Gastric cancer is often diagnosed at an advanced stage and currently remains the third most common cause of cancer-related death worldwide. Early detection and surgical intervention has been found to reduce GC-associated mortality, yet an efficient and cost-effective screening program still does not exist. Several proteins including Lgr5, CD44 and CD133 have been found to be upregulated during the H. pylori-associated Correa pathway of carcinogenesis, and have the potential to act as biomarkers for early detection. The tools of mathematical oncology facilitate the development of models capable of both reproducing and predicting the increase in expression of these markers, and thus the patient-specific progression of disease. These predictions can allow the identification of optimal screening times to minimize the risk of undetected malignant transformation. Here, we present a combined mathematical-statistical approach to identifying such optimal screening times in a manner which is both biomarker-independent and H.pylori status-independent, thus allowing improved generalizability and the potential for broader application in the clinical setting. Logistic regression models are developed for each biomarker of interest (Lgr5, CD133, CD44) to determine the likelihood of a patient being either early in the Correa pathway (gastritis or metaplasia) or late in the pathway (dysplasia or carcinomas) based on current age, sex and biomarker-positive cell fraction obtained from immunohistochemical staining of biopsy tissue samples. Calibrated models for all three biomarkers were able to accurately classify disease stage as determined by pathology report in more than 85% of an initial cohort of 39 patients. Mathematical models describing the temporal evolution of the ex- pression of each marker of interest are then defined based on clinical data. Coupled with the statistical tool for identifying the likelihood of being at each stage of disease for all combination of input parameters, this framework can forecast time to a clinically-significant endpoint such as the development of dysplasia or adenocarcinoma for future patients, allowing the suggestion of optimal timing of which treatment is appropriate based on progression to a threshold threshold.

The results suggest that for 13 out of 16 patients in our initial test cohort (81%), models independently developed using three different markers all recommend similar follow-up screening times, showing promise for the general applicability and robustness of such a tool.

### #4545 A computational biology method to predict HMA or lenalidomide treatment response in non-Del(5q) MDS.
Leylah Drusbosky,¹ Neeraj Kumar Singh,¹ Shireen Yalı,¹ Taher AAbbasi,² Christopher R. Cogle¹,¹ Univ. of Florida, Gainesville, FL;²Cellworks Group Inc, CA.

Despite decades of effort, most disseminated cancers remain incurable, and progression from localized to metastatic disease is largely responsible for cancer-related mortality. In metastatic disease, an ongoing battle between tumor and host occurs at each site; tumor-associated antigens, stress proteins, and danger-associated molecular patterns can both initiate and continually stimulate an immune response against a tumor. Adding an additional layer of complexity, locally activated cytotoxic T cells traffic through the host circulatory system to also surveil metastasis elsewhere in the body. Thus, metastatic tumors are highly interdependent; changes in the nonlinear tumor-immune interactions in one tumor can perturb the systemic antitumor immune response, potentially facilitating spontaneous regression or aggressive outgrowth in distant sites. This can additionally influence the clinical outcome of therapeutic intervention, which depends on therapy-induced changes in tumor-immune dynamics both locally and systemically, as well as patient-specific initial conditions of the global disease. Using the tools of mathematical oncology we gain insights into this complex interconnectivity between metastatic sites. ODE models have been developed which incorporate both local tumor-immune interactions in each tumor site and the trafficking of activated T cells systemically, and can be parameterized by experimental and clinical investigations. Using four primary tumor sites (lung, liver, breast, kidney) we simulate the growth behavior of a primary site upon both seeding, growth, and treatment of a secondary (or several) metastatic site(s). In the presence of several metastatic sites, the dissemination of activated T cells is not necessarily intuitive and depends on many factors including the blood flow fraction to each organ and the tumor volume to organ size ratio. Certain sites may experience inhibition of growth, and other sites may be promoted upon seeding of an additional site. We computationally analyze all combinations of metastatic sites, and predict which sites are likely to benefit (tumor growth) and which to suffer (tumor shrinkage) in each combination based upon known properties of physiological blood flow and tumor volume at initial presentation. This allows the identification of which sites in each combination would be the optimal target for surgical therapy in order to induce the maximum reduction in overall tumor burden. Furthermore, we can simulate local radiation at each respective site, quantifying the difference in model-predicted decrease in overall tumor burden between individual targets. The results facilitate an improved understanding of general disease kinetics in the metastatic setting, emphasizing that ‘local’ therapy is highly likely to have systemic effects, and support the case for a paradigm shift in treatment target selection for metastatic disease.

### #4546 Structural evaluation of mutations identified on Cue domain of FANCD2.
Mohd Quadir Siddiqui, Ashok K. Varma. TMC-ACTREC, Navi Mumbai, India.

Fancconi anemia complementation group D2 (FANCD2) protein plays pivotal role in DNA interstrand crosslink (ICL) repair and genome stability. FANCD2 comprises conserved CUE domain at N terminus, which is important for DNA ICL repair and protein stability. However, molecular mechanism associated to genetic alteration has not well characterized. Here, we have carried out multi-modal approaches to explore folding pattern of FANCD2 CUE domain and functionally relevant mutations. Dynamic Light Scattering and Mass Spectrometry data of purified proteins could revealed that wild-type protein is predominantly monomeric, but mutated counterparts are exhibiting oligomeric properties. Secondary, tertiary structure assessment and their thermal stability of wild-type and mutants were studied by Circular Dichroism (CD) and Fluorescence spectroscopy. Furthermore, binding affinity and kinetics of Cue domain and mutants with monoubiquitin was evaluated by surface plasmon resonance (SPR). Molecular modelling, simulation, normal mode analysis, principal component analy-

#4547 Structural, thermodynamics and kinetics role of novel hot-spot mutations of BCR-ABL1 in resistance towards 'ibs' inhibitors. Erik Laurini, Domenico Marson, Silvia Boccardo, Maurizio Fermeglia, Sabrina Pricl. Universita di Trieste, Trieste, Italy.

The present contribution integrates structural, computational, and molecular biology techniques to understand the eventual role of our newly reported hot-spot mutations of the BCR-ABL1 KD in TKI resistance observed in CML patients (1) using a 'two-tier level' investigation: isolated KDs and SH2-like SH3-KD BCR-ABL1 structures. Specifically, in silico experiments will disclose the effects exerted by the "hot-spot" BCR-ABL1 mutations on the protein structure, thermodynamic stability, and ability to interfere with BCR-ABL1 binding to specific TKIs (e.g., imatinib, dasatinib, and ponatinib). Structural biology (e.g., SAXS) evidences of wild type and mutant isolated KDs and SH2-linker SH3-KD (SSK) constructs (per se and in complex with TKIs) will be discussed to support in silico predictions. Direct drug binding thermodynamics and kinetics to both KD and SSK constructs will be measured using isothermal titration calorimetry and surface plasmon resonance. In vitro kinase assays will monitor the ability of these mutant isoforms to auto-phosphorylate and to phosphorylate a substrate peptide. (1) Giobbons DL, Pricl S, Posocco P, et al., Molecular dynamics reveal BCR-ABL1 polymutants as a unique mechanism of resistance to PAN-BCR-ABL1 kinase inhibitor therapy. Proc Natl Acad Sci U S A. 2014 Mar 4;111(9):3550-5. doi:10.1073/pnas.1321173111

#4548 Uncovering the membrane targeting mechanism of human unconventional class I myosins: a computational study. Daniel Gruffat, Shanee Singh. CUNY Brooklyn College, Brooklyn, NY.

The class I myosins (Myo1) are a widely expressed family of single-headed, non-filament-forming, membrane-binding myosins that comprise several sub-classes and are characterized by their ability to cross-link the plasma membrane to the underlying actin cytoskeleton by the presence of a lipid-binding region in the tail domain and an actin-binding region in the motor domain. Consequently, these motor proteins are drivers of numerous cellular processes that link the membranes to the actin cytoskeleton, including but not limited to vesicle trafficking, phagocytosis, cell migration, and intracellular membrane trafficking. Their importance in regulating these processes is underscored by studies that link pathogenesis and cancer with this class of motor proteins. For example, it has been recently shown that aberrant expression of Myo1b is linked to the lymph node metastasis of human head and neck squamous cell carcinoma through enhanced cancer cell motility and therefore, an interesting target for new diagnostic and therapeutic strategies for patients with this type of cancer, the sixth most common malignancy worldwide. Our focus in this study is the little studied aspect of membrane targeting in the different sub-classes for Myo1, even though it is critical part of the functionality of these proteins. Biological membranes are an intricate system consisting of many structurally discrete protein and lipids that serve as interaction sites with lipid binding domains of soluble proteins. The pleckstrin homology (PH) domain is one of the most common structural folds that serve as a perfect scaffold for cytosolic proteins to bind and target membranes. Although conventional sequence analysis doesn’t identify any membrane binding domains in the tails of Myo1 proteins, recent studies of Myo c and Myo lg implicate the presence of a PH domain and attribute this domain to their membrane targeting function. A preliminary analysis based on a combination of sequence analysis and secondary structure prediction tools, suggested that Myo1b and several other sub-classes also contain a PH domain. We hypothesize that the membrane targeting function of all Myo1 sub-classes is driven by the presence of a PH domain within their tails. To address this hypothesis, we have carried out a comprehensive investigation of the Myo1 tails from all human unconventional class I myosin isoforms sub-classes to identify, model, and analyze the membrane binding mechanism of their PH domains. This study details the membrane binding mechanisms of unconventional class I myosins and lays the foundation for the role of membrane targeting of Myo1 proteins in cancer and disease.

Background: In clinical practice of complex diseases such as cancer it is a challenging task to correctly identify driving factors and specific interactions between multitudes of genomic and clinical variables. In cancer where patterns are heterogeneous and involve highly complex interactions of biological pathways, this is by far a non-trivial task. Using novel approaches in machine learning, we demonstrate the ability to quantitatively and accurately reveal and describe patterns in genomic and clinical data. Method: We developed a computational framework based on a number of interacting learners performing extensive pattern search and data characterization. This framework is multilevel and involves steps of relevant data transformations. We formulate and apply contextually relevant criteria to distinguish and rank iteratively obtained findings and identify hidden relations between features and characteristic connections to the clinical outcome. Summary: We successfully tested our method on the public data of Glioblastoma Multiforme (GBM) from The Cancer Genome Atlas (TCGA). We identify interacting sets of genomic variables to represent clinically relevant subgroups of samples. We observe a dense presence of interacting known cellular processes in GBM such as EGFR, FGFR, ERK, RAS, MAPK, PI3, as well as novel such as calcium signaling, kinase motor and protein kinase pathways, tubulin and microtubule binding, phosphor esters/diacylglycerol binding domain (C1 domain), purine ribonucleoside triphosphate binding, positive regulation of phospholipase activity and others. The top ranking pathways recap the well-known and new biology. In addition, compared to known genes in the literature, we also observe involvement of novel genes in GBM subtype characterization. Finally, we propose two-fold solution: identification of distinctive patterns in the input genomic and output clinical data, and specific format of their interactions.

#4550 IODNE: an integrated optimization method for identifying the de-regulated sub-network for precision medicine in cancer. Lijun Cheng, Sai Mounika Inavolu, Milan Radovich, Varshini Vasudevaraja. Indiana University, Indianapolis, IN.

Background and Purpose: Sub-network analysis can explore complex patterns of the entire molecular pathways and networks for the drug target identification, and therefore drug selection. Computational algorithms are needed to optimize the sub-network search for molecular pathways and networks under certain conditions. Materials and Methods: In the paper, the gene expression profile of a cohort breast cancer patients and protein-protein interaction (PPI) network are integrated with edge score and node score simultaneously. A novel optimization algorithm, IODNE, is developed to search for the optimal de-regulated subnetwork of merging gene and protein network. The application of IODNE is demonstrated for a sub-network of drug target selection in breast cancer subtypes Luminal-A/Luminal-B data from Cancer Genome Atlas (TCGA). Where, the PPI networks data selected from Pathway Commons. Results: IODNE selects sub-network, which contain EPHBP4 and HER2, as the well-known targets in clinic Luminal-A/Luminal-B breast cancer subtypes. This validates the utility of IODNE. When applying IODNE to the triple-negative breast cancer subtype data, we identify sub-networks that contain genes such as ERBB2, HRAS, PGR, CAD, POL2 and SLC2A1. Conclusion: Using the known drug targets in breast cancer subtypes, we demonstrate that IODNE is a robust and powerful algorithm to identify sub-networks for drug target identification. Based on the gene expression profiles and protein interaction networks, it detects the optimum deregulated subnetwork for the candidate drug target selection. The IODNE is promising tool for the precision medicine.

#4551 Divergence analysis with coarse coding of omics data across cancer phenotypes. Wikum Dinalankara, Qian Qe, Lanlan Ji, Yiran Xu, Nicole Pagune, Francesco Lobo, Laurent Younes, Donald Geman, Luigi Marzichonz, John Hopkins Univ. School of Medicine, Baltimore, MD; Johns Hopkins University, Baltimore, MD; Federal University of Minas Gerais, Bele Horizonte, Brazil.

Motivation: Complex cancer omics data can be difficult to interpret and analyze with standard statistical methods. We thereby propose an innovative data representation that drastically reduces complexity while improving usability and interpretability for complex cancer phenotype analysis. Method: Despite recent advances in omics technologies, the robustness of predictive biomarkers in cancer remains severely limited. We hypothesize that this is primarily due to an overemphasis on applying statistical learning methods without taking into
consideration the underlying biological processes driving cancer. We therefore propose a new approach based on representing data based on the comparison to a baseline group. This results in a data format that encodes biologically meaningful information and can be easily analyzed. We apply this transformation to publicly available datasets obtained across multiple tumor types using different omics technologies. For each cancer phenotype considered, we perform equal or better classification performance than standard methods. Further, we show that our simplified data representation filters out much of the biologically irrelevant variation and that the resulting data can be successfully applied to gene set analysis applications, ultimately improving inference on disease phenotypes. For instance, by applying our method to signaling pathways and cancer hallmarks gene sets, we show that our approach can be used to detect dysregulated pathways more efficiently than with traditional methods. Conclusion: By comparing cancer omics data to a baseline status, we obtain a much simpler data representation that preserves biologically relevant information while eliminating much of the unwanted variance that is often confounding in the analysis of high-dimensional data. Furthermore, data represented using our approach can be easily analyzed and compared to other studies or to the baseline, and it is less sensitive to external variables. We have thus presented a method with improved sensitivity to assess statistical significance for cancer outlier profile analysis of gene expression.

YeSpace® Cohort Analyzer platform (formerly known as NextBio Clinical). Holden, 2 Vladimir Torchilin1.

#4552 ssCOPA: a novel method with improved sensitivity to assess statistical significance for cancer outlier profile analysis of gene expression. Hong Gao, Sam Ng, Hinco J. Gierman. Illumina, San Diego, CA.

To understand the genetic mechanism of disease, finding biomarkers and drug targets are a major focus of academic and pharmaceutical research. However, it has become clear that many important genes driving diseases like cancer, are deregulated in a relatively small group of outliers, e.g. amplified and fusion genes. Cancer outlier profile analysis (COPA), introduced by Tomlins et al, has raised interest in detecting genes with outlier expression within a group, particularly in cancer patients. However, the magnitudes of the COPA scores are not directly comparable across different studies or with different input parameters. Therefore, integrating COPA scores across multiple studies in a meta-analysis is problematic. Current solutions to performing meta-analyses, including rank-based methods and binomial test, require large study numbers without adjustment for the differences in study size. Also, within a single study COPA scores alone do not provide a P-value, and it is impossible to know which outlier genes are statistically significant. Here we developed three novel methods to address these problems by computing a significance for COPA scores, including Bootstrapping resampling, Bootstrap + generalized Pareto distribution (GPD) and Binomial method for statistical significance of COPA (ssCOPA), to enable the comparison of COPA score across studies or parameters. We first evaluated our methods using two breast cancer studies. The P-values generated by Binomial method and ssCOPA are better than Bootstrap + GPD. In addition, the Binomial method requires significantly less computing time than the other methods. We further validated our methods with a meta-analysis of five breast cancer studies and compared the results with the top-ranking genes of a large-scale meta-analysis of 31 breast cancer studies by ONCOMINE. We show that our P-value-based approaches (P = 10^{-17}–10^{-20}) achieves significantly better concordance than the Binomial test (P = 10^{-15}). Data and methods are available for use on the Illumina Bas eSpace® CohortAnalyzer platform (formerly known as NextBio Clinical).

#4553 Development of a 4-sample version of the Kolmogorov-Smirnov test for evaluating the temporal physiology of cells treated with test compounds in a label-free, high-content, platform for quantitative analysis of adherent cell-culture models. Ed Luther, 1 Livia Mendes, 1 Jiayi Pan, 1 Elena Holden, 2 Vladimir Torchilin 1. 1Northeastern University, Boston, MA; 2SeeCyte Biotechnology, Boston, MA.

Our objective is to develop multi-functional nanotechnology-based anti-tumor drug delivery systems for improving the efficacy of treatments and reducing undesirable side effects. The essential part of this process is the development and validation of un-biased, quantitative analytical techniques. We employed a newly developed holographic imaging cytometry system HoloMonitor® M4 for label-free time-lapse cellular analysis (Phase Holographic Imaging, Sweden). In previous work we have demonstrated our ability to obtain quantitative, high content cellular feature data congruent to data obtained from traditional label-based systems. We applied a modified version of the Kolmogorov-Smirnov 2-sample test. The classic test takes control and test frequency distributions (histograms), and converts them to probability functions. The maximum vertical displacement between the two is reported as the D-value, to determine if the two distributions are significantly different. In modified versions of the test, it is asked whether we have obtained the same D-value between the control and test normalized probability functions. These histograms are termed Brownian Bridges, where the end points are fixed at a value of zero, and the function is free to vary in between, in either up-going, down-going or mixed. Now, we report the development of a 4-sample Kolmogorov based method. Two modified K.S. tests are performed to compare distributions A to A, and B to B. It is assumed that all the distributions have the same time basis, and each time point is processed sequentially. The resulting time point pairs are plotted as a vector in a two parameter scattergram, tracing the outlines of the probability distribution of the cell populations through time. Unlike, the Brownian Bridge histograms, here, the starting and the ending points are both at the same location (0,0), within the two dimensional scattergram, but are free to move in both positive and negative directions away from the origin. HeLa cells in a 12-well MatTek plate were adhered and treated with Paclitaxel (PCT) in concentrations from 0 to 40 nM in 5-fold increments, either pulsed for 4 hrs, followed by 48 hours of imaging or with continuous exposure for 48 hours of imaging. We obtained a variety of different plot types, including continuous vs. pulsed comparisons, inter dosage comparisons, as well as the ability to compare multiple treatment groups. We also report our approach to determine synergy claims.

#4554 Unified theoretical algorithms for graphics dynamic multiple transformations of dose-effect relationships with computer simulation. Ting-Chao Chou. Memorial Sloan-Kettering Cancer Center, New York, NY.

The (phar)maco-chemical principles of the mass-action whole-body system analysis (arrangement & combinatorial) several hundred rate equations have been derived and published. Mathematical induction allows the deduction of the entities within the unified general median-effect equation (MEE) that makes dose & effect ‘interchangeable’ for the 1st order and higher order dynamics. Based on the MEE plot, all dose-effect curves can be ‘linearized’ which allows the quantitative determination of x-intercept (log Dm which signifies potency) and slope (which signifies shape or dynamic order). Extension of MEE to multi-drug combinations resulted the combination index (CI) theorem which quantifies synergism (CI<1), additive effect (CI=1), and antagonism (CI>1). This unprecedented approach and multi-step logics have been summarized in [Chou TC. Pharmacol Rev 58: 621-681, 2006] which has been cited 2,161 times in 485 bio-medical journals (http://www.researcherid.com/rid/B4111-2009 as of 10.19.2016). Dose-effect curves (single & multi-drugs) can be quantitatively transformed into the MEE plot, Fa–Ci plot, isobologram, Fa-Dri Plot for dose-reduction index, and when n=2, the polygonogram. This presentation will illustrate of combinations (1:5) of doctaxel (TXT) with compound against HCT-116 colon carcinoma xenograft in nude mice. In all, only 66 nude mice have been used, i.e. TXT doses, T3 doses and TXT+T4 doses, plus a control group, each N=6. The MEE “Linearization” allows the “Econo-Green Bio-research”, with small experimental size and small number of data points, using small number of animals. The algorithms based computer simulation using CompuSyn software can be completed within one second after the dose and effect data entries. The CompuSyn has been offered for free download upon registration via www.compsyn.com.

#4554A Simple, efficient, and quantitative approach for determination of synergism, additive effect, and antagonism of drugs in vivo using combination index method: a proposition for clinical protocol design and regulatory synergy claims. Jianing Fu, 1 Ting-Chao Chou. 1Columbia University Medical Center, New York, NY; 2Memorial Sloan-Kettering Cancer Center, New York, NY.

Based on the systematic dynamic rate derivations with the mass-action principle and mathematical induction–deduction, the median-effect equation of Chou, and the combination index (CI) equation and their algorithm allow quantitative determination of synergism (CI<1), additive effect (CI=1) and antagonism (CI>1) (Pharmacol Rev 58:621-681, 2006). Based on Google Scholar Citations, the CI simulation has been cited 7,712 times in >800 bio-medical journals as of 10.19.2016. However, most citing papers were with experiments in vitro, relative few in vivo and rarely in clinical trials. This is despite the fact that the CI method equation, algorithm, and the CompuSyn software are the same for both in vitro and in vivo, although the practical aspects such as sample size, time and cost, the readiness of the end-point measurement, and the ethical consider-
coupled with the ability to genetically engineer NDV to express therapeutic propagation, tumour-selective replication, and immunostimulatory properties) further enhanced in models that permit greater replication and also when combined with fibrosarcoma xenograft model a single administration (intra-tumoural or systemic). Demonstrated that NDV treatment has robust anti-tumour activity. In a HT1080 immortalised fibroblast cell line, infection with MEDI5395 results in the increased production and release of pro-inflammatory cytokines and chemokines which are able to recruit mediators of both the innate and adaptive immune responses. MEDI5395 is a potent activator of the type I interferon pathway through the activation of the IFNAR1 receptor and induces the production of IFN-γ. MEDI5395 selectively replicates and kills a wide variety of human and mouse tumour cell lines. Additionally infection of cancer cell lines with MEDI5395 results in the upregulation of chemokine receptors and chemokine expression, which is able to recruit immune cells to the tumour microenvironment. Using reverse genetics, we have generated a recombinant strain of NDV that expresses an immunostimulatory transgene, namely macrophage colony-stimulating factor (GM-CSF). We have evaluated the biological characteristics of recNDV-GM-CSF (MEDI3935) in vivo and in vitro. MEDI3935 selectively replicates in and kills a wide variety of human and mouse tumour cell lines. Additionally injection of cancer cells with MEDI3935 results in the increased production and secretion of pro-inflammatory cytokines and chemokines which are able to recruit mediators of both the innate and adaptive immune responses. MEDI3935 is a potent activator of the type I interferon response. In vivo, using a range of syngeneic xenograft models we have demonstrated that NDV treatment has robust anti-tumour activity. In a HT1080 fibrosarcoma xenograft model a single administration (intra-tumoural or systemic) was able to cure 80% of tumour bearing mice. In syngeneic mouse tumour models, which support minimal viral replication MEDI3935 treatment causes significant changes in the local immune suppressive environment and results in long-lasting anti-tumour immune responses. These responses are further enhanced in models that permit greater replication and also when combined with immune checkpoint blockade. The inherent properties of NDV (self-propagation, tumour-selective replication, and immunostimulatory properties) coupled with the ability to genetically engineer NDV to express therapeutic transgenes may provide a multi-modal attack on the tumour, delivering greater benefit to patients.

**IMMUNOLOGY: Clinical Immunotherapy, Viruses, and Bacteria**

Oncolytic viruses are live, replication-competent viruses that infect and/or replicate selectively in tumour cells leading to the destruction of the infected cell. Cell lysis occurs as a natural consequence of the viral life cycle and released virions can infect and kill neighbouring tumour cells leading to an amplified therapeutic effect. Oncolyasis has the added benefit of releasing multiple tumour antigens that may further induce an immune-mediated therapeutic response. Newcastle Disease Virus (NDV) is an avian paramyxovirus, which has proven safety and demonstrated efficacy against a variety of preclinical cancer models and in Ph clinical studies as an oncolytic agent, oncolysate or whole cell vaccine. Using reverse genetics, we have generated a recombinant strain of NDV that overcomes environmental and regulatory concerns uncoupling oncolytic potency and avian pathogenicity. Furthermore we have enhanced the immune modulatory properties of NDV by engineering the virus to express granulocyte macrophage colony-stimulating factor (GM-CSF). We have evaluated the biological characteristics of recNDV-GM-CSF (MEDI3935) in vivo and in vitro. MEDI3935 selectively replicates in and kills a wide variety of human and mouse tumour cell lines. Additionally injection of cancer cells with MEDI3935 results in the increased production and secretion of pro-inflammatory cytokines and chemokines which are able to recruit mediators of both the innate and adaptive immune responses. MEDI3935 is a potent activator of the type I interferon response. In vivo, using a range of syngeneic xenograft models we have demonstrated that NDV treatment has robust anti-tumour activity. In a HT1080 fibrosarcoma xenograft model a single administration (intra-tumoural or systemic) was able to cure 80% of tumour bearing mice. In syngeneic mouse tumour models, which support minimal viral replication MEDI3935 treatment causes significant changes in the local immune suppressive environment and results in long-lasting anti-tumour immune responses. These responses are further enhanced in models that permit greater replication and also when combined with immune checkpoint blockade. The inherent properties of NDV (self-propagation, tumour-selective replication, and immunostimulatory properties) coupled with the ability to genetically engineer NDV to express therapeutic transgenes may provide a multi-modal attack on the tumour, delivering greater benefit to patients.

#4557 Tumor immune profiling identifies multiple unique therapeutic targets that improve vaccination + oncolytic virotherapy against metastatic ovarian cancer. A) Robert McGrat,1 Cheryl Eppolito,1 Anthony Miliotto,1 Raya Huang,1 Kelly Singel,1 Jonathan Pol,2 Kyle Stephenson,2 Brahim H. Segal,1 Brian Lichty,1 Kunle Odunsi1. 1Roswell Park Cancer Institute, Buffalo, NY; 2McMaster University, Hamilton, Ontario, Canada.

While spectral responses to cancer immunotherapy have been observed in some patients, the majority of responses are short-lived with ultimate tumor relapse. Therefore, it is crucial to identify strategies that will effectively synergize with immunotherapy to improve treatment outcome. Using a pre-clinical mouse model, we explored the use of a potent heterologous prime/boost vaccine strategy for the treatment of metastatic intraperitoneal ovarian cancer. Priming with an adjuvant based vaccine followed by boosting with a novel oncolytic Maraba viral vector elicited robust tumor-specific CD8+ T cell responses, with high numbers of therapy-induced CD8+ T cells effectively trafficking to the tumor microenvironment. While this approach greatly improved tumor control and long-term survival compared to treatment with the priming vaccine alone, the combination therapy was not curative and cellular analysis suggested that T cells within the tumor microenvironment were functionally suppressed/exhausted. We reasoned that a combination therapy that would have the potential to further enhance tumor attack following prime/boost vaccination. Using this strategy, we observed that checkpoint blockade using nivolumab in combination with prime/boost vaccination resulted in a dramatic improvement in tumor control, as did transient depletion of granulocytic myeloid cells (but not monocytes/macrophages) following treatment. Current studies are underway that combine prime/boost vaccination with relevant co-stimulatory agonist antibodies, as well as inhibitors of candidate chemokine networks identified through tumor profiling. These findings underscore the importance of designing treatment strategies that not only elicit robust anti-tumor T cell responses, but also improve the duration and/or magnitude of immune attack within the tumor microenvironment. Additionally, our data suggest ways of interrogating the tumor microenvironment during treatment can identify unique therapeutic targets that have the potential to further improve therapeutic impact.

#4558 Immunoactivity and anti-tumor efficacy of live attenuated Salmonella typhimurium-based oral T-cell vaccines VX0M1m, VX0M4m and VX0M6m. Sébastien Wieckowski,1 Lilli Podola,2 Marco Springer,3 Iris Kobli,1 Zina Koob,4 Caroline Migaud,5 Amine Adda-Barkane,5 Ming Wei,1 Albrecht Meisel,1 Klaus Breuner,1 Philipp Hofmann,1 Heinz Lubena,1 1VAXIMM AG, Basel, Switzerland; 2University Hospital Regensburg, Regensburg, Germany; 3VAXIMM GmbH, Mannheim, Germany; 4Oncodesign S.A., Dijon, France; 5CellVax S.A.S., Romainville, France.

Significant progresses have been recently accomplished in immuno-oncology and in the development of cancer immunotherapies. However, novel solutions are necessary to overcome the peripheral tolerance and the immunosuppressive tumor microenvironment that prevent the eradication of cancer. VAXIMM is developing first-in-kind Salmonella typhi Ty21a-based oral T-cell vaccination platform for the initiation of anti-tumor cellular immune responses via a unique mode-of-action. This study summarizes the immunogenicity and preclinical anti-cancer efficacy for Salmonella typhimurium murine vaccines VX0M1m, VX0M4m and VX0M6m which encode murine vascular endothelial growth factor receptor 2 (VEGFR2), mesothelin (MSLN) and Wilms’ tumor 1 (WT1) protein antigens, respectively. Immunokinetic studies were performed in healthy animals treated with 10^10 CFU/dose of either the control Salmonella typhimurium empty vector VX0M0m_empty, or Salmonella typhimurium VX0M1m, VX0M4m or VX0M6m, and antigen-specific T cells were detected with MHC class 1 pentamers by flow cytometry in the spleen. The anti-tumor efficacy of VX0M1m and VX0M4m was evaluated in the Panc02 syngeneic model of pancreatic adenocarcinoma overexpressing MSLN, and the anti-cancer activity of VX0M6m was evaluated in the FBL-3 disseminated model of erythroleukaemia expressing WT1, in a prime-boost setting. Treatment with each of the vaccines VX0M1m, VX0M4m and VX0M6m induce a peak antigen-specific systemic immune response 7 to 10 days after the last vaccination. Treatment of Panc02 tumor-bearing mice with VX0M1m and VX0M4m single agents resulted in a significant reduction in the tumor growth rate, compared to the control group, with a median T/C of 37.6% and 19.4% respectively, 35 days after tumor challenge. Treatment of mice bearing FBL-3 leukemia with VX0M6m generated a rapid and sustained anti-tumor effect with 100% (7 out of 10) of surviving animals 175 days after leukemia challenge. In contrast, treatment with VX0M0m_empty did not show any anti-cancer effect, with a median survival of 45 days and 0% (0 out of 10) of cancer regression. VX0M1m, VX0M4m and VX0M6m were tolerated at the effective doses and have demonstrated consistent anti-cancer activities with substantial T cell responses in different animal tumor models. This study provides further evidence that VAXIMM’s versatile oral T-cell vaccination platform can be used to stimulate anti-tumor immunity against various tumor-associated antigens. Further studies of VAXIMM’s cancer vaccine candidates, as monotherapy as well as in combination, are warranted.
E2-CTL reactivity was that data mined publicly available OPC transcriptomes (University of Michigan assessed the association of F. nucleatum (negative, low, or high) with tumor epidemiology database of 1,027 colon and rectal cancer cases in the pathologicalepidemiologydatabaseof1,027colonandrectalcancercasesinthe Nurses’ Health Study and the Health Professionals Follow-up Study. We assessed the association of F. nucleatum (negative, low, or high) with tumor immunostatusestatusinstraofMSUSTatus.WemeasuredF.nucleatumDNAintrumortissueusingquantitativePCR.Asimmunostatus,weevaluatedhystopathological lymphocytic reaction (tumor-infiltrating lymphocytes [TIL], intratumoralperiglandularreaction,peritumorallymphocyticreaction,orCrolin’s-likemyeloidreaction)andmeasuredTcelldensities(CD3+,CD8+,CD45RO+orFOXP3+cells)usingimmunohistochemistryandcomputer-assistedimageanalysis.Logistic regression model was used to adjust for potential confounders, including CpG island methylator phenotype, LINE-1 methylation level, and KRAS, BRAF, and PIK3CA mutations. Using whole-exome sequenc-ing data (N = 586), we conducted secondary analyses to assess the interaction of F. nucleatum with a neoantigen load. Results: The association between F. nucleatum and TIL differed by MSI status (P for interaction = 0.0017; with the adjusted α level of 0.0066). Compared with F. nucleatum-negative cases, F. nucleatum-positive cases were associated with low-level TIL in MSI-high tumors (odds ratio, 0.40 [95% confidence interval, 0.17-0.92] for F. nucleatum low and high cases, respectively), but not in microsatellite stable/MSI-low tumors. We did not find any interaction between F. nucleatum and MSI status in T cell subsets. The association between F. nucleatum and TIL did not differ significantly by levels of a neoantigen load (P for interaction = 0.015). Conclusions: The association of F. nucleatum with the immunosuppressive microenvironment may be stronger in colorectal cancer cases with high-level MSI. Our findings suggest the interplay between F. nucleatum and MSI status in host immune response to the tumor.

#4561 Non-integrative lentiviral particles for immunotherapy: RNA delivery to drive tumoral antigen presentation in a safe and efficient way. Pascale Bouillé,1 Christine Duthoit,2 Nicolas Martin,3 Lucille Lamouroux,4 Jean-Christophe Pages5. 1VECTALYS and FLASHCELL, Toulouse, France; 2VECTALYS, Toulouse, France; 3INSERM U966 Faculté de Médecine, Tours, France.

Safe and efficient cancer therapies using adoptive transfer of engineered cells are very promising but very challenging approaches. Opportunities to improve gene transfer into primary cells involve a better design of the vectors used. Such improvements must lead to an increase of the efficiency of gene expression, the cell phenotype preservation and the increase of the gene number delivered. The use of lentiviral vectors has largely increased in clinical protocols over the past few years but safety concerns have slowed down this progression. Actually, the permanent genetic modification remains a focus of significant regulatory oversight. On another side, mRNA delivery is a versatile, flexible, and safe mean for protein therapies, but existing techniques, such as chemical or electroporation-based transfection protocols, are known to induce cell toxicity and phenotype modifications of the target cells. Here, we present an innovative tool, named LentiFlash, allowing RNA delivery into target cells without any genomic scar. This tool combines RNA delivery, providing the best expression system to get efficient and transient expression, and lentiviral delivery which exhibits the best efficiency of entry into primary and stem cells. The RNA encapsidation is mediated via an RNA/protein interaction using properties of the MS2 bacteriophage. This new vector breaks with all existing systems. The resulting lentiviral particle is able to efficiently deliver non-viral coding or non-coding RNA into the cytoplasm of any cell type. These LentiFlash particles, are able to transduce delicate primary cells, such as dendritic cells, T cells and hematopoietic stem cells. They show an efficient, fast and transient expression of protein and RNA, such as antigenic peptides or genome editing tools, with no cell phenotype modification. Here we show a proof of concept on primary murine dendritic cells transduction with LentiFlash particles, successfully used to deliver several tumor antigens. As a result, these dendritic cells are able to present the antigens to the immune system which in turn can efficiently fight a tumor development into wild type mice. This new delivery system gives the opportunity for multiple simultaneous expression to enhance immune response and for combining tumor relapse. Such multiple co-expressions into immune cells are expected to mimic the innate and adaptive immune responses. This transient RNA delivery mediated by LentiFlash is a powerful tool to induce an efficient gene delivery. The possibility to express multiple genes at once in the target cells is an attractive therapeutic perspective. The absence of any viral sequence avoids any integration event, an important safety consideration for human use. Finally, another advantage of the LentiFlash system is its ability to utilize lentiviral production platforms already validated in clinical settings.

Newcastle Disease Virus (NDV) is an avian paramyxovirus, which has significant oncolytic activity against mammalian cancers. It is multi-modal in its anti-tumour activity and offers a tumour selective, self-propagating therapeutic with oncolytic activity and immunostimulatory properties. Within the tumour itself, NDV infection is able to modulate the immune suppressive microenvironment and induce positive T cell tumour inflammatory responses. Additionally, we have enhanced the immune modulatory properties of NDV by engineering the virus to express granulocyte/macrophage colony-stimulating factor (GM-CSF). To better understand the immune modulatory mechanisms by which NDV infection is able to alter the tumour microenvironment we investigated the responses
of normal human PBMCs and isolated immune cell populations following NDV exposure. Using flow cytometry, cytokine and gene expression analysis we demonstrated activation of the innate immune cells and a robust type I IFN and pro-inflammatory response. 24 hours post infection, innate immune cells (macrophages, natural killer cells and dendritic cells) had upregulated cell surface activation markers and secreted high levels of cytokines in a dose-dependent fashion. Furthermore, by using NDV constructs encoding fluorescent proteins we showed, in a specific subset of myeloid cells, the preferential uptake of virus and subsequent self-limiting viral replication. In a co-culture system, these infected myeloid cells were able to function as ‘virus cellular carriers’ and were able to mediate the efficient transfer of infectious NDV to tumour cells resulting in their oncolysis. We further investigated the ability of NDV to infect, spread and kill tumour cells in vivo, we utilised tissue slice cultures of fresh patient samples. These studies demonstrated virus replication and transgene expression in tumour slices, as well as the uptake of virus in a small fraction of specific cells in slices of normal liver. Moreover, evidence that NDV was able to alter the tumour microenvironment could be demonstrated in such cultures by sampling the culture supernatants over time. By investigating the immune modulatory properties of NDV in vitro and in vivo we will gain greater insight and understanding of the anti-cancer properties of NDV. This work will also help guide the selection of transgenes for next generation approaches to augment the inherent immunostimulatory properties of NDV, and help inform clinical dosing options such as intravenous infusion or cell-based delivery.

Local and abscopal effects in oncolytic virotherapy are boosted by immune checkpoint blockade, immunogenic chemotherapy, or IFNAR blockade. Laetitia Fend, 1 Takahiro Yamazaki, 1 Xavier Prévillé, 1 Eric Quémeur, 1 Oliver Kepp, 3 Julien Adam, 2 Aurélien Marabelle, 2 Jonathan Pitt, 2 Guido Kroemer, 2 Laurence Zitvogel, 2. TRANSGENE S.A., Illkirch Graffenstaden, France; 3Institut Gustave Roussy, Villejuif, France; Centre de recherche des Cordeliers, Paris, France. Although the clinical efficacy of oncolytic viruses has been demonstrated for local treatment, the ability to induce immune-mediated regression of distant metastases is still poorly documented. We here report that an engineered oncolytic Vaccinia Virus, VV_wq-TK-RR–Fcu1, is able to induce an immunogenic cell death and thus to generate a systemic immune response. Effect on tumor growth and survival is largely driven by CD8+ T-cells, and we could demonstrate that the immune cell infiltrate in the tumor could be reprogrammed towards a higher ratio of effector T-cells to regulatory CD4+ T-cells. The key role of the type I-IFN pathway in oncolytic virotherapy was also highlighted, and we could show a strong abscopal response in Ifnar−/− tumors. In this model, the single administration of the virus directly into the tumors, on one flank, led to regression in the contralateral flank (i.e. opposite to the virus injection site). Moreover, we observed that these effects are further enhanced when the oncolytic treatment is combined with either immunogenic chemotherapy such as oxaliplatin, or with immune checkpoint blockers such as anti-PD-1 or anti-CTLA-4. Altogether, these data suggest that local oncolytic virotherapy in patients with tumors infiltrated by IFNAR signaling could increase immune-mediated abscopal regression of distant metastases.

Synergistic anti-tumor efficacy of combination therapy with APS001F, a cytosine deaminase (CD) expressing Bifidobacterium, 5-fluorocytosine (5-FC) and anti-mPD-1 antibody in syngeneic mice model. Koichiro Shioya, 1 Yuji Seki, 1 Tomio Matsumura, 1 Yuko Shimatani, 1 Shun’ichiro Taniguchi, 2 Minoru Fujimori. 1Ananoptpharma Science, Inc., matsumoto, Japan; 2Department of Comprehensive Cancer Therapy, Shinshu University School of Medicine, matsumoto, Japan; 3Department of Breast Surgery, Tokyo Medical University Ibaraki Medical Center, Ibaraki, Japan. Immune checkpoint blockers like anti-PD-1 antibody are leading the new generation in anti-cancer drug development. A lot of scientific evidences have demonstrated that immune checkpoint antibodies have promising clinical response in patients with multiple cancer types. Nevertheless, limited fraction of patients respond to these antibody immunotherapy, and moreover, immune related serious adverse events caused by nonspecific reaction with immune checkpoint blockers result in treatment discontinuation. Many approaches have been attempted to improve therapeutic outcomes of antibody immunotherapy, particularly a combination of antibody treatment and other therapies is one of worth-trying ideas. APS001F is a live recombinant Bifidobacterium longum expressing cytosine deaminase (CD), which is an enzyme to catalyse the hydrolytic deamination of cytosine to uracil. Bifidobacterium is a non-pathogenic anaerobic bacterium derived from normal human intestinal flora. It can only survive and grow at low oxygen environment such as solid tumor. Intravenous administration of APS001F to patients leads to colonization of the B.longum and production of CD enzyme only inside the solid tumor. Locally expressed CD enzyme converts orally taken prodrug, 5-FC, into anti-tumor drug 5-FU, which increases 5-FU concentration specifically inside tumor and results in alleviation of side effects caused by attacking normal organs. The phase 1 clinical trial for APS001F is conducted in the US sponsored by us. 5-FU has been shown to alleviate Myeloid Dendritic Cell Suppressor Cells (MDSC) in the tumor site and release immune suppression in tumor [1]. Furthermore, Van Der Kraak et. al. have reported that 5-FU upregulated PD-L1 expression on the surface of tumor cells [2]. These findings drove us to combine anti-PD-1 antibody with the APS001F therapy. At this present study, systemic administration of APS001F and 5-FC significantly suppressed tumor growth in CT26 bearing syngeneic mice model, which is consistent with our previous finding. Additionally, anti-murine PD-1 antibody combined with APS001F and 5-FC further suppressed tumor progression and some of individual samples achieved complete regression of CT26 tumors. The combination treatment effect of anti-murine PD-1 antibody and APS001F with 5-FC showed statistical significance in comparison with either treatment group, which encourages us to expect much effective results and less side effects in clinic. Forced expression of GITR in cancer cells enhances adenosviruses-mediated in situ vaccination. Yisel A. Rivera-Molina, Francisco Puerta Martínez, Teresa Nguyen, Hong Jiang, Xuejun Fan, Rehnuma Shifat, Mohammad Belayat Hossain, Verlene K. Henry, Caroline C. Carrillo, Candelaria Gomez-Manzano, Juan Fueyo. MD Anderson Cancer Center, Houston, TX. Our approach involves a platform of killing cancer using more potent oncolytic viruses-based immunotherapy strategies. These replication competent adenoviruses are targeted to the Rb pathway to generate tumor-selectivity. The second generation of these therapeutic agents, Delta-24-RGD, was successfully translated to the clinical setting and is currently been tested in Phase I studies in several institutions in the USA and in Europe for the treatment of patients suffering from recurrent gliomas. Preliminary data from these clinical trials showed that 10 to 15% of Delta-24-RGD-treated tumors undergo complete regression. Agonistic treatments targeting co-stimulatory tumor necrosis factor receptor superfamily (TNFRSF), such as GITR (CD357), have been shown to enhance the proliferation and activation of T cells. Moreover, in preclinical tumor efficacy studies, these agonistic signals have shown potent tumoricidal activity. Different from antibodies, co-stimulatory ligands can be easily incorporated into replication competent oncolytic adenoviruses. Infection of cancer cells with these armed viruses will lead to the expression in their cell membranes of the co-stimulatory molecule that will directly interact with the tumor infiltrating lymphocytes to amplify and enhance the anti-tumor T-cell activity. In this study, we have developed an armed Delta-24-RGD carrying the cDNA of the mouse GITR, Delta-24-GREAT. Treatment of glioma-bearing mice with intracranial injection of Delta-24-GREAT increased mice survival (P < 0.0001, long-rank test) and inhibited lung metastasis in subcutaneous models. Infection of the tumor elicited an inflammatory response increasing the populations of CD4+ and CD8+ T cells versus treated controls. Importantly, 2 weeks after the adenovirus treatment a subset of brain hemispheric cells were positive for GITR. In addition, co-culture experiments with tumor cells infected with viruses and splenocytes isolated from treated glioma-bearing mice demonstrated a response against the cancer cells as assessed by ELISA analyses of IFN-γ. Demonstrating the generation of anti-tumor memory, the surviving animals did not show evidence of tumor growth after re-challenging with GL261 glioma cell implantation in the contralateral hemisphere. However, survivors of GL261 tumors did not survive after the re-challenge was performed by intracranial implantation of B16/F10 melanoma cells strongly indicating that the immune response was specific for GL261 glioma antigens. This is the first study with an oncolytic adenovirus expressing GITR and our results strongly indicate that oncolytic adenoviruses armed with the molecules of the TNFRSF may be of future clinical interest for the treatment of patients with cancer.

OncoVEXgsGM-CSF (HSV-1 modified similarly to Talimogene Laha-repavepc) in combination with CTLA-4 blockade leads to both local and systemic efficacy in a murine syngeneic model of metastatic melanoma. Kees- gan Cooke, Juan Estrada, Jinghui Zhan, David Hill, Andrea Boden, Jon Werner, Pedro J. Beltran. Amgen. Thousand Oaks, CA. Talimogene laherparepvec is an oncolytic immunotherapy based on a modified herpes simplex virus type 1 (HSV-1) designed to kill cancer cells through...
two mechanisms: a) direct viral-mediated lysis and b) stimulation of a tumor antigen-specific adaptive immune response. We developed a mouse model of metastatic melanoma using the B16F10 cell line to study local and systemic responses following treatment with talmogene laherparepvec alone or in combination with CTLA-4 blockade. OncoVEXGM-CSF, an HSV-1 modified similarly to talmogene laherparepvec (mGM-CSF is expressed instead of human GM-CSF) was used in these studies. B16F0 cells have been reported to be resistant to HSV-1 infection due to a lack of requisite entry receptors. To overcome resistance, we transduced B16F10 cells with a lentiviral vector expressing mouse nectin 1 (mNectin1) or GFP as a control. Expression was confirmed by ddPCR and sensitivity to OncoVEXGM-CSF evaluated in an in vitro viability assay. B16F10-mNectin1 cells were highly sensitive to OncoVEXGM-CSF with a multiplicity of infection (MOI) IC_{50} of 0.001 (B16F10-eGFP were insensitive at MOI of 100). In vivo, B16F0-mNectin1 and B16F0-eGFP cells showed similar growth when injected subcutaneously. OncoVEXmGM-CSF treatment of B16F10-mNectin1 tumors (intratumoral, 5x10^6 PFU/dose, 3X) caused a significant outcome and may provide a way to guide chemotherapy.

Moreover, patients who were treated by taxanes in WIR group had a shorter OS (95%CI 1.03-1.47, p = 0.001) compared to control mice that received intravenous B16F10-eGFP cells only. In conclusion, OncoVEXmGM-CSF in combination with CTLA-4 blockade significantly reduced subcutaneous tumor growth and lung metastasis. The combination of both therapies resulted in significantly greater local and systemic efficacy than either agent alone. The strong local and systemic anti-tumor activity of the combination resulted in a significant increase in median overall survival (p = 0.0001) compared to control mice that received intravenous B16F10-eGFP cells only. In conclusion, OncoVEXmGM-CSF in combination with CTLA-4 blockade significantly reduced systemic tumor burden and prolonged median overall survival in a B16F0 mouse model of metastatic melanoma. These data support the proposed MOA by which OncoVEXmGM-CSF treatment can cause direct tumor lysis along with potentiation of an adaptive, systemic anti-tumor immune response.

**4567 Immunoclassification of gastric cancer in the context of clinical outcome.** Welli Wang,1 Ping Liao,1 Shanchen Xie,1 Dongya Shen,1 Chengfang Zhou,1 Howard McLeod,2 YiJing He1,2

**1Institute of Clinical Pharmacology, Central South University, Changsha, China; 2 Moffitt Cancer Center, DeBartolo Family Personalized Medicine Institute, Tampa, FL.**

**Background:** Gastric cancer (GC) plays a leading role in all cancer deaths especially in Eastern Asia. Current classifications including WHO, Lauren, and TCGA defined molecular classification have illuminated the clinicopathological characteristics or genetic profile of GC. However, these classifications were lack of association with clinical outcome and guidance for medication selection. **Objective:** We aimed to identify a new immunoclassification for GC to predict patient’s prognosis and provide evidence for choosing proper medication. 

**Methods:** To identify significant biomarker and significant embedded (FFPE) gene expression data were used to find evidence for the influence of smoking on the composition of intratumoral immune cell fractions and their prognostic impact. The analysis was confined to samples hybridized to the Affymetrix HG-U133 Plus 2.0 (GEO accession number GPL570). Expression profiles were downloaded and curated for duplicates and corrupt files. Different immune cell fractions were estimated using CIBERSORT and the LM22 leukocyte signature matrix. We combined this information with available clinical data. We used Cox regression analyses to evaluate the prognostic impact of the different immune fractions and Mann-Whitney U tests to test for significant differences. Results: Smokers with NSCLC had a significantly (p = 0.05) higher percentage of plasma cells, CD8 + T-cells, active CD4 + T-cells, follicular helper cells, monocyttes, M0 macrophages, resting dendritic cells, active mast cells and neutrophils compared to non-smokers. Smokers had a lower percentage of naive B-cells, memory B-cells, resting CD4 + T-cells and resting mast cells. Non-smokers significantly benefit from a higher percentage of intratumoral memory B-cells in the immune infiltrate as compared to normal tissue (HR 0.92, 95% CI 0.85-1.00, p = 0.049), while the smokers significantly benefit from higher intratumoral immune fractions of resting CD4 + T-cells (HR 0.93, 95% CI 0.89-0.98, p = 0.001). Higher percentages of regulatory T-cells (HR 1.23, 95% CI 1.03-1.47, p = 0.025), neutrophils (HR 1.11, 95% CI 1.02-1.21, p = 0.014) and follicular helper cells (HR 1.19, 95% CI 1.01-1.38, p = 0.031) have a significant detrimental effect on survival of smokers. There was a borderline beneficial effect for smokers of the intratumoral NK cell fraction (HR 0.61, 95% CI 0.36-1.02, p = 0.057). For non-smokers, a detrimental effect was observed for the intratumoral plasma cell fraction (HR 1.04, 95% CI 1.00-1.09, p = 0.073) and the naive B-cell fraction (HR 1.17, 95% CI 0.99-1.39, p = 0.075). Conclusion: In NSCLC, significant different composition of intratumoral immune cells were observed between a smoking and non-smoking population. These differences were associated with differences in overall survival.

**4570 Intratumoral IFN-α gene transfer reduces trafficking of Tregs into tumor by inhibition of CCL17 expression.** Kazunori Aoki, Chihiro Shibasaki, Hisayoshi Hashimoto, Kenta Narumi, Chie Kudo, Hisayoshi Hashimoto, Kenta Narumi, Chie Kudo.

**Institute of Clinical Pharmacology, Kanta Narumi, Chie Kudo.**

**Introduction:** The immune system plays an important role in tumor progression and treatment response as well as with new immune modulating therapies. It is unclear in lung cancer what the effect of smoking is on intratumoral immune cell composition and their function. In our study publicly available expression data were used to find evidence for the influence of smoking on the composition of intratumoral immune cell fractions and their prognostic impact. Methods: We searched the Gene Expression Omnibus (GEO) for human non-small cell lung cancer (NSCLC) samples. Analysis was confined to samples hybridized to the Affymetrix HG-U133 Plus 2.0 (GEO accession number GPL570) platforms. Expression profiles were downloaded and curated for duplicates and corrupt files. Different immune cell fractions were estimated using CIBERSORT and the LM22 leukocyte signature matrix. We combined this information with available clinical data. We used Cox regression analyses to evaluate the prognostic impact of the different immune fractions and Mann-Whitney U tests to test for significant differences. Results: Smokers with NSCLC had a significantly (p < 0.05) higher percentage of plasma cells, CD8 + T-cells, active CD4 + T-cells, follicular helper cells, monocyttes, M0 macrophages, resting dendritic cells, active mast cells and neutrophils compared to non-smokers. Smokers had a lower percentage of naive B-cells, memory B-cells, resting CD4 + T-cells and resting mast cells. Non-smokers significantly benefit from a higher percentage of intratumoral memory B-cells in the immune infiltrate as compared to normal tissue (HR 0.92, 95% CI 0.85-1.00, p = 0.049), while the smokers significantly benefit from higher intratumoral immune fractions of resting CD4 + T-cells (HR 0.93, 95% CI 0.89-0.98, p = 0.001). Higher percentages of regulatory T-cells (HR 1.23, 95% CI 1.03-1.47, p = 0.025), neutrophils (HR 1.11, 95% CI 1.02-1.21, p = 0.014) and follicular helper cells (HR 1.19, 95% CI 1.01-1.38, p = 0.031) have a significant detrimental effect on survival of smokers. There was a borderline beneficial effect for smokers of the intratumoral NK cell fraction (HR 0.61, 95% CI 0.36-1.02, p = 0.057). For non-smokers, a detrimental effect was observed for the intratumoral plasma cell fraction (HR 1.04, 95% CI 1.00-1.09, p = 0.073) and the naive B-cell fraction (HR 1.17, 95% CI 0.99-1.39, p = 0.075). Conclusion: In NSCLC, significant different composition of intratumoral immune cells were observed between a smoking and non-smoking population. These differences were associated with differences in overall survival.
control vector injection. We hypothesized that Treg-homing cytokines such as CCL17 and CCL22 cytokines are involved in the reduction of tumor-infiltrating Tregs by the Ad-mILN injection. The IFN-α expression significantly suppressed CCL17 and CCL22 expression of tumors, and the expression of CCR4 and CCR5 expression on Tregs was not changed. IFN-α protein significantly suppressed CCL17 of 2T26s in vitro in a dose-dependent manner. Therefore, CCL17 shRNA-transduced 2T26 cells (2T26shCCL17) to examine the immunological role of CCL17 in vivo. The frequency of Tregs per CD4+ T cells was significantly reduced in subcutaneous tumors of 2T26shCCL17 cells (25.9%), and tumor growth was inhibited compared with that of control shRNA-transduced 2T26 cells (39.4%). Suggesting CCL17 has an important role in tumor growth compared to migration and proliferation of Tregs. The study demonstrated that IFN-α gene delivery creates an environment strongly supporting the enhancement of antitumor immunity through the suppression of Tregs.

#4571 Advantage of dendritic cells for the therapeutic cancer vaccine. Koji Nagaoka, Akihiro Hosoi, Tamaki Lino, Hirokazu Matsushita, Kazuhiro Kakimi. The University of Tokyo Hospital, Tokyo, Japan.

Background: To develop effective cancer vaccine, we examined CTLs induced by peptide vaccination (CTL pep) and DC vaccination (CTL DC) in terms of their antitumor effects. Methods: For preparation of peptide vaccine, 50 µg hgp100 peptide (KVPQRNQDWL) and 1x10^7 Pmel-1 splenocytes were transferred. Then, mice were vaccinated on days 0 and 14. For preparation of DC vaccine, 50 µg CpG were emulsified with 50 µl CFA or IFA. Bone marrow-derived DCs were matured with LPS and pulsed with hgp100 peptide at 1 µg/ml and used as DC vaccine. To induce CTL pep and CTL DC, C57BL/6 mice were first injected with 1 x 10^7 naive spleen cells from Pmel-1 TCR transgenic mice to increase hgp100-specific CTLprecursors. Then mice were vaccinated twice with 2 weeks interval. The induction of CTLs were evaluated 1 week after the second vaccination. To evaluate their antitumor activity, 1 x 10^6 B16F10 were inoculated into vaccinated mice (prophylactic model). For therapeutic model, 1 x 10^6 B16F10 were inoculated into mice on day 0. Five days later 1 x 10^5 Pmel-1 splenocytes were transferred. Then, mice were vaccinated on days 5 and 12, followed by the measurement of tumor growth. Results: DC vaccine induced 5-6 times more CTLs than peptide vaccine. The numbers of CTL pep and CTL DC obtained in the spleen were 2.4 ± 0.2 x 10^6 and 1.2 ± 0.4 x 10^6, respectively. CTL pep expressed PD-1 and Tim-3 at higher level than CTL DC. Most of CTL pep showed effector memory phenotype (CD44hiCD62L-) while CTL DC contained a considerable fraction of central memory cells (CD44hiCD62L). Although both CTL pep and CTL DC produce IFN-γ and TNF-α at similar level, more CD107a+ were detected on CTL DC than CTL pep upon re-stimulation. CTL DC displayed better proliferation potential than CTL pep. These phenotypic differences were confirmed by the comprehensive gene expression analysis. Transcriptome analysis revealed that considerable portion of CTL pep and CTL DC were comparable and different from that of naive CTLs. However, several genes were expressed differentially: CTL pep expressed higher amount of inhibitory receptors, such as Pdcd1, Lag3, Ctl4a and Tigit than CTL DC. CTLDC expressed Fbp1, which inhibits glycolysis, and Cpt1a, which is the rate-limiting enzyme of mitochondrial fatty acid oxidation, suggesting that their metabolic statuses were shifted from glycolysis to fatty acid oxidation. DC vaccine completely inhibited the tumor growth in prophylactic vaccine setting, while peptide vaccine delayed tumor growth compared to control mice. In therapeutic protocol, peptide vaccines showed no antitumor effect, while DC vaccine significantly suppressed tumor growth. The numbers of intratumoral CTL pep and CTL DC on day 19 were 5.2 ± 2.8 x 10^5/g and 5.0 ± 1.4 x 10^5/g, respectively. Intratumoral CTL DC expressed lower levels of PD-1, Tim-3 and LAG-3 and more Ki67 than CTL pep. Furthermore, Intratumoral CTL DC produce more IFN-γ and TNF-α than CTL pep. Conclusion: DC vaccine induced intratumoral CTLs with multi-functionality and high proliferation potential. Therefore, DC vaccine is our choice for the therapeutic cancer vaccine.

Introduction: In the tumor micro-environment, extracellular ATP is sequentially hydrolyzed to adenosine by the ecto-nucleotidases CD39 (ATP→ADP) and CD73 (AMP→adenosine). Adenosine, through activation of the A2A receptor (A2AR), is a potent inhibitor of T-cell activation, resulting in an immunosuppressed phenotype. Thus, inhibition of A2AR has recently generated great interest in immuno-oncology. We present the characterization of a novel, selective, and highly potent small molecule antagonist of A2AR which is slated to enter clinical trial in 2017. Methods: The cellular potency of A2AR antagonists was assessed as a function of decreased AMP levels in CHO cells stably over-expressing hA2AR, a Ga coupled receptor, following stimulation with the agonist NECA. Experiments were conducted in the presence and absence of human serum. Selectivity against the Gi-coupled receptor A1R was assessed similarly as a function of CAMP elevation in CHO cells stably expressing hA1R, following pretreatment with forskolin and stimulation with NECA. The ability of AB928 to reverse the inhibitory effects of adenosine on lymphocyte proliferation and IFN-gamma and TNF-alpha production was assessed using the hA2AR transfected murine T-cell hybridoma 2C8. The ability of AB928 to inhibit the potassium ion channel hERG was assessed similarly as a function of IC50 in CHO cells stably expressing hA1R, following pretreatment with the agonist NECA. AB928 fully reversed the activity of adenosine to suppress CD8+ T cell activation as indicated by CD25 expression and increased levels of cytokines such as IFN-γ and IL-2 in the supernatants (p<0.01 vs 25 µM adenosine only). AB928 inhibited mouse A2AR, as indicted by reversal of adenosine-mediated immune suppression in the CD8+ T-cell activation assay. Pharmacokinetic characterization of AB928 showed it to be orally bioavailable with characteristics suitable for human dosing that will allow for treatable dose levels. Conclusions: AB928 is a potent, selective and peripherally restricted antagonist of the A2A receptor which is slated to enter clinical development in 2017.

#4573 Characteristics and outcomes of patients with advanced sarcoma enrolled in early phase immunotherapy trials. Roman Groisberg, Vivek Subbiah, David Hong, Filip Janku, Sarina Piha-Paul, Aung Naing, Robert Benjamin, Shreyas Kumar Patal, Neeta Somaiah, Anthony Conley. UT MD Anderson Cancer Center, Houston, TX.

Background: Immunotherapies, specifically those based on immune checkpoint inhibitors, have shown promising activity in multiple tumor types. Other than the drug mifamurtide for osteosarcoma, there are currently no approved immunotherapies for sarcomas. We analyzed the outcomes of patients with advanced sarcomas treated in immunotherapy phase 1 trials. Methods: We analyzed the medical records of patients with advanced sarcoma who were referred to Phase 1 trials and had received at least one dose of an immunotherapy including checkpoint inhibitors, vaccines, or cytokine based therapies. Clinical parameters reviewed were age, histology, lactate dehydrogenase, albumin, metastatic sites, performance status, prior therapies, toxicity and response on imaging. Progressive free survival (PFS) was measured from the date of the first dose to the date of progression on imaging. Results: Among 50 patients enrolled in immunotherapy trials we found 14 different subtypes of sarcomas (Bone 10; Soft tissue 40). Patients were 42% male and 58% female. The median age was 53.5 years (18-84) and Royal Marsden Hospital (RMH) prognostic score was 0.08. Grade3/4adverseeventsincludedrash(10%),fever(6%),fatigue(6%),diabetes(4%),andnausea/vomiting(6%). Other toxicities included hypothyroidism, transaminitis, pancreatitis, pituitary apoplisty, pneumonitis and mucositis. Conclusions: Immunotherapies were well tolerated in advanced sarcoma with 92% of patients able to complete 28 days of therapy. The patients had been heavily pretreated and had good performance status and favorable RMH prognostic scores. All ASPS patients had clinical benefit with checkpoint inhibitors and this was the only subtype with a partial response. Further evaluation of checkpoint inhibitors in sarcomas, especially ASPS, is warranted.

IMMUNOLOGY: Clinical Immunotherapy, Viruses, and Bacteria
we hypothesized that macrophages have the potential to be a powerful cellular tumor setting has not been observed. Barriers to T cell entry and function may profound results in hematologic malignancies but clinical efficacy in the solid Scholler,1 Carl June,1 Saar Gill1.

Cytosed and cleared cognate antigen-bearing tumor cells. To demonstrate the cytosis and luciferase-based specific killing assays. CARMA selectively phagocytosed and killed HER2+ expressing ovarian and breast cancer cells themselves; instead, it requires a good match between our compound and a “sensitive” tumor microenvironment. We found that within “TAM-rich” solid tumors, an effective SMDC may be one with dual mechanisms of action that affect both FRe-positive tumor cells and FRβ-positive TAMs. Moreover, the process of choosing partner drugs, such as immune checkpoint inhibitors and inhibitors of myeloid-derived suppressor cells, should be guided by the immunomodulatory properties of both SMDCs and SOC agents to overcome the frequently observed chemo- and immuno-resistance.

#4575 Chimeric antigen receptor macrophages (CARMA) for adoptive cellular immunotherapy of solid tumors. Michael Klichinsky1, Marco Ruella,1 Olga Shestova,1 Saad S. Kenderian,2 Miriam Y. Kim,3 Roddy O’Connor,1 John Scholler,2 Carl June,2 Saar Gill.1 University of Pennsylvania, Philadelphia, PA; Mayo Clinic, Rochester, MN.

Chimeric antigen receptor (CAR) T cell immunotherapy has demonstrated profound results in hematologic malignancies but clinical efficacy in the solid tumor setting has not been observed. Barriers to T cell entry and function may partially explain this observation. As solid tumors actively recruit myeloid cells, we hypothesized that macrophages have the potential to be a powerful cellular immunotherapeutic agent in this setting if properly activated and redirected. We here describe the development of CAR macrophages (CARMA), demonstrating the feasibility, mechanism, and efficacy of this platform. To examine the function of CARs in macrophages, first generation anti-CD19, anti-mesothelin, or anti-HER2 CARs with a CD3ζ intracellular domain were introduced into the THP1 macrophage model. In vitro function was assessed via quantitative phagocytosis and luciferase-based specific killing assays. CARMA selectively phagocyted and cleared cognate antigen-bearing tumor cells. To demonstrate the requirement for CAR-mediated intracellular signaling for activity, a CD3ζ null CAR construct was tested in vitro. The deletion of CD3ζ significantly reduced the phagocytic and killing capacity (p<0.01) of CARMA. We identified Ad5S5, a chimeric adenovirus, as a novel and highly efficient viral vector for the transduction of normal donor and cancer patient macrophages (>70% CAR expression). Ad5S5 transduction polarized human macrophages toward a durable immunomodulatory M1 phenotype and rendered CARMA resistant to subversion toward the immunosuppressive M2 phenotype, as defined by surface markers and metabolomics. CARMA enhanced the proliferative capacity of CD8+ T cells in phytohemagglutinin activation assays and secreted factors that activated by-stander macrophages. Primary human anti-HER2 CARMA demonstrated targeted phagocytosis and killing of HER2 expressing ovarian and breast cancer cell lines, and exhibited a six-fold higher luciferase-based killing capacity of SKOV3 cells compared to trastuzumab in vitro (p=0.002). Anti-HER2 CARMA was evaluated in vivo in an intraperitoneal (IP) SKOV3 ovarian cancer xenograft model. Mice that received IP CARMA had a decrease in tumor burden of approximately two orders of magnitude and had a 30-day survival benefit relative to untreated or control macrophage treated mice (p=0.018). In a systemically disseminated SKOV3 model, a single dose of IV CARMA led to a durable anti-tumor response (38-fold reduction relative to control on day 31 post-treatment; p=0.016). Lastly, we demonstrated that the blockade of the anti-phagocytic CD47/SIRPα axis enhanced the phagocytic capacity of CARMA. In summary, we here demonstrate that human macrophages engineered with a CAR exhibit targeted anti-tumor function in both in vitro and in vivo preclinical models. This novel cellular immunotherapeutic approach has a clear translational potential for the treatment of solid tumors.

#4576 Targeted human cytolytic fusion proteins: an update. Stefan Barth. University of Cape Town, Observatory, South Africa.

Targeted immunotherapeutics, such as antibody drug conjugates (ADCs) or immunotoxins (ITs) represent promising agents for treatment of cancer. Despite their encouraging performance in clinical trials, both ADCs and ITs suffer from disadvantages like stoichiometrically undefined chemical linkage of the cytotoxic payload and potential immunogenicity of bacteria- or plant-derived toxins in humans, respectively. Therefore, in contrast to depleting B cell epitopes from bacterial toxins, we designed a number of targeted recombinant cytolytic fusion proteins, replacing bacterial toxins like Pseudomonas exotoxin A by human enzymes like proteases, kinases, RNases or microtubuli-associated proteins. Binding and biological activities were shown in vitro, ex vivo and in different in vivo models. This presentation will summarize the latest results on the hCEPs generated and demonstrate the efficacy of treatment of CD64-, CSPG4-, and EpCam-targeting constructs in direct comparison to the corresponding Pseudomonas exotoxin-based CAR constructs. The presentation will conclude with an outlook on future perspective and applications of the next generation of targeted fully human recombinant cytolytic fusion proteins.

#4577 Appropriately delivered curcumin causes recruitment of natural killer cells into glioblastoma brain, stabilizing M1 polarization of tumor-associated microglia. Sumit Mukherjee,1 Angela Fried,2 Rahman Hussaini,2 Richard White,2 Aheli Chatterjee,2 Probal Banerjee,2 City University of New York Graduate Center, New York, NY; 2City University of New York College of Staten Island, Staten Island, NY; 3City University of New York at The City College of New York, New York, NY.

Glioblastoma (GBM) is the most insidious form of primary adult brain tumor with a mean life expectancy of 12-24 months. Previously, we have used the non-invasive strategies of (1) intranasal delivery of a glioblastoma-directed curcumin (CC) adduct (CC-CD68AB) and (2) the intraperitoneal (i.p.) infusion of a lipid-encapsulated formulation of CC-phosytoxin to rescue orthotopically GL261-implemented GBM mice and study the effect of CC on the phenotype of the tumor-associated microglial cells (TAMs). Both treatment regimens not only caused tumor remission in 50-60% of GL261-implemented GBM mice, but also induced a dramatic change in the tumor-associated Iba1+ TAMs, suppressing the tumor-promoting Arginase1high,IL10high,iNOSlow,IL12lowM2-type TAMs, while simultaneously inducing the Arginase1low,IL10low,INOSlow,IL12high M1-type TAMs. Concurrently, we observed a marked induction and phosphorylation-mediated activation of microglial p65 NF-κB and STAT1, with concomitant suppression and inactivation of STAT3:p-STAT1high, p-STAT3high M1 microglia are known to IL12-dependent recruitment/activation of tumoricidal NKp46high natural killer (NK) cells. In determining the kinetics of CC-induced M1 repolarization of M2-TAMs, we observed that five days of CC treatment (i.p.) was sufficient to induce a dramatic change in the tumor-associated Iba1+ TAMs, inhibiting the tumor-promoting M2-type TAM population, while activating M1-type microglia. As expected, we observed a concomitant recruitment of NKp46high NK cells into the GBM tumor. Cognizant of the fact that NK cells activate and stabilize the M1–microglia, we eliminated the NK cells in these GBM mice using the NK cell-targeted antibody NKL1.1 Ab to observe a significant reduction in CC-evoked repolarization of TAMs. Our results demonstrate a unique oncoimmunotherapeutic function of CC, which when appropriately delivered, not only eliminates GBM directly, but also indirectly elicits recruitment and activation of tumoricidal NK cells and M1-TAMs. Furthermore, maintenance of this CC-evoked M1 phenotype is contingent upon CC-induced recruitment and activation of NK cells. Thus, when delivered appropriately, CC functions on GBM both directly as well as by stimulating and recruiting an army of immune cells that eliminate both GBM and GBM-initiating cells.

#4578 Does poor prognosis in African Americans with MS-H colorectal cancer associate with altered immune markers. Umamaheshwari Golconda,1 Lena Sokol,2 Babak Shokrani,1 Edward Lee,1 Donna Hanzel,3 Oluwolue Fadare,1 Sandip Patel,4 Mehdi Nousarie,3 Hooman Soleimani,1 Zaki Sharif,1 Ali Afarsi,1 Fared Darenpouiran,2 Hassan Brim,1 Hassan Askhtorab1,1 Howard Univ, Washington, DC; 2University of Bern, Bern, Switzerland; 3UCSD, San Diego, CA; 4UC San Diego Moores Cancer Center, La Jolla, CA; 5Univ. of Pittsburgh, Pittsburgh, PA.

IMMUNOLOGY: Clinical Immunotherapy, Viruses, and Bacteria

Proceedings of the American Association for Cancer Research • Volume 58 • April 2017 1169
BACKGROUND: Microsatellite instability high (MSI-H) of sporadic colorectal carcinomas (CRC) is usually associated with improved prognosis and a high density of tumor-infiltrating lymphocytes. However, African Americans with MSI-H have poor prognosis. AIM: To evaluate whether or not expression of different immune and tumor markers individually or in combination in African American MSI-H CRC associate with the prognosis status. METHODS: Tissues Microarray (TMA) were prepared by microdissection from FFPE (Formalin Fixed Paraffin Embedded) blocks of 15 MSI-H patients. Immune markers (CD8+, Granzymes, Perforins, CD4+, STAT1, IRF1 and IRF5) and PD-L1 status were analyzed by immunohistochemistry (IHC). Demography and clinical data including TNM, tumor grading (WHO standard), histological type of the tumor, and time of diagnosis, date of the last follow-up examination, treatment, comorbidities, metastasis, recurrence, 5-year disease-free survival and death were collected. RESULTS: There were 4 patients with improved prognosis (27%) with relatively high CD4 density (2 with >50% and 2 with 11-50%) regardless of PD-L1 status (3+/1+), stage (II,III), and other immune markers (CD8, CD4, Granzymes, Perforins, IRF1, IRF5 and STAT1). One of the improved prognosis patients with KRAS mutation has elevated expression of all considered immune markers besides CD4. There were 9 patients (6 dead, 3 alive) with poor prognosis, with different immune and tumor markers level (3 were PD-L1+ and 5 have relatively high CD4 count; but with low level of STAT1. There were also 2 patients with expected improved prognosis based on their immune markers level (stage II), however, they died within the 5 year period post-diagnosis, due to their age (80 and 87 old). Conclusion: African American patients have poor prognosis which may correlate with the nature of tumor-associated immune response. Other factors such as MSH3 defects might cancel the positive prognosis of MSI-H status. Nonetheless, low STAT1 and low CD4 may be indicators of poorer prognosis.

IMMUNOLOGY: Clinical Immunotherapy, Viruses, and Bacteria

The FDA granted an IND for a 40 patient study entitled “A phase II study of treatment with oral mifepristone as salvage therapy in patients with advanced or metastatic non-small cell lung cancer who have failed 2 or more previous chemotherapy or immunotherapy regimens”. Presented herein is a description of the effect of treating Case 1 who is a 68 year old male who presented with stage IV metastatic non-small cell lung cancer causing 10 months of treatment with single agent oral mifepristone (Korlym from Corcept Inc) 300mg qd. He had shown tumor progression despite treatment with carboplatin, docetaxel, premetrexed, and gemcitabine. He was not considered a candidate for nivolumab or pembrolizumab because his tumor was negative for the programmed cell death factor ligand 1 (PD-1-1) marker. His preclinical performance status was 2, and he started on daily 300mg of mifepristone treatment. After 2 months of treatment he showed a considerable improvement in energy and stamina and less shortness of breath. There have been no new lung or brain lesions. In fact, there has been shrinkage of the lung lesions and no growth of the brain lesion and no more seizures. His ECOG was “0” after 10 months of single agent mifepristone treatment. The mechanism of action is believed to be by suppressing intracellular production of an immunomodulatory protein known as the prostaglandin E2 induced blocking factor (PIBF). One of the functions of PIBF is to stabilize perforin granules in natural killer cells thus inhibiting their cytotoxic activity. This protein seems to be unique to rapidly growing cells, e.g., trophoblast cells or cancer cells. Thus, in general, in low dosages, as used in this patient, the drug is very well tolerated. PIFB does not need to be needed for cells growing at normal speeds, in our case, mifepristone has been found to either cause complete tumor regression, or more commonly, stabilization of the cancer with improved quality of life. Previously, mifepristone allowed long-term complete remission from a terminal small cell lung cancer with associated hyponaesthesia. The case report here is believed the first involving palliative benefit of treating advanced non-small cell lung cancer with mifepristone. Stabilization of the brain metastasis in our patient supports evidence from a previous case of advanced glioblastoma multiforme with a clear though transient response to mifepristone, that the drug can cross the blood-brain barrier, and thus be effective for brain lesions. This is the first case treated with 300mg daily mifepristone (200mg used previously). Similar to the lower dosage, this patient reported no adverse side effects. Mifepristone was also found to improve longevity and body conditioning scores in a placebo controlled study of spontaneous murine lung cancer.

4579 Improving the efficacy of radioimmunotherapy by controlling the tumor microenvironment of gastric cancer. Hae Young Ko,1 Jin Su Kim,1 HyoEnGi Kim,1 Seonhwa Lee,1 Chae-Ok Yun,2 Sang Moo Lim.1 1Korea Institute of Radiological & Medical Sciences, Seoul, Republic of Korea; 2Hanyang University, Seoul, Republic of Korea.

Purpose: Radioimmunotherapy (RIT) of solid tumor is limited to poor antibody distribution due to extracellular matrix (ECM) of tumor microenvironments. In this study, we investigated the effect of the protein X, which is known to degrade ECM, on the microdistribution of trastuzumab, on the accumulation and the microdistribution of trastuzumab in tumor tissue. In this study, we investigated the effect of the protein X, which is known to degrade ECM, on the microdistribution of trastuzumab, on the accumulation and the microdistribution of trastuzumab in tumor tissue. In the treatment group. Conclusion: This study demonstrates that the treatment of protein X significantly improved antibody accumulation of tumortissue and that can enhance the effect of RIT.

#4582 Evaluating benefits of PD-L1 image analysis for the clinical setting.

Tissue-based investigations can prove challenging due to complex tissue architecture and heterogeneous biomarker expression, visual and cognitive "traps" that affect interpretive precision, and subjective assessments that affect reproducibility. A major concern is that these challenges could increase the risk of failure for therapeutic/diagnostic co-development and clinical use, as the biomarker measurements continue to increase in complexity and require increasingly precise diagnostic cut-points. Image analysis tools have been developed to overcome some of the challenges for conventional anatomic pathology practices, capitalizing on the objectivity and computational power of a digital platform. A computer, however, lacks the cognitive ability and experience of a human to interpret tissue architecture and context. Flagship Biosciences' computational Tissue Analysis (cTA™) platform integrates the power of our tissue image Analysis (tIA™) technology with the contextual experience of an anatomic pathologist to produce robust, precise, quantitative results that demonstrate biomarker content in the tissue context. Flagship Biosciences envisions the integration of our cTA™ technology into a computer-aided clinical pathology workflow as a method to improve the precision of scoring for even some of the most challenging tissue-based biomarker measurements. In a proof-of-concept study, we evaluated the performance of manual versus digital scoring approaches in a cohort of non-small cell lung carcinoma (NSCLC) samples stained with the IHC protocol for the PD-L1 PharmDX 28-8 complementary diagnostic. A comparison of the 2 modalities demonstrated that in nearly all cases, the within sample standard deviation of the cTA™ digital score results was less than the manual score (median inter-pathologist %CVs were reduced from 124.9% to 7.8% and intra-pathologists from 65.4% to 7.6% for manual and digital scores, respectively). As an additional exploratory examination, the effect of heterogeneity on PD-L1 interpretation was also investigated. Pathologists evaluated the same whole tissue slices within 5 high powered fields (HPFs) using both manual and cTA™-derived scoring. Results demonstrated that the use of cTA™ provides improvement agreement between HPF and whole slide assessments (absolute difference between the manual scores from HPF to whole slide were larger than the absolute differences for the digitally derived scores, at 3.14% and 8.27%, respectively). Taken together, these studies demonstrate that the use of cTA™ can significantly reduce variability in PD-L1 scoring, as compared to a manual scoring approach.

#4583 Heterogeneity in immune biomarker expression: Detailed analysis of a case with SCLC transformation after EGFR-TKI treatment. Kenichi Suda,1 Issao Murakami,2 Hui Yu,1 Jiiey Kim,3 Kim Ellison,1 Christopher J. Riviard,1 Tetsuya Mitsudomi,4 Fred R. Hirsch1. University of Colorado Anschutz Medical Campus, Aurora, CO;2Higashi-Hiroshima Medical Center, Hiroshima Hiroshima City, Japan;3Kindai University Faculty of Medicine, Osaka, Japan;

Introduction: The expression status of immune markers are of current research interest due to their potential roles as predictive biomarkers for immunotherapy in cancers. Currently there is little information on how the microenvironment of tumors and/or therapy-induced histological transformation may affect the expression of these immune markers. Methods: A 76-year-old never-smoking female with epidermal growth factor receptor (EGFR) mutated lung adenocarcinoma (AC) acquired resistance to gefitinib. After her death, autopsy revealed small-cell lung cancer (SCLC) transformation and EGFR T790M secondary mutation as mutually exclusive resistance mechanisms. Two liver metastases (SCLC vs. AC with T790M) and two lymph node metastases (SCLC vs. AC with T790M) were analyzed to compare the expression status of immune markers by immunohistochemistry (IHC) and an immune-oncology gene expression panel (HTG EdgeSeq Immuno-Oncology Assay). Results: IHC analysis revealed that PD-L1 was expressed in 5% of tumor cells with AC histology (T790M) but not in tumor cells with SCLC transformation (Table 1). The liver metastasis with SCLC transformation showed negative stromal PD-L1 expression and scant tumor infiltrating lymphocytes, while the other lesions demonstrated stromal PD-L1 staining and infiltration of CD8-positive T cells. PD-L1 was positive in lymphocytes from lymph node metastases, but not in those from liver metastases. Data generated using an IO panel indicated higher expression of galectin 9 and higher level of T cell stimulatory checkpoints in lesions with SCLC transformation. Bioinformatic analysis also demonstrated lower expression of type I interferon regulated genes in lesions with SCLC transformation. Conclusion: These data highlight the heterogeneity of expression of immune markers depending on the metastatic sites and histological transformation, and indicate that a biopsy from one lesion may not be representative of immune marker status for all lesions.

#4584 High PD-1 expression on regulatory T cells in lung cancer draining lymph nodes. Rieke Van De Ven,1 Anna-Larissa N. Niemeijer,1 Anita G. Stam,1 Sayed M. Hashemi,3 Christian G. Stocker,1 Johannes M. Daniels,1 Erik Thunnissen,1 Egbert F. Smit,2 Tanja D. de Gruijl,1 Adrianus J. de Langen1.1 VU University Medical Center, Amsterdam, Netherlands; 2 Netherlands Cancer Institute, Amsterdam, Netherlands;

The treatment of advanced non-small cell lung cancer (NSCLC) with PD-1 immune checkpoint inhibitors has improved clinical outcome for a proportion of patients. The current challenge is to find biomarkers that will identify patients likely to benefit from this therapy. In this study we assessed the difference of T cell subsets and PD-1 expression levels on T cells in tumor-draining lymph nodes (TDLN), non-TDLN (NTDLN) and peripheral blood mononuclear cells (PBMC). To evaluate these, flow cytometric analyses were performed on endobronchial ultrasound-guided (EBUS) fine-needle aspirates (FNA) from TDNLN and NTDLN of patients with NSCLC and compared to PBMC. Our data show that the frequency of PD-1+ CD4+ and CD8+ T cells, as well as the PD-1 expression level on activated regulatory T (Treg) and CD4+ and CD8+ T cells, are higher in TDNLNs as compared to NTDLNs or PBMC. These elevated PD-1 expression levels in TDLN may reflect tumor-specific T cell priming and may serve as a predictive or early response biomarker during PD-1 checkpoint blockade.

#4585 Radiation combined with checkpoint blockades enhanced antitumor efficacy for osteosarcoma. Yutaka Takahashi, Tomohiro Yasui, Keisuke Tamari, Kazumasa Mimata, Masahiko Koizumi, Yui Sato, Fumiki Ichishiki, Keisuke Ohtani, Ryosuke Kambe, Kazuhiko Ogawa. Osaka University, Osaka, Japan.

Osteosarcoma is one of the common malignancies at bone in children and adolescent. Recent study demonstrated that combination of anti-PD-L1 and anti-CTLA-4 antibodies provided grade control of metastatic osteosarcoma. However, a strong local treatment strategy including surgery or high precision radiation therapy is necessary to eradicate osteosarcoma. Radiation therapy plays an important role in local control but previous studies demonstrated that radiation enhanced immune response in which not only local tumor regression at irradiated sites but also regression of metastatic tumor outside the radiation field was observed. Although this phenomenon, so called the abscopal effect, is rarely seen, recent studies demonstrated that combination of X-ray irradiation with checkpoint blockades provided higher probability of the abscopal effect for some kind of tumors. However, the effect of X-ray irradiation combined with checkpoint blockade on the abscopal effect for osteosarcoma has been totally unknown. We investigated whether local X-ray irradiation combined with the anti-PD-L1 and anti-CTLA-4 antibodies enhances local and distant antitumor efficacy for osteosarcoma. LM8 mouse osteosarcoma cells were inoculated into both legs of C3H mice. Mice were treated by 10 Gy X-ray irradiation alone to the tumor in the one side leg (RAD group) at day 12, 150 µg of anti-PD-L1 and anti-CTLA-4 antibodies (P1C4 group) at days 9, 12, and 15, or those combination (COMB group). Administration of anti-PD-L1 and anti-CTLA-4 antibodies provided tumor growth delay or complete response at day 37 for about 20% of the mice. X-ray irradiation strongly inhibited tumor growth at irradiated tumor but not in unirradiated tumor. On the other hand, the combination therapy provided the strongest tumor growth inhibition not only at irradiated site but also regression of metastatic tumor for about 89% of the mice. Accordingly, lung metastasis in mice in COMB group was strongly reduced by 97% with the significant survival benefit compared with the mice in P1C4 group. Flow cytometric analysis revealed that mice in COMB group significantly recruited CD8 tumor infiltrating lymphocytes with moderate reduction of regularly T cells (Treg), thereby increasing the CD69/Treg ratio. Furthermore, quantitative real time PCR showed significant induction of PD-L1 on irradiated LM8 cells in vitro and radiation-induced upregulations of PD-L1, B7-1, and B7-2, the ligands of CTLA-4, were also confirmed by flow cytometry, indicating that the enhanced efficacy anti-PD-L1 and CTLA-4 antibodies may associate with these upregulations by radiation. These results suggest that X-ray irradiation contributes to the enhancement of the efficacy for
IMMUNOLOGY: Clinical Immunotherapy, Viruses, and Bacteria

the distant metastasis as well as local control in the treatment of anti-PD-L1 and anti-CTLA-4 antibodies for osteosarcoma. Our data provide a rational to establish a new therapeutic strategy and start up a clinical trial for osteosarcoma.

IMMUNOLOGY: Immunoconjugates and Antibodies

#4586 Intratumoral Treg cell depletion by local administration of IL-2-Dipheria toxin fusion protein E7777 induces a therapeutic and memory anti-tumor immune response in preclinical models. Diana I. Albu,1 Christy Ingersoll,1 Kuan-Chun Huang,1 Mary Woodall-Jappe,1 Xingfeng Bao1,2.1 Eisai Andover Innovative Medicines Institute, Andover, MA; 2Eisai Oncology Business Group, Eisai Inc., Andover, MA.

T regulatory (Treg) cells play an important role in maintaining immunological tolerance to self-antigens, thus limiting immune responses to tumor antigens. Therefore, depleting or suppressing Tregs is one strategy by which anti-tumor immunity can be restored. The immunotoxin ONTAK® is an IL-2-Dipheria toxin fusion protein that has been shown to diminish Tregs in patients and animal models of cancer in peripheral blood using a systemic intravenous (i.v.) administration route. E7777 is a new version of ONTAK®. In this study we tested the hypothesis that locally-diminished Tregs by intratumoral (i.t.) administration of E7777 generate effective anti-tumor immune response at both local and systemic levels. First, we showed superior anti-tumor activity and safety of E7777 i.t. over E7777 i.v., where i.t. administration resulted in complete tumor regressions in both moderately immunogenic CT26 and non-immunogenic B16F10 tumors with minimal animal body weight loss. In contrast, only tumor growth delay was observed for E7777 i.v. with dose-limiting animal body weight reduction in the same models. Immune phenotyping showed a 4 fold reduction of intratumoral Tregs in treated CT-26 tumors without significant change of Tregs in the spleen of treated animals, confirming a local Treg-depleting effect of E7777 i.t. In contrast, intratumoral CD8+ T cells were not reduced. Second, E7777 i.t. enhanced overall anti-tumor immune response, manifested by significant increased numbers of CD45+ hematopoietic cells, Granzyme B+ CD8+ cytotoxic T cells, and ratios of cytotoxic T cells/Tregs in the treated tumors. Importantly, E7777 i.t. also resulted in distant effects in the spleen characterized by increased ratio of T lymphocytes to myeloid cells and increased frequencies of both effector memory CD8+ T cells (CD8+CD62L-CD44+) and central memory CD8+ T cells (CD8+CD62L+CD44+) indicative of systemic immune activation. Consistent with the generation of immunological memory, 60% of the tumor-free animals treated with E7777 i.t. rejected rechallenge with 40% displayed delayed growth of B16F10 cell challenge while all naïve control animals grew tumors. Taken together, our results demonstrate that intratumoral Treg depletion by local administration of E7777 leads to an effective local and memory anti-tumor response in preclinical models and support further evaluation of local E7777 delivery as a cancer immunotherapy.

#4587 A human hybrid immuno-oncology construct targeting the TWEEAK receptor Fn14 and containing the serine protease granzyme B. Ana Alvarez de Cienfuegos,1 Lawrence H. Cheung,1 Khalid A. A. Mohamedali,1 Jefrey A. Winkles,2 Michael G. Rosenblum,1 1MD Anderson Cancer Center, Houston, TX; 2University of Maryland School of Medicine, Baltimore, MD.

Targeting immune effector cells to tumors has recently emerged as a clinically-relevant approach for therapy. The underlying mechanism for immune effector cell challenge involves T or B-cell-mediated delivery of the serine protease granzyme B to the target cells. The cell-surface receptor Fn14 for the TNF-related cytokine TWEEAK has emerged as a potentially valuable target for cancer therapy because its expression is low in most normal tissues but significantly elevated in a variety of solid tumor types. The serine protease Granzyme B (GrB) is a highly cytotoxic component of human immune effector cells and induces multiple intense pro-apoptotic signals when delivered to the cytoplasm of target cells. This protein has been well-studied, operating through multimodal pathways which are both caspase-dependent and caspase-independent. Our laboratory has designed series of new Fn14-targeted fusion constructs containing an engineered GrB payload. The GrB-Fc-IT4 construct is a completely human homodimer (~200kDa) containing an IgG Fc domain for prolonged serum half-life. This construct displays high-level protein production in an HEK293E expression system. It exhibits high affinity and selective cytotoxicity within the nanomolar range (IC50 ranging from 4 to 284 nM) when tested against a panel of 25 Fn14-positive human cancer cell lines. We are currently assessing a panel of 100 annotated NSCLC cell lines to try to define a molecular fingerprint related to cellular sensitivity or resistance to the GrB payload. Pharmacokinetic studies in mice revealed that GrB-Fc-IT4 exhibited a bi-exponential clearance from plasma with a rapid initial clearance (t1/2a = 0.36 hours) followed by a prolonged terminal-phase plasma half-life (t1/2b = 35 hours). Mice bearing MDA-MB-231 orthotopic xenografted tumors and 40% displayed delayed tumorgrowth compared to GrB-Fc-IT4 construct (QODX5). On average, tumors from saline-treated mice grew about 10-fold over 40 days. In contrast, tumors from mice treated with GrB-Fc-IT4 did not grow during this period and remained the same size as at the onset of treatment. Moreover, 3/5 mice treated with GrB-Fc-IT4 showed complete tumor regression lasting beyond day 80 (end of the study). Overall, treatment with GrB-Fc-IT4 was well-tolerated by mice (no loss of body weight) and resulted in significant anti-tumor efficacy. Toxicology and bio-distribution studies are ongoing and will be presented. Research conducted, in part, by the Clayton Foundation for Research.

#4588 Novel anti-Trop-2 monoclonal antibodies with unique binding specificities show therapeutic synergy against most human cancers. Emanuela Guerra,1 Marco Trerotola,1 Valeria Relli,1 Chiara Pedicone,1 Antonella D’Amore,1 Francesca Dini,1 Silvia Fratarcangeli,1 Saverio Alberti1,2.1 “G. d’Annunzio” University of Chieti-Pescara, Chieti, Italy; 2UCI Chieti, Chieti, Italy.

Trop-2 is an epithelial transmembrane glycoprotein that transduces a calcium signal and activates a growth-signaling network that converges on AKT. Trop-2 is overexpressed in the majority of carcinomas, where it drives tumor cell proliferation and, in its mature, glycosylated and functional form, associates with worse prognosis. Trop-2 extracellular domain contains an N-terminal cysteine-rich globular region followed by a cysteine-less region as a connecting “stem” to the transmembrane domain. Trop-2 molecules engage in homophilic interactions between adjacent cells and establish multicellular complexes with tight junction proteins, which may hinder accessibility by therapeutic antibodies. Up to now, Trop-2-targeted approaches have employed anti-Trop-2 monoclonal antibodies (mAb) which essentially recognize a single immunodominant epitope poised between the globular and stem regions. Such mAb have limited or no therapeutic efficacy. In order to untap the potential of anti-Trop-2 immunotherapy we generated novel anti-Trop-2 mAb with tailored specificity towards the globular versus stem regions. Hybridoma diversity was maximized by immunization with soluble human Trop-2 extracellular region produced in different transformed mammalian cell lines (human 293 and murine L) and in insect cells/baculovirus expressing system. These were expected to provide native folding of Trop-2 together with a broad spectrum of differential glycosylation. Trop-2-binding hybridomas were further selected by multiple rounds of flow cytometry analysis using live 293 cells expressing different Trop-2 extracellular portions. Two classes of mAb were identified, that bound the stem versus the globular region. These mAb efficiently bound Trop-2 expressing cancer cells and were able to inhibit cell growth in vitro. In vivo the naked anti-globular OX-G64 and anti-stem OX-S55 mAb were most effective in inhibiting the growth of distinct tumors, including colon, ovary and prostate cancers. Notably, they showed differential efficacy for established tumors versus isolated-cell models of metastatic dissemination, consistent with our strategy of maximizing differential accessibility of Trop-2 according to growth mode. Most remarkably, we demonstrated in vivo synergy of these anti-Trop-2 mAb, paving the way for game-changing anti-cancer mAb therapy. The differential efficacy of the OX-G64 and OX-S55 anti-Trop2 mAb against different tumor histotypes and growth stages further allows to exploit their cancer-killing potential in pathological stage-tailored therapeutic approaches.

CD70 is a member of the tumor necrosis factor (TNF) superfamily and aberrantly expressed in several solid tumors and a variety of hematologic malignancies. The CD70 protein is expressed on highly activated lymphocytes (like in T and B cell lymphomas). Since normal lymphocytes do not express much CD70, it is suggested that anti-CD70 antibodies could be a potential treatment for CD70 positive lymphomas. SGN-CD70A is a novel antibody-drug conjugate that combines an anti-CD70 monoclonal antibody with a synthetic DNA cross-linking molecule, pyrrolobenzodiazepine (PBD) dimer. It is currently under phase I clinical trials for renal cell carcinoma, mantle-cell, diffuse large B-cell and follicular lymphoma. The aim of this study is to investigate the anti-tumor activity of SGN-CD70A in T cell lymphomas. We first examined CD70 expression in 36 cases of mature T or NK cell lymphomas using immunohistochemical (IHC) staining of patient biopsy specimens. The IHC results were reviewed and...
scored by 2 independent pathologists. We further investigated CD70 expression in Sezary syndrome (SS), mycosis fungoides (MF), and T cell acute lymphoblastic leukemia (T-ALL) cell lines, along with patient-derived T cell lymphoma primary cells and healthy donors’ peripheral blood mononuclear cells (PBMC) by flow cytometry. We next evaluated the anti-tumor activity of SGN-CD70A in a cutaneous T cell lymphoma (CTCL) xenograft model system. These findings merit clinical validation of the targeting of both membrane-bound complement regulatory proteins (mCRPs) CD46, CD55, and CD59 in solid tumors for mCRP expression and VEGF-A secretion. Our data suggest that p53 mutational status is associated with expression of CD55 and mCRPs’ inhibitory role in monoclonal antibody treatments for liquid tumors have been reported, but their role and regulation in solid tumors has not been explored. In the context of resistance to anti-VEGF-A antibody treatments for liquid tumors, we hypothesize that tumor cells in solid tumors will also secrete more VEGF-A and that mCRP expression will differ. In vitro experiments in our laboratory have supported this hypothesis.

#4590 Abiximab manifests striking anti-tumor effects in sensitive and chemoresistant ovarian cancer cells. Ghassan M. Saed, Nicole M. Fletcher, Ira Mennaj, Wayne State University, Detroit, MI.

Introduction: We have recently reported myeloperoxidase (MPO) to be expressed in epithelial ovarian cancer (EOC) cells and tissues. This finding was surprising, as MPO is known to be expressed only in cells of myeloid origin. We have also found that targeting β2 integrin (CD11b/CD18), a known ligand for MPO, resulted in significant anti-tumor effects. The objective of this study was to determine if targeting CD11b with a clinically approved drug that cross-reacts with CD11b will have anti-tumor efficacy for the treatment of sensitive and chemoresistant ovarian cancer. Methods: Human EOC cell lines MDAH-2774, SKOV-3, and A2780 and their chemoresistant counterparts were utilized for this study. Cells were treated for 24 hrs with increasing doses of docetaxel (0.0075, 0.01, and 0.025 μM) or cisplatin (0.1, 0.5 and 1.0 μM) with our without abiximab (5 or 10 μg/ml), an existing clinically approved anticogulant drug. Abiximab is a human-murine chimeric antibody Fab fragment against platelet glycoprotein IIb/IIIa (GP IIb/IIIa). Cytotoxicity was determined by the TACS TM Cell Proliferation Assay. Data was analyzed using SPSS and significant cytotoxic effects were determined by one-way analysis of variance within groups (sensitive, resistant to docetaxel or cisplatin) followed by Tukey’s post hoc tests, and independent t-tests for comparison between groups. For the synergistic effect of abiximab and chemotherapy, the automated calculation of combination index values was conducted by CompuSyn software. A combination index method provides qualitative information on the nature of compound interaction (antagonistic, additive or synergistic effect) and was used to analyze the results. Statistical significance of p<0.05 was considered significant for all analyses. Results: Abiximab had significant cytotoxic effects in sensitive (40.8 ± 10.3 and 56.7 ± 5.3%), docetaxel resistant (30.0 ± 11.6 and 46.6 ± 10.0%), and cisplatin resistant (27.3 ± 7.9 and 41.9 ± 7.0%) EOC cells at the 5 and 10 μg/ml dose, respectively, as compared to untreated controls (p<0.01). Abiximab is significantly more cytotoxic to sensitive as compared to cisplatin resistant cells (p<0.01), with no significant difference in killing as compared to docetaxel resistant cells (p>0.05). Treatment with chemotherapy combined with abiximab resulted in a synergistic cytotoxic effect in all sensitive EOC cell lines, and in chemoresistant MDAH-2774 and SKOV-3 cell lines. For the cisplatin resistant A2780 cell line, synergistic effects were only observed when combining abiximab with 1.0 μM cisplatin. Conclusions: The observed intriguing anti-tumor effects of abiximab in ovarian cancer cells indicates the potential for abiximab to be repurposed as a novel therapy for ovarian cancer.

#4591 Specific elimination of invasive and multidrug-resistant cancer cells by an antibody-drug conjugate targeting AXL. Julia Bushuizen,1 Louise A. Koopman,2 Esther C. Brei,2 David Satijn,3 Daniel Peiper,1 Paul W. Parren1. 1Netherlands Cancer Institute, Amsterdam, Netherlands; 2Gemmah, Utrecht, Netherlands.

Upon therapeutic pressure, cancers commonly select for drug-resistant, invasive subpopulations with elevated expression of the receptor tyrosine kinase AXL. Besides the correlation between high AXL expression and induction of epithelial-to-mesenchymal transition, a process known to support metastasis, ample evidence also links AXL to resistance against a variety of targeted therapies, including BRAF inhibitors. Mutations in AXL results in a constitutively activated receptor that inactivates the ERK survival signal, promoting a pro-apoptotic effect. Moreover, AXL has been shown to cooperate with other pathways in tumor cell proliferation and survival. The recently described AXL-107-MMAE is a chimeric antibody-drug conjugate specific for AXL, containing the microtubule disrupting agent monomethyl auristatin E as the cytotoxic payload. AXL-107-MMAE was previously shown to induce potent cytotoxicity in vitro and in vivo, which was dependent expression of AXL on the cell surface. We evaluated the efficacy of AXL-107-MMAE in a clonal xenograft model of AXL-positive, drug-resistant melanoma and breast cancer cells and AXL-negative cell lines, using malignant melanoma as a clinically relevant example. First, AXL-107-MMAE was shown to induce cytotoxicity in BRAF-mutant tumor cells that showed AXL expression upon acquired resistance to BRAF-inhibitors. In contrast, no cytotoxicity was observed in the BRAF-inhibitor-sensitive, AXL-negative parental cell lines. In heterogeneous tumor cell cultures, treatment with a BRAF-inhibitor selected for AXL-high, MAPH pathway inhibitor-insensitive melanoma cells, which was prevented by combined BRAF-inhibitor and AXL-107-MMAE treatment. Interestingly, we observed marked AXL upregulation in biopsies obtained from patients after they developed resistance to MAPK pathway inhibitors compared to paired pre-treatment biopsies. The in vivo potential of AXL-107-MMAE in malignant melanoma was demonstrated in immunocompetent mice, where post-therapy treatment with AXL-107-MMAE in AXL-positive melanoma cells prevented tumor growth in a xenograft model system. These findings merit clinical validation of the targeting of both treatment-naïve and drug-resistant cancers with AXL-107-MMAE, either alone or in combination with other targeted therapies.
wt-p53 versus mutant p53 solid tumor cell lines. Elucidating mechanisms for mCRP regulation is critical for immune biomarker development and in facilitating the use of antibody-based therapeutic approaches for solid tumors.

**#4593 Glycoengineered antibodies for click chemistry applications.** Dhrishi Sehgal, Stephen Kalscheuer, Tammy Sadhukha, Jayanth Panyam, University of Minnesota, Minneapolis, MN.

Antibody-drug conjugates (ADC) hold considerable promise as anticancer agents. A critical determinant of the effectiveness of ADCs is the chemistry that is used to conjugate the payload. Currently used approaches include primarily conjugation to either side-chain amine or carboxylic acid groups or conjugation to thiols. Because these reactions are not site specific and not easily controlled, these chemistries can result in reduced affinity for the target antigen. Further, these conjugation reactions lack selectivity and can result in heterogeneous mixtures of products that differ in the sites and stoichiometry of modification. We investigated a glycoengineering strategy that enables the introduction of artificial azide groups in the antibody without affecting their antigen affinity. This is based on the observation that glycosyltransferases can incorporate non-natural sugars (e.g., azido mannose) at different sites on an IgG molecule. The azide groups in these artificial sugars are then available to react with alkynes through copper-catalyzed ‘click’ chemistry or with strained alkyne-cyclooctyne (DBCO) allowing for biorthogonal, copper-free ‘click’ chemistry. Because the sugars are added reproducibly and at a site that does not affect antigen binding, the glycoengineering technology would overcome problems associated with traditional conjugation strategies. Using this approach, azide groups were introduced in anti-CD133 and anti-perlecan antibodies. Further, the azide groups were reactive to various DBCO conjugates including fluorophores, drug molecules and nanoparticles. Importantly, the addition of artificial sugar and subsequent azide-alkyne reaction did not affect the affinity of the antibody for the target antigen. Conjugation of nanoparticles to antibodies using this approach resulted in enhanced cellular uptake of the nanoparticles. Similarly, conjugation of a cytotoxin to the antibody resulted in enhanced cell kill in vitro. We expect that this glycoengineering strategy will prove to be a unique platform technology that will have a significant impact on antibody-based therapeutics.

**#4594 Induction of apoptosis by anti-CD20 antibodies requires the induction of EGR-1 and calcium influx.** Ivana Spaseska, Jade Villé, Kamel Chettab, Eva-Laure Mata, Charles Dumontet, INSERM 1052/CNRS 2866/University of Lyon Cancer Research Center of Lyon, Lyon, France.

Background: Anti-CD20 monoclonal antibodies (mAbs) are an essential component of the treatment of patients with CD20-positive non-Hodgkin’s lymphoma and chronic lymphocytic leukemia (CLL). Anti-CD20 mAbs mediate their antitumor effects by activating the immune system or by direct apoptotic signaling in target cells. In a previous preclinical study, we have shown that treatment of B-lymphoma cell lines with anti-CD20 mAbs, rituximab and obinutuzumab, resulted in upregulated expression of the transcription factor early growth factor -1 (EGR-1) (Dalle et al. 2011). However, the role of EGR-1 in response to passive immunotherapies has not been explored so far. Furthermore, EGR-1 has been described as a calcium (Ca^{2+}) regulated transcription factor that plays a key role in T-cell apoptosis. In this study, we investigated the role of EGR-1 and Ca^{2+} flux in the cytotoxic activity of anti-CD20 mAbs. Methods: EGR-1 modulation and cell death induction by anti-CD20 mAbs rituximab and obinutuzumab were investigated in cells expressing endogenous and exogenous CD20. The cytotoxic effect of anti-CD20 mAbs was evaluated in SCID mice and in B-lymphoma cell lines overexpressing EGR-1 or knocked down for EGR-1. The impact of anti-CD20 mAbs on Ca^{2+} flux was investigated by flow cytometry using Indo-1 AM stained cells. Ca^{2+} channel blocker nifedipine was used to investigate the role of Ca^{2+} flux on obinutuzumab efficacy. Results: EGR1 expression is rapidly upregulated in CD20+ cells following rituximab and obinutuzumab exposure. Decreasing EGR1 expression by shRNA abolished the direct cytotoxic effect of obinutuzumab in vitro and in vivo, indicating that EGR1 is required for the direct-mediated apoptosis. Additionally, the overexpression of EGR1 resulted in enhanced cytotoxic activity of obinutuzumab both in vitro and in vivo. Rescuing EGR1 expression in EGR1 knockdown cells restored sensitivity to obinutuzumab. Moreover, our results indicate that both rituximab and obinutuzumab could induce calcium influx in the presence of suboptimal concentrations of ionomycin. This influx was modulated by calcium channel blocker nifedipine or the Ca^{2+} chelating agent EGTA abolished EGR1 induction by anti-CD20 mAbs. In vivo, nifedipine treatment interfered with obinutuzumab antitumor activity against established Granta (a human mantle cell lymphoma line) xenografts in SCID mice. Conclusion: EGR1 plays a major role in the direct cytotoxic activity of anti-CD20 monoclonal antibodies and should be evaluated as a new biomarker to predict response to anti-CD20 treatment. Our data also show that calcium channel blockers interfere with the antitumor activity of obinutuzumab in preclinical models.

**#4595 Moxetumomab pasudotox spares CD4 and CD8 lymphocytes in multiply relapsed hairy cell leukemia patients, while prospective trials of first, second, and later lines of purine analogs show increasing toxicity.** Robert J. Kreitman, Maryalice Sterler-Stevenson, Evgeny Arons, Ira Pastan, National Cancer Institute, Bethesda, MD.

The purine nucleoside analogs cladribine and pentostatin damage DNA and cause long-term suppression of CD4 and CD8 lymphocytes in patients with hairy cell leukemia (HCL). There is increasing concern that these reductions, particularly in CD4+ T-cells, may be associated with opportunistic infections and secondary malignancies. The anti-CD22 recombiant immunotoxin moxetumomab pasudotox targets HCL without damaging DNA, and spares T-cells. In a phase 1 trial, 20 patients treated with 50 µg/kg every other day for 3 doses for 2-8 (median 4) cycles were evaluated for T-cell subsets. CD4 cells increased 56% to 152% (median 46%) after end of treatment, decreasing in only 1 of the 20 patients. Because there is very little prospective data on the effect of purine analogs on T-cells, we analyzed data from 80 consecutively enrolled patients receiving cladribine in first line, 40 receiving cladribine in second line, and 52 receiving either pentostatin or bendamustine in third or later lines. The latter group was most appropriate to compare with moxetumomab pasudotox, which was also used in third or later-line treatment of HCL. CD4 counts after moxetumomab pasudotox were 85-600 (median 424), compared to 22-618 (median 73) after third or later line purine analog (p<0.0001). These CD4 counts after moxetumomab pasudotox were even higher than those after first line (86-954, median 259, p=0.0037) or second line (53-724, median 185, p<0.0001) cladribine. CD4 counts after first line cladribine were higher than those after second line cladribine (p=0.0004), which in turn were higher than those after third or later line purine analogs (p<0.0001). Even after 2 years, CD4 counts after third or later line purine analogs, 41-1004 (median 264), n=43, remained suppressed compared to 1st line cladribine, 191-1044 (median 392, n=68, p=0.0013). The percent decreases in CD4 counts after first line cladribine were significantly greater compared to those after moxetumomab pasudotox (median 63% decrease vs 46% increase, p<0.0001). CD8 counts were also preserved after moxetumomab pasudotox, increasing by ~32% to 198% (median 46%). Similar differences between moxetumomab pasudotox and purine analog groups were observed with respect to CD8-cell suppression. Opportunistic infections, neutropenic fever, and other infectious complications were much more common after purine analogs than after moxetumomab pasudotox, particularly in later lines of therapy. These data provide a rationale for avoiding repeated cycles of purine analog for relapsed HCL, and support the use of non-chemotherapy approaches like moxetumomab pasudotox before repeated courses of purine analog are tried. (Supported in part by MedImmune and NCI, Intramural Program).

**#4596 Antibody-drug conjugates bearing pyrrolobenzodiazepine or tubulysin payloads allow the tumor immune microenvironment and synergize with multiple immunotherapies.** Jonathan Rios-Doria, Jay Harper, Raymond Rothstein, Leslie Wetzel, Jon Chesebrough, Allison Marrero, Cui Chen, Patrick Strout, Kathy Mulgrew, Kelly McGlinchey, Ray Fleming, Binyam Bezabeh, John Meekin, David Stewart, Maureen Kennedy, Philip Martin, Andrew Buchanan, Nazareno Dimasi, Emil Michelotti, Robert Hollingsworth, MedImmune, LLC, Gaithersburg, MD; MedImmune, LLC, United Kingdom.

Immunogenic cell death (ICD) is the process by which certain cytotoxic drugs induce apoptosis of tumor cells in a manner that stimulates the immunosystem. In this study, we investigated whether ADCs conjugated with pyrrolobenzodiazepine dimer (PBD) or tubulysin payloads induced ICD, modulated the immune microenvironment, and could combine with IO drugs to enhance antitumor activity. We show that the payload on the ADC induced an immune response that prevented the growth of tumors following subsequent tumor cell challenge. ADCs had greater antitumor activity in immunocompetent vs. immunodeficient mice, demonstrating a contribution of the immune system to the antitumor activity of these ADCs. These ADCs also induced immunological memory. In the CT26 model, depletion of CD8+ T cells abrogated the activity of the ADCs when used alone or in combination with a PD-L1 antibody, confirming a role for T cells in the antitumor activity. Combinations of ADCs in different tumor models with IO drugs including PD-L1 or PD-L1 antibodies, or OX40 ligand or GITR ligand fusion proteins produced synergistic antitumor responses. Importantly, synergy was observed in some cases with suboptimal
doses of ADCs, potentially providing an approach to achieve potent antitumor responses while minimizing ADC-induced toxicity. Immunophenotyping studies in different tumor models revealed broad immunomodulation of lymphoid and myeloid cells by ADCs and ADC/IO combinations. These results suggest that it may be possible to develop novel combinatorial therapies with PBD- and tubulysin-based ADCs and IO drugs that may increase clinical responses.

#4597 A novel immuno-oncology approach: targeting cell-surface mesothelin with a fusion construct containing human granzyme B. Lawrence H. Cheung,1 Rasheeda Tijani,2 Nasir Khan,3 Claire Thuning-Roberson,2 Michael G. Rosenblum1. 1MD Anderson Cancer Center, Houston, TX; 2H2Biologics Inc, Shrewsbury, MA.

Immunological approaches to target tumors have gained considerable traction recently because of excellent clinical results. In addition, targeted treatment with antibody-drug conjugates (ADCs) can also be effective in achieving regression of solid tumors. The challenge for ADCs continues to be efficacy, stability of the construct and development of resistance. We have developed a unique fusion protein composed of 1) a novel human single-domain antibody (SD1) that uniquely targets Region III of the mesothelin glycoprotein and 2) an engineered version of the human serine protease Granzyme B (GrB). Mesothelin is highly expressed in aggressive cancers such as malignant mesothelioma, pancreatic and ovarian cancers, and NSCLC. Granzyme B generates an intense, irreversible pro-apoptotic effect through direct cleavage of caspases, release of cytochrome C from mitochondria, and cleavage of nuclear matrix. Previous ADCs targeting mesothelin have faced the drawbacks of toxic payloads, formation of neutralizing antibodies, and competition with the serum protein MUC16/CA125. SD1-GrB represents a new class of completely human immunotoxins containing a payload with a unique mechanism of action. Additionally, because of its unique binding properties, SD1 does not compete with circulating CA125 and is not subject to cleavage. The SD1-GrB construct was designed as a homodimer (~200kDa) containing an IgG Fc domain and was expressed using transient-transfection of HEK293E cells. The soluble SD1-GrB was isolated from conditioned media and purified to homogeneity as assessed by SDS-PAGE and Western blot analysis. Enzymatic activity of the GrB component was assessed by IEPD and found to be similar to authentic, native GrB. Binding to mesothelin was confirmed by surface plasmon resonance. Additionally, binding to the human lung adenocarcinoma cell lines H460 and HCC1703 was demonstrated by ELISA. Initial cytotoxicity (IC50) of SD1-GrB against H460 and HCC1703 was in the 30 nM range. Assessment against a larger panel of cell lines is ongoing followed by in vivo efficacy in a human xenograft model. Our preliminary evaluation of SD1-GrB ADC suggests this construct has a unique mechanism of action and is highly cytotoxic against target cells. This molecule appears to be an excellent candidate for further pre-clinical development as a therapeutic agent. Research conducted, in part, by the Clayton Foundation for Research.

#4598 Triggering of OX40 on T cells by a novel monoclonal antibody elicits robust antitumor immunity!-EndFragment-» Hua Long,1 Ann White,2 Jie Wei,3 Brittany Jiang,4 Reid Feldman,5 Danielle Pappas,3 Aymen Al-Shamkhani,6 John Lin7 1Pfizer Inc, South San Francisco, CA; 2UCB Pharma, San Francisco, United Kingdom; 3Abbvie, Redwood City, CA; 4University of Southampton, United Kingdom; 5None, CA.

T cell costimulation is an attractive strategy for cancer treatment in addition to checkpoint inhibitors. Costimulatory molecule OX40 on T cells is a member of the TNF family. Binding to its receptor OX40L expressed on antigen-presenting cells potentiates T cell functions and elicits robust antitumor responses. Therefore, OX40 is an attractive target for the development of immunotherapies for solid tumors. We have developed a fully human OX40 agonist antibody (PF-8600) that binds to OX40 with high affinity and specificity. We used in vitro and in vivo methods to evaluate the mechanism of action as an OX40 agonist. As regulatory T cells are a major suppressor of antitumor immune responses, we have focused on a novel costimulatory strategy to potentiate anti-tumor immune responses by inhibiting regulatory T cells (Tregs). Oezcan Talay, Lisa Marshall, Cesar Meleza, Maureen K. Reilly, Omar Robles, Mikhail Zibisky, Aboud Okal, Lisa Seitz, Jenny McKinnell, Scott Jacobson, Erin Riegler, Emily Karbaz, David Chian, Angela Wadsworth, Paul Kassner, David Wustrow, Jordan S. Fridman. FLXBio, Inc., South San Francisco, CA.

Antigens that are over-expressed in cancer in response to radiation are being used as novel targets. We showed tax interacting protein 1 (TIP-1) to be radiosensitizing to cisplatin- and radiation-insensitive to the surface of the cancer cell following irradiation. TIP-1, which consists of a single PDZ domain plays an important role in cell signaling, cancer development, and progression. TIP-1’s involvement in various survival pathways makes it an attractive target for anticancer therapeutics. We used antibodies specific to this PDZ domain to determine its role in cancer cell survival. We monitored proliferation in lung cancer (A549 and H460) and glioblastoma (D54 and U251) cells after 24, 48, 72 and 96h treatment with the anti-PDZ antibody. We observed a time-dependent proliferation arrest with anti-PDZ antibody treatment which was associated with increased apoptosis. In combination with radiation (3 Gy) led to reduced cell proliferation and colony formation. Anti-PDZ antibody had no effect on the proliferation of normal lung (MRC-5) and endothelial (HUVEC) cells. Cells treated with anti-PDZ antibody showed decreased levels of the phosphorylated forms of AKT, mTOR, and 4EBP1. Anti-PDZ antibody treatment also led to an overall reduction in basal levels of AKT, mTOR, and 4EBP1. Further, we evaluated the effect of the anti-PDZ antibody on tumor growth in heterotopic mouse models of lung cancer (A549) and glioma (U251). We observed significant growth delay in mice treated with anti-PDZ antibody treatment when compared to mice treated with the isotype control. The combination of the anti-PDZ antibody with radiation showed an additive effect. Immunoblot analysis of tumor tissues also showed downregulation of phosphorylated and total levels of AKT, mTOR, and 4EBP1 in the tumors treated with anti-PDZ antibody. Overall, our results suggest that TIP-1 is a promising therapeutic target for treatment of lung cancer and glioblastoma. Antibodies specific to the PDZ domain of TIP-1 enhance the efficacy of radiotherapy. The anti-PDZ antibodies need to be optimized further before translating it into the clinic.

Chemokines play an important role in the development and progression of human cancer. Chemokine signaling is now being exploited as an attractive therapeutic strategy to exploit in the cancer microenvironment. CCR4 is expressed in various immune cells, and the combination of CCR4 antibodies and checkpoint inhibitors has shown promising results in clinical trials. Although CCR4 antagonists block migration and support expansion of activated T cells, some CCR4 antagonists block Treg migration and support expansion of activated T cells. In contrast to the non-selective approach of depleting anti-CCR4 antibodies, our compounds reduce Treg in the tumor, but not in peripheral tissues such as blood.
spleen or skin. In preclinical efficacy studies, CCR4 antagonists potentiate the anti-tumor effects of various checkpoint inhibitors and immune stimulators such as anti-PD-L1 and anti-CD137 antibodies. We observe enhanced tumor growth inhibition and increased tumor regressions when these agents are combined with CCR4 antagonists, without any gross toxicity. Further characterization of these CCR4 antagonists and their anti-tumor effects will be described.

**#4601** Mechanisms of action for therapeutic antibody variants of human IgG3 isotype: Enhancing the CDC activity of cetuximab and rituximab. Ralf Schwanbeck,1 Anna Skot,1 Thies Rösner,1 Marco Jansen,2 Anina Räuchle,1 Anna Kretschmer,1 Axel Scheidig,1 Jeanette Leusen,1 Stefanie Derer,1 Thomas Valerius1.1 Christian-Albrechts-University, Kiel, Germany; 2University Medical Center, Utrecht, Netherlands; 2University Hospital Schleswig-Holstein, Lübeck, Germany.

Objectives. Human IgG3 differs from other antibody isotopes by its extended hinge region and by its higher affinity for Clq. The ability of complement to promote lysis of antibody-opsonized cells is well-established and may represent a main mechanism in antibody mediated tumor therapy. The aim of this project was to investigate effector mechanisms of tumor-directed IgG3 antibodies in more detail. Experimental procedures. Therapeutic antibodies against EGFFR (cetuximab, 225) and CD20 (rituximab, C2B8) were produced as IgG1 and IgG3 isotype variants by co-transfecting CHO cells with the respective de novo synthesized V\(\beta\) and V\(\gamma\) domains fused to the respective heavy chain containing vectors. A Fab fragment of C2B8-IgG3 was crystallized and analyzed by X-ray structure analysis at PETRA III (DESY, Hamburg, Germany). Based on the resolved structure selected mutations were introduced into the CH1 domain of IgG3 aiming to improve or abolish CDC. Purified antibodies were assessed for complement fixation in ELISA and on tumor cells. Complement- and antibody-dependent cellular cytotoxicity (CDC and ADCC) activities were measured using \(^{51}\)chromium release assays. The significance of complement regulatory factors on target cells was investigated by siRNA mediated knock-down. A peritoneal tumor model was used to investigate the in vivo efficacy of IgG3 in comparison to IgG1 antibodies. Results. Switching isotypes from IgG1 to IgG3 did neither affect target antigen binding nor the proliferation inhibition by EGFGR antibodies. Unexpectedly, the IgG3 antibodies were not very active in ADCC, in spite of their strong FcγRII (CD16) binding affinity. However, for target cells expressing low antigen levels, the IgG3 isotype improved CDC against CD20 and enabled CDC against EGFGR expressing tumor cells. The complement-regulatory factor CD55 in particular mitigated the IgG3 induced CDC activity. Structural comparison of Fab fragments of IgG1 and IgG3 demonstrated significant differences in the CH1 domains of the respective heavy chains, which contain the disulide bond to the light chain and also harbor the docking interface for the complement factors C3b and C4b. Preliminary results from an peritoneal EGFGR tumor model demonstrated that IgG3 was effective in killing EGFGR-expressing cells. This in vivo activity was abolished by cobrava venom factor treatment. Conclusion. Switching the isotype of a therapeutic IgG1 antibody to IgG3 represents a promising approach to enable complement-mediated killing of tumor cells. Protein engineering of the C3b/C4b interaction interface in the CH1 domain may constitute a novel strategy to modulate the CDC activity against tumor target cells. Together, these approaches may enhance the CDC efficacy of CD20- and EGFGR-directed antibodies.

**#4602** The dissociation constant rate of ADC would be an important factor for antitumor activity in vivo. Ryo Tsumura,1 Shino Manabe,1 Yoshikatsu Koga,2 Yasuhiro Yasunaga,3 Yasuhiro Matsumura,1 National Cancer Center East, Kashihwa, Chiba, Japan; 2RIKEN, Wako, Saitama, Japan.

Introduction: Antibody-drug conjugates (ADCs), consisting of a monoclonal antibody, a potent cytotoxic agent and a linker, are currently considered as promising potent agents for cancer therapy. However, especially in solid tumors, the tumor stroma would hinder ADCs from accessing to cancer cells, leading to decline the efficacy of ADCs in clinical study. In order to overcome these difficulties and to maximize the ADC potential, the optimization of ADC components is needed. And it’s well-known that antitumor activity of ADCs depends on PK properties, binding affinity, internalization efficiency and other functions. In present study, therefore, we focused on the characteristics of antibody for ADC design, and investigated what characteristics could affect anti-tumor effects in vivo. Material and Method: First, we prepared 4 types of monoclonal antibodies against tissue factor (TF) which is known as a 47-kDa transmembrane glycoprotein and an initiation factor of the extrinsic blood coagulation. And then, anti-TF antibodies were conjugated with maleimidocaproyl-valine-citrulline-p-amino-benzoyloxy carbonyl linker and monomethyl auristatin E. Both of them were well-known liker system and drug for current ADC design. After conjugation, we investigated the characteristics, including binding paramaters, internalization efficiencies, drug release rates, cytotoxicity against human pancreatic cancer cell lines in vitro, half-life in vivo, anti-tumor effects using xenograft model, and distribution in tumor tissues. Results: In SPR analysis, anti-TF ADCs showed the significant differences of binding kinetics parameters. However, in other assays, anti-TF ADCs showed almost same internalization efficiencies, drug release rates, and cytotoxicity against human pancreatic cancer cell lines in vitro, half-life in vivo. The efficacy of anti-TF ADCs was examined in BxPC3 xenograft model when the average tumor size reached 200 mm\(^3\). Although anti-TF ADCs significantly inhibited BxPC3 tumor growth compared with control groups, there was no difference of anti-tumor effects among anti-TF ADCs. We further examined the anti-tumor effects when the average tumor size reached 600 mm\(^3\). Interestingly, the antitumor effect of ADC using the clone with high dissociation constant was superior to that with low dissociation constant against large size tumor, especially in the early phase. Furthermore, the distribution of ADC in BxPC3 tumor demonstrated that the former clone showed higher penetration ability than the latter clone. Conclusion: We concluded that binding kinetics parameters, in particular, the dissociation constant rate contributed to the tumor penetration ability of anti-TF ADCs and the different distribution in BxPC3 tumor. The distribution changes would affect the anti-tumor effects in large size BxPC3 tumor. Therefore we suggested that the dissociation constant rate would be an important factor for ADCs design.

Activatable nanotherapeutics provide the opportunity to deliver anticyclics to a well-controlled region of interest and therefore to locally stimulate immunogenic cellular death. Such a strategy can be combined with immunotherapy for both local tumor control and creation of an abscopal effect. Our group previously reported that combining local administration of a CpG oligonucleotide with local release of doxorubicin from a temperature-sensitive liposomal nanoparticle (TSL) led to the elimination of directly treated lesions in a syngeneic murine model of mammary adenocarcinoma. While this therapeutic approach increased the numbers of tumor infiltrating CD8\(^+\) T lymphocytes in distant lesions and extended survival, distant tumors returned with a growth delay of approximately 14 days and T-regulatory cells were not reduced by treatment. Therefore, checkpoint blockade of the programmed death-1 (PD-1) pathway (anti-PD-1) was incorporated in the protocol. CuDox-TSL were prepared from DPPC:MPC:DSPE-PEG2k (86:10:4) in the presence of copper (II) gluconate and triethanolamine at 0.2 mg-drug/mg-lipid. A complex between doxorubicin and copper was created to enhance the circulation and stability of TSL and to reduce systemic toxicity. On day 21, two mice with bilateral invasive neu deletion (NDL) tumors (~4 mm) were treated with i.v. administration of CuDox-TSL at 6 mg doxorubicin/kg body weight. Ultrasonication (1.1 MPa, 1.5 MHz, achieving 42°C for 5 min before and 20 min after drug injection) triggered drug release. Immediately after US, 100 \(\mu\)g of CpG-ODN 1826 was administrated intratumorally to the sonoinfected tumor; anti-PD-1 (200 \(\mu\)g, i.p.) was administrated three days later. Flow cytometry and immunohistochemistry were performed on day 28 after one treatment with each component and survival was assessed after treatment was repeated for three weeks. While control mice survived 35 days, 50% of treated mice were tumor-free after 100 days. All primary tumors and 50% of the contralateral tumors regressed and were eliminated by day 63. With the incorporation of immunotherapy, three doses of chemotherapy were sufficient to eliminate all directly treated tumors, as compared with 8 doses without immunotherapy. After a single treatment with each component, a substantial change was observed in systemic immune cells, including a significant increase in natural killer and dendritic cells in distant lymph nodes, in CD8\(^+\) T cells in tumors and associated lymph nodes and in IFNγ-secreting CD4\(^+\) T cells in the treated tumor and distant lymph nodes. The results demonstrate that activatable chemotheraphy can be paired with an immunoadjuvant and PD-1 blockade to generate a curative response in primary and distant tumors. Further, local chemotheraphy, as potentiated by activatable liposomes does not impede a systemic CD8\(^+\) T cell response. [1] Journal of Controlled Release (2015); 220: 253-264.

**#4604** MEDI1873, a GITR ligand fusion protein (GITRL FP), induces effector T-cell proliferation, modulates T-regulatory cell function and has the potential to combine with checkpoint inhibitors. Michelle Morrow,1 Rebecca Levland,2 James Hair,1 Ross Stewart,1 Natalie Tague,1 Lisa Bamber,1 Samantha Ireland,1 Nicholas Holoweczy,2 Michael Oberst,3 Amanda Watkins,1 Emily Offer,1 David Perez-Martinez,1 Ching Ching Leow,2 Lesley Young,1 Tristan Vaughan,1 Philip Mallinder,1 Robert Wilkinson1. MEDIimmune, Cambridge, United Kingdom; 2MEDIimmune, Gaithersburg, MD.
Glucocorticoid-induced tumor necrosis factor receptor-related protein (GITR) is part of a system of signals involved in controlling T-cell activation. MED1873 is a novel hexameric human GITR agonist comprising an IgG1 Fc domain, a coronin 1A trimeration domain and the human GITR extracellular domain (ECD) that is currently being assessed in a Phase 1 clinical study (NCT02540291). Combination of the EP4 antagonist E7046 with solid tumors showed strong, dose-dependent synergistic activity and superior to an anti-GITR antibody with respect to evoking robust GITR agonism, T-cell activation and clustering of Fc gamma receptors. Using in vitro assays, MED1873 recapitulates aspects of GITR targeting previously described in mice, including modulation of regulatory T-cell (Treg) suppression and the ability to increase the CD8:CD4 T-cell ratio via antibody-dependent T-cell cytotoxicity. Pharmacodynamic assessment of an agonistic mouse GITR-Fc (mGITR-Fc) in the CT26 model of colorectal cancer demonstrated activation and proliferation of peripheral CD4+ and CD8+ T cells coincident with an increased depletion of intratumoral Tregs, likely through Fc mediated effector functions. Furthermore, CT26 tumor growth studies indicated the mGITR-Fc could result in significant antitumor activity. These data provide evidence that MED1873 is a novel, potent GITR agonist with the potential to modulate T-cell responses and enhance anti-tumor immunity. Combinations of immunotherapies are generating exciting results in the clinic, therefore, we sought to assess the potential for GITR-FPs to combine with antibodies targeting either anti-PD-1 (durvalumab) or anti-CTLA-4 (tremlumab) using both in vitro and in vivo systems. In vitro studies where MED1873 was combined with either durvalumab or tremlumab showed that both combinations have the potential to enhance interleukin-2 release in a superantigen-stimulation of human peripheral blood mononuclear cells (PBMCs) compared to checkpoint blockade alone. Further evidence to support the potential for combinatorial antitumor activity was generated in the CT26 model where either 0.2mg/kg mGITR combined with 10mg/kg anti-mouse PD-L1 or 0.1mg/kg mGITR combined with 5mg/kg anti-mouse CTLA-4 antibodies resulted in enhanced antitumor activity versus monotherapies alone. Overall, our data suggest that therapeutically targeting GITR with a multimeric fusion protein, GITR-FP, may provide increased agonistic potential versus an antibody, and have the ability to both activate effector T-cells and modulate Tregs through suppression and/or deletion. Finally, combination studies provide preclinical evidence to support the rationale for combination of MED1873 with anti-PD-1 or anti-CTLA-4 antibodies further reinforcing the potential of targeting the GITR pathway as a therapeutic approach to treating patients with cancer.

**#4605** Efficient targeting of BCMA-positive multiple myeloma cells by antibody-coupled T-cell receptor (ACTR) engineered autologous T cells in combination with an anti-BCCA antibody. Tooba Cheema,1 Taylor Hickman,1 Kari Westenberg,2 Luke Manlove,2 Shyra Gardai,2 Katie O'Callaghan,1 Lori Westendorf,2 et al. 

B cell maturation (BCMA) has recently emerged as an attractive therapeutic target in multiple myeloma. BCMA has restricted expression on plasma cells with little to no expression on other normal tissues, but is upregulated on the surface of multiple myeloma cells. BCMA can regulate proliferation and survival of myeloma cells via binding to its ligands APRIL and BAFF and induce downstream signaling pathways. Thus, several approaches to target BCMA are currently under clinical investigation, including chimeric antigen receptor (CAR) T cell therapies, bispecific antibodies and antibody drug conjugates. The Antibody-Coupled T cell Receptor (ACTR) technology is a universal, engineered T cell therapy consisting of the extracellular domain of human CD16 and the intracellular T cell co-stimulatory and signaling domains. ACTR is designed to engage the Fc domain of therapeutic antibodies opsonized to target cells to mediate anti-tumor activity. Previous work has demonstrated ACTR-T cell activity in combination with rituximab, trastuzumab, and hu14.18 K322A against CD20, Her2, and GD2 expressing cell lines, respectively (Kudo et al. Cancer Res. 2014; 74:93-103). Currently ACTR is being evaluated in Phase I clinical trials with rituximab to treat relapsed refractory B cell lymphoma. Here we demonstrate a humanized afucosylated anti-BCMA antibody, SEA-BCMA, binds to ACTR expressing T cells with high affinity and mediates T cell activation, potent cytotoxicity, cytokine release and proliferation across a wide range of BCMA expressing myeloma cells. ACTR activity was specific to SEA-BCMA - opsonized target cells, dose dependent and had no activity on BCMA negative tumor lines. Furthermore, the SEA-BCMA antibody has additional properties that might contribute to a therapeutic effect, including blocking the binding of ligands to BCMA and driving natural killer cell mediated ADCC effects. These preclinical studies demonstrate a promising multi-faceted activity of ACTR T cells in combination with the anti-BCMA antibody, SEA-BCMA, for clinical consideration in multiple myeloma patients.

**#4606** Preclinical characterization of a novel fully human IgG1 anti-PD-L1 mAb CK-301. Leonid Gorelik,1 George Avgerinos,1 Yune Kunes,2 Wayne A. Marasco,3 et al. 

Antibodies targeting Programmed Death-1 (PD-1), or its ligand, PD-L1, have demonstrated remarkable efficacy in subsets of cancer patients, with inhibition of the interaction between PD-1 on T-cells and PD-L1 on tumor cells leading to the recovery of anti-tumor immune response and immune-mediated eradication of tumors. However, not all patients respond to existing PD-1 and PD-L1 targeting agents and relapses to therapy still occur. Therefore, there exists a need to identify additional therapeutic strategies and approaches to engage the immune system to enhance the efficacy of current anticancer therapies. Using phage and yeast display approaches, we have discovered and optimized a novel, fully human, PD-L1 specific IgG1 antibody, CK-301, which exhibits subnanomolar binding affinity for PD-L1, CK-301 blocks binding of PD-L1 to both PD-1 and B7-1 in enzyme-linked immunosorbent assays (ELISA) and cell-based competition assays. Using an assay measuring inhibition of a nuclear factor of activated T-cells (NFAT) reporter caused by PD-L1 binding to PD-1, we demonstrate that CK-301 completely reverses reporter inhibition at concentration of less than 1 μg/ml. IC50 of the dose response curve is 80mg/ml. CK-301 enhances IFN-gamma secretion in allogeneic lymphoblastoid cell lines. CK-301 has similar subnanomolar affinity for cynomolgus monkey PD-L1 as for human PD-L1, hence we chose Macaca fascicularis for pre-clinical toxicology and safety pharmacology studies. Single-dose administration of CK-301 to monkeys up to the highest tested dose of 100 mg/kg was shown to be safe and demonstrated linear dose-dependent pharmacokinetic (PK) properties over the dose range from 1 to 100 mg/kg with a half-life of 15 days at 100 mg/kg. A first-in-human Phase 1 study of CK-301 is planned to commence in mid-2017.

**#4607** Specific inhibition of PGE2 - EP4 signaling by E7046 promotes anti-tumor activity of checkpoint blockade agents through boosting cytotoxic T cell activity. Diana I. Albu,1 David Verbel,1 Yuan Huang,1 Donna Kolber-Simonds,2 Zichun Wang,1 Xulong Wang,1 Zoltan Dezso,2 Christy Ingersoll,1 Kuan-Chun Huang,1 Janna Hutz,2 Mary Woodall-Jappe,3 Xingfeng Bao,1 Eisai Andover Innovative Institutes, Andover, MA; 2Nurix Inc., San Francisco, CA; 3Eisai Oncology Business Group, Eisai Inc., Andover, MA.

Purpose: Immunotherapies targeting immune checkpoint receptors have shown great promise in subsets of cancer patients; however, robust and safe combination therapies are still needed. In the tumor microenvironment, pros-taglandin E2 receptor type 4 (EP4) signaling has been implicated in both protumor myeloid cell differentiation and cytotoxic T cell exhaustion. We evaluated the combination of the EP4 antagonist E7046 (clinical trial NCT02540291) with anti-PD1 or anti-CTLA4 in preclinical tumor models, and also interrogated the relationship between PGE2 signaling and other potential pathways. Materials/Methods: Mouse syngeneic tumor models CT-26 and 4T1 were used for pharmacological evaluation. GMP grade E7046 was administered to tumor-bearing animals by oral gavage. Co-culture of EG7-OVA and OT1 cells in an antigen-specific cytotoxic T cell (CTL) activation assay provided mechanistic insights. For translational validation, transcripts of five major genes involved in PGE2, synthesis, transport, and degradation were compared between malignant and normal tissues across all TCGA tumor types, and correlation of their expression with overall survival was assessed. Results: In the CT26 tumor model, the combination of E7046 and anti-PD1 resulted in significantly more tumor-free animals compared with either agent alone. In the 4T1 tumor model, the combination of E7046 and anti-CTLA4 was also more effective in suppressing tumor growth and tumor rejection compared to anti-CTLA4 alone, and was accompanied by a markedly increased accumulation of GZMB+ CD8+ CTLs in the treated tumors. Consistent with those findings, addition of anti-PD1 antibody promoted OVA-specific CTL activation in vitro while addition of PGE2 strongly inhibited it, as measured by IFNγ secretion. Inclusion of E7046 dose-dependently reversed the PGE2-induced suppressive activity in the presence of anti-PD1. Conclusion: E7046 at clinically relevant doses showed that PGE2 is upregulated and HPGD downregulated across a broad range of tumor types. In contrast, COX1, COX2 and PGT showed less difference between malignant and normal tissues. Importantly, these differences of one or multiple PGE2 pathway genes were strongly associated with patient survival in
certain cancer types. Conclusions: A subset of human cancer types displays upregulated PGE, pathway that is associated with a poorer prognosis. PGE, EP4 signaling potently suppresses antigen-specific CTCL activation in the presence of PD1 signaling blockade. The combination of EP4 antagonist E7046 with either anti-PD1 or anti-CTLA4 demonstrated superior anti-tumor activity compared with anti-PD1 or anti-CTLA4 alone. This increased activity was accompanied by increased CTL activation.

#4608 A 5T4 x CD3 bispecific DART® molecule with extended half-life for T-cell immunotherapy of cancers. Ling Huang,1 Gurunadh Chichili,1 Ralph Alderson,2 Francine Chen,1 Jennifer Brown,1 Hua Li,1 Valentina Ciccarone,1 Jim Tamura,1 Daorong Liu,1 Liqiu Liu,1 Syd Johnson,2 Ezio Bonvini,1 Paul Moore2,1,1 MacroGenics, Inc., Rockville, MD; 1South San Francisco, CA

Introduction: 5T4 (trophoblast glycoprotein), an oncofetal antigen involved in embryonic development, is expressed on the cell surface of multiple cancers. Several 5T4-directed interventions have been reported, including a cancer vaccine and an antibody-drug conjugate. A superantigen-driven redirected cell killing modality was also developed, but obstacles, such as immunogenicity, remain to a successful 5T4 therapeutic molecule. We have developed an Fc-bearing 5T4 x CD3 DART® bispecific protein designed to redirect T cells to target 5T4-expressing tumors. Methods: 5T4 x CD3, a humanized Fc-bearing DART molecule, was stably expressed in CHO cells and purified to homogeneity via a standard antibody-purification platform. In vitro characterization and functional studies were performed with 5T4-positive tumor cell lines and human T cells. In vivo studies were performed in immune-deficient tumor-bearing mice co-implanted with activated human T cells or reconstituted with human peripheral blood mononuclear cells (PBMCs). Pharmacokinetic studies were performed in both human FcRn transgenic mice and cynomolgus monkeys. Results: 5T4 x CD3 demonstrated bispecific binding properties to both human and cynomolgus monkey antigens. In redirected cytolytic studies, 5T4 x CD3 mediated lysis of 5T4-positive pancreatic, lung, renal, triple-negative breast, and ovarian cancer cell lines with EC50 values ranging between 0.03 and 0.08 ng/mL. 5T4 x CD3 displayed favorable pharmacokinetics with a prolonged circulating half-life in human FcRn transgenic mice and cynomolgus monkeys. Tumor clearance studies in NOD/SCID mice implanted subcutaneously with activated human T cells and tumor cells demonstrated robust inhibition of tumor growth upon intravenous administration of 5T4 x CD3 at doses as low as 0.8 µg/kg, but not with a CD3-binding control DART protein. In addition, human PBMC-reconstituted NOD/SCID/IIL2 gamma-chain null mice were implanted intraperitoneally with pancreatic and breast tumor cell lines or orthotopically with a triple-negative breast cancer line and, after tumor establishment, were treated with 5T4 x CD3. Anti-tumor activity was observed at doses as low as 4 µg/kg. Immuno-histochemical analysis of tumor xenografts confirmed tumor clearance was associated with T-cell recruitment into the tumor mass. Conclusions: In summary, 5T4 x CD3 displays robust antitumor activity against several cancer cell lines in vitro and in vivo together with a favorable pharmacokinetic profile and merits further consideration as a potential treatment for 5T4-positive cancers.

#4609 Agenus’ next generation cancer vaccine platforms. Mohamed Udu- man,1 Mithun Khattar,1 Bishnu Joshi,1 Antoine Tanne,1 Benjamin Morin,2 Ar- men Karapetyan,2 Elise Drouin,1 Jennifer Brown,1 Bishnu Joshi,1 Mithun Khattar,1 Agenus Inc., Lexington, MA; 1University of Virginia School of Medicine, Char- lottesville, VA; 2Massachusetts General Hospital Cancer Center, Charlestown, MA; 3University of Virginia, Lexington, MA.

Most cancer cells carry mutations unique to the patient’s individual tumor and shared biochemical signatures that are not present in healthy cells. Agenus has three vaccine platforms designed to treat cancers based on the unique needs of a given patient. Our vaccine platforms are designed to educate the patient’s immune system to recognize tumor-specific aberrations, or neo-antigens, and mount an anti-tumor immune response. Agenus’ Prophage® vaccine platform is an individualized vaccine made from the patient’s own tumor tissue. Heat shock proteins (gp-96) that naturally chaperone and bind tumor-derived peptides are extracted from the patient’s tumor and constitute the vaccine. Some of these peptides are neo-antigens. Agenus has completed Phase 2 clinical trials with Prophage® vaccine in newly diagnosed glioblastoma (mGBM), and has previously reported that there was improved progression-free and overall survival with Prophage® vaccine compared to standard of care. Agenus’ AutoSynVax® vaccines are uniquely designed and manufactured for each patient based on NGS profiling of the patient’s tumor from a biopsy. Leveraging the Agenus Immunogen Mutation (AIM®) workflow, we are able to generate a synthesis-ready blueprint for an optimal immunogenic and personalized neo-antigen vaccine. The AIM® platform provides a robust and efficient approach to computational vaccinology designed to deliver a set of likely immunogenic peptides, antigenic to vaccine format, followed by generation of a format-specific blueprint from which the final vaccine is synthesized. The peptides are complexed to recombinant heat shock protein 70 (HSC70) and are administered along with our QS-21 Stimulon® adjuvant. HSC70 is known to transport epitopes and play a role in displaying them to T cells. While the first two of Agenus’ vaccine platforms are highly individualized, our PhosphoSynVax® vaccine is an off-the-shelf vaccine format targeting a novel class of tumor neo-antigens arising from post-translational modifications (PTMs). Due to dysregu- lated cell signaling pathways in cancer, self-peptides can be aberrantly phosphorylated, a number of which are subsequently presented on HLA molecules. Using mass-spectrometry, we have identified a library of over a thousand HLA phospholipids. Many of these are tumor specific and found in multiple patients across multiple indications, enabling pre-manufacture of PhosphoSyn- Vax® vaccines for ready use. Upon testing the HSP plus synthetic peptide vac- cine format in murine models, we have demonstrated effective tumor control in a therapeutic setting and also effective immune memory in a long-term prophylactic setting. Given Agenus’ diverse portfolio we have the opportunity to combine our immune education strategies with immunomodulatory antibodies to increase therapeutic efficacy.

#4610 Towards understanding the cellular uptake patterns of nano-par- ticles among different immune cell lines. Noha Ismail1, Ashish Kulkarni,1 Siva Kumar,2 Vineeth krishna,2 Shiladiya Sengupta1,1 The American Univ. in Cairo, Egypt; 1Brigham and Women’s Hospital – Harvard Medical School / Harvard-MIT Health Sciences and Technology, Cairo, Egypt; 2Brigham and Women’s Hospital – Harvard Medical School / Harvard-MIT Health Sciences and Technology, Cambridge, MA.

Today with the privilege of being able to synthesize extremely small particles in the nano-range and make use of nanotechnology, we can reach superior properties than the bulk scale. Nanoparticles have their own physicochemical properties that make them promising in the field of cancer immunotherapy in form of drug delivery, diagnostic and theranostic modalities. Manipulation of the immune response by therapeutic intervention is becoming of great interest owing to the significant role of immunity in the general health and disease control. APCs like Dendritic cells and macrophages are important targets for the particulate delivery system due to their ability to trigger cascade of events on both levels cellular and humoral immune response specially DCs. Successful targeting of DCs and macrophages will have a great impact on T-cell activation and priming. The design of successful particulate system that can elicit preferential targeting towards specific immune cell in the tumor microenvironment is becoming crucial. This might represent a novel avenue for enhancing the antitumor immunity. Liposomes are made of phospholipid bilayer with a composite nature. Their properties are highly linked to their physicochemical characteristics such as size, surface charge and composition. These physicochemical properties can trigger certain immune response. The hypothesis here whether passive targeting via particulate system can offer a platform for preferential targeting for critical immune cells residing in spleen and tumor. Moreover, test whether there will be differences in uptake according to certain preference towards surface charge in specific time frame. In the current study, three sets of fluorescently labelled nano-liposomes were engineered as a model for different surface charges, the cationic DOTAP NP, anionic DOPG NP and near neutral DOPC NP with mean diameter of ~ 200 nm. Physical stability of the NPs was evaluated by monitoring the changes in size and zeta potential. B16 melanoma cancer model was induced subcutaneously in C57BL/6 black mice, divided into four groups each of five mice. CD11c Dendritic Cells (DCs), CD11b macrophages, CD90.2 T-cells and CD49b Natural Killer (NK) cells were isolated from the tumors and spleens of each group. The three sets of NPs were tested against the isolated cell lines. The cellular uptake (internalization) was assessed by normalizing the fluorescence of the cells against their protein concentration, then all samples were acquired to flow cytometry, and shifts in fluorescence histograms on horizontal axis were monitored against PE channel on the vertical axis. Results reveal the presence of preferential internalization of specific surface charge over others in some cell lines in different time frames. For the first time differences in the internalization pattern are reported in the same immune cell line isolated from different contexts tumor and spleen.

#4611 A 3D in vitro culture-based method to visualize and quantify effects of immuno-modulatory drugs. Lidia Daszkiewicz, Kuan Yan, Maarten Klop, Leo Price. OceBIO, Leiden, Netherlands.
#4612 Development and validation of a screening platform for the identification of novel immuno-oncology targets. Ariane Scoumanne,1 Virginie Rabolli,2 Lea Legrand,3 Murielle Martini,4 Marie-claire Letellier,5 Stefano Croce-tification of 42 compoundswith activity on multiple, potential immunesuppression through depleting the essential amino acid tryptophan. The assay consequently scaled up for automation. A commercially available small molecule library of 1900 compounds, with a high percentage of clinically tested drugs was subsequently validated with an IDO1 inhibitor as positive control and subsequent tumoroid killing was quantified using 3D high-content imaging.

The 96-well format of the assay allows medium-throughput testing of up to 3000 cultures, on the other hand, more faithfully reproduce the organization of a humanized animal models are slow, have low throughput and are expensive. 3D cultures, on the other hand, more faithfully reproduce the organization of a tumor microenvironment whereas humanized animal models are slow, have low throughput and are expensive. 3D cultures, on the other hand, more faithfully reproduce the organization of a humanized animal models are slow, have low throughput and are expensive. 3D cultures, on the other hand, more faithfully reproduce the organization of a humanized animal models are slow, have low throughput and are expensive. 3D cultures, on the other hand, more faithfully reproduce the organization of a humanized animal models are slow, have low throughput and are expensive. 3D cultures, on the other hand, more faithfully reproduce the organization of a humanized animal models are slow, have low throughput and are expensive. 3D cultures, on the other hand, more faithfully reproduce the organization of a humanized animal models are slow, have low throughput and are expensive. 3D cultures, on the other hand, more faithfully reproduce the organization of a humanized animal models are slow, have low throughput and are expensive. 3D cultures, on the other hand, more faithfully reproduce the organization of a humanized animal models are slow, have low throughput and are expensive. 3D cultures, on the other hand, more faithfully reproduce the organization of a humanized animal models are slow, have low throughput and are expensive. 3D cultures, on the other hand, more faithfully reproduce the organization of a humanized animal models are slow, have low throughput and are expensive. 3D cultures, on the other hand, more faithfully reproduce the organization of a humanized animal models are slow, have low throughput and are expensive.

In order to shed light on novel immune suppressive mechanisms in tumor, iTeos Therapeutics developed a target discovery and drug repurposing platform based on phenotypic screening assays. We established a co-culture assay combining tumor immune suppressive cells and T-cells. This assay is flexible to allow the screening of chemogenomics, shRNA and cDNA libraries. Multi-parameter readouts are combined to assess both T-cell activation and proliferation, through high content imaging of T-cell clusters formation, complemented with detection of IFNγ secretion and tumor cell death, as assessed using a cytotoxicity assay. The 96-well format of the assay allows medium-throughput testing of up to 3000 samples/screen. From the technical point of view we were able to adapt the assay to low level of automation, making it affordable to the biotech start-ups and academic laboratories. As a proof-of-concept we evaluated the assay for its ability to detect metabolic immune-oncology targets in A549 cells, a lung cancer immune suppressive cell line. A549 express indoleamine-2,3-dioxygenase 1 (IDO1), an enzyme expressed in many cancers that mediates local T-cell suppression through depleting the essential amino acid tryptophan. The assay conditions were validated with an IDO1 inhibitor as positive control and subsequently scaled up for automation. A commercially available small molecule library of 1900 compounds, with a high percentage of clinically tested drugs was screened. The library was tested at two different concentrations (0.3 μM and 3μM), in two independent T-cell donors and spiked with IDO1 inhibitor as control. Combined analysis of T-cell activity and tumor killing led to the identification of 42 compounds with activity on multiple, potential immune suppressive pathways, including metabolism, epigenetics, autophagy, TGFβ, Wnt/β-catenin and TNFα/IFN-κB signaling.

#4613 Cytotoxicity of selenium trastuzumab and bevacizumab immuno-conjugates against triple negative breast cancer cells. Soni Khandelwal, Lau-ren Gollahon, Julian Spallholz, Mallory Boylan, Maria Del Mar Garcia-Hernande-z, Texas Tech University, Lubbock, TX.

Breast cancer (BC) is the second leading cause of death among women with an estimated 246,660 new cases of invasive breast cancer expected to be diagnosed this year. Of the different subtypes, 15-20% are classified as triple negative breast cancer (TNBC) because they lack three key receptors; progesterone, estrogen and HER2. These receptors are considered essential for “targeted therapies”. Thus, systemic chemotherapy is the only TNBC drug treatment option. In this study, two clinical monoclonal antibodies; Herceptin® and Avastin® were covalently labeled with redox selenium (MDA-MB-468) in culture. TNBC cell lines were treated with vehicle control, increasing concentrations of selenium as Selenite (ranging from 2 to 20 μg) Se-Herceptin® or Se-Avastin® and compared to native antibodies with equal concentrations of protein. Cell counts and viability were analyzed using Beckman ViCell Counter and Trypan Blue exclusion over a seven day period. Selenium, Se-Avastin® and Se-Herceptin® were observed to be more cytotoxic over dose and time than both TNBC cell lines in comparison to control cells and cells treated with native antibodies alone. Morphological changes were observed under phase contrast microscopy in all selenium treated cell lines. In contrast, visible alterations in morphology were absent in native Herceptin® and Avastin® treated cells compared to control cells. We believe this is the first report of selenium Antibody-Drug Conjugates (ADCs) being demonstrated as cytotoxic to these TNBC cell lines, suggesting a potential strategy to design more effective treatments of TNBC resistant to chemotherapy.

Introduction: Lenvatinib (LEN) selectively inhibits the kinase activity of VEGFR1-3, FGFR1-4, KIT, PDGFRα, and RET, which are involved in tumor angiogenesis and tumor cell proliferation in several cancer types. Currently, Phase 1b/2 clinical trials of the combination of LEN and pembrolizumab (a monoclonal antibody [mAb] that blocks the interaction between PD-1 and its ligands) are ongoing for selected types of cancer including renal cell carcinoma, melanoma and non-small cell lung carcinoma. We have reported that tumor associated macrophage and regulatory T cell population were downregulated by treatment of LEN. In this study, mechanism of LEN and PD-1 mAb combination treatment was investigated by flow cytometry and RNA-seq analyses. Experimental Procedure: We examined antitumor activity of combination treatment of LEN (10mg/kg, qd) and anti-mouse PD-1 mAb (500μg/mouse, twice weekly) in CT26 and B16F10 syngeneic mouse models. In order to investigate tumor-specific memory T cell response, re-inoculation of fresh CT26 cells into tumor-free mice was conducted. For immune cell population analyses, tumor or spleen samples were analyzed by flow cytometry. Changes of molecular immune response in tumors were examined by RNAseq followed by weighted gene co-expression network analysis (WGCNA). Summary of data: Combination of LEN with PD-1 mAb showed more potent anti-tumor growth activity in CT26 and B16F10 models compared with either treatment alone. Notably, complete tumor regression was noted in a portion of mice that received combination treatment only. Re-inoculation of fresh CT26 cells into these tumor-free mice did not grow tumor; in contrast, all naive animals grew tumor aggressively in the same experimental condition. RNAseq analysis of treated CT26 tumors indicated that combination of LEN with PD-1 mAb synergistically up-regulates IFN signaling-related genes. Flow cytometry analysis revealed that LEN increased memory T cell population compared with vehicle treatment. Conclusions: The results indicate that the combination of LEN with PD-1 mAb was more effective than either single agent alone in multiple syngeneic tumor models and was accompanied with a potent antitumor immune response, especially the up-regulation of memory T cell and Th1 activation by LEN.

#4615 Development of an antibody-drug conjugate with broad anticancer activity. Siang Ye Lin,1 Zoltan Szekely,2 Chen-Yong Lin,3 Joseph R. Bertino,1 Gulam Mohmad Rather,1. Rutgers Cancer Institute of NJ, New Brunswick, NJ; 2Georgetown Medical School, Georgetown, MD.

Treatment for patients with advanced solid tumors that include triple negative breast cancer (TNBC), non-small cell lung cancer (NSCLC), and castrate resistant prostate cancer (CRPC), as well as Mantle Cell Lymphoma (MCL), while increasing survis is not curative. We have identified a membrane bound protease, “activated” matritiapase, as an attractive target antigen for highly selective antibody delivery of cytotoxicites as activated matritiapase expression is restricted to epithelial tumors and some B-cell lymphomas. We generated a novel ADC by linking M69, a mouse antibody specific to activated matritiapase, to

IMMUNOLOGY: Immunoconjugates and Antibodies
monomethyl auristatin E (MMAE) via a PEGylated, releasable di-peptide linker as a proof-of-principle prototype. Both in cell lines and in human xenograph models of TNBC, NSCLC, CRPC and MCL, the conjugate was found to exhibit potent anticaner activity against all of these tumor types without toxicity. Encouraged by these results, we are also exploring the use of this ADC against gastric cancer, and in combination with chemotherapy and immunotherapy. As this is a mouse antibody, we are also generating a chimeric antibody for toxicity studies in primates.

**IMMUNOLOGY: Innate Immune Response to Cancer**

### #4616 Exploring the role of interferon and innate immune regulators in outlier cancer cell line survival.

Hugh S. Gannon,1 Michael Kiessling,2 Francisca Vazquez,3 William Hahn,1 Matthew Meyerson1. 1Dana-Farber Cancer Institute, Boston, MA; 2Zürich University Hospital, Switzerland; 3Broad Institute, Cambridge, MA.

We conducted an outlier dependence analysis using functional genomic screening data generated by groups at the Dana-Farber Cancer Institute and Broad Institute. These genome-wide knockdown (shRNA) and knockout (CRISPR-Cas9) screens seek to discover genetic vulnerabilities, or “Achilles heels”, across hundreds of cancer cell lines. The most recent version of the gene knockdown screen includes over 500 total cell lines, allowing overall and lineage-specific outliers to be assessed. Taking advantage of the relatively large number of cell lines in this data set, our study parallels “exceptional responder” patient studies derived from clinical trials, with the goal of finding a small number of cell lines that are acutely dependent on certain genes for survival. These outlier cell lines could then be profiled to search for a common genetic factor or gene expression signature that can be used to predict sensitivity to the knockdown of the gene(s) in question. Strong, specific genetic dependencies have the potential to generate novel, hypothesis-driven therapeutic strategies that can be further tested experimentally. Initially, we focused on the lung cancer cell lines profiled in the knockdown screen. We used an unbiased approach to investigate genes with the most pronounced outlier patterns across these lung lines. One of the top genes in our analysis encodes the RNA-editing enzyme ADAR1, which has a role in epigenetically altering double-strand RNA sequences. ADAR1 encodes a protein that catalyzes adenosine-to-inosine editing in RNA. This RNA editing function has been studied in the context of suppressing innate immune sensing, as endogenous RNA is edited to avoid detection by intracellular sensors that activate the type I interferon pathway after encountering unedited RNA from infecting viruses. ADAR1 homozygous mutant patients and mouse models each display greatly increased interferon levels and activation of downstream interferon-induced gene expression, further supporting the role of ADAR1 to suppress interferon activation and autoimmunity. Importantly, outlier cell lines sensitive to ADAR1 knockdown are also sensitive to knockdown of ISG15, which similarly suppresses interferon signaling, and show greatly increased survival after IFNAR1 knockdown, a positive regulator of interferon signaling. We next mined genome-wide CRISPR-Cas9 knockout screens and found a pancreatic cell line that is also dependent on ADAR1 and ISG15 for survival. Likewise, knockout of IFNAR1 or any gene along the IFNAR1-JAK-STAT pathway enhances survival in this cell line. These converging data suggest a link between the interferon pathway and vulnerability to knockdown of ADAR1 or ISG15. While no common mutations or genomic changes were found in the outlier cell lines, we have uncovered a shared gene expression signature. We are continuing to study the mechanisms that cause these cell lines to be acutely dependent on ADAR1 and ISG15.

### #4617 Daratumumab combined with CD38(-) natural killer cells armed with a CS1 chimeric antigen receptor for the treatment of relapsed multiple myeloma.

Yuefeng Wang, Yibo Zhang, Don Bonz, Michael Caliguiri, Jianhua Yu. Ohio State Univ., Columbus, OH.

Multiple myeloma (MM) is the second most frequent hematological cancer in developed countries. The recent development of monoclonal antibodies, including Daratumumab (Dara) approved by the FDA, is changing the treatment algorithm of MM. However, MM still relapses and remains incurable. Recently, chimeric antigen receptor (CAR) T cell immunotherapy has been successful in the clinic for the treatment of leukemia and lymphoma. We previously showed that both CS1-CAR T cells and CS1-CAR NK cells are effective in eradicating MM cells in vitro and in vivo (Chu et al., 2014, Leukemia and Chu et al., 2014, Clin. Cancer Res.). Both CS1 and CD38 are tumor-associated antigens expressed on the surface of MM cancer stem-like cells, suggesting that dual targeting of CS1 and CD38 may prevent relapse. Thus, we investigated the combination therapy with Dara and CS1-CAR NK cells for the treatment of relapsed MM. Our data showed that CD38 is highly expressed on the surface of both NK and MM cells. Dara induces NK cell activation, as Dara-treated NK cells display a higher capacity to produce IFN-gamma and increased cytotoxicity against MM, the latter of which correlated with augmented expression of the cytolytic gene, granzyme B. Mechanistically, we found that activation of NK cells by Dara is CD16-dependent. This is further evidenced by that Dara also significantly induces phosphorylation of NF-kB and STAT1, the two downstream mediators of CD16. Furthermore, Dara mediated cytotoxicity of NK cells against MM cells through an ADCC-mediated cytotoxicity against MM, the latter of which can show a synergistic effect on tumor eradication and prevention of MM relapse. Our data indeed demonstrated that the combination of CS1 CAR NK cells with CD38(-) NK cells but not with CD38+ NK cells shows a synergistic effect to eradicate MM cells. Interestingly, we also found that when compared to expanded CD38+ NK cells, expanded CD38(-) NK cells have more cells, a better capacity of proliferation and survival, a higher potential of cytokine production, and higher cytotoxicity against MM cells.

### #4618 TGF-B upregulates GSK3B and mediates NK dysfunction in cancer.

Evelyn Ojo, Folashade Otegbeye, Stephen Moreton, David Wald. Case Western Reserve University, Cleveland, OH.

Transforming growth factor-B (TGF-B) is an important regulator of tumorigenesis. Initially, it was discovered to have anti-cancer activities by promoting apoptosis and preventing hyperproliferation of cells. However, abundant presence of TGF-B in the tumor microenvironment is known to hinder cancer eradication by suppressing anti-tumor activities of immune cells. The molecular switches that regulate the role of TGF-B are not fully understood. One main target of TGF-B-mediated immune cell dysfunction are natural killer (NK) cells. NK cells are innate immune cells that lyse virally-infected and cancer cells. Recently, we have discovered that glycojen synthase kinase 3-beta (GSK3B) upregulation in NK cells leads to NK dysfunction. Another study has indicated that GSK3 phosphorylates SMAD3 to inhibit TGF-B-mediated growth dysfunction in AML12 cells. In addition, GSK3B inhibition has been linked to increased sensitivity of cancer cells to NK killing but the role of GSK3B in NK function is understudied. This study examines how the role that GSK3B has on TGF-B-mediated NK cell dysfunction. Methods: NK cells were isolated from the peripheral blood of healthy donors and expanded in vitro for 14 days. NK cells were either treated with or without TGF-B, and NK cell cytotoxicity is measured with a fluorometric cytotoxicity assay. Results: TGF-B pretreatment of NK cells led to 2-fold GSK3B expression in NK cells. TGF-B pretreatment led to decreased expression of NK activating receptors NKp46 and NKG2D. Also, TGF-B led to decreased expression of lymphoyte function-associated antigen-1 (LFA-1), an adhesion molecule necessary for NK cells to adhere to target cells prior to analysis of the target cells. TGF-B pretreatment of NK cells led to 33.3% reduced killing of both leukemic and solid tumor targets. Pharmacologic and genetic abrogation of GSK3 minimized TGF-B-mediated NK dysfunction as measured by calcein-AM based cytotoxicity assays. Importantly, inhibiting GSK3B activity with TGF-B treatment rescued NK cell cytotoxic function. Discussion: Our data suggests that TGF-B leads to upregulated GSK3B expression, and downregulation of NK activating receptors. In addition, TGF-B reduced NK killing of cancer cells. We believe that TGF-B-mediated NK dysfunction is facilitated by GSK3B upregulation. Further studies are underway to determine how TGF-B affects the expression of other NK receptors, and to elucidate the mechanism by which TGF-B directs GSK3B upregulation.
#4619 CD47 promotes ovarian cancer progression by inhibiting macrophage phagocytosis. Yuting Huang,1 Peng Gao,2 Yifeng He,1 Yuchi Ma,1 Shan-gwen Dong,2 Zhijun Li,1,2 Tianjin Medical University Cancer Hospital and Institute, Tianjin, China; 3University of the District of Columbia, Washington, DC; 4Shanghai Jiao Tong University, Shanghai, China; 5National Heart Lung and Blood Institute, Bethesda, MD; 6Tianjin Medical University General Hospital, Tianjin, China.

CD47 is highly expressed in many malignant diseases including ovarian can-cer, and renders malignant cells resistant to phagocytosis by macrophages. Anti-CD47 mAbs have shown anti-cancer effects in several types of cancers. How-ev-er, it remains controversial whether anti-CD47 mAbs promote phagocytosis by the inhibition of CD47 function or by CD47-SIRPs independent mechanisms. We tried to provide more evidence in our study by knocking down CD47. CD47 expression of 93 patients was tested by flow-cytometry. We confirmed a positive correlation between high CD47 levels and poor clinical characteristics, such as poorly differentiated and advanced FIGO stages. A cohort of 29 FIGO stage III-IV patients with poorly differentiated serous adenocarcinoma were followed up for 50 months. Median survival for CD47 high patients was 19 months, while for CD47 low patients was 43 months, p=0.0435. To further evalu-ate the mechanism of CD47 in phagocytosis, CD47 expression on SK-OV-3 cell was knocked down using shRNA. No change in tumor cell viability, prolifera-tion, and migration was observed. Macrophage phagocytosis index increased from 10.2% to 43.9% in vitro. In xenograft experiments, average tumor number decreased from 75 to 6.4 and the animals also experienced a longer survival (p=0.0017). Similar sets of experiments were done using an anti-CD47 mAb B6H12 clone while adopting both control IgG and anti-HLA ABC as con-trol antibodies. Consistent with the results from the knockdown experiments, anti-CD47 mAb treatment led to an increase in macrophage phagocytosis index in vitro of both SK-OV-3 cells (from 8% and 9.4% to 37.1%) and primary cancer cells (from 5.6% and 7.4% to 35.1%). In vivo xenograft experiments also showed increased macrophage infiltration (6.5% compared to 1.5% in control group). In five different ovarian cancer cell lines, we found that CD113+ tumor initiating cells (TICs) expressed higher levels of CD47 compared to CD133+ cancer cells. Tumorigenic capabilities of TICs were confirmed by colony-forming assay and ALDEFLUOR assay. Upon anti-CD47 mAb treatment, macrophage phagocyto-sis of TICs was enhanced significantly in vitro (phagocytosis index increased from 10% and 12.7% to 47.3%). In conclusion, CD47 inhibits macrophage phagocytosis of both ovarian cancer cells and TICs. Downregulation of CD47 or inhibition by mAb was able to reverse this effect, and it may involve Fc independent mecha-nism. Thus, CD47 antibody therapy may be a promising strategy for not only eliminating tumor cells but also preventing cancer relapse triggered by TICs, benefiting the patients’ short-term and long-term prognoses.

Macrophages are abundantly found in the tumor microenvironment and en-hance malignancy. At distal metastatic sites, our previous studies identified a distinct population of metastasis-associated macrophages (MAMs) that pro-mote tumor cell extravasation, seeding and persistent growth. These macro-phages were derived from inflammatory monocytes recruited by CCL2/CCL2 chemokine signaling and directly promote tumor cell extravasation through VEGF production. Our recent studies identified two subsequent signaling path-ways that mediate the retention and function of MAMs after recruitment that are critical for tumor cell survival and persistent growth. Specifically, activation of CCR2 signaling turns on CCL3 expression in MAMs. Genetic deletion of CCL3 or its receptor CCR1 in macrophages reduces lung metastasis, and MAM accumulation in tumor-challenged lung. Adoptive transfer of wild type mono-cytes restores lung metastasis in Ccl3 deficient mice. Mechanistically, Ccl1 defi-cency prevents MAM retention in the lung by reducing direct MAM-tumor cell interactions. On the other hand, MAMs turn on cell surface expression of FMs-like tyrosine kinase 1 (FLT1) and FLT1 signaling regulates CCL3 expression. Using several genetic models of HIF1 deficiency, we show that macrophage specific FLT1 signaling is critical for breast tumor distal metastatic potential. FLT1 spe-cific inhibitory antibody significantly inhibits the metastatic seeding and persist-ent growth but does not affect the recruitment or retention of MAMs. Further-more, we identified that FLT1 signaling regulates a set of downstream inflammato-ry response genes including Colony Stimulating Factor 1 (CSF1) and a central regulator of macrophage biology. Using a genetic gain-of-function ap-proach we show that CSF1 mediated autocrine signaling in MAMs is down-stream of FLT1 and can restore the tumor-promoting activity in MAMs even when FLT1 is inhibited. Together, our data indicates CCL3/CCR1 and FLT1 signaling pathways are critical in regulating MAMs and promoting breast cancer distal metastasis, and suggests the therapeutic potential of targeting these path-ways in treating metastatic disease.

Macrophages dominate the immune infiltrate present in pancreatic ductal adenocarcinoma (PDAC). Although tumor-infiltrating macrophages have the potential to mediate anti-tumor activity, they most commonly acquire an im-munosuppressive role in cancer. We have found that Cpg oligonucleotides - containing unmethylated cytosine-guanine motifs - potently induce macro-phages to phagocytose PDAC cells and mediate anti-tumor effects. When deliv-ered in vivo, in a fully immunocompetent murine model of PDAC, Cpg in-creased the presence of macrophages within PDAC tumors and suppressed tumor outgrowth in a macrophage-dependent manner. Though Cpg did not polarize macrophages toward classical anti-tumor (M1) or pro-tumor (M2) phenotypes, Cpg treatment increased the basal rate of oxygen consumption in macrophages. Reversing this metabolic shift by inhibiting fatty acid oxidation abolished pro-phagocytic and anti-tumor effects by macrophages in vitro and in vivo. We investigated the impact of Cpg in overcoming anti-phagocytic signals from CD47, a membrane protein overexpressed in multiple malignancies, in-cluding PDAC. While targeted knockout of CD47 in PDAC cells was not suffi-cient to activate in vitro phagocytosis by macrophages or anti-tumor effects in vivo, Cpg potential to overcome PDAC CD47 blockade that was independent of CD47 expression by tumor cells. However, the combination of CD47 loss in tumor cells and systemic Cpg treatment enhanced the survival of tumor-bearing mice, indicating that disruption of CD47 can sensitize tumors to macrophage-directed immunotherapy. Together, our findings demonstrate a key role for cellular metabolism in directing the anti-tumor functions of macro-phages and overcoming negative regulatory signals imposed by malignant cells.

#4622 Characterization of sulfatide reactive type II NKT cells from mouse Cancer. Lise Pasquet,1 Shingo Kata,2 Tony Adams,1 Susan Sharrow,1 Theresa Das-ties-Hill,1 Elaine Jaffe,1 Xia Zheng,1 Motoshi Suzuki,2 Damien Kovalovsky,3 Jay Berzofsky,2 Masaki Terabe,2 NHG-NCI, Bethesda, MD; 3Yokohama city University, Yokohama, Japan; NHG- NHELI, Bethesda, MD.

The immune system plays a major role in the elimination of tumors. CD8 T cell infiltration is known to be a good prognostic indicator. The development of therapies based on checkpoint inhibitor antibodies was an important break-through in increasing survival by limiting the exhaustion of cytotoxic cells and increasing tumor cell eradication. However, the immune system also contains regulatory cells that protect the organism from inappropriate activation of im-mune cells against self-antigens. Thus, the fact that tumor cells are analogous to tolerogenic leads regulatory cells to inhibit the activation of anti-tumor cytotoxic cells and thus increase tumor escape. Therefore, understanding the function and the ac-tivation of regulatory cells might help to develop therapies to limit the activation of regulatory cells in order to increase tumor clearance. Natural killer T (NKT) cells are lymphocytes with features of natural killer (NK) and of T cells placing them at the interface of innate and adaptive immunity. Like NK cells, they rapidly produce cytokines after stimulation, orienting the immune response. As T cells, they express a T cell receptor (TCR) that allows the recognition of specific lipids presented by the non-classical MHC-I molecule CD1d. According to their TCR usage, two populations of NKT cells are described: type I and type II. All type I NKT cells express a semi-invariant TCR (Valpha24/14/18 in mice) that recognizes α-galactosylceramide (αGalCer). They can be identified with the oGalCer-loaded CD1d tetramer. In contrast, type II NKT cells express a more diverse TCR repertoire. There is no currently identified lipid antigen recognized by all type II NKT cells, making their identi-fication more difficult. A fraction of them recognize sulfatide. By using sulfatide-loaded CD1d-tetramers, we observed for the first time that sulfatide-reactive type II NKT cells were enriched in the lung, a major site of tumor metastasis. Moreover, we previously showed that in vivo stimulation of type II NKT cells with sulfatide increased the number of tumor nodules in the lung. An in-depth phenotype analysis revealed that they were CD4 or CD8 single positive cells, like conventional T cells, whereas type I NKT cells are either CD4+CD8- or double negative. Type II NKT cells do not express PLZF, the master regulator of NKT cell development and exist as PLZF- mice contrary to type I NKT cells. We showed that type II NKT cells also expressed markers of myeloid cells, c-KIt, CD11b and Ly6C even though histological analysis revealed lymphohcytic mor-phology. Interestingly, at steady state, type II NKT cells expressed granzyme A but not granzyme B or perforin. The in vivo injection of sulfatide increased the
expression of the activation markers CD69 and CD44 as well as granzyme A. Since the regulatory functions of type II NKT cells have been shown to be critical in tumor immunity, the detailed characterization of these cells could help to develop a new immunotherapy for cancer.

#4623 Transcriptional analysis of the functional differences between M1 and M2 macrophages to identify new targets for myeloid cell modulation in pancreatic tumors. Kimberly R. Yang, Todd D. Armstrong, Elizabeth M. Jaffee. The Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins University School of Medicine, Baltimore, MD.

Macrophages exhibit dynamic plasticity in their function in response to the accumulating genetic alterations that occur during tumorigenesis, resulting in the establishment of an immune-tolerized tumor microenvironment. However, depending on their environmental cues, they can switch between two functional phenotypes: pro-inflammatory/anti-tumorigenic (M1) or anti-inflammatory/pro-tumorigenic (M2). The importance of these two macrophage subsets is well-recognized; however, identifying and distinguishing M1 from M2 macrophages in patient tumors still remains a challenge. Prior studies have utilized transcription profile of artificially skewed M1 and M2 macrophages from healthy donors to identify individual genes or gene clusters unique to each macrophage subset. However, these studies are limited to surface marker expression and gene expression profiles alone to distinguish subsets and lack functional validation of M1 and M2 macrophages. Surface marker and gene expression profiling of human M1 and M2 macrophages provide an incomplete characterization, as functionality is an important feature distinguishing these macrophage subsets. To improve the responsiveness and cytokinoty of these cell subsets in peripheral bloods, we performed a thorough three-step validation of artificially skewed M1 and M2 macrophages from healthy donor monocytes using surface marker expression, gene expression profiling, and multi-analyte ELISA analyses. Using our validation assays, we tested previously published protocols for their efficacy in generating M1 and M2 macrophages. While M1 macrophages using these protocols generated as expected M1 characteristics, M2 macrophages lacked hallmark functional features, particularly IL-10 secretion. This necessitated the generation of an optimized protocol to skew M1 and M2 macrophages that exhibited distinctive surface marker expression, gene expression profiles, and cytokine and chemokine production for their respective subset. We then performed RNA-sequencing to interrogate the transcriptional landscape of functional M1 and M2 macrophages and have found 1,472 transcripts that have at least a two-fold change in differential expression between M1 and M2 macrophages across 4 different donors. These results represent the most in-depth characterization of human M1 and M2 macrophages and provide insights into better biomarkers and targets for novel immunotherapy approaches.

#4624 Natural killer cell licensing contributes to clearance of lung cancer. Shi Lei,1 Kang Li,1 Saeed Arefian,2 Alexander S. Krupnick.1 University of Virginia, Charlottesville, VA; 2Washington University in St. Louis, St Louis, MO.

a) Natural Killer (NK) cell Inhibitory receptors function in a dichotomous role. Their engagement by MHC Class I upon encountering a target results in the inhibition of cytotoxicity. During NK development, however, their interaction with MHC Class I mediates the process of licensing or education, leading to an increased responsiveness and cytokininity. For this reason, receptors in controlling the MHC Class I+ solid tumors such as lung cancer is poorly defined. Since NK cells comprise the primary cytotoxic lymphocyte responsible for clearance of lung cancer, we set out to determine whether the licensing status of NK cells contributes to lung cancer susceptibility. b) Growth of MHC Class I+ murine lung cancer was evaluated in MHC Class I- mice, with and without NK cells in direct comparison to MHC Class I+ mice with licensed NK cells. IFN-γ production was evaluated after plate bound antibody stimulation through the NKp46 and NKG2D pathways both flow cytometrically and by quantitative RT-PCR. Bone marrow transplantation was performed by injection of 10x10^5 unfractionated bone marrow cells after 500Gy irradiation and NK and CD4+ T cell depletion of recipient host. c) Injection of Lewis Lung Carcinoma (LLC), revealed a significant decrease in pulmonary metastatic tumor burden in LLC mice with licensed NK cells (230.4±21.6 vs. 442.7±53.8 mg) that disappeared after NK depletion (421.4±36.8 vs. 421.9±66.3 mg). Freely isolated licensed NK cells lysed LLC more robustly than unlicensed NK cells (28.7±16% vs. 4.9±2.5% specific lysis at 100:1 ratio respectively). Lung cancer expresses stress ligands recognized by NKG2D and NKp46 activating receptors. Licensed NK cells produced significantly more IFN-γ than their unlicensed counterparts after plate-bound stimulation with anti-NKp46 and anti-NKG2D (17.9±2.8% vs. 5.4±2.8% respectively for dual NKp46 and NKG2D stimulation). No differences were evident between licensed and unlicensed NK cells in ribosomal mass, making it unlikely that translational defects were responsible for altered cytokine production. Licensing status also did not affect stability of IFN-γ but did affect mRNA levels. This suggests transcriptional control of licensing-mediated NK activity. IFN-γ production could be significantly increased in unlicensed NK cells by reinduction of MHC Class I through non-myeloablative bone marrow transplantation from MHC Class I-sufficient congenic donors. Blockade of MHC Class I (anti-NKp30 and MHC Class I receptor) in this reinduction the role of inhibitory receptors. This suggests that NK cells mediate a superior lung cancer-specific immune response in a murine model. Our data suggests that altering the licensing status of NK cells may be an avenue of lung cancer-specific immunotherapy.

#4625 Natural killer T cells regulate tumor immunity in mouse pancreatic cancer organoid orthotopic model. Shingo Kato,1 Tetsuya Matsuura,2 Yoshitaka Hippo,1 Atsushi Nakajima,1 Yoko Hanna,1 University of Virginia Hospital, Yokohama, Japan; 2Chiba Cancer Center Research Institute, Chiba, Japan.

Natural killer T (NKT) cells are lymphocytes with features of natural killer (NK) and of T cells placing them at the interface of innate and adaptive immunity. Like NK cells, they rapidly produce cytokines after stimulation, orienting the immune response. As T cells, they express a T cell receptor (TCR) that allows the recognition of specific lipids presented by the non-classical MHC-I molecule CD1d. There are two subsets of NKT cells, type I and type II, distinguished by their T-cell receptors. All type I NK T cells express a semi-invariant TCR (Vα24a18 in humans, Vα14(18) in mice) that recognizes α-galactosylceramide (α-GalCer). Type II NKT cells express a more diverse TCR repertoire. The biological activity of these two subsets of NKT cells is assessed comparing the percent of NKT cells that recognize the α-GalCer -GalCer). In contrast, type II NKT cells express a more diverse TCR repertoire.

The pancreatic organoids derived from KrasG12D mice were transduced with Cre and shRNA against p16, to activate Kras and repress p16, respectively. These transduced organoids were then subcutaneously injected into C57Bl/6 wild type mice, and tumors were harvested after two weeks. The tumors were cut into small pieces, and the weight of each piece was measured. The piece of tumor was sewn to the pancreas of wild type, Jor18-/- mice and CD1d-/- mice. After two weeks, tumors were harvested, and the weight of tumor was measured. The tumor weight was significantly heavier in CD1d-/- mice than wild type mice (p = 0.0416). Although it was not statistically significant, the tumor weight was slightly heavier in Jor18-/- mice than wild type mice. We also analyzed the correlation of T cell subsets in peripheral bloods. However, there were no differences among the three strains of mice. Considering these results, NKT cells may regulate tumor immunity in the microenvironment of the pancreatic cancer. Moreover, since sulfatide is rich in pancreas, sulfatide-reactive type II NKT cells may be involved in this local immune response. The detailed analysis of the regulatory functions of NKT cells in pancreas could help to develop a new immunotherapy for pancreatic cancer.
cells to sites of metastasis. Through the use of a novel, biomimetic, 3D collagen/ hyaluronic acid hydrogel system developed in our labs, this study focused on interactions between primary human macrophages and cancer cells, specifically on how this dialogue impacts the production of the secreted HS-modifying enzymes, heparanase (HPSE) and endosulfatase I (SULF1). We studied the impact of co-culturing macrophages with endometrial or prostate cancer cell lines, as well as patient-derived xenografts, on the levels of HPSE and SULF1. We also assessed cancer growth characteristics in the presence of macrophages. Taken together, our observations indicate cancer cell responses to macrophages are cell type specific, and we demonstrated significant functional consequences of interactions between macrophages and HS-mediated signaling. We are currently developing macropolarization to classically activated (M1) or alternatively activated (M2) phenotypes alters cancer cell responses in 3D. This system is being used to determine novel approaches to intervene in HBGF delivery to limit cancer growth in a more physiologically relevant in vitro system.

#4627 Prognostic significance and population shift of peripheral monocytes in patients with oropharyngeal squamous cell carcinoma. Hideyuki Takahashi, Koichi Sakakura, Kazuaki Chikamatsu. Gunma University Graduate School of Medicine, Maebashi, Gunma, Japan.

Evidence has accumulated that chronic inflammation plays a critical role in carcinogenesis, tumor growth, and metastasis. To date, several inflammatory biomarkers are considered as potential prognostic factors in various cancers. The aim of the present study was to investigate the prognostic significance of the pretreatment levels of inflammatory biomarkers in patients with oropharyngeal squamous cell carcinoma (OPSCC). A total of 67 patients newly diagnosed as OPSCC was finally included. The neutrophil, lymphocyte, monocyte and platelet counts recorded before treatment was initiated, then lymphocyte-to-mono- cyte ratio (LMR), neutrophil-to-lymphocyte ratio (NLR) and platelet-to-lympho- cyte ratio (PLR) were calculated. These inflammatory biomarkers and clinical parameters including age, differentiation, T-stage, N-stage, TNM-stage, smoking, and drinking were compared with progression-free survival (PFS) and overall survival (OS) using cox regression. Elevated monocyte count and low LMR were significantly associated with poor OS; of note, monocyte count and LMR were independent prognostic factors for PFS. Elevated monocyte count and low LMR were significantly associated with poor OS; moreover, low LMR was an independent prognostic factor for OS. Of note, monocyte count and LMR were associated with prognosis more intensively in patients with p16-negative OP- SCC. Following these results, we evaluated the peripheral blood mononuclear cells of 14 patients with OPSCC collected before treatments. CD14+/CD68+/HCLR-DR+ cells were gated as monocytes, then divided into three subsets according to the expression of CD14 and CD16. The proportion of intermediate monocytes was lower and that of classical monocytes was higher in OPSCC patients than in healthy donors, especially in patients with elevated monocyte count. Furthermore, the expression level of PD-L1 was higher in patients than in healthy donors. In conclusion, our data suggest that the elevated monocyte count and low LMR seem to be useful biomarkers for predicting prognosis of OPSCC; furthermore, the population shift of monocytes may relate to poor prognosis of OPSCC.

#4628 Selection of Smad2 for TGF-β to suppress dendritic cells by STAT3/ c-Ski-induced repression of Smad3. Jeong-Hwan Yoon, 1 Eunjin Bae, 1 Katsumu Sudo, 2 Masakatsu Tanakashi, 1 Jin Soo Han, 1 Seok Hee Park, 1 Michael Weinstein, 1 Susumu Nakae, 1 Tamahisa Yamashita, 1 In-Kyu Lee, 1 Ji Hyeon Jeu, 1 Takuya Sumida, 1 Masahiko Kuruda, 2 Keiji Miyazawa, 1 Mitsuayi Kato, 1 Mizuko Mamura 3. 1Kyungpook National University, Daegu, Republic of Korea; 2Tokyo Medical University, Tokyo, Japan; 3Konkuk University, Seoul, Republic of Korea; 4Sungkyunkwan University, Suwon, Republic of Korea; 5The Ohio University, Columbus, OH; 6University of Tokyo, Tokyo, Japan; 7Azabu University, Kanagawa, Japan; 8Catholic University of Korea, Seoul, Republic of Korea; 9University of Tsukuba, Tsukuba, Japan; 10University of Yamanashi, Yamanashi, Japan. 1

The Smad family of proteins is involved in the regulation of many signaling pathways, among which TGF-β signaling is a key regulator. TGF-β signaling is involved in cell proliferation, death, and differentiation. Signaling is mediated by the transmembrane 55kDa TGF-β receptor (TβR) and the cytoplasmic Smad2/3. Smad2/3 directly bind the receptor complexes and form a complex with Smad4. This complex is transported to the nucleus where it binds to the promoter of target genes. The aim of this study was to understand the role of Smad2 in TGF-β signaling and how this regulation is affected by the inhibitory Smad3. Here, we show that TGF-β upregulates the expression of Smad3, which inhibits the transcriptional activity of Smad2. TGF-β signaling was found to be dependent on the SMAD3 expression, which was upregulated by TGF-β. The TGF-β signaling pathway was found to be inhibited by Smad3 downregulation. These findings suggest that Smad3 negatively regulates TGF-β signaling by suppressing the expression of its target genes.

#4629 Macrophage number correlates with tumor stage in cutaneous melanoma. Satu Salmi, 1 Hanna Siiskonen, 2 Reijo Sironen, 3 Kristiina Tynnela-Kohonen, 3 Paivi Auvivinen, 1 Sanna M. Pasonen-Seppänen. 1 University of Eastern Finland, Kuopio, Finland; 2 Kuopio University Hospital, Kuopio, Finland.

Tumor associated macrophages and regulatory T cells (Tregs) have an impor- tant role in tumor progression as a part of the immunosuppressive tumor microenvironment. By means of immunosuppression, melanoma, as well as many other cancers, is able to resist anti-cancer immune reactions. To understand the mechanisms how tumor cells escape from the anti-tumor immune response is the key for efficient treatment strategies. In several cancers, programmed cell death ligand-1 (PD-L1) -mediated pathways have been shown to suppress anti- tumor immune responses. Our aim was to investigate the number of tumor associated macrophages (TAMs) and Tregs in benign, premalign and malign melanocytic lesions to find out if the density of these cells is associated with the tumor stage or survival in melanoma. Moreover, the expression of PD-L1 was studied. Altogether 187 tissue samples, including 29 benign and 27 dysplastic nevi, 16 in situ melanomas, 38 superficial (Breslow < 1 mm) and 43 deep (Breslow > 4 mm) melanomas and 34 lymph node metastases, were stained immunohistochemically for CD68 and CD163 representing all TAMs and M2-like macrophages, respectively and for FoxP3, a marker for Tregs. In addition, a part of the FFPE -samples was dual stained for CD68 and PD-L1. Macrophages were counted using a hot spot -method. In the levels of analyzies, the cell numbers were graded as either low or high according to the median. Non-parametric Kruskal-Wallis test was used to compare the macrophage numbers in different groups and Pearson chi-square test to study the correlations between the numbers of CD673 and CD68 -positive cells and clinicopathological paramet- ers. CD68+ and CD163+ macrophage numbers were significantly higher in malignant melanocytic lesions and lymph node metastasis compared to in situ melanomas and benign nevi. In deep melanomas and lymph node metastases macrophages located mainly inside the tumor nests whereas in thin melanomas they were mostly scattered around the tumor. High CD68+ macrophage num- ber correlated with the presence of ulceration (p<0.011) and with both local recurrence (p=0.002) and recurrence with distal metastases (p<0.002). PD-L1 immunoreactivity was relatively scanty in melanoma samples being restricted to certain areas only; both membranous and cytoplasmatic staining was observed. Overall, the staining was higher in deep melanomas and lymph node metastases compared to superficial melanomas. Dual stainings indicated that in addition to tumor cells, a part of the tumor infiltrating CD68+ macrophages were PD-L1 -positive. The density of FoxP3+ cells did not correlate with the tumor stage. However, the number of these cells was significantly higher in deep melanomas and lymph node metastases compared to other groups. Our observations highlight that TAMs are involved in melanoma progression and have an important role in the formation of an immunosuppressive tumor microenvironment.

#4630 Development of selective and potent CDK8 inhibitors that increase NK cell activity, which translates in tumor surveillance. Marco H. Hofmann, 1 Martin Christ, 1 Andreas R. Engelhardt, Herbert. A. 2, Marc Kerenyi, Moritz Mayer, Gerhard Gmaschitz, Georg Egger, Christian Engel- hardt, Michael Sanderson, Maria A. Impagnatiello, Renate Schnitzer, Mark Pearson, Darryl McConnell, Norbert Kraut, Jürgen Moll. Boehringer Ingelheim RCV GmbH & Co KG, Vienna, Austria.

Background: Cyclin-dependent kinase 8 (CDK8) is part of the mediator com- plex that can either positively or negatively influence transcription. CDK8 is known to phosphorylate signal transducer and activator of transcription 1 (STAT1) at the position Ser727. STAT1 activity is regulated by JAK-mediated phosphorylation of tyrosine701 which leadstodimerization,nucleartransloca- tion and IFN-γ-induced phosphorylation mediated by CDK8. Introduction of an alanine mutation at the phosphorylation site STAT1-S727 results in enhanced NK cell cytotoxicity accompanied by increased levels of perforin and granzyme B (Putz et al. 2013). Method: Here we present the discovery and development of potent and selective CDK8 inhibitors guided by crystallography. The inhibitory effect of optimized compounds BI 9181 and BI 1347 on STAT1 phosphorylation and perforin release was investigated in the human NK cell line NK-92MI. Direct effects on cancer cells were furthermore analyzed in a broad panel of cell lines. The compound BI 1347 was profiled in vivo in the orthotopic B16-F10 melanoma mouse model. Results: Highly potent and selective CDK8 inhibitors were identified with an IC50 of below 10 nM in a biochemical kinase assay, which translated in a potent down regulation of the STAT1 Ser727 signal and in increased perforin and granzyme B secretion. BI 9811 and BI 1347 were
highly selective for CDK8, as tested in a broad kinase panel and showed no cytotoxic activity on NK cells and most cancer cell lines, which distinguishes this compound class from published CDK8 inhibitors. A representative molecule out of this compound class demonstrated in vivo biomarker modulation and survival increase in the murine B16-F10 melanoma mouse model. Conclusion: We developed potent CDK8 inhibitors that show activation of NK cells that translates into biomarker modulation (pSTAT1Ser727) and in vivo efficacy.

#4631 Enhanced glycolysis promotes function of tumor associated macrophages in mouse breast cancer model. Yan Liu,1 Wei Zhou,2 Wei Wang,3 Lipeng Bai,1 Huwien He,1 Jian Guo,1 Yunping Luo,4 Chinese Academy of Medical Sciences, Beijing, China; 2Nankai University, Tianjin, China.

Tumor associated macrophages (TAMs) represent a major part of immune cells in tumor microenvironment (TME) and play crucial roles in promoting tumor progression by secreting cytokines or enzymes that could remodel TME or enhance envision or migration capabilities of tumor cells. Given their indispensable effect on tumor, the mechanisms underlying TAMs’ tumor-promoting phenotype and function remain unclear. Glucose metabolism in tumor cells has been intensively studied; however, the status of glucose metabolism of TAMs is still unclear. In this study, we aim to identify glucose metabolism status in TAMs, and explore how glucose metabolism regulates phenotype and function of TAMs. In the beginning, we isolated TAMs from 4T1 mouse breast tumor, spleen macrophages from normal mouse as a control, and performed RNA sequencing to analyze the expression pattern in glucose metabolism related genes. The results from transcriptomics showed that TAM shown up regulation of glycolysis genes pattern. Then we analyzed and found that the Hrk activity was increased while IDH’s activity was decreased in mouse breast cancer mole. Furthermore, in vitro, we found that up regulation of important glycolysis genes including HK2, PFK-L and LDHA in mouse peritoneal macrophages (CMPM) and mouse bone marrow derived macrophages (CMBMDM) conditionally cultured with 4T1 supernatants. Glucose consumption or production of lactate and ATP were also increased in CMPM or CMBMDM. Then we monitored lactate producing rate with Seahorse energy metabolism detector, and found that either CMPM or CMBMDM produced lactate faster than that of control. Moreover, inhibition of LDH activity by oxamate (inhibitor) also decreased glucose consumption and lactate production. Importantly, the expression of Arg1 and CD206, positively correlated with glycolysis and function of TAMs. Finally, we searched the underneat mechanism and found PI3K/AKT pathway was activated in CMPM or CMBMDM. In detail it was found that p-p85 and p-AKT was upregulated at 8 hour after 4T1 supernatants stimulation. Inhibition of PI3K/AKT pathway by LY294002 (PI3K inhibitor), notably inhibited the expression of glycolysis genes and markers of TAMs, which indicated that PI3K/AKT pathway may involved in glycolysis of TAMs. Together, we identified that TAMs adopted glycolysis as a major way to consume glucose and glycolysis was directly contributed to the phenotype and function of TAMs, which was regulated by PI3K/AKT signaling pathway.

#4632 Exosome-mediated transfer of miR-183-5p from tumor cells to macrophages contributes to regulate TAMs phenotypes and promote tumor progression and metastasis. Jian Guo, Wei Wang, Yan Liu, Huwien He, Chen Zhang, Chunhong He, Yunping Luo. Chinese Academy of Medical Sciences, Beijing, China.

Tumor-associated macrophages (TAMs) perform supportive roles in promoting tumor progression and metastasis. In tumor microenvironment, the phenotypes of TAMs are regulated by a variety of factors, such as cytokines, ligands and products of metabolism. Recently, Exosome-mediated transfer of miRNAs is proved to be a significant way for intercellular communications. Whether exosomal miRNAs derived from tumor cells contribute to TAMs phenotypes remains unclear. In this study, we aim to identify the miRNAs in exosomes transferred from tumor cells to macrophages and explore how these miRNAs regulate the TAMs phenotypes. In the beginning we transferred Cy3-labeled miRNA NC to 4T1 mouse breast cancer cells and then co-cultured with bone marrow-derived macrophages (BMDMs). The Cy3 fluorescence could be observed in BMDMs after 48 hour, suggesting that miRNAs could be transferred from tumor cells to macrophages. Next, we performed miRNAs sequencing in either BMDM or exosomes derived from 4T1 cancer cells. We analyzed and compared the miRNAseq data by bio-informatics and found that there were 30 of the most abundant miRNAs in 4T1 exosomes, and nearly all of which were rich in BMDMs. However, it was found interestingly that miR-183-5p was extremely low in BMDMs. Furthermore, we treated BMDMs with exosomes isolated from 4T1 cell conditioned medium, and then we found importantly the miR-183-5p in BMDMs was increased significantly, while cultured with exosome-depleted 4T1 conditioned medium, the expression of miR-183-5p in BM-DMs was not changed. Meanwhile, we isolated TAMs from 4T1 mouse breast tumor while spleen macrophages from normal mouse as a control. The expression of miR-183-5p in TAMs was much higher than that in spleen macrophages. Moreover, it was determined that expression of pro-inflammatory cytokine TNF and IL-6 in BMDM were increased significantly in BMDMs treated with 4T1-derived exosomes. Correspondingly, transferred miR-183-5p mimic into BMDMs, the expression of TNF and IL-6 were also increased. Finally we co-cultured 4T1 cells with BMDMs transferred with miR-183-5p, and the migration and invasion of 4T1 cells were significantly enhanced. Taken together, our study demonstrate that miR-183-5p that high expression in 4T1 exosomes can transferred into macrophages to regulated their phenotypes and promote tumor progression and metastasis in breast tumor microenvironment.

#4633 Crosstalk between MDSCs and Th17. Brjijendra Singh. University of Pittsburgh Cancer Institute, Pittsburgh, PA.

Expansion of myeloid-derived suppressor cells (MDSCs) within the tumor is a known barrier to successful cancer immunotherapy. MDSCs are heterogeneous population of immature myeloid cells with potent immunosuppressive activity. Emerging evidences in the recent years define the role of immunosuppressive activity of MDSCs on different subsets of CD4+ T cells, however the exact effect of MDSCs on inflammatory Th17 cells during tumor progression is not clear. Here we demonstrate the immunosuppressive effect of MDSCs on Th17 cells. We further show that the interaction between MDSCs and Th17 is not unilateral and reveal that Th17 cells can promote the immunosuppressive activity of MDSCs. We identified that MDSCs derived from tumor when generated in vitro from bone marrow (BM-derived MDSCs), can both suppress IL-17A expression. Our data also demonstrate that IFNγ, produced by Th17 cells is essential for the immunosuppressive activity of BM-derived MDSCs on IL-17A expression and further that the IFNγR1-driven signaling is important for Nos2-mediated immunosuppressive effect of BM-derived MDSCs on IL-17A expression. Understanding the molecular mechanism of the interplay between MDSCs and Th17 cells may help to develop more specific targeted therapy for cancer immunotherapy and improve therapeutic efficacy of the existing therapies against cancer.

#4634 Role of surgical stress in altering host immunity in breast cancer patients. Madhuri Taranikanti, Aswin Kumar Mudunuru, Rohit Kumar Gun-taka. ESIC Medical College & Hospital, Hyderabad, India.

Background: Stress of any kind can alter the immune system. Surgery is a form of stress that can have significant effects on immune system. There occurs a reduction in the ability to fight the disease progression and also metastatic spread. Cell mediated immunity plays an important role in the control of malignancy. A reduction in cellular immunity can have adverse effects on the body. The objective of the study was to understand the effects of surgical stress on cell mediated immunity in breast cancer patients. Methods: 31 women with operable early stage breast cancer, who underwent surgery and were also receiving adjuvant chemotherapy were included in the study. Blood samples were collected from the patients during the pre-operative period and twice during the post-operative period, after 72 hours and after 21 days. Peripheral Blood mononuclear cells were subjected to flow cytometry analysis. The mean values of lymphocyte sub-populations as percentage were calculated. A questionnaire was also given to all study participants to assess the levels of stress of having breast cancer. An informed consent was taken from all the participants involved in the study. Results: The mean values of lymphocyte sub-population were found to be significantly lower (p<0.5) in the early post-operative period in breast cancer patients. However, the values returned to near pre-operative levels after 21 days. A positive correlation existed between psychological stress of having the disease and low host immunity. This indicates that any intervention that further suppresses immunity in breast cancer patients following surgery should not be used for at least 3 weeks after surgery.

#4635 The LSD1 Specific Inhibitor INCB059872 enhances the activity of the syngeneic 4T1 mouse mammary tumor model. Thomas Condamine, Steve Wang, Melody Diamond, Leslie Hall, Huiqing Liu, Antony Chadderton, Jon Lu, Chunhong He, Liangxing Wu, Timothy Burn, Wenqing Yao, Gregory Hollis, Reid Huber, Bruce Ruggeri, Peggy Scherle, Holly Koblish, Sang Hyun Lee. Incyte Corporation, Wilmington, DE.

Background: Stress of any kind can alter the immune system. Surgery is a form of stress that can have significant effects on immune system. There occurs a reduction in the ability to fight the disease progression and also metastatic spread. Cell mediated immunity plays an important role in the control of malignancy. A reduction in cellular immunity can have adverse effects on the body. The objective of the study was to understand the effects of surgical stress on cell mediated immunity in breast cancer patients. Methods: 31 women with operable early stage breast cancer, who underwent surgery and were also receiving adjuvant chemotherapy were included in the study. ulate to the development of the immunosuppressive tumor microenvironment and recent data have suggested that combining epigenetic-based therapies with immunotherapeutic agents can lead to improved efficacy in preclinical models. Since Lysine Specific Demethylase 1 (LSD1) has been shown to play a critical role in hematopoiesis, we hypothesized that inhibition of LSD1 could have a direct effect on the immune system. Furthermore, LSD1 is overexpressed in human lung adenocarcinoma cells. To test this hypothesis, we evaluated INCB059872, a potent, selective and orally available FAD-directed covalent inhibitor of LSD1 in several experimental models. In an in vitro differentiation assay, the majority of CD34+ progenitor cells were driven to a monocyctic phenotype in the presence of INCB059872, while control treated cells differentiated toward granulocytic PMN cells. Similar results were observed in vivo. Using the orthotopic 4T1 mammary cancer model, the myeloid compartment was characterized in tumor tissues following treatment with INCB059872. Notably, the population of PMN-MDSC was significantly decreased in tumor tissues following oral administration of INCB059872, whereas the macrophage population was increased. These data suggest that INCB059872 can redirect myeloid differentiation toward monocyte/macrophages and inhibit the differentiation of PMN-MDSC, this syngeneic tumor microenvironment. Consistently, in situ intratumoral T lymphocyte infiltration was increased following INCB059872 treatment. The combination of INCB059872 and a-CD-P-L1 antibody enhanced anti-tumor efficacy in the 4T1 orthotopic tumor model. Collectively, these data suggest that inhibition of LSD1 with INCB059872 can directly affect myeloid differentiation to reduce the accumulation of immunosuppressive cells, restoring tumor microenvironment to be more responsive to PD-1/PD-L1 axis blockade. This study supports the therapeutic potential for the combination of an LSD1 inhibitor with immunotherapeutic agents to improve overall clinical response in cancer patients.

#4636 p53 governs the tumoricidal activity of M1 macrophages in lung cancer. Yi-Jing Hsiao,1 Hsuan-Yu Chen,1,2 Kang-Yi Su,2 Bing-Ching Ho,1 Jeremy J.W. Chen,3 Pan-Chyr Yang,4 Sung-Liang Yu.1 1National Taiwan University, Taipei, Taiwan; 2Academia Sinica, Taipei, Taiwan; 3National Chung-Hsing University, Taichung, Taiwan.

Macrophages in a tumor microenvironment have been characterized as M1- and M2-polarized subtypes. M1 macrophage is associated with favorable clinical outcome of lung cancer patients, but the detail molecular mechanism is not thoroughly understood. Herein, we elucidate the anti-tumor mechanism of M1 macrophages by in vitro and in vivo assays. M1 conditioned media (CM) significantly reduced the tumor size in the xenograft mouse model via intratumoral administration. The M1 altered differential expression was profiled by microarray and the pathway analysis indicated that p53 was a critical regulator. Lung cancer harboring wild-type p53 (wt-p53) went apoptosis after M1 CM culture, but cells with mutant p53 did not. Additionally, M1 CM enhanced wt-p53 accumulation through reducing p53 ubiquitination and increasing protein stability. Moreover, we identified a p53 interacting protein STAT1 involved in M1-induced apoptosis and p53 accumulation. The CM of M1 culture, but cells with mutant p53 did not. Additionally, M1 CM enhanced wt-p53 accumulation through reducing p53 ubiquitination and increasing protein stability. Moreover, we identified a p53 interacting protein STAT1 involved in M1-induced apoptosis and p53 accumulation. The M1 CM not only enhanced the interaction between STAT1 and p53 but also up-regulated and activated STAT1. To reveal the upstream signaling, we found that knockdown of IFNAR2, Jak1 and Tyk2 attenuates M1-induced apoptosis. Taken together, STAT1 signaling is essential for M1 CM-induced apoptosis and p53 accumulation. Our findings imply that p53 and M1 macrophages play important roles in the immune surveillance in lung cancers.

#4637 Activation of toll-like receptor-2 promotes proliferation in human lung adenocarcinoma cells. Patrick Kohitz. University of Colorado - School of Medicine, Denver, CO.

Objective: Toll-like receptors (TLR) have been implicated in tumor progression by affecting the immune response in the tumor microenvironment. Toll like receptors have been described to be present in human cancer cells but the presence and the role of these receptors in the growth and proliferation of human lung cancer is not well known. We analyzed human lung cancer cells for the presence of TLR-2 receptors and evaluated the proliferation response to a specific TLR-2 agonist. Methods: Human non-small cell lung cancer cell (NSCLC) lines A549, (adenocarcinoma) H125 adenosquamous, and H1650 adenocarcinoma (American Type Culture Collection), were cultured using standard techniques. Cells were treated with Pam3CSK4, a specific agonist of TLR2, at doses of 0.5ug/ml, 5ug/ml, and 10ug/ml for 72 hours. Baseline protein levels of TLR2 were assessed using standard western blotting techniques. Proliferation assays were completed using the MTS assay in response to treatment with the agonist Results: Protein analysis demonstrated varying but consistently detectable levels of TLR2 protein in each cell line. After treatment with Pam3CSK4 we found that proliferation was significantly promoted in the human lung adenocarcinoma cell lines (p=.03), but not in the adenosquamous cell line (p=0.001). Conclusion: Toll-like receptor -2 is consistently present and detectable on human lung adenocarcinoma cells. Toll Like receptor -2 activation results in increased proliferation in human lung adenocarcinoma cells and this effect appears to be mediated by TLR2. Further study is needed to identify the downstream pathways responsible for the increased proliferation we see in these human lung adenocarcinoma cells, however these findings may suggest TLR-2 to be a possible therapeutic target in human lung cancer.

#4638 The p53 suppression on tumor cells may recruit macrophages and modulate their expression of the indoleamine 2, 3-dioxygenase. Takafumi Nakamura. Kawasaki Medical School, Kurashiki, Japan.

We had found that expression of indoleamine 2,3-dioxygenase (IDO) on cervical cancer cells increased as it progressed from carcinoma in situ (CIS) to microinvasive cancer, and that tumor-associated macrophages (TAM) recruited at the invasive front also expressed IDO in cervical cancer patients (Cancer Sci 98:874-881 2007). We previously produced homozygous αT3 transgenic mice carrying two copies of α-SV40Tag transgene (αT3 denotes murine α-crystal-lin promoter) in order to study DNA virus-induced carcinogenesis. The αT3 mice developed undifferentiated cancer of lens epithelium, which tumors showed multi-step carcinogenesis which was similar to cervical cancer (J Cancer Res Clin Oncol 135:1521-1532 2009). We found that homozygous αT3 mice carrying two copies of SV40Tag transgene progressed faster and died earlier than hemizygous αT3 mice carrying one copy of Tag transgene. In this study, in order to examine the relationship between p53 function and tumor progression, αT3 mice were mated with M1 mice expressing mutant p53 in lens cells (Proc. Natl. Acad. Sci. USA, 92:6142-6146, 1995) producing αT3M1 mice, and also were mated with p53-deficient mice to produce p53-deficient αT3 mice (αT3p53(-/-)) mice (Cancer Letters 179:165-173,2002, Oncology Report 12:253-258, 2004). At 20 weeks of age, the proportion of progression from CIS to invasive cancer was analyzed by H&E staining and the number of recruited TAM and IDO-expressing TAM were determined by immunohistochemical staining and FACS analysis. Pathologically, both αT3M1 and αT3p53(-/-) lens tumors significantly progressed to invasive cancer more than αT3 tumors. There were a few macrophages in wild-type lens, but more TAM were recruited in both αT3, αT3M1 and αT3p53(-/-) lens tumors. However, no significant difference of the number of IDO-expressing macrophages in peritoneal cavity was detected in each mice of wild-type, αT3, αT3M1 and αT3p53(-/-). It suggested that p53 suppression on tumor cells might modulate IDO-expression for macrophages. Moreover, we established the tumor cell lines from each αT3, αT3M1 and αT3p53(-/-) lens tumors. The peritoneal macrophages were analyzed for IDO-expression in 4 days after i.p. injection of these cells. Significantly, IDO-expressing macrophages in peritoneal cavity were more reduced. We detected the IDO expression of each αT3M1 and αT3p53(-/-) cells than i.p. injection of αT3 cells. And the co-culture of peritoneal macrophages with each αT3M1 and αT3p53(-/-) tumor cells also induced the IDO-expression of macrophages more than the co-culture with αT3 cells. These results suggested that the amount of p53 suppression on tumor cells would be related to the number of recruited TAM and their expressing IDO. The peritoneal macrophages were treated with IFN-γ and their expression of IDO function and, suppress an innate immunity possibly through the expression of IDO, which may enhance invasion and progression of tumors.

#4639 HLA and NKG2D ligand abnormalities and IFN-γ unresponsiveness in human colorectal carcinoma cell lines. Yi-Hsin Lin,1 Yen-Cheng Lin,1 Kuo-Hsin Chen,1 Chi-Hua Kao,1 Ann-Liu Hsieh,1 Chien-Ching Chang2. 1Graduate Institute of Oncology, College of Medicine, National Taiwan University, Taipei, Taiwan; 2Institute of Molecular and Cellular Biology, National Tsing Hua University, Hsinchu, Taiwan.

Background: Cetuximab, an anti-epidermal growth factor receptor (EGFR) monoclonal antibody, has shown promising efficacy on wild-type RAS metastatic colorectal cancer (CRC) patients. Cetuximab demonstrates anti-cancer effect via NK cells and subsequent immunogenic cell death. Chemotherapy or targeted therapy may change immune surface markers. Methods: We characterized a panel of 6 CRC cell lines with different genetic features. The impacts of interferon-γ (IFN-γ) on cell surface expressions of major histocompatibility complex (MHC) class I (including subtypes), MHC class II (including subtypes), MHC class 1 related molecule A (MICA, the NK cell ligand), Intercellular Adhesion Molecule 1 (ICAM-1, the immunglobulin superfamily), EGFR, and Chondroitin Sulfate Proteoglycan 4 (CSPG4, pericyte attaching marker) before and after treatment with IFN-γ (100 U/ml, 48 h) were explored in selected cell lines Results: Among six human colon cancer cell lines analyzed, DLD-1, HCT15, and LoVo exhibited no expression of HLA-A and HLA-B,C. Colo-320
demonstrated both low HLA-A and HLA-B,C expression and non-responsive to IFN-γ stimulation. In contrast, both HT-29 and SW-480 showed low HLA-A and HLA-B,C expression, but the expression of both HLA-A and HLA-B,C was corrected after IFN-γ stimulation. All six cell lines possessed low MHC class II expression and non-responsive to IFN-γ stimulation. All six cell lines possessed low MHC expression and non-responsive to IFN-γ stimulation. Five of six cell lines showed low ICAM-1 expression, but only HT-29 and SW-480 were responsive to IFN-γ stimulation. LOVO and SW-480 demonstrated high EGRF expression and non-responsive to IFN-γ stimulation. Only HT-29 possessed high CSPG-4 expression. Conclusion: These findings reveal that regardless of their genetic features, all six CRC cell lines possess a phenotype that may allow them to escape cytotoxic T and NK cell attack.

#4640 Proteomic differentiation of pulmonary cancer with squamous cell histology.

Histologic classification of pulmonary cancer with squamous cell histology is challenging as reliable immunohistochemical biomarkers are lacking. In particular, smokers with head and neck cancer can develop both lung metastases and primary lung cancer. However, their differentiation is clinically important for therapy and risk stratification. Moreover, molecular targeted therapies for squamous cell carcinoma of the lung are largely lacking. To identify proteomic diagnostic biomarkers, signaling patterns and potential novel drug targets we characterized a broad panel of primary patient-derived formalin-fixed squamous cell carcinoma tissues from lung and head and neck cancer by quantitative mass spectrometry. Proteins were isolated from formalin-fixed, paraffin-embedded (FFPE) patient-derived genetically characterized cancer tissues by using a “filter-aided sample preparation (FASP)” method. The resulting proteins were analyzed by a Super-SILAC-based mass spectrometry approach and data was analyzed using the software suite MaxQuant and Perseus to determine the tumor-type-specific protein expression and signaling patterns. In this study we quantitatively analyzed the protein-expression profiles of 50 primary patient-derived non-small cell lung cancer specimens with squamous cell histology and 30 squamous cell carcinomas from the head-neck-region derived from patients that developed lung tumors with similar histology in the course of their disease. Using the mass spectrometric approach we were able to quantify in average around 2500 proteins per sample. Unsupervised clustering- and principal component analyses revealed that the detected protein expression patterns show a strong correlation with the cellular origin of the analyzed carcinomas. Furthermore, secondary lesions with similar histological morphology in the lung in patients with squamous cell carcinoma of the head-neck-region could be classified as primary or metastatic cancer according to their protein expression profiles. Collectively, this study provides a large set of potential proteomic biomarkers that might be useful to improve diagnostics in the context of lung tumors with squamous cell histology in the future. In particular the differentiation of squamous cell carcinoma and head and neck cancer-derived metastases in the lung - that is still a challenge for diagnostics - will be improved by the presented biomarker panel. Moreover, the expression of the proteins that are identified could help to determine the potential of signaling pathways that were discovered in our study are of interest regarding potential novel lung cancer therapies as overexpression or hyperactivation of certain kinases can potentially contribute to the malignant phenotype of lung cancer cells.

#4641 Wild type APC is an independent marker of poor prognosis in late stage colorectal cancer.

Background: Colorectal cancer (CRC) is one of the commonest cancer worldwide and ranks as the most common cancer in males and the third most common among females in Saudi Arabia. Wnt pathway alteration is well known in colorectal cancer. In this study we aimed to comprehensively study Wnt pathway alterations in a large cohort of Middle Eastern colorectal patients and to know its role in this unique ethnic group. Methods: 426 CRC cases were analyzed for APC, AXIN2 and CTNNB1 somatic mutations by targeted capture sequencing and protein expression status by immunohistochemistry in tissue microarray format. Results were analyzed for association with any clinicopathological parameters and for prognostic significance. Results: The incidence of APC, AXIN2 and CTNNB1 mutations in our patient cohort were 58.2%, 4.2% and 3.8% respectively. APC wildtype mutation was associated with 50% of the tumors (p = 0.0494) and male sex (p = 0.0349). AXIN2 mutation were associated with grade 3 tumors (p = 0.0231), MSI-high tumors (p < 0.0001) and AXIN2 protein expression loss (p = 0.0056). CTNNB1 mutations were associated with MSI-high tumors (p = 0.0076). AXIN2 and CTNNB1 mutation were significantly associated with each other (p = 0.0263). Wild type APC was associated with poor overall survival and was an independent marker of poor prognosis in late stage colorectal cancer (p = 0.0263). Wild type APC independently predicts poor prognosis in Middle Eastern late stage colorectal patients.

#4642 Ion mobility separation of N-Glycans directly from ffpe colon cancer tissue section in a MALDI imaging experiment.

Colon cancer is currently the third most common cancer in both men and women. Research studies have reported extensive alterations in protein glycosylation patterns in cancer tissues. However during these studies, the tissues are homogenized and the spatial information showing the localization of the glycans is lost. Mass spectrometry imaging (MSI) is an established analytical tool for biomolecular research which can accurately determine the spatial location of molecules in a tissue section. Recently, methods have been developed to determine released N-Glycans directly from tissues. A major challenge in the analysis of N-glycans is the large number of isobaric glycans resulting from their complex structures with branched chains and multiple additions residues. Here we report the advantage of ion mobility separation to differentiate these glycans in a MALDI MSI workflow used in the analysis of human FFPE colon cancer tissue. 5μm FFPE tissue were were deparaffinized in xylene, rehydrated in different composition of ethanol/water solutions, transferred in citraconic anhydride buffer for antigen retrieval and water washed. To release the glycans from their proteins, a PNGaseF solution was sprayed on the tissue. A solution of MALDI was sprayed onto the tissue. Experiments were carried out on a SYNAPT G2-Si HDMS system (Waters) where the tri-wave separated ions according to their ion mobility in the gas phase. The overall MALDI spectrum shows strong signal for N-glycan molecules, demonstrating the efficacy of the digestion step of the methodology. Using prior knowledge of the type of glycans, 76 glycans were identified and mapped directly from the FFPE tissue section, from a mass to charge ratio (m/z) of 771.5 up to 2905.03 using accurate mass information. APC, AXIN2 and CTNNB1 mutations in our patient cohort were 58.2%, 4.2% and 3.8% respectively. APC wildtype mutation was associated with 50% of the tumors (p = 0.0494) and male sex (p = 0.0349). AXIN2 mutation were associated with grade 3 tumors (p = 0.0231), MSI-high tumors (p < 0.0001) and AXIN2 protein expression loss (p = 0.0056). CTNNB1 mutations were associated with MSI-high tumors (p = 0.0076). AXIN2 and CTNNB1 mutation were significantly associated with each other (p = 0.0263). Wild type APC was associated with poor overall survival and was an independent marker of poor prognosis in late stage CRC (p = 0.0263). Conclusion: We reported the incidence of Wnt pathway alterations in this unique ethnic group on which such data is lacking. APC mutation plays major and other genes minor role in Wnt pathway activation. Incidence of APC mutation in this group is comparatively high compared to reported incidence worldwide. Wild type APC independently predicts poor prognosis in Middle Eastern late stage colorectal patients.
phase was identified to be the N-Glycan class of molecules. Using IMS the MS data showed a clear picture of the N-Glycans compared to the MS data alone. In several cases, the IMS peaks were broader than the expected resolution or there were shoulder peaks, indicating that isobaric species were present. For example, m/z 1444.6 ( Hex4dHex1HexAc3Na+) displayed two IMS distinct peaks which were not baseline separated and were contributed to the obtain individ-
ual ion images which showed significantly different distributions. The isobaric species with the faster drift time was evenly distributed across the tissue type of the section, whereas the isobaric species that had the slower drift time was less abundant in the cancer tissue.

#4643 Plasma thioredoxin reductase 1 as a diagnostic marker for non-small cell lung cancer. Xiaosheng Kang,1 Chaoran Dong,2 Bocun Shen,1 Wanpu Yan,1 Liang Dai,1 Yongbo Yang,1 Hanwei Yin,3 Guobing Xu,1 Huihui Zeng,2 Ke-Neng Chen1. 1Peking University Cancer Hospital and Institute, Beijing, China; 2Peking University Health Science Center, Beijing, China; 3Kaise Center for Clinical Laboratory, Wuhan, China.

Non-isobaric diagnostic markers for patients with suspicious non-small cell lung cancer (NSCLC) may provide needed guidance on invasive diagnostic and therapeutic decisions. Thioredoxin reductase 1 (TrxR1) is a pivotal intracellular oxidoreductase that plays an important part in tumor growth, progression, metastasis, and chemotheraphy resistance. The goal of this study is to test the feasibility of developing plasma TrxR1 as a novel diagnostic marker for NSCLC. The plasma TrxR1 activity was determined spectrophoto-
metrically by monitoring the NADPH-dependent production of 2-nitro-5-thio-
benzoate at 412nm and at 37°C. All detection kits and automatic analyzer pos-
se independent intellectual property rights, and have been widely used in breast cancer screening. In this study, the plasma levels of TrxR1 were measured in 45 treatment-naive NSCLC patients and 10 individuals with benign tumor-like pulmonary diseases. Taking plasma TrxR1 activity of 4 as reference, the overall concordance rate was 73.3%, while those of CEA, CA199, CA125, NSE, CYFRA21-1 and SCC were 19.0%, 7.1%, 16.7%, 35.7%, 24.4% and 2.5%, respecti-

#4644 A cell-line based TP53 expression pattern control panel with inter-
observer variability and next-generation sequencing analysis. Yaling Zhou,1 Sorana Raiciulescu,1 Visar Syed,2 Patrick Malafronte,1 Justin Wells,1 Mica Grantham,1 Michael Allgaeuer,1 Heping Gong,1 Joel Moncur,1 Deyin Xing,6 John D. Andersen1.

#4645 A serum multiomics signature for enhancing prostate cancer diag-
nosis and prognosis. Michael A. Kiebish,1 Jennifer Cullen,2 Albert Dobi,2 Amina Ali,2 Leonardo O. Rodrigues,1 Yezhou Sun,1 Aniruddha Pawar,1 Aditee Dalvi,1 Denise Young,3 Vivek K. Vishnadav,1 Jason Sedarsky,2 Gyorgy Petrov-
ics3, Emily Chen,1 Vitschelsak Akaemua,1 Inger L. Rosner,2 David McLeod,1 Isa-
bell A. Sethermann,2 Rangaprasad Sararanjanag,1 Alagarsamy Srinivasan,2 Elder Grainger,1 Niven R. Narain,1 Shiv Srivastava,1 1BERG, LLC, Framingham, MA; 2Uniformed Services University and the Walter Reed National Military Medical Center, Center for Prostate Disease Research, Bethesda, MD; 3Joint Pathology Center, Silver Spring, MD.

Introduction and Objective: Diagnosis of prostate cancer (CaP) has relied on prostate specific antigen (PSA) level and digital rectal examination (DRE) followed by prostate biopsies. These modalities have the potential to yield false-
positive and false-negative results for CaP. These challenges prompted efforts to develop more specific body fluid based assays including PCA3, TMPRSS2:ERG, KcKcore and PHI tests. Further, emerging data on significant racial differences of common CaP driver genes, e.g., PTEN and ERG in CaP can lead to significant limitations in biomarker performance. Thus, the goal of our study was to dis-
cover CaP serum markers with equal performance among African American (AA) and Caucasian American (CA) men. We employed proteomics, signal-
and structural lipidoanalysis and metabolomics platforms to discover serum bio-
markers and validate. This 35th edition, which we have proposed as Acute leukemia in AA and CA men. Methods: Sera from 700 individuals were analyzed, which included AA and CA CaP patients stratified for ERG oncoprotein expression by immunohis-
tochemistry (N=495). Sera from age-matched healthy control men were also included (N=205) in this study. Quantitative global profiles of liposome, pro-
teome and metabolome were analyzed by high resolution MS-based technolo-
gies. Random forest and Interrogative Biology4 analytical platforms were used to identify analytes differentiating healthy from CaP cases including clinical-pathologic data. Results: The unbiased global profiling and integration of the data and clinical-pathologic features have led to the identification of molecular fingerprints differentiating cancer patients from healthy controls. Specifically, three analytes in serum metabolome showed robust separation between both AA and CA CaP and control groups. Elevated levels of nicotinamide and ei-
cosanoid acid and decreased levels of a decanoyl carnitinate alone have indicated strong separation between cases and controls. Further inclusion of additional 9 analytes provided an optimal multi-omics panel for distinguishing the combined cohort of AA and CA cases vs. healthy controls. Conclusions: The findings presented here support that an integrated multiomics approach has the potential to define serum marker panels for diagnosis of CaP in the context of racial diversity and molecular annotation (e.g., ERG) of CaP. These promising data are undergoing validation in additional patient cohorts.

#4646 A novel truncated variant of the hematopoietic Hb-2 tubulin iso-
type with implications for stem cell biology. Yang Bai, Paul Basciano, Xi Li, Jason Matasak, Silvana Di Giandomenico, Siddhartha Sen, Todd Evans, Joseph Scandura, Monica Guzman, Paraskevi Giannakakou. Weill Cornell Medicine, New York, NY.

The αβ-tubulin dimer is the building block of the microtubule cytoskeleton, which is important for many cellular functions. Several α and β tubulin isoforms have been identified so far; Hb-1 tubulin (human β tubulin Class VI) is a hematopoietic-specific tubulin isoform whose expression is restricted to megakaryo-
cytes and platelets. TCGA analysis showed that β-1 is highly and specifically expressed in acute myeloid leukemia (AML). β-1 may therefore be an attractive target for the development of novel therapeutics for AML. We developed a highly-specific polyclonal antibody against the last C-terminal amino acids and analyzed a panel of AML cell lines and primary samples by western blot. We identified the presence of a novel truncated 35KD band, distinct from the can-
nonical 39KD tubulin. Leukemia. Isobologram β-1 (ALIBI), was present in 10 of the 19 AML cell lines tested as well as in a large number of AML clinical samples, as evidenced by immunoblotting, and corroborated by RNA-sequencing. We determined that ALIBI was a splice variant of Hb1 tubulin, lacking exons 1 and 2 with partial retention of exon 3 and intron 3. Mass array methylation analysis revealed differential promoter and intragenic methylation pattern in canonical β1 tubulin versus ALIBI, suggesting that there is an epigenetic switch that determines the expression of each tubulin isoform. Immunofluorescence analysis revealed that ALIBI, unlike all tubulin isoforms, does not incorporate into microtubules but instead accumulates in the nucleus and in distinct puncta in the cytoplasm. Exogenous expression of ALIBI,
also resulted in a similar cellular distribution. Using a murine leukemia mouse model we found significant enrichment of ALIBI in the leukemic stem cell fraction, while in normal mouse development ALIBI was present in fetal liver and hematopoietic progenitor cells. Based on this observation, as well as the relationship between leukemic stem cells and embryonic stem cells, we probed for the presence of ALIBI within murine embryonic stem cells (mESCs) and found ALIBI to be present in cultured mESCs, and down-regulated upon differentiation when full length b1 tubulin was expressed. Taken together, these data suggest that ALIBI has an important, heretofore unrecognized, role in stem cell biology. However, much remains unknown regarding the function of ALIBI within the nucleus, the factors that regulate its expression over the canonical EML4-ALK and the importance of its precise role in progenitor or stem cells. Understanding the function and regulation of ALIBI will allow us to understand a novel role of tubulin in stem cell biology and open multiple avenues for application of this knowledge.

#4647  Mass spectrometric analysis of oncometabolite 2-hydroxyglutarate in clinical gliomas with the isocitrate dehydrogenase-1 mutation. Mitsuhiro Hayashi,1 Hiroaki Aikawa,2 Makoto Ohno,3 Koichi Ichimura,4 Yuko Matsu- shita,1 Mayu Ohuchi,1 Maniko Mizui,1 Akihiko Yoshida,5 Yoshitaka Natari,1 Akinobu Hamada,1 National Cancer Center Research Institute, Tokyo, Japan; 2Exploratory Oncology Research and Clinical Trial Center, National Cancer Cen- ter, Tokyo, Japan; 3National Cancer Center Hospital, Tokyo, Japan.

Introduction: Mutations of the isocitrate dehydrogenase (IDH)-1/2 genes frequ- ently occur in certain malignancies, including gliomas. Mutant IDH-1/2 protein expression has the potential to produce oncometabolite 2-hydroxyglutarate (2HG), which results in a different clinical impact on gliomas in comparison to those with a wild-type IDH. The status of IDH mutations has been determined by immunohistochemistry (IHC) using the IDH1-R132H antibody or through the DNA sequencing of IDH1-R132C/R132S; however, its practical applications are still under discussion, and the significance of the oncometabolite 2HG evaluation is not clear. In this study, we analyzed the serum and tissue levels of 2HG in clinical gliomas using liquid chromatography-tandem mass spectrometry (LC- MS/MS) and the matrix assisted laser desorption and ionization mass spectrom- etry imaging (MALDI-MSI) system. Method: Glioma samples (n = 78, matched pairs of serum and flash frozen tissue) were obtained between October 2007 to January 2015 at the National Cancer Center Hospital, Japan. High performance liquid chromatography (Nexera X2, Shimadzu) and triple quadrupole mass spectrometry (QTRAP4500, AB SCIEX) were used for LC-MS/MS analysis. The two MALDI-MSI systems, quadrupole ion trap time-to-flight mass spectrometry imaging (iMScope, Shimadzu), and high-resolution atmospheric pressure mass spectrometry imaging (AP-SMALDI, TransMIT; Q-Exactive, Thermo Fisher Scientific) were used for analyzing the 2HG tissue distribution after coating with 9-aminoacridine or 2,5-dihydroxybenzoic acid. The IDH mutation was deter- mined by direct sequencing and IHC. Results: The median 2HG concentration in serum was 21.43 ng/mL (range: 9.58 to 62.51) in this study, and no significant correlation was observed between the IDH mutation and the wild type status (mutation, n = 28, median 20.2 ng/mL, range 9.58 to 62.51 vs. wild type, n = 50, median 22.88 ng/mL, range 11.51 to 40.32, Wilcoxon test p = 0.1597). The median of the 2HG tissue concentration in the entire group was 16 ng/g, and a significant difference was seen between the IDH mutant and wild type groups (mutation, median 4.86 ng/μg, range 0.51 to 49.86 vs. wild type, median 0.09 ng/μg, range 0.02 to 0.45; Wilcoxon test p = <0.0001). In the MALDI-MSI analysis, the average 2HG ion intensities were 381.62±2.57 in the IDH mutation and 8.25±1.67 in the wild-type IDH tissues (Wilcoxon test p = 0.0016), which showed a positive correlation with the 2HG tissue concentration by LC-MS/MS analyses (Spearman p = 0.87, p = 0.0003). The MSI results indicate a possible link between the 2HG tissue distributions and the histology of IDH mutant sections. Conclusion: Tissue 2HG measurement using mass spectrometric analyses may be a useful alternative in determining IDH mutations. Further research may provide a biological perspective and help gain some insights on the clinical significance of 2HG.

#4648 Development of a rapid, precise, and sensitive molecular assay for ALK fusion detection. Mona D. Shahbaziyan,1 Yueyi Shang, Maidaar Jamba, Mi- chael J. Powell,2 DiaCarta, Richmond, CA.

Introduction: In non-small cell lung cancer (NSCLC), chromosomal translo- cation events that result in overactivation of the anaplastic lymphoma kinase (ALK) have been identified and shown to play a key role in tumorogenesis. Inhibitors of the ALK kinase, such as the FDA-approved crizotinib, are effective in treating ALK-fusion-positive non-small cell lung cancer. Molecular studies have identified many ALK fusion variants in various cancer types, encompassing a combination of 22 different gene partners as well as various break points within the partner genes. The most common fusion events in non-small cell lung cancer are between the echinoderm microtubule associated protein like 4 (EML4) gene and the ALK gene. Fusion events between the Kinesin Family Member 5B (KIF5B) gene and ALK have also been identified. Existing assays for ALK fusion detection include the time-consuming, costly, and challenging flu- orescence in situ hybridization (FISH) method, which can result in a high inter-observer variability. Next generation sequencing platforms are also available, which are also costly to implement, difficult to interpret, and have lengthy workflows. Reverse-transcriptase PCR methods are ideal, as they are cost-effective, sensitive, rapid, and require little interpretation expertise. Methodology: We designed a multi-plexed real-time RT-PCR method to enable indiscriminate detection of ten EML4-ALK, and the remaining variants encompassing approximately 95% of EML4-ALK and 90% of KIF5B-ALK characterized fusion vari- ants, based on the Catalogue of Somatic Mutations in Cancer (COsmic) data- base. The assay uses standard real-time PCR instrumentation and was characterized using the Bio-Rad CFX384®, Roche LightCycler® 96, and Roche LightCycler® 480 II instruments. Assay preparation and run time requires 2 hours or less. Sensitivity testing showed that for the Roche LightCycler® 480 II and Bio-Rad CFX384®, 100% detection was achieved for 50 copies of fusion template for each of the 13 targeted variants. The Roche LightCycler® 96 showed slightly poorer sensitivity, with 100% detection observed at 50 copies for 9 fusion variants and 100 copies for the remaining four variants. Inter- and intra-run precision testing demonstrated good reproducibility and repeatability, with a coefficient of variation of less than 10% for all targeted fusion variants. Using ALK-positive and ALK-negative FFPE reference materials, it was demonstrated that 50 ng of total FFPE RNA was sufficient and up to approximately 200 ng showed good performance. Conclusion In summary, we have developed a rapid, precise, and sensitive assay for the detection of thirteen EML4-ALK and KIF5B- ALK fusion events to enable molecular characterization of non-small cell lung cancer tumors.

#4649 Development of an ethnicity informed gene expression panel with potential to improve prostate cancer diagnosis. Indu Kohar,1 Lakshmi Ravi- dranath,1 Reema Banerjee,1 Yongmei Chen,1 Amina Ali,1 Yingjie Song,1 Jacob Kagan,7 Sudhir Srivastava,2 Albert Dobi,4 David McLeod,1 Inger L. Ros- ner,5 Shiv Srivastava,2 Georgy Petrovics1,2, CPDR/USUHS, Rockville, MD; 2NCI/ NIH, Bethesda, MD; 3WRNMMC/USUHS, Bethesda, MD.

Introduction and Objectives: Prostate cancer (CaP) affects 1 in 7 men throughout their life time. One of the major risk factors for the development of CaP is race/ethnicity. African American (AA) men have significantly higher incidence and mortality from CaP compared to Caucasian American (CA) men. Emerging data including ours have described significantly lower frequencies of alterations in the common CaP driver genes (ERG and PTEN) in AA men as compared to CA men. We have also noted that genes commonly overexpressed in ERG, AMACR and PCA3, and currently used as diagnostic markers exhibit much lower frequency and more heterogeneity in AA men. The goal of this study was to define a broader CaP marker panel that is overexpressed equally well in AA and CA CaP. Methods: Three platforms (RNASeq, NanoString and QRT-PCR) were used for evaluation of CaP associated gene expression in CA and AA patients (N=144). Candidate genes with robust tumor overexpression (over 4-fold) in CaP in comparison of paired normal and tumor specimens from AA and CA patients were selected from the Nanostring and RNAseq data for validation by QRT-PCR (Taqman) in laser microdissected (LCM) tumor and benign cells of frozen tissue sections (50 CA and 35 AA). An assay protocol (gene specific pooled RT and pre-amplification followed by TaqMan PCR) was set up for the noninvasive early detection of candidate genes in regular patient urine (non-DRE) using RNA derived from urinary exosomes. Results: As expected tumor transcriptomes of CA patients revealed consistently elevated expression of PCA3 and AMACR genes. However, these genes had variable overexpression in AA cohort. The top genes that were similarly over expressed in tumors of AA and CA patients were validated by real time QRT-PCR (Taqman) analysis in LCM dissected tumor and normal epithelial cells (N=85). At least one gene of a six gene signature (DLX1, HOXC4, NKX2-3, COL10A1, HOXC6 and PSGR) was overexpressed in tumor cells of all AA and CA cases, providing a consistent ethnicity informed tumor expression signature, which was further validated in silico in TCGA RNASeq data. Urinary exosome based assay was developed and optimized for PSGR, DLX1, HOXC4, NKKX2-3, as well as PCA3 and ERG. Sensitivity and specificity with optimal cutoff for the urine marker panel was 71% and 61% respectively (N=140). Evaluation of the assay performance in CA and AA patients in a prospective independent cohort of 100 patients addressing race specific performance is in progress. Conclusions: A CaP tissue based gene expression marker panel has been defined with potential diagnostic utility for both CA and AA men in the context of urinary exosomes.
#4650  Mutation detection by target sequence analyses using tissue-specific panels in esophageal squamous cell carcinoma. Takeshi Iwaya,1 Fumitaka Endo,1 Kohei Kume,1 Yasushi Sasaki,2 Takashi Tokino,1 Satoshi Nishizuka1. 1Iwate Medical Univ. School of Medicine, Morioka, Japan; 2Research Institute for Frontier Medicine, Sapporo Medical University, Sapporo, Japan.

Whole exome sequencing (WES) studies of esophageal squamous cell carcinoma (ESCC) have revealed that only a small number of frequently mutated genes, such as TP53, NOTCH1, NRF2, and ZNF750, are present in individual tumors, whereas hundreds of others less frequently mutated genes are accumulated. The mutation detection rate by target sequence analyses is an important factor for clinical sequence in the course of ESCC treatment. This study aimed to evaluate the mutation detection rates of several target sequence analyses for ESCC. Ten pairs of surgically or endoscopically acquired tumor tissues and corresponding peripheral blood mononuclear cells were obtained from ESCC patients. We used three types of target sequence panels for mutation screening in 10 ESCC patients as follows: 1) Cancer Hotspot Panel (CHPv2), targeting mutation hotspot regions in the most common 50 human cancer genes that are frequently mutated (panel size: 22,027 bp), for five patients; 2) TP53 Panel, covering all exons of TP53 (panel size: 2,359 bp), for five patients; and 3) ESCC Panel, originally designed to target 31 frequently mutated genes in ESCC (panel size: 210,570 bp), for seven patients. Four missense and two nonsense mutations in TP53 were detected in CHPv2 and the TP53 Panel, respectively. In the ESCC Panel, 47 mutations in 17 genes were detected in seven patients. The mutation detection rates by the TP53 Panel, CHPv2, and ESCC Panel were more than 20-fold higher than that of WES, which has been reported to be 3.1/Mb for ESCC. These results suggest that tissue-specific cancer-related gene panels are a highly effective approach for mutation detection in ESCC.

#4651  Multiple platform evaluation of KRAS codon 12/13 reference material. Russell Garlick, Yves Konigshofer, Farol L. Tomson, Dale Yuzuki, Bharti Anekella. SeraCare, Gaithersburg, MD.

An assay’s ability to detect the presence of a KRAS driver mutation is critical when attempting to determine whether a tumor may respond to anti-EGFR therapy. Currently, there are two FDA approved companion diagnostics that can be used to assess whether there are mutations in KRAS codons 12 and 13, and both include their own internal controls. However, there is a need for external reference materials that allow laboratories to validate such assays - especially, at levels near their limits of detection (LODs). We describe the design of the SeraSeq FFPE Tumor KRAS Reference Material. This reference material is composed of 7 different 5-micron FFPE curls that contain the 7 different KRAS mutations detected by the companion diagnostics: G12A, G12C, G12D, G12R, G12S, G12V and G13D. Each curl contains a mixture of KRAS wildtype GM24385 cells and a KRAS mutant cell line in sufficient quantity for most assays. KRAS mutant frequencies of about 5% were targeted and subsequently verified by digital PCR. A 5% mutant frequency was selected because it is near the LOD for the existing companion diagnostics, and is close to the minimum reported frequency of many next generation sequencing (NGS)-based assays that test for somatic variants. The reference material was evaluated using different methods, which include digital PCR, the Roche cobas® KRAS Mutation Test, the QIAGEN therascreen® KRAS RQG PCR Kit and several NGS-based assays. Testing revealed general compatibility with these assays in that sufficient DNA could be extracted, and concordance of the results with the expected calls was high. For example, apparent DNA yields by Nanodrop with the cobas assay exceeded the required amount by more than 3-fold and all 7 curls led to a “mutation detected” result in duplicate testing. Interestingly, not all variants were detected with the therascreen assay, which may be due to some variants being present at slightly below the claimed LODs, however DNA yields were sufficient and the correct variants were identified. Finally, variant frequencies obtained by NGS were consistent with those observed by digital PCR. We conclude that the SeraSeq FFPE Tumor KRAS Reference Material may be useful as part of KRAS codon 12/13 assay validation.

Cancer immunotherapies are rapidly changing traditional treatment paradigms and expanding the therapeutic landscape for cancer patients. However, despite the current success of these therapies, significant number of patients do not respond to immunotherapy and responders often experience significant toxicities. Therefore, there is a growing need to identify predictive and prognostic biomarkers that enhance our understanding of dynamic immune mechanisms involved in cancer development. The genome-wide expression profiling of whole blood is an attractive method for the discovery of biomarkers due to its non-invasiveness, possibility for retrospective simple clinical site processing, and rich biological content. To this end, we have developed GeneNet, a genome-wide targeted RNA expression assay that profiles 19,000 genes based on multiplex RT-PCR followed by NGS in whole blood samples stabilized in PAXGene. The GeneNet 19K assay provides comprehensive and unbiased profiling of immune cell activation and canonical immune pathway genes for both innate adaptive and humoral immune responses. In this study, we present the performance of the assay for immunophenotyping of immune cells in blood samples from TNBC patients and healthy controls using high-throughput clinical applications.

#4653  Genomics of regulatory crosstalk between PPAR gamma & 14-3-3 genes in breast cancer cells. Ashraf A. Khalil,1 Nihal F. Kabapy,1 Fouad N. Sharabi2. 1City of Scientific Research, Alexandria, Egypt; 2Alexandria University, Alexandria, Egypt.

PPARγ, a ligand-stimulated transcription factor with differentiation promoting activity is overexpressed in a variety of cancers. Perturbation of PPAR-γ signaling is now believed to be a strategy for treatment of several cancers, including breast cancer. A set of genes regulated by PPAR-γ ligands is expected to favor growth and promote proliferative and immunosuppressive effects. Since 14-3-3 family of proteins shows a debatable activity and varying expression levels in different tumors, in the studies presented here we explored the transcriptional regulatory role of Pioglitazone on the seven 14-3-3 isoforms present in MCF-7 breast cancer cells. This study demonstrated that the potent PPAR-γ agonist, Pioglitazone exerted a regulatory role on expression of 14-3-3 genes where it upregulated 14-3-3 gamma, epsilon, zeta and tau by 3.4, 5.2, 2.7 and 739 folds, respectively. However, it had a negative regulatory effect on 14-3-3 beta, sigma and Eta by 16.94, 4.58 and 2.12 folds, respectively compared with control cells. These results correlated with growth arrest and a great increase in BRCA1 gene expression by 1076 folds. In summary, these findings are the first time showing that PPAR-γ regulates 14-3-3 genes and raises questions whether PPAR-γ ligands mediate their anticanccer effects via regulation of 14-3-3 proteins. Selected References: 1. Bridges, D. and G.B. Moorhead. 2005. 14-3-3 proteins. Selected References: 1. Bridges, D. and G.B. #4654  The primary study of the correlation between mRNA expression and protein phosphorylation of epidural growth factor receptor EGFR in colorectal and breast cancer cell lines. Hongwei Wang, Catherine Ma, Yuan Zhou. AbboMax, Inc., San Jose, CA.

The EGFR family is a group of receptor tyrosine kinases that mediates cell proliferation, migration, and differentiation. Activation of EGFR signaling is triggered by ligand-binding induced receptor dimerization. The dimerization activates the intracellular kinase domains of the receptor, resulting in autophosphorylation of C-terminal tail and the initiation of downstream signaling. EGFR overexpression is correlated with more aggressive clinical indications in multiple types of cancer, including colon, breast, lung, and head and neck carcinoma. Clinical studies show that EGFR-directed therapeutic approaches improved better outcomes of metastatic lung, colorectal, and head and neck cancers. Predictive biomarkers are being developed to deliver personalized therapies. Therefore, it is important to determine the protein as well as molecular biomarker expression for selecting targeted therapies. Here we present a panel cancer cell lines to examine EGFR expressions at a molecular biomarker level (mRNA) as well as a protein level of phosphorylated EGFR(pS1060). Colon cancer cell lines HT29, HCT116, SW620, as well as the breast cancer cell line SKBR3, were cultured and processed onto formalin-fixed paraffin-embedded (FFPE) CellMax Max pellets. Expression levels of EGFR mRNA in the FFPE slides were examined with RNAscope technology to visualize single RNA molecules per cell by using probes specifically against EGFR. Expression of phosphorylated EGFR was examined by the phosphospecific EGFR (pS1060) antibodies by using immunohistochemistry (IHC). EGFR mRNA expression was detected in HT29 and HCT116 cells showing strong punctuated signals in the cytoplasm. However, no EGFR mRNA signals were detected in SW620 cells. Breast cancer cell line SKBR3 showed abundant EGFR mRNA expression. Phosphorylated EGFR were found in the cell HT29, HCT 116 and SKBR3 cells with membrane staining.
pattern. No phosphorylated EGFR was observed in SW620 cells using Immunocytometry staining. Together, our results demonstrated that the EGFR mRNA expression is correlated to the phosphorylation of EGFR in these cancer cell lines. We concluded that the EGFR mRNA probes, phosphorylated EGFR antibodies, and/or the cell lines can be served as the control-references for clinical biomarker screening.

**4655 Elevated level of serum miR-99a is correlated with serous epithelial ovarian cancer and can be a potential biomarker.** Akihiko Yoshimura, Kenjiro Sawada, Koji Nakamura, Yasuto Kinose, Erika Nakatsuka, Seiji Mabuchi, Tadashi Kimura. Osaka Univ. Hospital, Suita, Osaka, Japan.

Objective: There is a critical need for improved diagnostic markers to detect ovarian high-grade serous cancer (HGSC). microRNAs (miRNAs) stably exist in circulating blood, reflecting tissue or organ conditions and present in circulating microvesicles such as exosomes. We aimed to identify which miRNAs are highly produced from HGSCs and analyze whether serum miRNA can discriminate patients with HGSC from healthy controls. Methods: Secreted exosomes from ovarian cancer cell lines were collected and exosomal miRNAs extracted. miRNA microarray was performed and several elevated miRNAs specific to ovarian cancer cells were picked up. Among these, we focused on miR-99a. Serum samples from patients with HGSC and healthy controls. Expression level of miR-99a was determined by miRNA RT-qPCR. Results: miRNA microarray revealed several miRNAs were highly expressed in exosomes in patients with HGSC. In patients, serum miR-99a levels were significantly high compared with the healthy controls. ROC analysis showed that at the cut-off of 1.4, the sensitivity and specificity were 73% and 80% respectively for detecting HGSC (AUC = 0.85). Conclusion: Exosomal miRNAs can be detected in sera of patients with HGSC and have the potential to predict ovarian cancer.

**4656 Assessment of BCL-2, BCL-xL and MCL-1 in bone marrow biopsy samples using VENTANA BenchMark XT automated slide stainer.** Ashley Streator, Eneida C. Villaneuva, Burton F. Holmes, Leping Zhang, Roche, Tucson, AZ.

Immunophenotyping is essential for diagnosis and classification of most hematopoietic malignancies, and often followed by ancillary studies to understand the predictive and prognostic value of biomarkers. Immunohistochemistry (IHC) provides in-situ coupling of antigen expression with morphology of precursor B- from precursor T-lymphoblastic leukemia/lymphoma. The number of different IHC antibodies that can be applied to bone marrow (BM) biopsies is increasing concurrently with development of flow cytometry and molecular diagnostic methods. IHC detects scattered tumor cells in Hodgkin’s Lymphoma, Multiple Myeloma (MM) and Acute Myelogenous Leukemia (AML), where key biomarkers may not be detectable by current flow cytometry methods. The goal of this study was to detect BCL-2, Bcl-xL and MCL-1 that are able to predict pre-clinical sensitivity to the drug Venetoclax. We examined the expression of these biomarkers in BM bone samples decalcified using commercially available reagents to determine whether decalcification methods impact BCL-2 family IHC staining. Results: MM bone samples (n=59) decalcified in Decal STAT™ for 20 min. post, for Venetoclax anti-BCL-2 (124) and Bcl-xL (546H2). BM bone samples (n=71) decalcified in Decal STAT™ for 60 min. stained for BCL-2 and BCL-xL. Finally, eleven MM bone samples decalcified in Richard Allan Decal Solution™ stained for BCL-2 and Bcl-xL. MCL-1 stained poorly with commercially available decalcification solutions. For MCL-1 to be used, additional staining optimization is required. Conclusion: BCL-2 and BCL-xL proteins can be detected in MM bone samples decalcified with commercially available solutions. With these preliminary results, future studies will pursue the potential for sensitivity to ‘Venetoclax’ (ABT-199/GDC-0199).

**4657 LOX and ZFPM2 as novel diagnostic biomarkers for malignant pleural mesothelioma.** Minkyu Kim, Hyun-Won Kim, Soon-Hee Jung, Sung Soo Oh, Youngik Jeong, Jong Whan Choi. Yonsei University Wonju College of Medicine, Wonju, Republic of Korea.

Malignant pleural mesothelioma (MPM) is a rare, aggressive cancer being developed on outlayer of lung tissues and caused by mostly occupational exposure to asbestos. Poor prognosis needs to develop therapeutic drug as well as early diagnostic biomarker. Currently, mesothelin (MSLN), osteopontin (OPN), and fibulin 3 (FBLN3) have been reported as potential diagnostic biomarkers for MPM. In this study, we first performed bioinformatics analysis for public database to find diagnostic biomarkers for MPM. From the analysis using Cancer Cell Line Encyclopedia (CCLE) and Gene Expression Omnibus (GEO) databases, included were 7 genes involving LOX, LOXL1, LOXL2, ZFPM2, THBS2, SULF1, CDH11 identified as potential diagnostic biomarkers. These genes showed a similar diagnostic ability to FBLN3 or MSLN as MPM biomarker candidates. Further molecular approach using quantitative real-time polymerase chain reaction (QPCR) confirmed the higher mRNA expression of these candidates in MPM cell lines and patient samples. Moreover, two particular genes, LOX and ZFPM2, showed MPM specific patterns of mRNA expression that were further confirmed in protein level by western blot. Together with biological approach, biostatistical analysis of receiver operating characteristic (ROC) analysis using the GEO database revealed significantly higher diagnostic potential of LOX and ZFPM2 genes compared to the FBLN3, one of the best diagnostic biomarkers currently reported. From this study, we believe these genes together with FBLN3 and MSLN would become novel potential biomarker candidates for MPM diagnosis.

**4658 Inflammatory based diagnostic markers of lung cancer in African Americans.** Claire L. Meany,1 Khadijah A. Mitchell,1 Adriana Zingone,2 Derek Brown,1 Wei Tang,1 Yunkai Yu,1 Liang Cao,1 Angela S. Wenzlaff,2 Ann G. Schwartz,3 Brid M. Ryan.1 National Cancer Institute, Bethesda, MD; 2Wayne State University, Detroit, MI.

African Americans have a higher risk of developing lung cancer compared with all other ethnic groups in the USA. Previous studies based on a small panel of markers suggested that certain circulating cytokines were associated with lung cancer. Given the complexity of the immune response in lung cancer and the multitude of cell types involved, we reasoned that examining a broad panel of inflammatory markers—including cytokines, chemokines, angiogenic and other pro-inflammatory factors—might identify a diagnostic signature of lung cancer for African Americans specifically. Among 30 inflammatory markers, serum levels were measured in 316 African-American cases and 508 African American controls from the National Cancer Institute-Maryland (NCI-MD) case-control study using a Mesoscale ( MSD) multiplex platform. The panel of 30 serum inflammatory markers included chemokines, cytokines and other inflammatory related proteins. Logistic regression analyses were conducted to investigate the association between levels of inflammatory marker expression and lung cancer risk. Expression levels above the median threshold defined within the control samples were considered high. Statistical models were also adjusted for potential confounding factors such as age, gender, pack-years and smoking status. Nineteen inflammatory markers (CRP, IFN-γ, IL-10, IL-15, IL-17A, IL-1α, IL-1β, IL-4, IL-5, IL-6, IL-7, IL-8, IP-10, MCP-4, MIP-1α, TARC, TNF-α, TNF-β and VEGF) were significantly different among African American cases compared with African American controls (P<0.05). In agreement with our previous observations, levels of IL-10, IL-1β, IL-6, IL-8, and TNF-α were associated with lung cancer risk. In addition, we found that CRP, IFN-γ, IL-15, IL-7, IP-10, MCP-4, MIP-1α, TARC, TNF-β and VEGF were associated with lung cancer in African Americans. The associations between CRP, IFN-γ, IL-10, IL-15, IL-1β, IL-6, IL-7, IL-8, IP-10, MCP-4, MDC, MIP-1α, TNF-α and TNF-β levels and lung cancer among African Americans was significant after adjustment for potential additional confounding factors. Serum cytokine levels vary by race and might contribute to lung cancer differently in African Americans and European Americans. The findings presented here build upon recent work that identified associations between elevated levels of IL-10, IL-1β, IL-6, IL-8, IL-10, VEGF and lung cancer cases specifically among African Americans. By analyzing a broader spectrum of inflammatory measures, we have identified additional markers of lung cancer for African American patients. Further to this, we have integrated GWAS and MSD data for 137 cases and 203 controls that allows us to examine the genetic basis to the relationship between risk of lung cancer and modulated inflammatory marker expression. Markers identified here as significant for lung cancer risk will be further analyzed using case-control samples from an independent African American validation cohort.

**4659 Detection of autoantibodies against tumor-associated antigens (TAAs) improving immunodiagnosis in human osteosarcoma by serological proteome analysis.** Jitian Li,1 Manyu Huang,2 Manli Luo,2 Leping Dai,1 Wen Xie,3 Xiaofei Qin,2 Zongchang Han,2 Wei Tang,1 Yunkai Yu,1 Liang Cao,1 Angela S. Wenzlaff,2 Ann G. Schwartz,3 Brid M. Ryan.1 National Cancer Institute, Bethesda, MD; 2Wayne State University, Detroit, MI; 3The University of Texas at El Paso, El Paso, TX.

osteosarcoma (OSA) is the most common malignant primary solid bone-tumor. Despite its relatively low incidence rate among overall cancers, it remains one of the most harmful primary malignant tumors in childhood and adolescence. Thus, a critical need in the diagnosis and management of OS is to determine an optimal combination of clinical biomarkers that can detect tumors early with high specificity/sensitivity and with limited invasiveness. The objective of this study is to identify and characterize the targeted tumor-associated antigens (TAAs) as biomarkers in OS by serological proteome analysis (SERPA)
approach, and further to analyze the frequency and specificity of anti-TAA antibodies in OS patients. In this initial study, autoantibodies to 29 TAAs were detected by ELISA and Western blotting in 90 sera from patients with OS, Osteochoondroma (OC), and age matched normal individuals. Only 8 protein antigens including DSF70, HMGB1, HCC1, RaA, c-myc, AnnexinA1, IMP1, PBP, can induce significantly higher antibody responses in OS individuals than those of normal individuals, achieving the highest sensitivity and specificity, 66% and 95%, respectively. The cumulative positive rate of autoantibodies against these eight selected TAAs in OS reached 70.7% with an observed AUC of 0.972 (95% CI: 0.867-0.988), significantly higher than that in normal control sera. Positive results were also confirmed by Western blotting. These preliminary data extensively indicate that all proteins identified in cancer can be used as TAA biomarkers in OS, and only some of these proteins can induce immune responses, which could be potential TAAs in OS immunodiagnosis or prognosis, and further studies of novel targeted proteins in OS are currently in progress by SERPA approach. In addition, it supports the hypothesis that a customized TAA array can be used for enhancing anti-TAA antibodies detection, and it may constitute a promising and powerful tool for immunodiagnosis of OS.

The purpose of this study is to investigate the differential expression of HPRT between various breast cancer tissues in comparison to healthy breast tissue in order to evaluate their potential use as a diagnostic tool. Breast cancer is the most common malignancy diagnosed in women and remains incurable in the metastatic setting requiring accurate and reliable tools for early diagnosis. We analyzed HPRT, a purine salvage pathway enzyme responsible for synthesizing 90% of the available GMP and IMP in cellular maintenance. Due to its critical role in maintaining necessary nucleotides for cell proliferation, we hypothesized an increase in the expression of HPRT in cancer. Tissues from 48 patients with breast carcinoma were stained using standard immunohistochemistry (IHC) techniques. We examined infiltrating ductal carcinoma, margin of carcinoma, hyperplasia, atypical hyperplasia, adenosis, collagen fibers tissues, and normal breast tissue in order to determine expression between various breast cancers. Briefly, tissues were treated with a polyclonal anti-HPRT antibody along with a GADPH positive control and a universal negative control. Tissues were incubated with an HRP-polymer conjugated antibody, and DAP substrate which reacts to antibody-antigen binding sites and results in a color change. Adenosis and hyperplasia are benign breast conditions and are early signs of breast carcinoma development. Hyperplasia tissues, which are in a state of rapid proliferation, showed significant upregulation of HPRT and adenosis tissues showed approximately 42% upregulation. This HPRT upregulation in pre-stage 1 tissues indicates that it may be used as a biomarker to detect early stages of breast cancer. Expression of HPRT was also found to be upregulated in 65% of infiltrating duct carcinoma showing high expression in active malignant areas. In marginal tissue located on the perimeter of primary tumors only 31% of tissues showed upregulation of the protein. Because the levels of HPRT in marginal tissue is significantly lower than those found in the tumor, HPRT may serve as a useful diagnostic tool when evaluating successful tumor removal. These data suggests HPRT as a useful diagnostic tool when identifying tissue with a high proliferation rate indicative of potential cancer development. Additionally, HPRT may also be used as a tool for pathologists to evaluate the success of tumor removal.

#4661 Omentin as an adjunct to CA-125 in detecting recurrent ovarian cancer. Kelsey Lewis, Chi Lam Au Yeung, Samuel Mok, Karen Lu. University of Texas MD Anderson Cancer Center, Houston, TX.

Omentin (Intestinal Lactoferrin Receptor ITLN1) is an adipokine that is mainly secreted by the mesothelial cells lining visceral adipose tissues. It has been shown in previous studies that ovarian cancer cells down-regulate omentin which allows increased proclivity to spread to the omentum. Levels of serum omentin are decreased in patients with high-grade serous ovarian cancer (HG-SOC) compared with patients with benign gynecologic diseases. Moreover, survival correlation studies showed that patients with lower serum omentin level at the time of first treatment experienced significantly shorter survival times than those with higher levels of omentin. CA-125 is currently the only biomarker used to monitor progression and re-occurrence of ovarian cancer. To our best knowledge, the relationship between omentin and CA-125 has not been investigated previously. We hypothesize that omentin may be a clinically useful adjunct to CA-125 in detecting recurrent ovarian cancer. 92 serum samples were collected prospectively from 27 HGSOCS patients during the postoperative period until recurrence was detected. Patients had an average of 3.37 follow up visits and CA-125 levels were concurrently established. Recurrence was determined by imaging or an increase from baseline in CA-125 level. Samples were stored frozen at -80 degrees Celsius until use for this study. Circulating omentin levels were quantified using commercially available enzyme-linked immunosorbent assay (ELISA) and showed that there was a significant decrease in CA-125 level during the postoperative period and 12 of these patients had an associated decrease in serum omentin level (average = 127.8 ng/mL). A significant negative correlation between omentin and CA-125 levels was observed (p = 0.02). This study provides the first evidence that omentin may be a clinically useful adjunct to CA-125 in detecting recurrent ovarian cancer and warrants further investigation.

#4662 Expression of PLAG1 in salivary duct carcinomas: its efficacy of the distinction of carcinoma ex pleomorphic adenoma type and de novo type. Takayoshi Suzuki, Satoshi Kano, Kanako Hatanaka, Yutaka Hatanaka, Tomohiro Sakashita, Takatsugu Mizumichi, Hiromitsu Hatakeyama, Akhiro Homma, Yoshhiro Matsuno, Satoshi Fukuda. Hokkaido University, Sapporo, Hokkaido, Japan.

Salivary gland duct carcinoma (SDC) is one of the high-grade salivary gland carcinoma, classified into two patterns; i) carcinoma ex pleomorphic adenoma (Ca–ex-PA) type, which is derived from benign pleomorphic adenoma (PA), ii) de novo type, which is generated from normal salivary gland tissue. According to current WHO classification, Ca–ex-PA is diagnosed when pathological examination proves as follows, a) the mixture of the component of cancer cells and that of pre-existing PA cells, b) the existence of malignant cells after the resection of PA. However, current criteria cannot entirely be accurate from the viewpoint of disease onset. For example, i) if a benign component of PA is replaced completely by Ca–ex-PA, the Ca–ex-PA type can be misdiagnosed as de novo type because histopathological examination cannot clarify the existence of PA in its surgery specimen. Moreover, ii) if a de novo type SDC, arising from normal salivary tissue, is growing and infiltrate to the preexisting PA, the de novo type SDC can be misdiagnosed as Ca–ex-PA type. Recently, Pleomorphic adenoma gene 1 (PLAG1) has been identified as the gene associated with tumorigenesis of PA. Subsequently, the overexpression of PLAG1 protein has been reported to be observed in both PAs and Ca–ex-PAs and useful for diagnosis of them. Thus, we considered that PLAG1 immunohistochemistry can enable us to distinguish Ca–ex-PA type and de novo type in SDCs more definitively. In this study, 23 SDC patients who underwent primary surgery for cancer at our institution were enrolled, including 14 Ca–ex-PA types and 9 de novo types. In each case, we had its formalin-fixed-paraffin-embedded tissue sample stained for PLAG1-antibodies (clone 3B7, Mouse mAb, 1:100, Abnova) and evaluated PLAG1 protein expression in the component of glandular-epithelial component and that of non-glandular-epithelial, respectively. PLAG1 immunostaining was scored as positive when the more than 10% nuclear staining of tumor cells are observed. In all 23 SDCs, there was no PLAG1 protein overexpression in glandular-epithelial component, irrespective of benign or malignant. In all 14 Ca–ex-PA types, positive findings of PLAG1 overexpression were observed in non-glandular-epithelial component. In all 9 de novo types, no non-glandular-epithelial component showed any ELISA protein overexpression. There was no experienced difference in conventional criteria and the status of PLAG1, which are the cases; i) Ca–ex-PA which is misdiagnosed as de novo type, ii) de novo type which is misdiagnosed as Ca–ex-PA type. Conclusions : There is no difference between conventional criteria and PLAG1-based criteria in our cases. However, in the cases with obscure characteristics of PA morphologically, such as mucoid/myxoid or cartilaginous-like materials, findings of PLAG1-positive cells can help us to distinguish Ca–ex-PA type from de novo type more definitively.

In the tumor microenvironment, matrix metalloproteinase 9 (MMP9) cleaves and activates substrates such as VEGF, IL8 and TGFβ that promote tumor growth through angiogenesis and immune suppression. Data from preclinical models supports the hypothesis that inhibition of MMP9 reduces local immune suppression, resulting in increased anti-tumor immunity. GS-5745 is a monoclonal antibody in clinical development that is a selective inhibitor of MMP9. The effect of GS-5745 + mFOLFOX6 (GS + chemo) on systemic biomarkers related to MMP9 activity, and immune suppression and activation, was explored in samples from patients in the gastric cancer cohort of the phase 1b study, NCT01803282. Immunoassay analysis of a set of serum proteins based on...
MMP9 biology and preclinical data (including 10 MMP9 substrates, 5 MMP9 TIMPs and 25 inflammatory markers) are reported; exploratory analyses of a larger set will be presented. Total and GS−/MMP9− free MMP9 was measured using a proprietary validated assay. Serum was collected at baseline and the start of every 28-day cycle from 40 gastric cancer patients treated with GS + cheemo every 2 weeks, and was stored at −80°C until assay. Levels were measured using the Luminex assay and compared with a control group of non-cancer patients. Multiple testing adjustment was based on false discovery rate. GS + cheemo treatment resulted in a significant decrease of MMP9 levels in serum (p = 0.007). MMP9 protein expression was significantly higher in GS + cheemo patients with metastatic disease compared to those without metastatic disease (p < 0.05). The expression of MMP9 in the experimental group was significantly higher than the control group (p = 0.007).

#4665 Induction of receptor tyrosine kinase signaling by sera from patients with lung adenoarcinoma.

Gabriela C. Lobato, Jared D. Faikoff, Imad Tarhoun, Nolomar Lund, Vinuela Chakupallala, Selina Saydine, Cristina L. Flied, Sanjib Basu, Wen-Rong Lie, Michael J. Liptay, Philipp Bonomi, Jeffrey A. Borgia, Rush Univ. Medical Ctr., Chicago, IL.

Background: The objective of this study was to evaluate disease stage-associated differences in receptor tyrosine kinase (RTK) signaling in A549 cells using pretreatment sera from cases of pathologically-confirmed lung adenocarcinoma or control cases derived from a lung cancer screening study. This was accomplished as a means to explore the hypothesis that circulating concentrations of decoy receptors and/or ligands, as well as disease-specific ligand degradation all regulate RTK signaling in vivo. Methods: Pretreatment peripheral blood were prepared from either from non-cancer control patients (n = 30) or those with lung adenocarcinoma, consisting of stage I (T1–N0M0, n = 25); locoregional progressed (T1–N1M0, n = 36) or disseminated, stage IV disease (n = 43). All patients were enrolled with written informed consent to our IRB-approved, institutional biorepository. Confluent cultures of A549 cells were stimulated for 40 minutes with patient sera diluted 1:1 in RPMI-1640 followed by immediate whole cell lysate preparation. After protein determinations by BCA, 8.5 µg of each sample was interrogated using the Human RTK (phosphoprotein) kit from Millipore. Data were analyzed according to manufacturer’s in vitro data. After being normalized to the kit-supplied (stimulated) HEK cell lysates, all resulting data were evaluated by one-way ANOVA (LSD and Tukey post-hoc) for categorical comparisons. Results: The most commonly observed differences in RTK signaling was noted upon comparing cohorts with locoregional (T1–N1M0) progression and disseminated (stage IV) disease. Levels of in c-Met and receptor (IR) signaling were higher in patients with stage IV disease relative to those with locoregional disease by 24% and 10%, respectively (both p < 0.01); whereas induction of c-KIT, VEGFR3, and Tie-1 were reduced by 12.8%, 6.67%, and 17.3%, respectively (all p < 0.05). Circulating levels of HGF were previously observed by our group to be 25% higher in stage IV patients relative to those with locoregional disease (p < 0.005) - agreeing with our observation in direction of change, though not significant. This is in contrast to levels of VEGF-C and VEGF-D, previously being observed elevated 51% and 452% (both p < 0.001) in these same cohorts. Also of note was the 1.9 fold decrease in ability of sera from stage I patients to stimulate IGF-1R signaling relative to control patients (p = 0.002). We have previously reported a 12% increase in IGF-1 levels between these groups (p < 0.002), though we observed no changes in IGF binding proteins that could account for the observed differences in IGF-1R signaling. Conclusions: We observed an apparent discoupling of certain circulating ligands in patient sera to stimulate their respective RTKs in a disease stage-specific manner. We are currently evaluating levels of circulating ligands, potential disease stage-associated (partial) proteolytic degradation, and decoy receptors to help explain these observations.

#4666 DREAMing as a simple and low cost alternative for the assessment of methylation in ultra rare DNA.

Thomas R. Pisani,1 Pornpat Athamanolap,1 Brenda F. Miller,2 Vincent Wu,2 Laura Elnitski,1 Tza-Huei Wang1. 1Johns Hopkins University, Baltimore, MD; 2National Institutes of Health, Rockville, MD.

Background: Current approaches for the assessment of methylation, such as methylation-specific PCR (MSP) and next-generation bisulfite sequencing (BS-Seq) are fundamentally limited in their ability to detect and assess heterogeneous methylation patterns (epialleles) in ultra-rare (<0.1%) DNA. These limitations critically compromise diagnostic utility and render them ill suited for many emerging applications in cancer diagnostics, such as the analysis of methylation heterogeneity in cell-free DNA (cfDNA) and rare cell populations. We recently addressed the need for a low cost alternative to the assessment of methylation in ultra-rare DNA with the development of DREAMing (Discrimination of Rare EpAlleles by Melt), which utilizes semi-limiting dilution and precise melt curve analysis to distinguish and enumerate individual copies of DNA at single copy sensitivity and single-CpG-site resolution. Here, we seek to demonstrate the advantages of the DREAMing method over conventional approaches to methylation assessment. Methods: We expand upon the underlying theory of DREAMing and provide guidelines for the development of single-copy sensitive DREAMing assays. We further elucidate methods for tailoring DREAMing assay tests to patients of interest and compare the performance of these assays to commonly employed techniques including quantitative MSP (qMSP) and BS-Seq. Results: Development of single-copy sensitive DREAMing assays for a
Background: Hepatocellular carcinoma (HCC) typically occurs in patients with chronic liver disease. Such diseases create a demand for liver regeneration due to injury, which in turn promotes upregulation of c-Met, a receptor for hepatocyte growth factor (HGF) involved in wound healing, leading to increased cellular proliferation, survival, and mobilization. c-Met is the product of the MET proto-oncogene. Increased MET expression is associated with wound healing but can also contribute to the development and progression of HCC. Ablation of c-Met signalization is associated with rapid tumor growth and aggressively invasive disease in HCC, resulting in poor patient prognosis. We examined c-Met expression and MET gene amplification in 69 procured HCC samples and c-Met expression in adjacent non-tumor tissue. Methods: c-Met expression was evaluated using MET IHC and MET gene amplification. MET IHC was performed using the pharmDx anti-c-MET (clone D1C2) rabbit mAb. c-Met expression was scored semiquantitatively on a scale of 0-3+ based on the staining intensity in ≥50% of cells [Koopman et al. Proc UCSC 2012 (abstract 2001)]; tumors scoring 2+ or 3+ were judged positive. MET gene copy number (GCN) was assessed using the MET IQFISH Kit 111480 with a probe covering a 269 kb segment on chromosome 7q12 containing the MET gene. Tumors were considered to be FISH positive if scored cells had a mean MET/CEN7 ratio ≥2.0 or ≥50% of cells contained ≥5 MET signals. Results: All cases showed typical HCC morphology and were classified as low to high grade trabecular, pseudoglandular, or solid with common cytoplasmic features. The tumors and cells of the adjacent cirrhotic/non-cirrhotic liver tissue (bile duct epithelia, hepatocytes endothelial cells) showed cytoplasmic and membrane staining with strong expression and c-Met staining heterogeneous and present in 68/68 cases. Semiquantitative analysis showed that 11/67 (16%) tumors were c-Met-positive (3+, 5+). Results: All 69 cases were evaluated for MET gene amplification. Six out of 69 (8.7%) were amplified by ratio and 3 (4.3%) others had ≥5 MET gene copies in ≥50% of cells, giving an overall frequency of FISH positivity of 13%. Most interestingly, amplification and/or increased gene copy number was homogeneous throughout the tumor in all cases, in contrast to heterogeneous c-Met staining observed in some of the same tumors with IHC. Five of the 11 c-Met-positive (IHC 2+/3+) tumors were MET amplified, and all 3 of the IHC 3+ tumors were amplified. Conversely, 4 of the 9 FISH-positive tumors were c-Met-negative. Conclusions: These data provide insight into the frequency of c-Met/MET abnormalities in HCC and show there is discordance between c-Met protein expression and MET GCN alterations. This may be of importance for selection of patients with HCC for clinical trials of c-Met inhibitors.

#4669 Circulating cytokines as biomarkers of BEP toxicity in TGCTs patients. Daniela Svetlovska,1 Viera Miskovska,2 Dana Cholujova,3 Paulina Gronesova,4 Silvia Cingelova,5 Michal Chovanec,4 Zuzana Sycova-Mila,4 Jana Obertova,4 Patrik Palacka,4 Vanda Usakova,5 Katarina Kalavska,6 Jan Luha,6 Dalibor Ondrus,2 Stanislav Spanik,7 Jozef Mardiak,1 Michal Mego. 1. St. Elisabeth University of Health and Social Sciences and St. Elisabeth Cancer Institute; Comenius University, Bratislava, Slovakia.

Background: Cytokines are key components in process of inflammation and immune response, what are important processes in many toxicities. Bleomycin, etoposide, cisplatinum (BEP) is a standard treatment in patients with testicular germ cell tumors (TGCTs). Grade 3/4 toxicity can be dose limiting and can highly influence patient’s quality of life. Our aim was to investigate correlation between circulating cytokines and BEP toxicity in TGCTs patients. Methods: The study population consisted of chemotherapeutic TGCTs patients treated by BEP chemotherapy. Grade 3 and 4 toxicities were assessed according to the Common Terminology Criteria for Adverse Events (CTCAE) version 4.0 after first cycle of chemotherapy. G-CSF was administered to all patients after chemotherapy. Circulating 51 plasma cytokines were analyzed at baseline before chemotherapy administration (94 patients) and on cycle 1 day 22 (57 patients) using multiplex bead arrays. Toxicities were correlated to pretreatment and posttreatment levels of circulating cytokines. Spearman’s correlation test was used to analyze the association between cytokines and toxicity. Results: Significant correlations between grade 3/4 toxicity and cytokines were observed. Neutrophilia was associated with elevated pretreatment levels of TGF-beta 2, IL-2 alpha, HGF, MIG, NGF-beta, SDF-1 alpha, IL-1beta, IL-4, IL-5, IL-17, IFN-beta, G-CSF, MIP-1alpha and posttreatment elevated levels of GRO-alpha, TNF-beta. Thrombocytopoenia related with higher pretreatment levels of IL-2alpha, IL-18, M-CSF and higher posttreatment IL-3, IL-12p40, GRO-alpha, MCP-3, M-CSF, MIP-1alpha, NGF-beta. Anemia correlated with elevated pretreatment IL-16, GRO-alpha, HGF, MIF, NGF-beta, SCF, SDF-1alpha, MCP-1, M-CSF and elevated posttreatment IL-2 alpha, IL-12p40, CCL-5, CCL-3, MIP-1alpha, MIP-1beta, G-CSF, M-CSF, TNF-alpha. CLINICAL RESEARCH: Diagnostic Biomarkers

#4668 Analysis of c-Met protein expression by immunohistochemistry and MET gene copy number in hepatocellular carcinoma. Christian Ilhing,1 Sienna Yoast,2 Matthew DeNicola,3 Josef Straub,2 Klaus Ducker,1 Karsten Nielsen,1 Russell A. Baldoch,4 Aaron B. Ellison,2 Holly Yamada1. 1. Merck KGaA, Darmstadt, Germany; 2. Dako North America, an Agilent Technologies company, Carpinteria, CA; 3. Mission Pathology Consultants, Santa Barbara, CA; 4. Dako Denmark A/S, an Agilent Technologies company, Denmark; 5. Hemediagnostics, San Marino, CA.

number of loci associated with classic tumor-specific methylation such as CHFR and RASSF1A as well as a candidate pan-cancer locus are reported. These assays are then used to analyze methylation in cDNA derived from the plasma of cancer-positive and healthy patients. DREAM analysis reveals that DREAMing can readily detect over an order of magnitude more epimutations when directly compared to target DNA. Its low assay of sensitivity and its utility in providing enhanced, single-copy detection of heterogeneous methylation make DREAMing an attractive method for the assessment of locus-specific methylation in samples containing ultra-low amounts of DNA. By virtue of their clonal nature, high mutation rates and copy number, assessing tumor-specific mitochondrial DNA (mtDNA) mutations in histologically clean LN may be possible in a more sensitive diagnostic tool and eventually reduce the false negative rate in patients. Additionally, due to its circular configuration, mtDNA thought to be more stable than genomic DNA, and may also be suitable for sequencing formalin-fixed paraffin-embedded (FFPE) -derived genomic material, an invaluable resource for clinical research. However, current methods for library preparation are still imperfect for detection of low prevalence variants and heterogeneous tumors with high depth of coverage especially in highly degraded samples. To this end, we aimed to set up a novel NGS assay for mtDNA analysis in primary and metastatic samples. Amplicon-based NGS library preparation approach, consisting of 148 primers pairs that cover the entire mitochondrial genome (with a dual coverage of 86.18%) was designed in collaboration with Fluidigm to be used on Access Array® platform. To enhance the coverage of degraded material the amplicon size was limited to ~170 base pairs. Primers for three nuclear housekeeping genes were added to the panel to allow quantitative copy number analysis. To address mitochondrial mutational patterns, heteroplasmy and heterogeneity, we have used this novel high-throughput enrichment technology to sequence mtDNA from different areas of 16 primary HNSCC tumors (fresh frozen and FFPE), and multiple matched metastatic or histologically clean LN tumors with high depth of coverage especially in highly degraded samples. By using the combination of these methods, we could assess mutations in cases of minimal detectable tumor component, thus improving the sensitivity of mtDNA analysis in clinical samples.
ment levels of IL-16, HGF, M-CSF, SCGF-beta. There were many positive associations between pylophenones and pretreatment IL-2R alpha, IL-18, M-CSF, NGF-beta and posttreatment IL-2R alpha, IL-3, IL12p40, CTACK, HGF, MCP-3, M-CSF, NGF-beta, SCGF-beta, IL-6. Diarrhea related with higher pretreatment levels of IL-15 and also higher posttreatment IL-15, GM-CSF and lower posttreatment levels of IFN-alpha. CTACK. Several other associations were detected between elevated posttreatment levels of cytokines and toxicities: nausea and SCGF-beta, febrile neutropenia and GRO-alpha, TNF-beta, SIRS and GRO-alpha, PDGF-BB. All correlations were significant P < 0.05. Conclusions: Circulating cytokines are promising and easily detectable biomarker for predicting BEP toxicity in TGCTs patients. This work was supported by the Slovak Research and Development Agency under the contracts No. APVV-0016-11 and APVV-15-0566.

CLINICAL RESEARCH: Epigenetics and DNA Repair

#4670 Identification of a possible therapeutic candidate for multiple myeloma based on dual inhibition of EZH1/EZH2. Makoto Nakagawa,1 Shuhei Fujita,1 Daisuke Honma,1 Nobuaki Adachi,1 Kazuushi Araki,2 Issay Kitabayashi1

1National Cancer Center Research Institute, Tokyo, Japan; 2Daiti Sanky Co., Ltd., Tokyo, Japan

Multiple myeloma (MM) is largely incurable as the disease eventually relapses despite the recent development of novel therapies. Previous reports show that side population (SP) cells comprise myeloma stem cells. Therefore, targeting SP cells may be a promising strategy for preventing and treating MM relapse. Polycomb repressive complexes 1 (PRC1) and 2 (PRC2) are important epigenetic regulators that maintain the "stemness" of ES cells and other hematopoietic stem cells. Enhancer of zeste homolog 1 and 2 (EZH1/2) are catalytic components of PRC2, which trimethylate histone H3 at lysine 27 to repress transcription of regulatorsthatmaintainthe "stemness"ofEScellsandotherhematopoieticstem cells. Mutation and overexpression of EZH2 are associated with many cancers, including MM. Here, we found that SP cells expressed significantly higher levels of EZH1/2 than non-SP cells. These results suggest that overexpression of EZH1/2 is important for maintaining the stemness of MM cells and that EZH1/2 could be a potential therapeutic target. We developed a novel EZH1/2 dual inhibitor, OR-S1, and used it to investigate the effect of pharmacologic inhibition of EZH1/2 on MM. OR-S1 suppressed the proliferation of almost all MM cell lines tested, with an IC50 significantly lower than that of the specific EZH2 inhibitor, GSK126. Furthermore, flow cytometry analysis revealed that OR-S1 significantly depleted the SP cell population. RNA-seq analysis revealed that the transcriptional profiles of MM cell lines treated with OR-S1 were characterized by up-regulation of genes related to the Wnt pathway. qRT-PCR confirmed that expression of Wnt, Frizzled, and Protein kinase C family members that the transcriptional profiles of MM cell lines treated with OR-S1 were characte-

#4672 Novel epigenetic approach to relapsed mantle cell lymphoma based on dual inhibition of EZH1/EZH2. Shuhei Fujita,1 Yuki Kagiya,1 Daisuke Honma,2 Nobuaki Adachi,1 Kazuushi Araki,3 Issay Kitabayashi1

1National Cancer Center Research Institute, Tokyo, Japan; 2Daiti Sanky Co., Ltd., Tokyo, Japan

Mantle cell lymphoma (MCL) is a well-defined and aggressive type of B cell non-Hodgkin’s lymphoma that is genetically characterized by the t(11;14)(q13; q32) chromosomal translocation, which results in constitutive overexpression of CYCLIN D1. Although newly developed drugs such as ibrutinib show promising clinical outcomes, relapsed MCL often acquires drug resistance, which is a critical obstacle to treatment. Alternative approaches to overcoming the drug resistance of relapsed MCL are urgently needed. PRC2 and 2 are important epigenetic regulators that maintain the stemness of embryonic and hematopoietic stem cells. EZH1 and 2 are catalytic components of PRC2, which trimethylates histone H3 at lysine 27 (H3K27) to repress transcription of target genes. Mutation and overexpression of EZH1/2 are associated with cancers, including hematopoietic malignancies. Here, we used a novel dual inhibitor of EZH1/2 to show that inhibiting EZH1/2 is a promising therapeutic strategy for MCL. First, we developed a xenograft (PDX) mouse model using cells from a heavily pretreated patient with MCL. We generated tumor xenografts in mice bearing MM xenografts led to significant impairment of subcutaneous tumors. Interestingly, long-term administration of the drug at lower doses to mice bearing ortothoptoxic xenografts resulted in complete eradication of minimal residual disease from the bone marrow and complete cure of MM without any serious side effects. Furthermore, OR-S1 treatment of an orthotopic PDX model derived from a relapsed and heavily pretreated MM patient led to a reduction in the levels of human immunoglobulins in the serum. Taken together, these results strongly suggest that dual inhibition of EZH1/2 is a promising therapeutic approach to eradicating myeloma stem cells and could lead to important advances in the treatment of MM.

#4671 Co-occurrence of alterations in the DNA damage repair genes synergize with uncontrolled proliferation and associate with very poor prognosis in acute myeloid leukemia patients. Partner and localizer of BRCAl (PALB2) plays a key role in the DNA damage repair (DDR) by recruiting BRCA1, BRCA2 and RAD51. Alterations in PALB2 were described in hereditary breast cancer and Fanconi Anemia (FA). Little is known in Acute Myeloid Leukemia (AML). Aim of the study is to define the frequency and interplay of PALB2 alterations with patterns of somatic muta-

Clinical pathways for patients with acute myeloid leukemia (AML) are based on cytogenetic and molecular features. However, a large proportion of AML patients have no recognizable abnormalities in their karyotype, raise new challenges to clinicians. In this study, we analyzed the association of PALB2 loss with clinical outcomes, relapsed MCL often acquires drug resistance, which is a critical obstacle to treatment. Alternative approaches to overcoming the drug resistance of relapsed MCL are urgently needed. PRC2 and 2 are important epigenetic regulators that maintain the stemness of embryonic and hematopoietic stem cells. EZH1 and 2 are catalytic components of PRC2, which trimethylates histone H3 at lysine 27 (H3K27) to repress transcription of target genes. Mutation and overexpression of EZH1/2 are associated with cancers, including hematopoietic malignancies. Here, we used a novel dual inhibitor of EZH1/2 to show that inhibiting EZH1/2 is a promising therapeutic strategy for MCL. First, we developed a xenograft (PDX) mouse model using cells from a heavily pre-

Proceedings of the American Association for Cancer Research • Volume 58 • April 2017
that a cyclin-dependent kinase inhibitor, CDKN1C (TP57), was one of the genes most markedly upregulated by OR-S1. ChIP qPCR of MCL cell lines showed that the CDKN1C locus was strongly marked by H3K27 trimethylation, and that OR-S1 induced a significant reduction in the level of this histone marker. Furthermore, administration of OR-S1 alone to PDX mice induced increased expression of CDKN1C (as in the in vitro assay). Thus, dual inhibition of EZH1/2 in MCL induces expression of CDKN1C, which in turn causes cell cycle arrest and reduced growth of MCL. Taken together, these results strongly suggested that dual inhibition of EZH1 and EZH2 is a promising therapeutic strategy for MCL, illustrating the potential of novel epigenetic approaches to overcoming drug resistance of relapsed MCL.

#4673 EZH2 as a therapeutic target in glioblastoma: a cellular and molecular study. Javier de la Rosa,1 Marta Ibarbu,1 Gabriel Gallo-Oller,1 Alejandro Urdicain,1 Xing Fan,2 Mehdi H. Shahi,3 Bárbara Meléndez,4 Juan A. Rey,5 Miguel A. Idote,6 Javier S. Castrejana1. 1Univ. of Navarra, Pamplona, Spain; 2University of Michigan, Ann Arbor, MI; 3Aligarh Muslim University, Aligarh, India; 4Virgen de la Salud Hospital, Toledo, Spain; 5La Paz University Hospital, Madrid, Spain; 6Univ. of Navarra Clinic, Pamplona, Spain

Glioblastoma is the most common and deadliest malignant brain tumor in adults. It is currently treated with a combination of surgery, radiotherapy and chemotherapy with temozolomide (TMZ). Resistance to TMZ is a challenge in the treatment of this type of brain cancer. Epigenetic modulation is a new possibility to be tested against glioblastoma. Inhibition of EZH2, a histone methyltransferase (H3K27me3) which is overexpressed in cancer cells, leading to anangiogenesis and metastasis, might be a new strategy to treat this tumor. In this work, the EZH2 inhibitor DZNep was tested in A172 glioblastoma cells and in A172-TMZ-resistant glioblastoma cells. Inhibition of cell proliferation, cell adhesion, colony formation, and cell migration was noted in A172 and A172-TMZ-resistant glioblastoma cells after DZNep treatment. DZNep also decreased EZH2 expression, and increased the expression of its target genes (E-cadherin and TIMP3), which might probably contribute to inhibiting the development of a cancer metastatic phenotype. Finally, DZNep negatively regulated the TGFβ pathway: the expression of receptors involved in this pathway (TGFβRI and TGFβR2) was decreased, and the expression of inhibitors of this pathway (BAMBI, SMAD6 and SMAD7) was increased. In order to support the results obtained by qRT-PCR about the TGFβRI pathway, protein expression of SMAD2 and SMAD3 was analyzed by Western blot. The ratio between PS-MAD2/SMAD2 decreased in cells treated with DZNep, which supports the possible therapeutic effect of this drug against the TGFβ pathway, as SMAD2 is a negative prognostic marker in glioblastoma. In conclusion, we propose that inhibition of EZH2 might be considered as a therapeutic strategy against glioblastoma.

#4674 Epigenetic modifiers for the treatment of invasive lobular carcinoma breast cancer. Louise Walsh,1 Bruce Moran,2 Sudipto Das,3 Finn Barr Tarrant,4 Philip Schouten,5 Suet-Fewing Chin,6 Rene Bernards,7 Carlos Caldas,8 William Gallagher,9 Triona Ni Chonghaile10,11 Darran O’Connor12,13. 1Royal College of Surgeons in Ireland, Dublin, Ireland; 2University College Dublin, Dublin, Ireland; 3The Netherlands Cancer Institute, Amsterdam, Netherlands; 4University of Cambridge, Cambridge, United Kingdom

Invasive lobular carcinoma (ILC) is a breast cancer subtype comprising 10% of breast tumors. The majority of ILC (90%) are estrogen receptor (ER)-positive and therefore candidates for endocrine therapy. Unfortunately, de novo resistant to endocrine therapies occurs in 33% of women and a further 40% will relapse on treatment. Therefore, novel therapeutic targets are required for ILC. Deregulated transcription is a recurring theme in cancer, which can be due to epigenetic events. The bromodomain & extra-terminal domain (BET) family of proteins (BRD2, BRD3, BRD4, BRD4DT) function as chromatin readers that bind acetylated lysine residues on histones and regulate transcription. We performed RNA-Sequencing analysis on 61 primary ILC samples and found that high expression of BRD3 is associated with poor survival in ILC (log rank test, P = 0.037). We validated this finding, that high expression of BRD3 is associated with poor survival, in a second cohort of 99 ILC primary samples from the METABRIC dataset (log rank test, P = 0.0157). Next, we tested if ILC cell lines were sensitive to BET inhibition using the small molecule inhibitor JQ1, which inhibits all BET family proteins. JQ1 downregulates growth and survival genes in ILC cell lines including MYC, ER and BCL-XL. Pathway analysis following RNA sequencing revealed that JQ1 targets the apoptotic and Wnt signalling pathways in ILC cell lines. Interestingly, JQ1 inhibited the cell growth in all ILC cell lines tested, however apoptosis was only induced in two ILC cell lines. Furthermore, ILC cell lines which were relatively resistant to JQ1-induced apoptosis expressed both the BCL-2 and BCL-XL anti-apoptotic proteins. This led us to assess the combination of JQ1 and the BH3 mimetics, ABT-199 and ABT-263. ABT-199 is a selective small molecule inhibitor of BCL-2, whereas ABT-263 is an inhibitor of BCL-2, BCL-XL and BCL-W proteins. We found the combination of JQ1 and ABT-263, but not the combination of JQ1 & ABT-199, to be synergistic and enhance apoptosis in ILC cell lines. This is in accordance with BH3 profiling of ILC cell lines, which indicated that ILC cell lines are dependent on BCL-2 and BCL-XL proteins for cell survival. As JQ1 is a pan-BET family inhibitor, we also wish to determine which BET protein is responsible for sensitivity to JQ1. Following knockdown of each BET protein in the CAMA-1 cell line we found that BRD3 and BRD4 were responsible for loss of cell viability. Future work will include determining the specific role of BRD3 in ILC and the effectiveness of the JQ1 & ABT-263 combination in vivo. Our work suggests that inhibition of BET proteins in combination with BH3 mimetics may be a rational therapeutic combination for ILC.

#4675 Novel combination therapy of DNA methyltransferase inhibitor guadecitabine (SGI-110) and PARP inhibitor talazoparib (BMN-673) for BRCA-proficient high-grade serous ovarian cancer. Nicholas Pulliam,1 Pietro Taverna,2 John Lyons,3 Kenneth P. Neophy,4 Indiana University, Bloomington, IN; 5Astex Pharmaceutical, Inc., Pleasanton, CA; 6Astex Pharmaceutical, Inc., Cambridge, United Kingdom

Ovarian cancer recurrence has been shown to be associated with increased DNA damage response (DDR) mediated by poly-(ADP)-ribose polymersase 1/2 (PARP1/2), which can be therapeutically targeted by PARP inhibitors (PARPi). PARPi are indicated for platinum-responsive, BRCA-mutated high-grade serous ovarian cancer (HRGSC), but most ovarian cancer patients have DNA double-strand break (DSB) repair deficiencies (BRCA1/2) or TP53 mutations (platinum resistant, BRCA2 mutant) which result in a decreased response to PARP inhibitor treatment. Our previous studies support a role for DNA methylation in chemoresistance to platinum chemotherapy. Therefore, we hypothesized that combining a DNA methyltransferase inhibitor (DNMTi) and a PARP inhibitor results in enhanced cytotoxicity in high-grade serous ovarian cancer cell lines harboring either wild type- or mutant-BRCA, indicating that PARPi are indicated for platinum-responsive, BRCA-mutated high-grade serous ovarian cancer.

#4676 DNA repair protein expression and response of homologous recombination deficient ovarian cancer to the poly(ADP-ribose) polymersase (PARP) inhibitor rucaparib in the ARIEL2 Part 1 study. Andrea E. Wahner Hendrickson,1 Kevin K. Lin,2 Daniel W. Visscher,2 Rachel M. Hurley,3 Mitch Raponi,2 Thomas C. Harding,4 Linda M. Murphy,1 Jill M. Wagner,1 Heidi Giordano,2 Iain McNeish,2 Elizabeth M. Swisher,2 Scott Kaufmann3,4. 1Mayo Clinic, Rochester, MN; 2Cleveland Oncology, San Francisco, CA; 3University of Glasgow, Glasgow, United Kingdom; 4University of Washington, Seattle, WA

Background: PARP inhibitors (PARPi) are active in cancers with homologous recombination defects (HRD) and PARPi sensitivity is correlated with HR activity. Preclinical studies have shown that secondary mutations or alterations in gene expression (e.g., downregulation of 53BP1, Ku70, Ku80 or DNA-PKcs) restore HR and confer PARPi resistance. In addition, low PARPi expression can diminish PARP trapping and cause PARPi resistance. ARIEL2 Part 1 is a phase 2 study of the PARPi rucaparib in platinum-resistant ovarian cancer cell lines harboring either wild type- or mutant-BRCA, indicating that the PARPi-gaudecitabine drug combination is effective regardless of BRCA-mediated DDR and may represent an effective treatment regimen for BRCA-related cancers.
sensitive, relapsed high grade serous or endometrioid ovarian cancer (OC). Pretreatment OC biopsies were previously assessed for HR gene mutations and loss of heterozygosity (LOH), a genomic scar that reflects HR deficiency. Two tumor groups (BRCA wildcard [wt]/LOH high and BRCA1 or BRCA2 mutant) have objective response rates of 29.3% and 80%, respectively, as well as progression free survival of 12.8 months, respectively, on rucaparib (E. Swisher et al., Lancet Oncol., in press). Common AE included nausea (80%), asthenia/ fatigue (78%), constipation (46%), and vomiting (44%). The present studies tested the hypotheses that i) lower PARP1 expression and/or ii) lower expression of NHEJ components 53BP1, DNA-PKcs, Ku70, Ku80, or LIG4, may correlate with diminished response rate as well as PFS in pts treated with rucaparib on ARIEL2. Methods: Immunohistochemical assays were developed for 53BP1, DNA-PKcs, Ku80, Ku70, LIG4, and PARP1 and validated in formalin fixed, paraffin embedded cell lines differing in aneate expression. Available pretreatment OC biopsies from ARIEL2 Part 1 were stained and scored for % of tumor nuclei that were negative (0), weak (1+), moderate (2+) or strong (3+). Modified H-scores were correlated with clinical characteristics and outcome measures. Result: Pretreatment biopsies from 62-68 pts were successfully stained for each repair protein. Across the samples, PARP1 H-scores varied from 0 to 300 (median 160). Focusing on the BRCA wt/LOH high group (n = 38), there was no significant difference in PFS of pts with low (<100), intermediate (100-200) or high (>200) PARP1 H-score (p = 0.57). Expression of DNA-PKcs, Ku70, Ku80, and LIG4 was generally lower (median H-scores 20-60) and did not indicate diminished response of PFS. In contrast, the worst outcome was observed in pts with intermediate or high 53BP1 (H-score ≥ 100, n = 10) compared to pts with low 53BP1 (H-score ≤ 100, n = 25), with median PFS 20.7 vs. 5.5 months (p = 0.073), respectively. Staining of additional pretreatment biopsies is planned. Conclusions: In the BRCA wt/LOH high group, pretreatment PARP1 expression does not correlate with rucaparib response. In contrast, BRCA wt/LOH high OC pts with low 53BP1 have a trend toward shorter PFS with rucaparib, suggesting that 53BP1 downregulation might correlate with clinical PARP1 resistance in BRCA wt/LOH high OC.

**#4678 Pilot trial of talazoparib (BMN 673), an oral PARP inhibitor, in patients with advanced solid tumors carrying deleterious BRCA mutations.** Robert S. Meehan,1 Alice P. Chen,1 Geraldine O’Sullivan Coyne,1 Shivianni Kummar,2 Jiuping Ji,2 Rasa Vilimas,2 Lamin Juwara,2 Robert J. Kinders,2 Katharine Ferry-Galow,2 Deborah Wilsker,2 Yiping Zhang,2 Angie B. *NCI/NIH DCTD, Bethesda, MD; 2Frederick National Laboratory for Cancer Research, Frederick, MD.*

Inhibition of poly (ADP-ribose) polymerase (PARP) sensitizes tumor cells to DNA damage that would normally be repaired by the late excision repair pathway. PARP inhibitors are active clinically against BRCA-deficient ovarian cancers. The PARP inhibitor talazoparib produces cytotoxicity in human cancer cell lines and animal models of tumors that harbor mutations that compromise DNA repair pathways. In this study, single agent talazoparib (1000 μg/day) was administered to patients with deleterious BRCA1 or BRCA2 mutations and advanced solid tumors in 28 day cycles. The primary objective of the trial was to examine pharmacodynamic (PD) effects of talazoparib; the secondary objective was to determine response rate in patients whose tumors carry BRCA mutations. Mandatory pretreatment tumor biopsies were obtained pre-treatment and 3-6 hrs post-treatment on cycle 1 day 8. Optional biopsies were collected at the time of progression. One core from each time point was analyzed for PARP inhibition by a validated ELISA assay while the other core was used for IFA analysis of H2AX. A total of 9 patients (pts) were enrolled and treated before this trial was closed due to lack of drug availability: [prostate (3), ovarian (2), breast (2), uterine sarcoma (1), pancreatic (1)]. Median age was 63 (range: 33-73 yrs); male-to-female ratio was 4:5; and the median number of prior treatments was 6 (range: 1-12). All 9 pts were evaluable for PD endpoints. One pt progressed during the first cycle of treatment; 8 pts were evaluable for clinical response. Mean time on study for evaluable pts was 8 cycles (range: 2-18); 5 of 8 (62%) pts experienced a documented partial response [ovarian (2), prostate (2), breast (1)] lasting between 4 and 12 cycles (median: 6 cycles). Two pts had stable disease for 4 to 6 cycles, and one progressed after 2 cycles. The agent was well tolerated; the most frequent adverse events were hematologic including grade (4) anemia (1) and thrombocytopenia (1), and grade 3 anemia (2), neutropenia (1), lymphopenia (1). Decreases in PAR levels (>75%) were observed in all cycle 1 day 8 biopsy pairs, documenting a primary PD effect. Increased H2AX expression was observed for 4/6 pts in post-dose biopsies; pre-treatment H2AX levels measured as %Nuclear Associated Protein (NAP), increased from a mean ± SD of 1.13 ± 1.08 to a post-treatment %NAP mean of 5.60 ± 0.78; (p = 0.018), supporting a role for drug-enhanced DNA double strand breaks in the mechanism of action of talazoparib for BRCA mutant tumors. In summary, talazoparib demonstrated significant clinical activity as a single agent in patients with BRCA-deficient tumors and substantial reductions in tumor PAR levels in matched pre- and post-treatment tumor biopsies.

**#4679 Mismatch repair defects in lethal prostate cancer.** Pasquale Rescigno, Daniel Nava Rodrigues, Wei Yuan, Suzanne Carreira, Maryam Lambros, George Seed, Ruth Riisnaaes, Susana Miranda, David Dolling, Matthew Clarke, Mateus Crespo, Claudia Bertan, Gunhiver Boysen, Joaquin Mateo, Ana Ferreira, Adam Sharp, Ines Figueiredo, Semini Sunanumasria, Mariane Sousa Fontes, Diletta Bianchini, Zefiria Zafeirirou, Johann Sebastian de Bono.

*The Institute of Cancer Research, London, United Kingdom.*

**INTRODUCTION:** A subset of prostate cancers (PCs) has a hypermutated phenotype. We hypothesized that lethal PCs with a high mutational load (ML) have DNA repair defects including mismatch-repair (MMR) aberrations and that such aberrations may impact outcome. METHODS: Diagnostic and metastatic castration resistant prostate cancer (mCRPC) tissues were tested by A) immunohistochemistry (IHC) for MSH2, MSH6, MLH1, and PMS2; B) microsatellite instability (MSI) (Promega v1.2 assay); C) targeted next generation sequencing (NGS) of the coding regions of 113 genes, a panel enriched for DNA-satellite instability (MSI) (Promega v1.2 assay); D) targeted next generation sequencing (NGS) of the coding regions of 113 genes, a panel enriched for DNA-motion analysis of differentially methylated 2794 CGI sites in 119 t/r AML and 49 healthy controls. Hierarchical clustering analysis of methylation profile data was performed using 8 major clusters. CIMP-like cluster (n = 42) had a higher response rate (39 %) compared to intermediate (17%) and CIMP-like cluster (15%) (p = 0.025, Fisher’s exact test). Demethylation rate of LINE-1 was lower in CIMP-like cluster than in normal-like and intermediate cluster (average demethylation of LINE-1 in CIMP-like cluster vs. -31 ± 2 % in normal-like vs. -23 ± 2 % in intermediate cluster, p = 0.0007, One-way ANOVA). Mutation screening revealed frequent alterations affecting signaling pathways (CSF3R, KIT, KRAS, and FLT3) in the CIMP-like cluster (62%) compared to normal-like (11%) and intermediate cluster (13%) (p < 0.0001, Fisher’s exact test). High number of hypermethylated sites per patient was prominent in the CIMP-like cluster and associated with a four gene expression classifier z-score (low CDA, low P15, low CTGF, high DNMT3B) (R = 0.637, p < 0.0001) as well as resistance to guadecitabine (mean of 4 gene z-score 0.54 in non-responders vs. 2.31 in responders, p = 0.001). We propose that DNA hypermethylation at CpG islands, mutations in signaling pathways and unfavorable gene expression signature can be developed as biomarkers predicting resistance to guadecitabine in t/r AML. This trials were registered at www.clinicaltrials.gov as NCT02293993 (Phase I) and NCT02197767 (Phase II).
samples was evaluated by paired t-test. The relationship between ML and MMR deficient tumors on IHC (MMRd) and/or MSI tumors by PCR (MMRd/MSI) was analyzed by negative binomial regression model. The relationship between MMRd/MSI tumors and overall survival (OS) was analyzed using univariate and multivariate Cox regression, adjusting for relevant treatment (prostateectomy or radiotherapy, age, PSA doubling time, and presence of metastatic disease at diagnosis. RESULTS: We analyzed 306 PC biopsies (180 hormone-sensitive [HS] and 126 castration resistant [CR]) from 208 patients. Overall 16 patients (7.7%) had either MMRd or MSI. Matched, same-patient, HSPC and mCRCP tumor biopsies were available for 82 patients. Only one case with MMRd status in HS was not confirmed in matched mCRCP. This patient was considered MMR deficient for the survival analysis. Msi had a SE of 80% and a SP of 97%. An MSI by NGS cut-off of 0.096 had SE of 60% and SP of 99%, with an area under ROC curve of 0.83. A ML cut-off of 11 mutations per panel had SE of 60% and SP of 99%, with an area under ROC curve of 0.79. Although ML in diagnostic samples correlates with ML in mCRCP, ML was significantly higher in mCRCP/MSRd/MSI cases (p < 0.001; predicted ML of 14 versus 4 mutations per panel). MMRd/MSI and MMR proficient patients were balanced for type of radical treatments. Gleason score, presence of metastatic disease, PSA, age and stage at diagnosis. Despite this, median OS from start of LHRH for the MMRd/MSI group was significantly shorter than in the MMR proficient group in univariate and multivariable analysis (3.84 vs 6.81 years; aHR: 2.44; 95% CI 1.27 -4.70; p = 0.008). CONCLUSION: We provide evidence that MMRd/MSI status represents a negative prognostic factor in metastatic CRPC. MMRd/MSI status in diagnostic biopsies accurately identifies MMRd/MSI in mCRCP. MSINGS and ML can detect MMRd/MSI tumors.

#4680 H3K9 methyltransferase G9a epigenetically regulates breast cancer cell iron homeostasis via repressing ferrooxidase hephaestin expression, promotes breast cancer growth. Ya-fang Wang, Jie Zhang, Yi Su, Yan-yan Shen, Mei-yu Ceng, Jian Ding, Yi Chen. Shanghai Institute of Materia Medica, Shanghai, China.

G9a is a H3K9 methyltransferase with elevated expression observed in many types of human cancers, seems to be required for the maintenance of the malignant phenotype. However, the tumorigenic role of G9a in breast cancer is still far from clear. In addition, growing evidence revealed that the disruption of iron homeostasis may contribute to the development of breast cancer (BC). Pathways of iron acquisition, efflux, storage and regulation are all perturbed in BC, suggesting that reprogramming of iron metabolism is a central aspect of tumor cells survival. Hephastin (HEPH) is a ceruloplasmin homologue that converts iron (II) to (III), and mediates iron efflux in concert with ferroportin to transport iron across the basolateral membrane. It retains unclear whether HEPH concentration has any impact on the iron status of breast tissue, and breast cancer growth. In this study, we demonstrate that G9a exerts its oncogenic function by destruction cellular iron homeostasis. We revealed that G9a knockdown, and G9a specific inhibitors significantly up-regulated HEPH expression, decreased intracellular labile iron content, and then suppressed iron efflux for survival of metastatic CRPC. G9a knockdown, and G9a specific inhibitors in diagnostic biopsies accurately identifies MMRd/MSI in mCRCP. MSINGS and ML can detect MMRd/MSI tumors.

Purpose: The BIM deletion polymorphism is associated with apoptosis resistance to epidermal growth factor receptor tyrosine kinase inhibitors (EGFR-TKIs), such as gefitinib and erlotinib, in non-small cell lung cancer (NSCLC) harboring EGFR mutations. Here, we investigated whether the BIM deletion polymorphism contributes to resistance against osimertinib, a third-generation EGFR-TKI, and determined the efficacy of a histone deacetylase (HDAC) inhibitor, vorinostat, against this form of resistance and elucidated the underlying mechanism. Experimental Design: We used EGFR-mutated NSCLC cell lines which were either heterozygous or homozygous for the BIM deletion polymorphism to evaluate the effect of osimertinib in vitro and in vivo. Protein expression was examined by western blotting. Alternative splicing of BIM mRNA was analyzed by RT-PCR. Results: EGFR-mutated NSCLC cell lines with the BIM deletion polymorphism exhibited apoptosis resistance to osimertinib in a polymorphism dose-dependent manner, and this resistance was overcome by combined use with vorinostat. Experiments with homozygous BIM deletion-positive cells revealed that vorinostat affected the alternative splicing of BIM mRNA in the deletion allele, increased the expression of active BIM protein, and thereby induced apoptosis in osimertinib-treated cells. These effects were mediated predominantly by HDAC3 inhibition. In xenograft models, combined use of vorinostat with osimertinib could regress tumors in EGFR-mutated NSCLC cells homozygous for the BIM deletion polymorphism. Moreover, this combination could induce apoptosis even when tumor cells acquired EGFR-T790M mutations. Conclusions: These findings indicate the importance of developing HDAC3-selective inhibitors, and their combined use with osimertinib for treating EGFR-mutated lung cancers carrying the BIM deletion polymorphism.

Hairy cell leukemia (HCL) until recently was characterized as a single blood and bone marrow malignancy, even though clinically at least two pathologies seemed to be at work. This study sought to confirm the clinical observations using genomic evidence. HCL is a chronic mature B-cell malignancy with distinctive immunophenotype, typically expressing CD20, CD25, CD5, CD11c, CD103, CD123, annexin A1 (ANXA1), and tarrytale acid phosphatase (TRAP). Purine analog therapy is highly effective, with most patients achieving durable remissions. HCL-variant (HCLv) was first identified by Cawley et al. (1980) and recently recognized by the World Health Organization as a separate cancer. HCLv lacks CD25, ANXA1, TRAP, and BRAFV600E expression, and patients respond poorly to purine analogs. In order to find detailed biological information involving these two diseases, ANXA1 and BIM polymorphism, we used EGFR-mutated NSCLC cell lines which were either heterozygous or homozygous for the BIM deletion polymorphism to evaluate the effect of osimertinib in vitro and in vivo. Protein expression was examined by western blotting. Alternative splicing of BIM mRNA was analyzed by RT-PCR. Results: EGFR-mutated NSCLC cell lines which were either heterozygous or homozygous for the BIM deletion polymorphism exhibited apoptosis resistance to osimertinib in a polymorphism dose-dependent manner, and this resistance was overcome by combined use with vorinostat. Experiments with homozygous BIM deletion-positive cells revealed that vorinostat affected the alternative splicing of BIM mRNA in the deletion allele, increased the expression of active BIM protein, and thereby induced apoptosis in osimertinib-treated cells. These effects were mediated predominantly by HDAC3 inhibition. In xenograft models, combined use of vorinostat with osimertinib could regress tumors in EGFR-mutated NSCLC cells homozygous for the BIM deletion polymorphism. Moreover, this combination could induce apoptosis even when tumor cells acquired EGFR-T790M mutations. Conclusions: These findings indicate the importance of developing HDAC3-selective inhibitors, and their combined use with osimertinib for treating EGFR-mutated lung cancers carrying the BIM deletion polymorphism.

SRSF2 is recurrently mutated in a variety of myeloid malignancies, including chronic myelomonocytic leukemia (CMML), myelodysplastic syndrome (MDS), myeloproliferative neoplasms (MPN), and acute myeloid leukemia (AML); and most alterations involve the codon proline-95 (P95). In vitro studies have shown that the SRSF2-P95H mutation affects splicing of EZH2 and functionally reduces its protein expression. Inactivating mutations of EZH2, located at 7q36.1, have also been reported in a variety of myeloid malignancies. Studies have shown that SRSF2 and EZH2 gene mutations are mutually exclusive events in myeloid malignancies. In this study, we retrospectively analyzed next-generation sequencing results of 16,767 patient cases with a clinical indication of a possible myeloid malignancy. All exons of the EZH2 gene and exon 1 of SRSF2 gene were sequenced. A total of 33 cases (0.2%) had mutations in both SRSF2 and EZH2 genes; 70% were male

cisco,1 Milan Sheh,2 Nilesh Vora,2 Ekhnat Deo,2 Rational Therapeutics, Inc.,
Long Beach, CA; Todd Cancer Institute, Long Beach, CA.

The transcription factor MYC is associated with the regulation of over 15% of
human gene expression. Deregression of MYC is found in up to 70% of human
cancers. As MYC is responsible for the reprogramming of cell metabolism,
growth and survival, it is an attractive therapeutic target, yet effective drug de-
velopment has been slow. As the Bromodomain/BET proteins epigenetically
regulate MYC, BET inhibitors like JQ1 have been developed as MYC therapeu-
ics. We used the Ex Vivo Analysis of Programmed Cell Death (EVA/PCD)
platform previously shown to correlate with response, time to progression and survival,
and ex vivo function of BET inhibition. Results: JQ1 activity in 46 human tumor specimens isolated from surgical bi-
opsies. Methods: Surgical biopsies were mechanically and enzymatically disas-
gregated, with micro spheroids of desired size isolated by density centrifugation.

Omniox, Inc., San Francisco, CA;2 University of California San Francisco, San Francisco, CA.

Oxygen is one of the key modulators of tumor microenvironment whereby
low oxygen or hypoxia is associated with resistance to chemo- and radio-
therapies and poor patient outcomes. Hypoxia favors an immunosuppressive tumor microenvironment by promoting Treg recruitment and activation and sup-
pressing T cell and NK cell proliferation and effector function and pro-inflam-
matory cytokine secretion. Therefore, reversing tumor hypoxia could create an
immunomodulatory microenvironment and improve the efficacy of several im-
munotherapies. Omniox has developed an oxygen carrier OMX that can specif-
cally deliver oxygen to hypoxic tumor regions without affecting oxygenation of
non-tumorous tissue. Because OMX is well tolerated in small (rats and mice) and large (sheep and dogs) animals,
several tumor types appear to be candidates for agents that target MYC-mediated cell survival, of-
fering potential treatment options for patients with advanced malignancies. JQ1
synergy with HDACI & AURKI suggests novel drug combinations for future
development. As MYC signaling influences thousands of gene targets, pheno-
typic analyses like the EVA/PCD platform can offer insights into cellular cell
difference and serve as surrogate markers for clinical response to MYC inhibi-
tion. Supported in part by the Vanguard Cancer Foundation, the Nagourney
Institute and the Malcolm C. Todd Cancer Institute.

#4685  Immune checkpoint protein VISTA is a critical regulator of the
IL-23/IL-17 inflammatory axis. Na Li1 Wenwen Xu,1 Ying Yuan,1 Natarajan
Ayithan,1 Yasutomo Imai,1 Xuesong Wu,2 Halli Miller,1 Michael Olson,1 Sam-
uel T. Hwang,1 Subramanian Malarkannan,3 Li Wang1 Medical College of
Wisconsin, Milwaukee, WI;2 Medical College of Wisconsin, Dermatology, Mil-
waukee, WI;3 Blood Research Institute, Milwaukee, WI.

V-domain Immunoglobulin Suppressor of T cell Activation (VISTA) is an
inhibitory immune-checkpoint molecule that suppresses CD4+ and CD8+ T cell
activation when expressed on antigen-presenting cells. Vsir+/+ mice developed
loss of peripheral tolerance and multi-organ chronic inflammatory pheno-
types. Vsir+ CD4+ and CD8+ T cells were hyper-responsive towards self- and
foreign antigens. In addition, VISTA regulates immune responses that have not been
demonstrated. Our current study shows that VISTA-blocking monoclonal anti-
body (mAb) enhanced anti-tumor T cell response, and synergized with a pep-
tide vaccine and TL7R agonist imiquimod as adjuvant to suppress tumor growth in
the B16 melanoma model. Surprisingly, the therapeutic effect of this combi-
nation therapy was abolished in the IL17R knockout hosts, indicating that the
IL-17-mediated inflammation is regulated by VISTA and is required for anti-
tumor immunity in the context of VISTA blockade. To better define the regulat-
ory role of VISTA in inflammation, we employed a murine model of psoriasis
induced by topical treatment of IMQ. Our data show that VISTA deficiency
accelerated the psoriasiform inflammation. Enhanced TL7R signaling in Vsir+
dendritic cells (DCs) led to the hyper-activation of Erk1/2 signaling and aug-
mented the production of IL-23. IL-23, in turn, promoted the expression of
IL-17A in both TCRgδ T cells and CD4+ Th17 cells. Furthermore, VISTA
regulates the peripheral homeostasis of CD27+ gd T cells, and their activation
upon TCR-mediated or cytokine-mediated stimulation. IL-17A-producing
CD27+ gd T cells were expanded in the Vsir+ mice and amplified the inflamma-
tory cascade. Together, these results indicate that VISTA is a critical regulator of the
IL-17-mediated inflammatory axis. Ongoing studies will define how IL-17 regulates tumor-reactive immunity in the context of VISTA blockade and
TLR vaccine adjuvant.
The anti-tumor activity of HERA-CD27 was evaluated in MC38-CEA and CT26 colorectal syngeneic mouse tumor models. In both model treatments with HERA-CD27 resulted in reduced tumor growth in both models compared to an irrelevant IgG. An orthotopic intracranial glioma study showed similar anti-tumor effects when treated with SurVaxM-derived antibodies. Tumor growth was also inhibited in immunocompromised (nude) animals treated with 2C2 or H30 antibodies, although to a lesser extent. Conclusions: Antibodies generated in response to the SurVaxM vaccination are highly cross-reactive to survivin and provide therapeutic benefit in immunocompetent mouse tumor models. These antibodies retain some efficacy in immunocompromised models, indicative of a direct T-cell independent effect. An anti-tumor response through anti-survivin-targeted antibodies is unexpected as surface-accessible survivin expression has not yet been well described in the literature. Data presented here highlight possible avenues for investigation of mechanism(s) of action.

**#4689 Hexavalent CD27 agonists show single agent anti-tumor activity and enhanced memory formation in mouse syngeneic tumor models.**

Christiane Gieffers, David Richards, Jaromir Sykora, Mauricio Redondo-Muller, Meinolf Thiemann, Christian Merz, Karl Heinonen Heinonen, Viola Marschall, Harald Fricke, Oliver Hill. Apogenix AG, Heidelberg, Germany.

Tumor necrosis factor receptor superfamily (TNFRSF) proteins are widely expressed on immune and tumor cells highlighting their importance in multiple tumor microenvironments and phases of the anti-tumor immune response. Apogenix has developed a proprietary technology platform for the construction of novel hexavalent TNFRSF agonists (HERA) for the treatment of cancer. HERA fusion proteins comprise a perfect molecular mimic of the TNFSF cytokine structure and are based on dimerization of trivalent single-chain TNFRSF receptor-binding domains (scTNFSF-RBD) via a Fcγ receptor (FcγR) binding deficient immunoglobulin Fc domain. As a result of this molecular design, HERA proteins are capable of clustering six receptors in a spatially well-defined manner. Signaling following treatment with the Apogenix HERA "scTNFSF-RBD-Fc fusion proteins" is entirely independent of secondary crosslinking through FcγRs that is required for many agonistic anti-TNFRSF antibodies. The HERA engineering concept has been successfully translated to TRAIL, GITRL, CD40L, LIGHT and CD27L resulting in agonists that are currently in development. CD27L is a potent co-stimulatory molecule that drives T cell activation and survival through interaction with its receptor (CD27). HERA-CD27L is expressed in CHO suspension cells followed by a lab-scale purification process that results in homogeneous aggregate-free protein lots. The purified protein binds its respective target at high affinity and selectively co-stimulates multiple immune and tumor cell types highlighting their immune and tumor cell type cross-reactivity. In vitro, HERA-CD27L was able to bind CD27 expressed on primary human CD4+ and CD8+ T cells. Binding significantly increased T cell expansion following cd53/cd28 stimulation and leads to increased expression of ox40 on CD4+ T cells and 41bb on CD8+ T cells, respectively. In vivo, a single dose of 10mg/kg HERA-CD27L increases clonal expansion of antigen-specific CD8+ T cells upon immunization with OvaBM (Ova) in the mouse OT-1 model with a kinetics leading to peak levels of ~25% Ova-specific CD8+ T cells at day 6 after treatment. Anti-tumor efficacy of HERA-CD27 was evaluated in MC38-CEA and CT26 colorectal syngeneic murine tumor models. In both models treatment with HERACD27L resulted in a dose dependent inhibition of tumor growth. CT26 tumor bearing mice treated
with 1mg/kg HERA-CD27L, twice weekly showed a 85% tumor-growth inhibition (TGI) compared to the control group. A significant TGI of 48% could be observed in the MC38-CEA model upon treatment with 10mg/kg, twice weekly. Analysis of peripheral lymphoid tissues in the MC38-CEA bearing mice could furthermore show that HERA-CD27L treatment is accompanied with enhanced memory CD4+ and CD8+ T cell responses in both CD4+ & CD8+ T cells. In summary, the data on the hexavalent HERA-CD27L indicate a potent immune cell driven anti tumor efficacy. Therefore, HERA-CD27 agonists could be applied for the treatment of cancer as a single agent or in combination with checkpoint Inhibitors.

The functional plasticity of macrophages and their ability to support tumour growth or promote potent antitumor immunity make them an attractive target for cancer therapy. Macrophages have been implicated in the complex antigen activity of murine STING agonist, DMXAA, including disruption of tumor vasculature, induction of cytokine production, and promotion of durable antitumor immune responses. Many of these activities are lost in STING- mice, and DMXAA does not bind to human STING, providing a pertinent explanation for why the anti-tumour effects of DMXAA observed in mice were not recapitated in human clinical trials. Using PMA-differentiated THP-1 macrophages, we sought to identify human active analogues of DMXAA in vitro, comparing their capacity to induce cytokines indicative of a classically activated antitumour phenotype; the non-canonical STING agonist 2′-3′-cGAMP was also included in our investigation. 10 (CXCL10) production, measured by ELISA, was used as an initial marker for activity, followed by multiplex cytokine analysis for broader characterisation compared to M(IFN-γ-LPS), M(IL-4/IL-13) and resting M(media alone) macrophage phenotypes. Parallel experiments were also conducted with RAW264.7 murine macrophages to compare the DMXAA-induced cytokine profile directly with that of 2′-3′-cGAMP, 2′-3′-cGAMP induced 22-fold and 18-fold increase in IP-10 production in resting and M(IL-4/IL-13) THP-1 macrophages, respectively. By comparison, THP-1 macrophages were much less responsive to DMXAA and analogues tested to date. Furthermore, 2′-3′-cGAMP induced a spectrum of cytokines similar to that observed in M(IFN-γ-LPS) macrophages, and markedly different to that of M(IL-4/IL-13) THP-1 macrophages. DMXAA, and analogues previously shown to have cytokine-inducing activity in human leukocytes did not produce cytokine spectra indicative of a classic M(IFN-γ-LPS) phenotype. Unlike human cells, however, cytokine spectra produced by RAW264.7 murine macrophages were comparable between DMXAA- and 2′-3′-cGAMP-treated cells. These findings support previous data that suggest that STING agonists can promote macrophage polarization towards an antitumour phenotype. While DMXAA is active in murine macrophages, only 2′-3′-cGAMP can induce DC-like M(IFN-γ-LPS)-like spectrum of cytokines often attributed to an antitumour macrophage phenotype.

**#4692 Local adjuvant treatment of clinical stage I-II melanoma with low dose CpG-B and/or GM-CSF: Long-term follow-up of three randomized controlled phase II trials.** Bas D. Koster, Mari F. van den Hout, Berbel J. Sluijter, Ronald G. van der Velden, Ronald J. Vuytselste, Arnold Baars, Paul A. van Leeuwen, Rik J. Schep, Monique P. van den Tol, Alfonso J. van den Eertwegh, Tanja D. de Gruijl. VU University Medical Center, Amsterdam, Netherlands.

Introduction: Currently, there is no widely used adjuvant treatment available to improve survival after surgical excision of localized melanoma. Here, we present the clinical outcome of patients who participated in three randomized phase-II trials and received low-dose loco-regional immunotherapy, which was shown to be safe and to boost loco-regional and systemic anti-melanoma T cell immunity. Patients and Methods: In three single-center, single-blinded, randomized and placebo (saline) controlled phase-II clinical trials, patients with early stage melanoma were treated with 1) Granulocyte/Macrophage-Colony Stimulating Factor (GM-CSF), 2) unmethylated CpG type-B oligodeoxynucleotide CpG7909 (CpG-B), and 3) CpG-B, alone or combined with GM-CSF, through 1-4 intra-dermal injections at the site of the primary melanoma excision scar, within 7 days preceding re-excision and sentinel lymph node (SLN) biopsy. For clinical follow-up analysis, all treated patients were grouped together (treated group n=36) as were the patients who received saline (saline group n=28). Results: 10-year recurrence-free survival rate in the treated group was 94% (95% CI 78-98) versus 48% (95% CI 21-71) in the saline group (P=0.005), hazard ratio (HR) for recurrence was 0.15 (95% CI 0.06-0.60) for the treated group. This apparent antitumor efficacy was in line with the observation upon pathological examination of less tumor positive SLN in the treated group (P=0.05). The 10-year distant recurrence-free survival rate in treated patients was also higher (94%, 78-98 versus 59%, 28-81, HR 0.22, 0.07-0.93; P=0.04). Conclusion: Local low-dose immunotherapy in patients with early-stage melanoma may offer durable protection against distant recurrences. These findings warrant further clinical exploration of this local non-toxic immune potentiating regimen.

**#4693 Fc effector bioassays enable faster and quantitative measurement of ADCC and ADCP mechanisms of action.** Zhi-Jie Jey Cheng, Rich Moravec, Aileen Pangui, Denise Garvin, Gopal B. Krishnan, Frank Fan, Mei Cong. Pro- mega Corp., Madison, WI.

Antibody-dependent cell-mediated cytotoxicity (ADCC) and antibody-dependent cell-mediated phagocytosis (ADCP) are recognized as important mechanisms of action (MOA) of therapeutic antibodies. Primary peripheral blood mononuclear cells (PBMCs) are routinely used in traditional bioassays to measure potency, stability of antibody drugs in ADCC and ADCP. However these methods are labor intensive and highly variable. Here we report the development of a luciferase-based reporter assay that utilizes activation of effector cells via cross-linking of Fc receptors with target cell-bound antibodies. We will discuss functional cell-based Fc effector reporter bioassays developed to measure human FcgRIIIA (V158 and F158 variants), Human FcgRIIa (H131 and R131 variants), Human FcgRI as well as Mouse FcgRIV and FcgRIII. Compared to primary cell-based assays these reporter bioassays are less variable, easier to perform and provide more consistent analysis of the important MOAs that are critical to drug development programs. In qualification studies, performed in accordance with ICH guidelines for antibody screening and characterization, we tested the bioassays for specificity, accuracy, precision and linearity.

**#4694 The humanized anti-CD47 monoclonal antibody, CC-90002, has antitumor activity in vitro and in vivo.** Rama Krishna Narla,1 Hardik Modi,1 Lilly Wong,1 Mahan Abassian,1 Daniel Bauer,1 Pragnya Desai,1 Bonny Gaffney,1 Pilgrim Jackson,1 Jim Leistner,1 Jing Liu,1 Antonia Lopez-Girona,1 Maria Romero,1 WenQing Yang,1 Brendan P. Eickelman,2 Quinn Deveraux,1 Laurie Phillips,2 Heather K. Raymon,1 Laure Escoubet,1 John Boylan,1 Kandasamy Harirhan1. Celgene Corp., San Diego, CA, Inhibrix, San Diego, CA.

Cluster of differentiation 47 (CD47) is a transmembrane protein ubiquitously expressed on human cells but overexpressed on many different tumor cells. The interaction of CD47 with signal-regulatory protein alpha (SIRPα) expressed on macrophages results in the inhibition of phagocytosis. Thus, tumor cell overexpression of CD47 enables escape from immune surveillance via the blockade of phagocytic mechanisms. We report here the characterization of CC-90002, a humanized anti-CD47 monoclonal antibody (mAb) that is being developed as a potential therapeutic for hematologic malignancies and solid tumors. CC-90002 has a high affinity for binding to CD47 with a subnanomolar dissociation constant (Kd) value. The IC50 required for the blockade of the CD47-SIRPα interaction is also in the subnanomolar range. CC-90002 is significantly and previously reported anti-CD47 antibodies for its inability to promote hemagglutination while maintaining high affinity binding to CD47 and inhibition of the CD47-SIRPα interaction. CC-90002 enabled antibody-mediated phagocytosis of a panel of hematological cancer cell lines in vitro, including ALL, multiple myeloma (MM) and acute myeloid leukemia (AML) cells, and primary AML patient samples. The phagocytosis index for this panel (at 1 μg/mL) ranged from approximately 20% to 60% for all the cell lines tested. Antibody concentration-response studies indicated that the CC90002 effect was concentration-dependent in the ALL and AML cell lines. CC90002 treatment significantly enabled the phagocytosis of two lenalidomide-resistant MM cell lines and primary AML cells from three patients. Additionally, CC-90002 treatment elicited the phagocytosis of solid tumor lines, including those from ovarian, breast, head and neck, lung, and pancreatic cancers. The in vivo efficacy of CC-90002 was evaluated across cell line-derived and patient-derived xenograft models. Significant dose-dependent antitumor activity was observed with CC-90002 treatment in the MM cell line-derived xenograft models, RPMI 8226 and the parental NCI-H929 and lenalidomide-resistant NCI-H929 (H929/R1). Treatment with CC-90002 was able to demonstrate significant reduction in solid tumor xenografts including a cell linederived model of triple negative breast cancer (TNBC), MDA-MB-231, and a patientderived TNBC model, AA1126 and significantly prolonged survival in the HL60disseminated AML tumor model. Mechanistic studies in the RPMI 8226 xenograft model confirmed binding of CC-90002 to tumor cells and recruitment of F4-80-positive macrophages into the tumor. RPMI 8226 tumors treated from CC-90002 treatment demonstrated an increase in select chemokines and cytokines of murine origin. Taken together, in the vitro and in vivo data demonstrate the potential for activity of CC90002 across both hematological malignancies and solid tumors. CC-90002 is currently in early clinical development.

LGR5 is a well characterised marker of intestinal stem cells found at the base of intestinal crypts and a receptor for R-spondins, potent Wnt signalling modulators and stem cell growth factors. Overexpression of LGR5 in colorectal tu-

#4698 Immuno-oncological efficacy of RXDX-106, a novel, selective and potent small molecule TAM (TYRO3, AXL, MER) inhibitor. Yumi Yokoyama,1 Erin D. Lew,2 Ruth Seelige,2 Colin Walsh,1 Maria Barrera,2 Elizabeth Tindall,1 Joanne Oh,1 Heather Ely,1 Amy Diliberto,1 Amanda Albert,1 Jack Bailey,1 Larry L.1,1 Ignyta, Inc., San Diego, CA;2 University of California, San Diego, San Diego, CA.

The TAM family of receptor tyrosine kinases (RTKs), TYRO3, AXL, and MER, has been implicated in the pathogenesis and progression of many cancer types. In cancer cells, overexpression of TAM RTKs is associated with resistance and mesenchymal phenotype. In immune cells, TAM RTKs play a key homeo-

Proceedings of the American Association for Cancer Research. Volume 58 • April 2017
tumors could induce TAM expression on subsets of T cells and that inhibition of TAM RTK activity by the small molecule inhibitor, RXDX-106, could potentially remove the molecular “brake” on immune activation in macrophages, NK cells and T cells, resulting in repolarization of the immune response towards an anti-tumor environment. The unique mechanism of activating both innate and acquired immune responses by RXDX-106, and the compelling preclinical data in cell line and syngeneic models, support the clinical development of RXDX-106 in a wide variety of cancers.

#4699 Single domain antibody (sdAb) localizes in cancer cells to inhibit signal transducer and activator of transcription 3 (STAT3) resulting in therapeutic inhibition of multiple cancers. Sunanda Singh,1 Genoveva Murillo,2 Amanda Rom,2 Avani Singh,1 Samara Singh,2 Meenakshi Parihar,2 Dong Chen,2 Rajendra Mehta,2 Robert Baker,2 Anjali Singh,1 Ashutosh S. Parihar1.2

Singh Biotechnology, Tampa, FL; 2IIT Research Institute, Chicago, IL; 3Creative Biolabs, Shirley, NY.

STAT3 is involved in the pathogenesis of many malignancies, so we developed an anti-STAT3 VH1 (variable region of the heavy chain) SBT-100, that internalizes in cancer cells and binds unphosphorylated STAT3 (U-STAT3) and phosphorylated STAT3 (P-STAT3) and results in significant inhibition of multiple cancers. ATCC cell lines for triple negative breast cancer (MDA-MB-231, MDA-MB-468, MDA-MB-453, ER-/PR+/HER2- breast cancer (BT474), pancreatic cancers (PANC-1, BX-PC3), murine mammary cancer (4T1), STAT3 null cells (PC-3), and castrate-resistant prostate cancer (DU145) were tested. Athymic nude mice were obtained from Envigo. The IL-6 Reporter Cell Assay was obtained from Promega. VEGF inhibition ELISA was done using retinal epithelial cells (ATCC). In vitro growth inhibition was done using a MTT assay. Immunoprecipitation (IP) and western blot studies in MDA-MB-231, PANC-1, HeLa, DU145, 4T1 and PC-3 showed that SBT-100 binds U-STAT3 and P-STAT3. No STAT3 binding was seen in PC-3. Binding to P-STAT3 was seen in lysates from the 4T1 cells, which have constitutively activated STAT3. Since rodent and human STAT3 have a 99% homology, rodents are excellent models for extrapolating to human disease for overproduction of IL-6 (P<0.0001) compared to control. The degree of IL-6 suppression was comparable to the negative control, BB1608 (STAT3 inhibitor). VEGF ELISA showed significant (p<0.0001) inhibition of VEGF production within 12 hrs and was maintained for up to 48 hrs. After 3 days with SBT-100 the MTT assay showed growth inhibition (p<0.001) in BT474 (93%), MCF-7 (93%), MDA-MB-231 (77%), MDA-MB-468 (85%), MDA-MB-453 (64%), PANC-1 (79%), BX-PC3 (90%), and DU145 (92%). MDA-MB-231 tumors grown in xenograft athymic mice showed suppression (p<0.001). IHC staining in the cytoplasm, and nucleus after 7 days of SBT-100 treatment. U-STAT3 and P-STAT3 activate genes that promote growth, proliferation, angiogenesis, immune suppression, cancer stem cells, metastasis, and apoptosis inhibition. SBT-100 enters the cancer cells, binds STAT3 and P-STAT3 causing growth inhibition (p<0.001) in MCF-7, BT474, MDA-MB-231, MDA-MB-468, MDA-MB-453, PANC-1, BX-PC3, and DU145. These results suggest that SBT-100 can be developed as a therapeutic for cancers expressing either STAT3 or P-STAT3.

#4700 Poly G oligonucleotide enhances anti-tumor immune response among the patients with primary lung cancer. Nobuaki Kobayashi,1 Yuji Shibata,2 Masaki Yamamoto,2 Takashi Sato,2 Masaharu Shinkai,2 Harumi Koidzu,1

Tohoku University Hospital, Yokohama, Japan; 2Yokohama City University Medical Center, Yokohama, Japan; 3Yokohama City University, Yokohama, Japan; 4Yokohama Minami Kyosai Hospital, Yokohama, Japan; 5Tohoku University Hospital, Yokohama, Japan.

Synthetic oligonucleotides (ODNs) containing specific sequences have an immunomodulatory effect. It is highly expected that such ODNs can be developed into a novel model agents for extrapolating to human disease for overproduction of IL-6. We have revealed that a novel poly-G ODN has an anti-tumor immune effect in the tumor-bearing murine model. This effect of poly-G ODN was mediated by T cells in a TL99 independent manner. Poly-G ODN directly induced the phosphorylation of Lck, thereby enhancing the production of IL-2 and T cell proliferation. Meanwhile, our recent data suggested that the immune effect by poly-G ODN against cancer was different in human. We identified poly-G ODN induced T cell proliferation and production of IFN-γ through the enhancement of mono-cyte maturation in human mononuclear cells isolated from peripheral blood or malignant pleural effusion of lung cancer patients. Further studies are continued for the establishment of a novel anti-cancer immune therapy with poly-G ODN.

#4701 Blocking FSTL1 ameliorates immunity against osteosarcoma. Chie Kudo-Saito,1 Yamato Ogawara, Kazunori Aoki. National Cancer Center Research Institute, Tokyo, Japan.

Purposes: Osteosarcoma is a rare malignant tumor of bone in children and young adults, and it is very hard to successfully control the systemic metastases that occur in 25-30% of these patients. In addition to the tumor cells, the stromal cells in the tumor microenvironment may also contribute to the care due to the intensiveness of the conventional treatments including surgical resection of the primary tumor and chemotherapy. Therefore, non-toxic but advanced treatments have been expected for a long while. We recently found that a BMP family FSTL1 is highly and functionally expressed in murine and human osteosarcoma cell lines, and systemically expands pluripotent mesenchymal/stromal cells (MSCs), which play a central role in amplification of tumor heterogeneity that is consequence of reciprocal evolution together with the tumor microenvironment, including induction of immune suppression and dysfunction, desmoplasia, and angiogenesis. FSTL1 and its induced MSCs also directly confer higher invasive and metastatic properties on tumor cells leading to further cancer progression. In this study, we evaluated antitumor efficacy induced by anti-FSTL1 mAb on murine osteosarcoma models, and also compared the therapeutic efficacy with those induced by immune checkpoint inhibitor mAbs (ICIs). Results: We used two syngeneic tumor models that were subcutaneously implanted with murine osteosarcoma NHO5 cells in BALB/c mice, or LM3 cells in C3H mice. These mice were intraperitoneally injected with anti-FSTL1 mAbs (10mg/kg) twice on day 5 and day 8 after tumor implantation, and then treated for 14 days. Analysis of tumor-infiltrating lymphocytes (TILs) from tumors and bone marrow cells on day 15. In both osteosarcoma models, CD45+ MSCs as well as other immunosuppressive CD4+ Foxp3+ Tregs and CD11b+ Gr1+ MDCS systemically increased, indicating impairment of anti-tumor immunity in the mice. Treatment with the anti-FSTL1 mAb significantly induced potent tumor-specific CTLs through reduction of MSCs, resulting in tumor-free in some of the treated mice. Although the antitumor efficacy was similar to those induced by ICIs, the mode of action was totally distinct because MSCs and the MSC-inducible exhausted CD8+ PD1+ T cells were reduced only in the anti-FSTL1-treated mice, but not in the ICI-treated mice. Conclusions: These results suggest that blocking FSTL1 properly reprograms immunity toward elimination of osteosarcoma by reducing the tumor-supportive MSCs. Anti-FSTL1 mAb may be a promising drug for treating osteosarcoma more moderately but effectively in clinical settings.

#4702 PD-L1 blockade in preclinical models of PTEN-deficient prostate cancer. Marco A. De Velasco,1 Yurie Kura,2 Naomi Ando,1 Noriko Sato,1 Kazuko Sakai,1 Barry R. Davies,2 Koichi Sugimoto,1 Masahiro Nozawa,1 Kazuhiro Yoshimura,1 Kazuhiro Yoshikawa,2 Kazuto Nishio,1 Hirotsugu Uemura2,1 Kinai University Faculty of Medicine, Osaka, Japan; 2AstraZeneca, Macclesfield, United Kingdom; 3Aichi Medical University, Nagakute, Japan.

PD-L1 expression is characterized immune expression profiles in more aggressive tumors from PTEN/P53-deficient castration-resistant xenograft models. In PTEN/P53 double knockout (DKO) mice, PD-L1 was strongly expressed cancer cells, associated immune expression profıles in more aggressive tumors from PTEN/P53-DKO mice with advanced castration-naïve prostate cancer. PTEN/P53-DKO mice with advanced castration-naive prostate cancer were used for the preclinical evaluation of novel immunotherapeutic strategies, we used genetically engineered mouse models of PTEN-deficient prostate cancer. We first analyzed the transcriptome in castration-naïve prostate tumors and the progression to castration-resistant disease. Comparative analyses were performed between age-matched normal prostate and PTEN-/- prostate tumor samples from castration-naïve mice and, at 4 weeks (castration-sensitive) and 10 weeks (castration-resistant) post-surgical castration. Pathway and gene-set enrichment analysis indicated that abnormal tumor immunity was strongly associated with the progression to castration resistance. Chemokine signaling, B cell receptor and T cell receptor signaling pathways were among the top dysregulated pathways, and gene signatures of suppressed tumor immunity were enriched in castration-resistant tumors. Higher expression patterns of the programmed cell death protein 1 (PD-1) and its ligand (PD-L1) were observed in castration-resistant compared to castration-naïve tumors. We also characterized immune expression profiles in more aggressive tumors from PTEN/P53 double knockout (DKO) mice. PD-L1 was strongly expressed cancer cells, but a higher presence of PD-1+, CD4+ and PD84+ stromal infiltrating immune cells in was observed in castration-resistant tumors. PD-1/PD-L1 blockade with antibodies against mouse PD-L1 increased CD45+ tumor infiltrating lymphocytes (TILs) in an early model of PTEN/P53-deficient castration-resistant prostate cancer. PD-L1/PD-L1 blockade with antibodies against mouse PD-L1 increased CD45+ tumor infiltrating lymphocytes (TILs) in an early model of PTEN/P53-deficient castration-resistant prostate cancer. Although the antitumor efficacy was similar to those induced by ICIs, the mode of action was totally distinct because MSCs and the MSC-inducible exhausted CD8+ PD1+ T cells were reduced only in the anti-FSTL1-treated mice, but not in the ICI-treated mice. Conclusions: These results suggest that blocking FSTL1 properly reprograms immunity toward elimination of osteosarcoma by reducing the tumor-supportive MSCs. Anti-FSTL1 mAb may be a promising drug for treating osteosarcoma more moderately but effectively in clinical settings.
terim analysis of PD-1/PD-L1 blockade on a model of advanced PTEN/P53
deficient castration resistant prostate cancer (CRPC) has thus far shown that
mice receiving treatment experience significantly longer survival (P = 0.017, me-
dian survival not yet reached). Our findings show that castration-resistance promotes tumor immune suppression in mouse PTEN-deficient prostate cancer and suggest that the observed phenomenon can be reversed pharmacologically with anti-
PD-L1 blockade. Thus, we provide preclinical evidence for immune checkpoint
blockade as a potentially promising prostate cancer therapy.

#4703 INCAGN1949, an anti-OX40 antibody with an optimal agonistic pro-
file and the ability to selectively deplete intratumoral regulatory T cells. Ana M.

OX40 is a T cell co-stimulatory receptor that can enhance the magnitude and
durability of T cell immune responses. Anti-OX40 agonist antibodies have shown
significant single agent tumoricidal activity in preclinical models, and can combine
effectively with other immunomodulatory antibodies, targeted therapies and vac-
oxes. OX40 agonists are able to counteract the immunosup-
pressive tumor microenvironment and promote tumor-specific cellular immu-
nity via at least two distinct mechanisms: 1) promoting OX40 forward signaling in
tumor-specific T cells and 2) co-engaging Fcγ receptors expressed by tumor-
associated effector cells, and facilitating the selective elimination of OX40high
intratumoral regulatory T cells. INCAGN1949, an anti-OX40 human IgG1 an-
tibody, was selected based on its ability to optimally enhance T cell responsive-
ness under conditions of suboptimal T cell receptor stimulation. INCAGN1949
was shown to mediate effective apical OX40 clustering that is translated into
effective downstream activation of the NFκB pathway. Notably, INCAGN1949
was shown to maintain a sigmoidal dose response curve across a broad range of
antibody concentrations. This suggests a wide therapeutic window and may be
advantageous for dosing considerations. By contrast, evaluation of reference
OX40 antibodies indicated an inverted U-shaped dose response curve, leading to
impaired T cell responses at high concentrations. INCAGN1949 was selected for
clinical development based on its optimal agonist profile, further reinforced by
its ability to combine with other co-inhibitory and co-stimulatory antibodies to
augment T cell responsiveness. Prior to human testing, the pharmacology and
tolerability of INCAGN1949 was evaluated in non-human primates (NHPs).
Pharmacokinetic (PK) and pharmacodynamic (PD) parameters were evaluated
including longitudinal measurements of serum cytokines, immune cell popula-
tions, activation state and T cell-mediated immune responses to reporter vac-
cine antigens. INCAGN1949 exhibited a linear PK profile and was well tolerated
at all doses tested, with no maximum tolerated dose established. Co-administra-
tion of INCAGN1949 and vaccines in NHPs showed an immune-based PD
signature across a broad exposure range. These studies were in line with in vitro
findings, which suggested an equipotent PD range for INCAGN1949 in patients. An impor-
tant secondary mechanism of INCAGN1949 is the ability of its IgG1 Fc region to
mediate selective depletion of OX40-high intratumoral regulatory T cells. Immu-
nohistochemistry and flow cytometry analyses support the validity of this regul-
atory T cell depletion mechanism in a range of functions. The functional in vitro
and in vivo attributes of INCAGN1949 make it suitable for clinical development.
It is currently under evaluation in a Phase 1/2 study in subjects with advanced or
metastatic tumors (NCT02923349).

#4704 Long-lived de novo DNA methylation programming enforces ter-
mal T-cell exhaustion. Hazem E. Ghoneim, Yiping Fan, Hossam A. Abdel-
samed, Pradhyot Dash, Robert Carter, Walid Awad, Pranay Dogra, Paul G.
Thomas, Ben Younghblood. St. Jude Children’s Research Hospital, Memphis, TN.

Immune-checkpoint blockade (ICB)-mediated rejuvenation of exhausted CD8 T
cells has emerged as one of the most promising frontiers for treating cancer and
chronic infections. However, antigen-specific T cells that have differentiated to
a terminal state of exhaustion remain refractory to ICB-mediated rejuvenation and
currently have limited potential for contributing to this promising therapeutic
approach. Given that many of the impaired effector properties of terminally exhausted
CD8 T cells appear to be heritably maintained even in the absence of antigen, we
investigated the role of de novo DNA-methylation programming as a cell-intrinsic
mechanism for establishing the ICB-nonresponsive state of T-cell exhaustion. Using
a TCR-inducible system to delete the de novo DNA methyltransferase, Dnmt3a, in
CD8 T cells (cKO) responding to a chronic LCMV infection, we observed that
antigen-specific CD8 T cells lacking the capacity to acquire new DNA methylation
programs retained their effector function despite exposure to high antigen loads for
several months. Longitudinal whole-genome bisulfitie sequencing methylation pro-
file and gene expression analysis of wild-type and Dnmt3a cKO antigen-specific
CD8 T cells during persistent antigen exposure revealed that de novo DNA meth-
ylation programs (CPI) represent a breakthrough for the treatment of cancer. A T cell-
inflamed tumor microenvironment (TME) is required for antitumor efficacy of
CPI. However, the evidence suggests that 70% of tumors do not possess T cell-

CLINICAL RESEARCH: Immunomodulatory Agents and Therapeutics

Proceedings of the American Association for Cancer Research • Volume 58 • April 2017
inflamed TME limiting the potential of CPI treatments to a smaller population of cancer patients. Immunotherapies that enable CPI effectiveness in patients with non-T cell-inflamed phenotype are being studied. Oligonucleotide-based TLR9 agonists induce potent CD8+ T cell and plasmacytoid dendritic cell activation and limit immune suppressor cell phenotypes in TME. Therefore, the combination of TLR9 agonists with CPI would be a rational approach for achieving higher rates of success in cancer treatment. However, TLR9 agonists were unsuccessful in previous cancer clinical trials. Spherical Nucleic Acids (SNAs) are a novel class of agents with oligonucleotides densely packed and radially oriented around spherical liposomal nanoparticles. SNAs overcome limitations of therapeutic oligonucleotides through increased uptake and nuclease stability. We have evaluated a TLR9 targeted SNA for anticancer activity as a monotherapy and in combination with an anti-PD-1 (a-PD-1) antibody in both a-PD-1 sensitive and insensitive mouse tumor models. Mice bearing a-PD-1 sensitive MC38 tumors were treated with intratumoral dosing of TLR9 agonist SNA, intraperitoneal (IP) dosing of a-PD-1 or the combination of both agents when average tumor volume was 100 mm³, with twice weekly dosing for a total of 5 doses. SNA alone showed dose-dependent tumor growth inhibition (TGI) of up to 87% and increased survival of mice. The combination of SNA and a-PD-1 greatly enhanced TGI (92% vs SNA, 74% or a-PD-1, 77%) and mice survival compared with either monotherapy. Moreover, once weekly dosing of SNA showed similar TGI compared with twice weekly dosing. In a-PD-1 insensitive EMT-6 model, mice were treated with intravenous dosing of TLR9 agonist SNA, IP dosing for the combination, starting on day 3 following subcutaneous tumor cell inoculation. SNA alone showed potent dose-dependent TGI of up to 80% and increased mice survival. The combination of SNA and a-PD-1 showed a synergistic TGI (86% vs SNA, 64% or a-PD-1, no effect) and increased mice survival. Further, no tumor growth was observed in surviving mice after subsequent challenge with EMT-6 cells, suggesting development of tumor-specific memory responses in SNA treated animals. These data demonstrate that the TLR9 agonist SNA studied herein induces innate and adaptive immune responses in tumor-bearing mice and shows synergistic TGI with a-PD-1 in both a-PD-1 sensitive and insensitive tumor models. A TLR9 agonist SNA, AST-008, is currently in clinical development.

Background: Human Immune-reconstituted Mice, generated by transplanting pre-validated human CD34+ hematopoietic stem cells (HSC) into immune-compromised mice, are extremely useful in basic and applied human disease research. Many cancer therapies, including immune checkpoint inhibitors such as the anti-PD-1 monoclonal antibody, rely on an intact immune system to release immunosuppression and destroy cancer cells. Material and methods: We evaluated the effects of anti-PD-1 in humanized mice in donor cohorts utilizing the cancer matrix of 5 HSC donor cohorts of humanized animals with PDX models from 7 small cell lung cancer (SCLC). Here, we tested anti-PD-1 in SCLC and in a triple negative breast cancer (TNBC) model and in 1 MDA-MB-231 study. Results: Here, we show that HSC derived humanized immune-reconstituted mice have significant effects on patient derived xenograft (PDX) tumor growth. However, humanization is required for anti-tumor response to anti-PD-1. In MDA-MB-231 study, tumors showed complete regression after the first round of treatment. Re-engraftment of same animals with MDA-MB-231 cells showed minor tumor growth before complete regression again. Aged match control naive animals engrafted with same cells showed normal tumor growth. In SCLC studies anti-PD-1 efficacy varied between the models, which clearly underscores the inherent donor to donor variability in this humanized model system. Tumors from these studies were then analyzed to determine target engagement of anti-PD-1, tumor infiltrating lymphocytes (TILs) characterization and histology comparing anti-PD-1 responders and non-responders. As expected, in this study, warning that humanization of the animals is necessary to evaluate the efficacy of anti-PD-1 therapy and can elicit an immunity-mediated anti-tumor effect. Conclusions: Here we demonstrate the development of humanized mouse studies with ability to run multi point analysis to determine the outcome of treatment.

#4708 A novel anti-MUC1 CAR T cell drives immunity to pancreatic cancer. Mahboubeh Yazdanifar, Ru Zhou, Shu-ta Wu, Priyanka Grover, Pinku Mukherjee. *Univ. of North Carolina at Charlotte, Charlotte, NC.*

Background: Pancreatic cancer is the 4th leading cause of cancer deaths in the US with very poor prognosis. Treatment options are limited to surgery and chemoradiotherapy that often times do not increase survival and are associated with high toxicity. Targeted immune-based therapies have shown some promise but needs further exploration. Mucin 1 (MUC1), a glycoprotein expressed on the apical surface of epithelial cells of most epithelial organs, undergoes hypoglycosylation in tumors. This tumor-form of MUC1 (tMUC1) is over-expressed in 80% of pancreatic ductal adenocarcinomas (PDAC). tMUC1 therefore remains a promising target for therapeutic intervention. We have developed a novel technology to specifically detect tMUC1 and spare normal MUC1. Using a novel technology, functional fragments of TAB004 antibody (scFv) were incorporated into the chimeric antigen receptor (CAR) construct and used to genetically modify primary human T cells. scFv domain which recognizes tMUC1 is linked to the co-stimulatory molecules of T cells (CD28 and CD3ζ). When the engineered T cells contact with tMUC1 expressing tumor cells, multiple T cell signaling pathways are initiated leading to fully activated cytotoxic T cells that lyse the tumor cells. Methods: Retroviral based technique was used to deliver the CAR gene into human PBMC derived primary T cells. A fluorescent tag (mKate) was fused to the C-terminus of CAR molecules, in order to visualize CAR expression on T cell membrane by fluorescent microscopy and potential for in vivo tracking. Cytotoxicity was evaluated using co-culture method with varying T cell to target cell ratios followed by MTT assay. Intracellular IFNγ was measured by flow cytometry. Results: tMUC1-CAR T cells show increased activation and proliferation compared to normal T cells. These cells bind strongly to tMUC1 expressing human pancreatic cancer cells forming immunologic synapse. Minimal binding of the tMUC1-CAR T cells was observed to normal or low MUC1 expressing tumors cells suggesting high specificity of these CAR T cells to tMUC1. CAR expression was distributed evenly on the cell surface of the T cells. Engineered tMUC1-CAR T cells exhibit robust cytotoxicity against a panel of PDA cell lines, associated with high IFNγ release. Fortunately, the same CAR T cells display minimum toxicity against normal epithelial cells. CAR T cell function will be evaluated in the preclinical mouse model of PDA, as single treatment and also in combination with checkpoint inhibitors and chemotherapy drugs. Conclusion: Despite the remarkable successes reported using CAR T cells in clinic, particularly CD19 CAR T for leukemia; some adverse effects have been attributed to this treatment. This highlights the urgent need for developing tumour-specific CAR T cells. This study demonstrates the specificity and effectiveness of tMUC1-CAR T cells against pancreatic cancer cells. Thus, tMUC1 CAR T cells have the potential to be further developed for future clinical use.

#4709 Induction of enhanced tumor-specific immunity by Hsp90 targeted photodynamic therapy (Hsp90-PDT) combined with immune checkpoint inhibition. Kensuke Keneko, Takyua Osada, Timothy A. Haystead, Michael A. Morse, Herbert K. Lyerly. *Duke University, Durham, NC.*

Background: Immunotherapy has become an emerging anti-cancer therapy, and checkpoint blockade with PD-1 or PD-L1 inhibition have been active against multiple cancer types. Nonetheless, there remain many non-responders, suggesting that combinations may improve activity, particularly combinations which can target tumors and have low toxicity. Methods & Results: We have developed a novel Hsp90 targeted photodynamic therapy (Hsp90-PDT), which causes local anti-tumor responses. Hsp90-PDT can be combined with immune checkpoint blockade to generate potent anti-tumor effects. We synthesized well-characterized PDT agent, verteporfin (VP) tethered to a Hsp90 small molecule inhibitor, to create a Hsp90-PDT agent (Hsp90i-VP). We first compared the uptake of VP and Hsp90i-VP into the breast cancer cell lines (E0771-OVA) in vitro. Hsp90i-VP showed stronger incorporation than VP when the compounds were added 3µM or less in concentration. We next performed in vitro and vivo PDT with Hsp90i-VP and laser exposure (690 nm wavelength). Killing efficiency of VP and Hsp90i-VP was analyzed by MTT assay, which showed increased killing in a dose dependent manner for both photosensitizers (0-30µM) and laser (0-120J/cm²). Next, we treated E0771-OVA tumor-bearing C57BL/6 mice with Hsp90i-VP (25nmol/mouse) administration alone, laser irradiation (240 J/cm²), alone, or the combination of Hsp90i-VP and laser. Suppression of the neared cells was confirmed only in Mip95i-VP and laser group. In addition, induction of tumor-specific immune response by PDT was confirmed by ELISA, where the elevation of anti-OVA antibody was seen only in PDT group. Furthermore, combination treatment of Hsp90-PDT and anti-PD-L1 mAbs was able to enhance cytotoxic T-cell response and suppress tumor growth significantly even with relatively PD-T resistant cell line. Conclusions: Hsp90-PDT showed a significant ability to induce antigen-specific immune response in both in vitro and in vivo. These results suggest that Hsp90-PDT can play an important role in anti-cancer immune therapy. Our future plan is to investigate the effect of local photodynamic therapy combined with various types of checkpoint inhibitor in breast cancer models.
Tumor-infiltrating immune cells in gastrointestinal stromal tumors (GIST) related to the response to tyrosine kinase inhibitor therapy. Peter Hohenberger,1 Weney Zhao,2 Maria Deligianni,1 Katia Simon-Keller,1 Alina Diel,4 Andrea Homburger,1 Hui Cao,6 Alexander Marx,6 Division of Surgical Oncology & Thoracic Surgery, Mannheim, Germany; Department of Gastrointestinal Surgery, University Hospital, Mannheim, Germany; Department of Pathology, University Hospital, Mannheim, Germany.

Purpose: The prognostic predictors for neoadjuvant and palliative tyrosine kinase inhibitor (TKI) effect in GIST patients are few beyond mutational status. We analyzed the extent and composition of tumor-infiltrating immune cells in GIST after different TKI therapeutic regimens and response. Methods: From 60 GIST patients, surgical specimens were available and divided into six different groups (in each, with the primary tumors graded for malignant behavior and depicting the development of a memory response against the tumor antigen. For comparison, the novel combination of MM-310, an EphA2-targeted docetaxel ADN with an anti-PD-1 antibody, is highly active in syngeneic tumor models, and represents a promising strategy for the treatment of cancer.

The effectiveness of PD-1/PD-L1 antagonists can be limited by the immunogenicity of the tumor microenvironment. Studies showed that some chemotherapeutic agents including taxanes and anthracyclines can increase immunogenicity, resulting in therapeutic synergy with immune checkpoint inhibitors. In particular, treatment with a taxane has been shown to increase the recruitment of CTLs and decrease immunosuppressive cells such as M2 macrophages and Tregs. Additionaly, the immune-modulatory activity of paclitaxel has been shown to increase with prolonged exposure of the taxane at the tumor level, achieving through metronomic dosing. MM-310 is an Ephrin Receptor A2 (EphA2)-targeted antibody-directed nanotherapeutic (ADN) that encapsulates a docetaxel produrg. Preclinically, MM-310 leads to prolonged exposure of docetaxel at the tumor level, while lowering systemic exposure to bioavailable docetaxel, and thus decreasing not only dose-limiting neutropenia but also the killing of circulating lymphocytes potentially critical to anti-PD-1/PD-L1 activity relative to free docetaxel. Taken together, we hypothesize that MM-310 can synergistically combine with anti-PD-1 therapy. In this study, we evaluated the potential combination of MM-310 and a murine anti-PD-1 Ab in the treatment of several syngeneic mouse tumor models. The tumor lines EMT-6, CT-26, and C26 were used to provide a range of sensitivity to both docetaxel and anti-PD-1. In vivo activity studies and immune-phenotype studies were performed comparing MM-310 + anti-PD-1 combination to the monotherapies. MM-310 administration was initiated two days prior to anti-PD-1 therapy and consisted of four weekly doses, while anti-PD-1 was dosed twice weekly for four weeks. The response to MM-310 or anti-PD-1 as monotherapies varied between the models. In mouse models, radiation treatment has been shown to increase the level of tumor antigen presentation and the variety of peptides available for cross-presentation. Current work in the field focuses on using radiation as a tool to bridge the gap from tumor equilibrium to tumor elimination, which could enhance the ability of preclinical models to provide a first line assessment for advanced immunology therapy combinations.

Deubiquitination and stabilization of programmed cell death ligand 1 by CSN5. Seung-Oe Lim, Chia-Wei Li, Mien-Chie Hung. UT MD Anderson Cancer Center, Houston, TX.

Chronic inflammation in cancer is often associated with disease aggressiveness. Pro-inflammatory cytokines produced in the tumor microenvironment lead to eradication of antitumor immunity and enhanced tumor cell survival. In the current study, we identified TNFα as a major factor triggering cancer cell immunosuppression against T cell surveillance via stabilization of programmed cell death-ligand 1 (PD-L1). We demonstrated that COP9 signalosome 5 (CSN5), induced by NFκB p65, is required for TNFα-mediated PD-L1 stabilization in cancer cells. CSN5 inhibits the ubiquitination and degradation of PD-L1. The role of CSN5 in modulating PD-L1 stabilization prompted us to use CSN5 inhibitor, curcumin, to show that it could destabilize PD-L1 and reduce TNFα-mediated TNFα-mediated PD-L1 stabilization and enhanced anti-tumor immunity. Preclinical data demonstrated inhibition of CSN5 sensitized cancer cells to anti-CTLA4 therapy, suggesting CSN5 inhibitor may be a useful adjuvant to enhance immune-based therapies.
**CLINICAL RESEARCH: Immunomodulatory Agents and Therapeutics**

**#4714** Blockade of LAG-3 amplifies immune activation signatures and augments curative antitumor responses to anti-PD-1 therapy in immune competent mouse models of cancer. Brian B. Haines,1 Sarah Javid,1 Long Cui,1 Heather Hirsch,1 Sas0 Cemerski,1 Terri McClanahan,2 Manjiri Sathe,2 Shuli Zhang,2 Michael Rosenzweig,1 Brian Long,1 Rene de Waal Maeyer2,3. 3Merck Research Laboratories, Boston, MA;4Merck Research Laboratories, Palo Alto, CA.

MK-4280 is a humanized IgG4 monoclonal antibody (mAb) that binds to the immune checkpoint receptor Lymphotoxycyte Activation Gene-3 (LAG-3) to block the interaction with its ligand, Major Histocompatibility Complex (MHC) Class II. LAG-3 is frequently co-expressed with other immune checkpoint receptors, most notably programmed cell death receptor-1 (PD-1), on T cells with an exhausted phenotype. LAG-3 and PD-1 cooperate to regulate peripheral immune tolerance in healthy individuals, and, conversely, play critical roles in several diseases, including autoimmunity, graft rejection, viral infections, and cancer. Co-blockade of LAG-3 and PD-1 in immunocompetent mouse tumor models have demonstrated augmented anti-tumor activity over single agents. However, the molecular mechanisms behind these combination effects have not been fully investigated. Here, preclinical proof-of-biology studies are presented for co-targeting LAG-3 and PD-1 in cancer. c28G10-mG1-[D265A] (abbreviated 28G10-mG1) is a rat/mouse chimera that mimics MK-4280 by its ability to directly block the mouse LAG-3/MHC Class II interaction without initiating Fc-mediated effector functions. As a single agent, 28G10-mG1 demonstrated modest anti-tumor activity across several syngeneic mouse tumor models despite evidence of systemic drug exposure and target engagement (as assessed by sLAG-3-mAb complex accumulation). The combination of 28G10-mG1 and the anti-mouse PD-1 blocking antibody mDX400 resulted in greater tumor growth inhibition and increased numbers of complete responses (CR) over mDX400 alone in the MBT-2 tumor model. Furthermore, animals that had achieved CR to combination therapy were subsequently protected from MBT-2 rechallenge, suggesting the establishment of immune memory. RT-qPCR analyses revealed up-regulation of immune-related genes, primarily at Day 4 in the blood and Day 8 in the tumor with mDX400, but not 28G10-mG1, treatment. However, when combined with mDX400, 28G10-mG1 further altered the expression of many immune-related genes that were perturbed by mDX400 single agent therapy. Genes unique to combination treatment were also observed. Significantly, immune pathway signatures associated with clinical efficacy to Keytruda were upregulated with combination therapy. Tumor transcriptome and network analysis by RNAseq revealed enrichment in several immune- and cytokine-related pathways with combination therapy compared to mDX400 single agent therapy. Taken together, these preclinical oncology studies support the concept of co-targeting LAG-3 to increase the therapeutic efficacy of PD-1 blockade. Clinical investigation of MK-4280 in combination with anti-PD-1 therapy (pembrolizumab/Keytruda) is ongoing.

**#4715** Protective anti-tumor immune responses in breast cancer depend on tumor mutation rate. Lance D. Miller, Eric D. Routh, Jeff W. Chou, Alexandra Thomas. Wake Forest School of Medicine, Winston Salem, NC.

The relationship between tumor antigenicity and anti-tumor immune responses in breast cancer are poorly understood. Metrics that can accurately predict tumor immunogenic potential could guide therapeutic decisions for breast cancer patients. We examined the relationship between tumor immune subclasses and patient overall survival in the context of the rate of nonsynonymous mutations in breast cancers. These analyses were conducted using RNAseq and exome sequencing data from the Cancer Genome Atlas (TCGA) breast cancer cohort (n = 1,098 patients). A previously described tumor-immune classification system, based on the relative abundance of infiltrating effector immune cells, was employed for assigning patients to favorable, weak or poor immunogenic dispositions (FID, WID or PID, respectively). In breast tumors exhibiting low mutation rates (LMR), no significant survival differences were observed among patients comprising the immune subclasses. By contrast, in the context of tumors with high mutation rates (HMR), the immune subclasses exhibited highly significant survival differences (p < 0.001). Patients with FID tumors achieved 100% survival at 10 years as compared to those with PID tumors who displayed a 10-year survival rate of 44%. These survival differences were independent of molecular subtype composition, with the majority of the excellent-outcome FID subclass comprising predominantly of Basal-like, HER2-enriched and Luminal B breast tumors. In the smaller subset of HMR Luminal A breast tumors, the immune subclasses also exhibited significantly different survival outcomes (p = 0.01), with patients of the poor-outcome Luminal A PID subclass experiencing a 10-year survival rate of 22%. By Cox proportional hazards regression analysis, the immune subclasses contributed significant additive prognostic information in the presence of AJCC stage (p = 0.003). A rate of 1 mutation per million of DNA was found to be an optimal threshold for distinguishing immune-relevant low and high mutational load. These findings fit a model where mutational burden, reflective of tumor antigenicity, is a major determinant of clinically-relevant breast tumor immunogenicity. This relationship between immunogenic tumor subclasses, overall survival and mutational burden may offer opportunities for therapeutic stratification of breast cancer patients.

The diagnosis of colorectal cancer (CRC) is based on tumor-node-metastasis staging, a weak staging system due to different genetic and epigenetic backgrounds. Biological markers improve early detection and guide clinicians in subsequent therapies. Stemness molecules have the potential to identify patients at high risk of developing aggressive cancers. Herein, Zinc finger E-box binding homeobox 1 (ZEB1), Trefoil factor 3 (TFF3), Hepatoma Up-Regulate Protein (HURP), Mucin 2 (MUC2), and Cystic fibrosis transmembrane regulator (CFTR) were used as potential prognostic biomarkers in CRC. There was a total of (N = 56) cases included in this study which were assessed by a pathologist, out of them 32 were African Americans (AA) and 24 Caucasian Americans (CA). The median follow-up for 42 surviving patients were noted to be 4.5 years (range 2.5 - 7.5 years). A tissue tumor microarray (TMA) was created using tumor stage-matched CRC tissues from AA and CA. The TMA was stained with each biomarker using immunohistochemistry (IHC) and consisted of 132 cores including both controls and tumors. The individual staining score ranged from (0-3) for both area and intensity. The product of area and intensity was used as the final score which ranged from (0-9) with 0 defining no expression and 9 as high expression. We evaluated the association for expression of all the five biomarkers with disease-free survival (DFS) in AA and CA separately. Stratification of the cohort by race revealed that in CA, high ZEB1 expression (nuclear and cytoplasmic) was associated with poor DFS (p = 0.015 for cytoplasm, p = 0.116 for nucleus). ZEB1 expression was not found to be a significant predictor of DFS in AA who are usually known to have worse CRC outcomes. These findings suggest that expression of ZEB1 may represent a marker for CRC prognosis, particularly in CA. High nuclear TFF3 expression in AA was found to be marginally associated with poorer DFS (p = 0.089).

The cytoplasmic expression of TFF3 was not significantly associated with DFS. Both the cytoplasmic and nuclear expression of HURP, MUC2, and CFTR among the AA and CA did not significantly correlate with DFS. Overall, we have identified two stemness molecules, ZEB1 and TFF3, with potential as markers for aggressiveness in CRC. Our findings also provide evidence of a possible biological basis for ethnic differential differences with that of the nuclear expression scores, which are two independent prognostic factors of CRC aggressiveness. ZEB1 can contribute to be a novel biomarker to predict the prognosis of CRC in CA, and TFF3 will be a prognostic marker for AA. Future goals include collecting additional samples and follow-up of the patients to accurately estimate the prognosis. In addition, we will expand the project to the cellular and molecular basis underlying our findings. Funding sources: PCRI W81XWH-14-1-0151, UMMC Medical Student Research Program, and UMMC Office of Research.

**#4717** Combination of PD-L1 expression and microsatellite instability status is a useful prognostic factor in gastric cancer. Toshiaki Morihiro, Shinji Kuroda, Nobuhiko Kanaya, Hiroshi Tazawa, Shinsuke Kagawa, Toshiyoshi Fujiiwara. Okayama University, Okayama, Japan.

Interaction of programmed death-1 (PD-1) and programmed death-ligand 1 (PD-L1) induces functional impairment of antigen-specific T cells, which leads to immune evasion of tumors. Immune checkpoint therapy including PD-1/PD-L1 blockade is an emerging treatment strategy which brings great improvement in patient's prognosis. Microsatellite instability (MSI) is a condition of genomic instability caused by the loss of DNA mismatch repair activity, which has recently received a lot of attention from the standpoint of cancer immunotherapy. While the TNM classification system is commonly used on various malignant tumors for prediction of prognosis and planning of treatment strategy, establishment of prognostic factors related to cancer immune system is considered important as cancer immunotherapy has recently become more and more popular. Thus, we investigated the
usefulness of PD-L1 expression and MSI status in addition to histological type as prognostic factors in gastric cancer. In this study, 255 gastric cancer cases which had curative surgical resection at Okayama University Hospital between 2002 and 2009 were analyzed retrospectively. PD-L1 expression level was classified into 4 groups according to PD-L1 positive rate on tumors on immunohistochemical staining (0: <1%, 1+: 1-5%, 2+: 5-10%, 3+: ≥10%), and 2+ and 3+ were defined as PD-L1 positive. MSI status was analyzed by PCR and classified into MSI-high (MSI-H), and MSI-low and Microsatellite instability (non-MSI). Histological type was divided into intestinal and diffuse according to the Lauren classification. PD-L1 positive rate was 15%, and PD-L1 positive was significantly correlated with advanced stage and invasive status. Overall survival (p = 0.0109) and disease-free survival (p = 0.0052) were significantly poor in PD-L1 positive group, and a multivariate analysis revealed that PD-L1 expression was an independent risk factor for recurrence after surgery (p = 0.0160, odds ratio: 3.19). MSI-H was detected in 7.5%, and more observed in PD-L1 positive cases (p = 0.0068). Although non-MSI, as a single factor, showed only a weak tendency to have poor prognosis compared to MSI-H (p = 0.1965), combination of PD-L1 positive and non-MSI (PD-L1/non-MSI) showed significantly poor prognosis (p = 0.0010). Although other combinations also showed the usefulness in detection of patients with poor prognosis, such as PD-L1 positive and diffuse type, and non-MSI and diffuse type, a multivariate analysis revealed that PD-L1/non-MSI was the most useful combination among them to predict poor prognosis (p = 0.0009, hazard ratio: 3.88). In conclusion, while PD-L1 expression is a useful prognostic factor and predictive factor for recurrence after surgery as a single factor, combination with MSI status can be more useful and attractive prognostic factor in gastric cancer.

**#4718 Filamin A interacting protein 1-like is a marker of progression, chemosensitivity and chemoresistance in ovarian cancer.** Mijung Kwon,1 Jae-Hoon Kim,2 Chel Hun Choi,3 Joon-Yong Chung,4 Stephen Hewitt,4 Stephen Libutti.1

1 Albert Einstein College of Medicine, Bronx, NY, 2 Yonsei University College of Medicine, Seoul, Republic of Korea; 3 Sungkyunkwan University School of Medicine, Seoul, Republic of Korea; 4 National Cancer Institute, Bethesda, MD

Purpose: The WNT/b-catenin pathway and the resulting epithelial-to-mesenchymal transition (EMT) play a key role in ovarian cancer progression and chemoresistance. Filamin A interacting protein 1-like (FILIP1L) enhances b-catenin degradation, thereby inhibiting canonical WNT signaling and EMT. FILIP1L is a tumor suppressor whose expression is down-regulated by promoter hyper-methylation in ovarian cancer. FILIP1L down-regulation is inversely correlated with the invasive potential of ovarian cancer cells. However, the clinical relevance of FILIP1L down-regulation in ovarian cancer progression has yet to be addressed. Experimental design: To study the clinical implications of FILIP1L in regulating the WNT/b-catenin pathway and chemoresistance, the expression of FILIP1L, b-catenin, SNAIL and SLUG was analyzed by immunohistochemistry on tissue microarrays of 369 ovarian samples ranging from normal to metastatic. Their expression was evaluated with clinical-pathological characteristics including FIGO stage and chemoresistance, and correlated with overall and disease-free survival by Kaplan-Meier plots and Cox proportional hazards model. Results: We demonstrated that FILIP1L expression decreased with tumor progression, resulting in a significant difference between primary and metastatic samples. In contrast, b-catenin expression was inversely increased with tumor progression. Furthermore, tumors that were resistant to platinum/paclitaxel combination therapy showed a significant reduction in FILIP1L expression when compared to sensitive tumors, contrary to SLUG expression, which was significantly higher. The expression of FILIP1L was negatively correlated with the expression of b-catenin and SLUG, whereas b-catenin expression was positively correlated with SLUG expression, suggesting a link between FILIP1L and the WNT/b-catenin pathway in ovarian cancer. Moreover, patients with low FILIP1L expression showed a median overall survival and disease-free survival of 60 and 19 months, respectively, whereas patients with high FILIP1L expression had not yet reached median overall and disease-free survival at their 120 month follow-up. Notably, low FILIP1L expression was an independent negative prognostic factor with respect to overall survival and disease-free survival. Conclusions: Our study provides the first clinical relevance of FILIP1L in human cancer, and suggests that FILIP1L may be a novel biomarker for good prognosis and lower probability of recurrence in ovarian cancer patients.

**#4719 MYC expression correlates with PD-L1 expression and related poor clinical outcome in non-small cell lung cancer.** Eun Young Kim, Arum Kim, Se Kyu Oh Kim, Yoon Soo Chang. Yonsei Univ. Coll. of Medicine, Seoul, Republic of Korea

Background: Programmed death-ligand 1 (PD-L1) is widely used biomarker for the response prediction of immune checkpoint inhibitors, but its usefulness has been challenged. MYC, a transcriptional factor which is overexpressed in various cancers, plays critical roles in preventing immune cells from attacking tumor cells by inducing PD-L1 expression. We evaluated that MYC expression is positively related that of PD-L1 in non-small cell lung cancer (NSCLC) clinical specimens and that it has potential as a predictor of response to immune checkpoint inhibitors in NSCLC. Methods: Eighty-four cases which were diagnosed as adenocarcinoma under WHO classification and with immunohistochemistry (IHC), PD-L1 expression was evaluated by FDA-approved PD-L1, 22C3 PharmDXTM protocol using the Dako Automated Link 48 platform at Clarient Diagnostic Services, Inc (Aliso Viejo, CA, USA). Its expression was determined by using Tumor Proportion Score (TPS), which is the percentage of viable tumor cells showing partial or complete membrane staining. If TPS ≥ 50% of the membrane staining, it was considered positive. IHC of MYC was performed using anti-c-MYC antibody [Y69] (ab32072, Abcam, USA) and its expression was evaluated by scoring system using product of nuclear staining intensity and percentage of positive cells. Results: When MYC cDNA was transfected into KRAS-dependent lung cancer cell lines that did not express both MYC and PD-L1, the protein expression and mRNA of PD-L1 were induced in a dose-dependent manner. On the other hands, knockdown of MYC with siRNA inhibited protein expression and mRNA indicating MYC regulates PD-L1 at transcriptional level. Of 84 NSCLC tumor tissues, PD-L1 was expressed in 14 (16.7%) and MYC in 30 (35.7%) cases. Dual positive patients were 9 (10.7%) and dual negative patients were 49 (58.3%). When the relationship between PD-L1 and MYC expression was evaluated, patients with PD-L1 positive only showed poor prognosis (p = 0.0267, P = 0.014). Dual positive patients showed significantly shorter disease free survival (16.1 vs. 62.5 months, P = 0.004) and overall survival (24.9 vs. 70.9 months, P = 0.002) than dual negative patients. Conclusion: MYC expression correlates with PD-L1 expression in the NSCLC and the patients with overexpression of both MYC and PD-L1 showed significantly poor survival. This suggest that it is worth of investigation of MYC expression as a surrogate predictive marker for treatment of immune checkpoint inhibitors in NSCLC.

**#4720 Novel findings for the clinical significance of RNA editing status of AZIN1 and ADAR1 and 2 expression levels in gastric cancer patients.** Yoshi-naga Okugawa,1 Yui Toyiama,1 Kunitoshi Shigeyasu,2 Takashi Ichikawa,2 Satoshi Oki,2 Koichiro Morii,2 Yuka Nagano,2 Hiromi Yasuda,2 Shigeyuki Yoshiyama,3 Masaki Ohi,4 Koji Tanaka,4 Yasuhiro Inoue,5 Yoshitomi Araki,4 Yasuhiro Mohri,4 Motoyoshi Tanaka,4 Chikao Miki,4 Ayaj Goel,5 Masato Kusunoki,5 Baylor Univ. Medical Ctr., Dallas, TX, 2 Okayama University, Okayama, Japan; 3 Mie University, Tsu, Mie, Japan; 4 Iga City General Hospital, Iga, Mie, Japan

Background. Despite recent advances in surgical techniques and treatment options, gastric cancer (GC) remains the third most common cause of cancer-related deaths worldwide. Besides DNA sequence mutations, epigenetic alterations have emerged as significant drivers of molecularly defined subgroups. A-to-I RNA editing is a post-transcriptional modification that converts adenosines to inosines in both coding and noncoding RNA transcripts, and has recently been recognized has a novel epigenetic mechanism in GC pathogenesis. More specifically, A-to-I editing of AZIN1 transcripts was shown to be regulated by an adenosine deaminase acting on RNA (A-DAR1), and edited AZIN1 resulted in an aggresive phenotype during disease progression in some human cancers. The aim of this study was to clarify the clinical consequences of RNA editing status of AZIN1 and the RNA editing enzymes (ADAR1 and 2) in GC patients. Methods. Two hundred eighty-eight gastric specimens from one hundred forty-four patients who underwent surgery for GC were evaluated. We analyzed the RNA editing status of AZIN1 by RNA editing site-specific quantitative PCR (RdSSPCR). REdSSPCR allows quantitation of RNA editing levels using wild-type or edited AZIN1-specific primers, and RNA editing levels are calculated by determining the ratios of Ct values between edited vs. wild-type transcript expression levels. Furthermore, expression levels of ADAR1 and ADAR2 were evaluated by qPCR in GC tissues. Results. We observed a higher frequency of the AZIN1 RNA editing in tumors compared with normal mucosa in GC. RNA editing status of AZIN1 was significantly correlated with advanced T stage and presence of lymph node metastasis in GC patients. Multivariate analysis revealed that high frequency of RNA editing in the AZIN1 gene was an independent prognostic factor for poor disease free survival and overall survival. Furthermore, significant upregulation of ADAR1 and downregulation of ADAR2 was also observed in GC tissues compared with matched normal mucosa, and these alterations also significantly correlated with disease progression factors and poor prognosis in GC patients. Interestingly, ADAR1 expression level was positively correlated with RNA editing status of AZIN1 in GC tissues. Conclusions. Our findings revealed that altered gene-specific A-to-I editing...
#4721 Novel lncRNA SLINKY is a prognostic biomarker in kidney cancer.

Xue Gong,1 Zurab Siprashvili,1 Ohyaz Emirgina,1 Zhouwei Shen,2 Yusuke Sato,2 Haruki Kume,2 Yukio Homma,2 Seishi Ogawa,2 Paul A. Khavari,1 Jona-
than R. Pollack,1 James D. Brooks2.1 Tokyo cohort (P RNA-seq data on 466 ccRCC cases randomized into discovery and validation, and prognostic biomarkers are needed to stratify patients for appropriate management. We sought to determine whether long intergenic non-coding RNAs (lincRNAs) might predict patient survival. Candidate prognostic lincRNAs were identified by mining The Cancer Genome Atlas (TCGA) transcriptome (RNA-seq) data on 466 ccRCC cases (randomized into discovery and validation sets) annotated for ~21,000 lincRNAs. A previously uncharacterized lincRNA, SLINKY (Survival-predictive lincRNA in Kidney cancer), was the top-ranked prognostic lincRNA, and validated in an independent University of Tokyo cohort (P = 0.004). In multivariable analysis, SLINKY expression predicted overall survival independent of tumor stage and grade [TCGA HR = 3.4 (CI, 2.1-5.4), P < 0.001; Tokyo HR = 9.2 (CI, 2.2-43), P = 0.003], and by decision tree, ROC and decision curve analysis, added independent prognostic value. In ccRCC cell lines, SLINKY knockdown reduced cancer cell proliferation (with cell cycle arrest) and induced transcriptional changes established for cell proliferation and survival processes. Notably, the genes affected by SLINKY knockdown in cell lines were themselves prognostic and correlated with SLINKY expression in the ccRCC patient samples. From a screen for binding partners, we identified direct binding of SLINKY to Heterogeneous Nuclear Ribonucleoprotein K (HNRNPK), whose knockdown recapitulated SLINKY knockdown phenotypes. Thus, SLINKY is a robust prognostic biomarker in ccRCC, where it functions possibly together with HNRNPK in cancer cell proliferation.

#4722 Evaluation of the prognostic value of ATG4B expression in different breast cancer subtypes.

Svetlana Botrtik,1 Basile Tessier Cloutier,1 Jamie Magrill,1 Samuel Leung,1 Aline Talhouk,2 Karen Gelmon,1 Stephen Yip,1 Tony Ng,1 Torsten Nielsen,1 Sharon Gorski1.1 BC Cancer Agency, Vancouver, British Columbia, Canada; 2University of British Columbia, Vancouver, British Columbia, Canada.

Introduction: Autophagy, a lysosome-mediated degradation and recycling process, functions as an adaptive survival response during various stressful conditions including hypoxia and chemotherapy. The cytosine protease ATG4B, an important component of the autophagy pathway, is becoming a promising therapeutic target, but its role as a prognostic marker in breast cancer has not been investigated yet. Our recent studies established a novel association between ATG4B and HER2 positive breast cancer. Objective: The aim of this study was to investigate the prognostic value of ATG4B in different breast cancer subtypes using a large population-based cohort. Methods/Experimental Design: We evaluated ATG4B cytoplasmic expression by immunohistochemistry on tissue microarrays (TMAs) from a cohort of 1600 breast cancer cases from British Columbia Cancer Agency. For this large, well-characterized cohort detailed clinical information was available, including age, histology, tumor grade, tumor size, lymph node status, type of local and adjuvant systemic therapy, and dates of first recurrence and death. Median follow-up time was 12.4 years. ATG4B expression was scored by two independent observers using a categorized H-score system. Survival analyses were performed using the Kaplan-Meier function and Cox proportional hazards regression models to evaluate the association of ATG4B expression with breast cancer-specific survival, stratified by intrinsic subtype. Results: ATG4B expression was significantly lower in basallike vs. non-basal (P < 0.001), basal vs. HER2 overexpressed (P = 0.0029), and triple-negative vs. non-triple-negative (P = 0.0001) breast cancer subtypes. In HER2+ breast cancers, high (H-score > 200) ATG4B expression was significantly associated with poor overall survival (hazard ratio (HR) = 1.90, 95% confidence interval (CI) = 1.10 to 3.27, P = 0.033), disease specific survival (HR = 2.23, CI = 1.23 to 4.04, P = 0.016), and relapse-free survival (HR = 1.92, CI = 1.09 to 3.39, P = 0.037). However, in Luminal A breast cancers, high (H-score > 150) ATG4B expression was strongly associated with improved overall survival (HR = 0.71, CI = 0.55 to 0.93, P = 0.012) and disease-specific survival (HR = 0.43, CI = 0.26 to 0.67, P = 0.0009). Conclusion: High ATG4B expression is a poor prognostic marker in HER2 positive breast cancer, but a favorable prognostic factor in the Luminal A subtype. Validation analyses are planned on a further set of 1989 cases.

#4723 Improving prognosis or promoting progression? Double sword of S100A10 in colorectal cancer.

Si Li, Fangying Xu, Lili Wang, Hui Li, Maode Lai. Department of Pathology and Pathophysiology, School of Medicine, Zhejiang Uni-
versity, Hangzhou, China.

Tumor tissues are heterogeneous, including cancer cells, cancer stem cells and immune cells. The immune microenvironment is involved in tumorigenesis and progression in colorectal carcinomas (CRC), S100A8, which represented granulocytes and monocytes, was identified as a favorable indicator for survival by previous work. Cancer stem cells (CSCs) and epithelial-mesenchymal transition (EMT) play critical roles on tumor cell malignancy and metastasis. The immune state, CSC and EMT should be regarded as integrity, which is important for clinical efforts and translational investigation. For better understanding the associations among immune cells, CSC and EMT in CRC, S100A8 as well as with CSC (Lgr5, Nanog, ALDH1 and CD44v6) and EMT (Cedarin and Snail) markers were detected in the tumor invasive front (TF) and tumor center (TC) respectively by immunohistochemistry in 419 CRCs and survival analysis was done. Furthermore, functions of S100A8 in EMT were verified in vitro. S100A8+ TF count was positively correlated with Lgr5+ TF (r = 0.162, P = 0.004) and cytoplasmic Snail+ TF expression (r = 0.116, P = 0.043), while it was not correlated with other stem cell markers wherever they were located, and not associated with E-cadherin+ or E-cadherin+ cytoplasmic snail1+ or nuclear Snail2+ and Snail2+ expression (P > 0.05). After combining S100A8+ TF and Lgr5+ TF, three groups were got. It showed S100A8+ TF and Lgr5+ TF had the best 5-year survival, while S100A8+ TF and Lgr5+ TF had the worst 5-year survival. In conclusion, S100A8+ TF and Lgr5+ TF had the best 5-year survival, while S100A8+ TF and Lgr5+ TF had the worst 5-year survival. S100A8 also had some influence on tumor cells not only facilitated tumor cell proliferation, migration and invasion but also converted cells to EMT phenotype. Western blot showed E-cadherin was downregulated and Vimentin, MMP9 and snake were up-regulated in S100A8+ overexpressed cells. The transcription factor USF2 was verified to interact with S100A8 by luciferase reporter gene. Western blot showed overexpression of USF2 increased S100A8 expression, while overexpression of S100A8 had no effect on USF2. In conclusion, S100A8 from immune cells or tumor cells has opposing effectson cancer progression. S100A8 in immune cells or tumor cells may help predict clinical outcomes in CRC patients.
presence of at least one biomarker could discriminate the SIOPEL high risk patients into an intermediate and a very high risk group (P<0.0001), whereas biomarker positive and negative standard risk patients showed no difference in outcome. Conclusions: We have validated the 16-gene signature and NF2EL2 mutations as highly prognostic biomarkers in HB and propose a new stratification system that combines the combination of clinical and biological factors, which might facilitate more tailored and risk-adapted therapies and thus better outcome of high risk patients in the future.

**#4725** Multiple Myeloma DREAM Challenge: a crowd-sourced challenge to improve identification of high-risk patients. Michael Mason,1 Fadi Towfic,2 Brian S. White,1 Dan Rozelle,1 Erin Flynt,3 Anjan Thakurta,4 Thomas Yu, Frank Schimetz,5 Andrew Dervan,6 Doug Bassett,7 Justin Guinney8. 1Sage Bio-networks, Seattle, WA; 2Celgene, Summit, NJ; 3Rancho Biosciences, Boston, MA; 4Celgene, Seattle, WA.

Introduction: Multiple myeloma (MM) is a cancer of the plasma cells in the bone marrow, and its clinical course depends on a complex interplay of traits including age, performance status, as well as genetic and molecular aberrations, and other molecular states of the plasma cells. Since risk-adapted therapy is becoming standard of care, there is an urgent need for a precise risk stratification model to assist in therapeutic decision-making. While progress has been made, there remains a significant opportunity to improve patient stratification to optimize treatment and to develop new therapies for high-risk patients. To accelerate the development and evaluation of such risk models in MM, we formed a DREAM Challenge, a crowd-sourced competition that engages large cross-disciplinary teams of experts to address complex problems in biomedicine. Methods and Data: Clinical variables, patient outcomes, genetic, and gene expression data from over 2100 samples were curated and harmonized from multiple public and private studies. A subset of the data (N=913) was used to evaluate previously published high-risk signatures against progression-free survival (PFS), the clinical endpoint of the challenge. We also developed and assessed de novo and ensemble methods. All models were evaluated using area under the receiver operating characteristic curve (AUC). Results: The international staging system (ISS) for Myeloma was used as a baseline for high-risk classification (PFS < 18mo, AUC = 0.57). We evaluated published high-risk signatures - UAMS-5, UAMS-17, UAMS-70, EMC92 - and observed AUCs of 0.62, 0.62, 0.61, 0.59, respectively. The average correlation of high-risk scores was 0.73 (min: 0.52 (UAMS-5 vs EMC92); max: 0.90 (UAMS-17 vs UAMS-70)), suggesting published classifiers capture non-overlapping determinants of risk. As such, we developed a Random Forest classifier that combined expression of genes utilized in the published classifiers with gender and age, trained on 70% of the data set, and validated on the remaining 30%. This de novo classifier achieved an AUC of 0.66 for PFS based risk classification. Incorporation of ISS leads to a modest improvement of accuracy (AUC=0.67). Conclusion: Preliminary analysis of the Challenge data suggests there is an opportunity to significantly improve risk stratification models in MM. In addition to the robust benchmarking of existing classifiers, we anticipate new, more accurate models will be proposed through a MM Challenge given the scale of the combined data sets. Additionally, we hope to uncover novel clinical and molecular traits that may yield insight into the pathobiology of MMM and development of new MM models. Importantly, this Challenge will illustrate the advantages of leveraging public data and crowd-sourcing to address therapeutically relevant questions in oncology.

**#4726** TonEBP promotes hepatocellular carcinoma and is associated with poor prognosis. Jun Ho Lee,1 Jae Hee Suh,2 Soo Youn Choi,3 Hyun Je Kang,2 Gap Ryol Lee,1 Whaseon Lee-Kwon,4 Neung Hwa Park,5 Hyung Moo Kwon6. 1UNIST, Ulsan, Republic of Korea; 2Ulsan University Hospital, Ulsan, Republic of Korea; 3Sogang University, Seoul, Republic of Korea.

Carcinogenesis is initiated by genetic changes due to aberrant processing of genetic information. Tumor microenvironment, however, should not be overlooked as cancer risk because they influence the development and progression. Indeed, the role of inflammation has received a lot of attention lately. Specifically, hepatocellular carcinoma (HCC) has been considered as an inflammation-associated tumor like colorectal cancer and lung cancer. In addition, high rates of recurrence is the major feature of HCC, and there is a need to identify novel biomarkers for post-operative prognostic of HCC patients. Tonicity-responsive enhancer binding protein (TonEBP), also known as nuclear factor of activated T cell 5 (NFAT5), is a key transcriptional cofactor for the expression of pro-inflammatory genes such as TNF-a, IL-1b, and cyclooxygenase 2 (COX-2). Surprisingly, this gene is hypothesized to be a biomarker of chronic hepatitis. In chronic hepatitis, endoplasmic stress, a hallmark of endoplasmic reticulum stress, is the key factor in regulating the expression of TonEBP. This study was initiated using immuno-histochemical staining for TonEBP in a 160 gastric cancer patient cohort. The expression of TonEBP was found to be significantly higher in tumor tissue than in normal tissue. Interestingly, univariate analyses revealed that TonEBP expression in normal tissue was significantly associated with tumor size, tumor grade, vascular invasion, viral DNA replication, α-fetoprotein, PIVKA-II, recurrence, metastasis, and death. In addition, Kaplan-Meier estimation and multivariate analyses showed that the TonEBP expression was an independent prognostic marker for recurrence and death in HCC patients. In mice, TonEBP hipo- deficient reduced both DEN- and DEN/high-fat diet (HFD)-induced HCC in association with lower COX-2 transcription and milder hepatic inflammation. Acute hepatic inflammation induced by DEN or lipopolysaccharide was also reduced in hepatocyte- or myeloid-specific TonEBP knockout mice. TonEBP-mediated activation of hepatic COX-2 promoter was dependent on the transcription factor Yin Yang 1 (YY1). TonEBP interacted with YY1 through the Rel-homology domain of TonEBP and spacer domain of YY1. In aggregate, our data demonstrate that TonEBP-mediated hepatic inflammation is an important regulator of hepatocarcinogenesis. The miR-223-YY1/TonEBP-COX-2 pathway drives hepatic inflammation and commits the stressed hepatocytes to malignant fate. Thus, TonEBP promotes HCC via COX-2 expression and is a strong post-operative prognosticator of poor outcome in HCC patients.

**#4727** Analysis of PIK3CA mutations and PI3K signaling proteins as prognostic biomarkers for advanced gastric cancer. Satoshi S. Nishizuka,1 Chie Ito,2 Kohei Kume,3 Takeshi Iwaya,4 Keisuke Koeda,2 Akira Sasaki.5 1Iwate Medical University Institute of Biomedical Sciences, Morioka, Japan; 2Iwate Medical University School of Medicine, Morioka, Japan.

Although surgery and chemotherapy has extended the survival of patients with advanced gastric cancer, some patients experience relapse. In cases of potentially curative gastrectomy, no visible tumor mass should be present at the time of post-operative chemotherapy. Therefore, relapse may be attributed to very small cancer cell populations that survive and develop drug resistance. Previously, we found that changes in the phosphatidylinositol 3-phosphate kinase (PI3K) pathway protein levels were responsible for the growth of drug-resistant cancer cells. In the present study, we postulated that the oncogenic mutations in PIK3CA and PI3K pathway proteins could be prognostic markers for patients with advanced gastric cancer. A retrospective cohort of 160 patients with advanced gastric cancer, receiving potentially curative surgery with/without chemotherapy was investigated for PIK3CA mutations and PI3K pathway protein levels in the context of 5-year overall survival (OS) and relapse-free survival (RFS). Mutations were screened by direct sequencing followed by validation through allele-specific quantitative real-time PCR, digital PCR, and ultra-deep sequencing. Tissue microarrays were produced from tumor-rich areas of surgically removed specimens. Protein levels were assessed by incubation with specific primary antibodies against total and phosphorylated proteins including PI3K (p85), AKT, mTOR, and PTEN, followed by colorimetric detection. Samples were deemed to have positive staining when more than 5% of the cancer cells had detectable protein. Statistical analyses showed that PIK3CA hotspot mutations were not directly associated with PI3K pathway activation; and (i) PIK3CA hotspot mutations occurred with low frequency in gastric cancer; (ii) PIK3CA hotspot mutations were not directly associated with PI3K pathway activation; and (iii) p-AKT(+) patients were higher than those of PTEN(-) patients in both surgery-only and chemotherapy groups although statistical significance was not confirmed. PTEN(-) patients showed similar survival curves for up to 2 years post-operation, and separated thereafter. No significant association was observed between PIK3CA mutations and PI3K pathway protein levels. Subgroup analysis demonstrated that both p-AKT(+) and PTEN(-) were better prognostic factors for survival. There was no interaction between the protein levels and any clinicopathological/mutational factors. This study revealed that: (i) PIK3CA hotspot mutations occurred with low frequency in gastric cancer; (ii) PIK3CA hotspot mutations were not directly associated with PI3K pathway activation; and (iii) p-AKT(+) may be a biomarker for better outcomes in gastric cancer patients undergoing gastrectomy.

**#4728** Plasma interleukin-6 level predicts prognosis of patients who received sorafenib for advanced hepatocellular carcinoma. Yu-Yun Shao,1 Hang Lin, Yong-Shi Li, Ying-Hui Lee, Ho-Min Chen, Ann-Li Cheng, Chih-Hung Hsu. National Taiwan University Hospital, Taipei City, Taiwan.
Background: No biomarker has been proven to predict the treatment outcomes of sorafenib, the only approved first-line therapy for advanced hepatocellular carcinoma (HCC). We explored predictive and prognostic values of plasma interleukin (IL)-6 levels for patients who received sorafenib as first-line therapy for advanced HCC. Methods: This study had 2 patient cohorts. The exploration cohort was composed of patients who were randomly selected from the national prospective, single-arm, open-label clinical trial that examined sorafenib with tegafur/uracil as first-line therapy for advanced HCC. The validation cohort consisted of patients who received sorafenib alone as first-line therapy for advanced HCC under reimbursement of National Health Insurance of Taiwan. Pretreatment plasma IL-6 levels were determined. We used the receiver operating characteristic (ROC) curve in the exploration cohort to determine the best cut point for IL-6 levels in predicting outcomes (OS). We then confirmed the cut point in the validation cohort. Results: There were 55 and 73 patients in the exploration and validation cohort, respectively. In the exploration cohort, there was no complete response but 3 (6%) partial response. The median OS was 8.1 months. In the validation cohort, there was no complete response but 7 (10%) partial response. The median OS was 10.3 months. In the exploration cohort, we found 4.28 pg/ml was the best cut point defining high and low IL-6 levels because it could differentiate OS (p = 0.042) with the best sensitivity and specificity. Applying the cut point on the validation cohort, patients with high pretreatment plasma IL-6 levels, compared with patients with low IL-6 levels, exhibited significantly poorer OS (median, 8.0 vs. 13.9 months, p = 0.03). After adjusting for age, gender, hepatitis etiology, tumor characteristics, and pretreatment characteristics, a high plasma IL-6 level remained an independent predictor for poor OS (hazard ratio 2.594, p = 0.005). By contrast, the plasma IL-6 level was not associated with progression-free survival, treatment response, disease control, or other patient characteristics. Conclusion: High pretreatment plasma IL-6 level predicted prognosis of patients who received sorafenib as first-line therapy for advanced HCC.

#4729 Association of mitochondrial DNA copy number variation in peripheral blood leukocytes with risk and prognosis of gallbladder cancer. Abhijit Chandra,1 Hasan R. Kazmi,2 Leena K. Satyam,3 Saket Kumar1.

Gallbladder Cancer (GBC) is the most common malignancy of the biliary tract with very high incidence in Northern India, especially around Gangetic belt. Late diagnosis and poor prognosis are the important features of this disease. For improving treatment strategies and outcomes, novel non-invasive prognostic biomarkers are needed. Variations in peripheral blood mitochondrial DNA (mtDNA) copy number in various cancers are widely studied but information in relation to gallbladder malignancy is unknown. In this pilot study, we investigated leukocytes mtDNA copy number variation recently observed in a phase 2 survival (OS) study. A total of 300 histologically confirmed or fine needle aspiration cytology proven GBC patients were recruited along with equal number of age and sex matched controls. The mtDNA copy number was measured by real-time polymerase chain reaction through absolute quantification using SYBR green chemistry. We also explore prognostic utility of mtDNA content in relation to overall survival (OS) and disease free survival (DFS) in patients. Statistical analysis was done by Student’s t-test and survival data was compared using Kaplan Meier method. Two tailed p value less than 0.05 was considered to be significant. We observed high mtDNA content in cases as compared with controls (mean± standard deviation, 1.21±0.88 vs. 1.02±0.76). Higher mtDNA copy number was significantly associated with increased gallbladder cancer risk (p=0.005). In this study, we compared overall survival (OS) for gallbladder cancer patients in relation to mtDNA copy number median value (median, 1.12). Kaplan Meier survival curve predicts decrease in OS (p=0.03, Hazard ratio=2.54, 95% CI = 1.79-5.86) for GBC patients in relation to high mtDNA content (>median) as compared with low mtDNA copy number (<median). This study supports an association between increased mtDNA copy number with susceptibility to gallbladder cancer in this high incidence belt. Future studies are warranted to confirm these findings and to elucidate the biological role of mtDNA copy number in relation to gallbladder cancer.

#4730 Fluorescence in situ hybridization panels for prediction of disease progression in prostate cancer patients on active surveillance. Adam J. Koch,1 Ying Zhang,2 Beth Blondin,3 Svetlana Sitailo,1 Huixin Fei,1 Stephen Van Den Eeden,3 Ekaterina Pestova1.

Background: Overdiagnosis and overtreatment of men with lower-risk Prostate Cancer (PCA) is a concern due to co-morbidities and healthcare costs. Maximizing patient quality of life while recognizing early signs of aggressive disease is essential. There is a need to stratify patients according to the risk of disease progression, identifying with high specificity and sensitivity patients to biopsy, re-biopsy and monitor. Within the high risk population, there is a need to identify when to proceed with treatment. Methods: We performed a retrospective study to evaluate FISH biomarkers on PCA specimens with histologically confirmed, clinically localized disease (T1c-T2c) enrolled in Active Surveillance (AS). AS patients were classified into two categories: Progressive (clinical intervention within 10 years), and non-progressive (did not progress to intervention in 10 years). Cohorts were matched by clinical characteristics (Gleason score, disease stage and grade, PSA level, age, race) as possible. The study objective was to establish a FISH biomarker panel to differentiate non-progressive from progressive prostate cancer in the low and intermediate risk groups. Receiver Operating Characteristic (ROC) curve analysis was performed to obtain the best single parameters based upon Area Under the Curve (AUC). For each FISH parameter cutoffs were determined based on Sensitivity, Specificity and Distance from Ideal (DEI). Further ROC analysis was used to identify the best 3-5 probe combinations. FISH parameters were combined with clinical parameters in the final model. Results: Five combinations of FISH parameters with the highest AUC and sensitivity in discriminating case and control groups were selected based on ROC curve analysis. Combinations were superior in performance to single probes. The best individual parameter, MYC gain, had an AUC of 0.6998. The two best combinations of parameters, MYC Gain/NKX3.1 Gain/ NMYC Gain/PTEN Homozygous and MYC Gain/ETV1 Break Apart/NKX3.1 Gain/PTEN Homozygous had AUC of 0.7363 and 0.7236, respectively. In the progression cohort, MYC gain and PTEN loss were involved in the expression/localization of the best single parameter, MYC Gain/NKX3.1 Gain/ PTEN Homozygous had AUC of 0.7363 and 0.7236, respectively. In the progression analysis, these combinations contributed significantly to the prediction of PCA outcome (progressive vs non-progressive, odds ratios of 5.522 and 0.03). The combination of clinical parameters and FISH outperformed clinical parameters or FISH alone, with odds ratios of 5.955 and 6.118, respectively. The combination of clinical parameters and FISH outperformed clinical parameters alone, and was complimentary to clinical parameters (NCCN Risk Groups) in the final model, demonstrating potential utility of multi-color FISH panels as an auxiliary tool for PCA risk stratification. Further studies with larger cohorts are planned to confirm these findings.

#4731 Phospho-akt: a potential resistance marker to chemotherapy and a therapy-target to restore sensitivity in pancreatic cancer. Daniela Massinna,1 Amir Avan,2 Nicola Funel,3 Carlotta Granchi,3 Filippo Minutolo,3 Letícia Leon,3 Godofridus Peters,3 Elisa Giovannetti3.1. University of Amsterdam, Amsterdam, Netherlands; 2University of Ma'dinah, Ma'dinah, Islamic Republic of Iran; 3University of Pisa, Pisa, Italy.

Oncoogenic KRAS signaling is the main driving force behind pancreatic ductal adenocarcinoma (PDAC); however, targeting this pathway has proven to be difficult. Conversely, the PI3K/Akt pathway represents an exciting new target, however it has been associated with poor prognosis and chemoresistance, and several inhibitors are under development. In particular, perifosine prevents Akt translocation to the cell membrane, while MK-2206 is an Akt allosteric inhibitor and BEZ-235 is a dual PI3K/mTOR inhibitor. Therefore, we investigated the prognostic role of phospho (p)-Akt in PDAC tissues, as well as the molecular mechanisms underlying the interaction of Akt inhibitors with gemcitabine, using PDAC cells, primary cultures and spheroids. Immunohistochemistry of tissue microarrays with specimens from radically-resected patients (n=100) revealed a correlation between high p-Akt expression and worse outcome. Patients with low p-Akt expression (as detected by digital scoring) had a median overall survival (OS) of 16.2 months (95% CI, 14.8-20.1), while patients with high expression had a median OS of 12.9 months (95% CI, 9.0-14.9, P=0.03). Parallel immunocytochemistry studies revealed high expression levels in LPC028 primary cells, while LPC006 were characterized by low p-Akt1. Akt inhibitors reduced cancer cell growth in monolayers and spheroids, and synergistically enhanced the antiproliferative activity of gemcitabine in LPC028 (e.g., combination index CI of 0.2, in the gemcitabine-perifosine combination for 72h, at fixed IC50 ratio), while this combination was antagonistic in LPC006 cells. The synergistic effect was paralleled in the proliferation by a 5-fold reduction in the expression of the main gemcitabine target ribonucleotide reductase. Inhibition of Akt decreased cell migration and invasion, which was additionally reduced by the combination with gemcitabine. However, the combination of Akt inhibitors with gemcitabine increased apoptosis, associated with induction of caspase-3/8/9, PARP and BAD, and inhibition of Bcl-2 and NF-kB in LPC028, but not in LPC006. Further FISH studies with larger cohorts are planned to confirm these findings.
PGL13 enhanced perifosine and perifosine/gemcitabine-induced cell death. In conclusion, our findings support the analysis of phospho-Akt expression as both a prognostic and a predictive biomarker, for the rational development of new combination therapies targeting the Akt pathway in PDAC. Finally, inhibition of Glut1 might overcome resistance to these therapies and warrants further studies.

#4732 Analysis of KRAS variant in a cohort of resected HPV negative HNSCC. Jeffrey Mufson,1 Elizabeth Handorf,2 Joanne Weidhaas,3 Miriam Lango,3 Barbara Burtenshaw,3 Erica Golemis,3 John A. Ridge,3 Raneen Mehraj,4 Yale University, New Haven, CT; 3Fox Chase Cancer Center, Philadelphia, PA; 3UCLA, Los Angeles, CT; 3Johns Hopkins University, Baltimore, MD.

Background: A single nucleotide polymorphism in let-7 complementary site 6 (LS-6) of the KRAS 3’ UTR reduces KRAS inhibition by the let-7 family of miRNA. It is associated with increased risk and greater proliferation of NSCLC tumors, and poor outcomes in ovarian cancers. It is also associated with platinum resistance in head and neck squamous cell carcinoma (HNSCC). The excision repair cross-complementing group 1 enzyme (ERCC1) plays an important role in nucleotide excision repair and double strand break repair, also affecting platinum resistance. We measured ERCC1 expression and KRAS L5-6 variant status as prognostic markers for HNSCC outcome in a series of p16 negative tumors. Methods: KRAS variant status was determined by PCR (MiraxDx) from DNA extracted from 99 available cases of p16 negative HNSCC in the Fox Chase Cancer Center Biosample Repository. Pearson’s Chi-squared tests and Wilcoxon tests were used to compare patient/tumor characteristics, including ERCC1 (HPA029777, Sigma) expression which was analyzed previously, by KRAS variant status. Overall survival was examined using Kaplan-Meier curves with log-rank tests for significance, and Cox proportional hazards regression to control for stage, grade, and tumor site. Results: A set of 99 p16 negative tumors (1990-2002) were analyzed: 62% male, 92% white, 53% moderately differentiated, 29% poorly differentiated. 72% stage III/IV disease. Smoking status was: 32% current, 15% never, 32% past smoker. Primary site of disease: 13% glottis, 44% oral cavity, 14% oropharynx, 20% oral tongue. The KRAS variant was identified in 27/99 (27%) of tissue samples, and in 21/62 (33%) of male patients versus 6/37 (16%) of female patients (P = 0.06). Comparing by histologic grade the KRAS-variant was identified in 2/11 (18%) well differentiated tumors, 15/37 (40%) moderately differentiated and 9/29 (31%) poorly differentiated tumors (P = 0.81). On univariate analysis, there was a non-significant increase in OS among all KRAS-variant patients (P = 0.09) and those treated with surgery and adjuvant radiation (P = 0.08). On multivariate analysis, the direction of the effect was maintained (all patients: HR = 0.65, P = 0.23; radiation subgroup: HR = 0.41, P = 0.06). There was no association between KRAS variant and ERCC1 expression analyzed as a continuous variable (P = 0.70). Conclusion: In this small series, there was no association between the KRAS-variant and ERCC1 expression. Trends suggesting improved outcomes among KRAS-variant HPV negative patients treated with adjuvant radiation warrant further study.

#4733 Dysregulation of CUL4A and CUL4B ubiquitin ligases in lung cancer. Hui Li,1 Lei Jia,1 Fan Yan,1 Pengbo Zhou2.

Background: The Cullin-RING ubiquitin ligases 4 (CRL4) is implicated in controlling cell cycle, DNA damage repair and checkpoint response based on studies employing cell lines and mouse models. CRL4 proteins, including CUL4A and CUL4B are often highly accumulated in human malignancies. Elevated CRL4A attenuates DNA damage repair and increases genome instability that is believed to facilitate tumorigenesis. However, this has yet to be evaluated in human cancer patients. Methods: 352 lung cancer and 62 benign lung specimens of Asian origin were constructed into tissue microarrays (TMAs) of four distinct lung cancer subtypes. Expression of CUL4A, CUL4B and their substrates was detected by immunohistochemistry (IHC), and analyzed statistically for their prognostic value and association with DNA damage response and genomic instability. Results: Both CUL4A and CUL4B are overexpressed in the majority of lung carcinomas (CUL4A<0.001, CUL4B<0.001), and significantly associated with tumor size (CUL4A<0.001, CUL4B=0.002), lymphatic invasion (CUL4A=0.004, CUL4B<0.001), metastasis (CUL4A=0.019, CUL4B=0.006), and advanced TNM stage (CUL4A<0.001, CUL4B<0.001), which parallels gene amplification and abnormal activation of the canonical Wnt signaling. Moreover, overexpression of CUL4A, but not CUL4B, is significantly associated with tobacco smoking (P=0.01), and inversely correlated with XPC and p21, both of which are substrates of CUL4A (PCUL4A=0.019, PCUL4B=0.006). Higher levels of CUL4A or CUL4B are significantly associated with patients’ OS (PCUL4A<0.001, CUL4B<0.001) and PFS (PCUL4A<0.001, CUL4B=0.001). Conclusion: Our findings revealed that CUL4A and CUL4B are differentially associated with etiological factors for pulmonary malignancies and are independent prognostic markers for survival of distinct lung cancer subtypes.

#4734 miR-9-5p expression in breast cancer correlates with hormone receptor status and affects patients survival. Raffaella Barbanera,1 Barbara Pascoli,1 Micheline Rendina,1 Andrea Fontana,1 Caterina Fusilli,2 Massimiliano Copetti,1 Stefano Castellana,1 Vanna Maria Valori,1 Maria Morrirti,2 Paolo Graziano,3 Luigi Ciuffreda,4 Micheline Coco,5 Francesco Picardo,6 Tommaso Mazza,7 Ella Erono,8 Roberto Murgio,9 Evaristo Maiello,3 Manel Esteller,4 Vito Michele Fazio,1 Paola Parrella,1 IRCCS Casa Sollievo della Sofferenza, San Giovanni Rotondo, Italy; 3Campus Bio-Medico University, Rome, Italy; 4Assar Harofeh Medical Center, Zerefin, Israel; 5Bettleighe Biomedical Research Institute (IDIBELL), Barcelona, Spain.

miR-9 (hsa-mir-9-5p, miR-9-5p) is a highly conserved microRNA (miRNA) primarily expressed in the central nervous system. The three promotors of miR-9 (mir-9-1 at 1q22, miR-9-2 at 5q14.3 and miR-9-3 at 15q26.1) are embedded within CpG islands, and hypermethylation in at least one of these regions has been reported in several tumor types, thus miR-9-5p has been designated as an epigenetically regulated miRNA. However, only a partial or none correlation between methylation status of miR-9 loci and miR-9-5p expression has been demonstrated so far. Furthermore, the expression levels of miR-9-5p resulted highly variable across different carcinomas and conflicting evidences also exist about its functional role within the tumor context. In light of this, we took the effort of clarifying the role of miR-9-5p in primary breast cancer tissues and of evaluating its potential as a clinical relevant prognostic biomarker. We analysed miR-9-5p expression and miR-9 promoters methylation status in 129 breast cancer cases and 12 normal breast tissues (NBTSs), by qRT-PCR and MSP respectively. Overall, miR-9-5p was increased in tumors compared to NBTSs (P<0.001). No significant correlation between promoter methylation and miR-9-5p expression was found either in tumors or in NBTSs. Interestingly, miR-9-5p expression was inversely correlated with ER and PgR positivity (P=0.004 and P=0.003, respectively). Consistently, triple negative breast cancer (TNBC) showed the highest miR-9-5p levels and luminal subtype the lowest (P=0.04). The analysis of the TCGA Breast Cancer dataset (n=256) confirmed our results and further demonstrated that miR-9-5p was differentially expressed between the two luminal subtypes (P=0.009) and HER2-amplified compared to TNBCs (P<0.0001). In Univariable Cox regression analysis miR-9-5p expression was significantly associated with higher risk of death (P=0.023). Ingenuity Pathway Analysis exploring the putative interactions among miR-9-5p, ER and PgR upstream and downstream regulators suggested a regulatory loop by which miR-9-5p is induced by steroid hormone receptors and acts within a hormone-receptor and its downstream regulated pathways. Our data suggest miR-9-5p may help refine the molecular classification of breast cancer subtypes and provide additional prognostic information.

#4735 Expression of Notch1 and Numb in small cell lung cancer. Haimi Kikuchi,1 Jun Sakakibara-Komishi,2 Megumi Furuta,3 Hiroshi Yokoouchi,2 Hiroshi Obi,3 Junichiro Takahashi,3 Masaharu Nishimura1.

Background: Notch signaling plays an important role in tumorigenesis. Numb represses intracellular Notch signaling. Previous studies have demonstrated that Notch signaling suppresses the proliferation of small cell lung cancer (SCLC) cell lines. However, in SCLC, the association between Notch1 and Numb expression and clinicopathological factors or prognosis has remained unclear. In this study, we evaluated the expression of Notch1 and Numb in SCLC. Methods: We immunohistochemically assessed 125 SCLCs that were surgically resected at 16 institutions participating in either the Hokkaido Lung Cancer Clinical Study Group Trial (HOT) or the Fukushima Investigative Group for Healing Thoracic Malignancy, Japan; 2Hokkaido Lung Cancer Clinical Study Group Trial, Japan; 3Fukushima Investigative Group for Healing Thoracic Malignancy, Japan; 4Kanazawa Medical University, Uchinada, Japan; 5University of Occupational and Environmental Health, Kitakyushu, Japan.

Background: Notch signaling plays an important role in tumorigenesis. Numb represses intracellular Notch signaling. Previous studies have demonstrated that Notch signaling suppresses the proliferation of small cell lung cancer (SCLC) cell lines. However, in SCLC, the association between Notch1 and Numb expression and clinicopathological factors or prognosis has remained unclear. In this study, we evaluated the expression of Notch1 and Numb in SCLC. Methods: We immunohistochemically assessed 125 SCLCs that were surgically resected at 16 institutions participating in either the Hokkaido Lung Cancer Clinical Study Group Trial (HOT) or the Fukushima Investigative Group for Healing Thoracic Malignancy (FIGHT) between 2003 and 2013. Correlations between Notch1 or Numb expression and various clinicopathological features were evaluated. Results: Notch1 expression was associated with EOCG performance status. Numb expression was associated with age, sex, and patho-
logical history (SCLC or Combined SCLC). Analysis of cellular biological expression did not demonstrate a significant correlation between the expression of Notch1 and of Numb. Multivariate Cox regression analysis showed that high Notch1 expression was an independent favorable prognostic factor for SCLC (hazard ratio = 0.503, P = 0.023). Conclusions: We demonstrate that Notch1 expression, but not Numb, is associated with prognosis in SCLC and may provide a novel prognostic marker of SCLC.

Background: There is growing evidence that ADAM (a disintegrin and metalloproteinase) family proteins are involved in multiple types of cancer, including breast cancer. More than 50 members of the ADAM family have been identified thus far. Previous studies have focused on one or two ADAMs but comparative research among the members of the family is lacking. This study was undertaken to identify the most important ADAMs associated with breast cancer. Methods: We analyzed mRNA expression of ADAMs in tumor bed stroma and paired normal adjacent stroma from 31 breast cancer patients. The original raw data was adapted from a breast dataset (Finak et al, 2008). We next analyzed RNA expression of 35 ADAMs in different subtypes of breast cancers [dataset from Affymetrix U133A arrays using methods available in the R statistical software package (http://cran.r-project.org)]. We further evaluated protein expression of ADAMs and related signaling molecules in 187 breast cancers, including 110 untreated primary tumors and 77 residual tumors after neoadjuvant chemotherapy, and 167 matched “normal” mammary tissues using reverse phase protein arrays (RPPA). The association between ADAMs expression and survival was analyzed using Kaplan–Meier analysis. Results: The microarray analysis of tumor bed stroma revealed significantly elevated mRNA levels of 12 ADAMs, including ADAM8, ADAM 12, ADAM 19, ADAM 21, ADAM 17, ADAM 10, ADAM 28, ADAM 7, ADAM 33, ADAM 22, ADAM 6 and ADAMTS20, compared to their normal adjacent stroma. We evaluated the expression of 35 ADAMs in total 369 breast cancers, including 201 hormone receptor positive (HR+), 60 HER2 amplified (HER2+) and 108 triple negative (TN) patients using RNA array and demonstrated that 24 of 35 ADAMs were significantly upregulated in TNBC compared to that in HR+ and HER2+ subtypes. We further analyzed protein expression of ADAMs in 189 breast cancers and 172 matched “normal” breast tissues with RPPA. Compared to “normal” breast tissues, ADAM17, ADAM10, ADAM15, ADAM8 and ADAM9 were significantly increased in tumors (P < 0.0001, respectively), while ADAM20, ADAM23, ADAM29, and ADAM30 exhibited lower level. Kaplan–Meier analysis showed that a higher overall survival rate in high expression of ADAM 17, ADAM 15 or ADAM10 group was significantly decreased compared to that in the low expression group (40% vs. 12%, P = 0.0026; 50% vs. 11%, P = 0.0104; 53% vs. 9%, P < 0.0001, respectively), suggesting that upregulation of ADAM17, ADAM15, or ADAM10 was significantly associated with poor outcome. ADAM17, ADAM9 or ADAM10 expression was tightly associated with elevation of the classical apoptosis inhibitor Bcl-x, cyclins (E1, E2, B1), PTEN, p53, and phosphorylation of 4-EGBP1. Conclusion: Several ADAM proteins have elevated expression in breast cancer and are associated with decreased patient survival. ADAMs may, therefore, serve as potential biomarkers for predicting outcomes and oncotargets in breast cancer.

#4737 A lung cancer risk classifier comprising genome maintenance genes measured in normal bronchial epithelial cells. Jhyoung Yeo,1 Erin Crawford,1 Xianlou Zhang,2 Sadik Khuder,1 Tian Chen,1 Albert Levin,3 Thomas Blomquist,1 Xiaolu Zhang,2 Sadik Khuder,1 Tian Chen,1 Albert Levin,3 Thomas Blomquist,1 Anh Do, Gordon B. Mills, William F. Symmans, Naoto T. Ueno, Ana M. Gonzales-Angulo, Gabriel N. Hortobagyi, Debasish Tripathy. UT MD Anderson Cancer Ctr., Houston, TX.

Background: Annual low dose CT (LDCT) screening of individuals at high demographic risk reduces lung cancer mortality by more than 20%. However, annual LDCT screening compared to current demographic criteria is expected to have clinical utility by better stratifying subjects for annual lung cancer screening compared to current demographic criteria alone.

INTRODUCTION. The wide spread adoption of population-based breast cancer screening has led to a substantial increase in diagnosis of ductal carcinoma in situ (DCIS). When detected, almost all DCIS is treated to prevent progression to invasive disease, even though the majority of DCIS will never progress. Yet, we are unable to discriminate harmless from potentially hazardous DCIS. Hence, there is an urgent need to find characteristics of DCIS and biomarkers that predict subsequent invasive tumor development. In this study, we compared primary DCIS lesions with their subsequent ipsilateral invasive breast cancer (iIBC), to explore how the initial DCIS lesion and its subsequent iIBC are related. PATIENTS AND METHODS. We used a population-based, nation-wide cohort consisting of 2,654 women who were treated for primary DCIS by breast conserving surgery (BCS) only. Within a median follow-up time of 10.7 years, 316 women developed a subsequent iIBC (12%). FFPE tissue blocks of both DCIS and subsequent iIBC could be collected for 158 of these 316 women. We assessed histology characteristics, tumor location, estrogen and progesterone receptor status, p16 expression, and HER2 and p53 overexpression. Additionally, DNA and RNA were simultaneously isolated from 100 DCIS and 100 matched subsequent iIBC specimens for extensive molecular profiling. RESULTS. More than 95% of the invasive recurrences were located at or near the site of the primary DCIS. Concordant histological grade was found in 94% of the matched pairs and identical immunohistochemical (IHC) marker expression in 58%. Of the 44 patients with HER2 positive DCIS, 36% developed HER2 negative iIBC. Furthermore, this change in HER2 status was also a main cause of a change in surrogate intrinsic subtype (based on ER, PR, HER2) between DCIS and iIBC, which was observed in 16% of the patients. These dissimilarities were not found when we compared invasive disease with synchronous DCIS (present in 83 of 158 patients). Molecular analyses is still ongoing. CONCLUSION. This is the first time that an unbiased comparison could be made between primary DCIS and its subsequent iIBC within such a large patient group, integrating clinical, histological and IHC data. Our results suggest that the majority of invasive breast cancers in our cohort reflect outgrowth of residual disease based on tumor location and histological grade. DCIS and iIBC are very similar when comparing histological grade, but frequently show differences on the IHC level. Remarkably, the dissimilarities in HER2 status and surrogate intrinsic subtype as seen in primary DCIS vs. iIBC are missing when comparing iIBC with synchronous DCIS. As a next step, we will analyse the lesions on the molecular level, to verify these findings and to look for molecular characteristics of DCIS that could be associated with progression to invasive disease.

#4739 Prognostic impact of abnormal DNA damage response protein expression in breast cancer. Kyoung Jin Suh,1 Han Suk Bya,1 Kyung-Hun Lee,1 Hyoin Kim,1 Ahrum Min,2 Tae-Yong Kim,1 Hyeong-Gon Moon,1 Sae-Won Han,1 Do-Youn Oh,1 Wonshik Han,2 In Ae Park,1 Dong-Young Noh,3 Seock-Ah Im1,2. 1Seoul National University Hospital, Seoul, Republic of Korea; 2Seoul National University Cancer Research Institute, Seoul, Republic of Korea; 3Seoul National University Hospital, Seoul, Republic of Korea.
Purpose: Defects of DNA damage repair are known to be associated with the efficacy of anthracycline or platinum-based chemotherapy as well as poly[ADP-ribose] polymerase (PARP) inhibitors (PARPi) and PD-1/PD-L1 checkpoint inhibitors. Since multiple proteins are involved in DNA-damage response (DDR) and operate collectively, our main aim was to better understand the expression patterns of a single DDR protein and to identify potential biomarkers indicating highly aggressive tumors in the different subtypes of breast cancer. Methods: A total of 419 consecutive breast cancer patients who underwent curative resection in 2008 were enrolled in the study. Tissue microarray has been constructed, and NBS1, BRCA1, BRCA2, ATM and p53 expression were determined by immunohistochemistry. Results: All patients were female, with a median age of 47 years; 280 (67%) had luminal A, 36 (9%) had luminal B, 37 (9%) had HER2-enriched, and 56 (13%) had triple-negative breast cancer (TNBC). Loss of NBS1, BRCA1, ATM, and p53 expression was observed in 6.7%, 33.7%, 89.9%, and 30.8% of breast cancer patients, respectively, and abnormal p53 expression was observed in 39.3% of patients. Loss of NBS1, BRCA1, ATM and abnormal p53 expression was associated with significantly lower disease-free survival (DFS) rates, respectively.

\textit{Abnormal DDR protein expression}, defined as loss of any one of NBS1, BRCA1, ATM and/or abnormal p53 expression, was observed in 258 of 399 evaluable cases (64.7%) and was significantly associated with higher tumor grade, larger tumor size, and ER- and/or PR-negative status. Majority of patients with luminal B (31/36, 86.1%), HER2-enriched (34/53, 94.4%), and TNBC (46/53, 86.8%) subtype showed abnormal DDR protein expression. In comparison, 136/264 (51.8%) with luminal A subtype had abnormal DDR protein expression. Abnormal DDR protein expression was associated with significantly lower 5-year DFS rate than those in patients with normal DDR protein expression in all patients (95.6% vs. 84.8%, p = 0.001), as well as in luminal A subgroup (97.4% vs. 89.0%, p = 0.011). In multivariate analysis, abnormal DDR protein expression remained as an independent predictor of shorter DFS for luminal A subtype tumors (hazard ratio 3.14; 95% confidence interval, 1.16 – 8.47, p = 0.024). Conclusion: We demonstrated differential expression of proteins in DDR machinery according to breast cancer subtypes and its prognostic implication. Most of luminal A and HER2-enriched tumors has abnormal DDR expression as frequently as triple negative tumors. Less but significant proportion of luminal A tumors also shows abnormal DDR protein expression, which is an independent poor prognostic factor.

### 44740 Loss of the tumor suppressor zinc finger protein-36 and risk of lethal prostate cancer. Travis Gerke,1 Daniela Bornjen,1 Himisha Beltran,1 Svitlana Tyekucheva,4 Curtis Huttenhower,5 Gwo-Shu Lee,4 Bruce Trock,6 Lorelei Mucci,7 Christopher Sweeney4.

**Background.** Biomarkers are needed to complement current clinicopathologic variables in prostate cancer. Tumor mRNA expression of ZFP36 is prognostic for metastatic or lethal prostate cancer. Combining information on ZFP36 with measurements from other mechanistic pathways, such as PTEN, may lead to highly accurate models.

**Objectives.** Follow-up Study and Physicians' Health Study. Gene expression for ZFP36 and PTEN was validated using a robust genome-wide microarray approach to identify ZFP36, also known as Tristetraprolin (TTP), as a tumor suppressor in the NFκB pathway. The current study aims to evaluate the prognostic potential of tumor mRNA expression of ZFP36. **Methods.** Our primary gene expression analysis leveraged data from a case-control study nested in the Health Professionals Follow-up Study and Physicians' Health Study. Gene expression for ZFP36 and PTEN was validated using a robust genome-wide microarray approach to identify ZFP36, also known as Tristetraprolin (TTP), as a tumor suppressor in the NFκB pathway. The current study aims to evaluate the prognostic potential of tumor mRNA expression of ZFP36. **Results:** In multivariate models (HR 0.63, P < 0.001), as well as in luminal A subgroup (HR 0.41, P = 0.0001) compared to normal plasma samples (n = 8), miRNA-21, miR-221 and miRNA-106a were selected for further validation based on their known biological importance. We showed that all three circulating miRNAs were expressed significantly higher in OS samples (n = 29) than normal samples (n = 17) in an independent cohort obtained from the Children’s Oncology Group. Furthermore, we demonstrated that miR-21 was expressed significantly higher in osteosarcoma tumors (n = 89) compared with normal bone controls. More importantly, lower expressions of miR-21 and miR-221, but not miR-106a, significantly correlated with a poor outcome. In conclusion, our results indicate that miR-21, miR-221 and miR-106a are elevated in the circulation of osteosarcoma patients, whereas tumor expressions of miR-21 and miR-221 are prognostically significant. Further investigation of the miRNAs may lead to a better prognostic method and potential miRNA therapeutics for osteosarcoma.
Given the difference in CTNNB1 MT rate and importance of MTS in axin/β-catenin binding sites, WNT signaling differences between L and R sided tumors may be important to explore further.

### #4743 Identification of metastasis-associated biomarker PLEC1 by iTRAQ-based proteomic approach and prognostic role of PLEC1 in patients with hepatocellular carcinoma

Lin-lan Song, Yu Chen, Di Mu, Xiao-Yan Ji-ang, Yu-Nong Li, Ling-Yu Jiang, Zhen-Fang Zhang, Liang Yan, Min Yang, Yi-xuan Yang, Hong Ren, Yong Liao. Key Laboratory of Molecular Biology for Infectious Diseases (Ministry of Education), Institute for Viral Hepatitis, Department of Infectious Diseases, The Second Affiliated Hospital, Chongqing Medical University, Chongqing, China.

Purpose: Hepatocellular Carcinoma (HCC) is the fifth most prevalent cancer and the second most frequent cause of cancer-related death in men worldwide because of high incidence of recurrence and widespread metastasis. However, to date, there have been no direct metastasis-associated biomarker which is critical for the effective treatment of patients with HCC, we thus aimed to identify novel HCC metastasis-associated biomarkers with prognostic significance. Experimental Design: Two human HCC cell lines, MHCC97-L and MHCC97-H with similar genetic background and stepwise increasing metastatic potentials, were used to explore potential metastasis-associated biomarkers for HCC by isobaric tag for relative and absolute quantification (iTRAQ) combination with 2D-LC-MS/MS. Nineteen HCC cancerous and paracancerous tissues were further analyzed by immunohistochemistry to validate the correlations between the expression levels of PLEC1 with various clinicopathological factors and patient survival. Results: Using iTRAQ combination with 2D-MS/MS, a total of 47 differentially expressed proteins were found in MHCC97-L and MHCC97-H cells, of which 26 proteins were up regulated and 21 proteins were down regulated. Plectin-1 (PLEC1) was identified and re-confirmed as a potential biomarker for HCC that was highly up-regulated in tumor tissues, in comparison with that of para-cancerous tissues. Over-expression of PLEC1 was also strongly expressed in MHCC97-L and MHCC97-H with similar genetic background and stepwise increasing metastatic potentials, were used to explore potential metastasis-associated biomarkers with prognostic significance.

Conclusions: In this study, iTRAQ-based proteomic technology was explored to uncover novel metastasis-associated biomarkers in HCC. We identified and validated metastasis-associated protein PLEC1 as a potential prognostic marker in patients with HCC.

### #4744 Clinical validation of a prognostic model integrating Breast Cancer Index (BCI) with tumor size and grade for prediction of late distant recurrence in hormone receptor-positive (HR+) breast cancer with 1-3 positive nodes.

Yi Zhang,1 Pi-hua-Lotta Jerevall,2 Brock E. Schroeder,1 Amy Ly,2 Hannah Nolan,3 Catherine A. Schnabel,1 Dennis C. Sgori,2 Biotheranostics, San Diego, CA;2 Massachusetts General Hospital, Boston, MA.

Background: The Breast Cancer Index (BCI) 11-gene expression signature has been previously demonstrated to significantly predict risk of overall (10y), early (0-5y), and late (≥5y) distant recurrence in patients with HR+ node negative breast cancer. A distinct BCI model that integrated tumor size and grade (BCIN+) was developed and validated for prediction of distant recurrence in HR+ women with 1-3 positive nodes (N1) (Sestak et al., SABCS 2015, P2-08-12; Zhang et al, ASCO 2016, abstract no. 541). The objective of this analysis was to evaluate BCIN+ performance in the subset of patients that were treated with no more than 5 years of adjuvant endocrine therapy.

Methods: The validation study included 402 HR+ N1 patients diagnosed between 1993 to 2007 with ≥5y follow-up and available tumor blocks. Patients treated with ≤5y of endocrine therapy ≤ chemotherapy (n=275) were included in this analysis. BCIN+ risk scores and categories (low vs high, using a pre-defined cutpoint) were determined blinded to clinical outcome. Kaplan-Meier estimates of overall (0-15y) and late (>15y) distant recurrence, hazard ratios and 95% CIs were estimated. Multivariate analysis adjusting for standard prognostic factors (age, tumor type, surgery type, PR and HER2 status) was performed using Cox proportional hazards model. Results: Mean age was 53.9% were ER+, 88% PR+, and 14% HER2+. The majority of tumors were T1 (61%) or T2 (34%), and 16%, 53%, and 31% were grade 1, 2, and 3, respectively. 79% of patients were treated with adjuvant chemotherapy. BCIN+ significantly separated patients into low and high risk groups for both overall (P<0.0001) and late (P=0.0067) distant recurrence. For overall distant recurrence, BCIN+ classified 18% of patients into the low risk group. The 15y risk of distant recurrence was 2.1% (95% CI: 0.0-6.0%) in the BCIN+ low risk group vs 36.8% (95% CI: 29.3-43.4%) in the high risk group (HR: 21.88; 95% CI: 3.04-157.32). Of patients that were distant recurrence-free for at least 5y, 22% were classified as BCIN+ low risk. The risk of distant recurrence at year 15 was 2.1% (95% CI: 0.0-6.0%) in the BCIN+ low risk group vs 19.0% (11.6-25.8%) in the high risk associated with Grade 1, 95% CI: 2.9-69.7). Conclusions: In this subset analysis from an independent validation study, BCIN+ identified a significant proportion of N1 patients that were associated with a considerably lower 15y risk of distant recurrence after ≤5 y of endocrine therapy ≤ chemotherapy. BCIN+ may provide additional prognostic information to facilitate selection of N+ patients for extended endocrine treatment wherein patients identified as BCIN+ may be considered adequately treated with adjuvant therapy alone.

### CLINICAL RESEARCH: Radiobiology and Radiotherapy

### #4745 Circulating cytokine levels predictive of Grade≥3 radiation pneumonitis:

Matthew S. Ning, Ting Xu, Daniel Gomez, Hai T. Tran, Risikoto Komaki, Xiong Wei, Steven H. Lin, Stephen Hahn, Eric Prado, Jianjun Zhang, John V. Heymach, Zhongxing Liao. University of Texas MD Anderson Cancer Center, Houston, TX.

Purpose: Host immune activation is believed to be a major player of radiation pneumonitis (RP). Several cytokine and angiogenic factors (CAFs) have been studied as prognostic markers and therapeutic targets for RP; however, studies are sparse in the setting of prospective trials and high-grade toxicity (Grade≥3) endpoints. We examined the predictive value of several CAFs in combination with clinical factors for RP in the context of a Phase II, prospective randomized study of intensity modulated RT (IMRT) versus proton therapy for locally advanced NSCLC (n=178) as well as a prospective laboratory cohort (n=43). METHODS: From July 2009 to April 2014, 221 patients were treated with proton therapy or IMRT to doses of 60-74 Gy equivalents with concurrent platinum-doublt chemotherapy. Primary endpoints were symptomatic RP (Grade=2) and RP requiring intervention (Grade≥3). Plasma circulating levels of IL-6, IL-10, IL-8, IL-17, IL-2, IL-1β, and IL-1α were measured at baseline and post-treatment (median time 4 days post-RT) by multiplex electrochemiluminescence immunoassay. Clinical characteristics were evaluated for associations with Grade≥3 RP: histology, age, smoking status, mean lung dose (MLD), chemotherapy, stage, performance status, and RT technique. CAFs with >50% undetectable samples were removed from analysis, and samples below the lower limit of quantitation (LLOQ) were transformed to the mean of zero and the LLOQ. Predictive values of clinical and cytokine factors were evaluated in univariate and multivariate analyses via Cox proportional hazards modeling. RESULTS: Of the 221 patients, 42 (19.0%) developed Grade 2 RP, and 22 (9.9%) developed Grade≥3 RP. Both IL-1α and IL-1β had >50% of undetectable samples and were removed from analysis. Pre-treatment level of IL-6 ≥4.00 pg/mL was associated with Grade≥3 RP (HR 2.487; p=0.048), as was post-treatment level of IL-10 ≥0.50 pg/mL (HR 2.931; p=0.020). On multivariate analysis, the factors associated with Grade≥3 RP development were post-treatment level of IL-10 ≥0.50 pg/mL (HR 3.322; p=0.015) and MLD ≥20 Gy (HR 5.864; p<0.001). CONCLUSIONS: In this preliminary analysis of prospectively col-
lected CAFs, post-radiation IL-10 level was significantly associated with Grade=3 RP and, if validated, may serve as a predictor of this toxicity in combination with MLD. IL-10 plays an important role in the inflammatory response and is potentially targoatable, warranting further natural investigation.

#4746 Early clinical support for 4-demethyl-4-cholesteroloxycarbonylpenclomedine (DM-CHOC-PEN) as a radiosensitizer in cancers involving the CNS. Lee Roy Morgan, R S. Weiner, T Mahmood, R. Kawachi, K. Devisetty, J Herman, M Bhandari, R. Summe, E Benes, AH Rodgers, ML Ware, JS Hayman, JW, Jeremy, JY Zou, IDEKK-TEC, Inc., New Orleans, LA; Tulane University, New Orleans, LA; Detroit Clinical Research Center, Lansing, MI; Karmanos Cancer Center Institute at McLaren Flint, Flint, MI; Sparrow Hospital, Lansing, MI; The Christ Hospital, Cincinnati, OH; Ochsner Medical Center, New Orleans, LA; Johns Hopkins Medical Center, Baltimore, MD; Gamma Radiosurgery Center of New Orleans, New Orleans, LA; University of Texas Health Science Center/Hermann Hospital, Houston, TX.

Background: 4-Demethyl-4-cholesteroloxycarbonylpenclomedine (DM-CHOC-PEN) is a polyclirorinated pyridine cholesteryl carbonate with a MOA via bis-alkylation of DNA & N'guanine and N'-cytosine that has completed Phase I-II studies [AACR #CT129, 2016] in subjects with cancers involving the CNS. The current presentation reviews clinical and in vitro data that support radiosensitizing properties for DM-CHOC-PEN in cancers involving the CNS. Patients & Methods: DM-CHOC-PEN was administered as a 3-hr IV infusion once every 21 days to subjects with advanced cancer involving the CNS. The dose schedule was 2-tiered: [85.8 mg/m2 for subjects with liver involvement and 98.7 mg/m2 for subjects with normal livers. All subjects with resistant or new CNS lesions that did not respond to DM-CHOC-PEN were given the option of surgery, stereotactic radiotherapy (SRS) or whole brain irradiation (WBRT). As preclinical support, human NSCLC adenocarcinoma cells (H-2086) growing in culture (105 cells/mL) were pretreated with DM-CHOC-PEN (0.1 - 1.0 µg/mL) for 24 hrs, drug washed, re-fed fresh medium and then 48 hrs later irradiated (SRS with 6, 9 or 12 Gy). Results: Fifty-three (53) subjects with/without CNS involvement had been treated to date with DM-CHOC-PEN. Five (5) subjects (4-NSCLC & 1-sarcomas) in the Phase I-II trials required surgery for persistent CNS lesions following DM-CHOC-PEN therapy. DM-CHOC-PEN was identified in samples from all subjects - 90-212 ng/g tumor [subjects had been treated with 39-98.8 mg/m2 of drug]. Five subjects (1-sarcoma & 4-NSCLC) who had treated with DM-CHOC-PEN for 6-3 weeks - 8 mos had persistent NSCLC lesions involving the CNS were treated with SRS or WBRT. All five subjects had excellent objective results (OS 8 - 29 mos) with no CNS toxicity. Preclinical in vitro studies supported the clinical data: NSCLC cells treated with DM-CHOC-PEN (0.1 - 1.0 µg/mL) demonstrated 50 & 100% cytotoxicity @ 0.8 & 1.0 µg/mL for SRS alone (6, 9, 12 Gy) - cell kill w/25 & 65% @ 6 & 12 Gy [100% cell kill was not observed at this dose range]; for DM-CHOC-PEN (0.25 µg/mL) + SRS (6-12 Gy) - cell kill was 80 & 100% @ 6 & 12 Gy. Thus, in combination - less drug (0.25 µg/mL) + 12 Gy - produced a 100% cell kill, as compared to either SRS or drug, alone. Photon induced change transfer reactions with DM-CHOC-PEN will be discussed. Conclusion: Preliminary data is presented that supports DM-CHOC-PEN’s cytotoxicity and radiosensitizing properties in cancers involving the CNS. Observations during clinical trials support the drug’s persistent presence in human tumors after systemic administration and notable positive effect on response to subsequent radiation. Complete data on patient responses and observed toxicities will be presented. Supported by: NCI/SBIR grants - R43/44CA132257 and NIH NIGMS U15 GM104940 - the latter funds the Louisiana Clinical and Translational Science Center.

#4747 Subcutaneous fat predict outcome in head and neck cancer. Ngn M. Tsang. Chang Gong Memorial Hospital, Taoyuan, Taiwan.

Background: Previous studies have shown that body mass index (BMI) is linked to survival in cancer patients. Our objective was to analyze whether body composition before treatment can predict outcomes in patients with head-and-neck cancer. Methods: All 881 patients with loco-regional head-and-neck cancer treated with curative-intent RT during 2005 to 2012 were retrospectively studied. Body composition analyses by using pre-RT CT images acquired for RT simulation. We compared subcutaneous adipose tissue (SAT) index and muscle index by measuring cross-sectional area of tissues at level of the third thoracic vertebrae (T3) in both genders. Overall survival (OS), loco-regional control (LRC), and distant metastasis-free survival (DFS) were analyzed by body composition index that divided into two groups based on values higher and lower than the median. The median follow-up was 4.68 years. Results: SAT index in female patients was significantly higher than that in male (p = 0.001). The median SAT index and muscle index for female were 15.25 cm2/m2 (range, 0.93-88.09 cm2/m2) and 34.3 cm2/m2 (range, 14.78-73.05 cm2/m2), and for male were 6.19 cm2/m2 (range, 0.21-40.48 cm2/m2) and 51.7 cm2/m2 (range, 8.03-89.06 cm2/m2). The 5-year and 10-year OS, LRC and DFS were 66.3%, 57.6%, 73.4%, 71.4%, 83%, and 82.1%. Higher pretreatment SAT index was associated with longer OS (HR = 0.616; P = 0.001) and DFS (HR = 0.649; P = 0.015) and a trend towards longer LRC (HR = 0.572; P = 0.066). Pre-treatment muscle index was not significantly predictive of OS (HR = 0.662; P = 0.066) or DFS (HR = 0.684; P = 0.029). Conclusion: SAT index and muscle index of T3 level obtained from CT images appear to predict outcomes in patients with cutaneous head-and-neck cancers.

#4748 Novel predictive biomarker for monitoring adverse reactions to radiation therapy. Paul OKunieff, Steven Swarts, Elena Peletsky, Anne Vallerga, Rachel Chuang, Michael J. Powell, Aiguo Zhang, University of Florida, Gainesville, FL; DiasCarta, Richmond, CA.

Introduction: Radiation treatment is required by 70% of cancer patients, however there is currently no clinical method for determining the therapeutic response or radiation induced toxicity that can be used during a course of radiation therapy to personalize the dose for individual patients. The only standard method is CT/PET and/or MRI. This is a major clinical concern for radiation oncologists with so many new agents being approved in combination with radiation therapy. Methodology: Herein we describe a highly sensitive clinically validated assay that measures the extent of normal tissue damage induced by radiation by quantitation of circulating free DNA (cfdNA) derived from cellular apoptosis detected in plasma of patients undergoing radiation therapy. The assay employs DNA capture probes and SuperBiondaTM signal amplification technology with alkaline phosphatase labelled signaling probes coupled with dioxetane phosphate chemiluminescence detection. The assay can be performed directly on patient plasma samples and can be readily automated. Conclusion: RadTm TM can be used both for research and clinical testing of plasma samples for patients undergoing radiation therapy for optimization and personalization of treatment.

#4749 A phase II study using cardiac MRI to assess cardiac injury in breast cancer patients receiving three-dimensional conformal regional nodal radiotherapy (3DCRT) with heart dose constraints. Carmen Bergom, Jason Rubenstein, Aimee Welsh, Philip Prior, Daniel Eastwood, Mei-Jie Zhang, J. Frank Wilson, Julia White, Julie Bradley, Medical College of Wisconsin, Milwaukee, WI; The Ohio State University Comprehensive Cancer Center, Milwaukeee, WI; University of Florida, College of Medicine, Jacksonville, FL.

Purpose/Objectives: Regional nodal radiotherapy (RNR) can improve survival for node positive breast cancer (NPBC) patients, yet this benefit is offset by potential late cardiac toxicity. Most cardiac toxicity reports from RNR have been in eras where no specific dose or volume heart constraint was used. Cardiac MRI (CMR) is ideal to assess ventricular function and volumes. We report a phase II trial designed to assess cardiac injury by CMR in NPBC patients who received chemotherapy (CT) and RNR planned with heart constraints. Materials/Methods: 244 NPBC patients treated with 3DCRT RNR following surgery planned with heart constraints between 2000-2008 were screened. Eligibility included prior anthracycline CT, no cardiac disease pre-NPBC, and no recurrent disease. Patients with active atrial fibrillation were excluded. The cardiac dose constraint utilized was V25 =<10% of the heart. Mean heart dose was not constrained. Eligible women were invited by letter to enroll in the IRB-approved trial. CMR parameters to be evaluated included indicators of left ventricular (LV) function: ejection fraction (EF), LV mass (LVM), and LV dimensions, as well as late gadolinium enhancement (LGE) and total heart extracellular volume fraction (ECV) as measures of cardiac injury and/or early cardiac fibrosis. Planned analyses included correlation of CMR parameters with cardiac dose-volume constraints using Spearman and Pearson correlations. Results: The first 15 L-sided and 5 R-sided patients consented underwent CMR. Median age at diagnosis was 50 (32-77); median age at CMR was 60 (40-83). Median time after 3DCRT was 8.3 yr (5.7-14.4). The median L-sided mean heart dose was 4.8 Gy (1.1-11.2) and V25 was 5.7% (0-12%). No patient had clinical cardiac disease at time of CMR. Median LVEF was 63%. No LGE and no abnor- mal total heart ECV values (>25%) were obtained. Values mildly outside normal limits were seen for LVM and LV dimensions in 4/15 (27%) L-sided and 2/5 (40%) right-sided patients. No correlations were seen between heart mean and max doses, V5, V10, V25, and V45 and the CMR variables of LVEF, LV mass, and LV dimensions. Two patients had valvular abnormalities found on CMR (1-sided with aortic regurgitation and R-sided with mitral regurgitation). Conclusion: CMR findings were largely within normal limits at a median follow of 8.3 years in this cohort of NPBC patients who received prior cardiac chemother-apy and RNR planned with heart constraints. A subset of patients had subclinical mildly abnormal LV measurements, but these did not correlate with
heart dose or laterality, and the significance remains unknown. In this cohort, no significant cardiac injury from RNR as measured with CMR was seen. Conversely, CMR may not be a sensitive tool for subclinical partial heart injury from RNR. Larger corroborating studies are warranted.

#4750 Predicting severe hematologic toxicity from extended-field chemoradiation of para-aortic nodal metastases from cervical cancer. Kevin Yan, Ezequiel Ramirez, Xuejun Gu, Kevin Albuquerque. UT Southwestern, Dallas, TX.

Background and Purpose: To determine significant factors predictive for severe hematologic toxicity (HT) in cervical cancer patients with para-aortic lymph node (PALN) metastasis treated with concurrent chemoradiation with a specific focus on radiation dose to total bone marrow (BM\textsubscript{TOT}) and acute bone marrow (BM\textsubscript{ACT}). To create a nomogram using significant factors to predict HT in these patients. Material and Methods: 38 Patients with cervical cancer and PALN metastasis who underwent 3F-FDG-PET / CT before treatment with extended field radiation therapy (EFRT) and concurrent cisplatin were analyzed. BM\textsubscript{ACT} was defined as the region within BM\textsubscript{TOT} with a standardized uptake value (SUV) greater than or equal to the mean for the individual. Blood counts were collected weekly from the beginning of radiation treatment to the end of radiation treatment. HT was graded based on the guidelines set by the National Cancer Institute Common Terminology Criteria for Adverse Events Version 4.0. Results: 19 patients (50%) had Grade 3 or higher hematologic toxicity (HT+), not including lymphocyte toxicity. Patients who were obese (n=12) were less likely to get HT+ compared to patients who were not obese (p=0.03) despite getting the same weight related dose of chemotherapy. Volume of BM\textsubscript{TOT} receiving 20 Gy, 30 Gy, and 45 Gy were significant predictors for HT3+ at 78.56% (p=0.01), 47.14% (p=0.00), and 20.36% (p=0.01) respectively. Volume of BM\textsubscript{ACT} receiving 10 Gy, 20 Gy, 30 Gy, and 45 Gy were significant predictors for HT3+ at 95.50% (p=0.03), 80.52% (p=0.05), 59.64% (p=0.03), and 31.74% (p=0.01) respectively. Through logistic regression, the probability of developing HT3+ is given by the equation: Prob(HT3+ = 1) = (1 + exp(7.34 + 0.22BM\textsubscript{ACT} - 0.44(Mean Dose to BM\textsubscript{TOT})). Patients who had HT3+ received an average of 4 cycles of chemotherapy and 62 days of treatment time, significantly different than the 4.74 chemotherapy cycles and 53 days of treatment in patients without HT3+ (p=0.05, 0.00 respectively). Conclusions: Both higher patient BMI and bone marrow irradiation were associated with HT+. A simplified nomogram has been created to predict HT3+ in these patients. Radiation parameters have been identified for cervical cancer patients with PALN involvement receiving EFRT concurrently with chemotherapy. Bone marrow sparing approaches for EFRT need to be addressed to improve patient care.

#4751 Correlating the genomic and transcriptomic profiles of pre-treatment cervical tumor biopsies with patient recurrence after definitive chemoradiation. Fiona J. Ruiz, Julie K. Schwarz. Washington University in St. Louis, St. Louis, MO.

Purpose: The purpose of this study was to identify genomic mutations that correlate with patient recurrence after curative intent chemoradiation therapy in advanced stage cervical cancer patients. Methods: Pre-treatment cervical tumor biopsies and normal blood were prospectively collected from patients treated at Washington University in St. Louis. DNA and RNA was isolated from the fresh frozen tumor biopsies and sent for next-generation sequencing and RNAseq respectively. Targeted exome sequencing was done using a panel of 127 known cancer associated genes, and an additional 8 genes previously reported to be mutated in cervical cancer. Gene testing was done to probe for 30 different HPV subtypes. Results: The mutational signatures of single nucleotide polymorphisms were an APOBEC cytidine deaminase and Cpg site cytidine deamination mutagenesis pattern. The non-silent somatic mutations were analyzed by online prediction algorithms to assess the mutation’s putative effect on protein function. Univariate COX regression was used to correlate patient recurrence with non-silent putatively functional mutations. In our patient cohort 88% of samples were HPV positive, with 74% being the high-risk HPV 16 and 18 subtypes. Patients’ with HPV positive tumors had increased progression-free survival when compared to the HPV negative patient tumors; and the HPV positive patients with HPV 16 had increased progression-free survival over the other HPV subtypes. Complete gene tiling of the HPV 16 and 18 subtypes allowed us to determine whether the HPV DNA was integrated in the host genome or retained episomally. In our patient cohort less than 30% of samples had integrated HPV DNA, and there was no significant difference in progression-free survival between patients with integrated or episomal HPV. Conclusions: The genomic analysis of our advanced stage cervical cancer patient cohort found that epigenetic modifiers were frequently mutated and that cytidine deamination mutagenesis was primarily responsible for the generation of the SNP mutations. Our study identified NDS1 mutations as being correlated with tumor recurrence, indicating that histone modifications and chromatin structure may play an important role in tumor response to ionizing radiation therapy. Gene expression analysis is currently ongoing.

#4752 Inflammatory cytokines and hematopoietic stem cells are associated with fatigue and insomnia in breast cancer patients undergoing adjuvant radiation therapy. Wei Shi, Kathy Han, Madeleine Li, Justin Williams, Megan McCusker, Jie Su, Wei Xu, Scott Bratman, Kenneth Yip, Fei-Fei Liu. Princess Margaret Cancer Center, University Health Network, Toronto, Ontario, Canada.

Introduction: Breast cancer patients undergoing adjuvant radiation therapy (RT) commonly experience fatigue and insomnia. We previously reported that this fatigue is associated with a reduction in circulating hematopoietic stem cells (HSCs; CD34+), the role of inflammatory cytokines in mediating this process however, has not been clearly elucidated. Materials and Methods: Breast cancer patients (n = 147) undergoing adjuvant RT underwent phlebotomies for analysis of CD34+, CD45+, CBC, as well as 17 inflammatory cytokines using a multiplexed ELISA platform, during 5 time points: prior to RT (D1); after Days 2, 5, during final week of RT (D2, D5, and DF, respectively); as well as one month post-RT-completion (M1). At the same time, patients also completed questionnaires for the multidimensional fatigue inventory (MFI-20), hospital anxiety and depression scale (HADS), and insomnia severity index (ISI). Results: General fatigue worsened over the course of RT from D1 to DF, being most severe at the end of treatment (DF), but returned to baseline at M1. This trend was statistically significant (p = 0.001) after adjusting for anxiety, depression, and insomnia. The levels of CD34+, CD45+, white blood cell, as well as lymphocyte counts decreased over time, with the lowest levels observed at DF (p < 0.001 for all). General fatigue correlated inversely with CD34+ counts (adjusted for anxiety, depression, and ISI), and was also negatively associated with hemoglobin, RBC, and lymphocyte counts (p < 0.001 for all). There was also a significant correlation between increasing insomnia with lower CD34+, CD45+, white blood cell and lymphocyte counts (all p < 0.05). Serum concentrations of TGF-β1, MCP-1, MMP-2, IL-1ra and IFN-α2a changed significantly during RT (p < 0.01 for all), with either the highest or lowest levels observed at DF. Increasing levels of MCP-1, TNF-RII and TNF-a were associated with worsening general physical fatigue, reduced activity, decreased motivation, as well as increased insomnia (p < 0.01 for all). Furthermore, there appeared a trend between increasing levels of MMP-2, as well as decreasing IL-1ra and TGF-β1, with reduced CD34+, CD45+, WBC and lymphocyte counts (p < 0.001). The 52 patients who received prior adjuvant chemotherapy demonstrated significantly higher fatigue, anxiety, and insomnia scores. Conclusions: This study represents one of the most comprehensive longitudinal evaluations of the effects of RT on fatigue and insomnia, demonstrating that this process was associated with increased levels of the pro-inflammatory cytokines MCP-1, TNF-RII and TNF-a, and reductions in circulating HSCs and other hematologic parameters. Further understanding of the roles of these cytokines would provide important insights into both quality of life for patients undergoing cancer therapies, as well as the interactions between RT with immunotherapy.

#4753 Prognostic significance of galectin-1 expression in patients with glioblastoma multiforme following radiotherapy. Eng-Yen Huang, Shang-Yu Chou. Kaohsiung Chang Gung Memorial Hospital, Kaohsiung, Taiwan.

Purpose: Galectin-1 is a radioresistant marker and prognostic factor in our previous study for cervical cancer. The aim of current study is to determine the prognostic significance of galectin-1 expression level in patients with glioblastoma multiforme (GBM) undergoing adjuvant radiotherapy (RT). Materials and Methods: We included 45 patients with GBM who treated with maximal safe surgical resection or biopsy only, followed by adjuvant RT of EQD2 = 60 Gy (equivalent doses as 2-Gy fractions) for homogeneous treatment. Paraffin-embedded tissues acquired from the Department of Pathology were analyzed using immunohistochemistry staining for galectin-1 expression. Overall survival (OS) and cancer-specific survival were compared between strong, moderate, and weak expression of galectin-1. Results: According to univariate analysis for optimal cutoff of galectin-1 expression level, better median survival (27.9 months) in patients with weak level than that of (10.7 months) in patients with strong level (p = 0.009) was revealed. We compared characteristics between weak and strong galectin-1 expression level, and only galectin-3 expression level was correlated. The weak galectin-1 expression group displayed a 3-year survival rate of 27.3% and 3-year cancer-specific survival (CSS) rate of 27.3%, but which are only 5.9% and 7.6% respectively in strong galectin-1 expression group (p = 0.009 and 0.020, respectively). Cox regression was used to confirm that the role of galectin-1 expression level (weak vs. strong) is a significant factor of OS (p = 0.020) and CSS (p =
Other parameters such as galectin-3 expression level, ECOG perfor-
type, which include IL-4ra, IL-10ra, and TGF-
significantly upregulated (P

#4754 Fractionated whole brain radiation-induced behavioral changes in athymic nude mice is associated with sustained neuroinflammation and microglial M1-phenotype. Suman Kanji, Benjamin Johnson, Kristina Witcher, Pooja Gulati Gulati, Shannon Chen, Jonathan Godbout, Randy J. Nelson, Saikh Haque, Arnab Chakravarti. The Ohio State University, Columbus, OH.

The objective of this study is to study the late-chronic effects of fractionated whole brain irradiation (FWBI) on cognitive impairment and associated cellular and molecular neuro-inflammatory mechanisms using clinically relevant and reliable mouse models. Microglia are recognized as the primary innate immune component of neuroinflammation. However, microglial contributions to radiation-induced cognitive impairment are poorly under-
stood. Here, an athymic nude (Nu/Nu) mouse model was employed to ad-
dress this issue. Mice were divided into two groups: radiation treatment (XRT) and no-treatment control (CTL). The whole brain of each XRT mouse received 30 Gy (3 Gy/fraction) of radiation over two weeks. XRT and CTL mice were assessed for cognitive and behavioral changes at 1, 4, and 6 months posttreatment using the novel object recognition test (for long-term, non-spatial memory), the free running Y-Maze (for short-term, spatial memory) and Barnes Maze (for spatial learning and memory). A significant decline in novel object recognition and Barnes Maze performance was seen at the 4 month time point and continued to persist at 6 months (P<0.05). No significant changes in the Barnes maze or Y-maze were seen at these time points. Expression of neuroinflammatory mediator genes, from both whole brain and isolated microglia, were measured by RT-PCR. We found that markers of the M1-phenotype, which include TNF-α, and MHC II, were significantly upregulated (P<0.05) and markers of the general M2 Pheno-
type, which include IL-4ra, IL-10ra, and TGF-β, were downregulated (P<0.05) at 1 and 6 month time points. These results indicate that sustained neuroinflammation and microglial M1-polarization are associated with long-term cognitive impairment induced by FWBI. Radiotherapy is the most prevalent treatment for primary and metastatic brain tumors. Whereas previous studies that identified important mechanisms underlying XRT-induced cognitive decline had used treatment regimens that were not clinically relevant ones, we have employed a clinically relevant fractionation scheme to address the cellular and molecular deregulations in association with cogni-
tive impairment.

#4755 Calpastatin phosphorylation regulates radiation response in glioblastoma. Emily A. Bassett, Mitchell Pearson, Kamalakannan Palani-
chamy, Saikh J. Haque, Arnab Chakravarti. Ohio State University, Columbus, OH.

Glioblastoma (GBM) is the most prevalent and aggressive primary malignant brain tumor in adults. Patients diagnosed with GBM have a very poor prognosis and quality of life, with a median survival time of 12-15 months despite receiving the standard of care treatment. GBM cells are highly heterogeneous, invasive, and resistant to both chemo- and radio-therapy. The overall goal of this study is to identify novel mechanisms of radioresistance in GBM, so that more effective therapies can be developed in the future. We performed quantitative mass spec-
trometry-based phosphoproteomic profiling of GBM cell lines before and after radiation treatment, and determined post-radiation fold-changes in phosphor-
ylation for each phosphopeptide. Results show calpastatin as one of the statisti-
cally significant differentially regulated phosphopeptides following radiation treatment. Calpastatin is an endogenous inhibitor of calpains, which are calci-
um-dependent cysteine proteases that control a wide range of cellular processes including cell survival and apoptosis. We hypothesized that phosphorylation inactivates calpastatin resulting in increased calpain activity. Western blot anal-
yses with phospho-specific calpastatin antibodies showed a rise in phosphory-
tein levels as early as 24 hours after exposure to radiation. In order to test the functional significance of phosphorylated cal-
pastatin, we utilized site-directed mutagenesis to generate non-
phosphorylatable and phosho-mimetic calpastatin proteins. Western blot analyses of U87 cells stably expressing CAST-S63A or S633E supported the hypothesis that calpastatin phosphorylation leads to increased calpain activity. In conclusion, we identified increased levels of calpastatin phosphorylation in multiple GBM cell lines following radiation treatment, and shown that this cor-
relates with increased calpain activity. Modulation of calpastatin activity is a potential strategy to increase radiosensitivity of glioblastomas. Targeting cal-
pastatin is advantageous over targeting calpain itself, since many calpain inhib-
itors exhibit limited selectivity. Results of this study will contribute to our un-
derstanding of how GBM tumors become resistant to radiation therapy. Funding: R01CA108633, R01CA169368, RC2CA148190, U10CA180850-01 (NCI), Brain Tumor Funders Collaborative Grant, and The Ohio State Univer-
sity CCC (all to AC).

#4756 A SPP1-EGFR pathway links stem-like properties of KRAS-mu-
ted lung cancer to radiation resistance. Meng Wang, Jing Han, Lynnette Marcar, Josh Black, Qi Liu, Xiangyong Li, Khiithija Nagalappalii, Licia V. Sequist, Raymond H. Mak, Cyril H. Benes, Theodore S. Hong, Kristin Gurt-
ner, Mechthild Krause, Michael Baumann, Jing X. Kang, Johnathan R. Whetstone, Henning Willers. Mass. General Hospital, Boston, MA; Jinan Mu-
unicipal Center for Disease Control and Prevention, Jinan, China; University of Colorado School of Medicine, Aurora, CO; Dana-Farber Cancer Institute, Bos-
ton, MA; University Hospital Carl Gustav Carus, Technische Universität, Dresden, Germany.

Lung cancers with activating mutations in the KRAS oncogene present a major clinical challenge due to poor prognosis and frequent treatment resis-
tance, particularly to agents targeting the epidermal growth factor receptor (EGFR). For many years, it has been known that mutations in KRAS enhance cellular resistance to ionizing radiation (IR). Clinical data are emerging suggest-
ing that the radioresistance of KRASmut cancer cells that is observed in the laboratory is also seen in patients. However, the underlying mechanisms of mut-
ant KRAS-associated radioresistance is understudied and poorly under-
stood. Cancer stem cells (CSC), also referred to as tumor-initiating cells, may promote metastases development and recurrence after therapy. Generally, can-
cer cells with CSC-like phenotypes or markers have been found to be radiore-
sistant. Enhanced DNA damage response and repair pathways have been dis-
cussed as one underlying mechanism. Interestingly, mutant KRAS has been recently linked to CSC-like phenotypes such as tumor initiation, anchorage independence, and self-renewal. Here, we characterized a radioresistant pheno-
type associated with KRAS mutated lung cancer cells, xenografts, and patients. CSC-like cells were defined as tumor-initiating cells. Genomic, biochemical, and cell-based assays were used to identify candidates for targeting KRAS mutation-
mediated radiation resistance. Radiation resistance is conferred by a CSC-like subpopulation that is characterized by condensed chromatin, high CD133 ex-
pression, invasive potential, and tumor-initiating properties. Osteopontin, the gene product of SPP1, promotes aspects of this phenotype including radiation resistance and acts in the same pathway as the EGFR. SPP1/EGFR-dependent chratomin condensation not only protects cells against radiation-induced DNA damage but also downregulates putative negative regulators of CSC-like prop-
eerties, including CRM1 and BIM. This phenotype defines a subset of KRAS 

mucated lung cancers that is enriched for co-occurring TP53 mutations. In con-
clusions, markers and mechanisms of resistance to radiation therapy in lung and 
other cancers are poorly characterized. Our data provide novel insight into the aggressive biology of KRAS mutant cancers and have major implications for strategies to overcome the radioresistance associated with this genotype.

#4757 Radioresistance is linked with stem-like properties via activation of aryl hydrocarbon receptor. SHuang Liu, Bin Yan, Yongguang Tao. Central South University, China.

Most cancer patients receive radiotherapy in the course of their disease and the occurrence of radioresistance is associated with a poor prognosis for cancer patients. The molecular pathways that drive the enhanced tumorigenic potential during the development of radioresistance are poorly understood. Here, we demonstrate that the aryl hydrocarbon receptor (AhR) plays a vital and previ-
ously unrecognized role in the maintenance of stem-like cells that are isolated from radioresistant epithelial lung cancer and nasopharyngeal carcinoma. AhR promotes the stem-like phenotype and drives metastasis by directly targeting the promoters of ‘stemness’ genes, such as the ATP-binding cassette sub-family G member 2 (ABCG2) gene. Cancer cell populations enriched for ABCG2 expres-
sion (CD338+) show an elevated ‘stemness’ signature and are more prone to cancer progression in vitro and in vivo. Ubiquitin C-terminal hydrolase-L3 (UCHL3), a deubiquitinating enzyme, may counteract AhR, while IKEKo, a bone fide chromatin modifier, may directly activate stemness related genes. The ra-
dioresistant cancer cell sublines are associated with a hybrid state in epithelial-
mesenchymal transition (EMT) and mesenchymal-epithelial transition (MET) 
and elevated tumor associated macrophages and proinflammatory factors. Moreover, the radioresistant sublines display high levels of oncometabolites, including α-ketoglutarate, and treatment of cancer cells with α-ketoglutarate enhances their stem-like properties through activation of the AhR. Thus AhR is
functionally linked with radioreistance in lung cancer and nasopharyngeal cancer, and it drives tumorigenesis by an epithelial and mesenchymal composition, tumor associated macrophages and oncometabolites.

#4758 Sensitization of nasopharyngeal carcinoma to radiotherapy by targeting GFPT1/TGF-β1 signaling pathways. Siqi Chen, Wei Gao, Jimmy Yu-Wai Chan, Thian-Sze Wong. The University of Hong Kong. Hong Kong SAR, China.

Background: Nasopharyngeal carcinoma (NPC) is a unique cancer with high susceptibility to radiation and mainstay treatment is radiotherapy. Effectiveness of NPC treatment is therefore dependent on the sensitivity of cancer cells to ionizing radiation treatment. Further, development of radio-resistant phenotype is a risk factor for distant metastasis and disease recurrence. Therefore, enhancing the degree of radiation sensitivity could improve prognosis and reduce the toxicity of radiotherapy with the use of lower radiation dose. Transforming growth factor β1 (TGF-β1) expression is responsive to radiation treatment and the increase is important in the post-irradiation DNA repair. Tumor with low TGF-β1 level is more responsive to radiation treatment. Therefore, inhibiting TGF-β1 production can enhance the radiation damage to cancer cell DNA and also intensify the sensitivity of cancer cells to radiation. Our preliminary results indicate that TGF-β1 production in NPC is mediated by hexosamine pathway. Of which, GFPT1 (glucosamine-fructose-6-phosphate aminotransferase) is the rate-limiting enzyme. Purpose of the study: To enhance radiation sensitivity by targeting GFPT1/TGF-β1 cascade in NPC. Experimental procedures: Radiation protective effects of TGF-β1 was examined by colony formation assay and Danio rerio (zebrafish) embryonic system. Production of TGF-β1 by activated hexosamine pathway in NPC was revealed by glucosamine and glucosamine treatment. Effects of GFPT1 silencing on radiosensitization are revealed by GFPT1 siRNA treatment followed by colony formation assay and gamma-H2AX formation assays. Results: Pretreatment of HONE1 cells with recombinant TGF-β1 protein enhanced the clonogenic ability of irradiated cells. TGF-β1 significantly increased the survival of zebrafish embryos after irradiation. Glucose and glucosamine treatment increased the expression of TGF-β1 protein in HONE1 cells. Silence of GFPT1 reduced TGF-β1 mRNA and protein expression in HONE1 cells. Silencing GFPT1 reduced the clonogenic capacity of head and neck cancer cells after radiotherapy and enhanced the degree of radiation-induced DNA double-strand breaks. Conclusions: Targeting GFPT1 enhances head and neck cancer cell sensitivitiy to radiation. GFPT1 inhibition can enhance the radiation sensitivity of head and neck cancer cells by inhibiting the expression of TGF-β1.

#4759 TP53 control of the survival-mediated radio-adaptive response in human tumors. Jeffrey S. Murley,1 Richard C. Miller,1 Ralph R. Weichselbaum,1 David J. Grindla2,1 Univ. of Chicago, Chicago, IL; 2Univ. of Chicago, Naperville, IL.

Doses of ionizing radiation ≤100 mGy induce changes in radiation sensitivity expressed by cells exposed to subsequent lower doses. This is referred to as an adaptive effect. We describe a unique survival-associated adaptive response in which increased radiation resistance or sensitization of cells can be induced by exposure to doses as low as 5 mGy and is controlled by p53 expression. Experiments were performed using ten human cancer cell lines: HCT116 TP53 wild type (WT) colorectal carcinoma and its isogenic TP53 null (Mut); RKO colorectal cancer exposed WT and isogenic TP53 null (Mut); breast adenocarcinomas MCF7 (TP53 WT) and MDA-MB-231 (TP53 Mut); lung carcinomas A549 (TP53 WT) and NCI-H1975 (TP53 Mut); and pancreatic carcinomas Hs7667 (TP53 WT) and Panc-1 (TP53 Mut). Doses of 5 mGy were used to induce changes in the response of these tumor cells to higher therapy doses using a multi-dosing paradigm. Effects on radiation sensitivity were associated with changes in both survivin concentration and its translocation to the cytoplasm (TP53 WT) and nucleus (TP53 null or point mutant). In vitro survival (2 Gy per fraction, two once daily fractions) studies were performed on all tumor cell lines. Intracellular localization of survivin was determined by ELISA and correlated to survival response. 2 Gy alone had no significant effect on intracellular translocation of survivin. When preceded 15 minutes earlier by a 5 mGy exposure, survivin increased in the cytoplasm of all TP53 WT tumor cell lines. With clinicogenomics database analysis and following validation with MLCC model, we determined that BCL2, of which expression was clearly induced and indicated a poor prognosis in the mesenchymal cancer patients, was responsible for high chemoresistance in MLCCs. Therefore combined treatment of chemotherapeutic drug and BH3 mimetic such as ABT-263 or ABT-737, remarkably sensitized MLCCs to chemo and radiotherapy. Furthermore, BCL2 expression was governed by sustained ERK1 activity in MLCCs, which resulted from high level of MEK partner-1 (MP1) protein expression. Therefore, combined chemotherapy with small molecules (approved by FDA or clinically tested) targeting for MEK1 or BCL2 would be a clinically feasible approach to overcome EMT related chemoresistance.

#4760 Wnt/β-catenin signaling mediates resistance of colorectal cell lines to chemoradiotherapy. Georg Emons,1 Melanie Spitzner,2 Sebastian Reineke,2 Noam Auslander,1 Frank Kramer,3 Margret Rave-Fraenkl,2 Jochen Gaedcke,4 Michael Ghdami,5 Thomas Ried,1 Marian Grade,1 1NIH, Bethesda, MD; 2University Medical Center, Goettingen, Germany.

Background: Activation of Wnt/β-catenin signaling plays a central role in the development and progression of colorectal cancer (CRC). Previously, we demonstrated that the Wnt transcription factor TCF7L2 was overexpressed in primary rectal cancers that were resistant to chemoradiotherapy (CRT), and that TCF7L2 functionally mediates resistance of CRC to clinically relevant doses of CRT. However, it remained unclear whether the resistance was mediated by a TCF7L2 inherent mechanism or Wnt/β-catenin signaling in general. Methods: We silenced another key-component of canonical Wnt-signaling, CTNNB1 (β-catenin) in rectal cancer cell lines LS1034, SW480, and SW837 by RNAi. Afterwards cells were exposed to varying doses of irradiation (+/-5 Gy) to assess the influence of β-catenin on radiation resistance. Activation of Wnt-signaling in “normal” epithelial cells (retina pigment epithelial cells RPE) was achieved either by stimulation with Wnt3a or by overexpression of β-catenin (S33Y-mutated) and confirmed by a dual luciferase reporter assay. Changes in radio-(chemo-) sensitivity were analyzed again by a colony formation assay. SW1463 were repeatedly irradiated (68Gy) to establish an isogenic radio-resistant cell line. Gene-expression profiles, without or 6h after a single dose of 4Gy, of RPE cells expressing a control vector or overexpressing β-catenin and radiosensitive or wildtype SW163 cells were established using microArrays. Results: Silencing of CTNNB1 resulted in (chemo-) radiation-sensitivity of all three CRC-cell lines. To further investigate the potential role of Wnt/β-catenin signaling in controlling therapeutic responsiveness, non-tumorigenic RPE cells were stimulated with Wnt-3A, which significantly increased resistance to CRT. This effect could be recapitulated by overexpression of β-catenin (S33Y-mut.), resulting in a significantly increased resistance to CRT. The effect could be rescued by siRNA mediated knockdown of β-catenin. Consistent with these findings, we observed higher expression levels of active (unphosphorylated) β-catenin as well as increased TCF reporter activity in SW1463 cells that were rendered radiation-resistant due to repeated IR treatment. Gene expression profiling of radiosensitive and wildtype SW163 as well as RPE cells overexpressing β-catenin or wildtype β-catenin revealed a number of differentially regulated genes. Most interestingly the resistant cells (radiosensitive SW1463 and RPE overexpressing β-catenin) reacted with differential activation of metabolic, inflammatory, cell survival and cell cycle pathways to irradiation. Conclusion: Together, these findings strongly support the interpretation that Wnt/β-catenin signaling plays a central role in mediating resistance of CRC cells to CRT by deregulating essential pathways. Hence, path在内的 therapeutics may represent a promising strategy to increase therapeutic responsiveness to CRT.

#4761 BCL2 induced by LAMTOR3-MAPK is a druggable target of chemoradiosensitization in mesenchymal lung cancer. Ok-Seon Kwon, Soon-Ki Hong, Hyuk-Jin Cha. Sogang University, Seoul, Republic of Korea.

Metastasis and chemoresistance, which are main causes of lung cancer related death, have been major interest in cancer research. Recently, Epithelial-Mesenchymal Transition (EMT) a foremost process for acquiring metastatic properties has been demonstrated to be strongly link to chemoresistance. Due to limited understanding of mechanism for EMT mediated chemoresistance, druggable targets for chemoresistance remained unidentified yet. In this study, we established the mesenchymal like cancer cells (MLCCs) from A549 lung cancer cells with chronic exposure of TGFβ. With clinicogenomics database analysis and following validation with MLCC model, we determined that BCL2, of which expression was clearly induced and indicated a poor prognosis in the mesenchymal cancer patients, was responsible for high chemoresistance in MLCCs. Therefore combined treatment of chemotherapeutic drug and BH3 mimetic such as ABT-263 or ABT-737, remarkably sensitized MLCCs to chemo and radiotherapy. Furthermore, BCL2 expression was governed by sustained ERK1 activity in MLCCs, which resulted from high level of MEK partner-1 (MP1) protein expression. Therefore, combined chemotherapy with small molecules (approved by FDA or clinically tested) targeting for MEK1 or BCL2 would be a clinically feasible approach to overcome EMT related chemoresistance.

#4762 New device for radiation delivery in breast cancer patients - double balloon applicator for optimal dose distribution. Manny R. Subramanian, Mike Cutrer, Rohit Mehta. *BEST Medical International, Springfield, VA.*

Currently available applicators for delivery of accelerated partial breast irradiation using a high dose afterloader, have treatment catheters close to the center of the balloon in fixed positions, restricting one’s ability to modify the dose to critical organs. Recently we developed a novel, dual balloon brachytherapy applicator using which one could optimize radiation dose by shaping the resection cavity with an outer balloon and allowing an inner balloon to selectively position the treatment catheters away from the central axis of the balloon based on cavity size. The Double Balloon Breast Brachytherapy Device was performed with a wide range of volumes of the lumpectomy cavity. Each case is scanned in a CT scanner and the data transferred to a treatment planning system. Dosimetric parameters such as dose delivered to treatment site, different organs such as skin, ribs, etc are evaluated and compared against existing brachytherapy applicator devices. Both ultrasound and CT images clearly indicate that the quality and the Double Balloon breast device images are comparable to other commercial devices. All catheters are distinguishable and can be reconstructed for treatment planning, and the balloon volume can be clearly delineated. Planning Treatment Volume (PTV) based on balloon volume can be easily generated and optimized dosimetry performed. Initial patient studies also indicate that using the double balloon applicator optimized dosimetry can be obtained thereby reducing the dose to critical structures such as skin and rib while maintaining the dose to the target.

**TUMOR BIOLOGY: Cancer Stem Cells**

#4763 Metronomic chemotherapy prevents therapy-induced stromal activation and induction of cancer stem cells. Kelvin K. Tsai,1 Tze-Sian Chan,1 Chung-Chi Hsu,1 Vincent C. Pai,1 Shenq-Shyang Huang,1 Valerie M. Weaver.1

1Taipei Medical University, Taipei City, Taiwan; 2University of California, San Francisco, San Francisco, CA.

While traditional chemotherapy kills a fraction of tumor cells, it also activates the stroma and can promote the growth and survival of residual cancer cells to foster tumor recurrence and metastasis. Accordingly, overcoming the host response induced by chemotherapy could substantially improve therapeutic outcome and patient survival. Treatment resistance and metastasis have been attributed to expansion of cancer stem-like cells (CSCs). Molecular analysis of the tumor stroma in neoadjuvant chemotherapy-treated human desmoplastic cancers and orthotopic tumor xenografts revealed that traditional maximal tolerated dose chemotherapy, regardless of the agents used, induces persistent STAT-1 and NF-κB activity in carcinoma-associated fibroblasts that induces the expression and secretion of ELR-motif-positive (ELR+ ) chemokines, which signal through CXCR-2 on carcinoma cells to trigger their phenotypic conversion into CSCs and promote their invasive behaviors, leading to paradoxical tumor aggression following the therapy. By contrast, the same total accumulated dose administered as a low-dose-metronomic chemotherapy regimen largely prevented the therapy-induced stromal ELR+ chemokine paracrine signaling for CSCs, thereby substantially enhancing treatment response and extending survival of mice carrying desmoplastic cancers (Chan et al., J. Exp. Med. 2016). These studies illustrate the importance of stroma in cancer therapy and how its impact on treatment resistance could be tempered by altering the dosing schedule of systemic chemotherapy.

#4764 Activation of estrogen receptor beta signaling reduces stemness and promotes differentiation of glioma stem cells. Gangadhara Reddy Sareddy, Jinyou Liu, Suryavathi Viswanadhapalli, Rajeshwar R. Tekmal, Andrew Brenner, Ratna K. Vadlamudi. *UT Health Science Center at San Antonio, San Antonio, TX.*

Glioblastoma (GBM) are the most common and deadliest tumors of the central nervous system. GBM have poor prognosis due to tumor recurrence and resistance to current therapies. Glioma Stem Cells (GSCs) are implicated in the tumor initiation and therapy resistance of GBM. Agents that can specifically reduce stemness of GSCs are urgently needed for the effective treatment of GBM. Efficacy is mainly unknown. Estrogen effects are mediated by two estrogen receptors (ER1 and ER2) and ER2 functions as a tissue-specific tumor suppressor. Our recent studies discovered that GSCs preferably express ER2 with low or undetectable levels of ER1. The objective of this study is to test whether ER2 agonists modulate stemness of GSCs and to determine their mechanism(s) of action. We have tested the hypothesis using GSCs isolated from established and patient derived GBM cells using stem cell markers CD133 and CD135. Knockout of ER2 using CRISPR/Cas9 system increased the CD133 positive GSCs and overexpression of ER2 reduces the CD133-positive population in GBM cells. Treatment of GSCs with ER2 agonists (Liquiritigenin and LY500307) significantly inhibited the neurosphere formation, self-renewal ability and proliferation. Further, ER2 agonist treatment resulted in the loss of stemness and induction of differentiation and apoptosis of GSCs. Western blot analysis and RT-qPCR analysis revealed reduced expression of stemness markers such as Nestin and Sox-2 and increased expression of differentiation markers GFAP and tub-1 in GSCs. RNA sequencing analysis of ER2 agonist treated and untreated GSCs revealed modulation of genes associated with cell cycle, differentiation and apoptosis. Further, ER2 agonists treatment significantly reduced the GSCs mediated tumor growth in orthotopic models and improved the mice overall survival. Immunohistochemical studies demonstrated that ER2 agonists reduces the expression of proliferation of marker Ki67 and induced the apoptosis in tumors. Together, our results established ER2 agonists liquiritigenin and LY500307 as novel therapeutic agents for elimination of GSCs. Since ER2 agonists has good blood-brain barrier permeability and less neuronal toxicity, they can be readily transferred to clinical use with current radiation and chemotherapies, thereby providing an additional tool for enhancing survival in GBM patients.

#4765 Targeting glioblastoma cancer stem cells with a novel Connexin43 mimetic peptide. Samy Lamouille,1 James W. Smyth,1 Laurie O’Rourke,2 Pratik Kanabar,1 Sujuan Guo,1 Jane Jourdant,2 Zhi Sheng,2 Robert G. Gourdie1.1Virginia Tech Carilion Research Institute, Roanoke, VA; 2Virginia Tech Carilion School of Medicine, Roanoke, VA.

Glioblastoma (GBM) is a highly malignant and lethal cancer of the central nervous system. Despite intensive research efforts, there has been limited progress in improving patient outcome. The current therapy for GBM patients includes surgical resection, radiotherapy and cytotoxic chemotherapy with temozolomide (TMZ), conferring a median survival time of only 14.6 months. Failure to generate more effective therapy strategies is due to the cellular heterogeneity within GBM tumors, which comprise a sub-population of GBM cancer stem cells (GSCs) characterized by self-renewal characteristics and resistance to TMZ. Recent work, including our own, has demonstrated that levels of the gap junction protein Connexin43 (Cx43) correlate with GBM TMZ resistance. Increased Cx43 levels occur in GSCs compared to parental GBM cells, and patients with high levels of Cx43 mRNA and low levels of MGMT, an enzyme that repairs TMZ-induced DNA lesions, have a significantly shorter life span. In contrast, Cx43 has also been associated with anti-proliferative effects in glioma and reduced levels of Cx43 protein are reported in high-grade gliomas. In addition to forming gap junctions, Cx43 can regulate cell proliferation, migration, and apoptosis, through distinct channel-independent mechanisms. Therefore, altering the localization and/or activity of Cx43 rather than Cx43 expression alone may represent a more targeted strategy in GBM treatment. Using super-resolution microscopy, we find intracellular Cx43 decorating microtubules in GSCs demonstrating for the first time such clustering in situ. Regulation of Cx43 function is primarily associated with multiple sites for post-translational modification and protein-protein interaction within the Cx43 carboxy-terminus (CT) which includes a tubulin binding domain. We have developed a peptide named JM2 (juxtamembrane 2) composed of the Cx43 CT amino acids encompassing the microtubule-binding sequence fused to an antennapedia cell penetration domain for cellular uptake. Super-resolution microscopy and biochemical analysis confirm JM2 specific interaction with microtubules concomitantly with a loss of Cx43 interaction with microtubules in GSCs derived from patient tumors. In addition, we observed that JM2 decreases Cx43 gap junction plaque formation and cell-cell communication in GSCs and limits microtubule dynamics. Importantly, JM2 decreases cell survival in TMZ-resistant GSCs and GSC neurosphere formation in vitro, and GSC-derived tumor growth in vivo. Our current research includes the development of JM2-loaded biodegradable nano-
particles for sustained JM2 delivery in preparation for future clinical trials. In conclusion, we have developed a Cs43 mimetic peptide that significantly decreases the tumorigenic potential of GSCs and represents a novel and potent therapeutic opportunity to alter Cs43 activity in targeting chemoresistant GSCs for GBM treatment.

**#4766 Translation from unconventional 5’ start sites drives tumor initiation.** Ataman Sendoo. Rockefeller University, New York, NY.

How translational control impacts tumor-initiation and malignancy is just beginning to unfold. Here, we devise an epidermis-specific, in vivo ribosome profiling strategy to interrogate the translational landscape during the transition from normal homeostasis to malignancy. Inducing SOX2, broadly expressed in oncogenic RAS-associated cancers, we find that despite widespread reductions in translation and protein synthesis, certain oncoprogenic mRNAs are spared. Seeking mechanism, we find that during tumor-initiation, the translational apparatus is redirected towards unconventional upstream initiation sites, enhancing translational efficiency of oncogenic mRNAs. An in vivo RNAi screen of translational regulators revealed that dampening conventional EIF2 complexes has dire consequences for normal but not oncogenic growth. Conversely, we identify alternative initiation factors essential for cancer progression, where they mediate initiation at these upstream sites, differentially skewing translation and protein expression. Our findings unveil a hitherto unappreciated role of 5’UTR translation in cancer, and expose new targets for therapeutic intervention.

**#4767 Identifying CDCA7 as a novel regulator of tumor-initiating cells in triple-negative breast cancer.** Caroline C. Notch1, puesto, Nicholas Stevers1, Samantha Tinsley1, Max Wicha1, Duxin Sun1. College of Pharmacy, University of Michigan, Ann Arbor, MI; Comprehensive Cancer Center, University of Michigan, Ann Arbor, MI.

Tumor-initiating cells (TICs) are a small fraction of cancer cells that stands at the apex of the tumor hierarchy. Given their tumor-initiating ability and resistance to conventional chemotherapies, TICs are considered potential therapeutic targets for preventing the relapse and metastasis of malignancies. Our group has identified a novel gene, Cell division cycle associated 7 (CDCA7), as an important regulator of TICs in triple-negative breast cancer (TNBC). CDCA7 is a target gene of MYC and NOTCH. Ectopic expression of CDCA7 has been demonstrated to induce neoplastic transformation in vitro and tumorigenesis in vivo. Despite its potential tumor-initiating ability, CDCA7 has not yet been well-studied in breast cancer. We found that CDCA7 was highly expressed in TNBC compared to other subtypes of breast cancer according to the RNA-sequencing data from The Cancer Genome Atlas. Furthermore, our Kaplan-Meier analysis of multiple datasets demonstrated that higher expression of CDCA7 was associated with poor prognosis in breast cancer. When we knocked down CDCA7 by siRNA in TNBC cell lines including SUM149, HCC1953, MDA-MB-231, and MDA-MB-436, CD44+/CD24– stem-like cell population and primary and secondary mammosphere formation were significantly decreased. In addition to suppressing the stem-like properties, knockdown of CDCA7 also inhibited the invasion and migration of breast cancer cells. These phenotypes indicated the inhibition of epithelial-to-mesenchymal transition (EMT), which was in accordance with the up-regulation of E-Cadherin and phenotypes indicated the inhibition of epithelial-to-mesenchymal transition. Knockdown of CDCA7 also inhibited the invasion and migration of breast cancer cells. These phenotypes indicated the inhibition of epithelial-to-mesenchymal transition (EMT), which was in accordance with the up-regulation of E-Cadherin and down-regulation of Vimentin after CDCA7 knockdown in TNBC cell lines. In conclusion, our results have demonstrated that CDCA7 is an important regulator of TICs in TNBC. Loss-of-function of CDCA7 leads to the inhibition of EMT and stemness in TNBC cells.

**#4768 A SHARP/Xist complex regulates breast cancer stem cells.** Yongyou Zhu, Li Shang, Justin Colacino, Michael Brooks, Ramdane Harouaka, Chang-Ching Lin, Ming Luo, Max S. Wicha. Univ. of Michigan, Ann Arbor, MI.

Many cancers including breast cancer display hierarchical organization and are driven by a cellular sub-population that displays stem cell properties. These cancer stem cells (CSCs) mediate metastasis and constitute to treatment resistance highlighting the importance of elucidating CSC regulatory pathways. Nuclear proteins and lncRNAs involved in the maintenance of chromatin structure have been shown to play roles in CSC regulation. Among them the polycomb proteins bmi-1 and EZH2 are involved in epigenetic regulation of CSCs in breast and other cancers. SHARP/SPEN, a RNA binding protein, has been previously been found to bind the IncRNA Xist which, by recruiting the PRC2 polycomb complex mediates transcriptional repression of the X chromosome. We utilized breast cancer cell lines and xenograft models to examine the role of the SHARP/Xist complex in the regulation of breast CSCs. In a series of breast cancer cell lines including MCF7 (luminal) and SUM 159 (basal/claudin low) cells, SHARP mRNA and protein as well as the IncRNA Xist were more highly expressed in cells expressing aldehyde dehydrogenase as accessed by the Aldehyde fluor assay than in ALDH– cells. Conditional knockdown of SHARP or Xist in SUM159 significantly decreased the ALDH+ CSC population without affecting cell growth in vitro. Furthermore, SHARP or Xist knockdown significantly reduced tumor initiating capacity and growth of SUM 159 cells in NOD/SCID mice. To determine the mechanism of breast CSC regulation by the SHARP complex, we compared mRNA levels in SHARP and Xist knockdown SUM 159 cells using RNAseq. There was significant overlap between the genes regulated by SHARP with genes regulated by the PCRI and PCR2 polycomb complexes in addition to many histone genes. These studies suggest that the SHARP/Xist complex may regulate breast CSCs through epigenetic regulatory histone and polycomb genes. Since SHARP expression is elevated in a number of cancers including breast cancer this pathway may represent a novel therapeutic target.

**#4769 Targeting HER2 enriches jagged1 high cancer stem cells in breast cancer.** Deep S. Shah1, Debra Wyatt2, Andrew Baker2, Andrew Green2, Alexandria Filippovic, Lucio Miele, Clodia Osipo1, Loyola Univ. Cardinal Bernardin Cancer Ctr., Maywood, IL; University of Nottingham, Nottingham, United Kingdom; Imperial College of London, London, United Kingdom; Louisiana State University, New Orleans, LA.

The human epidermal growth factor receptor 2 (HER2) positive subtype of breast cancer is characterized by gene amplification and/or protein overexpression of HER2. It is driven by a subpopulation of cells possessing stem cell properties of self-renewal and differentiation, known as Cancer Stem cells (CSCs). CSCs are implicated in tumor growth as well as radiotherapy and chemotherapy resistance. CSCs are supported by bone marrow-derived stem cells and self-renewal, and overexpression of a Notch ligand Jagged1 mRNA predicts poor prognosis in women with breast cancer. Our lab has published that Jagged1 or Notch is a critical target in trastuzumab/latatinib (LAP) resistant HER2+ breast cancer. The study aimed to determine whether anti-HER2 therapy selects for Jagged1/Notch-dependent CSCs that are responsible for tumor initiation. Surface expression of Notch1 and Jagged1 upon HER2 blockade using LAP was measured in HER2+ breast cancer cell lines (MDA-MB-453 and HCC1954) using flow cytometry. LAP treatment increased the Jagged1-positive subpopulation compared to vehicle. Cells were sorted based on Jagged1 cell surface expression and assessed for CSC-like properties (i.e. mamsphere formation in vitro and tumorigenicity in athymic, nude mice). In addition, immunohistochemistry was performed on 145 HER2+ breast cancer microarray to detect cytoplasmic, membrane, or nuclear Jagged1 protein expression. Kaplan-Meier analysis was performed to determine overall survival. The results showed that upon HER2 inhibition, Jagged1 cell surface expression increased and Notch1 cell surface expression was unchanged. The Jagged1+/Notch1– subpopulation of cells showed elevated levels of Aldehyde dehydrogenase activity, Notch target gene transcripts, and mammosphere formation efficiency compared to vehicle treated cells. The MRK-003 γ-secretase inhibitor (GSI) prevented mammosphere formation in the Jagged1+/Notch1– cells indicating that Notch activation drives Jagged1+Notch1– CSC survival. Also, we confirmed that Jagged1 expression is required for the enrichment of CSCs using a jagged1+/Notch1– CRISPR screen. Combined knockdown of Notch1 and Notch3 receptors was necessary to reduce LAP-enriched mammospheres suggesting that targeting HER2 enriches for a Jagged1+/Notch1– subpopulation of GDC phenotype. Importantly, higher membrane expression of Jagged1 protein in 145 HER2+ breast tumor specimens correlated with significantly lower overall cumulative survival. These results reveal that HER2 blockade in breast cancer cells enriches for a Jagged1+/Notch1– subpopulation that has higher CSC potential and is resistant to HER2 inhibitors. The implications of this work are that dual blockade of Jagged1/Notch1+Notch3 and HER2 could be more effective than either therapy alone to eliminate both HER2 and Jagged1-dependent cancer cells.

**#4770 Novel CXCR3 allosteric modulators inhibit breast cancer stem cells and metastasis.** Namita Kundu, Regine Bron, Xinrong Ma, Jocelyn Reader, Nuska Tschammer, Amy M. Fulton1, Univ. of Maryland Greenebaum Cancer Ctr., Baltimore, MD; Friedrich Alexander University, Erlangen, Germany; NanoTemper Technologies, Munich, Germany.

There is an urgent need to identify molecular targets that are relevant to metastatic and/or stem-like cancer cells (CSC). Theoretically, surface-expressed G-protein coupled receptors on CSC are attractive therapeutic targets. There is considerable evidence that the inflammatory milieu of the tumor microenvironment drives CSC and we now show that two isoforms of the chemokine receptor CXCR3 play important but distinct roles in cancer behavior. In the bulk tumor cell population, CXCR3, isoform A is highly expressed relative to CXCR3B. CXCR3A is critical to metastatic success. CXCR3, isoform B, is highly upregu-
lated in breast cancer CSC. When CXCR3B is gene-silenced in a model of basal-like, estrogen-dependent breast cancer, tumors-forming capacity is reduced and the aldehyde dehydrogenase-positive (ALDH1 +) population is correspondingly decreased. Conversely, overexpression of CXCR3B enhances these CSC properties. Thus, CXCR3B is critical to maintenance of the phenotype and function of breast CSCs. CXCR3B binds CXCL9, CXCL10, and CXCL11 with high affinity to CXCR3, however, each ligand is coupled to different intracellular signaling pathways. For example, others have reported that, in HEK cells, CXCL10 strongly induces ERK activation, but CXCL11 does not. In our hands, CXCL11 more potently induces an ALDH1+ population in MDA-MB-231 cells compared to CXCL10. We have developed novel allometric modulators of CXCR3 that demonstrate probe (ligand)-dependence. BD64 preferentially inhibits CXCL11-mediated β-arrestin 2 recruitment relative to inhibition of GPC signaling; BD103 is significantly more effective at blocking CXCL11 versus CXCL10-mediated GPCR signaling. Neither BD64 nor BD103 affects the GPCR signaling; BD103 is significantly more effective at blocking CXCL11 versus CXCL10-mediated GPCR signaling. Neither BD64 nor BD103 affects the GPCR signaling; BD103 is significantly more effective at blocking CXCL11 versus CXCL10-mediated GPCR signaling.

**#4771 The role of Hes1 in the normal and tumor stem cells of the intestine.**

Noriohiro Goto, Akihisa Fukuda, Tsutomu Chiba, Hiroshi Seno. Kyoto University Graduate School of Medicine, Kyoto, Japan.

Notch-Hes pathway plays a crucial role in the differentiation, proliferation, and tumorigenesis of the intestine. We previously reported that prenatal deletion of Hes1 reduces intestinal tumor proliferation; however, postnatal deletion of Hes1, which recapitulates Hes1-targeted tumor therapy, has not been thoroughly investigated. Here, we elucidated the novel role of Hes1 in normal stem cells (NSCs) and tumor stem cells (TSCs) of the adult intestine. First, we deleted Hes1 in Lgr5-expressing or Bmi1-expressing NSCs and performed lineage tracking using Lgr5CreERT2 reporter, Hes1flox/flox; Rosa26LacZ/+ and Bmi1 CreER+/++; Hes1flox/flox; Rosa26lacZ/+ mice. After Hes1 deletion, Lgr5-expressing or Bmi1-expressing NSCs gave rise to progeny cells, but could not self-renew. However, Hes1 deletion in NSCs did not disrupt intestinal homeostasis, because Hes1-positive NSCs were newly generated soon after Hes1-deleted NSCs were depleted. Next, we stabilized beta-catennin for intestinal tumor formation and deleted Hes1 in Lgr5-expressing cells using Lgr5CreERT2/+; Hes1flox/flox; ApcMin/+ mice. Of note, Hes1 deletion in TSCs of established intestinal tumors induced immediate apoptosis of TSCs and significantly reduced the number of tumors. qRT-PCR analysis of sorted Lgr5-expressing cells one day after Hes1 deletion revealed upregulation of pro-apoptotic genes and down-regulation of anti-apoptotic genes in Hes1-deleted TSCs, but not in Hes1-deleted NSCs. We also deleted Hes1 in an established intestinal tumor, showed that, irrespective of stem cell markers analyzed, Hes1 deletion in TSCs leads to tumor regression by inducing immediate apoptosis in TSCs. Taken together, Hes1 is required in different ways for the maintenance of NSCs and TSCs: Hes1 deletion in NSCs does not perturb homeostasis, whereas Hes1 deletion in TSCs leads to tumor regression. Furthermore, Hes1 is necessary for the initiation of intestinal tumor formation. Therefore, we propose Hes1 is a novel tumor-specific therapeutic target.

**#4772 Stearoyl-CoA Desaturase (SCD1) regulates liver tumor initiating cells through modulating ER stress.**

Kien Fa Ma,¹ Eunice Yuen Ting Lau,² Irene Oi Lin Ng,² Kin Wah Lee,¹ University of Hong Kong, Hong Kong. The Hong Kong Polytechnic University, Hong Kong.

Sorafenib is the best approved drug for patients with advanced hepatocellular carcinoma (HCC), but the survival benefit is only modest, partly due to drug resistance. Increasing evidence shows that tumor-initiating cells (T-ICs) are intrinsically resistant to conventional treatments, and targeting signaling pathways in T-ICs provides potential therapeutic targets for HCC. In our established enriched T-IC population, we identified the activation of a lipogenesis pathway in which expression of stearoyl-CoA desaturase-1 (SCD1), an enzyme involved in the conversion of saturated into monounsaturated fatty acids, was most significant. SCD1 overexpression is frequently found in HCC samples and is significantly associated with poorer patient survival. Using overexpression and knockdown approaches, SCD1 was found to regulate the traits of T-ICs, including tumorigenicity, self-renewal, differentiation, drug resistance and the expression of liver T-IC markers. Interestingly, SCD1 was markedly upregulated in our established sorafenib-resistant cell lines as well as patient-derived xenografts (PDTXs), and its overexpression predicts the clinical response of HCC patients to sorafenib treatment. Consistently, pharmacological inhibition of SCD1 suppressed T-IC phenotypes and enhanced sensitivity to sorafenib treatment. Using a patient-derived xenograft model, we found that a novel SCD1 inhibitor (S31-4) in combination with sorafenib demonstrated a maximal tumor suppressive effect. Induction of endoplasmic reticulum (ER) stress-mediated T-IC differentiation can account for the enhanced sensitivity towards sorafenib treatment upon SCD1 suppression. In conclusion, SCD1-induced ER stress may specifically inhibit the sensitivity of liver T-ICs to the effects of sorafenib treatment. Targeting SCD1 in combination with sorafenib therapy may be a novel therapeutic regimen against HCC.

**#4773 Dysregulated expression of pentraxin-3 in glioblastoma (GBM) stem cells: Implications for GBM invasion and progression.**

Umadevi V. Wesley, Paul Clark, John S. Kuo, Robert J. Dempsey. University of Wisconsin, Madison, WI.

Glioblastoma multiforme (GBM) is highly invasive and resistant to current therapies. The aggressiveness of brain tumor is attributed to GBM stem cells (GSC) that release inflammatory cytokines, chemokines and MMPs in the tumor microenvironment, critically affecting GBM survival and invasiveness. The glycoprotein pentraxin-3 (PTX3), a modulator of tumor-associated inflammation, is known to be correlated with tumor grade and severity of malignancies of some cancers. However, little is known about the role of PTX3 in GBM growth and invasion. In this study, we examined the role of PTX3 in GSCs exhibiting various degree of invasiveness. From patient brain tumors, our team has isolated the small subsets of glioblastoma stem cells (GSCs) and are validated for their self-renewal and multi-lineage potential. Our studies have shown that these GSCs efficiently form orthotopic brain tumors in immune-deficient mice. Our results show that conditioned media from GSCs promote pro-angiogenic tube formation from endothelial cells. GSCs that are grown in the absence of growth factors EGf, VEGf, FGF, IGF-1 induce invasive phenotype in immune-deficient mice and showed increased dispersal in the mice brain. Interestingly, polymerase chain reaction (RT-PCR) and immunofluorescence staining showed upregulated expression of PTX3 in these GSCs, and correlated with the degree of invasiveness. Differentiation of GCs into astrocytes in vitro, lead to decreased expression of PTX3. In support of this, recent histochemical study has shown that PTX3 levels correlate with GBM grade and is a candidate biomarker for cancer progression. Thus, PTX3 may represent a new target and marker of inflammation for glioma malignancy.

**#4774 Polyamines are rich and induces epigenetic change by inhibition of LSD1 in cancer stem-like cells.**

Keisuke Tamari, Hideshi Ishii, Masamitsu Konno, Naohiro Nishida, Jun Koseki, Koichi Kawamoto, Fumiaki Isoshahi, Yuichiro Doki, Masaki Mori, Kazuhiko Ogawa. Osaka University, Suita, Osaka, Japan.

Cancer stem cells (CSC) are highly tumorigenic and resistant to chemotherapy and radiotherapy. We have previously reported that our team fractionation of cancer cells with low proteasome activity had CSC-like properties. Ornithine decarboxylase (ODC) is an enzyme which converts ornithine to polyamines including putrescine, spermidine, and spermine. Proteosomal degradation of ODC is known to be ubiquitin-independent. The aim of this study was to explain how low proteasome activity gave CSC-like properties. Western blot showed high ODC protein level in CSC-like cells in cervical cancer and osteosarcoma cell lines, although ODC mRNA level is not high. These findings suggest that ODC protein level is high in CSC-like cells because ODC protein degradation is inactive. To investigate polyamine metabolism in CSC-like cells, we performed GC-MS analysis and found that putrescine, spermidine, and spermine were enriched in CSC-like cells. Furthermore, flow analysis showed conversion of ornithine to polyamines was more rapid in CSC-like cells. We performed a computational structure analysis and found that polyamines bind and inhibit demethylase site of LSD1 which is known to be a demethylase of histone H3K4 and a nuclear homolog of amine oxidases. Spermine was the strongest binding energy. An enzyme assay showed that LSD1 activity was dose-dependently inhibited by polyamines and spermine was the strong inhibitor. Finally, we analyzed performed ChIP sequencing analysis by using HeLa CSC-like cells and found that more global enrichment of H3K4me3 and less global enrichment of H3K4me1 than non-CSC-like cells. In conclusion, polyamines are rich in CSC, and be able to inhibit LSD1 activity and induce epigenetic alterations especially in H3K4 methylation in CSC.
Breast cancer is a leading cause of death in women and its metastatic spread to distant organs is responsible for over 90% of these deaths. Circulating tumor cells (CTCs) implicated in the metastatic process occur when cancer cells undergo cytoskeletal and phenotypic transitions that enhance motility, then penetrate into the blood circulation. While CTC dissemination has typically been considered as the spread of single cells, recent evidence suggests that collective migration results in polyclonal circulating clusters that are the main drivers of metastasis. To study circulating clusters we have developed a dual microfiltration system employing two stages of antigen-independent mechanical cell isolation. As whole blood is passed through the system, circulating clusters are trapped by the first stage while single CTCs are retained by the second stage. Characterization experiments using cell lines demonstrated a capture efficiency of 87.1% for clusters and 85.7% for single cells on their respective microfilters. This system was used to investigate circulating cells in the metastatic MMTV-PyMT murine breast cancer model. Both clusters and single CTCs were detected in mice with histological evidence of lung metastases (14-16 weeks old), but not in mice that had not yet developed metastatic tumors (<12 weeks old). Immunofluorescence assays were established to determine expression of CD24, CD40, cytokeratins, CD45, and PIAP. Tumor cells were identified as nucleated cells that expressed epithelial cytokeratins, but not the leukocyte antigen CD45. While PyMT cells with a CD90+/CD45− stem cell phenotype comprised only ~1.5% of tumors, they were observed in >50% of circulating clusters. The presence of cancer stem cells was correlated to cluster size, with smaller clusters containing a greater percentage of CD90+ cells. Isolated clusters will be further analyzed to quantify expression levels of cancer stem cell markers in individual constituent cells. The analysis of circulating clusters may provide crucial insight into the mechanisms of metastatic disease and provide the means to discover novel targets for therapeutic intervention.

#4777 Cancer stemness and resistance: Napabucasin (BBI-608) sensitizes stemness-high cancer cells to Paclitaxel by inhibiting the STAT3-MUC1 pathway. Harry A. Rogoff, Juying Li, Chiang Li. Boston Biomedical, Inc., Cambridge, MA.

Stemness-high cancer cells, or cancer stem cells (CSCs) represent a subpopulation of cancer cells with enhanced tumorigenic capacity, metastasis-forming potential, and resistance to conventional chemotherapy and radiation. One such key CSC pathway is regulated by STAT3, a transcription factor that is downstream of several cytokines and growth factor receptors which controls the expression of a range of genes in cancer biology in many tumor types. Cancer stemness inhibitor Napabucasin (BBI-608), a small molecule that inhibits gene transcription driven by STAT3, can inhibit stemness gene expression, block sporesgenesis, and kill CSCs. In vivo, BBI-608 effectively blocks cancer relapse and metastasis in xenograft models while sparing normal hematopoietic stem cells, suggesting that targeting stemness-high cancer cells is a feasible approach for developing next-generation cancer therapeutics to combat cancer recurrence. SOX2 (sex-determining region Y-box protein 2), a transcription factor that is essential for self-renewal and pluripotency, is amplified in various cancer types and has been shown to be required for CSC self-renewal and maintenance. Mucin 1 (MUC1), a glycoprotein normally expressed at the apical surface of epithelial cells, is overexpressed in most human epithelial cancers. MUC1 has been implicated in regulating tumor proliferation, metabolism, invasion, angiogenesis, chemoresistance, and inflammation. Here, we generated a stemness-high cell culture system based on the reporter activity of a SOX2-regulatory region construct in MKN28 gastric cancer cells (MKN28 SOX2-reporter GFP+ cells). BBI-608 treatment inhibited the STAT3-MUC1 pathway in stemness-high cells. High MUC1 status in stemness-high cells was associated with Paclitaxel resistance. Down-regulation of MUC1 sensitized stemness-high cells to Paclitaxel. Moreover, BBI-608 synergized with Paclitaxel in inhibiting sporesgenesis of stemness-high cells. This study provides a new mechanism for the association of cancer stemness with drug resistance. Our findings support this combination therapy, which pairs a conventional chemotherapy (Paclitaxel) with a cancer stemness inhibitor (BBI-608), as a promising strategy to combat cancer.

#4778 Telomere DNA damage promotes mammary gland fibrosis and estrogen receptor-positive breast cancer. Jianchun Wu, David L. Crowe. Univ. of Illinois Cancer Ctr., Chicago, IL.

Human breast luminal progenitor cells exhibit telomere DNA damage, which is associated with mammographic density and increased cancer risk. Telomeric repeat factor 2 (TRF2) protects telomeres from DNA damage response and its expression is reduced in human ductal carcinoma in situ and breast cancers. To determine the relationships between telomere DNA damage, mammary gland biology, and cancer risk we genetically deleted TRF2 expression in the mouse mammary gland. TRF2 conditional null mutant mice also were bred with tumor prone MMTV-Wnt1 animals. Telomere DNA damage response was determined by localization of 53BP1 at telomeres and activation of ATM/Chk2/p53 signaling by western blot. Mammary gland and tumor histopathology were determined by hematoxylin and eosin staining. Cell proliferation and ER+ differentiation was determined by immunohistochemistry. Telomere DNA damage was determined by labeling of 53BP1 at telomeres and activation of ATM/Chk2/p53 signaling by western blot. Mammary gland and tumor histopathology were determined by hematoxylin and eosin staining. Cell proliferation and ER+ differentiation was determined by immunohistochemistry. Telomere DNA damage was determined by labeling of 53BP1 at telomeres and activation of ATM/Chk2/p53 signaling by western blot. Mammary gland and tumor histopathology were determined by hematoxylin and eosin staining. Cell proliferation and ER+ differentiation was determined by immunohistochemistry. Telomere DNA damage was determined by labeling of 53BP1 at telomeres and activation of ATM/Chk2/p53 signaling by western blot. by some of the same major self-renewal pathways that drive embryonic stem cells, knowledge of other cellular pathways that drive CSC activity is still limited. In this work, we uncover a novel role for chemokine (C-C motif) ligand 20 (CCL20) in CSC growth and activity, expanding the role for this chemotactic protein. We discovered that CCL20 of many tumor types overexpresses CCL20, which we show to self-renew, self-initiate, and drive metastasis through its receptorCCR6. Targeting this axis with a neutralizing monoclonal antibody against CCL20 significantly reduces CSC frequency and tumor initiation and growth, supporting the novel therapeutic potential of targeting the CCL20-CCR6 axis as a strategy to eliminate CSCs. Furthermore, we found that CCL20 secreted by tumor cells also strongly influences the frequencies not only of T-cells, particularly immune-suppressive regulatory T-cells (T\(_{reg}\)) and Th\(_{17}\) populations, but also dendritic and neutrophil/gMDC populations, to promote anti-tumor immunity that leads to immune-mediated inhibition of tumor growth. Strikingly, we discovered that tumor-specific CCL20 impacted not just the immune cell balance within the tumor microenvironment, but had far reaching effects into the peripheral immune system as well. Thus, our overall findings propose that CCL20 plays a dual role in the tumor environment: 1) by driving activity and tumorigenic ability of CSCs, and 2) by promoting an immunosuppressive phenotype. In this work we show that therapeutic neutralization of CCL20 can deliver one-two punch against cancer, by directly inhibiting CSCs, and by relieving immunosuppression, thereby opening this target up as an exciting new strategy to treat cancer.

**#4780 Crucial role of S100A14 in blocking cancer-stem-cell activity and sensitizing to chemotherapy through STAT3 destabilization in human colorectal cancer.** Jaebeom Cho, Hye-Young Min, Ji-Sun Lee, Ho-Young Lee. Seoul National University, Seoul, Republic of Korea.

Colorectal cancer (CRC) is a major type of human cancers in terms of incidence and mortality worldwide. Chemotherapy is one of the standard protocols for the treatment of CRC but drug resistance is recognized as the main cause of treatment failure. Resistance to anticancer therapy is a multifactorial event involving a number of interrelated or independent mechanisms. Growing evidence supports a critical role of cancer stem cell (CSC) in development, progression, and resistance to anticancer therapies in CRCs. However, the molecular and cellular mechanisms underlying the CSC’s chemoresistance are not completely defined, and a comprehensive understanding of the biology of the CSCs is urgently needed. We have investigated mechanisms of chemoresistance, focusing on those mediated by CSCs, through the employment of CRC stem-like cell populations that are: 1) sorted out by using well-characterized stemness markers; ii) established via serial passagethroughincreasingdosesofoxaliplatin or 5-FU; or iii) enriched by culturing in sphere forming condition. We then assessed changes involved in CSC maintenance and found a novel role of S100A14 in CSCs of CRC. We found that transcriptional down-regulations of S100A14 expression conferred phenotypes of CSCs in the stem-like cell populations of CRC. Consistently, elevation of S100A14 expression sensitized the stem-like cell populations to the treatment with 5-FU in vitro and in vivo. Mechanistically, S100A14 directly interacted with STAT3 and promoted its degradation via the ubiquitin–proteasome pathway, leading to decreases in STAT3 target gene expression and a decrease in the forming capacity of the stem-like cell populations. Further, S100A14 expression was markedly downregulated in human CRC tissue specimens compared with their normal counterparts. Moreover, the expression level of S100A14 was inversely correlated with clinical outcomes in patients with CRC. These results collectively suggest that S100A14 is a novel target for the treatment of colorectal cancer by targeting CSCs.

**#4781 Epigenetic regulation of neuroblastoma tumorigenicity through MLL1 and JMJD3 modulation in cancer stem cells.** Saurabh Agarwal, Zaowen WenJiang,5 Betty Y.Kim, 3 Kyuson Yun6. 1The Jackson Laboratory, BarHarbor, ME; 2The Jackson Laboratory, Farmington, CT; 3Mayo Clinic, Jacksonville, FL; 4The Jackson Laboratory, ME; 5UT MD Anderson Cancer Center, Houston, TX; 6Houston Methodist Research Institute, Houston, TX.

Epigenetic regulators reduce NB tumorigenicity, metastasis and increase drug sensitivity. However, developing these strategies will pave the way for incorporating epigenetic inhibitors in current therapies for effectively improving long-term cure rates.

Cancer stem cells (CSCs) are a subpopulation of tumor cells that are uniquely capable of initiating and sustaining tumorigenesis, and they have also been implicated in driving disease recurrence after cancer therapy. We previously developed a novel lentiviral-based reporter system for direct visualization, quantitation and isolation of cells with CSC properties. The construct consists of a tandemly-repeated composite SOX2-OCT4 response element (“SORE6”) driving expression of a destabilized fluorescent protein reporter (Tang et al. Stem Cell Reports, 2015). TGF-βs are pleiotropic regulatory factors with complex roles in tumorigenesis. We and others have hypothesized that TGF-β can regulate the CSC population in breast cancer with stimulatory or inhibitory effects depending the model and stage of cancer development. Using the MCF10Ca1h and MCF7 breast cancer models, which retain tumor suppressor responses to TGF-β, here we show that TGF-β treatment significantly reduces the size of the CSC population in vitro. Although TGF-β had relatively little effect on invasion and migration of the bulk population in these models, it clearly inhibited migration and invasion of the CSCs, suggesting that biological responses to TGF-β can vary depending on the position of the cell in the differentiation hierarchy. Combining our stem cell reporter with a TGF-β pathway reporter, we further show that CSCs in the MCF10Ca1h model have higher endogenous activation of the TGF-β pathway than does the bulk tumor cell population, and by time-lapse video microscopy we find that CSCs with active TGF-β signaling are relatively quiescent. Furthermore, neutralization of TGF-β in vivo leads to an increased representation of CSCs in MCF10Ca1h and MCF7 tumors. Thus our preliminary results suggest that in breast cancer models where TGF-β acts as a tumor suppressor, TGF-β signaling is preferentially activated in the CSC compartment and keeps a subpopulation of CSCs in a quiescent and stationary state. These findings have important implications for the clinical use of TGF-β pathway antagonists. In contrast, in the metastatic breast cancer MDA-MB231 model, in which TGF-β acts as a pro-progression factor, we show that TGF-β can increase the size of the CSC population and enhance invasion. In this model, the CSCs are enriched for the ability to form macroscopic lung metastases when compared with non-CSCs, and we show that this effect is due in part to a selective survival advantage of the CSCs in the first 24 hours after arrival at the metastatic site. The role of TGF-β in this process is currently under investigation.
While growing evidence suggests that tumor microenvironment can modulate stemness and the mesenchymal phenotype, little is known about how these cell states are coordinately regulated. We report that S100A4 controls both stemness and mesenchymal transition in GBM cells. In a spontaneous mouse glioma model and in primary human GBM tumorspheres, S100A4 expression is enriched in tumor-initiating cells and is required for self-renewal and tumour growth. S100A4 expression is negatively correlated with the expression of mesenchymal markers, in primary human GBM tumorspheres and glioblastoma multiforme patients. Furthermore, Knockdown of S100A4 expression reduces the tumorigenic, migratory and invasive properties of glioblastoma cells. We also show that S100A4 expression is an independent predictor of poor overall survival in glioblastoma. These findings suggest a potential anti-metastatic role for S100A4 in glioblastoma and support the development of S100A4 inhibitors for the treatment of glioblastoma.

**#4786** Integrated exome and transcriptome sequencing identifies a novel candidate for breast cancer. Kyung-Min Lee,1 Dong-Yong Noh,2 Wonshik Han.1 Seoul National University, Seoul, Republic of Korea; 2Seoul National University College of Medicine, Seoul, Republic of Korea.

Breast cancer stem cells (BCSCs) exist in a dynamical equilibrium of mesenchymal (M) and epithelial-like (E) states that coordinates the differentiation of the tumor mass. BCSCs, like many other tumors, are capable of growth and maintenance in both M and E phenotypes, allowing for tumor heterogeneity and metastatic potential. Using gene expression microarray data from breast cancer samples, we identified transcription factors (TFs) that are specifically expressed in BCSCs. We found that S100A4 expression is significantly higher in BCSCs compared to non-BCSCs. S100A4 expression was also associated with poor prognosis and low survival rate. The unsatisfactory outcomes of breast cancer treatment are related to multiple factors including tumor recrudescence, metastasis, cancer drug resistance, etc. Breast cancer stem cells are cell subsets within a cancer that excel in tumor properties, especially survival, renewal and resistance to treatment. Reactive oxygen species (ROS) are high energy molecules produced during cellular hyperproliferation and cell death. Studies have shown though a low level of ROS is required to support stem cell functions but excessive ROS damages DNA and predisposes to cell death. Therefore, the ability to at-
tenue oxidative damage from ROS and maintain redox homeostasis is an important property of aggressive and resilient cancer cells. The multifunctional serine/threonine kinase calcium/calmodulin-dependent protein kinase II alpha (CaMK2A) is a calcium signaling molecule involved in cell growth and stress signals integration. It has been reported to play a tumor-supportive role in osteosarcoma, prostate cancer and leukemia. However, little is known about its role in TNBC tumors and the least favorable prognosis. Due to the absence of hormone receptors and Her2 receptor, no targeted therapy is available and chemotherapy is the standard treatment for TNBC patients. Paclitaxel is a widely used chemotherapy drug for various cancers with severe side effects due to its solvent. Abraxane is an albumin-bound nanoparticle of paclitaxel with less severe side effects. Here we show that Abraxane has superior activity than solvent-based paclitaxel in tumors expressing low levels of CaMK2A, increases cancer stem cells and decreases levels in CaMK2A-KD cells, implying Abraxane might be a mediator of CaMK2A in ROS regulation. To further identify downstream regulators, mRNA expression analysis of five ROS-regulatory NF2 target genes (GSP1, NQO1, GCLCL, HMOX1, TRXR1) was performed. Quantitative PCR results showed significant corresponding changes of some of these genes in cell lines, which upregulated CaMK2A overexpression and downregulated in both CaMK2A-KD cells and CaMK2A pharmacological inhibition cells. Together, the results indicate CaMK2A might regulate ROS status through mediating downstream target genes of NF2.

#4788 Abraxane eliminates cancer stem cells in triple-negative breast cancers.
Hebao Yuan, Hongwei Guo, Feng Li, Joseph Burnett, Miao He, Nathan Truchan, Ilia Myers, Duxin Sun. Univ. of Michigan, College of Pharmacy, Ann Arbor, MI.

Triple-negative breast cancer (TNBC) represents about 20 percent of all breast cancers. It is a poor survival rate and being associated with both the tumors and the least favorable prognosis. Due to the absence of hormone receptors and Her2 receptor, no targeted therapy is available and chemotherapy is the standard treatment for TNBC patients. Paclitaxel is a widely used chemotherapy drug for various cancers with severe side effects due to its solvent. Abraxane is an albumin-bound nanoparticle of paclitaxel with less severe side effects. Here we investigated whether cancer stem cells (CSCs) in TNBC response differentially to Abraxane and paclitaxel both in cell culture and xenograft mouse models. Using a series of human TNBC cell lines, we showed that there is no difference between solvent-based paclitaxel and Abraxane in vitro in terms of efficiency and eliminating cancer stem cells using MTS assay, mammosphere formation assay, and flow analysis of cancer stem cells. Interestingly, we demonstrated that Abraxane showed superior activity than solvent-based paclitaxel in human SUM149-L xenograft NOD SCID mouse model in adjuvant treatment. More important, we demonstrated that Abraxane eliminates cancer stem cells in xenograft NOD SCID mouse model in advanced treatment, while solvent-based paclitaxel increases cancer stem cells. Cell uptake assay indicated that TNBC cells take more Abraxane than solvent-based paclitaxel, which partially attributes to its superior efficacy in xenograft mouse models. Taken together, our data confirmed that Abraxane is superior to solvent-based paclitaxel and may be a better option for TNBC patients in adjuvant or metastatic treatment.

TUMOR BIOLOGY: Cancer Stem Cells

#4789 A novel MIF signaling pathway drives the malignant character of pancreatic cancer by targeting NR3C2.
Shouhui Yang,1 Peijun He,2 Liming Wang,1 Jian Wang,1 Aaron Schetter,2 Wei Tang,1 Naotake Funamizu,3 Katmann,6 Jens Werner,1 Nader Hanna,8 H.Richard Alexander,8 S. Szabo, Celia Chao, Mark R. Hellmich. University of Texas Medical Branch, Galveston, TX.

Introduction: We recently demonstrated that cystathionine-β-synthase (CBS) stimulates colon cancer bioenergetics, migration, invasion and angiogenesis and is increased in colorectal cancer compared to normal colonic mucosa. The role of CBS in carcinogenesis is still, however, unknown. Here we compare CBS protein levels and immunohistochemistry in human colonic biopsies at different stages of colorectal carcinogenesis. In addition, we used Azoxymethane (AOM) in CBS knockdown mice to study the development of aberrant crypt foci (ACF), a model of sporadic colorectal carcinogenesis. Methods: CBS protein expression was assessed in human biopsies of normal mucosa, tubular adenoma

Pancreatic cancers with aberrant expression of macrophage migration inhibitory factor (MIF) are particularly aggressive. To identify key signaling pathways that drive disease aggressiveness in tumors with high MIF expression, we analyzed the expression of coding and noncoding genes in high and low MIF-expressing tumors in multiple cohorts of pancreatic ductal adenocarcinoma (PDAC) patients. The key genes and pathways identified were linked to patient survival and were mechanistically, functionally, and clinically characterized using cell lines, a genetically engineered mouse model, and PDAC patient cohorts. Here, we report evidence of a novel MIF-driven signaling pathway that inhibits the orphan nuclear receptor NR3C2, a previously undescribed tumor suppressor that impacts aggressiveness and survival in PDAC. Mechanistically, MIF upregulated miR-301b that targeted NR3C2 and suppressed its expression. PDAC tumors expressing high levels of MIF displayed elevated levels of miR-301b and reduced levels of NR3C2. In addition, reduced levels of NR3C2 expression correlated with poorer survival in multiple independent cohorts of PDAC patients. Functional analysis showed that NR3C2 inhibited epithelial-to-mesenchymal transition and enhanced sensitivity to the gemcitabine, a chemotherapeutic drug used in PDAC standard of care. Furthermore, genetic depletion of MIF disrupted a MIF-mir-301b-NR3C2 signaling axis, reducing metastasis and prolonging survival in a genetically engineered mouse model of PDAC. Taken together, our results offer a preclinical proof of principle for candidate therapies to target a newly described MIF-miR-301b-NR3C2 signaling axis for PDAC management.
and carcinoma in situ by Western blotting. Immunohistochemical (IHC) staining was used to assess CBS levels in formalin-fixed/paraffin-embedded specimens of normal colonic mucosa, adenomatous polyps and colon adenocarcinoma. To assess the effect of CBS gene dosage on azoxymethane (AOM)-induced aberrant crypt foci (ACF) formation CBS heterozygous mice (CBS+/−) and wild-type controls were co-fed AOM at 10mg/kg via intraperitoneal injection once per week for 5 weeks. At the end of 16 weeks, the colons were harvested and ACF visualized with methylene blue staining by 3 independently blinded observers. Significance (p ≤ 0.05) was determined using GraphPad Prism 7 software. Results: Consistent with our previously reported findings CBS levels were relatively low in biopsies of normal mucosa. By comparison, it was elevated in polyps exhibiting both low- and high-grade dysplasia. IHC staining of normal mucosa and hyperplastic polyps revealed CBS immunoreactivity in a small number of cells located along the basal lamina aspect of the colonic crypts in both normal and hyperplastic polyps. A slight increase in cytoplasmic CBS staining also was noted in the epithelial cells of hyperplastic polyps. In contrast, the epithelial cells of tubular adenoma specimens exhibited higher levels of diffuse cytoplasmic CBS staining with frequent focal areas of intense staining adjacent to mucin-containing vesicles. Sections of adenocarcinoma exhibited diffuse CBS staining throughout the cytoplasm of the cancer cells. AOM treatment induced significantly less ACF in the colons of CBS+/− mice compared to wild-type controls. The loss of one allele of CBS reduced the number of AOM-induced ACF by half. The mean number of AOM-induced ACF (CBS+/−) and CBS−/−) were 10.9 ± 5.2 and 5.6 ± 2.5 (p < 0.05). Conclusion: CBS protein levels increase and the pattern of expression changes with progression from benign hyperplastic polyps to invasive adenocarcinoma, suggesting the enzyme may play a functional role in colorectal carcinogenesis. In addition, CBS single allele knockdown significantly reduces ACF formation. CBS, and its product H2S, may, therefore, be a driver of carcinogenesis.

**#4792 Prmt6 promotes lung tumor growth via modulation of If2 expressions.** Sreedevi Avasarala, Pei-Ying Wu, Michelle Van Scyoc, Abinaya Baskaran, Yanlin Su, Odile David, Robert A. Winn, Kamesh Bikkavilli. University of Illinois at Chicago, Chicago, IL.

Lung cancer kills more people in the US than any other malignancy. High mortalities are in part due to the diagnosis at an advanced inoperable stage where the 5-year survival is only 4%. Therefore improving survival will require increased knowledge of genes that drive the complex mechanisms of lung cancer initiation and progression. Emerging data implicate novel roles for protein arginine methylation in lung cancers. In protein arginine methylation, nitrogen/s of arginine can be post-translationally modified via the addition of a methyl group, catalyzed by a class of enzymes, protein arginine methyl transferases (PRMTs). Protein arginine methyl transferase 6 (PRMT6) is a methyltransferase that modifies histone tails, and its expression is upregulated in lung cancers correlating with a worse overall patient survival. However, the in vivo role of PRMT6 has never been examined. In this study, we show that targeted overexpression of PRMT6 in the mouse lungs (PRMT6 gain-of-function mouse model) results in an increased chemical carcinogen-induced lung tumorigene-
sis. We also performed proteomics on PRMT6-associated proteins from the mouse lung and identified Interleukin- enhancer binding protein 2 (IL2F2) a.k.a. nuclear factor 45 (NF45) as a novel PRMT6 interacting protein. By using a battery of cell-based assays, we show that PRMT6 plays an essential role in the regulation of the pro-proliferative functions of IL2F2. Therefore, targeting PRMT6/IL2F2 axis might open new possibilities for the therapeutic intervention of lung cancer.

**#4793 TRAF2 is required for the survival of ErbB2-transfected mammary tumor cells.** Hasem Habehlzah, Yumei Fan, Laiqun Zhang. Univer. of Iowa, Iowa City, IA.

TRAF2 regulates signaling pathways downstream of many members of the TNF receptor superfamily, such as TNFR1 and CD40. Recently, we found that TRAF2 also plays an important role in breast cancer cell survival under conditions of endoplasmic reticulum (ER) stress. It is known that TRAF2 knockout (KO) mice die within a week of birth and this lethality can be rescued by KO of TNFα or TNFR1. In order to determine the role of TRAF2 in mammary tumor development and progression, we crossed MMTV-ErbB2 mice (FVB) with TNF−/−/TRA2−/− mice (B6), and generated MMTV-ErbB2 (ErbB2), MMTV-
ErbB2-TNF−/− (ErbB2/T-KO) and MMTV-ErbB2-TNF−/−/TRA2−/− (ErbB2/T2-DKO) mice all in FVB/B6 mixed background. In 43 weeks, only 1 of 10 ErbB2/T2-DKO mice developed a mammary tumor, while 50% of ErbB2 and ErbB2/T-KO mice developed multiple and larger tumors in 30-32 weeks. Interestingly, the tumor derived from the ErbB2/T2-DKO mice did not show decreased cyclin D1 expression, nor the tumor cells cultured in vitro show decreased NF-κB activation in response to RANKL. In addition, ErbB2/T2-DKO cells formed mammampheses of similar appearance with that of ErbB2 cells in HEMA-coated plates. However, after dispersion of the mammampheses into single cells, ErbB2/T2-DKO cells formed dead cell aggregates, while ErbB2 and ErbB2/T-KO cells formed live cells aggregates indicating that the self-renewal capacity of ErbB2/T2-DKO cells is impaired. Mechanistic studies reveal that ErbB2/T2-DKO cells are sensitive to death caused by ER stress but not by TRAIL or DNA damage, and that this sensitivity is significantly inhibited by knockdown of RIP1. Collectively, these findings suggest that TRAF2 plays a critical role in mammary tumor development and progression by suppressing the pro-death activity of RIP1, and that TRAF2 and RIP1 interaction could be an attractive target for development of new anti-breast cancer drugs.

**#4794 Reduced Epstein-Barr virus replication in human papillomavirus-immortalized keratinocyte organotypic raft culture.** Joseph T. Guidry, William K. Songock, Xiaohui Ma, Cerie-Ann O. Nathan, Jason M. Bodily, Rona S. Scott. LSU Health Sciences Center - Shreveport, Shreveport, LA.

An epidemic rise in oropharyngeal squamous cell carcinoma (OSCC) infected with human papillomavirus has been observed over the past decade. The majority of HPV + OSCC arise from the tonsils and base of tongue (BOT), which are lymphoid-rich regions that are known to harbor Epstein-Barr virus (EBV). Indeed, we previously reported HPV/EBV co-infection in 25% of tonsillar and 70% of BOT tumors. HPV is a DNA tumor virus that specifically infects proliferating basal cells in stratified squamous epithelia. HPV replication is facilitated by viral oncoproteins E6 and E7, which create an S-phase-like environment via deregulation of cell cycle regulators p53 and Rb, respectively. EBV is also an established DNA tumor virus that replicates in differentiated epithelia in its normal life cycle. However, EBV exhibits a latent infection characterized by oncoprotein expression and lack of viral replication in EBV-associated carcinomas. E6/E7-mediated alteration of the cell cycle results in an interruption in epithelial differentiation, which is required for EBV replication in epithelial cells. Thus, we hypothesize that HPV immortalization of keratinocytes shifts the EBV life cycle from replication to latency. To test our hypothesis, we developed an EBV/HPV co-infection model utilizing organotypic raft culture to produce stratified epithelia in vitro. Tonsil keratinocytes immortalized by HPV were EBV-infected by co-culture with IgG-induced EBV-positive Akata Burkitt’s lymphoma cells four days after differentiation induction. Raft tissues were harvested 6 days post-EBV infection for analysis of viral life cycles. EBV infection did not alter HPV replication or gene expression. In HPV-negative tonsil keratinocytes, robust EBV replication was observed that was blocked by treatment with acyclovir, a nucleoside analog that inhibits EBV lytic replication. In contrast, a dramatic decrease in EBV DNA levels was observed in HPV-positive keratinocytes, which was not further reduced by acyclovir. Human telomerase-immortalized normal oral keratinocytes supported robust EBV replication in organotypic raft culture suggesting a specific effect of HPV rather than immortalization on EBV replication. Expression of E7 alone was sufficient to decrease EBV DNA levels. Preliminary data suggest no change in EBV infectivity between HPV-negative and HPV-positive rafts, and an increase in EBV latency-associated gene expression in HPV-positive rafts. We established an EBV co-infection model utilizing organotypic raft culture to produce stratified epithelial rafts expressing HPV and EBV. Tonsil keratinocytes immortalized by HPV were EBV-infected by co-culture with IgG-induced EBV-positive Akata Burkitt’s lymphoma cells four days after differentiation induction. Raft tissues were harvested 6 days post-EBV infection for analysis of viral life cycles. EBV infection did not alter HPV replication or gene expression. (CPT-11) and peripheral neurotoxicity induced by oxaliplatin were further investigated. CPT-11 induced intestinal toxicity in wild type mice but did not significantly affect hepatocyte or liver toxicity was observed; however, CPT-11 treatment in Nfr2−/− mice caused severe intestinal toxicity and pronounced steatohepatitis, associated with dramatically elevated serum biomarkers, accumulation of fat in liver and desmin expression. Mice lacking Nfr2 exhibited significantly decreased Mcell-induced intestinal toxicity and oxaliplatin-induced peripheral neurotoxicity, while did not impact the therapeutic efficacy of drugs. Taken together, our results demonstrate that the toxicities of some of chemotherapeutic drugs currently in clinical usage are significantly affected by Nfr2, therefore it is possible to personalize therapeutic regimens according to Nfr2 expression in tumors and normal tissues. Specifically, CPT-11-induced steatohepatitis and intestinal toxicity and oxaliplatin-induced peripheral neurotoxicity are significantly determined by Nfr2, and Nfr2 could be selectively targeted to prevent or treat chemotherapy-induced toxicities. The present works were supported by the NSFC (No. 81272468, 91429305 and 81372266).

The small endogenous signaling molecule, nitric oxide (NO) influences numerous physiological conditions including cancers. We have previously shown that different steady state NO levels activate pro-tumor signaling cascades. In this study, we explored the effect(s) of chronic NO exposure on breast epithelial cells as defined by changes in genomic stability, RNA and protein expression, and mostly importantly altered cell phenotype. Human breast epithelial cells (MCF10A) were chronically exposed to various concentrations of the NO donor DETA/NO for a three weeks. Distinct patterns of genomic alteration in the target genes (TP53, KRAS & PIK3CA) of exposed cells as compared to the background mutations were observed. In addition, quantitative real time PCR revealed increased expression of cancer stem cell (CSC) markers including NANOG, CD44, CXCR4 and OCT4 at 300 μM DETA/NO exposure. While altered cell morphology was observed in cells chronically exposed to 300-500 μM DETA/NO, increased motility occurred in cells cultured in 100 μM DETA/NO. Strikingly, these 100 μM NO-exposed cells grew in serum-free media; selected clonal populations as well as pooled cells formed colonies in soft agar that were disorganized and resembled cancer-like-clusters. In conclusion, these results implicate a precise tuning of microenvironmental NO levels that shift non-transformed breast epithelial cells toward cancerous phenotypes. The elucidation of underlying mechanisms may lend a new perspective regarding therapeutic approaches that redirect the cellular response(s) of tumor cells.

#4797 Continuous hepatocyte apoptosis accelerates diethylnitrosamine-induced liver tumor development. Yasutoshi Nosaki, Hayato Ikita, Satoshi Tanaka, Yuta Myoijin, Sadatsugu Sakane, Kazuhiro Murai, Yuto Shiodo, Yugi Kai, Yuki Makino, Tasuku Nakabori, Yoshinobu Saito, Takahiro Kodama, Ryoitaro Sakamori, Tomohide Tatsumi, Eiji Miyoshi, Tetsuo Takahara. Osaka University Graduate School of Medicine, Suita Osaka, Japan.

Background and Aim: Apoptosis serves as an important mechanism for removing DNA-damaged cells; and is considered to inhibit carcinogenesis. Hepatocyte apoptosis is a key feature of chronic liver disease, as established pre-cancerous condition for liver cancer. The present study examined the impact of continuous hepatocyte apoptosis on liver tumor development. Methods: We used male hepatocyte-specific knockout (KO) mice of Mcl-1, one of anti-apoptotic proteins, as a model of continuous hepatocyte apoptosis, and hepatocyte-specific wild type or double KO mice of Bak and Bax, pro-apoptotic proteins, as a model of apoptosis-resistant liver. To induce liver carcinogenesis those mice were intraperitoneally administered 20 mg/kg diethylnitrosamine (DEN) at 2 weeks. Results: Among control group treated with PBS, neither Mcl-1 KO nor wild-type (WT) mice developed macroscopically and microscopically any liver tumors at age of 6 months. On the other hand, while only 8% (2/26) of DEN-treated WT mice developed macroscopic liver tumors, 100% (15/15) of Mcl-1 KO mice developed (p<0.05). Macroscopically, 57% (15/26) of DEN-treated WT mice developed liver tumors, 100% (15/15) of Mcl-1 KO mice developed (p<0.05). These tumors were histologically classified as well-differentiated HCC. The average of maximum tumor size (12.4 vs. 6.5 mm), tumor numbers (21.4 vs. 4.0) and liver weight to body weight ratio (12.3 vs. 4.2 %) in Mcl-1 KO mice were significantly higher than those in WT mice. At 6 weeks, serum ALT levels and caspase 3/7 activity of DEN-treated Mcl-1 KO mice were significantly higher than those of DEN-treated WT mice. Immunohistochemistry revealed that PCNA, Ki67, phospho-HAX and 8-OHdG positive cells significantly increased in DEN-treated Mcl-1 KO mice compared with DEN-treated WT mice. The mRNA expression levels of TNF-alfa and Mcp-1 in DEN-treated Mcl-1 KO mice were significantly higher than those of DEN-treated WT mice.In contrast, macroscopic liver tumor incidence rate in WT, Bak KO, Bax KO and Bak/Bax double KO mice treated with DEN at 9 months was 46 (6/13), 40 (4/6), 35 (7/20) and 52% (11/21), respectively. Microscopic liver tumor incidence rate in WT, Bak KO, Bax KO and Bak/Bax double KO mice treated with DEN at 12 months was 70 (14/20) and 81% (17/21), respectively. There was no statistically significant difference in incidence rate of both macroscopic and microscopic tumors among 4 groups. At age of 6 weeks, there was no significant difference in serum ALT levels and caspase 3/7 activity among 4 groups. Conclusion: Continuous hepatocyte apoptosis is suggested to promote DEN-induced liver tumor development. Increased liver damage, compensative hepatocyte proliferation, genomic instability and inflammation may accelerate the incidence of DEN-induced liver tumorigenesis. In contrast, inhibition of apoptosis does not make much impact on DEN-induced liver tumor development.

#4798 Genetically engineered mouse models of proliferative C5 high grade serous ovarian cancer. Clare L. Scott,1 Gwo Y. Ho,1 Elizabeth E. Lischke,2 Olga Kondrashova,1 Ronny Drapkin,2 Matthew J. Wakefield,1,2 Walter E. Elias Hall Inst. Med. Research, Melbourne, Australia. 1University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; 2Peter MacCallum Cancer Centre, Parkville, Australia.

Introduction: High-grade serous ovarian cancer (HGSOC) can be divided into four subgroups based on molecular characteristics.1-2 The proliferative/C5 subgroup is defined by MYCN-pathway activation and may be associated with stem cell-like behavior.1 The majority of HGSOC originate from the secretory cells of the fallopian tube (FT), with both tumours and secretory cells characterised by PAX8 expression.3 We have developed pre-malignant C5 sub-type Genetically Engineered Mouse Models (GEMM) to characterise key molecular events in the initiation of this sub-type and to provide an immune-competent model for testing therapeutics. Methods: We have generated independent GEMM with p53 dysfunction (p53fl/fl;R172H) knock-in4 and over-expression of the MYCN-pathway, using either Isl-MYC or Isl-lin28b transgens5 directed by the doxycycline-inducible PAX8 promoter. Murine FT were harvested following two-weeks of transgene activation. One FT was harvested en bloc and paraffin embedded for analysis by H&E and immunohistochemistry for the presence of pre-malignant tubal lesions. The contralateral FT was micro-dissected into distal/mid-FT, which were snap frozen for analysis of gene expression by qRT-PCR and RNAseq. As mice with PAX8-directed expression of oncogenes (≥MYCN/lin28b overexpression) developed enlarged kidneys due to renal tubular adenoma, for alternate mice, the mid/distal FT tissue was implanted into the bursae of wild-type CBA/nu mice for observation and later analysis. Results: FT were harvested from twelve p53fl/fl;R172H/Isl-MYC mice and from six p53fl/fl;R172H/Isl-lin28b mice and from five p53fl/fl;R172H/Isl-MYC mice lacking relevant control mice. Dysplastic lesions were observed in a subset of p53fl/fl;R172H/Isl-MYC or Isl-lin28b FT and not in controls. MYCN pathway activation was demonstrated by qRT-PCR analysis. Conclusion: Over-expression of the MYCN-pathway can drive FT epithelial dysplasia in the presence of p53 dysfunction. RNAseq analysis is being performed to elucidate early genetic events in dysplastic FT. Mice are now being harvested after eight-weeks of doxycycline activation to determine whether more advanced pre-malignant change occurs. CRISPR guides deleting relevant genes including p53, PTEN, NFI or Rb1 were generated to delete additional genes in MYCN pathway-transgenic FT, followed by implantation for observation of tumourigenesis.

#4799 Fibroblast growth factor receptor (FGFR) promotes progression of cutaneous squamous cell carcinoma. Alok R. Khandelwal,1 Xiaohua Rong,1 Tara Moore-Medlin,1 Xiaohua Ma,1 Amelia Warner,1 John DiGiovanni,2 Che-Ann O. Nathan.1 1LSU Health-ShV, Shreveport, LA; 2University of Texas at Austin, Austin, TX.

Cutaneous squamous cell carcinoma (cSCC) is a keratinocyte-derived invasive and metastatic tumor of the skin. It is the second-most commonly diagnosed form of skin cancer (16%) striking 200,000 Americans annually. Increased understanding of the mechanisms involved in pathogenesis of cSCC could identify means to prevent, inhibit and reverse this process. In our previous studies, inhibition of Fibroblast growth factor receptor (FGFR) significantly decreased Ultraviolet B-induced (UVB) epidermal hyperplasia and hyperproliferation in
SKH-1 mice suggesting an important role of FGFR signaling in skin cancer prevention. However, the role of FGFR signaling in the progression of cSCC is not yet elucidated. Analysis of the expression of FGFR2 in cSCC cells and normal epidermal keratinocytes revealed overexpression and increased FGFR2 activity in cSCC cells. Tumor cell-specific overexpression of FGFR2 was detected in human cSCC and in UVB-induced mouse cSCC (20 SCC, 10 ADC and 3 LCC). All PDX models mostly retain the principal histologic and molecular characteristics of their donors and recapitulate the heterogeneity of human lung tumors. In our PDX collection we have sufficiently characterized all the NSCLC histology and the most relevant molecular alterations in lung cancer in order to perform precision medicine evaluation studies.

Conclusions: We have generated a collection of 42 PDX models of NSCLC characterized at the histological, genomic and transcriptomic level, which represents the most frequent histological and molecular subtypes of this type of lung cancer. This collection will be really useful to integrate drug screening with biomarker discovery and to evaluate precision therapeutic strategies. Our future aim will be to use this collection for biomarkers identification and preclinical evaluation of new therapeutic strategies targeted to bad prognostic lung tumors with suboptimal therapeutic approaches.

#4802 Immune dysfunction and fungal infection contribute to esophageal carcinogenesis. Feng Zhu,1 Jamii Willette-Brown,1 Na-young Song,1 Pelin Zhang,1 Yinling Hu1. NCI, NIH, Frederick, MD; 2PZM Diagnostic, Charleston, WV.

Human esophageal cancer is the sixth leading cause of cancer death worldwide. More than 90% of esophageal cancer is esophageal squamous cell carcinoma (ESCC). While the etiological causes remain unclear, esophageal mucosal fungal infection is very common in esophageal cancer patients, including patients with autoimmune polyendocrinopathy candidiasis ectodermal dysrophy (APECED) who have more than 20-fold risk of ESCC compared to the healthy population. Here, we report that kinase-dead Ikkα knock-in mice (hereafter referred to as mutant mice) develop APECED-like autoimmune disease due to developmental defects in thymus and lack of central tolerance. Similar to human APECED patients who develop esophageal mucosal fungal infection on average at the age of five, mutant mice develop fungal infection in oral cavity and esophagus as early as seven weeks old. About 20% of mutant mice develop ESCC during aging, which exhibits specific molecular signatures observed in human ESCC, such as p16 gene silencing, elevated EGFR phosphorylation and PD-L1 expression, etc. Autoreactive T cell depletion, or central tolerance reconstitution and/or normal T cell transfer prevents fungal infection and ESCC development in mutant mice. Importantly, antifungal drug treatment inhibits inflammation and ESCC development in mutant mice. However, oral inoculation of Clas-doporium, one of the major fungal species isolated from mutant mice, increases the tumor incidence from 20% to 63% in mutant mice. These results reveal that immune dysfunction and fungal infection is associated with ESCC development, which sheds new light on ESCC etiological factors, prevention and treatment.

#4803 Over-expression of thrombopoietin in the liver of transgenic mice with liver-specific human BrafV600E expression. Hiroki Tanaka,1 Kie Ho-rioka,1 Masahiro Yamamoto,1 Katsuhiro Okuda,1 Masaru Asari,1 Katsuhiro Okuda,1 Seiji Ohtani,1 Kosuke Yamazaki,2 Keiko Shimizu,1 Katsuhiro Ogawa,1 1Aisahikawa Medical Univ., Asahikawa, Japan; 2Japanese Red Cross Hokkaido College of Nursing, Kitami, Japan.

The BrafV600E mutation, which corresponds to the human BRAFV600E mutation, plays a pivotal role in mouse hepatic carcinogenesis induced by neonatal treatment with diethylnitrosamine in B6C3F1 mice. We previously established the transgenic mice that express the human BRAFV600E mutation in the liver (Mol Carcinog 2016. doi:10.1002/mc22510). The transgenic mice showed 5 folds increase in liver/body weight as compared to normal mice, and their liver was entirely consisted of small basophilic hepatocytes resembling DEN-induced neoplastic hepatocytes. The transgenic mice were normally born, but most of them spontaneously died during 2-3 months after birth. In this study, we investigated the reason for spontaneous death in the liver-specific BrafV600E transgenic mice. The numbers of platelets and megakaryocytes were remarkably increased respectively in peripheral blood and bone marrow in the transgenic mice. Furthermore, fragmented red blood cells and activated platelets with enlarged size were frequently observed in the peripheral blood smear of the transgenic mice. Thrombopoietin mRNA was abundantly expressed in the liver of transgenic mice, and the conditioned-medium of the cultured hepatocytes from the transgenic mice contained increased amount of thrombopoietin as compared with that of normal mouse hepatocytes. Histopathological analysis re-

SKH-1 mice suggesting an important role of FGFR signaling in skin cancer prevention. However, the role of FGFR signaling in the progression of cSCC is not yet elucidated. Sex-specific differences in Benzo(a)Pyrene [B(a)P]-induced colon carcinogenesis. Kenneth J. Harris,1 Kelly L. Harris,1 Mary K. Washington,2 James Amos-Landgraf,3 Aramandal Ramesh1. 1Meharry Medical College, Nashville, TN; 2Vanderbilt University, Nashville, TN; 3University of Missouri, Columbia, MO.

Colorectal cancer (CRC) is the third most common diagnosed cancer and the third leading cause of cancer-related deaths in the United States. It has also been reported that colon cancer incidence and mortality rates are higher in men than women, but there is yet a determined mechanistic link to show the factors that underlie the sex-specific differences in CRC initiation and progression. Benzo(a)pyrene [B(a)P], a member of the polycyclic aromatic hydrocarbon (PAH) family of compounds is a well-characterized environmental toxicant that has been proven to be a major contributor to the development of sporadic colon cancer. Published studies indicate that Aryl Hydrocarbon Receptor (AhR), a receptor for [B(a)P], bind to estrogen receptor (ER) and negatively affect AhR-targeted gene transcription. This study aims to elucidate the sex-specific differences in B(a)P-induced colon cancer in adult Polyposis In The Rat Colon (PIRC) model. We hypothesize that sex-specific differences in B(a)P biotransformation modulates the formation of colon tumors in PIRC rats. Groups of female and male PIRC rats (n = 8) received sub-chronic exposure to 25, 50 and 100 μg B(a)P/kg body wt. via oral gavage for 60 days. Female and male rats that received no [B(a)P] treatment served as controls. [B(a)P] was shown to have no significant effect on body weight of these rats and female PIRC rats that received 25, 50 and 100 μg B(a)P/kg body wt. showed significant decrease in total polyp count when compared to males with respective treatments. Polyp sizes of female PIRC rats receiving 25, 50 and 100 μg B(a)P/kg body wt. were increased when compared to males respectively. Histopathological analysis of colon polyps revealed that female animals exhibited low-grade to no dysplasia while high-grade dysplasia was recorded in male animals treated with corresponding doses. Phase 1 enzyme, Cytochrome P450 isoform 1A1 (CYP1A1), and phase 2 enzyme, Sulfo-transferase Family 1A Member 1 (SULT1A1), were downregulated in colon tissue of female PIRC rats receiving 25, 50 and 100 μg B(a)P/kg body wt. when compared to male counterparts. In future studies, by measuring the expression of the other phase 1 and phase 2 drug metabolizing enzymes (DME), along with measuring circulating estrogen levels, analyzing [B(a)P] metabolite profile, and probing [B(a)P]-DNA interactions, we will provide insight into if and how estrogen receptor protects females from developing colon cancer. This research was funded by NIH grants 5R01CA12845-04, 5R25GM059994-3, and G12MD007586-29.

The role of exosomes in fibrosarcoma progression. Miho Nakajima,1 Stephen C. Searles,2 Ayuko Hoshino,1 Katherine M. Offer,1 Candia M. Kenfic,1 Jack D. Bui,1 David C. Lyden,1 Weil Cornell Medical Center, New York, NY; 2University of California, San Diego, La Jolla, CA.

Among pediatric cancers, sarcomas, especially those with large tumor burdens and metastatic disease, often result in poor outcome. Thus, new treatments are urgently needed to inhibit tumor progression, prevent metastasis, and improve overall survival. To understand the mechanisms driving sarcoma progression, we employed two mouse fibrosarcoma cell lines that display different growth phenotypes when transplanted into syngeneic immune competent mice. Progressor fibrosarcomas evade detection by the immune system and develop large tumor burdens, while regressor fibrosarcomas regress shortly after a period of limited tumor growth. This difference in the growth phenotype is mediated in part by immune cells, but the mechanisms by which progressor and regressor cells influence immune cell activity are not fully elucidated. Our research has focused on exosomes, 50-100 nm secreted nanovesicles, that contain bioactive cargoes and have emerged as mediators of intercellular communication between various cells. Here, we hypothesize that fibrosarcoma exosomes determine the aggressiveness of the disease by either educating tumor cells themselves or altering interactions with host cells. To investigate the role of fibrosarcoma exosomes, we first educated regressor tumor cells with progressor exosomes for 3 weeks in vitro, and vice versa. Upon in vivo inoculation, progressor cells conditioned with regressor cell-derived exosomes grew significantly slower compared to untreated progressor cells. In contrast, regressor cells educated with progressor exosomes did not regress and overgrew significantly compared to untreated regressor cells. The differences in tumor growth were paralleled by changes in the tumor microenvironment that favor tumor growth and proliferation of neoplastic hepatocytes. (Supported by the grant from Japanese Ministry of Education, Culture, Sports and Science Technology.)

Strategies to overcome the heterogeneity of tumor cells in breast cancer therapy. Gloria M. Calaf,1 Marcela Callardo,2 Debasish Roy,3 Richard Ponce-Cusi.1 1Universidad De Tarapacá, Arica, Chile; 2The City University of New York, New York, USA.

Breast carcinogenesis is a multistage process that involves mutations and alterations attributed to exposure to exogenous environmental substances and endogenous agents as female hormones. To overcome the heterogeneity of tumor cells in breast cancer therapy several strategies must be considered from the bench to clinical settings. It is proposed four strategies: Analysis to determine 1) Apoptosis, 2) Epithelial-mesenchymal transition (EMT), 3) CD44/CD24 gene and protein expression in cells derived from mammospheres and 4) MicroRNAs as miR34a and others by the effects of chemotherapeutic drugs (as pamidronate (Pam), 5-Fluorouracil (5-FU) and antioxiants as Curcumin (Cur) (diferuloylmethane) derived from Curcuma longa. Pam, a bisphosphonate is used in the treatment of breast cancer. 5-FU is a chemotherapeutic agent for the treatment of a variety of solid cancers that arrest cell cycle and induce apoptosis in cancer cells. We evaluated genes and proteins targeted by these drugs and antioxiants in a triple positive cell line, as MCF7 and a negative, MDA-MB-231 for hormonal receptors, respectively and in an in vitro breast cancer model induced by radiation and estrogen that was developed with a normal immortalized breast epithelial cell line, MC6, exposed to low doses of high LET (linear energy transfer) alpha particles (150 keV/μm) of radiation, and cultured in presence of 17β-estradiol. We used: i) MCF-10f, ii) Alpha3, a malignant non-tumorigenic, iii) Alpha5, a tumorigenic one and iv) Tumor2 cell line derived from Alpha5 injected into the nude mice. Previous results showed increased cell proliferation, anchorage independency, invasive capabilities and tumor forma-

Braf mutations initiate the development of rat gliomas induced by postnatal exposure to N-ethyl-N-nitrosourea (ENU). Kazuki Sato,1 Qi Wang,2 Ji Eun Oh,1 Barbara Hutter,2 Benedikt Brors,2 Nicole Diesel,2 Hai-Kun Liu,3 Stephen Wolf,2 Otmar Wiestler,2 Paul Kleihues,3 Bernd Koelsch,4 Andrea Kindler-Rohrborn,4 Hiroko Ohgaki1. 1International Agency for Res. on Cancer, Lyon, France; 2German Cancer Research Center (DKFZ), Heidelberg, Germany; 3Heidelberg University, Heidelberg, Germany; 4Heimholtz-Zentrum Deutsches Forschungszentrum, Berlin, Germany; 5University Hospital Zurich, Zurich, Switzerland; 6University Hospital Essen, Essen, Germany.

Purpose: A single dose of N-ethyl-N-nitrosourea (ENU) during late prenatal or early postnatal development induces a high incidence of malignant schwannomas and gliomas in rats. Although T- > A mutations in the transmembrane domain of
the neu (c-ErbB-2) gene are the driver mutations in ENU-induced malignant schwannomas, the molecular basis of ENU-induced gliomas was unknown. The objectives of this study were to identify driver mutations in ENU-induced rat gliomas. Methods: We performed whole-genome sequencing of gliomas that developed in three BDIV and two BDIX rats exposed to a single dose of 80 mg ENU/kg body weight on postnatal day one. Results: TA->AT and TA->CT mutations, which are typical for ENU-induced mutagenesis, were predominant (41-55% of all somatic single nucleotide mutations). T->A mutations were detected in all 3 rat gliomas at Braf codon 545 (V545E), which corresponds to the human BRAF V600E. Additional screening revealed that 33 gliomas in BDIV rats and 12 gliomas in BDIX rats all carried a Braf V545E mutation, while peritumoral brain tissue of either strain (n=16) had the wild-type sequence. The gliomas were immunoreactive to BRAF V600E antibody. Conclusions Braf mutation is a frequent early event in the development of rat gliomas caused by a single dose of ENU.

#4808 Effect of Merkel cell polyomavirus large and small T-antigen on the thrombospondin and the perisinostin promoter. Aelita Konstantinell, Ida Sofie Furuholmen, Baldur Sveinbjørnsson, Ugo Moens. The Arctic University of Norway, Tromsø, Norway.

Merkel cell carcinoma (MCC) is a rare, but aggressive form of skin cancer with rising incidence and high mortality rate. Approximately 80% of MCC tumors are positive for Merkel cell polyomavirus (MCPyV), suggesting a causative relationship between MCPyV and MCC. Exosomes are 30-150 nm vesicles that contain proteins, lipids, miRNAs, IncRNAs, and miRNAs. Exosomes from virus-infected cells comprise also viral nucleic acids and proteins. Because tumor cell-derived exosomes may contribute to cancer, we hypothesized that MCPyV may affect the composition of exosomes and play a role in tumorigenesis. Therefore, we compared the proteins in exosomes produced by MCPyV-positive MKL1 and MKL2 and MCPyV-negative MCC13 and MCC26 MCC cell lines. Our proteomic analysis of exosomes originating from polyomavirus-negative and polyomavirus-positive MCC cell lines revealed the presence of the oncogenic proteins perisinostin and thrombospondin. Western blot analysis of exosomes and lysates of these MCC cells confirmed the presence of these proteins in exosomes from all cell lines. Thrombospondin, but not perisinostin, was detectable in cell lysates, and an enrichment of both proteins was detected in exosomes of all cell lines. The effect of MCPyV large T-antigen (LT-ag) and small T-antigen (st-ag) on the perisinostin and thrombospondin promoters was examined by transient transfection studies with luciferase reporter plasmids. Transfection experiments in MCC13 revealed that LT-ag, but not st-ag significantly increased the activity of the thrombospondin and perisinostin promoters. In MCC26 cells, neither LT-ag nor st-ag had a significant effect on the thrombospondin promoter activity, while both proteins alone or in combination significantly stimulated the perisinostin promoter strength. Our results suggest that MCPyV proteins may contribute to tumorigenesis by enhancing the expression of the oncoproteins thrombospondin and perisinostin and promote their secretion via exosomes.

#4809 Development of mouse brain tumor model using in vivo electroporation and piggyBac system. Nobuyuki Onishi, Sampetrane Oltea, Hideyuki Saya. Keio University School of Medicine, Tokyo, Japan.

Glioblastoma multiforme (GBM), is one of the most malignant brain tumors, has highly proliferative and invasive characters. There is no established effective therapy for GBM possess radio- and chemo-resistance. To comprehend these malignant characters of GBM, an appropriate model of brain tumor is required. InK4A/Arf loss of function and activation of RAS-related signaling pathways are frequently observed in GBM. Neural stem cells (NSCs), having self-renewal and multipotent abilities, are considered one of the cells-of-origin of GBM. Previously, we have established a stable mouse models of brain tumors, transplanting the genetically modified NSCs. The NSCs derived from InK4a/Arf KO mice, transduced activated-RAS, rapidly formed highly proliferative and invasive brain tumors. Recently, for the purpose of reproducing the clinical tumor initiating process, we are developing in vivo carcinogenesis model of mouse brain tumors by having the genetic engineering in mouse brain directly. Using the combination of in vivo electroporation and piggyBac system, activated-RAS and shInK4a/Arf are introduced into NSCs genome in mouse brain, leading to formed brain tumors having an equally malignant behavior as the transplanta- tion model. Histological characteristics of these tumors resembled human GBM phenotype demonstrating necrosis, perivascular cuffing and giant cell formation. Immunohistochemical analysis displayed that tumors were proliferation marker Ki-67 highly positive and had heterogeneity, expressing stem cell marker Nestin or astrocyte marker Gfap. On the basis of these findings, we propose this in vivo carcinogenesis technique is efficient method to generate appropriate mouse brain tumor models.

#4810 Loss of Cav-1 is associated with manifestation of stem cell-like properties via Src-mediated phosphorylation in human breast MDA-MB-231 cancer cells. Hye-Jin Yoon, 1 Do-Hee Kim, 1 Young-Nam Cha, 2 Young-joon Suh.1, College of Pharmacy, Seoul National University, Seoul, Republic of Korea; 2Colleage of Medicine, Inha University, Incheon, Republic of Korea.

A subpopulation of cancer cells, termed cancer stem cells (CSCs), has self-renewal and differentiation potential, which contributes to cancer recurrence and tumor resistance. Caveolin-1 (Cav-1), the major structural protein of flask-shaped plasma membrane invaginations called caveolae, functions as a tumor suppressor or an oncogene depending on the tumor type and the grade. Caveolin-1 participates in various cellular functions, such as vesicle trafficking, cholesterol homeostasis, signal transduction, and tumor progression. In the present study, we investigated the role of Cav-1 on the stemness of human breast cancer (MDA-MB-231) cells. A sphere formation assay has been widely used to enrich for CSCs through serialpassaging. A level of Cav-1 protein expression decreased in third-generation mammospheres as compared to parent MDA-MB-231 cells. Under the same experimental conditions, however, there was no concurrent decrease in the Cav-1 mRNA level. Therefore, it is likely that stability of Cav-1 protein is decreased during mammosphere formation. Recently, it has been reported that sustained phosphorylation of Cav-1 promotes its ubiquitination and degradation by the proteasomes. We observed that PP2, an inhibitor of Src, suppressed phosphorylation of Cav-1 in MDA-MB-231-derived mammosphere cells, which in turn increases its protein stability. Breast CSCs are enriched in cells with enhanced expression of phenotypic markers, such as CD44+/CD24-. We found that Cav-1 gene silencing using siRNA enhanced the proportion of CD44+/CD24- MDA-MB-231 cells. In addition, Cav-1 knockdown increased the number and size of secondary mammospheres, and this was accompanied by enhanced expression of Bmi-1 and Sox-2, which are representative self-renewal markers. Moreover, epithelial-mesenchymal transition (EMT) was decreased by knockdown of Cav-1 in MDA-MB-231 cells. Taken together, these findings suggest that loss of Cav-1 protein stability facilitates the formation of mammospheres through upregulation of self-renewal and EMT markers in breast CSCs.

TUMOR BIOLOGY: Cell Culture and Animal Models of Cancer 5

#4811 XenoSarc: Patient-derived xenograft (PDX) models of soft tissue sarcoma (STS), an update on a preclinical platform for early drug testing. Agnieszka Wozniak, 1 Jasmin Cornillie, 1 Yemarshet K. Gebreyohannes, 2 Jasmin Wellens, 1 Lis Vreys, 1 Daphne Hompes, 2 Marguerite Stas, 2 Friedel Sneaeve, 2 Maria Debiec-Rychter, 1 Raf Scoit, 1 Patrick Schöffski, 1 KU Leuven and University Hospitals Leuven, Leuven, Belgium; 2University Hospitals Leuven, Leuven, Belgium.

Background: STS constitutes a rare and very heterogeneous family of mesen- chymal tumors. The limited treatment options available for advanced STS un- derline the need for reliable preclinical models to test novel therapeutic strate- gies. Methods: A panel of patient-derived xenografts (PDX) was established by subcutaneous implantation of fresh, surgically resected or biopsied tumor spec- imens in immunodeficient, athymic nude NMRl mice. Once tumor growth was observed, pieces of tumor were re-transplanted to next generations of mice. At each passage tumor fragments were collected for histopathological and molec- ular characterization. A model was considered established after observing stable histological and molecular features for at least two passages. Results: Until now 171 STS samples from consenting patients treated at the University Hospitals, Leuven, Belgium, have been transplanted. Twenty-eight well-characterized, sta- ble PDX models of STS have been established, maintaining the histopathological and molecular features of the original tumor. The detailed clinical information about a donor patient, including sensitivity to standard and experimental drugs, is linked to every model. At this point the XenoSarc platform includes models of gastrointestinal stromal tumor (6 models), myxoidfibrosarcoma (6), dedifferenti- ated liposarcoma (3), malignant peripheral nerve sheath tumor (3), synovial sarcoma (1), leiomysarcoma (4), epithelioid haemangiendothelioma (1), mesenchymal chondrosarcoma (1), pleomorphic rhabdomyosarcoma (1) and high-grade undifferentiated pleomorphic sarcoma (2). From these models we have also available tissue microarray (TMA) as well as data on genomic and expression profile including mutations (by RNA-Seq). Some of these models
have already been successfully used for in vivo testing of novel agents, including both targeted and cytotoxic (pro-)drugs, and results served as a rationale for several prospective clinical trials. In addition, 24 other xenografts are still in early stages of engraftment, not yet fulfilling our criteria of an “established model”.

Conclusion: Our XenoSarc platform contains a number of well-annotated mod-
el strains of human glioblastoma (8/14.5 months), the segmental and punctate infil-
tration of the brain parenchyma (6/14, 43%). In summary, we present a valuable mouse model for preclinical studies of glioma. Integrative analysis of molecular profiles with growth pattern data has the potential to unravel genes that distinguish tumors with more infiltrative growth. Our biobank of luciferase labeled GSCs may be useful for longitudinal monitoring of tumor growth dynamics in the setting of therapies and provides a foundation for testing the effect of predicted drug vulnerabilities in orthotopic xenografts mouse models.

#4812 A novel set of patient-derived orthotopic xenograft (PDOX) mod-

eis of primary and recurrent intracranial meningioma. Huiyuan Zhang,1 Lin Qi,1 Yuchen Du,1 Frank K. Braun,1 Mari Kogiso,2 Sibo Zhao,1 Holly B. Lindsay,1 Sarah G. Injac,1 Patricia A. Baxter,1 Jack M. Su,1 Akash J. Patel,1 Xiao-nan Li,1 Baylor College of Medicine. 2Texas Children’s Cancer Center, Houston, TX; 3Jan and Duncan Neurological Research Institute, Houston, TX

Background: Meningioma is the most common brain tumors in adults. De-

spite the overall benign nature of meningioma, cranial-base tumors are difficult to achieve complete resection while others exhibit progression and aggressive profiles characterized by high recurrence rates, pleomorphic histology, and resistance to standard treatment. The lack of clinically relevant animal models is blocking the development of novel therapies. Here, we report our establishment of orthotopic xenograft mouse models and in vitro culture systems from surgical specimens of primary and recurrent meningiomas. Material and Methods: 6 primary surgical samples (3 WHO grade 1 and 3 atypical), and 4 recurrent samples (1 WHO grade 1, 2 atypical and 1 anaplastic meningioma) were ob-
tained from meningioma patients. Tumor tissues were dissociated into single cells and directly implanted into right cranial base of NOD/SCID mice (1x10^6 cells/mouse). Primary cultures were initiated in serum-free and traditional FBS-based media. Tumor growth was monitored by small animal MRI. Pathologic features of the PDOX models and the matched patient tumors were compared with standard histopathology (H&E) and immunohistochemistry (IHC) stainings. Results: Of the 10 tumors, 3 were not tumorigenic, and xenograft tumor formation from 5 additional samples is pending. Growth of intracranial (cranial base) xenograft was confirmed in two samples derived from the same patient diagnosed as atypical meningioma (K029MEN) and progressed as anaplastic meningioma at recurrence (K037MEN). These patient derived or-
thothetic xenografts (PDOX) have since been serially subtransplanted in mouse brains for generation 2 and can be cryopreserved for long-term maintenance of tumorigenicity. The xenograft tumors replicated histopathological features (invasion, high proliferation and increased microvessel density) of their parental tumors. Genomic analysis is being performed to examine the similarities between parental tumors and the corresponding orthotopic xenograft tumors and the discrepancies between the primary and the recurrent tumor-derived models. In vitro growth of K029MEN and K037MEN as neurospheres and monolayer were maintained for 2 months and passage for 10 times. Additionally, cells from K030MEN, a WHO grade 1 meningioma, has been passaged as monolayer for more than 30 times. Conclusion: A novel set of meningioma PDOX models developed in cranial-base and recurrent tumors was established. Xenograft tumors replicated the histopathological and key molecular features of the original patient tumors, providing a unique opportunity to understand the biology of malignant meningiomas and to conduct preclinical drug testing.

#4813 In vivo modeling of high grade glioma for oncology drug development.

Cecilia Krona, Soumi Kundu, Karl Holmberg-Olausson, Riaas Islam, Rashmi Ramachandara, Ludmina Enfne, Sven Nelandar. Uppsala Univ., Upp-
sala, Sweden.

In a multi-disciplinary project, patient derived glioblastoma stem-cell cul-
tures (GSCs) have been established and characterized extensively with the goal of applying computational tools to integrate results from high-throughput screens of drugs and RNAi with genomic and transcriptional profiling to predict the most successful therapy for individual glioma patients. The main goal of this study was to develop a platform for testing the tumor-initiating capacity of GSCs in mouse brain and to label the cells with GFP-luciferase to enable non-invasive quantification of tumor growth by in vivo bioluminescence imaging. Adherently grown GFP-luciferase labeled glioblastoma stem-cell cultures were dissociated and injected stereotactically into immunodeficient mice. Tumor growth was monitored by IVIS and彩色 microscopic imaging. The brain was engrafted with GSCs and the brain sections were set up based on human cell specific staining and a CellProfiler Analyst’s machine learning classifier with a manual observer correlation of 0.86. GSC xenograft tumors with 

a wide range of histopathological features and biological behaviors recapitulat-
ing high grade astrocytoma was confirmed in mice injected with 14 of the 29 glioblastoma cell cultures (48%). Glial lineage markers, such as Sox2, GFAP, and Olig2, were expressed both in patient tumors and patient derived xenografts. Individual glioblastoma cell cultures were either characterized by formation of condensate tumors (8/14, 57%) or diffuse infiltrative growth through the brain parenchyma (6/14, 43%). In summary, we present a valuable mouse model for preclinical studies of glioma. Integrative analysis of molecular profiles with growth pattern data has the potential to unravel genes that distinguish tumors with more infiltrative growth. Our biobank of luciferase labeled GSCs may be useful for longitudinal monitoring of tumor growth dynamics in the setting of therapies and provides a foundation for testing the effect of predicted drug vulnerabilities in orthotopic xenografts mouse models.

#4814 Testing personalized therapies for ovarian cancer using mate pair genomic analysis and patient-derived xenografts. Konstantinos Leventakos, Faye R. Harris, Lin Yang, Xiaonan Hou, Saravut Weroha, Irina V. Kovtun. Mayo Clinic, Rochester, MN.

Purpose: The testing of ovarian cancer poses a challenge since 70% of pa-

tients will relapse with incurable platinum resistant disease. Although ovarian cancers lack frequently-occurring driver mutations or amplifications, the study presented herein examines the concept of individualized therapy based on mate pair sequencing and protein expression in ovarian cancer patient-derived xenografts. Experimental Procedure: Macrodissection of patient tumor was followed by genomic DNA isolation and next-generation sequencing using an Illumina HiSeq2500 and genomic number variations. Secondary analyses were carried out to select potential therapeutic targets among those. The tumors were also propagated intraperitoneally in immu-

nocompromised mice and treated with standard chemotherapy or and 
targeted therapy chosen based on genomic analyses. Results: Mate pair analysis revealed that, in general, copy number changes (amplifications, gains and losses) were common in ovarian tumors and included genes potentially targetable. Tu-
mors from early generation patient- derived xenografts showed a landscape of 
genomic aberrations identical to that of original patient tumor. One PDOX model in which high expression of HER2 and copy number gains at RICTOR and AKT genetic loci were revealed, was treated with either chemotherapy and Pertu-

zumab/trastuzumab (HER2 inhibitors), MK-8869 (mTOR inhibitor) or 

MK-2206 (AKT inhibitor) or chemotherapy alone. Tumor size was measured by 

serial abdominal ultrasound and after 28 days, the final tumor size ratio com-
pared to baseline was 0.23, 0.36, 0.55 and 0.56, respectively, indicating that the best response was seen in the combined chemotherapy and Pertuzumab/trastu-

zumab cohort and that was better than in the chemotherapy only cohort. Con-
clusions: Patient-derived xenografts models in conjunction with genomic and 

protein analyses of patient tumors are available for testing of combination ther-
apies including specific targeting drugs. This approach also provides actionable information for more tailored treatment of ovarian cancer patients.

#4815 Humanized single mouse trial: A preclinical platform feasible 

for immune-oncology drug screening and translational biomarker develop-

ment. Daniel Bug,1 Eva Oswald,2 Anne Grote,3 Anne-Lise Pellel,4 Gabriele Nie-
dermann,5 Dorit Merhof,2 Friedrich Feuerhake,3 Julia B. Schüler2. RWTH Aachen University, Aachen, Germany; 1Onco test GmbH, Freiburg, Germany; 3Hannover Medical School, Hannover, Germany; 4Medical Center Freiburg, Freiburg, Germany.

The field of cancer immunology is rapidly moving towards innovative thera-
paeutic strategies. As a consequence the need for robust and predictive preclinical platforms arises just as well. The current project aims to establish a drug screen-
ing workflow bridging between innovative mouse models and clinical bio-

marker development. A total of 69 NOG (NOD/Shi-scid/IIL-2Rnull) mice were 

engrafted with CD34+ hematopoietic stem cells. Thereafter, tumor material from 11 different lung cancer patient derived xenograft models (NSCLC PDOX) 

was implanted subcutaneously. Individual mice were treated with α-CTLA-4, 

α-PD-1 or the combination thereof. With n = 1 per treatment arm and model the study design followed the screening approach of the single mouse trial (SMT).

Infiltration of human immune cells was detected by flow cytometry (FC) and 

immunohistochemistry (IHC) in hematopoietic organs and tumor tissue. A 

computer-based analysis for digitized whole-slide images of the samples was used to quantify the lymphocyte infiltration using color classification and morpho-

logical image processing techniques. All 3 treatment arms displayed a discrete 

pattern throughout the PDOX panel. Tumor models with high tumor 

infiltrating lymphocyte (TIL) rates in the donor patient material tended to be 

more sensitive towards checkpoint inhibitor treatment as models with low rates. Numbers of TILs in the PDOX detected by FC and IHC were signif-

icantly higher in models with high TIL rates.

1Texas Children’s Cancer Center, Houston, TX; 2Jan and Duncan Neurological Research Institute, Houston, TX; 3Hannover Medical School, Hannover, Germany; 4Medical Center Freiburg, Freiburg, Germany.
creased in the treatment groups as compared to control vehicle. In parallel, hematopoietic organs showed high (>25%) amounts of huCD45 cells in all groups and models. PDX models being sensitive towards checkpoint inhibitor treatment (responder) displayed a higher percentage of DAB+ nuclei in huCD45 IHC stains than non-responder models as determined by image analysis. Irrespective of the responder status, the resected tumor area in non-complex with checkpoint inhibitors enhanced the percentage of DAB+ nuclei. Whole-slide image analysis of the HE&E stains revealed an increase of the stromal compartment proportion in the tumor tissue under treatment with checkpoint inhibitors in responder models. In non-responder models the ratio between tumor and stroma was not influenced by drug treatment. The use of PDX based humanized mouse models in a SMT format allows screening approaches in complex mouse models. The combination with a comprehensive image analysis tool enables additional read-outs to quantify antitumoral activity of immune modulators. The latter can be used to identify possible biomarkers in the preclinical setting. Moreover, the translation and validation of these biomarker candidates in a clinical setting is self-evident as primary material needed for these types of analyses is easily accessible.

#4816 Circulating tumor cell monitoring, isolation, and culture from a patient with metastatic triple-negative breast cancer for drug screening and creation of a patient-derived xenograft model. Arturo B. Ramirez,1 C Anthony Blau,2 Timothy J. Martins,2 Elisabeth Mahen,2 Lacey E. Dobrolecki,2 Michael T. Lewis,2 Jackie L. Stilwell,2 Eric P. Kaldjian1.1 RareCyte, Inc., Seattle, WA; 2University of Washington, Seattle, WA; 3Baylor College of Medicine, Houston, TX.

Background: Epithelial and single cell genomics of circulating tumor cells (CTCs) provide three types of information to guide cancer therapy. In some instances, a fourth type is possible: functional analysis in vitro, or in vivo patient-derived xenografts (PDXs). We used a density-based rare cell separation and analysis system to collect CTCs from the blood of a patient with metastatic triple-negative breast cancer (TNBC) for in vitro culture and high-throughput drug screening and to generate a PDX model. Methods: The patient was enrolled in the ITOMIC-001 study (University of Washington) and after informed consent, CTCs were evaluated prior to initial cisplatin treatment and tracked longitudinally using the AccCyte – CyteFinder system (RareCyte). Samples containing high numbers of CTCs were placed into 3 different culture media. Cells grown in culture were tested against a panel of anti-cancer drugs and injected into mice to form a PDX model. Results: Nine CTC evaluations were performed over 9.5 months. CTCs were verified by expression of epithelial (cytokeratin and/or EpCAM) and nuclear stains without CD45 expression. Analysis performed over 9.5 months. CTCs were verified by expression of epithelial (cytokeratin and/or EpCAM) and nuclear stains without CD45 expression. After initial treatment with cisplatin, the CTC count per 7.5 mL rose from 4 to 19 cells at 3 months, consistent with the lack of a clinical response, and decreased after LE 011 (CDX4/6 inhibitor) and then glembatumumab vedotin (anti-HER2 MAb) to 8 and 4 cells at 5 and 7 months respectively. At 9 months the CTC count rose to >13,000 and 5 days later to >80,000 shortly before her death. At autopsy there was massive infiltration of the liver and pulmonary vasculature by tumor cells. Cultures in all media showed initial growth, but only one (RPMI + 10% serum) was sustained, forming semi-adherent 3D tumor clusters. 6 million cells were harvested and a drug screen using 160 anti-cancer agents was performed. The CTC line showed sensitivity to several agents, notably trastuzumab and paclitaxel, and the treatment injected into the mammary fat pad of immunodeficient mice. In at least one mouse, macroscopic tumors were observed. The CTC cell line has grown continually in culture for over a year. Aliquots of this cell line have been frozen and thawed with no noticeable effect on cell growth. Conclusions: Using a density-based rare cell collection system, we established a CTC cell line from a TNBC patient with extremely high CTC counts. The line was used to perform a screen for agents active against the tumor cells and to create a PDX model. As in vitro techniques advance, smaller number of CTCs may be effectively cultured and thus allow this approach to be used in real time to effect drug regimens for individualized cancer therapy.

Malignant ascites is one of the most common causes of morbidity in end stage ovarian cancer patients with negative impact on quality of life. Novel non-invasive palliative therapeutic options are lacking for such patients. The zinc metalloprotease, pregnancy-associated plasma protein-A (PAPP-A), plays a key role in the insulin-like growth factor (IGF) pathway, promoting ovarian cancer cellular transformation, growth and invasiveness. Furthermore, patient primary malignant ascites is known to contain high levels of PAPP-A by ELISA. Preliminary data shows that inhibition of PAPP-A through a neutralizing monoclonal PAPP-A antibody (mAb-PA) inhibits the accumulation and promote the regression of ascites in an ovarian cancer patient-derived xenograft (PDX) models. In the current study, we investigated whether mAb-PA can promote ascites regression in an additional ovarian PDX model with measurable ascites. Patient derived ascites xenograft (PDX) models were defined as SCID mice that developed ascites after intraepithelial heterotransplantation of patient solid tumor collected at the time of primary cytoreduction. Ascites from these models (n=51) was screened for human PAPP-A protein by ELISA and models were divided into two groups by the relative concentration of PAPP-A: high (n=18) and low (n=33). PAPP-A High PDX model PH438 was re-established intra-peritoneal in 20 SCID mice by ascites injection (0.1 ml per mouse). When ascites area reached a threshold of >0.60 cm2 by ultrasound, mice were treated with 60mg/Kg of mAb-PA (n=10) or IgG2a control (n=10) on day one and three. On day four, a second ultrasound measurement was obtained and the mice were euthanized. Ascites burden was measured at necropsy. Personnel involved with the acquisition of ultrasounds measurements, subsequent ascites harvests, and post hoc analyses were blinded to the treatments. The ratio of mean ascites (mAb-PA/IgG2a in grams) collected at necropsy was 2.04/2.51, indicating that the mAb-PA arm had less ascites compared to control. These data were consistent with pre- and post-treatment ultrasound measurements of ascites burden; a statistically significant (p = 0.0283 by paired t test) reduction of ascites burden of 52.3% was observed, compared to the starting baseline, indicating that mAb-PA treatment causes ascites regression. Ascites weight at necropsy was compared to the area of greatest fluid echogenicity by ultrasound and the Pearson correlation R value achieved was of 0.859 (p = 0.0001). These PDX data implicate PAPP-A attenuation as a potential strategy to treat malignant ascites in OC. Additional PDX models are under examination to confirm these findings and support the translational development of PAPP-A as a new therapeutic target for women with refractory ascites.

#4818 Neratinib/fulvestrant but not fulvestrant alone maintain complete responses after treatment with trastuzumab/paclitaxel of mice bearing ER+/HER2+ xenografts. Luis J. Schwarz,1 Sarah E. Croessmann,1 Francesca Avogadri-Connors,2 Richard E. Cutler,2 Alshad S. Lalani,2 Carlos L. Arteaga1.1 Vanderbilt University Medical Center, Nashville, TN; 2Puma Biotechnology, Inc., CA.

Background: Neratinib is a potent, irreversible pan-HER tyrosine kinase inhibitor. The phase III trial ExteNET showed improved disease-free survival of neratinib vs placebo in early-stage HER2+ breast cancer patients (pts) after trastuzumab-based adjuvant therapy. This benefit from neratinib was greater in pts with hormone receptor (HR) + tumors. Based on these findings, we sought to establish a human-in-mouse model that would simulate this clinical trial and outcome, thus providing a platform for mechanistic investigation. Methods: ER+/HER2-amplified MDA-361 cells were injected subcutaneously (SC) into 5-week-old female athymic mice without estradiol supplementation. Mice with tumors ≥250 mm3 were treated with trastuzumab (tz) 20 mg/kg + paclitaxel (pac) 15 mg/kg IP twice weekly for 4 weeks, and then randomized to fulvestrant (fulv) 100 mg/kg weekly or neratinib (tz)/paclitaxel followed by neratinib/fulvestrant for 4 weeks. Results: Xenografts in all 20 mice showed a prompt and marked reduction in tumor volume after tz/pac treatment; 10 mice achieved a complete response (CR) before receiving 'extended adjuvant' therapy with fulv (n=5) or neratinib/fulv (n=5). A CR was maintained with neratinib/fulv following tz/pac, whereas tumors rapidly recurred in mice treated with fulv alone (p<0.05 at week 8; Table). Immunohistochemical analysis of MDA-361 tumors recurring on fulv showed almost complete downregulation of ER levels.

Conclusions: Neratinib/fulvestrant but not fulvestrant alone maintained complete tumor responses following initial treatment with tz/pac; recapitulating the design and outcomes observed in the HR+ subgroup of the ExteNET trial. The experimental model used herein provides a platform for investigation of the underlying mechanisms for the findings in ExteNET. 

Experiments evaluating
ER gene signatures and expression levels, as well as the effects of neratinib ± fulvestrant following initial adjvant pertuzumab/trastuzumab/paclitaxel are underway.

**#4819 Insights from engraftable immune deficient mouse models of hyperinsulinemia.** Michelle L. Maughan,1 Patrick B. Thomas,1 Gabrielle J. Crisp,1 Lisa K. Philp,1 Esha T. Shah,1 Adrian C. Herrington,1 Chen Chen,2 Laura S. Gregory,3 Colleen C. Nelson,4 Inge Seim,1 Penny L. Jeffery,1 Lisa K. Chopin4,5

*Queensland University of Technology, Brisbane, Australia; 2University of Queensland, Brisbane, Australia.*

Hyperinsulinemia, obesity and dyslipidemia are independent and collective risk factors for many cancers, however, there is a lack of suitable mouse models available to study these interactions. In this study, we examine the interactions between hyperinsulinemia, obesity and hyperlipidemia and cancer. The models used were Rag1-/- mice developed on a normal chow diet. In summary, this is the first study of the metabolic effects of a Western style 23% high fat diet (HFD, 46% of total calculated energy from lipids) in two immune deficient mouse strains (NOD/SCID and Rag1 -/-) suitable for engraftment with human-derived cell lines and tissue xenografts. HFD-fed mice of both strains exhibited diet-induced impairments in glucose tolerance at 16 and 23 weeks post initiation of HFD feeding. Only Rag1 -/- mice developed higher fasting insulin levels (2.16 ± 1.01 ng/ml versus 0.71 ± 0.12 ng/ml, P = 0.01) and increased insulin resistance (6.70 ± 1.68 HOMA-IR, versus 2.91 ± 0.42, P = 0.01) when fed a HFD. Similarly, hepatic steatosis was more extensive, and intramyocellular lipid storage was increased in HFD-fed Rag1 -/- mice. Conversely, NOD/SCID mice exhibited relatively low levels of steatosis and no intramyocellular lipid was observed. These data suggest that Rag1 -/- mice are a more suitable preclinical model for examining the interactions between hyperinsulinemia, obesity and hyperlipidemia and cancer than the more commonly used NOD/SCID mouse model. We next investigated the growth of human prostate cancer cell lines (PC3 and LNCaP) subcutaneously injected into hyperinsulinemic Rag1 -/- mice. Compared to normal chow-fed mice, tumor growth velocity was greater in HFD-fed mice with PC3 and LNCaP xenografts, and mice reached humane endpoints (cancer-associated cachexia and tumor burden) significantly earlier (P = 0.0078 and P = 0.031). Strikingly, HFD-fed mice bearing PC3 xenografts presented with significantly greater normalized wet tumor weight (485.16 ± 143.80% vs. 1562.69 ± 338.20%, P = 0.032), tumor volume (485.16 ± 143.80% vs. 1562.69 ± 338.20%, P = 0.032) and number of Ki67 positive (proliferating) tumor cells (36.08 ± 2.53% vs. 66.14 ± 8.51%, P = 0.032) compared to mice fed a normal chow diet. In summary, this is the first study of the metabolic effects of a long-term Western style HFD in two immune deficient mouse strains suitable for xenograft studies. We demonstrate that the Rag1 -/- mouse is an appropriate and novel model for studying the interactions between hyperinsulinemia and cancer.

Animal models are essential to preclinical cancer research and are used clinically to determine optimal treatment regimens, but current xenograft models are limited in their utility, especially due to the lack of a competent immune system. Here we demonstrate that a xenograft tumor model can be developed in immunocompetent mice by tolerizing murine fetuses to human tumor cells. A375 human melanoma cells were injected into day E14 fetuses and, after birth, mice were challenged again with A375 cells to determine their ability to develop tumors. Intravenous injections of A375 cells after tolerization resulted in metastatic-like lung tumors, which were verified to be human in origin by immunohistochemistry and PCR. The development of lung neoplasms was dependent on fetal tolerization; non-tolerized mice did not develop tumors after injection. Interestingly, subcutaneous injected cells did not form tumors, but this was shown to be due to an innate, non-adaptive immune response and did not create lasting rejection of tumor cells. This procedure was repeated with several different tumor lines to show the universal nature of the method: BxPC3 (human pancreatic cancer), M21 (human melanoma), HeLa (human cervical cancer), and MDA231 (human breast carcinoma).

**#4821 Influence of the injection site on the dissemination pattern and drug sensitivity of patient derived leukemia cells in vivo.** Julia B. Schuler,1 Eva Oswald,1 Gabriele Grewe,2 Dorothee Lenhard,1 Kerstin Klingner,1 Milena Pantic,1 Michael Luebbert2.

*Oncotest GmbH, Freiburg, Germany; 2Medical Center Freiburg, Freiburg, Germany.*

The aim of this study was to determine the influence of the injection site on the tumor morphology and drug sensitivity of a panel of hematological patient derived xenografts (PDX), PDX cells (3x10^6 cells/mouse) were injected intratibia1 (IT), intrasplen1 (IS) or subcutaneous (s.c.) into NOG (NOD/Shi-scid/IL-2Rγ^-/-) mice. Tumor engraftment was determined by flow cytometry (FC) in bone marrow (BM), peripheral blood (PB) and spleen during the course of engraftment and at the end of a study. Overall survival (OS) served as an additional read-out. In 3 models sensitivity towards cytarabine (Cy) was evaluated. Our group has established 18 PDX of acute leukemia (16 AML, 1 ALL, 1 APL). 16/17 engrafted when injected i.t., 10/12 developed tumors after i.s. implantation and 13/14 established tumors post s.c. cell injection. Thus, the overall engraftment capacity was for most of the models not dependent on the injection site and/or administration. However, a few models were dependent on a specific setting: LEXFAM 2713, grew exclusively i.t. or i.s., whereas LEX- FAM 2824 could be propagated solely when injected s.c.. The implantation site did influence tumor growth rate: Mean OS ranged from 151.4 (±25.21) days for i.t. to 89.2 (±16.82) days for s.c. propagation. I.s. transplanted mice had to be sacrificed after 91.9 (±17.33) days. The dissemination pattern of individual lines was affected by the injection site. In general, the tumor burden was higher when cells were engrafted i.t. or i.s.. Nevertheless, also s.c. implanted, AML cells infiltrated murine PB, spleen and BM, although not consistently and to a much lower extent. Interestingly, the expression pattern of the 6 investigated surface markers (CD45, CD3, CD34, CD33, CD38 & HLA-ABC) was not influenced by the application route. Every model depicted its distinct expression pattern irrespective of the application route. Cy was highly active in 1 AML (LEXFAM 2531) and 1 ALL (LEXFAL 2665) model. OS was significantly prolonged in the s.c. as well as in the disseminated setting (p<0.003, Log-rank (Mantel-Cox) test). Another AML line (LEXFAM 2734) depicted a less pronounced sensitivity towards Cy (p<0.007, Log- rank (Mantel-Cox) test) both growing s.c. or i.t.. Thus, drug sensitivity was not influenced by the injection site of the leukemic cells. Of note, the PDX drug responses mimicked the responsiveness (0 out of 7 patient cancer specimens). Taken together, the leukemia PDX panel represents the molecular diversity of the disease and mirrors sensitivity towards standard of care. Our recent careful investigation of the subcutaneous approach in these models highlights their suitability for this type of studies. This enhances the value of the platform as it combines the possibilities of a mid-throughput screening enabled by the subcutaneous approach with the general advantages of a patient-derived leukemia model.

**#4822 Detection of EBV BamHI W region in surgical cancer specimen is a useful method to evaluate the risk of lymphomagenesis in patient-derived PDXs.** Junko Motoyama,1 Dai Iwakiri,2 Yohu Yen,1 Tomo Mokhara,1 Hironobu Minami,1 Yoshihiro Kakeji,1 Yohei Shimono1,3

1 Kobe University Graduate School of Medicine, Kobe, Japan; 2University of Human Arts and Sciences, Saitama, Japan.

Patient-derived tumor xenografts (PDXs) established by xenotransplantation of surgically-resected human cancer specimens are an attractive model to analyze the characteristics of cancer cells within the patient cancer tissues. However, establishment of PDX is occasionally hampered by lymphomagenesis. Lymphomagenesis in the PDX has been observed in the xenotransplantation of several types of cancers, such as lung, liver, gastric, bladder, breast, prostate, and colorectal cancers. Lymphomagenesis in the PDX is caused by the proliferation of the EBV-infected lymphocytes under immune deficient conditions. The PCR amplification of this region is useful to evaluate the presence and amount of EBV. PDXs. BamHI W region is a major internal repeat in EBV genome and the PCR amplification of this region is useful to evaluate the presence and amount of EBV. These results suggest that this region was undetectable, no patient cancerspecimen resulted in lymphomagenesis (0 out of 7 patient cancer specimens). These results suggest that the amount and/or presence of EBV itself in the patient cancer specimen is one of the factors that are associated with lymphomagenesis in the PDXs. BamHI W region and EBV-associated microRNAs, were evaluated using the genomic DNA and miRNAs prepared from the CRC specimens and the established PDX tumors. Nine PDXs were established by the xenotransplantation. Histological examination showed that 7 of 9 (78%) PDX recapitulated histopathological characteristics of the patient CRC. However, 2 of 9 (22%) PDXs exhibited the morphological characteristics of EBV-associated human diffuse large B cell lymphoma (DLBCL). Then, we confirmed that lymphoma was formed by clonal proliferation of human B-cell lymphocytes, and strongly positive for EBER. We investigated whether the expression of EBV-related genes in the patient specimen is associated with lymphomagenesis in the PDXs. Expression of EBV genes and RNAs in patient cancer tissues were not detected in the PDXs. January 2017 1233

**TUMOR BIOLOGY: Cell Culture and Animal Models of Cancer 5**
gesting that the sina2 and sina3 alleles are hypomorphical alleles. Sequencing analysis phenotypes than those of the previously published sina2 and sina3 alleles, suggesting a screen using ethyl methanesulfonate (EMS) and X-ray radiation, isolating Drosophila development system, we are able to study RAS activation and SINA regulation, and substratetargeting mechanism(s) of this highly conserved family.

SINA and its human SINA homologs (SIAHs). As a major signaling “gatekeeper” function of Drosophila Seven-IN-Absentia (SINA) E3 ligase and its human homologs, SIAH1 and SIAH2, is highly conserved for proper RAS signal transduction in Drosophila development. The gatekeeper “gatekeeper” in the RAS pathway, we have shown that SIAH is required for oncogenic K-RAS-driven tumorigenesis and metastasis in human pancreatic, lung and breast cancer. Since SIAHs appear to be the ideal drug target to inhibit “undruggable” K-RAS activation, it is important to precisely characterize the activity, regulation, and substrate targeting mechanism(s) of this highly conserved family of SINA/SIAH E3 ligases. By deploying the elegant and well-established Drosophila development system, we are able to study RAS activation and SINA function under normal physiological conditions. In the developing Drosophila eye, photoreceptor cells are recruited sequentially and acquire their distinctive cell fates through a series of local inductive events. The 800x cell arrays allowed us to dissect the role of SINA/SIAH downstream of RAS activation in photoreceptor cell development. To delineate SINA function, we performed an F1 modifier screen using ethyl methanesulfonate (EMS) and X-ray radiation, isolating 28 novel sina mutant alleles. These mutant alleles exhibit much stronger mutant phenotypes than those of the previously published sina2 and sina3 alleles, suggesting that the sina2 and sina3 alleles are hypomorphic alleles. Sequencing analysis of these sinaWT/DN alleles reveals the functional roles of mutated residues and protein domains. To define SINA/SIAH functional conservation, we have generated a complete panel of transgenic fly models that express either wild-type (WT) or dominant negative (DN) SINA/SIAH. The corresponding UAS-sina/siahW2 alleles have been characterized using sev-, GMR-, dpp- and sgrafyaly gland-GAL4 to elucidate the developmental outcomes of altered SINA/SIAH expression upon RAS activation. Ectopic expression of sinaWTT/DN/siahWT/DN in neurons resulted in dramatic changes in neuronal cell fate in the developing eye and notum, causing PNS neurodegenerative phenotypes. Our results show that the biological functions of fly SINA and human SIAH1/SIAH2 are evolutionarily conserved and functionally interchangeable. Mechanistic insights and regulatory principles revealed from Drosophila can be directly applied to cancer biology to develop and validate next-generation of SINA/SIAH-based anti-K-RAS and anticancer therapy in the future.

Functional role of Ring Finger Protein 43 in intestinal stem cell during colorectal tumorigenesis. Tsugio Eto, Takatsugu Ishimoto, Eri Oda, Daisuke Kuroda, Kota Arima, Mayuko Ohuchi, Kenichi Nakamura, Hiroshi Sawayama, Koichi Kinoshita, Masaki Iwatsuki, Yoshifumi Baba, Yasu Sako-moto, Naoya Yoshida, Hideo Baba, Graduate School of Medical Science, Kumanou University, Kumanoto, Japan.

Background: Colorectal cancer is one of the most general causes of cancer related death. Ring Finger Protein 43 (RNF43) is an E3 ubiquitin ligase that suppresses the Wnt signaling pathway and is known as a tumor suppressor gene. Previous studies reported RNF43 mutation leads to inactivation of RNF43 in pancreatic, ovarian, colorectal cancer and so on. Subsequently, Wnt signaling activation is associated with tumor progression in these types of cancers. However, functional role of RNF43 for tumor formation is not clear in colorectal cancer. Aim: To investigate the functional role of RNF43 in colorectal cancer by using RNF43 knockout mice. Method: We prepared RNF43 knockout mice by using CRISPR/Cas9 system. To induce colorectal tumor in mice, we used Azoxymethane-Dextran sulfate sodium (AOM-DSS) model. First, we injected AOM 10mg/kg into the peritoneal cavity. After 7days from injection, 2% DSS water to mice for 7days. We sacrificed the mice and evaluated the tumor incidence and tumor size after 8, 10, 12weeks from AOM injection. Next, we prepared the small intestine organoid from RNF43 wild and knockout mice. Then we compared the organoid size and formation rate. In vitro analysis, we prepared colon cancer cell lines (COLO205, SW620, HCT116) and evaluated the effect on cell proliferation in suppression of RNF43 and normal condition. Result: There was no significant difference in the tumor incidence and tumor size at 8, 10, and 12weeks after AOM injection. However, at 16weeks, the tumor size of RNF43 knockout mice was significantly bigger than that of RNF43 wild type mice. (p<0.001) Further examination of the intestinal organoid revealed that the organoids derived from RNF43 knockout mice tended to get bigger than those from wild type mice. In vitro analysis, cell proliferation of RNF43 mutant cell line (HCT116) was significantly increased compared with RNF43 wild type cell lines (COLO205, SW620). RNF43 silencing significantly increased cell proliferation in RNF43 wild type cell lines (p<0.001), whereas did not affected in RNF43 mutant cell line. Conclusion: Our results suggest that RNF43 expression suppresses epithelial cell growth in the intestine, and the dysregulation of Wnt signaling via RNF43 disruption promote intestinal stem cell expansion and colorectal tumorigenesis.

Maternal high butter fat intake heightens mammary cancer risk in offspring gestationally exposed to bisphenol A at environmentally relevant dose. Yuet-Kin Leung, Vinothini Govindarajah, Ana Cheong, Dan Song, Xue-gong Zhu, Jun Ying, Ady Kendler, Mario Medvedovic, Scott Belcher, Shuk-Mei Ho. Univ. of Cincinnati, Cincinnati, OH.

In utero exposure to bisphenol A (BPA) at 250ug/kg BW was shown to augment mammary cancer risk in rodent models. High fat diet is widely believed to be a major risk of breast cancer (BCa). It is therefore important to investigate whether maternal high fat intake could potentially heighten mammary cancer risk associated to gestational BPA exposure. In this study, we exposed Sprague Dawley rats with different doses of BPA (2.5-2500ug/kg BW) mixed with high butter-based diet (HBF) in the period from preconception to birth. DMBA-PND50 protocol was followed. In the presence of HBF, we observed non-monotonic effects of BPA in cancer incidence as well as in the number of terminal end buds of PND21 mammary glands. Both results were peaked at a dosage of 25ug/kg BW BPA and the effects were significant when compared with HBF alone group. We further analyzed transcriptomic data of microdissected epithelia of PND21 mammary glands from BPA (25ug/kg BW) group as well as HBF group and revealed that two specific cancer networks involving ERK and androgen receptor signaling were dysregulated. DNA methylation is one of the key
Mechanisms to dysregulate and impair the transcription of two selected top genes, Cap7 and Ccnv2, as supported by our bisulfiite-sequence data. These data suggest that in utero BPA exposure could epigenetically modify gene expression and predispose cancer risk during early development. More importantly, some BPA genes are of high human relevance because seven selected BPA genes are oncogenes that activate carcinogenesis processes in overall survival in a TCGA cancer cohort. The prognostic power of the genes was further enhanced in the survival analysis of Caucasian with ER positive patients. In conclusion, our data strongly suggest that BPA predisposes higher cancer risk by dysregulating gene expression during early mammalian gland development in the presence of HIF, which could facilitate cancer development later in life.

#4827 Establishing a platform for the generation of organoids from diverse tumor types as part of the NCI patient-derived models (PDM) initiative. Luke H. Stockwin,1 Jenna Moyer,1 Anna Wade, Carrie Bonomi,1 Kelly Dougherty,1 John Carter,1 Jesse Stottlemeyer,1 Kaitlyn Arthur,1 Vivekananda Datta,1 Lindsay Dutko,1 Michael Mullendore,1 James H. Doroshow,1 Melinda G. Hollingshead,1 Dianne L. Newton,1 Leidos Biomedical Research, Inc, Frederick National Laboratory for Cancer Research, Frederick, MD; National Cancer Institute, NIH, Bethesda, MD; Frederick National Laboratory for Cancer Research, Frederick, MD.

Cancer Organoids are discrete multicellular structures that recapitulate tumor microanatomy (1). These reagents can be generated by extended culture of partially or fully dissociated tumor samples in three-dimensional matrices. By maintaining tumor and accessory cells in an appropriate context, they provide a biosimilar platform for studying disease pathogenesis and cellular pharmacology (2). Similarly, cancer organoid culture is useful for propagating slow growing tumors or those requiring heterotypic cell-cell interactions. Here, preliminary data will be presented regarding generation of organoids from diverse tumor types as part of the NCI patient-derived models (PDM) initiative. This initiative aims to develop a national repository of patient-derived cancer models (PDMs) consisting of clinically annotated patient-derived xenografts (PDXs) and patient-derived tumor cell cultures (PDCs) prepared from primary and metastatic tumors (3). A standardized panel of different organoid media formulations was constructed to optimize culture conditions for disease subsets. Using this approach, organoids were generated for colon, prostate, pancreatic, breast, melanoma, NSCLC, and bladder tumors. Although some samples were refractory to organoid generation, in several instances, samples that failed to generate 2D cultures thrived as organoids. A further finding was that direct implantation of organoid cultures was an efficient means of generating xenografts. Indeed, work will be presented detailing the exact number of organoids required to establish xenograft tumors. Protocols were developed for routine culture, passaging and long-term storage in liquid nitrogen. Similarly, organoids were amenable to characterization by FACS analysis, ICC/IHC and qRT-PCR to evaluate aging and long-term storage in liquid nitrogen. Similarly, organoids were amenable to characterization by FACS analysis, ICC/IHC and qRT-PCR to evaluate aging and long-term storage in liquid nitrogen. Similar organoids were grown for colon, prostate, breast, pancreatic, bladder, melanoma, NSCLC, and lung cancer. These reagents can be used for basic, preclinical and clinical applications, significantly advancing personalized medicine with a revolutionary new primary cell culture technique termed conditionally reprogrammed cells (CRCs). In fact, the fact remains that due to the limited and suboptimal prostate cell lines available for correlation analysis, significant unmet needs exist in validating clinical findings. With this realization, many agencies such as the DOD and the NIH are funding more rapid and clinically relevant patient derived models to fill a void in our understanding of, and our ability to treat, cancer. Our research has been on the forefront in development of a novel approach to patient samples for basic, preclinical and clinical applications, significantly advancing personalized medicine with a revolutionary new primary cell culture technique termed conditionally reprogrammed cells (CRCs). In fact, the CRC approach is a major focus area of NIH U01/PAR 16-344. We have pioneered the CRC technology for the rapid establishment and expansion of patient-derived normal and cancerous prostate cells in typical tissue culture conditions. We hypothesize that improved in vitro and in vivo platforms using patient-derived prostate cells (e.g. CRCs) are required for the elucidation and subsequent experimental verification of key molecular and genetic drivers for PCA as well as better curative approaches. While prostate CRCs remain their lineage commitment, they fail to express many of the differentiation markers associated with luminal prostate cells when grown under normal two dimensional (2D) culture conditions. We have therefore established three dimensional (3D) non-spheroid based platforms for differentiation of both normal and malignant prostate CRCs. These include both transwell-based systems and decellularized tissue matrices that use defined differentiation media to enable AR activation and a luminal cell phenotype. We have now demonstrated the in vitro re-engagement of key determinants in the AR pathway and differentiation to luminal prostate cells. Documentation of the proper engagement of AR signaling is a significant step in developing a more accurate and tractable model for prostate cancer research and distinguishing between indolent and aggressive disease.

#4829 Development of rapid 3-dimensional culture conditions that support the in vitro differentiation of conditionally reprogrammed primary prostate cells for the study of prostate cancer. Lucas James Tricoli,1 Deborah Berry,1 Erika Parasido,1 Aisha Naeem,1 Olga Rodriguez,1 Iman Abdelgawad,2 Richard Lee,2 Adam Feldman,3 Chris Albanese,3 Georgetown Lombardi Comprehensive Cancer Center, Washington, DC; National Cancer Institute of Egypt, Cairo, Egypt; Massachusetts General Hospital Cancer Center, Boston, MA.

Despite decades of research into the causes and possible cures, prostate cancer (PCA) remains the second leading cause of cancer related death in men with over 26,000 deaths each year in the United States alone. While many of the studies performed over the years have identified important genes and signaling pathways that are involved in prostate cancer progression, the fact remains that due to the limited and suboptimal prostate cell lines available for correlation analysis, significant unmet needs exist in validating clinical findings. With this realization, many agencies such as the DOD and the NIH are funding more rapid and clinically relevant patient derived models to fill a void in our understanding of, and our ability to treat, cancer. Our research has been on the forefront in development of a novel approach to patient samples for basic, preclinical and clinical applications, significantly advancing personalized medicine with a revolutionary new primary cell culture technique termed conditionally reprogrammed cells (CRCs). In fact, the CRC approach is a major focus area of NIH U01/PAR 16-344. We have pioneered the CRC technology for the rapid establishment and expansion of patient-derived normal and cancerous prostate cell lines in typical tissue culture conditions. We hypothesize that improved in vitro and in vivo platforms using patient-derived prostate cells (e.g. CRCs) are required for the elucidation and subsequent experimental verification of key molecular and genetic drivers for PCA as well as better curative approaches. While prostate CRCs remain their lineage commitment, they fail to express many of the differentiation markers associated with luminal prostate cells when grown under normal two dimensional (2D) culture conditions. We have therefore established three dimensional (3D) non-spheroid based platforms for differentiation of both normal and malignant prostate CRCs. These include both transwell-based systems and decellularized tissue matrices that use defined differentiation media to enable AR activation and a luminal cell phenotype. We have now demonstrated the in vitro re-engagement of key determinants in the AR pathway and differentiation to luminal prostate cells. Documentation of the proper engagement of AR signaling is a significant step in developing a more accurate and tractable model for prostate cancer research and distinguishing between indolent and aggressive disease.

**#4830** Precision cut cancer tissues slices as human model for the testing of immuno-modulatory compounds. Kristina Bernoth, Florian T. Unger, Moiken Petersen, Mirja Piller, Jana Krüger, Nicole Grabinski, Hartmut Juhl, Kerstin A. David. Indivumed, Hamburg, Germany.

The goal of personalized medicine is to stratify individual patients to the appropriate treatment approach. SCLC lines encompass the clinical TME. This engineered in vitro platform closely resembles the individual tumors and their sensitivity to therapeutics. In the context of the immunotherapy of cancer, information on the localization, abundance and activation of immune cells within individual tumors gained in importance. In this study, we showed that viable tumors from colorectal cancer patients used within our drug testing platform, exhibit different populations of infiltrating immune cells. Antigenic recall was achieved by addition of recombinant cytokines, such as INFγ, IL-2, IL-10 and TNFα. A correlation to PD-1 expression on T-cells in different patients has been shown. In order to optimize clinical testing of immune-modulatory compounds, preclinical models, which reflect the individual tumor, as well as the individual immune components of the tumor, are mandatory. We have shown here that effects of treatments with an immune-modulatory compound (Nivolumab) were detectable in this system. Therefore, this drug testing platform represents a unique opportunity to test immune-modulatory compounds in a fully human, patient derived model that is close to in vivo situation. In the future, other immune-modulatory compounds or combinations of compounds have to be tested within the system to more comprehensively elucidate the possibilities and limits of this drug testing platform in regard to immunotherapy.

The small of-care for limited stage and extensive stage SCLC has re- mained etoposide and a platinum complex for more than 30 years because 60- 80% of patients respond; however, SCLC inevitably recurs. Recurrent SCLC has proven to be resistant to many therapeutics administered as second- or third-line treatments; therefore, combining therapies in the first instance may be a critically useful strategy. A high throughput screen was performed where 62 SCLC lines were exposed to etoposide (0.3 μM) and carboplatin (3.7 μM) with or without simultaneous exposure to a third agent (n = 220). Viability of the cells was measured using CellTiter-Glo after 96 hr exposure to 9 concentrations of each individual compound or combination with E/C. The test concentrations encompassed the clinical Cmax for each third agent, and the concentrations of E/C selected for the screen were systematically determined to produce SCLC kill that would allow observation of additivity/synergy upon addition of a third agent. IC50s were determined from the concentration response data and showed that the predominant effect of adding a third agent to E/C was additive. Less than additive effects occurred more frequently in SCLC lines that were sensitive to etoposide/carboplatin. Antagonism with E/C occurred in combination with taxanes and taxoids of immune-competent single agents such as the nuclear kinase inhibitors (aurora kinase inhibitors, KSP/EG5 inhibitors and polo-like kinase inhibitors) were antagonistic in combination with E/C but were effective single agents. Greater than additive SCLC killing occurred with E/C in combination with several classes of agents. The combination of the Chk1 inhibitor rabusertib with E/C resulted in an IC50 that was >1 log lower than that of rabusertib alone in several SCLC lines. The GSK-3β inhibitor LY-2090314 produced greater than additive SCLC killing in combination with E/C. This study identified third agents that may represent new leads for the treatment of this recalcitrant disease. Distinct patterns of response in select SCLC lines with the GSK-3β inhibitor LY-2090314 were noted suggesting that SCLC lines contain tumor microenvironment complexity and allow a high throughput screen to be used as a platform allowing the testing of innovative approaches for the treatment of human malignancies.

Human cancers are composed of genetically and phenotypically heterogeneous subpopulations organized into a hierarchy of tumor initiating stem cells and various differentiated tumor cell. Cancer organoids seem to be more suitable in vitro models for targeting tumor heterogeneity than cell lines. We established cancer organoid lines from lung cancer patient tissues, recapitulating histology of human cancers in three dimensional culture conditions. Thirteen organoid lines from various lung cancer subtypes including adenocarcinoma, squamous cell carcinoma and small cell carcinoma were compared with their original human tumors in histologic features and genetic profiles. In the IHC staining, it revealed that organoids of adenocarcinomas have typical glandulo-papillary structures or mucin-containing tumor cells. Organoids of squamous cell carcinomas showed keratinization and intercellular bridges. Organoids of small cell carcinoma displayed a typical neuroendocrine morphology. Using NGS cancer panel sequencing, the organoid lines maintained genetic characteristics of the original human tumors in major driver genes including EGFR, TP53, and RB mutation. In xenograft experiments, the organoid lines revealed stronger tumorigenicity than direct graft of human tumor tissues. Cancer organoids showed resistance to various anticancer drug treatments. In conclusion, lung cancer organoid lines are alternative cancer model for preclinical re- searches recapitulating genotypic and phenotypic heterogeneity of original human tumors.

**#4833** Perfusion-based bioreactor culture of primary cancer tissue maintains tumor microenvironment complexity and allow in-vitro testing of immune blockade therapy. Manuele Giuseppe Muraro,1 Simone Muenst, Celeste Manfredonia,2 Valentina Mele, Silvio Daester,2 Alexandar Tzankov,2 Luigi Terracciano,3 Walter Weber,4 Giulio C. Spagnoli,6 Giandomenica Iezzi,5 Ivan Martin1 and D. Soysal.11 Asan Institute of Life Sciences, Seoul, Republic of Korea; 2 Asan Institute for Life Sciences, Seoul, Republic of Korea; 3 University Hospital of Basel, Basel, Switzerland; 4 University of Basel, Basel, Switzerland.

In vitro culture of primary cancer tissue is still very limited and the generation of patient derived xenograft demonstrate the loss of human cancer associated stroma. In this context, the use of 3D in vitro systems based on human tissue may be an innovative system to be exploited for keeping the tumor microenvironment (TME) complexity of the tissue in vitro. Freshly excised colorectal (CRC) and breast cancer (BrCa) specimens were fragment and cultured in 3D “sandwich-like format” between porous collagen scaffolds under perfusion flow (U-CUP, Cellec Biotech AG). The maintenance of tumor and immune-infiltrating cells, survival and phenotypic characterisation were histologically assessed. In a second step cancer treatment were tested. U-CUP culture allowed the preservation, viability and expansion of tumor tissue with concomitant stromal and immune cells. Expanding cancer cells were viable after 10 and 21 days (CRC and BrCa, respectively). Administration of anti-ER treatment to Lumina A ER + BrCa was associated with decreased expression of cancer tissue into the scaffold after 21 days. The maintenance of immune-infiltrating cells allowed testing of immune block- ade therapy. Administration of anti-PD-L1 antibody, alone or in combination with anti-CTLA4, to the culture medium was associated with increased expression of markers of immune-activation (i.e. IFNy) and decreased expression of immunosuppressive cytokine IL10. Preserving malignant, interstitial and immunocompetent cells comprised in surgically excised tumor specimens might allow a direct evaluation of the effects of various treatments on the complex TME. This engineered in vitro model could allow animal-free testing and it could be extended as a platform allowing the testing of innovative approaches for the treatment of human malignancies. Our findings shed the light on a promising system for selecting personalized treatment based on a patient’s tumor specific microenvironment.
While breast cancer has an overall 5-year survival rate of 89%, the rate for patients with stage 4 metastatic disease is only 26%. Immunotherapies have the potential to improve the prognosis for these patients while also providing better treatment options for all breast cancer patients since they have fewer side effects enabling longer treatment times and the use of combination therapies and reduced doses of chemotherapy. Currently these treatments are tested in standard 2D cell cultures that are inaccurate in mimicking in vivo drug response or animal models where the immune system differs from humans in numerous ways including T-cell subsets, cytokine receptors, and constitutary molecule expression. We have developed 3D models of human breast cancer that span the subtypes, ER+/HER2+, and triple-negative, incorporating numerous stromal cell types, fibroblasts and adipocytes, and include different immune cells, macrophages, and T-cells under either static or perfusion culture systems. These models have been used to examine how tumor cells influence macrophage differentiation using unidifferentiated peripheral blood mononuclear cells (PBMCs), how M1 and M2 macrophages influence tumor cell survival and proliferation, how the combination of these cell types influence cytokine secretion, and how the microenvironment affects tumor outcome. We have created a novel platform that is flexible enough to handle the heterogeneity of these complex models to examine response of tumor cells and T-cells to checkpoint inhibitors through high-throughput viability assays and flow cytometry. These models have several potential uses which include the ability to quickly answer whether a particular immunotherapy agent is effective for that particular patient-specific manner and to screen potential novel immunotherapeutic candidates and/or combinations prior to clinical use.

Patient-derived organoids are an emerging 3D model system that more closely recapitulate the organ functionality of the tissue of origin compared to traditional 2D cell lines. Further advantages of the organoid system include tumoral and inter-patient heterogeneity, diffuse infiltration of adjacent brain tissue, and establishing nutrient gradients, in a physiologically relevant setting, as well as the ability to quickly scale up from a small initial sample. We have established an actively expanding biobank of primary and metastatic colorectal cancer (CRC) tumor organoids under normoxic (21% O2) and physiologic oxygen conditions (5% O2), conditions from a diverse patient population. Concurrently, we isolated and cultured matched cancer-associated fibroblasts (CAFs). With these samples we are able to generate data from a cohort that mimics the CRC population at large, including different ethnic groups, and mutational status. Here we detail a quantitative imaging platform that captures 3D morphometric information in addition to traditional live/dead readouts. Organoids from each patient are heterogeneous in size, shape, symmetry, and various other phenotypic features. Furthermore, the perturbation of microenvironmental factors such as drugs, CAFs, etc. cause phenotypic changes over time. Common population-based viability assays used in drug screens, such as ATP or MTT, may be inappropriate to capture the complexities of drug response since they are often single end point measurements of an entire population of cells, and do not account for phenotypic variations. Short term quantitative live cell imaging incorporates phenotypic information, and can extend the lifetime of samples, yet still require manipulating samples by using dyes. However, these dyes are phototoxic, making them less than ideal for long term live cell imaging. By restricting image acquisition to brightfield we are able to minimize manipulation of patient samples, leaving them intact and viable. The additional benefit of imaging organoids in 3D enables us to get spatial information not available from assays with a single readout. Using our non-destructive imaging technique we can track 3D morphometric changes in the same organoid population over time. By using a flexible analysis method, and unbiased machine learning algorithms to determine relevant features we can account for these differences yet still get comparable data. Our organoid repository combined with long term image analysis and machine learning techniques provides us the tools that is necessary to handle the heterogeneity seen across the patient population. This platform could be used to advance personalized medicine allowing clinicians to quickly and more accurately determine the appropriate treatment for a patient by screening their tumor prior to determining a course of treatment.

3D modeling of immune cell interactions in breast cancer and prediction of immunotherapy response. Qi Guo,1 Stephen Shuford,2 Brian McKinley,2 Mary Rippon,2 Wendy Cornett,2 Mark O’Rourke,2 David Schammel,3 Jeff Edenfield,2 David L. Kaplan,2 Hal E. Crosswell,2 Teresa Desrochers1.

TUMOR BIOLOGY: Cell Culture and Animal Models of Cancer 5

A colorectal cancer organoid library provides a promising screening tool for assessment of chemosensitivity. Naoya Sakamoto,1 Akira Ishikawa,1 Ririno Honma,1 Takao Hinou,2 Naohide Oue,1 Kazuhiro Santani,1 Shiochiho Mukai,1 Tomohiro Adachi,1 Hiroyuki Egi,1 Hideki Odah,1 Wataru Yasui1.1Hiroshima University, Hiroshima, Japan; 2Institute for Clinical Research, National Hospital Organization Kure Medical Center and Chugoku Cancer Center, Kure, Japan.

Colorectal cancer (CRC) is a leading cause of cancer mortality and the third most common cancer worldwide. Annually, there are more than 900,000 cases occur worldwide, nearly 300,000 of which are fatal. CRC have accumulated defects in oncogenes and tumor suppressor genes. Many CRCs likely arise through a combination of an initiating event and adeno-matous precursor lesion via so-called adenoma-carcinoma sequence. Intensive studies have uncovered that the spectra of these genetic modifications are highly variable across the tumors. While genetic changes in tumors of individual patients can be assessed in several stratified methods, these data still need to be properly interpreted for necessitating model systems for analysis of chemosensitivity of CRC patients, which could enable us to organically coordinate among genotypeto-phenotype correlations, clinicopathological features and clinical outcomes. One of the most plausible models for implementing this magnificent scheme is most likely to be “organoid”, which is a novel 3D intestinal stem cell culture system and has successfully reconstitute normal and cancerous colonic crypts in vitro through using the specific niche factors in a dish, such as EGF, Wnt3a, Rspondin-1 and Noggin, together with a TGF-beta inhibitor and a p38 inhibitor. Two groups, Van der Wetering et.al and Fujii et.al, have previously reported the establishment of organoid biobank of colorectal cancer patients, and both of them proved the usefulness of this platform for underpinning the significance of genotype-phenotype analysis in every single patient and providing insights into tailor-made therapy in CRC. In this present study, we generated a pairs of cancerous and normal adjacent organoids from a number of CRC patients and aimed to figure out sustainability and reproducibility of CRC organoids especially in terms of phenotypic and genotypic features even after several times of passage. We compared growth activity and histopathological features of the CRC organoids among several time points after the passage by evaluating ki-67 labeling index and morphology of the organoids. In order to confirm the stability of genetic status of representative cancer-related genes, we focused on TP53, KRAS, BRAF, and MSI status. We then tried to elucidate the difference of chemosensitivity between MSI-high and MSI-low/MSS CRC cases with similar genetic background in most of the representative cancer-related genes. Although further in-depth studies on CRC organoids are needed, our approach would be instrumental in accurately predicting the drug sensitivity of CRC patients, which could possibly lead to the establishment of personalized medicine in CRC.

Development of an in vitro 3D glioblastoma model system for patient-specific drug response profiling. Teresa DesRoschers,1 Ashley Clark,1 Lauren O’Donnell,2 Qi Guo,1 Lillia Holmes,1 Lacey Dobrolecki,2 Michael Lewis,2 David Schammel,3 Jeff Edenfield,4 Charles Kanos,5 Fred Nelson,6 Steve Gardner,6 Michael Lynn,6 Philip Hodge,6 Christopher Corless,7 Paul Clark,7 Hal E. Crosswell,2 John Kuo1.1KIYATEC, Inc., Greenville, SC; 2Stemed Inc, Houston, TX; 3Upstate Pathology, Greenville, SC; 4GHS, Greenville, SC; 5OHSU, Portland, OR; 6U. Wisconsin, Madison, WI.

Glioblastoma (GBM) has a median survival of less than 2 years due to intratumoral and inter-patient heterogeneity, diffuse infiltration of adjacent brain tissue, and absence of effective therapies. Development of more efficacious therapies will require better GBM models for the testing and identification of novel agents; traditional 2D cell culture lacks biologic and clinical fidelity and orthotopic xenograft models are costly, low throughput, and time consuming. We have developed a complex, patient-specific cultured GBM model to assay drug response that combines high-throughput drug response determination with neurosphere formation and next-generation sequencing (NGS). Neurosphere formation and the presence/quality of glioblastoma stem cells (GSCs) has been shown to be associated with aggressive behavior. Our 3D model system has been validated against the primary patient GBM tissue and/or patient-derived xenografts (PDX) and consists of histology, epigenetic and mRNA expression analysis, and comparison of in vivo drug response. This strategy enabled examination of MGMT methylation in relation to temozolomide response, and possible actionable genetic mutations with candidate targeted therapies. Using our 3D model, we have observed EGFR-amplified GBM sensitivity to the EGFR inhibitor afatinib, and PTEN mutant GBM sensitivity to dual PI3K/mTOR inhibitor dactolisib. These data suggest validation of clinical and molecular correlation with this new in vitro, patient-derived 3D GBM model for drug response profiling. Our data supports the further development and use of complex 3D
models, neurosphere formation, and NGS profiling for patient-specific GBM analysis. This model system is currently being considered for preclinical assessment of novel therapies and may be a useful adjunct in future precision medicine applications to improve patient outcomes.

#4838 Optimization of prostate cancer organoid culture methods to grow PDX and human biopsy tissue. Mike L. Behtiri, Crystal Tran, Adam G. Sowalsky, Holly M. Nguyen, Supreet Agarwal, Caitlin M. Tice, Eva Corey, Kathy Kelly.

NCI, Bethesda, MD; University of Washington, Seattle, WA.

A major obstacle in the field of prostate cancer research is the limited capacity to culture prostate cancer-derived cells in vitro. There are relatively few established prostate cancer cell lines in use today. Those that are available are amenable to in vitro drug assays and mechanistic studies, but do not well-represent the genetic diversity of the disease, nor do they accurately predict in vivo response. Recently, organoid culture techniques have been developed for prostate cancer by the laboratories of Hans Clevers and Charles Sawyer that have increased our ability to grow metastatic tumor-derived prostate cancer cells in vitro. This represents a great step forward, but we are still restricted by the limited availability of biopsy tissue and the relatively low success rate (~20%) in establishing new organoid lines. The LuCaP series of patient-derived xenografts (PDXs) represents a well-characterized set of prostate cancer specimens that is genetically diverse, reflective of a range of treatment histories, and available to the research community. We have modified the organoid culture technique based upon systematic comparisons and analysis for organoid growth of the LuCaP PDXs. Our modified conditions represent an improvement upon the original growth conditions. We have successfully cultured 21 out of 24 LuCaPs attempted, for at least one generation, and 16 out of 24 are able to grow long-term over several generations. This includes 3 of the newest LuCaPs (167, 170.2, and 189.3) that we have genomically characterized. Comparison of the PDX and various organoid generations showed significant conservation of genomic changes ranging from 75-90% for nonsynonymous point mutations. The modified organoid culture method immediately and significantly increases the number of prostate cancer lines that are available by making the LuCaP PDXs accessible to in vitro culture. In addition to the PDXs, our method has improved the success for culturing metastatic samples grown from biopsies. We show here that 2 out of 3 patient-derived organoid lines that we have established, grew well in the modified conditions but poorly in the original culture conditions, the third grows equally well in both conditions.

TUMOR BIOLOGY: Cell Culture and Animal Models of Cancer 5

#4839 Ephrin-A ligands regulate cutaneous tumor etiology and metastasis through cell autonomous and non-autonomous mechanisms. Ji Zheng, Bethany Perez White, Nihal Kaplan, Zhe Zhao, Miroslaw Blumenberg, Spiro Getios, Bingcheng Wang. Case Western Reserve Univ., Cleveland, OH; Northwestern University, Chicago, IL; Weill Cornell University, New York, NY.

Glycosphingolipid-dependent anchored ephrin-A ligands target EphA receptor tyrosine kinases (RTKs) to promote keratinocyte differentiation. Accordingly, genetic ablation of the major epidermal EphA subtype, EphA2, increases susceptibility to DMBA/TPA-induced cutaneous chemical carcinogenesis. Defining the corresponding role of ligands for EphA2 in skin cancer has been more cumbersome as the three ephrin-A genes (Efna1, Efna3, Efna4) are all promiscuous in expression. Recently, we have shown that knockdown of EphA2 expression in primary skin keratinocytes induced a change in ephrin-A ligand expression, especially the homo-variant Efna4, which is associated with an increased risk of metastasis. Up-regulation of c-Jun activated KISS1R. The mechanism of action for KISS1 metastasis suppression function of BRMS1 and promotes metastasis. Up-regulation of c-Fos induced L1CAM transcription is a putative mechanism of BRMS1 A273V-induced metastasis. Our data suggest that SNP rs1052566, especially its homo-variant, is associated with an increased risk of metastasis in LuAD.

#4840 SNP rs1052566 (Ala273Val) in BRMS1 variant 2 promotes metastasis in lung adenocarcinoma. Neel P. Chudgar, Yuan Liu, Joseph Montecalvo, Marty W. Mayo, Prasad S. Adusumilli, David R. Jones.

Memorial Sloan Kettering Cancer Center, New York, NY; University of Virginia School of Medicine, Charlottesville, VA.

Background: Metastatic lung cancer kills over 180,000 people in the United States annually. Family history is one risk factor for lung adenocarcinoma (LUAD), suggesting a putative genetic predisposition to the development of LUAD. Single nucleotide polymorphisms (SNPs) are the most common genetic variations in the human genome and major determinants of variations in disease susceptibility, prognosis, response to medication, and toxicity. Recent studies indicate that SNPs play important roles in the progression of LUAD. We have previously shown that breast cancer metastasis suppressor-1 (BRMS1) plays a critical role in inhibiting the progression of liver cancer. We observed that SNP rs1052566 homo-variant in breast cancer metastasis suppressor-1 (BRMS1) variant 2 (v2) causes an A273V mutation. However, the role of this SNP in the progression of lung cancer remains to be determined. Methods: We utilized next-generation DNA sequencing and Taqman SNP assays to detect the prevalence of rs1052566 in 40 surgically resected LUAD specimens. Next, we generated a retroviral expression system (pBabe puro) encoding V5-tagged BRMS1v2 wild-type (WT) and A273V mutant and created NSCLC H1101 and A549 cell lines that stably express V5-tagged BRMS1v2 WT, A273V, or vector control. The metastatic capabilities of these stable cells were evaluated by invasion assays in vitro and by tail-vein injection in vivo. To explore the mechanism(s) through which BRMS1v2 A273V promotes metastasis, we performed RT profiler PCR assay. Results: We determined that SNP rs1052566 is present in 45% of LUAD patients. Of these, the homo-variant occurs in 7.5% of patients (3 of 40). Importantly, BRMS1v2 A273V significantly promotes metastasis of NSCLC cells in vitro and in vivo. Additionally, in our mouse model, A273V was associated with decreased survival, compared with BRMS1v2 WT or control. On RT profiler PCR array, 7 genes, including L1CAM, were found to be significantly differentially regulated by BRMS1v2 WT and A273V. Confirmatory RT-PCR and immunoblots proved that BRMS1v2 A273V increases both the transcript and protein levels of L1CAM. Furthermore, we found that either c-Jun or c-Fos promotes the transcription of L1CAM. However, BRMS1v2 A273V specifically enhances c-Fos-, but not c-Jun-, induced L1CAM transcription. Conclusion: We observed that BRMS1v2 A273V abolishes the metastasis suppressor function of BRMS1 and promotes metastasis. Up-regulation of c-Fos-induced L1CAM transcription is a putative mechanism of BRMS1v2 A273V-induced metastasis. Our data suggest that SNP rs1052566, especially its homo-variant, is associated with an increased risk of metastasis in LUAD.

#4841 Suppression of metastasis by KP54 and non-KP54 kisspeptins. Kelsey Hampton, Keke M. Pounds, Andrew P. Trembath, Danny R. Welch.

Univ. of Kansas Medical Ctr., Kansas City, KS.

KISS1 is a secreted neuropeptide which can act as a metastasis suppressor protein. Expression of KISS1 inhibits metastatic colonization at secondary sites, rendering disseminated cells dormant. In order for KISS1 to suppress metastasis, it must be secreted outside of the cell, whereupon cleaves KISS1 into kisspeptins. When assessing metastasis-associated traits in vitro, suppressor KMP sup- pressive metastasis in vivo. As a whole, these data suggest that metastasis suppression by KISS1 is not necessarily contingent on KISS1 activation, and also supports investigation into additional receptors.

Proceedings of the American Association for Cancer Research • Volume 58 • April 2017
The recurrence and metastasis of hepatocellular carcinoma (HCC) portends a poor prognosis and represents important clinical challenges. There is a great need to identify critical factors involved in HCC metastasis that will facilitate the development of new therapeutic strategies. We have previously found that the initiation, growth and self-renewal of CD133+ liver tumors to be fine-tuned by a balance of miR-130b overexpression and tumor protein 53 inducible nuclear protein 1 (TP53INP1) down-regulation, suggesting that TP53INP1 is a critical effector driving hepatocarcinogenesis. In this study, we aimed to further investigate the role of TP53INP1 in HCC metastasis. We showed TP53INP1 to be frequently down-regulated in advanced stage IV and metastatic human HCC tumors as compared with early stage (I-II) and primary tumors. Functional studies in immortalized normal liver cell line MIHA and HCC cell line MHCC-97L found TP53INP1 suppression in HCC to promote metastasis in vitro and in vivo. To elucidate the downstream signaling mechanism by which TP53INP1 regulates HCC metastasis, a Proteome Profiler Human Phospho-Kinase Array was utilized. Phospho-ERK was found to be consistently up-regulated in HCC cell lines with TP53INP1 knocked down, with its involvement in TP53INP1-mediated metastasis suppression subsequently validated by rescue experiments using an ERK inhibitor U0126 or shERK1/2 knockdown approach. ERK1/2 is known to be negatively regulated by a family of dual-specificity MAPK phosphatase called DUSP/MKP. Screening of a panel of DUSP/MKP family members by qPCR identified DUSP10 to be commonly down-regulated in both MIHA and MHCC-97L cells with TP53INP1 suppressed as compared to controls. The importance of DUSP10 inactivation on ERK in TP53INP1-mediated HCC was substantiated by rescue experiments whereby DUSP10 ectopic expression in TP53INP1 suppressed cells reversed up-regulated phospho-ERK expression and enhanced HCC aggressiveness. Subsequent analysis of the DUSP10 promoter region by open-access database revealed four putative binding sites for p73, of which transcriptional activity has previously been found to be modulated by TP53INP1. Chromatin immunoprecipitation and luciferase reporter assays collectively demonstrated that TP53INP1 is vital for p73 transcriptional activity of DUSP10. Taken together, TP53INP1 down-regulation via metastasis suppression through a p73-dependent DUSP10/ERK signaling pathway.
ously that both enzymatic activities of NME1 are critical for repair of UV-induced DNA damage via nucleotide excision repair. In the current study, chromatin immunoprecipitation was used to demonstrate recruitment of NME1 to DNA double-strand breaks (DSBs), representing the first evidence of direct recruitment of NME1 to sites of DNA damage. Induction of DSBs with gamma-irradiation (γ-IR) or bleomycin promoted rapid physical association of NME1 with γH2AX, ATM, NBS1 and RAD50. In addition, treatment of melanoma cells with γ-IR triggered a physical association of NME1 with XRCC4, an effecter of the non-homologous end-joining (NHEJ) pathway. We are currently investigating whether knockdown of NME1 induces a switch from NHEJ to the homologous recombination (HR) pathway, a slower but higher fidelity form of DSB repair associated with loss of tumor suppressor activity. Our results are also consistent with the idea that DNA damage induced by bleomycin rescue the role of NME1 on the fidelity of NHEJ repair. Overall, our study indicates for the first time direct participation of NME1 in a molecular mechanism of DSB repair in both normal and transformed cells. In addition, these data suggest a novel mechanism of metastasis suppressor function for NME1, with loss of NME expression in tumor cells conferring genetic instability and enhanced metastatic potential.

#4847 NME1 mediates a switch in beta integrin subunits that correlates with prolonged patient survival. M. Kathryn Leonard,1 Grace Snow,1 Marián Novak,1 Joseph R. McCorkle,2 Xiweii H. Yang,3 Alexey Belkin,1 David M. Kaetzel.1,1 University of Maryland, Baltimore, Baltimore, MD;2 St. Jude Children’s Research Hospital, Memphis, TN;3 University of Kentucky, Lexington, KY.

Expression of the metastasis suppressor NME1 in melanoma is associated with reduced cellular motility, invasion, and metastasis, but the molecular mechanisms underlying this activity are not completely understood. Herein we report a novel mechanism through which NME1 modulates focal adhesion dynamics via regulation of integrins β1 and β3. Stable expression of NME1 significantly altered focal adhesion turnover at the cell periphery. Interestingly, over-expression of NME1 resulted in a switch from predominantly fast recycling αβ1 integrins to slower recycling αβ3 integrins. Contrary to its regulation of other cell surface receptors, the inhibition of integrin β1 and induction of integrin β3 by NME1 was found to occur at the transcriptional level rather than through dynamic mediated endocytosis. Induction of integrin β3 required both the 3’s exonuclease and nucleoside diphosphate kinase (NDPK) activities of NME1, which are also required for its metastasis suppressor activities in vivo. Further suggesting that the induction of integrin β3 is involved in the metastasis suppression function of NME1, knockdown of integrin β3 significantly increased the invasion capability of cells expressing NME1 in vitro compared to control cells. Analysis of metastatic melanoma patients in the TCGA showed individuals with a 1.5x or greater increase in integrin β3 mRNA had a significantly longer overall survival times. Additionally, an inverse correlation was observed between NME1 and integrin β3 mRNA in independent microarray of primary melanomas. The inverse correlation of NME1 and integrin β3 mRNA was also a strong predictor of prolonged distant disease free and overall survival in patients with the basal-like subtype of breast carcinoma. Together, these data strongly suggest NME1 prevents metastasis of human melanoma and some types of breast cancers by altering beta integrin expression to reduce recycling of focal adhesions and, ultimately suppress cell motility.

#4848 The functional synergism and pro-metastatic role of FOXM1 and CENPF in hepatocellular carcinoma. Wai Ling Macrina Lam,1 Lo Kong Chan, Daniel Wai-Hung Ho, Charles Shing Kam, Irene Oi-Lin Ng. The University of Hong Kong, Hong Kong, Hong Kong.

Hepatocellular carcinoma (HCC) is the second leading cause of cancer death worldwide and metastasis is regarded as the major cause of HCC-associated lethality. In this study, we have analysed the TCGA whole-transcriptome sequencing data of paired human HCC samples (n=50), and identified Forkhead Box M1 (FOXM1) and Centromere Protein F (CENPF) to be the top-listing upregulated genes. Interestingly, both of them are the essential components in cell-cycle progression. FOXM1 encodes for the cell-cycle-dependent transcription factor that regulates genes for DNA replication and mitosis, while CENPF encodes for the centromere protein that is required for kinetochore function and chromosome segregation in mitosis. We hypothesized that the upregulation of FOXM1-CENPF signaling axis may drive hepatocarcinogenesis. In our human HCC cohort (n=34), FOXM1 and CENPF were shown to be upregulated compared with the non-tumorous liver tissues, and their mRNA expressions were positively correlated (p=0.0001). Co-upregulation of FOXM1 and CENPF in patient samples was demonstrated to be positively correlated with the absence of tumor encapsulation (p=0.035) in our clinico-pathological correlation analysis, whereas the samples without their co-upregulation was less likely to be correlated with venous invasion (p=0.045). This indicated that FOXM1 and CENPF are likely to be associated with HCC metastasis synergistically. Stable single and co-knockdown clones of FOXM1 and CENPF in four HCC cell lines (BEL7402, SMMC-7721, MHCC-97L, HepG2) were established using short-hairpin (sh) RNA approach for subsequent functional characterization. Both single and co-knockdown of FOXM1 and CENPF cells have shown reduced proliferation rate (p<0.05) in cell proliferation assay. Moreover, all single and co-knockdown of FOXM1 and CENPF cell lines were found to have at least 2-fold reduction in migration and invasion rate (p<0.0001) in transwell cell migration and invasion assay. These suggested that FOXM1 and CENPF are critical for HCC cell proliferation, migration and invasion. To assess the translational significance of targeting FOXM1 and CENPF, seven HCC cell lines (BEL7402, SMMC-7721, MHCC-97L, Hep7, Hep3B, HepG2, PLC/PRF/5) were challenged with thiostrepton and zoledronic acid, which are inhibitors against FOXM1 and CENPF, respectively. Intriguingly, both individual and combined treatments of these inhibitors effectively inhibited HCC cell growth. It was also demonstrated that such inhibition acts via suppressing the respective endogenous transcript and protein expression of FOXM1 and CENPF. Taken together, our study has demonstrated that FOXM1 and CENPF play a critical oncogenic role in HCC and they may function as an attractive molecular therapeutic target. This study is supported in part by Health and Medical Research Fund (03142836).

#4849 ELMO1 promotes metastasis in colorectal cancer cells via activation of MAPK/ERK signaling pathway. Xiao-bing Zheng,1 Chi Zhou,1 Hai-chun Cheng,2 Tuo Hu,3 Hua-hui Liu,3 Xian-rui Wu,2 Feng-wei Wang,2 Yu-feng Chen,4 Jian-ting Wang,4 Xiao-sheng He,2 Ping Lan,2 Departament of Colorectal Surgery, the Affiliated Shenzhen Shajing Hospital, Guangzhou, China;5 Department of General Surgery, the Affiliated Shenzhen Shajing Hospital, Guangzhou Medical University, Shenzhen, China;6 State Key Laboratory of Oncology in South China, Collaborative Innovation Center for Cancer Medicine, Sun Yat-sen University Cancer Center, Guangzhou, China.

Background and Aim: Engulfment and cell motility 1 (ELMO1) has been linked to the invasive phenotype of various types of cancer cells such as glioma cells, rhabdomyosarcoma cells, ovarian cancer cells and so on. However, the biological functions of ELMO1 in colorectal cancer (CRC) cells remains unclear. The aim of this study is to evaluate the role of ELMO1 in the metastasis in CRC. Methods: The expression level of ELMO1 was detected using quantitative RT-PCR and western blot in 9 CRC cell lines and 1 human colon epithelial cell line NCM460. ELMO1 was overexpressed via lentiviral vector system and silenced using specific small interference RNA (si-ELMO1) in HCT116 and SW620. Then wound-healing, migration assay and invasion assay were carried out to investigate the function of ELMO1 in CRC cells. Western blot was performed to detect the change of signaling molecule extracellular signal-regulated kinase 1/2 (ERK1/2) following the down-regulated or up-regulated expression of ELMO1. Results: ELMO1 expression was inhibited by si-ELMO1 and was overexpressed by ELMO1-cDNA in HCT116 and SW620. Cytotoxic expression of ELMO1 in HCT116 and SW620 was shown to promote migration and invasion, while inhibited ELMO1 expression suppressed the capacity of cell migration and invasion. Furthermore, ELMO1 induced migration and invasion in CRC cells was found to be associated with the activation of MAPK/ERK pathway. Conclusions: High expression of ELMO1 plays an important role in the metastasis via the activation of MAPK/ERK signaling pathway. This finding provides a molecular basis for the role of ELMO1 in the progression of CRC, which may suggest a novel target for the treatment of CRC.

#4850 Overexpression of P62/IMP2 promotes metastasis in hepatocellular carcinoma via inhibition of E-cadherin expression. Mengtao Zheng,1 Chi Zhou,1 Hai-chun Cheng,1 Tuo Hu,3 Hua-hui Liu,3 Xian-rui Wu,2 Feng-wei Wang,2 Yu-feng Chen,4 Jian-ting Wang,4 Xiao-sheng He,2 Ping Lan,2 Departament of Colorectal Surgery, the Affiliated Shenzhen Shajing Hospital, Guangzhou, China;5 Department of General Surgery, the Affiliated Shenzhen Shajing Hospital, Guangzhou Medical University, Shenzhen, China;6 State Key Laboratory of Oncology in South China, Collaborative Innovation Center for Cancer Medicine, Sun Yat-sen University Cancer Center, Guangzhou, China.

P62/IMP2 is overexpressed in human HCC tissues compared with normal human liver tissues (score=10.30, n=40 vs. score=5.23, n=30, p<0.05). The expression of P62/IMP2 was scored by immune-staining intensity and positively immuno-staining cell numbers. At the same time, we found that p62/IMP2 was also overexpressed in several HCC cell lines. Stable p62/IMP2 overexpression and
depletion SNU449 human HCC cell line was made by using p62/iMP2 cDNA transfection and lentivirus mediated knockdown approaches, and it was further confirmed by western blotting analysis. Wound healing assay has shown that overexpression of p62/iMP2 can significantly enhance the cell migration ability in SNU449 cells. On the contrary, the depletion of p62/iMP2 can reduce the migration ability of SNU449 cells (p<0.05). As shown p62/iMP2 overexpressed cells may have a higher rate of proliferation at 72hr(p<0.05). In addition, we have observed that overexpression of p62/iMP2 can significant inhibit the expression of E-cadherin in western blotting analysis. In summary, our data would suggest that overexpression p62/iMP2 may promote metastasis via inhibition of E-cadherin expression in HCC.

Background: NOTCH oncogenic signaling induces epithelial-to-mesenchymal transition (EMT) and tumor stemness that play a critical role in driving tumor progression. Following interaction of NOTCH receptors (NOTCH1, 2, 3, and 4) with their ligands (DELTA-LIKE 1, 3, 4 and JAGGED 1, 2), γ-secretase complex performs an intra-membrane cleavage releasing the NOTCH intracellular domain (NNICD). NNICD translocates to the nucleus and induces the expression of HEY1 and HES1 transcription factors that in turn orchestrate the modulation of proteins related to cell cycle/apoptosis and immune regulation of PD-L1, PD-L2 and B7-H4, important negative regulators of immune function, often over-expressed in cancer cells; including breast cancer.

Conclusions: Promising candidates will be tested in follow-up mouse xenograft studies. Encouraging results in these pre-clinical models would provide a strong rationale for the development and testing of inhibitors to one or more of these potential targets as a new therapeutic for the 30% of breast cancers that are CREB3L1-deficient.

#4853 NRP2b, a unique isoform of NRP2, promotes aggressive lung cancer phenotypes. Anastasios Dimou,1 Patrick Nasarre,1 Joyce Nair-Menon,1 Federico Cappuzzo,2 Lorenzo Landi,3 Armida D’Incecco,2 Hidetaka Uramoto,3 Takeshi Yoshida,1 Eric Haura,5 Monica Gooz,1 Kent Armeson,1 Robert Gemmill,1 Harry Drabkin1.

Medical University of South Carolina, Charleston, SC; 4Istituto Toscano Tumori, Leghorn, Italy; 5Kanazawa Medical University, Uchinada, Japan; 2King’s University Faculty of Medicine, Charleston, SC; 5Moffitt Cancer Center, Tampa, FL.

Neuropilins (NRPNs) 1 and 2 are highly-related receptors for class 3 semaphorins, and interact with heparin-binding growth factors and their receptors (e.g. HGF-MET, VEGF-VEGFR2 etc.). We previously reported that NRP2 is upregulated by TGFβ and is required for its pro-tumorigenic activity. Here, we show that this upregulation preferentially involves NRP2b, a largely uninvestigated isoform encoding a divergent, yet highly-conserved C-terminus. Importantly, using a panel of lung cancer cell lines and orthotopic metastasis model, NRP2b promoted migration, invasion, metastasis and tumour formation, whereas the prototype receptor, NRP2a had opposite effects. TGFβ-mediated resistance to gefitinib in EGFR mutated tumors also was dependent on NRP2b expression. In addition, NRP2b, but not NRP2a, linked MET activation by HGF to AKT phosphorylation. In co-immunoprecipitation assays, we found that NRP2a robustly interacted with PTEN, while the interaction with NRP2b was weak. At the clinical level, NRP2b expression was commonly upregulated in patient lung cancer samples and this upregulation was a significant poor-prognostic factor. Collectively, these data indicate that NRP2b plays an important role in lung cancer invasion, metastasis and EGFR inhibitor resistance. Furthermore, isoform-specific interactions between NRP2 and PTEN may be responsible for the observed differences in MET signaling in response to HGF.

#4854 Evaluating HDAC6 as a causal factor in metastatic breast cancer to develop immunotherapy. Deborah Anderson,1 Shari Smith,2 Farah Goubran,2 Paul Mello,2 Saskatchewan Cancer Agency, Saskatchewan, Canada; 2University of Saskatchewan, Saskatoon, Saskatchewan, Canada.

Introduction: Our laboratory is interested in determining ways to block breast cancer metastasis. We discovered that CREB3L1 (cAMP responsive element binding protein 3-like protein), a stress-activated transcription factor, acts as a metastasis suppressor in breast cancer. CREB3L1 is expressed ubiquitously in noncancerous human breast cells and restricts expression of genes that promote cell growth, angiogenesis, and migration. Loss of CREB3L1 expression is a frequent event in high-grade metastatic human breast tumors and can result in enhanced metastatic properties. Experimental Procedures: To establish the mechanisms by which CREB3L1 exerts its tumor suppressive effects, a gene expression microarray analysis was performed to determine which genes are upregulated in CREB3L1-deficient breast cancer cells. Six hundred and eighty genes were statistically significantly upregulated at least 2-fold in all 4 of the CREB3L1-deficient cell lines assessed. To focus our analysis, 4 genes were identified as potential targets for this study, given that they have previously been shown to have a role in cancer progression. Knockdowns were generated for each of the 4 genes in a CREB3L1-deficient breast cancer cell line (HCC1806) and matched CREB3L1-expressing cells (HCC1806 + HA-CREB3L1), as well as a nontumorigenic control breast cell line (MCF10A). To knockdown expression of each of the 4 targets, shRNA directed at the gene of interest was transfected via a lentiviral system into the cells. Cell-based assays were performed to characterize the knockdowns. shRNA were screened for their ability to measure migration, soft agar assay to assess anchorage-independent growth, and the MTT assay to evaluate cell proliferation. Results: Successful knockdown at both the mRNA and protein level for each target gene was validated using quantitative real time PCR and immunoblotting. Results from the MTT assay verified that knockdown of each of the 4 gene targets did not affect cell survival in MCF10A. We confirmed that these test genes are downregulated in noncancerous breast cells (p > 0.05). Similarly, knockdown of each of the test genes did not affect cell proliferation in HCC1806 (≥ CREB3L1) cells, except for a significant decrease in proliferation in HCC1806 CREB3L1-deficient cells with Gene 1 knockdown (p = 0.02). Preliminary results indicate that knockdown of Genes 1, 2, and 4 in HCC1806 CREB3L1-deficient cells reduces cancer cell properties, including cell migration and anchorage-independent growth (p < 0.05).

Conclusions: Promising candidates will be tested in follow-up mouse xenograft studies. Encouraging results in these pre-clinical models would provide a strong rationale for the development and testing of inhibitors to one or more of these potential targets as a new therapeutic for the 30% of breast cancers that are CREB3L1-deficient.
is strongly suggestive of HDAC6 being a key player in metastatic cancer progression. In our initial studies we observed that the selective HDAC6 inhibitor Nexaturast A is capable of reducing the tumor growth in a highly aggressive murine mammary carcinoma that mimics human triple negative breast cancer (TNBC), under both orthotopic and subcutaneous conditions of implantation. Additionally, we showed that the size and number of secondary tumor nodules were significantly diminished after the HDAC6 treatment. In order to boost the anti-tumor T-cell response, we also tested check-point inhibitors against the tumor (such as anti PD-1 and CTLA4 antibodies). While each of the standalone anti-tumor T-cell response, we also tested check-point inhibitors against the tumor (such as anti PD-1 and CTLA4 antibodies). While each of the standalone treatments showed a certain degree of success in reducing tumor growth and enhancing intra-tumoral IFNγ response, we demonstrated that HDAC6 improves anti-tumor immune responses when combined with immune check-point blockade.

**#4855 Loss of USP18 represents invasion and metastasis of lung cancer.** Lin Zheng, Lisa Mustachio, Yulong Chen, Xi Liu, Jason Roszik, Jonathan Kurie, Ethan Dmitrovsky. UT MD Anderson Cancer Center, Houston, TX.

Metastasis is a major cause of human lung cancer mortality. Uncovering novel targets and mechanisms involved in regulating metastasis is critical for developing effective ways to improve lung cancer survival. It is reported that ubiquitin and ubiquitin-like pathways play an important role in invasion and metastasis. We previously found that USP18 (Ubiquitin Specific Peptidase 18) is substantially up-regulated in several cancers, including lung cancer. Engineered repression of the deubiquitinase USP18 decreased growth, increased apoptosis and augmented chemotherapeutic agent response of lung cancer cells. Our prior work showed that loss of USP18 can destabilize specific oncogenic proteins and this results in the marked reduction of lung cancer cell growth and in vivo tumorigenicity. Thus this study sought to explore the precise role of USP18 expression in invasion, migration and metastasis of lung cancer. In murine (KC2 and 344SQ) and human (A549 and H1299) lung cancer cells with varying degrees of metastatic potential, knock-down of USP18 by different short hairpin RNAs (shRNAs) decreased cell growth and increased cell death as compared to vector control transfectants. The findings from wound-healing migration and Transwell invasion assays established that USP18 knock-down in all studied lung cancer cell lines conferred substantial reduction of migration and invasion versus vector control transfected cells (p < 0.001). In mouse models, USP18 knock-down of lung cancer cell lines displayed a lower number of lung cancer metastasis in vivo. To discern engaged mechanisms, Reverse Phase Protein Arrays (RPPAs) were performed to interrogate over 300 growth-regulatory proteins in murine (344SQ and KC2) and human (A549 and H1299) lung cancer cells following USP18 knock-down. Using RPPAs, potential targets identified were differentially expressed between USP18 knock-down and vector control transfected lung cancer cells. Highlighted species included Myc, eEF2K (Eukaryotic Elongation Factor 2 Kinase), Programmed Cell Death 4 (PDCD4), Hes Family BHLH Transcription Factor 1 (Hes1) and Polo like Kinase1 (PLK1), among other species. In addition, phosphorylated Acetyl-CoA Carboxylase (ACC), a key component of the α5-adenosine monophosphate-activated protein kinase (AMPK) pathway, was significantly affected in lung cancer cell lines following USP18 knock-down (p < 0.05). Ingenuity Pathway Analysis and functional validation are now underway to uncover specific pathways directly involved in the observed reduction of lung cancer metastases. Taken together, this study implicates the deubiquitinase USP18 as a molecular target to combat lung cancer metastases.

**#4856 High mRNA expression of splice variant SYK short correlates with poor hepatic metastasis free survival in untreated lymph node negative colon cancer patients.** Robert R. Cochergh van den Braak, Anieta S. Siewerts, Zarina S. Lalmahomed, Sandra Bril, Annemieke M. Timmermans, Vanja de Weerd, Michelle van der Vlugt - Daane, Anne van Galen, Shan Shan Xiang, Katharina Biermann, John A. Foekens, John W. Martens, Jan N. Hjermes. Erasmus University Medical Center, Rotterdam, Netherlands.

Introduction: In lymph node negative (LN-) colon cancer 20% of the patients will develop recurrence of disease. Identification of these patients is an unmet need. SYK, a protein kinase, has been ascribed both a tumor promoter and suppressor role in epithelial cancers. The prognostic value of SYK and its splice variants, largely unknown in colorectal cancer however, was explored in a clinically well-defined cohort of colon cancer patients. Methods: Total mRNA expression of SYK (SYK[T]) and of its two splice variants SYK short(S) and SYK long(L) were measured using RT-qPCR in a clinically well-defined prospectively collected cohort of 240 colon cancer patients (n = 160 untreated lymph node negative [LN-] and n = 80 adjuvant treated lymph node positive [LN+] patients) selected from the MATCH-cohort. mRNA expression levels were related to microsatellite instability (MSI), mRNA expression of epithelial (EPCAM), stromal (BGN, FAP, INHBA) and infiltrate markers (VEGFA, CD45), known CRC mutations (n = 238), and disease free (DFS), hepatic metastasis free (HFS) and overall survival (OS). Results: Overall increased SYK levels were associated with stage I/II, a left-sided located primary tumor and MicroSatellite Stability (MSS). However, these associations and their interrelation differed significantly between SYK[T], SYK(S) and SYK(L) expression implicating an added value for measuring mRNA expression of the splice variants next to SYK(T). SYK[T], SYK(S) and SYK(L) levels all showed a significant positive correlation with the expression of EPCAM, FAP was weakly negatively associated with SYK(S) and VEGFA was weakly positively correlated with SYK(T) and SYK(S). This suggests a higher expression of SYK in epithelial-rich, stromal-poor tumors. SYK(T) and SYK(S) expression was significantly lower in tumors with a BRAF or PTEN mutation (mt) compared to wild type (wt) tumors. Although others reported differential expression of SYK between KRAS-dependent and KRAS-independent cell lines and KRAS mt versus wt tumors in 221 TCGA-samples (p = 0.008), we observed no significant differences for expression of SYK(T), SYK(S) and SYK(L) between KRAS-mutant (mt) and KRAS-wild type (wt) tumors. In the LN- group, using univariate Cox regression analysis increasing mRNA expression of SYK(T) (HR = 2.05 95%CI= 1.01-4.17 p = 0.047) and SYK(S) (HR = 1.83 95%CI= 1.09-3.05 p = 0.021) was associated with worse HFS, which remained significant for SYK(S) when correcting for the number of assessed lymph nodes (HR = 1.83; 95% CI = 1.08-3.12; p = 0.026 and HR = 1.27; 95%CI=1.09-1.60; p = 0.042). No other significant associations between SYK(T), SYK(S) and SYK(L), and DFS, HFS and OS were observed. Conclusion: In our untreated LN- colon cancer cohort SYK(S) is a pure prognostic marker for HFS. These results may help to identify LN- patients at overall low risk to develop liver metastases.

**#4857 TAK1 mediated IL1 expression as autocrine signaling to promote breast cancer metastasis.** Oihana Iriondo, Mostafa Elhodaky, Yarong Liu, Grace Lee, Julie E. Lang, Pin Wang, Min Yu. Univ. of Southern California, Los Angeles, CA.

TGFβ-activated kinase 1 (TAK1), a serine/threonine kinase from the MAPKK family, is regulated by different cytokines such as IL1, TGFβ, TNFα and BMPs, and it is therefore a key player in the cellular responses induced by changes in the microenvironment. TAK1 regulates cell survival, differentiation and inflammatory responses by activating other intracellular kinases such as p38, JNK or IKK. TAK1 activation is thought to influence the progression of several types of cancer, including lymphomas and pancreatic, colon, liver and breast cancer. In this study, we aimed to investigate the mechanisms by which TAK1 regulates breast cancer progression. (S2)–7–Oxooxetanol is a compound that inhibits the kinase activity of TAK1. Treatment of mice injected with MDA-MB-231 cells with (S2)–7–Oxooxetanol containing nanoparticles reduced metastasis formation, while growth of the primary tumor was not affected. TAK1 involvement in metastasis was confirmed by xenotransplantation experiments done with MDA-MB-231 cells overexpressing wild type or dominant negative forms of TAK1. Using these stable cell lines, we confirmed that TAK1 is required for p38 activation induced by several cytokines. Interestingly, cells cocultured with macrophages showed a TAK1-dependent increase in the expression levels of IL1α and IL1β, which could lead to TAK1 activation themselves. These cytokines were found to upregulate the expression of IL1. Using a transfilter setup it was found that TAK1 activation itself induced IL1 (S2)–7–Oxooxetanol was able to inhibit IL1 promoter activity in a dose-dependent manner. These findings suggest that the lung microenvironment could promote the initiation of a positive feedback loop by cancer cells, promoting the growth of metastatic lesions. Disruption of this positive autocrine feedback loop may be a potential therapeutic approach to suppress breast cancer metastasis to the lung.

**#4858 AK4 promotes colorectal cancer progression and metastasis.** Yau Hei Yu, Joanna Hung Man Tong, Yi Pan, Raymond Wai Ming Lung, Ka Fai To, Anthony Wing Hung Chan. The Chinese University of Hong Kong, Hong Kong.

Metastatic colorectal cancer (CRC) is a fatal disease with a poor prognosis. It is crucial to understanding the underlying pathogenesis to battle this dismal condition. We previously identified that AK4, a gene on chromosome 1p31.3 encoding a member of adenylate kinase family enzymes, was progressively up-regulated in colorectal cancer (CRC) to cancer to normal colon tissues. We further evaluated expression microarray of paired CRC samples. This study was aimed to validate the overexpression of AK4 and explore in-vitro effects in CRC. We firstly examined the mRNA expression level of AK4 in a panel of CRC cell lines. AK4 mRNA expression was higher in CRC cell lines (n=8) than normal colon cell line, and significantly higher in advanced stage cell lines (n=4, Duke’s C and D) than early stage ones (n=4, Duke’s A and B) (P=0.03). We further evaluated expression level of AK4 in two different cohorts of clinical samples. The first cohort consisted of 18 paired primary CRCs and its corresponding normal colon mucosa, and 27 metastatic CRC (including 15 cases with paired primary CRC and normal colon mucosa). AK4 mRNA level was significantly higher in metastatic CRC
than normal colon (P<0.001), and metastatic CRC than primary CRC (P<0.001). Among 15 cases with paired primary and metastatic tumors, 14 (93.3%) demonstrated higher AK4 in metastatic tumors than their primary counterparts (P<0.05). The second cohort composed of 190 consecutive primary CRCs. Upregulation of AK4 protein expression evaluated by immunohi-
tochemistry was found in 68.4% of CRCs, and its activation is independent of bothVMvesselformationanddrugdelivery. Wehave shownthatPRAMEoverexpressingcelllines(Mel290PRAME-V5andF41TET-
expression was not only a prognostic biomarker but also could be a therapeutic target. Since F41 cells remain epitome+- and highly metastatic, we constitutively silenced PRAME with a V5 tag (F41 shPRAME-V5). For Mel290 cells, we overexpressed PRAME to see whether this cell line, which does not induce metastatic death, became more malignant. We confirmed the silencing and overexpression of PRAME in our transformed cells with western blot. For cell proliferation, we found a slight increase in the Mel290 PRAME+ cells compared to non-transformed Mel290. Strikingly, in F41 cells, knockdown of PRAME led to complete cell death. In a xenograft animal model, NSG male mice were injected with either Mel290 PRAME-V5, Mel290, F41 shPRAME-V5 or F41 TET-empty vector cells. We found that PRAME overexpressing cell lines (Mel290 PRAME-V5 and F41 TET-
empty vector) induced rapid, multiple and aggressive liver metastases that led to death. Interestingly, the non-expressing PRAME cell lines (Mel290 and F41 shPRAME-V5) did not present macro or micrometastasis in any cases. This data highly suggests that PRAME overexpression is involved in UM metastasis. Thus, PRAME mRNA expression is not only a prognostic biomarker but also could be an important target for treatment.

#4862 SORB1-1AHNK complex regulates metastatic properties of cancer. Woo-Choil Cho, Ji-Eun Jang, Ja-Lok Ku. Seoul National University, Seoul, Republic of Korea

Purpose: CAP encoded by SORB1, Vinexin and ArgBP2 is participated in the SoHo family of proteins. The SoHo protein interacts with different signaling molecules and involves with cell migration, and has been implicated in a variety of cellular processes including insulin-stimulated glucose transport. CAP has
specific role in the stabilization of adhesion complexes and the consequent effect of cell migration. It is possible that CAP or complex between CAP and other proteins induces change of cancer cell characters. We assumed that SORB1 has substantial role of cell proliferation, migration and interaction with other subcellular proteins. Methods and materials: To elucidate endogenous role of SORB1 and AHNAK in metastatic cancer cells, we manipulated by plasmid, siRNA and shRNA in some colorectal cancer cell lines. Function of SORB1 as regulator of cancer proliferation was demonstrated by cell cycle assay. And several methods including western blotting, cell migration assay and immunoprecipitation assay were performed for determining role of SORB1 related other metastatic properties. Conclusion: Colony formation ability and proliferation were induced by SORB1 and AHNAK knockdown in HT29 cell line. In contrast, transient suppression of SORB1 inhibits cell proliferation. Moreover, when SORB1 was constantly suppressed in HCT-116 and SNU-C4 cell line, cell migration was impeded. According to immunoprecipitation data, we chose the AHNAK protein as the convincing candidate protein related with SORB1. An interaction of SORB1 and AHNAK was observed in both cytoplasm and nucleus. Expression level of SORB1 and AHNAK was also negative correlation in extraction of cytoplasm and nucleus. SORB1 and AHNAK bind each other as form of protein complex, however, AHNAK known as nucleoprotein is abundant in both cytoplasm and nucleus when SORB1 is suppressed. Consequently, these results indicate that SORB1 has a key role of cancer cell growth and invasiveness through regulation of AHNAK expression and degradation.

#4863 Aurora-A kinase: a nuclear driver of metastasis. Kristina Marinarik,1 Anna Kiselova,2 Yuriy Loskutov,1 Matthew Smolkin,1 Elena Pugacheva3.1 West Virginia University, Morgantown, WV; 2Fox Chase Cancer Center, Philadelphia, PA.

Aurora-A Kinase (AURKA) is a serine/threonine kinase that is critical for mitosis. AURKA is overexpressed in 96% of human cancers, including breast cancer. It has been previously shown that AURKA localizes to the nucleus in breast cancer metastases, and especially in metastases of Triple Negative Breast Cancer (TNBC). Our objective is to define the role of nuclear AURKA in breast cancer metastasis in TNBC. Here we report that TNBC cells vary in amount of nuclear AURKA and this potentially correlates with their metastatic capabilities. Based on our preliminary findings we hypothesized that nuclear AURKA promotes cell survival and resistance to apoptosis in the metastatic niche. To test this hypothesis we created TNBC cell lines with CRISPR/Cas9 based deletion of endogenous AURKA. We also constructed exogenous AURKA specifically targeted to the nucleus by addition of a nuclear localization signal (NLS) or cytoplasm via addition of a nuclear exclusion signal (NES), respectively. To allow for in vitro and in vivo rescue experiments with exogenous NES or NLS AURKA in sgAURKA expressing TNBC cells, we introduced several silent mutations to avoid sgAURKA targeting. In our pilot orthotopic xenograft study with MDA-MB-231-luc2-NLS-AURKA, colorectal cancer cells could have potent effects on malignant progression. To determine the functional significance of Δ4 in malignant progression we developed DCIS (ductal carcinoma in situ) cell lines that only express this isoform and not the full length protein. We engineered these lines by using CRISPR technology targeted at the exon 3/4 splice junction. The resulting lines were significantly more invasive in ECIS endothelial invasion assays. In vivo, intracardiac zebrafish injections of the Δ4-DCIS lines showed higher extravasation from the tail vasculature compared to the parental line. Subcutaneous xenografts in athymic nude mice grew larger tumors, presented more invasive lesions and metastases. Also, Δ4-DCIS spheres growing in matrigel, showed disorganization and enhanced invasion into the matrix. In conclusion these data suggest a model where the increased splicing of AIB1 to the Δ4 variant alters transcription at specific target genes and contributes to the metastatic phenotype.

#4865 The functional and clinicopathological analysis of hypoxia inducible factor-1α (HIF-1α) in head and neck squamous cell carcinoma. Yuichi Ikari,1 Hiroyuki Ozawa,1 Yorihisa Imanishi,2 Toshiki Tomita,1 Mariko Sekimizu,1 Yoshio Watanabe,2 Fumihiro Ito,1 Shin Saito,1 Kaooru Ogawa,1 Keio University School of Medicine, Tokyo, Japan; 2Kawasaki Municipal Hospital, Kawasaki, Japan; 3Saiseikai Central Hospital, Tokyo, Japan.

Introduction: Tumor hypoxia is considered to be associated with progression in various cancers. Hypoxia inducible factor-1α (HIF-1α) is one of the molecules which play a key role in tumor hypoxia. High HIF-1α expression is reported to have an impact on poor prognosis and resistance to chemotherapy or radiotherapy in head and neck squamous cell carcinoma (HNSCC). However, the effect and mechanism of HIF-1α on tumor metastasis in HNSCC is still unclear. The aim of the present study was to investigate the molecular targets of HIF1-α relevant to metastasis, and to reveal the impact of HIF-1α on HNSCC metastasis by using clinicopathological assays. Methods: The cell proliferation rate with or without HIF-1 inhibitor (KC7F2) in HNSCC cell lines (FaDu, Detroit512) was evaluated by MTS assay. Gene expression levels related to epithelial-mesenchymal transition (EMT), cancer stem cell (CSC) and HIF-1α in each HNSCC cell lines were measured by quantitative real-time PCR. Immunohistochemical expressions of HIF-1α and clinicopathological factors were analyzed using surgical specimens from 33 patients with hypopharyngeal cancer who had undergone trans-oral tumor resection without previous chemotherapy nor radiotherapy. Results: HIF-1 inhibitor suppressed the cell growth of HNSCC cell lines in a dose-dependent manner. HIF-1 inhibitor downregulated the expression of HIF-1α, twist, Oct3/4 and Nanog. In immunohistochemical study, the HIF-1α expression was higher in cancer cells than in normal cells of the adjacent normal mucosa. Univariate analysis revealed that high expression of HIF-1α was significantly correlated with T-classification (P = 0.012), lymph node metastasis (P = 0.002) and lymphatic invasion (P = 0.03). Conclusion: These results suggest that HIF-1α plays a key role in tumor progression of HNSCC through EMT and CSC properties. From the present study, HIF-1α inhibition may have the possibility to suppress tumor metastasis, making HIF-1α an attractive target for the treatment of HNSCC.

#4866 CD47 promotes metastasis and proliferation of colorectal cancer via MAPK/ERK pathway. Tuo Hu, Yu-feng Chen, Chi Zhou, Jia Ke, Hua-shan Liu, Xiao-bin Zheng, Jian-ping Wang, Xiao-jian Wu, Xian-rui Wu, Ping Lan. 1Department of Colorectal Surgery, the Sixth Affiliated Hospital of Sun Yat-sen University, Guangzhou, Guangzhou, China.

Background and Aim: A previous studies demonstrated that CD47 was overexpressed in several kinds of tumors including colorectal cancer (CRC). Furthermore, the level of CD47 was positively correlated with tumor proliferation, stemness and metastasis. The aim of this study is to evaluate the role of CD47 in the metastasis and proliferation in CRC. Methods: We used the data from GEO database GSE8671 to analyze the expression level of CD47 and its relationship with prognosis in CRC. The expression levels of CD47 in normal and CRC tissues from our hospital were detected using quantitative RT-PCR and western blot. CD47 was downregulated or overexpressed via lentiviral vector system. Then the RTCA assay and migration assay were carried out to investigate the function of CD47 in cell proliferation and migration. Western blot for cancer related pathways was performed to find out the downstream signaling pathways of CD47. Results: Increased expression of CD47 was found in CRC tissues. Inhibition of CD47 expression in HCT116 by shRNA attenuated the capacity of cell proliferation and migration. On the other hand, overexpression of CD47 in DLD1 increased the capacity for cell proliferation and migration. CD47 induced cell proliferation and migration was found to be associated with the activation of MAPK/ERK pathway. Conclusions: High expression of CD47 was found to be associated with the proliferation and metastasis in CRC via the activation of MAPK/ERK signaling pathway. These findings provide an SRP0-independent mechanism for CD47 in the progression of CRC, which may find a novel therapy target for the precise treatment of CRC.
TUMOR BIOLOGY: Pediatric Cancer 3: Genetics and Genomics

#4867 Exome- and whole genome sequencing for clinical evaluation and precision medicine in neuroblastoma. Ángela Martínez Monleon,1 Susanne Reinsbach,1 Niloufar Javarnavard,1 Anna Djos,1 Rose-Marie Sjögberg,1 Per Kogner,2 Tommy Martinsson,3 Susanne Fransson,1 1University of Gothenburg, Gothenburg, Sweden; 2Karolinska Institute, Stockholm, Sweden.

Background. Despite major progress in treatment of pediatric cancer, aggressive neuroblastoma (NB) still constitutes a major clinical problem. Currently, the event free survival of high-risk NB is about 40% implicating that 60% either don't go into full remission or falls into relapse. Most relapses have an acquired drug resistance meaning that conventional treatment options may not work. Therefore, further studies of this group are of great importance. Massive parallel sequencing has now become a valuable tool in both cancer research and in clinical evaluation as it provides valuable information regarding patient specific alterations that might be used in targeted therapy. Material and Methods. DNA from 54 patients in total have been sequenced for massive parallel sequencing; 16 tumor/normal pairs and 27 single tumors have been analyzed using exome sequencing, 8 tumor/normal pairs with whole genome sequencing and three using both exome and whole genome sequencing. Exome sequences were mapped using BWA with GATK realignment followed by variant calling through SNPeff and copy number analysis through ControlFree. Whole genome data were analyzed using the CLC Genomic Workbench with annotation and filtering done in Ingenuity variant analysis software. Results. On average, 14 somatic protein changing single nucleotide variants were detected per patient (range 2-71) with recurrent mutations being detected in ATRX. Predicted deleterious germ line alterations in well-established cancer genes were detected in three patients. Structural variants included genes such as ATRX and TERT, as described by others previously, but also novel homozygous focal deletions at chromosome 19. Shortest regions of overlapping deletions of this chr19 region include seven genes whereof CIC (Capicua) might be the most interesting in a cancer context. Copy number analysis of both exome- and whole genome sequencing gives genomic profiles that are comparable to the genome profiles generated from the SNP-microarrays that current are in use in clinical use. Specific breakpoints for structural variants could be detected in all sample subjects for whole genome sequencing as well as for all for all MYCN amplified neuroblastomas that subjects for exome sequencing. Conclusions. Exome- and whole genome sequencing can be used for clinical evaluation of NB providing information regarding both constitutional and tumor specific alterations. The information can be used for clinical decision of patient specific therapeutic options such as ALK- or CKD4/6 inhibitors, but can also in rare cases give information regarding which treatments not to use. Furthermore, whole genome sequencing also gives the possibility to identify tumor specific structural alterations such as translocation breakpoints that can be used to monitor tumor burden in liquid biopsies.

#4868 RD3 reprogramming in N-MYC non-amplified neuroblastoma evolution. Dinesh Babu Somasundaram, Karthikeyan Subramanian, Sheeja Reinsbach,1 Niloufar Javarnavard,1 Anna Djos,1 Rose-Marie Sjögberg,1 Per Kogner,2 Tommy Martinsson,3 Susanne Fransson,1 1University of Gothenburg, Gothenburg, Sweden; 2Karolinska Institute, Stockholm, Sweden.

RD3 in high-risk N-MYC neuroblastoma was shown to be reprogrammed in 30% of the high-risk neuroblastoma (NB), while the remaining 70% is N-MYC non-amplified (N-MYC-NA), yet still has a poor outcome with only 37% 5 Year OS and a miserable 9% 10Y OS. Recently, we demonstrated, Retinal Degeneration Protein 3 (RD3) regulates tumor cell migration, invasion and tumorosphere formation of the N-MYC-NA-NB. Assessing 15 different human derived stage-4 N-MYC-NA-NB, we observed RD3-loss in the tumor cell migration, invasion and tumorosphere formation of the N-MYC-NA-NB. RD3 in high-risk N-MYC-NA-NB, its novel tumor evolution stabilization function and further imply that continuous ongoing acquisition of RD3-loss in therapy resistant cells may directly relate to tumor progression and poor clinical outcomes.

#4869 The Signature Study: Molecular analysis of pediatric tumors with establishment of tumor models in a biology study. Elizabeth VanSickle,1 Ping Zhao,1 Deanna Mitchell,1 Jessica Foley,1 Julie Steinbrecher,1 Maria Rich,2 Abhinav Nagulapally,2 Jeff Bond,1 William Hendrickx,2 Giselle Saulnier Sholler.1 1Helen DeVos Children's Hospital, Grand Rapids, MI; 2Translational Genomics Institute, Phoenix, AZ.

Background: Pediatric cancer is the leading cause of death by disease in children in the US. Significant advances have been made in survival in the past 30 years and genomic understanding of tumors is underway. Gains in the identification of biomarkers, drug targets, and the molecular characterization of cancer are due to improved technology including gene sequencing, proteomics, and epigenetics. While this remains distinctly academic for cancer centers and patients with high risk/metastatic disease experience < 30% survival. Phase 1/2 trials not based on precision medicine result in poor response rates (<10%). Therefore, genomic understanding of tumors and molecular targeted therapies with aims of reaching all children and reducing toxicity while improving efficacy is needed. Methods: The Signature Study is an IRB-approved biology study that seeks to perform genomic analysis, high throughput (HTP) drug testing, and creation of patient derived xenograft (PDX) models of all pediatric cancer patients diagnosed/relapsed at Helen DeVos Children’s Hospital. Patients are consented, clinical history is collected in RedCap, and tumors are collected flash frozen and in cell culture media. Blood is collected for germline analysis. Tumors are analyzed through gene expression arrays, DNA panels and exomes and RNA sequencing in the in cells. The used for generation of patient specific cell lines (confirmed by IHC and STR) and immediate injection into NSG mice for PDX models. Cell lines undergo HTP drug testing using the Prestwick and NCI drug libraries, novel therapeutics and combinations. Results: Enrollment has increased since inception in 2011 with now >50 patients/year; a total of 284 pediatric tumors collected representing over 30 tumor types. The most common diagnosis is neuroblastoma, followed by medulloblastoma, osteosarcoma, and rhabdomyosarcoma. Sequencing for genomic analysis has been performed on 166 tumors to identify mutations, fusions, CNV, and deletions. To date 184 have been grown as primary patient cell lines and 75 as PDX models. Over 60 samples have been evaluated in HTP drug testing. Genomic analysis of cultured tumor cells has been correlated with response to drug libraries to establish correlative predictive markers for therapeutic decision making to be tested in clinical trials.

The study stores remaining tissue, cell lines, and PDX models for additional future research. Conclusion: This study shows it is feasible for a mid-sized hospital system to coordinate and collect tumors for genomic analysis in real time for clinical decision making in the future. This resource is an integrated TransMed database system which is a powerful resource which correlates clinical outcomes, therapies, genomic sequencing, PDX models and HTP drug testing used to answer research questions of biomarkers, biological characterization, drug sensitivity, and driver pathways within and between pediatric cancers.

#4870 Mutational landscape and timing of resistant clone emergence in 104 Chinese pediatric patients with relapsed acute lymphoblastic leukemia. Benshang Li,1 Dongying Lu,2 Shuhong Shen,3 Xiaofan Zhu,3 Xiaotu Ma,2 Ningling Wang,4 Yanling Liu,4 Yu Liu,5 Hui Zhang,4 Ting-Nien Lin,2 Michael Rusch,4 Michael Edmonson,4 John Easton,2 Yingchi Zhang,4 Jingliao Zhang,3 Cheng Cheng,5 Ingyan Tang,1 James R. Downing,6 Jingyan Tang,1 James R. Downing,7 Ching-Hon Pui,8 Jun J. Yang,5 Jun J. Yang,5 Tinghui Zhang,3 1Key Laboratory of Pediatric Hematology & Oncology Ministry of Health, Department of Hematology & Oncology, Shanghai Children’s Medical Center, Shanghai Jiao Tong University School of Medicine, Shanghai, China; 2Computational Biology, St Jude Children’s Research Hospital, Memphis, TN; 3State Key Laboratory of Experimental Hematology, Institute of Hematology and Blood Diseases Hospital and Center for Stem Cell Medicine, Chinese Academy of Medical Sciences and Peking Union Medical College, Tianjin, China; 4Department of Pediatrics, The Second Hospital of Anhui Medical University, Hefei, China; 5Department of Pharmacological Sciences, St Jude Children’s Research Hospital, Memphis, TN; 6Department of Biostatistics, St Jude Children’s Research Hospital, Memphis, TN; 7Department of Pathology, St Jude Children’s Research Hospital, Memphis, TN; 8Department of Oncology, St Jude Children’s Research Hospital, Memphis, TN.

Relapsed pediatric acute lymphoblastic leukemia (ALL), occurring in 15–20% of cases, is one of the leading causes of cancer-related death in children, confering a dismal survival rate of less than 40% primarily due to drug resistance. We performed whole-genome sequencing (WGS) and RNA-seq of matched diagnosis and relapse tumors as well as WGS of remission DNA from 104 pediatric ALL patients treated at Shanghai Children’s Medical Center (n=89), Institute of Hematology & Blood Disease Hospital in Tianjin (n=14) and the Second Hospital of Anhui Medical University (n=1) between 2003 and 2014. The median age at diagnosis was 6.29 (range, 0.23-16.05) years. Relapse occurred during
chemotherapy in 85 patients and after completion of therapy in 19 patients. Somatic mutation rate in ALL increased significantly from an average of 0.23 per Mb at diagnosis to 0.65 per Mb at relapse. We identified 34 potential driver genes at diagnosis and 45 at relapse based on significance of mutation recurrence and pathogenicity. The four most significant relapse-specific driver genes harbor known pathogenic germline mutations in purine metabolism genes (PRPS1/PRPS2, n=7), novel alterations affecting glucocorticoids receptor NR3C1 (n=13) and folyopolyglutamate synthetase FPGS (n=8). Functional characterization showed that all NR3C1 mutations resulted in significant loss of transcription activator function and subcellular mislocalization. Ecotopic expression of mutant NR3C1 in ALL cell lines consistently led to prednisone resistance. Five driver genes were BRBP, SMARCA4, TP53, MMR and WHSC1. The highest increase (2.5-fold) of mutation frequency from diagnosis to relapse with mutations collectively present in 28% of relapsed ALL. Truncation mutations in DNA mismatch repair genes MLH1, MSH2, MSH6 and PMS2 occurred exclusively at relapse in four ALL with the highest mutation burden. Targeted ultra-deep sequencing at 5,000X of 268 somatic alterations was performed on 214 serial bone-marrow samples collected during ALL therapy for 17 cases. The resulting mutant allele fraction (MAF) values showed high concordance with minimum residual disease (MRD) measured by flow cytometry, indicating suitability for quantifying leukemia burden. Temporal change of MAF in the serial samples also allows us to track clonal identity and emergence of drug-resistant clones during and after therapy. For example, one case had deep sequencing performed on 11 somatic lesions from 10 bone marrow samples collected over the 15 months between diagnosis and relapse. We found that a minor clone present in 0.5%-1% of ALL blasts at diagnosis emerged five months prior to relapse, from which two new subclones arose harboring NTSC2 mutations L406→SSF and D407→DRD. Preliminary data generated from serial bone marrow samples provides the first insight into the use of somatic alterations for monitoring leukemia progress during relapse.

#4871 Whole-exome sequencing identifies a high frequency of germline deleterious variants in cancer predisposition genes in individuals with osteosarcoma. Ruodol Kung,1 Bing Zhu,1 Meredith Yeager,1 Michael Dean,2 Matthew Gianferante,1 Lei Song,1 Joshua Sampson,1 NCIC DCEG Cancer Genomics Research Laboratory, Julie Gastier-Foster,1 Richard Gorlick,2 Silvia Regina Cami, nada de Toledo,1 Antonio Petralii,1 Ana Patiño-Garcia,2 Fernando Lecanda,3 Massimo Serra,2 Claudia Hattinger,4 Piero Picci,5 Katia Scottlandi,6 Adrienne Planagan,7 Roberto Tirabosco,8 Maria Amary,7 Nilgün Kurucu,9 Inci Ergunhan Ilhan,10 Neriman Sarı,11 Mandy Ballinger,12 David Thomas,13 Donald Barkauskas,13 Belynda Hicks,1 Margaret Tucker,1 Neil Caporaso,1 Robert Hoover,1 Stephen Chanock,1 Sharon Savage,1 Lisa Mirabello1.1 Division of Cancer Epidemiology and Genetics, National Cancer Institute, National Institutes of Health, Bethesda, MD; 2Nationwide Children’s Hospital, and The Ohio State University Department of Pathology and Pediatrics, Columbus, OH; 3Albert Einstein College of Medicine, Bronx, NY; 4Pediatric Oncology Institute, GRAACC/UNIFESP, Sao Paulo, Brazil; 5Department Of Pediatrics, University Clinic of Navarre, Universidad de Navarra, Madrid, Spain; 6Laboratory of Experimental Oncology, Orthopaedic Rizzoli Institute, Bologna, Italy; 7Royal National Orthopaedic Hospital NHS Trust, London, United Kingdom; 8.A.Y. Ankara Oncology Training and Research Hospital, Department of Pediatric Oncology, Ankara, Turkey; 9The Kinghorn Cancer Centre, Garvan Institute of Medical Research, Darlinghurst, NSW, Australia; 10Department of Preventive Medicine, Keck School of Medicine of the University of Southern California, Los Angeles, CA.

In children and adolescents, osteosarcoma (OS) is the most common malignant bone tumor. OS occurs in certain cancer predisposition syndromes at a higher than expected frequency. However, outside of these rare syndromes, OS is significantly more common and its genetic etiology remains poorly understood. We conducted an evaluation of rare exonic variants in 545 unselected OS cases compared with 1061 cancer-free controls using whole-exome sequencing of blood or buccal cell DNA to estimate the prevalence and burden of rare deleterious germline variants. We assessed potentially pathogenic rare variants in 126 well-characterized cancer predisposition genes (CPCG) and non-pathogenically mutated genes. We also surveyed the exome for genes with a higher burden of rare variants in 342 EUR cases with 994 EUR controls sequenced at the same time. Rare genetic variants, defined by a MAF <0.01 in 1000G, ESP or ExAC, that passed quality control filters were classified based on well-annotated databases (IARC-TP53, Telomerase Database, ARUP, BIC, Insight and COSMIC) and in silico predictions (Sift, PolyPhen, Mutation assessor, MutationTaster, FATHMM and ITRR). Rare variants matching known pathogenic variants, or inexact matches at the same residue, in selected well-annotated databases were labeled as putative pathogenic variants. High impact variants (frameshift, stop gain/loss, or known splice sites) not matching a previously identified pathogenic variant in the selected databases were categorized as probably pathogenic. Predictions based solely on in silico predictions were categorized as possibly pathogenic, uncertain or likely benign. A total of 14.5% of cases had a predicted pathogenic or high impact variant in an autosomal dominant CPG. A significantly higher pathogenic germline variant burden was present in EUR cases compared with EUR controls (Pburden = 3.7x10^-6). TP53 had the highest prevalence of pathogenic mutations (5% of EUR cases; Pburden = 1.05x10^-10). CDKN2A, MEN1, MLH1, MUTYH, PALB2 and VHL had a significantly higher variant burden in the EUR cases. 7.5% of cases had a predicted pathogenic or probably pathogenic variant in an autosomal recessive CPG (Pburden = 5.4x10^-7). Additionally, two males had a pathogenic variant in the X-linked genes, DKC1 and GPC3. In total, 21% of cases had a predicted pathogenic or high impact variant in a CPG (Pburden = 2.4x10^-7). Exome-wide analysis identified two novel genes with significantly higher rare variant burdens in the cases compared to controls. In conclusion, several CPCG and two novel genes, not previously associated with OS, had an enrichment of rare variants in OS and warrant further follow-up. Our results indicate that a clinically significant fraction of OS cases may harbor one or more mutations worthy of consideration for further investigation and genetic counseling.

#4872 Gene fusion detection in pediatric tumor samples utilizing multi-caller fusion detection approach and integrative data analysis. Alma Imamovic,1 Marian Harris,1 Alanna Church,2 Brian Crompton,3 Eliezer Van Allen,4 Katherine Janeway1.1 Dana-Farber Cancer Institute, Boston, MA; 2Boston Children’s Hospital, Boston, MA.

Gene fusions are an important mechanism of oncogenesis in pediatric cancers. Fusion detection from RNA sequencing data is challenging for several reasons including a high false positive rate by individual fusion callers. We developed a new pipeline for gene fusion detection utilizing a multi-caller fusion detection approach and focusing on improved specificity, annotation and visual presentation. Multiple fusion detection algorithms, integrative data analysis and known fusions and cancer genes annotation databases are integral parts of our new pipeline. The following fusion callers were included in the pipeline: Chimerascan, TopHat Fusion and STAR-Fusion. Fusions called by at least two fusion callers were included in the final results and annotated by utilizing the TARGET database (Tumor Alternatives Relevant for Genomics-driven Therapy) and TCGdb (Translocation Breakpoints In Cancer database). A Venn diagram was produced for visual presentation of candidate fusions detected by multiple fusion callers. IGV (Integrative Genomics Viewer) was used to visualize the alignment of reads at fusion break points. The fusion detection pipeline was tested with RNA sequencing data from 11 pediatric tumor samples either suspected to harbor fusions based on diagnosis (n=7); renal cell carcinoma, osteosarcoma, synovial sarcoma, glomus tumor, undifferentiated sarcoma) or known to have fusions based on standard methods (n=4; Ewing-like sarcoma, EWSR1 FISH + sarcoma, clear cell sarcoma). In most cases, fusions previously known to be present were identified with our pipeline. For the difficult to detect fusion CIC-DUX4, optimization by adding another fusion caller (FusionCatcher) and adjusting the filtering and annotation parameters was required to increase sensitivity. In some cases these novel fusions have been validated to be present with other methods. In one case (synovial sarcoma) the expected fusion, which was not detected with standard testing (FISH), was identified with our pipeline. The pipeline was also successfully utilized to analyze prostate cancer samples (PMID: 27676109). Our new multi-caller fusion detection pipeline has been successful in increasing specificity and decreasing the false positive rate for gene fusion calling in transcriptional data, while being sensitive enough to detect the more challenging fusions. Additional updates to the pipeline are anticipated like the realignment against a modified reference sequence including the gene rearrangement for improved sensitivity.

#4873 Shedding light on the unknown of Ewing sarcoma: Single cell study shows a co-expression pattern between TAPA-1 and EWSR1-FLI1. Roxane Khoogar, Doris Phelps, Peter Houghton. UT Health Science Ctr.at San Antonio, San Antonio, TX.

Introduction: Ewing Sarcoma (ES) is the second most frequent bone cancer found in children, and has the highest rate of recurrence among all childhood cancers. This suggests the need for a better understanding of heterogeneous cancer populations and rare cells that survive intensive cytotoxic therapy and cause recurrence in patients. It is widely accepted that ‘EWSR1-FLI1’ has a major role in determining ES survival and proliferation, but the mechanism is unknown. Most studies in which expression of ‘EWSR1-FLI1’ is correlated with the level of expression of ‘EWSR1-FLI1’ regulated genes have been conducted on
bulk populations that ignore potential heterogeneity of ‘EWSR1-FLI1’ in the cell population. To address this we have used single cell RNA-Seq approaches. Methods: The WaferGen iCell8 system was used to perform SMART whole transcriptome amplification using EW-8 ES cells. We sequenced single-cell RNA-seq libraries prepared from over 1260 ES parental cells. We combined computational analysis with strong quality control filters to produce candidate ES cells. We used EWSR1 expression profile to partition the entire population into two clusters. A population of cells with TAPA-1 expression was distinguished and studied for their co-expression patterns with EWSR1. Results: Results revealed that ES cells show considerable heterogeneity at the transcriptome level between seemingly identical EW-8 cells. We identified a subpopulation of EW-8 ES cells with a positive correlation between the expression of EWSR1 and Target of the antiproliferative antibody 1 and tetraspanin-28 (TAPA-1/CDB1). Our preliminary data from 200 cells indicate that EWSR1 (0-18 unique transcripts, median 1) and TAPA-1/CDB1 (0-8 unique transcripts, median 0) were correlated (r = 0.32, P < 0.10). TAPA-1, a surface membrane protein, most frequently associated with hematopoietic cells, that regulates cell development, activation, growth and motility and has been implicated in proliferation of many cancers. Conclusions: Taken together, our results suggest that there are two classes of cells with respect to the expression of TAPA-1 in EW-8 cells. We also show the relationship between TAPA-1 with EWSR1-FLI1 expression in a single cell level. This type of classification may lead us to identify a rare population with a poor response rate to cytotoxic treatments. Future studies will define if EW-8 ES cells having elevated TAPA-1 have differential sensitivity to cytotoxic agents compared with populations with low level expression.

**#4874 Application of quantitative analysis of mouse cell contamination and purification of human tumor cells in patient derived orthotopic xenograft mouse models of pediatric brain tumors.** Frank K. Braun, Mari Kogiso, Lin Qi, Huiyuan Zhang, Yuchen Du, Holly B. Lindsay, Siibo Zhao, Sarah G. Injac, Xiao-Nan Li. Baylor College of Medicine/Texas Children’s Cancer Center, Houston, TX.

Background: Pediatric brain tumors continue to be among the most difficult to cure and are the leading cause of cancer-related deaths in children. Research investigating pediatric brain cancer is still impaired by the lack of cancer models. We established a large panel of orthotopic xenograft models as well as several paired permanent cell lines using in vivo and in vitro culture techniques. However, an inherent risk of xenograft models is the contamination of isolates of human tumors with host (mouse) cells. Therefore strategies to correctly and timely identify the human/mouse ratio are essential. In this study we investigated Prostaglandin Receptor EP2 (PTGER2) as a useful target to identifying mouse cell contamination in PDXO models. Method: Species specific primers based on Alcozer et al., 2011 were used to detect PTGER2 in genomic DNA extracts of xenograft and cultured cells. Real-time qPCR was carried out using a StepOnePlus™ Real-Time PCR System. Reaction mix contained SYBR Green select master mix, respective primers and 5 ng of total genomic DNA in a total reaction volume of 10 μL. The qPCR conditions were as follows: 50°C-2 min, 95°C-10 min, 40 cycles of (95°C-15 sec, 61°C-1 min). Primer specificity was controlled in addition by analysis of amplified products on a 1.2% agarose gel. FACS analysis of human cells allowed us to analyze anti-HLA-ABC and mouse-specific Ab cocktail surface staining and subjected to qPCR. Results: Various models of pediatric brain cancer (PXA, MB, GBM, EPN, ATRT, DIPG, PNET) established in our group were investigated for mouse cell contamination. Cells from xenograft isolates as well as from culture xenografts were routinely analyzed. Our study confirms PTGER2 as a useful target for accurately estimate mouse cell contamination in brain cancer xenograft models. This further enabled us to improve detection and characterization of HLA-ABC/mouse-cocktail double negative population as seen in FACS. Conclusion: In conclusion we have successfully implemented an easy qRT-PCR approach to determine the human/mouse cell ration in any mixed cell population. PDXO models is paramount to have reliable information on mouse cell contamination.

**#4875 Identification of the cellular origin and ‘stemness’ phenotype of Malignant Rhabdoid Tumors (MRT) may represent a new therapeutic approach in paediatric oncology.** Ras A. Ramli, Martina A. Finetti, Matthew P. Selby, Yura Grabovska, Stephen Crosier, Amanda J. Smith, Steven C. Clifford, Daniel Williamson. Northern Institute for Cancer Research, Newcastle University, Newcastle Upon Tyne, United Kingdom.

Malignant Rhabdoid Tumors (MRT) are highly aggressive childhood malignancies characterized by a single mutation; biallelic inactivation of SMARCB1, a component of the SWI/SNF chromatin remodeling complex. These tumors may occur anywhere, most frequently in the brain (Atypical Teratoid/Rhabdoid Tu- mor, ATRT) and in the kidneys and soft tissues (Extra Cranial Rhabdoid tumor, ECRT). MRT presents immune markers from multiple lineages exhibiting a teratoid phenotype, characterized by cells with heterogeneous morphology within the same tumor leading to speculation that the MRT cell of origin is a type of multipotent stem cell. Despite recent advances in treating other solid tumors, treatments for MRT remain suboptimal and overall survival of patients that MRT patients remain poor. "stemness" characteristics are key to its aggressive clinical course and resistance to treatment. Here we analyze the expression profiles of primary MRT (n = 134) and catalog the expression of a program of "stemness" genes capable of driving aberrant self-renewal. Further, we show by re-expression of SMARCB1 in MRT cells that several of these key "stemness" genes are aberrantly activated by SMARCB1 mutation. One such gene, BMI1 was further demonstrated to be critical to MRT tumorigenesis by shRNA knockdown, and a novel anti-BMI1 drug, PTC209 was tested to show efficacy in MRT. Knockdown of BMI1 in MRT cells reduced the self-renewal capability of cells as seen from the number of tumourpheres formed in limiting dilution assay (LDA). Interestingly, BMI1 loss triggers upregulation of p16(INK4a) expression and this mimics the expression profile when SMARCB1 was re-expressed into MRT cells. To identify a putative MRT cell of origin we performed a meta-analysis cross-referencing expression profiles from primary MRT (n = 20), and functional models in which SMARCB1 was re-expressed (n = 5 lines) with expression profiles from multiple stem cell types including epithelial, embryonic, neural mesenchymal and neural crest (n = 446). Analysis by t-SNE and NMF consensus clustering suggested that MRT bore the closest resemblance to non-malignant neural crest cells. These results were confirmed in serial xenograft models in which ECRTs and ATRTs appear to have different cells of origin, despite having the same mutation and tumor appearance. For the first time, we show evidence that ECRTs and ATRTs appear to have different cells of origin, despite having the same mutation and tumor appearance. We further demonstrate that SMARCB1 expression is necessary for MRT cells to maintain a de-differentiated "stem-like" state and finally that the SMARCB1-dependent stemness gene BMI1 shows potential as a novel therapeutic target in MRT.

**#4876 Low frequent ALK hotspot mutations in neuroblastoma tumors detected by ultra deep sequencing: Implications for ALK inhibitor treatment.** Susanne M. Fransson,1 Niloufar Javanmardi,1 Rose-Marie Sjoberg,1 Per Kogner,2 Tommy Martinsson,3 Sahlensgrevska academy at University of Gothenburg, Gothenburg, Sweden; Karolinska Institutet, Stockholm, Sweden.

Background: The pediatric cancer neuroblastoma (NB) is heterogeneous in terms of both genotype and clinical behavior. NB patients show complex patterns of genetic abnormalities, which may include amplification, translocation or oncogenic mutations of ALK kinase in sporadic and familial cases. Three hot spot residues (F1174, F1245, and R1275) localized within the kinase domain of ALK, accounted for 85% of mutations in NB. In this study we used ultra deep sequencing for sensitive detection of ALK mutations. Methods: To detect the sub-clonal ALK mutations in 105 neuroblastoma tumors that can remain undetected using Sanger chemistry, we used two different approaches; hybridization-based Haloplex kit (Agilent) and PCR-based amplicron sequencing, both sequenced on the MiSeq Illumina platform. Coverage, uniformity and variant calling ability showed similar performance between both methods. Findings: ALK mutations were detected in 14/105 patients (13%) whereof six with allele frequency below 20%. At the I1171 locus an ALK mutation was detected in one case with variant allele frequency as low as 2.6%, the lowest level detected in our cohort. Mutations at the F1174 hotspot were observed in nine cases: six cases with F1174L, while the remaining three showed F1174C, F1174S and F1174I substitutions, with mutated allele fractions ranging from 14% to 60%. Interestingly the patient harboring F1174S mutation with 58% frequency, in parallel contained a small sub-clone of F1174I mutation with 8% frequency of the mutated allele. F1245-codon alterations were detected in three cases: two F1245I mutations and one F1245S mutation, with frequencies of 14%, 51% and 52%, respectively. A single case showed a L1240V variant with a mutated allele fraction at 57%. Sanger sequencing of all ALK mutated samples could confirm ALK status for all samples with variant allele fraction above 15%. Because of the limits of the detection, 4 out of 6 samples with a mutated allele fraction below 15% would have gone undetected relying on Sanger sequencing. Our results fail to reveal a distinct mutation spectrum in relation to neuroblastoma genomic subtypes. Moreover, a variety of neuroblastic tumors, from benign ganglioneuroma to very aggressive metastatic neuroblastoma, could be observed in the context of ALK mutation. Interpretation: These results indicate that, in neuroblastoma, ALK mutations can be present at sub-clonal level with the possibility of subsequent clonal expansion at the time of progression. Tyrosine kinase inhibitors have become the gold standard therapy in treating ALK positive NBs, making them a potential target for new therapeutic approaches.
diagnostic high sensitive detection of ALK mutations a necessary step in identifying optimal treatment modalities. This study is of utmost importance in clinical practice, highlighting the potential of NGS and the importance of serial samplings for therapeutic decisions.

### #4877 Transcriptome sequencing of pediatric hepatocellular carcinoma reveals genomic events involving APC and TERT.

Katherine Haines,1 Angshumoy Roy,2 Stephen Sarabia,2 Linghua Wang,2 Pavel Sumazin,2 Kyle Covenant,1 Harsha Dodapati,1 Oliver Hampton,1 Donna M. Muzny,1 Dolores Lopez-Terrada,2 David A. Wheeler,1 Sharon E. Plon,1 D. Williams Parsons1. TUMOR BIOLOGY: Pediatric Cancer 3: Genetics and Genomics.

The detection of chimeric transcripts by RNA-seq has allowed us to identify additional variants in APC. Reportsof inversion of APC are rare, however we have identified an additional published case of APC inversion in a pediatric HCC cohort with no additional fusions. Filtering by the COSMIC Cancer Gene Census list reduced the total number of fusion calls to 5 for the HCC dataset (3 unique events, 2 of which were confirmed by RT-PCR).

Results: The first event is an inversion disrupting APC, resulting in two in-frame fusion transcripts between APC and AP3B1. This fusion was confirmed and the intronic breakpoints were mapped in tumor and germline DNA through WGS by 10X Genomics. Variant calling by Platypus on tumor RNA-seq reads did not identify additional variants in APC. Reportsof inversion of APC are rare, however we have identified an additional published case of APC inversion in a patient with pediatric HCC. We will perform WGS on germline DNA from this patient to determine if the APC inversion breakpoint is recurrent.

The second event is a deletion encompassing the TERT promoter and results in an in-frame fusion between TERT and LCPAT1. An increase in TERT expression is seen in this tumor as compared to both normal liver and other pediatric HCCs.

Conclusions: The detection of chimeric transcripts by RNA-seq has allowed us to identify two structural variants involving known cancer genes in two tumors, including an inversion of APC which have been historically difficult to detect. These events present a possible genetic cause for the development and provide genes for further analysis in the remaining cases with no identified fusions. These results will inform future studies as we expand this cohort to include 18 additional pediatric HCCs which we plan to characterize through NGS and targeted sequencing.

### #4878 Sensitive and specific DNA and RNA sequencing techniques for detecting minimal residual disease. Erin L. Crowegry,1 Nitin Mahajan, Wing H. Wong,2 Edward A. Kolb,1 Todd Druley2. TUMOR BIOLOGY: Pediatric Cancer 3: Genetics and Genomics.

The goal of this study was to assess the clinical applicability of molecular genetic techniques in the study of minimal residual disease (MRD) in pediatric acute myeloid leukemia (AML) via DNA and RNA-based methods. Currently, multi-parametric flow cytometry (MPPC) for surface immunophenotypes is the gold standard for MRD with a limit of detection between 0.001-0.002. However, approximately one-third of children with no detectable MRD by MPPC after first induction still relapse and suffer inferior outcomes. One potential reason is that a majority of refractory or recurrent AML clones will present with altered immunophenotypes compared to diagnostic specimens. In contrast, DNA mutations present at diagnosis will remain in refractory disease and provide a gene-based MRD platform surveying many genes could enable targeted, gene-specific therapy. Recently, the heterogeneous and unique genomic landscape of pediatric AML was characterized in the TARGET project and highlights the potential for leveraging companion molecular screens in the analysis of AML MRD. Contrary to adult AML, pediatric AML is not primarily characterized by single nucleotide variants (SNVs), but rather by complex structural variants (SV) that are difficult to detect using standard next generation sequencing techniques and analysis pipelines. The need to detect these complex SV and SNVs, all of which are at low allelic ratios (AR) at the remission state, demands assays that are capable of analyzing both DNA and RNA molecules at levels of detection comparable to MPPC. As part of our platform, we leveraged a unique capture technique (ArcherDx; CoreAAML) to detect an important SV in pediatric AML, the internal tandem duplication in Fms related tyrosine Kinase (FLT3-ITD). Via a serial dilution of cells with known FLT3-ITD allelic ratio (MV4-11 cells), to determine a limit of detection, we were able to detect the mutation as low as 0.001%.

To complement the data-based approach, we compared two error-corrected (EC) RNA assays (a Druley lab developed protocol and the ArcherDx; Hemev2 panel) to further assess the assay performance and robustness emphasizing the importance of cell-type dependent sensitivity. Finally, we integrated the results from the FLT3-ITD assay and the RNA assay with our custom error-corrected sequencing data to create a novel bioinformatics workflow for assessing the biological implications of MRD clones detected. Collectively, our data support that EC sequencing, at both the DNA and RNA level, enable accurate detection of low allelic variants that could be used for improved clinical MRD diagnostics, prognostication and therapeutic selection.

### #4879 Genomic and epigenomic profiling of high-stage neuroblastoma. Miki Ohira,1 Yasutoshi Tatsumi,2 Yohko Nakamura,2 Kenji Tatsuno, Shuichi Tsutsui,1 Shogo Yamamoto,1 Genta Nagae,1 Claire Renard-Guillet,1 Ryuichi Sugino,1 Hiroki Nagase, Takahiko Kamijo,1 Hiroyuki Aburatani,1 Akira Naga- gwara1. TUMOR BIOLOGY: Pediatric Cancer 3: Genetics and Genomics.

Neuroblastoma (NB) is the most common pediatric extracranial solid tumor with a wide range of clinical phenotypes from spontaneous regression to highly resistant to chemotherapy. Despite intensive multi-modal therapy, NB remains the second most common cause of cancer deaths among children. MYCN amplification is the most prominent poor prognosis factor for NB, however, certain subgroup of high stage tumor without MYCN amplification also shows low survival rate in terms of long-term follow-up (10 years survival rate was 51%, n = 161). To elucidate the molecular basis of malignant subtype of NB, integrated genomic and epigenomic analyses were performed. Array CGH of 537 tumors indicated that genomic subsets of 17q gain, with 1p loss and/or 11q loss, exhibited aggressive characteristics even without MYCN amplification. Whole exome sequencing of 92 high stage, MYCN-non-amplified primary tumors (SureSelect XT Human All Exon V4, mean depth CDS:138, x20 coverage:96%) identified 1,735 non-silent somatic mutations, among which 53 were significant mutations observed more than once in the sample set. Aggressive tumors (died of disease, n = 48) had several notable features, with mutations in chromosome remodeling/modulating genes (27%, cf. ATRX), in DNA-damage response (30%), in TP53 (28%) and RB (22%)-related gene networks, as well as with high TERT expression (38%). By hierarchical clustering of methylome signature (Infinium HumanMethylation450 BeadChip), the 92 tumors were subdivided into four clusters. Unfavorable cluster 2 and 4 exhibited hyper-methylation phenotypes in CpG islands and the former was enriched by MYCN-amplified tumors. The two clusters included patients with high-risk NB (p = 0.0055). Thus, these prognosis-related genomic features could be useful markers for risk classification and help understanding molecular mechanism for aggressive phenotypes of MYCN-non-amplified NBs.

### #4880 MAGE gene family expression in pediatric medulloblastoma: frequency and possible therapeutic target. Rebecca R. Collins1, Klementina Fon Tacer1, Dinesh Rakhje1, Patrick Ryan Potts1. TUMOR BIOLOGY: Pediatric Cancer 3: Genetics and Genomics.

Background: The melanoma antigen gene family (MAGE) is a group of related genes that were first discovered in malignant melanoma. Among the approximately 40 MAGE genes in the human genome, two thirds are classified as Type 1 (MAGE-A, MAGE-B, and MAGE-C), referred to also as cancer testis antigens (CTAs), proteins that are restricted to testis but often aberrantly expressed in many adult cancers. Despite their common expression in adult cancers and their oncogenic potential, little is known about their expression and role in pediatric cancers. To determine the frequency of MAGE expression in pediatric medulloblastoma, we measured expression levels of Type 1 MAGEs in patient tumors. In addition, we examined how MAGE expression in medulloblastoma cells affects their growth and oncogenic potential.

Methods: We searched the Children’s Health pathology database for pediatric medulloblastoma between 2008 - 2015 and were able to recover an adequate amount of RNA from formalin-fixed paraffin-embedded tissue samples of 34 patients. The RNA
was converted to cDNA using reverse transcriptase, and the relative expression of 23 Type I MAGE genes was measured by qRT-PCR. To determine if MAGE expression is critical for medulloblastoma cell survival we knocked down several MAGEs using siRNAs in two MAGE-expressing medulloblastoma cell lines (D283 and DAOY) and evaluated the effect by cell viability (Alamar Blue and Cell Titer-Glo), apoptosis assays (Annexin V), and cell survival and clonogenic growth. The decreased cell survival after MAGE knockdown appears to be related, at least in part, to increased apoptosis. Our results indicate that targeting of MAGES in medulloblastoma may be a potential therapeutic option.

4988 Dissecting telomere maintenance mechanisms in neuroblastoma.

Background. Telomere maintenance is a major cancer hallmark and has recently attracted attention as an oncogenic mechanism in the pediatric malignancy, neuroblastoma (NBL), due to detection of frequent structural rearrangements near the telomerase (TERT) gene. NBLs display substantial clinical and molecular heterogeneity; tumors with MYCN amplification and TERT-associated rearrangements define separate groups of high-risk patients with active TERT. ATRX mutations are frequent in non-TERT active high-risk tumors, indicating use of alternative lengthening of telomeres (ALT) as a maintenance mechanism. Furthermore, the 4S low-risk NBLs display an elevated rate of spontaneous regression and overall good prognosis; it has been hypothesized that lacking a telomere maintenance mechanism ("telomere crisis") may be behind this phenomenon. Methods. To gain mechanistic insight behind this phenomenon, we introduce an integrative analysis of a cohort comprising 104 high-risk (32 MYCN-amplified) and 23 4S tumors with matched blood/tumor whole genome sequencing, CpG methylation, and RNA-seq data from the TARGET consortium. Here, we preformed structural variant (SV), allelic specific expression (ASE), and differential CpG methylation analyses. Additionally, we introduce a novel approach to measure relative telomere DNA abundance from short-read WGS measurements as the ratio between tumor and blood telomeric reads (containing canonical repeats TTAGGG/CCCTAA) per million (TBrpm). Results. We identified 26 tumors harboring TERT rearrangements (25% of all high risk tumors) and 3 tumors with ATRX mutations. We define 4 groups of high-risk NBL with different Telomere maintenance mechanisms: 1) Tumors with MYCN amplification or elevated MYCN activity, TERT gene body hypermethylation (β-value=0.8), and expression of biallelic TERT; 2) Tumors harboring TERT associated SVs, hemi-methylation (β-value=0.5), and expression of mono-allelic TERT; 3) Tumors without TERT expression, including ATRX mutants with hypo-methylated TERT (β-value=0.3); 4) Tumors with abnormally high telomeric DNA abundance (TBrpm > 1.5), hypo-methylation (β-value=0.3), and no expression of TERT. Intriguingly, while groups 1–3 show telomeric loss (TBrpm = 0.7-0.9), 4S tumors show conservation of telomere abundance between tumor and blood (TBrpm = 1); hence no indication of telomere crisis, perhaps due to early timing of biopsy at diagnosis. Conclusion. We have used ASE status and gene body methylation of TERT in order to understand and validate mechanisms underlying TERT activation; we extend MYCN-driven TERT activation to tumors with high MYCN/MYC activity in the absence of MYCN amplification. Our telomere analysis suggests that different ALT mechanisms might take place in NBLs. Defining the mechanism of 4S NBL spontaneous regression requires further investigation.

4988 Genomic mechanisms of disease progression in pediatric medullary thyroid cancer (MTC). IRA L. KRAFT, 1 SIVANDANA AKSHINTALA, 2 KEITH J. KILLIAN, 3 ROBERT B. HUFNAGEL, 3 JOHN W. GLOD, 4 CLAUDIA DERSIE-ANTHONY, 5 YUELIN ZHU, 1 HOLLY S. STEVENSON, 1 DIANA BRADFORD, 1 MARIA J. MERINO, 1 FRANK M. BALIS, 5 ELIZABETH FOX, 2 BRIDGETTE WIDEMANN, 2 JOHN J. P. SHEEN, 6 PAUL S. METZLER, 7 NATIONAL CANCER INSTITUTE, CENTER FOR CANCER RESEARCH, BETHESDA, MD; 8 NEW YORK UNIVERSITY, LANGONE MEDICAL CENTER, NEW YORK, NY; 9 NATIONAL EYE INSTITUTE, BETHESDA, MD; 10 CLINICAL RESEARCH DIRECTORATE/CLINICAL MONITORING RESEARCH PROGRAM, LEIDOS BIOMEDICAL RESEARCH, INC., NCI CAMPUS AT FREDERICK, FREDERICK, MD; 11 CHILDREN’S HOSPITAL OF PHILADELPHIA, PHILADELPHIA, PA.

Background: Multiple Endocrine Neoplasia (MEN) 2B is a rare hereditary disorder characterized by medullary thyroid cancer (MTC) in early childhood, pheochromocytoma, and mucosal neuromas. Patients with advanced MTC are treated with rearranged during transfection (RET) targeting tyrosine kinase inhibitors (TKIs) such as vandetanib. Despite initial responses, many patients progress on TKI therapy due to resistance mechanisms of resistance are yet to be elucidated. We analyzed tumor samples from seven children with MEN2B and MTC enrolled in a natural history study (NCIT01669984). Methods: DNA samples from tumor and adjacent normal tissue from paraffin embedded blocks or unstained slides were analyzed by a custom capture next-generation sequencing panel. Bioinformatics analyses identified point mutations, insertions, deletions and copy number variations within the RET gene. Results: Seven patients (median age at study enrollment 14 years, range 11–17 years) with the RET p.Met918Thr germline mutation were included in analysis. Tumor samples were available for three patients pre-TKI (four samples), two patients at progression on TKI (three samples), and two patients both, pre-TKI and at progression (five samples). Pre-TKI samples exhibited few tumor specific mutations or copy number variations and 4/5 patients had loss of chromosome 1p. For progression one patient was associated with acquisition of a previously unidentified p.Leu790Phe mutation within the kinase domain of the RET gene. Loss of heterozygosity and increase in copy number variations were noted in 4/5 samples at tumor progression. Two patients had copy number loss of chromosomes 13 and 14 and three had copy number gain of chromosome 1q. Recurrent, somatic, non-synonymous mutations were not identified. Conclusions: In children with MEN2, we identified increase in copy number variations and a somatic mutation within the RET gene as potential mechanisms of drug resistance. Our data imply that a common genetic mechanism for progression on TKI may not exist within this small sample set and highlight the need for serial collection of tumor tissue. Further, whole genome anaemolipoy may provide rationale for the evaluation of cytotoxic chemotherapy in patients who experience progressive disease on TKI therapy. Analysis of additional samples and whole exome DNA and RNA sequencing are ongoing.

4988 Targeting tumor-amplified ODC1 with difluoromethylornithine (DFMO) inhibits global protein translation and has antitumor activity in neuroblastoma.
Andrea T. Flynn, 1 Annette YU, 2 Kangning LIU, 2 Elizabeth SCADDEN, 3 Edward ATTIE, 3 MURRAY NOERIS, 2 Michelle HABER, 2 MICHAEL HOGARTY, 1 CHILDREN’S HOSPITAL OF PHILADELPHIA, PHILADELPHIA, PA; 5 CHILDREN’S CANCER INSTITUTE, SYDNEY, AUSTRALIA.

MYC genes are predominant oncogenic drivers in neuroblastoma, a lethal pediatric tumor, often via amplification of MYCN. MYC genes coordinately deregulate programs that link cell cycle entry with requisite biomass and energy creation. Polyamine synthesis is one such deregulated program that supports oncogenic Odc enzyme, and we have shown DFMO inhibits tumor progression and synergizes with chemotherapy in complementary murine models of neuroblastoma. We postulated DFMO inhibits protein translation as its principal mechanism of anti-tumor activity. Polyamines support protein translation via effects on both IF5A and IF4F-complex activities, yet their relative contributions remain poorly defined. Using the puromycin-incorporation assay we showed a marked decrease in global protein translation following DFMO exposure (by IEF) and eIF4F-complex status (polyamine-dependent 4E-BP phosphorylation). Moreover, eIF5A is required to resolve ribosome stalling at polyproline stretches, so we characterized the human proteome for polyproline motifs (PPP ≥3) to define an eIF5A-dependent translantome. Candidate genes of diverse polyproline content are being assessed for sensitivity to DFMO to define whether ribosome pausing and selective translation inhibition contributes to DFMO effects. Elucidating mechanisms of DFMO activity and correlating this...
with genomic status (MYCN and/or ODC1 amplified) will identify opportunities for drug synergy and provide a responder hypothesis to test in pivotal Phase 2 and 3 clinical trial of DFMO for neuroblastoma.

#4884 Focal 22q11.22 deletions combined with IKZF1 alterations are associated with worse clinical outcome in acute lymphoblastic leukemia. Julia A. Meyer, 1 Clint C. Mason, 2 Luke Maese, 2 Deqing Pei, 2 Cheng Cheng, 2 Ching-Hon Pui, 3 Mel Greaves, 3 Richard Aplenc, 3 Charles G. Mulligan, 4 Elizabeth Raetz, 1 Rodney R. Miles, 1 Karen R. Rabin, 1 Joshua D. Schiffer 1. 1 University of Utah, Salt Lake City, UT; 2 St. Jude Children’s Research Hospital, Memphis, TN; 3 Institute of Cancer Research, London, United Kingdom; 4 Children’s Hospital of Philadelphia, Philadelphia, PA; 5 Baylor College of Medicine, Houston, TX.

Introduction: Prognostic biomarkers in childhood acute lymphoblastic leukemia (ALL) are vital for risk-stratification and intensifying therapy for children at high risk for remission induction failure or relapse. Copy number alterations in genes such as IKZF1 and VPREB1 have been shown to correlate with poor outcome in ALL, highlighting genetic alterations as prognostic markers (NEJM 560:670, 2009, Leukemia 28(1):216-20, 2014). A second focal deletion in chromosome 22q11.22, 200 kilobases (KB) in length, occurs more frequently and in the same IGLL region as VPREB1 and is distinct from deletions associated with physiologic IGLL rearrangement. We further investigated this novel genomic lesion, 22q11.22, and the prevalence of co-occurrence with IKZF1. Methods: 22q11.22 deletions were characterized in a compiled childhood ALL cohort (N=832) and correlated with available clinical outcome using multiple previously published studies (Clinical outcome total N=730; Utah Cohort [N=56], TARGET [99906 cohort [N=215], St. Jude Children’s Research Hospital cohort [SJCRH, N=236], Children’s Hospital of Philadelphia cohort [CHOP, N=160], and Down Syndrome cohort [DS, N=63]). Microarray data was analyzed (Utah = Molecular Inversion Probe 330K [Affymetrix]; TARGET = SNP 500K [Affymetrix]; SJCRH = SNP 500K/6.0. [Affymetrix]; CHOP = 850K, 610K, and Omni Quadv1 [Illumina]; DS = SNP 500K, MIP 330K [Affymetrix]) by Nexus Copy Number (BioDiscovery, Inc.). Results: ALL patients that harbored copy number deletion 22q11.22 were present in about 30-45% of each cohort: Utah = 42.8%, TARGET = 29%, SJCRH = 40%, CHOP = 34%, DS = 46.7%. The majority of deletions, 93%, had a common recurring region just under 12 Kb in length. The 12 Kb deleted segment encodes no known genes. Patients that harbored a combined deletion in both IKZF1 and 22q11.22 (IKZF1 + 22q) were present in about 10-15% of each cohort: Utah = 12.5%, TARGET = 18%, SJCRH = 8.4%, CHOP = 6.3%, DS = 14.4%. IKZF1 +22q conferred worse event-free survival (N=730, P=0.0062) compared to those with only IKZF1 deletions and worse overall survival (N=507, P=0.0365). Additionally, those patients with IKZF1 +22q losses had a median decrease in event-free survival compared to those patients with neither deletion (normal cases): TARGET (high risk cohort) = 0.03 years (P=0.0001), SJCRH (low risk cohort) = 10 years, P=-0.0001, DS = 2.3 years, P=-0.0001. Conclusion: We present further evidence that non-physiological deletions within the IGLL locus is associated with worse outcome in pediatric ALL and combined with IKZF1, these double deletions identify a population of patients with very poor outcomes. These combined alterations may be useful to identify patients in the future for high risk protocols and further clinical interventions to understand the mechanism and biological consequence of this common loss at 22q11.22 in childhood ALL.

#4885 Identification of actionable targets for refractory/relapsed childhood cancer leading to personalized targeted therapy (TRICEPS Study). Fida Khater, Stephanie Vairy, Sylvie Langlois, Jasmine Healy, Sophie Dumoucel, Mathieu Laboie, Thomas Sontag, Pascal St-Onge, Dorothée Lajoie, Thomas Sontag, Pascal St-Onge, Henrique Bittencourt, A. Meyer, 1 ClintC. Mason, 1 LukeMaese, 2 DeqingPei, 2 Cheng Cheng, 2 Ching-Hon Pui, 3 Mel Greaves, 3 Richard Aplenc, 3 Charles G. Mulligan, 4 Elizabeth Raetz, 1 Rodney R. Miles, 1 Karen R. Rabin, 1 Joshua D. Schiffer 1.

The feasibility of performing genomic-driven targeted therapy in pediatric and adolescent (aged 0-21 years) patients with relapsed or refractory childhood cancer. This study offers in-depth genomic and transcriptomic investigation of patient’s tumoral material to identify patient-specific alterations and actionable driver mutation(s) that can be targeted with approved targeted drug and within the framework of clinically relevant genetic testing to assess the effect of biopsy to a detailed tumor analysis report. Over a period of 30 months, 44 relapsed/refractory cancer patients were recruited. Twenty-two of them underwent extensive genomic investigation (exomic and transcriptomic sequencing) within a median timeframe of 9.7 weeks from patient enrolment to return of results. Patient screen failures occurred due to benign/neurotic tumor biopsies or low tumor purity resulting in suboptimal DNA/RNA quantity or quality for genomic analysis. In all 22 patients, we have identified clinically relevant genomic alterations (SNVs, indels, fusions, CNAs) and relapse-specific mutations influencing patient management and providing options for personalized interventions. We assessed the functional impact of some of these cancer-specific alterations. This was the case of a novel relapse-specific rearrangement, identified on relapsed childhood ETP-ALL, and leading to asparagine synthetase (ASNS) up-regulation through a promoter exchange. The expression of this fusion was associated with reduced apoptosis following l-asparaginase treatment. This study shows that PPT based on next generation sequencing technology is a powerful approach that could be implemented in the clinic within a foreseeable future to guide treatment of hard-to-treat childhood cancers and to further improve patient care and outcomes.

#4886 The BRIP1 DNA helicase is a 17q dosage sensitive cooperative driver in neuroblastoma. Suzanne Vanhauwaert, 1 Kaat Durinc, 2 Els Janssens, 1 Givani Dewyn, 1 Bram De Wilde, 1 Genevieve Laureys, 1 Daniel Carter, 2 Chengu Belamy, 3 Katelyn De Preter, 1 Christophe Vanneste, 4 Frank Speelman, 3 Ghent University, Ghent, Belgium; 2 Children’s Cancer Institute, Sydney, Australia.

Neuroblastoma (NB) is an aggressive pediatric tumor arising from sympathic neuronal progenitors. NBs have a low mutation burden while copy number alterations are highly recurrent: MYCN amplification is present in half of high risk tumors often accompanied by 1p deletions while MYCN non-amplified aggressive NB frequently exhibit 1q deletions. Remarkably, both high risk groups show almost invariably chromosome 17q gain and we also reported that the mouse syntenic chromosome 11 region was gained during MYCN driven tumor formation. We and others have shown that mutations on 17q act as cooperative drivers during NB development. Using an integrated bioinformatics analysis, we identified several candidate drivers implicated in DNA repair including BRIP1, also known as FANCJ and located on 17q23.2. BRIP1 acts as a DNA helicase in unwinding of stable G-quadruplex (G4) structures in single stranded DNA during replication ensuring timely progression through S-phase. We show that BRIP1 knock down causes increased replicative stress in MYCN overexpressing NB cells as evidenced by increased RPA32 levels and reduced replication fork velocity. Overexpression of BRIP1 in dbMYCN-eGFP transgenic zebrash induced accelerated tumor formation supporting its role as cooperative driver gene. Gene expression profiling after BRIP1 knock down confirmed enrichment for gene sets implicated in DNA replication and repair and are indicative for perturbation of G4 enriched genes. We also identified further additional 17q dosage sensitive genes implicated in replication fork dynamics including BRCA1, BRCA2, ME1 and TOP2A. We propose that 17q gain acts as an amplifier for expression of multiple genes implicated in control of replicative stress and replication fork dynamics. Finally, we explored whether this replicative stress resistance phenotype could represent a novel therapeutic vulnerability for NB cells or other MYCN driven tumor entities. To this end, we tested several compounds for synergetic interaction with G4 stabilizing ligands such as TMPyP4, pyrdoxatin and BRACO-19 with promising results. In conclusion, we identified BRIP1 as 17q cooperative driver in NB tumors. Relief from G4 induced replication fork stalling in rapidly dividing tumor cells. Further, NB cells exhibit replicative stress resistance through upregulation of multiple critical regulators of replication fork dynamics, offering a new venue for therapeutic interventions.

#4887 Comprehensive molecular analysis of pediatric thalamic tumors. Heloisa H. Moser, 1 Suzanne Yoon, 2 Madhuri Kambhampati, 1 Sridevi Yadavalli, 1 Angela J. Waanders, 2 Adam Resnick, 2 Roger J. Packer, 1 Javad Nazarian 1.

Children's National Health System, Washington, DC; 2Children's Hospital of Philadelphia, Philadelphia, PA.

Childhood thalamic tumors are relatively rare cancers, accounting for 5% of all pediatric brain tumors and categorized as midline gliomas such as diffuse intrinsic pontine gliomas (DIPG). We and others have shown that mutations in
genes encoding for histone 3.3 (H3F3A), histone 3.2 (HIST2H3C) and histone 3.1 (HIST1H3B) along with their obligate partner mutations are the major driver mutations in DIPGs. Where recent studies have identified major histone partner mutations associated with DIPGs, more research is required to provide a clear landscape of genomic aberrations associated with thalamic tumors. We hypothesize that comprehensive whole-genome analysis may provide insights into the mechanism of action of the PGBD5 transposase. The PGBD5 protein is a member of the transposase superfamily of proteins, which are involved in the rearrangement of DNA sequences. This suggests that PGBD5 may play a role in the rearrangement of DNA sequences, potentially leading to the development of tumors.

The PGBD5 gene is overexpressed in the majority of rhabdoid tumors, a lethal childhood cancer, suggesting a potential role in the development of these tumors. The overexpression of PGBD5 in rhabdoid tumors is associated with a high frequency of somatic site-specific DNA rearrangements, which may contribute to the development of these tumors. The identification of PGBD5 as a potential oncogene highlights the importance of further research to understand its role in the development of rhabdoid tumors.

The study also highlights the importance of comprehensive whole-genome sequencing (WGS) for understanding the molecular landscape of tumors. The WGS approach is a powerful tool for identifying the genetic alterations associated with the development of tumors, and it can provide insights into the mechanism of action of the identified genes. The WGS approach can also identify potential therapeutic targets, which can be used to develop targeted therapies for the treatment of tumors.

Overall, the study highlights the importance of comprehensive whole-genome analysis for understanding the molecular landscape of tumors, and it provides insights into the mechanism of action of the identified genes. The identification of PGBD5 as a potential oncogene highlights the importance of further research to understand its role in the development of rhabdoid tumors. The WGS approach is a powerful tool for identifying the genetic alterations associated with the development of tumors, and it can provide insights into the mechanism of action of the identified genes. The WGS approach can also identify potential therapeutic targets, which can be used to develop targeted therapies for the treatment of tumors.
expression information into the clinical interpretation of pediatric cancer genomic data. We underscore the importance of releasing the data to the community immediately following generation, so that they may benefit new patients.

#4891 Identification of recurrent high-affinity MHC class I restricted neo-epitopes in neuroblastoma using ProTECT. Arjun A. Rao, Jugmohit Toor, Sarvind Tripathi, Jacob Pfeil, Nikolaos Sgourakis, Sohe Salama, David Haussler. UC Santa Cruz, Santa Cruz, CA.

Introduction: T-cells are trained to differentiate between cell-surface MHC-displayed peptide sequences from self- and non-self proteins and act on the latter. The numerous mutations often associated with cancers can occur in coding regions of the genome and modify the sequence of wild-type proteins, potentially creating targets for immunotherapies. We have developed an analysis pipeline ProTECT (Prediction of T-cell Epitopes for Cancer Therapy) to identify and rank neo-epitopes in terms of immunogenicity. Running ProTECT on a set of Neuroblastomas patients predicted hotspot mutations that bind well to high-frequency MHC alleles – combinations that would potentially benefit a large subset of NBL patients. Methods: ProTECT accepts paired tumor and normal DNA sequencing fastq files, and tumor RNA sequencing fastqs. Mutations are called using a panel of callers and, are annotated [5] to identify coding mutations. Prediction of self-MHC mutated peptides is carried out [6] and the final binding predictions are ranked using an in-house algorithm. Summary: Running ProTECT on 6 Neuroblastoma samples (NBL) from the TARGET (Therapeutically Applicable Research to Generate Effective Treatments) project revealed 2 well-known hotspot mutations in NBL (NRAS Q61K and ALK R1275Q) that bind to common MHC alleles (A*01:01 and B*15:01 respectively). We also found 2 closely related mutations in ALK F1174L and F1174I that are predicted to C*04:01 and C*07:02. We carried out in-vitro refolding and crystal- lization assays [7] for the five highest-ranking mutant NARS and ALK R1275Q predictions. Properly conformed MHC trimers were verified by a monodisperse peak after anion exchange chromatography. SDS gel electrophoresis and Mass-spect confirmed bound peptide for 4/5 tested predictions and 3 of these were used to set up hanging-drop crystallization trials in various conditions. Positive hits were obtained for one (AQDIYRASYY::HLA-B*15:01) and the structure was obtained at 1.7A. The structure suggested the binding of the 10-mer (AQDIYRASYY) to the MHC and this was shown to bind better than the 9-mer using Differential Scanning Fluorimetry [9]. We will run ProTECT on the remaining 100 + TARGET NBL trios, and on relevant cohorts within The Cancer Genome Atlas (TCGA). We aim to reveal clinically relevant hotspot-mutation/MHC pairs. Conclusion: We have described a pipeline for identification and ranking of therapeutically relevant neo-epitopes. We have predicted potential targets for NBL that have been validated in-vitro. #4892 MOSPD2, a newly characterized protein, promotes breast cancer metastasis. Itzhak Mendel, Yaniv Salem, Niva Yacov, Osrrat Propheta-Meiran, Eyal Breuer, Zvi Toren, Ohad regional Bioinformatics, Tel-Aviv University, Tel-Aviv, Israel.

Introduction: We have previously described motile sperm domain-containing protein 2 (MOSPD2), a protein which up until recently no function was ascribed to, as a key regulator of monocytemigration in-vitro. In this study, the role of MOSPD2 in promoting breast cancer migration and metastasis in-vitro and in-vivo was assessed. Experimental procedure: The prevalence of MOSPD2 was evaluated by IHC in tissue microarray layered with cores, representing different stages of invasiveness in breast cancer. MOSPD2 abundance was scored according to the staining intensity on a scale from 0 to 3. MOSPD2 expression was silenced in MDA-231 breast cancer cell line using lentiviral particles for sh-RNA or CRISPR-CAS9 (CRISPR). Cells were then tested by a trans-well assay for migration towards EGF in vitro as well as for lung dissemination following orthotopic or systemic inoculation in vivo. For mechanism studies, EGF-induced signaling events were analyzed. Results: Within normal adjacent tissue (NAT), 82% of the samples had no staining and the remaining 18% percent displayed an intensity of 1. In the tissue cores with in-situ carcinoma pathology, 79% of the samples had no staining intensity while the remaining 21% only scored 1 or 2. However, analysis of invasive and metastatic cancer demonstrated higher frequency in score of 2 and increased staining intensity up to score of 3 compared with NAT and in-situ carcinoma. Thus, the percent of combined scores 2 and 3 for invasive lobular carcinoma, invasive ductal carcinoma and metastatic invasive ductal carcinoma were 63%, 77% and 81%, respectively. MOSPD2 silenced cells, either by siRNA or by CRISPR, were severely impaired in their ability to migrate in-vitro towards EGF. Following EGF activation of CRISPR-Control MDA-231 cells, all tested proteins down-stream to the EGF pathway, including AKT and p38, became phosphorylated. However, in CRISPR-MOSPD2 silenced cells, phosphorylation of all tested proteins excluding p38 were markedly inhibited. Moreover, activation with IGF of CRISPR-MOSPD2 MDA-231 cells did not hinder AKT phosphorylation. In vivo, SCID mice injected orthotopically or systemically with CRISPR-MOSPD2 silenced MDA-231 cells displayed significantly reduced number of metastases in the lungs relatively to mice injected with CRISPR-Control treated cells. Conclusions: We suggest that MOSPD2 promotes metastasis of breast cancer cells and is a potential target for the treatment of metastatic breast cancer.

#4893 AKT1 signaling negatively regulates invasion and metastasis of non-small cell lung cancer cells carrying mutations in KRAS or EGFR. Guanghua Rao,1 Mariaelena Pierobon,2 In-Kyu Kim,1 Wei-Hsun Hsu,1 Jianghong Deng,2 Yong-Wha Moon,1 Emanuel F. Petricoin,2 Yu-Wen Zhang,1 Yisong Wang,1 Giuseppe Giacone1,2. 1George town Univ. Medical Ctr., Washington, DC; 2George Mason University, Institute for Advanced Biomedical Research, Manassas, VA.

Inhibition of AKT1 signaling driven by the phosphoinositide-3 kinase (PI3K) and AKT/protein kinase B (PKB) pathway plays an important role in cancer development and progression, and thus this pathway is an attractive therapeutic target. Although many different inhibitors targeting either PI3K or AKT have been developed, the therapeutic benefit of these inhibitors in the clinic remains elusive, in part because of the perplexing role of AKT signaling in the regulation of cell motility, invasion and metastasis. AKT activation is known to promote migration, invasion and metastasis; however under certain circumstances and different cellular systems, it also exhibits an inhibitory activity on these cellular processes and the underlying cause of these conflicting results is unclear. Through analysis of the Reverse Phase Protein Array (RPPA) performed on a series of non-small cell lung cancer (NSCLC) brain metastasis models generated via intracardiac injection in mice, we identified AKT1 (one of three AKT family members) as a critical negative regulator of A549 tumor metastasis. AKT1 tyrosine phosphorylation (but not AKT2 or AKT3) inversely correlated with the metastatic potential of A549 cells which carry a KRAS mutation. Using AKT1 siRNAs, we demonstrated that inhibition of AKT1 significantly enhanced migration and invasion of KRAS- or EGFR-mutant NSCLC cells, but not wild type KRAS and EGFR cells. Similarly, the AKT inhibitor MK-2206 also enhanced the migration and invasion of KRAS- or EGFR-mutant NSCLC cells in vitro, and promoted metastasis of KRAS-mutant A549 cells in vivo. The PI3K-AKT pathway is downstream of both EGFR and KRAS, whose constitutive activation caused by mutations likely alter the signal output of PI3K-AKT pathway and thus the activity on cell invasiveness. Therefore, our results provide a sound explanation that under certain tumor microenvironmental background (e.g. KRAS or EGFR mutations) the AKT signaling may switch from a promoter to an inhibitor of cell migration, invasion and metastasis. This observation may have strong clinical implications for the development of inhibitors of this pathway for cancer treatment. Furthermore, we found that AKT1 blockade induced phosphorylation of Myristoylated alanine-rich C-kinase substrate (MARKCS) and elevation of p38 were markedly inhibited. Moreover, activation with IGF of CRISPR-MARKCS-silenced cells, either by sh-RNA or by CRISPR, were severely inhibited. In contrast, activation of AKT by AKT1 siRNA knockdown abrogated the activities of migration and invasion induced by AKT1 inhibition. This study unravels an anti-metastatic role of AKT1 in NSCLC cells with KRAS or EGFR mutation, and provides mechanistic insights for the understanding of the potentially contrasting roles of AKT signaling in the regulation of cell invasiveness.

#4894 Identification of small molecules for the prevention and treatment of colon cancer. Deeksha Pal,1 Becca Von Baby,2 Balaji Chandrasekaran,1 Arun Sharma,2 Chandell Damodaran.1 1University of Louisville, Louisville, KY; 2Penn State University, PA.

Metastatic colon cancer or colorectal cancer (CRC) is associated with poor survival rate which is less than 5% due to chemo resistance. We previously showed that overexpression of AKT and Notch1 are key players for progression of metastasis of colon cancer cells. Witherin-A (WA) is a potent herbal molecule that inhibited CRC growth by down regulating AKT and Notch1 signaling in both in vitro and in vivo colon cancer models. We found that WA binds to

1252 Proceedings of the American Association for Cancer Research • Volume 58 • April 2017
AKT with a predicted binding affinity of -10.6 kcal/mol and induced its activation. So, we designed and developed several analogs of WA, that exhibits a stronger AKT binding (binding energy higher than -10 kcal/mole) and more potent than the parental WA. UL16 is one such compound which induced the growth of colon cancer cells (HCT-116 and SW-620; IC50, 300nM) at nanomolar concentration. Western blot analysis revealed that UL16 inhibits AKT/NF-κB in Re12- signaling axis in colon cancer cells. In addition, UL16 concurrently inhibited Notch1 signaling pathway in colon cancer cells. Then we systematically investigated the anti-migratory and anti-invasive effect of UL16 by cell migration and invasion assays. Inhibition of both migration and invasion of colon cancer cells corresponds with downregulation of mesenchymal markers of Sna1, Slug and β-catenin expression. We also examined the in vivo efficacy of UL16 in ApMin+/– mouse model. Treatment of ApMin+/– with UL16 (0.5 mg/kg/IP/ twice a week) over 12 weeks significantly reduced the number of intestinal polyps (distal 84%; Middle 63% and Proximal 2%) as compared to vehicle treated mice. In addition, we also observed 50% reduction in number of colon tumors in UL16 treated mice. Our ongoing immunohistochemistry studies may confirm the in vitro mechanistic results. In conclusion, our studies suggest that UL16 inhibits both AKT and Notch1 signaling and suppresses intestinal polyp formation in ApMin+/– mice. Therefore UL16 could be a viable therapeutic agent for treating patients with metastatic colon cancer.

#4895 CT20p as a therapeutic for lung cancer with elevated chaperoning containing TCP1 (CCT) expression levels. Ana C. Carr, 1 Amy Sm. Khaled, 2 Rania Bassouani, 3 Annette R. Khaled. 1University of Central Florida, Orlando, FL 2Orlando VA Medical Center, Orlando, Florida, FL

Lung cancer is the leading cause of cancer related fatalities worldwide and although there is a substantial effort in the development of improved, more specific, and less debilitating therapies, very little progress has been made accomplishing this goal. We propose the use of CT20p, a therapeutic peptide developed by our laboratory, as novel therapy for lung cancer. We have previously demonstrated that CT20p has tumor-specific cytotoxicity in breast cancer cells and it induces tumor regression in xenograft models of breast cancer. We have also determined Chaperonin containing T-complex (CCT) to be the intra-cellular target of CT20p and that susceptibility to CT20p correlates with its expression levels, with tumor cells expressing high levels of CCT being the most susceptible. CCT is a large macromolecular complex composed of 8 subunits (CCTα, CCTβ, CCTγ, CCTδ, CCTε, CCTζ, CCTθ, CCTη). Immunoblot probing against four relevant CCT subunits (CCTβ, CCTγ, CCTδ, CCTε) was used to determine their relative expression level in five small cell lung cancer (SCLC) cell lines when compared to normal lung cells. We determined that the expression levels of the four probed CCT subunits varied amongst the five SCLC cell lines, however, the four CCT subunits were always expressed at higher levels when compared to normal lung cells. Immunohistochemistry staining for CCTβ was used on tissue microarray (TMA) of lung cancer progression. Results were interpreted on a scale of 1 to 4 (with 4 being the strongest staining). We determined that CCTβ levels increase with cancer severity and identified a significant correlation between CCTβ levels and cancer progression in both small cell lung carcinoma (SCLC) and Squamous cell lung carcinoma (SqCLC). Using The Cancer Genome Atlas (TCGA) database, we found that SMAD4 (transcriptional mediator of TGF-beta pathway) induced TIMP3 expression levels and cancer progression in both small and non-small cell lung carcinomas. Immunohistochemical staining of CCTβ levels in clinical lung cancer cases range from 10% to 43%, however, only CCT4 gene amplification in SqCLC cases correlated with decreased survival. Altogether, these results suggest that CT20p has the potential for being a therapeutic for multiple types of lung cancer due to increased target expression.

#4896 Role of CDK8 in colon cancer hepatic metastasis. Jiaxin Liang, Mengqian Chen, Mythreya Karthikeyan, M. Marjorette Pena, Daniel Hughes, Vimala Kaza, Chang-Uk Lim, Eugenie Broude, Igor B. Roninson. University of South Carolina, Columbia, SC.

About half of all colon cancer patients will develop liver metastases and the 5-year survival for these patients is less than 13%, making colon cancer the second most lethal cancer worldwide. Cyclin dependent kinase 8 (CDK8), which regulates cell cycle progression, has been identified as an oncogene amplified in many colon cancers. CDK8 acts as a positive mediator of oncogenic transcription pathways regulated by Wnt/β-catenin and TGF-beta, both of which are strongly associated with tumor metastasis. In a colon cancer liver metastasis model based on splenic injection of CT26 murine colon carcinoma cells, treatment with Senexin B, a highly selective small-molecule inhibitor of CDK8 and its paralogue CDK9, strongly inhibited metastatic growth in the liver and prolonged the survival of mice with hepatic metastases. In contrast to the effect on liver metastasis, CDK8 inhibition had little or no effect on cell growth in culture or at primary tumor sites. Hepatic metastasis was inhibited to the same extent when Senexin B was administered starting from the time of tumor injection or only after a later part of the study, suggesting that the drug affected metastatic growth in the liver rather than just initial colonization. Liver metastasis was similarly decreased by CDK8 knockdown in CT26 cells, suggesting that the anti-metastatic activity of Senexin B was due at least in part to its effect on tumor cells. Transcription profiling indicated that CDK8 inhibition by Senexin B was associated with downregulation of several genes associated with cell cycle progression and upregulation of genes associated with cell death. CDK8 inhibition also blocked TGF-beta or Wnt3a-stimulated transwell migration of CT26 cells in vitro. Knockdown of beta-catenin in CT26 cells also increased the expression of MMP7 and MMP10, consistent with the idea that CDK8 and β-catenin act in a redundant manner in promoting tumor progression. Thus, CDK8 inhibition decreased the primary tumor growth in the spleen and metastatic growth in the liver, whereas SMAD4 knockdown, like that of CDK8, selectively inhibited liver metastasis. Senexin B also suppressed hepatic metastasis after splenic injection of human HCT116 colon carcinoma cells. In summary, our data identified CDK8 as a key transcriptional regulator of colon cancer metastatic growth in the liver, interacting with TGF-beta and Wnt/ beta-catenin pathways and regulating the expression of Mmp7 and Timp3. CDK8/19 inhibitors, which are now entering clinical trials, may be effective for the treatment of hepatic metastasis of colon cancer.

#4897 Circadian/melanatonin disruption by dim light at night drives human epithelial breast cancer to a metastatic phenotype. Steven M. Hill, Shulin Xiang, Robert T. Dauchy, Melissa Wren-Dail, Murali Anbalagan, Brian Rowan, Tripp Frasch, David E. Blask. Tulane Univ. School of Medicine, New Orleans, LA.

Epithelial cancers demonstrate 24-hour (circadian) rhythms that are disrupted by exposure to dim light at night (dLAN). This study examined if dLAN-induced circadian/melatonin (MLT) disruption by exposure to dim light at night (dLAN) results in constitutive phospho-activation of ERK1/2, CREB, NF-κB, and STAT3 in breast tumor xenografts. CDK8/19, which were expressed in tumors from rats housed in dLAN, was found to be upregulated in tumors from rats housed in dLAN compared to those from rats housed in LD. CDK8 knockdown decreased the primary tumor growth in the spleen and metastatic growth in the liver, whereas SMAD4 knockdown, like that of CDK8, selectively inhibited liver metastasis. Senexin B also suppressed hepatic metastasis after splenic injection of human HCT116 colon carcinoma cells. In summary, our data identified CDK8 as a key transcriptional regulator of colon cancer metastatic growth in the liver, interacting with TGF-beta and Wnt/ beta-catenin pathways and regulating the expression of Mmp7 and Timp3. CDK8/19 inhibitors, which are now entering clinical trials, may be effective for the treatment of hepatic metastasis of colon cancer.

#4898 eIF4E represses the surface expression of migrating AML cells through regulating Hyaluronic Acid synthesis & CD44 expression. Hiba Zahredine, 1 Biljana Krajcic-Culjovic, 2 Valbona Catal, 3 Mark Lauer, 2 Lucy Skrabanek, 4 Nahibal Khan, 5 Ronald Mudura, 6 Leandro Cerchietti, 3 Vincent Hascal, 5 Craig Jordan. 1Institute for Research in Immunology and Cancer, University of Montreal, Montreal, Quebec, Canada; 2Cleveland Clinic, Cleveland, OH; 3Cornell University, New York, NY; 4University of Denver, Colorado, CO; 5University of Denver, Denver, CO.

TUMOR BIOLOGY: Therapeutic Intervention of Cancer and Metastasis

Cancer patients with disrupted 24-hour (circadian) rhythms are reported to have poorer survival as compared to those with normal rhythms. Severe alterations in circadian rhythms predict an increased risk of death in patients with colorectal and breast cancer, suggesting that circadian disruption may impact tumor progression and metastasis. We recently reported that circadian/melanatonin (MLT) disruption by exposure to dim light at night (dLAN) resulted in constitutive phospho-activation of ERK1/2, CREB, NF-κB, and STAT3 in breast tumor xenografts. Included in the panel of targets tested were CDK8/19, which were expressed in tumors from rats housed in dLAN, was found to be upregulated in tumors from rats housed in dLAN compared to those from rats housed in LD. CDK8 knockdown decreased the primary tumor growth in the spleen and metastatic growth in the liver, whereas SMAD4 knockdown, like that of CDK8, selectively inhibited liver metastasis. Senexin B also suppressed hepatic metastasis after splenic injection of human HCT116 colon carcinoma cells. In summary, our data identified CDK8 as a key transcriptional regulator of colon cancer metastatic growth in the liver, interacting with TGF-beta and Wnt/ beta-catenin pathways and regulating the expression of Mmp7 and Timp3. CDK8/19 inhibitors, which are now entering clinical trials, may be effective for the treatment of hepatic metastasis of colon cancer.
Formation of cell surface protrusions has long been associated with tumor cell migration, metastasis, and bone marrow homing & retention. It was shown that increased expression of endogenous or exogenous hyaluronic acid synthesizing enzyme 3 (HAS3) induces growth of microvillus-like cell surface protrusions. Some of the biological signals triggered by HA are dependent on its recognition by the cell surface CD44. In osteosarcoma cell lines with metastatic potential, the activity of the eukaryotic translation initiation factor 4E (eIF4E) increases formation of cell surface protrusions resembling those produced by HAS3 upregulation. eIF4E regulates mRNA export & translation through binding to the 5′ cap of mRNA in the nucleus & the cytoplasm, respectively. Strikingly, analysis of our two complimentary screens (immunoprecipitation of mRNAs bound to eIF4E in the nucleus & mRNA export associated with surface CD44) of eIF4E that we carried out to identify candidate eIF4E mRNA export targets, showed that nearly all the enzymes involved in HA synthesis as well as CD44.

Here, we hypothesize that eIF4E regulates HA synthesis & CD44 overexpression to reshape the surface of cancer cells producing HA-rich microvillus-like pseudopods. Following validation of the positive hits, we used immunofluorescence staining with biotinylated HA binding protein (HABP) to determine the effect of eIF4E expression on protrusion formation. Our data revealed that eIF4E overexpression increased formation of HA-rich cell surface protrusions & was correlated with increased invasiveness of eIF4E overexpressing cells in vitro & matrigel assays, compared to respective controls. In mice, confocal microscopy indicated that protrusions positively stained for CD44.

To reshaping the surface of cancer cells producing HA-rich microvillus-like pseudopods, we directly measured HA using confocal microscopy. We also tested eIF4E expression on protrusion formation. Our data revealed that eIF4E overexpression increased formation of HA-rich cell surface protrusions & was correlated with increased invasiveness of eIF4E overexpressing cells in vitro & matrigel assays, compared to respective controls. In mice, confocal microscopy indicated that protrusions positively stained for CD44.

Eukaryotic translation initiation factor 4E (eIF4E) is a key regulator of mRNA translation in eukaryotic cells. eIF4E binds to the 5′ cap of mRNA and targets it for ribosome binding, allowing translation to proceed. It plays a crucial role in cell growth, proliferation, and survival.

Cysteamine is a small molecule inhibitor of matrix metalloproteinases (MMPs), which are enzymes that break down extracellular matrix. Cysteamine has been shown to suppress tumor metastasis in various models, including those for breast cancer, prostate cancer, and ovarian cancer. It appears to work by inhibiting the activity of MMPs, which are known to play a significant role in tumor invasion and metastasis. This is particularly important for patients with breast cancer, as it is the second leading cause of cancer-related death for patients in this age group. Current therapy for breast cancer is limited, and there is a significant need for novel therapies that can improve survival and quality of life for patients.

Therefore, the authors of the study measured cysteamine suppresses tumor metastasis by inhibiting activity of matrix metalloproteinases without inducing toxicity in mouse models of human ovarian cancer. Akiko Suzuki, Rukmini Bhardwaj, Pamela Leland, Bharat H. Joshi, Raj K. Puri. FDA-CBER, Silver Spring, MD.

Previously, we demonstrated that cysteamine, a small molecule inhibitor of matrix metalloproteinases (MMPs), inhibited the migration and invasion of LM-2-MDA-MB-231 in experimental metastasis in vivo in mouse models of human pancreatic and ovarian cancer. We have also shown that subcutaneous cysteamine administration improved the survival of mice with orthotopically transplanted pancreatic tumors. Herein, we examined the effect of cysteamine on total MMP activity, MMP isoforms and activity by substrate gel zymography in tumors obtained from orthotopic mouse model of human ovarian cancer. We also investigated any gastrointestinal and general toxicity in vital organs of mice treated with the highest dose of cysteamine (250 mg/kg). We developed orthotopic tumors by injecting two human ovarian cancer cell lines in the ovary of female athymic nude mice. After 4 days of tumor implant, the mice were treated with different doses of cysteamine and followed for 5 weeks. Total MMP activity by fluorogenic substrate, MMP-2, 9 and 14 by ELISA and MMP activity by substrate gel zymography were measured in tumor lysates and compared with untreated tumors. We performed H&E staining in vital organs such as heart, lung, liver, kidney, spleen and brain for evaluating general toxicity of cysteamine. In addition, we examined stomach and duodenum from cysteamine treated and untreated mice if they developed any ulcerations. In two orthotopic murine models of human ovarian cancer, consistent with our previous observations, tumor metastasis was significantly decreased compared to controls in cysteamine treated mice. Similarly, total MMP activity was also significantly decreased in primary tumors treated with cysteamine in a dose dependent manner (P<0.05). Zymographic MMP activity was also decreased significantly in cysteamine treated tumors compared to control rebororating with total MMP activity (P≤0.05). Interestingly, ELISA did not show any change. MMP expression in cysteamine treated and untreated tumors was not affected. Furthermore, we did not observe any symptoms of general toxicity in animals treated at the highest dose of cysteamine and major vital organs and gastrointestinal organs from treated animals showed no evidence of histological changes as evidenced by H&E staining. In conclusion, our results suggest that cysteamine is a potent inhibitor of MMP activity without affecting expression. Cysteamine has the potential to inhibit any gastro-intestinal or vital organ toxicity and may be useful therapeutic agent for ovarian cancer either alone or in combination therapy with known anti-cancer agents.

Urokinase-derived peptide UP-7 effectively inhibits metastatic growth of breast cancer through suppression of FAK activation. Young Ae Joe,Hyun-Kyung Kim, Purevjagai Naidasunare, Seung Woo Lee, Rae-Kwon Kim, Su-Jae Lee, Suk Keun Lee, Yong-Ki Hong. Cardiothoracic University of Korea, Seoul, Republic of Korea; 2Hanyang University, Seoul, Republic of Korea; 3Kangnung National University, Kangnung, Republic of Korea.

The urokinase kringle domain of urokinase-type plasminogen activator (UK) has been shown to inhibit angiogenesis in vitro and in vivo and suppress tumor growth in vivo. To avoid limitations in application due to mass production of recombinant proteins, we dissected UK1 sequences to seven peptides based on structure and amino acid characteristics, and examined the anti-angiogenic activities for the constructed peptides. UP-7 peptide derived from β-sheets region of UK1 was the most potent inhibitor of proliferation and migration of endothelial cells (ECs) in vitro, and it also inhibited in vivo angiogenesis in the mouse matrigel plug assay. Such anti-angiogenic activities were not exerted by the scrambled peptide. At molecular level, UP-7 inhibited the VEGF or bFGF-induced phosphorylation of FAK and ERK1/2 and suppressed formation of capillary-like networks in vitro. In a lung cancer animal model xenografted with UP-7-non-sensitive NCI H460, systemic treatment of UP-7 effectively suppressed tumor growth in vivo through inhibition of angiogenesis. Importantly, breast cancer cells such as MDA-MB231 were sensitive to UP-7 in proliferation differently from other cancer cells. It inhibited the migration and invasion of LM-2-MDA-MB231 and suppressed the phosphorylation of FAK. Accordingly, UP-7 potently inhibited lung metastatic growth of LM2-MDA-MB-231 in experimental metastasis model. Taken together, these results suggest that novel UK1-derived peptide, UP-7 can be effectively used for treatment of the metastatic growth of breast cancer. (NRF-2012R1A1A2007175, NRF-2012R1A5A2051476).

Celecoxib fixed-dose combination: antitumor activity on growth and metastasis. Cynthia Lee, Osmond J. D’Cruz, Kevin Ng, Vuong Trieu. Autotelic Inc, Costa Mesa, CA; 2Marina Biotech, Agoura Hills, CA.

The role of COX-2 in the regulation of the tumor microenvironment is well established. COX-2 is overexpressed in many human cancers and is involved in multiple processes such as angiogenesis, invasion, and metastasis. Celecoxib is a COX-2 specific inhibitor that has been shown to exhibit antitumor activity in various cancer models. In this study, the antitumor activity of celecoxib fixed-dose combination was evaluated in vivo and in vitro.

In vivo, the antitumor effect of celecoxib combination was assessed in a murine breast cancer model. Tumor growth was significantly inhibited in mice treated with the combination compared to control groups. Similarly, in vitro, the combination inhibited proliferation, migration, and invasion of cancer cells. These results suggest that celecoxib combination may have potential as an antitumor agent.
Background: Breast cancer and melanoma are associated with a high rate of lymphatic and hematogenous metastasis which results in high rate of cancer mortality. Inflammation and hypertension (HTN) have recently emerged as causal factors for tumor progression and anti-hypertensive agents have been shown to reduce inflammation and suppress tumor growth and metastasis. Lisinopril (LIS), an inhibitor of angiotensin-1 converting enzyme (ACE); ii) Losartan medoxomil (OLM), an angiotensin II receptor blocker (ARB); and iii) Hydrochlorothiazide (HCTZ), a thiazide diuretic along with Celecoxib (CEL), a selective COX-2 inhibitor, CEL, LIS, OLM, and HCTZ were evaluated either alone or in combination for tumor growth suppression and metastatic spread in an orthotopic xenograft model of triple-negative inflammatory breast cancer/SUM149 and subcutaneous xenograft models of melanoma/MDA-MB-435, glioblastoma/UB87-MG, and triple-negative SUM159. Luciferase-tagged SUM149 and MDA-MB-435 cell lines were used to determine the incidence and the burden of locoregional and systemic spread. Mice were monitored twice a week for 9-16 weeks for percent weight loss, tumor volume and survival outcome. Metastatic tumor burden was assessed by measuring tumor volumes and the survival rate of less than 5%. Cell-free DNA (cfDNA) has been well-validated as a biomarker that correlates with tumor burden. More recently, a role for cfDNA in facilitating tumor progression has also been identified. The latter occurs through activation of nucleic acid sensing receptors such as toll-like receptors (TLRs) in both tumor cells and the host environment, which can upregulate pro-metastatic signaling pathways. In addition, tumor-derived extracellular vesicles such as microparticles and exosomes have also been implicated in promoting metastasis by activating pro-invasive pathways in tumor cells and pre-conditioning secondary sites for metastatic establishment. Our laboratory has previously shown that cationic polymers can scavenge negatively charged nucleic acids like cfDNA and abrogate aberrant inflammation in disease models of autoimmunity and infection. Herein, we investigated the ability of the cationic polymer, PAMAM-G3, to inhibit cfDNA as well as anionic tumor-derived extracellular vesicles using in vitro models of pancreatic cancer cell line invasion. We also evaluated the effect of PAMAM-G3 treatment in a bioluminescent syngeneic murine model of pancreatic cancer metastasis. PAMAM-G3 significantly inhibited in vitro invasion of pancreatic cancer cell lines in response to both cfDNA and tumor-derived extracellular vesicles. Moreover, biweekly intraperitoneal treatment with PAMAM-G3 (20 mg/kg) starting 48 hours after pancreatic tumor cell implantation led to a significant reduction in liver metastasis without affecting primary tumor growth. Thus, cationic polymers such as PAMAM-G3 may represent a novel class of therapeutics to combat pancreatic cancer metastasis.

TUMOR BIOLOGY: Therapeutic Intervention of Cancer and Metastasis

#4904 GLUT4 exhibits a non-canonical role of regulating lung cancer metastasis. Changyong Wei,1 Abhinav Achreja,1 Jessica Konen,1 Gabriel Sica,1 Melissa Gilbert-Ross,1 Deepak Nagrath,2 Adam Marcus,1 Malu Shannugam1. 1Emory University, Atlanta, GA; 2Rice University, Houston, TX.

Lung cancer continues to be fatal, in part due to the inability to prevent and treat metastasis. Current treatment which is targeted on control of primary tumor is not sufficient to sustain all the metastatic proliferation and importantly, tumor invasion. Among the SL2CA family of facilitative glucose transporters, GLUT1 is largely attributed to be responsible for increased glucose uptake of cancer cells. GLUT1 is however responsible for glucose transport across the blood-brain barrier, expressed in many normal cell types and therefore a less desirable therapeutic target. We previously reported that multiple therapeutic modalities including chemotherapeutics, localizing agents and combinations of insulin-responsive glucose transporter, GLUT4. In this study we investigated a role for GLUT4 in lung cancer. To interrogate contributions of GLUT1 and GLUT4 in proliferation, invasion and migration we generated H1299 and A549 GLUT 1 or GLUT4 knockdowns. Knockdown (KD) of GLUT4 did not inhibit proliferation but suppressed migration and invasion assessed through scratch and Boyden chamber assays, respectively. On the contrary, knockdown of GLUT1 reduced proliferation of these lines. Treatment of H1299 and A549 with our newly developed GLUT4-selective inhibitors also reduced invasion, phenocopying the effects observed with GLUT4 KD. GLUT4 inhibition also reduced H1299 invasion in a spheroid model. We utilized H1299 cells to isolate highly invasive less proliferative “leader cells” and less invasive but highly proliferative “follower cells”. H1299 leader cells more sensitive to mitochondrial inhibitors compared to follower cells. High glucose levels and high glutamine consumption in leader cells resulted in enhanced glycolysis/OXPHOS was further supported by evaluation of glucose uptake/oxygen consumption. Isotope tracer and bioenergetics analyses further support altered nutrient dependencies of leader and follower cells. Lastly, we found that GLUT4 is expressed in patient lung adenocarcinoma specimens including more aggressive micropapillary lung adenocarcinoma. Examination of collective invasion packs in patient samples showed high GLUT4 expression in a subset of more proliferative “follower” cells. These results suggest that in lung cancer population a subset of more invasive cells are reliant on GLUT4 with reduced GLUT1 expression while more proliferative cells rely on high GLUT1 expression, making GLUT4 a promising candidate for targeting metastasis in lung cancer.

#4905 Metastasis promoting long non-coding RNA, FEZF1-AS1, is an important therapeutic target for Ewing sarcoma. Sheetal S. Mitra,1, Anirban P. Mitra,2,3 Jon O. Nagy,1 Jonathan D. Buckley,1 Timothy J. Triche,1 1Children’s Hospital Los Angeles, Los Angeles, CA; 2Children’s Hospital Los Angeles, Los Angeles, CA; 3NanoValent Pharmaceuticals, MT.

Ewing sarcoma (ES) is a universally metastatic tumor of bone and soft tissue. Five-year survival in patients with metastases at diagnosis is about 20% despite intense treatment strategies. 85% of these tumors harbor a chromosomal translocation resulting in a fusion gene, EWS-FLI1. EWS-FLI1 imparts an oncogenic phenotype by modifying critical genes in signaling pathways, thus allowing for uninhibited cell growth, invasion, and metastasis while evading differentiation. EWS-FLI1 is thus an ideal therapeutic candidate, but targeting this fusion protein has proven difficult. In an attempt to better understand ES biology and identify candidate therapeutic targets downstream of EWS-FLI1, we profiled RNA transcription in over 140 ES cases and compared the data to other pediatric cancers. Among the most highly expressed genes that were downregulated as a result of lncRNA knockdowns. FEZF1-AS1 expression was specific for ES and was increased more than a hundred fold in ES when compared to other pediatric tumors. Chromatin immunoprecipitation (ChIP) studies along with luciferase promoter assays showed that EWS-FLI1 induces FEZF1-AS1 expression by binding to promoter GGAA repeats. shRNA-mediated knockdown of FEZF1-AS1 did not affect cell growth or survival. Instead, metastatic potential was markedly reduced, based on Matrigel assays. Conversely, ES cells transfected to overexpress FEZF1-AS1 engrafted better in mice and metastasized faster than control cells. Expression profiling of lncRNA-knockdown cells showed that the lncRNA upregulated genes were involved in cell movement and cell organization. ChIP-seq documented significant reduction in H3K4me3 and the H3K27ac histone marks in the promoters of genes that were downregulated as a result of lncRNA-knockdown. In order to document FEZF1-AS1 function, we delivered FEZF1-AS1-specific antisense oligonucleotide (ASO) and GFP-ASO in anti-CD99-targeted-nanoparticles to ES cells. An efficient uptake of nanoparticles and lncRNA ASO delivery to ES cells led to a 70%

Despite extremely high morbidity and mortality of >90% from metastasis, it remains one of the most challenging process for targeted therapeutic interventions. Identification and characterization of chemical and bioactive compounds from medicinal plants targeting the cell-signaling pathways of Cancer Stem Cells (CSCs), tumor cells and their microenvironment that abet metastasis is of great clinical significance. Hence, MCF-7; a breast cancer cell line, was treated with fractionated alkaloidal extracts from Rhazya stricta with previously documented anti-cancer activity in lung and pancreatic cancer cell lines. RNA-seq analysis was performed for samples treated with compounds that actively inhibited cell migration in scratch assay to further substantiate their anti-metastatic role at the cellular and molecular level. Genomic data corroborated the presence of anti-metastatic compounds that actively down-regulated genes involved in metastasis (CD6), cell migration (KIF23, DLGAP5), in-vivo and in-vitro invasion of freshly isolated biopsy samples from breast cancer patients. For proof-of-concept studies, in mouse models of breast cancer, 21 days post-treatment with extracts, we observed a significant reduction in tumor burden. The study demonstrates the potential of Rhazya stricta extract for the development of new anti-metastatic drugs and provides a framework for further preclinical and clinical development.

#4908 Neuruplin-1 is up-regulated in the adaptive response of prostate tumors to androgen targeted therapies and is prognostic of metastatic progression and patient mortality. Marianna Volpert,1 Brian Tse,2 Elka Ratther,1 Nataly Stylianos,1 Mannan Nouri,1 Melanie Lehman,1 Stephen McPherson,1 Mani Roshan-Monir2, Mandeep Takhar,2 Nicholas Erho,3 Mohamed Atef,4 Ela David,4 Robert Jenkins,4 Asha Ross,1 Jeffrey Karmazin,1 Robert Den,2 Ladan Fazi,1 Martin Gleave,3 Elizabeth Williams,1 Paul Rennie,1 Ralph Buttyn,1 Pamela Russell,1 Colleen Nelson,1 Brett Hollier1. 1Queensland University of Technology, Brisbane, Australia; 2Translational Research Institute, Brisbane, Australia; 3University of British Columbia, Vancouver, British Columbia, Canada; 4GenomeDx Biosciences, Vancouver, British Columbia, Canada; 5Medical Clinic, Rochester, NY; 6Surgical and Medical Institutions, Baltimore, MD; 7Thomas Jefferson University, Philadelphia, PA.

Aims: Androgen-targeted therapies (ATTs) are the mainstream treatment for metastatic prostate cancer (PCa). However, ATTs promote adaptation of tumor cells and lead to castration resistant disease (CRPC). We have recently identified the cell surface receptor, Neuruplin-1 (NR1P1) as increased during EMT and in CRPC. However, the role of NR1P1 in the prostate epithelium is poorly understood. This study aims to determine whether the inhibition of NR1P1 will be a feasible therapeutic strategy for blocking PCa metastasis and therapy resistance. Methods: qPCR and western blotting were used to assess NR1P1 expression in PCa cell lines. NR1P1 expression in CRPC was assessed using a murine LNCaP xenograft model of castration. NR1P1 was knocked down with shRNA 1 and 2 in human and murine CRPC cell lines, respectively. Results: PCa cells were microinjected into the zebrafish yolk sac and metastatic dissemination was imaged 5 days later. NR1P1 expression in radical prostatectomy (RP) samples from Mayo Clinic (545 patients) and Johns Hopkins Medical Institutions (JHMI; 188 patients) cohorts was quantified by Affymetrix exon arrays and multivariable analysis performed. Box scratch migration and invasion assays were performed with the Wound maker” tool and IncuCyte™ FLR imaging systems. Results: NR1P1 levels were elevated in human CRPC xenografts, metastatic and castrate resistant clinical PCa samples (p < 0.0001), and PCa cell lines. NR1P1 suppression significantly reduced metastasis of human xenografts in zebrafish and the migratory and invasive behaviour of metastatic PCa cells (p = 0.0002). Multivariable analysis identified NR1P1 as a significant independent prognostic indicator of metastasis and prostate cancer specific mortality in two large clinical cohorts (Mayo Clinic and JHMI; p = 0.008/0.048 and 0.013/0.034 respectively). We show that NR1P1 knockdown promotes E-Cadherin expression and loss of vimentin in mesenchymal PCa cells. Conclusion: These results will provide the preclinical data necessary to rationalise the use of anti-NR1P1 directed adjuvant therapies for clinical use in PCa patients receiving ATTs, and will pave the way for larger scale preclinical and clinical trials in the PCa setting.

#4909 Androgen targeted therapy induces ZEB1 expression and is associated with progression of androgen loss and therapy resistance. Katrina G. Sweeney,1 Nataly Stylianos,1 Gregor Tezv,1 Atef heel Taherianfard,1 Katrina Pirlo,1 Akanksha Upadhyaya,1 Elka Ratther,1 Melanie Lehman,1 Martin Gleave,1 Jennifer Gunter,1 Elizabeth D. Williams,1 Colleen C. Nelson,1 Brett Hollier1. 1Australian Prostate Cancer Research Centre-Queensland, Institute of Health and Biomedical Innovation, Queensland University of Technology, Translational Research Institute, Brisbane, Australia; 2Vancouver Prostate Centre, British Columbia, Canada.

Reactivation of the embryonic developmental pathway, epithelial-to-mesenchymal transition (EMT) is associated with prostate cancer (PCa) metastasis and therapy resistance. Recent evidence has demonstrated EMT is stimulated following androgen targeted therapy (ATT). In the present study we investigated the role of EMT transcription factor ZEB1 in ATT-driven EMT, PCa metastasis and drug resistance. Immunohistochemistry (IHC) staining of ZEB1 on tissue microarrays of primary tumors from clinical samples demonstrated ZEB1 expression correlated with increased tumor aggressiveness and Gleason score. Upon stratification of patient data (n = 198), high ZEB1 protein expression correlated with a shorter time to biochemical recurrence (BCR). Furthermore, IHC staining of primary tumors from 148 treatment-naïve patients with and without metastasis demonstrated high ZEB1 levels and correlated to a reduced time to metastasis. To delineate the role of ZEB1 as a molecular driver of latent prostate cancer (PCa) metastasis and resistance to therapy, we performed a comprehensive analysis of ZEB1 expression in PCa cell lines and in clinical specimens. Our results demonstrate that ZEB1 expression is up-regulated in CRPC and is associated with increased tumor aggressiveness and Gleason score. These findings provide a potential therapeutic target for patients with CRPC and highlight the importance of developing new therapeutic strategies for the treatment of CRPC.
Interestingly, in models where ZEB1 expression was elevated this was accompanied with repression of classical androgen-receptor genes suggesting ZEB1 is able to regulate the AR transcriptional pathway. We also investigated the role of ZEB1 in cancer invasion and chemoresistance. An inducible model of ZEB1 overexpression in LNCaP cells produced a robust EMT upon ZEB1 expression and was accompanied by invasion induced by an invasive phenotype in 3D cultures. ZEB1 overexpression also conferred resistance to docetaxel (IC_{50} of 8.17±2.45 mM in ZEB1-expressing cells vs. 3.35±0.23 mM in control cells) potentially as a result of a reduced apoptotic cell death response mediated by ZEB1. At suboptimal doses of docetaxel, the percentage of apoptotic cells (annexin-V+/propidium iodide-) decreased 4-fold when ZEB1 was expressed compared with control cells and was accompanied by a reduction in PARP cleavage consistent with decreased caspase activity. In summary, we provide evidence that ZEB1 expression is increased in response to AT1s and correlates with disease progression, metastasis and therapy resistance. We also show ZEB1 is a transcriptional regulator of AR signalling in PCa, Together this provides the rationale to target ZEB1 for the development of novel therapies for the treatment of CRPC.

**#4910 Eribulin rapidly impairs TGF-β signalling.**roma Kaul, April L. Risinger, Susan L. Mooberry. University of Texas Health Science Center at San Antonio, San Antonio, TX.

Microtubule targeting agents (MTAs) continue to be valuable in treating breast cancer. While decades of research have shown that these drugs cause mitotic arrest in cells by suppressing the dynamic instability of microtubules, recent evidence demonstrates that the ability of MTAs to disrupt the microtubule-dependent transport of key signaling components in interphase cells likely contributes to their anticancer actions. Cell signalling messages are relayed by proteins that organize or scaffold signaling hubs. These signalling nodes facilitate the complex organization and coordination of multiple signaling partners. NEDD9 is a member of the CAS scaffold family and it has been shown to coordinate TGF-β signalling, a driver of oncogenesis and epithelial-to-mesenchymal transition (EMT). Ligand-mediated stimulation of TGF-β receptors leads to the activation of downstream canonical and non-canonical signalling pathways. These pathways collectively induce the expression of Snail and Slug, key transcriptional-repressors that promote EMT. We tested the hypothesis that a short-term treatment of breast cancer cells with eribulin or other clinically relevant MTAs would differentially disrupt interphase microtubules and alter TGF-β-dependent signalling. BT-549 cells were treated for 2 h with concentrations of MTAs that are clinically relevant and cause maximum disruption of the interphase microtubule network; 100 nM was used for the destabilizers, eribulin and vinorelbine and 1 μM was used for the stabilizers, paclitaxel and ixabepilone. The results showed that eribulin and vinorelbine significantly inhibited TGF-β-induced expression of Snail and Slug. The microtubule stabilizers had no effect on Snail and Slug expression following TGF-β stimulation. Further studies evaluated whether NEDD9 contributes to the downregulation of Snail and Slug. Co-immunoprecipitation and knockdown studies suggest that eribulin impairs the ability of NEDD9 to scaffold TGF-β signalling partners, thus inhibiting downstream transcriptional signalling. Consistent with the ability of eribulin to reverse EMT in experimental models within 7 days, this study begins to shed light on the mechanisms underlying its action. Funding for this work was provided by Eisai Inc.

**#4911 Allosteric inhibition of the Receptor Tyrosine Kinases c-MET, RON and VEGFR-2 via the co-receptor CD44v6 by the novel compound AMC303.**Vanessa Al-Rawi, Thorsten Lauerer, Katrin Glocker, Yvonne Heneka, Alexandra Matzke-Ogi. anncare GmbH, Eggenstein-Leopoldsheim, Germany.

Introduction: The receptor tyrosine kinases (RTKs) c-MET and RON and more importantly their crosstalk, play a crucial role in mediating local invasion, systemic dissemination and resistance in different types of cancer. Both RTKs are activated by the ligands HGF and MSP respectively and homo- or heterodimerize with each other. The RTK VEGFR-2 is the most important receptor for angiogenesis in solid epithelial tumors. CD44v6, a member of the CD44 receptor family of transmembrane glycoproteins, was identified as an essential co-receptor for activation of c-MET, RON and VEGFR-2. AMC303, a peptide based allosteric and selective inhibitor of CD44v6, was investigated for its inhibitory effects on c-MET, RON and VEGFR-2 pathways in vitro and its effect on tumor growth and metastases in vivo. Methods: Affinity was determined using Microscale Thermophoresis. For in vitro blocking assays AMC303 was added 30 min prior to induction with the ligands. Analysis of RTK activation was carried out by western blot. Analysis of cell migration and invasion was performed with Boyden Chamber assays. VEGF-A induced tube formation was microscopically analyzed. For in vivo studies nude mice were orthotopically implanted with human tumor cells (L3.6pl). Animals were treated with AMC303 i.v. at 0.1, 1, 10 mg/kg QOD or QWX for 3 weeks. Regression of metastases was investigated at 1 mg/kg QOD. HPLC was used to detect the amount of AMC303 in the primary tumor lysates. Results: AMC303 binds to the ectodomain of CD44v6 with high affinity. Various pancreatic, breast, colon, lung and HNSCC tumor cell lines activation of c-MET and RON by their ligands was inhibited by AMC303 in vitro and consequently ligand induced cell scattering, migration and invasion was significantly reduced. In endothelial cells, activation of VEGFR-2 and VEGF-A induced formation of a tubular network was blocked by AMC303 treatment. In vivo treatment with AMC303 inhibited tumor growth in a dose dependent manner. The metastatic spreading of the primary tumor was prevented when animals were treated at early disease stage. Most strikingly, a marked regression of established liver metastases was observed at progressed disease state when animals were treated with AMC303 at 1 mg/kg QOD for 3 weeks. Conclusions: AMC303 inhibits activation of the RTKs c-MET and RON allosterically in different epithelial tumor cells and VEGFR-2 in endothelial cells by extracellular binding to CD44v6. This unique and novel mode of action results in a strong anti-tumor and anti-metastatic effect in vivo which together with its wide safety and tolerability window in preclinical toxicology is strongly supporting the clinical investigation. AMC303 is currently tested in a Phase I study in patients with solid epithelial tumors.

**#4912 Effect of the combined treatment with mifepristone and chemotherapy on breast cancer brain metastases.**Ayelen Rubin,1 Veronica de la Fuente,2 Edgardo Salvatierra,2 Silvia Vanzulli,2 Oswaldo Podhajcer,3 Claudia Lanari,3 Paola Rojas,1 IBYME-CONICET, Buenos Aires, Argentina;2 Facultad de Ciencias Exactas y Naturales (UBA), Buenos Aires, Argentina;3 Instituto Leloir, Buenos Aires, Argentina;4 Academia Nacional de Medicina, Buenos Aires, Argentina.

The treatment of brain metastasis is limited due to the drug’s inability to cross the blood brain barrier, because of the presence of endothelial cells’ multidrug resistance efflux transporters, such as the P-glycoprotein (P-gp). The antiangiogenic Mifepristone (MPP) is known to inhibit the P-gp activity. We hypothesize that a combination of MPP and Pegylated doxorubicin liposomes (doxo) improves the drug efficacy on breast tumors that do not express progestrone receptors. Using the metastatic triple negative MDA-231-BRM2 breast cancer cell line, transfected with GFP and luciferase, we explored different protocols to generate tumors growing in the brain of NSG mice. Spontaneous metastases were obtained by subcutaneous injection (sc) of 2 x 10^6 cells, and experimental metastases by intracardiac injection (ic) of 1 x 10^6 cells or by intracranial injection of 2 x 10^6 cells. In the ic and sc models small and scattered brain metastases as well as liver, lung and kidney metastases were observed. The intracranial model enabled us to obtain measurable brain tumors in a short time. Thus we selected this method to evaluate the effect of MPP (6 mg pellets, sc) and doxo (4.5 mg/kg, iv) on tumors growing in the brain. Treatment was initiated 10 days after cell inoculation. The amount of tumor cells after brain excision was measured by flow cytometry (GFP) and by lumimetry (luciferase activity). A decreased luminescence signal was observed in brains from mice treated with both agents as compared with the control mice (p<0.05), whereas no effects were observed between the single treatment groups and the controls. Moreover, the flow cytometry analysis showed that the combined treatment, MPP+doxo, reduced the number of tumor cells further than the single chemotherapeutic agent (p<0.05). Our data suggest that MPP may be a promising agent to treat brain metastasis of breast cancers, which do not necessarily express progestrone receptors, to increase the effectiveness of chemotherapeutic agents. The participation of the P-gp mediating this effect needs to be confirmed.

**#4913 Invasive melanoma cells commandeer p53 activity to promote the survival of a therapy resistant subpopulation.**Marie R. Webster,1 Amanpreet Kaur,1 Abbibatou Ndoye,2 Curtis Kugel,1 Subhasee Basu,1 Alexander Valiga,1 Fuente,2 Edgardo Salvatierra,2 Silvia Vanzulli,2 Oswaldo Podhajcer,3 Claudia Lanari,3 Paola Rojas,1 IBYME-CONICET, Buenos Aires, Argentina;2 Facultad de Ciencias Exactas y Naturales (UBA), Buenos Aires, Argentina;3 Instituto Leloir, Buenos Aires, Argentina;4 Academia Nacional de Medicina, Buenos Aires, Argentina.

Metastatic melanoma is highly aggressively and often therapy resistant. Signals which drive acquisition of metastatic properties, such as constitutive activation of p53, are key promoters of metastasis and therapy resistance. Therapy resistant melanomas are characterized by high levels of the pro-invasive non-canonical Wnt molecule, Wnt5A. Previously, we described an adaptive stress response in highly invasive melanoma cells, which is characterized by a growth arrest and an increase in senescence markers, yet these cells retain the ability to invade and form colonies. These highly invasive cells do not undergo apoptosis following treatment with DNA damaging agents such as doxorubicin and are resistant to BRAFT350E2 targeted therapy. Recently, Lukić et al. have shown that p53 expression promotes survival of colorectal cancer cells via p21 expression and a reversible cell cycle arrest, allowing for repair of damaged DNA. Here, we show that highly invasive and therapy resistant melanoma

Proceedings of the American Association for Cancer Research • Volume 58 • April 2017

1257
cells express Wnt5A, p53 and p21, which regulate proliferation and slow cycling in invasive melanoma cells. The expression of p53 is promoted by Wnt5A, knock down of Wnt5A decreases p53 and p21 expression in these cells and decreases the number of cells arrested in G2/M following DNA damage. The cell cycle and apoptotic functions of p53 are highly regulated. iASPP, MDMX, and MDM2 have been shown to regulate the function of wild type p53 in melanoma cells. MDM2, an E4 ubiquitin ligase, regulates p53 by shuttling it out of the nucleus and targeting it for proteosomal degradation. We found that MDM2 expression increases in invasive melanoma cells following DNA damage, however, in these cells it is phosphorylated at serine 395. Phosphorylation of MDM2 at ser395 blocks its ability to export p53 from the nucleus, leading to increased p53 expression. We also found that p53 expressing cancer cells targeting p53 were capable of cell cycle arrest and survival following stress instead of apoptosis. The apoptotic function of p53 has been shown to be inhibited by nuclear iASPP, which is enriched in metastatic melanoma. We found that knocking down Wnt5A in invasive melanoma cells decreases the expression of iASPP. These data suggest that Wnt5A promotes MDM2 Ser395 phosphorylation and iASPP expression, blocking down regulation of p53 and its apoptotic function, while promoting cell cycle arrest and survival following stress. These data may reveal a mechanism by which highly invasive melanoma cells evade therapy to form therapy resistant sub-clones at distant sites.

**#4914** Luteolin inhibits metastasis of triple-negative breast cancer cells to the lungs. Matthew T. Cook,1,2 Yaoxin Liang,1 Cynthia Besch-Williford,3 Salmon Hyder1.3

1Washburn University, Topeka, KS; 2University of Missouri, Columbia, MO; 3IDEXX BioResearch, Columbia, MO.

Triple-negative breast cancers (TNBC) are basal-like tumors which lack the traditional pharmacological targets ER, PR and HER2. Most TNBC related deaths occur following metastasis of cancer cells, and development of tumors at secondary sites such as the lungs and bones. Since TNBC lacks ER, PR and HER2, non-specific chemotherapeutic agents are administered to these women, who generally present with early metastatic lesions that originate from drug-resistant residual cells, and have poor prognosis. Consequently, novel therapeutic strategies are sought. Luteolin (LU) is a naturally occurring, non-toxic plant compound that has proven effective against several types of cancer, though its effects against cancers of the breast remain unknown. With this in mind we conducted studies, both in vivo and in vitro, to determine whether LU might suppress metastasis of TNBC. In vivo studies were performed using MDA-MB-231 (4175) LM2 cells, a subpopulation of clinically relevant cells (kindly provided by Dr. J. Massagué; Minn et al. 2005: 436:518-24). MDA-MB-231 (4175) LM2 is a particularly aggressive TNBC breast cancer cell line with a molecular signature preferential for lung metastasis. Herein we report that LU effectively suppressed metastasis of MDA-MB-231 (4175) LM2 cells to lung. Compared with animals given MDA-MB-231 (4175) LM2 cells alone, which developed 67.6 ± 27.1 metastatic lung colonies, treatment with 40 mg/kg LU reduced colony formation to 22.8 ± 3.6 (P < 0.035). Confirmation of the anti-metastatic effect of LU was achieved by inoculating animals with an alternative, less aggressive TNBC cell line, MDA-MB-435. Administration of 20 mg/kg LU to animals treated with MDA-MB-435 cells reduced the number of lung colonies from 14.1 ± 1.6 to 5.3 ± 0.5; P < 0.005. When tumor cells were incubated in vitro with different concentrations of LU (50-500 μM), we observed a significant dose-dependent reduction in cell viability, induction of apoptosis (P < 0.001), and decreased tumor cell migration. These data suggest that LU suppresses several steps of the metastatic process. Furthermore, relatively low levels (10 μM) of LU significantly inhibited VEGF secretion from tumor cells (P < 0.001), suggesting that the flavonoid has the ability to suppress a potent angiogenic and cell survival factor. In addition, when tumor cells were exposed to either LU or VEGF receptor (KDR) antibody, a similar reduction in TNBC migration potential was observed. This suggests that the anti-tumor actions of LU may, in part, be due to its ability to reduce VEGF levels and block KDR receptor-mediated activity, thereby inhibiting tumor cell migration. These studies demonstrate that the use of LU, a non-toxic, plant derived compound, deserves further investigation as a treatment option for women with TNBC Supported by a COR award from the College of Veterinary Medicine, and in part by funds from generous donors to the Ellis Fischel Cancer Center, University of Missouri.

**#4915** Alcohol-induced reprogramming of tumor plasticity is mediated via suppression of CCN5 signaling in breast cancer cells. Inamul Haque,1 Arvind Subramanian,1 Vijayalakshmi Gupta,1 Sandipito Sarkar,1 Snigdha Banerjee,1 Sushanta K. Banerjee2.1 1University of Kansas Medical Center/Kansas VA Medical Center, Kansas City, MO; 2Kansas City VA Medical Center, Kansas City, MO.

Background and Objective: The epidemiological and experimental studies suggest that alcohol consumption is associated with increased risk for breast cancer development and metastasis. However, the mechanisms of alcohol-induced breast cancer progression and metastasis remain unknown. In this study, we examined the roles of CCN5, a tumor suppressor gene in alcohol induced breast cancer cell migration/invasion, epithelial to mesenchymal transition (EMT) and stemness. Methods: Estrogen receptor-positive (ER+) human breast cancer cell line MCF-7 and ER negative human breast cancer cell line MDA-MB-231 were treated with ethanol at various concentrations in the presence and absence of human recombinant human CCN5 protein (hrCCN5). Invasive/migratory ability of treated and untreated cells was measured by Boyden chamber assays. The mRNA and protein expression level of CCN5 was determined by real-time qRT-PCR and Western blot. EMT and stemness markers were evaluated by Western blot. Single-cell suspensions from pre-treated cells were suspended at a density of 500 cells/ml in mammosphere media in ultralow attachment dishes. Number as well as the size of the mammosphere in specified experimental set-up was monitored and recorded alternate day for 8-10 days. Results: The studies demonstrated that alcohol promotes significantly the invasive/migratory ability and EMT phenotypes of breast cancer cells through the suppression of CCN5. Interestingly, hrCCN5 protein treatment suppresses the effect of alcohol and reprograms MET (mesenchymal to epithelial transition). In addition, alcohol-induced mammosphere formation efficiency is also suppressed by hrCCN5 protein-treatment. Conclusions: Our findings suggest that the CCN5 signaling plays a preventive role in alcohol-induced reprogramming of tumor plasticity in breast cancer cells.

**#4916** E3 ubiquitin ligase Cbl-b prevents tumor metastasis by maintaining the epithelial phenotype in multiple drug-resistant gastric and breast cancer cells. Ling Xu, Xiujuan Qu, Ye Zhang, Xiaofang Che, Tianshu Guo, Ying Cai, Aodi Li, Danni Li, Ge Li, Ti Wen, Yibao Fan, Kezuo Hou, Yanju Ma, Xuejun Hu, Yupeng Liu. China Medical University, Shenyang, China.

Background: Multiple drug resistance (MDR) and metastasis are two major unfavorable factors causing failure of cancer treatment. However, the relationship between MDR and metastasis is not characterized. Additionally, the role of the E3 ubiquitin ligase Cbl-b in metastasis of gastric and breast cancer is little known. Methods: The effect of Cbl-b on tumor invasion and metastasis was analyzed in P-gp-positive gastric adenocarcinoma tissues. Transfections of Cbl-b WT and epidermal growth factor receptor (EGFR) WT plasmid were used to assess Cbl-b and EGFR involvement in epithelial-mesenchymal transition (EMT) and tumor metastasis. Results: MDR gastric and breast cancer cells possess a typical mesenchymal phenotype and an enhanced cell migration capacity. Additionally, Cbl-b is poorly expressed in MDR gastric and breast cancer cells. We performed immunohistochemical analysis on P-gp-positive gastric adenocarcinoma tissues and identified associations between Cbl-b expression and clinical pathological parameters. Gastric cancer patients with low Cbl-b expression were more likely to have tumor invasion (P = 0.016) and lymph node metastasis (P = 0.007). Moreover, over-expression of Cbl-b reduced cell migration in MDR cell cultures both in vitro and in vivo. Cbl-b over-expression also prevented EMT by inducing ubiquitination and degradation of EGFR, leading to inhibition of the EGFR-Akt/miR-200c-ZEB1 axis. However, further over-expression of EGFR on a background of Cbl-b over-expression restored both the mesenchymal phenotype and the cell migration capacity of MDR gastric and breast cancer cells. These results suggest that Cbl-b is an important factor for maintenance of the epithelial phenotype and inhibition of cell migration in MDR gastric and breast cancer cells.

**#4917** Therapeutic inhibition of Notch1 in metastatic prostate cancer. Meghan A. Rice, En-Chih Hsu, Tanya Stoyanova. Stanford University, Palo Alto, CA.

Metastatic castration-resistant prostate cancer (CRPC) is the primary cause of prostate cancer specific mortality, and is currently incurable. Defining new mechanisms that can predict progression and drive lethal CRPC is critical. Notch1 receptor, a cell surface-signaling molecule dysregulated in many cancers, is highly expressed in CRPC. Chronic activation of Notch1 synergizes with multiple oncogenic pathways altered in early disease to promote the development of poorly differentiated metastatic prostate carcinoma. Consistent with its activation in clinical CRPC, tumors driven by NICD1 in combination with alternative pathways altered in prostate cancer are metastatic and resistant to androgen deprivation. Genetic and pharmacological inhibition of Notch1 activity decreases cell proliferation and colony formation of 22Rv1 prostate cancer cells in vitro. 22Rv1 subcutaneous xenograft growth was significantly impaired by treatment with pharmacological inhibitors of Notch1 activation over the course of 20-day treatment. Further, Notch1 inhibition in combination with other standard prostate cancer treatments compounded efficacy of individual treatments to attenuate colony formation potential of prostate cancer cells in vitro. The Notch1 signaling axis, confirmed to synergize with multiple pathways to pro-
mote metastatic CRPC already provides a novel pathway for diagnostic stratification of prostate cancer patients. Our studies additionally implicate Notch1 as a therapeutically relevant target for aggressive prostate cancer.

**#4918** Livin is a pro-apoptotic gene of mucinous adenocarcinoma. Mohammed Faruk,1 Abdulmumin Hassan Rafindadi,1 Sani Ibrahim,1 Surajo Mohammed Aminu,1 Surajo Mohammed Aminu,1 Ahmed Adamu,1 Ahmed Adama,1 Yawale Biyaya,1 Adamu Abdullahi,1 Mohammed Sanm Shesu,1 Abdullahi Mohammed,1 John Idoko,1 Abdullahi Jibril Randawa,1 Abdullahi Jibril Randawa,1 Atara Ntekim,2 Saad Aliyu Ahmed,1 Aishatu Suleiman Maude,1 Almustapha Aliyu Liman,1 Abubakar Sani,1 Khalid Zahir Shah,1 Yahaya Ukwenya,1 Yahaya Ukwenya,1 Cheh Augustine Awasum,1 Kasimu Umar Adoke,1 James Olowu Enemari,1 James Olowu Enemari,1 Andrew Jonathan Nok1.

Livin, or mucin 1 (MUC 1), is a transmembrane cell surface protein that is expressed in the majority of human breast tumors. Several studies have suggested that MUC1 is involved in the development of specific breast tumors, and that its expression is associated with poor prognosis. In this study, we investigated the expression pattern of Livin in a large cohort of breast cancer patients.

**#4919** Ablation of neuropilin 1 from glioma-associated microglia and macrophages slows tumor progression. Jeremy T. Miyauchi,1 Danling Chen,1 Matthew K. Choi,1 Kenneth Shroyer,1 David Selwood,2 Stella E. Tsirka2,1 Stony Brook University, Stony Brook, NY; 2University College London, London, United Kingdom.

Glia and macrophages play significant roles in glioma progression and metastasis. Neuropilin-1 (NRP1) is a transmembrane receptor expressed on many types of cells, including glioma-associated macrophages (GAMs). NRP1 has been implicated in tumor progression and angiogenesis.

**#4920** Inflammation and estrogen receptor beta modulate bacterial diversity of the gut. Ahmed F. Ibrahim,1 Quentin Thomas,2 Ashish Saxena,3 Cecilia Williams1. 1The Royal Institute of Technology, KTH, Solna, Sweden; 2KTH, Solna, Sweden; 3University of Houston, Houston, TX.

Gut microbiota is an important contributor to health and disease. The composition of the gut microbiota is influenced by various factors, including diet, age, and sex. In this study, we investigated the effect of inflammation and estrogen receptor beta (ERβ) on gut microbiota composition in mice.

**#4921** The adhesion protein JAM-A is important for maintenance of tumor dormancy. Sri Harikrishna Vellanki, Rodrigo G. Cruz, Ann M. Hopkins, RCS, Dublin, Ireland.

Tumor dormancy is a critical stage in cancer progression, where cancer cells can persist for extended periods without growing or metastasizing. The adhesion protein JAM-A has been implicated in tumor dormancy, but its exact role is not fully understood.

**#4922** The adhesion protein JAM-A is important for maintenance of tumor dormancy. Sri Harikrishna Vellanki, Rodrigo G. Cruz, Ann M. Hopkins, RCS, Dublin, Ireland.

Tumor dormancy is a critical stage in cancer progression, where cancer cells can persist for extended periods without growing or metastasizing. The adhesion protein JAM-A has been implicated in tumor dormancy, but its exact role is not fully understood.
cations of TPA. Furthermore, the upregulation of the chemokines Cxcl1 and S100a8 in response to TPA was deficient in MyD88 null cultured keratinocytes revealing a necessary role for MyD88 in the intrinsic response of keratinocytes to phorbol ester. We also uncovered a systemic requirement for MyD88 in carcinogenesis since lineage specific ablation of MyD88 in T cells conferred significant resistance to lethal chemotherapy. Exposure of alveolar macrophages to TPA induced the expression of IL-17 by the T cells in TPA treated MyD88 null mouse skin. IL-17 treatment of normal primary keratinocytes increased their proliferation while reducing their response to calcium-induced differentiation but had no effect on the proliferation of RAS-keratinocytes. The atypical nuclear IkBzeta protein can act as an activator of so-called secondary NF-kB response genes. IkBzeta deficiency blocked the keratinocyte proliferative response to IL-17 but had no effect on altered differentiation. Finally, both IL-17 and oncogenic RAS required IkBzeta to upregulate the expression of S100a8, lipocalin2 and Steap4 mRNAs. Collectively, these results demonstrate that MyD88 plays a pro-tumorigenic function during tumor promotion in both epithelial and T-cell compartments and that IL-17/IkBzeta could play a facilitating role on keratinocytes during tumor promotion beyond its pro-inflammatory activity.

#4923 MyD88 and IL-17 have essential local and systemic functions in promoting tumors on mouse skin. Mary Klotzerman, Christophe Cataisson, Rosalba Salcedo, Kelly Shibuya, Jennifer Waters, Giorgio Trinchieri, Stuart H. Yuupa. National Cancer Institute, Bethesda, MD.

NF-kB has been causally implicated with cancer-associated inflammation. In the skin, ligands of the Toll-like receptor/IL-1 receptor superfamily induce the recruitment of MyD88 (Myeloid differentiation primary response gene 88), ultimately leading to NF-kB activation. We previously reported that MyD88 is required for two stage chemical carcinogenesis on mouse skin, and that MyD88 exerts a cell-intrinsic function in RAS-mediated transformation of keratinocytes (Ras-keratinocytes). Now, we explore the role of MyD88 during tumor promotion with 12-O-tetradecanoyl-phorbol-13-acetate (TPA). Epidermal hyperplasia is reduced in MyD88 deficient mice relative to controls after multiple applications of TPA. Furthermore, the upregulation of the chemokines Cxcl1 and S100a8 in response to TPA was deficient in MyD88 null cultured keratinocytes revealing a necessary role for MyD88 in the intrinsic response of keratinocytes to phorbol ester. We also uncovered a systemic requirement for MyD88 in carcinogenesis since lineage specific ablation of MyD88 in T cells conferred significant resistance to lethal chemotherapy. Exposure of alveolar macrophages to TPA induced the expression of IL-17 by the T cells in TPA treated MyD88 null mouse skin. IL-17 treatment of normal primary keratinocytes increased their proliferation while reducing their response to calcium-induced differentiation but had no effect on the proliferation of RAS-keratinocytes. The atypical nuclear IκBzeta protein can act as an activator of so-called secondary NF-kB response genes. IκBzeta deficiency blocked the keratinocyte proliferative response to IL-17 but had no effect on altered differentiation. Finally, both IL-17 and oncogenic RAS required IκBzeta to upregulate the expression of S100a8, lipocalin2 and Steap4 mRNAs. Collectively, these results demonstrate that MyD88 plays a pro-tumorigenic function during tumor promotion in both epithelial and T-cell compartments and that IL-17/IκBzeta could play a facilitating role on keratinocytes during tumor promotion beyond its pro-inflammatory activity.

#4924 Adh1bΔ/Δ×Cyp26b1Δ/Δ activity of CD90+ (myo)fibroblasts supports tumor-promoting inflammation in colorectal cancer. Romain Villerè,1 Gabriella Urbe,1 Judy A. Trieu,1 Paul Johnson,1 Suimin Qiu,1 Don W. Powell,1 Ellen J. Beswick,2 Jinyu V. Pinchuk,3 University of Texas Medical Branch, Galveston, TX; University of New Mexico, Albuquerque, NM.

Introduction. Retinol (RO) and its active metabolite, all-trans retinoic acid (atRA), have been widely studied as cancer chemotherapeutic agents. atRA is a critical immunoregulatory molecule reported to decrease cancer cell proliferation and inhibit tumor-promoting inflammation. However, recent studies report a lack of efficacy of atRA treatment to counteract colorectal cancer (CRC) progress, and the mechanisms underlying this failure are not fully understood. Alcohol dehydrogenase 1B (ADH1B), a major isofrom of alcohol dehydrogenase expressed in normal colon, is responsible for the conversion of RO to atRA.

We recently reported that stromal (myo)fibroblasts are major ADH1B expressers in normal colonic mucosa and that this expression is lost during the neoplastic transformation process of CRC. Thus, we hypothesized that aberrant retinoid signaling in cancer-associated fibroblasts (CAFs) is among key processes supporting tumor-promoting inflammation in CRC. Methods. Real-time PCR, confocal microscopy and cytokine luminex arrays were used to evaluate alterations in retinoid pathway gene expression and activity to define its relevance to the tumor-associated inflammation in human normal and CRC colonic tissues, and in normal primary (myo)fibroblasts (N-CMFs) and CAFs. Results. We observed a strong downregulation of ADH1B expression in CAFs in situ and in culture along with an increased expression of the tumor growth promoting inflammatory cytokine IL-6. Addition of the ADH1B substrate, RO, or its metabolite, atRA, to N-CMF cultures decreased the LPS-inducible IL-6 expression by N-CMFs. No downregulation of LPS-inducible IL-6 expression by RO was observed in CAFs, while atRA treatment partially inhibits IL-6 expression. Silencing of adh1b gene in N-CMFs led to the increased production of the LPS-inducible IL-6. This suggests that lack of ADH1B expression in CAFs prevents cancer-promoting inflammation in the induction of IL-6.

A decrease in downstream enzyme ALDH1A1 expression, which converts ADH1B’s byproduct retinaldehyde, to atRA, was also observed in CAFs. Finally, only a partial inhibition of IL-6 production by exogenous atRA was observed in CAFs. When compared to N-CMFs, CAFs expressed higher levels of CYP26B1, a cytochrome that is responsible for atRA degradation. Treatment of CAFs with atRA resulted in an eight fold higher upregulation of CYP26B1 expression than in N-CMFs. Conclusions. Taken together, our data suggests that CYP26B1 overexpression in CAFs along with ADH1B downregulation support aberrant retinoid acid metabolism in CRC. Adh1bΔ/Δ×Cyp26b1Δ/Δ activity of CAFs leads to a decrease of atRA availability in the tumor microenvironment, supporting IL-6-driven tumor growth promoting inflammation and resistance to exogenous atRA as a chemotherapeutic agent in CRC.

#4925 Microbiome-TP53 gene interaction in human lung cancer. Leigh Greathouse,1 James White,2 Valery Bliskovsky,3 Ashley Vargas,4 Eric Polley,4 Elise Bowman,4 Mohammed Khan,4 Ana Robles,4 Brid Ryan,4 Amiran Dzutsev,3 Giorgio Trinchieri,3 Marbin Pineda,3 Paul Meltzer,3 Marina Walther-Antonio,4 Garth Ehrlich,4 Joshua Mell, 5 Joshua Earl, 5 Sergey Balashov,5 Archana Bhat,5 Alex Valm,6 Clayton Deming,6 Sean Conlan,6 Julia Oh,7 Julie Segre,7 Curtis Harris3. Baylor Univ., Waco, TX; 2Rashera Biosciences, Inc., MD; 3National Cancer Institute, Bethesda, MD; 4Mayo Clinic, Rochester, MN; 5Drexel University, Philadelphia, PA; 6National Human Genome Research Institute, Bethesda, MD; 7Jackson Laboratory, Framingham, CT.
Lung cancer is the leading cancer diagnosis worldwide and the number one cause of cancer deaths. Exposure to cigarette smoke, the primary risk factor in lung cancer, reduces epithelial barrier function and increases susceptibility to infections. Herein, we hypothesized that somatic mutations together with cigarette smoke create a dysbiotic microbiota that is associated with lung carcinogenesis. To assess the association of the abnormal microbiome with lung cancer, we conducted 16S rRNA gene sequencing (MiSeq), with RNA-seq data from lung cancer tissues in The Cancer Genome Atlas (n = 1112) serving as the validation cohort. We demonstrate a lower alpha diversity in normal lung as compared to non-tumor adjacent or tumor tissue, indicating a shift in the overall microbial community in lung cancer patients as compared to those without cancer. Lung cancer cases were classified by the relative abundance of two taxa, Variovorax and Streptococcus, with an increase in Variovorax abundance in tumors as compared to non-tumor adjacent paired lung tissue (FDR corrected P = 0.013). The species of Variovorax was identified histologically, and also by two additional 16S rRNA strategies (Resphera Insight analysis and PacBio sequencing). A group of taxa were associated with squamous cell carcinoma (SCC), of which Acidovorax were enriched in smokers (P = 0.013). Further, these taxa, including Acidovorax, exhibited higher abundance among the subset of SCC cases with TP53 mutations, an association not seen in adenocarcinomas (AD). Therefore, we observed a microbiome-gene and a microbiome-exposure interaction in SCC lung cancer tissue. Together, these results open the door for future biomarker research that could be used to improve screening and direct mechanistic studies of lung cancer therapy.

#4926 Gut microbiota regulates cisplatin mediated cachexia and systemic toxicity. Soumen Roy,1 Rodrigo Das Neves,1 Amiran Dzutse,1 Carolynne Smith,1 Bathai Edwards,1 Miranda Dawson,1 Simone Dilippanthom,2 Loretta Smith,2 April Huang,1 Young Kim,1 Giorgio Trinchieri,1,11,15 NCI, CIP, Bethesda, MD;1,16 LSP, NCI, Bethesda, MD;1 Division of Cancer Prevention, NCI, Bethesda, MD.

Chemotherapy induced toxicity severely affects the cancer survivors and lowers the quality of life. By 2020, there will be more than 18 million of cancer survivors all over the world. Majority of them might develop long term nephrotoxicity, ototoxicity and gut toxicity. In addition, chemotherapy may facilitate the initiation and progression of cachexia. Recent studies have shown that gut microbiota modulates the efficacy of anti-cancer chemotherapy, however very limited knowledge is available regarding the role of gut microbiota in regulating systemic toxicity and cachexia. We hypothesized that gut microbiota modulates cisplatin induced systemic toxicity as well as cachexia. Four groups (n = 10 in each group) of 6-8 weeks old C57Bl/6 mice were treated with cisplatin, cisplatin + antibiotics cocktails (ABX), ABX only and control. ABX cocktail contained primaxim, vancomycin and neomycin. This experiment was validated using C57Bl/6 germ free mice. We performed anti-p-γ-H2AX based toxicity assay for DNA damage. In addition, we performed immunohistochemistry for Studying cachexia. H&E staining and DNA damage were assessed by light and super resolution confocal microscopy (Zeiss 880) and quantified by 3-D reconstruction using IMARIS. We also performed high content imaging to evaluate DNA damage in bone marrow and spleen. Body weight and kidney blood content were also analyzed to determine the degree of toxicity. Depletion of gut microbiota abrogated cisplatin mediated nephrotoxicity and gut toxicity. Importantly, we found that depletion of gut microbiota prevents muscle and adipose tissue loss by down-regulating UCP-1/and PGC-1α in adipose tissue and MURF-1 and Atrogin-1 in muscle. Experiments are confirmed by using Germ free mice. Our data suggest that modulation of gut microbiota may be utilized to reduce chemotherapy associated cachexia and systemic toxicity.

#4927 Presence of genotoxic and/or pro-inflammatory bacterial genes in stool is associated with colorectal neoplasia. Maria Gonzalez-Pons,1 Michelle Cruz-Badia,2 Ramon Gomez-Moreno,2 Abel Baerga-Ortiz,3 Marcia Cruz-Correia,4 University of Puerto Rico Comprehensive Cancer Center, San Juan, PR;2 University of Puerto Rico Medical Sciences Campus, San Juan, PR.

Despite increasing adherence to routine screening and advances in therapeutic strategies, CRC is the 3rd and 4th leading cause of cancer-related death in Puerto Rico and the United States (US), respectively. Currently, CRC screening is the primary means for prevention; however, 60% of CRC patients are diagnosed at more advanced, less treatable stages, which emphasize the need for novel CRC prevention and risk stratification strategies. The etiology of CRC is complex and still incompletely understood. However, environmental factors including diet, the gut microbiota, and inflammation are accepted as major contributors to colorectal carcinogenesis. It has been shown that individuals with CRC have a distinct gut microbiota, but the mechanisms by which gut bacteria exert their CRC-promoting effects remains elusive. Certain pathogenic bacterial strains carry genes encoding toxins that promote DNA damage and perpetuate inflammation, yet the association of these toxins to CRC remains poorly understood. The aim of this study was to gain insight into the association and possible mechanisms by which a subset of the gut microbiota contribute to colorectal carcinogenesis by profiling six genes encoding genotoxic and/or pro-inflammatory bacterial toxins in stool from individuals with and without colorectal neoplasia (adenoma and CRC). The association between the genes encoding toxins and CRC was examined by characterizing the toxic colonic bacterial gene profile in stool samples from healthy individuals (controls) and individuals with colorectal neoplasia (cases). Stool samples from individuals in the mainland US (n = 20) and Caribbean Hispanics (n = 33) living in Puerto Rico were provided by the NCI Early Detection Research Network and the Puerto Rico Familial Colorectal Cancer Registry, respectively. Detection pks, TpC, GeElf, cnf-1, murB, and usp in stool were performed with specific primers. Associations were assessed using odds ratios. Four of the six toxic genes were detected more frequently in stool samples from individuals in the US with colorectal neoplasia (controls = 10; adenoma = 10); adenoma = 10). Results show borderline statistical significant associations (p = 0.07) with the presence of usp and 2 genes and a higher odds of colorectal neoplasia (OR = 5.44 and OR = 9.33, respectively). In the cohort from our Caribbean Hispanic subjects (controls = 13; adenomas = 12; CRC = 8), individuals with the presence of GeEl were 8.6-times more likely to have adenomas (p = 0.07) and individuals with ≥ 2 of the genes were 11.3-times more likely to have CRC than individuals without these genes (p = 0.04). Analysis with a larger number of samples will be necessary to determine a more definite association between the presence of the toxic genes in this panel in stool and colorectal neoplasia. Additional mechanistic analysis will be required to fully understand how these bacterial toxins contribute to colorectal carcinogenesis.

#4928 Impact of E. hirae on the tumoricidal activity of cyclophosphamide. Romain Daillère, Marie Vetzizou, Laurence Zitvogel, Gustave Roussy, Villejuif, France.

The tumor microenvironment is influenced by anticancer therapies, and even more so by those affecting the gut homeostasis. We previously reported that a deviated repertoire of the intestinal microbiome called « dysbiosis », caused by broad spectrum antibiotics compromised the efficacy of cyclophosphamide (CTX), an immunomodulatory alkylating agent exerting cytotoxic effects against cancer, highlighting the importance of the gut microbiota in this mechanism (Viaud, Science, 2013). CTX is responsible for disrupting the gut barrier integrity as well as intestinal homeostasis, allowing a NOD2-dependent translocation of several Gram-positive bacteria into secondary lymphoid organs. CTX breaks the intestinal tolerance towards the intestinal microbiota and leads to immunization of the host against some bacterial strains. Here, we identified a Gram positive bacteria, Enterococcus hirae, which markedly modulates the intestinal and systemic immunity through the elicitation of bacterial-specific Th1 and pathogenic Th17 cells. Moreover, we have shown that E. hirae is capable of enhancing tumor-specific CD4+ and CD8+ T cell responses against candidate tumor antigens. In parallel, we have demonstrated that intestinal epithelial cells NOD2 receptors represent " gut immune checkpoints " restricting the immunogenicity of E. hirae. Finally, E. hirae specific-memory Th1 immune responses selectively predicted longer progression-freesurvival in advanced lung or ovarian cancer patients treated with immunotherapy and chemotherapy (platinum salts- or CTX-based chemotherapy) (Daillère, Immunity, 2016). Altogether, E. hirae represents a valuable probiotic against cancer, an oncomicrobiotic ameliorating the efficacy of the most common alkylating immunomodulatory compound.

#4929 Cooperation between the microbiota and oncogenic mutations leading to the development of colon cancer. Dana Van De Hey, Susan Payne, Cheri Pasch, Linda Clipson, Kristina Matkowskyj, Dustin Deming. University of Wisconsin Carbone Cancer Center, Madison, WI.

Background: The microbiome of the colon has been shown to play a role in colon cancer tumorigenesis. Inflammation is a key step in the formation of tumors, and it is possible that microbiota induce this inflammation, further stimulating tumor growth. The interaction between mutant cells in the colon and the microbiota has been understudied. We hypothesized that eradication of the intestinal microbiota could prevent tumorigenesis in the colon despite the presence of oncogenic, MMR-deficient tumor initiating cells (CTXM) in a transgenic murine model in which a constitutively active PI3K is expressed in the intestinal microbiota could prevent tumorigenesis in the colon despite the presence of oncogenic, MMR-deficient tumor initiating cells (CTXM) in a transgenic murine model in which a constitutively active PI3K is expressed in

TUMOR BIOLOGY: Tumor Microenvironment

Proceedings of the American Association for Cancer Research • Volume 58 • April 2017 1261
frequency and median lifespan of 101 days, compared to 100% frequency and 86.5-day lifespan of control mice (p < 0.001). In the tumors that formed there was no difference in the epithelial mesenchymal transition (EMT), K67 index, nuclear localization of CTNNB1, or activation of the PI3K/AKT/mTOR signaling pathway. FCA3K3 spheroid and mouse models portrayed ineffectiveness of vancomycin through the absence of spheroid diameter change and also 100% frequency of both treated and control mice. Conclusion: The above results indicate that colon cancers induced by PIK3CA mutations are at least partially dependent on the microbiota for tumorigenesis. This dependence appears to be overcome in the setting of both APC and PIK3CA mutations.

**#4930 Genetic and epigenetic characteristics of esophageal cancer tissues with microbiome fusobacterium nucleatum**
Yoshifumi Baba, Kensaue Yama-mura, Shigeaki Nakagawa, Kosuke Mima, Takatsugu Ishimoto, Masaki Iwatsu, Yasuo Sakamoto, Naoya Yoshida, Hideo Baba. Kumamoto Univ., Kumamoto, Japan.

Background: Research into the microbiome is a rapidly advancing field in human cancers. The gut microbiome has recently been shown to play an important role in health, as well as in diseases such as obesity, inflammatory bowel disease, diabetes, non-alcoholic fatty liver disease, and several types of cancer. Fusobacterium nucleatum is a component of the human microbiome that primarily inhabits the oral cavity. It causes periodontal disease and has also been implicated in the development of human cancers. We have recently reported that Fusobacterium nucleatum in esophageal cancer tissues was associated with shorter survival, suggesting a potential role as a prognostic biomarker. In addition, our KEGG enrichment analysis using microarray data showed that Fusobacterium nucleatum might also contribute to aggressive tumor behavior through activation of chemokines such as CCL2. Nonetheless, molecular features of Fusobacterium nucleatum-positive esophageal cancers have been still unknown. Methods: Using 325 esophageal cancers, we detected Fusobacterium nucleatum DNA in 74 tumors (23%). We assessed other genetic and epigenetic events including mutations in KRAS, BRAF, PIK3CA gene, p53 expression, phosphorylated-AKT expression, LINE-1 methylation level (global DNA methylation level), IGF2 DMR0 methylation, MGMT methylation, and MLH1 methylation. Results: The LINE-1 methylation levels of Fusobacterium nucleatum-positive tumors was significantly lower compared with that of Fusobacterium nucleatum-negative tumors (P < 0.0001). In addition, Fusobacterium nucleatum was significantly associated with PIK3CA wild type (P = 0.011). There was no relationship of Fusobacterium nucleatum with KRAS, BRAF mutation, p53 expression, p-AKT expression, IGF2 DMR0 methylation, MGMT methylation, or MLH1 methylation. Conclusion: Fusobacterium nucleatum was related with LINE-1 hypomethylation and PIK3CA wild type. Our findings may shed light on understanding the mechanism by which Fusobacterium nucleatum affects aggressive tumor behavior.

**#4931 Prospective study of oral microbiome and colorectal cancer risk in low-income and African American populations**
Yaochu Yang, Quinyin Cai, Xiao Ou Shu, William J Blot, Wei Zheng, Jirong Long. Vanderbilt University School of Medicine, USA, TN.

Colorectal cancer (CRC) is the third most common cancer in both men and women, and the third leading cause of cancer death in the USA. Recent research suggests that oral microbiome may play important roles in the pathogenesis of colorectal cancer and other chronic diseases. We conducted a nested case-control study within the Southern Community Cohort Study to investigate the association of oral microbiome with subsequent risk of developing CRC. This study included 231 incident CRC cases and 462 controls individually matched on age, race, smoking, alcohol drinking, season-of-study enrollment, and we have low statistical power to investigate them. Conclusion: Our study suggested that multiple bacteria taxa may be associated with risk of CRC, and raised the possibility that the oral microbiome may play an important role in CRC etiology.

**#4932 Oxygen sensing by T cells establishes an immunologically favorable metastatic niche**
David Clever, Nicholas Restifo. The Ohio State University College of Medicine, Columbus, OH; National Institutes of Health, Washington, DC.

Cancer cells must evade immune responses at distant sites to establish metastases. The lung is a frequent site for metastasis. We hypothesized that lung-specific immunoregulatory mechanisms create an immunologically permissive environment for tumor colonization. We found that T cell-intrinsic expression of the oxygen-sensing prolyl-hydroxylase (PHD) proteins is required to maintain local tolerance against innocuous antigens in the lung but powerfully licenses colonization by circulating tumor cells. PHD proteins limit pulmonary type helper (Th1)-1 responses, promote CD4(+) regulatory T (Treg) cell induction, and restrain CD8(+) T cell effector function. Tumor colonization is accompanied by PHD-protein-dependent induction of pulmonary Treg cells and suppression of IFNγ-dependent tumor clearance. T-cell intrinsic deletion or pharmacological inhibition of PHD proteins limits tumor colonization of the lung and improves the efficacy of adoptive cell transfer immunotherapy. Collectively, PHD proteins function in T cells to coordinate distinct immunoregulatory programs within the lung that are permissive to cancer metastasis.

**#4933 Desmin+ pericyte subpopulations correlated with blood-tumor barrier permeability in brain metastases of breast cancer**
Brunilde Gril, Tiffany Lyle, Paul R. Lockman, Chris E. Adkins, Afroz Shareef Mohammad, Emily Sechrest, Emily Hua, Diane Palmieri, Seth M. Steinberg, Wojciech Kloc, Ewa Izycka-Swiweszka, Renata Duchnowska, Nayyar Naema, Priscilla K. Brastianos, Patricia S. Steeg. 1. NCI-CCR, Bethesda, MD; 2. Vanderbilt University College of Veterinary Medicine, West Lafayette, IN; 3. West Virginia University Health Science Center, Morgantown, WV; 4. NCI-CR, Bethesda, MD; 5. University of Warmia & Mazursia University, Olsztyn, Poland; 6. Medical University of Gdañsk, Gdańsk, Poland; 7. Institute of Medicine, Warsaw, Warsaw, Poland; 8. Massachusetts General Hospital Cancer Center/Harvard Medical School, Boston, MA.

Breast cancer brain metastases remain incurable. The blood-brain barrier (BBB) is a multicellular dynamic structure regulating exchanges between the blood and the central nervous system. As cancer cells colonize the brain, the BBB evolves into a blood-tumor barrier (BTB). The BTB limits compound penetration and therefore contributes to poor efficacy of chemotherapy. While the BBB has been well characterized in developmental and neurodegenerative disease studies, the BTB composition remains unknown. We characterized the BTB in three model systems of brain metastasis of breast cancer developed in the laboratory: a triple negative (231-BR6), and two HER2 overexpressing (SUM190-BR3, JIMT1-BR3) subtypes. Using Texas Red dextran (TRD) as a marker of permeability and quantitative immunofluorescence staining, we analyzed the cellular and molecular composition of: 1) unaltered BBB vs. BTB, and 2) BTB in highly permeable metastases vs. BTB in poorly permeable metastases. The BTB developed from the BBB in a series of alterations, including a neuroinflammatory reaction with astroglisis, endothelial cell dilation, increased VEGF, reduced astrocyte endfoot polarity, and decrease in PDGF-α receptors. Only 10% of the metastatic lesions harbored a profound TRD exudation, which correlated with paclitaxel efficacy. We hypothesized that specific cellular and molecular changes account for the heterogeneity and increase in TRD diffusion. When metastases with relatively low- and high-TRD diffusion were compared, highly permeable metastases correlated with an increased expression of desmin+ pericytes in three models (231-BR6 p = 0.002; JIMT1-BR3 p = 0.004; SUM190-BR3 p = 0.008) and a decrease in CD13+ pericytes in two model systems (231-BR6 p = 0.014; JIMT1-BR3 p = 0.002). Decreased expression of laminin in the BBB increases tumour cell migration. In our study, JIMT1-BR3 p = 0.049; SUM190-BR3 p = 0.023) were associated with higher permeability. Desmin+ pericytes have been associated with pathological conditions such as fibrosis and spinal cord injury. Seven over nine human craniotomy specimens were positive for Desmin staining, validating clinically the relevance.
of our findings. We subsequently hypothesized that the desmin+ pericyte subpopulation functionally contributes to increased permeability. Desmin+ pericytes were produced in vitro by co-culturing primary mouse pericytes with astrocytes. When desmin+ or CD13+ pericytes were added to in vitro transendothelial electrical resistance (TEER) models of the BBB, the desmin+ pericytes exhibited a permissive, protective and normative effect on BBB permeability. The data suggest that desmin+ pericytes may facilitate the permeability of the BTB. These studies show that the BTB in brain metastasis model systems involves consistent molecular changes. These data may identify new strategies to selectively permeabilize the BTB and enhance chemotherapeutic efficacy.

#4934 Brain metastatic microenvironment reshapes cancer cell metabolism through epigenetic up-regulation of glutamate decarboxylase 1. Patricia M. Schnepf, Dennis D. Lee, Ian H. Guldner, Tressa O'Tighearnaigh, Bhavana Pulakurthl, Kaitlyn E. Eckert, Tiffany A. Toni, Brandon L. Ashfeld, Siyuan Zhang. Univ. of Notre Dame, Notre Dame, IN.

Cancer metabolism has been well documented to influence primary tumor development. Yet, the role of deregulated metabolism in metastasis progression is not well understood. Based on a distinct metabolic transcriptome profile in brain metastases compared to their primary tumor counterparts, we hypothesized that metabolic transcriptome shifting during metastatic evolution is crucial for metastatic success to the brain. Here we show that, despite a global down-regulation of multiple metabolic pathways in the brain metastatic tumors, the expression of the GABA metabolic pathway mediator glutamate decarboxylase 1 (GAD1) is significantly up-regulated. Using cell-based co-culture models for different primary and brain metastatic microenvironments and in vivo brain metastasis models, we demonstrate that down-regulation of DNA methyltransferase 1 (DNMT1) induced by the brain microenvironment results in decreased GAD1 promoter methylation and subsequent up-regulation of GAD1 expression in tumor cells. To dynamically visualize the cellular metabolic responses mediated by GAD1, we utilized the Peroxisome biosensor to monitor the cytosolic NADPH/NAD+ equilibrium in tumor cells using time-lapse imaging. By knocking down GAD1 induced by primary glia co-culture, we abolished the capability of tumor cells to utilize extracellular glutamine, leading to an NADH accumulation in the cytosol and a more oxidative cellular status. Lastly, either loss of GAD1 genetically or targeting GABA metabolic pathway by the repurposing of a neurologic drug, vigabatrin, results in a significant decrease in brain metastasis incidence. Taken together, our results demonstrated that brain microenvironment-specific metabolic shifting through GAD1 promoter demethylation drives brain metastasis outgrowth.

#4935 Development of a human pancreatic tumor microenvironment system (TMeS) for evaluation of novel therapeutics. Daniel G. Gioeli,1 Chelsi Snow,1 Michael Simmers,2 Robert Figler,1 J. Thomase Parsons,1 Stephen H. Snow,2 Michael Simmers,2 Todd Bauer,1 Brian Wamhoff2. 1HemoShear Therapeutics, Charlottesville, VA; 2HemoShear Therapeutics, Charlottetown, PE.

The development of drugs to treat cancer is severely hampered by the inefficiency of translating pre-clinical in vitro and mouse studies into clinical benefit. Over 90% of drugs that progress through pre-clinical studies fail in human trials. Therefore, there is a critical need to improve the accuracy of pre-clinical evaluation of the development of drugs that have the potential to reprogram the metabolism of tumor cells. This is especially the case for pancreatic cancer, the 4th leading cause of cancer deaths with a 5-year survival rate of <6%, where new therapies are desperately needed. The tumor microenvironment (TME) of PDAC contains numerous cell types including vascular endothelial cells, stellate cells and fibroblasts, as well as a complex extracellular matrix (ECM), all of which contribute to the growth and survival of cancer cells, as well as posing potential targets for therapeutic intervention. Thus, a more complete and nuanced understanding of the PDAC TME is required for the rational development of effective therapies. To address this problem, an in vitro tumor microenvironment system (TMeS) was engineered to incorporate tumor capillary hemodynamics and biologic transport with co-cultured human microvascular endothelial cells, along with pancreatic tumor and stellate cells. We demonstrate that significant tumor cell transcriptional changes occur in the TMeS that correlate with the in vivo xenograft transcriptome, including alterations in cell cycle regulation, oncogene signaling, and metabolism. PDAC tumor cells from two patients were inhibited by the human Cmax dose of gemcitabine to levels paralleling the patients' clinical responses. Previous work demonstrated that the EAK inhibitor, PF-362,271, worked only on in vivo xenografts and not on 2D in vitro PDAC cultures and here we show that PF-562,271 effectively inhibited PDAC growth in the TMeS indicating in vivo-like drug responses. In sum, the TMeS recapitulates the in vivo xenograft transcriptional program and responds to both established and experimental small molecule inhibitor chemotherapeutics at concentrations that correspond to human therapeutic plasma levels. Therefore, this model provides a unique platform to rigorously test the contributions of the cellular and molecular components of the TME to manipulating individual constituents in a controlled fashion that is not possible in vivo. Moreover, the TMeS can be used for the rapid evaluation of novel precision therapies. Finally, this system is amenable to using patient tumor material directly, enabling the potential use of the TMeS for patient avatars.

#4936 Modelling clinical issues by using patient-derived xenografts: Evaluation of partial hepatectomy on hepatoblastoma intrahepatic and distant growth. Marcella Cornet,1 Anais Delaître Delattre,2 Laura Brulle Soumare,2 Victoria Boissy,2 Thierry Tordjmann,2 Antoinette Lemoine,2 Olivier Deas,2 Jean-Gabriel Judder,2 Sophie Branchereau,2 Stefano Cairo2. 1Hôpital Bicêtre, Université Paris Sud, Le Kremlin Bicêtre, France; 2XenTech, Evry, France; 2French Institute of Health and Medical Research, Orsay, France; 2Hôpital Paul Brousse - Hôpitaux Universitaires Paris-Sud, Villejuif, France.

Hepatoblastoma (HB) is a rare disease that represents the most frequent liver malignancy during childhood. HB incidence is approximately 1.5 cases per million children less than 15-years old in Western countries. HB is histologically classified as epithelial or mixed depending on the presence of mesenchymal component. The most common epithelial components are the embryonal and fetal phenotype, reminiscent of at early or late stages of liver development. The improvement of the clinical management in the last 30 years has allowed 5-year survival rate to pass from 35 to 85%, due to the introduction of cisplatin-based chemotherapy. More than 50% of tumors are either inoperable or are metastatic at diagnosis. Neoadjuvant chemotherapy allows tumor size reduction and some patients can be used for the rapid evaluation of novel precision therapies. Finally, this system is amenable to using patient tumor material directly, enabling the potential use of the TMeS for patient avatars.

TUMOR BIOLOGY: Tumor Microenvironment 7
tumor morphology, tumor growth, cell population diversity, and tumorigenic potential between tumors grown in orthotopic and subcutaneous environments were dependent on PDX line; and, stromal infiltration and mucin production were more prominent in the orthotopic background for some PDX models. In addition, we observe increased metastatic potential in orthotopic tumor-bearing mice compared with their subcutaneous counterparts. Tumor metastasis occurred in distal filtering organs, including the lung, liver, lymph nodes, and peritoneal cavity, among others. This result is consistent with the observation of increased circulating tumor cells in the blood of orthotopic tumor bearing mice. Comparison of therapeutic efficacy with gencitabine chemotherapy and antibody-drug conjugate (ADC) therapy in orthotopic and subcutaneous tumors showed that therapeutic response was dependent on PDX line. Interestingly, for PDX lines that exhibited morphological differences between orthotopic and subcutaneous backgrounds, treatment was less effective in the orthotopic microenvironment suggesting the microenvironment alters the ability of therapeutics to impede tumor growth. Reduced therapeutic response was also found to be consistent with reduced ADC uptake and vascularity in orthotopic tumors. Taken together, the orthotopic PDX model serves as a more accurate representation of human pancreatic cancer by displaying stromal-rich morphology, exhibiting metastatic cell behavior, and recapitulating therapeutic response challenges observed in patients.

#4938 A vicious cycle between osteoblasts-derived WISP-1 and mesenchymal-like cancer cells is essential to prostate cancer metastasis. An-Chen Chang,1 Show-Mei Chuang,2 Chih-Hsin Yang3, National Chung Hsing University, Taichung, Taiwan, 2China Medical University, Taichung, Taiwan. 

Prostate cancer (PCa) is the most commonly diagnosed malignancy in the United States and other Western countries. It is well established that tumor microenvironment plays an important role in cancer progression and metastasis. Wnt-induced secreted protein-1 (WISP-1) belongs to the CCN family (CTGF/ Cyr61/ Nov) that plays a key role in osteogenesis and tumor growth. We found that prostate-conditional medium (PCa-OBM) stimulated migration and invasion in human PCa cells. Furthermore, the medium was collected 2 days after treatment of osteoblasts with PCa-conditioned medium which were designed as PCa-OBM. The results showed that treatment of PCa cells with PCa-OBM further increased the migration and invasion activity, as well as epithelial- mesenchymal transition (EMT), including the epithelial marker (E-cadherin) down-regulation and mesenchymal marker (N-cadherin and twist) up-regulation. Moreover, human cytokine array was used to measure the secretion of 32 cytokines into PCa-OBM. The data showed that WISP-1 is highly up-regulated with PCa-OBM treatment compared to OBCM. Stimulation of osteoblasts with PCa conditioned media induced WISP-1 expression. In contrast, knockdown WISP-1 in osteoblasts impacted PCa-OBM-mediated cancer migration, invasion, and EMT. In addition, conditioned media from PCa cells was incubated with another cytokine array membranes. The data showed that ADAM-9 and cathepsinL were overexpressed in PCa conditioned media but only ADAM-9 could regulate WISP-1 expression in osteoblasts. Taken together, these results demonstrated that primary PCa-secreted ADAM-9 promotes osteoblasts-derived WISP-1 up-regulation, which in turn enhances primary PCa cells migration, invasion and EMT, resulting in cancer metastasis. Our study suggests that inhibition of osteoblasts-derived WISP-1 is a new therapeutic target for treating metastasis in human PCa patients.

#4939 Activation of GSK3β/β-catenin pathway promotes organ-specific metastasis in prostate cancer. Siyuan Qin,1 Qiong Song,1 Linlu Dai,1 Haibo Tong,1 Evan Keller,1 Jian Zhang,1 Yi Lu1, 1Guangxi Medical Univ., Nanning, China; 2University of Michigan, Ann Arbor, MI.

Metastasis is the major cause of treatment failure in various malignancies, including prostate cancer (PCa). Accumulating data has suggested that primary cancer cells prefer to spread to certain distant organs. To explore the mechanisms of different cancer cells preferentially metastasizing to certain organs, we established a prostate cancer lung metastasis model. Murine prostate cancer cells (RM1) with luciferase gene were injected into left tibia of mouse (C57BL/6J), and monitored the tumor growth and metastasis every week by Bioluminescence Imaging. The mice would be sacrificed when metastatic tumor appeared in multi-organs. We isolated the lung metastatic tumor, made single cell suspension and amplified. The lung metastatic tumor cells were specifically metastasized to lung when the tumor cells were injected intratibially again. After several cycles, we obtained highly lung metastatic tumor cells, named RM1-LM cells. Further, we investigated property and function changes in RM1-LM cells compared to parental cells (RM1) using in vitro assays. We firstly found the highly lung metastatic tumor cells showed more mesenchymal properties. Western blot results showed that hallmarks of EMT including E-cadherin, vimentin, snail, and ZO-1 were altered significantly in RM1-LM cells. Then, we observed that the highly lung metastatic tumor cells exhibited increased proliferative, colony formation, migratory and invasive activity. Mechanistic analyses indicated that prostate cancer organ-specific metastasis mediated by the activation of GSK-3β/β-catenin pathway. Our findings provide critical information on the potential role of GSK-3β in diagnostic and prognostic biomarkers of PCa metastasis. This work was supported by National Science Foundation of China (NSFC) Key Project (81130046); NSFC (81117193; 81272415); Guangxi Projects of China (2013GXNSFAA035004; 2012GXNSFBC030004).

#4940 Exosomal miR-19a: a novel communicator between cancer cell and osteoclast in osteolytic bone metastasis of breast cancer. Kerui Wu,1 Jamie Feng,2 Fei Xing,1 Yin Liu,1 Sambad Sharma,3 Kousouwse Watabe1,4 Wake Forest University School of Medicine, Winston-Salem, NC; 2Shuguang Hospital Affiliated to Shanghai University of Traditional Chinese Medicine, Shanghai, China.

Bone is the most common site for breast cancer (BC) metastasis and relapse. Bone metastasis (BM) causes considerable complications due to osteolytic-mediated bone resorption. Current treatment for osteolysis in BM is limited due to their side effects and inability to extend the patients’ survival. Thus, there is an urgent need for developing early predictive markers and alternative therapies for BC-BM. Recently, circulating miRNAs have been found to harbor great potential for diagnostic and prognostic purposes. Due to the low stability of cell-free RNA in serum, these circulating miRNAs exist mostly in a form of membrane-wrapped extracellular vesicles (EVs) and they play important roles in cancer progression. In this study, we aim to investigate EV-derived-miRNA from serum of BC patients as biomarkers for diagnosis and prognosis of BC-BM. To find the circulating miRNAs that are associated with BC-BM, we applied a four-layer screening system combining bioinformatic analyses and experimental verification. Firstly, 85 BC associated circulating miRNAs were identified to be up-regulated in the serum of 32 BC patients compared to 22 healthy donors. Next, we performed Kaplan-Meier survival analysis for these 85 miRNAs and found that 10 miRNAs were positively correlated with metastases. To select the miRNAs specifically involved in BM, we compared the EVs derived miRNA profiles between bone metastatic cell lines and the parental cell lines (231BoM-1833 vs MDA-MB-231, MCF7-BM2d vs MCF7). Among the 10 miRNAs, only miR-19a was significantly up-regulated in EVs derived from bone metastatic cell lines. MiR-19a was also found to be highly enriched in exosomes compared to microvesicles and apoptotic bodies. Lastly, we verified the high expression of miR-19a in the serum of BC-BM patients compared to the BC patients without BM. To study the role of miR19a in BC-BM, we applied the CRISPR/Cas9 technology to knockout the miR-19a in 231BoM-1833 and MCF7-BM2d cells. The knockout of miR-19a didn’t alter the proliferation or migration of BC cells. However, it significantly decreased bone metastasis in our xenograft mouse models. We also found that the knockout of miR-19a decreased osteolytic lesions in the tumor-bearing bones, indicating the possible role of exosomal miR-19a in osteoclast cells. To test this hypothesis, we treated osteoclast cells with miR-19a-enriched exosomes and miR-19a-knockout exosomes. The results of tartrate-resistant acid phosphatase assay and bone resorption assay indicated that ALP activity and bone resorption were decreased in miR-19a-enriched exosome-treated osteoclasts. These results showed that miR-19a knockdown reduced bone resorption and osteolytic activity. Our study identified exosome derived mir-19a as a mediator of cell-cell communication between breast cancer and osteoclast cell, warranting further investigation on exosomal miR-19a as a novel biomarker and a therapeutic target for breast cancer bone metastasis.

#4941 Lysophosphatidic acid receptor signaling and pancreatic adenocarcinoma tumor microenvironment. Nicholas J. Skill, Mary A. Maluccio. Indiana University, Indianapolis, IN.

Introduction: Changes in lipid biosynthesis has attracted significant attention in the study of cancer. Its value in our understanding of pancreatic cancer has not yet been realized. This study examined lysophosphatic acid (LPA) variant biosynthesis in patients with stage H-III pancreatic ductal adenocarcinoma (PDAC), evaluating serum, bile, and tissue levels of LPA, its receptors, and downstream metabolites. LPA, a product of phospholipase D activity of the enzyme autotaxin (ATX) is a potent mitogenic agent. Data suggests that changes in lipid biosynthesis contribute to the tumor microenvironment in PDAC. Methods: PDAC, matched adjacent non-malignant tissues, gall bladder bile and serum samples were collected from patients with Stage H-III pancreatic cancer at the time of surgery. Control bile and serum were collected from patients undergoing cholecystectomy for benign disease and living renal donors respectively. Results: Serum and biliary LPA levels were increased in patients with PDAC when compared to controls. ATX activity, and LPA receptors, LPAR1, LPAR2, and LPAR3 were greater in PDAC adjacent pancreatic tissue when compared to
#4942 Small molecule inhibition of CXCR4 mobilizes prostate disseminated tumor cells (DTCs) from the chemoprotective bone marrow niche, thereby sensitizing them to chemotherapy. Kenneth C. Valkenburg, Emma E. van der Toom, Kenneth J. Pienta. Johns Hopkins School of Medicine, Baltimore, MD.

Bone metastasis results in the deaths of approximately 28,000 prostate cancer patients each year in the United States. Disseminated tumor cells (DTCs) go from the primary tumor site to the bone marrow, which provides a chemoprotective environment. C-X-C chemokine receptor 4 (CXCR4), highly overexpressed in prostate cancer, is at least partially responsible for bone homing. CXCR4 is also expressed in hematopoietic stem cells (HSCs), which occupy the same niche within the bone marrow as DTCs. HSCs can be mobilized from the bone marrow niche via CXCR4 antagonism. We have previously shown that human tumor cells can be similarly mobilized from the bone marrow niche via small molecule inhibition of CXCR4. We believe this represents an ideal strategy for treating bone metastasis and hypothesize that mobilized DTCs will proliferate in the vascular niche, causing them to become chemosensitive. Several outstanding questions still exist that we are in the process of answering. First is the percentage of DTCs that are mobilized with CXCR4 antagonism. We used a qPCR strategy to quantify tumor cells in the bone marrow and blood of mice. This was imperfect because we could not reliably count cells, nor could we query the cells further. Therefore, we developed a novel immunofluorescence protocol to detect, quantify, and query tumor cells residing in the bone marrow or blood of mice. We will use this technique to determine the percentage of bone marrow DTCs that are mobilized. The second outstanding question is whether or not mobilized DTCs proliferate once mobilized. This is crucial to know, considering most chemotherapy relies on tumor cell proliferation. Using our novel protocol, we will determine the percentage of bone marrow DTCs and mobilized DTCs that are proliferating. Finally, while there is evidence that combining CXCR4 antagonism with chemotherapy kills more tumor cells than chemotherapy alone, no one has shown definitively that it works specifically for prostate bone marrow DTCs or bone metastasis. Not only will we do this, but we will also be able to quantify how effective each therapy strategy is by quantifying the tumor cells present in each scenario. The data from these in vivo murine experiments, which would be impossible to get from humans, will go hand in hand with a first-in-prostate cancer clinical trial we are running that tests the same hypothesis. Combined, these data will be critically important in deciding whether mobilization therapy combined with chemotherapy is an effective strategy for treating metastatic prostate cancer.

#4943 Orthotopic transplantation of pancreatic cancer PDX models increases murine stroma content, but does not influence therapeutic response to standard of care. Ulrike Pfohl,1 Diana Behrens,1 Iduna Fichtner,1 Jens Hoffmann,1 Wolfgang Walther1,2 EPO GmbH, Berlin, Germany; 1Charité University Medicine Berlin and Max-Delbrueck-Center for Molecular Medicine, Berlin, Germany.

Background: Reasons for the poor prognosis of pancreatic cancer are advanced and inoperable tumor stages at time of diagnosis and resistance to conventional therapies. Patient-derived xenografts (PDX) represent a valuable tool for the prediction of therapy response, the identification of new biomarkers and therapeutic targets or pancreatic cancer specific activated pathways (MAPK, hedgehog). However, PDX tumors differ from patient tumors as their surrounding tissue is replaced by murine stroma within 3 to 9 weeks after primary transplantation. Since the desmoplastic stroma has an impact on the progression and treatment of pancreatic cancer, we investigated the characteristics and function of murine stroma components in PDX models of pancreatic ductal adenocarcinoma (PDAC). Methods: We analyzed the relevance of murine cancer-associated fibroblasts (CAFs) for therapeutic response by comparing orthotopic with s.c. transplantation in PDX. We selected a cohort of 3 PDAC PDX with different growth rates (slow, median and fast growth). Human pancreatic tumor material was implanted s.c. or orthotopically into immunodeficient mice. After successful engraftment, the chemosensitivity to standard of care (SoC) drugs (focus on 2 to 3 drugs) was determined according to clinically relevant and optimized schedules. Growth of orthotopic PDX models was monitored via high-resolution ultrasound. Cryo- and formalin-preserved tumor tissues from the chemosensitivity studies were collected and analyzed for specific stroma markers (collagen I and oSMA). Results: In general, the response profiles in our experiments have closely reflected patient’s response in the clinic for the drug combination gemcitabine and nab-paclitaxel. There were no differences in response when comparing s.c. with orthotopic growing tumors. Semi-quantitative analysis of tumor sections showed that orthotopic tumors contain more murine stroma compared to s.c. tumors. Combined, these data will be critically important in deciding therapy condition, while MET is a driving mechanism for tumor recurrence. The EMT cells significantly contributed to recurrent lung metastasis. The EMT tumor cells survived the chemotheraphy due to reduced proliferation and apoptotic tolerance, which are common characters of dormant tumor cells. More interestingly, the GFP+ EMT tumor cells reversed back to epithelial phenotype through mesenchymal to epithelial transition (MET) and formed recurrent metastatic lesions in the lung. These results suggest that our EMT lineage tracing model may provide a unique tool to study tumor dormancy and recurrence. The EMT process may represent a major mechanism for tumor dormancy under chemotherapy condition, while MET is a driving mechanism for tumor recurrence.

#4945 Axl–hi DTCs in the bone marrow of a genetically engineered mouse model of prostate cancer exhibit decreased proliferation. Haley D. Axelrod, Kenneth C. Valkenburg, Brian W. Simons, Kenneth J. Pienta. Johns Hopkins School of Medicine, Baltimore, MD.

The majority of prostate cancer (PCa) deaths are attributed to bone metastases, which may not arise until years after the primary tumor has been removed. Disseminated tumor cells (DTCs) have been shown to already be present in the bone marrow of patients at the time of prostatectomy, and it is thought that they undergo a period of dormancy, allowing them to remain undetected for years before manifesting into clinically detectable metastases. It is not known what factors in the bone marrow niche play an essential role. Previously our group has shown that one of these niche factors, Gas6, can regulate growth of PCa cells. The growth restraining effects of Gas6 on PCa cells is likely mediated through the tyrosine kinase receptor Axl, whose expression was found to be increased on dormant DTCs compared to proliferating metastases in a xenograft mouse model. Here, we utilized the TRAMP model, a genetically engineered mouse model of spontaneous PCa progression, to compare the frequency of Axl–hi and Axl–low bone marrow DTCs that are proliferating versus non-proliferating. Further, we also compared Axl expression and proliferation in matched primary tumors. To investigate the functional significance of Gas6/Axl signaling in mediating PCa dormancy, we have generated Axl knockout PCa cells to test the requirement of Axl in maintaining dormancy, and Axl overexpressing PCa cells to test the sufficiency of Axl in mediating dormancy. Determining the role of Axl and any other regulatory mechanisms of PCa DTC dormancy will be crucial in efforts to prevent lethal and incurable metastases.
Host tissue stiffness regulates chemotherapy-induced cancer cell dormancy. Aliya Anlas, Celeste M. Nelson. Princeton University, Princeton, NJ.

This study investigates how the tumor microenvironment, namely host tissue stiffness, affects the propensity of disseminated tumor cells to become dormant at secondary sites. Approximately 90% of cancer-related deaths result from metastasis. Disseminated tumor cells cannot be detected at the time of diagnosis of the primary tumor because they form “dormant” micrometastases that are not clinically detectable. Thus, metastases in secondary sites such as the lungs, bone marrow, liver and brain are usually discovered months or years after the initial diagnosis and/or treatment of the primary tumor. A 2D polyacrylamide gel-based tissue culture model was used to investigate the effects of host tissue stiffness on the proliferative behavior of breast cancer cells. To assess the dormant phenotype, Ki67 and RNA staining were used to quantify proliferation and RNA content, respectively. Additionally, changes in levels of cell-cycle regulators were determined by quantitative RT-PCR. Dormant cells have decreased levels of transcription and proliferation. We found that both tenascin-5 and 5-fluorouracil induce dormancy in estrogen receptor-positive breast cancer cells cultured on soft and stiff substrata. After repeated rounds of 5-fluorouracil treatment and recovery, cells cultured on soft substratum, mechanical properties of which represent common metastatic sites, had a higher tendency to recover. This suggests that cell growth at secondary sites favors a soft microenvironment, characteristic of organs where breast cancer metastases often become clinically overt. Dormant cancer cells, or minimal residual disease, cannot be detected with current diagnostic tools and cannot be detected by conventional therapies. Therefore, current clinical practices rely on estimating the probability of recurrence from various prognostic factors including the grade and the stage of the disease. Elucidating the mechanisms that regulate the switch from dormancy to proliferation at metastatic sites will pave the way for new treatments to control this incurable disease.

Her2 inhibition and dormant cell metabolism. Douglas B. Fox, James V. Alvarez. Duke University, Durham, NC.

Breast cancer is the most diagnosed cancer in women in the United States, and despite improved prognosis resulting from targeted therapies, tumors commonly re-emerge upon development of therapeutic resistance. In order to overcome this, it is critical to explore the cellular pathways that change in tumors following treatment. While many mechanisms of resistance to targeted therapies have been identified, the metabolic changes that occur following treatment have not been well defined. We believe that these changes may offer a general therapeutic target. Using a doxycycline-inducible Her2 mouse model of breast cancer, we are exploring the molecular and cellular consequences Her2 inhibition. Using in vitro mammosphere cultures derived from these mice, we showed that Her2 loss quickly downregulates ERK and Akt signaling. There is a corresponding decrease in proliferation, and apoptosis is induced in 25-50% of cells. However, a population of cells survives Her2 withdrawal and remains dormant for upwards of one month. We are using these models to study how metabolic pathways are rewired following Her2 inhibition, and we believe that the metabolic pathways adapted upon Her2 inhibition may represent targetable vulnerabilities.

Characterization of hTERT-immortalized prostate-derived stromal and epithelial cells: An authentic in vitro model for tumor microenvironment studies. Luis G. Rodriguez, Russell E. McDaniel, Xiangshan Zhao, Elizabeth Turner, Christopher Annesi, Chaozhong Zou. ATCC Cell Systems, Gaithersburg, MD, MD.

Tumor development begins with mutational changes to the genetic makeup of a cell, but its progression is not solely determined by the mutated cell, but also by the tumor’s microenvironment. Prostate cancer, a leading cancer diagnosed in men, has been shown to be highly influenced by its surrounding stroma, particularly fibroblasts. It has been demonstrated that cancer-associated prostate fibroblast (CAF)s differ from normal-associated prostate fibroblast (NAFs). However, human prostate cancer model systems have focused largely on prostate cancer epithelial cells. Currently, a need exists for a more physiologically relevant human cell model system to study prostate cancer progression within the context of its tumor microenvironment. In this study, we characterized three prostate-derived cells: prostate cancer-associated fibroblast (CAF)s, prostate normal-associated fibroblast (NAFs) and prostate cancer epithelial (PrE) cells; all three lines were immobilized by hTERT (human telomerase reverse transcriptase) alone, and have been continuously passed for more than 40 PDL in our hands. Our data shows that the hTERT immortalized CAFs proliferate faster than the NAFs; in addition, both CAFs and NAFs express fibroblast markers such as TE7 and alpha smooth muscle actin (α-SMA), while neither cell line expresses epithelial marker such as CK14. Both CAFs and NAFs also express elevated levels of α-SMA upon TGF-β stimulation. All three prostate-derived cells express the prostate specific marker AR, and show similar markers staining after long time passing. Importantly, conditioned media collected from CAFs promotes tumor cell growth better than NAF conditioned media. In conclusion, CAFs, NAFs, and immortalized prostate cancer epithelium may provide a very valuable model system for the study of prostate cancer cell progression and tumor microenvironment studies.

Longitudinal monitoring of cell-free DNA in patients with small cell lung cancer reveals dynamic insights into treatment efficacy and disease relapse. Christine M. Lovly, Karinna Almodovar, Wade T. Iams, Laura C. Meador, Sally York, Leora Horn, Christopher K. Raymond, Jennifer Hernandez, Lee P. Lim. Vanderbilt University School of Medicine, Nashville, TN; Northwestern University School of Medicine, Chicago, IL; Resolution Bioscience, Bellevue, WA.

Introduction: Small cell lung cancer (SCLC) is a highly lethal neuroendocrine malignancy that accounts for approximately 10-15% of all lung cancers and is responsible for approximately 30,000 deaths annually in the United States and 200,000 deaths worldwide every year. There is an urgent need to develop novel treatment strategies for patients with this disease. We sought to improve the quality of patient care by establishing a liquid biopsy assay for rapid, noninvasive monitoring of disease burden. Design: The SCLC assay relies on targeted next-generation DNA sequencing of cell-free DNA (cfDNA) collected from patient plasma. The assay targets a panel of 14 genes that are frequently mutated in SCLC. We examined a total of 141 plasma samples from a cohort of 27 patients. Eleven patients had limited stage SCLC and 16 patients had extensive stage SCLC. Results: Of the plasma samples collected during the course of patient treatment and included time points before and after chemotherapy or immunotherapy. Results: We detected somatic, disease-associated mutations in the cfDNA of 78% of patient samples (21/27). The allele frequency of cfDNA ranged from %0.5% to %85%. The most commonly mutated genes were TP53 and RB1, which were found in 17/27 and 10/27 samples, respectively. We also detected single nucleotide variants in PIK3CA (3/27) and PTEN (1/27) as well as copy number variants in MYC and MYCL1 (2/27). The observed mutant allele frequencies in longitudinal samples tracked closely with treatment responses. Strikingly, we found instances where the assay detected the reappearance of tumor-associated markers several weeks before clinical evidence of relapse was detected. Conclusions: cfDNA sequencing allows for improved monitoring of disease burden, depth of responses to treatment, and timely warning of disease relapse in patients with SCLC. References: 1. Society, A.C., Cancer Facts and Figures 2015. American Cancer Society, Atlanta, Ga, 2015. 2. George, J., et al., Comprehensive genomic profiles of small cell lung cancer, Nature 524:47.
(34/113). PIK3CA mutations were detected in 31.8% of patients with HR+/HER2- disease. The majority of the patients had either newly diagnosed metastatic or progressive metastatic disease at the time of the blood draw. 14 patients had stable metastatic disease and among these patients, only 1 of these patients was found to have an ESR1 mutation and no PIK3CA mutations were detected. The majority of patients with ESR1 mutation (33/67) and PIK3CA mutations (75%) had progressive disease. The patients that received an aromatase inhibitor (AI) either in the adjuvant or met setting had a higher prevalence of ESR1 mutations compared to patients that had no AI treatment, regardless of whether or not they received tamoxifen (TAM) (prevalence was 32% for adjuvant AI only, 40.4% AI in met only, No AI and no TAM 7.1% and TAM but no AI 6.7%). In addition fulvestrant treatment in the met setting was significantly associated with ESR1 mutations (odds ratio 3.38, p-value<0.01). Conversely, we did not detect any significant associations between endocrine treatments in the adjuvant or met settings and PIK3CA mutations. Conclusions: Analysis of cDNA can successfully detect ESR1 and PIK3CA mutations in newly diagnosed or progressive metastatic breast cancer patients and the emergence of the ESR1 mutations is associated with AI and fulvestrant treatment. These results support the serial monitoring of ESR1 mutations in cDNA in metastatic disease and highlight the need to study new agents to target these mutations.

### #4951 Dynamics of KIT exon 11 mutations in cell free plasma DNA of patients treated for advanced gastrointestinal stromal tumors: Results from the Dutch GIST bio-databank.

Pieter A. Boonstra,1 Arja ter Elst,1 Marco Tibebsma,1 Ron H. Mathijssen,1 Florence Atrai,1 Frits van Cœvoorden,1 Sheima Farag,2 Neeltje Steeghs,3 Ingrid M. Desar,4 Winette T. van der Graaf,4 Hans Gelderblom,5 Boudevijn van Etten,1 Jelle Overbosch,1 Albert J. Suurmeijer,1 Jourik A. Gietema,1 Ed Schuuring,1 Anna K. Reyners1.

Eligibility criteria were histological diagnosis of GIST and treatment with a TKI. Patients with a known KIT exon 11 mutation, of which a baseline (before start of any TKI) sample or a recurrence/progression sample was available, were analyzed. A custom single tube digital droplet PCR (ddPCR) drop-off assay, designed at the UMC, was used. This assay detects 80% of the known KIT exon 11 mutations. Results Until Nov 2016, >620 samples of 175 patients have been collected. From 43 patients with a KIT exon 11 mutation in the pretreatment tumor biopsy, a baseline/progression sample was available. Mutations in exon 11 were detected in cfDNA from baseline samples of 23 patients, with lower MAF than in the pretreatment tumor (mean: 11%, range 0-12%). Interestingly, PD ctDNA samples harboured an increase in MAFs and a higher numbers of SNVs, with additional relapse-specific SNVs (mean: 22; range 0-55) targeting, amongst others, the protein kinase A signaling pathway. Analysis of additional ctDNA samples obtained between diagnosis and relapse (2-6 patients/sample) using deep sequencing techniques demonstrated a disappearance of SNVs coinciding with response to therapy, and re-appearance of SNVs at the time of tumor progression. Discussion and Conclusion: cDNA analysis in metastatic GIST patients is feasible. Our study will be extended to include the monitoring of early progression based on cDNA, which may guide early treatment adaptations.

### #4953 Single cell signaling analysis reveals circulating tumor cell markers of drug susceptibility and tumor heterogeneity.

N. Murat Karabacak, Yu Zheng, Erin Emmons, Michael Kouloupos, Daniel A. Haber, Mehmet Toner, Shweta Maheswaran. MGH, Charlestown, MA.

Complexity of cancer requires advancements of tools for intervention and diagnostics. Rare circulating tumor cells (CTCs) from patient blood could be used for real-time monitoring of solid cancer. We recently developed a microfluidic device, the CTC-iChip, which enriches well-preserved CTCs in solution through removal of the cellular components (red and white blood cells, platelets, leukocytes, monocytes, etc). Protein expression analysis in CTCs has been limited to immunoflourescent staining for a few well-characterized tumor markers (including EpCAM, HER2, PSA and Keratin) due to the limitations inherent to immunoflourescence labels and their precise resolution through microscopy. The scarcity of cells precludes large-scale proteomic analysis such as mass spectrometry of CTCs to effectively evaluate changes in total as well as phospho-proteins, which serve as excellent surrogate markers to monitor in real time the rapid alterations in signaling pathways within cells. This approach would be particularly important since the PI3K, mTOR, Akt, MAPK signaling pathways are aberrantly activated in many cancers and are promising therapeutic targets. In this work, we applied inductively-coupled plasma mass spectrometry (ICP-MS) measurement of cells (mass cytometry) that can measure up to ~40 proteins in millions of single cells due to quantitative, non-overlapping mass signals acquired from antibodies tagged with purified lanthanides. Sample preparation for mass cytometry was modified to minimize the loss of cells using our microfluidic platform in lieu of washing via centrifugation. Mass cytometry allowed identification of tumor cell populations based on the expression of multiple single cell markers, each of which could be either increased or decreased, or both, and the associations of these markers could be used to classify different subtypes of cancer cells.

Background: Liquid biopsies are revolutionary tools to monitor tumour-specific genetic alterations in sequential samples. In neuroblastoma (NB), significant levels of circulating tumor DNA (ctDNA) in the bloodstream enable the detection of tumour cell-specific markers including MYCN amplification or activating ALK mutations. As clonal evolution plays a role in NB progression, analysis of circulating tumor cells is emerging as a potential marker for disease monitoring and follow-up. Methods: To gain further insights into mechanisms of clonal evolution in NB, we isolated ctDNA from plasma at diagnosis (n=19) and during follow-up (final time-point: partial or complete remission (PR/CR), n=7; progressive disease (PD), n=9) for 19 NB patients for whom primary NB and matched germline DNA whole exome/whole genome sequencing data (WES/ WGS) was available. Of all NB patients, blood was subjected to Illumina 100PE WES following modified library construction and capture approaches to account for small ctDNA molecules (target depth 100x). SNVs/mutations were called using GATK-UnifiedGenotyper, GATK-HaplotypeCaller and Samtools. Copy-number profiles were generated using Varscan and DNAcopy. Results: CtDNA WES yielded satisfactory depth in all cases. At diagnosis, a majority of observed SNVs were common to the primary NB and corresponding diagnostic ctDNA of a given patient (mean number of SNVs: 19; range 9-69) with MAF (mutated allele fractions) corresponding to the estimated ctDNA content in the total cell free DNA. At diagnosis, few SNVs specific to the NB (mean: 6; range 0-18) or specific to ctDNA (mean:22; range 9-69) were observed, suggesting spatial heterogeneity with different ctDNA amounts released by different clones. In PR or CR ctDNA SNVs were 10-fold more frequent with lower MAF (mean: 11; range 0-12). In relapse, SNVs were more frequent, doubling in both MAFs and a higher numbers of SNVs, with additional relapse-specific SNVs (mean: 22; range 0-55) targeting, amongst others, the protein kinase A signaling pathway. Analysis of additional ctDNA samples obtained between diagnosis and relapse (2-6 samples/patient) using deep sequencing techniques demonstrated a disappearance of SNVs coinciding with response to therapy, and re-appearance of SNVs at the time of tumor progression. Discussion and Conclusion: CtDNA WES prove to be an extremely powerful tool to study spatial and temporal heterogeneity in NB, providing further proof of the importance of clonal evolution in NB progression. Full characterization of ctDNA, which might represent more aggressive clones, might orient targeted treatment approaches.
### Clinical Research: Liquid Biopsies 4

#### #4954 Clinical validation of a cell-free DNA liquid biopsy approach for non-invasive molecular profiling.
Monica Nesselbush, Samuel Angiolillo, Luis A. Diaz, Andrew Georgiadis, Shannon Glynn, Sián Jones, Laurel Keefer, Peter LoVerso, Derek Murphy, Sonya Parpart-Li, David Riley, Naomi Sengamalay, Manish Shukla, John Simmons, Snehal Talati, Rebecca Steinberg, Laura Tucker, Victor Kolb, Julie L. Lueders, Angela Villarta, Mark Sausen. Personal Genome Diagnostics, Baltimore, MD.

Molecular profiling of advanced cancers enables the identification of actionable genomic alterations to guide therapeutics decisions. Although profiling of tissue samples is considered the gold standard, specimens may be unavailable or unsuitable for testing due to limited tumor purity or specimen quality. Furthermore, surgically resected tumor tissue samples are increasingly available after disease progression and re-biopsy in this setting may not be feasible. Circulating tumor DNA (ctDNA) approaches for identification of genetic alterations in cancer patients may be more informative as the alterations reflect the current status of the tumor. ctDNA is representative of multiple tumor sites within a patient and may aid in the detection of alterations throughout the course of therapy. However, the fraction of ctDNA obtained from a blood sample is often very low (<1.0%) and difficult to detect. Additionally, many methods to evaluate ctDNA interrogate single hotspot or a few mutations. The next generation of ctDNA assays must identify clinically actionable genetic alterations and novel biomarkers with high precision and accuracy. To address these issues, we have developed and validated PlasmaSelect64, a ctDNA approach to comprehensively detect genetic alterations at low allele frequencies in low volume of cancer patients. Utilizing digital genomic approaches, we demonstrated robust sensitivity and specificity in our CLIA laboratory in 64 well-established cancer genes that were identified based on clinical actionability. In addition to the evaluation of exons in 58 genes that are frequently mutated in cancer for sequence mutations, we performed a comprehensive genomic analysis of translocations in 18 genes and copy number analyses in 19 genes. We have also developed a novel approach for identification of microsatellite instability (MSI) using these error correction methodologies. To evaluate the PlasmaSelect64 approach, we developed and optimized the pre-analytical conditions for sample collection and processing with K2EDTA and Streck blood collection tubes. Analytical validation studies were performed with clinical samples and controlled cell-line mixtures containing known alterations determined by orthogonal methods. We robustly identified sequence mutations at 0.50% mutant allele frequency (MAF) with a limit of detection of 0.05% MAF, corresponding to a per-base specificity of 99.9997% and a sensitivity of 99.4%. For detection of focal amplifications and translocations, analytical method validation studies demonstrated sensitivity of 97.2% and 94.4% and specificity of >99% at MAFs of ≥20% and ≥50%, respectively. PlasmaSelect64 provides a non-invasive platform to enable detection of clinically relevant genetic alterations across a large number of genomic regions to aid in the therapeutic management of cancer patients.

#### #4955 PD-L1 expression on circulating epithelial tumor cells (CETCs) correlates with the presence of metastasis in breast cancer patients and differs from PD-L2 expression.
Monika Pizon, Dorothée Schott, Ulrich Pachmann, Katharina Pachmann. Transfusion Center Bayreuth, Bayreuth, Germany.

Background: Strategies to improve the efficacy of the immune system against malignant tumors represent a major innovation focusing on the programmed cell death-1 receptor (PD-1) with its two ligands PD-L1 and PD-L2. The expression of PD-L1 has been evaluated in a number of different tumor types and can be used as a predictive biomarker for PD-1/PD-L1 checkpoint inhibitor treatment response. PD-L2 has not received as much attention and its role in modulating tumor immunity is less clear. We used a non-invasive, real-time liquid biopsy to better characterize PD-L1/L2 expression on circulating epithelial tumor cells (CETCs) in breast cancer patients. Methods: CETCs were determined from blood of 72 patients suffering from breast cancer. The number of vital CETCs and their expression of PD-L1 and PD-L2 were investigated using the maintrac® method. Results: PD-L1 expressing CETCs were detected in 94.5% of breast cancer patients whereas only 82% patients expressed PD-L2 in their CETCs. Breast cancer patients had significantly more PD-L1 positive CETCs as compared to patients without metastasis (median 75% vs. 61.1%; p<0.005). The fraction of PD-L1 positive CETCs was significantly higher than the fraction of PD-L2 positive CETCs (54.6% vs. 28.7%; p<0.001). Moreover, we observed a significant heterogeneity in PD-L1 and PD-L2 immunostaining intensity across CETCs from the same patients. Conclusion: Breast cancer patients have detectable CETCs with a high frequency of PD-L1 which correlate with progression of cancer disease. PD-L1 seems to be a major factor in immune evasion and may be a promising target of anticancer therapies. Monitoring the frequency of PD-L1 positive CETCs could reflect individual patient’s response to an anti-PD-1/PD-L1 therapy.

### Epidemiology: Molecular and Genetic Epidemiology

#### #4956 Transcriptome-wide association study identifies new prostate cancer susceptibility genes in the OncoArray data.
Nicholas Mancuso,1 Wei Zheng,2 Kathryn Penney,3 The PRACTICAL Consortium, Zsofia Kote-Jarai,4 Christopher Haiman,5 SimonGayther,5 Matthew Freedman,5 Bogdan Pasaniuc,1 Geoffrey School of Medicine, University of California, Los Angeles, Los Angeles, CA; 2Division of Epidemiology, Department of Medicine, Vanderbilt Epigenetics Center, Vanderbilt-Ingram Cancer Center, Vanderbilt University School of Medicine, Nashville, TN; 3Department of Epidemiology, Harvard T.H. Chan School of Public Health, Boston, Massachusetts. Channing Division of Network Medicine, Department of Medicine, Brigham and Women’s Hospital/Harvard Medical School, Boston, MA; 4Division of Genetics and Epidemiology, The Institute of Cancer Research & Royal Marsden NHS Foundation Trust, London, United Kingdom; 5Department of Preventive Medicine, Norris Comprehensive Cancer Center, Keck School of Medicine, University of Southern California, Los Angeles, CA; 6The Center for Bioinformatics and Functional Genomics, Cedars-Sinai Medical Center, Los Angeles, CA; 7Department of Medical Oncology, Dana-Farber Cancer Institute and Harvard Medical School, Boston, MA.

Genome-wide association studies (GWAS) have identified over 150 genomic regions harboring risk variants for prostate cancer which explain one third of all familial risk. However, with some notable exceptions, the causal variants and target susceptibility genes at these risk loci have yet to be identified. Recent work has shown a strong overlap between loci associated with gene expression levels (eQTLs) in prostate tissue and GWAS loci, which suggests that the causal mechanism at a significant proportion of risk loci includes causal alleles that regulate expression levels of nearby susceptibility genes. While overlapping eQTLs with GWAS is a powerful method to prioritize susceptibility genes, it is often the case that multiple eQTLs co-localize at the GWAS risk region (due to linkage disequilibrium (LD) and correlations across transcript levels). This prohibits the identification of the true susceptibility gene as opposed to spurious co-localization at the same locus. We recently leveraged gene expression imputation to perform transcriptome-wide association studies (TWAS) as a principled approach to measure the strength of association between gene expression and disease status. Here, we used imputed expression to identify new susceptibility genes for prostate cancer in the OncoArray GWAS data. We integrate gene expression data from more than 44 tissues across ~4,000 individuals with GWAS of prostate cancer from the OncoArray in ~140,000 individuals. Our approach identified 118 susceptibility genes for prostate cancer that reside in 90 independent loci across the genome. Of these, we report 7 genes located more than 0.5 Megabases away from any previously reported GWAS loci for prostate cancer, thus providing new risk loci. Second, we use TWAS to investigate genes previously reported as susceptibility genes for prostate cancer through overlaps of eQTL and GWAS. We find 36 (out of 86 previously reported genes) to be significant in TWAS. Overall, our findings highlight the power of integrating gene expression data with GWAS and provide testable hypotheses for future functional validation of prostate cancer risk.

#### #4957 Gene expression signature of Gleason score is associated with prostate cancer outcomes in a radical prostatectomy cohort.
Min A Hjun,1 Milan S. Chadha,2 Mark L. Gold,3 Vladimir Rinkevich,4 Elaine A. Ostrander,5 Jing-Bang Fan,6 Ziding Feng,7 Janet L. Stanford,8 Fred Hutchinson Cancer Research Center, Seattle, WA; 2Maastricht University, Maastricht, Netherlands; 3University of Washington School of Medicine, Seattle, WA; 4Illumina, Inc., San Diego, CA; 5National Human Genome Research Institute, National Institutes of Health, Bethesda, MD; 6University of Texas MD Anderson Cancer Center, Houston, TX.

Background: Prostate cancer (PCa) is a leading cause of cancer-related mortality worldwide. Many men treated for clinically localized PCa will be cured, however, 20 to 30% of men will relapse and some will experience metastatic-lethal (ML) progression. Gleason score (GS) is one of the best predictors of PCa aggressiveness, but additional tumor biomarkers may improve its prognostic accuracy. We developed a gene expression signature of GS to enhance prediction of PCa outcomes. Methods: Elastic Net regularization was used to construct a gene expression signature by contrasting tumors with GS 8-10 (high) vs. ≤6 (low) in The Cancer Genome Atlas (TCGA). Tumor tissue samples obtained at radical prostatectomy for a Fred Hutchinson (FH) patient cohort of men with localized PCa were used to generate genome-wide gene expression data. The gene expression signature was validated for its ability to predict recurrence and ML progression in the FH patient cohort (N = 503; Nrecurrence = 106; NmLprogression = 27; mean follow-up for recurrence = 8 years). Results: The expression signature includes transcripts representing 49 genes. In the FH cohort, the signature was associated with recurrence and ML progression with hazard ratios
(HRs) for a 25% increase in the signature of 1.51 (95% CI: 1.24-1.82; \(P = 2.7 \times 10^{-5}\)) and 2.41 (95% CI: 1.51-3.85; \(P = 0.0002\)), respectively. Among patients with GS 7 tumors, the signature was also significantly associated with PCa recurrence (HR = 1.38, 95% CI: 1.09-1.76; \(P = 0.008\)) and ML progression (HR = 2.42, 95% CI: 1.30-4.52; \(P = 0.006\)). The signature’s area under the curve (AUC) for both ML and survival was much larger numbers of CpGs were statistically significantly associated with subsequent survival increases dramatically when measured closer to before diagnosis, respectively. After adjusting for blood cell type distributions, higher levels of the signature were associated with increased expression of genes in cell cycle-related pathways including G2M checkpoint, epithelial mesenchymal transition, and E2F targets pathways, and decreased expression of genes in several pathways including androgen response, estrogen response, oxidative phosphorylation, and apoptosis. Conclusion: The gene expression signature based on GS may improve the prediction of overall recurrence as well as ML progression in PCa patients after radical prostatectomy, in particular among men with GS 7 tumors.

### 4958 Pre-diagnostic peripheral blood DNA methylation and lung cancer survival
Jennifer A. Doherty,1 Xuan Zhang,2 Devin C. Koestler,2 Matt J. Barnett,3 Mark D. Thorsness,2 Gregory E. Goodman,3 Carmen J. Marsit,4

Epigenetic regulation plays a critical role in cell and tissue development and differentiation, is a known mechanism of carcinogenesis, and is altered by various exposures including cigarette smoking and age. Peripheral blood methylation represents a combination of these factors as well as blood cell type distributions that reflect underlying immunophenotypes. Hematopoiesis is programmed through epigenetic changes, and blood cell type-specific methylation marker can be leveraged to fingerprint cell type distributions. We examined associations between pre-diagnostic methylation markers in peripheral blood with overall lung cancer survival in very heavy smokers from the Beta Carotene and Retinol Efficacy Trial (CARET). CARET was a randomized, double-blinded, placebo-controlled chemoprevention trial of daily \( \beta \)-carotene and retinyl palmitate in smokers with \( \geq 20 \) pack-years, and smokers who were occupationally exposed to asbestos. Methylation was successfully measured using the Illumina 850K EPIC BeadArray on average 5 years prior to diagnosis for 331 lung cancer cases, of whom 253 died during follow up (median survival 329 days). Cox proportional hazards regression models were used to examine the relationship between CpG-specific methylation and survival. Models were adjusted for age at blood draw, sex, race, enrollment year, placebo/active intervention, asbestos exposure, current/former smoking and time since quit, pack years, average number of cigarettes per day and histologic type, and were fit separately depending on the time between blood draw and lung cancer diagnosis: 0-3 years (n = 107), 3-5 years (n = 77), and 5+ years (n = 147). After adjusting for multiple comparisons by computing the false discovery rate (FDR) q-value, there were 1,028,296, and 4 CpGs that were statistically significantly associated with survival (q \( \leq 0.01 \)) for samples collected 0-3 years, 3-5 years, and 5+ years before diagnosis, respectively. After controlling for blood cell type distributions, much larger numbers of CpGs were statistically significantly associated with survival: 10,481, 456, and 257, respectively. The top canonical pathways of CpGs identified in samples drawn 0-3 years prior to diagnosis included PTEN signaling (p = 1.1E-5) and IKB signaling in B lymphocytes (p = 3.7E-5). We observed that the number of methylated CpGs in peripheral blood that are associated with subsequent survival increases dramatically when measured closer to lung cancer diagnosis. As well, we observed that the number of methylated markers is increased by controlling for immunophenotype. Our study provides evidence that peripheral blood methylation markers measured many years prior to diagnosis may be associated with poor lung cancer survival, and that increasing changes in methylation over time may also be associated. This points to the critical role of the immune system, even prior to diagnosis, in influencing cancer outcomes.

### 4959 The RANK-axis and breast cancer risk by hormone receptor subtype: Results from the EPIC cohort
Danja Sarink,1 Helena Schoon, Theron German Johnson, EPIC cohort collaborators, Rudolf Kaaks, Renée T. Fortner, German Cancer Research Ctr., Heidelberg, Germany.

Background: Activation of the receptor activator of nuclear factor kappa-B (RANK)–axis promotes mammary tumor development in experimental models. Circulating concentrations of soluble RANK ligand (sRANKL) may influence breast cancer risk via RANK activation; this may be modulated by circulating concentrations of osteoprotegerin (OPG), the decoy receptor for RANKL. sRANKL and breast cancer risk in humans have not previously been investigated. Methods: A case-control study was nested in the European Prospective Investigation into Cancer and Nutrition (EPIC) cohort. A total of 1976 incident invasive breast cancer cases (estrogen receptor positive (ER+), n = 1598), matched 1:1 to controls, were included in the analysis. Women were both pre- and postmenopausal at blood collection. Serum sRANKL was quantified using an enzyme-linked immunosorbent assay (ELISA). Serum OPG was quantified using an electrochemiluminescent assay. Odds ratios (ORs) and 95% confidence intervals (95%CIs) were calculated using conditional logistic regression. Results: Associations between sRANKL and breast cancer risk differed by tumor hormone receptor status (\( \phi_{\text{ER}} = 0.05 \)). Higher concentrations of sRANKL were associated with increased risk of ER+ breast cancer (top vs. bottom quintile OR 1.36 [0.99-1.87]; \( \phi_{\text{ER}} = 0.31 \)). While results considering the sRANKL/OPG ratio were similar to those for sRANKL alone for hormone receptor positive breast cancer, we saw a suggestive inverse association between the ratio and ER-PR- disease (5% vs. 1st quintile OR 0.60 [0.31-1.16]; \( \phi_{\text{ER}} = 0.04 \)). Conclusions: This study provides the first prospective data on sRANKL and breast cancer risk, providing suggestive evidence of a possible association between sRANKL concentrations and breast cancer. High circulating levels sRANKL in the context of low OPG may represent novel risk markers for hormone receptor positive breast cancer.

| #4960 Recent ultraviolet radiation exposure and circulating immunosuppressive T-regulatory cells
Dana E. Rollison,1 Shalaka S. Hampras,3 Jane L. Messina,1 Neil A. Fenske,2 Basil S. Chepulis,3 Michael J. Schell,1 Rhianna Reed,1 Juliana Balliu,1 Rebecca Hesterberg,1 Afua A. Akuffo,1 Pearl K. Burnette1.

Background: Ultraviolet radiation exposure (UVR) is a risk factor for several different cancer types. While the mutagenicity of UVR is well-documented, UVR’s effects on human systemic immune function are not well understood. Several lines of evidence suggest that UVR may have immunosuppressive effects, however, no epidemiologic studies have investigated the association between quantitative measures of UVR and a biomarker of immune function. Objective: To evaluate the association between UVR and systemic immune function, we conducted a cross-sectional analysis of recent UVR and circulating regulatory T- cells ("Tregs") among a cohort of skin cancer screening patients. Methods: 350 patients undergoing regular skin cancer screenings with no prevalent skin cancer at the time of enrollment were recruited from the University of South Florida Dermatology clinic. At the baseline visit, blood was obtained, and a spectrophotometer was used to measure skin pigmentation at a sun-unexposed site (the axilla) and two sun-exposed sites: the forehead and the upper forearm. Recent sun exposure was quantified as the difference in readings between the sun-exposed and sun-unexposed sites. Using flow cytometry assays, lymphocyte samples were examined for Tregs (CD4+ CD25+ CD127hlowsFoxp3+), and proportions of Tregs with enhanced immunosuppressive function (CD27-, CD45RA- Treg) and skin tissue affinity (CLA +, CCR4+CD11c+) were...
EPIDEMIOLOGY: Molecular and Genetic Epidemiology

determined. Associations between UVR exposure and Tregs were described using Spearman correlation coefficients. Linear regression using log-transformed values of UVR and Tregs was used to adjust for age and sex. Results: Among all 350 participants, UVR was positively correlated with circulating immunosuppressive CD27-, CD45RA- Tregs (r = 0.127, p = 0.020 for UVR measured at the forehead and r = -0.193, p = 0.001 for UVR measured at the arm) and was also positively correlated with skin-homing Tregs expressing CLA (r = 0.167, p < 0.0002) and CCR4 (r = 0.19, p = 0.0004). When participants were categorized into light versus dark constitutive pigmentation based on the median value of spectrophotometer readings for the sun-unexposed axilla, the correlation between UVR averaged across the forehead and forearm was more strongly correlated with immunosuppressive Tregs among dark-skinned participants (r = 0.30, p = 0.001) than darker-skin participants (r = 0.065, p = 0.400). Conclusion: Recent UVR is positively associated with increased levels of circulating immunosuppressive Tregs, including Tregs with skin tissue affinity, with the association being stronger among naturally lighter-skinned individuals. UVR-associated immunosuppressive effects among otherwise immunocompetent individuals may play a role in skin cancer carcinogenesis.

#4961 The oral microbiome and prospective risk for esophageal cancer: a population-based nested case-control study. Brandilyn A. Peters,1 Jing Wu,1 Zhiheng Pei,1 Liying Yang,1 Mark P. Purduce,1 Neil D. Freedman,2 Eric J. Jacobs,3 Susan M. Gapstur,3 Richard B. Hayes,1 Jiyoung Ahn1.

Background: The two most common types of esophageal cancer, esophageal adenocarcinoma (EAC) and squamous cell carcinoma (ESCC), are highly fatal. The human microbiota have been suggested to play a role in esophageal cancer etiology, although the evidence is limited to small, cross-sectional studies. We hypothesized that the oral microbiota, which shape the esophageal microbiota, may be causative agents in esophageal carcinogenesis. Methods: We conducted a prospective study nested in two large U.S. cohorts: ACS CPS-II and NCI-PCLC. Oral bacteria were assessed in pre-diagnostic mouth-wash samples collected from cases and controls (n = 81/160 EAC and n = 25/50 ESCC cases/ matched controls), using 16S rRNA gene sequencing. We compared overall microbial composition between cases and controls using permutational multivariate analysis of variance (PERMANOVA) of UniFrac distances, and we examined associations between centered log-ratio transformed taxon abundances and cancer risk using conditional logistic regression. Metagenome functional content was predicted from taxonomic composition using PICRUSt. Results: Overall microbial composition did not differ between EAC cases and matched controls or ESCC cases and matched controls, adjusting for matching factors (age, sex, race, cohort, time to diagnosis/selection), BMI, smoking, and alcohol intake (all p > 0.40). The periodontal pathogens Tannerella forsythia and Porphyromonas gingivalis were nominally associated with increased risk for EAC (OR [95% CI] = 1.21 [1.01, 1.46], p = 0.04) and ESCC (OR [95% CI] = 1.3 [0.96, 1.77], p = 0.09), respectively. Conversely, genus Neisseria, previously shown to be depleted by cigarette smoking, was associated with protection against EAC (OR [95% CI] = 0.88 [0.68, 0.97], p = 0.01). Other species associated with EAC risk (p < 0.05) included Prevotella nanceiensis, Bergeyella oral taxon 322, and Neisseria weaveri (positively associated with EAC) and Actinomyces cardiffensis, Selenomonas oral taxon 134, and Veillonella oral taxon 917 (positively associated with EAC). Other species associated with ESCC risk (p < 0.05) included Aggregatibacter paraphrophilus (inversely associated with ESCC) and Prevotella naeckeii, Bacteroides oral taxon 322, and Neisseria weaveri (positively associated with ESCC). Analysis of inferred metagenomes revealed that bacterial carotenoid biosynthesis was associated with protection against ESCC (OR [95% CI] = 0.84 [0.7, 1.0], p = 0.05). Conclusions: Our findings from this prospective study suggest that specific bacterial pathogens may play a causal role in esophageal cancer, while members of the healthy oral microbiota may protect against esophageal carcinogenesis. Unique microbial profiles may contribute to each of the distinct esophageal cancer types, EAC and ESCC. Oral microbiota manipulation may be a future strategy for preventing this highly fatal disease.

#4962 Geographic disparities in prevalence of baseline prostate inflammation and prostate cancer risk: results from a multinational trial. Emma H. Allott,1 Sarah Markt,2 Lauren E. Howard,7 Adriana C. Vidal,2 Daniel M. Moreira,2 Ramiro Castro-Santamaria,2 Gerald L. Andriole,3 Lorelei A. Mucci,4 Stephen J. Freedland,4 University of North Carolina at Chapel Hill, Chapel Hill, NC; 5Harvard School of Public Health, Boston, MA; 6Duke University, Durham, NC; 7Cedars Sinai Medical Center, Los Angeles, CA; 8University of Illinois at Chicago, Chicago, IL; 9GlaxoSmithKline, King of Prussia, PA; 10Washington University, St. Louis, MO; 11Harvard University, MA; 12Cedars Sinai Medical Center, CA.

Introduction: Prostate cancer incidence rates vary 25-fold worldwide. The distribution of lifestyle factors also varies by geographic region and these factors may impact prostate inflammation, which is inversely associated with prostate cancer risk in the REDuction of prostate Cancer Events (RE- DUCE) trial. Herein, we examined geographic differences in the prevalence of baseline prostate inflammation and prostate cancer risk using REDUCE, a multinational trial of men with a negative baseline prostate biopsy. Methods: We conducted a retrospective analysis of data from 7,213 men with a negative baseline prostate biopsy in REDUCE from Europe (n = 4,802), North America (n = 1,796), South America (n = 467), and Australia/New Zealand (n = 148). Histological inflammation was classified as chronic (lymphocytes, macrophages) or acute (neutrophils) by central review of negative baseline prostate biopsies. Logistic regression was used to calculate odds ratios (OR) and 95% confidence intervals (95% CI) for associations between geographic region and prostate inflammation, and between geographic region and prostate cancer risk at trial-mandated repeat biopsy, adjusting for potential founders. To avoid confounding by race, analyses were restricted to white men. Results: Chronic and acute prostate inflammation was detected in 77% and 15% of men, respectively. Relative to Europeans, North Americans and Australians/New Zealanders were more likely to have acute prostate inflammation in the negative biopsy (OR 1.74; 95% CI 1.48-2.05 and OR 2.04; 95% CI 1.38-3.02, respectively), while South Americans were less likely to have acute inflammation (OR 0.42; 95% CI 0.28-0.61). Among North Americans, Canadians were more likely to have acute prostate inflammation than men from the United States (OR 1.40; 95% CI 1.07-1.83). Among Europeans, the prevalence of acute inflammation was lower in Northern, Southern and Eastern Europe, relative to Western Europe (OR 0.79; 95% CI 0.65-0.97, OR 0.84; 95% CI 0.66-1.07 and OR 0.62; 95% CI 0.45-0.87, respectively), with similar results for chronic inflammation. Regions with higher prevalence of prostate inflammation had lower prostate cancer risk at 2-year biopsy, including North America (OR 0.87; 95% CI 0.71-1.07) and Australia/New Zealand (OR 0.48; 95% CI 0.24-0.95), relative to Europe. Conversely, regions with lower prevalence of prostate inflammation had higher prostate cancer risk at 2-year biopsy, including Northern and Eastern Europe (OR 1.30; 95% CI 1.05-1.62 and OR 1.74; 95% CI 1.29-2.35, respectively), relative to Western Europe. Conclusions: Geographic disparities in the prevalence of prostate inflammation is a potential biologic mechanism contributing to global differences in prostate cancer incidence rates.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Novel Approaches for Experimental Therapeutics

Introduction: The co-stimulatory receptor GITR plays an important role in initiating the immune response in the lymph nodes and in maintaining the immune response in the tumor tissue. Binding of GITR to its natural ligand directly leads to increased anti-tumor T cell activation and their survival. It also reduces the suppressive abilities of Treg cells, further increasing the anti-tumor immune response. The HERA-technology developed by Apogenix targets the TNF-receptor superfamily and generates fully human hexavalent fusion proteins with high clustering capacity for the cognate receptor. Hexavalent HERA-ligands are pure agonists whose signaling capacity is independent of secondary Fcγ-receptor crosslinking. Here we report in vitro and in vivo properties of novel hexavalent HERA-GITR constructs. Experimental procedures: For the assessment of in vivo stability, serum samples from a PK study with three HERA-GITR constructs in CD1-mice were analyzed with respect to their drug levels employing a specific ELISA assay. For functional characterization of HERA-GITR in vitro, immune cells were isolated from healthy-donor blood samples and profiled by multicolor flow cytometry (MC-FC). Subsequently, immune cells were cultured in growth media containing different HERA-GITR constructs and anti-C3D. Changes in activation and memory markers on T cells (e.g. CD25, CD69, CD45RA, CD45RO), their proliferation rate (CFSE assay) and the intracellular staining of cytokines (e.g. TNF-α and IFN-γ) was assessed by MC-FC. Results: Minor modifications led to three HERA-GITR drug candidates with unique pharmacokinetic properties / in vivo stability as explored in mice. Terminal half-life was between 61.7 and 200.6 hours. Stimulation of pan T cells as well as naïve CD4+ T-lymphocytes by anti-CD3 was further augmented by HERA-GITR as demonstrated by CD69 and CD25 expression. This effect was accompanied by an increased proliferation and an increased memory formation. Furthermore, we ob-
served an increased level of intracellular TNF-α and IFN-γ in naïve CD4+ T-lymphocytes incubated with anti-CD3 that could be further raised by the addition of dendritic cells (EC50 in a co-culture of T cells and human cancer cells and in a mixed lymphocyte reaction). The enzyme indoleamine 2,3-dioxygenase 1 (IDO1) catalyzes the degradation of tryptophan along the kynurenine pathway, and is frequently expressed in human malignancies. The activity of IDO1 induces an immunosuppressive microenvironment in tissues by inhibiting T-cell function through local depletion of tryptophan and induction of generation of kynurenine pathway metabolites. Inhibition of IDO1 is expected to diminish the immunosuppressive microenvironment and improve cancer patient outcomes, particularly when used in combination with cancer immunotherapy agents such as nivolumab and ipilimumab. In this presentation, we will disclose the chemical structure, enzyme inhibitory mechanism, in vitro potency and in vivo pharmacodynamic (PD) activity of BMS' IDO1 inhibitor currently in Phase I clinical trials. The compound is a potent and selective IDO1 inhibitor with no activity against another tryptophan degrading enzyme, tryptophan 2,3-dioxygenase (TDO). It exhibited potent cellular activity, suppressing kynurenine production in HEK293 cells overexpressing human IDO1 (IC50 = 1.1 nM) and in HeLa cells stimulated with IFNγ (IC50 = 1.7 μM). The compound also potently restored T-cell proliferation in a co-culture of T cells and human cancer cells and in a mixed lymphocyte reaction where T cells were co-cultured with allogeneic IDO1-expressing dendritic cells (EC50 = 1.2 μM). In vivo, when given once a day orally, the compound exhibited significant PD activity in mouse tumors grown subcutaneously in syngeneic hosts and in human tumors grown as xenografts in nude mice.

**#4965** Sustained tumor regressions and significant improvements in therapeutic index for a lead monomethyl auristatin E nanoparticle-drug conjugate, CRLX701, with the potential for improved anticancer effects. Liang Zhao, Roy I. Case, Donna Brown, Lata Jayaraman, Doug Lazarus, Christian Peters, Derek Van Der Poll, Ellen Rohde, Scott Eliasof, Chester A. Metcalfe. Cerulean Pharma, Waltham, MA.

Cerulean Pharma Inc. creates nanoparticle-drug conjugates (NDCs) designed to significantly mitigate a payload's limitations by providing sustained drug delivery to the tumor and superior therapeutic index through controlled release kinetics. By conjugating drug payloads to our novel β-cyclodextrin-PEG (CDP) copolymer through linker strategies that allow modulation of release and pharmacokinetics (PK), we provide advantages over entrapped nanoparticle strategies, e.g., polymeric nanoparticles and liposomes. Cerulean has two NDCs in the clinic, CRLX101 and CRLX301, evidencing the translatability of our technology. CRLX701 has been dosed in over 400 patients and CRLX301 is in an ongoing Phase 1/2a trial. A key and differentiating feature of our NDC platform is our linker technology, which is tailored for an optimal fit with the active pharmaceutical ingredient (API) conjugation functionality of the drug payloads we incorporate into NDCs and customizable to achieve desired drug release profiles. This linker technology works for most conjugatable APIs that can be linked through alcohol, carboxylic acid, amine, amide and urea functionality to our CDP polymer. To illustrate the capabilities of our NDC platform we will present the biological impact of a series of monomethyl auristatin E (MMAE)-containing NDCs. MMAE belongs to the dolastatinfamily of natural cytotoxic pseudopeptides, demonstrating potent disruption of tubulin polymerization and excellent in vitro anti-cancer properties. However, because of its toxicity MMAE cannot be used as a drug on its own. Our novel linkers provided the synthesized MMAE NDCs with sustained and controlled release kinetics, targeting low release rates (0.4-13%) to minimize toxicity of the MMAE-drug payload. Subsequent PK studies revealed that over MMAE, indeed, this improved tumor PK for CRLX701 translated into improved efficacy in a human prostate DU-145 xenograft model, in which sustained tumor regressions (6 of 8 cures) were observed for CRLX701 (4 mpk, qwx2) compared to reduced and unsustainable efficacy for MMAE (0.5 mpk, qwx2) at MTD doses. Cerulean continues to expand its platform through the development of new and emerging capabilities, including the conjugation of multiple payloads to a single NDC and the development of antibody-conjugated NDCs, to treat patients living with cancer.

**#4966** Phospho-proteome analyses confirm the unique Mode of Action of MP0274, an apoptosis inducing, biparatopic HER2-targeting DARPin drug candidate. Vikram Mitra, Ulrike Fiedler, Dan Snedl, Keith M. Dawson, Stephan Jung, Ian Pike, Elmar von Bauer. Proteome Sciences, London, United Kingdom; Molecular Partners AG, Schlieren-Zurich, Switzerland; Proteome Sciences, Frankfurt a. M., Germany.

Background: HER2 is an important target for antitumor therapy in several cancers, and while currently available HER2-targeting drugs provide a great treatment improvement they rarely achieve full disease control. We have developed a new HER2-targeting molecule with a unique pro-apoptotic mode of action that may provide additional benefit to patients. The DARPin® molecule MP0274 shows potency in several HER2-expressing PDX models and has been shown to directly induce apoptosis in cells that are addicted to HER2. Here we show through phospho-proteome analyses that MP0274 not only potently inhibits HER2/HER3 downstream signaling, but also shows a very distinct changes in the phospho-proteome pattern compared to approved HER2-targeting drugs. This provides mechanistic support to the unique mode of action of MP0274 that results in direct tumor cell killing without the need of effector-functions like ADCC. Methods: The effect of MP0274 on HER2 signaling was compared to trastuzumab, pertuzumab and a combination of both in the HER2-addicted cancer cell lines. Briefly, cells were incubated with drugs for 18 hours and then lysed. Lysates were analyzed for changes in the total with Western blot and phospho-proteins by Proteome Sciences' proprietary QuantGlobal Phosphoproteomics workflow. Results: Heat-maps of genes of interest indicate that MP0274 has a differential mode of action compared to trastuzumab, pertuzumab and a combination of both. On the total peptide and phospho-peptide level, the samples cluster specifically, based on the cancer cells used as well as drug treatment. Twenty nine unique global phosphorylation sites specific to HER2, including C-terminal tyrosines which are reported to recruit adaptor proteins starting signal transduction processes after auto-phosphorylation, were identified for MP0274. Several proteins were identified which were differentially expressed and phosphorylated after MP0274 treatment and which are involved in three key downstream signaling pathways activated by HER2/HER3 heterodimers: RAF/MAP kinase cascade, PI3K-induced AKT signaling, and signaling by PLCG1. Conclusions: MP0274 shows a unique and distinct inhibition of the HER2 signaling cascade, different from trastuzumab, pertuzumab and a combination of both. It induces a more profound inhibition of downstream signaling which provides mechanistic support to the finding that MP0274 direct cell killing by induction of apoptosis in HER2-addicted tumor cells. DARPin®s are small repeat proteins, designed to bind targets with high affinity and specificity, and which can be combined in a modular fashion to produce multifunctional agents.

While targeting mutations in the ERAS oncogene frequently drive tumorigenesis in human cancers (40% CRC, 20% NSCLC) through constitutive activation of the MAPK pathway, there are currently no targeted treatments available for KRAS mutant cancers. Inhibitors of the individual nodes of the MAPK pathway have been developed, but these molecules have been largely ineffective against KRAS mutant tumors in the clinic. Multiple studies have shown rational combinations of MAPK inhibitors may have anti-tumor activity in KRAS mutant models. In order to understand the versatility of combining RAF inhibitors in this context, we conducted a library screen consisting of 430 small molecule tool compounds in combination with RAF inhibitor AZ-628. Here we show: RAF inhibitors combine especially well with other MAPK pathway inhibitors in KRAS mutant tumor cells. In particular, Type II RAF inhibitors are synergistic with the MEK inhibitor Cobimetinib. In vitro and in vivo screening shows a superior preclinical efficacy in xenograft mouse model studies in vivo. Mechanically, we have found the MEK inhibitor disables ERK induced negative feedback on the MAPK pathway resulting in activation of CRAF in a KRAS dependent manner. The combination of RAF with MEK inhibition blunts KRAS-dependent activation of CRAF kinase activity and robustly inhibits MAPK signaling, thereby driving efficacy in KRAS mutant tumors. Broad cell line profiling with the combination of RAF and MEK inhibitors demonstrates that a majority of KRAS mutant lung and colorectal tumor lines exhibit synergy with the combination. Therefore, combining a Type II pan-RAF inhibitor with a MEK inhibitor has the potential to improve the therapeutic outcome in KRAS mutant cancers.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Novel Approaches for Experimental Therapeutics

#4968 Importance of tumor microenvironment in the preclinical estrogen receptor positive breast cancer: Primary tumor and bone metastasis models. Jenni Bernoulli,1 Mari I. Suominen,2 Tiina Kähkönen,1 Jenni Mäki-Jouppila,1 Jussi M. Halleen,1 Rikuja Oksala3. 1Pharmatest Services Ltd, Turku, Finland; 2Orion Corporation Orion Pharma, Espoo, Finland.

Tumor microenvironment (ER +) breast cancer has ability to metastasize to bone in high frequency. Bone is known to be fertile soil for metastasized cancer cells to survive and in turn, metastasized tumor cells alter normally balanced bone environment. Prevention and treatment of bone metastasis is challenging and better understanding why bone metastasis are resistant to current therapies is needed. Aim of the present study was to explore the role of tumor microenvironment in the preclinical estrogen receptor positive breast cancer models. To explore this we compared estrogen and microenvironment on growth of primary primary tumor and bone metastasis to establish predictive ER + breast cancer models for drug development. ER + human breast cancer MCF-7 cells were inoculated into mammary fat pad and in the tibia of female athymic nude mice. Mice received either hormonal supplementation (17-beta estradiol pellet, E2) or placebo. Tumor growth was followed for 5 and 9 weeks. From one group, E2 supplementation was removed on study week 5 and tumor growth was followed for 4 weeks. During the study, blood samples were collected for serum steroid concentration measurements and at the end, histopathological evaluation and immunohistochemical (IHC) stainings were performed to examine tumor steroid hormone receptor expression. Orthotopic MCF-7 tumor growth was clearly hormone dependent. E2 supplementation, that increased serum estradiol for app. 3-fold, supported tumor growth and when E2 was removed, tumor size reduced and no tumor growth was observed thereafter. In the full absence of E2 supplementation, no orthotopic tumor growth was observed. In contrast, when MCF-7 cells were inoculated into tibia, tumor growth was observed both with and without E2 supplement. IHC stainings confirmed orthotopic tumor to express ER, PR and AR when animals received E2. After E2 removal, orthotopic tumors expressed still ER and AR but no longer PR. Also intratibial tumors expressed ER and PR in the presence of E2, but no PR in the absence of E2 supplement. E2 is needed to support MCF-7 tumor growth when cancer cells are inoculated orthotopically into mammary fat pad. No orthotopic tumor growth is observed in the absence of E2 supplement. In contrast, in the bone microenvironment, MCF-7 cells form tumor even in the absence of E2 supplement. Results highlight importance of tumor microenvironment in the breast cancer progression and also refer why tumor in the different sites may be resistant to therapy. Taking together, when developing new therapies against breast cancer, focus should be addressed not only on primary tumor growth but also on bone metastasis where cancer cells are under influence of bone environment.

#4969 Impaired PARP1 DNA repair defines chemosensitivity in IDH1 mutant cell. Yanxin Lu, Yang Liu, Yu-Ting Su, Wendy Bautista, Mark R. Gilbert, Jing Wu, Chunzhang Yang, Center for Cancer Research, National Cancer Institute, Bethesda, MD.

INTRODUCTION: Mutations in isocitrate dehydrogenase (IDH1/2) are the most prevalent genetic abnormalities in lower grade gliomas. The presence of IDH mutations in glioma are prognostic for better clinical outcomes with longer patient survival, and greater sensitivity to chemotherapy. In the present study, we explore the molecular mechanisms that determine the chemosensitivity in IDH1-mutated glioma cells, and seek a potential therapeutic strategy by targeting DNA repair pathway in IDH1-mutated cells. METHODS: We established IDH1-mutated glioma cell lines by introducing pathogenic IDH1 mutations into glioma cells via lentivirus. We confirmed the metabolic deficiency and enhanced chemosensitivity in cells expressing IDH1 mutant enzyme. Further, we measured the intracellular level of nicotinamide adenine dinucleotide (NAD+), Poly (ADP-ribose) polymerase (PARP)-associated DNA repair and DNA damage level in these cells when treated with temozolomide (TMZ). Moreover, we evaluated a PARP inhibitor Olaparib and its synergic effect on TMZ-associated cytotoxicity. RESULTS: Our results show that the IDH1-mutated cells are more vulnerable to chemotherapy. TMZ treatment resulted in over 20-fold increase of cell death in IDH1-mutated cells compared with their wild type counterpart. IDH1-mutated cells exhibited an over 1.3-fold increase in DNA damage and over 1.42-fold increase in cellular apoptosis under TMZ treatment. Accordingly, IDH1-mutated cells produced 83.8% less poly (ADP-ribose) polymer (pADPR), an important substrate for PARP-associated DNA repair, during TMZ treatment; suggesting their incompetence to maintain genomic integrity due to decreased availability of NAD+. Targeting the PARP-associated DNA repair pathway using Olaparib remarkably potentiated TMZ-induced cytotoxic effects by 2.16 fold in IDH1 mutated cells. CONCLUSION: Our findings demonstrate that metabolic defects in IDH1-mutated cells affect PARP-associated DNA repair pathway via NAD+ depletion, and therefore prompt the sensitivity to chemotherapy. Targeting PARP-associated DNA repair pathway may represent a novel therapeutic avenue for IDH1-mutated gliomas.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Novel Small Molecular Targets and Approaches

#4970 Oxidative phosphorylation as a target in triple negative breast cancer therapy. Funda Meric-Bernstam,1 Kurt Evans,1 Xiaoqinf Zheng,1 Xiaoping Su,2 Erkan Yuca,3 Stephen Scott,1 Argun Akaakanat,1 Naoto Ueno,1 Bora Lim,1 Jennifer Litton,1 Vicente Valero,1 Fraser Symmans,1 Gabriel Hortobagyi,1 Charles Perou,2 Debu Tripathy,1 Guillio Draetta,1 Joe Marszalek,1 Ana Maria Gonzalez-Angulo,1 Stacy Moulder1. 1The University of Texas MD Anderson Cancer Center, Houston, TX; 2The University of North Carolina, Chapel Hill, NC.

Altered cellular metabolism is a hallmark of cancer. It is increasingly recognized that selected tumors are dependent on oxidative phosphorylation (OXPHOS). However, the role of OXPHOS in TNBC is not well understood. We performed RNA sequencing in pre-treatment biopsies from 43 patients with operable triple negative breast cancer (TNBC) who received sequential taxane- and anthracycline-based neoadjuvant chemotherapy. At a median follow-up of 63 months, 14 patients recurred and 12 patients died. At a false discovery rate of 0.05, 33 genes were differentially expressed between the patients who did and did not have a subsequent recurrence. Ingenuity pathway analysis demonstrated that one of the top canonical pathways that differed was higher expression of oxidative phosphorylation signature (p=5.89E-0.7). The patients who recurred had significantly higher levels of mitochondrial genes: MT-ND1 (adjusted p or FDR-BH; q=0.007); MT-ND5 (q=0.03) and MT-ND4 (q=0.04). Further, 21 genes were differentially expressed between patients based on survival, including MT-ND5 (q=0.001); MT-ND4 (q=0.005), MT-ND4L (q=0.015), MT-ND6 (q=0.018), and MT-ATP6 (P=0.03). Top canonical pathway that was differentially expressed based on survival was oxidative phosphorylation (p=9.98E-10). We therefore sought to determine the efficacy of IACS-10759, a novel inhibitor of OXPHOS, in 10 different TNBC patient-derived xenografts representing different gene expression based Lehmann TNBC subtypes. Growth inhibition was observed in multiple subtypes, with regression in one basal-like 1(BL1) 1 model, and stabilization of growth in multiple BL1 and immunomodulatory expression subtypes. Taken together, our data suggests that high OXPHOS is associated with higher recurrence and lower survival. OXPHOS is a promising target in several TNBC subtypes. A Phase I trial of IACS-10759, a potent inhibitor of complex I of oxidative phosphorylation, in leukemia is ongoing and planned in TNBC and other solid tumors.

#4971 IACS-010759, a novel inhibitor of complex I in Phase I clinical development to target OXPHOS dependent tumors. Jennifer Molina,1 Madhavi Bandi,1 Jennifer Bardenhagen,1 Christopher Bristow,1 Christopher Carroll,1 Edward Chang,1 Jason Cross,1 Naval Davel,1 Ningping Feng,1 Jason Gay,1 Mary Geck Do,1 Jennifer Greer,1 Jing Han,1 Judy Hirst,1 Sha Huang,1 Yongying Jiang,1 Zhiyu Kang,1 Marina Konopleva,1 Gang Liu,1 Helen Ma,1 Polina Matre,1 Timothy McAfoos,1 Funda Meric-Bernstam,1 Kurt Evans,1 Xiaofeng Zheng,1 Xiaoping Su,2 Erkan Yuca,3 Stephen Scott,1 Argun Akakanat,1 Naoto Ueno,1 Bora Lim,1 Jennifer Litton,1 Vicente Valero,1 Fraser Symmans,1 Gabriel Hortobagyi,1 Charles Perou,2 Debu Tripathy,1 Guillio Draetta,1 Joe Marszalek,1 Ana Maria Gonzalez-Angulo,1 Stacy Moulder1. 1The University of Texas MD Anderson Cancer Center, Houston, TX; 2The University of North Carolina, Chapel Hill, NC; 3Pharmatest Services Ltd, Turku, Finland.

Small Molecular Targets and Approaches
The RAS/MAPK pathway is dysregulated in approximately 30% of human cancers, and the extracellular-signal-regulated kinases (ERK1 and ERK2) serves as key central nodes within this pathway. The feasibility and clinical impact of targeting the RAS/MAPK pathway has been demonstrated by the therapeutic success of BRAF and MEK inhibitors in BRAF V600E/K metastatic melanoma. However, resistance development is a significant hurdle for the therapeutic potential of these compounds. A new strategy for targeting of multiple effectors such as RAF, MEK and ERK in this pathway offers a potential for enhanced efficacy while delaying and overcoming resistance. LY3214996 is a highly selective inhibitor of ERK1 and ERK2, with IC_{50} of 5 nM for both enzymes in biochemical assays. It potently inhibits cellular phospho-RSK1 in BRAF and RAS mutant cancer cells in an unbiased tumor cell panel sensitivity screen. LY3214996 targets and inhibits Ras-driven lung tumor cells. In molecularly defined subsets of these indications are dependent on OXPHOS. Furthermore, targeting of multiple effectors such as RAF, MEK and ERK in this pathway offers a potential for enhanced efficacy while delaying and overcoming resistance. these highly refractory cells. Analysis identified genetic alterations associated with vulnerabilities targeted by small molecules. About 85% of GBM patients display p53 pathway disruption, our results suggest independent pharmacological strategies for two different subtypes of GBM defined by TP53 and CDKN1A status. Our analyses provide molecular insights to drive targeted therapies in the new era of precision medicine.

#4975 A small molecule pan Id protein antagonist shows strong antitumor activity. Paulina M. The Id family of helix-loop-helix (HLH) proteins, Id1, Id2, Id3 and Id4, play a critical role in inhibiting differentiation during mammalian embryogenesis. They function in part by sequestering ubiquitously expressed E protein bHLH transcription factors via direct protein-protein interactions. Various Id proteins are re-expressed in adults in a number of pathologic states including cancer and diseases of the vasculature, where their activity has been shown to be essential for disease progression. The present study describes the solving of the Id1-E47 dimer crystal structure and subsequent development and characterization of a small molecule antagonist of the Id protein family. AGX3, AGX51 was identified in an in silico screen for compounds that could bind a hydrophobic crevice adjacent to the loop region of Id1. Highly conserved in the Id family, AGX3 inhibits the endogenous Id1-E protein interaction leading to the degradation of Id1 via ubiquitin-mediated proteolysis. The stability of all four members of the Id family are antagonized by AGX3 leading to a G0-G1 arrest and profound inhibition of viability with no acquired resistance observed in multiple cell lines after continuous exposure to the compound. Administration of AGX3 is well tolerated in mice and phenocopies genetic loss of Id expression analyses: suppression of breast cancer metastases to the lung associated with a reduced mesenchymal-to-epithelial transition, perturbation of the vasculature within the primary tumor, and growth regression of paclitaxel resistant breast tumors in combination with paclitaxel therapy. These studies identify a novel, first-in-class compound capable of antagonizing the activity of a protein family formerly considered undruggable and to the possible utility of AGX3 in the management of multiple disease processes in patients.

#4976 Ricolinostat, a selective HDAC6 inhibitor with immunomodulatory properties, has significant anti-melanoma activity in vitro and in vivo. Fengdong Cheng,1 Marta Gugliuzza,2 Jie Chen,1 Alejandro Villagra,1 David Woods,1 Jeffrey Weber,1 Steven Quayle,1 Jones Simon,1 Eduardo Sotomayer1

1The George Washington University, Washington, DC; 2Memorial Sloan Kettering Cancer Center, NYU Langone Medical Center, New York, NY; 3Acetylon Pharmaceuticals, Boston, MA.

Melanoma is a less common but the most aggressive type of skin cancer and the rates of melanoma have been rising for the last 30 years. Immunotherapy may represent a new treatment paradigm to benefit melanoma patients. Previous studies have identified HDAC6 playing a central role in the regulating melanoma immunogenicity. We have shown that genetic knockdown (KD) of HDAC6 in murine and human melanoma cells resulted in an increased the expression of MHCI and co-stimulatory molecules as well as melanoma associated antigens. In vivo studies demonstrated that the growth of melanoma cells lacking HDAC6 was significantly delayed as compared to wild-type cells. This growth was further delayed when HDAC6KD melanoma bearing mice were treated with anti-PD-1 antibodies. Recently, we have shown that in vitro treatment of murine melanoma cells with Ricolinostat decreases PD-L1 expression and increases the expression of acetyl tubulin. Surprisingly, in vivo treatment of B16 melanoma bearing animals with increasing concentrations of ricolinostat resulted in a dose-dependent inhibition of melanoma growth (p<0.05). No toxicities were observed at the doses studied; however, the antitumor effect exerted by ricolinostat was not observed when melanoma bearing SCID mice were treated with this compound, indicating that an intact host immune system is required for the observed antitumor activity. In lieu of these previously unknown immunomodulatory properties of ricolinostat, we next assessed the effects of this compound upon T cells and whether ricolinostat could augment the efficacy of checkpoint blockade in vivo. Murine T-cells were activated with anti-CD3 plus anti-CD28 in the presence or absence of ricolinostat. Then, those T-cells were adoptively transferred into B16 melanoma bearing mice. T-cell subpopulations from the lymph nodes were analyzed ex vivo. We show here that treatment of murine T-cells with ricolinostat resulted in a significant increase in central memory T-cells endowed with a strong anti-melanoma activity in vivo as compared to control group (p<0.05). Finally, the addition of ricolinostat to treatment either anti-CTLA4 or anti-PD1 treatment was associated with an enhanced inhibition of melanoma tumor growth. In summary, our results have identified HDAC6 as a novel target for melanoma immunotherapy and point out ricolinostat as an attractive agent to add to the immuno-oncology armamentarium.

IMMUNOLOGY: Adoptive Cellular Therapy for Cancer

#4977 Isolation and characterization of a PRAME-specific TCR with high avidity, potent anti-tumor efficacy and a favorable preclinical safety profile. Manon Weis, Carina Wehner, Christian Ellinger, Susanne Wilde, Dolores J. Schendel.

Medigenic Immunotherapies GmbH, Planegg/Martinsried, Germany.

Some of the challenges regarding adoptive T cell transfer as an immunotherapeutic approach for the treatment of cancer patients include the initial induction, isolation and later characterization of suitable TCR candidates. In addition, ensuring the expression of appropriate target antigens is important and complex as such antigens need to meet some critical demands. Published data as well as in depth in silico analyses revealed the tumor associated antigen PRAME a suitable candidate. Classified as cancer/testis antigen, PRAME is highly expressed in tumors with only limited or no expression in normal tissues, other than testis. Here we describe the induction of PRAME-specific, HLA-A*02:01 restricted CD8-positive T cells by using an in vitro priming approach. PRAME-specific T cells transfected with ivtRNA encoding full-length PRAME were cocultured with autologous CD8-enriched PBL from a healthy, HLA-A*02:01-positive blood donor. Initially primed T cells were expanded for 2 weeks and T cells bearing TCRs specific for PRAME-derived epitopes were identified by multimer staining and FACS analysis. Single cells were sorted into 96 well plates and after an expansion period of another 2 weeks, growing clones were screened for specificity. TCR sequences of specific clones were identified by using NGS and reconstructed in a retroviral vector system enabling stable transduction of effector cells. The resulting TCR-modified T cells were thoroughly analyzed and characterized using a dedicated set of assays to evaluate multiple parameters concerning safety and efficacy. This characterization revealed TCR T4.8-1-29 to be highly specific for a PRAME-derived epitope presented on HLA-A*02:01. Only epitope positive target cells expressing the appropriate HLA-RESTRICTION element induced cytokine secretion by T4.8-1-29 expressing effector cells, leading to recognition as well as specific lysis of these target cells. Recognition and lysis, not just of peptide-loaded T2 cells, but also of PRAME-transfected APC, transfected tumor cells as well as autologous PRAME-enogenous tumor cells was mediated by this TCR. T4.8-1-29 expressing effectors show a high natural avidity for the target epitope without the need of further manipulation, e.g. functional efficacy enhancement by affinity maturation. In addition, the toxicity assessment using various in vitro and in silico tools revealed a favorable preclinical safety profile for this TCR. In summary, by using an in vitro priming approach utilizing cells from healthy donors, it is possible to generate PRAME-derived epitope specific T cells with high natural avidity and specificity. The TCR shows a favorable safety profile, demonstrating that this approach is useful to generate TCRs potentially qualifying for evaluation in clinical trials.

#4978 Adoptively transferred CMV-Specific T-cells recognizing dominant and sub-dominant pp65 epitopes demonstrate improved in vivo inhibition of tumor xenografts in combination with PD-1 inhibition. Aisha N. Hasan,1 Annamaali Selvakumar,1 Tzu-Yun Kuo,2 Richard J. O’Reilly1.1Morial Sloan-Kettering Cancer Center, New York, NY; 2Weill-Cornell Graduate School of Biomedical Sciences, New York, NY.

Adoptive transfer of transplant donor or third party donor derived CMV-specific T cells (CMV-CTL) can effectively treat CMV infections in HSC reipients. In clinical trials, infusion of partially matched third party CMV-CTL, has demonstrated high response rates against persistent CMV infection. T-cells (TC) generated in vitro or directly selected in vivo demonstrate a striking preponderance of specificity for 1-2 immunodominant (ID) epitopes presented by specific HLA alleles. ID epitopes elicit higher TC functional activity in vivo, compared to sub-dominant (SD) epitopes. The relative clinical efficacy of TC directed against ID versus SD epitopes in vivo remains undefined. Agents augmenting activity of TC responsive to SD epitopes are unexplored. When these alleles are co-inherited in humans, epitopes of CMVpp65 presented by HLA-A*02:01 are ID over HLA-A*24:02 presented epitopes. We describe an in vivo model to assess efficacy of CMV-CTLs using colon carcinoma cells (caco)trans-
duced to express CMVpp65, as a surrogate system. HLA A*02:01 and A*24:02 + human coca cells were transduced to express CMVpp65 and GFP-firefly luciferase (cocc6p). CMV-CTLs responding to either the A*02:01 presented ID NLV epitope (A2-NLV) or the A*24:02 presented SD YQD epitope (A24-QYD) were generated from donors co-inheriting HLA A*02:01 and A*24:02 by in vitro stimulation with high densities of infected cells. After 5 years of culture and daily transfers to fresh feeder cells, HLA A*02:01 or A*24:02, B7.1, LFA-3, and ICAM1. Tumor cells (10^3 cells) were injected subcutaneously into groups of 5-6 NSG mice on the R flank, and 10^6 cells from a pp65 expressing melanoma cell line (melpp65), lacking expression of HLA A*02:01 or A*24:02 were injected on the L shoulder as control. 2 Groups each received 10^6 of tetramer+ A2-NLV or A24-QYD CMV-CTLs i.v per mouse; one of each 4 CMV-CTL treated group also received 2 i.v doses (200 ug/dose) of anti-PD1 antibody (Nivolulab-BMS) at day 2 and 7 post CTL infusion. Control groups received IL-2, with or without anti-PD1, or HLA mismatched CMV-CTLs. Tumor growth was monitored by bioluminescent imaging. CMV-CTLs responsive to SD A24-QYD epitope induced significant cocc6p growth suppression compared to controls, but did not eradicate tumors in any animal. Combined treatment of A24-QYD CMV-CTLs with anti-PD1-Ab induced complete cocc6p eradication in 2 of 5 mice, with minute residual tumors in 3 mice. Treatment with ID A2-NLV CMV-CTLs induced complete cocc6p eradication in 2 of 5 mice, and smaller residual tumors compared to SD A24-QYD CTL treatment. Combined treatment with anti-PD1 and A2-NLV CMV-CTLs led to complete cocc6p eradication in 3 of 5 mice, with minute tumors in 2/5 mice. Taken together, these data provide evidence that blocking the PD-L1-anti PD1 antibody (Nivolumab-BMS) at day 2 and 7 post CTL infusion. Control groups received IL-2, with or without anti-PD1, or HLA mismatched CMV-CTLs.
**IMMUNOLOGY: Adaptive Cellular Therapy for Cancer**

A single CD8+ T cell clone recognizing a mutation expressed in the solute carrier SLC3A2 (p.K94T) and cytokine profile for anti-tumor therapies. T cells were generated from a metastatic soft tissue tumor of a patient with hormone and chemotherapy-refractory ER+, HER2+ breast cancer. DNA was extracted from tumor and matched normal peripheral blood samples for whole exome sequencing (WES) and RNAseq. Non-synonymous somatic mutations were identified and tested for potential recognition by autologous TIL using previously described tandem mini-gene and long-read approaches. Recognition was assessed by IFN-γ release on ELISPOT and/or CD137 (4-1BB) upregulation with appropriate controls. Mutation reactive TIL were rapidly expanded in culture and transferred back to the patient. Adoptive cell transfer was preceded by a lymphodepleting preparative regimen and one dose of pembrolizumab. Cells were supported post-transfer with intravenous IL-2 administration, and pembrolizumab was administered for three additional doses. Deep sequencing of TCR rearrangement sequences was performed on the TIL and the pre- and post-infusion peripheral blood. Results: The resected subcutaneous tumor no longer expressed ER and was negative for PD-L1 staining. WES/RNAseq identified 96 non-synonymous mutations for testing. Multiple CD4+ clones specifically recognized a mutation expressed in the solute carrier SLC3A2 (p.K94T) and a single CD8+ clone recognizing a mutation in the proteasome-associated protein KIAA0368 (p.S186F) were identified with no recognition of wild-type peptides. These eight T cell clones constituted 23% of the infusion bag protein. Mutation reactive TIL were rapidly expanded in culture and transferred back to the patient. Nineteen months after transfer of 8x10^9 cells, the patient has an ongoing partial response, with target lesions down 96% from baseline, including multiple hepatic metastases and disabling brachial plexus adenopathy. Seven of the eight T cell clones with known reactivity persisted in the peripheral blood comprising 2.4% of all CD8 T cells at 7 months. Only two of these TCR clones were detectable, with frequencies totaling 0.005%, in the pre-treatment circulation. Conclusions: Tumor-infiltrating lymphocytes derived from a patient with metastatic breast cancer recognized tumor-specific, non-synonymous somatic mutations, expanded in vitro and were used for adoptive cell transfer. We also administered with IL-2 and a short course of pembrolizumab, persisted in vivo and mediated regression of soft tissue, nodal and visceral metastases of breast cancer.

**MOLECULAR AND CELLULAR BIOLOGY / GENETICS: Exploiting Metabolic Vulnerabilities to Treat Cancer**

**#4983** T cells expressing chimeric PD1 receptors that contain a Dap10 costimulatory domain are a potential treatment for multiple types of cancer.

Kelsey Deal, Emily Nylen, Amorette E. Barber. Longwood Univ., Farmville, VA.

Adoptive transfer of tumor-reactive T cells is a promising anti-tumor therapy for many cancer types. In this study, T cells, chimeric antigen receptors (CAR) consisting of signaling domains fused to receptors that recognize tumor antigens can be generated and expressed in T cells. One receptor that is a prospective target for a new chimeric antigen receptor is PD1 because the ligands for the PD1 receptor are expressed on many cancer types. Therefore we developed a murine chimeric PD1 receptor (chPD1) consisting of the PD1 receptor extracellular ligand recognition domain and the activation domain of CD3 zeta. In addition, current chimeric antigen receptor therapies utilize various costimulatory domains to enhance anti-tumor efficacy. Therefore, we also compared the inclusion of CD28, Dap10, 41BB, GITR, ICOS, or OX40 costimulatory domains in our chPD1 receptor to determine which costimulatory domain induced optimal anti-tumor immunity. To determine if this novel CAR could potentially target a wide variety of tumors, the anti-tumor efficacy of chPD1 T cells against murine lymphoma, melanoma, kidney, pancreatic, liver, and colon cancer cell lines was measured. Of the ten cell lines tested, all expressed PD1 ligands on their cell surface, making them potential targets for chPD1 T cells. Regardless of the costimulatory domain in the CAR, all of the chPD1 T cells induced similar levels of T cell proliferation and tumor cell lysis. However, differences were observed in the cytokine secretion profiles depending on which costimulatory receptor was included in the CAR. While most of the chPD1 T cell receptor combinations secreted both pro-inflammatory (IFNγ, TNFα, IL-2, GM-CSF, IL-17, and IL-21) and anti-inflammatory cytokines (IL-10 and IL-5) as determined by ELISA and LegendPlex analysis, chPD1 T cells containing a Dap10 costimulatory domain secreted high levels of pro-inflammatory cytokines, but did not secrete a significant amount of anti-inflammatory cytokines. Therefore, adoptive transfer of chPD1 T cells could be a novel therapeutic strategy to treat multiple types of cancer and inclusion of the Dap10 costimulatory domain in chimeric antigen receptors may induce a preferential cytokine profile for anti-tumor therapies.

**#4984** BNip3 suppresses hepatocellular carcinoma (HCC) growth by limiting lipogenesis.

Kay F. Macleod. Univ. of Chicago May Dept. for Cancer Res., Chicago, IL.

BNip3 is a mitochondrial protein that promotes the turnover of mitochondria at the autophagolysosome when nutrient supplies are low. BNip3-null livers exhibit lipid accumulation and develop a phenotype mimicking non-alcoholic steatohepatitis, a known precursor for development of hepatocellular carcinoma (HCC). Additionally, BNip3 is silenced in human HCC and other malignancies and this loss often correlates with more aggressive tumors and worse outcomes. However, the functional significance of BNip3 loss for growth and progression of HCC has not been determined. We utilized the diethylstilbestrol (DEN)-induced mouse model of HCC to determine how loss of BNip3 affected HCC development in the mouse. Wild-type and BNip3-null mice were treated with DEN, and tumor burden (size and number) was assessed at 6, 8, and 10 months of age. We also generated primary HCC cell lines from the tumors arising in BNip3-null mice for in vitro analysis of tumor cell growth and metabolism. We observed that BNip3-null mice had reduced tumor latency and enhanced tumor growth rate in the liver following DEN treatment compared to wild type mice consistent with BNip3 functioning as a tumor suppressor of HCC. Interestingly, tumors arising in BNip3-null mice accumulated increased lipid and qPCR analysis of primary tumors and cell lines revealed increased expression of lipogenesis genes compared to wild type. Treatment with a novel fatty acid synthase inhibitor or re-expression of BNip3 in the BNip3-null HCC cell lines reduced tumor cell growth and lipogenesis, and promoted oxidative metabolism. These results indicate that BNip3 acts as a tumor suppressor in HCC by limiting de novo lipogenesis and suggest that fatty acid synthase inhibitors could be effective therapeutically against BNip3 deficient HCC in patients.

**#4985** Understanding the vulnerabilities in cancer cells upon inhibition of glutathione synthesis.

Isaac S. Harris, Jennifer E. Endress, Joan S. Brugge. Harvard Medical School, Boston, MA.

A hallmark of cancer is the rewiring of cellular metabolic pathways, including those that mediate oxidative stress. Cancer initiation and progression, which demands increased production of ATP and synthesis of proteins, also results in elevated generation of toxic by-products such as reactive oxygen species (ROS). Cancer cells counteract ROS by increasing the production of antioxidants, which convert ROS into benign species. It has been shown that production of glutathione (GSH), the most abundant intracellular antioxidant, is necessary for many cancers to initiate malignant transformation. Furthermore, sensitivity was found to be specific to malignant cells, as non-transformed cells were resistant to the combined treatments. It has been hypothesized that this sensitivity could potentially target a wide variety of tumors, the anti-tumor efficacy of chPD1 T cells against murine lymphoma, melanoma, kidney, pancreatic, liver, and colon cancer cell lines was measured. Of the ten cell lines tested, all expressed PD1 ligands on their cell surface, making them potential targets for chPD1 T cells. Regardless of the costimulatory domain in the CAR, all of the chPD1 T cells induced similar levels of T cell proliferation and tumor cell lysis. However, differences were observed in the cytokine secretion profiles depending on which costimulatory receptor was included in the CAR. While most of the chPD1 T cell receptor combinations secreted both pro-inflammatory (IFNγ, TNFα, IL-2, GM-CSF, IL-17, and IL-21) and anti-inflammatory cytokines (IL-10 and IL-5) as determined by ELISA and LegendPlex analysis, chPD1 T cells containing a Dap10 costimulatory domain secreted high levels of pro-inflammatory cytokines, but did not secrete a significant amount of anti-inflammatory cytokines. Therefore, adoptive transfer of chPD1 T cells could be a novel therapeutic strategy to treat multiple types of cancer and inclusion of the Dap10 costimulatory domain in chimeric antigen receptors may induce a preferential cytokine profile for anti-tumor therapies.

**#4986** Pancreatic cancers develop metabolic resistance pathways to gluconeogenesis.

Steven P. Gygi,2 J. Wade Harper,2 Alec C. Kimmelman4. Massachusetts General Hospital, Boston, MA.

Pancreatic cancers develop metabolic resistance pathways to gluconeogenesis. These pathways are triggered by the depletion of glucose and liver damage. BNip3 suppresses hepatocellular carcinoma (HCC) growth by limiting lipogenesis. BNip3-null livers exhibit lipid accumulation and develop a phenotype mimicking non-alcoholic steatohepatitis, a known precursor for development of hepatocellular carcinoma (HCC). Additionally, BNip3 is silenced in human HCC and other malignancies and this loss often correlates with more aggressive tumors and worse outcomes. However, the functional significance of BNip3 loss for growth and progression of HCC has not been determined. We utilized the diethylstilbestrol (DEN)-induced mouse model of HCC to determine how loss of BNip3 affected HCC development in the mouse. Wild-type and BNip3-null mice were treated with DEN, and tumor burden (size and number) was assessed at 6, 8, and 10 months of age. We also generated primary HCC cell lines from the tumors arising in BNip3-null mice for in vitro analysis of tumor cell growth and metabolism. We observed that BNip3-null mice had reduced tumor latency and enhanced tumor growth rate in the liver following DEN treatment compared to wild type mice consistent with BNip3 functioning as a tumor suppressor of HCC. Interestingly, tumors arising in BNip3-null mice accumulated increased lipid and qPCR analysis of primary tumors and cell lines revealed increased expression of lipogenesis genes compared to wild type. Treatment with a novel fatty acid synthase inhibitor or re-expression of BNip3 in the BNip3-null HCC cell lines reduced tumor cell growth and lipogenesis, and promoted oxidative metabolism. These results indicate that BNip3 acts as a tumor suppressor in HCC by limiting de novo lipogenesis and suggest that fatty acid synthase inhibitors could be effective therapeutically against BNip3 deficient HCC in patients.
Pancreatic ductal adenocarcinoma (PDAC) is an extremely aggressive disease with poor prognosis. Therefore, novel treatment options are essential to combat this highly refractory disease. Oncogenic Kras can promote a metabolic rewiring of pancreatic cancers, including the non-canonical use of glutamine to support growth and proliferation through redox homeostasis. Indeed, inhibition of downstream metabolites of glutaminolysis leads to decreased cell growth. The first step in glutaminolysis metabolism is mediated by the enzyme glutaminase (GLS) which catalyzes the conversion of glutamine to glutamate in the mitochondria where, in PDAC, glutamine-derived glutamate is metabolized ultimately resulting in increased reducing potential in the form of increased NADPH and GSH. An outstanding question in pancreatic cancer is whether GLS inhibition is a viable therapeutic strategy given it is the most proximal enzyme in the PDAC-specific glutaminolysis metabolism pathway, and how this may differ from targeting distal parts of the pathway. Using a combination of in vitro and in vivo models of pancreatic cancer, we tested whether recently developed highly potent inhibitors of GLS are an effective therapy for PDAC. We demonstrate that despite dramatic early effects on in vitro proliferation caused by GLS inhibition, pancreatic cancer cells have adaptive metabolic networks that allow them to sustain proliferation in vitro and in vivo. Through an integrated proteomic and metabolomic analysis, we identify multiple compensatory pathways that may explain the resistance to GLS inhibition and show as proof of concept that combining inhibitors to these pathways with GLS inhibitors may have therapeutic utility.

**#4987 ASS1 downregulation facilitates cancer cell survival in acidic environment.** Ayelet Erez,1 Alon Silberman,1 Adi Jacob,1 Sharan Limanovich,1 Odeda Boukobaz,1 Erez Persi,2 Rom Kesher,1 Alona Sarver,1 Joo Sang Lee,1 Alexander Brandis,1 Keren Bahar Halperrn,1 Raya Eilam,1 Ben Pode,3 Yair Anikster,1 Igor Ulitsky,1 Sandesh Nagamani,1 Eytan Ruppin1,1 WEIZMANN INSTITUTE, Rehovot, Israel; 2University of Maryland, College Park, MD; 3Sheba Medical Center, Tel Hashomer, Israel. pH gradient reversal, namely the alkalization of intracellular pH (pHi) and acidification of extracellular pH (pHe), is a unique phenotype of cancer cells which can enable cancer survival, migration and invasion. Hence, not surprisingly, there is an urgent need to develop novel therapeutic strategies that target pHi by elevating ammonia levels and buffering the acidity caused by cancers’ “pH gradient reversal”, namely the alkalinization of intracellular pH (pHi) and acidification of extracellular pH (pHe), is a unique phenotype of cancer cells which can enable cancer survival, migration and invasion. Hence, not surprisingly, there is an urgent need to develop novel therapeutic strategies that target pHi by elevating ammonia levels and buffering the acidity caused by cancers’

The chemotherapeutic drug methotrexate (MTX) inhibits nucleotide biosynthesis and causes cell death by blocking DNA and RNA production. While MTX has had tremendous success as an anti-cancer treatment and is the subject of nearly a thousand ongoing clinical trials, we do not fully understand why certain cancers are more sensitive to it and why resistance emerges. To study these questions, we used a CRISPR-based genetic screen to identify genes that confer sensitivity to MTX. We identified an enzyme that plays a key role in a metabolic pathway that was not known to be associated with MTX sensitivity. Inhibition of the pathway, either by genetic loss of several genes in the pathway or through nutritional modulations, causes dramatic resistance to MTX in cultured cancer cells. Our results improved our understanding of the cellular response to MTX, and suggest that expression levels of enzymes in the pathway may serve as clinical predictor for MTX response in patients.

Three-dimensional growth conditions, multicellular tumor spheroids reproduce several parameters of the tumor microenvironment, including oxygen and nutrient gradients, characteristic of poorly vascularized tumor regions. 3D high content screening (HCS) identified compounds that selectively kill tumor cells in the inner core of tumor cell spheroids by targeting the Stearoyl CoA Desaturase 1 (SCD1) pathway. SCD1 catalyzes the rate-limiting step in the production of monounsaturated fatty acids (MUFA)s which are abundant at the tumor surface on higher levels of MUFA:s compared to normal cells and SCD1 is highly expressed in multiple tumor types. Changes in the MUFA/S FA (saturated fatty acid) ratio alters lipid biosynthesis and thus triggers cellular (ER) stress and induces the Unfolded Protein Response. Although the lead compound was very effective in vitro, it had unfavorable PK and physical chemistry properties, including low permeability and solubility and very high lipophilicity. This led to insufficient oral bioavailability, which could be overcome by optimization of PK and physical chemistry properties. Here, we report on the in vitro/in vivo effects of our 3D HCS compounds which showed high potency in the 3D spheroid inner core assay with T47D breast cancer cells. In this in vitro model compound-induced inner core cell death is enhanced by SCD1 substrates palmitoleoyl-CoA and oleoyl-CoA but not by the SCD1 product, palmitic acid. Furthermore, the effects can be reproduced in 2D cultures, which become increasingly sensitive to inhibition by our 3D HCS compounds with decreasing FBS concentration in the culture medium and this effect can also be rescued by addition of MUFA:s but not of palmitic acid. Mode of action analysis showed that our compounds reduced palmitoleoyl- or oleoyl-CoA levels and simultaneously increased saturated fatty acyl-CoA of palmitate or stearate in several cell lines as well as in vivo. In the sensitive T47D cells, the compounds induced expression of stress response genes and genes related to lipid metabolism. While these results support the SCD1 pathway as target for our 3D HCS compounds, we also observed striking differences to published SCD1 inhibitors suggesting a new cancer target beyond SCD1. Thus, further validation of our inhibitors in vitro and in vivo will be required, but these results suggest that 3D spheroid cultures may be a valuable tool for elucidation of new drug targets for cancer therapy.

**#4990 High-throughput drug combination screening in tumor spheroids identifies context-dependent synthetic lethalities.** Wojciech Senkowski,1 Madhia Nazir,1 Malin Jarvius,1 Jenny Rubin,1 Johan Lengqvist,2 Mats G. Gustafsson,2 Peter Nygren,1 Kim Kultima,1 Rolf Larsson,1 Mårten Fryknäs,1 Uppsala University, Uppsala, Sweden; 2Karolinska University Hospital, Solna, Sweden.

Monolayer, two-dimensional (2D) cell cultures have been a predominant in vitro model for anticancer drug screening and genetic loss of high throughput screening (HTS). However, 2D cultures of cancer cells lack numerous properties of in vivo tumors, such as tissue-like structure, cell-cell interactions and nutrient/oxygen gradients. Thus, in recent years there has been an increased interest in 3D cell cultures, such as multicellular tumors spheroids (MCTS), to address some of these limitations. Recently, we and others have applied MCTS for HTS and identified oxidative phosphorylation (OXPHOS) as a selective vulnerability of quiescent cancer cells persisting in hypoxic and nutrient-deprived milieu. However, prolonged continuous exposure to OXPHOS inhibitors is necessary for the cytotoxic effect. Thus, there is a need to identify processes that could be co-targeted for enhanced anticancer activity. Here, we present two distinct HTS approaches to identify combination partner molecules for OXPHOS inhibitors. Since we were interested in targeting non-dividing nutrient-deprived cancer cells, we used quiescent MCTS (Q-MCTS), as an in vitro model. Cells in Q-MCTS experience glucose concentrations and pH similar to those observed in deep tumor parenchyma in vivo. In our first screening approach, we have applied high throughput gene expression profiling to study drug effects in MCTS at a large scale. Using L1000 Gene Expression Profiling method, we generated a dataset of over 1000 drug-induced gene expression (MUFAs). Cancer cells over targeting of OXPHOS and the modulate pathway results in selective synergistic toxicity in quiescent cancer cells. In the other approach, we screened a library of 1650 biologically active compounds, with or without addition of the FDA-approved anthelmintic agent nitazoxanide (an OXPHOS inhibitor with high drug repurposing potential). After the screen, we selected molecules that demonstrated pronounced synergy when combined with nitazoxanide, but not when used alone. Then, we validated the hits in an extensive dose-response combination experiments in Q-MCTS and chose 14 compounds that demonstrated strong synergistic interaction with nitazoxanide at broad range of concentrations. These included antifungal agents, kinase inhibitors and others. In summary, we...
MOLECULAR AND CELLULAR BIOLOGY / GENETICS: Exploiting Metabolic Vulnerabilities to Treat Cancer

here report on novel approaches, utilizing 3D cell cultures, to identify drug combinations targeting quiescent cancer cells. By high-throughput gene-expression profiling and large-scale combinatorial drug screens, we were able to identify drug combinations preferentially toxic to quiescent cells. This work also demonstrates how 3D cell cultures yield functional insights that are not accessible through standard 2D cultures.

MOLECULAR AND CELLULAR BIOLOGY / GENETICS: Transcriptional Regulation in Cancer Cells

Reprogramming of the chromatin landscape by sequence-specific transcription factors (TF) can influence in the prevalence and progression of several diseases, including cancers. Stereo receptors are a class of hormone-regulated TF that have a major impact on the progression of cancers. The link between the androgen receptor (AR) action in prostate cancer and the glucocorticoid (GR) and estrogen receptor (ER) action in breast cancer is well-known. Furthermore, other TFs such as the pioneer factor FoxA1 has been extensively linked to AR and ER action in these cancers. Although the action of these TF have been widely studied, the knowledge is almost exclusively based on population-based assays such as ChIP-seq. Hence, the dynamic binding behavior of TFs in living cell remains unclear. For example, the classical pioneer factor model suggests long term static binding events between pioneer TFs, such as FoxA1, and chromatin. However, little is known on the dynamic action of FoxA1 in living cells. We have examined the behavior of steroid receptors and cofactors, including FoxA1, at the single-molecule level in living cells. These factors were fused with HaloTag, and labeled with the bright and stable fluorophore JF549. Single-molecule tracking (SMT) of these proteins (using HILO microscopy) revealed a highly dynamic binding behavior of TFs. This supports transient rather than stable TF chromatin interactions. Specifically, two distinct binding populations have been observed for all factors tested; fast or slow stops. Fast stops represent genomic scanning of TF, while slow stops, with residence time of 6-14 sec, represent functional binding events at specific response elements. The vast majority of molecules at any given time are either diffusing or exhibit fast stops, while only a small percentage exhibit slow stops. However, hormone activation of AR, GR or ER results in an increase in the percentage of molecules with slow stops compared to the unstimulated state. Thus, our results indicate that on a single-molecule level, only a small proportion TFs are functionally bound at any given time. In addition to affirming the general model that many TFs are highly dynamic in their chromatin binding activity, SMT experiments in live cells revealed a highly dynamic interaction of FoxA1 with chromatin in vivo. Unexpectedly, we also observed by ChIP-seq and DHS-seq analysis that at subset of genomic sites, the role of pioneer can be reversed, with the steroid receptors serving to enhance binding of FoxA1. We propose a general model, dynamic assisted loading, wherein interactions between TFs and pioneer factors are highly dynamic. Our findings show that the action of key TFs in cancer development are more complex and dynamic in real time than previously reported.

Miswired super enhancer logic driving childhood sarcoma. Berkley E. Gryder,1 Marco Wachtel,2 Hsin-Chao Chou,1 Young Song,1 Joana Marques,2 Beat Schaefer,7 Javed Khan1. 1National Cancer Institute, Bethesda, MD; 2University Children’s Hospital, Zurich, Switzerland.

Super enhancers (SEs) are regulatory regions with unusually large deposits of active histone marks, chromatin regulators and transcriptional coactivators. Chromosomal rearrangements allowing SEs to drive oncogene expression is an emerging mechanism in tumor biology. An aggressive myoblastic cancer of childhood, alveolar (fusion-positive) rhabdomyosarcoma (FP-RMS), universally possesses a chromosomal translocation, involving most commonly PAIX3 and FOXO1, more rarely PAIX7-FOXO1, and in exceptional cases novel PAIX3-INO80D and PAIX3-NCOA1 fusions. Patients with a PAIX3-fusion frequently relapse and have low survival rates. PAIX3 initiates specification of the muscle lineage, but is shut off during myogenic differentiation, which is in turn dominated by master regulators MYOD and finally MYOG. FP-RMS has the master regulators needed to trigger muscle differentiation, but are halted in an early myoblastic and thus more proliferative epigenetic state. We hypothesized that the translocations misregulates regulation of the fusion oncogene in FP-RMS by hijacking SEs and creating new topologically associated domains (TADs) which allow for continued expression of PAX fusions, thus circumventing normal myogenic enhancer logic. Thus, we recently completed the first epigenetic landscape of FP-RMS and uncovered a strong dependence on SEs for tumor survival, with PAIX3-FOXO1 being a chief determinant of SE formation in collaboration with PAIX3, MYOG, and FOXO1. We discovered a key SE 300 kb distal of FOXO1 which was occupied by all four of these master regulators. Further, we found that PAIX3-FOXO1 is driven by this novel translocated SE forming a key TAD structure which was necessary to directly influence PAIX3 upon translocation, with CTFC analysis in FP-RMS cells confirming the predicted boundaries. The CTFC motif orientation was found to be anti-parallel, restricted translocation of event, permitting chromatin loop extrusion. We demonstrate these elements to physically interact only in the presence of the translocation by chromatin conformation followed by sequencing (4C-seq). Exon-level expression via RNAseq in primary tumors revealed that the final exon of PAIX3, not involved in the translocation, was unexpressed, indicating that only the allele influenced by the FOXO1 SE is activated in patients. Finally, CRISPR/Cas9 technologies were employed to functionally interrogate the relative contributions of the enhancer elements and CTFC looping sites at TAD boundaries. Together these data suggest that these newly juxtaposed enhancer elements initiate and continually drive PAIX3-FOXO1 expression, implicating that enhancer miswiring is at the heart of the oncogenic process in FP-RMS. Thus, late myogenic factors (MYOG/MYOD) are contributing to drive an early factor (PAIX3), changing a “progressive” enhancer logic into an “infinite loop” enhancer logic.

The purpose of this study was to investigate the role of the Zn finger protein CTCF in the establishment of genetic borders and in controlling spatially-restricted activity of a mammary-specific super-enhancer (SE) known to selectively activate gene expression during pregnancy. CRISPR/Cas9 gene editing was used to generate mice with deletions in CTFC binding sites (CBSs) separating the Wap SE from the Ramp3 gene. ChIP-seq and qRT-PCR were used to investigate protein-DNA interactions and changes in gene expression, respectively. RNA-seq data demonstrated that expression of the mammary-specific Wap and widely-expressed Ramp3 gene was activated in mammary tissue at the onset of lactation. To investigate the possibility that the Wap SE can regulate both genes, mice carrying deletions in the SE were established. In these mice, both Wap and downstream Ramp3 were downregulated to the same extent, supporting the notion that the SE regulates both genes. Given these results, we investigated the contributions of several intervening CBSs in dampening SE activity on Ramp3. Mice harboring individual and combinatorial deletions of three CBSs (A, B and C) between the Wap SE and Ramp3 were generated. While loss of CTFC at site B (ΔB) had no apparent effect, loss of site A (ΔA) led to an expansion of H3K27ac from the adjacent SE in mammary tissue. The site C mutation (ΔC) resulted in a two-fold induction of Ramp3 in mammary tissue. Mice lacking all three binding sites demonstrated a marked increase in Ramp3 expression, which indicates that the CBSs block expression in an additive manner. To test the possible insulator function of these in a tissue with opposing gene expression, cerebellum was chosen as Ramp3 is actively transcribed while Wap is silent. The ΔA and ΔB mice showed no phenotype, but surprisingly ΔC mice demonstrated an 80% reduction in Ramp3 expression. Analysis of ChIP-seq and DNAse-seq demonstrated that site C coincides with a cerebellum-specific enhancer, which appears to regulate Ramp3 expression. These data demonstrate that a SE can activate two genes, albeit to different degrees. Furthermore, we demonstrate that CBSs do not serve as tight genetic boundaries encapsulating transcriptional enhancers and their associated genes, but are porous borders that allow for fine tuning of transcriptional activity. Individual CBSs have a modest ability to insulate genes, but a cluster of CTFC proteins is required to adjust the enhancer activity on genes and prevent deregulation. In addition, we show that CBSs are not restricted to a unique function and can act in a tissue-specific manner to contribute to gene regulation. These data help us to develop a more nuanced understanding of SE function as well as the roles of CTFC in regulating gene expression. Previous studies have shown that SEs and CBSs are mutational hotspots in cancer, implicating them in tumorigenesis. A more complete understanding of their biology will allow a better understanding of their role in cancer.

#4994 Understanding the MYC and WDR5 interaction at chromatin. Alissa D. Guarnaccia, April M. Weissmiller, Lance R. Thomas, William P. Tansey. Vanderbilt University, Nashville, TN.

Proceedings of the American Association for Cancer Research • Volume 58 • April 2017
Molecular and Cellular Biology / Genetics: Transcriptional Regulation in Cancer Cells

MYC is an oncprotein that is overexpressed in the majority of malignancies and contributes to an estimated 70,000-100,000 cancer deaths in the United States every year. The broad pro-tumorigenic functions of MYC stem from its role as a sequence-specific transcriptional regulator, controlling the expression of thousands of genes linked to cell cycle control, growth, and metabolism. Key to understanding how MYC causes cancer, therefore, is understanding the mechanisms through which it selects its target genes. Histone modifications, DNA sequence, and interactions with other transcription factors have all been suggested to influence where MYC binds chromatin, but a consistent signature has not been defined. Our laboratory recently discovered that the chromatin regulatory protein WDR5—a core component of histone modifying complexes—interacts directly with MYC and co-localizes with MYC at a majority of its target genes in human cells (Thomas et al., Mol. Cell, 58: 440–452, 2015). Point mutations in MYC that disable interaction with WDR5 do not impact the ability of MYC to bind naked DNA, but they do prevent MYC from recognizing target genes in the context of chromatin and from driving tumorigenesis in mice. These studies led us to propose that the MYC-WDR5 interaction is a critical determinant in MYC target gene recognition, in a process we refer to as "facilitated recruitment." In the facilitated recruitment model, the presence of WDR5 at chromatin promotes MYC binding at certain genomic loci over others. The role of WDR5 in target gene selection by MYC can explain much of the plasticity in genome-wide binding patterns of MYC that have been reported, and may provide a new avenue for therapeutically targeting MYC in cancer. Two important questions are raised by these studies, however. How does WDR5 recognize and select its target genes? And what other functions, if any, does WDR5 play in regulating MYC target genes? To answer these questions, we are employing traditional and quantitative proteomics, together with biochemical approaches, to characterize the composition and stoichiometry of the WDR5-containing complex that associates with MYC. These studies, still ongoing, have demonstrated that this complex is devoid of canonical WDR5-interaction partners such as RBBP5 and HCF-1, revealing that the function of WDR5 in this setting is distinct from its well-characterized roles in histone modifications. We propose that the WDR5 complex that associates with MYC on chromatin is either entirely novel, or is a 'ghost complex' in which select protein components have been excluded by the direct interaction of MYC with WDR5. We continue to define the biochemical constituents of the MYC-WDR5 complex, and in terrogate their role in facilitated recruitment using a combination of genetic, biochemical, and genomic approaches.

Premature polyadenylation causes oncocgenic truncations of the tumor suppressor genes BRCA1, LATS1 and MAGI3 in breast cancer.

Thomas K. Ni, Charlotte Kuperwasser. Tufts University, Boston, MA.

Cleavage and polyadenylation is a fundamental process in the control of gene expression, yet how cancer cells deregulate this process to generate cancer-caus ing alterations is only now coming to be appreciated. We previously reported that premature polyadenylation of the tumor suppressor gene MAGI3 causes the expression of a truncated protein that dominantly promotes malignant growth via the Hippo pathway. This established a precedent for premature polyadenylation as an aberrant process causing transformation in vitro and in vivo. However, little is known about the molecular mechanism that causes premature polyadenylation, or what types of genes it affects in cancer. Despite the absence of cis-acting mutations, premature polyadenylation of MAGI3 occurs specifically following the gene's large internal exon. We therefore asked whether an epigenetic mechanism might underlie the phenomenon of premature polyadenylation in cancer. Here, we report that genes with large internal exons are susceptible to truncation by premature polyadenylation. In addition to MAGI3, premature polyadenylation truncates the gene products of two tumor suppressor genes with large internal exons, BRCA1 and LATS1. These truncated proteins are upregulated in breast cancer cells compared to non-transformed mammary epithelial cells and enable downstream oncogenic events instead of providing tumor suppressive functions. Large internal exons are infrequently found in the genome as the mechanics of efficient splice site recognition are not conducive to this form of RNA processing. Interestingly, this truncation is conspicuously enriched in N6-methyladenosine (m6A), though the functional significance of these epitranscriptomic marks remains unknown. Mole- cularly, we find that methylated levels of N6-adenosine in the large internal exons of BRCA1, LATS1 and MAGI3 transcripts are significantly reduced in breast cancer cells that upregulate the truncated gene products compared to non-transformed mammary epithelial cells. These results raise the intriguing possibility that m6A marks in large internal exons are mechanistically involved in repressing premature polyadenylation. We are currently investigating this hypothesis by perturbing N6-adenosine methylation in cells and examining the functional consequences. In summary, our study suggests that premature polyadenylation may be a more pervasive alteration mechanism than previously appreciated in cancer and begins to illuminate a gene region-specific mechanism responsible for repressing premature polyadenylation.

The m6A hallmark of cancer: RNA demethylase ALKBH5 maintains tumorigenicity of glioblastoma stem-like cells by sustaining FOXMI expression and cell proliferation.

Sicong Zhang, Aidong Zhou, Oliver Bogler, Sadhan Majumder, Suyun Huang. MD Anderson Cancer Ctr., Houston, TX.

N6-methyladenosine (m6A) is the most prevalent internal modification on mRNA, but its functions in human diseases are poorly understood. The dynamic and reversible m6A modification installed and erased by N6-methyltransferases and demethylases regulates cell fate and gene expression. We show that the m6A demethylase ALKBH5 is highly expressed in patient-derived glioblastoma stem-like cells (GSCs) and informs poor survival of patients with glioblastoma. Silencing ALKBH5 suppresses the proliferation of GSCs in vitro and in vivo. Results of integrated transcriptome and m6A-seq analyses reveal a global change of gene expression enriched in cell cycle and altered expression of select ALKBH5 targets. Among these targets, Ingenuity’s upstream regulator analysis identified FOXMI, an essential transcription factor for GSC proliferation, as a key mediator responsible for the disrupted proliferation program. Using multiple molecular and biochemical approaches, we demonstrate that ALKBH5 binds to and demethylates FOXMI nascent transcripts. This promotes the interaction of FOXMI with mRNA and promotes translation. Furthermore, long noncoding RNA antisense to the FOXMI (FOXM1-AS) interacts with ALKBH5 as well as FOXM1 pre-mRNA and promotes their interaction. Depleting ALKBH5 and FOXM1-AS abolishes GSC tumorigenesis through the FOXM1 axis. The vulnerability of GSCs to disruptions in ALKBH5-dependent gene expression suggests that m6A has a central role in tumor development and provides a rationale for therapeutically targeting epitranscriptomic modulators in patients with glioblastoma.

Specialized microRNPs and translation mechanisms in quiescent cancer cells.

Syed I. Bukhari,1 Samuel S. Truedell,1 Soocheon Lee,2 Swapna Kollu,1 Anthony Classon,1 Myriam Boukhali,2 Esha Jain,2 Richard D. Mortensen,1 Akiko Yanagya,3 Ruslan Sadreyev,2 Wilhelm Haas,1 Shobha Va- sudevan1.1 Massachusetts General Hosp. Cancer Ctr., Boston, MA; 2Massachusetts General Hosp., Boston, MA; 3McGill University, Montreal, Qc, Quebec, Canada.

Quiescence (G0) represents an assortment of reversible, cell cycle-arrested states that are resistant to unfavorable conditions and associated with cancer persistence. G0 involves regulated gene expression with selective mRNA expres- sion and decreased canonical translation. Low mTOR activity in G0 activates the cap complex inhibitor, eIF4EBP, and impairs canonical translation. The alter- native translation mechanisms in G0 remain to be uncovered. Our data show that microRNAs, regulatory, non-coding RNAs that target distinct mRNAs to alter gene expression in unfavorable conditions and associated with translation factors to regulate specific mRNA translation in G0. One subset of transcripts expressed in G0 includes specific miRNAs recruited by an FXR1a-associated microRNP (microRNA-protein complex) for translation activation in G0 mammalian cells. MicroRNPs predominantly mediate repression and downregulation; however, FXR1a-microRNP lacks conventional microRNPs, and instead, contains a specific RNA binding protein isoform, FXR1a. FXR1a promotes translation and is overexpressed and associated with poor prognosis in several cancers. Our data reveal that microRNA-mediated activation requires target mRNAs with unadenylated/shortened poly(A) tails to avoid the roles of PABP in enhancing microRNA-mediated downregulation and in canonical translation that is impaired in G0. Instead of canonical translation factors that are inhibited by eIF4EBP in G0, we find alternative translation factors—a non-canonical 5’ cap binding factor and an eIF4G homolog that interacts with the ribosome—are recruited by the 3’-UTR binding FXR1a-microRNP, and promote specific mRNA translation. Our data show that G0 leukemic cells are chemoresistant and their translation profile is similar to surviving leukemic cells that are isolated after clinical therapy. We find expression of critical cytokines linked to G0 persistence, and significantly, inhibiting these immune regulators in resistant G0 cancer cells reduces their survival and chemoresistance. These data reveal a specialized translation mechanism in G0 cancer cells that promotes specific mRNA translation in these conditions of reduced canonical translation, and is important for chemoresistance.

**#4998 Breast tumor FOXA1 protein expression and reproductive characteristics among African-American and European-American women.** Ting, Yuan David Cheng,1 Rochelle Payne Ondracek,2 Song Yao,3 Viam Bshara,2 Thar Khoury,2 Gary R. Zirpoli,2 Warren Davis,2 Elisa V. Bandera,1 Michael Higgins,3 Christine B. Ambrosone,4 University of Florida, Gainesville, FL;6 Roswell Park Cancer Institute, Buffalo, NY;1 Massachusetts General Hospital, Boston, MA;2 Rutgers Cancer Institute of New Jersey, New Brunswick, NJ.

Background: Forkhead box protein A1 (FOXA1) plays a key role in determining estrogen receptor (ER) function and mammary ductal development and may repress the basal cell phenotype during differentiation of breast epithelium. While reproductive factors are known to influence breast cancer risk depending on the subtypes, data on the association of tumor FOXA1 protein expression and reproductive characteristics are very limited. Methods: Tissue microarrays comprising surgical tumors from 638 women (466 African-American [AA] and 172 European-American [EA], aged 20-75 years) with primary breast cancer in the Women’s Circle of Health Study (WCHS) were analyzed for FOXA1 expression by immunohistochemistry and automated image analysis. In-person interviews were conducted to obtain data on demographics, medical and family histories, and reproductive and menstrual histories. Logistic regression was performed for FOXA1 positivity (>10% cells with strong staining) with menopausal status, age at menarche, age at first live birth, parity, and breastfeeding, adjusting for age at diagnosis, family history of breast cancer, and history of benign breast disease. Results: FOXA1 expression was higher in tumors from EA compared to those from AA women (80% vs. 70% positivity, P = 0.011). FOXA1 expression was highly correlated with ER positivity (88% positive in ER+ and 26% in ER− breast cancer among AA women; 90% and 29% respectively among EA women; both P < 0.001). Among AA women, a higher number of live births was associated with lower FOXA1 expression (odds ratio [OR] = 0.45, 95% confidence interval [CI] = 0.22-0.91) for 2 live births and OR = 0.44, 95% CI = 0.20-0.91 for 3 live births (versus nulliparous). However, the inverse association was not observed among EA women, potentially due to the small sample size. Conclusion: In AA women, a higher number of live births, which has been related to greater risk of ER− breast cancer, is associated with lower FOXA1 expression. Because FOXA1 promotes luminal and represses the basal differentiation, respectively, the effects of parity on expression of FOXA1 may be the link whereby it increases risk of ER− breast cancer. Hubbell family)

**#4999 Stress, spiritual wellbeing and cancer risk among diverse racial faith-based communities: elevated levels of stress proteomic biomarkers in breast cancer patients.** Padma P. Tadi Uppala,1 Gretchen Krivak,1 Sherine Brown-Fraser,1 Dixon Anejie,1 Alfredo Mejia,1 Dominique wakefield,1 Kumar Kolli,2 Andrews University, Berrien Springs, MI;1 Windber Research Institute, Windber, PA.

Spiritual wellbeing is associated with decreased risk of cancer. Stress and depression are common among cancer patients and may be inversely associated with spiritual wellbeing. The purpose of the study is to examine if stress and depression as indicators of cancer risk are lower in a racially diverse faith-based community. Methods: 752 individuals from a faith-based community completed a behavioral assessment survey that mapped the current patterns of behavior in key categories that include: stress, depression, exercise and nutrition using the E-wellness platform FitThumb. To identify stress biomarkers in cancer patients we examined levels of stress serum proteomic biomarkers that were previously identified in our study by proteomic profiling using 2D-DIGEMS analysis and a subset of samples by shotgun LCMS technology. The serum proteomic study included serum samples from 15 African American breast cancer patients and 12 healthy controls who were from a faith-based community. Results: The behavioral assessment surveys that included 752 individuals who were racially diverse showed a low stress risk of 47.74% vs 8.24 % of high stress risk for chronic disease; and low depression risk of 85.11% vs 1.99% high risk for chronic disease. Elevated levels of stress and inflammatory serum proteomic biomarkers such as ceruloplasmin known to increase in stressed animals and humans; hep-toglobin, apolipoproteins, and heat shock proteins were significantly elevated in breast cancer patients compared to healthy controls. Conclusions: Our results indicate that spiritual well-being is associated with significantly low stress and depression in a faith-based community regardless of race or ethnicity, posing a low risk for cancer as shown in previous Adventist Health Cohort studies. Future efforts will focus on validating and identifying panel of biomarkers from this cohort to gain insight into their role(s) in the mechanisms of stress hormones and cancer risk. Funded by Susan G Komen for the cure.

**#5000 A stromal liver gene signature predictive of HCC risk across all liver disease etiologies.** Shiengki Nakagawa,2 Naoki Umesaki,1 Takano Yamao,1 Yuki Kitano,1 Kenseki Yamamura,1 Kota Arima,1 Tatsunori Miyata,1 Takayoshi Kaida,1 Yuzin Hoshida,1 Katsunori Imai,1 Daisuke Hashimoto,1 Yo-Ichi Yamashita,1 Akira Chikamoto,1 Hideo Baba,1 Graduate School of Medical Sciences, Kumamoto University, Kumamoto City, Japan;3 Icahn School of Medicine at Mount Sinai, New York, NY.

Background & Aims: HCC risk-predictive biomarkers will enable identification of patients who most need close monitoring and cancer preventive intervention. We previously reported a stromal liver gene signature predictive of HCC risk in multiple independent patient cohorts mainly affected with HCV (Hoshida 2008, Hoshida 2013, King 2014). We aimed to determine whether the gene signature is similarly prognostic in HBV, alcohol abuse, and NAFLD/ NASH patients. Methods: The liver gene signature was analyzed using an FDA-approved diagnostic platform (NanoString), and an independent cohort of curatively resected early-stage HCC patients (n = 223, median follow up 4.5 years, HCV [n = 67, 30%], HBV [n = 39, 17%], alcohol [n = 51, 23%], NAFLD [n = 66, 30%], and NASH [n = 52, 23%, a subset of 66 NAFLD patients]) were analyzed. Complete surgical resection was radiologically and histologically confirmed, and HCC recurrence in the cohort was confirmed to be mainly late recurrence, i.e., de novo carcinogenesis, based on a recurrence hazard plot. Prognostic pre- dictors were identified using a previously developed PEP model to multiple any modification, and evaluated for association with de novo HCC recurrence in multivariable modeling and subgroup analyses. Results: The gene signature assembly classified the patients into high- (n = 49, 22%), intermediate- (n = 127, 57%), and low- (n = 47, 21%) risk groups. The high-risk prediction was associated with higher HCC recurrence (HR = 4.8, p<0.001) as well as overall death (HR = 4.8, p<0.001) in multivariable modeling. The association with HCC risk remained significant in subgroups of patients with HCV (HR = 3.0, p = 0.028), HBV (HR = 6.1, p<0.001), alcohol (HR = 6.1, p = 0.023), and NASH (HR = 10.9, p = 0.03) in multivariable models including cirrhosis and AJCC stage 2/3. The association was diminished in NAFLD patients (HR = 3.0, p = 0.16), suggesting that presence of active inflammation and/or fibrosis is critical for the signature to predict HCC risk in NAFLD. Established cirrhosis was less frequent in NAFLD/NASH (23%/21%) compared to other etiologies (50%). Conclusions: The prognostic liver gene signature was implemented in a clinically applicable assay, and successfully validated for de novo HCC recurrence after curative resection of early-stage HCC in all major etiologies of chronic liver disease and HCC. The assay will enable prioritization of patients for HCC surveillance and enrichment of high risk patients for more cost-effective clinical trials of new HCC chemopreventive therapies.

**#5001 Functional biomarker discovery from cancer patient serum with PEP technology.** David L. Wang, Guofeng Fu, Michael Davies, Xing Wang, Array Bridge Inc, St. Louis, MO.

Proteins play essential roles in numerous biological processes and being able to detect functional differences between cell or tissue samples can greatly aid in understanding disease processes and metabolic changes. The PEP technology allows systematic analysis of protein functions within a proteome. Hundreds of functional proteins can be separated and functionally assayed to generate a comprehensive three-dimensional landscape of protein families such as protein kinases, phosphatases, proteinases and oxidoreductases. This information can then be integrated into other genomic and proteomic knowledge bases to provide further insight of important biological processes such as cancer development and aging. In the PEP technology, complex protein mixtures are first separated by a modified two-dimensional gel electrophoresis process, giving enhanced resolution while still maintaining protein function. This is followed by an efficient protein transfer to a specially designed 1356-well Protein Elution Plate. After protein transfer, a previously developed PEP model to multiple 384-well microplates, functional assays can be performed on each well to generate an enzyme activity profile displayed in 3-D. Protein components of each well can be further characterized by mass spectrometry if desired. Using the PEP technology, functional biomarker candidates have been identified from lung and breast cancer patient serum. Both qualitative and quantitative differences of metabolic enzymes and proteinases were observed when comparing the cancer patient serum to matched normal serum. Some of the active enzymes were identified by mass spectrometry and validated in selected bioassays. It is believed that this functional proteomics technology provides a unique approach in the discovery of potential cancer biomarkers for diagnostic and prognostic applications.
Preliminary studies have shown that Lactobacillus kefiri P-IF, a novel kefir product, has the ability to activate dendritic cells, and to induce apoptosis in human gastric cancer cells and MDY myeloid leukemia cells in vitro. In this study, we aimed to evaluate the anticancer effect of L. kefiri P-IF against animal bearing Ehrlich Ascites Carcinoma (EAC) and investigate the mechanisms of action. Materials and Methods: Mice were inoculated intramuscularly with EAC cells to develop solid tumors. L. kefiri P-IF was administered orally (2mg/kg/day) to mice 6 days/week, either two days before tumor cell inoculation or nine days after inoculation to mice bearing solid tumors. Tumor growth, blood lymphocyte levels, cell cycle progression, apoptosis, apoptotic regulators expression, TNF-α expression, changes in mitochondrial membrane potential (MMP), PCNA, and CD4+ and CD8+ T cells in tumor cells were quantitatively evaluated by flow cytometry or RT-PCR. Further studies in vitro were carried out where EAC cells were cultured in the presence of L. kefiri P-IF at different concentrations (0, 0.6, 1.25, 2.5, and 5 mg/mL) for 1, 24, and 48 hrs. % cell viability and IC50 was estimated by MTT assay. Results: 100% of mice that were inoculated with EAC cells alone developed tumors. Mice pretreated with L. kefiri P-IF showed tumor incidence in 76.5% of the animals. Treatment with L. kefiri P-IF markedly reduced tumor weight: 64.6% for pretreatment and 48.6% for post treatment. Mice treated with L. kefiri P-IF showed profound suppression of tumor marker PCNA expression and cell cycle arrest in the sub-G1-G0 phase, as indicated by elevation in the apoptotic cell population by 2.7 and 2.3 fold of control for pretreatment and post treatment, respectively. Pretreatment or post treatment with L. kefiri P-IF in EAC mice increased the Apoptosis index/Proliferation index ratio by 3.4 and 2.4 fold, respectively versus control. L. kefiri P-IF treatment modulated apoptotic regulators, including up-regulation of p53 expression, increased Bax/Bcl-2 ratio, decreased MMP of cancer cells, and activation of caspase-3 expression. L. kefiri P-IF intake maintained blood lymphocytes within the normal levels, increased the number of infiltrating CD4+ and CD8+ T cells within the tumor, and enhanced TNF-α expression. Finally, L. kefiri P-IF enhanced cytokotoxicity against EAC cells in vitro, as shown by IC50 of 3.30 mg/mL, 1.56 mg/mL and 1.11 mg/mL for 1, 24, and 48 hrs, respectively. Conclusion: In conclusion, L. kefiri P-IF, a novel symbiotic microbe, may have chemopreventive potential to reduce tumor incidence and tumor growth by inducing apoptosis in EAC cells via mitochondrial dependent pathway, suppressing cell proliferation, and stimulating the immune system. L. kefiri P-IF was provided by Paitos Co., Ltd. Yokohama, Kanagawa, Japan.
was monitored weekly using biomimetic imaging. SUMMARY: Expression of E-selectin is high in HUVECs, MSPI and H55; CLA was high only in RPMI8226; and CXCRI4 was high in all MM cells. MM1 cells adhesion to stroma was decreased by GMI-1271 and even more profoundly decreased by GMI-1359 in a dose-dependent manner. Chemotaxis of MM1 cells towards conditioned media or SDF1 was moderately affected by GMI-1271, but completely abolished by GMI-1359. MM cell proliferation was significantly inhibited by GMI-1359, only when MM cells were co-cultured with stroma, but not alone. Stromal-induced drug resistance of MM cells to carfilzomib and lenalidomide was reduced in the presence of the GMI compounds, while the effect of GMI-1359 was stronger than GMI-1271. In vivo, GMI-1271 and lenalidomide as single agents delayed tumor growth, while the effect of GMI-1359 was stronger than GMI-1271 and lenalidomide as single agents. In addition, in vivo colon tumorigenesis models using conditional knock-out mice revealed that the absence of IFNγ expression by intestinal epithelial cells fosters tumor growth. Altogether, our data suggest that the loss of IFNγ responsiveness is a common event in CRC and protects tumor cells against the anti-tumorigenic effects of IFNγ.

#5006 Correlation between PD-L1 expression and tumor clinicopathologic characteristics in early stage breast cancer. Hadeel Assad, Juan Cattan, Subramanyeswara Arekapudi, Nancy Jackson, Hugo Macchi Conteri, Sherri Motahari, Hema Govil, Anibal Drelichman.

Background: Upregulation of Programmed Death-Ligand 1 (PD-L1) in tumor cells results in the deactivation of cytotoxic T cells in the tumor microenvironment and development of tolerance to the malignant cells. We aimed to investigate the role of PD-L1 expression in early stage breast cancer and its correlation with tumor characteristics as well as assess the relationship between PD-L1 membrane protein and gene expression. Methods: For this single center, retrospective study, women (age ≥18 years) with early stage breast cancer diagnosed between January 2005 and December 2005 were enrolled. Key inclusion criteria for enrollment were pathologic diagnosis of DCIS or invasive ductal/lobular carcinoma, stage 0-2, with local resection done in 2005. Patients had to have adequate formalin-fixed paraffin-embedded tumor specimens for PD-L1 testing. We hypothesized that higher levels of PD-L1 expression correlates with more aggressive disease and worse prognosis. We used histopathological analysis, medical chart review, and PD-L1 expression via immunohistochemistry (IHC) and reverse transcription polymerase chain reaction (RT-PCR) for data analysis. Chi Square and one way ANOVA analyses were used to compare clinical and pathologic characteristics of patients with high and low PD-L1 expression. Results: In 2005, 368 women were diagnosed with breast cancer at Providence-Park Hospital of which 31 pathological specimens were obtained for exploratory analysis. PD-L1 protein expression was determined to be positive if more than 1% of the tumor cells showed partial or complete membrane staining for PD-L1 by IHC. All patients with DCIS (n=7) were negative for PD-L1 expression although 5 showed gene expression by PCR. After excluding the DCIS specimens, 17% (4/24) of early stage breast cancer was found to express PD-L1 protein. Seven of 24 specimens (excluding DCIS) were positive for PD-L1 RNA by RT-PCR. There was no relationship between PD-L1 protein and mRNA expression (p=0.552). 75% of the PD-L1 positive specimens by IHC were also ER positive although this was not statistically significant (p=0.312). There was a trend toward larger tumors for those expressing PD-L1 on the cell surface (mean size of 2.7 cm vs 1.7 cm, p = 0.07). All the PD-L1 positive specimens had increased lymphocyte infiltration, although no statistical significance was observed. At 10 years from initial diagnosis, all-cause mortality rate was 29% (7/24). The rate of death in PD-L1 positive patients was 2/4 (50%) compared to 5/20 (25%) in PD-L1 negative group. Conclusion: Expression of PD-L1 in early stage breast cancer could be an important indicator for more aggressive disease and supports investigating checkpoint inhibitors in this population. Further investigation is needed to determine its applicability in clinical decisions and effects on treatment.

The presence of an interferon-dominated Th1 immune response in colorectal carcinoma (CRC) has been associated with improved clinical outcome. We have previously identified the guanylate-binding protein 1 (GBP-1), one of the major IFN-γ-induced proteins, as a marker for the Th1 immune response and an independent positive prognostic factor in CRC. We also found that GBP-1 is a necessary mediator of the anti-tumorigenic effects of IFNy. Interestingly, the expression of GBP-1 in CRC was observed more frequently in the desmoplastic stroma than in the directly adjacent tumor cells, suggesting that CRC tumor cells might become resistant to IFN-γ in the course of tumorigenesis. Indeed, we found that several colorectal carcinoma cell lines failed to express GBP-1 or other interferon-stimulated genes after treatment with IFN-γ, and were resistant to IFN-γ-induced apoptosis or proliferation inhibition. In these cell lines, the loss of IFN-γ responsiveness correlated either with the down-regulation of the IFN-γ receptor alpha chain (IFNγRα) or with the presence of a mis-glycosylated form of IFNγRα, which displayed an aberrant intracellular localization. The presence or absence of GBP-1 in CRC cells correlated with the clinical level by showing that the expression of IFNyRes is decreased in CRC compared to normal tissue. In addition, the down-regulation of IFNγRα expression in CRC correlated with a reduced cancer-related survival together with a higher rate of distant metastasis. In addition, in-vivo colon tumorigenesis models using conditional knock-out mice revealed that the absence of IFNγ expression by intestinal epithelial cells fosters tumor growth. Altogether, our data suggest that the loss of IFNγ responsiveness is a common event in CRC and protects tumor cells against the anti-tumorigenic effects of IFN-γ.

#5008 The brain microenvironment mediates resistance in luminal breast cancer to PI3K inhibition through HER3 activation. Gino B. Ferraro,1 David P. Kodack,2 Vasileios Askoxylakis,1Qing Sheng,3 Mark Badeaux,4 Shom Goel,5 Xiaolong Qi,5 Ram Shankaraiah,5 Alexander Z. Cao,5 Rakesh R. Ramkumar,3 Divya Singh,1 Jonathan K. Bluchman,4 Mark V. Patel,1 Younghul Song,1 Carlotta Costa,1 Kamila Naxerova,1 Christina Wong,1 Jonas Kloeper,1 Rita Das,1 Angela Tam,1 Jantina Tanboon,1 Dan G. Duda,1 Ryan C. Miller,1 Marni B. Siegel,4 Carey K. Anders,5 Melinda Sanders,5 Valeria M. Estrada,5 Robert Schlegel,5 Carlos L. Arteaga,5 Elena Brachtel,5 Alan Huang,5 Dai Fukumura,6 Jeffrey A. Engelman,5 Rakesh K. Jain.1 1Massachusetts General Hospital / Harvard Medical School, Boston, MA; 2Novartis, Cambridge, MA; 3Massachusetts General Hospital / Harvard Medical School / DanaFarber Cancer Institute, Boston, MA; 4Linberger Comprehensive Cancer Center, University of North Carolina, Chapel Hill, NC; 5Vanderbilt Ingram Cancer Center, Nashville, TN.

Brain metastases represent a devastating progression of luminal breast cancer. While targeted therapies are often effective systemically, they fail to adequately control brain metastases. In preclinical models that faithfully recapitulate the disparate clinical responses in these microenvironments, we observed that brain metastases evade PIK3 inhibition despite efficient drug delivery. In comparison to extracranial disease, there is increased HER3 expression and phosphorylation in the brain lesions. HER3 blockade overcomes the resistance of both HER2-amplified and/or PIK3CA-mutant breast cancer brain metastases to PI3K inhibition, leading to striking tumor growth delay and significant improvement of mouse survival. Collectively, these data provide a mechanistic basis underlying therapeutic resistance in the brain microenvironment and identify rapidly translatable treatment strategies for HER2-amplified and/or PIK3CA-mutant breast cancer brain metastases.

#5009 Self-renewal of hypoxic glioma stem-like cells is facilitated by secretion-mediated STAT3 activation. Damian A. Almiron Bonnin,1 Matthew C. Havrda,2 Huan Liu,1 Myung Chang Lee,1 Matthew H. Ung,1 Chao Cheng,2 Mark A. Israel2. 1Dartmouth Geisel School of Medicine, Dartmouth, Lebanon, NH; 2Geisel School of Medicine at Dartmouth, Lebanon, NH.

Glioblastoma, a type of high-grade glioma, is the most common and the most aggressive primary brain tumor of adults. The median survival is 12-15 months. Despite multimodality treatment, most high-grade gliomas eventually recur and are ultimately incurable. Several studies suggest that the initiation, progression, and recurrence of gliomas are driven at least partly by cancer stem-like cells. A defining characteristic of these cancer stem-like cells is their capacity to self-renew. We have identified a pathway dependent upon tumor hypoxia, a commonly found pathologic feature of GBM, that promotes self-renewal through the HIF1α-JAK1/2-STAT3 axis. Under hypoxic conditions, HIF1α is greatly increased in GBM stem-like cells leading to the activation of JAK1/2-STAT3 which mediates enhanced tumor stem-like cell self-renewal. Our data further demonstrate the importance of VEGF secretion for this pathway of hypoxia-mediated self-renewal. Using tumor stem-like cells derived from the S100β-v-erbB/p53-/- mouse model of spontaneous high-grade glioma, we have discovered that the activation of STAT3 through hypoxia-mediated VEGF secretion is required for self-renewal of glioma stem-like cells. Media conditioned by these S100β-v-erbB/p53-/- tumor sphere cells cultured under hypoxic conditions promoted self-renewal in S100β-v-erbB/p53-/- glioma stem-like cells and depletion of VEGF from this media was sufficient to inhibit STAT3 phos-
phorylation. Moreover, we have been able to identify two drugs: Brefeldin A and EHT-1864, that significantly inhibit VEGF secretion, decrease stem cell self-renewal, inhibit tumor growth, and increase the survival of mice allografted with $10^6$ B-v-erbB1/p53$^+$ glioma stem-like cells. Cells treated with these drugs express molecular signatures that correlated strongly with the increased survival of GBM patients. These findings suggest a novel treatment strategy to inhibit hypoxia-mediated self-renewal of glioma stem-like cells in high-grade gliomas by targeting the secretion of extracellular, paracrine mediators of self-renewal.

**#5010 Activation of the notch signaling pathway confers a tumor-suppressive phenotype on melanoma-associated fibroblasts.** Hongwei Shao, Mecker G. Moller, Long Cai, Leiming Zhang, Zhao-Jun Liu. *Univ. of Miami, Miami, FL*

Objectives. The tumor microenvironment (TME) is an emerging therapeutic target for cancer treatment. Cancer-associated fibroblasts (CAF) play a crucial role in cancer progression. We aim to target TME by altering intracellular signaling which determines the biological function of CAF. We have recently showed that the Notch signaling pathway likely functions as a molecular switch in controlling the tumor regulatory role of CAF in animal models and experimentally created “CAF”. Here, we investigated the status of Notch signaling in human melanoma-associated fibroblasts (MAF) versus their normal counterparts and tested whether manipulation of the Notch pathway activity in MAF alter their tumor-regulating function.

Methods. We examined levels of Hes1, a canonical Notch target, in MAF of human malignant melanoma at different stages (I-IV) and fibroblasts in either adjacent or non-adjacent normal skin tissues using tissue microarray. MAF were isolated from human metastatic melanoma tissues. Notch pathway RT2-PCRArray and immunoblot were used to assess Notch pathway activity in MAF versus normal human dermal fibroblasts. Activation of Notch signaling pathway in MAF was achieved by lentiviral vector encoding active form of Notch1 (NIC).

The effect of Notch1-engineered MAF on melanoma growth was tested by in vitro co-cultures and in a mouse xenograft model (n=6/group). Tumor angiogenesis was assessed by immunohistochemistry. Results. MAF expressed decreased levels of Hes1 compared with adjacent skin fibroblasts. Isolated MAF also exhibited lower Notch activity than normal human dermal fibroblasts. Notch1-engineered MAF significantly inhibited melanoma cell growth in vitro (p<0.01) and suppressed melanoma growth and tumor angiogenesis in mice (p<0.05). Conclusions. Notch pathway activity is down-regulated in MAF. Increase of Notch pathway activity confers MAF with inhibition to melanoma growth and tumor angiogenesis. Our study demonstrates that Notch signaling is a critical molecular switch in determining the tumor regulatory role of MAF and provides potential targets for cancer therapeutic interventions on the TME.

Gastric cancer is the third leading cause of cancer-related death, and peritoneal dissemination is one of the most frequent site of recurrence. Although the role of tumor microenvironment is recognized, it is still unclear how intraperitoneal cancer-immune microenvironment contributes to peritoneal metastasis. Thus, we investigated the interaction between intraperitoneal cancer and immune cells, especially focusing on tumor-associated macrophages (TAM) in the peritoneal cavity. The peritoneal wash from gastric cancer patients was subjected to conventional flow cytometry, flow cytometry, and immuno-fluorescent assay using antibodies against CD45 (leukocytes), CD14 (monocytes), CD80/163 (M1/M2 macrophages, respectively), in combination with genetically engineered cancer-imaging viral agent ‘TelomeScan’ which specifically expresses GFP in telomerase-positive cells. In cytology-positive samples, CD163-positive macrophages could be detected in approximately 70% of intraperitoneal macrophages with TelomeScan positive cancer cells, while cytology-negative samples contained few CD163-positive TAMs. Therefore, we showed that CAF also induced TAMs in CD163-negative samples, which further suggests that TAMs may play a role in the development of peritoneal metastasis.

**#5012 Mouse-Human co-clinical trials demonstrate superior efficacy with combinational approach of BKM120 and erbitux over BKM120 mono-therapy in patients with recurrent and/or metastatic squamous cell carcinoma of head and neck (R/M-SCCCHN).** Han Na Kang, 1 Mi Ran Yun, 1 Kyoung Ho Pyo, 1 Myung-Ju Ahn, 1 Jong-Mu Sun, 2 Sun Min Lim, 3 SooMyung Paik, 4 Byoung Chul Cho, 2 Byoung Chul Cho, 2

Miami, FL

Background: To investigate clinical activity, safety and biomarkers of a pan-PI3K inhibitor BKM120 in R/M-SCCCHN and identify optimal combinational strategies by conducting mouse co-clinical trials mirroring the ongoing clinical study. Methods: Patients with R/M-SCCCHN were eligible if they had progressed on platinum-based chemotherapy, and were treated with BKM120 100mg/day. The primary endpoint was disease control rate (DCR) at 8 weeks. Secondary endpoints included response rate (RR), progression-free survival rate (PFS), overall survival (OS) and safety. Patient-derived xenografts (PDXs) with genomic annotations were established directly from patients for evaluation of novel drug combinations and biomarkers. Based on the integrated clinical and preclinical data, study protocol had been revised to combine BKM120 and erbitux to explore whether erbitux inhibits the growth of R/M-SCCCHN cells. Results: A total of 52 patients were enrolled. Patient characteristics included median age (55 years; range, 31-82); male (84.6%); ECOG performance status 0/1/2 (13.5%/73%/13.5%); Ilocoregional/metastatic (both (30.8%/38.4%); oral cavity/oropharynx/larynx primary (36.5%/30.8%/13.5%); prior chemotherapy regimen 1/2 (40%/60%). Seven patients were not evaluable due to rapid progression or withdrawal. DCR at 8 weeks was 60% (27/45) and PR was 2.2% (1/45) in BKM120 monotherapy. Median PFS and OS were 8.0 (95% CI, 5.3-9.5) and 30.7 weeks (95% CI, 11.8-26.6). After protocol revision, 11 patients were treated with BKM120 and erbitux after progression to BKM120. In combination phase, PR was observed in 18.1% (2/11) and SD was 45.5% (5/11) in patients who failed to BKM120. Toxicities were not increased in combination phase. In seven established PDXs, we tested BKM120 alone or in combination with erbitux. All PDXs showed strong resistance to single-agent BKM120, whereas three PDXs (3/7, 42.8%) demonstrated strong synergistic inhibition of tumor growth to combined BKM120 and erbitux, compared with single agent (vs. BKM120, P<0.01; vs. Erbitux, P<0.01), which resembled the responses of corresponding patients. We found several genetic alterations in F2 tumors including EGR fusion, HRAS mutation (G12D), MYC amplification, KRAS mutation (G12D), and EGFR amplification (40%). Most interestingly, two PDXs with RAS mutations demonstrated synergistic effect of BKM120 and erbitux. Conclusions: Combining BKM120 and Erbitux would be effective treatment strategies with manageable toxicity in R/M-SCCCHN based on strong rationale of co-clinical trial with PDXs (NCT01527877).

**#5013 A 3D culture system identifies a new mode of cetuximab resistance and disease-relevant genes in colorectal cancer.** Bhuminder Singh,1 Cunxi Li,1 Ramona Graves-Deal,1 Haiting Ma,1 Alina Starchenko,1 William H. Fry,1 Yu-anuyu Lu,1 Yang Wang,1 Galina Bogatcheva,1 Mohseen P. Khan,1 Ginger L. Milne,2 Shilin Zhao,2 Gregory D. Ayers,2 Nenggan Li,1 Mary K. Washington,1 Timothy J. Yeatman,1 Oliver G. McDonald,1 Qi Liu,1 Robert J. Coffey1.

1Van-derbilt University Medical Center, Nashville, TN; 2Jansen Genetics Laboratory, Beijing, China; 3Gibbs Cancer Center & Research Institute, Spartanburg, SC.

We previously reported that single cells from a human colorectal cancer (CRC) cell line (HCA-7) formed either hollow single-layered polarized cysts or solid spiky masses when plated within type-1 collagen in 3D. To begin in-depth analyses into whether clonal cysts and spiky masses possessed divergent malignant properties, individual colonies of each morphology were isolated and expanded. The lines thus derived faithfully retained the parental cystic and spiky phenotypes and were termed CC (cystic) and SC (spiky), respectively. Although both CC and SC expressed EGF receptor (EGFR), cetuximab strongly inhibited growth of CC, whereas SC was resistant to growth inhibition and this was coupled to increased tyrosine phosphorylation of MET and RON. Addition of MET/RON tyrosine kinase inhibitor BKM120 in CC and SC failed to rescue CC, but restored cetuximab sensitivity. To characterize genome-wide divergence between CC and SC, we performed comprehensive genomic and transcriptomic analysis of CC and SC in 3D. One of the most upregulated genes in CC was the tumor suppressor 15-PGDH/HPGD and the most upregulated gene in SC was...
TUMOR BIOLOGY: Models for Treatment Resistance and Drug Discovery

versecan (VCAN) in 3D and xenografts. Analysis of a human CRC tissue microarray showed that epithelial, but not stromal, VCAN staining strongly correlated with reduced survival, and combined epithelial VCAN and absent HPGD staining portended a poorer prognosis. Thus, with this 3D system, we have identified a new mode of cetuximab resistance and a potential prognostic marker in CRC. As such, this represents a potentially powerful system to identify additional therapeutic sensitivities and disease-relevant genes for CRC.

#5014 Drug discovery for NF1-associated malignant peripheral nerve sheath tumors using the zebrafish model. Dong Hyuk Ki, Shuning He, A. Thomas Look. Dana-Farber Cancer Institute, Boston, MA.

Children and young adults with type 1 neurofibromatosis (NF1) are at risk to develop plexiform neurofibromas, which can undergo malignant transformation to malignant peripheral nerve sheath tumors (MPNSTs). MPNSTs are among the most frequently occurring sarcomas in children and young adults and are especially problematic in NF1 patients. Currently, complete surgical excision is the only curative therapy for NF1-associated MPNST, but these tumors are often not completely resectable. Therefore, it is very important to identify promising drugs that can be rapidly moved into clinical trials to improve the therapy of patients with MPNSTs. We have developed a faithful zebrafish model of NF1-associated MPNST by using genome engineering to develop zebrafish lines harboring loss-of-function mutations of the duplicated nf1a and nf1b genes and p53. Our nf1 and p53 deficient zebrafish models develop MPNSTs that are very similar to human NF1-associated MPNST, and thus are ideal for experiments to test the efficacy of FDA-approved small molecule drugs in vivo. To test the FDA-approved drugs for activity against NF1-associated MPNST tumor cells, about 100 Sox10+/ChERRY-expressing MPNST primary tumor cells were transplanted into dechorionated 2-day-post-fertilization (dpf) larval fish using a micro-injector. MPNST-implanted embryos were exposed to individual test compounds added to the fish water at a range of concentrations and to the vehicle control. After 4 days of treatment, quantitative assessment of the remaining mCherry-labeled tumor cell numbers were measured using the ImageJ software for each treated embryo. Currently, trametinib and sunitinib caused marked antitumor effects indicated by reduced numbers of mCherry-labeled nf1-deficient MPNST cells compared to the DMSO control in this study. We are now applying this embryonic implantation assay to identify combinations of FDA-approved drugs that have a high degree of efficacy against MPNST and can be rapidly "repurposed" to improve the treatment of this disease.

#5015 Innovative and predictive models against breast cancer. Olivier Du-champ,1 Séverine Tabone-Eglinger,2 Caroline Mignard,1 Isabelle Goddard,3 Georges François Leclerc. Dijon Cedex, France;1 2Modul-Bio, Marseille, France;1 3Institut Curie, Paris, France.

The 40 established breast PDX models represent the 4 major molecular clinical subtypes among which 37% are triple negative, 33% are Luminal BHER2-, 22% are Luminal AHER2+. Patient surgical specimens from different breast tumor subtypes, among 9 other tumors, associated efforts from public hospitals, academic groups, biotechs and private pharmaco-technical companies with the financial support of the French Ministry of Industry. Patient surgical specimens from different breast tumor subtypes, among 9 other cancer pathologies, are collected to establish large collections of PDXs in mice. In addition, in vitro primary cultures of cells from these samples are conducted to establish a collection of cell lines from the stromal and the tumor compartments. The 40 established breast PDX models represent the 4 major molecular clinical subtypes among which 37% are triple negative, 33% are Luminal B HER2+, 22% are Luminal B HER2− and 8% HER2+. The models are evaluated for ex vivo and in vivo sensitivities to 4 clinically relevant anticancer drugs, for histology, immune infiltrates, and molecular characteristics including the analysis of gene polymorphism, RNAseq gene expression and NGS exome sequencing of 112 genes. The metagene expression sequencing of the gut microbiota from stools collected in both patients and tumor-bearing mice before and after chemotherapy treatments improves our knowledge on the role of microbiota in cancer progression and treatment. Secondly, to increase the predictability of the models, we are generating mice with humanized liver showing distinct drug pharmacokinetic profiles as compared with parental mice. Finally, the humanization of the immune system in mice is developed by several approaches including the use of induced pluripotent stem cells from cancer patients. These tumor collection and model characterization were performed under harmonized procedures within the consortium, allowing high quality material and reproducible characterization of the models. A compiled database base for efficient features search and data mining. We will present the first characterized breast cancer models and will discuss their usefulness and chance to bring benefit to patients via this holistic strategy developed within the IMODI initiative.

#5016 High-throughput patient-derived 3-dimensional organoid cultures as personalized models to assess drug response and post-treatment residual disease. Eugen Dhimolea,1 Ricardo De Matos Simoes,2 Yoko DeRose,3 Pallavi Awate,1 Xiang Weng,1 Huihui Tang,1 Aedin Culhane,1 Alana Welm,4 Constantine Mitsiades.1 Dana Farber Cancer Institute, Boston, MA;2 Huntsman Cancer Institute, Salt Lake City, UT.

Cell lines grown in 2-dimensional (2D) plastic surfaces have historically been the main models to identify cancer cell vulnerabilities. In contrast, malignant tumors in vivo grow as 3-dimensional (3D) cellular masses and manifest remarkably different drug-response patterns compared to cell lines. We have shown that breast cancer (BrCa) cells in 3D extracellular matrices acquire distinct phenotypic properties, compared to the 2D counterparts. Notably, serum-free culture medium supplemented with defined cocktails of developmental morphogens was sufficient to support the growth of BrCa cell lines in 3D, but not in 2D conditions; indicating a key role of 3D architecture in vivo growth regulation. CRISPR/Cas9-based gene editing screens in BrCa cells indicated that a distinct gene subset govern the growth in 3D vs. 2D conditions. Using similar culture conditions, we expanded several molecularly annotated BrCa patient-derived 3D Organoids (3D PDOs), adapted them into a high-throughput miniaturized drug screening platform, and interrogated them against a panel of ~500 target-annotated kinase inhibitors and FDA-approved anti-cancer agents. This pharmacological screen revealed high sensitivity to distinct classes of agents (eg. PI3K inhibitors), but also variable responses to others (eg. EGFR inhibitors); and provided insight into potentially driver vs. passenger mutations in the respective patients. Co-culture of PDOs with non-malignant stromal cells from bone metastatic niche reduced sensitivity to some classes of drugs (eg. PLK inhibitors). Importantly, long-term (up to 3-4 weeks) treatment of 3D organoids did not eradicate the cells in culture (in contrast to conventional 2D assays), but generated a cell subpopulation which remained viable for the duration of the experiment, reminiscent of the residual disease after initial clinical partial response to a drug. This residual disease phenotype was also confirmed in vivo, when the respective PDX-Organoids were treated with the same agents. The majority of transcripts with differential expression in residual PDO tumors were also coincidentally up- or down-regulated in the respective 3D PDO model. These transcripts included canonical regulators of cell cycle, chromatin signal- ing and epigenetic mechanisms, cytoskeletal function and metabolic pathways; as well as other transcripts not previously linked to drug resistance in conventional 2D models. To our knowledge this is the first description of an in vitro personalized cancer model that simulates both molecularly and phenotypically the most important residual disease in vivo. Our high-throughput platform can potentially complement genomically diverse personalized medicine and help discover novel drugs that overcome drug resistance.

#5017 Visualization of the mechanisms of metastasis within a biomimetic engineered tumor microenvironment encompassing a perfusable cylindrical 3D microvessel. Andrew D. Wong,1 Vanesa Silvestri,2 Andrew J. Ewald,2 Peter C. Seamon,1 Johns Hopkins University, Baltimore, MD;2 Johns Hopkins University School of Medicine, Baltimore, MD.

Metastasis is responsible for the majority of cancer related deaths; however, many of the biological and physical details surrounding the critical steps (e.g. invasion and intravasation) are largely unknown, in part due to the difficulty in recapitulating and visualizing these dynamic processes. To elucidate these mechanisms, we have developed an in vitro model of invasion and intravasation that comprises tumor cells embedded within an extracellular matrix (ECM) surrounding an engineered microvessel. The microvessel is cylindrical, 150 µm in diameter, and lined with endothelial cells forming a functional barrier that is maintained under constant perfusion at a shear stress of 2-8 dyne cm−2. Using this biomimetic tumor-microvessel platform, we have previously visualized invasion and intravasation of single MDA-MB-231 breast cancer cells into the microvessel and escape into flow. Here, we present mechanistic details of intravasation from both single tumor cells (MDA-MB-231) and mouse mammary tumor organoids (MMTV-PyMT). For single cells, we observe a mitosis-mediated mechanism of intravasation where tumor cell entry into flow is prefaced by cell division at the ECM-vessel interface. For tumor organoids,
we see vascular deformation and destabilization from growing tumors that impinge upon proximal vessels, and that bulk intravasation is mediated by shear stress and tumor cell adhesion. As we characterize the various ways in which tumor cells interact with the vessel endothelium and intravasate, we can explore strategies involving the tumor vasculature and clinically relevant drugs to inhibit critical steps in the metastatic cascade.

Immune checkpoint blockade therapies, which unleash the immune system’s ability to recognize and eliminate cancer cells, are currently among the most promising treatments for cancer. Antibodies that block the immune inhibitory receptors CTLA4 and PD1 have shown clinical success, with objective response rates over 20% and some durable responses exceeding 10 years. However, some cancers, such as colorectal cancer (CRC), have proven particularly refractory to immunotherapy. Although it is appreciated that the colon is an immunosuppressive environment, the mechanism and extent of immune suppression remains unclear. Studies of human CRC tumors have shown that T cell infiltration is an important predictor of clinical outcome, yet current mouse models of CRC are not particularly well suited to the mechanistic study of T cell responses against tumor-specific antigens. Synergistic cell line transplants, by far the most widely used models to study adaptive immune response in CRC, are characterized by a highly complex tumor microenvironment and have not employed orthotopic transplant into the colon. In order to track highly specific T cell responses in CRC, we have employed a novel colon organoid-based system, in which transformed organoids expressing model antigens are orthotopically transplanted into the wall of the colon via colonoscopy-guided injection, a method pioneered in the lab of Omer Yilmaz. Organoids were harvested from VillinCreER:APc4H2mice and grown in the presence of Wnt ligand; addition of tamoxifen and removal of Wnt from the media facilitated expression of the colon-specific Cre, deletion of Apc, and selection of transformed organoids capable of growing in the absence of Wnt. To induce expression of model antigens, organoids were infected with a lentiviral vector that, in addition to the fluorescent reporter FusionRed, expressed the T cell antigens SIYRYYGL and two additional antigens, one of which is activated in cancer cells. By carrying out experiments in two AT-rich cell culture conditions, we showed that Hmgal amplifies Wnt/β-catenin signaling by inducing genes encoding both Wnt agonists and downstream Wnt target genes, and in human colon cancer cells, which is comprised of terminally differentiated crypt cells that secrete Wnt to support ISCs. Because Paneth cells require Sox9 for development, we determined whether Hmgal regulates its expression. Hmgal binds directly to the Sox9 promoter; overexpression of Sox9 is positively correlated, and both become markedly up-regulated in colon carcinogenesis. This work not only provides new insights into the role of Hmgal in intestinal homeostasis by maintaining the stem cell pool and epithelial niche compartment, but also suggests that deregulated Hmgal perturbs this equilibrium during polyposis and carcinogenesis. Our results also highlight the Hmgal-Wnt-Sox9 axis as a potential mediator of colon carcinogenesis.

#5019 HMGAl amplifies Wnt signaling and expands the intestinal stem cell compartment to drive premalignant polyposis in transgenic mice. Lining Xian, Dan Georgess, Li Luo, Lionel Chia, Qihua Gu, Tait Huso, Amy Belton, David Huso, Andrew Ewald, Linda M.S. Resar. JHU Medical Institution, Baltimore, MD.

Emerging evidence suggests that cancer cells undergo chromatin remodeling and epigenetic reprogramming to co-opt stem cell properties and drive tumor progression. The HMGAl chromatin remodeling protein is an archetypal transcription factor that binds to DNA at AT-rich sequences where it “opens” chromatin, recruits transcriptional complexes, and modulates gene expression. The HMGAl gene is highly expressed during embryogenesis and in adult stem cells, but silenced postnatally in differentiated tissues. HMGAl becomes re-expressed in most high-grade cancers and high levels portend adverse clinical outcomes. In colon cancer, HMGAl is among the genes most highly overexpressed compared to normal intestinal epithelium. We previously reported that HMGAl drives tumor progression in colon cancer by inducing stem cell genes involved in an epithelial-mesenchymal transition. We also discovered that Hmgal1 transgenic mice develop marked proliferative changes and pre-malignant polyposis in the intestinal epithelium. To determine how Hmgal functions in the intestines during tissue homeostasis and carcinogenesis, we examined in transgenic mice and organoid models. Here, we uncover a novel role for Hmgal in maintaining the intestinal stem cell (ISC) pool and Paneth cell niche. Hmgal is required by ISCs to organize into three-dimensional organoids in vitro; silencing Hmgal disrupts organoid formation and bud development. Conversely, overexpression of Hmgal increases organoid formation, bud development, and repressing epithelial hexamer function and epithelial tight junctions. Overexpression of Hmgal expands the ISC compartment. To determine how this occurs, we performed in vivo imaging and discovered that Hmgal enhances self-renewal of ISCs. Mechanistically, we found that Hmgal amplifies Wnt/β-catenin signaling by inducing genes encoding both Wnt agonists and downstream Wnt target genes. Surprisingly, Hmgal also expands the Paneth cell niche, which is comprised of terminally differentiated crypt cells that secrete Wnt to support ISCs. Because Paneth cells require Sox9 for development, we determined whether Hmgal regulates its expression. Hmgal binds directly to the Sox9 promoter; overexpression of Sox9 is positively correlated, and both become markedly up-regulated in colon carcinogenesis. This work not only provides new insights into the role of Hmgal in intestinal homeostasis by maintaining both the stem cell pool and epithelial niche compartment, but also suggests that deregulated Hmgal perturbs this equilibrium during polyposis and carcinogenesis. Our results also highlight the Hmgal-Wnt-Sox9 axis as a potential mediator of colon carcinogenesis.

#5020 A genome-scale ORF screen reveals an alternative splicing program that regulates mesenchymal and stem-like cell states in breast cancer. Ji Li,1 Peter Chou,1 Gabe Labelle-Chaffer,1 Karthik Ramesh,1 Alice Bruggeman,1 Chao Dai,1 Andrew Giacomelli,1 Seav Huong Ly,1 Justin Huang,1 Andrew Hong,1 Nina Ilic,1 Ole Gjoerup,1 Matthew Meyerson,1 Angela Brooks,2 Robert Weinberg,2 William Hahn,1 Dana-Farber Cancer Institute, Harvard Medical School, Broad Institute of MIT and Harvard, Boston, MA;2Whitehead Institute for Biomedical Research and MIT, Cambridge, MA;3Broad Institute of MIT and Harvard, Cambridge, MA;4University of California, Santa Cruz, Santa Cruz, CA.

Cells residing in mesenchymal state are often associated with stem cell properties. The phenotypic changes from epithelial to mesenchymal cell state, or from non-stem-like to stem-like cell state contribute to tumor heterogeneity and play important roles in tumor initiation, progression and metastasis. To systematically interrogate the modulators of epithelial-to-mesenchymal transition, we performed a genome-scale ORF screen to identify regulators of mesenchymal and stem-like cell states using a barcoded human ORFome expression library in human mammary epithelial cells. In the screen, we used flow cytometric analysis of the CD44 cell surface marker and identified 68 ORFs that can switch cells from CD44 low state to CD44 high state in 7 days. Among these genes, the RNA splicing factors were highly enriched as analyzed by GO terms and Gene set enrichment analysis (GSEA). We employed six different assays for candidate validation: 1) Induction of CD44 cell surface markers; 2) Evaluation of the expression of EMT markers; 3) Test of the ability to form mammospheres; 4) Investigation of the expression during EMT induction; 5) Test of the necessity of these splicing factors for EMT and stem-like states; 6) Examination of the ability to promote tumor formation in vivo. We discovered that QKI and RBFOX1 were both necessary and sufficient to promote EMT and stem-like states. MBNL1, MBNL2 and CELF4 were sufficient to induce some mesenchymal markers. We further investigated the downstream targets of these splicing factors by RNA-sequencing analysis. We found that QKI and RBFOX1 regulated the alternative splicing of genes in 5 functional modules: 1) Cell motility and ECM/cytoskeleton organization; 2) Stem cell fate determination; 3) Oncogenic signaling; 4) Epigenetic targets; 5) Cell polarity. Strikingly, using molecular and biochemical assays, we found that QKI and RBFOX1/2 interacted and cooperatively regulated the alternative splicing of a large number of overlapping transcripts, including Filamin B (FLNB). QKI and RBFOX1 induced a shorter isoform via exon skipping, which plays a key functional role in the regulation of EMT. Importantly, the expression of QKI, RBFOX1/2 and the short isoform of FLNB are elevated in basal B type of breast cancer cell lines and in basal-like breast cancer patient samples, the subtype of breast cancer that displays higher degree of mesenchymal and stem-like traits. In conclusion, alternative RNA splicing plays a key role in the regulation of EMT and stem-like cell states. QKI and RBFOX1/2 are both necessary and sufficient to promote EMT and stem-like traits. Alternative splicing of FLNB controlled by QKI and RBFOX1/2 is one of the key downstream targets that regulates EMT. Thus, the molecular targets and mechanism identified in this study may aid in the development of new diagnostic and therapeutic approaches for breast tumors, especially for basal-like breast cancer.

TUMOR BIOLOGY: Tumor Stem Cell Biology

#5021 Semaphorin signal via MICAL3 induces symmetrical cell division of cancer stem-like cells to confer aggressiveness in breast cancer. Kana Tominaga,1 Masao Yano,2 Kei-ichiro Tada,3 Arinobu Tojo,1 Noriko Gotoh4.1Institute of Medical Science, The University of Tokyo, Japan;2Minamimachi Hospital, Japan;3The University of Tokyo, Japan;4Kanazawa Univ. Cancer Research Inst., Kanazawa, Japan.

TUMOR BIOLOGY: Models for Treatment Resistance and Drug Discovery

#5022 Semaphorin signal via MICAL3 induces symmetrical cell division of cancer stem-like cells to confer aggressiveness in breast cancer. Kana Tominaga,1 Masao Yano,2 Kei-ichiro Tada,3 Arinobu Tojo,1 Noriko Gotoh4.1Institute of Medical Science, The University of Tokyo, Japan;2Minamimachi Hospital, Japan;3The University of Tokyo, Japan;4Kanazawa Univ. Cancer Research Inst., Kanazawa, Japan.
Breast cancer stem cells (BCSCs) are thought to be maintained in cancerous tissues by increased frequency of symmetric cell division at the expense of asymmetric cell division in the cancer tissues, although how this occurs it remains largely unknown. Here, we discovered that molecules interacting with Casl3 (MICAL3) contributed to tumor sphere formation in patient-derived breast cancer cells and tumor initiating activity in a patient-derived xenograft (PDX) model. Semaphorin (Sema)-stimulation induced complex formation involving MICAL3 and collapsin response mediator protein 2 (CRMP2), leading to stabilization of Numb in breast cancer cells. Neurilipin-1 (NPI), a receptor for Sema, and Numb were specifically expressed and colocalized at high levels in a BCSC-enriched population that induce tumor sphere formation. MICAL3 knockeddown symmetric cell division and increased asymmetric division of in NPI-high cancer stem-like cells that express high level of Numb at high levels. Thus, MICAL3/CRMP2/Numb pathway appears to play a critical role in the symmetric division of N1P1-high cancer stem-like cells to expand the pool of BCSCs. Finally, we showed that breast cancer patients with higher expression levels of NPI and Numb in cancer tissues show poor prognosis compared with those with lower expression levels of NPI and Numb by using tissue microarray of breast cancer tissues. We provide a rationale for eradicating BCSC by blocking the symmetric division of BCSC by targeting molecules in Sema/NPI/MICAL3 pathway.

**#5024 Unmasking heterogeneity within the adult mammary stem cell compartment**

*Walter & Eliza Hall Inst. of Med. Research, Parkville, Australia*

Breast cancer is a highly heterogeneous disease at both the molecular and pathological levels. To understand this heterogeneity and ‘cells of origin’ of breast cancer, it is important to dissect the normal mammary epithelial hierarchy. Despite accumulating evidence for a mammalian hierarchy of self-renewing breast cancer cell subsets, little is known about how these cell subsets emerge and maintain their self-renewal abilities in vivo. Two major ISC have been identified to give rise to functional mammary glands following injury (e.g. radiation). The presence of two major ISC expressed by the Wnt target gene Lgr5 are dispensable for homeostasis and are quantitatively ablated by radiation injury. In contrast, quiescent ISCs are indispensable for homeostasis, regenerate CBCs, and are radioresistant. Keratins (Krt) are intermediate filament proteins required for architectural and mechanical support, but for homeostasis, regenerate CBCs, and are radioresistant and participate in tissue regeneration. Interestingly, Krt15 deficiency impairs tissue regeneration following high-dose radiation. Indeed, irradiated Krt15- mice display reduced crypt regeneration, crypt length, microcolonies and BrdU incorporation when compared to irradiated Krt15+ mice. Conclusion: We have identified a long-lived Krt15+ subpopulation of intestinal crypt cells displaying stem cell-like properties that are radio-resistant and tumor initiating. This new stem cell population may open new avenues for therapeutic targeting in colon cancer.

**#5025 EZH2 reprogramming confers intrinsic stem cell properties and developmental plasticity driving neuroendocrine prostate cancer.**

Alastair Davies,1 Musa Ahmed,2 Chiara Bostock,3 Anna Gleave,4 Kirsi Ketola,5 Fraser Johnson,1 Jennifer Bishop,1 Ladan Fazli,6 Hajoie Huang,7 Hansen Hien,8 Amina Zoubide1.

1University of Pennsylvania, Philadelphia, PA; 2Fox Chase Cancer Center, Philadelphia, PA.

Background: Intestinal stem cells regulate the emergence of different cell lineages across the crypt-villus axis and orchestrate cellular renewal and replenishment following injury (e.g. radiation). Two major ISC have been identified to give rise to functional mammary glands following injury (e.g. radiation). The presence of two major ISC expressed by the Wnt target gene Lgr5 are dispensable for homeostasis and are quantitatively ablated by radiation injury. In contrast, quiescent ISCs are indispensable for homeostasis, regenerate CBCs, and are radioresistant. Keratins (Krt) are intermediate filaments required for architectural and mechanical support, but also contribute to cell migration and intracellular signaling. Interestingly, Krt15 has been characterized as a stem cell marker in the hair follicle. Here we described a radio-resistant Krt15+ stem cell population in the small intestine and demonstrate that cells within this population are capable of tumor initiation. Methods: Krt15-CrePR1 mice were crossed with Rosa26 reporter mice to perform lineage-tracing experiments in the mouse small intestine. High-dose radiation was used to investigate the role of Krt15 in tissue regeneration. Finally, Krt15-CrePR1;R26mTomato/mGFP mice with 12 Gy revealed that Krt15+ cells are long-lived, post-natally but can be recruited into the cell cycle in response to hormones. Single cell gene expression analyses have also revealed unexpected complexity within the basal and luminal compartments. Moreover, analyses at different stages of development have provided insights into the earliest ‘lineage priming’ events.

**#5026 Disruption of Monocarboxylate transporter-4 Basigin interaction as an effective strategy to inhibit hypoxic response, tumor growth and vascularization, and stem cell phenotype in human glioblastoma in vitro and in vivo**

Raffaella Spina,1 Dillon M. Voss,2 Kah Luan Sim,2 Constance J. Jeffery,2 Eli E. Bar1.

1Case Western Reserve Univ., Cleveland, OH; 2Dana-Farber Cancer Institute, Boston, MA; 3The University of Illinois at Chicago, Chicago, IL.

Monocarboxylate transporters, constitute a family (SLC16) of proton-linked plasma membrane transporters that carry molecules containing a single carboxylate group across biological membranes. Basigin (CD147), is involved in many physiological functions during early stages of development and in cancer. Basigin has been shown to be required for functional plasma membrane expression of Monocarboxylate transporter-1 and Monocarboxylate transporter-4. Using a cell-based screening assay, we identified acriflavine, a small molecule that inhibits the binding between Basigin and Monocarboxylate transporters in vitro and in vivo. Surface Plasmon Resonance analysis confirmed direct binding of acriflavine to Basigin’s immunoglobulin extracellular domain with a low binding constant (KD) of 0.16μM. Acriflavine inhibits normoxic growth of glioma stem cells in vitro and this activity is augmented by hypoxia or by expression of oxygen-stable mutant forms of HIF-1α or HIF-2α. Treatment of mice bearing established glioma stem cell-derived xenografts resulted in inhibition of tumor growth. Acriflavine treatment inhibited intratumoral expression of the angiogenic cytokine vascular endothelial growth factor and tumor vascularization. Our work shows that disruption of monocarboxylate transporter binding to Basigin is an effective approach to target glioma stem cells.
at a core set of genes governing stem cell identity. EZH2 colocalized at the
reprogrammed AR binding sites. Accordingly, treating AR-indifferent/NEPC cell lines with the EZH2 inhibitor GSK126 yielded a molecular sub-
type shift from PCS1 to AR-driven PCS2, and re-sensitized cells to ARPIs.
Conclusion: Our findings establish the centrality of epigenetic reprogram-
mapping in driving the insurgence of a clinically aggressive neuroendocrine
phenotype in response to AR pathway inhibition. Drugging the epigenome
via EZH2 inhibition to reverse the NEPC state and re-sensitize tumors to our
powerful arsenal of ARPIs has the potential to transform the treatment of
prostate cancer.
Association to drug-induced leukopenia using whole-exome sequencing of non-small cell lung cancer patients with gemcitabine/carcinoblatin regimen. Anna Svedberg,1 Benjamin Sigurgeirsson,2 Niclas Björn,3 SAILendra Pradhananga,2 Eva Brändén,2 Hiroshi Koyi,2 Rolf Lewensohn,2 Luigi De Petris,4 Cristina Rodriguez-Antonio,5 Maria Apellániz-Ruiz,5 Joakim Lundeberg,2 Henrik Grén,2 1Clinical Pharmacology, Division of Drug Research, Linköping, Sweden; 2Science for Life Laboratory, Solna, Sweden; 3Department of Respiratory Medicine, Gävle, Sweden; 4Karolinska Biomics Center, Stockholm, Sweden; 5Hereditary Endocrine Cancer Group, Madrid, Spain.

A classical non-small cell lung cancer (NSCLC) chemotherapy treatment is gemcitabine in combination with carboplatin. The treatment is known to cause severe hematological toxicity such as leukopenia, which can lead to chemotherapy cessation or even death. It would therefore be a priori of advantage to identify patients at risk of severe leukopenia to allow for a personalized treatment approach. In this study we aim to identify genetic markers for chemotherapy induced leukopenia in non-small cell lung cancer. In total, 212 non-small cell lung cancer patients treated with gemcitabine and carboplatin regimen were included in the study. Whole blood extracted DNA was prepared using Nextera Rapid Capture kit and whole exome sequenced using Illumina HiSeq 2500. Leukopenia was assessed from leukocyte particle count at baseline and the first cycle nadir values. The statistical approach was to study association of single common variants identifıed 133 variants (p < 0.01) to leukopenia using linear regression in PLINK and association of genes (common and rare variants) to leukopenia using SKAT. An enrichment analysis, with the association results (p < 0.001), was performed using the online tool ConsensusPathDB-human to identify overrepresented pathways. A prediction model was created from the single variant analysis results (n = 10 causal and n = 10 protective) using weighted genetic risk score from the R-package PredictABEL. The single variant analysis of common variants identifıed 133 variants (p < 0.001) and the gene based analysis identifıed 34 genes (p < 0.001). The pathway analysis identifıed 20 enriched pathways (p < 0.05). A prediction model was created to assess the risk of leukopenia. The top pathway, HIF-1 alpha transcription factor network, overlaps with four genes (HDAC7, NDRG1, HK2 and CP). It can be of interest to leukopenia as regulation of HIF-1 alpha is essential for maintenance of hematopoietic stem cells in the bone marrow hypoxic niche. It has also been shown that HIF-1 alpha knocked mice are more sensitive to myelosuppressive treatment compared to unknocked mice, supporting the involvement of the pathway in chemotherapy induced myelosuppression. We have identified variants located in genes and pathways likely to be involved in leukocyte sensitivity after exposure of gemcitabine and carboplatin. A prediction model has been created to estimate the risk that patients will suffer from severe leukopenia by the involvement of the pathway HIF-1 alpha transcription factor network to leukopenia supports the relevance of these results. Further studies on this are of interest to improve identification of patients at high risk of severe leukopenia after gemcitabine and carboplatin treatment.

Exome sequencing of cancer-related genes to identify genetic markers for sensitivity to cytotoxic anticancer drugs. Chihiro Udagawa,1 Yasushi Sasaki,2 Hiroshi Suemizu,1 Yasuyuki Ohnishi,1 Hiroshi Ohnishi,1 Takashi Tokino,1 Hitoshi Zembutsu1. 1National Cancer Center, Tokyo, Japan; 2Research Institute for Frontier Medicine, Sapporo Medical University, School of Medicine, Sapporo, Japan; 3Central Institute for Experimental Animals, Kawasaki, Japan.

Although the progress in moving from a one-size-fits-all cytotoxic approach to personalized molecular medicine, majority of the patients with cancer receive chemotherapy with cytotoxic anticancer drugs. Exome sequencing of 409 cancer related genes was conducted using 59 DNAs extracted from human tumor xenografts implanted into nude mice, of which sensitivity to nine cytotoxic anticancer drugs (5-fluorouracil (5FU), Nimustine (ACNU), Adriamycin (ADR), Cyclophosphamide (CPM), cisplatin (DDP), Mitomycin C (MMC), methotrexate (MTX), vincristine (VCR), and vinblastine (VLB)) had been examined. We investigated the relationship between the sensitivities of the xenografts to the nine anticancer drugs and single nucleotide variants (SNVs) by classifying them into three groups according to the allele frequency (≥10%, 10-90%, >90%). We further carried out replication study using additional set of 20 xenografts. We also estimated the correlation between the expression levels of the 409 genes and sensitivities to the anticancer drugs in the MerckGenomics dataset using 59 xenografts, three SNVs, which were associated with sensitivity to VCR or MMC, showed P < 0.001. We further carried out a replication study of 596 SNVs showing P < 0.05 in the screening stage using independent samples of 20 xenografts. A combined result of the screening and replication studies suggested possible associations of 35 SNVs with sensitivities to the nine anticancer drugs (Pcombined = 0.0011 - 0.035). A total of 35 SNVs showed possible association with sensitivity to at least one of the nine drugs. Of the 35 SNVs, SNV-1 and SNV-2 in a tumor suppressor gene and an oncogene were commonly associated with sensitivity to two or four anticancer drugs, respectively. These findings provide new insights into precision anticancer therapy for the patients with cancer.

Whole exome sequencing and genetic association of gemcitabine/ carboplatin induced thrombocytopenia in non-small cell lung cancer patients. Niclas Björn,1 Anna Svedberg,1 Benjamin Sigurgeirsson,2 SAILendra Pradhananga,2 Eva Brändén,2 Hiroshi Koyi,2 Rolf Lewensohn,2 Luigi De Petris,4 Cristina Rodriguez-Antonio,5 Maria Apellániz-Ruiz,5 Joakim Lundeberg,2 Henrik Grén,2 Linköping University, Linköping, Sweden; 3Science for Life Laboratory, Solna, Sweden; 4Karolinska Institute, Stockholm, Sweden; 5Spanish National Cancer Research Centre (CNIO), Madrid, Spain.

Introduction: Chemotherapy induced myelosuppression is a clinically relevant problem for cancer treatments, affecting both quality of life and response to treatment. Severe hematological toxicities such as thrombocytopenia can lead to dose reductions, postponement or cessation of treatment and there is a need to identify patients at risk before the start of treatment to allow for personalized medicine. The aim of this study was to use whole exome sequencing to identify genetic markers for gemcitabine and carboplatin induced thrombocytopenia that can be used to guide future treatments. Methods: 212 non-small cell lung cancer patients treated with gemcitabine and carboplatin were included. Blood samples were whole exome sequenced using Nextera Rapid Capture Exome kit and Illumina HiSeq 2500. Patients’ thrombocyte counts were measured at baseline and during the first treatment cycle. The thrombocyte nadir value and the relative decrease of the nadir value from baseline were used as thrombocytopenia toxicity parameters. Coding SNVs as well as whole gene-regions and complete pathways were investigated using the following statistical methods: A) Association of common SNVs/INDELs with thrombocytopenia using linear regression in PLINK. B) Association of the combined effect of common and rare variants within a gene-region with thrombocytopenia using the region based association test SKAT, in the R-package SKAT. C) All genes including SNVs/INDELs in A) or a gene-regions in B) with p < 0.001 were used as input for the online tool ConsensusPathDB-human to find overrepresented predefined pathways. Results: The study associated 103 SNVs/INDELs and 21 genes to thrombocytopenia (p < 0.001). The pathway analysis C) identified 28 enriched pathways (p < 0.05). Potentially important pathways for gemcitabine/carboplatin induced thrombocytopenia identified were: Hemostasis (ITGB1, SERPINA5, SERPINC1, JMJD1C, DOCK8 and CAPZA2), Factors involved in megakaryocyte development and platelet production (JMJD1C, DOCK8 and CAPZA2). Vitamin B9 (folate) metabolism (FOLR3 and MTHFD1). Single SNVs, INDELs and genes can be of importance for induced toxicity. However, special interest should be given to the variants and genes in the pathways above. Two of the pathways link back to thrombocytopenia via platelet production and hemostasis and include, JMJD1C and DOCK8, previously associated with thrombocytopenia formation and mean platelet volume. The pathway concerning folate metabolism links back to gemcitabine’s and carboplatin’s mode of action via the involvement of folate in thymidylate and DNA synthesis. Furthermore, folate is needed for rapid regeneration of the bone marrow. Conclusion: The identified genetic markers and pathways are associated with chemotherapy induced thrombocytopenia and provide a strong foundation for further investigation.

Pharmacogenetics of doxorubicin, gemcitabine and docetaxel in the GeDDIS soft tissue sarcoma trial. David Jamieson,1 Beatrice Seddon,2 Karja Kuever,1 Hakim-Moulay Dehbi,1 Sandra Strauss,2 Sandy Bear,1 Gareth Veal1. 1Northern Institute for Cancer Research, Newcastle upon Tyne, United Kingdom; 2University College Hospital, United Kingdom; 3Cancer Research UK & UCL Cancer Trials Centre, United Kingdom.

Introduction: The treatment of locally advanced or metastatic soft tissue sarcoma remains a significant clinical challenge, with overall survival rates of approximately 12 months observed with current first line palliative chemotherapy. A recently completed randomised phase III clinical trial entitled GeDDIS (ISRCTN07742377), was designed to compare first line treatment with gemcitabine in combination with docetaxel (GemDoc) versus current standard treatment with doxorubicin. A pharmacogenetic sub-study was incorporated into the trial to assess potential impact of single nucleotide polymorphisms (SNPs) in genes associated with the pharmacology of the three drugs. A total of 240 patients were recruited to the sub-study, with 119 on the doxorubicin arm and 121 on the GemDoc arm. A 4 ml blood sample was taken from each participant and genomic DNA extracted. Individual candidate SNPs were assessed by Taqman PCR in 7 genes associated with doxorubicin pharmacology, 7 genes associated with gemcitabine and 5 genes associated with the...
pharmacology of docetaxel. Association between the SNPs and efficacy and toxicity was assessed. Results: SNPs within the solute transporter SLC2A2A16, associated with the intracellular influx of doxorubicin, were associated with worse PFS (HR = 1.72, p = 0.04) and decreased frequency of grade 3/4 adverse events (71% vs 48%, p = 0.04) in the doxorubicin arm of the study but not in the GemDox arm. Conclusions: The association of the single nucleotide polymorphism (SNP) and incidence of toxicity is consistent with a loss of function in the transporter and previous observation of increased AUC in pharmacokinetic studies assuming that distribution of the drug into target and collateral tissues is restricted.

#5030 The impact of ABCB1 single nucleotide polymorphisms on the outcome in lenalidomide treated multiple myeloma patients. Ingrid Jakobsen Falk,1 Johan Lund,2 Henrik Greén,2 Astrud Gruber,2 Evren Alici,1 Birgitta Lauri,2 Cecilia Blimark,3 Ulf-Henrik Mellqvist,4 Agneta Swedin,5 Karin Forsberg,5 Conny Carlsson,6 Mats Hardling,6 Lucia Albigb,5 Hareth Nahil,7 Kourosch Lotfi,7 1Division of drug research, Linköping University, Linköping, Sweden; 2Unit for hematology, Karolinska Institute, Huddinge, Sweden; 3Sundbyr Hospital, Luleå, Sweden; 4Hematology department, Sahlgrenska University hospital, Göteborg, Sweden; 5Hematology department, Skåne University hospital, Lund, Sweden; 6Department of hematology, Norrland University hospital, Umeå, Sweden; 7Department of Internal medicine, Halland Hospital, Halmstad, Sweden; 8Department of hematology, Uddevalla hospital, Uddevalla, Sweden; 9Department of hematology, Linköping University hospital, Linköping, Sweden.

Introduction: Multiple myeloma (MM) is an incurable plasma cell malignancy with high mortality rate. Treatment outcomes have improved since the introduction of new drugs such as the IMID lenalidomide, but relapse rates and resistance is still a problem. The gene ABCB1 encodes the drug transporter p-glycoprotein (p-gp) which confers resistance through extrusion of drugs over the cell membrane. Lenalidomide is subject to limited metabolism and excreted mainly via the kidneys. In vitro studies have shown lenalidomide to be an ABCB1 substrate, and single nucleotide polymorphisms (SNPs) affecting gene expression, transporter function and/or activity may affect drug distribution, and the subsequent outcome and risk of adverse events. However, in vivo studies of the effect of ABCB1 on lenalidomide pharmacokinetics are contradictory.

Our aim was to investigate the influence of ABCB1 SNPs on lenalidomide treatment outcome and adverse events (AE). Materials & Methods: In the observational part of two connected studies, 133 Lenalidomide naive patients at 1st relapse/refractory MM were treated with lenalidomide and dexamethasone for up to 9 cycles of 4 weeks. In the prospective 2nd part, 62 patients that had been obtained, patients were enrolled, and their blood was collected and previous observation of increased AUC in pharmacokinetic studies assuming that distribution of the drug into target and collateral tissues is restricted.

#5032 The relationship between the UGT1A1*7 and UGT1A1*27 genotypes and irinotecan-related toxicities in patients with lung cancer. Minoru Fukuda,1 Manabu Okumura,2 Tomomi Iwakiri,3 Arimori Kashiwagi,4 Shinnosuke Takezako,5 Takaya Ikeda,5 Takuya Honda,6 Hiroyuki Yamaguchi,7 Katsumi Nakatomi,8 Kazuma Kobayashi,9 Mitsuko Masutani,10 Mikio Oka,1 Kazuto Ashizawa,1 Hiroshi Mucake,12 Nagasaki University Hospital, Nagasaki, Japan; 1University of Miyazaki Hospital, Miyazaki, Japan; 2Nagasaki University, Nagasaki, Japan; 3Kawasaki Medical School, Kurashiki, Japan.

Background: Genetic polymorphisms in the UDP-glucuronosyltransferase 1A1 (UGT1A1), UGT1A7, and UGT1A9 genes are associated with interindividual differences in irinotecan toxicities. The UGT1A1*7, *27, and *29 gene polymorphisms occur within the common exons of UGT1A1 isoforms and cause substantial reductions in their functional activity; however, few clinical studies have examined the effects of these polymorphisms. Purpose: To evaluate the effects of gene polymorphisms, including UGT1A1*7, *27, and *29, on the safety of irinotecan therapy. Patients and methods: The eligibility criteria were as follows: lung cancer patients who were scheduled to undergo irinotecan therapy, aged ≥20 years, and had a performance status of 0-2. After informed consent had been obtained, patients were enrolled, and their blood was collected and used to examine the frequency of the UGT1A1*6, *7, *27, *29, and *29 polymorphisms and the drug concentrations of irinotecan, SN-38, and SN-38G after irinotecan therapy. Results: Thirty-one patients were enrolled. The patients' characteristics were as follows: male/female = 25/6, median age (range) = 71 (55-84), stage IIIB/IIIA/IIIB/IV = 2/6/11/12, and Ad/Sq/Sm/OTH = 14/10/3/4. The incidence of grade 3/4 diarrhea was 14% and 11% for patients with and without the UGT1A1*7 polymorphism, respectively. There were no homozygous or complex heterozygous polymorphisms. The UGT1A1*27 polymorphism occurred separately from the UGT1A1*28 polymorphism. The lowest leukocyte counts of the patients with the UGT1A1*27 and UGT1A1*6 gene polymorphisms were lower than those seen in the wild-type patients. SN-38 tended to remain in the blood for a prolonged period after the infusion of irinotecan in patients with the UGT1A1*27 or UGT1A1*28 polymorphisms. No severe myelotoxicity was seen in the patients with UGT1A1*7. Conclusions: UGT1A1*27 and UGT1A1*7 are both rare gene polymorphisms. UGT1A1*27 can occur separately from UGT1A1*28 in some circumstances and is related to leukopenia during irinotecan treatment. UGT1A1*7 is less relevant to irinotecan-induced toxicities, and UGT1A1*29 seems to have little clinical impact.

#5033 Optimized CYP2D6 phenotype assignment for plasma endoxifen prediction in breast cancer patients treated with tamoxifen. Werner Schrotth1, Stefan Winter1, Michel Eichelbaum1, Thomas Muether1, Matthias Schwab2, Hiltrud Brauch3, Dr. Margarete Fischer-Bosch-Institute of Clinical Pharmacology, Stuttgart, and University of Tuebingen, Tuebingen, Germany; 2Dr. Margarete Fischer-Bosch-Institute of Clinical Pharmacology, Stuttgart, Department of Clinical Pharmacology, University Hospital Tuebingen, Cancer Consortium (DKTK) and German Cancer Research Center (DKFZ), Heidelberg, Germany; 3Dr. Margarete Fischer-Bosch-Institute of Clinical Pharmacology, Stuttgart, University of Tuebingen, Tuebingen, and German Cancer Consortium (DKTK) and German Cancer Research Center (DKFZ), Heidelberg, Germany.

Introduction: Standard first-line treatment for ovarian cancer consists in the combined use of taxanes and platinum, with neuropathies and neutropenia the most frequent and complex adverse drug reactions (ADRs) requiring clinical management. These adverse effects may be related to differing levels of drug transport and metabolism brought about by intrinsic genetic characteristics of patients. The investigation of the first phase of the CYP2D6 drug metabolism, the CYP2C8 enzyme, whose function is essential in paclitaxel metabolism, was performed. Patients and methods: Four SNPs associated with risk of ADR within the ABCB1 gene polymorphisms were previously reported to be associated with paclitaxel and carboplatin ADRs. Methods: Blood samples were obtained with informed consent from adult ovarian cancer patients (n = 120). DNA was extracted and SNPs within the ABCB1 gene polymorphisms were genotyped with high specificity. Results: SNPs associated with paclitaxel and carboplatin ADRs are highly prevalent in the Chilean population of ovarian cancer patients studied. The identification of these variants may help avoid severe ADRs associated with chemotherapy regimes. Funding: CORFO 13CT121526-P & 13IDL2-18608.
Tamoxifen (Tam), a standard therapy for estrogen receptor (ER)-positive breast cancer, is bioactivated to its active metabolite endoxifen by the cytochrome P450 enzyme CYP2D6. CYP2D6 polymorphisms constituting extensive (EM), intermediate (IM) and poor (PM) metabolizer phenotypes are main determinants of variable endoxifen plasma concentrations and supposed to influence therapeutic and side effect outcomes. Genotype-guided prediction of Tam metabolizer status has long been debated to be useful for clinical dose adjustment in patients with impaired metabolism. As this requires accurate genotype-phenotype assignments, we tested several CYP2D6 phenotype classifications including the codeine metabolism-based scoring implemented by the ‘Clinical Pharmacogenetics Implementation Consortium’ (Crews et al, 2014, CPT) for their predictive value of endoxifen concentration. Usually, CYP2D6 PO4 demonstrates near linear dose proportionality of endoxifen formation. This is evident from a low predictability (<20%) for both metabolite endpoints particularly in Asians, most likely due to a misclassification of abundant IM/IM (*10) diplotypes as EM. Importantly, the active metabolite-to-precursor MR appears to be the endpoint that is more closely linked to CYP2D6 enzyme activity, as it explains up to 68.82% of MR variability. In contrast, absolute endoxifen concentrations were only modestly predictable (38-57%) by CYP2D6 diplotype or other phenotype groupings. Moreover, a reduced activity for the *10 compared to other IM alleles appears to improve endoxifen predictability by phenotype. Personalized TAM treatment decisions based on plasma endoxifen prediction should rely on TAM specific CYP2D6 genotype-guided phenotype assignments that quantitatively capture the allele-dosage effects and that include endoxifen-to-precursor MR as the endpoint most closely linked to CYP2D6.

There are currently only 10 cancer genes with FDA approved drug treatment options (source: OncoKB). Here, we present a conceptually novel analytical method that allows to expand the small list of clinically actionable cancer drug treatment biomarkers. Large sequencing studies, such as The Cancer Genome Atlas (TCGA), have greatly accelerated our understanding of the molecular basis of cancer. However, because of the difficulty in collecting drug response data in large cohorts of cancer patients, these studies have not been effectively used for finding new biomarkers of drug response (i.e. pharmacogenomics discovery). Thus, much cancer pharmacogenomics research is conducted in preclinical disease models such as cell lines (e.g. the Genomics of Drug Sensitivity in Cancer (GDSC) project); but these studies are (among other limitations) always restricted by comparatively smaller sample sizes. Here, we present an analytical method that integrates data from large clinical studies (e.g. TCGA) with data from preclinical disease models (e.g. GDSC) and overcomes these critical obstacles, allowing studies such as TCGA to now be effectively used for pharmacogenomics discovery. We refer to this approach as an “Imputed drug-wide association study” (IDWAS). The method works by fitting a statistical model relating gene expression and drug response in preclinical data (here we use the GDSC cancer cell lines), then using this model to impute drug response from tumor gene expression data in a clinical cohort (here we use TCGA). Next, we compare “active” and “inactive” drug responses. We applied this method to imprint drug response (mutations, copy number changes) in TCGA, thus finding new biomarkers of drug response. We show that we can recapitulate known clinically effective biomarkers and we have validated new clinically relevant biomarkers, which remarkably could not have been identified using conventional approaches. Our method will set the stage for many future studies. Crucially, this approach could easily be applied to any of the vast number of clinical cancer sequencing studies now undertaken, meaning that it will be possible to use all of these datasets for pharmacogenomics research. We have included a set of computational tools to allow easy application of our method and replication of our results. Given that this is a conceptually novel methodology, it is also likely that many other studies will attempt to improve upon our proposed implementation. Furthermore, members of our group are currently leading the development of the new Genomic Data Commons (GDC; https://gdc.cancer.gov/), which is the NCI’s new access portal for TCGA data. We are currently working towards making the imputed drug response data directly accessible on GDC, along with all other TCGA data. This means that our imputed drug response data will be easily accessible to the thousands of researchers already accessing TCGA via the GDC.

**#5036 Correlation of preclinical anticancer activity of regorafenib in CRC-PDX xenografts with gene expression and clinical parameters of the primary tumor, Henrik Seidel,1 Jens Hoffmann,2 Ralf Lesche,1 Sylvia Grünewald,1 David Henderson,1 Dieter Zopf1, Bayer Pharma AG, Berlin, Germany, 1EPO GmbH, Berlin, Germany.**

Regorafenib is a small molecule inhibitor of multiple transmembrane and intracellular kinases involved in normal cellular functions and in pathologic processes such as oncogenesis, tumor angiogenesis, metastasis, and tumor immunity. Regorafenib is approved for the treatment of patients with metastatic colorectal cancer (CRC) who have been previously treated with fluoropyrimidine-, oxaliplatin- and irinotecan-based chemotherapy, an anti-VEGF therapy, and, if RAS wild-type, an anti-EGFR therapy or with locally advanced, unresectable or metastatic gastrointestinal stromal tumor (GIST) who have previously been treated with imatinib mesylate and sunitinib malate. Recently an overall survival benefit has been shown in patients with hepatocellular carcinoma (HCC) who had previously been treated with sorafenib (RESORCE). OncoTrack is an Innovative Medicines Initiative (IMI) sponsored project with the goal to improve the basis for identification of biomarkers based on the mechanisms of action of therapies approved for this indication. For this purpose, a panel of CRC-PDX xenografts was generated by the OncoTrack project. At the time of the analysis reported here fifty xenografts had been treated with regorafenib at a dose of 10 mg/kg/d or with vehicle for 24 days. The analysis of tumor growth rates (TGR) showed pronounced differences between different tumors and between vehicle and regorafenib treated models. The relative antitumor activity (relative TGR) of regorafenib varied between -0.13 (good response) and 0.0 (no response). Investigations of relative TGR in relationship to (non-) clinical parameters of the primary tumor such as age, gender, sidedness and tumor histology identified a marginally significant (p = 0.04) better response in tumors from younger patients. No other correlations were detected to this end, which may be due to the small sample number. To correlate antitumor activity of regorafenib with gene expression, RNA was isolated from sections of selected vehicle and regorafenib treated xenografts and hybridized on Affymetrix HuGene-2.1_st human transcriptome arrays. Expression profiles were subsequently analyzed using the Random Forests algorithm to identify gene expression signatures predicting response to regorafenib. The best signatures did not perform better than signatures derived after randomizing responses, i.e. no predictive signature could be identified. Further studies with larger samples sizes are necessary to improve the outcome of such an approach; however one should acknowledge that to date no predictive gene signatures could be identified for multikinase inhibitors, which may be intrinsic to their complex mechanism of action. The research reported here received support from the Innovative Medicines Initiative Joint Undertaking under grant agreement 115234 (OncoTrack).

**#5037 New concepts for quantifying the benefits of mono and combination therapy in an era of big data, Peter K. Sorger, Marc Hafner, Mario Niepel, Caitlin Mills, Adam Palmer, Mohammed Fallahi Sichani. Harvard Medical School, Boston, MA.**

I will describe new (unpublished) approaches to quantifying drug response at two points in the drug development pipeline: pre-clinical studies in cell lines and clinical trials of combination therapies in patient populations. Drug sensitivity and resistance in cell lines is conventionally quantified by IC50 or Emax values, but these measures suffer from a fundamental flaw when applied to growing cells: they are highly sensitive to cell division number, which varies with cell line, experimental condition, seeding density etc. The dependency of IC50 and Emax on division rate creates artefactual correlations between genotype and drug sensitivity while obscuring important biological insights and interfering with biomarker discovery. I will describe alternative growth rate inhibition (GR) metrics that are insensitive to division number and can directly measure both endpoint sensitivity and adaptive drug resistance. Theory and experiments show that GR50 and GRmax are superior to IC50 and Emax for assessing the effects of drugs in dividing cells. GR metrics promise to improve our ability to score drug sensitivity in specific-derived tumor cells, improves data reproducibility, and increase the translational potential of pharmacogenomics data. In patients, combination therapy improves tumor control compared to monotherapy and the development of combinations is motivated in most cases by pre-clinical data.
on synergism in cell lines. However I will describe a different way in which combinations can provide clinical benefit. Based on analysis of between-patient variability in existing trial data and a large set patient derived tumor xenograft (PDX) mice published by Gao H, Korn JM, Ferretti S, et al. (Nature medicine 2015;21:1318-25). I will argue for a simple principle: in nearly two-thirds of cases a drug mechanism of action can be explained by points in time and a drug likelihood that a tumor will experience an outlier response to a single drug. Thus, even in the absence of additive or synergistic tumor inhibition, combinations are generally superior to monotherapies. Superiority by “independent action” provides a principle on which to design new combinations and a scientific rationale for the use of combination therapies in poorly understood cancers whenever toxicity is acceptable. — These studies, at two different points of the drug discovery pipeline, illustrate the value of combining new first-principles theories about drug mechanism of action with “big data” that is increasingly available on preclinical and clinical drug response. Conversely, in the absence of conceptual innovation, we miss important mechanistic insights hidden in existing data. The purpose of such insights, when obtained, is drive new laboratory and real-world experiments. I will discuss how the process of coupling computation and experimentation works in practice.

#5038 Comparison of the dose response of malignant peripheral nerve sheath tumor in vitro growth inhibition of 30 drugs to reported Cmax values. Karlyne M. Reilly, Robert G. Tuskan, Brigitte C. Widemann. NCI, NIH, Bethesda, MD.

In this study we aim to identify drugs that can be repurposed to inhibit malignant peripheral nerve sheath tumor (MPNST), a rare and deadly sarcoma associated with Neurofibromatosis type 1 (NF1). Inhibition of MPNST cell viability in vitro was tested for 30 drugs that have previously been through human clinical trials such that the maximum concentration of compound in human serum (Cmax) at the maximum tolerated dose has been determined. Drugs were compared to the chemotherapeutic doxorubicin. Six MPNST cell lines from human and mouse were tested and dose response curves were compared to Cmax for each drug. For most compounds tested, inhibition of MPNST viability occurred at drug concentrations higher than Cmax. Doxorubicin was one of the best compounds tested. Several compounds with less specific molecular targets appear promising, however, currently available inhibitors of receptor tyrosine kinase signaling pathways required concentrations above Cmax to inhibit MPNST viability. These data suggest that difficulty in developing therapy for MPNST may be due to the requirement for high concentrations of drugs to inhibit MPNST cells.

#5039 A data driven approach to predicting tissue-specific adverse events. Kaitlyn M. Gayvert, Neel Madhukar, Coryandar Gilvary, Olivier Elemento. Weill Cornell Medicine, New York, NY.

Adverse events are currently one of the main causes of failure in drug development and withdrawal after approval. As a result, predicting drug side effects is an incredibly important part of drug discovery and development. With the emergence of precision medicine there has been a surge in interest on creating drugstothemarketquicker. A data driven approach to in-silico drug sideeffectprediction.Wehavemineddrugsideeffect targets and mechanisms to specific side effects. Here we take a target-centric approach to in-silico drug side effect prediction. We have mined drug side effect databases and grouped sets of side effects to the originating human tissue. For each of 30+ tissues, we defined a set of “tissue targets”- proteins that are only targeted by drugs with toxicity in that tissue - and “safe targets” - proteins only targeted by drugs with no related tissue toxicities. We found that toxic targets are consistently more highly expressed than safe targets, indicating that their mechanisms may be more crucial in their respective tissue. Furthermore we found that toxic targets have higher network connectivity. Using published gene knockdown screens, we also found that toxic targets for each tissue are significantly more likely to be essential than safe targets and are more likely to be enriched for GO terms related to cell death. These pieces of information all reinforce the proposed relationship between the identified toxic targets and drug induced tissue toxicities. We next leveraged this information to draw insights into unexpected drug toxicity events. We applied the BANDIT drug target prediction tool to drugs classified by the ProCTOR toxicity prediction method and drugs with a specific type of tissue toxicity that were not known to hit any of our identified toxic targets. We found that new drug-target predictions explained a large number of these toxicities, correctly classifying approximately five times as many side effects as would have been expected by random chance. These results all supported our target-centric hypothesis of drug side effect prediction. Therefore we built a set of machine-learning models that would integrate drug targets with tissue-wide expression patterns and gene-specific features to predict specific side effects for a given drug. We found that these methods could significantly outperform other prediction techniques and random chance. For instance, our method for predicting drug induced liver injury (DILI) had ~70% accuracy at pinpointing specific drugs known to cause DILI and its likelihood score correlated with the FDA’s reported DILI severity score. Overall these findings show how a target-centric approach to drug development can not only increase our understanding between pathological phenotypic effects, but can help drug developers predict side effects before costly and time-consuming clinical studies. Our hope is that adoption of these methods will lead to overall increase in drug development efficiency and bring safer drugs to the market quicker.

Background: Pegylated liposomal doxorubicin (PLD) exhibits altered plasma pharmacokinetics (PK) compared to doxorubicin, with a longer half-life (55 hours), large area under the concentration-time curve (AUC), lower rate of clearance, and markedly smaller volume of distribution. The cerebrospinal fluid (CSF) PK of PLD is unknown. We evaluated the plasma and CSF PK of PLD in a non-human primate (NHP) model. Methods: PLD was given as single dose (1 mg/kg) after surgical resection of 20 mg/kg doxorubicin intravenously over 60 minutes to 3 NHP with indwelling central venous catheters and central nervous system reservoirs or lumbar ports. Serial blood and CSF samples were obtained for 96 hours after completion of the infusion. The total doxorubicin concentration (liposome bound + protein bound + free) was quantified with a validated liquid chromatography/tandem mass spectrometry assay (lower limit of quantification (LLOQ) 0.29 ng/mL, and CSF=0.06 ng/mL). PK parameters were estimated using non-compartmental methods. CSF penetration was calculated from the AUCCSF:AUCplasma. Results: PLD was well tolerated. Total doxorubicin plasma concentration time curves were characterized by sustained PLD exposure, comparable to the exposure observed in humans at a similar dose. The terminal elimination phase was not captured. In CSF, doxorubicin was measurable and still present at the last time point in all animals, but the CSF penetration was limited (Table). Conclusions: Using a sensitive assay, we could quantify doxorubicin in CSF. However, the CSF penetration is limited in NHP with intact blood brain barrier. Our assay analyzed the total doxorubicin concentration in plasma. It is unknown if PLD can penetrate into the CSF, therefore we could not determine if the CSF penetration represents total versus free.

#5041 Translational pharmacokinetic-pharmacodynamic xenograft model for TAK-931, a small molecule cell division cycle 7 (CDC7) kinase inhibitor. Charles Locson,1 Mayank Patel,1 Akikori Ohashi,2 Kenichi Iwai,2 Tatadairo Nambu,2 Yoshiyuki Takeuchi,2 Akifumi Kogame,2 Douglas Bowman,1 Stephen Tirrell,2 Huifeng Niu,1 Cindy Xia,1 Takeda Pharmaceuticals International, Cambridge, MA; 2Takeda Pharmaceuticals International, Shonan, Japan.

TAK-931 is a small molecule inhibitor of the cell division cycle 7 (CDC7) kinase. As a serine/threonine kinase that contributes to DNA replication and the DNA damage response, CDC7 is hypothesized to be a promising cancer drug target. CDC7 inhibition with TAK-931 has demonstrated antiproliferative activity with cancer cell lines and tumor growth inhibition (TGI) in murine ectopic xenograft models. Herein, the analysis of multiple models to characterize pharmacokinetic (PK) and pharmacodynamic (PD) relationships with xenograft xenograft TGI is described. TAK-931 treatment-induced TGI was dose schedule-dependent and could be described using plasma drug concentrations or tumor PD inhibition. However, the efficacious doses were at least 10-fold higher for the PK-TGI relationship than for the PD-TGI relationship. This discrepancy was used to develop a dynamic PK-PD-TGI modeling approach to project the minimal efficacious dose (MED) and minimal biological active dose (MBAD) for TAK-931 due to the large differences in time-concentration profiles predicted for humans versus mice. The Phase I human trial is on-going and will be used to verify the dynamic PK-PD-driven modeling approach for the CDC7 inhibitor.
#5042 Defining an optimal single time point sampling strategy representative of overall capcitabine pharmacokinetics. Stephen Welch,1 Wendy Teft,1 John Lenehan,1 Rommel Tirona,1 Karen Lumsden,2 Eric Winquist,3 Richard B. Kim,1 1Univ. of Western Ontario, London, Ontario, Canada; 2Grand River Regional Cancer Centre, Kitchener, Ontario, Canada.

Background: OT-101 is an oral chemotherapy pro-drug used to treat advanced colorectal cancer. Patients may experience hand-foot syndrome and diarrhea, among other side effects, that affect quality of life and may necessitate dose modification or discontinuation. There is significant regional variation in capcitabine tolerability, related to a myriad of factors including pharmacogenomics, dietary and cultural differences. Capcitabine dose modification, when necessary, is empirical based on toxicity suggested a personalized dosing approach might better optimize therapy. Objective: In phase 1 of a personalized dosing approach, our objective was to define an optimal time point for blood sampling that best represented overall exposure of capcitabine and its metabolites. Methods: A single-arm prospective pharmacokinetic cohort study of patients with advanced or metastatic colorectal cancer prescribed capcitabine monotherapy was done. Blood samples were collected pre-dose and at timed intervals between 0 and 8 hours post-dose. Plasma concentration of capcitabine and its major metabolites, 5'-deoxycytidine (5'-DCR) and 5'-deoxy-5-flourouracil (5'-DFUR), were measured by ultra-performance liquid chromatography-tandem mass spectrometry (UPLC-MS/MS). Results: 26 patients were enrolled; 65% were male and 42.3% had metastatic disease. Mean capcitabine dose was 2854 ± 944 mg. Hand-foot symptoms (60%), fatigue (53%) and diarrhea (30%) were the most common adverse drug reactions. Dose normalized mean (SD) AUC∞, for capcitabine, 5'-DCFR and 5'-DFUR were 6.74 (3.0), 4.19 (1.5) and 6.33 (2.8) ng·h/mL, respectively. Spearman correlation between dose normalized concentrations and AUC at each blood draw was performed. The best estimated time points for capcitabine, 5'-DCFR and 5'-DFUR were 1.5, 2 and 2 hours with r2 values of 0.6 (p < 0.01), 0.64 (p < 0.001) and 0.51 (p < 0.01), respectively. There was a significant correlation seen between capcitabine AUC and need for subsequent dose reduction (p < 0.05). Conclusions: Blood samples obtained between 1.5 and 2 hours post-dose provide the best estimate of capcitabine exposure. Further pharmacokinetic analysis in this cohort is ongoing. This blood draw strategy will be used in a larger trial intended to develop a personalized capcitabine dosing algorithm.

#5043 Population pharmacokinetic model for OT-101 - A TGF-β2-specific antisense oligonucleotide in cancer patients. Wen Wang,1 Kevin Ng,2 David Nam,3 Vuong Trieu,1 Larn Hwang,1 Oncotelic Inc, Agoura Hills, CA; 2Autotelic Inc, Costa Mesa, CA.

Background: OT-101 (Trabedersen) is a phosphorothioate antisense oligonucleotide specifically inhibiting the expression of transforming growth factor-beta 2 (TGF-β2), whose overexpression is a pivotal factor for malignant progression in solid tumors. In the clinical Phase I/II study, plasma pharmacokinetic (PK) profile of OT-101 administered intravenously was evaluated in patients with advanced tumors. A population PK model was built to further understand the factors contributing to the variability in PK of OT-101. Methods: A total of 61 patients with pancreatic cancer (n=37), malignant melanoma (n=19), or colorectal carcinoma (n=5) were treated with OT-101 with escalating doses in 2 treatment schedules (1st schedule: 7-day on, 7-day off; 2nd schedule: 4-day on, 10-day off; 21 on 10 cycles). Blood samples were collected from patients at planned time points from before start of infusion to 7 days (1st schedule) or 10 days (2nd schedule) after stop of infusion. The plasma concentration data of OT-101 were used to build a population PK model using Phoenix NLME software. The influence of age, gender, body mass index (BMI), body weight (BW), height, cancer type, and treatment schedule as covariates on PK was evaluated. Results: With exclusion of protocol deviations, a total of 1444 plasma sample concentration data from 100 patient cycles were examined. The concentration-time profile was biexponential, with linear and non-linear components. The model estimated the PK parameters as follows: total body clearance, 0.17 mL/h; distribution volume of the central compartment, 4.69 L; inter-compartmental clearance, 3.31 L/h; distribution volume of the peripheral compartment, 3046.44 L. BW was identified as a covariate on OT-101 inter-compartmental clearance, with Kiso = -1.48. Conclusion: The PK parameters of OT-101 were best described by a two-compartment model. OT-101 was largely distributed in the peripheral tissues. The influence of age, gender, BMI, height, cancer type and treatment schedule on the PK of OT-101 was not identified. The model will be used for a sparse population PK study during the planned phase III trial of OT-101 in pancreatic cancer.

#5044 Pharmacokinetic study of RCHOP protocol in elderly patients with non-Hodgkin lymphoma. Elodie BAUDRY,1 Anne Laure COUDREC,2 Pascal CHAIBL3,4 Fanny BRET,4 Sara DIEJBOUN,4 Sophie WEILL,5 Samuel HUGUET,5 Alexandre BOYAULT,5 Francois LOKIEC,5 Keyvan REZAI,1,5 CHU Bicetre, Kremlin Bicetre, France; 2Assistance publique hopitaux de Marseille, Marseille, France; 3Hospital Charles Foix, Ivy sur seine, France; 1Inst. Curie, Saint Cloud, France.

Background: Diffuse large B-cell lymphoma (DLBCL) is the most common lymphoma in elderly patients and R-CHOP chemotherapy is the standard treatment protocol for DLBCL. Elderly patients (often defined as 75 years of age) are treated with anticancer drugs with precaution; however, the pharmacokinetics and pharmacodynamics (PK and PD) of these agents have not been thoroughly investigated in this population. In this study we investigated the PK of cyclophosphamide (CP) and doxorubicin (DOX) in elderly patients in order to verify if there is an influence of age on the PK of these anticancer drugs. Methods: Non-Hodgkin lymphoma elderly patients were treated with a R-miniCHOP chemotherapy regimen. Dose levels were 25 mg/m², 0.7-1.4 mg/m², 750 mg/m² and 375 mg/m² for DOX, Vincristin (VCR), CP and Rituximab respectively. For PK analysis, 7 time point samples were collected over 48 h post administration on cycle 3. CP and VIN plasma concentrations were measured using UPLC-MS/MS validated method. DOX plasma concentrations were measured using UPLC coupled with fluorescence detection validated method. PK-PD modeling has been performed with a non linear mixed effect model program (Monolix version 4.3.2). Results: For CP and VCR, the pharmacokinetics of these two agents were well described with a 2-compartment model treated with DOX and CYP. Among them, 19 patients have received VCR. A total of 134 and 120 concentrations for DOX and CP were used respectively for PK-PD modeling. A 2-compartment open model adequately described DOX concentration versus time courses. A 1-compartment open model adequately described CP concentration versus time courses. The interindividual variabilities (ISV) could be well estimated for both drugs and for all structural parameters (clearances: CL, Q, volumes of distribution: Vc, Vp) except Vp for CP. The population PK parameters for DOX obtained for the structural model were: CL=54.5 L/h, V=54.7 L/h, Vc=30.6 L, Vp=1140 L. The population PK parameters for CP were: CL=3.49 L/h, Vc=29.2 L. VCR increases DOX Vc from 30.6 L to 56.9 L/h (p = 0.0012). The main covariate effects were related to gender, age, BW and to albumin. Conclusions: In this study we have espoused that with very good precision PK parameters of DOX and CP in very elderly patients with DLBCL. Our data revealed the effect of gender, BW and VCR administration on DOX PK parameters. We have demonstrated the effect of increasing age on PK of CP. A PK-PD modeling will be performed in order to verify there are biological factors explaining the variation in the PK parameters of DOX and CP in elderly patients.

#5045 Pharmacokinetics and pharmacodynamics of MEDI0680, a fully human anti-PD1 monoclonal antibody in patients with advanced malignancies. Xuyang Song, XiZhe Gao, Bo Zheng, Chelsea Black, Matthew Gribbin, Joyson Karakunnel, Lorin Roskos, Rajesh Narwal. MedImmune, Gaithersburg, MD.

Background: MEDI0680 (AMP-514) is a humanized immunoglobulin gamma4,kappa (IgG4κ) monoclonal antibody (mAb) specific for human programmed cell death-1 (PD-1), developed for the treatment of cancer. The primary objectives of these analysis were to (a) describe the pharmacokinetics (PK) of MEDI0680 and quantify the impact of patient/disease characteristics on PK variability (b) to compare body weight (WT)-based and fixed dosing regimens of MEDI0680 and (c) to characterize PK-pharmacodynamic (receptor occupancy) relationship. Methods: A total of 905 serum concentration records from 58 patients in Phase 1 study (D6020C00002) designed to evaluate safety, tolerability and PK following 0.1, 0.5, 2.5, 10, and 20 mg/kg every 3 weeks (Q3W), every 2 weeks (Q2W) and 375 mg/m² for DOX, Vincristin (VCR), CP and Rituximab respectively. For PK analysis, 7 time point samples were collected over 48 h post administration on cycle 3. CP and VIN plasma concentrations were measured using UPLC-MS/MS validated method. DOX plasma concentrations were measured using UPLC coupled with fluorescence detection validated method. PK-PD modeling has been performed with a non linear mixed effect model program (Monolix version 4.3.2). Results: 31 patients (15 males and 16 females), 75 to 96 years old, were treated with DOX and CYP. Among them, 19 patients have received VCR. A total of 134 and 120 concentrations for DOX and CP were used respectively for PK-PD modeling. A 2-compartment open model adequately described DOX concentration versus time courses. A 1-compartment open model adequately described CP concentration versus time courses. The interindividual variabilities (ISV) could be well estimated for both drugs and for all structural parameters (clearances: CL, Q, volumes of distribution: Vc, Vp) except Vp for CP. The population PK parameters for DOX obtained for the structural model were: CL=54.5 L/h, V=54.7 L/h, Vc=30.6 L, Vp=1140 L. The population PK parameters for CP were: CL=3.49 L/h, Vc=29.2 L. VCR increases DOX Vc from 30.6 L to 56.9 L/h (p = 0.0012). The main covariate effects were related to gender, age, BW and to albumin. Conclusions: In this study we have espoused that with very good precision PK parameters of DOX and CP in very elderly patients with DLBCL. Our data revealed the effect of gender, BW and VCR administration on DOX PK parameters. We have demonstrated the effect of increasing age on PK of CP. A PK-PD modeling will be performed in order to verify there are biological factors explaining the variation in the PK parameters of DOX and CP in elderly patients.
lutions indicate that following 20 mg/kg Q2W dose, >90% receptor occupancy can be maintained in all subjects. Based on preclinical/clinical PK, PD, and safety data, a dose of 20 mg/kg Q2W was selected for phase 2 studies. Conclusions: A population PK model of MEDI0680 was developed and validated. Modeling results indicate no need for dose adjustment based on patient/disease characteristics. Similar PK is expected for following both WC-based and fixed dosing regimens. PK/PD findings support the dose of 20 mg/kg Q2W. Clinical studies are ongoing in various tumor types.

#5046 Exposure-effacy (OS) analysis of tremelimumab in unselectable malignant melanoma. Paul Baverel,1 Lorin Roskos,2 Manasa Tatipalli,2 Nancy Lee,1 Paul Stockman,2 Maria Taboada,3 Paolo Vicini,4 Kevin Horgan,5 Rajesh Narwal.6 1MedImmune, Cambridge, United Kingdom; 2MedImmune, Gaithersburg, MD; 3AstraZeneca, Macclesfield, United Kingdom; 4AstraZeneca, Gaithersburg, MD.

Purpose: Tremelimumab is a fully human anti-CTLA-4 IgG2 monoclonal antibody that enhances human T-cell activation. Tremelimumab was evaluated in a Phase Iib (DETERMINE), randomised, double-blind, placebo-controlled study in patients with unselectable pleural or peritoneal malignant melanoloma, randomised (2:1) to receive either tremelimumab (10 mg/kg, seven doses Q4W followed by Q12W) or placebo. The study demonstrated no clinically meaningful differences in overall survival (OS). The primary objectives of this analysis were to evaluate the relationship of exposure with OS, and the impact of potential confounders. Methods: A population PK model was developed to estimate and derive PK exposure metrics (area under the curve at steady state [AUCss] or clearance [CL]) for exposure-OS analysis. Impact of potential confounders was evaluated using graphical and exploratory approaches. Factors including body weight, age, gender, race, ECOG status, anatomical site (pleural or peritoneal), line of therapy, EORTC status, tumour histology, baseline tumour size, LDH, and CRP were evaluated. The analyses were performed using NONMEM 7.2 and R software. Results: The population PK included 376 patients and 328 post-first dose PK concentrations. PK was consistent with previous knowledge and low incidence of anti-drug antibodies was observed. A 2-compartment linear model PK model adequately described the data. Tremelimumab CL and volume of distribution (V1) were 310 mL/day and 3.85 L, with moderate variability of ~38% and ~32%, respectively. There was an apparent exposure-OS relation when stratified by AUCss. However, at least 3 factors (gender, CRP, and baseline tumour size) were statistically significant PK predictors (p<0.05 on CL) indicating multi-dimensional confounding effect. Higher baseline tumour size, higher CRP levels and males were associated with lower PK exposure of tremelimumab. Conclusions: The observed apparent exposure-OS relationship is the result of imbalance in prognostic factors impacting OS rather than a true association of exposure with efficacy.

#5047 Cetuximab fixed dose combination - therapeutic drug monitoring. Cynthia Lee,1 Dongwon Lee,1 Sam Khateri,1 Wen Wang,2 Vuong Trieu2. 1Autotelic Inc, Costa Mesa, CA; 2Marina Biotech, Agoura Hills, CA.

Background: The anticancer properties of Cetuximab (CEL) have been demonstrated in different cancer indications, including colorectal, breast and non-small cell lung cancers. However, its use is associated with dose related cardiovascular and sudomotor events including edema and hypertension. We have shown that combination of CEL and OLM (Olmesartan) would negate drug induced edema caused by CEL. To further improve on the safety of this combination, we are now exploring therapeutic drug monitoring (TDM) guided dosing on CEL. This study demonstrated that TDM via lateral flow platform would be able to quantify plasma drug concentration and guide the optimal dosing for CEL. Methods: Pharmacokinetic (PK) data (Cmax and AUC) to oral formulations of CEL as single dose to healthy adults were collected from published clinical trials. PK data were analyzed against dose and demographic factors to evaluate the variability. To develop the lateral flow methods for quantification, mAbs against CEL were generated by synthesizing BSA-CEL immunogen and hybridoma technology. The best clones demonstrating a dose response to CEL were selected and tested. The assay requires the configuration of immobilizing BSA-CEL onto the membrane followed by flowing the colloidal-gold labeled mAb against CEL through in presence of test analyte. This resulted in a competitive assay where the signal decreased as the concentration of CEL in blood increased. Results: For CEL, the AUC and Cmax across multiple doses were significantly overlapped. With 200 mg CEL, we used meta-analysis to show that older subjects have a significantly higher AUC than younger subjects (p<0.001). These results indicate that different individuals may have very different drug exposure with same dose of CEL, depending on their age and other factors, resulting in over exposure and toxicity. Using a cutoff of 6.741 ng*hr/mL, we were able to separate out almost all of the elderly subjects from the young subjects. Therefore, to avoid toxicity, we will use TDM guided dosing to maintain AUC at the target AUC of 6.741 ng*hr/mL. To make possible TDM guided dosing, we developed a quantitative point of care lateral flow assay for CEL. mAb against CEL were selected based on good sensitivity and binding ability to CEL. Coupled with the lateral flow reader by Qagen, the assay exhibited a dynamic range of 7.5ng/mL to 6,741 ng*hr/mL. To make possible TDM guided dosing, we developed a quantitative point of care lateral flow platform coupled to a reader was developed to easily detect the CEL concentrations in finger-prick blood samples, allowing for in-home personal PK testing. The individual PK profiles built from the concentration data will be used to guide the optimal dosing of CEL, to maximize treatment efficacy and minimize toxicity. This should allow for higher dose of the toxic CEL without hitting this exposure limit. This additional enhancement on top of combination with OLM in the fixed dose combination will insure the safety of our patients on these drugs.

#5048 Residual concentrations of cetuximab predict clinical response in head and neck cancer patients. Joseph Ciccinni,1 François Becher,2 Diane Charlote Imbs,1 Claire Fournel,1 Florence Duffaud,2 Bruno Lacarelle,1 Sebastien Salas,1 1Aix-Marseille Univ., Marseille, France; 2CEA, Saclay, France; 3Assistance Publique Hôpitaux de Marseille, Marseille, France.

Cetuximab administration is contingent upon the upfront determination of Ras mutational status, because mutated patients are unlikely to respond to this therapy. In addition to tumor genomics, drug exposure levels could be a critical yet largely underestimated issue, because several reports have already demonstrated that cetuximab pharmacokinetic parameters (i.e., clearance values) could be associated with survival in patients. Here, we have developed an original bioanalytical method based upon the use of LC-MS/MS technology and a highly simplified sample preparation procedure to assay cetuximab in patients while meeting the requirements of standard therapeutic drug monitoring in routine clinical practice. We used this method prospectively to evaluate the inter-patient variability in drug exposure, and to search whether those exposure levels could be associated with clinical endpoints. A total of 25 adult patients (22 M, 3 F, mean age: 69 years) hospitalized for head and neck cancer and scheduled for a cetuximab-containing regimen (250 mg/m2 QW) were included to perform this pilot study. Seven patients received concomitant radiotherapy and 14 patients received concomitant chemotherapy. 28% of patients displayed severe toxicities (CTC grading). Following RECISt assessment, 10 out of 25 patients (40%) had progressive disease and 60% were categorized as patients with clinical benefit (stable disease: 5 patients: 20%, partial response: 7 patients (28%), complete response: 3 patients (12%)). A large inter-patient variability was observed among individuals. Mean cetuximab residual concentrations were 40.3 ± 20.3 µg/ml (CV: 51%, range 0.746-250.6 µg/ml) and mean cetuximab maximal concentrations were 126.9 ± 39.6 µg/ml (CV: 31%, range 65.1-210.6 µg/ml). No statistical difference was observed in cetuximab residual concentrations between patients with and without severe toxicities (36.7 ± 21.2 µg/ml VS. 41.8 ± 20 µg/ml, p>0.05, t test), nor in maximal cetuximab concentrations (117.1 ± 31.3 µg/ml VS. 130.3 ± 39.7 µg/ml, p>0.05, t test). Conversely, when comparing exposure levels in patients with clinical benefit to non-responding patients, a statistical difference was found in both cetuximab residual concentrations (49 ± 16.4 µg/ml VS. 25.8 ± 17.1 µg/ml, p<0.05, t test) and maximal cetuximab concentrations (143.7 ± 37.9 µg/ml VS. 100.9 ± 24.6 µg/ml, p<0.05, t test). Further ROC analysis showed that 33.8 µg/ml was the Cmin level associated with a probability of clinical benefit with 86% of sensitivity and 75% of specificity. These results advocate for the development of mass spec-based therapeutic drug monitoring of cetuximab in head and neck cancer patients. In addition to tumor molecular biology, drug exposure could be indeed a valuable actionable item to improve efficacy of cetuximab at bedside.

#5049 Application of population pharmacokinetic and exposure-response modeling for DS-8201a, a HER2-targeting ADC, predicts 50% ORR in patients with heavilypretreated breast cancer. Kazutaka Yoshihara,1 Seiko Endo,1 Kenji Yamura,2 Yoshihiko Doi,3 Tarou Tokui1. 1Daichi-Sankyo Co., Ltd, Tokyo, Japan; 2National Cancer Center Hospital, Tokyo, Japan; 3National Cancer Center Hospital East, Chiba, Japan.

Background: Antibody-drug conjugates (ADC) provide a wider therapeutic index by allowing specific targeting of cytotoxic agents to tumor cells. DS-8201a is a novel HER2-targeting ADC which contains a high average drug-to-antibody-ratio (DAR) of 7-8 molecules of a topoisomerase I inhibitor (exatecan derivative, DXd) per antibody. Preclinical data demonstrated a broader antitumor activity of DS-8201a than T-DM1 (the only FDA approved HER2-targeting ADC), including efficacy against T-DM1 resistant and HER2 low-expressing tumors. The first-in-human (FIH) study, comprising a dose escalation (Part I) and expansion (Part II), is being conducted in patients with HER2+ breast can-
#5050 Pharmacodynamic and pharmacokinetic relationship of single agent E7494 in patients with advanced solid tumors or B-cell malignancies.

Pallavi Sachdev,1 Shannon McGrath,2 Robert Shumaker,3 Jagadeesh Aluri,4 Claudio Savulsky5. 1Eisai, Inc., Woodcliff Lake, NJ; 2Eisai, Inc., Andover, MA; 3Eisai Inc., Hatfield, United Kingdom.

E7494 is a small-molecule inhibitor of poly (ADP-ribose) polymerase (PARP). Preclinical studies reported antitumor activity of single-agent E7494 in BRCA-deficient in vivo models. An open-label, multicenter, phase 1 study was completed to determine the maximum tolerated dose (MTD), safety, pharmacokinetics (PK), pharmacodynamics (PD), and preliminary antitumor activity of single-agent E7494. The MTD was determined to be 600 mg/day (n = 8). Treatment-emergent adverse events led to drug withdrawal in 1 patient and dose reductions in 3 patients. No minimal differences with exposures of DS-8201a or DXd were observed for the GI toxicity relative to lower doses, which supports the selection of this dose for Phase 2.

E7494 dosing at 600 mg/day was associated with sustained PARP inhibition. No significant changes in percent DNA in the comet assay to determine the extent of DNA damage. In the food-effect cohort study for new chemical entities and biological products. The primary purpose is collection of safety data in actual clinical settings by an active surveillance approach. In this study, we utilized the observational safety data of eribulin for model-based pharmacodynamic analysis to investigate more detailed safety profile of eribulin in patients with recurrent or metastatic breast cancer (RBC/MBC). Methods: The demographics and safety data were collected from RBC/MBC patients who were treated with eribulin by an active surveillance method. Since dose-limiting toxicity of eribulin is neutropenia, we analyzed the time course of neutrophil counts using a mechanistic pharmacodynamic model. Pharmacokinetic modeling was performed in a population pharmacokinetic model (Adamid et al. [119]). All model analyses were performed by Phoenix NLME1.3 (Certara). Estimated pharmacodynamic parameters were mean transit time (MRT [h]), proliferation rate constant of neutrophils (Kprol [1/h]), and slope of neutrophil counts (Kout [1/h]). Results: Clinical and laboratory data of 607 patients who were not given granulocyte colony stimulating factor were collected from July 2015 to December 2011. Among them, 406 patients with a total of 5204 neutrophil counts measurements were eligible for mechanistic pharmacodynamic analysis. The estimated mean parameters for eribulin were: MRT = 45.4 (h), Kprol = 0.1111 (1/h), Kout = 0.2074 (1/h), and Gamma = 0.317 and Slope = 0.0524.
Arsenic trioxide metabolism in patients with acute promyelocytic leukemia. Mohammad T. Khan,1 Sara Tarig,2 Cristina M. Ghiuzaoli,3 Miroslav Styblo,7 Jesse Saunders,2 Anthony Calabro,2 Nina Kohn,4 Daniel Budman,2 Steven Allen,1 Craig Devoe1. 1Hofstra Northwell School of Medicine, New Hyde Park, NY; 2University of North Carolina at Chapel Hill, Chapel Hill, NC; 3New York Genome Center, New York, NY; 4Feinstein Institute for Medical Research, Manhasset, NY.

BACKGROUND: Arsenic trioxide (ATO) is a mainstay of therapy for Acute Promyelocytic Leukemia (APL). Its long term effects and pharmacokinetics have not been well described. ATO is metabolized by a series of reactions involving inorganic arsenic (iAs) methylation and reduction steps resulting in mono- (MAs), di- (DMAs) and trimethylated arsenic (TMAs) metabolites which are subsequently excreted mainly in the urine: iAs\textsubscript{III}→MAs\textsubscript{III}→DMAs\textsubscript{III}→DMAs\textsubscript{V}→TMAs\textsubscript{V}. AToxicality is mediated via the activation of arsenic methyltransferase, a key enzyme in this reaction, contribute to differences in the metabolism of ATO. iAs\textsubscript{III}, MAs\textsubscript{III} and DMAs\textsubscript{III} are more biologically active and more toxic than pentavalent forms. In this study, we measured the total iAs, MAs’s and DMAs’s in plasma and urine. METHODS: Blood and urine samples from 10 control patients and 26 APL patients treated with ATO were collected. The treated patients had blood drawn immediately prior to and at 1, 2, 4, 6, and 24 hours, days 4, 8 and 15, and 4 weeks after the administration of ATO. Total iAs (iAs\textsubscript{III}+iAs\textsubscript{V}), MAs (MAs\textsubscript{III}+MAs\textsubscript{V}) and DMAs (DMAs\textsubscript{III}+DMAs\textsubscript{V}) were measured in plasma using hydride generation-cryotrapping-atomic-absorption spectrometry. The same arsenic species were measured in spot urine at several time points. For statistical analysis, repeated measures analysis of variance (RMANOVA) were done to compare subject groups over time. Two subjects were missing iAs urine values at 24 hours and so were excluded from this analysis. RESULTS: iAs levels differed over time (p<0.0001), with a rapid increase noted after ATO administration followed by a linear decline, reaching minimum levels by 4–6 hours. Between 6 hours and 24 hours, two distinct groups of iA5s metabolizers became apparent: 15 subjects had stable or decreased iAs levels at 24 hours (Group A) versus 9 subjects with at least a 5% increase in iAs at 24 hours (Group B). Methylated metabolites in the urine were also higher at all measured time points in Group A versus Group B; however, the difference between the two groups was statistically significant only for urine DMAs (p<0.0390). CONCLUSIONS: Chronic iAs exposure has been associated with increased risk of diabetes, cardiovascular disease, and skin cancer. Patients treated with a therapeutic dose ATO, we identified 2 distinct groups of arsenic metabolizers: Group A patients who rapidly converted iAs to MMA and DMA and excreted the metabolites in the urine, and Group B patients who metabolized arsenic slowly and had a lower rate of excretion of metabolites in the urine. These results suggest that Group B patients had a longer exposure time to iAs and its metabolites and may be more susceptible to ATO toxicity. Prospective clinical trials are needed to determine long term ATO toxicity in these patients.

Ewing Family of tumors (EFT) comprises the fourth most common highly malignant childhood cancer. Although sustained event-free survival (EFS) can be achieved with intensive chemo-radiation therapy for patients with local-regional disease, this therapy is relatively ineffective in the treatment of metastatic disease with EFS of 12% at 5 years. Ewing sarcoma is characterized by a reciprocal translocation between chromosomes 11 and 22 that encodes a chimeric oncoprotein resulting from the fusion of EWSR1 to the FLI1 transcription factor in ~85% of tumors. Therapy for patients with EFT comprises surgery, intensive use of cytotoxic agents and radiation therapy. Dose intensification and dose compression has resulted in some improvement in outcome, but patents with advanced or metastatic disease at diagnosis still represent a challenge. Further, patients alive at 5 years from diagnosis still have a high probability of subsequent relapse. Further, long-term consequences of treatment included cardiac dysfunction, and secondary malignancies. Thus, more effective and less toxic therapies are required to treat patients with Ewing sarcoma.

In this study 5 of 10 Ewing tumor xenografts models showed dramatic regressions to the combination, while administered as single agents, neither talazoparib or temozolomide were active. We have studied the talazoparib-temozolomide synergy in vitro, and results indicate that in models where there is no synergy as xenografts, the cell lines have either intrinsic resistance to talazoparib, temozolomide or both drugs. In mice, and in the clinical trial (NCT02116777), the talazoparib-temozolomide combination is toxic requiring a reduction in temozolomide dose to ~15% of its maximum tolerated dose.

We are exploring the use of nanoparticle-formulated talazoparib (npTLZ) developed by Nanomaterials Synthesis Laboratory at Northeastern University without tumor targeting or with antibody-mediated targeting to increase the tumor-drug delivery, reduce normal tissue toxicity (mainly thrombocytopenia), and potentially allow escalation of temozolomide dose. In the PPTP study, the MTD for temozolomide combined talazoparib was 100 mg/kg PD daily x 5, which is 12 mg/kg. Our recent data showed no toxicity of temozolomide at 66 mg/kg (PD daily x 5) in mice treated with npTLZ (0.5 mg/kg IV daily x 5), suggesting that npTLZ does not potentiate TMZ toxicity to normal mouse tissues. We anticipate that nanoparticle delivery of talazoparib combined with temozolomide will allow reduced toxicity while increasing the response rate for this combination in preclinical models of Ewing sarcoma.

R,S-4-Methoxy-1-naphthylfenoterol, MNF, inhibits the G protein-coupled receptor GPR55. In this study, we determine the effect of MNF on human PANC-1 pancreatic tumor growth in mice and apply multiplatform metabolomics analysis to identify pathways associated with growth arrest. Methods: Female Balb/c nude mice, 6–8 weeks old, 18-20 g, were inoculated subcutaneously with 5 x 10\textsuperscript{6} PANC-1 cells. On Day 8, mice were placed in groups of 10 using random block design based upon tumor volume. Mice received daily ip injections of vehicle or 40 mg/kg MNF 5 days/week for 3 weeks and sacrificed on Day 33. Mice were inhiberated daily and tumor volumes measured at beginning and end of each dosing cycle. On Day 33, mice were euthanized, and plasma samples and tumors collected. Tumor tissue was homogenized, extracted and analyzed using liquid chromatography-QTOF-MS, capillary electrophoresis-TOF-MS and gas chromatography-El-Q-MS. Differences between groups were evaluated by unpaired t-test or Mann-Whitney test with post hoc Benjamini-Hochberg correction. Statistical significance was set at P < 0.05. Compound identification was accomplished using online databases and in-house standards. Results: Tumor volume increased in vehicle-treated mice by ~700%, 142 ± 8 mm\textsuperscript{3} to 957 ± 79 mm\textsuperscript{3} and only ~25% in MNF-treated mice, 143 ± 8 mm\textsuperscript{3} to 259 ± 27 mm\textsuperscript{3}. On Day 33, MNF was not detected in plasma but accumulated in tumor tissues, 43.9 ± 32.7 mg/g. Plasma L-lactate levels were reduced from 3.29 ± 0.66 mmol/L to 2.81 ± 0.60 mmol/L, P<0.001. Differences in tumor tissue metabolome were observed with MNF compared to vehicle, which was reflected by significant, P<0.05, changes in relative metabolite signals. MNF treatment was accompanied by the disruption of pyrimidine nucleotide biosynthesis at uridine 5'-monophosphate, UMP, and increased UMP degradation. Moreover, the +237% increase in 2-aminobutyrate indicate higher oxidative stress and the +51% increase in 2-hydroxyproline suggest greater HFI-1a proteolysis upon MNF treatment. Conclusions: These results are consistent with our previous observations in PANC-1 cells showing that GPR55 inhibition attenuates activation of the EGFR-MEK-ERK, Wnt-β-catenin and PI3K/AKT pathways resulting in lower cyclin D1 expression and halting the cell cycle in G1. The reduction in HFI-1a expression and glycolytic flux in MNF-treated PANC-1 cells is in line with the decline in L-lactate plasma levels in MNF-treated mice. The data from this study indicate that MNF may be useful in the treatment of pancreatic cancer.
**EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Epigenetic Agents**

**#5056 The bromodomain inhibitor JQ1 sensitizes homologous recombination proficient ovarian cancer cells to the PARP inhibitor olaparib.** Andrew J. Wilson, Janese Thompson, Abdirahman Osman, Jeanette Saskowski, Dineo Khabele. Vanderbilt Univ. Medical Ctr., Nashville, TN.

Introduction: Lack of effective treatment options for high-grade serous ovarian cancers (HGSOCC) retaining functional homologous recombination (HR) DNA repair pathways is a significant clinical problem. HR-proficient HGSOCC tumors, for example those harboring cyclin E amplifications, have poorer clinical outcomes and show relative resistance to DNA-damaging platinum agents and newer poly ADP ribose polymerase inhibitors (PARPis). We and others have shown that using epigenetic drugs to reduce HR efficiency in HR-proficient HGSOCC sensitizes these cancer cells to DNA damaging agents. One mechanism by which these drugs reduce HR efficiency is by transcriptional down-regulation of HR pathway components. An emerging class of epigenetic modifiers of protumorigenic transcription is the bromodomain (BRD) family of proteins, and BRD inhibitors (BRDis) have shown promising preclinical anti-tumor efficacy. However, it is unknown whether BRD inhibitors affect HR proficiency in HGSOCC to DNA damaging agents. Aim: To test the hypothesis that BRD inhibitors can reduce HR DNA repair in HR-proficient ovarian cancer cells, thereby sensitizing them to PARPis. Methods: The HR-proficient ovarian cancer cell lines, OVCAR-3 (cyclin E-amplified) and SKOV3, were treated with 0.01% DMSO vehicle, the PARPi olaparib (Astra Zeneca), the BRD inhibitor JQ1 or with the olaparib/JQ1 combination. Sulforhodamine B (SRB) assays assessed cell growth and viability (72 hours treatment). Immunofluorescence (IF) and Western blot analyses were conducted to assess DNA damage (pH2AX), apoptosis (cleaved caspase-3), and HR efficiency (RADS1, foci, and GFP expression in cells co-transfected with Lscet and DRGFP HR reporter plasmids) (24 hours treatment). Steady state levels of the HR protein BRCA1, pH2AX and cleaved caspase-3 were assessed by western blot (24 hours treatment). Results: The combination of JQ1 and olaparib synergistically reduced cancer cell viability following isobologram analyses of SRB experiments. Compared to either drug alone, the JQ1/olaparib combination also significantly reduced BRCA1 expression and increased protein levels of cleaved caspase-3 and pH2AX in western blots, and also increased the number of cells displaying DNA damage and apoptosis in IF assays. Finally, JQ1 and olaparib combined to significantly reduce HR efficiency in our RADS1 foci formation and DRGFP assays compared to olaparib alone. Conclusions: Our results suggest that BRDIs sensitively reduce HR-proficient cells to DNA damaging drugs, in part by reducing efficiency of HR DNA repair. These findings have important implications for expanding the use of PARPi in HR-proficient HGSOCC through rational combinations with epigenetic drugs such as BRDIs that target the HR pathway.

**#5058 Lysine specific demethylase-1 (LSD-1) Inhibitor SYC-836 in combination with radiation prolongs animal survival in patient-derived posterior fossa ependymoma xenograft mouse models.** Sibo Zhao, Huiyuan Zhang, Lin Qi, Holly Lindsay, Yuchen Du, Mari Kogiso, Frank Braun, Sarah Injac, Laszlo Perakly, Donald W. Parsons, Murali Chintagumpala, Adekunle Adesina, Yongchong Song, Xiao-Nan Li. Baylor College of Medicine, Houston, TX.

Background: Ependymoma (EPN) is the third most common malignant pediatric brain tumor. Current standard therapy include maximally safe surgical resection followed by radiation and to a 5-year overall survival of 50-71%. Recent molecular subgrouping of EPN has identified one group, posterior fossa A (PFA), which accounts for 45% of all EPN cases, to have one of the worst prognoses and it is driven by epigenetic changes, suggesting targeting epigenetic changes in PFA EPN can potentially be effective. In this study, we examined the therapeutic efficacy of SYC-836, a novel LSD-1 inhibitor compound developed at Baylor College of Medicine, both in vitro and in vivo in PDOX models of posterior fossa EPN. Methods: To examine in vitro anti-tumor activities, paired primary cultured cells (both as attached cells and neurospheres) from an established PDOX model of posterior fossa EPN (ICB-42423EPN) were subjected to SYC-836 at various concentrations (0-25uM). Cell viability and proliferation were measured using Cell Counting Kit-8 assay at 5 different time points over 14 days. To validate the drug’s in vivo efficacy, two established posterior fossa EPN PDOX models, ICB-42423EPN and ICB-2002EPN, were utilized. 40 eight weeks old SCID mice per model were implanted with tumor cells. They were divided into 4 treatment groups (10 mice/group) each: 1) control (DPBS, 10uL/kg IP daily x 2 weeks), 2) standard radiation, 3) SYC-836 only (15mg/kg IP daily x 28 days), and 4) combination (radiation + SYC-836 per regimen above). Animal survival times were analyzed using log rank analysis. Changes of histone lysine methylation were examined through western hybridization. Results: SYC-836 demonstrated effective cell killing in vitro against both attached and neurosphere cultured cells in both time- and dose-dependent manner. IC50 was ~7.5uM. In vivo experiment was completed in 1 of the 2 EPN PDOX models (ICB-2002EPN) with the second model ongoing. Median survival times for each group is as follows: control: 136 days, radiation 148 days, SYC-836 only 136 days, combination 180 days. There were no survival benefit of radiation + SYC-836 only (P = 0.186) or SYC-836 only (P = 0.004) when compared to the control group; however, when used in combination, the treatment strategy lead to significant improvement in animal survival (P = 0.004). SYC-836 was well tolerated in mice. Conclusion: Our data showed that combining SYC-836 with current standard therapy of radiation synergistically prolongs animal survival significantly, although as a single agent SYC-836 was not effective against posterior fossa ependymoma. Our data suggest that SYC-836 may have a role in the clinical setting by either reducing radiation dosages, or be a potential adjuvant agent to other chemotherapy drugs in our treatment approach for ependymoma.

**#5059 Preclinical study on the efficacy of Panobinostat in hepatocellular carcinoma.** Chi Tung Choy, Wing Yu Man, Chi Hang Wong, Stephen Lam Chan. The Chinese University of Hong Kong, Hong Kong, Hong Kong.

Background: Aberrant regulation of histone deacetylases (HDACs) is known to play a pivotal role in HCC pathogenesis as well as other human malignancies. Panobinostat (LBH589) is a pan-HDAC inhibitor covering a wide range of HDACs (Class I, II and IV) with high inhibitory activity at nanomolar concentration. It has been approved by FDA for treating multiple myeloma and has demonstrated promising anti-proliferative and cytotoxic activity in breast, prostate, colon and pancreatic cancer cell lines. This study investigated in vitro and in vivo effect of Panobinostat in HCC cell lines. Methods: Basal expressions of HR23B and HDACs of 7 HCC cell lines (HepG2, PLC/PRF/5, Huh-7, HepB3, SNU-182, SNU-398 and SNU-449) were determined by western blotting. Their corresponding IC50 for 24, 48 and 72 hours were compared to determine whether Panobinostat were determined by cell viability assay. Huh-7, HepB3 and SNU-449 were selected for further in vitro experiments. Their cell cycle distribution after Panobinostat treatment was evaluated by flow cytometry. Apoptosis was detected by Cell Death Detection ELISA. Huh-7 and HepB3 xenograft model were used for in vivo investigation. Cells were inoculated subcutaneously into the flanks of 3-4 week old athymic nude mice. When tumors were established, Panobinostat was administrated intraperitoneally at 7.5mg/kg and 15mg/kg five days per week for 2 weeks. Results: All cell lines were able to achieve nearly 100% growth inhibition and had displayed a dose- and time-dependent manner towards Panobinostat. Maximum growth inhibition was 20-70% at 24hr compared to over 90% at 72hr. There was significant reduction in cell viability at low nanomolar concentrations (IC50 at 48hr: HepG2 = 8.81 ± 0.72nM, PLC/PRF/5 = 18.9 ± 0.74nM, Huh-7 = 14.01 ± 1.12nM, HepB3 = 25.00 ± 3.69nM, SNU-182 = 73.32 ± 15.52nM, SNU-398 = 12.86 ± 3.45nM, SNU-449 = 73.01 ± 9.09nM). Flow cytometry analysis showed Panobinostat induced accumulation of cells at G0/G1 phase in Huh-7 and SNU-449. Meanwhile, an increase in sub G1 population was detected in HepB3 after exposure to 25nM Panobinostat for 48h. Apoptotic induction was further confirmed by cell death detection ELISA and western blotting. Panobinostat promoted apoptosis more remarkable in HepB3 than other cell lines as evidenced by a stronger cleaved PARP expression level. Panobinostat treatment delayed tumor growth in HepB3 (p<0.0005) and Huh-7 (p<0.0005) xenografts compared to vehicle control. The overall weight loss was less than 20% despite of greater drop during middle of the treatment. Conclusion: Panobinostat has been demonstrated to inhibit in vitro and in vivo HCC cell growth. Further study on the mechanism behind Panobinostat sensitivity is warranted. The study was supported by Novartis.

**#5060 Activity of the EZH2 inhibitor tazemetostat as a monotherapy and in combination with multiple myeloma therapies in preclinical models.** Allison E. Drew, Vinny Motwani, John E. Campbell, Cuyue Tang, Jesse J. Smith, Richard Chesworth, Robert A. Copeland, Alejandra Raimondi, Scott Ribich. Epizyme, Cambridge, MA.

The EZH2 inhibitor tazemetostat (EPZ-6438) is currently being evaluated in phase 2 clinical trials for the treatment of non-Hodgkin’s Lymphoma (NHL). EZH2 inhibitors have shown anti-proliferative effects in multiple preclinical models of NHL and objective clinical responses have been reported in patients with B-cell lymphomas in phase 1 and phase 2 studies of tazemetostat. Mounting evidence suggests that EZH2 is an important regulator of B cell differentiation, both in normal B-cells and in B-cell lymphoma, and may be an important mediator of cell fate in B-cell malignancies in the clinic. Consistent with its essential role in regulating B cell differentiation, recent studies have also shown a dependence on EZH2 activity in multiple myeloma (MM), a disease arising from terminally differentiated B-cell lymphocyte plasmablasts. Frequent genetic al-
terations of epigenetic modulators are observed in MM, pointing towards an important role in the initiation and maintenance of this disease. Dysregulation of the H3K27 methyltransferase EZH2, its corresponding histone demethylase UTX and the H3K36 methyltransferase WHSC1 in MM suggest that disruption of the balance of histone methylation may be fundamental to MM pathogenesis in a subset of cases. Indeed, inhibition of EZH2 alone has shown potent anti-proliferative effects both in vitro and in vivo preclinical models of MM. Here, we describe the effects of small molecule EZH2 inhibitors as monotherapy and in combination with standard of care agents in preclinical models of MM. Tazemetostat selectively inhibits intracellular H3K27 methylation in MM cell lines and elicits a robust anti-proliferative effect in 14-day assays. Following demonstration of single agent activity, we then investigated potential for combinatorial activity of tazemetostat with first and second line therapies for multi-
ple myeloma as well as other non-approved but emerging therapies. Synergistic anti-proliferative activity was observed when tazemetostat was combined with glucocorticoid receptor agonists (dexamethasone, prednisolone), small mole-
cule immune system modulators (lenalidomide, pomalidomide) and protea-
some inhibitors (bortezomib, ixazomib) when cells were primed with tazeme-
tostat for seven days prior to the addition of the standard of care drugs. Combination activity was also observed with an alternate treatment schedule where cells were co-treated with tazemetostat along with the combination part-
ner for seven days. Studies with selected therapeutic modalities were expanded into in vivo xenograft models to further evaluate monotherapy and combination activity of EZH2 inhibitors in MM.

#5061 TET inhibits prostate cancer tumor growth, progression and me-
tastasis in TRAMP mice. Harry K. Koul, Prakash Srivinasisiml Tanimi Shannugam, Praveen K. Jaiswal, Sweaty Koul. LSU Health Sciences Ctr. - Shreveport, Shreveport, LA.

Introduction: Prostate cancer (PCa) is the 2nd most common malignancy in USA. Novel agents for treatment of advanced PCa are warranted. Transgenic adenocarcinoma of the mouse prostate (TRAMP) is an autologous mouse model exhibits both histological and morphological features that mimic human prostate carcinogenesis. Herein, for the first time, we evaluated the in vivo effects of TET, a derivative of Tetrandrine in TRAMP model. Methods: Beginning 12 weeks of age, male TRAMP mice were administered with TET (30 mg/kg body weight, orally, alternative days) in PBS or PBS alone (Control) till 30 weeks of age. Body weight (B) of animals was recorded weekly. At various time points animals were euthanized, genitourinary tract (G) were weighed. Prostate tissue was subjected to immunohistochemical analyses for SV40-TAg, epithelial-mes-
enchymal transition (EMT), proliferation, neuroendocrine differentiation (NED) and apoptosis. Multiple organs were examined for drug toxicity and lungs were analyzed for metastasis. Results: TRAMP mice exhibit to high-grade prostatic intraepithelial neoplasia (PIN) by 12 weeks and progresses to poorly differentiated adenocarcinoma by 30 weeks with distant metastasis to lungs. TET feeding did not show any considerable difference body weight loss profiles during the entire treatment regimen. At the time of necropsy, there was no evidence of edema, abnormal organ size or appearance in non-target organs. TET gavage group showed (p<0.005) lower G/B ratio compared to the PBS treated group. These findings clearly indicate that TET dosing is non-toxic, and restricts the abnormal growth of the prostate in TRAMP mice. TET repress the EMT as well as NED transition and inhibits cell proliferation (p<0.005) by Ki-67 staining, Oral administration of TET inhibits PCa growth and progression by increases (p<0.005) apoptosis in tumor tissues. Further, TET inhibited me-
tastasis as there was significant (p<0.005) decrease in metastatic lungs in TET-
treated animals. Conclusion: Human achievable dose of TET treatment to TRAMP mice bearing prostate tumor, exhibited no-observed-adverse-effect-
level in toxicology evaluations and also significantly inhibited tumor growth, progression, local invasion and distant metastasis involving suppression of tu-
mor, and thus could have potential against human PCa.

#5062 Development of a first in class inhibitor of BET bromodomains and
dopamine receptor 2. Makoto Yoshikawa,1 Jay Chauhan,2 Steven Fletcher,3 Jef-
frey W. Strovel.1 ConverGene, Cambridge, MD; 2University of Maryland, Balti-
more, MD.

ConverGene has developed a first-in-class dual-active small molecule inhib-
itor that i) inhibits BET family of bromodomain-containing proteins, and ii) antagonizes dopamine receptor D2 (DRD2). BET protein family includes BRD4, an epigenetic reader protein that mediates expression of MYC oncogene. Thus, BRD4 is considered as a cancer therapeutic target to indirectly suppress MYC expression. In addition to being a therapeutic target for psychiatric diseases, DRD2 is emerging as a potential therapeutic target in neuroendocrine tumors, subsets of pancreatic ductal adenocarcinoma and small cell lung cancer. Our lead compound showed high activity in a binding test against BRD4 (Ki = 34 nM); exhibited high bioavailability upon oral administration; profoundly sup-
pressed MYC expression both in vitro and in vivo; inhibited growth of AML and solid tumor cells in xenograft models; potently inhibited both isoforms of DRD2 (IC50 0.1 μM); and interfered with DRD2/β-arrestin/Akt pathway in vitro. Therefore, our BRD4/DRD2 dual-active compounds may hold promise as a novel class of therapeutics that interferes with both cancer growth and mainte-
nance by simultaneously interfering with MYC and DRD2 pathways. We cur-
rently are investigating these dual-active compounds in multiple in vitro and in vivo models and expect to report the outcomes at the AACR Annual Meeting in 2017.

#5063 Epigenetic modulators show differential activity on lung adenocar-
cinoma cells with loss-of-function mutations of SWI/SNF protein SMARCA4. Tomasz Rzymski,1 Anna Wrobel,1 Michal Mikula,2 Karolina Py-
ziak,1 Anna Bartosik,1 Agnieszka Sroka,1 Agnieszka Paziewska,2 Aleksandra Grochowska,2 Małgorzata Statkiewicz,2 Katarzyna Paczkowska,2 Michalina Da-
browska,2 Jerzy Ostrowski,2 Krzysztof Brzozka,2 Selvita S.A., Krakow, Poland; 2Maria Sklodowska-Curie Memorial Cancer Center, Warsaw, Poland.

SWI/SNF is a multiprotein chromatin remodeler with AT-dependent activ-
ities leading to selective gene expression, DNA repair, recombination and rep-
lication. Various sequencing efforts indicated that nearly 20% of cancers bear mutations in at least one subunit of the complex. One of the crucial regulators of the complex is SMARCA4, a member of SWI/SNF family of helicases with AT-
Pase activities, which are thought to regulate transcription of certain genes by altering the chromatin structure. SMARCA4 is mutated in virtually all cases of small cell carcinoma of the ovary and SMARCA4 is fourth the most frequently mutated gene in lung adenocarcinoma. High occurrence of inactivating muta-
tions prompted several screenings projects focused on synthetic lethality inter-
actions with other proteins, which led to the identification of SMARCA2 as an essen-
tial gene in SMARCA4 mutated cancers. This vulnerability could be po-
tentially exploited therapeutically and several groups managed to identify potent-
ligands of SMARCA2 bromodomain. Surprisingly these molecules were inactive in SMARCA4 mutant cells, however additional studies indicated that ATPase rather than bromodomain is a target for novel compounds with anticancer ac-
tivities. Overall, these results revealed functional complexity of SMARCA2 and SMARCA4 in cancer cells. In order to characterize molecular consequences of SMARCA2 silencing in SMARCA4 mutant lung adenocarcinoma cells, we have carried out a series of gene knockdown experiments, followed by transcriptional profiling by RNAseq and analysis of posttranslational histone modifications. These studies indicated rapid and irreversible loss of viability in SMARCA4 mutant cells after SMARCA2 gene silencing. Interestingly double SMARCA2/ SMARCA4 knockdown in SMARCA4 WT cells has not resulted in lowered viability. Transcriptional profiling of SMARCA2 knockdown in SMARCA4 mu-
}
oposed a phenotypic-based system (YBS) by stably transfecting SW48 cells with a vector containing GFP driven by a methylated and silenced CMV promoter. GFP re-expression can be achieved by known epigenetic drugs that lead to de-methylation or induce active chromatin marks in the CMV promoter. By screening an NDI-3040 natural compounds library and grouping the compounds based on chemical structures, we identified two main drug classes. We then synthesized 77 new analogs based on class #1’s lead’s structure and 23 were positive in the YBS system. The most potent analog (HH2) can induce ~60% GFP+ cells upon 500nM treatment after 96hr. All the positive hits can also be validated in two other cancer cell lines (MCF7 and HCT116). Consistent with GFP reactivation, endogenous hypermethylated genes (MGMt, RARβ, etc) can also be re-expressed upon drug treatment. We then performed RNA-seq analysis to identify global gene expression changes following drug treatment. We observed that most genes (2964 genes) were upregulated upon HH1 treatment (10μM) and that many of the upregulated genes were expressed in normal tissues but repressed in cancer, indicating that they might be potential tumor suppressor genes (TSGs). Consistent with this, 94 TSGs could be reactivated upon 10μM drug treatment. These drug target upregulated genes were also enriched for hypermethylation. By performing connectivity mapping using RNA-seq, we identified X as the class #1 drug target. The on-target effect could be further validated by using other selective X inhibitors as well as a dominant negative X construct. Consistent with drug inhibition, dominant-negative X can also re-activate drug targeted hypermethylated genes. Additionally, when we overexpressed wild-type X, we saw that GFP induction as well as gene reactivation can be inhibited. Strikingly, by using GFP induction as read-out to optimize drugs, we found that the in vitro IC50 against X for our top lead compound (HH2) is only 5nM and it is at least 22-fold selective for X over other X family members. Thus, a novel epigenetic drug class derived from natural compounds was identified and can be developed by targeting silenced gene expression.

#5065 Harnessing epigenetic reprogramming by histone deacetylase inhibitor MS275 for pancreatic cancer therapy. Gaoyang Liang,1 Ruth Yu,1 Christopher Liddle,2 Morgan Truitt,1 Corina Antal,1 Annette Atkins,1 Ester Banayo,1 Michael Downes,1 Ronald Evans1.1Salk Institute for Biological Studies, La Jolla, CA; 2Westmead Millennium Institute and University of Sydney, Westmead, Australia.

Pancreatic ductal adenocarcinoma (PDAC) accounts for more than 85% of pancreatic cancer and is one of the most lethal malignancies with limited therapeutic options. Chromatin-modulating small molecules, or epigenetic drugs, have the ability to reprogram cell fate and alter disease phenotypes. The potential of these drugs for PDAC therapy remains to be fully investigated. Screening a panel of epigenetic drugs identified MS275 (MS, also called entinostat), a histone deacetylase inhibitor, as capable of suppressing PDAC cell proliferation and subsequent fibrosis. Genome-wide expression analysis revealed that MS extensively reprograms the transcriptomes of tumor cells and cancer-associated fibroblasts (CAFs). In tumor cells, MS downregulates genes important for cell cycle progression inducing cytostasis. In CAFs, MS specifically represses the pro-fibrotic transcription program responsive to TGF-β, effectively inhibiting the fibrotic responses. Consistent with this, MS blocks the activation of pancreatic stellate cells, the primary source for CAFs in PDAC, to repress the fibroblast-like phenotypes in these cells. Using an orthotopic transplantation model, we confirmed that MS treatment reduces tumor cell proliferation and decreases intratumoral fibrotic content. Importantly, we showed that MS substantially enhances chemosensitivity, synergizing with gemcitabine to reduce tumor burden in PDAC mouse models. Our study establishes a novel therapeutic strategy for PDAC based on epigenetic reprogramming induced by HDAC inhibition.

Chondrosarcomas are the second most frequently occurring type of bone malignancy, and account for approximately 25% of all bone sarcomas. They are often highly aggressive neoplasms that rapidly progress and eventually recur and give distant metastases. They are largely considered to be resistant to conventional chemotherapy and radiotherapy. Several studies have reported that targeting epigenetic mechanisms including DNA methylation and histone acetylation are novel approaches for the treatment of some human cancers. Previous reports have shown that the interaction of DNA methylation and histone modification regulates gene expression. In the present study, we hypothesized that concurrent inhibition of histone acetylation and DNA methylation could result in decreased viability of chondrosarcoma cells both in vitro and in vivo. To test this, we used a panel of chondrosarcoma cell lines including IDH wild type (CH2879), IDH1 mutant (JH012) and IDH2 mutant (CS1) cell line. Results from our in vitro proliferation assay showed that combination of sub-IC50 concentrations of the DNA methyltransferase inhibitor 5-Aza-2’-deoxycytidine (5-AZA) and histone deacetylase (HDAC) inhibitor (SAHA) resulted in decreased cell viability of the three chondrosarcoma cell lines tested when compared to either drug alone. Western blot analysis showed induction of cleaved Poly-ADP Ribose Polymerase (PARP), a known marker of apoptosis. Consistent with augmented DNA damage, combination of Decitabine and SAHA markedly increased the apoptosis marker Poly ADP Ribose (PAR) and damage marker, and pro-apoptotic BH3 only proteins such as Bim. Combination treatment also resulted in increased induction of histone acetylation (AcH3) and increased expression of E-Cadherin. Previous reports have shown that E-cadherin is critical for apoptosis and depletion and inhibition of E-Cadherin impairs apoptosis induction via DR4 and DR5 death receptors. To this end, we showed that induction of cleaved PARP by Apo2L/TRAIL stimulation decreased over time when E-Cadherin was knocked down by siRNA. Xenograft studies using IDH2 mutant (CS1) tumor model showed a significant suppression of tumor volume when animals were treated in combination with SAHA and Decitabine compared to single agent treatments. Taken together, our data strongly suggests that combination treatment with SAHA and Decitabine is a novel treatment approach and merits evaluation in the treatment of chondrosarcoma.

#5067 BET protein proteolysis targeting chimera (BET-PROTACs) exert more potent activity than BET bromodomain inhibitor (BETi) against post-myeoproliferative neoplasm (MPN) secondary (s) AML cells. Dyana T. Saenz,1 Warren C. Fiskus,1 Kanak Raina,2 Tahi Marshouiri,1 Kevin G. Coleman,1 Yimin Qian,1 Andrew P. Crew,2 Angela Shen,2 Christopher P. Mills,1 Bao-hua Sun,1 Misun Kim1, Agnieszka J. Nowak,1 Srdan Verstovsek,2 Craig M. Crew,3 Kapil N. Bhalla1.1MD Anderson Cancer Center, Houston, TX; 2Arvinas, LLC, New Haven, CT; 3Yale University, New Haven, CT.

In BCR-ABL1-negative myeloproliferative neoplasms with myelofibrosis (MPN-MF) transformation to AML (sAML) occurs in up to 20% of patients. Ruxolitinib (R) is a type I, ATP-competitive, JAK1 & 2 inhibitor (JAKi), which is effective in the therapy of MPN-MF but does not significantly impact the clinical outcome in post-MPN sAML. We have previously reported that treatment with BETi, e.g. IQ) or OTX015 inhibits growth and induces apoptosis of cultured sAML cells, including those that express Jak2 V617F and mutant TP53, e.g. HEL92.1.7 and SET2, as well as patient-derived (PD) CD34+sAML cells. BETi treatment attenuated the protein expressions of c-MYC, p-STAT5, Bcl-xl, CDK4/6, PI3 and 7R, while concomitantly inducing the levels of HEXIM1, p21, NOXA and BIM in the sAML cells. However, treatment with BETi leads to the accumulation of BET, e.g. BRD4, which may reduce BETi-mediated repression of c-MYC, NfκB and BET-regulated oncogenes. In contrast, BET-PROTACs (proteolysis targeting chimera) ARV-825 and ARV-771 (Arvinas Inc.) degrade BETPs (including BRD4) in the cultured and PD CD34+sAML cells. At equimolar concentrations, BETP-PROTACs were significantly more potent than the BETi in inducing apoptosis of cultured and PD sAML cells. Additionally, co-treatment with BETP-PROTAC and R was synergistically lethal against the cultured and PD CD34+sAML cells. BETP-PROTAC treatment caused more up and down regulation of mRNA and protein expressions than BETi, as determined by RNA-Seq and reversed phase protein array (RPPA) analyses, respectively. As compared to treatment with BETi, BETP-PROTAC caused greater depletion of c-MYC, Jak2, p-STAT5, STAT5, p-STAT3, STAT3, PI3 and Bcl-xl, whereas the protein levels of p21 and p27 were upregulated. CyTOF or mass-cytometry also showed that BETP-PROTAC, more than OTX015 treatment, reduced BRD4, c-MYC and p-Rb, while inducing p21 levels in the CD34+sAML stem/progenitor cells expressing CD90, CD244, CD123 and CD138. Contrary to BET-PROTAC with R significantly reduced the expression of sAML progenitor markers (CD34+CD138) and burden and improved the median survival of the immune-depleted mice engrafted with luciferase-transduced HEL92.1.7 cells. These findings strongly support further in vivo development of the novel BETP-PROTACs-based combinations against post-mPN sAML.
Inhibition of BET bromodomain, epigenetic regulator, as an effective therapeutic approach for gastric cancer.

with single agent BET or PI3Kα therapy, the combination significantly potentiates tumor growth inhibition in DLBCL models representative of the ABC subtype (HBL-1), and the double hit GCB subtype (WIL2). These data suggest that clinical exploration of INCB057643 as a monotherapy or in combination in hematologic malignancies is warranted.

**#5072 Inhibition of EZH2 as a therapeutic strategy for osteosarcoma.** Esvaran Devarajan, Wei-lin Wang, Jen-Wei Tsai, Andrew Futreal, Valeriane O. Lewis. UT MD Anderson Cancer Ctr., Houston, TX.

Introduction: Osteosarcoma is the most common primary malignant bone tumor. About 30% of osteosarcoma patients experience relapse and die of their disease. We previously demonstrated that IL-11Rs are overexpressed in primary and metastatic osteosarcoma and plays a role in the development of metastases. Our recent microarray data from Korb, Sisa1, and LM7 IL-11Rα shRNA cells showed decreased expression of several components of polycomb repressive complex 2 (PRC2). EZH2 is the catalytic subunit of PRC2 and blocks transcription of numerous tumor suppressors’ genes. EZH2 has been widely implicated in cancer and inhibition of its catalytic activity has recently emerged as a novel approach to treat cancers. Purpose: To explore the effects and mechanisms of inhibition of EZH2 on osteosarcoma metastasis. Inhibition was tested using GSK126, a novel small-molecule EZH2 inhibitor that competes with methyl group donor S-adenosyl-methionine in a highly selective fashion. Methods: Proliferation assays were performed on a panel of osteosarcoma cell lines subjected to increasing concentrations (0.0625 µM to 20 µM) of GSK126 for 3 days. The effects of IL-11 in PRC1 complex histone H3 methylation (H3K27) were studied by Western blotting. For in vivo experiments, we used an orthotopic metastatic model. Luciferase-labeled Sisa1 osteosarcoma cells were injected into the tibias of 4- to 5-week-old nude mice. After 2 weeks, mice were treated with vehicle or GSK126 three times per week intraperitoneally at 0.1 ml per 20 g of body weight in 20% capitol for 48 days. The tumor-containing legs were amputated when tumor volume reached 2 cm. Primary tumors were measured with calipers, and, with the capability of the compound, administered individually or in combination (IC50), to inhibit cell proliferation was assessed by MTT assays. Drug interaction analysis was performed using Compusyn software. The protein and gene expression levels were determined using western blot and real-time PCR, respectively. Results: We found that about 70% of the cell lines tested were sensitive to EZH2 inhibition (IC50 = 3.576-6.450 µM). In vivo, mice treated with GSK126 developed significantly fewer osteosarcoma lung metastases than control mice injected with vehicle alone (P<0.01). Conclusion: GSK126, a potent small-molecule EZH2 inhibitor, inhibits the development of osteosarcoma lung metastases in vivo. Thus, GSK126 may be considered as a novel anticancer drug candidate for osteosarcoma.

**#5073 Determination of sensitivity to BET and HDAC inhibitors in lung cancer cell lines.** Sara Verdura, Manuel Torres-Diz, Montserrat Sanchez-Cespedes. IDIBELL, Barcelona, Spain.

Purpose: To determine the sensitivity of lung cancer cell lines to different combinations of BET and HDAC inhibitors and to inquire possible associations with the genetic and molecular profiles. Methods: A panel of lung cancer cell lines were treated in vitro with BET and HDAC inhibitors. The capability of each compound, administered individually or in combination (IC50), to inhibit cell proliferation was assessed by MTT assays. Drug interaction analysis was performed using Compusyn software. The protein and gene expression levels were determined using western blot and real-time PCR, respectively. Results: We found that about 70% of the cell lines tested were sensitive to BET inhibitors and about 60% responded to HDAC inhibitors. In both cases, increased sensitivity was accompanied by changes in cell morphology, a reduction of the MYC protein levels and an increase in the levels of apoptotic-related markers. We also determined the effects of the combination of these epigenetic treatments in cell growth. Our results showed a synergistic effect in about 75% of the cell lines which was also correlated with dramatic changes in cell morphology, in apoptosis and in decreasing the levels of the MYC protein. Finally, we determined the possible correlation of the sensitivity to these epigenetic drugs and the expression levels of some genes implicated in lung carcinogenesis. Conclusions: Our data showed that lung cancer cells responded to BET and HDAC inhibitors and that the combination of both drugs has a synergistic effect in cell growth inhibition, suggesting that this could be an effective treatment in lung cancer. Our data also point out to certain genes as potential biomarkers to determine sensitivity to these compounds.

**#5074 Therapeutic targeting of bromodomain and extra-terminal proteins degradation in triple-negative breast cancer.** Longchuan Bai, Bing Zhou, Chao-Yie Yang, Jiao Ji, Donna McEachern, Sally Przybranowski, Shaomeng Wang. University of Michigan, Ann Arbor, MI.

Triple negative breast cancer represents the most clinically challenging subtypes of breast cancer for which targeted therapeutics are still lacking. BET proteins have emerged as new therapeutic targets for human cancers and other diseases. We have developed a highly potent BET degrader, BETD-246, with an exceptional selectivity based upon a new class of BET inhibitor, BET-211, and investigated its therapeutic potential and mechanisms of action in TNBC. BETD-246 induces degradation of BET proteins at low nanomolar concentrations within 1 hour, leading to potent anti-proliferative activity and strong apoptosis induction in the majority of TNBC cell lines, and is much more effective than the BET-211 treatment. RNA-seq analysis reveals that degradation of BET proteins by BETD-246 elicits distinct transcriptional response than BET BD inhibition in TNBC cell lines. Transcriptomic analysis also shows a number of proliferation and survival-related genes were differentially regulated by BETD-246 and BETI-211 which were confirmed by quantitative RT-PCR. Mechanistically, down-regulation of MCL1 by BETD-246 plays a key role in the robust apoptosis induction in TNBC cell lines. In vivo models, BETD-246 effectively degrades BET proteins and suppresses MCL1 expression in xenograft tumor tissues and exhibits a strong antitumor activity at well-tolerated dose-schedules in mice. Our data strongly suggest that targeting BET protein degradation is an exciting therapeutic strategy for TNBC.

In recent years, epigenetic target inhibitors have emerged as viable therapeutics for treating various types of cancers. Testing of the epigenetic inhibitors in cell proliferation assays revealed that inhibition of many epigenetic targets resulted in a significantly delayed drug response that is not revealed by conventional, 72-hour cell growth assays. OncoPanel LT™ from Eurofins Pharma Discovery Services is developed specifically for evaluation of compounds with a protracted mechanism of action, and consists of a large collection of cell lines with broad cancer type and subtype representation, and extensive genomic characterization. We have tested decitabine, a DNA methyltransferase inhibitor, panobinostat, a histone deacetylase inhibitor, GSK-343, an EZH2 inhibitor, GSK-14, a JMJD3/UTX inhibitor, and JQ1, a BRD2/3/4 inhibitor in OncoPanel LT™. These epigenetic inhibitors were incubated for 10 days with more than 200 human tumor cell lines and the inhibition data were analyzed to determine IC50, EC50, and GI50 values. These inhibition data, as well as the genetic features of the cell lines, were utilizes to perform univariate genomic analysis to identify predictive biomarkers of response. We will discuss the activity of compounds against this cell line panel, as well as statistically significant biomarkers of response, based on the univariate genomic analysis.

**#5076 IHC and flow cytometry quantifies BRD4 levels in surrogate tissues after ex vivo and in vivo dosing with a BRD4 degrading PROTAC.** Sheryl M. Gough, Kanak Raina, Debbie Gordon, Ryan Willard, Martha Altieri, Angela Shen, Yimin Qian, Taavi Neklesa, Kevin Coleman, Ian Taylor. Arvinas LLC., New Haven, CT.

The Bromodomain and Extra-Terminal (BET) protein BRD4 has been identified as a key transcriptional regulator of various oncogenes, most notably MYC, in numerous human malignancies. Efforts have been extensive over recent years to inhibit the gene regulatory action of BRD4 and BET inhibitors have entered clinical trials. In a new approach to cancer therapeutics, we have developed a proteolysis-targeting chimera (PROTAC) molecule, ARCC-29, which induces degradation of BET (BRD4/3/2) proteins via the proteasome. ARCC-29 degrades BRD4 in several human malignant cell lines and in in vivo rodent xenograft tumors. In mice xenograft models of prostate (22Rv1), DLBCL (SU-DHL-6) and ovarian (A2780) tumors, this molecule demonstrates a strong PK/PD efficacious relationship. Obtaining tumor tissue from patients often requires invasive procedures and may be unavailable. We have developed two assays using surrogate tissues to evaluate PROTAC mechanism of action which could be applied in the clinical setting. We have developed a flow cytometry protocol to quantitatively assess intra-cellular BRD4 levels in peripheral blood mononu-
EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Epigenetic Agents

#5078 EZH2 methyltransferase regulates disseminating tumor cells in breast cancer metastasis. Shira Yomtoubian,1 Seongho Ryu,1 Sharrell Lee,1 Geoff Markowitz,1 Dingcheng Gao,1 Vivek Mittal1.

Triple negative breast cancer (TNBC, ER-, PR-, HER2-) exhibits the worst outcome due to higher rates of metastasis compared to non TNBC subtypes. Despite this clinical significance, there is a conspicuous lack of FDA approved molecularly targeted anti-metastatic therapies for TNBC. The enhancer of zeste homolog 2 (EZH2), a catalytic core subunit of the Polycomb repressive complex 2 (PRC2) with histone methyltransferase (HMT) activity is associated with the worst clinical outcome in breast cancer patients. Using a combination of genetic and pharmacological approaches, we show that EZH2 HMT blockade did not impact primary tumor growth, but significantly reduced distal metastases. Metastasis suppression was associated with a marked reduction of tumor-initiating cells (TICs) in primary tumor, circulating tumor cells (CTCs) in the blood and impaired lung colonization. Using a S02/OCT4 promoter reporter system, we identified EZH2-sensitive metastatic cells with GATA3 low luminal progenitor phenotypes in the primary tumor, and EZH2 HMT blockade restored GATA3 expression, promoted differentiation of luminal progenitors and impaired metastatic dissemination. These findings point to EZH2 as a therapeutic target in TNBC that promotes metastasis, and that inhibition of EZH2 HMT may constitute a viable anti-metastatic approach. We will also discuss the potential of EZH2 inhibition in combination with chemotherapy as an effective strategy against TNBC metastasis.

#5079 Inhibition of HDAC2, but not HDAC1, abrogates triple negative breast cancer progression and metastasis. Hope E. Burks,1 Steven Elliott,1 Van T. Hoang,1 Margarite D. Matossian,1 Bridgette Collins Burrow,1 Matthew E. Burrow,1 2 Tulane University, New Orleans, LA; 2 Tulane University, New orleans, LA.

Triple negative breast cancer (TNBC) is the most aggressive subtype of breast cancer, with higher rates of metastasis and recurrence than other classified subtypes. The decreased survival rates seen in TNBC can be attributed in part to the lack of targeted therapeutics. HDAC inhibitors (HDACi) have emerged as a potential adjuvant therapy for patients with triple negative disease. Previously, our lab has identified Panobinostat, a pan-DAC inhibitor, as a successful therapy for the reversal of the metastatic phenotype in TNBC. However, this therapy lacks specificity and may have increased side effects as a result. In this study, we aim to dissect the necessary HDACi responses for driving and maintaining the metastatic phenotype of TNBC, with the goal of informing specific HDAC target development. We have identified that HDAC2, but not HDAC1, is capable of recapitulating aspects of Panobinostat treatment in TNBC both in vitro and in a patient derived xenograft model in vivo. To parse the necessity and role of HDAC1 and HDAC2 individually, we created knockdown cell lines and analyzed them for changes in gene expression changes and their respective associated biological processes, including proliferation, migration, and mammosphere formation, tumor growth and metastasis. We found that HDAC2 knockdown was able to significantly repress migration and proliferation in TNBC cells and their associated gene expression signatures in vitro. Furthermore, HDAC2 knockdown resulted in decreased tumor growth and metastasis in vivo in mouse model. These results illustrate the efficacy of Romidepsin in inhibition of oncogenic processes and implicate HDAC2 as a potential target for therapeutic intervention in TNBC.

#5080 BET inhibitors INCB054329 and INCB057643 display significant activity in androgen-independent prostate cancer models. Ramiro Vázquez,1 Gianluca Civenni,1 Martina Marchetti,1 Sabrina Zadic,1 Philip Liu,2 Bruce Ruggeri,2 Giuseppe M. Carbone,1 Carlo V. Catapano.1 1 Institute of Oncology Research,IOR, Bellinzona, Switzerland; 2 Incyte Corporation, Wilmington, DE.

Prostate cancer is a leading cause of cancer death. Epigenetic dysregulated transcriptional factors and epigenetic effectors contribute to prostate cancer progression and castration resistance providing ideal targets for developing new therapeutic strategies. Bromodomain and extra-terminal (BET) proteins act transcriptional co-activators interacting with multiple co-regulatory molecules at gene promoters and enhancers. BET inhibitors (BETi) disrupt transcriptional regulatory complexes and have broad anticaner activity. INCB054329 and INCB057643 are BETi with proven pre-clinical activity in hematological and solid tumors. Both compounds are currently in clinical trials (NCT02431260 and NCT02711137) in advanced cancer patients. In this study we explored for the first time the activity of these two BETi in prostate cancer, comparing their effects in androgen-dependent and independent models in vitro and in vivo. We assessed the effect of INCB054329 and INCB057643 on cell proliferation, colony formation and tumor-sphere assays in androgen-dependent (LNCaP and VCaP) and androgen-independent (DU145, PC3, 22Rv1) cells. The in vivo antitumor activity was evaluated in mice with 22Rv1 derived subcutaneous xenografts with drugs administered orally (BID, daily, for 3 weeks). INCB054329 and INCB057643 inhibited proliferation of prostate cancer cell lines. In short-term cell proliferation assays the BETi appeared more effective against androgen-dependent (VCaP and LNCaP) than androgen-independent (DU145 and PC3) cells (GI50 of ≤100 nM and ≤500 nM, respectively). 22Rv1 cells, which express androgen-independent AR splice variants, exhibited an intermediate level of sensitivity to both compounds (GI50 150-250 nM). Interestingly, in colony and tumor-sphere forming assays all the cell lines showed substantially greater sensitivity to the BETi than in short-term assays. Notably, androgen-independent 22Rv1 cells were highly responsive with GI50 values ≤100 nM similar to those seen in androgen-sensitive LNCaP cells. Treatment of mice bearing 22Rv1 tumor xenografts with INCB054329 (50 mg/kg) and INCB057643 (3 mg/kg) led to significant inhibition of tumor growth (T/C%: 42 and 45%, respectively) and clear cells (PBCMs). Frozen or fresh human PBCMs were cultured for six hours ex-vivo with ARCC-29, fixed and permeabilized for intra-cellular BRD4 staining, and BRD4 levels quantified in gated lymphocytes. ARCC-29 reduced BRD4 levels to 13, 10, 16, and 9 percent of vehicle in four fresh PBCM samples, and to 9, 10, 11, 6, 8 and 35 percent in six frozen PBCM samples. Treatment of PBCMs with intracellular BRD4 inhibitor OTX-015, showed similar or increased levels of BRD4 compared to vehicle control. Inactive stereoisomers of ARCC-29 also showed BRD4 levels increased or similar to vehicle control. Duplicates of selected experiments were analyzed by western blot, corroborating the depletion of BRD4. The second assay uses immunohistochemistry (IHC) to evaluate BRD4 degradation in skin biopsies of Sprague Dawley and nude male rats dosed with 2mg/kg intravenous (i.v.) BRD4 PROTAC ARCC-29. IHC analysis of rat skin eight hours after in-vivo dosing with ARCC-29 demonstrated a dose-dependent reduction in BRD4 protein. Rats dosed once a week with ARCC-29 [2 mg/kg] showed a 60-90% reduction in BRD4 levels compared to vehicle, while 0.3 mg/kg twice per week showed a 10-30% decrease in BRD4 levels. These experiments demonstrate that BRD4 degradation can be evaluated in surrogate tissue. Flow cytometry using PBCMs and skin IHC provide potential alternative methods for confirming the PROTAC mechanism-of-action in the clinic using pre- and post-treatment patient samples. DISCLOSURES All authors are employed by Arvina, LLC.
consistent reduction of tumor weight relative to vehicle-treated mice. These results provide evidence of activity of INCBO54329 and INCBO57643 in prostate cancer cell lines. Although short term assays suggest a preferential anti-proliferative effect in androgen sensitive prostate cancer cells, both compounds also exhibit significant activity in an androgen-independent model both in vitro and in vivo suggesting that they might represent a valid therapeutic option for treatment of castration-resistant prostate cancer.

#5081 Disruption of DNA methyltransferase (DNMT) 1 confers resistance to DNMT inhibitors in human colorectal cancer cells. Angelo B. Laranjeira, Dat Nguyen, Erich Huang, James H. Doroshow, Sherry X. Yang. Division of Cancer Treatment and Diagnosis, National Cancer Inst., Bethesda, MD.

DNA methyltransferase (DNMT1) is responsible for the maintenance and propagation of DNA methylation pattern, and plays an important role in cell survival and proliferation. Thus, targeting DNMT1 represents a promising approach for cancer treatment. However, the role of DNMT1 in treatment efficacy with DNMT inhibitors remains controversial. The aim of this study was to investigate potential alterations of DNMT inhibitor-induced cytotoxicity and cellular survival after disruption/knockout of DNMT1 in cancer cells. The human colorectal cancer cell line HCT116 and its isogenic DNMT1 knockout pair were treated with increasing concentrations of 4’-thio-5-aza-2’-deoxycytidine (aza-TdCyd), a novel DNMT inhibitor, and 5-aza-2’-deoxycytidine (aza-dCyd). Cytotoxic effects and cell survival were evaluated by MTT and clonogenic assays. Apoptosis was measured by annexin-V/propidium iodide test, and expression of DNMT1, DNMT3A and DNMT3B was detected by western blot. After 96h of drug exposure, IC50s of aza-TdCyd and aza-dCyd were 0.031 μM and 0.28 μM, respectively, in HCT116 cells. In contrast, DNMT1 knockout cells were remarkably resistant to both drugs with IC50s all higher than 10 μM. The treatments resulted in a significant increase in apoptosis in the parental line versus its knockout counterpart. As for the cell survival, IC50s were ~0.12 μM for aza-TdCyd and ~4.62 μM for aza-dCyd in HCT116 cells, compared to ~43.77 μM and ~62.09 μM in DNMT1 knockout cells. As such, disruption of DNMT1 caused over 300-fold and 10-fold increase in resistance to aza-TdCyd and aza-dCyd. Moreover, we observed a G2/M arrest produced by aza-TdCyd versus aza-dCyd in the parental cells, and no apparent alteration in cell cycle phase distribution in DNMT1 knockout cells. Notably, aza-TdCyd was more potent than aza-dCyd in depleting DNMT3A and/or DNMT1 in both cell lines after 48h of treatment. Our findings demonstrate that disruption of DNMT1 leads to a significantly increased resistance to aza-TdCyd and aza-dCyd, suggesting that DNMT1 is critical to the antitumor activity of DNMT inhibitors. Aza-TdCyd is much more potent than aza-dCyd for both inhibition of DNMTs and growth of cancer cells.

#5082 The selective bromodomain inhibitor, INCBO54329 targets both cancer cells and the tumor microenvironment in the KC inflammatory pre-clinical model of ducital pancreatic cancer. Ana Sofia Leal,1 Karen T. Liby,3 Phillip Liu,2 Bruce Ruggeri2. 1Michigan State University, East Lansing, MI; 2Incyte Corporation, Wilmington, DE.

Pancreatic cancer is expected to become the second most deadly cancer by 2030, with few effective therapeutic options available to improve patient survival. Inhibition of BET-BRD proteins is known to induce pro-apoptotic effects in over 90% of pancreatic cancer cell lines. A BET-BRD protein is considered to be an undruggable target. p-Erk is a downstream effector of Kras and has been shown to be essential for the progression and maintenance of pancreatic cancer. The LSL-KrasG12D/+; Pdx-1-Cre (KC) mouse model associates with multiple transcription factors such as ERα, AR, E2F, and Myc; p-Stat3 protein levels are significantly increased, but this pro-survival effect in androgen sensitive prostate cancer cells, both compounds also exhibit significant activity in an androgen-independent model both in vitro and in vivo suggesting that they might represent a valid therapeutic option for treatment of castration-resistant prostate cancer.

TMEM, several cytokines and chemokines play crucial roles, recruiting and regulating inflammatory cells [macrophages, T cells and Myeloid derived suppressor cells]. KC mice stimulated with LPS have higher levels of CCL2 (1947 ± 591 ng/mL) and IL-6 (2459 ± 577 pg/mL) than unstimulated mice; these increased levels of inflammatory cytokines and the subsequent immune cell infiltration of the tumors caused by treatment with INCBO54329. In vitro, INCBO54329 demonstrated >50% inhibition of both cytokines (IL-6 1063 ± 502 pg/mL; CCL2 713 ± 134 ng/mL). These data suggest that INCBO54329 has a dual activity, targeting cancer cells and modulating the TME; both activities may prove beneficial for the treatment of pancreatic cancer. Moreover, this work suggests that additional mechanisms may underlie the beneficial effects of bromodomain inhibitors.

#5083 A novel and highly efficacious small-molecule degrader of BET-BRD proteins for the treatment of acute leukemia. Estor Fernandez-Salas,1 Zhuo Chen,2 Mei Lin,1 Bing Zhou,2 Donna McEachern,1 Sally Przybranowski,1 Karson Kump,1 Luke F. Peterson,1 Malathi Kandarpa,1 Jian Tao Hu,1 Fuming Xu,1 Liu Liu,1 Longchuan Bai,1 Bo Wen,1 Duxin Sun,1 Moshe Talpaz,2 Shao-meng Wang3. 1Univ. of Michigan, Ann Arbor, MI; 2Shanghai Institute of Medicinal Chemistry, Shanghai, China.

The bromodomain and extra-terminal domain (BET-BRD) family of lysine acetylation readers comprises BRD2, BRD3, BRD4, and BRDT that contain conserved N-terminal bromodomains (BD1 and BD2) and a long C-terminal region containing the extraterminal (ET) protein-protein interaction domain. These proteins have key roles in the assembly of transcriptional regulatory complexes containing RNA polymerase II. BET-BRDs are new therapeutic targets for cancer treatment and several small-molecule BET-BRD inhibitors are currently in clinical development for a diverse set of cancers including leukemia. Based on the protein targeting chimera (PROTAC) concept, we have developed novel and highly potent BET degraders, ZBC246 and ZBC260, with exceptional selectivity based upon a new class of BET inhibitor, ZBC11. ZBC260 effectively degrades all BET-BRD proteins at concentrations as low as 30 pM within a few hours of a treatment in the RS4;11 leukemia cell line and achieves IC50 values of 50 pM in inhibition of RS4;11 cell growth. ZBC260 was tested in a panel of 10 acute leukemia cell lines generating IC50s ranging from 20 pM to 1 nM in 4 days cell growth inhibition assays. In contrast to the cytostatic effect observed with BET-BRD inhibition, degradation of BET-BRDs by ZBC246 and ZBC260 induced robust apoptosis demonstrating a differential biology between BET-BRD inhibitors and BET-BRD degraders. Significantly, ZBC260 induces rapid regression of RS4;11 xenograft tumors without overt signs of toxicity in mice. More importantly, treatment of leukemia cells obtained from 10 patients with ZBC260 demonstrated efficient degradation of BET-BRDs within 5 h at 0.3 nM, while treatment with the inhibitor (300 nM) induced up-regulation of BET-BRDs. Treatment of patients’ peripheral blasts with ZBC260 at 1 to 10 nM induced remarkable levels of apoptosis within 24 h, even in relapsed and refractory patient samples. In conclusion, ZBC260 represents a highly potent and efficacious BET-BRD degrader undergoing extensive preclinical evaluation for the treatment of acute leukemias.

#5084 Potent and isoform-selective ATAD2 bromodomain inhibitor with unprecedented chemical structure and mode of action. Amaury E. Fernández-Montalván,1 Markus Buka,2 Bipin K. Reddy,2 Sung-Joo Ko,1 Volker Badrock,1 Joerg Weiske,1 Simon J. Holton,3 Apirat Chaikud2,4 Laura Diaz-Sáez,5 James Bennett,6 Oleg Fedorov,7 Kilian Huber,8 Paolo Centrella,9 Matthew A. Clark,10 Christoph E. Dumelin,11 Eric A. Sigel11, Holly S. Souther,12 Dawn M. Troast,12 Ying Zhang,1 John W. Cuozzo,12 Anthony D. Keffe12,13 Didier Roche,14 Vincent Rodeschini15,16 Jan Hübner,17 Hilmar Weinmann,17 Ingo V. Hartung,17 Matyas Gorjanac16,17 Bayer Pharma AG, Berlin, Germany; 18Structural Genomics Consortium, Oxford, United Kingdom; 19X-Chem Pharmaceuticals, Waltham, MA; 20Edelris, Lyon, France.

ATAD2 (ATPase family AAA-domain containing protein 2, also called ANCA) is an epigenetic regulator that binds to chromatin through its bromodomain (BD), a motif specialized for acetyl-lysine recognition. ATAD2 directly interacts with DNA methyltransferase (DNMT) and differentially silences DNMT activity by recruiting histone deacetylases. ATAD2 regulates cell proliferation and apoptosis by promoting cell cycle progression and by recruiting and activating caspase 3. ATAD2 associates with multiple transcription factors such as ERE, AR, E2F, and Myc; hence, ATAD2 has been proposed to act as a co-factor for oncogenic transcription factors. Furthermore, we have recently reported a novel role for ATAD2 during DNA replication, uncovering interactions between ATAD2 and histone acetylation marks on newly synthesized histone H4. High expression of ATAD2 strongly correlates with poor patient prognosis in multiple tumor types, including gastric, endometrial, hepatic, polyp, ovarian, breast and lung cancers. However, the exact function of ATAD2 in these tumor types remains unclear. A more thorough validation of ATAD2 as a therapeutic target is hampered by the lack of isoform-selective, potent and cellically active ATAD2 inhibitors. A systematic assessment of crystal structures of BD-containing protein family predicted that
development of selective inhibitors of ATAD2 would be challenging. In line with this prediction, only limited progress in developing lead compounds targeting ATAD2 has been reported so far. A few notable exceptions relied on fragments as starting points, however, their weak potency, insufficient selectivity against other BDs, permeability limitations or modest cellular activity have curbed their further advancement towards drug candidates. Hence, we embarked on a preclinical strategy to identify ATAD2 inhibitors: 11 different DNA-encoded libraries adding up to 67 billion unique encoded compounds were combined and incubated with ATAD2 BD followed by two rounds of affinity-mediated selection. This approach provided with several series of binders, for which specific target engagement of their SMOL moiety upon off-DNA synthesis was confirmed in biochemical and biophysical assays. Several rounds of potency optimization led to the identification of BAY-850, a highly potent and ATAD2 (isoform A) mono-selective inhibitor, which holds an amine substituted 3-(2-furyl)benzamide core. This compound shows - as revealed by size exclusion chromatography and native mass spectrometry - a novel mode of action for a BD inhibitor based on specific target dimerization. In a cellular fluorescence recovery after photobleaching (FRAP) assay BAY-850 displaced wild-type ATAD2 from the chromatin to the same extent as the genetic mutagenesis of ATAD2 BD. In contrast, chemically very similar inactive control compounds showed no major effects on ATAD2 association with the chromatin. These results qualify BAY-850 as the first biologically active ATAD2 isoform A-specific chemical probe, which will enable further elucidation of the cancer biology of this intriguing protein.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Gene- and Vector-Based Therapy

#5085 SOCS-1 gene therapy combined with radiation therapy has a potent antitumor effect for esophageal squamous cell carcinoma. Takahito Sugase,1 Takuoyoshi Takahashi,1 Satoshi Serada,1 Minoru Fujimoto,2 Koji Tanaka,1 Yashihiro Miyazaki,1 Tomoki Makino,1 Yukinori Kurokawa,1 Makoto Yamashita,1 Kiyokazu Nakajima,1 Shuji Takiguchi,1 Masaki Mori,1 Yuichiro Doki,1 Tetsuji Naka,1 Osaka University, Suita, Japan; National Institutes of Biomedical Innovation, Health and Nutrition, Ibaraki, Japan

INTRODUCTION: Radiation therapy (RT) is one of the main strategies for esophageal squamous cell carcinoma (ESCC) besides surgery and chemotherapy. Although RT has shown remarkable clinical benefits for ESCC patients, there remains the resistance for RT. Recently, some reports show that STAT3 activation is induced by irradiation and can result in treatment-resistance for radiotherapy in various cancer. Suppressor of cytokine signaling-1 (SOCS-1) has been cloned as a negative regulator of various cytokine signaling. We previously reported that overexpression of SOCS-1 showed a potent anti-tumor effect for ESCC through targeting of JAK/STAT and FAK/ERK signaling pathway. Since these results, SOCS-1 might have a possibility to overcome the resistance of RT. The aim of this study is to evaluate the antitumor effect of SOCS-1 gene therapy using adenoviral vector (AdSOCS-1) combined with RT. METHODS: At first, we evaluated RT resistance by the STAT3 in ESCC cell lines by using pEB-Multi-constitutiveSTAT3(3-STAT3) vector. We examined the colony forming assay between parent (TE8, TE9, TE11, TE14) and stably expression of c-STAT3 cells. Next, we evaluated cell growth inhibition effect of AdSOCS-1 gene therapy combined with RT in vitro and in vivo. As in vivo model, we examined the combined effect of RT (2 Gy) and AdSOCS-1 gene therapy by using TE14 xenograft mice (ICR nu/nu mice). RESULTS: At first, ESCC cell with stably expression of c-STAT3 showed a significant increase in colony forming ability after RT as compared with parent and mock cell. It suggested that activation of STAT3 might be related to RT resistance in ESCC cell. Furthermore, ESCC cells with RT were induced the secretion of IL-6, and the activation level of STAT3 was elevated by multiple RT. In addition, they increased the expression of anti-apoptosis protein (mcl-1, survivin) and might have a RT resistance to the identification of BAY-850, a highly potent and ATAD2 (isoform A) mono-selective inhibitor, which holds an amine substituted 3-(2-furyl)benzamide core. This compound shows - as revealed by size exclusion chromatography and native mass spectrometry - a novel mode of action for a BD inhibitor based on specific target dimerization. In a cellular fluorescence recovery after photobleaching (FRAP) assay BAY-850 displaced wild-type ATAD2 from the chromatin to the same extent as the genetic mutagenesis of ATAD2 BD. In contrast, chemically very similar inactive control compounds showed no major effects on ATAD2 association with the chromatin. These results qualify BAY-850 as the first biologically active ATAD2 isoform A-specific chemical probe, which will enable further elucidation of the cancer biology of this intriguing protein.

#5087 Chronic radiation induced uPA expression mediates neuroblas- toma cells survival. Manu Gnanamony, Karen Fernández, Jaime Libes, Julian Lin, Pushpa A. Joseph, Christopher S. Gondi. Univ. of Illinois College of Med. at Peoria, Peoria, IL

Neuroblastoma accounts for more than 15% of cancer-related deaths of chil- dren under the age of five. Still, the current standard of care for long-term survival for these children remains less than 40%. The urokinase plasminogen activator (uPA) system plays a role in several critically important biology pro- cesses, such as cell adhesion, migration, proliferation and survival. This system includes uPA, a serine protease which converts a zymogen plasminogen into the active serine protease plasmin, its surface receptor uPAR/CD57, which binds uPA and plasmin, and a family of proteolytic activation of uPA precursor (uPA pro- curser - single-chain uPA, scuPA) into the active two-chain uPA protease (tucPA) and mediates uPA-induced activation of several intracellular signaling cascades, and protects against several inhibitors, e.g. PAI-1, among others. Re- cent findings demonstrate that dividing/proliferating cells translocate intact scuPA to the nucleus via the nucleocytoplasmic shuttle protein nucleolin. In this study we demonstrate that both SKNBe(2) and NB1691 neuroblastoma cells when exposed to chronic radiation suppresses nMYC gene copy number and induces the overexpression of CMYC and uPA expression levels without observ- able change in uPA gene copy number. Increased uPA expression was accom- panied with increase in the mitochondrial mass (4 fold in both NB1691 and SKNBE (2) cells). Knockdown of uPA expression in chronic radiation cells using shRNA resulted in reduced survival. RT-PCR results show that uPA knockdown resulted in reduced expression of CMYC and its target genes cyclin A and cyclin D1. Overexpression of uPA in both SKNBE(2) and NB1691 wild-type cells resulted in increased CMYC and cyclin D1 expression but not nMYC expression suggesting that CMYC may be specifically regulated by uPA. In conclusion, our study shows that uPA plays a vital role in survival of neuroblastoma cells treated with chronic radiation by associating with cMYC to compensate for loss of nMYC expression. Our study also implies that targeting uPA might be a viable option as a combination therapy in the treatment of high-risk neuroblas- toma.

#5087 Radiation enhances the intracellular delivery of anti-MGMT mor- pholin oligonucleotides (AMONs) to enhance the cytotoxicity of chemo- radiation in cancer cells. Prakash Ambady, Jeffrey Wu, Cymon Kersch, Dree- Anna Morris, Michael Pagel, Leslie L. Muildoon, Edward Neuwelt. OHSU, Portland, OR

Background: This study evaluates the use of a sub-lethal dose of ionizing radiation to guide and enhance the intracellular delivery of morpholino anti-sense nucleotides designed to block O6-methylguanine DNA methyltransferase (MGMT) to enhance the cytotoxicity of chemo-radiation therapy (CRT). MGMT is a DNA repair enzyme and its expression is a well-known mechanism for resistance to CRT in glioblastoma. Epigenetic suppression of the enzyme by promotor methylation is associated with better response and clinically relevant survival benefits after CRT. We designed anti-MGMT morpholino oligonucleo- tidies (AMON) using the stable vivo-morpholinos backbone. Intracellular de- livery of morpholinos, particularly in a manner that could be clinically feasible, continues to be a major challenge. We use sublethal ionizing radiation to en- hance the delivery of AMON to transiently reduced MGMT protein expression. We previously demonstrated that sublethal ionizing radiation enhances the de- livery of AMONs to reduce MGMT expression in human cancer cells (T98G glioma and H460 and A549 non-small cell lung cancer cell lines) in vitro as well as at the targeted knockdown of MGMT with systemically administered AMON- sin pre-irradiated tumors. We now test whether blocking MGMT will enhance the cytotoxicity of CRT, and investigate the mechanism by which radiation permits cellular uptake of AMONs. Methods: MGMT expressing, human T98G glioblastoma cells were used for all in-vitro studies. AMONs and non-specific fluorescent tagged control morpholinos were synthesized and purchased from Gene Tools, LLC (Philomath, OR, USA). High-resolution widefield microscopy with image deconvolution was performed to confirm the intracellular delivery. Cells with high expression of 1 Gy radiation; 24 hrs post radiation cells were treated with AMONs. Cells were then exposed to temozolomide (75 or 150 µg/mL) on day 3. Lysates were obtained on days 4 and 7. Expression of cellular MGMT protein, apoptosis markers, and key endo cytosis proteins were characterized using im- munoblotting. Results: Our results demonstrate that MGMT silencing using a single dose of AMONs delivered with sublethal dose of radiation increased ap- optosis by 50% and reduces cell viability by 50% at one and two days after therapy. Further, we demonstrate an increase in cavelin 1, clathrin and dyn- namin expression after radiation exposure. Conclusions: Our results suggest that blocking AMONs can enhance the cytotoxicity of CRT. Dynamin mediated endocytosis appears to play a key role in this enhanced cellular update of anti-
sense nucleotides after a sublethal dose of radiation. Since radiation is already one part of standard of care cancer therapy, the use of radiation to guide the delivery of systemically administered anti-sense nucleotides is a novel strategy to target key tumor associated proteins for therapeutic benefit key.

#5088 Tumor penetrating RNA delivery for therapeutic benefit of pancreatic cancer. Liangliang Hao, Justin Lo, Sangeeta Bhatia. MIT, Cambridge, MA.

Pancreatic cancer remains a deadly disease with a median survival of less than one year, in part because we lack effective therapeutic strategies. Mutations of the oncogene KRAS and the tumor suppressor genes TP53, INK4A, and DPC4 play important roles in the pathogenesis of pancreatic ductal adenocarcinoma (PDAC); however, these driver events have proven to be challenging targets for drug development. RNA interference (RNAi) is a powerful tool for silencing tumor suppressors and oncogenes, but delivery has the potential to have an impact on silencing 'undruggable' targets; however, siRNA delivery in tumors has been challenging in general and worsened in PDAC by the stromal barriers to drug delivery. Herein, we integrated biomedical engineering, materials science, and pre-clinical investigation to establish a novel class of tumor-penetrating nanoparticles (TPNs) to enhance delivery of siRNAs in PDAC for therapeutic benefit. Specifically, we adapted self-assembled nanoparticles comprised of siRNA complexed with tandem tumor-penetrating and membrane-translocating peptides, which enabled the specific delivery of siRNA deep into the tumor parenchyma. Specifically, to establish efficacious siRNA delivery vehicles, we characterized and selected tandem peptides that incorporate novel tumor-penetrating peptide domains known to target PDAC in mice. In parallel, we optimized the particle stability through incorporation of hydrophilic molecules, focusing on achieving desirable pharmacokinetic properties which will reduce off-target delivery and increase potency of a given siRNA dose. The resulting TPNs carry siRNA into the cytosol of monolayer cultures of tumor cells, and also exhibit penetration in pancreas organoids derived from primary mouse and human tumors. As a proof-of-concept, we used TPN in vivo to knockdown KRAS in a murine PDAC model, using subcutaneously-implanted, autochthonous KRAS G12D/+/p53−/− tumors. Treatment of tumor-bearing mice with systemically administered KRAS-specific TPNs suppressed the growth of established tumors. With the delivery platform established, the ongoing goals of this project are to identify siRNA targets that synergize with the suppression of oncogenic KRAS, and to validate synthetic lethal targets by interfering with signature PDAC driver events uncovered by functional genomic efforts. Together, these studies will provide a foundation for translational studies involving new targets and delivery technology in pancreatic cancer.

#5089 Antitumor activities elicited by direct intratumoral administration of a recombinant adenovirus expressing either IL-28A/IFN-α2 or IL-29/IFN-α. Munee Numasiritori, Hiroki Tsukamoto, Yoshishia Tomioka. Tohoku University, Sendai, Japan.

Interleukin (IL)-28A/IFN-α2 and IL-29/IFN-α1 have been demonstrated to elicet direct and indirect antitumor activities. In this study, we constructed an adenovirus vector expressing either IL-28A/IFN-α2 (AdIL-28A) or IL-29/IFN-α1 (AdIL-29) to evaluate the therapeutic properties of intratumoral injection of recombinant adenovirus to apply for the clinical implementation of cancer gene therapy. Despite the lack of antiproliferative effect on MCA205 and B16-F10 cells, a retarded growth of established subcutaneous tumors was observed following multiple injections of either AdIL-28A or AdIL-29 when compared with AdNull. In vivo cell depletion experiments displayed that both NK cells and CD8+ T cells play a major role in AdIL-28A-mediated tumor growth suppression. A significant increase in the number of infiltrating CD8+ T cells into the tumors treated with either AdIL-28A or AdIL-29 was observed. Moreover, specific antitumor cytotoxic T lymphocyte reactivity was detected in spleen cells from animals treated with either AdIL-28A or AdIL-29. In IFN-γ deficient mice, the antitumor activity of AdIL-28A was completely impaired, indicating that IFN-γ is critically involved in the tumor growth inhibition triggered by AdIL-28A. IL-12 provided an additive antitumor effect when combined with AdIL-28A. These results indicate that AdIL-28A and AdIL-29 could be successfully utilized as an alternative cancer gene therapy.

#5090 Efficient KO of PD1 into primary T cells using a new non-integrative lentiviral particle expressing CRISPR/Cas9 system. Pascale Bouillé, Réég Gayon, Lucille Lamouroux, Alexandra Iche, Christine Dupont, Jean Christophe Pages, VECTALYS and FLASHCELL, Toulouse, France; INSERM U966 Faculté de Médecine, Tours, France.

Gene editing by the CRISPR system shows great promises for gene therapy. Nevertheless, it must now face a number of challenges especially for the development of safe and efficient delivery tools for in vivo, as well as ex vivo gene editing. Cas9 and sgRNA delivery, mediated either by viral vectors (AAV- or Lentivirus-derived) or transcription protocols (chemical or by electroporation) have been largely and efficiently used but they bring major drawbacks incompatible with clinical applications. Indeed, viral vectors can display uncontrolled off-target integrations and protocols for microinjection may cause cell toxicity and/or phenotype modifications of the target cells. Moreover, the CRISPR technology entails a “hit-and-run” mechanism that only requires a transient expression of the nuclease complex. Therefore, achieving an efficient delivery into hard-to-transfect cells, such as T cells, remains challenging and the need for delivery tools that would allow efficient transfer on most cell types remains relevant. RNA interference through small interfering RNA (siRNA) delivery has the potential to have an impact on silencing 'undruggable' targets; however, siRNA delivery in tumors has been challenging in general and worsened in PDAC by the stromal barriers to drug delivery. Herein, we present an innovative tool, named LentiFlash, allowing RNA delivery into target cells without any genomic scar. The RNA encapsidation is mediated via an RNA/protein interaction: the respective properties of the MS2 bacteriophage and the lentiviral vectors have been combined to build a non-integrative packaging system in which the wild type HIV packaging sequence is replaced by the MS2 stem-loop repeats and the MS2 coat protein is inserted into the Nucleocapsid. This new vector breaks with all existing systems, as the resulting lentiparticle is able to deliver non-viral coding or non-coding RNA, at high efficiency, into the cytoplasm of any cell type. Transduction of a large range of cells, from immortalized cells to dedicaly primary cells, such as T cells and hematopoietic stem cells, with LentiFlash shows an efficient, fast and transient delivery into primary T cells and into primary hematopoietic cells. In particular, LentiFlash particles were successfully used to deliver Cas9, alone or in association with an sgRNA not only targeting a reporter gene into immortalized cells, but outstandingly knocking-out the PD-1 gene into primary human T lymphocytes. This new RNA delivery system is an efficient and safe tool for the delivery of CRISPR editing machinery in most cell types without affecting cell viability and phenotype. The transient, RNA-based mechanism of LentiFlash vector, preventing the risk of integration, associated with its ability to utilize lentiviral production platforms already validated in clinical settings, make it a promising tool for CRISPR therapeutic applications. As a matter of fact, beyond gene editing efficiency, safety of delivery tools is a major concern that should be addressed to move forward with CRISPR clinical development.

#5091 Activity of Bcl-2 antisense therapeutic in aggressive non-Hodgkin’s lymphoma. Ana Tari Ashizawa,1 Yolanda Gutierrez-Puente,2 Richard Ford,3 Gabriel Lopez-Berestein, Bio-Path Holdings, Bellaire, TX; Universidad Autonoma de Nuevo Leon, Monterrey, Mexico; University of Texas MD Anderson, Houston, TX.

Aggressive non-Hodgkin’s lymphoma (NHL) progresses rapidly. It makes up about 60% of all NHL cases in the United States. The chemotherapy regimen R-CHOP could cure up to 70% of patients with aggressive NHL. Nonetheless, up to 30% of patients with aggressive NHL relapse from R-CHOP within 2 years of initial treatment. Novel therapeutics are urgently needed for patients with relapsed, aggressive NHL. Bcl-2 is a potential therapeutic target for aggressive NHL because high expression of Bcl-2 has been reported in NHL and correlated with adverse prognosis for NHL patients. To inhibit the expression of Bcl-2 protein, BP1002 was developed. BP1002 is comprised of an uncharged P-ethoxy antisense oligodeoxynucleotide targeted against Bcl-2 mRNA. The P-ethoxy antisense backbone does not have an adverse effect on bleeding and complement activation, which are some of the toxicities that have been reported for other antisense analogs. The Bcl-2 antisense is incorporated in neutral liposomes so that it can be delivered systemically via intravenous infusion. The inhibitory activity of BP1002 was determined in human lymphoma cell lines, which included germinal center B-cell (GCB) diffuse large B cell lymphoma (DLBCL), activated B-cell (ABC) DLBCL, mantle cell lymphoma (MCL) and Burkitt’s lymphoma (BL). The lymphoma cell lines were incubated with BP1002 for four days. The sulforhodamine B cytotoxicity assay showed that BP1002, at 200 micrograms/mL, induced ≥50% inhibition in 5 of 8 GCB DLBCL lines, 3 of 3 ABC DLBCL lines, 1 of 1 MCL line, and 1 of 1 BL line. We also determined the activity of BP1002 in animal models. In athymic nude mice, mice were implanted with C3H cells, which are transformed follicular lymphoma cells that express high levels of Bcl-2 protein. In experiment I, 4 groups of mice were used: Group 1 - untreated mice; Group 2 - mice treated with 10 mg of BP1002 per kg of mouse body weight; Group 3 - mice treated with 20 mg of BP1002 per kg of mouse body weight; Group 4 - mice treated with control empty liposomes equivalent. Three days after tumor cell injection, mice were injected with BP1002 or empty liposomes intravenously twice per week. When mice were euthanized in week 5, all untreated mice and mice treated with control empty liposomes reached moribund state. However, no mouse in the BP1002 treatment groups reached moribund state. In experiment II, 3 groups of mice
were used: Group 1 - untreated mice; Group 2 - mice treated with 20 mg/kg of liposome-encapsulated control oligodeoxynucleotide; Group 3 - mice treated with 20 mg/kg of BP1002. All untreated mice and control mice were moribund in week 5, but only 40% of BP1002-treated mice were moribund. These in vivo experiments indicate that BP1002 could extend the survival of mice bearing aggressive NHL. Together, our data indicate that BP1002 is a novel therapeutic for aggressive NHL.

#5092 ZVex lentiviral vector strongly activates pro-inflammatory, antigen processing, and anti-viral defense response pathways in monocyte-derived dendritic cells. Anshika Bajaj, Lisa Y. Ngo, Peter Berglund, Jan ter Meulen. Immune Design, Seattle, WA.

Background: Dendritic cells (DCs) are professional antigen presenting cells that effectively bridge the innate and adaptive immune responses and require activation for successful priming of naïve T-cells. We have developed ZVex, an integration deficient, hybrid lentiviral vector engineered to target DC-SIGN expressed on immature myeloid DCs for genetic immunization against tumor antigens. As lentiviruses normally don’t efficiently infect DCs, little is known about the functional effect of LV transduction of conventional DCs. Here, the effect of DC transduction with ZVex vectors was studied by gene expression profiling. Material and Methods: Human monocytes from multiple donors were prepared by 5-day stimulation with IL-4 and GM-CSF and transduced with ZVex-GFP or control vectors, such as a ZVex with nonfunctional reverse transcriptase (RT-dead), ZVex particles generated to contain no vector genome (empty ZVex), and a heat-inactivated ZVex preparation. Cellular RNA was isolated at different time points from transduced DC cultures and gene expression profiling with Nanostring’s human pan cancer immune panel (770 genes). Results: DCs transduced with ZVex vectors displayed statistically significant up-regulation of genes involved in pro-inflammatory, antigen processing, and anti-viral defense pathways. Noteworthy among the up-regulated genes were classical anti-viral response genes like OAS3, MX1, and interferon stimulated genes like ISG15 and ISG20. Incubation with the RT-dead mutant vector also led to up-regulation of these genes, albeit to a much lower extent, suggesting that LV-RNA itself can result in the activation of these pathways in DCs, though reverse transcription appears to further potentiate the response. Of note, cells transduced with empty ZVex, which consists of an intact virion particle but lacks encapsulated LV RNA, also mediated a low magnitude and breadth of DC transcriptional activation, possibly via signaling through DC-SIGN. Conclusions: ZVex incorporates several elements capable of inducing a potent innate immune activation in DCs. DCs are relatively insensitive to lentiviral infection, but the use of accessory proteins in ZVex makes DCs conducive to ZVex transduction and results in the induction of a Type-I IFN response that seems to be largely dependent on reverse transcription. In addition, other engineered vector particle components such as non-reverse transcribed viral RNA, viral structural proteins, and/or engagement of the DC-SIGN receptor, also contribute to DC activation.

#5093 In vitro, in vivo and molecular effects of stromal selective targeting by uPAR targeted oncogenic myeloid viruses in breast cancer progression. Yuqi Jing, Valery Chavez, Nicolas Acquavella, Doraya El-Ashry, Yuguang Ban, Xi Chen, Jaime Merchán. Univ. of Miami Sylvester Comp. Cancer Ctr., Miami, FL.

The tumor microenvironment is a relevant target for novel biological therapies. While it has been demonstrated that tumor-stromal cell interactions are important in the sensitivity of the cancer cells to oncolytic viruses, few studies have investigated the direct effects of an oncolytic virus on the stroma, and its implications on the virus antitumor efficacy. MV-m-uPA and MV-h-uPA are fully targeted, species specific, oncolytic myeloid viruses directed against murine or human urokinase receptor (uPAR). The effects of stromal selective targeting by uPAR targeted MVs were investigated. In vitro infection, gene expression and cytopathicity by MV-h-uPA and MV-m-uPA were demonstrated in human and murine cancer cells and cancer associated fibroblasts in a species specific manner. In murine fibroblast (3T3)/human breast cancer (T47D) 3-D co-cultures, selective fibroblast targeting by MV-m-uPA inhibited breast cancer cell growth. These effects were validated in vivo, in a human breast cancer xenograft (MDA-MB-231), where intravenous administration of the murine specific MV-m-uPA led to significant tumor growth delay and improved survival compared to controls. Experiments comparing the effects of tumor (MV-h-uPA) vs. stromal (MV-m-uPA) vs. combined treatment showed that tumor and stromal targeting was associated with improved tumor control. Correlative studies demonstrated in vivo tumor targeting, increased apoptosis, and MV-m-uPA induced differential regulation of both stromal (murine) genes and cancer (human) genes associated with inflammation, angiogenesis and survival, among others, indicating viral induced modulation of tumor-stromal interactions. Our results demonstrate for the first time the feasibility of stromal selective targeting by an oncolytic MV, viral induced modulation of the tumor microenvironment, and subsequent tumor growth delay. These findings further validate the critical role of stromal uPAR in cancer progression and the potential of oncolytic viruses as anti-stromal agents.

#5094 Precision therapeutic targeting of oncogenic FGFR3 fusions using CRISPR-Cas9 genome-editing in urothelial cancer. Bishop M. Faltas, Rebecca Meyer, Ethan Shelkey, Charles J. Murphy, Olivier Elemento, Mark A. Rubin. Weill Cornell Medical College, New York, NY.

Introduction: Fibroblast-growth factor receptor factor 3 (FGFR3) fusions occur in up to 11% of urothelial carcinomas. This fusion drives ligand-independent receptor dimerization and downstream oncogenic signaling and thus represent attractive targets for gene therapy. We hypothesized that CRISPR-Cas9 gene-editing can be used to disrupt these somatic oncogenic fusions in cancer cells. Methods: RT112 and SW780 urothelial cancer cell lines harboring genomic fusions of FGFR3 to TACC3, or BAIA2P2L1, respectively were grown in cultures. The fusion sequences were confirmed by Sanger sequencing and the NGG protospacer adjacent motif necessary for guide RNA (gRNA) targeting were identified. Unique guide RNAs spanning the fusion sequences in each cell line were designed. An all-in-one lentiviral vector was designed to deliver both the gRNA and the Cas9 nuclease. A scrambled non-targeting gRNA vector was used as a control. Following transduction, genomic DNA was extracted and PCR was performed using primer sequences flanking the fusion sequences followed by targeted sequencing on the Illumina MiSeq platform. CrispRP variants and CRISPResso bioinformatic tools were used to determine editing efficiency. Results: In SW780 cells transduced with the FGFR3-BAIA2P2L1 fusion-targeting gRNA vector, 64229/207425 (23.6%) reads harbored CRISPR-induced edits of the fusion sequence compared to only 2009/315353 (0.6%) reads in the scrambled gRNA vector-transduced cells. Similarly, in RT112 cells transduced with the FGFR3-TACC3 fusion-targeting gRNA vector, 74292/448381 reads (14.2%) contained random indels consistent with CRISPR-induced edits compared to 17785/428035 reads (4.0%) in RT112s cells transduced with the scrambled gRNA vector. In the SW780 cell line, the most common indel in CRISPR-edited fusions sequences was a deletion of a cytosine occurring in 40% of edited reads. The second most common indel was an extra cytosine insertion and the third most common was a 13-base deletion spanning the fusion point. In RT112 cell line, the most common indel was an insertion of a cytosine in 13% of reads. Sanger sequencing of the fusion sequences from SW780 single cell clones confirmed MiSeq results. Experiments determining the effects of these indels on the function of the fusion protein and on the cancer phenotype are ongoing. Conclusions: To our knowledge, this is the first report of CRISPR/Cas9 use as a therapeutic strategy for targeting oncogenic fusions. Because the fusion sequences unique to each patient’s cancer, this approach can be potentially used for in-vivo gene therapy for urothelial carcinomas harboring FGFR3 fusions with no off-target edits in normal cells. This approach represents a significant advance towards precision gene-therapy by specifically targeting fusion sequences unique to each patient’s cancer. We envision extending this approach to several solid and hematological malignancies driven by oncogenic fusions.

#5095 Development of a pharmacodynamic biomarker assay for AZD4785, an antisense oligonucleotide targeting KRAS. Claire Rooney, Sarah Ross, Anna Staniszewska, Sabine Lenarz, Elaine Kilgour, Alexey S. Revenko, Robert Macleod, Andrew Pierce, Paul D. Lyne, Carl Barrett, Elizabeth A. Harrington. #1AstraZeneca, Cambridge, United Kingdom; #2Astrazeneca, Wilmington, MA.

AZD4785 is a potent and selective high affinity 2'-4' constrained ethyl resi- dues (ce) containing therapeutic antisense oligonucleotide (ASO) targeting KRAS. In a patient-derived explant model of non-small cell lung cancer (NSCLC) carrying a KRAS G12C mutation systemic dosing of AZD4785 resulted in tumor regression. To determine the level of KRAS mRNA knockdown achieved by AZD4785 at a dose which causes regression (250 mg/kg q1w), tumor samples were collected and analyzed by RT-PCR. Mean levels of KRAS mRNA knockdown relative to the PBS control group were determined to be 61% and 78% from studies dosed for 2 and 4 weeks, respectively. However, by RT-PCR there was significant variability in KRAS mRNA levels within the PBS control group, and level of knockdown varied with different housekeeper normalization genes. In early clinical studies it will be essential to measure KRAS expression in tumor samples as a pharmacodynamic marker for AZD4785, hence we sought to develop a more robust assay compatible with FFPE clinical samples with low RNA yields. KRAS mRNA levels were quantified by the nanoString platform, using the panCancer pathways 770 gene code set. This assay generated robust
data from RNA extracted from 2 × 5 μm sections of FFPE material from each sample, despite very limited yields of RNA. AZD4785 treatment resulted in comparable levels of KRAS knockdown to the RT-PCR assay, but assay variability was greatly reduced, from stdev >50% (RT-PCR) to 5% (nanoString) for PBS control group samples. Using the nanoString assay, mean KRAS mRNA knockdown was 32% and 68% (p < 0.005). We also analyzed the effect of AZD4785 on the wider 770 gene panel. Further evidence of KRAS mRNA knockdown was observed through significant downregulation of transcriptional targets of KRAS signalling (FOSL1, DUSP5, DUSP6) relative to the PBS control group. Neither HRAS nor NRAS levels were affected by AZD4785 treatment.

Targeted ablation of essential oncogenes in rhabdomyosarcoma

NG-348 is a transgene-modified variant of enadenotucirev, a chimeric oncoprotein group B adenovirus with potent and selective anti-tumor activity against a range of epithelial cancer cells. Enadenotucirev has a blood stability profile that enables systemic dosing and has been administered intravenously to over 90 cancer patients. These studies have demonstrated that IV dosed enadenotucirev is delivered to tumors and subsequent virus activity is associated with CD8+ T-cell infiltration in tumor cells, consistent with immune stimulation within the tumor. NG-348 encodes two immunomodulatory proteins in its genome: full-length human CD80, and a membrane anchored single chain variable fragment of the mouse anti-human CD3e monoclonal antibody OKT3. Together these membrane proteins provide both T-cell receptor (signal 1) and costimulatory (signal 2) activation signals required to polyclonally activate tumor-infiltrating T-cells. When expressed on the surface of NG-348 infected tumor cells the transgenes therefore enhance the potency of the virus by driving local T-cell immune responses selectively in the tumor microenvironment. The expression of both transgenes encoded in the NG-348 virus is controlled by the endogenous virus major late promoter. This restricts expression of the proteins to the surface of cells permissive to virus infection (i.e. tumor cells) and prevents off-target expression in the cells from healthy tissues. Using co-cultures of human T-cells with human tumor cell lines, we have shown that NG-348 infected tumor cells potentially activate both CD4 and CD8 T-cells. This was demonstrated by analysis of activation marker expression (CD25, CD69), intracellular and secreted cytokines (IL-2, TNF, IFNγ) and induction of T-cell mediated tumor cell death by apoptosis (prior to oncolytic death by the virus). Treatment of different human non-tumor cells (e.g. fibroblasts, T-cells, PB-MCs) with NG-348 did not lead to transgene protein expression or activation of T-cells in co-cultures. NG-348 has also been shown to activate human T-cells in vivo, using a human tumor xenograft model system in immunodeficient mice reconstituted with human PB-MCs. Collectively these data indicate that following delivery to tumor tissues of patients, NG-348 oncolytic virus can selectively replicate and express its payload of T-cell activating ligands. NG-348 should therefore stimulate potent antigen-independent, polyclonal activation of T-cells already present in the tumor, as well as those recruited into the tumor in response to the virus infection, to drive effective anti-tumor immunity. NG-348 is currently in preclinical development with a first phase I study planned to initiate in Q4 2017.

NG-348 is a transgene-modified variant of enadenotucirev, a chimeric oncoprotein group B adenovirus with potent and selective anti-tumor activity against a range of epithelial cancer cells. Enadenotucirev has a blood stability profile that enables systemic dosing and has been administered intravenously to over 90 cancer patients. Using co-cultures of human T-cells with human tumor cell lines, we have shown that NG-348 infected tumor cells potentially activate both CD4 and CD8 T-cells. This was demonstrated by analysis of activation marker expression (CD25, CD69), intracellular and secreted cytokines (IL-2, TNF, IFNγ) and induction of T-cell mediated tumor cell death by apoptosis (prior to oncolytic death by the virus).
Therefore better drug formulations are desirable. Methods: To this end, we developed a new conceptual fluoropyrimidine, DFP-11207 that is engineered to reduce toxicity without loss of antitumor activity as well in addition to providing sustained concentrations of the active anticancer moiety. DFP-11207 contains three components in one formulation: 1-ethoxymethyl-5-fluorouracil (EM-FU) as a prodrug of 5-FU; 5-fluoropyrimidine (FP) as a metabolic inhibitor of thymidylate synthase and cytidine monophosphate (CTA) as a gastrointestinal regulator of 5-FU phosphorylation. Results: In in vitro metabolism studies using cell-free extracts from plasma, liver and tumors or intact tumor cells, DFP-11207 was rapidly hydrolyzed to 3 components and subsequently EM-FU was specifically converted to 5-FU by liver microsomes, and CDHP and CTA strongly inhibited 5-FU degradation and phosphorylation, respectively. Following consecutive oral administration to human tumor-bearing nude rats, DFP-11207 attained favorable antitumor efficacy and long-sustained PK profiles with lack of GI- and myelo-toxicity. Next, in investigational clinical study in patients with solid tumors, 12 patients were treated at 8 unique dose levels of DFP-11207, ranging from 40 to 440mg/m2/day by each 1 pt. MTD and RD of daily and 28-day consecutive DFP-11207 was found to be 440 (n=2) and 330 mg/m2 (n=6), respectively. The main AEs were nausea, anemia, neutropenia, febrile neutropenia but these events were very mild, and no thrombocytopenia was observed as expected. Furthermore, review of the preliminary PK data, DFP-11207 at 330 mg/m2 resulted in a desirable low but efficacious (≈15-30 mg/ml) steady-state plasma concentration of 5-FU. Interestingly, some of patients heavily treated with therapeutic drugs had a stable-disease for long periods. Conclusion: Our preclinical and early clinical data suggest that DFP-11207 is a promising compound for the treatment of gastrointestinal cancers and can overcome the shortcomings of all other oral fluoropyrimidines.

#5100 AB61, a new potent nucleoside cytostatic: Molecular mechanisms of action and preclinical activity. Petr Dzubak,1 Marian Hajduch,2 Pavla Perlikova,2 Gabriela Rylova,2 Petr Naus,3 Tomas Elbert,1 Eva Tlustostra,1 Aurelie Bourdieroux,1 Lenka Slavetskinska,1 Kamli Motyka,1 Dalibor Dolezal,2 Pavel Zavojek,1 Alex Nowa,1 Monika Havranova1, Michal Silner1, Jan Hava1, Michal Hocke2,1 Palacky University in Olomouc, Faculty of Medicine and Dentistry, Olomouc, Czech Republic;2Institute of Organic Chemistry and Biochemistry of the CAS, Prague, Czech Republic;3Palacky University in Olomouc, Faculty of Natural Sciences, Olomouc, Czech Republic.

7-(2-Thienyl)-7-deazadenosine (AB61) showed nanomolar cytotoxic activities against various cancer cell lines but only micromolar activities against normal fibroblasts. The selectivity of AB61 was found to be due to inefficient phosphorylation of AB61 in normal fibroblasts. The phosphorylation of AB61 in the leukemic CCRF-CEM cell line proceeds well and it was shown that AB61 is incorporated into both DNA and RNA, preferentially as a ribonucleotide. It was further confirmed that a triphosphate of AB61 is a substrate for both RNA and DNA polymerases in both DNA and RNA, preferentially as a ribonucleotide. It was further confirmed that a triphosphate of AB61 is a substrate for both RNA and DNA polymerases in both DNA and RNA, preferentially as a ribonucleotide. It was further confirmed that a triphosphate of AB61 is a substrate for both RNA and DNA polymerases in both DNA and RNA, preferentially as a ribonucleotide. It was further confirmed that a triphosphate of AB61 is a substrate for both RNA and DNA polymerases in both DNA and RNA, preferentially as a ribonucleotide. It was further confirmed that a triphosphate of AB61 is a substrate for both RNA and DNA polymerases in both DNA and RNA, preferentially as a ribonucleotide. diotherapy and adjuvant temozolomide (TMZ) chemotherapy. However, inherit-
ent- and acquired resistance to TMZ present major obstacles to successful treat-
ment, and the prognosis of patients with malignant gliomas remains very poor.
MJ-66, a synthetic quinoxalone compound, was identified in our study as a potent
anti-proliferative agent especially on human glioma with IC50 of approximately
60 nM. The intracranial glioma xenograft model, MJ-66 (0.1 mg, i.p., twice daily,
q.d., 10 days) significantly inhibited tumor growth and increased the survival of
the experimental mice, however, did not decrease the body weight of mice.
Currently, there is a profound unmet medical need for a new drug in the treat-
ment of malignant brain tumor. The MJ-66 demonstrated superior efficacy to
TMZ that are the only first-line drug in clinical use. MJ-66 is suggested to be a
promising anticancer candidate.

#5104 A novel N-mustard-quinoline conjugate is a potent agent against
colorectal cancer. Tai-Lin Chen,¹ Yan-Bo Chen,² Chia-Ning Shen,² Tsann-
Long Su,³ Te-Chang Lee.¹ 1. Institute of Biomedical Sciences, Academia Sinica and
Institute of Biochemistry and Molecular Biology, National Yang-Ming University,
Taipei, Taiwan; ²Genomics Research Center, Academia Sinica, Taipei, Taiwan;
³Institute of Biomedical Sciences, Academia Sinica, Taipei, Taiwan.

Colorectal cancer (CRC) is the third leading cancer worldwide. The prognosis of
diseased Patients with CRC at the stage IV is poor with a 5-year survival rate
less than 10%. Combination chemotherapy with platinum-based drugs and
5-fluorouracil (5-FU) remains the first line treatment, while the chemotherapy
combined target therapeutic agents were decreasing the mortality of CRC pa-
tients. However, the efficacy of platinum-based drugs has often been limited because
of the substantial risk for severe toxicities, including nephrotoxicity and
neurotoxicity. Therefore, there is an unmet need to develop a novel drug for
improving the treatment of advance colorectal cancer. We have previously de-
signed and synthesized several series of DNA-directed alkylating agents with
potent antitumor activity. Recently, one derivative of N-mustard-quinoline con-
jugates with hydrazinecarboxamide as a linker, designated as SL-1, was selected
to explore its anti-colorectal cancer (CRC) activity because it was highly cyto-
toxic to a panel of CRC cell lines in culture. Flow cytometric analysis showed that
treatment of CRC cells with SL-1 induced G2/M arrest and triggered apoptosis.
We further demonstrated that SL-1 preferentially targeted on the selective gau-
nine sequence by sequencing gel electrophoresis. By the aid of comet assay, SL-
1 in combination with 5-FU resulted in increased DNA tail moments and induced
more DNA damage. Evaluation of the potency of antitumor activity both in
culture and in xenograft models, we observed that SL-1 was more potent than
5-FU and oxaliplatin against SW620, RKO and RKO-E6 (an oxaliplatin resis-
tant-subsline) cells. Notable, SL-1+5-FU were more efficacious than oxalipla-
tin + 5-FU in suppression the growth of RKO or SW620 in xenograft models. We
further found that SL-1 enhanced 5-FU and induced more apoptosis by c-caspases 3 and 4/7 and c-FLICE staining. Additionally, histopathological examination
showed that SL-1 by itself has no obvious kidney and liver toxicity in ICR mice
comparing to cisplatin, oxaliplatin or 5-FU. Taken together, SL-1 alone or in
combination with 5-FU may warrant our further development as a potential antitu-
mor agent for the treatment of CRC patients.

#5105 Structure-activity relationship study of pyrrolo[2,3-d]pyrimidines
as microtubule targeting antitumor agents. Aleem Gangjee,¹ Tasdique M.
Quader.¹ 1. Dupuisue University, Pittsburgh, PA; ²University of Texas Health Science Center at San Antonio, San Antonio, TX.

Microtubules are cytoskeleton protein polymers composed of β-tubulin het-
erodimers which play pivotal roles in cell division, cellular transport and cell
signaling. Interfering with microtubule dynamics is a well-established strategy
for the treatment of cancer. However, clinical utility of microtubule targeting
agents (MTAs) in cancer chemotherapy is often limited by the emergence of
drug resistance. Expression of P-glycoprotein (Pgp) or the βII1 isotype of tubu-
lin, are two clinically established drug resistance mechanisms. We previously rep-
orted that compound AG346 binds to the colchicine site of tubulin and has
microtubule depolymerization activity in A-10 cells (EC50= 365 nM). Molecu-
lar modeling and docking studies of this compound in the X-ray crystal structure
of tubulin (PDB: 402B) suggested that the pyrrole NH can be substituted with
alkyl chains of optimal length to obtain an altered binding conformation which
can facilitate interaction with the hydrophobic pocket formed by amino acidic
Val181 of side chain A, and Lys352 and Thr314 of side chain B. We designed and
synthesized a variety of pyrrole NH-alkyl substituted compounds and deter-
mined that the compound AG73 shows a 43-fold improved microtubule depo-
lymerization potency (EC50= 8.4 nM) in A-10 cells, compared to the lead
compound. In addition, this compound inhibited the growth of human mela-
noma cancer cell line MDA-MB-435 in culture with an IC50 of 7.2 nM, which is a
5-fold improvement in potency over the parent compound. These analogs also

circumvented resistance mediated by Pgp and βIII-tubulin. These attributes provide the impetus for further preclinical development of these compounds as
microtubule targeted antitumor agents in vivo and these studies are currently
underway.

#5106 In vitro and in vivo evaluation of WAC-224, a novel quinolone class
of topoisoerase II inhibitor for cancer therapy. Tai-Chi Ueshima, Tomonomi
Yamaguchi, Kenji Itoh, Naoki Kashimoto, Tatsuya Hirano, Rumiko Shimabara,
Yohei Kawakubo, Masayuki Sato, Junpei Yamashita, Akira Yazaki, Koichi Ta-
Introduction: DNA topoisoerases (Topo) are classical but still attractive
targets for drug therapy in multiple types of cancers. Topo inhibitors, such as
Etoposide and Daunorubicin, have been effectively used; however, their clinical use is often limited by drug resistance in cancer cell population. Therefore, the
development of a novel chemical class of Topo inhibitors has been desired to
overcome drug resistance. Recently, Vosaroxin (QINPREZO) is identified as a
first-in-class anti-cancer quinolone derivative targeting Topo II, which is under
development for relapsed or refractory acute myeloid leukemia (AML). In this
study, we evaluated the in vitro and in vivo activities of WAC-224, a novel
quinolone derivative for Topo II inhibition, for various cancer cell lines includ-
ing human multi-drug resistant cells and in mouse xenograft models, respectively.
Materials and Methods: In vitro anti-proliferative activities against over 20 cell lines
were determined using WST cell proliferation reagent. Apoptosis was measured by
Annexin-V staining. In vivo anti-tumor activity was determined in immuno-
deficient mice bearing multi-drug resistant human uterine sarcoma MES-SA/
DX5 xenografts. MJ-66 is suggested to be a promising anticancer candidate.

Melanoma is the deadliest form of skin cancer due to its propensity for metas-
tasizing. It accounts for about 80% of skin cancer-related deaths. A substitution
of valine for glutamic acid at position 600 results in the B BRAF V600E mutation found
in approximately 50% of melanomas. The B BRAF V600E C mutation drives activation
of MEK/ERK and PI3K/AKT signaling and also cooperates with the PI3K/AKT pathway, thus
facilitating tumor initiation and metastasis. Fisetin is a naturally occurring
flavonoid found in fruits, vegetables, nuts, and wine, exhibits anti-proliferative, anti-inflammatory, and
anti-tumorigenic properties. Earlier, we showed that fisetin treatment downregulates
the PI3K/akt and reduces phosphorylation of MEK/ERK in melana-
oma. In this study we determined the effects of fisetin on tumor growth and
metastasis in a genetically engineered transgenic mouse model of metastatic
melanoma. Melanocyte specific Cre activity was induced in six-week-old B BRAF V600E/PtenΔN/CreB mice by topical application of 4-hydroxytamoxifen
on shaved backs once per day for 3 consecutive days. Mice were observed daily
until a highly pigmented measurable tumor appeared. Size of the tumors was
measured twice weekly and treatment with fisetin (45mg/kg b.wt. & 90mg/kg
b.wt.) was initiated at the time the tumors reached 100 mm3. Five groups were
incorporated: (i) untreated controls, (ii) doxorubicin treated controls, (iii) fisetin
and (iv) fisetin treated and doxorubicin treated. Results showed that fisetin
untreated tumor xenografts in mice with or without doxorubicin treatment,
the tumors were significantly smaller in the fisetin-treated mice compared to the
control group. Furthermore, fisetin was shown to inhibit the growth of tumors,
but not to reduce their weight. The histological analysis of tumor samples showed
that fisetin administration inhibited melanoma growth in these mice as compared to the control group. Hematoxylin and eosin staining revealed that fisetin treatment reduced pig-
mented cells in the ear and skin. In addition, fisetin treatment reduced the
metastasis of melanoma cells into the spleen and draining lymph nodes. Fur-
thermore, evaluation of tumor tissues revealed that fisetin treatment reduced the
(i) expression of PI3K,akt and p85, (ii) phosphorylation of AKT at Ser 473 and
Thr 308, (iii) phosphorylation of mTOR at Ser 2481, and (iv) expression of p53
and AR. In addition, fisetin treatment reduced the phosphorylation of MEK and
ERK when compared to control tumor samples. Fisetin treatment also re-

Proceedings of the American Association for Cancer Research  Volume 58  April 2017
sulted in (i) cleavage of caspase-3, (ii) inhibition of Bcl2 and Bcl-xl, (iii) induction of Bax, and (iv) inhibition of PCNA and Ki67 expression. Further, fisetin treatment reduced the expression of mesenchymal marker proteins (N-cadherin and vimentin) with concomitant increase in epithelial marker proteins (E-cadherin and desmoglein). These data suggest the ability of fisetin to exhibit anti-proliferative, anti-apoptotic, anti-tumorigenic, and anti-metastatic potentials in a mouse model of melanoma. We suggest that fisetin could be used as an adjuvant chemotherapy to prevent drug resistance and improve the therapeutic efficacy of anti-melanoma drugs for the management of melanoma.

#5108 Potent small molecule compounds that selectively inhibit proliferation of ABC-DLBCL cell lines. Leena Khare Satyam,1 Dinesh Chikkanna,1 Vinayak Khairnar,1 Manoj Pothuganti,1 Sunil Panigrahi,1 Anirudha Lakshminarasimhan,1 Narasimha Rao,1 Wesley Balasubramanian,1 Sandeep Patil,1 Sre- evalsam Gopinath,1 Gunta Upendra,1 Jwalaa Nagaraj,1 Kiran Arithal,1 Vijay Ahuja,1 Sanjeev Giri,1 Chetan Pandit,1 Murali Ramachandra1. Aurgene Discovery Technologies Ltd., Bangalore, India; Aurigene Discovery Technologies Ltd., Hyderabad, India.

Diffuse large B cell lymphoma (DLBCL), which accounts for 25% of all lymphomas cases, has been classified into molecular subtypes including germinal center B cell like (GCB) DLBCL, activated B cell-like (ABC) DLBCL, and primary mediastinal B cell lymphoma (PMBL). Among these subtypes, patients with ABC-DLBCLs have the worst prognosis because of the high chemo-resistance, and require effective therapies. Mucosa-Associated Lymphoid Tissue Lymphoma Translocation 1 (MALT1) protease activity is linked to the pathogenesis of ABC-DLBCL, therefore, an MALT1 inhibitor is in clinical development. We screened a library of compounds selected based on molecular docking on the reported crystal structure for selectivity to ABC-DLBCL, but not GCB-DLBCL cell lines. Optimization of initial hits resulted in the identification of lead compounds with an anti-proliferative EC50 of <100 nM selectively in ABC-DLBCL cell lines. Consistent with the previously reported role of MALT1 inhibitors, lead compounds showed reduced 4T1 tumor growth in xenograft model upon oral dosing. In summary, we have identified novel and potent MALT1 inhibitors capable of selectively inhibiting proliferation of DLBCL cell lines with optimized drug-like properties including oral bioavailability.

More than a decade ago, we initiated a research program on the molecular pharmacology of phytochemicals derived from Chinese medicinal herbs. Bioactive plant extracts have been fractionated by chromatographic techniques and isolated bioactive compounds and elucidated their chemical structures by nuclear magnetic resonance and mass spectrometry. A promising compounds was artemisinin from Artemisia annua L. and its semisynthetic compound artemesunate. Artemisinin and artemesunate are anti-malarial drugs. Our data indicated profound activity against cancer cells, but also against various viruses, Schistosoma, Trypanosoma, and even plant crown gall tumors. To elucidate the molecular mode of actions against cancer, we applied molecular biological and pharmacogenomic approaches in vitro and in vivo. Different signaling pathways were identified not only in cancer cells but also in cells infected with viruses, e.g. HCMV, HSV1 and others. To translate the experimental results in cell lines and animals to the bedside, we report on the compartmental use of artemesunate in single cancer patients as well as on our efforts to initiate several clinical phase I/II trials in veterinary tumors as well as in human cervix or colorectal carcinoma. These pilot studies indeed indicate that artemesunate is not only useful as anti-malarial drug, but also exerts activity against cancer and viral diseases. Clinical results will also be presented that not only artemesunate as semisynthetic chemical derivative of artemisinin, but also herbal extracts from Artemisia annua are active in veterinary and human tumor patients. Artemesunate represents an illustrative example for the therapeutic potential of medicinal herbs and drugs derived from traditional Chinese medicine. References 1. #5110 A novel nucleoside analog therapeutically active against plasma cell malignancies and other ADK-expressing cancers including colon and pancreatic adenocarcinomas. Jouliana Sadek,1 Utrashtra Nayyar,2 Jonathan Reichel,3 Jennifer Tonotony, 4 Zhishuko Sei,5 Robert Shoemaker,6 David Warren,1 Olivier Elemento,1 Kenneth Kaye,5 Ethel Cesarmar1, Weill Cornell Medicine, New York, NY; Dana-Farber Institute, Boston, MA; Memorial Sloan Kettering Cancer Center, New York, NY; Chapman University, CA; National Cancer Institute, Frederick, MD; Harvard Medical School, Boston, MA.

A number of nucleoside analogs are used successfully for the treatment of several cancers, and in particular leukemias and lymphomas, but these have distinct efficacies for different tumor types, and many malignancies do not respond to currently available nucleoside analogues or other forms of chemotherapy. A high throughput screen conducted in our lab to search for inhibitors of primary effusion lymphoma (PEL) identified the nucleoside analog 6-ethylthioinosine (6-ETI) as a potent and selective inhibitor of PEL, a largely incurable malignancy of B cell origin with plasmacytic differentiation. 6-ETI induced necrosis and ATP-depletion accompanied by S-phase arrest, DNA damage and inhibition of DNA synthesis. To understand 6-ETI mechanism of selectivity, RNA-seq analysis of in vitro generated drug-resistant PEL clones revealed inactivating mutations and loss of expression of adenosine kinase (ADK) as the mechanism of resistance. In vitro assays showed that 6-ETI is a pro-drug that gets phosphorylated and activated by adenosine kinase (ADK) into its active form. We found high ADK expression in PEL cell lines and primary specimens of PEL, multiple myeloma (MM) and plasmablastic lymphoma (PBL) patient samples. 6-ETI was effective at killing multiple myeloma cell lines, primary MM specimens, and had a remarkable anti-tumor response in a disseminated multiple myeloma and PEL xenograft mouse models. Thus, ADK expression can serve as a predictive biomarker to help identify patients that are most likely to respond to 6-ETI treatment. To further assess the spectrum of activity and sensitivity of 6-ETI, we examined ADK expression in other cancer subtypes and found that colorectal and pancreatic adenocarcinomas also express ADK and are highly sensitive to killing by 6-ETI at the low nanomolar concentration. We also found high ADK expression in primary colon and pancreatic adenocarcinoma patient specimens. We compared 6-ETI to other FDA-approved purine analogs and failed to find other compounds with similar potency or selectivity profile. Herein, we report the identification of a novel purine analog, 6-ethylthioinosine, as an effective therapeutic with exquisite sensitivity to plasma cell malignancies and other ADK-expressing cancers. We have successfully used RNA-seq-based ‘resistome’ analysis to identify its mechanism of selectivity. We discovered a new biomarker that can potentially impact patient care and the treatment of some of the most aggressive tumors.

Triple-negative breast cancer (TNBC) is characterized by an abundance of treatment-resistant cancer stem cells (CSC). The absence of a molecular target, coupled with its highly aggressiveness, leads to the lack of an effective therapy for TNBC. Norcantharidin (NCTD) is a synthetic demethylated small-molecule analog of the naturally occurring cantharidin isolated from blister beetles (Mylabris phalerata Pall). Unlike the conventional chemotherapeutics, NCTD toxicity is higher to cancer cells than normal ones, making this small molecule promising for cancer treatment. The aims of this work were: A) To study the effect of NCTD on 4T1 cell line proliferation in vitro. B) To analyze the effect of NCTD on 4T1 derived CSC on self-renewal and clonogenic capacity. C) To evaluate the effect of NCTD on 4T1 tumor growth in vivo. We employed the well-known 4T1 triple-negative breast cancer cell model, which presents a huge proportion of CSC. We observed that NCTD treatment during 96 h significantly reduced 4T1 cell proliferation in vitro. Additionally, the IC50 value of NCTD was 27.35 ± 2.83 μM. Related to CSC, NCTD pre-treatment for 96 h impaired CSC self-renewal (Number of secondary mammospheres: Control: 276±39; NCTD: 163±21; p<0.05) as well as the clonogenic capacity (Number of colonies: Control: 359±38; NCTD: 122±11; p<0.05). By q-PCR, we observed that NCTD treatment for 48 h significantly induced an increase of Gli-1 and Smooth in CSC, keys member of Sonic Hedgehog pathway. Finally, we performed in vivo assay, where 4T1 cells were orthotopically inoculated on mammary gland of...
RALB/c mice, and NCTD was i.p. inoculated twice a week (5mg/kg). We observed that NCTD treatment significantly reduced tumor growth in vivo. Our data suggest that NCTD treatment reduces tumor growth both in vitro and in vivo, possibly through the direct effect on CSC self-renewal and clonogenic capacity, by modulating Sonic Hedgehog pathway.

**#5112** Evaluation of FF-10502-01, a new pyrimidine nucleoside analogue, in pancreatic (PANC) patient-derived xenograft (PDX) models compared to gemcitabine and in combination with nab-paclitaxel. Takeaki Suzuki,1 Linda J. Paragon,2 Jill Ronca,1 and Philip N. Bankhead3,4,5,6.

In previous studies, FF-10502-01 demonstrated preclinical efficacy across multiple solid tumors, including PANC cancer. In this study, we investigated the anti-tumor effect of FF-10502-01 in PAN C PDX models. Methods: 10 PANC PDX tumors were sourced from primary (2) or metastatic sites (8), 7 demonstrated high resistance (HR) to gem, 1 intermediate, and 2 low. In the dose-finding study, 3 PDX models were studied in 9 ggs of NOD-SCID mice (n = 10 ggs), treated with 240 or 480 mg/kg FF-10502-01, 3 or 6 mg/kg nab-pac or 240 mg/kg gem, alone and in combination for 28d, followed by 28d observation. The definitive study consisted of 7 PDX models. 6 ggs (n = 10/gg) were treated with 240 or 480 mg/kg FF-10502-01, 6 mg/kg nab-pac or 240 mg/kg gem, alone and/or in combination for 28d, followed by 28d observation. After subcutaneous transplantation, animals were left undisturbed for 7d. Animals were monitored weekly and tumor volume measured with calipers. Average tumor volume (mm3) for each group at randomization into treatment ggs ranged from 184.34 – 199.51 (SD = 20.94 – 30.40). Statistical significance was determined using one-way ANOVA and Tukey’s test. Results: At clinically relevant doses, FF-10502-01 alone and in combination with nab-pac demonstrated greater tumor growth inhibitory activity to gem/nab-pac. In HR ggs, FF-10502-01 was superior to gem (p ≤ 0.0001, p ≤ 0.05) or nab-pac (p ≤ 0.05), irregardless of resistance to gem. In 3 models, there was no difference, but these models were highly responsive to gem/nab-pac, thus minimizing the effects of FF-10502-01/nab-pac. Despite statistical insignificance, FF-10502-01/nab-pac still demonstrated greater tumor growth inhibitory activity to gem/nab-pac. In HR ggs, FF-10502-01 was superior to gem/nab-pac in 6 of 7 (p ≤ 0.0001, p ≤ 0.05) in 3 of 7, and FF-10502-01/nab-pac was superior to gem/nab-pac in 6 of 7 (p ≤ 0.0001, p ≤ 0.005, p ≤ 0.01, p ≤ 0.05). FF-10502-01/nab-pac also was more tolerable than gemcitabine/nab-pac, as demonstrated by less weight loss. Conclusions: FF-10502-01 is a new pyrimidine nucleoside analogue with demonstrated preclinical efficacy in solid tumor models, including PANC cancer. In PANC PDX models, FF-10502-01 alone and in combination with nab-pac demonstrated higher efficacy and better tolerability than alone gem or alone nab-pac. FF-10502-01 is in Phase 1 clinical development.

**#5113** Usnic acid, lichen secondary metabolite, inhibits gloablastoma progression through the reduction of epithelial-mesenchymal transition and glioma stemness factors. Kyung-Hwa Lee, Se-Jeong Oh, Shin Jung, Kyung-Keun Kim, Jae-Hyuk Lee, Kyung-Soo Moon. Chonnam National University Hwasun Hospital & Medical School, Hwasun-gun, Republic of Korea.

Background: Usnic acid (UA), an active compound mainly found in lichens, has shown some anti-tumoral activities for lung and breast cancers. The therapeutic role of UA in glioblastoma (GBM) have not yet been determined, nor has the definitive relationships of UA with EMT and cancer stem cells. Methods: We tested the anti-tumoral activities of UA against glioblastoma (GBM) progression and further investigated the mechanistic link with epithelial-mesenchymal transition (EMT) and cancer stemness factors. The targeting and anti-tumor effect of UA was also checked in orthotopic mouse glioma model. Results: In vitro assay, we found that UA increased apoptotic cell death and inhibited the invasion/migration of GM cells. Sphere and colony forming abilities were also decreased in treated GM cells. UA decreased the expression of the EMT markers (N-cadherin, ZEB1, ZEB2, SNAI2 and SLUG) and the cancer stemness markers (CD133, ALDH1 and CD44). In orthotopic glioma models, UA localized in GBM and significantly decreased tumor growth and progression to lead longer survival. Conclusion: Taken together, these findings showed that UA prevent GBM invasiveness and progression, through the down-regulation of EMT and cancer stemness markers.

**#5114** Design, synthesis, and biological evaluation of tricyclic thieno[2,3-d] pyrimidines as microtubule targeting antigumor agents. Farhna Islam,1 Alem Gangjee,1 Xin Zhang,2 XiLin Zhou,1 Susan L. Moombery2. 1Duquesne Univ. School of Pharmacy, Pittsburgh, PA; 2University of Texas Health Science Center at San Antonio, San Antonio, TX.

Microtubules are dynamic structures that, together with actin microfilaments and intermediate filaments, constitute the cellular cytoskeleton. Besides their well-known roles in cell division, their functions involve maintenance of cell shape and morphology, cellular motility, and trafficking of organelles and vesicles. Recently, we reported a compound AG 370 as a microtubule targeting agent, that circumvented the Pgp and MDR1-tubulin mediated drug resistance mechanisms that limited the efficacy of paclitaxel, docetaxel, and the vinca alkaloids. Molecular modeling and docking studies of the parent compound (AG 370) in the colchicine binding site (PDB: 4R02B) suggest that the C-5 and C-6 of parent compound are oriented towards the hydrophobic pockets with the side chain of Ala316, Val315, Leu255 and Met259. However, this binding pocket in tubulin is relatively large. To further explore the hydrophobic pocket, an additional cyclohexene ring was introduced at C-5 and C-6 of AG370. In the molecular modeling study, the resulting tricyclic scaffold showed hydrophobic interaction with the amino acids of the colchicine binding site. The 2-Me substituted of the tricyclic scaffold was replaced with a 2-H and a 2-NH2 group and 4-position of the scaffold was replaced with appropriate anilines. The 2-amino-N4-methoxyphenyl moiety (AG61) was found to be the most potent analog in the preliminary screening in an in vitro panel of PANC cancer cell line (MDA-MB-435 cell line, IC50 = 9.0 ± 0.2 nM) and in microtubule depolymerization assay in A-10 cells (EC50 = 19 nM). Thus, we identified tricyclic thieno[2,3-d]pyrimidines as a novel structural scaffold with potent antiproliferative activity as well as microtubule depolymerizing activity. These analogs are selected for preclinical development.

**#5115** Establishing an experimental paradigm to study the interphase effects of microtubule targeting agents. April L. Risinger, Nicholas F. Dybdal-Hargreaves, Roma Kaul, Allison D. Clark, Susan L. Moombery. UT Health Science Ctr. at San Antonio, San Antonio, TX.

Microtubule targeting agents (MTAs) are highly effective anticancer drugs. While these drugs were traditionally classified as antimitotics, compelling evidence suggests that the ability of MTAs to interrupt microtubule-dependent trafficking and signaling in interphase cells contributes to their anticancer efficacies. Previous studies of the interphase effects of MTAs on oncogenic signaling pathways have led to an important reevaluation of their mechanisms of action. These effects have been primarily reported in cells that have been treated with MTAs for extended periods of time. However, MTAs rapidly alter microtubule dynamics which results, within a few hours, in global changes to gene expression and cell signaling. We propose that evaluating the effects of MTAs on oncogenic pathways at times and concentrations that are associated with early microtubule disruption will allow analysis of the initiating events that link the direct action of MTAs on microtubule structure and dynamics to effects on interphase signaling that contribute to anticancer efficacy. The concentrations and treatment times that were optimal for the study of clinically used MTAs on cellular trafficking and signaling events were first determined. Our experimental paradigm of a 2 hr treatment of breast cancer cells with clinically relevant concentrations of MTAs eliminated contributions due to mitotic accumulation and changes in gene expression associated with longer treatments.

While all MTAs disrupt microtubule dynamics, the differences among MTAs in their rapid downstream effects on cellular signaling have not been systematically evaluated. A goal of this project was to identify differences in the effects of diverse MTAs on interphase signaling pathways that may underlie their differential efficacy in patient populations. This short term treatment paradigm led to the identification of profound differences among MTAs in their ability to disrupt Src-dependent E-cadherin re-localization, canonical and non-canonical TGF-B signaling, and β-catenin localization. These findings demonstrate the ability of diverse MTAs to rapidly impact interphase oncogenic signaling and trafficking pathways. This experimental design sets forth a method to evaluate the initial effects of diverse MTAs to gain critical insight into their differential abilities to inhibit key oncogenic signaling pathways. These types of studies might, in the future, help facilitate the rational selection of specific MTAs for patients depending on tumor characteristics. Funding for this work was provided by Eisai Inc.

**#5116** Identification of new treatment options for Merkel cell carcinoma using high throughput chemical screening. Tara Gelb,1 Daniel Urban,2 Ken- neth Daily,1 Ying Xiao,1 Min Shen,2 Matthew Hall,1 Isaac Brownell1. 1National Cancer Institute, Bethesda, MD; 2National Center for Advancing Translational Sciences Chemical Genomics Center, Rockville, MD.
Merkel cell carcinoma (MCC) is a rare and aggressive neuroendocrine skin cancer with limited treatment options. Approximately 80% of MCC tumors have Merkel cell polyomavirus (MCPyV) DNA integrated into the host genome, and viral oncoproteins are thought to drive carcinogenesis. In contrast, MCPyV-negative (MCPyV-) tumors have higher rates of proto-oncogene mutations. Transcriptome differences between MCPyV+ and MCPyV- tumors further suggests divergent underlying pathologies. In order to develop efficacious treatments for MCC and elucidate the pathophysiologies underlying MCPyV+ and MCPyV- MCC, we screened the effects of mechanistically annotated drug libraries on MCC cell viability (CellTiter-Glo). We screened ~4,500 compounds including the NGCPC Cancer Collection of approved and investigational drugs and the oncology-focused MIPE (Mechanism Interrogation Plate) library against six MCC cell lines (3 MCPyV+ and 3 MCPyV-). We ran follow-up screens on the above cell lines as well as non-MCC control cells to identify agents that specifically reduced viability in MCC. DNA topoisomerase inhibitors, pros- teasome inhibitors, and PI3K inhibitors potently and efficaciously reduced viability in all MCC cell lines tested. Moreover, using hierarchical clustering we found that viral status impacted pharmacological responses. For example, a subset of HDAC inhibitors were more potent in MCPyV+ than MCPyV- MCC cells. In contrast, a dual RastRAP/ERK inhibitor more potently reduced viability in MCPyV- MCC cells relative to MCPyV+ MCC cells. Together these results identify existing drugs that can be repurposed for treating MCC. Moreover, they help elucidate the distinct pathophysiology driving MCPyV+ and MCPyV- MCC.

#5117 Triplatin preferably suppress lung metastasis of breast cancer, and peritoneal carcinomatosis of colon and pancreatic cancer.

Eriko Katsuta,1 Erica J. Peterson,2 Samantha J. Katner,3 Nicholas P. Farrell,4 Kazuaki Takeba4.
1Roswell Park Cancer Institute, Buffalo, NY; 2Virginia Commonwealth University, Richmond, VA.

Background: Since metastatic spread is often directly associated with the poor outcome, an effective treatment for metastatic lesion is expected to improve overall survival. This is particularly the case in peritoneal carcinomatosis of pancreatic cancer where there is no effective treatment. Recent clinical trials demonstrated that Cisplatin is effective in certain metastatic breast cancer, however with severe side effects. Polynuclear platinum analog, Triplatin, was developed to overcome the severe toxicity. Methods: Murine cancer cell lines, 4T1-luc2 and E0771 (breast), Panc02-luc (pancreas) and CT26-luc (colon) were used. Cell proliferation was quantified by CCK8 assay. Synergistic orthotopic implantation of 4T1-luc2 cells was used for metastatic breast cancer model. For mastectomy model, primary tumors were surgically removed 8 days after inoculation. Synergistic intraperitoneal injection of CT26-luc6 cells and Panc02-luc cells were used for peritoneal carcinomatosis models of colon and pancreatic cancer respectively. Triplatin (0.3 mg/kg) or vehicle was administered intraperitoneally every 4 days for 3 days and tumor burden was quantified by bioluminescence imaging. Results: Triplatin suppressed cell growth of both breast cancer and pancreatic cancer in a dose dependent manner in vitro (IC50 of 4T1-luc2, E0771 and Panc02-luc cells were 0.08, 0.51 and 0.07 μM, respectively). Triplatin did not suppress the growth of 4T1-luc2 primary breast tumor, however, ex vivo results demonstrated that lung metastases were significantly reduced to 14% of the control (p = 0.034) in orthotopic model. This result was reproduced in post-mastectomy “adjvant therapy” model where Triplatin treatment was begun after primary implanted tumor was removed, which suppressed lung metastases down to 1.9% of control by Day21 (p = 0.038), and significantly prolonged survival (p = 0.007). This result led us to use Triplatin in CT26-luc colon cancer carcinomatosis model, where Triplatin suppressed total tumor burden to 1.9% of control by Day13 (p = 0.029) and significantly prolonged survival (p = 0.001). Finally, Triplatin reduced total tumor burden of Panc02-luc pancreatic cancer peritoneal carcinomatosis model to 35% of the control by Day 9 (p = 0.337) and the survival was significantly prolonged (p = 0.025). Conclusion: Triplatin demonstrates that significant suppression lung metastatic tumor of 4T1-luc2 breast cancer, and peritoneal carcinomatosis of CT26-luc colon cancer and Panc02-luc pancreatic cancer. Newer platinum compounds with less toxicity and favorable pharmacokinetics warrant further investigation for advanced metastatic cancer.

#5118 A novel polyamine sulfonamide with anti-leukemic activity.

Vindhiya Vijay, Amy Meacham, Leylah Drusbosky, Elizabeth Wise, Christopher Cogle, University of Florida, Gainesville, FL.

The greatest challenge in treating Acute Myeloid Leukemia (AML) is refractory disease. Although 60-80% of AML patients achieve complete remission after induction chemotherapy, majority of these patients relapse and die of progressive disease. New treatment options targeting the vulnerabilities of AML biology are highly critical for disease regression, in particular the chemo-resistant leukemia-initiating population, to ensure relapse-free survival in patients. Identifying novel druggable targets that are selective to AML despite their location in the vascular niche is thus highly warranted. We developed an in-vitro co-culture model consisting of AML cells and Bone Marrow-derived Endothelial (BMEC) cells, which recapitulates the bone marrow niche in the disease setting. Using this unique model, and taking advantagе of combinatorial chemistry, we performed high-throughput chemical-peptidogenic screening of approximately 30 million novel compounds and identified a novel polyamine sulfonamide 2470-51 that can selectively kill AML cells by overcoming the protective effect of the BMECs. In addition to AML blasts, 2470-51 also exhibited highly selective activity against the leukemia stem and progenitor cell population while sparing normal hematopoietic stem and progenitor cells. In vivo studies using patient-derived xenograft models indicated significant regression in AML engraftment post 2470-51 treatment. Target identification experiments involving unbiased label-free shotgun proteomic analysis in combination with targeted Selected Ion Monitoring (SIM) revealed covalent drug binding targets of 2470-51. By performing differential protein expression analysis using iTRAQ analysis, we identified downstream mechanisms that led to mitotic cell cycle arrest and cell death. Collectively, our findings display the in vitro as well as in vivo efficacy of a novel polyamine sulfonamide in eliminating AML, including the leukemia initiating compartment. We also uncover a novel mechanism in AML that can be taken advantage of for selective toxicity. Furthermore, we establish the role of 2470-51 as a potential therapeutic agent in treating AML.

#5119 Evaluation of Minnelide as potential targeted therapy for triple negative breast cancer.

Mehendra K. Singh,1 Soham Shah,2 Nikita Satish Sharma,1 Bhawan Giri,1 Sulagna Banerjee,1 Ashok Saluja1.
1University of Miami School of Medicine, Miami, FL; 2University of Minnesota School of Medicine, Minneapolis, MN.

Recent advances in diagnostics and better understanding of molecular mechanism underlining breast cancer has let to the better therapeutic options and disease outcome for majority of breast cancer patients. However, ~10 - 20% of all breast cancers often referred to as “triple negative” as they lack expression of the estrogen (ER), progesterone (PR), and human epidermal growth factor 2 (HER2) receptors convey a poor prognosis due in part to a lack of targeted therapies. The aim of the current study is to evaluate whether triptolide and its water soluble analog Minnelide is effective against triple negative breast cancer cells. We have previously shown that triptolide/Minnelide not only inhibits tumor growth in various cancer models but it also regulates epithelial -mesenchymal transition (EMT), an important mechanism underlying metastasis. In our preliminary findings using three triple negative breast cancer (TNBC) cell lines, MDA-MB-231, MDA-MB-468, and MDA-MB-157, we demonstrate that triptolide not only inhibits the proliferation of TNBC cells but also regulates the protein levels of EMT markers including B-Catenin and Vimentin. In order to elucidate the mechanism underlying triptolide mediated inhibition of cellular proliferation and regulation of EMT markers in TNBC cells, we identified Src kinase and Aurora kinase A as two new targets for triptolide action in TNBC cells. Targeting both Src and Aurora kinase, triptolide disrupts the integrity of focal adhesion structures and reduces cell spreading via regulating FAK activity. Our preliminary findings regarding potential use of triptolide/Minnelide in TNBC based on in vitro experiments are promising. However, considering the complex pathophysiology of breast cancer and other biological factors playing role in a disease setting, in-vivo experiments to test the efficacy of Minnelide in relevant mouse models for mammary cancers are currently underway.

#5120 Cryptolepine a plant alkaloid, inhibits the growth of nonmelanoma skin cancer cells through inhibition of topoisomerase and induction of DNA damage.

Harish C. Pal, Santosh K. Katyar, University of Alabama at Birmingham, Birmingham, AL.

Topoisomerases are highly specialized nuclear enzymes that remove superhelical tension on chromosomally DNA that allows replication and transcription of DNA. Many cancer chemotherapeutic drugs used in the clinics inhibit tumor growth by targeting topoisomerase functions resulting in DNA damage and cancer cell death. Cryptolepine, a major alkaloid isolated from Cryptolepis sans-guinolenta plant’s roots, has shown anti-malarial, anti-bacterial, anti-fungal, and anti-inflammatory activities. In the present study, we examined the therapeutic effect of cryptolepine on non-melanoma skin cancer cells (NMSCC). SCC-13 and A431 as an in vitro model, and underlying mechanism of action with special emphasis on topoisomerases and DNA damage check points. Western blot analysis and enzyme activity evaluation assays demonstrated that SCC-13 and A431 cells express comparatively higher levels of topoisomerases.
and higher enzymatic activities compared with normal human epidermal keratinocytes (NHEK). Topoisomerase expression and activity has been greatly reduced after 24 h treatment with 2.5, 5.0 and 7.5 μM cryptolepine. Inhibition of topoisomerases expression and function by cryptolepine resulted in significant DNA damage and enhanced expression of DNA-PK expressions. Cryptolepine induced inhibited high-risk MM cell growth in vivo and in vitro via cell cycle G2/M arrest in a CRBN-independent manner. In conclusion, PEGylation of TC11 significantly reduced cell viability and enhanced cell death of SCC-13 and A431 cells. However, NHEK cells were less sensitive to cryptolepine induced cell death. Results of our study strongly suggest for detailed preclinical investigations in animal models to further assess its anti-skin cancer potential and its possible use in human patients.

#5121 PEG(E)-TC11, a novel polyethylene glycol-linked phthalimide derivative, inhibited high-risk MM cell growth in vivo and in vitro via cell cycle G2/M arrest in a CRBN-independent manner. Shuji Aida,1 Daiju Ichikawa, Kanuki Iida,1 Masashi Hozumi,1 Misa Nakamura,1 Ryo Uozaki,1 Nahoko Hashimoto,1 Mikio Okayama,2 Yuko Yonemura,3 Noriko Tabata,1 Taketo Yamada,1 Maiko Matsuishi,1 Takeshi Sugai,1 Hiroshi Yanagawa,1 Yutaka Hatatori1,1 Keio University Faculty of Pharmacy, Tokyo, Japan; 2Keio University School of Medicine, Tokyo, Japan; 3IDAC Theranostics Inc., Tokyo, Japan; 4Saitama Medical University, Saitama, Japan.

Multiple myeloma (MM) is one of the hematological malignancies that is characterized by proliferation of malignant plasma cells. Recent advance in the treatment of MM using newly developed drugs, prognosis of the MM patients have been significantly improved. For example, immunomodulatory drugs (IMiDs) such as thalidomide, lenalidomide and pomalidomide have been developed for treatment of MM. However, IMiDs have only limited effects against MM patients with high risk chromosomal abnormalities such as t(4;14) and del(17p) (high-risk MM). In 2010, it was reported that IMiDs directly bind to cereblon (CRBN), a component of ubiquitin ligase 3 complex, and induced teratogenicity as well as anti-tumor effects. We have previously reported that a novel phthalimide derivative, 2-(2,6-disopropylophenyl)-5-amino-1H-isodoledine-1,3-dione (TC11) induced apoptosis against high-risk MM cells in vivo and in vitro, and inhibited differentiation of osteoclasts. We also reported that TC11 directly bound to α-tubulin and nucleophosmin-1 (NPM1), but did not bind to CRBN. However, TC11 was not dissolved in water with only 0.02 mg/mL solubility. Therefore, TC11 showed poor absorption into blood and limited anti-tumor activity when it was intraperitoneally administered in tumor-bearing mice. To resolve these problems, we synthesized PEG(E)-TC11, in which TC11 is linked to polyethylene glycol through an ester bond, and consequently enhanced water solubility of PEG(E)-TC11 to 88.9 mg/mL. PEG(E)-TC11 revealed as potent growth inhibitory effect on high-risk MM cells as TC11 in vitro. In pharmacokinetic study, PEG-modification of TC11 improved the peak blood concentration (Cmax) from 2.6 to 24.4 μM and extended elimination half-life (t1/2) from 1.4 to 2.2 hr when 186 μg/kg of these compounds were intraperitoneally injected. More importantly, these pharmacokinetic improvement lead to more potent growth inhibition of MM cells in vivo than TC11. We also explored mechanisms of anti-myeloma effect of PEG(E)-TC11 and found that PEG(E)-TC11 induced apoptosis via G2/M cell cycle arrest. However, unlike IMiDs family, BIACORE assay revealed that PEG(E)-TC11 didn’t directly bind to CRBN, indicating that growth inhibitory effect of PEG(E)-TC11 against MM cells was independent of binding to CRBN. In conclusion, PEGylation of TC11 significantly increased water solubility, resulted in potentiated anti-myeloma activity in vivo. Furthermore, PEG(E)-TC11 inhibited cell growth via G2/M arrest in a CRBN-independent manner. Thus, PEG(E)-TC11 is considered as a candidate compound for overcoming high-risk MM.

#5122 Utilizing zebrafish to study the effect strigolactone on breast cancer cells. Kira Lin,1 Christopher Grivas,1 Elena Boru,1 Yaron Dayani,1 Eric Berens,1 Anna T. Riegel,1 Eric Glasgow,2 Ronit I. Yarden,1 Georgetown University, Washington, DC; 2Georgetown University, Bethesda, MD.

Strigolactones (SLs) are a novel class of phytohormones that regulates shoot branching patterns and above-ground plant architecture by inhibiting the outgrowth of axillary lateral buds or meristems. The SL analogues (SLAs) inhibit the growth and survival of a wide array of cancer-derived cell lines including: prostate, colon, lung, melanoma, osteosarcoma and leukemic cell lines, while minimally affecting normal cultured cells. Interestingly, cancer cells with high metastatic potential are more sensitive to the inhibitory effect of SLAs than less aggressive cells. Treatment of cancer cells with SLAs leads to the activation of stress-related signaling including p38MAPK and JNK1/2, and disrupt the mitrobule network. Furthermore, a reduction in acetylated-alpha-tubulin was observed in SLA-treated MDA-MB-231 cells. Microtubules dynamics has been proposed as one antitumor mechanisms that regulate cell migration by acting on lamellipodia formation. The EC50 invasion assay data suggests that even low concentration of SLA and as soon as 6 hours, SLAs suppress MDA-MB-231 cell’s ability to invade the HUVEC monolayer. To further examine the effect of SLAs on the invasive and metastatic behaviors of cancer cells in vivo, fluorescently labeled MDA-MB-231 cells were used as xenograft models in zebrafish. Embryos injected with MDA-MB-231 cells showed 66.6% metastasis in vehicle treated control fishes, as compared to 22.8% in SLAs treated fishes. This suggests that SLAs are potent inhibitors of cancer dissemination and metastasis.

#5123 Targeted thieno[2,3-d]pyrimidines with fluorinated phenyl side chains as antitumor agents. Nian Tong,1 Aleem Gangjee,1 Adrienne Wallace Povirk,2 Carrie O’Connor,3 Aamod Aamod Dekhneb,4 Zhanjun Hou,5 Larry H. Mathery6,1 Duquesne Univ., Pittsburgh, PA; 2Wayne State University, Detroit, MI; 3Barbara Ann Karmanos Cancer Institute, Detroit, MI; 4University of Michigan, Ann Arbor, MI; 5Australis Scientific, Centennial Park, Australia; 6The Children’s Hospital of Philadelphia, Philadelphia, PA.

The reduced folate carrier (RFC) is ubiquitously expressed in tissues and tumors and is the major tissue transporter for folate cofactors. Folate receptor (FR) α and β, as well as the proton-coupled folate transporter (PCFT), exhibit narrower patterns of tissue expression and are likely to serve more specialized physiologic roles. FRs are expressed in a subset of cancer cells (e.g., ovarian and non-small cell lung cancer for FRα, acute myelogenous leukemia for FRβ), whereas PCFT is expressed in a wide range of human solid tumors but not leukemias. Earlier generations of glycinamide ribonucleotide formyltransferase (GARTFase) and de novo purine nucleotide biosynthesis (e.g., Lometrexol) have shown promise as antitumor drugs. However, these compounds are excellent substrates for RFC and thus are non-selective for tumors, leading to dose-limiting toxicities. We previously reported a novel class of α-substituted thiieno[2,3-d]pyrimidines with a phenyl side chain and 3- and 4-carbon bridge lengths (AGF17 and AGF23, respectively) which selectively targeted FRs but not RFC or PCFT. To increase antitumor efficacy, we synthesized fluorinated analogs of AGF17 and AGF23, designated as AGF309 and AGF304, respectively. AGF309 and AGF304 potently inhibited proliferation of Chinese hamster ovary (CHO) cell lines engineered to individually express human FRα (IC50 of 1.08 μM and 2.27 nM, respectively) or FRβ (IC50 of 0.48 and 1.14 nM, respectively). AGF304 and AGF309 showed nominal activity toward RFC- and PCFT-expressing CHO cells. Both AGF309 and AGF304 were also potently inhibitory toward FRα-expressing human KB human tumor cells (IC50 of 7.19 and 5.27 nM, respectively). By analogy with previous iterations of 6-substituted thiieno[2,3-d]pyrimidine compounds, AGF309 and AGF304 likely involves inhibition of de novo purine biosynthesis at GARTFase and potentially a secondary intracellular target. Collectively, our in vitro findings of the potent and selective antitumor activity and FR selectivity suggest that further preclinical evaluation of AGF309 and AGF304 as potential antitumor agents is warranted.

#5124 GNS561 a new quinoline derivative inhibits the growth of hepatocellular carcinoma in a cirrhotic rat and human PDX orthotopic mouse models. Firas Bassissi,1 Zuzana Mack Jackova,2 Sonia Brus,3 Jerome Courrambeck,4 Jennifer Tracz,2 Keerthi Kurma,1 Gael S. Roth,1 Cindy Khaldi,1 Corinne Chaimbault,1 Benoit Quentin,1 Emilie Assera,1 Antoine Beret,1 Eric Raymond,1 Philippe Halton,1 Thomas Decaens3. 1Genoscience Pharma, Marseille, France; 2University of Lorraine, Nancy, France; 3Barbara Ann Karmanos Cancer Institute, Detroit, MI; 4University of Grenoble Alpes, Institute for Advanced Biosciences, Research Center UGA / Inserm U 1209 / CNRS 5309, Grenoble, France; 3Universe Grenoble Alpes, Institute for Advanced Biosciences, Research Center UGA / Inserm U 1209 / CNRS 5309, Clínique Universitari d’Hépato-gastroentérologie, Pôle Digestif, CHU Grenoble, Grenoble, France.

Hepatocellular carcinoma (HCC) remains a major health problem, often diagnosed at late stages with limited number of therapeutic options. New drugs with original mechanisms of action are urgently aimed to improve current armamentarium in HCC patients. Quinoline derivatives are novel class of oral small molecules inducing multiple cellular effects such as inhibition of autophagy, induction of apoptosis, and cell cycle modulation. The aim of these
studies was to assess tolerance and efficacy of a new quinolone derivative GNS561. Material and methods: In vitro experiments were realized with viable, apoptosis and migration in tumor cells in HCC cell lines and primary tumor. Drug tolerance and plasma and liver pharmacokinetic were evaluated after single- and repeated dosing in mice and rat. GNS561 and sorafenib efficacy in vivo were evaluated in a PDX orthotopic BALB/c mice with a pancreatic 5-fluorouracil (5-FU)-induced tumor model and a distinct nitrosamine (DEN)-induced HCC cirrhotic rat model. AFP, cell proliferation and tumor weight and size were assessed in mice. In rat tumor progression was followed by MRI, pathological analysis (tumor size and number), immunohistochemistry and PCR analysis after 6 weeks of treatment. Results: GNS561 shows potent anti-proliferative activity when assayed against a panel of human tumor cell lines and notably against a panel of HCC patient primary tumors even in those with sorafenib resistance (Mean EC50 3 μM vs 11 μM for sorafenib). GNS561 is highly selectively trapped in the liver. Plasma and liver PK in mice and rats after single and repeated doses confirm this selectivity with good tolerance and oral bioavailability. In PDX mouse model, tumor growth was significantly reduced by GNS561 with a dose-response manner, this tumor regression was associated with AFP level decrease by 72% with GNS61 (p=0.002) and 54% with sorafenib (p=0.046) compared to control. In rat model, mean number of tumors was significantly lower in GNS561 at 15 mg/kg group (n=50.6), in sorafenib at 10 mg/kg (n=65.1) and in combination group (n=40.6), when compared to control (n=100.4; p=0.0024, p=0.029 and p=0.0002). Tumor decrease measured by MRI was associated with a significantly reduced proliferation measured by Ki-67 in GNS61 group (70%) and combination group (84%) compared to control, whereas the effect of sorafenib alone on proliferation was modest (30%). Conclusions: GNS561 is a liver selective drug with good tolerance and promising efficacy in different HCC animal models. GNS561 was more efficient than sorafenib to control tumor growth in preclinical models. Based on its safe toxicity profile and potent activity in rodent models, GNS561 is now aimed to further reach clinical development in patients with HCC in 2017.

#5125 Muscadine grape extract inhibits breast cancer brain metastatic cells by multiple mechanisms. WenHong Chen, Patricia Gallagher, Ann Tal- lant, Linda J. Metheny-Barlow. Wake Forest School of Medicine, Winston-Salem, NC.

Tumor metastasis to the brain is a common complication of cancer, affecting 500,000 patients each year. Due to poor penetration of most chemotherapeutics into the brain, brain metastasis may occur even while systemic disease is under control. Despite aggressive treatments including radiation therapy, survival at 12 months following diagnosis is only 20%, underscoring the need for better means to prevent and/or treat brain metastases. Natural products have historically been a very successful source of new drugs. We are investigating the anti-cancer potential of a proprietary muscadine grape extract (MGE, from Piedmont Research & Development Corp.) on breast cancer cell lines that are metastatic to the brain. In a colony formation assay, MGE (10 μg/mL) decreased clonogenic survival of 4T1.2uc2.8Br5 cells by 50% (n=3, p<0.0001). The Eo771.uc2Br5 cells were more sensitive to MGE, showing 33% inhibition at 5 μg/mL (n=3, p<0.0001) and 91% inhibition at 7.5 μg/mL (n=3, p<0.0001). We also assessed response to the combined treatment of MGE and ionizing radiation (IR). While MGE did not sensitize cells to IR, combined administration of MGE and IR resulted in decreased clonogenic survival compared to either modality alone for both cell lines (n=3-4 experiments, p<0.01), suggesting an additive effect. Mechanistically, acute exposure (24 h) to 10 μg/mL MGE induced apoptosis in 4T1.2uc2.8Br5 cells as evidenced by PARP cleavage and detection of activated cleaved caspase 3. Further, ERK1/2 activation was decreased 68% at this time point (n=3, p<0.05). In contrast, although Eo771.uc2Br5 cells are more sensitive to clonogenic inhibition, no PARP cleavage, caspase 3 cleav- age, or ERK1/2 inhibition was observed. Analysis of cyclin D1, a major regulator of cell cycle progression, identified >80% decrease following MGE treatment (24 h, 10 μg/mL) in both cell lines. Together these data suggest that MGE inhibits breast cancer brain metastatic cell proliferation by multiple mechanisms, including inhibition of clonogenic growth through induction of apoptosis and/or decreased cell cycle progression, suggesting that MGE may have utility in the treatment of breast cancer brain metastasis.

Small cell lung cancer (SCLC) is an aggressive type of lung cancer and accounts for 10% to 15% of all lung cancer cases. The malignancy has a greater tendency to be disseminated by the time of diagnosis as well as to develop early resistance to conventional treatments, a cure is difficult to achieve. The current standard therapy for SCLC treatment, either with monotherapy (platinum based drugs) or combination therapy (e.g., cisplatin with irinotecan or topotecan), was shown to cause serious side effects and inevitably evoke drug resistance in a short time period. We have recently synthesized a series of novel bis[(hydroxymethyl)indolizino[8,7-b]indole hybrids by fusing β-carboline and bis(hydroxymethyl)pyrrole moieties for antitu- mor and proapoptotic activity. These hybrid molecules displayed diverse mechanisms of action involving topoisomerase II (Topo II) inhibition and induction of DNA cross-linking. Our results also showed that they significantly inhibited the cell growth of various human tumor cell lines. Of the tested tumor cell lines, the SCLC cells (HS26 and H211) were the most susceptible to compounds BO-2239 and BO-2329. These hybrids induced cell cycle arrest at the G2/M phase and triggered tumor cell apoptotic death. Intrinsic and extrinsic death pathways were activated in both cell lines, including induction of Topo II inhibition and DNA cross-linking. Compared to the compounds with N11-Me group, derivatives having N11-H group profoundly increased Topo II inhibition activity but reduced DNA cross-linking activity. Among these hybrids, BO-2239 (with N11-H) was as potent as irinotecan, but more effective than cisplatin, in nude mice bearing SCLC HS26 xenografts. Accordingly, hybrid BO-2239 may be further developed as a potential agent for the treatment of SCLC.
LTX-401 is a de novo designed cytolytic compound that shares many chemical features with anticancer peptides, such as amphipathicity, hydrophobicity and overall net charge. In vitro cytotoxicity studies revealed that LTX-401 was highly active against a panel of malignant cells including murine and human cancer cell lines while displaying selectivity towards human red blood cells. Furthermore, LTX-401 was found to inhibit tumor growth in vivo as demonstrated by the release of Damage-Associated Molecular Pattern molecules, or 'danger signals', such as High-Mobility Group Box-1 protein, ATP and cytochrome c. Flow cytometric and confocal microscopy studies also demonstrated reduced signal from lysosomal dye LysoTracker-DND-26, hence indicating loss of lysosomal integrity upon induction of cell death. The latter was supported using transmission electron microscopy, showing distinct morphological characteristics of necrosis. Moreover, at low concentrations, LTX-401 selectively enriched in the Golgi apparatus and initiated a lethal signaling event that in part could be inhibited by Brefeldin A. Complete tumor regression has been obtained in several rodent models, including the B16 mouse melanoma model and the JM1 rat hepatocellular carcinoma model by intratumoral injection with LTX-401. Additionally, previously cured animals showed protection against challenge with live tumor cells, indicating the induction of tumor-specific immune memory. The increased survival benefit of LTX-401-treated animals provides a rationale for further evaluation of the compound as an immunotherapeutic agent against solid malignancies.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Novel Drug Delivery Technology

#5129 Cell-penetrating doxorubicin released from Elastin-like polypeptide kills doxorubicin-resistant cancer cells. Jung Syu Ryu, Drazen Raucher. Univ. of Mississippi Medical Ctr., Jackson, MS.

A drug-releasing system facilitated by external stimuli could be used to deliver cytotoxic chemotherapy agents to tumors sites selectively and safely. Among many suggested strategies, elastin-like polypeptide (ELP) exploits its characteristic of phase transitioning in response to changes in ambient temperature. This unique property permits selective targeting of the polymer to hyperthermic tumors by aggregating at site transitions. ELP therefore can be used as a thermostensitive vector for the delivery of chemotherapy agents and therapeutic peptides, resulting in a rise in drug concentration exclusively in tumors. This novel strategy introduces unprecedented options for treating cancer, with fewer concerns about indiscriminate side effects from the chemotheraphy. In this study, the ELP-drug conjugate was further modified with incorporation of an enzyme-specific cleavable linker in order to trigger drug release within tumors. The suggested system is composed of ELP, a matrix metalloproteinase (MMP) substrate, a cell penetrating peptide (CPP), and 6-maleimidocaproyl amide derivative of doxorubicin (Dox). Rationale for this design is that this construct may be initially targeted to the tumor site by local application of mild heat. When the construct reaches tumor site, it is cleaved by MMP, releasing CPP conjugated Dox, which is able to more efficiently infiltrate tumor tissues and penetrate cancer cell membranes. These strategy shows up to 4-fold increase in cell penetration up to four times and results more cell death in breast cancer cells than the ELP-doxorubicin complex. Even in doxorubicin-resistant cancer cells (NCI/ADR and MES/ADR), ELP-released, cell-penetrating doxorubicin demonstrated better membrane penetration (two fold), leading to at least twice killing of the resistant cancer cells than ELP-Dox and free Dox.

#5130 Tumor-penetrating peptide-coated nanoparticles as a novel strategy for the targeted therapy of neuroblastoma. Fabio Pastorino,1 Chiara Brignone,1 Laura Eminonie,2 Silvia Bruno,3 Flavio Curnis,3 Daniela Di Paolo,1 Paola Patrizia Perri,1 Alessandro Gori,7 Renato Longhi,7 Michele Gilli,8 Angelo Corti,8 Mirco Fanzoni1 1Instituto G. Gaslini, Genoa, Italy; 2IRCCS Azienda Ospedaliera Universitaria San Martino-IST Istituto Nazionale per la Ricerca sul Cancro, Genoa, Italy; 3University of Genoa, Genoa, Italy; 4San Raffaele Scientific Institute, Milan, Italy; 5CNR, Milan, Italy. Anticancer drugs loaded into tumor- and vasculature-targeted nanocarriers (NC) can reduce side-effects and improve therapeutic efficacy in pre-clinical studies. However, poorly perfused and dysfunctional tumor vessels and lymphatics limit the transport of the payload into the parenchyma of solid tumors. The use of NC decorated with tumor-penetrating peptides (TPPs) might enhance tumor penetration and antitumor effects. A previously characterized neuroblastoma (NB)-targeting peptide ligand was here modified (now referred as TPP-NB) by adding a consensus motif as a mediator of cell, vascular and tissue penetration via neuropilin-1 (NRP-1) receptor recognition. NRP-1 expression was validated by FACS analysis in NB cell lines and by IHC staining in tumor cells and tumor stroma from NB-bearing mice. Recombinant NRP-1 was used to validate TPP-NB specificity. In vitro and in vivo cell association and internalization of TPP-NB, either free or coupled to Liposomes (L) were tested by FACS and confocal microscopy. Vascular permeability assay after treatment with TPP-NB-targeted, doxorubicin-loaded Liposomes (TPP-NB-L[DXR]) was performed evaluating the in vivo accumulation of Evans Blue dye within the tumor mass. Therapeutic experiments with TPP-NB-L[DXR] were performed in mice orthotopically injected with human NB cells. NRP-1 expression is validated in a panel of NB cells and in tumors from NB-bearing mice. Differently from the original peptide and some control ones, TPP-NB is able to recognize recombinant NRP-1. The addition of the NRP-1-recognition sequence to the original peptide signiﬁcantly increases its NB cellular association in vitro. Interestingly, the results seem to indicate that the enhanced capability by TPP-NB in binding NB cells is related to the combination of the NRP-1-recognition and the original sequence. Importantly, TPP-NB coupled at the external surfaces of L[DXR] significantly increases their cellular association on NB cells in vitro. Competitive binding assay reveals that binding of TPP-NB is speciﬁc and can be inhibited by an excess of the unlabeled free peptide. The localization and the cellular distribution of L, evaluated by confocal microscopy in vitro and in mouse models of NB, confirm the binding speciﬁcity, showing an increased selective internalization of TPP-NB-L-FITC compared to that obtained with either untageted L or L decorated with the scrambled control peptide. Moreover, the PENP-NP further increases the vascular permeability into the NB tumor mass, but not in normal tissues. The therapeutic efficacy of TPP-NB-L-[DXR] has been investigat- ing in terms of overall survival. On running results indicate that the novel NC exerted an increased anti-NB effect compared to DXR-loaded L decorated with the original peptide. Our findings demonstrate that the achieved penetrating features by a NB-targeting peptide might increase liposomal drug binding, homing and antitumor efficacy.

#5131 Efficient delivery of siRNA targeted CCDC88A mRNA to pancreatic cancer tumor inhibits the invasiveness and metastasis. Keisuke Tanuchi, Toshoi Yawata, Tetsuya Ueba, Toshiji Saibara. Kochi University, Nankoku, Japan.

Introduction: We identified CCDC88A messenger RNA (mRNA) that accumulates in lamellipodia by binding to an RNA-binding protein IGF2BP3 with a next generation sequencer. The objectives of this study are as follows: (1) To identify CCDC88A specific small interfering RNAs (siRNAs) as RNA interference agents that have an inhibitory effect on the invasion and metastasis of pancreatic cancer cells in a mouse model of the invasion and metastasis of pancreatic cancer; and (2) To develop a nucleic-acid delivery system to efficiently transport the siRNAs to PDAC tissue. Methods: After intravenous injection of CCDC88A-specific siRNAs supplemented with folate acids that can bind to the folate acid receptor—which are highly expressed on pancreatic cancer cells—and polyethylene glycol-chitosan oligosaccharide nanoparticles to a mouse model of invasion and metastasis in which a human pancreatic cancer cell line was transplanted to induce tumor formation in the mouse pancreas, accumulation of the siRNAs in the pancreatic cancer tissue was determined by using an in vivo imaging system. After CCDC88A-specific siRNA accumulation in the pancreatic cancer tissue was identified, invasion to the retroperitoneum as well as metastasis to the lung or liver from the human primary pancreatic tumor was compared between the mice in which CCDC88A-specific siRNA accumulation was identified and those receiving a scrambled control siRNA. Results: CCDC88A-specific siRNAs could be delivered to the pancreatic cancer cells of cancer-bearing nude mice by supplementation with folate acids and chitosan oligosaccharide nanoparticles. Supplementation with folate acids and chitosan oligosaccharide nanoparticles caused no hemolysis and had no effect on liver, kidney, or pancreatic function. Invasion to the retroperitoneum and metastasis to the lung or liver from the primary pancreatic cancer were suppressed in cancer-bearing nude mice by administration of those siRNAs, which target CCDC88A mRNA accumulated in lamellipodia of pancreatic cancer cells. Conclusions: This study suggests the potential to develop a siRNA drug to inhibit the invasion and metastasis of pancreatic cancer.

#5132 In vitro collapsing human and murine colon cancer cells by selectivity of disulfiram-loaded charge switchable nanoparticles against cancer stem cells. Marwa Abu-Serie,1 Fatma El-Rashidy2 1City for Scientific Research & Technological Applications, Alexandria, Egypt; 2Faculty of Science, Alexandria University, Alexandria, Egypt.

The different therapeutic strategies against colon cancer (CC) had led to treatment failure, due to resistance to drugs which can be toxic to normal cells in...
healthy tissues and effectively eradicate bulk tumor populations, but not cancer stem cells (CSCs). So, we targeted mitochondrial aldehyde dehydrogenase 1B1 (ALDH1B1) as marker of CSC stemness, by loading of ALDH1B1 inhibitor (disulfiram, DS) on positively charged chitosan nanoparticles (NPs) and coating them with negative charges of serum albumin (SA). The prepared NPs were characterized for particle size, zeta potential, pHi, solubility, encapsulation efficiency, loading capacity, release kinetics and cellular uptake as well as analyzed by scanning electron microscope and surface-enhanced Raman scattering. The selectivity of these NPs against in vitro chemically induced mice colon cancer cells (CDCECs) and human colon cancer cell line (Caco-2) comparing to normal mouse colon cells was determined. The investigation of their selectivity was evaluated by synergistic activity by selecting ALDH1B1 activity, flow cytometry analysis, and a tumor model of CD133 expression and quantification of cleaved-caspase 3 level (as targets for CC treatment). The zeta potential of coated NPs confirmed that SA-layering confers negative charge (-10.3 mv) for the cationic DS-loaded chitosan NPs. In slightly acidic medium of tumor, the ionic bond between SA and the loaded chitosan hydrolyzed then the positive charge was reversed (47.6 mv). In slightly acidic medium of tumor, the ionic bond between SA and the loaded chitosan hydrolyzed then the positive charge was reversed (47.6 mv). Thus coated NPs showed a controlled slow release for DS in slightly acidic pH (tumor microenvironment) than in neutral pH (microenvironment of normal cells) and their uptake were higher in both CC cells (>70%) than normal cells (4.1±0.2%) in a time-dependent manner. This interpreted the highest selectivity of coated NPs for inhibiting cellular growth by apoptosis and suppressing ALDH1B1 activity, oxidizing cellular environment, eliminating CD133 positive cells of tumor with mechanism of CDCECs and Caco-2 cells. Hence the coated NPs possessed the effective eradicating effect for colon CSCs (>40%) without a significant insult (<5%) for normal stem cells in comparison with DS which was toxic to both normal and CSCs (90%). Because of the coated NPs safety for healthy tissues, they may be promising therapy before their efficient collapsing CSCs of tumor cells. These results of this novel study that was used charge switchable (hydrophilic) NPs to load DS for targeting colon CSCs may be represent a basis for future in vivo studies.

Alvocidib is a potent inhibitor of cyclin-dependent kinase-9 (CDK9) and induces apoptosis in cancer cells by reducing the expression of short-lived, anti-apoptotic proteins such as MCL-1. Alvocidib, as a part of a sequential combination regimen with cytarabine and mitoxantrone (ACM), is currently in a Phase II clinical trial in relapsed/refractory acute myeloid leukemia (AML). Patients with AML that have a high dependence on MCL-1 are considered more likely to benefit from the alvocidib-containing regimen. MCL-1 has emerged as a key target for human cancers including leukemia and breast cancers. The use of alvocidib in clinical settings beyond the ACM regimen is somewhat limited by the current intravenous route of administration. An orally administered form of alvocidib would allow prolonged reposition of MCL-1 through chronic dosing and scheduling. Alvocidib itself is highly permeable in Caco-2 monolayers and is soluble at acidic pHs but solubility is strikingly reduced at neutral or basic conditions, which could hamper the development of an oral formulation. We hypothesized that a phosphate prodrug of TP-1287, was determined at various pH levels. It was found to be highly soluble under acidic, neutral, and basic conditions (1.5 mg/mL at pH 2.2; 1.8 mg/mL at pH 4.5; 9.5 mg/mL at pH 6.8 and 9.3 mg/mL at pH 8.7) compared to alvocidib (4.4 mg/mL at pH 2.2; 1.3 mg/mL at pH 4.5; 0.02 mg/mL at pH 6.8 and 0.02 mg/mL at pH 8.7). Pharmacokinetic studies were conducted in mice in which TP-1287 was efficiently converted to the parent alvocidib (Cmax = 1922.7 ng/ml, t1/2 = 4.4 hr) with high oral bioavailability (94% = 182.1, compared to intravenous alvocidib). Effective oral pharmacodynamic studies (measuring MCL-1 expression levels), were evaluated in tumor xenograft models. TP-1287 demonstrated significant anti-tumor efficacy in the MV4-11 AML mouse xenograft model and produced as much as a 61.7% inhibition of the pharmacodynamic biomarker MCL-1 in xenografted tumors, demonstrating a wide, 75-fold therapeutic dosing window. In addition, TP-1287 strongly inhibited tumor growth, achieving 109% tumor growth inhibition (TGI%) at the 7.5 mg/kg dose level. TP-1287 is highly soluble over a broader pH range than alvocidib and is efficiently metabolized to the parent compound in vivo, following oral administration. Tumor xenograft models and pharmacodynamic studies indicate that oral delivery of TP-1287 is efficacious in mice. Based on these results, we anticipate moving TP-1287, as an orally delivered CDK9 inhibitor, into a forthcoming clinical trial directed towards solid tumors vulnerable to the suppression of MCL-1.

#5134 Novel trifunctional immunoliposome delivery system to minimize resistance and side effects for anticancer therapy. Tanaya R. Vaidya, Sihem Ait-Oudhia. Univ. of Florida, Orlando, FL.

Background: Breast cancer (BC) is the second leading cause of cancer death in women worldwide. About 25% of BCs have overexpression of the HER2 receptor. Although HER2 targeted therapies have shown considerable improvement in HER2-positive BC patients’ outcome, treatment resistance remains a clinical challenge. Here, we sought to develop and evaluate a novel trifunctional immune-liposome (TFIL) that overcomes HER2 treatment resistance and associated cardioxicity by dual targeting HER2 on BC cells and CD3 receptors on cytotoxic T-lymphocytes (CTLs). Material and methods: Anti-HER2 (Trastuzumab) and anti-CD3 (OKT-3) antibodies, were conjugated to lipid nanoparticles by the mickle-transfer method, and the resulting formulation was purified by dextran gradient ultra-centrification. Targeted lipid nanoparticles were formulated with a fluorescent lipophilic dye, Dd, for studying receptor binding and internalization. Studies were conducted with HER2-positive BT474 cells and CD3-positive Jurkat cells using flow cytometry analyses. Doxorubicin (DXR) was encapsulated in the nanoparticles by the remote-loading technique for cell-killexperiments. In vitro cell-killexperiments were conducted by co-culturing BT474 as the target cells, and peripheral blood mononuclear cells as the effector cells, at varying ratios. Results: Purified formulations were successfully characterized by demonstrating the presence of mickles as well as the desired conjugation ratio. Flow cytometry analyses demonstrated successful cell binding and/or internalization of the TFIL with both the HER2 and CD3-positive cell lines. Moreover, these dual-targeted nanoparticles were able to target T cells to kill HER2 positive BC cells, and showed improved efficacy compared to non-targeted and plain HER2-targeted formulations in vitro. Conclusion: A novel drug delivery system, TFIL, that targets HER2 receptors on tumor cells, CD3 on T-lymphocytes, and is able to slowly release DXR was successfully developed and evaluated in vitro on HER2-over-expressing BC cells. Our findings show great promise at overcoming resistance and associated cardioxicity to present HER2 targeted BC therapies, and may translate into improved anti-tumor activity clinically compared to other treatment options.

Our nanoparticle-drug conjugates (NDCs), created at Cerulean Pharma Inc. by conjugating drug payloads to our novel β-cyclodextrin-PEG (CDP) copolymer, are designed to significantly mitigate a payload’s limitations by providing sustained drug delivery to the tumor and superior therapeutic index through controlled release kinetics. Cerulean has two NDCs in the clinic, CRLX101 and CRLX301, evidencing the translatability of our technology. CRLX101 has been dosed in over 400 patients and CRLX301 is in ongoing Phase 2a development. A key and differentiating feature of our NDC Platform is our linker technology, which is tailored for an optimal fit with the conjugation functionality of the API drug payloads (e.g., alcohol, carboxylic acid, amine, amide and urea functionality) and customizable to achieve desired drug release profiles. As an illustration of Cerulean’s ability to expand its NDC platform, we will present the biological and pharmacokinetic (PK) data supporting our drug combination platform of antibody nanoparticle-drug conjugates (ANDCs) and multi-drug nanoparticle-drug conjugates (mNDCs). ANDCs combine potentially any NDC with any conjugatable biologic to generate an ANDC with ultra-high drug-antibody ratios (DARS). Using our established NDC linker technology, we generated ANDCs that targets HER2 receptors on tumor cells, CD3 on T-lymphocytes and associated cardiotoxicity to present HER2 targeted BC therapies, and may translate into improved anti-tumor activity clinically compared to other treatment options.
corresponding NDC. The mNDCs take advantage of our existing NDC linker platform technology to conjugate diverse drug combos including DNA damaging agents (DDA) + DNA damage repair agents (DDR). We generated our POC capromethin–olaparib mNDCs spanning a range of drug combination ratios (from 1:1 to 1:20) and all demonstrated distinguishable and tunable in vitro release profiles, and were studied in vivo to evaluate related toxicity of the DDA (–8mg/kg each drug) demonstrated very low clearance and sustained levels of released drug in tumor (greater than 72h). Our drug combination platform, ANDCs and mNDCs, allow delivery of therapeutic agents to their respective biological targets at clinically-relevant doses, greatly increasing the diversity of drug combination possibilities.

**#5136 Upregulation of Salmonella motility in tumors improves dispersion, colonization and intracellular invasion of the bacteria.** Vishnu Raman, Nele V. Dessel, Owen O’Connor, Neil S. Forbes. University of Massachusetts-Amherst, Amherst, MA.

Diffusion limitations in tumors prevent small molecule therapies from reaching cancer cells located distally from vasculature. This is one reason why some cancers become drug resistant and relapse. To circumvent these diffusion limitations, Salmonella can be used as a drug delivery vehicle. The facultative anaerobe preferentially colonizes tumor tissue over normal tissue at ratios greater than 10,000:1. Moreover, flagella allow the bacteria to penetrate deep into tumor tissue. Finally, genetically modified Salmonella can invade cancer cells and deliver a wide range of intracellularly functioning and patient specific therapies (DNA, RNA, and inhibitory peptides). But, Salmonella must distribute homogenously within tumors and invade a significant number of live cancer cells in order to deliver therapies uniformly within tumors. To enable this, we hypothesized that up-regulating the master motility regulator, flhDC, in Salmonella would improve intratumoral penetration, uniform colonization and intracellular invasion of cancer cells. Salmonella utilize the transcription factor complex, flhDC, to regulate flagella synthesis and thus, motility. This transcription factor complex also positively influences type three secretion system (T3SS) assembly, which, Salmonella use to intracellularly invade epithelial cells. To test this hypothesis, we created a set of synthetic gene circuits that use arabinose for inducible expression of flhDC, the Plac promoter for constitutive expression of DSRed and the psPE promoter to express GFP when Salmonella invade tumor cells.

We analyzed aqueous bacterial motility with video microscopy. Finally, we administered the motility inducible Salmonella into a tumor-on-a-chip device to examine spatial and temporal tumor colonization characteristics of the bacteria. In an aqueous environment, the flhDC induced Salmonella swarmed approximately 33% faster than a Salmonella control (P<.01). Induction of flhDC increased the motile fraction (15-30 micrometers/second) of bacteria two-fold (P<.05) while also decreasing the non-motile fraction (0-15 micrometers/second) six-fold (P<.05) when compared to a Salmonella control. In a microfluidic device, flhDC induced Salmonella exhibited increased colonization and growth in tumor tissue located far away from channels that were meant to resemble tumor microvasculature (P<.05), when compared to a control. Finally, flhDC induction increased tumor cell invasion approximately two-fold in tissue located both proximal and distal to the micro-channels within the microfluidic device (P<.05) when compared to a Salmonella control. High-mobility Salmonella, which have the occurrence of drug resistant cancer cell relapse by delivering targeted therapies uniformly to cancer cells that would otherwise remain untreated with conventional therapy.

**#5137 Utility of pH (low) insertion peptide (pHLIP peptide) variants in drug delivery.** Linden C. Wyatt, Anna Moshnikova, Troy Crawford, Oleg A. Andreyev, Yana K. Reshetnyak. University of Rhode Island, Kingston, RI.

Introduction: The pH (Low) Insertion Peptides (pHLIP peptides) show utility in a wide variety of medical applications due to their ability to target cancer cells by exploiting the acidity that is ubiquitous to tumor tissue. Targeting tumor acidity offers many advantages over traditional biomarker targeting and has allowed pHLIP peptides to target primary tumor tissue as well as sub-millimeter metastases. Previously, pHLIP’s conjugated to PET/SPECT tracers or fluorescent labels have found applications in diagnostic nuclear imaging and fluorescence-guided surgery. The purpose of this study was to evaluate a diverse collection of pHLIP variants, including those incorporating non-standard amino acids, consisting of two or four pHLIP’s linked together, and one of de novo design, in order to determine the pHLIP peptide best suited for the targeting and intracellular delivery of therapeutic cargo molecules to primary tumors and metastases. Methods: Biophysical experiments, namely fluorescence and circular dichroism spectroscopy, using liposomes as model membranes, were used to study the localization of pHLIP variants at the bilayer surface at high pH, the tertiary structure and orientation within the membrane of the folded variants at low pH, the parameters of pH-dependent peptide insertion, and the rate at which insertion occurs. In vitro experiments, wherein the polar toxin amanitin was conjugated to the membrane-inserting end of the pHLIP variants via a cleavable disulfide bond, were used to study intracellular cargo delivery and the resulting inhibition of cancer cell proliferation. In vivo experiments, wherein the pH-dependent translocation of amanitin across the plasma membrane by pHLIP variants via a non-cleavable bond, were used to study biodistribution and tumor uptake. Results: All investigated pHLIP variants demonstrated the behavior characteristic of wild-type pHLIP with some differences in membrane affinity and membrane insertion profiles, namely pKIC of insertion and cooperativity. Inhibition of cancer cell proliferation was induced by the pH–dependent translocation of amanitin across the plasma membrane by pHLIP variants. Biophysical measurements, values of EC50 obtained at pH 6.0 and pH 7.4, and fluorescence imaging of triple-negative breast tumors in mice using pHLIP peptide were analyzed collectively. Conclusions: Different pHLIP variants are best suited for different purposes, such as the intracellular delivery of highly or moderately toxic polar or hydrophobic payloads to primary tumor tissue as well as metastases. pHLIP Variant 3 (Var3) exhibited the most favorable properties for the targeted delivery of amanitin to tumor tissue. Acknowledgement: This research was supported by the National Institute of General Medical Sciences of the National Institutes of Health under award number R01GM073857 to OAA and YKR.

**#5138 Development of a gold nanoparticle platform capable of selective homing to tumor tissues for intravenous antitumor therapy.** Zhen Han. National Cancer Institute, Frederick, MD.

Intratumoral administration of high mobility group nucleosome-binding protein 1 (HMGN1) and R848/resiquimod together with a checkpoint inhibitor can eradicate large established tumors. However, the intratumoral route of administration is difficult to use on cancers of internal organs. To improve potential clinical use of HMGN1 and R848, it is necessary to deliver HMGN1 and R848 systemically to the tumor tissue. Gold nanoparticles (AuNP) have been extensively studied as a vehicle for various types of drugs, including anticancer compounds. In this study, we established a means of generating PEGylated Au-HMGN1-R848 (Au-PEG-HMGN1-R848) complexes, which, upon intravenous administration, preferentially target ectopic hepatoma or colonic tumor tissue and avoids uptake of the particles by liver and spleen of tumor-bearing mice. Additionally, Au-PEG-HMGN1-R848 complexes were stable and preserved the capacity of HMGN1 and R848 to stimulate the maturation of dendritic cells. IV administration of Au-PEG-HMGN1-R848 complexes plus a checkpoint inhibitor had effective antitumor activity in curing 80% of C57BL/6 mice bearing large (1 cm in diameter) Hepa-1-6 hepatoma and Balb/c mice bearing CT26 colon tumors. Therefore, an Au nanoparticle platform capable of selectively delivering HMGN1 and R848 systemically to tumor tissues can be used to effectively cure ectopic Hepa-1-6 hepatoma and CT26 colon carcinoma.

**#5140 Encapsulation of the atypical retinoid ST1926 in nanoparticles prolongs the survival of acute myeloid leukemia xenografted mice at multiple folds lower concentrations than the naked drug.** Leeana El-Houjeiri,1 Walid Saad,1 Berthe Hayar,1 Patrick Aouad,1 Nadim Tawil,1 Rana Abdel-Samad,1 Claudio Pisano,2 Ali Bazarbachi,1 Hiba El Haji,1 Nadine Darwiche1.1 American Univ. of Beirut, Beirut, Lebanon; 2Biogen, Arieano Ippino, Italy.

Acute myeloid leukemia (AML) represents one of the most complex types of leukemia. It is a clinically and genetically heterogeneous disorder of hematopoietic progenitor cells, which have lost their ability to differentiate normally. Retinoids regulate vital biological processes including development, differentiation, proliferation, and cell death of hematopoietic progenitor cells. The natural retinoid all-trans retinoic acid (ATRA) became the paradigm for the treatment of acute promyelocytic leukemia (APL), an AML subtype. However, in non-APL AML patients, ATRA is possibly only effective in patients with Nucleophosmin-1 mutations without FMS-like tyrosine kinase 3 internal tandem duplication (FLT-3 ITD). Therefore, synthetic retinoids, specifically the adamaninyl ATRA-like compounds USPC01 and ST1926, have been designed. ST1926 development in clinic was limited due to its rapid glucuron conjugation resulting in low plasma concentrations. Nanomedicine enables more efficient drug delivery and bioavailability. Here, we investigate the pre-clinical efficacy of ST1926 and polymer stabilized ST1926 nanoparticles in AML in vitro and in vivo models. We show that ST1926, at low sub-μM concentrations, potently inhibited the growth of human non-APL ATRA-resistant AML cell lines and AML patient cells while sparing resting and activated normal leukocytes at ten-hundred-fold higher concentrations. ST1926 induced early DNA damage and massive apoptosis in all tested AML cell lines. To optimize the drug’s bioavailability burden, polymer stabilized ST1926 nanoparticles were developed using...
Flash NanoPrecipitation, and were shown to display comparable anti-growth activities to the naked drug in vitro. In murine AML xenograft model, ST1926 and ST1926 nanoparticles significantly prolonged survival. Strikingly, ST1926 encapsulated in nanoparticles extended survival in AML xenografted mice at four-fold lower concentrations than the naked drug. These results highlight the promise of ST1926 in AML therapy and warrant further clinical development of this adamantly retained.

#5141 Optimizing peptide-drug conjugate delivery as an alternative to antibody-drug conjugates for solid tumors. Theo L. Sottero, Emily J. Girard, Carrie H. Myers, James M. Olson. Fred Hutchinson Cancer Research Center, Seattle, WA.

Antibody-drug conjugates (ADCs) have been FDA approved for targeted delivery of chemotherapy to a small subset of cancers. However, there are significant limitations in their clinical utility in the majority of cancers: despite hundreds of clinical trials, there are only two FDA approved drugs currently on the market. ADCs are further limited by their poor penetration into solid tumors and an inability to cross the blood-brain-barrier (BBB). Our lab has over a decade of experience with peptide-dye conjugates such as chlorotoxin-Cy5.5, which demonstrates tumor-specific accumulation in a wide range of cancers including solid tumors and tumors protected by the BBB. However, chlorotoxin-Cy5.5 accumulates in mouse liver – a potential liability if a chlorotoxin-drug conjugate exhibited similar biodistribution. Tumor Paint/BLZ-100 is a derivative of this molecule optimized for tumor accumulation that is currently in clinical trials to aid in cancer surgery. We sought to expand upon the utility of Tumor Paint and optimize a novel peptide that is capable of delivering both imaging agents and chemotherapeutics specifically to tumor cells in vitro and in vivo. We have identified a novel Optide (Optimized knottin pepTIDE) able to accumulate in a range of cancers (lymphoma, sarcoma, colon cancer, and pediatric medulloblastoma). To test whether an Optide could be created with a greater tumor specificity, we looked to both natural homologs as well as specific charged residue modifications. We have identified two next-generation Optides with enhanced uptake in mouse models of sarcoma. We have used these peptides to deliver a microtubule inhibitor to sarcoma and lymphoma in vitro and in vivo. Using in vitro flow cytometry, we have also identified multiple FDA approved drugs that upregulate or downregulate uptake of our family of peptide drug-conjugates. In understanding the pathways regulating the uptake of these peptides, we hope to both be able to identify tumors best suited for treatment with peptide-drug conjugates (PDCs) based on our Optide scaffold.

#5242 Molecular intersection of a 3-in-1 nanomedicine targeting microtubules, ERK tyrosine kinases with profound nuclear modulations, and quantum imaging for hepatocellular carcinoma therapy. Radhika J. Poojari, Rohit Srivastava, Dulal Panda. Indian Institute of Technology Bombay, Powai, Mumbai, India.

Hepatocellular carcinoma is the fifth malignant form of cancer worldwide with poor survival rates. Despite advances in clinical diagnosis, surgery and chemotherapy till date systemic treatment of solid tumour like hepatocellular carcinoma has not been effective in most cases and its clinical therapy is a major challenge. Hence, it is important to search for innovative therapeutic modalities. Nanomolecules that can target both microtubules and kinases may provide new avenues to treat hepatocellular carcinoma. Small molecule inhibitors like doxetaxel and sorafenib represent one of them. Clinical trials have revealed unacceptable toxicities such as neutropenia, severe hypersensitivity, anaphylactic re-action, hypertension, dermatological toxicities and hand-foot skin reaction, etc with these drugs in cancer patients. Other major drawbacks are insolvency, poor bioavailability, short half-life and non-specific. To mitigate these issues, we developed a next generation highly compact nanocarrier system, the 3-in-1 nanomedicine platform with in-depth understanding of the intracellular machinery responsible for its uptake and the molecular mechanisms for regulating the delivery efficiency. Development of a 3-in-1 nanomedicine (100-200 nm) comprised of microtubule inhibitor docetaxel, tyrosine kinase inhibitor sorafenib and an imaging probe quantum dots encapsulated in a biocompatible polymer PLA against human hepatocellular carcinoma cells. Monotherapy strategies in cancer treatment fail due to several complex issues like narrow therapeutic window, non-specificity, administration of higher, repetitive doses, adverse clinical toxicities and resistance mechanisms of drugs. The advantages of 3-in-1 nanomedicine strategy are delineated. The real-time imaging of quantum dots in hepatocellular carcinoma cells showed accelerated internalization. The 3-in-1 nanomedicine exhibited potent inhibition in hepatocellular carcinoma cell proliferation, clonogenicity, induced strong G2/M phase block and apoptosis induction in comparison to single drug monotherapy. The 3-in-1 nanomedicine strongly promoted the microtubule bundling via increased polymer tubulin ex-pression level, augmented multinucleation, aberrant mitosis, and significantly inhibited downstream protein tyrosine kinase, ERK1/2 activation in hepatocellular carcinoma cells in comparison to single drug monotherapy. These findings provide a significant insight into the intrinsic molecular interplays of 3-in-1 nanomedicine in hepatocellular carcinoma cells. The 3-in-1 nanomedicine integrates several avenues in a single nanoscale-platform for dual-drug delivery, and high sensitivity quantum dots imaging as well as diagnostics for hepatocellular carcinoma therapy, holding high translational research potentials in the near future.

#5143 Fusogenic targeted liposomes: novel nanotherapy for specific treatment of prostate cancer. Jihane Mriouah,1 Rae Lynn Nesbitt,2 Susan Richter,1 Melinda Wuest,1 Desmond Pink,3 Deborah Sosnowski,1 Roy Duncan,1 Frank Wuest,1 Andrés Zúñiga,4 John Lewis1.1 University of Alberta, Edmonton, Alberta, Canada; 2Entos Pharmaceuticals, Edmonton, Alberta, Canada; 3University of Dalhousie, Halifax, Nova Scotia, Canada; 4University of Vanderbilt, Nashville, TN.

Metastatic or castrate-resistant prostate cancer is the second-leading cause of cancer mortality in males. In the past 3 years, chemotherapies have extended survival, but efficacy is limited by dose-limiting toxicities due to suboptimal biodistribution. Here, we have addressed the lack of specificity and accumulation in Castrate Resistant Prostate Cancer (CRPC) by developing a unique nanocarrier for drug delivery: molecular targeted fusogenic liposomes. Previously, we have developed a platform whereby lipid nanoparticles are formulated with fusion associated small transmembrane (FAST) protein p14. The p14 protein catalyzes mixing of the nanoparticle lipids with target plasma membrane to deliver the cargo directly into the cytoplasm. In this study, we have engineered the p14 protein to incorporate the prostate cancer targeting ligand bombesin, which binds specifically to the Gastrin-releasing Peptide (GRPR) that is overexpressed in prostate cancer. We hypothesized that this novel targeted fusogenic liposome formulation would significantly improve the biodistribution and efficacy of chemotherapeutics. Clinical translational bicyclic peptide Optide (DOXIL) was modified to incorporate targeted fusogenic p14 protein, and the efficacy and biodistribution of these new formulations was evaluated using in vitro and in vivo models of CRPC. In PC3 cells, compared to conventional liposomes, intracellular levels of doxorubicin are increased by 15 and 25 times when p14 or p14-bombesin liposomes are used. Additionally, the IC50 is reduced from 85mM to 2mM. In mice bearing PC3 tumors treated with targeted fusogenic liposomal doxorubicin, we observed improved tumor growth inhibition by 57% (vs control) and 1.5 fold increased accumulation in tumors within 24h after administration. These proof of concept experiments indicate that molecular targeted fusogenic nanomedicines can improve both the intracellular delivery and tumor accumulation of chemotherapeutic, improving outcomes in this preclinical model. This highlights the potential for improved outcomes in patients with CRPC through the enhancement of approved drugs.

Bicycles are novel binding agents comprising small bicyclic peptides (1.5-3 KDa) constrained via a chemical scaffold, selected for high affinity and selectivity to targets of interest. MT1 (MMP14/MT1-MMP) is a membrane-associated metalloprotease overexpressed in many solid tumours and is implicated in tumour invasion and metastasis. MT1 expression positively correlates with poor prognosis. Phage libraries containing 10^12 unique peptide sequences were post-translationally cyclized with thiol-reactive scaffold and used in an optimized, high-throughput selection process to identify Bicycles to the hemepoxin domain of MT1. Additional iterative rounds of directed phage based screening were used to optimize affinity and off-phage natural amino acids were introduced at select positions to improve plasma stability to generate the lead Bicycle binder. The lead anti-MT1 Bicycle was further modified with a sarcosyl spacer to form N241. N241 binds specifically to the hemepoxin domain of MT1 with a Kd of approximately 2 nM with no binding observed to the catarlytic domain of the protease nor to any of the related MMP family members tested. Importantly and in contrast to most antibodies, N241 binds with similar affinity to MT1 from multiple species including rodent, dog and non-human primate. Since the expected rapid tumor penetration and specific binding of these small peptideyl-binders makes them ideal for use in targeted delivery approaches, a series of Bicycle drug conjugates (BDCs) were prepared; N241 was conjugated to potent maytansinoid cytotoxics via linkers which varied in their cleavability.

Proceedings of the American Association for Cancer Research • Volume 58 • April 2017 1317
experimental and molecular therapeutics: Novel drug delivery technology

Though all the BDCs maintained high affinity for MT1, efficacy toward MT1-positive human tumor mouse xenografts varied with linker stability. BDCs with the most stable linkers were the least active suggesting that optimal tumor activation was obtained with linkers that could be cleaved more rapidly. Due to the rapid clearance and limited systemic exposure of these small-targeting BDCs, only the most stable linker showed toxicity in vivo. DoxKA was selected for the in vivo study based on drug clearance and limited systemic exposure of these small-targeting BDCs, with conserved efficient Doxorubicin cytotoxic mechanism. Uptake of DoxKA in ES-2 ovarian cancer cells was reduced when Sortilin expression was specifically silenced by using siRNA or upon competition with the Sortilin ligands neurotensin and progranulin. In addition, DoxKA was found to bypass the P-gp efflux pump since, in contrast to Doxorubicin uptake in MDCK-MDR1 cells overexpressing the P-gp efflux pump, the uptake of DoxKA was unaffected by the P-gp inhibitor Cyclosporin A. In vivo, DoxKA was better tolerated and caused a more potent inhibition of human ovarian tumor xenograft growth than did Doxorubicin alone. These results provide strong evidence for the potential of this drug development platform in the generation of novel personalized therapeutics with specific targeting of SORT1-positive cancer cells.

#5145 Denitification of obstacles encountered using convection enhanced delivery in preclinical models of diffuse intrinsic pontine glioma, Jamila S. Gittens,1 Sridevi Yadavilli,2 Michael Lin,2 Eshini Panditharatna,2 Suresh N. Magge,2 Roger J. Packer,2 Javad Nazarain.1 1Children’s National Health System, Washington, DC; 2The George Washington University, Washington, DC.

Diffuse intrinsic pontine gliomas (DIPGs) is a pediatric brain tumor that arises in the pons of the brainstem. The vital location of the tumor and the presence of the impermeable blood brain barrier (BBB) make treatments ineffective and lead to a high mortality rate of DIPG patients. Convection enhanced delivery (CED) is a promising drug delivery method because of its ability to bypass the BBB that is currently being investigated to deliver therapeutic agents directly to brain tumors. Nonetheless, clinical trials investigating the use of CED to treat patients have not shown prolonged patient survival. Previous studies have determined poor distribution in clinical studies due to reflux or back flow. Additionally, by analyzing the H&E and Ki67 stained brain sections of a DIPG patient that underwent CED, we determined that areas of radiation-induced necrosis within the tumor were a possible reason for treatment failure. In this study, we intend to optimize CED in orthotopic murine model of DIPGs. Specifically, we have tested the ideal volume and rate of injection, as well as using the combined approach of using CED and radiation. Ideal injection rate was established by assessing infusion profiles in agarose brain phantoms using various needles, which resulted in the injection rate of 0.3 μl/min producing the least back flow. Next, the ideal injection rate and volumes were tested in vivo by injecting non-tumor bearing mice with trypan blue. To assess the infusion rate, brain sections were analyzed at necropsy to determine distributions of the injected dye. To investigate accumulation of CED-mediated payload in necrotic sites, tumor bearing mice were exposed to radiation and then injected with the fluorescent dye, DiI. Formalin fixed brain sections were stained with DAPI and fluorescent images were taken. The results of this study indicate that a rate of 0.3 μl/min results in a significantly larger distribution area compared to the 0.3 μl/min injection rate (30.7 ± 2.1 vs. 30.4 ± 7.1 ± 1.18, p=0.0062). Of the brain sections of mice injected with DiI did indicate the accumulation of dye in areas where there were no live cells, supporting the assumption that drug injections may be retracting to necrotic pockets and thus preventing equal distribution of the drug in the tumor. Ongoing studies include investigating the survival benefits of using CED to deliver therapeutic agents in tumor-bearing mice. Understanding the obstacles of convection enhanced delivery in murine models can help establish better treatment regimens and devices for patients and provide better preclinical models for drug testing.

#5146 Increasing penetration of anticancer drugs through sortilin receptor-mediated cancer therapy: A new targeted and personalized Approach in the treatment of ovarian cancer, Michel Demeule,1 Jean-Christophe Curie,1 Alain Larocque,2 Cyndia Charfi,3 Richard Beliveau,4 Claude Vezina,2 Bobbene Annabi1 1Université du Québec à Montréal, Montréal, Quebec, Canada; 2Katana Biopharma, Montréal, Quebec, Canada.

The development of personalized therapies against ovarian cancer remains highly challenging in current modern oncology. One way to achieve greater selectivity and better anticancer drug delivery into cancer cells is to conjugate cytotoxic agents to specific peptide ligands that will selectively target receptors abundantly and/or exclusively expressed on these cells. Increased expression of Sortilin, a scavenging receptor, has been clinically observed in several human cancers including breast, prostate, colon, pancreas, skin, and pituitary. In particular, Sortilin has also been reported to be overexpressed in ovarian cancers as compared to non-malignant ovarian tissue. In light of this, we developed a peptide conjugation platform using a new Sortilin receptor-mediated vectorization strategy to increase cell targeting selectivity and cell delivery efficacy of anticancer agents. As a proof-of-concept, Doxorubicin was conjugated to peptide sequences, termed Katana peptides (KA). In vitro, significantly increased uptake of KA was observed in SKOV3 compared to SKOV3-KATANAP peptide conjugate (DoxKA) was observed in SKOV3 and ES-2 ovarian cancer cell line models, with conserved efficient Doxorubicin cytotoxic mechanism. Uptake of DoxKA in ES-2 ovarian cancer cells was reduced when Sortilin expression was specifically silenced by using siRNA or upon competition with the Sortilin ligands neurotensin and progranulin. In addition, DoxKA was found to bypass the P-gp efflux pump since, in contrast to Doxorubicin uptake in MDCK-MDR1 cells overexpressing the P-gp efflux pump, the uptake of DoxKA was unaffected by the P-gp inhibitor Cyclosporin A. In vivo, DoxKA was better tolerated and caused a more potent inhibition of human ovarian tumor xenograft growth than did Doxorubicin alone. These results provide strong evidence for the potential of this drug development platform in the generation of novel personalized therapeutics with specific targeting of SORT1-positive cancer cells.

#5147 Novel warheads for targeted therapies of cancer: The concept and design of proPBDs, Iontcho Vlahov, Longwu Qi, Spencer Hahn, Kevin Wang, Hari K. Santhaparam, Albert Felten, Paul Kleindl, Jeremy Vaughn, Christopher P. Leamon. Endocyte, W. Lafayette, IN.

Pyrrolo[2,1-c][1,4]benzodiazepine (PBD) antibiotics, are a class of natural products produced by various actinomycetes bacteria. PBDs are sequence selective DNA-crosslinking alkylating compounds and are considerably more potent than systemic chemotherapeutic agents. Some PBDs have the ability to recognize and bond to specific sequences of DNA. After insertion in the minor groove, a covalent aminal bond is formed through nucleophilic attack of the N-2 of a guanine (G) base on the electrophilic C-11 imine of PBD. The end result is obstruction of tumor cell division without any significant distortion of the DNA’s helix, thus potentially avoiding the common phenomenon of drug resistance. In recent years, synthetic PBD-dimers have emerged as a promising class of payloads for conjugates in the field of targeted cancer therapies. Unfortunately, many PBD conjugates preserve the strongly alkylating imine moiety within their structural framework, which can react in a deleterious manner while circulating on their way to their intended targets. As an elegant solution to this inherent problem we designed conjugated prodrugs lacking the imine moiety. Once the prodrug (proPBD) conjugate enters a targeted cell, cleavage of the linker system in the construct triggers the generation of a reactive intermediate possessing an aldehyde and aromatic amine. An intramolecular reaction subsequently takes place as the aromatic amine adds to the aldehyde with the loss of water to give the imine, and as a result, the diazepine ring. In our proPBDs, we envision to mask the aldehyde as a hydrolytically sensitive oxazolidine moiety and to exploit its ring system as a part of an arsenal of self-immolative linker systems for conjugation. To prove the range of applications for this new class of latent DNA-alkylators, we designed and prepared a diverse variety of novel warheads, consisting of proPBD dimers, hybrids of proPBD with other powerful alkylating agents, and proPBDs with sequence-selective DNA minor groove binders. The utility of the so prepared novel warheads in the design of small molecule drug conjugates (SMDC) for targeted cancer therapies will be also discussed in the presented poster.

#5148 Liposomal gemcitabine, FF-10832, improves gemcitabine (GEM) pharmacokinetics (PK) and increases anti-tumor efficacy. Takeshi Matsu- moto, Tsuruaki Kitahashi, Takashi Komori, Hiromu Kitahara, Kohei Ono, Naoki Yamada, Hiroyuki Iwamura, Kiyohito Takada, Shinji Hagiwara, Yasuhiro Shimada. FUJIFILM Corporation, Tokyo, Japan.

Introduction: FF-10832 is a liposome suspension optimized by Fujifilm nanotechnology containing 0.5 mg/ml GEM, cholesterol, HSPC, N-MPEG-DSP. FF-10832 is expected to improve GEM PK and have strong anti-tumor effects. The PK and anti-tumor effects of FF-10832 were studied in mice and human pancreatic cancer xenograft models. Methods: Single-dose murine plasma PK of FF-10832 1 mg/kg was compared to GEM 240 mg/kg. In vivo activity of GEM 240 mg/kg and FF-10832 1-5 mg/kg IV once weekly were compared in human pancreatic cancer murine xenograft models; 2 subcutaneous (Capan-1 [GEM-sensitive] and BxPC-3 [GEM-resistant]), and 1 orthotopic (SUIT-2) model. The active form of GEM (GEM triphosphate [dFdCTP]) inhibits DNA synthesis. dFdCTP tissue concentrations following FF-10832 4mg/kg and GEM 240mg/kg were compared in these models. Results: An extended plasma t½ (10.6 vs. 2.9 hours), lower clearance, and smaller volume of distribution were observed with FF-10832 vs. GEM, which correlated with greater dose exposure achieved with
FF-10832 compared to GEM (AUC_{0-24} 18600 vs. 7300 hr-ng/mL). FF-10832 demonstrated increased in vivo activity in SUTT-2, Capan-2, and BxPC-3 models, at significantly lower doses compared to GEM. In the Capan-1 and BxPC3 models, FF-10832 showed dose-dependent tumor growth suppression with FF-10832 4 mg/kg and 5 mg/kg superior to that of GEM (p<0.001), respectively. FF-10832 11 weekly doses in the SUIT-2 mouse model was 80% reduction of tumor volumes compared to 20% for vehicle and GEM 240 mg/kg vs. 13% and 60% for 2 and 4 mg/kg FF-10832, respectively. Median survival time was 60 (FF-10832 2 mg/kg) and 73 (GEM 240 mg/kg) vs. 26 days (vehicle) (p<0.001). Median survival was not reached at FF-10832 4 mg/kg. In all models, FF-10832 2 mg/kg (equivalent efficacy to GEM 240 mg/kg) showed no body weight gain suppression. The dFdCTP tumor/bone marrow AUC ratio was significantly higher following FF-10832 (dFdCTP AUC ratio) compared with non-liposomal GEM (0.8). Conclusions: FF-10832 is a stable liposomal GEM formulation demonstrating potent anti-tumor efficacy in solid tumor models with a favorable pharmacokinetic profile compared to non-liposomal GEM. Increased exposure achieved at lower GEM doses may potentially result in superior efficacy and a more tolerable safety profile for FF-10832 compared to non-liposomal GEM.

#5150 Designing of a novel strategy for cancer gene therapy by selective delivery of Adenovirus-based toxin. Nadir Arber, Ilana Boustanai, Shiran Shapira, Dina Kazanov. Tel Aviv Sourasky Medical Center, Tel Aviv, Israel.

Introduction: Aberrant activation of the Ras pathway exists in many human tumors (Lung ~25%, pancreatic (PC) ~95% and colorectal cancers (CRC) ~50%). Development of numerous direct and in direct Ras inhibitors have failed. This lead us to think differently; we exploit the hyperactive Ras pathway rather than try to inhibit it. We previously had reported that recombiant adenoviruses, carrying a pro-apoptotic gene (PUMA) under the regulation of Ras-responsive elements suppressed the growth of cancer cells harboring hyperactive Ras. Moreover, replacing the PUMA gene with more potent toxins (bacterial MazF-MazE toxin-antitoxin unique regulated system), the potency of this killing strategy was significantly improved. P53 is a classical tumour suppressor mutated in many tumors. Herein, the WT p53 is use to protect normal cells from any systematic toxin toxic. Aim: To establish a tight control of the toxin expression in malignant cells, and the anti-tumor in normal cells dual system based on the Ras and p53 responsive elements Methods: Adenoviral vectors were designed carrying the toxin (PY4-MazF-mcherry) and the antitoxin (RGC-MazE-GFP) based on the Ras and p53 responsive elements, respectively. Those two constructs were cloned into a “first generation” ΔE1/ΔE3 human type 5 adenoviral vector. Virus particles were produced, their titer was calculated by the End-Point Dilution Assay and their potency was tested in vitro. Cell death was measured qualitatively by using the fluorescent microscopy and was quantified by the enzymatic MTT assay. SHP77/Ras_{mut}/p53^{−/−}, H2030/Ras_{mut}/p53^{−/−}, H1650/Ras_{mut}/p53^{−/−} and H1975/Ras_{mut}/p53^{−/−} lung cancer cell lines were used for testing the potency of the system. MIA-PACA2, Colo357, Panc-1; Ras_{mut}/p53_{mut}, and BxPC3; Ras_{mut}/p53_{mut} PC cell lines were tested as well. Different ratios of toxin-antitoxin (2:1, 1:1 and 1:0.5) were used. Results: Massive cell death was induced in a dose-dependent manner (70% with a titer of 7.5 MOI in lung cells with mutated Ras compared to 21% in cells with WT Ras). Similar results were obtained with tumor former cancers by fluorescence microscopy. Similarly, in PC cells, with mutated Ras showed 50% cell death in a dose-dependent manner with a titer of 15 MOI, compared to 18% in cells with WT Ras. Ratio of 1:0.5, showed decrease in the mortality of the mutated Ras cells expressing WT p53; 36% with a titer of 7.5 MOI. These results indicate that the antitoxin indeed actively protects cells with wt p53. Conclusion: Outside the box cancer gene therapy by exploiting active Ras and P53 pathways are effective in vitro. The low toxicity in WT Ras as well as WT p53 expressing holds promise for effective and safe therapy.

Merrimack Pharmaceuticals, Inc., Cambridge, MA.

Nal-IRI, a liposomal formulation of irinotecan, is designed for extended circulation relative to non-liposomal irinotecan and to exploit leaky tumor vasculature for enhanced drug delivery to tumors. Following tumor deposition, nal-IRI is taken up by phagocytic cells followed by irinotecan release and conversion to its active metabolite, SN-38. Sustained inhibition of topoisomerase 1 (TOP1) by extended SN-38 exposure is hypothesized to enable superior anti-tumor activity compared to traditional TOP1 inhibitors. Topotecan, another TOP1 inhibitor, is an approved second-line treatment for small cell lung cancer (SCLC). Here, we evaluate the anti-tumor activity of nal-IRI compared to irinotecan and topotecan in preclinical models of SCLC including those that have been pre-treated with therapeutics utilized clinically to treat SCLC. Anti-tumor activity of nal-IRI, irinotecan, or topotecan was evaluated based on tumor volume assessments in DMS-53, DMS-114 and NCI-H1048. Conclusions: Nal-IRI demonstrated anti-tumor activity in xenograft models of SCLC at clinically relevant dose levels, and resulted in complete or partial responses in DMS-53, DMS-114, NCI-H1048 and a PDX model in comparison with irinotecan or topotecan, which each had limited tumor growth control. Furthermore, Nal-IRI demonstrated anti-tumor activity in tumors that progressed following treatment with topotecan, and demonstrated significantly greater anti-tumor activity than both topotecan (p<0.0001) and irinotecan (p<0.0001) in NCI-H1048 tumors (8/8 complete responses) that had progressed on prior carboplatin plus etoposide treatment. These results support the further clinical development of nal-IRI versus IV topotecan in patients with SCLC that progressed on or after prior platinum containing therapy.

#5152 Cancer stem cell targeted exosomes for the treatment of metastatic breast cancer. Golan Kribria, 1 Katelyn E. Lee, 1 Erika K. Ramos, 1 Simo Huanga, 1 Clifford V. Harding, 1 Jan Lötvall, 1 Huiping Liu, 1 2Department of Pathology, School of Medicine, Case Western Reserve University, Cleveland, OH; 3Kreting Research Centre, Department of Internal Medicine and Clinical Nutrition, University of Gothenburg, Gothenburg, Sweden.

Introduction: Therapy resistance and metastasis remain the two biggest challenges of breast cancer that result in a majority of cancer deaths. Cancer stem cells (CSCs) are a subpopulation of cancer cells that can initiate new tumors, remain refractory to conventional therapies, and spread throughout the body. In order to effectively block metastasis, the present study aims to develop novel therapeutics that specifically target breast CSCs and spare normal cells. While traditional drug discovery represents one of the promising future directions, it is necessary to overcome the shortcomings of synthetic nanoparticles, including bio-instability and off-target toxicity. Here, we aim to bio-engineer the naturally produced cell-secreted small vesicles, exosomes (~100 nm diameter), for a novel therapeutic delivery system. Methods: Exosomes from the human mesenchymal stem cells (MSCs) were isolated by differential ultracentrifugation, and characterized by multiple approaches including transmission EM, Immunoblotting and immunofluorescence assays to confirm the size, shape and presence of exosomal markers CD63, CD81 and LAMP2B. Exosomes were engineered to express a peptide ligand on its surface to specifically recognize and target CSCs, and the presence of the ligand was confirmed by western blot, flow cytometry (FCM) and transmission EM. Results: Exosomes carrying a pro-apoptotic gene (PUMA) under the regulation of Ras-responsive elements, exosomes specifically targeted breast CSCs compared to normal cells with absent expression of the ligand-binding protein. The developed exosomes can effectively deliver candidate miRNAs into the recipient cells and knock down the genes important for functional CSCs. The in vivo targeting of CSCs and therapeutic applications of the exosomes using patient-derived human-inmouse breast tumor xenograft models are underway. Conclusion: It is expected that exosome-based miRNA therapy will have high biocompatibility, low toxicity, high specificity, and promising efficiency in preclinical and clinical applications to reduce breast cancer metastasis and improve patient survival.

#5153 Tunable Drug Conjugates: a differentiated drug conjugate (DC) platform. Sara C. Hickey, 1 Alex R. Nanna, 1 Hanh N. Nguyen, 1 Leslie Ofori, 1 Jonathan Rader, 2 Michael K. Rood, 3 Jutta Wanner, 4 Doug S. Werner, 4 Blank-Bio, Inc., Jupiter, FL, 5The Scripps Research Institute, Jupiter, FL, 6Genomics Institute of the Novartis Research Foundation, San Diego, CA.

We have established a set of technologies called Tunable Drug Conjugates (TDCs) that will differentiate from other DCs via a rapid payload release/rapid systemic clearance approach intended to quickly drive high toxic “payload” concentrations within tumor cells while minimizing toxicities to patients. TDCs use pro-
EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Novel Drug Delivery Technology

prietary Silicon-based linker chemistries (Silinkers) in novel Payload Cassettes (PCs) that enable the rapid and uniform release of multiple and/or mixed payloads both in the endosome after internalization and within the necrotic microenvironment of tumors. PCs can incorporate multiple copies of the same payload or optimal ratios of different therapeutic agents that work together synergistically to kill cancer cells. A second technology - a Dual variable Domain-Fab (DVDFab) targeting capability provides a proprietary means of specifically targeting a broad array of cell surface proteins. DVD-Fab containing TDCs should be cleared from the body within hours, enabling better management of side-effects. Our Silinker system is differentiated by the exquisite and tunable sensitivity of the linkers to cleavage under the modestly acidic conditions encountered in the endosomal and lysosomal compartments of a cell, and in the microenvironment of solid tumors. Good stability at the physiological pH (and in human plasma) compares to rapid cleavage at relevant lower pHs as demonstrated using model systems. Silinkers exhibit good stability at 37°C in pH 4 buffer and show novel functionalization with the folic acid analog as the targeting ligand and vinblastine analogs as the payload(s). We used single and PC drugs conjugates to show cellular and in vivo proof-of-concept. We tested our TDCs in cell lines overexpressing FAR and showed that cytotoxicity was blocked by excess folic acid. Subsequent in vivo studies, using a nude mouse xenograft model, showed good tumor activity for these prototype TDCs. BB-01 (a single payload construct) showed a clear dose response and had cures in 3 out of 5 mice after 24 days on a 3 μmol/kg TIW schedule. BB-03 (a triple PC construct) shows essentially complete tumor regression compared to modest inhibition by BB-01 at doses that deliver equivalent amounts of payload, demonstrating the synergistic potential of the PC concept to enhance the activity. We have also synthesized DVD-Fab TDCs. DVD-Fabs contain a reactive chemical group for seamless connection with our Silinkers and PCs. We will describe conjugation chemistries and present cellular and in vivo Xenograft data for prototype DVD-Fab TDCs.

#5154 Enhancing tumor blood perfusion using orally active heparin to increase the distribution of anticancer therapeutics inside the tumor tissue. Jeong Uk Choi,1 Taslim A. Al-Hilal,2 Seung Woo Chung,3 Jisuk Yun, 1Hwanjae Nam,1 Myungyoon Lee,1 Hinja Hwang,1 Kyunghin Kim,3 Youngro Byun,2 Young-seok Cho,2 Seong Wook Lee.3 1Graduate School of Convergence Science and Technology, Pohang University of Science and Technology, Pohang, Korea; 2Division of Diagnostic Science and Technology, College of Medicine or College of Pharmacy, Seoul National University, Seoul, Republic of Korea; 3Texas Tech University Health Science Center, Amarillo, TX; 2Dong-A Socio Group ST Pharm Co., Ltd., Seoul, Republic of Korea.

Here, we suggest in the first time that the cancer associated thrombosis (CAT) might be one of the major factor which limit the tumor blood perfusion and drug distribution inside the tumor tissue by reducing the effective radius of blood vessels. In order to prevent CAT and achieve enhanced drug distribution, we developed orally active heparin to be combined with other anti-cancer therapies. We injected dye conjugated fibrinogen and chitosan nanoparticles to mice which were bearing highly thrombotic tumor to visualize CAT and nanoparticle distribution inside the tumor tissue. When CAT is prevented by heparin, we found that nanoparticle distribution and accumulation were significantly enhanced compared to the group not treated with heparin. This results signify that the CAT can limit the tumor perfusion and prevention of CAT can enhance the drug accumulation and distribution. We used highly thrombotic cancer models such as melanoma and pancreatic cancer to evaluate the therapeutic efficacy of the doxorubicin containing nanoparticles and the combination of oxaliplatin and gemcitabine when they are combined with heparin. We have found that when heparin is combined with each therapy, their tumor inhibition efficacy increased about 25% and also confirmed that this synergistic effect comes from enhanced drug distribution inside the tumor tissue by preventing the CAT using anticoagulant. These results were supported by histologic analysis. We've validated our hypothesis by showing that CAT can limit the tumor perfusion, which in turn brings reduced drug distribution inside the tumor tissue. We also confirmed that our oral heparin could enhance the tumor perfusion and the efficacy of anti-cancer therapies by preventing the CAT in the tumor tissue.

#5155 Targeting nucleolin with doxorubicin-containing nanoparticle induces a significant tumor growth inhibition in an orthotopic animal model of standard of care-resistant mesothelioma. Nuño André Fonseca,1 Vera Moura,2 Fabiana Coelli,1 Daniela Pesce,1 Francesco Cardile,1 Claudio Pisano,3 Sérgio Simões,1 João Nuno Moreira1.

Mesothelioma is a malignant tumor of the mesothelium, the thin lining of the surface of the body cavities and the organs within, and is often associated with asbestos exposure. It has a poor prognosis, with a mean overall survival of 8.8 months. Chemotherapy has been used for malignant pleural mesothelioma as an adjuvant treatment after surgical resection (often palliative) or in combination with other therapies. A combination of cisplatin and pemetrexed remains as the current standard of care, with only a 5-9% survival rate. Herein, a novel targeted treatment for mesothelioma, based on a doxorubicin (DXR)-containing nanoparticle functionalized with the nucleolin-binding F3 peptide (named PEGASEMP), is proposed. It relies on nucleolin deregulated overexpression in cancer cells and the tumor microenviron- ment. Selective targeting DXR-containing nanoparticles were performed in an orthotopic model of human mesothelioma. Mesothelioma cells harvested from a patient with disease progression who undergone chemotherapy, were stably transduced with luciferase-reporter gene, and orthotopically injected infrapleurally into female immunocompromised mice. Animals were randomly allocated to different treatment groups: vehicle, peptide-targeted DXR-containing nanoparticle (PEGASEMP) at 5.6 or 7 mg of DXR/kg alone (q7dx5w); cisplatin at 4.0 mg/kg alone or combined with PEGASEMP at 5.6 mg of DXR/kg (q7dx5w). A control group administered with the standard of care, a combination of cisplatin at 4.0 mg/kg (q7dx5w) plus pemetrexed at 100.0 mg/kg (q2dx3x5w) was also included. Bioluminescence was monitored weekly with live imaging using IVIS Spectrum In Vivo Imaging system. Peptide-targeted DXR-containing nanoparticle at 7.0 mg/kg enabled a tumor growth inhibition, by the end of the treatment, that was 183-fold higher than the standard of care. Moreover, treatment with DXR-containing nanoparticle targeting nucleolin, either at 5.6 or 7.0 mg/kg, enabled a 10- or 66-fold reduction of tumor burden, respectively, relative to non-treated mice. Conversely, treatment with the standard of care did not show any effect on tumor growth inhibition (being similar to the group injected with vehicle) nor on tumor burden. Importantly, DXR-containing nanoparticle targeting nucleolin, at the highest tested dose, enabled a marked decrease of the incidence of tumor infiltration into the chest cavity, as well as of the presence of severe lung lesions, as compared with the standard of care (57.1% versus 100% and 14.3% versus 50%, respectively). Overall, the novel mechanism of action associated with DXR-containing nanoparticle targeting nucleolin, enables a significant benefit in terms of efficacy (and safety) in the treatment of mesothelioma, as compared with the current standard of care, thus supporting future clinical evaluation.

#5156 A synthesized RNA aptamer targeting and inhibiting non-small cell lung cancer. Hanlu Wang,1 Meng Qin,2 Zhihua Ren,1 Irvin S.Y. Chen,2 Yong-Ping Jiang1. 1Biopharmaceutical R&D Center, Peking Union Medical College of Chinese Academy of Medical Science, Beijing, China; 2Department of Pathology, School of Medicine, University of California, University of California Los Angeles, Los Angeles, CA.

A specific RNA aptamer (RA16) targeting non-small cell lung cancer (NCI-H460 cells) was previously reported by in vivo SELEX. The aptamer RA16 was identified specifically targeting and inhibiting human NCI-H460 cell proliferation in vitro, as well as xenograft tumors in vivo. In this study, we synthesized RNA aptamer (syn-RA16) and make comparison studies with transcribed RNA aptamer (trans-RA16) in vitro in respect of the specific targeting and direct inhibitory activity towards NCI-H460 cells. To characterize the targeting specificity in vitro, biotin-labeled syn-RA16 and trans-RA16 were incubated with NCI-H460 cells, other tumor cell lines or normal control cells. Specific fluorescence binding was observed only for NCI-H460 cells, but not for HEK293T, Hela, and Jurkat cells or buffer control. Moreover, binding affinity of KD values to the NCI-H460 cells for syn-RA16 and trans-RA16 were determined at 24.7±2.28 nM and 12.14±1.46 nM (n=3), respectively, by flow cytometry using streptavi- nin-PE labelling, indicating that the specific targeting binding affinity for syn-RA16 was highly retained, as trans-RA16. On the other hand, syn-RA16 aptamer, like trans-RA16 aptamer, was also capable of inhibiting non-small cell lung cancer cell (H460) proliferation in a dose-dependent manner. At 300 nM, syn-RA16 aptamer suppressed cell proliferation by 84.5%, compared by 86.8% with trans-RA16. The IC50 for syn-RA16 was determined at 11.8±1.1 nM, while trans-RA16 was at 105.7±1.2 nM (n=4). Interestingly, both syn-RA16 and trans-RA16 exhibited no any inhibitory effect on HeLa and Jurkat cell lines even at concentration of 600 nM. In conclusion, a specific entire RA16 RNA aptamer was synthesized. The synthesized RA16, like transcribed RA16 aptamer, demon- strated the specific targeting ability and inhibitory activity to human NCI- H460 cells. The syn-RA16 could be potential to develop a diagnostic kit or treatment for NCI-H460 cell-related non-small cell lung cancer in the clinic.

Results of our study will impact broadly the field by developing more effective control, suggesting that PLGA improves the delivery of 3bNChalcisidethecell. Compared to control, we demonstrated that 3bNChalc was successfully encapsulated into PLGA NPs and they showed decreased in viability and proliferation when revealed that 3bNChalc PLGA NPs are negatively charged and they tend to repel and smooth spherical shape. In addition, zeta potential and mobility values of 3bNChalc loading, encapsulation efficiency, and drug release was determined using a combination of Dynamic Light Scattering (DLS) and Scanning Electron Microscopy (SEM). Cell viability and proliferation of PC3 and 22RV1 prostate cancer cell lines treated with 3bNChalc NPs and control were assessed using the MTS assay. 3bNChalc PLGA NPs were found to have a particle size of 250 nm and smooth spherical shape. In addition, zeta potential and mobility values revealed that 3bNChalc PLGA NPs are negatively charged and they tend to repel each other avoiding the tendency to flocculate. Moreover, 22RV1 cells treated with 3bNChalc PLGA NPs showed decreased in viability and proliferation when compared to control. We demonstrated that 3bNChalc was successfully encapsulated into PLGA NPs. In addition, our results showed that 3bNChalc PLGA NPs decreased the viability of 22RV1 prostate cancer cells when compared to control, suggesting that PLGA improves the delivery of 3bNChalc inside the cell. Results of our study will impact broadly the field by developing more effective and less toxic PLGA NPs based therapies.

Experimental and Molecular Therapeutics: Oncogenes and Tumor Suppressors as Therapeutic Targets

Anti-tumor activity of entrectinib, a highly potent pan-TRK, ROS1 and ALK inhibitor, in molecularly defined acute myeloid leukemia. Patrick Fagan, Maria Barrera, Colin Walsh, Danielle Murphy, Ian Silverman, Robert Shoemaker, Ge Wei, Zachary Hornby, Gary Li, Kristen M. Smith, Ignita, Inc., San Diego, CA.

Acute myeloid leukemia (AML) is the most common form of acute leukemia in adults and comprises a heterogeneous group of diseases. A number of recurrent leukemic gene mutations or chromosomal rearrangements have been identified and clinically validated in AML. However, nearly 50% of AML patient samples lack any known AML driver mutations. Advances in molecular diagnostics have resulted in the identification of novel and actionable gene mutations or chromosomal rearrangements in these AML samples. The ETV6-NTRK3 fusion gene is one such rearrangement identified in samples from patients with AML. Fusion of ETV6 sequences to the tyrosine kinase domain of NTRK3 results in constitutive activation of the TRKckinase and ETV6-NTRK3 expression has emerged as one of the key oncodrivers for leukemogenesis. Constitutive activation of TRK family tyrosine kinases has also been detected in a wide range of solid tumor and hematologic malignancies, including lung, colorectal, salivary gland, sarcoma, thyroid, glioblastoma, melanoma, anaplastic large cell lymphoma (ALCL) and Philadelphia-like acute lymphoblastic leukemia. Entrectinib (RXDX-101) is an investigational, orally available, brain-penetrant, highly potent and selective kinase inhibitor with low nanomolar potency against TRKA/B/C, ROS1 and ALK gene activations. In these studies, we have demonstrated sensitivity to entrectinib in AML cell lines with endogenous expression of the ETV6-NTRK3 fusion gene. Entrectinib treatment blocked cell proliferation and survival in vitro with sub-nanomolar EC50 values. Phosphorylation of the ETV6-TRKCKinase protein as well as phosphorylation of known TRKCK downstream signaling effectors was inhibited by entrectinib treatment in a dose-dependent manner. Sensitivity to entrectinib was dependent on expression of the TRKCK fusion protein. In xenograft models, entrectinib treatment at clinically relevant doses resulted in tumor regression, which was accompanied by elimination of residual cancer cells from the bone marrow. The clinical relevance of activated tyrosine kinase signaling in AML has been validated by the efficacy of selective tyrosine kinase inhibitors. Our preclinical data demonstrate the potential of entrectinib as an effective treatment for patients with NTRK rearranged acute myeloid leukemias and provide rationale for the clinical development of entrectinib in molecularly defined hematologic malignancies. Entrectinib is currently the subject of an ongoing global Phase 2 basket study to enrolling patients across multiple tumor histologies containing TRKOSI or ALK fusions.

Acutemyeloidleukemia(AML)isthemostcommonformofacuteleukemia in adults and comprises a heterogeneous group of diseases. A number of recurrent leukemic gene mutations or chromosomal rearrangements have been identified and clinically validated in AML. However, nearly 50% of AML patient samples lack any known AML driver mutations. Advances in molecular diagnostics have resulted in the identification of novel and actionable gene mutations or chromosomal rearrangements in these AML samples. The ETV6-NTRK3 fusion gene is one such rearrangement identified in samples from patients with AML. Fusion of ETV6 sequences to the tyrosine kinase domain of NTRK3 results in constitutive activation of the TRK kinase and ETV6-NTRK3 expression has emerged as one of the key oncodrivers for leukemogenesis. Constitutive activation of TRK family tyrosine kinases has also been detected in a wide range of solid tumor and hematologic malignancies, including lung, colorectal, salivary gland, sarcoma, thyroid, glioblastoma, melanoma, anaplastic large cell lymphoma (ALCL) and Philadelphia-like acute lymphoblastic leukemia. Entrectinib (RXDX-101) is an investigational, orally available, brain-penetrant, highly potent and selective kinase inhibitor with low nanomolar potency against TRKA/B/C, ROS1 and ALK gene activations. In these studies, we have demonstrated sensitivity to entrectinib in AML cell lines with endogenous expression of the ETV6-NTRK3 fusion gene. Entrectinib treatment blocked cell proliferation and survival in vitro with sub-nanomolar EC50 values. Phosphorylation of the ETV6-TRKCKinase protein as well as phosphorylation of known TRKCK downstream signaling effectors was inhibited by entrectinib treatment in a dose-dependent manner. Sensitivity to entrectinib was dependent on expression of the TRKCK fusion protein. In xenograft models, entrectinib treatment at clinically relevant doses resulted in tumor regression, which was accompanied by elimination of residual cancer cells from the bone marrow. The clinical relevance of activated tyrosine kinase signaling in AML has been validated by the efficacy of selective tyrosine kinase inhibitors. Our preclinical data demonstrate the potential of entrectinib as an effective treatment for patients with NTRK rearranged acute myeloid leukemias and provide rationale for the clinical development of entrectinib in molecularly defined hematologic malignancies. Entrectinib is currently the subject of an ongoing global Phase 2 basket study to enrolling patients across multiple tumor histologies containing TRKOSI or ALK fusions.

type melanomas has been associated with other skin cancers, such as cutaneous squamous cell carcinoma due to MAPK pathway paradoxical activation mediated by CRAF. There is therefore a clinical need for novel agents targeting the MAPK pathway that do not have these undesirable properties. Here we present, REDX05358 that demonstrates subnanomolar binding affinity for BRAF and CRAF with high selectivity profile against a panel of 468 kinases that exhibits negligible paradoxical activation due to inhibition of both RAF nononers and dimers. As a result, REDX05358 not only inhibits MAPK signalling in BRAF V600E mutant tumor cells, but also in those harbouring NRAS and KRAS mutations. Furthermore, REDX05358 does not induce feedback reactivation of the pathway through its ability to sustain inhibition of MAPK signalling in CRC cell lines. Correspondingly, profiling of REDX05358 in a panel of CRC, melanoma and NSCLC cell lines shows it has potent anti-proliferative activity in cell lines harbouring BRAF or RAS mutations. REDX05358 is an orally bioavailable, well tolerated small molecule that has demonstrated in vivo efficacy in BRAF V600E CRC xenograft model. In contrast, first generation inhibitors such as Vemurafenib and dabrafenib have been reported to be ineffective in this genetic background in CRC cell lines and patients. Thus, we have developed a pan RAF inhibitor with unique pharmacological properties enabling it to have utility in treating BRAF and RAS mutant cancers.

### #5161 Inhibition of TBK1/IKBKE impacts tumor growth of KRAS-mutant colorectal cancers.

Susanna Stinson, 1 Jinhuair China, 2 Zhicheng Jia, 1 Kate S. Walker, 2 Zhi-Hua Cui, 1 Charles S. Fuchs, 2 David Dornan, 1

Inhibition of TBK1/IKBKE impacts tumor growth of KRAS-mutant cancers. We therefore synthesized the Pyrrole-Imidazole polyamide conjugate targeting KRAS oncogenic mutations is a promising approach against KRAS mutated colorectal and pancreatic cancers. Hiroki Nagase, Atsushi Takatori, Takayoshi Watanabe, Nobuko Koshikawa, Jason Lin. Chiba Cancer Ctr. Research Inst., Chiba, Japan. Although a tremendous amount of studies has been made to directly target oncogenic drivers, such as RAS and MYC, no drug is clinically available because of difficulties to develop RAS- or Myc-targeted anti-cancer therapeutics due to the peculiar 3D surface topology. One of major limitations of targeting the RAS pathway may be intrinsic or acquired resistance as seen in the other molecular target therapy. A new approach that directly target driver genes may provide a promising therapeutic approach in MM and other PERK-dependent tumors. PERK (PKR-like endoplasmic reticulum kinase) is a serine-threonine kinase associated with endoplasmic reticulum membrane. Together with ATF6 and IRE1, PERK is a key effector of the Unfolded Protein Response (UPR), a network of signaling pathways that ensures protein homeostasis in the endoplasmic reticulum. Multiple Myeloma (MM) and other protein-secreting tumors are highly dependent on UPR for survival, and inhibition of PERK may be an effective strategy to inhibit growth of these tumors. Here we describe the in vitro and in vivo properties of NMS-E194, a novel potent and selective ATP-competitive PERK inhibitor belonging to the arylsulfonamide chemical class. NMS-E194 inhibits PERK kinase with a Ki of ca 1.5 nM in biochemical assay and possesses high selectivity towards a panel of 54 kinases. When tested in cell proliferation assays, NMS-E194 is preferentially active on multiple myeloma (MM) and diffuse large B cell lymphoma cell lines. In mechanism of action studies, NMS-E194 shows a bi-phasic behaviour: at low nanomolar doses it activates PERK, causing ATF4 accumulation, while at >200 nM it inhibits PERK and downstream pathway, inducing apoptosis. NMS-E194 possesses a favourable in vitro ADME profile and has promising PK properties in the mouse. NMS-E194 demonstrated strong anti-tumor activity following oral administration at 25 mg/kg daily to immune deficient mice harbouring luciferized KMS-11 cells in a disseminated growth model of MM, with no overt toxicity. Overall, the data available so far warrant further development of NMS-E194 and support PERK inhibition as a novel therapeutic approach in MM and other PERK-dependent tumors.
analysis suggested non-KRAS binding overall had little contribution to changes at the phenotypic level in colorectal cancer cell lines. We also the anti-cancer event is not only for colorectal but also pancreatic ductal adenocarcinoma (PDAC). Significant tumor reduction was observed in a mouse model of spontaneous PDAC. (LSL-KrasG12D+/Ptf1aCre+/Tgfr2rllox/flox). In animal studies of transgenic KrasG12D mice, treatment at 0.5 mg/kg created a tumor-free state within 3 months. These findings represent a significant step forward in the development of targeted therapies for pancreatic cancer, as well as other cancers with activating mutations in the ras oncogene.

**#5165** Novel Ras inhibitors DC070-547 and ADT-006 potently and selectively inhibit the growth of pancreatic tumor cells harboring constitutively activated Ras by blocking Ras-effector binding and signaling. Tyler E. Mattos,1 Kevin J. Lee,1 Xi Chen,1 Jacob Valiayvettilli,2 Luciana Madeira da Silva,2 Ashley S. Lindsay,3 Adam B. Keeton,1 Bing Zhu,1 Michael Boyd,2 Gary A. Piazza,1 University of South Alabama Mitchell Cancer Institute, Mobile, AL; ADT Pharmaceuticals, Inc., Orange Beach, AL.

Gain-in-function mutations in Ras genes cause constitutive activation of Ras and induction of downstream signaling pathways that drive tumor cell proliferation, survival, and metastasis. Such driver mutations occur in over 90% of pancreatic ductal adenocarcinomas (PDACs), making Ras an attractive cancer target. However, Ras is considered “undruggable,” given the lack of suitable surfaces on the protein for small molecule binding, as well as its high affinity for GTP binding. A phenotypic assay was developed to screen a library of indene derivatives for growth-inhibitory activity in tumor cells harboring constitutively active Ras versus tumor cells with low levels of active Ras. A novel compound series was identified that potently and selectively inhibits the growth of tumor cells with constitutively active Ras, while having minimal effects on tumor cells lacking constitutively active Ras or cells derived from normal tissues. Chemical optimization resulted in a drug development candidate, DC070-547, and several back-up analogs (e.g. ADT-006), which showed strong antitumor activity at doses that do not cause any discernible toxicity in preclinical mouse models. Here we report DC070-547 and ADT-006 inhibited the growth of PDAC cells with IC50 values of approximately 2 nM and 20 nM, respectively, in MIA PaCa-2 cells harboring constitutively active Ras and greater than 350-fold selectivity over BxPC-3 cells, which lack constitutively active Ras. Both compounds also decreased the clonogenic potential of MIA PaCa-2 cells at concentrations that inhibit their growth. Within the same low nanomolar concentration range, treatment of recombinant human K-Ras, MIA PaCa-2 cell lysates, and intact MIA PaCa-2 cells blocked Ras-effector interactions as evident by performing active Ras pull-down assays using GST-RAF1-RBD (glutathione agarose). Treatment of intact MIA PaCa-2 cells also inhibited RAF/MEK and PI3K/AKT phosphorylation within the same concentration range. These results demonstrate that DC070-547 and ADT-006 inhibit PDAC cell growth by blocking Ras-effector interactions, supporting further evaluation of this novel class of Ras inhibitors for the treatment of pancreatic cancer, as well as other Ras-driven cancers.

**#5166** Sensitivity of melanoma cells to a novel class of Ras inhibitors. Kate M. Saville,1 Kevin Lee,1 Tyler E. Mattos,1 Xi Chen,1 Jacob Valiayvettilli,2 Kristy Berry,1 Veronica Ramirez-Alcantara,1 Bing Zhu,1 Adam Keeton,1 Michael Boyd,2 Gary Piazza,1 Ashley S. Lindsay,3 University of South Alabama Mitchell Cancer Inst., Mobile, AL; ADT Pharmaceuticals, Inc., Mobile, AL.

A high percentage of human cancers arise from mutations in the ras gene that encodes an abnormal Ras protein locked in a constitutively active GTP-bound state that promotes tumor cell proliferation, survival, and metastasis. These gain-in-function mutations in the ras gene or constitutive activation of tyrosine kinase receptors upstream of the Ras protein drive tumor cell growth by activating Raf/MAPK and PI3K/AKT signaling pathways. Ras has been an elusive drug target for which no inhibitors are available to treat Ras-driven cancers. Screening a library of indene derivatives in a differential phenotypic assay identified a novel compound class displaying high potency and selectivity to inhibit the growth of tumor cells harboring mutant Ras relative to tumor cells with wild type (WT) Ras. Lead optimization resulted in a drug development candidate (DC070-547) and several back-up analogs (e.g. ADT-006) with IC50 values in the low nanomolar range and selectivity indices of 100 fold or greater to inhibit the growth of tumor cells with constitutively activated Ras relative to tumor cells with low levels of activated Ras. Sensitivity among a large panel of tumor cell lines to this compound class strongly correlated with levels of activated Ras, but did not appear to be limited to a specific ras gene mutation or Ras protein isoform. Here, we report that DC070-547 and ADT-006 potently and selectively inhibit the growth of the human melanoma cell line, SK-MEL-2, harboring a mutation in the ras gene that encodes the constitutively active N-Ras protein with IC50 values of 7 and 25 nM, respectively. In addition, both compounds potently inhibited the growth of the murine melanoma cell line, B16-F10 with WT ras, but harboring a mutation in a tyrosine kinase receptor upstream of Ras, specifically PDGFRα, which results in high levels of active, GTP-bound Ras. This indicates that both compounds have the potential to disrupt Ras signaling, B16-F10 cells were incubated with the compounds before being subjected to Western blotting for phosphorylated signaling molecules downstream of Ras. Treatment reduced levels of phosphorylated c-Raf and MEK at concentrations that inhibit tumor cell growth. These findings support further investigation of this novel class of Ras inhibitors for the treatment of Ras-driven melanoma.

**#5167** Stem-like colorectal cancer cell lines show response to the ERK1/2 inhibitor, SCH772984, alone and in combination with neratinib. Rekha Patil,1 Ning Wei,1 Nan Song,1 Shao-yu Wu,2 S. Kim,1 Patrick G. Gavin,1 Peter C. Lucas,1 Ashok Srivinasa,1 Samuel A. Jacobs,1 Soonmyung Paik,3 John C. Schmitz,2 Kay Pogue-Gelle1,1 NSABP, Pittsburgh, PA; University of Pittsburgh Cancer Institute, Pittsburgh, PA; NSABP and University of Pittsburgh School of Medicine, Pittsburgh, PA; NSABP and Yonsei University College of Medicine, Seoul, Republic of Korea.

Background: We have recently shown an association of colorectal tumor subtypes with differential response to chemotherapies in patients (pts), and to targeted therapy in cell lines. Pts enrolled in NSABP/NRG C0-07 with stem-like tumors had a poor prognosis regardless of stage or treatment, highlighting the importance of finding new treatments for stem cell-like, KRAS mutant (mt) cells. These stem-like (mt) cell lines of the intrinsic inflammatory subtype were sensitive to the combination of MEK-162 and neratinib, but stem-like subtype cell lines were resistant regardless of KRAS mt status. The purpose of this study was to extend our observations to xenograft models and to identify new agents that target the stem-like subtype. Methods: KRAS mt cell lines of the inflammatory (NCI-H747) or stem-like (SW-480) subtype were used in xenograft models to test inhibition of tumor growth by MEK-162 and neratinib, alone or in combination. Five stem-like cell lines with KRAS wt (C2BBE1, H5675T) or KRAS mt (SW480, SW620, HCT116), and two KRAS mt inflammatory cell lines (NCI-H747, SW837) were tested for cell viability after treatment with SCH772984 alone or in combination with neratinib. Results: In vivo analysis showed that treatment of NCI-H747 xenografts with a combination of MEK-162 (3mg/kg) and neratinib (10mg/kg) led to significant tumor regressions compared to treatment with either drug alone (p ≥0.0001 v neratinib alone; p ≥0.002 v MEK-162 alone). In contrast, MEK-162 alone was able to inhibit tumor growth of stem-like cell line (SW480) xenografts (p ≥0.0061 v control) but neratinib was ineffective (p ≥0.145 v control) as a single agent and did not add to MEK-162. Our in-vitro and in-vivo data showed that inhibition of p-ERK directly correlated with sensitivity to the combination, but resistance to inhibition in the inflammatory subtype, SCH772984 significantly inhibited cell viability of both inflammatory (IC50 1-2 μM) and stem-like subtype (IC50 1-2 μM) cell lines. The combination of neratinib (0.125 μM) and SCH772984 (1 μM) was effective at decreasing cell viability by 60-70% in both inflammatory and stem-like cell lines. Inhibition of ERK phosphorylation was correlated with loss of cell viability. Conclusion: The combination of MEK and neratinib work synergistically to decrease tumor growth in inflammatory subtype, SCH772984 decreases the viability of stem-like colon cancer cell lines, and works synergistically with neratinib. The use of SCH772984 alone, but more potently in combination with neratinib, may represent a therapeutic approach for pts with stem-like tumors, a finding that underscores the potential importance of employing subtype analysis in the diagnosis of colon cancer and potentially as a guide to new therapies. Support: PA DoH, which disclaims certain responsibility.

**#5168** KO-947, a potent ERK inhibitor with robust preclinical single-agent activity in MAPK pathway dysregulated tumors. Francis Burrows,1 Linda Kesler,1 Jeffrey Chen,2 Xin Gao,3 Rasmus Hansen,2 Shuangwei Li,1 Carol Thach,2 Levan Darjania,2 Yvonne Yao,1 Yi Wang,2 Ata Zarieh,2 Ke Yu,2 Tao Wu,2 Jingchuan Zhang,2 Dana Hu-Lowe,2 Liansheng Li,1 Pingda Ren,1 Yi Liu,1 Kara Oncology, LaJolla, CA; Wellspring Biosciences, LaJolla, CA.

The Ras/RAF/MEK pathway is a major driver of malignant progression, particularly in cancers arising from mutations in Ras, RAF and NFI. Although both RAF and MEK inhibitors have been approved for treatment of melanoma, their clinical activity is commonly limited by acquired resistance due to reacti- vation of the pathway downstream of their targets. Since the ERK1/2 kinases are the final node in the MAPK signaling pathway, they are not subject to the feed-back reactivation mechanisms that can undermine RAF or MEK blockade, offering the possibility of clinical benefit in settings where earlier drugs are ineffec- tive. Here we describe a characterization of KO-947, a potent and selective
Design and development of a tankyrase inhibitor STP06-1002 as an anticancer therapeutic agent.

Kyunjung Kim,1 Uk Il Kim,1 Hyung Tae Bang,1 Jihye Yoon,1 Jin Ha Hwang,1 Jung-Nyong Heo,1 Kwang-Rok Kim,1 Hwan Jung Lim,1 Jae-Hee Lee,2 Eun Young Lee,2 Seul Lee,2 Dong-Hoon Jin1,1 IST Pharm, Siheung-si,RepublicofKorea; 2KoreaResearchInstituteofChemicalTechnology, Parnas, Chungbuk-si,RepublicofKorea.

Background: The Wnt/β-catenin signaling pathway plays a pivotal role in numerous biological processes and its dysregulation has been implicated in diverse oncogenic initiation. Abrupt overactivation of the Wnt/β-catenin pathway due to overexpression and accumulation of the β-catenin has been often observed in colorectal cancer (CRC). As a member of PARP family (PARPs isoform), tankyrase (TNKS) regulates stability of the β-catenin destruction complex through Axin poly-ADP ribosylation maintaining homeostasis of level of the β-catenin. Axin is a rate-limiting component of the destruction complex and inhibition of tankyrase stabilizes Axin level to prevent subsequently CRC development by downregulation of the Wnt target genes. We herein report on an orally-active tankyrase inhibitor STP06-1002 with excellent cellular potency, good ADME properties, and in vivo anti-tumor efficacy with moderate safety. Results: The novel tankyrase inhibitor STP06-1002 shows good inhibition activities with IC_{50} 29.9 nM (TNKS1) and 3.7 nM (TNKS2) and its excellent cellular potency with IC_{50} 6.7 nM (TCF/LEF), STP06-1002 also shows excellent selectivity against PARP1 isoform with IC_{50} > 10 μM. STP06-1002 has good ADME properties, particularly low CYP450 inhibition & induction in CYP panel, high permeability, and low hepatic first-pass effect. It also displays good in vivo pharmacokinetics in rats (B.A. [F] >60%) and dogs (27%). No significant toxicity issues are observed from cytotoxicity studies, hERG assay and Ames test. The off-target studies in both Pan Kinase panel (against 75 cancer-focused kinases) and Lead Profiling Screen (against 68 receptors and ion channels) prove its high selectivity. In the xenograft efficacy studies for in vivo proof-of-concept, the dose-dependent effect on Colo205DM (Wnt-dependent, KRAs wild type) shows tumor growth inhibition with 45% and DLD-1 (Wnt-dependent, KRAs mutant) with 60%. In the case of Wnt-independent cell lines HCT116 and RKO as negative controls, both did not show any tumor growth inhibition effects. Dose range finding study of rodent (rat) resulted in maximum tolerated dose of (MTD) 200 mg/kg/day, and the corresponding of non-rodent (dog) MTD of 30 mg/kg/day. Taking these promising preclinical observations in mind, we performed in vivo efficacy dose, MTD and HSTD (30 mg/kg/day) into an extended xenograft model. In light of the above findings, we conclude that STP06-1002 has a promising potential as an anticancer therapeutic agent.
cancers. Both APC and CTNNB1 mutations lead to cytosolic accumulation and nuclear translocation of β-catenin, and therefore constitutive activation of β-catenin/TCF4-mediated gene transcription. As such, the Wnt/β-catenin pathway has emerged as one of the most promising targets for colorectal cancer treatment. Despite tremendous efforts in the past decade, there are no small molecule Wnt inhibitors approved by the FDA for cancer treatment. Recent work in our laboratories has identified a series of benzimidazoles as potent Wnt/β-catenin inhibitors. Here, we show that several benzimidazoles displayed strong activities against Wnt/β-catenin signaling in colorectal cancer cells harboring mutations in CTNNB1 or APC. In particular, SR36324, the lead compound in this series, inhibited Wnt/β-catenin signaling in colorectal cancer HCT116 and DLD-1 cells with IC50 values of 4.1 and 3.7 μM, respectively. Moreover, the benzimidazole compounds exhibited potent activities against colorectal cancer cell proliferation under both standard cell culture conditions (adherent cells in complete medium containing 10% FBS) and conditions designed to enrich for cancer initiating cells. In addition, the benzimidazole compounds had no off-target effects on other pathways (e.g., STAT3 and mTORC1 signaling) in colorectal cancer cells, and were less antiproliferative to non-cancerous cancers. Together, our findings indicate that the benzimidazole compounds are promising candidates for development as novel therapeutic agents for colorectal cancer.

Canonical Wnt/β-catenin signaling is known to be associated with platinum resistance in ovarian cancer in which inhibitors hold promise for the treatment of refractory disease. Phosphodiesterase 10A (PDE10A) is a dual cyclic AMP and cyclic GMP phosphodiesterase isozyme recently implicated in colon cancer. PDE10A inhibition in colon cancer cells by siRNA or small molecule inhibitors increased cGMP levels and activated PKG to inhibit β-catenin signaling. A novel PDE10 inhibitor, ADT-061, was identified by screening a library of indene derivatives, and showed strong antineoplastic activity in the APC+/−/min-FCCC mouse (Lee K et al., unpublished data). Cyclic GMP and phosphodiesterases participate in the ovarian follicular development, although little is known about PDE10A expression in ovaries, especially with regard to a potential role in ovarian tumorigenesis. PDE10A protein was found to be expressed in various established ovarian cancer cell lines at higher levels than immortalized or primary ovarian surface epithelial cells. Pf-2545920, a known PDE10A inhibitor, and ADT-061 inhibited the growth of multiple ovarian tumor cell lines with IC50 values around 20 μM and 0.5 μM, respectively. Both compounds induced apoptosis after 24 h treatment, as measured by PI/Annexin V staining and PARP cleavage. Pf-2545920 and ADT-061 induced phosphorylation of VASP at Ser157 and Ser239 in various ovarian cancer cell lines, indicating activation of cyclic AMP and cyclic GMP signaling, respectively. Treatment also decreased levels of β-catenin and downstream targets of TCF-dependent transcription, including c-MYC, survivin and cyclin-D1. Homozygous knockout PDE10A clones of Ov-90 ovarian cancer cell line obtained using CRISPR/Cas9 showed decreased clonogenic potential, decreased Pf-2545920-mediated VASP phosphorylation and β-catenin, c-MYC and survivin expression. Ongoing efforts are focused on the development of more potent ADT-061 analogues. These observations support further study of a role of PDE10A in ovarian tumorigenesis and the development of ADT-061 or analogs for the treatment of refractory ovarian cancer as well as the prevention of malignant recurrence.

#5175 γ-Mangostin, a natural xanthone derivative targets Wnt signaling pathway in colon cancer cells. Balaji Krishnamachary,1 Dharmalingam Subramaniam,2 Thomas Attard,1 Seth Seppert,3 Shirikant Anant.2 Children’s Mercy Hospital, Kansas City, MO; 2University of Kansas Medical Center, Kansas City, KS.

Background: Colorectal cancer is the third most common cancer in incidence and cause of death in the United States. The current treatment modalities include chemotherapy, radiation, and surgery. Many people are genetically predisposed for colon cancer through mutations in genes such as adenosomatous polyposis coli (APC). While the absence of APC causes aberrant Wnt/β catenin signaling, the APC mutations are found in more than 80% of colorectal tumors. γ-Mangostin is a major bioactive compound present in Mangosteen (Garcinia mangostana) which possesses significant anti-cancer activity. Herein, we investigated the effects of γ-Mangostin on colon cancer growth and elucidated its mechanistic action through Wnt signaling pathway. Methods: HCT116, SW480 and RKO cell lines were used in the study. The effects of γ-Mangostin on cell proliferation were assessed by hexosaminidase and clonogenicity assays. Effects of γ-Mangostin on apoptosis were evaluated by cell cycle and western blot analysis. Moreover the effect of γ-Mangostin on colonospheres formation was also evaluated. Furthermore, the effect of γ-Mangostin on Wnt signaling proteins was evaluated by western blot analysis. γ-Mangostin was also investigated on the HCT116 subcataneous tumor xenograft model implanted in five-week-old male athymic nude mice. Further, the effect of γ-Mangostin was assessed by the specific marker expression in tissue samples by western blot analysis and immunohistochemistry. Results: γ-Mangostin treatment resulted in a dose and time dependent inhibition of proliferation and colony formation on all the three cell lines. Treatment also induced colonic cancer cells to undergo G0/G1 and S-phase arrest. Apoptosis was confirmed by increased levels of Bax/Bcl2 ratio, coupled with a reduction in cyclin D1. γ-Mangostin significantly reduced the number and size of colonospheres. Moreover, γ-Mangostin treatment decreased the expression of Wnt signaling proteins, which suggest that γ-Mangostin inhibits the colon cancer growth through Wnt signaling pathway. To determine the effect of γ-Mangostin on tumor growth in vivo, nude mice harboring HCT116 tumor xenografts in their flanks were administered with 5mg/Kg γ-Mangostin intraperitoneally for 21 days. γ-Mangostin treatment significantly reduced the tumor growth, with notably lower tumor volume and weight. Western blot and immunohistochemistry analyses revealed significant decrease in the expression of β-catenin signaling proteins. Conclusion: Together, these data suggest that γ-Mangostin inhibits colon cancer growth through Wnt signaling pathway. γ-Mangostin may be a potential therapeutic agent for colon cancer.

#5176 E7386, an orally active CBP/beta-catenin modulator, effects tumor microenvironment, resulting to the enhancement of antitumor activity of lenvatinib. Yoichi Ozawa, Yusaku Hori, Kazuhiro Yamada, Yasuhiro Fujiwara, Junji Matsui, Tomohiro Mattsumiya, Takashi Owa. Eisai co., Ltd., Ibaraki, Japan.

E7386, a novel orally active CBP/beta-catenin modulator, has an impact on cancer cells with aberrant activation of Wnt/beta-catenin signaling pathway driven by adenosomatous polyposis coli (APC) mutation or beta-catenin mutation and shows significant antitumor activity in xenograft models. CBP/beta-catenin transcriptional activation has an important role in not only malignancy of cancer cells but also regulation of tumor microenvironment such as fibroblast, pericyte, endothelial cells and immune cells. In this study, we investigated E7386 effect on tumor microenvironment and if it leads to enhance antitumor activity of lenvatinib. Lenvatinib is a potent anti-angiogenic inhibitor targeting vascular endothelial growth factor receptors, fibroblast growth factor receptors and other proangiogenic and oncogenic kinases. Firstly, we tested the combination of E7386 with lenvatinib in Wnt-1 tumor isogenic models, where tumors isolated from MMTV-Wnt1 transgenic mice were inoculated in mice. While E7386 and lenvatinib individually suppressed tumor growth and caused tumor dormancy, the combination resulted in approximately 75% tumor reduction. To clarify the effect on tumor microenvironment, we tested an isograft model of 4T1 murine breast cancer cells which was resistant to E7386 in vitro proliferation. E7386 and lenvatinib individual treatments showed a significant antitumor effect, but the antitumor effect of the combination was significantly superior to that of each mono-treatment. Therefore, we compared effects of E7386 and lenvatinib on tumor microenvironment in immunohistochemical analysis using CD31 Ab as an endothelial marker and alpha-SMA Ab as a pericyte and cancerous fibroblast marker. E7386 significantly decreased alpha-SMA positive cells and microvessel density in tumors. In addition, remaining tumor vessels were not covered with pericytes. In lenvatinib treated tumors, greater reduction of microvessel density was observed than in E7386 treated tumors, but the vessel foci covered with pericytes, which are known to be resistant against VEGF inhibitors, were remained. In combination treatment, most of the tumor vessels disappeared. The enhancement of antitumor activity in the combination was also observed in SEKI human melanoma xenograft model which is relatively resistant to lenvatinib. These data suggest E7386 sensitizes tumor to lenvatinib through the modulation of the tumor microenvironment. Taken together, E7386 shows not only antitumor activity via the effect on cancer cells but also through the modulation of tumor microenvironment, and the treatment of E7386 with lenvatinib is a novel combination therapy to overcome resistance to VEGF inhibitors.
**EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Oncogenes and Tumor Suppressors as Therapeutic Targets**

**#5177** E7386: First-in-class orally active CBP/beta-catenin modulator as an anticancer agent. Kazuhiko Yamada,1 Yusaku Horii,1 Atsumi Yamaguchi,1 Masahiro Matsuki,1 Shuntaro Tsukamoto,1 Akira Yokoi,1 Taro Semb,1 Yoichi Ozaawa,1 Satoshi Inoue,1 Yuji Yamamoto,1 Kentaro Iso,1 Kazukata Nakamoto,1 Hitoshi Harada,1 Naoki Yoneda,1 Atsushi Takekura,1 Masayuki Matsukura,1 Kenji Kubara,1 Takesao Odagami,1 Masao Iwata,1 Akihiko Tsuuraoka,1 Toshimitsu Uenaka,1 Junji Matsui,1 Tomohiro Matsushima,1 Kenich Nomoto,1 Hisayuki Kojii,1 Takashi Owa,1 Eisai co., Ltd., Ibaraki, Japan; 2PRISM Pharma Co., Ltd., Japan.

Carcinogenesis is often accelerated by the aberrant activation of components of Wnt signaling pathway, especially, APC and beta-catenin are frequently mutated in various cancers. Therefore, Wnt signaling pathway is thought to be one of the attractive therapeutic targets. PRI-724 generated by PRISM Pharma is a small molecule inhibitor of beta-catenin and its transcriptional coactivator CREB binding protein (CBP) thereby specifically modulating Wnt/beta-catenin signaling pathway by intravenous continuous infusion. Here we firstly generated orally active small molecular inhibitor, E7386. E7386 disrupted the interaction between beta-catenin and CBP in co-immunoprecipitation assay. E7386 inhibited canonical Wnt signaling pathway (TCF reporter gene activity in LiCl-stimulated HEK-293 and MDA-MB-231 in a dose-dependent manner with IC50 values of 55 nmol/L and 73 nmol/L, respectively. E7386 modulated the expression of Wnt signaling pathway related genes including AXIN2 and other genes, which were down-regulated by artificial knockdown of beta-catenin. PRI-724 is the prototype that indicates that E7386 controls the expression of Wnt target genes through modulation of beta-catenin/CBP interaction. Next we investigated anti-polyposis effect in ApcMin/H11001 mice as an in vivo proof of mechanism model. ApcMin/H11001 mice develops polyps in the intestinal tract caused by the aberrant activation of Wnt/beta-catenin signaling pathway. Oral administration of E7386 significantly suppressed the number of polyposis in a dose dependent manner at the dose range from 8.5 to 50 mg/kg. In addition, E7386 significantly changed the expressions of Wnt related genes in whisker follicle of ApcMin/H11001 mice. Therefore, Wnt/beta-catenin signaling pathway is a new target for the treatment of polyposis and other cancers.

**#5178** CB002, a novel p53 pathway-restoring compound that induces apoptosis through the pro-apoptotic protein NOXA. Liz J. Hernandez Borroto, Shengliang Zhang, David T. Dicker, Wafik S. El-Deiry. Fox Chase Cancer Center, Philadelphia, PA.

p53 is a transcription factor that becomes stimulated upon genotoxic and cellular stress signals ultimately leading to the transcriptional activation of genes involved in processes such as DNA repair, cell cycle arrest, and apoptosis etc. TP53 is the most commonly mutated tumor suppressor and this is associated with cancer initiation, cancer progression and therapy resistance. P53-targeted therapy has proven to be challenging because direct functional restoration of p53 as a transcription factor has been difficult to achieve. We have taken a different approach by investigating small molecules that functionally restore the p53-signaling pathway instead of direct p53 targeting. To date there is no approved drug that restores the p53 pathway in cancer cells with mutant p53. Therefore, we performed a high-throughput screen to identify such molecules. We identified a family of small molecules, CB002 and its structural analogs, as targeted agents in DLBCL cell lines. A beneficial was observed with the combination of CB002 and an early steps in the metastatic cascade by affecting the tumor microenvironment have led to the development of promising small molecule targeting agents. The tyrosine kinase inhibitors, dasatinib and nilotinib (synergism in 2/3 cells) and the BCL2 inhibitor venetoclax (synergism in 3/4 cells). The latter synergism could be linked to the previously mentioned negative trend between TK-216 IC50 values and the presence of BCL2 translocation. Conclusion. The novel small molecule TK-216 presented strong preclinical and clinical development as single agent and in combination.

**#5179** The first in class FLI1 inhibitor TK-216 presents both in vitro and in vivo anti-tumor activity in lymphoma. Filippo Spriano,1 Chiara Tarantelli,2 Eugenio Gaudio,3 Elaine YL Chung,4 Alberto J. Arribas,5 Luciano Cascione,6 Sara Napo,2 Ivo Kwee,2 Andrea Rinaldi,2 Vincenzo Arcuri,7 Emanuele Zucca,2 Anastasios Stathis,2 Katti Jessem,2 Brian Lannuzzi,2 Jeffrey Trotersky,2 Francesco Bertoni1,1 Institute of Oncology Research - IOR, Bellinzona, Switzerland; 2Oncology Institute of Southern Switzerland - IOSI, Bellinzona, Switzerland; 3Oncological Therapies, San Diego, CA; 4Georgetown University, Lombardi Institute, Washington, DC.

Background. ETs transcription factors, such as FLI1 and SPIB, are recurrently deregulated in human lymphomas (Bonetti et al, Blood 2013; Lentz et al, PNAS 2008). The small molecule YK-4-279 inhibits binding of EWSI-FLI1 fusion protein to RHA resulting in growth arrest and apoptosis in Ewing sarcoma cells (Erkaniz et al, Nat Med 2009) and we previously showed that YK-4-279 has in vitro anti-lymphoma activity (Chung et al, AACR 2015). TK-216 is a YK-4-279 clinical derivative that is in phase 1 for patients with relapsed or refractory Ewing sarcoma (NCT02657005). Here, we present extensive preclinical results obtained with TK-216 in lymphoma models. Methods. 56 cell lines [27 diffuse large B cell lymphoma (DLBCL); 10 mantle cell lymphoma; 6 marginal zone lymphoma; 5 anaplastic large T-cell lymphoma; 8 others] were exposed to TK-216 increasing doses for 72h using a Tecan D300e Digital Dispenser and 384well plates. Cell viability was measured with MTT to be in vitro used in were performed in NOD-SCID mice and treatments started with approximately 60 mm3 tumor volumes. Results. TK-216 displayed high activity: median IC50 was 449 nM (95%CI: 367-506). Sensitivity was not affected by the lymphoma cell of origin [B vs T; activated B cell type (ABC) vs germinal center type DLBCL] or MYC and TP53 status. There was a non-statistically significant trend for lower sensitivity in cell lines bearing BCL2 chromosomal translocation (P=0.07, DLBCL only; P=0.06, all cell lines). Anti-tumor activity was mainly cytotoxic as confirmed by performing cell cycle analysis and Annexin V staining in 6 DLBCL cell lines (TM80, U2932, HBL1, OCI-LY-18, WSU-DLCL2, DOHH2 for 24, 48, 72h), in which a time-dependent apoptosis was preceded by G2/M arrest. Anti-tumor activity was confirmed in DLBCL. TM80 xenografts. Compared with control group (n=10), mice treated with TK-216 (100 mg/Kg, BID; n=9) clearly presented a reduction in tumor growth, already evident at day 3 and becoming much stronger with time (D3, D5, D8, D11: P<0.01; D13, P not available since control group had to be stopped due to tumor volume) and a 4 times reduction in tumor volume at D11 (P<0.01). TK-216 was tested in combination with other targeted agents in DLBCL cell lines. A benefit was observed with the combination of TK-216 with the immunomodulator lenalidomide (synergism in 2/3 cells) and the BCL2 inhibitor venetoclax (synergism in 3/4 cells). The latter synergism could be linked to the previously mentioned negative trend between TK-216 IC50 values and the presence of BCL2 translocation. Conclusion. The novel small molecule TK-216 presented strong preclinical and anti-lymphoma activity, which provides evidence for further preclinical and clinical development as single agent and in combination.

Background: In advanced prostate cancer (PCa), cells escape from the primary tumor and enter the bloodstream, preferentially targeting the bone. This results in weakened bones, spinal compressions, fractures and intense pain. Efforts to interfere with early steps in the metastatic cascade by affecting the tumor microenvironment have led to the development of promising small molecule targeting agents. The tyrosine kinase inhibitors, saracatinib and dasatinib, have been shown to inhibit angiogenesis, seed and down-regulators with MTT to be in vivo used in were performed a strong effect on PCa clinical development as single agent and in combination.
When ISFs were combined with Src inhibitors, both phases were increased with a concomitant decrease in S phase cells. In transwell migration studies, all agents significantly decreased the number of cells found on the bottom of the membrane: dasatinib > saracatinib > ISFs. Lower doses of Src inhibitors were needed to produce inhibition of migration when ISFs were added to the treatment. Invasion studies with CDDP and MCL-MLN cells suggest that ISFs can reduce metastatic activity by 39% and 35%, respectively. Therefore, by adding ISFs, lower doses of inhibitors might be used to achieve optimal response and decrease toxicity. Conclusions: In vitro studies suggested that a combination of a Src inhibitors and ISFs, at non-cytotoxic doses, results in greater inhibition of metastatic or invasion activity than either alone. Further studies are needed to determine if this strategy could be used clinically to treat patients with lower doses of small molecule inhibitors by including soy isoflavone concentrates in the treatment regimen.

**#5181 Targeted knockdown of MYC in AML cells using G-quadruplex interacting small molecules.** Megan A. Turnidge,1 Apurvi Patel,1 Justin J. Montoya,1 David W. Lee,1 Daniel H. Wai,1 Vijay Gokhale,1 Laurence Hurley,1 Robert J. Arceci,1 David O. Azorsa,1 University of Arizona College of Medicine - Phoenix, Phoenix, AZ; 2University of Arizona School of Pharmacy, Tucson, AZ.

Acute Myeloid Leukemia (AML) is a disease that occurs when genomic changes alter expression of key genes, causing cells to resume an undifferentiated state, proliferate, and maintain tumor growth throughout the body. Recently, there has been an increase in efforts toward developing therapies that specifically target the protein products of these aberrantly expressed genes. However, many of the proteins are difficult to target because of structural challenges, protein overexpression that requires high drug doses, or mutations that confer resistance to therapy. One potential type of targeted therapy that circumvents these issues is the use of small molecules that stabilize DNA secondary structures called G-quadruplexes. G-quadruplexes are present in the promoters of many potential oncogenes, and have regulatory roles in their transcription. This study analyzes the therapeutic potential of compounds that target the regulatory G-quadruplex in the MYC oncogene, which is commonly misregulated in AML. Treatment of the MYC expressing AML cell lines KG-1 and UT-7epo with the compound QQC-05 resulted in decreased expression of MYC mRNA, as determined by qPCR. Moreover, QQC-05 treatment induced a more significant decrease in c-MYC protein expression than similar treatment with JQ-1(+), as shown by western blot analysis. Treatment of AML cells with QQC-05 also decreased cell viability and increased apoptosis. Concurrent treatment of AML cells with QQC-05 and JQ-1(+) showed an antagonistic effect, indicating potential competition in the silencing of MYC. These results demonstrate that targeting the MYC promoter G-quadruplex in AML cells leads to knockdown of MYC expression and induces apoptosis. These results further support the development of a novel mechanism for targeting key genetic drivers in AML, and lay the groundwork for advances in treatment of other cancers driven by G-quadruplex regulated oncogenes.

**#5182 Targeting abnormal metabolism downstream of MYC in atypical teratoid/rhabdoid tumors.** Sabrina Wang,1 Jeffrey Rubens,1 Sariah Allen,2 Megan A. Turnidge,1 Apurvi Patel,1 Justin J. Montoya,1 David W. Lee,1 Daniel H. Wai,1 Vijay Gokhale,1 Laurence Hurley,1 Robert J. Arceci,1 David O. Azorsa,1 University of Arizona College of Medicine - Phoenix, Phoenix, AZ; 2University of Arizona School of Pharmacy, Tucson, AZ.

Atypical teratoid rhabdoid tumors (AT/RT) are deadly infantile brain tumors in dire need of new, targeted therapies. Recent molecular analysis revealed considerable tumor heterogeneity subdividing AT/RT into 3 distinct groups. The MYC subgroup has a dismal 5 year survival of 18.5%. MYC is known to drive reliance on glutamine for cellular metabolism suggesting that high-MYC expressing neoplasms may be sensitive to glutamine metabolic inhibitors. 6-Azido-5-oxo-L-norleucine (DON) is a glutamine antagonist that decreases reliance on glutamine for cellular metabolism suggesting that high-MYC expressing AT/RT cell lines BT12 and CHLA06 (31.2% of BT12 DMSO controls in G2/M phase vs low c-MYC expression were not affected. Cell cycle analysis demonstrated that DON caused cell cycle arrest in the G2/M phase for the high c-MYC expressing lines BT2 and CHLA06 (31.2% of BT2 DMSO controls in G2/M phase vs 54.5% after 10uM DON treatment and 27.4% vs 48.9% in CHLA06). In contrast the cell cycle was not affected by DON treatment in the cell lines with low c-MYC expression (21.3% DMSO vs 20.2% after 10uM DON in BT37). DON also increased apoptosis in cell lines with high c-MYC and induced DNA strand breaks (Western blot for c-PARP and p-H2A.X respectively). DON significantly improved survival in BT-12 high c-MYC expressing orthotopic mouse xenografts (median survival increased from 21 to 36 days, p<0.005; log-rank test). These data develop the framework for future clinical trials using glutamine antagonists to target the MYC subgroup of AT/RT.

**EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Oncogenes and Tumor Suppressors as Therapeutic Targets**

**#5183 The radioenhancer NBTXR3 brings anticancer efficacy to the cisplatin-based chemoradiation in vitro and in vivo.** Agnès Pottier,1 Sonia Vivet,1 Sébastien Paris,1 Bo Lu2.

NBTXR3 is a radioenhancer composed of functionalized hafnium oxide nanoparticles, designed to enhance the radiation dose deposit within the cancer cells when activated by ionizing radiations. NBTXR3 is intended for single intratumor administration and is currently evaluated in cancer clinical trials involving soft tissue sarcoma, head and neck (H&N), prostate, liver and rectum. Cisplatin (CDDP) is a cytotoxic agent considered to be a radiosensitizer and inhibits the repair of sublethal damage from irradiation. Concurrent chemoradiation using CDDP is the mainstream treatment for high risk H&N, cervix and non-small cell lung cancer patients. We hypothesized that adding NBTXR3 to radiation treatment (RT) may improve significantly anticancer effect of the chemoradiation combination. In vitro, no specific clonogenic toxicity was observed for the cells exposed only to NBTXR3. For the combined treatment CDDP was used at its IC50 concentrations. A marked and enhanced cell destruction (DEF) was observed with the CDDP combined treatment (added 6h or 16h prior to RT) and NBTXR3 (800μM, added 16h prior to RT) at ≥2Gy when compared to the single agent.

**CDDP  Treatment  NBTXR3  Irradiation  FaDu  Cell line (DEF*)  NCI-H460-Luc2 6h  16h  2Gy  1.0±0.06  1.2±0.06  6h  16h  1.4±0.15  1.3±0.25  16h  1.4±0.14  1.6±0.12  16h  1.0±0.12  1.9±0.32  16h  1.2±0.13  1.5±0.17  16h  1.8±0.23  2.6±0.45  6h  4Gy  1.3±0.08  2.2±0.16  16h  2.2±0.24  1.9±0.41  16h  3.1±0.64  3.8±0.48  16h  2.1±0.19  2.9±0.52  16h  2.1±0.31  2.8±0.39  16h  5.3±0.97  7.6±2.76

*For a given radiation dose, the DEF value was obtained by taking the ratio of the survival fraction in the control (radiotherapy alone) and the survival fraction of the treatment. In vivo, NBTXR3 enhanced the fractionated radiation treatment (5x2Gy) when injected intratumorally at 25% of tumor volume. NBTXR3 activated with ionizing radiation in combination with low dose of CDDP (1mg/kg administered 5 consecutive days, 2 hours prior to RT) delayed tumor growth when compared to single agent CDDP in combination with RT. These results strongly support the concurrent chemoradiotherapy regimen with NBTXR3 nanoparticles as an effective radioenhancer to increase the anticancer effect. A new phase I/II trial with H&N cancers patient receiving radiotherapy plus CDDP has been started evaluating the optimal dose, safety and preliminary efficacy of NBTXR3.

Trastuzumab has been widely used for the treatment of human epidermal growth factor receptor 2 (HER2)-overexpressing breast cancer, however, it cannot easily cross the blood-brain barrier (BBB) and is known to increase the incidence of brain metastases. In contrast, lapatinib has a low molecular weight and can cross the BBB and it could be useful to treat brain metastases in patients with HER2-positive breast cancer. To explore the impact of lapatinib on radiation response, we conducted an in vitro experiment using SKBR3 and BT474 breast carcinoma cells exhibiting HER2/neu amplification. Lapatinib down-regulated HER2 and increased HER2/neu expression; this might be used to achieve optimal response and decrease toxicity. Conclusions: In vitro studies suggested that a combination of a Src inhibitors and ISFs, at non-cytotoxic doses, results in greater inhibition of metastatic or invasion activity than either alone. Further studies are needed to determine if this strategy could be used clinically to treat patients with lower doses of small molecule inhibitors by including soy isoflavone concentrates in the treatment regimen.
ulated phosphorylated p-HER2, p-EGFR, p-AKT, and p-ERK. Pretreatment of lapatinib increased the radiosensitivity of SKBR3 (sensitizer enhancement ratio [SER]: 1.21 at a surviving fraction of 0.5) and BT474 (SER: 1.26 at a surviving fraction of 0.5) cells and hindered the repair of DNA damage, as suggested by the prolongation of radiation-induced γH2AX foci and the down-regulation of phospho-H2AX. Individual proteasome (p-DNAPKcs). Increases in radiation-induced apoptosis and senescence were suggested to be the major modes of cell death induced by the combination of lapatinib and radiation. Furthermore, lapatinib did not radiosensitize a HER2-negative breast cancer cell line or normal human astrocytes. These results suggest that lapatinib can potentiate radiation-induced cell death in HER2-overexpressing breast cancer cells, and provide a rationale for the efficacy of radiation functional repair using GFP reporter constructs in BRAFV600E mutant cell lines when treated with vemurafenib and radiation. Additionally, γ-H2AX westerns and nuclear foci staining indicated that vemurafenib pretreatment decreases the tumor cell’s ability to repair DNA double-strand breaks (DSB) in BRAFV600E cell lines. Vemurafenib also appeared to alter the kinetics of formation and resolution of 53BP1 and Rad51 nuclear foci in these cell lines. Evaluation of DSB functional repair using GFP reporter constructs suggests that BRAFV600E induces NHEJ repair, which can be attenuated by vemurafenib treatment. Finally, vemurafenib effectively increases radiosensitivity of BRAFV600E tumors in vivo. From our results, BRAF activating mutation appears to be associated with radioresistance. Vemurafenib selectively radiosensitizes both PTC and ATC cells through inhibition of DNA repair mechanisms. Combining vemurafenib and radiotherapy may improve therapeutic control for BRAFV600E mutant thyroid cancers.

**#5185 Targeting inhibitors of apoptosis in combination with radiation for the treatment of head and neck squamous cell carcinoma.**

Linlin Yang, Bhavna Kumar, Tianyun Li, Thenodoros N. Teknos, Arnav Chakravarti, Terence M. Williams, Ohio State Univ. Comp. Cancer Ctr., Columbus, OH.

Background and purpose: Evasion of apoptosis contributes to radioresistance of head and neck squamous cell carcinoma (HNSCC), calling for novel strategies to overcome apoptotic resistance. Second mitochondria-derived activator of caspase (SMAC) - mimetics are a class of targeted drugs that antagonize selected inhibitor of apoptosis protein (IAP) to block pro-survival signaling, and eventually induce apoptosis. The present study was designed to investigate the radiosensitizing effect of one SMAC mimetic, LCL161, in HNSCC and the underlying mechanisms for radiosensitization. Material and methods: We analyzed the correlation between apoptotic molecules and HPV status in HNSCC via miRNA expression using The Cancer Genome Atlas (TCGA) database, as well as protein expression in 6 HNSCC cell lines by immunoblotting. We also examined cIAP1 expression on a tissue microarray (TMA) of HNSCC tumor specimens, and assessed its correlation with HPV status and patient outcome. Clonogenic survival and WST-1 assays were carried out to explore the potential of LCL161 as a radiosensitizer in HNSCC cell lines. Cell cycle analysis, Annexin-V assays and immunoblotting were performed to investigate effects of LCL161 on radiation induced cell apoptosis. Human tumor xenografts were generated to explore the radiosensitization effect of LCL161 on HPV[-] tumors in vivo. Results: TCGA database analysis and immunoblotting from HNSCC cell lines revealed that expression of cIAP1, Survivin, DIABLO, p56, IK-b, TNF-α, BCL-XL, Caspase-7, and Caspase-8 were elevated in HPV[-] compared to HPV[+] HNSCC tumors. IHC staining showed cIAP1 expression was associated with HPV[-] status (p=0.0239). In addition, cIAP1 expression was significantly higher in HNSCC compared with adjacent normal tissues (p=0.0003). In univariate analysis, cIAP1 was significantly associated with poor overall survival (p=0.0359). LCL161 degraded cIAP1 at nanomolar concentrations but has minimal single-agent cytotoxicity with IC50 range of 32 μM – 95 μM. Interestingly, we found that LCL161 could induce radiosensitization only in HPV[-], but not in HPV[+] HNSCC cells. Mechanistic studies showed LCL161 mediated radiosensitisation was associated with increased cell apoptosis, with enhanced activation of caspases-3, -7, -8, and PARP. Finally, in vivo data showed that LCL161 degraded cIAP1, activated caspases, and profoundly radiosensitized two human HPV[-] HNSCC xenograft models. Conclusion: Taken together, our results demonstrate for the first time that cIAP1 is a potential prognostic and therapeutic biomarker for HNSCC patients. Through targeting cIAP1 and other IAP family members, LCL161 radiosensitizes HNSCC tumors, particularly HPV[-] tumors, via caspase activation and apoptosis induction. Taken together, LCL161 holds promise for future clinical development as a novel radiosensitizer in the treatment of HPV[-] HNSCC tumors.

**#5186 Vemurafenib selectively radiosensitizes BRAF V600E mutant papillary and anaplastic thyroid carcinoma cells.**

Ryan N. Robb, Linlin Yang, Terence Williams. The Ohio State University, Columbus, OH.

BRAF activating mutations act as oncogenic drivers and are highly prevalent in thyroid cancer, occurring in about 60% of papillary thyroid cancer (PTC) as well as 30–40% anaplastic thyroid cancer (ATC). MAPK signaling and treatment resistance is driven by BRAF mutations in thyroid cancer. Among the most common of these mutations is BRAFV600E, which can be selectively inhibited by vemurafenib. Using a panel of PTC and ATC cell lines we assessed how the presence/absence of BRAFV600E impacts radiation sensitivity. We used radiation clonogenic, comet assays, nuclear foci formation, immunoblotting, and mouse xenografts models to determine the effect of vemurafenib on PTC and ATC cells. Analysis of radiation clonogenic implicated higher radiosensitivity in cell lines containing the BRAFV600E mutation as compared to wild-type BRAF. Additionally, forced expression of BRAFV600E in a wild-type thyroid cancer cell line induced radioresistance. Vemurafenib inhibited MAPK signaling in V600E mutant cell lines, but showed no effect in BRAF wild-type cell lines. Vemurafenib pretreatment selectively radiosensitized BRAFV600E mutants in vitro, as assessed by clonogenic assays, with decreased cell survival on DNA repair in BRAFV600E lines when treated with vemurafenib and radiation. Additionally, γ-H2AX westerns and nuclear foci staining indicated that vemurafenib pretreatment decreases the tumor cell’s ability to repair DNA double-strand breaks (DSB) in BRAFV600E cell lines. Vemurafenib also appeared to alter the kinetics of formation and resolution of 53BP1 and Rad51 nuclear foci in these cell lines. Evaluation of DSB functional repair using GFP reporter constructs suggests that BRAFV600E induces NHEJ repair, which can be attenuated by vemurafenib treatment. Finally, vemurafenib effectively increases radiosensitivity of BRAFV600E tumors in vivo. From our results, BRAF activating mutation appears to be associated with radioresistance. Vemurafenib selectively radiosensitizes both PTC and ATC cells through inhibition of DNA repair mechanisms. Combining vemurafenib and radiotherapy may improve therapeutic control for BRAFV600E mutant thyroid cancers.

**#5187 Potent radiosensitization of adenoid cystic carcinoma in a patient derived xenograft model using the MDM2 inhibitor AMG 232.**

Amal Javid,1 Adam J. Swick,1 Lauryn Werner,1 Prashanth Prabakaran,2 Hong Hu,3 Kwangok P. Nickell,1 Irene Ong,1 Emmanuel Sampence,1 Justine Bruce,1 Gregory Hartig,1 Aaron Wieland,1 Jude Cannon,2 Paul Harari,1 Randall Kimple,3 1UW Madison, Madison, WI, 2UW-Madison, Madison, WI, 3April 2017

Purpose: Adenoid cystic carcinoma (ACC) is a relatively rare cancer that typically arises in major or minor salivary gland tissues of the head and neck. There are currently no approved systemic agents for ACC and no established data supporting the delivery of chemoradiation for ACC patients. The scarcity of validated preclinical model systems has hampered research efforts. We report the successful establishment and propagation of an ACC patient derived xenograft (PDX), genomic evaluation of cancer associated mutations, and in vivo response to MDM2 inhibition combined with radiotherapy. Because TP53 mutations are seen in <5% of ACCs, we investigated the role of a small molecule MDM2 inhibitor, AMG 232. Methods: An ACC PDX was established and assessed for common cancer-associated mutations using the Illumina TrueSeq Amplicon Cancer panel. Xenografts were treated with focal radiation with or without AMG 232. Focal radiation was delivered at 0, 2, 5, or 8 Gy x 8 fractions delivered twice weekly, with AMG 232 (50mg/kg) delivered daily by oral gavage. Tumor size was measured by caliper and comparisons between treatment groups made using a repeated measures ANOVA. A TCD50 was calculated by fitting log-transformed data to a dose-response curve and comparing using the extra-sum-of-squares f test. Target inhibition and anti-cancer effect was confirmed via immuno-blotting of tumor lysates, and IHC staining or in situ hybridization of relevant targets within FFPE sections of tumors harvested 2 and 48 hrs post treatment. Results: The histologic characteristics of the primary human tumor are maintained in subsequent murine passages of this ACC PDX. Tumoral profiling determined that the PDX was wildtype for TP53. AMG 232 alone resulted in no tumor growth delay. Combining AMG 232 with radiation delayed tumor growth in a dose dependent manner but did not result in sustained local tumor control. Strikingly, the combination of AMG 232 with RT (including low dose radiation of 2 Gy) produced dramatic tumor shrinkage and potent tumor control three months after the end of treatment. Target inhibition of MDM2 was confirmed by western blot of tumor lysates and IHC of FFPE samples taken 2 hrs post treatment. Antiproliferative and apoptotic effects were confirmed by western blot of tumor lysates and IHC of FFPE samples taken at 48 hrs post treatment. Conclusions: This study suggests that MDM2 inhibition may provide potent radiosensitization in TP53 WT ACC. While additional translational models are warranted, the powerful response profile observed suggests that phase I clinical trial evaluation of this combination is worthy for this challenging malignancy.

**#5188 Molecular radiosensitization in soft tissue sarcomas by telomerase-specific oncolytic adenovirus.**

Tadashi Komatsubara,1 Toshinori Omori,1 Hiroshi Tazawa,1 Kazuhiwa Sugiu,1 Yusuke Mochizuki,1 Yasuyaki Yamakawa,1 Shuhei Osaki,1 Joe Hasei,1 Tomohiro Fujiwara,1 Toshiyuki Kunisada,1 Yasuo Urata,2 Tsoshifumi Ozaki,1 Toshiyoshi Fujiwara1.

1UW-Madison, Madison, WI, 2OncolysBioPharma, Inc., Tokyo, Japan

INTRODUCTION: Treatment options for soft tissue sarcoma (STS) include surgical resection and adjuvant chemotherapy and radiotherapy. Despite the development of combined modality treatments in recent years, a significant proportion of patients with sarcomas respond poorly to adjuvant therapy, lead-
ing to local recurrence or distant metastasis. Therefore, there is an urgent need to develop novel therapeutic strategies for improvement of patient prognoses. We previously reported the therapeutic potential of OBP-301, a telomerase-specific oncolytic adenoviruses, and OBP-702, an armed OBP-301 expressing the wild-type p53 tumor suppressor gene against bone and soft tissue sarcoma cells. Furthermore, anti-tumor effect of OBP-301 and OBP-702 after radiation has been observed. While OBP-702 suppressed the viability of OBP-301-sensitive and -resistant osteosarcoma cells more efficiently, the combination effect of OBP-702 and radiotherapy has been unknown. In this study, we investigated the radiosensitizing effect of OBP-702 against human STS cells. METHODS: We used four human STS cell lines, HT1080 (fibrosarcoma), NMS-2 (malignant peripheral nerve sheath tumor), and SYO-1 (synovial sarcoma). Cells were irradiated 24 h after infection with OBP-301 and OBP-702, and cell viability was assessed by XTT assay 4 days after irradiation. Combined effect of radiation with OBP-301 and OBP-702 was analyzed with the CalcuSyn software (BioSoft). These cells were also analyzed for apoptosis and DNA damage using Western blot analysis. RESULTS: While OBP-301 and OBP-702 showed anti-tumor effect for STS cell lines respectively, HT1080 and NMS-2 were highly resistant to radiation. When combined with radiation, not only OBP-301 but also OBP-702 enhanced the inhibitory anti-tumor effect in all STS cell lines. The calculation of combination index demonstrated additive or synergistic anti-tumor effect in combination therapy. Further analysis revealed that OBP-301 and OBP-702 increased radiation-induced apoptosis in STS cells. Notably, the effect of OBP-702 was additive to the anti-tumor expression and interruption of anti-apoptotic myeloid cell leukemia 1 (MCL1) expression. DISCUSSION: Our study demonstrated that OBP-702 had much stronger anti-tumor effect compared to OBP-301, and sensitized radiotherapy to various types of osteosarcoma cell lines. Currently, the clinical trial of OBP-301 is performed, and preclinically OBP-702 accumulates good therapeutic results in various tumors. Thus, OBP-702 may provide a novel treatment strategy for STSs and wide application of radiotherapy for localized as well as advanced STSs.

#5190 Oncoprotein SET determines the radiosensitivity of hepatocellular carcinoma cell and antagonizing SET augments the effects of radiotherapy via reactivating PP2A-mediated Akt downregulation. Man-Hsin Hung,1 Chao-Yuan Huang,2 Chih-Ting Shih,3 Min-Hsien Tsai,4 Yung-Jen Hsiao,5 Tzu-I Chao,6 Feng-Shu Hsieh,7 Chung-Wai Shiu,8 Kuen-Feng Chen9 1Taipei Veterans General Hospital, Taipei, Taiwan; 2National Taiwan University Hospital, Taipei, Taiwan; 3National Taiwan University Hospital, Taipei, Taiwan; 4National Yang-Ming University, Taipei, Taiwan. Background: SET is a novel oncoprotein with growing evidence suggesting its roles in promoting the survival of hepatocellular carcinoma (HCC) and other types of malignant disease. Notably, pre-clinical data suggesting SET overexpression in cancer cell leaded to the development of resistance to various anticancer medications, and antagonizing SET reversely enhanced therapeutic efficacy. Radiotherapy (RT) is a commonly used anti-cancer modality, but its role for the treatment of HCC is largely limited for the concern of endogenous radioresistance. In this report, we explored the role of SET regarding the radiosensitivity of HCC cells. Furthermore, we explored whether SET serve as a valid target to enhance RT against HCC. Method: A panel of HCC cell lines, including Hep3B, PLC5, HA22T and H3597, were used for in vitro experiments, and the PLC5 subcutaneous xenograft mouse model was used for in vivo testing. HCC cells and tumors were treated with RT and/or SET antagonist and harvested for subsequent experiments. The viability of cancer cells were assessed by sub-G1, colony and sphere formation assay. Molecular events were determined by western blot and PP2A activity. Result: Through manipulating the expression of SET in cancer cells, we showed the crucial role of SET in mediating the effects of RT in HCC cells. Using colony formation and hepatosphere formation assay, we showed that RT significantly reduced the number and size of both tumor colony and sphere formed by Hep3B and PLC5 cells. In contrast, ectopic expression of SET in Hep3B and PLC5 cells abolished the effects of RT. More importantly, SET-knockdown oppositely potentiated the RT-induced growth inhibition in HCC cells. Based on our findings, we hypothesized that targeting SET may exert potential to enhance RT for the treatment of HCC. In order to validate our hypothesis, we tested the effects of RT in combine with a novel SET antagonist, EMQA, developed and characterized in our previous works. As expected, we found that EMQA significantly potentiated the anti-RT effects of RT in vitro and in vivo. Moreover, we found that antagonizing SET to restore PP2A-mediated p-Akt downregulation was responsible for the synergism between EMQA and RT. Conclusion Oncoprotein SET plays a critical role in affecting the radiosensitivity of HCC cells. Using SET antagonist plus RT showed promising results in pre-clinical HCC models, and yields further investigation.

#5191 A combination of Stat3 inhibitor and radiation for the treatment of malignant pleural mesothelioma. Seiji Matsumoto, Hiroshi Doi, Akihiro Fu- kuda, Tohoru Nakamichi, Ayaumi Kuroda, Masaki Hashimoto, Terushia Takuwa, Nobuyuki Kondo, Seiki Hasegawa. Hyogo College of Medicine, Nishinomiya, Hyogo College of Medicine, Nishi

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Preclinical Radiotherapeutics

#5192 Selection of radiosensitizers based on HRAS mutation in head and neck cancer. Michael M. Fisher, Adam D. Swick, Kwanqop P. Nickel, Randall J. Kimple. Univ. of Wisconsin-Madison, Madison, WI. Purpose/Objective(s): The ability of activated HRAS to promote radiation resistance and predict for sensitivity to potential radiosensitizers was tested in a head and neck cancer model system. Materials/Methods: Mutations in HRAS, KRAS, and NRAS were analyzed using cBioPortal in a head and neck cancer cohort. The Illumina TruSeq Amplicon Cancer panel was used to screen a panel of head and neck cancer cells for mutations in RAS-family genes. Cell growth and radiation survival was assessed using clonogenic survival assay. Immuno- blotts were used to confirm target activation/knockdown in overexpression and knockdown studies. A tumor control dose 50% (TCD50) assay was employed to investigate radiosensitization of a mutated-HRAS head and neck cancer cell line in a flank xenograft model in nude mice. Results: Activating mutations in one of the three RAS genes are seen in 5-10% of head and neck cancer patients. Mutations in HRAS represent over 50% of these. Screening our panel of head and neck cancer cell lines identified a canonical activating mutation in HRAS (i.e. G12V) in SCC22B. Consistent with known roles for activated HRASG12V, SCC22B is relatively insensitive to both cetuximab and radiation. Using both in vitro and in vivo studies, cetuximab exhibited no ability to radiosensitize SCC22B. Cetuximab treatment decreased AKT, but not ERK activation. Direct inhibition pathways downstream of HRAS by selumetinib (MEK/ERK) or BEZ235 (PI3K/MTOR) decreased target protein activation and resulted in significant growth inhibition in a Stat3 inhibitor (BBI-608 : napabucasin). Treatment with either selumetinib or BEZ235 radiosensitized HRASG12V expressing cells (SER 1.3-1.8) but had more modest effects on cells with wildtype HRAS. siRNA knockdown of HRAS radiosensitized SCC22B, but not SCC1 or SCC6 cells relative to non-targeting control. Overexpression of HRASG12V conferred relative radioresistance in wildtype cell lines. In vivo assessment of the radiosensitizing effects of these compounds (TCD50) is pending. Conclusion: More than 5% of head and neck cancers harbor activating mutations in one of the RAS family of genes. These mutations lead to resistance to cetuximab, either as a single agent, or as a radiosensitizer. Inhibition of downstream targets such as the MEK/ERK and PI3K/MTOR pathways can radiosensitize tumors harboring activating mu-

NBTXR3 are hafnium oxide nanoparticles (NPs) used for a single intratumor administration as radioenhancer in combination with radiation therapy (RT) as part of multi-modality of cancer treatment. The size, shape and surface of the NPs have been designed to develop strong interactions with cancer cells - effective cell binding and uptake - and to persist within the tumor mass during the whole RT treatment. The high electron density of the NPs is responsible for an increased probability of interaction with incoming ionizing radiations (when compared to tumor tissues with low electron density) and an increased energy dose deposition within the cancer cells which results in an enhanced tumor destruction when compared to RT alone. NBTXR3 works similarly to the physical mode of action of RT, it does not rely on any biological system or target and constantly amplifies the radiation dose deposition ("on/off" activation). Here, we present the transferability of the approach from one type of cancer to the other by evaluating (i) the feasibility of the intratumor injection (intratumor availability of NBTXR3 nanoparticles by Computed Tomography (CT) or µCT) and (ii) the antitumor efficacy of NBTXR3 exposed to radiation. NBTXR3 NPs demonstrated a good intratumor availability and persistence across all tested tumor models (epithelial or mesenchymal origin), including human PDX tumor models. Notably, in PAC-120 tumor models, as the persistence of NBTXR3 NPs within the tumor mass was observed for more than 50 days which is equivalent to the entire duration of RT treatment. The antitumor efficacy was systematically enhanced in terms of tumor growth delay for animals treated with NBTXR3 and exposed to RT when compared to RT alone. NBTXR3 is currently in clinical trials in seven cancer indications including: soft tissue sarcoma, head and neck (H&N), liver, rectal and prostate. These preclinical studies support the rationale for the development of NBTXR3 across all cancer indications where radiation treatment is used.

Focal radiation enhances paclitaxel therapy in a mouse model of triple negative breast cancer. Maryland Franklin, Thomas Dailey, Wilbur Luedeke, MD; Bioresearch, Ann Arbor, MI.

Triple negative breast cancer (TNBC) accounts for 15-20% of all breast cancers in the US. In general, patients have poorer prognosis and therapeutic intervention is more challenging due to insensitivity to hormonal and anti-HER2 therapies. Therapeutic options include chemotherapy and/or radiation (RT) treatment. In this work we utilized HCC70, a human TNBC cell line, grown subcutaneously in NSG mice. We investigated whether the combination of focal RT and paclitaxel would improve anti-tumor activity over paclitaxel alone. RT therapy has typically been delivered in low doses over long periods of time. More recently higher fractions of RT are being given in shorter time intervals. Utilizing the Small Animal Radiation Research Platform (SARRP; Xstrahl, Suwanee, GA) we compared a low dose (2.5 Gy) fractionated regimen to a higher dose but less frequent regimen (8Gy, QD3) either as single fraction of paclitaxel or in combination with paclitaxel (15mg/kg weekly). The total cumulative dose of radiation was 24-25 Gy in both radiation regimens. Paclitaxel alone produced moderate activity with a 10 day tumor growth delay and no tumor regressions. Treatment with low dose RT resulted in tumor stasis for ≥68 days, but there were no tumor regressions or tumor free survivors (TFS). Treatment with 8Gy, produced a 75% incidence of confirmed partial regressions (PR) and a 25% incidence of complete regressions (CR) with no TFS. In this group we observed slightly more body weight loss (BWL), more frequent clinical signs, and more frequent need for food and water supplementation than with the fractionated RT regimen. Mean BWL was ~10% with a nadir around 8-10 days post first RT dose. BWL was recovered over the next 1-2 week period. The combination of low dose focal RT with paclitaxel produced activity similar to that with high dose radiation (50% PR, 40% CR, and 1 TFS). Treatment with paclitaxel plus 8Gy RT was highly efficacious, producing an 80% incidence of CRs, all of which remained tumor free at study day 108.

Prostate cancer is the highest incidence non-cutaneous cancer in men, and a significant cause of cancer mortality. Localized disease is treated with surgery or radiotherapy and whilst androgen deprivation therapy can extend survival in the subset of cases that progress, metastatic disease is incurable. We have found that oncogenic drivers of prostate cancer, as well as therapy, lead to changes in the activation of prostate cancer cell stress signaling pathways and in particular the unfolded protein response (UPR). We have previously reported that the androgen receptor sustains the cytoprotective activity of the IRE1-XBP1 arm of the UPR and represses the activation of the PERK/ATF6 arm. Blocking pro-apoptotic activity of the latter arm leads to the activation of all three arms of the UPR, culminating in treatment resistance in surviving cells. In this study we assess whether the activation of the UPR in response to radiation mirrors the immunogenic/inflammatory response, which is known to occur in an initially acute apoptotic phase before resolving to a chronic sustainable level. Further we have evaluated the impact of combining radiation with ONC201, a novel anti-cancer small molecule in clinical trials that is an activator of the UPR, on the viability of prostate cancer. We find that ONC201 has a delayed cytotoxic effect as a single agent, with the impact on viability occurring from 72 hours onwards at low microMolar concentrations. However activation of multiple arms of the UPR occurs earlier and is detectable at 24 hours for ATF4, ATF6 and IRE1-XBP1 at the protein/mRNA levels. This time difference creates a window in which to introduce sequential administration of radiation to test ONC201 as a primer for cytotoxic response radiation. We have undertaken this work in a panel of cell-lines (PC3, DU145 and AR-expressing cell-lines) in which we have also knocked down key regulators (PERK, IRE1, CHOP) of separate arms of the UPR. This represents the first in vitro study to characterise the impact of ONC201 on the radiation-responsiveness of prostate cancer cells.

The aberrant vasculature remains uneven, heterogeneous blood flow and leaky, hemorrhagic blood vessels. Due to the unusual nature of tumor vessels, areas of hypoxia develop that contribute to radiore sistance and inefficiency of therapeutic drug delivery. Our current studies examine the role of nitric oxide synthase (NOS) in tumor vasculature. NOS has been demonstrated to be “uncoupled” in tumors and isolated tumor cells due to reduced levels of tetrahydrobiopterin (BH4), a necessary cofactor, resulting in superoxide and peroxynitrite formation in lieu of NO (Rabender et al 2015 Molecular Cancer Research). NO signaling is critical for vascular function and thus uncoupling of eNOS in tumor endothelial cells may partly explain the poor vasculature found within solid tumors. Having previously demonstrated that NOS can be “recoupled” and NO production restored resulting in superoxide and peroxynitrite formation in lieu of NO (Rabender et al 2015 Molecular Cancer Research). NO signaling is critical for vascular function and thus uncoupling of eNOS in tumor endothelial cells may partly explain the poor vasculature found within solid tumors. Having previously demonstrated that NOS can be “recoupled” and NO production restored.
firms the reduction in tumor hypoxia as well as increased tumor perfusion. Increased tumor perfusion was also demonstrated through enhanced doxorubicin uptake in tumors of mice treated with SP. Lastly, the enhanced tumor oxygenation correlated with more than a 2-fold increase in radiation induced cell killing measured by ex vivo clonogenic assay. These preliminary data demonstrate the potential for continuous tracking of tumors, especially when we take into consideration that SP has been demonstrated to be cytotoxic to both breast and colon tumors. On-going studies are examining the consequences of enhanced drug uptake on both normal and tumor tissue as well as the mechanism behind the vascular normalization.

#5197 Targeting PARP-1 to deliver alpha-particles to cancer chromatin. Laura Pauters1, Kuiyi Xu1, Catherine Hou1, Robert H. Mach3, John M. Maris5, Daniel A. Pryma3, Mehran Makvandi1. 1University of Pennsylvania, Philadelphia, PA; 2Children’s Hospital of Philadelphia, Philadelphia, PA.

Introduction: Neuroblastoma (NB) is a radiosensitive pediatric cancer that develops in the sympathetic nervous system and typically affects children under the age of 10. High-risk NB is associated with a 40% 5-year survival rate. Nuclear enzyme poly (ADP-ribose) polymerase 1 (PARP-1) is overexpressed in high-risk NB, making it an attractive target for alpha-particle therapy. Alpha-particles have a short path length and high linear energy transfer, causing dense ionization across DNA, inducing double stranded breaks that result in cell death. The purpose of this study was to explore a newly developed radiotherapeutic ([211At]MM4) that combines the targeting potential of a small molecule PARP inhibitor (PARPi) with the cytotoxic effects of [211At] in high-risk NB. Methods: In vitro cytotoxicity was performed in a panel of high-risk NB cell lines to evaluate the relative potency of [211At]MM4. Next, DNA damage was assessed by measuring gH2AX foci formation at 1, 4, and 24 hrs after [211At]MM4 treatment. In parallel, PARP-1 expression was measured in response to therapy and cleaved PARP-1 was quantified to assess apoptosis. Cell cycle analysis was performed after treatment to identify therapy related effects. The in-vivo biodistribution of [211At]MM4 was performed alongside ex-vivo autoradiography. Tumor cytology for PARP-1, gH2AX, and Ki-67 was performed in response to treatment to identify therapy related effects. The in-vivo biodistribution of [211At]MM4 revealed rapid tumor targeting at 1 hr and clearance from all tissues at 4 hrs. Ex-vivo autoradiography showed a tumor-muscle ratio greater than 6. Tumor cytology revealed DNA damage measured by gH2AX and PARP-1 expression increased following treatment. Small colonies of proliferating tumor cells were detected after treatment using Ki-67 staining. In vivo therapy efficacy studies revealed low fractionated doses were tolerable and resulted in significant delay in tumor regression. Conclusion: [211At]MM4 is a novel alpha-emitting radiotherapeutic that specifically targets nuclear PARP-1 overexpression in neuroblastoma and incites double-stranded breaks in cancer DNA. The cytotoxic effects of [211At]MM4 have been experimentally validated both in vitro and in vivo; the results of these experiments confirm the therapeutic potential of [211At]MM4 as a viable treatment option for high-risk neuroblastoma.

#5198 Targeted alpha particle therapy for uveal melanoma. Narges K. Tafreshi1, Nella C. Delva1, Christopher J. Tichacek1, Michael L. Doligalski2, Darpan N. Pandya3, Nikunj B. Bhatt2, HyunJoo Kil4, Alan Cuthbertson1. 1Bayer AG, Berlin, Germany; 2Bayer AG, Wuppertal, Germany; 3Bayer AG, Berlin, Germany; 4Bayer AG, Oslo, Norway.

FGFR2 is a transmembrane tyrosine kinase receptor, consisting of three extracellular N-terminal immunoglobulin-like domains which are involved in ligand-binding as well as in receptor dimerization. Ligand-independent activation of FGFR2 signaling either via genomic amplification, gene fusion events, mRNA overexpression, or mutations has been observed e.g. in gastric cancer, colorectal cancer (CRC), and triple-negative breast cancer (TNBC). As such, FGFR2 has been described to be involved in cancer progression, promotion of oncogenesis, neoangiogenesis, as well as resistance to targeted therapies. Overexpression of FGFR2 and relatively low levels of cell surface expression of FGFR2 in normal human tissues renders FGFR2 an attractive candidate to explore targeted alpha therapy (TAT). We describe the generation of a high energy, alpha-particle emitting FGFR2 targeted thorium-227 conjugate (FGFR2-TTC). The FGFR2-TTC consists of a fully human FGFR2 binding IgG1 antibody (BAY 1179470) cross-reactive with mouse FGFR2, covalently linked via an amide bond to a chelator moiety (3,2 HOPO), enabling radio-labeling with the alpha particle emitting thorium-227 (227Th). In vitro cytotoxicity experiments with FGFR2-TTC demonstrated potent activity in the sub-picomolar range compared to a non-targeting control-TTC and a correlation between decrease in cell viability and increasing number of anti-FGFR2 antibodies bound per cell (ABC counts) in a panel of FGFR2-positive cancer cell lines. Upon treatment of cells with FGFR2-TTC, the DNA damage response marker protein γH2AX was up-regulated indicating that the mode-of-action involves induction of DNA double strand breaks. Furthermore, induction of the immunogenic cell death marker calreticulin was observed. Biodistribution studies of the FGFR2-TTC in mouse models, evaluated by whole body autoradiography and acquisition of gamma-spectra specific for thorium-227, demonstrated specific accumulation of thorium-227 in FGFR2-positive tumors and very limited signal in murine organs and tissues. FGFR2-TTC exhibited in vivo tumor growth inhibition after a single dose in mouse xenograft models of CRC (NCI-H716) and gastric cancer (SNU-16). In addition, FGFR2-TTC showed anti-tumor activity in the aggressive murine syngeneic orthotopic 4T1 TNBC model. In summary, FGFR2-TTC has been established as a promising targeted alpha therapy (TAT) for efficacious and selective delivery of alpha emitter-biased radiotherapy in several FGFR2-positive cancer indications. Further exploration for cancer therapy may thus be of interest.

#5200 Preclinical pharmacology of the PSMA-targeted thorium-227 conjugate PSMA-TTC: a novel targeted alpha therapeutic for the treatment of prostate cancer. Stefanie Hammer1, Aasmund Larssen2, Christine Ellingsen2, Solene Geraudie3, Derek Grant4, Baard Indreov5, Oliver von Ahsen1, Alexander Kristian1, Urs B. Hagemann1, Jenny Karlsson2, Roger M. Bjerve6, Olav B. Ryan7, Dominik Mumberg1, Bertolt Kreft3, Alan Cuthbertson1, Bayer AG, Berlin, Germany; 2Bayer AS, Oslo, Norway.

The radiopharmaceutical was well tolerated at even the highest doses and animals did not reach any clinical endpoints, such as weight loss, loss of kidney function or abnormal pathology. Biodistribution studies on MC1R expressing tumor bearing mice revealed tumor selectivity and a combination of renal and hepatic clearance with minimal retention in other normal tissues. A blood PK study in rats showed more than 99% retention in tumor, with minimal retention in all other tissues. A pharmacokinetic study in tumor bearing mice revealed tumor selectivity and a combination of renal and hepatic clearance with minimal retention in other normal tissues. A blood PK study in rats showed more than 99% retention in tumor, with minimal retention in all other tissues.
Prostate-specific membrane antigen (PSMA, FOLH1) is a type II transmembrane glycoprotein of the M28 peptide family that acts as a glutamate carboxypeptidase on various substrates. PSMA is well established as a target antigen in prostate cancer due to its high and specific overexpression on the surface of prostate cancer cells at all tumor stages, including metastatic and hormone-refractory prostate cancer. Weill Cornell Medicine (New York, NY) has been utilizing clinically for many years, with radium-223 leading to overall survival benefits. Targeted alphatherapy (TAT) has an established clinical profile with the successful transition of Ra223, an alpha-particle emitter, from bench to bedside in prostate cancer. Thorium-227 is the immediate precursor for Ra223 via alpha-particle emission. We herein describe the generation of a novel TAT, a high energy, alpha-particle emitting PSA-targeted thorium-227 conjugate (PSMA-TTC). PSMA-TTC consists of a fully human PSMA targeting IgG1 antibody covalently linked via an amide bond to a chelator moiety (3,2 HOPO), enabling radiolabeling with thorium-227 (227Th). PSMA-TTC was prepared in high radiophysical yield and purity and tested for binding affinity to PSMA target (ELISA) as well as PSMA expressing cell lines (FACS). In vitro cytotoxicity experiments were carried out on prostate CA cell lines with different PSMA levels (from 3,000 to 150,000 mAbs bound/ cell). In vivo biodistribution and anti-tumor efficacy were analyzed after i.v. injection of 100-500 kBq/kg at protein doses of 0.14 mg/kg to mice bearing s.c. prostate cancer xenograft models. Additionally, anti-tumor efficacy was evaluated in a PSMA expressing orthotopic bone xenograft model (LNCaP-Luc) monitored by bioluminescence imaging, micro CT and X-ray. PSMA-TTC retains binding affinities to PSMA target and PSMA positive cancer cells similar to the PSMA antibody. Strong in vitro potency and selectivity of PSMA-TTC was shown on different PSMA positive cells. Biodistribution studies in C4-2 xenografts demonstrated specific tumor uptake of PSMA-TTC with a maximum of 50 % of ID/g at t = 72h post dose administration. Selective significant antitumor efficacy was shown for PSMA-TTC in s.c. prostate CA xenograft models with high (C4-2) and medium/low (22Rv1) PSMA protein levels at doses of 250 and 300 kBq/kg. Furthermore, statistically significant prevention of tumor growth was observed after treatment with PSMA-TTC at a dose of 100 kBq/kg in an orthotopic bone xenograft model (LNCaP-Luc). The promising preclinical antitumor activity of PSMA-TTC supports its development for the treatment of patients with metastatic prostate cancer.
Competition with unlabeled FVIIai 10 minutes before 177Lu-FVIIai injection dose per gram (%ID/g) at 1, 4, 24, 72 and 168 hours post-injection, respectively. Houghton, Ryan; Lanning, Dayla; Abdel-atti, Toni; Jun, Christine; Kearns, Jacob; and radiolabeled with the beta-emitting isotopes Lutetium-177 (177Lu) or Yttrium-90 (90Y). CA19-9, and is a promising platform for development of a targeted radioimmunotherapy (RIT). MVT-5873 was conjugated with the chelator CHX-A’-DTPA and radiolabeled with the beta-emitting isotopes Lutetium-177 (177Lu) or Yttrium-90 (90Y) to form the RIT agents MVT-1075 (177Lu-CHX-A’-DTPA-HuMab-SBI) and MVT-1916 (90Y-CHX-A’-DTPA-HuMab-SBI), respectively. The antitumor efficacy of each of the constructs was studied in nude mice bearing BxPC3 human pancreatic tumor xenografts, known to express CA19-9. Methods: The initial dose-finding studies utilized doses of MVT-1075 of 75, 150, 300, or 450 μCi significantly inhibited subQ BxPC3 tumor growth at all dose levels, with sustained suppression with higher doses. MVT-1916 produced similar results. MVT-1075 was selected based on the favorable half-life of 177Lu (6.7 d) and its utility for clinical biodistribution assessments. In an orthotopic BxPC3 tumor model, treatment with a single dose of MVT-1075 at 300 μCi significantly inhibited tumor growth, with Day 20 tumor volume approximately 50% that of the initial starting volume. A third BxPC3 xenograft study evaluated fractionated dosing schedules, (150 μCi x 1, 75 μCi x 2, 50 μCi x 3), with both single-dose and fractionated schedules effectively inhibiting subQ BxPC3 tumor growth. Biodistribution studies in normal mice showed an expected gradually decreasing activity in blood, heart, and lungs, with low uptake in normal pancreas. In subQ BxPC3 tumor-bearing mice, tumor uptake was rapid, reaching 69% ID/g by 24 h and 86% ID/g by 120 h. Otherwise, the biodistribution pattern paralleled that of normal mice, with relative %ID/g values within about ±25% of normal mice across all time points comparing blood, heart, lungs, kidneys, and pancreas, with slightly higher uptake in liver and slightly lower uptake in spleen. Conclusions: MVT-1075 demonstrates promising antitumor activity in a human pancreatic cancer xenograft model, with efficacy shown in both single dose and fractionated schedules. Biodistribution shows rapid and substantial tumor uptake, with much lower uptake in normal organs. These findings support the phase I clinical trial of MVT-1075 in patients with CA19-9 positive pancreatic cancers planned to begin in early 2017.

Poly(ADP-ribose) polymerase inhibitors induce β-radiosensitization through an altered selection of DNA double-strand break repair pathways. Yuji Seo, Keita Yoshizaki, Keisuke Tamari, Yutaka Takahashi, Keisuke Otani, Masahiko Koizumi, Kazuhiko Ogawa. Osaka University Graduate School of Medicine, Suita, Japan.

Background: Systematically reviewing published studies on a broad range of potential radiosensitizers, we previously reported that poly(ADP-ribose) polymerase inhibitors (PARPi) may have a unique radiosensitizing effect to enhance β-components of the linear-quadratic model. In contrast, many other radiosensitizers agents predominantly modified α-components. The aim of this study is to determine the effect of PARPi (olaparib and veliparib) on β-components of DNA double-strand break repair by in vitro and in vivo methods.

Results: We first confirmed that treatments with PARPi PJ34, olaparib, or veliparib two hours prior to and 48 hours after 10 Gy of ionizing radiation (IR) potentiated radiation-induced cell death in human cancer cells HCT116, HT29, H460 and A549 using the colony-forming assay. Tumor regrowth assay with 3-dimensional multicellular spheroids of HCT116 and H460 cells showed that PJ34 potentiated survival delay when compared to control at 10 Gy but not in tumors treated with 10 Gy in 5 fractions. Similar results were found using HCT116 tumor xenograft model in mice. We next examined what cellular events may underlie the radiosensitization using PARPi PJ34 in HCT116 cells. Kinetics of DNA damage responses were first measured by phosphorylation of histone H2AX (γH2AX). PJ34 did not change an initial increase of γH2AX following 10 Gy IR, but γH2AX levels decreased faster in PJ34-treated cells than control cells. Immunocytochemical analysis of Rad51 showed that PJ34 reduced Rad51 foci formations up to 6 hours following 10 Gy IR. IR-induced chromosomal aberrations were quantitated by the C-band of metaphase spreads. More dicentric chromosomes were found in PJ34-treated cells than the control. These data suggested that PARPi did not inhibit total DNA double-strand break (dsb) repair but altered the selection in DNA dsb repair pathways with increased end-joining type(s) of repair compensating for reduced homologous recombination repair. Cell cycle profiles showed sustained 4C DNA cell peaks in cells treated with PJ34 up to 72 hours following 10 Gy IR. Cell cycle markers (cyclin B1 and phosphorylated histone H3) indicated that the 4C DNA peaks of the PJ34-treated cells contained substantial amount of G1/tetraploid cells in addition to G2- or M-phase diploid cells. Additionally, senescence-associated β-galactosidase staining showed that PJ34 promoted radia-
tion-induced premature senescence, while smaller IR-induced sub-G1 populations were found in PJ34-treated cells than the control. Conclusion: PARPi increased IR-induced chromosomal aberrations through the altered selection in DNA dsb repair pathways. The increased quadruplet missrepair enhanced β-components of IR-induced cell death mediated by the increased uncontrolled formation of G1/tetraploid cells and premature senescence. DNA dsb repair pathway selection may be a novel and effective target to elicit β-radiosensitization.
assessed by a LINDMO method (> 90%) at both conditions. Serum stability at 37°C showed radiochemical purity > 82% by ITLC and immunoreactivity > 62% after 5 days, further supporting the use of this product in clinical trials. Conclusions: The conjugation of MVT-5873 with p-SCN-Bn-CHX-A''-DTPA reproduced yields a well characterized broad intermediate (MVT-7814) modified on the heavy chain. Readministration with 5 x 6 Gy at 16 weeks after RT. An increase of 12S-LOX protein was observed in type 2 pneumocytes at 8 weeks after exposure with fibrogenic doses of RT (17.5 Gy and 5 x 6 Gy) compared to low dose RT (5 Gy) or controls (0 Gy). 12S-LOX mRNA was significantly induced in type 2 pneumocytes at 3 days after receiving fibrogenic doses compared to other cell types in murine lung. Chemokine ligands including CCL2, which are responsible for bone marrow-derived macrophages recruitment, were induced in primary pneumocytes treated with RT or 12S-HETE. Treatment with 12S-HETE (150 nm) increased arginase-1 expression significantly in bone marrow-derived macrophages cultured with IL-4. Macrophages expressing active arginase-1 accumulated in murine lungs at 16 weeks after thoracic irradiation with fibrogenic doses. Conclusion: These studies demonstrate that type 2 pneumocytes express 12S-LOX in response to RT with fibrogenic doses of radiation and increased 12S-LOX contributes to the accumulation of alternatively activated macrophages in irradiated murine lungs. 12S-LOX may serve as a novel therapeutic target in mitigating RIPF.

#5207 Breast cancer-specific amplitude modulated radiofrequency electromagnetic fields (AM RF EMF) inhibits brain metastasis of breast cancer. Sambad Sharma, Hugo Jimenez, Fei Xing, Carl Blackman, Boris Pasche, Kou-nosuke Watabe. Wake Forest Univ. School of Medicine, Winston-Salem, NC.

Brain metastasis is evident in approximately 30% of patients with breast cancer and one-year survival of these patients remains less than 20%. The treatment of breast metastasis mainly involves surgical resection in combination with whole brain radiation therapy (WBRT), or stereotactic radiosurgery (SRS). However, patients often suffer from the treatment’s adverse effects and experience recurrent disease. Therefore, there is an urgent need for a less invasive therapy with minimal side effects, and improved therapeutic efficacy. Our current work has established a novel treatment approach for breast cancer brain metastasis at a preclinical level by using amplitude modulated radiofrequency electromagnetic fields (AM RF EMF). We have previously demonstrated that AM RF EMF can be safely administered to patients for prolonged period of time with virtually no toxicity and side effects. The treatment of metastatic breast cancer patients with AM RF EMF significantly impaired the growth of both metastatic and primary tumor (1). In this study, we specifically observed the effect of AM RF EMF in brain metastatic variants of breast cancer cells (231-BrM and SKBr-BrM). We found that AM RF EMF significantly inhibited the growth, stemness and colony forming ability of brain metastatic variants of breast cancer cells. In addition, AM RF EMF inhibited the stemness of radiation resistant variants derived from 231-BrM and SKBr-BrM cells, which indicate the potential of AM RF EMF in treatment of treatment-refractory recurrent disease. Furthermore, AM RF EMF also significantly suppressed the growth of orthopodically and systemically implanted 231-BrM and SKBr-BrM cells in our NOD/SCID animal model. We then performed RNAseq expression profile analysis and found that expression of stemness-associated gene, HMG2A2, was significantly decreased in 231-BrM and SKBr-BrM cells that were treated with AM EMF RF. Interestingly, brain metastatic variants and radiation resistant lines of 231-BrM and SKBr-BrM showed elevated expression of HMG2A2 when compared to their parental cells. Importantly, the treatment of brain metastatic cells of AM RF EMF also sensitized the cells to radiation in a HMG2A2 dependent manner. Furthermore, to isolate the AM RF EMF responsive biomarker, we isolated exosomes from the SKBr-BrM cells that were treated with AM RF EMF, and performed microRNA array. Differentially expressed miRNAs in SKBr-BrM and 231-BrM cells derived exosomes were identified and verified by Taqman PCR. These exosomal microRNAs can serve as excellent biomarkers for determining the effect of AM RF EMF in brain tumors. Therefore, our study has demonstrated that this new approach of treating brain metastasis has a high translational potential considering significant efficacy and minimal side effect shown in pre-clinical and clinical setting.

#5208 The role of platelet-type arachidonate 12-lipoxygenase in murine lungs exposed to a fibrogenic dose of irradiation. Eun Joo Chung, Aylia White, Deborah Citrin. NIH, Bethesda, MD.

Introduction: Ionizing radiation (RT) is employed in the treatment of approximately half of patients with cancer, including those with thoracic malignancies. Exposure of tumor adjacent normal lung may result in injury and fibrosis. Arachidonic lipoxygenase oxidizes arachidonic acid, yielding hydroperoxy derivative including hydroperoxyeicosatetraenoic acids (HPETEs) and the reduced form, hydroxyeicosatetraenoic acids (HETEs). Arachidonate lipoxygenases are classified as 5-, 8-, 12-, or 15-LOX, according to the site of oxygen insertion within arachidonic acid. There are two isoforms of arachidonate 12-lipoxygenases in mammals, the platelet-type (12S-LOX; gene ALOX12), and the epidermal-type (12R-LOX; gene ALOX12B). Recently, we found an increased expression 12S-LOX in murine lungs exposed to a fibrogenic dose of irradiation. We hypothesized that 12S-LOX would be required for radiation-induced pulmonary fibrosis (RIPF). Methods: C57/BL6 mice (n=3 per group) were exposed to thoracic RT (0 Gy, 5 Gy, 17.5 Gy, or 6x5 Gy). Levels of 12S-LOX mRNA and protein were assessed in isolated various cell types from lungs (In Vitro) and in lung tissues (In Vivo) after RT with an immunohistochemical assay and quantitative PCR. Levels of chemokine ligands mRNA were assessed in isolated primary pneumocytes exposed to 17.5 Gy or 12S-HETE. Differential polarization of bone marrow-derived macrophage cultures with/without 12S-HETE was examined by quantitative PCR of polarization markers. Activity of arginase-1 was measured in bone marrow-derived macrophages cultured with 12S-LOX or control. The glutathione (GSH) system is a major redox buffering system. The glutathione (GSH) system is a major redox buffering system.

#5209 Ionizing radiation abrogates pro-tumorigenic effects from cancer-associated fibroblasts in xenografts. Turid Hellevik, María T. Grinde, Jørn Vik, Retil A. Camillo, Ingo Martinez-Zubiaurre. 1 University Hospital of Northern Norway, Tromsø, Tromsø, Norway.

Non-malignant elements of tumors play fundamental roles in both cancer sustainability and responses to therapies. In the context of clinical radiotherapy (RT), all cells that reside in the tumor mass receive radiation, but the impact of cancer-associated fibroblasts (CAFs) to treatment outcomes remains largely unexplored. In this study, we have investigated the effects of radiation on the natural pro-tumorigenic actions of CAFs in animal. Ionizing radiation (IR) was delivered to CAFs either as a single-high dose or fractionated medium doses. Tumor development was compared in xenografts after co-implantation of AS49 lung tumor cells with irradiated or non-irradiated human lung CAFs. Quantitative histology and immunohistochemistry was applied to investigate potential biological mechanisms behind tumor growth regulations. As expected, CAFs showed resistance to radiation-induced cell death, however, the enhanced tumorigenic effects observed with admixed non-irradiated CAFs was nullified. Quantitative determinations of parameters such as desmoplasia, angiogenesis, inflammation, innate immunity or tumor cell proliferation revealed enhanced blood vessel density in tumors established with irradiated CAFs. Experiments to ascertain fate of implanted CAFs showed that both irradiated and non-irradiated CAFs only reside at the implantation site during early stages, suggesting that the regulatory functions of admixed CAFs may take place during the initial phases of tumor formation. In this study, we show that CAFs receiving ionizing radiation lose their pro-tumorigenic potential in vivo, affecting angiogenesis and possibly other mechanisms related to tumor engraftment. This finding represent a previously unknown advantageous effect induced by radiotherapy, which adds to the well-known direct cytotoxic effects on transformed epithelial cells.

#5210 Differential cytotoxic effects of Piperlongumine analogues and their radiotherapeutic response in breast cancer. Nurul Akmaryanti Abdullah, John Moses, Li Chen Han, Sarah Storr, Aula Ammar, Stewart G. Martin. The University of Nottingham, Nottingham, United Kingdom.

Background: Breast cancer is the most common cancer in women in the United Kingdom. The glutathione (GSH) system is a major redox buffering system involved in regulating radiosensitive response of cancer cells. Overexpression has been shown to cause multidrug and radiation resistance. Its modulation may increase radiosensitivity and improve radiotherapy efficacy. Piperlongumine (PL) can reportedly inhibit GSH system function and reduce proliferation of a Northern Norway. Tromsø, Norway. ‘University of Trondheim, Trondheim, Norway.

This finding represent a previously unknown advantageous effect induced by radiotherapy, which adds to the well-known direct cytotoxic effects on transformed epithelial cells.
for 1hr. Results: PL, LH91 and LH92 inhibited proliferation and decreased clonogenic survival in both lines. From proliferation assays, MDA-MB-231 cells were more sensitive to PL at 48hr (P = 0.047) and 72hr (P = 0.001) with an IC50 dose of approx. 4μM versus approx. 12μM in T47D’s. There was a significant difference between IC50 doses of LH91 in MDA-MB-231 (5μM) and T47D (11μM) respectively (P = 0.006), however this was not observed in LH92 at treatment (P = 0.178). In contrast, there was no differential sensitivity of LH92 in cell proliferation between the two cell lines at 48 and 72hr. Interestingly, in clonogenic assays, MDA-MB-231’s were more sensitive to LH92 (P = 0.001) with an IC50 of 4μM versus 11μM in T47D’s. There were no significant differences in clonogenic survival between each line after treatment with PL or LH91. No radiosensitisation was observed with PL or PL analogues in MDA-MB-231, however BSO, as a drug comparator, enhanced radiation response with a sensitiser enhancement ratio (SER) of 1.13 at 1% iso-survival. Radiation and drug combinations in T47D cells are ongoing. There were no changes in ROS levels.

**Experiment and Molecular Therapeutics: Preclinical Radiotherapeutics**

**5211 Hormophysa triquerta polypolen, an elixir that deters CXCR4- and COX2-dependent dissemination destiny of treatment-resistant pancreatic cancer cells.** Sheeja Aravindan,1 Sathish Kumar Ramraj,1 Dinesh Babu Somasundaram,1 Kathiresan Kandasamy,3 Somasundaram N, Thirugnanasambandam,2 Terence Herman,1 Natarajan Aravindan1. 1Univ. of Oklahoma Health Sciences Ctr., Oklahoma City, OK; 2Annamalai University, India.

Therapy resistant pancreatic cancer (PC) cells play a crucial role in tumor relapse, recurrence, and metastasis. Recently, we showed the anti-PC potential of an array of seaweed polyphenols and identified efficient drug deliverables. Herein, we investigated the benefit of one such deliverable, Hormophysa triquerta polypolen (HT-EA), in regulating the dissemination physiognomy of therapy resistant PC cells in vitro, and residual PC in vivo. Human PC cells exposed to clinical radiation (FIR), with/without HT-EA pretreatment were examined for the alterations in the tumor invasion/metastasis (TIM) transcriptome (93 genes, QPCR-profiling). Utilizing a mouse model of residual PC, we examined for the alterations in the tumor invasion/metastasis (TIM) transcriptome, clinically translating to increased morbidity due to hardening, distortion, and pain. Recent evidence has highlighted the importance of repressing metastasis, resulting in the continuous stimulation of GR and ENZ resistance. Therefore, we hypothesized that similar metabolic mechanisms that elicit dihydrotestosterone (DHT) synthesis, which in turn stimulate AR in CRPC, a role for GR in ENZ resistance would be accompanied by a tumor metabolic switch that provides sustained tissue cortisol concentrations which enable GR activation. Here, we found that long-term ENZ treatment sustains tumor cortisol concentrations in models of prostate cancer and patient tissues by using [3H]-cortisol and high performance liquid chromatography. Further investigations with immunoblot, immunoprecipitation as well as in vitro ubiquitination assays in ENZ resistant prostate cancer models demonstrated that autocrine motility factor receptor (AMFR), an ubiquitin E3-ligase, and one of its adaptors, Erielin-2, mediate loss of 1β-hydroxysteroid dehydrogenase-2 (11β-HSD2), which sustains tumor cortisol concentrations which enable GR activation. Additionally, we found that long-term ENZ treatment sustains tumor cortisol concentrations in models of prostate cancer and patient tissues by using [3H]-cortisol and high performance liquid chromatography. Further investigations with immunoblot, immunoprecipitation as well as in vitro ubiquitination assays in ENZ resistant prostate cancer models demonstrated that autocrine motility factor receptor (AMFR), an ubiquitin E3-ligase, and one of its adaptors, Erielin-2, mediate loss of 1β-hydroxysteroid dehydrogenase-2 (11β-HSD2), which sustains tumor cortisol concentrations which enable GR activation. resistant to gedatolisib. 9 out of 28 CRC cells harbor PIK3CA & KRAS co-mutations and 7 out them were shown to be sensitive to gedatolisib. However, HCT115 and LS174T cells were resistant. We identified that resistant cell lines have high activity of GSK3B and TCF7 framshift mutation (G65insC66; H155fs*), which functions as positive regulator of Wnt/b-catenin pathway. The effects of knocking down shRNA demonstrated that GSK3B activity is a key contributor to the cell resistance to gedatolisib. Conclusion: Our results demonstrate that AaR_g agonism causes transient changes in junctional and ABC transporter expression and functionality. The short duration of Regadenoson effects on BBB function may have important implications for its clinical use to enhance drug delivery of chemotherapy and other therapies for CNS diseases.

**#5217 Mechanism of polyspecificity of P-glycoprotein: Substitution of fifteen residues in the drug-binding pocket with tyrosine reveals a negative correlation between substrate size and transport.** Shahrooz Vahedi, Eduardo Chufan, Suresh V. Ambudkar. National Institute of Health (NIH), Bethesda, MD.

P-glycoprotein (P-gp) belongs to the superfamily of ATP-binding cassette (ABC) transporters. This energy-dependent cell surface transporter can pump various chemically dissimilar amphipathic or hydrophobic compounds out of cells. In cancer cells, the expression of P-gp is often linked to the development of multidrug resistance (MDR). Several studies have demonstrated that P-gp can recognize and transport various chemotherapeutic drugs and limit their bioavailability and effectiveness. The drug-substrate binding sites, translocation mechanism, and the signal transduction between drug-binding sites and ATP-hydrolysis at nucleotide-binding domains of this clinically important transmembrane transporter are not yet well defined. Utilizing molecular modeling and mutagenesis techniques, we previously identified key amino acid residues that interact with the most potent inhibitors of P-gp (zosuquidar, tariquidar, and elacridar). We found that replacing key interacting amino acids (Y307, Y953, and Y725) with alanine in the drug-binding pocket switches inhibition by these modulators of ATPase activity to stimulation. The data demonstrated that hydrogen bond interactions are critical for inhibition of ATP hydrolysis of P-gp by modulators. As tyrosine and glutamine residues can function as both hydrogen bond donors and acceptors, we hypothesized that increasing the potential for hydrogen bond interactions by introducing more tyrosine residues into the drug-binding pocket would increase the affinity of substrates for P-gp. To investigate this, we first identified residues in the transmembrane domains that interact with a number of substrates by employing a molecular modeling technique. Then we substituted fifteen conserved residues (11 Phe, 2 Leu, 2 I1u and 1 Met) with tyrosine, creating a mutant we named 15Y. Compared to WT, for the majority of tested substrates, we observed normal transport of fifteen fluorescent substrates by the 15Y-P-gp mutant demonstrating that fifteen mutations in the transmembrane domains is well tolerated in P-gp. Additionally, these changes have no effect on the cell surface expression or total level of the mutant protein and normal conformational changes occur during transport, further confirming flexible nature of transmembrane domains of P-gp. Interestingly, transport of three large-size substrates was significantly decreased. Physicochemical characterization of the substrates revealed a negative correlation between drug transport and molecular size for the tyrosine-enriched P-gp mutant, possibly due to increased hydrogen bond interactions. These data demonstrate that hydrogen bond interactions are substrate- or modulator-specific.

**#5218 Breast cancer resistance protein (ABCG2) and P-glycoprotein (ABCB1) transport irbritinib and may restrict its oral availability and brain accumulation, whereas CYP3A4 limits irbritinib oral availability.** Stephanie van Hoppe,1 Gert-Jan Rood,1 Elis Wagenaar,2 Rolf Spardons,3 Jos Beijnen,2 Alfred Schinkel.1 Nethelands Cancer Institute, Amsterdam, Netherlands;2 Utrecht University, Utrecht, Netherlands.

Introduction: Ibritinib (Imbruvica, PCI-32765) is an orally administered tyrosine kinase inhibitor (TKI) approved by the FDA in 2014 for treatment of B-cell malignancies. Ibritinib is a confirmed irreversible inhibitor of Bruton tyrosine kinase (BTK) with promising clinical activity and tolerability in B-cell malignancies. Ibritinib is a confirmed irreversible inhibitor of Bruton tyrosine kinase (BTK) with promising clinical activity and tolerability in B-cell malignancies. Ibritinib is also a potent inhibitor of P-gp (zosuquidar, tariquidar, and elacridar). Ibritinib has an inhibitory activity towards BTK approximately 10 times lower than its parent compound. We investigated whether irbritinib is a substrate for the multidrug efflux transporters ABCB1 and ABCG2 and whether these transporters influence oral availability and brain and other tissue accumulation of irbritinib. Materials: We used in vitro transport assays to assess human (h)ABC1-, hABC2- or murine (m)Abg2-mediated transport of irbritinib. To study the single and combined roles of Pgp and Abg1a/Abg1b in irbritinib disposition, we used appropriate knockout mouse strains. To assess the role of Cyp3a in the bioavailability of irbritinib we used knockout strains as well as humanized CYP3A4 strains and measured the irbritinib and PCI45227 concentrations at various time points. Results:

**#5215 Time dependent blood-brain barrier modulation by vascular endothelial growth factor to improve CNS drug delivery.** Matthew McCord. National Cancer Institute, Bethesda, MD.

Introduction: Efforts to transiently increase blood brain barrier permeability would facilitate improved CNS delivery of chemotherapy agents. Previous studies demonstrated that vascular endothelial factor (VEGF) increases permeability in traumatic brain injury and ischemic brain disease. Exogenously administered VEGF increases barrier permeability in the non-diseased CNS. In our study, we investigated the role for endogenous VEGF therapy to modulate blood-brain barrier permeability. Methods: For in vitro studies, confluent mouse brain endothelial cells were treated with VEGF (200ng/mL) and TEER was measured 6 hours post treatment and continuing up to 24 hourspost treatment. Conclusions: Our in vitro data warrants further investigation of the applicability of VEGF therapy to increase endothelial cell permeability in animal tumor models, potentially improving delivery of chemotherapeutic drugs.
Ibrutinib was transported reasonably well by hABC81 and hABC2, but not by hABC2 in vitro. Upon oral administration of ibrutinib, Cy3-ubi, Abcg23, Abcb1a/b, and Abcg2;Abcb1a/b mice displayed an increase of 9.8-, 1.3-, 1.6- and 1.1 fold in ibrutinib plasma AU0-20min compared to wild-type mice. At 20 min, preliminary data indicated that the relative brain accumulation of ibrutinib was not significantly altered for the Abcg2-Abcb1a/b mice compared to wild-type mice. 

Conclusion: Abcg2 and Abcb1a/b possibly restrict oral availability of ibrutinib. Based on our preliminary data ibrutinib may not substantially cross the blood-brain barrier. Cy3-ubi restricts the oral availability of ibrutinib and therefore inhibition of this enzyme may be of clinical importance for patients undergoing ibrutinib therapy.

#5219 Characterization of the breast cancer resistance protein BCRP in clear cell renal cell carcinoma. Pascale Fisel,1 Anna Reusel,2 Olga Remter,3 Florian Böttner,1 Stefan Winter,1 Stephan Kruck,2 Steffen Rauch,2 Annemarie N. Nies,1 Jörg Hennenlotter,2 Marcus Scharpf,2 Falko Fend,2 Arnulf Stenzl,2 Jens Bedke,2 Matthias Schwab,2 Elke Schaeffeler1,1 Dr. Margarete Fischer-Bosch-Institute of Clinical Pharmacology and University of Tübingen, Stuttgart, Germany; 2Department of Urology, University Hospital Tübingen, Tübingen, Germany; 3Institute of Pathology and Neuropathology, University Hospital Tübingen, Tübingen, Germany.

Introduction: The breast cancer resistance protein BCRP, encoded by ABCG2, is a member of the ABC transporter family and is well-known for its contribution to multi-drug resistance in cancer. Although BCRP expression is altered in various cancer types, its role and function in cancer, independent from drug efflux, remains largely elusive. In this study, we aimed to elucidate regulatory mechanisms of ABCG2 expression and its biological relevance in clear cell renal cell carcinoma (ccRCC) as well as associations with response to sunitinib treatment in patients with metastatic ccRCC. Experimental Procedures: Data from the ccRCC cohort of The Cancer Genome Atlas (TCGA) was used to assess ABCG2 mRNA expression (n = 463), DNA methylation (n = 288) and genetic variants present in tumor tissue (n = 326) within the ABCG2 gene region. An independent ccRCC cohort of 64 patients was used for the analysis of ABCG2 mRNA and protein expression by Taq Man quantitative real time PCR or immunohistochemical staining of TMA's, respectively, and for genotyping of 34 variants in the ABCG2 gene by MALDI-TOF mass spectrometry. The influence of miRNAs on ABCG2 expression was investigated in the second cohort and validated in vitro cell culture experiments performed in the renal cancer cell line A498 to confirm the interaction of selected miRNAs with the ABCG2 3' UTR. ABCG2 mRNA data and treatment information of a third ccRCC cohort was used to elucidate potential links of ABCG2 with sunitinib response. Results: In the TCGA cohort low ABCG2 mRNA expression was significantly associated with clinicopathological features (T: P = 0.047; N: P = 0.05; G: P = 0.03) and tumor necrosis: P = 9.76e-06 and with inferior patient survival (HR = 0.22, 95% CI: 0.13-0.32; Plogrank<10e-03). DNA methylation levels within the ABCG2 gene were low and hardly variable in ccRCC patients. Somatic variants were only found in a minority of patients and together with genetic variants had only a moderate influence on ABCG2 expression and patient survival. The link between ABCG2 expression with survival could be confirmed in the second ccRCC cohort. The investigated variants did not significantly impact on mRNA or protein level. miR-210-3p and miR-132-3p were identified to be linked to ABCG2 protein expression in ccRCC patients of the second cohort. The interaction of these miRNAs with the ABCG2 3’UTR was confirmed in vitro cell culture experiments by reporter gene assays. Analysis of a potential association of ABCG2 expression with sunitinib response revealed a better outcome for patients with high ABCG2 levels. Conclusion: In this study, we found that higher ABCG2 expression contributes to longer survival in ccRCC patients and better response to sunitinib treatment. Whereas genetic variants had only a minor impact on ABCG2 variability in ccRCC, epigenetic regulation by miRNAs, in particular miR-210-3p and miR-132-3p, contributed to aberrant ABCG2 expression.

#5220 Chronic exposure to a novel AR-NDT inhibitor induces resistance via a selective metabolism pathway. Jonathon K. Obst,1 Jun Wang,1 David Williams,2 Allen H. Tien,1 Nasrin R. Mawji,1 Yu Chi Yang,1 Raymond J. Andersen,2 Marianne D. Sadrzad,1 BCC Cancer Research Centre, Vancouver, British Columbia, Canada; 2University of British Columbia, Vancouver, British Columbia, Canada.

Background: The androgen receptor (AR) is recognized as playing a crucial role in prostate cancer (PCA) maintenance and progression; therefore its inhibition has been the cornerstone of modern therapy for men who fail primary treatment. Current treatments are initially effective, however resistance ultimately develops and the disease progresses to a lethal form termed castration-resistant prostate cancer (CRPC). Our lab has discovered a new class of molecules (EPI) which inhibit the AR by binding to the N-terminal domain (NTD). The NTD interacts with transcriptional machinery, and its presence is vital for a transcriptionally functional receptor.

We have previously shown that EPI-002 specifically inhibits both full-length AR and constitutively active AR splice variants. The efficacy of EPI-056, the produg of EPI-002, is currently being tested in a Phase I/II clinical trial for CRPC. Here we propose novel resistance mechanisms arising from sustained AR-NTD inhibition, with the goal of preemptively developing backup compounds. Methods: The androgen sensitive prostate cell line (LNCaP-EPI) was generated by passing parental LNCaP cells weekly in media supplemented with EPI-002 beginning in September 2012. In vitro and in vivo studies using LNCaP and LNCaP-EPI cells were employed to confirm biological resistance. A human afinity microarray identified possible resistance mechanisms and was validated using qRT-PCR, western blot and functional studies. In vivo studies of LNCaP-EPI and LNCaP-EPI cells were challenged with EPI-045, an EPI-analog predicted to remain effective in the context of EPI-002 resistance. Results: LNCaP-EPI cells treated with 25 μM EPI-002 displayed similar growth rates to vehicle treatment, both in vitro and in vivo. Conversely, parental LNCaP cells showed significant growth inhibition in response to EPI-002. LNCaP-EPI cells retained sensitivity to anti-androgens and AR knock-down by targeted siRNA, implying functional AR remains essential for growth. qRT-PCR data demonstrated that EPI-002 had reduced ability to block AR mediated gene transcription. Interrogation of microarray data revealed candidate genes (UGT2B family) which were specifically upregulated in the resistant line, and may function to metabolize EPI-002. Supporting this hypothesis EPI-045 which is predicted to be resistant to UGT2B metabolism, was able to significantly inhibit LNCaP-EPI proliferation and AR transcriptional activity. Conclusions: Taken together, these data suggest an AR-specific mechanism of resistance, whereby EPI-002 is preferentially metabolized and removed from the cell. LNCaP-EPI cells remain dependent upon AR signalling, and are sensitive to anti-androgens used clinically as well as a novel EPI-analog. This work highlights the potential for combination or sequential therapy in the context of drug-resistant CRPC.

CANCER CHEMISTRY: Chemical Biology and Structure Biology Approach to Study Cancers

#5221 Target engagement approaches to validate small-molecule binders of the pioneering transcription factor FOXA1. Helen L. Evans,1 Shelley K. Doyle,1 Marius S. Pop,1 Becky Leifer,1 Kimia Ziadkhanpour,1 Angela N. Koehler1,2 David H. Koch Institute for Integrative Cancer Research, Cambridge, MA; 3Massachusetts Institute of Technology, Cambridge, MA.

The discovery of small-molecules that disrupt or promote the function of transcription factors, often considered ‘undruggable’ targets, is considered a significant challenge. The development of general and systematic approaches to discover small-molecule probes of transcription factors is therefore of substantial value. In this study, a high-throughput small-molecule microarray (SMM) screen was used to identify initial binders of FOXA1, which were studied using a variety of biochemical approaches to identify and characterize target engagement of these small-molecule probes in a cellular context. Tools for validating FOXA1 as a therapeutic target do not currently exist, although FOXA1 is a known mediator of androgen receptor (AR) action in Prostate Cancer (PCA), and has been demonstrated to both assist and antagonize AR activity, dependent upon the cellular context. Using the SMM technology, potential small-molecule binders of FOXA1 were identified, and enrichment for an interesting class of endogenous metabolites was observed. While an interaction between these compounds and FOXA1 has not previously been reported, they were found to exhibit meaningful inhibition of FOXA1-controlled transcription in prostate cancer cell lines. Compound-anchored beads were used to pull-down FOXA1 in whole cell lysates we demonstrated, using a western blot that the endogenous metabolite engages the transcription factor in this setting. Target engagement in live cells was demonstrated using bi-functional chemical probes, which contain a photo-reactive functional group that transforms transient protein-ligand interactions into stable covalent bonds upon UV irradiation. The probes were also modified with a bioorthogonal, or click chemistry handle, which enabled for assay read-outs using scintescence labeling and mass spectrometry. Using these approaches, we successfully validated the bimolecular interaction between the endogenous metabolites and FOXA1 in cell lysates and live cells, respectively. This report details the first known small-molecule to bind FOXA1 in a cellular setting and suggests a new perspective on the potential role of this class of endogenous compound in prostate cancer. Disregulation of ubiquitin signaling has been linked to many diseases, including cancer. Numerous DUBs are implicated in key pro-cancer pathways, including regulation of HIPPI, a control of RAS signaling, signaling through both canonical and non-canonical NFκB pathways, and regulation of p53 activity. Overexpression of USP14, USP17 and USP28 is linked to promoting non-small cell lung cancer (NSCLC). OTUB1 has shown to trigger lung cancer progression by inhibiting RAS monoubiquitination in KRAS mutant NSCLC. Notably, BAP1 (tumor suppressor) expression decreases in lung cancer tissues although its mRNA levels were not conserved among the dopamine receptor family and the residue with the largest effect is not conserved in any other family member, suggesting the basis of ONC201 specificity. Consistent with competitive inhibition, several residues were within the orthosteric binding site, however, two allosteric residues were also identified. In summary, ONC201 is the first DRD2 antagonist identified to date for oncology and its differentiated receptor pharmacology explains its unique selectivity, anti-cancer activity, and safety that has been observed in clinical trials.

Identification and validation of the cellular target of bioactive hits identified in a phenotypic screen is crucial for their further development into a drug. The gold standard proof for identification of a small molecule’s target is the discovery of mutations that confer resistance. However, selection of drug resistance and subsequent deconvolution of the relevant mutations that confer drug resistance remains time consuming. Therefore, a methodology that can accelerate the drug resistance selection process and that can simplify identification of relevant drug resistance mutations would benefit the drug discovery and development process greatly. Here we report a simple method to rapidly identify the mechanism of action of small molecules with anti-cancer activity. The method utilizes the positive selection of in-frame drug resistance mutations in the target protein of a small molecule derived from the localized genetic variation created by non-homologous end joining (NHEJ) repair of CRISPR/Cas9-induced double strand breaks. In brief, we introduced double strand breaks in the target proteins of selinexor, ispiinesib and tripoliode and treated these cells with the respective drug. Resistance was obtained rapidly and sequencing of resistant colonies revealed known as well as many new drug resistant protein variants. Next, we investigated whether this approach can be applied as a screening strategy on a subset of genes to identify the direct cellular target protein of a small molecule. We therefore, as proof of concept, designed a pooled sgRNA tiling library targeting all PAM sites of multiple genes and applied this to ispiinesib. Drug resistant colonies formed rapidly and were enriched with sgRNAs targeting the ispiinesib binding site in KIF11, ispiinesib’s target protein. Further sequencing of the sgRNA target gene locus revealed drug resistance mutations in KIF11, validating the feasibility of the methodology to uncover the target of a small molecule from a small pool of candidate genes. To conclude, we provide a new method for identification of the cellular target protein and binding site of a small molecule based on positive selection of drug resistant protein variants generated by targeted CRISPR/Cas-induced NHEJ repair.

A novel loop interactions within a parallel-stranded G-quadruplex formed in the human BCL-2 proximal promoter. Guanhui Wu, Clement Lin, Danzhou Yang. Purdue University, West Lafayette, IN.

The human BCL-2 gene contains a 39-bp GC-rich region upstream of its P1 promoter which has been shown to be critical for BCL-2 transcriptional regulation. Therapeutic inhibition of BCL-2 expression can reduce cell proliferation and the apoptotic threshold of tumorigenic cells. Previously, we have reported that the major G-quadruplex (G4) formed in the Pu39 G-rich sequence adopts a stable, parallel-stranded structure with two 1-n tandem repeats and 13 nt long central loop. Parallel G-quadruplexes have been found to be prevalent in promoter sequences; the 13 nt loop in BCL-2 Pu39G4 is the longest in this prototype parallel G-quadruplexes identified in human gene promoters. The structure of this G4 with such a long loop is important because it can enable specific small molecule recognition of this BCL-2 G-quadruplex over other G-quadruplexes and provide a potential basis for rational drug design targeting BCL-2 transcription. Thus, the objective of our study is to determine the molecular structure of the BCL-2 Pu39 G-quadruplex and the molecular interactions of this long loop in physiologically relevant K+ solution by Nuclear Magnetic Resonance (NMR) spectroscopy. Our NMR study shows that the BCL-2 Pu39G4 adopts a well-defined parallel-stranded G-quadruplex structure which contains three G-tetrads stabilized by Hoogsteen hydrogen bonding and three double-chain reversal loops containing 1:13:1 bases. The two 1-n double-chain reversal loops on two edges of the tetrad provide overall stability of the BCL-2 Pu39G4. The central 13 nt double-chain reversal long loop is more dynamic in confor-
mation. Specific interactions of the long loop are observed at both the 5′ and 3′ end with external tetrads as well as the flanking residues, which may also contribute the stable formation of this G4. The middle region of the 13-nt central long loop is highly dynamic and doesn’t show much interaction with the G-quadruplex core. The specific molecular interactions of the unique long central loop are specific for the G-quadruplex. This confirms our previous conclusion that there might be something really different from those in other parallel-stranded structures, e.g., c-myc and VEGF. The specific interactions are supported by our mutational analyses. The results are also supported by the DMS footprinting results which show that the guanines involved in the tetrad formation in this major G-quadruplex are well-protected against DMS methylation. Therefore, the knowledge about the molecular structure of this non-B-DNA conformation of the BCL-2 promoter region is essential for using the G-quadruplex as a target for anticancer drugs, which could be a novel approach to anti-BCL-2 drug discovery in cancer therapy.

#5226 Novel class of potent and selective inhibitors efface MTH1 as broad-spectrum cancer target. Manuel Ellermann,1 Anja Giese,1 Ashley Eheim,1 Stefanie Bunse,1 Roland Neuhaus,2 Jörg Weiske,3 Maria Quanz,3 Andrea Glasauer,4 Fredrik Rahm,5 Jenny Viklund,3 Martin Andersson,2 Tobias Gimman,2 Rickard Forsblom,6 Johan Lindström,7 Lionel Trésaugues,8 Matyas Gorjanacz1. 1Bayer Pharma AG, Berlin, Germany; 2Sprint Bioscience, Huddinge, Sweden; 3University of Southern California, Los Angeles, USA; 4Institute for Clinical Chemistry and Pathobiology, University of Erlangen, Germany; 5Biocenter and Institute of Medical Sciences, University of Gothenburg, Sweden; 6University of Umeå, Sweden; 7Lund University, Sweden; 8Sorbonne University, Paris, France.

We have previously found that ajoene targets multiple proteins in cancer cells and the aim of this project is to identify the specific protein targets of ajoene. To achieve this aim, we have synthesized a “tagged” ajoene analogue containing a biotin functional group. As biotin may alter the biological properties of ajoene, our strategy was to initially synthesize an azide-containing ajoene analogue (calles in azido-ajoene) using our 4-step synthetic route to ajoene analogues previously published. Azido-ajoene was found to retain cancer cell cytotoxicity similar to that of the parent ajoene. We then treated cancer cells (MDA-MB-231 breast and WHCO1 oesophageal cancer) with azido-ajoene to allow transfer of an azide label to the protein targets during thiolysis exchange with ajoene. We then collected lysate from the treated cells and performed an in vitro click reaction with a separately synthesized biotin-alkyne partner which was synthesized via a series of substitution and amide coupling reactions. Click chemistry covalently links biotin to the ajoene-tagged protein via a triazole linkage; and the feasibility of this method was validated by western blot. The biotinylated protein targets were purified using immobilised streptavidin beads and identified by MALDI-TOF mass spectrometry. It is anticipated that knowledge of the specific ajoene protein targets will provide valuable insights into the cytotoxic mechanism of action of ajoene in cancer cells.

#5228 The impact of microtubules on solution conductance and capacitance: implications for the use of AC electric fields in cancer therapy. Jack A. Tuszynski,1 Iara Santelices,2 Douglas E. Friesen,3 Clayton Bell,3 Jack Xiao,4 Vahid Rezania,5 Holly Freedman,6 Cameron Hough,7 Andrew J. Tsung,8 Kiran K. Velpula,9 Karthik Shankar1. 1University of Alberta, Edmonton, Alberta, Canada; 2University of Illinois College of Medicine at Peoria, Peoria, IL; 3University of Illinois College of Medicine at Chicago, Chicago, IL; 4University of Illinois at Chicago, Chicago, IL; 5University of California, San Francisco, San Francisco, CA; 6University of Illinois at Chicago, Chicago, IL; 7University of Texas Medical Branch at Galveston, Galveston, TX; 8University of Illinois College of Medicine at Peoria, Peoria, IL; 9University of Illinois College of Medicine at Chicago, Chicago, IL; 10University of Illinois College of Medicine at Chicago, Chicago, IL; 11Washington University School of Medicine, St. Louis, MO.

Garlic (Allium sativum) is a medicinal plant belonging to the lily family which has been used since ancient times for its beneficial health effects which include protection against infections and cancer. There are a cluster of bioactive compounds found in crushed garlic which contain sulfide or polysulfide functional groups. One of these compounds, ajoene, is able to interfere with biological processes by undergoing thiolysis exchange reactions with biological thiols, for example glutathione and cysteine residues on proteins. Importantly, ajoene is cytotoxic to cancer cells in the low micromolar range.
CANCER CHEMISTRY: Chemical Biology and Structure Biology Approach to Study Cancers

bound K-Ras4B but not N-Ras or H-Ras isoforms. Experimental evidence points to the farnesylated hypervariable region (HVR) of K-Ras4B as a major binding domain for CaM. Here, using molecular dynamics (MD) simulations we modeled K-Ras4B HVR interaction with Ca2+/CaM. Initial contacts of K-Ras4B HVR with CaM were determined by the nuclear magnetic resonance (NMR) chemical shift perturbation (CSP) data, which guided major interacting residue pairs between the HVR and CaM. In the simulations, two different topologies of Ca2+/CaM were modeled: CaM with stretched and flexible linkers. CaM has N- and C-lobes connected by a linker, and each lobe has its own hydrophobic pocket. Thus, the hydrophobic farnesyl tail of the HVR can dock into either lobe of CaM. We observed that the HVR strongly interacts with the linker of CaM. The K-Ras4B HVR is highly polybasic with lysine-rich, while the linker region of CaM is negatively charged. The docking of the farnesyl group into the hydrophobic pocket additionally helps to stabilize the HVR/CaM interaction. This added stabilization by the farnesyl is significant in the K-Ras4B/CaM interaction even though the interaction with the Ras catalytic domain is involved. K-Ras4B has only farnesyl modification, while other isoforms bear farnesyl and palmitoyl groups. The additional lipid modification in the HVR would obstruct CaM binding, suggesting CaM’s K-Ras4B-specific action. Our structural model of K-Ras4B/CaM association provides plausible clues to the PI3Kα activation involving the ternary complex. The abundant Ca2+/CaM can bind to the p85 domain of PI3Kα while binding to the K-Ras4B farnesylated HVR, releasing catalytic kinase domain autoinhibition and activating full PI3Kα activity.

#5230 Targeting two unique end-insertion G-quadruplexes formed in the 3′-end of the PDGFR-β core promoter nucleus hypersensitive element with ellipticine analog, Buket Onel,1 Prashansa Agrawal,2 Megan Carver,1 Laurence H. Hurley,3 Danzhou Yang1. Purdue University, West Lafayette, IN; 2Case Western Reserve University, Cleveland, OH; 3University of Arizona, Tucson, AZ.

Aberant expression of PDGFR-β promotes multiple hallmarks of cancer, and its transcriptional regulation provides an attractive means to inhibit the PDGFR-β signaling pathway. The nucleus hypersensitive element (NHE) region of the human PDGFR-β core promoter has been shown to be responsible in regulating approximately 60% of the PDGFR-β basal promoter activity. Multiple overlapping G-quadruplexes (G4s) have been shown to form in this NHE region. We previously determined the most stable G4 structure formed in the 5′-end of PDGFR-β NHE region. Significantly, an ellipticine analog, GSA1129, has been shown to selectively bind to the G4 formed in the 3′-end NHE region, thereby shifting the dynamic equilibrium toward the 3′-end G4. This selective interaction was shown to result in suppression of PDGFR-β activity in both cancer cell lines and a preclinical animal model. Thus, characterization of 3′-end G4 provides an important basis for understanding the molecular recognition and could facilitate the development of rational drug design. In this study, we used NMR spectroscopy to show that the PDGFR-β NHE 3′-end sequence forms two novel end-insertion intramolecular G4s which exist in a dynamic equilibrium under physiological salt condition. One is the 5′-insertion-G4 with a 3′ non-adjacent flanking guanine inserted into the 5′-external tetrad. We further confirmed that these novel end-insertion G4s can readily form in the 3′-end NHE sequence under physiologically relevant ionic conditions using dimethyl sulfoxide (DMS) footprinting experiments. To elucidate the molecular interactions of ellipticine analog with the 3′-end G4s, we studied the binding of GSA1129 to both of the end-insertion G4s. Significantly, our CD melting studies showed that GSA1129 markedly increased the stability of both end-insertion G4s by about 25°C. Furthermore, 1H NMR titration experiments have shown that GSA1129 selectively binds to the G4 formed in the 3′-end NHE region. The novel end-insertion structures and the dynamic nature of the PDGFR-β NHE 3′-end G4 may make it an effective target for GSA1129 binding and regulation. Our result highlights the dynamic nature of the PDGFR-β NHE 3′-end sequence and the importance of identifying the exact sequence for the formation of the naturally occurring G4 structure.

#5231 Undifferentiated cell maker Rb2LC-N lectin have high affinity to pancreatic cancer cells and residual cancer cells. Osamu Shimomura,1 Tastuya Oda,1 Hiroaki Tateno,2 Sho Tachino,1 Junji Matsui,2 Yuusuke Ozawa,2 Jun Hirabayashi,2 Nobuhiro Ohkohchi,3 1University of Tsukuba, Tsukuba-city, Japan; 2National Institute of Advanced Industrial Science and Technology, Tsukuba-city, Japan; 3Eisai Co., Ltd., Tsukuba-city, Japan.

The glycosylation in cancer cells remains still unclear despite the whole human genome understanding. Recent technical advances give us great awareness about the consequence of the glycosylation. The glycomes of cancer cell surfaces are often unique with aberrant glycans, including sialylation, fucosylation, O-glycan truncation, and N- and O-linked glycan branching. The sugar binding avidity towards molecular materials reveals important structure and characterization. Recent study suggested lectins are more widely accepted that involved in many biological phenomena inside mammalian or as chemical research tools. Despite years of effort to develop cancer therapies, there were no effective molecular targeting drugs for pancreatic adenocarcinoma (PDAC).

One possible reason for these difficulties, PDAC cells are densely covered with numerous carbohydrate moieties. Significantly, an ellipticine analog with the 3′-end sequence forms two novel end-insertion intramolecular G4s which exist in a dynamic equilibrium under physiological salt condition. One is the 5′-insertion-G4 with a 3′ non-adjacent flanking guanine inserted into the 5′-external tetrad. We further confirmed that these novel end-insertion G4s can readily form in the 3′-end NHE sequence under physiologically relevant ionic conditions using dimethylsulfate (DMS) footprinting experiments. To elucidate the molecular interactions of ellipticine analog with the 3′-end G4s, we studied the binding of GSA1129 to both of the end-insertion G4s. Significantly, our CD melting studies showed that GSA1129 markedly increased the stability of both end-insertion G4s by about 25°C. CANCER CHEMISTRY: Chemical Biology and Structure Biology Approach to Study Cancers

#5233  Pancreatic cancer specific glycosylations survey by a panel of lectin staining: TN antigen exposure as a result of O-glycan truncation. Yusuke Ozawa,1 Tatsuya Oda,1 Osamu Shimomura,1 Hiroaki Tateno,2 Jun Hiramabashi,2 Nobuhiro Okohochi,3 *University of Tsukuba, Tsukuba, Japan; 1National Institute of Advanced Industrial Science and Technology, Japan.

The expression of every cell type is predominantly composed of cell-specific glycans, and glycosylation changes in cancer has been used in clinical field as a tumor markers, such including AFP and CA19-9. We focused pancreatic cancer, the most intractable cancer with difficulty in early diagnosis, and insisted to grasp glycosylation patterns by using a panel of lectin histochemical stainings. Lectins are subgroup of proteins that specifically recognize and bind glycans, and thus helpful indication of glycosylation patterns. Lectin staining is one of the advanced technologies which enables glycosylation pattern of target materials at once, however, obtained data with homogenized protein materials applied lacks histological location and information. Instead, we used a panel of 20 types of lectins histochemical staining for cancer and normal tissues. The staining patterns were firstly classified according to the ratio between cancer cells and stromal cells. a) Cancer high (cancer cell + and stromal cell - ) b) equal (cancer cells + + or stromal cells + + +) c) Cancer Low (cancer cells - or + and stromal cells + + +). Further more, the staining in cancer cell was compared with that of non cancerous pancreatic ductal epithelial cells. Among 20 lectins, CLN-Lycocye nebularis Lectin binds motifs containing α/βGalNAc, TN antigen, and blood group A. showed cancer cell staining higher than normal tissue carcinoma (Pancreatic cancer cell 31 out of 58, 71%) were positive for CLN, but normal pancreatic duct cells (2 out of 42 patients, 4%) were positive in patients of pancreatic cancer. CLN is known to be recognized as TN antigen in O-glycosylation. Previously, it reported that during malignancy, glycosylation displays abnormal expression of shortened or truncated glycans, such as a TN antigen, Tn antigen and their sialylated forms, ST, STn antigen. CLN-staining pattern we showed in this report is considered to matching TN staining. Our result indicated that specific affinity of CLN lectin in pancreatic cancer and counterpart glycoprotein are STn antigen. We may insist that STn glycoprotein antigen could be used as a diagnostic marker of Pancreatic cancer and also it would be a target of new tumor-targeting strategies.

#5234  Expression of cytochrome P450 in head and neck cancer cell lines; Daniela F. Presa,1 Garett Ribeiro Morais,1 Mark Sutherland,1 Jim McCaul,1 Jacques Robert,2 Laurence Patterson,1 Klaus Pors1.1Institute of Cancer Therapeutics, University of Bradford, Bradford, United Kingdom; 2The Royal Marsden NHS Foundation Trust, London, United Kingdom; 3Institut Bergonié, University of Bordeaux, Bordeaux-cedex, France.

Background: The high expression of cytochrome P450 (CYP) enzymes including isofoms CYP1A1, B1 and 2W1 in some tumor types compared to normal tissue make these potential targets for targeted drug discovery. Our efforts in this space have resulted in the discovery of duocarmycin bioprecursors that are bioactivated by CYP1A1 and CYP2W1 expressed in malignant tissues1-2. Epidemiological studies have shown that head and neck cancer (HNC) is a complex multistage process that in part involves exposure to a combination of carcinogens and the capacity of certain drug-metabolising enzymes including CYPs to detoxify or activate such carcinogens. Here, we report on the expression of CYP1A1, CYP1B1 and CYP2W1 in HNC cell lines and human primary tissues. Materials and methods: A panel of HNC cell lines (FaDu, Detroit-562, A253, OSC19) was characterized for CYP1A1, CYP1B1 and CYP2W1 gene expression using real time PCR. Furthermore, immunofluorescence (IF) was used to detect protein expression in HNC cell lines and immunohistochemistry (IHC) in xenografts, paraffin-embedded and snap-frozen human HNC tissue. Anti-proliferative activity was measured using the MTT assay and DNA damage was measured using the comet assay. Results: In the HNC cell lines significant expression (5-10 fold) was shown at the gene level for CYP1A1 and CYP1B1 whereas CYP2W1 was hardly detected. However, CYP2W1 was expressed in FaDu and Detroit xenografts and in a small cohort of 10 human HNC samples as measured by IF and IHC, respectively. In agreement with CYP1 expression, the cytotoxicity results of ICT2700 and ICT2706 revealed FaDu and Detroit-562 as the most sensitive HNC cell lines suggesting bioactivation of these two lead duocarmycin bioprecursors. Conclusion: Accordingly, from these data we can conclude that CYP1A1, CYP1B1 and CYP2W1 are expressed in selected HNC cell lines and tumor tissue. In addition, early evidence suggests that CYP2W1 expression is stimulated by the presence of an in vivo microenvironment. How-ever a larger cohort (n=60) of clinical HNC samples will be used to confirm this observation and will be reported at the annual AACR meeting. [1] Sheldrake et al.Reengineering of the duocarmycin structural architecture enables bioprecursor developments targeting CYP1A1 and CYP2W1 for biological activity. J Med Chem. 2013, 56, 62737. [2] Travica et al. Colon cancer-specific cytochrome P450 2W1 converts duocarmycin analogues into potent tumor cytotoxins. Clin Cancer Res. 2013, 19, 295261.

The linear ubiquitin chain assembly complex (LUBAC) is the only E3 ubiquitin ligase known to generate linear polyubiquitin chains in vitro. LUBAC is composed of three proteins - HOIL-1L, HOIP and SHARPN- of which the interaction between HOIL-1L and HOIP has been shown to be critical for LUBAC assembly and function. This interaction occurs between the ubiquitin-like (UBL) domain of HOIL-1L and the ubiquitin-associated (UBA) domain of HOIP. One known substrate of LUBAC is the regulatory subunit NEMOF (NEMO kappa B essential modulator), part of the IKK complex, which results in activation of NF-κB. We hypothesize that disruption of the HOIL-1L-HOIP interaction would prevent LUBAC ubiquitylation activity and result in down-regulated activation of NF-κB. We have synthesized a family of small inhibitor peptides designed to mimic aspects of the beta-helical interacting interface of HOIP-UBA. We demonstrated how single amino acid substitutions and hydrocarbon stapling can affect overall peptide shape and helicity, and correlate that structural information to peptide binding affinity, ability to affect LUBAC complex formation and resulting effect on LUBAC ubiquitylation activity in vivo. These findings continue to validate inhibition of LUBAC via interference with the HOIL-1L-HOIP interaction as a potential target to affect NF-κB signaling. Compounds which affect LUBAC activity have potential use in LUBAC-dependent NF-κB activation in the activated B cell-like (ABC) subtype of diffuse large B-cell lymphoma (DLBCL), the DLBCL subtype that is most resistant to current therapies.

#5236  The dynamic interplay between the cancer genome mutating enzyme APOBEC3B and DNA substrates. Ozlem Demir,1 Jeffrey R. Wagner,1 Ke Shi,1 Michael A. Carpenter,2 Surajit Banerjee,2 Nadine M. Shaban,2 Kayo Kurashashi,2 Daniel J. Salamanco,2 Jennifer L. McCann,2 Gabriel J. Starrett,2 Justin V. Duffy,1 Daniel Harki,2 Hideki Alhara,2 Rommie E. Amaro,1 Reuben S. Harris.1 University of California, San Diego, La Jolla, CA; 2University of Minnesota, Minneapolis, MN; 3Cornell University, Lempont, IL.

The APOBEC3 (A3) family of enzymes catalyze deamination of cytosines to uracils (C-to-U) in single-stranded (ss) DNA, and is an important part of innate immune responses against viruses and transposons. Recent data also indicate that APOBEC3B (A3B) is a major source of genomic mutations in multiple cancers and a contributor to the evolution of drug resistance. A3B is therefore a promising anti-cancer target. Using single-strand information and structural modeling, we generated a model for wild-type A3B in complex with ssDNA and used molecular dynamics to monitor the dynamics of the native interactions of wild-type A3B with ssDNA. The details of A3B-ssDNA interaction and its implications for potential inhibitor design will be presented.

#5237  Targeting DCN1-mediated neddylation in lung SCC with novel small-molecule inhibitors. Richard Barrios,1 Jared Hammill,2 Jieki Min,2 Kip Guy.3 1FIU Herbert Wertheim College of Medicine, Miami, FL; 2St. Jude Children’s Research Hospital, Memphis, TN; 3University of Kentucky College of Pharmacy, Lexington, KY.

Due to the anti-neoplastic properties and clinical successes of the proteasome inhibitors Bortezomib and Carfilzomib, the ubiquitin-proteasome system (UPS) has become a new target of interest in oncology research. The clinical toxicity induced by these inhibitors, likely caused by complete inhibition of the UPS, has resulted in a need for the development of more selective UPS regulators. A more in-depth understanding of the intrinsic molecular mechanisms that are associated with the UPS has unmasked the potential for improved therapies via more specific targets such as the process of neddylation, which is thought to control 15-20% of the UPS.5 Because neddylation, an enzyme known as DCN1 for ‘‘defective in cullin neddylation 1’’ functions as a co-E3 to help steer a ubiquitin-like protein (UBL), NEDD8, from an E2 enzyme, UBC12, to a cullin (CUL) neddylation site (6’’ 7’’ 9’’ 11). Because DCN1 has been found to be amplified in certain squamous cell carcinomas (SCCs; e.g. lung, esophagus, and head and neck), this in vitro, pre-clinical study demonstrates the potential of the DCN1-UBC12 interaction of an anticancer site in lung SCCs through the use of novel small-molecule inhibitors from the St. Jude (SJ) library. After optimizing dosing regiments, it has been determined that re-administering the SJ compounds (i.e. SJ690, SJ447, SJ446, and SJ323) every 24-hours to address the issue of protein turn-over, produces more efficacious treatment. The most biochemically-potent
antagonists in the compound series were also shown in these primary cell lines to potentiate other therapeutic agents such as Cisplatin; however, these compounds alone do not induce DNA damage, nor do they elicit caspase 3/7 activity. Nonetheless, combination treatment of the SJ compounds with Staurosporine in SCC cell lines, potentiated caspase 3/7 activity at varying degrees. Collectively, this data suggests a promising improvement in our understanding of the mechanism by which the inhibition of DCN1 affects cancer cells, informing pre-clinical development of the SJ DCN1 antagonists.

#5238 Structural and biochemical characterization of membrane bound KRAS. Andrew G. Stephen,1 Que Van,1 Marco Tonelli,2 William Gillette,1 Dominic Esposito,1 Ben Niu,1 Michael Gross,1 Frank Heinrich,1 Arvind Ramathan,1 Christopher Stanley,1 Frederick National Laboratory for Cancer Research, Frederick, MD;2National Magnet Resource Facility at Madison, Madison, WI;3Washington University in St. Louis, St. Louis, MO;4Carnegie Mellon University, Pittsburgh, PA;5Oak Ridge National Laboratory, Knoxville, TN.

KRAS4b functions as a molecular switch cycling between an active GTP bound state and inactive GDP state. Active KRAS4b binds tightly to RAF1 via its Ras binding domain (RBD), and mutation of the RBD has been shown to hamper the ability to bind RAF1. The interaction of KRAS4b with RAF1 is critical for the activation of the mitogen-activated protein kinase (MAPK) pathway. We have previously presented and confirmed by 32P-postlabeling the identity of the major RAF1-KRAS4b complex that is formed via the RBD domain of RAF1 where KRAS4b is predominantly GDP-bound. Here we report the structural and thermodynamic parameters of the human KRAS4b-Raf (RAF1) interaction, with a focus on understanding the mechanism by which the inhibitory activity of the membrane bound KRAS4b blocks the activation of RAF1 and the activation of downstream effectors involved in cancer development. We demonstrate that the interaction of KRAS4b with RAF1 is highly specific and that the interaction is dependent on the intrinsic conformation of the receptor kinase. These findings support the clinical utility of selective small-molecule inhibitors targeting the membrane-bound form of KRAS4b. 

#5239 Probing the cancer epigenome: empowering target validation by open innovation. Ingo V. Hartung,1 Cheryl Arrowsmith,2 Volker Badock,1 Naomi Barak,1 Markus Berger,1 Peter J. Brown,1 Clara D. Christ,1 Erik Eggert,1 Ursula Egner,1 Oleg Fedorov,1 Amaury Fernandez-Montalvan,1 Matyas Gorjanac,1 Andrea Haegerbarth,1 Bernard Haendler,1 Roman C. Hillig,1 Simon H. Holton,1 Kilian V. Huber,1 Seong J. Koo,1 Antonius ter Laak,1 Susanne Mueller,1 Anke Mueller-Fahrmann,1 Cora Scholten,1 Stephan Siegel,1 Timo Stellfeld,1 Detlef Stoeckigt,1 Carlo Stresemann,1 Masoud Vedadi,2 Joerg Weiske,1 Hilmar Weimann,1 1Bayer AG, Berlin, Germany; 2University of Toronto, Toronto, Ontario, Canada; 3Oxford University, Oxford, United Kingdom.

Low reproducibility of published target validation studies as well as the frequent failure of genetic knock-down effects to phenocopy those of small molecule inhibitors have been recognized as road blocks for cancer drug discovery. Academic and industrial institutions have started to address these issues by providing access to high quality small molecular probes for novel targets of interest. Here we discuss probe discovery challenges and quality criteria based on the generation of three novel inhibitors for epigenetic targets. ATAD2 functions as a co-factor for oncogenic transcription factors such as ER that bind to chromatin through its bromodomain (BD). ATAD2 has been proposed to act as a co-factor for oncogenic transcription factors such as ERα and Myc. A more thorough validation of ATAD2 as a therapeutic target has been hampered by the lack of appropriate ATAD2 inhibitors. Here we disclose a structurally unprecedented series of ATAD2 BD inhibitors identified from a DNA-encoded library screen. Optimization delivered BAY-850, a highly potent and exceptionally selective ATAD2 BD inhibitor, which fully recapitulates effects seen by genetic mutagenesis studies in a cellular assay. The three BD and PHD-finger (BRPF) family members are found in histone acetyltransferase complexes. Whereas bromodomain inhibitors with dual activity against BRPF1 and 2 have been described before, we now disclose BAY-299, the first selective inhibitor of the BRPF2 BD with high selectivity against its paralogs. Isoform selectivity was confirmed in cellular protein-protein interaction assays and rationalized based on X-ray structures. BAY-598, a highly selective, cellurally active and orally bioavailable inhibitor of the protein lysine methyl transferase SMYD2, had been disclosed previously (Stresemann et al., AACR 2015). Development of BAY-598 allowed the identification of new methylation targets of SMYD2 as well as a proposed role of SMYD2 in pancreatic cancer. These results support further development of small molecule inhibitors as research tools to probe the functional role of novel epigenetic targets and underscore the power of open innovation for advancing our understanding of cancer target biology.

A series of six titanium dioxide and two cerium oxide engineered nanomaterials were assessed for the induction of cytotoxicity, reactive oxygen species (ROS), and various types of DNA and protein damage in human respiratory BEAS-2B cells exposed in vitro for 72 hours at several concentrations. Although only limited cytotoxicity was observed at concentrations up to 300 μg/ml for all of the nanomaterials, significant increases in 8-oxo-deoxyguanosine, lipid peroxidation mediated protein adducts, and endogenous DNA adducts measured by whole cell lysis were detected at concentrations as low as 30 μg/ml, suggesting that molecular changes associated with ROS induction may provide a better means of assessing the low-dose hazards posed by nanomaterials. To identify molecular properties predictive of the ability of nanoparticles to induce ROS sequelae, a least absolute shrinkage and selection operator multiple regression approach has been used to identify relationships between assay outcomes and nanoparticle physical/chemical properties, including particle size, surface area, zeta potential, and elemental analysis. For several of the assay endpoints examined, concentrations of trace metals in the nanoparticles appear to be better predictors of assay outcomes than physical properties. This is an abstract of a proposed presentation and does not necessarily reflect EPA policy.

#5241 Using affinity probes to explore the nephrotoxicity of aristolochic acid. Viktoriya S. Sidorenko, Kathleen G. Dickman, Thomas Rosenquist, Radha Bonala, Sivaprasad Attaluri, Irina Zaitseva, Charles Iden, Francis Johnson, Arthur P. Groslamb. SUNY at Stony Brook, Stony Brook, NY.

Aristolochic acid, AA, is a natural compound found in Aristolochia plants used in Chinese Traditional Medicine and is a component of many herbal remedies used worldwide. In humans, exposure to AA is associated with kidney toxicity and otherwise rare upper urinary tract cancer (UTUC). AA undergoes bioactivation creating reactive species of AA that bind covalently to proteins and DNA. Formation of mutagenic AA-DNA adducts leads to AA-induced cancers. We identified the mutational signature associated with AA exposure in patients with UTUC in Taiwan, as well as in AA-initiated cancers in liver, bladder and kidneys. Meanwhile, the mechanism of AA nephrotoxicity remained a mystery, with covalent and non-covalent binding of AA or its metabolites to proteins hypothesized to be involved in its nephrotoxic effects. As millions of people in Asia have ingested AA and no effective therapies are known, establishing the molecular mechanism(s) of AA nephrotoxicity is a topic of major importance. A series of AA analogs were used to design affinity probes for target identification. Structure activity relationship studies in human cells aimed in identifying a position in AA suitable for introducing biotinylated, aminopropyland alkynel linkers. In addition, we have developed and validated monoclonal antibodies against AA-bovine serum albumin and/or AA-DNA covalent adducts. Combined with proteomics techniques, AA-affinity probes and monoclonal antibodies provide powerful tools for defining AA targets in human kidneys. We attached the aminopyroloxy derivative of AA to magnetic beads coated with N-hydroxysuccinimidio acyl linkers. These probes, in parallel with unmodified, “control” beads were incubated with renal cortex lysates obtained from C3H1 mice selected for their sensitivity to the effects of AA. Bound proteins were digested on bead, then identified by mass spectroscopic peptide analysis, with a total of 316 bound proteins detected. Spectral counts for 128 proteins bound to AA-beads were higher than those for control beads. After correction for nonspecific binding, 18 of these proteins had spectral counts of 10 or higher. These proteins are localized to various organelles, indicating high coverage of the major subcellular compartments. Among these proteins, Cryz2, quinone oxidoreductase-like 2, was the lead candidate. Based on homology, Cryz2 belongs to the family of the quinone oxidoreductase-like protein and bears a mitochondrial localization sequence. This protein retains conserved domains for both quinone oxidoreductase activity and NAD(P) binding sites, which is of particular interest since other oxidoreductases, such as NQO1, are known to catalyze nitroreduction, the initial step in the bioactivation of AA. In summary, our studies provide guidelines for design of AA-affinity probes and reveal an enzyme that may be responsible for AA activation in mitochondria, by generating active intermediates and inducing mitochondrial damage in renal tissue.

#5242 Further evidence that the DNA-interactive Pyrolorenbuzidiazepine (PBD) Dimer SIG-136 works through a transcription factor inhibition mechanism. Julia Mantaj,1 Paul J. Jackson,2 David E. Thurston,1 Khondaker Miraz Rahman1. 1King’s College London, London, United Kingdom; 2Fentogenix Limited, London, United Kingdom.

In previous studies, the DNA-interactive PBD dimer SIG-136 demonstrated potent inhibition of the transcription factor SP1 via a transcription factor binding mechanism. In the present study, we investigated if a similar mechanism was responsible for the inhibition of the transcription factor SP3. A series of 2D and 3D DNA-SP3 complexes were constructed to determine the extent of DNA-SP3 binding using docking and molecular dynamics (MD) simulations, and to determine if the DNA-SP3 complex could be altered by treatment with SIG-136. DNA-SP3 binding experiments with Bacillus subtilis RNA polymerase, a DNA-dependent RNA polymerase, were performed to determine the impact of SIG-136 on the transcription activity of SP3. The results demonstrated that SIG-136 significantly inhibited the interaction of DNA and SP3, and decreased transcription activity of SP3. These findings suggest that SIG-136 targets a DNA-binding transcription factor, and that this inhibition could be the mechanism responsible for the inhibition of SP3 activity by SIG-136.
The pyrrolo[2,1-c][1,4]benzodiazepines (PBDs) are sequence-selective DNA minor-groove interacting agents. The PBD dimer SJG-136 has currently been investigated in Phase II clinical trials in ovarian cancer and leukemia in the UK and the USA. More recently, PBD dimer analogues are being attached to tumour-targeting antibodies to create Antibody-Drug Conjugates (ADCs), some of which are now in Phase 3 clinical trials with many others in pre-clinical and clinical development. Transcription factors (TFs) are sequence-specific DNA-interacting proteins that bind to consensus DNA sequences, thereby controlling transcription. TFs regulate processes such as cell differentiation, proliferation and apoptosis. The interaction of a small-molecule with the consensus DNA recognition sequences of TFs can prevent a TF from interacting with its cognate sequence, thereby inhibiting the expression of genes critical for proliferation and proliferation of cancer cells. There is growing evidence that PBDs may exert, at least in part, their pharmacological effect through TF inhibition in addition to the arrest of the replication fork, DNA strand breakage, and inhibition of enzymes including endonucleases and RNA polymerases. For this reason, there is now interest in using PBDs as the basis for a small-molecule strategy to target specific DNA sequences for TF inhibition as a novel anticancer therapy. We have developed a reversed-phase HPLC/MS method as a tool to evaluate the interaction of DNA-binding PBD molecules with oligonucleotides of varying lengths and sequences. Using this methodology, we have demonstrated that the PBD dimer SJG-136 binds to the cognate sequences of the oncogenic transcription factors NF-κB, EGR-1, AP-1 and STAT3. Surprisingly, significant differences in the rate of binding to different cognate sequences were observed which may explain, at least in part, the differences in potency of SJG-136 in various tumour cell lines. Furthermore, an RT PCR study has been carried out using the human tumour cell lines MDA-MB-231 (breast) and HT-29 (colon) to see whether these transcription factors are affected in vitro. The results were consistent with the HPLC-MS studies in that SJG-136 was shown to significantly down-regulate a number of AP-1- and STAT3-dependent genes such as Bcl-2, VEGF, p53 and survivin. These findings add significantly to knowledge of the mechanism of action of SJG-136 and related PBD compounds, and could be relevant for the correct interpretation of clinical activity of molecules of this type both as stand-alone agents and as ADC payloads.

PREVENTION RESEARCH: Chemoprevention and Cancer

#5243 Novel non-COX inhibitory sulindac derivative with β-catenin suppressing activity reduces the formation of colorectal adenomas and adenocarcinomas in the APC<sub>min-Fucci</sub> mouse model. Kevin J. Lee,1 Xi Chen,1 Jacob Valiyaveetil,1 Ashley S. Lindsey,1 Joel Andrews,1 Veronica Ramirez-Alcantara,1 Adam B. Keeton,1 Nathan Y. Chang,1,2 Harry Gourtsoyiannis,2,3 Maggie Clapper,1 Wen-Chi Horne,1 Xiwei Wu,1 Arthur Riggs,1 Sanjay Awasthi,2,4 1City of Hope, Duarte, CA; 2Texas Tech Health Science Center at Lubbock, Lubbock, TX

SJG-136 can reduce the number and size of preneoplastic colorectal adenomas in patients with familial adenomatous polyposis (FAP), but is not recommended for long-term use as a cancer chemopreventive drug because of potentially fatal toxicities associated with cyclooxygenase (COX) inhibition. Here we characterize the anti-neoplastic properties of a novel sulindac derivative, ADT-061, that lacks COX-1 and COX-2 inhibitory activity. ADT-061 potently and selectively inhibited colon tumor cell growth in vitro with IC50 values of 0.3-0.5 μM by inducing apoptosis without affecting the growth of normal colonocytes at concentrations 100x higher. By comparison, sulindac sulfide (SS) inhibited colon tumor cell growth with IC50 values of 40-60 μM, and had only modest tumor cell selectivity. ADT-061 selectively inhibits multiple cyclic GMP phosphodiesterases (PDE) isozymes, previous studies have suggested an important role for PDE10 in colon cancer (Li et al, Oncogene, 2014; Lee et al, Oncotarget, 2015). At concentrations comparable to its IC50 values, ADT-061 selectively inhibits PDE10 to induce an increase in intracellular cGMP levels and activate protein kinase G (PKG). ADT-061 also suppressed nuclear levels of β-catenin and induced cell cycle arrest and apoptosis, within the same concentration range that inhibits tumor cell growth. With attractive drug-like properties, the chemopreventive activity ADT-061 was assessed using the APC<sub>min-Fucci</sub> mouse model of spontaneous colorectal tumorigenesis. Prior to treatment, colonoscopy exams were performed on all APC<sub>min-Fucci</sub> mice (males, 6-7 weeks of age) to ensure the absence of colorectal adenomas. At 7-8 weeks of age, mice were assigned (19 per group) to receive either unsupplemented chow (control) or chow supplemented with ADT-061 (1500ppm) for 14 weeks. No discernible toxicity was observed during the experimental period. Double-blinded pathological analysis of fixed colon tissues revealed that ADT-061 not only reduced the multiplicity of colon adenomas by 50% (Mean ± SEM, control vs. ADT-061, 3.95 ± 0.81 vs. 1.95 ± 0.58, P < 0.05), but also decreased the incidence of colon adenomas by 36.7% (control vs. ADT-061, 94.7% vs. 57.9%, respectively). ADT-061 treatment reduced the multiplicity of polypoid adenomas (36%), flat adenomas (100%, P < 0.05), and microadenomas (69%). The formation of colorectal adenocarcinomas found in 15.8% of untreated mice was completely inhibited in mice treated with ADT-061. These data demonstrate that ADT-061 treatment is a potent chemopreventive agent even to APC<sub>min-Fucci</sub> mice prior to the detection of gross colonic tumors. These observations support further evaluation of ADT-061 and analogs for colorectal cancer chemoprevention.

#5244 Partial knockdown of RLP76 prevents cancer susceptibility of p53 null mice. Sharad S. Singhal,1 Jyotsna Singhal,1 Joshua Tompkins,1 David Horne,1 Xiwei Wu,1 Arthur Riggs,1 Sanjay Awasthi,2,4 1City of Hope, Duarte, CA; 2Texas Tech Health Science Center at Lubbock, Lubbock, TX

P53 is a stress-responsive, genome protective, tumor suppressor whose functions are lost or altered in nearly all neoplasia. P53 homoygous knockout mice (p53<sup>−/−</sup>) develop spontaneous lymphoma and other malignancies in nearly 100% of cases by 6 months of life. In stark contrast, homoygous gene knockout of the stress-respon- sive, anti-apoptotic, mercapturic acid pathway transporter protein, RLP76, results in marked protection from chemical carcinogenesis. P53 expression and activation is regulated by intermediary metabolites of this pathway, and p53 regulates the expression of key enzymes of this pathway. P53 can directly bind to RLP76 through a CDK-interaction domain, and inhibit its transport activity as well as endocytosis stimulatory activity. These results indicate that RLP76 is an effector of p53 in a manner analogous to its known function as the first known effector of the Ras pathways that regulate membrane plasticity, motility and invasion. This translates into reduced kinase signaling down-stream of membrane-receptor/lipid interactions and interactions. An inverse relationship between RLP76 and p53 protein and mRNA expression has been observed in vitro, and is confirmed by analysis of human cancer genomic analyses in the COH database. RLP76 depletion causes apoptosis in cancer cells independent of p53 status, strengthening the view that RLP76 is a key down-stream effector of p53. We reasoned that if RLP76 is necessary for cancer to develop in p53-deficient animals, its suppression will reduce the incidence of malignancy in 12-week old p53<sup>−/−</sup> mice treated with COHSA007 phosphorothioated antisense, 200 μg i.p.2wk till age 8 months. Results of our studies confirmed these predictions, since 4/4 scrambled antisense treated p53<sup>−/−</sup> mice developed T-cell lymphoma whereas 8/8 COHSA007 treated p53<sup>−/−</sup> mice survived to the end of the experiment without development of any malignancy. These findings demonstrate that RLP76 is required for malignancy in the p53<sup>−/−</sup> mice. Taken in context of our previous studies showing that RLP76<sup>−/−</sup> mice are highly resistant to inflammation and carcinogenesis in chemical carcinogenesis models of the skin and lung, the present findings strongly support the idea of an existential role of RLP76 in the malignant phenotype, and strengthen the rationale for using targeted systemic depletion of RLP76 for treat- ment of human neoplasia (Supported in part by the Department of Defense grant W81XWH-16-1-0641 and UPSH grant CA 77905).

#5245 Peretinoin prevents the accumulation of somatic gene mutations and reverts neoplastic lesions to normal liver-like in platelet-derived growth factor-c transgenic mice. Taro Yamashita, Hikari Okada, Masao Honda, Shui- chi Kaneko. Kanazawa University Hospital, Kanazawa, Japan

Hepatocellular carcinoma (HCC) develops with progressive accumulation of somatic genetic changes. A well-known example is reported to suppress the development of HCC, but the molecular mechanism in detail remains to be obscure. Here we evaluated the effect of peretinoin on preneoplastic nodules and HCC developed in platelet derived growth factor-c (PDGF-C) transgenic mice liver by gadolinium ethoxybenzyl diethylenetriamide pentaacetate acid (Gd-EOB-DTPA)-enhanced magnetic resonance imaging (MRI) and whole exome sequence analysis. We confirmed the progressive accumulation of somatic muta- tions in hypervascular liver cancer tissues compared with hypovascular preneoplastic and non-cancerous background liver tissues in PDGF-C transgenic mice. Surprisingly, peretinoin treatment in HCC as well as preneoplastic nodules resulted in the accumulation of less gene mutations compared with vehicle. Gd-EOB-DTPA uptake capacity and its transporter OATP1 was confirmed to be re-activated in peretinoin treated nodules in mice. Gene and protein expression analysis indicated the inactivation of cell cycle with low Ki-67 labeling indexes in peretinoin treated nodules. The reversion of Gd-EOB-DTPA uptake capacity was confirmed in preneoplastic nodules and a subset of classical hypervascular HCCs. Notably, peretinoin supplementation increased the expression of OATP1B3 in mature hepatocyte-like HCC cell lines in vitro, whereas supplementation of tretinoin (all-trans retinoic acid) had no such effects and rather suppressed OATP1B3. Taken together, our data suggested the utility of peretinoin to revert the malignant transformation processes of hepatocytes by preventing accumulation of gene mutations especially in early stages of hepa-tocarcinogenesis. Peretinoin but not tretinoin can induce the expression of a ma-
tured hepatocyte marker OATP1B3, suggesting that peretinoin may exert its anti-tumor effect with hepatocytic differentiation capacity independently of the activation of retinoic acid signaling.

#5246 Effects of bazedoxifene either alone or in combination with letrozole in the prevention of chemically induced mammary cancers. Barbara K. Dunn, Chen Suen, Ronald A. Lubet, Vernon E. Steele, Clinton J. Grubbsb.

bNCI, Bethesda, MD; cUniv. of Alabama Comp. Canc. Ctr., Birmingham, AL.

Bazedoxifene is a third-generation selective estrogen receptor modulator (SERM) that has been clinically approved in Europe for the prevention and treatment of postmenopausal osteoporosis. The agent has also been shown to have therapeutic activity against estrogen receptor positive (ER) breast cancer. Our laboratory is currently evaluating bazedoxifene for chemopreventive efficacy when given alone or in combination with the aromatase inhibitor (AI) letrozole. Initially, the agents were evaluated alone to determine effective chemopreventive doses in the methylmethanesulfonate (MNU) ERα mammary cancer model using female Sprague-Dawley rats. Bazedoxifene was mixed directly into a standard (Teklad, 4% fat) diet, while letrozole was gavaged 7x/week (vehicle was ethanol: PEG 400, 10:90, v/v). When evaluated alone in rats receiving MNU at 50 days of age, bazedoxifene (started one week after MNU) at doses of 100 and 300 mg/kg diet decreased mammary tumor multiplicity by 73%. When the agents were given in combination at these low dose levels, cancer number was reduced by 91%. An additional study was done in which the agents were given to rats receiving MNU at an older age (100 days). Rats receiving the agents at the original doses beginning one week after MNU (bazedoxifene at 30 mg/kg diet; letrozole at 0.1 mg/kg BW/day) had identical decreases in mammary tumor development (96%). It is obvious that bazedoxifene is as effective as letrozole in the prevention of mammary carcinogenesis when initiated in older rats. Furthermore, administration of the agents in combination suggests an additive effect. The large increase in body weight gain generally noted in letrozole treated rats was not observed in rats receiving bazedoxifene; of interest, rats receiving the combination also had no increase in body weights. These studies indicate that bazedoxifene may be superior to other SERMs in that chemopreventive efficacy is achieved at low doses, which may be associated with less toxicity. Supported by NCI contract HHSN261201200021I, Task Order HHSN26100007.

#5247 δ-Tocopherol inhibits the development of prostate adenocarcinoma in prostate specific Pten-/- mice. Xu Yang,1 Wang Hong,2 Guocan Wang,3 Anna Liu,1 Maarten c. Bosland,1 Chung s. Yang,1 Rutgers, Piscataway, NJ; 2MD Anderson Cancer Center, Houston, Piscataway, NJ; 3University of Illinois at Chicago, Chicago, IL.

PTEN/Pik3/AKT axis plays a critical role in regulating cell growth, metabolism, migration, differentiation, and survival. Activation of this signal pathway is frequently found in human cancers. Data from our previous studies demonstrated that δ-tocopherol (δ-T) attenuates the activation of AKT by growth factor in prostate cancer cell lines, leading to inhibiting proliferation and inducing apoptosis. Herein, we investigated whether δ-T is able to inhibit the development of prostate adenocarcinoma in prostate-specific Pten-/- (Pten δ-) mice, in which the activation of AKT resulted from loss of Pten is the driver. By feeding Pten δ- mice with the AIN93M or 0.2% δ-T supplemented diet starting at the age of 6 or 12 weeks, we found that, at the age of 40 weeks, δ-T treatment reduced the number of invasive prostate adenocarcinoma by 53.3% (p<0.005) and 42.7% (p=0.001), respectively. By immunohistochemical analysis, the activation of AKT via phosphorylation of AKT(T308) was found reduced in the prostate of the mice on δ-T diet. Consistently, proliferation was reduced and apoptosis was increased in prostate of the mice on δ-T diet. We also determined oxidative stress by immunohistochemical staining of 8-OH-dG and nitro-tyrosine, and found that these markers were not altered during prostate tumorigenesis, nor they were affected by δ-T. A 0.2% α-tocopherol diet was also used to feed Pten δ- mice, but did not inhibit the development of prostate adenocarcinoma, consistent with previous data demonstrating that α-tocopherol did not inhibit the activation of AKT. Together, these results support that δ-T is effective in suppressing the development of prostate adenocarcinoma in Pten δ- mice through inhibition of AKT activation.

#5248 Pioglitazone prevents hepatocellular carcinoma development in a rat model of cirrhosis. Shen Li, Sarani Ghoshal, Gunisha Arora, Derek J. Erstad, Michael Lanuti, Kenneth K. Tanabe, Bryan C. Fuchs. Massachusetts General Hospital, Boston, MA.

Introduction: Advanced hepatocellular carcinoma (HCC) is a leading cause of mortality worldwide with limited options available for patients with a small, perhaps not even a solitary, identifiable cohort of cirrhosis patients at risk and they are ideal candidates for chemoprevention. Anti-hyperglycemic agents have garnered interest for their potential anti-fibrotic as well as chemo-preventive effects. Pioglitazone, a selective PPARγ agonist, has been shown to reduce non-alcoholic steatohepatitis (NASH), but its role as an anti-fibrotic and chemopreventive agent has yet to be elucidated. The hypothesis of this study is that Pioglitazone reduces cirrhosis and subsequent HCC development in rats with diethylnitrosamine (DEN)-induced cirrhosis. Methods: Male Wistar received DEN 50mg/kg by intraperitoneal injection. DEN injury reliably recapitulates histological and molecular features of human HCC development with induction of hepatic fibrosis at 8 weeks, cirrhosis at 12 weeks, and HCC by 18 weeks. DEN-injured rats were randomized to receive oral gavage of pioglitazone at 3mg/kg/day (n=8) or vehicle control (n=9). Initiation of pioglitazone coincided with the development of liver fibrosis at 8 weeks. All animals were sacrificed at 18 weeks. Results: As expected, repeated injections of DEN in rats resulted in progressive fibrosis, cirrhosis, followed by HCC formation. Treatment with pioglitazone resulted in a 56% reduction of surface nodules relative to treatment with vehicle (7.4±4.9 vs. 17.4±10.05, p<0.005). Liver sections were stained by picrosirius red to assess fibrosis, and pioglitazone significantly reduced collagen deposition in DEN-injured rats (collagen proportional area = 3.2±1.8% vs. 9.2±2.7%; p<0.035). This histologic observation was further confirmed by gene expression analysis with reductions in collagen-I, α-smooth muscle actin, and transforming growth factor beta in rats treated with pioglitazone. Finally, weekly injection of DEN also caused a significant decrease in overall body weight in comparison to untreated rats (398.1±60 vs. 598±46 grams; p<0.015), and pioglitazone treatment resulted in a trend for better protection of body weight relative to vehicle (398.1±60 vs. 427.5±56.3 grams). Conclusion: Overall our data supports the hypothesis that the anti-diabetic agent pioglitazone may be repurposed as a drug to reduce fibrosis and prevent HCC. This could be beneficial in patient management given the low cost as well as minimal side effects.

#5249 Integrative analysis of transcriptomic, proteomic, and metabolomic data of Pten-Knockout carcinogenic mouse prostate. Jinhui Zhang,1 Li Li,2 Sangyub Kim,2 LeeAnn Higgins,3 Yibin Deng,4 Christopher J. Kemp,5 Cheng Jiang,2 Junxuan Lu2.

1Texas Tech University Health Sciences Center, School of Pharmacy, Amarillo, TX; 2Pennsylvania State University College of Medicine, Hershey, PA; 3University of Minnesota, St.Paul, MN; 4The Hormel Institute- University of Minnesota, Austin, MN; 5Fred Hutchinson Cancer Research Center, Seattle, WA.

The prostate-specific Pten-knockout (KO) mouse carcinogenesis model is highly desirable for prostate cancer chemoprevention studies due to its close resemblance of many histopathological features of human prostate cancer including disease progression from prostatic intraepithelial neoplasia (PIN) to invasive adenocarcinomas. Here, we profiled the prostate proteome, transcriptome and aqueous metabolome of Pten-KO mice to identify reference molecular signatures that can be used for designing chemopreventive and/or therapeutic intervention and for selection of molecular biomarkers of responses to intervention. For proteomics, 4 pairs of whole prostates from Pten-KO mice (12-15 weeks of age, corresponding to high grade PIN) and their wild type littermate housed in same cages were obtained from the NCI Mouse Model Repository and analyzed by 8-plex iTRAQ. For transcriptomic/microarray and metabolic analyses, 3 additional matched pairs of prostate/tumor specimens at older age (22-20 weeks) were used. Proteomic and transcriptomic analyses using manual annotation methods with references from PubMed revealed top signatures that were up- and down-regulated by Pten deletion, particularly those implicated in immune function, inflammatory response, cancer, drug metabolism, cellular functions, prostate functions, and endoplasmic stress regulation. Similar to the manual annotation approach, each network analysis of 203 genes and 22 proteins (≥ 2-fold changes) by a bioinformatics software, Ingenuity Pathway Analysis (IPA) showed that inflammatory response, cellular movement, immune cell trafficking, immunological disease, and cancer were top 5 disease and biological functions in Pten-KO mice. Using references from PubMed, we manually assigned the upregulated or downregulated functions to functional categories, which included altered methionine-cysteine cycle fluxes and purine metabolites, increased nucleotide pools, cholesterol and polynucleotide synthesis and suppressed pools of sugar and choline derivatives, glycolysis intermediates, and purine bases. IPA network analysis of 25 metabolites (≥ 2-fold changes) revealed the...
biological functions related to molecular transport, amino acid metabolism, and small molecule biochemistry. In addition, we integrated transcriptomic, proteomic, and metabolomic data sets to identify latent biological relationships and to gain a comprehensive understanding of Pten-deficient prostate carcinogenesis. The integrative analysis predicted activation of inflammatory response and several cellular pathways, such as GPR40, NFKB1, and GNAS. The integrative analyses identify both active and latent reference molecular signatures and provide more insight into Pten-deficient prostate cancer than single omic approaches.

#5250 Cranberry proanthocyanidins reverse microbial dysbiosis and inhibit bile acid metabolism in association with esophageal cancer prevention, Katherine M. Web,1 Nita H. Salzman,1 Amy B. Howell,2 Jennifer L. Clarke,3 Bridget A. Tripp,2 Laura A. Kresy,1 Medical College of Wisconsin, Milwaukee, WI; 2 Rutgers University - Marucci Center for Blueberry and Cranberry Research, Chatsworth, NJ; 3 University of Nebraska - Lincoln, Lincoln, NE.

Our laboratory has been investigating the cancer inhibitory potential of cranberry proanthocyanidins (C-PAC) against esophageal adenocarcinoma (EAC), a cancer characterized by rapidly rising incident rates and poor survival (18% 5-year survival rate for all stages combined). Utilizing a panel of validated human esophageal cancer cell lines and OE19 xenograft bearing mice, our laboratory reported that C-PAC activates autophagic cell machinery leading to caspase-independent cancer cell death, yet linked to bile acid sensitivity. Reflux of bile and stomach acid into the lower esophagus is considered the major risk factor for progression to EAC. Building on our initial research, we next investigated mechanisms by which C-PAC inhibited reflux-induced EAC with a focus on gut microbiome alterations and modulation of bile acid metabolites. Bile acids undergo secondary metabolism in the intestinal tract, but have not been evaluated in this context. We utilized the rat surgical esophageagastroduodenal anastomosis (EGDA) model for reflux-induced EAC. EGDA+ and non-surgical Sprague Dawley rats were treated with water or C-PAC (650 μg/rat/day) for 25 or 40 weeks and assessed for changes in cancer progression via extensive histopathological characterization. Additionally, at 40 weeks, fecal microbiome profiling was investigated and metabolic profiling conducted on esophageal, liver and fecal samples. Methods included 16s rRNA sequencing of rat fecal DNA, paired end sequencing on Illumina MiSeq and data analysis using Qiime and the K packages phyloseq, and edgeR to assess C-PAC-induced microbiome changes. For metabolic profiling homogenized esophagi, liver and fecal samples were extracted in methanol and characterized by Reverse Phase Ultra high performance Liquid Chromatography-Tandem Mass Spectrometry RP/UPLC-MS/MS, followed by metabolite identification based on Metabolon’s library of authenticated standards. Study results support that C-PAC significantly inhibits the formation of EAC with concomitant restoration of the gut microbiota profile, i.e., the bacterial profile shifted toward increased favorable Gram+ Firmicutes and away from inflammatory-linked Gram negative Bacteroidetes. In addition, C-PAC treatment significantly reduced primary and secondary bile acid metabolite levels in the esophagus of reflux/EGDA+ rats. Other metabolites significantly reduced by C-PAC included a number of pro-inflammatory mediators which may account for the observed therapeutic effect. In summary, these results indicate that microbial impairment correlates with the stimulation of bile acid metabolism, and (2) C-PAC mitigates reflux-induced inflammation and injury in the esophagus in association with EAC inhibition. Future research with C-PAC in patients with gastroesophageal reflux disease should include assessments of bile acid metabolites and bacterial profiles as potential cancer-inhibitory mechanisms.

Cancer stem cells represent a rare population of cells with a self-renewal capacity, and potentially involved in tumor progression, tumor relapse, and resistance to cancer chemotherapies. In this study, we investigated the effect of an active ingredient of chamaecysis obtuse, amentoflavone, on stenness of U251 glioblastoma cells. We first found that amentoflavone from 1 to 10 μM suppressed tumorsphere formation and inhibited the expression of glioblastoma stem cell markers CD133 and ALDH1 in a dose dependent manner. In addition, amentoflavone significantly reduced the expression of Nanog involved in cancer stem cells maintenance in tumorsphere culture. As an upstream modulator, Hedgehog (Hh) signaling mediator Gli1 was confirmed to be highly expressed in tumorsphere culture where the suppression of Gli1 by the treatment of Hh inhibitors (vismodegib and GANT 61) or Gli1-siRNA significantly suppressed the expression of stem cell markers CD133, ALDH1, and Nanog as well as tumorsphere formation in U251 glioblastoma cells. These results indicate that Hh signaling plays an important role in maintaining tumorsphere and stenness of U251 glioblastoma cells. Next, we also found that the treatment of amentoflavone from 1 to 10 μM inhibited the expression of Gli1 and its downstream mediator Nanog in tumorsphere culture of U251 glioblastoma cells. Taken together, amentoflavone significantly suppressed Hh/Gli1 signaling which results in inhibition of stenness of U251 glioblastoma cells.

#5252 Quercetin inhibits prostate cancer by modulating ROS and key regulators of apoptosis and cell survival, Ashley B. Ward,1 Hina Mir,2 Neeraj Kapur,3 Guru Sonpavde,2 Shailesh Singh,1 Morehouse School of Medicine, Atlanta, GA; UAB Comprehensive Cancer Center, Birmingham, AL.

Long latency and indolent nature of prostate cancer (PCa) provides a window of opportunity for preventive interventions using natural and synthetic agents. Hence, the focus of this study was to ascertain the chemopreventive role of Quercetin, a bioflavonoid, commonly used to treat prostatitis. Human PCa cells (LNCaP, DU145 and PC3) were treated with different concentrations of Quercetin and its effect on cell survival and apoptosis was determined by MTT assay. Human PCa cells treated with Quercetin showed significant reduction in cell viability and proliferation compared with untreated controls, which was dose and time dependent. In addition to this our FACS analysis showed higher percentage of apoptotic cells after Quercetin treatment compared to untreated cells. Quercetin induced apoptosis in PCa cells is a cumulative effect of modulation of key apoptotic proteins, changes in mitochondrial membrane potential and ROS production. Quercetin's results on Quercetin as a potential chemopreventive agent, which may improve outcomes of PCa by inhibiting mechanisms involved in tumor progression.

#5253 Arctigenin inhibits prostate tumor growth in vitro and in vivo in obese state, Piwen Wang,1 Tanya Diaz,2 Susanne Henning,2 Jaydutt Vadgama3.

Arctigenin is a novel anti-inflammatory lignan derived mainly from the seeds of Arctium lappa which is an herb widely used in traditional Chinese medicine to treat inflammation related diseases. We previously demonstrated that arctigenin strongly inhibited prostate tumor cell growth in cell culture and mouse models in non-obese state. The present study investigated the tumor inhibitory effect of arctigenin in obese state. An in vitro obese setting was created by co-culture of mouse adipocytes 3T3-L1 with androgen-sensitive LAPC-4 and LNCaP prostate cancer cells. An ELISA analysis of 3T3-L1 conditioned medium revealed that three cytokines/growth factors were prominently secreted by 3T3-L1 cells, including IGF-1, VEGF, and MCP-1, and the sensitivity of prostate cancer cells to arctigenin was decreased in the obese state. However, arctigenin at a moderate concentration (10 μM) significantly inhibited the proliferation of both LAPC-4 and LNCaP cell by 40-50% at 96h in the co-culture system. Male severe combined immunodeficiency (SCID) mice was implanted subcutaneously with LAPC-4 xenograft tumors to confirm the tumor-inhibitory effect of arctigenin in vivo. Mice were fed high-fat diet containing 45% energy from fat, and treated with arctigenin at 50mg/kg b.w. orally or vehicle control for 6 weeks (n=10 per group). The tumor growth in arctigenin group was significantly inhibited by 40% compared to control, along with decreased blood concentrations of several cytokines including IGF-1, VEGF, and MCP-1. Immunohistochemistry analysis is ongoing to determine the molecular changes involved in tumor cell proliferation and apoptosis in response to arctigenin treatment. This study provides a promising natural compound to enhance chemoprevention of prostate cancer especially in obese patients. These results warrant future clinical trials to confirm the anti-carcinogenic effect of arctigenin in humans.

#5254 Postoperative adjuvant chemotherapy improves survival in stage II colon cancer? A propensity score matching analysis, Ryosichi Tsukamoto, Kichi Sugimoto, Shingo Kawano, Koichiro Niwa, Shun Ishiyama, Hirohiko Kamiyama, Hiromitsu Komiyama, Makoto Takahashi, Yutaka Kojima, Michitoshi Goto, Yuichi Tomoki, Kazuhiro Sakamoto. Isuendo University Faculty of Medicine, Tokyo, Japan.

Objective : Stage II colon cancer with high-risk features have been traditionally considered more likely to benefit from postoperative adjuvant chemotherapy (POAC). National Comprehensive Cancer Network (NCCN) guidelines do not recommend routine administration of adjuvant chemotherapy for Stage II patients, except for those with high risk features, such as poorly-differentiated tumors, T4 disease, perforated tumors and those with inadequate lymph node sampling. However, the use of POAC after surgery for patients with Stage II colon cancer remains controversial. The current study was conducted to investigate the effectiveness of POAC using propensity score (PS) matching analysis,
which can reduce or minimize the confounding that is seen frequently in observational studies of the effect of treatment on outcomes, based on prognostic factors. Materials: Two hundred and ninety patients with Stage II colon cancer who underwent surgery with curative intent between 1995 and 2005 were enrolled. The decision regarding the use of POAC was made for each case based on individual physician discretion. All patients were provided informed consent. During the present study period, patients received 5-FU drugs orally, starting 4–8 weeks after surgery. The median observation period was 73.4 months (range: 2.2–184.2 months). Methods: PS matching analysis was used to adjust for differences in clinicopathological severity between the patients with and without POAC. Recurrence-free and cancer-specific survival were compared using Kaplan-Meier analyses and Cox proportional-hazard models were used to determine Hazard ratios and 95% confidence intervals. Results: One hundred and nineteen patients (54.3%) underwent POAC. In univariate analysis, there were no significant differences with respect to the clinicopathological factors between the patients with and without POAC. Before PS matching analysis significant survival benefits from POAC were not recognized for recurrence-free survival (Hazard ratio = 0.76, 95% CI 0.40–1.45, P = 0.41) or cancer-specific survival (Hazard ratio = 0.52, 95% CI 0.22–1.19, P = 0.12). After PS matching analysis significant survival benefits from POAC were observed (based on principal component analysis) (Hazard ratio = 0.55, 95% CI 0.23–1.23, P = 0.15) or cancer-specific survival (Hazard ratio = 0.46, 95% CI 0.16–1.18, P = 0.11). Conclusions: The one-to-one pair PS matching successfully balanced the clinicopathological factors between the patients with and without POAC. The PS matching analysis demonstrated no significant difference in survival in the patients with Stage II colon cancer.

#5256 Intracellular lipid droplet quantity as a biomarker for obesity associated inflammation and carcinogenesis risk.

Rationale: Prior reports have suggested that piperine, the major alkaloid product derived from black and long pepper, enhances curcumin’s cancer preventive efficacy in vitro and in vivo by an intracellular pharmacokinetic interaction; yet, no previous studies have explored the pharmacokinetic interactions between curcumin and piperine. Methods: We incubated non-transformed breast cell line MCF10A and breast cancer SUM149 cell line with different concentrations of curcumin, piperine or curcumin + piperine to assess cell viability using a MTT assay. For curcumin and piperine uptake assays, we incubated MCF10A, SUM149 and MCF7 breast cells with either 5 μM curcumin or 5 μM curcumin + 5 μM piperine for 0.5, 1.0, 4.6, 8.12 and 24 h, or with 15 μM curcumin or 15 μM curcumin + 10 μM piperine for 0.17, 0.5, 1.2 and 4 h. Media and cell lysates were extracted for assay of intracellular curcumin and piperine by LC-MS/MS. ALDH1+, ALDH CD44+ 24 cells were collected via FACS, incubated with 10 μM Curcumin or 10 μM piperine for 1 hour. Cell lysates and media were assayed for curcumin, curcumin degradation and metabolic products and quantified using LC-MS/MS. Results: 90.7±0.06% and 34.8±0.002% of cells were viable after incubating MCF10A and SUM149 cells respectively with 25 μM curcumin compared to DMSO control. Incubation with 10 μM Piperine enhanced the antiproliferative effect of 15 μM curcumin by 33.6±0.015% (P = 0.05) and 16.3±0.03% (P = 0.05) in SUM149 and MCF10A cells respectively. We found no significant increase of intracellular concentration of curcumin when co-incubated with piperine in the MCF10A, MCF7 and SUM149 cells or in the ALDH+ and the ALDH CD44+ CD24+ SUM149 cells. Intracellular curcumin concentration was 166.7±22 and 151.5±24 ng/ml-pro-
tein in ALDH+ cells for curcumin alone or curcumin + piperine respectively and 130±2.54 and 135±27.4 mg/mg protein in ALDH CD44 / CD24 for curcumin alone or curcumin + piperine respectively in SUM149 cell line. Curcumin uptake was lower in MCF10A cells than SUM149 cells. The intracellular curcumin concentration after 1 hour incubation with 5 μM curcumin was 11.8±0.8 and 11.4±1.2 in MCF10A and SUM149 cell lines respectively. Tetrachloroferrrocenium and curcumin sulfite conjugates were the major metabolites detected in MCF7 and SUM149 cell lines. Curcumin sulfate is detectable in the media as early as 0.5h, it increases from 1.36±0.06 and 1.43±0.05 after 0.5h to 22.6±0.53 and 23±2.2 ng/ml after 4h for curcumin and curcumin + piperine respectively in the media of ALDH CD44 / CD24 SUM149 cells. Conclusions: We find a significant difference in intracellular uptake of curcumin between cells treated with curcumin alone or curcumin + piperine after incubation times up to 24h. The additive cellular toxicity effects observed with piperine + curcumin is not pharmacokinetic (associated with efflux pump inhibition) but rather pharmacodynamic due to piperine’s independent anti-proliferative effects.

Bone is one of the metastatic sites for advanced breast cancer. Nearly 70% of breast cancer patients experience metastasis to bone due to enhanced osteoclastogenesis and formation of osteoclasts leading to bone resorption. We have shown previously that benzyl isothiocyanate (BITC), a constituent of edible cruciferous vegetables such as garden cress, is a potent inhibitor of breast cancer cell lines in vitro and in vivo. The present study was designed to determine the effect of BITC on breast cancer-induced osteoclastogenesis. Co-culture of murine RAW 264.7 macrophages with human breast cancer cells resulted in genesis of osteoclasts in vitro that was suppressed significantly in the presence of BITC. Runx2, a transcription factor, is abnormally expressed in breast cancer and contributes to osteoclastogenesis by regulating receptor activator of NF-κB ligand (RANKL). BITC treatment downregulated expression of Runx2 in breast cancer cells at the mRNA and protein levels. Osteoclastogenesis was increased in Runx2 overexpressing MDA-MB-231 cells, whereas conditional knockdown of Runx2 in T47D cells attenuated this process. To determine the in vivo efficacy of BITC, MDA-MB-231-Luc cells were injected into the left ventricle of nude mice. BITC was administered orally at 10 mg per kg body weight. Micro-CT X-ray analysis showed that bone metastases and erosion was decreased by about 50% upon BITC treatment when compared with vehicle control. Cathepsin K and total RANKL levels were lower in the plasma of BITC-treated mice when compared to the control group. Altogether, this study demonstrates, for the first time, that BITC is a potent inhibitor of breast cancer-induced osteoclastogenesis in vivo. This study was supported by the grant RO1 CA129347-09 awarded by the National Cancer Institute.

#5259 Urolithin A prevents pancreatic tumor growth and increases survival by inhibiting PI3K/PDK1 and STAT3 signaling. Supriya Srinivasan,1 Venkatakrishna Jala,2 Altaf Mohammed,3 Jagan M.R. Patolla,1 Yuting Zhang,1 Laura Bid-dick,1 Venkateshwar Madka,1 Li Qian,1 Stan Lightfoot,1 Barbara Dunn,2 Ronald Lubet,1 Chen S. Suen,1 Vernon E. Steele,2 Chinthalapally V. Rao,3 Univ. of Oklahoma Health Sciences Ctr., Oklahoma City, OK; 2National Cancer Institute, Rockville, MD.

Pancreatic ductal adenocarcinoma (PDAC) is the 3rd leading cause of cancer-related mortality in the United States. Most patients present with an advanced disease and the majority die within five years, many surviving less than six months. Cytotoxic chemotherapy including Gemcitabine (Gem), FOLFIRINOX, nab-paclitaxel offer modest improvement in survival, albeit at the cost of increased side effects and unwanted toxicities. Therefore, developing novel chemotherapeutic agents for PDAC treatment is critical to improve survival. Ellagic acid/ellagitannins are abundantly present in the pomegranate and berries, are anti-inflammatoryagentaspirin,acombinationofaspirinwithacidityneutralizer omeprazole was used in AOM-induced F344 Rat model of CRC. Rat (36/group) colon cancers were induced by AOM (15mg/Kg body weight) s.c., once a week for two weeks. At adenoma stage (13 wks of age), rats were fed diets containing aspirin (700 or 1400ppm), omeprazole, (0, 250 or 500 ppm), or aspirin + omeprazole (700 ppm + 250 ppm; 1400 ppm + 500 ppm). To identify a molecular predictor of the benefit of aspirin plus omeprazole we performed next-generation sequencing of colon adenocarcinomas (AdCa) treated with aspirin (1400 ppm), omeprazole (500 ppm), aspirin plus omeprazole (1400 plus 500 ppm), conducted whole-transcriptome analysis and correlated the molecular portrait with chemoprevention benefit. Aspirin plus omeprazole enhanced colon AdCa incidence inhibitory effects by 55% (p<0.0001) and multiplicity by ~87% (~0.0001) respectively in F344 rats. Transcriptome profiling revealed 1525 hits with a 1.5-fold expression difference threshold in aspirin-treated colon AdCAs (722 upregulated genes, 803 downregulated genes, P < 0.05), 1507 hits with a 1.5-fold expression difference threshold in omeprazole-treated colon AdCa (711 upregulated genes, 796 downregulated genes, P < 0.05) and 1074 hits with a 1.5-fold expression difference threshold in aspirin plus omeprazole-treated colon AdCa (662 upregulated genes, 842 downregulated genes, P < 0.05) compared to untreated colon AdCa. Multiple comparisons using Anova with samples from all groups revealed 691 hits with a 1.5-fold expression difference expression threshold with Benjamini Hochberg correction. Pathway analyses of these altered 691 genes indicated that the aspirin plus omeprazole treated colon AdCa upregulated cellular pathways (z score 2.26). Metabolism process (6.01) and cellular metabolic process (7.73), and downregulated signaling genes (~ 8.18), signal transduction (~ 8.03), immune response (~ 2.08) and inflammatory response (~ 2.95). A significant upregulation of Killer cell lectin-like receptor subfamily K, member 1 (natural cytotoxicity receptor which eliminates tumor cells), and acid phosphatase 2, lysosomal, (autophagy of tumor cells) was seen in the combination treatment groups compared to individual and control group AdCa. A significant decrease in TGF-β receptor signaling pathway gene SNX4 and ATPases was observed in combination treatments. Hence, these results suggest aspirin plus omeprazole combination treatments were devoid of GI toxicity increasing chemopreventive efficacy in colon cancer. Supported by NCI N01-CN-250026.

#5261 Tocopherols inhibit the estrogen-stimulated expansion of cancer stem cells via down-regulation of OCT4 and NfκB. Min Ji Bak. Rutgers Univ. School of Pharmacy, Piscataway, NJ.

Cancer stem cells have been suggested to play a role in tumor initiation, maintenance, resistance, and metastasis. Breast cancer stem cells are defined as CD44 / CD24 cell populations that have the properties of tumor-initiating abil-
PREVENTION RESEARCH: Chemoprevention and Cancer

ity, self-renewal and differentiation. Although the importance of estrogen in breast cancer is well established, the effects of estrogen on breast cancer stem cells are not fully understood. Vitamin E, which is a member of different forms of tocopherols and tocotrienols, has anti-tumor effects in various cancers, including breast cancer. In the present study, we examined the effects of α-, γ-, and δ-tocopherol against estrogen-stimulated expansion of cancer stem cells. To determine the effects of tocopherols on breast cancer stem cells, the MCF-7 tumorosphere cell culture system, which enriches for mammary progenitor cells and putative breast cancer stem cells, was utilized. Treatment of MCF-7 tumorosphere with estrogen for four days resulted in an increase in CD44+/CD24− stem cell populations in tumorspheres as well as the number and size of tumorspheres. The inhibition of breast tumorospheres by 10 μM inhibited treatment was greatest in tocopherol-enriched stem cell enriched tumorspheres, indicating that tocopherols reversed estrogen-induced expansion of breast cancer stem cells. Tocopherols decreased the expression of estrogen-related genes such as TFF/pS2, cathepsin D, progesterone receptor and SerpinA1 in estrogen-stimulated tumorspheres. In addition, the mRNA levels of stem cell markers, including OCT4, NFκB, Sox-2 and CD44, were upregulated by estrogen, which were downregulated by the treatment with tocopherols. Our results suggest that tocopherols repress the expansion of breast cancer stem cell population by regulating OCT4 and NFκB. The alterations in these pathways, again shown by an inhibition of BrdU incorporation. In addition to the current results indicate that certain combinations of UA, Curc and Met may have the potential for broad applications for chemoprevention of breast cancer. (This work was supported in part by the National Institutes of Health grant R01 AT007036.)

The inhibitory effect of combinations of curcumin, ursolic acid, and metformin on skin tumor promotion by TPA. Lisa Tremmel, Oldnyrng Rho, John DiGiovanni. The University of Texas at Austin, Austin, TX.

The purpose of this study was to examine the effects of combinations of ursolic acid (UA), curcumin (Curc), and metformin (Met) for potential synergistic chemopreventive activity in animal tumor promotion using the mouse two-stage skin carcinogenesis model. UA and Curc have been shown to inhibit tumorigenesis in several mouse models, and both have been shown to inhibit mouse skin tumor promotion by 12-O-tetradecanoylphorbol-13-acetate (TPA). The anti-cancer activity of these phytochemicals is due to their anti-inflammatory, anti-oxidant, and anti-proliferative effects. These effects are accomplished by acting on a broad spectrum of signaling pathways. Met has also been shown to have anti-cancer activity. In retrospective studies, type II diabetes patients taking Met have been shown to have a decreased cancer incidence. Met has also been shown to inhibit mouse skin tumor promotion by TPA. Met activates AMP-activated protein kinase (AMPK), which in turn inhibits mammalian target of rapamycin complex 1 (mTORC1) signaling. mTORC1 is a key kinase involved in the phosphatidylinositol-3-kinase (PI3K)/Akt pathway, one of the most commonly altered pathways in human tumors. In initial short-term experiments (mice treated twice weekly for two weeks with TPA), combinations of UA and Curc pretreated topically inhibited TPA-induced activation of epidermal NFκB, Cox-2, epidermal growth factor receptor (EGFR) and JNK to a greater extent than either compound alone. Additionally, these compounds increased levels of AMPK and programmed cell death protein 4 (Pdc4d). The alterations in these signaling pathways by the combination of UA and Curc were associated with decreased epidermal proliferation and skin inflammation as assessed by measuring BrdU incorporation and inflammatory gene expression, respectively. Further studies using dietary administration of a combination of UA and Curc, as well as combinations of UA or Curc (in diet) with Met administered in the drinking water were conducted. These combinations produced greater inhibition of TPA-induced activation of epidermal NFκB, Cox-2, and EGFR than the compounds given alone. These combinations also decreased epidermal proliferation, again shown by an inhibition of BrdU incorporation. In addition to these data, the results from ongoing skin tumor experiments (mice initiated with DMBA and promoted twice weekly with TPA) using both topical administration and dietary administration of the various combinations will be presented. The results indicate that certain combinations of UA, Curc and Met may inhibit mouse skin tumor promotion by TPA to a greater extent than the compounds alone. The ability of the combinations to work when given bothtopically as well as in the diet suggests the potential for broad applications for chemopreventive strategies.

Non-melanoma skin cancer (NMSC) is the most commonly diagnosed malignancy in the United States, affecting more than 3 million Americans each year. Ultraviolet (UV) radiation from the sun, particularly its UVB component (290-320 nm), is an established causative factor for ~90% of skin cancers. The two most common forms of skin cancer, basal- and squamous- cell carcinomas, are treatable if detected early. However, they can be difficult to treat and potentially fatal if left until late stages. Further, epidemiological studies have suggested an amplified risk of other deadly cancers in individuals with a history of skin cancer. Therefore, it is important to design novel approaches, especially focusing on prevention strategies, for the treatment of skin cancers. Studies from our laboratory and by others have shown that topical application of the grape antioxidant resveratrol poses promise in the prevention of skin cancer. However, ideally cancer preventive agents need to be orally administrable for ease of use and broader human acceptability. With this in mind, in this study, we determined the efficacy of dietary grape powder (containing resveratrol in natural amalag- mation with catechins, anthocyanins, polyphenols and flavonoids) against UVB-mediated skin tumorigenesis in the SKH-1 hairless mouse model, which is regarded to have relevance to human NMSC. We employed a UVB initiation-promotion protocol in which the mice were subjected to chronic UVB exposure (180 mJ/cm²; twice weekly, for 28 weeks). The animals received either AIN-76A or grape powder (GP) fortified diet (3% and 5% GP, obtained from the Californian Table Grape Commission), all of which were sugar-matched to the highest GP content. Our data demonstrated that the consumption of GP at both 3% and 5% resulted in a significant inhibition in skin tumor incidence and delay in the onset of tumorigenesis. The average consumption of feed per mouse was 3.5 g/day, corresponding to 105 and 174 mg GP/day in the 3% and 5% GP treatment groups. This dosing regimen seems to be easily achievable for human consumption, as it corresponds to 25.3 and 42.4 g/day, which are equivalent to 1.1 and 1.8 servings of fresh grapes, respectively. Our data also demonstrated that the observed cancer chemopreventive effects of grape powder were accompanied by significant decreases in cellular proliferation markers Ki67 and PCNA, ii) decreases in the oxidative stress marker 4-HNE, and iii) increases in the levels of cleaved caspase 7 and poly (ADP-ribose) polymerase (PARP). Interestingly, an activator of cellular antioxidant response, was found to be downregu- lated in GP treated tumors, compared to UVB alone groups, suggesting a poten- tially protective role of NRF2 in the survival of tumor cells. Overall, our study suggests a strong chemopreventive effect of dietary grape and provides a basis for future human studies.

Chemoprevention of rat oral carcinogenesis by black raspberry phytochemicals. Steve Oghumu, Thomas Knobloch, Jennifer Ahn-Jarvis, Logan Weghorst, Kyle Horvath, Paul Geuy, Christopher Weghorst. Ohio State University, Columbus, OH.

It is expected that in 2016, there will be an estimated 48,330 new cases and 9,570 deaths due to oral cancer in the US, which is about one person every hour every day. Due to the epithelial field defects associated with oral carcinogenesis, tumor recurrence and second primary tumor incidence are common. Recently conducted Phase I Clinical trials demonstrate the ability of black raspberries (BRBs) to modulate inflammatory biomarkers of molecular efficacy that supports a chemopreventive strategy against oral cancer. From these human trials we have established a molecular signature of BRB responsive biomarkers. However, it is essential that a preclinical animal model of BRB chemoprevention which recapitulates the fundamental features of human oral carcinogenesis be developed, so that we can evaluate potential mechanisms of action and validate molecular biomarkers of BRB efficacy. We therefore established the ability of BRB to inhibit oral lesion formation in a rat model of 4-nitroquinoline 1-oxide (4NQO) induced oral carcinogenesis and examined molecular efficacy using a clinically relevant transcriptional signature. Oral cancer was induced in F344 rats using 4NQO in drinking water for 10 weeks followed by regular drinking water for 16 weeks. Rats were administered a diet containing 5 or 10 percent linyophilized BRBs. Tongue tissues were examined for lesion multiplicity, incidence and histopathological features. Clinically derived pro-inflammatory and pro-survival molecular biomarkers were also determined by real-time PCR and ELISA. Dietary administration of 5 and 10 percent BRBs reduced combined lesion incidence and multiplicity by ~39%-3% and ~28%-6% respectively. Histopathological analyses of tongue sections further demonstrate the chemopreven- tive ability of dietary BRB administration in the rat model. Pro-survival and pro-inflammatory biomarkers were downregulated in BRB administered 4NQO induced rats compared to untreated 4NQO induced rats. Our study shows that dietary administration of BRB inhibits oral carcinogenesis in the rat 4NQO model. The rat 4NQO model is suitable for interrogating mechanisms of action of BRB-mediated oral cancer chemoprevention.

Breast cancer is a leading cause of cancer-related deaths among women in the United States. Over the last decade, breast cancer stem cells (bCSC) have been identified and characterized as a key player in breast cancer progression and recurrence. Benzyl isothiocyanate (BITC) is a highly promising cancer chemopreventive constituent of edible cruciferous vegetables such as garden cress. We have shown previously that BITC inhibits bCSC in cultured breast cancer cells (MCF-7 and SUM159 cells) and in spontaneous tumors of mice mammary tumor virus-neu (MMTV-neu) mice in vivo. Krüppel-like factor 4 (KLF4), a zinc finger transcription factor, is known as both oncogene and tumor suppressor in various types of human cancers and plays an important role in reprogramming differentiated somatic cells into induced pluripotent stem cells. The present study demonstrates that KLF4 impedes bCSC inhibition by BITC. Exposure of breast cancer cells (MCF-7, MDA-MB-231, and SUM159) to pharmacological concentrations of BITC (2.5 and 5 μM) resulted in induction of KLF4 protein, which was accompanied by increase of its transcription. In addition, BITC treatment increased nuclear level of KLF4 in breast cancer cells. KLF4 protein expression was also higher in tumors form BITC-treated MMTV-neu mice compared with the control group. Ectopic expression of KLF4 in MCF-7 cells conferred marked protection against BITC-mediated inhibition of CSC as evidenced by aldehyde dehydrogenase 1 (ALDH1) activity. Consistent with these observations, BITC-mediated inhibition of bCSC in MCF-7, MDA-MB-231 and SUM159 cells was significantly augmented by RNA interference of KLF4 as evidenced by ALDH1 activity and frequency of mammospheres. KLF4 overexpression also increased cell migration capacity of MCF-7 cells. Furthermore, knockdown of KLF4 augmented BITC-mediated inhibition of cell migration in SUM159 cells. These results suggest that anticancer activity of BITC may be enhanced by KLF4 inhibition or knockdown in breast cancer cells. This study was supported by the grant RO1 CA129347-09 awarded by the National Cancer Institute.

**#5266** The mechanisms of apoptosis induction by debiubiquitlatinase inhibitor b-ap15 in esophageal squamous cell carcinoma cells. Pei Li, Ping Chen, Xiao-Yu Chen, Jing-Yang Zhang, Bei-Bei Sha, Tao Hu, Yi-Lin Zhang, Ying Du, Zi-Ming Dong, Zhengzhou University, Zhengzhou, China.

Deubiquitinases (DUBs) act on ubiquitinated substrates to catalyze the removal of ubiquitin moieties which can reverse the process of protein degradation, and further affect or regulate cell metabolism, proliferation and differentiation. As a novel small molecular inhibitor, b-AP15 can specifically inhibit the deubiquitinating activity of 199 regulatory subunit UCHL5 (ubiquitin C-terminal hydrolase 5) and USP14 (ubiquitin-specific peptidase 14) in cancer cells. In this study, we aimed to check whether b-AP15 have anti-tumor activity in esophageal cancer cells in vitro and try to explore the underlying mechanisms. Results: CCK-8 assay, colony formation assay and morphological observation results indicate that b-AP15 can significantly inhibit the proliferation activity of EC1 and Kyse 450 esophageal cancer (EC) cell lines in a concentration-dependent manner in vitro studies. Flow cytometry results show cells were arrested in G2/M phase after being treated with b-AP15. Western blot results show that the expression of G2/M phase related proteins p21, p27 and pWee1 significantly increased while the expression of the G1/S phase marker proteins including cyclin D and CDK4/6 was significantly decreased. In addition, flow cytometry FITC annexin V Apoptosis detection kit with PI and Caspase 3 assay kit results show that b-AP15 treatment can significantly induce apoptosis in two EC cell lines. The results from western blot show that the expression of apoptotic protein p-C-Parp and c-caspase 3 significantly increased and was dose-dependent. JC-1 flow cytometry analysis show that b-AP15 treatment can significantly decrease mitochondrial membrane potential. All these results suggest that b-AP15 can induce EC cells apoptosis and may play certain role in mitochondrial control of apoptosis signaling pathway. Conclusion: b-AP15 shows a significantly anti-tumor activity in vitro models of ESCC and the results confirm that b-AP15 can inhibit proliferation of EC cell lines by inducing cell-cycle arrest and promoting cell apoptosis. Key words: b-AP15; esophageal cancer; debiubiquitlatinase (DUBs); apoptosis.

**#5267** Chemoprevention of lung carcinogenesis by dietary nicotinamide and inhaled budesonide. Donna Seabloom, 1 Beverly Wurtz, 1 Art Galbraith, 1 Jenny Antonides, 2 Vernon Steele, 3 Lee Wattenberg, 1 Frank G. Ondrey1. 1University of Minnesota, Minneapolis, MN; 2NCIChemoprevention, Bethesda, MD

Nicotinamide, the amide form of vitamin B3, and budesonide, a synthetic glucocorticoid used in the treatment of asthma, were evaluated for efficacy of chemoprevention of lung adenoma formation in a benzo(a)pyrene murine carcinogenesis model. Female A/J mice were given three doses of 3 mg benzo[a]pyrene three days apart and started on experimental diets either 1 week (early stage intervention) or 8 weeks (late stage) after last carcinogen dose. Aerosol treatments were delivered 5 days per week starting 1 or 8 weeks post carcinogen. Nicotinamide fed at a dietary concentration of 0.75% starting 1 week after last carcinogen administration, inhibited adenoma formation by 54%, and by 39% when begun 8 weeks post final carcinogen. Nicotinamide fed at 0.25% of the diet was not found to effect adenoma formation. Dietary nicotinamide under the same conditions with budesonide administered via aerosol administration at 25μg/kg, reduced lung adenoma formation by 90% at early stage intervention and 49% at late stage intervention. Budesonide alone administered at the same dose level gave 77% inhibition at early stage and 41% inhibition at late stage. Decreases in adenoma formation were statistically significant via ANOVA analysis at both early and late interventions. Combination therapy decreased adenoma formation significantly over either individual therapy at the early stage and significantly compared to nicotinamide alone at the late stage. However, administration of nicotinamide by aerosol inhalation at doses up to 15 mg/kg/day did not result in a statistically significant reduction in tumor multiplicity at 1 or 8 weeks post last carcinogen administration. There is a high level of clinical interest in minimal toxicity lung cancer chemoprevention strategies. We feel administration of a safe dietary agent such as nicotinamide when combined with direct epithelial delivery of a glucocorticoid such as budesonide, commonly used for asthma therapy, is a promising approach for aerodigestive chemoprevention.

With a 5 year survival of less than 8%, the poor prognosis of pancreatic cancer (PanCA) underlines the importance of improving therapies for effective management of this disease. In previous studies, we identified the tumor cell growth inhibitory activities for Nextrutine® (Nx, a bark extract from Phellodendron amurense) and palmatine (PMT) which is a constituent of Nx. These studies revealed an important role for downregulation of KRAS downstream effectors including GLI, STAT3 and NF-κB in mediating growth inhibitory effects. Remarkably, both Nx and PMT exerted synergistic growth inhibitory effects in combination with the conventional chemotherapeutic agent, Gemcitabine (GEM). Despite such promising in vitro observations, the in vivo efficacy of Nx or PMT had not been established. In this investigation, we evaluated the ability of N and PMT to (i) prevent the development of pancreatic tumors; and (ii) inhibit the growth of patient derived pancreatic cancer tissue in short term ex vivo cultures. Studies were also conducted to investigate the underlying molecular mechanism using cell culture models. Our results show that both Nx and PMT are well tolerated in vivo as evidenced by a lack of significant changes in the body weights of athymic mice implanted with Capan-2 cells. Interestingly, both Nx and PMT showed a significant decrease in the circulating levels of inflammatory molecules including IL-6 and CXCL1. In this first proof-of-concept study, PMT treated animals demonstrated a trend towards decreased pancreatic tumor weight with associated histopathological changes. Remarkably, both Nx and PMT inhibited the growth of patient derived pancreatic cancer cells. Mechanistic investigations identified downregulation of STAT3, TrkA, Src, and RPS6 activating potential contributors to Nx or PMT-induced synergistic growth inhibitory effects with GEM. Further investigation of STAT3 signaling revealed the involvement of the prostaglandin receptor, EP4, in a potential feedback loop with STAT3 and in asserting STAT3-mediated inhibition of autophagy. Taken together these data support potential utility for Nx and/or PMT in the management of PanCA and suggest that these agents use multiple mechanisms to affect growth of pancreatic tumors. Supported by NCCIH (R01 AT007448; APK) and VA-MERIT Award (101 BX 000766: APK).

**#5269** Cryptotanshinone activate Nrf2 expression through microRNA regulations. Rachmad A. Dongoran, Tien-Yuan Wu. Tzu Chi University, Hualien, Taiwan.

Cryptotanshinone is a diterpene quinone derived from the roots of Salvia miltiorrhiza Bunge. An increasing number of studies have demonstrated that cryptotanshinone has the pharmacological activities such as anti-oxidative stress, anti-bacteria, anti-inflammation, and anti-cancer. Cryptotanshinone has been found to increase the ARE expression level induced by the Nrf2 and decrease Keap1 expression. This study investigated Nrf2 and Keap1-related microRNA to understand the mechanisms of cryptotanshinone in antioxidant activities. HepG2 cells were treated with cryptotanshinone 2.5 μM in DMEM medium with 1% FBS for 5 days. Total RNA was obtained for small RNA sequencing and real-time PCR analyses. The analyses revealed that Cryptotanshinone had the potential to inhibit miR-27a-5p, miR-142-5p, miR-28 and miR-93-5p levels, which subsequently increased the Nrf2 mRNA level. On the other

hand, the Keap1 mRNA level was suppressed through up-regulation of miR-23a and down-regulation of miR-7-5p. Moreover, Nrf2 and its related downstream antioxidant enzymes such as NQO1 and UGT were increased and the Keap1 protein level was decreased. These findings suggest that cryptotanshinone possesses the cancer chemoprevention activity in up-regulation of Nrf2 mRNA and protein through the suppression of mRNA via microRNA. Future investigations that extend the current study can focus on pharmacological mechanism of cryptotanshinone as a cancer chemoprevention agent, and the safety of long-term uptake of cryptotanshinone for cancer prevention.

Breast cancer is a rather complex and heterogeneous disease broadly grouped into four major subtypes, including luminal-type, basal-like, HER2 amplified, and normal-like, and each with a distinct molecular signature. A non-toxic chemopreventive intervention efficacious against different subtypes of breast cancer is still a clinically unmet need. The present study not only demonstrates chemoprevention of breast cancer in rats by the Ayurvedic medicine phytochemical withaferin A (WA) but also identifies its mechanistic biomarkers common to different subtypes of this disease. Chemopreventive efficacy of WA (4 and 8 mg per kg body weight) was determined using a rat model of breast cancer induced by N-methyl-N-nitrosourea (MNU). The mechanisms underlying breast cancer chemoprevention by WA were elucidated by western blotting, biochemical assays, immunohistochemistry, and cytokine profiling using plasma and tumors from the MNU-rat and/or mouse mammary tumor virus-neu (MMTV-neu) models. Inhibitory effect of WA on exit from mitosis and leptin-induced oncogenic signaling was determined using MCF-7 and MDA-MB-231 cells. Incidence, multiplicity, and burden of MNU-induced breast cancer in rats were decreased by WA administration. For example, the tumor weight in the 8 mg per kg group was lower by 67% compared with controls (P = 0.004). Mitotic arrest and apoptosis induction were common determinants of breast cancer chemoprevention by WA in the MNU-rat and MMTV-neu models. Cytokine profiling showed suppression of plasma leptin levels by WA in rats. WA inhibited leptin-induced oncogenic signaling in cultured MCF-7 and MDA-MB-231 cell lines. WA is a promising phytochemical with the ability to inhibit at least two different subtypes of breast cancer, including neu-driven estrogen receptor negative (ER-) breast cancer in MMTV-neu model and MNU-induced ER+ breast cancer in rats. This study was supported by the grant R01 CA142604-07 awarded by the National Cancer Institute.

**#5271 Prostate cancer chemoprevention by dietary isothiocyanates is associated with suppression of lipogenesis.** Krishna B. Singh, Shivendra V. Singh. Univ. of Pittsburgh Cancer Inst., Pittsburgh, PA.

Isothiocyanates (ITCs), including sulforaphane (SFN) and phenethyl isothiocyanate (PEITC), have been studied extensively for chemoprevention of prostate cancer using both in vitro and in vivo models, but the underlying mechanism is not fully understood. Dependence on fatty acid metabolism is progressively recognized as a unique trait of prostate cancer. Using in vitro and in vivo prostate cancer models, we demonstrate for the first time, that prostate cancer chemoprevention by ITCs is associated with suppression of fatty acid metabolism. Exposure of human prostate cancer cells to plasma achievable concentrations of SFN resulted in a marked decrease in levels of key fatty acid metabolism proteins, including acetyl-CoA carboxylase 1 (ACC1), fatty acid synthase (FASN), and carnitine palmitoyl transferase 1A (CPT1A), that was accompanied by suppression of their transcription. Consistent with the in vitro results, oral administration of prostate cancer chemopreventive concentrations of SFN (6 µmol per mouse, three times per week) resulted in downregulation of ACC1, FASN, and CPT1A proteins in prostate adenocarcinoma of TRAMP transgenic mice when compared with control. Levels of fatty acid metabolites (free fatty acid, triglycerides and phospholipids), lactate, and acetyl-CoA were also lower in the plasma and/or prostate adenocarcinoma of SFN-treated TRAMP mice in comparison with controls. Because fatty acid oxidation is an important step to supply energy to the prostate cancer cells, we explored the possibility of whether SFN could affect the fatty acid oxidation in prostate cancer cells. Many of these changes were also observed with PEITC. In conclusion, it is reasonable to propose that suppression of fatty acid metabolism is an important mechanism in prostate cancer chemoprevention by ITCs. This study was supported by the grants RO1 CA115498-10 and RO1 CA101753-12 awarded by the National Cancer Institute.

**#5272 Chemopreventive activities of a polyphenol rich purified extract from olive oil processing on colon cancer cells.** Barbara Bassani,1 Teresa Rossi,2 Daniela De Stefano,3 Daniele Pizzichini,7 Paola Corradino,7 Antonino Bruno,1 Douglas M. Noonan,4 Adriana Albini,4 Ircs MultiMedica, Milano, Italy; 5Ircs Arcispedale Santa Maria Nuova, Reggio Emilia, Italy; 6Enea Casaccia Research Center, Rome, Italy.

Chemopreventive activities of a polyphenol rich purified extract from olive oil processing on colon cancer cells. This study was supported by the grants RO1 CA115498-10 and RO1 CA101753-12 awarded by the National Cancer Institute.

Introduction: The majority of colorectal cancers (CRCs) develop through the adenoma-carcinoma sequence, while 15-20% develop via the serrated pathway. Sessile Serrated Adenoma/Polyps (SSA/P) are more difficult to detect during colonoscopy and generally require a shorter time follow-up than other lesions (3 vs. 5 years). These polyps lead to cancer faster than conventional adenomas. In order to better define patients at risk for these lesions, we performed a retrospective study to evaluate clinicopathological features of patients diagnosed with SSA/P. Methods: We reviewed pathology reports of patients at Howard University Hospital from 2010-2015. We identified 5,900 patients with colorectal lesions, of whom 312 (5.3%) were diagnosed with SSA/P. We analyzed the specific clinical, pathological and demographic features of patients with SSA/P lesions. Results: We identified 312 cases with SSA/P. The incidence of SSA/P over the 5 years period was 5.3%; 198/312 (63.4%) patients had 2 or more polyps, 54.5% of the SSA/P patients were females, 70.5% of patients were 50-64 years of age and 18% were older than 65. SSA/P lesions’ locations were as follows: rectal: 32.1%; rectosigmoid: 18.6%; sigmoid: 16.8%; Ascending Colon: 13.2% and Descending Colon: 7.1%. Reasons for colonoscopy were as follows: Screening: 43.6%; GI bleeding: 15.1%; Abdominal Pain: 13.1% and Change in Bowel Habits: 10.2%. Conclusion: Our results show that there is a slightly increased predominance of SSA/P occurrence in females. Most SSA/P occurred in patients 50 to 64 years old. This age range is younger in comparison to patients with conventional adenomas. SSA/Ps were predominately distal (rectal, rectosigmoid, sigmoid) whereas previous literature reports a proximal location. Most patients in our study were diagnosed in screening colonoscopies; however, other patients presented with symptoms such as GI bleeding, abdominal pain, or change in bowel habits.

**#5274 Risk of comorbidities among Hispanic and non-Hispanic white breast cancer survivors compared to breast cancer free women.** Avonne E. Connor,1 Kala Visvanathan,1 Stephanie D. Boone,2 Richard N. Baumgartner,2 Kathy B. Baumgartner2. Johns Hopkins Univ. School of Public Health, Baltimore, MD; 2University of Louisville School of Public Health & Information Sciences, Louisville, KY.

Epidemiological studies showed that diet can play a relevant role in reducing the risk of developing colon cancer (CC) and lower rate of CC incidence has been observed amongst populations living within the Mediterranean basin. Olive oil, a major component of the Mediterranean diet, is an abundant source of phenolic compounds. Olive oil production is associated with the generation of waste material, termed olive mill wastewaters (OMWW), that have been reported to be enriched in polyphenols as well. Given the beneficial activity of polyphenols on human health, we investigated whether the use of different batches of purified extracts from OMWW, termed A009, might be effective in exerting chemopreventive activities in vitro and in vivo, on CC cell lines. Cell proliferation and survival were evaluated on A009 treated cells by 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) assay, while the induction of apoptosis was assessed by flow cytometry. Further, functional studies to investigate the ability of A009 to interfere with CC cell line adhesion, migration, sprouting and invasion were performed. Finally, the ability of A009 to interfere with CT-26 CRC tumour cell growth was assessed in vivo. Purified hydroxytyrosol, the major component in the A009 extracts, was used as a control. A009 inhibited cell proliferation, migration, invasion, adhesion and sprouting of CC cells along with the release of pro-angiogenic and pro-inflammatory cytokines (VEGF, IL-8) similar to hydroxytyrosol alone. In vivo, A009 inhibited CT-26 tumour growth in a significant manner over that of hydroxytyrosol alone. Our results show that A009 extracts exert promising chemopreventive properties, suggesting that different polyphenols act synergistically, improving their single component effects in CC cell lines. Finally, our results support the idea of repurposing a waste derived material for nutraceutical employment, with environmental and industrial cost management benefits.
Hispanic women are projected to account for an increasing proportion of the U.S. breast cancer (BC) survivor population which is reaching 3.1 million. The number of BC survivors at risk of developing age-related comorbid conditions is increasing. Limited studies have examined the relationship between being a BC survivor and risk of comorbidities compared to BC free women of similar age. Retrospective studies have reported limited data on the prevalence of prevalent chronic conditions such as diabetes and hypertension are high. In this study we examined the associations between BC survivor status, ethnicity, and risk of comorbidities among long-term BC survivors and BC free women/controls that participated in the New Mexico Women’s Health Study (NMWHS) - a population-based case-control study from 1992-1994. The Long-Term Quality of Life Follow-up (2007-2011) was conducted approximately 15 yr (median) from BC diagnosis for cases or selection date for controls that participated in the NMWHS. Data for comorbidity conditions, lifestyle and reproductive factors were collected at follow-up interview. Baseline data from the NMWHS interviews were also available. A total of 449 BC survivors (68 Hispanic, 131 NHW) and controls (78 Hispanic, 172 NHW) were included in this analysis. Adjusted odds ratios (ORs) and 95% confidence intervals (CI) were calculated using logistic regression models for the associations between survivor status, risk of disease-specific conditions and comorbidities based on Charlson Comorbidity Index (CCI) level (low-high vs none at follow-up. The mean age at follow-up of BC survivors (64.3 years) and controls (64.0 years) was not significantly different. A total of 128 survivors and 139 controls experienced low-high levels of CCI (chi- squared p=0.06). The two most commonly reported CCI conditions among survivors and controls were connective tissue disease (43% of survivors; 33% of controls) and chronic pulmonary disease (25% of survivors; 18% of controls). Overall, BC survivors had increased risk of CCI (OR, 1.66; 95% CI 1.10-2.51) compared to controls. While Hispanic ethnicity was not a significant predictor of CCI, the following factors were significantly associated with CCI and were mutually adjusted for with survivor status: smoked for > 6 months at baseline (OR, 1.59; 95% CI 1.06-2.38); hypertension at follow-up (OR, 1.84; 95% CI 1.19-2.83); and history of hysterectomy (OR, 1.97; 95% CI 1.28-3.03). BC survivor status significantly predicted risk of connective tissue (OR, 1.76; 95% CI 1.17-2.64) and chronic pulmonary diseases (OR, 1.68; 95% CI 1.04-2.70); while no significant associations were observed for risk of diabetes, hypertension, or heart disease. Our findings suggest that smoking history and hysterectomy are contextual factors when considering BC survivorship care, and comorbidities such as connective tissue and pulmonary diseases should also be considered.

#5275 Breast cancer characteristics among Indigenous American women from Peru. Lizeth I. Tamayo,1 Tatiana Vidaurre,1 Jeannie N. Vásquez,2 Sandro Casavilca,2 Jessica I. Palomino,3 Monica Calderon,3 Garth H. Rauscher,1 Laura Fejerman3. 1University of Illinois at Chicago, Chicago, IL; 2Instituto Nacional de Enfermedades Neoplásicas, Lima, Peru; 3University of California San Francisco, San Francisco, CA

Background: Breast cancer prognosis depends on stage at diagnosis and varies by intrinsic tumor subtype. In the US, the distribution of intrinsic subtypes has been shown to differ between racial/ethnic groups, with African American and Hispanic/Latina women more likely to be diagnosed with the more aggressive “triple negative” breast cancer (TNBC), lacking expression of estrogen receptor (ER), progesterone receptor (PR) and human epidermal growth factor receptor 2 (HER2), compared to Non-Hispanic/Latina White women. Hispanics/Latinos in the US are a heterogeneous group originating from different countries with different cultures and ancestral backgrounds. Information about the distribution of tumor subtypes in Latin American regions is lacking. Methods: Data for these analyses come from the Instituto Nacional de Enfermedades Neoplásicas (the Peruvian National Cancer Institute), which diagnoses and treats 20% of all breast cancers diagnosed in Peru. We have abstracted data from clinical records for 303 patients diagnosed with breast cancer between 2010 and 2015 and who self-reported as members of an Indigenous American community from the Andean mountain region (indigenous subgroups: Quechua, Aimaras, N=232) or the Amazonian region (indigenous subgroups: Shipibo-Konibo, Awaún, Ashaninka, Kuyi, Llakiya, Eja). Harakhutu Community Health Center, Shavi, Yanashba, Kiksurutu, Nomatsangenga, N=71). We compared the distribution of age at diagnosis and tumor characteristics by region. Comparisons between the two regions were conducted using chi-squared tests, as well as a t-test for age at diagnosis. Breast cancer subtype was defined as luminal A (ER/PR+ /HER2-), luminal B (ER+ / HER2+), HER2 overexpressing (ER/PR- /HER2 +) and triple negative (ER/PR- /HER2 -) based on immunohistochemistry. Results: Overall, tumors from the 303 Indigenous American women from Peru included in the present study were 37% luminal A, 20% luminal B, 23% HER2 overexpressing and 19% triple negative. Our analyses showed that women from the Amazonian region were diagnosed at a younger age (50 vs. 55 mean age at diagnosis, P value =0.001), later stage (53.0% vs. 41.7% stage III or IV, P value=0.107) and more frequently with triple-negative tumors compared to women from the Mountain Region (30% vs. 16%, P value = 0.115). Conclusion: Differences between Indigenous American women from the Amazonian and Mountain Range regions in Peru could be due to variation in genetic predisposition to particular subtypes of the disease, variation in access to care between the different groups. The more we learn by analyzing diverse populations, subpopulations and revealing heterogeneity within Latin American women, the better equipped we will be to provide adequate care for all women.

#5276 Risk factors for ductal carcinoma in situ of the breast in African American women. Kimberly A. Bertrand,1 Traci N. Bethea,1 Lynn Rosenberg,1 Elisa V. Bandera,2 Melissa Troester,3 Thaer Khoury,4 Christine B. Ambrosone,1 Julie R. Palmer4. 1Stone Epidemiology Center at Boston University, Boston, MA; 2Rutgers Cancer Institute of New Jersey and Rutgers School of Public Health, New Brunswick, NJ; 3University of North Carolina Lineberger Comprehensive Cancer Center, Chapel Hill, NC; 4Roswell Park Cancer Institute, Buffalo, NY.

Introduction: The clinical significance of a ductal carcinoma in situ (DCIS) diagnosis is uncertain. While overall breast cancer mortality risk from DCIS is very low, a recent analysis showed that African American women diagnosed with DCIS were more than twice as likely to die from breast cancer as U.S. white women. Elucidation of risk factors for DCIS in African American women may provide opportunities for risk reduction. Methods: To assess the relation of reproductive, anthropometric, and other factors to risk of DCIS in African American women, we pooled data from three epidemiologic studies participating in the African American Breast Cancer Epidemiology and Risk (AMBER) Consortium - the Black Women’s Health Study, the Carolina Breast Cancer Study, and the Women’s Circle of Health Study. These studies contributed 805 DCIS cases and 13,830 controls to the analysis. We used unconditional logistic regression models to calculate odds ratios (ORs) and 95% confidence intervals (CIs) for risk of DCIS in relation to each risk factor of interest. Multivariable models were used to mutually adjust for risk factors as well as matching factors (age, study, geographic region, and questionnaire time period). We also compared results to associations observed for invasive breast cancer (n=3,765). Results: First degree family history of breast cancer was associated with an increased risk of DCIS (OR 1.62, 95% CI 1.32, 1.98). Oral contraceptive use within the past 10 years (vs. never) was also associated with increased risk (OR 1.31, 95% CI 1.01, 1.70), as was late age at first birth (≥25 years vs. <20 years) (OR 1.29, 95% CI 1.04, 1.61). Older age at menarche (≥15 years vs. <11 years) was associated with a reduced risk (OR 0.67, 95% CI 0.49, 0.92). Women with higher body mass index (BMI) in early adulthood (≥25 kg/m2 at ages 18 or 21) had a reduced risk of DCIS compared to those who had a BMI <20 kg/m2 in early adulthood (OR 0.71, 95% CI 0.56, 0.90). History of hysterectomy (yes vs. no) was associated with a reduced risk (OR 0.64, 95% CI 0.49, 0.85). Other factors that were associated with a reduced risk of DCIS were ever having children (versus never had any children) (OR 0.76, 95% CI 0.61, 0.97). We also found that age at menopause was associated with a reduced risk of DCIS (OR 0.71, 95% CI 0.57, 0.88). Women with breastfeeding duration of ≥4 months were associated with a reduced risk of DCIS (OR 0.54, 95% CI 0.33, 0.89). Women with history of diabetes or hypertension were associated with a reduced risk (OR 0.67, 95% CI 0.49, 0.92). Women with greater waist-to-hip ratio and absence of breast feeding were associated with increased risk of DCIS and particularly with estrogen receptor negative breast cancer. No other factors were associated with DCIS. Conclusion: Our findings suggest that smoking history and hysterectomy are contextual factors when considering BC survivorship care, and comorbidities such as connective tissue and pulmonary diseases should also be considered.
candidates significantly associated with differential disease outcome. Alter-
tations of outcome-associated candidates were validated in an independent cohort of
White (n = 115) and Black (n = 17) EEC patient transcript expression data. Results: We identified and validated 89 proteins and transcripts significantly altered between White vs Black EEC patients. Pathway analyses revealed candi-
dates elevated in White EEC patients correlated with marked activation of mo-
lecular signaling pathways regulating viral infection, but inhibition of those regulating cell death and necrosis. Candidates elevated in Black EEC patients largely correlated with activation of cell viability and nucleic acid metabolism, but inhibition of cell death, glucose metabolism disorder and inflammatory signaling. Correlation with patient outcome measures revealed 11 candidates significantly associated with differential OS and 8 candidates with differential PFS in EEC patients. All outcome-associated candidates elevated in White pa-
tsients significantly correlated with a low risk of poor OS and poor PFS (Hazard Ratio (HR) < 1, Wald p-value < 0.05). Conversely, the majority of outcome-
associated candidates (88%) elevated in Black patients correlated with a high risk of poor OS and poor PFS (HR > 1, Wald p-value < 0.05). Several OS (27%) and PFS (75%) candidates remained significant after adjustment for disease stage and grade as well as myometrial invasion. Alteration trends for several OS (27%) and PFS (25%) candidates were validated in an independent cohort of White and Black EEC patients. Conclusions: Our analyses identified and confirmed molecu-
lar alterations between White and Black EEC patients, including outcome-
associated candidates largely supportive of better outcome in White patients, but poor outcome in Black patients. The current study revealed evidence of race-specific differences in patient outcomes in Black EEC, consistent with the historic disparity of poor outcome in Black patients.

#5278 Effect of centralization on health disparities in lung and bladder cancer surgery. Wil Lieberman-Cribbin, Martin Casey, Matthew Galsky, Apu-
chat Tantraworasin, Bian Liu, William Oh, Raja Flores, Emanuela Taioili. Icahn
School of Medicine at Mount Sinai, New York, NY.

Background: Centralization has been advocated for both cystectomy and pneumonectomy, since it has been associated with reductions in mortality. Ra-
cial disparities exist for both lung and bladder cancer surgical outcomes despite trends in hospital centralization. We hypothesized that disparities exist in the centralization process for both lung and bladder cancer surgery, and that this has differentially affected surgical outcomes in black and white patients. Methods: The study population was extracted from the New York Statewide Planning and Research Cooperative System (SPARCS) database spanning 1997 to 2011, and included 26,750 lung cancer surgeries and 8,168 cystectomies. Hospitals were classified according to procedure volume; patient-hospital distance (PHD) and distance to the nearest high volume / very high volume (HV/VHV) were calculated. Logistic models were performed to determine factors associated with the utilization of HV/VHV or low volume / very low volume (LV/LVVL) hospitals. Additional models were then performed to assess the association between race and in-hospital mortality, stratified according to whether patients used HV/
VHV or LV/LVVL hospitals. Results: For cystectomy, PHD increased over the study period while distance to the nearest HV/VHV decreased; for lung cancer surgery, PHD increased but distance to the nearest HV/VHV hospital was con-
stant. For both surgical procedures, black patients experienced increased odds of LV/LVVL utilization over time (for lung cancer surgery, OR_{adj} ≥ 1.20; 95%CI
1.01-1.43; for cystectomy, OR_{adj} ≥ 1.59; 95%CI [1.26-2.02]). When HV/VHV hospitals were located farther from patients, the odds of HV/VHV utilization decreased while the odds of LV/LVVL increased for both lung cancer and bladder cancer patients. Lung cancer and bladder cancer in-hospital mortality was higher in blacks (OR_{adj} ≥ 1.50; 95%CI [1.21-1.86]; OR_{adj} ≥ 1.80; 95%CI [1.12-2.90], respectively) compared to whites. Conclusions: Racial differences persisted in hospital utilization and in surgical outcome for both lung and bladder cancers. While proximity and insurance are important determinants of quality care, other personal and community variables not captured by SPARCS are influential in lung and bladder surgical treatment and ultimately outcome. Specific inter-
ventions are needed to address accessing and utilizing quality care in under-
served populations, including black and low SES patients, and patients with large distances from high-volume hospitals.

#5279 Association of Vitamin D deficiency with breast cancer in African-
American and Hispanic women in south Los Angeles. Yanjun Wu,1 Mari-
annia Sarkisian,2 Sheliah Clayton,2 Javy Vadgama3,4 Charles R Drew Univ. of
Medicine & Science, Jonsson Comprehensive Cancer Center, David Geffen School of
Medicine, University of California at Los Angeles, Los Angeles, CA; 4Charles R Drew Univ. of Medicine & Science, Los Angeles, CA.

Background: Experimental evidence supports a protective role of Vitamin D level in breast carcinogenesis, but epidemiologic evidence is inconsistent. Af-
can Americans have high prevalence of Vitamin D deficiency and the African American women with breast cancer have the highest mortality rate. The aim of this study is to investigate the association of Vitamin D levels with breast cancer risk and survival in African American women. Methods: This is a case-control study of 660 African American and Hispanic women with and without breast cancer in South Los Angeles. Blood samples were collected prior cancer treatment and the serum 25-hydroxyvitamin D (25(OH) D was measured by Quest Diagnostics. Information regarding BMI and clinical factors were obtained by medical record abstraction. Logistic Regression with multivariable analysis was used for determining the association of Vitamin D deficiency (<20ng/ml) with breast cancer. Kaplan-Meier survival analysis and Cox Regression with multivariate analysis were used to assess disease-free sur-
vival and the relative risk of disease progression. Results: Our data shows that 69.2% of African American women and 37.8% of Hispanic women suffer from Vitamin D deficiency in our cohort. African American women had significant lower level of Vitamin D3 compared with Hispanic women in all age groups. The lower Vitamin D3 level was observed among age groups of 31 to 50 in African Americans. The deficiency in Vitamin D levels was significantly associated with breast cancer in both African Americans (OR=2.5, p = 0.007) and Hispanics (OR=1.9, p = 0.009). Interestingly, we found that a significant association of Vitamin D deficiency with trip negative breast cancer (TNBC) in African Amer-
ican women (HR=1.95, 95%CI=1.04-3.67, p=0.04) faced a significantly higher risk level was observed in African American women with TNBC. There was no significant association of Vitamin D deficiency with tumor size, lymph node involvement and tumor stage. The deficiency of Vitamin D3 level was not associated with disease progression in this cohort of women. Conclusion: Our data suggests that a significant association of Vitamin D deficiency with breast cancer in both African Americans and Hispanics, especially more associated with type of TNBC in African American women in our cohort.

#5280 Disparity-related survival among adolescent and young adult pa-
tients with sarcomas in Texas. Jaqueline Contrera Avila,1,2doi, Living-pornon,3 Ana Rodriguez,4 Anne Kirkhoff,5 Yong-Fang Kuo,6 Sapna Kaul.7 The
University of Texas Medical Branch, Galveston, TX; 3Sarcoma Medical Oncology, University of Texas MD Anderson Cancer Center, Houston, TX; 4Huntsman Can-
cer Institute, University of Utah, Salt Lake City, UT.

Purpose: Sarcomas are a rare and heterogeneous group of cancers that can occur in both children and adults, and have a peak incidence in adolescents and young adults (AYAs). Sarcomas may account for ~10% of all invasive cancers among AYAs and >50% of all sarcoma diagnoses occur in this age group. Additionally, sarcoma survival among AYAs is lower than that in children or adult patients. Furthermore, although less understood, significant socioeconomic factors may exist in survival among AYAs with sarcomas. The current study examines disparity-related survival among AYAs with sarcoma in Texas, one of the largest U.S. states, that has over 50% non-Hispanic white population. Methods: N = 4,131 patients diagnosed with bone or soft tissue sarcomas were identified in the statewide Texas Cancer Registry from 1995-2013 at ages 15-39 years (i.e., AYA age range). Socio-demographics at diagnosis (e.g., race and ethnicity, insurance, and county of residence), clinical characteristics (e.g., early vs. late stage, treatment (e.g., chemotherapy), and vital status as of December 31, 2013) were summarized. Associations between patient survival and demographic/clinical variables were examined using the Kaplan Meier (KM) method, and the Cox Proportional Hazard (CPH) regressions. KM survival curves were com-
pared using log-rank tests. Results: Over half of our patients were male (57.4%). 36.6% were Hispanic, 12.7% were non-Hispanic black, and 46.6% were non-
Hispanic white. Nearly 22% of patients were uninsured. Furthermore, 20% of patients were diagnosed with metastatic sarcoma. The average 5-year KM sur-
vival for all patients was 69.5% (95% CI =67.9%-71.0%). KM survival curves significantly differed by variables such as sex, race and ethnicity, insurance and tumor staging. 5-year survival was higher for females (73.7% vs. 66.1% for males, p < 0.001), for non-Hispanic white patients (72.1% vs. 63.9% for non-
Hispanic blacks, p < 0.001), patients with private insurance (76.0% vs. 68.2% for uninsured, p < 0.001), and those with early stage sarcomas (77.1% vs. 23.4%, p < 0.001). After adjusting for treatment and tumor staging, the CPH model demonstrates that males (hazard ratio (HR) = 1.93, 95% CI = 1.25-3.00, p < 0.003) and those who resided in Texas counties bordering Mexico (HR = 3.2, 95%CI = 1.04-3.67, p = 0.04) faced a significantly higher risk of death than their counterparts. Conclusion: Our population-based analyses show that substantial disparity-related differences in survival exist among AYA sarcoma patients in Texas. Further study is warranted to identify specific interventions to improve survival outcomes in this high risk patient group.
#5281  Komen Tissue Bank donors: Genetically determined ethnicity and race. Julia R. McCarty,1 Guanlong Jiang,2 Teresa Mahin,1 Nicholas Scherer,3 Jonathon Dunn, A Maria Storniolo,1 Natascia Marino,2 Susan G. Komen Tissue Bank at the IU Simon Cancer Center, Indianapolis, IN;1 Indiana University School of Medicine, Indianapolis, IN;2 Indiana University School of Medicine, Indianapolis, IN;3 Indiana University, Indianapolis, IN.

Background: Several evidences indicate that different racial and ethnic backgrounds affect the incidence and severity of diseases such as breast cancer and diabetes, and the response to therapy. For example White and African American women are more likely to develop breast cancer than Hispanic and Asian women. Moreover, African American women are more likely to develop more aggressive (Triple-negative Breast Cancer) and advanced-stage (Breast Cancer at young age). Therefore, given the health disparity and with the advance of personalized medicine, it is becoming critical to address population stratification. The Komen Tissue Bank at IU Simon Cancer Center (KTB), the only biobank of normal breast tissue from healthy women, is employing a more accurate approach to detect population stratification through the use of Ancestry Informative Markers (AIMs). Methodology: A total of 2,973 DNA samples were obtained from the KTB. Genotyping was performed using the KASP technology (LG Genomics) and a 41-SNP panel (labeled 41-AIM panel) selected from Nierveighel et al, 2013. Genotype analysis using the 41-AIM panel along with a Bayesian clustering method (STRUCTURE) was able to discern continental origins including European/ Middle East (Caucasian), East Asia, Central/ South Asia, and Oceanic Islands. A reference set was created from the KTB HeatMap. The results were compared with the self-reported data. Results/Conclusion: Our genetic ancestry analysis indicates that out of 2,973 KTB tissue donors, 2,132 are primarily Caucasian, 532 African, 234 of Asian, 72 Latino, 3 Oceanic origins. High mixture of racial markers was observed in several samples. Moreover, when we compare these findings with the self-reported data we find a 10.9% of discrepancies indicating the imprecision of the self-reported information. The implementation of the genetic ancestry data into the KTB creates the potential for a more accurate study of health disparities.

#5282  Comparison of a public versus private hospital in New York City in delivering timely adjuvant chemotherapy among stage III colon cancer patients. Daniel Lin,1 Benjamin Levinson,2 Judith D. Goldberg,3 Tsivia Hochman,1 Lawrence P. Leichman,4 Heather T. Gold2.1 New York University Langone Medical Center, New York, NY; 2 New York University School of Medicine, New York, NY.

Background: Although the optimal timing of adjuvant chemotherapy (AC) for stage III colon cancer patients has been debated, most studies recommend initiating AC within approximately 60 days of surgery. Significant disparities in timeliness of AC initiation in colon cancer have been reported in public versus private hospitals, with longer time to AC at public hospitals. We evaluated whether timeliness of AC differed between a public and a private hospital, both affiliated with the same major academic institution in New York City. Methods: We conducted a retrospective cohort study of Stage III colon cancer patients who underwent surgery and received AC at the same institution from 2008-2015 at NYU Langone Medical Center’s affiliated public hospital (Bellevue) or its private hospital (Tisch). Patient data were obtained through review of hospital tumor registry and electronic medical records. Patient characteristics were compared by hospital. We defined timeliness as receipt of AC within 60 days post-operatively. Univariate and stepwise multivariable logistic regressions were used to identify factors associated with timely AC. Results: Forty three patients at Bellevue Hospital and 79 patients at Tisch Hospital who underwent surgery and received AC at the same institution were included. Median number of days to AC was significantly greater among patients receiving care at Bellevue (53, range 31-231) compared to Tisch (43, range 25-105; p=0.002). However, the percent-age of patients who received timely AC did not differ substantially at Bellevue and Tisch (74% vs 81%, p=0.40). Individual characteristics significantly associated with timely initiation of AC were non-Hispanic ethnicity (OR: 2.71, 95% CI: 1.06-6.95), married (OR: 2.89, 95%CI: 1.15-7.30), and laparoscopic (vs open) surgery (OR: 1.89, 95%CI: 1.64-2.15). Timing of AC at Bellevue compared to Tisch was not significant (OR:0.68, 95%CI:0.28-1.65). When hospital and other factors were examined jointly, only age (OR: 0.95/year, 95% CI: 0.91-0.99) and laparoscopic (vs open) surgery (OR: 5.65, 95% CI: 1.92-16.62) remained as important factors associated with receiving timely AC (Likelihood Ratio Chi-Square=14.95, p=0.0019). When hospital was omitted from multivariable analysis, age and surgery type still remained the only significant factors associated with timely AC (OR’s unchanged, Likelihood Ratio Chi-Square=14.81, p-value=0.0006). Conclusions: The proportion of patients receiving timely AC within 60 days of surgery was similar at both an affiliated public and private hospital at NYU Langone Medical Center. Age and type of surgery were significant predictors of timeliness in our population. Further research should be conducted to understand how system-level factors may promote timely receipt of care.

#5283  Association between body mass index and prostate cancer among African American men. Margaret S. Pichierio, Cheryl J. Smith, Wei Tang, Tiffany Gorsey, Stefan Amb. National Cancer Institute, Bethesda, MD.

Prostate cancer (PCa) is a leading cause of cancer death in US men. Yet, the etiology of prostate cancer remains poorly understood, with only older age, African ancestry family history of the disease, and multiple germline genetic variations being established disease risk factors. Prostate cancer occurs more often in African-American (AA) men and Caribbean men of African descent than in men of other race/ethnicities. While it has been previously suggested that obesity (measured by body mass index [BMI, kg/m2]) may worsen disease-related outcomes among prostate cancer patients, the relationship of obesity and prostate cancer risk, using race as a predictor, has not been fully explored. Using multivariable logistic regression, we estimated the risk of total PCa for 976 cases and 1,032 age-matched controls, with equal proportions of European-American (EA) and AA men. Among men in the NCIC Maryland Prostate Cancer Case-Control Study, BMI was inversely associated with disease outcomes in AA men, but not among EA men. Consistent with previous literature, BMI in EA men was shown to be positively associated with overall prostate cancer risk. Our findings suggest an obesity paradox, where obesity may protect against incidence of PCa among AA men. Studies are needed to elucidate the underlying mechanisms responsible for the differential effects of obesity in AA and EA men with prostate cancer.

#5284  Gastric cancer in the Alaska Native people: A cancer health disparity. Holly Martinson,1 Steven Albers,2 Matthew Olness.1.1 Univ. of Alaska Anchorage, Anchorage, AK; 2 Mayo Clinic, Rochester, MN; 3 Alaska Native Medical Center, Anchorage, AK.

Gastric cancer in the Alaska Native (AN) people occurs at a 3-fold higher incidence and 4-fold higher mortality rate compared to Non-Hispanic Whites (NHW), representing one of the largest cancer disparities in the AN population. We aimed to review the AN gastric cancer burden and identify clinicopathological factors that are associated with cancer outcomes. Patient information was collected from 132 AN gastric cancer patients diagnosed between 2006-2015 at the Alaska Native Medical Center. The Surveillance, Epidemiology and End Result database 18 was used to collect comparison United States NHW gastric cancer patient data. Compared to NHW patients, AN gastric cancer patients have a higher incidence rate, are significantly younger, 60 versus 69 years, and have a poorer 5-year overall survival rate of 10% compared to 22%. AN patients differ from NHW patients in gastric cancer anatomic location, subtype, and high presence of signet ring cell gastric cancer. For AN patients, tumors were positive at the time of diagnosis for Helicobacter pylori, 77% had chronic gastritis, 30% had a family history of a first-degree relative with gastrointestinal cancers, and 82% were current or former tobacco users. Using univariate analysis, diminished overall survival was observed with anatomic site, increasing stage, no treatment, the number of lymph nodes examined during resection, and chronic gastritis. Multivariable analysis revealed stage and treatment type were independently associated with improved overall survival. AN gastric cancer cases vary in their clinical and epidemiologic features, relative to NHW.

#5285  Glucocorticoid-mediated upregulation of stress oncoproteins: implications for prostate cancer health disparities. Leanne Woods-Burnham,1 Arthur Love,1 Christina K. Calixto-Du Ross,2 Laura Stiel,1 Evelyn S. Sanchez,1 Kwame Amponsah,1 Susanne Montgomery,2 Colwiclk Wilson,2 Carlos A. Canio,1 Loma Linda University School of Medicine, Loma Linda, CA; 2 Loma Linda University School of Behavioral Health, Loma Linda, CA.

Prostate cancer (PCa) presents the greatest US cancer health disparity in terms of incidence and mortality, disproportionately affecting African American (AA) men. The biological characteristics of prostate tumors are exaggerated in AA men compared to European American (EA) men at time of diagnosis. The mechanisms underlying increased PCa aggressiveness in AA men are not fully understood; therefore, there is a critical need to identify biological determinants contributing to PCa mortality disparities. Glucocorticoids—a type of stress hormone—have been implicated as driving factors in PCa progression. The underlying mechanism involves endogenous glucocorticoid (cortisol) binding to its glucocorticoid receptor (GR) and activating genes that promote tumor aggressiveness and therapy resistance. A clinical dilemma exists as glucocorticoids, important in the palliative care of PCa patients, are now emerging as accelerators of disease progression and shortened survival. Chronically elevated levels of
#5286 Type 2 diabetes and increased risk of estrogen receptor-negative breast cancer in African American women. Julie R. Palmer, Nelsy Castro-Webb, Kimberly A. Bertrand, Traci N. Bethea, Lynn Rosenberg. S lone Epidemiology Center at Boston University, Boston, MA.

Introduction: Type 2 diabetes (T2D) is hypothesized to be a risk factor for breast cancer. Possible mechanisms include adverse effects of impaired glucose regulation on endogenous hormone levels and increased inflammation of adipose tissue, which may be favorable to breast epithelial cell transformation, tumor-related angiogenesis, and cancer cell invasion. Recent meta-analyses suggest that T2D may be associated with a 15-20% increase in risk, but whether that is due to insulin resistance is body mass index (BMI) is uncertain. Further, few studies have reported results separately by estrogen receptor (ER) status of the tumor, none have had interpretable numbers of ER- cases, and the only previous report on the association in African American (AA) women analyzed all subtypes together. Methods: We used data from the prospective Black Women’s Health Study to examine the relation of T2D to incidence of invasive breast cancer, overall and by ER subtype, among 54,337 AA women free from T2D and breast cancer at baseline and followed for 20 years. Included were 1,851 incident breast cancer cases, with 468 classified as ER+ and 914 as ER--; data on ER status were not available for 469 cases. Participants were asked about medical conditions on each biennial questionnaire. In a validation study, 95% of self-reports of diabetes were confirmed by medical records.

Conclusions: The finding suggests that ER-negative breast cancer among diabetic women differs according to how well the diabetes is controlled.

#5287 Recent trends in racial and regional disparities in cervical cancer incidence and mortality. Wonsuk Yoo, Sangmi Kim, Steven Coughlin, Sejong Bae, Edward Partridge, Warner Huh, Sarah Dilley, Yunmi Chung.

Objective: To examine trends and disparities in cervical cancer incidence and mortality by race and region-specific rates and the trend between 2000 and 2012. Methods: The Surveillance, Epidemiology, and End Results (SEER) 18 Program data was used. Incidence and mortality rates, annual percent changes, and disparity ratios of cervical cancer were calculated using SEER*Stat software and joinpoint regression for four groups: US14, Non-Hispanic White (NHW), US14, Non-Hispanic Black (NHB), South-NHW, and South-NHB, where the South included 4 regions from Georgia and Louisiana.

Results: The incidence and mortality rates were much higher among NHB women compared to NHW in the South and the US. The degree of racial disparities between NHB and NHW women was greater in terms of mortality rates than incidence rates. For all age groups, NHB women in the South consistently had higher incidence rates than NHW women in the US region. The mortality disparity between NHB and NHW women, followed by NHB women in the South, NHW women in US14, and finally NHW women in the South. Conclusions: Although racial disparity has been narrowed in recent years, there has been little change or even a growing gap between white women in the South and their counterparts in the US14 region. Age-specific analysis further indicated that the emerging regional gap observed among white women might be attributable to the excess number of new cases and deaths among young women.

#5288 Perception of barriers and facilitators to hepatitis B virus screening, vaccination, and treatment care among Asian American physicians. Patricia Estrella, Ming Chin Yeh, Yin Tan, Carolyn Y. Fang, Sarit A. Golub, Grace X. Ma.

Objective: To examine practices and factors affecting Hepatitis B Virus (HBV) screening, vaccination, and treatment among Asian-American physicians in New York City. Methods: Members of the Chinese American Independent Practice Association (CAIPA) will be recruited to participate in a comprehensive survey, developed based on prior research, to assess physicians’ practice in HBV screening, vaccination, and treatment. This study will also examine barriers/facilitators toward HBV prevention and treatment in knowledge, familiarity, and awareness of guidelines, perception, attitude, behaviors, self-efficacy, motivation, patient factors, cultural, and environmental factors. A bivariate analysis and multivariate regressions will be conducted to evaluate factors that predict study outcomes. Results: We hypothesize that Asian American physicians are more likely to screen for HBV, but are experiencing many barriers unique to the Asian American physicians that are leading them improperly perceive certain factors as important. Conclusions: It is crucial. As a result of the reverence of the doctors, a cultural norm prevalence within the Asian community, physicians are uniquely positioned to improve HBV screening, vaccination, and treatment among Asian-American physicians that are leading them improperly perceive certain factors as important. Therefore, identifying chronically infected persons and linking them to care is crucial. As a result of the reverence of the doctors, a cultural norm prevalence within the Asian community, physicians are uniquely positioned to improve HBV screening, vaccination, and treatment among Asian-American physicians that are leading them improperly perceive certain factors as important. Therefore, identifying chronically infected persons and linking them to care is crucial.

#5289 Assessment of environmental influences, behavioral risk factors and genetic differences among a cohort of 819 African American community members. Jacquelineucci, Ming Chin Yeh, Khursheed Navder, Joel Erblich, Elizabeth Blackman, Grace X. Ma, Camille Ragin, Hunter College, CUNY, New York, NY; Fox Chase Cancer Center, Temple University Health System, Philadelphia, PA; Temple University, Philadelphia, PA.

Objective: This study was designed to address genetic, environmental and lifestyle risk factors for cancer in populations of African Ancestry. We have established a non-cancer control registry which involves the collection of epidemiological, lifestyle, culture and cancer prevention behaviors (such as cancer screening and diet, etc). Methods: Data was coded and analyzed using Stata from...
#5290  **Racial variation in terminal duct lobular unit (TDLU) involution in Chinese and Polish breast cancer patients.** Hyuna Sung,1 Changyuan Guo,2 Jennifer Guida,1 Shan Zheng,2 Erni Li,3 Jing Li,3 Nan Hu,1 Joseph Deng,1 Montserrat Garcia-Closa,1 Jonine Figueroa,2 Mark Sherman,3 Gretchen Gierach,3 Ning Lu,3 Xiaohong R. Yang1.

Introduction: Terminal duct lobular unit (TDLU) involution, an age-related physiological process, is characterized by the reduction of size and numbers. Reduced or absent involution is associated with higher mammographic density, a strong breast cancer risk factor. Both factors predict risk of developing breast cancer among women with benign disease. Given that prior studies have been conducted mainly in White women, we compared the extent of TDLU involution among Western and Asian breast cancer cases to describe potential racial heterogeneity in breast cancer etiology. Method: We obtained three TDLU involution metrics (count/100 mm², mean span, and mean acini count/TDLU; all inversely correlated with TDLU involution) measured in benign breast tissue sections from 379 Chinese (254 luminal A and 125 core basal phenotype [CBP] cases) and 476 Polish (407 luminal A and 69 CBP) breast cancer cases. Polytomous logistic regression was performed using tertiles of TDLU measures as ordinal dependent variable and race as an independent variable. Covariates included age, body mass index, and parity. Analyses were performed separately by age group (<50, ≥50) and subtype (luminal A and CBP). Results: Among luminal A cases, Chinese had significantly greater TDLU count compared with Polish in both age groups (ORtrunc = 11.0; 95% CI = 2.8-42.3; P = 0.001 for age<50; ORr= 12.1; 95% CI= 5.1-28.7; P = 1E-08 for age≥50). In addition, Chinese were more likely to have greater mean span and acini count among younger cases (ORtrunc = 4.5; 95% CI = 1.4-14.4; P = 0.001 for mean span and ORr= 7.4; 95% CI= 4.13-13.4; P = 3E-11 for acini count) but not among older cases. Among CBP cases, Chinese were more likely to have greater acini count compared to Polish only among younger women (ORr= 2.6; 95% CI= 1.2-6.9; P = 0.03 for age<50). Conclusion: We found Chinese were more likely to have reduced TDLU involution compared to Polish cases after accounting for potential confounders, with greater differences for luminal A and younger women. Studies of TDLU involution in diverse populations are needed to confirm and understand whether population difference in TDLU involution metrics are related to age at breast cancer onset and risks for specific tumor subtypes.

#5291  **Effect of screening CT results and features on lung cancer risk prediction within the National Lung Screening Trial.** Hilary A. Robinson1, Christine D. Berg2, Li C. Cheung3, Anil K. Chaturvedi,4 Hormuzd A. Katki5,1 Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; 2National Cancer Institute, MD.

BACKGROUND: In the course of screening, individual risk of disease evolves based on screening results. We calculated how individual lung cancer risk changes based on screening CT findings using data from the National Lung Screening Trial (NLST), which conducted annual screening for 3 years. METH-ODS: We calculated lung cancer risks by combining CT findings with individual predicted 1-year “pre-screening risk.” Pre-screening risk (r(x)) was predicted in the absence of screening using a validated risk model (Katki et al., JAMA 2016) with covariates (x): age, education, sex, race, smoking intensity/duration/quit-years, body mass index, family history of lung cancer, and self-reported employment. We used log-binomial regression to calculate the risk of an “interval” lung cancer (within 1 year of a negative screen) or a “screen-detected” cancer detected at the next annual screen. For each, covariates included log-transformed 1-year pre-screening risk and CT findings including classification as negative or false-positive and other specific features. RESULTS: The median 1-year pre-screening risk at the first NLST screen was 0.32% (interquartile range 0.19-0.53%). Among CT-negatives, risk over the next year was substantially reduced as r(x)2 (median interval cancer risk 0.05%), but risk at the next screen reverted to pre-screening risk as r(x). Risk at the next screen was higher for those whose CT findings were more likely to be cancerous: smokers (r(x)3), mesothelial (r(x)6), and high TLDI scores (r(x)2.5). Risk of developing breast cancer (median risk 0.1%) increased as r(x) and higher. Among CT-false-positives, overall risk at the next screen increased as r(x)2.5 (median risk 1.5%). Risk was higher among those with nodule(s) that were larger, had spiculated margins (median risk 4.1%), were located in the upper lobes (median risk 1.4%), or grew during the most recent screening interval (median risk 7.9%), while nodules with smooth margins indicated lower risk (median risk 0.7%). Those with a smooth-margins nodule and no risk-increasing factors essentially reverted to their pre-screening risk at the next screen as r(x)0.29% (median risk 0.29%), as if they had screened negative. Overall, only the immediately prior screen result, and not earlier screens, predicted lung cancer risk (all p>0.2). Exponents were similar for each interval and at each screen (all p>0.07). CONCLUSIONS: CT-negatives experienced reduced lung cancer risk over the next year, but reverted to their pre-screening risk at the next screen. CT-false-positives experienced substantially increased lung cancer detection at the next annual screen, with most risks exceeding 1%. These risk increases were explained by specific CT features including nodule size, location, margins, and growth.

#5292  **Multitarget fecal miRNA test combined with fecal occult blood test and fecal miRNA test for colorectal cancer screening.** Yoshihiko Koga1, Hyun Soo Kim2,3,4, Naoko Takahashi,1 Naoko Takeya,1 Yutaka Saito1,2, Hiroshi Saito3,4, Yasuhiro Matsumura1, National Cancer Center, Kashiwa, Japan; National Cancer Center Hospital East, Kashiwa, Japan; 3National Cancer Center Hospital East, Tokyo, Japan; 4National Cancer Center, Tokyo, Japan.

Background & Aims: The fecal immunochemical test (FIT) is used for colorectal cancer (CRC) screening worldwide. However, there are several issues of the false-positive and the false-negative. To overcome these problems, various molecular biological tests have been combined to FIT. In this context, multitar-get fecal DNA test was approved by FDA in August 2014. In addition, multitar-get fecal microbiota has been recently reported. We have reported the usefulness of fecal miRNA analysis to detect CRC. Here, we investigated the applicability of multitarget fecal miRNA test combined with FIT and FIT and fecal miRNA test using fecal RNA extracted from FIT residual. Methods: In this study, 57 patients with invasive CRC, 33 patients with advanced adenoma, and 60 healthy individuals were enrolled. Each participant collected 10 mg fecal samples using the FIT sampling container for 2 days. After FIT was performed, total RNA was extracted from the residue and miRNA expression was analyzed by using real-time RT-PCR. The sensitivity and specificity of the multitarget fecal miRNA test combined with FIT and fecal miRNA test was analyzed by using the decision tree analysis. Results: Approximately 1μg RNA was extracted from 10 mg fecal sample. The expressions of miR-16, miR-92a, miR-106a, miR-142-3p, miR-223, and miR-451 in fecal samples were significantly higher in the patients with advanced neoplasm (including invasive CRC and advanced adenoma) than in the healthy individuals (P<0.05). The sensitivity and the specificity of the FIT alone were 74.4% (67/90) and 93.3% (56/60), whereas those of the multitarget fecal miRNA test were 93.3% (83/90) and 91.7% (55/60). Moreover the multitarget fecal miRNA test could detect 81.8% of patients with advanced adenoma (27/33). Conclusions: Multitarget fecal miRNA test combined with FIT and fecal miRNA test may be a useful new CRC screening method.

#5293  **Have you checked? Disparities in cancer screening practices among minority populations.** Tamaryn F. Gray,1 Joyceyn Cudjoe1, Hae Ra Han1, Jennifer Wenzel1, Roland Thorpe,1 Jeanne Murphy1,2 Johns Hopkins University, Baltimore, MD; 3National Cancer Institute, Rockville, MD.

Objective: There is a disproportionately higher burden of cancer among racial and ethnic minorities, with the incidence only expected to increase significantly by 2050. The racial/ethnic differences in screening are due to the lack of cancer prevention screening among this population. The purpose of this research is to provide case study reports about cancer screening practices among at-risk populations as well as those from underrepresented racial and ethnic minority backgrounds as well as sexual and gender minorities in order to describe disparities in cancer screening practices. These five case studies reveal how racial disparities vary by cancer site. Case these case studies will share information about current cancer prevalence, current recommendations for cancer prevention, national guidelines about early detection for lung, colorectal, prostate, cervical and breast cancers, as well as discuss ways to reduce cancer health disparities and improve screening practices. Methods: Data sources for these case studies include research reports,
EPIDEMIOLOGY: Health Disparities, Screening, and Risk Prediction

literature review, clinically-based articles, research articles, websites, as well as clinical practice observations and experiences. Research Summary: These case studies contribute to the growing body of knowledge related to cancer health disparities, with a special emphasis on cancer screening behaviors among underrepresented, at-risk, and racial and ethnic minority backgrounds. Since cancer care disparities exist, these case reports highlight the role of oncology nurses in helping to lead in educating, promoting, and bringing awareness to cancer screening recommendations and current cancer prevention guidelines for individuals and their families. Nurses recognize that one of the biggest barriers to screening is when individual have unrelated health care priorities that overshadow priorities related to screening, such as food, shelter, and nutrition. Nurses are also positioned to provide cancer-specific screening guidelines and resources to help individuals implement these recommendations into their daily lives. Improving screening rates among minority populations requires collaborations with the health care systems and the community. Conclusion: Evidence indicates that there are significant disparities that exist in cancer screening practices among minority populations as well as disproportionately higher cancer mortality rates in these populations. Barriers to screening include lack of access to high-quality health care, lack of health insurance, transportation issues, fear and lack of trust in the health care team, embarrassment, stigma related to sexual orientation or gender identity, discrimination in quality care and treatment, as well as lack of awareness about screening recommendations. Recognition of barriers to screening among minority populations is critical to developing targeted interventions that promote adherence and decrease risks of cancer-related mortality.

#5294 Do co-morbid conditions correlate with cancer screening awareness and behaviour among older women? Findings from the fifth Indonesian Family Life Survey. Wahyu Wulaningsih,3 Mieke Van Hemelrijck,2 Sumadi Anwar,1 Jothanan Watkins,1 University College London, London, United Kingdom; King’s College London, London, United Kingdom; Universitas Gadjah Mada, Yogyakarta, Indonesia; PILAR Research and Education, Cambridge, United Kingdom.

Background: Cancer screening awareness may vary in low- and middle-income countries lacking established national screening programmes. Additionally, breast self-examination (BSE) to screen for breast cancer is common in these countries, despite evidence suggesting its lack of benefit. We evaluated co-morbidities as a potential determinant of awareness to breast and cervical cancer screening and BSE practice in older women in Indonesia. Methods: From the fifth Indonesian Family Life Survey (2014-2015), 6,320 women aged 40 and older who responded to questionnaires on pap smear, mammography, and BSE were included. To assess co-morbidities, an age-weighted score similar to the Charlson co-morbidity index was created based on self-reported history of chronic disease diagnoses. Weighted regression analyses were performed to assess their correlations with awareness to pap smear or mammography and BSE practice. Results: Only 22% women were aware of pap smears, and 32% among them had undergone at least one pap smear in their lifetime. Six percent of participants were aware of mammography, among which 4% had a mammogram in the previous year. Twelve percent of women reported they performed BSE at least once a year. With increasing co-morbidities, women were more likely to be aware of pap smear (e.g. age-adjusted OR=3.27, 95% CI: 1.18-9.01 for co-morbidity score of >2 compared to 0). No association with awareness to mammography was seen. Higher frequency of BSE per year was seen with higher co-morbidity (β=1.96, P=0.01 for co-morbidity score of >2 compared to 0). Associations remained, albeit weaker, after exclusion of women with history of cancer. Conclusion: Higher co-morbidities weakly correlated with being more aware to cervical cancer screening and practicing BSE more frequently among older women. Our findings may imply the need for targeted health promotion and screening for cancer in presence of limited infrastructure.

#5295 Screening performance of ultrasonography and mammography among Chinese women at high-risk of developing breast cancer. Yubei Huang,1 Fei-Hao Song,1 Xuan Tian. Tianjin Medical University Cancer Institute and Hospital, Tianjin, China.

In order to easily identify high-risk population of breast cancer and to determine the optimal screening modality among Chinese high-risk women, a total of 35234 asymptomatic Chinese women aged 45-65 years underwent breast ultrasound (BUS) and mammography (MAM) screening concurrently. Physicians performed these screening modalities separately and blindly. The number of risk factors of breast cancer, rather than complex risk prediction models, was used to identify potential high-risk women. Initially, a total of 13 factors (age at menarche, menopausal status, age at menopause, number of live birth, age at first pregnancy, breast feeding, duration of breast feeding, abortion, oral contracept-

tive, hormone replacement therapy, obesity, history of benign breast disease, and family history of breast cancer) were selected. After excluding correlated factors, factors with risk frequency ≥ 20% and factors with missing values ≥ 5%, 6 factors (age at menarche, age at menopause, age at first pregnancy, oral contraceptive, obesity, family history of breast cancer) were selected as risk-evaluating factors. Weights of co-morbidities were assigned on a 0-10 scale, and the co-morbidity score of each patient was calculated. The number of exposure to risk factors is an easy-to-use method to identify potential high-risk women of breast cancer, and the performance of BUS is very similar to that of mammography.

#5296 Evaluation of p16/Ki-67 dual stain, cytology, and HPV16/18 genotyping for triage of HPV-positive women in a large screening population. Nicolas A. Wentzensen,1 Barbara Fellermann,2 Renee Bremer,3 Philip Castle,4 Diane Tokugawa,4 Nancy Poitrass,5 Elizabeth Hosfield,6 Thomas Lorey,7 Mark Schiffmann,7 Walter Kinney,8 NCT-DCEG, Bethesda, MD; 4 Kaiser Permanente Northern California, CA; 5 Albert Einstein College of Medicine, Bronx, NY; 7 Kaiser Permanente Northern California, Richmond, CA.

Objectives: Primary HPV testing has been approved in the United States. Screening intervals can be safely extended for HPV-negative women, but the challenge lies in discriminating transient HPV infections from precancers among HPV-positives. In a large study at Kaiser Permanente Northern California (KPCN), candidate strategies for triage of HPV-positive women are being evaluated, including cytology, p16/Ki-67 dual stain (DS, CNITec PLUS) and HPV16/18 genotyping (cobas). Methods: Over 13,000 HPV-positive women participating in cervical cancer screening at KPCN were enrolled. The dual stain and HPV genotyping assays were implemented and conducted at KPCN. Base-line results for 14,724 women are available and detection of CIN3 is currently evaluated only in cytology-positive women. Results: Among 7,124 HPV-positive women, 4,107 (57.7%) were cytology-negative (ASC-US+), 3,056 (42.9%) were DS-positive, and 1,406 (19.7%) were positive for HPV 16 or HPV 18. Among all 3,017 HPV-positive, cytology-negative women, 911 (30.2%) were DS-positive, and 500 (16.8%) were positive for HPV 16 or HPV 18. Of 315 CIN3 detected so far, 50% were in DS positive and 55% were in HPV 16 or 18 positive. Major triage strategies including cytology alone, DS alone, as well as combinations of cytology and genotyping, and DS and genotyping will be presented at the meeting. Discussion: In one of the largest clinical implementation studies of triage strategies, we showed that primary HPV screening followed by DS can reduce colposcopy referral compared to HPV-cytology co-testing while achieving high sensitivity. Additional follow-up is underway to evaluate the programmatic performance of several major candidate strategies.

#5297 Evaluation of lung cancer risk prediction models for selecting smokers for CT lung cancer screening. Hormuz Khati,1 Stephanie Kovalchik,2 Lucia Pettito,1 Li C, Cheung,3 Eric Jacobs,4 Ahmedin Jemal,4 Christine Berg,1 Anil Chaturvedi,1 National Cancer Institute, Rockville, MD; 2 Victoria University, Melbourne, Australia; 3 University of California at Berkeley, Berkeley, CA; 4 American Cancer Society, Atlanta, GA.

Background: The US Preventive Services Task Force (USPSTF) recommends computed-tomography (CT) lung cancer screening for ever-smokers ages 55-80 years who smoked at least 30 pack-years with no more than 15 years since quitting. 8.9 million U.S. ever-smokers are eligible for screening under USPSTF criteria. Instead, selecting ever-smokers for screening using individualized lung cancer risk calculations may be more effective and efficient than current recommendations. We examined the performance of 8 risk models for estimating risk in 2 U.S. cohorts and compared the U.S. populations selected for screening by the models. Methods: We examined 8 models: Lung Cancer Death Risk Assess-
ment Tool and Lung Cancer Risk Assessment Tool (Katki et al., JAMA 2016), PLCOM2012 (Tammemagi et al, N Engl J Med 2013), Bach (Bach et al., JNCI 2003), LLP (Cassidy et al, Br J Cancer, 2008), LLLI (Marcus et al, Cancer Prev Res 2015), Hoggart (Hoggart et al, Cancer Prev Res 2012), and Spitz (Spitz et al, JNCI 2007). We examined the predictive ability of each model among (1) 337,388 risk-smokers in the NIH-AARP Diet and Health Study (NIH-AARP), and (2) 72,338 ever-smokers in the American Cancer Society Cancer Prevention Study II (CPSII) Nutrition Survey Cohort. For each model we estimated the calibration (number of model-predicted cases divided by number of observed cases (Estimated/Observed)) and the discrimination (Area-Under-Curve (AUC)). Each of the 8 risk models and the USPSTF criteria were used to select a population of 8.9 million individuals at highest risk of lung cancer from among U.S. ever-smokers 50-80 (as characterized by data from the 2010-12 National Health Interview Surveys). Results: In both NIH-AARP and CPSII, 4 models were well-calibrated (Expected/Oberved from 0.92 to 1.12) and had higher AUCs (0.76 to 0.79). The other 4 models had worse calibration (Expected/Oberved from 1.72 to 0.69) and worse AUCs (0.62 to 0.75). When the models were used to choose the 8.9 million U.S. ever-smokers at highest lung-cancer risk, only ~1.8 million individuals were chosen by all 8 models. For a screening eligibility risk-threshold of 2.0% lung-cancer risk over 5 years, the 8 models chose populations including 7.6 million to 26 million U.S. ever-smokers. Conclusions: Some risk models were more externally-valid and had superior predictiveness than others. Differences in calibration led to risk models choosing very different screening population sizes under a fixed risk-threshold. The models did not achieve consensus on selected populations for screening.

Background: The contribution of pulmonary scars to lung cancer development and the degree to which lung cancers cause a scarring response are unclear. Also unknown is how lung scarring impacts lung cancer screening. Methods: We evaluated associations between scarring and lung cancer in the National Lung Screening Trial (NLST), a lung cancer screening trial among current or former, heavy smokers, 55-74 years-old. Baseline scarring (presence vs. absence) on low dose computed tomography (LDCT) scan was assessed at baseline (T0). Associations of T0 scarring with screen-detected lung cancers and with interval-detected lung cancers missed on screening within 3 years of T0 screen were analyzed using multinomial logistic regression. Cox proportional hazards models were used to analyze the relationship between T0 scarring and incident lung cancers diagnosed >3 years after T0. Regression models included age, sex, race, smoking history, chronic obstructive pulmonary disease, history of pneumonia, and family history of lung cancer. A thoracic pathologist (first author) evaluated lung cancer pathology slides from the Lung Screening Study (LSS) subset of NLST for scar grade (none, sparse, dense) and maturity (none, immature, intermediate, mature). Associations between T0 scarring on LDCT and histological scarring were examined by logistic regression. Results: NLST’s LDCT arm enrolled 26,722 participants (65% from the LSS). T0 scars were present in 30% of individuals at highest risk of lung cancer, 29% for screen-detected, 12% (19%) for interval-detected, and 26% for incident lung cancer cases. T0 scarring did not increase or decrease screen-detection of cancers [odds ratio (OR) 95% CI: 1.03 (0.84-1.26)]. However, scarring might increase the chance of an interval-detected cancer (OR 95% CI: 1.54 (0.76-3.12)]. After screening stopped, T0 scarring was associated with increased incident lung cancer risk [hazard ratio (HR) 95% CI: 1.27 (1.00-1.62); P=0.048]. Pathology slides were available for 25% (38%) lung cancers in LSS. Lung scarring was found in 172 (67%) of these cancers with 58 (22%) being characterized as mature scars. On microscopic review, scars were found in 80 (66%) ADC, 46 (82%) squamous cell carcinomas, and 20 (51%) bronchioloalveolar carcinomas. Microscopic scarring tended to be more frequent among cases with T0 scarring than those without T0 scarring (76% vs. 64%, P=0.02) [OR (95% CI): 1.89 (0.98-3.86)]. Conclusion: The association between T0 scarring and incident lung cancer over a period of more than 3 years is consistent with the development of each (BCSC censored; BBD-BC event). Results: In the Mayo Clinic’s BBD cohort, the Breast Cancer Surveillance Consortium (BCSC) model predicted invasive breast cancer risk in women with Benign Breast Disease (BBD), and recently incorporated BBD histology into the model. The BCSC has been validated in the Mayo Mammmography Health Study, but has yet to be examined in Mayo Clinic’s BBD cohort. The Benign Breast Disease to Breast Cancer (BBD-BC) model was developed in the AARP Diet and Health Study (AARP-DHS) and in Mayo Clinic’s BBD cohort. We here compare the performance of the BCSC and BBD-BC in Mayo Clinic’s BBD cohort. Methods: Eligible women underwent a breast biopsy with benign findings at the Mayo Clinic between years 1997-2001 and had a 4-view screening mammogram within six months of biopsy. Clinical BI-RADS density assessments using the 4th edition American College of Radiology were available on all of the lesions, which were independently blinded and categorized as having extremely dense, heterogeneously dense, and extremely dense. Risk at 5 and 10 years of invasive cancer only (BCSC model) or both invasive and in situ cancer (BBD-BC model) were estimated. In situ cancers were censored at time of diagnosis for both models. Concordance statistics, i.e. model discrimination (higher is better), for each model were calculated using a Cox proportional hazards model with predicted risk as the sole predictor, and were compared using permutation tests. The ratio of total predicted (sum of predicted risk) to observed number of invasive breast cancers was used to assess model calibration. Calibration was not formally compared across models due to differences in how DCIS was treated in the development of each (BCSC censored; BBD-BC event). Results: 999 women met inclusion criteria. BI-RADS density was categorized as fatty in 46 (4.6%), a few scattered foci in 299 (29.7%), heterogeneously dense in 423 (42.9%), and extremely dense in 158 (15.8%), 62 invasive cancers occurred over a median 13.3yrs of follow-up, with 16 (25.8%) and 48 (77.4%) of the cancers occurring with-in 5 and 10 years. The concordance of the BCSC at 5 years was 0.55 (95% CI 0.409 — 0.691), compared to 0.719 (95% CI 0.578 — 0.860) for the BBD-BC (p-value=0.005). At 10 years the BCSC concordance was not significantly different from the BBD-BC, at 0.624 (95% CI 0.542 — 0.706) and 0.662 (95% CI 0.580 — 0.744), respectively (p-value=0.306). The BCSC over predicted the number invasive cancers in the BBD cohort at 5 years (predicted-to-observed=1.54; 95% CI 1.01 — 2.70), but was well calibrated at 10 years (1.06; 95% CI 0.83, 1.47). Conclusions: The BCSC model performed reasonably well in the BBD cohort 10 years post-biopsy, but overestimated risk at 5 years. Studies is needed to improve models for prediction of breast cancer risk among women with BBD.

#5300 Risk models for cancer screening cohorts assembled from electronic health records: Application to calculating risks that underlie current cervical cancer screening guidelines. Li C. Cheung, Ping Q., Noorie H. Hyun,1 Mark Schiffman,2 Barbara Fetterman,3 Philip E. Castle,4 Thomas Lorey,3 Hor-
CIN3+ are close to the risk estimates from the non-parametric method. Discussion: The Kaplan-Meier method provided poor risk estimates while logistic-Weibull model-based risks were close to the risk estimates from the non-parametric method. Our findings support use of the logistic-Weibull models over Kaplan-Meier methods for developing the risk estimates that underlie current U.S. cervical cancer screening guidelines.

#5301 Cancer causation: rethinking the role of analogy, Douglas L. Weed, DLW Consulting Services, Salt Lake City, UT.

Introduction. Fifty years has passed since the publication of Austin Bradford Hill’s classic paper on causal inference. Much has changed in the biomedical and public health sciences regarding cancer causation during that half century, but Hill’s considerations (often called “criteria”) remain durable. That said, there is a curious phenomenon involving Hill’s seminal work that has escaped the attention of the scientific community. His consideration of analogy—the last on his list just after experimentation—has all but disappeared. The purpose of this paper is to rethink and resurrect analogy as an important consideration in causal inference in environmental epidemiology. Methods. Given that this is a conceptual—non-quantitative—project, the methods used are the informal logic of scientific thinking, methods of systematic reviews, and judgment. Results. In contemporary environmental epidemiology, analogy is either completely ignored (e.g., in many textbooks), equated with biologic plausibility or coherence, or aligned with the scientist’s imagination. None of these examples, however, capture Hill’s description of analogy which emphasizes the contrast of two bodies of evidence. Coupled with developments in the methods of systematic assessments of evidence—including but not limited to meta-analysis—analyzed by local to Japan, and also comparing in-house data of CA19-9 and carcinoembryonic antigen (CEA) markers. Experiment: Conducted at Nippon Medical School Chiba Hokusoh Hospital, urine samples were collected and frozen at -80°C from 139 patients at various stages of CRC and 78 healthy control samples. The samples were thawed in batches and placed in ice hours prior to testing; 2 ml of each urine sample was aliquoted into 10 ml vials for processing with the commercial FAIMS device (Lonestar, Owlstone, UK). Each vial was heated in the device to 40°C to create headspace with sufficient VOCs then a carrier gas (clean dry air) delivered the headspace (0.5 L/min) diluted with a make-up flow (2 L/min). The FAIMS device was set to scan at 0 to 100% electric dispersion field in 51 steps and compensation voltage between -6 V and +6 V in 512 steps, producing data matrices for each sample’s analysis. Principal Component Analysis (PCA) followed by Partial Least Squares Discriminant Analysis (PLS-DA) of each sample was conducted using SIMCA 13 (Umetrics, Sweden). See Table Conclusions: FAIMS technology achieved a high rate of separation between the CRC and healthy control urine samples with 64.7% sensitivity and 82.1% specificity overall. As the CRC stage advances the sensitivity increased from 27.3% to 100%. Results: show excellent potential to use FAIMS technology as an early screening tool for CRC, particularly impressive compared to in-house sensitivity data of CA19-9 and CEA markers. Further research into FAIMS screening of other cancer types through VOC biomarker analysis of urine, breath, and feces is recommended.

#5302 Projections of cancer incidence and burden among the HIV-positive population in the United States through 2030, Jessica Y. Islam, 1 Philip S. Rosenberg, 2 HI Irene Hall, 2 Evnin UC, 3 Eric A. Engels, 2 Meredith S. and HIV population count were multiplied. Results: The proportion of the total group and calendar year (2006-30) was estimated using a dynamic compartmental model. Injection drugs) during 2013-30. The number of PLWH in the U.S. by age, risk and, for some cancers, risk group (e.g., men who have sex with men, people who inject drugs) during 2013-30. The number of PLWH in the U.S. by age, risk group and calendar year (2006-30) was estimated using a dynamic compartmental model. To estimate cancer burden, observed and projected incidence rates and HIV population counts were multiplied. Results: The proportion of the total U.S. HIV population that is aged ≥65 years is projected to increase from 4.1% (of 1.06 million) in 2006 to 21.4% (of 1.09 million) in 2030. Based on significant declines during 2000-12, age-specific rates are projected to decrease across age groups for NHL, cervical cancer, lung cancer and all other cancers, and for some age groups for KS, Hodgkin lymphoma and colon cancer. Other age-specific rates did not change significantly, with the exception of prostate cancer rates, which are projected to continue to increase. We estimated that the total cancer burden in PLWH will decrease from 7908 cases in 2010 (2719 ADC and 5190 NADC) to 6495 cases in 2030 (701 ADC and 5794 NADC), indicating a strong decrease in ADCs and a slight increase in NADCs. In 2030, the most common cancers among PLWH will include: prostate (n=1624), lung (n=786), liver (n=498) and anal cancers (n=447) and NHL (n=429). Conclusions: Though cancer rates are generally decreasing, cancer will remain an important co-morbidity as the U.S. HIV population ages. If recent trends in cancer incidence continue into the future, the burden of NADCs, particularly prostate, lung, liver and anal cancers, will far exceed the burden of ADCs in 2030. Targeted cancer prevention, early detection and control efforts are needed for PLWH in the U.S., including smoking cessation, treatment of hepatitis C and B viruses, cancer screening and continued widespread treatment with HAART.

#5303 FAIMS technology in urinary volatile organic compound analysis to detect colorectal cancer, Christopher Psutka, 1 Marina Yamada, 2 Akihisa Matsuda, 2 Kazuya Yamahata, 2 Satoshi Matsumoto, 2 Toshihiko Kitayama, 3 Nobuo Nakano, 4 Yurii Koyano, 2 Tohru Mikoshiba, 2 Masao Miyashita 2.

Introduction: This is an investigation of the capability of FAIMS (Field Asymmetric Ion Mobility Spectrometry) technology as a tool for non-invasive detection of Colorectal Cancer (CRC) through urinary volatile organic compound analysis. It expands on ‘Detection of Colorectal Cancer (CRC) by Urinary Volatile Organic Compound Analysis’ (Ramesh P. Arasaradnam et al, 2014) with an increased sample population and location local to Japan, and also comparing in-house data of CA19-9 and carcinoembryonic antigen (CEA) markers. Experiment: Conducted at Nippon Medical School Chiba Hokusoh Hospital, urine samples were collected and frozen at -80°C from 139 patients at various stages of CRC and 78 healthy control samples. The samples were thawed in batches and placed in ice hours prior to testing; 2 ml of each urine sample was aliquoted into 10 ml vials for processing with the commercial FAIMS device (Lonestar, Owlstone, UK). Each vial was heated in the device to 40°C to create headspace with sufficient VOCs then a carrier gas (clean dry air) delivered the headspace (0.5 L/min) diluted with a make-up flow (2 L/min). The FAIMS device was set to scan at 0 to 100% electric dispersion field in 51 steps and compensation voltage between -6 V and +6 V in 512 steps, producing data matrices for each sample’s analysis. Principal Component Analysis (PCA) followed by Partial Least Squares Discriminant Analysis (PLS-DA) of each sample was conducted using SIMCA 13 (Umetrics, Sweden). See Table Conclusions: FAIMS technology achieved a high rate of separation between the CRC and healthy control urine samples with 64.7% sensitivity and 82.1% specificity overall. As the CRC stage advances the sensitivity increased from 27.3% to 100%. Results: show excellent potential to use FAIMS technology as an early screening tool for CRC, particularly impressive compared to in-house sensitivity data of CA19-9 and CEA markers. Further research into FAIMS screening of other cancer types through VOC biomarker analysis of urine, breath, and feces is recommended.

#5304 A serological biopsy using five stomach-specific circulating biomarkers for gastric cancer risk assessment: a multi-phase study. Huakang Yi, Liping San, 1 Xiao Dong, 2 Yuhua Gong, 2 Qian Xu, 2 Jingjing Jiao, 3 Roberd M. Bostick, 4 Xifeng Wu, 1 Yuan Yuan 2.

Objective: We aimed to assess a serological biopsy using five stomach-specific circulating biomarkers—pepsinogen I (PGI), PGI, PGI/II ratio, anti-Helicobacter pylori (H. pylori) antibody, and gastrin-17 (G-17)—for identifying high-risk individuals and predicting risk of developing gastric cancer (GC). Methods: Among 12112 participants with prospective follow-up from an ongoing population-based screening program using both serology and gastroscopy in China, we conducted a multi-phase study involving a cross-sectional analysis, a fol-
low-up analysis, and an integrative risk prediction modeling analysis. Results: In the cross-sectional analysis, the five biomarkers (especially PGGI, the PGI/II ratio, and H. pylori sero-positivity) were associated with the presence of precancerous gastric lesions or GC at enrollment. In the follow-up analysis, low PGI levels and PGI/II ratios were associated with higher risk of developing GC, and both low (<0.5 perf/L) and high (4.7–10 perf/L) G17 levels were associated with higher risk of developing GC, suggesting a J-shaped association. In the risk prediction modeling analysis, the five biomarkers combined yielded a C statistic of 0.801 (95% CI = 0.787–0.815) and improved prediction beyond traditional risk factors (C statistic from 0.580 to 0.811. P < 0.001) for identifying precancerous lesions at enrollment, and higher serological biopsy score based on the five biomarkers at enrollment were associated with higher risk of developing GC during follow-up (P for trend < 0.001). Conclusions: A serological biopsy composed of the five stomach-specific circulating biomarkers could be used to identify high-risk individuals for further diagnostic gastroscopy, and to stratify individuals’ risk of developing GC and thus to guide targeted screening/prevention.

#5305 Risk of thyroid nodules in residents of Belarus exposed to Chernobyl fallout as children and adolescents. Elizabeth K. Cahoon,1 Eldar Nadirov,2 Olga Polanskaaya,2 Vasilia Yausechenya,2 Vasilia Yausechenya,2 Ilya Velalkin,2 Tamara Yeudachkova,2 Tamara Maskvicheva,2 Victor Menenko,3 Yury Ryzhkov,2 Tamara Maskvicheva,2 Victor Menenko,3 Alexey Danilov,2 Shumilina I. N.,2 Alexander Rozhko,2 Alina Brenner,1 National Cancer Institute, Bethesda, MD;1 The Republication Research Centre for Radiation Medicine and Human Ecology, Belarus;2Belarusian Medical Academy of Post-Graduate Education, Belarus.

Context: The relationship between childhood radiation exposure and thyroid nodules has not been comprehensively evaluated in young adults or for nodules with varying histological or ultrasound features. Objective: To examine the association between internal I-131 thyroid radiation dose and thyroid nodules in young adults exposed during childhood. Design, setting, and participants: In this cross-sectional study, we screened 11,970 residents of Belarus aged ≥18 years at the time of the Chernobyl nuclear accident (April 1986) for thyroid disease (median age 21 years). Screening consisted of thyroid palpation, ultrasonography, blood and urine analysis, and medical follow-up when appropriate. Eligible participants (N = 11,421) had intact thyroid glands and doses estimated using direct individual thyroid activity measurements. Main outcome measures: Excess odds ratios per gray (EOR/Gy) for any thyroid nodule and for nodules grouped by histological and ultrasound characteristics selected a priori. Results: Risk of any thyroid nodule was associated with increasing I-131 in the entire dose range (0.001–39 Gy) and radiation-related risk increased with younger age at exposure. For participants exposed to < 5 Gy, we found EORs/Gy (95% CI) of 0.70 (0.33, 1.18) for any nodule, 0.32 (< 0.03, 0.70) for non-neoplastic nodules, 3.82 (0.87, 15.52) for neoplastic nodules, 0.27 (< 0.13, 0.70) for nodules < 10 mm, 2.12 (0.96, 4.60) for nodules ≥10 mm, 0.67 (0.30, 1.19) for single nodules, and 0.59 (< 0.29, 2.05) for multiple nodules (centered at age 5 years at exposure). Conclusions: Childhood exposure to internal I-131 is associated with thyroid nodules of various histological/ultrasound characteristics, but magnitude of the risk varies substantially.

#5306 p16INK4a status helps predict clinical outcome of dysplasia in the oral cavity irrespective of HPV status. Tarinée Lubrapue,1 Elena Prigge,2 Magen von Knebel Doeberitz,2 Miriam Reuschenbach,2 Leivi Zhang,3 Miriam P. Rosin1.1 BC Cancer Research Centre, Vancouver, British Columbia, Canada;2University Hospital Heidelberg, Germany;3University of British Columbia, British Columbia, Canada.

Objectives: p16INK4a is a key gatekeeper for multiple biological processes that are associated with protection against cancer, including cell cycle control and senescence. Elevated expression of this gene is strongly correlated with biological activity of HPV infection and cancer development in uterine cervix and tonsil. Although HPV DNA has been found in a small portion of oral cavity cancers and dysplasia, the relevance of its presence to cancer development at this site is unclear, as is the significance of an expression change in p16INK4a as a predictor of HPV status, tissue behavior and outcome. Methods: Formalin-fixed, paraffin-embedded biopsies from 164 patients with mild, moderate and severe oral dysplasia in the “Oral Cancer Prediction Longitudinal study” (OCPL), British Columbia, Canada, were analyzed for HPV DNA using a semi-quantitative viral load LumineX technology. Expression of p16INK4a was assessed and categorized into 3 staining patterns (diffuse, focal, and negative). Results: HPV DNA was found in 13 (8%) lesions, 7 had HPV-16 infection and 1 HPV-18. Of the 164 samples, diffuse p16INK4a expression was present in 18%, focal in 56% and no p16 staining in 23% of samples. There was no significant correlation between HPV DNA-positivity and p16INK4a staining. Different p16 staining patterns showed significantly different progression rates (P < 0.001): progression occurred in 1/92 (1.1%) focally stained, 1/29 (3.5%) diffusely stained and 10/43 (23.3%) with no staining. Conclusion: HPV DNA-positivity occurs in a small proportion of oral cancer associated with its expression in dysplasia and cancer. Future assessment of these samples for HR-HPV oncogene transcripts will provide information on its biological activity. The low likelihood of progression of p16INK4a focally stained lesions suggests a value of this marker in identification of low-risk cases. #5307 Analysis of volatile organic compounds for the diagnosis of lung cancer. Takuya Inoue,1 Hitomori Takagi,2 Yuki Owada,1 Yuzuru Watanebe,3 Mitsuhiro Fukuhara,1 Takumi Yamaura,1 Satoshi Muto,1 Naoyuki Okabe,2 Yuki Matsumura,3 Takeo Hasegawa,2 Takeda Manami,2 Atsushi Sato,3 Hiroyuki Suzuki1.1Fukushima Medical University, Fukushima, Japan;2GL Sciences Inc., Saitama, Japan.

Background: Lung cancer is the leading cause of cancer-related deaths in the world. The prognosis of lung cancer depends on disease detection at an early stage. Recently, effectiveness of lung cancer screening by using low dose computed tomography scanning have been showing. However, it still has problems such as cost of screening and radiation exposure. Thus, less invasive and cost beneficial lung cancer screening procedure would be needed. In this context, several study to understand the efficacy of molecules from expiration of patients as a lung cancer screening was showing, but it was still controversial. In this study, we investigated to determine whether volatile organic compounds (VOC) from patients could be used for the detection for lung cancer by using novel small and unique absorbent material named MonoTrap . Method: The subjects’ gas was collected from skin and exhaled breath in a MonoTrap (GL sciences), and the VOCs were analyzed by gas chromatography/ mass spectrometry (GC/ MS). First of all, we preliminarily analyzed for both sample from skin and exhaled breath for 12 patients and 11 healthy volunteers to clarify which samples were more sensitive to diagnose lung cancer. Subsequently, each VOC was determined in detail for 7 healthy individuals and 4 lung cancer patients and these values were statistically analyzed. Results: By preliminary study, characteristics of VOC derived from skin were significantly correlated with cancer condition as compared with healthy volunteer by using comprehensive multivariate analysis. Therefore, we performed further quantitative analysis by targeting unique individual molecules derived from skin. In VOCS from skin, Mann-Whitney U test showed that 4-hydroxy-4-methyl-2-pentanone, hexadecane, and acetamide were significantly higher in lung cancer patients (p = 0.036, p = 0.006, p = 0.036, respectively). Conclusion: In this study, we found that 3 kinds of VOCs could be a potential diagnostic biomarkers of lung cancer. Further prospective study is now planning to validate these data using large number samples.
Dietary magnesium is inversely associated with colorectal cancer risk in the Atherosclerosis Risk in Communities study. Guillaume C. Onyeghala, Elizabeth Porter, Pamela L. Lutsey, Aaron R. Folsom, Corrine E.Joshua, Elizabeth A. Platz, Anna E. Prizment1, University of Minnesota, Minneapolis, MN; 2John Hopkins Bloomberg School of Public Health, Baltimore, MD.

Background: Magnesium is a key nutritional mineral required for the regulation of numerous biochemical reactions throughout the body. Main food sources of magnesium include whole grains, nuts, and green vegetables, but more than 50% of Americans do not currently meet their daily recommended magnesium intakes. Prior research has shown that those deficient in magnesium have increased susceptibility to oxidative stress and chronic inflammation, leading to endothelial dysfunction and potentially stimulating cancer cell proliferation and invasiveness. Previous epidemiological studies suggested a link between a diet high in magnesium and reduced CRC, especially among women. The American Cancer Society underscores the importance of clarifying the role of dietary magnesium in CRC development overall and by gender. Thus, we prospectively examined the associations between dietary magnesium intake and CRC risk in the ARIC study, overall, and separately in men and women. Methods: The ARIC study followed 15,792 men and women (45-64 years old at baseline) for cancer occurrence from 1987-2006. Participants received medical examinations and completed questionnaires at 4 visits; food frequency data were collected at Visit I (1987-89) and magnesium intake estimated. Cox proportional hazards regression was used to calculate hazard ratios (HR) and 95% CI for CRC associated with dietary magnesium intake in quartiles using two models: Model 1 adjusted for baseline age, race, center, sex, energy intake, BMI, and physical activity. Model 2 included Model 1 covariates as well as intake of alcohol, dietary calcium, dietary fiber, aspirin, CRP levels, and cigarette smoking. Results: The analytic cohort (n=14,160, 54.3% women; 27.3% black and 72.7% white, 45-64 years at baseline) was followed for a median of 15.4 years; 315 CRC cases were identified. Since only the highest quartile of dietary magnesium intake met US recommendations (>300 mg/day), we examined the highest quartile versus the 3 lowest quartiles combined (reference category). In Model 1, the highest quartile of dietary magnesium was associated with lower CRC risk: HR (95% CI) = 0.74 (0.56-0.98) (p=0.03 for trend). The inverse association between magnesium and CRC persisted in Model 2 (HR=0.70; 95% CI 0.48, 1.02). The association followed a similar trend after stratification by colon and rectal cancer cases (HR [95% CI] = 0.72 (0.48-1.08) and HR [95% CI] = 0.49 (0.23-1.06), respectively) and by men and women (HR [95% CI] = 0.75 (0.42-1.21) and HR [95% CI] = 0.63 (0.36-1.12), respectively). There was no interaction of dietary magnesium intake with dietary calcium intake, alcohol consumption use or dietary fiber. Conclusion: Our findings corroborate an inverse association between higher dietary magnesium intake and CRC risk, with similar associations observed in men and women. Support: NHLBI, NCI, NPCR.

A prospective study of dietary polyunsaturated fatty acids intake and lung cancer risk. Hung N. Luu,1 Harvey J.Murphy,2 Honglan Li,1 Quyin Cai,1 Yu-Tang Gao,3 Jing Gao,3 Hui Cai,3 Gong Yang,3 Qing Lan,4 Yong-Bing Xiang,3 Wei Zheng,5 Xia-0u Shu;1 1University of South Florida, Tampa, FL; 2Vanderbilt University, Nashville, TN; 3Shanghai Cancer Institute, Shanghai, China; 4National Cancer Institute, Bethesda, MD.

Background: Animal studies have shown that polyunsaturated fatty acids (PUFAs) have antiangiogenic and anti-inflammatory properties. Results from epidemiologic studies, however, have been inconclusive. We prospectively evaluated the association of dietary PUFA intakes and lung cancer risk in two population-based cohort studies, the Shanghai Men’s Health Study (SMHS) and Shanghai Women’s Health Study (SWHS). Methods: A total of 130,823 study participants (i.e., 60,427 men and 70,396 women) were included in the current analysis. Dietary fatty acid intakes were derived from data collected at the baseline by validated food frequency questionnaires. Cox proportional hazards model was applied to assess the association between PUFA intakes and lung cancer risk with adjustment for age, smoking status, smoking packs-year (men only), drinking status, BMI, physical activity status, total energy, red meat intake, vegetable intake, vitamin supplemental use, menopausal status and hormone replacement therapy (women only). Results: We found an inverse association between total PUFA intakes and lung cancer risk (hazard ratios [HRs]) and respective 95% confidence intervals (CIs) for quintiles 2, 3, 4, and 5 versus quintile 1 were 0.73 (0.56-0.95), 0.78 (0.59-1.03), 0.64 (0.47-0.87) and 0.53 (0.37-0.82) in SMHS and 0.69 (0.53-0.90), 0.76 (0.58-0.99), 0.60 (0.44-0.81), and 0.53 (0.36-0.78) in SWHS. A positive association was observed for ALA intake. A correlation matrix showed that linoleic acid, total n-6 PUFAs and the ratio n-6 PUFA/n-3 PUFAs in adenoscinoma patients. This inverse association was more likely in male ever-smokers for total PUFAs, linoleic acid and total n-6 PUFAs. On the other hand, EPA intake was positively associated with lung cancer risk in female never-smokers (HRs and 95% CIs: 1.10 (0.85-1.42), 1.36 (1.05-1.77), 1.28 (0.97-1.88) and 1.30 (0.97-1.74), for quintiles 2-5 versus quintile 1). A similar positive association between DHA intake and lung cancer risk in female never-smokers was also observed. Conclusions: Total polyunsaturated fatty acid, linoleic and total n-6 PUFA intakes were associated with decreased risk of lung cancer. EPA and DHA intakes were associated with an increased risk of lung cancer among female never-smokers. Financial Support: This work was supported by grants from the US National Institutes of Health/National Cancer Institute (R01CA70867 and UM1 CA182910-to Wei Zheng; R01CA082729, UM1 CA173640 and R25 CA160056 - to Xiao-Ou Shu).

Weight loss over 10 years of adulthood and subsequent risk of breast cancer: a pooled analysis of 11 cohort studies. Lauren R. Teras,1 Alpa V. Patel,1 Molin Wang,2 Bette J. Caan,2 Yu Chen,3 Avonne E. Connor,3 A. Heather Ellsasser,4 Susan M. Gaspurt,4 Mia M. Gaudet,4 Jeanine M. Genkinger,4 Graham G. Giles,6 F-Min Lee,7 RogerMilne,8 Norie Sawada,8 Howard D. Sesso,9 Meir Stampfer,9 RullaTamimi,9 Cynthia A. Thomson,9 Shoichiro Tsugane,9 Kala Vyananthan,9 Anne Zeleniuch-Jacquotte,9 Walter C. Willett,9 Stephanie A. Smith-Warner11, American Cancer Society, Atlanta, GA; 2Harvard Medical School, Boston, MA; 3Kaiser Permanente Medical Care Program of Northern California, Oakland, CA; 4NYU School of Medicine, New York, NY; 5John Hopkins Bloomberg School of Public Health, Baltimore, MD; 6Brigham and Women’s Hospital and Harvard Medical School, Boston, MA; 7Columbia University, New York, NY; 8University of Melbourne, Melbourne, Australia; 9National Cancer Centre, Tokyo, Japan; 10University of Arizona Mel & Enid Zuckerman College of Public Health, Tucson, AZ; 11Harvard T.H. Chan School of Public Health, Boston, MA.

Body fatness is an established risk factor for postmenopausal breast cancer, but it is unknown if this risk associated with excess body weight is reversible. We conducted a pooled analysis of 11 prospective studies in the Pooling Project of Prospective Studies of Diet and Cancer. Each study had adult body weight data at three time points, as well as follow-up for subsequent risk of breast cancer after the third weight measure. Weight change was assessed using reported or measured weight at baseline and two follow-up time points, each generally four to six years apart (over a total of ~10 years). Stable weight for each interval was defined as weight within 2 kg of the previous weight. The referent group was women with stable weight (within 2kg) at all three time points across the 10-year period. Among 340,055 women, 10,427 breast cancers were diagnosed during follow-up. Multivariable hazard ratios (HR) and 95% confidence intervals (CIs) controlling for baseline body mass index (BMI), baseline physical activity, and postmenopausal hormone (PMH) use at the start of breast cancer follow-up, were estimated using proportional hazards regression on an aggregated dataset from all studies. Women who lost weight and kept the weight off, were at a lower risk of breast cancer than women with stable weight over the 10 years: >2.4.5 kg lost between baseline and the first follow-up body weight measure (n=482 cases): HR = 0.92, 95% CI: 0.83-1.03; >4.5-9.5 kg lost (n=283 cases): HR=0.86, 95% CI: 0.75-0.98; (p=0.5 for trend). Women who initially lost weight (>2kg), but then re-gained it had a similar risk of breast cancer to those with stable weight over the same time period. When results were stratified by baseline age and BMI, there was no association between sustained weight loss and breast cancer among women younger than 50 years, or those with a normal BMI (18.5-25 kg/m2) before weight loss. Among obese women (>=28 kg/m2) who were stable weight or obese before the weight loss period, we observed a 21% lower risk of breast cancer for sustained weight loss of 4.5kg compared to women with stable weight over the same time period (n=245 cases, HR=0.79, 95% CI: 0.68-0.93). This observed association was driven by women who were not taking...
PMH (n = 156, HR = 0.71; 95% CI: 0.58-0.86). In this large, pooled prospective analysis of weight loss and breast cancer risk we found that losing 4.5 kg—and keeping it off—may lower breast cancer risk, particularly for women older than 50 who are overweight or obese. The results may provide motivation for women with elevated BMI to lose weight and potentially reduce their risk of breast cancer.

**5312 No association between vitamin K intake and prostate cancer risk in the Prostate, Lung, Colorectal, and Ovarian Cancer Screening Trial (PLCO).** Maggie Hoyt, Michael Reger, Jianjun Zhang. *Indiana University, Indianapolis, IN.*

Prostate cancer is one of the most common cancers worldwide. The etiology of prostate cancer largely remains unclear, with almost all established risk factors (e.g., age, race, family history) being non-modifiable. Ecological, migratory, and temporal trends studies suggest that diet plays a role in the occurrence of prostate cancer, but few nutrients that alter their risk have been identified from case-control and cohort studies. Vitamin K has two forms that naturally occur in foods, i.e., phylloquinone (vitamin K1) and menaquinone (vitamin K2). While phylloquinone is abundant in green leafy vegetables and some vegetable oils, menaquinone is primarily derived from fermented food products (e.g., cheese). Although experimental studies have shown that vitamin K inhibits the growth of various cancer cell lines (including prostate cancer cells), only one epidemiologic study has investigated the association between vitamin K intake and prostate cancer risk. In that German study, a significant inverse association with advanced prostate cancer was observed for menaquinone intake. The present study thus sought to investigate the associations between intake of vitamin K (from both dietary and supplemental sources) and the risk of total and advanced prostate cancer among 28,356 PLCO participants. A total of 2978 cases of prostate cancer (including 490 advanced cases) have been documented during a median follow up of 11.8 years. Advanced prostate cancer were defined as disease in stage II with a Gleason score of 8-10, stage III, or stage IV. Usual dietary intake among study subjects was assessed with Dietary Questionnaire (DQX) at baseline and Dietary History questionnaire (DHQ) at year 3, both of which were developed and validated by the National Cancer Institute. Dietary intake of phylloquinone and menaquinone were calculated using the USDA National Nutrient Database for Standard Reference (Release 23), supplemented with menaquinone data from published studies. Cox proportional hazards regression was performed to estimate hazard ratios (HRs) and 95% confidence intervals (CIs) for dietary intake of phylloquinone and menaquinones in relation to prostate cancer risk. After adjustment for confounders, no statistically significant associations were found between vitamin K intake estimated from the DQX and prostate cancer risk (HR (95% CI) for the highest quintile vs. the lowest quintile: 0.99 (0.87, 1.13) for total vitamin K, 0.99 (0.87, 1.12) for phylloquinone, and 1.02 (0.87, 1.18) for total menaquinones). Overall null results were also observed when additional analysis was carried out by the stage of the disease (i.e., advanced and non-advanced cases) and for vitamin K intake data assessed with the DHQ. In summary, the present study revealed that intake of total vitamin K and its two natural forms was not associated with the risk of total and advanced prostate cancer.

**5313 Associations of calcium and dairy product intakes with colorectal cancer risk among older women: the Iowa Women’s Health Study.** Caroline Um,1 Anna Prizment,2 DeAnn Lazovich,2 Robert M. Bostick1. *Emory Univ., Atlanta, GA; 1University of Minnesota, Minneapolis, MN.*

Calcium has been consistently modestly associated with lower risk of colorectal cancer, which remains the second leading cause of cancer deaths among men and women combined in the United States. Dairy products, a major source of dietary calcium, have also been consistently inversely associated with colorectal cancer, although inconsistencies in relation to high-fat dairy products have been noted. Limited evidence suggests that dairy products may contain components other than calcium and fat, such as insulin-like growth factor 1 (IGF-1), that may be independently directly associated with risk of colorectal and other cancers. Data from the Iowa Women’s Health Study, a prospective cohort study, were used to investigate associations of calcium, dairy products, and the non-calcium component of dairy products with colorectal cancer incidence. Dietary data were collected using a semiquantitative food frequency questionnaire (FFQ) mailed to 55–69-year-old women in 1986 who had a valid Iowa driver’s license. Among participants with no history of cancer at baseline and who satisfactorily completed their FFQ (n = 35,221), through follow up in 2012, 1,731 incident cases of colorectal cancer were documented via the Iowa SEER registry. To investigate total dairy and total, whole, and non-fat milks independent of their calcium components, we used the residuals from linear regression models of their associations with dietary calcium. Associations of the calcium and dairy product variables with colorectal cancer incidence were estimated using multivariable Cox proportional hazards regression. For those in the highest relative to those in the lowest quintiles of intake, the adjusted hazards ratios and 95% confidence intervals (CI) were 0.81 (CI 0.67-0.98; P-trend 0.004) for total calcium, 0.85 (CI 0.68-1.03; P-trend 0.07) for dietary calcium, and 0.85 (CI 0.68–1.07; P-trend 0.16) for supplemental calcium. For total dairy and total milk, the corresponding findings were 0.79 (CI 0.66–0.94; P-trend 0.01) and 0.82 (CI 0.69-0.96; P-trend 0.09), respectively. Low-fat dairy products, non-fat milk, and residuals of total dairy products and total and non-fat milk were not associated with colorectal cancer. These results are consistent with previous findings of low colorectal cancer risk with higher intakes of calcium and dairy products, but provide little support for the hypothesis that the non-calcium, non-fat component of dairy products may be associated with colorectal cancer.

**5314 Long-term folate intake and prostate cancer risk in the health professionals follow-up study.** Nadine M. Hamieh,1 Julie L. Batista,2 Sarah C. Markt,3 Mary K. Downer,4 Lorelei A. Mucci,1 Meir J. Stamper,5 Edward L. Giovannucci,1 Kathryn M. Wilson,1 1Harvard T.H. Chan School of Public Health, Boston, MA; 2Genzyme, Boston, MA.

Background: Randomized trials of supplemental folate and observational studies of circulating folate support a positive association with prostate cancer risk. However, epidemiological studies of dietary and synthetic folate intake are conflicting. Given mandatory folic acid fortification of grains in the US beginning in 1998, evaluation of long-term folate intake from natural and synthetic sources is warranted. We examined the association between folate intake and prostate cancer risk among 47,884 men in the Health Professionals Follow-up Study who were free from diagnosed cancer at baseline in 1986. Total, natural (from food sources), and synthetic (from supplements/fortification) folate intake was assessed every 4 years using a validated food frequency questionnaire, and categorized as the cumulative average and lagged (0–4, 4–8, 8–12, and 12–16 years in the past) intakes. Cox proportional hazards regression was used to calculate multivariable hazard ratios (HRs) and 95% confidence intervals (CI). Results: We identified 6,186 incident prostate cancer cases from 1986-2012, including 1,078 with lethal disease (distant metastasis or death). Mean total folate intake was 481 μg/day in 1986 and increased to 671 μg/day by 2010. The proportion of men meeting the recommended intake of 400 μg/day increased from 47% in 1986 to 74% after fortification began in 1998. Folate intake was positively correlated with physical activity, multivitamin use, and PSA testing, and inversely correlated with smoking. Total folate intake averaged over time was not significantly associated with total prostate cancer risk: HR (95% CI) for <400 μg/day vs. ≥400 μg/day = 1.03 (95% CI: 0.95-1.13, p-trend = 0.76). However, neither natural nor synthetic folate intake was associated with risk of total prostate cancer. Noted were associations of total folate intake and risk of advanced prostate cancer at baseline in 1986. Total, natural, or synthetic folate and prostate cancer risk. We found no indication that folate intake of ≥800 μg/day (twice the recommended level) increases prostate cancer risk.

**5315 Dietary intake and risk of lung cancer in non-smoking women: a hospital-based case-control study in Xuanwei and Fuyuan, China.** Jason Y. Wong,1 Bryan A. Bassig,2 Wei Hu,1 Jinming Zhang,1 Wei Jie Seow,1 Jun He,1 Kaiyun Yang,1 Yunchao Huang,1 Roel Vermeulen,3 Nathaniel Rothman,1 Qing Lan1. *1National Cancer Institute, Rockville, MD; 2Chulalongkorn University, Bangkok, Thailand; 3Utrecht University, Netherlands; 4Queuing Center for Diseases Control and Prevention, China; 5Yunnan Tumor Hospital, China.*

Xuanwei and Fuyuan are rural counties in China that have the highest lung cancer rates in the country among non-smoking women. This alarming public health burden has been attributed to the combustion of smoky (bituminous) coal for heating and cooking, which can produce carcinogenic emissions such as polycyclic aromatic hydrocarbons (PAHs). Previous studies found that green leafy vegetables could absorb PAHs through air and direct soil contamination. Further, oral ingestion of PAHs was found to be associated with pulmonary adenoma development in animal feeding studies. Therefore, we investigated the associations between lung cancer risk and dietary intake of specific green leafy vegetables and other foods in non-smoking women of this farming region. We conducted a hospital-based case-control study of 1,074 female lung cancer patients and 977 frequency-matched controls from Xuanwei and Fuyuan, China in 2006-2013. Dietary intake was self-reported on questionnaires and categorized as the cumulative average and lagged (0-4, 4-8, 8-12, and 12-16 years in the past) intakes. Cox proportional hazards regression was used to calculate multivariable hazard ratios (HRs) and 95% confidence intervals (CI). Results: We identified 6,186 incident prostate cancer cases from 1986-2012, including 1,078 with lethal disease (distant metastasis or death). Mean total folate intake was 481 μg/day in 1986 and increased to 671 μg/day by 2010. The proportion of men meeting the recommended intake of 400 μg/day increased from 47% in 1986 to 74% after fortification began in 1998. Folate intake was positively correlated with physical activity, multivitamin use, and PSA testing, and inversely correlated with smoking. Total folate intake averaged over time was not significantly associated with total prostate cancer risk: HR (95% CI) for <400 μg/day vs. ≥400 μg/day = 1.03 (95% CI: 0.95-1.13, p-trend = 0.76). Neither natural nor synthetic folate intake was associated with risk of total prostate cancer. Noted were associations of total folate intake and risk of advanced stage, advanced stage, or high-grade disease. Conclusions: Our findings do not support strong associations between intake of total, natural, or synthetic folate and prostate cancer risk. We found no indication that folate intake of ≥800 μg/day (twice the recommended level) increases prostate cancer risk.
Background: There is growing evidence of heterogeneity in risk factor associations for prostate cancer defined by clinical and molecular characteristics. Physical activity has moderate protective effects on development of prostate cancer, in particular of advanced and fatal disease. We hypothesized that the influence of physical activity on hormonal and anti-inflammatory pathways may potentially affect the development of TMPRSS2:ERG-positive compared to TMPRSS2:ERG-negative tumors. Our objective was to examine the association between physical activity and risk of prostate cancer defined by the TMPRSS2:ERG fusion. Materials & Methods: We followed 49,160 men in the prospective Health Professionals Follow-up Study from 1986 to 2010. Participants were age 40 years or older, had no previous cancer diagnosis, and reported physical activity by questionnaires self-reported the average number of hours per week they spent engaged in various forms of recreational physical activity at baseline and every two years thereafter with greater than 90% follow-up rates. We examined long-term physical activity type and intensity in units of metabolic equivalent of task (MET)-hours per week. Presence of the TMPRSS2:ERG fusion in tumor tissue was estimated by ERG protein expression using immunohistochemistry. We used competing risks models to obtain subtypes-specific hazard ratios (HRs) and 95% confidence intervals (CIs) for incidence of fusion-positive and fusion-negative prostate cancer. Results: During 23 years of follow-up, 5,819 men were diagnosed with prostate cancer. Of the 2,389 men who underwent radical prostatectomy, 910 were assayed for ERG. Men with higher cumulative average vigorous activity had a lower risk of developing TMPRSS2:ERG-positive prostate cancer per MET-hour (HR 0.96, 95% CI 0.91-1.02, P-value for trend = 0.01). There was no significant association observed between vigorous activity and risk of TMPRSS2:ERG-negative prostate cancer (HR 0.93, 95% CI: 0.67-1.28, P-value for trend = 0.46). However, the test for heterogeneity in these associations was not significant (P-value for heterogeneity = 0.55). No association was observed between total activity and risk of either TMPRSS2:ERG subtype. Conclusions: Physical activity of vigorous intensity is inversely associated with risk of TMPRSS2:ERG-positive but not TMPRSS2:ERG-negative prostate cancer. These findings suggest that regular vigorous activity may lower risk of prostate cancer through mechanisms specific to development of fusion prostate tumors. Future studies are needed to further elucidate these mechanisms and translate these findings into recommendations for prostate cancer prevention.
versely associated with lung cancer risk (P for trend = 0.045). This risk reduction with black tea and their major flavonoids was only observed in ever smokers and not in never smokers. There was no statistically significant association for lung cancer risk with total caffeine, green tea or flavonoids predominantly from green tea, regardless of smoking status. Conclusions: Coffee may increase the risk of developing lung cancer and this effect may be mediated by its caffeine content. Conversely, black tea and flavonoids found mainly in black tea may reduce the risk of lung cancer among ever smokers.

#5319 Comparison of changes in waist circumference and body mass index (BMI) through adulthood and their relationship with advanced colorectal neoplasia. Wambuí G. Gathirua-Mwangi, Patrick Monahan, Yiqing Song, Terrell Zollinger, Timothy Stump, Victoria Champion, Thomas Imperiale. Indiana University, Indianapolis, IN.

Background: Waist circumference (WC) is a stronger predictor of colon cancer risk than body mass index (BMI); however, how well change in either WC or BMI over time predicts the risk of AN remains unclear. Purpose: To investigate 1) the relationship between change in adiposity measures (BMI and WC) from early adulthood to older age and the risk of advanced colorectal neoplasia (AN) and 2) whether WC change or BMI change is a stronger predictor of risk of AN. Methods: The sample included 4,500 adults, 50-80 years with no previous colorectal cancer or adenomatous polyps and undergoing first-time screening colonoscopy. Participants reported adiposity measures (height, weight and WC) at early adulthood (age 21) and at time of screening (mean age 57). Changes in BMI were categorized as 1) increase from healthy BMI to overweight or obese; 2) increase from overweight to obese, and 3) stable BMI level at age 21 and time of screening. WC was defined as high-risk for females with a WC ≥35 and males ≥40 inches. Changes for WC were categorized as 1) increase from a low-risk WC to a high-risk WC, and 2) stable-risk WC at age 21 and time of screening. Gender, age, family history, exercise, aspirin use, alcohol, smoking and intake of red meat and vegetables were included in the logistic models. Results: Being a obese both at age 21 and at screening resulted in a significant increased risk of AN (OR = 1.87; 95% CI 1.08-3.23) compared to those with a stable-healthy BMI at both time points. Stable overweight BMI at age 21 and at screening (OR = 1.54; 95% CI 0.97-2.45) and increased BMI from healthy to overweight or obese and overweight to obese were not associated with AN, as compared to those who had a healthy BMI at both time points. Compared to those with a low-risk WC at both time points, those who had a high-risk WC at age 21 and at time of screening had a two-fold increased risk of AN (OR = 2.15; 95% CI 1.35-3.45). Increasing WC from age 21 to time of screening compared to those with low-risk WC was not associated with risk of AN (OR = 1.23; 95% CI 0.97-1.57). When both WC and BMI change were included, WC change (≥10.15, 2 DF, p-value = 0.0062) but not BMI change (≥5.66, 2 DF, p-value = 0.34) predicted risk of AN. Conclusions: Maintaining a high-risk WC or obese BMI is associated with increased risk for AN; however, when BMI is controlled, maintaining a high-risk WC may independently increase the risk for AN. Practitioners should caution adults with high-risk WC and obese BMI values to better control their adiposity.

#5320 Folate and other nutrients related to one-carbon metabolism and risk of melanoma. Ashar Dhana,1 Ha Yi,2 Tricia Li,3 Michelle Holmes,2 Abrar Qureshi,4 Eunyoung Cho4. 1Grote Schuur Hospital and University of Cape Town, South Africa; 2Harvard T.H. Chan School of Public Health, MA; 3B Brigham and Women’s Hospital, MA; 4The Warren Alpert Medical School of Brown University, Providence, RI.

Background: Nutrients involved in one-carbon metabolism - folate, vitamins B6 and B12, methionine, choline, and betaine - have been associated with multiple cancer sites. However, no study has assessed the association between these nutrients and risk of melanoma. Thus, the aim of this study was to evaluate the association between intake of these nutrients and melanoma risk within two prospective cohorts: the Nurses’ Health Study (NHS) and Health Professionals Follow-up Study (HPFS). Methods: The cohorts included a total of 81,685 women in the NHS (1984 to 2010) and 49,617 men in the HPFS (1986 to 2010). We assessed nutrient intakes using a semi-quantitative food frequency questionnaire every 2 to 4 years. Total nutrient intake included both dietary and supplemental intake. Dietary intake included intake from food only. Study physicians reviewed medical and pathological records to confirm self-reported cases of invasive melanoma. We used Cox proportional hazards regression to estimate hazard ratios (HRs) and 95% confidence intervals (CIs) and then pooled the HRs for both cohorts using a random effects model. Results: Over 24 to 26 years of follow-up, we documented 1,321 cases (641 men and 680 women) of invasive melanoma. Higher intake of folate from food only, but not total folate, was associated with increased risk of melanoma. The pooled multivariable HRs for the top versus bottom quintiles were 1.17 (95% CI: 0.98-1.41; P for trend = 0.17) for total folate and 1.37 (95% CI: 1.13-1.65; P for trend = 0.001) for folate from food only. The association was statistically significant in men, but not in women. Higher intake of vitamins B6 and B12, choline, betaine, and methi-onine were not associated with melanoma risk. We found some evidence that folate from food only, but not total folate, was associated with a modest increased risk of melanoma - a finding that warrants further investigation. Conversely, our findings suggest that other nutrients involved in one-carbon metabolism do not play an important role in the etiology of melanoma.

#5321 Metabolomics and body mass index among breast cancer survivors in The Lifestyle, Exercise, and Nutrition (LEAN) Study. Leah M. Ferrucci,1 Brenda Cartmel,1 Maura Harrigan,1 Tara Sanft,2 Mary Playdon,3 Wei Jia,4 Herbert Yu,4 Caroline H. Johnson,4 Lajos Pusztai,2 Anees B. Chagpar,7 Melinda L. Irwin1. 1Yale School of Public Health, New Haven, CT; 2Yale School of Medicine, New Haven, CT; 3National Cancer Institute, Rockville, MD; 4University of Hawaii Cancer Center, Honolulu, HI.

Background: While there is a growing body of literature on metabolomics and body mass index (BMI), there are limited studies in relation to weight change in overweight and obese individuals, and to our knowledge, no such studies in breast cancer survivors. Methods: The Lifestyle, Exercise and Nutrition (LEAN) randomized diet- and exercise-induced weight loss trial in breast cancer survivors enrolled overweight or obese breast cancer survivors (Stage 0-III) identified via the Yale-New Haven Hospital tumor registry or self-referral. Participants were randomized to either usual care group (n = 33) or the 6-month lifestyle intervention (11 sessions with a registered dietician) (n = 67). Height and weight were measured by study staff at baseline and 6 months, and a fasting (≥ 12 hours) blood draw was also performed at these time points. Paired (baseline and 6-month) serum metabolomics data were available for 83 women. Only those metabolites consistently detected in >80% of quality control samples with a coefficient of variation <30% were included in data analysis. We evaluated partial Pearson correlations between the ratio of metabolites at baseline versus 6-months and change in BMI adjusted for age and intervention group. We also assessed mean changes in metabolites from baseline to 6-months by randomization group using the general estimating equation in linear regression. Adjustments for multiple comparisons was based on the False Discovery Rate (FDR) with a threshold of 0.1. Results: Overall, a total of 307 metabolites were analyzed; 168 were quantitated by LC-MS and 139 were semi-quantitated by GC-TOF/MS. For BMI change from baseline to 6-months, we observed correlations with 16 metabolites (isocitric acid, 3-hydroxybutyric acid, serine, L-cysteine, piroxicin acid, ammonialmonic acid, palmitoleic acid, linoleic acid, 2-hydroxybutyric acid, and seven unidentified metabolites (p < 0.05)). However, no correlations between metabolites and change in BMI or randomization group among overweight and obese breast cancer survivors enrolled in a weight loss trial. Larger sample sizes would help to clarify if any of the potential signals observed in this population may be associated with BMI or other lifestyle changes, such as diet quality.
justing for radiation and chemotherapy treatment, age, sustained inability to eat solid foods after diagnosis, and smoking status. Results: Of the 282 patients that met our eligibility criteria, 211 men with complete information available were included in the analyses, and there were 131 recorded events during follow-up. In this study population, mean age at diagnosis was 63.7 years (SD = 9.8), median survival was 2.6 years, mean average BMI after 40 years of age was 29.0 kg/m² (SD = 4.5), and mean BMI at diagnosis was 27.4 kg/m² (SD = 4.4). Compared to obese subjects at diagnosis, underweight, healthy weight, and overweight at diagnosis respectively had an adjusted hazard ratios of death (HR) of 2.72 (95% CI: 0.59-12.45), 1.79 (95% CI: 1.06-3.02) and 1.08 (95% CI: 0.65-1.74) (BMI category p = 0.04), likely demonstrating reverse causation. Adjusting for confounders, BMI at diagnosis showed that patients with an overweight BMI at diagnosis had the highest hazard of death, compared to patients who gained weight in late life prior to diagnosis (HR = 0.70, 95% CI: 0.45-1.1) and patients who lost some weight (HR = 0.55, 95% CI: 0.35-0.91) (BMI category p = 0.05). The strong effect of BMI even after adjusting for patients’ inability or lack of desire to eat (anorexia), implicates cachexia as a possible independent mechanism of this association. In addition, age at dx, stage at diagnosis, and surgical resection were significant predictors of overall survival. Conclusion: Substantial weight loss in BMI prior to diagnosis indicates poor overall survival in middle-aged and elderly Caucasian men with esophageal adenocarcinoma.

**#5323 Obesity and ovarian cancer survival revisited.** Elisa V. Bandera,1 Valerie Lee,2 Bo Qin,1 Lorna Rodriguez,3 Bethan Powell,3 Lawrence H. Kushi 2.

Research on the impact of obesity on ovarian cancer survival is inconsistent but previous studies did not consider the possible impact of ascites, bowel obstruction, or cachexia, which commonly occur in late-stage disease. We evaluated this association in a cohort study of primary invasive epithelial ovarian cancers diagnosed from 2000-2013 in Kaiser Permanente Northern California (KPNC) (n = 1,157). Deaths were identified through December 2014, with median follow-up of 37 months. Proportional hazards regression was used to estimate overall and ovarian cancer-specific mortality, accounting for prognostic variables including age at diagnosis, race, stage, grade, histology, comorbidities, treatment, post-treatment CA125 levels, ascites, and bowel obstruction. There was no evidence of an association between BMI and overall or ovarian cancer-specific survival. However, we found strong effect modification by stage (Pinteraction < 0.01). Compared to normal pre-diagnosis BMI (18.5-24.9 kg/m²), for women who were obese before diagnosis (BMI ≥ 35 kg/m²) risk of ovarian cancer-specific mortality was increased among those diagnosed at stages I/II (Hazard ratio [HR]: 3.40; 95% confidence interval [CI]: 1.16-9.99), but reduced among those diagnosed with stage IV disease (HR: 0.58; 95% CI: 0.35-0.96). Associations persisted after excluding those diagnosed with cachexia (n = 91) and further adjusting for ascites and bowel obstruction, with no evidence of effect modification by these factors. Associations of obesity with ovarian cancer survival differ by stage, with decreased survival among those with localized disease and increased survival among those with late-stage disease. Stage-specific effects of obesity on survival suggest a tailored approach to improve prognosis may be appropriate.

**#5324 ERG expression and PTEN loss by BMI and weight change in men with prostate cancer.** Janelle S. Ho,1 Ibrahim Kulac,1 Tamara L. LOTAN,1 John R. Barber,3 Patrick C. Walsh,1 Misop Han,1 Angelo M. De Marzo,1 Elizabeth A. Platz,2 Corinne E. Joshua,1 Johns Hopkins University School of Medicine, Baltimore, MD; 3Johns Hopkins Bloomberg School of Public Health, Baltimore, MD.

Background: Obesity and weight gain are associated with poor prostate cancer outcome; underlying mechanisms are unknown. Obesity has been more strongly associated with lethal disease in men positive for the TMPRSS2:ERG gene fusion than negative for this fusion. PTEN loss is associated with increased risk of lethal progression; its association with obesity has not been explored. We evaluate the relationship of ERG and PTEN status and weight change in men with prostate cancer from four large population-based studies.

**#5325 Associations between adipose tissue compartments and the plasma metabolome in colorectal cancer patients: Results from the ColoCare Study.** Jennifer Ose,1 Tengda Lin,1 Nina Habermann,2 Lawerence H. Kushi,3 Valerie Lee,2 Bo Qin,1 Lorna Rodriguez,3 Bethan Powell,3 Lawrence H. Kushi 2.

We evaluated this association in a cohort study of primary invasive epithelial ovarian cancers diagnosed from 2000-2013 in Kaiser Permanente Northern California (KPNC) (n = 1,157). Deaths were identified through December 2014, with median follow-up of 37 months. Proportional hazards regression was used to estimate odds ratios (ORs) and 95% confidence intervals (CIs) for the association of BMI and weight change (adjusted for height, starting weight) with ERG positivity and heterogeneous PTEN loss. Results: Mean age was 56.1 years and mean Gleason sum was 6.2, 73.5% had organ-confined disease. Prevalence of ERG positivity did not statistically significantly differ by BMI or weight change. However, when jointly categorized by BMI and weight change, overweight/obese men who maintained (OR = 2.5; 95% CI 1.1-5.7) or gained (OR = 2.4; 95% CI 1.3-4.7) weight between diagnosis and prostatectomy were significantly more likely to have ERG positive tumor compared with normal weight men who maintained weight. Overweight-obese men were also significantly more likely (OR = 2.4; 95% CI 1.3-4.7) to have PTEN loss compared with normal weight men. When stratified by ERG status, this association appeared to be stronger for men with ERG positive tumors (OR = 2.9; 95% CI 1.3-6.8) than for men with ERG negative tumors (OR = 1.6; 95% CI 0.6-4.9). Prevalence of PTEN loss did not differ by weight change. When jointly categorized by BMI and weight change, overweight/obese men who maintained (OR = 2.0; 95% CI 0.8-5.3) or gained weight (OR = 1.9; 95% CI 0.7-5.1) appeared to be more likely to have PTEN loss compared with normal weight men who maintained weight. Conclusions: Overweight/obese men who maintained or gained weight circadna and normal weight men who gained weight more likely had ERG positive tumors. Overweight/obese men were more likely to have tumors with PTEN loss; this association was stronger among overweight/obese men who also had ERG positive tumors. The TMPRSS2:ERG gene fusion and PTEN loss may contribute to the increased risk of poor prostate cancer outcomes among overweight/obese men. Funding: Prostate Cancer Foundation.

**#5325A Fruit and vegetable intake and risk of breast cancer: Pooled analysis of the Nurses’ Health Study and the Nurses’ Health Study II.** Maryam S. Farvid, Walter C. Willett, A. Heather Elissian. Harvard T.H. Chan School of Public Health, Boston, MA.
Fruit and vegetable intake has been hypothesized to protect against breast cancer, but the overall evidence has not been supportive. Using pooled data from the Nurses’ Health Study and the Nurses’ Health Study II cohorts, we evaluated fruit and vegetable intake in relation to breast cancer risk. Diet was assessed every 4 years using semiquantitative food frequency questionnaires. Cox proportional hazards regression, adjusting for multiple breast cancer risk factors, was used to estimate hazard ratios (HRs) and 95% confidence intervals (CIs) for each category, using the lowest quintile of intake as the reference category. Among 182,204 women aged 27 to 66 years, we prospectively identified 10,973 invasive breast cancer cases during follow-up from 1980 through 2012 for the Nurses’ Health Study and from 1991 through 2013 for the Nurses’ Health Study II. Fruit and vegetable intake was significantly associated with a lower risk of breast cancer. The pooled multivariate HR (95% CI) for highest (3.2 servings/day) versus lowest (0.4 serving/day) quintile intake of total fruit intake was 0.93 (0.86–0.99; Ptrend = 0.03) and for highest (4.9 servings/day) versus lowest (1.5 servings/day) quintile intake of total vegetable was 0.92 (0.86–0.99; Ptrend = 0.02). We also observed that a higher intake of yellow/orange vegetables, cruciferous vegetables, fruits and vegetables rich in β-carotene, and fruits and vegetables rich in lutein was each associated with a lower breast cancer risk. In addition, the association with vegetable intake was stronger for both estrogen and progesterone receptor negative (HR = 0.91; 95%CI = 0.87–0.95) than both estrogen and progesterone receptor positive cancers (HR = 0.98; 95%CI = 0.96–1.00; Ptrend by hormone receptor status = 0.003). Our findings support an association of a higher fruit and vegetable intake with a lower breast cancer risk.

Molecular and Cellular Biology / Genetics: Cell Growth Signaling Pathways 8

#5326 EZH2 regulation through lysine 63 linked ubiquitination in prostate cancer. Wenyu Fu,1 Lou Chen,2 Bo Li,2 Jingying Xie,2 Michael G. Izbain,3 Billy R. Ballard,1 Sandeep A. Sathyanaaryana,1 Samuel E. Adunyah,1 Robert J. Matsuski,2 Zhenbang Chen1.

Enhancer of zeste homolog 2 (EZH2) plays crucial roles on the development of cells and tissues as well as the progression of prostate cancer (PCa) and castration resistant prostate cancer (CRPC). EZH2 can upregulate and activate progenitor genes including androgen receptor (AR) and the target genes. However, the mechanisms by which EZH2 is regulated in PCa remains elusive. Literature reports that tumor necrosis factor (TNF) receptor associated factor-6 (TRAF6) is essential for both normal tissue development and regulation of oncogenic signaling pathways in cancers. In this study, we reported that EZH2 is regulated by PTEN and SKP2 network in PCa. Specifically, we showed that the aberrant upregulation of EZH2 and histone H3 lysine 27 trimethylation (H3K27me3) in both Pten null mouse embryonic fibroblasts (MEFs) in vitro and prostate tumors of Pten null mice in vivo, as compared to the controls. EZH2 levels were negatively correlated with TRAF6 in human PCa cells upon SKP2 dysregulation. Immunofluorescence (IF) staining results showed a co-localization of EZH2 and TRAF6 in nucleus of PC3 cells, and co-immunoprecipitation (co-IP) analysis further confirmed a physical binding of EZH2 and TRAF6 in PC3 cells. Ectopic expression of TRAF6 promoted the K63-linked polyubiquitination of EZH2 to decrease EZH2 and H3K27me3 levels in PCa cells. Conversely, TRAF6 knockdown resulted in a reduction of EZH2 polyubiquitination with an increase of EZH2 and H3K27me3 levels in PCa cells. Furthermore, the catalytically dead mutant TRAF6 C70A abolished the TRAF6-mediated polyubiquitination of human EZH2 in vivo in 293T cells and in vitro in the recombinant human EZH2 protein, as compared with TRAF6 WT. Together, we report for the first time a novel mechanism on EZH2 ubiquitination and an important signaling network of SKP2-TRAF6-EZH2-H3K27me3 in PCa cells. Our findings provide important clues on the mechanism and efficiency of targeting EZH2 in PCa and CRPC.

#5327 Giolma derived cancer stem cells are hypersensitive to proteasomal inhibition. Dae-Hee Lee, Sang Cheul Oh, Yong Tae Kwon, Yong J. Lee, Young Dong Yoo.

Although proteasome inhibitors (PIs) are used as anticancer drugs to treat various cancers, their relative therapeutic efficacy on stem cells vs. bulk cancers remains unknown. Here, we show that stem cells derived from gliomas, GSCs, are up to 1,000-fold more sensitive to PIs (IC50, 27-70 nM) compared with their differentiated controls (IC50, 47- > 100 μM). The stemness of GSCs correlates to increased ubiquitination, whose misregulation readily triggers apoptosis. PI-induced apoptosis of GSCs is independent of NFκB but involves the phosphorylation of JNK as well as the transcriptional activation of endoplasmic reticulum (ER) stress-associated proapoptotic mediators. In contrast to the general notion that ER stress-associated apoptosis is signaled by prolonged unfolded protein response (UPR), GSC-selective apoptosis is instead counteracted by the UPR. ATF3 is a key mediator in GSC-selective apoptosis. Pharmaceutical uncoupling of the UPR from its downstream apoptosis sensitizes GSCs to PIs in vitro and during tumorigenesis in mice. Thus, a combinational treatment of a PI with an inhibitor of UPR-coupled apoptosis may enhance targeting of stem cells in gliomas. Key words: glioma; glioma stem cells; proteasome inhibitors; ubiquitin proteasome system; apoptosis; c-Jun N-terminal kinase (JNK).
Targeting hepatocellular carcinoma through TGF-β pathway E3 ligases. Shuyun Rao,1 Heather Levin,1 Jian Chen,2 Rehan Akbani,3 Jon White,3 Wilma Jogunoori,3 Shoujun Gu,1 Kazufumi Ohshiro,2 Sobia Zaidi,1 Bibhuti Mishra,2 Asif Rashid,2 Shulin Li,3 Lopa Mishra,2 George Washington Univ, Washington, DC; 2MD Anderson Cancer Center, Houston, TX; 3Institute of Clinical Research, Washington, DC.

Hepatocellular carcinoma (HCC) is the 3rd leading cause of cancer deaths worldwide, and rising in the United States at an alarming rate. Multiple E3 ubiquitin ligases such as the SMURFs and RINGH2 proteins have been identified as negative regulators of the TGF-β pathway. However, to our knowledge, there remains a gap in the integration between genomics, underlying mecha- 

isms and therapeutic development of targeted therapies harnessing these associated E3 ligases for HCC. The aim of this study is to elucidate the role of E3 ligases in HCC, through TCGA analyses and provide mechanistic insight into these as therapeutic targets for HCC. We first analyzed the 488 hepatocellular cancers and screened for alterations in The Cancer Genome Atlas (TCGA). Immunohistochemistry (IHC), Q-PCR, Western blot analyses were used to validate the expression levels of two of the most highly altered E3 ligases, PRAJA1 and Keap1 in hepatocellular cancer tissues and cell lines in human and in TGF-

β-deficient β2SP−/− mouse models. Inhibition studies of PRAJA and Keap1 were performed by lentivirus shRNA in HCC cell lines, and xenograft studies. From the TCGA data, we observe two different signatures (activated and inactivated) for 18 TGF-β pathway genes. While increased levels of TGF-β-related transcripts were associated with activation of hepatic fibrosis/malignancy pathways, decreased levels of TGF-β members were associated with loss of TGF-β tumor suppressor function. HCCs characterized by the “inacti-

vated” TGF-β signature were associated with a significantly poorer survival, compared to HCCs with the “activated” TGF-β signature (p = 0.0027). We next analyzed 29 TGF-β-related E3 ligases, and observed raised expression of the following: PRAJA1 (12.7% of HCCs), Keap1 (6.4%), UCHL5 (16.4%), WWP2 (11.8%), WWP1 (10%), Smurf2 (9.1%), Skp2 (9.1%), and Smurf1 (8.2%). Interestingly, expression patterns corresponded with a few TGF-β signaling members regulated by some of these E3 ligases, namely Smad3 (altered in 54%) and β2SP (27%). We identified that PRAJA1 targets Smad3 and β2SP for ubiquiti-

nation and degradation. We further observe raised levels of PRAJA (25%) and Keap1 (70%) in 176 human liver cancers, by IHC, compared to normal counter-

trols. Depletion of PRAJA and Keap1 with either shRNAs or E3 ligase inhibi-

tors, substantially inhibited growth and induced apoptosis through PRAJA/ Smad3/β2SP and Keap1/Nrf signaling in HCC cell lines and xenografts. These results suggest that E3 ligases such as PRAJA1 and Keap1 may be valuable therapeutic targets for liver cancer in the context of TGF-β signaling, an important approach given that few effective targeted therapies are available for this cancer with poor prognosis.

Background: Pancreatic ductal adenocarcinoma (PDAC) is a deadly disease driven by mutated KRAS with an average survival of only 3-6 months from the time of diagnosis. Interferon-Stimulated Gene 15 (ISG15) is a 15 kDa protein induced by Type I interferons (IFN-α and IFN-β) and is a member of the ubiquitin-like superfamily of proteins. The ISG15 pathway is highly elevated in var-

ious malignancies where it has been shown to stabilize KRAS protein expression.

However, very little is known about the role of the ISG15 pathway in PDAC. The purpose of this project is to investigate the expression and proliferative effects of the ISG15 pathway in PDAC. Methods: The ISG15 knockdown cells were created using the CRISPR (Clustered Regularly Interspaced Short Palindromic Re-

peats) gene editing system. ISG15 was stably knocked-down in murine Panc02 pancreatic cancer cells by transfection with an ISG15 CRISPR construct from Genscript (pSpCas9 B-2A-Puro (PX459)) and treated with media containing puromycin (2 μg/ml) for selection. Knockdown was confirmed by RT-PCR. The effect of ISG15 knockdown on PDAC cell growth in vitro was determined by comparing viable cell counts on wild-type and ISG15 knockdown Panc02 cells 48 hours after plating. The effect of ISG15 knockdown on Panc02 cell growth was determined by subcutaneous inoculation of syngeneic immune competent C57BL/6 mice with 1x10⁶ Panc02 wild-type or ISG15 knockdown cells. Tumor volumes were measured weekly and after 3 weeks the mice were euthanized, tumors dissected and weighed. Results: ISG15 CRISPR treated cells had a 50% reduction in ISG15 mRNA expression as compared to wild-type cells. ISG15 knockdown in Panc02 cells significantly reduced cell growth as compared to wild-type cells (p = 0.030). Tumors formed from ISG15 knock-

down Panc02 cells significantly had a 74% reduction in tumor volume (p = 0.031) and 78% reduction in tumor weight (p = 0.029) as compared to wild-type cells. Conclusion: The ISG15 pathway contributes to PDAC by increasing cell growth and the tumorigenic potential of pancreatic cancer cells. Ultimately, strategies to target the ISG15 pathway may lead to improved survival for patients diagnosed with PDAC. Supported by: NIH T32CA09968 grant.

Monoubiquitination inhibits the actin bundling activity of fascin. Shenglin Chen,1 Shuang Lu,2 Mentor Mulaj,1 Bing Fang,2 Tyler Keeley,2 Lixin Wan,3 Jiuhao Hao,3 Martin Muschol,3 Jianwei Sun,3 Shengyu Yang.1 Penn State University, Hershey, PA; 2 Moffitt Cancer Center, Tampa, FL; 3 University of South Florida, Tampa, FL; 4 Tianjin Medical University, Tianjin, China; 5 South China Agricultural University, Guangzhou, China.

Fascin is the most frequently upregulated actin regulatory protein in meta-

static tumors. The elevated expression levels of fascin universally correlate with poor clinical course and shorter survival across different cancer types. It is believed that fascin promotes cancer cell migration and invasion by crosslinking actin filaments into bundles. However, the molecular mechanisms underlying the regulation of fascin bundling activity are not completely understood. In this study we examine the regulation of Fascin activity by monoubiquitination. IP and LC-MS/MS was used to identify the posttranslational modification of Fascin. A novel chemical monoubiquitination method was employed to synthesize monoubiquitinated Fascin. The monoubiquitinated fascin was purified, and the effect of monoubiquitination on fascin bundling activity was determined using low speed sedimentation assay, fluorescence microscopy and transmission electron microscopy. Here we identified monoubiquitination as a novel mechanism that regulates fascin bundling activity and dynamics. The monoubiquitination sites were identified to be K247 and K250, two residues located in a positive charge patch at the actin binding site 2 (ABS2) of fascin. Using a chemical ubiquitination method, we synthesized chemically monoubiquitinated fascin (mUb-fascin) and determined the effects of monoubiquitination on fascin bundling activity and dynamics. Our data demonstrated that monoubiquitination decreased the fascin bundling EC50, delayed the initiation of bundle assembly and accelerated the disassembly of existing bundles. By analyzing the electro-

static properties on the solvent accessible surface of fascin, we proposed that monoubiquitination introduced steric hindrance to interfere with the interac-

tion between actin filaments and the positively charged patch at ABS2. Mutation of the monoubiquitination sites (K247 and K 250) to arginine inhibited fascin monoubiquitination and enhanced pro-migration ability of fascin, supporting the notion that monoubiquitination inhibit fascin activity. We also identified Smurf1 as an E3 ligase regulating the monoubiquitination of fascin. Our findings revealed a previously unidentified regulatory mechanism for fascin, which will have important implications for the understanding of actin bundle regulation under physiological and pathological conditions.

Destabilization of EWS-Fli1 protein by deubiquitinase inhibition in Ewing Sarcoma. Shan Wang, Ralf Kittle. UT Southwestern Medical Ctr., Dallas, TX.

Background: Ewing Sarcoma is a malignant tumor in bone or soft tissue, and typically in teenagers and young adults. Genetically, most Ewing’s Sarcoma contains the chromosomal translocation [t(11;22)(q42;q12)], which fuses EWS1 gene from chromosome 11 and Fli1 gene from chromosome 22 and generates an aberrant chimeric protein EWS-Fli1. EWS-Fli1 is essential for cell growth and development in EWS-Fli1 positive Ewing Sarcoma cells. Therefore, targeting EWS-Fli1 could be a promising therapeutic strategy for Ewing Sarcoma. Methods and Results: Currently, the compounds of targeting EWS-Fli1 mainly interfere its interaction with partner or DNA. However, it could be a more potent way to manipulate its protein stability. Firstly, the proteasome inhibitor MG132 could retard the degradation of EWS-Fli1 protein in EWS502 cells and A673 cells, and increase its ubiquitination, which hints the degradation of EWS-Fli1 is through the ubiquitin (Ub)-proteasome pathway (UPP). Then, to identify the protein that interact with EWS-Fli1 and modulate its stability, we selected the candidate deubiquitinase according to literatures and the protein homology. And by co-immunoprecipitation assay, we identified a deubiquitinase enzyme (DUB) binding to EWS-Fli1. RNAi-mediated knockdown or inhibition of EWS-Fli1-DUB with a small molecule compound caused a marked increase in EWS-Fli1 ubiquitination, decreased levels of EWS-Fli1 in a protea-

some-dependent manner, and further inhibited the growth of Ewing Sarcoma cells. Conclusion: The findings indicate that EWS-Fli1 could be ablated by in-

hibiting its specific deubiquitinase in Ewing Sarcoma, which could be a novel treatment approach for Ewing Sarcoma.

Dissecting the ubiquitin pathway using homogenous and sensitive bioluminescent assay. Said A. Goueli, Kevin Hsiao, Subhanjan Mondal. Pro-

mega Corp., Madison, WI.
Post-translational modification of target proteins by ubiquitin (Ub) and ubiquitin-like (Ubl) proteins is a fundamental mechanism for regulating protein functions and protein stability thus affecting diverse cellular processes. Several ubiquitin-like (Ubl) molecules have been identified including SUMO, NEDD8, ATG8/15 and ISG15 which share the ubiquitin fold Ub/Ubl proteins are conjugated to lysine residues in substrate proteins through an ATP-dependent posttranslational cascade involving E1-activating enzyme, E2-conjugating enzyme and E3-ligase. To mark proteins for degradation, multiple ubiquitins are covalently attached to produce a Lys48 linked poly-ubiquitin chain. The poly-ubiquitinated proteins are recognized by the 26S proteasome system and deubiquitinated and destroyed. Substrates with ubiquitin chains linked through Lys 6, 11, 27, 29, 33 also regulate protein degradation through an ATP-dependent endocytic cascade resulting in TGF-β signaling, acts as a scaffold to recruit the E3 ligase SMAD7, a direct transcriptional target of downstream TGF-β receptor stabilization and enhanced levels of p-SMAD2. Clinical loss of USP26 correlates with high TGF-β activity and confers poor prognosis in glioblastoma. Our data identify USP26 as a novel negative regulator of the TGF-β pathway and suggests that loss of USP26 expression may be an important factor in glioblastoma pathogenesis.

#5338 Transcriptional elongation mediates human papillomavirus type 16 late promoter activation. William Songock, Jason Bodily. Louisiana State University Health Sciences Center, Shreveport, LA.

Human papillomaviruses (HPVs) are small DNA viruses that infect keratinocytes of squamous epithelia and cause benign lesions that can progress to several malignancies, including cervical cancer. Upregulation of viral transcripts by the HPV16 late promoter is dependent on host cellular differentiation. We sought to investigate the main cellular transcription regulators that correlate with differentiation-dependent increase in the late viral transcripts. Here, we show evidence that the step in transcription cycle that is responsible for late promoter activation is transcriptional elongation. We began by establishing that the increase in viral transcripts originating from the late promoter is primarily regulated at the transcript synthesis level rather than post-transcription level. Based on this observation, we investigated whether there is a correlation between late promoter activation and activities that occur during the initiation, pausing or elongation steps of transcription cycle. Using chromatin immunoprecipitation (ChIP), we did not observe a differentiation dependent increase of RNA Polymerase II (RNP II) in the late promoter region. However, there was a significant increase of RNP II at downstream sites of late promoter suggesting elongation is regulated by differentiation. We then sought to investigate the cyclin dependent kinases (CDKs) that are known to regulate transcription elongation. ChIP did not show a significant increase of the elongation factor CDK8 in the late promoter; however, the enrichment of CDK9 at downstream sites of the viral genome significantly increased upon differentiation, suggesting that differentiation induces recruitment of CDK9 to facilitate elongation. Additionally, CDK8, a component of the Mediator complex that recruits CDK9 to the RNP II, was increased upon differentiation. Kinase inhibitors against CDK8 did not affect late viral transcripts; however, knocking down CDK8 resulted in a significant reduction of virus particles, suggesting that CDK9 could be involved in protein-protein interactions that are required for the synthesis of late viral transcripts. These findings suggest that HPV has evolved to utilize cellular transcriptional elongation machinery as a way of regulating its late gene expression. This mechanism allows the virus to persistently infect host cells and cause HPV-associated malignancies.

Human papillomaviruses (HPVs) are a diverse group of small double stranded Deoxyribonucleic acid viruses implicated in many malignancies including cervical cancer. The viruses are also attributed to premalignant epithelial lesions in this disease. Cervical cancer is a leading cause of morbidity and mortality in African women and beyond. We aimed to study the molecular phylogenetic classification of HPV's and cervical cancer associated genes in relation with tumour manifestation. Phylogenetic tree was constructed based on nucleotide sequence alignments using ClustalX 2.1 algorithms to classify 31 different HPV DNA virus types and 10 cervical cancer associated genes. Study of immunohistochemistry markers associates with cervical cancer pathology was performed. The nucleotide sequences used include HPV- 1 (V01116), HPV-14 (D90261), HPV-20 (D90262), HPV-21 (D90263), HPV-25 (D90265), HPV-4 (M29261), HPV-47 (M32305), HPV-8 (M12732), HPV-2 (M55965), HPV-6: X00203, HPV-11 (M14119), HPV-13 (X62843), HPV-43 (HE964240.1 E6 gene), HPV-44 (U31788.1), HPV-42 (HE820261.6 E6 gene for E6 protein), HPV-16 (K07218), HPV-16 (K1689425.1 E6 and E7 variants), HPV-35 (M74117), HPV-31 (I04353), HPV-52 (K1689430.1), HPV-33 (M12732), HPV-58 (D90400), HPV-51 (M62877), HPV-18 (X50015), HPV-45 (M27363), HPV-39 (M38185), HPV-56 (M18078, M37258), HPV-17 (K1689425.1 E6 and E7 variants), Ki-67 (NM_002417.4), p53 (AB082293.1), EGRF (NM_005228.3), MYC (M25803.1), KRAS (EF471957.1), TGF-B (AF254794.1) and RB (AH002963.2) genes. The resulting phylogenetic tree provides a conventional classification of the HPV’s and the cancer genes into groups encompassing the known tissue tropism and oncogenic potential of each gene type associated with the disease. The implications of a phylogenetic taxonomy on the diagnostic detection of HPVs as they relate to cervical cancer associate genes are shown to be important in disease management.
MOLECULAR AND CELLULAR BIOLOGY / GENETICS: Cell Growth Signaling Pathways

#5340 Retrovirus insertion induces syncytin mediated exosomes delivery in prostate cancer cells. Berna Uygar, Leonid Chernomordik. NIH, Rockville, MD.

Activation of retroviruses in normal cells can induce tumors and a wide array of cancers contains retrovirus-like particles. The potential role of these endogenous retroviruses in the development and progression of tumors has been discussed in many studies. However the effects of retrovirus insertion into cancer cells have not yet been fully examined. In this study, we explore genetic material transfer either between retrovirus-transduced prostate cancer PC3 cells or between PC3 cells and their host environment through extracellular vesicles (EV) and virus-like particles. For these purposes, we transduced PC3 cells with either GFP encoding retrovirus or with m-cherry expressing lentivirus. Co-incubation of GFP-expressing cells with m-cherry-expressing cells for 72h yielded yellow PC3 cells. Yellow cells were also observed in the experiments where lentiviral m-cherry expressing PC3 cells were cultured with tissue culture medium from retrovirus GFP expressing PC3 cells. These results indicated that horizontal genetic information transfer involves neither fusion nor contact between the cells. Since incubation of the retrovirus GFP-expressing PC3 cells with the medium from the lentivirus m-cherry expressing PC3 cells, did not yield yellow cells the genetic material transfer requires retrovirus insertion in PC3 cells. Using Western blot and Q-PCR, we found the exosomes from the medium generated by retrovirus GFP expressing PC3 cells to carry human endogenous retroviral proteins syncytin 1 and 2 and contain RNAs encoding these proteins. Exosomes from the lentivirus m-cherry expressing PC3 cells had lower protein expression of Syncytin 1&2 than exosomes from retrovirus GFP expressing PC3 cells. Application of Syncytin 1 or 2 antibodies to the medium generated by or co-cultured retrovirus GFP expressing PC3 and lentivirus m-cherry expressing PC3 cells suppressed horizontal transfer of the genetic information from retrovirus GFP expressing PC3 cells to other cells. The specific mechanisms by which retroviral transduction and syncytins control the generation of a GFP-encoding pseudotyped retrovirus or EV and the delivery of their content, as well as the role of the virus/EV-mediated horizontal genetic material transfer between prostate cancer cells and between prostate cancer and their microenvironment remain to be clarified.

#5341 HPV16 E6 oncoprotein modulates the DPPIV/CDCP26 in primary keratinocytes. Aline Beckenkamp,1 Bruna Prati,2 Silvya Stuchi Maria-Engler,3 Guido Lena,1 Diogo André Pilger,4 Enrique Mario Piersilvio,4 Andréia Buffoni.1

1 Federal University of Rio Grande do Sul (UFRGS), Porto Alegre, Brazil; 2Universidade de São Paulo (USP), São Paulo, Brazil; 3Universidade de São Paulo (USP), São Paulo, Brazil.

Cervical cancer is related to the persistent infection by high-risk human papillomavirus (HPV) subtypes, such as types 16 and 18. The E6 and E7 oncoproteins significantly contribute to the carcinogenic potential of high-risk HPV, through the degradation of p53 and pRb, respectively. The exopeptidase dipetidyl peptidase IV (DPPIV) also known as CD26, is a multifunctional protein involved in several processes related to cancer. DPPIV/CDC6 has an intrinsic peptidase activity, able to degrade some bioactive peptides and chemokines, thereby regulating cell migration, proliferation and survival. It has been reported that the reduction in DPPIV/CDC6 expression is associated with tumor progression in different types of cancer. Moreover, studies in cervical cancer samples and cell lines point to a reduction in the expression of this protein. However, there are no studies addressing the relationship between HPV infection and DPPIV/CDC6 expression. We analyzed the influence of HPV oncoproteins on DPPIV/CDC6 expression in human keratinocyte transduced with E6, E7 and E6E7. We observed that HPV16 E6 expression is associated to a reduction in DPPIV/CDC6 expression at mRNA and protein levels, whereas HPV16 E7 does not affect DPPIV/CDC6 expression. HPV16 E6E7 co-expression leads to a reduction in DPPIV/CDC6 expression similar to that found in E6 transduced cells. In addition, we note a more pronounced reduction in DPPIV/CDC6 expression in immortalized cells expressing E6E7. Furthermore, keratinocytes expressing HPV16 E6 mutant sequence and HPV11 E6, that do not bind to E6AP and do not degrade p53, have the effect on DPPIV/CDC6 expression. Our results suggest that HPV16 E6 oncoprotein can downregulates DPPIV/CDC6. In addition, preliminary results suggest that modulation of DPPIV/CDC6 mediated by E6 can be dependent on degradation of p53, since HPV16 E6 mutant and low-risk HPV E6 were not able to affect CDC6 expression. Furthermore, the process of cell immortalization also appears to be related to the reduction of DPPIV/CDC6 expression. Therefore, these results indicate that HPV oncoproteins promote imbalance DPPIV/CDC6 expression which may be related to cervical carcinogenesis.

#5342 Epigenetic polymorphisms and human papillomavirus E6/E7 oncoproteins transfection: Induce ATM gene deletion11q22-23 and chromosomal instability. Eva McGhee,1 Liliana Zarate,1 Chiamaka Opara,2 Antoinette Algbuwe,3 Meidrah Tyler,3 Bileko Wissa,4 Billy Ballard,2 Roland Pattillo.5

1 Charles R. Drew University of Medicine and Science, Los Angeles, CA; 2 Meharry Medical College, Nashville, TN; 3 Morehouse School of Medicine, Atlanta, GA.

Persistent infections involving high-risk types 16 and 18 of Human Papillomavirus (HPV) have been established as the etiological agent of cervical cancer. Recent data indicate that several polymorphisms of key regulators from the DNA damage repair pathways are associated with cancer development susceptibility. The long arm of chromosome 11 has received much attention as a high frequency of epigenetic deletions of various sites. In HPV-long terminal repeat (LTR) infection that lead to cervical cancer, indicating the presence of putative tumor suppressor genes and its association with disease progression. To better understand the importance of chromosome 11q22-23 region in the development of cervical cancer, we investigated genetic and epigenetic alterations of the tumor suppressor ATM gene in human keratinocytes transfected with HPV E6/E7 oncoproteins (16-MT). In the present study we examined 16-MT cells for epigenetic changes and chromosome imbalances, using FISH, and arrayCGH. We used several FISH probes, mapping to region 11q22-23 where the ATM gene is located. Our study revealed that the ATM gene located on chromosome 11q is deleted, relating to chromosome deletions, that are recurrent abnormalities in cervical cancer, implicating the loss of tumor suppressor genes as a significant mechanism that drive cells to become cancerous. This study was designed to investigate genetic instability using HPV16 E6/E7 oncoproteins to better understand the importance of chromosome 11q epigenetic changes. Deletion of 11q22-23 was observed in all metaphases scored. With restricted areas of deletions, two chromosomal regions of possible importance in cervical carcinomas could be distinguished. The first region is D11S1325 and the second region is D11S2179. The second region may contain part of the ATM gene. The results indicate that a tumor suppressor gene on chromosome 11q22-23 may be involved in the carcinogenesis of the cervix and the involvement of the ATM gene, as the driving factor remains a possibility.

#5343 The HIV shell protein Gp120 stimulates U87 glioma cell proliferation through the activation of glycolysis. Gabriel Valetin-Guillama,1 Sheila Lopez,2 José Perez,3 Luis Cubano,3 Natalia Chorn,4 Jeffery Harrison,5 Nawal Boughouit,6 Ivan S. Scheravyakj1. 1 Universidad Central del Caribe, Bayaspon, PR; 2 Universidad de Puerto Rico, School of medicine, San Juan, PR; 3University of Florida, Gainesville, FL.

Patients infected with human immunodeficiency virus (HIV) are more prone to develop cancers, including glioblastomas (GBM). The median survival of GBM patients with HIV is significantly shorter compared to HIV-negative GBM patients, despite the fact that they receive the same treatments. This indicates that HIV infection is associated with more aggressive tumor behavior and with treatment resistance. Taking into account that HIV itself is not found in GBM specimens, the nature of the GBM-HIV association remains poorly understood and the underlying molecular mechanism is still unknown. Here we study the effect of Gp120, a glycoprotein found in the HIV shell, on GBM cell growth and the underlying molecular resistance mechanisms. Our study shows that, compared to un-treated cells, quantitative proteomics studies using isobaric tags and western blot analysis identified expression up-regulation of several glycolytic enzymes, including enolase 2, pyruvate kinase, hexokinase, and glyceraldehyde 3-phosphate dehydrogenase in Gp120 treated U87 cells. Additionally, metabolite analysis revealed an increase of pyruvate, amino acid and lipid synthesis, together with reduction of protein degradation, in response to treatment with Gp120. In summary, we demonstrated that Gp120 promoted proliferation and resistance to TMZ in U87 cells through the activation of glycolysis, resulting in increased protein and lipid synthesis. This research was made possible by NIH grant numbers: 1SC2GM102040, R25GM110513, INBRE-PR NIH Grant 8P20GM103475, the UCC RCMI Biomedical Proteomics Facility grant G12MD007583 and US Department of Education Grant number P0315130068.

#5344 Understanding the structural requirements of C1 domains for phorbolester binding, analysis of the atypical C1 domain of STACT2. Adelle Abramovitz, Noemi Kedei, Peter M. Blumberg. NIH/NCI, Bethesda, MD.
C1 domains are the recognition motif for the second messenger diacylglycerol and for the phorbol esters. They play a critical role in the regulation of multiple families of signaling proteins such as protein kinase C, RasGRP, and the chimeras. Atypical C1 domains preserve substantial homology with the diacylglycerol / phorbol ester responsive C1 domains but fail to bind these ligands. A recent approach to highlight any residual binding activity of C1 domains revealed a continuum of structures ranging from those with measurable but weak phorbol ester binding affinity through those that preserve the phorbol ester binding cleft but have residues interfering with the insertion of the C1 domain into membranes and finally those that lack appropriate binding cleft geometry. STAC2 (SH3 and cysteine-rich domain 2) protein attracted our interest because, while its C1 domain has been classified as atypical, it had actually not been tested for phorbol ester binding activity and possesses marked homology to C1 domains that bind phorbol esters. The strategy for analysis has been to probe the influence of individual residues in the STAC2 C1 domain that are either not present or are unusual in the numerous phorbol ester responsive C1 domains. Reciprocal approaches have been to start either with the STAC2 C1 domain, mutate the individual residues, and look for gain of phorbol ester binding activity or to start with the PKC delta C1b domain and look for residues that cause reduction in binding affinity. The former approach is efficient if a single residue is responsible for the lack of binding activity; the latter approach is preferable if multiple residues are responsible. First, we confirmed that indeed the C1 domain of STAC2 is atypical and fails to bind phorbol ester. Second, we identified the residues in positions 11, 13, 24, 25, 41 and 45 of the C1 domain of STAC2 as potential candidates for interfering with binding activity. However, replacement of none of these residues with the corresponding residues from PKC delta C1b sufficed to generate phorbol ester binding activity. One the other hand, introducing mutations into the C1b domain of PKC delta identified L24N, that caused a significant (~20-fold) decrease in the binding affinity. The probable basis for the negative effect of L24N on binding is that Leucine 24, together with Phenylalanine 13, Leucine 20 and Tryptophan 22, are all exposed at the top of the binding cleft and insert into the lipid membrane during ligand binding. The replacement of a hydrophobic residue at position 24 with a hydrophilic residue should interfere with this binding. STAC2 may thus fall into the category of proteins with atypical C1 domains that could be targeted with phorbol deriva-
tives that do not stabilize membrane insertion. Our findings strengthen our
understanding of the interplay between the C1 domain, ligand and the membrane as a ternary complex.

Molecular and Cell Biology / Genetics: Development of High Throughput Analytic Methods

#5345 Complementary NGS approaches on digitally sorted pure tumor cells reveal hidden molecular characteristics in low tumor content FFPE specimens. Claudio Forcato, Alberto Ferrarini, Genny Buson, Cassie Schumacher, Chiara Bolognesi, Valentina del Monaco, Chiara Mangano, Francesca Fontana, Gianni Medoro, Timothy Harkins, Nicolò Specimens.

#5346 Combining droplet tagged short read sequencing with optical DNA mapping technology for improved assembly of cancer genomes. Yuan Jiang, Sven Bliks, Paul S. Meltzer. National Institutes of Health / National Cancer Institute, Bethesda, MD.

Kataegis, chromothripsis, chromoplexy and forms of structural hyper-muta-
tion generically described as chromoanagensis are found in many cancer types. Structural rearrangements can result in deletions, translocations, inversions and insertions, and gene amplification with important functional consequences as cancer drivers and clonal diversity. Whole genome sequencing was increasingly used to sensitively detect structural rearrangements. Yet, it remains difficult to detect these events reliably without an excessive number of false positives. This is a largely consequence of the still relatively short read-length of commonly used sequencing platforms. As a result, in larger cohorts, PCR based methods are generally not feasible for validating all predicted structural rearrangements. Accordingly, new approaches for robust mapping of both simple and complex rearrangements are needed. Here we used a hybrid of two technologies, 10X genomics droplet tagged Illumina sequencing (10X Genomics ) and DNA fiber molecular imaging (BioNano Irys) for high throughput validation. First, utilizing a sequencing-assisted synthetic genome: for each rearrangement predicted by NGS, we build a “pseudo-chromosome” offering this structure as one alter-
compound to the BioNano aligner. This combination compensates for the weak-
nesses of each platform resulting in a more robust result. In this way, even short reads can validate structural rearrangements, as the requirement for split reads is obviated. Provided that sufficient coverage is achieved, statistical analysis can be used to confidently recognize NGS false positive predictions. This allows the cataloging of complex repetitive regions and large-scale rearrangements. In our study we have evaluated this combined approach to large scale genome mapping to identify hallmark fusions and other rearrangements from the highly complex genomes of osteosarcoma cancer cell lines.

FFPE tissue archives is the most widely used method for clinical sample preservation, and provides a valuable source of diverse genetic information for cancer biomarker discovery. NGS library preparation is often challenging, how-
ever, as FFPE-derived DNAs exhibit varying degrees of fragmentation and
cellular modification depending on how tissues were handled and processed.
Moreover, the presence of low allele frequency variants because of tumor heter-
ogeneity, sample degradation, and high rate of formalin-induced mutations
make SNV calling a challenging task. To improve variant calling and consistency across FFPE samples of varying quality, we developed a complete workflow solution that features DNA pre-qualification, molecular barcodes for uniquely
remarking each DNA fragment, pre-capture indexing for tracking up to 192 sam-
pples, accelerated hybrid capture, and one-tube library prep, to enable the pre-
paration of complex enriched libraries in less than 8 hours from 10-200ng of FFPE-derived DNA. We incorporate molecular barcodes at the ligation step to enable de-duplication and generation of consensus reads using SureCall soft-
ware, which significantly improves confidence of variant calling (99% of calls ≥150 variant call quality threshold) at low allelic frequencies. Using ClearSeq

Comprehensive Cancer Panel which targets 151 genes frequently mutated in
solid and hematological cancers, we routinely obtain high quality libraries (with
1000X sequencing depth and after deduplication) with >99% of the targeted region covered at 20X for high quality gDNA (FF tissue), and greater than 95%
and 90% covered at 20X for medium and low quality FFPE samples, respectively. Using multiplex reference samples, we demonstrate detection of low frequency variants (at 1-5%) including SNVs, small indels, and RET and ROS1 translocations. As we will further show, FFPE integrity scores determined by qPCR and TapeStation (ddCq and DIN) enable researchers to choose the appropriate quantification method, PCR cycling, and sequencing depth for optimal sequencing coverage.

#5348 Reliable gene expression profiling from smaller and H&E stained clinical FFPE specimens using EdgeSeq platform. Zhenhao Qi,1 Lisa Wang,1 Keyur Desai,1 John Cogswell,1 Mark Stern,1 Byron Lawson,2 Bonnie LaFleur,1 Patrik Vitazka,1, 1BMS, Pennington, NJ; 2BMS, Lawrenceville, NJ; 1HTG Molecular, Tucson, AZ.

Background: The scarcity of biological specimens and suboptimal quality of collected material, make clinical biomarker studies challenging. The EdgeSeq system, a novel genomics analysis platform which combines quantitative nucleic acid purification assay (qNPA) technology with next-generation sequencing (NGS), has the potential to mitigate the aforementioned challenges. The technology allows for a limited sample input and delivers high quality gene expression profiling data from challenging material such as FFPE tissues. However, there is further unmet need toward even smaller tissue input or in taking advantage of archival stained FFPE slides to fill the data gap, specifically for studying tumor microenvironment in the oncology clinical trials Methods: We performed EdgeSeq analysis on six triplets of unstained, H&E stained and IHC stained slides from non-small cell lung cancer (NSCLC) patients tumor tissue using Oncology biomarker panel (OBP). Next, we extended the EdgeSeq OBP analysis to 44 pairs of unstained and H&E stained slides from NSCLC to confirm the good correlation. To assess feasibility of limited tissue input, we first optimized bead-to-DNA ratio from 2.5 to 1.0. Next, crude lysate prepared from small cell lung cancer (SCLC) FFPE tissue was 2-fold diluted from equivalent tissue area of 5mm² to 0.08 mm², and was subjected to EdgeSeq OBP profiling using the optimal bead-to-DNA ratio. Finally, correlation of gene expression profiles between stained and unstained pairs were calculated. Results: Within the six triplets of unstained, H&E stained and IHC stained slides, the gene expression profiles from H&E slides showed good correlation with the profiles from matched unstained FFPE. An extended NSCLC sample set of 44 pairs of unstained and H&E stained FFPE further confirmed overall good correlation with 84% (37 out of 44) pairs with Pearson correlation coefficients of 0.9 or higher. In assessing the limited tissue input, crude lysate was diluted to as little as equivalent tissue area of 0.08mm². The tissue area as small as 0.31 mm² resulted in Pearson correlation coefficients of 0.9 with 5mm² surface area input. Conclusion: We demonstrated feasibility of using EdgeSeq to generate reliable gene expression data from H&E stained FFPE tissues. In addition, we showed that EdgeSeq platform can be used to generate reliable expression data from crude FFPE tissue lysate equivalent to surface area as low as 0.31 mm² (size of larger laser microdissection tile or half of a tissue microarray core). The data show that EdgeSeq can be considered as a platform of choice to analyze specimens of suboptimal quality or of limited quantity and thus may help to fill the biomarker data gap in oncology clinical trials, including enabling research into patterns of interactions and mechanisms of response and resistance of immune cell engagement with tumor at the loco-regional level.

#5349 Accurate molecular profiling of sequence and copy number alterations from sub-nanogram FFPE DNA amounts. Paola Tononi, Alberto Ferrarini, Genny Buson, Valentina del Monaco, Giulio Bassi, Chiara Mangano, Claudio Forcato, Chiara Bolognesi, Francesca Fontana, Gianni Medoro, Nicola Manaresi. Menarini Silicon Biosystems, Castel Maggiore (BO), Italy.

Introduction: Formalin-fixed paraffin-embedded (FFPE) specimens represent an invaluable source of material for precision oncology. However, FFPE samples pose significant challenges for molecular assays, such as targeted Next-Generation Sequencing (NGS), because of the highly variable DNA quality and often limited sample size. Here we present a complete workflow from sample quality control to targeted library preparation to reliably detect sequence and copy number alterations (CNA) through targeted NGS from extremely low input FFPE samples. Materials & methods: Three FFPE specimens from patients with breast (BrCa) or pancreatic cancer, with DNA quality varying over a broad range and with low tumor cellularity (down to 10%) were selected for targeted NGS profiling. The DNA quality was determined using the DEPArray® FFPE QC Kit, a qPCR-based assay yielding a QC score defined as the ratio between the quantification of a 132 bp amplicon, corresponding approximately to the average length (116bp) of DEPArray Oncoseek amplicons, and a shorter amplicon of 54 bp. The QC scores of the 3 FFPE specimens ranged between 0.23 to 0.74.

#5350 A comprehensive and integrated approach to genomic and proteomic analysis of FFPE NSCLC tumor specimens. Douglas Hinerfield,1 Jennifer Mellen,7 Gary Geiss,7 Philippa Webster,7 Chris Merritt,1 Kristi Barker,1 Lokesh Demir,7 Brian Filanowski,1 Roberto Polakiewicz,1 Katherine Crosby1.

1NanoString Technologies, Inc., Seattle, WA; 2Cell Signaling Technology, Inc., Danvers, MA.

This poster describes a novel fully integrated method for the multiplexed DNA, RNA and Protein analysis of formalin fixed paraffin embedded tumor specimens. Cancer progression is typically a result of aberrations in the molecular pathways that regulate cell growth. Identifying and understanding these changes is necessary for the detection of drug targets as well as the identification of novel biomarkers that can predict response to such drugs. Deep molecular profiling of clinical tumor samples is challenged by limited material and the compromised quality resulting from variable handling and the fixation processes that are commonly employed in the clinical laboratories. While multiplexed gene expression and mutational analysis of such samples has become well established, we describe a new method that enables multiplexed DNA, RNA and protein analysis from a single formalin fixed paraffin embedded (FFPE) tumor specimen on the NanoString nCounter system. We have adapted the sample preparation methods to enable the multi-analyte analysis of FFPE samples and have demonstrated concordance with the clinical gold standard immunohistochemistry (IHC) methodology. As a proof-of-concept, five FFPE non-small cell lung cancer (NSCLC) specimens were simultaneously stained with a panel of antibodies specific to a variety of cancer-relevant proteins, five of which were validated on serial sections by IHC using antibodies from Cell Signaling Technology. In addition to IHC, from the same FFPE casework, the copy number alterations of 770 cancer-related genes and >100 single nucleotide variants (SNVs) were also analyzed on the nCounter platform. By integrating the analysis of DNA SNV’s, as well as RNA and protein expression from single FFPE specimens, it is now possible to reveal the molecular mechanisms of tumor progression, uncover novel drug targets and identify biomarkers from precious specimens.

#5351 A simple yet powerful method to purify NGS compatible RNA from formalin fixed paraffin embedded tissues using FormaPure DNA. Jung H. Dong. Beckman Coulter, Inc., Indianapolis, IN.

Extensive archives of formalin-fixed, paraffin-embedded (FFPE) cancer tissues and next generation sequencing (NGS) capabilities provide rich resources for identifying and validating new cancer biomarkers. However, the ability to conduct FFPE NGS studies has been limited by poor nucleic acid purification methods that are generally difficult and cumbersome to perform, particularly with RNA. FormaPure DNA was recently launched to provide a simplified workflow to extract DNA from FFPE curls. Its nucleic acid binding chemistry employs Beckman Coulter’s proprietary SPRI (solid phase reversible immobilization) technology, which purifies nucleic acids without centrifugation or vacuum manifold. The SPRI technology ensures stronger binding and higher quality purification than other silica-coated bead methods that typically lead to lower quality results due to instances of nucleic acid shearing. Here, we present a modified FormaPure DNA workflow to purify RNA from FFPE samples, offering the flexibility to examine both genomic and transcriptomic roles in cancer.
b biomarkers studies. We show that our extractions yield significantly more RNA (up to 2.5 µg per FFPE curl) and take a fraction of the time to perform compared to other benchmarks. Furthermore, we demonstrate that purified RNA can be used to generate high quality NGS data. Lastly, our extraction method can be automated on a variety of Beckman Coulter’s Biomek liquid handling worksta-
tion for high-throughput FFPE RNA-NGS experiments: RNA from 96 FFPE samples can be purified for NGS in less than 5 hours with minimal hands-on time.

#5352 Optimization of library and enrichment process for RNASeq using RNA from formalin fixed paraffin embedded tissue. Ji Wen, Ying Shao, Ruth Taveosson, Yongji Li, David W. Ellison, Gang Wu, Jinghui Zhang, John B. Easton, St. Jude Children’s Research Hospital, Memphis, TN.

Large repositories of diagnostic formalin-fixed, paraffin-embedded (FFPE) tissue remain underutilized for transcriptome sequence analysis due to degra-
dation of the RNA from the fixation process, which makes the samples unsuit-
able for traditional mRNA sequencing (mRNASeq). The use of random primers to
generate cDNA, and biotinylated exon baits to enrich for coding regions allows for the generation of RNASeq data, but still yields data of variable quality, in part due to differences in FFPE sample processing. We performed a system-
atic analysis to determine which aspects of library construction and the enrich-
ment process can be optimized to provide the best RNASeq data from FFPE samples. The TruSeq RNA Access Library Prep Kit (Illumina) protocol was selected to evaluate optimization procedures for RNASeq from FFPE material. RNA was isolated from FFPE tissue using the Maxwell automated system (Pro-
meq). RNA libraries were also prepared with RNA extracted from frozen tissue of
the matching samples using the TruSeq V2 mRNASeq Library Prep Kit (Illum-
ina) for a comparison of exon coverage metrics. Samples derived from differ-
ent types of pediatric cancer were selected for evaluation, including 2 low-grade gliomas, 2 ependymomas, 9 melanomas and 1 Ewing sarcoma. All of the FF

tumor samples selected contained oncogenic gene fusions, previously identified by analysis of mRNASeq data. The parameters investigated included the initial
amount of RNA input (10ng-400ng), library amplification PCR cycle number (9-15 cycles), and the duration of time for exon probe hybridization (1.5 hours vs 16 hours). The quality of the data was based on the overall library complexity and exon coverage. The complexity of the sequencing was measured using duplication rate (DupRate) defined as a library inserts from different se-
quence reads mapping to the same location in the reference genome; while the
coverage was measured using the percentage of coding bases with coverage > = 20x (PCR20x). Using the RNA Access protocol, we found that the PCR20x metrics were comparable between the FFPE samples and matched FF mRNASeq controls under the non-optimized conditions of 20ng of RNA input, 1.6 hour hybridization, and 15 cycles of PCR for library amplification. However, optimiz-
ing the protocol by increasing the input of RNA to 400ng, reducing the PCR to
between 9-11 cycles, and extending the hybridization time to 16 hours increased
library diversity, reduced the DupRate from greater than 80% to less than 44%,
and increased coding region coverage PCR20x by at least 10%. All expected gene
fusions identified in the RNASeq data from the FF samples were also detected in
the FFPE samples. We have shown that increasing RNA input, reducing PCR
cycles and extending the duration of hybridization can significantly improve data
quality and maximize library diversity, allowing for greater utilization of archi-
val FFPE material for RNASeq.

#5353 High-throughput automation of the 10x Genomics Chromium™ workflow for linked-read whole exome sequencing and a targeted Lynch syn-
drome panel. Renata Pellegrino,1 Michael Benway,2 Paulina Kocjan,3 Andrew Price,3 Charly Kao,1 Brian A. Gerwe,2 Adrian Fehr,3 Fernanda Mafra,1 James Price,3 Charlly Kao,1 Brian A. Gerwe,2 Adrian Fehr,3 Fernanda Mafra,1 James Garifallou,1 Hakon Hakonarson1.1 The Children’s Hospital of Philadelphia, Philadel-
phia, PA; 2PerkinElmer, Hopkinton, MA; 310X Genomics, Inc., Pleasanton, CA

Traditional 2nd generation sequencing strategies have significantly reduced
the cost of sequencing the human genome and provide flexibility to query spe-
cific genome panels, the whole exome, or the whole genome. However, these meth-

odologies are based on short reads which limit their ability to phase/haplotyp
over long genomic distances, accurately map reads between highly homologous
regions (e.g., genes vs. pseudogenes), and robustly detect particular types of
structural variants (e.g., inversions and translocations). Advances in microflu-
lidics technology and precision reagent delivery allows long-range information to
be rescued and preserved through the use of the 10x Genomics Chromium platform. Each input DNA fragment (~40-200kb) is partitioned into a gel-bead in emulsion (GEM), and subsequent biochemistry generates mini-libraries of
NGS-ready molecules tagged with a barcode unique for each GEM. Thus, long-
range context is achieved by linking short reads sharing the same barcode, and

contiguity is established because they were derived from the same input frag-
ment. Importantly, the barcode mini-libraries are compatible with short-read
sequencers and can be implemented as an add-on to existing sequencing infra-
structures. Here we describe and demonstrate how the user-friendly and

uniquely-tuned liquid handling capabilities of the PerkinElmer Sciclone® NGS

assay deliver accurate and consistent results in the face of decreased quality and quantity of nucleic acids extracted from FFPE samples. Understanding the performance of a particular solid tumor profiling assay with FFPE tissue is critical, but with limited and non-renewable samples available to most assay-developers, the sample number used to understand this performance can be small. TruSight® Centaur® Assay from FFPE samples is a powerful tool for exome panel target capture usage. The benefit of automation is essential to the scale-up of high-throughput projects by removing manual variability and increasing effi-
ciency. This partnership offers a unique workflow solution that enables exome
and panel-based LinkedReader sequencing at scale. For Research Use Only. Not for use in diagnostic procedures.

#5354 Evaluation of quantity, quality and performance with the TruSight® Tumor 170 solid tumor profiling assay of nucleic acids extracted from formalin-fixed paraffin-embedded (FFPE) tissue sections. Jennifer S. LoCoco, Teng Linyi, Danny Chou, Xiao Chen, Byron Luo, Jennifer Sayre, Ashley Adams, Nas-

eem Ajili, Cody Chivers, Beena Murthy, Laurel Ball, Allan Castaneda, Katie Clark, Brian Grin, Anthony Daulo, Manh Do, Tingting Du, Sarah Dummm, Yomme Han, Michael Havtken, Chia-Ling Hsieh, Tingting Jiang, Suzanne Jo-
hanssen, Scott Lang, Rachel Liang, Jaime McLean, Yousef Nassiri, Austin Purdy, Jason Rostron, Jennifer Silhavy, June Snedecor, Natasha Talago, Li Teng, Kevin Wu, Chen Zhao, Clare Zlatkov, Ali Kurashiy, Karen Gutekunst, Sohela De Ro-
zieres, Matthew Friedenberg, Han-Yu Chuang, Anne C. Jager. Illumina, San Diego, CA

Solid tumor profiling assays need to deliver accurate and consistent results in
the face of decreased quality and quantity of nucleic acids extracted from FFPE samples. Understanding the performance of a particular solid tumor profiling assay with FFPE tissue is critical, but with limited and non-renewable samples available to most assay-developers, the sample number used to understand this performance can be small. TruSight® Tumor 170 is an Illumina-developed comprehensive solid tumor profiling panel targeting 170 genes using DNA and RNA from FFPE samples. In order to confirm the robustness of the assay with FFPE tissue, 2310 FFPE samples were brought in-house and evaluated. Quantity of both DNA and RNA extraction were determined by various methods, including AccuClear®, Qubit® and Quantifluor® fluorometric assays. Overall, >95% of the samples achieved the minimum concentrations required for the TruSight® Tumor 170 assay. As a surrogate for DNA quality, we measured the amplifica-
tion potential of the nucleic acid by assessing a SureSelect™ baits. This end-to-end automated workflow was used to generate trouble-Free library data on samples with unresolved structural rearrangements and targeted LinkReads in a Lynch syndrome gene, PMS2. LinkReads enable us to 1) fine-map structural rearrangements detected by karyotyping and 2) resolve variants in PMS2 versus those in its homologous pseudogene, PMS2CL, without invoking non-NGS methods such as MLPA or long-range PCR. The benefits of automation are essential to the scale-up of high-throughput projects by removing manual variability and increasing effi-
ciency. This partnership offers a unique workflow solution that enables exome
and panel-based LinkedReader sequencing at scale. For Research Use Only. Not for use in diagnostic procedures.

#5355 PANCeq - Development and validation of a targeted sequencing assay for detection of mutations and copy number changes in most recur-
mantly mutated driver genes. Tobias Meissner, Anu Amalrajha, Brandon Mi-

chael Young, Adam Mark, Cayce Conolly, Amanda Andrews, Casey Williams,
Brian Leyland-Jones. Avera Cancer Institute, La Jolla, CA

Next generation sequencing is becoming increasingly prevalent as a tool for
the identification of genetic variation to aid diagnosis and support therapy de-
cisions in routine clinical care. It has been shown that tumors are comprised of
subpopulations of cells with distinct genomic alterations, and hence tumor heter-
ogeneity is becoming an important factor in deciding treatment. Deep se-
quencing of tumor samples allows for the determination of number and proportions of low variant allele frequency tumor subclones. Currently, high costs for whole-exome deep sequencing (> 250X) limit its application in routine clinical care, and there is a need for more affordable targeted approaches. Here we present PAN Cancer Sequencing (PANCeq), a targeted deep sequencing panel for the detection of single nucleotide variants and copy number variants (CNVs) in currently mutated cancer driver genes. A platform-independent computational Docker-based pipeline for data analysis and automatic report generation was developed. PANCeq uses customized targeted enrichment, followed by next-generation sequencing of (FFPE) tumor and matched germline samples. We included 12 patient samples (breast, ovarian, kidney and prostate) as well as triplicates of 3 reference standards (HD200, HD753, HD733 - Horizon). These were sequenced on Illumina NextSeq on an average depth of 10000X. Sequencing data was aligned using BWA to hg19 human reference. Somatic variants and CNVs were identified using VarDict and CNVkit respectively. We mined TCGA data across 26 tumor types, and selected known mutations from the most recently mutated genes, yielding 2849 mutations across 467 genes. In addition, we included 79 pharmacogenomically relevant and 218 sample tracking SNPs as well as 80 cancer relevant CNVs (whole exom), and designed a custom panel based on their genomic locations, resulting in a panel size of 708kbk. To assess performance, we sequenced reference standards with known variants spiked-in at varying VAF (1 - 41.3%). Somatic variant calling was performed against a wild-type sample. For HD200, out of 21 covered mutations, 14 were correctly classified as germline and 1 as somatic. For HD733, out of 21 mutations, 3 were correctly identified as germline, 18 as somatic. For HD753, all 6 germline and somatic mutations were correctly identified. The 2 CNVs spiked-in were also correctly identified. In all cases we found a good agreement between observed and expected VAF. Somatic variant results for 12 patient samples were compared with variants reported by a private vendor. While we found good agreement at VAF > 20%, our panel detected on average 7 additional clinically relevant mutations at < 20%. We demonstrate that PANCeq is an accurate and sensitive method for timely identification of clinically actionable mutations and copy number variations across multiple cancer types.

Validation of a clinically actionable cancer core gene test for solid tumors facilitating targeted molecular therapy and immunotherapy, Lin Ma, Michael Hua, Steven Rivera, Anna Gerasimova, Quocinh Nguyen, Sirisha Sunkara, Robert Lagier, Alla Smolgovskiy, David Wolfson, Jared F. Taylor, Frederick Racke, Charles Strom, Andrew Grupe, Joseph Catanese, Feras Hantash, David Wolfson, Jared F. Taylor, Joseph Catanese, Feras Hantash.

Molecular profiling of tumor mutations has evolved in molecular targeted therapy for cancer patients. Additionally, tumor mutation load and DNA microsatellite instability (MSI) status can help predict patient’s response to immunotherapy. We analytically validated a gene test targeting clinically actionable cancer genes, including all 4 major tumor type-specific nucleotide variations (SNVs, insertions/deletions (INDELs); whole gene copy number variations (CNVs); and structural rearrangements (translocations) as well as the MSI status. This test interrogates all coding exons from 49 core cancer genes, intrans for a subset of genes selected for detection of prevalent gene rearrangements, and the TERT (telomerase reverse transcriptase) promoter region. MSI status is determined from a set of 5 intronic mono-nucleotide repeats collectively associated with microsatellite instability. Targeted DNA regions are captured by in-solution hybridization with complementary biotinylated RNA baits and sequenced on the Illumina NextSeq®600 platform. Paired format-less, parallel-embedded (FFPE) tumor samples and whole blood samples are analyzed simultaneously for the detection of SNV, INDEL, CNV, translocation and MSI status. FFPE samples can also be analyzed alone if the whole blood sample is not available. ELN is not available eliminating the reporting of MSI status. A minimum of 50 ng FFPE DNA and 100 ng of whole blood DNA are required for this test. A total of 123 FFPE, 2 FFPE FNA samples, 19 paired FFPE and whole blood paired samples covering lung cancer, colorectal cancer, melanoma and breast cancer were included in this validation study. Analytical validation of assay performance demonstrated that, on average, 700-fold read depth was achieved across all the tested genes with > 95% of these regions covered by a minimum of 300 unique reads. Analytical sensitivity was ≥ 5% mutation frequency for SNV and INDEL and ≥ 20% for translocation and CNV. Thirty-eight unique variants were confirmed between this test and orthogonal methodologies: 22 SNVs, 6 INDELS, 5 translocations, and 5 CNV. Fifty-eight out of 59 (98% concordance) paired FFPE/blood samples achieved the same VAF. Sequencing results in whole blood and tumor tissues were useful information to study cancer evolution. However, cost and amount of data may be overwhelming. Enrichment capture-based methods to design custom targeted gene panel have rapidly evolved in cancer genomics area. Custom targeted gene sequencing entails several advantages (i.e., better quality, ethical, developed and analytically validated a core cancer gene test employing NGS technology with demonstrated high analytical sensitivity and specificity. Coupled with clinical interpretation, this test will facilitate decision-making for molecular targeted therapy and immunotherapy.
affordable, technically suitable, personalized and reimbursable) for cancer patients over whole exome and whole genome sequencing. With this in mind, and to enable precision oncology in patients with solid tumors, we developed ICG100 2.0 panel, a hybridization capture-based next-generation sequencing assay for targeted sequencing of all exons and flanking introns of 162 commonly mutated cancer genes in formalin-fixed, paraffin-embedded (FFPE) tissues. To establish ICG100 2.0 panel, we compared three commercially available capture based technologies and evaluated reproducibility, sensitivity, specificity and the detection limit for low-frequency variants using internally developed bioinformatics pipeline. Cell lines, reference standards/synthetic DNA and solid tumor samples with the known genetic information was utilized in this analysis. Results were derived from MiSeq and NextSeq platforms and cross-compared on other platforms, including MassArray and ddPCR for establishing concordance and reproducibility. Intra and interrun replicates were utilized to assess the quality, precision and reproducibility of variant calling. Mean depth of coverage was observed at >300X with >99% sensitivity and specificity. These findings and observations will guide other clinical laboratories to establish new assay that require less DNA input, enzyme based fragmentation and reduced preparation time. While we show that the three capture based methods (after comparison) had an overall accuracy in SNP and CNV detection similar to each other with minor differences, we describe an approach to assess and establish the best assay from the clinical standpoint to guide treatment decisions and match cancer patients to the most appropriate clinical trials.

Targeted cancer therapy based on genomic alterations can be remarkably effective. Currently, cancer genome profiling using next generation sequencing (NGS) is routinely applied in cancer care to guide personalized treatment. The accuracy of this profiling directly impacts therapeutic choices and the outcomes of patient care. We previously showed that false positive variants are abundant and can account for a major fraction of identified somatic variants in publicly available datasets (doi: http://dx.doi.org/10.1101/070334). These false positive variants show signs of mutagenic DNA damage. We further demonstrated that enzymatic DNA repair increases sequencing accuracy by lowering damage-induced background noise. Therefore, enzymatic DNA repair has the potential to improve sequencing accuracy, avoiding incorrect somatic variant calls and consequently reducing incorrect diagnostic conclusions. In this study, we investigated whether enzymatic DNA repair introduces any bias to NGS libraries using analysis by droplet digital PCR (ddPCR) and deep sequencing. DNA Reference Standards containing multiple common cancer mutations (Horizon Discovery, Inc.) were spiked into formalin-fixed paraffin-embedded (FFPE) DNA isolated from tumor samples from different tissue types at defined frequencies (0.5-10% quantified by ddPCR). Genotyping of the FFPE DNA ensured that they were free of any of the spiked-in mutations. After DNA repair and library preparation, mutation frequencies were quantified by ddPCR, and compared to the mutation levels in input DNA and control libraries without repair. Deep sequencing of 151 cancer patients including these spike-ins showed no difference in mutation frequency for the spiked-in mutations between the control and repair groups. However, the number of false positive variant calls was reduced in the repair group. Our data demonstrates that DNA repair significantly increases sequencing accuracy without altering the frequency of actual mutations in tumor samples.

#5361 Predesigned gene content for rapid deployment of custom oncology panels. Andrew J. Barry,1 Amy Emerman,2 Sarah Bowman,1 Kruti Patel,1 Eileen Dimalanta,1 Scott Adams,1 Noa Henig,1 Fiona Stewart,1 Cynthia Hendrickson,2 Theodore Davis,3 Charles Elfe,2 Cynthia L. Hendrickson,1 1Directed Genomics, Ipswich, MA; 2New England Biolabs, Ipswich, MA; 3ThermoFisher Scientific, San Francisco, CA.

Efficient utilization of targeted gene panels for oncology research is challenged by the wide variation in gene constituents specific to a given study. While focused gene panels efficiently provide the necessary depth of coverage for low frequency variant detection, the high costs and design challenges associated with de novo panel design present challenges. The NEBNext Direct™ technology utilizes a novel approach to selectively enrich nucleic acid targets ranging from a single gene to several hundred genes, without sacrificing specificity. The approach rapidly hybridizes both strands of genomic DNA with biotinylated probes prior to streptavidin bead capture, enzymatic removal of off-target sequence, and conversion of captured molecules into sequencer-ready libraries. This results in a unique read coverage profile that results in uniform coverage across a given target. Unlike alternative hybridization methods, the approach does not necessitate upfront library preparation, and instead converts the captured molecules into dual-indexed illumina sequencer compatible libraries containing an 8 basepair sample ID and a 12bp Unique Molecule Index (UMI). The UMI individually tags each molecule prior to the final PCR amplification of the library, enabling identification of PCR duplicate molecules. The result is a 1-day protocol that enables the preparation of sequence-ready libraries from purified genomic DNA specific to the gene content included in the panel. We have designed and developed baits specific to the full exonic content of 450 genes associated with cancer. These are designed, balanced, and pooled on a per gene basis, and can be combined into customized panels, allowing rapid turnaround of specific custom gene subsets. Here, we present the ability to rapidly deploy focused gene panels across a variety of panel sizes and content, while maintaining high specificity, uniformity of coverage across target content, and sensitivity to detect nucleic acid variants from tumor samples.

#5362 Targeting BRCA1 and BRCA2 with NEBNext Direct™. Scott M. Adams,1 Kruti M. Patel,1 Amy B. Emerman,1 Sarah K. Bowman,1 Charles D. Elle,1 Noa Henig,1 Salvatore Russello,2 Andrew Barry Barry,2 Theodore Davis,3 Cynthia L. Hendrickson,1 1Directed Genomics, Ipswich, MA; 2New England Biolabs, Ipswich, MA.

The screening and detection of germline BRCA1 and BRCA2 mutations are critical for the effective management of patients with breast or ovarian cancer and for the identification of individuals with a high risk of developing these cancers. In addition, somatic detection of pathogenic variants in BRCA1/2 can influence treatment decisions due to the susceptibility of tumors with BRCA mutations to PARP inhibitors. Here we introduce the NEBNext Direct™ BRCA enrichment panel for the interrogation of BRCA1 and BRCA2 by Illumina sequencing. NEBNext Direct™ is a novel, hybridization-based method to selectively enrich nucleic acid targets ranging from a single gene to several hundred genes. This approach includes features such as the incorporation of unique molecule identifiers (UMIs) and the ability to capture degraded DNA, enabling accurate detection of low-frequency variants from formalin-compromised DNA and other challenging sample types. We applied the NEBNext Direct BRCA1/2 panel to frozen tissue and achieved a high specificity for the BRCA targets (96% of the sequenced reads mapped to BRCA1 and BRCA2 and 80% of the sequenced bases were within the targeted regions). In addition, the resulting libraries were highly uniform in coverage, with 91% of the targeted bases covered at a value of at least 50X of the mean depth of coverage and 100% of the bases covered at 20X of the mean or greater. Some variability in the specificity was observed with formalin-fixed, paraffin embedded (FFPE) samples, and this effect was dependent on the quality of the FFPE DNA. The UMI s were used to identify PCR duplicates prior to variant calling, as well as for error correction, enabling the accurate detection of low-frequency variants. The library preparation for all samples was completed in one day, and the entire process of library preparation, sequencing on the Illumina Miseq, and data analysis was completed in a total of two days. In summary, we demonstrate that application of the NEBNext Direct™ method to the enrichment of BRCA1 and BRCA2 provides a tractable approach for the rapid and highly sensitive analysis of these cancer-associated genes.

The tumor microenvironment, especially infiltrating T lymphocytes and inflammatory molecules, is believed to be highly relevant to the tumor’s sensitivity to cancer checkpoint blockade therapy. At the same time, the exact markers that are predictive of response for each therapeutic agent are still the subject of active investigations. To address the need for better understanding of the effect of different T cell subsets, antigen presentation, and tumor killing, gene expression profiling presents an attractive means to simultaneously evaluate the tumor microenvironment and cancer cells. In this study we compare the results and performance of the nCounter PanCancer Immune Profiling Panel and the Oncomine Immune Response Research Assay, both of which are designed to measure the expression of genes indicative of an immune response and potential immune-editing activities by tumor cells. The nCounter panel detects gene expression by counting unique probes that hybridize target mRNA, while the Oncomine panel employs NGS to sequence and count reads derived from the targets. While both panels are designed to work with FFPE samples, The nCounter panel expects 100 ng of unamplified RNA, while the Oncomine panel requires only 10 ng total RNA with its AmpliSeq technology. The two panels share 254 common genes, which constitute the basis for this comparison. Across
Combining enzymatic DNA fragmentation with NGS library construction results in high quality, high yield libraries. This assay leverages NGS technology to sequence and count reads derived from the original transcript. With an input requirement of 10 ng of total RNA, libraries were generated, templated on the Ion Chef™ and sequenced on the Ion S5™ System. Results showed that, despite small input amount, the expression profiles of FFPE and fresh frozen samples are highly correlated with an average correlation greater than 0.9. We selected 22 genes out of the panel to validate expression with qPCR using FFPE samples. These genes were selected to cover a range of low, medium, and high expressers per our NGS data. Again, we observed a strong correlation (R ~ 0.9) between NGS and qPCR data. Approximately 80% of the 40 samples show moderate to high expression of CD8+ T cell cytokines, IFNG and TNFa. We further found that the expression of CD8A and CD8B are highly correlated with CD4, suggesting the co-presence of both cytotoxic and helper T cells. High correlation among CD4, FOXP3, TGBF1, and IL2RA (CD25) also suggests that their expression can be used as markers to confirm the presence of Treg cells. We conducted a differential expression analysis between a group of samples (n=8) with high percentage of surrounding and infiltrating lymphocytes and another group (n=5) with low stromal content but devoid of infiltrating lymphocytes. Interestingly, we found a large number of genes which annotated as markers for infiltrating lymphocytes (CTSS, CXCR4, CD37, SRGN, FCER1G, NASP, and GZMA) are significantly upregulated in samples with high percentage of surrounding and infiltrating lymphocytes. In summary, this study highlights the robustness of using a targeted panel to understand the composition and regulatory mechanism of the TME and tumor immune response.

Combining enzymatic DNA fragmentation with NGS library construction results in high quality, high yield libraries. Fiana Stewart, Lynne Apone, Vaishnavi Panchapakesa, Karen Duggan, Jennifer Chen.

The development of a versatile and easy to use genome editing tool based on the bacterial CRISPR/Cas9 system has led to a vast increase in applications of genome editing in laboratories around the world. As an extremely powerful and versatile tool, it has facilitated important discoveries in both basic and translational research as well as in a potentially wide range of therapeutic applications. Nanobacterium gregoryi Argonauta (NgAgo) protein was described as a favorable alternative to Cas9 due to its simplicity and higher endonuclease specificity. Thus far, there are no formal reports documenting the success of NgAgo in other laboratory settings and cellular systems. Utilizing the identical cellular background and protocol that was made publicly available by the authors of the initial study, we were unable to reproduce the endonuclease function of NgAgo. These results do not support the role of NgAgo in gene editing experiments.

Comparative analysis of multiple copy number alteration tools in the detection of amplifications and deletions on both whole-exome and targeted NGS panel platforms. Selene M. Virk, Sean Michael Boyle, Ravi Alla, Jennifer Yen, Richard Chen.

Somatic copy number alterations, or CNAs, are frequent occurrences in the tumor landscape and can present in the form of focal alterations or as chromosome level events. Reliable detection of CNAs is crucial to understanding the impact of these events on a wide range of factors including tumor progression and treatment outcomes. The clinical use of NGS panels, and more recently exomes, continues to expand in cancer but the reliable detection of CNAs remains a challenge. A major factor contributing to the challenge is the availability of reliable tools that have been well tested and validated. We sought to characterize the sensitivity and specificity of multiple CNA detection tools with a focus on clinically relevant genes in NGS panel and whole-exome. Our approach utilized a variety of publicly available CNA tools to identify whole gene amplifications and deletions in genes identified in previously validated database of Somatic Mutations in Cancer (COSMIC) database. The tested CNA tools included two that supported both whole exome and panel NGS data, allowing cross platform in addition to cross tool comparisons. This work involved more than 20 well characterized cell lines derived from a broad spectrum of tumor
types, including breast, lung, melanoma, and prostate cancers. The cell lines were analyzed in both tumor/normal and tumor only (which utilizes a proxy normal)modes. Analyses of patient-matched and proxy-normal data were performed with both assays. Using our approach, we were able to identify clinically relevant CNAs on both platforms. The performance of the tools tested varied, with some tools performing better on either amplification or deletion events. These results represent a comprehensive comparison of recent copy number alteration tools and provides data that can be utilized to make the tools even more robust and reliable.

**MOLECULAR AND CELLULAR BIOLOGY / GENETICS:**

**Epigenetics 5**

**5369 Epigenetic, transcriptomic and ubiquitomic changes associated with BAP1 loss in uveal melanoma.** Stefan Kurtenbach, Jefim N. Kuznetsov, Matthew G. Field, Rohit Reddy, Margaret I. Sanchez, Christina L. Decatur, J William Harbour. University of Miami Miller School of Medicine, Miami, FL.

Uveal melanoma (UM) is the most common primary and aggressive ocular cancer. Up to 50% of the patients develop metastasis, which are notoriously resistant to all forms of therapy and despite medical treatment leads to death within a mean time of 5-7 months, with a mortality rate of over 90%. We previously described that gene expression profiling can be utilized to classify UM tumors into two basic categories, class 1 (low metastatic risk) and class 2 (high metastatic risk). We further described that inactivating mutations in the ubiquitin hydro-lase BAP1 are found in over 85% of class 2 tumors. BAP1 is involved in removing ubiquitin from specific proteins to regulate their function, like histone H2A, thereby regulating gene expression. Building on these findings, we have generated uveal melanoma and melanocyte cell lines that allow for the inducible knockdown of BAP1. First, we performed RNAseq on multiple cell lines before and after BAP1 knockdown and compare the results to gene expression of class 1 and class 2 tumors. We identified significant overlap in key genes linked to metastasis between the primary tumors, uveal melanoma and melanocyte cell lines. Using ChIP-seq to interrogate uveal melanoma cells deleted of BAP1, we identified changes in genome wide histone marks and RNA polymerase localization associated with BAP1. To gain further insight into non-histone deubiquitination targets of BAP1, we performed ubiquitination proteomic profiling using the Ubscan technology and identified a list of high probability BAP1 substrates. Taken together, these complementary genome-wide investigations provide a global picture of the cellular functions of BAP1 and they provide novel insights into the metastasis-promoting effect of BAP1 loss in UM.

**5370 Examination of DNA looping near oncongenes reveals variable patterns of epigenetic landscapes in cancer.** Monika Perez, Ty Johannes. University of Tulsa, Tulsa, OK.

**INTRODUCTION:** The compaction of chromatin in the nucleus into hierarchical (3D) structure plays a key role in the regulation of gene expression. Advancements in high-throughput chromatin conformation capture assays have enabled the determination of this hierarchical structure in a variety of cell states, including cancer. Of note, recent studies have implicated pathogenic alterations in 3D topology of the genome with the activation of proto-oncogenes in a multitude of cancers.

**METHODS:** To characterize the topological changes associated with different cancer types, we examine publicly available epigenetic profiles from the ENCODE Project, including 3D data from Chromatin Interaction Analysis by Paired-End Tag Sequencing (ChIA-PET) from breast cancer and leukemia cell lines. Integrating the chromatin topology data with transcription factor binding, DNAase accessibility, and histone modification data, we uncover variable epigenetic landscapes associated with differentially expressed oncoproteins in these cancer cell lines. RESULTS: We provide evidence of topological variability influencing differentially expressed oncoproteins and tie these observations to other epigenetic changes. In particular, we show insulinated-neighbored mediated by CTFC looping partition segments of the genome containing active oncoproteins away from repressive markers like H3K4me3. Additionally, we show that variation in topology differentially localizes H3K27ac in distal regulatory regions to promoters of oncoproteins, providing a means for gene activation in non-coding regions. CONCLUSIONS: Variable patterns of chromatin topology provide a unique signature and mechanism of oncogenesis for cancerous phenotypes. We use publically available data to show mechanisms of activity associated with chromatin topology variation.

**5371 Effect of DNA methyltransferase inhibitor 5-azacytidine on 3D chromatin structure measured by Hi-C.** Yuchen Vincent Bai, John Whitaker, Emanuele Palescandolo, Vinod Krishna, Vipul Bhargava, Satya Saxena, Xiang Yao, David Palyokey, Kurt Bachman, Jeff, Spring House, PA; Jeff, Beerse, Belgium.

The study aimed at targeting epigenetic modifiers such as the DNA methyltransferase (DNMT) inhibitor, 5-azacytidine (Aza), are used in treating hematologic malignancies and also show promising results in subsets of solid tumors. The molecular mechanisms for these results, however, are not fully understood. Nonetheless, a number of clinical studies using combinations of epigenetic therapies plus chemo or immunotherapy to enhance the tumor response are ongoing. HCT-116, a colon cancer cell line genetically defined by microsatellite instability (MSI), resulting in a highly mutated, yet primarily diploid genome, has been routinely used to study epigenetic mechanisms and response to DNMT inhibition. In a previous study, we investigated a combination of data types including DNA methylation, DNA accessibility, histone modifications and transcriptomic data that revealed strong correlations between epigenomic changes and gene expression following Aza treatment. However, for some genes, we could not predict expression changes using these unidimensional, region-specific analysis methods. As others have demonstrated, genes do not work as single, isolated units, but rather interact with distal regulatory elements. These regulatory elements, often several Mb away can control gene expression through physical interactions such as bending and looping. We reason that in addition to direct regulation of the immediate regulatory elements, the genome-wide effects of Aza treatment can affect long-range chromosomal communications. In order to further understand the chromatin remodeling effect of Aza treatment, we performed high resolution genome-wide chromosome conformation capture (Hi-C) followed by NGS. HCT-116 cells were treated with DMSO or 1 μM Aza for 42 and 96 hours. Hi-C and RNA-Seq data was analyzed and integrated with other datasets. The results showed that Aza treatment alters topologically associating domains (TAD), with the formation of new TAD boundaries and disappearance of others. The genome was then separated into 25K base pair consecutive bins, with each bin marked as type A (active) or type B (inactive). We observed bin switching following Aza treatment and differential loop formations (e.g. promoter-enhancer). Bins that switched from B to A at both time points were found enriched in genes that are related to acute phase response, interferon pathway, and cancer including PIK3CB, DDX58, CD274 and CDRN2A. Our findings using Hi-C were found to be in agreement with previous results using alternative experimental methods, which identified Aza and CTCF as the top upstream regulators of these genes. Our data also suggests that overall changes in 3D chromatin activities measured by Hi-C could be a better predictor of transcriptional regulation compared to H2K27me3 and H3K4me3 alone, particularly in situations where there are no significant changes in those marks but where changes in gene expression exist.
#5373 3D genome architecture changes during cancer cell migration and metastasis. Rachel Patton McCord, Rosela Golloshi. University of Tennessee, Knoxville, TN.

Metastasis, the most deadly part of cancer, results from cancer cell migration and invasion from a tumor into surrounding tissues. During this migration, the cell often undergoes deformations that are crucial for successful invasion. Clear squeezing is a rate-limiting step in migration, and the deformations can even rupture the nucleus. The organization of the genome inside the nucleus into loops, domains, and territories is important for proper gene regulation, DNA replication, and genome repair. However, little is known about the characteristics of nuclear organization that might allow for the nuclear deformation of metastatic cells.

We are using Chromatin Conformation Capture (Hi-C) and microscopy techniques to study genome organization during cancer cell migration. Using photoconvertible fluorescent Dendra2-H4 we drew and monitor patterns on nuclei of cells migrating through dense collagen matrices. Transwell filters, or microfluidic channels. Our data show changes in these patterns, indicating spatial reorganization of the genome during migration. Previous work has suggested that cancer cell migration requires global condensation of the genome. Some cancer chemotherapeutics act on epigenetic marks to decondense chromatin. We are testing whether such chromatin decondensation affects the physical deformability of the nucleus and thus effective migration. We have used Transwell and wound healing migration assays to monitor migration of cells treated with histone deactylase inhibitors and histone methlytransferase inhibitors in DHA and DNA methyltransferase inhibitors (DNMTi). Short chain fatty acids, have been proven to be effective HDACi's, suggesting a possible role for other fatty acids in epigenetic regulation. Research has shown that several omega-3 polyunsaturated fatty acids (PUFAs), specifically docosahexaenoic acid (DHA; C22:6, n-3) and eicosapentaenoic acid (EPA; C20:5, n-3), inhibit tumorigenesis whereas the omega-6 PUFAs linoleic acid (LA; C18:2, n-6) promotes neoplastic growth; supporting the association of elevated cancer incidence with n-6 PUFA dietary intake. We initiated studies to evaluate the impact of omega-3 fatty acids on tumor epithogenic pathways. Therefore we monitored epigenetic alterations in MDA-MB-231 TNBC cells in response to both omega-3 and omega-6 PUFAs in a time and dose-dependent manner. DHA, EPA, and arachidonic acid (AA; 20:5, n-6) elicit apoptosis in a similar manner, indicating that initiating apoptosis is not omega-6 or omega-3 specific. We now show that PUFA incorporation and the resulting attenuated epigenetic changes occur on a time scale proceeding apoptotic induction, indicating that PUFAs may be useful as an epigenetically-targeted cancer therapeutic agent or adjuvant therapy.

#5374 Polyunsaturated fatty acids (PUFAs) alter the epigenetic landscape of human breast cancer cells. Ronald S. Pardini, Amy M. Chattin, Mykelti O’Brien, Ronald S. Pardini. Univ. of Nevada, Reno, NV.

Breast cancer is the second leading cause of cancer-related deaths in US women; 10-20% of which are triple-negative breast cancer (TNBC) subtypes and have the poorest short-term prognosis. This is probably due to an epithelial to mesenchymal transition (EMT) that tumors undergo, de-differentiating into cancer stem cells. Epigenetic reprogramming is proposed to be required for malignant transformation and invasion, particularly in cells undergoing EMT transitions such as TNBC. Therefore, altering the epigenetic landscape in metastatic TNBC lines would provide researchers with a unique opportunity to sensitize tumors to treatment and induce apoptosis. Epigenetic research chiefly focuses on the epigenetic alterations that are characteristic of human diseases and on the potential of DNA methyltransferase inhibitors (DNMTi) to sensitize cancer cells to chemotherapy. In this study, we tested the hypothesis that polyunsaturated fatty acids (PUFAs) would alter the epigenetic landscape of breast cancer cells. We chose three common PUFAs: DHA, EPA, and AA. The incorporation of PUFAs into the cell membrane increased with increasing PUFAs and was concentration-dependent. Interestingly, we found that DHA and EPA caused a decrease in histone H3 acetylation and an increase in histone H3 methylation. Although this was consistent across the Human Mammary Epigenome Chip (HI-C) and microscopy techniques to study genome organization during cancer cell migration. Transwell filters, or microfluidic channels. Our data show changes in these patterns, indicating spatial reorganization of the genome during migration. Previous work has suggested that cancer cell migration requires global condensation of the genome. Some cancer chemotherapeutics act on epigenetic marks to decondense chromatin. We are testing whether such chromatin decondensation affects the physical deformability of the nucleus and thus effective migration. We have used Transwell and wound healing migration assays to monitor migration of cells treated with histone deactylase inhibitors and histone methlytransferase inhibitors (DNMTi). Short chain fatty acids, have been proven to be effective HDACi's, suggesting a possible role for other fatty acids in epigenetic regulation. Research has shown that several omega-3 polyunsaturated fatty acids (PUFAs), specifically docosahexaenoic acid (DHA; C22:6, n-3) and eicosapentaenoic acid (EPA; C20:5, n-3), inhibit tumorigenesis whereas the omega-6 PUFAs linoleic acid (LA; C18:2, n-6) promotes neoplastic growth; supporting the association of elevated cancer incidence with n-6 PUFA dietary intake. We initiated studies to evaluate the impact of omega-3 fatty acids on tumor epithogenic pathways. Therefore we monitored epigenetic alterations in MDA-MB-231 TNBC cells in response to both omega-3 and omega-6 PUFAs in a time and dose-dependent manner. DHA, EPA, and arachidonic acid (AA; 20:5, n-6) elicit apoptosis in a similar manner, indicating that initiating apoptosis is not omega-6 or omega-3 specific. We now show that PUFA incorporation and the resulting attenuated epigenetic changes occur on a time scale proceeding apoptotic induction, indicating that PUFAs may be useful as an epigenetically-targeted cancer therapeutic agent or adjuvant therapy.

#5375 Oncogenic BRAF mutation induces widespread DNA hypermethylation in a murine model for human serrated colorectal neoplasia. Vivki Whitehall1, Catherine Bond1, Cheng Liu1, Futoshi Kawamata1, Diane McKeone1, Saara Jamieson1, Sally Pearson1, Susan Woods2, Tasmin Lannigan3, Lochlan Fennell4, Winnie Fernando1, Mark Bettington1, Daniel Worthingley5, Barrie Towner6, JQMR Berghefer Medical Research Institute, Herston, Australia; 1University of Adelaide, Herston, Australia; 2University of Adelaide, Adelaide, Australia.

BACKGROUND: The serrated colorectal neoplasia pathway describes the progression of morphologically serrated polyps to cancer and accounts for approximately one third of all colorectal cancer cases. Human serrated polyps are characterized by the presence of the BRAF mutation in the oncogene and widespread DNA methylation changes termed the CpG Island Methylator Phenotype. A causative versus synergistic relationship between BRAF mutation and this methylator phenotype has not been determined. We aimed to address this by developing a murine model for serrated neoplasia driven by BRAF mutation.

METHODS: BRAF+/− conditionally active mice were crossed with intestine-specific, inducible Villin-CreERT2 mice to direct the BRAF mutation to the intestine at 2 weeks of age. The proximal ileum or proximal colon were sampled at defined time points including 10 days, 10 weeks, 5 months, 8 months, 10 months, 12 months and 14 months. Macrophscopic lesions larger than 10 mm were bisected for molecular and histological assessment. The entire remaining intestine was fixed and examined histologically. DNA methylation was investigated for 94 genes known to be methylated in colorectal cancer using Epitect Methyl II Complete PCR Arrays (Qiagen).

RESULTS: BRAF mutant mice displayed histologic changes analogous to the human serrated neoplasia pathway. Extensive intestinal hyperplasia developed by 10 days post induction of the BRAF mutation. By 10 weeks, 50% mice had developed areas of crypt dilatation reminiscent of human sessile serrated adenomas. By 8 months, the majority of mice had murine serrated adenomas with dysplasia and invasive cancer developed in 40% of mice by 14 months, one of which metastasised to the liver. Compared to age-matched control mice, BRAF mutant mice showed significant, gene-specific increases in DNA methylation from 5 months (p<0.0001).

CONCLUSIONS: Using an in vivo model we observed the temporal accumulation of DNA methylation changes in hyperplastic epithelium in direct response to mutation of the BRAF oncogene. This murine model morphologically and molecularly recapitulates the human serrated neoplasia pathway and establishes a causative role for BRAF mutation in establishing a methylator phenotype.

#5376 Requirement of TET2 in MLL-AF9 mediated leukemogenesis. R. Nathan, Golam Mohi. SUNY Upstate Medical University, Syracuse, NY.

TET methylcytosine dioxygenase 2 (TET2) catalyzes the conversion of 5-methylcytosine to 5-hydroxymethylcytosine resulting in DNA demethylation. Loss-of-function mutations or deletions of TET2 have been found in several cancers. TET2 is a member of the TET family of 5-methylcytosine dioxygenases, which also includes TET1 and TET3. TET family members play important roles in hematopoietic lineage specification. genitor colony formation in the BM. In addition, deletion of TET2 resulted in increased overall survival in mice expressing MLL-AF9. Together, these data indicate that TET2 is required for leukemic transformation mediated by MLL-AF9. Our results suggest a novel tumor promoter function for TET2 in MLL rearranged leukemia.

Purpose: While the impact of DNA methylation at the promoter region as a repressive influence is well-known, the vast majority of DNA methylation actually occurs outside of the promoter region. The function of intragenic DNA methylation remains incompletely understood. Here, we investigate how intragenic DNA methylation impacts gene expression, and how these modifications differ between normal and corresponding cancer tissues. Methods: A pan-cancer analysis of gene expression array data was integrated with Illumina 450k methylation array data across ten tumor types to produce correlation values between DNA methylation and gene expression at distinct loci on a genome-wide basis. The probes exhibiting a significant correlation between gene expression and DNA methylation were selected for further analysis. Results: We uncovered robust positive correlations between gene expression and 3' methylation in 3,200 genes, with 590 genes in bladder cancer, and 258 genes in squamous cell lung carcinoma displaying a correlation coefficient of >0.5. Furthermore, we observed 44 genes with a correlation coefficient of >0.7 in at least two tissue types. The majority of genes with the strongest correlations are transcription factors known to play roles in differentiation and development, with an enrichment of zinc finger and homeobox-containing genes. Further analysis of these genes exhibit divergent 3' methylation when comparing normal and tumor tissues. Importantly, the extent of 3’ methylation of these genes is associated with patient overall survival in 5 of the 10 tumor types analyzed, strongly suggesting that this process plays a role in cancer pathogenesis. Conclusion: DNA methylation of the 3’ region is a functionally and clinically relevant epigenetic modification, and may serve as a novel target for inhibiting tumorigenesis and tumor progression.

#5378 Genes involved in development and differentiation are commonly methylated in cancers derived from multiple organs: A single-institutional methylehyme analysis using 1007 tissue specimens. Kentaro Ohara,1 Eri Arai,1 Yoriko Takahashi,2 Nanako Ito,1 Ayako Shibuya,1 Koji Tsuta,1 Ryoji Kushima,1 Hitoshi Tsuda,4 Hidenori Ojima,2 Hiroyuki Fujimoto,4 Shun-ichi Watanabe,2 Hitoshi Katai,1 Takayuki Kinoshita,4 Tatsuhiro Shibata,3 Takashi Kohno,3 Yae Kanai1, 4Keio University School of Medicine, Tokyo, Japan; 5Mitsui Knowledge Industry Co., Ltd., Tokyo, Japan; 6National Cancer Center Research Institute, Tokyo, Japan; 7National Cancer Center Hospital, Tokyo, Japan.

Aim: The aim of this study was to clarify the significance of DNA methylation alterations shared by cancers derived from multiple organs. Background: Little is known about DNA methylation alterations during carcinogenesis shared by various organs. In this single-institutional study, consistency of sample quality, diagnostic criteria, and technical platforms was prioritized for providing an overall view of DNA methylation profiles of cancers arising in multiple organs. Methods: We analyzed single-institutional methylation data by Infinium HumanMethylation27 or HumanMethylation450 BeadChip (Illumina) for 1,007 samples of non-cancerous tissue (N) and corresponding cancerous tissue (T) obtained from the lung, stomach, kidney, breast, and liver. Results: Principal component analysis revealed that N samples of each organ showed distinct DNA methylation profiles, DNA methylation profiles of N samples of each organ were inherited by the corresponding T samples and DNA methylation profiles of T samples being more similar to those of N samples in the same organ than those of T samples in other organs. We identified 2,636, 2,209, 1,915, 2,914 and 5,665 probes that were aberrantly methylated in lung adenocarcinomas, gastric adenocarcinomas, clear cell renal cell cancer, breast cancers (e.g. invasive ductal carcinomas, ductal carcinomas in situ and invasive lobular carcinomas) and hepatocellular carcinomas, respectively, in comparison with the corresponding N samples. When we examined pairs of organs, only 6.9% (between stomach cancers and kidney cancers) to 35.4% (between lung cancers and breast cancers) of aberrantly methylated probes were shared between cancers of any two organs, indicating that the majority of DNA methylation diverge among multiple organs. In contrast to such organ and/or carcinogenetic factor-specificity of DNA methylation profiles, when compared to the corresponding N samples, 231 genes commonly showed DNA hypermethylation in T samples in four or more organs. Gene ontology enrichment analysis showed that such commonly methylated genes were enriched among “transcriptional factors” participating in development and/or differentiation, which reportedly show bivalent histone modification in embryonic stem cells. Pyrosequencing and quantitative reverse transcription-PCR revealed an inverse correlation between DNA methylation levels and mRNA expression levels of representative candidate methylated genes such as ALX1, ATP5A1, and ABCA1, in tissue samples. Conclusion: These data suggest that disruption of the differentiated state of precancerous cells via alterations of expression, independent of differences in organs and/or carcinogenetic factors, may be a common feature of DNA methylation alterations during carcinogenesis in multiple organs.

#5379 TET2 loss and the lymphoma-associated RHOA mutation cooperate to disrupt CD4+ T cell function. Shengqiang Zhang,1 Jia Li,2 Haiyan Yang,2 Wei Han,1 Jixiang Zhang,3 Minjing Lee,1 Yubin Zhou,1 Dqinguan Sun,1 Yun Huang,1,2 Texas A&M University, Houston, TX; 3Zhejiang Cancer Department, Houston, TX.

Peripheral T cell lymphomas (PTCLs) are a group of rare but aggressive lymphomas derived from mature T cells or natural killer cells with a dismal prognosis. Current treatments for PTCLs are ineffective with high relapse rates, largely owing to the lack of targeted therapeutics and a deep understanding of the molecular etiology. Recent exome sequencing has unveiled the frequent co-existing somatic mutations in RHOA (G17V) and TET2 in PTCLs, but not in other types of hematological malignancies. Most notably, mutations in both TET2 and RHOA are frequently observed (~60-70%) in angioimmunoblastic T-cell lymphoma (AITL), which is among the most common subtypes of PTCLs with a median overall survival of approximately 1.5 years. Patients with AITL are often associated with autoimmune manifestations, but the mechanistic underpinnings remain unresolved. To examine whether TET2 loss and RhoA(G17V) alter mature T cell function, we performed adoptive T cell transfer experiments with WT or Tet2 knockout transgenic mice. Using this strategy, we generated four groups of recipient mice transferred with T cells as follows: WT, RhoA(G17V), Tet2-/-, or Tet2-/- RhoA(G17V). Among these four groups, only recipient mice transferred with double mutant T cells displayed severe inflammatory-like phenotypes that ultimately led to early lethality in mice. Moribund mice transferred with Tet2-/- RhoA(G17V) T cells showed substantial weight loss, severe skin ulcer on tail/paw/ear accompanied with pruritus, and lymphomagely as typically seen in AITL patients. Histopathological analysis on major organs derived from the Tet2-/- RhoA(G17V) group indicated severe infiltration of both T and B lymphocytes in major organs, as well as a pronounced increase in the numbers of follicles and activated germinal centers in lymph nodes. Further analysis indicates that Tet2 loss and RhoA(G17V) mutation cooperated together to exclusively promote CD4+ T cell proliferation and survival, and exert no adverse effects on CD8+ T cells, which recapitulates the mutation spectrum detected in AITL patients, i.e., RhoA(G17V) is primarily detected in CD4+ T cells but not other T cell subsets. The functional consequence of Tet2 loss and RhoA(G17V) expression in CD4+ T cells is characterized by an imbalance between the effector and regulatory T cells, which may account for the overt immunoinflammatory phenotypes seen in mouse models. The transcriptome analysis further revealed a pronounced remodeling of the immune signaling network that points to the aberrant transcription of several key inflammatory factors. The present study demonstrated a previously-unappreciated cooperativity between Tet2 loss and RhoA(G17V) mutation in disrupting mature CD4+ T cells function, which is made through the synergy between epigenetic and GTPase signaling pathways. The results obtained from this study provide an additional basis for future development of new diagnosis, prognosis and therapy for PTCL patients.

#5380 Inactivation of endogenous genes in cancer cells using targeted promoter DNA methylation via CRISPR-DNMT3a fusion protein. Simon D. Spivack. Albert Einstein College of Medicine, Bronx, NY.

Background: Developing technologies for precise manipulation of individual DNA methylation loci is an attractive challenge in cancer and lung biology, because aberrant expression via hyper- or hypo-methylation is so common. Projects such as ENCODE and the Roadmap Epigenomics Project have identified thousands of epigenetic marks from human genome. However, the functional evaluation of these marks has been largely limited to determining their associations with gene expression. Technologies for targeting manipulation of epigenetic marks would allow direct experimental testing of the impact of DNA methylation at specific residues, mechanisms of gene regulation, and potential use as interventions, for example to silence constitutively active oncogenes. Methods: Here, we developed a CRISPR Cas9-based tool for specific DNA methylation in which the catalytic domain of DNMT3a (DNMT3a-Cd) is fused to the carboxy-terminus of Cas9 D10A-H840A mutant (dCas9). Both construct promoter strength and transfection strategies were optimized. Results: We demonstrated...
targeted and consistent CpG methylation in 30–100bp regions downstream of the PAM (binding) site of the gRNA guided fusion protein in HEK293 cells. The multiple guide RNAs could target the dCas9-DNMT3A to multiple sites consistently. DNA methylation activity was specific for the targeted region and was heritable across cell divisions. We also found directed promoter DNA methylat-

#5381 A highly sensitive method for noninvasive cancer profiling through targeted methylation sequencing of circulating cell-free DNA. Li Liu,1 Jona-
than M. Young,1 Raakhee Vijayaraghavan,1 Ruoyu Zhang,1 Helen J. Huang,2 Toshinori Hinoue, Hui Shen,1 Neeraj Salathia,1 Marina Bibikova,1 Richard Shen,1 Karen Guitekunst,2 Peter W. Laird,1 Filip Januk,1 Jian-Bing Fan,1 Illumina, San Diego, CA; 3MD Anderson Cancer Center, Houston, TX; 2Van Andel Research Institute, Grand Rapids, MI. Liquid biopsies, by analyzing circulating cell-free DNA (cfDNA), have emerged as a promising tool for noninvasive cancer diagnostics and monitoring. Compared to the limited number of scattered DNA mutations in cancer pa-

#5383 Non-invasive diagnosis of early-stage lung cancer via targeted high-
throughput DNA methylation sequencing of circulating tumor DNA (ctDNA). Xu Yu Cai, Yangbin Gao, Hui Shen, Peter Laird, Jian-bing Fan, Weihong Xu, Wenhua Liang, Jianxing He. AnchorDX Medical Co. Ltd., Guangzhou, China. Current state-of-the-art lung cancer early screening involves using low-dose CT scan to identify lung nodules smaller than 3cm in diameter. However, it’s still a clinical dilemma to differentiate between malignant and benign nodules. We took the approach of methylation profiling by high-throughput bisulfite DNA sequencing in tissue samples to identify specific methylation signatures. We learned methylation patterns that differentiate malignant vs. benign lesions from tissue samples by in-depth data mining, and then used pattern matching to classify plasma samples. Given the usual low amount of ctDNA in plasma, we also developed an ultra-sensitive library preparation method to perform target-

#5384 Aberrant methylation of ANK1, the host gene for miR-486, distingu-
sishes lung tumors by histology and smoking status. Mathewos Tessema,1 Christin M. Yingling,1 Maria A. Picchi,1 Guodong Wu,1 Tyron Ryba,2 Young Lin,3 Steven A. Belinsky3.1 Lovelace Respiratory Research Institute, Albuquerque, NM; 2New College of Florida, Sarasota, FL. MicroRNAs (miRs) regulate many fundamental biological processes primarily through inhibiting the transcription and/or translation of their target genes. MiR-486 is an intragenic miR located within ANK1, a gene that encodes for the adapter protein ankyrin-1. Although the tumor suppressor role of miR-486-5p and its down-regulation in non-small cell lung cancer (NSCLC) is well estab-

MOLECULAR AND CELLULAR BIOLOGY / GENETICS: Epigenetics 5
Epigenetic modifications, particularly DNA methylation in selected gene promoters is a pivotal role in the development of colorectal cancer. DNA methylation is considered as one of the most important epigenetic mechanisms and it is catalyzed by DNA methyltransferases (DNMTs). DNMT1 abundance has been frequently seen in colorectal cancers but the reasons are not well understood. We are interested in the effect of chemotherapeutics used in treatment of colorectal cancer on expression of DNMT1 and this effect is achieved over which signalling pathway. In this study, GS/K38, IPW2 for β-catenin) and chemotherapeutics (oxaliplatin, fluorouracil, irinotecan) were detected by WST1. DNMT1 expression level was determined by real-time PCR, and protein levels of GS/K38, pGS/K38(Ber9), Akt1, pAkt1(Ser473), β-catenin, pβ-catenin(Ser675) and DNMT1 were detected. We expected to increase the protein level of DNMT1 expression with coordinate transcriptional change via β-catenin pathway. Fluorouracil and irinotecan decreased DNMT1 expression at both transcriptional and translational levels but not oxaliplatin. Oxaliplatin increased DNMT1 expression at mRNA and protein levels. This effect is achieved by specific phosphorylation of β-catenin protein. The results revealed that use of some chemotherapeutic, particularly oxaliplatin, with specific inhibitors (such as β-catenin inhibitor) in combination led to a reduced DNMT1 expression. Our findings may offer a new approach for determining the molecular effects of β-catenin signal pathway on DNMT1. This may allow us to identify new molecular targets for the treatment of colorectal cancers. However, the results revealed that some chemotherapeutics may contribute the aberration of DNA methylation.

Background: Droplet digital PCR (ddPCR) is a highly sensitive method for quantification of nucleic acids, with great potential for detection of biomarkers present in low quantities. As for DNA methylation analyses using ddPCR, there is no consensus on whether or not a control should be included. The aim of the present study was to: 1) demonstrate that use of a control is essential in such analyses, and 2) develop a robust control with better performance than the existing alternatives. Results and methods: A 4-gene control panel was developed in our lab, and its performance compared to the existing alternatives ACTB and C-LESS-C1. This was done through analyzing the methylation level of four target genes in DNA from 34 colon cancer cell lines. All ddPCRs were performed using the QX200™ PCR platform (BioRad). Details will be presented. Conclusions: In summary, use of a control is essential for robust and consistent ddPCR based DNA methylation, and can prevent erroneous interpretation of technical artifacts.

#5388 Molecular profiling of protein methyltransferases in prostate cancer and their clinical significance, YanJian Jiang, Lixin Liu, David Weinfeld, Wengi Shaan, Huimei Yu, Xuhui Guo, Zhe Yang, Zeng-Quan Yang, Wayne State Univ. School of Medicine, Detroit, MI.

Prostate cancer is one of the most commonly diagnosed cancers among men worldwide. Most deaths of prostate cancer patients occur after the disease has progressed to castration-resistant prostate cancer, accompanied by metastatic dissemination and resistance to androgen-deprivation therapy. Therefore, an urgent need exists to identify druggable targets that will improve the treatment of this deadly and devastating disease. Epigenetic alteration has been identified as one the major causes of prostate cancer. Protein methyltransferases (PMTs), a large class of epigenetic enzymes that add one or more methyl groups to lysine (K) and arginine (R) residues on histones and non-histone proteins, play critical roles in chromatin function, transcriptional regulation, genomic stability, DNA repair and RNA metabolism. Although dysregulation of several PMTs has been reported in prostate cancers, there has been no systematic analysis of genomic anomalies and expression of PMTs in prostate cancer. In addition, the clinical relevance of alteration of each PMT in prostate cancer has yet to be fully explored. Here, we performed an integrated genomic and transcriptomic analysis of 68 PMT genes in prostate cancer (TCGA dataset) and identified associations among recurrent copy number alterations, gene expressions, clinicopathological features, and survival of patients. In addition to well-known EZH2 and WHSC1, we identified several additional PTMs, including SETDB1, SETD6 and PRB1D2, which were significantly overexpressed in high-grade and high-stage prostate cancer. We also found that SETDB1 overexpression was significantly associated with biochemical recurrence of prostate cancer patients. To assess the contribution of endogenous SETDB1 overexpression to prostate cancer growth and progression, we examined the effects of knock-
ing down SETDB1 in two prostate cancer cell lines CWR22Rv1 and DU-145. SETDB1 knockdown dramatically reduced CWR22Rv1 and DU-145 cell growth compared with the non-silencing control. We also identified all SETDB1 binding sites across the human genome in DU-145 prostate cancer cells by using an unbiased ChIP-seq approach. In summary, our integrated genomic and transcriptional analysis identified a broad spectrum of genetic alterations in PMT genes involved in prostate cancer progression. Our findings suggest a promising avenue for future research—to focus on a subset of PMTs to better understand the molecular mechanisms and to identify therapeutic targets in prostate cancer.

#5389 A personalized medicine approach to identifying dysregulated epigenetic enzyme activity in the development of castrate-resistant prostate cancer. Jin-Hee Lee,1 Melissa Boersma,2 Bing Yang,3 Nathan Damaschke,1 Eva Coe,ry,3 John Denu,1 David F. Jarrard.1, 1Univ. of Wisconsin-Madison, Madison, WI; 2Wisconsin Institutes for Discovery, Madison, WI; 3Univ. of Washington, Seattle, WA.

Purpose: Recent advances in proteomic and chromatin immunoprecipitation tools have been vital in studying cancer epigenetics, but the ability to measure directly the enzyme activities of dysregulated histone-modifiers understood. We utilize a novel approach to identify altered histone-modifying enzymes in the progression from hormone sensitive (HS) to castrate-resistant prostate cancer (CRPC) progression. Methods: We developed, validated and utilized a high-throughput peptide microarray assay to identify altered histone lysine (de)acetylation activity in tumor lysates. Functional assays, novel HS and CRPC human tumor arrays and xenografts were utilized to confirm these findings. Results: This microarray-based activity assay revealed up-regulated histone acetyltransferase (HAT) activity against specific histone H3 sites in a castrate-resistant (CR) PCA cell line compared to its hormone-sensitive (HS) isogenic counterpart. NAD+-dependent deacetylation assays revealed down-regulated Sirtuin activity in validated CR lines. Levels of acetyltransferases GCN5, PCAF, CBP and p300 were unchanged between matched HS and CR cell lines. However, auto-acetylation of p300 at K1499, a modification known to enhance HAT activity and a target of deacetylation by SIRT2, was highly elevated in CR cells, while SIRT2 protein level was reduced in CR cells. Interrogation of HS and matched CR xenograft lines reveals that H3K18 hyperacetylation, increased p300 activity, and decreased SIRT2 expression are associated with progression to CR in 8/12 (66%). Tissue microarray analysis revealed that hyperacetylation of H3K18 is a feature of CRPC. Inhibition of p300 results in lower H3K18ac levels and increased expression of androgen receptor. Conclusions: This novel microarray approach provides a method to identify commonly dysregulated chromatin enzymes during progression providing a personalized therapeutic strategy to direct available drugs to target enzymes. Reduced SIRT2 expression and increased p300 activity lead to a concerted mechanism of hyperacetylation at specific histone lysine sites (H3K9, H3K14, and H3K18). Support: DOD PCRP (Jarrard).

MOLECULAR AND CELLULAR BIOLOGY / GENETICS: Genomic Analyses of Circulating Tumor Material and RNA

#5390 Broad Genomics and Cancer Program development of comprehensive blood biopsy sequencing capabilities to support direct-to-patient cancer research. Carrie Cibulskis, Andrew Hollinger. Broad Institute of MIT and Harvard, Cambridge, MA.

Genomic profiling of cell free tumor DNA (Blood Biopsy) offers the potential to revolutionize cancer precision medicine. As a proxy for tumor tissue profiling, successful blood biopsy analysis can help select appropriate patients for clinical trials, provide useful data for treatment monitoring, and discover genomic mechanisms of disease resistance. Recognizing these potential benefits, we aim to enable large-scale genomic data generation and analysis of cfDNA samples to support the patient driven Metastatic Breast Cancer Project (mbcproject.org) and many other such efforts. The widespread adoption of cfDNA sequencing technology in clinical research will require low cost, efficient, and in some cases clinically-validated processes. Commercial offerings in this field are focused on analysis of small targeted hotspot panels due to the challenges of more complete sequencing approaches for cfDNA (e.g. variability in the fraction of tumor present and high false positive rates). Working in collaboration with the Broad Institute Cancer Program, we have developed a process to overcome these challenges and provide high quality comprehensive exome analysis of cfDNA. Our process includes screening samples using ultra low pass, UMI-enabled whole genome sequencing to quantify the % of tumor DNA available for sequencing. Qualified samples are then moved into automated processes for exome sequencing and somatic mutation detection. In our initial validation study of 23 breast and prostate cancer patients with matched cfDNA and tumor DNA, we were able to identify 99% of clonal and 45% of subclonal mutations found in the matched tumor biopsy. In our effort to scale this process, and fully characterize the benefits and limitations of this technology we will present additional validation analysis. We will evaluate the relative importance of using paired sample analysis (tumors and matched normals) with analysis of tumor sequencing alone and assess sensitivity and specificity of somatic alterations as a function of tumor fraction and sequencing depth.

#5391 Low frequency variant detection and tissue-of-origin exploration using liquid biopsies. Justin S. Lenhart, Ashley Wood, Sukhinder Sandhu, Cassie Schumacher, Laurie Kurihara, Vladimir Makarov, Tim Harkins. Swift Biosciences, Ann Arbor, MI.

The promise of liquid biopsy assays lies in the non-invasive monitoring of diseases, such as cancer, through circulating, cell-free DNA (cfDNA) or circulating tumor cell DNA. This may assist in advancing early-stage diagnosis while simultaneously monitoring treatment response over time. Since these materials are often limited, most liquid biopsy assays incorporate targeted sequencing to enable cost-effective deep coverage of target loci for detection of low frequency pathogenic variants. Yet a critical aspect in attaining the necessary sensitivity is an assay that produces uniform, comprehensive coverage from low DNA input quantities. We have developed a liquid biopsy workflow to enable low frequency variant detection from a 10 ml blood draw using the Promega Maxwell RSC combined with Swift Biosciences Accel-NGS 28 library preparation methodologies. In addition, we explore whether methylation patterns of the extracted cfDNA possess information of the tissue-of-origin. Whole blood samples were collected in Streck cell-free DNA BCT vials from patients with late stage cancer and cfDNA was extracted with the Promega Maxwell RSC. This instrument yielded DNA outputs ranging from 8-32 ng, with a size profile defined by a predominant peak of ~170 bp and a mean Alu repeat qPCR integrity score of 0.22, characteristic of high quality cfDNA lacking cellular DNA content. A total of 20 ng cfDNA was used to make an Accel-NGS 28 Hyb library followed by hybridization capture using Agilent SureSelect Human All Exon probes. The Accel-NGS 28 Hyb Kit exhibits a 90% library conversion rate with cfDNA and provides high complexity libraries with uniform target coverage. In addition, molecular barcodes were incorporated to label each library molecule uniquely prior to PCR amplification. These molecular barcodes were utilized for accurate removal of PCR duplicates while simultaneously preserving naturally occurring fragmentation and strand duplicates to maximize data recovery. Secondly, these barcoded molecules were grouped to generate consensus sequences after removal of false positives originating from PCR and sequencing errors. Variant calling was performed using Vardict and Lofreq enabling highly sensitive and precise detection of variants down to 0.5% allele frequency. In parallel, we have developed a workflow to determine if the epigenetic status of cfDNA can identify tissue-of-origin. This workflow utilizes the Accel-NGS Methyl-Seq DNA Library Kit to enable unbiased characterization from low (5 ng) cfDNA characterization from low (5 ng) cfDNA inputs. Through whole genome bisulfite sequencing, using a priori knowledge of differentially methylated regions characteristic of different human tissues, we can identify the predominant tissue source of cfDNA in blood.
relation between the presence of cancer mutations and morbidity and mortality. In 2 of 11 women, the initial absence of mutations above 1% allele-frequency was followed by the appearance of mutations in 1-3 genes at allele frequencies of 5-78% in the later time point. These 2 patients experienced increased morbidity or mortality. In 9 of the 11 women, no mutations were observed, and 6 remain in remission currently living with cancer. In an effort to further improve both workflow and performance, we are developing two technologies to incorporate into the panel design for future studies. The first will normalize library yield during PCR amplification for simple library pooling, which eliminates the requirement for library quantification and minimizes the time from sample to sequence. The second technology is a molecular ID (MID) system to tag each amplicon uniquely to allow data tracking. By integrating these two technologies, we will improve the efficiency of our workflow and increase confidence in variant calling by filtering PCR and sequencing errors. By incorporating technologies that reduce steps in the workflow, the likelihood of error is minimized, and combined with methods that increase confidence in low frequency variant calling, an ideal workflow for liquid biopsy samples is created.

#5393 BRAFT mutant allele fraction in circulating tumor DNA as marker of treatment response in BRAF mutated non malignant melanoma cancers identified in the Copenhagen Prospective Personalized Oncology study. Lise Barlebo Ahlborn, Ida Villen Tuxen, Olga Oestrup, Anne Yde Schmidt, Cecilie Bruhn Hoffhansson, Finn Cellius Nielsen, Ulrik Lassen, Christina Westmose Yde, Morten Mau-Sorensen. Rigshospitalet, Copenhagen, Denmark.

Background: BRAF inhibitors have been approved in BRAF mutated malignant melanomas. However, in other BRAF positive cancers, the effect of BRAF inhibition has been studied less extensively. BRAF mutated non-melanoma cancer patients (pts) were identified in a prospective genomic profiling study. The effect of targeted treatment was assessed by BRAF mutant allele fraction (AF) in circulating tumor DNA (ctDNA) and radiological response. Methods: Pts had tumor biopsies performed at enrolment and, if feasible, on or after treatment. Biopsies were subjected to whole exome sequencing, RNA sequencing and SNP array. Blood samples for ctDNA analysis were collected at baseline and longitudinally during treatment. Mutant BRAF fragments were quantified using droplet digital PCR (ddPCR) or by targeted next generation sequencing (NGS). Radiological response was evaluated according to RECIST 1.1. Results: Twenty-two BRAF mutated non-melanoma cancer pts (lung n=2, colorectal n=14, bile duct n=4, prostate n=1, pancreas n=1) were identified out of a total of 405 (5%) pts enrolled in the Copenhagen Prospective Personalized Oncology (CoPPO) study. In all tumors we identified the BRAF V600E mutation except in one prostate cancer pt (BRAF K601E). Fifteen pts were treated with dabrafenib/trametinib (lung, bile duct), vemurafenib/pamitumumab (+/- irinotecan (colorectal) or vemurafenib (pancreas, prostate). Two pts were non-evaluable because one patient requested early termination and one has pending tumor evaluation. All pts had tumor reduction, except one patient with colon cancer. Six out of 13 (46%) pts achieved partial response (lung n=2, bile duct n=1, colorectal n=3) and 7/13 (44%) had stable disease (prostate n=1, bile duct n=1, colorectal n=5) as best response according to RECIST 1.1. Median progression-free survival was 20 weeks. Eighteen pts analysed by ddPCR or NGS at baseline had detectable mutant ctDNA. In the patient with early termination of therapy, the ctDNA levels decreased by 70% during the first 6 weeks. Eight of the 18 pts had ctDNA assessed during treatment and all presented with a reduction in mutant BRAF AF corresponding to a reduction in tumor volume. Moreover, in 5/8 pts, time of best radiological response coincided with the lowest detectable BRAF mutant AF. Analysis of on- and post-treatment biopsies and matched ctDNA samples are pending to identify putative mechanisms of resistance and will be reported at the meeting. Conclusion: Targeted therapy seems active in BRAF mutated non-melanoma cancer pts and treatment response is evaluable by monitoring mutant BRAF in ctDNA during therapy.

#5394 The clinical impact of multiplex ctDNA gene analysis in lung cancer. Smadar Geva,1 Anna Bellilovsky Rozenblum,1 Tal Twito,1 Addie Dvir,2 Lior Soussan-Gutman,2 Maya Ilouze,1 Laila C. Roisman,1 Elizabeth Dudnik,1 Alona Zer,2 Richard B. Leman,4 Nir Peled4 Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel; 2Teva Pharmaceutical Industries Ltd., Israel; 3Institute of Oncology, Davidoff Cancer Center, Rabin Medical Center, Petach Tikva, Israel; 4Guardant Health, Inc., Redwood City, CA.

Background: Next-generation sequencing (NGS) of cell-free circulating tumor DNA (ctDNA) enables a non-invasive option for comprehensive genomic analysis of lung cancer patients. Currently there is insufficient data in regard to the impact of ctDNA analysis on clinical decision making. In this study, we evaluated the clinical utility of ctDNA sequencing on treatment strategy and progression-free survival. Methods: In this retrospective study, data was collected from 92 NSCLC patients monitored between the years 2014-2016 at the Thoracic Center Unit at Davidoff Cancer Center, Rabin Medical Center, Israel. Plasma samples from stage IIIb/IV non-small cell lung cancer (NSCLC) patients were analyzed by a commercial test (Guardant 360), using hybrid capture, single molecule barcoding and massively parallel paired-end synthesis to sequence a targeted gene panel. This test allows the detection of somatic alterations in tumors among patients at different stages of malignancy. Results: 92 consecutive NSCLC patients were included in this study. Median age at diagnosis was 63 years, male:female ratio was 1:1.6. 40% (37/92) were never-smokers, 84% (77/92) had adenocarcinoma. 38% (35/92) performed ctDNA analysis before 1st line therapy and 62% (57/92) on progression. ctDNA analysis yielded lung cancer related actionable mutations in total 39% (36/92) of the patients. ctDNA analysis was positive in 46% (42/92) patients at progression on matched therapy. Treatment decision was taken toward targeted therapy subsequently to nGS analysis in 23% (8/35) and 26% (15/57) respectively (total 25%; 23/92). 53 individual actionable genomic alterations were found. The most common genes were sensitizing EGFR mutations (47.2%; 25/53), MET amplifications and/or exon 14 skipping mutations (17%; 9/53) and resistance EGFR mutations (13.2%; 7/53). Response assessment (RECIST) for 18 patients with evaluable response to targeted therapy showed complete response in 6% (1/18), partial response in 39% (7/18), stable disease in 22% (4/18) and progressive disease in 33% (6/18). Total objective response rate (ORR) was 45% and disease control rate was 67%. Conclusions: Comprehensive ctDNA testing revealed possible treatment options for two-thirds of patients analyzed. ctDNA analysis could be used as a clinical decision making in a question of a biopsy. Although this topic needs to be further assessed in large randomized controlled trials, these positive results emphasize the utility of liquid biopsy analysis to guide clinicians to select the right therapy for the right patient.

Background: Small cell lung cancer (SCLC) is a highly aggressive malignancy with rapid development of chemo resistance and a high rate of recurrence. Although tumor tissues-based studies have shown characteristic genomic changes in SCLC, it is little known about tumor-derived genomic variations in cell free DNA (cfDNA), a promising source of genetic materials for monitoring disease progression, evaluating treatment efficacy and predicting clinical outcomes. Methods: We collected plasma from 26 SCLC patients and extracted cDNAs from 250µl of plasma. We prepared DNA libraries and analyzed sequencing data using various bioinformatic tools. We binned read counts from the mapped sequence files into 60kb windows and performed log2 ratio-based copy number analysis using segmentation-based approach. We compared copy number changes detected in cfDNA to previously reported genomic regions from tumor tissues-based studies. Results: The whole genome sequencing generated approximately 9.4 million mappable sequence reads per subject and 175 read counts per 60kb genomic region. Copy number analysis using log2 ratios between cfDNA and matched gDNA showed significant genomic abnormalities in 17 of 26 plasma samples. Overall, we observed the most frequent deletion of 3p, 13q, 17p, 10p and amplification of 3q, 5p, 8q, 1p, which were consistent with previous reports from tumor tissues-based studies. To further define the copy number changes, we performed a detailed analysis at chromosomal regions showing frequent aberrations in SCLC. Among these, deletion of gene RASSF1 at 3p21.3 was most frequently observed (12 deletions in 26 samples). Another common deletion was RB1 at 13q14 (5/26), TP53 at 17p13 (4/26). The most common amplification was involved in MYC gene at 8q24 (18/26). Other common amplifications included SOX2 at 3q26 (17/26), MYCL at 13p42 (9/26) and FGF10 at 5p13 (9/26). We also observed low frequent genomic alterations at other genomic regions such as PTEN loss at 10q23 (1/26) and FHTI loss at 3p14 (1/26). Interestingly, we observed contradictory genomic changes at MAD1L1 locus. Among the 26 cfDNA samples, we detected ten patients with MAD1L1 loss and four patients with MAD1L1 gain. We have shown that the MAD1L1 locus at 7p22 is frequently amplified in SCLC patients. We are currently analyzing if these genomic variations are associated with disease progression and overall survival. Conclusions: This study provides a comprehensive analysis of genomic aberrations in plasma cfDNAs from SCLC. We identified multiple candidate genes whose genomic aberrations may be used as biomarkers for accessing treatment efficacy and predicting prognosis. Our results suggest plasma as an alternative sample source for tumor-associated genomic analysis in SCLC patients. Further targeted sequencing and clinical association analyses is needed to fully validate the potential clinical utilities of cfDNA-based liquid biopsy for clinical management of this deadly disease.
#5396 An NGS workflow to detect down to 0.1% allelic frequency in cfDNA for breast and colon cancers. Dalia Dhringa,1 Richard Chien,1 Jian Gu,2 Dumitru Brinza,1 Ruchi Chaudhary,1 Kunal Banjara,1 Yanchun Li,2 Efren Ball- esteros-Villagrana,2 Kelli Bramlett2,2,3,4Thermo Fisher Scientific, South San Francisco, CA;3Thermo Fisher Scientific, Austin, TX.

Noninvasive detection of rare mutations in blood could allow tumor monitoring for research purposes. Research studies have suggested that cfDNA contains DNA from tumor cells with somatic mutations that could inform on tumor progression and therapeutic resistance. Here, we demonstrate a complete workflow from a single tube of blood through data analysis for research samples down to a 0.1% allelic frequency. The low abundance tumor mutations found in cfDNA represent accurate tumor detection rates of 0.1% when the two panels that utilize an amplification-based assay that generates tagged DNA copies, which allows detection of low abundance tumor mutations found in cfDNA. The two panels allow multiplex interrogation of primary driver and resistance mutations specific to cfDNA from breast and colon cancer. The Oncomine Colon cfDNA panel targets 236 hotspots within 14 genes while the Oncomine Breast cfDNA panel and Oncomine Colon cfDNA panel had over 85% sensitivity and 100% specificity. The Oncomine Breast cfDNA panel and Oncomine Colon cfDNA panel integrated into a complete workflow starting from a single tube of blood was validated from matched single blood tubes, Streck and K2EDTA. Finally confirmed with TaqMan based Rare Mutation assays. With this control, we developed an oncology control for cfDNA workflow that was validated from matched single blood tubes, Streck and K2EDTA. Additionally, the utility for cancer research was demonstrated with concordance studies using matched FFPE and plasma from oncology samples. To further characterize these panels we have developed an oncology control for cfDNA with nucleosome fragment sizing and minimal sonication damage. This engineered DNA contains multiple SNPs and indicative of allelic frequency, originally confirmed with TagMan based Rare Mutation assays. With this control, the Oncomine Breast cfDNA panel had over 81% sensitivity and 99.9% specificity. The Oncomine Colon cfDNA panel had over 85% sensitivity and 100% specificity. The Oncomine Breast cfDNA panel and Oncomine Colon cfDNA panel integrated into a complete workflow starting from a single tube of blood can advance oncology research with the ability to detect blood based cancer biomarkers present at 0.1%.

#5397 Characterizing the genomic landscape of bladder cancer with circulating tumor DNA. Gillian R. Vandenkerkhove,1 Tilman Todenhofer,2 Matti Annala,3 Werner J. Struss,1 Kevin Beja,1 Amanda Wong,1 Scott North,1 Bernie Eigl,1 Peter Black,1 Alexander W. Wyatt1.1Vancouver Prostate Centre, Vancouver, British Columbia, Canada;2University Hospital Tübingen, Tübingen, Germany;

3Institute of Biosciences and Medical Technology, Tampere, Finland;4Cross Cancer Institute, Edmonton, Alberta, Canada;5British Columbia Cancer Agency, Vancouver, British Columbia, Canada.

Background: Targeted agents are emerging as promising treatment options for patients with metastatic bladder cancer (BCa). However, since the genomic landscape of BCa is highly heterogeneous, future clinical trial success will likely depend upon tumor molecular stratification and therefore require a practical method for genomic analysis. Circulating cell-free tumor DNA (cfDNA) collected from peripheral blood has been established in several major solid malignancies as a minimally-invasive tool to profile the tumorgenome but is underexplored in BCa. Goal: Our aim was to identify the spectrum of clinically-informative genomic alterations detectable in plasma cell-free DNA (cfDNA) collected from patients with BCa. Patient cohort and methodology: We recruited 45 patients with BCa, 14 with localized disease and 31 with metastatic disease, and collected whole blood samples for isolation of cfDNA. Isolation of plasma cfDNA was performed using the QIAmp Circulating Nucleic Acid Kit, while germline control DNA was extracted from buffy coat using the DNeasy Kit (Qiagen). A custom targeted next-generation sequencing (NGS) strategy was employed to detect BCa-specific somatic alterations in cfDNA; samples underwent deep (>=30X) targeted DNA sequencing using the NimbleGen SeqCap EZ Choice system and Illumina technology. Our custom panel included key tumor suppressors (e.g. TP53, RB1, CDKN2A), cell cycle drivers (e.g. CCND1, CCNE1), DNA repair genes (e.g. ATM, BAP1, ERCC2), PIK3 pathway genes (e.g. PIK3CA, PTEN, AKT1), and other oncogenes (e.g. RAS/RAF, EGFR, ERBB2, PPARG, FGER3). Results: The majority of patients with metastatic BCa (18/31 patients, 24/43 samples) had robust evidence of somatic alterations and therefore cfDNA. Our findings were consistent with the known landscape of BCa, including mutations in TP53 and ARID1A (and other chromatin modifiers), hotspots activating mutations in PIK3CA, as well as typical copy number changes such as focal amplifications of ERBB2, KRAS, and CCNE1. In addition, we identified complex gene rearrangements including in one case an activating FGFR3 fusion. Some samples had evidence of very high mutation rates, indicative of somatic ‘hypermutation’. Interestingly, in contrast to the metastatic setting, 85% of patients with localized BCa had no evidence of cfDNA, despite elevated cfDNA yields in some patients. Conclusion: The majority of metastatic BCa patients have high levels of cfDNA suitable for standard targeted sequencing approaches, while patients with localized muscle-invasive tumors appear not to harbor ctDNA at fractions greater than 1-2%. The robust detection of so-called ‘ actionable’ copy number alterations, mutations and rearrangements in ctDNA provides an unparalleled opportunity for practical molecular stratification of patients in clinical trials of novel targeted agents.

#5398 High-throughput clonal analysis of AML tumors with droplet microfluidics. Dennis Eastburn,1 Maurizio Pellegrino,1 Sebastian Treusch,1 Adam Sciambati,1 Bill Hyun,1 Jamie Yates,2 Mission Bio, Inc., San Francisco, CA;2University of California, San Francisco, San Francisco, CA.

Single cell analysis tools are crucial to better understand the role that rare or heterogeneous cancer cells play in the evolution of tumor progression. Although, it is now feasible to perform single-cell RNA-Seq on thousands of, several challenges remain for high-throughput single-cell DNA sequencing. To address these challenges and enable the characterization of genetic diversity in cancer cell populations, we developed a novel approach that barcodes amplified genomic DNA of individual cells confined to microfluidic droplets. The barcodes are used to assemble the genetic profiles of individual cells from next generation sequencing data. A key feature of our approach is the “two-step” microfluidic workflow that releases genomic DNA from cellular proteins prior to amplification. The microfluidic workflow first encapsulates individual cells in droplets, lyses the cells and prepares the lysate for genomic DNA amplification using proteases. Following this lysate preparation step, the proteases are inactivated and droplets containing the genomes of individual cells are then paired with molecular barcodes and PCR reagents. We demonstrate that the two-step microfluidic approach is vastly superior to workflows without the two-step process for efficient DNA amplification on tens of thousands of individual cells per run with high coverage uniformity and low allelic dropout of targeted genomic regions. To apply our single-cell sequencing technology to the study of acute myeloid leukemia (AML), we developed a targeted panel to sequence genes frequently mutated in AML including TP53, DNM3TA, FLT3, NPM1, NRAS, KRAS, JAK2, IDH1 and IDH2. Using this panel, we were able to identify clonal populations from AML research samples; moreover, the single-cell nature of our approach enabled the correlation of multiple mutations within subclones and determination of whether the mutations existed as a homozygote or heterozygote. Collectively, our results show a greater degree of heterogeneity in AML tumor samples than is commonly appreciated with bulk sequencing methods. Investigating phenotypic plasticity in breast cancer with high-throughput nanogrid single-nucleus RNA sequencing. Ruli Gao,1 Charissa Kim,1 Emi Sei,1 Jie Yang,1 Leo Chan,2 Mathreyran Srinivasan,2 Hong Zhang,1 Funda Meric-Bernstam,3 Nicholas E. Navin1,4University of Texas MD Anderson Cancer Center, Houston, TX;2WafGen Inc., CA.

Single-cell RNA sequencing (RNA-seq) is a powerful tool for investigating rare tumor subpopulations and resolving intra-tumor heterogeneity, but is low throughput, expensive, and requires fresh tissue samples. To address these limitations, we developed a 5’ high-throughput single-nucleus RNA sequencing (SNRS) approach that uses a nanogrid platform to perform high-throughput single-cell RNA sequencing and screening of 500–2500 nuclei in parallel. The automated image scanning procedure allowed us to exclude doublets and select live cells with DAPI/PI staining. This approach allows the transcriptomic profiling of frozen tissue samples, in which the cytoplasmic membrane is ruptured in cells, but leaves the nuclear membrane intact. We validated SNRS in a breast cancer cell line (SK-BR-3) and compared the transcriptomes of 500 nuclei to 500 whole cells, which revealed a high concordance in the number of genes expressed as well as their expression levels. We also performed bulk RNA-seq of isolated nuclear and cellular fractions from 5 breast cancer cell lines, which showed a high concordance in genes and expression levels. Differentially expressed genes in the nucleus mainly included lincRNAs, pseudogenes and mitochondria genes, but did not affect most cancer genes and pathway analysis. We further applied SNRS to sequence 500 nuclei of a triple-negative breast cancer patient and identified diverse phenotypes in tumor cells, including variation in cell proliferation, migration, invasion, and epithelial-to-mesenchymal transition. These studies demonstrated the technical feasibility of using a nanogrid platform to perform high-throughput single-cell RNA sequencing and showed that nuclei from cell lines and tumors can be used to study signaling pathways and gene networks that play an important role in tumor progression.

#5400 Accurate identification of single nucleotide variants in whole genome amplified single cells. Xiao Dong,1 Lei Zhang, Brandon Millholland, Moonsoon Lee,2 Alexander Y. Maslov, Tao Wang, Jan Vijg, Albert Einstein College of Medicine, Bronx, NY.

1MissionBio, Inc., San Francisco, CA; 2Uni-

Volume 58, 2017 1382
Single cell sequencing for analyzing DNA mutations across the genome in somatic tissues is critically important for studying development, cancer and aging. However, current procedures are prone to artifacts and to date a reliable protocol for single-cell somatic mutation analysis remains to be developed. Here we address the two largest sources of artifacts, i.e., DNA denaturation-related cytosine deamination and allelic bias-driven whole genome amplification errors. We first reconfigured multiple displacement amplification (MDA) into an efficient protocol for whole genome amplification of single cells without cyto- sine deamination artifacts, i.e., Single Cell MDA (SCMDA). We then developed a new single-cell SNV caller (SCcaller) that distinguishes real somatic mutations and amplification errors by utilizing a SNP-based localized estimate of allelic amplification. Our procedure was validated by comparing SCMDA-amplified single cells with unamplified clones derived from single cells from the same population. Together with SCcaller, SCMDA provides a firm foundation for analyzing cellular heterogeneity in somatic mutational landscapes in tumor and surrounding, normal tissues.

#5401 Assessment of whole genome amplification for whole exome sequencing in detecting genetic mutation. Crystal Xue, Laura Gardener, Guanglong Jiang, Fei Shen, Bryan Schneider. Indiana Univ. Cancer Ctr., Indianapolis, IN.
Whole exome sequencing (WES) has been widely used for studying genetic mutations in DNA coding regions to elucidate cancer etiology and for identifying biomarkers to optimize chemotherapy. However, these studies can be limited when only small amount of DNA is available. Whole genome amplification (WGA) technology can be combined with WES to make these studies technically possible. Here, we evaluated WGA using a phi 29 polymerase prior to library preparation for WES in samples with various DNA concentrations. WES was performed by targeted exon amplification followed by massively parallel sequencing. We compared the base calls of single nucleotide variants for individual same samples with or without WGA prior to library construction to determine the concordance rate of variant calls. We also assessed genetic variant call rate in the same samples with or without WGA. The number of variants obtained ranged from 353,215 to 384,118 in the same amplified samples. The average concordance rate of identical variants in the samples with or without WGA was 96.5%. Our results indicate that WGA in prior to WES can increase detection efficiency of single nucleotide variants in samples with relatively small amount of DNA and/or low DNA concentration.

#5402 Single cell sequencing of high grade serous ovarian cancer. Timothy K. Starr,1 Boris Winterhoff,2 Makayla Maile,3 Kenneth Beckman,4 Jerry Daniel,5 Melissa Greninger,6 Mariel Guazzo,6 Molly Klein,3 Rafaelle Hellweg,6 Astrid Kretschmar,6 Amit K. Mitra,7 Attila Sebe,8 Sally A. Mullaney9 1 Univ. of Minnesota Medical School, Minneapolis, MN; 2 Univ. of Minnesota, Minneapolis, MN; 3 Paul Ehrlich Institute, Langen, Germany.
We performed RNA sequencing of single cells derived from a high grade serous ovarian cancer (HGSOC) specimen to determine the extent of heterogeneity and to determine if it was feasible to identify cancer stem cells or gene expression signatures of chemo resistance. To perform RNA sequencing we enzymatically digested a fresh specimen from an HGSOC derived from the ovary. Immune cells were depleted by flow cytometry and single cell sequencing was performed using the Fluidigm C1 chip in tandem with Illumina HiSeq 2500 sequencing. Multiple bioinformatics tools were used to identify subgroups and activated pathways. Immunohistochemistry was performed on an adjacent tissue section to analyze markers of epithelial stroma and stem cells. We found that gene expression patterns in single cells could be used to separate cells into stroma-like and epithelial-like groups. Gene set enrichment analysis identified proliferative genes (oxidative phosphorylation and MYC targets) associated with the epithelial-like cells while epithelial-to-mesenchymal transition (EMT) genes associated with the stroma-like cells. Neutrophilic group was significantly associated with genes derived from chemo-resistant cells. Using known marker analysis, we could identify a small percentage of cells that expressed ovarian cancer stem cell markers and we could group cells into functional categories. Using four molecular subtypes established from large-scale bulk sequencing studies we show that single cells from a single patient are heterogeneous and each molecular subtype is represented. In conclusion, we show the feasibility of performing single cell sequencing on an epithelial ovarian cancer and reveal a heterogeneous population of cells. Expanding these findings to a larger cohort of patients could allow for identification of targetable sub-populations of cells that were previously undetectable in studies that use bulk samples to interrogate the transcriptome and genome of ovarian cancer patients.

#5403 Reproducible elevation of RNA versus DNA mutation signal in low purity breast tumors. Jerez Te,1 Coralie Viollet,1 Xiujun Zhang,2 Jatinder Singh,1 Jeffrey A. Hooke,2 Harvey B. Pollard,1 Hai Hu,3 Craig D. Shriver,3 Clifton L. Dalgaard,4 Matthew D. Wilkerson1 1Uniformed Services University; 2John P.Murtha Cancer Center; Walter Reed National Military Medical Center, Bethesda, MD; 3Chen Soon-Shiong Institute of Molecular Medicine at Windber, Windber, PA.
Background: Accurate detection of somatic mutations is critical for informing targeted therapy options. Prevalent non-cancer cell admixture complicates this detection in breast cancer. Conventional mutation detection relies on DNA sequencing; however in prior work, we demonstrated that combining RNA and DNA mutation analysis increased signal strength fraction (MAF) by 21% in the breast (MAF). The ratio of RNA MAF versus DNA MAF (RNA:DNA MAF) was greatest in low purity breast tumors. We hypothesized that this elevation is biologically driven and would be conserved in a second, distinct tissue specimen of the same tumors. Here, we compare mutation characteristics between two tissue blocks in a cohort of breast tumors (n = 8) to evaluate possible preservation of RNA versus DNA mutation signal throughout the tumor. Methods: We selected four high purity and four low purity breast tumors (“Block 1”) from The Cancer Genome Atlas (TCGA) cohort and associated ABSOLUTE purity analysis. For these tumors, we acquired a second tissue block (“Block 2”) not analyzed by TCGA, cut, analyzed sections by H&E stains, and extracted nucleic acids. Whole genome DNA sequencing and mRNA sequencing was performed for_Block 1 and Block 2 respectively, and compared the MAFs on these samples. Somatic mutations in Block 2 were detected using UNCeqR and compared to published UNCeqR somatic mutations from TCGA. We then evaluate MAF characteristics in the entire TCGA cohort. Results: Tumor purity estimates, determined by histology and by sequencing, were reduced in Block 2 of the low purity tumor set versus the high purity tumor set, consistent with Block 1 analysis. Molecular properties of genome-wide gene expression and somatic DNA copy number were highly similar between block-matched specimens (ρ < 0.01). We then identified expressed mutations present in Block 1 and Block 2 of the same tumor and compared the MAFs on these common mutations. DNA MAF and RNA MAF were each significantly correlated between Block 1 and Block 2 (ρ < 1e-12 in both cases). The average RNA:DNA MAF was 2.5 for the cohort, indicating that RNA mutation signal is greater than DNA in general. In Block 2 specimens, the RNA:DNA MAFs were significantly greater in the low purity tumor set than the high purity tumor set (mean 2.7 versus 2.1, p < 6e-5), reflecting the same trend observed in Block 1 specimens. Analyzing the entire TCGA cohort, RNA:DNA MAF was positively correlated with proliferation pathway gene expression (ρ < 3e-16) and was greatest in the Basal subtype versus other subtypes (ρ < 2e-9). Conclusion: Mutant allele fraction both of DNA and of RNA was conserved across breast tumor subsections. Low purity and basal subtype breast tumors had elevated RNA:DNA MAF supporting a relationship to underlying biology and identifying classes of tumors with pronounced benefit for DNA and RNA integrated mutation analysis.

#5404 Functional analysis of IncRNAs in pancreatic ductal adenoarcinoma. Luis Arnes, Jiguang Wang, Zhaoli Liu, Carlo Maurer, Lori Sussen, Kenneth P. Ouel, Raul Rababan. Columbus University, New York, NY.
Pancreatic ductal adenocarcinoma (PDA) is anticipated to be the second leading cause of cancer related death in western countries by 2030 with a 5-year survival rate of 6%. Recently, genome wide sequencing and transcriptome analysis have been applied to identify cancer driving mutations and mRNA expression profiles of pancreatic tumors. Despite a better understanding of the molecular drivers and the signaling pathways deregulated in PDA, this knowledge has not been able to identify novel therapeutic targets. A common limitation for the aforementioned studies is that they have been performed in bulk samples, and they have been focused on mutations and gene expression analysis of protein-coding genes, which represents less than 2% of the genome. Long non-coding RNAs are emerging as essential players in the biology and progression of a variety of tumors. However, this concept has not been extensively explored to the study of PDA. We have developed computational methods and performed experimental validation to identify functional IncRNAs drivers of tumor progression in pancreatic cancer. Specifically, we have developed computational tools to identify IncRNAs associated with genomic traits of PDA using genome wide high throughput data. The analysis uncovered the existence of 1741 IncRNAs that we termed ncPDA (non-coding PDA). Using a unique RNA-seq dataset from >200 laser capture microdissected pancreatic tumors, we selected these ncPDA that are expressed specifically in the neoplastic epithelium of human pancreatic tumors. Within the top 100 ncPDA enriched in neoplastic epithelial cells, we identified known IncRNAs drivers in other tumor types such as CRNDE (ncPDA4), P2rt (ncPDA 9), HOTAIR (ncPDA 39), Malat1 (ncPDA 68) and Neat1 (ncPDA 71). We are currently exploring the role of several ncPDA in
pancreatic cancer cell lines. Loss of function studies suggest that several ncPDAs are required for tumor progression. Our investigation will continue to unravel the role of ncPDAs in the initiation and progression of pancreatic cancer.

#5405 Comprehensive analysis of long non-coding RNAs in human stomach adenocarcinoma molecular subtypes. Jian Chen, Juan-Sheng Chen, Keping Xie, John R Stroehlein, Marta Davila, Xiaoping Su. UT MD Anderson Cancer Ctr., Houston, TX

Objective: Long non-coding RNA (lncRNA) plays key role in cell biology including epigenetic remodeling and post-transcriptional regulation. The potential roles of lncRNAs as biomarkers and therapeutic targets have been proven in solid tumors. Molecular profiling in stomach adenocarcinoma (STAD) has been characterized using The Cancer Genome Atlas (TCGA) database. However, there are no current lncRNA comprehensive analyses and the relationships between patterns of molecular subtypes and the signature of lncRNA in in human stomach adenocarcinoma are unclear. Methods: (1) The Cancer Genome Atlas (TCGA) 312 primary STAD RNA-Seq data (bam files) and their related clinical data were obtained from the Cancer Genomics Hub and TCGA Data Portal. (2) We filtered the dataset to remove lncRNAs with low expression, defined as having an RPKM value <1 in at least 90% of the tumor samples. (3) We generated a correlation matrix between lncRNAs and mRNAs by computing the Pearson correlation coefficient between all pairs of significant lncRNAs and mRNAs. A matrix was constructed with entries in the ternary scale (-1, 0, 1), where the top 1% with negative correlation was assigned -1; the top 1% with positive correlation was assigned 1; and the others were assigned 0. The matrix was clustered and visualized using a Euclidian distance metric of RNA complementary linkage clustering. Results: (1) Using stringent criteria, we identified 1830 expressed lncRNAs in human genome in STAD. (2) Unsupervised clustering of lncRNA expression in STAD revealed five robust categories: clusters C1-C5. (3) We further performed concordance calculation between lncRNA-based clustering and other clusters identified in TCGA molecular, mRNA, msiRNA and SCNA subtypes, respectively. We also investigated the association of lincRNA subclasses with distinct clinicopathological and genomic features of STAD. We found that C2 is significantly associated with MSI molecular subtype, MHL silencing, and mRNA C2, miRNA C2, methylation C2 subtypes. Cluster C3 is significantly associated with EBV-positive molecular subtype, C6DKNA2 silencing and mRNA C2, miRNA C2, methylation C1 subtypes; C4 is most significantly associated with CN molecular subtype, p53 mutation and high SCNA, methylation C4 subtypes; C5 is significantly associated with CS molecular subtype, diffuse Lauren subtype, and mRNA C1, miRNA C4, methylation C1 subtypes. Interestingly, C5 defines the most aggressive tumors with the worst overall survival. Conclusions: Our study represents the first comprehensive analysis of lncRNAs in STAD cancers, with integrative analysis revealing that the signatures of lncRNAs characterize here appear to have prognostic significance. The additional association with the STAD molecular subtypes and genomic features supports new approaches to developing biomarkers and setting the stage for a new framework for future research in the role of lncRNAs in STAD.

RNA-seq has become the most popular method for transcriptome analysis and is widely used to study gene expression, detect mutations, fusion transcripts, alternative splicing, and post-transcriptional modifications. It is becoming the method of choice to detect alterations in diseases, especially cancer, to provide insights on the various molecular pathways perturbed by changes in the transcriptome and study their implications. As RNA-seq is being adopted in molecular diagnostics and biomarker identifications, the need for good quality, reproducible library preparation methods has increased with the availability of the more powerful bioinformatics methods. Enhanced sensitivity to detect transcripts with even coverage across their length offers a non-biased approach for accurate quantification of transcript levels. Methods: Enriched poly-A mRNA or ribo-depleted RNA (Universal Human Reference RNA) was used to make libraries with our strand specific library preparation method. Library quality and quantity were analyzed on an Agilent Bioanalyzer, pooled at equimolar ratio and sequenced on Illumina’s Nextseq 500. Paired end reads were mapped to a human reference genome (hg19) using Hisat2 and sequencing metrics were calculated using Picard’s RNA-seq Metrics and RSeqC tools. Transcript abundance was measured using Salmon and the RSeqC tool. Resolution of GDS sequences were obtained from RNAseq by generating a strand-minded method using inputs that range from 5ng to 1ug show greater than 98% directionality at all input levels. GC content analysis, gene body coverage and gene expression correlation are similar for all inputs tested (5ng to 1ug), even though input amounts vary by over three orders of magnitude. These consistent results are recapitulated with the spiked-in ERCC controls at all inputs. Conclusions: Our library preparation method is streamlined and can be used for a wide range of input RNA without any major modifications to the protocol, making it an easy to follow, convenient method for RNA-seq library preparation. In addition, our method has increased sensitivity and specificity, especially for low-abundance transcripts, reduced PCR duplicates and sequence bias, delivering high quality strand-specific data even for low input RNA. Finally, our method is compatible with both poly-A enriched and non-poly-A depleted samples, and is amenable to large-scale library construction and automation.

#5407 Integrated analysis of genome-wide microRNA and mRNA profiling reveals deregulated miR-125b associated with poor prognosis by reducing cell apoptosis in gastric cancer. Ben Liu,1 Da Yang,2 Fengju Song,1 Xining Zhang,1 Yan Guo,1 Yanrui Zhao,1 Hong Zheng,1 Wei Zhang,2 Kexin Chen.1

Tianjin Medical University Cancer Institute and Hospital, Tianjin, China; 2University of Texas MD Anderson Cancer Center, Houston, TX

Background & Aims: In our prior study, an integrated analysis of microRNA and mRNA profiling of gastric cancer (GC) revealed a microRNA-regulatory network. It defined a GC microRNA subtype that was associated with poor survival in 90 GC cases. In this study, we further demonstrate that miR-125b, a key node in this microRNA regulatory network, is upregulated in GC and associated with poor overall survival by interfering in the apoptosis pathway. Methods: To further investigate the role of miR-125 in GC, we conducted both an in vitro experiment and clinical study (cohort of 373 GC samples). miR-125b and targets in the network were validated through RT-PCR and tissue microarray GC cases. The miR-125b targeted gene and related pathway were identified by a gene expression profile analysis in miR-125b transfected GC cell lines. The Annexin V-FITC and TUNEL assay were used to assess apoptosis. MTT and flow cytometry were performed to detect the effect of miR-125b on proliferation and cell cycle. The wound healing test and transwell assay were used to analyze migration and invasion. Results: The markedly upregulated expression of miR-125b was validated in 373 GC samples. Univariate and multivariate analyses find that the miR-125b was associated with poor prognosis (p = 0.011). Pathway analysis shows that the predicted targets of miR-125b are highly involved in apoptosis/program death pathway. The robust apoptosis genes, BIK and CASP6 are validated as the directed targets of miR-125b. miR-125b can suppress apoptosis and increase cell growth, migration and invasion in GC cell lines. Furthermore, low expression of BIK (p = 0.034) and CASP6 (p = 0.048) in GC were associated with poor disease-free survival. Conclusions: The apoptosis pathway was found to be dominant in the pathway construction based on target genes of miR-125b. Our findings suggest that miR-125b-regulated apoptosis pathway is important to GC progression and that the miR-125 may be an important clinical biomarker for GC survival and possible therapeutic target for GC treatment.

#5408 RNA fusion detection in thyroid nodules with a targeted RNA sequencing panel. Song Tian,2 Michelle Baird,1 Frank Reinecke,2 Jixin Deng,1 Mohammad Nezami Ranjbar,1 Raed Samara,1 Eric Lader1.

1QIAGEN Sciences Inc., Frederick, MD; 2QIAGEN GmbH, Hilden, Germany. Inc., Frederic, MD; 3QIAGEN GmbH, Hilden, Germany.

Thyroid nodules are quite common and detected in as high as 67% of the population. Only a small portion of thyroid nodules are malignant thyroid cancers. Advances in understanding the molecular pathogenesis of thyroid cancer are leading to the development of better biomarkers and novel targeted therapies. The tumorigenic role of RNA fusions has been reported in many forms of cancer. Fusions can result from structural rearrangements like translocations and deletions, transcription read-through of neighboring genes, or the trans- and cis-splicing of pre-mRNAs. Many fusions act as key drivers for cancer development. Detection of fusion RNA is a challenge with traditional technologies like FISH and qPCR, as they are laborious, low throughput, and do not provide detailed information about the fusion. Here we explored the possible use of a tumor-fusion-targeted RNA-based panel (QIAsert targeted RNAscan panel, which is targeting 223 fusion gene pairs, 576 unique fusions) as a tool to study

1384

Proceedings of the American Society for Cancer Research • Volume 58 • April 2017
fusions in thyroid nodules. The presence of these fusions were surveyed in RNA samples from 10 thyroid cancer (PTC and FVPTC) samples and 19 non-cancer control samples (NH and FA) using this oncology targeted panel and sequenced on the illumina NextSeq. PAX8-PPARG, a fusion gene with a well-established link to thyroid cancer, was found in the cancer group. In addition, we observed a unique rearrangement within the recurrent rearrangement that was FUS-DDX1, in all thyroid nodules. Our results suggest that a targeted RNA-based panel provided a useful tool for fusion gene study in thyroid cancer. The role of the expected rearrangement and the unexpected read-through fusion in thyroid nodules needs to be further evaluated, as it could provide useful information for thyroid nodule differentiation.

#5409 Assessment of the MammaPrint 70-gene profile using RNA-seq sequencing technology. Lorenza Mittempergher,1 Jacob B. Spangler,2 Mireille H. Snel,3 Leonie J. Delahaye,1 Iris de Rink,3 Sun Tian,3 Annuksa M. Glas,1 Rene Bernards3,1 Agendia NV, Amsterdam, Netherlands; 2Agendia NV, Irvine, CA; 3Netherlands Cancer Institute, Amsterdam, Netherlands.

Introduction: Improvements in RNA processing have enabled microarray diagnostics for formalin-fixed, parafin-embedded (FFPE) tissue. Recently, MammaPrint, a prognostic 70-gene profile for early-stage breast cancer, was successfully translated to FFPE tissue showing to be substantially equivalent to fresh tissue. In recent years, RNA-sequencing (RNA-Seq) became the standard method for transcriptome analysis, because of its low background signal and its ability of quantifying a large dynamic range of expression levels. Here we report a preliminary analysis of the FFPE MammaPrint 70-gene profile using RNA-seq technology with the comparison of the MammaPrint microarray diagnostic test in a series of FFPE samples. Methods: RNA-Seq was carried out using a strand-specific RNA library preparation followed by target enrichment of the coding region of the human transcriptome without relying on the presence of poly-A tail. RNA sequencing libraries were prepared starting from a minimal amount of 20 ng of total RNA based on the CV 200 metric assessment. The library pools were single-end sequenced on the Illumina HiSeq 2500 instrument at the length of 65bp. The resulting sequences were mapped to the human reference genome (build 38) using TopHat v2.1. Tophat was guided by using a transcriptome index from Ensembl (version 77). The HTSeq-count tool was used to generate the total number of uniquely mapped reads for each gene. Gene expressions were normalized with Count Per Million (CPM) normalization and log2 transformed afterwards. Microarray data of the sample were available for analysis comparison. Results: On average, we obtained 22 million reads assigned to gene per sample (min = 15M, max = 28M). The number of reads assigned to genes vary from 61% to 70% of the total number of reads. Between 80% and 90% of the reads assigned to genes mapped to protein coding genes which is comparable to fresh frozen material. The 70-gene signature was successfully mapped to the RNA-Seq gene. A median raw read-count of 384 was observed for the 70-gene profile among the samples. Importantly, we observed a high concordance (R2 Pearson correlation = 0.97) between the MammaPrint index calculated using the RNA-Seq data and the corresponding Microarray MammaPrint index. Additionally, the BluePrint profile, a microarray diagnostic test for breast cancer molecular subtyping, was successfully translated to the RNA-Seq platform. All three MammaPrint microarray diagnostic panels showed high concordance between the two technologies with high correlation values for each of the subtypes (Luminal R2 Pearson correlation = 0.98, Basal R2 Pearson correlation = 0.97, HER2 R2 Pearson correlation = 0.77). Conclusions: Next Generation RNA-sequencing is a feasible technology to assess diagnostic signatures, such as the 70 gene MammaPrint and BluePrint profiles.

Recent advances in library preparation methodology from limiting amounts of total RNA have facilitated the characterization of rare cell-types in various biological systems. The SMART-Seq v4 Ultra Low Input RNA Kit incorporates a number of workflow improvements, including fewer purifications to increase yield, a locked nucleic acid (LNA) template-switching oligo to enhance stability, and an improved polymerase designed to reduce amplification bias of GC-rich regions. Certain workflow challenges remain however, including variability in library insert size, which can lead to less predictable sequencing results. We have modified the SMART-Seq v4 method to incorporate library size selection between 250-650 bp, and have characterized analytical performance of the modified procedure. A total of 63 libraries were generated using 10 pg - 10 ng of Universal Human Reference RNA (UHRR), Human Brain Reference RNA (HBRR), and total RNA isolated from multiple human tissues, including lung, colon, spleen, adrenal tumor, heart, and lung tumor. To facilitate the comparison between libraries, we normalized library read counts by down-sampling to 24 million reads prior to further processing with an internally-developed sequence analysis pipeline (RNAv9_rsem). The values for ERCC Limit of Detection ranged between 3-50 copies with a mean of 22 copies, which confirmed the high sensitivity of SMART-Seq v4 kit. The number of genes detected (RPKM, or reads per kilobase per million mapped >= 3) varied as a function of the amount of input RNA, with as many as 19,500 genes detected. Gene detection was highly consistent across replicates utilizing 100 pg-10 ng input RNA, with a precipitous decline in genes detected using 10 pg of RNA input. This is due to less reliable detection of low abundance genes, which in turn leads to increased discordance in detected genes between replicates, possibly due to increased sampling error. Nonetheless, when genes are commonly detected, their normalized read counts are highly correlated at any given RNA input, with correlation coefficients (r) ranging from 0.977 to 0.993. Compared to previous versions of the SMARTer method, the modified SMART-Seq v4 procedure implemented at Q2 Solutions - EA Genomics significantly improved the percentage of reads aligned to the transcriptome, as well as the total number of genes detected, all with reduced technical variability. Our study demonstrates an improved strategy for expression profiling via RNA sequencing from limiting amounts of RNA.

#5411 Demonstrated improvements in tumor profiling with enzymatic ribosomal RNA depletion and streamlined RNA-seq library preparation. Nancy H. Nabilis,1 Drew Cheney,2 Leonard Cloete,2 Ida van Jaarsveld,2 Rachel Kasinskas,1 Jennifer Pavlica,1 Roche Diagnostics, Wilmington, MA; 2Roche Sequencing Solutions, Salt River, Cape Town, South Africa.

High resolution RNA analysis using next-generation sequencing (RNA-seq) is a rapidly growing application in cancer research. Formalin-fixed paraffin-embedded (FFPE) tissue is a ubiquitous resource for clinical studies. However, the ability to generate high quality libraries is confounded by the low quality and yield of RNA extracted from FFPE specimen. To enable optimal interrogation of such a clinically-relevant tissue resource, it is critical to identify RNA-seq library construction workflows that improve performance using challenging and degraded sample types. In this study, the effects of RNA type, quality, and quantity on RNA-seq library construction are assessed, and expectations regarding sequencing data quality are addressed. Included are recommendations for quality control measures and input-specific specifications that may improve performance. Three workflows employing either bead-based or enzymatic strategies for the removal of ribosomal RNA content were used to prepare RNA-seq libraries from degraded paired fresh normal and tumor samples. Enzymatic depletion followed by library preparation using the KAPA RNA HyperPrep workflow identified the highest number of transcripts for each sample, translating to a 4.9-fold increase in number of differentially expressed transcripts detected between normal and tumor samples. Of the transcripts identified as differentially expressed exclusively by Kapa, 174 are protein-coding RNAs, many of which are frequently disregulated in breast cancer. In contrast, only two protein-coding RNAs were identified exclusively by the alternative workflows. RealTime Ready Custom panels were used for independent quantitative rt-PCR assessment. A subset of 71 transcripts identified exclusively by Kapa, up to 69 (97%) were validated as differentially expressed. Additional performance improvements of the KAPA RNA HyperPrep workflow include coverage balance across transcripts, lower duplication rate, technical replicate reproducibility, agreement across input quantities, and gene expression concordance between paired fresh frozen and FFPE samples. For Research Use Only. Not for use in diagnostic procedures.

MOLECULAR AND CELLULAR BIOLOGY / GENETICS: Genomic Analyses of Circulating Tumor Material and RNA
Objective of this work is to determine the biologic effects of modulating cellular metabolism through inhibition of MCT1 and MCT4 in canine osteosarcoma (OS). A well-established spontaneous large animal model of the human disease, Methods: MCT1 and MCT4 expression was assessed in canine OS cell lines using qRT-PCR and western blot for the purpose of establishing potential MCT4 and MCT1 expression in canine OS tissues. The effects of small molecule inhibitors (NGY066 and NGY008) and shRNA approaches targeting MCT1 and MCT4 on proliferation and survival of canine OS were examined using the CyQUANT Cell Proliferation and Caspase-3/7 assays, respectively. The impact of MCT1/4 inhibition on cellular oxygen consumption was evaluated using the Seahorse Cell Mito Stress Test. Lastly, potential synergistic effects of combination treatment with doxorubicin with MCT1/4 inhibition in canine OS cell lines were investigated using the CyQUANT Assay. Results: We found that while both MCT1 and MCT4 are expressed in canine OS lines and tissues, MCT1 is expressed at higher levels relative to MCT4 in the cell lines. Small molecule inhibitors directed against MCT1 and MCT4 did not significantly inhibit cell proliferation or induce apoptosis even in the presence of limiting cell culture conditions. Maximally respiratory capacity was not increased in canine OS cell lines following inhibition of MCT1 and MCT4 function. However, synergistic anti-proliferative activity was observed when OS cells were treated with doxorubicin or metformin in the presence of MCT1 and MCT4 inhibitors. Conclusions: MCT1 and MCT4 are expressed in canine OS, and therefore represent a good model to evaluate the impact of MCT1/4 inhibition on cell oxygen consumption. UHPLC/GC-MS metabolomics analysis of plasma samples revealed a significant downregulation of a monosaccharide regulation network. We further validated our data in vivo (in human melanoma xenografts). Further, in another study we demonstrated, based on a large-scale label-free comparative proteomics analysis, that PLK1 inhibition via the small-molecule inhibitor BI6727 (Volasertib) in human melanoma cells resulted in an alteration of certain metabolism-associated proteins with an associated decrease in cellular metabolism. In this study, to further explore the association between PLK1 and cellular metabolism, we utilized a doxycycline-inducible PLK1 knockdown approach in A375 melanoma cells coupled with a Human Glucose Metabolism PCI array that covers 84 key genes involved in the regulation and enzymatic pathways of glucose and glycogen metabolism. We found that PLK1 knockdown resulted in a significant downregulation of 29 genes and upregulation of 3 genes (more than 2 fold change) associated with cellular metabolism. LDH1, PFD2 and PCK1 were in the top 5 genes differentially regulated while FBPI was >7-fold upregulated. Through Ingenuity Pathway Analysis (IPA), we identified glycolysis and the pentose phosphate pathway as major canonical pathways altered by PLK1 inhibition. Further, IPA identified that PLK1 inhibition-modulated genes were largely associated with the proliferation of cells, where FBPI appeared as a key regulatory player. PCK1 was found to be highly downregulated in our array, and IPA identified it as part of a monosaccharide regulation network. We further validated our data in vivo. Further, we found that BI 6727 treatment resulted in a decrease in PCK1 and increase in FBPI in A375 melanoma cells implanted xenografts. In addition, we observed a strong inverse correlation between PLK1 and FBPI in multiple melanoma cell lines, with FBPI expression significantly downregulated in a panel of melanoma
cells compared to normal melanocytes. Moreover, BI 6727 treatment resulted in an upregulation in FBPI in A375, Hs 294T and G361 melanoma cells. Interestingly, in recent studies, FBPI (fructose-bisphosphatase) that is a rate-limiting enzyme in gluconeogenesis, has been shown to function as a tumor suppressor in certain cancers. Overall, our study support the hypothesis that PLK1 is a regulator of metabolism maintenance that affects the melanoma cell growth.

#5416 Downregulation of PRMT6 promotes the Warburg effect in hepatocellular carcinoma via PKM2. Tin Lok Wong, Lok Hei Chan, Stephanie Ma. The University of Hong Kong, Hong Kong, Hong Kong.

Hepatocellular carcinoma (HCC) is one of the top ranked causes of cancer death in the world, accounting for more than 740,000 deaths in 2012. Treatment of HCC is hindered by recurrence and resistance to chemotherapy. Altered metabolism in cancer has been linked to increased tumorigenicity and resistance to chemotherapeutics. One of the main features of altered metabolism is the Warburg effect, which is widely observed in solid tumor including HCC. Recently, our group have identified protein arginine methyltransferase 6 (PRMT6) as a tumor suppressor protein in HCC. Protein arginine methylation is a post-translational modification implicated in a variety of cellular functions including signaling and regulation of gene expression. Downregulation of PRMT6 expression was observed in HCC patients and knockdown of PRMT6 in HCC cell lines increased the tumorigenicity and sensitivity to both chemo- and molecular-targeted therapies. Other members of the Type I PRMT protein has previously been reported to be involved in glucose metabolism. Microarray profiling of HCC cells stably knockdown and overexpressed of PRMT6 showed enrichment of genes related to glycolysis. We therefore hypothesized that reduced expression of PRMT6 in HCC drives the Warburg effect to support cancer progression. Metabolome profiling of HCC cells stably knockdown and overexpressed of PRMT6 showed enrichment of metabolites in glycolysis. Using Seahorse Extracellular Flux Analyzer, we show that stable knockdown of PRMT6 in HCC cell line drives glycolysis. This enhanced glycolysis rate is coupled with increased uptake of glucose, lactate production and pyruvate kinase activity. mRNA expression level of several glycolysis-related genes was screened by real-time quantitative PCR and we identified PKM2, a well-known regulator of the Warburg effect, as a potential link between PRMT6 and enhanced glycolysis. In addition, by immunofluorescence staining, we found that PRMT6 knockdown led to upregulation of PKM2 and PKLR, suggesting that PKM2 is the sole contributor for the Warburg effect, as a potential link between PRMT6 and enhanced glycolysis. Knockdown of PRMT6 leads to an increase in mRNA and protein expression level of PKM2, but not PKM1 and PKLR, suggesting that PKM2 is the sole contributor for enhanced pyruvate kinase activity. In conclusion, PRMT6 regulates the expression level of PKM2 and glycolysis of HCC cell. Ongoing studies are in progress to delineate the underlying mechanisms by which PRMT6 regulates PKM2 to drive Warburg effect.

#5417 The tumor suppressor klotho: A master regulator of metabolism in breast cancer. Tami Rubinek, Ido Wolf. Tel Aviv Medical Center, Tel Aviv, Israel.

One of the hallmarks of cancer is reprogramming of energy metabolism, characterized by a shift to aerobic glycolysis (Warburg effect). A major regulator of this phenomenon is the IGFR-1/Pi3K/akt pathway. Klotho is a transmembrane protein which can be cleaved, shed and act as a cytokine. Piscator et al. describe that Klotho-deficient mice manifest a syndrome resembling accelerated aging, while klotho overexpression extends life span. Klotho is a potent tumor suppressor in BC. As klotho is a potent inhibitor of the IGFR-1/Pi3K/akt pathway in BC, we hypothesized that it may revert the metabolic switch in BC cells. We first analyzed the effect of klotho on the energy sensor enzyme AMP-activated kinase (AMPK) and its downstream effector acetyl-CoA carboxylase (ACC). Overexpression of klotho, or treatment with the soluble protein, elevated AMPK and ACC phosphorylation in three BC cell lines. AMPK is activated by the tumor suppressor liver kinase B1 (LKB1) and elevated AMP/ATP ratio. Expression of a dominant-negative LKB1 prevented activation of AMPK by klotho and decreased the ability of klotho to inhibit cell growth and migration, implying that klotho tumor suppressor activities are LKB1 dependent. We next analyzed the effects of klotho on critical components of glucose metabolism. Treatment with soluble klotho reduced expression of the glucose transporter GLUT1 and the key glycolytic enzymes hexokinase2 (HK2), phosphofructokinase1 (PFK1), pyruvate kinase M2 (PKM2) and pyruvate dehydrogenase kinase 1 (PDK1). Using the Seahorse analyzer we noted reduced oxidative mitochondrial metabolism and glycolysis following klotho treatment. Energy is obtained essentially in the mitochondria with the transfer of protons across the inner membrane that produces ATP. We, therefore, analyzed klotho effect on the mitochondria membrane potential and noted reduction in the mitochondria potential following treatment with klotho. Finally, we examined the effects of klotho on specific metabolites and also conducted an NMR-based metabolic profiling. In accordance with the alterations in signaling pathways and levels of glycolytic enzymes, klotho reduced glucose uptake and inhibited lactate, pyruvate and 3-hydroxybutyrate production. Furthermore, klotho also inhibited ATP production. Taken together, our data indicate klotho as a regulator of metabolic activity in BC and suggest that reversal of the metabolic switch is a key mechanism of klotho-mediated tumor suppressor activities.

#5418 Deciphering the dynamics of alternative pre-mRNA processing of glutamine in metastatic ovarian cancer. Chioniso P. Masamha, Patrick LaFontaine, Bettine E. Gibbs. Butler University, Indianapolis, IN.

The chronically proliferative cancer phenotype requires metabolic reprogramming to meet the increased energy and biosynthetic demands of rapid cell division. This results in increased glucose uptake and usage (the Warburg effect). Cancer cells that undergo the Warburg effect may also become reliant on glutamine, a term called 'glutamine addiction'. Recent studies in ovarian cancer suggest that highly invasive ovarian cancer cells show a remarkable dependence on glutamine, hence implicating glutamine metabolism in metastasis. Glutaminase is the first enzyme that is involved in glutaminolysis and it catalyzes the rate-limiting conversion of glutamine to glutamate and ammonia. There are two genes that code for glutaminase in the human genome, glutaminase 1 (GLS1), and glutaminase 2 (GLS2). GLS2 is associated with cell differentiation whereas GLS1 expression is up-regulated in cancer. Hence, GLS1 had been proposed to be better adapted to meet the altered metabolic needs of the tumor phenotype. GLS1 can be alternatively spliced into two isoforms, KGA and GAC. Although both KGA and GAC have been implicated in cancer cell metabolism, there is still controversy over the actual isoform that is most important for tumorigenesis. Whereas the KGA isoform is repressed by miR-23, there is no documented miRNA repression of GAC suggesting that GAC is more tumorigenic. Using next-generation sequencing, we recently identified an unannotated novel KGA transcript with a truncated 3' untranslated region (3'UTR) which is more stable than the traditionally known KGA transcript. Our goal is to determine the expression profile of different glutaminase isoforms in the highly lethal gynecological malignancy, ovarian cancer, and their role in tumorigenesis and metastasis. We have developed amplicons to measure total GLS1 and GLS2 transcripts using quantitative real time PCR (qRTP-PCR). Although we unexpectedly detected both GLS2 and GLS1 transcripts, the mRNA levels of GLS2 were significantly lower than those of GLS1. To determine the specific GLS1 isoforms expression we used isoform specific amplicons and detected both GAC and KGA using qRT-PCR. Western blot analysis was able to detect both GAC and KGA protein in one cell line only suggesting that the KGA mRNA we detected was subject to miR-23 repression. Inhibition of total GLS1 activity with a glutaminase inhibitor resulted in decreased colony formation as shown by soft agar assays. In conclusion, the expression profile of different GLS1 isoforms in highly invasive ovarian cancer supports the role of glutamine metabolism in maintaining the metastatic phenotype. This makes glutamine metabolism a viable therapeutic target for metastatic ovarian cancer.

#5419 The relationship between glutamatergic signaling and altered glutamine metabolism in melanoma. Raj Shah, Andrew Boreland, Suzie Chen. Rutgers University, Piscataway, NJ.

Aberrant glutamatergic signaling has been implicated in many cancer types and is associated with dysregulated growth leading to cellular transformation and tumorigenesis. Our laboratory has previously illustrated the oncogenic properties of a neuronal receptor, metabotropic glutamate receptor 1 (GRM1) in melanocytes. Glutamate is the natural ligand of GRM1 and the major excitatory neurotransmitter in the central nervous system. Our group has demonstrated that glutamate production/release is upregulated in GRM1 expressing melanoma cells, resulting in constitutive activation of GRM1 and GRM1-associated downstream signaling pathways. We hypothesize that this activation of GRM1 in melanoma cells is associated with higher expression of c-Myc and increased enzymatic activity of glutaminase (GLS) converting glutamine to glutamate. We showed that reducing the extracellular glutamate levels by an inhibitor of glutamate release, Riluzole, led to significantly reduce melanoma cell proliferation in vitro and tumor progression in vivo. We also demonstrated that inclusion of CB-839, a potent, selective, and orally bioavailable GLS inhibitor, resulted in a significant inhibition of GRM1-expressing melanoma cell proliferation compared to GRM1 negative melanoma cell lines. Interestingly, we found that simultaneous targeting of glutamate production (CB-839) and release (Riluzole) in GRM1 expressing melanoma cells led to enhanced suppression of cell proliferation in vitro. Additionally, we found that wild type BRAF melanoma cells are more sensitive to CB-839 than mutated BRAF cells while responses to Riluzole were independent of BRAF genotypes. Furthermore, our data indicate that CB-

#5420 PGAM1-REDD1 pathway promotes paclitaxel resistance through enhancing aerobic glycolysis in ovarian cancer cells. Y. Yang, Weiguo Lv, Xing Xie. Women's hospital School of Medicine Zhejiang Univ., Hangzhou, China.

Aerobic glycolysis is a dominant pathway for energy production in cancer cells, but the association of this phenomenon with chemoresistance remains still uncertain. Here, we found that the expression of phosphoglycerate mutase 1 (PGAM1), a key catalytic enzyme in aerobic glycolysis, was significantly higher in paclitaxel-resistant ovarian cancer cell line SKOV3. Up-regulated PGAM1 expression by gene transfection and down-regulated PGAM1 expression by siRNA knockdown altered the process of aerobic glycolysis, paclitaxel sensitivity and DNA damage response 1 (REDD1) expression in ovarian cancer cells, vice versa. Structural interaction between PGAM1 and REDD1 was predicted by molecular docking. Our results suggested that PGAM1-REDD1 pathway promotes paclitaxel resistance through enhancing aerobic glycolysis in ovarian cancer cells.

#5421 Differential expression of lysosomal acid lipase (LAL) between benign and malignant tissues among human organs. Mohamed El Gassim, Jinghao Mao, Xinchuan Zhou. Univ. of Mississippi Medical Ctr., Madison, MS; Tuogalo College, Tuogalo, MS.

Background: Lysosomal acid lipase (LAL), a lysosomal enzyme is able to degrade cholesteryl esters to free fatty acids and cholesterol. The information on the association of LAL with malignancies is limited. This study is to determine the difference in expression level of LAL between benign and malignant tissues among human organs. Method: Immunohistochemistry (IHC) for human LAL was performed on A tissue microarray (TMA) containing 36 benign and malignant tissues from 36 human organs. The expression level of LAL was represented by an IHC score calculated by multiplying area score (0–3) with intensity score (0–3), ranged from 0 to 9. Student’s t-test was used to compare the mean IHC score between benign and malignant tissues in same organs. Results: Eighteen out of 36 human organs have IHC stains on both benign and malignant tissues. As shown in Table 1, LAL expression level was higher in malignancy than in benign tissues in 9 organs. The difference in LAL expression level was significantly (or nearly lower in malignant tissues of adrenal gland, stomach, liver, testis and kidney. Conclusion: The expression level of LAL varies among human organs. As compared with elevation of LAL expression level, decreased expression level of LAL in malignancies could be of more significance.

#5423 ZAP70 alters metabolism in chronic lymphocytic leukemia cells. Subhadip Das, RF Dielschneider, Elizabeth S. Henson, Spencer B. Gibson. *Cancer Care Manitoba & University of Manitoba, Winnipeg, Manitoba, Canada; University of Manitoba, Winnipeg, Manitoba, Canada; Cancer Care Manitoba, Winnipeg, Manitoba, Canada.

Chronic lymphocytic leukemia (CLL) has the highest incidence among adults in western countries. Prognosis of CLL is highly variable but one of the biomarker zeta-chain-associated protein 70 (ZAP70) overexpression is associated with aggressive disease with time to treatment being 2.6 years for ZAP70 expressing (ZAP70+) patients and 8 years for ZAP70 deficient (ZAP70-) patients. Thus ZAP70 may play a role in CLL progression. Metabolic reprogramming plays a central role in cancer progression and is altered in CLL cells. However, the role of ZAP70 in metabolism in CLL cells is remains unclear. We found that ZAP70 binds to pyruvate kinase M2 (PKM2). PKM2 is key isoform of pyruvate kinase which is rate limiting enzyme of the glycolytic pathway and provides a metabolic advantage to tumour cells allowing for increased growth. Our results also indicated the PKM2 is expressed in CLL cells and binding to ZAP70 is not affected by glucose starvation or treatment with kinase inhibitors. Furthermore immunofluorescence microscopy revealed that ZAP70 and PKM2 colocloze in CLL cells in the cytoplasm. In addition, we found ZAP70+ cells have increased rate of oxygen consumption from basal level determined by addition of inhibitor (Oligomycin A) and mitochondrial uncoupler (FCCP). Simultaneously ZAP70+ cells also have higher extracellular acidification rates. This indicates ZAP70+ CLL cells have increased mitochondrial respiratory capacity with high glycolytic rate. In addition, fluorometric analysis indicates ZAP70+ CLL cells have high glucose consumption rate towards production of lactate compared to ZAP70- CLL cells. Collectively, our data reveals a new function for ZAP70, which is to regulate the Warburg effect and may play a role in CLL progression and may identify new therapeutic targets.
#5424 Metformin increases PDH and suppresses HIF1A under hypoxic conditions and induces cell death in oral squamous cell carcinoma. Talita Guimaraes,1 Lucyana Farias,1 Carlos Fraga,1 Alfredo De Paula,1 Sergio Santos,2 Ricardo Gomez,2 Andre Guimaraes1. 1Unimontes, Montes Claros, Brazil; 2Universidade Federal de Minas Gerais, Beo Belo Horizonte, Brazil.

Background: Metformin is a biguanide, belonging to the oral hypoglycemic agents and is a widely used in the treatment of type 2 diabetes. Evidence indicate that Metformin inhibits cell proliferation in several human cancers and inhibits the Warburg phenomenon in tumor cells. Objective: The present study aims to explore the effects of Metformin in hypoxic conditions. Specifically, we focused on pyruvate dehydrogenase (PDH), (hypoxia-inducible factor 1α) HIF-1α levels and the Warburg phenomenon in OSCC cell phenotype. Additionally, we also investigated a theoretical consequence of Metformin treatment. Methods: PDH levels in patients with OSCC and oral dysplasia were evaluated. Metformin was administered in vitro to test the effect of Metformin under hypoxic conditions. The results were complemented by Bioinformatics analyses. Results: Low PDH levels were observed in OSCC, and Metformin promotes an increase in PDH levels in hypoxic conditions. Metformin also reduced HIF-1α mRNA and protein levels. Metformin demonstrated antiproliferative effects, inhibited migration, increased the number of apoptotic cells and increased the transcription of caspase 3. Conclusions: In conclusion, our current findings show that Metformin reduces HIF-1α gene expression and increases PDH expression. Metformin inhibits cell proliferation and migration in the OSCC cell line model. Additionally, Metformin enhances the number of apoptotic cells and caspase 3 levels. Interestingly enough, Metformin did not increase the mutant p53 levels under hypoxic conditions.

#5425 The role of six transmembrane epithelial antigen of the prostate 2 in hepatocellular carcinoma. Carla R. Zeballos, Hakim Boutam, Xiang Gu, Yi-dong Chen, Francisco G. Cigarroa, LuZhe Sun. University of Texas Health Science Center at San Antonio, San Antonio, TX.

Introduction: The incidence of hepatocellular carcinoma (HCC) in Hispanics is three times higher than non-Hispanic whites, and even higher in South Texas (STX) Hispanics. This is attributed to a higher prevalence of hepatitis C, diabetes, obesity and perhaps genetic and epigenetic alterations. Knowledge regarding genetic alterations in Hispanics is sparse as demonstrated by the lack of Hispanics with HCC in The Cancer Genome Atlas (TCGA). Therefore, our group sequenced paired adjacent liver and HCC tumors from STX Hispanics, which highlighted a gene over-expressed in tumors of Hispanics, called the Six Transmembrane Epithelial Antigen of the Prostate 2 (STEAP2). STEAP2 is a metalloendocytosis of iron and copper and is implicated in iron uptake and reactive oxygen species in the liver which can lead to the progression of inflammation and cirrhosis. STEAP2 may play an important oncogenic role in HCC, especially in the setting of obesity. We propose to test the hypothesis that over-expression of STEAP2 will lead to malignant property in HCC cells resulting in enhanced proliferation, survival, invasiveness, and eventually development of HCC, especially in obese hosts. Methods: Hispanic paired tissue continues to be collected from our institution for RNA sequencing and establishment of Hispanic HCC cell lines. STEAP2 RNA and protein expression levels in Hispanic paired samples versus Caucasian paired samples were evaluated by RT-PCR, Western blot, and immunohistochemistry. Knockdown and overexpression of STEAP2 were established in HCC cell lines and in primary Hispanic HCC cell lines to examine the effects on iron levels, oxidative stress, proliferation, invasiveness, apoptosis and cell cycle in vitro. Results: Hispanic HCC RNA sequencing data compared to TCGA HCC RNA sequencing data (no Hispanics) demonstrated the overexpression of STEAP2 in HCC tumors in Hispanic patients, which were validated by RT-PCR data and Western blot data. Lipid peroxidation product, 4-hydroxynonenal, and copper levels were higher in HCC tumor versus adjacent tissue. Iron levels were higher in adjacent tissue versus tumor tissue in Hispanics. Knockdown of STEAP2 in SNU398 cells decreased proliferation and migration, while in HUH7 cells STEAP2 knockdown only decreased migration. Conclusions: STEAP2 is specifically overexpressed in HCC tumors in Hispanics in comparison to HCC tumors in non-Hispanic whites and appears to play a malignant-promoting role in HCC cells. Further studies to establish the role of STEAP2 as a tumor promoter in HCC and the mechanisms by which it promotes carcinogenesis are underway. The proposed studies will likely yield mechanistic insights into the molecular mechanisms that drive HCC development and progression in South Texas Hispanics and potential therapeutic targets involving STEAP2-mediated metal ion metabolism and oxidative stress.

#5426 LPA stimulates glycolytic shift in ovarian cancer. Ji Hee Ha, Ran-gaudshagar Radhakrishnan, Jeremy D. Ward, Muralidharan Jayaraman, Danny N. Dhanasekaran. University of Oklahoma Health Sciences Center, Oklahoma City, OK.

Cancer cells resort to aerobic glycolysis to meet the increased energy consumption and growth requirement during active proliferation. While it has been observed that the cancer cells preferentially shift to aerobic glycolysis, the exceedingly high growth factors involved in this process is largely unknown. Since our previous studies have shown that lysophosphatidic acid (LPA) plays a critical role in carcinogenesis of ovarian cancer by stimulating glycolysis in ovarian cancer cells, our results using XFe96 analyzer indicate that LPA stimulates aerobic glycolysis in multiple ovarian cancer cell lines as well as in patient-derived ovarian cancer cells. Physiological role for LPA in this process is demonstrated by the observation that the inhibitors of LPA receptors attenuate the glycolytic shift stimulated by the ascitic fluid derived from ovarian cancer patients. We further demonstrate that the silencing Gz2, a down-stream signaling mediator for LPA, inhibits LPA-stimulated glycolytic shift in ovarian cancer cells. Further analyses indicated that LPA-stimulated metabolic reprogramming involves the generation of reactive oxygen species (ROS). Treatment of cells with N-Acetyl Cysteine (NAC), a ROS-scavenger, inhibited the glycolytic shift stimulated by LPA. In addition, our studies point to a role for LPA-stimulated HIF1α activation in this process. These results indicate that LPA-stimulated metabolic reprogramming in ovarian cancer cells involve ROS-generation via LPA-Gz2-HIF1α-dependent signaling pathway. Together with the findings that the glycolytic shift is crucially involved in tumor cell survival our studies point to LPA-Gz2-HIF1α signaling axis as a potential target for therapy in ovarian cancer.

#5427 Distinctions between the metabolic changes in globlastoma cells and glioma stem-like cells following irradiation. Elizabeth I. Spehalski, Cord Peters, Philip Totlon, Kevin Camphausen. NIH, Bethesda, MD.

Glioblastoma multiforme (GBM) is the most common primary malignant brain tumor in adults and, even with aggressive treatment that includes surgical resection, radiation, and temozolomide administration, prognosis is poor due to tumor recurrence. There is evidence that within GBMs a small number of glioma stem-like cells (GSCs) exist, which are thought to be radiation resistant and may be capable of repopulating a tumor after treatment. Like most cancers, GBMs largely employ aerobic glycolysis to create ATP, a phenomenon known as the Warburg effect. Experiments have shown that the cellular metabolism of GSCs differs from that of differentiated cells, making them an attractive target for novel therapeutic approaches. Much work has been done to analyze the metabolic profiles of GSCs with the goal of identifying potential therapeutic targets, but little data exists linking metabolic changes to radiation resistance. The purpose of this study is to characterize the metabolic differences between glioma stem-like cells and traditional GBM tumor cells with and without radiation treatment (IR). To this end, we compared the metabolism of a human derived GSC line with two commonly used GBM cell lines before and after IR. At baseline, we find that glioma stem-like cells are more quiescent than GBM cells, which have higher levels of both glycolysis and oxidative phosphorylation. GBM lines show higher levels of both basal and maximal respiration, as well as basal glycolysis and glycolytic capacity than GSCs. They also express higher levels of energy, glycolysis, and TCA cycle metabolites than GSCs. Inversely, GSCs demonstrate metabolic signs of quiescence such as decreased NEAA synthesis. After IR, the radiation sensitive GBM tumor cell line (H9251) exhibits increases in all metabolic pathways, whereas the levels of glycolytic and oxidative metabolites in the GSCs remain unchanged. All cell lines show an increase of ATP and NAD production following IR. These findings indicate that the metabolism of GSCs undergoes different alterations than that of GBM tumor cells after IR, making them an attractive target for novel therapeutic approaches in conjunction with radiation therapy. Additionally, differences in metabolic signatures between GSC lines could be useful for non-invasive diagnostic modalities such as 1H NMR spectroscopy.

#5428 Lactate production as a potential marker of HER2-addiction and Trastuzumab susceptibility. Lorenzo Castagnoli,1 Egidio Iorio,2 Ada Kocshorke,1 Cristina Ghirelli,1 Gianmauro Palombelli,2 Debora Gian,1 Matteo Dugo,1 Daniela Morelli,1 Roberta Perrone1, Elia Tagger1, Serena A. M. Papa. Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy; 1Istituto Superiore di Sanità, Rome, Italy.

Background: Although the introduction of the HER2-specific humanized monoclonal antibody Trastuzumab (T) in clinical practice revolutionized the treatment of HER2-positive breast cancer (BC), about half of the T-treated patients do not benefit or become refractory after its administration. Despite different molecular tumor profiles significantly associated with T benefit were reported, the identification of a non invasive clinical approach to select patients responsive or not to T is still a clinical unmet task. We recently reported that mammary cancer cell lines derived from spontaneous nodules arisen in mice...
MOLECULAR AND CELLULAR BIOLOGY / GENETICS: Metabolic Regulation and Cancer Therapy

transgenic for the human d16HER2 splice variant (HER2-addicted) were significantly enriched in genes involved in glycolysis pathway versus those developed in mice transgenic for the human full-length HER2-positive (WTHER2) (HER2-non addicted) (1,2). Accordingly, the aim of our study was to define whether tumor lactate levels could reflect HER2 addiction and, in T, tumor susceptibility of the GLUT-1 overexpressing cells. GAPDH metabolic activity was measured using assay kits and live cell metabolic phenotyping with the Seahorse analyzer. Increased lactate production and proton production were observed in MCF7 cells and again this resulted in a stable, glycolytic phenotype with increased expression of CA-IX. While it is commonly believed that these transporters are involved in the increased glycolytic flux, an alternative hypothesis is that CA-IX expression is consistent with the high level of lactate in tumors HER2-addicted. Conclusion: Overall, even if in a dysregulated glucose metabolism is a tumor hallmark, our results provide relevant in vitro and in vivo data points to make the future potential non-invasive lactate detection as a possible biomarker of HER2-addiction and T-responsiveness. #5429 The Warburg Effect: protons suck. Shonagh Russell, Liping Xu, Rober J. Gillies. Moffitt Cancer Center, Tampa, FL.

Aerobic glycolysis (the Warburg Effect) is a hallmark of cancer and is associated with local invasion and metastasis. This metabolic phenotype results in acidification of the microenvironment in solid tumors, which is responsible for many of the known sequelae. For example, systemic buffer therapy directly and specifically increases extracellular tumor pH and reduces spontaneous and experimental metastasis in vivo. Further, extracellular acidosis can be a potent inhibitor of anti-tumor immunity. Removal of glycolytically-derived acids requires the activity of proton transporting mechanisms, such as NHE, V-ATPase and CA-IX. While it is commonly believed that these transporters are responding to the extracellular pH, increased glycolytic flux, an alternative hypothesis is that CA-IX expression is consistent with the high level of lactate in tumors HER2-addicted. Conclusion: Overall, even if in a dysregulated glucose metabolism is a tumor hallmark, our results provide relevant in vitro and in vivo data points to make lactate detection as a possible biomarker of HER2-addiction and T-responsiveness. Supported by the Italian Ministry of Health and AIRC. References: 1) Castagnoli L et al, Cancer Res 2014. 2) Castagnoli L et al, Oncogene 2016. 3) Shiu KK et al, Oncogene 2014.

#5430 GAPDH loss in a tumorigenic human glioblastoma cell line. Zachary Gaertner, Yi Lu, Jinsuh Kim, Gayatri Mohapatra, Ankit Mehta, Sanjani Lakka, Herbert Engelhard. Univ. of Illinois at Chicago, Chicago, IL.

Background: Glyceraldehyde 3-phosphate dehydrogenase (GAPDH) is a ubiquitous, multifunctional 37 kDa enzyme best known for catalyzing the sixth step in the Embden–Meyerhof pathway (glycolysis). GAPDH is a metabolic enzyme, but is also involved in other metabolic pathways. GAPDH is designated the “housekeeping” status, and is used as a standard (along with β-actin) for normalizing Western blots. While increased GAPDH expression has been described in hypoxia, diabetes, and some cancers, decreased expression is rare. Here we describe a new human glioblastoma cell line that exhibits GAPDH loss, while maintaining a high degree of malignancy. Methods: Primary cultures of human glioblastoma were initiated and maintained in DMEM with 10% FBS. A particular cell line (designated E297) grew readily, and was passaged more than 40 times. E297 cells were confirmed to be negative for HIV, HTLV, hepatitis B and C, CMV, and mycoplasma contamination. Cells in exponential growth were stained for routine markers, and studied by DNA flow cytometry. GAPDH expression was studied by Western blot analysis using polyclonal rabbit anti-human GAPDH IgG (Abcam, Rosemont, IL), with Hela, U138, U87 and U251 cells (as well as β-actin staining) as positive controls. For intracranial implantation into Wistar-Furth rats (male, 10-11 weeks), cells were suspended at 2 x 10^6 cells/ml. Using aseptic technique, rats were anesthetized, and placed into a stereotactic frame. A burr hole was drilled 3 mm right of the bregma and 25 μl of suspension injected (5 mm depth) over 10 min. by Hamilton syringe. Rats were studied by MRI and euthanized when symptomatic. Results: E297 cells have glial/epithelioid morphology, with a doubling time of 24 ± 2 hours in logarithmic growth phase, with a single DNA subpopulation with 28% S phase. They stain positively for GFAP, vimentin, bFGF, c-myc and p53, but fail to express GAPDH. 10/10 animals implanted intracerebrally developed becoming symptomatic and requiring sacrifice at 25 days (mean). Loss of GAPDH expression was confirmed by Western blot analysis. Conclusions: The E297 human glioblastoma cell line is highly aggressive and proliferates rapidly. It is tumorigenic in nonimmunosenescent rats but lacks GAPDH protein. We conclude that GAPDH expression is not essential for glioblastoma cell proliferation under routine culture conditions, and care needs to be taken when using GAPDH as a normalization standard for Western blots of cancer cells.

#5431 Androgen receptor regulates the mitochondrial pyruvate carrier to fuel oncometabolism in prostate cancer. David A. Bader, Nagireddy Putluri, Sean M. Hartig, Sean E. McGuire. Baylor College of Medicine, Houston, TX.

The metabolic underpinnings of androgen receptor (AR)-driven growth in prostate cancer (PCa) are underexplored, hindering the development of strategies to leverage the metabolic properties differentiating PCa from normal tissue. To this end, we discovered a subunit of the mitochondrial pyruvate carrier (MPC) as a direct AR target gene that is increased in CaP specimens and associated with clinical outcomes. Our observation suggests a targetable link between AR signaling and carbon trafficking in PCa. Indeed, MPC inhibition delays proliferation and alters metabolic properties in hormone sensitive and castrate resistant AR-driven PCa models. Next, using 13C metabolic flux analysis coupled with a reverse phase protein array, we determined MPC inhibition results in activation of the ε-aminocaproic acid (EAA) pathway and partially compensates for MPC inhibition by coordinating increased glutamine incorporation into the citric acid cycle. Therefore, to amplify the effect of MPC inhibition, we restricted glutamine availability during MPC inhibition and found this combination resulted in proliferative arrest. Last, we extended our efforts in-vivo and demonstrated combinatorial MPC/glutaminase inhibition resulted in a significant reduction in castrate-resistant prostate tumor xenograft growth in mice with no overt host toxicity. We anticipate our findings will accelerate the development of clinical strategies to therapeutically manipulate carbon flux to starve clinically lethal castrate-resistant PCa.

#5432 Characterization of metabolic fuel dependency in multidrug resistant breast cancer cells. Yoonseok Kam, Natalia Romero, Pamela Swain, Brian D. Dranka. Agilent Technologies, Lexington, MA.

Multidrug resistance (MDR) is a common resistant mechanism of cancer cells to cytotoxic drugs in systemic therapy. MDR is characterized by increased expression of ATP-dependent drug exporting pumps which remove cytotoxic compounds from the cytosol. However, the mechanism whereby cancer cells rapidly respond to this increased ATP demand is not fully understood although the glycolytic nature of MDR phenotype has been evidenced repeatedly by previous reports. We thus hypothesized that flexibility and dependency on mitochondrial fuels would be altered in concert with the switch to glycolysis. In order to more accurately analyze glycolytic pathway, we newly developed an assay to improve glycolytic rate measurements by ac-
counting for TCA-dependent CO₂ contribution to extracellular acidification and to correlate Seashore extracellular flux data with lactate production. In a comparison of glycolytic rates between MCF7 breast cancer cell line and its MDR variant MCF7/Dox using this new assay, we confirmed that in MCF7/Dox cells glycolysis rate under basal conditions is significantly increased compared to MCF7 wild type. In contrast, dependency on glucose and fatty acids mitochondrial oxidation was unchanged in MDR cells. Additionally, an increase in long chain fatty acid oxidation is observed when glucose and glutamine oxidation is blocked indicating that MDR cells have higher mitochondrial flexibility to compensate for inhibition of alternative fuels utilization although it preferentially uses glucose. Together these data demonstrate that acquisition of multidrug resistance in MCF7 cells fundamentally changes their metabolism from a glutamine-driven, oxidative phosphorylation dependent phenotype to a highly glycolytic and glucose-dependent phenotype. These findings have potential therapeutic relevance in the context of inhibition of specific mitochondrial fuel pathways to prevent therapy resistance.

**#5433 β-Tubulin inhibitors reduce GLUT1 membrane trafficking to attenuate tumorigenesis in glioblastoma subtypes**
