the hydrolase’s active site to better accommodate a protein-conjugated ADP-ribose. Mutants have demonstrated improved catalytic efficiency for ADP-ribose hydrolysis. Radioabeled immunoo- nas of assay, as that is the only known method for concur with I-TAC, which is overexpressed in blood and tissue of men with advanced prostate adenocarcinomas. Finally, we found hnRNP-1, a cancer asociated splicing factor, and the cold shock proteins RNPL and A18 hnRNP. Knock-down of these cold shock proteins has been shown to enhance chemotherapeutic cell killing of prostate cells. ADAPT is an unbiased profiling plat- form that identifies cancer associated proteins expressed on exosomes. This platform can be deployed against multiple cancer types and offers broad poten- tial applications in biomarker discovery.

#2213 aberrant glycoprotein expression in recurrent and non-recurrent prostate cancer tissue. Sarah M. Totten, Cheylene Tanimoto, Abel Bermudez, Amy Hembree, James D. Brooks, Sharon J. Pitteri. Stanford University School of Medicine, Palo Alto, CA.

The primary aim of this study is to identify and quantify aberrancies in gly- cosylation patterns and glycoprotein levels expressed in high grade prostate cancer tissue from men with and without recurrence following radical prosta- tectomy using multi-dimensional chromatography and tandem mass spectrom- etry techniques. Glycosylation is a common and highly complex posttransla- tional modification, and is linked to protein function. Elucidating specific glycan structures is key to understanding the underlying role glycosylation plays in regulating cellular activity, including tumorigenesis, invasion, and metastasis. Aberrant glycosylation is an emerging hallmark of various cancers, demonstrat- ing that alterations in glycosylation disrupt cellular behavior in key pathways. Furthermore, comprehensive glycan characterization can lead to more effective biomarkers with increased clinical utility for distinguishing indolent disease from cancers that are more likely to become metastatic, recur and/or pose higher risk. In this study, glycoprotein analysis was performed on prostate cancer tissue and matched normal prostate tissue from ten men with high grade prosta- tectomies (Gleason 7-8) - five of which experienced recurrence. Proteins were extracted from tissue lysates, denatured, reduced and alkylated. Isotopic labels for quantitation were incorporated during alklylation - normal and cancer tissue was labeled with 13C2 and 13C acrylamide respectively. Paired normal/cancer tissues were combined. Glycosylated proteins from each pair were separated by multi-lectin chromatography designed to capture sialylated, core-fucosylated, and highly branched complex glycans, fractionating the complex mixture into four discrete fractions containing specific glycoforms. LC-MS/MS was used to analyze the tryptic digest from each fraction for protein identification and quanti- tation. This experimental design reveals differences between the glycosylation pat- terns and protein levels of cancerous and normal tissue in ten men, but also allows for the comparison between those with recurrent cancers. The glycosylation pat- terns across hundreds of prostate tissue proteins were systematically screened, en- abling the detection and relative quantification of specific glycoforms of proteins that may be dysregulated in prostate cancer. Preliminary results reveal the identification of 6,202 unique proteins, and quantitation of 2,894 proteins, most of which con- tained sialylated glycoforms. In all patients (regardless of treatment outcome), sev- eral hundred proteins had elevated total protein levels in the 13C-labeled cancer tissue compared to the 13C-labeled normal tissue proteins, such as TACSTD2 and LPP, whose expression was demonstrated. Furthermore, we found that urapregulation only among certain glyco- forms. Other glycoproteins were up-regulated in cancer only in recurrent patients, including CPNE1, TXNDS, and CASCA.

In the recent years it was demonstrated that a multitude of body fluids con- tains substantial amounts of exosomes, extracellular vesicles with sizes ranging between 40 and 100 nm. Those vesicles have protein profiles characteristic of their cells of origin. It was shown that exosomes play a role in cell-to-cell commu- nication making them attractive targets to identify early disease stage bio- markers. Cancer heterogeneity is known for a long time to be an important clinical determinant of patient outcome. We developed the highly multiplexed ADAPT platform to capture systems-based biological signatures that may reflect the molecular heterogeneity of various cancer types and help to improve diag- nosis of the disease. Exosomes from two prostate cancer cell lines, VCaP and LNCaP, were used to train sDNA libraries to discriminate them. A highly di- verse library of 10^12 oligonucleotides (ODNs) was subjected to five rounds of positive and negative selection against exosomes from VCaP and LNCaP pros- tate cancer cell lines. Individual ODNs that bound preferentially to exosomes from VCaP cells were identified by NGS, resynthesized and binding of co-precipitated ODNs to VCaP exosomes was verified by qPCR. LC-MS/MS was used to identify binding partners of ODNs bound to VCaP exosomes. Several of those binding partners (CHMP1b/2a/4b, VPS28, Syntenin-1) were found to be part of the ESCRT machinery, which participates in exosomes biogenesis. It was found that those proteins are overexpressed in human cancers. In addition, we identified the chaperone HSC70, which is overexpressed in blood and tissue of men with advanced prostate adenocarcinomas. Finally, we found hnRNP-1, a cancer asociated splicing factor, and the cold shock proteins RNPL and A18 hnRNP. Knock-down of these cold shock proteins has been shown to enhance chemotherapeutic cell killing of prostate cells. ADAPT is an unbiased profiling plat- form that identifies cancer associated proteins expressed on exosomes. This platform can be deployed against multiple cancer types and offers broad poten- tial applications in biomarker discovery.

#2215 detection of novel markers of transitional cell carcinoma of the ovary, the TCC-like variant of high grade serous carcinoma, using proteom- ics and immunohistochemistry. Basile Tessier-Cloutier,1 Jamie Magrill,2 Ste- fan Komnoss,3 Blake C. Gills,1 David G. Huntsman,3 Dawn R. Cochrane,1 Aline Talhouk,2 Robert Soslow,4 Gregg B. Morin,5 Chris J. Hughes,5 Anthony N. Karnezis,5 Christine Chow,6 Angela S. Cheng,7 Andreas de Bois,8 Jacobus Pfs- terer,9 Friedrich Komnoss,1 1Vancouver General Hospital, Vancouver, British Columbia, Canada; 2BC Cancer Agency, Vancouver, British Columbia, Canada; 3Tübingen University Hospital, Tübingen, Germany; 4Memorial Sloan Kettering Cancer Center, New York, NY; 5Klinikum Essen Mitte, Vancouver, Germany; 6Gy- necologic Oncology Center, Kiel, Germany.

Background: The current WHO classification does not separate transitional carcinoma of the ovary (TCCO) from conventional high grade serous carcinoma of the ovary (HGSC). TCCO has a better prognosis, possibly due to better chemosensitivity or less infiltrative growth pattern. The available immunohis- tochemical (IHC) markers do not differentiate between the two subtypes. There- fore, we sought to compare the proteomic profiles of conventional HGSC and TCCO to identify surrogate biomarkers of good prognosis from TCCO that could identify conventional HGSC tumors with a better prognosis. Design: Full proteome analysis of 12 cases of TCCO and 12 cases of HGSC was performed using SP3-clinical proteomics, run on an ThermoFisher Orbitrap Fusion. For validation, tissue microarrays of HGSC (n=89) and HGSC (n=237) were subject to a panel of antibodies against proteins found to be enriched in TCCO. All cases and immunostains were scored by a gynecologic pathologist. Univariate analysis was performed comparing IHC expression in TCCO vs. HGSC. Results: We identified 1220 proteins that were significantly enriched in TCCO over HGSC. Claudin 4 and Ubiquitin carboxy-terminal esterase L1 (UCHL1) were selected as potential markers of TCCO-like biology (p=0.0017, 0.0322). By IHC, Claudin 4 (95% confidence interval (CI) 0.171, 0.438) and UCHL1 (95% CI 0.291, 0.550) showed a significantly higher expression in TCCO as compared to HGSC (see table).

Legend: Mixed TCCO: TCCO with minor component of conventional HGSC. Conclusion: Proteomic analysis showed differing protein profiles for TCCO and HGSC. By IHC, Claudin 4 and UCHL1 were identified as potential markers for TCCO-like differentiation of high-grade serous carcinomas. Further studies will focus on the prognostic significance of these and other markers in larger cohorts of HGSC. This study presents a novel approach at identifying potential diagnostic and prognostic biomarkers as well as therapeutic targets.

Background: High mobility group box 1 (HMGB1) is a versatile protein with dual roles. Within the cell, this highly conserved chromosomal protein functions as a DNA chaperone. Outside of the cell, it functions as the prototypical damage-asso- ciated molecular pattern. There is significant evidence that HMGB1 dysfunction contributes to cancer development, particularly in mesothelioma, where its role in carcinogenesis is better defined. Goal: To develop a mass spectrometry based immu- nune-multiple reaction monitoring (iMMRM) assay to quantify HMGB1 and its dis-
ease-associated post-translationally modified forms. Methods: Mesothelioma cell lines (Ren, Phi and PP-Mill) known to secrete HMGB1 were used. Concentrated cell supernatants, anti-HMGB1 antibody-loaded magnetic beads were incubated overnight. Beads were extensively washed and the HMGB1 released from the beads was enzymatically digested prior to targeted MRM mass spectrometry. Known synthetic peptides corresponding to the digested HMGB1 were used as internal standards to assay the HMGB1 levels. The protocol was optimized for HMGB1 release, digestion and analysis.

Introduction: More than 260,000 women die of cervical cancer every year. Screening methods have reduced the incidence of cervical cancer in high-income countries, but detection continues to lag in low and middle-income countries (LMICs). IgG antibody (Ab) immunity to early (E) HPV antigens (Ags) are potential biomarkers of disease progression. Since HPV16 accounts for only 20% of invasive cervical cancers, we developed protein microarrays expressing the proteomes of two low-risk HPV types (HPV6 and HPV11) to detect high-risk HPV16 serotypes to detect host IgG Abs to a broad spectrum of viral Ags to detect high-grade pre-invasive cervical lesions. These results suggest that serology is a potential method for early detection of cervical cancer.

**#2219** Cancer prevention using a novel fatty acid synthase inhibitor. Neil L. Spector, Tim Haystead, Sunil Zhao, Yaaan Alwarawrah, David Alcorta, William Kim, Jose E. Rivera, Michael Trinkler, David B. Darr. Duke University Medical Center, Durham, NC; "UNC-Chapel Hill, Chapel Hill, NC.

Tumor growth and survival is dependent upon de novo fatty acid synthesis regulated via preferential upregulation of fatty acid synthase (FASN) in tumor cells. Here a novel FASN inhibitor that has shown antitumor activity in established tumor models (Alwarawrah Y et al., 2016), now shows promise blocking oncogene-induced cell transformation and significantly delaying time to tumor development in a prevention study using a GEMM of triple negative breast cancer. Non-malignant, immortalized MCF10A human breast epithelial cells were infected with lentivirus encoding for the highly oncogenic 110 kDa truncated form of HER2, herein referred to as p110, under a doxycycline inducible promoter. The p110 containing cells were seeded as a control. Forty-eight hours after lentiviral infection, p110 was induced by dox and cells treated with FASN (2 and 4 µM) or vehicle alone for 21 days, and then assayed for cell growth and evidence of senescence. The C3TAg GEMM model of triple negative breast cancer was used to study FASN in the prevention setting. The mice (FVB/N background) express C3TAg and TGN-53, a sham insert served as a control. Forty-eight hours after lentiviral infection, p110 was induced by dox and cells treated with FASN (2 and 4 µM) or vehicle alone for 21 days, and then assayed for cell growth and evidence of senescence. The C3TAg GEMM model of triple negative breast cancer was used to study FASN in the prevention setting. The mice (FVB/N background) express C3TAg and TGN-53, a sham insert served as a control. Forty-eight hours after lentiviral infection, p110 was induced by dox and cells treated with FASN (2 and 4 µM) or vehicle alone for 21 days, and then assayed for cell growth and evidence of senescence.

**#2220** Quantitative multiplex analysis of immune checkpoint protein expression in circulation and in the tumor microenvironment. Wen-Rong Lie, Jehangir Mistry. MilliporeSigma, St. Charles, MO.
### Repurposing statins for prevention of triple-negative breast cancer.

Anjana Bhardwaj,1 Harpreet Singh,1 Kimal Rajapakshe,2 Cristian Coarfa,2 Isabella Bedrosian1.1 UT MD Anderson Cancer Ctr., Houston, TX; 2Baylor College of Medicine, Houston, TX.

Introduction: Although triple negative breast cancer (TNBC) accounts for 15% of the 250,000 annual cases of breast cancer, its more aggressive nature coupled with lack of targeted therapy, results in a disproportionate rate of mortality in women with this disease underscoring the critical need for prevention-based approaches. We hypothesized that identifying miRNA-mRNA functional pairs and their driver pathway(s) deregulated during preneoplastic progression would provide the most informative insights into the molecular drivers of TNBC carcinogenesis. We performed next generation RNA sequencing of TNBC-like MCF10A based model system and focused on identifying the molecular changes preceding the development of in situ carcinoma (DCIS). We used ki67, MTT and colony formation assays to study the growth inhibitory effect of miRNA and pathway targeting. To identify direct gene targets of a miRNA, we cloned the 3' untranslated region containing miRNA-binding sites from its predicted gene targets in a luciferase reporter vector, and studied the effect of miRNA overexpression on the repression of luciferase reporter activity. Results: In silico analyses of small RNA seq data showed loss of miRNA-140-3p as one of the top deregulated miRNA relevant to preneoplastic transition from MCF10A parental to MCF 10A1 preneoplastic cell line. Staining of breast tissue samples also confirmed loss of miRNA-140-3p in tumors compared to normal breast epithelium from normal mouse mammary tissue. To assess the potential functional role of miRNA-140 during TNBC development, we ectopically expressed miRNA-140 in MCF10.A1 and MCF10.DCIS cells. Interestingly, these studies revealed miRNA-140 replacement to preferentially inhibit colonizing ability and cell proliferation of preneoplastic MCF10.A1 cells in contrast to a much weaker cell inhibitory effects in DCIS cells. Next, we identified the functional gene targets of miRNA-140-3p by integromics studies involving next generation RNA-seq on the MCF10A model employing bioinformatics pipeline. SigTerms. These analyses identified HMGCR and HMGCS1 as top 2 gene targets of miRNA-140-3p that map to cholesterol biosynthesis pathway. Consistently, we found miRNA-140-3p to directly bind in 3'UTR of HMGCR, HMGCS1 and repress their expression as shown by luciferase assays. miRNA-140 binding of these gene targets is also functionally relevant as inhibition of HMGCR activity by an FDA approved statin inhibitor, fluvasatin, preferentially inhibited the cell proliferation and colonizing ability of preneoplastic MCF10A1.T1 cells. Further studies focused on testing the potential of fluvasatin to prevent progression of breast atypia cells in mouse xenografts are underway. Conclusions: Our results suggest miRNA-140 and its downstream functional cholesterol biosynthesis pathway targeting, especially by FDA approved Fluvasatin, may be a novel strategy for targeted prevention of TNBC.

### Honokiol stimulates immune reactivity in UV-irradiated skin through DNA demethylation-dependent functional activation of dendritic cells in mice.

Santosh K. Katiyar, Tripti Singh, Harish C. Pal, Ram Prasad. Univ. of Alabama at Birmingham, Birmingham, AL.

Solar ultraviolet radiation (UVR), and in particular UVB spectrum (290-320 nm), are considered as a complete carcinogen for cutaneous malignancies. The over-exposure of UVR suppresses the development of allergic contact hypersensitivity (CHS) response in both laboratory animals as well as in humans. CHS response is considered to be a prototypic T-cell mediated immune response. UVR-induced suppression of immune sensitivity has been implicated in skin cancer risk. Therefore, the treatment options which can inhibit UVB-induced suppression of immune sensitivity may be useful in the management of skin cancers, including both melanoma and non-melanoma. Previously, we have shown that topical treatment of honokiol inhibits UVB induced immune suppression, which was associated with the reduction in UVB-induced inflammatory mediators in the mouse skin. Here, we have further determined the underlying mechanism of action of honokiol on UVB-induced immunosuppression including its effect on epigenetic regulators and their relationship with immune sensitivity. Topical treatment of C3H/HeN mice with honokiol (0.5 and 1.0 mg/cm2 skin area) in hydrophilic-cream based topical formulation significantly inhibits UVB-induced suppression of CHS response (P<0.01-0.005), which was associated with reduced levels of DNA methylation as well as Dnmt activity in the mouse skin compared with non-honokiol-treated and UVB-exposed control mice. To characterize the cell population responsible for the honokiol mediated inhibition of UVB-induced immunosuppression, we used an adoptive transfer approach. DNA-methylated (most of cells) dendritic cells (DCs), isolated from the draining lymph nodes of donor mice that had been UVB-exposed and sensitized to 2,4-dinitrofluorobenzene (DNFB) with and without honokiol (0.5 and 1.0 mg/cm2 skin area) treatment, were transferred into naive recipient mice. The CHS response of the recipient mouse to DNFB was then measured. Honokiol treatment of UVB-exposed donor mice relieved this suppression of the CHS response in naive mice, while the recipient mice, obtained DNA-methylated DCs from UVB-exposed donor mice that were not treated with honokiol, showed significant suppression in the CHS response. The DCs from non-honokiol-treated and UVB-exposed donor mice was also associated with enhanced secretion of Th1-type cytokines compared with the Th1-type cytokines from the DCs obtained from non-honokiol-treated and UVB-exposed donor mice. These data suggest that honokiol mediated inhibition of UVB induced suppression of CHS response is associated with functional activation of dendritic cells and that is dependent on DNA methylation in DCs.

### Sildenafil suppresses inflammation-driven colorectal cancer in mice.

Bianca N. Islam,1 Sarah K. Sharmam,1 Yali Hou,1 Allison Bridges,1 Ravi- dra Kolhe,1 Jimena Trillo-Tinoco,1 Nagendra Singh,1 Sangmi Kim,1 Subbar- miah Sridhar,1 Franklin G. Berger,1 Darren D. Brownings,1 Augusta University, Georgia Cancer Center, Augusta, GA; 2Augusta University, Medical College of Georgia, Augusta, GA; 3University of South Carolina, Columbia, SC.

Intestinal cyclic guanosine monophosphate (cGMP) signaling regulates epithelial homeostasis, and has been implicated in the suppression of colitis and colorectal cancer (CRC). In this study, we investigated the cGMP-specific phosphodiesterase-5 (PDE5) inhibitor sildenafil to prevent tumorigenesis in the azoxymethane/dextran sodium sulfate (AOM/DSS) inflammation-driven colorectal cancer model. Treatment of mice with sildenafil activated cGMP signaling in the colon mucosa and protected against DSS-induced barrier dysfunction. In mice treated with AOM/DSS, oral administration of sildenafil throughout the disease course reduced polypl multiplicity by 50% compared to untreated controls. Polyps formed in sildenafil-treated mice showed less proliferation and were more differentiated compared to polyps from untreated mice, but apoptosis was unaffected. Polyps in sildenafil-treated mice were also less inflamed; they exhibited reduced myeloid-cell infiltration, and reduced expression of iNOS, IFNγ and IL-6 compared to untreated controls. Most of the protection was observed when sildenafil was added during the initiation stage of carcinogenesis (40% reduction in multiplicity), whereas administration of sildenafil later during the promotion stages did not affect polypl number. While later treatment with sildenafil did not affect multiplicity, it did have a similar effect on polypl phenotype, including increased mucus production, reduced proliferation and inflammation. In summary, our results demonstrate that oral administration of sildenafil suppresses inflammation and polyp formation in mice treated with AOM/DSS. This suggests that PDE5 inhibitors could have therapeutic value for the prevention of CRC in inflammatory bowel disease patients.

### Rapamycin suppresses ErbB2-overexpressing mammary tumors through selective inhibition of luminal progenitor cells and tumor-initiating cells.

Qingxia Zhao,1 Amanda B. Parriss,1 Erin W. Howard,1 Ming Zhao,3 Zhiying Guo,1 Ying Xing,2 Zhikun Ma,1 Xiaohe Yang1.

Rapamycin is a potent inhibitor of the mTOR pathway and has demonstrated anti-cancer properties in various cancer models. Although rapamycin was reported to inhibit mammary carcinogenesis at multiple stages, including initiation, invasion, and metastasis, the underlying mechanisms remain unclear, especially in individual breast cancer subtypes. Specifically, ErbB2/Her2 amplification occurs in approximately 25% of invasive human breast cancers, and is characterized by Akt-mTOR pathway deregulation. Recent reports also suggest that cancer stem cells (CSCs) play a critical role in tumor development and metastasis. Therefore, we investigated the efficacy of rapamycin in the prevention of mammary tumor development in MMTV-ErbB2 transgenic mice by focusing on its effects on CSCs/tumor-initiating cells (TICs). In this study, MMTV-ErbB2 mice were inoculated with syngeneic 78617 cells, which are derived from MMTV-ErbB2 mammary tumors, followed by rapamycin treatment (1.5 mg/kg/day) for 12 days. We found that rapamycin elicited strong anti-tumorigenic effects on the syngeneic tumors, as indicated by substantially reduced tumor volume and weight. To determine the effect of rapamycin on mammary epithelial cells (MECs) in premalignant tissues, MMTV-ErbB2 mice were treated with low-dose rapamycin (1 mg/kg/day) between weeks 10 and 20 of age. Rapamycin significantly inhibited mammary morphogenesis at 20 weeks of age as UVB-exposed to the control mice. As such, the branching density, ductal elongation, and proliferative index of the mammary glands from the rapamycin-treated mice were markedly decreased. Flow cytometric analysis of primary MECs demonstrated that rapamycin selectively inhibited the C61+CD49f+SP subpopulation, which are enriched with luminal progenitor
PREVENTION RESEARCH: Molecular Targets and Cancer Prevention

cells and TICs. 3D culture of FACS-sorted MEC subpopulations indicated that CD61-CD49d+ cells are the major subpopulation that gives rise to 3D colonies. We further demonstrated that rapamycin significantly suppressed colony-forming cell (CFC) number and primary/secondary sphere formation of primary MECs and spontaneous MMTV-erbB2 tumor cells, indicating rapamycin-induced inhibition of mammary progenitor cells and CSC self-renewal, respectively. Furthermore, molecular analysis of MECs demonstrated that rapamycin inhibited signaling associated with ER, ErbB2, and mTOR. In particular, rapamycin strikingly inhibited Wnt/β-catenin and TGFβ/Smad3 signaling. Taken together, our results demonstrate that rapamycin-mediated prevention of MMTV-ErbB2 mammary tumor development involves selective targeting of mammary progenitor cells and CSCs in the premalignant mammary tissues through regulation of MEC stenness and multiple signaling pathways, which contributes to its potent anti-tumor effects on ErbB2-overexpressing breast cancer.

Pro-inflammatory signaling has been shown to promote colorectal tumorigenesis and is a target for the development of effective chemopreventive approaches. The specialized pro-resolving lipid mediators (SPMs, e.g. resolvins), bioactive metabolites of eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA), actively terminate inflammation and have been proposed to possibly contribute to the anti-tumorigenic effects of DHA and EPA. 15-lipoxygenase-1 (ALOX15) is a key biosynthetic enzyme in generation of resolvins. However, 15-LOX-1 expression is commonly lost during human CRC tumorigenesis starting in premalignant stages through transcriptional mechanisms independent of substrate availability. The impact of ALOX15 on DHA and EPA’s effects on tumorigenesis remain unknown. Mice with intestinal epithelium-specific expression of human ALOX15 (15-LOX-1-gut mice) and wild-type FVB controls were injected with azoxymethane (AOM, 7.5mg/kg) once weekly for 6w and followed for 20w. Mice were fed diet with 1% omega-3-acid ethyl esters (O3AEE, a pharmaceutical grade fısh oil preparation of EPA and DHA ethyl esters) or control diet starting 3w before initiation with AOM. Colonic tumors developed in 10 of the 13 (77%) wild type (WT) mice fed control diet, 5 of the 10 (50%) WT mice fed O3AEE diet, 5 of the 12 (42%) 15-LOX-1-gut mice fed control diet, and 3 of the 10 (30%) 15-LOX-1-gut mice fed control diet. Lipid mediator levels were measured by liquid chromatography/tandem mass spectrometry (LC-MS/MS). The SPMs resolvin E1 and D2 (RvE1, RvD2) as well as DHA-stable phosphodiesterase-5 (PDE5) inhibitor that was previously shown to reduce polyp formation in familial adenomatous polyposis (FAP) patients. Despite this validation of PDE5 as a therapeutic target, the failure of Exsulin due to toxicity halted further trials of cGMP elevating agents. The present study tested the effect of the PDE5 inhibitor sildenafil, and the receptor guanylyl-cyclase C (GCC) agonist nitroguanylic acid to tumor growth, invasion, angiogenesis (as assessed by quantitation of VEGF, MMP-2, and MMP-9 levels) and each of the tumor suppressors RECK and TIMP3 gene and significantly enhanced their protein expression in the ALOX15-gut mice model of colon cancer. Administration of either sildenafil or nitroguanylic acid reduced tumor growth, invasion, angiogenesis (as assessed by quantitation of VEGF, MMP-2, and MMP-9 levels) and each of the tumor suppressors, RECK and TIMP3 gene and significantly enhanced their protein expression in the ALOX15-gut mice model of colon cancer. Administration of either sildenafil or nitroguanylic acid reduced tumor growth, invasion, angiogenesis (as assessed by quantitation of VEGF, MMP-2, and MMP-9 levels) and each of the tumor suppressors. While the tumor suppressive mechanism is not fully understood, the results presented here demonstrate in a preclinical model, that increasing intestinal cGMP levels by targeting PDE5 or GCC may be a viable chemoprevention strategy for human FAP patients.

#2225 Green tea polyphenols suppress tumor growth and invasion by targeting matrix metalloproteinases, RECK and TIMP3, in a mouse model implanted with prostate tumors. Debrup Chakraborty, Venessa Benham, Elena Y. Demireva, Blair Bullard, Jamie J. Bernard. Michigan State University, East Lansing, MI.

Background: Adiposity plays a crucial role in the pathogenesis and prognosis of different types of cancers. Epidemiological evidence suggests visceral adipose tissue (VAT) and high-fat diets (HFD) are associated with increased cancer risk however the mechanism is not understood. The aim of this study was to explore the factors in VAT that stimulate neoplastic transformation. Methods: We modeled visceral adiposity-stimulated neoplastic transformation using our novel ex vivo system of VAT conditioned medium stimulated epithelial cell transformation (measured by growth in soft agar) and our in vivo murine lipemia model of ultraviolet light B (UVB)-induced, VAT promoted skin tumor formation. FgrR1+/− stable cells were generated by using CRISPR-Cas9 technology and were used to investigate the role of fibroblast growth factor-2 (FGF2) and FGFRI dependent signaling in neoplastic transformation, both in vitro and in vivo. Results: Only the VAT of obese mice fed a HFD [not VAT from low-fat diet (LFD) fed mice] stimulated neoplastic transformation of skin epithelial cells. Furthermore, human VAT stimulated both skin and mammary epithelial cell transformation. The differences in VAT activity between LFD and HFD fed mice and human donors were associated with the levels of FGF2. Circulating

#2226 Sildenafil supresses tumorigenesis in ApexSmad3/− mouse model. Sarah K. Shurmeir, 1 Bianca N. Islam, 1 Yali Hou, 1 Allison Bridges, 1 Nagendra Singh, 1 Subbaramiah Sridhar, 1 Frankin G. Berger, 1 Darren D. Brownling, 1 Augusta University, Georgia Cancer Center, Augusta, GA; 2Augusta University, Medical College of Georgia, Augusta, GA; 3University of South Carolina, Columbia, SC.

The cGMP signaling pathway regulates homeostasis in the colon epithelium and has been implicated in the suppression of colorectal cancer. Exsulin is a weak phosphodiesterase-5 (PDE5) inhibitor that was previously shown to reduce polyp formation in familial adenomatous polyposis (FAP) patients. Despite this validation of PDE5 as a therapeutic target, the failure of Exsulin due to toxicity halted further trials of cGMP elevating agents. The present study tested the effect of the PDE5 inhibitor sildenafil, and the receptor guanylyl-cyclase C (GCC) agonist nitroguanylic acid on tumorigenesis in the ApexSmad3/− mouse model of colon cancer. Administration of either sildenafil or nitroguanylic acid to both wild type and ApexSmad3/− mice caused dramatic effects on homeostasis that included reduced proliferation and increased goblet cell differentiation. With treatment beginning at 4 weeks, sildenafil and nitroguanylic acid caused a 50% and 67% (respectively) reduction in the number of polyps per mouse. Furthermore, the polyps in sildenafil and nitroguanylic acid treated animals exhibited a reduced proliferative index and increased mucus density compared to polyps from untreated mice. The mean polyp size was not changed by treatment with either drug. In support of a tumor-suppressive role for cGMP signaling in the intestine, the ApexSmad3/− mice showed reduced levels of endogenous GCC agonists in the intestinal mucosa compared to wild type animals. This suggests that part of the tumor preventative effects observed here could be due to compensation for this deficit by augmenting cGMP signaling with PDE5 inhibitors or GCC agonists. While the tumor suppressive mechanism is not fully understood, the results presented here demonstrate in a preclinical model, that increasing intestinal cGMP levels by targeting PDE5 or GCC may be a viable chemoprevention strategy for human FAP patients.

#2227 Fgf2 from visceral adipose tissue stimulates neoplastic transformation of nonmalignant epithelial cells. Debrup Chakraborty, Venessa Benham, Elena Y. Demireva, Blair Bullard, Jamie J. Bernard. Michigan State University, East Lansing, MI.

Background: Adiposity plays a crucial role in the pathogenesis and prognosis of different types of cancers. Epidemiological evidence suggests visceral adipose tissue (VAT) and high-fat diets (HFD) are associated with increased cancer risk however the mechanism is not understood. The aim of this study was to explore the factors in VAT that stimulate neoplastic transformation. Methods: We modeled visceral adiposity-stimulated neoplastic transformation using our novel ex vivo system of VAT conditioned medium stimulated epithelial cell transformation (measured by growth in soft agar) and our in vivo murine lipemia model of ultraviolet light B (UVB)-induced, VAT promoted skin tumor formation. FgrR1+/− stable cells were generated by using CRISPR-Cas9 technology and were used to investigate the role of fibroblast growth factor-2 (FGF2) and FGFRI dependent signaling in neoplastic transformation, both in vitro and in vivo. Results: Only the VAT of obese mice fed a HFD [not VAT from low-fat diet (LFD) fed mice] stimulated neoplastic transformation of skin epithelial cells. Furthermore, human VAT stimulated both skin and mammary epithelial cell transformation. levels of FGE2 were associated with non-melanoma tumor formation in vivo. Human and mouse VAT failed to stimulate transformation in FGR1-/- cells and do not form tumors when injected in Nude mice in vivo. Conclusion: Collectively, our data show FGE2 released from VAT and its interaction with FGR1 is a novel and potential direct path of VAT-enhanced tumorigenesis. Blocking the FGR1/FGE2 interaction in VAT of abdominally obese individuals may be an important cancer prevention strategy as well as an adjuvant therapy for improving outcomes following cancer diagnosis.

#2288 Altering rictor with diosmetin reduces tumor progression in orthotopic prostate cancer model. Rebecca Pakradooni, Ahmad Khalifa, Riddhi Patel, Sanjeev Shukla. Case Western Reserve Univ., Cleveland, OH.

Rapamycin insensitive companion of mTOR (Rictor) is an essential subunit of mTORC2, maintains the integrity of the complex and functions as full activator of Akt. Rictor has been implicated to be involved in growth and progression of malignancies. Reports suggested that overexpression of Rictor in prostate cancer tissues, which may have potential role in prostate cancer progression. We demonstrated silencing Rictor in PC-3 cells decreased p-Akt (Ser-473) expression; conversely p-Akt (Thr-308) and p-PKC expression were increased. However, expression of mTOR complex 2, maintained the integrity of the complex and functions as full activator of Akt. Treatment of human prostate cancer DU145 and 22Rv1 cells, which possess high constitutive EZH2 expression, with 5-20 µM luteolin significantly inhibited EZH2 and SUZ12 protein expression in dose and time dependent manner, although luteolin treatment did not affect protein expression of EED and RBAP48. In addition, treatment of both cell lines with luteolin also reduced H3K27me3 and H3K27me2 and its enzymatic activity in dose and time dependent manner without affecting total H3 protein. In addition, luteolin was also effective in suppressing in vitro methylation performed using recombinant PRC2 complex. These events led to increase in the expression of downstream tumor suppressors including E-cadherin, SLIT2 and TIMP3, respectively. Interestingly, treatment of cells with proteasome inhibitor, MG132 together with luteolin did not prevent EZH2 degradation indicating that proteasomal degradation might not contribute to EZH2 inhibition. Taken together, our study suggests that luteolin acts on the catalytic binding site of EZH2 to exhibit downregulation of histone H3 methylation and could be developed as a potential promising agent for the prevention and/or treatment of various human cancers including prostate cancer with EZH2 overexpression.

#2231 15-Keto prostaglandin E2 inhibits STAT3 signaling in H-Ras-transformed mammary epithelial cells. Eun-Ji Lee,1 Young-Ill Hahn,2 Su-Jung Kim,1 Young-Joon Surh,1 Hye-Kyung Na.2 1Seoul National University, Seoul, Republic of Korea; 2Sungchun Women’s University, Seoul, Republic of Korea.

Prostanoid 15-keto PGE2 (15-kPGE2) is a potent lipid mediator that plays a key role in inflammation and carcinogenesis. The intracellular level of PGE2 is regulated by NAD+ dependent 15-hydroxyprostaglandin dehydrogenase (15-PGDH). This enzyme catalyzes the oxidation of the (15S)-hydroxy group of PGE2 to generate 15-keto PGE2. Down-regulation of 15-PGDH was observed in various malignancies and overexpression of 15-PGDH has been known to suppress carcinogenesis. However, mechanisms underlying anti-carcinogenic effects and tumor suppressive functions of 15-keto PGE2 are poorly understood in various cancer. H-Ras transformed mammary epithelial cell line MCF10A has greatly facilitated by the absence of a second gene copy. In addition, our studies demonstrate that diosmetin fed animals resulted in growth inhibition and induction of apoptosis by altering Rictor signaling cascade. We are demonstrating that diosmetin modulates molecular targets viz., Rictor and Akt to alter cellular events and elicit anticancer effects in prostate cancer cells.

#2229 Prevention by tofotenolic acid and characterization of the molecular targets in Pirc and FAP colorectal adenomas. Furkan U. Ertém, Wenzang Zhang, Kyle Chang, Wan-Mohaiza Dashwood, Praveen Rajendran, Deqiang Sun.1,2 1University of Pittsburgh Medical Center, Pittsburgh, PA; 2Texas A&M Univ. Health Science Ctr., Houston, TX.

A critical need exists in sporadic and high-risk colorectal cancer patients for endoscopic screening combined with safe and effective preventive agents. To prioritize molecular targets for prevention studies in vivo, RNA-seq analyses were conducted on colorectal adenomas from familial adenomatous polyposis (FAP) patients, and from the Apc-mutant polyposis in rat colon (Pirc) model. Using a new murine endoscopic polypectomy methodology (F.U. Ertém et al., Gastrointest Endosc 2016;83:1272-6), we evaluated agents that might substitute for the current standard of care. Sulindac, and identified tofotenolic acid (TA) as a promising candidate for further investigation. At clinically-relevant doses in the Pirc model, TA suppressed tumorigenesis significantly both in the small intestine and in the colon. Inhibition by TA of colonic crypt cell proliferation, and the concomitant activation of apoptosis, coincided with reduced expression in target tissues of β-catenin, cyclin D1, Survivin and matrix metalloproteinase 7. Based on the oncogene candidates defined by RNA-seq analysis, endoscopic tracking revealed the time-course of tumor suppression by TA, and the temporal changes in S100a9, Nppb, Aldh1a3 and Mmp7, highlighting their value as potential early biomarkers for prevention in the clinical setting. As an “old drug” repurposed from migraine, TA appears to offer an exciting new therapeutic avenue in FAP and other high-risk colorectal cancer patient populations. This work was supported in part by NIH grants CA090890, CA122959, ES00210, ES023512, the John S. Dunn Foundation, and a Chancellor’s Research Initiative.
PREVENTION RESEARCH: Molecular Targets and Cancer Prevention

STAT3 has several cysteine residues in its activation sites. We observed that reducing agents N-acetyl-L-cysteine and dithiothreitol abrogated the suppressive effect of 15-keto PGE₂ on STAT3 phosphorylation, suggesting that the involvement of the thiol modification. Biotinylated 15-keto PGE₂ covalently bound to STAT3 as determined by immunoprecipitation with STAT3 f-Blocker by immunoblotting with streptavidin. Molecular docking analysis predicted Cys²⁵¹ and Cys²⁶⁹ residues of STAT3 as putative binding sites of 15-keto PGE₂. In conclusion, 15-keto PGE₂ inhibits STAT3 signaling through cysteine thiol modification, thereby suppressing MCF10A-ras cell growth and proliferation. Thus, tumor suppressor function of 15-PGDH is through cysteine thiol modification, thereby suppressing MCF10A-ras cell growth and proliferation. Therefore, agent that inhibits tumor growth caused by STAT3 phosphorylation has the potential to inhibit tumor growth. STAT3 has several cysteine residues in its activation sites. We observed that reducing agents N-acetyl-L-cysteine and dithiothreitol abrogated the suppressive effect of 15-keto PGE₂ on STAT3 phosphorylation, suggesting that the involvement of the thiol modification. Biotinylated 15-keto PGE₂ covalently bound to STAT3 as determined by immunoprecipitation with STAT3 f-Blocker by immunoblotting with streptavidin. Molecular docking analysis predicted Cys²⁵¹ and Cys²⁶⁹ residues of STAT3 as putative binding sites of 15-keto PGE₂. In conclusion, 15-keto PGE₂ inhibits STAT3 signaling through cysteine thiol modification, thereby suppressing MCF10A-ras cell growth and proliferation. Thus, tumor suppressor function of 15-PGDH is through cysteine thiol modification, thereby suppressing MCF10A-ras cell growth and proliferation. Therefore, agent that inhibits tumor growth caused by STAT3 phosphorylation has the potential to inhibit tumor growth.

The role of dietary flavonoid intake in colorectal carcinogenesis might differ according to flavonoid subclasses and individual genetic variants related to carcinogen metabolism. Therefore, we examined whether greater habitual dietary intake of flavonoid subclasses was associated with a lower risk of colorectal cancer and whether CYP1A1 genetic variants altered this association. A semi-quantitative food frequency questionnaire was used to assess the dietary intake of six flavonoid subclasses (flavonols, flavones, flavanones, flavan-3-ols, anthocyanins, and isoflavones) in 923 patients with colorectal cancer and 1,846 controls; furthermore, CYP1A1 genetic variants (rs4646903 and rs1049843) were genotyped. A logistic regression was used to investigate dietary intake, CYP1A1 genetic variants, and their interaction in relation to colorectal cancer risk. Among the subclasses of flavonoids, flavonols (OR [95% CI] = 0.10 [0.06, 0.16], highest vs. lowest quartile) and flavan-3-ols (OR [95% CI] = 0.54 [0.41, 0.71], highest vs. lowest quartile) were significantly associated with colorectal cancer risk after adjusting for confounders. Homozygous variants of CYP1A1 rs4646903 showed a protective effect on the risk of rectal cancer (OR [95% CI] = 0.60 [0.37, 0.96], CC vs. TT/TC). Carriers of the CC homozgyous variant with high flavonol intake showed a greater decrease in colorectal cancer risk compared with T allele carriers with low flavonol intake (P for interaction = 0.02), particularly regarding rectal cancer (P for interaction = 0.005). In conclusion, the effect of dietary flavonoid intake on colorectal cancer risk differs by flavonoid subclasses and CYP1A1 genetic variants.

#2233 The fatty acid amide hydrolase inhibitor URB937 ameliorates radiation-induced lung injury in a mouse model. Rui Li, Jianxin Xue, You Lu. West China Hospital, West China School of Clinical Medicine, Chengdu, China.

Radiation-induced lung injury (RILI) is a common and potentially serious complication from radiotherapy to the thoracic region. In the current study, we examined the potential protective effects of URB937, an inhibitor of fatty acid amide hydrolase in a mouse model of RILI. Here we challenged male C57BL/6 mice with irradiation (16Gy to the thoracic region), and then injected intraperitoneally either URB937 (1 mg/kg) or vehicle three times a week for 30 days. Mice were sacrificed either at the end of treatment or 120 days from irradiation to evaluate the extent of RILI and mice survival. Potential effects of URB937 on irradiation induced tumor growth inhibition were also evaluated. We found URB937 increased endocannabinoids in the lungs, attenuated the extent of RILI, prolonged the survival. Inhibited mice developed pathological alterations of pneumonitis and lung fibrosis. Radiation-induced increases of proinflammatory and profibrotic cytokines were decreased, including interleukin-1β, interleukin-6, tumor necrosis factor-α, transforming growth factor-β1 in plasma and lung tissue. Moreover, malondialdehyde in plasma and inflammation cells in bronchoalveolar lavage fluid were lower in mice treated with irradiation plus URB937. URB937 did not affect tumor growth inhibition caused by irradiation. These results suggested that inhibiting fatty acid amide hydrolase through URB937 could ameliorate the RILI, without affecting the efficacy of irradiation on tumor control.

#2234 Efatazutane reduces mammosphere formation in Brca1WT/Bl1+Ctcp/p53+/+ and Brca1Bl1/Bl1+Ctcp/p53−/− mice. Sahar J. Alothman, Shan Chao, Weisheng Wang, Priscilla A. Furth. Georgetown University, Washington, DC.

Introduction: Efatazutane, a PPAR gamma agonist, may affect tumor growth through the induction of terminal cell differentiation. Thus, we hypothesized that efatazutane could affect progenitor cell number. Here, we evaluate progenitor cell number by measuring mammospheres, which is considered one way to measure potential progenitor cells. Methods: Two month old Brca1WT/Bl1+Ctcp/p53+/+ (n = 14) and Brca1Bl1/Bl1+Ctcp/p53−/− (n = 10) C57B/6 mice were randomly placed on either control or treated with efatazutane through the diet (30 mg/kg concentration, F3028, rodent diet, grain-based, 1/2-in pellets; Bio-Serv, Frenchtown, NJ) with necropsy at four months and isolation of primary mammary epithelial cells from thoracic glands for studies of mammosphere formation using SCIVAX 96-well low adhesion nanoculture plates (Organogenix, Inc., Vancouver, Canada) with 0.1,5, and 10% fetal bovine serum (FBS) added. Thoracic mammary gland tissue was frozen at -20°C followed by isolation of RNA and evaluation of PPAR gamma pathway gene expression by real-time RT-PCR using TaqMan® Array Mouse Lipid Regulated Genes (Thermo Fisher Scientific, Inc., Waltham MA). One inguinal gland was fixed for mammary gland whole mount and the other inguinal gland was formalin-fixed and paraffin embedded for histology. Results: SCIVAX nanoculture plates showed reproducible increases in mammosphere numbers with increasing FBS concentrations (p < 0.05 one-way, Kruskal-Wallis). An increased significant increase in sphere number was seen in Brca1WT/Bl1+Ctcp/p53+/+ compared to Brca1Bl1/Bl1+Ctcp/p53−/− (p < 0.05 one-way, Kruskal-Wallis). Efatazutane treatment significantly decreased sphere numbers in Brca1WT/Bl1+Ctcp/p53+/+ and in Brca1Bl1/Bl1+Ctcp/p53−/− mice (p < 0.05 one-way, Kruskal Wallis). Expression of PPAR gamma pathway genes were increased at the RNA level with statistically significant increases in Acdavl, Tnf, Alox5 (p < 0.05) and Il1B, Srebf2, Hmgs1, Hmrg (p <0.01) genes (Bootstrap Ratio, http://rht.iconcologia.net/stats/br/several.html) in mice on efatazutane as compared to control diet. Discussion: SCIVAX nanoculture plates can be used to quantitatively evaluate and compare mammosphere numbers between different genotypes and treatment groups. The higher numbers of mammospheres found with loss of both Brca1 copies as compared to one copy is consistent with previously published literature. The decrease in mammosphere numbers with efatazutane treatment could be secondary to its differentiating impact on mammary epithelial cells. Conclusion: While efatazutane statistically significantly reduced mammosphere numbers, the absolute reduction was less the 25%.

#2235 Preventive effects of the sodium glucose cotransporter 2 inhibitor tofogliflozin on liver tumorigenesis in obese and diabetic mice. Yohei Shirakami, Koki Obara, Masaya Ohnishi, Takayasu Ideta, Hiroyasu Sakai, Takuki Tanaka, Masahito Shimizu, Mitsuuru Seishima. Gifu Univ. Graduate School of Medicine, Gifu, Japan.

Obesity, diabetes mellitus, and their related metabolic abnormalities are associated with increased risk of hepatocellular carcinoma (HCC). Sodium glucose cotransporter (SGLT)-2 inhibitors, recently approved anti-diabetic agents, are expected to ameliorate the abnormalities associated with metabolic syndrome including non-alcoholic fatty liver disease (NAFLD). In this study, we investigated the effects of the SGLT2 inhibitor tofogliflozin on the development of NAFLD-related liver tumorigenesis in C57BL/KsJ-Leprdb/+ Leptin−/− mice (db/db) obese and diabetic mice. The direct effects of tofogliflozin on human HCC cell proliferation were also evaluated. Male db/db mice were administered diethyl-nitrosamine-containing water for two weeks and were treated with tofogliflozin throughout the experiment. Tofogliflozin was kindly provided by Kowa Co., Ltd. and the chemical structure will be disclosed at the time of presentation at the meeting. In mice treated with tofogliflozin, the development of hepatic pre-cancerous lesions was found to be retarded, and the proliferation of SGLT2 protein-expressing HCC cells was not inhibited by this agent. These findings suggest that tofogliflozin suppressed the early phase of obesity- and NAFLD-related liver carcinogenesis by attenuating chronic inflammation and steatosis in the liver, while the agent had no significant direct effect on the proliferation of HCC cells. Therefore, SGLT2 inhibitors may have a chemopreventive effect on obesity-related HCC.

#2236 High-throughput screen for chemopreventative agents that influence adipose-tissue driven epithelial neoplastic transformation. Vanessa Benham, Debrup Chakraborty, Blair Bullard, Thomas S. Drexheimer, Jamie J. Bernard. Michigan State University, East Lansing, MI.

Epidemiological studies have established a link between excess adiposity and cancer risk. Our previous data demonstrate that adipose tissue stimulates the transformation (steps a cell undergoes to become malignant) of both skin and mammary epithelial cells as measured by anchorage-independent growth in soft agar. Therefore, agents that influence growth in soft agar may be used therapeutically for skin and breast cancer prevention. However, soft agar in a 24-well format is unsuitable for high-throughput screens. Our objective was to develop a high-throughput assay to evaluate chemopreventative agents that influence...
Novel selenium-containing aspirin molecule AS-10 suppresses an- 
drogen receptor signaling and induces apoptosis of LNCaP prostate cancer cells. Deepkamal N. Karelia, Sangyub Kim, Srinivasa Ramisetti, Cheng Jiang, Shantu Amin, Arun K. Sharma, Junxuan Lu. Penn State College of Medicine, Hershey, PA.

Aspirin as the best known low cost Non-Steroidal Anti-inflammatory drug (NSAID) has been associated with lowering risk of colorectal cancer, in addition to its cardiovascular health benefit at low dose (baby Aspirin) and over-the- 
counter pain medication. Through an innovative research program aiming at enhancing the bioactivities of NSAIDs by incorporation of selenium, we have discovered AS-10 as a novel Aspirin-selenium compound with promising anti- 
cancer drug-like properties in terms of potency enhancement (at least 3 orders of magnitude compared to Aspirin), selective cytotoxicity against cancer cells in- 
cluding majority of NCI-60 panel, while sparing normal mouse embryonic fibro- 
basts in cell culture screening assays. Preliminary toxicity study in mice had shown a wide safety margin. Extensive structure-activity relationship investiga- 
tion suggested a novel structural basis, instead of releasable selenium, that ac- 
counted for the striking potency. To investigate the potential chemopreventive attributes of AS-10 against prostate carcinogenesis, we selected LNCaP cells (wild type p53, functional androgen receptor, AR) to examine the growth sup- 
pression and apoptosis responses in cell culture. The rationale for choosing LNCaP cell line as target cells rests in the fact that precancerous prostatic lesions that are the intended targets of chemoprevention as well as early stage prostate cancer retain wild type p53 and they are critically dependent on AR signaling for survival. Our results show that cell viability (MTT) test detected a potent growth inhibition of LNCaP cells in a time and concentration dependent manner, with an EC50 in range of 1.7 to 2.5 μM compared to Aspirin. We found the lead compound 15k, as determined by using molecular biology assays, was found to be due to inhibition of apoptosis, tubulin inhibition, and inhibition of stemness pathways (Wnt-β-catenin-EMT). The 15k had significant anti-metastatic effects as shown by their inhibition of migration and invasion potential on OC cells. In silico findings suggest that pharmacokinetic [PK] profiles of these compounds are favorable compared to Aspirin. Further in vivo PK/pharmacodynamic studies are underway to establish the clinical use of lead molecule in advanced me- 
tastasized, drug resistant OC patients.

Establishment of lung cancer CTCs competent for lung metastasis. Zujun Que,1 Bin Luo,2 Qihui Shi,1 Jianhui Tian.2 Shanghai Institute of Tradit- 
tional Chinese Medicine, Institute of TCM Oncology, Shanghai, China;1 Longhua Hospital, Shanghai University of Traditional Chinese Medicine, National Clinical Research Centre for Traditional Chinese Medicine and Oncology, Shanghai, Chi- 
na;2 Systematic Biomedical Research Center of Shanghai Jiao Tong University, Shanghai, China.

Circulating tumor cells (CTCs) have been implicated as a population of cells that may seed metastasis, which led to the 90% of dead in cancer patients. Though the detection technologies has been developing swiftly, how to culture the cells successfully and established a permanent cell line are the bottleneck in the research of metastasis mechanism. Here, we report, for the first time, the establishment of permanent cell line from CTCs of one Non-small cell lung cancer patient and identifying the biological characterization. The cell line design- 
ated CTC-0430 has been cultured for more than one and half years, and the cells have been characterized at the genome, proliferation, drug resistance, the expression of surface marker, cytokine secretion level and the characterization of tumor formation in vivo by immunohistochemistry and immunofluorescence. This thorough analysis showed that CTC-0430 cells display a stable phenotype characterized by an intermediate epithelial/mesenchymal phenotype, stem-cell like properties and the drug sensitivity test indicating stronger drug resistance compared to A549 and 95-D. When compare with A549 and 95-D cells, CTC- 
0430 cells high expression of ICAM-1 and ICAM-3, low expression of CXCL12 and CXCL1. Functional studies showed that CTC-0430 cells induced rapidly in vivo tumors after subcutaneous transplantation in immunodeficient mice, and the lung metastasis were found after six months later. Besides, three months after we injected the cells into the caudal vein of NOD/SCID mice, the lung metastasis were formed. And then the metastasis lung tissue were used to make IHC and IF, which indicated that the biological characterizations of this cell line are different from A549. The establishment stable cell line of lung cancer CTCs can provide in vivo research platform for the intervention study of postoperative metastasis of lung cancer.
induced cell death and attenuated p53, p21 and p-H2AX. Moreover, siRNA knockdown of p53 did not suppress ROS production, but decreased ISC-4-induced Annexin V-positive apoptosis, PARP cleavage and the DDR proteins. Taken together, these data suggest that ISC-4 inhibits LNCaP cell growth and survival with concomitant suppression of AR signaling and induction of ROS- and p53-dependent apoptosis. Given the importance of AR signaling in prostate epithelial survival, cancer genesis and progression, and the preservation of wild type p53 in precancerous lesions and early stage prostate cancer, our findings suggest attractive chemopreventive potential of ISC-4 against prostate carcinogenesis.

#2244 Pharmacological TLR4 antagonism using topical resatorvid blocks solar UV-induced skin tumorigenesis in SKH-1 mice. Sally E. Dickinson, 1 Karen Blehm-Mangone, 2 Nichole B. Burkett, 2 Shehla Tahsin, 2 Paul B. Myrdal, 1 Kelly L. Karlage, 1 Jaroslav Janda, 2 Kathylynn Saboda, 2 Denise J. Roe, 1 Zigang Dong, 1 Ann M. Bode, 2 Emanuel F. Petricoin, 1 Valerie S. Calvert, 2 Clara Curiel-Lewandrowski, 1 David S. Alberts, 1 Georg T. Wondrak 1. 1Department of Pharmacology, University of Minnesota, Austin, MN; 2Department of Biopharmaceutical Sciences, University of Minnesota, Minneapolis, MN. An urgent need exists for the development of more efficacious molecular strategies targeting non-melanoma skin cancer (NMSC), the most common malignancy worldwide. Inflammatory signaling downstream of Toll-like receptor 4 (TLR4) is a causative factor in several forms of tumorigenesis, yet its role in solar UV-induced skin carcinogenesis remains undefined. In our recently published work based upon immunohistochemical (IHC) analysis of NMSC tissue microarrays and proteomic analysis of reverse-phase protein microarrays (RPMA) from banked human tissue, we observed increased TLR4 expression in association with tumorigenic progression from normal skin to actinic keratosis and cutaneous squamous cell carcinoma. In immortalized keratinocytes expressing luciferase reporter constructs, resatorvid potently inhibits UV-induced AP-1 and NF-κB signaling, associated with downregulation of inflammatory mediators (IL-6, IL-8, IL-10) and MAP Kinase phosphorylation. In a subsequent acute exposure model in SKH-1 mice, topical resatorvid efficiently antagonized UV-induced stress signaling while potentiating UV-induced epidermal apoptosis. In the current study, we show for the first time that pharmacological inhibition of TLR4 using the specific antagonist resatorvid (TAK-242) blocks UV-induced tumorigenesis in SKH-1 mice. After assessing photostability, efficient cutaneous delivery, and skin residence time of topical resatorvid, we then tested the feasibility of TLR4-directed inhibition of UV-induced tumorigenesis. To this end, SKH-1 mice were split into three groups (n = 20). Each group was exposed to solar-simulated UV (three times a week; 15 weeks duration), followed by another 10 weeks in the absence of UV exposure (sacrifice at week 25). The control group received topical vehicle (acetone) on their backs 1 hour prior to UV exposure (three times a week until sacrifice). The “Prevention” group received topical resatorvid following an analogous dosing regimen. The “In-
tivation" group received vehicle 1hr prior to each UV treatment but switched to topical resatorvid three times a week only after UV was terminated. In the Prevention model, topical treatment with resatorvid significantly inhibited both tumor area (66% reduction, p < 0.0052) and tumor multiplicity (32% reduction, p = 0.0329; cross sectional Kruskal-Wallis test). In the Repair model, resatorvid, a marketed anti-inflammatory drug, did not yield was observed but it did not reach statistical significance. Likewise, suppression of UV-induced TLR4-driven signaling was also confirmed in murine skin harvested at week 14 (prior to tumor onset), as assessed by IHC and RPPA analysis. Taken together, these data generated using resatorvid in a murine photocarcinogenesis model suggest that pharmacological TLR4 antagonism may represent a novel molecular strategy for topical prevention of solar UV-induced NMSC.

#2245 Evaluation of new rexinoids for lung cancer. Di Zhang, 1 Ana S. Leal, 1 Sarah E. Carapellucci, 1 Kayla Zydeck, 1 Nicole Chaaban, 1 Michael B. Sporn, 2 Carl E. Wagner, 3 Karen T. Liby, 1 Michigan State University, East Lansing, MI; 2Dartmouth Medical School, Hanover, NH; 3Arizona State University, Phoenix, AZ.

Lung cancer remains the leading cause of cancer deaths around the world. It is estimated that there will be over 150,000 deaths in the United States alone from this disease every year. With no significant improvement in 5 year survival rates over the past 30 years, effective prevention or early intervention is a promising approach to reduce the high mortality of lung cancer. Rexinoids are selective ligands for retinoid X receptors (RXR), which regulate the expression of a wide variety of genes. As transcription factors, rexinoids play important roles in proliferation, differentiation and apoptosis, which are highly relevant in cancer. Bexarotene is the only synthetic rexinoid that has been approved by the FDA and is used for the treatment of refractory cutaneous T-cell lymphoma. It has also been tested in various clinical trials for lung cancer and breast cancer. However, Bexarotene is not potent or selective enough for RXRs, causing limited efficacy and unacceptable toxicities. Therefore, we synthesized a series of new rexinoids and screened them for their ability to inhibit nitric oxide (NO) production in RAW264.7 macrophage-like cells stimulated with LPS. Several of these compounds inhibited NO production at nanomolar concentrations. Based on this screening and other in vitro assays, two new rexinoids were chosen for in vivo testing. Female A/J mice were injected i.p. with vinyl carbamate (16 mg/kg). One week later, the mice were fed control diet or rexinoids in diet (40-80 mg/kg diet) for 16 weeks. Tumor number, size and histopathology were then evaluated. All of the rexinoids reduced the number and size of the lung tumors. However, Bexarotene only reduced the average number of tumors by 8-17%, while a new pyrimidine-analog of Bexarotene—henceforth, pyrimidine-Bexarotene—reduced the number of tumors by 24-28%. The average tumor burden on lung sections was also reduced by pyrimidine-Bexarotene by 25% compared to the controls (from 0.47 ± 0.19 mm3 in the control group to 0.19 ± 0.05 mm3 in the treated group). In contrast, average tumor burden was 0.35 ± 0.08 mm3 in the group treated with Bexarotene, a reduction of 26%. Notably, the percentage of high grade tumors (both histological and nuclear characteristics) were significantly (p < 0.05) higher in the mice fed Bexarotene (68%) compared to the control group (38%), while the percentage of high grade tumors was only 34% in the pyrimidine-Bexarotene group. Since a major side effect of rexinoids is a elevation in triglyceride levels, we measured total triglycerides in both liver and plasma. Pyrimidine-Bexarotene induced a 24% elevation in triglycerides in plasma. However, Bexarotene only induced a 7% elevation in plasma triglycerides, which is high when compared to the 34% elevation in liver triglycerides. Pyrimidine-Bexarotene, a new rexinoid with TXR1 selectivity and significant antitumor activity, is a promising agent for the treatment of lung cancer.

#2246 Anti-proliferative activities of lipid fraction of extract from the skin of the catfish Arius Bilineatus, Valenciennes. Peiyung Yang, 1 Jibin Ding, 1 Yong Pan, 1 Yan Jiang, 1 Mohammad Afzal, 1 Bincy M. Paul, 1 Somasoma G. George, 1 Assam M. Al-Hassan, 1 UT MD Anderson Cancer Ctr., Houston, TX; 2Kuwait University, Safat, Kuwait; 3CMS College, Kottayam, Kerala, India.

The catfish (Arius bilineatus, Val.) secretes a gelatinous substance composed of biochemically active lipids and proteins from its skin upon stress or injury. Preparations from the skin have previously been shown to affect blood clotting and accelerates healing of non-healing diabetic foot ulcers in man. We have reported previously fish skin preparation (CSP) derived from the skin of the Catfish and it’s lipid fraction exerted anti-inflammatory activity in the in vitro cells and in vivo animal models. Here anti-proliferative effect of a lipid fraction of fish skin preparation (CSP-L) derived from the skin of the catfish and its plausible mechanism were investigated in human hepatocellular carcinoma (HCC) Hep3B and human pancreatic cancer Panc-1 cells. Cells were treated with CSP-L (0 to 100 µg/ml) for 72 hrs and cell proliferation was measured by the MTT assay. The results showed much stronger inhibition by CSP-L in Panc-1 cells than that of Hep3B cells with IC50 of 5.3 ± 1.4 µg/ml and 19.5 ± 7.7 (Clone F7) respectively. CSP-L (25 - 100 µg/ml) led to G1 phase arrest in Hep3B cells whereas S phase arrest was observed in Panc-1 cells, suggesting the differential molecular mechanisms responsible for CSP-L induced cell growth suppression in Hep3B and Panc-1 cells. The alteration of cell cycle was concentration dependent. Additionally, CSP-L concentration dependently suppressed the invasion of Hep3B and Panc-1 cells. The anti-invasion mechanism with CSP-L was concentration dependent and was examined by Western blotting in both Hep3B and Panc-1 cells. Intriguingly, CSP-L (50 and 100 µg/ml) notably decreased protein levels of cyclin D, Stat3, p53 and pERK in Hep3B cells in a concentration dependent manner. In contrast, only pRB and pERK protein expression were reduced in CSP-L treated Panc-1 cells. These results suggest that CSP-L inhibited the proliferation of Hep3B and Panc-1 cells by different molecular mechanisms. Collectively, our preliminary data suggest that CSP-L has a great potential to be developed as an anticancer or preventive agent for both HCC or pancreatic cancer and warrants further investigation. This study was supported by a grant from Kuwait Foundation for the Advancement of Science No. KFAS 2013-127071-A, D, and Kuwait University Research Grant No. SLO314.

EPIDEMIOLOGY: Biomarkers of Risk and Prognosis

#2247 Associations between total T-lymphocytes and colorectal cancer survival in a prospective cohort study of older women. Anna E. Prizment, 1 Robert A. Vierkant, 1 Thomas C. Smyrk, 1 Lori S. Tillmans, 2 Heather H. Nelson, 2 Charles F. Lynch, 3 Stephen N. Thibodeau, 1 Timothy R. Church, 1 James R. Cerman, 1 Kristin E. Anderson, 1 Paul J. Limburg, 2 University of Minnesota, Minneapolis, MN; 3Mayo Clinic, Rochester, MN; 1University of Iowa, IA.

Background: The increased number of T-lymphocytes residing in the tumors of colorectal cancer (CRC) patients is consistently shown to predict better survival of CRC patients independent of stage. In addition to tumor itself, T-lymphocytes also infiltrate normal tissues adjacent to tumors; however, little is known about how the interplay between T-cell variability in tumor-adjacent tissues affects CRC prognosis. Our goal was to characterize total T-cells in colorectal tumor and tumor-adjacent tissues and study their associations with all-cause and CRC-specific survival in the Iowa Women’s Health Study. Methods: We constructed tissue microarrays and quantified CD3 antibody staining (clone F.7.238; Dako), an established marker for total T-cells, in paraffin-embedded tissue samples from 463 women diagnosed with incident CRC from 1986-2002 (mean age at diagnosis was 74 years). Up to 3 tumors and 3 tumor-adjacent cores were immunostained for each patient. An experienced pathologist quantified CD3+ T-cells in each area using 4 categories: non-detected, mild (1-10 cells per 0.28 mm2); moderate (11-29 cells per 0.28 mm2); and strong infiltrations (>30 cells per 0.28 mm2). The obtained scores were averaged over all quintiles of scores for each core per patient. Cox regression was used to estimate the hazard ratio (HR) and 95% CI for all-cause and CRC mortality in relation to (1) tumor score; (2) tumor-adjacent score; and (3) the ratio of tumor to tumor-adjacent score, hereafter called Score ratio. All scores were categorized in quartiles. The final model adjusted for age at diagnosis, SEER stage, tumor grade, body mass index, race, and smoking history. Results: During follow-up for a maximum of 25 years, 67% of participants diagnosed with CRC died (≈30% died from CRC). There was a weak but significant correlation between CD3 tumor and tumor-adjacent scores (Spearman coefficient: r = 0.15, p = 0.02). CD3 tumor score was inversely associated with stage and was higher in those with proximal colon cancer, and for MSI-high, CIMP-high and BRAF-mutated tumors. The HRs (95%CI) for the highest versus lowest category of CD3 tumor score were 0.61 (0.44-0.84) (p-trend = 0.003) for all-cause mortality and 0.27 (0.15-0.48) (p-trend < 0.0001) for CRC-specific mortality. The tumor-adjacent score was not associated with any characteristics or death. The associations between the Score ratio and all-cause and CRC survival mirrored those for the tumor score but were weaker. The HRs (95%CI) for the highest versus lowest quartile of the Score ratio were 0.70 (0.45-1.09) (p-trend = 0.09) for all-cause and 0.45 (0.23-0.87) (p-trend = 0.003) for CRC-specific mortality. Conclusions. Based on data from prospectively identified CRC cases in the IWHS cohort, colorectal tumor T-cell infiltration is associated with improved survival. Further investigation is needed to determine the T-cell subtypes that are most predictive of CRC survival outcomes.
EPIDEMOIOLOGY: Biomarkers of Risk and Prognosis

#2248 Common TDP1 polymorphisms in relation to survival among small cell lung cancer patients in a multicenter study from the International Lung Cancer Consortium. Pawadee Lohavanichbutr,1 Lori C. Sakoda,2 Christopher I. Amos,3 Susanne M. Arnold,4 David C. Christiani,5 Michael P. Davies,6 John K. Field,7 Eric B. Haura,8 Takashi Kohno,9 Maria Teresa Landi,10 Zhi Li,11 Aileen Baecker,1 Helena R. Field,6 Eric B. Haura,7 Rayjean J. Hung,9 Marilyn Kwan,1 Jingjie Xiao,1 Stacey Alexeef,7 Erin K. Weltzien,1 Adrienne L. Castillo,2 Bette J. Caan,1 Kaiser Permanente Division of Research, Oakland, CA;1 Dana Farber Cancer Institute, MA;2University of Alberta, Edmonton, Alberta, Canada;3University of California, Berkeley, CA.

Introduction: DNA topoisomerase inhibitors (e.g. etoposide, irinotecan, teniposide, topotecan) are commonly used for treating small cell lung cancer (SCLC). Tyrosyl-DNA phosphodiesterase (TDP1) plays a role in repairing DNA damage caused by DNA topoisomerase inhibitors and it is believed to be responsible for resistance to this class of drugs. The purpose of this study was to determine whether TDP1 polymorphisms or survival-associated polymorphisms were associated with survival among SCLC patients. Method: Two common TDP1 SNPs (rs942190 and rs241863) were associated with poorer survival compared to those carrying both major alleles (AA), with a hazard ratio (HR) of 1.36 (95% confidence interval [CI]: 1.07-1.75, p-value=0.001), but there was no association with survival for patients with the heterozygous genotype (HR=1.02, 95% CI: 0.83-1.27, p-value=0.83). For rs241863, patients carrying both major alleles (CC) tended to have better survival than patients carrying AA alleles, but this was within the limits of chance given no significant association (HR=0.97, 95% CI: 0.61-1.02, p-value=0.07). In addition, multi-locus expression quantitative trait loci (eQTL) analyses from the Genotype-Tissue Expression Project indicated a potential effect of rs942190 on lung tissue, with higher TDP1 gene expression for the GG than AG or AA genotypes. Conclusion: We found that among SCLC patients the TDP1 rs942190 GG genotype was associated with poor overall survival. Further study could determine if this genotype can serve as a predictive marker for the treatment efficacy of DNA topoisomerase inhibitors in SCLC.

#2249 Integrated multi-level omics-based biomarker models for ovarian cancer survival. Alan Pa,1 Shen-Chih Chang,2 Aileen Baeker,1 Helena R. Chang,3 Zuo-Feng Zhang,1 UCLA Fielding School of Public Health, Los Angeles, CA;2David Geffen School of Medicine at UCLA, Los Angeles, CA.

Background: Although a number of prognostic biomarkers for ovarian cancer have been proposed, the pool of clinically useful biomarkers remains small. While the predictive power of individual biomarkers may be weak, the advent of more affordable high-throughput technologies and readily available ‘omics’ level data point toward the possibility of high performance biomarker panels. In this study, we used tumor-based somatic mutation, mRNA and miRNA expression, and DNA methylation data from The Cancer Genome Atlas (TCGA) to construct integrated biomarker models for overall and progression-free survival. Methods: The somatic mutations, mRNA expression, and DNA methylation of 451 candidate genes, as well as the expression of the miRNAs targeting them, were individually analyzed for association with overall and progression-free survival in 488 TCGA serous cystadenocarcinoma patients of predominantly Caucasian descent. Following correction for multiple comparisons, molecular variations associated with survival were combined to construct integrated cross-validated prediction models for overall and progression-free survival. The discriminative power of these models was then evaluated for 1-, 3-, and 5-year overall and progression-free survival using ROC analysis. Results: Our cross-validated integrated molecular models were demonstrated to predict 5-year overall survival in the total patient pool with a ROC AUC of 0.801 and 5-year overall and progression-free survival in Caucasian patients with ROC AUCs of 0.866 and 0.809, respectively. Conclusions: Our findings suggest the potential utility of our multi-omics-based biomarker models in helping to inform clinical decisions following ovarian cancer diagnosis. Although extensive efforts were made to maximize the predictive potential of our models, further retrospective and prospective validation efforts are necessary before their clinical utility can be accurately assessed.

#2250 Systemic inflammation and sarcopenia predict colorectal cancer survival. Elizabeth M. (Cespedes) Feliciano,1 Candicey H. Krowen,2 Jeffrey Meyerhardt,3 Carla M. Prado,4 Patrick T. Bradshaw,5 Marilyn Kwan,1 Jingjie Xiao,1 Stacey Alexeef,7 Erin K. Weltzien,1 Adrienne L. Castillo,2 Bette J. Caan,1 Kaiser Permanente Division of Research, Oakland, CA;1 Dana Farber Cancer Institute, MA;2University of Alberta, Edmonton, Alberta, Canada;3University of California, Berkeley, CA.

Importance: A higher neutrophil-to-lymphocyte ratio (NLR, indicating systemic inflammation), and sarcopenia (reduced skeletal muscle mass) predict morbidity/mortality in a variety of cancers, but no prior research examines associations of pre-diagnostic NLR with at-diagnosis sarcopenia, nor whether NLR and sarcopenia combined identify early-stage patients with poor prognosis in colorectal cancer (CRC).Objective: To evaluate the association between pre-diagnosis NLR and at-diagnosis sarcopenia of their combination with CRC survival, controlling for age, ethnicity, sex, body mass index, stage, and cancer site. Design, Setting, and Participants: This observational cohort with prospectively-collected data included 2470 patients diagnosed with stage I-III CRC at Kaiser Permanente from 2006-2011 with computed tomography (CT) scans from clinical care (mean days pre-diagnosis=6). Exposures: Systemic inflammation measured via average NLR in the 24 months pre-diagnosis (mean count=3 measures, mean months pre-diagnosis=7). The reference value for NLR below 3, indicating low/no inflammation. Main Outcomes and Measures: Sarcopenia, defined by published cutoffs for skeletal muscle index (CT muscle area in cm2 at the third lumbar vertebra divided by squared height in m2; below 52-cm2/m2 and 38-cm2/m2 for normal/overweight men and women, respectively, and below 54-cm2/m2 and 47-cm2/m2 for obese men and women, respectively), and incident death (overall or CRC-related). Results: Average age was 63 years; half of patients were female. NLR above 3 and sarcopenia were common (46% and 44%, respectively). Over a median of 6 years, we observed 656 deaths, 357 from CRC. Elevated NLR was associated with sarcopenia in a dose-response manner (compared to NLR below 3, Odds Ratio [OR]=1.33; 95% CI:1.10-1.67 for NLR 3-5; OR=1.47; 95%CI:1.16-1.85 for NLR above 5). NLR above 3 and sarcopenia were also independently associated with survival (Hazard Ratio [HR]=1.15; 95% CI:1.45-1.98 for overall death and HR=1.29; 95% CI:1.09-1.53 for CRC death); patients with both sarcopenia and NLR above 3 (versus neither), had double the risk of death overall (HR=2.53; 95% CI:1.87-3.41) and from CRC (HR=2.19; 95% CI:1.74-2.75). Conclusions and Relevance: Host inflammatory/immune response shortly prior to diagnosis predicts muscularity at diagnosis. Low muscle combined with systemic inflammation predicts worse CRC prognosis regardless of stage. A better understanding of the crosstalk between inflammatory/immune responses and the onset of changes in skeletal muscle may open new therapeutic avenues to improve cancer outcomes.

#2251 Tumor tissue gene expression in association with survival of triple-negative breast cancer. Shiyang Wang,1 Quiyin Cai,1 Hui Cai,1 Pingping Bao,1 Jie Wu,1 Fei Ye,1 Wei Zheng,2 Ying Zheng,2 Xiao-Ou Shu,1 Vanderbilt University School of Medicine, Nashville, TN;2Shanghai Municipal Center for Disease Control and Prevention, Shanghai, China.

Triple-negative breast cancer (TNBC) is an aggressive type of cancer with limited treatment options. Previous studies have shown that gene expression profiles were associated with TNBC prognosis. Information on specific genes that are predictive of TNBC outcome is limited. Using data and samples from a cohort of 469 TNBC cases from Shanghai Breast Cancer Survival Study (SBCC), we systematically evaluated expressions of 302 genes in tumor tissue with survival of TNBC. Genes included in the study are PAM50 genes, genes encoding drug metabolizing enzymes and, genes implicated in TNBC biology and progression based on literature reviews. Gene expression levels were measured in total RNA isolated from formalin-fixed paraffin-embedded breast cancer tissues using the NanoString nCounter assay. Cox regression was applied to evaluate disease-free survival (DFS) and overall survival (OS) in association with gene expression. Analysis was adjusted for known predictors of TNBC outcome, including age, disease stage, basal like subtype and DUSP4 gene expression. During a median follow-up of 5.3 years (range: 0.7-8.9 years), 100 deaths and 92 recurrences/breast cancer deaths were documented. Expression levels of 17 genes were significantly associated with OS, and 15 genes with DFS (P<0.05). The top 5 most significant genes are EOMES (Hazard Ratio, HR = 0.88; 95% Confidence Interval, 95% CI:0.82-0.96), GZMK (HR = 0.91, 95% CI:0.85-0.97),
inated by Fusobacterium may indicate a poor prognosis following chemoradiation. Prevotella may serve as a biomarker of improved prognosis, while profiles dominated by Treponema (cluster 4). Fungal ITS profiling revealed that the tumor microenvironment of HNC patients with incomplete responses were dominated by Streptococcus (cluster 3) and Fusobacterium (cluster 4) than any other genus. None of the Treponema. HNC patients with incomplete clinical responses (3, 6, or 12 months) demonstrated that intratumoral bacterial profiles dominated by Treponema (cluster 4). Fungal ITS profiling revealed that the tumor microenvironment of HNC patients with incomplete responses were dominated by Streptococcus (cluster 3) and Fusobacterium (cluster 4) than any other genus. None of the Treponema. HNC patients with incomplete clinical responses were dominated by Treponema (cluster 3) or Streptococcus (cluster 4). Fungal ITS profiling revealed that the tumor microbiome was largely dominated by the fungi Malassezia. CONCLUSIONS: The current study demonstrates that intratumoral bacterial profiles dominated by Prevotella is a potential biomarker of improved prognosis, while profiles dominated by Fusobacterium may indicate a poor prognosis following chemoradia-

#2252 Microbial profiling of the head and neck tumor microenvironment as a biomarker of clinical response to chemoradiation. Christine M. Pierce Campbell,1 Bo-Yeong Hong,2 Maria F. Gomez,3 Blake M. Hanson,4 Erica So-dergren,5 Sybil T. Sha,6 Jeffrey S. Russell, George M. Weinstock. 7 Moffitt Cancer Center, Tampa, FL;8 The Jackson Laboratory for Genomic Medicine, Farming-ton, CT;9 Cornell University, Ithaca, NY.

PURPOSE: Despite advances in cancer treatment, patients with advanced head and neck cancer (HNC) have a median overall survival of <1 year and 30% cure rate. Evidence suggests that microbiota may modulate the response to therapy through a crossstalk with cancer cells, immune cells, and inflammatory mediators. This study was conducted to profile the tumor microbiome of HNC patients to determine whether bacteria and fungi in the tumor microenvironment are associated with the clinical response to chemoradiation. METHODS: Fresh frozen tumor tissues from 30 newly diagnosed, treatment-naïve patients who received chemoradiation at Moffitt Cancer Center for squamous cell HNC were evaluated. Genomic DNA was extracted from 25mg of tissue. The V1-V3 hypervariable region of the bacterial 16s rRNA gene and fungal internal transcribed spacer (ITS) 1 region were sequenced using a PCR amplicon-mediated workflow on the Illumina MiSeq. 165 sequences were clustered into operational taxonomic units and taxonomic identification was determined using the RDP database and ITS sequences were classified using an in house reference database. Patients’ charts were reviewed to ascertain clinical response 3, 6 and 12 months after treatment cessation. Response was dichotomized as complete (no evidence of disease) and incomplete (partial response, stable disease, and progressive disease). RESULTS: At the time of tumor collection, patients ranged in age from 20-79 years, and were predominantly men (83%) and current smokers (40%). The most common anatomic site was the oral cavity (70%) followed by the larynx (20%) and oropharynx (10%), and most were diagnosed at stage 4 (87%). Three, 6 and 12 months after treatment cessation, 4 (14%), 9 (36%), and 10 (40%) patients had an incomplete response to therapy, respectively. Bacterial sequencing was successful in 29 (97%) samples and fungal in 15 (50%). Clustering analyses of bacterial abundance profiles suggested that 4 types of communities existed, each dominated by Fusobacterium, Prevotella, Streptococcus, or Treponema. HNC patients with incomplete clinical responses (3, 6, or 12 months after treatment) were more likely to have treatment-naïve tumors dominated by Fusobacterium (cluster 1; 56%) than any other genus, whereas patients with complete clinical responses were more likely to have treatment-naïve tu-
mors dominated by Prevotella (cluster 2; 40%) than any other genus. None of the patients with incomplete responses were dominated by Streptococcus (cluster 3) or Treponema (cluster 4). Fungal ITS profiling revealed that the tumor microbiome was largely dominated by the fungi Malassezia. CONCLUSIONS: The current study demonstrates that intratumoral bacterial profiles dominated by Prevotella is a potential biomarker of improved prognosis, while profiles dominated by Fusobacterium may indicate a poor prognosis following chemoradia-

#2253 Gene prognostic signature for differentiated liposarcomas. Deanna Ng, Nicholas Shannon, Johnny Ong, Melissa Teo. National Cancer Cen-
tre Singapore, Singapore, Singapore.

Introduction: Liposarcomas, despite being rare consist of a number of entities spanning low to high grade sarcomas. De-differentiated liposarcoma (DDLs) is associated with increased frequency of recurrence and lower overall survival. We aimed to identify gene expression changes associated with OS in DDLs. Secondary aims was to postulate a mechanism for DDLs. Meth-
ods: We analysed data from gene expression omnibus (GEO, ID = GSE30929) to identify genes associated with DDLs (n = 39). A signature representing genes overexpressed in DDLs was then applied to an indepen-
dent dataset, utilising data from The Cancer Genome Atlas (TCGA, n = 58 DDLs) to segregate samples based on gene expression and groupings com-
pared for survival. Results: A 5 gene signature was generated consisting of genes with increased expression in DDLs and its relation to OS. The signa-
ture was significantly enriched for genes involved in lipid metabolism (AQP7, PRKAR2B, FABP4 < p < 0.01) and genes involved in the cell cycle and cell proliferation (FBN2, CEBPA < p < 0.01). Segregation of DDLs in the TCGA cohort on the basis of median gene signature score gave a significant difference in overall survival. High score (stronger DDLs signature) was associated with a lower median survival (33.5 vs 76.4 months, p = 0.027), and poorer 2 year (63.4% vs 89.2%) and 5 year survival (20.6% vs 71.1%). The survival difference remained significant when applied to retroperitoneal DDLs only (n = 51, median survival 34.5 vs 54.2 months, p = 0.034) and poorer 2 year survival (. A postulated mechanism is that DDLs have gained deficiency in AQP7, PRKAR2B and FABP4 leading to fatty acid and glycerol accumulation in cells, increasing cancer cell replication. CEBPA inhibits CDK4 and a deficiency of CEBPA in DDLs leads to up regulation of CDK4, increasing cell proliferation. An upregulation of FBN2 in DDLs upregulates TGF-β1, increasing cell proliferation. Conclusion: Gene expression changes associated with differentiated liposarcomas include changes in cell cycle checkpoint regulation. The signature is associated with poorer overall sur-
vival in DDLs and can be used to prognosticate patients.

#2254 Reactive oxygen species modifier 1 (Romo1) predicts unfavorable prognosis in colorectal cancer patients. Min Jee Jo, Hong Jun Kim, Suk-Young Lee, Dae-Hee Lee, Sang Cheul Oh. Korea University Guro Hospital, Seoul, Re-
public of Korea.

Reactive oxygen species modifier 1 (Romo1) is a novel protein that has been reported to be crucial for cancer cell proliferation and invasion. How-
ever, its clinical implications in colorectal cancer (CRC) patients are not well-known. For the first time, we investigated the association between Romo1 and the clinical outcomes of CRC patients. We examined Romo1 expression in resected tumor tissues immunohistochemically and assessed it with histological scores. We conducted survival analyses for patients who had curative resection (n = 190) in accordance with clinical parameters in-
cluding levels of Romo1 expression and the association between Romo1 expression and cell invasion using Matrigel invasion assay in CRC cell lines. We observed significantly longer mean disease-free survival (DFS) in the low Romo1 group compared with the high Romo1 group (161 vs 127.6 months, p = 0.035), and the median overall survival (OS) of the low Romo1 group was significantly longer than that of the high Romo1 group (196.9 vs 94.7 months, p = 0.036). Cell invasiveness decreased in the Romo1 knockdown CRC cells in contrast to the controlled cells, Romo1 overexpres-
sion in tumor tissue was associated with a high lymph node ratio (LNR) between the metastatic and examined lymph nodes (p = 0.025). Romo1 over-
expression in tumor tissue was significantly associated with survival in cu-
ratively resected CRC patients, suggesting Romo1 expression as a potential adverse prognostic marker. Increased Romo1 expression was found to be associated with high LNR. Cancer invasiveness appeared to be a key reason for the poor survival related to highly expressed Romo1.

Background: Colorectal cancer (CRC) is major cause of morbidity and mortality in cancer patients worldwide and it ranked the third most common cancer in males and the third most common among females in Saudi Arabia. Alteration in TGF-β pathway has been reported in many cancers. So In search for new molecular targets we analyzed the role of SMAD4, critical TGF-β pathway mediator, in Saudi colorectal cancers Methods: 426 CRC cases were analyzed for SMAD4 mutations by targeted capture sequencing and protein expression status by immunohistochemistry in a tissue microar-
ray format. Results were analyzed for association with any clinicopatholog-
ical parameters and for prognostic significance. Results: SMAD4 mutations were detected in 11.9% (50/418) cases of Saudi colorectal cancers. CRC with SMAD4 mutations were significantly associated with NRAS mutations (p = 0.0481). SMAD4 complete loss of expression by immunohistochemistry was seen in 12.8% (52/414) cases. CRC with SMAD4 mutations associated with young age (p = 0.0236) and inversely with MSI-high tumors (p = 0.0005). SMAD4 ex-
pression loss by immunohistochemistry and mutation were significantly as-
bected with each other (p = 0.0028). In the multivariate analysis using the Cox proportional hazard model SMAD4 expression loss was an independent marker of poor prognosis (p = 0.0119) Conclusion: SMAD4 alteration was found to be associated with a poor overall survival in the Saudi colorectal cancer patients. With the advent of targeted anticancer therapy, this study confirms the findings of other investigators and highlights a potential target which can be exploited to improve the survival of CRC patients in the King-
dom of Saudi Arabia.
Background: Generally, Semaphorins are secretory or transmembrane-bound molecules that act as axon guidance cues in the nervous system. Recent research showed increased expression of semaphorin 3C correlates with cancers that possess higher invasive and metastatic characteristics. For example, in breast cancer, inhibition of semaphorin 3C reduces adhesion and invasion. The aim of this study was to evaluate a possibility that semaphorin 3C might be a new prognostic marker in colorectal cancer. In each cohort, we divided the patients in to the two groups i.e., high or low semaphorin 3C expression group using receiver operating characteristic (ROC) curve based on the information of the recurrence of colorectal cancer. Disease-free-survival (DFS) rates were calculated using Kaplan-Meier methods. Differences between curves were compared with the log-rank test. Results: In the cohort 1, the DFS in the patients with higher expression was worse than that in the patients with lower expression ($P = 0.0467$). Semaphorin 3C has two probes (203788_s_at and 203789_s_at) in GSE14333 dataset as Cohort 2 which included 226 patients with the colorectal cancer. In both cohorts, the patients with high expression were worse than that of those patients with lower expression ($P = 0.0015$ and $P = 0.0003$). Conclusions: This study suggested that Semaphorin 3C might be a new prognostic marker in colorectal cancer.

**#2257 Pre-diagnostic sex hormone levels and breast cancer survival in the Nurses’ Health Study.** Kevin H. Kessler,1 A. Heather Ellässen,2 Bernard A. Rosner,2 Susan E. Hankinson,3 Myles Brown,4 Rulla M. Tamimi,5 Harvard T. H. Chan School of Public Health, Boston, MA; 2Brixham and Women’s Hospital, Boston, MA; 3University of Massachusetts School of Public Health and Health Sciences, Amherst, MA; 4Dana-Farber Cancer Institute, Boston, MA.

Background The role of estrogens has been well established in the development of breast cancer, while an independent function of androgens remains to be fully elucidated. There is consistent evidence that increased levels of circulating sex steroid hormones predict subsequent breast cancer risk. However, few studies to date have evaluated circulating sex hormones in relation to breast cancer risk, and the limited available evidence suggests that higher estrogen and androgen levels are associated with worse prognosis. Identifying the distinct roles of estrogens and androgens and their hormone receptor signaling pathways in breast cancers may inform novel approaches to breast cancer prevention and treatment. Methods We evaluated the association between pre-diagnostic circulating sex hormones and breast cancer survival among 683 breast cancer cases from the Nurses’ Health Study (NHS) cohort. The NHS began in 1976 with the enrollment of U.S. registered nurses between the ages of 30 and 55. The women in this analysis provided a blood sample in 1989-1990, were postmenopausal and not using menopausal hormone therapy at the time of blood draw, and were diagnosed with invasive breast cancer between 1990 and 2010. Levels of estradiol, estrone, estrone sulfate, testosterone, androstenedione, DHEA, DHEAS, and SHBG were measured in plasma. The association between hormone levels and survival was assessed through construction of Kaplan-Meier survival curves and through use of Cox proportional hazards models to estimate hazard ratios and 95% confidence intervals adjusted for patient, tumor, and treatment covariates. Results Over follow-up through 2014, a total of 219 deaths occurred, including 57 breast cancer deaths. For each hormone, we found no association with breast cancer risk evaluated by the log-rank test. Upon adjustment for patient, tumor, and treatment covariates, we observed non-significant 47% increases in breast cancer mortality per unit increase in log estradiol ($HR=1.47, 95\% CI 0.94-2.31$) and estrone sulfate ($HR=1.47, 95\% CI 0.97-2.24$). Log testosterone was not associated with breast cancer survival ($HR=0.84, 95\% CI 0.46-1.53$) and the findings were null for the other hormones. These findings were robust when evaluating overall survival and when stratifying by tumor estrogen receptor expression. Conclusions We observed no significant associations between pre-diagnostic sex hormone levels and breast cancer survival among postmenopausal women. This is the first analysis to evaluate pre-diagnostic hormone levels in relation to survival. Though limited by sample size, it improves upon past analyses of post-diagnostic hormone levels by reducing the possibility of the tumor affecting hormone levels and by better accounting for tumor and treatment characteristics. The findings should be replicated in a larger population to further assess the prognostic value of circulating sex hormones in breast cancer survival.

**#2258 Genome-wide association studies of breast cancer prognosis.** Marjanka K. Schmidt,1 Qi Guo,2 Thilo Dörk,3 Diana Eccles,4 Renke Keenan,5 Jacques Simard,6 Peter Kraft,7 Douglas F. Easton,8 Paul D. Pharoah,9 on behalf of the Breast Cancer Association Consortium.1 Netherlands Cancer Institute, Amsterdam, Netherlands; 2University of Cambridge, Cambridge, United Kingdom; 3Hannover Medical School, Hannover, Germany; 4University of Southampton, Southampton, United Kingdom; 5Laval University, Quebec City, Quebec, Canada; 6Harvard School of Public Health, Boston, MA.

Introduction: The prognosis and response to treatment in women with breast cancer varies considerably after taking into account clinical-pathological variables. Other factors such as host genotype are also likely to be important. We therefore investigated the role of germline genetic variation on survival after breast cancer using data from the Breast Cancer Association Consortium. Materials and methods: We included data from ten projects in which breast cancer case cohorts were genotyped using arrays providing genome-wide coverage of common variants. The majority of samples was genotyped using the Illumina custom iCOGS or OncoArray chips. Data were imputed using the 1000 Genome phase 3 as a reference panel using a two-stage procedure. We assessed the association between genotype and 10-year breast cancer specific survival for each sex hormone (estradiol, estrone, estriol, estrone sulfate, estradiol sulfate, estrone sulfate, estradiol-17ß, androstenedione, DHEA, DHEAS, and SHBG) in the GRS/PRS. Each sex hormone was included in the cohort of European women classified by country, and stratified by 10-year breast cancer risk in the analyses. Results: Preliminary analyses showed that in all invasive cases, ER-positive and ER-negative disease 123, 110, and 212 variants respectively, were associated with breast cancer-specific mortality at $P < 5 \times 10^{-5}$. A single variant, rs2295683, was associated with higher mortality at genome-wide significance in all patients: $HR = 1.16$ (95\% CI 1.10-1.22); $P = 2.8 \times 10^{-8}$ (risk allele frequency: 0.12). We identified four variants to be associated with mortality in ER-negative disease at $P < 5 \times 10^{-8}$. The strongest association was for rs145963877: $HR = 1.32$ (95\% CI 1.20-1.46); $P = 2.3 \times 10^{-8}$. No variant reached genome-wide significance for ER-positive disease; the most significant variant was rs741406313 with an HR = 1.17 (95\% CI 1.10-1.24); $P = 1.8 \times 10^{-7}$. In addition, using OncoArray data, we provided independent validation of higher mortality of CHEK2 c.1100deC carriers compared with non-carriers (HR = 1.56 (95\% CI 1.22-2.01)), previously reported in Weischer et al 2012. Using iCOGS data, we evaluated the association between mortality and the polygenic risk score (PRS) based on 77 known breast cancer susceptibility SNPs. A higher PRS was significantly associated with lower breast cancer-specific mortality: $HR = 0.87$ (95\% CI 0.81-0.93) (per unit of PRS) with a similar association in ER-negative and ER-positive disease. The association was attenuated after adjusting for tumor grade. Conclusion: We have identified a novel set of germline genetic variants that are associated with breast cancer prognosis. The effect sizes are small for each of the variants and unlikely to be of immediate clinical relevance. However, understanding of the biology that underlies these associations may identify novel pathways and targets for therapy. Being at higher risk of breast cancer, as defined by the breast cancer susceptibility PRS, is not associated with an adverse prognosis.

**#2259 Evaluation of polymorphisms in myeloid-associated genes and glioma survival.** Daniel I. Jacobs,1 Yanhong Liu,1 Konrad Gabrusiewicz,2 Spiridon Tsavachidis,2,3,4 Susan Amirian,1 Georgina N. Armstrong,1 Renke Zhou,1 Jun Wei,1 Cristina Ivan,1 George Calin,2 Michael Scheurer,5 Anna Dahlin,5 Terri Rice,5 Paige M. Bracci,6 Helen M. Hansen,1 John K. Wiencke,1 Margaret R. Wrensch,3 Beatrice Melin,7 Amy B. Heimberger,2 Melissa L. Bondy5 1 Baylor College of Medicine, Houston, TX; 2University of Texas MD Anderson Cancer Center, Houston, TX; 3Umeå University, Umeå, Sweden; 4University of California, San Francisco, San Francisco, CA.

BACKGROUND: Gliomas are highly infiltrated by immune cells including microglia, macrophages, and myeloid-derived suppressor cells (collectively, glioma-associated myeloid cells). These cells have been shown to be induced by the tumor to be immune-suppressive and tumor-supportive, and are a negative prognosticator for survival in mouse models. Here, we examine whether inherited variants in genes important to the function of glioma-associated myeloid cells are associated with survival following low-grade glioma diagnosis. METHODS: Subjects for this study were 484 patients with WHO grade II or grade III glioma treated at The University of Texas MD Anderson Cancer Center in Houston, Texas between 1992 and 2008 and followed up for survival through
August, 2016. We selected 100 genes for analysis including transcription factors, cytokines and chemokines, receptors, enzymes, and other genes central to the function of glioma-associated myeloid cells. Genotyping was originally performed using the Illumina Human 610-Quad Bead Chip platform and 2,040 tagging SNPs as determined by Haplovie Tagger software were selected for analysis that is highly expressed on macrophages and may play a role in macrophage-mediated anti-inflammatory responses, while MET is a receptor tyrosine kinase and well-studied proto-oncogene that is also involved in the expansion of myeloid-derived suppressor cell populations. Further investigation of these associations is warranted, and validation of these findings is planned in an independent population.

#2260 Haplotypes of chromosome 17q21.31 affect liver metastasis by small intestinal neuroendocrine tumors. Shinta Kobayashi,1 Edaise da Silva,2 Tanupriya Contractor,2 Laura Yang,3 Chris R. Harris3.

Neuroendocrine tumors are the most common tumors of the small intestine. Very little is known about genetic changes that cause SI-NETs, which have a very low frequency of mutations. SI-NETs are highly metastatic to the liver, and patients with liver metastases have a five year survival rate of less than 50%. Caucasian patients are more likely to develop metastasis than patients of other races. We have studied a 900 kB inversion at chromosome 17q21.31, which is common to Caucasians but rare in other races. Within a collection of 117 Caucasian patients with ileal carcinoids, patients with the inversion haplotype were significantly less likely to have liver metastasis. A second Caucasian-specific haplotype in this region, beta2, was also tested for potential association with metastasis of ileal carcinoids. Unlike the inversion haplotype, beta2 associates with increased metastasis of ileal carcinoids. We suspect that the fact that the metastasis-promoting beta2 haplotype is more common among Caucasians than the metastasis-suppressing inversion haplotype (44% incidence vs. 33% incidence) is probably why Caucasians wind up with a higher frequency of metastasis than races that carry neither beta2 nor the inversion.

#2261 Synergistic effect and VEGF/HSP70-hom haplotype analysis: Relationship to prostate cancer risk and clinical outcome. Sana Star,† Hamadi Saad,† Fauzi Mosbah,† Lotfi Chouciane,‖ Faculty of Medicine, Monastir, Tunisia; †EPS Fatouma Bourguiba, Monastir, Tunisia; †EPS Salhou, Sousse, Tunisia.

Prostate cancer (PCA) is a complex disorder resulting from the combined effects of multiple environmental and genetic factors. Our previous single-locus analysis showed that VEGF and HSP70-hom polymorphisms were significantly associated with PCA susceptibility and prognosis. Both genes encoding these proteins were located on chromosome 6p21, and combining the neighboring single nucleotide polymorphisms (SNPs) into haplotypes may increase the association with the disease. Three tagging polymorphisms, the HSP70-hom 2437 T/C, the VEGF-1154 G/A, and the VEGF-634 G/C SNPs were genotyped in 101 cases and 80 controls. For the combined analysis of VEGF and HSP70-hom, we found a positive gradient in the odds ratios (ORs) related to the number of high-risk genotypes with a 3.53-fold increase of prostate cancer risk (OR = 3.53; p = 0.015). Furthermore, the TAG and CAG haplotypes at positions HSP70-hom, VEGF-1154 and VEGF-634 exhibited a two-fold (OR = 0.46; p = 0.014) and a seven-fold (OR = 0.14; p = 0.00005) reduction in PCA risk, respectively. Regarding PCA prognosis, the TAG haplotype had a negative association with the aggressive phenotype as defined by the histopathological grade (OR = 0.28; p = 0.006). Our findings confirm the role of at-risk haplotype across the HSP70-hom/VEGF gene cluster in determining susceptibility to PCa.

#2262 Correlation between number and sites of metastases and differentially treated EBV DNA load profiles and their effects on outcomes in patients with metastatic nasopharyngeal carcinoma. Cheng-Lung Hsu, Hung-Ming Wang, Tung-Liang Lin, Yung-Chia Kuo. Chang Gung Memorial Hospital, Taipie, Taiwan.

Differential overall survival of different organ site metastases in nasopharyngeal carcinoma (NPC) had been reported but the underlying mechanism was unclear. We try to find out the possible mechanism from plasma and tumor tissue markers. Total 178 patients of metastatic NPC were enrolled. Their pre-treatment plasma EBV DNA concentrations and cytokines and tissue macrophage, proliferation and apoptosis markers were determined. The overall patient response rate after treatment was 51.7% and median overall survival (OS) was 19 months. Single organ site metastasis had better outcome than multiple organs involved (median OS: 26 months vs. 16 months) with statistical significance. Among single organ site involved, pure lung metastasis had longer survival than bone or liver involved (median OS: 50 months vs. 21 months vs. 18 months) with P = 0.001. Pretreatment plasma EBV DNA concentrations were lower in patients with metastatic bone or liver metastasis in single organ involved group. Plasma IP-10 and MCP-1 expression level correlated with the differential single organ site metastasis OS and EBV DNA load. Liver metastatic tissue had higher macrophage infiltration density and higher proliferation index than lung metastatic group. In single organ site metastasis of NPC, lung involved patients had better outcome than bone or liver metastasis. Low pretreatment plasma EBV DNA load, cytokines expression such as IP-10 and MCP-1, tissue macrophage infiltration, and proliferation index may contribute these results.

#2263 Neonatal hormone levels and risk of testicular germ cell tumors (TGCT). Libby Morimoto,1 David Zava,2 Katherine McGlyn,2 Frank Stanczyk,3 Joseph Wiemels,2 Xiaomei Ma,3 Catherine Metayer.2

Testicular germ cell tumors (TGCT) are the most commonly occurring cancers in adolescent and young adult males in the U.S. Steroid sex hormones play a central role in the development of the testsis. As proposed by the testicular dysgenesis syndrome hypothesis, the origins of TGCT are likely to be in utero or early in life, and to be a manifestation of disturbed prenatal testis development. However, no studies have provided direct, empirical evidence to date. Using an innovative linkage between the California birth records and cancer registry data, we conducted a population-based case-control study of neonatal hormone levels and risk of TGCT diagnosed at 0-19 year of age. We obtained archived neonatal dried blood spot (DBS) specimens from 370 TGCT cases (276 adolescent and young adults [AYA] aged 15-19 years) at the time of diagnosis, 94 0-4 yrs at diagnosis), and 344 age- and race/ethnicity-matched controls, born between 1982 and 2009. Liquid chromatography with tandem mass spectrometry was used to measure a panel of 17 sex steroids, glucocorticoids, and mineralcorticoids; 12 were present at detectable levels in the newborn DBS samples, including estrone (E1), estradiol (E2), estriol (E3), testosterone (T), dehydroepiandrosterone (DHEA), and androstenedione (A4). Logistic regression was used to estimate odds ratios (OR) and 95% confidence intervals (CI), adjusting for matching factors and age (in hours) of child at blood spot collection. A4, a precursor for T and E1, was positively associated with TGCT (OR: 1.71, 95% CI: 1.09-2.69). Analyses stratified by age group showed that this association was limited to AYA, and was of stronger magnitude in this group (OR: 2.33, 95% CI: 1.37-3.97). A similar, though weaker, trend was observed for T (ORoverall: 1.37, 95% CI: 0.86-2.17; ORAYA: 1.73, 95% CI: 1.09-2.68). There was no significant association of the other measured hormones with risk. In the first case-control study of TGCT with direct measures of neonatal hormone levels, we found that higher levels of T and A4 were associated with increased risk of TGCT, particularly among males diagnosed at 15-19 years of age. These results oppose the dominant theory in TGCT etiology, that TGCT is related to androgen insufficiency in utero, and provides an important link in the etiologic pathway of this increasingly common cancer.

#2264 Telomere biology gene methylation and cancer risk. Brian T. Joyce,† Yang Li,† Yinan Zhang,† Lei Liu,† Hushan Yang,‡ Chad Achenbach,† Pantel Vokonas,§ Joel Schwartz,¶ Andrea Baccarelli,† Ilifang Hou,¶ Northwester University, Chicago, IL; †Thomas Jefferson University, Philadelphia, PA; §VA Boston Healthcare System, Boston, MA; ¶Harvard University, Boston, MA; ‡Columbia University, New York, NY.

#2266 A prospective study of serum metabolites and glioma risk. 

Huang, Stephanie J. Weinstein, Cari M. Kitahara, Edward Karoly, Joshua N. Sampson, Demetris Albanes, NIH, Bethesda, MD; NIH, Bethesda, MD; Melatonol, Inc., Morrisville, NC.

Malignant glioma is one of the most devastating adult malignancies. Although there exists an urgent need for actionable leads regarding its prevention and early detection, the etiology of glioma remains largely unknown. We conducted a pros-

#2267 A prospective assessment for telomere length in relation to risk of cancer in the Singapore Chinese Health Study.

Jian-Min Yuan, Renwei Wang, Jian-Min Yuan,1 Renwei Wang,1 2

Telomeres are crucial in the maintenance of chromosome integrity and genomic stability. A critically short telomere length can trigger cell to enter replicative senescence with a result of cell death; alternatively, cells continue to divide if death does not occur, which results in genomic instability and chromosomal ab-

Author: Telomeres are crucial in the maintenance of chromosome integrity and genomic stability. A critically short telomere length can trigger cell to enter replicative senescence with a result of cell death; alternatively, cells continue to divide if death does not occur, which results in genomic instability and chromosomal ab-

Following the cohort of Chinese men and women aged 45-74 years recruited from 1993 through 1998, 28.219 provided baseline blood samples, we used quantitative polymerase chain reaction (PCR) method to quantify relative telomere length determined by the ratio of telomere repeat copy number (T) to single-copy gene for albumin (S) (i.e., TSR) on all subjects. The present analysis included
24,847 subjects with valid TSR values after excluding samples with insufficient DNA (n = 1,908) and/or patients with prevalent cancer at baseline blood draw (n = 1,464). As of December 31, 2015, 3,778 participants developed cancer, including 722 colorectal cancer, 599 lung cancer, and 412 breast cancer. Cox models were used to estimate hazard ratio (HR) and 95% confidence interval (CI) of developing any cancer and these selected specific cancer types for different quintiles of TSR. Results: Women had a 5.7% higher TSR value than men (P < 0.0001). Age, level of education, number of cigarettes/day, years of smoking, and pack-years of smoking were all inversely associated with TSR (P < 0.0001). High TSR was associated, in a dose-dependent manner, with significantly increased risk of total cancer and breast, colorectal and lung cancer. Compared with the lowest quintile, the HRs (95% CIs) of total cancer for the 2nd, 3rd, and 4th, and 5th quintile of TSR were 1.03 (0.89, 1.20) 1.08 (0.93–1.26), 1.15 (0.98–1.34), and 1.36 (1.16–1.58), respectively, after adjustment for age, sex, education and smoking (P_trend = 0.001). The corresponding HRs (95% CIs) were 1.21 (0.72–2.03), 1.59 (0.97–2.60), 1.59 (1.04–2.75) and 1.62 (0.99–2.60) for breast cancer (P_trend = 0.023); 1.44 (1.03–2.00), 1.10 (0.76–1.59), 1.32 (0.92–1.90) and 1.58 (1.32–2.66) for colorectal cancer (P_trend = 0.004); and 1.41 (0.98–2.05), 1.57 (0.93–2.02), 1.31 (0.86–1.99) and 1.88 (1.26–2.81) for lung cancer (P_trend = 0.010).

Conclusions: This prospective cohort study demonstrates that longer telomere length is associated with significantly increased risk of total and major cancers in a general population. These results suggest a complex role of telomere in the development of cancer.

#2268 Serum insulin and glucose, indices of insulin resistance, and risk of lung cancer. Iolina Argirion,1 Stephanie J. Weinstein,2 Satu Männistö,3 Demetrios Albanes,3 Alison M. Mondial,4 University of Michigan, Ann Arbor, MI; 2National Cancer Institute, Bethesda, MD; 3National Institute for Health and Welfare, Helsinki, Finland.

Background: Although insulin is crucial in human growth and development, it also harbors antipapoptotic properties and acts as a growth factor by stimulating mitosis through the Akt pathway, which could lead to tumor growth and promotion. Insulin also harbors antiapoptotic properties and acts as a growth factor by stimulating proliferation of cancer cells. Several studies have had the ability to evaluate differences in association by ovarian tumor subtype. Methods: We pooled existing data on CRP and ovarian cancer risk among nested case-control studies conducted within 6 studies participating in the Ovarian Cancer Cohort Consortium (OC3). (OR:1.10;95%CI:0.91-1.32) or the top vs. bottom quartile (OR: 1.10; 95% CI: 0.89-1.36). However, there was a strong, positive association between very high CRP (≥10 mg/L vs. <1 mg/L) (OR: 1.96; 95% CI: 1.36-2.84). Associations of very high (≥10 mg/L vs. < 1 mg/L) did not differ by histologic type: serous OR: 1.63; 95% CI: 1.11-2.43; endometrioid OR: 1.78; 95% CI: 0.63-5.00; mucinous OR: 10.43; 95% CI: 1.27-85.86; clear cell OR: 2.30; 95% CI: 0.39-13.34). Conclusion: Our results confirm the consistent observation of a positive association between very high CRP levels and ovarian cancer risk. Pooled analyses accounting for potential confounders are ongoing.

#2271 DNMT1 expression is peripheral mononuclear cells is associated with increased breast cancer risk. Lissette Delgado-Cruzat,1 Xinran Ma,2 Yuyan Liao,3 Maya Kapili,3 Regina M. Santella,2 Mary Beth Terry,1 John Jay College, City University of New York, New York, NY; 2Mailman School of Public Health, Columbia University, New York, NY. Loss of global DNA methylation in peripheral tissue has been identified as a biomarker of breast cancer susceptibility in several studies. DNA methyltransferases or DNMTs are the enzymes in charge of catalyzing the addition of the methyl group to the DNA molecule. Of the different DNMTs described in humans, only DNMT1 has been found to be in charge of adding methyl groups to the newly synthesized DNA strand. Therefore, compromised levels of this en-
zyrne might lead to a loss of global DNA methylation and concomitantly an increase in breast cancer risk. However, to date no study has examined the association between peripheral levels of DNMT1 and breast cancer. To investigate this relation, we conducted a case-control study including sisters in the New York site of the Breast Cancer Family Registry. We extracted mRNA from peripheral blood mononuclear cells (PBMC) in 196 sister sets, a total of 479 female participants, and assayed DNMT1 gene expression levels using Taqman expression assays. The results were analyzed using generalized estimating equations (GEE). We found that there were no large differences between the mean levels of DNMT1 expression levels of women with breast cancer and controls; mean level in cases was 0.46 ± 0.71 versus 0.63 ± 1.42 in controls (p = 0.10). When examining expression levels as a continuous variable, there also were no associations in GEE regression models adjusting for age at blood drawn and smoking status. Odds Ratio (OR) = 1.17 (95% confidence interval (CI) = 0.97 – 1.40 per one unit increase in expression levels), p = 0.11. However, when results were analyzed by categorizing DNMT1 expression in tertiles, lower DNMT1 expression (≤ 0.17%) was associated with statistically significantly higher odds of breast cancer (OR = 1.47% (95% CI = 1.02 – 2.10), p = 0.04). If replicated in other studies, these findings suggest that low DNMT1 expression in PBMC has the potential to be used as a biomarker of breast cancer risk in women at high risk of the disease.

#2272 A prospective study of urinary prostaglandin E2 metabolites in helicobacter pylori and gastric cancer risk. Tianyi Wang,1 Hai Cai,2 Wei Zheng,2 Angelika Michel,2 Michael Pavlita,3 Ginger Milne,3 Yong-Bing Xiang,4 Yu-Tang Gao,5 Hong-Lan Li,5 Nathaniel Rothman,6 Qing Lan,6 Xiao-Ou Shu,5 Meira Epplein2.1 Peking University Health Science Center, Beijing, China; 2Division of Epidemiology, Department of Medicine, Vanderbilt Epidemiology Center and Ingram Cancer Center, Vanderbilt University Medical Center, Nashville, TN; 3Division of Molecular Diagnostics of Oncogenic Infections, Research Program in Infection, Inflammation, and Cancer, German Cancer Research Center (DFKZ), Heidelberg, Germany; 4Division of Clinical Pharmacology, Department of Medicine, Vanderbilt University Medical Center, Nashville, TN; 5Department of Epidemiology, Shanghai Cancer Institute, Shanghai, China; 6Division of Cancer Epidemiology and Genetics, Occupational and Environmental Epidemiology Branch, National Cancer Institute, National Institutes of Health, Rockville, MD.

Background. Previous studies suggest that a stable end-product of prostaglandin E2, the urinary metabolite PGE-M, is excrised in the urine and can be used as an index of systemic prostaglandin E2 (PGE2) production. In the present study we investigate the PGE-M, Helicobacter pylori (H. pylori), and gastric cancer association. Methods. The present analysis included 859 prospectively ascertained gastric cancer cases and 700 individually matched controls from two population-based prospective cohort studies, the Shanghai Women’s Health Study and Shanghai Men’s Health Study. Urinary PGE-M was measured by a liquid chromatography/tandem mass spectrometric method. Sero-positivity to H. pylori was determined by immunoblotting. Adjusting for H. pylori, increasing PGE-M was associated with higher risk of gastric cancer (Quartile 4 vs. 1, OR = 1.76, 95% CI: 1.17-2.66, I²/meta = 0.004). This association remained after excluding those diagnosed within two years from sample collection (OR = 1.73, 95% CI: 1.12-2.65, I²/meta = 0.007). However it was no longer present among individuals with 10 or more years of follow-up (2-4.9 years, OR = 3.15, 95% CI: 1.11-8.91; 5-9 years, OR = 2.23, 95% CI: 1.22-4.06; ≥10 years, OR = 0.73, 95% CI: 0.31-1.70). The association of PGE-M with gastric cancer risk was not modified by H. pylori status, but added predictive ability beyond H. pylori; compared to H. pylori-negative individuals with below-median PGE-M levels, H. pylori-positive individuals with above-median PGE-M levels had a 5-fold increase in the odds ratio of gastric cancer (OR = 5.08, 95% CI: 2.47-10.43). Conclusion. In China, higher PGE-M levels may indicate an increased risk of gastric cancer independent of the risk conferred by H. pylori infection status, particularly for cancers diagnosed within 10 years of sample collection.

#2273 Serum choline, methionine, betaine, dimethylglycine, and trimethylamine-N-oxide in relation to pancreatic cancer risk in two nested case-control studies in Asian populations. Joyce Huang,1 Lesley Butler,1 Olivia Midttun,2 Renwei Wang,4 Aizhen Jin,4 Yu-Tang Gao,5 Per Ueland,6 Woon-Puay Koh,6 Jian-Min Yuan1.1 Univ. of Pittsburgh, Pittsburgh, PA; 2National Registry of Diseases Office, Health Promotion Board, Singapore, Singapore; 3Department of Epidemiology, Shanghai Cancer Institute/Shanghai Jiao-tong University, Shanghai, China; 4Department of Clinical Science, University of Bergen; Laboratory of Clinical Biochemistry, Haukeland University Hospital, Bergen, Norway; 5Duke-NUS Medical School, and Saw Swee Hock School of Public Health, National University of Singapore, Singapore, Singapore.

Background: Choline, methionine, and betaine are methyl group donors associated with DNA methylation. Deficient in choline and methionine have been shown to promote pancreatic carcinogenesis in experimental animals. We have previously reported an inverse association between dietary intake of choline and pancreatic cancer risk in a prospective cohort of Singapore Chinese. In the present study biomarkers of dietary choline and other methyl donor nutrients were evaluated in relation to pancreatic cancer risk. Method: Two case-control studies were nested within the Shanghai Cohort Study (129 cases and 258 matched controls) and the Singapore Chinese Health Study (58 cases and 104 matched controls). Concentrations of choline, methionine, betaine, dimethylglycine (DMG), and trimethylamine-N-oxide (TMAO) were measured by LC-MS/MS in pre-diagnostic serum samples. Odds ratios (ORs) and 95% confidence intervals (CIs) were calculated using conditional logistic regression method with adjustment for potential confounders. Results: Choline, methionine, and betaine were moderately associated with other (spearman correlation coefficient: 0.28 – 0.43). In the pooled analysis, serum choline, betaine, and methionine were inversely associated with risk of pancreatic cancer, while TMAO, an oxidative metabolite of choline produced by gut microbiota, was positively associated with risk of pancreatic cancer. Compared with the lowest quartile, ORs (95% CIs) of pancreatic cancer for the highest quartiles of choline, methionine, betaine, and TMAO were 0.37 (0.17-0.80), 0.39 (0.22-0.69), 0.49 (0.28-0.85), and 1.60 (0.94-2.74), respectively (all P for trend < 0.05). DMG was not associated with pancreatic cancer risk. Conclusion: The novel inverse association of serum choline, methionine, and betaine with pancreatic cancer support the notion that methyl groups related to DNA methylation may modulate the risk of pancreatic cancer development. The positive association between TMAO and pancreatic cancer risk suggested gut microbiota may play an important role in pancreatic carcinogenesis.

#2274 Extreme telomere length was associated with gastric adenocarcinoma risk: The Singapore Chinese Health Study. Zhensheng Wang,3 Woon-Puay Koh,1 Aizhen Jin,4 Renwei Wang4, Jian-Min Yuan1.1 Univ. of Pittsburgh, Pittsburgh, PA; 2National University of Singapore, Singapore City, Singapore; 3National Registry of Diseases Office, Singapore City, Singapore; 4University of Pittsburgh Cancer Institute, Pittsburgh, PA.

Background: Evidence regarding extreme telomere length and increased gastric cancer risk has been limited in retrospective case-control study which was potentially subjected to selection bias and reverse causality. We conducted a prospective analysis in an Eastern Asian population to examine the hypothesis that extreme telomere length is associated with increased risk of gastric adenocarcinoma. Methods: Among 63,257 participants of the Singapore Chinese Health Study, a population-based prospective cohort of Chinese men and women aged 45-74 years recruited between 1993 and 1998, 28,219 provided baseline blood samples. We used quantitative polymerase chain reaction (PCR) method to quantify relative telomere length determined by the ratio of telomere repeat copy number (T) to single-copy gene for albumin (S) (i.e., T/S) on all subjects. The present analysis included 24,846 subjects with valid T/S values after excluding samples with insufficient DNA (n = 1,908) and/or patients with prevalent cancer at baseline blood draw (n = 1,465). As of December 31, 2014, 101 patients who developed gastric adenocarcinoma have previously reported an inverse association between dietary intake of choline and pancreatic cancer risk in a prospective cohort of Singapore Chinese. The present study biomarkers of dietary choline and other methyl donor nutrients were evaluated in relation to pancreatic cancer risk. Method: Two case-control studies were nested within the Shanghai Cohort Study (129 cases and 258 matched controls) and the Singapore Chinese Health Study (58 cases and 104 matched controls). Concentrations of choline, methionine, betaine, dimethylglycine (DMG), and trimethylamine-N-oxide (TMAO) were measured by LC-MS/MS in pre-diagnostic serum samples. Odds ratios (ORs) and 95% confidence intervals (CIs) were calculated using conditional logistic regression method with adjustment for potential confounders. Results: Choline, methionine, and betaine were moderately associated with other (spearman correlation coefficient: 0.28 – 0.43). In the pooled analysis, serum choline, betaine, and methionine were inversely associated with risk of pancreatic cancer, while TMAO, an oxidative metabolite of choline produced by gut microbiota, was positively associated with risk of pancreatic cancer. Compared with the lowest quartile, ORs (95% CIs) of pancreatic cancer for the highest quartiles of choline, methionine, betaine, and TMAO were 0.37 (0.17-0.80), 0.39 (0.22-0.69), 0.49 (0.28-0.85), and 1.60 (0.94-2.74), respectively (all P for trend < 0.05). DMG was not associated with pancreatic cancer risk. Conclusion: The novel inverse association of serum choline, methionine, and betaine with pancreatic cancer support the notion that methyl groups related to DNA methylation may modulate the risk of pancreatic cancer development. The positive association between TMAO and pancreatic cancer risk suggested gut microbiota may play an important role in pancreatic carcinogenesis.
EPIDEMIOLOGY: Tobacco, Alcohol, and Other Risk Factors

#2277 Adherence to cancer prevention guidelines and risk of cancer among older white and black adults in the Health ABC Study. Audrey Y. Jung,1 Christina Gu,1 Iva Milijkovic,2 Susan Rubin,3 Suzanne Satterfield,4 Stephen B. Kritskevsky,5 Heidi Klepin,3 Anne B. Newman,5 Jane Cauley,6 Hilsa Ayonoyan,7 Tamara B. Harris,5 Rachel A. Murphy,1 1University of British Columbia, Vancouver, British Columbia, Canada; 2University of Pittsburgh, Pittsburgh, PA; 3University of California at San Francisco, San Francisco, CA; 4University of Tennessee Health Science Center, Memphis, TN; 5Wake Forest School of Medicine, Winston-Salem, NC; 6National Institute on Aging, Bethesda, MD.

Background: About one-third of cancers can be prevented by healthy lifestyle behaviors. The American Cancer Society (ACS) have guidelines for reducing the risk of cancer by maintaining a healthy body weight, being physically active, eating well and limiting alcohol. Few studies have examined adherence to cancer preventive behavior and subsequent cancer risk in older populations that are inclusive of men, women and minorities. Methods: We evaluated adherence to ACS cancer prevention guidelines and subsequent risk of all incident cancer in the Health, Aging and Body Composition Study. The population included 2,124 white and black men and women aged 71-80 years who were initially free of cancer at baseline (1998-1999). Adherence to ACS guidelines was scored from 0 (lowest adherence) to 8 (greatest adherence). Maintenance of healthy body weight was determined from body mass index at ages 25 and 30 (recalled at baseline) and measured height and weight at baseline. Physical activity and alcohol intake were assessed by a dietary questionnaire. Diet was assessed by food frequency questionnaire (servings of fruits and vegetables, the ratio of whole grains to refined grains and intake of red meat and processed meats). Incident cancer (all types except non-melanoma skin cancer) was confirmed from pathology reports when available, or medical records and death certificates. Risk of cancer was estimated with Cox regression adjusted for gender, age, and study site. Participants with the lowest adherence to ACS guidelines were the reference group.

Results: The lowest adherence category (scores 0-2) had 297 participants (14% of all participants), 1,316 (62%) were in the moderate adherence category (scores 3-5), and 511 (24%) were in the highest adherence category (scores 6-8). Adherence was lowest among men (P<0.001), black (P<0.001) and older participants (P<0.001). After a median follow-up of 12.5 years, 517 people developed incident cancer. Participants with moderate adherence had a 23% lower risk of cancer [HR=0.77, 95% CI=0.60-0.97]. Participants with the greatest adherence had a 26% lower risk of cancer [HR=0.74, 95% CI=0.56-0.98]. Conclusions: Only 1 in 4 older adults closely followed healthy lifestyle behaviors outlined by the ACS for cancer prevention. Greater adherence to recommendations was associated with lower likelihood of total cancer in older white and black adults. Public health efforts to increase preventive lifestyle behaviors may be particularly needed among men, black and older individuals.

#2278 Risk factors by molecular subtypes of breast cancer: a pooled analysis of nine cohorts. Mia M. Gaudet,1 Gretchen Gierzach,2 Brian Carter,1 Juhua Luo,3 Roger Milne,1 Elisabete Weiderpass,4 Graham Giles,5 Wendy Chen,3 Kulla Tammela,6 Elke-Mari Hannink,4 Tsung-Yu Chen,7 Kyung-il Park,1 Seung-Eun Park,1 Mia M. Gaudet, 1 Gretchen Gierzach,2 Brian Carter,1 Juhua Luo,3 Roger Milne,1 Elisabete Weiderpass,4 Graham Giles,5 Wendy Chen,3 Kulla Tammela,6 Elke-Mari Hannink,4 Tsung-Yu Chen,7 Kyung-il Park,1 Seung-Eun Park,1 "American Cancer Society, Atlanta, GA; National Cancer Institute, Rockville, MD; 2Indiana University, IN; 3Cancer Council Victoria, Australia; 4Karolinska Institutet, Sweden; 5Brigham and Women’s Hospital and Harvard Medical School, Boston, MA; 6Karolinska Institute, Sweden; 7Dana Farber/Harvard Cancer Center, MA; 8HealthPartners, Minneapolis, MN.

Etiological differences between molecular subtypes of breast cancer, defined by estrogen receptor (ER), progesterone receptor (PR), and human epidermal growth factor receptor 2 (HER2), have been examined in previous studies but results are inconsistent, most likely due to small numbers of rarer subtypes. In a recent systematic review of these studies, only six of the possible 44 associations had consistent findings, primarily with the most common luminal A subtype (ER+ or PR+ /HER2-). To provide larger numbers from prospective studies for these associations, we utilized a harmonized dataset of nine cohort studies (Cancer Prevention Study-II Nutrition Cohort, Melbourne Cancer Cohort Study, the National Cancer Institute-America n Association of Retired Persons cohort study, Nurses’ Health Study, Nurses’ Health Study-2, Prostate, Lung, Colorectal, and Ovarian Cancer Screening cohort, Swedish Mammographic Cohort, Swedish Women’s Lifestyle and Health Study, and Women’s Health Initiative) that had case data on ER, PR, and HER2 from medical records or state tumor registry records. Multivariate, joint Cox proportional hazard regression models were used to examine the associations between lifestyle factors and subtype-specific risk of breast cancer.
#2279 Burden of colorectal cancer attributable to lifestyle-related risk factors: a pooled study of seven Australian cohorts. Claire M. Vajdic,1 Maria Arriaga,1 Peter Hull,3 Karen Canfell,2 Robert MacInnis,3 Emily Banks,4 Graham Giles,5 Paul Mitchell,6 Robert Cumming,7 Barbara-Ann Adelstein,1 Julie Byles,6 Dianna J. Magliano,3 Jonathan Shaw,7 Anne Taylor,5 Kay Price,7 Vasant Hirani,5 Maartit a. Laaksonen1,2,3,8 1University of Sydney, Sydney, Australia; 2Canterbury Medical Research Foundation, Christchurch, New Zealand; 3University of New South Wales, Sydney, Australia; 4University of Adelaide, Adelaide, Australia; 5Aurantine National University, Canberra, Australia; 6University of Newcastle, Newcastle, Australia; 7Baker IDI Heart and Diabetes Institute, Melbourne, Australia; 8University of Sydney, Sydney, Australia.

Aim: To quantify the burden of colorectal cancer in Australia attributable by modifications to established lifestyle-related risk factors: smoking, excess body weight, excessive red and processed meat consumption, excessive alcohol consumption and physical inactivity. Methods: Data on exposure to lifestyle-related risk factors from seven Australian cohort studies (N = 367,772) were harmonized and pooled. The cohorts were linked to the Australian Cancer Database and National Death Index to identify incident cancers and deaths. The strength of the exposure-cancer and exposure-death associations were estimated using a proportional hazards model, adjusting for age, sex and the other lifestyle exposures. Age- and sex-specific exposure prevalence was estimated from the Australian National Health Survey 2011-2012 or from the latest 45 and Up cohort study when not available in the NHS. These estimates were then combined to calculate the Population Attributable Fractions (PAFs), i.e. fractions of cancer attributable to the lifestyle-related risk factors, and their 95% confidence intervals (CIs) using an advanced method accounting for competing risk of death. Results: During the first 10-years follow-up, 3,498 incident colorectal cancers and 20,348 deaths were ascertained as first events. Smoking, physical inactivity and insufficient fruit intake were statistically significantly associated with both lung cancer incidence and death. Most of the lung cancer burden (PAF = 73%, CI = 69-76%) was attributable to current or past smoking, with 31% (CI = 27-35%) of the burden attributable to current smokers. Physical activity below Australian recommendations (< 150 minutes of moderate or 75 minutes of vigorous exercise per week) explained 14% (CI = 6-22%) and fruit intake below Australian recommendations (< 2 daily serves) explained 6% (CI = 0-12%) of the lung cancer burden. Each risk factor contributed more to the lung cancer burden in men than in women. Overall, 78% (CI = 74-81%) of the lung cancer burden was attributable to current or past smoking, physical inactivity and insufficient fruit intake. The combined contribution of modifiable risk factors (i.e. excluding past smoking) was 45% (CI = 37-50%). Based on projected Australian cancer incidence rates, this would translate to 59,000 avoidable lung cancers in the next 10 years. Conclusions: According to these joint PAF estimates, the current lung cancer burden in Australia could be reduced by up to half in 10 years by quitting smoking and increasing physical activity and fruit intake to the recommended levels. As the combined effect of risk factors is rarely additive, knowing both individual and joint effects of risk factors on cancer burden is essential in planning cancer interventions and public health policies and predicting their potential impact.

#2280 Burden of lung cancer in Australia avoidable by modifications to lifestyle-related risk factors. Maartit a. Laaksonen,1 Maria Arriaga,1 Peter Hull,3 Karen Canfell,2 Robert MacInnis,3 Emily Banks,4 Graham Giles,5 Paul Mitchell,6 Robert Cumming,7 Barbara-Ann Adelstein,1 Julie Byles,6 Dianna J. Magliano,3 Jonathan Shaw,7 Anne Taylor,5 Kay Price,7 Vasant Hirani,5 Maartit a. Laaksonen1,2,3,8 1University of Sydney, Sydney, Australia; 2Canterbury Medical Research Foundation, Christchurch, New Zealand; 3University of New South Wales, Sydney, Australia; 4University of Adelaide, Adelaide, Australia; 5Aurantine National University, Canberra, Australia; 6University of Newcastle, Newcastle, Australia; 7Baker IDI Heart and Diabetes Institute, Melbourne, Australia; 8University of Sydney, Sydney, Australia.

Aim: The cancer burden avoidable through risk factor modification can be quantified using the Population Attributable Fraction (PAF) which combines estimates of the prevalence of the risk factor exposure in the population and the strength of the exposure-cancer association. PAF for risk factors causally related to cancer is most accurately estimated from cohort studies, using analytical approaches that account for death as a competing risk. We provide the first such estimates of the lifestyle-related avoidable lung cancer burden. Methods: Seven contemporary Australian cohort studies (N = 367,772), with comprehensive data on exposure to lifestyle-related risk factors, were linked to the Australian Cancer Database and National Death Index to identify lung cancers and deaths from any cause. The risk factors were harmonised across the studies and the data pooled. The strength of the exposure-cancer and exposure-death associations were estimated using a proportional hazards model, adjusting for age, sex and the other lifestyle exposures. Age- and sex-specific exposure prevalence was estimated from the Australian National Health Survey 2011-2012. These estimates were then combined to calculate the PAFs and their 95% confidence intervals (CI) using a newly developed method accounting for competing risk of death. Results: During the first 10-years follow-up, 2,030 incident lung cancers and 20,348 deaths were ascertained as first events. Smoking, physical inactivity and insufficient fruit intake were statistically significantly associated with both lung cancer incidence and death. Most of the lung cancer burden (PAF = 73%, CI = 69-76%) was attributable to current or past smoking, with 31% (CI = 27-35%) of the burden attributable to current smokers. Physical activity below Australian recommendations (< 150 minutes of moderate or 75 minutes of vigorous exercise per week) explained 14% (CI = 6-22%) and fruit intake below Australian recommendations (< 2 daily serves) explained 6% (CI = 0-12%) of the lung cancer burden. Each risk factor contributed more to the lung cancer burden in men than in women. Overall, 78% (CI = 74-81%) of the lung cancer burden was attributable to current or past smoking, physical inactivity and insufficient fruit intake. The combined contribution of modifiable risk factors (i.e. excluding past smoking) was 45% (CI = 37-50%). Based on projected Australian cancer incidence rates, this would translate to 59,000 avoidable lung cancers in the next 10 years. Conclusions: According to these joint PAF estimates, the current lung cancer burden in Australia could be reduced by up to half in 10 years by quitting smoking and increasing physical activity and fruit intake to the recommended levels. As the combined effect of risk factors is rarely additive, knowing both individual and joint effects of risk factors on cancer burden is essential in planning cancer interventions and public health policies and predicting their potential impact.

#2281 Environmental tobacco smoke exposure and breast cancer risk in the Norwegian women and cancer study cohort. Inger T. Gram,1 Tonje Braaten, Eili Lund. Idiri Lica, UiT The Arctic University of Norway, Troms, Norway.

Background: Today, the majority of middle-aged women in Norway are ever (i.e. either former or current) smokers, who started to smoke in their teens. Many of those who have never smoked themselves were exposed to environmental tobacco smoke (ETS) as children. The purpose of the study, was to examine the effect of ETS in childhood on breast cancer risk in the Norwegian Women and Cancer Study, a nationally representative prospective cohort study. Material and Methods: We followed 121 662 women, that were aged 34-70 years at enrolment, who completed a baseline questionnaire between 1991 and 2007, through linkages to national registries through December 2014. Questionnaire data included information on lifestyle factors, including lifetime history of smoking. We used Cox proportional hazards regression to estimate hazard ratios (HRs) and 95% confidence intervals (CIs) while adjusting for relevant confounders and stratified by birth cohort. We included the following variables in the final multivariable models: age at enrolment, years of education (0, 3-11, 12, 13-14, 15+, ) and age at menarche (0, 3-8, 9-14, 15+, ) ever oral contraceptives use (yes, no), a variable including nulliparous and a combination of total number of births, (1, 2, 3+, ) and of age at first childbirth (age 10-12, 2-3, 4-6, 7-10, 11+, ) for a total of 13 categories, family history of breast cancer in the mother (yes, no), body mass index (calculated from current height and weight (lt 20, 20-24.9, 25-29.9, 30+, ) kg/m , menopausal status (yes, no), postmenopausal hormone therapy use (never, former, current) and average alcohol consumption, based on the
content of pure alcohol in different sorts of beverages and portion sizes, as grams of alcohol per day (0.0, 0.1-1.40, 4.1-10, >10). Women who reported to be teetotalers and those answering ‘seldom or never’ had their alcohol consumption set to 0. Results: During a mean follow-up of 15 years, 4501 women developed invasive breast cancer confirmed by histology. Altogether, 23.7% of the women reported to be exposed to ETS during childhood. The smoking attributable fraction of the cancer was 0.6% for the father, 0.66% for the mother, and 0.57% both parents, and in 11.8% the information about the active smoker was missing. Compared with never smokers, the multivariable adjusted HR estimate for ETS during childhood where the father was the smoker was statistically significantly increased with 23% (HR = 1.23; 95% CI 1.07-1.42). The corresponding figures for those being exposed to ETS by the mother was a HR of 1.22 (95% CI 0.88-1.69), for those being exposed by both parents was a HR of 1.06 (95% CI 0.88-1.26) and for those with no information about the active smoker the HR was 1.03 (95% CI 0.89-1.20). In conclusion, we found that exposure to environmental tobacco smoke during childhood was associated with a higher risk of breast cancer for women who reported that the father was the active smoker.

#2282 Smoking and alcohol and the risk of myelodysplastic syndrome: The JPHC study. Tomotaka Ugai,1 Keitaro Matsuoka,1 Norie Sawada,2 Motoki Iwasaki,2 Taiki Yamaji,2 Taichi Shimazu,2 Shizuka Sasazuki,2 Manami Inoue,2 Yoshinobu Kanda,3 Shoichiro Tsugane2,4 Aichi Cancer Center Research Institute, Nagoya, Japan; National Cancer Center, Tokyo, Japan; aitama Medical Center, Nihonmatsu, Japan. Background. Myelodysplastic syndromes (MDS) are a heterogeneous group of clonal disorders of hematopoietic stem cells that are characterized by ineffective hematopoiesis, multilineage dysplasia, peripheral cytopenias, and susceptibility to leukemic transformation. Even without progression to leukemia, there is substantial morbidity and mortality. Therefore, a better understanding of the etiology of this disease can lead to a significant reduction in the incidence and the mortality as a consequence, but it remains largely unknown. Smoking and alcohol are important modifiable risk factors for human cancers. However, only a few epidemiological studies have investigated their association with the risk of MDS. Here, we evaluated the association of smoking and alcohol consumption and the risk of MDS in a large-scale population-based cohort study in Japan. Methods. We included 95,950 Japanese subjects (45,451 men and 50,059 women; age 40-69 years at baseline) of the Japan Public Health Center-based Prospective Study who completed a questionnaire about their smoking and alcohol habits. During 18.3 years of follow-up, we identified 70 MDS cases (50 men and 20 women). We calculated hazard ratios (HRs) and their 95% confidence intervals (95% CI) using the Cox proportional hazards model to describe the relative risk of MDS associated with the smoking categories at baseline (never smokers, former smokers, current smokers, ever smokers of >30 pack-years) and the drinking categories at baseline (non-drinkers, occasional drinkers, regular drinkers of 1-299 or ≥300 g/week of ethanol) after adjustment for potential confounders. Results. Smoking was marginally associated with an increased risk of MDS among men, with a HR for current smokers relative to never smokers of 2.11 (95% CI 0.91-4.89). This risk increase was also observed in ever smokers when considered as a continuous variable (HR = 1.07-1.42). The corresponding figures for those with no information about the active smoker was a HR of 1.22 (95% CI 0.88-1.69). A linear increase in HR with increasing pack-years was also seen, albeit without statistical significance (p-trend = 0.008). In contrast, alcohol consumption was associated with a dose-dependent decrease in the risk of MDS among men (non-drinkers: reference, occasional drinkers: HR = 0.48, 0.16-1.43; 0-299 g/week: HR = 0.37, 0.19-0.74; ≥300 g/week: HR = 0.45, 0.20-0.99, p for trend = 0.008). All types of alcohol beverages (sake, distilled spirit and beer) consistently showed a protective effect. We also explored a possible interaction between smoking and alcohol consumption, but no obvious interaction was observed. Conclusions. This study showed that alcohol has a significant protective effect on the risk of MDS among Japanese men. In addition, this study also provides evidence that smoking increases the risk of MDS among Asian population, as it does among Western populations. Previous findings on the association between alcohol and the risk of MDS have been inconsistent, and further investigation across multiple populations is needed.

#2283 Population-level relevance of lifestyle-related risk factors for pancreatic cancer in Australia. Maria E. Arriaga,1 Maarit A. Laaksonen,1 Karen Canfell,2 Robert MacInnis,3 Emily Banks,4 Graham Giles,5 Paul Mitchell,6 Robert Cumming,6 Barbra-Ann Adelstein,1 Julie Byles,5 Manami Inoue,2 Yoshinobu Kanda,3 Shoichiro Tsugane2,4 Aichi Cancer Center Research Institute, Nagoya, Japan; National Cancer Center, Tokyo, Japan; aitama Medical Center, Nihonmatsu, Japan. Background. Population-level relevance of lifestyle-related factors for human cancers. However, only a few epidemiological studies have investigated their association with the risk of MDS. Here, we evaluated the association of smoking and alcohol consumption and the risk of MDS in a large-scale population-based cohort study in Japan. Methods. We included 95,950 Japanese subjects (45,451 men and 50,059 women; age 40-69 years at baseline) of the Japan Public Health Center-based Prospective Study who completed a questionnaire about their smoking and alcohol habits. During 18.3 years of follow-up, we identified 70 MDS cases (50 men and 20 women). We calculated hazard ratios (HRs) and their 95% confidence intervals (95% CI) using the Cox proportional hazards model to describe the relative risk of MDS associated with the smoking categories at baseline (never smokers, former smokers, current smokers, ever smokers of >30 pack-years) and the drinking categories at baseline (non-drinkers, occasional drinkers, regular drinkers of 1-299 or ≥300 g/week of ethanol) after adjustment for potential confounders. Results. Smoking was marginally associated with an increased risk of MDS among men, with a HR for current smokers relative to never smokers of 2.11 (95% CI 0.91-4.89). This risk increase was also observed in ever smokers when considered as a continuous variable (HR = 1.07-1.42). The corresponding figures for those with no information about the active smoker was a HR of 1.22 (95% CI 0.88-1.69). A linear increase in HR with increasing pack-years was also seen, albeit without statistical significance (p-trend = 0.008). In contrast, alcohol consumption was associated with a dose-dependent decrease in the risk of MDS among men (non-drinkers: reference, occasional drinkers: HR = 0.48, 0.16-1.43; 0-299 g/week: HR = 0.37, 0.19-0.74; ≥300 g/week: HR = 0.45, 0.20-0.99, p for trend = 0.008). All types of alcohol beverages (sake, distilled spirit and beer) consistently showed a protective effect. In addition, this study also provides evidence that smoking increases the risk of MDS among Asian population, as it does among Western populations. Previous findings on the association between alcohol and the risk of MDS have been inconsistent, and further investigation across multiple populations is needed.

EPIDEMIOLOGY: Tobacco, Alcohol, and Other Risk Factors

#2284 Effects of smoking on breast tumor pathology. Nicholas Costantino,1 Craig D. Shriver,2 Rachel E. Ellsworth3. 1Chan Soon-Shiong Institute of Molecular Medicine at Windber, Windber, PA; 2Martha Cancer Center, Bethesda, MD; 3Martha Cancer Center, Windber, PA. Background: Although smoking is not a well-established breast cancer risk factor, proximity of lungs to the breasts and findings that tobacco smoke constituents serve as mammary carcinogens in animal models suggests that smoking may alter the breast microenvironment and affect breast tumorigenesis. To determine whether there are relationships between smoking and pathological characteristics and outcome were evaluated in 1,707 women with invasive breast cancer. Methods: Patients enrolled in the Clinical Breast Care Project 2001-2013 filled out a questionnaire that included answers to current smoking status, current and previous pack use/day, number of years smoked, and length since last smoked. Smoking status was categorized as 0, 20, 20-34 or >35 pack-years. Current smokers were categorized according to hormone receptor status and metastasis (OR 1.44; 95% CI 1.03-2.01), positive HER2 status (OR 1.54, 95% CI 1.04-2.25), larger tumor size (OR 1.53; 95% CI 1.14-2.11) and higher tumor stage (OR 1.54, 95% CI 1.16-2.04) when compared to never smokers. Current smokers were less likely to be diagnosed with late stage tumors (OR 0.77, 95% CI 0.62-0.96) compared to never smokers. No significant associations were detected when pack years were considered as a continuous variable; when categorized as 0, <20, 20-34 or >35 pack years, >35 pack years was associated with positive HER2 status (OR 1.80, 95% CI 1.06-3.03) and tumors of the ER+HER2+ subtype (OR 1.99, 95% CI 1.07-3.7). Overall survival was significantly lower for former and current smokers compared to never smokers (P=0.014); however, breast cancer specific survival did not differ significantly among the smoking categories when stratified by metastasis status (P=0.226). Conclusions: Current smokers are at increased risk for having larger and later stage tumors with positive lymph node and HER2 status. Tumor size, stage and lymph node status are temporal factors, thus suggest that current smokers may have delayed diagnosis compared to never and former smokers. In contrast, HER2 status re-
EvAluation of Risk (CLEAR) study. reluceptor subtypes: results from the New South Wales Cancer Lifestyle and Evaluation of Risk (CLEAR) study. Usha G. Salagame,1 Emily Banks,2 Dianne O'Connell,3 Sam Egger,4 Karen Canfell,5 Cancer Council NSW, NSW 2011, Australia;3 Australian National University, Australian Capital Territory, Australia;2 University of Sydney, Sydney, Australia;1 University of California San Francisco and Veterans Affairs Medical Center San Francisco, CA

Background: Prior observational studies have identified an elevated breast cancer risk associated with current MHT use for ER+ (Estrogen Receptor positive), and for ER+/PR+ (Estrogen and Progesterone Receptor positive) breast cancers than for ER- and ER-/PR- subtypes respectively. We have previously reported, from a large case-control study for all cancer types (the NSW CLEAR study) that current MHT use was associated with a doubling of the odds of breast cancer. Here, we describe further analyses investigating the MHT-breast cancer association for the breast cancer tumor receptor subtypes defined by ER expression, by ER and PR expression and by the joint expression of ER, PR, and HER-2 (Human Epidermal growth factor Receptor-2). Methods: Analyses were carried out for a subset of registry-verified CLEAR breast cancer cases with hormone receptor status data (n=410) and CLEAR (cancer-free) controls recruited over the same period (n=324). We used a multinomial logistic regression model to estimate Odds Ratios (ORs) adjusted for other breast cancer risk factors and 95% Confidence Intervals (CI) for current and past MHT use in subgroups defined using Cox receptor subtypes. Never users comprised the reference group. Findings: In a multinomial model, current MHT use was associated with an elevated risk of ER+/breast cancer (aOR = 2.04, 95%CI: 1.28 -3.24). When breast cancers were categorised by ER and PR status, current use was associated with an elevated risk of developing ER+/PR+ breast cancer (aOR = 2.29, 1.41-3.72). Current MHT use was associated with the surrogate luminal A breast cancer characterised by ER+/PR+/HER2- phenotype (aOR = 2.30, 1.42-3.73). None of the other subtypes of breast cancer (ER+/PR-/HER2+, ER-/PR-/HER2+, and ER-/PR-/HER2-) were significantly associated with current MHT use. A significant difference in the odds of developing breast cancer for current MHT users was detected between the surrogate luminal A and luminal B (ER+/PR+/HER2-) subtype only (aOR= 0.28, 0.09-0.88, p=0.029). None of the other groups were significantly differently associated with MHT use although this may be due to lack of power. Past MHT use was not associated with an increased risk of breast cancer for any breast cancer subtype. Conclusion: The findings from this contemporary Australian study are consistent with findings from other studies that current, but not past, use of MHT is associated with increased risk of breast cancer with higher risks reported for ER+, ER- and PR+ and ER+/PR+/HER2- (surrogate luminal A) subtypes. Our findings are consistent with the hypothesis that breast cancers induced by MHT may occur through receptor-mediated mechanisms.

Atoxic allergic conditions and risk of pancreatic cancer: the Multi-ethnic Cohort. Brian Z. Huang,1 Loic Le Marchand,2 Christopher A. Haiman,3 Kristine Monroe,3 Lynne Wilkens,2 Zuo-Feng Zhang,1 Veronica Wendy Setiawan7.1 UCLA School of Public Health, Los Angeles, CA;2 University of Hawai'i Cancer Center, Honolulu, HI;3 University of Southern California, Los Angeles, CA

Background: Previous studies, mostly case-control studies, have suggested that allergic conditions (AACs) are associated with a decreased risk of pancreatic cancer. Scarc data, however, are available from prospective, US multi-ethnic populations. In this largest prospective study to date, we investigated the association between AACs (asthma, hay fever, or allergy) and risk of developing pancreatic cancer in the US Multietnic Cohort Study (MEC). Methods: AACs were assessed via a baseline questionnaire when participants joined the MEC in 1993-1996. Hazard ratios (HRs) and 95% confidence intervals (CIs) for pancreatic cancer risk were estimated using Cox proportional hazards models, adjusting for age, sex, race/ethnicity, education, smoking status, family history of pancreatic cancer, body mass index, diabetes, and alcohol intake. Results: During an average of 16.2-year follow-up, 1,455 incident cases of pancreatic cancer were identified among 187,226 white, African-American, Native Hawaiian, Japanese-American, and Latino men and women. AACs were not associated with pancreatic cancer incidence (HR = 1.00; 95% CI: 0.88, 1.12). The null association was observed in men and women and across racial/ethnic groups, smoking status, BMI groups, diabetes status, and family history of pancreatic cancer. Conclusions: Based on these results, AACs is unlikely to be associated with risk of pancreatic cancer.

Number of risky lifestyle behaviors and breast cancer subtypes in a large nested case-control study from Norway. Merete Ellingjord-Dale,1 Linda Vos,1 Steinar Tretli,1 Solveig Hofvind,2 Anette Hjartaker,2 Hege Russnes,2 Isabel dos-Santos-Silva,3 Giske Ursin3.1 Cancer Registry of Norway, Oslo, Norway; 3University of Oslo, Oslo, Norway; 2Oslo University Hospital, Oslo, Norway; 4London School of Hygiene and Tropical Medicine, London, United Kingdom.

Background: Alcohol, smoking, physical inactivity, high body mass index (BMI) and menopausal hormone therapy (MHT) use and breast cancer risk by receptor subtypes: results from the New South Wales Cancer Lifestyle and Evaluation of Risk (CLEAR) study. Usha G. Salagame,1 Emily Banks,2 Dianne O'Connell,3 Sam Egger,4 Karen Canfell,5 Cancer Council NSW, NSW 2011, Australia;3 Australian National University, Australian Capital Territory, Australia;2 University of Sydney, Sydney, Australia;1 University of California San Francisco and Veterans Affairs Medical Center San Francisco, CA

Objective: The cancer risk associated with current MHT use was detected between the surrogate luminal A and luminal B (ER+/PR+/HER2- phenotype (aOR = 2.30, 1.42-3.73). Current MHT use was associated with an increased risk of breast cancer for any breast cancer subtype. Methods: We conducted a case-control study nested within a cohort of 457,036 women who participated in the Norwegian Breast Cancer Screening Program (NBCSP) in 2006-2014, and who completed a questionnaire at baseline screening. In all, 4,686 breast cancer cases with information on risk factors and hormone receptor status (i.e. estrogen receptor (ER), progesterone receptor (PR) and human epidermal growth factor 2 (HER2) occurred during the follow-up. The following surrogate definitions of breast cancer subtypes were used: ER+PR-HER2- (luminal A-like), ER+PR-HER2- (luminal B-like, HER2 negative), ER+PR+/PR+/HER2- (luminal B-like, HER2 positive), ER+PR-HER2+ (HER2 positive) and ER-PR-HER2- (triple negative). We defined risky lifestyle behaviors as ever smoking, weekly consumption of more than 2 glasses of alcohol per week, less than 3 hours leisure time physical activity per week, more than 7 hours of sleep per night, ever use of menopausal hormone (estrogen and progesterone) therapy and BMI (kg/m2) >25. We used conditional logistic regression to estimate odds ratios (ORs), with 95% confidence intervals (CIs), adjusted for age, education, age at menarche, number of pregnancies and menopausal status. Results: Number of risky lifestyle behaviors was associated with an increased risk of breast cancer overall (p-trend<0.0001). Compared to women with no lifestyle behaviors, women with 1 (OR= 1.28, 95% CI 0.87-1.88), 2 (OR = 1.63, 95% CI 1.13-2.36), 3 (OR = 1.85, 95% CI 1.28-2.68), 4 (OR = 2.27, 95% CI 1.56-3.29) and 5 (OR=2.38, 95% CI 1.58-3.59) risky lifestyle behaviors had increased risk of luminal A-like subtype (p-trend <0.0001). However, number of risky lifestyle behaviors was not associated with increased risk of the triple negative subtype (p-trend=0.27). Conclusions: This study showed that number of risky lifestyle behaviors was positively associated with a marked increased risk for luminal A-like breast cancer. These findings suggest that healthy lifestyle choices may play an important role in the prevention of the commonest form of this cancer.

Effects of tobacco smoking and alcohol consumption on risks of CYP1B1 polymorphisms for prostate cancer. Taku Kato, Yutaka Hashimoto, Shigekatsu Maekawa, Marisa Shina, Mitsuho Imai-Sumida, Pritha Dasgupta, Masahiko Takashima, Soichiro Yamamura, Varahram Sharryari, Guoren Deng, Rajivv Daihah, Yuichiyo Tanaka. University of California San Francisco and Veterans Affairs Medical Center San Francisco, San Francisco, CA

Cytochrome P450 1B1 (CYP1B1) converts xenobiotics to carcinogens and polymorphic variants have been shown to increase activity levels. Lifestyle choices such as tobacco smoking and alcohol consumption are known to enhance the carcinogenesis process and in this study, how these factors may interact with CYP1B1 polymorphisms and affect prostate cancer risk was assessed. Blood genomic DNA from a Caucasian population consisting of 405 healthy men and 400 prostate cancer patients were obtained. Of these, 507 were current or former smokers and 407 were alcohol drinkers. Eight polymorphic sites of the promoter region of CYP1B1 (rs2551188 G to A, rs2567206 G to A, rs2567207 A to G, rs162558 A to G, rs10175368 C to T, rs163090 T to A, rs162330 T to G, and rs162331 A to G) were analyzed in samples using Taqman genotyping assays and real-time PCR. Lifestyle factors and its influence on CYP1B1 polymorphisms toward cancer risks were also evaluated. Overall, both alcohol (P=0.006) and smoker (P=0.009) status were associated with prostate cancer. CYP1B1 variants were also risks for cancer at rs2551188 (P=0.043), rs2567206 (P=0.008), and rs10175368 (P=0.001). Evaluation of linkage disequilibrium show rs2551188, rs2567206, rs2567207, and rs10175368 to be linked and interestingly, the G-G-A-C haplotype (wildtype at respective sites) was significantly reduced in cancer (P=0.0287). When classified by lifestyle factors, no associations for CYP1B1 variants were found for cancer among non-smokers with rs10175368 (P=0.051) being a risk among non-drinkers. On the other hand, variants at both rs2567206 and rs10175368 showed increased cancer risk among smokers (P=0.032 and 0.002, respectively) as well as drinkers (P=0.044 and 0.019, respectively). No genotyping differences were observed when analyzing cancers by pathological grades. These results demonstrate...
smoker and alcoholic drinker status to modify the risks of CYP1B1 polymorphisms for prostate cancer and this is of importance in understanding their role in the pathogenesis of this disease.

#2289  B-carotene supplementation and lung cancer risk in the ATBC Study: the role of tar and nicotine. Pooja Middha,1 Stephanie J. Weinstein,2 Satu Mannisto,3 Demetrias Albanes,4 Alison M. Mondul.1 1University of Michigan School of Public Health, Ann Arbor, MI; 2National Cancer Institute, Bethesda, MD; 3National Institute for Health and Welfare, Helsinki, Finland.

Background: Globally, lung cancer is the most common cancer and the leading cause of cancer death. Early observational studies reported a protective association between intake of B-carotene rich vegetables and lung cancer risk, which led to interest in B-carotene supplementation as a potential chemopreventive strategy, particularly in high-risk populations such as cigarette smokers. A large randomized controlled trial, the Alpha-Tocopherol, Beta-Carotene Cancer Prevention (ATBC) Study, demonstrated that B-carotene supplementation increased lung cancer incidence by 18% in smokers, and led to an 8% excess in overall mortality. It is also well-documented that cigarettes with higher (versus lower) tar and nicotine content are associated with a higher risk of lung cancer. To our knowledge, however, no studies have examined whether the increased risk associated with B-carotene supplementation in smokers varies by cigarette tar or nicotine content. Methods: The ATBC Study was a randomized, double-blind vitamin supplementation trial conducted among 29,133 male smokers in southwest Finland. Participants were randomly assigned to one of four groups in a 2x2 factorial design (a-tocopherol alone, B-carotene alone, both supplements, or placebo). A detailed smoking history was collected to be used in the analysis of cigarettes smoked (for which machine measured tar and nicotine content was available). Cox proportional hazards models were used to estimate the hazard ratio (HR) and 95% confidence intervals (CI) of lung cancer risk by trial B-carotene assignment stratified by a priori categories of cigarette tar (ultra-light, light, medium, regular, medium 15-20 mg, high, non-filtered/self-made >20 mg) and nicotine content (ventilated filtered <0.8 μg, unventilated filtered 0.8-1.3 μg, non-filtered >1.3 μg). Statistical interaction was estimated using the likelihood ratio test. Results: The B-carotene supplemented arm had a statistically significantly higher risk of developing lung cancer in all categories of tar content [yes vs. no B-carotene supplementation - ultra-light: HR = 1.31 95% CI = 0.91-1.89; non-filtered: HR = 1.22 95% CI = 0.91-1.64; p-interaction = 0.91]. Similarly, there was no apparent interaction with cigarette nicotine content [yes vs. no B-carotene supplementation - ventilated cigarettes: HR = 1.23, 95% CI = 0.98-1.54; non-filtered cigarettes: HR = 1.22, 95% CI = 0.91-1.64; p-interaction = 0.83]. Conclusion: These findings indicate that supplementation with B-carotene increases lung cancer incidence in smokers regardless of the tar or nicotine content of cigarettes smoked. Our data suggest that all smokers, regardless of the type of cigarette smoked, should continue to avoid B-carotene supplementation.

#2290  Perceived stressfulness of life events impacts breast cancer risk. Avital Fischer, Argos Ziegos, Hoda Anton-Culver. UCI, Irvine, CA.

Background: Breast cancer is the most prevalent malignancy and the second most common cause of cancer mortality among women. Approximately 60% of breast cancers are attributed to breast cancer risk (BCR) factors that are not modifiable and the majority of these women do not have a family history of breast cancer. Therefore, it is important to perform further research focusing on identifying preventable risk factors for breast cancer. The relationship between psychological stress and breast cancer risk is unclear. Psychological stress arises when environmental demands are appraised as going beyond one's coping abilities. Higher perceived stress has been linked to increased cortisol levels and HPA perturbations. The purpose of this study is to understand the relationship between stressfulness appraisal of salient life events and breast cancer risk. Methods: A case-control design was used and included 664 female cases identified for breast cancer and this is of importance in understanding their role in the pathogenesis of this disease.

Results: The relationship between psychological stress and breast cancer risk in a dose response fashion (OR = 0.83, 95% CI = 0.64-1.04) for stressful vs. not stressful (OR = 1.22, 95% CI = 1.03-1.45). The role of psychological stress on breast cancer risk only when reported as being stressful (OR = 0.54, 95% CI = 0.32-0.92; OR = 0.63, 95% CI = 0.43-0.93 respectively). Conclusions: This study broadens our understanding of the relationship between major life events and breast cancer risk and underscores the importance of stressfulness appraisal. Our results indicate the importance of incorporating assessments of perceived stressfulness in future epidemiological investigations focusing on the assessment of life events and breast cancer risk.

#2292  Lung function and lung cancer risk: a Mendelian randomization study of UK Biobank cohort and the International Lung Cancer Consortium. Linda Kachuri,1 Matthias Johansson,2 Paul Brennan,3 Phillip Haycock,3 Geoffrey Liu,4 Maria Teresa Landi,5 David C. Christiani,6 Neil E. Caporaso,7 Xifeng Wu,8 Melinda C. Aldrich,9 Demetrios Albanes,10 Adolina Tardón,11 Gad Rennert,12 Chu Chen,13 Gary E. Goodman,14 Jennifer A. Doherty,15 Heike Bickeboller,16 Dawn Teare,17 Lambertus A. Kiememeny,18 Stig E. Bojesen,19 John K. Field,20 Aage Haugen,9 Stephen Lam,9 Loic Le Marchand,20 Matthew B. Schabath,21 Angelique S. Andrew,1 Jonas Manjer,2 Philip Lazarus,23 Susanne M. Arnold,24 Valérie Gaborieau,2 Richard Martin,2 Caroline Relton,2 George Davey Smith,2 Christopher I. Amos,3 James D. Mc-Kay,2 Rayeun J. Hung,3 Lunfenfeld-Fandenbaum Research Institute, Sinai Health System, Toronto, Ontario, Canada; National Institute of Public Health, Orange County, CA; University of California, Irvine, CA; National Cancer Institute, Bethesda, MD; National Cancer Institute, Health and Welfare, Helsinki, Finland. 

Background: Lung function (LF) is strongly associated with increasing lung cancer risk. However, since airflow obstruction is a diagnostic criterion for obstructive lung disease, and a consequence of tobacco smoking, isolating the causal relationship between LF and lung cancer has remained a challenge. Methods: We investigated 3 standardized (mean = 0, standard deviation = 1) LF phenotypes (forced expiratory volume in 1 second (FEV1), forced vital capacity (FVC), and FEV1/FVC) and assessed their association with lung cancer risk in the ATBC Study of UK Biobank cohort and the International Lung Cancer Consortium. Findings: 1) a genome-wide association study of UK Biobank cohort and the International Lung Cancer Consortium and, 2) a Mendelian randomization (MR) analysis using genetic instrumental variables (IVs) developed in UK Biobank and tested using individual-level data from the OncoArray, a genome-wide array with in-depth coverage for common cancers. Results: 702 incident lung cancers were diagnosed in 484,194 UKB participants during follow-up. Cox regression was used to estimate hazard ratios (HR) and 95% confidence intervals (CI), adjusted for age, sex, smoking status, socioeconomic status, and assessment center. Adjustment for other smoking metrics yielded similar results. Lung cancer risk increased per 1 unit decrease in FEV1 (HR = 1.80, 95% CI: 1.64-1.98, p = 3.3x10^-34), FVC (HR = 1.45, 1.30-1.60, p = 2.3x10^-12), and FEV1/FVC (HR = 1.39, 1.31-1.46, p = 1.3x10^-30). This pattern was observed for adenocarcinoma (n = 300): FEV1 (HR = 1.77, p = 6.0x10^-12), FVC (HR = 1.48, p = 1.4x10^-7), FEV1/FVC (HR = 1.34, p = 8.3x10^-9); and squamous cell carcinoma (n = 166): FEV1 (HR = 1.97, p = 9.0x10^-5), FVC (HR = 1.60, p = 1.0x10^-5), FEV1/FVC (HR = 1.38, p = 5.9x10^-5). Next, a genome-wide association study of 67,708 UKB participants and 12.6 million variants was carried out to develop genetic IVs for LF. Results were filtered to retain independent variants (R²<0.2) associated with each LF phenotype (p<5x10^-8). The following IVs were developed: FEV1 (n = 28 variants, 0.72% of variation explained), FVC (n = 44, 1.08%), and FEV1/FVC (n = 45, 1.85%). Odds ratios (OR) for each IV and lung cancer were estimated for 18,868 cases 15,190 controls (>80% European ancestry) from 23 studies. Effect estimates were combined using a maximum-likelihood MR models to estimate causal ORs. MR results indicate that genetic scores associated with increased airflow are unrelated to lung cancer risk: FEV1 (OR = 1.00, 95% CI = 0.96-1.03, p = 0.86), FVC (OR = 1.00, 0.97-1.03, p = 0.93) and FEV1/FVC (OR = 1.00, 0.91-1.10, 1.587
p = 0.95). The null association observed for the genetic determinants of FEV1, FVC and FEV1/FVC was not modified by tumor histology or smoking status. Conclusions: LF is a robust predictor of lung cancer risk, however, our findings do not support the existence of causal pathways that are independent of obstructive lung disease or smoking. This apparent lack of a causal relationship should be interpreted with caution since pleiotropic effects of LF loci cannot be ruled out.

**#2293 Oligomenorrhea, polycystic ovary syndrome, and risk of ovarian cancer histotypes, evidence from the Ovarian Cancer Association Consortium.** Holly R. Harris,1 Susan Jordan,2 Harvey Risch,3 Mary Anne Rossing,4 Marc T. Goodman,5 Francesmary Modugno,6 Susanne Kruger Kjer,7 Joellen M. Schildkraut,8 Elisa V. Bandera,9 Nicolas Wentzensen,10 Catherine Phelan,11 Hoda Anton-Culver,11 Anna H. Wu,12 Kathryn L. Terry13, 1Fred Hutchinson Cancer Research Ctr., Seattle, WA; 2QIMR Berghofer Medical Research Institute, Herston, Australia; 3Yale School of Public Health, New Haven, CT; 4CEDars-Sinai Medical Center, Los Angeles, CA; 5University of Pittsburgh School of Medicine, Pittsburgh, PA; 6Danish Cancer Society Research Center, Copenhagen, Denmark; 7The University of Virginia, Charlottesville, VA; 8Rutgers Cancer Institute of New Jersey, New Brunswick, NJ; 9National Cancer Institute, Bethesda, MD; 10Moffitt Cancer Center, Tampa, FL; 11University of California Irvine, Irvine, CA; 12University of Southern California Norris Comprehensive Cancer Center, Los Angeles, CA; 13Brigham and Women’s Hospital, Boston, MA.

Background: Oligomenorrhea, defined as infrequent or irregular periods has been shown to be associated with epithelial ovarian cancer risk in some but not all studies. Polycystic ovary syndrome (PCOS), which is characterized by oligomenorrhea and abnormal hormone levels including hyperandrogenism, hyperinsulinemia, and gonadotropin imbalance, has been suggested to increase ovarian cancer risk. However, these associations have been rarely examined by histologic subtype. We sought to examine these associations among 14 studies participating in the Ovarian Cancer Association Consortium. Methods: Participants included 16,594 patients with invasive (n = 13,719) or borderline (n = 2,875) ovarian cancers and 17,718 controls who had answered questions regarding menstrual cycle irregularity, menstrual cycle length, and/or PCOS. Study specific odds ratios (ORs; 95% confidence intervals [95% CI]), adjusted for ovarian cancer risk factors, were calculated and then combined using a random-effects meta-analysis. Pooled histologic subtype specific ORs (95% CI) were calculated using polytomous logistic regression. Results: Women reporting menstrual cycle length > 35 days had decreased risk of invasive ovarian cancer compared to women reporting cycle length ≤ 35 days (OR = 0.70; 95% CI = 0.58-0.84). Decreased risk of invasive ovarian cancer was also observed among women who reported irregular menstrual cycles compared to women with regular cycles (OR = 0.89; 95% CI = 0.76-0.98). No significant association was observed between self-reported PCOS and invasive ovarian cancer risk (OR = 0.87; 95% CI = 0.65-1.15). For menstrual cycle length > 35 days, decreased risk was observed for all invasive histotypes: low grade serous (OR = 0.48; 95% CI = 0.25-0.92), high grade serous (OR = 0.62; 95% CI = 0.48-0.80), mucinous (OR = 0.38; 95% CI = 0.19-0.76), endometrioid (OR = 0.75; 95% CI = 0.54-1.06), and clear cell (OR = 0.43; 95% CI = 0.13-1.13) but not for serous borderline tumors (OR = 1.18; 95% CI = 0.87-1.59). For endometrioid, low grade serous and clear cell carcinomas, serous borderline disease was observed among women reporting irregular cycles (OR = 1.34; 95% CI = 1.16-1.55) (p(heterogeneity)<0.0001). No statistically significant differences by histologic subtype were observed for self-reported PCOS.

Conclusion: In this large consortium analysis we observed a decreased risk of most invasive epithelial ovarian cancer histotypes among women reporting longer or irregular menstrual cycles. In contrast, such cycles were associated with increased risk of the serous borderline tumors.

**#2294 Atypical nevi and risk of incident skin cancer in US men: a prospective study.** WEN-QING LI,1 Eunyoung Cho,1 Alisa Goldstein,2 Yen-Tsung Huang,3 Martin Weinstock,1 Aabir Qureshi1, 1Brown University, Providence, RI; 2National Cancer Institute, Bethesda, MD.

Background and Aims: Atypical nevi (AN) are a strong risk factor as well as a precursor of melanoma. However, most previous studies on the associations between atypical nevi (AN) and the risk of melanoma have been conducted in retrospective case-control settings and the few available prospective studies have been based on small sample sizes. Further, few studies have examined the associations between AN and risk of keratoacanthomas (formerly called non-melanoma skin cancer). We prospectively examined the risk of incident melanoma, squamous cell carcinoma (SCC) and basal cell carcinoma (BCC) associated with AN. Methods: In the Health Professionals Follow-up Study, information on AN was collected by self-report. Only those confirmed cases of AN by a supplementary questionnaire, the Atypical Nevi Screening Questionnaire (ANQ), were included in the analyses. Diagnosis of skin cancers was reported biennially and information on melanoma and SCC was pathologically confirmed. A total of 50193 men were included in our study, with 1239 confirmed cases of AN with information on diagnosis year. Cases of AN that were not confirmed or did not respond to the ANQ were excluded from the analyses. Time-dependent Cox-regression analyses were conducted for the associations between AN and risk of incident melanoma, SCC, and BCC respectively.

Results: We identified 545 melanoma cases, 1721 SCC cases, and 13498 BCC cases during the follow-up (1986-2012). A history of AN was significantly associated with increased risk of incident melanoma (hazard ratio [HR] = 3.50, 95% confidence interval [CI]: 2.13-5.76) overall and at different body sites (head and neck, trunk, or limbs). The risk of melanoma was particularly augmented with the increasing number of AN that were surgically removed (HR = 1.26, 95% CI: 1.16-1.37 per AN) and for cases of AN with tissue re-excision from the nevus removal sites (HR = 4.59, 95% CI: 1.70-12.41). A history of AN was also significantly associated with increased risk of BCC (HR = 1.84, 95% CI: 1.60-2.10) and was only associated with risk of SCC at the trunk sites (HR = 3.09, 95% CI: 1.24-7.72). Conclusions: A history of AN significantly increased the risk of subsequent melanoma in a prospective study of men. A history of AN may also be associated with increased risk of BCC overall and trunk SCC, which requires further studies to replicate.
son-years, respectively, in ever and never users. The overall hazard ratio (0.691, 95% confidence interval: 0.578-0.826) suggested a significantly lower risk in metformin users. While compared to never users, the hazard ratio (95% confidence interval) for the first (<20.00 months), second (20.00-45.20 months) and third (>45.20 months) tertile of cumulative duration of metformin therapy was 1.455 (95% CI: 0.926-2.280), 1.710 (95% CI: 0.997-2.941) and 1.455 (95% CI: 0.720-2.541) respectively. The protective effect of metformin on colon cancer was not affected by the use of aspirin and statin or the infection of Helicobacter pylori in additional analyses.

Conclusions: Metformin reduces colon cancer risk in patients with type 2 diabetes. The protective effect is more remarkable when the cumulative duration is more than 20 months.

**EPIDEMIOLOGY: Tobacco, Alcohol, and Other Risk Factors**

#2297 Household stove improvement and risk of chronic obstructive pulmonary disease in Xuanwei, China: a cohort study. Jinning Zhang, 1 Bryam A. Bassi, 2 Roel Vermeulen, 2 Wei Jie Seow, 1 Jason Y.Y. Wong, 1 Wei Hu, 1 Bofu Ning, 1 George S. Downward, 2 Hormuzd A. Katki, 1 Bu-Tian Ji, 1 Nathaniel Rothman, 1 Robert S. Chapman, 1 Qing Lan, 1 National Cancer Institute, Rockville, MD; 2 Utrecht University, Utrecht, Netherlands; 3 Xuanwei Center of Disease Control, Xuanwei, China; 4 Chulalongkorn University, Bangkok, Thailand.

Background: In Xuanwei County, China, chronic obstructive pulmonary disease (COPD) rates are over twice the national average. Patients with COPD have higher risks of both lung cancer and poor treatment outcomes after lung cancer diagnosis. In a prior retrospective cohort study (1976-1992), household stove improvement was found to be associated with decreased COPD incidence among lifetime smoky (bituminous) coal users. However, whether the protective effect persists over time is unclear. Our objective was to evaluate the associations between risk of COPD, and vented and portable stove use with extended follow-up (1976-2011). Methods: The study population comprised 22,833 residents who were born between 1917 and 1951 and lived in Xuanwei as of January 1, 1976. Participants were followed retrospectively from 1976 to 1992, and then followed prospectively through 2011. We conducted two surveys in 1992 and 2011. During each survey, we collected comprehensive information on household stove type, fuel use, family size and number of rooms in each residence during the lifetime, smoking, education, age starting cooking food and time spent indoor from each subject. Participants were also asked to report any medically diagnosed chronic bronchitis or emphysema, age and place of diagnosis, which we combined into a single category of COPD. COPD cases diagnosed before January 1, 1976 were excluded. Sex-specific time-dependent Cox regression models were used to estimate the hazard ratio (HR) of stove improvement for COPD incidence among lifetime smoky coal users. Results: The analysis was restricted to lifetime smoky coal users. A significant reduction in COPD incidence was found after change to vented stoves (Men’s model: HR=0.66, 95% confidence interval: 0.59-0.75; Women’s model: HR=0.60, 95% CI: 0.55-0.67) and portable stoves (Men’s model: HR=0.77, 95% CI: 0.67-0.88; Women’s model: HR=0.63, 95% CI: 0.54-0.74). There was a downward trend of COPD incidence over time after change to vented stove or portable stove (p-trend<0.01). Similar findings were noted in both men and women. Conclusion: Consistent with prior research, our findings suggest that household stove improvement was associated with a substantially decreased risk of COPD, a strong risk factor for COPD. Our findings support the need for replacing smoky coal with less carcinogenic fuels in areas where domestic coal combustion are important risk factors for COPD. Our findings support the need for replacing smoky coal with less carcinogenic fuels in areas where domestic coal combustion are important risk factors for COPD. Similarly, elevated IRRs for kidney cancer were observed for both the 2nd and 3rd tertile of Mn (2nd tertile: 37.33-51.74 ppb; IRR 1.05, 95% CI 1.00, 1.10) and the 2nd tertile of Pb (3.88-5.05 ppb: IRR 1.05 (95% CI 1.00, 1.10)). A dose response was observed for kidney cancer incidence and Mn (2nd tertile: 37.33-51.74 ppb: IRR 1.06 (95% CI 1.02, 1.11); 3rd tertile: 52.95-146.60 ppb: IRR 1.13 (95% CI 1.08, 1.19)). For bladder cancer, no relationship was observed with As but IRRs were elevated for the other metals including potential dose-response trend with Cd and Mn (Pb 2nd tertile: 3.88-5.05 ppb: IRR 1.03 (95% CI 1.00, 1.07); Cd 3rd tertile: 0.61-2.98 ppb: IRR 1.10 (95% CI 1.06, 1.15); Mn 3rd tertile: 52.95-146.60 ppb: IRR 1.12 (95% CI 1.08, 1.16)). Conclusion: In North Carolina, counties with higher mean private well metal levels had elevated kidney and bladder cancer incidence rates. The conclusions are limited by the ecological approach, but the consistency of the associations suggests that the exposure of metals in private well water in North Carolina on health outcome deserves additional investigation.

#2299 Toxic metals in private well water and bladder and kidney cancer incidence in North Carolina. Deepika Shrestha, 1 Selin Crenkrite, 1 Alison Sanders, 2 Rebecca Fry, 3 Katie M. Applebaum, 1 George Washington University, Milken Institute School of Public Health, Washington, DC; 3 hath School of Medicine at Mount Sinai, New York, NY; 4 University of North Carolina, Gillings School of Public Health, Chapel Hill, NC.

Introduction: There are a limited number of studies conducted in the US that have related metals in well water with kidney and bladder cancer. We investigated levels of arsenic (As), cadmium (Cd), manganese (Mn), and lead (Pb) in private well water and the association with incidence of bladder and kidney cancer in 100 counties in North Carolina, a state that has among the highest proportion of well water consumers in the country. Methods: Between 1998-2010, private wells across 100 NC counties were analyzed for levels of As, Cd, Mn and Pb (n=63,836, n=22,915, n=70,675 and n=65,535 measurements, respectively) and geocoded. Bladder and kidney cancer incidence for each county between 1990 and 2011 were obtained from the North Carolina Department of Health and Human Services. County-level data on potential confounders were obtained from US Census Bureau data (2010) and the Behavioral risk factor surveillance study (2003, 2005). For each county, the mean concentration of each metal and the incidence rate ratio (IRR) with 95% confidence interval (CI) were calculated separately. Using counties as the unit of analysis, we used Poisson regression to estimate incidence rate ratios (IRRs) and 95% confidence intervals (CIs) between mean concentration of the four metals and kidney and bladder cancer incidence, adjusting for age, gender, race, education, physical activity, smoking, diabetes, hypertension and residential well water supply. County mean metal levels were analyzed in tertiles. Covariates included: age, sex, county, case less than 10 well measurements for any metal were excluded from the analysis. Results: Ninety-eight counties were included in the final analysis. In the fully adjusted model, elevated IRRs for kidney cancer were observed in counties with the highest tertile of As (3rd tertile: 0.99-11.44 ppb, IRR=1.05 (95% CI 1.00, 1.11)). Similarly, elevated IRRs for kidney cancer were observed for both the 2nd and 3rd tertile of Cd (2nd tertile: 1.08, 1.19); 3rd tertile: 1.05 (95% CI 1.00, 1.10) and the 2nd tertile of Pb (3.88-5.05 ppb: IRR=1.05 (95% CI 1.00, 1.10)). A dose response was observed for kidney cancer incidence and Mn (2nd tertile: 37.33-51.74 ppb: IRR 1.06 (95% CI 1.02, 1.11); 3rd tertile: 52.95-146.60 ppb: IRR=1.13 (95% CI 1.08, 1.19)). For bladder cancer, no relationship was observed with As but IRRs were elevated for the other metals including potential dose-response trend with Cd and Mn (Pb 2nd tertile: 3.88-5.05 ppb: IRR=1.03 (95% CI 1.00, 1.07); Cd 3rd tertile: 0.61-2.98 ppb: IRR 1.10 (95% CI 1.06, 1.15); Mn 3rd tertile: 52.95-146.60 ppb: IRR=1.12 (95% CI 1.08, 1.16)). Conclusion: In North Carolina, counties with higher mean private well metal levels had elevated kidney and bladder cancer incidence rates. The conclusions are limited by the ecological approach, but the consistency of the associations suggests that the exposure of metals in private well water in North Carolina on health outcome deserves additional investigation.

#2300 Pesticides and primary liver cancer: A systematic review and meta-analysis. Hamidi Abdi, Jennifer Lee, Gary Ellison, Gabriel Lai, Tram Lam. National Cancer Institute, Rockville, MD.

Background: Primary liver cancer is the sixth most occurring cancer worldwide and the second most common cause of cancer mortality. Hepatocellular carcinoma (HCC) is the most prevalent histologic type of liver cancer, with well-established risk factors (e.g., chronic infections with hepatitis B virus or hepatitis C virus, and alcohol-related liver disease). Exposure to pesticides may also contribute to the etiology of liver cancer. The use of pesticides has increased.

Proceedings of the American Association for Cancer Research • Volume 58 • April 2017 589
significantly in both developed and developing countries within the last few decades. The association between pesticides and liver cancer is unclear. We conducted a systematic review and meta-analysis to investigate the relationship between exposure to pesticides (e.g., organophosphates, organochlorines, carbamates, dichlorophenyltrichloroethane, dichlorodiphenylchloroethylene, and organometallics) and cancer incidence and mortality. We searched PubMed and EMBASE databases using a combination of medical subject heading terms and key words for articles published before June 2016. Articles were identified as relevant if they were original studies and met the following criteria: 1) primary liver cancer was an identified outcome for risk or mortality, 2) pesticides were the main exposure of interest, 3) exposure to pesticides was assessed historically (e.g., blood serum) or through questionnaires, and 4) the estimates for the association between liver cancer risk/mortality and pesticide exposure were reported. Titles and abstracts meeting search criteria were reviewed and relevant full-text articles were read and analyzed independently by two researchers. We calculated the summary estimates [Odd Ratios (ORs) or Relative Risks (RR)] and 95% confidence intervals (CIs) using random-effects models. All analyses were conducted using STATA 14.0. Results: Of 1664 articles reviewed, a total of 34 observational studies were identified as relevant and 20 were included in the meta-analysis for liver cancer risk (5 case-control and 15 cohorts). All of the identified studies investigated HCC as the outcome; none investigated other types of liver cancer. The results showed that pesticide exposure was associated with a 73% increased risk of HCC (RRsummarized:1.73, 95% CI 1.40–2.13; I² = 85.5% and I² < 50% for the highest design of analyses by study design). Furthermore, the summary stratified by sex and type of pesticide similar elevated risks were observed. Analysis of articles that reported on liver cancer mortality (n = 7) showed an excess in mortality from HCC for individuals exposed to pesticides. Conclusion: The existing epidemiological data supports the hypothesis that exposure to pesticides is associated with a significant increased risk of HCC and death from liver cancer.

Genital use of talc and risk of ovarian cancer: A meta-analysis, Paolo Boffetta,1 Wera Berge2.

Some epidemiological studies suggest an association between genital use of talc powders and increased risk of ovarian cancer, but the evidence is not consistent. We performed a meta-analysis of epidemiologic studies to formally evaluate this suspected association. A systematic search was conducted in Medline, Embase and Scopus, leading to the identification of 24 case-control studies and 3 cohort studies, including 302,705 women with ovarian cancer. In the meta-analysis, we used a random-effect model to calculate summary estimates of the association between genital use of talc and occurrence of ovarian cancer. We assessed potential sources of between-study heterogeneity and presence of publication bias. The summary relative risk (RR) for ever use of genital talc and ovarian cancer was 1.22 (95% confidence interval [CI] 1.13–1.30). The RR for case-control studies was 1.26 (95% CI 1.17-1.35) and for cohort studies was 1.02 (95% CI 0.85-1.20, p heterogeneity=0.007). Serious carcinoma was the only histologic type for which an association was detected (RR 1.24; 95% CI 1.15-1.34). There were no significant differences in risk for ovarian cancer between talc users and non-users. In this meta-analysis resulted in a weak but statistically significant association between genital use of talc and ovarian cancer, which appears to be limited to serous carcinoma. The heterogeneity of results by study design and the lack of a trend for duration and frequency of use, however, detract from a causal interpretation of this association.

Differences in risk factor-colorectal adenoma associations according to non-steroidal anti-inflammatory drug use. Sobia Mujtaba, Roberd M. Bostick. Emory University, Atlanta, GA.

Multiple observational studies and large, randomized controlled trials indicate that non-steroidal anti-inflammatory drugs (NSAIDs) strongly reduce risk for colorectal neoplasms. The strengths of these findings suggest that NSAIDs may so markedly reduce risk of colorectal neoplasms, that they may be undetectable among NSAID users. Temporal changes and between-population differences in regular NSAID use prevalence may account for some of the inconsistencies in reported findings for risk factor–colorectal neoplasm associations. We investigated whether associations of known colorectal cancer risk factors with colorectal adenoma differed by non-aspirin NSAID use pooled data from 3 colonscopy-based case-control studies of incident, sporadic colorectal adenoma conducted in Minnesota, North Carolina, and South Carolina between 1991 and 2002. Participants (n=789 cases, 2,035 polyp-free controls) provided risk factor data prior to colonoscopy. The multivariable-adjusted odds ratios (OR) (95% confidence intervals [CI]) for those in the highest relative to the lowest quartiles of exposure, by regular non-aspirin NSAID non-use/use, respectively, were 1.57 (CI 0.96, 2.55) vs. 1.22 (CI 0.40, 3.70) for total fat, 1.37 (CI 0.86, 2.18) vs. 0.78 (CI 0.26, 2.35) for saturated fat, 0.92 (CI 0.67, 1.26) vs. 1.31 (CI 0.62, 2.76) for total calcium, 0.88 (CI 0.64, 1.22) vs. 1.38 (CI 0.65, 2.93) for total fruits and vegetables, 1.05 (CI 0.73, 1.50) vs. 0.73 (CI 0.33, 1.62) for red and yellow vegetables, and 0.97 (CI 0.60, 1.59) vs. 0.78 (CI 0.53, 1.14) for physical activity. For current smokers relative to never smokers, the ORs (CIs) among regular non-NSAID users/non-users were 2.88 (CI 2.20, 3.77) vs. 1.64 (CI 0.85, 3.17), respectively, and for those who were obese relative to those who were normal weight, they were 1.65 (CI 1.27, 2.16) vs. 1.20 (CI 0.70, 2.04). The associations of age, height, and intake of alcohol, dietary fiber, and total folate with adenoma incidence were not substantially different according to NSAID use. These findings suggest that regular non-aspirin NSAID use may mask, beyond simple confounding, associations of various risk factors with colorectal adenoma, suggesting that differential proportions of regular NSAID users between study populations may explain some inconsistencies in reported risk factor–colorectal neoplasm associations, and support routinely assessing such associations stratified by regular non-aspirin NSAID use.

Entacapone and prostate cancer patients with Parkinson’s disease: A large Veterans Health Administration study. Jacqueline M. Major,1 Francesca Cunningham,2 Diane Dong,2 Kuntel By,3 Kwan Hur,2 David C. Shih,1 Simone P. Pinheiro,1 Gerald D. Podaskalny,1 David J. Graham.1 *US Food and Drug Administration/CEDER/OSE, Silver Spring, MD; °US Department of Veterans Affairs, Hines, IL; †US Food and Drug Administration/CEDER/OB, Silver Spring, MD; ‡US Food and Drug Administration/CEDER/OND, Silver Spring, MD.

Background: An increased risk of prostate cancer was observed in Parkinson’s disease (PD) patients treated with entacapone during a pre-approval randomized clinical trial. Objective: To investigate a potential association between entacapone use and prostate cancer in an ambulatory setting. Methods: Using data from the Department of Veterans Affairs (VA) healthcare system, we tested the null hypothesis that usage of entacapone over the past 10 years was associated with an increased risk of prostate cancer in a sample of VA health-plan enrollees. A nested case-control study was conducted with a case-cohort design. We matched cases, defined as deceased prostate cancer patients, with a randomly selected cohort of prostate cancer-free enrollees from the VA cancer registry linkage. Cox proportional hazards regression was used to estimate HRs and 95% CIs for prostate cancer mortality among individuals receiving entacapone vs. non-users. Results: The joint model resulted in a HR of 1.57 (95% CI 1.06, 2.34) for prostate cancer mortality among entacapone users vs. non-users. Conclusions: Use of entacapone during a previous period of long-term exposure in PD patients was not associated with increased risk of prostate cancer.

Environmental pollutants and breast cancer: 2006-2016 epidemiological studies designed to evaluate biological hypotheses provide evidence of risk for certain pesticides, organic solvents, and products of combustion. Kathryn M. Rodgers, Julia O. Udesky, Ruthann A. Rudel, Julia G. Brody. Silent Spring Institute, Newton, MA.

Common environmental chemicals have plausible links to breast cancer because they are mammary gland carcinogens in animal studies or are known to activate relevant hormonal pathways or enhance susceptibility of the mammary gland to carcinogenesis. An institute of Medicine report prioritized human studies of these exposures. Yet the long latency and multifactorial etiology of breast cancer make evaluation of these chemicals in humans challenging, adding to the importance of study designs that are well-suited to capture hypothesized breast cancer mechanisms. With this in mind, we updated Brody et al.’s 2007 review in Cancer to evaluate the strength of the epidemiologic evidence for several classes of chemicals with widespread exposure. We conducted a systematic search of the PubMed database for articles published in 2006-2016 using 147 terms and the inclusion/exclusion criteria defined in Brody et al.’s 2007 review. We critically reviewed articles identified by our search, including whether study designs were suited to the biological evidence. We identified 158 new articles since 2006. In the past 10 years, the strength of evidence for an association between breast cancer and banned but persistent endocrine disrupting chemicals polychlorinated biphenyls (PCBs) and organochlorine pesticides has increased, based on a unique 50-year cohort study that captured exposure during potentially critical
windows for breast development (in utero, adolescence, pregnancy) and at the time when the chemicals were still in use. Studies that considered early life exposure to organic solvents and/or exposure of long duration also added to evidence for an association with breast cancer. Solvents are used in dry cleaning, electronics manufacturing, leather and fur processing, and metal, auto, textile, and some medical work. Other important reports included the National- 

#2305 Residential airborne heavy metal concentrations and breast cancer characteristics. Jacob K. Kresovich, Serap Erdal, Maria Argos, Hua Yun Chen, Peter H. Gann, Garr H. Rauscher. University of Illinois-Chicago, Chicago, IL.

Background: Ambient air metal concentrations have recently been implicated in the etiology of breast cancer. Previous studies have shown airborne concentrations of arsenic and cadmium are associated with the development of estrogen receptor-negative tumors. This study aims to replicate these findings and examine the role of other toxic and essential heavy metals. Methods: Participants were women who were diagnosed with breast cancer in Chicago between 2005 and 2008. We examined estrogen and progesterone receptor-negative (ER-/PR-) and high-grade tumors as markers of aggressive breast cancer, and estimated 15-year markers of exposure of 11 heavy metals. Exposures were calculated using census tract-level airborne concentrations from the National-scale Air Toxics Assessment and participants’ residential histories. We adjusted all models for socioeconomic status and reproductive factors. Results: We found that prevalent ER-/PR- tumors were associated with increased residential exposure to airborne concentrations of antimony (Q4 vs Q1: OR = 1.81; 95% CI: 0.95, 3.44; Ptrend = 0.04), cobalt (Q4 vs Q1: OR = 2.37; 95% CI: 1.26, 4.59; Ptrend < 0.01), manganese (Q4 vs Q1: OR = 2.55; 95% CI: 1.24, 5.24; Ptrend = 0.04), and selenium (Q4 vs Q1: OR = 1.85; 95% CI: 1.03, 3.29; Ptrend = 0.05), and also identified marginally significant trends for arsenic (Ptrend = 0.06), chromium (Ptrend = 0.08), lead (Ptrend = 0.08), and mercury (Ptrend = 0.07). We did not identify any overall associations with high-grade tumors, however when stratifying by menopausal status we found that antimony (Q4 vs Q1: OR = 6.97, 95% CI: 1.61-30.19) and arsenic (Q4 vs Q1: OR = 6.97, 95% CI: 1.61-30.19) were associated with prevalent high-grade tumors in premenopausal women only. Discussion: This study found further support for a role of airborne arsenic concentrations, and novel evidence implicating other airborne estrogen-pathway disrupting metal concentrations, in the development of aggressive breast cancer subtypes. Additionally, this is the first study to implicate heavy metal exposure in the etiology of high-grade tumors. The results suggest that long-term low-dose exposures to certain heavy metals play a role in the etiology of aggressive breast cancer characteristics. Airborne exposures have the ability to affect large populations and findings from this and similar studies have large public health implications.

#2306 Sleep duration and risk of fatal prostate cancer in CPS-I and CPS-II. Susan M. Gapstur, Victoria L. Stevens, Brian D. Carter, Ying Wang, Eric J. Jacobs. American Cancer Society, Atlanta, GA.

There is growing evidence that factors associated with circadian rhythm disruption may be associated with prostate cancer risk. In a previous analysis focusing on shift work in the Cancer Prevention Study (CPS-II) that included only employed men, we observed an association between short sleep duration and higher risk of prostate cancer death that was limited to the first eight years of follow-up of the cohort. To corroborate and expand on these results, we examined the association between sleep duration and death from prostate cancer in a combined analysis of men in CPS-II and men enrolled in an earlier cohort study, CPS-I, regardless of employment status. After excluding men with uninterpretable sleep information, prevalent cancer and prevalent prostate disease at baseline, the analysis included 407,649 men from CPS-I followed from 1950 through 1972, and 416,040 men from CPS-II followed from 1982 through 2012. During follow-up, 1,546 men in CPS-I and 8,704 men in CPS-II died of prostate cancer. Cox proportional hazards regression was used to estimate multivariable-adjusted relative risks (RR) and 95% confidence intervals (CI) and estimates were meta-analyzed using a fixed-effects model because the design and population of CPS-I and CPS-II were similar. Among men aged 65 years and younger, short sleep duration was associated with higher risk of death from prostate cancer during the first eight years of follow-up; compared to 7 hours/night, the RRs (95% CIs) for 5-3, and 6 hours/night were 1.61 (1.10-2.37), and 1.25 (0.99-1.58), 8 years of follow-up suggests that short sleep duration could affect later stages of prostate carcinogenesis. Reasons for lack of an association in older men are unclear but may include the marked decline in nocturnal melatonin levels with age, which could reduce the relative biologic impact of melatonin inhibition by sleep-deprivation.
caused the disintegration of preformed spheroids. Conclusion: This study indicates that targeting sigma-2 receptors with novel sigma-2 ligands (XYZ-XII-14 and XYZ-VII-69) effectively inhibits TNBC cancer cell growth by inducing apoptosis and cell cycle arrest, thus presenting a unique and effective pathway for treating TNBC. Additionally, the sigma-2 receptor ligands (XYZ-XI-14 and XYZ-VIII-69) are also effective in halting tumor growth and prevent tumor regression, as seen in our 3D culture assays. Thus, the sigma-2 receptor has the potential to be a valuable target for the development of novel agents for the treatment of TNBC.

**#2309 Acetylation of survivin represses transactivation of STAT3 to induce sodium butyrate-induced apoptosis in human mucopidermoid carcinoma cell lines.** Sung-Dae Cho, Seoul National University, School of Dentistry, Seoul, Republic of Korea.

Sodium butyrate (NaBu) is one of histone deacetylase inhibitors and possesses anticancer activity. Here, the aim of this study is to determine the molecular mechanism by which NaBu controls apoptosis in MC3 and Y151 human mucopidermoid carcinoma (MEC) cell lines. NaBu caused growth inhibition and induced apoptosis in both cell lines accompanied by the acetylation of histone proteins H2A and H3. NaBu clearly increased survivin and cleaved caspase 3 evidenced by human apoptosis array and it regulated survivin molecule at a post-transcriptional level. NaBu caused nuclear translocation of survivin protein and increased survivin acetylation in both cell lines. In addition, STAT3 and survivin were co-localized in nucleus by NaBu resulting in the decrease in the expression level of Bcl-xL mRNA which is one of STAT3 downstream molecules. In addition, NaBu induced caspase-dependent apoptosis in human MEC cells. Taken together, these results suggest that NaBu is a potent apoptosis inducer in human MEC cell lines through survivin-STAT3 signaling cascades and these findings provide the basis of its clinical application for the treatment of human MEC. This abstract is supported by SNU Invitation Program for Distinguished Scholar and the Basic Science Research Program through the National Research Foundation of Korea (NRF) funded by the Ministry of Education (2014R1A1A205874).

**#2310 Molecular dynamics simulation of permeation pathway of cytochrome C through Bax pore.** Mingzhen Zhang,1 Jie Zheng,1 Ruth Nussinov,2 Buyong Ma.1 University of Akron, Akron, OH; 2Leidos Biomedical Research, NCI-Frederick, Frederick, MD, USA.

How cytochrome C is released from the mitochondria to the cytosol via Bax oligomeric pores, a process which is required for apoptosis, is still a mystery. Based on the residue-residue distances detected experimentally for Bax and its homologous protein (Bak), we recently computationally solve the first atomic model for Bax oligomeric pores at the membranes. Next, we investigate the mechanism at the microscopic time- and nanometer space-scale using coarse-grained replica exchange and all-atom MD simulations. Our free energy landscape depicts a low barrier for the permeation of cytochrome C into the Bax C-terminal mouth, with the pathway proceeding to the inner cavity and exiting via the N-terminal mouth. Release is guided by organized charged/hydrophobic surfaces. The hydrophilicity and negative charge of the pore surface gradually increase as the pore depth increases. The pore entry path is the preferred one. Rather than inert passing of cytochrome C through a rigid pore, the flexible pore may selectively aid the cytochrome C passage. The energy barrier is under 4 kcal/mol. Thus, once the Bax pore is formed in the membrane, the release of cytochrome C may be readily achieved through energy fluctuations. Collectively, our work provides mechanistic insight and atomic detail into the release of cytochrome C through Bax oligomeric pores.

Cupredoxins are a family of low-molecular weight, water soluble, copper-containing redox proteins involved mainly in the electron transfer chain in prokaryotes. Auracycin is a member of the cupredoxin family secreted by Pseudomonas aeruginosa, of which a 28-amino acid sequence (p28) was identified to acquire the capability of preferential entry into cancer cells of various histogenesis. Upon entry, it exerts a cytostatic effect in these cancer cells via a p53-mediated pathway. Our aim was to study whether the other members of the cupredoxin family possess a similar function to that of auracin in the eukaryotic cancer cells. Based on structural and sequence analyses, helical regions of auracycin A & B were shown to resemble p28 closely. Thus, we studied the biologic function of two 28-amino-acid peptides derived from auracycin A (aurA; pl 4.5, MW 2.6 kD), and auracycin B (aurB; pl 3.4, MW 2.7 kD). Cancer growth and MTT assays demonstrated that aurB, but not aurA, induced cytotoxicity in various cancer cell lines in a dose-dependent (range 0.1uM-100uM) and time-dependent (~72 hours) pattern, including p53-null (prostate cancer PC-3) and dn-p53 (breast cancer MDD-2 and ovarian cancer SKOV-3) in which p28 did not demonstrate a significant growth inhibition. Annexin-V assays showed that a dose-dependent apoptosis in prostate cancer cell lines of various p53 statuses (wt-p53 LNCaP, mut-p53 DU-145, p53-null PC-3) following treatment with aurB at 5-50uM for 48 hours, whereas p28 did not demonstrate an apoptotic activity in p53-null cell lines, suggesting an aurB-induced apoptosis via a p53-independent pathway. In contrast, aurA did not appear to induce apoptosis in any of the above cell lines. Induction of apoptosis was mediated through depolarization of the mitochondrial membrane and caspase cascade activation in cancer cells. Moreover, fluorescence microscopy demonstrated that aurB, unlike p28, does not acquire a similar pattern of preferential entry into cancer cells. This proposes that aurB acquires the potential as an anticancer cell penetrating peptide, and differs from p28 in its mode of entry and p33-mediated action. Our studies pertaining to auracin and auracycin, suggest that cupredoxins, as a family of prokaryotic metalloproteins, may represent a novel family of antineoplastic agents against various cancer cell lines.

**#2312 Feasibility study of a fractionation method in the treatment of tumor treating fields.** Yunhui Jo,1 Jiwon Sung,1 Hyo Sook Song,2 Eun Ho Kim,3 Myounggeun Yoon.1 1Korea University, Seoul, Republic of Korea; 2Korea Institute of Radiological and Medical Sciences, Seoul, Republic of Korea; 3University of Illinois at Chicago, Chicago, IL.

Tumor treating fields (TTFs) using a fractionated treatment scheme originally designed for radiotherapy were applied to cancer (Human glioblastoma, U373) and normal cells (intestinal epithelial, IEC-6) for three days with durations of 3, 6, 9, or 24 hours/day. As the treatment time of TTFs increases from 3 to 24 hours/day, the relative cancer cell growth rates in both cell lines were reduced. While the difference in cancer cell growth rate compared to control was ~25% (decreased from 100% to ~75%) for the treatment time of 6 hours/day, the growth rates of cells treated for additional 6 hours (i.e., 12 hours/day) and additional 18 hours (i.e., 24 hours/day) differed only ~5% and ~8% from that of cells treated for 6 hours/day, respectively. Our results suggested that the dependence on treatment time in cancer cell inhibition is weakened distinctively at treatment times over 6 hours/day. For normal cells, the relative growth rates corresponding to the treatment time of TTFs was not decreased much for the treatment time of 3, 6, 12 hours/day revealing 93.3%, 90.0%, 89.3% of cell growth rates compared to control, respectively, but it suddenly reduced to ~73% for 24 hours/day of treatment. The experimental results indicated that the effects of TTF on growth rate of cancer cells are higher than the effects of TTFs on growth rates of normal cells for treatment times of 3-12 hours/day, but the difference became minimal for treatment times of 24 hours/day. Our results suggest that the fractionated scheme in the treatment of tumor treating fields may reduce treatment time while maintaining efficacy, suggesting that this method can increase patients’ quality of life.

**#2313 Promoting caspase-8-dependent apoptosis signaling using 17-beta-hydroxywithanolides.** Alan D. Brooks,1 Ya-ming Xu,2 E. M. Kithsiri Wijeratne,2 Curtis J. Henrich,1 Poonam Tewary,1 Leslie Gunatilaka,2 Thomas J. Sayers,1 1Frederick National Laboratory for Cancer Research, Frederick, MD; 2The University of Arizona, Tucson, AZ.

We have previously reported that withanolide E (WE), a steroidal lactone from Physalis peruviana, was highly active in sensitizing various human carcinoma cell lines to TRAIL-mediated apoptosis. Therefore, over 100 natural and semi-synthetic withanolides were evaluated for their ability to promote caspase-8-dependent cancer cell death. Our studies identified several withanolides that were 4-8 fold more potent than WE in sensitizing the renal carcinoma cells and melanoma cells to caspase-8-dependent apoptosis in response to either TRAIL or the TRAIL ligand body (TTF). All active withanolides were 17-beta-hydroxy withanolides (17-BHW). The highly active 17-BHWs were more efficient than withanolide E at reducing cellular levels of both cFLIP, and cFLIP, and enhancing caspase-8 activation. Furthermore, immunoprecipitation of the TRAIL death-inducing signaling complex (DISC), or the related ripoptosome, demonstrated enhanced levels of both FADD and RIP1 in these macromolecular apoptotic signaling complexes following treatment with active 17-BHWs. The 17-BHWs used in this work were obtained by the application of an efficient method of plant biomass production involving our innovative and patented soil-less aeroponic cultivation of P. crassifolia and P. peruviana and by chemical modification of natural withanolides produced by these plants. Preliminary structure
activating relationship (SAR) studies suggested that the enone moiety in ring A was essential for activity. In addition, acetylation at C-18, an alpha orientation of the side-chain lactone group and the double bond at C-24(25) of the lactone ring played important roles in determining the activity of 17-BHWS as apoptosis sensitizers. This suggests that the 17-BHW scaffold is amenable to optimization to develop novel chemical entities—miR-147h-miRNA-based screen showed a significant pro-apoptotic induction in the various ovarian cancer cell lines alone and in combined therapy with carboplatin. Western Blot analysis revealed an enhanced expression of the pro-apoptotic proteins Bak1 and Bax and a decrease in Bcl-2 and Bcl-xL. We characterized the miRNAs in regard to their endogenous expression and detected an enhanced expression after apoptosis induction by chemotherapeutic drugs.

**#2314 Novel BH3 mimetic based therapeutic strategies for the treatment of breast cancer.** Zachary Kratche, MacKenzie Adams, Robert Wilson, Stephen Ehier, Stephen Guest. Medical Univ. of South Carolina, Charleston, SC.

Bcl-2 homology domain 3 (BH3) mimetics are a new class of targeted anti-cancer compounds that function by inducing cancer cell apoptosis. Testing in a variety of pre-clinical tumor models has shown that BH3 mimetics are capable of inducing remarkable tumor regressions. Recently, a clinical trial of the BH3 mimetic venetoclax in Chronic Lymphocytic Leukemia (CLL) resulted in an impressive response rate of 80% leading to FDA approval. Using unbiased genomic and functional genomic approaches, we identified gene amplification of the BCL2L1 gene, which encodes the anti-apoptotic protein BCL-XL, as a novel driver event in breast cancer. We identified focal amplification of the BCL2L1 gene in the SUM-185 breast cancer cell line and a genome-wide RNAi-based screen identified BCL2L1 as one of the top genes necessary for viability of this cell line (ranked 5th out of 15,256 genes). Treatment of SUM-185 cell lines with low doses of navitoclax showed that these cells are intrinsically sensitive to this drug (IC50 = 100nM). This sensitivity was 1-2 logs greater than what was observed for breast cancer cell lines that do not harbor BCL2L1 gene amplification. To expand the relevance of these findings beyond the SUM-185 cell line, we used the cancer cell line encyclopedia (CCLE) database to identify an additional breast cancer cell line, HCC38, that also harbors a focal BCL2L1 gene amplification. Treatment of HCC38 cells with navitoclax revealed a high level of sensitivity that was equivalent to that of SUM-185 cells. These findings demonstrated that a subset of breast cancers that harbor BCL2L1 gene amplification are highly sensitive to a BH3 mimetic that targets BCL2L1 suggesting that BH3 mimetics could be used as a single agent to effectively treat these breast cancers. We also examined the effectiveness of BH3 mimetics when used as part of a combination therapy approach. In addition to a focal amplification of the BCL2L1 gene, the SUM-185 breast cancer cell line also harbors a focal amplification of the fibroblast growth factor receptor 3 (FGFR3) gene as well as an activating mutation in the phosphatidylinositol-4,5-bisphosphate 3-kinase catalytic subunit alpha (PIK3CA) gene. Treatment of SUM-185 cells with low doses of navitoclax, a FGFR inhibitor, or a PIK3CA inhibitor had little effect on colony forming efficiency. At these same low doses, combined treatment with navitoclax and the FGFR inhibitor or the PIK3CA inhibitor resulted in a strikingly synergistic effect with near complete loss of colony forming ability (less than 10% of controls). We further showed that this loss of clonogenicity was the result of a rapid induction of apoptosis by the combination therapies. These results suggest that combining BH3 mimetics with inhibition of FGFR or PIK3CA is a promising novel therapeutic strategy for a subset of breast cancer patients.

**#2315 Overcoming treatment resistance in cisplatin-resistant ovarian carcinoma cells by tissue-specific miRNAs.** Michael Kleemann, ¹Jermes Bereuth, ¹Simon Fischer, ¹Kim Marquart, ¹Simon Hänle, ¹Kristian Unger, ¹Verena Jendressek, ¹Christian U. Riedel, ¹René Handrick, ¹Kerstin Otte, ¹University of Applied Sciences Biberach, Biberach, Germany; ²Boehringer Ingelheim, Biberach, Germany; ³Heinholz Zeitschrif München, München, Germany; ⁴University of Essen, Essen, Germany; ⁵University of Ulm, Ulm, Germany.

Ovarian cancer is a common human cancer with a poor outcome and a high risk of death. Due to resistances to current standard therapies (carboplatin and paclitaxel for 5 to 6 cycles) additional therapeutic approaches are required and novel specific biomarkers for ovarian cancer patients are necessary. MicroRNAs (miRNA) are conserved, small non-coding RNAs regulating gene expression by binding to their target mRNA which have been shown to regulate biological processes including apoptosis. Apoptosis is a irreversible process that allows cells to undergo a highly regulated form of cell death. However, the final role of miRNAs in apoptotic signaling has not yet been fully determined. Modulating the expression of key molecular components of the cell death machinery is an attractive strategy for cancer therapy overcoming chemo drug resistance. To extend the pool of potential miRNA as anticancer agents and biomarkers, we transferred a high content miRNA screening for pro-apoptotic miRNAs to human cancer cell lines. Based on the high recovery rate of apoptosis inducing miRNAs in SKOV3 cells analyses were extended to multiple ovarian carcinoma cell lines with different genetic background. After transfection of miR-1912-5p the apoptosis rate increased strongly in cisplatin-resistant cells. In combination treatment with carboplatin the apoptotic effect increased after transfection of miR-1912-5p in the cisplatin-resistant A2780 cells. Furthermore, we applied a tissue-specific miRNA approach shown to the identification of highly active natural product-based sensitizers of cancer cells to caspase-8-dependent apoptosis. The cellular molecular target(s) of active 17-BHWS are currently under further investigation. Funded by FNL- Contract HHSN26120080001E.

**#2316 Elevated H-Ras suppresses death receptor-mediated apoptosis in cancer cells.** Su-Byun Kim, FDA, Silver Spring, MD.

TNF-related apoptosis inducing ligand (TRAIL) induces apoptosis through its death receptors (DRs) 4 and/or 5 expressed on the surface of target cells. Despite its selectivity in killing cancer cells over most normal cells, recombinant human TRAIL or its receptor agonists (monoclonal antibodies against DR4 or DR5) encountered resistance in many tumor cells while the underlying mechanisms remain to be systematically upregulated in TRAIL-resistant cells compared to TRAIL-sensitive cells. The elevated H-Ras expression correlated with a deficiency of DR4 and DR5 on plasma membrane in TRAIL-resistant cell lines. Notably, knockdown of H-Ras in TRAIL-resistant cells successfully restored the surface expression of DR4 and DR5, thereby sensitizing the cells to TRAIL-induced apoptosis. Consistently, ectopic expression of H-Ras in TRAIL-sensitive cells reduced surface DR4 and DR5 which was associated with a loss of TRAIL sensitivity. By contrast, the status of K-Ras or its mutations was not causally linked to TRAIL receptor expression or TRAIL sensitivity across the panel of cancer cell lines tested. These data suggest that H-Ras may play a distinct role to negatively regulate TRAIL receptors and apoptosis. The upregulated H-Ras could be a predictor of tumor resistance to TRAIL-targeted agents and a potential therapeutic target for combinatorial therapy to achieve better treatment outcomes.

Prostaglandin E2 (PGE2) has been reported to play critical roles in cell fate decisions by interacting with 40 types of G protein-coupled membrane receptors such as EP1, EP2, EP3 and EP4. We previously reported that EP4 stimulation by treatment with its agonist CAY10598 induced apoptosis via reactive oxygen species (ROS) formation in colon cancer HCT116 cells. Moreover, treatment with CAY10598 diminished the phosphorylation of JAK2 and induced degradation of this oncoprotein, leading to the attenuation of STAT3 activation in HCT116 cells. In the present study, we attempted to delineate the molecular mechanisms underlying the degradation of JAK2 by activation of EP4. HSP90, a member of the heat shock protein family, is a molecular chaperone that supports stability of client proteins, such as EGFR, MET, Akt and JAK2. HSP90-mediated stabilization/activation of these client proteins contributes to the acquisition of cancer cell hallmarks, including proliferation, survival, angiogenesis and invasion. It has been recently reported that the chaperoning function of HSP90 may be disrupted by post-translational modification induced by oxidative stress. Treatment of human colon cancer HCT116 cells with CAY10598 down-regulated expression of HSP90 client proteins in a concentration- and time-dependent manner and the down-regulation was restored by pretreatment with ROS scavenger N-acetyl cystine (NAC) or proteasome inhibitor MG132. However, cotreatment with cycloheximide, protein synthesis inhibitor, accelerated the CAY10598-induced degradation of HSP90 client proteins. These data suggest that CAY10598-induced HSP90 client protein degradation may be caused by ROS generation. In renal carcinoma Caki cells, CAY10598 also down-regulated expression of HSP90 client proteins, suggesting that EP4 stimulation may regulate HSP90 activity in colon cancer cells as well as renal cancer cells. We found that HSP90α was cleaved to 40 or 55 kDa, while HSP90β was cleaved to 25 kDa by CAY10598 treatment and the cleavage of HSP90α and β was blocked by NAC treatment. Furthermore, EP4 inhibition by treatment with antagonist GW627368x attenuated not only degradation of HSP90 client proteins but also cleavage of HSP90 in CAY10598-treated HCT116 cells. In conclusions, EP4...
agonist CAY10598 induces degradation of HSP90 client proteins via ROS-dependent HSP90 cleavage, leading to apoptosis in HT116 cells. This is a novel mechanism by which EP4 activation induces apoptosis of cancer cells that involved inhibiting HSP90 function.

#2318 Cyclopamine sensitizes endoplasmic reticulum stress-mediated increase of death receptor 5 and survivin degradation in the resistant gastric cancer cells. Yoo Jin Na, Dae-Hee Lee, Jung Lim Kim, Bo Ram Kim, Seong Hye Park, Min Jee Jo, Yoon A Jeong, Sang Cheul Oh. Korea University, Seoul, Republic of Korea.

Tumor necrosis factor (TNF)-related apoptosis-inducing ligand (TRAIL) has been known as one of the most effective cancer treatment owing to its selective killing effect of cancer but not normal cells. However it has been reported that several gastric cancer cells showed resistance to TRAIL because of scarcity of death receptor 5 (DR5) expressed on the cell surface. In this study, we elucidated cyclopamine sensitizes to TRAIL-induced apoptosis by elevating the expression level of DR5 in gastric cancer cells. Interestingly, survivin hampers existence of death receptor 5 (DR5) protein under normal condition. Cyclopamine decreases expression level of survivin. It is a reason for cyclopamine to act as a TRAIL sensitiser. Mechanistically, cyclopamine induces endoplasmic reticulum (ER) stress by Reactive Oxygen species (ROS), and CHOP, which as a last protein of ER stress pathway regulates stability of survivin protein by proteasome degradation. Taken together, our results indicate that cyclopamine can be used for the purpose of combination therapy in TRAIL-resistant gastric cancer cells.

#2319 Deficiency of protease-activated receptor 2 signaling sensitizes EGFR-TKI-induced apoptosis in colorectal cancer. Weiwei Li, Yiming Ma, Longmei He, Hongying Wang. National Cancer Center/Cancer Hospital, Chinese Academy of Medical Sciences and Peking University Medical College, Beijing, China.

Colorectal carcinoma (CRC) patients show resistance to EGFR-TKI (epidermal growth factor receptor-tyrosine kinase inhibitor) treatment. Protease-activated receptor 2 (PAR2) has been shown to transactivate EGFR. We aim to investigate whether PAR2 sensitizes EGFR-TKI-induced apoptosis in CRC. Firstly, inhibition of PAR2 with shRNA or ENMD-1068 (a selective antagonist of PAR2) significantly sensitized EGFR-TKI (gefitinib or AG1478)-induced apoptosis, which was measured with Annexin V/PI staining and activation of caspase-3 in different CRC cell lines. In xenograft tumor model, gefitinib treatment dramatically reduced the tumor volume in HT-29-shPAR2 compared with HT-29-vector. Mechanism study showed that PAR2 knockdown significantly reduced bcl-xL expression at both mRNA and protein level. Consistently, activation of PAR, upregulated bcl-xL. Furthermore, inhibition of protein phosphatase (PP) with okadaic acid significantly downregulated bcl-xL. Moreover, knockdown of PP1 with shRNA blocked PAR-regulated induction of bcl-xL. In summary, our findings suggest that inhibition of PAR2 sensitizes EGFR-TKI-induced apoptosis via downregulation of bcl-xL in colorectal cancer. Considering the extensive expression of PAR2 and PAR2-activating proteases in colon, it strongly indicates that inhibition of PAR2 may be a potential avenue to overcome EGFR-TKI resistance in patients with CRC.

Objective: We examined whether curcubitacin D affects doxorubicin resistance of MCF7/ADR breast cancer cells. Methods: Cell viability was measured by MTT assay. Levels of p-STAT3, p-NF-κB, 1bB, and caspases were measured by western blot analysis. Nuclear staining of Stat3 and NF-κB was measured by immunocytochemistry. STAT3 and NF-κB transcriptional activity was detected by STAT3 and NF-κB luciferase reporter gene assays. Analysis of cell cycle arrest was performed by flow cytometry. Induction of apoptosis by curcubitacin D was measured by annexin V/FITC/PI assay. Results: More than 90% of MCF7/ADR cells lived upontreatment with doxorubicin for 24 h. However, upon treatment with curcubitacin D, cell death was more than 60%. Co-administration of curcubitacin D and doxorubicin induced apoptosis, G2/M cell cycle arrest, and inhibited upregulated Stat3 by doxorubicin on MCF7/ADR cells. Additionally, curcubitacin D led to an increase in the IκBα level in the cytosol and a decrease in the p-NF-κB level in the nucleus. Finally, curcubitacin D inhibited translocation of Stat3 and NF-κB and decreased transcriptional activity in the nucleus. Conclusion: Curcubitacin D decreases cell proliferation and induces apoptosis by inhibiting Stat3 and NF-κB signaling in doxorubicin-resistant breast cancer cells. Curcubitacin D could be used as a useful compound to treat Adriamycin-resistant patients.

#2321 Reactive oxygen species dictate the apoptotic response of melanoma cells to TH588. jiayu wang, Jin Lei, Xu Guang yan, Simonne Sherwin, Margaret Farrelly, Yuan Yuan Zhang, Fen Liu, Chuan Yan Wang, Su Tong Guo, Hamed Yari, Ting La, Jennifer McFarlane, Fu Xi Li, Hessay Tabatabaee, Ji Zhong Chen, Amanda Croft, chen cheun Jiang, Xu Dong Zhang. Life sciences building, Newcastle, Australia.

Cancer cells commonly contain elevated levels of reactive oxygen species (ROS) resulting from oncogenic stimulation. On one hand, ROS promote cancer cell survival, proliferation, and metastasis. On the other, high levels of ROS suppress tumour growth through inhibition of proliferation and induction of apoptosis and senescence via damage to DNA. Incorporation of oxidized dNTPs such as 8-oxo-deoxyguanine (8-oxo-dGTP) and 2-OH-deoxynucleosine (2-OH-dATP) into genomic DNA plays an important role in apoptosis induced by ROS. Human MutT homolog 1 (MTH1) is an enzyme that sanitizes oxidized dNTP pools through converting 8-oxo-dGTP and 2-OH-dATP into monophosphates, thus preventing their incorporation into genomic DNA. Inhibition of MTH1 by small molecule inhibitors has been suggested as a promising strategy to improve cancer treatment. However, we have found that while silencing of MTH1 does not affect survival of melanoma cell, TH588, one of the first-in-class MTH1 inhibitors, kills melanoma cells through apoptosis independently of its inhibitory effect on MTH. Induction of apoptosis by TH588 was not alleviated by MTH1 overexpression or introduction of the bacterial homologue of MTH1 that has 8-oxoGTPase activity but cannot be inhibited by TH588, indicating that MTH1 inhibition is not the cause of TH588-induced killing of melanoma cells. Although knockdown of MTH1 did not impinge on the viability of melanoma cells, it rendered melanoma cells sensitive to apoptosis induced by the oxidative stress inducer elesclomol. Of note, treatment with elesclomol also enhanced TH588-induced apoptosis, whereas a ROS scavenger or an antioxidant attenuated apoptosis triggered by TH588. Indeed, the sensitivity of melanoma cells to TH588 was correlated with endogenous levels of ROS. Collectively, these results suggest that: 1) TH588-induced apoptosis of melanoma cells is not associated with its inhibitory effect on MTH1; 2) TH588 remains a promising candidate for the treatment of melanoma; 3) MTH inhibition in combination with oxidative stress inducers may be a useful approach in melanoma treatment; and 4) the endogenous levels of ROS are a potential biomarker for prediction of the response of melanomas to TH588 and MTH1 inhibition in combination with oxidative stress inducers.

#2322 Antitumor activity of spicatoside A, a steroidal saponin, via induction of switch from autophagy to apoptotic cell death. Won Kyung Kim, Yuna Pye, Hyen Joo Park, Ji-Young Hong, Sang Kook Lee. Seoul National University, Seoul, Republic of Korea.

The antitumor activity of spicatoside A (SA), a steroidal saponin isolated from the tuber of Lirioper platyphylla (Liliaceae), and its underlying mechanisms were investigated in HCT116 human colorectal cancer cells. SA induced autophagy and apoptotic cell death and inhibited tumor growth in a nude mouse xenograft model implanted with HCT116 cells. Treatment with SA for 24 h enhanced the formation of acidic vesicular organelles in the cytoplasm, indicating the induction of the onset of autophagy. This event was associated with the regulation of autophagic markers including microtubule-associated protein 1 light chain 3 (LC3)-II, p62, beclin 1, lysosomal-associated membrane protein 1, and cathepsin D by inhibiting the PI3K/Akt/mTOR signaling pathway, regulating mitogen-activated protein kinase signaling, and increasing p53 levels. However, a prolonged exposure to SA resulted in apoptosis characterized by the accumulation of a sub-G1 cell population and an annexin V/propidium iodide-positive cell population. Apoptosis induced by SA was associated with the regulation of apoptotic proteins including Bcl-2, Bax, and Bid, the release of cytochrome c into the cytosol, and the accumulation of cleaved poly (ADP-ribose) polymerase (PARP). Further study revealed that cleavage of beclin 1 by caspase-8 plays a critical role in the SA-mediated switch from autophagy to apoptosis. Taken together, these findings highlight the significance of SA in the modulation of crosstalk between autophagy and apoptosis, as well as the potential use of SA as a novel candidate in the treatment of human colorectal cancer cells. Acknowledgement: This work was supported by a National Research Foundation of Korea (NRF) grant funded by the Korean Government (MEST) (No. 2009-0085533).
The inhibitory role of Kaempferol-3-O-rutinoside induced AMPK activation on the growth of human breast cancer cell lines. Chea Ha Kim.

Solvado virginia-aurea, herbaceous perennial plant of the family Asteraceae, has astrigenic, diuretic, and antiisipetic assets. In our current study, we found that kaempferol (3,7,4-trihydroxy-4,7-dimethoxyflavone) from Solvado virginia-aurea extract prompted cellular apoptosis in breast cancer cells. The present study was conducted to investigate its effects on MCF-7 cells with respect to the induction of inhibitory effect on cell viability against MDA-MB-231 and MCF-7 breast cancer cell lines. In addition, apoptotic protein, especially Bim, was also increased in KR treated MDA-MB-231 and MCF-7 cell line. However, an anti-apoptotic protein, Bcl-xl, was not changed by KR. To find out positive regulator of Bim expression, FOXO3a (forkhead-box transcription factor, group O) 3a and AMPK (5’ AMP-activated protein kinase) protein expressions were examined in KR treated cells. Immunoblot analysis showed dramatically increased expressions of FOXO3a and AMPK in KR treated MDA-MB-231 and MCF-7 cells. In addition, cell cycle analysis indicated that G0/G1 arrest was intensely increased in KR treated MDA-MB-231 and MCF-7 cells. Moreover, phospho-AMPK (pT172) and phospho-FOXO3a (S472) expression were also increased in KR treated MDA-MB-231 and MCF-7 cells. Our results suggest that KR induces apoptosis by AMPK-FOXO3a mediated Bim expression. The mechanisms of KR mediated AMPK and FOXO3a regulation is not fully elucidated yet, but further studies about these molecular mechanisms between two proteins will give some ideas for cancer therapies for certain breast cancer patients.

The role of SERCA pump in cell death and autophagy. Paula Szalai,1 Morten Løhr,1 Frank Sætre,1 Søren B. Christensen,2 Jesper V. Møller,3 Poul Nissen,3 Nikolai Engedal,1 University of Oslo, Oslo, Norway;1University of Copenhagen, Copenhagen, Kopenhagen, Denmark;3University of Aarhus, Aarhus, Denmark.

The purpose of the study is to elucidate structural and molecular determinants of SERCA inhibition by Thapsigargin (Tg) and related analogs for their effects on intracellular calcium homeostasis, ER stress, cell death and autophagy. Tg specifically binds and blocks the sarco/endoplasmic reticulum Ca2+ ATPase (SERCA), which pumps Ca2+ from the cytosol to the ER. Sustained SERCA inhibition leads to calcium depletion from the ER causing ER stress and ultimately cell death. Recently we showed that Tg-induced calcium perturbation potently blocks autophagy (1). Tg is an attractive potential anti-tumor drug because it effectively kills both slow and fast proliferating cancer cells. However, since Tg is toxic also to normal cells, it must be targeted towards the cancer cells. Replacing a side chain with a linker connecting the Tg core to a peptide prevents Tg from entering cells. Two different linker-peptide sequences have been introduced in clinically tested Tg prodrugs; one is cleaved by PSA, secreted by prostate cancer cells, and the other is cleaved by PSMA, which is secreted by neovascular tissues of a broad range of tumors. The Tg analogs unmasked by the cleavage are able to enter cells and exert their toxic effects. Interestingly, however, in vitro experiments indicate that Tg analogs have different potencies and cellular effects depending on the terminal amino acid residue (2). Exploring why this is the case may lead not only to better Tg prodrug formulations, but also to a deeper understanding of the biological functions of SERCA pump activity. We compare a broad panel of Tg analogs in various cell types for their biological effects. Methods used so far are western blotting, real-time RT-PCR, live-cell imaging, flow cytometry, and assays that measure autophagic sequestration and degradation activity. Our unpublished data indicate the ER-stress sensors PERK, ATF4, CHOP, and IRE1 but not XBP1 and ATF6 to be involved in cell death signaling in LNCaP prostate cancer cells. Moreover, Tg-induced cell death required death receptor 5 and caspase-8. All Tg analogs tested displayed exactly the same molecular requirements for induction of cell death, although some required 5 to 10 times higher doses than Tg to evoke the same strength of death signal. Like Tg (1) the analogs inhibited autophagy before the closure of phagophores, but at higher doses and/or with slower kinetics. These results indicate that thapsigargin and its analogs evoke similar anti-autophagic and death signaling pathways. Further investigations are aimed at exploring the causes for differential potencies, and include measurements of cytosolic and compartmentalized calcium, as well as solving crystal structures of selected analog:SERCA complexes complemented with biophysical studies of analog:SERCA interactions. Deconstruction of circulating tumor cells by fluid shear stresses generated in a microfluidic system. Sagar Regmi,1 Aft Fu1, Yabin Li,2 Kathy Qian Luo,3 Nanyang Technological University, Singapore; Singapore; 2University of Macau, Taipa, Macau, China; 3Macao, China.

Sargopregimel-3-O-rutinoside induced AMPK activation on the growth of human breast cancer cell lines. Chea Ha Kim.

Circulating tumor cells (CTCs) are mainly responsible for the cause of cancer metastasis. Although most CTCs can be destroyed by the bloodstream, some of them can still manage to withstand hemodynamic shear stress in blood stream. To study the effects of fluidic micro-environment on CTCs, we designed a microfluidic system that can produce various levels of shear stress which can be operated in human artery undergoing or exercise condition. We also generated three human breast cancer cell lines with increased ability to form lung metastases in nude mice (i.e. 213-M1A > 231-M1 > 231-C3). All three cell lines can produce a fluorescence resonance energy transfer (FRET)-based sensor which can reveal apoptosis in real-time by changing its color from green to blue. Besides these, we also investigated the effects of shear stress on multiple types of cancer cells including lung cancer (A549), ovarian cancer (2008), breast cancer (UAJC-893) and leukemia (K562). For all the cell lines, except the non-attached K562 cells, cells were cultured on petri-dishes, detached by trypsinization and re-suspended in a normal culture medium to a cell density of 2x10^6 cells/ml. One milliliter of this cell suspensions was circulated in our microfluidic system under the shear stresses of 15, 30, 45 and 60 dyne/cm^2 for 2-18 h. The effects of shear stress on morphology and viability of CTCs were determined by FRET imaging microscopy and MTT assay. And the impact of shear stress on causing necrosis in CTCs were examined by propidium iodide (PI) staining and LDH assay. Our findings are summarized below: 1) High shear stress (SS60, 4h) is more potent to destroy CTCs than low shear stress (SS15, 4h). 2) High shear stress can destroy most of the CTCs via necrosis. 3) This high level of shear stress is theoretically achievable via physical exercise. Additionally, the findings that high shear stress is more resistant to high shear stress compared to less metastatic 231-C3 cells. 5) Leukemia K562 cells representing the white blood cells showed stronger resistance to high shear stress compared to the cancer cells tested in this study. We think these findings can help people to understand how metastatic CTCs resist shear force-induced cell death which are useful for designing more effective therapies against metastatic CTCs. Additionally, the findings that high shear stress is more effective to kill CTCs may inspire cancer patients to consider exercise as a way to increase their hemodynamic shear stress, consequently destroy CTCs and prevent cancer metastasis.

A high-throughput screen identified cancer selective small molecules that kill independent of mitochondrial apoptosis. Catrina M. Dowl- ing,1 Michæl Heßmann,1 James Bradner,2 Anthony Letai,3 Triona Ni Chonghaile1,5 Royal College of Surgeons, Dublin, Ireland;2Koch Institute for Integrative Cancer Research at MIT, Massachusetts Institute of Technology, MA;3Dana Farber Cancer Institute, Harvard Medical School, Department of Medical Oncology, MA;4Dana-Farber Cancer Institute, Boston, MA.

Triple negative breast cancer (TNBC) lacks expression of oestrogen receptor (ER), progesterone receptor (PR) and human epidermal growth factor 2 (HER2). Importantly, there have been fewer advances in the treatment of TNBC with the mainstay of treatment being cytotoxic chemotherapy. All too often tumor responses poorly to chemotherapy, or relapse and resistance follow. We recently found that thapsigargin and its analogs evoke similar anti-autophagic and death signaling effects. Methods used so far are western blotting, real-time RT-PCR, live-cell imaging, flow cytometry, and assays that measure autophagic sequestration and degradation activity. Our unpublished data indicate the ER-stress sensors PERK, ATF4, CHOP, and IRE1 but not XBP1 and ATF6 to be involved in cell death signaling in LNCaP prostate cancer cells. Moreover, Tg-induced cell death required death receptor 5 and caspase-8. All Tg analogs tested displayed exactly the same molecular requirements for induction of cell death, although some required 5 to 10 times higher doses than Tg to evoke the same strength of death signal. Like Tg (1) the analogs inhibited autophagy before the closure of phagophores, but at higher doses and/or with slower kinetics. These results indicate that thapsigargin and its analogs evoke similar anti-autophagic and death signaling pathways. Further investigations are aimed at exploring the causes for differential potencies, and include measurements of cytosolic and compartmentalized calcium, as well as solving crystal structures of selected analog:SERCA complexes complemented with biophysical studies of analog:SERCA interactions. Melanoma is the most dangerous type of skin cancer, which mostly related with the exposure of ultraviolet (UV), and especially happened to those who have low skin pigment levels. Epidemiological studies showed Europeans and North Americans have a high incidence of melanoma, while it is less common in Asia and Africa. Therefore, the new and more effective methods to treat melanoma are urgently needed. Non-thermal atmospheric pressure bio-compatable plasma (NBP) is defined as a partially ionized gas with electrically charged particle, which has been reported have cytotoxicity on various cancer cells induce DNA damage and apoptosis other than normal cells. Reactive oxygen and/or nitrogen species (RONS) were proved to play the most important role during this process, by inducing oxidative stress and depolarization of mitochondrial membrane potential with the consequence of various cancer cells apoptosis. The plasma activated media (PAM), which the media treated directly by NBP with different time, containing mostly long-live secondary species such as hydrogen peroxide (H2O2) which have been confirmed anti-microorganism and cytotoxic activity. Researches already investigated that PAM also effective in cancer therapy via inducing apoptosis. However, the underlying molecular mechanisms of apoptosis are remaining elusive. The purpose of this study was to evaluate the potential of PAM as an effective tool to induce apoptosis in melanoma cells. Our results showed that PAM has a killing effect to melanoma cells in a time-dependent manner, for 3minutes treatment could induce almost 40% cells entry death, after treated by 5 minutes more than 60%, and 10 minutes treatment reduced the cell viability to approximately 30%. Annexin-V/PI staining demonstrated that PAM overexpression with strong apoptosis pathway and found that with a manner of treatment time PAM significantly increased the concentration of intracellular NO and H2O2, reflecting an influx of extracellular RONS may result in melanoma cells apoptosis. Besides, western blot assay showed that P53 and caspase 3 increased after PAM treatment. Taken together, PAM is effective to induce the apoptosis in melanoma cells in vitro, further in vivo experiments will be performed to test the functional effects in the animals.

#2328 Race specific hyper-activation of CCR9-mediated survival signals and its impact on efficacy of docetaxel in prostate cancer. Neera Kapur,1 Hina Mir,1,2 Guru Sonpavde,2 Shallesh Singh1. 1Morehouse School of Medicine, Atlanta, GA; 2UAB Comprehensive Cancer Center, Birmingham, AL.

Current approaches to treat and manage prostate cancer (PCa) have failed to reduce racial disparity primarily due to undefined molecular mechanisms. We have shown higher expression of chemokine receptor-9 in PCa cells and CCR9 expression was higher in PCa cells (MDA-PCa-2b) derived from African American (AA) patient compared to PCa cells derived from European American (EA) patients (LNCaP and PC3). Using antibody microarray we observed hyper activation of survival molecules and down-regulation of apoptotic molecules in AA PCa cells compared to EA PCa cells, following CCL25 stimulation. Comparative heat map analysis showed significant increase (~2-3 fold) in phosphorylation of pro-survival proteins in AA cells compared to EA cells treated with CCL25, which was further confirmed by western blot analysis. Furthermore, CCL25 treated PCa cells showed decreased expression of pro-apoptotic proteins (Bim, Bid, Bak), which was significantly abrogated by CCR9 shRNA. This effect was more pronounced in AA cells compared to EA cells. Efficacy of docetaxel (DTX) was higher after CCR9 blockade in presence of CCL25 compared to cells treated with CCL25 without blocking CCR9. Improvement in efficacy of DTX was due to inhibition of cell survival and activation of pro-apoptotic signals following CCR9 blockade. These observations suggest potential involvement of CCR9 mediated molecular pathways in disparity associated with outcome of PCa.

#2329 TMEM33 induces apoptosis via UP signaling and autophagy in breast cancer cells. Hong Hu, Xiuyan Zhang, Leena Hilakivi-Clarke, Usha Kasid, Robert Clarke. Georgetown Lombardi Comp. Cancer Center, Washington, DC.

TMEM33 is a novel transmembrane protein that resides in the endoplasmic reticulum (ENR). It has been shown to activate the PERK and IRE1α branches of the unfolded protein response (UPR). However, the underlying mechanism of action of this ENR resident protein TMEM33 and the cellular functions that it regulates remain largely unknown. In this study, we show that overexpression of TMEM33 induces robust cell death in breast cancer cells. Inhibition of the PERK/eIF2alpha pathway with eIF2alpha inhibitor ISRBK blocks the TMEM33 induced cell death. TMEM33 overexpression strongly activates UP associated pro-death JNK-p53 signaling. We also observed a significant inhibition of the downstream survivin, which blocks cell death activation by binding to caspases and inhibiting their activation. We further show that the blockage of JNK activation with either an inhibitor or overexpression of survivin, protects cells against TMEM33 induced apoptosis. In addition, we show that TMEM33 overexpression induces autophagy in breast cancer cells. Inhibition of autophagy with using either the inhibitor chloroquine or knockdown of the Atg5 gene, further sensitizes breast cancer cells to the effects of TMEM33 overexpression. Cell death induced by TMEM33 is also decreased by overexpression of the antioxidant master regulator SOD2. TMEM33 overexpression induces ER stress in breast cancer cells. However, TMEM33 overexpression did not sensitize breast cancer cells to ER stress inducers, thapsigargin, tunicamycin, or 4-phenylbutyric acid. The data presented herein demonstrate that the novel ENR resident protein TMEM33 induces cell death by activating IRE1α-IRE3-nisky-p53 survivin signaling in breast cancer cells. Concurrently, autophagy is also activated by TMEM33, and functions as a pro-survival mechanism. Cell fate reflects the balance between the pro-death and pro-survival activities as regulated by TMEM33.

Background: Inhibitors of apoptosis proteins (IAPs) regulate cellular apoptosis by interfering with the proteolytic activities of caspases. IAP inhibitors (SMAC mimetics) have been developed to restore the defective apoptosis that characterizes many tumour cells. Emerging evidence demonstrates that IAPs are critical components of immune-modulatory pathways that control innate and adaptive immunity. Accordingly, SMAC mimetics hold the promise of both inducing tumour cell killing and stimulating the immune system to recognize and eliminate dying tumour cells. Here we show that B15 primes immune components and synergises with PD-1 checkpoint inhibitors to promote eradication of syngeneic tumors. Methods: Here we report the efficacy and modulation of the immune response by a potent and selective SMAC mimetic, B15. We characterised the effect of B15 on tumor growth inhibition as a single agent and in combination with an anti-PD-1 antibody in syngeneic mouse tumor models. A detailed 17-colour multi-color flow cytometry analysis was used to investigate the mechanisms by which the SMAC mimetic interacts with anti-PD-1 therapy in vivo. Results: Treatment of the syngeneic mouse tumor models MBT-2 and EMT-6 with the SMAC mimetic in combination with an anti-PD-1 antibody results in remarkable tumor regressions in vivo. Importantly, the combined effect of the SMAC mimetic and anti-PD-1 on tumor growth was dependent on the adaptive immune system in vivo. Mechanistic studies show that degradation of IAP triggers tumor cell death, which leads to a potent activation of dendritic cells in the draining lymph nodes and a subsequent influx of T and NK cells into the tumor microenvironment. Interestingly, in the presence of the SMAC mimetic alone, an induction of PD-1 expression on tumor infiltrating CD8+ T cells was observed, which in turn resulted in the exhaustion of these cells and tumor outgrowth. In the presence of the anti-PD-1 antibody, T cells are reactivated leading to potent and long term tumor eradication. Conclusion: We show that our SMAC mimetic leads to a potent induction of immunogenic cell death and sets up a “virtuous cycle” by potentiating dendritic cell and T cell mediated immune responses that further promote induction of cell death. These effects are preserved even when combined with anti-PD-1 monotherapy. Tumours with minimal T-cell infiltration are poorly responsive to PD-1 monotherapy. These studies indicate that SMAC mimetics, such as B15, represent promising and tolerated combination partners for checkpoint inhibitors in patients that lack a strong immune inflammatory signature.

#2331 FAM3B/PANDER inhibits cell death and increases tumor growth by modulating the expression of Bcl-2 and Bcl-XL cell survival genes. Izabela Caldeira,1 Paula Maciel-Silva,2 Flavia Ramos Siqueira,3 Anna Carla Goldberg,2 Viviane Abreu Nunes,1 Jose Ernesto Belizario,1 Humberto Miguel Garay-Malpartida,1 1University of Sao Paulo, Sao Paulo, Brazil; 2Hospital Israelita Albert Einstein, Sao Paulo, Brazil.

FAM3B/PANDER is a novel cytokine-like protein that induces apoptosis in insulin-secreting beta-cells. Since in silico data revealed that FAM3B can be expressed by prostate and breast tumors, we evaluated the putative role of this cytokine in prostate and breast tumor progression. The FAM3B expression was compared by quantitative PCR in LnCAP, PC-3 and DU145 prostate tumor cell lines and MCF-7, ZR-75 and MDA-MB-231 breast tumor cell lines. After treatment with either recombinant FAM3B protein or secreted FAM3B obtained from conditioned medium (CM) derived from FAM3B-overexpressing 293FT cells, the cell death and viability of DU145 and MDA-MB-231 cell lines were evaluated. DU145 and MDA-MB-231 cells overexpressing FAM3B protein were produced by lentiviral-mediadated transduction of full-length FAM3B cDNA. Cell viability and apoptosis were analyzed in DU145-FAM3B and MDA-231-
**MOLECULAR AND CELLULAR BIOLOGY / GENETICS: Apoptosis and Other Regulated Cell Death in Cancer**

FAM3B cells after treatment with several cell death inducers. Anchorage-independent growth and scratch wound assays were used to evaluate in vitro tumorigenicity and cell migration, respectively. In vivo tumorigenicity and invasiveness were evaluated by tumor xenograft growth in nude mice. We observed that FAM3B was highly expressed by hormone-responsive cells (LnCAP and MDA-MB-231) cultured in unresponsive hormone cells (PC-3, DU145 and MDA-MB-231). Cell viability and survival of DU145 and MDA-MB-231 cells increased after exogenous treatment with recombinant FAM3B protein or CM containing FAM3B-secreted protein. Overexpression of FAM3B in DU145 and MDA-MB-231 cells promoted an inhibition of apoptosis triggered by TNF-alpha, staurosporine and serum-deprived conditions. Cell death inhibition was accompanied by increased gene expression of survivin, survivin-like, Bcl-xL and Bcl-xl genes, and by slight decrease in expression of pro-apoptotic gene Bax and diminished caspases-3, 8 and 9 proteolytic activities. When compared to control, cells overexpressing FAM3B displayed a decreased anchorage independent growth and increased motility in vitro, as well as an increased tumor growth in xenografted nude mice. The immunohistochemistry analysis from tumor xenografts revealed similar anti-apoptotic effect displayed by FAM3B-overexpressing tumor cells. Taken together, by activating pro-survival mechanisms, FAM3B overexpression contributed to increased cell death resistance and tumor growth in nude mice, highlighting a putative role for this cytokine in prostate and breast cancer progression.

#2332 Integration modulatory role of nuclear factor-kappa B activation by C/EBPβ and the endoplasmic reticulum stress sensor PERK to mediate estrogen-induced apoptosis in estrogen-deprived breast cancer cells. Ping Fan,1 Amit K. Tyagi,1 Fadke A. Agboke,2 Niranjana Pokharel,3 V. Craig Jordan1,2

1University of Texas MD Anderson Cancer Center, Houston, TX; 2University of Toronto, Toronto, ON; 3Georgetown University, Washington, DC.

Stress responses are critical for estrogen (E2) to induce apoptosis in E2-deprived breast cancer cells. Nuclear factor-kappa B (NF-kB) is well known as a therapeutic target to prevent stress responses in chronic inflammatory diseases including cancer. However, whether E2 activates NF-kB to participate in stress-associated apoptosis in E2-deprived breast cancer cells is unclear. We demonstrated that E2 differentially modulates NF-κB activity in E2-deprived breast cancer cells according to the treatment time. Because E2 initially has significant potential to down modulate the NF-κB activation, it completely suppresses the tumor necrosis factor alpha (TNFα)-induced NF-κB activation. We found that E2 preferentially and constantly enhances the expression of transcription factor CCAAT/enhancer binding protein beta (C/EBPβ) which is responsible for suppression of NF-κB activation by E2 in MCF-7/5C cells. The MTOR signaling pathway promotes repression of NF-κB by C/EBPβ which is confirmed by the evidence that inhibition of MTOR is synergistic with E2 to upregulate NF-κB-dependent genes, such as TNFRα. Interestingly, NF-κB p65 activity is upregulated when E2-treatment is administered for 48 hours, leading to induction of TNFα. Blocking the nuclear translocation of NF-κB completely prevents E2 from induction of TNFα and apoptosis. Importantly, protein kinase RNA-like endoplasmic reticulum kinase (PERK), a stress sensor of unfolded protein response, is activated by E2 and plays an essential role in increasing NF-κB p65 mRNA and protein expression through the activation of STAT3, independently of canonical IκBα signal pathway. Thus, inhibition of PERK kinase activity completely blocks nuclear activation of NF-κB and NF-κB-dependent induction of TNFα, thereby preventing E2-induced apoptosis. All of these findings illustrate a crucial role for the novel PERK/NF-κB/TNFα axis in E2-induced apoptosis which is integrally modulated by the stress responsive transcription factor C/EBPβ and endoplasmic reticulum stress. This study provides an important rationale for exercising caution in clinical trials when considering targeting PERK or NF-κB following the development of acquired resistance to aromatase inhibitors whereas mTOR may be a target to enhance the therapeutic effects of E2 in aromatase resistant breast cancer.

#2333 Modulation of Bax and mTOR for cancer therapeutics. Rui Li,1 Chinyong Ding,2 Jun Zhang,1 Maohua Xie,1 Dongkyoo Park,1 Ye Ding,4 Guo Pandita,1 1Inova Schar Cancer Institute, Falls Church, VA; 2The Houston Methodists Research Institute, Houston, TX.

Circulating tumor cells (CTCs) are cancer cells which dissociate from the primary tumor and circulate within the peripheral blood, initiating metastasis at a distant location. CTCs present a “non-invasive, liquid biopsy”, making them attractive targets for the development of cancer biomarkers and therapies. In order to form metastases, these cells must undergo a phenotypic shift acquiring the ability to survive anoksis within the blood stream and evade immune surveillance. In addition, CTCs are enriched for autophagy, as detected on the surface of cancer cells. Under physiological conditions, these CTCs can be activated by circulating cytokines such as TNFα, Fas ligand, and TNF-related apoptosis inducing ligand (TRAIL), triggering cell death. In vitro studies have demonstrated that environmental stress caused by non-adherent suspension culture conditions, similar to circulation, will increase autophagy in cancer cell lines aiding anoksis survival. Our lab has previously identified a link between increased autophagic rates and decreased DR surface expression. Based on this we were interested in determining whether increased autophagy due to non-adherent conditions caused breast cancer cell lines to decrease death receptor expression, evading immune surveillance and resisting death-ligand induced apoptosis. To this end, breast cancer cell (BCC) lines were cultured in monolayer or a non-adherent suspension condition for 7 days. Following 7 days of culture, death receptor expression and autophagy initiation were measured using immuno blot and flow cytometry microscopy. BCCs were treated with TRAIL and analyzed over 24 hours for apoptosis and caspase activation. We found that the BCC lines decreased total and surface expression of DR5 and total expression of TNFRI over the 7 days of suspension condition. The reduced expression of DR5 in suspension cultured cells resulted in a delayed response to TRAIL-mediated apoptosis, with delayed caspase activation and PARP cleavage compared to monolayer cultured parental cells. Under suspension condition, autophagy was initiated by increased LC3-II/LC3-I turnover and p62 degradation. This initiation of autophagy is potentially due to increased expression of the mitochondrial related proteins BNP3 and BNPIP2, which have been implicated in anoksis survival. This suggests a delay in death receptor signaling in a non-adherent condition. This delay in death receptor signaling brings about a potential of targeting CTCs within the blood to limit metastatic spread and disease progression in breast cancer. Our findings suggest the potential to sensitize CTCs to anoikis and circulating death ligands through autophagy inhibition.

#2335 Targeting the DNA repair as well as survival functions of MCL-1 enhances cancer cell killing. Abid Matteo,1 J Milburn Milburn Jessup,2 Tej K. Pandita1, 1Inova Schar Cancer Institute, Falls Church, VA; 2The Houston Methodist Research Institute, Houston, TX.

MCL-1 is a pro-survival BCL2 protein family member which is over-expressed in drug resistant cancer cells. Our purpose was to assess whether MCL-1 increases genomic instability along with its anti-apoptotic function in cancer cells. Depletion of MCL-1 by treating human small cell lung cancer (SCLC) lines with immunotoxin sensitizes these cells to increased killing by BH3 mimetic Navitoclax (ABT-263) both in vitro and in mice xenograft models. These SCLC cell lines are resistant to both single agent Immunotoxin or ABT-263. In addition, inhibition of NANOOG or NANGP8 with lentivirus delivered shRNA depletes MCL-1 in human colorectal cancer cells and sensitizes these cells to increased cell killing by venetoclax (ABT-199). This increased killing depended on loss of MCL-1, was caspase-dependent and reversed by re-expression of MCL-1. Depletion of MCL-1 in cancer cells, increases cell sensitivity to ionizing radiation (IR) induced death, which was reversed by expression of MCL-1. In response to IR, MCL-1 depleted cells showed reduced survival even at radiation.
Disregulation of the CDK4/6-Rb pathway is a hallmark of various tumor types. Cancer cells subvert different cell cycle checkpoints to continue unchecked growth and proliferation. Some common mechanisms of overcoming cell cycle checkpoints involve loss of tumor-suppressor proteins such as p16 INK4a or Retinoblastoma (Rb). Alternately, cancer cells can also increase expression of pro-apoptotic CDKs by gene amplification or gene translocation. Thus, targeting different oncoproteins in the cell cycle pathway, particularly CDKs has been considered an important therapeutic strategy. Events of overexpression of cell cycle oncogenes and suppression of tumor suppressors are mutually exclusive and tumor-type specific. In colorectal cancer (CRC), it has been shown that there is overexpression of CDK4/6. We conducted a TCGA analysis of 50 matched tumor and normal CRC tumors, and validated that CDK4 and CDK6 are significantly overexpressed in patient tumor samples by RNA-seq (p = 1.55 e-09 and p = 4.39 e-05). Thus, ongoing clinical trials for CRC patients with advanced disease are currently evaluating the efficacy of CDK4/6 inhibitors as single agents and in combination with chemotherapy (J Clin Oncol 33, 2015; suppl 3; abstr 626; Zhang 2016). We evaluated the efficacy of miRNAs targeting CDK4/6 as novel therapeutics in CRC. We performed in silico analysis using TargetScan to identify miRNAs that can target the 3'UTR regions of CDK4/6. We have identified a novel family of miRNAs (based on seed sequence similarity) that can potentially target CDK4/6 mRNA and thereby reduce both the RNA and protein levels of CDK4/6 in cancer cells. Of the four miRNAs in the family, we chose to characterize miR-6883-5p and miR-149* in a panel of CRC cell lines and primary tumors to identify targets. Our preliminary TCGA analysis in 11 matched T/N samples shows miR-149* expression is significantly lost (p = 0.0049) in CRC samples and this further positively correlates with the stage of the tumor. Ongoing in vitro studies using miRNA mimics in CRC cell lines indicate that both miR-6883-5p and miR-149* have anti-proliferative effects as assayed by CellTiterGlo (CTG) and MTT. Further, both miRNAs induce G1-arrest as a consequence of downregulation of CDK4 and CDK6 in all cell lines and we also observe induction of apoptosis in a subset of CRC cell lines. Knockdown of CDK4 and CDK6 mimics the phenotypes observed with restoring expression of both miR-6883 and miR-149* in CRC cell lines. Combination of miR-6883 with FDA-approved drugs Irinotecan and 5-FU showed strong synergy and led to apoptosis as assayed by CTG and PARP cleavage. Our ongoing work is further looking into the mechanisms of synergy and identifying additional target genes in CRC cell lines. Thus, our novel miRNA based strategy to target CDK4 has potential to translate as both a single agent/combinatorial therapy and to identify biomarkers of response, which is critical for understanding the clinical results seen with CDK inhibitors.

#2334 CDK4/6 and autophagy inhibitors synergize to induce senescence in cancers with an intact G1/S checkpoint. Smruthi Vijayaraghavan,1 Cansu Karakas,1 Xian Chen,1 Imran Doostan,1 Akshara S. Raghavendra,1 Min Yi,2 Ravi Arora,1 Arpan Fahemi,1 Kelly Hunt,1 Debu Tripathy,1 Khandan Keyomarsi1.

Deregulation of apoptosis is central to cancer progression and a major obstacle to effective treatment. The B-c2 gene family members play important roles in the regulation of apoptosis and are frequently altered in cancers. One such member is Bcl-2-related Ovarian Killer (BOK), which is a pro-apoptotic protein. Despite its critical role in apoptosis, the regulation of BOK expression is poorly understood in cancers. Here, we discovered that miR-296-5p regulates BOK expression by binding to its 3'UTR in breast cancer. Further, we showed that depletion of BOK by either miR-296-5p or siRNA against BOK protected breast cancer cells from undergoing paxilactal-induced apoptosis. Interestingly, miR-296-5p also regulates the expression of Mcl-1, which is an anti-apoptotic protein and is highly expressed in breast cancers. Our results reveal that Mcl-1 is important for suppression of BOK function as ectopic BOK expression induced Mcl-1, while silencing of BOK resulted in reduced Mcl-1 levels in breast cancer cells. In addition, we show that specific silencing of Mcl-1 reduced the long-term growth of breast cancer cells, whereas BOK inhibition didn’t have any effect on the growth of breast cancer cells. Surprisingly, silencing of both Mcl-1 and BOK rescued the effect of Mcl-1 silencing on breast cancer cell growth, suggesting that BOK is important for attenuating cell growth in the absence of Mcl-1, and also showing a tight feedback regulatory loop between BOK and Mcl-1 in breast cancer cells. Furthermore, we demonstrated that BOK protein level is regulated post-translationally by GSK3α/β and to some extent GSK3β as GSK3 inhibitor (CHIR99021) or silencing of GSK3 significantly increased BOK protein levels in breast cancer cells. Notably, we found that Mcl-1 interacts with GSK3α/β and silencing of Mcl-1 using siRNA significantly attenuated endogenous GSK3α/β levels in breast cancer cells. Taken together, our results suggest that the regulation of BOK (either post-transcriptionally by miR-296-5p or post-translationally by GSK3α/β) of the levels of pro-apoptotic protein BOK and anti-apoptotic protein Mcl-1 decide the fate of cancer cells to either undergo Apoptosis or proliferation.

**MOLECULAR AND CELLULAR BIOLOGY / GENETICS: CDKs and CDK Inhibitors**

Doses less than 6 Gy, however an increase in caspases 3/7 activity was observed at 6 Gy and above, suggesting that apoptosis is activated only when MCL-1 depleted cells are irradiated with higher IR doses. In order to explain the decreased survival post-irradiation the genomic instability and DNA repair pathways were analyzed in MCL-1 depleted cells. Post-irradiation MCL-1 depleted cells exhibited increased genomic instability as measured by increase in chromosome aberrations at different phases of the cell cycle. The increase in aberrations were significantly higher in G2 and S phases of the cell cycle suggesting defect in Homologous recombination repair pathway (HR). Moreover, the MCL-1 depleted cells show decreased gamma-H2AX foci at earlier time points (30 and 90 minutes) post-irradiation indicating defect in DNA Damage response (DDR) and high residual foci at 90 minutes, indicating defective DNA repair. These observations were further confirmed by decreased phosphorylation of ATRX suggesting defect in DNA Damage response and higher levels of residual 53BP1 and RIF1 foci in MCL-1 depleted cells, confirming DNA DSB repair by homologous recombination (HR) was compromised. Consistent with this model, MCL-1 depleted cells exhibited a reduced frequency of IR-induced MRE11, BRCA1, RPA and Rad51 foci formation, decreased DNA end resection and decreased HR repair in the DR-GFP DSB repair model. Similarly, after Hydroxyurea (HU) induction of stalled replication forks in MCL-1 depleted cells there was a decreased ability to subsequently restart DNA synthesis, which is normally dependent upon HR mediated resolution of collapsed forks. In summary, MCL-1 is an important therapeutic target in cancer cells and its depletion increases cell killing by either increase in apoptosis or suppression of HR and increased replication stress.
other cancer cell lines. Several solid tumors (ovarian, lung, pancreatic, colon, prostate) and triple negative breast cancer (TNBC) cell lines exhibited a synergistic response to palbociclib/HQ combination treatment dependent upon an intact G1/S transition (Rb+/LMW-). This was also verified in a TNBC patient derived xenograft (PDX) model. Thus, this study addresses the aforementioned limitations and provides a novel and promising biomarker-driven combination therapeutic strategy to treat breast and other solid tumors. We predict that this combination of CDK4/6 and autophagy inhibitors would be more beneficial than standard dose palbociclib in patients, allowing to lower the dose, minimize palbociclib mediated toxicities and potentially improve overall patient survival - a goal that has not yet been met with currently approved treatment combinations.

#2339 Downregulation of cell cycle genes in HNSCC by erufosine. Shariq S. Ansari,1 Ashwini K. Sharma,1 Michael Zepp,1 Frank Bergmann,2 Rainer Bergqvist2.

1The German Cancer Research Center (DKFZ), Heidelberg, Germany; 2University Clinic Heidelberg, Heidelberg, Germany; 3Leibniz Institute for Natural Products Research and Infection Biology, Jena, Germany.

Head and neck cancer ranks amongst the sixth most prevalent cancers worldwide and oral squamous cell carcinomas (OSCC) constitute 90% thereof. Erufosine is an ether-lipid-derived synthetic compound belonging to alkylphosphocholines (APCs), which has been shown to inhibit the proliferation of OSCC cells. It simultaneously induces apoptosis and autophagy by modulating the Akt-mTOR signaling pathway, however, its exact mechanism of action is not fully understood. Here, we describe the activity of erufosine on the expression of cell cycle related genes in OSCC cells. The anti-proliferative effect of erufosine in cells of two human OSCC cell lines, HN-5 and SCC-61, was determined by MTT assay after 24h, 48h and 72h exposure. Based on these results, HN-5 cells were exposed to erufosine at concentrations corresponding to IC25, IC50 and IC75 concentrations, and then their mRNA was isolated and analyzed by Illumina Chip array. Gene expression modulation was confirmed by RT-PCR and Western blot. Gene set enrichment analysis was performed to identify core KEGG (Kyoto Encyclopedia of Genes and Genomes) pathways and GO (Gene Ontology) terms. In addition, erufosine’s effect on cell cycle distribution and colony formation was determined as well as its antineoplastic effect on respective xenografts in nude mice. As shown from TCGA data, cell cycle deregulation in HNSCC ranks amongst the top three out of 24 different types of cancers. In line with this, the median expression of cell cycle genes was higher than that of other genes within HNSCC. We also looked at the median gene expression of all CDKs and cyclins in 519 HNSCC patient samples from TCGA and found that the expression levels were higher than the global gene expression. This was in agreement with IHC-staining of CCND1 in tumors from 30 South East Asian HNSCC patients. Furthermore, increased CCND1 and CDK6 expression levels from TCGA data had negative implication on patient survival. In our experimental results erufosine caused a dose dependent growth inhibition of OSCC cell lines and negative enrichment of genes related to the cell cycle process. Our microarray findings revealed that cyclins and CDKs were downregulated in a dose dependent manner in response to erufosine exposure. These findings were verified at both mRNA and protein levels. Erufosine not only massed a mass2G block but also inhibition of colony formation thus preparing the OSCC cells to undergo apoptosis. We are the first to show that erufosine inhibited tumor growth in vivo in a HNSCC xenograft model and caused downregulation of cyclinD1, CDK4 and CDK6 in lesions of the animals. These findings collectively show the potential of erufosine to be used as a cell cycle inhibitor in HNSCC progression and support the future evaluation of erufosine as a therapeutic approach in cancer treatment alone, or in combination.

#2340 Thymidine kinase activity as a response marker for CDK 4/6 inhibition. Geoffrey Shapiro,1 Magnus Neumuller,2 Sara Lööf,3 Smaranda Bacanu,3 Takahiro Seki,4 John Hilton,1 Khan Do,1 Nicole Chau,1 Leena Gandhi,1 Joseph W. Gibson,1 Robert Distel,1 Pawel Nieginski,2 Edward M. Suh,2 Mattias Bergqvist1.

1Dana-Farber Cancer Institute, Boston, MA; 2Biovica International AB, Uppsala, Sweden; 3Karolinska University Hospital, Stockholm, Sweden; 4Karolinska Institute, Stockholm, Sweden.

Selective CDK4/6 inhibition is now part of standard treatment for HR+ breast cancer. There is a pressing need for a practical biomarker that can provide early indication of the biologic activity of these agents and correlate with clinical outcomes. Expression of thymidine kinase (TK) occurs in actively proliferating cells, is E2F-dependent and is downregulated after CDK4/6 inhibitor-mediated G1 arrest. Here, we have investigated TK activity (TKA) as a pharmacodynamic marker for CDK4/6 inhibition in both preclinical and clinical contexts and demonstrate the potential of this assay as CDK4/6 inhibitors are further developed. TKA in response to the CDK 4/6 inhibitor palbociclib (palbo) was studied in cell culture, mouse models and samples from clinical studies. TKA was determined by the DiviTum Assay (Biovica, Sweden). In culture, the intracellular TKA and TKA release in response to palbo were determined by analysis of cellular extracts and tissue culture media. In vivo, mice bearing human xenografts were treated every 28 days or 4/4-week (continuous) schedules. In K562 cells, intracellular TKA levels exhibited a clear dose response to palbo. Reductions in TKA were seen at lower drug concentrations than those affecting cell viability. Similar results were observed in MCF-7 xenografts, where lower TKA in serum and tumor was observed after palbo treatment, whereas in E0771 xenografts, no change in TKA was observed. Clinically, serum samples were obtained before and at various time points after palbo exposure in 20 cancer patients. One patient, who discontinued study treatment at the end of cycle 1, demonstrated an increase in s-TKA. In contrast, for the other 19 patients, there was a marked decrease in s-TKA at day 21. Pre-treatment s-TKA values were higher than C1D21 (paired t-test, p<.0001). In 11 patients there was a reduction in s-TKA to below the assay detection limit. Five patients exhibited a reduction in s-TKA within the working range, with mean residual activity at day 21 of 32%. In the 6 patients receiving continuous palbo, s-TKA remained low after day 21. Of the 14 patients using the 3/4-week schedule, 9 exhibited an increasing level of s-TKA between day 21 and day 1 of cycle 2, consistent with reversible effects of palbo on cell cycle progression after cessation of exposure. These data suggest that s-TKA reflects MOA response to the selective CDK4/6 inhibitor palbo. The DiviTum Assay may provide a practical, non-invasive tool for monitoring the effects of CDK4/6 inhibitors in both preclinical models and patients. We plan inclusion of the assay into additional studies to determine whether the assay can predict clinical outcome or portend development of resistance.

#2341 In situ labelling identifies a novel landscape of nuclear CDK2 substrates. Bruce E. Clurman, Yong Chi, Fred Hutchinson Cancer Research Ctr., Seattle, WA.

Cellular signal transduction pathways rely heavily on protein kinase-mediated phosphorylation events. Comprehensive identification of the physiologic target protein kinases is key to understanding their functions and elucidating cellular signalling pathways. Various direct and indirect approaches, combined with advanced mass spectrometry technologies, have made it possible to identify many candidate targets of a given kinase, but have also yielded many false-positive identifications, largely due to technical limitations. Identifying direct and physiological kinase targets thus remains a difficult task. We developed a mass spectrometry-based in situ approach that utilizes substrate phospho-rylation and ATP analog-sensitive CD2 (AS-CD2) to identify over one hundred potential cyclin-dependent kinase 2 (CDK2) substrates in intact nuclei. More than one-third of these candidates are known CDK substrates, indicating significant enrichment for physiologic CDK2 substrates, and we also identified and validated new CDK2 substrates. Importantly, many of these new CDK2 substrates are substrates that are important in tumor histone modification, DNA replication, and DNA repair, which likely reflects our use of AS-CD2 within its normal nuclear context, and regulated by endogenous cyclins. These methods should be broadly applicable to the study of other kinases with complex substrate networks.

#2342 TNFAIP8 promotes prostate cancer cell survival by modulating autophagy. Suresh Niture,1 Malathi Ramalinga,2 Habib Kedir,3 Deepak Kumar,1 North Carolina Central University, Durham, NC; 2University of District of Columbia, Washington, DC; 3North Carolina Central University and UDC, Durham, NC.

TNF-α inducible protein (TNFAIP8) is an antiapoptotic protein with roles in tumor cell growth and survival. Mechanisms of cell survival by TNFAIP8 remain elusive. In the current study, we investigated the role and molecular mechanism related to TNFAIP8 in the modulation of cell cycle, autophagy and drug resistance/cell survival in prostate cancer cells. Microarray data from PC3 prostate cancer cells ectopically expressing TNFAIP8 demonstrated modulation of cell cycle related genes such as CDKs, CDCs and PCNA. Immunoblotting data from overexpression of TNFAIP8 in PC3 cells shows upregulation of cell cycle proteins cyclin A, cyclin B1, Myt1 and Chk1. However, no change in cell cycle was found. Phosphorylation of Histone-S10, CDC2-Tyr15 and Weel1-S642 was also observed. Autophagy plays an important role in tumor cell survival. We evaluated the effects of TNFAIP8 in modulating autophagy. Overexpression of TNFAIP8 leads to induction of autophagy. TNFAIP8 positively
modulates the expression/stabilization of autophagy markers and effectors such as LC3β I/II, Beclin1, 4EBP1, oncogene p62 and SIRT1. Knockdown of TNAIP8 inhibits autophagy induced by nutrient starvation in PC3 prostate and MCF7 breast cancer cells. We also evaluated cell growth and survival in PC3 cells. We demonstrate that TNAIP8 promotes cell growth and proliferation in PC3. LNCaP prostate cancer cells. Further work has revealed that TNAIP8 increase resistance against anticancer drugs docetaxel and doxorubi- cin. These data collectively suggest that the creation of cellular autophagy events TNAIP8 promotes cell survival and drug resistance in prostate cancer cells.

#2343 The novel potential of palbociclib (CDK4/6 inhibitor) in the treat- ment of triple-negative breast cancer. Shinchiro Kashiwagi, Yuka Asano, Wa- taru Goto, Koji Takada, Tsutomu Takashita, Tamami Morisaki, Satoru Noda, Naoyoshi Onoda, Kosei Hirakawa, Masashi Ohira. Osaka City University Gradu- ate School of Medicine, Osaka, Japan.

Background: The effectiveness of palbociclib (CDK4/6 inhibitor) for estrogen receptor positive breast cancer has been demonstrated by large-scale clinical studies, with the drug garnering attention as a key drug for breast cancer sub- types with endocrine sensitivity in the future. According to PALOMA-3 trial, palbociclib has been demonstrated to contribute to the extension of progres- sion-free survival in patients with advanced hormone receptor-positive and HER2-negative metastatic breast cancer after endocrine therapy. On the other hand, in the case of triple-negative breast cancer (TNBC), luminal AR (LAR) related to androgen signaling is believed to have endocrine activity. Previous clinical data revealed that palbociclib shows high sensitivity in luminal breast cancer cell lines with androgenic activity, with effectiveness also expected in LAR. In this study, we created TNBC cell lines that forcibly express AR and examined the effectiveness of palbociclib for TNBC. Materials and Methods: MCF-7 and T-47D were used as luminal breast cancer cell lines, while MDA-MB-231 and BT-549 were used as TNBC cell lines. In addition, we created TNBC cell lines that forcibly express AR, called AR-MDA-MB-231, by the transfection of pEGFP-C1-AR Plasmid Vector using Lipofectamine® 3000 Reagent. We con- firmed the expression of AR by qRT-PCR as well as Western blotting and exam- ined the impact of palbociclib on proliferation as well as apoptosis of breast cancer cell lines. Results: AR was found to have been expressed only in luminal breast cancer cell lines but not TNBC cell lines. It was confirmed that AR was expressed in AR-MDA-MB-231 which are stable cell lines with the properties of LAR. In a CCK assay, palbociclib showed high sensitivity in AR-MDA-MB-231 as in luminal breast cancer cell lines. Furthermore, in an apoptosis assay using FACS and cell cycle assay, apoptosis was induced in AR-MDA-MB-231 and cell cycle arrest at the G1S check point was confirmed. Conclusion: palbociclib (CDK4/6 inhibitor) showed effectiveness for TNBC cell lines that compulsively express AR, suggesting it may be one treatment option for TNBC in the future.

Introduction: Urothelial carcinoma is characterized by a high incidence of molecular alterations involving loss of the cyclin dependent kinase inhibitor p16 encoded by CDKN2A or amplification of CDK4/6 is associated with sensitivity to CDK4/6 inhibitors in various cancers. Functional RB1 is believed to be canonically required for mediating the effects of CDK4/6 inhibition in this setting. However, muscle-invasive urothelial carcinomas harbor RB mutations and copy-number losses in 21% of patients. To extend the activity spectrum of CDK4/6 inhibitors to these RB1-deficient cancers, we in- vestigated the role of pocket protein p130 encoded by the Retinoblastoma-Like 2 (RBL2) gene, in mediating the downstream effects of CDK4/6 inhibition. Meth- ods: CRISPR-Cas9 was used for CDKN2A knockout in the 5637-urothelial cancer cell line with an RB-mutant background and in TCCSUP cell line with wild- type RB. CDKN2A cells were subsequently treated with CDK4/6 inhibitor palbociclib. Levels of RB1, phospho-RB (at serine 807/ serine 811), p130 and phospho-p130 (specifically, the CDK4/6-dependent serine 672 phosphoryla- tion) proteins were quantified using SDS-PAGE. Cell-cycle phase analysis was performed using flow cytometric measurement of BrdU and PI staining. Results: CRISPR-induced disruption of CDKN2A was validated using genomic PCR and targeted MiSeq sequencing. p16 protein knockdown was validated using SDS- PAGE. CRISPR-induced CDKN2A knockout resulted in increased cell pro- liferation and faster G1/S transition even in the absence of functional RB in the 5637-urothelial cancer cell line. A significant increase in the levels of phospho- p130 was observed after p16 knockdown without changes in the levels of un- phosphorylated p130. TCCSUP cell line with functional RB demonstrated a similar increase in proliferation, faster G1/S transition and an increase in phos- pho-p130. Palbociclib was effective in reversing these changes in all the tested cell lines. Conclusions: the pocket protein p130 plays an important role in me- diating downstream effects of CDK4/6 inhibition in urothelial cancer cell lines with both wild-type and more importantly, deficient RB. CDK4/6-deficient tumors are a significant proportion of prostate cancer, whereas RB is preserved for the functional status of RB1. Through p130 acting as a dominant activator of E2F family of transcription factors that control G1/S checkpoint. These findings potentially explain the lack of correlation between RB and re- sponse to CDK4/6 inhibitors in clinical trials. These results provide a mechanistic rationale for extending clinical trials of CDK4/6 inhibitors to patients with RB1-deficient tumors.

#2345 CD4K inhibition enhances anti-melanoma effects of BRAF/MEK inhibition. Yanping Zhang, Eddy C. Hsueh. Saint Louis Univ., St. Louis, MO.

Introduction: Targeted therapy against BRAF-mutated melanoma has shown clinical efficacy. However, resistance to therapy often occurs. CD4K (IN4K)-retinoblastoma (RB) pathway controls cell cycle progression by regulating the G1-S checkpoint. Defect in the p16INK4A, cycling D-CDK4/6:RB pathway is also detected in melanoma. We study the effect of combining CD4K-RB pathway inhibition with BRAF/MEK inhibition as a possible strategy to overcome resis- tance to therapy. Methods: Three BRAF wild-type and three BRAF-mutated melanoma cell lines were selected. CD4K/6 inhibitor (PD0323991; PD), BRAF inhibitor (PLX4032; PLX), MEK inhibitor (AZD6244; AZD), and PI3K/AKT inhibitor (XL765; XL) were used alone or in combination. Cell proliferation assay was performed using Cell Titer Blue assay. Cell migration assay was per- formed using Bioassay. Cell migration inhibition was noted with PD and PD + XL combination compared with PD + PLX alone. No correlation was observed between expres- sion of CDK4 and cyclin D1 and sensitivity to single agent or the combination.

Inhibition of phosphorylated RB1 and ERK expression was observed with expo- sure to single agent PD, PLX, XL, AZD. Enhancement of pRB1 and pERK inhibi- tion was noted with PD + PLX and PD + AZD combination but not PD + XL. Conclusion: CD4K inhibition can enhance anti-proliferation and migration ef- fects of BRAF/MEK inhibition in melanoma cells. The mechanism is via aug- mented down-regulation of pRB expression.

#2346 Preclinical selectivity profile of the CDK4/6 inhibitor ribociclib (LEE011) compared with that of palbociclib and abemaciclib. Ralph Tiedt,1 Scott Delach,2 Steven Kovats,3 Thomas Horn,4 Michael Acker,5 Barbara Sch- acher Engstler,1 Giordano Caponigro.1 1Novartis, Basel, Switzerland; 2Novartis, Cambridge, MA.

A hallmark of cancer is unchecked cell division. Retinoblastoma protein (Rb) is a human tumor suppressor that guards a cell’s entry into S phase by binding E2F transcription factors and keeping them inactive. Many growth-promoting stimuli increase expression of D-type cyclins, which bind to and activate cyclin- dependent kinases 4 and 6 (CDK4/6). The cyclin D–bound CDK4/6 holo- enzymes phosphorylate RB, resulting in release of E2F, which in turn activates genes required for S phase entry and DNA replication. Numerous oncogenic aberrations converge at the CDK4/6–E2F pathway, providing a strong rationale for developing CDK4/6 inhibitors as cancer therapeutics. Ribociclib (LEE011) is a selective CDK4/6 inhibitor that has received FDA breakthrough therapy and priority review designations for treatment of hormone receptor–positive breast cancer in combination with letrozole and is being tested in additional clinical trials. Here we describe the preclinical selectivity profile of ribociclib in bio- chemical and cellular assays. Ribociclib inhibits both CDK4–cyclin D1 and CDK6–cyclin D3 kinase activity with nanomolar IC50s in biochemical assays. To comprehensively address the selectivity of ribociclib in direct comparison with 2 other clinical CDK4/6 inhibitors, palbociclib and abemaciclib, we made use of the KINOMEscan assay consisting of >450 kinase active site–directed competition-binding assays. We adjusted the test concentrations in the kinase- selectivity panel per the binding constants for CDK4 and CDK6 to account for the higher potency of abemaciclib. Data showed that both ribociclib and palbo- ciclib have high selectivity for CDK4 (CDK6 was not covered in the panel), with
very few distinct additional binding events detected. In contrast, abemaciclib is a much more promiscuous kinase inhibitor. Next, we sought to determine the relative potencies of the 3 inhibitors against CDK4 vs CDK6 in cellular assays. When testing different routinely used readouts of cellular viability, we found that assays that measured metabolic activity (eg, CTG) tended to underestimate the effects of CDK4 inhibition; thus, all assays were normalized to assayed cell number were used instead. We first identified cancer cell lines primarily dependent on either CDK4 or CDK6 as judged by combined RNA expression analysis and shRNA or CRISPR-based functional assays. When determining IC50 of the 3 CDK4/6 inhibitors in these cell lines, we found that ribociclib and abemaciclib demonstrated greater activity in CDK4-dependent cells vs CDK6-dependent cells, whereas palbociclib was active in both cell types. The high degree of CDK4 selectivity of ribociclib suggests that off-target kinase inhibition is an unlikely complication in patients. Moreover, the apparent preference for CDK4 over CDK6 could be an advantage in certain cancer types that are primarily dependent on CDK4.

#2347 MicroRNA mediated CDK4/6 inhibitor resistance via extracellular signaling. Liam Cornell, Geoffrey I. Shapiro. Dana Farber Cancer Institute, Boston, MA

Multiple potent and highly selective inhibitors of the cell cycle kinases - CDK4 and CDK6 are in development. One such inhibitor, palbociclib, was recently approved for use in combination with letrozole for the treatment of estrogen receptor positive (ER+) breast cancer. Cyclin D-dependent kinase activity is a driving factor for ER+ breast carcinogenesis, irrespective of CCND1 amplification, making CDK4/6 inhibition a promising approach for this breast cancer subset. However, as with all cancer treatments, resistance will be a major issue limiting the efficacy of this approach. To date, mechanisms of palbociclib resistance have not been extensively investigated. Through interrogation of the generated CDK4/6 inhibition resistant cells we discovered overexpression of CDK6, specifically, mediates resistance. CDK6 depletion reversed resistance and overexpression caused resistance, whereas the same was not true when CDK4 or D cyclin protein levels were manipulated. Interestingly, when generating and analyzing resistant cell populations, we observed a “bystander effect”, by which resistance was transmissible between cells. The "resistant bystander" cells display all characteristics of the drug exposure induced resistant cells, however became resistant in just 48 hours as opposed to 14 weeks. Analysis of conditioned medium revealed that the transmission of resistance is dependent on exosomes, but not protein or DNA. We identified a specific miRNA, present in the exosomes of resistant cells, by microarray which caused resistance when excreted. Additionally, overexpression and inhibition of the miRNA confirmed that it is responsible for causing resistance. miRNA overexpressing cells exhibited the same phenotype as drug induced resistant cells, and furthermore, could cause resistance in neighboring cell populations by exosome mediated signaling. Using Biotin labelled miRNA-miRNA pulldown followed by RNA-seq, we identified the TGFβ pathway as the miRNA target. Downregulation of the TGFβ caused a decrease in the CDK inhibitors, p15 and p21, resulting in an increased CDK6 protein level and palbociclib resistance. We subsequently confirmed these data in patient samples by comparing before treatment and post relapse biopsies. These findings highlight a novel mechanism of conferred drug resistance as well as new insights into acquired CDK4/6 inhibitor resistance.

#2348 Targeting the p27kip1/cdk4/cdk2/Rb axis in breast cancer using a peptidomimetic of Brk’s SH3 domain. Stacy W. Blain,1 Jason Quinones,1 Priyank Patel,2 Velaslav Tisperson,3 Susan Gottesman,1 Jonathan Somma,1 Yun Wu1. 1State University of New York, Downstate Medical Center, Brooklyn, NY; 2State University of New York, University of Buffalo, Buffalo, NY.

Purpose: Cyclin D-cdk4 (DK4) has been a highly sought after therapeutic target because it drives cancer proliferation in a majority of human tumors. We have explored the clinical utility of a recently discovered mechanism of cell cycle control exerted on DK4 by p27Kip1 and its activator, the Breast tumor Related Kinase (Brk), in predicting responsiveness to therapy and as a new target for treatment. Although known as a DK4 assembly factor and cdk2 inhibitor, p27 also acts as a DK4 ON/OFF switch. Tyrosine (Y) phosphorylation of p27 (pY) by Brk gatekeeps both ATP binding and CAK phosphorylation of cdk4’s T loop, essential for DK4 activation. This function is restricted to cdk4-p27 association with cdk2, whether Y phosphorylated or not, appears to be inhibitory. However, in vivo Y phosphorylated p27 is a target for cdk2-dependent ubiquitin-mediated degradation, reducing p27’s association with cdk2, indirectly activating this complex. We showed that blocking p27 pY inactivates cdk4 directly AND cdk2 indirectly, and thus represents a novel way to block cancer cell proliferation. pY also serves as a predictive biomarker of cdk4 activity and tumor response. Methods: We used a small peptide, ALT, which contains a portion of Brk’s SH3 domain. ALT binds to p27, blocks Brk’s association and ability to phosphorylate p27, inhibiting cdk4 and increasing p27’s ability to inhibit cdk2. We engineered a lipid-based nanoparticle delivery vehicle (NP-ALT), permitting us to test ALT as a first generation therapeutic in breast cancer cell lines that were both responsive and non-responsive to cdk4 therapy. ALT was also used with Palbociclib to determine if combination therapy reduced drug resistance. We developed a dual IHC assay for p27 and pY, which we used to analyze paraffin-embedded, archival human tumor samples, to determine whether we could pinpoint patients who would have responded to cdk4 inhibition therapy. Results: NP-ALT blocks pY, cdk4 and cdk2 activity, and proliferation in both Palbociclib sensitive and resistant cell lines. As a dual therapy, ALT treatment synergized with Palbociclib to ablate cells for >30 days, increased senescence, and in animal models caused tumor regression instead of just slowing tumor growth as seen with Palbociclib alone. Analysis of human cancer, obtained from archival sources, demonstrated that pY is never detected in quiescent benign mammary tissue, but is detected in about half of the advanced ER/PR+ /Her2- tumors analyzed, and using explant culture techniques, we were able to stratify pY with Palbociclib response. Conclusion: Use of an Brk SH3 based peptide (NP-ALT) has proven effective in blocking p27 pY, inhibiting both cdk2 and cdk4, inducing senescence and increased durability. pY levels correlate with Palbociclib sensitivity in low, moderate and non-responders, suggesting that this may be a biomarker highlighting responsiveness to cdk4 therapy.

#2349 Sensitivity and resistance to cell cycle and IGF-1R inhibitors in rhabdomyosarcoma. Justin Montoya, David W. Lee, Eiman Alem. Institute of Molecular Medicine, Medicine, and Pharmacology, Boston, MA

Rhabdomyosarcoma (RMS) is the most common soft tissue sarcoma in children and young adults. The five-year survival rate for RMS has hardly improved over the last three decades despite intensive and toxic chemotherapy, radiotherapy and surgery. Therefore, novel treatment approaches are required to change these outcomes. RMS has two major subtypes, embryonal RMS (ERMS) and alveolar RMS (ARMS), the most aggressive subtype, is characterized by PAX3-FKHR translocations that fuse two transcription factor-encoding genes; creating novel PA3X/PA7-FOXO1 fusion proteins. The PA3X-FOXO1 is highly expressed in the G2 phase of the cell cycle, allowing the cell to divide following a sustained checkpoint arrest despite DNA damage induced by chemotherapy, suggesting that PA3X-FOXO1 may enhance the survival of tumor cells in response to chemotherapy. Many cell cycle regulators are altered in RMS, including CDK2, CDK4 and p53. Furthermore, RMS cells are highly dependent on the insulin-like growth factor -1 receptor (IGF-1R) signaling, however, IGF-1R targeting was not successful in the clinic. Therefore, targeting key cell cycle regulators individually or in combination with IGF-1R inhibition may expand the available therapeutic options for RMS. Purpose: The goal of the present study was to investigate the cytotoxicity of 15 small molecule inhibitors targeting the IGF-1R and cell cycle regulators in RMS cell lines and to determine potential mechanisms of drug sensitivity or resistance. Methods and Results: Seven RMS cell lines including ERMS and ARMS were studied. The IC50 values were determined for the following targeting compounds: Imitinib, BMS-754807 and picopodocellphilmycin (PPP) (IGF-1R), ribociclib and palbociclib (CDK4/6), dinaciclib and flavopiridol (CDK4/6 and IGF-1R) and MK-7724 (CHK1), alisertib (AURKA) and volasertib (PLK1). The most potent compounds with ICG<10 nM were dinaciclib and alisertib. The ARMS cell lines were resistant to alisertib in comparison to the ERMS cell lines. Most cell lines were sensitive to flavopiridol, MK-1775, BMS-754807 and PPP with ICG<100 nM. The most resistant was RS-181 HCL, resistant to B5-181 HCL, resistant to B5-181 HCL and MK-7724 with ICG(1-70 µM). Palbociclib and BMS-754807 showed a synergistic effect in some RMS cell lines. Ongoing studies are focusing on determining the mechanisms of interaction of these two compounds through studying cell cycle, apoptosis, and mRNA and protein expression of key regulators in the IGF-1R and RB pathways. Conclusion: These data demonstrate that dinaciclib, volasertib, flavopiridol, MK-1775, BMS-754807 and PPP are highly toxic in RMS cell lines. The CDK4/6 inhibitor palbociclib may sensitize selected RMS cell lines to IGF-1R inhibitors. Targeting selected cell cycle regulators individually, or in combination with IGF-1R inhibitors may thus provide an efficacious treatment approach to be further validated in RMS patients with poor outcome.

#2350 In vivo E2F reporting on efficacious dosing schedules of MEK plus CDK4/6 inhibition in melanoma. Jessica Teh,1 Neda Nikbakht,1 Timothy Purtin,1 Inna Chernova,1 Priyank Patel,1 Michael Davies,2 Andrew Aplin1. Thomas Jefferson University, Philadelphia, PA; 2MD Anderson Cancer Center, Houston, TX.

Pharmacological targeting of cyclin dependent kinases 4 and 6 (CDK4/6) could represent a viable therapeutic option in combination with BRAF and/or...
MEK inhibitors in different genetic subsets of melanoma. Indeed, continuous and concurrent dosing of MEK inhibitor (MEKi) plus a CDK4/6 inhibitor (CDK4/6i) leads to melanoma regressions in in vivo models and delays the onset of MEKi resistance. Current scheduling in breast cancer patients for the CDK4/6i, palbociclib, is intermittent due to adverse effects resulting in neutropenia. It is unclear what the most efficacious schedules are of palbociclib plus a MEKi. Utilizing an E2F reporter system, we sought to analyze the efficacy of different CDK4/6i plus MEKi schedules in a quantitative and temporal manner. Intermit- tent dosing (3 weeks on/1 week off) of both CDK4/6i and MEKi combination therapy resulted in tolerant tumors and rapid reactivation of E2F activity during drug holiday. Continuous MEKi with intermittent CDK4/6i led to more complete responses as compared to continuous CDK4/6i with intermittent MEKi. Weight loss of mice was also evident in the continuous CDK4/6i plus intermittent MEKi arm suggesting adverse events related to continuous CDK inhibition. Importantly, functional proteome analysis revealed distinct mechanisms of acquired resistance/drug tolerance that arose from the three scheduling arms. Here, we report that upregulation of S6 phosphorylation is associated with acquired resistance to MEK plus CDK4/6i inhibition and can be overcome with an mTOR inhibitor. Taken together, in vivo reporting allows for quantitative measurement of pathway activity associated with inhibitor resistance and can be utilized to optimize combination schedules to improve the therapeutic index in patients.

#2351 The novel potential of palbociclib (CDK4/6i inhibitor) in the treat- ment of triple-negative breast cancer. Yuka Asano, Shinichiro Kashiwagi, Wa- taru Goto, Katsuyuki Takahashi, Tsutomu Takahama, Saburo Noda, Noriyuki Onoda, Shuhei Tomita, Kosei Hirakawa, Masaochi Ohira. Osaka City University Graduate School of Medicine, Osaka, Japan.

Background: The effectiveness of palbociclib (CDK4/6i inhibitor) for estrogen receptor positive breast cancer has been demonstrated by large-scale clinical studies, with the drug garnering attention as a key drug for breast cancer sub- types with endocrine insensitivity in the future. According to PALOMA-3 trial, palbociclib has been demonstrated to contribute to the extension of progression-free survival in patients with advanced hormone receptor-positive and HER2-negative metastatic breast cancer after endocrine therapy. On the other hand, in the case of triple-negative breast cancer (TNBC), luminal AR (LAR) related to androgen signaling is believed to have endocrine activity. Previous clinical data revealed that palbociclib shows high sensitivity in luminal breast cancer cell lines with endocrine activity, with effectiveness also expected in LAR.

In this study, we created TNBC cell lines that forcibly express AR and examined the effectiveness of palbociclib for TNBC. Materials and Methods: MCF-7 and T-47D were used as luminal breast cancer cell lines, while MDA-MB-231 and BT-549 were used as TNBC cell lines. In addition, we created TNBC cell lines that forcibly express AR, called AR-MDA-MB-231, by the transfection of pEGFP-C1-AR Plasmid Vector using Lipofectamine® 3000 Reagent. We con- firmed the expression of AR by qRT-PCR as well as Western blotting and exam- ined the impact of palbociclib on proliferation as well as apoptosis of breast cancer cell lines. Results: AR was found to be more expressed only in luminal breast cancer cell lines but not TNBC cell lines. It was confirmed that AR was expressed in both MDA-MB-231 which are stable cell lines with the properties of LAR. In a CCK assay, palbociclib showed high sensitivity in AR-MDA-MB-231 as in luminal breast cancer cell lines. Furthermore, in an apoptosis assay using FACS and cell cycle assay, apoptosis was induced in AR-MDA-MB-231 and cell cycle arrest at the G1/S check point was confirmed. Conclusion: palbociclib (CDK4/6i inhibitor) showed effectiveness for TNBC cell lines that compulsively express AR, suggesting it may be one treatment option for TNBC in the future.

#2352 Effect of inhibition of cell cycle versus transcription cyclin-depen- dent kinases (CDKs) in ovarian cancer cells. Rosaria Chilia, Nicola Panini, Eugenio Erba, Giovanna Damia, Massimo Brogini. IRCCS - Istituto di Ricerche Farmacologiche Mario Negri, Milan, Italy.

Background: Cell cycle is regulated by cyclin-dependent kinases (CDKs) ac- tivity, which can lead to uncontrolled proliferation and cancer. Other CDKs are engaged in the regulation of transcription and post-transcrip- tional mRNA processing through the phosphorylation of the C-terminal do- main of RNA polymerase II, such as CDK9 and CDK12. Inhibitors of cell cycle CDKs have been developed as anticancer agents and some of them are under clinical validation (e.g. palbociclib). While recent data would suggest that inhi- bition of CDK9 is feasible and has antitumor effect, the data on the therapeutic role of CDK12 inhibition are very scanty. Methods: Ovarian cancer cell lines were maintained in RPMI medium supplemented with 5% glutamine and 10% FBS. Cells were treated using drug concentrations and after 72 hours cell survival was evaluated by MTS assay (Promega). IC50 values were calculated by interpolation method. Cell cycle analysis and apoptosis were performed with standard flow cytometric methods. A2780 and SKOV3 ovarian cancer cell lines knocked out for CDK12 were generated with CRISPR/CAS9 genome editing tool.

Results. The cytotoxicity of palbociclib (a CDK4/6 inhibitor) and LDC000067 (a CDK9 inhibitor) was tested in a panel of ovarian cancer cell lines (A2780, SKOV3, OVCAR3, OVCAR5, OVCAR8, OVC432, OVC433, IGROV1, EFO27). Sensitivity of cells was similar for palbociclib and LDC000067, ranging from 10 to 33 and from 8 to 60 μM, respectively. A prefer- ential G1 block was observed with palbociclib, while LDC000067 caused a S-G2 block. A higher induction of apoptosis was observed after LDC000067 than after palbociclib treatment in both A2780 and SKOV3. The palbociclib-induced G1 block was associated with decreased Rb phosphorylation, while no modulation was observed in the Ser2 in the carboxyterminal domain of RNA polymerase II was observed after LDC000067 treatment. We generated CDK12 knockd out cells transfecting CRISPR/CAS9 engineered plasmid in both A2780 and SKOV3 ovarian cancer lines. The biological and pharmacological characterization of these clones is under study. Conclusions: Palbociclib and LDC000067 showed a dose dependent cytotoxic effect in the panel of ovarian cancer cell lines tested and were active in the μM range. Preliminary data of treatment induced cell cycle perturbation and apoptosis suggest that the two drugs behave in a different manner and have distinct molecular effects on cells.

Cyclin D dependent kinases CDK4 and CDK6 are crucial regulators of the G1 to S phase transition of the cell cycle. The fact that myriad cancer types show abberance in INK4-CDK4/6-cyclin D-Rb-E2F pathway, and the rapidly emerging clinical pharmacological evidence of most validated CDK4/6 as anticancer drug targets. As the first commercialized CDK inhibitor, palbociclib in combination with bevacizumab or fulvestrant has received regulatory ap- proval for the treatment of breast cancer. This represents an important scientific advance in the field. However, the limited structural diversity and undesired side effects due to broader kinase interactions of existing inhibitors mean that the hunt for new and highly selective CDK4/6 inhibitor drug candidates continues.

Using our advanced medicinal chemistry, targeted biochemical and cell-based assays, and animal pharmacology, we synthesized and evaluated a novel series of inhibitors. Many compounds were highly potent and selective against CDK4/6, & exhibited low nanomolar potency against a range of human cancer cell lines. Notably, inhibition of CDK4/6 by compound CDKI-15 (KICD4/6 = 4 nM) was over 3 orders of magnitude greater than CDK1B, CDK2A, CDK7H and CDK9T1. In- terrogation of a panel of 369 protein kinases revealed CDKI-15 to be highly selective for CDK4/6 with only 3 other kinases inhibited potently. CDKI-15 reduced the level of Rb phosphorylation and induced G1 cell cycle arrest, con- firming cellular inhibition of CDK4/6 in cancer cells. Moreover, CDKI-15 poss- esses superior pharmacokinetic profile with oral bioavailability of 100% in mice. Treatment of nude BALB/c mice bearing human MV4-11 acute myeloid leukemia xenograft with CDKI-15 resulted in 100% inhibition of xenograft growth, with a 30% tumor regression, and a 50% overall survival. CDKI-15 resulted in a robust inhibition of tumor growth compared to vehicle treated animals (T/C = 30%, p < 0.00001). Strikingly, CDKI-15 caused a complete and sustained tumor regression in one-third of the animals. No detectable toxicity was observed in the animals during and post treatment. Taken together, our data provide a rationale for CDKI-15 to be developed towards clinic for cancer therapy.

#2354 Identification of CDK1 as an aspargin and salicylic acid binding protein: a potential role in chemoprevention. Jayarama B. Gunaje,1 D.Ramesh Kumar,2 Siddharth Kesharwani,1 Eduard Callegari,3 Hemachand Tummalad,4 Rakesh Dachini,5 Frank Lam, Minfeng Yu, Shudong Wang. 1South Dakota State Univ. College of Pharmacy, Brookings, SD; 2University of Kentucky, Lexington, KY; 3University of South Dakota, Vermillion, SD.

Palbociclib, a novel and highly selective CDK4/6 inhibitor, has been shown to be an effective therapeutic agent in preclinical models and clinical trials of the past 10 years have consolidated the rationale for investigating the use of aspirin for chemoprevention; however, the mechanisms leading to its anti-cancer effects are still being elucidated. We hypothesized that aspirin’s ability to exert chemopreventive effects may involve altering the levels and activity of cell cycle regulatory proteins. In the present study, using HT-29 colon cancer cell lines and other cancer cell lines, we demonstrated that both aspirin and salicylic acid downregulated the protein and mRNA levels of cyclin B1 and cyclin dependent kinase-1 (CDK1). Lactacystin, a 26S proteosomal inhibitor, prevented aspirin and salicylic acid mediated degrada- tion of cyclin B1, but not CDK1. Decrease in protein levels of cyclin B1/CDK1 was correlated with a corresponding decrease in CDK1 kinase activity. Molecu-
lar docking studies showed that aspirin and salicylic acid independently can dock on CDK1 through interactions with Leucine 83. Incubation of recombinant CDK1 with aspirin resulted in acetylation at lysine residues, this was also observed in cell culture experiments. Pre-incubation of CDK1 with salicylic acid dose dependently prevented aspirin’s ability to acetylate CDK1 in purified preparations confirming the data obtained from molecular docking studies. Our results show that CDK1 is a salicylic acid binding protein (SABP) and the chemopreventive actions of aspirin may involve modulation of levels and activity of cyclin B1 and CDK1.

#2355 Palbociclib enhances the antitumor activity of taxanes by abrogating cell cycle checkpoints and alleviating hypoxia in squamous cell lung cancer.
Joan Cao,1 Zhou Zhu,1 Hui Wang,1 Tim Nichols,1 Edward Rosfjord,1 Christine Hopel,2 Erik Upselson,2 Paul Rejto,2 Scott Weinrich,3 Todd Vanardas,1 James Hardwick,3 Ping Wei1.1 Pfizer, Inc., San Diego, CA; 2Pfizer, Inc., Pearl River, NY.

Lung cancer remains one of the leading causes of cancer-related mortality. Squamous cell lung cancer (SqCLC) is the second most common subtype of non-small cell lung cancer (NSCLC) and is responsible for ~100,000 deaths in the US and EU. Most SqCLC patients receive chemotherapy as first-line treatments and have a high unmet medical need for new therapies. Therapeutic approaches that enhance the efficacy of chemotherapy would therefore improve clinical outcomes for this patient population. CDK inhibitors comprise a class of drugs that target the dysregulated cell cycle in malignant cells. Treatment of tumor cells with the CDK4/6 inhibitor palbociclib inhibits tumor growth by down-regulating retinoblastoma (RB) protein phosphorylation and inducing cell cycle arrest at the G1/S phase transition. Based on promising clinical trial results, palbociclib in combination with letrozole was granted accelerated approval by the US FDA for the treatment of postmenopausal women with ER-positive, HER2-negative advanced breast cancer. Like hormone receptor positive breast cancer patients, the vast majority of SqCLC patients harbor wild type RB and HER2-negative advanced breast cancer. Like hormone receptor positive breast cancer patients, the vast majority of SqCLC patients harbor wild type RB and HER2-negative advanced breast cancer. cell cycle regulation in LNCaP-MST cells with and without nutlin-3 treatment. Our study clearly demonstrated a significant increase in the expression level of Aurora Kinase B (AURKB), CDC25C and CDK1 in MDM2 transfected LNCaP-MST cells as compared with non-transfected LNCaP cells. However, after treating the cells with 20 \mu M of MDM2 specific inhibitor nutlin-3, for 24 h, the expression levels of the above mentioned proteins were significantly altered when compared to untreated controls. In addition, inhibition of MDM2 with nutlin-3 leads to increased expression of pro-apoptotic proteins p53, p21, and Bax. Our results offer significant evidence towards the effectiveness of MDM2 inhibition in causing cell cycle arrest via blocking the transmission of signals through AURKB-CDK1 axis and inducing apoptosis in cancer cells. It is clearly evident from our data that MDM2 overexpression probably is the primary cause for CDK1 up-regulation in the LNCaP-MST cells, which might have occurred possibly through activation of AURKB. However, further studies in this direction should shed more light on the intracellular mechanisms involved in the regulation of CDK1 in MDM2 positive cancers. (This project was supported by The Royal Dames of Cancer Research Inc., Ft. Lauderdale, Florida).

#2363 Targeting Src-family kinases to combat acquired inhibitor resistance in FLT3-ITD AML. Ravi K. Patel, Mark Weir, Sabine Hellwig, Heather Dormann, Thomas E. Smithgall. University of Pittsburgh, Pittsburgh, PA.

Activating internal tandem duplication (ITD) mutations in the FMS-like receptor tyrosine kinase 3 (Flt3) are found in approximately 30% of acute myeloid leukemia (AML) patients. Flt3-ITD expression is associated with aggressive, chemotherapy-resistant disease and decreased overall survival. Multiple selective Flt3 kinase inhibitors have been developed as targeted therapy for Flt3-ITD AML. However, the clinical utility of these kinase inhibitors has been limited by the rapid recurrence of drug-resistant disease that often results from Flt3 kinase domain mutations that prevent inhibitor action. Recent studies revealed that multiple non-receptor tyrosine kinases are over-expressed in AML, including the tyrosine Src-family kinases Hck, Lyn and Fgr, and may cooperate with Flt3 to drive disease. These observations suggest that kinase inhibitors with specificity profiles targeting Flt3 and these AML-associated cytoplasmic kinases may be less prone to acquired resistance. In the present study, we determined the contributions of Hck and Fgr kinase activities to Flt3-ITD AML cell growth using a chemical genetics approach. While RNAi-mediated knockdown of each of these kinases reduces proliferation and increases apoptosis in primary AML cells, the impact of pharmacologic inhibition of their kinase activities on AML cell growth is not known. Because no selective Hck or Fgr inhibitors exist, we developed kinase domain mutants that desensitize each kinase to the broad-spectrum Src-family kinase inhibitor, A-419259. Examination of a crystal structure of Hck with A-419259 bound to the active site suggested a role for the ‘gatekeeper’ residue in compound binding. Substitution of the gatekeeper threonine of Hck and Fgr with methionine conferred 3-fold resistance to A-419259 in vitro without diminishing kinase activity. When expressed in human TF-1 myeloid cells transformed with Flt3-ITD, these inhibitor-resistant Hck and Fgr mutants conferred resistance to growth inhibition by A-419259 to a similar extent, while expression of the corresponding wild-type kinases was without effect. The sensitivity of the TF-1/Flt3-ITD cell lines to A-419259 correlated with inhibition of mutant Hck and Fgr kinase activity in the cells. Our findings suggest that suppression of AML cell growth by A-419259 is due in part to inhibition of Hck and Fgr, and identify these AML-associated kinases as therapeutic targets. Ongoing studies are addressing the role of Hck and Fgr as inhibitor targets in Flt3-ITD AML cell lines and patient samples as well as the propensity of A-419259 and other multi-targeted inhibitors of AML-associated kinases for acquired drug resistance.

Type III receptor tyrosine kinases (RTKs) including FLT3 and KIT play a major role in cell differentiation, proliferation, and survival of hematopoietic stem cells. FLT3-ITD and KIT-D816V mutations are the most common oncogenic mutations in FLT3 and KIT found in hematological cancers. These mutations lead to constitutive activation of proliferative and survival signals. Tyrosine kinase inhibitors (TKIs) in combination with chemotherapy display promising results in a clinical setting, but patients develop resistant disease after short-term response. Protein substrates that regulate the activity of FLT3 will be alternative targets for patients carrying these mutations. Activation of FLT3 and KIT results in phosphorylation on several tyrosine residues that recruit SH2 domain-containing signaling proteins. In this study we identified Src-like adaptor protein 2 (SLAP2) as a potent FLT3 and KIT interacting protein. The interaction requires an intact SH2 domain of SLAP2 as well as phosphorylation of the receptor. Overexpression of SLAP2 in murine proB/Ba/F3 cells inhibited oncogenic FLT3-ITD-mediated cell proliferation and colony formation. SLAP2 displayed a similar inhibitory potential in cells expressing KIT-D816V. SLAP2 partially blocked phosphorylation of several FLT3 and KIT downstream signaling proteins such as AKT, ERK and p38. Moreover, SLAP2 expression inhibited FLT3-ITD-mediated STAT5 phosphorylation and KIT-D816V-mediated STAT3 phosphorylation. SLAP2 expression significantly accelerated ubiquitination-mediated degradation of FLT3 and KIT. Collectively, these data suggest that SLAP2 negatively regulates FLT3 and KIT signaling and therefore, modulation of SLAP2 expression levels may become a potential target for anticancer therapy.

#2365 Dual inhibition of the PI3K/Akt and MEK5/ERK5 pathways in tamoxifen resistant breast cancer. Thomas D. Wright, Mahmoud Hasan, Paula Witt-Enderby, Jane Cavanaugh. Duquesne Univ. School of Pharmacy, Pittsburgh, PA.

Approximately 70% of breast cancers are considered estrogen receptor alpha (ER) and/ or progesterone receptor (PR) positive, and their growth is primarily driven by the hormone estrogen. Initially these cancers are responsive to endocrine therapies such as tamoxifen. However, over time patients become resistant to conventional endocrine therapy and treatment becomes more difficult. Tamoxifen resistance occurs due to several mechanisms: loss of ER expression, gain of function mutations, pharmacological tolerance, and co-inhibition of other tyrosine kinases by various kinase cascades. Aberrations in the Phosphoinositide-3-kinase (PI3K) and Mitogen Activated Protein Kinase (MAPK) pathways have been linked to increased breast cancer proliferation and survival. It has been proposed that these survival characteristics are enhanced through compensatory signaling and crosstalk mechanisms. The crosstalk between PI3K/Akt and MEK5/ERK5 has been shown in several breast cancer cell lines. However, new evidence suggests that MEK5/ERK5, a member of the MAPK family, is a key component in the proliferation and survival of therapy resistant cancers. MEK5/ERK5 has been shown to promote ER alpha driven transcription in ER+ breast cancers and act reorganization and metastasis in ER+ breast cancers. Furthermore, MEK5/ERK5 promotes hormone independent tumorogenesis in breast cancer. Our lab has previously investigated these pathways in hormone independent breast cancers, TNBC (triple negative breast cancer). Our previous results indicate that combinations of PI3K/Akt and MEK5/ERK5 blockade are promising because they inhibit both the pro-proliferative and pro-metastatic pathways in TNBC. Additionally, PI3k/Akt and MEK5/ERK5 inhibition was shown synergistically reduce viability in a range of cell lines (HTNCB, EBC+, and Triple Positive). Based on these initial results we hypothesize that PI3k/Akt and MEK5/ERK5 inhibition decreases viability through a hormone independent mechanism: perhaps by reducing the cytokolic sequestration of Bad. In this study we investigate the utility PI3k/Akt and MEK5/ERK5 inhibition in a MCF-7 TamR cell line. The goal of our study is to elucidate the roles of PI3k/Akt/mTOR and MEK5/ERK5 in endocrine resistant breast cancer and broaden the scope of a dual inhibition strategy.

#2367 Identification of ALK alternative transcription initiation in BRAF-negative metastatic melanoma patients. Shan Zhong,1 Christine Lovly,2 Christopher Malbone,1 Kristina Brennan,1 Douglas Johnson,1 Kelsie Rienschneider,2 Catherine Meador,2 Emily White,2 Geoff A. Otto,2 Doron Lipson,2 Philip Stephens,2 Vincent Miller,2 Jeffrey Ross,1 Jie He,1 Foundation Medicine, Inc, Cambridge, MA;2Vanderbilt University, Nashville, TN.

Background: Genetic alterations in the ALK tyrosine kinase, such as copy number gains, point mutations, and ALK gene fusions, have been described in a broad spectrum of malignancies. Recently a novel mechanism of ALK activation in melanoma was discovered in which ALK transcription was initiated from a de novo alternative transcription initiation (ATI) site in ALK intron 19 (ALK-ATI) [1]. In this study, whole transcriptome sequencing (WTS) re-sequenced a cohort of clinical melanoma specimens in order to identify those that express ALK-ATI. Method: RNA-seq libraries of 33 BRAF-negative clinical metastatic melanoma specimens were prepared using the KAPA Stranded RNA-Seq Kit with RiboErase with 200ng RNA as input and sequenced on Illumina HiSeq 4000 at 2x75bp. The specimens were sequenced to an average of 69.4 million total read pairs with 11.3m on-target distinct read pairs. Sequencing reads were mapped to the human genome and transcriptome, gene- and exon-level expressions were quantified. An algorithm to identify the ALK-ATI was developed based on assessing 1) transcription of intron 19 putative ATI region, 2) ALK relative RNA expression and 3) ALK 3′ to 5′ differential expression. In addition, immunohistochemistry (IHC) staining for ALK (using DSF3 antibody) was done on 10 of the 33 specimens to confirm the expression of ALK-ATI with the whole transcriptome sequencing (WTS) results. Results: Two of the ALK IHC positive cases harbor the highest ALK expression, and the other two ALK-ATI positive cases are ALK IHC weak positive. ALK-ATI occurred in cutaneous, mucosal, and unknown primary melanoma, and co-occurred with other driver mutations (NRAS, NFI, KIT). None of the above specimens had ALK rearrangements detected from DXNaseq (by FoundationOne) or WTS. Conclusions: Our findings confirmed previously reported ALK activation through ALK-ATI in an independent melanoma cohort, and provided direct evidence that such events can be detected using whole transcriptome sequencing and align with IHC results in clinical FFPE tumor specimens. This confirmation together with future functional validation and clinical evidence may provide new therapeutic opportunities for BRAF-negative metastatic melanoma patients. I. Wiesner, T. et al. Alternative transcription initiation leads to expression of a novel ALK isoform in cancer. Nature 526, 453–457 (2015).

#2368 Differential role of Pik3caH1047R and PtenH103 mutation in thyroid cancer development. Michela Ranieri, Antonio Di Cristofano. Albert Einstein College of Medicine, Bronx, NY.

Anaplastic thyroid cancer (ATC) is one of the most lethal malignancies, with a median survival of less than 6 months from time of diagnosis. Molecular changes that characterize ATC involve most often p53 loss or inactivation (up to 80%), activation of the PI3K cascade through PTEN loss (12%) and PIK3CA activating mutations (20%) or gene amplification (30-60%), RAS family members activation (6-50%), and BRAF activation (25-50%). Studies performed in endometrial and breast cancer suggest that although PI3K activating mutations and PTEN loss of function both enhance P13K signaling, these mutations are not equivalent. We have tested whether Pik3caH1047R and PtenH103 mutations have the same impact on thyroid cancer development and if these two mutations differ in their ability to cooperate with additional genetic alterations, such as p53 deletion and the KrasH12 mutation. We have generated a series of mouse models and cell lines carrying thyroid-restricted p53−/−, KrasH12, Pten−/−, and Pik3caH1047R alleles. Analysis of single and compound mutants has revealed important and striking differences between Pten and PIK3CA abilities to cooperate with additional genetic alterations, such as Cfl1, Actb, and Tubb6, we observed that Pik3caH1047R mice have the potential to develop thyroid hyperplasia and subsequent transformation than Pten−/− mice, even though the two mutations appear to have similar ability to induce AKT activation. This differential activity correlates with lower levels of pAkt found in the thyroids of Pik3caH1047R mice, compared to that of Pten−/− mice. We also observed that Pten loss synergizes with Trp53 loss to induce anaplastic thyroid cancer, activation of Pik3caH1047R leads to the development of a smaller and well differentiated tumors. On the other hand, Pten loss and Pik3caH1047R are equivalent in inducing poorly differentiated tumors in the presence of a KrasH12 mutation. However, KrasH12, Pik3caH1047R cell lines are more sensitive to PI3K, MEK and combined PI3K/MEK inhibition than KrasH12, Pten−/− cell lines. Accordingly, tumors developing in mice carrying the KrasH12, Pik3caH1047R alleles are more sensitive than KrasH12, Pten−/− mice to a dual PI3K/mTOR inhibitor as well as a MEK inhibitor. All together these results suggest that Pten loss has a stronger impact than Pik3ca activation to thyroid cancer development and resistance to small molecule inhibitors.

#2369 Transcription activators that regulate PKC-i expression and are downstream targets of PKC-i. Andre H. Apostolatos, Wishrawana S. Ratnayake, Tracess Smalley, Anisul Islam, Mildred Acevedo-Duncan. University of South Florida, Tampa, FL.

Protein Kinase C-iota (PKC-i) is an anti-apoptotic oncogene over-expressed in multiple cancers including prostate, ovarian, and glioma. PKC-i is part of a cycle that helps cancer cell avoid senescence by releasing the transcription factor NFκB and promoting apoptotic resistance. PKC-i is activated extracellularly by factors such as loss of PTEN (Paget 2012). However, while under the effect PKC-i specific inhibitors, expression levels decreased, suggesting PKC-i regulates a role in regulating its own expression. A previous study showed the ELK1 transcription factor to be a regulator of PKC-i (Gustafson 2003). Other transcription factors including Jun, IGF3, PAX3, EGRI, and FOXO1 bind on or near the promoter sequence of the gene and their role in PKC-i regulation was analyzed. Each transcription factor was systematically silenced with its own siRNA. Western Blotting revealed expression of PKC-i in the transcription factor silenced cells determining which transcription factors are key players in regulating PKC-i. Each siRNA was performed to analyze the transcription of treated cells to match protein levels with mRNA levels. Targets both up and downstream of PKC-i were analyzed to find the pathway that PKC-i uses to help regulate itself.

#2370 Depletion of p21-activated kinase 4, PAK4, inhibits cellular proliferation, motility and clonogeneity in oral squamous cell carcinoma. Felicia F. Chong,1 Si-Hoe Y. Tan,1 Vijay J. Raju,2 Pei Yuen Ng,1 Ian C. Paterson,4 Chye Ling Tan,1 Chee-Onn Leong,1 International Medical University, Kuala Lumpur, Malaysia;2 Weil Cornell Medical College, New York, NY;3 The National University of Malaysia, Kuala Lumpur, Malaysia;4University of Malaya, Kuala Lumpur, Malaysia;Agency for Science, Technology and Research (A*STAR), Singapore, Singapore.

Oral squamous cell carcinoma (OSCC) accounts for 90% of all malignancies in the oral cavity, and is often associated with low survival and poor prognosis. While considerable progress in OSCC treatment has been made, options for targeted therapy remain limited. Thus, it is imperative that new druggable targets are identified and characterized. p21-activated kinase 4 (PAK4) is a member of the PAK family of serine/threonine kinases, which are known modulators of a diverse range of oncogenic pathways including cell proliferation, escape from apoptosis, and anchorage-independent growth. Previous reports have indicated that PAK4 is overexpressed in a subset of invasive OSCC, and is highly associated with poor prognosis. However, the specific role of PAK4 in OSCC has yet to be elucidated. Here, we show that RNAi-mediated depletion of PAK4 conferred reduced clonogeneity, cell motility, and cell proliferation in OSCC cell lines in a cell-line-dependent manner. Global proteomic profiling of PAK4-depleted H103 and H357 cells was conducted to identify the molecules and signaling pathways responsive to PAK4 depletion. In addition to reported targets of PAK4 such as CFL1, ACTB, and TUBB6, we observed that p16INK4a, pre-mRNA splicing factors (SRFS2, SRFS5, SRFS6, SL7U), and proteasome activator subunits (PSME1-4) were dysregulated as a result of PAK4 depletion. These results indicate that PAK4 plays a role in promoting OSCC progression by regulating multiple signaling pathways. Of note, there have yet to be any reports describing interactions between PAK4 signaling and mRNA splicing or proteasome activation. Further investigation is thus warranted to further delineate the potential role of PAK4 in regulating these targets.

#2371 Oncogenic transformation of FLT3-ITD is partially dependent on signaling through the PI3K pathway. Tun-Tao Lu,1,2 Hidetoshi Takahashi,3 Eslam Nazarian,3,4 A. Ammar M. Makri,1,5 Andre H. Apostolatos, Wishrawana S. Ratnayake, Tracess Smalley, Anisul Islam, Mildred Acevedo-Duncan, University of South Florida, Tampa, FL.

About 30% of AML patients carry an oncogenic mutant of the type III receptor tyrosine kinase FLT3. Among the various mutations in FLT3, the internal tandem duplication (ITD) mutations in the juxtamembrane domain are the most common type of mutation, while point mutations in the kinase domain also occur. Although oncogenic FLT3 mutant cells are constitutively active, the wild-type receptor needs its ligand (FLT3 ligand, FL) for activation. Ligand binding to the receptor induces dimerization, auto-phosphorylation, and activation of the receptor. Tyrosine phosphorylation sites on FLT3 constitute docking sites for RTK-specific signaling factors (SRSF2, SRSF5, SRSF6, SL7U), and proteasome activator subunits (PSME1-4) which are regulated by the ELK1 transcription factor to be a regulator of PKC-i (Gustafson 2003). Other transcription factors including Jun, IGF3, PAX3, EGRI, and FOXO1 bind on or near the promoter sequence of the gene and their role in PKC-i regulation was analyzed. Each transcription factor was systematically silenced with its own siRNA. Western Blotting revealed expression of PKC-i in the transcription factor silenced cells determining which transcription factors are key players in regulating PKC-i. Each siRNA was performed to analyze the transcription of treated cells to match protein levels with mRNA levels. Targets both up and downstream of PKC-i were analyzed to find the pathway that PKC-i uses to help regulate itself.
interacting proteins that transduce pro-survival and proliferative signals. The so-called activation loop tyrosine residue (in FLT3, Y842) is well conserved in all receptor tyrosine kinases and long been known essential for the activity of some but not all receptor tyrosine kinases. Recently we have shown that activation loop tyrosine residue in KIT is not essential for its activation but plays an important role in cellular translocation and maturation of specific T cell subsets. PKC-θ isozyme has been extensively studied particularly in the context of hematopoiesis and immunity, where is required for the development and maturation of specific T cell subsets. PKC-θ also plays a role in Notch-driven T cell leukemia and in a subset of gastrointestinal stromal tumors and melanoma. Furthermore, the tyrosine phosphorylation of Xkr5 is not dependent on Src family kinases that play a crucial role in the activation of wild-type KIT. In KIT/D816V expressing mast cells, phosphorylation of Xkr5 inhibits KIT/D816V downstream signaling molecules Akt, Erk and p38. As a consequence, cell proliferation and colony formation is inhibited by the tyrosine phosphorylation of Xkr5 as well, indicating that Xkr5 is a negative regulator of KIT/D816V signaling.

**#2373 Analysis of the distinct activities of the C1a and C1b domains of protein kinase C theta.** Agnes Czikora,1 Satyabrata Pany,1 Youngki You,2 Amandeep Saini,1 Noemi Kedei,1 Nancy E. Lewin,1 Adelle Abramovitz,1 Joydip Das,2 Peter M. Blumberg1.

PKC isozymes, the major receptors for tumor-promoting phorbol esters, play a central role in cellular signal transduction downstream of the second messenger diacylglycerol. The PKCθ isozyme has been extensively studied particularly in the context of hematopoesis and immunity, where is required for the development and maturation of specific T cell subsets. PKCθ also plays a role in Notch-driven T cell leukemia and in a subset of gastrointestinal stromal tumors, melanoma and breast cancers. The C1 domains represent the regulatory motif in the PKCs responsible for their recognition of diacylglycerol / phorbol esters. PKCθ is unique among the conventional and novel PKC isoforms in that one of the two C1 domains of PKCθ, the C1a domain, has been reported to show little or no affinity for diacylglycerol or phorbol ester, unlike the C1b domain. Likewise, the PKCθ C1b domain has been reported to play the predominant role in the membrane translocation and activation process of PKCθ. We observed that the C1a domain in fact has appreciable binding activity for [H]phorbol 12,13-dibutrate (PDBu), with a Kd of 254 nM, albeit much less than that of the C1b domain, 1.38 nM. Replacing individually in the C1a domain ten of the amino acid residues that differed between the C1a and C1b domains, using the correspon- ding residue from the C1b domain, we found that only the P9K replacement restored [H]phorbol 12,13-dibutyrate binding activity to the C1a domain, yielding a Kd of 3.60 nM, close to that of the C1b domain. Strikingly, the reciprocal replacement in the C1b domain of K9P still preserved appreciable binding affinity, 11.7 nM. We conclude that other features in the C1a domain contribute to the extent to which the P9 residue negatively influences binding. We further explored the role of the C1 domains of PKCθ on translocation using confocal microscopy with a variety of full length constructs in which the C1 domains were manipulated. Consistent with the binding studies, we showed that the C1b domain was the main contributor to translocation, that the full length PKCθ with the C1b K9P retained response, albeit more weakly, and that deletion of the C1a domain or its replacement with a second C1b domain enhanced the translocation to the plasma membrane. Exploitation of the structural differences between the C1 domains in PKCθ and those of other PKC isoforms, both at the level of the direct ligand interactions and the more complexly intercalated between C1 domain, ligand, and phospholipid bilayer, may help to afford specific ligands for this member of the PKC family.

**#2374 Mixed-Linear Kinase 3 signals through the FRA1-MMP1 axis to drive triple-negative breast cancer invasion and transendothelial migration.** Chotirat Rattanasinchai, Brandon Llewellyn, Susan E. Conrad, Kathleen A. Gallo. Michigan State Univ., East Lansing, MI.

Mixed-lineage kinase 3 (MLK3), a mitogen-activated kinase kinase kinase (MAP3K), contributes to metastasis of triple-negative breast cancer (TNBC), in part through its regulation of paxillin phosphorylation and focal adhesion turnover. However the signaling mechanisms through which MLK3 promotes invasion and metastasis are not fully understood. We found that in non-metastatic, estrogen receptor positive (ER+ ) breast cancer cells, induced MLK3 expression robustly upregulates the oncogenic transcription factor, FOS-related antigen 1 (FRA-1), as well as matrix metalloproteinases (MMPs), MMP-1 and MMP-9. MLK3-induced MMP-1 induction is abrogated by FRA-1 silencing, demonstrating that MLK3 signals through FRA-1 to control MMP-1. In complementary experiments performed in metastatic TNBC models, high levels of FRA-1 are significantly reduced upon gene silencing of MLK3 or by MLK3 disruption using the CRISPR/Cas9a approach. Furthermore, both MMP-1 and MMP-9 are decreased upon FRA-1 silencing, and decreased endothelial permeability and transendothelial migration is observed in experiments with MLK3-depleted TNBC cells compared with parental counterparts. In addition, MLK inhibitor treatment or MLK3 deletion renders TNBC cells defective in Matrigel invasion. Furthermore, circulating tumor cells (CTCs) derived from a TNBC-bearing mouse which show an intermediate epithelial-mesenchymal phenotype display increased levels of MLK3, FRA-1, and MMP-1 compared with parental cells, supporting a role for the MLK3-FRA-1-MMP-1 signaling axis in tumor cell invasion and vascular invasation. Consistent with the role of MMP-1 in multiple steps of metastasis, high levels of MMP-1 in breast cancer patient tumor samples are associated with increased distant metastases and poorer overall survival, particularly in TNBC. Our results demonstrating the requirement for MLK3 in controlling the FRA-1/MMP-1 axis suggest that MLK3 is a potentially effective therapeutic target for TNBC.

**#2375 Functional role of the tumor suppressor protein phosphatase, PP2A-B55α, in breast cancer.** Nikita Panicker,1 Abdul Mannan,1 Lauren F. Watt,1 Ben Copeland,1 Matt D. Dun,2 Simon King,2 Megan Clarke,2 Kathryn Skelding,1 Severine Roselli,1 Nicole M. Verrills 1. Unv. of Newcastle, Callaghan, Australia; 2Pathology North Lamington, Australia; #2Huntier Cancer Research Alliance, New Lambton, Australia.

Breast cancer is the most common cancer in women and a leading cause of death. Dysregulation of cellular signalling pathways controlling proliferation, survival and migration, such as the PI3K/Akt and Ras/MAPK pathways, are key features of breast cancer. Protein phosphatase 2A (PP2A) negatively regulates these components of these pathways. PP2A is a family of trimeric serine/threonine protein phosphatases, each consisting of a structural, a catalytic and a regulatory subunit of which there are multiple isoforms. The addition of specific regulatory subunits provides subcellular targeting and substrate specificity to the enzyme. While PP2A is generally considered a tumor suppressor, a specific role for individual PP2A subunits in breast cancer has not been described. To address this, we first examined PP2A subunit expression in human breast tumors. Immunohistochemical analysis revealed significantly lower expression of the structural subunit, PP2A-A, and regulatory subunits PP2A-B55α and PP2A-B56α, in primary tumors and metastases, compared to adjacent normal mammary tissue. We further found an association of low PP2A-B55α with aggressive breast cancer subtypes, and with worse disease-free and overall survival. Functionally, shRNA-mediated knockdown of PP2A-B55α in breast cancer cell lines disrupted focal adhesion and enhanced 3D cultures induced a tumorigenic phenotype, characterised by increased proliferation and enlarged multi-lobular acini. In contrast, overexpression of PP2A-B55α in breast cancer cells inhibited proliferation. Thus PP2A inactivation, in particular loss of B55α, is functionally important in breast tumorigenesis. PP2A-B55α complexes play an important role in DNA damage repair, and we found PP2A-B55α knockdown impaired DNA damage repair. Thus low PP2A-B55α may contribute to genomically instability. To examine the functional role of PP2A-B55α in vivo, we have generated the first PP2A-B55α (Pprr2ra) knockout mouse. Constitutive knockout of Pprr2ra is embryonic lethal, with embryos dying during late development, post 14.5 days p.c. Heterozygous Pppr2ra mice
MOLECULAR AND CELLULAR BIOLOGY / GENETICS: Cell Growth Signaling Pathways 5

(Ppp2r2a-/-) are viable, despite expressing only ~10% of Pp2a-B55ε protein levels compared to WT mice. Interestingly, Ppp2r2a-/- mice have significantly reduced branching in the developing mammary gland, similar to that observed in mice with mammary-specific loss of the breast tumor susceptibility gene, Brca1. Analysis of breast tumor formation in these mice, either alone or when crossed with MMTV-Neu animals, is underway. We further characterized the pathological activation of Pp2a, using FTY720, or the non-phosphorylatable analogue, AAL(S), inhibits tumor growth and metastases in an orthotopic xenograft model of aggressive, triple negative breast cancer (MDA-MB-231). Together this work demonstrates the importance of Pp2a as a tumor suppressor in breast cancer, and suggests that targeting Pp2a is a potential therapeutic strategy for poor outcome patients.

#2376 Novel insights into the regulation of ERK3's kinase activity and its ability to promote cancer cell invasiveness. Lobna Elkhdag, Hadel Alseran, Weiwen Long. Wright State University, Dayton, OH.

In comparison with the well-studied conventional MAPKs, such as extracellular-signal-regulated kinase (ERK)1/2, much less is known about the regulation and downstream targets of ERK3, an atypical MAPK. Whereas dual phosphorylation of the TXY activation motif in ERK1/2 is critical for their activation, it is unclear if phosphorylation of the single phospho-acceptor site (S189) in the SEG activation motif of ERK3 is critical for its kinase activity or function. In addition, little is known about the functions of the structurally distinct elongated C-terminus extension of ERK3. Recent studies have revealed important roles for ERK3 in promoting cancer progression. Of note, our previous study showed that ERK3 increases cancer cell invasiveness by phosphorylating the oncogenic protein steroid receptor co-activator 3 (SRC-3) and upregulating SRC-3-mediated matrix metalloproteinase gene expression. Here we aimed to elucidate the importance of the phospho-site S189 and the C-terminus in regulating ERK3 kinase activity and its functions in cancer cells. By performing in vitro kinase assays, we found that as compared to the wild type (WT) ERK3 protein, ERK3-S189A has remarkably reduced kinase activity towards auto-phosphorylation and phosphorylating SRC-3. In line with the critical role of S189 in ERK3 kinase activity, mutation of S189 to alanine greatly reduced ERK3's activity in promoting the migration and invasion of lung cancer cells. To study the regulatory role of the C-terminus in ERK3 kinase activity, we expressed and purified the N-terminal ERK3 (aa 1-340) that retains the kinase domain but has deletion of the C-terminus. While it showed higher auto-phosphorylation ability than the full length ERK3 protein, ERK3 (aa 1-340) had greatly decreased ability to phosphorylate SRC-3. Interestingly, ERK3-S189A (aa 1-340) exhibited kinase activity equivalent to that of ERK3 (aa 1-340). These results suggest that on one hand, the C-terminus may play an auto-inhibitory role on ERK3 kinase activation through intramolecular interaction and that the phospho-S189 is required for relieving this auto-inhibition. On the other hand, C-terminus plays a critical role for ERK3 to recruit substrates, such as SRC-3. In agreement with its inability to phosphorylate SRC-3, ERK3 (aa 1-340) had decreased ability to stimulate migration and invasion of lung cancer cells as compared to full length ERK3. Taken together, our study unravels the importance of ERK3 S189 residue as well as the C-terminus for the intramolecular regulation of ERK3 kinase activity and invasiveness-promoting ability in cancer cells.

#2377 The AML linked Src family kinase Fgr is uncoupled from SH2 and SH3 domain regulation and drives oncogenic transformation. Kexin Shen, 1 Heather R. Dorman, 1 Haibin Shi, 1 Ravi K. Patel, 1 Jamie A. Moroco, 2 John R. Engen, 1 Thomas E. Smithgall, 1 Engen, 2 Thomas E. Smithgall1. Univ. of Pittsburgh School of Medicine, Pittsburgh, PA; 2Northeastern University, Boston, MA.

Fgr is a member of the Src family of non-receptor protein-tyrosine kinases, which are over-expressed and constitutively active in many human cancers. Fgr expression is restricted to myeloid hematopoietic cells and strongly upregulated in a subset of primary human AML bone marrow samples, suggesting that Fgr kinase activity may contribute to AML pathogenesis. To investigate the oncogenic potential of Fgr, we expressed the wild-type kinase in Rat-2 fibroblasts and scored transformation in soft agar colony-forming assays. Remarkably, Fgr expression resulted in strong transforming activity, suggesting that over-expression of the kinase is sufficient to overcome regulatory control by its SH2 and SH3 domains. To test this idea, we mutated the negative regulatory tail tyrosine of Fgr. Phosphorylation of the homologous tyrosines in c-Src, Hck and other Src-family members by the regulatory kinase Csk causes intramolecular engagement of the SH2 domain to suppress kinase activity. Substitution of the Fgr tail tyrosine with phenylalanine did not further enhance the transforming or kinase activity of Fgr in Rat-2 cells, suggesting that its kinase domain is uncoupled from regulation by its non-catalytic SH3-SH2 region. To explore the regulatory mechanism further, we expressed near-full-length Fgr in insect cells, purified it to homogeneity, and confirmed that it was singly phosphorylated on its negative regulatory tail (and not the activation loop). Hydrogen-deuterium exchange mass spectrometry demonstrated that the SH3 and SH2 domains are protected from deuterium uptake as observed previously for recombinant, downregulated Hck, suggesting that they are packed against the back of the kinase domain. We then tested recombinant Fgr for sensitivity to activation in vitro using peptide ligands for the SH3 and SH2 domains, as well as a peptide that engages both domains simultaneously. Fgr kinase activity was unaffected by these peptides, providing further evidence that the kinase domain is not allosterically coupled to SH3 and SH2 control. In contrast, Hck and c-Src were both stimulated by these peptides, consistent with a domain displacement mechanism of activation described previously. Control experiments using surface plasmon resonance spectroscopy confirmed that the SH3 and SH2 domains of both Hck and Fgr bind to each of the peptide ligands with similar kinetics and affinity. Taken together, our data show that Fgr is a unique Src family member in that its kinase domain is not subject to regulatory domain control despite evidence for intramolecular interactions with the SH3 and SH2 domains. As a consequence, simple over-expression of Fgr is sufficient to induce transformation of rodent fibroblasts, unlike Hck or other Src family members. By extension, over-expression of Fgr may contribute to AML development and selective targeting of its kinase activity may be of therapeutic benefit.

#2378 A kinome analysis of the molecular pharmacodynamics of PT-112 in a human cancer cell line. Diego Tosi, 1 Esther Perez-Gracia, 1 Philippe Pourquier, 2 Tyler D. Ames, 2 Richard A. Wing, 2 Jose Jimeno, 2 Celine Gongora. 3 Institut de Recherche en Cancérologie de Montpellier, Montpellier, Montpellier, France; 4Phos- platin Therapeutics, New York, NY.

Background: To better understand the mechanism of action of PT-112, we investigated the effects of PT-112 on kinase activity within HCT116 human colorectal cancer cells. PT-112 is a pyrophosphate-conjugated platinum (Pt) containing new chemical entity under clinical development in the US and Tai- wan. Designed to reduce certain toxicities associated with Pt agents and drug resistance from DNA-repair pathway activity, PT-112 differs in significant ways from traditional Pt therapies. PT-112 results in potent anti-proliferation effects with lower Pt accumulation in whole cell and DNA extracts. Upregulation of p16 and p21, and consistently, inhibition of the cell cycle at the G1/S phase transition is observed with PT-112 use, a finding not commonly associated with Pt agents. Further, sensitivity to PT-112 is not significantly affected by the functionality of DNA repair pathways. Finally, the induction of immunogenic cell death by PT-112 has been indicated via release of HMGB1, cell surface localization of calreticulin, and suppression of STAT3. Methods: A broad analysis of the phosphorylation pattern of kinase targets was achieved by utilizing the Tyrosine Kinase and Serine / Threonine Kinase PamChip® Arrays, each spotted with 144 peptides harboring kinase phosphorylation sites. Data were collected after 1, 6, and 24hr of exposure to 10 μM PT-112, a concentration achievable in human patient plasma at sub-toxic doses, and the degree of phosphorylation of these peptide targets was measured by the PamStation®, results: A set of kinase targets was identified as differentially phosphorylated relative to untreated control samples. In total, 4/1/5 targets were more phosphorylated than controls at the 1/6/24 hour time points, respectively, while seven less phosphorylated. Several of these targets connect to key cancer relevant pathways, including anti-angiogenesis (VGFRI), apoptosis (BAD), cell cycle regulation (CDC2, Rb, RBL2), cell growth (EGFR, MK07, RBL2), and cancer immunity (STAT4, CSFIR). Conclusions: A narrow set of initial effects on kinase activity from PT-112 exposure, which broaden over time, was observed. While we cannot discriminate direct from indirect effects, these data are consistent with PT-112 having mechanistic targets independent of nuclear DNA. Several observations were consistent with findings from previous experiments (e.g. evidence of impacts on apoptotic, cell cycle, and immunological pathways), while others were novel (e.g. impact on VGFRI, EGFR, MK07). In conclusion, PT-112 at pharmacologically achievable concentrations leads to a unique pattern of kinase disruption in vitro. Further work will be conducted to validate these findings, identify the driver kinases, and connect these observations into a coherent network of kinases and targets affected by PT-112 treatment, and to understand the clinical impact of the unique pharmacodynamic profile of PT-112.

#2379 Nuclear lemur tyrosine kinase 2 regulates RNA polymerase II dependent transcription in prostate cancer. Kalpit Shah, 1 Justin Foley, 1 Michael L. Nickerson, 1 Michael Dean, 1 Neil Bradbury 2. 1National Cancer Institute, Bethesda, MD; 2Rosalind Franklin University of Medicine & Sciences, North Chi- cago, IL.

The Androgen Receptor (AR), a DNA-binding transcription factor plays a key role in the development and maintenance of prostate epithelia by modulat-
ing expression of growth-promoting genes. AR has been proposed to regulate gene expression by enhancing the efficiency of RNA polymerase II (RNAPII) dependent transcription elongation. Dysregulation of this AR-dependent transcriptional activity has been implicated not only in prostate cancer but also androgen-independent prostate cancer. Recently, we showed that protein expression of LMTK2 in the Kiessig-2 (LMTK2) serine/threonine kinase is downregulated in prostate cancer. Importantly, our study ascribed a novel role for LMTK2, as a negative regulator of AR-dependent transcriptional activity in prostate epithelial cells. However, the mechanism through which LMTK2 is able to regulate AR remains to be determined. Here, we show that LMTK2 is not only present in cytoplasmic fraction but also, within the nucleus of mammalian cells where it co-localizes with AR, newly transcribed mRNA and with RNA polymerase II (RNAPII). Interestingly, our data reveals that LMTK2 colocalizes with elongating RNAPII, phosphorylated on serine 2 of the carboxyl-terminal domain. This presents an interesting possibility that LMTK2 might be able to regulate transcription of AR-dependent genes by interacting with the elongating RNAPII and transcription & epigenetic factors. As such, our study potentially identifies LMTK2 as an important player regulating the AR-RNAPII mediated transcription machinery in mammalian cells.

#2380 Insertion mutations in the tyrosine kinase domain of FLT3 display a higher oncogenic potential than the D835Y mutation in acute myeloid leukemia. Alissa Marhall,1 Thomas Fischer,2 Florian Heidel,2 Julhass U. Kazi,1 Lars Rönstrand1. 1Translational Cancer Research, Lund University, Lund, Sweden; 2Otto-von-Guericke University Medical Center, Magdeburg, Germany; 3University Hospital, Ruhr, Germany.

Acute myeloid leukemia (AML) remains the most common form of acute leukemia among adults and accounts for a large number of deaths. Mutation in FMS-like tyrosine kinase 3 (FLT3) is one of the most prevalent factor in this heterogeneous disease. The major mutations in FLT3 can be categorized as internal tandem duplications (ITD) and point mutations. Recent studies suggest that ITDs are subdivided in to two groups depending on their location: the juxtaphal and end duplicated (ITD) and the kinase domain (ITD-TKD). Although, ITD-JM has been characterized well the ITD-TKD has not yet been studied well due to its recent discovery. For this reason, we compared ITD mutations in TKD and JM, as well as the most frequently occurring point mutation located in the TKD, D835Y. The purpose of this study was to understand whether it is the mutation’s nature or location that plays the driving role in leukemogenesis. We used a cytokine-dependent mouse pro-B cell line, BaF3, to overexpress different FLT3 mutants. We first examined the colony formation capacity in semisolid cytokine- and serum-free medium. The assay resulted in indistinguishable number and size of colonies for both ITD-JM and ITD-TKD, while D835Y-TK3 transfected cells failed to form colonies suggesting that the ITD-TKD mutations have stronger transforming potential than other TKD mutations. In addition to colony formation assays, cell proliferation and survival was significantly higher in ITD-TKD expressing cells compared to cells expressing D835Y-TKD. Finally, we showed that phosphorylation of STAT5 and AKT is increased in ITD-TKD, while other FLT3 downstream signaling remained unaffected. All together, our data suggest that ITD-TKD displays higher oncogenic potential than other TKD mutants.

#2381 The effect of ERK5 inhibition in clear cell renal cell carcinoma. Hidenori Kanno, Sei Naito, Osamu Ichiyangi, Norihiko Tsuchiya. Yamagata University, Yamagata City, Japan.

Introduction: Clear-cell renal cell carcinoma (cRCC) is the most prevalent kidney cancer and is characterized by von Hippel-Lindau tumor suppressor gene (VHL) mutation. VHL, protein acts in a ubiquitin ligase complex, mediating the proteosomal degradation of ubiquitinated proteins, including hypoxia-inducible factor (HIF). Therefore, HIF accumulates in VHL-defective cell lines. A recent study revealed that extracellular signal-regulated kinase 5 (ERK5) is degraded through the ubiquitin-proteasome system, in a process mediated by VHL and HIF. Our objectives were to examine the effects of ERK5 in cRCC and to investigate the potential therapeutic target. Methods: ERK5 expression was investigated in surgically resected cRCC specimens using immunohistochemistry. To confirm that ERK5 is degraded by the VHL pathway, ERK5 levels were examined by western blotting in Caki-1 VHL wildtype renal cell carcinoma (RCC) cells and in A498 and A704 VHL-mutant RCC cells with or without the MG132 proteasome inhibitor. Furthermore, VHL-mutant cell lines were examined, with or without siRNA and XMD8-92-mediated ERK5 inhibition, to investigate the role of ERK5 in RCC cells using flow cytometry, MTS assays, and western blotting. Results: In surgical specimens, RCC cells showed higher levels of ERK5 expression than did normal cells. In addition, MG132 enhanced ERK5 expression in wildtype cell lines, but not in VHL-mutant cell lines. Therefore, ERK5 degradation involves the VHL pathway. Furthermore, ERK5 inhibition resulted in increase of the sub-G1 population as observed by flow cytometry and cleaved RARP expression as seen by western blotting, indicating an increase in apoptotic cells. ERK5 inhibition also suppressed cell viability and downregulated p16 and Bcl-2 expression. Conclusion: Our results show that ERK5 inhibition contributes to the downregulation of anti-apoptotic and cell cycle proteins and suggest that ERK5 is a promising therapeutic target for cRCC.

RACK1 (Receptor for Activated C Kinases) is a scaffolding protein with 7 WD repeats that interacts with the insulin-like Growth Factor I receptor (IGF-IR), integrins, and other signalling proteins. RACK1 functions as a scaffolding protein and regulator of many key biological processes and it is highly expressed in most tissue. We recently reported that RACK1 is essential for IGF-1-mediated regulation of PP2A activity and AGAP2 activity at focal adhesions. Downstream of IGF-1R signaling in cancer cells, the scaffolding properties of RACK1 are altered providing distinct migratory advantages to the cell and suggesting that RACK1 is an important regulator of IGF-I signaling in cancer progression. It is important to further characterise the role of RACK1 in cancer and to delineate the molecular mechanisms by which it regulates key signalling pathways. We have identified Protein Kinase A (PKA) as RACK1 interacting protein. PKA is a complex, multicomponent enzyme which is a fundamental protein that functions in cell survival, proliferation, and cytoskeletal remodelling among others. Our hypothesis is that RACK1 regulates the PKA axis in cancer cells leading to a higher oncogenic potential than the D835Y mutation in acute myeloid leukemia. RACK1 has the potential to mediate PKA activity in colon cancer cells. Although we show that PKA expression is not altered in colon cancer tissue, we believe that PKA activity is altered significantly in the disease state. Using PKA inhibitors, we have shown that PKA regulates IGF-1R-mediated MAP Kinase activation in colon cancer cell lines. In conclusion, this research project will help elucidate the role of PKA in colon cancer. Inhibiting or promoting specific protein interactions with RACK1 will provide very novel therapeutic opportunities and anti-cancer drug targets.

#2383 Nicotinamide N-methyltransferase inhibits Protein Phosphatase 2A activity by promoting T307 phosphorylation. John R. Jacob, Arnab Chakravarti, Kamalakannan Palanichamy. Ohio State Univ. College of Medicine and Comprehensive Cancer Center, Columbus, OH.

Recent evidence indicates that suppression of protein phosphatase 2A (PP2A) activity plays an essential role in malignant transformation and cancer cell survival. Despite the essential role of PP2A in cancer, the mechanisms by which other enzymes regulate PP2A remain largely unknown. We recently identified Nicotinamide N-methyltransferase (NNMT) as a novel regulator of PP2A activity in glioblastoma (GBM). NNMT is a cytosolic N-methyl transferase which utilizes methyl groups from S-Adenosyl methionine (SAM), forming the by-product S-Adenosyl Homocysteine (SAH). SAH, PP2A becomes activated following the trimer formation of the three PP2A subunits, which requires the methylation of the catalytic subunit of PP2A (PP2A C) at L309. In cancer, NNMT has been reported to decrease the cellular methylation potential (SAMS/AH) and correspond with decreased PP2A activity. It was hypothesized that the decrease in methylation potential accounts for the decrease in PP2A activity by kinetically disfavoring the methylation of PP2A C. Interestingly, when we overexpressed NNMT in GBM cell lines and used LC-MS/MS (LC-MS Quadrupole Time-of-Flight and LC-MS Triple Quad) to monitor the methylation potential, we discovered that overexpression of NNMT increased methylation potential, however, still lead to a decrease in PP2A activity. As a result, we hypothesized that NNMT suppresses PP2A activity in a methylation-independent manner. In an effort to identify an alternative mechanism by which NNMT decreases PP2A activity, we found that NNMT expression was required for the phosphorylation of PP2A C at residue T307, which inhibits PP2A trimer formation and activation. Further, we found that NNMT expression leads to the constitutive activation of the PP2A target serine/threonine kinases (STks): Akt, MAPK, and SAPK/JNK. NNMT silencing resulted in the inactivation of these downstream PP2A target stress kinases, which was not sufficient to rescue their activation. This suggests that NNMT-induced PP2A suppression is essential for the activation of these kinases. Overall, this study demonstrates a novel mechanism independent of methylation by which NNMT represses the activity of tumor suppressor PP2A.
#2384 Aberrant expression of PDZ binding kinase modulates human pancreatic cancer cell invasion. Charles Hinzman,1 Jose Trevino,2 Partha P. Banerjee1.1Georgetown Univ. Medical Ctr.; Washington, DC; 2University of Florida Medical Center, Gainesville, FL.
Pancreatic ductal adenocarcinoma (PDAC) is the fourth leading cause of cancer-related death and is projected to become the second leading cause of cancer deaths by 2030. Incidence to mortality ratio for PDAC is almost one suggesting its aggressive phenotype. The poor survival rate of PDAC patients is due to metastasis to distant organs, and therefore, recent focus has been aimed towards the identification of molecular targets that drives metastatic disease. We are investigating an under-studied kinase, PDZ-domain binding kinase (PKB) as a target for pancreatic cancer (PanCa) therapy. PKB is a dual-specificity serine/threonine kinase involved in mitosis and invasive behavior of cancer cells. It is expressed physiologically in tests, but aberrant expression results in an aggressive phenotype in a variety of cancers. Our results demonstrate that PKB expression varies across a panel of human PanCa cell lines, and directly correlates with their invasive ability. Similarly, a panel of patient-derived primary PanCa shows higher PKB levels associated with aggressive behavior and invasion. To assure specificity of PKB to this invasive phenotype, we measured the effect of PKB overexpression or knockdown on the PanCa lines invasive ability. Overexpression of PKB in low PKB expressing cells increased PanCa invasion ~10-fold, while PKB knockdown reduced invasive ability ~5-fold. Immunohistochemical analyses of resected human PanCa specimens revealed that PKB is present in the majority of human PanCa tissue samples tested but not in the adjacent normal pancreatic tissue. Interestingly, aberrant PKB localization was found in even early stages of PanCa development and was sustained throughout its progression. In search of molecular effectors of invasion regulated by the PKB, we examined various genes/proteins that are involved in cancer cell invasion and metastasis. ReblA well-known metastatic inducer in various cancers was found to be a major player in PanCa and regulated by PKB. These data indicate a novel molecular pathway of PKB where its presence plays a role in invasion of human PanCa cells. Therefore, the role of PKB in promoting cancer cell invasion, combined with its general lack of expression in normal cells, nominates PKB as a potentially important therapeutic target for pancreatic cancer.

#2385 Systematic characterization of kinase inhibitors reveals heterogeneity in responses by class and cell line. Caitlin E. Mills1, Marc Hafner,2 Dejan Juric,2 Peter K. Sorger1.1Harvard Medical School, Boston, MA; 2Massachusetts General Hospital, Boston, MA.

Several publications have addressed concerns surrounding drug response screens by pointing out sources of variability and by presenting recommendations for better experimental methods and more robust analytical approaches. In the presented profiling effort, we integrated the latest advances in drug response measurement and focused on data diversity and quality rather than on breadth. We selected 32 breast cancer cell lines with a strong bias towards triple negative lines as well as 4 cell lines established from relevant patient-derived xenografts. We evaluated a panel of clinically relevant kinase inhibitors using a microscopy-based drug response assay to measure drug potency, and to quantify drug efficacy in terms of growth inhibition (GR metrics) and cell death. The use of the GR metrics to assess the sensitivity enabled us to identify and study differences between cytostatic and cytotoxic responses. This systematic dose response dataset is complemented by measurements of baseline mRNA expression levels by RNAseq and endogenous protein levels by shotgun mass spectrometry across all cell lines. The completeness and controlled conditions under which these data sets were collected provide confidence in their integration. The baseline RNA and protein expression levels were used to build predictors of the measured drug responses with the goal of identifying the biological processes responsible for the differences in sensitivity across drugs and cell lines. Differences in the phenotypic responses of cell lines to kinase inhibitors with the same nominal targets have been investigated, and associated with variable inhibitor polypharmacology.

#2386 HDAC6 regulates ERK1’s kinase activity via deacetylation. Jheng-Yu Wu,1 Xiaohong Zhang2.1Univ. of South Florida College of Medicine, Tampa, FL; 2Karmanos Cancer Institute, Wayne State University, Detroit, MI.
Extracellular signal-regulated kinases 1/2 (ERK1/2) are important kinases regulating cell proliferation and cell migration, and have been established as therapeutic targets for cancer treatment. Previously, we found that ERK1 phosphorylates histone deacetylase 6 (HDAC6), a class IIb HDAC, to regulate its enzymatic activity. HDAC6 plays an important role in several types of cancers. HDAC6 governs cancer cells’ migration by cooperating with cytoskeleton proteins and their associated proteins, and HDAC6 is arising as a determinant for cisplatin-resistance in non-small cell lung cancer (NSCLC) and ovarian cancer.

Here, we have shown that HDAC6 manipulates ERK1’s kinase activity via deacetylation. We demonstrated that both ERK1 and ERK2 interact with HDAC6 physically via GST pull-down assays. To examine whether ERK1/2 are acetylated, we transfected GST-ERK1 or GST-ERK2 into HEK293T cells, and treated the cells with a pan-HDAC inhibitor, Trichostatin A. We showed that the level of acetylated HDAC6 was increased in a dose-dependent manner. Furthermore, when GST-ERK1 or GST-ERK2 expressed cells were treated with an HDAC6-specific inhibitor, ACY-1215, the level of acetylated GST-ERK1/2 increased. These results suggest that HDAC6 is a deacetylase for ERK1/2. In addition, we determined that acetyltransferases CBP and p300 acetylate ERK1/2. We found a novel acetylation site located in ERK1 N-terminus by mass-spectrometry analysis. We then mutated this lysine (K) site with either Glutamic acid (Q) or Arginine (R) to mimic the acetylation or deacetylation status, and performed kinase assays using ELK1 as a substrate. The acetylation mimicking mutant exhibits a decreased kinase activity toward ELK1, while the deacetylation mimicking mutant exhibits a similar level of kinase activity as the wild-type ERK1 does, suggesting that acetylation/deacetylation alters ERK1 enzymatic activities. Therefore, HDAC6 may regulate ERK1’s kinase activity via deacetylation of this site. Furthermore, we have shown that HDAC6 is overexpressed in lung cancer tissue samples and plays an important role in chemosensitivity in lung cancer. We predict that inhibition of the HDAC6-ERK1 pathway may provide clinical benefit for lung cancer patients.

MOLECULAR AND CELLULAR BIOLOGY / GENETICS: Cell Growth Signaling Pathways 5

#2387 Overexpression of NSUN2 by DNA hypomethylation is associated with metastatic progression in human breast cancer. Jie Yi,1 Yu Chen,2 Ran Gao,3 Zhou Yang,4 Jinhua Wang,5 Yingchun Xu1. 1Peking Union Medical College, Beijing, China; 2Chinese Academy of Medical Science and Peking Union Medical College, Beijing, China.

NSUN2 is a RNA methyltransferase that has been shown to be implicated in development of human cancer. However, the functional role of NSUN2, mechanism of NSUN2 overexpression and its association with clinicopathologic features in breast cancer remain unclear. To investigate alterations in the expression and functional role of NSUN2 in breast cancer, NSUN2 expression was assessed in breast cancer cells and tissues obtained from cancers at different American Joint Committee on Cancer (AJCC) stages, and its functions were investigated using breast cancer cell lines. NSUN2 expression was shown to be significantly higher in breast cancer cells and tissues than in normal breast epithelial cells and tissues, at both mRNA and protein levels. Overexpression of NSUN2 was shown to promote cell proliferation, migration, and invasion while NSUN2 knockdown inhibited these processes in vitro and in vivo. NSUN2 expression level was associated with the methylation level of its promoter. Our results demonstrated that the overall expression of NSUN2 significantly correlated with clinical stage (P=0.027), tumor classification (P=0.012), pathological differentiation (P=0.023), as well as with the expression levels of estrogen receptor (P<0.001), progesterone receptor (P<0.001), and Ki-67 (P<0.001). Our findings provide a unique insight into the roles and effects of NSUN2 overexpression in breast cancer cells, and highlight the necessity of the investigation of novel therapeutic targets, such as NSUN2, for the improvement of breast cancer treatments.

#2388 Low grade gliomas exhibit distinct patterns of epigenetic aging associated with prognostic molecular subtype. Peter Liao, Jill Barnholtz-Sloan. Case Western Reserve University, Cleveland, OH.

Background: Low grade gliomas make up a significant proportion of malignant brain tumors and possess a high degree of heterogeneity, highlighting a need for clinically useful markers for prognosis and further biologic investigations. We used an existing model of biological age based upon DNA methylation to characterize epigenetic age in low grade gliomas (LGG) according to existing molecular classifications and assessed the prognostic utility of epigenetic age. Methods: We analyzed the full TCGA LGG cohort consisting of 516 patients; 216 grade 2 and 241 grade 3 tumors. Age at diagnosis ranged from 14-87 years with median age 43. We calculated "DNA methylation age" (DNAm age) based upon 353 Cpg probes according to the epigenetic clock developed by Steve Horvath, and calculated age acceleration according to the DNAm age of tumor tissue relative to reported chronological age of patient at diagnosis. DNAm age was assessed for prognostic value using Cox proportional hazards regression. Age acceleration differences were assessed across LGG molecular classification.

Proceedings of the American Association for Cancer Research • Volume 58 • April 2017
methods using the Wilcoxon Ranked Sum test. Results: DNA methylation age remained highly correlated with chronological age in LGG tumor tissue (cor=0.58, p<0.001), with an average age acceleration of 33.5y. DNA methylation age was weakly positively correlated with mutational burden (cor=0.12, p=0.01). Higher DNA methylation age was positively associated with survival independent of chronological age and tumor aggressiveness (data from Sorrows et al., 2013). Although the regu-
lation of DNA methylation age in cancers remains poorly understood, significant associa-
tion of DNA methylation age with acceleration of prognostically useful molecular subtypes in LGGs underscores biological differences that cannot be discerned in LGGs based upon histological classification. This association suggests that LGGs may provide an avenue for investigating DNA methylation age, molecular subtype, and their relation to tumor behavior and clinical prognosis.

**#2389 LINE-1 tumor hypomethylation is associated with shorter recurrence-free survival in localized clear-cell renal cell carcinoma.** Gabriel G. Malouf, Roger Mouawad, Frederick Allanic, Eva Compérat, Morgan Roupert, David Khayat, Jean-Philippe Spano. Salpêtrière Hospital, Paris, France.

Background: Cancer cells are characterized by alterations of DNA methyl-
ation patterns involving global DNA hypomethylation and site-specific CpG island promoter hypermethylation. Global DNA hypomethylation is thought to play a role in genetic instability and tumor aggressiveness. Long interspersed nucleotide element-1 (L1/LINE-1) repetitive elements represent 40% of the ge
nome and their methylation is a good indicator of the global DNA methylation level. Although LINE-1 methylation has been previously shown to be associated with prognosis of patients with cancer, the value of LINE-1 methylation in pre-
dicting recurrence of patients with localized clear-cell renal cell carcinomas re-
main unknown. Material and Methods: We quantified the LINE-1 methylation using bisulfite pyrosequencing in cohort of 200 patients with resected clear-cell renal cell carcinomas (AJCC stage I-III). LINE-1 methylation of adjacent normal kidney was also assessed in 128 cases. Threshold of tumor LINE-1 hypomethyl-
ation was defined as LINE-1 methylation in normal samples minus three stan-
dard deviation. Results: Median methylation of tumor samples was 59.01% ver-
sus 61.61% for normal adjacent kidney samples (p<0.10). LINE-1 methylation level of normal adjacent kidney was associated with tumor size (Spearman R=0.21, P=0.02) but not with age (p=0.24) or Leibovitch score (p=0.05). Tu-
mor LINE-1 hypomethylation was observed in 20 samples (n=10). Strikingly, those were enriched for tumors occurring in female (60% versus 27.7%) (p=0.005) of note, no association was found between LINE-1 tumor hypom-
ethylation and tumor grade (p=0.31), stage (p=1), age (p=0.24) and Leibovitch score (p=0.82). In multivariate analysis, only Leibovitch score and LINE-1 hy-
pomethylation were independently associated with poor recurrence-free sur-
vival. Conclusion: LINE-1 hypomethylation is associated with shorter recur-
rence-free survival in patients with resected clear-cell renal cell carcinomas, suggesting the possibility of using it as predictive biomarker of recurrence.

**#2390 Clinical validation of an epigenetic field of susceptibility to detect significant prostate cancer from 2 non-tumor biopsies.** Bing Yang1, Johna-
thon McCormick,1 Adam Schultz,1 Glen Leveson,1 Geoffrey Sonn,2 Cristina Magi-Galluzzi,3 Eric A. Klein,4 Michael Fumo,4 David F. Jarrard.1 1Univ. of Wis-
cconsin-Madison, Madison, WI; 2Stanford University, Palo Alto, CA; 3Glickman Urological and Kidney Institute, Cleveland, OH; 4Rockford Urological Associates, LTD, Rockford, WI; 5Univ. of Wisconsin-Madison Carbone Cancer Center, Mad-
ison, WI.

Background: An epigenetic field of cancer susceptibility exists for prostate cancer (77) and the control group (52) were similarly matched except for PSA (7 vs 5.8; p<0.03) and prostate size (46 vs 36; p<0.02). We observed robust methylation differences for all genes (p<0.05) (Table). A multiplex regression model for biomarker performance incorporating a gene combination of EVX1, NCR2, PLAG2 and SPAG4 discriminated non-tumor from tumor-associated cases (AUC 0.744, p=0.0001). A multiplex model in-
corporating 3 genes (EVX1, PLAX2G16, NCR2) and clinical information (PSA, age) identified patients with GS=7 prostate cancers (AUC 0.808, p=0.001). Conclusions: A widespread epigenetic field defect can be used to detect GS>7 prostate cancers in patients with histologically negative biopsies. This assay is sensitive in requiring only 2 biopsies and detects alterations in nontumor cells at distances from the cancer. This has the potential to decrease the need for repeat prostate biopsies, a procedure associated with cost and complications.

**#2391 Integrated analysis of methylation and expression profile of telom-
ere-related genes in breast cancer patients.** Jianfu Heng,1 Xinwu Guo,2 Lili Fang,3 Fan Zhang,3 Limin Peng,3 Ming Chen,3 Xipeng Luo,3 Xunxun Xu,3 Shou-
man Wang,3 Jun Wang,4 Central South University, Changsha, China; Sunan Gene Technology Inc, Changsha, China; Xiangua Hospital, Central South Uni-
versity, Changsha, China.

Telomeres at the ends of chromosomes are critical in maintaining the integ-
rity and stability of the genome. Abrupt telomere or telomerase dysfunction participates in tumorgenesis. A majority of human cancers exhibit critically aberrant telomere length, suggesting that tumors can arise from genetically in-
stable cells with dysregulated telomeres. Many genes are involved in the com-
plex regulatory mechanisms of telomere length and telomerase activity. In ad-
dition, the methylation and expression pattern for most of telomere related genes in breast cancer are still unknown. Using microfluidic-PCR based target enrichment and next-generation bisulfite sequencing technology, we explored the promoter methylation profile of 29 telomere-related genes in 184 breast cancer patients with paired tumor and matched normal tissues. The average methylation level was significantly higher in tumor (8.13%) than that in matched normal tissues (7.08%) (P=4.30E-21). Four genes showed significant hyper-
methylation in the breast tumor tissues. All of these 4 genes are annotated with potential TFBs in the promoter regions. In subtype analysis, RAD51D showed significant methylation difference among four subtypes. In analysis of the asso-
ciation between methylation and clinicopathologic characteristics, TERC showed significant difference between ER+/ER- tumors. The expression profile of the 4 significant hyper-methylated genes was explored in the same cohort using qPCR method. All of them showed significantly lower expression in breast tumor tissues compared with the matched normal tissues. Two genes showed significant and negative cis correlation between methylation and gene expres-
sion in the breast tumor tissues (TERC), whereas the other two genes showed a negative correlation. These findings suggest that the 4 genes showed a good performance in predicting breast cancer with ROC analysis. In summary, our results revealed the methylation pattern of telomere related genes in breast cancer and illustrated the epigenetic regulatory mechanism on expres-
sion of aberrant methylated genes. Our study provides a novel panel of telomere related genes which may be a valuable diagnostic biomarker for breast cancer prediction.

**#2392 A multiplex histone H3 PTM assay for epigenetic biomarker dis-
cover in tissue biopsy and archived clinical samples.** Mary Anne Jelinek, Melissa Ritland, AJ Westergen. Active Motif Inc., Carlsbad, CA.

Disregulation of epigenetic mechanisms is known to play an important role in the development and progression of cancer. One such mechanism is mani-
fested as altered levels of histone modifications involved in regulating gene tran-
scription. N-terminal histone tails can have a variety of modifications, such as phosporylation, methylation and acetylation at specific amino acid residues which are conserved throughout eukaryotes and function by altering chromatin structure and creating binding sites for chromatin readers, writers or erasers. Numerous studies have reported aberrant global levels of several histone H3 and H4 post-translational modifications (PTMs) in a wide range of solid tumor types. These changes have been shown to be predictive of clinical outcome, raising the possibility that histone modifications have potential as epigenetic biomarkers. Clinical samples have immense potential for biomarker identifica-
tion since they are often accompanied with valuable information pertaining to patient history, treatment courses and disease outcome. The preferred method for clinical sample profiling is formalin-fixation followed by paraffin embed-
ding (FFPE). While extraction and downstream analysis of DNA and RNA from FFPE samples is now routine, proteomics studies of FFPE samples is hampered by extensive protein cross-linking generated by formalin fixation. Analysis of histone PTMs in patient archival samples is limited to low-throughput immu-
Proceedings of the American Association for Cancer Research • Volume 58 • April 2017 611
Molecular and Cellular Biology / Genetics: Epigenetics 2

Nohistochemical staining, and is not an ideal approach for mining large sample cohorts for biomarker identification. Western blot or ELISA methods, which have large sample requirements, are simply not an option for FFPE samples. We have developed a multiplex bead-based ELISA assay which enables simultaneous interrogation of thirteen histone H3 PTMs. The assay is performed in 96-well plates and is ideal for profiling tumor subpopulations within or across small samples. We will present the application of this technology in a variety of sample types including frozen tissue, formaldehyde-cross linked cells and tissues, and in small molecule inhibitor screens with as few as 2,000 cells per well. The ability to simultaneous detect up to thirteen histone H3 PTMs provides a unique feature that enables determination of for on-target and off-target effects within the same sample.

#2393 Decreased expression of 5-hydroxymethylcytosine is associated with grade of malignancy in lung cancer. Yoshiaki Tominga, 1 Ken-ichi Ito, 1 Jun Nakayama, 2 Division of Breast, Endocrine and Respiratory Surgery, Department of Surgery(II), Shinshu University School of Medicine, Matsumoto, Japan; 2 Department of Molecular Pathology, Shinshu University Graduate School of Medicine, Matsumoto, Japan.

Purpose: The ten-eleven translocation (TET) proteins are critical regulators in epigenetic modification. It is well known that TET proteins catalyze the oxidation of 5-methylcytosine (5-mC) to generate 5-hydroxymethylcytosine (5-hmC), and 5-hmC levels reflect diverse functions of TET proteins. It has been reported that the expression of 5-hmC in cancer tissues is decreased compared with that in normal tissues in several organs. However, 5-hmC expression in lung cancer has not been fully analyzed. To examine whether or not 5-hmC was associated with phenotypes or progression of lung cancer, we evaluated 5-hmC expression in a variety of histological types of lung cancers. Materials and methods: The expression of 5-hmC was analyzed by immunohistochemistry in 109 paired specimens of lung cancer and adjacent normal tissues obtained from the patients underwent operation at Shinshu University Hospital. Eighty-nine adenocarcinomas, 17 squamous cell carcinomas, two large cell carcinomas, and one small cell carcinoma were analyzed in the study. Results: 5-hmC expression in female was significantly lower than that in male, and was lower in smokers than non-smokers. 5-hmC expression was positive in 34.1±22.0% of lung cancer tissues and 69.4±18.8% of normal tissues. The expression of 5-hmC was significantly decreased in the lung cancer tissues compared with that in the adjacent normal tissues (p<0.001). With regard to the histological types, the positive ratios of 5-hmC expression were 36.0±21.7% in adenocarcinoma, 24.0±20.3% in squamous cell carcinoma, 8.0±7.3% in large cell carcinoma, and 13.0±8.3% in small cell carcinoma. Thus, the frequency of positive expression of 5-hmC was decreased in accordance with the increase of grade of malignancy of lung cancer, and a negative correlation between 5-hmC expression and the grade of malignancy of lung cancer was observed. In the other hand, no association between the expression of 5-mC was observed between lung cancer tissues and normal tissues. Conclusion: Our results indicate a possibility that 5-hmC may be related to carcinogenesis and progression or differentiation of lung cancer.

Background: Clinicopathological features including MGMT methylation have been correlated to prognosis in Glioblastoma (GBM). Tumor infiltrating lymphocytes (TILs) are predictive of clinical outcome in different malignancies. We evaluated association between clinicopathological features including MGMT methylation and IHC infiltrating immune cell subpopulations in 43 resected GBM cases who came from 2008 to 2013. Methods: A prospective evaluation of TIL (CD3, CD4, CD8 and CD20) and macrophages (CD68 and CD163) through H&E was performed by a pathologist and evaluated Immune cell subpopulations was evaluated through scanning, and software analysis (BX63 Olympus and TissueMorph-VisionPharm) with pathologist support. MGMT evaluation was prospectively performed by bisulfite PCR test in paraffin samples. Results: Median age was 47.9 years (men 51.2%, Karpoffsky scale 90% (62.8%), median tumor size of 5.1 cm, and partial complete tumor resection (22/21). Methylation MGMT test was performed in 31 cases and 17 showed unmethylated, 4 partially methylated and 10 methylated. TILs evaluation by HE showed low intensity (29 cases), intermediate intensity (1) and high intensity levels (9). Patterns of distribution was focal (9 cases), multi focal (13) and diffuse (17). Median CD3, CD4, CD8, CD20, CD68 and CD163 were 1.6%, 0.032%, 1.6%, 0.03%, 9.1% and 2.2% (regarding total cells), respectively. Higher CD163 level was associated to male (p=0.03) and larger size (p=0.05). Higher levels of CD8 was associated to larger size (p=0.05). Higher CD8 and CD20 were associated to unmethylated MGMT (p=0.041 and 0.013). Median follow-up was 14 months. Total only resection (p<0.05) and MGMT methylation (p<0.05) was associated to outcome. Lymphocyte infiltration (H&E) was not associated to outcome. Lymphocyte intensity (p=0.703), distribution (p=0.61). Longer OS was associated to lower CD4 levels (p=0.01). Conclusion: Tumor infiltrating immune cell and not common in GBM, CD8 and CD20 was associated to unmethylation, and CD4 and MGMT methylation were associated to prognosis.

#2395 Differentiation of carcinoma ex pleomorphic adenoma from pleomorphic adenoma by TERT promoter hypermethylation and elevated TERT mRNA expression. Seungjae Lee, 1 Sumit Borah, 1 Kurt Patton, 2 Armita Bahrami, 1 St. Jude Children’s Research Hospital, Memphis, TN; 2 Trumbull Laboratories, Memphis, TN.

The purpose of this study was to determine whether ii) genetic or ii) epigenetic aberrations of the TERT promoter, iii) elevated TERT mRNA level or iv) abnormal p53 expression pattern effectively distinguishes cases of carcinoma ex pleomorphic adenoma (CA ex PA) from pleomorphic adenoma (PA). PA is the most common salivary gland tumor which in rare cases progresses into an epithelial malignancy, termed CA ex PA. Fusion genes involving PLAG1, or less commonly HMGA2, are common in both PA and CA ex PA and thought to be early genetic drivers in their development. Although the key molecular events which occur during malignant transformation of PA are still unknown, some genetic and epigenetic changes proposed to play a role include amplification of PLAG1, HMGA2, MYC, ERBB2, or chromosome 12q and aberrant promoter hypermethylation of RASSF1, especially in combination with promoter hypermethylation of p16, TERT and WT1. The importance of TERT promoter hypermethylation for malignant transformation in PA may be underestimated since hypermethylation of that region most critical for malignancy in several cancers, termed the upstream of transcriptional start site (UTSS), has not previously been assayed in PA or CA ex PA. Point mutations or genomic rearrangement in the TERT promoter and elevated TERT mRNA levels are also characteristic of many cancers. We used a panel of 10 PA and 6 CA ex PA clinical samples to determine whether these alterations of TERT, or aberrant expression of TERT mRNA or p53 protein, could effectively distinguish CA ex PA from PA. UTSS hypermethylation in each sample was determined by treatment of genomic DNA with sodium bisulfite followed by MassARRAY and Sanger sequencing. Mutation and arrangement of TERT were screened for by Sanger sequencing and fluorescence in situ hybridization, respectively. p53 expression pattern was visualized by immunohistochemistry and TERT mRNA levels were measured by RT-qPCR. Mutation or rearrangements of the TERT promoter were not observed. However, all 6 CA ex PA samples harbored hypermethylated TERT promoter and had much higher TERT mRNA levels than the PA samples. Two of these samples also had aberrant p53 expression patterns, suggesting the presence of a TP53 missense mutation. None of the PA samples had aberrant p53 expression patterns, although 2 had hypermethylated TERT promoter and elevated TERT mRNA levels as compared with the other PA samples. The significance of this for long term outcome in these patients was unclear. Overall, these results suggest that TERT is commonly upregulated in CA ex PA and that this upregulation is often mediated through hypermethylation of the TERT promoter UTSS. Future largescale studies are warranted to determine the usefulness of TERT promoter hypermethylation for differentiating benign PA from CA ex PA, or the PAs at risk of malignant transformation.

#2396 Methylation of subtelomeric repeat D4Z4 in peripheral blood leucocytes is associated with biochemical recurrence in localized prostate cancer patients. Yuyan Han, Jeng Kim, Xifeng Wu, Jian Gu. UT MD Anderson, Houston, TX.

Background: Global DNA methylation may affect chromosome structure and genomic stability and is involved in carcinogenesis. In this study, we aimed to investigate whether methylation of pericentromeric repeat (NBL2) and subtelomeric repeat (D4Z4) in peripheral blood leucocytes was associated with the aggressiveness of prostate cancer (PCa). Methods: We measured the methylation status of different CpG sites of NBL2 and D4Z4 in 900 PCa patients via pyrosequencing after bisulfite treatment. We then used multivariate logistic regression to estimate the odds ratio (ORs) and 95% confidence intervals (CIs) for analyzing the association of NBL2 and D4Z4 methylation with the aggressiveness of PCa at diagnosis. We then analyzed the association of CpG sites with the risk of biochemical recurrence (BCR) in patients receiving radical prostatectomy or radiotherapy using a multivariate Cox proportional hazards model adjusting for age, BMI, smoking status, pack year, D’Amico risk groups, and treatments. In addition, we used the Kaplan-Meier survival function and log-rank tests to assess BCR-free survival associated with these markers. Results: There was no significant differences in the methylation level of NBL2 and D4Z4

612 Proceedings of the American Association for Cancer Research • Volume 58 • April 2017
between clinically defined aggressive and non-aggressive PCa at diagnosis. However, the methylation of subtelomeric region D4Z4 was associated with the relatively low rate of BCR among patients, we combined the highest and second tertiles to increase statistical power. Patients in the second and third (highest) tertiles had an increased risk of BCR (HR=1.74, 95% CI, 1.14-2.65; p=0.0096) compared to patients in the lowest tertile after adjustment of age, BMI, smoking status, pack year, D’Amico risk groups, and treatments. We assessed 4 CpG sites in this region. In detailed analysis of each CpG site, the association was mostly attributable to methylation of the 4th methylation site of D4Z4 (HR=1.80, 95% CI, 1.19 - 2.72). Conclusion: These data suggest that methylation in the subtelomeric region D4Z4 may be able to predict worse prognosis of localized PCa patients.

Epigenetic silencing in clear renal cell carcinoma: KEAP1 promoter hypermethylation. Federico Pio Fabrizio,1 Manuela Costantini,2 Massimiliano Copetti,1 Anna Maria la Torre,2 Angelo Sparaneo,1 Andrea Fontana,1 Maria terGroningen, Groningen, Netherlands

Campus Bio-Medico University Hospital, Rome, Italy; 6 University Medical Center. Muscarella,1 Vito Michele Fazio1.

#2397 Epigenetic silencing in clear renal cell carcinoma: KEAP1 promoter hypermethylation. Federico Pio Fabrizio, Manuela Costantini, Massimiliano Copetti, Anna Maria la Torre, Angelo Sparaneo, Andrea Fontana, Maria terGroningen, Groningen, Netherlands

Campus Bio-Medico University Hospital, Rome, Italy; 6 University Medical Center. Muscarella, Vito Michele Fazio.

The Keap1/Nrf2 pathway is a master regulator of the cellular redox state through the induction of several antioxidant defense genes implicated in chemotherapy drugs resistance of tumor cells. An increasing body of evidence supports a key role for Keap1/Nrf2 pathway in kidney diseases and renal cell carcinoma, but data concerning the molecular basis and the clinical effect of its deregulation remain incomplete. Here we performed a comprehensive genetic and epigenetic analysis of the KEAP1 gene in 37 tumor-normal paired tissues of clear cell Renal Cancer (ccRCCs). Promoter methylation analysis was performed by using a quantitative methylation specific PCR assay in real time, whereas mutation scanning was performed on FFPE tissues by direct sanger sequencing of the exons 4-7 codifying for the DGR domain of the Keap1 protein. A tumor-specific DNA methylation of the KEAP1 gene promoter region was found in 18 out of 37 ccRCCs (48.6%) and a direct effects on the modulation of Keap1 mRNA levels was confirmed by in vitro 5-azacytidine treatment on three different ccRCCs cell lines. Analysis of an independent TCGA data set corroborate the epigenetic findings and reveals a significant correlation in multivariate analysis of epigenetic KEAP1 silencing with Overall Survival in ccRCCs. Our results further suggest that epigenetic deregulation of the Nrf2/Keap1 system could play a pivotal role in the cancerogenesis of ccRCCs. In addition identifying patients with KEAP1 epigenetic abnormalities may contribute to disease progression prediction and response to therapy in ccRCC affected patients.

The incidence of head and neck cancer as well as its mortality rates continues to increase, evidencing the need for diagnostic and prognostic markers that can improve clinical management of these patients. Histone Methyltransferases (HMT) are responsible for the methylation of histone tails, a mechanism important for the regulation of gene transcription, cell differentiation and proliferation. Although alterations on these enzymes have been associated with many types of cancer, their relationship with head and neck carcinogenesis is not yet understood. SUV420H1 and SUV420H2 are members of the SUV family of HMTs that contain the conserved SET domain, which catalyzes the addition of methyl groups to specific lysine residues, leading to chromatin compaction and gene repression. In the present study, we investigated the tissue expression profile of SUV420H1 and SUV420H2 using immunohistochemistry in 10 formalin-fixed paraffin-embedded human oral cancer samples and adjacent non-tumor tissues. We also investigated the alterations of SUV420H1 and SUV420H2 genes in head and neck cancer with in silico analyses from public databases. Immunohistochemistry revealed moderate to strong SUV420H1 and SUV420H2 expression in the majority of oral cancer cells, mainly with cytoplasmic staining in the invading tumor cells. In silico analyses using data from 530 head and neck squamous cell carcinoma samples (The Cancer Genome Atlas - TCGA, via ciBioPortal) revealed that amplification is the most frequent genetic alteration in SUV420H1. Considering all known lusine methyltransferases, SUV420H1 was among the top three with the highest frequency of amplification. For SUV420H2, the frequency for amplification and deletion alterations was similar. The SUV420H1 and SUV420H2 methyltransferase expression showed a high expression of mRNA in head and neck cancer samples, with a moderate correlation (R: 0.588) between genetic copy number alteration and mRNA level. SUV420H2 did not show significant altered expression. In addition, SUV420H1 mRNA overexpression was associated with decreased overall survival in head and neck cancer patients (p: 0.0233). Since these enzymes are important in chromatin compaction and gene transcription repression, an increase in their expression level, as detected in this study, could lead to changes in histone methylation pattern, resulting in aberrant silencing of genes essential to maintain normal cellular function, such as tumor suppressor genes. Taken together, our data indicates a possible role of SUV420H1 in head and neck carcinogenesis, with the potential to be used as a prognostic marker for the disease.

Molecular and cellular biology / Genetics: Epigenetics 2

#2399 Metabolic and epigenetic targets in multiple myeloma therapy. Laure Maneix, Fu-Yuan Shih, Polina Jakova, Joanne I. Hsu, Andre Catic. Baylor College of Medicine, Houston, TX.

The dynamic interaction of dynamic transcription factors (TFs) with promoters and enhancers allows cells to continuously adjust gene expression. Whereas the composition and binding of TFs at genomic sites is the focus of a widespread research effort, relatively little is known about how these complexes are being removed. We previously devised a method to detect genomic locations that are associated with nuclein protein turnover mediated by the ubiquitin-proteasome system (UPS). Multiple myeloma, the second most common hematopoietic malignancy, has become a model disease for drugs that interfere with the UPS through either blocking or facilitating protein elimination. The proteasome inhibitor Velcade, for instance, has become first-line treatment in myeloma. Yet, our knowledge of how myeloma cells are killed by this drug is completely limited. Our research is focused on defining how proteolysis regulates transcriptional dynamics in this disease and how this impacts Velcade sensitivity. Following proteosome inhibition, we are utilizing next generation sequencing to identify sites of nuclear protein turnover and evaluate epigenetic changes. Our aim is to identify TFs and epigenetic marks that may qualify as more specific targets for treatment compared to blunt proteosome inhibition. Our findings reveal that certain TFs, including metabolic and cell growth regulators, are particularly sensitive to Velcade. Among these transcriptional regulators, the co-repressor NCoR1 plays a key role in controlling cell metabolism by adjusting mitochondrial gene expression. We are currently validating the mechanism of NCoR1 degradation, with a particular emphasis on the new role of its E3 ubiquitin ligase Seven in absentia 2 (Siah2) in mitochondrial regulation, to better understand how this degradation pathway impacts myeloma proliferation and metabolism. This research project will contribute to our understanding of epigenetic and transcriptional dynamics in multiple myeloma. With the focus on gene programs that are continuously adapting or changing, we seek to unlock new attractive targets for molecular therapy.

Tamoxifen is widely used to treat estrogen receptor-alpha positive breast cancer. However, resistance to tamoxifen often prevent the success of endocrine therapy. Epigenetic change in tumors are associated with cancer development and progression. Although altered histone modification has been implicated in tumorigenesis, their role in endocrine resistance was little known. To identified tamoxifen-resistance associated histone methylation modifying enzyme, we examined the global histone H3 methylation patterns in tamoxifen-resistance MCF7 breast cancer cells. Our results show that, the levels of methylated histone H3 lysine 4 (H3K4) and histone H3 lysine 9 (H3K9) was upregulated in tamoxifen resistant MCF7 breast cancer cells. Next, we examined expression levels of H3K4 and H3K9 methylation modifying enzyme in tamoxifen resistance breast cancer cell lines. qRT-PCR results show that H3K4 methyltransferases (KMT2A and KMT2C) is upregulated in tamoxifen resistance breast cancer cells. Moreover, we observed that siRNA mediated knockdown of KMT2C was more susceptible to tamoxifen-induced growth inhibition. Finally, Analyses of publicly available tamoxifen patient data sets indicated that KMT2A and KMT2C levels are higher in patients after endocrine therapy failure (recurrence), compared to those of responders (non-recurrence). Our study indicates that elevated levels of KMT2A and KMT2C in the tamoxifen-resistance breast cancers may contributed tamoxifen resistance.
#2401 Connecting oxidative DNA damage to epigenetic alterations during inflammation-driven tumorigenesis. Ashley Maiuri, Ning Ding, Heather M. O’Hagan. Indiana University, Bloomington, IN.

Inflammation contributes to the development of a diverse array of diseases, including cancer. At sites of chronic inflammation, epithelial cells are exposed to high levels of reactive oxygen species and undergo cancer-associated DNA methylation changes, suggesting that inflammation initiates epigenetic alterations. Cancer cells are globally DNA hypomethylated, but have aberrant gains in promoter DNA methylation that transcriptionally silence tumor suppressor genes (TSGs), linking DNA methylation directly to tumorigenesis. However, the mechanisms of targeting and initiation for these stable disease-specific epigenetic modifications are unknown. We have linked inflammation and oxidative DNA damage to acute changes in the interaction of epigenetic silencing proteins with each other and the chromatin. Recently, we demonstrated that the mismatch repair (MMR) protein heterodimer MSH2-MSH6 participates in the oxidative damage-induced recruitment of DNA methyltransferase 1 (DNMT1) to chromatin and provided evidence that the role of DNMT1 at sites of oxidative damage is to reduce transcription. To connect these findings to epigenetic changes in tumors we use a model of inflammation-driven tumorigenesis where we infect mice with the human commensal bacterium enterotoxigenic Bacteroides fragilis (ETBF). ETBF infection causes colon inflammation that drives tumorigenesis in Multiple intestinal neoplasia (Min) mice. The central hypothesis for this work is that oxidative damage at sites of inflammation causes acute genome-wide changes in binding and recruitment of epigenetic silencing proteins that results in acute epigenetic silencing of genes in tumors that form at the sites of exposure. Using genome-wide DNA methylation techniques we identified TSGs with increased promoter DNA methylation and decreased expression in tumors from ETBF infected Min mice as compared to normal tissue. In Min mice lacking expression of Msh2 in their intestinal epithelium (Msh2tm109Vcm110) there is a loss of the inflammation-induced change in binding of epigenetic proteins that occurs in Min mice even though the cytokine response to infection is normal. Because they lack functional MMR, ETBF infection of Msh2tm109Vcm110 mice causes an increase in colon tumor number and these tumors are positive for microsatellite instability, unlike tumors from ETBF infected Min mice. Importantly, DNA hypo- and hypermethylation changes in tumors from Msh2tm109Vcm110 ETBF infected mice are reduced both globally and at promoters of TSG islands of candidate TSGs as compared to tumors from Min ETBF infected mice. Altogether, this work suggests a novel mechanism by which oxidative damage induces acute epigenetic changes through the interaction of DNMT1 with MMR proteins and that this acute change drives DNA methylation alterations during tumorigenesis.

Our major goal is to determine the role of Chromodomain-helicae-DNA-bind ing protein 7 during breast cancer (BC) metastasis. This protein is an ATP-dependent nuclease-remodeling factor and is critical for embryonic development in both animal models and human patients. Our most recent studies provide direct evidence suggesting its novel role in repressing BC metastasis. We found that this protein, but not the mRNA, is highly expressed in a low-metastatic breast cancer cell line (Mcf-7), while its expression is much reduced in metastatic cell lines (MDA-MB-468 and MDA-MB-231). Furthermore, this protein is predominantly localized in the cytoplasm of 468 and 231 cells, in contrast to its nuclear localization in Mcf-7 cells. In the cytoplasm of 468 and 231 cells, this protein is colocalized with a lysosome marker, suggesting that in high metastatic BC cells, this protein is exported to the cytoplasm to be degraded in lysosomes. Blocking the activity of lysosomes increased expression of this protein in high metastatic BC cell lines. This result suggests a mechanism accounting for the reduced expression of this protein in high metastatic BC cell lines. To further support the potential clinical relevance of our results, this protein is localized in the nucleus of almost all duct epithelial cells in normal breast tissues; however, in a large portion of epithelial cells of breast tumors, this protein is localized in cytoplasm. Thsby reporter and mutagenesis analysis, we identified the nuclear exporting signal (NES) sequence responsible for exporting this protein into cytoplasm. In the next set of experiments, we attempted to determine the function of this gene in BC metastasis. We found that knocking down expression of this gene in 468 cell significantly increased their migration and invasion. We next applied the CRISPR genome editing technique to mutate the critical amino acids within the NES region in the endogenous gene locus and found that the amount of protein in the nucleus is significantly increased compared to wild type cells. Migration/invasion of these cells was also dramatically decreased. At the molecular level, we found that forced expression of this protein in nucleus reduced expression of epithelial markers and increased expression of epithelial-mesenchymal-transition markers. We are now applying ChiP-Seq and RNA-Seq approaches to determine direct regulatory network of this protein in 231 cells. We will further test whether this protein acts through modulating the epigenetic status of the enhancers/promot ers to regulate expression of its target genes to repress BC metastasis. In summary, our data collectively suggest that Chromodomain-helicae-DNA-binding protein 7 is a novel epigenetic regulator to repress BC metastasis. To the best of our knowledge, our study represents the first to address the activity of this protein in BC.

#2404 Paternal intake of an obesity-inducing diet before conception modulates the risk of pancreatic cancer in offspring in a mouse model. Raquel Santana Da Cruz, Johan Clarke, Ali Baird, Hong Cao, Carlos Benitez, M. Idalia Cruz, Sonia De Assisi. Georgetown University Medical Center, Washington, DC.

Pancreatic cancer is a mostly untreatable malignancy, with 5-year survival rates of about 5%. Lifestyle and dietary factors have been associated with pancreatic cancer risk. Particularly, the consumption of high-fat diets and obesity (and underlying metabolic dysfunction) have been linked to increased susceptibility to this cancer. Recent studies have shown that the paternal diet and life-style can have a significant influence on offspring’s health via epigenetic information transmitted in the germ-line. Paternal overweight before conception has been shown to increase offspring’s susceptibility of developing metabolic diseases and some types of cancer. Here, we evaluated the effects of paternal overweight in the susceptibility of pancreatic cancer in offspring using the P48Cre+/KrasG120V mouse model of pancreatic cancer. LSL-KrasG120V and P48Cre+/KrasG120V male mice were fed either an obesity-inducing (OID) or control (CO) diet for 8 weeks from weaning to sexual maturity. After this period, OID fed and CO fed male mice were housed together with 7-week-old female mice, with free access to CO diet, for 3 days. Pregnant dams were kept on the CO diet during pregnancy and after giving birth. Pups were weaned from mothers at 21 days of age, fed a standard chow diet for the extent of the study and weighed weekly. The offspring of CO or OID fathers were used to study body weight, metabolic parameters and pancreatic cancer development. Fathers fed an OID gained significantly more weight (CO 15.7±1.0 g; OID 19.7±1.3 g; p=0.02) and had higher leptin levels (p=0.04), compared to CO group fathers. Body weight analyses of OID and CO offspring, showed gender-specific effects. While the OID female offspring had higher weight at birth (p=0.005) and at weaning (p=0.02), compared to CO group, no significant differences were observed between the CO and OID male offspring. Those gender-specific differences were also observed in metabolic parameters such GTT with the OID male, but not female, offspring showing impaired glucose tolerance (p=0.0004) compared to CO. While the monitoring period is still ongoing, the 8-week old OID offspring present gender-specific differences in susceptibility to pancreatic cancer: Males OID offspring have higher number/area (481±25; 2.6±0.3) of pancreatic intraepithelial neoplasia (Panln), compared to CO (359±61; 2.0±0.5). On the other hand, female OID offspring have similar levels of Panln, but have higher incidence of PDA’s compared to CO. In conclusion, an ancestral history of overweight through the paternal lineage may be associated with an increased susceptibility to pancreatic cancer development in adulthood. The mechanisms mediating this effect remain to be elucidated.

#2405 The 8p11 amplicon oncogenes ASH2L and NSD3 alter the epigenomic landscape and provide the foundation for novel application of epigenetic therapy in luminal B breast cancers. Jamie N. Mills, Stephen P. Ethier. Medical University of South Carolina, Charleston, SC.

The 8p11-12 genomic region is amplified in 15% of breast cancers and is associated with poorer prognosis, especially in the luminal B (ER+ /HER2-) subtype. This region harbors several oncogenes, three of which are epigenetic modifiers of chromatin: NSD3 (WHSC1L1) and ASH2L, which are histone methyltransferases, and KAT6A, a histone acetyltransferase. NSD3 preferentially di-methylates histone 3 lysine 36 (H3K36me2) in gene bodies to facilitate elongation, and ASH2L, primarily trimethylates histone 3 lysine 4 (H3K4me3) in promoter regions, which is also associated with active transcription. Previous work in the ampiclon-bearing cell line SUM-44 implicated NSD3 in growth, survival, and overexpression and estrogen-independent activation of the estrogen receptor. Current work is focused on elucidating the mechanism behind these transforming features and exploring the epigenomic interactions of 8p11 oncogenes. Chromatin immunoprecipitation and high throughput sequencing (ChIP-seq) using an NSD3 antibody confirmed the presence of this factor in the gene body of ESR1, as well as several other important genes. As NSD3 lacks the ability to bond chromatin directly, it relies on adaptor proteins such as BRD4, a member of the BET bromodomain family that binds acetylated histones such as those generated by KAT6A. Indeed, we have shown that BRD4 binds NSD3 in SUM-44 cells. Similar to our previous findings with NSD3, knockdown of BRD4 and ASH2L reduced cell proliferation and clonogenic potential. To examine the influence of ASH2L on histone methylation in gene promoters, we performed ChIP-seq using an H3K4me3 antibody. The data showed a dramatic decrease in the number of peaks called following knockdown of ASH2L and peaks in
the NSD3 promotor disappeared. This finding solidifies the connection between these oncogenes and their cooperative regulation of the epigenome, and therefore the transcriptome, in this cell line, explaining the effects of NSD3 on cell growth and behavior. Amplification and overexpression of oncogenes in the 8p11 region is most prevalent in ER+ breast cancer, treated clinically with endocrine therapies. Patients with poor response to endocrine therapies have higher levels of 8p11 oncogenes in their disease. This study and continued investigation of 8p11 amplon oncogenes opens an important new treatment opportunity for these patients: epigenetic therapy. Previous work identifying these patients as candidates for novel anti-estrogen SERD compounds suggests that combination therapy with a BET bromodomain inhibitor could have major therapeutic benefit in a patient group currently without treatment options, thereby improving patient outcomes by a novel mechanism in luminal B breast cancer.

#2406 LSD1 promotes castration-resistant prostate cancer cell survival independently of the androgen receptor and of histone demethylation. Archana Sehrawat,1 Linda Gao,2 Junior Tayou,1 Armand Bankhead,2 Laura M. Heiser,3 Carly J. King,1 Yuiliang Wang,1 Jacob Schwartzman,1 Joshua Urrutia,1 Daniel J. Coleman,1 Sheila Weinmann,2 Bhaskar V. Kallakury,3 Deborah L. Berry,2 Reina Haque,2 Stephen K. Van Den Eeden,1 Tomaxx M. Beer,1 George V. Thomas,1 Shannon McWeeny,1 Joshi J. Alumkal1.1 OHSU Knight Cancer Institute, Portland, OR; 2Kaiser Permanente NW, Portland, OR; 3Georgetown University Medical Center, Washington, DC.

Background: Androgen deprivation therapy (ADT) or interference with androgen receptor (AR) function is the principal treatment for advanced prostate cancer. However, progression is universal, and therapies following the emergence of castration resistance do not offer durable control of the disease. Lysine specific demethylase 1 (LSD1) is a histone demethylase and a key regulator of gene expression in cancer. Prior work demonstrates that LSD1 may act as a cofactor of the AR in androgen-dependent prostate cancer cells. In this report, we describe a distinct role of LSD1 as a driver of proliferation and survival of castration-resistant prostate cancer (CRPC) cells independently of the AR and independently of histone demethylation. Methods: We used gain and loss of function studies to determine the importance of LSD1 for survival of prostate cancer cells. To identify transcriptional networks that contribute to cell survival, we suppressed LSD1 with RNAi and measured gene expression changes with microarrays. To determine the importance of histone demethylation in regulation of these gene networks, we suppressed LSD1 and measured levels of LSD1 canonical histone substrates (H3K4me2 and H3K9me2) genome-wide with chromatin immunoprecipitation-sequencing. Results: Cell viability assays demonstrated that LSD1 is important for proliferation and survival of CRPC cells independently of the AR. Microarray studies demonstrated that LSD1 regulates key pathways in CRPC through demethylation of non-histone substrates or via a scaffold function—mechanisms we are currently investigating. In summary, LSD1 contributes to CRPC cell survival through non-canonical mechanisms and represents an attractive therapeutic target in lethal prostate cancer.

#2407 Inhibition of gene expression during non-alcoholic steatohepatitis (NASH)-related hepatocarcinogenesis is mediated by histone H4 lysine 16 deacetylation. Kostiantyn Dreval,1 Aline de Conti,1 Orish Ebere Orisakwe,1 Frederick A. Beland,1 Igor P. Pogribnyi,1 JFA-DNA National Center for Toxicological Research, Jefferson, AR;2University of Port Harcourt, Rivers State, Nigeria.

Hepatocellular carcinoma (HCC) is one of the most aggressive human cancers and the incidence is steadily increasing worldwide. The molecular mechanisms leading to the development of HCC consist of genetic and epigenetic aberrations, including changes in global and gene-specific DNA methylation and altered expression of several classes of non-coding RNAs. While changes in DNA methylation and microRNA expression during the development of HCC are well-studied, the role of aberrant post-translational histone modifications remains unexplored. Using a mouse Stellic Animal Model (STAM) of NASH-associated liver carcinogenesis, we have investigated alterations in hepatic histone modifications at steatotic (6 weeks), fibrotic (12 weeks), and full-fledged HCC (20 weeks) stages of the HCC development. NASH-related liver carcinogenesis was characterized by a progressive decrease in the levels of histone H4 lysine 20 trimethylation (H4K20me3) and histone H4 lysine 16 acetylation (H4K16ac), with the greatest decrease occurring in full-fledged tumors. Mechanistically, the deacetylation of H4K16ac was associated with nuclear protein 1 (Nupr1)-mediated inhibition of histone lysine acetyltransferase Kat7. In addition to a global loss of hepatic H4K16ac, there was a significant decrease of gene-specific H4K16ac, as indicated by a reduced level of H4K16ac in 16 out of 20 HCC cell lines and the levels of gene expression. The extent of gene-specific H4K16 deacetylation were positively correlated with the level of gene transcription (r = 0.965, p < 0.01). These results indicate that a reduction of global and gene-specific H4K16ac is a key pathophysiological mechanism contributing to the development of NALFD-derived HCC.

#2408 Epigenomic characterization of MSC from myeloid malignancies. Manuel Rodriguez-Paredes,1 Stefanie Geyh,2 Mahshid Gazorpak,1 Julian Gutekunst,1 Felix Bormann,1 Rainer Haas,3 Thomas Schröder,1 Frank Lyko1.

1OHSU Knight Cancer Institute, Portland, OR; 2University of PortHarcourt, Rivers State, Nigeria; 3University of Düsseldorf Medical Faculty, Düsseldorf, Germany.

Ineffective hematopoiesis is a hallmark of myeloid malignancies such as Myelodysplastic Syndromes (MDS) or Acute Myeloid Leukemia (AML). Our previous research has shown that mesenchymal stromal cells (MSC), one of the main cellular regulatory components of the bone marrow niche and essential for the differentiation of new blood cells from Hematopoietic Stem Cells (HSC), are molecularly and functionally impaired in MDS and AML patients. More specifically, these cells display reduced proliferative and differentiation capacities, an increased cellular senescence, or the altered expression of key hematopoietic factors, deficits that can provide an explanation for the cytopenia associated with these diseases. But most interestingly, we have also discovered that MDS- and AML-derived MSC present aberrant histomethylomes. Our data, based on 450k DNA methylation microarrays, show that these abnormalities are shared by the MSC from both malignancies and affect key transcription factors like TFIIBX5, PITX2 or HOX86, formerly linked to differentiation and development. This results can account for some of the defects observed in the disease-related MSC and represent an important paradigm for cancer-induced epigenetic changes in normal cells. Aiming to further explore the importance of this epigenetic deregulation, we performed RNAseq experiments using MSC from healthy donors as well as from MDS and AML patients. This approach not only suggests a profound impact of the epigenetic aberrancies on gene expression, but also allowed us to identify TGFβ as the soluble factor that, released by the malignant cells in the bone marrow, appears to trigger the above-mentioned defects in the MDS- and AML-derived MSC. Indeed, our results show that, when treated with TGFβ, healthy MSC undergo the deregulation of TFIIBX5, PITX2 or HOX86 and develop some of the observed aberrant phenotypes. Conversely, the treatment of MDS- and AML-derived MSC with a TGFβ antagonist like SD208 can abrogate these effects. Finally, our preliminary DNA methylation data reveal a very similar deregulation in the methylome of MSC from Multiple Myeloma (MM) patients, strongly suggesting that the same scenario could also be common to other hematological malignancies from the lymphoid branch.

#2409 Loss of LIT1DI suppresses Notch1 induced LINE1 methylation and genomic stability. Chia-Chia Chu1,1 Wei-Chen Huang,2 Kuan-Der Lee,1 Chih-Cheng Chen,1 Chia-Chen Hsu,2 Mei-Ling Kang,1 Yu-Wei Lee,1 Shue-Huei Hsiao1.1National Chung Chern Medical College, ChiaYi County, Taiwan; 2Chang Gung Memorial Hospital, ChiaYi County, Taiwan.

The silencing of endogenous retrotransposon like LINE1 is critical for the maintenance of genomic stability and the LINE-1 type transposase domain containing 1 (LIT1DI) gene possesses the repeated, putative LINE-1 RNA-binding domains and was hypothesized to regulate the activity of LINE-1 through DNA methylation. To verify if LIT1DI is responsible for LINE-1 silencing and the maintenance of somatic genome stability, CRSPR/Cas9 system was used to knock out (KO) LIT1DI locus in gastric, colon and breast cancer cells so as in the mesenchymal stem cells (MSCs). We observed that LIT1DI KO blocked the entrance of SV39H1, histone methyl transferase, into cell nucleus which suppressed the tri-methylation of histone 3 at lysine 9 (H3K9me3) and LINE-1 methylation. A global demethylation and reduced HDAC recruitment were also observed. The global distribution of CTCF binding loci was also distorted as well as the bivalent histone marks. Further, LIT1DI KO distorted normal distribution of RassFlaX expression, cytoskeleton conformation and therefore cell stiffness. The MSC-to-neuron differentiation was also blocked by the KO. Further, we found that overexpressed Notch1 increased DNA methylation within LINE1 promoter, and this increase was attenuated by LIT1DI KO. Therefore, we concluded that the external signals like Notch1 affect LINE1 methylation and genome stability through possible LINE1 interacting LIT1DI. Since LIT1DI hypermethylation was observed in colon (n=100), gastric (n=19) and breast (n=79) cancers, LIT1DI abnormality is then a candidate for cancer biomarker. (Sup-
Non-coding mutations found in regulatory elements can function as driver mutations in breast cancer by changing the binding affinity of transcription factors for DNA, thereby resulting in direct change of expression of genes that promote cancer development. Identifying such additional driver mutations can reveal the molecular mechanisms favorable to breast cancer development and progression, as well as reveal new biomarkers to better tailor personalized/precision cancer medicine. In this study we have collected 20 primary luminal breast tumors and optimized experimental workflow to dissociate solid tumors and map open chromatin using ATAC-seq. In our initial experiments using ATAC-seq profiling of bulk tumor tissues, we were able to call an average of 15x10^3 peaks. Subsequently, flow cytometry analysis showed the presence of 15-25% of immune cells in our primary tumors. Therefore, we have optimized a workflow to eliminate immune cells and focus mainly on epithelial tumor cells. Primary breast tumors were digested using collagenase and further dissociated with dispase. Cells were sorted into two populations (mammary epithelial and immune cells) using anti-CD45, anti-CD49f and anti-EpCAM antibodies. Sorted mammary epithelial cells were then used for ATAC- and RNA-seq library preparation as well as for generation of patient derived organoids. Our new workflow resulted in an increased number of called peaks (40x10^3 vs 15x10^3), as well as a significant increase in the percentage of unique peaks compared to bulk sequencing (45% vs 15%). By refining our workflow to enrich for tumor content, we will continue our ongoing effort to profile these open chromatin regions and contextualize the mutations within a large cohort of luminal breast cancers using targeted sequencing. These data will be compared with large-scale whole genome data generated by our group and made publicly available by others.

It is well recognized that methylation/demethylation of not only DNA, RNA, Proteins but also methylation of small molecules play major roles in modulation of the epigenome, transcriptome, neurotransmitter uptake and metabolic regulation. Recent biochemical and biological data suggest that the activity of these enzymes and their expression level are under very strict regulation and any abnormal alteration in either one or both results in a wide variety of pathogenic conditions such as cancer, inflammation, and neurodegenerative diseases. In addition to chromatin modulation, altered methylation of DNA and more recently mRNA have been recognized to regulate the transcriptome and the rate of message translation and stability. Furthermore, methylation of small molecules such as catechols and nicotineamide play critical roles in neurotransmitters uptake and function, and metabolic regulation, respectively. Thus, pharmacological modulation of these enzymes by small molecules will be beneficial in developing novel therapeutics for multiple unmet medical needs. Towards this goal of searching for activators/inhibitors of these enzymes for the development of next generation of drugs, screening assays for these modulators are urgently needed. To address these unmet needs, we have developed a novel assay that monitors the activities of these enzymes and their modulation by small molecules. The assay is bioluminescent based, HTS formatted and highly sensitive. A unique feature of this assay is its universality since it is based on monitoring the formation of the universal product S-adenosylhomocysteine (SAH), i.e., capable of detecting changes in activity of a broad range of methyltransferases such as DNA, RNA, protein, and small molecules. In addition, the assay has been validated for all classes of protein methyltransferases (Lysine and Arginine), and with different types of substrates (small peptides, large proteins, or even nucleosomes). This enables determining the specificity of these enzymes and their substrate requirements. The assay has high signal to background, low CV., robust (Z’ value > 0.7), and has been validated using various plate densities such as 96-, 384, and 1536-well plates. A strong feature of this assay is its utility with broad range of substrates concentrations or the composition of the substrates (short vs. long peptides), thus enabling the generation of kinetic data and determining the mechanism of action of various modulators of methyltransferases of interest.

MOLECULAR AND CELLULAR BIOLOGY / GENETICS: Genome-Wide Analysis of Transcriptional Regulation

To address these unmet needs, we have developed a novel assay that monitors the activities of these enzymes and their modulation by small molecules. The assay is bioluminescent based, HTS formatted and highly sensitive. A unique feature of this assay is its universality since it is based on monitoring the formation of the universal product S-adenosylhomocysteine (SAH), i.e., capable of detecting changes in activity of a broad range of methyltransferases such as DNA, RNA, protein, and small molecules. In addition, the assay has been validated for all classes of protein methyltransferases (Lysine and Arginine), and with different types of substrates (small peptides, large proteins, or even nucleosomes). This enables determining the specificity of these enzymes and their substrate requirements. The assay has high signal to background, low CV., robust (Z’ value > 0.7), and has been validated using various plate densities such as 96-, 384, and 1536-well plates. A strong feature of this assay is its utility with broad range of substrates concentrations or the composition of the substrates (short vs. long peptides), thus enabling the generation of kinetic data and determining the mechanism of action of various modulators of methyltransferases of interest.

MOLECULAR AND CELLULAR BIOLOGY / GENETICS: Epigenetics 2
ANSA, and p < 0.05 was considered statistically significant. The Ethical Review Board of the academic institution approved this study. Results: Fibromodulin expression at protein level was evaluated in 378 cores representing PCa (143 cores), HGPN (58), PIA (102), and BPT (78). Mean fibromodulin expression in cores with PCa, HGPN, and PIA was significantly higher than mean of fibromodulin expression in normal glands (p < 0.05). There was a higher mean staining score in PCa (156, 95% CI: 144–167), compared to HGPN (151.4, 95% CI:109–153), PIA (128, 95% CI:117–138), and BPT (33.3, 95% CI:27–38). Thus, fibromodulin expression increased across the PCa progression model. Conclusions: The expression pattern of fibromodulin showed a significant increase from benign prostate tissue through pre-cancerous lesions to PCa. These findings suggest that the fibroblastic phenotype may be involved in the process of prostate cancer progression, with low levels in pre-cancerous lesions and higher levels in cancer tissue. Additional studies are required to determine the biological role and potential clinical implications of fibromodulin in prostate cancer.

#2415 Genome-wide alterations in gene expression of prostate cancer (PC) cells surviving neo-adjuvant androgen deprivation therapy. Anna C. Ferrari,1 Haten Sabsawy,1 Mark Stein,1 David Foran,1 Ying Chen,2 Srinivasan Yegnasubramanian3.1 Rutgers Cancer Institute of New Jersey, New Brunswick, NJ; 2Johns Hopkins University Sidney Kimmel Cancer Center, Baltimore, MD.

Background: Although androgen deprivation therapy initially decreases PC tumor burden, resistance to further androgen receptor (AR)-directed treatments or chemotherapy is inevitable once CRPC is established. We postulated that the stress of ADT triggers widespread alterations in expression that renders a metastable physiologic state conditioned by epigenetic changes that might be initially reversible by targeting non-androgen pathways. We conducted a pilot study to explore genome-wide expression alterations in PC surviving 3 months ADT (eADT). Methods: mRNA from 7 frozen microdissected PC foci from the dbGAP study to explore genome-wide expression alterations in PC surviving 3 months ADT (eADT). Methods: mRNA from 7 frozen microdissected PC foci from the NJ;2JohnsHopkinsUniversitySidneyKimmelCancerCenter,Baltimore,MD.

#2417 Large scale integrated transcriptomic and epigenetic profiling define the molecular hallmarks of HGSOCS and disease origins. Karen Lawrenz,1 Marcos Abraao,2 Felipe Segato,3 Janet M. Lee,1 Simon Coetzee,2 Ji-Heui Seo,2 Matthew L. Freedman,1 Dennis Hazlett,1 Simon Gayther,1 Houtan Noushmehr4.1Rutgers Cancer Institute of New Jersey, New Brunswick, NJ; 2Johns Hopkins University Sidney Kimmel Cancer Center, Baltimore, MD; 3Dana-Faber Cancer Center, Boston, MA; 4Henry Ford Hospital, Detroit, MI.

High-grade serous ovarian cancers (HGSOCS) are the most common subtype of epithelial ovarian cancer. Pathways driving HGSOCS development are poorly understood, and the cellular origins are debated in the literature. Previously, ovarian surface epithelial cells (OSECs) were thought to be cellular precursors of HGSOCS, but there is now strong evidence that at least half of all HGSOCS arise from fallopian tube secretory epithelial cells (FTSECs). We took a large-scale integrated transcriptomic-epigenomic profiling approach to define the molecular hallmarks of HGSOCS and to explore the disease cell-of-origin. RNA sequencing was performed on 121 OSEC cultures and 84 FTSEC cultures and integrated with 394 HGSOCS transcriptomes profiled by TCGA. We identified 4747 gene sets that differentiate OSECs and FTSECs, and a pathway analysis of this gene list identified ovarian cancer genes as highly enriched (p = 2.2x10^-8), with ZEB1 and estrogen the most significant predicted upstream regulators (p < 3.7x10^-7). We integrated gene expression data with clinical metadata to identify signatures between gene expression signatures and clinical variables and found that in patients diagnosed with ovarian cancer, OSEC and FTSEC profiles converged, suggestive of a field carcinization phenotype occurring in the normal OSECs on the unaffected ovary contralateral to a clinically diagnosed ovarian carcinoma. Transcriptomic signatures for OSECs, FTSECs and HGSOCS were then merged with superenhancers defined by performing chromatin immunoprecipitation for acetylated H3K27 profiled in primary HGSOCS tissue specimens. We detected many more superenhancer-target gene relationships in the normal cells than in the tumor cells, suggesting superenhancer fingerprints define the cell of origin rather than determining upregulation of oncogenes driving cancer. To explore this further we determined the similarities of HGSOCS to OSEC and FTSEC using a machine learning model. Using a pre-defined gene signature of OSECs and FTSECs, our model (high specificity and sensitivity, 99% CI = 0.77–1, p-value = 6.1^-7) was applied to HGSOCS and found that HGSOCS were classified as FTSEC-like. Interestingly, the mesenchymal subtypes were enriched as FTSEC-like. Moreover, a subset of HGSOCS were characterized as OSEC-like, and these tumors were associated with poorer outcomes. Our data describe molecular subgroups within HGSOCS precursor tissues as well as defining the transcriptional networks that define HGSOCS precursor tissues, drive HGSOCS development; furthermore our model provided the landscape between the epigenetic landscape and the transcriptome in these cell types. In closing, these large-scale integrative analyses support a predominantly FTSEC origin for HGSOCS, but reinforce conclusions that OSECs cannot be excluded as origins of HGSOCS, and may represent a subset of tumors with a different biology.
Characterization of the PAX8 regulatory network in epithelial ovarian cancer. Rosario I. Corona,1 Emily Adler,2 Janet M. Lee,1 Norma Rodriguez-Malave,1 Paulette Mhawech-Fauceglia,2 Heidi Sowter,3 Dennis J. Ha- 

the biological role of PAX8 during cancer initiation and development is poorly understood, and the genome-wide transcriptional targets have yet to be comprehensively identified. Using stable, mock-transfected HEYA8 and IGROV1 EOC cell lines we show that PAX8 knockdown reduces cell proliferation in vitro and tumor growth in vivo. To understand how PAX8 regulates neoplastic phenotypes in cancer cells we performed RNA expression profiling by microarray in HEYA8 and IGROV1 before and after PAX8 knock- 

down. We also performed chromatin immunoprecipitation followed by next generation sequencing (ChiP-seq) for PAX8 and a marker of active chromatin (H3K27ac) in both cell lines. De novo motif discovery in the ChiP-seq profiles identified a PAX-like binding motif and several potential PAX8 cofactors in IGROV1 that are not enriched in HEYA8. These cofactors include members of the TEAD and Sp/KLF families of transcription factors. We divided the genes from our differential expression (DE) analysis in PAX8 knockdown into three non-overlapping categories: (a) direct regulatory targets (RTs), i.e. DE genes with PAX8 binding sites in their promoter regions; (b) putative enhancer RTs, where DE genes and PAX8 binding sites reside within the same topological association domain (TAD) defined from embryonic stem cells; and (c) indirect RTs. Our findings reveal that PAX8 can function as either an activator or a repressor, and that PAX8 regulates a very different set of genes in each cell line, as only a small fraction RTs (~50%) is shared between HEYA8 and IGROV1. Nonetheless, independent pathway enrichment analysis reveals four pathways downstream of PAX8 that are common to both cell lines: DNA replication, cellular response to lipopolysaccharides, TNFA signaling via NFkB and anatomical structure morphogenesis. Individually, we discovered enrichment for G2M checkpoint and EMT signaling in HEYA8, and tissue morphogenesis and mesenchymal cell development in IGROV1. Collectively, our results suggest that PAX8 regulates cell proliferation and cancer promoting processes via highly tissue-specific regulation of common oncogenic pathways.

#2419 Genome-wide profiling of PAK4 DNA-binding sites and transcriptionome reveals its potential transcriptional control on DNA repair-related genes in ovarian cancer cells. Ivy Tsz-Lo Wong,1 Oscar Gee-Wan Wong,1 Yim- 

qin,1 Junwen Wang,2 Annie Nga-Yin Cheung1.

The University of Hong Kong, Hong Kong; Mayo Clinic Arizona, Scottsdale, AZ.

Oncogenic roles of the p21-activated protein kinases (PAKs) in relation to cell growth and migration through various signalling cascades has been well studied in multiple cancer types. Such roles might be contributed largely by cytoplasmic PAK4 as most of the known PAK4 signalling events occur in the cytoplasm. However, recent studies have demonstrated that PAK4 is capable of shuttling between nucleus and cytoplasm. The precise function of nuclear PAK4 (nPAK4) remains poorly understood, as most of the known PAK4 signalling events occur in the cytoplasm. Herein, we aimed to identify nPAK4-regulated genes by delineating the PAK4-binding landscape in ovarian cancer genome and mapping the PAK4 transcription in ovarian cancer cells. PAK4-enriched genomic regions were identified by chromatin immunoprecipitation with a PAK4 antibody followed by next-generation sequencing (ChiP-seq) in OVCAR3 cells. PAK4 transcription data was generated using RNA extracted from SKOV3 cells stably expressing PAK4 in the Affymetrix GeneChipTM Human Transcriptome Array 2.0 system. Gene lists generated from both ChiP-seq and microarray dataset were subjected to pathway enrichment analysis by Partek® PathwayTM. Among the 20 most significantly enriched pathways from microarray studies, several pathways in which PAK4 has no known reported function by far have been identified as potential cancer drug targets using cBioPortal database. Our results support the potential role of PAK4 in regulating pathways that have been implicated in tumorigenesis. The list of genes that are potentially regulated by PAK4 includes: cyclin-dependent kinase 7 (CDK7), E2F1, and the ETS domain transcription factor ERG. These genes are involved in various cellular processes, including cell proliferation, differentiation, and survival. Further experiments are needed to validate the functional role of PAK4 in regulating these pathways.
ray analysis results in our lab correctly identified a subset of about 300 genes that when mutated altered the chemoresistance of the ovarian epithelial cells in culture. Of the genes identified in the analysis we further set out to characterize oncogenes and tumor suppressor genes that interact with the guardian of the genome, TP53, to determine if we could elucidate the mechanism by which it increases survival. Using several in-vitro assays, we determined if the loss of p53 in conjunction with SOX9 decreased the level of apoptosis in response to carboplatin. Furthermore, in cells with mutated p53/ SOX9 and epigenetic regulators may present a valid treatment option for increasing carboplatin sensitivity in resistant patients.

#2422 Simultaneous detection of activating somatic DNA mutations and expressed fusion transcripts from lung tumor FFPE samples. A. McGarry Houghton,1 Gavin Meredith,2 Julia Kargl,3 Jill McKay-Fleisch,4 P. Martin Ross,2 Anisha Kharkia,1 Afshin Mashadi-Hossein,3 Dae Kim,7 Joseph Beechem,1 Fred Hutchinson Cancer Research Center, Seattle, WA; 2NanoString Technologies, Inc., Seattle, WA.

Worldwide, lung cancer is the most commonly diagnosed form of cancer with a survival rate among the lowest. Combined, somatic mutations (in the form of SNVs and InDels) and gene fusions, account for the majority of interpretable and actionable genomic alterations. Importantly, this typically requires the analysis of DNA and RNA from limited amounts of FFPE-preserved specimens. Currently, these analyses typically require complex sample pre-processing for separate platforms or separate complex library preparation methods for assessment by high throughput sequencing. To provide a unified and simpler alternative, NanoString’s molecular barcoding technology has been modularized to permit simultaneous digital measurement of cancer-relevant targets that span these two analyte classes. Novel ‘SNV’ probes enable sensitive and specific identification of DNA mutant allele sequences down to a level of detection of ≤ 5% from 5 ng of FFPE-extracted genomic DNA. Fusion transcripts are detected with 5’/3’ imbalance probes and toehold-mediated junction probes. This dual analytic workflow requires just a single 5-10 micron section of FFPE tissue and provides to sample-to-answer results within approximately 5 minutes of hands-on time per sample after nucleic acid extraction.

To demonstrate utility, 37 lung cancer samples were assayed simultaneously with an SNV panel that targets ≥100 solid tumor somatic mutations and a lung cancer fusion gene panel that provides general evidence of ALK, RET, and ROS1 gene fusion events along with specific detection of 35 unique fusion transcripts that correspond to known break-points. In this particular cohort, 16 samples were positive for activating KRAS SNVs (one of which was also positive for an activating STK11 variant), 3 were positive for activating EGFR mutations including two SNVs and an 18-base InDel and one was positive for an activating KIF5B/RET fusion transcript. Positive mutation calls obtained with the SNV panel could only be confirmed by whole-exome sequencing (average depth of 100X) for 13 of 20 variants detected; however, ultra-deep (average depth of 4400X) targeted sequencing revealed that the 7 additional panel-detected mutations were, in fact, present. Measured against the sequencing datasets, the SNV panel provided 100% sensitivity, specificity, accuracy and precision, indicating the potential clinical utility of the protocol as a platform for FFPE specimen analysis.

Combined, these results show that these two important classes of activating mutations can be readily and efficiently assayed together on a NanoString nCounter® system (for research use only).

#2423 Bronchial airway gene expression signatures in mouse lung squamous cell carcinoma and their modulation by cancer chemopreventive agents. Donghao Xiong,1 Jing Pan,1 Qi Zhang,2 Eva Szabo,1 Mark S. Miller,3 Ronald A. Lubet,3 Ming You,1 Yian Wang,1 Yian Wu,4 1Fred Hutchinson Cancer Research Center, Seattle, WA; 2NanoString Technologies, Inc., Seattle, WA; 3Division of Cancer Prevention, National Cancer Institute, Bethesda, MD; 4Department of Pathology, Johns Hopkins Univ., Baltimore, MD; 5Moscow State University, Moscow, Russian Federation; 6Univ. of California, San Diego, La Jolla, CA.

This project develops a novel experimental technique to perform ChIP-Seq (chromatin immunoprecipitation with massively parallel DNA sequencing) analysis of chromatin structure in primary tumor tissues from high risk HPV-related head and neck squamous cell carcinomas (HPV+ HNSCC). Recent data suggest that chromatin structure is the central regulator and predictor of cancer-specific expression and mutagenesis landscape of diseased cells. Genome-wide gene expression dysregulation in many tumors, including HPV+ HNSCC, are incompletely described by current knowledge. Methods for study of chromatin structure in primary tumor tissues are needed to better understand the role global epigenetic changes may play in tumor development. However, ChIP-Seq, which is the state-of-the-art method of elucidating chromatin structure, until now, has not been reliably performed on any HNSCC samples. Because chromatin structure is disrupted at room temperature, ChIP-Seq is especially complicated for primary patient tissues, which are primarily obtained as surgical waste after pathology review. Snap freezing of leftover waste surgical tissues and further tissue thawing for the analysis decreases chromatin structure integrity necessary for highly sensitive ChIP-Seq methodology, especially for tumor samples with chromatin structure deformed during carcinogenesis. To improve the chromatin structure integrity in tumor sample we added a xenografting step and minimized the exposure of cancer tissue to room temperature conditions after mouse surgery. We also minimized patient non-cancer tissue preservation at ambient temperature after patient surgery. We successfully performed ChIP-Seq for H3K4me3, H3K9me3, and H3K9ac on frozen uveal melanocytoma patient primary tumor tissue, frozen patient derived xenograft tissue, and freshly cultured head and neck squamous cell carcinoma cell lines, revealing comparable success rates between tissue type and sample preservation techniques. ChIP-Seq techniques were performed and cross validated using tried and true qRT-PCR methods to demonstrate data reproducibility. The biological relevance of the ChIP-Seq data was further confirmed by the NanoString analysis of 47 HPV+ HNSCC samples and 25 non-cancer controls. Analysis revealed that most H3K9ac and H3K9me3 enrichment is similar in primary tissues, regardless of disease status. Only small portion of them showed differential histone enrichment, which correlated with differential expression of corresponding genes. On the other hand, H3K4me3 showed strong tissue specificity and were found differentially enriched especially in normal and benign control samples. This is a novel evidence of the stability and reliability of biological between biological replicates, diversity of tissue models, and low dependence of ChIP-Seq analysis on tissue preservation techniques.

#2425 Delving into molecular phenomena of methylation, polyadenylation and mutation suggests their importance in regulating gene expression in GBSCC. Richa Singh,1 Esita Chattopadhyay,1 Roshni Roy,1 Bidyut Roy1. 1In- dian Statistical Institute, Kolkata, India; 2Baylor Scott and White Health, TX.

Background: Gingivo-buccal squamous cell carcinoma (GBSCC) is one of the most prevalent types of oral cancers in India. Although whole exome studies in oral cancer have reported somatic mutational driver genes, studies on methylation, mutations and alternative polyadenylation (APA) to identify differentially expressed transcripts and exons, respectively, are rare. The aim of our study is to investigate possible causes of expression deregulation due to methylation, APA or mutations. Methods: Whole transcriptome data was generated from 12 tumor-normal paired GBSCC tissues and analyzed for differential gene expression, differential exon usage and predicting APA site. Whole exon sequencing was performed with same sample set and the data was analyzed to identify somatic mutations. Reduced representation of bisulfate sequencing (RRBS) was also done for some of these samples to inquire about the methylation status of deregulated genes. Results: A total of 465 genes were found to have differential exon usage in tumor leading to expression of different isoforms and change in overall gene expression. About 194 genes were predicted to utilize alternate polyadenylation site in tumors. Amongst these, 11 genes including ERBB3, CDC25B and LTRBP4 were shown to have differential exon
MOLECULAR AND CELLULAR BIOLOGY / GENETICS: Genome-Wide Analysis of Transcriptional Regulation

usage in tumor with altered gene expression hinting upon the influence of polyadenylation in expression change. From the exome sequencing study, 180 SNVs and 11 indel somatic mutations per sample were observed. Apart from other non-silent exonic mutations at TP53, CASP8, DIS3 and DLG1, splice site mutations were also found in 37 and 4 genes due to point and indel mutations respectively. Genes such as TP53, CASP8, DIS3 and others were found to harbor somatic mutations and APA site. This suggests for coupled regulation by APA and mutation in altering expression of those genes. Apart from this, a subset of deregulated genes (n = 54) were observed to have differential methylation in tumors. Expression change of TAPI, SLN, ELN etc. corroborated with their methylation status suggesting the influence of methylation in regulating expression of these genes. Deregulated differential expression also suggested differential epigenetic reprogramming leading to overall change in gene expression in tumor. Upon excavating into the regulatory causes, a subset of genes showed change in methylation pattern while few others showed change in APA site with/without somatic mutation effect. These molecular phenomena explain how different mechanisms are involved in expression deregulation of genes observed in GBSCC which would help in further functional research for cure of the disease.

#2426 Oncopig soft-tissue sarcomas recapitulate key transcriptional features of human sarcomas. Kyle M. Schachtschneider, Y. Yingkai Liu, Suyi Makekalema, Ole Madsen, L. Laura A. Rund, Martin A. Groenen, Regina M. Schwind, Ron C. Gaba, Schook B. Lawrence, University of Illinois at Chicago, Chicago, IL; University of Illinois, Urbana, IL; Wageningen University, Wageningen, Netherlands.

Human soft-tissue sarcomas (STS) are rare, aggressive mesenchymal tumors with a late stage 5-year survival rate (50-60%) that has for decades remained unchanged. Research into STS treatment is hampered by the limited human STS cell line availability and the large number of STS subtypes. Therefore, there is a need to develop STS cell lines and animal models representative of diverse human STS subtypes. Pigs represent ideal human disease models due to their similar size, anatomy, metabolism, genetics, and epigenetics compared to humans.

In this regard, porcine cancer models provide the opportunity to produce STS cell lines and in vivo tumors similar to those clinically observed in humans. The Oncopig encodes Cre recombinase inducible porcine transgenes encoding KRAS and TP53, allowing the Oncopig to model a number of human sarcomas in an inducible and temporal manner. However, comparative analysis is required to determine to what extent the Oncopig STS model mimics human STS on a molecular level. The purpose of this study was to identify similarities between Oncopig and human STS transcriptional profiles to validate the Oncopig model as a viable model for human STS. Towards this end, Oncopig fibroblasts were isolated from ear notches of 4 Oncopigs and cultured in vitro. Following confirmation of their mesenchymal origin (positive vimentin immunostaining), Oncopig fibroblasts were transformed via Cre recombinase exposure, resulting in the formation of Oncopig STS cell lines. Oncopig STS tumors were produced in vivo through intramuscular injection of adenovirus encoding Cre in 2 Oncopigs (2 sites/Oncopig), resulting in the formation of 4 tumors detectable by 10 days post injection. The mesenchymal origin of the resulting tumors was confirmed through histological characterization. Genome-wide expression of Oncopig STS cell lines and tumors was profiled via RNA-seq. Reproducible Oncopig STS cell line and tumor expression profiles were observed, and Oncopig STS cell lines also displayed high temporal reproducibility. Differential expression analysis was performed by comparing Oncopig STS cell lines and tumors to untransformed fibroblasts and skeletal muscle, respectively. A total of 3,360 and 7,652 differentially expressed genes were identified in the Oncopig STS cell lines and tumors, respectively. Commonly identified alterations in human STS gene expression and pathway regulation were identified in Oncopig STS, including altered TP53 signaling, activation of Wnt signaling, and evidence of epigenetic reprogramming. Furthermore, master regulators of Oncopig STS gene expression were identified, including FOXL1, which was previously identified as a potential therapeutic target for human STS. These results demonstrate the Oncopig STS model’s ability to mimic human STS on a transcriptomic level, making the Oncopig a valuable resource for sarcoma research and cell line development.

#2427 Alterations in gene expression after exposure of MDA-MB-231 cells to isobutylparaben. Christine Strelchuk,2 Holly Jones Taggart*. 1University of Toronto, Toronto, Ontario, Canada; 2University of Ontario Institute of Technology, Oshawa, Ontario, Canada.

Parabens are a group of chemical compounds extensively used as preservatives in consumer products such as cosmetics, pharmaceuticals and processed food. Parabens have been shown to have endocrine disrupting properties, to accumulate in breast tissue and to increase the proliferation of hormone recep-

tor positive breast cancer cell lines through competitive binding to the estrogen receptor. Studies have shown that isobutylparaben has the highest binding affinity for the aryl hydrocarbon receptor (AhR), reported to bind environmental toxins. This study examined the alterations in gene expression correlated to exposure of the hormone receptor negative breast cancer cell line MDA-MB-231 to isobutylparaben over a 72 hour time frame. Exposure of the cells to concentrations of isobutylparabens commonly found in consumer products alters the genetic expression profile of the cells. In our study, detectable expression levels of AhR mRNA decreased, while cytochrome P450 (CYP1A1) and receptor activator of NFκB ligand (RANKL) mRNA levels increased, as analyzed by qPCR. The downregulation of AhR and altered expression levels of invasion related genes is suggestive of an increased metastatic phenotype with exposure to isobutylparaben.

#2428 The cytidine deaminase APOBEC3B is a regulator of gene expression in breast cancer. Manikandan Periyasamy, Imperial College London, Du Cane Road, London, United Kingdom.

The APOBEC3B (A3B) cytidine deaminase gene has been implicated driving the mutational landscape in breast and other cancer types. We have discovered that A3B is a co-activator of estrogen receptor (ER) mediated gene expression in breast cancer. Mechanistic studies established that A3B regulates gene expression by promoting C-to-U deamination at ER binding regions. We show that these C-to-U changes lead to the generation of DNA strand breaks through activation of base excision repair (BER) and to repair by non-homologous end-joining (NHEJ) pathways. We have also performed RNA-seq and ChIP-seq in multiple ER+ and ER- breast cancer cell lines. Remarkably, these studies demonstrate that A3B regulates the expression of many genes in inflammatory and interferon signaling pathways, in addition to the regulation of ER target genes. These findings, together with other data to be presented, provide a clear role for A3B in transcription regulation. These findings also raise the possibility that transcription factor mediated recruitment of A3B to DNA may facilitate acquisition of A3B driven cancer mutations.

#2429 Generation of a transcriptome of oncogenic mutant p53 in triple-negative breast cancer. Rebecca E. Steele, Simon S. McDade, Paul B. Mullan, Queen’s University Belfast, Belfast, United Kingdom.

The purpose of this study was to generate a transcriptional profile specific for mutant p53 in triple-negative breast cancer (TNBC), representing potential novel therapeutic targets. The highly heterogeneous TNBC tumor subgroup is established as having a poor clinical outcome. There are currently no targeted therapies for women with TNBC; consequently, there is an unmet clinical need to identify targetable pathways. Approximately 75% of these tumors are known to harbour a mutation inTp53 (mutp53). Chromatin Immunoprecipitation Sequencing (ChIP-seq) for mutp53 and ets-1 (a known mutp53 interactor) was carried out using the D0-1 (sc-126) and sc-20 antibodies respectively, in the MDA-MB-468 TNBC cell line. The aim of these ChIP-seq experiments was to identify sites bound by endogenous R273H mutp53 and ETS-1 and to confirm that target genes were co-regulated. We identified 282 novel mutp53 specific genomic binding sites and 38 mutp53 and ets1 shared binding sites. In-house data analysis and peak calling generated a list of potential transcriptionally co-regulated genes adjacent to these genomic sites. PDGFB, TRIB3, BTRC, TNFSF18 & PI3 were successfully validated as being transcriptionally regulated by R273H mutp53 and not wild-type p53 (as shown by MCF7 ChIP-seq comparisons). A number of these genes are known to be aberrantly expressed in TNBC patient tumors and harbor interesting immune biology, providing potential opportunities for novel therapeutic strategies. In addition, DNA damaging chemotherapy-resistant MDA-MB-468 derivatives express elevated levels of mutp53 protein and altered expression of our validated transcriptional targets, suggesting that they may also have roles in promoting resistance to current chemotherapy treatments, downstream of mutp53. In conclusion, we have identified a cohort of ‘mutp53 specific’ transcriptional targets which may have roles in modulating immune responses to TNBCs, driving resistance to current chemotherapies and could provide opportunities for the development of novel treatments for TNBCs.

#2430 The expression of BCL6 and ZEB family transcription factors and their correlation in breast cancers. Min Zhao, Lin Ang, Li Zheng, Jin Wang, Jin Huang, Hongguang Hu, Qiang Zou, The Second People’s Hospital of Heifei, Heifei, China.

The proto-oncogene B-cell lymphoma 6 (BCL6) is an evolutionarily conserved zinc finger protein and a potent transcriptional repressor. It is also the master regulator of B-lymphocyte development. Emerging evidence indicates
that BCL6 may play an important role in breast cancer progression. In this study, we investigated the expression of BCL6 and its correlation with the expression of epithelial-mesenchymal transition (EMT)-associated transcription factors zinc finger E-box-binding homeobox 1 (ZEB1) and ZEB2 in invasive breast cancers. The mRNA and protein expression of BCL6, ZEB1 and ZEB2 were examined using in situ hybridization and immunohistochemistry, respectively, in 228 breast cancer patients and 80 patients with breast benign diseases. The association of BCL6, ZEB1 and ZEB2 expression with clinicopathological parameters and patient survival were analyzed. We found that the expression of BCL6, ZEB1 and ZEB2 protein and mRNA were significantly higher in breast cancer tissues than in breast benign disease tissues (P<0.05). The expression levels of BCL6, ZEB1 and ZEB2 were all positively correlated with the tumor size, lymph node metastasis and higher tumor stages (P<0.05). Furthermore, patients with BCL6, ZEB1 and ZEB2 protein-positive primary tumors were associated with a significant lower overall survival (OS) rate (P=0.001, 0.002 and 0.001, respectively) and post-operative relapse-free survival (RFS) rate (P=0.002, 0.001 and 0.003 for the expression of BCL6, ZEB1 and ZEB2, respectively). The mRNA expression of ZEB1 and ZEB2 were positively correlated with BCL6 mRNA expression (r=0.326, P<0.001; and r=0.382, P<0.001, respectively); the protein expression of ZEB1 and ZEB2 were also positively correlated with BCL6 protein expression (r=0.449, P<0.001; and r=0.669, P<0.001, respectively). These results indicate that BCL6, ZEB1 and ZEB2 may be as potential biomarkers for predicting invasion, metastasis and prognosis of breast cancer and that BCL6, ZEB1 and ZEB2 may be as potential biomarkers for predicting invasion, metastasis and prognosis of breast cancer and that BCL6 may be a regulator of ZEB family transcription factors (ZEB1 and ZEB2).

#2431 Single cell gene expression profiling in breast cancer cells with the Her2/neu gene knockout by CRISPR-Cas9. Xiaoyang Wang,1 Chip Lomas,1 Michael A. Tycon,1 Craig Betts,2 Suzanne Weaver2. 1New Mexico State Univ.-Las Cruces, Las Cruces, NM  

The Her2/neu gene is amplified and overexpressed in 15%-30% of breast cancers. The overexpression of this oncogene is strongly correlated with decreased survival, increased cancer relapse, and poor prognosis. Although therapy has been successfully developed to target this oncogene, a better understanding of this oncogene will provide further insight for breast cancer biology and future drug development. In recent years, the CRISPR-Cas9 system has emerged as an efficient method for genetic engineering, enabling targeted gene knockout with minimal off-target effects. In this study, we employed a plasmid-based CRISPR-Cas9 system to knock out the Her2/neu gene in breast cancer cells. Puromycin selected, GFP-positive (two indicators of the incorporation of the CRISPR-Cas9 system), Her2-negative individual cells were index-identified by a BD FACSMelodyTM system into individual wells of a 96-well BDTM Precise plate with sample barcoding and molecular indexing. A whole transcriptome amplification (WTA) assay was performed to obtain a gene expression profile for each of the Her2/neu knockout cells. Her2 gene knockout was performed on two cell lines: T47D, a ductal carcinoma-derived breast cancer cell line with no Her2 amplification that shows low to intermediate Her2/neu expression; and SKBR3, an adenocarcinoma-derived breast cancer cell line known for Her2/neu gene amplification and overexpression. For comparison, WTA assays were also carried out on parental cells without gene editing. Comparison of the gene expression profiles of these cell lines shows changes in gene expression correlated to the Her2 knockout. The profiling of gene expression in Her2/neu CRISPR-Cas9 knockout cells on a single cell level promises to provide insight into the mechanisms in these aggressive cancers that could help future drug discovery. For Research Use Only. Not for use in diagnostic or therapeutic procedures. 23-19341-00.

#2432 GPER1 expression is modulation by D-glucose concentration in estrogen-responsive cancer and tumor cells. Yan Zheng, Kevin D. Houston. New Mexico State Univ.- Las Cruces, Las Cruces, NM.  

G protein-coupled estrogen receptor 1 (GPER1, aka GPR30), is a 7-transmembrane receptor that mediates rapid cell signaling events stimulated by 17B-estradiol (E2) in cancer and tumor cells. In breast cancer cells, GPER1 mediates E2-induced CTGF-dependent cell migration and cyclin E expression resulting in cell cycle progression. GPER1 has also been shown to mediate antiproliferative cell signaling such as p53-dependent inhibition of cell cycle progression in breast cancer cells treated with the GPER1-specific agonist G1 and the inhibition of IGF-1R signaling in a tamoxifen-treated breast cancer cells. In addition to E2, both natural and synthetic compounds have been shown to activate GPER1 in breast cancer cells. GPER1 has also been shown to regulate cell signaling in cells that lack E2R. For example, GPER1 is antiproliferative in triple-negative breast cancer cells. While the importance of GPER1 in the modulation of E2-responsive tumor and cancer cells as been demonstrated, there is very little information regarding the regulation of GPER1 expression in these cell types. The work presented here is aimed at determining the molecular mechanisms that regulate GPER1 expression. To determine if GPER1 expression is sensitive to D-glucose concentration in breast cancer cells, MCF-7 and T47D human breast cancer cells were cultured in media containing increasing concentrations of D-glucose and GPER1 expression was measured using real-time PCR and immunoblot. Data from these experiments showed that GPER1 expression was sensitive to D-glucose concentrations (0 and 2.5mM) and significantly reduced in media containing high D-glucose (25 mM). Since low D-glucose concentration is known to activate the energy-sensing AMP kinase (AMPK), the observed GPER1 induction in low D-glucose conditions was determined after pretreatment with the AMPK inhibitor compound C. GPER1 expression was inhibited in both MCF-7 and T47D breast cancer cell lines in media containing low D-glucose when pretreated with compound C. Additionally, the AMPK activator metformin induced GPER1 expression in MCF-7 and T47D breast cancer cells cultured in high D-glucose (25mM) conditions. These data suggest that AMPK mediates GPER1 expression in cells cultured in low D-glucose. The D-glucose sensitivity of GPER1 expression was also determined in the Eker rat-derived uterine leiomyoma cells (ELT-3 and ELT-6) which are characterized by hyperactive AMPK. In both ELT-3 and ELT-6 cells, GPER1 expression was not sensitive to D-glucose concentration nor was the activation state of AMPK sensitive to D-glucose concentrations. However, the inhibition of AMPK by compound C in both ELT-3 and ELT-6 cells resulted in decreased GPER1 expression. These findings reveal a previously unknown mechanism that regulates GPER1 expression in E2-responsive tumor and cancer cells.

#2433 Altering nuclear size impacts cancer cell characteristics in melanoma cell lines. Lidija D. Vukovic,1 Bradley A. Stohr,2 Dan L. Levy1. 1University of Wyoming, Laramie, WY; 2University of California, San Francisco, CA  

Nuclear size is altered in breast cancer cells, a change used by pathologists to distinguish cancer from normal cells. Previous studies in Xenopus identified two nuclear transport proteins, importin α and NTF2, as regulators of nuclear size. In general, importin α and NTF2 levels positively and negatively affect nuclear size, respectively. Increased importin α expression is used as a biomarker in non-small cell lung carcinoma and breast cancer and correlates with increased nuclear size. We identified decreased NTF2 protein expression as a potential biomarker in melanoma, consistent with NTF2 levels negatively regulating nuclear size. Following up on this result, our current studies focus on manipulating nuclear size in melanoma cells to assess the impact on cancer cell characteristics, including proliferation rate, migration potential, and apoptosis. First, we measured nuclear size and NTF2 expression levels in different stage melanoma cell lines. Compared to a normal melanocyte cell line, we consistently observed larger nuclear size and lower NTF2 protein levels in all melanoma cell lines examined. Next, we performed transient transfections in HeLa, MRC5, and melanoma cell lines, demonstrating that ectopic NTF2 expression leads to reduced nuclear size. The most dramatic effects were observed in primary melanoma cell line WM3211 where higher NTF2 expression caused a 40% reduction in nuclear cross-sectional area. To obtain more precise control over NTF2 expression levels, we generated a stably transfected metastatic melanoma cell line (WM983B) in which NTF2 expression can be titrated by varying the concentration of doxycycline in the growth media. Higher doxycycline levels lead to increased NTF2 expression and smaller nuclei. In particular, 20 ng/ml doxycycline induced a 10% reduction in nuclear cross-sectional area. In a wound healing assay, doxycycline-treated cells exhibited a 40% reduction in cell motility compared to non-treated cells or the parent cell line treated with doxycycline. Furthermore, the doxycycline-treated cells exhibited an increased rate of apoptosis. We propose that reduced nuclear size in the doxycycline-treated cells causes changes in chromatin organization and gene expression, thus giving rise to observed effects on cell migration and apoptosis. To test this idea, we are currently performing a global transcriptomics analysis of our cell lines to identify genes whose expression is altered by nuclear size. Using this information, we will use DNA FISH to map the intranuclear position of differentially-expressed genes as a function of nuclear size. Also in vivo experiments are ongoing in which we have subcutaneously injected NTF2-inducible melanoma cells into NGS mice in order to examine tumor formation and metastatic capacity of cells with differently-sized nuclei. Regarding that in most cancer cells nuclear size is enlarged, understanding the causes and effects of these changes can help us to better understand cancer biology.
A novel oncogene that show a crucial role in the tumorigenesis and progression of HCC via activating Notch signaling pathway and inhibiting the differentiation and stemness of HCC, resulting in poor pathologic differentiation and leads to high degree of malignant. All the findings suggest a novel treatment possibility and a new target for liver stem cell eradication. LEF1 could be investigated for clinical early diagnosis and prognosis prediction of HCC patients and improving the development of new therapy against HCC.

#2435 Smoothened a new perspective for uterine leiomyoma treatment.
Natalia Garcia,1 Laura Gonzalez Anjos,2 Giovana De Nardo Maffazoli,1 Nilo Bozini,3 Edmund Chada Baracat,4 Katia C. Carvalho.5 1Univ. of São Paulo Faculty of Medicine, Mogi das Cruzes, Brazil; 2Univ. of São Paulo Faculty of Medicine, São Paulo, Brazil.

Background: Uterine leiomyomas (LM) are the most common gynecologic tumors occurring in women of reproductive age. Patients may present clinical complications such as bleeding, pain and infertility. Additionally, some researchers believe that a leiomyosarcoma can arise from a degenerated LM. Efficient treatments for LM are still limited. Identification of gene markers can help to elucidate these tumors pathogenesis and to reveal molecules that can be used as therapeutic targets. Objective: To assess gene and miRNAs expression, and DNA methylation profiles of genes related to the Sonic Hedgehog (SHH) signaling pathway in uterine leiomyoma samples in order to look for potential therapeutic targets. Methods: 80 samples of LM and 20 myometrium (MM) were obtained in the Department of Obstetrics and Gynecology at HCFMUSP/Sao Paulo - Brazil. Expression profile of 106 genes and 84 miRNAs sequences related to SHH regulation and the percentage of methylation in the promotor region of the SHH, PTCH1, SMO, SUFU, GLI and GLI3 genes were performed by quantitative Real Time PCR. Results: Among 106 genes evaluated, 16 showed hyper- and 11 showed hypoexpression in LM samples, compared to MM. Only SMOOTHENED (SMO) was found hyperegulated in LM. miRNAs analysis also showed 16 sequences with different regulation profiles between LM and MM. None of them is involved in the regulation of SMO expression. DNA methylation profile showed a higher percentage of methylation in LM samples, but this difference did not exceed 2% of methylation for the PTCH1, SMO, GLI1 and GLI3 genes. Conclusion: Our results suggest an activation of SHH pathway in LM by hyperexpression of SMO. These results are very interesting because there are SMO specific drugs approved by FDA for other tumors types.

#2436 Non canonical activation of Sonic Hedgehog pathway in uterine leiomyosarcoma.
Natalia Garcia, Bianca C. Oliveira, Kelly P. Ferreira, Edmund C. Baracat, Katia C. Carvalho. Univ. of São Paulo Faculty of Medicine, São Paulo, Brazil.

Background: Uterine leiomyoma (ULM) and leiomyosarcoma (ULMS) are smooth muscle tumors with distinct clinical and biological behavior. They can be a cause of infertility and even death. Little is known about the factors that can to influence these tumors behavior and biology. Sonic Hedgehog (SHH) pathway components were previously implicated in the ULMs malignancy risk; however its activation mechanism is unknown. In this study, we investigated the gene expression profile of Sonic Hedgehog Signaling and pathway upstream genes in myometrium (MM), ULM and LMS cell lines. Methods: Total RNA obtained from cell lines were submitted to cDNA synthesis and quantitative real time PCR (qRT-PCR), using 7500 System (Life Technologies, USA). Gene expression of SHH, PTCH1, SMO, SUFU, GLI 1-3, CCND1, BCL-2 and BMP4 were assessed. Results: Gene expression data showed an upregulation of SMO, SUFU, GLI1, BCL-2 and BMP4 in LMS cells when compared to MM. GLI1 (RQ=11) and BCL-2 (RQ=20) genes had higher expression. In the other side, SHH, PTCH1, GLI2 and GLI3 showed upregulation in MM cells. Conclusion: Our results showed that the Sonic hedgehog pathway is activated in LMS cells but by SHH independent form (non-canonical pathway). This could be explained by the downexpression of SHH ligand and the PTCH1 receptor, and by the expression of low level tumor and normal samples. SHH in uterus LMS cells compared to LM and MM. These results suggest a new therapeutic perspective for LMS by target drugs to inhibit SMO and GLI1 molecules.

#2437 Overexpression of MYL5 promotes cervical cancer cell metastasis through SLUG and HIF-1α signaling.
Lan Zhang. Sun Yat-sen University Cancer Center, Guangzhou, China.

Myosin light chains (MLC) serve important regulatory functions in a wide range of cellular and physiological processes. Previous research found that MLC are also chromatin-associated nuclear proteins which regulate gene transcription. In this study, we show that the MLC member myosin regulatory light chain 5 (MYL5) controls metastasis in cervical cancer. We uncover this role of MYL5 through clinical cervical cancer samples and various in vitro and in vivo models of metastasis. MYL5 promotes metastasis by enhancing the transcription of SLUG and hypoxia inducible factor-1α (HIF-1α). Moreover, we reveal a bidirectional regulation between MYL5 and HIF-1α. HIF-1α specifically binds to the MYL5 promoter region, and hypoxia leads to increased levels of MYL5 in cervical cancers. Overexpression of MYL5 sustained HIF-1α expression in normoxic condition. Clinical data confirmed a positive correlation between MYL5 and HIF-1α. In summary, our observations suggest a potential application of MYL5 in prognosis prediction and cancer treatment.

#2438 Analysis of IL-13 signaling through IL-13Rα2 in human brain tumor specimens in situ.
Rukmini Bhadra, Akiko Suzuki, Pamela Leland, Bharat H. Joshi, Raj K. Puri. FDA-CBER, Silver Spring, MD.

Previously, we have demonstrated that IL-13 receptor-α2 (IL-13Rα2), a high affinity receptor for Th2 cytokine IL-13, is overexpressed in most glioblastoma multiforme (GBM) cell lines and approximately 78% of the patient-derived samples. We have also demonstrated that IL-13Rα2 can be targeted by a number of immunotherapeutic agents including chimeric antigen receptor modified T (CAR-T) cells, targeted lentivirus and adenovirus vectors, and a chimeric fusion immunotoxin consisting of IL-13 and truncated Pseudomonas exotoxin (IL-13-PE). However, the signal transduction initiated by IL-13 in GBM tumor is not known to occur through the IL-13Rα2, which has a high affinity for IL-13. We have recently observed that IL-13 can signal through IL-13Rα2 by activating AP-1 transcription factors in human brain tumor cell lines. In this study, we have examined IL-13Rα2 expression in human brain tumor and normal brain specimens, and the subsequent signaling through the AP-1 pathway in situ. Using six human glioblastoma and three astrocytoma specimens, we evaluated the expression of AP-1 transcription factors by immunohistochemistry (IHC) and compared the extent of immunostaining and percent positive cells with three normal brain specimens. Six GBM specimens examined showed high degree of immunostaining for c-Fos, c-Jun, Jun D and Fra-1 (AP-1 family transcription factors) and a high percentage of positive cells. These specimens also showed strong immunostaining for IL-13Rα2 (4+) in >70% cells (P<0.001 compared to normal brain). Three astrocytoma specimens showed staining for IL-13Rα2 (2+ and 32% cells, P<0.01 compared to normal brain), but the extent of staining was lower compared to GBM. Similar to IL-13Rα2 expression, the extent of staining and percentage of positive cells for AP-1 transcription factors were highly statistically significant between tumors and normal brain (P<0.001 for GBM compared to normal brain and P<0.01 for astrocytoma compared to normal brain). The extent of immunostaining in GBM was highest for c-Fos (4+, >78% fields) followed by c-Jun (3+, 57% fields), Fra-1 (2+, 70% fields) and Jun-D (2+, 28% fields). Jun-B expression was low among the AP-1 transcription factors (<1+, 7% fields) in GBM specimens. Astrocytoma specimens showed lesser extent of immunostaining for AP-1 members compared to GBM; c-Fos showed 2+ staining and 42% positive fields followed by c-Jun (2+, 12% fields), Fra-1 (2+, 48% fields) and Jun-D (<1+, 18% fields). Jun-B staining intensity was <1+ in only 6% fields. Normal brain specimens showed no immunostaining for AP-1 family members. Our results generally corroborate with data obtained from GBM cell lines and confirm that IL-13 can signal in IL-13Rα2 positive GBM tumors in-situ through the AP-1 pathway, thus indicating that this pathway may be an important target for therapeutic intervention of GBM in addition to targeting IL-13Rα2.
Introduction: Development of improved cancer diagnostics and therapeutics requires detailed understanding of the genomic, transcriptomic, and proteomic profiles in the tumor microenvironment. Current technologies can excel at measuring a single analyte, but it remains challenging to simultaneously collect high-throughput DNA, RNA, and protein data from small samples. We have developed an approach that generates the multi-omics profile of DNA, RNA, and proteins from as little as 5ng DNA, 25ng RNA, and 250ng protein or just 2 5mm FFPE slides, and simplifies data analysis by generating digital counts for each analyte. Methods: The approach uses paired capture and reporter oligonucleotide probes and optical barcodes to enumerate up to 800 targets. The platform was initially developed to measure RNA, and we have adapted it to measure DNA single-nucleotide variants (SNVs), short intergenic RNAs, and protein expression. Results: Combining of sequence discriminating probes to the wild-type and mutant sequence of interest. Proteins are detected via binding of oligonucleotide-conjugated antibodies. Results: Combinations of DNA, RNA, and protein in biological and experimental contexts. SNV probes are able to detect variant alleles down to 5% abundance within a wild type population and can discriminate variants within mutation hotspots. It was >90% accurate at identifying variants from samples displaying a range of allele frequencies and DNA integrity when benchmarked against next-generation sequencing. Protein detection has been developed for cell surface, cytosolic, and nuclear proteins, as well as phospho-proteins. It was validated against flow cytometry, western blot, and mass spectrometry using cells line with ectopic target expression and primary cells. To demonstrate concurrent measurement of DNA, RNA, and protein expression in the genome and proteome, BRAFV600E/BRAFV600E and BRAFV600E/BRAFV600E cell lines were treated with the BRAFV600E inhibitor vemurafenib and the MEK inhibitor trametinib. We measured the allele usage at the BRAFV600E locus, as well as BRAFV600E dependent changes in mRNA expression, protein expression and protein phosphorylation in a single experiment. Conclusions: 3D Biology has several advantages over other analytical approaches. Direct, single-molecule digital counting allows detection over a broad dynamic range with high reproducibility, often over 98% concordance between technical replicates. The simultaneous interrogation of DNA, RNA, and protein maximizes the amount of data obtained from precious samples and minimizes instrumentation demands by leveraging a single detection platform. The 3D Biology approach allows holistic, digital analysis of biological samples with high specificity and precision. This technology is currently available for research use, but may also have clinical application in the future.

MOLECULAR AND CELLULAR BIOLOGY / GENETICS: Genome-Wide Analysis of Transcriptional Regulation

#2439 Establishment of six human colorectal cancer cell lines: identification of genes that have metastatic potential. Soon-Chan Kim, Chang-Won Hong, Sang-Geun Jang, Seung-Yong Jeong, Jae-Gabh Park, Jia-Lok Ku. Seattle National University, Medical Campus, Seoul, Republic of Korea.

A number of genes have been studied in accordance with their metastatic potential. Nevertheless, little is known about the metastatic profile of human colorectal cancer cell lines such as SW-620 or IS3 only show the influence of metastatic genes within limited mutational landscape. Here, three pairs of primary CRC (SNU-235A, SNU-235D, SNU-240A, SNU-240B, SNU-241A, and SNU-241B) and corresponding metastasis cell lines were established and analyzed by whole exome sequencing and microarray. Three pairs of primary CRC (SNU-235A, SNU-240A, and SNU-241A) and corresponding post-translational level and of extra-nuclear components. Our efforts to confirm the mRNA expression level in the paired CRC cell lines. The genes selected for examination were calponin 3, acidic (CNN3); sorbin and SH3 domain containing 1(SORBS1); epithelial stromal interaction 1 (EPS1T); bone marrow stromal cell antigen 2(BST2); kelch-like 5 (KLHL5); trypsinogen C (TRY6); and synaptogatin-like 5 (SYT5L5). We calculated the intersection of all three metastatic CRC cell lines. Five genes (BST2, SORBS1, CNN3, EPS1T, and KLHL5) were up-regulated in metastatic cell lines compared to primary cell lines. Two genes (TRY6 and SYT5L5) were down-regulated in metastatic cell lines compared to primary cell lines. Then, we ranked 15 genes that were up-regulated and 15 genes that were down-regulated in post-translational and single-nucleotide polymorphisms (SNVs) on both cell lines. We selected top 20 SNV genes that were differentially expressed, we selected three genes (CNN3, SORBS1, and TRY6) that showed the highest fold changes and are found in 2-fold change analysis. We identified 7 genes that were differently expressed in metastatic CRC cell lines compared to primary CRC cell lines. These genes may serve as diagnostic markers and therapeutic targets for patients with metastatic CRC.

#2440 Cross-tissue interactome analyses unravel novel oncogenic roles of SOX2. Thorsten Schaefer,1 Silvia Candido,1 Hui Wang,1 Thomas Bock,2 Alexander Schmidt,2 Claudia Lengerke1. 1University of Basel and University Hospital Basel, Basel, Switzerland; 2Biozentrum, University of Basel, Basel, Switzerland.

First recognized for its significance in early embryogenesis, SOX2 (sex-determining region Y box 2)morerecentlyreceivedmajorattentionasa(i)transcrip-
tional master regulator of stemness driving the re-programming of terminally differentiated somatic cells back into a pluripotent stem cell state and (ii) pow-
ertextual function of SOX2. As expected, a powerful oncogene of the cancer stem cell (CSC) compartment. We and others have shown that SOX2 expression relies on canonical PSE/AKT signaling involving direct physical contact and phospho-modification by AKT. Interestingly, we observed that these interactions are highly tissue specific which prompted us to perform a systematic proteomic analysis of co-factors regulating SOX2 biology. The SOX2 interactome was analyzed in human breast cancer-inoma and glioblas-
toma cell lines by co-immunoprecipitation (co-IP) and HPLC/MS revealing 2 500 conserved proteinaceous co-factors, thus underscor-
ing a hitherto underestimated scaffolding function of SOX2. As expected, a major proportion of binding partners cluster in functional categories implicated in DNA binding and/or nucleotide modification (e.g. helicases, transferases, and ligases). However, a near equal share of SOX2 associated factors fall into func-
tional classes formally unrelated to transcription modulation such as cell adhe-
sion, cytoskeletal organization, or metabolic adaptation. Using SOX2 knock-
down and overexpression cells generated by lentiviral technology, we confirm co-regulation of SOX2 with selected binding partners. Moreover, we observe co-depletion of SOX2 and protein co-factors in cells of stalled AKT activity, and a molecular restoration of both upon prosesational inhibition. We conclude that, besides its known significance in DNA activity control, the SOX2 protein en-
gages in various interactions seemingly unrelated to transcription modulation. These newly discovered interactions are likely to synergize with canonical SOX2 functions (i.e. the induction and maintenance of stemness), but involve regu-
lation at post-translational level and of extra-nuclear components. Our efforts thus add an exciting new facet to SOX2 biology and eventually, may open new therapeutic avenues for targeted anti-CSC therapy.

#2443 Massively parallel single-cell RNA-Seq identifies diverse subpopulations displaying EMT and stem-like features. Billy Lau, Jianmin Chen, Hanlee P. Ji. Stanford School of Medicine, Stanford, CA.

Single-cell transcriptome analysis enables a new paradigm for studying complex systems in cancer. As opposed to bulk sequencing, which averages genomic signals...
across thousands or millions of cells and obscures the presence of rare subtypes, single cell sequencing enables the interrogation of individual cells. In cancer, intratumoral heterogeneity is observed at both genomic and epigenomic levels, and its analysis enables the discovery of new actionable targets and treatment modalities tailored to individual subpopulations. As an example, many cancer cell lines and those derived from patients contain subpopulations defined by distinct patterns of surface markers such as CD44, and are linked to drug resistant and tumor initiating phenotypes. A complete characterization of such cellular populations ideally requires marker-free sampling, followed by clustering into distinct subgroups. In this study, we demonstrate the significant advantages of such an approach; we utilize a high-throughput single-cell RNA-Seq method to characterize the transcriptional profiles of cellular populations. We performed single-cell RNA-Seq on thousands of cells in the matched SW480 (primary) and SW620 (metastatic) colorectal cell lines using a microfluidic droplet barcoding technology that enables the tracking of single cells during library preparation. By focusing on genes with high inter-cell variability, we discovered a small subpopulation of cells that displayed a distinct gene expression signature from the major subpopulation. Differential gene expression analysis of this subpopulation yielded genes virtually all enriched in the epithelial-to-mesenchymal transition (EMT) pathway. These cells showed significant increases in canonical mesenchymal marker genes such as VIM, CD44, and SOX9. Gene expression profiles of these subpopulations also correlated with established EMT signatures. Remarkably, this subpopulation did not display mutual exclusivity in expression with the epithelial marker EPCAM, which possibly indicates an intermediate mesenchymal phenotype. We also observed in the major population cluster a small subset of cells totaling less than 1% of the population that were significantly enriched for LGR5 expression, a common stem-like marker in colorectal cancer. Overall, we demonstrate the use of single-cell RNA-Seq to discover and characterize a diversity of cellular states that would otherwise be impossible from bulk analysis.

**MOLECULAR AND CELLULAR BIOLOGY / GENETICS: Genome Landscape of Lymphoma, Leukemia, and Lung, Bladder, and Other Cancers**

### #2444 Recurrent mutations and clinical outcomes in patients with follicular lymphoma

Klannin Krysiak,1 Cody Ramirez,1 Felicia Gomez,1 Christopher A. Miller,1 Robert S. Fulton,1 Friederike Kreisel,1 Amanda F. Cashen,1 Laura H. Sehn,2 Joseph M. Connors,1 Ryan D. Morin,3 Marco A. Marra,4 Sohrab P. Shah,5 Christian Steidl,6 David W. Scott,7 Randy D. Gассоyne,7 Centre for Lymphoid Cancer, British Columbia Cancer Agency, Vancouver, British Columbia, Canada; 2Molecular Oncology, British Columbia Cancer Agency, Vancouver, British Columbia, Canada; 3Genome Studio, British Columbia Cancer Agency, Vancouver, British Columbia, Canada.

Introduction: Diffuse large B-cell lymphoma (DLBCL) comprises two distinct cell-of-origin (COO) subtypes: the germinal center B-cell-like (GCB) and the activated B-cell-like (ABC) subtypes. Several sequencing studies have informed on DLBCL biology and identified numerous candidate genes implicated in pathogenesis. However, comprehensive analysis of recurrent genetic alterations and related prognostic significance according to COO subtypes has not yet been performed. To understand the molecular distinctions and their therapeutic relevance specific to COO subtype in DLBCL, we performed a comprehensive genetic analysis on a population registry-based cohort of 347 patients with de novo DLBCL uniformly treated with R-CHOP. Methods: Tissue biopsies from 347 patients were analyzed using deep single-cell sequencing. Immunohistochemical staining was performed on tissue microarrays. COO subtype was assigned by Lymph2Cx assay. Results: We detected COO-specific mutations, copy number alterations (CNAs) and gene fusions. Furthermore, integrative analysis showed COO-specific trans gene expression effects on CNAs, demonstrating that CNAs in GCB-DLBCL are tightly linked to the deregulation of networks associated with PI3K-AKT signaling. We also identified the significant prognostic impact of recurrent genetic alterations within each COO subtype, including deletions of MIR15a/16-1 and TP53 and NFATC1 gain in ABC-DLBCL, TP53 and CREBBP mutations, PRAE deletions and MYC gain in GCB-DLBCL. In addition, deletions of PTEN and INPP4B, which are negative regulators of PI3K-AKT signaling, were identified as a marker associated with poor outcome in GCB-DLBCL (p = 0.01 and 0.0045, respectively). Furthermore, patients whose tumors harbored both genetic alterations had an even worse prognosis (p = 0.004), suggesting the clinical importance of PI3K-AKT signaling in GCB-DLBCL. Based on these genetic data, we found that the PI3K-AKT signaling pathway was more commonly altered in GCB-DLBCL than in ABC-DLBCL (64% vs 23%; p = 0.0001). We also observed more frequent genetic alterations of the TCR signaling pathway in ABC-DLBCL (80%), while this pathway was less frequently altered in GCB-DLBCL (54%; p < 0.0001). In addition, epigenetic modification and immune recognition pathways were more commonly altered in GCB-DLBCL compared to ABC-DLBCL (70% vs 44%; p < 0.0001, 71% vs 56%; p = 0.015, respectively). Finally, we demonstrated that the majority of DLBCL cases are altered for at least two of the four pathways mentioned above (86% of ABC-DLBCL and 87% GCB-DLBCL). Conclusion: We describe the landscape of common genetic aberrations in a population-based uniformly-treated DLBCL cohort, broadly representative of patients treated with curative intent, providing the genetic foundation for implementing precision medicine in this disease.

### #2446 Integrated analysis of somatic mutations in subcutaneous panniculitis-like T-cell lymphoma by whole-exome and -transcriptome sequencing

Hyojin Song,1 Youngil Koh,2 Daeyeon Kim,1 Hongseok Yun,1 Choong-Hyun Sun,1 Hogune Im,1 Dong-Yeop Shin,2 Sung-Soo Yoon2, Seoul National University College of Medicine, Seoul, Republic of Korea; 2Seoul National University Hospital, Seoul, Republic of Korea.

Subcutaneous panniculitis-like T-cell lymphoma (SPTCL) is a rarely differentiated form of non-Hodgkin lymphoma. This uncommon disease is triggered by preferential lymphoma infiltration into subcutaneous adipose tissue, and nodular formation in the fatty tissue. Consequently, the early stage symptoms of SPTCL is found as multiple subcutaneous nodules beneath the skin. Due to the low incidence rate and indolent progression of the disease, the genetic altera-
and karyotyped. Results: The total number of coding mutations in patient 509 of diagnosis (T1) and relapse (T2), using unaffected peripheral blood to exclude whole exome sequencing (WES) performed on tumor cells obtained at the time these patients to study the tumors in more detail. Methods: Both patients had therapeutic resistance would be enriched in the tumor cellstaken at the time of completing intensive chemotherapy. We hypothesized that mutations implicated in young men at our institution experienced a BL relapse within 3 months of completing panniculitis-like T-cell lymphoma is yet thoroughly understood. Hence, establishing the genetic basis and profiling the genomic landscape of SPTCL will establish the genetic basis and profiling the genomic landscape of SPTCL. We performed whole-exome sequencing of both biopsy sample collected from the patient and matched saliva, and matched tumor sample to 200X depth of coverage, respectively. Whole-transcriptome sequencing of the tumor sample was also performed for expression level analysis; gene fusions are also explored by TopHat-fusion-post. Somatic mutations were precisely detected by our internally developed somatic variant caller, which is an adjusted version of VarScan2 with additional filters based on thresholds of p-value and odds ratio. Overall, we identified 13 missense variants of 1588 SVs, 34 SVs were validated by using somatic variant detection algorithm of our own. By applying the additional filters to these variants, two genes were remarkably identified: SQSTM1 and BAGE3. SQSTM1 (sequestosome 1), also known as ubiquitin-binding protein p62, encodes proteins that regulate ubiquitination, autophagy, and activation of NFKB1. Through CbioPortal database search, SQSTM1 found to be highly amplified across the various cancer types, such as neuroendocrine prostate cancer (NEPC), kidney renal clear cell carcinoma (RCC), and pancreatic cancer. On the other hand, BAGE3, B melanoma antigen 3, was reported to be a candidate gene encoding tumor antigens. Gene fusions were identified by comparing the number of spanning reads and mate pairs, and fusion of NO7 and RANBP9 on chromosome 6 showed the highest fusion score of 604.45. Comprehensively characterized, two signatures of the initial disease progression, clinicopathological, and therapeutic resistance to chemotherapies. Furthermore, to strengthen the statistical power of the somatic mutation analysis, we are planning to expand the cohort and conduct functional validation study of selected genes by using secured paraffin blocks of SPTCL patients.

#2447 The mutational landscape of chemo-refractory Burkitt lymphoma. Claudia M. Wever,1 Maryse Lemaire,1 Donald C. Vinh,1 Josée Hébert,2 Yasser Gomez,1 Kilannin Krysiak,1 Cody Ramirez, Nancy Bartlett, Amanda Cashen, Friederike Kreisel, Eric Duncavage, Malachi Griffith, Todd Fehminger, Obi Griffith. Washington University, St. Louis, MO.

High-throughput sequencing provides insights into cancer pathogenesis. The application of genomics technologies to cancers characterized by rare cell populations is a challenge. DNA extracted from bulk tumor samples is a mixture of malignant and non-malignant cells. This is a problem in cancers defined by rare cell populations because it complicates the task of identifying true somatic mutations. Hodgkin lymphoma (HL) exemplifies this challenge. The pathologic hallmark of HL is Hodgkin-Reed-Sternberg (HRS) cells. HRS cells have a low abundance within an affected lymph node (1-30% of tumor microenvironment). Because HRS cells are rare, a limited number of studies have described characteristic genomic events. These studies have examined HL cell lines, and, recently, a small number of flow-sorted HRS-cells (Reichel et al. 2015). We hypothesized that recurrent somatic mutations can be identified in HRS cells using bulk HL biopsies and ultra-deep exome sequencing. The Illumina HiSeq X, which can generate >1.6 Tb of sequence data per run, is a applicable tool for the discovery of somatic mutations in HL. Frozen tumor (lymph node)/normal (skin) pairs from 31 patients with HL were examined. Th1, Th2, CD8+ T cells were flow sorted and pooled for sequencing. The libraries were pooled, size selected, and captured using an Illumina Xgcn sequen captive reagent. The pools were sequenced across eight lanes of a HiSeq X. A total of 7.04 x 10^12 bases were sequenced across all samples with an average of 1.10 x 10^10 bases per sample. The mean depth of coverage achieved across all samples was 783.4x (425.9x - 1091.9x). Given the low abundance of HRS cells we anticipated most somatic sites would have a VAF of 1-5%. Given the level of coverage we anticipate that most somatic variants will have >5 reads of support. Instrument data were processed using the McDonnell Genome Institute somatic variant calling pipeline that includes 5 SNV callers and 3 indel callers. We used these steps to filter variants: min. 50X coverage, max. 5000X coverage, min. 1% tumor VAF, max. 5%, normal VAF, and min. 5 variant reads in the tumor. Here we report preliminary data on mutations in five pilot samples. The remaining 26 will be presented at the meeting. We confirmed 7 previously documented recurrent mutations in HL (Reichel et al. 2015). Within our pilot data 13 recurrently mutated genes were found. The most interesting of our recurrent genes is TNFAIP3, which was the second most frequently mutated gene in Reichel et al. 2015. These data suggest that ultra-deep sequencing of tumor samples containing rare HRS-cells will identify recurrent somatic mutations. Thus, ultra-deep exome sequencing may be a useful discovery tool for rare tumor populations, and will improve our understanding of HL.

#2449 Transcriptome and whole-genome sequencing analysis of a novel murine model of chronic lymphocytic leukemia. Lili Wang,1 Jing Sun,2 Amaro Taylor-Weiner,2 Jaegil Kim,2 Zachary J. Cartun,3 Angela N. Brooks,2 Donna M. Cipolat,4 Benjamin D. Ellens,2 Emily A. O’Malley,2 Christine M. Carrazzo,2 Catherine J. Wu,2 Dana-Farber Cancer Institute, Boston, MA; 3Broad Institute, Cambridge, MA; 4University of California, Santa Cruz, CA; 5Boston Children’s Hospital, Boston, MA.

Large-scale cancer sequencing of primary chronic lymphocytic leukemia (CLL) has identified SF3B1, an RNA splicing factor, as one of the most frequently mutated CLL genes. SF3B1 mutations localize to a hotspot (>50% at K700E site) and highly co-occur with mutations in ATM or deletion of chromosome 11q (minimally deleted region contains ATM). How this splicing factor mutation alone or in cooperation with ATM deletion contributes to CLL remains elusive. Genetically engineered mice are powerful tools in understanding genetic lesions and cancer phenotypes. We therefore generated a mouse line that conditionally expresses heterozygous SF3B1-K700E mutation. We modeled the effects of the combined alterations by crossing mice with conditional knockout of ATM and mice with SF3B1-K700E. By breeding these mice with homozygous CD19-Cre transgenic mice, we achieved B cell-restricted expression of heterozygous SF3B1 mutation and ATM deletion. B cell co-expression of these two mutations in vivo led to clonal expansion of CD19+ CD5 + B cells in blood, marrow and spleen in aged mice (18 to 24 month old) at low penetrance. No leukemia cells were found in the SF3B1-K700E mice (up to 24-month old). The CLL cells from the double mutant mice could be engrafted in both immunocompetent and immunodeficient mice, with detectable disease within 2-4 weeks following transfer, thus making this mouse line amenable to drug discovery and biological validation.
investigations. To investigate how Sf3b1 mutation and Atm deletion synergistically contribute to CLL, we asked if there are RNA and DNA level changes in the double mutant mice with CLL. First, we performed transcriptome sequencing of splenic B cell RNA collected from age-matched mice that either express wild-type, singly mutant alleles of Sf3b1 or Atm, or doubly mutant alleles with or without the deletion. Using the tool JunctionBASE, we classified and quantified splice variants associated with the different genetic alterations. Consistent with prior findings in human CLL, we observed that splice variants in Sf3b1 mutant mice alone were highly enriched at 3′ splice sites. Sf3b1 and Atm doubly mutant B cells displayed a splicing pattern similar to that in Sf3b1 singly mutant cells. Moreover, we identified unique CLL splice variants in genes (Setdb2, Pthc1c) previously reported to be associated with CLL. Next, we examined the expression rate in DNA derived from splenic B cells collected from mice with a singly mutated allele of Sf3b1 or Atm, or with doubly mutated alleles with and without CLL-like disease through comparison against matched germine DNA from kidney by whole-genome sequencing. We have observed that co-expression of Sf3b1 mutation and deletion of Atm results in a higher DNA from kidney by whole-genome sequencing. We have observed that co-expression of Sf3b1 mutation and deletion of Atm results in a higher alteration rate compared to single mutant cells. Our analysis has revealed that altered RNA splicing and genomic instability all contribute to CLL leukemogenesis. We will further dissect how the two lesions contribute to CLL functionally using this model.

Mutational profiling of MLL-PTD acute myeloid leukemia. Ling-wen Ding,1 Qiaoqiao Sun,1 Kar-Tong Tan,1 Wenwen Chien,1 Anand Maya-konda,1 Dechen Lin,1 Xinxi Loh,1 Jinfen Xiao,1 Minjae Jeon,1,2 Tamaras Alperman,2 Manoj Garg,1 Su-Lin Lim,1 Vikas Madan,1 Norimichi Hattori,3,4 Singapore, Singapore;2 MLL Munich Leukemia Laboratory, Munich, Germany; Tokyo, Tokyo, Japan;5 National Taiwan University Hospital, Taiwan, Taiwan;3 Department of Pathology and Tumor Biology, Kyoto, Japan;4 The University of Tokyo, Tokyo, Japan; Japan; National Taiwan University Hospital, Taiwan, Taiwan; 4 Cedars-Sinai Medical Center, Los Angeles, CA; 5 Keio University School of Medicine, Tokyo, Japan; 6 MD Anderson Cancer Center, Houston, TX.

In this study, we performed whole-exome and targeted sequencing on 85 MLL-PTD AML patients. These AMLs have oncogenic tandem duplication of the MLL gene. At least one well-known oncogenic driver mutation was identified in over 90% of the MLL-PTD patients. In line with earlier sequencing studies, we identified the most altered genes in MLL-PTD patients. IDH2 (16.1%), NF2 (18.8%), PTEN (9.4%), TP73 and SMAD2 (2.5%). Single-copy gains and deletions were enriched (p < 0.001) for genes mapping into the following pathways: aberrant PI3K and PI3K/AKT signaling, loss of function of SMAD4 in cancer and SMAD4 MH2 Domain mutants in cancer. The functional pathways significantly (p < 0.001) deregulated in our cohort with single copy gain and homozygous amplification were: regulation of transcription and nuclear acid, negative regulation of metabolic processes, constitutive signaling by aberrant PI3K in cancer and PI3K/AKT network. Finally, in order to define driver alterations, we correlate deletions and losses with mutational data. Interestingly, we found losses which are also targeted by mutations (BRCA2, LRRK1). Moreover, some deleted genes, as CASK, CDK6 and MALT, were involved in pathways affected by genomic mutations (CASK deletion and MPP6 mutation, CDK6 deletion and PPM1D mutation, MALT deletion and SPAG5 mutation). Conclusion: We have identified new CNAs and pathways involving novel potential leukemia-related genes. Our results suggest that the comparison between SNP and WES data could provide important findings on prognosis of AML patients. Minimal deleted regions of genes implicated in deregulated pathways deserve further investigation in order to identify which candidate genes could be relevant AML biomarkers.

Detailed genomic characterization of CML/aCML/MPN-U/CML reveals disease subgroups that may benefit from rationally-designed combination therapies. Hajiao Zhang,1 Beth Wilmot,1 Daniel Bottomly,1 Libbey Milon,1 Jie Pan,1 Angela Hsu,1 Juliette Rofelty,1 Sophie Means,1 Brian Junio,1 Samantha Savage,1 Emily Stevens,2 Kim-Hien Dao,3 Julia E. Maxson,1 Jeffrey W. Tyner,1 Oregon Health & Science University Knight Cancer Institute, Portland, OR;4 Fred Hutchinson Cancer Research Center, Seattle, WA.

Purpose: Chronic neutrophilic leukemia (CNL), chronic myelomonocytic leukemia (CMM), atypical chronic myeloid leukemia (aCML), and unclassified myeloproliferative neoplasms (MPN-U) are a group of heterogeneous disorders belonging to rare entities of myeloproliferative or myelodysplastic/myeloproliferative (MDS/MPN) syndromes. Due to lack of specific molecular markers and the limited understanding of pathogenesis, the treatment of these diseases remains empirical, resulting in poor outcomes. Recently, recurrent mutations in ASXL1, TET2, SRSF2 and cell signaling genes have been identified in these diseases. In this study we aim to analyze the co-occurrence patterns of these gene mutations, as well as the association of different mutations with disease subtypes and treatment outcomes. Methods and results: We performed whole exome sequence and RNA-Seq on primary patient samples. Consistent with previous studies, high frequencies of ASXL1, TET2, SRSF2 and cell signaling pathway mutations were observed; whereas mutations of MPL, CEBPA, IDH1/2, and TP53 were rare. Further variant allelic frequency analysis demonstrated that mutations of the chromatin modifiers, epigenetic markers and splicing factors are mostly present in the major clones indicating early acquisition of these mutations.

626
Proceedings of the American Association for Cancer Research • Volume 58 • April 2017
In addition, ASXL1/2, splicing factor and signaling pathway mutations co-occur in around 45% of all patients with these mutations, indicating that they drive these diseases in a cooperative manner. RNA-seq analysis demonstrated two major gene expression clusters with high levels of either RAS or JAK-STAT signaling alterations respectively, indicating a potential need for distinct therapeutic strategies for specific subsets of specimens. In addition, we observed that 17% of patients have more than one signaling pathway mutation, possibly in distinct subclones, providing rationale for drug combination treatment. Furthermore, we observed that mutations related to RAS signaling pathway are prevalent in CMML; CSF3R and JAK2 mutations are enriched in CNL; whereas, RAS and JAK-STAT pathway double mutations are enriched in CMML. Similar to other cancers, copy number alterations and epimutations are observed across all these diseases. Conclusions: CNL/aCML/MPN-U/CMLM is a group of heterogeneous diseases associated with chromatin modifier, epigenetic, splicing factor and signaling pathway mutations in concomitant manner. We propose future studies of rational drug combinations with agents, targeting epigenetic and splicing factors, together with the appropriate signaling pathway inhibitors. Our study represents a large-scale comprehensive genomic analysis of these diseases, which reveals novel insight into patterns of mutation co-occurrence which could translate into new treatment paradigms for these difficult to treat hematologic malignancies.

#2453 Chromatin remodeling genes are frequently somatically altered in cervical carcinomas. Akinyemi Ojesina, Aishwarya Sundaresan, Vinodh Shrinivasan, Risma Sarema, Hemanth Tiwari, Warner Huh. University of Alabama at Birmingham, Birmingham, AL.

Introduction: Cervical cancer is responsible for 15% of all deaths due to cancer in women worldwide. There is a need to identify somatic mutations driving this cancer in order to facilitate development of novel therapeutic strategies. Experimental procedures: We analyzed whole exome sequencing data from 430 cervical carcinomas. The data were derived from a combination of our previously published work (Ojesina et al. Nature 2014; Chung et al., Int J Cancer 2015), and publicly available data generated by the Cancer Genome Atlas (TCGA). The Mutect2.0 and MutSig2CV algorithms were used to identify somatic mutations and significantly mutated genes (SMGs) respectively. Copy number alterations were analyzed using the GISTIC algorithm. Findings: Based on MutSig2CV false discovery rate threshold of 0.1, we identified MLL3 (19%) and MLL2 (13%) as novel significantly mutated genes (SMGs) in cervical cancer. In addition, other chromatin modifying genes including EP300 (12%) and ARID1A (7%) were confirmed as SMGs. Further investigation of genes that did not meet the threshold revealed that 228 of 430 (53%) of cervical tumors harbored at least one somatic mutation in chromatin modifying genes. These include genes in the myeloid/lymphoid or mixed-lineage leukemia (MLL) family (28%), lysine (K)-specific demethylase (KDM) family (23%), AT rich interactive domain (ARID) family (13%), SWI/SNF related, matrix associated, actin dependent regulator of chromatin (SMARC) family (8%) and histone cluster 1 (HIST1) family (4%). Conclusions: We have demonstrated that a majority of cervical cancers harbor somatic mutations in chromatin remodeling genes. This novel finding was facilitated by the larger sample size derived from combining multiple datasets, and may have diagnostic and therapeutic implications in cervical cancer.

#2454 Genetic landscape of glioma reveals defective neuroactive ligand receptor interaction pathway as a poor prognostic marker in glioblastoma patients. Jagriti Pal1, Vikas Patil1, Anupam Kumar2, Kaymeet Kaur2, Chitra Sarkar3, Kumaravel Somasundaram1. 1Indian Institute of Science, Bangalore, India; 2All India Institute of Medical Science, New Delhi, India.

Glioblastoma (GBM; grade IV), is highly proliferative, infiltrative and treatment refractory. Hence, understanding the complete genetic alteration profile of GBM would help us in identifying molecules or pathways that have strong implication in GBM pathogenesis and in the design of targeted therapy. Recent large scale studies suggest that three pathways - receptor-tyrosine kinase, TP53 and RB, are significantly altered in GBM. However, even with the tremendous increase in our understanding of the tumor, advancement in therapeutics is minimal and the median survival still remains at 15 months. Hence, we need to elucidate novel altered molecules and pathways in GBM progression such that more effective therapeutic opportunities can be explored. Here, we have carried out whole exome sequencing of grade II, grade III and GBM samples which revealed the mutation spectrum of glioma from our patient set. Further, we performed integrative analysis of mutated genes from our patient cohort as well as TCGA cohort (The Cancer Genome Atlas) to find out mutated pathways that predict survival in GBM patients. The most significant pathway - neuroactive ligand-receptor interaction pathway was explored further. Patients with mutations in one or more genes of this pathway had poor survival. The pathway comprises of G-protein coupled receptors, ion channels and ligands which functions in modulating a variety of cellular processes, behavior etc. Of the enriched genes belonging to this pathway, Calcitonin Receptor (CALCRL), which was highest mutated in GBM (2.75%), was taken up for further investigation. CALCRL was found to be downregulated in GBM and mutation or downregulation of the gene was found to predict poor survival in patients. Functional studies through cell-line based experiments revealed CALCRL is a tumor suppressor in GBM. The peptide hormone calcitonin (CT), a high affinity CALCRL ligand, inhibited proliferation, migration and anchorage-independent growth of glioma cells expressing CALCRL with a concomitant decrease in the phosphorylation levels of ERK, AKT and JNK signaling molecules. However, CT failed to do these functions in CALCRL silenced gloma cells. Exogenous overexpression of CALCRL in glioma cells expressing low levels of the receptor was found to inhibit proliferation, migration and anchorage independent growth and this effect was further augmented when CT was added. Further, introduction of tumor-derived mutations in CALCRL led to the abrogation of its tumor suppressor function. Studies are ongoing to demonstrate the tumor suppressive nature of CALCRL using in vitro astrocyte transformation and intracranial orthotopic mouse glioma model. Thus, our study suggests CALCRL signaling is an important tumor suppressor pathway in glioma development and underscores the importance of using CT as a novel therapeutic molecule for GBM treatment.

#2455 Human glioblastoma arises from the distant subventricular zone normal appearing but harboring tumor-initiating mutations. Joo Ho Lee,1 Jeong Eun Lee,2 Jee Ye Kahng,3 Jinseong Park,3 Seon Jin Yoon,3 Se Ho K immun,2 Jong Hee Chang,3 Seok Gu Kang,3 Jeong Ho Lee,3 Korea Advanced Institute of Science and Technology, Daejeon, Republic of Korea; 4Chungnam National University Hospital, Daejeon, Republic of Korea; 5Severance Hospital, Yonsei University College of Medicine, Seoul, Republic of Korea.

Glioblastoma multiforme (GBM) is the most devastating and incurable brain tumor. Although the identification of cells with tumor initiating mutations or their location can provide the fundamental basis for understanding disease progression, the origin of GBM remains controversial due to the lack of direct evidence in human GBM patients. Here, we performed ultra-deep sequencing of triple-matched tissues of i) radiologically and pathologically normal subventricular zone (SVZ), which is distant from tumor, ii) GBM tumor, and iii) blood (or normal cortical tissues) from patients with GBM (IDH-wildtype), compared to those with other type of brain tumors such as GBM (IDH-mutant), meningioma, oligodendroglioma, metastatic brain tumor and C (IDH-wildtype with SVZ-invasion. Surprisingly, we found that in 55.5% of IDH-WT GBM patients (5 of 9), normal appearing and distant SVZ already contained the low level of GBM mutations such as TP53, EGFR, RB1, PDGRF or TERT variations observed in the matched tumor. Single cell sequencing of GBM tumors and laser capture microdissection analysis of the SVZ show that mutations are enriched in the region of neuronal progenitor cell clusters, with neuronal processes, behavior etc. of the cell closest to the IDH-WT GBM tumor. Furthermore, using CRISPR-Cas9 system in the postnatal mouse brain, we showed that neural stem cells with TP53, PTEN, EGFR mutations migrated away from the mutated SVZ site and then formed the high grade malignant glioma in the distant cortical region. Taken together, this study provides the direct evidence that human glioblastoma arises from the distant SVZ that is normal-appearing but harboring tumor-initiating mutations.

#2456 Distinct genomic landscape of upper urinary tract urothelial carcinoma. Yoichi Fujii1, Yusuke Sato2, Hiromichi Suzuki1, Tetsuichi Yoshizato1, Yusuke Shiozawa1, Kenichi Yoshida1, Yuichi Shiraiishi2, Kenichi Chiba3, Hiroko Tanaka4, Tomoharu Nakagawa2, Haruki Kume3, Hiroaki Nishimatsu1, Toshikazu Okane4, Masashi Sanada5, Hideki Makishima4, Satoru Miyano3, Yukio Hompa4, Seiki Ogura4, Graduate School of Medicine, Kyushu University, Kyushu, Japan; 2Chungnam National University Hospital, Daejeon, Republic of Korea; 3Severance Hospital, Yonsei University College of Medicine, Seoul, Republic of Korea; 4The Fraternity Memorial Hospital, Sumiduka, Japan; 5Toranomon Hospital, Minato, Japan; 6Clinical Research Center, Nagoya Medical Center, Nagoya, Japan.

Backgrounds: Upper urinary tract urothelial carcinoma (UTUC) is relatively rare, accounting for 5-10% of urothelial malignancies with frequent multifocal development. To clarify distinct characteristics of UTUC, we comprehensively investigated the genetic alterations of this disease. Materials & methods: Surgical specimens of UTUC and matched normal samples were obtained from 99 patients with various stages who underwent nephroureterectomy, and subjected to
whole exome and RNA sequencing. We compared our results in UTUC with datasets previously reported in bladder urothelial carcinoma (BUC). Mutations in apparently normal urothelial epithelia in 5 cases were also interrogated. Results: Genetic alterations were most frequently observed in TERT promoter (51% of cases), followed by KMT2D (48%), FGFR3 (44%), CDKN2A (42%), TP53 (31%), and RAS pathway (HER2/KRAS/NRAS, 21%). More than 95% of cases harbored either TP53/MDM2, FGFR3, or RAS pathway mutations in an almost mutually exclusive manner, based on which UTUCs are classified into 3 molecularly and clinically distinct subtypes based on the status of mutations in TP53/MDM2, FGFR3, and RAS pathway. Depending on their location, urothelial cancers have different genetic backgrounds, where a field effect unique to urothelial epithelia might contribute to multifocal occurrence of UTUC.

### #2457 Investigating the functional significance of novel, recurrent non-coding mutations of TBC1D12 in bladder cancer. Angela S. Li, Jason A. Reuter, Can Cenik, Michael P. Snyder. Stanford University School of Medicine, Stanford, CA.

Somatic noncoding mutations remain widely unexplored despite examples of critical importance such as driver mutations in the promoter of the TERT gene. We recently identified novel somatic mutations in the regulatory Kozak sequence (just upstream of the translation start site) of TBC1D12 in ~15% of bladder cancer patients, making it one of the most frequently mutated noncoding regions in bladder cancer. Using two independent case-control studies, we identified novel noncoding mutations in TBC1D12 in ~15% of patients with bladder cancer. To experimentally test the functional relevance of these mutations, we performed co-transfection experiments with a RAB-specific GTase-activating protein (GAP). To investigate the functional implications of TBC1D12 mutations in bladder cancer, we undertook a combined computational and experimental approach. We analyzed clinical correlations, identified downstream effector candidates, and assessed the impact of these mutations on gene expression. To determine the clinical relevance of the TBC1D12 mutation, we did correlation and survival analyses of clinical data of bladder cancer patients from TCGA. We found that TBC1D12 mutations confer slightly worse survival but were not linked to other clinical correlates. To identify potential downstream effectors, we used reverse phase protein array (RPPA) data from 127 patients to search for proteins that were differentially expressed or phosphorylated between patients with or without TBC1D12 mutations. We found differential expression of GSK3 and differential phosphorylation of p90RSK and c-Jun, suggesting three potential downstream effector candidates. Hierarchical clustering of RPPA data for these three proteins revealed 4 subgroups with distinct molecular phenotypes. Furthermore, most of the TBC1D12 mutations were clustered within one molecular subtype. To experimentally test these downstream effector candidates and identify new ones, we modulated the levels of TBC1D12 in bladder cancer cell line Ku-19-19 using overexpression plasmids or siRNAs. After validating that these transfections were effective in changing TBC1D12 expression, we performed RNA-Seq experiments. Results from this study are expected to be presented at the meeting. In summary, these studies suggest that the novel and recurrent noncoding mutations in TBC1D12 may affect patient survival and alter the expression or post-translational modification of downstream targets. Potential molecular mechanisms associated with the presence of TBC1D12 mutations will be discussed, and a series of follow-up studies are underway. These studies also demonstrate that applying both computational and experimental approaches can help develop and test evidence-based hypotheses, contributing to an understanding of the clinical and functional impact of TBC1D12.

Urothelial cancer (UC) is a well-known multifocal disease with frequent recurrences. The clonal origin of spatially separated UC foci is controversial. Here we propose to elucidate the multifocal UC genome by next generation sequencing (NGS) and thereby identify novel clonal heterogeneity among the lesions of a single bladder. Until now, all experiments aimed at understanding the molecular heterogeneity were generated mostly by candidate gene approach and older technologies. There is a lack of comprehensive molecular information in these multifocal lesions partly due to inadequate sample size for comprehensive molecular studies. Identification of mutational status at the gene level in different multifocal lesions will allow us to identify markers for prognostic classification, and predictive classification of response to UC therapies, as well as identify potential therapeutic targets. To understand the molecular heterogeneity among the lesions of a single bladder, we used The Ion AmpliSeq™ Comprehensive Cancer Panel (CCP) (ThermoFisher). The Ion AmpliSeq™ CCP was designed to target all exons of 409 key tumor suppressor genes (TSGs) and oncogenes most frequently cited and mutated in cancer. We tested 41 lesions from 16 cystectomized bladder cancer patients with this panel, enabling an initial analysis of 21 lesions and 8 germ line controls from 8 patients. We further technically validated selected mutational events found by NGS with a complementary approach, namely droplet digital PCR (ddPCR). We then compared the intra- and inter-tumor mutation profiles. Two separate lesions were used for analysis in 3 patients and 3 lesions were taken from each of the remaining 5 patients. Our initial analysis showed mutational heterogeneity among the lesions of most of the samples. Briefly, two of the patients had one clone found at all sites, while the rest of the patients showed more variation amongst their lesions. For instance, ARID2, TRRAP, PDGFB, and FBXW7 were mutated in two out of three lesions in one of the patients, indicating hotspot for heterogeneous mutational events. Three mutational events were confirmed by ddPCR, denoting the accuracy of our NGS data analysis. Our analysis demonstrates that targeted next generation sequencing is a sensitive and reliable method for interrogating the molecular landscape of bladder cancer, and indicates that both clonal and spontaneous events can account for multifocal bladder cancer. Our data suggests that sequencing of multiple lesions from an individual patient is necessary to accurately elucidate the clonal and tailoring profile of targeted treatments. Further analysis in an extended number of samples is necessary to fully understand the molecular heterogeneity at the mutational level in urothelial cancer.

### #2460 Copy number alterations in NOTCH2 and PTP4A3 are associated with prognosis and support novel therapeutic strategies for malignant pleural mesothelioma. Leticia G. Leon,1 Maria Gemelli,2 Paolo A. Zucali,2 Christos Zografos,2 Giuseppe Fabbri,2 Elisa Giovannetti1. 1 University of Pisa, Pisa, Italy; 2 Humanitas Clinical and Research Center, Rozzano, Italy; 3 University of La Laguna, La Laguna, Spain.

Malignant pleural mesothelioma (MPM) is an aggressive cancer, which incidence has constantly increased over the past two decades and is expected to peak in 2020. The overall prognosis is poor, and predictive biomarkers of drug activity are missing. Given the heterogeneous and complex nature of MPM, it is likely that genomic aberrations changing the expression of several genes, might affect therapeutic response. Therefore, the aim of the present study was to identify genes whose copy number alterations might predict the MPM prognosis. Recurrent copy number alterations of genes were analyzed by high-resolution whole-genome sequencing in DNA obtained from a “discovery cohort” of 26 resected MPM patients treated with pemetrexed chemotherapy (8 with progressive disease, vs. 10 with stable disease and 8 with partial response). Prognostic markers identified by Copy Number Variation analysis with Nexus, ControlFREEC and ReadDepth software were validated by PCR gene copy number and gene expression analyses both in the “discovery” and in two “validation” cohorts of pemetrexed-treated and untreated patients (N=45 and 40). The role of emerging genes was evaluated through siRNA and pharmacological studies using proliferation, migration and apoptosis assays in MPM cells. As reported previously we observed copy number loss of CDKN2A (15.4%) and BAP1 (7.7%). Interestingly, copy number gain of NOTCH2 was observed in 50% of samples of the patients who underwent progression, whereas losses of PTP4A3
were associated with clinical benefit (SD+PR). The prognostic relevance of NOTCH2 was confirmed by PCR analysis. NOTCH-2 silencing reduced MPM cell migration and enhanced apoptosis induction by pemetrexed, while a PTP4A3 inhibitor overcame pemetrexed resistance in MPM cells characterized by high NOTCH2 and PTP4A3 expression. These results support the role of NOTCH2 as a molecular target with therapeutic potential for MPM, prompting prospective randomized trials for its validation. Moreover, preclinical data suggest that NOTCH2 and PTP4A3 are oncogenes suitable for effective therapeutic targeting in pemetrexed-resistant MPM cells.

#2461 Molecular classification and clinical characterization of a large uterine leiomyoma patient cohort. Nettta Makinen,1 Hanna-Riikka Heinonen,1 Annukka Pasanen,2 Jaana Tolvanen,3 Simonna Bramante,1 Miika Mehine,3 Jari Sjöberg,3 Oskari Heinikimo,5 Ralf Büttow,2 Lauri A. Aaltonen,1 Genome-Scale Biology Research Program and Department of Medical and Clinical Genetics, University of Helsinki, Helsinki, Finland;3Department of Pathology and Laboratory of Helsinki University Hospital (HUSLAB), Helsinki University Hospital, University of Helsinki, Helsinki, Finland;1Department of Obstetrics and Gynecology, Helsinki University Hospital, Helsinki, Finland.

Uterine leiomyomas (ULs), benign smooth muscle tumors, represent one of the most common neoplasms in women with an estimated prevalence varying from 20% to over 70% during the reproductive years. Approximately every fourth woman with ULs has clinically relevant lesions, which cause morbidity and thus require treatment. Still today, hysterectomy is the primary treatment option for ULs worldwide, and remarkably, their annual societal costs exceed those of colon and breast cancer combined. Our previous findings, derived from the use of high-throughput technologies, suggest that there are at least three distinct molecular UL subclasses, each displaying a characteristic genetic driver aberration and unique global gene expression profile: MED12 (mediator complex subunit 12) mutation-positive, HMG2A (high mobility group AT-hook 2) -overexpressing, and FH (fumarate hydratase)-deficient ULs. The aim of this study is to examine the molecular subclasses, their respective proportions, and clinical characteristics in a large UL patient cohort. The study material consists of 1026 ULs and corresponding normal myometrium tissue from 322 patients, who had ultrasound-diagnosed ULs and underwent hysterectomy in Helsinki University Hospital, Finland between October 2013 and June 2016. From each uterus, we harvested all feasible ULs $\geq 1$ cm in diameter and a piece of the corresponding normal myometrium tissue. The location of the collected samples in the uterus, their size, and any observed special characteristics were carefully documented at the time of sample removal. In addition, comprehensive clinical information of the patients was obtained from medical and pathology reports, as well as from a questionnaire, and the histopathology of all lesions were characterized according to the WHO 2014 criteria. All collected ULs have been systematically screened for MED12 mutations by Sanger sequencing. Overexpression of HMG2A typically arises from a chromosomal translocation, and deletions at FH locus suggest the presence of potential biallelic FH inactivation. Therefore, HMG2A-overexpressing and FH-deficient ULs have tentatively been identified using a high-density customizable Infinium® Human6 BeadChip with over 305,000 markers. Currently, the data analyses are ongoing, and the clinical significance of the identified genetic variants is being investigated. From the targeted sequencing, the Illumina Amplicon-DSSo Profiling, called from the SNP data by hapLOH, showed that sarcoma samples were more aberrant than their carcinoma counterparts (abstract 131, AACR 2016). From the targeted sequencing, the Illumina AmpliSeq-DS Somatic Variant Caller was employed to call somatic mutations. Mutations were identified in TP53 in both the sarcoma and carcinoma samples of all 10 patients. Frequently mutated genes included APC, EGRF, MET and MSH6 which were found in 60-80% of the patients. Genes mutated in less than 50% of the patients included PTEN, KRAS, KIT, FBXW7, PIK3CA, FGFR2, and CTNNB1. Current results showed no association of a mutated gene to either the carcinoma or sarcoma component of UC. RSM, STAR and EBSeq were applied to the RNA-seq data for gene expression quantification. Approximately 2500 genes were identified as being differentially expressed (DE) between normal and carcinoma samples. Deregulated pathways identified in both carcinoma and sarcoma include: cell cycle, transcriptional regulation, Ras and p53 signaling. Some additional pathways affected in the carcinoma but not in the sarcoma component also suggest their importance (abstract 791, AACR 2016). The next step of this study is to examine the global gene expression profile of UC by RNA sequencing.

#2462 Whole-exome sequencing reveals genetic variants in ERC1 and KCNG4 in complete hydatidiform moles from Chinese Han women. Yan Yu,1 Bingjian Lu,1 Weiguo Lu,1 Xinyu Wang,1 Pengyu Liu,1 Yan Lu,1 Xiaodong Cheng,1 Xing Xie1. Women’s Hospital School of Medicine Zhejiang UNIV., Hangzhou, China;1Institute for Translational Medicine School of Medicine, Zhejiang University, Hangzhou, China.

Complete hydatidiform mole (CHM) is an uncommon pregnancy-related disease with an invasive potential. The genetic background of the sporadic CHM has not been addressed previously despite the possible mechanisms of maternal genetic variants to the development of this disease with biparental origin. We performed the whole-exome sequencing analysis on 51 CHM patients and 40 normal healthy women. Finally, the candidate genetic polymorphisms were validated by direct Sanger sequencing in 247 cases and 599 controls with another 205 new controls. We found that two SNPs c.G48C(p.G16H) in ERC1 and c.G1114A(p.G372S) in KCNG4, were associated with an increased risk for CHM (p<0.05). These genetic variants will facilitate our understanding on the pathogenesis of CHM and related tumors as well as the oogenesis and embryonic implantation. They will provide additional information for the pregnant women both in physiology and psychology. Further multiple-disciplinary collaborations should be encouraged to clarify the accurate pathogenesis of CHM.

#2463 Tumor profiling of separated carcinomatous and sarcomatous components from uterine carcinosarcoma biopsies provides insights into their development. Yuhua Liu,2 Zachary Weber,2 Anthony San Lucas,1 Aditya Deshpande,1 Raed Sulaiman,3 Mary Fagerness,2 Natasha Flier,2 Joseph Sulaiman,3 Christel M. Davis,4 Jerry Fowler,2 Gareth E. Davies,2 David Starks,2 Luis Rojas-Espalliat,8 Paul Scheet,2 Erik A. Ehli,1 Graduate School of Biomedical Science, University of Texas at Houston Health Science Center, Houston, TX;2Avera Institute for Human Genetics, Sioux Falls, SD;3University of Texas MD Anderson Cancer Center, Houston, TX;4Weill Cornell Graduate School of Medical Sciences, New York, NY;5Avera Cancer Institute, Sioux Falls, SD.

Uterine carcinosarcoma (UCS) is a rare and aggressive form of uterine cancer. It is bi-phasic, exhibiting histological features of both malignant epithelial (carcinomatous) and mesenchymal (sarcomatous) elements. Studies have indicated that UCS arises from sarcomatous differentiation of high-grade carcinoma while others have suggested a bi-clonal nature. Given these differences, we sought to separate the carcinoma and sarcoma elements of UCS to try to understand their molecular differences and gain further insights into how these tumors develop. We macrodissected carcinomatous, sarcomatous, and normal tissues from formalin fixed paraffin embedded FFPE tumor samples of 10 UCS patients. DNA and RNA were isolated and extracted using the Qiagen AllPrep DNA/RNA FFPE kit. Whole-genome SNP microarrays and deep sequencing of 26 cancer genes was performed, using the Illumina Infinium HumanExome Array and the TruSight Tumor panel respectively. Illumina HiSeq mRNA sequencing was also performed to quantify gene expression. The genomic allelic imbalance (AI) profiling, called from the SNP data by hapLOH, showed that sarcoma samples were more aberrant than their carcinoma counterparts (abstract 131, AACR 2016). From the targeted sequencing, the Illumina AmpliSeq-DS Somatic Variant Caller was employed to call somatic mutations. Mutations were identified in TP53 in both the sarcoma and carcinoma samples of all 10 patients. Frequently mutated genes included APC, EGFR, MET and MSH6 which were found in 60-80% of the patients. Genes mutated in less than 50% of the patients included PTEN, KRAS, KIT, FBXW7, PIK3CA, FGFR2, and CTNNB1. Current results showed no association of a mutated gene to either the carcinoma or sarcoma component of UC. RSM, STAR and EBSeq were applied to the RNA-seq data for gene expression quantification. Approximately 2500 genes were identified as being differentially expressed (DE) between normal and carcinoma samples. Deregulated pathways identified in both carcinoma and sarcoma include: cell cycle, transcriptional regulation, Ras and p53 signaling. Some additional pathways affected in the carcinoma but not in the sarcoma component also suggest their importance (abstract 791, AACR 2016). The next step of this study is to examine the global gene expression profile of UC by RNA sequencing.

#2464 Papillary renal cell carcinoma, proposal of a new classification system based on integrated molecular, histological and clinical analysis. Rola Saleh,1 Mina Farag,1 Fadi Brimo,2 Fabio Rotondo,1 Pamela Plant,1 George Youset1. 1.1Lil Ke Shing Knowledge Institute, St. Michael’s Hospital, Toronto, Ontario, Canada; 2McGill University Health Center, Montreal, Quebec, Canada.

Background: Papillary Renal Cell Carcinoma (PRCC) is divided into histological subtypes 1 and 2. Type 2 is known to have worse clinical behavior. A number of PRCC cases (~ 50%) fail to meet all reported morphological criteria for either type, hence are best characterized as PRCC not otherwise specified (NOS). There are yet no reliable markers to resolve the PRCC NOS category. That in turn reflects the clinical dilemma of how to manage these patients. Experimental Design: PRCC patient cohort of 115 cases was selected for the study. Cases were subtyped histologically into PRCC types 1, 2 and NOS. Potentially distinguishing markers ABC2C2, CA9, SAI4, and BCL2 selected from our previous genomic analysis, were assessed by immunohis-

#2466 Identifying confidently measured genes in single pediatric cancer patient samples using RNA sequencing. Holly Beale,1 Du Linh Lam,2 John Vivian,1 Yulia Newton,1 Avanthi Tayi,1 Ted Goldstein,1 Ananta Shankar1. 1UCSC Genomics Institute, Santa Cruz, CA; 2Stanford University, Stanford, CA

In the UC Santa Cruz Treehouse Childhood Cancer Initiative (treehousegenomics.soee.ucsc.edu), we are exploring the utility of using RNA-Seq analysis of tumor samples from children to identify potential novel therapeutic options for each individual. Within a single RNA-Seq data set, the gene expression measurements are not equally accurate. The identification of activated, druggable pathways requires accurate gene-level expression measurements. We receive samples from a variety of clinical and research settings, and the quantity and complexity of the available input material and the depth of sequencing differ. These factors inspired us to develop a tool that will allow us to identify accurate measurements in most RNA-Seq samples we receive. First, we characterized the relationship between depth of sequencing and the accuracy of the gene expression measurement. We analyzed subsets of reads in samples with more than 50 million Uniquely Mapped, Non-duplicate (UMEND) reads. UMEND reads typically constitute over 80% of the reads in a high quality experiment with sufficient starting material. We compared gene expression across the subsets of reads to calculate how many UMEND reads are required to produce consistent measurements. We found that, on average, genes expressed at 1-5 TPM in our data require 30 million reads to be accurately measured. For this calculation, we define accuracy as the condition in which 75% of genes are measured to within 25% of the true value. Secondly, we use these known relationships to identify genes that have been accurately measured in our tumor RNA-Seq samples. For a sample with 15 million UMEND reads, we find that genes expressed above 5 TPM can be accurately measured and are retained. In the first twelve samples analyzed, samples with more than 10 million UMEND reads retained at least 46% of the genes expressed above zero. We exclude as references those samples with fewer than 10 million UMEND reads due to the marked gene loss after thresholding for this group. Using accurately measured genes allows us to more confidently assess similarity to other samples, identify enriched pathways, and confirm the expression of drug targets and related molecules under consideration. For example, we reconsidered the CDK4 inhibitor Palbociclib in one patient because the expression of RB1, downstream effector required for Palbociclib-mediated tumor cell death, was under our accuracy threshold. Accuracy thresholds can also be used in experiment planning. Accuracy thresholds allow us to better assess the value of an RNA-Seq data set and, if necessary, identify the subset of genes whose expression can be confidently considered in a clinical setting. Our experience points to the importance of careful quality control in this process.

#2467 Mutation analysis using next-generation sequencing in histologically heterogeneous primary lung cancers. Hayato Koba, Hideharu Kimura, Kazuo Kasahara, Kanazawa University Hospital, Kanazawa, Japan

Rare cases of primary lung cancer are known to have different histological types. Recently, small cell carcinoma was reported to be developed in adenocarcinoma patients with epidermal growth factor receptor (EGFR) mutations after EGFR tyrosine kinase inhibitor (EGFR-TKI) treatment. The purposes of this study are to evaluate mutational status in two different histological types separately, and to further understand the molecular pathogenesis. Twelve tumor samples from 6 patients were collected in our institution. 4 patients had primary adenocarcinoma and small cell carcinoma transformed after EGFR-TKI. One patient had primary adenocarcinoma and squamous cell carcinoma transformed after EGFR-TKI. The other one patient had carcinomas in a surgically resected tumor. Two patients had samples collected from different histologically different areas within a resected tumor or the 2 distinct metastatic sites. DNA was extracted from formalin-fixed, paraffin-embedded tumor tissues. Next-generation sequencing in the 12 samples were performed on 160 cancer-related genes using GeneReadTM DNAseq Targeted Panels V2 Human comprehensive Cancer Panel (Qiagen). In a carcinomas case with deletional mutation in EGFR gene, a total 586 in adenocarcinoma and 595 in sarcoma variants in 166 genes were detected with high confidence. The gene of identical alterations, as truncal alterations, were EGFR, CBLB, TP53 and MEN1 and the number of that as an unique alteration corresponding to each histology is 25 for adenocarcinoma and 85 for sarcoma. We show relationships between the histological types and the genomic alterations, identical alterations and unique alterations, in each patient. Furthermore, we raise essential factors for the histological transformation.

#2468 Gene aberrations for precision medicine against lung adenocarcinoma. Motonobu Saito,1 Koji Kono,2 Takashi Kohno.1 1National Cancer Ctr. Japan, Tokyo, Japan; 2Fukushima Medical University, Japan

Lung adenocarcinoma (LADC) is often triggered by an aberration in a driver oncogene. LADC harboring EGFR mutation and ALK fusion can be treated with anti-cancer drugs that target the aberrant gene products. For example, we reconsidered the CDK4 inhibitor Palbociclib in one patient because the expression of RB1, downstream effector required for Palbociclib-mediated tumor cell death, was under our accuracy threshold. Accurately measured genes expressed above 5 TPM can be accurately measured and are retained. In the first twelve samples analyzed, samples with more than 10 million UMEND reads retained at least 46% of the genes expressed above zero. We exclude as references those samples with fewer than 10 million UMEND reads due to the marked gene loss after thresholding for this group. Using accurately measured genes allows us to more confidently assess similarity to other samples, identify enriched pathways, and confirm the expression of drug targets and related molecules under consideration. For example, we reconsidered the CDK4 inhibitor Palbociclib in one patient because the expression of RB1, downstream effector required for Palbociclib-mediated tumor cell death, was under our accuracy threshold. Accuracy thresholds can also be used in experiment planning. Accuracy thresholds allow us to better assess the value of an RNA-Seq data set and, if necessary, identify the subset of genes whose expression can be confidently considered in a clinical setting. Our experience points to the importance of careful quality control in this process.

Aptamers have recently gained prominence for their diagnostic and therapeutic potential. The DNA aptamer C10.36 forms a G-quadruplex and has been shown to bind the Ramos Burkitt’s lymphoma cell line. However, its binding partner on the cell surface remains unknown. Here we report on the identification of the molecular target of C10.36, which suggests its application in the therapy of B-cell lymphoma and leukemia. Aptamer-affinity purification, followed by LC-MS/MS revealed unique proteins pulled down with C10.36 associated with Ramos cells but not Jurkat, a T-cell lymphocyte cell line. The majority of the identified target molecules were found to be associated within ribonucleoprotein complexes, of which the abundant and consistent ones belong to the nucleolin complex including nucleolin (NCL) itself and its interacting partners, i.e. nucleophosmin (NPM1), heterogeneous nuclear ribonucleoprotein (HNRNP) family members such as HNRNP C1G2 and U, RNA Z-’O-methyltransferase fibrillarin (FBL), actin (ACTB), nucleolar RNA helicase 2 (DEx2), and proline- and glutamine-rich splicing factors (PSFQ). All the proteins identified in the above ribonucleoprotein complex are aberrantly expressed on the surface of several disparate cancer cell types and have been shown to play oncogenic role in cancer. Another G-rich anti-NCL aptamer, AS1411, has been shown to induce cell death in >100 cancer cell lines. Therefore, we tested the effect of C10.36 on viability of Ramos and other non-Hodgkin B-cell lymphoma (NHL) cancer cell lines. Our results indicate that C10.36 treatment causes specific cell death of certain lymphoma cell lines such as Ramos but not Jurkat cells. The present study identifies C10.36 as a novel anti-B cell lymphoma aptamer and underscores its potential for the development of a new targeted therapy to treat B-cell lymphomas.
Compromised BRCA1-PALB2 interaction is associated with breast cancer risk. Tzeh Keong Foo,1 Marc Tischkowitz,2 Srialatha Simhadri,1 Taiya Boshari,3 Kathleen A. Burke,4 Samuel H. Berman,5 Nadia Zayed,6 Yuan Chun Ding,7 Susan L. Neubauer,8 Britta Weigelt,7 Jorge S. Reis-Filho,9 William D. Foulkes,10 Bing Xia,11 Rutgers Cancer Institute of New Jersey, New Brunswick, NJ; 2University of Cambridge, Cambridge, United Kingdom; 3Jewish General Hospital, McGill University, Montreal, Quebec, Canada; 4Memorial Sloan Kettering Cancer Center, New York, NY; 5Beckman Research Institute at the City of Hope, Duarte, CA.

The major breast cancer suppressor proteins BRCA1 and BRCA2 play essential roles in homologous recombination (HR)-mediated DNA repair, which is thought to be critical for tumor suppression. The two BRCA2 proteins are physically and functionally linked by a third tumor suppressor, PALB2 (partner and localizer of BRCA2), in the HR pathway. Heterozygous PALB2 mutation carriers have increased risk of breast, ovarian and pancreatic cancer. While truncating mutations in BRCA genes are generally pathogenic, interpretations of missense variants remain a challenge. To date, patient-derived missense variants that disrupt PALB2 binding have been identified in BRCA1 and BRCA2; however, there has not been sufficient evidence to establish their pathogenicity in humans. Variants in PALB2 that disrupt either its BRCA1 or BRCA2 binding have not been reported. Here, we report on the identification of a novel PALB2 variant, c.104T>C [p.L35P], that segregated in a family with a strong history of breast cancer. Functional analyses showed that L35P abrogates the PALB2-BRCA1 interaction, resulting in impaired HR and sensitivity to platinum salts and PARP inhibitors. Whole-exome sequencing of breast tumor from a c.104T>C carrier revealed a somatic, truncating mutation in the second allele of PALB2, with the tumor displays hallmark genomic features of tumors with BRCA mutations and HR defects. Using a combination of traditional clinical genetics, tumor whole-exome sequencing and in-depth functional analyses, we have provided direct evidence to cement the pathogenicity of L35P. Parallel analyses of other germline variants in the PALB2 N-terminal BRCA1-binding domain also identified multiple variants that affect HR function to varying degrees, suggesting their possible contribution to cancer development. Our findings establish p.L35P as the first pathogenic missense mutation in PALB2 identified to date and directly demonstrate the requirement of the PALB2-BRCA1 interaction for breast cancer suppression.

Role of PALB2-BRCA1 interaction in tumor suppression. Amar H. Mahdi, YanYing Huo, Bing Xia. CINJ, New Brunswick, NJ.

Homologous recombination (HR) is the only error-free pathway for the repair of DNA double strand breaks (DSBs). BRCA1 and BRCA2, the two major breast cancer suppressor proteins, play essential roles in HR-mediated repair of DSBs by promoting the recruitment of RAD51, the recombination enzyme, to DNA damage sites for the initiation of HR. PALB2 (partner and localizer of BRCA2) plays a key role in this pathway by acting as a chromatin adaptor for BRCA2 and a linker between BRCA1 and BRCA2. Like BRCA1 and BRCA2, PALB2 is a tumor suppressor gene itself. Germline, heterozygous mutations in the gene increase the risk of breast, ovarian and pancreatic cancers. However, its mechanism is not fully understood. To investigate the in vivo role of the PALB2-BRCA1 interaction, we previously generated a Palb2 knockout mouse strain which contains a mutation that disrupts BRCA1 binding. This mouse model also allows us to bypass the embryonic lethality of the Palb2 KO mice. In this study, we hypothesized that the direct communication between the two proteins is critical for proper DNA damage repair and response in vivo and for suppression of tumorigenesis. Indeed, both immunohistochemistry (IHC) and immunofluorescence (IF) demonstrated that different tissues of the mutant mice have higher levels of endogenous DSBs (γH2AX foci) and slower DSB repair kinetics after ionizing radiation (IR). Yet, mutant cells were more resistant to cell death. When aged under normal conditions, mutant mice showed increased tumor incidence in multiple tissues, particularly in the liver. When challenged by IR, mutant mice quickly developed thymic lymphoma and later in other tissues including liver and ovary, etc. Interestingly, when crossed with Trp53 mutant mice, the resulting Palb2m/m;Trp53−/− mice showed greatly accelerated development of thymic lymphoma and osteosarcoma which are typically associated with Trp53 but not Palb2 mutations. Exome sequencing revealed focal deletion of the wild-type allele of Trp53 in the majority of the tumors, suggesting that disruption of BRCA1-PALB2/BRC2 axis promotes regional genomic deletions that may lead to loss of other tumor suppressors such as p53. Our results underscore the importance of the BRCA1-PALB2/BRC2 pathway for tumor suppression and suggest a potentially novel mechanism for BRCA1/PALB2-mediated tumor suppression, which is by preventing Trp53/TP53 loss of heterozygosity (LOH), which allows for tumor development.

Defining the role of the XAB2 complex during homologous recombination. David O. Onyango, Jeremy Stark. City of Hope, Duarte, CA.

Several factors associated with RNA processing are important for homologous recombination (HR), but the mechanistic links between these processes remain poorly understood. To this end, we have examined the function of the transcriptomic binding factor XAB2 in HR, since this factor has a conserved function in RNA processing. We have found that XAB2 is important for chromosomal double strand break (DSB) repair via two pathways of HR that require end resection as an intermediate step, end resection of camptothecin (Cpt) induced DNA damage, and RAD51 recruitment to ionizing radiation induced foci (IRIF). Furthermore, XAB2 mediates Ctp-hypophosphorylation induced by Cpt and BRCA1 IRIF, as well as histone acetylation events linked to HR proficiency. The capacity for XAB2 to promote HR correlates with its ability to form a complex with ISY1 and PRP19, which show a similar influence as XAB2 on HR. Our recent efforts include examining other members of the XAB2 complex, as well as the transcriptional alterations caused by loss of this complex, which may contribute to the defects in HR.

Breast cancer whole genomes link homologous recombination deficiency (HRD) with therapeutic outcomes. Eric Y. Zhao,1 Yaqing Shen,1 Erin Pleasance,1 Katayoon Kasaian,1 Martin R. Jones,1 Carolyn Ch’ng,1 Caralyn Reisle,1 Peter Eirew,2 Karen Mungall,1 Nina Thiessen,1 Yussanne Ma,1 Alexander Fok,1 Andrew J. Mungall,1 Yongqiu Zhao,1 Richard Moore,1 Diego Villa,2 Tamar Shenker,2 Caroljne Lohrihch,2 Stephen Chia,2 Stephen Yip,1 Karen Gelmon,2 Howard Lim,1 Sophie Sun,1 Kasmintan A. Schrader,2 Sean Young,1 Aly Karsan,1 Robyn Boscoe,3 Janessa Laskin,3 Marco A. Marra,4 Steven J. Jones,1 Canada’s Michael Smith Genome Sciences Centre, Vancouver, British Columbia, Canada; 2British Columbia Cancer Agency, Vancouver, British Columbia, Canada; 3The University of British Columbia, Vancouver, British Columbia, Canada.

Background: Homologous recombination deficiency (HRD) is common in cancer - germline BRCA1 & BRCA2 mutations account for 5-10% of breast cancers and over 65% lifetime risk. HRD-expressing tumors exhibit genome instability and sensitivity to platinum-based therapy and PARP inhibitors. While not all causes of HRD are known, recent sequencing efforts have revealed genome-wide somatic mutation signatures that characterize the HRD genomic instability phenotype, also known as “BRCA-ness”. This provides a promising new assay to predict sensitivity to platinum-based therapy. Here, we integrate two whole-genome sequencing (WGS) signatures to assess their association with therapeutic outcomes in a breast cancer cohort. Methods: Whole-genome sequencing of 47 breast cancer tumors (100x coverage) and matched normals (60x) was performed on an Illumina HiSeq. Alignment, assembly, SNV calling, and loss of heterozygosity (LOH) detection were performed with BWA, ABSS, Strelka, and APOLOLH respectively. SNV signatures were deciphered by non-negative matrix factorization with Monte Carlo resampling. An HRD score comprised of LOH, telomeric allele imbalance (TAI), and large scale transition (LST) counts was computed. Clinical endpoints were obtained by retrospective review of treatment and imaging reports. Analysis is ongoing in an independent validation cohort of 62 sequenced cases. Results: The HRD-linked SNV signature was significantly associated with radiographic clinical response (CR) to platinum-based therapy (p=0.015). Logistic regression demonstrated a 59% improved odds of CR to platinum-based therapy per 1000 somatic SNVs attributed to HRD (odds ratio 1.16-2.50). Tumors carried up to 10,246 such SNVs and all patients with CR were among the top quartile. The LOH-TAI-LST score was correlated with SNV signature (r = 0.6, p =7×10^-4) and associated with CR (p=0.025). Notably, elevated HRD signatures associated with CR were identified in tumors with wild-type BRCA2 or variants of unknown significance. Tumors with above median HRD signatures were associated with a 69-day longer time to treatment failure and a 18% daily decreased probability of treatment failure per 1000 HRD-attributed SNVs (hazard ratio 0.71-0.95, p =0.007). Discussion: We found that HRD mutation signatures are associated with clinical response and longer time to treatment failure with platinum-based therapy. While similar benefits were observed in patients with somatic bi-allelic loss of BRCA1/BRC2, such cases are less common (8% of our cohort) compared to those with elevated HRD signature. Thus, mutation signature methods may identify patients who stand to benefit from platinum-based therapy missed by BRCA screening alone.
Preclinical assessment of the PARP inhibitor rucaparib in homologous recombination deficient prostate cancer models. Minh Nguyen, Andrew D. Simmons, Thomas C. Harding, Clovis Oncology, Inc., Boulder, CO.

Rucaparib (CO-338) is an oral small molecule inhibitor of the poly(ADP-ribose) polymerase (PARP) enzymes PARP-1, PARP-2 and PARP-3 that is being developed for cancer patients with evidence of homologous recombination (HR) deficiency, including BRCA1 and BRCA2 mutations. PARP inhibitors have demonstrated clinical activity in BRCA1, BRCA2, and ATM mutant prostate cancer patients (Mateau et al. N Engl J Med. 2015;373:1697-708); however, limited preclinical validation of PARP inhibitors in prostate cancer has been reported to date, since no BRCA mutant nor HR deficient prostate cell lines have been identified. To further understand the functional inactivation of DNA repair genes using siRNA and CRISPR/Cas9, and examined the impact on PARP inhibition, in the DU145 and PC-3 prostate cancer cell lines. These cell lines were chosen based on transfection efficiency, lack of obvious genetic defects in DNA repair pathways, and baseline insensitivity to rucaparib (IC50 > 10 μM). A panel of 26 DNA repair genes were individually knocked down by siRNA, and changes to rucaparib potency were examined in a 7-day cell viability assay. The knockdown of BRCA1 or BRCA2 increased rucaparib cytotoxicity in both prostate cell lines. For example, the IC50 of rucaparib in DU145 and PC-3 cells with reduced BRCA2 levels was 275 and 297 nM, representing a 36- and 37-fold increase in rucaparib sensitivity, respectively. In addition to BRCA1 and BRCA2, the knockdown of several other genes including BARD1, CDK12, PARP2, XRCC2, RAD51, and BARD1 increased rucaparib efficacy ≥ 2-fold in at least 1 cell line examined. To further investigate HR deficiency in prostate cancer, BRCA2 was knocked out in the human 22Rv1 prostate cancer cell line using CRISPR/Cas9. Clone 1-20 displayed biallelic BRCA2 inactivation due to the introduction of a deleterious premature stop codon, and immunoblot analysis verified lack of the full-length BRCA2 protein. The IC50 of rucaparib in the parent and clone 1-20 cells was 504 and 287 nM respectively, demonstrating a 33-fold increase in rucaparib cytotoxicity in this BRCA2 deficient model. Androgen receptor (AR) signaling and proliferation were also examined in clone 1-50. In contrast to published reports (Schiewer et al. Cancer Discov. 2012;2:1134-49), no impact of PARP inhibition on dihydrotestosterone (DHT) induced gene expression was observed in the parental 22Rv1 and BRCA2 deficient clone 1-50 cell lines. In vivo model development and efficacy studies with the 22Rv1 and clone 1-50 cell lines are ongoing. Taken together, these findings support the hypothesis that deficiencies in BRCA1 and BRCA2, as well as additional HR genes, may sensitize prostate cancer cells to rucaparib. A phase 2 study investigating rucaparib in patients with metastatic castration-resistant prostate cancer and HR gene deficiency (TRITON2) is ongoing (NCT02952534).

Genomic instability in BRCA1-deficient cells is a result of the anti-recombinogenic activity of BLM helicase. Dharm S. Patel, Sarah M. Miseno, Samuel F. Bunting, Rutgers University, Piscataway, NJ.

Mutations in BRCA1 are responsible for approximately 5% of cases of breast cancer, and there are few treatment options that substantially alter the probability of relapse in individuals with BRCA1 mutations. BRCA1-deficient cells have demonstrated increased genomic instability following DNA damaging treatments due to a defect in the homologous recombination (HR) DNA repair pathway. Presently, Olaparib, a PARP inhibitor, is approved as a targeted monotherapy for germline BRCA1 mutated advanced ovarian cancers. As use of this treatment has expanded, data suggests that patients exhibit a further relapse and resistance to PARP inhibitors via mechanisms that include the development of secondary BRCA1 reversion mutations, enhanced drug efflux relating to P-glycoprotein, and mutations in other DNA repair proteins that restore HR. Here, we show that the RECQ helicase, BLM, mediates the genomic instability observed in BRCA1-deficient cells by a mechanism that depends in part on its anti-recombinogenic activity. We have generated conditional knockout mice with single and combined deficiencies in BRCA1, BLM, and 53BP1 in the B lymphocyte cell population. Ablation of BLM in BRCA1-deficient cells allows the HR repair pathway to be restored, leading to a partial rescue of the genomic instability that is present in BRCA1-deficient cells. The stable accumulation of RAD51, a marker for HR, at DNA double-strand break sites is inhibited by BLM in BRCA1-deficient B cells. However, DNA end resection is not impacted by single or co-deletion of BLM and 53BP1. Furthermore, BLM deficiency alone can display limited sensitivity to PARP inhibition. The rescue in HR and PARP sensitivity phenotypes following deletion of BLM is only present in hypomorphic BRCA1(1/4)cells and not the RING domain deficient BRCA1(1/2). These results demonstrate that the anti-recombinogenic activity of BLM is of potentially great significance for regulating the balance of HR versus other error-prone
repair pathways. Mutation of BLM in BRCA1-deficient tumors is therefore a functionally null RAD51D missense mutation is strongly associated with ovarian carcinoma. Barbara Rivera. McGill University, Montreal, Quebec, Canada.

Background and goal: RAD51D is a key player in DNA repair by homologous recombination (HR) and carries of truncating RAD51D mutations have an increased risk of ovarian cancer (OC). However, the contribution of truncated RAD51D variants to cancer predisposition remains uncertain. We sought to fully characterize the previously described missense RAD51D variant c.620C>T; p.S207L in order to elucidate its role in OC. Methods: A clinical panel screening was used to identify the RAD51D variant c.620C>T; p.S207L in two French Canadian (FC) kindreds affected by HGSC of the ovary and endometrium. High resolution melting, TaqMan genotyping and Sanger sequencing were used to genotype the p.S207L variant in a series of unselected cases of HGSC of the ovary and endometrium, breast, pancreas and colorectal cancer and healthy controls, all of FC origin. Whole exome sequencing (WES) was performed to study the genetic signature characterizing RAD51D associated tumors. RAD51 foci formation and CRISPR-Cas9-stimulated and CRISPR-Cas9-induced DSBs in immunoglobulin genes to promote B-cell maturation. However, AID is capable of broadly damaging the B-cell genome. We have shown that AID-induced DSBs require the homologous recombination factor RAD51 to sensitize AID-overexpressing tumor cells. Here we build on those observations, finding that AID-RAD51 synthetic lethality occurs via mitotic catastrophe, involving the mTOR pathway. We have now developed potent and selective RAD51 modulatory small molecules that preferentially kill AID-expressing tumor cells. Using mouse models of lymphoma and leukemia we demonstrated in vivo efficacy data demonstrating the potential therapeutic feasibility of RAD51 modulation. These studies provide evidence for a novel “synthetic lethal” approach for treating AID-expressing malignancies, via the induction of mitotic catastrophe.

Inhibition of RAD51 with a cell penetrating antibody, 3E10. Peter M. Glazer, Audrey Turckich. Yale University, New Haven, CT.

Many human malignancies arise in the setting of defective DNA repair pathways, leading to genetic instability, carcinogenesis and tumor progression. However, DNA repair deficiency can provide for a therapeutic window that can be exploited with targeted agents. One such anti-cancer agent is 3E10, a unique cell penetrating, anti-DNA autoantibody. 3E10 by itself is considered non-toxic to normal cells but has been shown to have deleterious effects on cells with DNA
repair deficiencies. Specifically, 3E10 has been shown to reduce the efficiency of homologous recombination (HR). This has been attributed to its ability to preferentially bind to ssDNA tails, thereby inhibiting Rad51-mediated strand exchange. Prior work has shown that treatment with 3E10 alone can selectively kill cells with genetic mutations that lead to abnormal DNA repair. For example, 3E10 has been shown to be synthetically lethal in BRCA2 deficient human cancer cells. Additionally, 3E10 sensitizes cells to radiation and other DNA damaging therapies. The goal of this project is to characterize the specific mechanism by which 3E10 inhibits DNA repair pathways. Previously, the mechanism by which 3E10 inhibits HR was attributed to 3E10’s DNA binding ability. Through the biochemical analysis of 3E10 variants, new evidence now suggests that 3E10 inhibits HR by competing with the binding of 3E10’s substrate to its DNA binding domain. We have found that this HR inhibition is a result of a physical interaction between 3E10 and Rad51. Biochemical analysis revealed that 3E10 binds to the N-terminal domain of Rad51, the domain that plays a role in Rad51 homo-oligomerization and filament formation. This 3E10-Rad51 interaction impairs Rad51’s ability to localize to the nucleus and form repair foci. Taken together, this data suggests that 3E10 inhibits HR by physically interacting with Rad51. Overall, 3E10 holds promise as a novel therapeutic agent for certain subsets of cancer.

#2483 Molecular mechanisms of dihydrogalactitol (VAL-083) in overcoming chemoresistance in glioblastoma. Beibei Zhai, 1 Anna Gobielska, 2 Anne Steino, 3 Jeffrey A. Bacha, 4 Dennis M. Brown, 5 Simone Niclou, 6 Mads Daugaard, 7 "University of British Columbia, Vancouver, British Columbia, Canada; 2Luxembourg Institute of Health, Luxembourg, Luxembourg; 3DelMar Pharmaceuticals, Inc., Vancouver, British Columbia, Canada; 4DelMar Pharmaceuticals, Inc., Menlo Park, CA.

Standard treatments for glioblastoma (GBM) include surgery, radiation and chemotherapy with temozolomide (TMZ). Nearly all tumors recur and 5-year survival is less than 3%, largely due to chemoresistance. Evidence shows that cancer cells utilize DNA damage repair pathways to overcome cytotoxic effects of chemotherapy. GBM tumors expressing O6-methylguanine-DNA-methyltransferase (MGMT) display intrinsic chemoresistance to TMZ and nortosoureas, while a deficient DNA mismatch repair system (MMR) confers chemoresistance to TMZ and platinum agents. Alterations in p53, particularly gain-of-function mutations, are correlated with increased MGMT-expression and poor prognoses in GBM. Second line anti-angiogenic treatment with bevacizumab has not improved overall survival and has been shown to induce intratumor hypoxia and increased chemoresistance. VAL-083 is a bi-functional alkylating agent that readily crosses the blood-brain barrier, accumulates in brain tumor tissue and has demonstrated activity against GBM in prior NCI-sponsored clinical trials. VAL-083 induces interstrand cross-links at guanine-N1 causing DNA double-strand breaks and cancer cell death. VAL-083 is equitoxic against GBM cancer stem cells (CSCs) and non-CSCs independent of MGMT and p53 status, in vitro. We recently showed that VAL-083 leads to irreversible S/G2-phase cell cycle arrest, proposing synergy with S-phase specific chemotherapeutics, including topoisomerase and PARP inhibitors. VAL-083 further showed persistent activation of the homologous recombination (HR) DNA repair pathway and its potency was increased when HR was impaired, demonstrating the potential of VAL-083 in HR-deficient cells. Functional repair assays. In this study, we investigated the potential of VAL-083 in GBM under hypoxia either in vitro or in vivo as part of a combination treatment with bevacizumab. Our results demonstrate a distinct anti-cancer mechanism for VAL-083, resulting in the ability to overcome resistance to TMZ and nortosoureas, increased activity in cancers with impaired HR and synergy with etoposide or carboplatin.

Response to DNA-damaging agents, such as platinum and recently emerged PARP inhibitors, is associated with homologous recombination deficiency (HRD) pathway. In fact, as reported by multiple clinical trials, patients with advanced breast, prostate, and ovarian cancers who have harmful mutations in BRCA1 and BRCA2 have demonstrated a great benefit from treatment of PARP inhibitors including olaparib, niraparib, and talazoparib. Current companion diagnostic assays that mainly examine germline defects from blood or somatic alterations from tumor tissues have shown several practical challenges: germline mutations are underrepresented in tumor samples or can be somatically altered, and results are not always consistent between tumor and matched blood samples. In addition, the sensitivity of current companion diagnostic tests is insufficient. Most companion diagnostic assays are designed for specific PARP inhibitors, and patients who are predicted to be sensitive by these assays may not respond to treatment. To improve companion diagnostic testing for PARP inhibitors, a liquid biopsy test is needed that can be easily incorporated into routine clinical care. The Predi-HRD liquid biopsy test, a non-invasive, next-generation sequencing (NGS)-based multiplex assay that enables real-time monitoring of temporal change of tumor heterogeneity and highly sensitive detection of defects in HR genes including BRCA1, BRCA2, ATM, CHEK2, among others. Technical validation was performed to evaluate assay sensitivity, specificity and accuracy using reference samples with known genetic profiling and further validated on a variety of orthogonal platforms such as digital PCR, allele-specific PCR and Sanger sequencing. Mutation prevalence of HR genes was examined in clinical plasma samples from patients with advanced ovarian cancer after systemic chemotherapy. The successful development of Predi-HRD liquid biopsy test offers an efficient solution to stratify and monitor cancer patients who may benefit from HRD-targeted therapeutics such as PARP inhibitors.

#2486 Tumor hypoxia induces DNA repair vulnerabilities through contextual loss of heterozygosity. Osman Mahamud, 1 Melvin Chua, 2 Winnie Lo, 3 Gaetano Zafara, 4 Robert Bristow. 5 University of Toronto, Toronto, Ontario, Canada; 2Princess Margaret Cancer Centre, Toronto, Ontario, Canada; 3University Health Network, Toronto, Ontario, Canada.

Introduction: Intratumoral hypoxia leads to decreased expression in DNA damage response (DDR) and repair pathways. Given the ‘two-hit’ model for loss of function germline mutations in BRCA2 affect its role in the homologous recombination (HR) DNA repair pathway through contextual ‘loss-of-heterozygosity’, which marries the tumour genetic profile with environmental factors. To interrogate this relationship, isogenic DLD-1 cells heterozygous and homozygous null for BRCA2, were placed under normoxic (21%) or hypoxic (0.2%) conditions for 72 hours. Hypoxia-mediated changes in DDR response and DNA repair were evaluated by cell proliferation, cell cycle analysis, western blots, qPCR, immunofluorescence, clonogenic assays and functional repair assays. Results: No differences in proliferation and cell survival were observed betweenoxic and hypoxic cells (72 hours - 0.2% O2). Under chronic hypoxic conditions, confirmed by the up-regulation of VEGF and HIF1α, mRNA and protein expression of key homologous recombination (HR) genes (BRCA1, BRCA2, RAD51) were down-regulated. Functionally, BRCA2-/- cells proved unable to recruit Rad51 foci and were profoundly sensitivity to PARP inhibition. Conversely, heterozygote BRCA2+/- cells retained the ability to recruit Rad51 foci under both oxic and hypoxic conditions. However, exposure to chronic hypoxia resulted in a reduction of foci formation. Chronically hypoxic BRCA2+/- cells exhibited a 30-40% increase in sensitivity to PARP inhibition compared to their oxic counterparts. Preliminary data shows a similar synthetically lethal relationship in genetic (BRCA2+/-) and tumor microenvironment induced (BRCA2+/-) loss of function germline mutations in human tumor cells. Conclusions: Herein, we demonstrate a novel mechanism of contextual ‘loss-of-heterozygosity’, which marries the tumour microenvironment and innate genetic alterations. The resultant increased sensitivity to DDR kinase inhibitors and PARP highlights the therapeutic significance of this phenomenon.

#2487 Functional characterization of the BRCA2 variant, K3326X. Srilatha R. Simhadri, Sonia C. Dolfi, Atul Kulkarni, Bing Xia, Shridar Ganesan, Kim M. Hirshfield. Rutgers Cancer Institute of New Jersey, New Brunswick, NJ.

Individuals with germline mutations in the breast cancer susceptibility gene, BRCA2, have an approximate 70% risk of developing breast cancer, a 30% risk of developing ovarian cancer, a 20% risk of developing prostate cancer and a 10% risk of developing colorectal cancer. The presence of a deleterious BRCA2, ATM, CHEK2, among others. Technical validation was performed to evaluate assay sensitivity, specificity and accuracy using reference samples with known genetic profiling and further validated on a variety of orthogonal platforms such as digital PCR, allele-specific PCR and Sanger sequencing. Mutation prevalence of HR genes was examined in clinical plasma samples from patients with advanced ovarian cancer after systemic chemotherapy. The successful development of Predi-HRD liquid biopsy test offers an efficient solution to stratify and monitor cancer patients who may benefit from HRD-targeted therapeutics such as PARP inhibitors.

breast cancer cases and to increase the risk for lung, pancreatic, ovarian, and upper aero-digestive tract cancers. Preliminary data, obtained from the Rutgers Cancer Institute of New Jersey breast cancer case-control study, identified K3326X enrichment in 1.25% of cases compared to 0.7% of controls. Several of the carriers had second primaries and displayed a trend toward increased number of family members diagnosed with breast cancer, which is consistent with reports of a breast cancer risk associated with the 3326X variant. The K3326X variant was also identified in 1.38% (11 of 796) of our histologically-diverse cohort of genomically-profiled tumors that included cancers of the breast, ovarian/fallopian tube, lung, vulvar, cancer of unknown primary, and one breast cancer case having prolonged response to platinum-based therapy. Thus, K3326X may represent a functional loss of wild type BRCA2 function, as we observe concomitant loss of heterozygosity at this locus. In a preliminary work with a different cell line, the K3326X variant, in vitro, in a functional DR-GFP-based reporter assay measuring HR. Our data reveal the BRCA2 K3326X variant to be impaired in the HR pathway indicating a loss of a wild-type protein function. We will also evaluate cell viability of the K3326X variant in the presence of DNA damaging drugs like cisplatin, poly-ADP ribose polymerase inhibitors and mitomycin C. Future studies will also incorporate a retrospective evaluation of tumor specimens that have undergone comprehensive genomic profiling. These data would indicate that BRCA2 K3326X represents a functional hypomorphic variant that may have implications in therapeutic approaches and cancer risk evaluations across a spectrum of tumor types.

#2488 Tumor necrosis factor-alpha signaling determines cytotoxicity induced by BRCA2 deficiency. Anne M. Heijink, Francien G. Talens, Anouk Blaars, Marjelle A. van Vught. University Medical Center Groningen, Groningen, Netherlands.

Introduction Breast cancer 2, early onset (BRCA2) is involved in DNA-damage repair via homologous recombination (HR). Defective HR leads to severe genomic instability and homozygous deletion of BRCA2 is therefore deleterious for survival of normal cells. In apparent contrast, inherited heterozygous mutations in BRCA2 increase the risk to develop cancer, which goes along with somatic loss of the wild type allele. So paradoxically, BRCA2 loss is lethal in normal cells, but can be tolerated in cancer cells. It is currently unclear how tumor cells can survive without BRCA2. To address this question, we performed a genome-wide functional genetic screen and identify Tumor Necrosis Factor-alpha (TNFα) signaling, via TNF receptor 1 (TNF-R1) and Src-associated-substrate during mitosis-of-68Da (Sam68), as an important determinant of cell death induction upon BRCA2 inactivation. Material & Methods A genetic screen was performed in human near-haploid KMB-7 cells. Two monoclonal KMB-7 lines were engineered to express independent doxycycline-inducible BRCA2 short hairpin RNAs (shRNAs). Cells were randomly mutagenized using retrovirus carrying a strong splice-acceptor, resulting in gene knock-outs. Deep sequencing of surviving colonies revealed gene mutations that prevented shBRCA2-mediated cell death. Validation of TNF-R1 and Sam68 was done by shRNAs in multiple breast- and leukemic cell lines. Cell viability was determined by MTT and clonogenic assays. Competition assays with vectors expressing shRNA including IRES-driven mCherry were analysed with flow cytometry. Biochemical analyses were assessed by western blotting and ELISA. Immunoprecipitation tagged TNF-R1 was performed to study the protein-protein interaction. Results From our genetic screens, loss-of-function mutations involved in TNFα signaling were found to significantly rescue cell death in BRCA2-depleted cells. To validate these findings, BRCA2 was stably depleted in a panel of cancer cell lines, which decreased viability. Subsequent co-depletion of TNF-R1 or Sam68 rescued survival. Notably, BRCA2 depletion resulted in the production of TNFα. In line with this finding, the majority of tested cancer cell lines were found to be sensitive to recombinant TNFα upon BRCA2 depletion. This phenomenon was not restricted to BRCA2 inactivation, since depletion of related DNA repair genes (BRCA1, FANCQ2) or hydroxyurea-induced replication stress also sensitized cells to recombinant TNFα. Mechanistically, BRCA2 depletion was induced to observe differential complex formation of TNF-R1 with downstream effector proteins upon TNFα activation. Conclusion Our data reveal that down-regulation of TNF-R1 or its downstream signaling component Sam68 rescued cytotoxicity upon BRCA2 inactivation. These findings and mechanistic follow-up experiments describe a novel mechanism by which auto-crine TNFα signaling, induced by loss of BRCA2, limits tumor cell viability.

#2489 Mre11-CDK2 interaction during the DNA double-strand break repair. Mary J. Morgan, Todd A. Festerling, Jeffrey Buis, David O. Ferguson. University of Michigan, Ann Arbor, MI.

The MRN (Mre11/Rad50/NBS1) complex is a group of highly conserved proteins central to the detection and repair of DNA double-strand breaks (DSBs). Inherited deficiencies in DNA DSB signaling result in a spectrum of disorders featuring cancer predisposition, neurodegeneration, and immunodeficiency. MRN directly binds DNA DSB ends and facilitates activation of ataxia-telangiectasia mutated (ATM) kinase, which initiates cellular responses including DNA repair, cell cycle checkpoints, and in some circumstances, apoptosis. Cellular responses to DNA DSBs require rapid communication between DNA repair complexes and the cell cycle machinery, with which mitotic recombination and repair pathways interact. To test this hypothesis, we identified an interaction between Mre11 and Cyclin-dependent kinase 2 (CDK2), a key component of the cell cycle machinery (Buis et al., NCBM, 2012). CDK2, when bound to its regulatory partner Cyclin A, promotes cell cycle progression through G2 phase. We demonstrated that the Mre11-CDK2/Cyclin A interaction is important in regulating the capacity for DNA repair by homologous recombination in normally cycling fibroblasts. Unrepaired DNA damage leads to tumorigenesis. CDK2 is a multifunctional protein that plays a central role in DNA replication and homologous recombination repair. It is known that defects in Rad51 function can cause cancer. The goal of this study is to identify a novel role for Rad51 outside of its known functions in DSB repair and replication fork processing. Methods: Since Rad51 knockout is lethal to cells, we generated an inducible system in which we can down-regulate Rad51 expression in HT1080 cells after Doxycyline treatment. To determine the effect of Rad51 knockdowm in global gene expression pattern, we carried out unbiased microarray gene expression analysis and after induction of DNA damage and replication stress by radiation. ssDNA and dsDNA in the cytosolic fractions were quantified using Quanti-IT OliGreen and PicoGreen Assay Kits. For cytoplasmic BrdU detection, exponentially growing cells were labeled with BrdU for 18-22h and then immunostained with anti-BrdU antibody. Additionally, we measured the expression and post-translational modification of proteins involved in innate immune signaling by western blotting. We also employed DNA fiber assay to determine the role of Rad51 in replication fork processing. Results: We found that defects in Rad51 lead to the accumulation of self-DNA in the cytoplasm, triggering a STING-mediated innate immune response after replication stress and DNA damage. Mechanistically, the unprotected newly replicated genome in the absence of Rad51 is degraded by the exonuclease activity of Mre11, and the fragmented nascent DNA accumulates in the cytosol, initiating an innate immune response. Our data revealed that in addition to playing roles in homologous recombination-mediated DNA double-strand break repair and replication fork processing, Rad51 is also implicated in the suppression of innate immunity. Conclusion: Rad51 plays a novel role in immunity outside its known functions in DSB repair and replication fork processing. We discovered that the lack of Rad51 leads to the up-regulation of innate immune pathway genes upon DNA damage and replication induced by irradiation. We found that in the absence of Rad51 the newly replicated genome is degraded by the exonuclease activity of Mre11. We also showed that these degraded nascent DNA fragments are exported to the cytoplasm, triggering innate immune response signaling. Our study reveals a previously unidentified role for Rad51 in triggering an innate immune response, and places Rad51 at the hub of new interconnections between DNA replication, DNA repair, and immunity. Funding: This work was supported by NIH R01AG053441 grants.

#2491 Beclin1 promotes DNA double-strand breaks repair. Fei Xu, Lili Yan, Jianrong Wang, Jingming Yang. Soochow University, China, Suzhou, China; Penn State Univ., PA.

Meaningful DNA double-strand break (DSB) repair mechanisms are evolutionarily conserved and are essential for maintaining genomic integrity in organisms from yeast to mammals. Mammalian cells utilize two major DSB repair pathways: homologous recombination (HR) and non-homologous end joining (NHEJ). In this study, we found that Beclin1, a known regulator of autophagy, is also involved in DNA DSB repair. The results indicate that Beclin1 promotes DNA DSB repair through the recruitment of MRN (Mre11/Rad50/NBS1) to the DSB sites, which is essential for the efficient repair of DNA DSBs.

Proceedings of the American Association for Cancer Research. Volume 58. April 2017
Beclin1 is a well-established core mammalian autophagy protein that has been presumed to suppress oncogenesis via an autophagy-mediated mechanism. Since its discovery, studies have also shown that Beclin1 interacts with an increasing number of cofactors. However, the tumor suppressive roles of Beclin1 remain a major research focus, and the exact mechanism by which Beclin1 promotes tumor suppression has remained largely obscure. Our confocal analysis showed that in embryonic and neonatal mice, Beclin1 is primarily located in the cytoplasm in hepatocytes, with a very small portion located in the nucleus. When the mice were 15d, roughly half of the total Beclin1 was located in the nucleus. Thereafter, Beclin1 progressively distributed from cytoplasm to nucleus within a few weeks after birth. This pattern was observed not in all cell types and tissues. We and others found both 0-50 and 254-278 residues are required for Beclin1 nuclear localization. Furthermore, loss of Beclin1 resulted in reduced DNA damage repair. We found that the beclin1−/− cells showed a marked increase in γ-H2AX foci that are considered as a biomarker of DNA DSBs. Moreover, beclin1−/− cells showed approximately 60-fold and 30-fold reductions in DSB repair by NHEJ and HR pathways. A series of key DSBs repair proteins were significantly reduced in beclin1−/− cells. Interestingly, Beclin1 regulates DSB repair independent of autophagy. Autophagic flux was maintained in the beclin1−/− cells. Perhaps an alternative autophagy may be activated when beclin1 is deleted asULK1 was upregulated. We further found that Beclin1 promotes DSB repair via a direct interaction with DNA topoisomerase II (Top2b). Pull down results showed that Top2b is one of the major Beclin1-interacting proteins in the nucleus. And we found that this interaction was intensified after exposure to IR. Top2b and Beclin1 were found to be colocalized to the DSB sites, after exposure to IR. Strikingly, depletion of Top2b by gene silencing completely inhibited Beclin1 localized to the DNA break sites. We constructed a beclin1−/− cell line using CRESRPR/Cas9 system. The spot counts of protein foci were measured by imaging flow cytometry after exposure to 6 Gy IR. HR and NHEJ reporter assays were used to detect the activity of DSBs repair pathways. We pulled down nuclear proteins with ectopically expressed Flag-tagged Beclin1. The identities of the Beclin1-interacting proteins were determined using mass spectrometry. Our work establishes that Beclin1 plays an autophagy-independent role in maintaining genomic integrity by promoting DNA damage repair. The finding challenges the long-standing paradigm of the mechanisms that are involved in the autophagy-mediated tumor suppressive role of Beclin1. This finding suggests that when manipulating cytoplasmic Beclin1 that is involved in the autophagy pathway in order to explore targeted tumor therapies, the non-autophagy cytoprotective role of Beclin1 in the nucleus should also be considered.

Beclin1 and beclin1−/− mice had a severe depletion of stem cells in the hematopoietic system and brain, and large deletions. We further demonstrate that beclin1−/− cells have increased sensitivity to DNA damaging agents that induce double-strand breaks and that there is persistent accumulation of DSBs in these cells. In combination, our results suggest that Pol β is critical for double-strand break repair.

#2493 Identification of the mutant p53-PARP-MCM chromatin axis as a triple negative breast cancer replication stress target. Wei-Gang Qiu,1 Alla Polotskaia,2 Gu Xiao,3 Lia Di,2 Yuhan Zhao,4 Wenwei Hu,5 John Philip,4 Ronald Hendrickson,4 Jill Bargonetti,1 City Univ. of New York at Hunter College and The Graduate Center, New York, NY; 2City Univ. of New York at Hunter College, New York, NY; 3Rutgers Cancer Institute of New Jersey, Rutgers, NJ; 4Memorial Sloan-Kettering Cancer Center, New York, NY.

Approximately 15% of all breast cancer is triple-negative and of these about 80% are found to have mutations in the gene for the tumor suppressor p53 (TP53). Many TP53 mutations encode gain-of-function oncogenic mutant p53 (GOF mtp53) protein. We used inducible knockdown of endogenous mtp53 in mtp53 MDA-MB-468 cell lines and compared the effects on DNA damage in wild type and mtp53-H2AX foci that are considered as a biomarker of DNA DSBs.

#2494 ATR inhibitor AZD6738 as monotherapy and in combination with olaparib or chemotherapy: defining pre-clinical dose-schedules and efficacy modelling. Alan Y. Lau,1 James Yates,2 Zena Wilson,3 Lucy A. Young,4 Adina M. Hughes,5 Aileen Berges,6 Amy Cheung,7 Rajesh Odedra,8 Elaine Brown,9 Mark J. O’Connor,10 Simon Hollingworth,11 Astrazeneca, Cambridge, United Kingdom; 2City of Hope, Duarte, CA; 3City of Hope, Duarte, CA; 4Memorial Sloan-Kettering Cancer Center, New York, NY; 5AstraZeneca, Macclesfield, United Kingdom; 6Astara, Cambridge, United Kingdom.

Introduction: AZD6738 is a potent and selective oral inhibitor of the ataxia telangiectasia and rad3 related (ATR) protein kinase. ATR has a key role in the DNA replication stress response (RSR) pathway of DNA repair, facilitating the recovery and repair of potentially cytotoxic persistent, stalled DNA replication forks. Inhibition of ATR leads to the inability to resolve replication forks associated damage and the accumulation of DNA strand breaks, which if remains unrepaired leads to cell death. AZD6738 is currently in Phase I/II clinical trials being evaluated as a monotherapy and in combination with novel agents olaparib / Lynparza (PARP DNA damage response inhibitor), durvalumab (PD-L1 immune checkpoint inhibitor) and DNA-damaging agents such as carboplatin and ionising radiation. Critical in helping to guide the clinical usage of AZD6738 and maximise patient benefit, pre-clinical studies were performed to determine optimal doses and schedules as monotherapy and in combination with olaparib and carboplatin.

Experimental procedures: Human cancer cell lines, xenograft and patient-derived explant (PDX) models of non-small cell lung cancer (NSCLC), head & neck squamous cell carcinoma (HNSCC), and triple-negative breast cancer (TNBC) were tested comparing once daily versus twice daily dosing, the number of consecutive days dosing (3 days/week, 5 days/week, continuous) and co-dosing versus sequential or intermittent dosing with AZD6738 alone or in combination with olaparib or carboplatin. The magnitude and duration of anti-tumour responses were then compared with AZD6738 mouse pharmacokinetic (PK), pharmacodynamic (PD) and in vitro target (IC / growth inhibition (GI) / growth inhibition) profiles. Results: A mathematical model was derived which adequately described the AZD6738 PK/PD-eficacy relationship. This modelling confirms that duration of coverage (time) above cellular ATR target inhibition thresholds (IC50 pCHK1 / GI50) per day, rather than Cmax or exposures per se, is the major determinant of anti-tumour responses. As monotherapy, a short, non-CO4 mtp53 in MDA-MB-468 cells in combination with ATRA continuously to give tumour stabilisation, which can be achieved through repeated daily of AZD6738 over several weeks. Co-dosing AZD6738 in combination with olaparib or carboplatin gives best efficacy compared to sequential dosing and PK cover over the first 48-72 hours is necessary to give tumour regressions. The models predict that extending the duration of ATR coverage, achieved through continuous dosing, further increases efficacy. These pre-clinical dose-schedules were compared to human free plasma AZD6738 PK data and predicted efficacious exposures found to be clinically achievable. Conclusions: Together these data further support the clinical evaluation of AZD6738 and suggest optimal dosing schedules for ATR inhibitors.
#2495 The metabolic secretome of cachexia inducing pancreatic ductal adenocarcinoma. Santosh K. Bharti,¹ Paul T. Winnard,¹ Louis Dore-Savard,² Yelena Mironchik,¹ Marie-France Penet,¹ Zaver M. Bhuwalia.¹ The Johns Hopkins University School of Medicine, Baltimore, MD;²McGill University Health Center, Montreal, Quebec, Canada.

Cachexia is an unexplored and yet devastating consequence of cancer that is the cause of 20% of all cancer related deaths.¹ Cachexia inducing tumors cause a ‘wasting away’ of the body. The condition is associated with poor treatment outcome², fatigue, and extremely poor quality of life.³ Because of the multifactorial characteristics of this condition, it has been difficult to understand the mechanisms driving the impact of the tumor on body organs and the sequence of events that leads to this lethal condition. Here we have used ¹H MRS to characterize the metabolic profile of tumor interstitial fluid (TIF) obtained from non-cachexia (Panc1) and cachexia inducing (Pa04C) tumors to further understand the impact of the deranged metabolism of cachexia inducing-tumors on the tumor metabolic secretome. The human pancreatic cancer cell line, Panc1, was obtained from ATCC. The human pancreatic cancer cell line, Pa04C, was provided by Dr. Maitra.⁴ Six to 8 week old male SCID mice were inoculated both the right and left flank with cancer cells (5x10⁶, Panc1 N=2, Pa04C N=2). We created a collection chamber to collect TIF. The chamber was implanted together with small tumor pieces harvested from the subcutaneous flank tumors, into the subcutaneous flank space of SCID mice (Panc1 N=8 and Pa04C N=6) until the tumor encompassed the chamber (4-5 weeks). The tumor was then removed, washed in saline, freeze dried, and TIF were collected. To obtain control TIF, an empty chamber was implanted in the subcutaneous flank space of healthy mice. Dual phase solvent extraction was performed on tumor tissue. The water phase was separated, freeze dried, reconstituted in D₂O PBS for spectral acquisition. All ¹H MR spectra were acquired on an Avance III 750 MHz (17.6T) Bruker NMR spectrometer equipped with a 5 mm broadband inverse (BBI) probe. Spectral acquisition, processing and quantification were performed using TOPSPIN 2.1 software. Notable differences between Pa04C compared to Panc1 TIF or normal interstitial fluid were a significant decrease of polyunsaturated fatty acids (PUFA) and lipids, and formate, pyruvate, glutamine, and glycine. Lactate, glutamate, succinate, glycine and acetone significantly increased in Pa04C TIF compared to Panc1 TIF or normal interstitial fluid. These differences in TIF cannot be explained solely by the differences in the tumor metabolic profile. Our study was nested with the prospective US Health Professionals Follow-up Study during the study period 1993-2014. We selected 212 advanced prostate cancer patients with stage T3b, distant metastasis or cancer death during follow-up. Patients and 212 matched controls for whom pre-diagnostic bloods were collected with a median 5.5 years prior to diagnosis. Metabolomics profiling was performed at the Broad Institute using liquid chromatography-tandem mass spectrometry to assay 295 known metabolites. We estimated odds ratios and 95% confidence intervals using multivariable conditional logistic regression to examine associations of individual metabolites and cancer risk. When we stratified by a man’s obesity status, we observed unique metabolomics profiles associated with advanced prostate cancer. Circulating amino acids (including carnitines) were associated with advanced prostate cancer in overweight men while lipid metabolites (including DAGs and TAGs) were associated with advanced cancer in the healthy weight men. Conclusion: Altered levels of TAG and DAG metabolites in prediagnostic bloods are strongly associated with an increased risk of advanced prostate cancer, independent of obesity. The finding that circulating lipids were specifically associated with advanced prostate cancer in healthy weight patients suggests there are men with normal body mass index but who are metabolically obese. The specific lipid metabolite classes enriched in advanced prostate cancer support the hypothesis that obesity acts through dysregulation of liver fatty acid metabolism rather than through metabolic actions of the adipose tissue itself.

#2497 Differential requirement of amino acids on cell survival of ovarian cancer cells. Akiko Furusawa,¹ Jun Inoue,¹ Hiitoshi Tsuda,² Naoyuki Miyasaka,³ Johi Inazawa.¹ ¹Tokyo Medical and Dental University, Tokyo, Japan; ²National Defense Medical College Hospital, Tokorozawa, Japan.

Amino acids (AAs) are traditionally classified into nutritionally essential AAs (EAAs) and non-essential AAs (NEAAs) for animals. Recent studies have demonstrated that not only EAAs but also NEAAs play important role on energy metabolism in cancer cells. However, which AAs are indispensable for human cancer cell survival has not been fully elucidated. The purposes of this study were 1) to determine the indispensable AAs for ovarian cancer (OVC) cells and 2) to investigate the relationship between the AAs survival for each cell line. Firstly, OVC cell lines were cultured with different medium in which each AA was depleted and cancer cell survival was examined. Among 17 OVC cell lines, EAAs were required in 12 cell lines, whereas others did not require EAAs for cell survival. Interestingly, cancer cell lines which required EAA also required at least one NEAAs, including arginine, cystine, glutamine, serine and tyrosine. Although extra-cellular glutamine has been known to be a critical factor for cancer cell survival and growth, 3 OVC cell lines did not require extracellular glutamine. Hence, we next examined glutamine synthetase (GS) gene, which is a critical enzyme for production of endogenous glutamine from glutamate. In OVC cell lines which did not require extracellular glutamine, GS expression level was positively correlated with cell survival rate under glutamine-depleted condition. Further, we found that the expression of this protein was negative in 38 of 645 primary OV tumors (5.9%). Taken together, these results suggest that GS-down-regulated OVC cells require extracellular glutamine for their survival. Therefore, uptake inhibition of extracellular glutamine or reduction of extracellular glutamine level may be a novel therapeutic strategy for patients with ovarian cancer with “GS down-regulation”, as well as development of an AA-based precision medicine of OVC.

#2496 Targeting brain tumor stem cells by interfering with choline metabolism: Evidence for an EMT-choline oncometabolic network. Katharina Koch,¹ Rudolf Hartmann,¹ Abigail K. Suwala,¹ Dayana Herrera Rios,¹ Ulf D. Kahler,¹ Jaroslav Maciayczyk,² University Hospital Dusseldorf, Dusseldorf, Germany;³Forschungszentrum Juelich, Juelich, Germany.

Glioblastoma (GBM) is the most lethal primary malignant brain tumor with a median survival of less than two years. High levels of therapy resistance, strong cellular invasiveness and rapid cell growth demand aggressive multimodal therapies involving resection as well as radio-chemotherapy. Recent evidence has pointed to the existence of brain tumor stem cells (BTSCs), a subpopulation of human brain tumors which is thought to be responsible for tumor dissemination, relapse and chemo resistance. BTSCs have been associated with the expression of mesenchymal features as a result of epithelial-mesenchymal transition (EMT). Using high resolution proton nuclear magnetic resonance spectroscopy (¹H NMR) we compared the intracellular metabolic composition of GBM cells after induction vs. inhibition of EMT as well as under stem cell or differentiated conditions. We identified that both EMT and enrichment for stemness induces the cholinic phenotype which is characterized by high intracellular levels of phosphocholine and total choline derivatives. Furthermore, interference with choline metabolism by targeting choline kinase alpha (CHKA) reversed EMT in GBM cells as we observed reduced invasiveness, changes in protein expression of EMT associated genes. Taken together, interfering with choline metabolism is a powerful strategy to suppress EMT and thus target BTSCs. Moreover, the newly identified BTSC-oncometabolic network could be used to non-invasively monitor the invasive properties of glioblastomas and the success of anti-CTSC therapy.
Arginine deprivation-induced autophagy renders ASS1-deficient sarcomas dependent on serine metabolism. Jeff Kremer, Bethany Prudner, Brian Van Tine. 1National Cancer Institute, 2Columbia University College of Physicians & Surgeons, NEW YORK, NY; 3University of Louisville, Louisville, KY, 4University of Kentucky, Lexington, KY.

Stable Isotope-Resolved Metabolomics (SIRM) has been a useful tool in interrogating metabolic reprogramming in cancer. We have recently published several protocols using SIRM in patient-derived models of non-small cell lung cancer (NSCLC)1. In this case study, we compared cellular metabolism in three different model systems, all derived from the same patient. Slices from the human tumor (Warburg slices 2,3), slices from an NSG mouse bearing the human tumor 4, and the patient-derived cell culture were incubated in [U-13C]-glucose or [U-13C,15N]-glutamine for 24 hours. Samples were then harvested and analyzed by gas chromatography-mass spectrometry and NMR. All three models displayed similar levels of fractional enrichment after 24 hours, making metabolic comparison possible, despite their very different 3D architectures. Glucose metabolism in particular, showed consistent labeling patterns of metabolites in glycolysis and the Krebs cycle. Glutaminolysis metabolism, however, was distinct in the cell culture, with a pattern that indicated upregulation of anaplerotic glutaminolysis. Activation of glutaminolysis may be an important transformative step in the establishment of a viable cell culture. We are also in the process of validating the present finding by comparing multiple patient-derived models of NSCLC and tracking the evolution of their metabolic activity. 1 Lane, A. N., Higashi, R. M. & Fan, T. W. - M. Preclinical models for interrogating drug action in human cancers using Stable Isotope Resolved Metabolomics (SIRM) Metabolomics 12, 1-15 (2016). 2 Fan, T. W. - M. & et al. For five days a week during 21 days. The treated groups received 40 mg/kg of melatonin. Blood sample were collected every 3 hours during 24 hours (eight time points) and the plasma was extracted for analysis by liquid chromatography-mass spectrometry (LC-MS) using the Absolute IDQ p180 Kit (BioCrates). Orthogonal Partial Least Squares (OPLS) analysis showed evident separation of the animals in two different groups, one containing malignant ascites and the other containing indolent disease.

In summary our work reveals a strong relationship between the metabolic profile and the entire circadian variation as well as the exosome melatonin can regulate the metabolism. This pre-clinical trial so far unpublished has shown an increase of arginine, its precursors and acylcarnitines at specific time points in the plasma of breast-tumor-bearing animals. The treatment with melatonin is capable to deacrese the concentration of these amino acids and acylcarnitines achieving basal levels. Our results corroborate the literature which characterizes these metabolites as biomarkers for cancer and increasingly allows the use of melatonin as an adjuvant therapy for breast cancer.

**#2505 High-resolution MRS characterization of malignant ascites in two models of ovarian cancer.** Santosh Bharti,1 Flonne Wildes,2 Chien-Fu Hung,2 TC Wu,2 Zayer Bhujwalla,1 Marie-France Penet,3 JHU ICMIC Program, Division of Cancer Imaging Research, Department of Radiology, Johns Hopkins University School of Medicine, Baltimore, MD; 3Department of Pathology, Johns Hopkins University School of Medicine, Baltimore, MD.

Build-up of malignant ascites occurs in more than one third of ovarian cancer patients and significantly contributes to poor quality of life and mortality. Advances in understanding malignant ascites formation and finding new therapeutic options are urgently needed. High-resolution 1H MRS has been described as an extremely useful in detecting endogenous metabolites to diagnose cancer, by providing a detailed overview of metabolic pathways in a single measurement. In the present study, we are using two ovarian cancer cell lines, the murine IDr-VEGF-Defb29 cell line and the human OVCA3R cell line. Implanted orthotopically, these two ovarian cancer models are characterized by different profile of ascites formation. The mouse cell line IDr-VEGF-Defb29 induces large volumes of ascites, often more than 10 mL, while the human OVCA3R cell line induces ascites less frequently and at smaller volumes, usually less than 0.2 mL. We applied high-resolution 1H MRS to compare the metabolic composition of both ascitic fluids. To better understand the differences observed, we characterized the metabolism of these ovarian cancer cell cultures in vitro by analyzing cell lysates and conditioned culture media with 1H MRS to advance our understanding of cancer cell metabolic reprogramming in malignant ascites formation and the role of the tumor microenvironment in ascites formation and composition. The two tumor models used in this study induced different ascitic profiles. While OVCA3R tumor-bearing mice developed small viscous volume of ascites, IDr-VEGF-Defb29 induced higher volumes. IDr-VEGF-Defb29 ascitic fluids were characterized by higher levels of glutamine, glucose, poly-unsaturated fatty acids and pyruvate compared to the OVCA3R fluids, while all the other metabolites, including glutamate, lactate, myo-inositol, choline and acetate, were lower. To determine if the differences observed in the ascitic fluids were only due to a different metabolism of the cancer cells, we investigated their metabolism in vitro. We analyzed the metabolites present in the conditioned cell culture media, and in the cells, and observed differences in OVCA3R and IDr-VEGF-Defb29 cells metabolism in vitro, without replicating the differences observed in vivo. A Venn diagram of the different metabolites present in the cells, media and ascites showed differences in the metabolites present in those 3 compartments, and highlighted the ones in common. Beta-hydroxybutyrate, lipids, malic and citrate were found in both ascites, and not in the cells or media as. Ascites MRS derived biomarkers could help in ovarian cancer diagnosis, and enhance our understanding of the biochemical and metabolic changes associated with ovarian cancer, and with ascites formation. Supported by Tina’s Wish Foundation, NIH P50CA013175 and P30CA06973.

**#2506 Untargeted and targeted multiplex metabolomic and lipidomic approaches for monitoring biological effects in serum from total body irradiated humans.** Evagelia C. Laiakis,1 Evan L. Pannikak,1 Siddeshwar Chau- 

the,2 Yi-Wen Wang,1 Ming Lian,2 Tyts D. Mak,3 Christopher A. Barker,2 Giuseppe Astarita,1 Albert J. Fornace1.1JHU ICMIC Program, Division of Cancer Imaging Research, Department of Radiology, Johns Hopkins University School of Medicine, Baltimore, MD; 2Memorial Sloan Kettering Cancer Center, New York, NY; 3National Institute of Standards and Technology, Gaithersburg, MD.

Multicellular tumor systems arise from interactions between tumor cells and the tumor microenvironment. The circadian rhythm regulates the whole metabolism modulating the concentration of various circulating substances through the clear and dark variation. Melatonin is the main mediator of this flow and breast tumors development is linked to imbalance of this rhythm. This hormone has several anti-cancer effects extensively proved by our group. Currently metabolomics analysis have been used in cancer research to provide a comprehensive profile of the metabolic changes. Important tumor features are regulated by amino acids likewise fatty acids metabolism. Therefore the comprehension of specific metabolic pathways modulated by melatonin is essential to verify its useful as adjuvant treatment. The aim of this study was to evaluate the metabolic profile in breast cancer xenograft model treated with melatonin and according the circadian cycle. We used 160 female Balb/c nude athmic mice divided into four groups: Tumor / Melatonin, Tumor / Vehicle, Non-tumor / Melatonin and Non-tumor / Vehicle. The tumor-bearing animals were developed by implantation of 3x10⁴ triple negative human breast cancer cells (MDA-MB-231) in the mammary fat pad. All the animals received 100 ul of solution by intraperitoneal injection (IP).
Investigation of responses to radiation therapy or exposure to radiation in an intentional or accidental manner have identified significant biomarkers for biodosimetry and monitoring of individuals in urine through metabolomics (1). We extend the investigation in serum by combining targeted and untargeted methodologies with a multiplatform approach. Serum was collected from patients exposed to total body irradiation (TBI) prior to hematopoietic stem cell transplantation at Memorial Sloan Kettering Cancer Center. The underlying diseases (chronic myelogenous leukemia, acute lymphoblastic leukemia, acute myeloid leukemia, non-Hodgkin lymphoma, or myelodysplastic syndrome) were in remission and the cohort included both males and females. Serum was collected prior to irradiation, at 3-8 h after a single dose of 1.25 Gy, and at 24 h after three fractions of 1.25 Gy each. Untargeted metabolic and lipidomic approaches with liquid chromatography (LC) mass spectrometry (MS) and gas chromatography (GC) MS demonstrated significant perturbations at the later time point and higher total dose. Alterations in circulating levels were observed in lipids from monoaoylglycerol, triacylglycerol, phosphatidylycholine, phosphatidylglycerol, phosphatidylserine, and phosphatidic acid lipid classes. Fatty acids were some of the most dysregulated lipids, with increased levels linked to pro-inflammatory processes. To further investigate the presence of low abundance pro-inflammatory metabolites, we utilized a targeted and highly quantitative approach measuring downstream molecules from fatty acids, such as thromboxanes, prostaglandins, and leukotrienes that can act as signaling molecules and mediators of systemic inflammation. Results identified a rapid response within the first 3-8 hours primarily through the enzymatic action of lipoxigenase (LOX) and cyclo-oxygenase P450 (CYP450), although some dissipated at the later time point. Less significant alterations were observed in the anti-inflammatory pathway, although the fatty acid precursor α-linolenic acid remained elevated in both time points. Finally, as observed in our previous published study of a similar cohort (1), sex-dependent differences were analyzed and utilized to identify more responsive and quantifiable small molecules in blood following radiation exposure can therefore be utilized to not only monitor systemic effects of radiotherapy but also to generate signatures that can be utilized to identify accidentally exposed individuals that may require medical intervention. 1. Laiakis EC et al. Radiat Res 2014; 181: 350-361. 

**#2508 Profiling the metabolic effects of AGI-5198 treatment on IDH1-mutated gliomas.** Víctor Ruiz Rodado, Adrián Lita, Tyrone Dowdy, Mark R. Gilbert, Mioara Larion. National Institutes of Health, Bethesda, MD. 

Background: AGI-5198 (a specific IDH1mut inhibition) inhibits the formation of D-2-hydroxyglutarate (D-2HG) typically produced in millimolar quantities by the R132H mutation of isocitrate dehydrogenase I (IDH1). AGI-5198 was found to delay growth, to promote differentiation in cells and to decrease tumor volume in IDH1-mutant (IDH1mut) mice xenographs, and as a result, has been advanced to clinical trials in IDH1mut glioblastomas. However, no metabolic study of this drug has been reported to date. Here, we investigated the metabolic changes induced by AGI-5198 treatment in order to determine if the drug restores the normal metabolic status once D-2HG concentration is decreased. Methods: We treated glioma cells carrying an IDH1 mutation with 10 μM AGI-5198 for 72 h. Metabolic changes were explored using an untargeted metabolomics approach. Cell viability analysis verified that the concentration of drug does not lead to significant cell death. NMR and MS-linked metabolomics together with in vivo cell imaging using RAMAN were used. Principal component analysis was employed to explore the differences in the metabolic profiles comparing treated and untreated glioma cells. Results and Conclusions: We confirmed that AGI5198 treatment reduced D-2HG levels in the cell lines investigated, validating previous reports. Moreover, we observed a decrease in phospholipid levels upon AGI-5198 treatment, which suggests a decreased proliferative potential for these cells; of particular importance for clinical application. Our preliminary analysis also suggests that metabolites involved in one carbon metabolism are altered upon AGI-5198 treatment. This pathway provides the methyl group for the DNA methylation by DNA methylases producing a hypermethylated phenotype. Our findings suggest that combining the AGI-5198 treatment with a DNA methylase inhibitor may improve outcomes in IDH1-mutated gliomas.

**#2509 High-resolution 1H NMR metabonomics to study breast cancer and endothelial cell metabolic interactions.** Sucelay Acovedo-Acovedo, Sean P. Palecek. University of Wisconsin-Madison, Madison, WI. 

Breast cancer is the second most commonly diagnosed cancer among women worldwide. Patient death is typically caused by metastasis development rather than the primary tumor. Metastasis in breast cancer has been shown to occur via blood and lymphatic vessels. Research shows that breast cancer cells ‘educate’ lymphatic and blood endothelial cells to support tumor growth by stimulating growth factor secretion; specifically VEGF, PDGF-BB and EGF secretion. In addition, cell metabolism is altered during malignant transformation. Cancer cells have increased energy and macromolecule biosynthesis requirements to sustain rapid proliferation. Increased angiogenesis observed in tumors points to a need for an increased nutrient supply. However, it remains unclear how tumor endothelial cell metabolism is altered and how metabolism regulates tumor angiogenesis. Therefore, this study aims to use 1H NMR metabonomics to identify breast cancer-endothelial cell metabolic interactions in a high-throughput manner. Firstly, we studied if in vitro co-culture with breast cancer altered endothelial cell metabolism. We identified distinct metabolic profiles for HUVECs grown in monoculture or co-culture with three different breast cancer cell lines. Metabolism of HUVEC co-cultured with MCF7 and SKBR3 breast cancer cell lines was significantly altered compared to mono-culture control. The most impacted metabolic pathways by co-culture were amino acid metabolism, energy metabolism and lipid biosynthesis pathways. Culturing HUVECs with MDA-MB-231 triple negative breast cancer cells did not have a significant impact on HUVEC metabolism, however. Together, these results indicate that culturing HUVECs with certain breast cancer lines causes significant changes in endothelial metabolism. Alterations in endothelial cell metabolism in response to breast cancer co-culture can further our understanding of tumor-vascular interactions and may lead to identification of metabolic biomarkers or therapeutic targets that can disrupt tumor angiogenesis.

**#2510 Interrogating liver metabolic stress due to cancer-induced cachexia.** Santosh K. Bharti, Paul T. Winnard, Yelena Mironchik, Anirban Majtara, Zaver M. Bhujwalla. 1 The Johns Hopkins University School of Medicine, Baltimore, MD; 2 The University of Texas MD Anderson Cancer Center, Dallas, TX.

Early detection of pancreatic ductal carcinoma (PDAC) is critically important because by the time PDAC is detected almost 80% of patients are surgically unresectable1. While imaging with CT, MRI and ultrasound is making significant inroads in PDAC detection, the costs associated with imaging impose a barrier for routine screening. Plasma based detection of PDAC would provide a relatively inexpensive and easy method for routine screening for the purpose of early detection. Metabolic profiling of plasma samples using high resolution 1H NMR provides an opportunity to assist in the detection of PDAC. Here we characterized the plasma metabolome of normal subjects, subjects with benign pancreatic disease, and subjects with PDAC to evaluate the ability of 1H NMRs to identify metabolic changes in plasma associated with PDAC. Plasma from patients with PDAC (n=4), patients with benign pancreatic disease (n=2) and from healthy control subjects (n=4) were included in this study. Final diagnosis was established by histopathological evaluation of surgical specimens. Three hundred micro liter of D2O phosphate buffer saline (NaCl 0.9% in 90% D2O) was mixed with 300 μL of plasma and transferred to 5 mm NMR tubes. High resolution 1H NMR was performed on an Avance 750 MHz Bruker MR spectrometer. The Carr-Purcell-Meiboom-Gill (CPMG) pulse sequence with water suppression [PRESET-90°-(d-180-d)n-Aq] was performed to remove short T2 components arising due to the presence of macromolecules. The metabolites were identified and quantified from 1H NMR spectra from the three groups. Even with a small sample size clear differences were identified in metabolites such as lactate, pyruvate, β-hydroxybutyrate, acetate and acetoacetate in plasma from PDAC subjects compared to normal subjects. The increase of lactate and pyruvate detected in plasma may reflect altered glucose metabolism occurring in PDAC. β-hydroxybutyrate, acetate and acetoacetate are involved in ketone body synthesis and may reflect altered ketone body metabolism occurring in PDAC. In a recent study, higher levels of ketone bodies and lactate were detected in the serum of rats with 7,12-dimethylbenz(a)anthracene (DMBA)-induced pancreatic intraepithelial neoplasia (PanIN) compared to plasma. Interestingly, with progression to PDAC several of these metabolites decreased3. Our data support further investigation of 1H NMRs of human plasma to detect PDAC in combination with techniques such as circulating tumor cell phenotyping. References: (1) Kortes, E., et al. Cancer-induced cachexia accounts for approximately 20% of all cancer deaths. In pancreatic cancer, the syndrome affects nearly 80% of patients. Cachectic patients experience a wide range of symptoms affecting the function of several organs such as muscle, liver, brain, and heart, that decrease quality of life and worsen prognosis. A major characteristic of cachexia is the accelerated skeletal muscle and fat tissue burning resulting in increased energy expenditure. Here, for the first time, we have performed high-resolution quantitative 1H magnetic resonance spectroscopy (MRS) of liver tissue obtained from noncachectic and cachectic mice bearing PDAC that are cachectic (Pa04C) and noncachectic (Panc1). A significant reduction in liver weight and significant changes in 1H MRS derived metabolite profiles were detected with cachexia. Human pancreatic cancer cell lines, Panc1 and Pa04C, were used for the study. Six to 8 week old male combined immunodeficient mice were inoculated in the right flank with cancer cells (5×10^6) and in the right hind leg muscle with reporter myoblasts (2×10^6) to monitor the development of cachexia in mice. Live animal optical imaging was done using a Xenogen IVIS® Spectrum (PerkinElmer) optical scanner. Dual phase solvent extraction was performed on liver tissue to extract water soluble metabolites. All 1H MRS spectra were acquired on an Avance 750 MHz Bruker NMR spectrometer. We found, for the first time, that the liver in Pa04C tumor bearing mice underwent a profound weight loss; although Panc1 tumor bearing mice showed some liver weight loss this was not as profound as observed with Pa04C tumors. Significant decreases in lactate, glucose and glutathione were observed in cachetic mouse liver compared to noncachectic mouse liver, and the liver from healthy control mice. The significant decrease of these metabolites in cachectic livers may reflect increased utilization of glucose, lactate and glutathione by the tumor or other organs during the cachexia cascade. These results provide new insights into changes in liver metabolism during cachexia, and support investigating metabolic strategies such as supplementing glutathione or glucose to reduce cachexia associated morbidity.

**#2511 The role of lipids metabolism in bladder cancer.** Gang Wang, Rui Cao, Qiangqiang Ge, Yu Xiao, Xinghuan Wang, Zhongnan Hospital of Wuhan University, Wuhan, China.

Lipid metabolism in bladder cancer (BCa) is one of the most common malignancies of the urinary tract. Many risk factors for BCa has been demonstrated, including aging, smoking, exposure to chemicals, dietary total cholesterol intake, dietary fatty acids intake, etc. In order to investigate the roles of lipids metabolism in bladder cancer, we collected several human BCa tissues and normal bladder tissues to generate an affected pathway network by microarray analysis, and it revealed that glycolipids, lipidic acid level, and lipidic level was down-regulated in tumor tissue. We will discuss the raised questions, which metabolic dysfunction or reprogramming the use of M1N combination for cancer treatments. For instance, among the amino acids, the content of aspartate, a key metabolite in electron transport system in the mitochondria, was specifically suppressed by M1N. Deep RNA sequencing analysis demonstrated that there were sixteen genes whose expressions were found altered following the M1N treatment. Ameboid motility and tumorigenicity of BCa cell lines were both decreased following the M1N treatment. Therefore, the results were strongly supported the use of M1N combination for cancer treatments.

**#2512 Understanding metabolic dysfunction in retinoblastoma development.** Nilanjan Guha, Carolina Livi, Vishnu Suresh Babu, Lisa Winer, Deepak SA, Syed Lateef, Srinivasan Sundaram, Brian Dranka, Arka Subhra Ghosh, Agile Technologies, Bangalore, India.

Metabolic dysfunction or reprogramming is the underlying cause of many diseases including cancer. In this study, we looked into the transcriptomic and metabolomic profile of retinoblastoma (Rb), a pediatric eye cancer, from tumor and normal tissue, aqueous humor, vitreous humor and tear. The samples were collected from enucleated eyes of 9 subjects and 2 deceased controls, whose cause of death is not due to any eye related disease. The study was corroborated with cell line models of retinoblastoma, used for metabolic phenotyping. Combined pathway analysis of transcriptomics data from subject tissue samples and retinoblastoma cell line WERI-Rb1 revealed a significant overlap in the differentially regulated genes belonging to both glycolysis and OXPHOS pathways. The results were correlated with Rb1 overexpressed and its respective control also. To better understand the implications of these two major pathways in the progression of retinoblastoma, metabolic study using Seahorse analyzer enables measurement of extracellular flux (oxygen consumption rate and extracellular acidification rate) to provide insight into mitochondrial function and glycolytic activity. Using a pharmacological approach, the contribution of glucose, glu-
#2516  Pokemon functions as a metabolic oncprotein integrating glucose & lipid metabolism in hepatocellular carcinoma. Yibo Jin,1 Shangfu Li,2 De- liang Cao,3 Dan Gao,2 Hongxia Liu,2 Feng Liu,2 Tiejie Wang,2 Yuyang Jiang,2 Shenzhen Institute for Drug Control, Shenzhen, China; 3The State Key Labora-
tory Breeding Base-Shenzhen Key Laboratory of Chemical Biology, Tsinghua Uni-
versity, Shenzhen, China; 4Southern Illinois University School of Medicine, Springfield, IL; 5Department of Pharmacology and Pharmaceutical Sciences, School of Medicine, Tsinghua University, Shenzhen, China.

Pokemon (also known as FBL1 or LRF) is a proto-oncogene encoded by ZBTB7A gene. It functions as a transcription factor, playing important roles in embryonic development, cell differentiation and neoplasia. Pokemon is abnor-

mally expressed in hepatocellular carcinoma (HCC) and may contribute to the metabolic homeostasis of HCC cells, but the mechanism of action remains to be fully understood. This study demonstrated that Pokemon may integrate glyco-
ylation and lipid metabolism in hepatocellular carcinogenesis. Our data showed that Pokemon was upregulated in HCC cell lines and clinical samples. Epictopic expression of Pokemon stimulated HCC cell growth and proliferation in culture and tumorigenesis in nude mice. Lipid metabolic analysis by LC/MS revealed that in HCC cells lipogenesis was positively correlated with Pokemon ex-
pression levels, and targeted expression of Pokemon in HCC cells promoted the flux of radiolabeled glucose to lipids, including membrane phospholipids through the aerobic glycolysis-acetyl-CoA metabolic stream. Mechanistic stud-
ies revealed that Pokemon stimulated glycolysis through activation of PDK and its mediated Raf/c-Myc pathway. In the tested HCC cells, Pokemon activated fatty acid synthase (FASN) and suppressed AMPK, an inhibitor of acetyl-CoA carboxylase α (ACC-α), stimulating fatty acid and lipid synthesis. Together our results suggest that Pokemon correlates glycolysis and lipid synthesis and thus promotes lipogenesis and hepatocellular tumorigenesis.

#2517  Prognostic biomarkers of PDAC - a cross-validation study. Hung-Jen Wu,1 Smriti S. Menon,2 Keith Unger,2 Massimo S. Fiandaca,3 Yassi Fallah,3 Mark Mapstone,4 Howard J. Federoff,2 Amrita K. Cheema.1 1Georgetown Uni-

versity, Washington, DC; 2Med-Star Georgetown University Hospital, Washing-
ton, DC; 3UCI, Irvine, CA.

Introduction: Pancreatic ductal adenocarcinoma (PDAC) represents 90% of pancreatic neoplasms and the fourth leading cause of cancer death in the United States. Recently, several research groups have focused on conducting metabolomics based clinical investigations to identify metabolite markers of PDAC. Since a central biomarker repository for PA is lacking, however, it remains challenging to delineate the total number of metabolites reported, and comparatively difficult to test bio-signatures overlap between the disparate studies. Approach: We performed an extensive literature search to delineate PDAC case-control studies reporting dysregulated metabolite biomarkers for PDAC utilizing three main sources: PubMed, EDRN and GDOC. We refined our search to 36 publications that reported blood based metabolomics/lipidomic biomarkers. Data from these studies were analyzed for up/down-regulation of specific metabolites in PDAC, study sample size, and other clinical determinants. The final list consisted of 12 metabolites (including amino acids, fatty acids and small organic acids), that were reported by two or more research groups as being dysregulated in PDAC. Of note, these 36 disparate studies were carried out using different methodologies, analyzed on diverse analytical platforms, and utilized different statistical and bioinformatics methodologies. Resultant common features, therefore, were deemed significant as candidate biomarkers for cross-validation. Next, we used stable isotope dilution multiple-reaction monitoring mass spec-
trometry (SID-MRM-MS) for targeted quantification of these 12 metabolite markers in plasma samples obtained from patients that were diagnosed with PDAC and compared the same profiles to matched normal controls. Results: We delineated a sub-set of the original 12 metabolites that showed concordance with those reported in the literature. Statistical analyses to determine the sensi-
tivity and specificity of the resultant panel, and any influence provided by age, gender, and type 2 diabetes, on the predictive performance of the biomarker panel are ongoing. These data will be presented at the AACR meeting. Conclu-
sion: Developing a specific and sensitive panel of blood-derived biomarkers offers a unique opportunity towards screening and allows increasing overall sur-

vival rates for PDAC with early diagnosis. Such disease-specific bio-signatures allow identification of molecular targets for therapeutic development; improve early treatment strategies and thereby clinical outcomes. Creating a compendium of existing biomarker data and performing cross-validation studies repre-

sent the first steps for developing clinical assays for the diagnosis and prognosis determination of PDAC. The integration of data generated from multiple analy-

tic platforms and diverse subject cohorts is likely to help identify robust bio-
signatures that would then be ready for large scale validation studies. Supported by American Cancer Society.

#2518  Accumulation of a liver- and microbiome-derived metabolite in human breast tumors is associated with patient survival. Wei Tang,1 Tiffany Dorsey,1 Vasanta Putluri,2 Nagireddy Putluri,2 Stefan Ambks3.1 1NCI-CCR Bethesda, MD; 2Baylor College of Medicine, Houston, TX.

Breast cancer is the most common cancer in women in the United States. Gene expression profiling studies of breast tumors led to the discovery of disease subtypes with different biologies. These studies also described novel biomarkers for therapy response and disease survival. However, it remains a challenge to define breast cancer biology solely based on gene expression. Recently, metabo-

lomics emerged as a new discovery tool with the promise of identifying prognostic biomarkers and targetable metabolic dependencies of cancer cells. We previously measured the abundance of 536 metabolites in 67 breast tumor and their tumor adjacent noncancerous tissue by untargeted mass spectrometry. In the current study, we explored the prognostic power of the metabolome and conducted an integrated analysis comprising of the metabolome, transcriptome, and proteome to explore the association of metabolites with cell systems, tumor biology, and disease outcome. We built a predictive model based on multivari-
able Cox proportional hazards using the L1 penalized log partial likelihood (LASSO) method after pre-selecting prognostic metabolites following cross-

validation with 1000 iterations. The median C-index was 0.73, indicating a cer-
tain robustness of metabolites as classifiers of breast cancer outcome. The mod-
els identified five metabolites including a bile acid-related metabolite, glycochenodeoxycholate (GCDC), as the most frequently selected features and outcome markers among these metabolites. An increased GCDC tumor content was associated with improved patient survival. We corroborated the presence of GCDC and three other bile acids in the human breast tissues using absolute measurements and confirmed their occurrence in breast tumors. Because additional large-scale transcriptome and proteome data were available for the same tissue samples, we further characterized the tumors based on their GCDC abund-
ance, which showed that cell cycle-related pathways were enriched for differ-
ently expressed genes and tumors with a high GCDC content tended to have a low cell proliferation score, indicating that accumulation of GCDC leads to growth inhibition. We also conducted a correlation analysis for the relationship between GCDC abundance with other metabolites and identified 51 metabolites that were significantly correlated with GCDC. In this analysis, metabolite abund-
ance in the sterol/steroid pathway associated most strongly with the GCDC tissue content. Lastly, we evaluated the effect of bile acids on breast cancer cell lines. The data showed a strong reduction of cancer cell proliferation under bile acid treatment, consistent with the tumor data, and distinct changes in gene expression. In conclusion, we propose that integrated metabolomics can provide powerful prognostic information with GCDC being a novel prognostic marker in breast cancer because accumulation of GCDC reduces cancer cell prolifera-

#2519  Analysis of gene expression patterns and metabolomics correlations related to obesity, diabetes, and outcomes in patients with epithelial ovarian cancer. Allison M. Montgomery,1 Angelina I. Londono,1 Eric R. Craig,1 Cindy Tawfik,1 Haller J. Smith,1 Charles A. Leath,1 Ashwini A. Katre,1 Sara J. Cooper,2 Rebecca C. Arend,1 1University of Alabama at Birmingham, Birmingham, AL; 2Hudson Alpha Institute for Biotechnology, Huntsville, AL.

Objective: Diabetes and obesity have been associated with a poor prognosis in ovarian cancer (OVCA); the exact mechanism has yet to be determined. Data suggests that obesity diminishes normal immunological response and better prognosis in non-obese patients may be attributable to an intact immune re-
sponse. The objective of this study was to analyze the correlation between gene expression pattern/metabolomics and obesity/diabetes in OVCA patients. Methods: Following IRB approval, UAB patients with suspected OVCA undergoing surgery were consented. Tissue was collected during cytoreduction and 35 samples were analyzed using RNAseq technology and mass spectrometry-based metabolomics. DESeq2 was used for RNAseq analysis to identify gene expression differences between diabetics and non-diabetics stratified by BMI: obese (BMI ≥30) and non-obese (BMI <30). Gene set enrichment analysis was con-
ducted to determine whether there was an over-representation of immune path-
ways among altered genes. Profiles were normalized in the analysis of the met-
abolite profiles using ChromaTOF. Results: 76 genes (p-value <0.05) were dif-

differentially expressed in the tumor samples from patients with BMI ≥30 to those <30. These genes were highly enriched for immune-related genes, includ-

Metabolism in cancer cells is significantly altered as compared to their normal counterparts. Metabolic reprogramming can assist cancer cells to meet their requirements for uncontrollable proliferation and survival. In addition to their role in protein synthesis and energy generation, metabolites also act as signaling molecules, antioxidants and perform oomorgulatory functions. Differences in genetic makeup and phenotype of cells can lead to differences in these metabolic needs. A detailed analysis of metabolic signatures of different cancer cells can therefore prove useful in understanding metabolic interactions with the phenotype in cancer cells. This study aims at identifying these metabolic differences among distinct breast cancer cell lines and gaining mechanistic insights into possible reasons for differential abundance of metabolites. We used nuclear magnetic resonance (NMR) spectroscopy to quantify intracellular metabolites in five breast cancer cell lines having distinct genetic and phenotypic compositions. We show that the intracellular abundance of essential amino acids depends on cell type and medium composition. We also show that myo-inositol abundance was significantly higher in ER-/PR- than ER+/PR+ breast cancer cells due to increased expression of inositol-3-phosphate synthase 1 expression. Myo-inositol is an osmolyte and also a precursor of inositol phosphates which participate in PI3K and calcium signaling pathways. Although the reason for ER+/PR- cells contain greater concentrations of myo-inositol than ER+/PR+ cells is not yet known, increased myo-inositol abundance could potentially serve as a marker of ER-/PR- breast cancer cells. We also observed significant changes in phospholipid metabolism, specifically, glycero phosphocholine (GPC) concentration correlated with doubling time. We also found that reducing serum concentration in the growth medium reduced the growth rate of MCF7 cells, which led to increased GPC abundance in the cells. GPC is also an intracellular osmolyte and is a degradation product of phosphatidylincholine (PtdCho). Phospholipid metabolism has been shown to be significantly altered in breast cancer cells and has been used as prognostic marker in breast cancer cells. A positive correlation of doubling time with GPC irrespective of ER/PR status may prove useful in deciding therapeutic options. Our results highlight the differences in metabolic requirements in different breast cancer cell lines and suggest potential for gaining mechanistic understanding of these differences using metabolomics.

Inhibition of metabolic reprogramming by zerumbone alters the tumorigenic potential of hepatocellular cancer. Nissan A. Wani, Bo Zhang, Kun-yu Teng, Juan Barajas, Kalpana Ghoshal, Rafael Brüschweiler, Samson T. Jacob. Ohio State Univ., Columbus, OH.

Incidence of hepatocellular carcinoma (HCC) that represents ~90% of all cases of primary liver cancer is on the rise worldwide. Sorafenib, the only approved targeted therapy, prolongs median survival only by ~3 months. Thus, new therapeutic strategies are urgently needed. In this study, we investigated therapeutic potential of zerumbone, a sesquiterpene from an edible ginger, against HCC. Zerumbone inhibited proliferation and clonogenic survival of HCC cells by blocking glycolysis and pentose phosphate pathway, arresting cells at G2/M phase of cell cycle and inducing apoptosis. To uncover the underlying molecular mechanisms of its action on HCC cells, we employed several unbiased approaches. First, phosphokinease array showed significant inhibition PI3K/AKT/mTOR and STAT3 signaling in zerumbone-treated HCC cells. Gene Set Enrichment Analysis (GSEA) and Ingenuity Pathway Analysis (IPA) of the microarray data revealed that zerumbone-deregulated genes showed positive correlation with PI3K/AKT/mTOR and STAT3 pathways and those involved in metabolism, apoptosis and cell cycle. Notably, the alteration in expression of genes regulated by PI3K/AKT/mTOR or STAT3 pathways and downregulated by zerumbone in HCCs is associated with poor patient survival. These results imply that treatment with this dietary sesquiterpene might lead to a better outcome in HCC patients. Indeed, zerumbone treatment significantly inhibited growth and lung metastasis of orthotopic HCC xenografts in NSG mice. These findings reveal novel therapeutic strategies targeting cancer metabolism. Collectively, these observations underscore the therapeutic potential of zerumbone in HCC.

Key cluster for prostate cancer diagnosis and therapy; miR-888 cluster. Tsyutso Hasegawa, Aurora Kerscher. Eastern Virginia Medical School, Norfolk, VA.

Prostate cancer (PCa) is the 2nd leading cause of cancer death among men in the U.S. No accurate biomarkers exist and therapeutic options are limited for advanced PCa. MicroRNAs (miRNAs), small non-coding RNAs, act as negative regulators of gene expression. miRNAs have recently emerged as promising therapeutic tools for cancers. It is poorly understood how they function to promote cancer progression. We found miR-888 was involved with PCa progression. miR-888 belongs to a genomic cluster on human chromosome Xq27.3, linked to hereditary PCa. I hypothesized additional members of this cluster (miR-892c, -890, -892a, -892b, -891b, -891a) function to promote PCa progression. Our lab profiled miR-888 expression cluster in paired syngenic human PCa cell lines (RWPE1 & WPE1-NB26, LNCaP & C4-2, PC-3 N & PC-3 ML) differing in metastatic status and androgen response. We hypothesized the miR-888 cluster was preferentially elevated in metastatic PC-3 ML and under-expressed in non-aggressive PC-3 N cells. We examined miR-888 cluster function in vitro and found that forced expression (via miRNA mimics) of certain miR-888 cluster members, notably miR-888 and miR-891a, promoted cell proliferation, colony formation, migration and invasion in PC-3 N cells. Conversely, other
MOLECULAR AND CELLULAR BIOLOGY / GENETICS: MicroRNAs and Other Noncoding RNAs as Tumor Suppressors or Oncogenes

In Multiple myeloma (MM), abnormal plasma cells accumulate in the bone marrow and spread to new bone sites. However, the mechanisms underlying this spread of MM cells remain unclear. Runx2 is a bone specific transcription factor upregulated in various human tumors, including MM. Our studies have previously demonstrated that Runx2 is a major driver of MM progression in bone. In this report, we investigated the role of miR-124 and miR-363 in Runx2 regulation and promote tumor growth and dissemination of MM to new bone sites and assess their therapeutic potential. Expression analysis of a panel of miRNA's regulating Runx2 revealed an inverse relationship between Runx2 expression and two miRNAs: miR-342 and miR-363. MiRNA expression analysis using the Gene Expression Omnibus database showed that miR-342 and miR-363 are highly expressed in MM cells. miR-342 suppressed p62 and p65/NFkB to regulate autophagy, in low-grade disease. My work indicates miR-888 and miR-891 are novel oncogenic factors in the prostate and may use miRNAs to exert their effects. This is the first report to explore the functional role of the miR-888 cluster in any tissue and may lead to promising clinical strategies for PCa.

#2524 MiR-124 suppresses p62 and p65/NIK to regulate autophagy, inflammation and cell death in KRAS mutant mesenchymal NSCLC cells. Anita K. Mehta,1 Kevin Hua,1 William Whipple,1 Mihn-Thuy Nguyen,1 Rushika M. Perera,1 Johanns Haybaeck,3 Joanne Weidhass,4 Jeffrey Settleman,5 Anurag Singhal,3 Perera,2 Johanns Haybaeck,3 Joanne Weidhass,4 Jeffrey Settleman,5 Anurag Singhal,3 1Graduate School of Medicine, Chiba University, Chiba, Japan; 2Institute of Medical Science, St. Marianna Medical University, Kawasaki, Japan; 3University of California at San Francisco, San Francisco, CA; 4University of California at Los Angeles School of Medicine, Los Angeles, CA; 5Calico Life Sciences, South San Francisco, CA.

Background KRAS mutant non-small cell lung cancers (NSCLC) cells are molecularly and histologically diverse. Epithelial-like cells are more KRAS dependent, whereas mesenchymal-like cells are less KRAS dependent. These two subtypes are designated KE (epithelial) and KM (mesenchymal), respectively. A KE versus KM subtype transcriptional signature reveals specific modes of KRAS dependent survival signaling in the KE subtype. This KRAS dependence signature is significantly enriched with predicted microRNA (miRNA) target genes of miR-205 and miR-34b/c. MiRNAs can function as tumor suppressors by coordinately regulating multiple oncogenic signaling pathways. The role of deregulated miRNA function in mediating the survival of KM versus KE NSCLC cells has not been investigated to date. Methods Differential miRNA expression in KRAS mutant cell lines was determined using Taqman low-density qPCR arrays (TLDA). Functional miRNA reconstitution experiments of downregulated miRNAs were performed in a panel of KM cell lines. Effects on apoptosis and autophagy were performed by Western blotting, immunofluorescence and live cell microscopy and caspase assays. The molecular targets of miR-124 were computationally identified by TargetScan or miRWalk and experimentally verified using 3’UTR luciferase-based assays. Functional rescue of miRNA-dependent cell viability defects was determined by ectopic predicted target gene expression. Results Comparison of KE to KM cells yielded a KE-KM miRNA subtype classifier/signature. This signature revealed a number of silenced or suppressed miRNAs in KM cell lines, including members of the miR-200 family. MiR-200 and miR-205 reconstitution in KM cells modulated epithelial plasticity by Zeb1 protein suppression and increased E-cadherin levels. Reconstitution of miR-124, miR-625 and miR-518-3p in KM cells caused pronounced loss of cell viability. Furthermore, miR-124 caused autolysosome maturation defects. We identified SQSTM1/p62, TRAF6 and RELA/p65 as key predicted targets of miR-124. MiR-124 reconstitution in KM cells caused decreased p62, TRAF6 and p65 protein levels. The effect of miR-124 on p62 expression was verified using a Luciferase-p62-3’UTR reporter construct. Overexpression of p62 in KM cells rescued the cell viability defects caused by miR-124. Conclusion These studies implicate miR-124 as a context-dependent tumor suppressor miRNA in KM subcutaneous tumors. MiR-124 directly suppresses expression of SQSTM1/p62 to promote defects in autolysosome maturation. In parallel, miR-124 suppresses RELA/p65 and in some cases, TRAF6, to alter expression levels of several cytokines. Thus, miR-124 coordinate regulates autophagy and inflammation to disrupt the finely-tuned balance between pro and anti-inflammatory signals, resulting in cytotoxic effects in a specific subtype of mesenchymal-like KRAS mutant NSCLC cells.

in multiple myeloma cell-derived runx2 by miRNAs suppresses multiple myeloma growth and progression. In Multiple myeloma (MM), abnormal plasma cells accumulate in the bone marrow and spread to new bone sites. However, the mechanisms underlying this spread of MM cells remain unclear. Runx2 is a bone specific transcription factor upregulated in various human tumors, including MM. Our studies have previously demonstrated that Runx2 is a major driver of MM progression in bone. In this report, we investigated the role of miR-124 and miR-363 in Runx2 regulation and promote tumor growth and dissemination of MM to new bone sites and assess their therapeutic potential. Expression analysis of a panel of miRNA's regulating Runx2 revealed an inverse relationship between Runx2 expression and two miRNAs: miR-342 and miR-363. MiRNA expression analysis using the Gene Expression Omnibus database showed that miR-342 and miR-363 are highly expressed in MM cells. miR-342 suppressed p62 and p65/NFkB to regulate autophagy, in low-grade disease. My work indicates miR-888 and miR-891 are novel oncogenic factors in the prostate and may use miRNAs to exert their effects. This is the first report to explore the functional role of the miR-888 cluster in any tissue and may lead to promising clinical strategies for PCa.

#2526 MicroRNA expression signature of patients with tyrosine kinases inhibitors failure: miR-10a-5p inhibits cancer cell aggressiveness in renal cell carcinoma. Takayuki Arai,1 Atsushi Okato,1 Akira Kurozumi,3 Mayuko Kato,1 Yusuke Goto,1 Keiichi Koshizuka,1 Satoko Kojima,2 Yukio Naya,2 Tomohiko Ichikawa,1 Naohiko Seki,1 Graduate School of Medicine, Chiba University, Chiba, Japan; 2Teikyo University Chiba Medical Center, Ichihara, Japan.

Renal cell carcinoma (RCC) is a disease in which cells undergo oncogenic transformation in the kidney tubules. The five-year survival rate of advanced cancerous kidney tissue is poor (5-10%). There has been an urgent need for novel treatments extending progression-free survival of patients with RCC, and angiogenesis-blocking drugs have been developed to selectively inhibit the growth of tumor vasculature. Inhibitors of angiogenesis, e.g., VEGF and FGF, are the basis for current anti-angiogenic multi-tyrosine kinase inhibitors (TKIs) have been developed and have been used as first and second line treatments for RCC. However, these treatments extend progression-free survival only slightly, and relapse and metastasis eventually develop in most patients. The molecular mechanisms of RCC recurrence, metastasis and drug resistance are not yet fully understood. Therefore, analysis of the molecular mechanisms underlying RCC development and progression plays a critical role in identifying targets for the development of novel drugs for RCC treatment. Therefore, dysregulated expression of miRNAs and their regulated RCC pathways based on the signature approach could significantly improve diagnosis, therapy, and prevention of the disease. miRNAs (miRNAs) are small noncoding RNAs that function to fine tune the expression of protein coding/noncoding RNAs by repressing translation or cleaving RNA transcripts in a sequence-dependent manner. The unique characteristic function of miRNAs is to regulate RNA transcripts in human cells. Therefore, dysregulated expression of miRNAs can disrupt tightly regulated RNA networks in cancer cells. In this study, we constructed a miRNA expression signature to identify pathways activated by TKI treatment using cDNA microarrays. We have sequentially identified tumor-suppressive miRNAs of RCC cancers and their regulated RCC pathways based on the signature approach. The aim of this study was to investigate the functional significance of miR-10a-5p and to identify the molecular targets and pathways mediated by miR-10a-5p in RCC cells. The expression levels of miR-10a-5p were significantly reduced in RCC clinical specimens and RCC cell lines compared with non-cancerous kidney tissues (P < 0.001). TCGA data showed that the overall survival of low miR-10a-5p expression group was significantly shorter than that of high miR-10a-5p group (P = 0.034). Restoration of miR-10a-5p significantly inhibited cancer cell migration and invasion in RCC cell lines (P < 0.001). Spindle and kinetochore associated complex subunit 1 (SKA1) was identified as a direct target gene of miR-10a-5p by genome-wide gene expression analysis and in silico analysis. Overexpression of SKA1 was observed in RCC clinical specimens.
The overall survival of high SKA1 expression group was significantly shorter than that of low expression group by TCGA analysis (P = 1.44E-07). Tumor-suppressive miR-10a-5p was identified by using miRNA signature of patients with TKI failure. Overexpression of SKA1 might be involved in RCC aggressiveness, metastasis and drug resistance. Elucidation of tumor-suppressivemicroRNAs regulated molecular pathways and targets could provide newinformation on potential therapeutic strategies in the disease.

**#2527** The role of miR-601 in prostate cancer progression. Jessica L. Fleming, Erica H. Bell, Kathryn Andrews, Arnab Chakravarti. The Ohio State University, Columbus, OH.

Prostate cancer (PCa) is the second most common cancer among men worldwide. In order to advance treatment options for these men, it is crucial to understand the molecular underpinnings behind this cancer. Previously, our group identified miR-601 as a biomarker of significance in PCa. Few studies to date have functionally validated molecular biomarkers and currently little is known about the function of miR-601 in PCa. Based on our previous publication, we hypothesized that miR-601 plays a role in PCa progression and radiation response. To test this hypothesis, miR-601 was over-expressed and knocked down in DU145 and PC3 cell lines and assays were performed evaluating cell proliferation, colony formation, apoptosis, and cell cycle progression. Additionally, to provide more information regarding miR-601-associated pathways, we identified putative gene targets of miR-601 using in silico prediction programs, microrna.org and TargetScan. org and evaluated top gene targets in vitro. To date, our data suggest that miR-601 may be playing a role as a tumor suppressor. Over-expression of miR-601 in cell lines resulted in a significant reduction in cell viability. This was confirmed both by MTS as well as colony formation assays. We looked into the mechanism behind the reduction in cell viability by testing the effect of miR-601 on apoptosis and cell cycle progression. We found that cells over-expressing miR-601 had slightly higher levels of apoptosis, however miR-601 did not induce a substantial effect on cell cycle progression. Additionally, we found that miR-601 enhances radiosensitivity in DU145 and PC-3 cell lines. Similar results have been observed in breast cancer as well as in a large miRNA screen performed in the LNCaP cell line. Two putative gene targets of miR-601 were identified and investigated in vitro, SIRT1, a histone deacetylase known to be both an oncogene and tumor suppressor, and BCL2L2, an anti-apoptotic gene known to be an oncogene. SIRT1 and BCL2L2 had strong scores on both online prediction programs as likely targets of miR-601. Our in vitro results confirmed this. We saw reduced miRNA and protein expression of these targets in cells over-expressing miR-601. Our data thus far suggest that miR-601 is acting as a tumor suppressor in PCa. Targeted therapies for miR-601 and/or its targets may be promising in the treatment of PCa, however additional work is needed to validate this. Future work will focus on the role of miR-601 in cell migration and invasion as well as identifying the direct molecular mechanism(s) by which miR-601 is reducing cell viability and conveying radiation sensitivity. **#2528** miR-452 inhibits migration and invasion of prostate cancer cells by targeting E3 ubiquitin ligase-1 (WWP1). Satoko Kojima, Yusuke Goto, Akira Kurozumi, Mayuko Kato, Atsushi Okato, Takayuki Arai, Tomohiko Ichikawa, Yukio Naya, Naohiko Seki. Teikyo University Chiba Medical Center, Chiba, Japan; Chiba University Graduate School of Medicine, Chiba, Japan

Introduction: Most prostate cancer (PCa) patients initially respond to androgen-deprivation therapy (ADT), but eventually acquire resistance to ADT and progress to castration-resistant prostate cancer (CRPC). CRPC, resulting in metastasis causing PCa death. We have developed the miRNA (miRNA) expression signature of PCa using clinical specimens and determined the target genes of the tumor suppressive miRNAs, whose expressions are significantly decreased in PCa specimens. Based on the signature, our previous study revealed that miR-224 functions as a tumor suppressor, especially contributes to cancer cell metastasis directly targeting miR-224-TDP52 signaling. In human genome, miR-452 is located near the human tumor-suppressive miR-224, forming clustered miRNAs on chromosome Xp28 region. The aim of the study was to investigate the functional significance of miR-452 and to identify novel miR-452-mediated cancer pathways and responsible genes in PCa cells. Material and methods: Clinical prostate specimens were obtained from patients admitted to the Teikyo University Chiba Medical Center from 2008 to 2013. Ninety-two patients with elevated PSA levels underwent transrectal prostate needle biopsy, and three patients who died of CRPC underwent autopsies. PCa tissues (n=54), noncancerous prostate tissues (non-PCa, n=36), were used for analysis of expression levels of miRNAs. Functional studies of differentially expressed miRNAs were analyzed using PC3 and LNCaP cell lines under CRPC conditions. The expression levels of miRNA was estimated using the Kaplan-Meier methods. In silico database and genome-wide expression analyses were performed to identify molecular targets regulated by the miRNAs. Results: (The miRNA expression signature of PCa specimens showed that the cluster miRNAs miR-224 was significantly downregulated, suggesting that this miRNA may act as tumor suppressor.) Clinical and in vitro analysis of miR-452 overexpression showed that low expression of miR-452 predicted a short duration of progression to CRPC. Restoration of miR-452 in PC3 and DU145 cells revealed significant inhibition of cancer cell migration and invasion. WW domain-containing E3 ubiquitin protein ligase-1 (WWP1) was confirmed as a direct target of miR-452 by in vitro transfection of miR-452 and Luciferase assay. Knockdown of the expression of WWP1 using siRNA showed inhibiting cell migration and invasion in PC3 and DU145 cells. Immunohistochemistry showed overexpressed WWP1 in advanced PCa. Conclusions: Loss of the tumor suppressive miR-452 enhanced migration and invasion in PCa cells. Regulation of the miR-452-WWP1 axis contributed to PCa cell migration and invasion, and elucidation of downstream signaling of this axis will provide new insights into the mechanisms of (progression to CRPC) metastasis of PCa.

**#2529** TTF-1/NKX2-1 induced miR-532-5p targets KRAS and MKL2 oncogenes and causes apoptosis in lung adenocarcinoma cells. Sebastian Griesing, Taisuke Kajino, Mei Chee Tai, Zhuanan Liu, Masahiro Nakatoh, Toshi Suzuki, Takashi Takahashi, Nagoya University Graduate School of Medicine, Nagoya, Japan; Nagoya University Hospital, Nagoya, Japan.

Our group and others have previously identified TTF-1/NKX2-1 as a lineage survival oncogene in lung adenocarcinoma. Subsequent studies revealed double-edged sword characteristic of TTF-1 in the development of lung adenocarcinoma. TTF-1 elicits lineage-survival signaling by inducing transcriptional targets such as ROR1, while TTF-1 also inhibits tumor progression by decreasing cell motility through direct activation of genes such as MYBPH. It is thus clear that a more comprehensive picture of this still enigmatic lineage-survival oncogene needs to be elucidated. Whereas most of the previous studies on TTF-1 have focused on its regulation of protein-coding genes, very little is known about regulation of microRNA by TTF-1. In the present study, we combined in vivo patient data with in vitro data from lung adenocarcinoma cell lines, aiming at identifying miRNAs, which are transcriptionally regulated by TTF-1. Our integrative approach identified miR-532-5p as a microRNA regulated by TTF-1. Expression of miR-532-5p decreased, when cell lines with a high endogenous level of TTF-1 were transfected with siRNA against TTF-1, while it was increased by overexpression of exogenous TTF-1 in TTF-1-negative cell lines. By ChIP and luciferase assays, TTF-1 was found to induce miR-532-5p expression through its binding to the MIR532 promoter region, identifying miR-532-5p as a direct target of TTF-1. We next employed microarray analysis and target prediction using TARGETSCAN to search for potential targets of miR-532-5p. We consequently identified KRAS and MKL2 as candidate targets of miR-532-5p by screening their potential mechanistic link. We found that miR-532-5p induced apoptosis and inhibited colony formation in lung adenocarcinoma cell lines, while depletion of MKL2 phenocopied the effects of miR-532-5p introduction, similarly exhibiting occurrence of marked apoptosis. In addition, miR-532-5p significantly decreased tumor formations in vivo in a mouse xenograft model. It was also of note that miR-532-5p inhibited lung adenocarcinoma cell lines regardless of the presence or absence of KRAS mutations. In summary, we have found that TTF-1 transactivates miR-532-5p, which potently induces apoptosis in lung adenocarcinoma cells. MiR-532-5p directly targets MKL2, which we have also uncovered to be crucially involved in lung adenocarcinoma survival. In addition, while previous reports have shown that TTF-1 inhibits KRAS-driven tumorigenesis, van der Vlugt-Daane et al. showed that expression of miR-532-5p provides their potential mechanistic link. Our results thus shed light on how TTF-1 plays a tumor-suppressive role in the process of lung carcinogenesis, which might ultimately lead to development of a novel therapeutic strategy for this devastating disease.

**#2530** Validation and pathway analysis of a metastasis-specific microRNA signature in primary colon cancer. Robert R. Coebergh van den Braak, Anieta S. Sweerts, Zarina S. Lalmahomed, Marcel Smid, Vanja de Wereld, Michelle van der Vlugt - Daane, Anne van Galen, Shanashp Xiang, Katharina Biermann, John A. Fockens, John W. Martens, Jan N. IJzermans. Erasmus University Medical Center, Rotterdam, Netherlands.

Introduction: In lymph node negative (LNN) colon cancer 20% of the patients develops disease recurrence. Identification of these patients is needed. Micro-
RNAs (MiRNAs), a group of short non-coding RNAs, can function as tumor suppressors or oncogenes. Hur et al recently found 6 differentially expressed MiRNAs when comparing primary colorectal cancer and matched liver metastasis (MiR-320, MiR-221, MiR-30b, MiR-10b, MiR-885-5p, Let-7i). The expression of 2 MiRNAs was significantly correlated with distant metastasis (low Let-7i expression and MiR-30b) in primary colorectal cancer patients. We identified a median and combined into a signature (Let-7i high and MiR-10b low [n = 22] vs. Let-7i low and/or MiR-10b high [n = 122]), the first group showed 100% metastasis free survival (MFS). We assessed the prognostic value of these MiRNAs and the signature in a clinically well-defined cohort of primary colon cancer. Methods: Expression of the 6 MiRNAs were measured using RT-qPCR in a cohort of 232 colorectal cancer patients. Results: The LNN group showed significantly higher expression of the EMT pathway in the Let-7i high group. MiR-30b and Let-7i expression was split at the median level and combined into two groups (‘Let-7i high and MiR-30b low’ vs. ‘Let-7i low and/or MiR-30b high’). The ‘Let-7i high and MiR-30b low’ group in the total group (n = 741) had a significantly better 5-yr MFS (100% vs 87.4% p = 0.002), and it had a significantly better 5-yr MFS (91.7% vs 78% p = 0.036) and HFS (100% vs 87.8% p = 0.01) in the LNN group (n = 52). Conclusion: In our cohort and more specifically the LNN group, we confirmed Let-7i and identified MiR-30b as a prognostic factor for MFS and HFS. We did not confirm the prognostic value of MiR-10b. The combination of Let-7i and MiR-10b identified a group with a 100% HFS. Pathway analysis showed higher expression of the TGF-beta pathway in the MiR-30b high group, and a significantly higher expression of the EMT pathway in the Let-7i high group. MiR-30b and Let-7i expression was split at the median level and combined into two groups (‘Let-7i high and MiR-30b low’ vs. ‘Let-7i low and/or MiR-30b high’). The ‘Let-7i high and MiR-30b low’ group in the total group (n = 741) had a significantly better 5-yr MFS (100% vs 87.4% p = 0.002), and it had a significantly better 5-yr MFS (91.7% vs 78% p = 0.036) and HFS (100% vs 87.8% p = 0.01) in the LNN group (n = 52). Conclusion: In our cohort and more specifically the LNN group, we confirmed Let-7i and identified MiR-30b as a prognostic factor for MFS and HFS. We did not confirm the prognostic value of MiR-10b. The combination of Let-7i and MiR-10b identified a group with a 100% HFS. Pathway analysis showed higher expression of the TGF-beta pathway in the MiR-30b high group, and a significantly higher expression of the EMT pathway in the Let-7i high group.

#2531 Regulation of androgen signaling axis and tumor suppressive function of miR-149-5p in prostate cancer. Savita Singh,1 Jey Sahith Ebron,2 Eswar Shankar,2 Sanjan Gupta,2 Daniel Lindner,2 Girish Shukla1. 1Cleveland State University, Cleveland, OH. 2Case Western Reserve University & University Hospitals Cleveland Medical Center, Cleveland, OH; 3Taussig Cancer Center, Learner Research Institute, Cleveland, OH.

Prostate cancer growth and proliferation depends on androgen signaling mediated by transactivation of Androgen Receptor (AR). Androgen ablation remains the mainstay therapy for treatment of the disease. However, despite androgen ablation, the disease relapses to more aggressive form known as castration-resistant prostate cancer (CRPC). Androgen Signaling Inhibitor such as Abiraterone Acetate and Enzalutamide are the main effective treatment methods currently being used to treat CRPC. However, more than one-third of CRPC patients develop resistance to these treatments, mostly due to the gain of function in the AR protein and increase in intratumoral dihydrotestosterone (DHT) synthesis. Intratumoral DHT synthesis from steroid precursors in tumors is augmented by up-regulation of enzymes of cholestero genesis and steriodogene sis, such as HMG-CoA reductase, SCAR81, and 17βHSD respectively. Tumor-specific downregulation of microRNAs which regulate the AR and steroid biosynthesis has been implicated in tumor growth and resistance to therapeutics in CRPC. We are focusing on tumor suppressive role of miR-149-5p in CRCA. We discovered that miR-149-5p expression was significantly lower in prostate cancer tissues compared to normal tissues. The mechanistic investigation revealed that miR-149-5p regulates wild type and alternatively spliced variant of AR. It also down regulates the expression of SCAR81, HMGCoA and HMG-CoA reductase, the proteins known to facilitate intratumoral DHT synthesis. Ectopic expression of miR-149-5p negatively regulated the expression of prostate specific antigen, a downstream target of androgen signaling and it also inhibited invasion and proliferation of CRPC cells. Our findings indicate a significant role of miR-149-5p in regulating androgen signaling and possibly DHT synthesis in CRPC. This provides a strong rationale for further investigating the significance of miR-149-5p for generation of new therapeutic for CRPC.

#2532 High expression of MiR-432-3p is associated with the chemoresistance by NFR2 stabilization via directly targeting KEAP1. Burak Akdemir,1 Jun Inoue,1 Tatsuyuki Kawano,2 Joji Inazawa,1 1Department of Molecular Cyto genetics, Tokyo Medical and Dental University, Tokyo, Japan; 2Department of Espohageal and General Surgery, Tokyo Medical and Dental University, Tokyo, Japan.

NF-E2-related factor 2 (NRF2) is a master transcriptional regulator that integrates cellular stress responses and is negatively regulated by Kelch-like ECH-associated protein 1 (KEAP1) at the post-translational level. In human cancers, aberrantly stabilized NRF2, either by mutation of NRF2 or KEAP1, plays a vital role in chemoresistance through the activation of target genes, suggesting that targeted inhibition of NRF2 is a potential therapy for NRF2-stabilized tumors. MicroRNAs (miRNA) are endogenous small noncoding RNAs that can negatively regulate gene expression by interfering with the translation or stability of target transcripts. Previously, we identified miRNAs negatively regulating NRF2 pathway via directly targeting NRF2 itself by a reporter-coupled miRNA library screening and demonstrated the potential of miRNA-based therapy against NRF2-stabilized tumors in esophageal squamous cell carcinoma (ESCC) (Mot Cancer Res 2014, Cancer Res 2015). In the present study, we further identified miR-432-3p as a miRNA positively regulating NRF2 pathway. MiR-432-3p could directly targeted KEAP1 via binding to its seed sequence within the coding region. Overexpression of miR-432-3p resulted in enhanced resistance to cisplatin via activation of NRF2 in ESCC cell lines. Furthermore, miR-432-3p was also used as control to show that overexpression of corresponding non-cancerous esophageal mucosa (65.5%). Importantly, we showed the negative correlation between the expression level of KEAP1 and miR-432-3p in primary ESCC tumors. Taken together, these findings suggest that the high expression of miR-432-3p may contribute to the chemoresistance by NRF2 stabilization via down-regulation of KEAP1 expression in ESCC.

#2533 miRNA expression as potential biomarker for synvalcoraloma. Laura Pazzaglia, Serena Pollino, Mattia Vitalé, Amalia Conti, Piero Picci, Maria Serena Benassi, Istituto Ortopedico Rizzoli, Bologna, Italy.

Synvalcoraloma (SS) is a rare tumor, with dismal survival when metastatic. SS contains a characteristic translocation (X;18)(p11;q11), representing the fusion of SYT on chromosome 18 with either SSX1, SSX2, or rarely SSX4 on chromosome X. The resulting fusion genes appear to be mutually exclusive and concordant in primary and metastatic tumours. New prognostic and predictive factors are needed. Chemokine receptor 4 (CXCR4) is a seven-transmembrane G protein–coupled chemokine receptor and it is the chemokine receptor most commonly expressed in tumour cells, involved in cell migration and invasion, as well as angiogenesis. microRNAs (miRNAs) are involved in post-transcriptional gene expression regulation and control important physiological processes like development, cell differentiation and cell signaling. Altered expression of SOX2 is strongly correlated with the malignant phenotype and there is data showing the negative correlation between the expression level of SOX2 and miRNA-432 expression in synvalcoraloma tissues compared with the corresponding non-cancerous esophageal mucosa (65.5%). Importantly, we showed the negative correlation between the expression level of SOX2 and miR-432-3p in primary ESCC tumors. Taken together, these findings suggest that the high expression of miR-432-3p may contribute to the chemoresistance by NRF2 stabilization via down-regulation of KEAP1 expression in ESCC.
SS. Correlation with clinical data, with CXCR4 expression and in vitro studies also with miR-494 in several SS cell lines are on-going to better investigate their role as potential prognostic and therapeutic markers.

#2535 MicroRNA-518c-5p promotes the metastasis of oral cancer. Makoto Kinouchi, Daisuke Uchida, Nobuyuki Kuribayashi, Yuske Komiyama, Shuji Tsuchida, Hitoshi Kawamata. Dokkyo University School of Medicine, Tochigi, Japan.

We have demonstrated that CXCR4 system is involved in the metastatic process of oral cancer. Recently, we identified the miR-518c-5p as a downstream target of the CXCR4 system. In this study, we examined the function of miR-518c-5p on the metastasis of oral cancer. We transfected miR-518c expression vector into oral cancer cells, B88 and CAL27, and isolated stable transfectants, B88-518c and CAL27-518c, respectively. The growth and migration of both cells were significantly enhanced in compared with those of mock cells. LNA-based miR-518c-5p inhibitor significantly impaired the enhanced cell growth and migration of these cells, indicating that these phenomena were dependent on the expression of miR-518c-5p, not on that of miR-518c-3p. Next, we examined the function of miR-518c-5p in vivo. miR-518c or mock transfectants were inoculated into the masseter muscle or the blood vessels of nude mice. Tumor volume, lymph nodes metastasis, and lung metastasis were significantly increased in the mice inoculated with miR-518c transfectants. Furthermore, we examined the mRNA expression induced by miR-518c-5p using B88 cells and B88-518c cells by cDNA microarray analysis. Consequently, some of the genes involved in the cell growth and metastasis were upregulated in the B88-518c cells. These results indicate that CXCR4 system regulates the metastases of oral cancer via induction of miR-518c-5p.

#2536 miR-187-5p and miR-219a-1-3p: potential biomarkers associated with chemotherapeutic response and prognosis in ovarian cancer. Chia-Yen Huang,1 Hsien-Da Huang2.

We identified the most significant altered miRNAs between different groups of patients of chemotherapy response. We then used Kaplan-Meier and log-rank methods to analyze the relationship between these miRNAs and progression-free and overall survival in TCGA (n = 460) and Bagnoli (n = 130) datasets. In vitro study for response to chemotherapy agents were performed in human ovarian cancer cell lines and their transfectants. The biological relevance of putative miRNA targets was also analyzed using bioinformatics. Results: MiR-187-5p and miR-219a-1-3p were associated with better response to chemotherapy and longer progression-free and overall survival in two independent epithelial ovarian cancer patient cohorts (all p <0.05). These two miRNAs also sensitized ovarian cancer cells to chemotherapy, thus recapitulating the clinical observation. Conclusions: This study showed that miR-187-5p and miR-219a-1-3p could be useful biomarker for prediction of chemotherapy response and survival in serous ovarian cancers. MiR-187-5p and miR-219a-1-3p may be potential molecules in the treatment of EOC for sensitizing cancer cells to chemotherapy.

#2537 MicroRNA targeting anti-apoptotic and G2/M pathways as therapeutic targets for castration resistant prostate cancer. Pheruza Tarapore,1 Sarah To,2 Bin Ouyang,3 Yuet-Kin Leung,4 Ana Cheong,1 Shuk-meI Ho.1 1University of Cincinnati, Cincinnati, OH; 2Hudson Institute of Medical Research, Melbourne, Australia.

Prostate cancer (PC) is one of the most common cancers in men. Unfortunately, limited treatment options currently exist for those who have developed advanced castration-resistant PC (CRPC). G-1 is a GPER1/GPR30 agonist, and a promising candidate for CRPC therapy. G-1 is effective in halting the growth of CR tumors but not those grown in intact hosts. These findings suggest GPER1 is a therapeutic target for CRPC. We found that G-1, through activation of GPER1, inhibited growth of CRPC cells via cell-cycle arrest at the G2-M phase, probably leading to mitotic catastrophe. However, the exact mode of action of G-1 was not known. To better understand the pathways involved in G-1 action, we conducted a genome-wide mRNA-seq and miRNA-seq study on G-1 treated xenografts. We identified a panel of novel G-1-associated tumor suppressive miRNAs and genes. Moreover, Ingenuity Pathway Analysis revealed that the G-1 differentially regulated genes are involved in “Cellular Growth and Proliferation”, “endocrine function” and “Cancer” pathways. We validated the expression of the key miRNA (miR-34c, miR-10b, miR-138 and miR218) and genes in G-1 treated castration resistant xenografts and cell lines (C4-2 and 22Rv1). Furthermore, we have shown the tumor suppressor function of these miRNAs in cell survival and apoptosis. The predicted target gene set was examined for decreased expression by qRT-PCR. We confirmed decreased expression of some of the downstream targets, which consist of genes involved in cell cycle regulation (CCNA and CCND, CDK1, CDK4, PLK1), cell survival (Bcl2, Survivin), cell migration/F-actin formation (LAP5, PCDH7, ITGA9, ROBO1, SLIT1) and G2/M checkpoint (CDK1, PLK1, BCL-2 Survivin). Thus these miRNAs - miR-34c, miR-10b, miR-138 and miR218 - are ideal candidates for therapy of CRPC.

#2538 MiR-638 promotes autophagy and malignant phenotypes of cancer cells via directly suppressing DACT3. Ming Yang, Shandong Cancer Hospital and Institute, Jinan, China.

Autophagy is implicated in human cancers and the mechanistic details remains largely unclear. Herein we report the regulatory role of miR-638 in autophagy of esophageal squamous cell carcinoma (ESCC) and breast cancer cells. We found that miR-638 overexpression promotes starvation- and rapamycin-induced autophagy. In ESCC and breast cancer cells, miR-638 acts as an oncogene and promote cell proliferation, migration, as well as invasion in vitro and in vivo. In accordance with this, we observed significantly higher miR-638 expression in ESCC and breast cancer tissues compared to normal tissues. To further elucidate regulatory mechanisms of miR-638 in autophagy, we performed a computational nomination of its target genes through intersecting the results of multiple prediction algorithms. DACT3, a key regulator of Wnt/b-catenin signaling, was predicted to be regulated by miR-638 by all programs and confirmed by experimental results. Depletion of DACT3 phenocopied effects of miR-638 overexpression, demonstrating its importance in autophagy. These results elucidate that the miR-638-DACT3 axis might be an important molecular pathway in controlling and autophagy and tumorigenesis. Our data in clinical tissue samples highlight miR-638 and DACT3 with histological marker for cancer detection and potentially therapeutic implications.

#2539 MiR-96-5p functions as an oncogenic miRNA by inhibiting apoptosis in hepatocellular carcinoma. Naoto Iwai, Kohichiroh Yasui, Akira Tomie, Kei Teasaki, Tomoko Kitaichi, Osamu Dohi, Yasuyuki Gen, Yoshito Ito. Kyoto Prefectural University of Medicine, Kyoto, Japan.

Hepatocellular carcinoma (HCC) is one of the most aggressive cancers with high mortality worldwide. MicroRNAs (miRNAs) are small non-coding RNAs that have been used as cancer-related biomarkers and expected to be therapeutic agents. We performed genome-wide miRNA expression profiling of paired HCC tumors and non-tumorous liver tissues from patients with primary HCCs using the miRNA microarray (Agilent). We found that miR-96-5p was most significantly up-regulated in HCC tumors compared to non-tumor tissues. Although miR-96-5p is suggested to be an oncogenic miRNA, the function of miR-96-5p remains largely unknown. We identified the caspase-9 gene (CASP9) as a novel target of miR-96-5p. The predicted target gene FOXO1 is the known target of it. Caspase-9 protein is thought to play a central role in apoptosis and to be a tumor suppressor. Overexpression of miR-96-5p decreased caspase-9 protein expression and resulted in resistance to apoptosis induced by doxorubicin and UV in HCC cells. Our results suggested that miR-96-5p functions as an oncogenic miRNA by inhibiting apoptosis through decreasing caspase-9 expression in HCC.

#2540 miR-196b as a potential biomarker for human esophageal cancer. Xiaohui Tan,1 Tao Chen,2 Robert Siegel,3 Sidney Fu. 1 *George Washington Univ., Washington, DC; 2Chengdu Military General Hospital, Chengdu, China.

Esophageal cancer is the sixth most common cause of cancer related death. Although multiple genetic and epigenetic alterations have been detected in esophageal cancer, molecular markers for early diagnosis and prediction of prognosis or treatment responses are quite limited. microRNA (miRNA) is a class of small-regulatory non-coding RNA, acting as either a tumor suppressor or oncogene by regulating gene expression through pairing with complementary seed of the targeted messenger RNAs (mRNA). A number of miRNA expression profiling studies have been conducted in esophageal. In our current study, we analyzed the most recent studies on miRNAs expression profiles in esophageal cancer. Consistently dysregulated miRNAs have been identified in esophageal cancer, including upregulation of miR-196b, miR-135a, and down-regulation of miR-141, miR-200a-5p, miR-200b-3p, miR-27b, miR-210. We first assessed expression of miRNAs in esophageal cancer cell lines and primary
esophageal cancer tissues by real-time reverse transcriptase-polymerase chain reaction (qRT-PCR). Significantly overexpressed miR-196b was observed in human esophageal squamous cell carcinoma KYSE-70 and KYSE-180 compared with normal esophageal squamous cell line, HET-1A. Furthermore, overexpression of miR-196b was detected in 12 out of 14 (86%) cancer tissues compared to the matched normal tissues. Forced expression of miR-196b promotes the proliferation and invasion in esophageal cancer cell lines. TargetScanS and miRanda were used to identify the target genes of miR-196b. A list of target genes were predicted, including GATA6, ARHGAP28, E3P15 and EPJAH7. Forced expression of miR-196b resulted in significant downregulated E3P15 and EPJAH7 expression in esophageal cancer cell lines. Our present work suggested that miR-196b acts as an oncomir by regulating EPJAH7 and EPJAH7. Therefore, miR-196b could be used as a biomarker for esophageal cancer.

### #2541 Two miR-34 loci, miR-34a and miR-34b/c, have differential anti-cancer effects in lung adenocarcinomas.

Jeong Seon Kim, Young-Ho Ahn. Ewha Womans University College of Medicine, Seoul, Republic of Korea.

Three miR-34 family members (miR-34a, miR-34b, and miR-34c) are clustered on two different chromosomal loci, miR-34a and miR-34b/c, and have identical seed-sequences predicted to target the same set of genes; however, miR-34a and miR-34c have different sets of negatively correlated genes in TCGA data of human lung adenocarcinomas. Therefore, we hypothesized that miR-34a family members, which are tumor suppressive miRNAs, might have differential effects on lung tumorigenesis. To prove this, we overexpressed each miR-34 cluster, miR-34a and miR-34b/c, in murine lung cancer cells. miR-34b/c enhanced cancer cell attachment and suppressed cell growth and invasion compared with miR-34a. In the xenograft model, both miR-34a and miR-34b/c blocked lung metastasis; whereas, miR-34b/c suppressed tumor growth more than miR-34a. miR-34b/c also decreased mesenchymal markers (Cdh2 and Fn1), and increased epithelial markers (Inadl, Grb3, Ocn, and Dsp) and miR-200 family members better than miR-34a, implying that miR-34b and miR-34c partially inhibit EMT. Furthermore, miR-34b and miR-34c are more effective tumor suppressors than miR-34a.

### #2542 MS12 binds lncRNAs and promotes self-renewal and oncogenesis through MYC expression.

Backgrounds and Aims: RNA-binding protein MS12 is elevated in several cancers and is linked to poor prognosis. Here, we sought to elucidate the role of MS12 in regulating the expression of proto-oncogenes or tumor suppressor genes in hepatocellular carcinoma (HCC). Methods: We performed RIP-seq using anti-MS12 antibody in tumor-initiating stem-like cells (TICs) and subsequent validation by qPCR analysis. Results: Among the MS12-bound RNAs, MYC mRNA and long non-coding RNA (lncRNA) miR22 host gene (MIR22HG) and Marat1 were identified in RIP-qPCR analysis. Furthermore, MARAT1 binding derepresses polycomb repressor to recruit E2F1 in MYC promoter regions. It is known that the 5’-untranslated region of MYC contains an internal ribosome entry sequence (IRES) which allows IRES-dependent translation initiation along with canonical cap-dependent mechanisms. Our data show that MS12 acts as an IRES trans-acting factors for MYC mRNA translation. MS12 does not have any effect on the steady state level of MYC mRNA but significantly increases MYC protein levels, indicating that MS12 regulates MYC at the post-transcriptional level. Further, we observed that MS12 reduced the level of mature miR22 derived from MIR22HG processing. We showed that miR22 suppresses the expression of MYC through a 3' UTR dependent process. Overexpression of MS12 promotes TIC self-renewal and tumor initiation property in xenograft tumor mouse models, whereas silencing MS12 reduces this occurrence. Conclusion: We demonstrate that MS12 promotes liver tumorigenesis by maintenance of MYC expression through derepression of polycomb repressor and an IRES-dependent translation mechanism and possibly by inhibition of miR22 processing. Thus, MS12 may be a useful prognostic factor for HCC and MS12 targeted therapy and thus may be beneficial in the treatment of HCC patients.

### #2543 The novel long non-coding RNA TALNEC2 regulates tumor cell growth and the stenness and radiation response of glioma stem cells.

Wei Jiang,1 Shlomit Brodie,2 Simona Cazacu,1 Gunli Xiang,1 Laila Poisson,1 Steve Kalkanis,1 Doron Ginsburg,1 Chaya Brodie,1 1Henry Ford Hospital, Detroit, MI; 2Bar-Ilan University, Ramat Gan, Israel.

Despite advances in novel therapeutic approaches for the treatment of glioblastoma (GBM), the median survival of 12-14 months has not changed significantly. Therefore, there is an imperative need to identify molecular mechanisms that play a role in patient survival. Here, we analyzed the expression and functions of a novel lncRNA, TALNEC2 that was identified using RNA seq of E2F1-regulated lncRNAs. Besides, we utilized the knock-down of this lncRNA expression model in the GSCs, and the loss of TALNEC2 was E2F1-regulated and cell-cycle dependent. TALNEC2 was highly expressed in GBM with poor prognosis, in GBM specimens derived from short-term survivors and in glioma cells and glioma stem cells (GSCs). Silencing of TALNEC2 inhibited cell proliferation and arrested the cells in the G18 phase of the cell cycle in various cancer cell lines. In addition, silencing of TALNEC2 decreased the self-renewal and mesenchymal transformation of GSCs. In conclusion, we identified a novel E2F1-regulated lncRNA that is highly expressed in GBM and in tumors from patients of short-term survival. The expression of TALNEC2 is associated with the increased tumorigenic potential of GSCs and their resistance to radiation. We conclude that TALNEC2 is an attractive therapeutic target for the treatment of GBM.

### #2544 The lncRNA Meg3 acts as an epigenetic determinant of oncogenic signaling in multiple endocrine neoplasia type 1.

Sacharuth Iyer, Sunita Agarwal. National Institutes of Health, Bethesda, MD.

Loss of tumor suppressors and gain of oncogenic properties is a hallmark of cancer. But the pathways leading to tumor formation are poorly understood. A good example is the multiple endocrine neoplasia type 1 (MEN1) syndrome, in which patients inherit germline mutations in the MEN1 gene, predisposing to tissue-specific loss of the encoded tumor suppressor protein menin. Consequently, tumors develop in multiple endocrine organs - the pituitary, the parathyroids, and the duodeno-pancreatic tissues, including pancreatic neuroendocrine tumors (PNETs). In-silinomas are the most common type of functioning PNETs that also occur in MEN1 patients. We investigated the molecular pathways associated with in-silinomas. We previously showed that menin loss downregulated Maternally Expressed Gene 3 (MEG3), a long non-coding RNA (lncRNA), by eliciting promoter hypermethylation along with the loss of Histone H3 lysine 4 trimethylation (H3K4me3). Gene expression microarray analyses and RT-PCR, of mouse in-silinoma MIN6 cells stably transfected with Meg3, showed a 5-fold decrease in the proto-oncogenic signaling receptor c-Met, suggesting a tumor suppressor function for Meg3. We also found MEG3 downregulation with concurrent upregulation of c-MET in PNETs. However, the molecular underpinnings of MEG3 governed c-MET repression remain elusive. To identify the mechanisms by which MEG3 inhibits oncogenic c-MET signaling to suppress tumorigenesis, we examined the effect of various in-silinoma isofoms, explored Meg3 association with the epigenetic regulatory machinery, and RNA-DNA triplex formation. We provide direct evidence for the first time that ectopically expressed MEG3 isofoms could attenuate the highly abundant c-Met transcript. MIN6 in-silinoma cells also interacted with c-MET repression of the epigenetic machinery, such as the Polycomb Repressive Complex 2 (PRC2) protein conglomerate, to regulate c-MET RNA expression. Additionally, analyses of triplex forming oligos (TFOs) in MIN6 cells revealed that tripe helix formation between Meg3 and dsDNA could potentially disrupt c-Met transcription. Combined, these data offer mechanistic insight into the dysregulation of c-MET repression in PNETs, and support the conclusion that MEG3 acts as an important determinant of oncogenic signaling in MEN1-associated endocrine tumor cells (in-silinomas). These findings warrant further investigation into the tumorigenic pathways that may result from the loss of tumor suppressor MEG3 and gain of oncogenic c-MET signaling in other MEN1-associated endocrine tumors.

### #2545 Upregulated lncRNA HNGA1, a target of miR-378a, contributes to aerobic glycolysis of head and neck squamous cell carcinoma through increasing levels of the C-C chemokine receptor type 7 (CCR7).

Yun Wang, Sun-Yat-sen University, Guangzhou, China.

Introduction: Long non-coding RNAs ( IncRNAs) have been regarded as key regulators in aerobic glycolysis of human cancer. However, the role and function of IncRNAs in Head and Neck Squamous Cell Carcinoma (HNSCC) aerobic glycolysis remain unclear. Here, we report a novel IncRNA, HNGA1, which could promote HNSCC aerobic glycolysis and malignancy by competing for miR-378a binding to regulate CCR7. Materials and methods: Microarrays were performed to explore the IncRNA/miRNA profiles in tissues samples. qRT-PCR and functional analysis were used to confirm the expres-
tion and role of IncRNA/miRNA. Bioinformatics approach and luciferase assay were used to verify the miRNA target gene and the interaction between IncRNA and miRNA. Nude mouse model was utilized to observe the effect of IncRNA/miRNA in vivo. Tissue array was performed to explore the association between IncRNA and postoperative survival. Results: 1. IncRNA HNSCC glycosylation-associated 1 (HNGA1) was up-regulated in tumor tissues, while miR-378a was down-regulated significantly. These observations were confirmed in 60 pairs of HNSCC tissues/non-tumor tissues samples and 7 cohorts of HNSCC cell lines. 2. Silencing of HNGA1 inhibited HNSCC cells proliferation and glycolysis, while overexpression of HNGA1 had the opposite effect. 3. Ectopic expression of miR-378a repressed HNSCC cells proliferation and glycolysis, whereas miR-378a inhibition resulted in opposite effect. MiR-378a could repress the CCR7 expression by binding to the 3'-UTR region of CCR7 directly. 4. There was an inverse correlation between HNGA1 and miR-378a in HNSCC specimens. Moreover, miR-378a suppressed HNGA1's expression and function by directly binding to HNGA1. In addition, HNGA1 could reverse the inhibitory effect of miR-378a on HNSCC cell growth and glycolysis, while HINGA1 could accelerate this process. 6. The clinicopathological findings suggested that the up-regulation of HNGA1 in HNSCC patients was associated with the poorly differentiated degree and more metastasis. Moreover, the above-identified mechanisms were strongly supported by the above-identified mechanisms. Combined analysis of these data highlights the pivotal role of HINGA1 in HNSCC aerobic glycolysis. More importantly, we elucidate a novel IncRNA-miRNA-mRNA regulatory network that is HINGA1-miR-378a-CCR7 axis in HNSCC malignancy and progression.

#2546 The long noncoding RNA SChLAP1 inhibits the SWI/SNF complex, revealing a therapeutic opportunity in prostate cancer. Julia Dan- court,1 Antonio Bala,1 John R. Premont,1 Benjamin Chandler,1 Dori G. compounds with metastatic and lethal disease. SChLAP1 enhances cell invasiveness in part by interacting with and abrogating genome-wide binding of the tumor-suppressive SWI/SNF complex. Approximately 20% of all cancers harbor a mutation in SWI/SNF, and several recent studies have identified therapeutic opportunities arising from SWI/SNF inactivation. We hereby investigate the relationship between SChLAP1 and SWI/SNF and its potential therapeutic implications. Methods: In silico data mining was used to correlate the SWI/SNF complex mutation frequency with SChLAP1 expression in prostate cancer samples. A systematic tilting deletion approach was then used to map important domains on the SChLAP1 gene. In vitro migration and invasion assays as well as cell proliferation assays were used to quantify phenotypes associated with over-expression of SChLAP1 and its deletion mutants. Moreover, CHIP was used to study the influence of SChLAP1 on the genomic binding of SWI/SNF. Results: In prostate cancer samples, SWI/SNF mutations correlate with low SChLAP1 expression while high SChLAP1 expression may represent a mutation-independent modality of SWI/SNF inhibition. We identify a 250 nucleotide region necessary for SChLAP1 to bind to SWI/SNF and to confer invasiveness to a prostate epithelial cell line. Further studies suggest that SChLAP1 inhibition is selective for the BRG1-containing SWI/SNF sub-complex, inferring potential genomic specificity. Moreover, we show that SChLAP1 over-expression is associated with enhanced sensitivity to BRM knockdown, in accordance with the BRG1/BRAF synthetic lethality previously described in BRG1-deficient cancers. Conclusions: Our findings indicate that SChLAP1-mediated SWI/SNF inhibition may function similarly to SWI/SNF mutation, exposing similar therapeutic opportunities.

#2547 Discovery and characterization of late-stage breast cancer estrogen receptor alpha 1 bound long non-coding RNAs. Jessica Monique Silva-Fisher,1 Amanda Y. Han,1 John R. Premont,1 Benjamin Chandler,1 Dori G. Cheng,1 Meng Chen,1 Ondrej Slaby,1 Ayaj Goel,1 Milan Radovich,2 George Calin1,1 MD Anderson Cancer Center, Houston, TX; 2Masaryk University, Czech Republic; 3Baylor University Medical Center, TX; 4Indiana University School of Medicine, TX.

The clinical significance of long noncoding RNAs (IncRNAs) in colorectal cancer (CRC) remains largely unknown. We analyzed a large panel of cancer-associated IncRNAs in 483 TCGA CRC cases, and identified that H19 correlates most significantly with overall survival and disease-free survival, independent of stage and other clinical parameters. We validated the TCGA findings with two additional CRC cohorts. As one of the “oldest” IncRNAs, diverse activities of H19 including interaction with epigenetic regulators, regulation of microRNAs as competing endogenous RNA (ceRNA), and production of miR-675 as a primary transcript have been reported. However, an unbiased study to clarify the essential mechanisms of H19 is lacking. To decipher the functional involvement of H19 in CRC, we used an integrative approach combining unbiased microarray analysis, experimental validation, and bioinformatic analysis of clinical data. With such approach, we revealed not only previously reported mechanisms such as the ceRNA and miRNA regulatory ceRNA mechanism, but also several novel mechanisms that have not been appreciated before. We discovered a mechanism of H19 on regulating BR-E2F signaling and accordingly controlling cell cycle progression. We also identified for the first time that H19 regulates CDK8, an oncoprogenic driver in CRC pathogenesis, and consequently affects β-catenin activity (Firestein et al., Nature, 2008). We further identified an interaction of H19 with macroH2A, a histone variant reported to repress CDK8 transcription (Kapoor et al., Nature, 2010). Importantly, expression correlation analysis with clinical samples strongly supported the above-identified mechanisms. Combined analysis of H19 with its targets showed strong independent prediction power for CRC survival. These data indicate the clinical relevance of BR-E2F and CDK8/β-catenin signaling in mediating H19’s oncogenic activity in CRC.

Breast cancer (BC) is the second most common newly diagnosed cancer and the second leading cause of cancer death among women in the United States. Despite the proven benefits of adjuvant endocrine therapy in women with hormone receptor positive BC, relapses still occur even after initial treatment with endocrine therapy for 5 years, referred to as late-stage relapse. Long non-coding RNAs (lncRNAs) have been shown to be dysregulated in breast cancer. Recent studies have also shown IncRNAs to function by interfacing with corresponding RNA binding proteins to play critical regulatory roles of diverse cellular processes. Therefore, we hypothesize that IncRNAs may interact with ER to promote genes promoting late-stage relapse. To address this, we aimed to identify IncRNAs bound to the estrogen receptor alpha 1 protein (ESR1) that promote late-stage relapse. We first used transcriptome sequencing to identify altered expression levels of IncRNAs between 72 primary tumors and 24 late-stage relapse breast cancer patients. We detected 1192 altered IncRNAs when comparing the metastatic to the primary samples (FDR <0.05). Next, to identify ESR1 bound IncRNAs associated with late-stage BC, we conducted RNA Immunoprecipitation Sequencing of all transcripts bound to ESR1 as compared to an IgG control in the ER+ T47D cell line. We identified 217 IncRNAs bound to ESR1 of which 50 were up-regulated in late-stage BC, termed Late-Stage Relapse BC ESR1-bound IncRNAs (LASERs). Next, we focused on characterizing the most up-regulated differentially expressed IncRNA, LASER1. We found that LASER1 has increased expression in ER+ breast cancer cell lines. Further, elevated expression of LASER1 was also detected in MCF7 long-term hormone deprived breast cancer cells, which might act as an endogenous ‘sponge’ by competing for miR-378a binding to regulate CCR7. The xenograft mouse model unveiled the suppressive effects of miR-378a on HNSCC tumor growth and glycolysis, while HINGA1 could accelerate this process. The 6. The clinicopathological findings suggested that the up-regulation of HINGA1 in HNSCC patients was associated with the poorly differentiated degree and more metastasis. Moreover, the above-identified mechanisms were strongly supported by the above-identified mechanisms. Combined analysis of these data highlights the pivotal role of HINGA1 in HNSCC aerobic glycolysis. More importantly, we elucidate a novel IncRNA-miRNA-mRNA regulatory network that is HINGA1-miR-378a-CCR7 axis in HNSCC malignancy and progression.

#2548 Oncogenic function and molecular mechanism of H19 noncoding RNA in colorectal cancer. Hui Ling1, Masahisa Ohtsuka,2 Cristiana Ivan,3 Marin Pichler,1 Meng Chen,1 Ondrej Slaby,1 Ayaj Goel,1 Milan Radovich,2 George Calin1,1 MD Anderson Cancer Center, Houston, TX; 2Masaryk University, Czech Republic; 3Baylor University Medical Center, TX; 4Indiana University School of Medicine, TX.

The clinical significance of long noncoding RNAs (IncRNAs) in colorectal cancer (CRC) remains largely unknown. We analyzed a large panel of cancer-associated IncRNAs in 483 TCGA CRC cases, and identified that H19 correlates most significantly with overall survival and disease-free survival, independent of stage and other clinical parameters. We validated the TCGA findings with two additional CRC cohorts. As one of the “oldest” IncRNAs, diverse activities of H19 including interaction with epigenetic regulators, regulation of microRNAs as competing endogenous RNA (ceRNA), and production of miR-675 as a primary transcript have been reported. However, an unbiased study to clarify the essential mechanisms of H19 is lacking. To decipher the functional involvement of H19 in CRC, we used an integrative approach combining unbiased microarray analysis, experimental validation, and bioinformatic analysis of clinical data. With such approach, we revealed not only previously reported mechanisms such as the ceRNA and miRNA regulatory ceRNA mechanism, but also several novel mechanisms that have not been appreciated before. We discovered a mechanism of H19 on regulating BR-E2F signaling and accordingly controlling cell cycle progression. We also identified for the first time that H19 regulates CDK8, an oncoprogenic driver in CRC pathogenesis, and consequently affects β-catenin activity (Firestein et al., Nature, 2008). We further identified an interaction of H19 with macroH2A, a histone variant reported to repress CDK8 transcription (Kapoor et al., Nature, 2010). Importantly, expression correlation analysis with clinical samples strongly supported the above-identified mechanisms. Combined analysis of H19 with its targets showed strong independent prediction power for CRC survival. These data indicate the clinical relevance of BR-E2F and CDK8/β-catenin signaling in mediating H19’s oncogenic activity in CRC.

#2549 A long non-coding RNA regulates the androgen receptor and mediates prostate cancer progression. Sethuramasundaram Pitchaiya, Rohit Malik, Marcin Cieslik, Yajia Zhang, Xia Jiang, Arul M. Chinnaiyan. Univ. of Michigan Comp. Cancer Citr., Ann Arbor, MI.

The pervasive expression of long non-coding RNAs (lncRNAs) and their roles in a plethora of cellular processes has revolutionized our understanding of functional genetic elements. Emerging evidence suggest that lncRNAs are promising cancer biomarkers and dysregulation of IncRNAs results in attenuated or accelerated oncogenic phenotypes. In support of these findings, recent reports from the Chinnaiyan lab suggest that lncRNAs can potentially drive and act as independent predictors of aggressive prostate cancer (PCA). Central to PCA progression is the androgen receptor alpha 1 bound long non-coding RNAs. Jessica Monique Silva-Fisher,1 Abdallah M. Eteléb,1 Torsten Nielsen,1 Charles M. Perou,1 Jorge S. Reis-Filho,1 Matthew I. Ellis,2 Elaine R. Mardis,2 Christopher A. Habel,2 Washington University School of Medicine, St. Louis, MO; 3Vancouver Hospital & Health Sciences Centre, British Columbia, Canada; 4University of North Carolina, NC; 5Memorial Sloan Kettering, NY; 6Baylor College of Medicine, TX; 7Nationwide Childrens Hospital, OH.
The biological function of long noncoding RNAs (lncRNAs) is only partially understood. We investigated the expression of the novel HOXA11 antisense (HOXA11as) lncRNA and its oncogenic role in serous ovarian cancer (SOC). HOXA11as expression was examined in 129 serous ovarian cancer tissue samples by real time RT-PCR. Clinicopathologic factors and patient survival were compared. HOXA11as expression was significantly higher in TNM stage III (N = 102). To investigate the role of HOXA11as in cell proliferation, invasion, and migration, HOXA11as expression in ovarian cancer cells was knocked down using RNA interference. HOXA11as expression in cancer tissue was 77-fold higher than that of noncancerous tissue (P < 0.05). Higher HOXA11as expression significantly correlated with histologic grade (P = 0.017) and preoperative CA125 (P = 0.048). HOXA11as overexpression in SOC cells led to increased cell proliferation, invasion, and migration. In addition, HOXA11as was associated with the expression of genes that involve in cell proliferation, invasion, and migration. Moreover, Knockdown of HOXA11as decreased the expression of vascular endothelial growth factor, matrix metalloproteinase-9 and epithelial-mesenchymal transition (EMT), which are important for cell motility and metastasis. Mechanistic investigation revealed that Notch1, Hes1 and p300 proteins could be inhibited by HOXA11as depletion. In multivariate analysis, HOXA11as was a prognostic factor of progressive disease and mortality (HR = 1.730, 2.170 and P = 0.043, 0.035, respectively). Progression-free and overall survival were significantly shorter in patients with high HOXA11as expression. These findings highlight the clinical significance of HOXA11as in predicting the prognosis of SOC patients and suggest its potential in promoting tumor aggressiveness by regulation of the Notch signaling pathway and EMT-related mechanisms.

MOLECULAR AND CELLULAR BIOLOGY / GENETICS: MacroRNAs and Other Noncoding RNAs as Tumor Suppressors or Oncogenes

The functional significance of lncRNA as microRNA sponge is emerging. Here we provide evidence of a lncRNA-miRNA interaction network in ovarian cancer. HOXA11 antisense (HOXA11as) lncRNA and its oncogenic role in serous ovarian cancer (SOC) was investigated. HOXA11as expression was significantly higher in TNM stage III compared to stage I/IIC. Positive correlation of HOXA11as expression with clinicopathologic parameters such as histologic grade, preoperative CA125 and postoperative 5-year overall survival was observed. In multivariate analysis HOXA11as was associated with overall survival. HOXA11as expression in cancer tissue was 77-fold higher than that of noncancerous tissue. Higher HOXA11as expression significantly correlated with histologic grade and preoperative CA125. HOXA11as overexpression in SOC cells led to increased cell proliferation, invasion, and migration. In addition, HOXA11as was associated with the expression of genes that involve in cell proliferation, invasion, and migration. Moreover, Knockdown of HOXA11as decreased the expression of vascular endothelial growth factor, matrix metalloproteinase-9 and epithelial-mesenchymal transition (EMT), which are important for cell motility and metastasis. Mechanistic investigation revealed that Notch1, Hes1 and p300 proteins could be inhibited by HOXA11as depletion. In multivariate analysis, HOXA11as was a prognostic factor of progressive disease and mortality (HR = 1.730, 2.170 and P = 0.043, 0.035, respectively). Progression-free and overall survival were significantly shorter in patients with high HOXA11as expression. These findings highlight the clinical significance of HOXA11as in predicting the prognosis of SOC patients and suggest its potential in promoting tumor aggressiveness by regulation of the Notch signaling pathway and EMT-related mechanisms.
underlying mechanisms. PRR14 is commonly upregulated in lung cancers, PRR14 promotes tumorigenesis through activating the PI3-kinase/Akt/mTOR signal pathway. The regulatory effect is mediated by direct interaction with GRB2, a docking protein upstream of both PI3K and Ras. Indeed, PRR14 is commonly elevated in many cancer types including lung cancer and breast cancer, but our understanding of the underlying molecular mechanism is still very elusive. Many of these minute deletions were not contiguous but rather they alternated with segments showing oscillating copy number changes along the 3p21 region. Functional assays revealed that SETD2, PBRM1 and SMARCC1 act as tumor suppressor in MM. In summary, we found that in MM: 1) multiple minute simultaneous biallelic deletions are frequent in chromosome 3p21, where they occur as distinct events involving multiple genes; 2) in addition to BAP1, mutations of SETD2, PBRM1 and SMARCC1 are frequent in MM; 3) our results suggest that high-density aCGH combined with tNGS provide a more precise estimate of the frequency and types of genes inactivated in human cancer, than approaches based exclusively on NGS strategy.

The Second Xiangya Hospital of Central South University, Changsha, China; 2 The Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China; 3 Harvard T.H. Chan School of Public Health, Boston, MA; 4 The University of Texas Health Science Center at San Antonio, San Antonio, TX.

PRR14, a component of nuclear lamina, has recently been identified as a novel oncogene in lung cancer. Frequently upregulated in lung cancers, PRR14 promotes tumorigenesis through activating the PI3-kinase/Akt/mTOR signal pathway. The regulatory effect is mediated by direct interaction with GRB2, a docking protein upstream of both PI3K and Ras. Indeed, PRR14 is commonly elevated in many cancer types including lung cancer and breast cancer, but our understanding of the underlying molecular mechanism is still very elusive. ZC3H8 is an oncogene with substantial effects on the cancer cell phenotype. These effects are hypothesized to be associated with ZC3H8 integrity is key to maintainance of PML bodies. Other studies have identified ZC3H8 as a component of the LEC (little elongation complex), and we found that another identified component, ICE2 (Narg) also localizes to PML bodies. The ZC3H8 gene encodes a protein with three zinc finger motifs in the C-terminal region, suggesting a role as an RNA binding protein, whose specific function remains unclear. ZC3H8 protein localizes to both PML bodies and Cajal bodies within the nucleus, as confocal microscopy demonstrates colocalization of ZC3H8 with both PML and Cajal bodies. ZC3H8 has a cassease kinase 2 phosphorylation site in the N-terminal region, and treatment with a cassease kinase 2 inhibitor causes the numerous PML bodies and their associated ZC3H8 to coalesce to a few larger bodies. Removal of the inhibitor restores PML bodies to their original state. We constructed a mutant of ZC3H8 that removed the predicted phosphorylation site by replacing the serine with an alanine residue. Cells transfected with this mutant had reduced numbers of PML bodies, similar to cells treated with the CK2 inhibitor. In contrast, a mutant constructed with a glutamic acid in place of the phosphorylatable serine was predicted to behave as a constitutive mutant. This mutant did not exhibit differences from wild type localization. These experiments suggest that ZC3H8 integrity is key to maintainance of PML bodies. Perhaps this is why ZC3H8 displays the altered expression pattern and the potential protective role of progesterone, we discovered that PR is downregulated in multiple tumors, including breast, endometrial, ovarian, cervical, pancreatic and lung cancers, and loss of PR was consistently associated with a poorer prognosis based on analysis of the Oncomine database. Similarly, PR expression was low in multiple ovarian, pancreatic and lung cancer cells. Mechanistic studies revealed that PR downregulation was mediated by the polycomb repressor complex and DNA methylation, though the precise mechanism differed among cell lines and cancer types. Treatment with epigenetic modulators, which are FDA-approved for multiple myeloma, restored functional PR expression at both the mRNA and protein level and promoted marked cell death through induction of apoptosis. Moreover, overexpression of PR or treatment with epigenetic modulators in combination with progesterone enhanced this effect, indicating a key protective role for progesterone signaling through PR. Conclusion: These data suggest loss of PR may be a general theme for tumorigenesis in transformed cells. We also observed that expression was low in multiple ovarian, pancreatic and lung tumors, and that overexpression of PR or treatment with epigenetic modulators, which are FDA-approved for multiple myeloma, restored functional PR expression at both the mRNA and protein level and promoted marked cell death through induction of apoptosis. Moreover, overexpression of PR or treatment with epigenetic modulators in combination with progesterone enhanced this effect, indicating a key protective role for progesterone signaling through PR.

#2555 ZC3H8 associates with PML bodies and influences aggressive tumor cell behavior. John A. Schmidt, Emily Duffner, Gerard Walker, Keith G. Danielson, Janice E. Knepper. Villanova Univ., Villanova, PA.

The ZC3H8 gene encodes a protein with three zinc finger motifs in the C-terminal region, suggesting a role as an RNA binding protein, whose specific function remains unclear. ZC3H8 protein localizes to both PML bodies and Cajal bodies within the nucleus, as confocal microscopy demonstrates colocalization of ZC3H8 with both PML and Cajal bodies. ZC3H8 has a cassease kinase 2 phosphorylation site in the N-terminal region, and treatment with a cassease kinase 2 inhibitor causes the numerous PML bodies and their associated ZC3H8 to coalesce to a few larger bodies. Removal of the inhibitor restores PML bodies to their original state. We constructed a mutant of ZC3H8 that removed the predicted phosphorylation site by replacing the serine with an alanine residue. Cells transfected with this mutant had reduced numbers of PML bodies, similar to cells treated with the CK2 inhibitor. In contrast, a mutant constructed with a glutamic acid in place of the phosphorylatable serine was predicted to behave as a constitutive mutant. This mutant did not exhibit differences from wild type localization. These experiments suggest that ZC3H8 integrity is key to maintainance of PML bodies. Other studies have identified ZC3H8 as a component of the LEC (little elongation complex), and we found that another identified component, ICE2 (Narg) also localizes to PML bodies. The ZC3H8 gene is overexpressed in a number of human and mouse breast cancer cell lines, and elevated mRNA levels are associated with a poorer prognosis for women with breast cancer. We have used RNA silencing to decrease levels of expression in two independent mouse mammary tumor cell lines. Cells with lower ZC3H8 expression have dramatic phenotypic changes, showing decreased rates of proliferation, slower migration in wound healing assays, formation of fewer and smaller colonies in soft agar assays, and decreased ability to invade through a basement membrane. Further experiments with ZC3H8-decreased cells are needed to determine if increased expression of aCGH. Many of these minute deletions were not contiguous but rather they alternated with segments showing oscillating copy number changes along the 3p21 region. Functional assays revealed that SETD2, PBRM1 and SMARCC1 act as tumor suppressor in MM. In summary, we found that in MM: 1) multiple minute simultaneous biallelic deletions are frequent in chromosome 3p21, where they occur as distinct events involving multiple genes; 2) in addition to BAP1, mutations of SETD2, PBRM1 and SMARCC1 are frequent in MM; 3) our results suggest that high-density aCGH combined with tNGS provide a more precise estimate of the frequency and types of genes inactivated in human cancer, than approaches based exclusively on NGS strategy.

#2556 Loss of progesterone receptor through epigenetic regulation is associated with poor prognosis in multiple solid tumors. Yiyan Li, Tamar Kavlashvili, Cheng Huang, Yuping Zhang, Xiangbing Meng, Kristina Thiel, Kimberly Leslie, Shuiey Jhang. Univ. of Iowa, Iowa City, IA.

Introduction: As a tumor suppressor in the endometrium, progesterone and its synthesized analogs have a long history as a treatment for endometrial cancer. Loss of progesterone receptor (PR) in endometrial cancer leads to therapeutic failure, and our group has identified several mechanisms underlying PR loss, most notably epigenetic silencing of PR transcription. Recently, a Finnish group demonstrated that progesterin therapy in premenopausal women is associated with a lower incidence of not only endometrial cancer, but also ovarian, pancreatic and lung cancers. This unexpected protective function of progesterin in organs outside of the reproductive system led us to hypothesize that tumor progression effects in endometrial, ovarian, pancreatic and lung cancer is occurs due to the loss of progesterone’s protective effects. Methods and results: Supporting a potential protective role of progesterone, we discovered that PR is downregulated in multiple tumors, including breast, endometrial, ovarian, cervical, pancreatic and lung cancers, and loss of PR was consistently associated with a poor prognosis based on analysis of the Oncomine database. Similarly, PR expression was low in multiple ovarian, pancreatic and lung cancer cells. Mechanistic studies revealed that PR downregulation was mediated by the polycomb-repressor complex and DNA methylation, though the precise mechanism differed among cell lines and cancer types. Treatment with epigenetic modulators, which are FDA-approved for multiple myeloma, restored functional PR expression at both the mRNA and protein level and promoted marked cell death through induction of apoptosis. Moreover, overexpression of PR or treatment with epigenetic modulators in combination with progesterone enhanced this effect, indicating a key protective role for progesterone signaling through PR.

Conclusion: These data suggest loss of PR may be a general theme for tumorigenesis in transformed cells. We also observed that expression was low in multiple ovarian, pancreatic and lung tumors, and that overexpression of PR or treatment with epigenetic modulators, which are FDA-approved for multiple myeloma, restored functional PR expression at both the mRNA and protein level and promoted marked cell death through induction of apoptosis. Moreover, overexpression of PR or treatment with epigenetic modulators in combination with progesterone enhanced this effect, indicating a key protective role for progesterone signaling through PR.

#2557 Role of microRNAs in breast cancer. Hesham Abbas El-Mahdy,1 Ossama Abdelmotala Mansour,1 Mohamed Mohamed Badr,1 Reham Aly Elshimy2. 1Faculty of pharmacy, Cairo, Egypt; 2National Cancer Institute, Cairo, Egypt.

Background: Breast cancer (BC) is one of the most common cancers in women around the world and the second leading cause of death worldwide. MicroRNAs (miRNAs) expression participates in breast cancer. Objectives: The purpose of this study is to investigate the expression of miR-133a and miR-155 in breast cancer. Methods and results: Their correlation with tumor suppressor protein (p53) carcinobryonic antigen (CEA) and cancer antigen-15-3 (CA-15-3) concentrations in serum of breast cancer patients and also study their correlations with clinicopathological features. Material and methods: In this study the expression of miR-133a and miR-155 in serum were measured using quantitative real-time
polymerase chain reaction (qRT-PCR), P53 concentration was measured by enzyme-linked immunosorbent assays (ELISA), CEA and CA-15.3 concentration were measured using ARCHITECT immunosay in women with breast cancer (n=60) and controls (n = 80). Results: In this study miRNA-155 was significantly overexpressed (P<0.001) while miR-133a had significant down expression (P<0.001) in the serum of breast cancer patients compared to control serum. P53 had no significant correlations with any of the studied miRNAs. Carcinoembryonic antigen and CA-15.3 have significant higher concentration in the serum of breast cancer patients compared to control serum. A significant association was observed between miR-133a with tumor grade (P<0.05) and miR-155 with lymph node involvement (P<0.05). A significant correlation between P53 and miRNA-122 (P<0.05). Note: miRNA-122 results were low between miR-133a and P53. CEA, CA-15.3. By using receiver operating characteristic (ROC) curve, the two miRNAs showed higher sensitivity, specificity, positive predictive value and negative predictive value than routine markers. Our Conclusion: These miRNAs have a significant signature in the pathogenesis of breast cancer and can be used as non-invasive potential biomarkers for breast cancer detection.

Recent comprehensive breast cancer studies examining mutations and genomic alterations have determined that deregulation of MYC and the PI3K pathway occur frequently during breast cancer progression and may be useful targets for therapy. A recent large essay effort to develop PIK3CA and mTOR inhibitors (PIK3CA and mTOR inhibitors as PAM inhibitors) for clinical use, however clinical trial data demonstrates that many patients treated with PAM inhibitors develop resistant disease. An alternative strategy would be to target MYC, though a lack of effective and specific inhibitors makes this difficult. To identify the core vulnerabilities in these cancers we developed an in vivo xenograft model of triple-negative breast cancer driven by deregulated PI3K signaling and MYC. We hypothesized that determining how these pathways cooperate to transform normal human breast cells into breast carcinomas will reveal a tumor progression signature and highlight new therapeutic opportunities. We developed our model using the spontaneously immortalized, basal, triple-negative MCF10A cell line. By expressing the hotspot PIK3CA/H1047R protein alone in MCF10A cells (MCF10A.H) in addition to MYC (MCF10A.HM), we can model normal early breast cancer and invasive ductal carcinoma respectively. This is the first in vivo human model of breast cancer dependent on MYC for transformation. When injected into female NOD-SCID mice, MCF10A.H cells form organized acini embedded in extracellular matrix. MCF10A.H ducts form with hollow lumens and a single layer of myoepithelial cells, recapitulating normal human breast histology. Alternatively, MCF10A.HM cells grow as high-grade carcinomas indicative of invasive disease. MCF10A.H benign growths and MCF10A.HM tumors remain basal-like and triple-negative by immunohistochemistry. Importantly, MCF10A.HM tumors are sensitive to MYC repression and therefore may be a suitable model to evaluate direct and indirect anti-MYC therapies. Having relevant human xenograft samples representing both normal and IDC tissue, we performed RNA-seq to identify a MYC-signature driving breast cancer transformation. Our current work will involve targeting the resulting MYC-driven pathways identified by RNA-seq to therapeutically target MYC in breast cancer.

#2559 FoxF1 is a potential oncogene in prostate cancer. Carolin Bossmann, Constanze Merz, Yuri Tolkach, Jessica Carlsson, Sven Perner, Ove Andrén, Glen Kristiansen, Michael Nowak. University Hospital Bonn, Bonn, Germany; University Hospital of Ourebro, Ourebro, Sweden; University Medical Center Schleswig-Holstein, Lübeck, Germany.

Background: FoxF1 belongs to the family of forkhead box transcription factors. Many forkhead box proteins are linked to cancer development and progression. However, the regulation and exact function of FoxF1 remains unclear. The aim of this study was to elucidate how the transcriptional activity of FoxF1 is controlled and to assess the role of FoxF1 within prostate cancer. Design: For assessment of FoxF1 functions tumor cell lines were stably transfected with wild type FoxF1 or mutant FoxF1 constructs lacking putative phosphorylation sites. Protein expression and localization of FoxF1 were analyzed by immunoprecipitation and Western Blot. Using tissue microarrays of prostate cancer cohorts we analyzed the protein expression and intracellular localization of FoxF1 in tumors compared to benign tissue. Results: Primary tumors and distant metastases exhibited a significantly higher FoxF1 expression compared to benign prostate tissue. In tumors and metastases nuclear localized FoxF1 was more abundant compared to benign tissue. Transfection of tumor cell lines with FoxF1 followed by immunoprecipitation and Western Blot showed that nuclear FoxF1 but not cytoplasmic FoxF1 is phosphorylated in tyrosine residues, conceivably tyrosine-39, as suggested by literature data. We further transfected tumor cell lines with different amino acid exchange mutants of putative phosphorylation sites and analyzed the transcription of the known FoxF1 target gene Pcam-1, revealing a complex pattern of regulation, dependent on the site of phosphorylation. Overexpression of FoxF1 in tumor cell lines resulted in epithelial-mesenchymal transition in vivo xenografts. FoxF1 is phosphorylated in tyrosine residues, conceivably tyrosine-39, as suggested by literature data. We further transfected tumor cell lines with different amino acid exchange mutants of putative phosphorylation sites and analyzed the transcription of the known FoxF1 target gene Pcam-1, revealing a complex pattern of regulation. Conclusion: In summary, our results point to a role of FoxF1 as a potential oncogene in prostate cancer whose nuclear localization and activity is regulated by phosphorylation.

#2560 Identification and characterization of EWS-FLI1 binding partners in Ewing sarcoma cell lines. Matthew L. Rotondi, Peter J. Houghton. Greehey Children’s Cancer Research Institute, San Antonio, TX.

Ewing sarcoma (ES) is characterized by a reciprocal translocation t(11;22) that results in a fusion of the EWSR1 and FLI1 genes (EWS-FLI1). The objective of this study is to identify protein binding partners of the purportedly undruggable chimeric transcription factor EWS-FLI1 to serve as alternative pharmacological targets for potential ES-selective drug therapies. The literature identifies the orphan nuclear receptor DAX1 (encoded by NR0B1) as a binding partner of EWS-FLI1 the expression of which is restricted outside ES, thereby providing a target for a potential ES selective drug. Yeast two-hybrid (Y2H) screening using EWS-FLI1 as the bait was employed to identify other potential targets. The importance of the binding partners identified by the Y2H screen was initially assessed by a series of proliferation assays involving the ES cell lines EW8, ES7 and ES6 as well as rhabdomyosarcoma cell line Rh30 (Non-Ewing control). Prior to measuring proliferation, cells were transfected a siRNA designed to target the putative binding partner of EWS-FLI1. These cells were then grown alongside cells transfected with a control siRNA over a period of 96 hr. The change in cell confluence in the wells was measured by a live-cell real-time measurement (Incucyte). Gene knockdown was confirmed by RT-PCR and western blot analysis. The proliferation assays showed that the knockdown of DAX1 produces a notable reduction in cell proliferation compared to siRNA control proliferation in all three of the Ewing cell lines (10% to 25%). No significant DAX1 siRNA based inhibition of cell proliferation was detected in the Rh30 non-Ewing control cell line. Three of the proteins identified by the Y2H screen showed significant reductions in ES cell proliferation. Methyl-CpG-Binding Domain Protein 1 (MBD1) knockdown caused the proliferation of the ES cell lines to levels at 60% to 80% within 2 to 4 days. Proportion of MBD1 siRNA and control siRNA transfected Rh30 cells was similar for the full 4 days of the assay. Mannosidase-α-class 2B-member 2 (MANZ2B) knockdown caused the proliferation of the ES and Rh30 cell lines to levels at 25% to 65% within 1 to 2 days. Mixed-Lineage Leukemia Protein 3 (MLL3) knockdown was shown to decrease proliferation of ES cell to levels of the control by 50% to 85% within 2 days. MLL3 knockdown did not inhibit the proliferation of Rh30 cells when compared to siRNA control cells. In contrast, ES6 cell proliferation was also not inhibited by MLL3 knockdown when compared to their siRNA control cells. The knockdowns of DAX1, MLL3 and MBD1 suggest that these EWS-FLI1 binding partners would likely provide potential targets for ES drug development. The effect of knocking down Y2H-identified EWS-FLI1 interactors on colony formation, migration and tumorigenicity is ongoing.

#2561 Wip1 constrains p53 activity during embryogenesis to permit normal neuronal development. Sharlyn J. Mazur, Yantene Ge, Aamir Akbarali, Charles Halsey, R Mark Simpson, Ettore Appella. National Cancer Institute, Bethesda, MD.

The oncoproteins MDM2 and Wip1 (PMM1D) each negatively regulate tumor suppressor p53 activity and overexpression of either promotes tumorigenesis. Both MDM2 and PMM1D genes are characterized by induced by p53 following exposure to DNA damage and both negatively regulate p53, but by different mechanisms. In mice, homozygous deletion of Mdm2 is embryonically lethal (E5.5-6.5) resulting from excess p53-dependent apoptosis, whereas Pmm1d−/− embryos exhibit partial mid-gestation lethality. To investigate the role of p53 in the partial lethality of Pmm1d−/− embryos, we generated an enogenous Ppm1d promoter β-galactosidase reporter allele, Ppm1d+/−;LacZ, and a new Ppm1d knockout allele, Ppm1d−/−. We also generated Tp53−/− Ppm1d+/−;LacZ double knockout embryos and mice. From Ppm1d+/−;LacZ × Ppm1d−/− crosses, 652 Proceedings of the American Association for Cancer Research • Volume 58 • April 2017
proximately 40% of Pmm1Δ3/Δ3 embryos die between E10.5 and E12.5 and an additional 40% die shortly after birth, leading to the survival of only approximately 20% of Pmm1Δ3/Δ3 pups to adulthood. Sections of Pmm1Δ3/Δ3 embryos show dispersed LacZ staining activity with regions of higher activity, especially in specific regions of developing neural tissues. The developing neural tissues of Pmm1Δ3/Δ3 embryos are characterized by distorted cellular architecture, cell dropout, and dark, pyknotic nuclei. Although the frequency of apoptotic cells was nearly three-fold higher in Pmm1Δ3/Δ3 compared with Pmm1Δ+/Δ embryos (p < 0.005), the number of apoptotic cells were less than 1%, even in the knockout. Interestingly, the numbers of pH3 positive cells (M phase) in ventricular and sub-ventricular regions of neural tissue were reduced in E10.5 (p < 0.01) and sharply reduced in E11.5 (p < 0.005) Pmm1Δ3/Δ3 embryos compared with Pmm1Δ+/Δ embryos. Moreover, the number of γ-H2AX foci per cell observed in Pmm1Δ3/Δ3 sections were approximately three-fold higher than in Pmm1Δ/Δ sections (p < 0.002). The specific phenotypes of excess mid-gestation embryonic lethality, excess neuronal apoptosis, and deficient ventricular and sub-ventricular pH3 cell numbers, but not excess in γ-H2AX foci numbers, were rescued by loss of p53 in Trp53−/− Pmm1Δ3/Δ3 embryos. These results support a specific function of Wip1 in regulating p53 activity to ensure normal development of the brain and spinal cord during embryogenesis.

Molecular and Cellular Biology / Genetics: Nuclear Oncogenes and Tumor Suppressors

#2562 Stromal antigen 1 (SA1) as a potential pro-neoplastic factor in non-small-cell lung cancer (NSCLC). Michelle Zhang, Mart Dela Cruz, Navneet Momi, Sanjib Chowdhury, Hemant Roy, Adam Lerner. Boston Medical Center, Boston, MA

Introduction: SA1, encoded by the STAG1 gene, is a subunit of the higher order chromatin remodeler cohesin. SA1 deficiency has been implicated as a driver of aneuploidy and tumorigenesis (Remesiero et al, EMBIO J 2012). Furthermore, our lab has recently shown that SA1 functions as a tumor suppressor protein in early colon cancer (Wali et al, Cancer Prev Res 2016). The aim of this project was to investigate the role of SA1 in NSCLC. Combining data from The Cancer Genome Atlas (TCGA), human lung tissue, and in vitro gene knockdown, we have surprisingly identified SA1 as a potential pro-neoplastic factor in NSCLC.

Method: Data was extracted from TCGA and plotted to characterize STAG1 gene alteration in NSCLC. Immunohistochemistry (IHC) was performed on human lung tissue microarray assay (TMA) to assess SA1 protein expression. Transient knockdowns were performed on A549 human lung adenocarcinoma cells using STAG1 siRNA (Dharmacon) with an incubation time of 48 hours. Following this, quantitative real-time polymerase chain reaction (qPCR, Life Technologies) and WST-1 cell proliferation assays (Promega) were performed as per protocol. Results: STAG1 alterations occur in about 3% of lung adenocarcinoma cells and 17% of lung squamous cell carcinoma. Of these alterations, the majority were amplifications. Furthermore, although not reaching statistical significance, there was a trend towards decreased survival with STAG1 gene alteration. Of the alterations, 11.6 months vs. 46 months. IHC demonstrated a 1.7-fold increase in SA1 protein expression in NSCLC when compared with non-malignant lung tissue (p<0.001). Transfected A549 cells showed a 78% decrease in SA1 RNA expression (qPCR, p=0.0002) and a 50% decrease in cell proliferation (WST-1, p=0.0001). Proliferating cell nuclear antigen (PCNA), a marker of cell proliferation, was decreased by 37% in transfected cells (p<0.001). Conclusions: Using TCGA data, we found that STAG1 alterations occur with some frequency in NSCLC and that many of these alterations are amplifications of the gene. Furthermore, there is a trend towards decreased survival with a STAG1 gene alteration. Our IHC data shows robust over-expression of SA1 in NSCLC when compared with non-malignant lung tissue. Our qPCR data showed a profound decrease in SA1 mRNA expression following transfection; accordingly, our WST-1 proliferation data suggests that knockdown of the STAG1 gene significantly decreases proliferation of A549 lung adenocarcinoma cells. Decreased PCNA confirms a true anti-proliferative effect, rather than a pro-apoptotic effect. This novel data suggests a link between SA1 and NSCLC, of which there are no prior published accounts. Even more compelling is the implication that in NSCLC, SA1 may be pro-neoplastic rather than anti-neoplastic, which introduces a new potential target for future gene therapy.

#2563 LSD1 maintains differentiation and survival of mammary luminal cells by suppressing invasion of luminal breast cancer cells via GATA3. Xin Hu, Dongxi Xiang, Luwei Tao, Yuexing Xie, Yuxin Jin, Yidi Guo, Luca Pinello, Guo-Cheng Yuan, Zhe Li.

LSD1 (also known as KDM1A) is a histone demethylase that has been shown to play both oncogenic and tumor suppressor roles in breast cancer. However, the exact context under which it functions as a tumor suppressor or oncoprotein remains largely elusive. To address this, we characterized its role in normal mammary epithelial cells (MECs) and found MEC-specific ablation of Lsd1 largely phenocopied that of Gata3, which encodes a master regulatory transcription factor for luminal MECS. In the luminal lineage, LSD1-loss led to reduction in both mature ductal and alveolar luminal subpopulations. In human luminal breast cancer cells, we found LSD1 interacts with GATA3 and their common transcriptional target genes are highly related to breast cancer. In particular, our data suggest that LSD1, by silencing GATA3, might be recruited by GATA3 to the GATA3 promoter region, to positively regulate GATA3 expression via demethylation of H3K9me2. Knockdown of LSD1 led to increased invasion of luminal breast cancer cells, in part via down-regulation of GATA3 and multiple cell junction genes (e.g., CDH1, VCL, CTNNAI), as well as upregulation of mammalian stem/progenitor cell genes (e.g., CDK6, WNT2). Moreover, LSD1 knockdown led to down-regulation of PTEN in luminal breast cancer cells, in part via downregulation of RBP4 (encoding a Histone-binding protein) and upregulation of CDKN1A (encoding p21). Collectively, our data suggest that LSD1 is required for maintaining luminal MEC differentiation and survival and for suppressing luminal breast cancer cell invasion, in part via GATA3. As inhibitors of LSD1 are currently under clinical trials (e.g., in leukemia), our data suggest that although treatment of luminal breast cancer by the LSD1 inhibitor may lead to reduced tumor cell proliferation (and thus tumor shrinkage), the treatment may also lead to increased invasion of surviving breast cancer cells. Thus, our study is expected to have important implications for developing better epigenetic therapy in an individualized, context-dependent fashion.
evaluate the potential regulation of ERα on ZBTB7A, ERα was silenced and ZBTB7A mRNA and protein expression were determined. ERα silencing had no effect on ZBTB7A mRNA levels, but led to decreased ZBTB7A protein expression. These effects on ZBTB7A protein expression were attenuated by the presence of the proteasomal inhibitor MG132. Together, these data suggest a model in which ZBTB7A promotes ERα expression at the transcript level while ERα stabilizes ZBTB7A post-transcriptionally conferring a positive feedback loop and sensitivity to estradiol and endocrine therapies. ZBTB7A may contribute to the transcriptional program maintaining a hormone and endocrine response therapy responsive phenotype in breast cancer.

#2567 CYP24A1-induced vitamin D insufficiency promotes breast cancer growth.

Vitamin D plays a critical role in the maintenance of tissue homeostasis by regulating the expression of genes affecting cell proliferation, differentiation, and apoptosis. The vitamin D 24-hydroxylase CYP24A1 functions in vitamin D target tissues to degrade the hormonal form of vitamin D. Existing knowledge regarding dysregulated CYP24A1 expression supports its candidacy as a putative oncogene. In our presentation, we demonstrate that the suppression of constitutive CYP24A1 expression by CYP24A1-specific shRNA conferred target cells with increased susceptibility to apoptosis and consequently inhibited anchorage-independent growth in breast carcinoma cells. In addition, suppression of CYP24A1 expression following knockdown of CYP24A1 revealed no evidence of CYP24A1 expression in breast carcinoma cells, which suggests that CYP24A1 expression is required for breast cancer cell growth. These findings suggest that CYP24A1 expression promotes breast cancer growth.

#2568 Mutant p53 regulates HSP70 expression and nuclear localization.
Kishore Polireddy, Kanchan Singh, Melissa Pruski, Wasin Dar, John S. Bynon. Jennifer M. Bailey. University of Texas Health Science Center, Houston, TX.

Pancreatic cancer is the 3rd leading cause of cancer-related deaths in the US with a median survival of less than one year. No effective therapies or early detection tests are available for these patients. Scientists have been studying cellular origins of pancreatic cancer to aid in the development of novel treatments and biomarkers. Several studies have demonstrated that acinar cells have a high propensity to undergo acinar to ductal metaplasia and form precursor lesions of pancreatic ductal adenocarcinoma. We have recently shown that simultaneous expression of Kras and mutant TP53 can generate invasive ductal adenocarcinoma. We show that HPNE-KrasG12D cells, as cells expressing either vector control or TP53R273H have different mechanisms of transforming ductal cells. In order to understand the role of mutant TP53 in transforming pancreatic ductal cells into invasive ductal adenocarcinoma, we used a lentiviral system to express mutant TP53R273H and TP53R273H, one of the most frequently mutated TP53 alleles in pancreatic cancer patients, in immortalized pancreatic ductal epithelial cells carrying a Kras mutation (HPNE-KrasG12D). Transient blue dye exclusion assay and Spheroid formation assays were used to study cellular proliferation and cancer stem cell (CSC) populations. mutant TP53 over expression enhanced CSC populations without altering cellular proliferation in HPNE-KrasG12D cells. Reverse phase protein array (RPPA) was carried out to detect gene expression changes in HPNE-KrasG12D cells upon mutant TP53 over expression. RPPA assay results suggested that TP53R273H uniquely induced HSP70 expression in HPNE-KrasG12D cells, as cells expressing either vector control or TP53R273H failed to do so. HSP70 expression was further validated by transiently overexpressing TP53R273H and TP53R273H. Surprisingly, TP53R273H specifically promoted nuclear localization of HSP70 without altering the expression of a recently identified HSP70 nuclear transport, Hikeshi. Future studies will determine 1) whether HSP70 is required for p53-mediated stemness in HPNE-KrasG12D cells and 2) the function of nuclear HSP70. In summary, overexpression of mutant p53 enhanced cancer stem cell properties of HPNE-KrasG12D cells, through upregulation HSP70. The exact mechanism behind HSP70 nuclear localization and increased cancer stem cell properties is being more rigorously explored.

#2569 BCL6 promotes glioma and serves as a novel therapeutic target.
Liang Xu, YI Ye CHEN, 1 Marina Dutra-Clarke, 2 Anand Mayakonda, 3 Masaharu Hazawa, 2 Steve E. Vinsonof, 2 Ngan Doan, 2 Jonathan W. Said, 2 William H. Yong, 3 Henry Yang, 1 Ling-Wen Ding, 1 Yan-Yi Jiang, 3 Jeffrey W. Tyner, 2 Jennifer Bailey. 1 Virginia Commonwealth University, Richmond, VA; 2University of Virginia, Charlottesville, VA.

The acetyltransferase CBP, in conjunction with the E3 ubiquitin ligase enzyme, MDM2, maintains physiological levels of the tumor suppressor protein p53 in the absence of cellular stress, via a cytostatic, but not nuclear, p53-directed E4 polyubiquitin activity. CBP also possesses cytostatic, but not nuclear, E ubiquitin ligase, auto ubiquitination activity. To understand the mechanism by which the ubiquitin ligase activities of CBP are compartmentalized in the cell, we have employed Multidimensional Protein Identification Technology (MudPIT) to identify cytoplasmic and nuclear CBP interacting proteins. MudPIT analysis revealed that Cell Cycle and Apoptosis Regulator protein (CCAR2), also known as Deleted in Breast Cancer 1 protein (DBC1), is a novel CBP- interacting protein in both the nucleus and cytoplasm. The N-terminus of DBC1 bound to multiple CBP domains, including the putative E4 domain of CBP located at ZBTB transcription factors orchestrate gene transcription during tissue development. However, their roles in glioblastoma multiforme (GBM) remain unexplored. Here, through a functional screening of ZBTB1 genes, we identify that DBC1 is required for GBM cell proliferation and is overexpressed in GBM samples. Using a somatic transgenic mouse model, BC6 confers the proliferative selective advantage to GBM tumor cells. Mice with conditional deletion of DBC1 using Axl as a novel downstream target of BCL6. Through Axl, BCL6 enhances both MEK-ERK and S6K-RPS6 axes. Pharmacological inhibition of BCL6 activity effectively blocks GBM growth and inhibits Axl expression. Together, these findings uncover a novel glioma-promoting role of BCL6, and provide the rationale of targeting BCL6 as a potential therapeutic approach.

#2570 Induction of mild oxidative stress as a strategy for reactivation of mutant p53 proteins: KSS72, a small molecule derived from ethacrynic acid restores the biological functions of R248W/Q mutant.

p53 gene mutations in 50% of human cancers drive the emergence of oncogenic genomes and confer resistance to anticancer drugs & apoptosis. Therefore, a pharmacological reactivation of p53 mutant proteins to their wild-type forms has emerged as an intense research area. We have shown that induction of oxidative protein modifications primarily underlie the mechanistic conversion of mutant to wt or wt-like p53 forms (Eur J Med Chem 107:237, 2016; Int J Oncol 48:1426, 2016). R248W/Q DNA contact mutations in the p53 core are highly frequent and cause functional inactivation. No small molecules reactivating this p53 mutation are available. Here, we describe the design and synthesis of a small molecule KSS72 using a cell-based screening and its potency in reactivating the R248 p53 mutants. KSS72 is a non-diuretic hydrophobic analog [1-(2,3-dichloro-4-methoxyphenyl)-2-methylenebutan-1-one] of ethacrynic acid (Edecein) obtained by removing the carbohydrate side chain. KSS72 retained the ability to bind with GSH, inhibit GSTs and induce marked redox-imbalance in tumour cells. KSS72 displayed preferential cytotoxicity (3-4 fold more cell killing) against cancer cells expressing the allele specific R248W mutation (MiaPaca-2) in comparison with the wt p53 or p53-null cancer cell lines. Further, we developed isogenic cell lines expressing the R248W and R248Q mutants in the p53-null H1299 lung cancer cells and evaluated their sensitivity towards KSS72; these models again verified the greater drug efficacy. To prove the hypothesis the higher efficacy of KSS72 stems from the reactivation of mutant p53, the conformation-specific antibodies (Pab1620 for wt and Pab420 for mutant) were employed. Immunoprecipitation and immunostaining using confocal microscopy showed that KSS72 treatment of R248W or R248Q p53 cells results in a marked reciprocal loss of mutant protein and gradual increase of wt-like protein. EMSA revealed a time-dependent restoration of DNA-binding of the mutant p53, which was accompanied by a distinct upregulation of pro-apoptotic signaling pathways mediated by PUMA, Bax, p21(34) and MDM2 proteins. A strong G2/M arrest and significant apoptosis were observed. Other data showed that KSS72 restores the wt structure and function by covalently binding the p53R248W protein. Pharmacokinetics showed that KSS72 has excellent oral bioavailability with a half-life of 3.5 h. In MiaPaca-2 xenografts developed in nude mice, there was a marked anti-tumor growth suppression by KSS72 as a single drug. In conclusion, KSS72 is an attractive lead compound for further development because p53 reactivation occurred without discernible organ toxicities after oral doses and a wide therapeutic window. The redox-sensitive cytokines involved in the p53 reactivation are being identified by mass spectrometry (supported by CPRIT grants RP130266 & RP170207 to KSS).

#2571 DBC1, a novel CBP-interacting protein, promotes p53 stability by regulating CBP-dependent p53 polyubiquitination.
Olawatoinyin E. Akande, 1 Priyadarshan K. Damle, 1 Nicholas E. Sherman, 2 Steven R. Grossman 1.

1Virginia Commonwealth University, Richmond, VA; 2University of Virginia, Charlottesville, VA.

The acetyltransferase CBP, in conjunction with the E3 ubiquitin ligase enzyme, MDM2, maintains physiologic levels of the tumor suppressor protein p53 in the absence of cellular stress, via a cytostatic, but not nuclear, p53-directed E4 polyubiquitin activity. CBP also possesses cytostatic, but not nuclear, E ubiquitin ligase, auto ubiquitination activity. To understand the mechanism by which the ubiquitin ligase activities of CBP are compartmentalized in the cell, we have employed Multidimensional Protein Identification Technology (MudPIT) to identify cytoplasmic and nuclear CBP interacting proteins. MudPIT analysis revealed that Cell Cycle and Apoptosis Regulator protein (CCAR2), also known as Deleted in Breast Cancer 1 protein (DBC1), is a novel CBP- interacting protein in both the nucleus and cytoplasm. The N-terminus of DBC1 bound to multiple CBP domains, including the putative E3/E4 domain of CBP located at...
the N-terminus. Interaction between DBC1 and CBP suppressed the in vitro E3 auto ubiquitination activity of CBP. Functional studies demonstrated that DBC1 directly regulates the cellular compartmentalization of CBP E3 and p33-directed E4 ubiquitin ligase activities. Knockdown of DBC1 in U2OS cells stimulated normally absent nuclear p53 polyubiquitination, and also caused a decrease in p53-dependent apoptotic proteins bim and bax and cell cycle inhibitor p21waf/cip1 and revealed that in both MCF7 and MCF10A cells, DBC1 antagonized the p53-mediated apoptosis. Recent studies demonstrated that DBC1 loss inactivates p53 function through destabilization, we queried the TCGA database for co-occurrence of DBC1 knockdown with p53 status which showed that 33% of breast, 40% of lung, and 96% of prostate cancer cases with DBC1 alterations maintained wild-type p53 status. Therefore, by restoring DBC1 function, this work could lead to reactivation of p53 tumor suppressor activity in tumors with DBC1 alterations. We further explored the mechanism of action that PANCR activates.

#2572 The novel long non-coding RNA PANCr is an intracellular p53 activator. Yu Cao, Southern Illinois University, Springfield, IL.

Long non-coding RNAs (lncRNAs) function as oncogenes or tumor suppressors in development and progression of cancer. Chromosome 16q22.1 region is frequently deleted in breast cancer, which may contribute to breast carcinogenesis by inactivation of tumor suppressor genes. This study characterized a new lncRNA tumor suppressor named p53activating non-coding RNA (PANCR), located in this Chromosome 16q22.1 region. This PANC RNlncRNA consists of 1.5kb in length. Our data showed that PANCR was downregulated in breast cancer cell lines and tissues. In breast cancer cell lines, PANCR expression appeared reversely correlated with cell malignancy, and in breast cancer tissues, PANC was downregulated over 2 times in 31(62.0%) of 50 cases when compared to adjacent normal breast tissues. In breast cancer cells MCF7 and immortalized human mammary epithelial cells MCF10A, ectopic expression of PANCR induced marked apoptosis, suppressing cell proliferation in culture and tumor growth in xenografts, but in contrast, shRNA-mediated silencing of PANCR induced apoptosis, suppressing cell proliferation in culture and tumor growth in xenografts.

TP73 is the homologue of the master tumor suppressor TP53. It is involved in cellular responses to stress and development. The TP73 gene encodes two different proteins, Tap73 and ANP73, and maps to a region on chromosome 1p36 that is frequently deleted in neuroblastoma and other tumors, and thought to contain multiple tumor suppressor genes. However, the analysis of TP73 knockout mice yielded conflicting results with respect to tumor suppression. Worldwide efforts in sequencing the TP73 gene in patient tumor samples have not provided evidence for genetic alterations as a common cause of p73 inactivation in human cancer. The role of TP73 in tumorigenesis has remained elusive to date. In this study, we isolated two stem cell lines from normal young and old human liver tissues and determined TP73 expression in human breast cancer cell lines (MCF7 & MDA231), human hepatocellular carcinoma (HCC) cell lines (HepG2, SNU398, SNU449 & SNU475), neuroblastoma cell lines (IMR32 & SK-N-SH), normal liver stem cell, non-cancerous Li-Fraumeni Syndrome (LFS) skin fibroblasts cells and normal skin fibroblasts. Results show that Tap73 only expresses in cancer cell lines. Moreover, when HepG2 and MDA231 were treated with paclitaxel, a cytotoxic drug that targets tubulin, Tap73 expression was drastically down-regulated in HepG2 cells and abrogated in MDA231 cells at 1 to 5 μM concentrations. Furthermore, ChIP assay results demonstrated that TP73 only expresses in cancer cell lines. Moreover, when HepG2 and MDA231 were treated with paclitaxel, a cytotoxic drug that targets tubulin, Tap73 expression was drastically down-regulated in HepG2 cells and abrogated in MDA231 cells at 1 to 5 μM concentrations. Furthermore, ChIP assay results demonstrated that TP73 only expresses in cancer cell lines. #2574 The PICT-1 is required for USP7 to effectively stabilize p53 protein, and codon 389 polymorphism is a risk factor for ovarian cancer. Masafumi Yoshimoto, Aki Tokuda, Yuji Yaginuma. Kumamoto Univ. Graduate School of Health Sci., Kumamoto, Japan.

The ovarian cancers causes the deaths of more than 100,000 women per year worldwide, and it is a disease independent with multiple etiological subtypes and molecular characteristics recognized; therefore, overall survival rates have improved little in the last 30 years. We have to precisely identify genetic and molecular events which could serve as markers for early diagnosis or targets for new therapeutics for ovarian cancers. The PICT-1 (also named GLTSCR2), one of the nuclear proteins, has several tumor suppressor functions, such as the stabilization of TP53 and p73. Our studies revealed that the loss of or low expression of PICT-1 is the common alteration in many cancers, such as skin, lung, esophageal, prostate, kidney, breast, and cervix, and its association with ovarian carcinogenesis has been unknown. Therefore, we investigated its alteration, regulation mechanism, and the effect for p53 stabilization in ovarian cancer. We found that polymorphism on codon 389 (rs1849944) was a statistically significant association with the risk of ovarian cancers. Furthermore, ectopic expression of PICT-1 was required for USP7 to effectively stabilize p53 protein. Because PICT-1 was reported to bind both p53 and MDM2 that enabled to form USP7-p53-MDM2 complex, we investigated whether PICT-1 was regulated by USP7-p53-MDM2 complex. Our results suggested that this complex was the important regulator for PICT-1. In the investigation of the role of PICT-1 that plays in the ovarian carcinogenesis using immunohistochemical staining, we found that PICT-1 protein levels decreased in ovarian cancer tissues compared to normal ovaries, and there was a positive correlation between PICT-1 and USP7 protein expression. Our findings suggested that PICT-1 involved in exactly p53 regulation along with MDM2 and USP7, and PICT-1 should be considered as a potential target for therapeutic human cancers.

#2575 Concurrent mutation of CDKN2A and TP53 loci in primary keratinocytes. Bin Li, Edmund A. Mroz, James W. Rocco. The Ohio State University Comprehensive Cancer Center, Columbus, OH.

Concurrent inactivation of the p16INK4a and p53 tumor suppressors, often through mutation of CDKN2A and TP53, is frequent in early development of head and neck squamous cell carcinoma (HNSCC) and other cancers. The role of this early combined inactivation, and the oncogenic drivers that subsequently lead to tumor development, are poorly defined. To characterize the precursor role of concurrently mutated CDKN2A and TP53, we combined a number of recent advances to disrupt both loci in primary cells. First, we grew primary keratinocytes in media conditioned by irradiated J2-3T3 cells and containing an inhibitor of ROCK kinases, conditions that greatly extend their normally limited proliferative potential. Second, we transfected primary keratinocytes with plasmid vectors expressing both Cas9 and sets of guide RNAs targeting specific regions of C DKN2A and TP53. We targeted either or both of the p14ARF and p16INK4a protein products of C DKN2A for knockout (KO), together with either TP53 KO or a TP53 point mutation (R248Q) in a protein product), two major categories of genetic alterations of TP53 in HNSCC. Third, we evaluated usage of nutilin-3, an inhibitor of p53-MDM2 interaction, to try to select against cells that still contained wild-type p53. We assessed K0 efficiency by PCR of genomic DNA; the TP53 point mutation introduced a Sau3AI site into TP53. Two weeks of nutilin-3 treatment led to a 3 fold increase in p53 KO efficiency versus untreated cells (50% versus 14%), p16INK4a K0 efficiencies were enhanced 2 to 14 fold after nutilin-3 treatment, depending on the specific Cas9/guide-RNA constructs used. In cells transfected to produce p53 R248Q, 14% of PCR products amplifying the mutated region after nutilin-3 exposure showed Sau3AI digestion, whereas no Sau3AI digestion was detected in untreated cells. This result suggests that up to 14% of nutilin-3 treated keratinocytes had integrated the mutated donor oligo sequence. We similarly enrich for mutated keratinocytes having p14ARF specific or combined C DKN2A/TP53 KO along with TP53 K0 or point mutation. Combined transfection to generate concurrent CDKN2A and TP53 mutations under conditions that allowed extended proliferation in culture, followed by selection for successful TP53 mutation with nutilin-3, will facilitate identification of keratinocyte clones with bi-allelic knockout genotypes. This panel of keratinocytes with concurrent C DKN2A and TP53 mutations will help delineate the roles of these genes in early cancer development and will allow screening for the oncogenic drivers required for tumor development and metastasis, with emphasis on discovering more effective and specific druggable targets for improving treatment.

#2576 Benzy1 isothiocyanate potentiates p53 signaling and antitumor effects against breast cancer through activation of p53-LKB1 and p73-LKB1 axes. Arumugam Nagalingam, Bei Xie, Panjamurthy Kuppusamy, Nethaji Muniraj, Peter Langford, Balazs Györfi, Neeraj Saxena, Dipali Sharma. 1Johns Hopkins University, Baltimore, MD; 2University of Maryland, Baltimore, MD; 3Hungarian Academy of Sciences, Hungary.
Molecular and Cellular Biology / Genetics: Nuclear Oncogenes and Tumor Suppressors

Functional reactivation of p53 pathway, although arduous, can potentially provide a broad-based strategy for cancer therapy owing to frequent p53 inactivation in human cancer. Using a phosphoprotein-screening array, we found that Benzyl Isothiocyanate, (BITC) increases p53 phosphorylation in breast cancer cells and reveal an important role of ERK and PRAS40/MDM2 in BITC-mediated p53 activation. We show that BITC rescues and activates p53-signaling network and inhibits growth of p53-mutant cells. Mechanistically, BITC induces p73 expression in p53-mutant cells, disrupts the interaction of p73 and mutant-p53, thereby releasing p73 from sequestration and allowing it to be transcriptionally active. Furthermore, BITC-induced p53 and p73 axes converge on tumor-suppressor LKB1 which is transcriptionally upregulated by p53 and p73 in p53-wild-type and p73-mutant cells respectively, and in a feed-forward mechanism, LKB1 tethers with p53 and p73 to get recruited to p53-responsive promoters. Analyses of BITC-treated xenografts using LKB1-null corrob-orate in vitro mechanistic findings and establish LKB1 as the key node whereby BITC potentiates as well as rescues p53-pathway in p53-wild-type as well as p53-mutant cells. These data provide first in vitro and in vivo evidence of the integral role of previously unrecognized crosstalk between BITC, p53/LKB1 and p73/LKB1 axes in breast tumor growth-inhibition.

Expression of P53/PTEN/c-Myc in peripheral blood leukocytes from patients with breast cancer and its clinical significance. Guancheng Huang, Qiang Ma, Jiang Zou, Ru Sun, Lei Xu, Dongsheng Wang, Xiaoan Guo. North Sichuan Medical College, Nanchong, China. Affiliated Hospital of North Sichuan Medical College, Nanchong, China.

Breast cancer is the fifth leading cause for cancer-associated deaths among women in the US. High-grade serous ovarian carcinoma is the most common histological subtype and is characterized by frequent (>90%) mutations in the TP53 (p53) gene. Gain-of-function (GOF) p53 mutant proteins form highly stable aggregates that accumulate in ovarian cancer cells and have been shown to have oncogenic activity. Increasing evidence indicates the stabilization of GOF p53 mutants to be important for tumor progression and drug resistance. Therefore, selective degradation of the GOF p53 mutant proteins is a highly attractive therapeutic strategy to specifically target ovarian cancer cells. We identified that a small molecule named MCB-613, originally discovered as a stimulator of ste-roid receptor coactivator-3 (SRC-3), causes rapid degradation of the usually stable p53R175H/172H stabilization of macromolecular aggregates leading to catastrophic cell death in human ovarian cancer cell lines. Our results indicate this effect is independent of SRC-3 mediated gene expression, but rather by post-translational mechanisms underlying the metastatic properties of ESCC. p53 is one of the most commonly mutated genes in ESCC, and our group has shown that esoph-ageal cells lines expressing a mutation in human p53 shows signs of malignancy and increased invasion in 3D organotypic culture. A mouse model of mutant p53 (H11005) in ESCC is lacking the role of stabilizing mutant p53 in ESCC we developed a novel mouse model utilizing a genetic and carcinogenic approach. L2cre;p53R175H/172H mice were generated and treated with 4NQO in their drinking water for 16 weeks, which resulted in the development of ESCC. Compared to wildtype mice, p53R175H/172H mice and p53 mutant mice displayed similar tumorigenic properties. RNA-seq was performed on cell lines established from wildtype and p53 mouse models and revealed different gene expression profiles between wildtype, p53R175H/172H, and p53 mutant cells. p53R175H/172H cells displayed an increase in mesenchymal and decrease in epithelial marker expression, supporting the idea that they are undergoing EMT. In addition, several endocytic recycling related genes, including Rab11-fip1, Rab26, and Myo5b were downregulated in mutant and null p53 compared to wildtype cells. Further examination of the differing genetic profiles in our mouse models can provide novel insight into the role of mutant p53 in ESCC tumorigenesis and lead to the identification of new therapeutic targets.

Identifying pathways that regulate the turnover of gain-of-function p53 mutant proteins in ovarian cancer cells. Achuth Padmanabhan, Nicholas Candela,

Cancer is the leading cause of cancer-associated deaths among women worldwide. Current data showed that the morbidity of breast cancer has been rising shifting with younger age in the last decades, therefore early detection is urgently needed to improve the management of breast cancer as what has been working on many other malignancies. Dysfunction of tumor suppressor gene and/or oncogene may play vital roles in tumorigenesis and cancer progression, such as P53, PTEN and c-Myc. In this study we aim to detect the expression of P53/PTEN/c-Myc mRNA in peripheral blood leukocytes from patients with breast cancer and benign breast diseases, and investigate its correlation with the clinicopathologic characteristics, further to explore the potential clinical application significance. In this study, fluorescent quantitation Real-time Polymerase Chain Reaction (FQ-RT-PCR) was employed to detect the expression of P53/PTEN/c-Myc mRNA in peripheral blood leukocytes from 304 cases, including 105 patients with breast cancer. 107 cases of benign breast diseases and 92 healthy women as control. 2-ΔΔCT was used to calculate the relative quantitative gene expression and Mann-whitney U test was carried to distinguish the differences among the independent cohorts. The results showed that P53 and PTEN mRNA were significantly reduced in both breast cancer group and benign breast diseases group, respectively (P<0.01), moreover, the P53 mRNA in benign breast diseases was even lower than that in breast cancer (P<0.01). However, c-Myc didn’t show any obvious difference among the three groups. Further investigation the genes expression with clinicopathologic characteristics, we found that PTEN in patients with breast cancer was correlated with lymph nodes metastasis, and dysregulation of P53/PTEN was found in patients with benign breast diseases, even more obvious than that in breast cancer patients. Moreover, c-Myc mRNA might predict and/or display the early events of breast cancer carcinogenesis and lymph nodes metastasis. Our findings suggest that detection of tumor related genes in peripheral blood leukocytes would serve as a unique potential approach in early and noninvasive diagnosis of tumors, also would be very promising in clinical applications as well.

Esophageal squamous cell carcinoma (ESCC) is a highly aggressive cancer characterized by a high rate of metastasis, limited therapeutic options, and a poor prognosis. However, there is limited information regarding the molecular mechanisms underlying the metastatic properties of ESCC. p53 is one of the most commonly mutated genes in ESCC, and our group has shown that esophageal cells lines expressing a mutation in human p53 shows signs of malignancy and increased invasion in 3D organotypic culture. A mouse model of mutant p53 (H11001) in ESCC is lacking the role of stabilizing mutant p53 in ESCC we developed a novel mouse model utilizing a genetic and carcinogenic approach. L2cre;p53R175H/172H mice were generated and treated with 4NQO in their drinking water for 16 weeks, which resulted in the development of ESCC. Compared to wildtype mice, p53R175H/172H mice and p53 mutant mice displayed similar tumorigenic properties. RNA-seq was performed on cell lines established from wildtype and p53 mouse models and revealed different gene expression profiles between wildtype, p53R175H/172H, and p53 mutant cells. p53R175H/172H cells displayed an increase in mesenchymal and decrease in epithelial marker expression, supporting the idea that they are undergoing EMT. In addition, several endocytic recycling related genes, including Rab11-fip1, Rab26, and Myo5b were downregulated in mutant and null p53 compared to wildtype cells. Further examination of the differing genetic profiles in our mouse models can provide novel insight into the role of mutant p53 in ESCC tumorigenesis and lead to the identification of new therapeutic targets.

Identifying pathways that regulate the turnover of gain-of-function p53 mutant proteins in ovarian cancer cells. Achuth Padmanabhan, Nicholas Candela, Kwonok Wong, Bryan C. NikoI, David Leonard, Bert W. O’Malley, JoAnne S. Richardson. Baylor College of Medicine, Houston, TX; M D Anderson Cancer Center, Houston, TX.

Ovarian cancer is the fifth leading cause for cancer-associated deaths among women in the US. High-grade serous ovarian carcinoma is the most common histological subtype and is characterized by frequent (>90%) mutations in the TP53 (p53) gene. Gain-of-function (GOF) p53 mutant proteins form highly stable aggregates that accumulate in ovarian cancer cells and have been shown to have oncogenic activity. Increasing evidence indicates the stabilization of GOF p53 mutants to be important for tumor progression and drug resistance. Therefore, selective degradation of the GOF p53 mutant proteins is a highly attractive therapeutic strategy to specifically target ovarian cancer cells. We identified that a small molecule named MCB-613, originally discovered as a stimulator of ste-roid receptor coactivator-3 (SRC-3), causes rapid degradation of the usually stable p53R175H/172H stabilization of macromolecular aggregates leading to catastrophic cell death in human ovarian cancer cell lines. Our results indicate this effect is independent of SRC-3 mediated gene expression, but rather by post-translational mechanisms underlying the metastatic properties of ESCC. p53 is one of the most commonly mutated genes in ESCC, and our group has shown that esophageal cells lines expressing a mutation in human p53 shows signs of malignancy and increased invasion in 3D organotypic culture. A mouse model of mutant p53 (H11001) in ESCC is lacking the role of stabilizing mutant p53 in ESCC we developed a novel mouse model utilizing a genetic and carcinogenic approach. L2cre;p53R175H/172H mice were generated and treated with 4NQO in their drinking water for 16 weeks, which resulted in the development of ESCC. Compared to wildtype mice, p53R175H/172H mice and p53 mutant mice displayed similar tumorigenic properties. RNA-seq was performed on cell lines established from wildtype and p53 mouse models and revealed different gene expression profiles between wildtype, p53R175H/172H, and p53 mutant cells. p53R175H/172H cells displayed an increase in mesenchymal and decrease in epithelial marker expression, supporting the idea that they are undergoing EMT. In addition, several endocytic recycling related genes, including Rab11-fip1, Rab26, and Myo5b were downregulated in mutant and null p53 compared to wildtype cells. Further examination of the differing genetic profiles in our mouse models can provide novel insight into the role of mutant p53 in ESCC tumorigenesis and lead to the identification of new therapeutic targets.

Ceramide (Cer), a sphingolipid metabolite, has crucial functions in anti-proliferation, cell differentiation and apoptosis. Cellular Cer levels highly correlates to therapeutic efficacy of anticancer drugs, however, the hydrophobicity Cer has limits to develop it as a therapeutic agent. Here, we report that Cer-rubusoside (Cer-RUB) nanomicelles enhanced Cer bioavailability and restored p53-mediated tumor suppression. These nanomicelles significantly increased the levels of NBD-C6-Cer by more than 50-fold in serum, 40-fold in tumor and 70-fold in lung of tumor-bearing mice (1 mg/kg, i.p., 24 hr), respectively. Cer-RUB (3 µM)
significantly increased OVCAR-3 (p53 R248W) cell sensitivity to cisplatin, and the IC50 values decreased by 3-fold, even though these values were no significant changes in A2780 (wt p53) cells. Furthermore, Cer-RUB treatments (1 mg/kg, i.p. every 3 days for 24 days) significantly increased cisplatin efficacy in tumor growth-arrest in OVCAR-3 tumor-mice, and the tumor volumes reduced by 52% (IC50 values decreased by 3-fold) as compared to cisplatin alone. We found that ovarian cancer stem cells (CD44+/CD133−) decreased by 10-fold (0.85 ± 0.08% of total cells) in OVCAR-3 tumors treated with Cer-RUB combined with cisplatin, as compared to cisplatin alone, respectively. Western blotting showed that Cer-RUB treatments selectively increased the expression levels of phosphorylated p33 (Ser15), BAX and p21 in OVCAR-3 cancer cells and tumors, respectively. These studies indicate that the gain-of-function (GOF) of p53 R248W leads OVCAR-3 cell resistance to cisplatin and tumor growth. Cer-RUB can restore p53 and eliminates the GOF of p53 R248W in cancers.

#2581 VGLL4 suppresses the human breast cancer progression through the inhibition of YAP oncogenic function. Jianmin Zhang, Roswell Park Cancer Inst., Buffalo, NY.

VGLL4 is a Vestigial-like (VGLL) protein that is deregulated in various types of cancer. However, the functions of VGLL4 in breast cancer remain largely unknown. Here, we demonstrate that VGLL4 expression positively correlates with survival for breast cancer patients. The overexpression of VGLL4 in breast cancer cells reduced cell proliferation, colony formation, cell migration and invasion in vitro and inhibited tumor growth in vivo. We found that the 2nd TEAD-interacting domain (TUD2) of VGLL4 is involved in interactions between VGLL4 and the transcription factor TEAD and that the deletion of this domain completely abolished the phenotype induced by VGLL4 overexpression. Interestingly, RNAseq analysis indicated that VGLL4 overexpression not only inhibits YAP targets but also activates the TGF-β and Notch signaling pathways. Our study provides evidence of the tumor-suppressive effects of VGLL4 on breast cancer progression and suggests that VGLL4 and its TUD2 domain may become promising and efficient therapeutic targets for delaying the development of breast cancer and improving patient survival.

BIOMETRICS AND SYSTEMS BIOLOGY: Computational Tools and Databases

In this study, we tried to develop valid KIR calling algorithm from WES/WGS data. As a consequence, here we suggest KIRnome (KIR typing for whole genome and exome sequencing) which is a KIR typing method for applying sequencing data such as WES/WGS. A total of 71 sequencing data (18 WES and 53 WGS data, respectively) and matched experimentally validated KIR genotype data are used to train and validate. Before developing this method, two types of allele references (genomic and coding, here after called gSeq and cSeq) are constructed by allele sequence of IPD/KIR. KIRnome consists of two part, first part is calculating normalized depth (here after called depth) of 16 KIR genes and considering allele reference length and second is estimating KIR type based on depth. In general, we get higher normalized depth when using genomic references for WGS data and using coding references for WES data. This coincides with scheme KIRnome and the characteristics of WGS and WES data. Given 71 samples of 3 data sets, we evaluated KIR genotyping performance of KIRnome per each KIR gene. For all 16 KIR genes, KIRnome shows >98.5% accuracy. When KIRnome performance was tested only in 13 WES samples, the accuracy slightly drops to 94%. We assume this is attributable to relatively small number of the samples. In conclusion, we developed a novel and unique method named KIRnome for KIR typing from NGS data. KIRnome could determine KIR geno- type accurately from WES and WGS data respectively. We expect KIRnome would facilitate revelation of immunogenetic factors in various disease. More- over, future generation of KIR specific NGS data and improved reference sequence information of KIR would enable KIRnome to type KIR at allele level in a near future.

#2583 A model for capturing and integrating complex molecular altera- tions related to clinically relevant efficacy evidence. Cara M. Statz, Sara E. Patterson, Taofei Yin, Susan M. Mockus. The Jackson Laboratory for Genomic Medicine, Farmington, CT.

The ability to capture data relevant to different types of oncology-related variables, including clinical variables, copy number variations, and fusions in a single system is crucial to a comprehensive understanding of cancer biology. However, collectively linking these varied types of molecular alterations to capture their compound impact to clinically relevant efficacy evidence within a database can prove challenging. Thus, we have built the JAX Clinical Knowledgebase (JAX-CKB), a flexible relational da- tabase that allows curation of complex molecular profiles and provides the abil- ity to associate these profiles with documented efficacy evidence, thereby pro- viding a more detailed overview of therapeutic relevance. To demonstrate the utility of creating molecular complex signatures in relation to efficacy evidence, the JAX-CKB was queried to first determine the overall degree of efficacy evi- dence content related to complex profiles. Additionally, two specific types of complex molecular profiles were queried, which included EML4-ALK plus a missense mutation(s) and BRAF V600E plus any type of molecular alteration(s). Within the JAX-CKB, there are 1,383 unique efficacy evidence lines linked to complex molecular profiles. The complex molecular profiles consisting of EML4-ALK and one or more additional missense mutations were associated with 174 unique efficacy evidence lines. Of the 174 lines, 69 were annotated with a specific response type, while 68 were annotated with a non-specific response type. The combination of BRAF V600E with one or more molecular alterations was linked to 229 unique efficacy evidence lines. The majority of the lines, 118, were specific to a resistant response type and 83 were associated with sensitivity. Comprehensive genomic profiling of cancer patient samples can often reveal complex molecular signatures. The JAX-CKB is an inclusive knowledgebase that allows one to interpret these complex signatures and rapidly identify appropri- ate targeted therapies, which could be critical in a clinical setting.

#2584 The UCSC Xena system for cancer genomics data visualization and interpretation. Mary Goldberg, Brian Craft, Jingchun Zhu, David Haussler. UC Santa Cruz, Santa Cruz, CA.

The UCSC Xena platform (http://xena.ucsc.edu/) allows biologists and bioin- formaticians to securely analyze and visualize their private functional genomics data in the context of public genomic and clinical data. The Xena platform consists of a set of federated data hubs and the Xena browser, which integrates across hubs, providing one location to analyze and visualize all data. Our expanding public Xena Data Hubs currently hosts 1400+ data sets from more than 35 cancer types, as well as Pan-Cancer data sets. Our public data hubs serve seminal cancer genomics and functional genomics data set to the scientific community, including the latest TCGA, TARGET, ICGC, and GTEx data sets. We support most data types including somatic and germline SNPs, INDELs, large structural variants, CNV, gene-, transcript-, exon- protein-, miRNA-expression, DNA methylation, phenotypes, clinical data, subtype classifications and genomic biomarkers. Additionally, investigators’ own functional genomics data can be hosted on private hubs running on their laptop or behind the firewall. Data is integrated on the UCSC Xena Browser, allowing biologists to view and interpretation of their genomic data in the context of a large collection of cancer genomics data sets such as TCGA. The lightweight Xena data hubs are straightforward to install on Windows, Mac and Linux operating systems and loading data is easy using either our application or command line interface. This system of the browser and hubs helps researchers combine new or preliminary results from their laptops or internal servers, or even data from a new paper, securely with vetted data from the public sphere. Visualizations and analyses include dynamic Kaplan-Meier survival analysis to assess survival stratification by any information in addition to our visual spreadsheet, scatter plots and bar graphs. We seek feedback at our poster on new visualizations and functionalities.

#2585 viGEN: An open source bioinformatics pipeline for viral RNA de- tection and quantification in human tumor samples. Kritthika Bhuvaneswar, Lei Song, Yuriy Gusev. University of Maryland School of Medicine, Baltimore, MD.

We present a novel pipeline for viral RNA detection and quantification in human RNA-seq data. Our pipeline has been tested on the TCGA liver cancer cohort, can not only detect the presence of a viral species, but also provide gene level read counts for individual viral species and extract viral-variants. Introduction Approximately 20% of human cancer types are associated with viral infec- tion that is routinely detected in blood samples. However the extent and biolog- ical significance of viral presence/infection in actual tumor samples is generally unknown but could be measured using existing Human RNA-seq data from tumor samples. We have developed a bioinformatics pipeline viGEN combining...
CellMinerCDB: Enabling cross-database exploration of molecular pharmacology data and response determinant discovery in cancer cell lines.

Vinoth N. Rajapakse,1 Augustin Luna,2 Chris Sander,2 William C. Reinhold,3 Yves Pommier1
1National Cancer Institute, Bethesda, MD; 2Dana-Farber Cancer Institute, Boston, MA.

Cancer cell line panels are widely used for evaluating drug response across diverse tissue types. A growing set of molecular profiling data is providing measurements of chemosensitivity, providing novel avenues for response determinant discovery and clinical translation. Accessing and inter-relating data from different sources is essential for evaluating such determinants, but remains challenging. To enable wider access to cell line pharmacogenomic data, we have developed CellMinerCDB (CellMiner Cross-Database, discover.nci.nih.gov/cellminercdb), a web application integrating data from several widely studied cancer cell line panels, including the NCI-60 (NIH), GDSC (Sanger/MIH), and CCLE/CTRP (Broad). All together, our database spans over 1300 distinct cell lines, 400 clinically relevant cancer drugs, 20,000 experimental compounds, and molecular profiling data, such as gene/protein expression, DNA copy, methylation, and mutational status. Cell line and tested drug overlaps allow cross-database validation of genomic and drug data, and CellMinerCDB simplifies this by transparently matching differently named entities between sources. Data exploration can be additionally restricted to particular tissue types, with individual cell lines annotated to the OncoTree ontology for consistent treatment across sources. A range of analysis tools support interactive data exploration, from 2D plots of drug response and molecular profiling features to exhaustive correlation analyses and multivariate predictive models. We illustrate the power and utility of CellMinerCDB with examples of response determinant discovery and predictive modeling for Top1 and PARP inhibitors. Beginning with established individual determinants, such as SLF11 mRNA expression, we show how both unbiased and biological knowledge network-based feature selection methods enable iterative refinement of a multivariate genomic signature of drug response. For Top1 inhibitors, additional predictive features include expression of chromatin remodeling factors and genes modulating apoptosis capacity, while complementary PARP inhibitor response determinants include PARP1 and drug efflux pump expression. Pathway and process-based gene annotations allow biological interpretation of response predictive features. CellMinerCDB also includes ongoing algorithmic work to improve the construction of multivariate predictive models using constraints from biological networks. These approaches bridge a limiting gap in existing methods, which either ignore biological knowledge altogether or are limited to exploration within known pathways and processes.

VCF2CNA: a tool for efficiently detecting copy number alteration using VCF genotype data.

Daniel K. Putnam, Xiaotu Ma, Stephen V. Rice, Yu Liu, Jinghui Zhang, Xiang Chen. St. Jude Children’s Research Hospital, Memphis, TN.

Whole genome sequencing (WGS) is increasingly used in both research and clinical settings. The Variant Call Format (VCF) specification is a widely adopted file format for genetic variation data exchange partially due to its smaller file size compared to raw WGS BAMs. Each variant in a typical VCF file contains its chromosome position, reference/alternative alleles and corresponding allele frequencies. VCF can also be used to store other biological information, such as synonymous mutations. To this end, we developed VCF2CNA (http://vc2cna.stjude.org), a web interface tool for CNA analysis from VCF files. A user of VCF2CNA uploads a VCF file via the provided web interface. The entire analysis runs remotely with an average run time of 23 minutes. Results are emailed to the user as either a downloadable link or file attachments. VCF2CNA also accepts input in the Mutation Annotation Format (MAF) and the variant file format produced by the Barabina program. We analyzed 22 TCGA glioblastoma tumor/normal pairs by Illumina technology to evaluate VCF2CNA’s performance. It achieved high consistency (average F₁-score: 0.952 ± 0.082) with CONCERTING, a tool that incorporated read-depth and SV data from raw BAMs for CNA detection. A segment-by-segment comparison between results from CONCERTING and VCF2CNA indicated that the latter was less sensitive to focal CNAs. This is expected because there is less information in the VCF input than in raw BAMs. Further analysis using samples with a “fractured genome” pattern revealed that VCF2CNA was more robust to library artifacts and produced relatively clean CNA profiles (on average 76.2-fold reduction compared to the number of segments reported by CONCERTING). Finally, we analyzed 137 pediatric neuroblastoma samples from the Children’s Cancer Group’s Complete Exome sequencing (CCGEX) project. The majority of tumors were known to be infected with both HBV and various subtypes of HCV. Once the viral genomes are detected at the genome level, we examine the differences in viral-variant level. Conclusion: Our results show that it is possible to detect viral infection in complex diseases, tumorsigenes and cancer immunology.

GenePattern Notebook: an environment for reproducible cancer research.

Michael M. Reich,1 Thorin T. Tabor,2 Ted Liefield,3 Barbara Hill,3 Helga Thorvaldssdottir,3 Jill P. Mesirov,4 University of California, San Diego, La Jolla, CA; 2Broad Institute, Cambridge, MA.

As the availability of genetic and genomic data, and analysis tools from large-scale cancer initiatives continues to increase, the need has become more urgent for a software environment that supports the entire “idea to dissemination” cycle of an integrative cancer genomics analysis. Such a system would need to provide access to a large number of analysis tools without the need for programming, be sufficiently flexible to accommodate the rapidly evolving nature of computational biology as well as experienced bioinformaticians, and would provide a way for researchers to encapsulate their work into a single "executable document" including not only the analytical workflow but also the associated descriptive text, graphics, and supporting research. To address these needs, we have developed GenePattern Notebook, based on the GenePattern environment for integrative genomics and the Jupyter Notebook system. GenePattern Notebook unites the phases of in silico research – experiment design, collaborative analysis, and publication – into a single interface. GenePattern Notebook presents a familiar lab-notebook format that allows researchers to build a record of their work by creating “cells” containing text, graphics, or executable analyses. Researchers add, delete, and modify cells as the research evolves, supporting the initial research-to-publication cycle. When an analysis is ready for publication, the same document that was used in the design and analysis phases becomes a research narrative that interleaves text, graphics, data, and executable analyses, serving as the complete, reproducible, in silico methods section for a publication. GenePattern Notebook features are designed to make it easy for nonprogramming users to create and adapt notebooks. We have developed new cell types that allow users to choose analyses, specify input parameters and datasets, navigate results, send result files to new analyses, and create richly formatted text, all without the need for programming. We have released a freely available online GenePattern Notebook workspace, http://notebook.genepattern.org, where researchers can develop and publish notebook documents. We have provided a collection of template notebooks that walk users through various macroscopic analysis pipelines, and are collaborating with cancer research laboratories to create integrative cancer genomics notebooks as well. Notebook topics in development include characterization of intratumor heterogeneity from single cell RNA-Seq data, effective clinical interpretation of comprehensive genomic profiling from whole exome sequencing of a patient’s...
tumor and germ line samples, and identification of master regulators/transcription factors associated with the downstream transcriptional effects associated with the activation of an oncogene.

#2589 Identifying cancer susceptibility variants and genes using whole exome and genome sequencing: a literature review. Melissa Rotunno,1 Mindy Clyne,1 Tam Lam,1 Leah Mechanic,1 Danielle Daee,1 Stefanie Nelson,1 Elizabeth Gillanders,1 Alisa Goldstein,1 1NCI-DCCPS, Rockville, MD; 2NCI-DCEG, Rockville, MD.

The application of Next Generation Sequencing (NGS) technologies in cancer research enabled the discovery of novel somatic mutations at an unprecedented speed through efficient high-throughput profiling of DNA variation in tumor samples. In contrast, the identification through NGS studies of germline variation associated with cancer has been more difficult and with limited consensus around best practices for study design and analytical techniques. We performed a review of the 2005–2016 PubMed English literature for genome-wide germline sequencing studies that were aimed at identifying new cancer susceptibility variants or genes. We extracted and summarized the experimental and analytical designs, methods and tools implemented in the selected literature together with their degree of success and limitations in identifying cancer susceptibility variants. About 80 in-scope publications were identified and examined in depth. The most studied cancer types were colorectal, breast, blood and lung and were investigated predominantly via whole exome sequencing (primarily using Illumina HiSeq) in familial cases of Caucasian ethnicity. Only studies that used whole genome sequencing and 15 adopted a case control study design. A large fraction of the familial studies was limited to 1 or 2 families. The most common cancer types included the top few variants or genes. About 60% of the studies included replication in an independent group of cancer patients and 55% functionally validated their findings to some extent. Our work provides valuable data and insights to inform future sequencing studies of cancer genetic susceptibility, and points to the need for improving standardization and completeness in reporting of quality control metrics, study design rationale and interpretation of findings.

#2590 Analysis of APOBEC3A and APOBEC3B mutational signatures using next-generation sequencing data from cancer cell lines. Suleyman Vural, Julia Krushkal, Richard Simon. National Cancer Institute, Rockville, MD.

The APOBEC (apolipoprotein B mRNA editing enzyme, catalytic polypeptide-like) gene family of cytidine deaminases includes evolutionarily conserved genes that play important roles in DNA repair and mRNA editing. Activity of at least two APOBEC family members, APOBEC3A and APOBEC3B, can lead to kateisias, a mutagenic process in cancer cells that generates clusters of closely spaced, single strand specific C→T DNA substitutions. APOBEC mutagenesis has a characteristic signature, most commonly represented by the 5’-Tp(C→TpW)-3’ sequence motif, with additional substitutions also reported. This hypermutation signature and high mRNA expression of APOBEC3A and APOBEC3B have been associated with several cancer types. Most previous studies of APOBEC signatures have examined tumor sequence data from clinical samples, for which limited or no information about drug response was available. We investigated the presence of the mutational signature and mRNA expression patterns of the APOBEC3A and APOBEC3B genes in extensively characterized cell lines, in order to identify those cell lines that carry mutations generated by kateiasis, with the aim of establishing associations between the APOBEC mutational signature, individual cancer types, and the patterns of sensitivity to anti-tumor agents. For this purpose, we analyzed whole exome sequencing (WES) data and mRNA expression of the APOBEC3A and APOBEC3B genes in two resources with extensive drug response data: the NCI-60 cell line panel, which includes 60 cancer cell lines, and the CANCER Cell Line Encyclopedia (CCLE), which provides WES, whole genome, and RNA-seq sequence information for thousands of anticancer agents, and the Cancer Cell Line Encyclopedia (CCLE), which provides WES, whole genome, and RNA-seq sequence information on hundreds of cancer cell lines and drug response data to over 200 agents. We analyzed WES data of 325 CCLE cell lines and 59 NCI-60 cell lines, with variants identified using GATK pipeline and Varscan2 software. The variants in each cell line were filtered to remove common polymorphisms in dbsNP and 1000 Genome Project databases. We searched the discovered variants for the presence of APOBEC signatures, 5’-Tp(C→TpAG)Pn-3’, 5’-Tp(C→TpAGT)P-3’, and 5’-Tp(C→TpAGTPW)-3’ in closely spaced (1000 and 10,000 bp) windows that appeared on the same DNA strand. We will discuss the use of optimal filters for detecting APOBEC mutational signatures and will present the analyses of associations between APOBEC signatures, mutation load of the tumor cell lines, APOBEC gene expression, and chemosensitivity to treatment. These results contribute to additional characterization of available cell lines by providing information about specific mutational signatures in different cancer cell types associated with identifying antitumor agents that would be appropriate for treatment of cancer cells with specific signature patterns generated by APOBEC mutagenesis.

#2591 A guide to filtering TARGET Complete Genomics germline variants. James P. Evans,1 Rajesh Patidar,2 Zalman Vaksman,1 Sivashish Sindiri,2 Douglas R. Stewart,2 Javed Khan,3 Jun S. Wei,1,5 Sharon J. Diskin1. 1Children’s Hospital of Philadelphia, Philadelphia, PA; 2National Cancer Institute, Bethesda, MD.

With the public release of TARGET’s pediatric cancer data, researchers are eager to investigate and integrate variants from both tumor and germline sequencing data, but caution should be used when interpreting TARGET variant calls from Complete Genomics data, as they unlike the Illumina based calls for which most of our databases and tools are customized. Here, we use germline samples from 55 neuroblastoma cases with both whole genome Complete Genomics variants and whole exome Illumina variants from GATK, Pindel, Platypus, and bam2mpq to investigate differences between germline variant calls from Complete Genomics and Illumina platforms. Our study of ~160,000 single nucleotide polymorphisms (SNPs) and ~19,000 insertions or deletions (indels) reveals that while SNP sets largely agree between Complete Genomics and Illumina, Complete Genomics data sets have many indels not present in Illumina calls, making it difficult to screen Complete Genomics indels against popular Illumina based variant databases like those provided by the Exome Aggregation Consortium and the National Heart, Lung, and Blood Institute Exome Sequencing Project. Further probing of Complete Genomics indels uncovered inconsistent indel formatting resulting in a loss of recurrent variants, and miscalculated read depths in earlier versions of the Complete Genomics platform. To solve these issues and make Complete Genomics variant calls comparable to Illumina calls, we introduce a Snakemake pipeline that reforms Complete Genomics variant files and creates variant features for use in decision tree or random forest classifiers trained to recognize Complete Genomics variants that will be present in Illumina variant call sets. We determine that the most important features for locating Complete Genomics variants likely to be found in Illumina germline variant call sets are the presence of reads from both directions, average variant allele fraction across the cohort, a variant call in the matched tumor, the variant fraction of reads, and read depth. Using ten fold cross validation with our decision tree, we obtain >95% recall and >98% precision for SNPs, and >99% recall and >85% precision for indels. We advocate the use of our pipeline and filtering scheme for making Complete Genomics variant calls comparable to Illumina based calls.

#2593 Accelerating pediatric brain tumor research through team science solutions. Amanda Christini,1 Angela J. Waanders,2 Joost B. Wagenaar,1 Alex S. Felmeister,2 Mariarita Santi,2 Nittin R. Wadhwani,1 Jennifer L. Mason,2 Mateusz Kopytya,2 Jena V. Lilly,2 Jeffrey W. Pennington,2 Rishi R. Lulla,3 Adam C. Resnick2. 1Blackfynn, Incorporated, Philadelphia, PA; 2The Children’s Hospital of Philadelphia, Philadelphia, PA; 3Ann & Robert H. Lurie Children’s Hospital of Chicago, Chicago, IL.

Introduction: The Children’s Brain Tumor Tissue Consortium (CBTTC), an international repository of genomic and phenotypic data, has partnered with Blackfynn, Inc., to create a cloud-based data management platform to facilitate team-science across disciplines. Background: The CBTTC and Blackfynn through the CHOP Department of Biomedical and Health Informatics (DBHI) has developed a network of informatics and data applications for researchers across the globe to work together and perform real-time analyses on existing clinical, phenotypic, and genomic data. Historically, rare disease datasets are siloed, locked in proprietary formats, segregated by data types, and hidden from the view of experts in the field. This has been a significant barrier to finding effective therapeutics for children with pediatric brain tumors. Blackfynn was founded by a group of multidisciplinary experts in neuroscience, neurology, medicine, software development, engineering, computer science and business with the goal to empower researchers to cure neurologic disease and provide solutions to these challenges. Description of Methods: The CBTTC and Blackfynn teamed up to provide a cloud-based, team-focused data management and analytics platform. The platform provides a commercial grade, scalable approach to upload, view, and integrate digital pathology images with relevant subject data such as MRIs, pathology reports and genomic information. Stakeholders can search integrated data
without requiring users to change their current workflow or conform to imposed data standards. This platform is a simple, intuitive, end-to-end software platform for teams of scientists and pathologists to review, annotate and discuss cases, enabling rapid diagnostic consensus, quality control, and empowered discovery. Summary of Unpublished Results: The CBTT/Cornell BlackFynn data platform enabled us to engage in a cross-institutional, cross-disciplinary collaboration to create a cancer cloud platform that allows for efficient, reproducible data analysis. The Cancer Cloud Pilot project seeks to directly address these challenges by co-localizing data with the computational resources to analyze it where researchers can access it securely and easily. The project was designed to curate, store, harmonize and jointly use these omics data sets together for big biomedical data. Existing software components in the Explorer™ Technology Platform can quickly and efficiently be used to construct custom UI tools to query, analyze and visualizing data. This is not only important to have effective solutions for data storage and data management, but for data curation and data analysis and visualization. Data curation ensures that data from various sources are harmonized, standardized and cross-comparable. Powerful data analytics and visualization is pivotal in transforming data into information, new insights and added value. To address these problems, MediSapiens has developed the Explorer™ Technology Platform solution, based on its extensive experience in both industrial software development and academic biomedical research. The Explorer™ Technology Platform has been designed for all of the three major parts of the data research workflow: for curating data, storing and managing data, and analyzing and visualizing data. This web browser based, integrated solution provides functionalities to import, curate, ontology map and store rich clinical data, as well as very large data sets of gene expression, copy number, mutation and other profiling data for both bulk and single-cell analyses (e.g. single-cell RNA-seq), and perform various analyses and visualization on the data. Existing software components in the Explorer™ Technology Platform can quickly and efficiently be used to construct custom UI tools to query, analyze and interpret data according to individual customer needs. Further, the platform provides APIs which enable retrieval of data for integration with other systems, or development of custom analyses using e.g. R. Here, we will illustrate the implementation of Explorer Technology Concept to solve a variety of problems in preclinical cancer research and personalized medicine, starting from efficient automated curation of clinical data through to integration of clinical and multi-omics data.

**#2594 Optimizing the replication of cancer genomics workflows: case studies.** Jerry Fowler,1 F. Anthony San Lucas,1 Smruthy Sivakumar,1 Aditya Deshpande,2 Humam Kadara,2 Paul A. Scheet.1 UT MD Anderson Cancer Center, Houston, TX; 2Weill Cornell Graduate School of Medical Sciences, New York City, NY; 3American University of Beirut, Houston, TX.

Replicating results is a major issue in cancer biology, whose “workbench” is dynamic and complex, with frequently updated algorithms and software. The better to manage our work in this environment we have developed SyQADA, a System for Quality-Assured Data Analysis – a workflow automation system designed to simplify common sequential analysis processes on the same or different data. SyQADA manages many of the details of procedural bookkeeping involved in bioinformatics workflows. What samples are we using? Where are the raw data? Were all the samples processed? Did every job complete satisfactorily? Is there as much output as expected? Where are the input files for the next step? How long does a typical job take to run? Which program versions did we use? Can we easily compare these results with the output of a different version of a program, or with different input data? Using SyQADA, we have found our selves better able to reproduce results while at the same time reducing the human effort required to manage our upstream data analyses. Here, we briefly describe how our lung cancer studies have benefitted from the use of SyQADA. To understand the effect of different variant callers for Ion Torrent deep sequencing data in a lung cancer genomics study, we created a work protocol that allowed us to compare the different sets of variants called on 34 distinct somatic DNA samples from 4 patients. This complex processing framework involved running multiple variant callers, annotating variants, filtering germline variants using quality control metrics, and collating results across samples and callers. With SyQADA, we were able to re-run individual processes changing parameters with trivial changes to our configuration, yielding improved output. We then applied that unmodified protocol to the 500 samples from 48 individuals in our study, and rapidly produced data from which we could perform biological analysis. We then applied the protocol to a study of pre-malignant lesions in 25 lung cancer patients. In both studies, our workflow allowed us to generate comparable results in a matter of hours rather than days. SyQADA has been used by individuals with backgrounds ranging from expert programmer to Unix novice, to perform and repeat dozens of diverse analytical workflows. Projects to which SyQADA has been applied include allelic imbalance studies of TCGA samples for cancers of the breast, pancreas, lung, and colon, processing roughly 6000 samples through a dozen steps. A zipline containing the SyQADA executable source code, documentation, tutorial examples, and workflows used in our lab will be available.

**#2595 Enabling petabyte-scale cancer genomics with the NCI Cancer Cloud Pilots.** Gaurav Kaushik, Yilong Li, Erik Lehnhert, Zeynep Onder, Devin Locke, Brandi N. Davis-Dusenbery, Deniz Kural.

The advent of next generation sequencing has accelerated the generation of genomic data and created a need for methodologies to organize, share, and analyze large volumes of data. To date, petabytes of multi-dimensional information from thousands of patients have been collected. Access and analysis of this information becomes increasingly challenging as the amount of data grows. This difficulty is exemplified when we consider data generated by the efforts of The Cancer Genomics Atlas (TCGA) network, which encompasses more than 2.5 petabytes with a highly optimized network connection and access to large institutional compute clusters to perform integrated analysis, which is out of reach for many researchers. The Cancer Cloud Pilot project seeks to directly address these challenges by co-localizing data with the computational resources to analyze it where researchers can access it securely and easily. The project was designed to curate, store, harmonize and jointly use these omics data sets together for big biomedical data. Thus, it is not only important to have effective solutions for data storage and data management, but for data curation and data analysis and visualization. Data curation ensures that data from various sources are harmonized, standardized and cross-comparable. Powerful data analytics and visualization is pivotal in transforming data into information, new insights and added value. To address these problems, MediSapiens has developed the Explorer™ Technology Platform solution, based on its extensive experience in both industrial software development and academic biomedical research. The Explorer™ Technology Platform has been designed for all of the three major parts of the data research workflow: for curating data, storing and managing data, and analyzing and visualizing data. This web browser based, integrated solution provides functionalities to import, curate, ontology map and store rich clinical data, as well as very large data sets of gene expression, copy number, mutation and other profiling data for both bulk and single-cell analyses (e.g. single-cell RNA-seq), and perform various analyses and visualization on the data. **#2596 MediSapiens Explorer Technology Platform - Integrated Solution for big biomedical data.** Henrik Edgren, MediSapiens bioinformatics and development teams. MediSapiens Ltd, Helsinki, Finland.

During recent years, the increasing throughput and decreasing cost of technologies for genomic, transcriptomic, proteomic and other high throughput profiling of samples has enabled collection of very rich data sets on large sample cohorts. As methods have been developed to analyze e.g. large human germline sequencing studies, it has simultaneously become clear that the potential of the data can be fully and effectively leveraged only if technical solutions are developed to curate, store, harmonize and jointly use these omics data sets together with clinical and phenotypic data on the samples. In the field of modern data-driven research, heterogeneous data is increasingly available through many dispersed resources, and in many cases, data from public sources is combined with proprietary data for analysis. Thus, it is not only important to have effective solutions for data storing and data management, but for data curation and data analysis and visualization. Data curation ensures that data from various sources are harmonized, standardized and cross-comparable. Powerful data analytics and visualization is pivotal in transforming data into information, new insights and added value. To address these problems, MediSapiens has developed the Explorer™ Technology Platform solution, based on its extensive experience in both industrial software development and academic biomedical research. The Explorer™ Technology Platform has been designed for all of the three major parts of the data research workflow: for curating data, storing and managing data, and analyzing and visualizing data. This web browser based, integrated solution provides functionalities to import, curate, ontology map and store rich clinical data, as well as very large data sets of gene expression, copy number, mutation and other profiling data for both bulk and single-cell analyses (e.g. single-cell RNA-seq), and perform various analyses and visualization on the data. Existing software components in the Explorer™ Technology Platform can quickly and efficiently be used to construct custom UI tools to query, analyze and interpret data according to individual customer needs. examined the impact of celecoxib intake on HTN and edema. The concomitant intake of celecoxib and one of the antihypertensives (AH) was also evaluated as means to suppress the side effects of celecoxib. Methods: This is a retrospective study that uses two patient level data (PLD) sources: (1) anonymous PLD from Symphony from Jan 2012 to Dec 2014 (3 years), and (2) Pinnacle registry data from American College of Cardiology (ACC) over the same time period with demographics such as blood pressure (BP) readings, peripheral edema flags, etc. In Symphony dataset there are 162 million (M) unique patients, 4.3M patients on celecoxib, 16.3M patients with osteoarthritis (OA) (15.4M only OA), and 2.3M patients with rheumatoid arthritis (RA) (1.4M only RA). In ACC dataset, there are 1.5M unique patients with BP readings, 870K patients with edema flag. Results: There was no impact of celecoxib consumed on the change in BP readings. There were as many increases as decreases, regardless of the amount of celecoxib consumed between BP readings. A breakdown by baseline BP readings did not reveal any trends. Concomitant use of AH with celecoxib did not impact BP. Onset of edema was not correlated with total dose of celecoxib. Less than 10% of the observations indicated a change in edema status. However, unlike BP, increasing % of edema was observed for increment in levels of celecoxib but not BP in OA patients. Here we confirmed our meta-analysis using PLD data. Celecoxib with ARB exhibited the lowest incidence of edema and with non-thiazide diuretics the highest incidence (Odds ratio = 3.34 (95% CI = 2.85-3.94), p<0.0001). ARB with celecoxib displayed a significant reduction in edema incidence compared to celecoxib alone (Odds ratio = 0.626 (95% CI = 0.539-0.724), p<0.0001). The celecoxib–ARB and celecoxib–ACE FDCs are being investigated further as therapy for FAP and more on oncogenesis.

#2598 Paradigm to ensure curation transparency and consistency of a cancer genomic database - the JAX Clinical Knowledgebase (CKB).

In the era of personalized medicine, comprehensive cancer genomic databases represent critical tools for interpreting gene variants and their relevant therapies. As the number of cancer genomic databases grow, it is challenging for users to compare and assess the data integrity and validity of such databases. The lack of disclosure of curation processes makes it difficult to cross reference different databases. The JAX Clinical Knowledgebase (CKB) is a comprehensive relational database providing evidence-based information on gene variants, targeted therapies, efficacy evidence, and clinical trials. At the Jackson Laboratory for Genomic Medicine, we have developed a curation paradigm to ensure curation transparency and consistency of the JAX-CKB. First, to ensure standardization of nomenclature, we have integrated standard nomenclature and ontologies, including ICGNC approved nomenclatures for genes, HGVS guidelines for somatic mutations, and Oncotree for cancer types. To ensure curation transparency, we implemented decision matrices to maintain uniformity of our evaluation of scientific and clinical data. For example, evaluation of the effect of gene variants on protein function is solely based on changes in the intrinsic activity of the protein instead of downstream pathway activation or the effects on pathogenesis; the response type of gene variants to therapies are classified based on the evidence of targeting specificity; and the efficacy evidence are further classified as actionable, diagnostic, prognostic, risk factor, emerging, or not active centered on the response type and the strength of the evidence. Third, to provide convenient evaluation of the clinical relevance of efficacy data, we further developed a tier ranking system based on emerging consensus guidelines, which takes response type, evidence type, and approval status into consideration. Finally, all decision matrices are clearly outlined on the JAX-CKB open access website for users’ reference. In summary, we have curated a highly structured and systematically consistent cancer genomic database following a set of specific curation guidelines. As a result, JAX-CKB open access has become a valuable resource for both the clinical and research communities, and is utilized by numerous independent groups for variant interpretation.

The Cancer Gene Census is an ongoing effort to catalogue genes for which somatic mutations have been causally implicated in cancer. The Census comprises manually curated summaries of the most relevant information for cancer-driving genes and their somatic mutations and brings together the expertise of a dedicated curation team, cancer scientists and the comprehensive resources of the COSMIC database. Current research focuses on characterising the participation of 609 census genes in hallmarks of cancer and identification of additional genes involved in these biological traits primarily via altered expression, CNA or epigenetic changes. New overviews of cancer gene function focused on hallmarks of cancer pull together manually curated information on the mutation of proteins coded by cancer genes and summarise the data in simple graphical presentations of the most relevant facts with quick access to the literature source, aiming to provide summary characteristics of a cancer gene, rather than a full monography, to avoid information overload. This functional characterisation enables the creation of lists of genes of interest focused on the particular role they play in the development of cancer, as well as aiming to identify the cellular functions affected by mutations in particular tumours, and help to choose right targets for targeted therapy or synthetic lethal experiments. The Census is available from the COSMIC website for online use or download at: http://cancer.sanger.ac.uk/census.

#2600 Analysis of drug resistance mechanisms and strategies for overcoming resistance in cancer therapy using a curated clinical knowledgebase.

Emergence of resistance to targeted therapies is a critical problem in cancer therapy, and understanding both the mechanisms of resistance and strategies for overcoming resistance are crucial to effective treatment of cancer patients. The JAX Clinical Knowledgebase (JAX-CKB), which incorporates data on therapeutic efficacy in the context of molecular alterations, enables rapid analysis of known therapy resistance mechanisms and current data surrounding strategies for overcoming resistance, both in the preclinical and clinical setting. Using the JAX-CKB, we have identified over 1250 lines of evidence corresponding to therapy resistance across tumor types. Of those lines, 147 correspond to therapy resistance in lung cancer. The JAX-CKB contains 22 variants in ALK associated with ALK therapy resistance. Within ALK fusion-positive lung cancer, evidence lines corresponding to ALK inhibitor resistance are associated primarily with complex molecular profiles containing secondary ALK mutations, and mechanisms for overcoming resistance in this setting were associated with use of novel agents. Within EGFR mutation positive lung cancer, lines associated with resistance to EGFR inhibitor therapy included copy number alterations, primary resistance mutations, secondary resistance mutations, and expression level changes. Strategies for overcoming resistance in these settings include novel agents, resistance-focused combination therapies. The JAX-CKB provides a unique global view into current data on resistance to targeted therapies in oncology, which may enable more rapid assessment of effective therapy options and expose opportunities for additional research into strategies for overcoming resistance.

#2601 COSMIC-3D: exploring cancer mutations in three dimensions for drug design and discovery.

Explosions in the availability of cancer genomic data and protein structure data give us the potential to explore cancer molecular biology at an unprecedented scale, and in atomic detail. We present COSMIC-3D, which combines COSMIC, the most comprehensive cancer mutation database available (http://cancer.sanger.ac.uk), with the wealth of publicly available 3D protein structure data, to create a resource with which the protein-structural nature of cancer can be probed. COSMIC-3D will help us understand which cancer mutations drive the progression of cancers, by identifying which are in functional sites that have an effect on driving cell growth and proliferation, and where they are clustered in forms of across the targeted therapies cancer types. Through understanding the effects of cancer mutations on known and predicted drug binding sites, we aim to predict potential new drug targets in cancers, and improve the specificity and efficacy of new or existing drugs, by using protein structure with cancer mutation data to guide mutation-specific drug design. COSMIC-3D is available as a web interface at http://cancer.sanger.ac.uk/cosmic3d, and enables interactive exploration of the cancer mutome in a 3D peptide environment, showing all forms of exonic point mutation. Individual mutant locations can be highlighted as molecular surfaces, while recurrence across nonsynonymous substitutions is visualized as 3D heat-maps. Cancer mutations can also be visualised in combination with precalculated small-molecule “drugable” bind-

Proceedings of the American Association for Cancer Research • Volume 58 • April 2017 661
ing sites, providing a powerful visual approach for development of hypotheses across structural, functional, and drug-resistance impacts of cancer variants. COSMIC-3D shows, for example, the steric occlusion of the binding site of ATP-competitive small-molecule inhibitors in the EGFR kinase domain by the mutation of L858 to arginine; these kinds of insights can be applied to novel cancer therapies. The capability of the fully-structured 3D representation of the structural proteome comprising COSMIC-3D extends to nearly 8,500 human genes; 1/3rd of genes in COSMIC. Over 30,000 human protein structures are available across these genes, to which over 345,000 cancer mutations are mapped. From structure based druggability prediction, over 6,500 proteins in COSMIC are predicted to have small-molecule druggable binding sites, making COSMIC-3D a powerful and exciting resource for the exploration and guidance of drug design and discovery in oncology.

The goal of the International Cancer Genome Consortium (ICGC) is to analyze the cancer genomes of at least 500 tumor samples with matched controls from 50 different cancer types and subtypes, building a comprehensive catalogue of somatic abnormalities for the benefit of the research community. The amount of data ICGC members will generate is close to that of 50,000 human genome projects and, to date, has received commitments for 107 projects to study more than 27,000 tumor genomes. The ICGC Data Coordination Center (DCC) is responsible for collecting, curating, aggregating, and disseminating the data generated by the consortium’s member projects. Given the size and the complexity of the ICGC data, these tasks represent significant scientific and technological challenges that require a performant, robust software infrastructure. Key to this infrastructure is the ability to scale as data grows. Using state-of-the-art Big Data, bioinformatics and cloud computing technologies, we developed a suite of web-based applications and microservices that enable member projects to first submit their data and validate their submissions according to the rules defined in the submission specification. Following validation, the data is processed, annotated and loaded into the data portal using a modular Extract-Transform-Load (ETL) pipeline. Submission, ETL and portal systems are built using scalable and distributed technologies such as Hadoop, Spark, MongoDB and ElasticSearch. Spark is used to validate, join, index, and harmonize annotations on submitted variants while ElasticSearch powers our variant query engine, API and portal displays. Here we present the ICGC Data Portal and describe both the current features and capabilities accessible to users along with the architecture of the underlying infrastructure. The portal provides scientists with powerful and unique tools for exploring and visualizing the millions of variants and annotations available. These include sophisticated features that enable making data exploration extremely fast and easy, a suite of interactive JavaScript components for in-depth analysis and visualization of specific genomic features, embedded genome and pathway browsers, synthetic cohorts comparisons and a streaming data download service. The portal integrates a large variety of annotations such as variant consequences and frequencies, functional impact factors and druggability. The portal also offers cloud-based tools for searching a catalog of raw ICGC data files stored in worldwide repositories and compute clouds. All source code is open to the community under the GPLv3 license.

**#2603** A patient driven cancer database to collect information, analyze data, and predict outcomes. Lori Marx-Rubiner, 1 AnneMarie Ciccarella, 2 Vincent An, 3 Jared Bass, 2 Will Berman, 3 Jackson Berry, 3 Chloé Chan, 3 Christopher Han, 3 Louis Harboe, 3 Joshua Lurie, 3 Sara Ma, 3 Parker Malachowsky, 3 Nayēe Nagda, 3 Simon Schneider, 1 E. Bircan Çopur, 4 Jorge J. Nieva, 4 Jan Liphardt, 4 Peter Kuhn, 7 Jeremy M. Mason. 7

1 Independent Research Advocate and Metastatic Breast Cancer Patient, Los Angeles, CA; 2 Independent Research Advocate and Breast Cancer Patient, Glen Head, NY; 3 University of Southern California, Irvine and Young Academy, Los Angeles, CA; 4 Zymed Ltd. Munich, Germany; 5 Norris Comprehensive Cancer Center, Los Angeles, CA; 6 Stanford University, CA; 7 University of Southern California, Los Angeles, CA.

It is widely held that major breakthroughs in cancer treatment will result from properly analyzing, analyzing and utilizing existing and emerging “big data.” To date there is no single vehicle that integrates the data available, and of those being developed, none that put patient needs and outcomes as primary focus. CancerBase was released as part of the Cancer Moonshot launch in June 2016. It is a global, real-time data collection tool designed by and for patients. Patients were recruited through social media to share their information, including but not limited to, demographic details, personal cancer data, and history of treatment. Combining open text boxes and drop down preselected response boxes allows for the capture of information in a way that patients understand. In addition to cancer data, Facebook comments demonstrated immediate engagement with the tool and captured the organic community of patients who eagerly shared their stories with others. Personal interviews and a communal Twitter chat event led to user feedback, and we subsequently developed CancerBase to be more user-friendly and better understanding in a more easily familiar CancerBase. In addition to medical data, general information and questions CancerBase participants wanted to add to the system have been collected. Incorporation of patient-driven deliverables is unique in the space of big data and cancer in that other tools, both existing and still in development, are geared toward the needs of researchers, payors, policy-makers and clinicians. CancerBase provides a database tool that resonates with the patient community and is driven by patient needs and interests. As the tool becomes increasingly robust it will grow to support the decision-making needs of clinicians and guide the investigations of the researchers. The launch of CancerBase in Spring 2017 will address emerging patient concerns, integrate collected data, and utilize existing forecasting databases to add value to patients.

Introduction An overarching goal of biomedical research is to improve the use and dissemination of rapidly growing biomedical datasets to support precision medicine. Individualized molecular profiling and the identification of predictive biomarkers can powerfully inform the choice of therapies for cancer patients. However, both require integration of extensive molecular, clinical, and pharmacological data, often from disparate and diverse sources. The Georgetown Database of Cancer (G-DOC) was designed and engineered to be a unique multi-omics data analysis platform to enable translational research and precision medicine. Methods G-DOC is home to 61 datasets that contain data from over 10,000 patients across 14 diseases (10 cancers and 4 non-cancers). 1700 researchers from over 48 different countries worldwide currently use the platform. The data and tools in the G-DOC system have enabled over 40 research publications. G-DOC has the largest public collection of brain cancer patients from NCI Rembrandt dataset (671 patients). G-DOC integrates clinical, transcriptional, and imaging data types and presents datasets as COSELUS data and MRI medical images with systems-level analysis tools into a single, user-friendly platform. The “Variant Search” feature in G-DOC currently enables exploratory analysis of mutations based on genes, chromosomes, and functional location. A researcher can use this feature to 1) identify clinically actionable mutations in their dataset 2) identify pathways that may be affected by these mutations, and 3) identify novel mutations in their dataset and explore their potential impact on protein function. Results and Conclusion We are currently working on developing features to support the import, integration, search, and retrieval of CLIA/CAP-certified cancer molecular diagnostic (molDx) data. This will enhance G-DOC’s interoperability with clinical and patient molecular profiling data that may be already stored in other databases. Our vision is to continuously improve and expand G-DOC with the long-term vision of supporting integration of informatics techniques into everyday research and practice.

**#2605** Improving data quality in oncology immunotherapy clinical research by big data analytics and data visualization. Chengsen Xue, Joanne Cuomo, Walter Meyers, Thomas W. Mc Closkey, ICON Laboratory Services, Farmingdale, NY.

Flow cytometric assessment of cellular and intracellular biomarkers facilitates the development of new classes of cancer immunotherapy therapeutics. This powerful tool has multiple applications including 1) detecting PD1, PDL-1 and caspase-3 for apoptosis, 2) isolating, defining, and quantifying dendritic cells and their intracellular cytokine profile, 3) immunophenotyping subpopulations
of B, T, NK, regulatory T, and helper T cells, and, 4) using tetramer analysis to detect and monitor the frequency of antigen-specific cytotoxic T lymphocytes (CTL). However, lack of knowledge of normal distributions and standard ranges for the esoteric reportables generated by flow cytometry is one of the most challenging problems in this promising field. Here we describe a new method to improve data quality in clinical research by big data analytics and data visualization. Each data point was tagged. By applying a simple statistical analysis, a self-defined range allowed all of the outlier numbers to be identified. By repeating this process, clear patterns emerged, and all questionable data points were marked. In addition, the system can differentiate biodiversity in subjects from a more homogenous population, which can be exploited further for the purpose of precision medicine. Other benefits of the new system are to predict the outcome of the clinical study and to generate new clues in the understanding of the underlying biological mechanisms. Big data analytics and data visualization show unparalleled advantages in oncology studies through simultaneously monitoring unlimited data points related to surface and intracellular biomarkers. It opens a new avenue in cost saving for long, time-consuming clinical trials by using all available data to detect a status change of the immune system. With the improvement of data quality, big data analytics has become an essential tool and an integrated part of cancer immunotherapy and the development of cancer vaccines.

*#2606 Accelerating clinical research using cloud technology.* Arun Apte,1 Shonali Paul,1 Aditi Gade,1 Carolyn Compton.2 CloudLIMS.com, Wilmington, DE; 1Arizona State University, AZ.

Introduction: Existing protocols for clinical trials are typically slow and error-prone due to lack of informatics tools for sharing and accessing clinical data in real time. There is an increasing pressure on clinical trial laboratories to change the way clinical research is performed so as to minimize costs and speed up R&D, which in turn will produce better and faster outcomes. Cloud-based technologies are emerging as one of the most viable options for streamlining the heavily regulated clinical research processes. Description: Cloud-based software tools such as laboratory information management systems (LIMS) are much more capable than traditional paper-based or desktop tools for accelerating a clinical trial life cycle. Cloud-based LIMS enhance collaboration between sponsors and investigators, enabling more timely and accurate sharing of information with pharmaceutical companies. Summary: Many sponsors are now adopting cloud-based LIMS for conducting clinical trials. The onus is on service providers to keep pace with the demands of the industry, comply with the regulatory framework and at the same time deliver value to CROs and testing labs by reducing costs and maintaining efficiency. Conclusion: CloudLIMS.com has developed a cloud based software called CloudLIMS Lite for managing clinical research workflows to provide a cost effective solution to the clinical research industry. Being on the cloud, CloudLIMS Lite facilitates users to access and share data in real time, across multiple laboratories in different geographical locations and adhere to the regulatory framework. This in turn improves their operational efficiency. CloudLIMS Lite uses 256-bit AES encryption SSL protocol, thereby enabling secure data transmission. CloudLIMS Lite deploys a separate database layer for each of its customers making it impossible for any third party to view or access data.

*#2607 The eBioPortal for Cancer Genomics: an open source platform for accessing and interpreting complex cancer genomics data in the era of precision medicine.* Jianqiong Gao,1 Erisin Ciftci,2 Pichai Raman,1 Pieter Lukkasse,1 Istemi Bahcecci,1 Adam Absehouse,1 Hsiao-Wei Chen,1 Ino de Bruijn,1 J. Benjam Gross,1 Zachary Heins,1 Ritika Kundara,1 Aaron Lissam,1 Angelica Ochoa,1 Robert Sheridan,1 Onur Sumer,1 Yichao Sun,1 Jiaoqia Wang,1 Manda Wilson,1 Hongxin Zhang,1 James Xu,1 Andy Duñile,1 Priti Kumari,1 James Lindsay,1 Anthony Cros,2 Karthik Kalletta,2 Fedde Schaeffer,2 Sander Tan,4 Sjoerd van Hagen,1 Jorge Reis-Filho,1 Kees van Bochove,1 Ugur Dogrusoz,2 Trevor Pugh,6 Adam Resnick,3 Chris Sander,1 Ethan Cerami,1 Nikolaus Schultz,1 Memorial Sloan Kettering Cancer Center, New York, NY; Dana-Farber Cancer Institute, Boston, MA; Children’s Hospital of Philadelphia, Philadelphia, PA; 3The Hyve, BilkentUniversity, Turkey; 4Washington University School of Medicine, Saint Louis, MO; 5Institute for Research in Biomedicine, Barcelona, Spain; 6Dana-Farber Cancer Institute, Boston, MA; 1Memorial Sloan Kettering Cancer Center, New York, NY; 2Well Cornell Medical College, New York, NY; 3Oregon Health & Science University, Portland, OR.

The eBioPortal for Cancer Genomics is an open-access platform (http://cbioportal.org) that enables interactive, exploratory analysis of large-scale cancer genomics data. It integrates genomic and clinical data, and provides a suite of visualization and analysis options, including cohort and patient-level visualization, mutation visualization, survival analysis, enrichment analysis, and network analysis. The user interface is user-friendly, responsive, and makes genomic data easily accessible to translational scientists, biologists, and clinicians. The eBioPortal is a fully open source platform. All code is available on GitHub (https://github.com/cBioPortal/) under GNU Affero GPL license. The code base is maintained by multiple groups, including Memorial Sloan Kettering Cancer Center, Dana-Farber Cancer Institute, Children’s Hospital of Philadelphia, Princess Margaret Cancer Centre, and The Hyve, an open source bioinformatics company based in the Netherlands. More than 30 academic centers as well as multiple pharmaceutical and biotech companies maintain private instances of the eBioPortal. This includes the recently launched BioPortal instance at the Netherlands Genome Center, hosting two large eBioPortal instances hosting genomic and clinical data at MSK and DFCI, supporting the MSK-IMPACT and DFCI Profile projects, of two of the largest clinical sequencing efforts in the world. Our multi-institutional software team has accelerated the progress of evolving the core architectural technologies and developing new features to keep pace with the rapidly advancing fields of cancer genomics and precision cancer medicine. For example, we have integrated multi-platform genomics data with extensive clinical data including patient demographics, treatment history, and survival data. We have also developed a patient-centric view that visualizes both clinical and genomic data with annotation from OncoKB knowledge base. In the next few years, the development team will focus on the following areas: (1) Implementing major architectural changes to ensure future scalability and performance. (2) New features to support precision medicine, including (i) improved integration of knowledge base annotation, (ii) enhanced visualization of patient timeline, drug response, and tumor evolution, (iii) new patient similarity metrics, (iv) improved support for immunogenomics and immunotherapy, and (v) new visualization and analysis features for understanding response to therapy. (3) New analysis and target discovery features for better, including (1) supporting user-defined virtual cohort by selecting samples from multiple studies, and (ii) comparison of genomic or clinical characteristics of two or more selected cohorts. (4) Expanding community outreach, user support and training, and documentation.
BIOINFORMATICS AND SYSTEMS BIOLOGY: Computational Tools and Databases

#2609 Columbia University’s Center for Cancer Systems Therapeutics (CaST) 2017 Scholars Program: A synergistic partnership with students from Brooklyn College, CUNY. Rahimah Ahmad,1 Tasnim Azad,1 Carlos Barreto,1 Kamrun Begum,1 Mahliaa Butt,1 Daniel Griffaft,1 Aulon Jeru,1 Jonathan Kwia1, Mikaela Murphy,2 Katherine A. Rivera Gómez,2 Barry Honig,2 Andrea Califano1, Shannen Jaffe1,2 Diana Murray1,2 CUNY Brooklyn College, Brooklyn, NY. 1Columbia University, New York, NY.

The Cancer Systems Therapeutics (CaST) Outreach helps foster community building throughout the NCI Cancer Systems Biology Consortium (CSCB). The overall mission of the CaST Outreach Core is to advance progress in cancer systems biology by tapping into and making connections across research talent at all stages of education, with the objective of increasing the attraction and recruitment of motivated undergraduate, post-baccalaureate, and graduate students from Brooklyn College of the City University of New York (CUNY). These students comprise the first cohort of the CaST Scholars Program and are immersed in the cutting-edge biological and biomedical science underlying Cancer Systems Biology. In subsequent years, CaST Outreach will partner with students from other CUNY Senior Colleges while continuing interactions with our Brooklyn College Scholars. This integrative approach will create a network of CaST Scholars throughout the CUNY system. Because Systems Biology is highly interdisciplinary, participants in the program can come from many backgrounds, including biology, computer science, physics, chemistry, genomics, engineering, and other fields. The program has no fixed curriculum and each of nine Brooklyn College students has developed an individualized CSCB educational plan tailored to their interests. The CaST Scholars Program opportunities include: 1) tuition-free attendance at a master’s level Systems Biology course taught by a CaST investigator and offered through Columbia University’s School of Professional Studies; 2) supported attendance at the AACR annual meeting; 3) monthly informal discussion meetings with CaST investigators; 4) weekly formal tutorials in the design and applications of CaST computational algorithms; 5) research internships with CaST investigators; 6) participation in a wide range of Center activities; 7) a scholarship to support participation; and 8) ongoing mentorship from CaST investigators. This poster provides summaries of the collaborative, synergistic experiences and achievements of each scholar and of the group as a whole. The CaST Scholars Program offers a unique opportunity for early-stage scientists to learn how Systems Biology is transforming cancer research and precision medicine at Columbia University Medical Center. Regardless of their chosen professional path, CaST Scholars will obtain a solid foundation in the methods and potential of Cancer Systems Biology.

#2610 A database for evaluating methylation biomarkers in bladder cancer. Meaghan M. Kennedy, Garrett M. Dancik. Eastern Connecticut State University, CT.

Bladder cancer is the fourth most common cancer in men, one of the most expensive cancers to treat, and recurrence is frequent. While the genomic alterations associated with high-grade, muscle invasive (MI) tumors and low-grade, non-muscle invasive (NMI) tumors are well-established, recent studies have also found that MI and NMI tumors have unique methylation patterns, and that methylation may play a role in the development of early-stage bladder cancer. Interestingly, bladder cancer patients have frequent mutations in chromatin remodeling genes that alter known histone markers of DNA methylation. Since methylation marks are pharmacologically reversible, the identification of methylation biomarkers is a promising avenue for therapeutic treatment. Indeed, several candidate prognostic methylation biomarkers have been identified, but await prospective evaluation. The Bladder Cancer Biomarker Evaluation Tool (BC-BET) is a web-based resource for rapidly evaluating biomarkers in publicly available genomic datasets. Initially developed for gene expression biomarkers, BC-BET includes 1451 patients across 13 cohorts, and 40 bladder cancer cell lines, with gene expression profiles. In this work, we describe the addition of methylation data to BC-BET, so that candidate methylation biomarkers can be rapidly evaluated across multiple patient cohorts. BC-BET now contains methylation profiles from four patient cohorts (250 patients) and includes the available bladder cancer data from the Gene Expression Omnibus and The Cancer Genome Atlas. In ‘evaluation’ mode, a user selects a gene of interest, and BC-BET evaluates whether the selected gene is differentially methylated between tumor vs. normal samples, NMI vs. MI tumors, and low- vs. high-grade tumors. Alternatively, the “biomarker discovery” mode allows a user to identify all differentially methylated genes at a desired false discovery rate (FDR). In both cases, graphical summaries of the results are displayed and statistical results can be downloaded to an Excel spreadsheet. The methylation module of BC-BET is implemented using shiny, a web application framework for R for developing interactive web pages. The addition of methylation data to BC-BET makes it a valuable resource for evaluating methylation biomarkers in bladder cancer. BC-BET is available from the following link: https://gdanck.github.io/bioinformatics/BCBET

#2611 A crowdsourcing-based clinical trial information curation and searching system. Pengfei Yu, Qingxuan Song, Yang Han, Guanghui Hu. Admera Health, South Plainfield, NJ.

Targeted cancer therapies based on actionable mutations identified are the future of cancer treatment. Besides those approved by the Food and Drug Administration (FDA) for different types of cancers, many other target therapy drugs are in development under different phases of clinical trials. Access to information about these clinical trials is important to health care professionals and patients. Public clinical trials database (www.clinicaltrials.gov) provides a very comprehensive resource for clinicians and researchers to search for relevant clinical trials based on different kinds of searching criteria. However, due to the complexity of wording and phasing upon submission, some of the searching results returned by native search engine did not perfectly match the search criteria. Many undesired results are presented with false positives and false negatives when users are searching for clinical trials targeting specific actionable mutations. To tackle this problem, we developed a crowd-sourcing based clinical trial curation and searching system on top of the information extracted from public database. We divide the information extracted from clinicaltrials.gov into three different levels: standard, easy-to-clean and unstructured. With the crowdsourcing approach, our online system can harness the brainpower of biological scientists to translate the most unstructured information such as cancer types, gene mutations into standard format that is easy to be queried. In the searching phase, we combine the aspects of actionable mutation, cancer type, location, and clinical trial phase to select the best matches between patient conditions and clinical trials in our curated database. With the same searching criteria, our system can provide more relevant clinical trials compared with those provided by clinicaltrials.gov. The curation system is currently open to reviewers with eligibility check. The search engine is publicly available at: https://agis.admerahealth.com/AGIS/ClinTrials/

IMMUNOLOGY: Checkpoints 2: Small-Molecule Inhibitors

#2612 Anti-Tigit induces T cell mediated anti-tumor immune response and combines with immune checkpoint inhibitors to enhance strong and long term anti-tumor immunity. Minu K. Srivastava, Kui Yun, Erin Mayes, Janice Yu, Huyn-Bae Jie, Fumiko Axelrod, Ming-Hong Xie, Jorge Monjeon, Andrew Lam, May Ji, Yuwang Liu, John Lewicki, Tim Hoey, Austin Gurney, Angie Inkyung Park. OncoMed Pharmaceuticals, Inc., Redwood City, CA.

TIGIT (T cell immunoreceptor with Ig and ITIM domains) has been recently described as an inhibitory receptor which blocks CD8 T cell-mediated anti-tumor immune responses. We have generated an anti-mouse TIGIT antibody (313R12) to evaluate drug efficacy and mechanism of action in pre-clinical tumor models. Anti-TIGIT as a single agent promoted an anti-tumor immune response in multiple syngeneic mouse tumor models. Anti-TIGIT enhanced tumor specific T cell responses, particularly of the Th1 type and reduced Th2 type responses and also increased the function of cytotoxic T cells. Furthermore, anti-TIGIT displayed combination activity with immune checkpoint inhibitors anti-PD1 and anti-PDL1 in inhibiting tumor growth, promoting complete tumor rejection and significantly increasing mouse survival in the murine CT26 colon carcinoma model as compared to controls and single agents alone. Mice “cured” with anti-TIGIT/anti-PDL1 or anti-TIGIT/anti-PD1 combination treatments did not form tumors upon subsequent re-challenges with increasing number of CT26 tumor cells, suggesting the existence of immunologic memory. IL2 and tumor-specific IFNγ production by splenic T cells were increased in mice who responded to combination treatment compared to controls. Additionally, both effector and memory CD8 T cell frequencies were increased within the total CD8+ T cell population in responding mice. We also demonstrated a systemic increase in tumor-specific CD8 T cells after anti-TIGIT/anti-PDL1 combination treatment compared to controls. Therefore, these results suggest that co-targeting of TIGIT and PD1 or PDL1 may be an effective and durable cancer therapy by increasing T cell-mediated anti-tumor immune responses and promoting long-term immunological memory.

#2613 Combination agonist and antagonist antibody therapy enhances vaccine induced T cell responses in non-immunogenic cancers. Hayley S. Ma, Evantha Roussos Torres, Brian Christmas, Blake Scott, Tara Robinson, Todd Armstrong, Elizabeth Jaffee. Johns Hopkins University School of Medicine, Baltimore, MD.

Immune tolerance by multiple mechanisms is a major obstacle in the implementation of successful immunotherapy. T regulatory cells (Tregs) and myeloid derived suppressor cells (MDSCs) suppress the immune response, and the presence of extensive stromal networks within the tumor microenvironment (TME)
can prevent T cell infiltration in many tumor types. Furthermore, tumor anti-
gen-specific T cell tolerance limits the efficacy of therapeutic cancer vaccines. CD40 is expressed on antigen presenting cells, and CD40 signaling is critical to the decision of whether cytotoxic T lymphocytes become primed or tolerized. Administration of monoclonal CD40 agonistic antibody (Ab) has been shown to promote CD8 activation in vivo, and likely alters the myeloid component of the TME. Our study asks the question of whether combining a T cell inducing vaccine and PD-1 inhibition with CD40 agonistic Ab can induce T cell priming and tumor infiltrating lymphocyte (TIL) activation in non-immunogenic solid malignancies. We utilized an orthotopic transplant model in which HER2/neu expressing breast tumor cells were implanted into the mammary fat pad of syngeneic neu-N mice to assess the effects of drug combinations on intratumoral immune responses. Tumor-bearing mice were treated with a granulocyte macrophage colony-stimulation factor secreting vaccine (GVAX) + anti-PD-1 Ab alone or in combination with CD40 agonist Ab, and monitored for tumor clearance and survival. A separate cohort of mice were analyzed by IHC and multi-color flow cytometry to assess T cell infiltration and activation, myeloid maturation, and MDCs after one week of treatment. We demonstrated delayed tumor progression and increased median survival in mice treated with GVAX + anti-PD-1 Ab + CD40 Ab relative to CD40 Ab alone, although endogenous T cell infiltration remained low across treatment groups. However, adoptive transfer of neo-specific TCR transgenic cells revealed 100% tumor clearance in the combination-treated mice, along with significant T cell infiltration and activation as assessed by intracellular Granzyme B and TNFα staining. In contrast, only 20% of mice treated with GVAX + anti-PD-1 Ab were able to clear tumor, and none of the mice receiving vehicle or CD40 Ab alone had long-term survival. Trends were also observed in monocyte and dendritic cell infiltration and maturation in the tumors of combination-treated mice, and warrant further investigation. In conclusion, GVAX, anti-PD-1 Ab and CD40 agonist Ab have potential synergy in modulating anti-tumor immunity in breast cancer. These results support further studies more broadly in non-immunogenic solid tumors.

#2614 Decrease of benefit from immune checkpoint inhibitors in women with non-small cell lung cancer. Joseph A. Pinto,1 Luis A. Mas,2 Carlos S. Vallejos,1 Jhajaara Araujo,1 Levy Brav2, Alfredo Aguilar,1 Zaida Morante,1 Denisse Bretel,1 Henry L. Gomez,1 Christian Rolfo,1 Oncosalud, Lima, Peru; Universidad Privada San Juan Bautista, Lima, Peru; Antwerp University, Limma, Belgium.

Introduction: In a previous work we found differences in immune gene sets enrichment in NSCLC between genders, including their smoking status, where women had higher expression of gene sets associated with immune processes. Based in this fact, we hypothesize fewer benefits from immune checkpoint inhibitors in women patients compared than men patients. Objectives: Evaluate the benefit (in terms of progression-free survival) of women patients from immune checkpoint inhibitors nivolumab and pembrolizumab in published randomized phase III trials. Methods: We evaluated by meta-analysis four randomized phase III studies, two of pembrolizumab (Herbst et al., 2015 and Reck et al., 2016) and two of nivolumab (Borghaei et al., 2015 and Brahmer et al., 2015). We analyzed TCGA data for lung adenocarcinoma to evaluate differences in the expression of PD1 and PD1, CD274 gene (encoding for PD1 and PD-L1, respectively).

Results: For all studies, it was observed an overall HR = 0.79 (CI95%: 0.71-0.87; P<0.00001), although it was observed a significant heterogeneity between studies (P=0.002). In male patients, was observed an overall HR = 0.71 (CI95%: 0.62-0.80; P<0.00001) with significant heterogeneity between studies (P=0.002). For female patients, there was not seen a clear benefit from nivolumab or pembrolizumab (overall HR = 0.97, CI95%:0.82-1.14; P=0.67). There was not heterogeneity between the cohorts (P=0.45). There were not differences in the expression of PD1 and CD274 genes according to gender in the TCGA data (P=0.371 and 0.144, respectively). Conclusion: Although there are not differences between genders in the expression of PD1 and PD1, CD274 genes, such as is previously described for expression for PD1 and PDL-1 proteins, in our meta-analysis we shown that women have more benefit from anti-immune checkpoint inhibitors. Blockade of PD1 and PD-L1 is a promising therapy in lung cancer; however, a better stratification of patients should be done.

#2615 Preclinical evaluation and mechanistic characterization of M7824 (MSB0011359C), a novel bifunctional fusion protein targeting M7A1 and TGFβ pathways. Yan Lan, Dong Zhang, Chuxiao Xu, Bo Marelli, Jin Qi, Huakei Qi, Guozhong Qin, Xiaomei Xu, Hong Wang, Aroop Sirbar, Beatrice Brunkhorst, Eric Austin, Laszlo Radvanyi, Kin-Ming Lo. EMD Serono Research and Development Institute, Inc., Billerica, MA.

Dual targeting of the programmed death ligand 1 (PD-L1) and transforming growth factor β (TGFβ) pathways, 2 key mediators of tumor immune evasion, may provide synergistic antitumor activity. The novel bifunctional fusion protein M7824 (MSB0011359C) is a fully human IgG1 monoclonal antibody against PD-L1, fused via a glycine-serine linker at the CH3-C terminus to the extracellular domain of human TGFβ receptor II, which functions as a TGFβ “trap.” Thus, M7824 is designed to exert independent and complementary anti-immunosuppressive functions by simultaneously blocking the PD-L1 and TGFβ pathways. The purpose of this study was to evaluate M7824 preclinically. M7824 was efficacious in multiple syngeneic tumor models (EMT-6, MC38, PANCO2, 4T1, CT26, and GL261). In orthotopic EMT-6 and intramuscular MC38 models, M7824 showed superior additive antitumor effects compared to anti-PD-L1 antibody or TGFβ trap monotherapy. M7824 also inhibited spontaneous metastases in EMT-6 and 4T1 models. Furthermore, M7824 extended survival and conferred long-term protective antitumor immunity, as demonstrated by protection of cured mice against tumor cell rechallenge. Mechanistically, the dual anti-immunosuppressive activity of M7824 in the MC38 model resulted in unique activation of both the adaptive and innate immune systems, including increased tumor infiltration, proliferation, and cytotoxicity of CD8+ T cells; increased prevalence of splenic tumor antigen-specific CD8+ T cells; increased CD8+ T cell infiltration and CD8+ T cell/natural killer (NK) cells; increased ratio of M1/M2 macrophages; and decreased anti-immunosuppressive activity of M7824. Improved activation of tumor-associated neutrophils and myeloid-derived suppressor cells. Similar immunophenotypic changes were observed in the EMT-6 model. Activation of both the adaptive and innate immune systems contributed to the antitumor activity of M7824 in the MC38 model, as depletion of CD8+ T cells and NK cells led to a substantial decrease in M7824-mediated tumor regression. CD4+ T cells and antibody-dependent cellular cytotoxicity, however, appeared dispensable. Toxicologic evaluation in cynomolgus monkeys indicated M7824 was well tolerated, with only minor hematologic effects observed. Although M7824 is a bifunctional molecule, its antitumor activity can be further improved by combination with standard-of-care therapies: in the MC38 model, combining M7824 with radiotherapy or chemotherapy resulted in more effective inhibition of tumor growth and an increased frequency of tumor antigen-specific Fcγ-requiring producing CD8+ T cells vs either monotherapy. Collectively, our preclinical data suggest that M7824 elicits potent and synergistic antitumor activity via the simultaneous blockade of the PD-L1 and TGFβ pathways. Phase 1 clinical trials with M7824 are under way in patients with solid tumors.

Correlation between clonal neoantigen burden (neoantigens generated early in tumorigenesis and therefore represented at high frequency in all tumor lesions) and responsiveness to checkpoint blockade has underscored the relevance of neoantigens in promoting tumor immunogenicity. Yet, the most of patients do not express, or express low numbers of, clonal neoantigens, and consequently will be less likely to benefit from checkpoint blockade. We describe strategies to generate neoantigen-directed therapies that may be incorporated into the standard chemotherapeutic strategy (CIT) in a cohort of locally advanced ESCC patients. In baseline ESCC tissues, 7 of 19 (37%) exhibited positive PD-L1 expression on tumor cells, and 10 of 21 (48%) exhibited positive expression on immune cells. In 21 ESCC tissues obtained a median of 18 days after initiating chemotherapy, 9 of 18 (50%) and 15 of 21 (71%) demonstrated positive PD-L1 expression on tumor cells and immune cells, respectively. The expression of PD-L1 was significantly increased in post-chemotherapy ESCC tissues compared to baseline tissues (p=0.010); and the increased PD-L1 expression between paired tissues was significant on immune cells (p=0.0056) but did not reach statistical significance on tumor cells (p=0.11). The positive PD-L1 expression in baseline ESCC tissues was correlated with better survival (HR:0.37, p=0.023). Besides, patients with more increase of PD-L1 expression after chemotherapy had significantly worse survival than those with less (median survival: 19.4 vs 71.20 months, HR: 4.07, p=0.0089). Conclusion: PD-L1 expression of ESCC can be up-regulated by chemotherapy. The up-regulation of PD-L1 is associated with poor outcome for locally advanced ESCC patients. (The study was supported by the grant NTUH 104-M2891 and the grant MOST 105-2314-B-002-186-MY3).

#2618 Agonist antibodies targeting OX40 and GITR enhance the activity of the IDO1-selective inhibitor epacadostat in preclinical models. Holly K. Koblish,1 Brendan Horton,2 Michael Hansbury,1 Sybil O’Connor, Kerri Lasky,1 Christina Stevens,1 Thomas Condamine,1 Leslie Hall,1 Liang-Chuan Wang,1 Yue Zhang,1 Horacio Nastrì,1 Gregory Hollis,1 Reid Huber,1 Thomas Gajewski,2 Peggy Scherle.1 Incyte Corporation, Wilmington, DE; 2University of Chicago, Chicago, IL.

The majority of immunotherapeutic agents developed thus far either attempt to stimulate a more productive anti-tumor immune response or to inhibit key proteins in the immunosuppressive tumor milieu. PD-1/PD-L1 axis blockade, CTLA-4 blockade and IDO1 inhibition are examples of the latter approach and have been utilized to reverse the suppressive tumor microenvironment, resulting in clinical benefit for cancer patients. Recent clinical and preclinical data have also demonstrated that combining these approaches results in enhanced therapeutic benefit. Notably, the IDO1-selective inhibitor epacadostat has been shown to increase the efficacy of two checkpoint inhibitors, the anti-CTLA-4 antibody ipilimumab and the anti-PD-1 antibody pembrolizumab, in patients with melanoma. Because both checkpoint receptors and IDO1 serve as negative regulators of the immune response, we also explored the ability of IDO1 inhibition to combine with checkpoint blockade to more effectively activate T cells through costimulatory receptors. In the tumor necrosis factor receptor (TNFR) superfamily. Rodent active surrogate agonist antibodies to 4-1BB, OX40 and GITR were tested with epacadostat in multiple preclinical models. In the B16-SIY melanoma model that does not express IDO1 in tumor cells, both epacadostat and anti-OX40 had little effect, but the combination resulted in enhanced efficacy. This was associated with increased infiltrates of CD8+ T cells and decreased numbers of FoxP3+ TILs. Increased numbers of SIY-reactive T cells were found in both the tumor and the TDLN post-treatment. In contrast, epacadostat did not provide any enhancement to the activity seen with 4-1BB. Clear combinatorial effects were seen with anti-GITR and epacadostat in the more immuned, IDO1-expressing PAN02 pancreatic cancer model. These data suggest that IDO1 inhibition can be effective in combination with agents that agonize T cell costimulatory receptors as well as with agents that block coinhibitory receptors.

#2619 Combination of ECP1014 and anti-PD-L1 reduces tumor growth in the CT26 murine colon carcinoma model of a cold tumor. Bobby W. Sandage,1 John J. Talley,1 Eduardo J. Martinez,2 Maryland R. Franklin,3 Mary C. Leopold3. 1Euclises Pharmaceuticals, Inc., St. Louis, MO; 2Rgenix, Philadelphia, PA; 3M Bioresearch, Ann Arbor, MI.

Objective: The objective of this study was to evaluate the effect of ECP1014, a new selective COX2 inhibitor, in combination with a PD-L1 inhibitor on tumor growth in a CT26 murine colon carcinoma model. Colon cancer has been described as a “cold tumor” since the immunosuppressive tumor microenvironment results in clinical benefit for cancer patients. Recent studies have demonstrated that combining ECP1014, which we have shown to potentially decrease PG2E2 in CT26, with a checkpoint inhibitor would increase immune response to the tumor, turning it “hot” and producing superior tumor control versus either agent alone. Methods: Balb/C mice were implanted with CT26 cells and randomly assigned to 7 treatment groups; vehicle (G1), 10mg/kg rat IgG2b control (G2), 10mg/kg antiPD1 (G3), 10mg/kg ECP1014 (G4), 10mg/kg ECP1014+10mg/kg rat IgG2b (G5), 10mg/kg ECP1014+10mg/kg antiPD1 (G6), 1mg/kg ECP1014+10mg/kg antiPD1(GL), ECP1014 was given daily by oral gavage; rat IgG2b and antiPD1 (clone 10F.9G2) were administered IP. Treatment was started on day 3 post implant and mice were followed for 16 days. Tumor measurements were taken every 2 to 3 days, and a nonparametric approach was taken to assess the pairwise differences among groups using day 16 tumor volumes. In addition, a responder analysis was used. Tumor infiltrating lymphocytes (TIL) were also assessed by flow cytometry on day 16. Results: All animals developed tumors. G4 to 7 demonstrated statistically significantly (p<0.05) slowing of tumor growth when compared to vehicle (G1). In particular, G7 produced an 87% suppression of tumor growth compared to vehicle. Three animals in G7 showed regression of tumor growth and one additional animal had no detectable growth until day 16. G6 produced 65% suppression of tumor growth compared to G1. G2 to 5 produced 30, 54, 73 and 50% suppression of tumor growth respectively when compared to G1.
checkpoint inhibitor in endometrial cancer.

To address this concern, we analyzed the expression of CD8+ and PD-L1/PD-1 in 60 patients with endometrial cancer. We examined whether MSI was associated with the expression of CD8+ lymphocytes (CD8) and PD-L1/PD-1.

**Method**

We included patients with MSI endometrial cancers. Therefore, immune checkpoint inhibitor therapy (anti PD-1/anti-PD-L1 antibody) has been shown to have clinical responses in endometrial cancers with MSI. MSI testing is likely to be a biomarker for PD-1/PD-L1 immunotherapy in endometrial cancer.

**Conclusion**

These results suggested that immune checkpoint inhibitor (anti PD-1/PD-L1 antibody) is effective in endometrial cancers with MSI. MSI testing is likely to be a biomarker for PD-1/PD-L1 immunotherapy in endometrial cancer.

**#2622** Two novel TLR9 agonists for cancer immunotherapy: Combination with checkpoint inhibitors. Kerstin Kapp,1 Barbara Volz,2 Detlef Oswald,3 Burghardt Wittig,4 Manuel Schmidt1.

**Introduction**

TLR9 agonists are developed as anti-cancer therapies based on their broad activation of the innate and adaptive immune system. Single-stranded oligodeoxynucleotides (ODN) containing non-methylated CG-motifs activate TLR9. Previously, chemical modification was used to prevent their degradation by exonucleases. To avoid the off-target effects observed with chemical modifications, new TLR9 agonists containing only natural DNA were stabilized by structural components. The dSLIM® family of TLR9 agonists is protected from exonucleolytic degradation by its covalently-closed dumbbell-shaped structure. It contains an immunomodulatory sequence with CG-motifs in its loops. The linear single-stranded EnanDIM® family of TLR9 agonists utilizes L-deoxyribonucleotides (natural enantiomers of D-deoxyribonucleotides) at their 3’-ends to prevent degradation. Since the mode-of-action of TLR9 agonists starts upstream of the targets of checkpoint inhibitors anti-PD-1/anti-PD-L1 a combinatorial approach may support synergistic immune activation and thus enhanced anti-tumor effects. Methods: The impact of dSLIM2006 and EnanDIM-1 on T cell responses was analyzed employing an in vitro assay using human peripheral blood mononuclear cells (PBMC). PBMC were treated with different doses of TLR9 agonists and combination with anti-PD-1 and anti-PD-L1. In vivo studies were used to investigate the anti-tumor effect of dSLIM2006 and EnanDIM-1 in combination with anti-PD-1 in a syngeneic murine CT26 tumor model. Results: The IFN-gamma secretion of human PBMC after stimulation of CEF peptides was roughly 5-fold increased by EnanDIM-1 and dSLIM2006, whereas treatment with anti-PD-1 resulted barely in a two-fold increase. The combination of the TLR9 agonists and anti-PD-1 further enforced IFN-gamma secretion by about 7-fold. In the murine colon cancer model CT26 the subcutaneous injection of EnanDIM-1 or intraperitoneal injection of anti-PD-1 had a moderate effect on the tumor growth when used in monotherapy (28.3% or 57.0% tumor growth inhibition, TGI). Notably, a combination of EnanDIM-1 and anti-PD-1 further reduced tumor growth (74.7% TGI). Intratumoral injection of dSLIM2006 in combination with intraperitoneal injection of anti-PD-1 reduced tumor growth (54.2% TGI) whereas the single components had more limited effects (dSLIM2006: 18.7%, anti-PD-1: no inhibition). Combined treatment with TLR9 agonist and anti-PD-1 prolonged survival of the mice in comparison to single treatments. Conclusions: The TLR9 agonists and immune surveillance reactivators (ISR) EnanDIM-1 and dSLIM2006 enhance T cell responses and anti-tumor effects of the anti-PD-1 checkpoint inhibitor. These data show their promising potential not only for monotherapy but also combinatorial approaches.

**#2623** Identification of neo-antigens driving melanoma response to immune checkpoint blockers via in vivo screening. Chi-Ping Day,1 Eva Perez-Guijarro,2 Rajaa El Meskini,2 Zoe Weaver Ohler,3 Maxwell Lee,1 Howard Yang,1 Suman Vodnala,1 Shyam Sharan,1 Glenn Merlino1.

**Immune checkpoint blockers (ICBs) have rendered unprecedented, durable responses in metastatic melanoma, but the heterogeneous response among patients continues to be the major obstacle for their therapeutic development.** It is generally hypothesized that neoantigens derived from mutated genes are involved in tumor response to ICBs, since the latter is correlated with mutational loads of tumors. However, direct experimental evidence showing that threshold optimal post-therapy 시행한 결과를 바탕으로 a) maintain an adequate T, APC and NK cell activity, b) reduce Treg and myeloid suppressors, c) avoid toxicity, and d) target cancer cells.

**#2620** Selecting the right chemotherapy partner for checkpoint inhibitors: an in vivo comparison of different drugs and dosages. Stefania Orechioni, Giovanna Talarico, Valentina Labanca, Patrizia Mancuso, Francesco Bertolini. European Inst. of Oncology, Milan, Italy.

**Introduction**

Immune checkpoint blockers (ICBs) have rendered unprecedented, durable responses in metastatic melanoma, but the heterogeneous response among patients continues to be the major obstacle for their therapeutic development. It is generally hypothesized that neoantigens derived from mutated genes are involved in tumor response to ICBs, since the latter is correlated with mutational loads of tumors. However, direct experimental evidence showing that threshold optimal post-therapy 시행한 결과를 바탕으로 a) maintain an adequate T, APC and NK cell activity, b) reduce Treg and myeloid suppressors, c) avoid toxicity, and d) target cancer cells.

**#2621** Microsatellite instability is a potential biomarker for immune checkpoint inhibitor in endometrial cancer. Hitomi Yamashita, Kentaro Nakayama, Noriyoshi Ishikawa, Toshiko Minamoto, Tomoka Ishibashi, Kohei Nakamura, Kaori Sanuki, Runiko Ono, Masako Ishikawa, Takeshi Iseobe, Satoru Kyo. Shimane University Faculty of Medicine, Izumo city, Japan.

**Introduction** In recent years, tumor cells have immune escape mechanism and immune checkpoint inhibitor therapy (anti PD-1/ PD-L1 antibody) has shown benefit in various cancers. Somatic mutations have the potential to encode "non-self" immunogenic antigens and lymphocytes infiltrate tumor cells in Microsatellite-instable (MSI) endometrial cancers. Therefore, immune checkpoint inhibitor therapy might be effective in MSI endometrial cancers. [Method] Mismatch repair protein (MLH1, PMS2, MSH2, and MSH6), tumor-infiltrating lymphocytes (CD8), and PD-1/PD-L1 expression were assessed by immunohistochemistry in 60 patients with endometrial cancer. We examined whether MSI status has enhanced immune microenvironment and become the therapeutic effect predictor of PD-1/PD-L1 immunotherapy in endometrial cancer. [Results] Loss of mismatch repair protein (MSI group) was identified in 8 (13.3%) of 60 patients with endometrial cancer. Expression of tumor-infiltrating lymphocytes (CD8) and PD-L1/PD-1 were significantly higher in MSI group compared to MSS group (p=0.001, p=0.044 and p=0.013). [Conclusion] These results suggested that immune checkpoint inhibitor (anti PD-1/PD-L1 antibody) is effective in endometrial cancers with MSI. MSI testing is likely to be a biomarker for PD-1/PD-L1 immunotherapy in endometrial cancer.
characterizing putative neoantigens. A “neo-epitope” library was generated by cloning the DNA sequences flanking non-synonymous mutations in frame with the eGFP gene in a lentiviral vector. We further showed that such eGFP-fused epitopes can be presented by the cells to induce specific T cell responses. The library will be transduced into the “resistant” Braf/PKDD melanoma, which will be treated with anti-CTLA-4 mAb in mice to test the immunotherapy response. To prevent immunity against eGFP expressed by tumors, the library-transduced melanoma cells will be transplanted into the eGFP-tolerant “glowing head” mice. The results will be used to determine if one, or more, of our candidate neo-epitopes can induce a response to anti-CTLA-4. We will also analyze if the response to this IC is an epitope-specific reaction or require multiple epitopes, which will help to identify resistance mechanisms. We hypothesize that our results will provide insight into the role of neoantigens in IC response. Moreover, our models will serve as a platform to study the specific contribution and predictive value of neoantigens for melanoma response to immunotherapy, which could help improve therapeutic strategies involving ICs.

**#2624** An FKBP51s-based immunophenotype for assessment of the immunosuppression status and possible prediction of immunotherapy response in melanoma patients. Simona Romano,1 Ester Simone,1 Anna D’Angelillo,1 Paolo D’Arrigo,1 Mario Capasso,1 Vito Alessandro Lasorsa,1 Martina Tufano,1 Anna Rea,1 Michele Russo,1 Nicola Zambrano,1 Paolo Antonio Asciento,2 Maria Fiammetta Romano,1,2 Univ. of Naples Federico II, Napoli, Italy; “National Cancer Institute “G Pascale”, Napoli, Italy; “National Cancer Institute, Napoli, Italy.

Background and aim: FKBP51s is an immunophilin encoded by FKBP5 gene on chromosome 6. It is a protein resident in lymphocytes and involved in immune response. Recently, our group demonstrated that the inhibitory checkpoint PD-L1/PD1 promoted the alternative splicing of FKBP5 gene, resulting in increased expression of its variant 4, in PRMC of melanoma patients. The aim of this study was to address whether such a molecular signature could help in identifying an immune profile associated with increased probability of immunotherapy response. Experimental Design: The splicing FKBP51isoform or FKBP51s was measured in peripheral blood T lymphocytes subsets (CD3/CD4, CD3/CD8, CD25 and PD-L1) and CD14 monocytes from a cohort of 118 patients and 77 age- and sex-matched healthy controls, by flow cytometry. Blood samples were collected before patients underwent ipilimumab treatment. Furthermore, in 64 out of 118 patients, expression of FKBP51s was also assessed in regulatory T cells. Results: Physiologically, each PBMC subset analyzed contained a fraction of an FKBP51s neg component, which resulted expanded in melanoma patients. We also measured an increased in CD3/CD8 and PD-L1 lymphocytes in patients. CD4 T lymphocytes showed the FKBP51s neg fraction significantly impaired, which might reflect the condition of impaired T cell help. Treg count was increased, in accordance with previous studies. The count of FKBP51s neg Treg defined a subgroup of nonresponders patients to ipilimumab, by 92.6%. A 2D hierarchical partitioning of data from FKBP51s-immunophenotype (heatmap) revealed 3 main clusters: C1 (33 pts, 51.5%), C2 (14 pts, 22%) and C3 (17 pts, 26.5%). FKBP51s neg Treg subset appeared globally increased in all clusters. In C1, values of effector T cells and monocytes were not different from normal donors. C2 showed a significant increase of FKBP51s pos PD-L1 monocytes and a significant probability of not responding (Chi-square 0.0019). C3 showed a significant increase of FKBP51s in overall lymphocyte subsets analyzed. Patients in this cluster showed reduced overall survival. This finding suggests that a prevalence of activation (CD25) and co-inhibitory (PD-L1) markers together with the expansion of FKBP51s pos effector T cells might reflect a condition of chronic lymphocyte stimulation in some advanced melanoma patients, contributing to T cell-exhaustion. Conclusions: FKBP51s-based immunophenotype of melanoma patients revealed several profiles virtually related to a negative immune regulatory control and highlights an impairment of a Treg subset endowing with increased suppressive potential. Such FKBP51s neg Treg subset is likely to be associated with immunotherapy response (Chi-square = 9.916, p = 0.002).

**#2625** Clinopathological features of programmed cell death ligand 1 (PD-L1) expression in resected non-small cell lung cancers. Yoshiohi Ohhara,1 Ichiro Kinoshita,1 Utano Tomaru,2 Kanako C. Hatanaka,2 Yutaka Hatakanaka,2 Hiroshi Takeuchi,1 Yasushi Shimizu,1 Ichiro Kaga,2 Yo-shihiro Matsumoto,2 Hiroshi Dosaka-Akita,1,2 Hokkaido University Graduate School of Medicine, Sapporo, Japan; Hokkaido University Hospital, Sapporo, Japan.

Background: Antibodies against programmed death 1 (PD-1) and programmed death ligand 1 (PD-L1) have recently demonstrated a survival benefit in several types of cancer, including melanoma and non-small cell lung cancer (NSCLC). PD-L1 expression has provided a predictive biomarker for anti-PD-1/PD-L1 therapy. However, the relationship between PD-L1 expression and clinical and clinicopathological characteristics remains unclear in NSCLCs. The aim of this study was to investigate the relevance of PD-L1 expression to clinical and clinicopathological characteristics in NSCLC. Methods: PD-L1 expression was evaluated in 154 surgically resected NSCLC specimens by immunohistochemistry (IHC) using the SP142 antibody. Before the IHC of clinical samples, we performed a concordance study of Western blot analysis and IHC in 17 lung cancer cell lines. We evaluated the relationship between PD-L1 expression and clinical and clinicopathological factors by univariate and multivariate analyses. Results: PD-L1 expression was strongly associated with tumor differentiation (P = 0.0019, Fisher test). The prevalence of PD-L1 in the NSCLC patient cohort was 68% (68/100) using a H-score cutoff of ≥ 7. Analysis revealed a lower positivity of 61.7% (37/60) in squamous carcinoma as compared to 77.5% (31/40) in non-squamous NSCLC. Analysis of the patient outcome data demonstrated that higher levels of PDV protein expression is correlated with poorer outcomes in patients both with non-small cell lung cancer (NSCLC) and adenocarcinoma. Conclusion: PDV protein expression could potentially serve as a new immune checkpoint biomarker in lung cancer. This study demonstrates that high PDV protein levels predict poorer outcomes in lung cancer patients; suggesting that PDV may be an important target for future immunotherapy.

**#2626** Expression of human poliovirus receptor, an immune checkpoint biomarker in lung cancer. Camila Kokczara,1 Hui Yu,1 Kim Ellison,2 Christopher Rivard,3 Leslie Rozeboom,1 Daniel Chan,1 Kenichi Suda,1 Kristine Brovsky,1 Rafal Dzdziszuk,3 Fred Hirsch,1,2 University of Colorado Anschutz Medical Campus, Aurora, CO; Medical University of Gdansk, Gdansk, Poland.

Background: Recently, immune therapy has shown notable efficacy in melanoma, non-small-cell lung cancer (NSCLC), among others, indicating that the targeting of immune checkpoints may be a promising treatment for malignant tumors. The human Poliovirus Receptor (CD155), an immune checkpoint, has been found to be overexpressed on the membranes of various tumor cells including colorectal and ovarian carcinoma. Examining PVR’s expression in NSCLC could shine light on PVR’s potential role and its possible correlation to the prognosis and outcomes for NSCLC patients. Material and Methods: Gene expression data for lung cancer cell lines and tumor tissues was derived from the Cancer Cell Line Encyclopedia (CCLE [www.broadinstitute.org/ccle]) and the TCGA database (www.cbioportal.org), respectively. Immunohistochemistry (IHC) was performed on a Ventana Benchmark XT platform using an anti-PVR antibody (Cell Signaling #D3G7H-1:100 dilution). IHC staining was evaluated for a NSCLC Cell Line Tissue MicroArray (TMA) and a NSCLC patient cohort TMA. The H-score system was used to generate a semi-quantitative score, ranging from 0 to 300, that evaluates the intensity and prevalence of staining on tumor cells. Patient data was analysed to uncover correlations between outcome and PVR expression in the NSCLC TMA cohort. Western blot analysis was performed to confirm antibody specificity and PVR expression levels in three NSCLC cell lines. Results: Analysis of mRNA expression data from CCLE and TCGA databases identified that PVR is highly expressed in lung cancer. Three lung cancer cell lines were chosen based on mRNA expression for this study: NCI-H211 (high), NCI-H1650 (moderate) and NCI-H1187 (negative). Cell line data revealed that PVR demonstrated higher expression levels in lung cancer than other immune checkpoints, such as PD-L1, PD-L2, and Gal-9 among others. In addition, PVR expression was not correlated with other negative immune checkpoints including PD-L1 and Gal-9. Western blot analysis confirmed the Cell Signaling antibody was specific to the PVR protein in NSCLC cell lines. IHC staining of NSCLC cell lines revealed that non-squamous NSCLC cell lines express higher levels of PVR than squamous NSCLC cell lines (p = 0.0001, Fisher test). The prevalence of PVR in the NSCLC patient cohort was 68% (68/100) using a H-score cutoff of ≥ 7. Analysis revealed a lower positivity of 61.7% (37/60) in squamous carcinoma as compared to 77.5% (31/40) in non-squamous NSCLC. Analysis of the patient outcome data demonstrated that higher levels of PVR protein expression is correlated with poorer outcomes in patients both with non-small cell lung cancer, and adenocarcinoma. Conclusions: PVR protein expression could potentially serve as a new immune checkpoint biomarker in lung cancer. This study demonstrates that high PVR protein levels predict poorer outcomes in lung cancer patients; suggesting that PVR may be an important target for future immunotherapy.
The synergy between BXLCL701, a DPP inhibitor, and immune checkpoint inhibitors discovered using AI and Big Data analytics. Luca Rastelli, Snigdha Gupta, Akhil Dahiya, Zeenia Jagga, Krishnan Nandabalan, Sana-tan Upmanyu. BioXcel, Branford, CT.

Using the proprietary Big Data PharmGPS® Discovery platform, BioXcel has created a comprehensive relationship map between immune-evasion and immune-activation pathways, comprising interacting genes and all overlapping pharmacological agents and tumors. This map was used to identify clinically validated compounds that would act synergistically in combination with immunotherapies. Such an effective therapeutic approach could counteract the tumor-promotive microenvironment and transforming cold, non-inflamed tumors into hot immune-sensitive tumors. One of the several compounds thus identified is BXLCL701, previously known as Talabostat/PT-100, a DPP inhibitor that by inducing a wide panel of cytokines and chemokines stimulates both the innate and acquired immune system. BXLCL701 has a dual immune-oncology related MOA. Via the Fibroblast Activating Domain (FAD) of BXLCL701, it up-regulates stress-responsive genes in fibroblasts and through an angiogenic related effect, it increases immune cell extravasation into the tumor tissue. Via the DPP8/9 targets, it depresses the immune-suppressive activity of MDCs by inducing a granulocytic differentiation while it stimulates the priming, migration and cytotoxicity of T-cells and NK cells and the formation of memory T-cells. The hypothesis that BXLCL701 immune-mediated MOA would complement the action of ICIs was validated in-vivo in the syngeneic MC38 mouse model of colon adenocarcinoma. Co-administration of BXLCL701 combined with anti-PD1 showed a synergistic inhibition of tumor growth as well as synergistic up-regulation of immuno-stimulatory cytokines, IL-2, IL12 and GM-CSF. The effects of the combination on the immune-phenotyping of the circulating and tumor infiltrated immune cells will be presented at this meeting. The demonstrated anti-angiogenic and immune-suppressive tumour microenvironment to an immuno-permissive milieu sensitive to immune-checkpoint inhibitors. Further supporting the therapeutic potential of BXLCL701, an analysis of genomic alterations in FAP, DPP8 and DPP9 across a wide range of tumors singled out castration-resistant prostate cancer with a high level of DPP9 amplification (14%) and overexpression of DPP8 in 50% of the patients which could make this patient population uniquely sensitive to the combination as shown by in-vitro and in-vivo experiments. This study provides further evidence of the capability of Big Data analytics to generate in-silico hypothesis of synergistic combination effects that can be converted in validated therapeutic opportunities to benefit patients non-responsive to ICI therapy.

The cellsurfaceantigenLymphocyteantigen75(LY75,CD205,DEC-205)isnotableas a target for a novel ADC. MEN1309 is a humanized IgG1 antibody drug conjugate (ADC) targeting Ly75 antigen, induces complete responses in several xenografts of solid tumors. Mario Bigioni,1 Giuseppe Merlino,1 Cristina Bernardino Morales,2 Rossana Bugnani,1 Attilio Crea,1 Rossanna Manno,1 Joaquin Arribas,2 Rachel Dusek,4 Nickolas Attanasio,1 Keith Wilson,4 Christian Rohlff,5 Monica Binaschi1. 1Mennarini Ricerche S.p.A., Pomezia (RM), Italy; 2Vall D’Hebron, Institute of Oncology, Barcelona, Spain; 3Research Toxicology Center, Pomezia (RM), Italy; 4Oxford BioTherapeutics, Inc., San Jose, CA, USA; 5San Jose, CA, USA; 6Oxford BioTherapeutics, Ltd., Abingdon, UK.

The cell surface antigen Lymphocyte antigen 75 (LY75, CD205, DEC-205) is over-expressed in several tumor histotypes. It is a type I C-type lectin receptor (CLR), normally expressed on various APC subsets, characterized by a cytoplasmic domain containing protein motifs crucial for endocytosis and internalization upon ligation. These features make the antigen ideal to be exploited as a target for a novel ADC. MEN1309 is a humanized IgG1 antibody directed against the cell surface antigen Ly75, conjugated through a cleavable linker to a potent maytansinoid microtubule disruptor, DM4. In this study, we evaluated the in vitro and in vivo (xenografts and PDX) efficacy of MEN1309 in different tumor histotypes. A PK/PD relationship was also investigated in tumor-bearing mice. HIC demonstrated high prevalence of LY75 in human pancreatic, triple negative breast, and bladder cancers, as well as in diffuse large B-cell lymphoma. In vitro experiments showed that cytotoxic activity of MEN1309 was in mM/sub mM range against several lymphoma, pancreatic, bladder and triple-negative breast cancer (TNBC) cell lines. Moreover, MEN1309 exhibited high cell-kill ability against cells having either strong as well as low to moderate antigen expression. In vivo, MEN1309 at 2.5-5 mg/kg (schedule varying from single dose, q2dx3, or q21dx3) showed an impressive antitumor activity, resulting in complete and long lasting responses in most of the xenograft models representing lymphoma, TNBC, bladder and pancreatic cancers, expressing the antigen at high but also at low levels. No treatment related toxicity in terms of change of body weight and death events were detected. Moreover, the administration of (i) the control-DM4 and (ii) the non-conjugate antibody IgG1 and (iii) the free toxin DM4 (at a dosage corresponding to the equimolar concentration linked at 10 mg/kg ADC) showed little to no therapeutic efficacy on tumor growth. In TNBC patient-derived xenograft (PDX) model (coming from a heavily pre-treated patient and expressing high level of the antigen
In syngeneic mouse model.

large fraction of cancer patients doesn’t respond to the antibody immunotherapy and lots of patients are suffered from immune-related adverse events. Still, large fraction of cancer patients doesn’t respond to the antibody immunotherapy. INF-α/β contributes to tumors suppression in a CT26 bearing syngeneic mouse model. Cancer immunotherapies like antibodies targeting immune checkpoint molecules have resulted in an extraordinary success in cancer treatment. Still, large fraction of cancer patients doesn’t respond to the antibody immunotherapy and lots of patients are suffered from immune-related adverse events (irAEs) which sometimes cause discontinuation of the treatment. The above problems highlight the needs in the cancer immunotherapy for attempting various approaches like synergistic combination therapy to minimize adverse events and enhance efficacy. Interferon-γ is a cytokine having antitumor activity and has been developed as an anticancer drug in multiple cancer indications but failed due to its limited efficacy and severe adverse events. In several publications, IFN-γ has been clarified to induce PD-L1 expression in tumors. Upregulation of PD-L1 renders tumor resistance to cytotoxic T cell and it may cause the limited efficacy of IFN-γ therapy. Our preliminary experiments suggested that an intratumoral injection of purified IFN-γ and following addition with anti-murine PD-1 antibody showed significant tumor suppression, implying a combination effects of regional IFN-γ and immune checkpoint blockers. Here in the present report, in an aim of decreasing adverse events, we have created recombinant Bifidobacterium, which is a non-pathogenic anaerobic bacterium to secrete INF-γ specifically inside solid tumor, and then demonstrated the combination of IFN-γ producing Bifidobacterium and anti-murine PD-1 antibody significantly suppress tumor growth whereas each single treatment moderately contributes to tumor suppression in a CT26 bearing syngeneic mouse model. In addition, INF-γ antibody indicated that there are substantial IFN-γ detected in tumor tissue but none of them are detectable in blood on the Day 4 of treatment. All in together, combination treatment with IFN-γ producing Bifidobacterium and anti-murine PD-1 antibody offers a promising anti-tumor approach. Reference: 1. Abiko K., Br J Cancer, 2015 Apr 28;112(9):1501-9. INF-γ from lymphocytes induces PD-L1 expression and promotes tumor progression. 2. Matsumoto, Y., H. Ishida, T. Yamamoto, et al., Cancer Sci. 2014 Apr;105(4):1236-44. Inhibition of mitogen-activated protein kinase pathway can induce upregulation of human leukocyte antigen class I without PD-L1-upregulation in contrast to interferon-γ treatment.

4SC-202 induces inflamed tumor microenvironment, strongly enhances tumor infiltration with cytotoxic T cells and primes tumors for anti-PD1/PD-L1 therapy. Tanja Wulf, Kerstin Kronthaler, Svena Schrepfer, Ulrike Parmitzke, Anne Catherine Bretz, Roland Baumgartner, Svetlana Hamm. 4SC Martinried, Germany.

Various HDAC inhibitors were described as beneficially affecting antitumor immune response. Although different HDAC inhibitors were investigated in syngeneic tumor models, the mode of anti-tumoral action is not yet fully understood. Here, we analyzed the anti-tumoral mode-of-action (MOA) of 4SC-202, an orally available clinical stage epigenetic small molecule inhibitor specifically targeting histone deacetylases HDAC class I as well as the lysine-specific demethylase LSD1. To ensure that the conclusions would be relevant for the clinical situation we used a clinically equivalent dose and schedule. Anti-tumoral efficacy and the impact of 4SC-202 alone or in combination with an anti-PD-L1 antibody on the tumor microenvironment were analyzed in the syngeneic colorectal CT26 model in immunocompetent BALB/c or in nude/irradiated BALB/c mice. A broad spectrum HDAC inhibitor was used for comparison. Transcriptome analysis was performed by RNA-Seq, and the composition of immune cell subpopulations in the tumor was determined by flow cytometry. 4SC-202 treatment at clinically relevant dosage regimen significantly inhibited growth of CT26 tumors. A competent immune system was apparently necessary for the anti-tumoral effect of 4SC-202 since its tumor-reducing effect was lost in immunocompromised mice. 4SC-202 treatment led to an increase of MHC class II molecules and CD8+ T cells in combination with anti-PD-L1 enhanced expression of inflammatory markers like IFN-γ and various chemokines in the tumors. Detailed analysis of the tumor microenvironment revealed that 4SC-202 strongly increased the number of tumor-cidal cytotoxic T cells (CTL). In contrast, a broad-spectrum HDAC inhibitor tested in the same model demonstrated anti-tumoral efficacy but did not affect the number of CTLs in tumors demonstrating that HDAC inhibitors employ different MOAs for their anti-tumoral response and that the effect on CTLs is not attributed to HDAC inhibition in general. Since the T cell abundance is pre-requisite for the efficacy of PD1/PD-L1 blockade, we tested the combination of clinically relevant dosage regimen of 4SC-202 with an anti-PD-L1 antibody. The combined treatment was more efficacious than monotherapies and resulted in significantly longer survival. 4SC-202 already demonstrated a favorable safety profile in a phase I clinical trial with relapsed or refractory hematological malignancies with two objective responses (1 CR, 1 PR) and disease stabilizations in several patients. 4SC-202’s immune priming capacity offers further options for clinical development of 4SC-202 in combination with various cancer immunotherapy approaches.

In collaboration with Sanoﬁ, we previously showed that inhibition of the VEGFR3 pathway by SAR131675 leads to reduction of tumor growth by acting on the tumor microenvironment. We have identiﬁed a new drug candidate, EV801, and evaluated its activity on tumor models expressing VEGFR3. For proof-of-concept, we transfected the mouse BNL hepatoma cell line with VEGFR3. EV801 displayed a strong therapeutic activity by acting on both VEGFR3 and PD-1 expressing cells. We then employed a functional analysis in the following model: VEGFR3 small molecule inhibitor (SAR131675) and CD4+ regulatory T cells by and increasing macrophages with a M1 phenotype inside the tumor. As a consequence the T-cell:MDSC ratios were increased in the TME and also in peripheral blood. In addition to its immunomodulatory properties, EV801 decreased angiogenesis without increasing hypoxia. We have evaluated EV801 therapeutic activity in syngeneic tumor mouse models which are not expressing VEGFR3 such as 4T1 mammary carcinoma and CT26 colon carcinoma models. As expected, we observed an intermediate therapeutic activity of the compound on
both tumor models. Positive modulation of the TME was equivalent to what we observed with the VEGFR31 tumor model. With this unique mechanism of action of EVT801 on the TME, we evaluated its ability to increase therapeutic activity of standard Immune Checkpoint Therapies (ICT) such as anti-CTLA-4 and anti-PD-1 mAbs. Strong additive therapeutic activities were observed with EVT801 in combination with these ICTs, indicating the potential of long-term tumor-specific memory CD8 T cell responses. Toxicological data show that EVT801 has a favorable pharmacological profile consistent with its entry into pre-clinical development. Taken together, these results indicate that EVT801 represents an innovative drug for cancer Immunotherapy which provide a favorable microenvironment to promote tumor regression. In addition, EVT801 may improve the frequency of response to ICT.

The anti-PD-1 monoclonal antibody nivolumab is clinically active in a variety of tumor types including squamous (sq) and non-squamous (non-sq) NSCLC in second-line, where randomized phase III trials have shown a survival benefit. However, no predictive/prognostic or diagnostic biomarkers have been found so far to correlate with clinical benefit in patients treated with anti-PD-1 antibod-ies. The aim of the present study is to investigate the potential role of baseline peripheral blood cell counts in relation to survival and response rate in NSCLC patients treated with nivolumab in a second-line setting. From July to May we evaluated 45 patients with Sq (n = 10) and non-Sq (n = 35) NSCLC, previously treated with first-line platinum-based chemotherapy, who received nivolumab 3 mg/kg iv on day 1 of each 2 week treatment cycle. Clinical characteristics (T-Stage, lymph nodes involvement, M-Stage) were assessed, total numbers of white blood cells, myeloid-derived suppressor cells (MDSCs, including both monocytic [Mo-MDSC] and polymorphonuclear [PMN-MDSC] types), regulatory T cells (T-reg), and serum lactate dehydrogenase (LDH) were assessed. Endpoints were correlations with objective response rate (RR), progression-free survival (PFS, categorized as 3 or > 3 months) and overall survival (OS). Tumor response was assessed using RECIST criteria, version 1.1, at week 9 and every 6 weeks thereafter until disease progression. Statistical in-vestigations were based on univariate analyses by the Wilcoxon rank test. The median PFS of the overall study population was 3 months. Data about PMN-MDSCs (identified by flow cytometry as Lin-CD14+CD11b+HLA-DRhigh), Mo-MDSCs (Lin-CD14+CD11b+HLA-DRhigh) and absolute eosino-phil count (AEC) were available in 37/45 patients (82% of treated patients). Baseline absolute numbers of PMN-MDSCs, Mo-MDSCs and AEC were greater in patients with a good prognosis (PFS > 3 months) and a better RR. In particu-lar, among patients with shorter PFS and lower RR, the median numbers of PMN-MDSCs, Mo-MDSCs and AEC were significantly lower than those de-tected in patients with longer PFS (4 vs 13 cell/μl, p=0.01; 4 vs 21 cell/μl, p=0.006; 55 vs 155 cell/μl, p=0.02, respectively). Our data suggest that a baseline blood signature characterized by low levels of PMN-MDSCs, Mo-MDSCs and AEC is associated with a poor clinical outcome (median PFS ≤ 3 months and low RR) in 67.6% of patients treated with nivolumab. In contrast, patients with high levels of these three biomarkers showed a median PFS significantly longer than 3 months and a higher RR. The OS analysis is ongoing, and further studies have been planned to understand whether this signature has a biomarker poten-tial also in chemotherapy-naive, first line NSCLC patients.

#2636 Targeted therapies to ERBB receptors downregulate expression of PD-1: implications in combination therapies. Christopher A. Hamm,1 Sumin Zhao,2 Cesar A. Santa-Maria,3 Massimo Cristofanilli,4 Neil L. Spector,2 Sarah Bacus1.

1American Molecular Laboratories, Vernon Hills, IL; 2Duke Uni-versity Medical Center, Durham, NC; 3Northwestern University Feinberg School of Medicine, Chicago, IL.

Background: Inflammatory breast cancer (IBC) is the most aggressive and lethal form of primary breast cancer. Inflammatory signaling pathways are active in IBC, but the function of the immune response remains elusive. ErbB receptors play a role in IBC. ERBB2 is amplified in 50% of IBCs, and ERBB3 is also mutated in IBC. Currently, Lapatinib, a dual ErbB inhibitor, is used in IBC patients with ERBB2 amplification. Although immune cell inflammatory signaling may promote IBC tumor growth and metastasis, the presence of cytotoxic tumor-associated lymphocytes has also been associated with a more favorable breast cancer prognosis. The contradictory nature of the immune data high-lights the need to elucidate the relationship between the immune response and subsequent treatments. Given the active IBC immune component and the recent clinical benefit of immune checkpoint inhibitors in cancer treat-ment, IBC’s may represent a clinically unique breast cancer population that may benefit from immunomodulating agents. Interestingly, Myc is a down-stream effector of ErbB signaling, and Myc is thought to regulate the expres-sion of immune checkpoint proteins CD47 and PD-L1. The presence of PD-L1-positive IBC immune infiltrate suggests that IBC’s may benefit from therapies that disrupt PD-L1 signaling together with ErbB inhibitors. METHODS: IHC was used to examine immune checkpoint signaling and characterize the tumor-immune infiltrate. Tumor tissues were also charac-terized using a RNA-seq panel that examined the expression of 377 im-mune-related genes. Cell lines (BT474, SKR3, AU565, and SUM225) were treated with Lapatinib and Neratinib to examine the relationship between growth factor receptors and downstream immune signaling pathways. RE-SULTS: RNA-seq revealed the expression of specific immunosuppressive signaling pathways in tumors. Treatment of breast cancer cells with ErbB inhibitors resulted in a decrease in the levels of PD-L1. Treatment with Lapatinib and Neratinib diminished PD-L1 in all cell lines. Levels of Phos-pho-Stat3 decreased in BT474 and Sum225 but not in SKBR3 and AU565, implying that PD-L1 is regulated by another mechanism (ERK-MYC). CONCLUSION: Our results provide mechanistic insight into ErbB receptor acti-vation and the expression of downstream signaling molecules (Stat3, PD-L1, Myc) in IBC. In addition, our unique RNA signature reveals the expression of several genes that may serve as biomarkers of in-hibitory immune signaling pathways. Our laboratory is currently examining the correlation between PD-L1 expression and the activation of ErbB2 in model systems and clinical trials using ErbB inhibitors in combination with PD-L1 inhibitors. Our immune panel gene signature may serve as a useful diagnostic tool that, in conjunction with traditional ErbB testing, can identify patients that will benefit from combination therapy of an ErbB inhibitor and an immune checkpoint inhibitor.

#2637 Anti-tumor activity of cisplatin is enhanced by PD-1 blockade in preclinical models of head and neck squamous cell carcinoma. Linda Tran,1 Clint T. Allen,2 So-Jin Park,2 Roy Xiao,3 Carter Van Waes,4 Nicole C. Schmitt.5 NIDCD, Bethesda, MD; 6Johns Hopkins University and NIDCD, Bethesda, MD.

Rationale: Cisplatin, which remains the most commonly used systemic drug for head and neck squamous cell carcinoma (HNSCC), reduces numbers of circulating immune cells. However, recent studies suggest that cisplatin may enhance some aspects of anti-tumor immunity in the tumor microenvironment. We previously found that cisplatin increases expression of major histocompati-bility (MHC) class I and programmed death ligand 1 (PD-L1) in HNSCC cell lines in vitro. Methods: In the current study, we investigated other components of the antigen processing machinery (APM) by flow cytometry following treat-ment with cisplatin. Using the syngeneic mouse oral cancer 1 (MOC1) model of HNSCC, we then investigated the effects of cisplatin and anti-PD-1 antibody, alone or in combination, on tumor growth and survival. Results: Using three different HNSCC-cell lines, we found that levels of the APM components TAP1/2 and HLA-DRA were significantly increased in all cell lines treated with cisplatin, whereas TAP1/2 were dramatically increased only in one cisplatin-treated cell line with wild-type TP53 (UMSCC-74A). In MOC1 tumor-bearing mice, tumor growth was partially delayed by treatment with cisplatin and anti-PD-1 antibody alone and substantially delayed when these agents were given in combination, with result-ant increased survival. Comparison of different treatment schedules suggested that concurrent administration is more effective than giving cisplatin one day prior to anti-PD-1 or one day prior to cisplatin. Conclusions: Despite upregulating PD-L1 on tumor cells and decreasing levels of circulating immune cells, cisplatin may enhance some aspects of anti-tumor immunity in the tumor microenvironment. While no mice were cured with concurrent cis-platin and anti-PD-1 antibody, tumor growth was substantially delayed. These results suggest a rationale for combining cisplatin and anti-PD-1 monoclonal antibodies, perhaps with radiation or other therapies, in additional preclinical studies and clinical trials of HNSCC. Supported by NIDCD intramural project ZIA-DC-D000090.

Introduction: Pulmonary sarcomatoid carcinoma (PSC) is a poorly differen-tiated non-small cell lung cancer (NSCLC) containing a component of spindle cell or giant cell. Because the prevalence of PSC is very rare, there is
insufficient data about clinical feature, therapeutic strategy and prognosis. Method: We reviewed the medical records of 26 patients diagnosed with PSC from January 2009 to June 2015, and analyzed the clinicopathological characteristics, treatment modality and their outcome, and risk factors of overall survival (OS). Programmed death ligand 1 (PD-L1) expression was tested in 13 patients using immunohistochemical staining of formalin-fixed tissue sections on the A058 antibody. Potent and highly selective small molecules were generated to block either A0 generation or A0 signaling. The therapeutic potential of these molecules was assessed in CD8+ T cell assays, MLR assays and in various tumor models. CD73 inhibition blocked the conversion of AMP to A0. CD73 inhibition blocked the conversion of AMP to A0 and A0R inhibition abolished the increase in adenosine concentration. Results: The median age of PSC patients was 286 days. Age and the time from symptom onset to diagnosis were significantly associated with OS. PD-L1 expression showed the trend of positive prognostic value on OS in univariate analysis but was insignificant in multivariate analysis. 12 patients were treated with chemotherapy, 9 with platinum-based doublet therapy, 2 with tyrosine kinase inhibitor and 1 with docetaxel. 7 patients showed partial response or stable disease. The median OS and progression free survival of patients receiving chemotherapy were 260 days and 85 days, respectively. Conclusions: It has poor prognosis compared with normal NSCLC. However, PSC patients showed comparatively fair response to chemotherapy and generally showed higher PD-L1 expression. A0 staining was correlated with treatment with cytotoxic chemotherapy. EGFR TKIs or immune checkpoint inhibitors are necessary to achieve a better results of PSC management.

#2639 Development of small molecule selective inhibitors of GCN2 as an immunotherapy aimed at preventing immune escape of tumor cells. Michał Gałązowski, Kamil Sitarz, Eliza Majewska, Stefan Chmielewski, Kinga Michalik, Magdalena Masieczyk, Agnieszka Adamus, Arkadiusz Bialas, Joanna Fogt, Marcin Bien, Magda Rzóska, Maciej Mikulski, Julian Zachmann, Krzysztof Brzózka, Selvita S.A., Kraków, Poland.

GCN2 is a protein kinase capable of sensing amino acid (AA) shortage. It gets activated by binding of unloaded tRNAs and subsequently phosphorylates translation initiation factor 2 alpha (eIF2a) eventually leading to induction of ATP4-mediated integrated stress response (ISR). Elevated catabolism of one of the essential amino acids - tryptophan (Trp), driven by overexpression of critical enzymes in Trp metabolism - IOD and TDO, leads to immunosuppressive microenvironment in many types of cancer. GCN2 is a key effector signaling component for IOD/TDO and is considered as a metabolic checkpoint of highly Trp-dependent T-cells. GCN2 activation through accumulation of unloaded tRNAs leads to inhibition of CD8+ effector T-cells and increase in generation and activation of regulatory T-cells. According to these findings, selective inhibition of GCN2 may be an effective strategy for targeting Trp-dependent immune surveillance of tumor cells. In this study, we report the results for a series of novel small molecule GCN2 kinase inhibitors that have been developed at Selvita and, to our best knowledge, are the most potent GCN2 inhibitors reported so far. Newly synthesized compounds exert low nanomolar potency for GCN2, good selectivity as well as by using archival tissues (PD-L1 IHC 22C3 pharmDx assay), GCN2 was highly selective relative to related enzymes/receptors, as well as a large panel of unrelated targets. Inhibition of one of the three targets robustly reversed adenosine-mediated inhibition of proliferation, CD25 expression, and IFN-g and granzyme B production by human CD8+ T-cells. Robust inhibition of tumor growth in combination with anti-PD1 antibody was observed for several of these compounds. Conclusions: Highly potent and selective inhibitors of each of the 3 molecular targets involved in the ATP/adenosine pathway have been identified. Their ability to interfere with the extracellular generation of A0 and the immune-suppressive effects of A0, as well as their effects on experimental tumor biology, have been demonstrated in various in vitro and in vivo models.

#2641 AZD4635 A0R receptor occupancy in cyromulgous monkey using PET and its application to the genomic clinical trial: Peter Johnström,1 Pablo Morentin Gutierrez,2 Katarina Varna,3 Magnus Schou,1 Akhiro Takano,2 Lorraine Jones,1 Ganesh Mugundu,3 Patricia McCoon,2 Paul Lyne,3 Jeffrey Infante,4 Gerald Falhcook,5 Manish Patel,5 Janet Karlis,6 Melinda Merchant,5 James Clarke,5 Alan Cross,6 Nicholas Seneca,6 Lars Farde,6 Miles Congreve,5 Jon S. Mason,7 Fiona H. Marshall3 1AstraZeneca, Stockholm, Sweden; 2AstraZeneca, Cambridge, United Kingdom; 3Karolinska Institutet, Stockholm, Sweden; 4AstraZeneca, Macclesfield, United Kingdom; 5AstraZeneca, Waltham, MA, 6Sarah Cannon, Nashville, TN; 7Heptares, Welwyn Garden City, United Kingdom.

Introduction: AZD4635 is an A0R receptor antagonist currently being tested as monotherapy and in combination with durvalumab in patients with advanced solid cancers. High adenosine levels found in tumors are immune suppressive and therefore AZD4635 could potentiate immune checkpoint inhibitors such as durvalumab (anti-PD1). Predictions of A0R receptor engagement in patients at different doses and at different time points may enable better interpretation of clinical biomarker data measuring effects on immune modulation. A quantitative assessment of the receptor occupancy in the brain of non-human primates was conducted for AZD4635 with PET imaging and the resulting PK/PD model was applied to predict occupancy in humans in tumors. Methods: PET measures of A0R occupancy in brain was performed using the radioligand [18F]MNI-444 in three anesthetized cyromulgous monkeys. PET data acquisition was performed for 120 min following IV-administration of [18F]MNI-444 at baseline and following pretreatment of AZD4635. Sampling for AZD4635 plasma exposure determination was performed. As part of PK/PD analysis of the occupancy data, a novel modification of the non Invasive-LOGAN data analysis of the PET data was performed to obtain a time course of occupancy for each dose. A bio-phase PK/PD mathematical model was then used to describe the relationship of occupancy with circulating concentrations of AZD4635. In parallel, a PK model for AZD4635 in humans was developed using data from cohort 1 (Clinical trial NCT02740985) after 125 mg and used for PK predictions for alternative doses of AZD4635 in the clinic. Results: A Clear Exposure-Effect relationship was observed for AZD4635-driven A0R occupancy in cyno brain when dosed 30 min prior to PET measurement. The PK/PD analysis of cyno PET-determined receptor occupancy provided an OCC50 that is in line with the in vitro potency for the compound under physiological concentrations of adenosine in the brain. The PK/PD model provided a prediction of the level of occupancy in human tumours at other clinically relevant doses. Different simulations were done varying the amount of endogenous adenosine levels. Conclusions: AZD4635 was shown to occupy A0R in cyno brain in an exposure dependent manner. The resulting PK/PD model built using this data set was used to run simulations of expected tumor receptor occupancy in man and the results correlated well with clinical findings. The PK/PD program is predicted to provide ~90% receptor occupancy over the whole dosing interval at a clinically relevant dose.

#2642 Preclinical efficacy of daratumumab in acute lymphoblastic leukemia. Karen Lee Bride, 1 Tiffaney Vincent, 1 Soo-Yeon L. Im, 1 Tori Fuller, 1 The- reesa Ryan, 2 David M. Barrett, 1 Shannon L. Maude, 1 Mignon L. Loh, 2 Michelle L. Hermiston, 2 Stephan A. Grupp, 1 Brent L. Wood, 2 David T. Teachey, 1 CHOP, Philadelphia, PA; 2UCSF Medical Center - Mission Bay, San Francisco, CA; 3Seattle Children's Hospital, Seattle, WA

Targeted immunotherapy has become critical for the successful treatment of many forms of cancer, particularly therapeutic antibodies with cytotoxic abilities. No safe and effective immunotherapies have been developed for T-cell acute lymphoblastic leukemia (T-ALL). CD38 is a transmembrane glycoprotein found on the cell surface of activated T cells, terminally differentiated B cells, but relatively low levels on normal lymphoid and myeloid cells. Daratumumab (dara) (Darzalex, Janssen Biotech, Inc.) is a human IgG1 monoclonal antibody that binds to a unique CD38 epitope and was recently FDA approved for the treatment of refractory multiple myeloma. In order to ensure CD38 is a relevant target in T-ALL and surface expression does not change with chemotherapy, we evaluated CD38 expression by flow cytometry (FACS) from 21 patients with T-ALL (10 early T-cell precursor (ETP) and 11 non-ETP) at diagnosis and one month of induction chemotherapy. All of the samples had detectable CD38 expression which did not change significantly after induction (mean CD38 MFI at diagnosis vs end-induction: 3.27 log vs 3.19 (S.I.; p = 0.25). Therefore we hypothesized that targeting CD38 with dara would be effective against T-ALL. In order to test this hypothesis, we xenographed primary ALL blasts from 15 different patients with ETP-ALL and 8 with non-ETP-ALL with ara randomized to dara (200 μg/mouse intraperitoneally (IP) weekly) vs control (isotype control at 200 μg/mouse IP weekly; 5 mice per arm for each sample) after they developed ≥1% peripheral blood (pb) blasts by FACS. Disease burden was assessed by FACS enumeration of pb blasts weekly and splenic blasts at sacrifice. We demonstrate striking efficacy of dara monotherapy in 6 of 7 ETP-ALL samples with reduction of pb and splenic blasts. Mice treated with high disease burden from 5 of the 8 non-ETP samples were moribund immediately after dara injection, possibly from aggregates of antibody bound to tumor cells leading to pulmonary embolism or tumor lysis, and were therefore inevaluable. We have since repeated the experiments for 5 of the samples, treating the mice after injection but before detectable engraftment of peripheral blasts. Dara was effective in all 3 samples. Experiments are ongoing for the other 2 samples. In summary, we found dara is a highly effective novel monotherapy for T-ALL in preclinical models. Based on these results, we are developing an early phase trial for children and young adults with relapsed/refractory T-ALL.

#2643 Thymic precursor cells generate acute myeloid leukemia in NP23-NHD13 double transgenic mice. Subhadip Kundu, 1 Eun Sil Park, 2 Yang Jo Chung, 1 Trevor Stephen Barlowe, 3 Peter D. Aplan 1, 3

1NIH/NCI, Rockville, MD; 2Syros Pharmaceuticals, Cambridge, MA

In previous studies, we have shown that thymic progenitors are potently leukemogenic, and that AML cells or residual CD4-/CD8-doublenegative (DN) thymocytes can be selectively targeted for elimination by the immune system by engaging cross-talk with T and B cells as well as activation of NK cells. In this study, we wanted to test if thymic progenitors can generate AML. We generated NP23-NHD13 double transgenic mice that express Mac1 in DN1 thymocytes again transmitted a Mac1 + Gr1+ AML. These cells were transplanted; all recipients were anemic, and demonstrated engraftment of NP23-NHD13 myeloid cells as well as a less prominent (7.5%-38.5%) population of CD11b+ Ter119+ erythroid cells in the BM and spleen. Taken together, these results indicate that NP23-NHD13 thymic progenitors are potentially leukemogenic, and retain myeloid and erythroid differentiation potential.

#2644 SY-1425, a selective RARα agonist, induces high levels of CD38 expression in RARA-high AML tumors creating a susceptibility to anti-CD38 therapeutic antibody treatment. Kathryn Austgen, Michael R. McKeown, Darren Hicok, Emily Lee, Chris Fiore, Matthew Richter, Christian Fritz, Tracey Lodie, Eric Olson, Syros Pharmaceuticals, Cambridge, MA

CD38 is a cell surface protein expressed primarily on white blood cells and considered a marker of differentiation initiation. CD38 is involved in the immune system by engaging cross-talk with T and B cells as well as activation of NK cells. In multiple myeloma (MM), a subset of tumor cells have high CD38 expression (CD38+), which has led to the development of effective anti-CD38 therapeutic antibodies, such as daratumumab (DARA). Thus, cancer cells that express CD38 can be selectively targeted for elimination by the immune system using these therapeutic antibodies. In multiple myeloma, DARA is most effective in patients whose tumor cells are CD38+ . In contrast, CD38 expression in AML tumors is generally observed to be negative (CD38−) or dim (CD38dim), and DARA has not shown activity in preclinical AML models. We previously reported that SY-1425, a clinical stage RARα agonist with improved pharmacokinetics, potency, and selectivity over pan-retinoic acid agonists, induces differentiation in non-APL AML cell lines and primary patient samples with a RARA super-enhancer associated biomarker (RARA-high). Since CD38 was found to be among the most differentially expressed genes in response to SY-1425, we hypothesized that SY-1425 mediated CD38 induction to levels comparable to MM may sensitize RARA-high AML cells to anti-CD38 therapy. We demonstrate that SY-1425 treatment of four RARA-high AML cell lines and four RARA-primary AML patient PBMCs induces the CD38+ phenotype, as measured by flow cytometry, similar to that found in the DARA sensitive MM cells. In contrast, we see no induction in RARA-low cell lines. We then demonstrated the activity of the SY-1425 and DARA combination on an ex vivo NK cell co-culture assay. Two RARA-high AML cell lines treated with SY-1425 and DARA were co-cultured with NK cells and monitored for both antibody dependent cell-mediated cytoxicity (ADCC) and NK cell activation by interferon gamma production. The combination of SY-1425 and DARA led to a six-fold increase in tumor cell death relative to the single agent controls, and 5-10 fold increases in NK cell activation is observed only in the SY-1425 and DARA combination treatment of RARA-high AML cell lines. Neither single agent, when administered alone, resulted in ADCC. Furthermore, a RARA-low AML cell line does not respond in the ADCC assay following the combination treatment due to the lack of CD38 induction in this SY-1425 insensitive line. In summary, we have identified a novel and rational combination treatment approach for a subset of patients with RARA-high AML. By inducing the expression of CD38, SY-1425 in combination with DARA elicits tumor cell death and NK cell activation. Based on these findings, a phase 2 clinical study with SY-1425 in combination with an anti-CD38 antibody is planned in AML using a RARA biomarker patient selection strategy.

#2645 Development of a first in class APRIL fully blocking antibody BION-1301 for the treatment of multiple myeloma. John Dulio, 1 Lilian Driesen, 1 Marc Snipper, 1 Marco Guadagnoli, 2 Astrid Bertens, 3 David Lutje Hulsik, 1 Tai Yu Tsu, 4 Kenneth Anderson, 5 Jan Paul Medema, 5 Kate Cameron, 5 Hans Femmena, 6 Andrea Elzas, 3 1Aduro Biotech Europe, Oss, Netherlands; 2Jerome Lipper Multiple Myeloma Center, Harvard Medical School, Boston, MA; 3ELow Institute for Myeloma Therapeutics and Jerome Lipper Multiple Myeloma Center, Dana Farber Cancer Institute, Harvard Medical School, Oss, MA; 4University of Amsterdam, Amsterdam, Netherlands.
APRIL, or tumor necrosis factor super family member 13 (TNFSF13), is a ligand for the receptors B-cell maturation antigen (BCMA) and transmembrane activator calcium modulator and cyclophilin ligand (CAML) interactor (TACI). APRIL serum levels are enhanced in patients diagnosed with multiple myeloma (MM), chronic lymphocytic leukemia (CLL) and colorectal cancer, is correlated with poor prognosis. APRIL is produced by osteoclasts, macrophages and other cells in the bone marrow niche. APRIL binds to BCMA to drive proliferation and survival of human Multiple Myeloma (MM) cells and induces resistance to several standard of care agents. Using a mouse anti-human APRIL blocking antibody 01A initially discovered using Aduro’s B-Select platform, we demonstrated that osteoclasts, bone marrow derived macrophages (BMDMs) and MM cells in vitro proliferation and survival is dependent on APRIL. In these co-cultures, cytokalic activity of lenalidomide and bortezomib is significantly enhanced by 01A in a dose-dependent fashion. Importantly, APRIL drives and inhibits expression of an immunosuppressive gene set including the immune checkpoint programmed death ligand-1 (PD-L1), interleukin-10, vascular endothelial growth factor, and transforming growth factor beta. The human APRIL antagonist antibody 01A was humanized and designated BION-1301. The antibody binds an epitope overlapping the BCMA and TACI binding sites potently and fully blocks BCMA and TACI binding (IC50 < 1 nM). Biophysical and functional experiments indicated that BION-1301 recapitulated all characteristics of 01A. In vivo, BION-1301 was shown to suppress T-cell dependent B cell responses to NP-Ficoll. Furthermore, APRIL blockade on both M1 and M2 TAM populations anti-multiple myeloma activity in a humanized SCID model confirming its activity in vivo, and potentially indicating that BION-1301 is active targeting multiple myeloma cells in a tumor-protective bone marrow microenvironment. To our knowledge, BION-1301 is a first-in-class humanized APRIL antagonist demonstrated in to inhibit multiple myeloma survival, drug resistance and an immune suppressive phenotype preclinical. These data suggest a rationale to develop BION-1301 as a single agent, and in combination with lenalidomide, bortezomib, or possibly checkpoint inhibitors such as anti-PD-1. BION-1301 is expected to enter Phase I in 2017. 1) Guadagnoli at al. Blood. 2011 Jun 23;117(25):6856-65. 2) Yu-Tzu et al. Blood. 2016 Jun 23;127(25):3225-36.

Tumor cells often evade macrophage-mediated destruction by increasing cell surface expression of CD47, which delivers an anti-phagocytic (“do-not-eat”) signal by binding the inhibitory signal-regulatory protein α (SIRPα) receptor on macrophages. We have previously shown that blockade of the CD47-SIRPα pathway using TTI-621, a soluble SIRPα-IgG1Fc fusion protein, triggers macrophage phagocytosis of tumor cells in vitro as well as inhibits tumor growth in vivo when delivered systemically. In the current study, the efficacy of intratumoral delivery of TTI-621 was evaluated in a subcutaneous diffuse large B-cell lymphoma (Toledo) xenograft model. Tumor bearing mice were randomized into treatment groups when tumor volumes reached approximately 120 mm3. Weekly intratumoral administration of TTI-621 at 10, 1 and 0.1 mg/kg dose levels resulted in statistically significant decreases in tumor growth and improved survival relative to vehicle control treatment. Notably, at day 50 post tumor implantation 100% survival was achieved at the highest dose level (vs. 0% survival with vehicle control treatment). Moreover, weekly intratumoral administration of TTI-621 was efficacious even at a high tumor load setting in which the pre-dose volumes were approximately 300 mm3. Flow cytometry analysis of the dissociated tumor samples demonstrated no significant change in the numbers of M1 and M2 tumor-associated macrophages (TAMs) following intratumoral administration of TTI-621. Nevertheless, TTI-621 dramatically increased the phagocytosis of Toledo cells by both M1 and M2 TAMs to a similar extent in vivo, suggesting that TTI-621 is efficacious in increasing the phagocytosis of tumor cells by a heterogeneous population of TAMs. Collectively, these results demonstrate that TTI-621 is efficacious when delivered intratumorally and can increase the phagocytosis of tumor cells by both M1 and M2 TAM populations. These data support the evaluation of intratumoral administration of TTI-621 in cancer patients, and a Phase I study of intratumorally delivered TTI-621 in patients with percutaneously accessible solid tumors and mycosis fungoides is ongoing (NCT02890368).

#2647 TGF-β type I receptor inhibitor (TEW-7197) diminishes myeloma progression by multiple immunomodulatory mechanisms in combination with ixazomib. Byung-Gyu Kim,1 Olga Sergeeva,2 George Luo,3 Sung Hee Choi,1 Zhenghong Lee,2 Seong-Jin Kim,1 John Letterio,1 Ehsan Malek,1 Case Western Reserve University, Cleveland, OH; Seoul National University, Republic of Korea.

Background: Multiple myeloma (MM) is an incurable cancer of plasma cells. MM thrives in the bone marrow tumor microenviron (TME) where several factors sustain MM growth and viability. TGF-β is a multi-functional cytokine elaborated by MM cells and by cells in the bone marrow (BM) TME. TGF-β stimulates MM progression through promotion of catabolic bone remodeling, an adverse TME phenotype, and by its anti-apoptotic activity. TGF-β induces ostoclast bone disease, immune suppression and myeloma progression. Therefore, we evaluated the anti-MM therapeutic potential of a small molecule inhibitor of the TGF-β type I receptor kinase (TβRI), TEW-7197, in combination with the proteasome inhibitor, ixazomib. Currently, TEW-7197 is being evaluated in phase I clinical trials in patients with solid tumors, and exposure to this agent is associated with an acceptable tolerability profile. Methods: The preclinical immunocompetent ST33MM model (C57BL/6J nearing viation of the role of TGF-β signaling in the BM TME. Mice bearing ST33MM cells expressing luciferase were treated with TEW-7197, ixazomib and the combination of TEW-7197 plus ixazomib daily for 3 weeks, and evaluated for MM growth by bioluminescence imaging (BLI). Cellular and molecular assays were performed to determine the effects of TEW-7197 and ixazomib on MM cell survival, MM cell apoptosis, real-time PCR and Western blotting. Immunological assays were performed using anti-hematochemical and FACS analysis. Peripheral blood mononuclear cell protein concentration, M-spoke, was measured by ELISA. Results: TEW-7197 attenuated the growth and viability of human and murine MM cells by inducing apoptosis and it inhibited TGF-β-induced activation of Smad2/3 in MM cells in vitro. In our ST33MM preclinical model, oral administration of TEW-7197 as single agent inhibited MM progression measured by peripheral blood mononuclear protein concentration and BLI before and after treatment. TEW-7197 also induced a decrease in mortality and an increase in body weight of mice bearing MM. TEW-7197 alone or combination with ixazomib also attenuated TGF-β activation of Smad2/3, reduced the expansion of CD11b+CD11c+ myeloid derived suppressor cells (MDSCs) in the BM TME, and diminished the population of Foxp3 regulatory T cells (Treg) in the spleen. Combination therapy of TEW-7197 plus ixazomib prolonged survival and exhibited a synergistic anti-tumor effect when compared to either TEW-7197 or ixazomib alone by significant reduction in both the M-spoke and BLI. Conclusion: Our data demonstrate that the small molecule inhibitor of the TβRI, TEW-7197, effectively modulates the MM TME and is associated with a potent anti-myeloma effect in an immunocompetent murine model of MM. These data provide a rationale for clinical evaluation of the combination therapy of ixazomib and TEW-7197 as a potential therapeutic strategy to improve outcomes in patients with MM.

#2648 CD47 antibody-induced engulfment of human T-cell leukemia cells by bone marrow-derived macrophages. Gillian Lovell,2 Clare Szyb,2 Kalpana Patel,1 Hinaham Campwala,1 Nicole Bevan,1 Dan Appledorn,2 Tim James,3 Derek John Trezise,2 Essen BioScience Ltd, Welwyn Garden City, United Kingdom; 2 Essen BioScience Inc, Ann Arbor, MI.

CD47 is a trans-membrane "don’t-eat-me" signaling protein that enables tumor cells to evade clearance by neighboring phagocytes. Blocking CD47 allows phagocytes to identify and clear tumor cells and is a promising new approach for cancer immunotherapy. In this study, we characterized anti-CD47 antibody-mediated engulfment of living tumor cells (CCRF-CEM) by mouse bone-mar- row derived macrophages (BMDMs) or immobilized mouse macrophages (J774A.1). Phagocytosis was quantified using a pH-sensitive cell-labeling fluorescent probe, pHrodo, and automated kinetic live-cell analysis (IncuCyte). CCRF-CEM cells were first labeled using pHrodo (250ng ml-1 for 1h), washed and then treated with antibody for 1h. Target cells were then added to BMDMs or J774A.1 which had been loaded overnight on 96-well plates. Phase- and fluorescent images were captured and quantified every 15min. Anti-CD47 anti-body (B6H12.2, 0.04-5μg ml−1), but not IgG-control, produced time- and concentration-dependent engulfment of CCRF-CEMs by BMDMs (30-4h), as evidenced by an increase in intracellular fluorescence as the label accumulates in the acidic phagosome. After 4h the red fluorescence area was increased by 25-fold (1975 ± 391 μm2 vs 80 ± 41 μm2). From close inspection of the time-lapse images cellular engulfment could be clearly observed, coincident with the appearance of the fluorescent signal. Similar observations were made with J774A.1 as the effector cell. Interestingly, the rate and degree of engulfment appeared effector cell-dependent. The mechanism of engulfment was not via induction of
target cell apoptosis since anti-CD47 did not induce PS externalization (Annezin V) or activate caspase 3/7. Anti-CD47 had no direct effect on CCRF-CEM proliferation for the first 4 h but upon longer exposures (>8 h) cell growth was attenuated. Our experimental findings substantiate the known pro-phagocytic effects of anti-CD47 antibodies, and provide a model system and method for quantitative functional analysis and mechanistic insight of CD47 modulators as cancer therapeutics.

The chemokine receptor CXCR4 triggers signaling pathways that control cell migration to tissues where its ligand, CXCL12, is highly expressed, including the bone marrow (BM). In hematologic cancers, CXCR4 expression is associated with poor prognosis. CXCR4-driven homing of malignant cells to the BM protective niche is a key mechanism of chemotherapy resistance. PF-06747143 is a novel humanized IgG1 therapeutic antibody that binds to CXCR4 and inhibits CXCL12-driven pathways. Human IgG1 antibodies can induce strong cytotoxicity mediated by the antibody Fc-region, including antibody-dependent cytotoxicity (ADCC) and complement-driven cytotoxicity, whereas human IgG4 antibodies show minimal or no Fc-driven cytotoxicity. Here we generated an IgG4 version of PF-06747143 (m15-IgG4), which has similar binding to CXCR4 as the IgG1 antibody. We then characterized the role of Fc-driven cytotoxic function, comparing both antibodies in efficacy and safety studies. In an ADCC assay, PF-06747143 showed strong cytotoxicity of non-Hodgkin’s lymphoma (NHL) and acute myeloid leukemia (AML), while m15-IgG4 had no significant cytotoxicity. In a NHL mouse tumor model, the IgG1 CXCR4 antibody resulted in superior tumor growth inhibition, with 50% of mice exhibiting complete tumor regressions, compared to the m15-IgG4 antibody, which had limited activity, with no tumor regressions (p<0.01). The two antibodies had comparable exposure, suggesting that the difference in efficacy is due to the IgG1 antibody Fc-driven cytotoxic function. Furthermore, CXCR4 inhibition was previously shown to induce leukocyte mobilization from the BM; however, prolonged cell mobilization may lead to safer related issues, including hyperleukocytosis. In a study in non-human primates, we show that the IgG1 CXCR4 antibody elicited short leukocyte mobilization, lasting 16-24 hrs, while m15-IgG4 induced prolonged cell mobilization lasting > 4 days. Since both antibodies had comparable exposures, the different mobilization duration is likely due to the ability of the IgG1 CXCR4 antibody to reduce the number of mobilized cells via Fc-driven cytotoxic function. Finally, CXCR4 has been shown to play a key role in chemotherapy resistance. In a chemo-resistant PDX AML mouse model, in which the standard of care agents daunorubicin and cytarabine had limited activity, resulting in 30% of tumor cells remaining in the BM post-treatment, we show that combination of PF-06747143 with these chemotherapeutic agents led to synergistic activity, with tumor burden reduced to 0.3% tumor cells in the BM. In conclusion, PF-06747143 attributes offer potential efficacy and safety-related advantages over other CXCR4 antagonists currently in development, which do not have Fc-driven cytotoxic activity. PF-06747143 is now being evaluated in a Phase 1 clinical trial in relapsed and refractory AML (NCTID 02946533).

#2650 Radioimmunotherapy for acute myeloid leukemia targeting human aspararyl (asparaginyl) β-hydroxylase. Michael S. Lebowitz, Ekaterina Revskaya, Kanam Malhotra, Amir Shallaee, Steven Fuller, Maria R. Baer, Noa G. Holtzman, Ashkan Emadi, Ekaterina Dadachova, Hossein A. Ghanem, Panacea Pharmaceuticals, Inc., Gaithersburg, MD; Albert Einstein College of Medicine, Bronx, NY; Institute for Asthma and Allergy Prevention, LLC, Chevy Chase, MD; University of Maryland School of Medicine, Baltimore, MD; University of Saskatchewan, Saskatoon, Saskatchewan, Canada.

Treatment options for acute myeloid leukemia (AML) are limited and have modest impact on 5-year survival rates in patients <60 years of age (~35-40%) and on median survival of older patients (< 1 year). The incidence of AML has been rising, with an anticipated 19,950 new cases in 2016. Thus, the need for new, more efficacious and better tolerated therapy for AML is urgent. Human aspararyl (asparaginyl) β-hydroxylase (HAH) is an embryonic/developmental protein, which is down-regulated in normal cells after birth but overexpressed on the surface of many malignant cells, where it has been demonstrated to be sufficient to induce cancer cell proliferation, motility and invasiveness. We hypothesized that HAAH is selectively overexpressed on leukemia cells and thus targeting it with a fully human monoclonal antibody (mAb) conjugated to the short half-life α-emitter 212Bi could provide a novel radioimmunotherapy (RIT) treatment option with a reasonable therapeutic index. Using immunocytochemistry and flow cytometry with human mAb, PAN-622, we investigated the expression of HAAH on a variety of cytogenetically- and mutationally heterogeneous leukemia cell lines, as well as normal human leukocytes. PAN-622 was further modified with DTPA-maleimide to allow chelation of radionuclides, specifically 212Bi, to the human IgG1 anti-HAAH antibody with the aim to measure selective dose-dependent killing of leukemic cells. HAAH was highly expressed, as detected by flow cytometry, on all tested leukemia cell lines with KG1α and HL-60 demonstrating the highest levels of expression amongst the AML lines. Binding was observed only between PAN-622 and the modified DTPA-PAN-622 conjugate. Interestingly, expression of HAAH was not detected on CD45 normal human leukocytes, including in subpopulations of monocytes (CD14+), B-cells (CD19+), T-cells (CD3+) or hematopoietic stem cells (CD34+). To determine whether PAN-622 could selectively target leukemia cells in a background of normal human blood, flow cytometry was performed on leukemia cells spiked into whole blood. Only leukemia cells were stained with the PAN-622 antibody as indicated by simultaneous staining for surface markers of various leukemia and normal cell populations. Staining of leukemia cell lines was demonstrated following incubation with 212Bi-DTPA-PAN-622 which induced dose dependent specific killing over a 6.7-670 pM concentration range. No killing was detected when using 212Bi conjugated to an isotype-matched control antibody at a similar specific activity and dose range. Thus, HAAH is a novel oncogenic target expressed on leukemia cells, which can be selectively targeted for RIT via the fully-human PAN-622 mAb. Experiments targeting primary leukemia cells in patient-derived bone marrow aspirates are ongoing.

#2651 A novel CD19 targeting antibody-drug conjugate, huB4-DGN462, shows promising in vitro and in vivo activity in CD19-positive lymphoma models. Eugenio Gaudio, Chiara Tarantelli, Alberto J. Arribas, Roberta Pittau Bordone, Andrea Rinaldi, Georg Stussi, Emanuele Zucca, Davide Rossi, Anastasios Statthis, Min Li, Alan Willehm, Kate Lai, Qifeng Qiu, Stuart Hicks, Callum Sloss, Francesco Bertoni. Institute of Oncology Research - IOSI, Bellinzona, Switzerland; Oncology Institute of Southern Switzerland - IOSI, Bellinzona, Switzerland; Immunogen Inc., Waltham, MA.

Background. CD19 is a cell surface membrane protein expressed in mature and immature B cell neoplasms, making it a promising target for antibody-drug conjugate (ADC) therapy for B cell malignancies. Here we describe the preclinical activity of a novel B cell targeting fully humanized potent indolino-benzodiazepine DNA-alkylating payload DGN462. Methods. The humanized anti-CD19 antibody, huB4, was conjugated to DGN462 via a cleavable disulfide linker, sulfo-SPDB. In vitro activity of the huB4-DGN462 ADC or the unconjugated DGN462 toxin was evaluated in 54 lymphoma cell lines [27 diffuse large B cell lymphomas (DLBCL); 10 mantle cell lymphomas; 6 marginal zone lymphomas; 5 anaplastic large T-cell lymphomas; 6 others]. Cell proliferation/avialability/after 72 h of exposure was measured using a MTT assay. Apoptosis activation was defined by at least 1.5-fold increase in caspase 3/7 signal activation in respect to controls using the Promega ApoTox-Glo Triplex Assay. Gene expression profiling (GEP) was performed with the Illumina HumanHT-12 Expression BeadChips on untreated cell lines followed by GSEA. Results. huB4-DGN462 was cytotoxic against a broad panel of 48 B cell lymphoma cell lines (median IC50 100 pM; 95%CI, 38-214). The cytotoxic activity was not limited by P53, BCL2, MYC or CDKN2A status, or associated with DLBCL cell of origin. Consistent with overall lower CD19 expression, huB4-DGN462 was significantly less active in eight T cell-derived lymphomas (median IC50 of 1.75 mM (95%CI, 0.5-5.75)) than in B cell lymphomas. huB4-DGN462 induced caspase 3/7 activation in 48/54 cell lines (89%) consistent with an apoptotic mechanism of action. huB4-DGN462 demonstrated compelling anti-tumor activity after a single intravenous dose in two diffuse large B-cell lymphoma cell line xenograft models (human CD19+ lymphoma model and Farega’s disseminated model). In the DoHH2 model, huB4-DGN462 resulted in a significant, dose-dependent tumor growth delay and survival benefit at 1.7 mg Ab/kg compared to a non-targeted control DGN462 ADC. In the disseminated Farega model, a significant dose-dependent increase in survival was observed in mice treated with as low as
IMMUNOLOGY: Immune Response to Hematopoietic Tumors: New Development in Tumor Immunology

0.17 mg Ab/kg of huB4-DGN462. At 1.7 mg Ab/kg, the life span was increased >400% compared to untreated mice. Conclusions. The novel ADC huB4-DGN462 presented strong preclinical anti-lymphoma activity, which provides evidence for further study.

Background: Primary Mediastinal Large B-Cell Lymphoma (PMLBCL) is a unique type of B-cell lymphoma probably arising from a putative thymic medulla B-cell. One to 2% of NHL, 7% of all diffuse large B-cell lymphomas (DLBCL), occurring more often in young females. Often presents with superior vena cava syndrome and airway compromise. Treatment is with chemotherapy combined with Rituximab, followed by involved field radiation therapy to mediastinum. PMLBCL has better outcome than others DLBCL. We aimed to develop a more dose-dense/intense regimens that improves the rate of cure with an attempt to avoid mediastinal radiation. Patients and methods: A prospective study was conducted in our department from January to December 2015, in 6 patients with untreated primary mediastinal B-cell lymphoma. An infusional study was conducted in our department from January to December 2015, in 6 patients. PMLBCL has better outcomes than others DLBCL. We aimed to develop a more dose-dense/intense regimens that improves the rate of cure with an attempt to avoid mediastinal radiation. Patients and methods: A prospective study was conducted in our department from January to December 2015, in 6 patients with untreated primary mediastinal B-cell lymphoma. An infusional study was conducted in our department from January to December 2015, in 6 patients.

#2653 The anti-myeloma activity of TTI-621 (SIRPaFc), a CD47-blocking immunomodulatory agent, is enhanced when combined with a proteasome inhibitor. Emma Linderoth, Simone Helke, Vivian Lee, Taptuma Mutukura, Mark Wong, Gloria H. Lin, Lisa D. Johnson, Xinli Pang, Jeff Winston, Penka S. Petrova, Robert A. Uger, Natasja N. Viller. Trillium Therapeutics Inc., Mississauga, Ontario, Canada.

CD47 is transmembrane glycoprotein that delivers an anti-phagocytic (“do not eat”) signal to the receptor signal-regulatory protein (SIRPα) on the surface of macrophages. Many tumors, including multiple myeloma (MM), express high levels of CD47 as a means to evade the CD47-SIRPα pathway and escape macrophage-mediated immune surveillance. TTI-621 (SIRPaFc) is a soluble recombiant fusion protein consisting of the CD47-binding domain of human SIRPα linked to the Fc region of human IgG1. It is designed to promote anti-tumor responses by blocking the CD47-“do not eat” signal and engaging activating Fcy receptors on macrophages. We have previously shown that TTI-621 enhances phagocytosis of malignant cells in vitro and exhibits anti-tumor activity in acute myeloid leukemia and B lymphoma xenograft models. In this study we investigated the anti-myeloma activity of TTI-621 as both a single agent and in combination with bortezomib or carfilzomib, two proteasome inhibitors that are approved for use in MM patients. The ability of TTI-621 to trigger macrophage phagocytosis of MM cells was assessed using a flow cytometry-based phagocytosis assay. Blockade of CD47 using TTI-621 effectively triggered macrophage-mediated phagocytosis of MM cells, and this anti-tumor effect was significantly enhanced by pre-treatment of MM cells with bortezomib or carfilzomib. In order to understand the molecular mechanism behind this enhanced phagocytic effect, we performed immunophenotyping of the tumor cells and observed an upregulation of pro-phagocytic “eat” signals on the tumor cell surface that potentially augment the phagocytic response. To investigate whether CD47 blockade in the context of proteasome inhibition translates to enhanced anti-tumor activity in vivo, we employed a MM xenograft model. NOD-SCID mice were subcutaneously engrafted with human MM cells followed by treatment with TTI-621, in the absence or presence of concurrent administration of a proteasome inhibitor. As monotherapies, both TTI-621 and the proteasome inhibitor reduced tumor burden relative to vehicle controls. Moreover, the combination of CD47 blockade and proteasome inhibition resulted in greater tumor growth reduction compared to each drug alone. In conclusion, these data demonstrate that TTI-621 exerts anti-myeloma activity that is further enhanced by combination with bortezomib or carfilzomib. TTI-621 monotherapy is currently being evaluated in a Phase 1b study in patients with MM and other hematological malignancies (NCT02663518). These data provide a rationale to evaluate a combination study of TTI-621 and a proteasome inhibitor in MM patients.

The interaction of programmed cell death-1 (PD-1) and its ligand programmed cell death-1 ligand (PD-L1) is a major focus of recent immune oncology therapy efforts. The expression of PD-1 on T lymphocytes and its subsequent interaction with PD-L1, either from antigen presenting or tumor cells, will result in apoptosis-dependent inactivation of the T lymphocytes. This interaction plays an integral role in tumor immunology, specifically augmenting immune evasion. Relative little is known about the regulation of PD-L1 in either the tumor or normal environment. We investigated the ability of natural dietary compounds to induce PD-L1 expression on normal epithelial cells and various cancer cell lines. These molecules have been evolutionarily selected to control inflammation and cancer cell transformation and progression, understanding their mechanism of action could be important to understanding how this system works. Using flow cytometry and immunohistochemistry, we focused our studies on resveratrol and its metabolite piceatannol, key phytochemicals extracted from grapes, after an initial screen of various natural products. Experimental data showed that both compounds can individually up-regulate the expression of PD-L1 on tumor cell lines and normal epithelial cells, by an IFN-γ-independent mechanism. PD-L1 induction by both of these compounds was higher in tumor than in normal epithelium, suggesting greater significance in tumor regulation than inflammation. Additionally, the combination of resveratrol and piceatannol acted synergistically, leading to a significantly greater induction of PD-L1 expression across multiple tumor indications. Understanding whether resveratrol and piceatannol use a common signaling pathway to induce PD-L1 expression in tumor cells, was critical to understand the synergistic induction observed. Studies utilizing specific inhibition of IKK phosphorylation were accompanied by a significant reduction in the ability to induce PD-L1 expression on tumor cells, either as single agents or in combination. These results are consistent with the hypothesis that induction of PD-L1 by resveratrol or piceatannol, or their combination involves molecular determinants downstream of NF-kB signaling.

#2655 Drug resistant B-cell tumors eliminated by novel therapeutic antibodies in vivo. Hong Qin, Guowei Wei, Ipeki Sakamaki, Zhouyuan Dong, Wesley A. Cheng, Diane L. Smith, Feng Wen, Han Sun, Soung-chul Cha, Sattva S. Neelapu, Larry W. Kwak. 1City of Hope, Duarte, CA; 2University of Fukui, Awaru, Japan; 3Sichuan University, China; 4University of Texas MD Anderson Cancer Center, Houston, TX.

B-cell malignancies have been successfully targeted in the clinic by therapies such as anti-CD20 antibody rituximab or Bruton’s tyrosine kinase inhibitor ibrutinib. However, leukemias and lymphomas remain incurable due to primary or acquired resistance, ultimately leaving patients without an effective treatment option. We sought to circumvent this drug resistance by pursuing an alternative target known as B cell activating factor receptor (BAFF-R). Despite past limited success, BAFF-R remains a prime target for B-cell lymphoma and leukemia therapeutic antibody development due to its key role in B-cell proliferation and development. We report the development of two novel monoclonal antibodies (mAbs) against human (h) BAFF-R. The mAbs were generated by immunizing mice with (h)BAFF-R-expressing mouse fibroblast cells presenting a natively folded, cell-surface immunogen. The two mAbs presented unique complementarity determining regions that specifically bound (h)BAFF-R-expressing mouse fibroblast cells but not the parental counterpart. Furthermore, the antibodies were specific to B-cell containing organs such as tonsil and spleen, by immunohistochemical staining and without detectable reactivity in heart, lung, brain, liver, and kidney tissues. To tailor the antibodies for clinical application, a human IgG1 Fc capable of eliciting an immune response was substituted, creating chimeric...
versions. We showed that both chimeric mAbs bound with high affinity to human B-cell lymphoma cell lines including JeKo-1 (mantle cell lymphoma; MCL), SU-DHL-6 (diffuse large B cell lymphoma; DLBCL), Raji (Burkitt lymphoma), and RL (fOLLicuLar lymphoma). The chimeric antibodies also elicited antibody-dependent cell-mediated cytotoxicity (ADCC) with primary human B cells, as well as primary lymphoma samples (n = 5) from patients who progressed after rituximab exposure. Most notably, the antibodies demonstrated effi-
cacy in two in vivo drug resistant lymphoma models we developed, a ritux-
imab-resistant CD20 genomic knockout variant of JeKo-1 and the naturally
tubulin-resistant Z-138. Using these lymphomas lines for xenogenic tu-
mor models in NOD scid gamma (NSG) mice, we found our antibodies
significantly inhibited tumor growth, conferring long-term and tumor free
survival on the mice. Our in vitro and in vivo results robustly demonstrate
the high specificity and significant anti-tumor effects of our anti-BAFF-R
antibodies against a broad variety of B-cell malignancies, especially against
cases of rituximab and tubulin resistance. This successful development of
novel anti-BAFF-R therapeutic antibodies warrants support for further
translational development for clinical use in light of current resistance cases.

**#2656** Polatuzumab vedotin significantly enhances *in vitro* cell death and overall survival against CD79b+ Burkitt lymphoma (BL)/primary mediastinal large B-cell lymphoma (PMBL) xenograft mice. Aradhana A. Tiwari, Janet Ayello, Christeen Azmy, Carmella van de Ven, Mitchell S. Cairo. New York Medical College, Valhalla, NY.

Background: Malignant B-NHL, including Burkitt lymphoma and primary mediastinal large B cell lymphoma express CD79b+ and have an excellent prognosis with chemo-immunotherapy (Cairo et al Blood, 2007; Gerrard/Cairo et al Blood, 2013). However, a subset of patients with relapsed/refractory mature B-NHL has chemioimmunotherapy resistant disease (Rao et al Blood, 2013). PD-L1 expression on Karpas1106pmBL (PMBL) is unknown. Objective: To determine the efficacy of the PV against CD79b+ PMBL and rituximab (RTX) sensitive/resistant BL tumor cell lines *in vitro* and *in vivo*. Design/Methods: Raji/RajiRHF (BL, provided by M. Barth, Roswell Park Cancer Institute) and Karpas1106P and MedB-1 (PMBL) were cultured in 10-20% RPMI. Tumor cells were incubated with hu anti-CD79b-vcMMAE, and/or anti-CD79b, MMAE or hulgH1 (generously supplied by Genen-
tech Inc.) for 24 hrs. Cell death was evaluated by staining with annexin V/7AAD and analyzed by flow cytometry, n=3. Six to 8 week old female NSG (NOD-
Cg-Prkdcscid Il2rgtm1Wjl/Sjcl), were divided into 2 groups: PBS only (control), isotype control (IgG), PV (5mg/kg), anti-CD79b mAb (5 mg/kg) and MMAE (5 mg/kg).
Mice were xenografted with intravenous injections of Luc+ Raji/ RajiRHF and Karpas1106P cells as we have previously demonstrated (Awasthi/ Cairo et al, BJH, 2015). Mice were treated twice a week for 6 weeks. Tumor burden was monitored by IVIS spectrum system. Results: Anti-CD79b-vcMMAE treated Karpas1106P xenografted mice significantly enhanced cell death in Raji, 47.2 ± 1.3% vs 29.1 ± 6.0% vs 28.2 ± 4.3% (p = 0.0008 and p = 0.00006), RajiRHF, 29.8 ± 9.1% vs 25.4 ± 3.9% vs 18.0 ± 8.2% (p=NS and p = 0.03), Karpas1106P, 46.8 ± 5.3% vs 33.8 ± 3.3% vs 26.2 ± 0.4% (p = 0.02 and 0.006) and MedB-1, 47.4 ± 2.2% vs 27.6 ± 2.4% vs 23.9 ± 1.7% (p = 0.002 and 0.001), respectively. Further, median survival time in mice receiving 5 mg/kg of PV was significantly increased when compared to mice receiving
5 mg/kg of anti-CD79b Ab or isotype control in Raji, RajiRHF and Karpas1106P (35.5 ± 17 vs. 19.5 days, p = 0.0001, 0.0003, 50 vs 18 vs 18.5 days and 150 vs 89 vs 64 days, p = 0.03, 0.003, respectively) Conclusions: Our prelimi-
nary data indicates that PV significantly enhances cell death in RTX sensitive/resistant BL and PMBL compared to CD79b Ab or isotype control. Furthermore, PV significantly increased survival in BL and PMBL NSG xenografts.

**#2657** PD-L1 blockade enhances T cell cytotoxicity against primary medias-

Background: Primary Mediastinal B cell Lymphoma (PMBL) represents 2-4% of Non-Hodgkin Lymphomas (NHL) in adolescents and young adults (AYA) (Ger-
rand/Cairo et al, Blood, 2013). Disease progression, relapse and long-term toxicity remain a concern for patients treated on current chemo-immunotherapy and me-
diastinal radiotherapy. Alternative therapeutic regimens are urgently needed, espe-
cially in patients without an early response to therapy. Programmed Death 1 (PD-1) is a negative co-stimulatory receptor critical for suppression of T-cell activation, with binding of PD-1 and Programmed Death Ligand 1 (PD-L1) resulting in T cell exhaustion (Postow/Wolchok et al, J Clin Oncol, 2015). Gain in 9p associated with amplification of PD-L1 has been reported in up to 60% of PMBL specimens, leading to overexpression of PD-L1 and potential immune cell evasion of PMBL (Rosen-
wald/Staudt et al, J Exp Med, 2003; Twa/Staudt et al., Blood, 2014). Blockade of PD-1/PD-L1 interaction, therefore, constitute a potentially promising alternative for treatment of resistant PMBL. Objective: In the current study, we sought to inves-
tigate whether PD-L1 blockade enhances T cell responses in PD-L1 expressing
PMBL. Methods: PD-L1 expression on Karpas 1106p PMBL treated with or without IFN γ was investigated by western blotting and flow cytometry analyses. T cells were isolated from human PBMC followed by activation and expansion using anti-CD2, 
anti-CD3 and anti-CD28 coated MACS beads particles. T cell activation was confirmed by CD25 and CD69 expression using flow cytometry. Activated T cells were incubated with or without anti-PD-L1 (Clone 6E11, Genentech) at a dose of 10 ug/ml together with Karpas 1106p cells treated with or without IFN-γ. Cell prolif-
eration was assessed with MTS assays after incubation for 24 hours. Results: We dem-
onstrated that Karpas 1106p cells express a low level of PD-L1. However, following IFN γ treatment (48 hours) there was a significant increase in PD-L1 expression.
Anti-PD-L1 had no significant effect on T cell mediated inhibition of cell prolifera-
tion in Karpas 1106p cells with low PD-L1 expression. However, anti-PD-L1 and T cell treatment significantly inhibited cell proliferation in IFN γ treated Karpas 1106p cells when compared to T cell treatment alone (32±18% vs. 3±5% at E:T=5:1, p = 0.048). Conclusion: PD-L1 blockade enhances T cell cytotoxicity against PMBL, which is dependent on PD-L1 expression level on PMBL cells. Future in-vivo NSG xenograft studies are ongoing.

**#2659** MT-4019: a de-immunized engineered toxin body targeting CD38 for multiple myeloma. Garrett L. Robinson, Sangeetha Rajagopalan, Brigitte Brieschke, Jane Neil, Jennifer Erdman, Rodney Flores, Jensu Liu, Jack P. Hig-
gins, Erin K. Willert. Molecular Templates Inc., Austin, TX.

Molecular Templates is developing engineered toxin bodies (ETBs), po-
tent recombinant immunotoxins that combine the specificity of an antibody fragment with the powerful direct cytotoxicity of the Shiga-like toxin A subunit (SLTA). ETBs can induce their own internalization, route through the cell in a predictable manner, enzymatically and irreversibly destroy ri-
bosomes to shutdown protein synthesis and induce apoptosis of tumor cells. This mechanism of action is distinct from that of other therapeutics, making ETBs an attractive treatment for patients who have become resistant to che-
emothapy and other treatments. Safety and efficacy in refractory non-
Hodgkin’s lymphoma patients has been observed in a phase I study with Molecular Template’s first-generation CD20-targeting compound, MT-
3724. CD38 is a surface receptor that is highly expressed on malignant plasma cells. CD38 is a clinically validated target of monoclonal antibodies for treatment of multiple myeloma and is known to persist after failure of antibody treatment. MT-4019 is a CD38-targeted next-generation ETB, uti-
izing a modified SLTA. The SLTA subunit of the next-generation ETB scaf-
fold has been modified through proprietary genetic engineering to systemat-
ically and comprehensively reduce B cell and CD4+ T cell epitopes, as well as
to dampen the innate response by decreasing binding to TLR-4. This de-
immunization strategy also reduces the innate and adaptive immune response to the ther-
apeutic. MT-4019 is a promising lead and is under further development to
enable clinical studies in rodent and non-human primate models have demonstrated the tolerability of MT-
4019, along with a decreased anti-drug antibody response. Additionally, in
the non-human primate model, MT-4019 showed reduced neutrophil and monocyte activation as compared to an ETB with an unmodified SLTA sub-
unit, indicating that SLTA modification also exhibits a diminished innate immune response. Molecular Template’s ETB technology has resulted in potent, targeted therapeutic agents that have a unique mechanism of action in the field of oncology. MT-3724, a first-generation CD20-targeted ETB, has shown promising clinical results in the refractory setting for non-Hodgkin’s lymphoma. The next-generation MT-4019, as exemplified in the CD38 tar-
gated MT-4019, retains potent and specific direct cell kill activities, and
additionally reduces the innate and adaptive immune response to the ther-
papeutic. MT-4019 is a promising lead and is under further development to
enable clinical studies in multiple myeloma.
IMMUNOLOGY: Immune Response to Hematopoietic Tumors: New Development in Tumor Immunology

Purpose: Blockade of PD-1 receptor may provide proof of concept for the activity of an immune-modulation approach for the treatment of a breast cancer (BC). Zoledronic acid (ZA) has been proven to inhibit angiogenesis, invasion, and adhesion of tumor cells. The aim of this study was to investigate the potential of antibody treatment towards the T-cell checkpoint inhibitor PD-1 alone or in combination with ZA in BC mouse model. Experimental Design: The 4T1-Luc mouse mammary tumor model was used in this study. The anti-tumor efficacy of anti-PD-1 antibody alone or in combination with ZA was monitored by measuring tumor volume and bioluminescence imaging (BLI). At the end of study, the tumor immunohistochemistry was performed to confirm the in vivo observation and flow cytometry was used to determine the immune cell population in tumor sections. For survival analysis, the Kaplan–Meier method, Cox proportional hazards regression, and Gehan’s survival tests were used. Results: The results showed that mice treated with combination therapy exhibited the best antitumor response compared to untreated controls or single therapy. Furthermore, Combination therapy inhibited tumor regrowth as determined by BLI imaging, and thus significantly improved the median overall survival compared to other groups. Conclusions: Our study provides evidence for enhanced clinical BC treatment benefit from targeting co-signal molecules by combining PD-1 blockade with ZA treatment.

ALKS 4230 is a selective agonist of the intermediate-affinity IL-2 receptor (IL-2R). A phase 1 study is ongoing to evaluate the safety and tolerability of ALKS 4230 in the treatment of patients with refractory solid tumors. The selectivity of ALKS 4230 is achieved through the stable fusion of circularly permuted IL-2 to the extracellular portion of the IL-2Rα chain, CD25. The resulting fusion protein has a unique surface expression that is sterically protected from biodegradation to the high-affinity IL-2 complex comprised of IL-2Rα, IL-2Rβ, and common gamma chain, expressed preferentially on CD4+ FOXP3+ regulatory T cells (CD4+ Treg) yet retains full ability to signal through the intermediate-affinity IL-2R complex, comprised of IL-2Rβ and common gamma chain, expressed on memory CD8+ T cells and NK cells. Repeated dosing of ALKS 4230 drives the significant expansion of various CD8+ T cells, including tumor-infiltrating lymphocytes, in a dose-dependent manner. Mimicking the effects seen in vivo, ALKS 4230 also inhibited phosphorylation of STAT1. In addition, EGCG inhibited EGFR-induced PD-L1 gene expression and protein level in Lu99 cells via inhibition of phosphorylation of Akt. In order to study the effects of EGCG in combination with CD40 ligand (CD40L) expression in CD40L-ligand 1 (PD-1) expression on tumor cells is involved in PD-L1/PD-1 pathway. PD-L1 protein levels varied among 6 non-small human lung cancer cell lines (NSCLCs): LC-A1 and Lu99 cell lines showed the highest PD-L1 expression, A549 and H322 cell lines were medium, and H1703 and H1299 were very low, independent on cancer cell lines. Since PD-L1 expression is induced by various cytokines and growth factors, we studied the effects of IFN-γ and EGFR on cell-surface PD-L1 level using flow cytometry, and its gene expression using RT-PCR. Treatment with IFN-γ dose-dependently stimulated PD-L1 expression in both A549 and H1299 cells, and not effective on Lu99 cells, whereas treatment with EGFR-stimulated PD-L1 in Lu99 cells only. Pretreatment with EGCG for 3 h, dose-dependently inhibited INF-γ-induced PD-L1 gene expression and protein level on cell-surface in both A549 and H1299. It is important to note that EGCG also inhibited phosphorylation of STAT1. In addition, EGCG inhibited EGFR-induced PD-L1 gene expression and protein level in Lu99 cells via inhibition of phosphorylation of Akt. In order to study the effects of EGCG in vivo, we used a mouse model of breast cancer and treated tumor-bearing mice with different treatments. The results strongly suggest that EGCG enhances antitumor immunity via inhibition of PD-L1 expression in cancer cells, resulting in significant cancer preventive activity. Using “omics” to select immunotherapy and conventional therapy combinations. Sarit Schwartz,1 Robert Heaton,2 Yuan Tian,3 Zack Sanborn,3 Shankar Sellappan,4 Kenny Scott,5 Fabiola Cecchi,6 Steve Benz,6 Todd Hembrough.1 1NantOmicS, Rockville, MD; 2NantOmicS, Santa Cruz, CA.

Background: As only a subset of patients respond to immunotherapies, therapeutic biomarkers are needed to predict which patients will benefit and which should be spared from potentially toxic treatment. Proteins expressed by tumor cells and by the immune microenvironment may predict response to immune checkpoint inhibitors. In non-inflamed tumors, chemotherapy and targeted therapy may stimulate an immune response thereby affecting the relationship between tumor and immune system. Combinations of immunotherapies and conventional therapies are the subject of ongoing clinical trials. We hypothesized that genomic and proteomic evaluation of multiple immune biomarkers in tumor tissue and in lymphocytes would identify a signature that could (a) differentiate between responders and non-responders to checkpoint inhibitors and (b) identify candidates for combination therapy. Methods: A pathologist marked areas of tumor and tumor-associated lymphocytes on archived tissue sections (N=2) of non-small cell lung cancer (NSCLC) and melanoma. The marked areas were microdissected and solubilized to tryptic peptides. In one liquefied tumor sample, 110 protein biomarkers, including 60 immunomarkers were quantified with a mass spectrometry-based proteomic assay. The genomic

#2665 Green tea catechin, EGCG, enhances antitumor immunity via down-regulation of PD-L1 expression in non-small human lung cancer cell lines. Ancheale Rawangkan,1 Keisuke Iida,1 Ryo Sakai,1 Hirota Fujiki,2 Masami Suganuma,1 1Saitama University, Saitama, Japan; 2Saga University, Saga, Japan.

(−)-Epigallocatechin gallate (EGCG) is now widely accepted as a non-toxic, effective cancer preventive compound. EGCG also acts as a synergist with anti-cancer drugs for cancer treatment. Considering the wide beneficial effects of EGCG, we have hypothesized that EGCG might have a role in inhibiting cancer cell death. The objective of this study is to investigate the effects of EGCG on cell death in a non-small cell human lung cancer cell line A549. EGCG treatment decreased the tumor size. Treatment with Wortmannin, a PI3 kinase inhibitor, as a control, did not inhibit PD-L1 expression in A549 and H1299 cells. The results strongly suggest that EGCG enhances antitumor immunity via inhibition of PD-L1 expression in cancer cells, resulting in significant cancer preventive activity.
Antibody of human IgG4 isotype, that binds selectively and with similar potency antagonistic activities of PF-06801591. PF-06801591 is a humanized anti-PD-1 monoclonal antibody that specifically targets programmed death receptor-1 (PD-1) or its cognate ligand, programmed death receptor ligand-1 (PD-L1), alone or in combination, have demonstrated clinical benefıts and durable responses in patient subsets with various cancers (including metastatic melanoma, NSCLC, RCC, urothelial cancer, cHL and others). Here we report on the biological characteristics and non-clinical-antagonistic activities of PF-06801591, PF-06801591 is a humanized anti-PD-1 antibody of human IgG4 isotype, that binds selectively and with similar potency to human and cynomolgus PD-1 receptor and blocks its interaction with its cognate ligands PD-L1 and PD-L2 (IC50 < 1 nM) with no detectable Fc effector function. The interaction of PF-06801591 to PD-1 rescues T cell suppression and exhaustion that translates into NFAT activation, IL-2 and IFN-gamma secretion and T cell proliferation both in vitro cultures and in vivo experiments using an acute xeno GVHD model with human PBMC transfer. Binding of PF-06801591 to human and cynomolgus PD-1 is characterized by the formation of a very stable complex (T1/2 = 2 h) as measured by SPR at 37°C, resulting in high affinity (Kd = 20 pm) as measured in solution by KinExA at 23°C. In addition, we explored therapeutic potential of anti-PD-1 in combination with other immunotherapy agents using surrogate antibodies in non-clinical tumor models. The data presented here support future development of PF-06801591 as a single agent or in combination with other immunotherapies.

#2667 In vitro properties and pre-clinical activity of PF-06801591, a high-affinity engineered anti-human PD-1

Sawssen Youssouf, Yasmina Abdiche, Hoang Kim Nguyen, Joyce Choi, Sherman Michael Chin, Kris Kamer- schroer, Patricia A. Schneider, Eugenia Kraynov, Heike I. Kuprka, Arvind Raijli, John Liu, Peter J. Arnett, South San Francisco, CA; Waitsich Microfluidics, Salt Lake City, UT; RMS, Redwood City, CA.

Monoclonal-antibody-based therapies targeting the immune checkpoint receptors have become the new standard of care in many cancers. Antibodies that specifically target programmed death receptor-1 (PD-1) or its cognate ligand, programmed death receptor ligand-1 (PD-L1), alone or in combination, have yielded clinical benefits and durable responses in various cancers (including metastatic melanoma, NSCLC, RCC, urothelial cancer, cHL and others). Here we report on the biological characteristics and non-clinical-antagonistic activities of PF-06801591, PF-06801591 is a humanized anti-PD-1 antibody of human IgG4 isotype, that binds selectively and with similar potency to human and cynomolgus PD-1 receptor and blocks its interaction with its cognate ligands PD-L1 and PD-L2 (IC50 < 1 nM) with no detectable Fc effector function. The interaction of PF-06801591 to PD-1 rescues T cell suppression and exhaustion that translates into NFAT activation, IL-2 and IFN-gamma secretion and T cell proliferation both in vitro cultures and in vivo experiments using an acute xeno GVHD model with human PBMC transfer. Binding of PF-06801591 to human and cynomolgus PD-1 is characterized by the formation of a very stable complex (T1/2 = 2 h) as measured by SPR at 37°C, resulting in high affinity (Kd = 20 pm) as measured in solution by KinExA at 23°C. In addition, we explored therapeutic potential of anti-PD-1 in combination with other immunotherapy agents using surrogate antibodies in non-clinical tumor models. The data presented here support future development of PF-06801591 as a single agent or in combination with other immunotherapies.

#2668 Efficacy study of immuno-checkpoint antibodies in humanized CDX and PDX models

Feifei Zhang, Yang Yang, Hongkui Chen, Lijin Jia, Kedong Ouyang, Danyi Wen, Taiping Chen. LIDEBiotech Ltd, Shanghai, China.

Immunotherapeutic intervention has been accepted widely for many hematopoietic malignancies and solid malignancies in past several years. Preclinical animal models with reconstitution of immune cells and target-expressing tumor cells were urgently needed for proof of concept studies demonstrating stimulatory immune system activation. Here we describe two established models of human PBMC co-transplantation of CDX and PDX. The study design was based on co-inoculation of human PBMC and PD-L1 expressing cell in NOG mice for reconstitution of immuno-checkpoint blockage. A therapeutic anti-PD1 antibody was applied for immune system activation and tumor growth inhibition measurement. Tumor growth experiments were administered i.p. for three weeks, 95% TGI for A375 CDX model were observed. At the termination of the efficacy study at 28 days post therapeutic intervention, tumors of vehicle (tumor only, PBMC only), PD1 Ab treated groups were collected for immunostaining of CD45. Infiltrating T-cell with CD45+ label was found within the tumors when co-inoculated with human PBMC. PBMC humanized PDX models of ovarian cancer was implanted into mice which reconstituted with human PBMC for therapeutic intervention. Results showed that 85% TGI for PBMC humanized ovarian PDX models were observed. In conclusion, the models established here are feasible for immuno-therapeutic evaluation and further additional immune therapeutic test articles can be explored with similar approaches.

#2669 Antitumor activity of the CMP-001 (TLR9 agonist) alone or combined with immune modulators in syngeneic tumor models

Francis Bichat, Sylvie Maubant, Jean-François Mirjolet, Philippe Slos, Arthur M. Krieg, Aaron Morris.

The combination of checkpoint inhibitors such as CTLA-4 or PD-1 with antigen monoclona monoclonal antibodies (mAbs) has shown impressive and durable clinical responses in patients with advanced cancer. An alternative strategy to boost anti-tumor immunity is to promote T cell activation through co-stimulatory receptors such as OX40 and 4-1BB. OX40 is of particular interest as treatment with an activating anti-OX40 mAb augments T cell differentiation and cytolytic activity from multi-kinase-tolerant T cells in each of the two arms of these agents benefits only a subset of patients, highlighting the critical need for more effective combinatorial therapeutic strategies. Toll-like receptor 9 (TLR9) agonist CpG oligodeoxynucleotides (ODN) are candidates to promote an antitumor immune response. CMP-001, a CpG-A ODN formulated within a virus-like particle, is designed to activate TLR9 (the receptor for CpG-A) in tumor-associated plasmacytoid dendritic cells (pDC) within the tumor or tumor-draining lymph nodes. Resting or immature pDC promote tumor growth, but when activated by CpG-A, the resulting mature pDC promote a robust anti-tumor immune response. Activation of pDC causes secretion of very large quantities of type I interferons, increased expression of costimulatory molecules, and recruitment and activation of other DC subsets to enhance tumor antigen presentation and generation of protective T cell responses. The preclinical efficacy of intratumorally administered CMP-001 alone or in combination with an intraperitoneally administered PD-1 agonist and/or an OX40 agonist was examined and assessed in a variety of syngeneic tumor models: CT-26 colon tumor model, MBT-2 bladder tumor model, RenCa kidney tumor model, 4T1 breast tumor model and LLC-1 lung tumor model. Tumors were implanted into left and right flanks while only one tumor was injected with CMP-001. In addition to body weight and overall survival, tumor volume was monitored on both flanks to assess direct and abscopal/systemic anti-tumor activity. Some discrepancies were observed between evaluated syngeneic tumor models with non-responders (LLC-1, 4T1) and responders (CT-26, MBT-2, RenCa). The most efficacious results were registered in the CT-26 model with a 80% tumor response rate as a single agent, which improved when combined with another treatment modality. The best therapeutic efficacy was obtained with the combination of all three agents resulting in cures of both treated and untreated CT-26 tumors in 40% of the mice. The median survival time was increased for these animals compared to those treated with only vehicle or one or two immune modulators (50 vs 18 vs 21 vs 23-28 days, respectively). Similar results were generated in the MBT-2 model (and to a lesser extent in RenCa model) though no complete response was recorded. These data support the clinical investigation of these combinations in cancer patients.

#2670 Combination of anti-HER2 ADC XMT-1522 and checkpoint inhibitor pembrolizumab for treatment of NSCLC in preclinical models

Natalya Bodyak, Marina Protopopova, Yingxiang Zhang, Alex Yurkovetskiy, Mao Yin, Liuliuang Qin, Laura L. Poling, Rebecca Mosher, Donald A. Bergstrom, Timothy B. Lowinger. Merusana Therapeutics, Inc., Cambridge, MA.

The combination of antibody-drug conjugates (ADCs) and immunomodulatory cancer therapies is emerging as a powerful strategy for cancer treatment. Tumor-targeted delivery of a cytotoxic payload capable of inducing immunogenic cell death (ICD) can trigger both an innate and an adaptive immune response, whereby increased recruitment of effector T-cells to the tumor and formation of tumor specific immunological memory can result in a durable treatment response. The ADC XMT-1522 consists of a novel human IgG2 anti-HER2 monoclonal antibody and a novel, auristatin-based cytotoxic payload (Auristatin F-hydroxypropylamide, AF-HPA). An average DAR of 12 AF-HPA molecules is achieved via a biodegradable polymer conjugation platform. We have characterized the ability of both the free payload AF-HPA and the ADC XMT-1522 to induce ICD in vitro in multiple cell lines (NCI-N87, HT-29, SKBR3). Both payload and the ADC demonstrated robust activity as a single agent, which improved when combined with another treatment modality. The best therapeutic efficacy was obtained with the combination of all three agents resulting in cures of both treated and untreated CT-26 tumors in 40% of the mice. The median survival time was increased for these animals compared to those treated with only vehicle or one or two immune modulators (50 vs 18 vs 21 vs 23-28 days, respectively). Similar results were generated in the MBT-2 model (and to a lesser extent in RenCa model) though no complete response was recorded. These data support the clinical investigation of these combinations in cancer patients.
fied in whole blood and in tumor by FACS and IHC. XMT-1522 treatment alone induced tumor growth delay after 3 weekly doses of 1 mg/kg. Pembrolizumab as a single agent administered every 5 days for 6 doses (q5dX6) at a dose of 2.5 mg/kg led to less tumor growth delay than XMT-1522 treatment. The combination of these two treatment regimens resulted in a better response than either of the two monotherapies. These data provide a rationale for XMT-1522 to be tested clinically as a single agent in HER2-expressing NSCLC, as well as a rationale for combination of XMT-1522 and immunomodulatory therapies in NSCLC.

**#2671 Antitumor activity of NKTR-214 in combination with pmel-1 ACT in an aggressive murine melanoma model.** Giulia Parisi,1 Justín Saco,1 Siwen Hu-Lieskovsk,1 Ruixue Zhang,1 Paige Krzywinski,1 Cristina Puig Saus,1 Deborah H. Charych,1 Antoni Ribas1.1UT MD Anderson Cancer Ctr., Houston, TX; 2Baylor College of Medicine, Houston, TX.

The adoptive cell transfer (ACT) of genetically engineered T cells expressing cancer-specific T-cell receptors (TCR) has been shown to induce effective anti-tumor response. However, tumors frequently relapse after an initial response. Another strategy towards stimulating the immune system is the use of high-dose interleukin-2 (IL-2) to target the IL-2 receptor (IL2R), leading to immune cell expansion. However, clinically approved IL-2 expands both tumor-killing CD8+ effector T cells (CD8T) as well as regulatory T cells (Tregs) through binding the IL-2Rββ and IL-2Rαβ complexes, respectively. Tregs in the tumor lead to immune suppression, which hampers the antitumoral response. NKTR-214 is a bi-specific cytokine agonist conjugated with multiple releasable chains of polyethylene glycol and designed to provide sustained signaling through the heterodimeric IL-2 receptor pathway (IL-2Rββ) to preferentially activate and expand effector CD8+ T and NK cells over Tregs. We used the pmel-1 ACT/B16 melanoma tumor model to test the antitumor activity of NKTR-214 and evaluate its effects on tumor-specific TCR transgenic T cells. On Day 0 (D0) C57BL/6 mice were implanted with B16-F10 mouse melanoma cells and lymphodepleted with 500 Gγ on D6. On D7, mice were treated with either the combination of ACT (T lymphocytes activated in vitro with 1 μg/ml gp100) plus NKTR-214 (0.8 mg/kg, q3dx3, i.v.) or with C57/B6 T cells plus PBS (vehicle control). The tumors of the vehicle control mice (n=12) rapidly grew to the 1500mm3 endpoint in 12 days post-treatment, versus 35 days for the NKTR-214 group (n=12) with only 1 out of 12 mice reaching endpoint. Bioluminescence imaging was used to visualize the in vivo distribution and tumor-homing of antigen-specific T cells. Interestingly, the reporter T cells were retained in the spleen until D7 and could be seen migrating to the tumor at D9 reaching peak of bioluminescence at day 12, a delayed time point compared to the 5 days usually observed in mice treated with standard IL-2. The signal persisted in the NKTR-214 + ACT group until D20 versus D7 in the vehicle-control animals. These data suggest that NKTR-214 + ACT is well tolerated and provides a robust anti-tumor response in the aggressive B16F10 model. Treatment with NKTR-214 + ACT robustly mobilizes T cells into the tumor where they durably persist. The robust and long-lasting effect of NKTR214 supports its potential use in combination with cell-based therapeutics.

**IMMUNOLOGY: Inflammation and Cancer**

**#2672 Response to anti-PD-1 based therapy in metastatic melanoma patients is associated with the diversity and composition of the gut microbiome.** Vancheri,1 Alexander Groher,1 Prieto,1 Diego Vicente,1 Tatiana V. Karpinets,1 Courtney W. Hudgens,1 Diane S. Hutchinson,2 Michael Tetzlaff,1 Alexander Lazár,1 Michael A. Davies,1 Jeffrey E. Gershewad,1 Robert Jenq,1 Patrick Hwu,1 Padmanee Sharma,1 James Allison,1 Andrew Futreal,1 Nadim Ajami,2 Joseph Petrosino,2 Carrie Daniel-MacDougall,1 Jennifer A. Wargo,1 UT MD Anderson Cancer Center, Houston, TX; 2Baylor College of Medicine, Houston, TX.

Background: Melanoma therapy has benefitted greatly from immune check-point blockade, although responses are variable and not always durable. There is a growing appreciation of the role of the microbiome in cancer-related outcomes and recent evidence in murine models suggests that modulation of the gut microbiome may enhance responses to immune checkpoint blockade in melanoma. However this has not been investigated in patients. Here, we demonstrate that differential bacterial “signatures” exist in the gut microbiome of responders (R) and non-responders (NR) to anti-PD-1 therapy, and that insights gained could be used to derive actionable strategies to enhance responses. Methods: We collected buccal (n = 105) and stool (n = 53) samples from a cohort of anti-PD-1 treated metastatic melanoma patients (n = 110). Patients were classified as either R or NR based on RECIST criteria, and 16S rDNA, and whole-genome shotgun sequencing was performed to characterize the diversity, composition and functional capabilities of the microbiomes. Immune profiling (via ?-marker IHC panel of CD3, CD8, PD-1, PD-L1, Granzyme B, ROYR and FoxP3) and cytotoxic analyses were also performed on available tumors and serum samples at baseline. Results: In these studies, we observed significant differences in the diversity and composition of the gut microbiome in R versus NR to PD-1 blockade at baseline, but no clear differences in buccal microbiota. Specifically, R had a significantly higher alpha diversity compared to NR (p = 0.017), and the Ruminococcaceae family of the Clostridiodales order was enriched in R whereas Prevotellaceae family of the Bacteroidales order was enriched in NR. Immune profiling demonstrated significantly increased immune infiltrates in baseline tumor samples of R, with a positive correlation between CD8, CD3, PD-1 and FoxP3 T-cell density and abundance of specific bacteria enriched in R (e.g. Faecalibacterium). Low diversity was also associated with elevated levels of chronic inflammation markers in the serum at baseline. Lastly, we saw differentially abundant metabolic pathways in the gut microbiomes of R (pyrimidine nucleotide biosynthesis, fatty acid biosynthesis, shikimate pathway) vs NR (Tri-carboxylic acid cycle, assimilatory sulphate and nitrate reduction, tryptophan biosynthesis). Conclusion: Differences exist in the diversity and composition of the gut microbiome in R vs NR to anti-PD-1 therapy and these microbiota could bridge the gap between host metabolism and anti-tumor immunity. These results further support the notion that modifications to the gut microbiome could potentially enhance therapeutic responses to immune checkpoint blockade.

**#2673 Divergent therapeutic responses to CD40L blockade or CD40 activation in Ras-driven skin cancers determined by origin of tumor initiating cell.** Adam B. Glick,1 Jacob T. Bailey,1 Andrew Gunderson,1 Kyle Breech,1 Michael Podolsky,1 Pennsylvania State University, University Park, PA; 2Earle A. Chiles Research Institute, Portland, OR.

Heterogeneity in tumor immune responses is a poorly understood yet critical parameter for successful immunotherapy. We used doxycycline-inducible epithelial squamous cancer models driven by oncogenic Ras to test whether the origin of the tumor-initiating cell influenced the tumor immune response. Threshold doxycycline induced expression of H-RasV12 in either the basal/ stem cell layer with a Keratin14-rtTA transgene (K14-Ras), or committed progenitor/suprabasal cells with an Involucrin-rtTA transgene (InvRas), caused distinct immune responses despite similar levels of Ras, tumor latency, and tumor numbers. End stage K14-Ras tumors had an immunosuppressed microenvironment with abundant Tregs and Bregs which evolved from an initially Th1 dominant environment in the earliest detectable lesions. In contrast InvRas tumors had a Th2 pro-inflammatory microenvironment, with significantly fewer Tregs or Bregs at any time point. This difference in immune microenvironment between the tumor models was also found in hyperplastic skin after 5 days of maximal Ras expression, indicating that it was not simply a property of the end stage tumor. Surprisingly, adaptive immunity had opposite roles in tumor development. InvRasRag1−/− mice developed fewer and smaller tumors that regressed while K14RasRag1−/− mice developed more tumors with shorter latency than Rag1+/+ controls. In both models adoptive transfer and depletion studies showed that cooperation between B and CD4 T cells drove the opposing tumor responses, lymphocyte polarization, and tumor immune phenotype. Culture of tumor-conditioned but not splenic B cells from each model with naïve CD4 T cells showed that direct contact and CD40-CD40L ligation was required for opposite polarization towards either a Th2 or Treg phenotype. Importantly, we found that anti-CD40L mAb caused regression of preexisting InvRas tumors but enhanced growth of K14 Ras tumors. In contrast, CD40 agonist mAb enhanced growth of preexisting InvRas tumors, and suppressed growth of K14 Ras tumors. Thus in an in vivo setting the type of tumor immune microenvironment and opposing role of CD40-CD40L signaling in tumor development determines distinct responses to therapeutic antibodies. Together these data show that the position of a tumor initiating cell within the stem cell hierarchy in a stratified squamous epithelia has important consequences for the type of tumor immune microenvironment and response to checkpoint therapy.

**#2674 Fusobacterium nucleatum subspecies animalis influences pro-inflammatory cytokine expression and monocyte activation in human colorectal adenocarcinoma cell lines.** Xiangcang Ye,1 Pu Wang,1 Ruiqiang Li,1 Delphine R. Boulares,1 Fan Fan,1 Ling Xia,1 Adoni Harish,1 Nadim J. Ajami,1 Matthew C. Wong,2 Daniel P. Smith,1 Joseph F. Petrosino,2 Susan Venable,2 Wei Qiao,1 Veera Baladandayuthapani,1 Dipen Maru,1 Lee M. Ellis1; 1UT MD Anderson Cancer Ctr., Houston, TX; 2Baylor College of Medicine, Houston, TX.

Fusobacterium nucleatum is an abundant peri-tumoral commensal bacteria that is strongly associated with colorectal carcinogenesis. However, the role of fusobacteria in colon cancer is still poorly understood. To investigate the role of F. nucleatum subspecies animalis in human colorectal cancer, we treated two colorectal adenocarcinoma cell lines, HCT116 and SW480, with Fusobacterium nucleatum subspecies animalis. As a positive control, we used the well-known pro-inflammatory cytokine Th1 stimulator, IFNγ. Our results showed that Fusobacterium nucleatum subspecies animalis significantly increased the expression of pro-inflammatory cytokines, IL-6, IL-8, and TNFα, in both cell lines in comparison to control. Furthermore, we found that Fusobacterium nucleatum subspecies animalis induced monocyte activation, as indicated by increased expression of CD86 and CD80. These results suggest that Fusobacterium nucleatum subspecies animalis may play a role in the pro-inflammatory environment of colorectal adenocarcinoma. Future studies are needed to further investigate the role of Fusobacterium nucleatum subspecies animalis in colorectal cancer.
Chronic infection and associated inflammation have long been suspected to promote human carcinogenesis. Recently, certain gut bacteria, including some in the Fusobacterium genus, have been implicated in playing a role in human colorectal cancer (CRC) development. However, the Fusobacterium species and subspecies involved and their oncogenic mechanisms remain to be determined. We sought to identify the specific Fusobacterium spp. and ssps. in clinical CRC specimens by targeted sequencing of Fusobacterium 16S ribosomal RNA gene. Five Fusobacterium spp. were identified in clinical CRC specimens. Additional analyses confirmed that Fusobacterium nucleatum ssps. animalis was the most prevalent F. nucleatum subspecies in human CRCs. We also assessed inflammatory cytokines in CRC specimens using immunoassays and found that expression of the cytokines interleukin-17A and tumor necrosis factor-alpha was markedly increased but interleukin-21 decreased in the colorectal tumors. Furthermore, the chemokine (C-C motif) ligand 20 was differentially expressed in colorectal tumors at all stages. In vitro co-culture assays, F. nucleatum ssps. animalis induced CCL20 expression in CRC cells and monococytes. It also stimulated the monocyte/macrophage activation and migration. Our observations suggested that infection with F. nucleatum ssps. animalis in colorectal tissue could induce inflammatory response and promote CRC development. Further studies are warranted to determine if F. nucleatum ssps. animalis could be a novel target for CRC prevention and treatment.

#2675 MMP9 modulates ROS levels and DNA repair pathway to maintain genomic stability in colitis associated cancer. Lewins Walter, Adani Pujada, Brandon Canup, Hamed Lariou, Pallavi Garg, Georgia State University, Atlanta, GA.

Introduction: Chronic inflammation predisposes tissues to oncogenic, and in the colon this condition is termed as colitis associated cancer (CAC). CAC is the inflammation-dysplasia-carcinoma pathway which is significantly different compared to the adenoma-carcinoma pathway of sporadic colon cancer (CRC). In CAC, chronic inflammation causes accumulation of reactive oxygen species (ROS) resulting in DNA damage that nurtures tumor microenvironment and accelerates cancer cell growth. Gut microbiota is important in regulating ROS levels, and DNA repair pathways are critical in restoring the genomic instability. Matrix Metalloproteinases (MMPs) are a family of zinc dependent endopeptidases which mediate inflammation, tissue remodeling, and tumorigenesis. MMP9 is the most unique MMP because it is undetectable in healthy tissue but highly upregulated during inflammation and cancer. We have previously shown that MMP9 plays a protective role in CAC which is opposite to its conventional role of mediator in acute inflammation and cancer. Aim: In this study, we examined if MMP9 acts as a tumor suppressor by modulating gut microbiota and mismatch repair (MMR) genes to reinstate genomic stability in CAC. Methods: We used C57/B6 transgenic MMP9 mice which can express MMP9 under villin promoter (TgM9) and their wild type (WT) littermates. CAC was induced by azoxymethane (AOM) and dextran sodium sulfate (DSS, inflammation induction) to establish the monocyte/macrophage activation and migration. Our observations suggested that infection with F. nucleatum ssps. animalis in colorectal tissue could induce inflammatory response and promote CRC development. Further studies are warranted to determine if F. nucleatum ssps. animalis could be a novel target for CRC prevention and treatment.

#2677 Role of CLEC4D in inflammation-driven liver carcinogenesis. Elena Riboldi,1 Luca Di Tommaso,2 Nausicia Clemente,2 Chiara Raggi, Elisa Forti,3 Simone Merlin,2 Antonia Follenzi,2 Antonio Sica2. 1Università del Piemonte Orientale, Dept. of Pharmacological Sciences, Novara, Italy; 2Università del Piemonte Orientale, Dept. of Medical Sciences, Novara, Italy.

Hepatocellular carcinoma (HCC) accounts for approximately 90% of all primary liver tumors and is the second most deadly cancer in the world. HCC commonly arises in a chronically damaged liver that contains large amounts of inflammation and fibrosis. Indeed, interactions among hepatocytes, stromal, and inflammatory cells create a complex microenvironment permissive to tumor development. Myeloid cells are crucial players in cancer-related inflammation. From transcriptional profiling of liver myeloid cells, we identified the gene encoding for the C-type lectin receptor CLEC4D as one of the genes upregulated during the inflammatory response that precedes cancer development in a spontaneous model of murine HCC. We hypothesized that CLEC4D may be involved in the molecular mechanisms that shape HCC pathogenesis. We used the murine model of diethylnitrosamine (DEN)-induced liver carcinogenesis and evaluated tumor growth in genetically modified mice lacking CLEC4D (CLEC4D KO mice), as compared to C57BL/6 wild type (WT) mice. We observed that tumor burden (number of tumors per mouse and tumor dimensions) was reduced in CLEC4D KO mice compared to WT mice. Gene expression analysis of tumor lesions showed that the tumor microenvironment of CLEC4D KO mice was less inflammatory. CLEC4D expression was then evaluated in surgical specimens and tissue microarrays from HCV+ HCC patients. CLEC4D-positive inflammatory cells (macrophages and granulocytes) were present both in the peritumor and in the tumor areas. The percentage of intratumor CLEC4D-positive cells inversely correlated with the degree of the lesion: CLEC4D expression was higher in dysplastic nodules compared to high grade HCCs. Our results indicate that the CLEC4D-dependent pathway contributes to the initiation and the progression of HCC. By targeting CLEC4D, we could modulate immune responses and provide an environment less favorable to tumor neoplasms including pancreatic cancer. Our laboratory recently found that RON serves to mediate pancreatic duct carcinogenesis initiated by KRAS. We demonstrated that RON overexpression in the pancreas results in more rapid local and metastatic progression ultimately associated with decreased survival. We also discovered profound changes in the immunophenotype within the tumor microenvironment and RON expression in tumors established that RON expression drives the polarization of tumor-associated macrophages into an alternative, pro-tumorigenic state. We hypothesize that these unique activities help to shape the immunosuppressive milieu of the pancreatic cancer microenvironment and that RON directed therapy has the potential to serve as a novel immunomodulatory strategy in this disease. The aim of this work is to define how KRAS mediated overexpression of RON can impact the tumor microenvironment in pancreatic cancer. In order to further interrogate the role of RON during pancreatic carcinogenesis, we bred kinase-dead RON mice (KD) to Pdx1-Cre/LSL-KRASG12D mice. We observed a significant delay in the onset of pancreatic neoplasia and a significant decrease in tumor weight. The absence of functional RON kinase markedly reduced trafficking of CD11b+ cells to the pancreas and immunophenotyping in tumors showed a clear reduction of alternatively polarized macrophages when compared to RON overexpression or KRAS mutation alone. Because RON is expressed in both epithelial and stromal cell populations, we further sought to dissect the relevance of RON function to tumor growth within these cellular compartments. We performed orthotopic injections of organoid-3D cells derived from tumors of KPC mice (LSL-KRASG12D mice) into NOD-SCID (Ngbmumu) mice. The effects of the angiogenesis inhibitor bevacizumab on tumors established in wild type (WT) or RON KD mice. Preliminary results show that tumor growth is impaired in KD mice, suggesting that RON activity in the host microenvironment influence tumor growth. In order to identify all immune populations regulated by RON, we will conduct an exhaustive immunophenotyping of murine pancreatic tumors. A transcriptomic analysis will then be conducted on selected cell populations to better define the molecular mechanisms associated with the RON regulation. Finally, given the effect of RON targeting on macrophage polarization, we will also dissect the effects of RON signaling from bone marrow derived myeloid cells versus resident tissue macrophages. Preliminary results and future experiments will significantly narrow the gap in our understanding of how RON signaling contributes to shaping the pancreatic cancer chimera and therefore how RON-directed therapies could be most successfully utilized to benefit those afflicted with this most deadly disease.
IMMUNOLOGY: Inflammation and Cancer

growth. An intervention at this level could represent a chemopreventive strategy to arrest the development of HCC in a cirrhotic liver. This work has been supported by Fondazione Cariplo, grant n° 2014-0962.

About 20% of the cancer incidences worldwide have been estimated to be associated with infections. There is a strong correlation of some pathogens with various cancer types. Although presence of commensal microbiome helps chemotherapy to be more effective, pathogenic microbiota increases the cancer risk. Invading pathogens interact with the host mainly through proteins. To subvert host defense, pathogens hijack host pathways by mimicking the binding surfaces (interfaces) of host proteins. This similarity in interfaces permits the pathogenic protein to compete with host proteins to bind to a target protein, alter the physiological signaling and cause persistent infections as well as cancer. Detection of host-pathogen interactions (HPIs) and mapping the re-wired HPI network - along with its structural details - is critical for in-depth understanding of the underlying pathogenesis mechanisms of infections and pathogen-triggered cancers, and developing efficient therapeutics. Here, we developed a novel computational approach to identify novel HPIs by employing “interface mimicry.” We applied this approach to Helicobacter pylori, dominant species in gastric microbiome that greatly increases the gastric cancer risk in order to understand how they modulate host immune responses and influence tumorigenesis.

We found that HP pylori interacts with the function of the host apoptosis pathway, cytomegaly and cytokine pathways, and also cell-cell adhesions. Our results shed light on the molecular mechanisms of resistance to apoptosis, immune evasion and loss of cell junctions that are seen in Helicobacter pylori-infected host cells. In conclusion, HP pylori can help us unravel which human pathways are targeted by the pathogenic proteins and how they contribute to pathogenesis of infections and pathogen-triggered cancer. With a better grasp on immunomodulatory strategies of pathogens, we can develop better therapies against them.

#2679 A promoting role for the epithelial MyD88/IRAK4/NF-κB signaling in K-ras mutant lung tumorigenesis. Susana Castro,1 Soudabeh Daliri,1 Maria Miguelina De La Garza,2 Amber M. Cumpian,3 Misha Umer,4 Diana Del Bosque,2 Sahab Akhani,2 Scott E. Evans,2 Seyed Javad Moghaddam.2 The University of Texas MD Anderson Cancer Center, Houston, TX;2University of Houston, Houston, TX.

K-ras mutation is the most common oncogenic alterations associated with lung cancer development. Unfortunately, all attempts to develop therapies directly targeting K-ras have been failed thus far, clearly stating the need for new strategies to arrest effective cooperativity pathways of K-ras to overcome lung cancer displaying such a molecular profile. Using a conditional K-ras mutated lung cancer mouse model, CC-LR (CCSP1/LSL-K-rasG12D), we previously showed that K-ras mutated lung tumorigenesis is associated with lung inflammation due to activation of NF-κB pathway and increased expression of its downstream targets in the lung. Here we have shown that lack of NF-κB activity in the airway epithelial cells by selectively targeting IKKβ, which is required for NF-κB activation, significantly reduces lung tumor burden (3.4-fold) and changes the inflammatory cells and mediators in the bronchoalveolar lavage fluid (BALF) of CC-LR mice. Immunohistochemically staining of lung tissues with specific markers, Ki-67 and CD-31, demonstrated significantly lower tumor cell proliferation and angiogenesis in CC-LR mice with lack of epithelial NF-κB activity. To further dissect the role of NF-κB pathway in this process, CC-LR mice were crossed with MyD88l−/− mice to develop a mouse with lack of MyD88 (an adaptor protein upstream to IKKβ) in the airway epithelial cells (CC-LR/MyD88l−/− mice). As we had hypothesized, the resulting tumor numbers in the lungs were significantly lower (1.9-fold) in CC-LR mice with lack of MyD88 in the airway epithelial cells compared to control CC-LR mice. Tumor reduction in CC-LR/MyD88l−/− mice was also associated with decreased tumor cell proliferation and angiogenesis compared to control CC-LR mice. Surprisingly, unlike to lack of epithelial NF-κB activity, absence of MyD88 in the airway epithelium did not change the BALF inflammatory cell component of CC-LR mice. We then targeted another upstream signaling molecule to NF-κB, IRAK4, which is down stream of MyD88 by crossing CC-LR mice to IRAK4 knockout (LPSK:CC-LR/IRAK4−/−). Surprisingly, in lack of MyD88, we found a significant reduction in lung tumor number (1.8-fold) with no changes in BALF inflammatory cell component in CC-LR mice with lack of IRAK4 compared to control CC-LR mice. Taken these together, we conclude that there is an essential role for MyD88/IRAK4/NF-κB pathway activation in promotion of K-ras mutant lung cancer.

#2680 A novel pro-tumorigenic role for IDO1 in inflammatory neovascularization. Arpita Mondal,1 Erika Sutanto-Ward,1 James B. DuHaddaway,1 Ar-turo Bravo-Nuevo,2 Sunil Thomas,1 George C. Prendergast,1 Alexander J. Muller,1 Lankenau Inst. for Medical Research, Wynnewood, PA;1ArtDemi Therapeutics, Holmes, PA.

Sidmouth inhibitors of the tryptophan catalyzing enzyme IDO1 (in-doleamine 2,3-dioxynase 1) have shown early promise in clinical trials as immuno-oncology agents. While the tolerogenic activity of IDO1 has been well established, we have recently identified an additional role for IDO1 in supporting neovascularization at the regulatory interface between the inflammatory cytokines IFNγ (interferon γ) and IL6 (interleukin 6). IFNγ is a primary inducer of IL6, but is also a key mediator of immune-based tumor suppression, which studies have associated with its anti-angiogenic activity. Conversely, genetic studies in mice have clearly established the tumor-promoting role of IDO1, suggesting that it may act in a negative feedback capacity. Targeted disruption of the Idol gene in mice resulted in enhanced resistance to lung tumor and metastasis development. As we have previously shown with attenuated induction of the pro-angiogenic cytokine IL6b, which, when provided by ectopic expression, was able to restore pulmonary metastasis susceptibility to Idol−/− mice. These initial findings led us to hypothesize that IDO1 might contribute to cancer promotion by countering the anti-angiogenic effect of IFNγ, possibly through IDO1-potentiated end of IL6. Testing this hypothesis in mouse models of oxygen-induced retinopathy and pulmonary metastasis, we determined that loss of IDO1 did not result in reduced neovascularization with impaired metastasis outgrowth, effects that were completely reversed by the concurrent elimination of IFNγ. Loss of IL6b was likewise associated with IFNγ-dependent reductions in neovascularization and impaired metastasis outgrowth, as predicted. Having established a novel role for IDO1 in inflammatory neovascularization, current investigations are focused on the underlying molecular and cellular mechanisms involved. At the molecular level, one of the consequences of tryptophan catalysis by IDO1 can be to trigger the ISR (in-tegrated stress response) through activation of the GCN2/CHOP pathway that has previously been linked to the downstream induction of IL6. Thus far, data collected in both the oxygen-induced retinopathy and pulmonary metastasis models are consistent with the ISR being the relevant downstream signaling pathway from IDO1 in this biological context. At the cellular level, we have detected the incorporation of non-endothelial, IDO1-positive cells into the vessels that comprise the neovascular tufts, implicating IDO1 in the process of vasculogenesis. These insights into this unrecognized aspect of IDO1 biology are likely to have important ramifications for IDO1 inhibitor development, especially in other cancers where clinical trials are currently ongoing, but in other disease indications involving neovascularization as well.

#2681 Oral micro biome enhances stemness in oral cancer cells by activat-ing Toll like receptor signaling. Kavi Krishna laboratory, Guwahati Biotech Park, IIT, Guwahati, India;1Kavi Krishna Laboratory, Guwahati Biotech Park, IIT, Guwahati, India;1Kavi Krishn Lab, Guwahati, India;1Kavi Krishn Laboratory, Guwahati Biotech Park, IIT, Guwahati, India. 2Dr. Y. Na, University of Cambridge, MA; 2Gauhati University, Gauhati, India; 3B Borooah Cancer Institute, Guwahati, India.

Background: The resistance and progression of cancers after chemotherapy to invasive and metastatic stages accounts for the overwhelming majority of cancer deaths. Recent studies suggest, microbiomes can induce a cascade of host events to either support or inhibit tumor growth. Specially, in oral cancer, chemother-apy treatment may alter the oral microbial flora, which may favor or inhibit tumor growth. Hence, it is important to develop novel experimental approaches to study the role of oral microbial flora in oral cancer stemness (self-renewal and undifferentiated state of cancer stem cells). Importantly, patients in developing area, including Assam, where Kavi Krishna laboratory is located, may have distinct oral microbial flora that could favor oral cancer growth. Hence, it is important to include patients from developing countries for such studies. Our previous research showed that chemotherapy changes stemness in many cancer cell types, including oral squamous cell carcinoma cell line SCC-25. The stemness switch is characterized by enhanced expression of stemness associated genes including Nanog, Lin28/28A, Oct-4, MYC, HIF-2alpha and inflammation associated genes including TLRs.

Methods: SCC-25 oral cancer cell line was treated with bacterial product lipopolysaccharide (LPS), and the stemness switch evaluated by isolation of cancer stem cells (self-renewal and undifferentiated state of cancer stem cells). Importantly, patients in developing area, including Assam, where Kavi Krishna laboratory is located, may have distinct oral microbial flora that could favor oral cancer growth. Hence, it is important to include patients from developing countries for such studies. Our previous research showed that chemotherapy changes stemness in many cancer cell types, including oral squamous cell carcinoma cell line SCC-25. The stemness switch is characterized by enhanced expression of stemness associated genes including Nanog, Lin28/28A, Oct-4, MYC, HIF-2alpha and inflammation associated genes including TLRs.

Conclusion: The resistance and progression of cancers after chemotherapy to invasive and metastatic stages accounts for the overwhelming majority of cancer deaths. where KaviKrishna laboratory is located. The sputum was processed and then added to the culture medium of SCC-25 cells. These post-sputum treated cells were subjected to phenotypic stemness switch analysis. Results: We found, LPS and sputum treatment led to the enhanced stemness of ABCG2+ cells, including the high expression of TLR2/4, MTC, Nanog, Sox-2, and HIF-2alpha. These data supported the hypothesis that ABCG2+ cells exhibited high expression of TLR2/4 and associated increase of HIF-2alpha and MYC transcriptional activity. The sputum treated with broad spectrum ciprofloxacin did not enhance the stemness and showed inhibitory activity on ABCG2+ cell self-renewal. In contrast, sputum obtained from oral cancer subjects with relapse showed enhanced stemness of ABCG2+ cells, and also increased tumorigenic potential. The post-sputum treated ABCG2+ cells exhibited high expression of TLR2/4 and associated increase of HIF-2alpha and MYC transcriptional activity. To determine whether the microbiome may enhance response to immune checkpoint inhibition, and indicate that the gastrointestinal microbiome and its composition are critical for the antitumor efficacy of αPD-L1.

Pancreatic ductal adenocarcinoma (PDAC) is the fourth-leading cause of cancer-related deaths in the United States with metastasis to the liver as the major cause of mortality. While the propensity of PDAC to spread to the liver may reflect mechanical trapping of tumor cells that enter the portal circulation, primary tumor cells in the liver are not required for invasion and metastasis of PDAC. We previously reported that inflammation and IL-6/STAT3 signaling in the liver play a role in tumor seeding in the liver even prior to development of invasive PDAC. To investigate the impact of PDAC development on the formation of a pro-metastatic niche in the liver, we found that KPC mice (compared to age- and gender-matched control mice) demonstrated an increased susceptibility to tumor seeding in the liver even prior to development of invasive PDAC. Examination of the liver of KPC mice revealed diffuse activation of Signal Transducer and Activator of Transcription 3 (STAT3) signaling, particularly in hepatocytes. Although hepatocytes are recognized as important regulators of inflammation, their role in establishing a pro-metastatic niche is undefined. To define the role of the liver associated with development of a pro-metastatic niche, we performed QuantiSeq analysis on RNA isolated from the liver of KPC vs control PC mice. Our results showed increased transcriptional levels of myeloid chemokine receptors, particularly serum amyloid A proteins that are predominately produced by hepatocytes. Consistent with this finding, we observed an accumulation of F4/80+ and Ly6G+ myeloid cells in the liver of KPC mice by immunofluorescence microscopy. We next determined the role of tumor cells in driving cellular activation seen in the liver by establishing intraperitoneal and orthotopic models of PDAC. Using these models, we found that implantation of pancreatic tumor cells induced STAT3 activation in hepatocytes and stimulated F4/80+ and Ly6G+ myeloid cell recruitment to the liver. To determine whether cellular activation in the liver was associated with systemic release of soluble factors, we performed parabiotic joining of tumor-implanted mice and control wild type mice, and we found evidence of STAT3 activation and myeloid recruitment to the liver in parabiotic pairs. As interleukin-6 (IL-6) is a key inflammatory cytokine that can activate STAT3 signaling, we hypothesized a role for IL-6 directed STAT3 activation in hepatocytes for development of a pro-metastatic niche in the liver. Consistent with this hypothesis, we found that IL-6 receptor blocking antibodies administered after tumor implantation reduced STAT3 activation in hepatocytes and decreased transcriptional levels of hepatocyte-derived chemoattractants. Together, our findings provide support for IL-6/STAT3 signaling in hepatocytes in driving a pro-metastatic niche in the liver during PDAC development.

The intestinal microbiome has become increasingly appreciated as a significant mediator of systemic antitumor immunity/response in both naive and treatment contexts. In naive contexts, an intact intestinal microbiome has been demonstrated to enhance tumorigenesis, and its composition to mediate primary tumor growth kinetics. In the context of cancer treatment, antibiotic depletion of the intestinal microbiota has been reported to inhibit the efficacy of cyclophosphamide and that of the immune checkpoint inhibitor oCTLA4. Compositional modulation of the intestinal microbiota has been found to be sufficient to enhance the antitumor efficacy of αPD-L1. Here, we assessed the relative importance of the intestinal microbiota in mediating αPD-L1 antitumor efficacy in a B16.F10.SIY murine model of melanoma, by performing parallel efficacy studies in C57BL/6 germ-free (Taconic) or specific pathogen free (Taconic or Jackson) mice. We observed that αPD-L1 treatment provided significant antitumor efficacy in Taconic mice carrying an intact microbiome; however, this efficacy was abolished in germ-free Taconic mice. Furthermore, we observed that tumors of Jackson mice carrying an intact but compositionally different microbiome did not respond to αPD-L1 treatment. Phenotyping of local tumor and systemic immune responses, as well as characterization of the intestinal microbiome in responder vs nonresponder animals provided mechanistic insights. Taken together, these data suggest that modulation of the microbiome may enhance response to immune checkpoint inhibition, and indicate that the gastrointestinal microbiome and its composition are critical for the antitumor efficacy of αPD-L1.

#2684 Multiplex immunofluorescence profiling of tumor infiltrating immune subsets in HNSCC biopsies provides a powerful tool when combined with patient outcome data. Matt Levin, Mark Lingen, David Schwartz, Helen Snyder. Cell Idx, San Diego, CA.

Head and neck squamous cell carcinoma (HNSCC) is one of the growing number of tumors for which an anti-tumor immune response is implicated to play a role in the course of the disease. Profiling of the tumor microenvironment including specific infiltrating lymphocyte subsets, antigen present- ing cells, and expression of regulatory cytokines in immune cells has also been suggested to secrete factors that may promote recruitment of myeloid cells to establish a pro-metastatic niche. In this study, we used the LS-L-KrasG12D+/H11001, LS-L-Tprp53R127H+/H11001, Pdx-1-Cre (KPC) mouse model of PDAC to investigate the impact of PDAC development on the formation of a pro-metastatic niche in the liver. We found that KPC mice (compared to age- and gender-matched control mice) demonstrated an increased susceptibility to tumor seeding in the liver even prior to development of invasive PDAC. Examination of the liver of KPC mice revealed diffuse activation of Signal Transducer and Activator of Transcription 3 (STAT3) signaling, particularly in hepatocytes. Although hepatocytes are recognized as important regulators of inflammation, their role in establishing a pro-metastatic niche is undefined. To define the changes in the liver associated with development of a pro-metastatic niche, we performed QuantiSeq analysis on RNA isolated from the liver of KPC vs control PC mice. Our results showed increased transcriptional levels of myeloid chemokine receptors, particularly serum amyloid A proteins that are predominately produced by hepatocytes. Consistent with this finding, we observed an accumulation of F4/80+ and Ly6G+ myeloid cells in the liver of KPC mice by immunofluorescence microscopy. We next determined the role of tumor cells in driving cellular activation seen in the liver by establishing intraperitoneal and orthotopic models of PDAC. Using these models, we found that implantation of pancreatic tumor cells induced STAT3 activation in hepatocytes and stimulated F4/80+ and Ly6G+ myeloid cell recruitment to the liver. To determine whether cellular activation in the liver was associated with systemic release of soluble factors, we performed parabiotic joining of tumor-implanted mice and control wild type mice, and we found evidence of STAT3 activation and myeloid recruitment to the liver in parabiotic pairs. As interleukin-6 (IL-6) is a key inflammatory cytokine that can activate STAT3 signaling, we hypothesized a role for IL-6 directed STAT3 activation in hepatocytes for development of a pro-metastatic niche in the liver. Consistent with this hypothesis, we found that IL-6 receptor blocking antibodies administered after tumor implantation reduced STAT3 activation in hepatocytes and decreased transcriptional levels of hepatocyte-derived chemoattractants. Together, our findings provide support for IL-6/STAT3 signaling in hepatocytes in driving a pro-metastatic niche in the liver during PDAC development.

#2685 Modulating tumor microenvironments through inflammasome and IL-1 pathways. Beichu Guo, Jinyu Zhang, Shun-Jun Fu. Medical University of South Carolina (MUSC), Charleston, SC.

Chronic Inflammation has been shown to play important roles at all stages of tumor development including initiation, growth, invasion and metastasis. The inflammasome is an important innate immune pathway critical for the production of active IL-1β, a potent inflammatory cytokine. While extensive evidence indicates that inflammasomes are involved in infections and autoimmune diseases, their full potential in tumor development remains to be discovered. To dissect the roles of the inflammasome and IL-1 pathway in tumor development, we utilized the MMTV-PyMT transgenic model, which develops mammary gland tumors with a high incidence of lung metastasis. Our results have demonstrated that inflammasome and IL-1β play a critical role in promoting tumor growth and metastasis. We found that tumor growth was associated with inflammasome activation and elevated levels of IL-1β in tumor microenvironments in mouse mammary tumor models and in human breast cancer tissues. Mice deficient for inflammasome components or IL-1 receptor signaling exhibit significantly reduced lung metastasis. Our data also show that inflammasome activation led to the accumulation of myeloid cells, such as such as myeloid-derived suppressor cells (MDSCs) and tumor-associated macrophages (TAMs) in tumor microenvironments. Furthermore, blocking IL-1R signaling with IL-1R antagonist (IL-Ra) or anti-IL-1R antibody inhibited tumor growth and metastasis. Our results suggest that targeting the tumor microenvironment through inflammasome and IL-1 blockade may provide a novel approach for the treatment of breast cancer.

#2686 Dual inhibition of BCR and TLR signaling has therapeutic potential in chronic lymphocytic leukemia. Eman L. Dadashian, Sarah Herman, Adrian Wiestner. NIH/NHLBI, Bethesda, MD.

Introduction: The Bruton’s tyrosine kinase (BTK) inhibitor ibrutinib is clinically active in lymphoproliferative diseases driven by B-cell receptor (BCR) and Toll-like receptor (TLR) signaling, including chronic lympho-
cytic leukemia (CLL) and Waldenstrom macroglobulinemia (WM), respectively. However, deep remissions are uncommon and resistance to single agent has been described. The hallmark of WM is an activating mutation in MYD88 in the TLR signaling pathway. While mutations in MYD88 are uncommon in CLL, our previous study identified gene signatures indicative of aggressive behavior in cases associated with MYD88 mutations (Herishanu, Blood 2011). Further, TLR9 activating CpG oligonucleotides induce proliferation and extend CLL cell survival in vitro. These observations suggest that BCR and TLR signaling may cooperate to activate CLL cells in the tissue microenvironment. Here, we tested the hypothesis that targeting both BCR and TLR signaling could improve therapy for CLL. Methods: CLL PBMCs were treated with ibrutinib in the presence or absence of IRAK1/4 inhibitor (Calbiochem) for 1h and then stimulated with soluble IgM, CpG, or both. We quantified changes in phosphorylation of BTK, PLCγ2 and ERK (BCR pathway) and STAT3 and STAT1, as well as total IRAK1 (TLR pathway). Results: As expected, ibrutinib inhibited phosphorylation of BTK, PLCγ2 and ERK (P<.05) and decreased the survival of CLL cells stimulated with IgM (P=.001). CpG stimulated TLR signaling degrades IRAK1 and the stimulates cytokine secretion that can, in autocrine fashion, activate STAT phosphor- ylation. The IRAK1/4 inhibitor effectively inhibited TLR signaling resulting in stabilization of IRAK1 (P=.002), decreased phosphorylation of STAT1/3 (P=.04) and decreased viability compared to CpG stimulated but not IRAK inhibitor treated cells. Ibrutinib had no effect on IgM-induced IRAK1 deg- radation, but was comparable to IRAK1/4 inhibition in reducing STAT phosphorylation, suggesting that inhibition of BTK can antagonize down- stream effects of TLR activation but not upstream IRAK dependent steps. In contrast, IRAK1/4 inhibition had no effect on IgM-induced BCR activa- tion. Next we evaluated the effect of dual BCR and TLR activation, modelling co-operative activation of both pathways in the tumor microenvironment. Under these in vitro conditions, ibrutinib prevented BCR activation and partial TLR activation, while IRAK1/4 affected only the TLR pathway. When ibrutinib and the IRAK1/4 inhibitor were combined, activation of both BCR and TLR signaling was prevented resulting in a significant reduction in CLL cell viability (P=.01) compared to co-activation of both pathways. Conclu- sion: While ibrutinib partially inhibited TLR signaling, an IRAK1/4 inhibi- tor was required for full inhibition of the pathway. The combination of BTK and IRAK1/4 inhibition for the treatment of lymphoproliferative diseases warrants further investigation.

#2687 Toll like receptors mediated inflammatory signals mediate promo- tion of K-ras mutant lung cancer by chronic obstructive pulmonary disease. Nasim Khoosravi,1 Nelly Torres-Garza,2 Soudabeh Daliri,1 Maria Miguelina De La Garza,3 Amber Cumpian,2 Evelyn Beltran,2 Mishia Umer,2 Diana Del Bosque,3 Saba Akbani,1 Scott Evans,1 Seyed Javad Moghaddam1.

Lung cancer is the leading cause of cancer death worldwide, and cigarette smoking is its main cause. However, smoker with chronic obstructive pul- monary disorder (COPD), an inflammatory disease of the lung, have an increased risk of lung cancer (3 to 10 fold) compared to smokers without COPD. Importantly, lung inflammation persists and lung function continues to deteriorate as does the increased risk of lung cancer even after cessa- tion of cigarette smoking among former smokers. These facts suggest a strong link between COPD-related airway inflammation and lung cancer promotion, however, the precise mechanistic link is not known. We have previously developed a COPD-like mouse model of airway inflammation through repeated aerosol challenge to a lysate of nontypeable (i.e., unencap- sulated) Haemophilus influenzae (NTHi). NTHi is the most common colon- izing bacteria in the lower respiratory tract of patients with COPD and could be a potential cause of perpetuating and promoting airway injury and inflammation in these patients. We then showed that this type of airway inflammation promotes lung cancer in a K-ras mutant mouse model of lung cancer (MC-LKR), which was associated with and/or an activation of MyD88/NF-κB pathway and increased expression of its downstream targets in the lung. We have further shown that lack of NF-κB or MyD88 (an adaptor protein up- stream to NF-κB) in the airway epithelium of CC-LR mice changes the bronchoalveolar lavage fluid cellular component of CC-LR mice and inhibits the promoting effect of COPD-like airway inflammation on lung tumorigen- sis. Upstream to MyD88 and NF-κB and downstream to bacterial stimuli is the toll-like receptors family (TLRs), which play critical role in the innate immune response. Among TLRs, TLR-2, TLR-4, and TLR9 play critical roles in mediating inflammatory responses in lung and are required for primary epithelial response to inflammatory stimuli and activation of MyD88/NF-κB pathway in the airway epithelium. Accordingly, we further hypothesized that TLR-2, -4, and 9 mediate promoting effect of inflammation on lung tumori- genesis in an MyD88/NF-κB dependent manner. Therefore, CC-LR mice were separately cross to TLR-2, TLR-4 and TLR-9 knock out mice in order to test this hypothesis. We found that genetic ablation of these TLRs in vivo significantly reduced lung tumor burden compared to age and sex matched control CC-LR mouse in the presence of COPD-like airway inflammation. This tumor reduction was associated with significant reduction in the numbers of inflammatory cells in bronchoalveo- lar lavage fluid of mice with lack of these TLRs. Taken these together, we conclude that promoting effect of COPD on lung cancer is mediated through TLR2, 4, 9-mediated activation of epithelial MyD88/NF-κB pathway.

As immune checkpoint blockade has been shown to partially reverse the ex- hausted T cell phenotype and consequently lead to a decrease in tumor burden, there is a need for an understanding of this T cell type. Using recently developed, highly validated antibodies, we have developed a fluorescent multiplex, TSA-based assay in order to examine the interaction of PD-1 with PD-1-expressing exhausted T cells in various tumor types. Here, we construct a seven-color mul- tiplex panel in order to simultaneously visualize cytokeratin (the tumor mask), DAPI (nuclear counterstain), CD8 (cytotoxic T cell marker), the exhausted T cell markers PD-1, Tim-3 and Lag-3, and the ligand for PD-1, PD-L1. This technique not only enabled the concurrent detection of these markers, but also provided high-resolution visualization of interactions between PD-1-expressing CD8+ T cells and PD-L1-expressing CD68+ macrophages in the tumor mi- croenvironment. The seven-plex panel was applied to FFPE tumor microarrays (TMAs) consisting of breast, lung and ovarian tumor tissue and each core was subsequently analyzed for the distribution, co-localization, frequency and prox- imity of these targets in relation to one another. While we often visualized co- expression of Lag-3 and PD-1 on T cells, Tim-3 was frequently observed on PD-L1+ macrophages in several tumor types. This data provides valuable in- sight into the co-expression profiles of these markers in multiple tumor types and has implications for the use of combination therapies that aim to target both the innate and adaptive immune systems.

#2689 The protumorigenic, proinflammatory effects of obesity are re- versed by weight loss via bariatric surgery, but not a low-fat diet. Laura W. Bowers,1 Emily L. Rossi,1 Subreen A. Khattib,1 Steven Doerstling,1 Alfor Lewis,2 Randy J. Seelye,3 Stephen D. Hursting1. #1Univ. of North Carolina, Chapel Hill, NC; #2Univ. of Michigan, Ann Arbor, MI.

Background: Obesity negatively impacts basal-like breast cancer (BLBC) prognosis, but the reversibility of these pro-cancer effects via weight loss re- mains unclear. However, there is consistent evidence suggesting that weight loss via bariatric surgery reduces breast cancer risk. This may be related to the re- ductions in metabolic perturbations and inflammation that follow bariatric sur- gery, effects that could be mediated by epigenetic reprogramming and/or changes in the gut microbiome. Purpose: We previously demonstrated that mammary tumor growth and inflammation remain elevated in formerly obese mice, in concordance with aberrant methylation of inflammation-related genes. Here we aim to determine the differential effects of surgical versus non-surgical weight loss on inflammation, DNA methylation, the gut microbiome, and tumor burden in a mouse model of BLBC. Methods: Mice were fed a low fat control (n=25) or high fat diet-induced obesity (DIO, n=75) regimen for 15 weeks to model chronic obesity. DIO mice were then randomized to remain on DIO (Obese) or receive either a surgical (sleeve gastrectomy) or dietary (low fat control diet) weight loss intervention, resulting in formerly obese (FOb)-Surg or FOB-Diet mice, respectively. The Control mice were maintained on the low fat diet throughout study. Four weeks after weight stabilization in the FOB mice, all mice were orthotopically injected with E0771 mammary tumor cells, which model BLBC. Stool samples were collected at baseline and prior to tumor cell injection. Results: The average weight and percent body fat of the FOB-Surg and FOB-Diet mice were equivalent to Control and significantly lower than Obese mice at study endpoint. Average tumor weight in FOB-Surg mice was statistically equivalent to Control mice, but tumor weight in FOB-Diet mice was sig- nificantly greater than Control mice and statistically equivalent to Obese mice. Furthermore, FOB-Surg mice had significantly lower serum tumor necrosis fac- tor alpha, mammary gland interleukin-6 expression, and tumor-infiltrating adi- poocyte area in comparison to FOB-Diet. To further define the effects of surgical versus non-surgical weight loss, characterization of the gut microbiota as well as global mammary tissue gene expression and DNA methylation via paired RNA
sequencing and reduced representation bisulfide sequencing is in progress. Conclusions: Our results suggest that the strong anti-cancer benefits seen with bariatric surgery may be related to a significant reduction in systemic and local inflammation, which did not occur with non-surgical weight loss. Identification of the mechanisms mediating the protective effects of bariatric surgery against breast cancer could help identify new targets and strategies for breaking the obesity-cancer link.

#2690 MK2 pathway blockade inhibits inflammatory cytokine production and colorectal cancer growth and invasion. Anita L. Ray, Amanda S. Peretti, Wade Johnson, Gregory Gan, Ellen J. Beswick. The Univ. of New Mexico, Albuquerque, NM.

Introduction: Colorectal cancer is the third most common malignancy diagnosed for both men and women in the United States of America. High levels of inflammatory cytokines in colorectal tumors cause increased growth and invasion and carry a higher risk of metastasis. Identifying new targets to control inflammation is important for developing improved treatment approaches. Mitogen-activated protein kinase-activated protein kinase 2 (MK2) is a regulator of pro-inflammatory cytokines that may promote colorectal tumor progression. MK2 signaling is known to induce IL-1, IL-6, and TNF-α production. This pro-inflammatory cytokines are associated with CRC development, invasion, and metastasis. We hypothesized that the MK2 pathway could be an important component of CRC growth, invasion and tumor regrowth. Methods: To investigate this pathway, CT26 CRC cells were examined. Cells were flask-injected into Balb/c mice with and without MK2 inhibitor treatment. At day 19 after tumor injection, tumors were harvested and measured using calipers. Cytokines were quantitated by multiplex bead array in organ culture supernatants and in supernatants from tumor cells plated in fibronectin coated wells. In culture, tumor cell invasion was measured in scratch wound assays containing matrigel. Results: Treating CT26 cells with MK2 inhibitors markedly reduced tumor growth in mice by a mean of 60% compared to vehicle control treated cells. Inflammatory cytokines were also dramatically decreased with MK2 inhibition compared to controls by up to 80%. Cytokines affected included both known MK2 downstream cytokines (IL-1, IL-6, and TNF-α) and also chemokines such as MIP-1α and MCP-1 in both supernatants from cultured tumor cells and in organ culture supernatants. MK2 inhibition also decreased invasion of tumor cells in a cytokine dependent manner. Conclusions: The MK2 pathway regulates production of multiple pro-inflammatory cytokines in colorectal tumors, including several previously unreported chemokines. Inhibition of this pathway markedly decreases tumor growth and invasion. Thus, MK2 may be a promising tumor target to prevent colorectal cancer progression.

#2691 Cigarette smoke induced upregulation of endothelin axis in the initiation of pancreatic cancer. Suprit Gupta, Satyanarayana Rachagani, Sushil Kumar, Surinder Kumar Batra, Maneesh Jain. University of Nebraska Medical Center, Omaha, NE.

Background: Cigarette smoke is an established risk factor for pancreatic ductal adenocarcinoma (PDAC). Smoke induced inflammation accelerates the progression of PDAC in presence of constitutively active K-Ras mutation. Endothelin (ET) axis comprising of endothelin converting enzymes (ECE-1, ECE-2, and ECE-3) and endothelin receptors (ETa, ETb, ETc) has been implicated in various cancers. Previous studies from our group reported that colon tumors from AAs displayed hypermethylation of DNA regions in inflammatory genes such as NELL1, GDF1, ARHGEF4, and ITGA4 when compared to Caucasian Americans (CA). To assess potential differences in the inflammatory response, we utilized two AA colon cancer cell lines generated in our laboratory and compared them with the commercially available CA colon cancer cell lines, Caco-2 and HT-29. Recent experiments by our group with the anti-inflammatory drugs Ibuprofen, Sulindac and Aspirin, showed significantly higher IC50 values in proliferation assays for AA cell lines compared to CA cell lines. Therefore, we evaluated the anti-inflammatory effects of these drugs by determining secretion of inflammatory cytokines and MAPKs activation in response to pro-inflammatory cytokine TNF-alpha. The same parameters were tested for the anti-inflammatory cytokine IL-10. As hypothesized, our results in the CA cell lines demonstrated down-regulation of MAPKs activation in response to TNF-alpha after pre-treatment with Ibuprofen. On the contrary, Ibuprofen concentrations as high as the IC50 values for the CA cell lines were not able to induce down-regulation of MAPKs in the AA cell lines. Interestingly, IL-10 treatment was more effective in the AA compared to the CA cell lines, suggesting that the main anti-inflammatory cytokine of the colon will be more effective in controlling inflammation in AA colon tumors. Further studies are needed to elucidate the major differences in inflammatory responses between AA and CA colon cancer cell lines and their potential role in CRC health disparities. As it has been documented that AA colon cancer patients are less responsive to the chemotherapeutics Fluorouracil and Cetapcinib, in future studies we will evaluate the effect of these therapeutic agents on AA and CA cell lines in terms of inflammation, cell viability, apoptosis and invasion.

The colon tumour microenvironment (TME) comprises many cell types including endothelial cells, stromal cells and immune cells. Recent evidence suggests that high tumour stromal cell density correlates with a poor prognosis for colon cancer patients. The majority of these stromal cells are of mesenchymal origin (MSCs) and are known contributors to tumour angiogenesis and invasiveness. Little is known about the role of their immunosuppressive potential in the colon TME. We investigated the molecular regulation of the induced immunosuppressive, tumour-promoting phenotype of tumour-associated MSCs, and the effect of inflammation on this process. Balb/c bone marrow derived MSCs were treated with conditioned medium from untreated CT26 tumour cells (MSCCTRL) or TNF-α treated CT26 cells (MSCTNF-TCM). MSC cell surface analysis of MSCs after 72h revealed an increased expression of TCR ligands MHC-I, MHC-II and PD-L1 compared to MSCCTRL. This was further potentiated by TNF-α-induced tumour cell inflammation. MSCCTRL co-cultured with syngeneic activated T cells displayed an enhanced ability to suppress CD8+ T cell proliferation, which was further potentiated by inflammatory activation of CT26 (MSCCTRL-TCM). This effect was dependent on induced PD-L1 expression on MSCs as PD-1 blockade restored CD8+ T cell proliferation, activation and granzyme B secretion. In an immunocompetent Balb/c syngeneic model, we assessed tumour growth and anti-tumour immune responses following subcutaneous injection of CT26 cells alone or co-injection with MSCCTRL.

IMMUNOLOGY: Inflammation and Cancer
MSC^{TNF-TCM}. Co-injection of MSC_{Control} significantly promoted tumour growth, and this was further potentiated by the co-injection of MSC^{TNF-TCM}. This effect was associated with significantly reduced tumour infiltration of CD8+Granzyme B secreting T cells. We showed that this stromal cell mediated tumour promotion could be reversed by administration of a PD-1 blocking antibody, via restoration of granzyme B secreting CD8+T cells. Our observation supports that stromal cells in the inflammatory TME directly modulate anti-tumour immune responses via PD-L1. This data could lead to better stratification of patients for immunotherapeutic regimens resulting in more targeted and durable responses to overcome stromal mediated tumour immunosuppression in colon cancer.

#2694 Target obesity-associated inflammation to decrease murine basal-like mammary tumor burden. Emily L. Rossi, Subreen A. Khatib, Laura W. Bowers, Steven S. Doerstling, Andrew J. Dannenberg, Stephen D. Hursting. Univ. of North Carolina at Chapel Hill, Chapel Hill, NC; Weill Cornell Medical College, New York, NY.

Background: Adipose tissue dysregulation, a hallmark of obesity, contributes to a chronic state of low-grade inflammation that promotes cancer growth through multiple signaling pathways. We previously showed that inflammation and basal-like breast cancer (BLBC) growth are increased in chronically obese mice and persist following weight normalization. Purpose: We tested the hypothesis that targeting inflammation in obese mice by treating them with the nonsteroidal anti-inflammatory drug (NSAID) Sulindac would offset the pro-cancer effects of obesity in a mouse model of BLBC. Methods: Mice were administered a control diet (10 kcal % fat; n = 34) or diet-induced obesity regimen (DIO, 60 kcal % fat; n = 34). After 15 weeks on control or DIO diets, mice were randomized to either receive Sulindac supplementation at 160 ppm in the diet (n = 17/diet) or no supplementation (n = 17/diet). Twelve weeks later, all mice were orthotopically injected with E0771 cells, a model of basal-like breast cancer. Five mice/group were killed at a 4-week interim time-point after injection, and their tissue collected and stored. The remaining 12 mice/group continued in a survival study; these mice were killed when tumor size reached 1.2 cm in diameter at any future. Results: Sulindac supplementation in DIO mice significantly reduced serum insulin and leptin to levels statistically equivalent to control mice, but had no effect on body weight, body fat percentage, or ex vivo visceral white adipose weight. Sulindac supplementation in DIO mice (but not control) significantly reduced mean tumor volume in the interim tumor study and significantly increased tumor latency in the survival study. Analysis of H&E stained tissue demonstrated that DIO mice had significantly increased adipocytes infiltrating into the tumor (relative to control), but Sulindac supplementation in DIO mice decreased adipocyte infiltration to levels observed in control. Conclusions: Sulindac supplementation significantly reduced insulin and leptin in DIO mice, and increased tumor latency in DIO mice, but had no effects on body weight or fat depots, suggesting that Sulindac offsets some of the pro-tumorigenic effects of obesity rather than targeting obesity directly. Preliminary analyses of inflammatory surrogates, including circulating cytokines and prostaglandins, mammary gland crown-like structures and collagen-2X collagen-2 levels, suggests Sulindac’s effects in obese mice are mediated through its eicosanoid-depressing effects.

#2695 Role of tumor generated acidity in immune stromal interactions during prostate carcinogenesis. Asmaa El-Kenawi, Jasreman Dhillon, Arig Ibrahim-Hashim, Dominique Abrahams, Shari Pilon-Thomas, Brian Ruffell, Robert Gatenby, Robert Gillies. Moffitt Cancer Ctr., Tampa, FL.

Insufficiency in tumor perfusion and high rate glycolysis combine to reduce the pH of tumor microenvironment. In a TRAMP model of prostate cancer, we had shown that carcinogenesis is associated with increasing acidification of the microenvironment and that neutralization of this acidity can prevent cancer emergence or metastases. Carcinogenesis in the TRAMP model is also associated with increased fibrosis and immune cells infiltration. We thus sought to determine if fibrosis drives immune infiltration in early carcinogenesis or vice-versa; and whether this dynamics is affected by tumor acidity. To investigate this, we harvested prostates from TRAMP mice or their matching non-transgenic controls at different time points and stained serial prostate tissue sections with F4/80 (macrophages), SMA (cancer-associated fibroblasts, CAFs), and Masson’s Trichrome (collagen). Quantitative image analysis reveals that increase in fibrosis occur prior to macrophage infiltration and that both events preceded tumor development. However, the relative amount of collagen fibers was unchanged across all time points. Notably, neither fibrosis nor macrophage infiltration occurred in mice treated with buffer, suggesting an involvement of acidity in this immune stromal interactions. Interestingly, macrophages isolated from latter time points in the untreated group as well as macrophages co-cultured with prostate tumor cells at acidic pH, possessed an M2-like phenotype by expressing immunosuppressive genes (e.g. Arginase 1, Arg1) and a range of scavenging receptors (e.g. mannose receptor, CD206), as well as releasing more angiogenic factors (e.g. VEGF and MMPs). Similar results were recapitulated when M2 macrophages were stimulated at acidic pH by showing enhanced CD206 and Arg1 expression. On the functional level, macrophages activated at acidic pH had a higher ability to uptake fluorescently labelled ovalbumin and collagen, as examples of mannosedified ligands that prevail the fibroitic microenvironment. In summary, these results suggest that tumor acidity may promote fibrosis, with subsequent macrophage infiltration and phenotypic switching, leading to increased collagen turnover. It is suspected that this extracellular matrix remodeling may be permissive for tumor progression.

#2696 PD-1 antibody treatment induces gut microbiota changes in CT-26 colon cancer syngeneic model. Jian Ding, Binchen Mao, Qian Shi. CrownBio, Taicang, Jiangsu Province, China.

The gut microbiota plays an important role in shaping systemic immune response. One novel frontier in cancer research is investigating how the gut microbiota change immune response and influence the efficacy of anticancer immunotherapy drugs; this has been reported in CTLA4 and PD-L1 antibody treatment, both in laboratory and clinical settings. One recent study reported that composition of patient’s gut microbes appears to be a determining factor for immunotherapy, at least in melanoma patients. These findings shed light on the potential use of gut microbial as a biomarker for responders in cancer immunotherapy. Here, we evaluated the gut microbiota profiling upon PD-1 antibody (RMPI-14) treatment in CT-26 colon cancer syngeneic mouse model. Fresh feces were collected at different time points before and after treatment, snap frozen and sent for 16S RNA sequencing for microbiome profiling. Our results identified top 25 abundant taxa in genus level in CT-26 feces. Significant abundance changes were observed in several genera after PD-1 antibody treatment, especially in Akkermansia. These findings indicate that immunotherapy like PD-1 antibody can induce the profile changes of gut microbiota in CT-26 model. Furthermore, we also investigated the correlation of gut microbiome with immune microenvironment and the efficacy upon IO therapy, as well as the possibility to utilize microbiota profiling as a quality control step that may help to explain the variability observed in many syngeneic studies.

#2697 A role for the membrane type-1 matrix metalloproteinase in the transcriptional regulation of carcinogen-induced inflammasome components. Samuel Sheehy, Borhane Annabi. Université du Québec à Montréal, Montréal, Quebec, Canada.

BACKGROUND: Signal transduction functions driven by the cytoplasmic domain of membrane type-1 matrix metalloproteinase (MT1-MMP) are believed to regulate many inflammation-mediated cancer cell functions including migration, proliferation, and survival. Besides the upregulation of the inflammation biomarker cyclooxygenase (COX)-2 expression, MT1-MMP’s role in relaying the signals triggered from pro-inflammatory cues remain poorly understood. METHODS: Here, we treated HT1080 fibrosarcoma cells with phosphol-12-myristate-13-acetate (PMMA), a well-known carcinogen and inducer of COX-2 and MT1-MMP. In order to assess the global transcriptional regulatory role that MT1-MMP may exert on inflammation biomarkers, we combined gene array screens to transient MT1-MMP gene silencing strategy. RESULTS: 1. We found that MT1-MMP expression exerted both stimulatory and repressive transcriptional control of several inflammation-related biomarkers such as IL-1B, IL-6, IL-12A, and IL-33, as well as of transcription factors such as EGR1, ELK1, and p105 KF-integrin. We also highlight a signaling axis linking MT1-MMP to MMP-9 transcriptional regulation. CONCLUSIONS: Altogether, our data evidence an important involvement of MT1-MMP in the transcriptional regulation of inflammatory biomarkers consolidating its contribution in signal transduction functions, in addition to its classical hydrolytic activity.

#2698 IL-17A alone or in combination with IL-4/IFN-y induces Duox2/DuoX2 expression and reactive oxygen production in human colon and pancreatic cancer cells. James H. Doroshow, Yongzhong Wu, Jiamo Lu, Jian Ding, Binchen Mao, Qian Shi. Moffitt Cancer Ctr., Tampa, FL.

Insufficiency in tumor perfusion and high rate glycolysis combine to reduce the pH of tumor microenvironment. In a TRAMP model of prostate cancer, we had shown that this stromal cell mediated tumour promotion could be reversed by administration of a PD-1 blocking antibody, via restoration of granzyme B secreting CD8+T cells. Our observation supports that stromal cells in the inflammatory TME directly modulate anti-tumour immune responses via PD-L1. This data could lead to better stratification of patients for immunotherapeutic regimens resulting in more targeted and durable responses to overcome stromal mediated tumour immunosuppression in colon cancer.
#2699 NFATc2 in non-small cell lung cancer mediates inhibition of peripheral blood mononuclear cell proliferation. Ian K. Lam, Zhi-Jie Xiao, Vicky P. Tin, Fang Ping Huang, Maria P. Wong. The University of Hong Kong, Hong Kong, Hong Kong, Hong Kong.

Lung cancer is the leading cause of cancer death worldwide. While genetic mutations that provide growth advantages to cancer cells are fundamental to malignant transformation, ability to evade the immune system is also crucial in tumorogenesis. We have previously shown that human lung cancers with high expression of nuclear factor of activated T cells, cytoplasmic 2 (NFATc2) are associated with reduced recurrence-free and overall survival. NFATc2 is expressed in most immune cells and has been extensively studied in immune cells. However, its function in cancer development is not completely understood. In this study, we examined the role of NFATc2 in lung cancer on immune escape is explored. Lung cancer cell lines with high NFATc2 expression were co-cultured with peripheral blood mononuclear cells (PBMCs). We observed a significant inhibition of PBMC proliferation in co-culture with NFATc2 knockdown cancer cells. When cancer cells and PBMCs were separated by a membrane using Transwell inserts, the anti-proliferative effect on PBMC was not observed suggesting that cell-cell contact was required for the NFATc2-mediated inhibition. Moreover, interleukin-2 (IL-2) was produced by PBMC irrespective of the presence or absence of lung cancer cells. These results showed that the inhibition of proliferation was independent of the activation of PBMC. Taken together, we have shown NFATc2 in lung cancer plays a role in immune modulation by inhibiting PBMC proliferation and this could be a novel mechanism of immune evasion in lung cancer.

#2700 Intestinal Vitamin D receptor deficiency increases susceptibility for the DSS-induced colon disease. Jung-Hwan Kim, Satoshi Yamamoto, Frank J. Gonzalez, 2 Gyeongsang National University, Jinju, Republic of Korea; 2National Cancer Institute, Bethesda, MD.

To investigate the function of the intestinal Vdr gene in inflammatory bowel disease (IBD), in conjunction with the discovery of possible metabolic markers for IBD using intestine-specific Vdr knockout mice. Vdr-/- mice were generated, phenotyped and treated with a twice-course of 3% dextran sulfate sodium (DSS) to induce colitis. Colitis was diagnosed by evaluating clinical symptoms and intestinal histopathology. Gene expression analysis was carried out. In addition, metabolic markers of IBD were explored by metabolomics. Vdr-/- mice showed abnormal body size, colon structure and feces color. Calcium, collagen, and intestinal proliferation-related gene expression were all decreased, and serum alkaline phosphatase was highly increased. In the acute model which was treated with 3% DSS for six days, Vdr+/+ mice showed a high score of IBD symptoms; enlarged mucosal layer and damaged muscularis layer. In the recovery experiment model, where mice were treated with 3% DSS for four days and induced for 13 days, Vdrc/+- mice showed a high score of IBD symptoms; severe damage of mucosal layer and increased expression of genes encoding proinflammatory cytokines. Feces metabolomics revealed decreased concentrations of taurine, taurocholic acid, taurodeoxycholic acid and cholic acid in Vdr+/+ mice. In conclusion, disruption of the intestinal Vdr gene showed phenotype changes. These factors combined may exacerbate IBD. Taken together, the results suggest that VDR may play an important role in IBD.

Clinical Research: Clinical Molecular Genetics and Laboratory Correlates

#2701 Large-scale ex vivo generation of human neutrophils from cord blood CD34+ cells. Zhenwang Liu, 1 Yu Zhang, 2 Chen Wang, 2 Bin Shen, 3 Xin Guan, 1 Zhihua Ren, 1 Xinxin Ding, 1 Wei Dai, 2 Yongping Jiang, 1 Biopharmaceutical R&D Center, Peking Union Medical College of Tsinghua University, Suzhou, China; 3Biopharmagen corp., Suzhou, China; 2College of Nanoscale Science and Engineering, SUNY Polytechnic Institute, Albany, NY; 4Environmental Medicine, NYU Langone Medical Center, Tuxedo, NY.

Ex vivo expansion of hematopoietic stem cell and subsequent differentiation into mature neutrophils remains a challenge. Here, we have developed a three-stage culture system to produce efficiently functional neutrophils derived from cord blood CD34+ cells. A procedure of ex vivo expansion and differentiation in a large-scale was developed in a modified IMDM basal
medium supplemented with transferrin, insulin, fetal bovine serum, and some other nutrients with selected cytokine combination that contained stem cell factor (SCF), Flt-3 ligand (FL), granulocyte-colony stimulating factor (G-CSF), granulocyte macrophage colony-stimulating factor (GM-CSF) and thrombopoietin (TPO) in stage I (days 0–6); SCF, FL, G-CSF, interleukin-3 (IL-3), and GM-CSF in stage II (days 7–14); and SCF, FL, and GM-CSF in stage III (days 15–21), respectively. Enriched CD34⁺ cells were firstly cultured and expanded in 25 T-flasks. After 6 day-culture, the cells were transferred to a 2-L bottle with 500 ml of medium in the bottle-turning device system. During the differentiation process, neutrophil marker CD66b was evaluated by flow cytometry. Ex vivo generated neutrophils or medium only were used for the E. coli overnight for bacteria killing assay. All then the E. coli colony-forming units were counted separately. Matured neutrophils or vehicle were transplanted into NOD/SCID mice intravenously for chemotactic activity in vivo. The cells that accumulated in the pouch with chemotoxarin were collected and subjected to flow cytometric analysis for human CD66b antigen. The ex vivo generated neutrophils/progenitors were then injected into sub-lethal irradiated NOD/SCID mice to monitor the viability and maturation in vivo. After the three-stage culture, proliferation fold of total cell reached 3001 ± 286.5 with 60.2% ± 2.4% for CD66b⁺ neutrophils. The calculated yield of matured neutrophils from each CD34⁺ cell was ranged from 1.8 × 10⁶ to 1.87 × 10⁶ for 18-day culture. There was no E.coli colony formed after incubation with neutrophils in bacteria killing assay (10⁴/ml). The ex vivo generated neutrophils were functional. Post in vivo chemotaxis assay, the neutrophils collected from 18-day culture were injected into mice and detected at 1.08% ± 0.16% for human CD66b⁺ cells and no any CD66b⁺ cells observed for negative control group. In addition, the CD66b⁺ cells were extended for 4 days from a 15-day cultured neutrophil group in mouse peripheral blood (PB), while only for 2 days from a freshly isolated human PB neutrophils post injection, indicating that the ex vivo generated neutrophils/progenitors could further matured in vivo. Taken together, we have established a pilot-scale culture system to produce functional human neutrophils ex vivo. Considering that one neutrophil transfusion unit (100ml) contains 2 × 10¹⁰ cells, the CD34⁺ cells from one CB unit (80 ml) would generate 1.6 × 10¹¹ neutrophils, which are equivalent to 8 unit neutrophils in the clinical application.

**#2702** Mutations of SPOP, FOXA1 and IDH1 are associated with prostate cancer metastasis and biochemical outcomes. Jinlu Ma, Suzia Han, Xin Sui, Wenyan Lu, Yonghe Li, Bo Xu. The First Hospital, Xi’an Jiaotong University, Xi’an, China; Southern Research Inst., Birmingham, AL.

Recent genomic studies have shed light on cataloging genomic alterations in prostate cancer. Mechanistic studies allow the use of this information to subclassify the heterogeneous prostate tumors for optimized treatment planning. SPOP (small proteasome subunit RING finger protein), SOX17 (Sex determining region Y box 17), FOXA1 (Forkhead box A1), and IDH1 (isocitrate dehydrogenase 1) are among the genes that show frequent point mutations in primary prostate cancers. However, the clinical significance of these gene mutations in cancer patients is less clear. To determine the whether SPOP, FOXA1 and IDH1 mutations are associated with clinical outcomes in prostate cancer, we pyro-sequenced the three genes in over 200 prostate cancer patients and the clinical and prognostic significance. 198 patients from the first hospital of Xi’An Jiaotong University (China) were analyzed. All patients were newly diagnosed with prostate cancer from January 2010 to December 2015. No patient was lost to follow-up. The average follow-up time after the primary diagnosis was 27 months. The Fisher’s exact tests were used to compare categorical data. The risk of metastasis among patients with SPOP, FOXA1 and IDH1 mutations was evaluated using univariate and multivariate logistic regression models. The prognostic significance of clinical and gene mutations was determined using multivariate Cox regression analysis. SPOP mutations were found in 16 patients (8.1%), with all of the mutations clustered in the substrate-binding MATH domain. FOXA1 mutations were found in nine patients (4.5%), and were clustered in the homeodomain. IDH1 mutations were found in three patients (1.5%). Mutation frequencies of SPOP, FOXA1 and IDH1 were associated with prostate-specific antigen (PSA), a biochemical marker of prostate tumor presence/risk which is decided by Gleason Score, T stage and PSA level, along with prostate cancer PSA failure and metastasis. Among patients with SPOP mutation, 56.3% showed metastasis at the time of diagnosis of primary cancer, compared to only 11.5% of patients with wild-type SPOP. Similarly, the probabilities of FOXA1 and IDH1 mutations with metastasis were approximately 44.4% and 66.7% versus 13.8% and 14.4%, respectively, comparing to their wild-type counterparts. The metastasis risk for patients with SPOP mutation was 1.27 times of the SPOP wild-type patients (P = 0.003). We also found that patients with SPOP (P < 0.0001) and FOXA1 (P = 0.0403) mutations showed higher risk of PSA failure compared with wild-type. The PSA failure risk for patients with SPOP mutation was 35.49 times of the SPOP wild-type patients. In contrast, IDH1 mutation was not associated with PSA failure (P = 0.054). Multivariate analyses demonstrated that SPOP was the only mutation associated with prostate cancer metastasis and PSA failure recurrence. These findings underscore the clinical significance for profiling SPOP, FOXA1 and IDH1.

**#2703** Extraskeletal myxoid chondrosarcoma: a clinicopathologic and molecular study reveals novel genetic aberrations by targeted next-generation sequencing. Marcel Trautmann, Magdalene Cyra, Ilka Isfort, Inga Grünewald, Konrad Steinestel, Reinhard Büttner, Eva Wardemann, Wolfgang Hartmann. University Hospital Münster, Gerhard-Domagk-Institute of Pathology, Münster, Germany; University Hospital Cologne, Institute of Pathology, Cologne, Germany.

Background: Extraskeletal myxoid chondrosarcomas (EMCs) are rare mesenchymal neoplasms comprising 3% of all soft tissue tumors. EMCs arise mainly from the deep soft tissues of the extremities, accompanied with high rates of recurrence and metastases. The molecular hallmarks of EMCs are various cytogenetic NR4A3 rearrangements, generating chimeric -NR4A3 proteins. The most common reciprocal translocation (9;22)(q22;q11) results in a fusion of the EWS RNA binding protein 1 gene (EWSR1) to the nuclear receptor subfamily 4 group A member 3 gene (NRF4A3 or TEC; approximately 75% of cases). Further cytogenetic (9;17)(q22;q11) rearrangements involve TAF15 RNA polymerase II, TATA box binding protein associated factor (TAF15; approximately 15% of cases). The less frequent reciprocal translocations t(9;15)(q22;q21) and t(9;3)(q22;q12), result in transcription factor 12 (TCF12)NR4A3 and TRKfused gene (TFG)-NR4A3 fusion proteins. Although the oncogenic NR4A3 fusions transcripts seem to have a crucial role in EMC tumorigenesis and progression, the specific biological function and the mechanism of action remain to be defined. Methods: We characterized the cytogenetic rearrangements of 25 comprehensive EMC tumors by RT-PCR and/or fluorescence in situ hybridization (FISH). Next generation sequencing (NGS) was performed (Illumina MiSeq platform) to reveal additional genetic alterations besides the known chromosomal translocation. Therefore, a comprehensive cancer panel was designed, comprising 27 cancer-related genes known to be frequently mutated across various malignancies. Results: Overall, fusion transcripts were detected in 22 of 25 samples (88%). Sixteen were positive for the EWSR1-NR4A3 and six for the TAF15-NR4A3 fusion gene. The t(9;15) and t(9;3) translocations, resulting in TCF12NR4A3 and TFG-NR4A3 fusion proteins were not identified in any EMC case. In addition, several known oncogenic mutations were detected which have not been previously reported in EMC. Conclusions: The combination of RT-PCR and FISH on paraffin-embedded tissue is a sensitive and specific method for the molecular detection of the pathogenic translocations to be applied in the differential diagnosis of extraskeletal myxoid chondrosarcomas. Our results emphasize that cytogenetic NR4A3 rearrangements are the initiating events in the pathogenesis of EMC. Furthermore, our results indicate the occurrence of additional genetic aberrations providing a rational base for novel targeted therapeutic approaches.

**#2704** Pathogenic mutations and variants of unknown significance (VUS) in cancer predisposition genes are associated with over 10% of pediatric rhabdomyosarcoma: a report from the Children’s Oncology Group. Erin L. Young, Luke Maese, Rosann Robinson, Lance Pflieger, Barry Moore, Shawn Rynearam, Trent Fowler, Sean V. Tartaglini, Mark Yandell, Clinton C. Macon, Douglas S. Hawkins, Philip J. Lupo, Joshua D. Schiffman. University of Utah, Salt Lake City, UT; University of Washington, Fred Hutchinson Cancer Research Center, Seattle, WA; Baylor College of Medicine, Houston, TX.

Approximately 5% of rhabdomyosarcoma (RMS) cases are due to known cancer predisposition syndromes (e.g., Li-Fraumeni syndrome, Neurofibromatosis-1), but these estimates have not been confirmed in large-scale studies. Furthermore, no recommended germline testing protocols exist for RMS. We tested the hypothesis that germline mutation burden is greater than previously reported and present several new predisposition genes as potential drivers of pediatric RMS. We sequenced 59 cancer susceptibility genes in 213 children with RMS enrolled on one clinical trial (COG ARST0531), unselected for family history of cancer. Validation was performed with Sanger sequencing. Our analysis included determining the incidence of pathogenic variants in known RMS predisposition genes, followed by other cancer predisposition genes on our panel but not previously associated with RMS. In our cohort, 3.9% of unselected RMS cases harbor a pathogenic variant in a known predisposition gene (Table 1). Using VAAST, we next identified the top 10 genes possibly associated with

**CLINICAL RESEARCH: Clinical Molecular Genetics and Laboratory Correlates**

#2707 **Targeted RNA sequencing reveals thus far unknown diagnostically relevant fusion partners confirming its diagnostic potential.** Niroshan Nadarajah, Manja Meggendorfer, Torsten Haferlach, Wolfgang Kern, Claudia Haferlach. *Munich Leukemia Laboratory, Munich, Germany.*

Introduction: The genomic landscape of hematological malignancies has been resolved mainly based on whole genome and whole exome sequencing, primarily focusing on targetable gene mutations. In addition to mutations, gene fusions have also been identified as therapeutic targets, impressively shown e.g. for BCR-ABL1 and ETV6-PDGFRB. Even though fluorescence in situ hybridization (FISH) is the current gold standard in fusion detection, it is by concept limited to the selected genes it is applied to. In contrast, targeted RNA sequencing is a valuable hypothesis-free approach to discover all possible fusion junctions in a single reaction. Aim: Explore the value of targeted RNA sequencing in a routine diagnostic work up. Patients and Methods: We sequenced 134 cases in parallel to our routine diagnostics workflow using chromosom e banding analysis (CBA), FISH and real-time quantitative (RQ-PCR). Targeted RNA sequencing was performed on the NextSeq 500 using the TrueSight RNA Fusion panel (Illumina, San Diego, CA) consisting of 7690 probes covering 507 genes known to be involved in gene fusions. Analysis was performed with the RNA-Seq Alignment App v1.2.0 (BaseSpace Sequence Hub) using Star for Alignment and Manta for gene fusion calling with default parameters (Illumina, San Diego, CA). Results: In 127 of 134 (95%) cases the results of FISH, subsequently confirmed with RT-PCR were also picked up by RNA Seq. This included diagnostically highly relevant fusions like BCR-ABL1 (n = 8), KMT2A rearrangements (n = 7), PML-RARA (n = 2), NPM-PDGFRA (n = 2), and NPM-MDM2 (n = 1). In addition to observation of orthogonal results, we were able to identify novel rare gene fusions, which we subsequently confirmed by RQ-PCR. This included immediately targetable fusions like TNN1-PDGFRB and ETV6-TEL1, ETV6-FOX1, IRF2BP1-RARA, RARA-SE1. Conclusion: In the vast majority of instances targeted RNA sequencing confirmed results obtained by FISH/RT-PCR and in addition discovered novel rare gene fusions. Targetable genetic aberrations were identified, which were not identifiable by chromosome banding analysis but would now lead to more individualized treatment. 3) Thus, targeted RNA sequencing may be a valuable tool in routine diagnostics and for patients with rearrangements unresolved by standard techniques, also paving the way to precision medicine in a considerable number of patients.

#2708 **A custom gene expression panel for consensus molecular subtype classification of archival primary and metastatic colorectal cancers.** Ling-Yuh Huw, Robert Piskol, Felipe de Sosa e Melo, Doris Kim, Xueping Qu, Hartmut Koeppen, Mark Lackner, Garret Hampton, Omar Kabbarah, Rachel Tam. *Genentech, Inc., South San Francisco, CA.*

Stratification of Colorectal Cancer (CRC) into actionable molecular subtypes has tremendous clinical value. Recently, a consolidated classifier identified four molecularly distinct CRC subtypes (CMS1-4) that were associated with unique biology and clinical outcomes based on global transcriptional analysis of frozen tissues. Here, we developed and applied a novel CRC panel that is ideally suited for transcriptional classification of archival clinical samples. Findings from in silico analysis demonstrated that the 800 genes on our panel could accurately classify cancer samples from external public datasets into the correct CMS subtypes. We applied our panel in the analysis of a novel cohort of 312 formalin-fixed paraffin-embedded (FFPE) tissues from 205 patients, and were able to detect all 4 CMS subtypes in primary CRCs and in metastases. When we examined the CMS subtypes of primary tumors and matched metastases from 50 patients we found 70% of cases to be concordant, as were key biologies, such as WNT/MYC pathway activation in CMS2 and EMT features in tumors of the CMS4 subtype. This was confirmed by in situ hybridization (ISH) using the markers ASC2L for CMS2 and SPARC for CMS4, respectively. Discordance in the CMS subtypes between primary tumors and matched metastases was observed in 30% of cases and may reflect tumor heterogeneity. Our findings suggest that our CRC-focused panel many have clinical utility for CMS classification of FFPE samples, and point to potential risks of using CMS subtypes of primary tumors to inform clinical decision-making at the metastatic stage in a subset of patients.

#2709 **Evaluation of CD373 expression and binding of AG676E, an anti-body-drug conjugate (ADC) against CD373, on white blood cells (WBCs) collected from phase I non-Hodgkin lymphoma (NHL) patients.** Sher Karki,1 Hector Avina,1 Jacqueline Lackey,2 Ahmed Sawaas,2 Kerry J. Savage,2 Raymond Perez,2 Ranjana Advani,3 Jasmine Zain,2 Owen A. Connor,4 Sara Guilese- rian,1 Hui Zhao,1 Peng Yang,1 Karen Morrison,1 Leonard Reyno,1 Fernando Donate,4,1 Agensys Inc., an affiliate of Astellas Pharma, Santa Monica, CA;2 Columbia University Medical Center, New York, NY;3 British Columbia Cancer Center, British Columbia, Canada;4 University of Kansas, Kansas City, KS; Stanford University, Stanford, CA;1 City of Hope, Duarte, CA.

AGS67E is an antibody drug conjugate (ADC) against CD37 conjugated to monomethylauristatin E (MMAE). CD37 is expressed on normal WBCs, but is also highly expressed in NHL, CLL and AML. (Pereira et al., 2015). A phase I study is currently evaluating the safety, PK and anti-cancer activity of AGS67E with or without growth factor (GF) in subjects with relapsed/refractory NHL. To assess CD37 on WBCs, biopsy samples were collected at day 15, after dose 1, D5 and analyzed by flow cytometry. CD37 expression on subject tumor samples was also evaluated by immunohistochemistry (IHC). Our results demonstrated that CD37 was highly expressed in tumor samples and that AGS67E binds to WBCs causing down-regulation of CD37, achieving saturation of binding at 24 hours post-treatment (earliest time measured) or above 0.9 mg/kg, and reversibly depleted WBCs, with no significant difference of mutation frequency between primary tumors from patients with liver metastasis and those from other patients. Notably, four recurrently mutated genes (FBXW7, EDIL3, KCNK9 and PCDHGA7) were more highly expressed in the tumors associated with liver metastasis. Furthermore, in vitro analyses showed that EDIL3 and KCNK9 overexpression resulted in an enhanced cell migration and invasion, while CRISPR-mediated deletion of FBXW7 and PCDHGA7 exhibited enhanced migratory and invasive properties as well. For clinical relevance, highly expressed EDIL3 and KCNK9 was significantly associated with liver metastasis, whereas the expression of FBXW7 and PCDHGA7 negatively correlated with it in our cohorts. Pathway enrichment analysis also indicated a role for cell adhesion signaling in liver metastasis of CRC patients. Conclusion: Our study identified candidate genes, which might respond to the initiation of metastasis, exclusively mutated in tumors associated with liver metastasis. These findings also provided potential therapeutic targets for personalized treatment.

#2711 Whole exome sequencing analyses of colorectal cancers associated with liver metastasis. Yanlei Ma,1 Wenhao Weng,2 Yongzhi Yang,1 Qing Wei,3 Sanjun Cai.1 1Fudan University Shanghai Cancer Center, Shanghai, China; 2Tongji University, Shanghai, China; 3Shanghai Tenth People’s Hospital, Shanghai, China.

Purpose: Liver metastasis is one of the major causes of death in colorectal cancer (CRC) patients. But the process is still unknown. Here, we analyzed genetic differences between primary tumors associated with liver metastasis and those without liver metastasis and predicted clinical significance. Experimental design: Eight primary tumors associated with liver metastasis and twelve without liver metastasis of CRC were analyzed by whole-exome sequencing. The functional characterisation for the role of metastasis-related genes was investigated through in vitro migration and invasion assays. For clinical relevance, TMAs were used for immunohistochemistry assay. Results: The mutation spectrum was similar to that of previous studies. TP53, APC and KRAS were the three most frequently mutated genes, with no significant difference of mutation frequency between primary tumors from patients with liver metastasis and those from other patients. Notably, four recurrently mutated genes (FBXW7, EDIL3, KCNK9 and PCDHGA7) were more highly expressed in the tumors associated with liver metastasis. Furthermore, in vitro analyses showed that EDIL3 and KCNK9 overexpression resulted in enhanced cell migration and invasion, while CRISPR-mediated deletion of FBXW7 and PCDHGA7 exhibited enhanced migratory and invasive properties as well. For clinical relevance, highly expressed EDIL3 and KCNK9 was significantly associated with liver metastasis, whereas the expression of FBXW7 and PCDHGA7 negatively correlated with it in our cohorts. Pathway enrichment analysis also indicated a role for cell adhesion signaling in liver metastasis of CRC patients. Conclusion: Our study identified candidate genes, which might respond to the initiation of metastasis, exclusively mutated in tumors associated with liver metastasis. These findings also provided potential therapeutic targets for personalized treatment.

#2710 Molecular and clinical characteristics of IGHV4-34 expressing cells and variant HCL. Evgeny Arons, Katherine Potocka, Maryalice Stetler-Stevenson, Hong Zhou, Mark Raffeld, Mark Sokolsky, Sarah Davies, Robert J. Kreitman. National Cancer Inst, Bethesda, MD.

Classic HCL (HCLc) is a malignant disorder with distinctive immunophenotype, typically expressing CD20, CD22, CD5, CD21c, CD103, CD123, annexin A1, tartrate-resistant acid phosphatase (TRAP), and Braf V600E mutation. Purine analog therapy is highly effective with complete remission rates of approximately 85% in first line. HCL variant (HCLv) is recognized as a distinct entity, lacking CD25 and usually lacking annexin A1, tartrate-resistant acid phosphatase expression, CD123, and also lacks the Braf V600E mutation. Patients respond poorly to purine analogs, with partial response in less than 50% and relatively poor overall survival from diagnosis. HCLc expressing B-cell receptor (BCR) with the IGHV4-34 immunoglobulin rearrangement has a poor prognosis like HCLv, whether immunophenotypically consistent with HCLv or HLC, and also lacks Braf V600E. We previously reported a series of 17 patients expressing IGHV4-34, immunophenotypically resembling HCLv in 7 and HLC in 10 cases. Using routine deep sequencing of patient samples for immunoglobulin rearrangements, we have been able to accumulate 42 IGHV4-34 expressing cases including 23 classic HCL and 19 HCLv. Six (26%) of 23 HCLc vs 12 (63%) of 19 HCLv were truly unmaturated, with VH gene germline identity (GI) 100%. Eleven (48%) of 23 HCLc and 7 (37%) of 19 HCLv were borderline-mutated (97<GI<100), and 6 (26%) of 23 HCLc were significantly mutated (97<GI). There was no significant difference between the 5 groups with respect to either IGHD or IGJH genes usage, or CDR3 length. However, we found a significant restriction of IGHD genes between 12 HCLc truly unmaturated and 6 HCLc truly unmaturated cases, in that there was no overlap of any IGHD genes between these 2 groups. Of 28 cases tested for Braf V600E, only 5 were positive, all HCLc with GI 93.18-97.49. The 23 Braf wild-type (WT) cases included one with only one with GI = 93.64%, but GI was >98.7% for the remaining 22 cases (p<0.0001). Of the 23 Braf WT cases, 9 patients died of disease, 9 had active disease, and only 2 are in remission. Patients commonly had highly aggressive courses, with infiltration of HCL/HCLv into spinal cord and cranial nerves, cardiac muscle, lungs, and cervical lymph nodes. Complete remission was achieved only through either recombinant immununotoxin therapy of combination purine analog and rituximab, but not by purine analogs alone. Additional clinical and genetic studies are ongoing to better characterize this poor-prognosis syndrome and determine if therapy can be optimized.

Introduction: Gastric cancer (GC) in young adults comprises a small part of this disease population having the distinctive clinicopathological features, such as diffuse tumor growth and peritoneal dissemination. Genetic alterations underlying these features and the development of cancer in early ages remain unclear. Comprehensive molecular analyses by TCGA have suggested 4 molecular subtyping of GC and revealed enrichment of CLDN18-ARHGAP fusion gene in Genomically stable (GS) type which mainly included diffuse type. In this study, we examined the relationship between CLDN18-ARHGAP and clinicopathological features of GC affecting young adults. Method: Patients (pts) diagnosed at the age younger than 40 years-old were defined as the GC in young adults, and underwent surgery at our institute between Jan 2006 and Dec 2015 were enrolled to this study. Tissue microarrays were prepared from formalin-fixed and paraffin-embedded surgical specimen. DNA probes for CLDN18, ARHGAP-26 and -6 were created using bacterial artificial chromosomes and fusion genes were detected by a FISH method. Results: Out of 155 surgical specimens available for analysis, we found CLDN18-ARHGAP fusion gene in 21 pts (13.5%). Among these, 19 cases were CLDN18-ARHGAP26 fusion and the others were CLDN18-ARHGAP6. Cancers with CLDN18-ARHGAP fusion genes were all diagnosed as diffuse type and included more large-sized, multiple lymph node metastases and advanced stages tumors (table 1). The proportion of detected fusion genes in this study was almost equivalent to that of GS type in TCGA cohort. Analysis of variations of breakpoint is planned to confirm by RT-PCR and sequencing. Additionally, we are going to study the association of CLDN18-ARHGAP with RHOA or CDH1. Conclusion: CLDN18-ARHGAP fusion gene might account for the characteristic of a part of diffuse type GC. Further comprehensive molecular analysis comparing to general GC population is warranted.
Coverage (ods): Sequencing was performed on DNA extracted from the primary tumors. In recurrent cases, the mutational landscape of recurrent and non-recurrent tumor samples is compared to that of HPV-negative HNSCC. Among the non-recurrent cases (p = 0.05), the ratio of nonsynonymous to synonymous variants among primary tumors of recurrent cases was 2 vs 5 among the non-recurrent cases (p = 0.224). Among primary tumors of recurrent cases, 17% of variants involved indels, splice site, and nonsense mutations vs 14% of variants among the non-recurrent cases. The mean (SD) number of tumor suppressor mutations per tumor was 1.2 (1.3) among recurrent cases vs 1.0 (1.0) among non-recurrent cases (p = 0.81). Interestingly, the mean (SD) number of mutations in DNA damage response (DDR) genes among the primary tumors of recurrent cases was 2.7 (2.4) compared to 0.7 (1.2) mutations per tumor among non-recurrent cases (p = 0.07). Conclusion: We observed a greater mutational burden among the primary tumors of recurrent HPV-associated HNSCC compared to non-recurrent HNSCC. Moreover, among the primary tumors of recurrent cases, there were more mutations in DNA damage response genes coupled and relatively fewer deleterious mutations compared to non-recurrent cases. Dysregulation of DDR genes may select for advantageous mutations via genomic instability. Alternatively, gain of function of DDR genes may promote treatment resistance. Future work aims to further characterize mutational differences between the primary tumors of HPV-associated recurrent and non-recurrent HNSCC and evaluate mechanisms promoting treatment resistance.

**#2714 Analytical validation of whole genome and transcriptome sequencing of patient derived tumors: clinical application of whole genome sequencing for reporting targetable variants in cancer.** Kazimierz O. Wrzeszczynski, Avinash Abhyankar, Vanessa Felice, Esra Dikoglu, Lukasz Kozon, Nicolas Robine, Anne-Katrin Emde, Olca Basturk, Umesh K. Bhanot, Alex Kent, Manisha Mansukhani, Shalini Bhagat, New York Genome Center, New York, NY; Memorial Sloan Kettering Cancer Center, New York, NY; Columbia University Medical Center, New York, NY.

Next Generation DNA Sequencing (NGS) technologies are currently being applied in the clinical setting for the treatment of disease. The goal is to use high-throughput sequencing to identify specific variants within each tumor and recommend personalized treatment approaches or clinical trials tailored to the individual’s disease and genomic profile. These assays are comprised of either predefined sequencing panels, where a handpicked set of clinically significant genes are examined within each patient, or are cancer type specific targeted sequencing protocols or whole exome platforms covering only the coding region of the patient’s genome. Whole genome sequencing allows hypothesis-free interrogation of both coding and non-coding regions of the genome revealing more potential therapeutic options than examining a small set of genes or genomic loci. The protocol eliminates sequence capture related bias observed in whole exome or panel sequencing. The New York Genome Center therefore has performed analytical validation of whole genome and transcriptome sequencing (WGT) of patient derived tumors to established normal control purposes. We have devised a clinical reporting strategy of significant driver and therapeutic associated mutations. Many clinical NGS guidelines are directed toward targeted panel or exome sequencing validation. Here, we expanded on New York State’s Department of Health NGS guidelines developing them into novel standards applicable to WGTs for the purposes of clinical test validation. We first sequenced a virtual tumor at very high coverage (30X) and downsampled to determine the optimum depth of sequencing necessary for high confidence somatic variant calling across the entire genome. We then validated whole genome sequencing laboratory protocols for DNA and RNA sequencing on a total of 50 specimens derived from fresh frozen (FF) and formalin-fixed paraffin-embedded (FFPE) tumor samples. We performed a series of experiments to assess the accuracy and reliability of the results based on our laboratory and bioinformatics protocols. We performed our validation on the 50 tumor normal pairs, a subset of which had known genomic profiles. Comparisons were also made for variant calling concordance and reproducibility between matched FF and FFPE tumors. Here, we present our validation results and clinical WGTs standards for depth of sequencing, reproducibility, sensitivity, and present limit of detection analysis for SNV calling, copy number identification and structural variants. RNA sequencing is performed to call fusion or exon skipping events and to confirm the DNA variants. The New York Genome Center WTGS clinical assay is intended to provide a more comprehensive patient variant discovery approach suitable for directed oncological therapeutic applications.

**#2715 Precision-designed, rapid and low-cost single molecule detection of mutations from circulating tumor DNA.** Christina M. Wood-Bouwens, Christine Handy, Billy Lau, Hanlee Ji.

Automated ddPCR is a technique for quantifying DNA copy number using a digital PCR method. Single molecule detection was performed using ddPCR for the detection of circulating tumor DNA (ctDNA) mutations. We have developed a novel molecular assay that utilizes single color digital droplet PCR (ddPCR) to both genotype and quantify the number of tumor derived DNA molecules in a given sample. Our assay routinely detects as few as three mutant DNA molecules per a reaction volume, can be tested efficiently for fewer than ten dollars per reaction, and generates usable mutation information within four hours. Additionally, the assay can be rapidly configured to detect different sets of genes. By demonstrating the single molecule sensitivity and specificity for clinically relevant hotspot mutations, we have validated the assay using multiple input sources including high quality cell line DNA, formalin-fixed paraffin embedded tissue (FFPET) DNA, and ctDNA. Our ddPCR assay utilizes a novel primer design that is not rely on fluorescent probes. The overall simplicity of assay design enables one to detect nearly any coding mutation; practically, this means that any cancer or DNA sample can be tested efficiently. We have created customized precision mutation assays for two individual cancer patients. After extracting ctDNA from 500µL of plasma we prepare a controlled mixed wild type and mutant standard curves which contain between 150-3 detectable mutant molecules of interest per reac-
understand pathobiology of this lymphoma. We used the AccuCyte®-pathogenesis of this lymphoma have been difficult to study because HRSCells derived from germinal center B cells. The geneticalterations involved in the frequently occurring lymphomas and is marked by Hodgkin and Reed-Sternberg cells. The assignment ofHRSCells to the diagnostic workup has been difficult to study because HRSCells are rare and are surrounded by robust, non-neoplastic infiltrate, therefore they frequently represent less than 0.1% of cells within involved lymph nodes. Consequently, methods that isolate these rare cells are required to understand pathobiology of this lymphoma. We used the AccuCyte®-CyteFinder system (RareCyte) to develop a method for detection and isolation ofHRS cells. Methods: A 6-parameter immunofluorescence assay was designed to identify HRS cells that included HRS markers (CD40, CD30, CD15), CD3, combined CD20/CD14 and a cell membrane permeability viability dye. The assay was tested using the KMH2 Hodgkin lymphoma cell line spiked into PBMC and transferred to well slides for imaging by CyteFinder. This instrument utilizes 6-color scanning microscopy coupled with predefined algorithms to identify rare cell populations. The assay was then applied to a frozen fine needle aspirate (FNA) sample taken from the lymph node of a patient with histologically confirmed CHL. The FNA sample was thawed, prepared into a suspension, stained and analyzed as above. Cells identified with HRS phenotype were individually retrieved using the integrated CytePicker module. PCR of regions of the immunoglobulin heavy chain (IGH) was performed on single HRS cells (GeneScribe) to assess clonality. Results: Of ~200 KMH2 cells spiked into blood, the assay identified 180 cells (90%) with the correct HRS phenotype. HRS phenotype cells were identified in the patient lymph node FNA sample. Two individual cells analyzed by IGH framework region PCR demonstrated identical size PCR products, indicating clonality of the B cell receptor rearrangement. Concurrently, a multi-parametric assay was successfully used for identifying rare HRS cells with the CyteFinder system. Cells with HRS phenotype in a lymph node FNA sample were demonstrated to have clonal IGH rearrangements, demonstrating that actual HRS cells were identified. This method may be a useful tool for the diagnosis of CHL by identification of rare HRS cells from FNA specimens, as well as to investigate the molecular genomics of CHL.

Identification of three distinct molecular subtypes in meningioma samples using microarrays for copy-number variants. Josel Srovnal,¹ Vladi-mir Balik,⁷ Magdalena Houdova Megova,¹ Jiri Ehrmann,⁷ Miroslav Vaverka,¹ Lumin Hrabalek,² Radek Trojancé,¹ Katerina Stalova,¹ Jana Vrbkova,¹ Marian Hajduck.¹ ¹Palacky University, Olomouc, Czech Republic; ²University of Groningen, Groningen, Netherlands; ³University of Groningen, Groningen, Netherlands.

Background: Meningioma represents one of the most common intracranial tumors. They are generally thought to progress from low to high-grade lesions. However, the molecular mechanisms underlying their pathogenesis remain still uncertain. Identification of meningioma molecular subgroups may have significantpotential to improve clinical management, through molecular disease risk stratification strategies and the identification of patients who could benefit from targeted molecular therapeutics. Methods and patients: Formalin-fixed paraffin embedded tumor samples were obtained from 45 meningioma patients and 5 healthy controls (dura mater). Comprehensive clinical-pathological data were mined. There were 15 males and 30 females; median age was 54 years, range 28 – 99 years. Total DNA was purified from FFPE samples after pathological verification using proteinase K treatment followed by QiAmp DNA FFPE Tissue Kit (Qiagen). Microarray analysis was performed using the OncoScan FFPE Assay Kit (Affymetrix), raw data were obtained using Chromosome Analysis Suite (Affymetrix) in default manner. The data were processed using “R” software, version 3.2.3. Results: Our results confirm that chromosome 22 deletion and del(1p) are the most common (55%, resp. 47% of cases) deletions in meningioma. We revealed chromosomal gains not as rare as was published previously while the dup(3p) was present in 31% of cases. Three meningioma molecular patterns were identified based on CNV profiling - normal-like profile, deletion profile and complex profile. Chromosome 22 deletion, del(1p) and dup(3p) are the most common CNV (55%, resp. 31% of cases) in meningioma. Potential CNV changes in recurrent meningioma were identified. However, it will require further validation using FISH. Acknowledgment: This work was financially supported by Ministry of Health of the Czech Republic, grant nr. 15-29021A, IGA UP LF 2016_010 and NPU LO1304.

A multi-parameter assay for the detection of rare malignant cells in classical Hodgkin lymphoma. Lance U’Ren,¹ David Wu,² Jonathan R. Fromm,³ Jackie Stiwell,⁴ Eric Kaldjian¹ ¹RareCyte Inc, Seattle, WA; ²University of Washington, Seattle, WA.

Background: Classical Hodgkin Lymphoma (CHL) ranks among the most frequently occurring lymphomas and is marked by Hodgkin and Reed-Sternberg (HRS) cells, frequently multi-nucleated neoplastic cells that are derived from germinal center B cells. The genetic alterations involved in the pathogenesis of CHL have been difficult to study because HRS cells are rare and are surrounded by robust, non-neoplastic infiltrate, therefore they frequently represent less than 0.1% of cells within involved lymph nodes. Consequently, methods that isolate these rare cells are required to understand pathobiology of this lymphoma. We used the AccuCyte®-CyteFinder system (RareCyte) to develop a method for detection and isolation of HRS cells from FNA specimens, as well as to investigate the molecular genomics of HRS cells. The assignment of HRS cells to the diagnostic workup has been difficult to study because HRS cells are rare and are surrounded by robust, non-neoplastic infiltrate, therefore they frequently represent less than 0.1% of cells within involved lymph nodes. Consequently, methods that isolate these rare cells are required to understand pathobiology of this lymphoma. We used the AccuCyte®-CyteFinder system (RareCyte) to develop a method for detection and isolation of HRS cells from FNA specimens, as well as to investigate the molecular genomics of HRS cells.

Purpose: To evaluate treatment response following the Multidisciplinary Molecular Tumor Board (MTB) decisions which focused on EGFR exon 20 mutations in lung adenocarcinoma. Methods: Molecular studies were routinely performed using the Ion Torrent sequencing platform for histologically or cytologically diagnosed lung adenocarcinoma. Since October 2014 patients with rare (prevalence <1%) or combinations of rare mutations were discussed at the MTB of the University Medical Center Groningen. More common, known sensitive EGFR, BRAF V600E, as well as KRAS, and PIK3CA mutations were excluded. To predict the best therapy for a subset of patients with EGFR exon 20 insertion mutations the literature is reviewed and molecular models were built using SWISS-MODEL, is used to predict protein tertiary structure (https://swissmodel.expasy.org/interactive/wcurbt/models/). Summary of data: Over a period of 2 years 1389 samples were tested. A total of 170 (12.2%) rare mutations were detected in lung cancer. Among these rare mutations we observed 16 EGFR exon 20 insertions and other mutations like e.g. p.T790M, p.D761N, p.D770delinsG, p.S768_D770dup, p.V769_D770insSFL, p.N771_H773dup, p.T790S. Using an in silico modeling of protein responses with TKI were predicted to be likely in EGFR T790M mutations and p.S766_V769delinsIL, but not in p.D770delinsGY, p.S768_D770dup, p.V769_D770insSFL, and p.N771_H773dup mutations. Eight patients with an exon 20 mutation were treated with an EGFR TKI. One patient (p.D761N) had a partial response on erlotinib 300mg daily. On afatinib monotherapy 2 out of 3 pts had stable disease (PFS 3-11 months). On afatinib/ cetuximab treatment 1 out of 2 pts (p.D770delinsGY) had a partial response and the other patient had stable disease (p.S768_D770dup) (PFS 11 and 4 months, resp.). Two evaluable patients were treated with osimertinib: the first patient initially progressed on afatinib (p.V769_D770insSFL). The protein model predicted no response, since we predicted hindrance of osimertinib. The model predicted no response on osimertinib in the second patient as well, and during treatment a stable disease for 4 months was observed (p.N771_H773dup). This molecular framework from the weekly MTB meeting was delivered within 2 weeks to the treating physician. Feedback on treatment outcome helped to further improve treatment predictions. Conclusion: The Molecular Tumor Board is an effective multidisciplinary team to discuss rare mutations. Our pilot data show that the evaluation of the use and effectiveness of a theoretet

Background: Molecular diagnosis has become a standard of care in many cancers and BRAF mutations analysis in FFPE tumor specimens is needed to initiate personalized therapy using BRAF tyrosine kinase inhibitor (vemurafenib, dabrafenib) in BRAF-mutated metastatic melanoma. Accelerated BRAF mutation analysis is achievable using CE-IVD fully automated (FA) PCR-based platform (Idylla, Biocartis) and enables the determination of BRAF mutational status in less than 2 hours including sample preparation and proved suitable for routine molecular diagnosis of metastatic melanoma (Harlé et al. PloS ONE 11(4); e0153576).

Patients and methods: MELFAST trial is an observational monocentric study aiming at evaluating the clinical impact of reducing BRAF status determination delay in patients with metastatic melanoma. 40 patients (pts) were included in MELFAST trial, 31 pts were included retrospectively with BRAF mutation analysis being performed according to standard operating procedures (SOP) using conventional PCR, 10 pts were included prospectively with BRAF mutation analysis being performed using FA-PCR. Results: Among the 40 pts included, 3 pts were excluded because of violation of inclusion criteria. 37 pts were analyzed (29 pts with retrospective inclusion and 8 pts with prospective inclusion). BRAF mutational status was not known at the time of treatment decision in 11/29 (38%) pts included retrospectively and in all the pts included prospectively. Using FA-PCR enables to provide BRAF mutational status within the same day for most of the samples and the reporting delay was significantly reduced using FA-PCR as compared to SOP (0 vs 7 days, p<0.001) and the delay of initiation of anti-BRAF therapy was substantially reduced (16 vs 26 days, p=0.035). This reduced delay was found to be consistent with that observed when BRAF mutational status had been anticipated and was already available at the time of treatment line decision (20 days, p=0.798). Conclusion: As compared to conventional SOP, using FA-PCR accelerates BRAF mutation analysis reporting and significantly reduces the delay before initiation of personalized therapy in pts with metastatic melanoma. This warrants the investigation of the impact on the patients outcome i.e. progression free and overall survival.

Association between five common polymorphisms of plasminogen activator inhibitor-1 gene and colorectal cancer risk in Korean population.

Jisu Oh. CHA Medical Center, CHA University, Seongnam, Republic of Korea.

Background: The plasminogen activator inhibitor-1 (PAI-1) is expressed in many cancer cell types and plays the modulation of cancer growth, invasion, and angiogenesis. The present study investigated the association between five polymorphisms in PAI-1 gene and colorectal cancer (CRC) risk. Material and Methods: Genotyping of five PAI-1 polymorphisms (-844G>A [rs2237631], -675 4G/5G [rs1799899], +3G/A [rs6092], +978S/A [rs2227694], and +11053G>T [rs7242]) was assessed by polymerase chain reaction-restriction fragment length polymorphism (PCR-RFLP) in 459 CRC cases and 416 controls. Results: The increased risk of CRC was found for the PAI-1-675 4G/5G polymorphism compared with 4G/4G (AOR=1.556; 95% CI, 1.021 to 2.391, p=0.044). In contrast, the PAI-1 11053 polymorphism, we found a reduced risk of CRC for GG genotype (AOR=0.620; 95% CI, 0.413 to 0.932, p=0.022) than TT genotype, as well as for recessive carriers (TT > TG vs. GG, AOR=0.662; 95% CI, 0.469 to 0.933, p=0.019). For patients with age < 61 years (AOR= 1.942; 95% CI, 1.247 to 3.024, p=0.003), without HTN (AOR= 1.694; 95% CI, 1.093 to 2.627, p=0.019), without DM (AOR= 1.464; 95% CI, 1.051 to 2.039, p=0.024), with folate ≥ 3.8ng/mL (AOR= 1.449; 95% CI, 1.030 to 2.039, p=0.033), with homocysteine ≤ 13.2umol/L (AOR= 1.630; 95% CI, 1.163 to 2.285, p=0.005), PAI-1 675 4G/5G polymorphism was shown increased risk of CRC. For patients with age ≥ 61 years (AOR= 1.942; 95% CI, 1.247 to 3.024, p=0.003), with homocysteine ≤ 13.2umol/L (AOR= 1.630; 95% CI, 1.163 to 2.285, p=0.005), PAI-1 11053 GG genotype was shown increased risk of CRC. For patients with age < 61 years (AOR= 1.942; 95% CI, 1.247 to 3.024, p=0.003), however, PAI-1 11053 GG genotype was related to protective effect about CRC. In multivariate Cox proportional analysis, compared with the +43 AA genotype, +43 AA genotype was associated with poor OS (HR=8.551; 95% CI, 1.833 to 39.89; p=0.006) and DFS (HR=12.71; 95% CI, 1.30 to 121.3; p=0.027). Moreover, OS (HR=9.330; 95% CI, 2.043 to 42.61, p=0.004) and DFS (HR=11.97; 95% CI, 1.433 to 100; p=0.022) were shown decreased in recessive genotype (GG+GA vs. AA). Conclusion: Our results support the relationship between CRC susceptibility and PAI-1 gene polymorphisms. Our study suggests that the -675 4G/5G genotype is associated with an increasing CRC development but +11053 GG genotype is vice versa. Additionally, we found evidence that the +43 AA genotype may be related to unfavorable CRC prognosis. This is the first study to identify an association between five PAI-1 polymorphisms and CRC susceptibility in the world. Further research into the association between fibrinoly sis and cancer could lead to the discovery of novel drug targets for cancer prevention or treatment.
mutations (4/9) were identified: a deletion (c.1044delG); one nonsense mutation (c.3406G>T), and a missense mutation (c.1488C>A). None of the mutations had been previously reported. Conclusions: NGS of PTCH1 gene in 9 Mexican patients with clinical criteria for NBCCS allowed the identification of four novel pathogenic mutations (44%) frequently affecting PTCH1 and SUFU gene in our population. The perspectives of the current study lie in the molecular testing of other genes involved in NBCCS (PTCH2, SUFU), and other mechanisms (whole gene deletion), as well as the review of possible phenotype-genotype correlations.

**#2723** MET exon 14 skipping mutations in advanced non-small cell lung cancer (NSCLC) are not associated with MET amplification and overexpression. Ana Gimenez-Capitan, Cristina Teixido, Cristina Aguado, Sonia Rodriguez, Jordi Bertran-Alamillo, Josep Castellví, Zaira Yeste, Ana Perez, Rafael Rosell, Miguel Angel Molina-Vila, Paua Oncology, Barcelona, Spain; Institut Català d’Oncologia, Badalona, Spain. Background: Activating alterations of the mesenchymal epithelial transition (MET) oncogene in NSCLC are potentially actionable with targetted MET inhibitors. MET exon 14 skipping mutations have been described in 3% of patients (p) in NSCLC. Fluorescent in situ hybridization (FISH) and immunohistochemistry (IHC) are currently used for detecting MET amplification and overexpression, respectively, but are not useful to detect MET splicing variants. On the other hand, the reverse transcription–polymerase chain reaction (RT-PCR) technique has the potential to detect this actionable alteration. Methods: We designed and validated a custom set of 5’ and 3’ primers to detect the MET exon 14 splicing variant by RT-PCR. RNA isolation from FFPE samples was performed with Roche High Pure FFPE RNA isolation kit and M-MLV Reverse Transcriptase enzyme was used in the RT-PCR. A panel of cell lines was initially employed to assess the performance of the technique. Subsequently, a total of 232 formalin-fixed paraffin-embedded (FFPE) samples from advanced NSCLC patients were analyzed. Of them, 15 were positive by RT-PCR (n=209) for the MET exon 14 variant. The bands corresponding to the splicing variant were submitted to Sanger sequencing. Results were compared with FISH (Zytovision Dual Color probe Z-2087-200) and IHC (Ventana CONFIRM anti-total c-MET). Results: A total of 232 EGFR-wt advanced NSCLC p were analyzed by IHC and 42 (18.1%) were considered as positive (cut-off 3 ≥ 50%). Regarding FISH, MET amplification was detected in 13 out of 58 p (22.4%) evaluable while the MET exon 14 skipping variant was detected in 15 (7.2%) out of 209 p. Regarding RT-PCR, MET amplification was detected in 13 out of 58 p (22.4%) evaluable while the MET exon 14 skipping variant was detected in 15 (7.2%) out of 209 p. Conclusions: MET exon 14 skipping variant was detected in 15 (7.2%) out of 209 p. FISH, MET amplification was detected in 13 out of 58 p (22.4%) evaluable while the MET exon 14 skipping variant was detected in 15 (7.2%) out of 209 p.

**#2724** Brush biopsy miRNA based OSCC detection and diagnosis. Guy R. Adam, Joel L. Schwartz, Yali Zhou, Jessica L. Tang, Michael Markiewicz, Gina D. Jefferson, Joel Epstein, Antonio Kolokythas, University of Illinois at Chicago, Chicago, IL; Cedars-Sinai Medical Center, Los Angeles, CA; University of Rochester Medical Center, Chicago, IL. RNA based diagnosis and prognosis of squamous cell carcinoma has been slow to come to the clinic. Improvements in RNA measurement, statistical evaluation, and sample preservation still have not made these methods accurate enough to allow truly independent external validation. We propose that in the case of squamous cell carcinoma of the oral cavity that a chief source of variability is sample dissection which leads to variable amounts of stroma mixed in with tumor epithelium. We have used brush biopsy of suspicious lesions to characterize miRNA expression in OSCC epithelium. We used it to show an 11 miRNA signature for OSCC that can differentiate OSCC in both smokers and never smokers from normal tissue. We will report on efforts to optimize this classifier to distinguish OSCC from benign oral lesions such as lichen planus and leukoplakia that can be mistaken for OSCC. We also provide evidence that body fluid samples show similar changes in RNAs with OSCC that are seen in brush biopsy samples -suggesting much of the RNA is coming from the same source tumor epithelium. Finally, using a variation of mirPath designed to eliminate false positive, we have identified the neurotrophin signaling pathway as deregulated in most OSCC epithelium, and for the first time highlight the miRNAs that may control this pathway in OSCC, mir-486-5p, mir-7-5p, mir-146-5p, mir-101-3p, mir-18b-5p, mir-10b-5p, mir-21-5p, mir-20b-5p, mir-126-3p and mir-31-3p.

**#2725** Circulating CD9-GFAP-survivin exosomes during active specific immunotherapy, a potential biomarker for glioma. Michael J. Ciesielski, Phillip Galbo, Sheila Figel, Cheryl Frank, Jingxin Qiu, Robert A. Fenstermaker, Roswell Park Cancer Inst., Buffalo, NY. Background: We evaluated circulating exosomes isolated from the serum of glioma patients in a large clinical trial of an anti-survivin vaccine (SurVaxM). Exosomes are mesenchymal bodies with potential mechanisms for cell–cell communication. Identifying circulating exosomes from cancer patients as potential indicators of disease status and response to therapy is of interest. The inhibitor of apoptosis protein (IAP) survivin (SVN) promotes cancer cell proliferation and resistance to chemotherapy. In glioma, survivin is often over expressed in many cancer types and is a malignant glioma and is a potential target for active immunotherapy. In the above mentioned clinical trial, five patients experienced early tumor progression with a mean of 2.8 months (1.9-5.4 months) from study entry, while three patients had either late (20.5-22.5 months) or no tumor progression (no evident disease at 48 months in one patient). Methods: To determine whether changes in CD9+/GFAP+/SVN+ exosomes correlated with disease progression, patient serum was evaluated prior to treatment (study entry), 8-10 weeks after initial vaccination, and at the time of MRI-defined tumor progression. By employing ImageStream flow cytomtery technology we were able to analyze multiple markers on individual exosomes, identifying specific populations of survivin+ exosomes which co-expressed other tumor markers. Results: The levels of CD9+/GFAP+ +, CD9+/SVN+ +, and CD9+/GFAP+/SVN+ + exosomes were significantly increased in patients. Serum from three patients who experienced the longest progression-free intervals, showed 98-99% decreases in SVN+ exosomes after treatment with SurVaxM, and maintained similarly low exosome levels over several months. Five early progressing patients experienced a detectable persistence of, or increase in SVN+ exosomes at 9 weeks following initial vaccination. One patient had rising SVN+ exosomes detectable 16 weeks prior to the discovery of tumor progression by brain MRI scan. One patient with no tumor progression sustained a 99% reduction in serum SVN+ exosomes which was sustained over 48+ months. Conclusion: This study demonstrates that increased numbers of CD9+/GFAP+/SVN+ specific exosomes appear to be associated with early tumor progression in recurrent malignant glioma patients. Larger studies are needed to determine whether the correlation between SVN+ exosome levels and disease progression is specific to SurVaxM treatment, and whether rises in SVN+ levels are predictive of generalized glioma progression. Our study suggests that levels of circulating SVN+ exosomes may be altered during anti-survivin immunotherapy and could serve as a potential biomarker for clinical trials and tumor monitoring.

**#2726** Guidance by molecular selection improves the outcome of early phase treatment for gynecological (GYN) cancers. Rowan E. Miller, Michael John Devlin, Nicholas Brown, Kin Woo, Tami Grunewald, Arran Speirs, Miriam Mitchison, Michelle Lockey, Mary McCormack, Jonathan Ledermann, Martin Forster, Tim Meyer, Rebecca Kristeleit. NHR Clinical Research Facility, University College London Hospitals, London, United Kingdom; University College London Hospitals, London, United Kingdom. Background: Patients (pts) with advanced gynecological (GYN) cancers have limited therapeutic options and the prognosis is poor. Early phase trials may be a suitable option for pts with good performance status. Increasingly, molecular characterisation guides pt selection for early phase trials. We sought to determine the outcome of GYN pts treated in a phase 1 unit and examined the role of molecular selection to inform therapeutic decision making. Methods: Medical records of all pts with a GYN malignancy treated within an early phase trial between 2010 and 2016 were reviewed. Data comprising patient and tumor characteristics, prior treatment, trial therapy and outcome were analysed. Results: 81 pts with a median age of 60 years (range 20-75) were included. 60/81 pts had a platinum resistant ovarian (OC, 54), endometrial (EC, 15) or cervical/vulval (CC, 12) cancer. The median number of prior therapies for advanced disease was 3 (range 1-6). 9 pts (11%) entered a second and one a third phase 1 study on disease progression. Next Generation Sequencing (NGS) using a targeted panel was performed in 32 pts (40%) with an actionable mutation identified in 9 including: KRAS (3pts), PIK3CA (2pts) and EGFR (2pts). Germline BRCA (gBRCA) testing was performed in 35 OC pts (65%) with 24 gBRCA mutations identified. Pts were allocated, in order of priority, where available, to (1) a trial selected on the basis of NGS or gBRCA (‘genomic 35%), (2) a ‘tumor specific’ cohort within an early phase trial (15%) or (3) a...
"generic" study (51%). For the whole cohort there was an overall response rate (ORR) of 18% with 41% stable disease (SD) and median progression free survival (PFS) and overall survival (OS) of 13 and 46 weeks respectively. Outcomes were best for pts in the genomic group. Both PFS and OS were significantly longer with genomic selection (p < 0.01 for both, Mantel-cox test) with median PFS of 29.7, 14.2, 18.0 weeks and OS of 84.1, 69.7, 33.6 weeks for genomics, tumor specific and generic studies respectively. The ORR was also greatest for the genomic cohort (32%) compared to the tumour specific (7%) and generic (11%) groups. Within the heavily pre-treated EC and CC cohorts there was an OS of 30 and 42 weeks respectively. 24% of EC pts had an ORR with a further 24% with stable disease (SD). There was only one response (9%) in the CC cohort, however SD was seen in 64%. The OS for the CC was 35 weeks with an ORR of 20% and 46% SD. Conclusions: Early phase trials represent a good option for pts with advanced GYN malignancies. Whilst applicable to all GYN cancers, this is particularly relevant for EC and CC pts as standard treatment options are limited. For OC patients (median 3 prior lines of chemotherapy in this cohort) where standard treatment options exist, early access to phase 1 genomic trials may result in improved response rates and allow for further standard options to be given subsequently, NGS is feasible in real time and may have a positive impact on outcome.

#2727 Clinical significance of PTEN in UTUC, Liang-Chen Li,1 Hung-Ying Chiang,1 Ying-Tzu Chen,2 See-Tong Pang,2 Wen Hui Weng1.1, National Taiwan University of Technology, Taipei, Taiwan; 2Chang Gung Medical Foundation, Taoyuan, Taiwan.

Upper tract urothelial carcinoma (UTUC) is a rare malignancy accounts for about 5% of all urothelial tumours. The cancer cells start in the layer of tissue urothelium, and found in the renal pelvis, renal calyces or ureters. When compare the UTUC to the bladder urothelial carcinoma, the pathological and clinical findings are often look and act alike. Previous studies indicated that deletion of phosphatase and tensin homologue (PTEN) gene is common to be found in bladder cancer. As known tumor suppressor gene PTEN is located on chromosome ten and considered as an important negative regulator for the PI3/Akt signaling pathway to promote cell proliferation and inhibit apoptosis. Thus, this study we aimed to determine clinical significance of PTEN in UTUC. We collected sixty-eight formalin-fixed paraffin-embedded (FFPE) UTUC samples, the tumor stage was according to American Joint Committee on Cancer (AJCC) with Ta (n = 40), T1 (n = 18), T2 (n = 10), T3 (n = 18), T4 (n = 7) and seven patients with unknown; in which male no.32, female no.36; the median age is 68 y/o (range 40-85 y/o). Fluorescence in situ hybridization (FISH) was performed to examine the PTEN gene copy number or gene structure alterations of UTUC; besides, immunohistochemistry (IHC) analysis were used to observe the PTEN protein expression in the tumor. Our results showed PTEN mutations were observed in twenty-two tumors with heterozygous PTEN deletion; one tumor with homozygous PTEN deletion, and three tumors with PTEN monosomy. Further, heterozygous PTEN deletion was shown significantly associated with stage of pTa, pT1 and pT2 (P = 0.048) and history of smoking (P = 0.030). The IHC results showed lower expression level was common to be observed in the tumors with PTEN deletion as compared with the tumors with normal PTEN expression levels. Our findings indicated PTEN genomic loss might act a predictive indicator of classification of UTUC histology. In conclusion, PTEN genomic loss might act a predictive indicator of classification of UTUC, however, the clinical treatment could be different due to the underlying diversity of the molecular activities.

#2728 Frequency and prognostic value of PI3KCA mutations in early stage of colorectal cancer in Mexican patients. Erika Ruiz-Garcia,1 Alette Ortega,1 Antonio Bahena,2 Edith Fernandez,2 Cesar Lopez-Camarillo,1 Laurence Marchat,3 Jorge Guadarrama,1 Abelardo Meneses-Gariga,1 Horacio Astudillo-de la Vega3.1 National Cancer Institute, Mexico City, Mexico; 2Universidad Autónoma de la Ciudad de México, Mexico City; 3Escuela Nacional de Medicina y Homeopatía, Instituto Politécnico Nacional, Mexico City, Mexico; 4Lab Investigacion Translacional en Cancer, HOCMN SXXI, IMSS, Mexico City, Mexico.

Background: There are molecular associations between mutated profiles and microsatellite instability, both related with tumor growth and oncogenic development by activating tyrosine receptors families in colorectal cancer (CRC). It is known that exon 9 and exon 20 (H1047R) mutations in PIK3CA increased PI3K activity. Moreover, PIK3CA mutations are significantly associated with tumor recurrence and poor overall survival. The frequency of PIK3CA mutations in CRC occurs in 15–20%, being the catalytic subunit more frequently affected. The aim of our study was to investigate the frequencies and clinical implications of these genetic alterations in advanced CRC. Methods: Retrospectively, we analyzed the initial paraffin embedded tissue block of 71 Mexican patients with CRC stage II. We evaluated mutations frequency of PIK3CA exon 9 (E542K, E545K) and exon 20 (H1047R) using qPCR marker Somatic Mutation PCR for real-time analysis. We confirmed the mutations by Sanger sequencing. This study was approved by the Ethics Committee of the National Cancer Institute. Results: We found in our population a frequency of PIK3CA mutations of 26%. Of those, double mutants were present in 7% with a higher frequency for E545K/H1047R. Clinical implication that we found is that any active mutation of PIK3CA is associated to increase of recurrence risk (HR 1.86 CI 95% 0.46-7.5), but most important is for E545K mutation (HR 1.17 CI 95% 0.85-20.39) compared to PIK3CA wild-type, meanwhile comparing no mutated with H1074R mutated samples there were no difference in HR (0.53 vs. 0.60, respectively). Conclusions: We found a higher number of PI3KCA mutations that literature reports and that E545K mutation have a worst prognostic implication but we need to increase our sample looking for statistical significative results. Data from H1047R mutation raise de hypothesis that it exist a compensatory mechanism related to structural interactions between both helicoidal and catalytic domains.

#2729 A significant differential sensitivity to AKT inhibitors GSK690693 and MK-2206 2HI was identified in primary cells established from a low-grade mucoepidermoid carcinoma. Ahmad M. Alamri, Priscilla A. Furr. Georgetown University, Washington, DC.

The AKT pathway is frequently activated in cancer cells and is a defined target for therapeutic intervention. A comprehensive method for RNA expression levels of candidate AKT pathway genes (AREG, EGFR, AKT, mTOR, GSK3α/β) were defined following RNAseq of replicate primary cell cultures (GUMC220 and GUMC221), which were established independently from two areas of the same low-grade mucoepidermoid carcinoma (MEC). Protein expression and phosphorylation levels of the corresponding gene products were characterized using immunohistochemistry on FFPE sections from the original patient tumor, cell pellets, and cell line generated patient-derived xenografts and through western blotting of proteins extracted from cells grown under different culture conditions before and after treatment with AKT inhibitors GSK690693 (ATP-competitive) and MK-2206 2HI (allosteric inhibitor). The effects of GSK690693 and MK-2206 2HI on cell viability were tested at different concentrations ranging from 1.2-40μM in 2D and 3D conditions with three different culture media (Conditioned media + ROCK kinase inhibitor Y27632, conditional media without Y27632, and EpiCult-C Basal™) using CellTiter-Glo™. Doxorubicin was used as a comparative control for evaluating the impact of a chemotherapeutic on cell viability and DMSO as a negative vehicle control. MDA-MB-453 cells were tested as a positive control for MK-2206 2HI and GSK690693 sensitivity. Results: Replicate primary cell cultures showed the same chemosensitivity results. MK-2206 2HI induced a significantly greater reduction in cell viability as compared to GSK690693 in the MEC primary cells. This differential response was replicated in all three 2D culture media tested (GUMC220 CM p = 0.0017, GUMC220_CM p = 0.0004, GUMC220 EpiC p = 0.001, GUMC221 CM p = 0.0010, GUMC221 CM p = 0.0001, and GUMC221 EpiC p = 0.0041. One-way ANOVA analysis with the same pattern reproduced in 3D cultures. Expected changes in levels of p-AKT(Ser473), GSK3α/β, p-GSK3α/β, and p-mTOR were found following treatment with both drugs as compared to vehicle controls. In MK-2206 2HI treated cells, expression levels were all reduced whereas in GSK690693 treated cells, p-AKT(Thr537) and p-AKT(Thr380) were increased and GSK3α/β, p-GSK3α/β, and p-mTOR reduced. Conclusion: Characterization of primary cell cultures using RNAseq led to the identification of a potentially druggable pathway. Direct testing revealed a differential response to the two AKT inhibitors evaluated. Although the two primary cell cultures were established from two geographically distinct areas of the same tumour, response to drug testing was the same and reproducible across different culture modalities. Studies establish the feasibility of deriving primary cells for drug testing and personalized therapy, even from small tumors.

#2730 Image-based single cell-sorting to separate and recover distinct cell populations from complex heterogeneous mixed tissue: precise sample preparation upstream of FISH. Amanda Gerber,1 Aditi Khurana,2 Lisa Koenig,3 Lindsay Strotzman,4 Lori Millner,3 Valeria Sero,2 Chiara Bolognesi,2 Sabine Kasimir-baur,4 Gianni Medoro,5 Matthew Moore,2 Philip Cotter,2 Nicolo Manaresi,5 Farideh Bischoff1.

Res. Da, Irvine, CA; 2Universitätssklinikum Essen, Essen, Germany; 3PGX Laboratories, Louisville, KY; 4Menarini Silicon Biosystems SpA, Bologna, Italy. Fluorescent in Situ Hybridization (FISH) is commonly used for assessment of chromosomal alterations. Guidelines for determining FISH-based classification
CLINICAL RESEARCH: Clinical Molecular Genetics and Laboratory Correlates

of clinical biomarkers exist but are based on pre-analytical factors, including fixation/sectioning/thickness/age, that can greatly influence biomarker status determination. Here, we use single-cell image-based cell sorting by DEPArray™ for the separation and recovery of pure distinct cell populations prior to FISH. Methods: A multi-center study to evaluate HER2-FISH based analysis on FFPE paraffin-in, Andres Alonso, Robert Storr, Grant Armstrong, Anthony D’Ovidio, James Yarbrough, and Naomi Simon. Cells were then stained and sorted using the DEPArray™ platform for sectioned. One curl from each sample was sent to each of four centers (3 US; 1 Europe). Each site performed disassociation of curls to generate a single cell suspension. Cells were then stained and sorted using the DEPArray™ platform for recovery of tumor (cytokeratin+/vimentin-/DAPI+) and stromal (cytokeratin+/vimentin+/DAPI+) cells. Dual-probe FISH for HER2 and centromere 17 was performed on the sorted cells and compared with conventional tissue section FISH. Results: Overall, ≥ 90% concordance between the sorted tumor cells and the conventional HER2 FISH result was observed. Among the 7 HER2+ cases, HER2 ratio scores for the sorted tumor cells ranged slightly higher, from 2.60 to 8.95, as compared to the conventional method (from 2.10 to 5.14). In all cases in which stromal cells were also recovered, an expected normal ratio was observed, thus verifying that the populations were efficiently separated. Discordance can be attributed to intra-tumoral heterogeneity and the fact that conventional FISH on FFPE requires only a 4-micron section for analysis. Conclusion: Today, a percentage of patients are likely misclassified for the biomarker of interest as result of pre-analytical factors. We demonstrate here the ability to overcome these pre-analytic factors and ultimately improve the accuracy in determining biomarker status using the DEPArray™.

CLINICAL RESEARCH: Liquid Biopsies 2: cfDNA

#2731 Identifying circulating tumor DNA in patients with osteosarcoma.

David M. Barris, Michael Fremed, Robert Durbin, Xusheng Zhang, Sajida Piperdii, Wendong Zhang, Shahina Maqbool, Jonathan Gill, Michael Roth, Bang Hoang, David Geller, Richard Gorlick, Daniel Weiser. Albert Einstein College of Medicine, Bronx, NY.

Introduction: Osteosarcoma (OS) is the most common primary malignant bone tumor and primarily affects children and adolescents. During and after treatment there is no non-invasive test to assess disease response and early relapse. We hypothesize that circulating tumor DNA (ctDNA) can be used to assess tumor burden, evaluate response to treatment, and monitor for recurrence in OS. We effectively tested this hypothesis on a mouse model and have utilized our methods on a first cohort of human patients. Materials and Methods: Twenty blood samples with matched primary tumor material were obtained from 10 patients with OS who were at various stages of treatment or post treatment. Cell-free DNA was isolated from blood collected in Cell-Free DNA blood collection tubes using the QIAamp Circulating Nucleic Acid Kit. We performed massively parallel sequencing (MPS) with the Illumina HiSeq 2500 in the Epigenetics Core Facility of Albert Einstein College of Medicine. MPS was performed on whole blood using the TruSeq Nano DNA Sample Prep Kit from Illumina and the TruSeq PE Cluster Kit v3-HS from Illumina. Reads were aligned to the genome using BWA-MEM. cfDNA was called using VarScan2. Results: In every sample there were ≥ 100000 reads. Ten samples were sequenced with ≥ 200000 reads. Conclusion: Circulating tumor DNA is a potential biomarker in OS. Future studies using larger cohorts will determine if this is a viable test for disease monitoring.

#2732 Novel methods for enrichment of mutations and differentially methylated sequences from liquid biopsy genomes.

Chen Song, Yibin Liu, Mariana Fitearelli-Kiehl, Ioannis Ladas, Harvey Mamon, Mike G. Makrigiorgos. Dana-Farber Cancer Inst., Boston, MA.

Presence of excess unaltered, wild-type DNA providing no information of biological or clinical value may often mask rare alterations containing diagnostic or therapeutic clues for cancer. With the surge of high-throughput technologies there is a growing demand for removing unaltered DNA over large pools-of-seq. Here we present nuclease-assisted minor-allele enrichment with probe-overlap (NaME-PrO), a single-step approach with broad genome-cover- age that removes WT-DNA prior to DNA-amplification, following which current genomic analysis procedures remain unaltered. NaME-PrO employs a dou-ble-strand-DNA-specific nuclease and overlapping oligonucleotide-probes interrogating multiple DNA targets. Following genomic-DNA denaturation, or upon partial denaturation, the probes form transient double-stranded regions with their targets, thereby guiding nucleic acid digestion to selected sites. Mutations create mismatches that inhibit digestion, thus subsequent amplification yields DNA with alterations enhanced at multiple targets. In this manner, WT DNA at hundreds or thousands of DNA regions can be digested simultaneously. We demonstrate several-hundred-fold multiplexed mutation-enrichment in diverse human samples on multiple clinically-relevant targets in 50-247plex reactions. By adjusting conditions it is possible to sequence mutations down to 0.00003% abundance, essentially isolating mutated-DNA. Application with targeted re-sequencing algorithms demonstrated detection of mutations at the 0.01-0.1% levels with few sequence reads. In another adaptation of the same approach in the field of methylation detection, we developed methyla-tion-sensitive nuclease-assisted minor allele enrichment, MS-NaME. Aberrant methylation changes, often present in a minor allelic fraction in clinical samples such as cfDNA, are potentially powerful prognostic and predictive cancer bio-markers. During MS-NaME, oligonucleotide probes targeting unmethylated se-quences in bisulfite-treated DNA generate local double stranded regions result-ing to digestion of unmethylated targets, and leaving methylated targets intact; and vice versa. We validated MS-NaME by demonstrating enrichment of pro-moters from cancer-related genes like RARB2, ATM, MGMT and GSTP1 in multiplexed 177-plex reactions using dilutions of methylated/unmethylated DNA as well as clinical lung cancer samples and matched normal tissue. NaME-PrO and MS-NaME introduce simple, low-cost, broad genomic coverage pro-cesses that combine seamlessly with next generation sequencing. This reveals clinically useful DNA alterations that normally would stay undetectable or re-quire very high read-depth to be detected. Applications in liquid biopsy-based diagnostics using circulating DNA will be presented.

#2733 Comparison of copy number aberrations (CNAs) between plasma cell free DNA (cfDNA) and tissue DNA in metastatic castrate resistant prostate cancer (mCRPC).

Chun Chen Lin,1 Hua Huang,1 Liewei Wang,2 Liang Wang,2 Manish Kollhi,3 Univer-sity of Wisconsin, Milwaukee, Milwaukee, WI; 2Medical College of Wisconsin, Milwaukee, WI; 3Mayo Clinic, Rochester, MN.

Background: Circulating cell-free DNA (cfDNA) analysis is emerging as a less invasive approach to assessing tumor genomic alterations in cancer patients. Although high concordance has been reported between tumor tissue NGS and cfDNA in studies investigating specific genetic alterations, the fidelity of cfDNA to tumor tissue DNA in the global genomic scale is largely unknown. In a correlative study of a prospective clinical trial (NCT# 01935640) conducted in mCRPC stage patients treated with abiraterone acetate/prednisone (A/P), we evaluated correlation of genomic CNA in tumor DNA obtained from biopsy of metastatic lesions and matched plasma cfDNA. Methods: mCRPC patients (pts) underwent two image-guided core biopsies at the time of the core biopsies and cfDNA was extracted using DNA Blood Mini Kit (Qiagen, Valencia, CA). High coverage (for tumor tissue) and low coverage (for cfDNA) whole genome sequencing reads were first mapped to the human genome hg19. Read counts (RC) from the mapped sequence files were then binned into 1MB windows. The RC ratio in each genomic bin was calculated by comparing tumor tissue DNA to lymphocyte gDNA derived from the same patient, and was further log2 transformed, corrected for GC content, and normalized by CGHnormalizer. The fully normalized log2 ratios data was subjected to segmentation using DNAcopy algorithm. Results: Between 05/2013 and 09/2015, 92 patients (pts) were enrolled of which tissue and plasma NGS data both visits was available for 18 pts. The correlation of CNAs between tumor tissue and its cfDNA counterpart ranges from 0.013 to 0.83 for V1 samples, and -0.05 to 0.92 for V2 samples. The decreased correlation in some pairs of samples is

Proceedings of the American Association for Cancer Research • Volume 58 • April 2017
largely due to low tumor content and heterogeneity in the cfDNA. Although there is a wide range of correlation, commonly shared CNAs were identified in multiple chromosomal regions, including loss in 8p, gain in 8q and chromosome 5 and X. On the other hand, several genomic regions show inconsistent CNAs between tumor tissue and cfDNA among 15 pairs of samples in which one tumor contained 6 CNAs (3 gains and 3 losses). The CNAs most commonly observed in tumor tissue were tumor-specific and expressed in cfDNA but not in tumor tissue, marked loss in chromosome 22 and gain in p arm of X chromosome in tumor tissue but much less evident in cfDNA. Conclusion: High concordance of CNAs between cfDNA and tumor tissue DNA can be achieved given sufficient tumor content of cfDNA. However, more CNAs can be identified in cfDNA than its tumor tissue counterpart. Our result suggests that cfDNA NGS is a useful tool to investigate clonal evolution associated with cancer progression.

#2734 Impact of circulating and tissue biomarkers in patients with metastatic colorectal cancer treated with first-line FOLFOX/alfibercept therapy. Results of the GERCOR VELVET Phase II Study. Annemilai Tijeras-Raballard, Armand de Gramont, Marielle Chiron, Jean-Baptiste Bachet, Thierry Andre, Dominique Auby, Jerome Desramé, Baba-Hamed Nabil, Lecaille Cedric, Valerie Lebrun, Christophe Roux, Annette Larsen, Christophe Tourigny, Sylvie Benner, Melika Attia, Aimerie de Gramont, Franck Bonnetain, Benoit Chibaudel, AOF Oncology, Paris, France; Sanofi France, Vitry-sur-Seine, France; Salpêtrière University Hospital, Paris, France; Saint-Antoine University Hospital, Paris, France; Mont de Marsan Hospital, Paris, France; Jean Mermoz Hospital, Paris, France; Saint-Joseph Hospital, Paris, France; Clinique Nord, Paris, France; Limoges University Hospital, Paris, France; Institut Mutualiste Montsouris, Paris, France; Inserm U938-Institut Universitaire de Cancérologie/UPMC, Paris, France; Henri Mondor University Hospital, Paris, France; GERCOR group, Paris, France; Institut Hospitalier Franco-britannique, Paris, France; Inserm UMR 1098-Beauvoin University Hospital, Paris, France.

Background: The combination of alfibercept to OPTIMOX (VELVET study) was evaluated in patients with previously untreated advanced colorectal cancer. A biomarker program was set-up to explore the expression of several tissue biomarkers at baseline and circulating biomarkers upon treatment cycles to identify the best monitoring biomarkers of the treatment strategy. Methods: VELVET was a prospective, single arm phase II trial. Patient’s plasma samples were collected at baseline, and during induction therapy at day 1 of the first 6 cycles. Circulating biomarkers were analyzed using multiplexing immunoassays (31 biomarkers, 3 panels). Assays were conducted on a Biorad Bioplex platform, expect for PIGF, VEGF-A and Neutrophil-1 which were assessed using ELISA assays. Tissue biomarker were analyzed at baseline by IHC, using a BOND-Max autostainer (Leica biosystems). EGFR mutation status were analyzed using next generation sequencing. Results: Among 49 patients included in the VELVET study from May 2013 to May 2014, 44 (90%) patients were evaluable for circulating biomarkers expression. The proportion of patients with tumor response (CR or PR) was higher in patients with high baseline levels of sVEGFR2, sEGFR, G-CSF, Prolactin and low baseline levels of VEGF-A and MIF. Progression-free survival was longer in patients with baseline levels of Haptoglobin (HR: 0.53; P = 0.045) and in patients with high baseline levels of VEGF-C (HR: 0.45; P = 0.014) and sVEGFR3 (HR: 0.50; P = 0.045). Overall survival was higher in patients with high sVEGFR3 (HR: 0.36; P = 0.030) levels. In both responders and non-responders, sVEGFR-1 and PIGF dramatically increased upon exposure to alfibercept and remained overexpressed for the all course of induction therapy. Circulating biomarkers modifications will be analyzed upon the 6 cycles. Tumor tissue biomarker assessment at baseline using IHC and the EGFR pathway mutations status will be added. Conclusions: Exposure to alfibercept is associated with an increase of sVEGFR-1 and PIGF at cycle 1. Elevated baseline expression levels of on-target sVEGFR3 predict favorable outcome in patients treated with alfibercept.

#2735 Targeted molecular profiling of tumor and matched circulating tumor DNA in patients with early stage endometrioid type endometrial adenocarcinoma. Ana M. Bolivar, Rajyalakshmi Luthra, Meenakshi Mehrotra, Wei Chen, Bedia A. Barkoh, Peter Hu, Rajesh R. Singh, Russell R. Broadus. The University of Texas MD Anderson Cancer Center, Houston, TX.

Endometrioid-type endometrial adenocarcinoma (EEA) is the most common type of gynecological cancer in the USA and the fourth most common cancer in women. Contrary to other cancer types, its incidence is rising, likely due to its tight association with obesity. A major clinical problem for EEA patients presenting with early stage disease is identifying those at risk of recurrence, as extra-vaginal recurrence is incurable. If these at-risk patients could be identified up-front, they could receive more aggressive surgical treatment and adjuvant radiation therapy/chemotherapy/targeted therapy to help prevent the development of incurable recurrences. The long-term goal of our work is to develop a blood-based molecular diagnostics platform that can help to identify women with early stage EEA who are at highest risk for tumor recurrence. To achieve this goal, we have performed a large cohort study to identify genetic alterations that could be used to detect common EEA associated mutations in circulating tumor DNA (ctDNA) of early stage EEA patients. From our previous work, we have shown that 98% (43/44) of EEA patient’s tumors have somatic mutations in CTNNB1, KRAS, PTEN, and/or PIK3CA. Using a custom panel designed by Swift Biosciences targeting 30 amplicons in these 4 genes, MiSeq NGS analysis was performed on both cfDNA and matched tumor tissue DNA. We then performed a droplet digital PCR in detecting circulating nucleic acid kit and on the matching tumor DNA (tDNA) extracted from FFPE slides using an Arcturus Pico Pure DNA extraction kit from 33 stage I and II EEA patients (stages in which tumor is confined to the uterus). NGS data were analyzed using a custom bioinformatics pipeline. Using a cutoff of 0.5% allele frequency (AF) in the ctDNA and 5% in the tDNA, at least one EEA associated mutation was detected in both ctDNA and tDNA in 5/33 (15%) of cases. Mutations with more than 5% AF in the tumor and 0.02-0.49% AF in the ctDNA (total coverage >250X and variant coverage >25) were also detected in another 6/33 patients. Each of these 11 cases was re-sequenced at a higher depth (>20,000X), with comparable results. For the remaining 22 patients at least one EEA associated mutation was detected only in the ctDNA, with no mutation detected in the matched tumor tissue DNA. The most common mutation detected in ctDNA was a frameshift mutation in 10p which leads to missense mutations in the group in which mutations were only present in ctDNA (mean 3.6 cm: p=0.005). To improve the analytical sensitivity in the ctDNA and confirm the current findings, all cases will be analyzed using digital droplet PCR. Molecular barcodes will also be incorporated into our custom panel. In this proof-of-principal study, we have demonstrated that relevant mutations can be detected in the plasma of a subset of patients when endometrial carcinomas are confined to the uterus.

#2736 A digital droplet PCR assay for the quantitation of androgen receptor and splice variant expression in CTCs from metastatic castration resistant prostate cancer patients. Ada Gyerezi, Giuseppe Galletti, Arei Strati, Seho Kim, Evi Lianidou, David M. Nansus, Jun Luo, Emmanuel Antonarakis, Scott T. Tagawa, Andrew Armstrong, Paraskeni Giannakakou, Weil Cornell Medicine, New York, NY; University of Athens, Athens, Greece; John Hopkins Medicine, Baltimore, MD; Duke University School of Medicine, Durham, NC.

Prostate cancer (PC) is the second leading cause of cancer death in men in the US. The aberrant functioning of androgen receptor signaling is the central driving force behind prostatic tumorigenesis and its transition into metastatic castration resistant disease. Here, we took advantage of the first-line of treatment for PC patients. However, many patients progress becoming resistant to ADT therapy, due to expression of AR splice variants (AR-Vs), which lack the ligand binding domain and are constitutively active in the nucleus. Expression of the AR splice variant, AR-v7, in circulating tumor cells (CTCs) isolated from the blood of PC patients was correlated with resistance to enzalutamide and abiraterone, which are the next generation AR signaling inhibitors in CRPC. Further, there is evidence that AR-Vs may convey cross-resistance, not only to enzalutamide and abiraterone, but also to taxanes, highlighting that their assessment in the clinic may have clinical utility. We developed a novel, specific and highly sensitive assay to measure mRNA expression of the AR full length (AR-FL) and the splice variants ARV7 and ARS676x, by using Droplet Digital PCR in CTCs isolated from CRPC patients. The analytical specificity of the assay was determined by transfecting cells with plasmids encoding AR-FL, AR-v7 and AR-v676 and showed that each probe detected signal only in cells expressing the respective transcript. No signal was detected against genomic DNA, indicating lack of non-specific binding. Also, the assay detected endogenous expression of AR-FL and AR-v7 in VCAP or 22Rv1 cells, indicating specificity of the assay in healthy donor tissue. The analytical sensitivity of the assay was determined in a series of serial dilution experiments that showed sensitivity down to single cell. We then used this assay to determine the clinical prevalence and expression pattern of each of these variants in CTCs from about 200 mCRPC patient samples and blood from 40 healthy donors. CTCs were enriched by EpCAM or PSMA positive selection or by CD45 negative depletion in an antigen-agnostic manner. AR-FL was detected in ~80% of mCRPC samples irrespective of CTC-enrichment technology. AR-FL was expressed in 65% of the samples in which in CTCs were enriched either by PSMA-positive selection or by negative depletion. In contrast, EpCAM-based CTC enrichment showed lower AR-v7 expression both in terms of expression
levels and prevalence. In addition, CTC enrichment following negative deple-
tion showed that 30% of the samples had higher AR-v7 expression levels as compared to AR-FL. This expression pattern was not observed in the samples using EpCAM-based selection. Collectively, these data suggest specific CTC subpopulations are present in CRPC patient samples, with differential expres-
sion of AR-Vs that could have important predictive and prognostic implica-
tions.

#2377 Development of a clinically actionable, ultra-sensitive multi-onco-

Background: Circulating tumor DNA (ctDNA) is rapidly emerging as a viable alternative to tissue molecular diagnostics for the detection of actionable onco-
genic mutations. In non-small cell lung cancer, identifying the emergence of EGFR T790M in patients receiving first line EGFR tyrosine-kinase inhibitors (TKIs) is a clinical need. Obtaining a tissue biopsy to determine T790M status is associated with significant cost and patient morbidity. In a retrospective analysis of the TIGER-X trial, patients had similar therapeutic response to a 3rd genera-
tion TKI, independent of the sample type positive for T790M; tissue, plasma, or urine. This indicates that non-invasive urine liquid biopsy is a viable diagnostic option (Wakele et al, ASCO, 2016). We report on the expansion of single mu-
tation assays to a multiplex-panel of clinically actionable mutations having high analytic sensitivity and specificity. We previously developed two next generation sequencing methodologies with high sensitivity and specificity for ctDNA detection: 1) A series of individual ultra-sensitive ctDNA hotspot assays capable of detecting ultra-short DNA fragments (31-45 base pairs) and a 0.01% lower limit of detection (LLoD). The short sized amplicons coupled with mutant allele enrichment enabled high clinical sensitiv-
ity for plasma and urine ctDNA (Reckamp et al, J Thorac Oncol, 2016) 2) A multiplex panel using sequence-specific synchronous coefficient of drag altera-
tion (SCODA) technology that enriches for mutant ctDNA to obtain a LLoD of 0.001%-0.03% (Pel et al, PNAS, 2009; Kidess et al, Oncotarget, 2015). By com-
bining a multiplex of short amplicons with SCODA enrichment capabilities, we developed an assay enriched for over 200 clinically actionable driver and resis-
tance mutations within 7 oncogenes. Results: An iterative process was used to design and optimize primer and enrichment probe length and placement to produce a panel where mean coverage across hotspots regions was within 2 to 3-fold (read uniformity) and greater than 1,000-fold enrichment of mutant DNA prior to sequencing. Technical validation was performed utilizing in-
house and commercially available model systems for plasma and urine demon-
strating mutation detection from inputs ranging from hundreds to fewer than 10 copies and LLoD as low as 0.001%. Clinical performance evaluation of the newly developed multiplex assay is ongoing using urine and plasma ctDNA from pa-
tients with advanced cancer. Conclusions: High sensitivity is critical when identi-
ifying targetable driver mutations as well as emergence of resistance mutations which can inform therapeutic decision making. By combining short amplicon and multiplex enrichment technologies, we developed an ultra-sensitive ctDNA assay for use in sample types with highly degraded and fragmented DNA.

#2378 A commutable circulating tumor DNA (ctDNA) reference mate-
rail. Yves Konigshofer,1 Farol L. Tomson,1 Matthew Ryder,1 Russell Garlick,1 Bharathi Anekella1.1 SeraCare Life Sciences, Inc., Gaithersburg, MD; 2SeraCare Life Sciences, Inc., Milford, MA.

We developed and assessed a novel ctDNA reference material that was designed with an emphasis on commutability. Possessing qualities that are well-
matched with clinical specimens is critical for a reference material, however many existing methods of preparing ctDNA analogues result in material that is not commutable for certain assays. For example, sonication of genomic DNA yields fragments across a broad range of sizes that must be used at greater input amounts relative to native cell-free DNA (cfDNA) - even after enzymatic end-
repair to reduce damage. This can affect the utility of the reference material for assays that depend on the ligation of adapters to double-stranded DNA, such as many hybrid/capture-based Next Generation Sequencing (NGS) assays. If higher input amounts are not used, then the LOD and precision of such an assay may appear substantially lower than expected. At the same time, sonicated DNA has been shown to be acceptable for amplicon-based cfDNA assays. We created commutable ctDNA reference material by starting with genomic DNA from GM24385 cells and mixing with synthetic variant-containing DNA se-
quences at defined ratios. The use of GM24385 cells allows for the comparison of detected variants against the NIST RM 8391 high confidence variants. The use of synthetic DNA permits addition of large numbers of different cancer-associated variants at defined allele frequencies. Fragmentation was followed by size-selec-
tion in order to obtain ctDNA-like sizes. Additional steps were performed to increase the amount of output material from the size-selection step. The general method of preparing the reference material is also compatible with native cfDNA. The reference material was submitted to several testing laboratories along with similar sonicated material. When tested using hybrid/capture-based assays, variant detection was superior in the novel reference material compared to sonicated DNA when similar amounts of material were used as the input. We therefore conclude that our new reference material has greatly improved commutability compared to existing materials composed only of sonicated DNA.

#2379 Low-pass whole genome sequencing detects copy number varia-

Circulating tumor DNA (ctDNA) is released from necrotic/apoptotic tu-
mor cells into the bloodstream. Recent studies have demonstrated the value of using ctDNA as biomarkers in cancer diagnosis, prognosis, and drug resistance. Unlike local tissue biopsy, ctDNA collection and analysis is non-
invasive, allows continuous monitoring of clonal evolution, and provides an overview of tumor heterogeneity. Copy number variations (CNVs) play an important role in cancer biology. However, traditional CNV analyses of ctDNA using droplet digital PCR (ddPCR) and SNP arrays can only assess a small number of genes due to the low abundance of ctDNA in the majority of patient samples. Next generation sequencing (NGS) offers a more efficient and high-throughput way to study CNVs in ctDNA. Here, we evaluated the use of low-pass whole genome sequencing (WGS) in determining CNVs in ctDNA. In this work, cell-free DNA was isolated from 1-5 ml of plasma from phase II clinical trial patients with metastatic breast cancer and non-small cell lung cancer (NSCLC) using the QIAamp Circulating Nucleic Acid Kit (QIAGEN). DNA yield was determined by ddPCR, with a range from 2-4000 ng. Sequencing libraries were prepared using 2-10 ng DNA by the TruPLEX Plasma-Seq Kit (Rubicon Genomics). WGS at 0.1x, 0.25x, 0.5x, and 1x cov-
erage was performed on Illumina NextSeq, and data was analyzed using Nexus Copy Number software (BioDiscovery). As a reference, we sequenced DNA from peripheral blood mononuclear cells (PBMCs) of 20 healthy do-
nors at the same coverage. Low-pass WGS was also performed on a subset of matched tumor tissue samples as comparisons. Our results showed that WGS of ctDNA at 0.5x coverage was efficient to identify CNVs. CNVs were detected in ctDNA from about half of the patients analyzed, and in general CNVs identified in ctDNA matched the ones found in tumor tissue from the same patient. We also found that CNV patterns from different time points of the same patients clustered together. With this promising system, we will present CNV analysis in ctDNA from breast cancer and NSCLC patients enrolled in phase II clinical trials of the PI3K inhibitor pictilisib. We will evaluate the ability of the method to classify patients into different sub-
groups, monitor tumor progression, and identify drug resistance mecha-
isms.

#2380 High-throughput and sensitive quantification of circulating tumor DNA. Yinghui Guan, Oleg Mayba, Shan Lu, Thomas Sandmann, Younjeong Choi, Walter Darbonne, Vincent Lequeve, Lisa Ryner, Eric Humke, Nga W. Tam, Sundari Sujathasarma, Anna Cheung, Richard Bourgon, YueLi Wang, Genentech, A Member of the Roche Group, South San Francisco, CA.

Circulating tumor DNA (ctDNA) has a great potential to serve as non-
invasive biomarkers for monitoring disease progression and treatment re-
sponse. However, its broad clinical applications have been hindered by sen-
sitivity, throughput and complexity of existing ctDNA detection methods. Here we report an adaptation of a multiplex PCR pre-amplification (Pre-
Amp) into the microfluidic multiplex PCR (MMP-Seq) technology for high-
throughput and sensitive quantification of ctDNA. We have demonstrated that PreAmp MMP-Seq enabled sensitive (down to 0.6% allele frequency), reproducible (R²=0.97), accurate and quantitative mutation detection from as low as 1.6 ng DNA input. An empirical Bayesian Model has been estab-
lished to estimate background error rates for every base of amplicons in the ctDNA panel using data from 43 normal plasmas. 0.1-0.3% of median error rate were observed across all positions. 149 longitudinal plasma samples from 12 ovarian and 10 pancreatic cancer patients of PhI DMUC7554A anti-MUC16 ADC trials were then profiled using PreAmp MMP-Seq. 79% (11/14) driver mutations found in tissue samples were also identified in matching baseline plasma samples at frequencies well above estimated error.
rates. Moreover, we found that changes of corresponding ctDNA concentration in post-treatment plasma samples were correlated with changes in tumor burden and circulating protein marker levels. In conclusion, the MMP-seq PreAmp workflow provides an inexpensive, reproducible and flexible solution for mutation detection in plasma DNA samples.

#2741 Assessing the utility of circulating tumor DNA as a surveillance tool for sarcomas and Li-Fraumeni syndrome using a pre-clinical model. San-geetha Paramathas, Nathan Lewis, Tanya Guha, Zainab Motala, David Malkin. The Hospital for Sick Children, Toronto, Ontario, Canada.

Li-Fraumeni Syndrome (LFS) is a hereditary cancer predisposition syndrome commonly characterized by the presence of inherited mutations in the tumor suppressor gene TP53. This leads to an early onset of a wide spectrum of tumors in multiple organ systems. Current surveillance protocols for early tumor detection include biochemical screening, MRI and ultrasound scans, colonoscopy and mammography (for adults). While early detection is associated with improved survival, the complexity of testing, potential to ‘misdiagnose’ tumors (false positive/negative) and requirement for multiple imaging modalities makes clinical surveillance challenging to implement and interpret. Liquid biopsies are a recently described diagnostic and prognostic tool that takes advantage of analyzing circulating tumor DNA - fragmented genomic material that are released into the blood from dying tumor cells. In this proof-of-principle study, we use mouse xenograft tumor models to assess the dynamic relationship between tumor burden and ctDNA concentrations, as well as resolve the sensitivity of capturing tumor lesions in their earliest stages of growth. Characterization of ctDNA from serially collected blood were performed on mice xenografts of rhabdomyosarcoma (Rh4 and Rh30), osteosarcoma (HOS) and non-small cell lung carcinoma (H1975) of both localized and simulated metastatic tumors. We characterized ctDNA using droplet digital PCR (ddPCR) for known gene mutations that were specific for the cancer cell lines used. We observe obvious increases in ctDNA with increased tumor burden and a complete clearance of ctDNA after tumor resection. In addition, using the mutation model, we have conducted synchronized imaging and blood-based biopsies to determine the smallest lesion able to be detected in the blood by ctDNA. These studies provide the foundation for early tumor detection with ctDNA inTp53 mutant mice that develop spontaneous tumors analogous to LFS. This model will help further our understanding on the utility of ctDNA as a surveillance and diagnostic tool for LFS as well as assess its potential for clinical use.

#2742 Cross-platform comparison of four leading technologies for detecting EGFR mutations in circulating tumor DNA from plasma of patients with non-small cell lung carcinoma. Ting Xu, Xiaozheng Kang, Xiaofang You, Dai Liang, Dequan Tian, Wanpu Yan, Yongbo Yang, Hongchao Xiong, Zhen Liang, Grace Q. Zhao, Shengrong Lin, Ke-Neng Chen, Guobing Xu. Peking University Cancer Hospital and Institute, Beijing, China; 2AccuSensor, Merlo Park, CA.

Analysis of circulating tumor DNA (ctDNA) is emerging as a powerful tool for guiding targeted therapy and monitoring tumor evolution in patients with non-small cell lung cancer (NSCLC), particularly when fresh tissue biopsy is not available. In this study, we compared the ability of four leading technology platforms to detect epidermal growth factor receptor (EGFR) mutations (L858R, exon 19 deletion, T790M and G719X) in ctDNA from NSCLC patients. The platforms included two amplification refractory mutation systems (cobas-ARMS and Adx-ARMS), a droplet digital polymerase chain reaction platform (ddPCR) and a next-generation sequencing platform (Firefly NGS). Fifteen EGFR mutations across twenty NSCLC patients were identified. We observed superior sensitivity and specificity of cobas-ARMS, ddPCR and Firefly NGS platforms, while Adx-ARMS was only suitable for the qualitative detection of EGFR mutations with allele frequency higher than 1% in plasma samples. We observed high concordance between the plasma and tissue EGFR mutational profiles for three driver mutations that are known targets of the first generation EGFR-TKI therapy (L858R, E19-dels, and G719X). Discrepancies between plasma and tissue EGFR mutational profiling could be attributed to spatial and temporal tumor heterogeneity. This pilot study illustrates the promise of ctDNA analysis in the context of treatment evaluation and drug resistance detection, and results will be validated in follow-up studies.

#2743 Comparison of enhanced Tagged-Amplicon Sequencing and digital PCR for circulating tumor DNA analysis in advanced breast cancer. Isaac Garcia-Murillas, Matthew Beanny, Michael Epstein, Karen Howarth, Andrew Lawson, Sarah Hreibien, Emma Green, Nizan Rosenfeld, Nick Turner.1 The Institute of Cancer Research, London, United Kingdom; 2Inviva, Cambridge, United Kingdom.

Background: Circulating tumor DNA (ctDNA) analysis allows non-invasive detection of tumor mutations and amplifications in advanced breast cancer. Multiple technologies have been developed to analyse ctDNA and here we compared two leading ctDNA detection technologies, enhanced Tagged-Amplicon Sequencing (eTAm-Seq) and digital PCR (dPCR) assays, in advanced breast cancer. Methods: We recruited a cohort of 35 women with advanced breast cancer, of whom 23 had two separate blood samples taken in a standard EDTA tube processed immediately or in preservative Streck tubes processed up to 120 hours after venipuncture. Digital PCR was conducted with assays for hotspot actionable mutations in 3 known drivers in breast cancer: PIK3CA exon 9 and 20, ESR1 ligand binding domain and AKT1 (c.49G>A; p.E17K), and ctDNA sequencing with eTAm-Seq within a 35-gene panel including cancer hotspots, entire coding regions and copy number variants (CNVs). Results: Across both assays, 37 mutations were detected in 35 patients, with PIK3CA mutation in 13 patients (37%), ESR1 mutations in 10 patients (29%), and no AKT1 mutations. ESR1 mutations were polyclonal in 8 patients, with ctDNA eTAm-Seq method revealing substantially more diversity in mutations, up to 8 individual mutations detected in a patient. There was 96.15% agreement for PIK3CA mutation detection between assays (Kappa 0.89, 95% CI 0.743 to 1.000), 100% agreement for ESR1 mutations (Kappa 1.00, 95% CI 1.000 to 1.000). There was very high correlation in mutation allele frequency between eTAm-Seq and dPCR (r=0.93, 95%CI 0.86 to 0.96, p<0.0001). The sensitivity and specificity for HER2 amplification detection by eTAm-Seq was 100% (true positive) to tumor HER2 status. Comparing different sample processing methods, Streck tubes revealed 97.92% agreement (Kappa 0.95, 95% CI0.868 to1.000) for mutation calling. Conclusions: This study demonstrates that ctDNA analysis using eTAmSeq and dPCR have very high agreement in mutation detection in patients with advanced breast cancer patients. Streck tubes present a robust alternative to immediate processing of samples. eTAm-Seq and digital PCR have high clinical validity in mutation detection.

#2744 Inter-site comparison of performance of an ultra-sensitive sequencing technology for circulating tumor DNA. Stephanie Yang,1 Alex Lovejoy,1 Dan Klass,2 Fergal Casey,1 Aruna Arcot,1 Melissa Loyzer,1 William Chiu,2 Nabil Azhar,2 Sophie Beckert,3 Maria Lange,3 Sandra Siemann,3 Sebastian Froehler,3 Shelly Gunn,3 John F. Palma,1 Roche Sequencing Solutions, Pleasanton, CA; 2ResearchDx, Irvine, CA; 3Roche Sequencing Solutions, Potsdam, Germany.

The combination of liquid biopsies and ultra-sensitive next-generation sequencing (NGS) holds tremendous promise in oncology for the detection and surveillance of somatic mutations that correlate with diagnosis, prognosis, response prediction, resistance monitoring and tumor burden. We have developed a capture-based NGS workflow that provides ultra-sensitive detection of 4 mutation classes - single nucleotide variants (SNVs), insertions/deletions, copy number amplifications (CNAs) and fusions - from low input cell-free DNA isolated from plasma. Sensitivity and specificity of 2 different AVENIO ctDNA Analysis Kits (for Research Use Only) across 3 sites for 48 samples that included contrived DNA blends with known mutations validated by digital PCR and normal reference plasma samples were assessed. The AVENIO ctDNA Targeted Kit and AVENIO ctDNA Expanded Kit (Expanded) was designed to detect mutations in 17 genes, across 80kb, included in NCCN Guidelines for solid tumors plus additional variants relevant for therapy selection. The AVENIO ctDNA Expanded Kit (Expanded) was designed to detect mutations in 77 genes, across 200kb, associated with solid tumor including variants relevant for clinical trial research. Testing sites achieved 100% sensitivity for SNVs and fusions at 0.5% and 1% allele frequency, respectively, from 30 ng of input DNA for both kits. Median coverage of 2,400-6,400X was greater with the Targeted kit relative to that of 2,700-3,800X with the Expanded kit. Specificity was 100% for the Targeted kit either by sample or variant. The Expanded kit had a specificity of 91.7-100% by sample and 99.7-100% by variant. At an expected 5X or 8X copy number amplification for multiple genes, both the Targeted and Expanded kits were 100% sensitive and 93.1-98.4% specific per gene. The specificity for fusion detection was 100% for both kits down to 1% mutant allele frequency. The AVENIO ctDNA Analysis Kits for plasma and NGS applications provide exquisite sensitivity and specificity for the simultaneous detection of 4 different mutation classes.

#2745 Evaluation of a new system for collection, stabilization, and purification of circulating tumor DNA. Michael Fleischhacker, Bernd Schmidt, Michael Fleischhacker, Bernd Schmidt, Roehan Baker, Susanne Pedersen, Natasha Cant, Maryam Zahedi-nejad, Thorsten Voss, Andrea Ullius, Daniel Groedz.1 University of Halle, Germany; 2DK-Kliniken Berlin-Mitte, Germany; 3Clinical Genomics, North Ryde, Australia; 4Qiagen Ltd., Manchester, United Kingdom; 5PreAnalytiX Gmbh, Hilden, Germany.

MultipletectologieshavebeendevelopedtoanalysectDNAherewecom-
CLINICAL RESEARCH: Liquid Biopsies 2: cfDNA

Introduction: The current preanalytical workflows for circulating tumor DNA (ctDNA) analysis have limitations that affect the accurate detection and quantification of these plasma cancer biomarkers. Release of genomic DNA (gDNA) from white blood cells (WBCs) due to cell lysis or apoptosis during whole blood storage in EDTA tubes creates higher gDNA background levels, affecting the detection of ctDNA as a biomarker. Circulating cfDNA often contain crosslinking reagents, which have negative effects on sensitive downstream assays, including methylation-based assays. Using ctDNA assays, the new PAXgene® Blood cfDNA System*, consisting of a blood collection tube with unique, non-crosslinking chemistry and an automated circulating cell-free DNA (ccfDNA) extraction kit, was evaluated in three research studies. Methods: Blood samples were collected into paired PAXgene and EDTA tubes and stored for 7 days at room temperature (RT). cfDNA was isolated from plasma using the PAXgene kit or the QIAGEN QIAamp® Circulating Nucleic Acid Kit. Study 1: The ccfDNA from lung cancer patients was quantified by real-time PCR for the amount of ERV (sequence (as a measure of the total plasma DNA quantity) and after bisulfite treatment for mSHOX2 as a marker for ctDNA. Study 2: Blood from healthy donors was spiked with fragmented, fully-methylated CpGenome DNA. During storage, tubes were intermittently inverted to simulate tubes in transit. Subsequent to bisulfite conversion, PCR assays targeting ACTB and methylated BCAT1 and IKZF1 DNA were used to determine the yields of ccfDNA and ctDNA, respectively. Study 3: Restriction enzyme treated EGFR DNA containing exon 19 deletions and exon 20 and 21 substitutions (T790M) were spiked into healthy donors’ blood; DNA purity was tested with the QIAGEN herescan® EGFR Plasma RGQ PCR Kit*. Results: Both study 1 and 2 demonstrated constant levels of the methylation ctDNA markers. SHOX2, BCAT1 and IKZF1, over the investigated time course. There was no significant release of gDNA in the PAXgene tube whereas a significant release of gDNA was detected in EDTA samples. Likewise, study 3 showed constant EGFR Ct values in the PAXgene system with reliable mutation detection, whereas the high DNA concentration from the EDTA system resulted in false-positive callings. Conclusions: The new system allows researchers to accurately detect and quantify plasma cancer biomarkers from blood samples that have been stored in the tube for up to 7 days at RT. This includes challenging assays based on methylated ctDNA. The system provides the required assay sensitivity to allow the correct assay interpretation beyond the typical 3–6 hour storage limit for EDTA tubes. *For Research Use Only. Not for use in diagnostic procedures.

#2747 Plasma DNA methylation marker and hepatocellular carcinoma risk prediction model for the general population. Hui-Chen Wu,1 Hwai-I Yang,2 Qiao Wang,1 Chien-Jen Chen,2 Regina M. Santella1.

Metastases in the later stages of hepatocellular carcinoma (HCC) cause the majority of deaths associated with the disease, making early detection crucial to patient survival. Risk models that assess HCC risk in the general population can be used for risk stratification for further HCC surveillance, however, none have been validated externally. Methylation of circulating DNA shows potential for noninvasive and early diagnosis of HCC. Most evidence, however, comes from cross-sectional studies raising concerns about temporality. We conducted a prospective case-control study nested within a community-based cohort. We measured methylation levels in of 6 genes (CDKN2A, RASSF1A, STEAP4, TBX2, VIM, and ZNF154) using pre-diagnostic plasma DNA from 237 HCC cases and 537 matched controls. We found TBX2 hypermethylation was associated with increased HCC risk, with ORs (95%CI) of 3.7 (1.9-7.2). The associations were mainly among high-risk subjects; among subjects infected with HBV/HCV, the OR (95%CI) of TBX2 methylation was 5.3 (2.2-12.7). Among subjects with high risk, the ORs (95%CI) were 8.9 (1.0-73.9) for Wen-HCC score ≥16, 5.6 (2.1-14.6) for Hung-HCC score ≥15, and 7.2 (2.1-24.4) for Michikawa-HCC score ≥4. Adding information on TBX2 methylation improved the accuracy of risk models for a high risk population, with the area under the curve (AUC) of 74% for TBX2 methylation and Wen-HCC score compared with 66% with Wen-HCC score alone. The AUCs were 63% for Hung-HCC score and TBX2 methylation, 53% for Hung-HCC score alone, 65% for Michikawa-HCC score and TBX2 methylation and 59% for Michikawa-HCC-risk alone. Our findings suggest the potential increase in risk assessment discrimination and accuracy from incorporation of DNA methylation.

#2746 Detection of tumor-specific mutations in plasma DNA: A potential esophageal adenocarcinoma biomarker. Matthew Egyud,1 Jennifer Jackson,1 Emiko Yamada,1 Anders Ståhlberg,2 Paul Krzyzanowski,3 Virginia Litle,1 Lincol Stein,2 Tony Godfrey1, 3Boston Medical Center, Boston, MA; 2University of Gothenburg, Gothenburg, Sweden; 3Ontario Institute for Cancer Research, Ontario, Canada.

Introduction: The current preanalytical workflows for circulating tumor DNA (ctDNA) analysis have limitations that affect the accurate detection and quantification of these plasma cancer biomarkers. Release of genomic DNA (gDNA) from white blood cells (WBCs) due to cell lysis or apoptosis during whole blood storage in EDTA tubes creates higher gDNA background levels, affecting the detection of ctDNA as a biomarker. Circulating cfDNA often contain crosslinking reagents, which have negative effects on sensitive downstream assays, including methylation-based assays. Using ctDNA assays, the new PAXgene® Blood cfDNA System*, consisting of a blood collection tube with unique, non-crosslinking chemistry and an automated circulating cell-free DNA (cDNA) extraction kit, was evaluated in three research studies. Methods: Blood samples were collected into paired PAXgene and EDTA tubes and stored for 7 days at room temperature (RT). cfDNA was isolated from plasma using the PAXgene kit or the QIAGEN QIAamp® Circulating Nucleic Acid Kit. Study 1: The ccfDNA from lung cancer patients was quantified by real-time PCR for the amount of ERV (sequence (as a measure of the total plasma DNA quantity) and after bisulfite treatment for mSHOX2 as a marker for ctDNA. Study 2: Blood from healthy donors was spiked with fragmented, fully-methylated CpGenome DNA. During storage, tubes were intermittently inverted to simulate tubes in transit. Subsequent to bisulfite conversion, PCR assays targeting ACTB and methylated BCAT1 and IKZF1 DNA were used to determine the yields of ccfDNA and ctDNA, respectively. Study 3: Restriction enzyme treated EGFR DNA containing exon 19 deletions and exon 20 and 21 substitutions (T790M) were spiked into healthy donors’ blood; DNA purity was tested with the QIAGEN herescan® EGFR Plasma RGQ PCR Kit*. Results: Both study 1 and 2 demonstrated constant levels of the methylation ctDNA markers. SHOX2, BCAT1 and IKZF1, over the investigated time course. There was no significant release of gDNA in the PAXgene tube whereas a significant release of gDNA was detected in EDTA samples. Likewise, study 3 showed constant EGFR Ct values in the PAXgene system with reliable mutation detection, whereas the high DNA concentration from the EDTA system resulted in false-positive callings. Conclusions: The new system allows researchers to accurately detect and quantify plasma cancer biomarkers from blood samples that have been stored in the tube for up to 7 days at RT. This includes challenging assays based on methylated ctDNA. The system provides the required assay sensitivity to allow the correct assay interpretation beyond the typical 3–6 hour storage limit for EDTA tubes. *For Research Use Only. Not for use in diagnostic procedures.

#2747 Liquid biopsy using extracellular vesicular DNA for EGFR mutation testing in the patients with NSCLC. Jae Young Hur,1 Hee Jung Kim,1 Chang-Min Choi,1 Jae Cheul Lee,2 Kyoung Lee1.

Background: Tumor-derived extracellular vesicles (EV) have been proved to carry double-stranded DNA including oncogenic mutations and expected to be a novel biomarker in cancer detection. Liquid biopsy using cell-free (cf) DNA for EGFR mutation testing is being actively investigated. In this study, we investigated whether liquid biopsy using EV DNA is superior to cfDNA for EGFR mutation testing in the patients with NSCLC. Methods: EV was isolated using ultracentrifugation and confirmed by transmission electron microscopy and zetasizer in 20 plasma samples (all tissue-proven EGFR mutated) and 32 bronchoalveolar lavage fluid (BALF) samples (23 EGFR-mutated including 14 TKI-naïve and 9 TKI resistant, and 9 wild-type). EV and cf DNA was separately extracted from each samples and EGFR mutation testing was performed by peptide nucleic acid (PNA)-clamping method. Results: In 20 plasma samples, the concordance rate of EV DNA for tissue EGFR genotyping was 55% (11/20), while 30% (6/20) in of cf DNA. In 32 BALF samples, however, the sensitivity, specificity and concordance rate of EV DNA for activating EGFR mutations were 100% (23/23), 100% (9/9), and 100% (32/32), while cf DNA showed 73.9% (17/23), 100% (9/9) and 81.3% (26/32), respectively. The kappa value (p-value) of EV DNA was 1.0 (>0.001), while it was 0.714 (0.001) in the case of cf DNA. As for 9 re-biopsy cases for T790M detection in which only 3 patients (33%) was proved as positive T790M, BALF EV DNA identified 2 more T790M patients (total 5 among 9 patients, 56%) without non-matching with tissue typing, while BALF cfDNA found 1 more T790M positive patient with missing 1 tissue proven case (total 3 among 9 patients, 33%) Conclusions Liquid biopsy using EV DNA is significantly superior to cf DNA in both plasma and BALF. A little low sensitivity in plasma EV DNA is supposed to be improved with much more sensitive method such as ddPCR or BEAMing. Liquid biopsy using BALF EV DNA showed almost 100% matching with tissue EGFR typing and seems to be highly promising for T790M detection. A large number of clinical trials should be prompted.

Liquid biopsies have the potential to revolutionize the way physicians select personalized anti-cancer therapies, monitor patient responses to treatment, and characterize acquired resistance to cancer drugs. New tests that use a simple peripheral blood draw offer snapshots of a patient’s total tumor DNA mutation profile and are attractive because of their minimally-invasive modality and because they integrate information from both primary and metastatic disease.

Currently, most plasma cell-free DNA (cfDNA) mutation detection tests used in clinical research detect known hotspot mutations in a limited number of genes. Technologies that interrogate multi-gene panels in cfDNA are advancing, but commercially-available options suitable for clinical use are limited, come at a high cost, and are not customizable. We designed and developed a customized, next-generation sequencing-based, liquid biopsy assay capable of detecting somatic mutations in 87 breast cancer-related genes in cell cycle and estrogen receptor signaling. Targeted regions (147 Kb) were enriched using hybrid capture resulting in an average capture specificity and uniformity of 65.93% and 96.38%, respectively. When tested on cfDNA from healthy donors (n=14), we demonstrated a level of specificity >99.99%. Analytical sensitivity of 0.1% was established on HapMap and reference mutant cell line DNA. Using a pool of 10% mutant DNA, we were able to detect mutations at 0.001% in 96% of samples. A minimum allele frequency of 0.1% were detected. In reference mutant cell line DNA with 1% or 0.1% mutant allele frequencies, we were able to reliably detect all mutations present at 1% and mutations at 0.1% in 50% of the cases. Assay validation on plasma cfDNA with matching tumor from ER+, HER2- breast cancer patients will be presented. In conclusion, we developed a highly sensitive and specific liquid biopsy assay to interrogate 87 breast cancer-related genes. The high level of specificity and sensitivity makes the test ideal not only for detecting known cancer gene hotspot mutations but also for detection of novel gene mutations that may arise during treatment as a result of acquired drug resistance.

Detection resistance mechanisms in patients on EGFR TKI treatment by liquid biopsy. Laure Sorber,1 Karen Zwaenepoel,1 An Wouters,2 Jansens Annelyes,2 Birgitta Hiddinga,3 Jan Van Meerbeck,2 Filip Lardon,2 Christiaan Rolfo,2 Patrick Paweels4. Antwerp University Hospital (UZA), Wilrijk, Belgium; 2Antwerp University (UA), Wilrijk, Belgium; 3Antwerp University Hospital (UZA), Wilrijk, Belgium; 4Antwerp University Hospital (UZA), Edegem, Belgium.

The rise of liquid biopsy, including the molecular analysis of circulating cell-free tumor DNA (ctDNA), has enabled real-time follow-up of cancer patients who receive targeted therapy. Here, we report the case of a lung cancer patient (adenocarcinoma), initially harboring the activating EGFR L858R mutation. Blood and tissue samples were collected during treatment with the EGFR tyrosine kinase inhibitor (TKI) gefitinib, and during the appearance of resistance. Analysis of the tissue biopsies consisted of EGFR mutational analysis by high-resolution melting analysis (HRMA) (all tissue samples), immunohistochemistry (IHC) of cMET (sample 2); droplet digital PCR cMET analysis of both the plasma and tissue samples are now being processed to determinethe course of the mutational load and the best course of treatment. As such, real-time follow-up of cancer patients is crucial to detect the underlying mechanisms of resistance to targeted therapies. Correlation of molecular analysis with the disease course is key. Our case study highlights the potential of ctDNA analysis for detection of both the EGFR T790M resistance mutation and cMET amplification. Hence, tissue biopsies can be supplemented by liquid biopsies in the screening for resistance mechanisms.

Automatic DNA extraction system can improve the EGFR point mutation detection rate of liquid biopsy. Chihoko Nakashima,1 Akemi Sato,1 Tomonori Abe,2 Tomomi Nakamura,1 Kazutoshi Komiya,1 Eisaburo Sueoka,1 Shinya Kimura,1 Naoko Sueoka-Aragane,2 Junichi Kato,2 Mitsuharu Hirai2. 1Saga University, Saga city, Japan; 2ARKRAY Inc., Kyoto, Japan.
The usefulness of liquid biopsy to detect mutations from cancer patients has been well recognized today. However, because the mutation detection rates from plasma DNA were relatively lower than those of tissue re-biopsy, its clinical utility has not been confirmed yet. As previously we reported, we have developed fully automatic high-sensitive point mutation detecting system named mutation-biased PCR and quenched probe (MBP-QP) system for liquid biopsy. Recently, the importance of pre-analytical procedures for plasma DNA analysis has been highlighted. In this study, we examined whether the automatic DNA extraction system can improve the mutation detection rate in our MBP-QP system. Sixty-one plasma samples were obtained from advanced non-small cell lung cancer patients, and plasma DNA extraction was performed from 200μl plasma by manually (200-M), and 200μl (200-A), 1000μl (1000-A) plasma by automatically. We used silica membrane spin column for DNA extraction and high-sensitive point mutation detecting system named mutation-biased PCR and quenched probe (MBP-QP) system for liquid biopsy. The median DNA concentrations quantified by quantitative real-time PCR of 200-M, 200-A, 1000-A were 4.92, 6.00, 20.1 ng/mL plasma, respectively. In terms of the epidermal growth factor receptor (EGFR) L858R point mutation detection, the sensitivity of 200-M, 200-A, 1000-A were 36.6%, 58.5%, 77.5%, that of the specificity were 93.3%, 100%, 96.7%, and the concordance rates were 66.6%, 76.1%, 85.7%, respectively. The size distribution of automatically extracted plasma DNA represented two peaks characteristics at 170 bp and 5 Kb. In this study, we indicate the automatic DNA extraction can improve mutation detection rates in plasma DNA.

Liquid biopsy analysis of FGFR3 and PIK3CA hotspot mutations for disease surveillance in bladder cancer. Emil Christensen,1 Karin Birken-kamp-Denmtröder,1 Iver Nordenfelt,1 Soren Hoyer,2 Kirstin Van Der Keur,3 Kim Van Kessel,4 Ellen Zwarthoff,5 Mads Agerbak,6 Todd Holscher,2 Matteo Pastorino,1 Gabriella Sozzi1. 1Aarhus University Hospital, Aarhus, Denmark; 2University Hospital, Copenhagen, Denmark; 3Aarhus University Hospital, Aarhus C, Denmark; 4Erasmus MC Cancer Institute, Rotterdam, Netherlands; 5Radiology, Maastricht University Medical Centre, Maastricht, the Netherlands; 6Gensignia LifeSciences, Inc, San Diego, CA.

Detecting resistance mechanisms in patients on EGFR TKI treatment by liquid biopsy. Laure Sorber,1 Karen Zwaenepoel,1 An Wouters,2 Jansens Annelyes,2 Birgitta Hiddinga,3 Jan Van Meerbeck,2 Filip Lardon,2 Christiaan Rolfo,2 Patrick Paweels4. Antwerp University Hospital (UZA), Wilrijk, Belgium; 2Antwerp University (UA), Wilrijk, Belgium; 3Antwerp University Hospital (UZA), Wilrijk, Belgium; 4Antwerp University Hospital (UZA), Edegem, Belgium.

The use of liquid biopsies to detect mutations from cancer patients has been gaining traction due to improved detection rates in plasma DNA. The usefulness of liquid biopsy to detect mutations from cancer patients has been well recognized today. However, because the mutation detection rates from plasma DNA were relatively lower than those of tissue re-biopsy, its clinical utility has not been confirmed yet. As previously we reported, we have developed fully automatic high-sensitive point mutation detecting system named mutation-biased PCR (MBP-QP) system for liquid biopsy. Recently, the importance of pre-analytical procedures for plasma DNA analysis has been highlighted. In this study, we examined whether the automatic DNA extraction system can improve the mutation detection rate in our MBP-QP system. Sixty-one plasma samples were obtained from advanced non-small cell lung cancer patients, and plasma DNA extraction was performed from 200μl plasma by manually (200-M), and 200μl (200-A), 1000μl (1000-A) plasma by automatically. We used silica membrane spin column for DNA extraction and high-sensitive point mutation detecting system named mutation-biased PCR and quenched probe (MBP-QP) system for liquid biopsy. In this study, we indicate the automatic DNA extraction can improve mutation detection rates in plasma DNA.
In order to increase cost-effectiveness of low-dose computed tomography (LDCT) lung cancer screening programs, a change in the management of screening-detected lung tumors should be considered. The higher percentage and the better 5-year overall survival of early stage tumors in LDCT screening series than in clinical practice argue in favor of screening programs. The overall limited reduction of mortality observed in screening trials with an observational control arm suggests that some of the screening-detected early stage tumors might be over-diagnosed.

In our Institution we are trying to address this issue by the development of complementary biomarkers able to improve detection of aggressive disease. Targeted next-generation sequencing was performed in 94 LDCT screening-detected tumors selected from 2008 to 2010 participating in 3 screening trials enrolling 9,248 volunteers. Mutation profile was associated with subjects’ clinicopathologic features and with the risk profile of a plasma microRNA signature classifier (MSC). Using data available through The Cancer Genome Atlas database (TCGA), we compared the mutations of a selected set of non-small cell lung cancer (NSCLC) cases detected in standard clinical practice to LDCT screening-detected NSCLC cases. The 5-year overall survival (OS) of screening patients with and without mutations in the tumors was 64% and 100%, respectively (p = 0.019). By combining the mutational status with the MSC, patients were stratified into 3 groups with 5-year OS ranging from 41% to 96% (p < 0.0001) and the prognostic value was significant even when controlling for stage (p = 0.017). The comparison with TCGA data revealed a higher number of non-mutated NSCLC among screening patients (21% vs. 13%), despite the similar spectrum and frequency of mutations. In addition, the difference in 5-year OS between subjects with and without mutations was exclusively detected in screening patients. The mutation profile of screening-detected tumors, while similar to that of clinically detected tumors, was a strong predictor of OS. The combination of tumor mutational status and a circulating miRNA-based risk classifier predicts tumor aggressiveness and clinical outcome and may find rapid application in LDCT screening programs.

#2754 A novel liquid biopsy method for development of aptamer libraries that bind blood plasma exosomes from breast cancer patients. Valeriy Domeynuk, Symon Levenberg, Adam Stark, Mark Miglarese, David Spetzler. Caris Life Sciences, Phoenix, AZ.

Improved technologies capable of characterizing system-wide changes associated with complex diseases will be required to be able to detect millions of proteins and their isoforms as well as multi-molecular complexes. We present a method for developing aptamer libraries using blood plasma exosomes that provides unprecedented system-wide coverage of native exosomal complexes. To train a naïve aptamer library toward cancer samples (positive selection), the library (10^11 biotinylated ssODN species) was incubated with plasma from individual cancer patients and aptamer-bound exosomes were isolated using polymer-based precipitation. Negative selection was performed by contacting the aptamer library with exosomes from donors without breast cancer and recovering unbound aptamers from the supernatant. In all, 12 libraries trained toward 12 individual breast cancer patients were used to probe additional samples. Receiver operator analysis (ROC) was performed to compare expression of mRNA transcripts across all four methods. Results showed PCA specific genes were detected in whole blood, Exo-52 exosome prep and samples enriched for CTCs, while exosomes isolated using CellSearch EpCAM capture failed to detect any PCA transcripts. ROC showed ExoRNAeasy exosome prep detected PCA specific mRNA transcripts with significantly higher sensitivity and specificity compared to three other methodologies. Area under curve (AUC) for ExoRNA prep 0.65 to 0.75 (average of z score at 3.27 p = 0.0023), compared to AUC for PAXgene is 0.55 to 0.83, (average of z score at 2.64 and p = 0.05) and CTC samples is 0.52 to 0.67, (average of z score at 1.63 and p = 0.19). For CellSearch exosome method, the AUC is 0.47 to 0.52, average of z score at 0.66 and p = 0.32). These results and in vitro studies investigating cytotoxicity profiles of this assay as a viable alternative to whole blood and CTC based assays. Further testing for expression of markers associated with prognosis and treatment response is necessary to warrant its prognostic or predictive clinical utility.

#2755 Comparison of blood based liquid biopsy methodologies for improved risk assessment of prostate cancer (PCa). Yashoda Rajputohit, Shibu Thomas. Lung tumors detected from subjects participating in 3 screening programs, Approximately 28,000 men die from prostate cancer in the US each year. Predictive biomarkers can provide patient risk assessment to enable therapeutic decision making. Compared to tumor, blood based liquid biopsies offer greater flexibility for non invasive sample collection and allows for continuous monitoring of treatment response. While various liquid biopsy sample types and methodologies are currently available, it is critical to identify which method offers the highest sensitivity and specificity for clinical decision making. In this study we systematically compared specificity and sensitivity of prostate cancer detection using a pre-selected panel of PCA specific mRNA transcripts using four different methodologies. In this prospective laboratory study, we collected five blood tubes from a cohort of 40 metastatic castrate resistant prostate cancer (mCRPC) patients and 20 age matched healthy volunteers (HV). Circulating tumor cells (CTCs) were enumerated and blood samples enriched for CTCs were isolated for mRNA evaluation. Technology platform, based on fluorescent labeling mRNA, and multiplex, high-sensitivity assays using universal primers, thus leveraging PCR sensitivity while eliminating the need for separate reverse transcription reactions and mitigating amplification biases introduced by target-specific qPCR. The Firefly assays have been validated in a wide range of biological samples including plasma, serum, urine and cell culture supernatant, providing experimental flexibility. The 96well plate assay format enables high-throughput screening of samples with readout conducted on standard flow cytometers, thereby omitting the need for complex and expensive dedicated instrumentation. Finally, the integrated Firefly Analysis Workbench software enables easy and rapid data analysis, visualization, and export in under ten minutes, and includes key features such as standard curve analysis and publication-quality heatmaps and graphs. Here we present several studies investigating cytokine profiles in human and rodent samples, and circulating tumour microRNA profiles, using the Firefly Platform. Together, this novel combination of bioinformatics tools and multiplex, high-sensitivity assays enables rapid discovery and validation of biomarker signatures from fluid samples.
Using liquid biopsies and NGS as tools to analyze mutation burden and copy number variation in the blood of a patient with triple negative breast cancer to better inform therapeutic targets. Kellie Howard, Kimberly Kruse, Brianna Greenwood, Elliott Swanson, Mathias Ehrich, Christopher K. Ellison, Taylor Jensen, Sharon Austin, Arturo Ramirez, Debbie Boles, John Pruett, Elizabeth Mahan, Michael Dorschner, Sibel Blau, Marcia Eisenberg, Steve Anderson, Anup Madan, Covance, Redmond, WA; Sequenom Laboratories, San Diego, CA; RareCyte, Inc., Seattle, WA; Laboratory Corporation of America® Holdings, Research Triangle Park, NC; University of Washington, Seattle, WA; Northwest Medical Specialties, Payzallup, WA; Covance, Durham, NC.

The ability to characterize molecular signature of cancer from liquid biopsies is resulting in the development of innovative health care for patients. Longitudinal changes in the mutational profiles of DNA isolated from liquid biopsies are being used to better understand and monitor the development, progression, and evolution of therapy resistance in cancer patients. To define changes in the mutational landscape and predict drug susceptibilities in Triple Negative Breast Cancer (TNBC) patients, we used whole exome analysis to profile circulating tumor cells (CTCs) and circulating tumor DNA (ctDNA) from eight selected time points of a patient enrolled in the Intensive Trial of OMics in Cancer clinical Trial (ITOMIC-001). The patient initially received weekly cisplatin infusions followed by additional targeted therapy. Peripheral blood samples were collected at specific time points over a period of 272 days, starting several months after cytoreduction and the clinical trial. Our data indicate that the identified mutations in genomic DNA isolated from CTCs and ctDNA can be used to understand and mitigate the impact of tumor heterogeneity in addition to identifying clinically relevant mutations at these selected time points. To further increase the resolution of our analysis, we profiled ctDNA from these samples to a higher depth targeting only clinically relevant genes. These analyses increased the sensitivity of detection and identified additional targets that could have been used for therapeutic intervention. In addition to sequence variants, copy number variations (CNVs) have also been significantly associated with the development of metastasis and changes in CNVs have been used to monitor disease progression. We performed a bioinformatics analysis of genomic instability and CNVs across 32 different time points from ctDNA from the same patient throughout the treatment period. The genomic instability number (GIN) calculated for each of the 32 time points seems to mirror the overall CTC burden in the patient at each time point tested. CNV analysis is ongoing and these data sets are being further analyzed in combination with TCGA data to define possible cancer driver genes for the functional prediction of significant TNBC candidate alterations and the results of these analyses will be presented.

Critical biomarkers such as cell-free DNA (cfDNA) derived from tumors and circulating tumor cells (CTCs) can be detected and analyzed from a simple blood draw. These analytes are fragile, prone to degradation, and present in extremely low quantities. Therefore, proper preservation of these analytes is necessary to ensure accuracy of test results. Several blood collection tubes are commercially available for cfDNA applications, and selecting the ideal blood collection tube for cfDNA impacts test results, sample collection logistics and costs. However, no comprehensive and systematic evaluation of performance among these tubes is available. This study evaluates five commercial blood collection tubes: Lbgard™ Blood Tube (Biomatrica), Streck cfDNA BCT™ (Streck), PAXgene Blood cfDNA Tube (PreAnalytiX), Cell-Free DNA Collection Tube (Roche), and EDTA (BD). Healthy donor blood samples were collected in each tube type and incubated over several days at different temperatures. Total plasma DNA was subsequently isolated, and the yield, fold increase versus time 0 and quality of purified DNA were compared. cfDNA controls were also spiked into blood samples collected in each tube type and measured by droplet digital PCR to determine the mutant allele frequencies over time. Finally, the yield and quality of cfDNA isolated from stage IV colorectal cancer blood collected in Lbgard Blood Tube, Streck cfDNA BCT and EDTA were compared. Additionally, the inhibition of hemolysis and CTC stabilization were also assessed. Our results show that Lbgard Blood Tube, Streck cfDNA BCT, PAXgene cfDNA Tube and Cell-Free DNA Collection Tube are superior to EDTA tubes in maintaining cfDNA yield and quality over 7 days at ambient temperature. Lbgard Blood Tube out-performs all tested blood tubes in inhibiting genomic DNA release for the longest duration (14 days) and across the widest temperature range (4°C, 25°C and 37°C). Lbgard Blood Tube shows equivalent inhibition of genomic DNA release to Streck cfDNA BCT for clinical samples, and both tubes out-perform EDTA blood tubes. Lbgard Blood Tube also consistently shows better CTC stabilization and inhibition of hemolysis over Streck cfDNA BCT. This comprehensive and systematic study of blood collection tube performance will inform the precautionary and exhaustive assessment of blood sample stability, allowing researchers to make informed decisions based on their sample stabilization needs.

Technical limitations of capture-based, targeted deep sequencing for the detection of somatic variations in cell-free DNA. Gahee Park, Seoul National University/ Samsung Genome Institute, Seoul, Republic of Korea.

Despite widespread applications of capture-based targeted deep sequencing, its limitations on detecting circulating tumor DNA (ctDNA) have not been systematically elucidated. Here, we analyze and characterize parameters critically determining its detection limits; depth of coverage and background errors. The depth increase by using more cell-free DNA (cfDNA) was saturated at around ~300x with ~50 ng of cfDNA primarily due to a duplication artifact, which limited the detection sensitivity of the method. Next, characterizing background errors, we uncovered that a majority of errors were not derived from biological origins but technical artifacts, especially during sample preparation and library construction rather than sequencing. Thus, it is important to use an appropriate protocol for those steps minimizing background errors. Considering the depth of coverage and the background error rate, we estimated the detection depth approximately to be 0.4% variant allele frequency at 95% confidence level. Applying the method to pancreatic cancer patients, we found that the levels of ctDNAs measured by cfDNA sequencing well correlated with clinical responses to therapy and/or disease progression, but biopsy-free profiling of somatic variants was limited by the moderate sensitivity of 72% and PPV of 74% at the variant level. Our results clarify technical limitations of targeted deep sequencing and provide a guideline for applying the technique to analyze cfDNA.

Proof of principle studies for detection of circulating renal cancer cells from blood samples using diverse technologies. Yvonne Maertens, Verena Humberg, Julie Steineisel, Martin Boegemann, Andres J. Scharader, Christof Bernemann. University Hospital Muenster, Muenster, Germany.

Background: During the past years, much progress has been made in detection and analysis of circulating tumor cells (CTCs) in several tumor entities, including prostate cancer, breast cancer or lung cancer. However, little is known about circulating tumor cells in patients suffering from clear cell renal cell carcinomas. The majority of technologies detecting CTCs is based on expression of the surface antigen EpCAM. Additionally, biophysical approaches have been invented to detect CTCs based on size, invasive capacity or density. In order to be able to detect CTCs in patient samples, in vitro establishment of the most accurate isolation procedure followed by precise detection techniques has to be performed. Aim of our studies was to build a stable in vitro fundamental of isolation and subsequent detection of CTCs in ccRCC patients. Methods: We made use of 4 different technologies, all of which have been approved for detection of CTCs in distinctive tumor entities. We used EpCam based positive enrichment of CTCs, Ficolld density centrifugation followed by CD45-positive cell depletion, rosette formation followed by CD45 positive cell depletion as well as size and deformability based enrichment technologies by using the Parsortix system. Furthermore, by using 4 phenotypically distinct ccRCC cell lines, we tried to detect markers unique for tumor cells in demarcation to blood cells. Results: By performing spiking experiments of renal cancer cells, we found the highest recovery rates by using the size based Parsortix system. Interestingly, the most established technique of EpCam based isolation failed in three out of four cell lines to recover more than 40%. Expression of well-established markers in ccRCC, PAX8, was weak to absent in ccRCC patients. Method: We made use of 4 different technologies, all of which have been approved for detection of CTCs in distinctive tumor entities. We used EpCam based positive enrichment of CTCs, Ficolld density centrifugation followed by CD45-positive cell depletion, rosette formation followed by CD45 positive cell depletion as well as size and deformability based enrichment technologies by using the Parsortix system. Furthermore, by using 4 phenotypically distinct ccRCC cell lines, we tried to detect markers unique for tumor cells in demarcation to blood cells. Expression of well-established markers in ccRCC, PAX8, was weak to absent in ccRCC patients.
cells. The usage of the size based Parsortix system showed the highest recovery rates and should therefore be analyzed in more detail on samples of ccRCC patients. Secondly, an exclusive marker for defining a renal CTC is still missing. Some well-established ccRCC markers, like CA-9, failed to specifically detect renal cancer cells in blood samples, as they were either present also in healthy blood samples or absent in renal cancer cell lines.

**CLINICAL RESEARCH: Outcomes in Patients and Survivors**

#2761 Adjuvant chemotherapy outcomes of node negative, T1a,Tib, T1c hormone receptor-negative HER2-positive breast cancer patients. Anu Paul, Runhua Shi, Prakash Peddi, Gary Burton. LSU Health, Shreveport, LA.

Background: Patients (pts) with early stage HER2neu-positive breast cancers have a higher risk of recurrence and death compared to hormone receptor-positive patients. NCCN guidelines recommends adjuvant chemotherapy for Stage II and above HER2-positive breast cancer patients. It is unclear what benefit patients with Stage I HER2-positive breast cancer receive from adjuvant chemotherapy. The current study evaluates the effect of adjuvant chemotherapy on the survival of early stage ER/PR negative, HER2-positive breast cancer patients registered to the National Cancer Data base (NCDB) from 2010-2012. Patients and Methods: 3416 women from the NCDB were identified with Stage I ER, PR negative, HER2-positive breast cancer diagnosed between 2010-2012. The primary measured outcome was overall survival. Pts were grouped by tumor size (T1a,Tib,T1c) and adjuvant chemotherapy or no adjuvant chemotherapy. Additionally, patients were also grouped into lumpectomy with radiation and mastectomy with or without radiation. Adjusted variables included age, race, Charlson Comorbidity Index (CCI), payer status, income, education, distance travelled, diagnosing/treating facility and treatment delay. Multivariate Cox regression was used to investigate the effect of adjuvant chemotherapy on overall survival while adjusting for other factors. Results: There were a total of 3416 patients, mean age at diagnosis of 57.9 (range 22-90). The mean age was 56.2 years for the chemotherapy group and 61.8 for the no chemotherapy group. Pathological stage distribution was T1a (24.9%), T1b (24.7%) and T1c (50.2%). Adjuvant chemotherapy was received by 95.5% of T1a, 83.5% of T1b and 95% of T1c pts. Mean patient follow up was 2.7 years (range 0.05-5 years). In univariate analysis, the hazard ratio (HR) of death for chemotherapy vs no chemotherapy in each T stage was: T1a: 1.22 (0.46-3.28), T1b: 0.221 (0.095-0.512), T1c: 0.217 (0.094-0.498). In multivariate analysis, adjusting for other factors in the model, HR of death was 0.51 (95%CI: 0.26-1.03) for chemotherapy vs no chemotherapy. The HR of death was 1.92 (95%CI: 1.11-3.32) for pts who received mastectomy without radiation compared to lumpectomy with radiation. In addition, we observed a HR of 5.16 for CCI score of 2 or above as compared to score of 0. There was no difference in outcome based on payer status or race. Conclusion: Patients with early stage T1 a-c HER2-positive breast cancer had a marginal improvement in overall survival with the addition of chemotherapy. Patients who underwent lumpectomy with radiation were also found to have better overall survival compared to mastectomy without radiation. However, the relatively short follow up and the lack of cancer recurrence information preclude making definitive conclusions relative to adjuvant therapy for pts with these tumors. Longer follow-up and prospective controlled trials will be needed to quantify these potential benefits.

#2762 The comparison of allogeneic stem cell transplantation outcomes between haploidentical donor and international donor: A retrospective multi-institutional study in Korea. Hyunkyung Park, Yoo Jin Lee, Sang-Jin Shin, Jayoun Lee, Anu Paul, Sabine Rohrmann, Volker Arndt. Epidemiology, Biostatistics and Prevention Institute, University of Zurich, Zurich, Switzerland; National Institute for Cancer Epidemiology and Registration, Zurich, Switzerland.

Introduction: Due to improving prognosis for prostate cancer survivors and increased awareness of late- or long-term treatment effects, monitoring long-term well-being among prostate cancer survivors has gained increasing attention. In this systematic review, we identified and synthesized studies comparing health-related quality of life (HRQoL) among long-term prostate cancer (PC) survivors (i.e. >5 years past diagnosis) by primary treatment. Methods: In order to summarize current literature research results, we searched multiple databases, including Pubmed, Medline, Embase, PsycINFO, Cinahl, Web of Science and Cochrane Central Register of Controlled Trials to identify all relevant articles. Studies had to assess at least overall quality of life (QoL) of prostate cancer patients. A total of 20 studies were included in the systematic review. Results: A total of 24,107 patients were identified for inclusion across studies. Conclusion: This review was useful for cancer centers to identify gaps in their current care and to inform future research and clinical practice.

#2763 Health-related quality of life among long-term prostate cancer survivors by primary treatment: A systematic review. Salome Adam, Anita Feller, Sabine Rohrmann, Volker Arndt. Epidemiology, Biostatistics and Prevention Institute, University of Zurich, Zurich, Switzerland; National Institute for Cancer Epidemiology and Registration, Zurich, Switzerland.

Introduction: Due to improving prognosis for prostate cancer survivors and increased awareness of late- or long-term treatment effects, monitoring long-term well-being among prostate cancer survivors has gained increasing attention. In this systematic review, we identified and synthesized studies comparing health-related quality of life (HRQoL) among long-term prostate cancer (PC) survivors (i.e. >5 years past diagnosis) by primary treatment. Methods: In order to summarize current literature research results, we searched multiple databases, including Pubmed, Medline, Embase, PsycINFO, Cinahl, Web of Science and Cochrane Central Register of Controlled Trials to identify all relevant articles. Studies had to assess at least overall quality of life (QoL) of prostate cancer patients. A total of 20 studies were included in the systematic review. Results: A total of 24,107 patients were identified across studies. Conclusion: This review was useful for cancer centers to identify gaps in their current care and to inform future research and clinical practice.

#2764 Creating a review process of a digital photo database collected on NRG NSABP B39/RTG 0413 phase III clinical trial for evaluation of cosmetic results from breast conserving therapy (BCT). Ashley Sekhon, Ruiqi Zhao, Yan Wang, Debora Grant, Kathryn A. Winter, Jennifer Moughan, Douglas W. Arthur, Stephen J. Chmura, Atif J. Khan, Simona F. Shaitelman, Alex M. Martinez, Frank A. Vicini, Julia R. White. Ohio State University, Columbus, OH; NRG Oncology, Philadelphia, PA; Virginia Commonwealth University, Richmond, VA; University of Chicago, Chicago, IL; Rutgers Cancer Institute of New Jersey, New Brunswick, NJ; MD Anderson Cancer Center, Houston, TX.

Introduction: The success rate of hematopoietic stem cell transplantation (HSCT) from HLA-mismatched donor has been increased according to the development in management of complications including graft versus host disease (GVHD) and infections. Especially, haploidentical HSCT provides an opportunity for all patients who do not have HLA-matched sibling donor. Methods: In this study, we compared HSCT outcomes between haploidentical familiar donor and international donor (donors from Japan, China, Germany, Unites States of America and Taiwan) in acute leukemia patients. We reviewed the overall survival (OS), relapse free survival (RFS) and complications. Results: Total 142 acute leukemia patients performed HSCT from 2000 to 2016; 98 patients underwent haploidentical donor transplantation and 44 patients underwent international donor transplantation. Major variables such as age, sex, disease status or race. Conclusion: These data suggest that HSCT from haploidentical donor shows similar outcomes including survival outcomes and complications with international donor transplantation. Therefore, haploidentical donor transplantation can be good choice for acute leukemia patients who have no HLA-matched sibling donor.
CLINICAL RESEARCH: Outcomes in Patients and Survivors

Background: Esophageal cancer is the 6th leading cause of cancer death globally, with geographical high-risk areas in Asia, the Middle East, and eastern and southern Africa. Esophageal squamous cell carcinoma (ESCC) is the more common variant in Africa. In Kenya, its incidence is 2nd in men after prostate cancer and 3rd in women after breast and cervix-uteri cancers. Late presentation is a common occurrence in developing countries and is multifactorial due to challenges in access to health care, low socioeconomic status and delayed or missed diagnosis. A large percentage of these tumors are thus unresectable and are only eligible for palliative care via stenting. Our hospital is a 300-bed referral center in southwestern Kenya, which is a hotspot for ESCC, and we see over 400 cases of ESCC annually. Methods: We have developed a technique for placement of esophageal self-expanding metallic stents (SEMS) without fluoroscopy that is safe and easily reproducible. This is an outpatient procedure, with the majority done under conscious sedation, and routine follow-up is not necessary. The tumor margins are noted at time of video endoscopy, a guidewire is placed, and dilation done with Savary dilators as required. The SEMS are then loaded on the stent delivery device and deployed into the proper position based on measurements, and placement is subsequently confirmed via endoscopic visualization. Results: A total of 3000 SEMS have been placed to date at our hospital, without using fluoroscopy. The male/female ratio has been 1.5:1, and the average age has been 60.4 years. The distribution of tumor locations was 67% in the middle and distal third. The most common complications were tumor overgrowth with obstruction and stent migration. Procedure related mortality was 0.3%. Post-procedure improvement in dysphagia score was seen in over 80%, and patient satisfaction was high. Initial data on post stent survival time around 8 months 250 days. Conclusions: Placement of SEMS for ESCC, without fluoroscopy, is a safe and reproducible procedure which has a low rate of adverse events. This procedure results in effective palliation of a difficult disease and can easily be done in resource-limited settings which have endoscopy capabilities. Current efforts are ongoing to increase opportunities for training endoscopists in this procedure and for provision of affordable stents in Africa.

Introduction: Breast cancer presents a challenge to the totality of a woman’s life. Correlates of life satisfaction among married women with breast cancer have not been very well explored. Purpose: This study seeks to determine the relationship that exists between life satisfaction with depression, cognitive emotional regulation, sexuality, self-concept, dejection, interpersonal conflict and social support among married women with breast cancer in Southwest Nigeria. It also seeks to study some of these variables predict life satisfaction in the respondents. Method: The variables in the study were assessed using modified standardized instruments which were revalidated for cultural suitability after ethical approvals were obtained in each of the 5 centres involved in the study. The instruments were given to breast cancer patients after informed consent to participate in the study have been obtained. Result: The larger proportion (148 or 40.5%) of the participants were in the age range of 46-55 years and 112 (30.7%) had stage III disease. Analysis of data showed that significant linear relationship exists between life satisfaction of married women with breast cancer and depression (r = 0.200**; p < 0.001), self-concept (r = 0.306***; p < 0.001), cognitive emotional regulation (r = 0.398***; p < 0.001), dejection (r = 0.226***; p < 0.001), interpersonal conflict and social support (r = 0.316**; p < 0.01), anxiety (r = 0.315**; p < 0.01) and social support (r = 0.534; p < 0.001). There were also significant correlations among the independent variables. Conclusion: Psychosocial factors are potent predictors of life satisfaction among married women with breast cancer. Based on the findings, it was recommended that psychosocial intervention based on the factors identified as causative agents of life satisfaction should be developed and implemented for married individuals.

Introduction: After local control and overall survival, acceptable cosmesis is the next most important goal of BCT. Digital photos (DP) are commonly used for assessing cosmesis on clinical trials. On NRG NSABP B39/RT0G 0413, DP at baseline, 1, and 3 years post-radiation were submitted for review by a panel of breast cancer specialists. Given no current standards for central DP review, it is difficult to develop a standard for subjective DP evaluation. The initial standardization of the photo database and reliability of the panel review is described. Methods: De-identified DP submitted and stored at NRG SDMC were downloaded to a secure FTP site. Cases with only 1 time point, no baseline, or photos from different patients were excluded. A minimum photo quality was set, including pre-specified criteria for contrast/ brightness, background, and cropping to eliminate unnecessary DP below and above the umbilicus. DP were edited with MATLAB and saved in a Reformatted Digital Photo Database (RDPD). A training set was created defining 4 global cosmetic scores, and each individually assessed criteria of cosmesis and the DP were reviewed. A 14 case calibration set followed the training set. The process for panel review was adapted from the methods reported in the START and RAPID trials. The review panel consisted of 6 breast-specific radiation oncologists, who reviewed in groups of 3. For each session, the training set was reviewed and calibration set scored. A separate 30 case test set randomly selected from the RDPD was reviewed by 2 groups of 3. The calibration and test sets were evaluated for agreement of categorized scores (excellent/good vs. fair/poor). Results: There were 2064 DP from 892 patients on NRG NSABP B39/RT0G 0413 documenting the anterior view of both breasts. After exclusions, 1712 reformatted DP were saved in the RDPD. Five 1-3 hour review sessions resulted in scoring of 7777 DP (~155 per session). Only 2/7777 (0.1%) DP were deemed poor quality and not able to be scored. There was full agreement in categorized scores for 12/14 cases (86%; kappa = 0.82) across the 5 calibration sets; and 27/30 (90%; kappa = 0.71) for the 2 test set reviews. Conclusions: Cosmesis DP prospectively collected on a large phase III clinical trial can be digitally formatted in a systematic fashion for consistent photo quality, allowing for cosmesis consensus panel review without photo quality bias. High agreement in categorized scores allowed reviews to be completed by multiple 3-person review groups. Future work will focus on creating an updated and systematic analysis tool of these photos for objective evaluation of cosmesis using the same scoring guidelines that can then be compared to physician reported outcomes. CONCLUSIONS: We observed wide variation in the current application of standing orders. Intermediate risk regimens had the most inconsistent practices, with a near equal number of clinics choosing either actively including or excluding CSF order sets. The majority of clinics using standing orders included CSF for dose dense and high risk regimens but only 19% (38%) actively excluded CSF for low risk regimens. These results support the need for more evidence to inform clearer guidelines on CSF use in intermediate risk regimens and studies that evaluate the effects of existing CSF standing orders on guideline adherence and patient outcomes. #2768 Treosulfan induces differential gonadal toxicity profile compared with Busulfan. Mattan Levi,1 Salomon Stemmer,1 Jerry Stein,2 Ruth Shalgi,1 Irit Ben-Aharon1.1 Institute of Oncology, Davidoff Center, Rabin Medical Center, Beilinson Campus, Petah-Tiqva, Israel;2 Schneider Children Medical Center, Petah-Tiqva, Israel.

Background: Treosulfan (1-treitol-1,4-bis-methanesulfonate), an alkylating agent with myeloablative and immunosuppressive traits, has been increasingly incorporated as a main conditioning protocol for hematopoietic stem cell transplantation (HSCT) in pediatric malignant and non-malignant diseases. Treosulfan has been shown to present lower toxicity profile compared with conventional myeloablative regimens such as busulfan. Yet, while busulfan is considered highly gonadotoxic, the gonadal toxicity profile of treosulfan remains to be elucidated. Our aim was to study the short and long term gonadal effect of treosulfan in comparison to busulfan. Methods: Maturity 2 months old male and 3 months old female mice (“pubertal cohort”) were injected with treosulfan 2000 mg/kg or busulfan 40 mg/kg and were sacrificed one week, one month or six months post drug administration. Immature male and female mice (“prepubertal cohort”) were injected with treosulfan 750 mg/kg or busulfan 15 mg/kg and were sacrificed one week or three months post drug administration. Testicular function was assessed by measurements of sperm count and motility, testes and epididymides weight, serum anti-Mullerian Hormone (AMH) and testicular ID4 or GFRA1 mRNA (markers for stem spermatogonia). Immunohistochemistry was performed to evaluate testicular proliferation (Ki-67), apoptosis (TUNEL) and meiotic-active spermatocytes (DAZL-PGNA). Ovarian function was assessed by measurements of ovary weight, serum AMH, follicles count and ovarian SOHLH2, NOBOX of FIGLA mRNA (markers for primordial follicles). Immunohistochemistry was performed to evaluate ovarian proliferation (Ki-67), apoptosis (TUNEL) and growing follicles (AMH-PGNA). Results: Treosulfan testicular toxicity was milder compared to busulfan toxicity, in both mature and immature male mice, while stem spermatogonia were spared. However, ovarian toxicity of both treosulfan and busulfan was severe and permanent in both mature and immature female mice; possibly by a short term irreversible reduction of reserve primordial follicles in the ovaries. Conclusion: Our results indicate that treosulfan exerts a differential gonadal toxicity profile compared with busulfan, manifested by mild testicular toxicity and severe ovarian toxicity.
